Drug treatment failures may result from a variety of factors. Initial failure to respond to α-adrenergic antagonists occurs in 20% to 70% of treated patients. It is likely in these patients that the static factor may predominate as the cause of symptoms in these patients. In these patients, adding a 5α-reductase inhibitor may be helpful. Initial failure to respond to 5α-reductase inhibitors occurs in 30% to 70% of treated patients. It is likely that the dynamic factor may predominate as the cause of symptoms in these patients. In these patients, switching to or adding an α-adrenergic antagonist may be helpful. In contrast, drug treatment failures after an initial good response to drug therapy will likely be an indication of progressive BPH disease. In such patients, modifying the drug regimen or surgical intervention may be indicated.

Table 52–8 summarizes the adverse effects of the agents used to treat BPH and includes management suggestions for these situations.

## Abbreviations Introduced in This Chapter

AUA     American Urological Association
BPH     Benign prostatic hyperplasia
BUN     Blood urea nitrogen
DRE     Digital rectal examination
IVP     Intravenous pyelogram
LUTS    Lower urinary tract symptoms
PSA     Prostate specific antigen
PVR     Postvoid residual urine volume
TURP    Transurethral resection of the prostate

# Urinary Incontinence and Pediatric Enuresis

Sum Lam

## URINARY INCONTINENCE

### INTRODUCTION

Urinary incontinence (UI) is defined as the complaint of involuntary leakage of urine.[1] It is often associated with other bothersome lower urinary tract symptoms such as urgency, increased daytime frequency, and nocturia. Despite its prevalence across the lifespan and in both sexes, it remains an underreported health problem that can negatively impact an individual's quality of life. Patients with UI may sense a loss of self-control, independence and self-esteem, and often modify their activities for fear of an "accident." Patients with UI may also suffer from other consequences, including perineal dermatitis and infections, pressure ulcers, urinary tract infections (UTIs) and falls. In the United States, the estimated national cost of urge urinary incontinence (UUI) in 2007 was $66 billion, with projected costs of $76 billion in 2015 and $83 billion in 2020.[2]

### EPIDEMIOLOGY AND ETIOLOGY

The true prevalence of UI is unclear because of varying definitions of UI and reporting bias.[3]

- About 44% of noninstitutionalized persons aged 65 and older reported UI[4]
- 7% to 37% of women aged 20 to 39 report some degree of UI
- 9% to 39% of women age 60 and over report daily UI

- 11 to 34% among older men report some degree of UI
- 2 to 11% of older men reporting daily UI
- In the noninstitutionalized setting, more than 50% of elderly women and more than 25% of elderly men reported UI
- 46% of short-term and 76% of long-term nursing home residents report UI[4]

UI can result from abnormalities within (intrinsic to) and outside of (extrinsic to) the urinary tract. Within the urinary tract, abnormalities may occur in the urethra (including the bladder outlet and urinary sphincters), the bladder, or a combination of both structures. Focusing on abnormalities in these two structures, a simple classification scheme emerges for all but the rarest intrinsic causes of UI. **KEY CONCEPT** *Accurate diagnosis and classification of UI type is critical to the selection of appropriate drug therapy.*

### PATHOPHYSIOLOGY
#### Stress Urinary Incontinence[5]

Stress urinary incontinence (SUI) occurs most frequently in women and is related to the underactivity of urethra and/or urethral sphincters, leading to inadequate resistance to impede urine flow from the bladder. SUI occurs when intra-abdominal pressure is elevated by exertional activities like exercise, running, lifting, coughing, and sneezing. SUI is usually episodic, associated with small volume leakage and rarely causes nocturia or enuresis. The etiology for urethral underactivity is not

## Patient Encounter 1, Part 1

A 62-year-old Asian woman presents to the clinic with the chief complaint of "not being able to make it to the toilet in time." Every day she experiences a strong, sudden urge to urinate which is difficult to postpone. She makes about 10 trips to a bathroom while awake on a daily basis and gets up twice each night to urinate. She reports no clothes-wetting accidents so far, but is fearful of the embarrassment, especially when she is in the public. Because of the urinary condition, she has given up shopping in large malls, which was her favorite pastime. She also avoided several social and family events in the past month. She states that "life would be so much better if I don't need to run for the bathroom." She denies any urinary leakage when she coughs, laughs, or exercises. Her PVR is less than10 mL. She is diagnosed with overactive bladder without urinary incontinence.

*List symptoms that are consistent with her diagnosis.*

*What additional information do you need to know before creating a treatment plan for this patient?*

completely understood, although the loss of the trophic effects of estrogen on the uroepithelium at menopause is thought to be important. The peak of SUI prevalence in the perimenopausal years supports this hypothesis. Clearly established risk factors for SUI include the following:

- Pregnancy (increased risk with increased parity)
- Childbirth (vaginal delivery)
- Menopause
- Cognitive impairment
- Obesity
- Increasing age

SUI is exceedingly rare in males unless the sphincter mechanism is compromised by surgery or trauma. The most common surgeries predisposing to SUI in males are radical prostatectomy for prostate cancer and transurethral resection of the prostate for benign prostatic hyperplasia (BPH).

### Urge Urinary Incontinence[5]

UUI is related to the overactivity of detrusor muscle in the bladder, which contracts inappropriately during the filling (urinary storage) phase and generates urgency, or a compelling desire to void which is difficult to defer. The bladder contractions are due to the stimulation of muscarinic cholinergic receptors, especially M2 and M3 subtypes. UUI is associated with large volume leakage, sometimes complete bladder emptying, nocturia and enuresis; thus UUI may disrupt sleep. Overactive bladder (OAB) is a symptom syndrome with or without associated UUI.[6]

Most women with UUI or OAB have no identifiable causes (idiopathic), while in men similar symptoms are associated with benign prostatic hyperplasia (See Chapter 52). Overactivity may be myogenic and/or neurogenic. Clearly established risk factors for UUI include:

- Older age
- Neurologic disorders (eg, stroke, Parkinson disease, multiple sclerosis, and spinal cord injury)
- Bladder outlet obstruction (eg, benign or malignant prostatic enlargement or hyperplasia)

- Hysterectomy
- Recurrent UTIs

### Overflow Urinary Incontinence[5]

Overflow urinary incontinence (OUI) is a less common form of UI in men or women. It is related to urethral overactivity and/or bladder underactivity. In short, the bladder is filled to capacity at all times but cannot empty, causing urine to leak out episodically. If caused by bladder underactivity, the progressively weakened detrusor muscle eventually loses the ability to voluntarily contract, which lead to incomplete voiding and large residual urinary volume after micturition. Both myogenic and neurogenic factors have been associated with impaired bladder contractility that leads to OUI. Common neurogenic factors are diabetes, lower spinal cord injury, multiple sclerosis, or radical pelvic surgery.

If due to urethral overactivity, incomplete bladder emptying occurs because the resistance of the urethra and/or sphincters cannot be overcome by detrusor contractility. In men, this most frequently occurs in cases of long-term chronic bladder outlet obstruction due to BPH, prostate cancer, or abdominal-pelvic surgeries. In women, urethral overactivity is rare, but may result from cystocele formation or surgical overcorrection for SUI. In both genders, systemic neurologic diseases such as multiple sclerosis or spinal cord injury may be the etiology.

### Functional UI[5]

Functional UI is generally caused by extrinsic factors to the urinary tract, such as:

- Immobility (due to pain, physical limitations)
- Inadequate or delayed access to toileting facilities
- Neurologic impairment (Parkinson disease, multiple sclerosis, spinal cord injury, stroke, apathy due to depression)
- UTIs
- Postmenopausal atrophic urethritis and/or vaginitis
- Diabetes mellitus (glucosuria leading to polyuria)
- Diabetes insipidus (polyuria due to decreased antidiuretic hormone [ADH])

## Clinical Presentation of Stress Urinary Incontinence (SUI) Related to Urethral Underactivity[5]

**General**

Usually occurs during activities like exercise, running, lifting, coughing, or sneezing; much more common in females.

**Symptoms**

Urine leakage volume is proportional to activity level; not associated with nocturia. No SUI with physical inactivity, especially when supine. May develop urgency and frequency as a compensatory mechanism (or independently as a separate component of bladder overactivity).

**Diagnostic Tests**

Observation of urethral meatus (opening) while patient coughs or strains.

<div style="border:1px solid #000;">

## Clinical Presentation of Urge Urinary Incontinence (UUI) Related to Bladder Overactivity[5]

**General**

If sensory input from the lower urinary tract is absent, may have bladder overactivity and urine leakage without urgency. Patient with overactive bladder (OAB) may not have UUI.

**Symptoms**

Patients with OAB typically present with symptoms of urgency, frequency (8 or more micturitions in 24 hours), nocturia (one or more awakening per night to void) with or without UUI.

**Diagnostic Tests**

Urodynamic studies are the gold standard for diagnosis. Urinary tract infection must be ruled out by urinalysis and urine culture.

</div>

<div style="border:1px solid #000;">

## Clinical Presentation of Overflow Urinary Incontinence (OUI) Related to Urethral Overactivity and/or Bladder Underactivity[5]

**General**

Rare type of UI in both genders. Urehral overactivity is usually due to prostatic enlargement (males) or cystocele formation or surgical overcorrection for SUI (females). Bladder underactivity is usually due to a weakened detrusor muscle.

**Symptoms**

Lower abdominal fullness, hesitancy, straining to void, decreased force of stream, interrupted stream, sense of incomplete bladder emptying. May have urinary frequency and urgency, as well as abdominal pain if acute urinary retention occurs.

**Signs**

Increased postvoid residual urine volume.

</div>

- Pelvic malignancy (extrinsic pressure on urinary tract structures causing obstruction)
- Constipation or fecal impaction
- Congenital malformations of the urinary tract system

### Mixed and Drug-Induced UI[5]

Mixed urinary incontinence (MUI) occurs when two or more types of UI coexist in a given patient, which may lead to diagnostic and therapeutic difficulties. Patients may experience worsening of symptom due to the opposing effects of treatments indicated for specific and different types of UI.

**KEY CONCEPT** *Many medications can influence the lower urinary tract system, and can precipitate or aggravate existing voiding dysfunction that leads to UI (Table 53–1).*

## CLINICAL PRESENTATION AND DIAGNOSIS

Guidelines are available for the assessment and diagnosis of UI or OAB.[6–8] In general, obtaining a complete medical history and performing a targeted physical examination are essential to correctly classify the type(s) of UI. The degree of annoyance perceived by the patient due to urinary symptoms must be assessed, although it may not correlate well with quantitative tests such as symptom frequency/severity, use of absorbent products, and postvoid residual (PVR) urine volume (Table 53-2). Major components of the physical examination include the following:[5]

- Abdominal examination for distended bladder, organomegaly, and masses
- Neurologic evaluation of perineum and lower extremities to evaluate lumbosacral nerve function (includes digital rectal

### Table 53–1

**Medications Influencing Lower Urinary Tract Function**

| Medication | Effect |
|---|---|
| Diuretics | Polyuria, frequency, urgency |
| α-Adrenoceptor antagonists | Urethral relaxation: may relieve obstruction in males, induces/worsens SUI in females |
| α-Adrenoceptor agonists | Urethral constriction: aggravates obstruction in males (may cause urinary retention), potential SUI treatment in females |
| Calcium channel blockers (dihydropyridines) | Urethral constriction (may cause urinary retention), especially in males |
| Opioid analgesics | Impaired bladder contractility (may cause urinary retention) |
| Sedative-hypnotics | Functional UI due to immobility, delirium, sedation |
| Psychotherapeutics with anticholinergic properties; anticholinergics | Urinary retention due to impaired bladder contractility or potential UUI treatment |
| TCAs | Combination of anticholinergic and α-adrenoceptor blocking activities can lead to unpredictable effects on UI |
| Ethanol | Polyuria and frequency (via effects on ADH), functional UI (delirium, sedation), urgency |
| ACEIs | Cough leading to SUI (ARBs do not induce cough) |
| Cyclophosphamide | Hemorrhagic cystitis due to acrolein metabolite (prevent with MESNA) |

ACEIs, angiotensin-converting enzyme inhibitors; ADH, antidiuretic hormone (or vasopressin); ARB, angiotensin II receptor blocker; MESNA, sodium 2-mercaptoethanesulfonate; SUI, stress urinary incontinence; TCA, tricyclic antidepressant; UI, urinary incontinence; UUI, urge urinary incontinence.

**Table 53–2**

**Items to Address during Diagnostic Evaluation of UI**

| Item | Comments |
|---|---|
| **Urine Leakage** | |
| Use of absorbent products | Type(s), quantity, times of day worn |
| Urine leakage per episode | Dribbling, small or large volumes, intermittently; Consistent or varied quantities |
| Precipitants | Physical activity, excessive fluid intake, drug(s) |
| Times of day | Daytime/nighttime/both |
| **Symptoms** | |
| Urgency | Frequency, severity, duration from urge onset to micturition |
| Frequency | Daytime/nighttime/both, how often |
| Nocturia | How often, proportion associated with UI |
| Obstructive symptoms | Type(s) (hesitancy, strain to void, decreased force of stream, start and stop stream, sense of incomplete emptying), severity |
| Lower abdominal fullness | Frequency, severity |
| **Comorbidities** | |
| Current medication use | See Table 53–1. Remember CAMs, OTCs |
| Evidence of preexisting or new-onset: | |
| Diabetes mellitus | |
| Metastatic or genitourinary malignancy | |
| Multiple sclerosis or other neurologic disease | |
| CNS disease above the pons | Usually UUI |
| Spinal cord injury | UUI or OUI, depending on level and degree of completeness of injury |
| Recent nongenitourinary surgery | Functional UI |
| Previous local surgery/radiation | Prostate surgery, lower abdominal cavity surgery (direct injury versus denervation), radiation (direct injury) |
| Gynecologic history | Childbirth (vaginal versus cesarean section), prior gynecologic surgery, hormonal status (pre- versus peri- versus postmenopausal) |
| Pelvic floor disease | Constipation, diarrhea, fecal incontinence, dyspareunia, sexual dysfunction, pelvic pain |
| UTI | Dysuria, CVA tenderness, frequency |
| Gross hematuria | Possible bladder or other genitourinary cancer |

CAM, complementary and alternative medications; CVA, costovertebral angle; OTC, over-the-counter; OUI, overflow urinary incontinence; UTI, urinary tract infection; UUI, urge urinary incontinence.

examination to check rectal tone, reflexes, ability to perform a voluntary pelvic muscle contraction in females; size and surface quality of prostate in males)

- Pelvic examination in women for evidence of prolapse of bladder, small bowel, rectum, or uterus, or signs of estrogen deficiency

- Genital/prostate exam in men

- Urinalysis, PVR urine volume

- Direct observation of urethral meatus (opening) when patient coughs/strains (urine spurt consistent with SUI) (cough stress test)

- Perineal examination for skin maceration, redness, breakdown, ulceration, and evidence of fungal skin infection

- Optional: voiding diary, assessment of incontinence severity[9] (Table 53–3), quality-of-life measures

## TREATMENT

Desired and realistic treatment outcomes should be individualized and discussed with each patient. **KEY CONCEPT** *The treatment goals for UI may change with time, often requires reaching a compromise between efficacy and tolerability of drug therapy.*

## Desired Outcomes

- Restoration of continence

- Reduction of the number of UI episodes (daytime and nighttime) and nocturia

- Prevention or delaying of complications associated with UI (eg, pressure ulcers, skin conditions)

- Minimization of adverse effects and costs related to treatment

- Improvement in quality of life

## Nonpharmacologic Treatment

At the primary care level, nonsurgical, nonpharmacologic intervention constitutes the chief approach to the management of UI. It has no adverse reactions, is minimally invasive, and can be utilized adjunctively with other treatment modalities. **KEY CONCEPT** *Nonpharmacologic treatment gives at least an additive effect in efficacy when combined with drug therapy, and can allow the use of lower drug doses.* It is ideal for patients who fit the following scenarios:

- Medically unfit for surgery

- Planning for pregnancies/childbirths, which can compromise the long-term results of certain types of continence surgery

| Table 53–3 | | | |
|---|---|---|---|
| **Overactive Bladder Symptom Score (OABSS)** | | | |
| **Question** | **Symptom** | **Score** | **Frequency Over the Past** |
| 1 | How many times do you typically urinate from waking in the morning until going to bed in the evening? | 0 | 7 or less |
| | | 1 | 8–14 |
| | | 2 | 15 or more |
| 2 | How many times do you typically wake up to urinate from going to sleep at night until waking in the morning? | 0 | 0 |
| | | 1 | 1 |
| | | 2 | 2 |
| | | 3 | 3 or more |
| 3 | How often do you have a sudden compelling desire to urinate, which is difficult to postpone? | 0 | Not at all |
| | | 1 | Less than once week |
| | | 2 | Once a week or more |
| | | 3 | About once a day |
| | | 4 | 2–4 times a day |
| | | 5 | 5 times a day or more |
| 4 | How often do you leak urine because you cannot postpone the sudden desire to urinate? | 0 | Not at all |
| | | 1 | Less than once week |
| | | 2 | Once a week or more |
| | | 3 | About once a day |
| | | 4 | 2–4 times a day |
| | | 5 | 5 times a day or more |
| | Sum of OABSS scores _____ | | |

The sampling period is usually defined as "the past week" but, depending on the usage, it can be amended to, for example, "the past 3 days" or "the past month." Whatever the case, it is necessary to specify the sampling period.

Diagnostic criteria for OAB are "an urgency score for Question 3 of 2 or greater, and an OABSS of 3 or greater." OABSS may also be used for assessing the severity of OAB: a total score of 5 or less (mild), 6 to 11 (moderate), and 12 or more (severe).

- Having OUI whose condition is not amenable to surgical or drug treatment
- Avoiding drug therapy or surgery due to safety concern or patient preference

These approaches include lifestyle/behavioral modifications, fluid management, scheduled voiding regimens, pelvic floor muscle rehabilitation (PFMR), external neuromodulation, anti-incontinence devices, acupuncture, and supportive interventions.[3,5] Many of these are best utilized through attendance at multidisciplinary UI clinics staffed by specialized healthcare providers. Of note, weight loss of 5% to 10% in overweight or obese women has an efficacy similar to that of other nonpharmacologic treatments for treating SUI.

Bladder training and prompted voiding improves symptoms of UUI and MUI. PFMR is an effective treatment for adult women with SUI and MUI.[8] Combination therapy with PFMR plus behavioral training achieved better outcomes than drug therapy in women with UUI.[10] Also, this combination treatment was the only nonpharmacologic treatment that renders true objective evidence of restoring continence.[11] However, these methods require motivation from patients. Medical conditions, such as cognitive dysfunction, may interfere with active participation and compromise efficacy. Regular follow-up is important for monitoring outcomes and for providing reassurance and support. Lifestyle/behavioral interventions should be continued during drug therapy in patients with UI, even if the results have not fully achieved the desired outcomes.

External neuromodulation may include nonimplantable electrical stimulation, percutaneous tibial nerve stimulation, or extracorporeal magnetic stimulation. This treatment option is typically prescribed when traditional PFMR has failed. Anti-incontinence devices, such as bed alarms, catheters, pessaries, penile clamps, and external collection devices, are reserved for special situations depending on patient's symptoms, cognition, mobility status, and overall health status. Supportive interventions such as physical therapy may be beneficial for patients with muscle weakness and slow gait that hinder their reach to the toilet in a timely manner. Last, absorbent products provide greater patient confidence in dealing with unpredictable urine loss.[5]

Surgery is rarely an initial treatment for UI; only considered in patients with significantly bothersome symptoms, and when nonsurgical options are undesired or ineffective. Surgery is not as helpful for bladder underactivity but can be used to manage urethral overactivity due to BPH and bladder outlet obstruction (via endoscopic incision using a cystoscope). It is most effective for SUI by stabilizing the urethra and bladder neck and/or augmenting urethral resistance. Common approaches are injection of periurethral bulking agents and midurethral sling procedure. In males, SUI is best treated by implanting an artificial urinary sphincter.[5]

Posterior tibial nerve stimulation is an office-based percutaneous treatment for UUI or OAB. Therapy consists of weekly 30-minute treatments with a needle placed posterior to the medial malleolus of the ankle over the course of 3 months. Efficacy appears similar to or slightly better than oral pharmacotherapy.[5]

Surgical treatment for UUI generally consists of implantation of a sacral nerve stimulator (neuromodulation) or endoscopic

## Patient Encounter 1, Part 2: Medical History, Physical Examination, and Diagnostic Tests

**PMH:** Hypertension, dyslipidemia, seasonal allergy

**FH:** Noncontributory

**SH:** Retired high school teacher; now volunteers as a story teller at a local daycare center. Widowed and lives alone. Two married daughters (ages 30 and 32 years) live in the neighborhood. Denies tobacco or alcohol use; drinks five cups of coffee in the morning and two cups of herbal tea at bedtime

**All:** NKDA

**Meds:** Lisinopril 10 mg once daily; simvastatin 20 mg once daily; OTC allergy meds as needed for itchy eyes

**ROS:** Alert, sociable, and pleasant. (–) UI or recent history of UTIs; (+) nocturia; dysuria, lower abdominal fullness, or decreased force of stream

**PE:**

**Gen:** Postmenopausal woman with mild kyphosis; NAD

**VS:** BP 140/80 mm Hg, HR 75 beats/min, RR 18 breaths/min, T 98.3°F (36.8°C), Wt 63 kg, Ht 5′5″ (165 cm)

**HEENT:** PERRLA; EOMI, TMs WNL

**Neck/LN:** Supple w/o LAD or masses

**Lungs/Thorax:** CTA

**CV:** RRR w/o murmurs, rubs, gallops

**Abd:** soft, NT/ND w/o masses; (+) BS; bladder not palpable

**GU:** WNL; no atrophic vaginitis or uterine prolapse

**MS/Ext:** WNL, no edema

**Neuro:** DTRs 2+, CN II–XII intact

**Labs:** Na 135 mEq/L (134 mmol/L); K 4.0 mEq/L (4.0 mmol/L); Cl 100 mEq/L (100 mmol/L); $CO_2$ 22 mEq/L (22 mmol/L); BUN 9 mg/dL (3.2 mmol/L); SCr 1.0 mg/dL (88 μmol/L); Fasting glucose 90 mg/dL(5.0 mmol/L); Hb 12 g/dL (120 g/L; 7.45 mmol/L); Hct 37% (0.37); Plts 300,000/mm³ (300 × 10⁹/L); WBC 6.1 × 10³/mm³ (6.1 × 10⁹/L) with normal differential

LFTs within normal limits

UA not indicated

*Given this additional information, what is your assessment of the patient's condition?*

*What are the goals of pharmacotherapy for this patient?*

*What nonpharmacologic and pharmacologic alternatives are available to the patient?*

---

office based injection of botulinum toxin A directly into the smooth or striated muscle.[5] The injections are performed in the office generally with local anesthesia. The duration of effect of the toxin is about 4 to 8 months after which repeat injection is necessary to maintain effect. Intravesical (bladder) botulinum toxin A injections increased bladder capacity/compliance and improved quality of life in patients with refractory OAB.[5]

Patients with UUI and an elevated PVR urine volume may require intermittent self-catheterization along with frequent voiding between catheterizations. Surgical placement of a suprapubic catheter may be necessary in cases when intermittent catheterization is not possible. Catheterization can be combined with pharmacologic treatment for symptom relief.[5]

### Pharmacologic Treatment

The ideal treatment agent must have clinical efficacy, minimal side effects, minimal drug–drug/drug–disease interactions, convenient administration, and low cost. **KEY CONCEPT** *Patient characteristics (eg, age, comorbidities, concurrent drug therapies, and ability to adhere to the prescribed regimen) can influence drug therapy selection.*[5] Although a recent systematic review has shed light on the comparative data on newer agents,[12,13] selection of an initial agent should be based on patient individual characteristics.

▶ *Urge Urinary Incontinence*

**Anticholinergic/Antimuscarinic** Antimuscarinic agents are the first-line pharmacologic treatment for UUI or OAB (Table 53–4).[6] They are effective in suppressing premature detrusor contractions, enhancing bladder storage, and relieving symptoms. When used with or without bladder training, these agents improved symptoms and quality of life in patients with UUI or OAB; however, they restore continence in less than 15%

of patients and reduce episodes of incontinence by only 0.5 to 1 episodes per day.[12,14,15] They are considered equally effective based on statistical superiority over placebo or active controls.

All antimuscarinic agents have similar contraindications and precautions, including urinary retention, gastric retention, and uncontrolled narrow-angle glaucoma.[5] Older immediate release (IR) agents, such as oxybutynin and tolterodine, have been associated with higher rates of dry mouth, constipation, headache, dyspepsia, dry eyes, cognitive impairment, tachycardia, and urinary retention (Table 53–5). Older patients are especially susceptible to these adverse events. Significant dry mouth can be associated with dental caries, ill-fitting dentures, and swallowing difficulty. Chewing sugarless gum or use of saliva substitutes can help to alleviate dry mouth.

Orthostatic hypotension and sedation can be particularly troublesome to patients with cognitive impairment or at risk for falls. Issues with tolerability and multiple daily dose administration associated with IR products may jeopardize medication adherence and can prevent dose titration to achieve optimal clinical response. Thus, these IR products are not preferred in patients with functional limitations and/or those who are already taking complicated drug regimens. Nevertheless, adverse events are not universal and the severity varies with individuals. Older agents, when initiated at the lowest possible doses and gradually titrated, are reasonable to consider in patients where a long-acting product is undesirable.

Extended-release (ER) agents (oxybutynin XL, tolterodine LA, trospium ER, darifenacin ER, fesoterodine ER) cause less dry mouth compared with IR products.[5,7,15] These products cannot be chewed, crushed, or divided, and must be swallowed whole. Oxybutynin transdermal patch and topical gel are alternatives for patients who cannot take or tolerate oral drugs; they have lower rates of dry mouth but are associated with application site

**Table 53–4**

**Approved Drugs for the Management of UUI**

| Parameter | Oxybutynin | Tolterodine | Trospium Chloride | Solifenacin | Darifenacin | Fesoterodine | Mirabegron |

Significantly altered in hepatic disease (decreased CL in cirrhosis) and renal disease (decreased CL) | Food: decreased BA by 70%–80%<br>Significantly altered in renal disease (decreased CL) but not in hepatic disease or advanced age | Metabolized via CYP 3A4 but only one active metabolite (4-hydroxy)<br>Significantly altered in severe renal impairment, moderate hepatic impairment (Child-Pugh B), and advanced age (decreased CL in all) | Complex metabolism (polymorphic CYP 2D6, CYP 3A4)<br>Not altered in advanced age, renal impairment, mild hepatic impairment (Child-Pugh A)<br>Significantly altered in moderate hepatic impairment (Child-Pugh B) (decreased CL) | Prodrug (for 5-hydroxmethyl tolterodine)<br>Inactive metabolites<br>Not altered in advanced age<br>Significantly altered in renal disease (decreased CL) and moderate hepatic impairment (Child-Pugh B) (decreased CL) | Terminal elimination half-life 50 hours<br>Moderate inhibitor of CYP 2D6 |
| Contraindications and precautions | Use with caution if CYP 3A4 inhibitors are also being taken (decreased oxybutynin CL) | Reduce dose 50% in those taking CYP 3A4 inhibitor(s) or with hepatic cirrhosis or with CrCl less than 30 mL/min (0.50 mL/s)<br><br>Antacid-SR (oral) prep, interaction (dose-dumping) (not seen with PPIs) | Give on empty stomach<br>Decrease dose 50% when CrCl < 30 mL/min (0.50 mL/s) and use IR formulation | Do not exceed 5 mg/day if CrCl < 30 mL/min (0.50 mL/s), patient has moderate hepatic impairment, or patient is taking CYP 3A4 inhibitor(s)<br>If severe hepatic impairment, do not use | Do not exceed 7.5 mg/day if patient is taking potent CYP 3A4 inhibitor(s)<br>Use caution if patient is taking moderate CYP 3A4 inhibitor(s) or CYP 3A4 or 2D6 substrate(s)<br>Do not chew, divide, or crush the ER tablets | Do not exceed 4 mg/day if CrCl less than 30 mL/min (0.50 mL/s) or patient is taking potent CYP 3A4 inhibitor(s)<br>If severe hepatic impairment, do not use | Limit dose to 25 mg once daily if severe renal impairment or moderate hepatic disease<br>Avoid in end-stage renal disease or severe hepatic impairment, or more BP 180/110 mmHg<br>Monitor for increased BP and urinary retention |

BA, bioavailability; BP, blood pressure; CL, total body clearance; CrCl, creatinine clearance; TD, transdermal; ER, extended release; IR, immediate release; LA, long acting; PPIs, proton pump inhibitors; SR, sustained release.

## Patient Encounter 1, Part 3: Creating a Care Plan

Patient prefers to try a drug that is least likely to cause dry mouth. She is willing to try topical agents.

*Based on the information presented, create a care plan for this patient's OAB. Your plan should include:*

*(a) A statement of the drug-related needs and/or problems*

*(b) The goals of therapy*

*(c) A patient-specific detailed therapeutic plan, including patient counseling to enhance medication adherence, ensure successful therapy, and minimize adverse effects*

*(d) A plan for follow-up to evaluate therapeutic outcome and drug tolerability*

reactions. Rotation of application sites can be helpful to minimize the side effects.

Patients receiving any antimuscarinic agent should be informed about sedation as a possible side effect and warned against operating heavy machinery, such as driving, especially during the initial phase of therapy. Patients with existing cognitive dysfunction or difficulty with balance should be monitored closely for mental status changes and risk for falls. Older individuals are more prone to have constipation of age-related physiologic changes and the increased likelihood of receiving other medications that may exacerbate constipation. Patients should be advised to contact their physician if they experience severe abdominal pain or become constipated for 3 or more days. An important drug–drug interaction to avoid is the concurrent use of acetylcholinesterase inhibitors, which are used to treat dementia (antagonism) and any other anticholinergic agents (increase side effects).[16]

**KEY CONCEPT** *Antimuscarinic agents should be initiated at the lowest possible dose and gradually titrated upward based on clinical response; not to exceed the maximum recommended doses.* A trial of at least 4 weeks is required to evaluate its efficacy. Consider switching to another agent if the patient reports intolerable side effects or inadequate symptom relief despite optimized dose.

**Mirabegron** Mirabegron is a $\beta_3$-adrenergic agonist approved in June 2012 for the treatment of OAB with UUI. Like antimuscarinic agents, it reduces urinary frequency and incontinence episodes by less than one per day and is also considered the first-line drug therapy for OAB (see Table 53–4).[6,17] It increases bladder capacity by relaxing the detrusor smooth muscle during the storage phase of the urinary bladder fill-void cycle. It requires 4 to 8 weeks of therapy for optimal efficacy.[17]

Mirabegron is available in ER tablets, and should be swallowed whole without chewing, dividing, or crushing. Most commonly reported adverse reactions were hypertension (7%–11%), nasopharyngitis (4%), urinary tract infection (3%–6%) and headache (3%–4%). Patient should be monitored for increased blood pressure and urinary retention, particularly in patients with bladder outlet obstruction or those who are taking anticholinergic drugs.[5] Currently, there is no direct comparison of mirabegron and antimuscarinics for efficacy or tolerability.

**Older Agents[5]** Tricyclic antidepressants (TCA), such as desipramine, nortriptyline, imipramine, and doxepin, are generally no more effective than oxybutynin IR. They may cause potentially serious adverse effects (eg, orthostatic hypotension, cardiac conduction abnormalities, dizziness, and confusion); thus should be limited to individuals who have one or more indicated comorbidities (eg, depression or neuropathic pain); patients with MUI (because of their effect of decreasing bladder contractility and increasing outlet resistance); and possibly those with nocturnal incontinence associated with altered sleep patterns. Propantheline, flavoxate, dicyclomine, and hyoscyamine are not recommended due to lack of efficacy and/or significant adverse effects.[5]

### ▶ Stress Urinary Incontinence

The goal of pharmacologic therapy of urethral underactivity is to improve the urethral closure mechanism:

- Stimulating α-adrenoceptors in the smooth muscle of the proximal urethra and bladder neck
- Enhancing the supportive structures underlying the urethral mucosa
- Enhancing the positive effects of serotonin and norepinephrine in the afferent and efferent pathways of the micturition reflex

### Table 53–5

**Adverse Event Incidence Rates with Approved Drugs for Bladder Overactivity[a]**

| Drug | Dry Mouth (%) | Constipation (%) | Dizziness (%) | Vision Disturbance (%) |
|---|---|---|---|---|
| Oxybutynin IR | 71 | 15 | 17 | 10 |
| Oxybutynin XL | 61 | 13 | 6 | 14 |
| Oxybutynin TDS | 7 | 3 | NR | 3 |
| Oxybutynin gel | 10 | 1 | 3 | 3 |

| Fesoterodine | 27 | 5 | NR | 3 |
| Mirabegron ER | 3 | 3 | 3 | NR |

IR, immediate-release; LA, long-acting; NR, not reported; TDS, transdermal system; XL, extended-release; XR, extended-release.

[a]All values constitute mean data, predominantly using product information from the manufacturers.

In generally, there is no role for pharmacologic therapy in SUI in men resulting from surgery or trauma.[18] Initial data, however, suggest a possible role for duloxetine added to PFMR in males status postradical prostatectomy, at least over the first 4 to 6 months.[19] Unlike UUI, SUI in women is frequently curable by surgery, thus obviating years of drug therapy that may not provide adequate symptom relief. Surgery (tension-free vaginal tape sling) is a more cost-effective therapy of SUI than duloxetine in women failing PFMR.[20]

**Estrogens**[5] KEY CONCEPT *Vaginally administered estrogen plays a limited role in managing SUI unless local signs of estrogen deficiency (eg, atrophic urethritis or vaginitis) are present.* Estrogen products are believed to work by a trophic effect on uroepithelial cells and underlying collagenous subcutaneous tissue, enhancement of local microcirculation by increasing the number of periurethral blood vessels, and enhancement of the number and/or sensitivity of α-adrenoceptors.

Since 1940s, estrogens administered by various routes (oral, transdermal, and local) have been used to manage SUI although recent trials showed them to be no better than placebo. Actually, oral hormone replacement therapy increases the risk of new-onset UI (SUI, UUI, MUI) while carrying numerous short- and long-term risks, including mastodynia (pain in the breast), uterine bleeding, nausea, thromboembolism, cardiac/cerebrovascular ischemic events, and breast/endometrial cancer.[11,21] In contrast, local estrogens (estriol [not available in the US] tablets, conjugated equine estrogen cream, estradiol rings, pessaries) have demonstrated subjective improvement in SUI and UI in general.[21,22] Thus, clinicians may consider only locally administered estrogen products for SUI while monitor for individual response (Table 53–6).

**α-Adrenoceptor Agonists**[5] Phenylpropanolamine, ephedrine and pseudoephedrine have been used alone or with estrogen for mild and moderate SUI. However, recent data showed that they are not better than placebo or PFMR.[21] Phenylpropanolamine has been removed from the market in the United States due to associated risk of ischemic stroke. However, clinicians should be aware that it can still be purchased via the Internet and should discourage its use. Ephedrine, although still available by prescription, should not be used for SUI due to toxicity and lack of efficacy data. The major impediment to using α-adrenoceptor agonists is the extensive list of contraindications (see Table 53–6). Side effects of pseudoephedrine, an over-the-counter drug, include hypertension, headache, dry mouth, nausea, insomnia, and restlessness.

**Duloxetine** This selective serotonin-norepinephrine reuptake inhibitor can be used for SUI in the United States. It enhances central serotonergic and adrenergic tone, which is involved in ascending and descending control of urethral smooth muscle and the internal urinary sphincter, and thereby enhances urethral and urinary sphincter smooth muscle tone during the filling phase.[23–25] Recent review shows that it slightly improved incontinence,[11] and may give greater benefit when combined with PFMT.[26] Preliminary results suggest that it may also benefit incontinence and quality of life in men with SUI after radical prostatectomy.[26]

The use of duloxetine in SUI is complicated by intolerability (eg, high rates of nausea), numerous precautions or contraindications, cytochrome P450 (CYP) drug–drug interactions, and possibility of withdrawal symptoms if abruptly discontinued.[23] Duloxetine discontinuation rate at 1 year is as high as 66%, with two-thirds of discontinuations related to adverse events and one-third for lack of efficacy.[27] The most common adverse events reported with duloxetine for SUI were nausea (up to 46%), headache (up to 27%), constipation (up to 27%), dry mouth (up to 22%), and insomnia (up to 14%). Overall, adherence to long-term duloxetine therapy is poor due to adverse events and lack of efficacy.[28]

The usual dosage is 40 to 80 mg/day (in one or two doses) for 12 weeks. Gradual dose titration (starting from 20 mg once daily for at least 1 week, then titrate no shorter than weekly interval) may help to reduce the risks of nausea, dizziness, and premature therapy cessation. Similarly, taper the dose to avoid withdrawal symptoms if duloxetine is discontinued. Dose reduction of 50% for 2 weeks before discontinuation or slow tapering over 4 to 6 months is reasonable. If intolerable withdrawal symptoms occur following a dose reduction, consider resuming the previously prescribed dose and/or decrease dose at a more gradual rate.

▶ *Overflow Incontinence*[5]

There is no established effective pharmacologic therapy for OUI due to bladder underactivity (atonic bladder). A trial of bethanechol (25–50 mg three or four times daily) may be reasonable if contraindications do not exist. Bethanechol is a cholinomimetic that has uncertain efficacy but is associated with bothersome and potentially life-threatening side effects (muscle and abdominal cramping, hypersalivation, diarrhea, and bronchospasm), particularly in patient with preexisting conditions. α-Adrenoceptor antagonists, such as silodosin, prazosin, terazosin, doxazosin, tamsulosin, and alfuzosin, may be beneficial for OUI by relaxing the bladder outflow tract and hence reducing outflow resistance. If pharmacologic therapy fails, intermittent urethral catheterization by the patient or caregiver three or four times per day is recommended. Less satisfactory alternatives include indwelling urethral or suprapubic catheters or urinary diversion. In OUI due to obstruction, such as BPH, the goal of treatment is to relieve the obstruction.

▶ *Mixed Urinary Incontinence*

MUI is usually a combination of UUI plus SUI with one dominant component. It accounts for one-third of UI cases in women. A reasonable management approach is a combination of lifestyle/behavioral modifications and PFMR with pharmacotherapy appropriate to the dominant type of UI. For instance, antimuscarinics can be offered in UUI-predominant cases, whereas duloxetine, local estrogen, and α-adrenoceptor agonists in SUI-predominant cases. In some cases, the less dominant form of UI may respond, but usually not to a degree that is considered adequate by the patient. Most experts feel that SUI-predominant MUI is best treated initially using the nonpharmacologic approach plus surgery for SUI. Unfortunately, these patients with MUI are expected to have a lower success rates with surgery compared to those with pure SUI. The urge component may get better, stay the same, or get worse after surgery. Unfortunately, there is no a priori way to predict the response in a given individual.[29,30]

## OUTCOME EVALUATION

- Monitor the patient for symptom relief. Have the treatment achieved the desired outcomes jointly developed by the health care team and the patient/caregiver? If so, to what

| | Table 53–6 | | |
|---|---|---|---|

**Drugs Used for SUI[a]**

| Parameter | Estrogens | Pseudoephedrine | Duloxetine |
|---|---|---|---|
| Dosage forms | Avoid systemic (parenteral, oral, TD); use vaginal: tablet, cream, intravaginal ring | Tablets, solution | DR capsules |
| Dosing | Estradiol 25-mcg vaginal tablets (insert one PV daily for 14 days, then one PV twice weekly)<br>Estradiol vaginal cream (0.1 mg/g) (2–4 g daily PV for 1–2 weeks; then 1 g PV daily or less frequently)<br>CEE vaginal cream (0.625 mg/gm) (0.5–2 g daily PV; consider 3 weeks on, 1 week off; may be able to decrease frequency of use over time)<br>Estradiol 2-, 12.4-, 24.8-mg vaginal rings (1 ring PV every 3 months) | 15–60 mg three times daily | 40–80 mg/day in one or two doses for 12 weeks (titrate and taper dosage) |
| Kinetics | Use local route to minimize systemic BA and side effects<br>Estradiol less likely to be absorbed; CEE 1 mg or more daily sufficiently absorbed to cause systemic side effects | Less than 1% of dose is metabolized (inactive metabolites)<br>Primarily renal elimination of unchanged drug<br>Would not expect hepatic impairment to have an effect (no data)<br>Expect significant effect if renal impairment and no effect if advanced age (beyond decreased CrCl with age) (no data) | Extensive metabolism via CYP 2D6 and 1A2 (inactive metabolites)<br>Not altered in advanced age, mild to moderate renal impairment (CrCl 31–80 mL/min [0.51–1.34 mL/s]), mild hepatic impairment (Child-Pugh A)<br>Significantly altered in severe renal disease (CrCl < 30 mL/min [< 0.50 mL/s]) and moderate hepatic impairment (Child-Pugh B) |
| Contraindications/ precautions | Contraindications include known or suspected breast or endometrial cancer<br>Abnormal genitourinary bleeding of unknown etiology<br>Active thromboembolism (or history of TE associated with previous estrogen use) | Contraindications include hypertension, tachyarrhythmias, coronary artery disease, MI, cor pulmonale, hyperthyroidism, renal failure, narrow-angle glaucoma | Multiple drug–drug interactions possible with CYP 2D6 and 1A2 substrates/inhibitors<br>Avoid if CrCl < 30 mL/min (0.50 mL/s) and in all patients with hepatic disease<br>Can raise BP<br>Do not discontinue abruptly (withdrawal syndrome)<br>Suicide risk even in patients without psychiatric disease<br>Avoid in uncontrolled narrow-angle glaucoma (causes mydriasis)<br>Hepatotoxic; avoid in alcoholics even if signs/symptoms of hepatic disease are absent |

BA, bioavailability; BP, blood pressure; CEE, conjugated equine estrogens; CrCl, creatinine clearance; CYP, cytochrome P-450; DR, delayed-release; MI, myocardial infarction; PV, per vagina; TD, transdermal; TE, thromboembolism.

[a]None of these agents are FDA approved for treatment of SUI. Duloxetine is approved in Europe only.

degree? Inspect the daily diary completed by the patient/caregiver and quantitate the clinical response (eg, number of micturitions, number of incontinence episodes, and pad use) since the last visit. If a diary has not been used, ask the patient how many incontinence pads have been used and how they have been doing in terms of "accidents" since the last visit. If appropriate, administer a short-form instrument to measure the impact of symptoms, including quality of life. Compare the findings with previous results.

- Ask patients about adverse effects of drug therapy using a nonleading approach. Ask the patient/caregiver to judge

their severity and what measures, if any, they have used to alleviate. Assess medication adherence (ask patient/caregiver about missed doses or do a pill count if the prescription containers are available at the visit).

- The balance of clinical response and tolerability should guide whether the drug dosage is increased, decreased, or left unchanged. Consider stopping/tapering off the regimen and initiate another drug option if bothersome adverse effects compromise patient safety and/or medication adherence.

## Patient Care Process: Urinary Incontinence

**Patient Assessment:**

- Identify urinary symptoms and assess their severity. Assess changes in quality of life (physical, psychological, social functioning, and well-being). Identify exacerbating factors and UI complications. Determine whether a referral to specialized professionals is required.
- Review concurrent medical conditions and assess whether or not urinary symptoms could be disease-related.
- Obtain a thorough medication history, including use of prescription, nonprescription, and complementary/alternative drug products. Assess whether or not urinary symptoms could be drug induced (see Table 53–1). Determine if any current or previous treatments are helpful for UI.
- Include the patient and caregiver to set realistic goals of therapy. In cognitively intact elderly patients, focus communications to elicit the preferences of the patient, not those of potential proxies.

**Therapy Evaluation:**

- Evaluate the appropriateness of treatment regimen (drug choice, dosage, administration) for his or her type(s) of UI.
- Evaluate the patient for medication adherence, drug-related adverse events, allergies, and drug interactions with concomitant medications or disease states.

**Care Plan Development:**

- Educate the patient on lifestyle modifications that may improve symptoms: smoking cessation (for patients with cough-induced SUI), weight reduction (for those patients with SUI and UUI), prevention of constipation in patients at risk, caffeine reduction, and modification of diet and fluid intake. Note the timing and quantity of fluid intake, as well as possibility of avoiding foods or beverages that worsen UI.
- Provide patient education regarding the disease state, lifestyle modifications, and drug therapy (see Table 53–4).
- Causes of UI and possible complications:
  - Lifestyle modifications
  - Timing of medication intake
  - Potential adverse events
  - Potential drug–drug or drug–disease interactions
  - Importance of treatment adherence

**Follow-up Evaluation:**

- Monitor for patient response in 1 or 2 weeks after therapy initiation.
- Develop a plan to assess efficacy after a minimum of 4 weeks.

# PEDIATRIC ENURESIS

## INTRODUCTION

UI is a common problem in children, and treatment is unnecessary in children younger than 5 years, in whom spontaneous cure is likely. Pediatric enuresis (also called "intermittent nocturnal incontinence" or "nocturnal incontinence") is a condition, which can present alone or coexist with other disorders in children and adolescents. It is defined as discrete episodes of UI during sleep in children at least 5 years old.[31-33] Common terms associated with enuresis are as follows:

- Monosymptomatic enuresis: Enuresis in children without any other lower urinary tract symptoms and without a history of bladder dysfunction
  - Primary enuresis: A process wherein the patient has never been consistently dry throughout the night
  - Secondary enuresis: A process wherein the patient has resumed wetting after a period of dryness of at least 6 months in duration
- Nonmonosymptomatic enuresis: Enuresis in children with other lower urinary tract symptoms (eg, urgency, frequency, daytime incontinence, genital or lower urinary tract pain)[32,33]

Enuresis is not a benign disorder that children will just "grow out of." The emotional and developmental damage produced by enuresis may be more significant to the child than the enuresis itself. Emotional and/or physical abuse of the child by adult caregivers can lead to secondary problems such as chronic anxiety, low self-esteem, and delayed developmental milestones (attending camp, "sleepovers" at the homes of friends, etc).

## EPIDEMIOLOGY AND ETIOLOGY

Five to seven million children and adolescents in the United States suffer from nocturnal enuresis. With each year of maturity, the percentage of bed-wetters declines by 15%. Primary enuresis is twice as common as secondary enuresis, which is present in 15% to 25% of bed-wetters.[34] In the enuretic population, 80% to 85% are monosymptomatic, 5% to 10% are nonmonosymptomatic, and less than 5% have an organic cause. Every year about 15% of those suffering from primary monosymptomatic nocturnal enuresis have spontaneous resolution without treatment.[34,35] The prevalence of enuresis is as follows:

- At age 5: 15% to 25%
- At age 12: 8% (boys) and 4% (girls)
- Adolescents: 1% to 3%

The etiology of enuresis is poorly understood, but there is a clear genetic link. Loci for enuresis have been located on chromosomes 5, 12, 13, and 22. The incidence in children from families with both parents had enuresis as children reaches as high as 77%, compared to 44% in whom from families with one parent had enuresis as a child, and 14% in whom from families with no members with enuresis. Sleep disorders are not considered major contributors, with the exception of sleep apnea. Enuresis occurs in all sleep stages in proportion to the time spent in each stage. However, a small proportion of individuals are not aroused from sleep by bladder distention and have uninhibited bladder contractions preceding enuresis.[34]

## PATHOPHYSIOLOGY

There are potentially treatable organic causes of enuresis (Table 53–7). Vast majority of children with enuresis have normal urodynamics, including functional bladder capacity, or maximum voided volume. Expected bladder capacity can be estimated by this formula: $(30 + [30 \times \text{age}])$ mL.

In some children, there appears to be a relationship between developmental immaturity in motor and language milestones and enuresis, but the mechanism is unknown. There is evidence that affected individuals have an attenuated vasopressin circadian rhythm (more significant in girls) with lower vasopressin plasma concentrations.[36] Other contributors include detrusor over-activity at night, increased threshold for arousal, and taking certain drugs (eg, lithium, clozapine, risperidone, valproic acid, selective serotonin reuptake inhibitors, and theophylline). Interestingly, caffeine ingestion does not correlate with enuresis.[37] In a minority of cases, psychological factors (eg, divorce of parents, school trauma, sexual abuse, or hospitalization) are clearly contributory to secondary enuresis. In very rare cases, severely dysfunctional families may neglect to properly toilet train the children.

## TREATMENT
### Desired Outcomes

- Reduction in the number of enuresis episodes and restoration of continence[32]

### Table 53–7

**Major Potentially Treatable Organic Causes of Enuresis**

**Potentially Treatable by Surgery**
- Ectopic ureter
- Lower UTI (correct congenital anomalies)
- Neurogenic bladder
- Bladder calculus (stone) or foreign body
- Obstructive sleep apnea

**Potentially Treatable by Drugs**
- UTI
- Diabetes mellitus
- Diabetes insipidus
- Fecal impaction
- Constipation

UTI, urinary tract infection.

- Partial response: a 50% to 89% decrease
- Response: 90% or more decrease
- Full response: a 100% decrease or less than 1 symptom occurrence monthly
- Prevention of relapse (greater than 1 symptom recurrence monthly) and maintenance of treatment success[32]
  - Continued success: No relapse in 6 months after the interruption of treatment
  - Complete success: No relapse in 2 years after the interruption of treatment
- Prevention or minimization of disease complications (delay in childhood developmental milestones, adverse psychological effects on the child/caregivers)
- Minimization of adverse effects and costs related to treatment
- Improvement in the quality of life of the child and caregivers

### General Approach to Treatment

Treatment is guided by the findings of the patient assessment. A referral to urologists is needed in cases of daytime wetting, abnormal voiding (eg, unusual posturing, discomfort, straining, poor stream), history of recurrent UTIs, and abnormalities of the genitalia. Crisis intervention strategies and individual and/or family psychotherapy are recommended in the rare circumstance of a true psychological cause.

Guidelines for the evaluation and management of nocturnal enuresis have been developed.[33,38,39] Management of primary monosymptomatic nocturnal enuresis in children may involve one or a combination of interventions. The management of secondary nocturnal enuresis focuses on addressing the underlying stressor. However, most children with secondary enuresis have

## Patient Encounter 2, Part 2

**PMH:** Unremarkable pregnancy/delivery. Developmental milestones WNL

*What initial treatment would you suggest?*

no identifiable causes and are treated in the same manner. The algorithm within the NICE guideline (**Figure 53–1**) is inclusive of the most potentially useful treatments and distinguishes approaches based on the child's age, maturity, and abilities; the frequency of enuresis; and the motivation and needs of the family.[39]

Initial management with education and motivational/behavioral therapy (**Table 53–8**) should be utilized for 3 to 6 months, provided that the patient and family are sufficiently motivated.[35] More active intervention (eg, enuresis alarm, pharmacologic treatment) is warranted if initial management fails or provides inadequate response. **KEY CONCEPT** *Enuresis alarms are the most effective long-term therapy, but desmopressin is effective in the short-term (eg, for sleepovers or camp attendance).* **KEY CONCEPT** *Pharmacotherapy is most valuable in patients who have difficulty in adhering to nonpharmacologic therapy or in those who fail to achieve desired outcomes with nonpharmacologic therapy.*

### ▶ Nonpharmacologic Treatment

The standard first-line therapy demands for commitment from the child and/or caregiver (see Table 53–8). It involves education about the condition, fluid/diet modification, journal keeping, and behavioral or motivational therapy.[35,40] Motivational therapy allows about 25% of children to achieve 14 consecutive dry nights and 70% of them at least a partial response. About 5% of children experience more than 2 wet nights in 2 weeks. If motivational

therapy fails to lead to improvement after 3 to 6 months, active interventions, such as enuresis alarms (**Table 53–9**) or desmopressin, may be added.[35]

Enuresis alarms are indicated for motivated families and children with frequent enuresis of more than twice per week. They conditioned the child to learn to wake or inhibit bladder contraction in response to the physiologic conditions present before wetting. They are the most effective ways of controlling nocturnal enuresis and preventing relapse, and may be used in children younger than 7 years. They are more effective than TCAs for pediatric enuresis.[41] Alarm therapy can be an effective add-on in patients who are partial- or nonresponders to drug therapy alone. Similarly, drug therapy can be added in patients who achieved suboptimal results from nonpharmacologic therapy alone.[42,43]

Use of enuresis alarms does not provide rapid or short-term improvement, and requires the child be able to wake to sound or touch. Approximately 30% of patients discontinue enuresis alarms for various reasons, including skin irritation, disturbance of other family members, and/or failure to wake the child.[35] Adverse effects of alarms include alarm failure, false alarms, failure to wake the child, disruption of other family members, and lack of adherence because of difficulty using the alarm.[41]

Efficacy may be assessed within 1 to 2 weeks of initiating alarm therapy. Treatment should be continued if the child demonstrates early signs of response. It often requires 3 to 6 months to achieve a minimum of 14 consecutive dry nights. After 3 months of therapy, if the child has achieved at least some response, alarm therapy should be continued.[35,39] If no improvement is seen in 3 months, alternative interventions should be considered. However, enuresis alarm can be reinitiated for relapses.[35]

Measures that do not help or are of questionable value in pediatric enuresis include the following:[44]

- Bladder stretching exercises (done by delaying voiding despite the urge to do so)
- Hypnotherapy
- Dietary changes
- Desensitization to allergens
- Acupuncture
- Chiropractic

### ▶ Pharmacologic Treatment

**Desmopressin (DDAVP)[35,45]** A synthetic analogue of vasopressin, desmopressin was first studied in enuresis in the 1970s. It is indicated for nocturnal enuresis in children at least 6 years of age who do not respond to initial management (see Table 53–8), or as an alternative for alarm therapy. It is most effective in children with nocturnal polyuria (nocturnal urine production greater than 130% of expected bladder capacity for age) and normal functional bladder capacity (maximum voided volume greater than 70% of expected bladder capacity for age). It decreases the number of wet nights per week by about one night. About 30% of children become full responders while on the drug, but 60% to 70% of them experience relapses.[35]

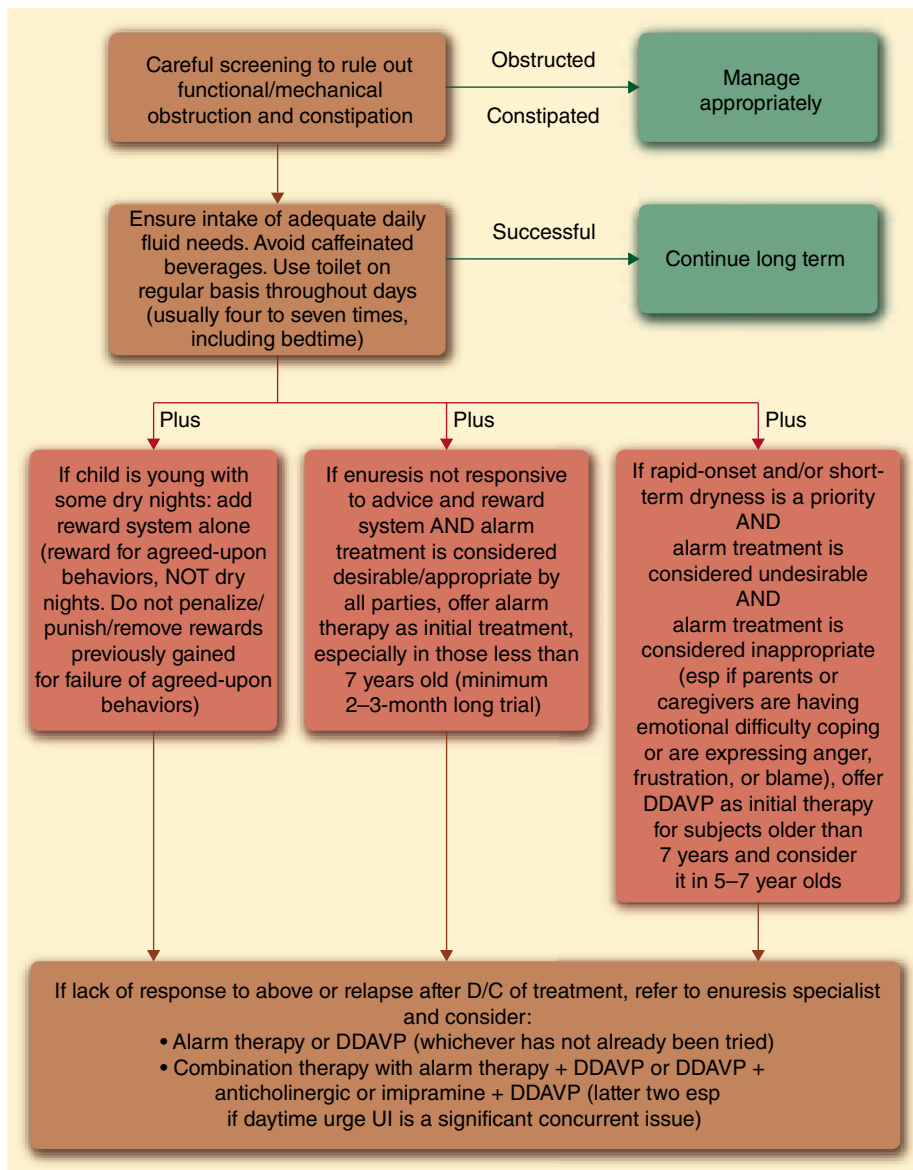
**KEY CONCEPT** *Desmopressin is the drug of choice in pediatric enuresis.* In many countries the enuresis indication has been removed for nasal desmopressin due to higher risk for hyponatremic seizure. Oral desmopressin is an ideal agent for rapid-onset, short-term use (camp attendance or "sleepovers"). To aim for long-term benefit, consider a trial for at least 3 to 6 months. Regular tablets may be started at 0.2 mg (one tablet) 1 hour


**FIGURE 53–1.** Enuresis treatment protocol. (D/C, discontinuation; DDAVP, desmopressin; UI, urinary incontinence.) (Modified from Nunes VD, O'Flynn N, Evans J, Sawyer L; Guideline Development Group. Management of bedwetting in children and young people: Summary of NICE guidance. BMJ. 2010;341:c5399.)

---

**Table 53–8**

**Initial Management of Pediatric Enuresis**

**Education and Advice to Children and Caregivers**
- Enuresis is common; it occurs at least once per week in up to 25% of 5 year olds; enuresis resolves on its own in the majority of children.
- Enuresis is the fault of neither the child nor the caregivers; children should not be punished for bedwetting.
- Reduce the impact of bedwetting by using bed protection and washable/disposable products; using room deodorizers; thoroughly washing the child before dressing; and using emollients to prevent chafing.
- Keeping a calendar of wet and dry nights helps to determine the effect of interventions.
- The child should attempt to void regularly during the day and just before going to bed (a total of four to seven times); if the child wakes at night, the caregivers should take him/her to the toilet.
- Avoid high-sugar and caffeine-based drinks, particularly in the evening hours.
- Concentrate daily fluid intake in the morning and early afternoon. Restrict fluid and solute intake during the evening. A recommendation is to drink 40 % of their total daily fluid in the morning (7 AM to 12 PM), 40 % in the afternoon (12 PM to 5 PM), and only 20 % in the evening (after 5 PM).
- Discourage routine use of diapers and pull-ups, except when the child is sleeping away from home.

**Motivational Therapy**
- Motivational therapy is a good first-line therapy for nocturnal enuresis in younger children between the ages of 5 to 7 years who do not wet the bed every night.
- Motivate the child by keeping a record of progress and receive rewards for accomplished agreed-upon behavior, such as going to the toilet before bedtime. For example, a sticker on a calendar for each dry night, a book for seven consecutive dry nights, etc. Do not use penalties (ie, removal of previously gained rewards).

---

| **Table 53–9** | |
|---|---|
| **Behavioral Treatments for Enuresis** | |
| Lifting | Procedure wherein the caregiver takes the child to the toilet at regular intervals during the night to urinate without fully awakening him or her |
| Night awakening | Procedure wherein the caregiver fully awakens the child to void shortly before he or she would usually have wet the bed; once the child is consistently dry, the frequency of awakening drops or (for single awakenings) the time of awakening is gradually moved to earlier in the night (ie, closer to bedtime) until the child is dry when awakened 1 hour after going to bed |
| Alarm | An alarm device and a moisture-sensitive sensor are used in combination, with the sensor being placed under the sheets, or more commonly, attached to the child's pajamas or underwear near the urethra. The arousal devise is usually an auditory alarm and/or a vibrating belt or pager |
| Overlearning | This is commenced at a minimum of 2 weeks after the alarm has rendered the child dry; the child drinks 500 mL (about 16 oz) during the hour before going to bed; alarm use is continued until he or she is dry for 14 consecutive nights with the extra fluid intake; is used to reduce relapse rates seen with alarm use alone |
| Dry-bed training | This begins with an intensive first night of training that involves increased fluid consumption, hourly awakenings, praise when the bed is dry at hourly awakenings, and, when the alarm goes off, a mild reprimand and cleanliness training (child changes wet clothes and bed linens, remakes the bed, resets the alarm); before going to bed and after each wetting, the child engages in 20 practice trials of appropriate toileting (ie, positive practice): for each practice trial, the child lies in bed, counts to 50, arises and attempts to urinate in the toilet, then returns to bed; on subsequent nights, child is woken only once, usually about 3 hours after the child has gone to bed; after a dry night, the night awakening moves up 30 minutes earlier; it is discontinued when it is scheduled to occur 1 hour after bedtime; after 7 consecutive dry nights, the alarm is discontinued, but is reinstated if two episodes of wetting occur in a 1-week period |

before bedtime; if needed after 10 to 14 days, may increase dose to the maximum dose of 0.4 mg. Sublingual tablets of 120 mcg are available in Canada may be given 30 to 60 minutes before bedtime; if needed after 10 to 14 days, may increase dose to the maximum dose of 240 mcg.[33,35]

The most serious complication of desmopressin therapy is water intoxication with dilutional hyponatremia and seizures. This occurs most frequently with the nasal formulation. Electrolyte monitoring in patients taking the oral formulation is recommended if comorbidities may exacerbate renal or electrolyte complications. To reduce the risk of water intoxication, children should drink no more than 8 oz (240 mL) of fluid from 1 hour before to 8 hours after administration of desmopressin. Treatment should be interrupted during episodes of fluid and/or electrolyte imbalance (eg, fever, recurrent vomiting or diarrhea, vigorous exercise, or other conditions associated with increased water consumption).[35]

Treatment response should be assessed within 1 to 2 weeks. If signs of response are present, desmopressin should be continued for 3 months. If enuresis improves or remits, the family and child can determine whether to use desmopressin every night or just for special occasions, such as sleepovers. When it is administered daily, desmopressin should be withheld for 1 week every 3 months to determine whether continued use is necessary.[35]

Lack of response to desmopressin may be due to reduced nocturnal bladder capacity (the most common reason for unresponsiveness) or persistent nocturnal polyuria (related to increased fluid intake in the evening, increased nocturnal solute excretion) or suboptimal dosing. To minimize relapses, daily desmopressin should be tapered over at least 2 weeks using one-half of the effective doses or giving the effective dose every other day for 2 weeks before discontinuation.[35]

Diuretics play a minor role in the treatment of enuresis for most patients. However, in cases of presumed desmopressin resistance that leads to poor response to usual doses or symptom deterioration after established positive response, oral furosemide 0.5 mg/kg in the early morning may be helpful. Furosemide works by reversing the abnormal circadian rhythm of renal tubular sodium handling, which is common in individuals with enuresis. In a study with 12 children with desmopressin-resistant enuresis, adding furosemide appeared beneficial in 75% of study subjects.[46]

**Imipramine**[47] Imipramine was first used in the treatment of enuresis in the 1960s. It is considered as the third-line option for monosymptomatic enuresis and may be used in children who have failed alarm therapy and desmopressin. Its mechanism of action is unclear but anticholinergic and antispasmodic effects may increase plasma ADH concentrations. About 50% of patients may respond to treatment and can expect approximately one less wet night per week. Although trials involving other TCAs have been performed over the years, there is insufficient evidence to assess their relative efficacy compared with imipramine.

Treatment with imipramine is associated with a reduction of approximately 1 wet night per week and relapse rates after cessation as high as 50%. The usual initial dose is 10 to 25 mg at bedtime and may be increased by 25 mg if there is no response after 1 week. On average, the bedtime dose is 25 mg for children 5 to 8 years of age and 50 mg for older children. The dose should not exceed 50 mg in children between 6 and 12 years of age and 75 mg in children age 12 or older.[35]

About 25% of children treated with TCAs experience gastrointestinal symptoms. About 5% of children experience neurologic side effects including nervousness, personality change, or sleep disturbances. Clinicians should monitor for the possibility of increased suicidality, particularly in children and young adults with preexisting depressive symptoms.[35] The most serious adverse effects of TCAs are cardiac conduction disturbances and myocardial depression, particularly in cases of overdose. Therefore, safer options should be considered before starting any TCA for pediatric enuresis.[33,35]

**Anticholinergics** Monotherapy with anticholinergic drugs is ineffective in treating monosymptomatic nocturnal enuresis. These agents should be used only if the child has nocturnal enuresis and daytime incontinence (see Urinary Incontinence). In this case, anticholinergic therapy may be used in combination with desmopressin to increase bladder capacity during sleep.[35]

The usual initial dose of oxybutynin is 5 mg, tolterodine 2 mg, or 0.4 mg/kg propiverine (not available in the United States) at bedtime, titrate upward based on clinical response; the maximal therapeutic effects can be seen within 2 months or sometimes much earlier.[33] Children should be monitored for major adverse events, such as urinary retention (may lead to urinary tract infections), constipation (worsens urinary tract dysfunction) and decreased saliva secretion.

**Other Drugs** Various medications, such as indomethacin, phenmetrazine, amphetamine sulfate, ephedrine, atropine, furosemide, diclofenac, and chlorprothixene have been tried in the treatment of nocturnal enuresis. Data suggest that indomethacin, diclofenac, and diazepam are superior to placebo, but not better than desmopressin.[47] Current guidelines do not recommend any of these agents for pediatric enuresis.

### ▶ Comparison of Therapies

Multiple meta-analyses have been conducted to compare treatments for enuresis, although most trials enrolled a small number of subjects and were of poor methodological quality.[45,47–49] Overall, data suggest that use of enuresis alarms is the most effective nonpharmacologic method. The initial rate for success (less than 1 wet night per month) is 66%, with 45% long-term success rate after discontinuation (vs 1% with no treatment). Alarm therapy is at least as effective as desmopressin, but with a significantly lower relapse rates (46% vs 60%–70% for desmopressin).[50] Combining enuresis alarms and other behavioral therapy further reduces relapse rates. There is inadequate data to compare the various commercial brands of alarms available to consumers.

### ▶ Treatment of Relapse

A relapse is defined by more than 1 wet night per month after a period of dryness.[32] When it occurs, reinitiate the intervention which was previously effective (see Figure 53–1). For children with multiple recurrences after discontinuation of desmopressin, gradual dose tapering of desmopressin may be helpful. Combination alarm and desmopressin therapy may be beneficial for children who have more than one recurrence following successful treatment with an alarm.[45] Management of therapy-resistant monosymptomatic nocturnal enuresis may include periodic new trials of the enuresis alarm with or without desmopressin, desmopressin alone, or a trial of imipramine.[35]

Nonresponders experience less than 50% improvement in symptoms despite active interventions.[32] When motivated children and families do not respond to at least 3-month therapy of enuresis alarm and/or desmopressin, referral to a specialty clinic (eg, developmental-behavioral pediatrician, pediatric urologist) may be warranted.[35]

### OUTCOME EVALUATION

- Monitor the patient for symptom relief. Has the treatment plan achieved the desired outcomes jointly developed by the health care team, the patient, and parents/guardians? If so, to what degree? Evaluate the daily diary completed by the patient or parents/guardians since the last clinic visit and

---

## Patient Care Process: Pediatric Enuresis

**Patient Assessment:**

- Assess the patient's symptoms. Determine whether the child should be referred to a specialty clinic. Assess whether there are any exacerbating factors or enuresis related complications.
- Review past medical history and available diagnostic data. Are there any potentially treatable organic causes of enuresis (see Table 53–7)?
- Obtain a thorough medication history, including use of prescription, nonprescription, and complementary/alternative drug products. Could any of them contributing to enuresis (see Table 53–1)? Determine which, if any, treatments in the past had been helpful.
- Establish realistic treatment goals with the involvement of the child and caregiver.

**Therapy Evaluation:**

- If patient is already receiving nonpharmacological interventions and/or drug therapy, assess treatment choice, drug dosing, efficacy, side effect, adherence, etc.
- Have the child and caregiver given the current treatment plan an adequate duration of trial? How is the child responding to current treatment plan?

**Care Plan Development:**

- Educate the patient and/or caregiver on pediatric enuresis, lifestyle modifications, and motivational therapy (see Table 53–8). The patient and/or caregiver should be referred to local enuresis clinics (if available) for training in behavioral treatments, such as use of enuresis alarms (see Table 53–9). May follow treatment algorithms from current guidelines (see Figure 53–1).
  - Evaluate the patient for adverse events, allergies, and interactions (drug–drug and drug–disease) and adherence.
  - Provide the patient and/or caregiver with education regarding drug therapy (timing of drug administration, side effects, potential drug–drug interactions, etc).

**Follow-Up Evaluation:**

- Evaluate treatment response in 1 to 2 weeks after therapy initiation.
- Allow at least 3 months to assess efficacy of treatment.

quantitate the clinical response (the number of dry nights per week, the number of nights with two or more enuresis episodes). If a diary has not been used, elicit from the patient and caregiver the clinical response since last visit.

- Elicit adverse events of therapy, including severity, using a nonleading manner. Ask the patient or parents/guardians what measures, if any, were used to alleviate adverse effects. Assess therapy adherence.

- The balance of clinical response, tolerability, and burden on the caregiver will determine the approach to management. As most nonpharmacologic approaches are "all or none" and drug titration is limited by the maximum recommended dose, clinicians may consider changing therapy if clinical results are inadequate over an adequate trial period.

- Refer patients with refractory enuresis to a health care professional who specializes in the management of bedwetting.

## ACKNOWLEDGMENT

The author and editors wish to acknowledge and thank Dr. David Guay, the primary author of this chapter in the first, second and third editions of this book.

# 54 Allergic and Pseudoallergic Drug Reactions

J. Russell May and Dennis Ownby

## LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Describe the potential incidence of allergic and pseudoallergic reactions and why it is difficult to obtain accurate numbers.
2. Describe the Gell and Coombs categories of reactions.
3. Identify the classes of drugs most commonly associated with allergic and pseudoallergic reactions.
4. Recommend specific treatment for a patient experiencing anaphylaxis.
5. Recommend an approach to drug selection in patients with multiple drug allergies.
6. Describe drug desensitization procedures for selected drugs.

## INTRODUCTION

Allergic and pseudoallergic drug reactions are reported together. They are rarely confirmed by testing, making statistical analysis imprecise, with both over-reporting and under-reporting. **KEY CONCEPT** *Approximately 5% to 10% of adverse drug reactions are allergic or immunologic; however, allergic and pseudoallergic reactions represent 24% of reported adverse drug reactions in hospitalized patients.[1,2] These reactions are costly and cause considerable morbidity and mortality.* Between 10% and 20% of hospitalized patients incur drug reactions (7% in the general population), with about one-third possibly due to hypersensitivity; however, most of these reactions are not reported, especially in pediatrics.[1,3,4] Patients experiencing an allergic drug reaction in the hospital have increased costs of $275 to $600 million annually.[5] This financial burden can occur due to several reasons, including increased indirect cost of (a) time and lost labor; (b) use of more costly alternative medications; and (c) treatment failures. Outpatient rates are not well studied and are much harder to collect. Relying on a patient's history without an attempt to verify the relationships between drugs taken and symptoms experienced results in confusion. Health care professionals and patients use the term "drug allergy" in such a general way that it is not medically useful and, further, perpetuates a level of fear and concern in the public and in medical practice that is inappropriate and costly. This same confusion and anxiety sometimes lead medical personnel to ignore or forget "drug allergy" with potentially catastrophic results. Clearly, an understanding of how allergic and pseudoallergic reactions occur and how they might be managed or prevented is important to health care professionals and their patients.

## PATHOPHYSIOLOGY

Drug allergies are immune responses resulting from different mechanisms of immunologic recognition and activation, and reactions are produced by multiple physiologic pathways. This produces a confusing spectrum of clinical pictures and complex pathophysiologic mechanisms. The Gell and Coombs classification has been used for decades and still provides a framework for thinking about mechanisms of immunologic drug reactions, as shown in **Table 54–1**.[6,7]

However, as knowledge has advanced, the immune mechanisms active in most drug reactions have been found to be more complex and interrelated than suggested by the Gell and Coombs classification.[8] The complexity and unpredictability of most immune-mediated drug reactions combined with the lack of appropriate animal models have hindered a better understanding of the mechanisms of these reactions. However, even with these shortcomings, the classification remains the most commonly used method for attempting to describe drug reactions resulting from hypersensitivity. **KEY CONCEPT** *Immediate or Type I reactions are those allergic reactions mediated by IgE antibodies specific to the drug; Type II reactions are cytotoxic reactions mediated by drug-specific IgG or IgM antibodies; Type III reactions result from immune complexes circulating in the serum; and Type IV reactions are mediated by cellular mechanisms. Type IV reactions are further subdivided into Type IVa involving recruitment of monocytes, Type IVb with predominately eosinophils, Type IVc composed of* CD4+ *or* CD8+ *T cells, and Type IVd showing neutrophils.[9]*

### Immune Mechanisms

The immune mechanisms involved in drug allergies are quite complex.[10] Immune recognition of non-self material is predominantly controlled by specific receptors on the surface of T-cells during interactions with cells specialized for presenting antigens to T-cells. The antigen presenting cells must concomitantly provide a second signal in addition to the antigen to activate the T-cell. If a second signal is not provided, the T-cell becomes nonresponsive or anergic. The second signal controls the type of immune response that will be initiated by the T-cell.

| Table 54–1 |
| :--- |

**Reaction Classification, Clinical Symptoms, and Potential Causative Drugs[6,7]**

| Gell and Coombs Classification | Immune Response | Clinical Symptoms | Potential Causative Drugs[a] |
| :--- | :--- | :--- | :--- |
| Type I | IgE | Anaphylaxis, urticaria | β-Lactam antibiotics: penicillins (primarily), cephalosporins, carbapenems |
| | | | Non–β-lactam antibiotics: sulfonamides, vancomycin |
| | | | Others: insulins, heparin |
| Type II | IgG | Hemolytic anemia, thrombocytopenia | Quinidine, methyldopa, penicillins, heparin |
| Type III | IgG, IgM | Vasculitis, serum sickness, lupus | Penicillins, sulfonamides, radiocontrast agents, phenytoin, minocycline |
| Type IV | | | β-Lactam antibiotics, sulfonamides, phenytoin |
| IVa | Th1 cytokines | Tuberculin reaction eczema | See text for examples |
| IVb[b] | Th2 cytokines | Maculopapular and bullous exanthema | |
| IVc[b] | Cytotoxic T cells (CD4 and CD8) | Same as IVb, also eczema, pustular exanthema | |
| IVd | T cells (IL-8) | Pustular exanthema | |

[a]These drugs represent a list of causative agents. Many drugs can cause these reactions.

[b]IVb and IVc reactions may combine to produce erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necroylsis.

Ig, Immunoglobulin.

Depending on the exposure to antigens and the cytokines involved, naïve T-helper cells (CD4+ T cells) can differentiate into at least five types of effector-helper cells: Type 1 effector helper T cells (Th1), Th2, Th17, Th9, and Th22. Each of these subsets of T cells appears to have a unique regulatory element, pattern of cytokine production, and function. Th1 responses are typically associated with activation of T-cells to induce B-cell immunoglobulin G (IgG) antibody production and to provide direct T-cell recruitment of cells to kill cells infected with viruses or intracellular bacteria. Th2 immune responses typically lead to IgE production and immediate allergic-type reactions. Th17 responses are varied but usually highly inflammatory and important in the clearance of extracellular bacterial and fungal infections. Th17 cells have also been found to be involved in a variety of autoimmune disorders such as psoriasis, rheumatoid arthritis, and inflammatory bowel disease. Th9 cells promote tissue inflammation and cause mucous production but do not have suppressor functions. Th22 cells produce abundant quantities of interleukin 22 (IL-22) and are important in various inflammatory diseases of the skin.

## Antigens

The immune system normally is not capable of recognizing small molecules. This fact has resulted in several hypotheses concerning how drugs can elicit an immune response.[10] The first widely accepted hypothesis was the haptenation hypothesis. This hypothesis states that the drug becomes covalently bound to a normal "self" protein and the combination of the drug bound to the protein is large enough to be recognized as foreign by the immune system, leading to an immune response.[10] Another hypothesis is the pro-hapten hypothesis which states that a non-reactive drug becomes chemically reactive during metabolism and then covalently binds to self-proteins. An example of this is sulfamethoxazole which is metabolized to sulfamethoxazole-nitroso which is highly reactive. Another hypothesis is the pharmacologic interaction (p-i) hypothesis which states that the drug (or metabolite) directly binds to the T-cell receptor, initiating

an immune response. In this case, T-cells are directly activated, despite not interacting with antigen presenting cells.

As suggested by several of these hypotheses, the metabolism of the drug often plays a critical role. The fact that many drugs are primarily metabolized in the liver helps to explain why the liver is often involved in adverse drug reactions. It has also been recognized that skin keratinocytes are a site of drug metabolism. This discovery helps explain why the skin is involved in many forms of reactions elicited by different drugs.[11] Indeed some of the most common of the life-threatening drug reactions are predominately cutaneous, including Stevens-Johnson syndrome (SJS), toxic epidermal necrolysis (TEN), and drug reaction with eosinophilia and systemic symptoms (DRESS) or drug-induced hypersensitivity syndrome (DIHS).[12]

## Pseudoallergic Drug Reactions

KEY CONCEPT *Reactions that clinically resemble allergic reactions but lack an immune basis are referred to as "pseudoallergic." They include almost the entire range of immediate hypersensitivity clinical patterns. Pseudoallergic reactions range in significance from the alarming but trivial anxiety or vasovagal reactions caused by local dental anesthetics to sometimes fatal reactions to ionic radiocontrast media.*

Pseudoallergic reactions are important in patient counseling and management considerations. They represent common biological functions such as direct histamine [H] release by vancomycin or opiates, whereas immunologic (allergic) reactions are based on the structure of the drug. Even a mild drug allergy may carry significant potential for anaphylaxis on readministration. In contrast, pseudoallergic reactions tend to remain constant whether mild or severe and are dose related.

Pseudoallergic reactions, then, are reactions where the components of the immune system are used in exactly the same way, but without the "learning" response by T cells and generally without the much greater danger that true immunologic sensitization implies. Pseudoallergic reactions may be thought of as a subtype

## Clinical Presentation and Diagnosis of Allergic and Pseudoallergic Drug Reactions

The clinical presentation of a patient experiencing an allergic reaction varies greatly. The primary reactions are as follows:

### Anaphylaxis

Anaphylaxis is an acute life-threatening allergic reaction. Signs and symptoms involve the skin (eg, pruritus, urticaria), respiratory tract (eg, dyspnea, wheezing), gastrointestinal tract (eg, nausea, cramping), and cardiovascular system (eg, hypotension, tachycardia). Onset is usually within 30 minutes, but can be as long as 2 hours. Treatment must begin immediately. Anaphylaxis may recur 6 to 8 hours after exposure, so patients should be observed for at least 12 hours.

### Cytotoxic Reactions

These reactions usually take the form of hemolytic anemia, thrombocytopenia, granulocytopenia, or agranulocytosis.

### Immune Complex Reactions

These reactions usually involve a serum sickness-like syndrome (eg, arthralgias, fever, malaise, and urticaria) that typically develops 7 to 14 days after exposure to the causative antigen.

### Dermatologic Reactions

Rashes may range from mild to life-threatening.

- *Urticaria*: These are itchy, raised, swollen areas on the skin. Also known as hives.
- *Maculopapular rash*: A rash that contains both macules and papules. A macule is a flat, discolored area of the skin, and a papule is a small raised bump. A maculopapular rash is usually a large area that is red and has small bumps.
- *Erythema multiforme*: A rash characterized by papular (small raised bump) or vesicular lesions (blisters) and reddening or discoloration of the skin, often in concentric zones about the lesion.
- *Stevens-Johnson syndrome*: A severe expression of erythema multiforme (also known as erythema multiforme major). It typically involves the skin and the mucous membranes, with the potential for severe morbidity and even death.
- *Toxic epidermal necrolysis*: A life-threatening skin disorder characterized by blistering and peeling of the top layer of skin.

of idiopathic reactions, rather than an activation of the patient's immune system. The pathophysiology of pseudoallergic reactions is generally unknown, but indicators of immune activation are not seen when they occur.

## PROBLEMATIC DRUG CLASSES AND TREATMENT OPTIONS

The first priority is to avoid doing serious harm by administering a drug the patient cannot tolerate. We can generally establish the likelihood of a relationship between the suspected drug and observed reaction, and also whether it is likely to be an immune or idiopathic reaction by examining the time course and specific signs and symptoms as precisely and objectively as possible. Reevaluating the patient's physical findings and laboratory values (taking into account preexisting diseases) allows further clarification of the need to change treatments and add therapy for the reaction itself.

Reviewing the original indications for the treatment that caused the reaction is important. For example, in many respiratory illnesses, a prescribed antibiotic may be unnecessary. If the disease persists and indications for some treatment are established, alternatives must be sought, either by adjusting dose or administration rate, finding an effective and unrelated alternative medication, or desensitizing the patient to the original drug.

When adverse drug reactions occur, the health care provider should carefully describe all aspects of the reaction and assess the potential for it to reoccur. Many patients have frightening associations of the term "allergy" with severe and unpredictable anaphylaxis. It is difficult to undo fears created by injudiciously labeling a patient as allergic in the medical record. Labeling a person "allergic" may hamper future medical care, as the patient may refuse treatment or fail to adhere to medication regimens. If the original reaction is clearly documented, health care providers can appropriately counsel patients about any true dangers.

Anaphylaxis is a true medical emergency and must be treated promptly. Otherwise, managing allergic reactions begins with stopping the offending agent. Understanding the allergic reaction and potential for cross-allergenicity between similar drugs will assist in selecting an alternative medication. Desensitization is a management option if the patient truly needs the medication and alternative drugs are not available. Although any drug may cause an allergic or pseudoallergic reaction, several drugs and drug classes are strongly associated with such reactions (Table 54–2). These classes will be discussed individually.

### β-Lactam Antibiotics

Hypersensitivity reactions with β-lactam antibiotics, especially penicillin, may encompass any of the Types I through IV Gell-Coombs classifications. The most common reactions are maculopapular and urticarial eruptions.[13] Although rare (less than 0.05%), anaphylactic reactions to penicillins cause the greatest concern, because they are responsible for the majority of all drug-induced anaphylaxis deaths in patients, accounting for 75% of all anaphylaxis cases in the United States.[6,14] The treatment of anaphylaxis is given in Table 54–3.[15]

The health care professional is faced with a difficult task when approaching a patient who claims a history of penicillin allergy. Although as many as 12% of hospital patients state they have an allergy to penicillin, about 90% will have negative skins tests.[16] Table 54–4 shows the traditional protocol for penicillin skin testing.[17] This test only evaluates IgE-mediated reactions. A patient with a history of other serious reactions such as erythema multiforme, Stevens-Johnson syndrome, or toxic epidermal necrolysis should not receive penicillins and should not be tested.

**KEY CONCEPT** *Penicillins and cephalosporins both have a β-lactam ring joined to an S-containing ring structure (penicillins: a thiazolidine ring; cephalosporins: a dihydrothiazine ring). The extent of cross-allergenicity appears to be relatively low, with an estimate of approximately 4%.[18] Cross-allergenicity is less likely with newer*

*generation cephalosporins compared with the first-generation agents.* Anaphylactic reactions to cephalosporins are rare, with a predicted range of 0.0001% to 0.1%. Minor skin reactions including urticaria, exanthems, and pruritus are the most common allergic reactions with cephalosporins, showing severe reactions less often than with penicillins.[19]

For other β-lactam agents, the recommendations are fairly straightforward. Carbapenems should be considered potentially

### Table 54–3

**Pharmacologic Management of Anaphylactic Reactions**

**Immediate Intervention**
Epinephrine 1:1000 (1 mg/mL)
   Adults: Give 0.2–0.5 mg IM, repeat every 5 minutes as needed
   Pediatrics: 0.01 mg/kg (maximum 0.3 mg) IM, repeat every 5 minutes as needed

**Subsequent Interventions**
Normal saline infusion
   Adults: 1–2 L at a rate of 5–10 mL/kg in the first 5 minutes, followed by slow infusion
   Pediatrics: up to 30 mL/kg in the first hour
Epinephrine infusion
*If patient is NOT responding to epinephrine injections and volume resuscitation:*
   Adults: epinephrine infusion (1 mg in 250 mL $D_5W$):
   1–4 mcg/min, titrating based on clinical response or side effects
   Pediatrics: epinephrine infusion (0.6 × body weight (in kg) = number of mg diluted to a total of 100 mL normal saline: 1 mL/hour delivers 0.1 mcg/kg/min

**Other Considerations After Epinephrine and Fluids**
Diphenhydramine
   Adults: 25–50 mg IV or IM
   Pediatrics: 1–1.25 mg/kg (maximum of 300 mg/24 hour)
Ranitidine
   Adults: 50 mg in $D_5W$ 20 mL IV over 5 minutes
   Pediatrics: 1 mg/kg (up to 50 mg) in $D_5W$ 20 mL IV over 5 minutes
Inhaled β-agonist (bronchospasm resistant to epinephrine)
   2–5 mg in 3 mL of normal saline, nebulized, repeat as needed
Dopamine (hypotension refractory to fluids and epinephrine)
   2–20 mcg/kg/min titrated to maintain systolic blood pressure > 90 mm Hg
Hydrocortisone (severe or prolonged anaphylaxis)
   Adults: 250 mg IV (prednisone 20 mg can be given orally in mild cases)
   Pediatrics: 2.5–10 mg/kg/24 hours

$D_5W$, dextrose 5% in water; IM, intramuscularly; IV, intravenous.

Adapted from Lieberman P, Nicklas RA, Oppenheimer J, et al. The diagnosis and management of anaphylaxis practice parameter:2010 update. J Allergy Clin Immunol. 2010;126:477–480.

### Table 54–4

**Procedure for Performing Penicillin Skin Testing**

**A. Percutaneous (Prick) Skin Testing**

| Materials | Volume |
| --- | --- |
| Pre-Pen $6 \times 10^6$ M | 1 Drop |
| Penicillin G 10,000 Units/mL | 1 Drop |
| β-Lactam drug 3 mg/mL | 1 Drop |
| 0.03% albumin-saline control | 1 Drop |
| Histamine control (1 mg/mL) | 1 Drop |

1. Place a drop of each test material on the volar surface of the forearm.
2. Prick the skin with a sharp needle inserted through the drop at a 45° angle, gently tenting the skin in an upward motion.
3. Interpret skin responses after 15 minutes.
4. A wheal at least 2 × 2 mm with erythema is considered positive.
5. If the prick test is nonreactive, proceed to the intradermal test.
6. If the histamine control is nonreactive, the test is considered uninterpretable.

**B. Intradermal Skin Testing**

| Materials | Volume |
| --- | --- |
| Pre-Pen $6 \times 10^6$ M | 0.02 mL |
| Penicillin G 10,000 Units/mL | 0.02 mL |
| β-Lactam drug 3 mg/mL | 0.02 mL |
| 0.03% albumin-saline control | 0.02 mL |
| Histamine control (0.1 mg/mL) | 0.02 mL |

1. Inject 0.02–0.03 mL of each test material intradermally (amount sufficient to produce a small bleb).
2. Interpret skin responses after 15 minutes.
3. A wheal at least 6 × 6 mm with erythema and at least 3 mm greater than the negative control is considered positive.
4. If the histamine control is nonreactive, the test is considered uninterpretable.

   **Antihistamines may blunt the response and cause false-negative reactions.**

Adapted from Sullivan TJ. Current Therapy in Allergy. St. Louis, MO: Mosby; 1985:57–61.

cross-reactive with penicillins and used with caution.[20] Monobactams (eg, aztreonam) do not cross-react with any β-lactam drugs except ceftazidime because they share an identical R-group side chain.

## Sulfonamide Antibiotics

Sulfonamides are compounds that contain a sulfonamide moiety (ie, $SO_2NH_2$). This group includes sulfonamide antibiotics (sulfonylarylamines), and nonarylamine sulfonamides such as furosemide, thiazide diuretics, sulfonylureas, and celecoxib. The sulfonamide antibiotics contain an aromatic amine at the N4 position and a substituted ring at the N1 position. Allergists generally agree that most, but not all, patients allergic to antimicrobial sulfonamides will tolerate nonarylamine sulfonamides.[21] Predisposition to allergic reactions is a more likely reason than cross-reactivity between these differing molecules.[22] The term "sulfa allergy" should not be used as it can be confusing to patients and health care providers. The sulfonamide antibiotics are significant because they account for the largest percentage of antibiotic-induced toxic epidermal necrolysis and Stevens-Johnson syndrome cases.[23]

## Patient Encounter 1

A 72-year-old man with weight of 137 lb (62 kg) was admitted to a general medicine unit 9 days ago for an upper gastrointestinal bleed. Overnight, he spiked a fever of 104°F (40.0°C) and now has difficulty breathing. A preliminary diagnosis of hospital-acquired pneumonia is made. The medical record states the patient indicated on admission that he does not remember if he has any drug allergies. A combination of piperacillin/tazobactam and vancomycin is ordered. About 10 minutes after the start of the piperacillin/tazobactam infusion, the patient appears agitated and is having greater difficulty breathing. A family member hits the nurse call button.

*What type of allergic reaction is the patient most likely having?*

*What is the first drug (dose and schedule) that should be administered?*

*What subsequent interventions may be necessary in this patient?*

**KEY CONCEPT** *Reactions to sulfonamide antibiotics, ranging from mild (most common) to life-threatening (rare), occur in 2% to 4% of healthy patients, with rates as high as 65% in patients with acquired immunodeficiency syndrome (AIDS).*[24] Anaphylaxis or **anaphylactoid** reactions almost always occur within 30 minutes but may be up to 90 minutes after exposure, most commonly after parenteral administration. Isolated **angioedema** or urticaria can occur within minutes to days. Serum sickness occurs within 1 to 2 weeks. Fixed drug eruptions (lesions) occur within a half hour to 8 hours. These lesions resolve within 2 to 3 weeks after drug removal. The more severe conditions of Stevens-Johnson syndrome and toxic epidermal necrolysis tend to occur 1 to 2 weeks after initiation of therapy. Because trimethoprim-sulfamethoxazole is the drug of choice for patients with *Pneumocystis jiroveci* pneumonia, desensitization may be necessary. A history of Stevens-Johnson syndrome or toxic epidermal necrolysis is an absolute contraindication for the desensitization procedure.

### Patients with Multiple Antibiotic Allergies

Dealing with patients who claim to have multiple antibiotic allergies can be challenging. Combining knowledge of cross-allergenicity with a careful assessment of patient history may be helpful in designing an antimicrobial regimen. Table 54–5 outlines a series of questions that can be useful in developing an effective treatment plan.[25] If available and indicated, skin testing may be useful to complete the puzzle. Often with careful assessment, an antibiotic of choice may be used when the patient's initial history would have ruled it out. Based on data gathered, the patient's record should reflect antibiotics safe to use if needed, antibiotics to be avoided, and antibiotics that can be used only after desensitization. Although Table 54–5 was designed with antibiotics in mind, it can be modified for multiple allergy situations.

### Aspirin and Nonsteroidal Anti-Inflammatory Drugs

Aspirin and the nonsteroidal anti-inflammatory drugs (NSAIDs) can induce allergic and pseudoallergic reactions. Because these

### Table 54–5

**Multiple Antibiotic Allergies: Obtaining Background Information**

For **each** antibiotic to which the patient claims to be allergic, gather the following information:
- What type of infection was being treated?
- Have you ever received the drug without experiencing a reaction?
- How many times have you received the drug and experienced a reaction?
- What was the drug dose and route of administration with the last reaction?
- How many doses did you take before the onset of the last reaction?
- How many doses did you take after the last reaction?
- Can you describe the adverse reaction?
- What was the duration of the reaction?
- What treatment was given for the reaction?
- Was there any permanent damage?

For **each** antibiotic the patient has received and does not claim allergy, gather the following information:
- What was the last type of infection being treated?
- What was the drug dose and route of administration?
- Have you received this drug more than once without reactions?

Other information to be gathered:
- Have you had adverse reactions to any other drugs? If so, give dates and describe the reaction.
- Document any risk factors for allergic reactions such as chronic urticaria, liver or kidney disease, HIV (human immunodeficiency virus), or any other immune deficiencies.

Adapted from Macy E. Multiple antibiotic allergy syndrome. Immunol Allergy Clin North Am 2004;24:533–543.

drugs are so widely used, with much over-the-counter use, the health care professional must have a basic understanding of the types of reactions that can occur and how to prevent them. Three types of reactions occur: bronchospasm with rhinoconjunctivitis, urticaria/angioedema, and anaphylaxis. Remember that patients with gastric discomfort or bruising from these agents may describe themselves as being allergic; however, these are not allergic or pseudoallergic reactions.

Two specific conditions—aspirin-exacerbated respiratory disease (AERD) and chronic idiopathic urticaria—are important because they are commonly seen. AERD may include asthma, rhinitis with nasal polyps, and aspirin sensitivity.[26] Upon exposure to aspirin or an NSAID, patients with AERD experience rhinorrhea, nasal congestion, conjunctivitis, laryngospasm, and asthma. Chronic idiopathic urticaria may also be seen with aspirin or NSAID-induced pseudoallergic reactions.[27] Patients with a history of chronic idiopathic urticaria are likely to see a flare of urticaria if aspirin or a cyclooxygenase (COX)-1 inhibiting NSAID is given. Cross-reactions between aspirin and older COX-1 inhibiting NSAIDs exist in patients with AERD and chronic idiopathic urticaria. Even though product warning labels for COX-2 inhibitors state these agents should not be used in these two conditions, there are no reports of cross-reactivity in AERD and only rare reports in chronic idiopathic urticaria.[28]

**KEY CONCEPT** *IgE-mediated urticarial/angioedema reactions and anaphylaxis are associated with aspirin and NSAIDs. Urticaria is the most common form of an IgE-mediated reaction. However, most reactions are the result of metabolic idiosyncrasies, such as*

*aspirin-induced respiratory disease which may produce severe and even fatal bronchospasm. This class is second only to β-lactams in causing anaphylaxis.* Most reactions in this class are due to a complex metabolic pattern which causes increasingly recurrent and severe nasal polyps and often refractory asthma. The metabolic problem is constant once it emerges, accounting for the persistence and difficulty of these clinical problems. The metabolic problem is also capable of causing severe, sometimes fatal, acute reactions to aspirin or many if not all other NSAIDs. Rare reports of non–cross-reactive severe reactions suggest possible specific IgE-mediated reactions to individual NSAIDs, and there are some occurrences of urticaria related to NSAIDs as well. Because aspirin therapy is highly beneficial in primary and secondary prevention in coronary artery disease (CAD), aspirin desensitization should be considered in patients who have had reactions to aspirin. Desensitization is contraindicated in patients who have experienced an aspirin-induced anaphylactoid reaction, hypotension, tachypnea, or altered consciousness. Alternate agents must be used. A comprehensive approach to aspirin-sensitive patients with CAD has been described.[29]

## Radiocontrast Media

**KEY CONCEPT** *Radiocontrast media may cause serious, immediate pseudoallergic reactions such as urticaria/angioedema, bronchospasm, shock, and death. These reactions have been reduced with the introduction of nonionic, lower osmolality products.* Because a small percentage of patients who have reacted previously to radiocontrast media will react if reexposed, several steps (listed below) should be taken to prevent reactions in these patients. These steps should also be followed in patients with high-risk factors: asthmatic patients, patients on β-blockers, and patients with cardiovascular disease.[5] The steps are as follows:

- Determine whether the study is essential.
- Be sure the patient understands the risks.
- Ensure adequate hydration.
- Use nonionic, lower osmolar agents.
- Pretreat with prednisone 50 mg orally 13, 7, and 1 hour(s) before the procedure and diphenhydramine 50 mg orally 1 hour before the procedure.

Delayed reactions with these agents occur in 1% to 3% of patients.[30] Although reactions are occasionally severe, most are mild and manifest as maculopapular rashes, fixed eruptions, erythema multiforme, and urticarial eruptions.

## Opiates

**KEY CONCEPT** *Opiates (morphine, meperidine, codeine, hydrocodone, and others) stimulate mast cell release directly, resulting in pruritus and urticaria with occasional mild wheezing. Though these reactions are not allergic, many patients state they are "allergic" to one or more of the opiates. Pretreatment with an antihistamine may reduce these pseudoallergic reactions which are rarely, if ever, life-threatening.*[6] Avoiding other mast cell degranulating medications while patients require opiates also reduces the chances of frightening and uncomfortable reactions. Patients may state they are allergic if they have experienced gastrointestinal upset, a common side effect to opiates, with previous exposures. Obtaining a thorough history from the patient will prove useful. If a more serious reaction has occurred, a non-narcotic analgesic should be selected.

**Patient Encounter 2**

A 20-year-old woman is admitted to the hospital for treatment of a painful wound infection on her thigh. She has a history of hypertension, controlled with lisinopril, and periodic insomnia treated with over-the-counter medications. She is a nonsmoker and reports having one to two glasses of wine per week. Blood and wound cultures were obtained. Before initiating antibiotic therapy, you obtain her drug allergy history. She lists allergies to penicillin, vancomycin, clindamycin, and codeine. The reactions are described as follows:

*Penicillin*: When receiving penicillin for a sore throat as a teenager, she could not breathe and received an epinephrine injection from her physician.

*Vancomycin*: When receiving this drug for a previous wound infection several years ago, she developed a red rash on her upper body around her neck and shoulders. It went away a few hours later but came back the next time they infused the drug. Someone suggested that the nurse should infuse the drug slower on the next dose and the rash did not return. The patient states that she does not want to experience that allergy again.

*Clindamycin*: Several years ago she received a prescription for clindamycin solution. The patient states that it tasted so bad it caused her to throw up, so she must be allergic to it.

*Codeine*: The patient received a prescription for acetaminophen and codeine the previous summer. The patient says she took it around the clock and it helped the pain. However, she developed constipation and had to take a laxative for a week.

*Based on the patient's allergy history, which if any, of the antibiotics listed above could she safely receive?*

*Can the patient receive an opiate analgesic to relieve the pain from her wound?*

## Cancer Chemotherapy

Hypersensitivity reactions have occurred with all chemotherapy agents. Reactions are most common with the taxanes, platinum compounds, asparaginases, and epipodophyllotoxins.[13] Reactions range from mild (flushing and rashes) to severe (dyspnea, bronchospasm, urticaria, and hypotension). IgE-mediated Type I reactions are the most common. To reduce the risk, patients are routinely premedicated with corticosteroids and $H_1$- and $H_2$-receptor antagonists. The platinum compounds have produced anemia, probably via a cytotoxic immunologic mechanism.

## Insulin

Insulin is one of a very few medications that is itself a whole protein and can induce IgE sensitivity directly. This can result in anaphylaxis. Adverse reactions to insulin also include erythema, pruritus, and indurations, which are usually transient and may be injection site related.[31] For sensitivity reactions, treatment options include dexamethasone or desensitization. If the reaction is injection site related, a change in delivery system (ie, insulin pump or inhaled insulin) may be helpful.

## Anticonvulsants

A wide range of hypersensitivity reactions, ranging from mild maculopapular skin eruptions to severe life-threatening reactions, can occur with anticonvulsants.[32] Aromatic anticonvulsants, primarily phenytoin, carbamazepine, phenobarbital, and primidone as well as some of the newer agents (lamotrigine, oxcarbazepine, felbamate, and zonisamide) can cause a life-threatening syndrome with symptoms including fever, a maculopapular rash, and evidence of systemic organ involvement. The rash may be mild at first but can progress to exfoliative dermatitis, erythema multiforme, Stevens-Johnson syndrome, or toxic epidermal necrolysis. This syndrome is known as anticonvulsant hypersensitivity syndrome (AHS) or drug rash with eosinophilia and systemic symptoms (DRESS). The causative agent should be withdrawn immediately. Cross-sensitivity among aromatic anticonvulsant drugs ranges between 40% and 80%.[33] If a patient is hypersensitive to an aromatic anticonvulsant, a nonaromatic agent (ethosuximide, gabapentin, levetiracetam, topiramate, lacosamide, and valproic acid) or the benzodiazepines may be useful.[33]

## Drug Desensitization

Drug desensitization may be undertaken for some drugs in the absence of useful alternative medications. The risk of severe systemic reactions and anaphylaxis associated with desensitization must be compared with the risk of not treating the patient. A thorough evaluation should establish that the drug probably caused the reaction by an allergic mechanism. Because of the dangers involved with drug desensitization, an expert review of the patient's indication for the drug should be conducted. Consider the possibility that the patient does not really need the drug.

**KEY CONCEPT** *Desensitization is a potentially life-threatening procedure and requires continuous monitoring in a hospital setting, with suitable access to emergency treatment and intubation if required. It should only be undertaken under the direction of a physician with suitable training and experience. In such hands, desensitization may present less risk than treatment failure with a less effective alternative medication.*

The possibility of readministering a suspected drug may be safely tested by gradual dose escalation in some cases, and there are certainly many more patients who are harmed by inappropriately withholding medications than there are those who suffer significant harm from testing and desensitization.[34]

Only Type I IgE-mediated allergy may be treated by classical desensitization. Desensitization may occur within hours to several weeks, unlike specific immunotherapy injections for inhalant allergy (ie, "allergy shots," which may take months of therapy before a patient realizes any benefit and years to complete). The mechanism of drug desensitization is poorly understood but produces temporary drug-specific tolerance of the offending drug. Any interruption of therapy of 24 hours or more requires full repeat desensitization, and abrupt significant increases of dosage have been reported to break through the tolerance with some drugs.

The desensitization process probably involves either: (a) cross-linking small subthreshold numbers of bound IgE molecules gradually depleting mast cells of their mediators, or (b) binding of the IgE by monomers or hapten-protein entities that cannot cross-link the antibody. The low doses used at the beginning of all protocols would provide small amounts of antigen, favoring these mechanisms. Both drug-specific IgE and IgG serum concentrations increase after successful desensitization, but skin test positivity generally decreases.[35]

**Patient Encounter 3**

A 62-year-old man is visiting his new primary care physician for follow-up after being hospitalized for a myocardial infarction 10 days ago. The patient's father and older brother died from myocardial infarctions when they were in their late 60s. The patient saw a television commercial touting the benefits of aspirin in preventing heart attacks and wants to start taking it immediately. Upon review of the patient's medical record, his new physician notices that the patient was previously diagnosed with an aspirin allergy. His reaction was primarily a moderate urticaria.

*Does this patient's potential benefit of aspirin therapy outweigh the risk when considering his history of allergy?*

*What course of action would you recommend for this patient?*

Oral and intravenous (IV) protocols are available for most drugs in this category, with the oral route producing somewhat milder reactions, but the IV route providing more precision in dosing. IV administration can also be used in unresponsive patients for whom the oral route is not feasible. Protocols generally begin at about 1% of the therapeutic dose and increase in intervals defined by the patient's reaction and the distribution and metabolism of the drug itself. Half-log$_{10}$ dose increases (about threefold) are often tolerated.

Penicillin desensitization is the most common drug desensitization protocol. It is required for penicillin-allergic patients when penicillin is clearly the only treatment option, for example, when syphilis is present in pregnancy. Protocols have been adopted for most antibiotics. Specific procedures for oral and IV penicillin desensitization have been developed.[36]

Aspirin desensitization is useful in diseases for which low-level antiplatelet action is needed and in the care of patients with aspirin sensitivity and intractable nasal polyps. Lysine aspirin availability in Europe allows desensitization by inhalation at greatly reduced risk. New procedures utilizing ketorolac as a nasal topical application may allow similar reduction of risk in the United States.[37] As with all desensitizations, constant daily administration must be maintained once the desired dose is reached. Several aspirin desensitization protocols have been described in the literature.[38,39]

All desensitization procedures are expected to produce mild symptoms in the patient at some point, and the patient must be made to understand this before doses are started. Mild sensitivity to the drug still remains, and large dose increases as well as missing doses should be avoided. Late complications, such as urticaria, may occur with Type I desensitization, and serum sickness or hemolytic anemia may also occur with high-dose therapy in allergic, desensitized patients.

Some regimens are designed for outpatient administration over much longer time periods and have been used, for example, with allopurinol dermal reactions. Such late-onset morbilliform reactions, sometimes overlapping with erythema multiforme minor, are difficult to evaluate, because it is often unclear to what extent the patients were at risk for a recurrent reaction.

Severe life-threatening reactions not mediated by IgE, such as Stevens-Johnson syndrome and toxic epidermal necrolysis, are absolute contraindications to testing, desensitization attempts, and readministration.

## Patient Care Process

**Patient Assessment:**

- Based on the medication history, physical examination, and review of systems, determine the likelihood of the reaction being a drug-related problem. See Clinical Presentation and Diagnosis of Allergic and Pseudoallergic Drug Reactions. Tables 54–1 and 54–2 may also be helpful.

- Use questions given in Table 54–5 to establish the nature of the reaction and the likelihood it was caused by the suspected drug. For nonantibiotics, the first question regarding infection type is not needed.

- If appropriate, see Table 54–4 for procedures for performing penicillin skin testing.

**Therapy Evaluation:**

- Document the reaction, in detail, in the patient's medical record.

- Recommend an alternative choice if the prescribed drug is contraindicated, and develop a plan to assess safety and effectiveness.

- Consult with health care professionals trained in desensitization if the patient has a true allergy and no acceptable alternative medication is available.

**Care Plan Development:**

- If reaction is anaphylactic in nature, see Table 54–3.

- The offending drug should be discontinued.

- The treatment goal is relief of symptoms. For mild symptoms such as rash or itching, an antihistamine such as diphenhydramine may be used. For wheezing, bronchodilators such as albuterol may be helpful.

- Recommend an alternative option for the contraindicated drug, or if no alternative is available, consult with health care professional regarding desensitization.

- Educate the patient about the allergy or pseudoallergy so they are able to work with health care providers to avoid the reaction in the future.

**Follow-up Evaluation:**

- Follow-up daily or more often, if necessary, to assure resolution of the reaction and optimal response to the alternate therapy.

## OUTCOME EVALUATION

To successfully treat a patient with a drug allergy or pseudoallergy, several goals must be accomplished:

- If a reaction occurs, it must be identified and managed quickly.
- The patient should be educated about the reaction.
- True drug contraindications should be avoided if possible.
- Patients should receive the medications they need or a suitable alternative. If this is not possible due to an allergy, desensitization should be considered.
- Patients should always be monitored for adverse drug reactions.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| AERD | Aspirin-exacerbated respiratory disease |
| AHS | Anticonvulsant hypersensitivity syndrome |
| AIDS | Acquired immunodeficiency syndrome |
| CAD | Coronary artery disease |
| COX | Cyclooxygenase |
| $D_5W$ | Dextrose 5% in water |
| DIHS | Drug-induced hypersensitivity syndrome |
| DRESS | Drug reaction with eosinophilia and systemic symptoms |
| H ($H_1$, $H_2$) | Histamine |
| HIV | Human immunodeficiency virus |
| Ig | Immunoglobulin (followed by the specific type of immunoglobulin: E, G, or M) |
| IL | Interleukin |
| IM | Intramuscular |
| IV | Intravenous |
| NSAIDs | Nonsteroidal anti-inflammatory drugs |
| p-i | Pharmacologic interaction |
| SJS | Stevens-Johnson syndrome |
| TEN | Toxic epidermal necrolysis |
| Th | T-helper cell |

# 55 Solid Organ Transplantation

Steven Gabardi, Spencer T. Martin, and Ali J. Olyaei

## LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Describe the reasons for solid organ transplantation.
2. Differentiate between the functions of cell-mediated and humoral immunity and how they relate to organ transplant.
3. Describe the roles of antigen-presenting cells in initiating the immune response.
4. Compare and contrast the types of rejection including hyperacute, acute, chronic, and humoral rejection.
5. Define the terms "host–graft adaptation" and "tolerance," paying close attention to their differences.
6. Discuss the desired therapeutic outcomes and appropriate pharmacotherapy utilized to avoid allograft rejection.
7. Compare and contrast currently available immunosuppressive agents in terms of mechanisms of action, adverse events, and drug–drug interactions.
8. Develop a therapeutic drug-monitoring plan to assess effectiveness and adverse events of the immunosuppressive drugs.
9. Design an appropriate therapeutic regimen for the management of immunosuppressive drug complications based on patient-specific information.
10. Write appropriate patient education instructions and identify methods to improve patient adherence following transplantation.

## INTRODUCTION

The earliest recorded attempts at organ transplant date back thousands of years.[1] More than a few apocryphal descriptions exist from ancient Egypt, China, India, and Rome describing experimentation with transplantation. However, it was not until the early 1900s that French surgeon, Alexis Carrel, pioneered the art of surgical techniques for transplantation.[1] Together with Charles Guthrie, Carrel experimented in artery and vein transplantation. Using revolutionary methods in **anastomosis** operations and suturing techniques, Carrel laid the groundwork for modern transplant surgery. He was one of the first to identify the dilemma of rejection, an issue that remained insurmountable for nearly half a century.[1]

Prior to the work of Alexis Carrel, malnourishment was the prevailing theory regarding the mechanism of **allograft** rejection.[1] However, in 1910, Carrel noted that tissue damage in the transplanted organ was likely caused by multiple, circulating biological factors. It was not until the late 1940s with the work of Peter Medawar that transplant immunology became more understood. Medawar was able to define the immunologic nature of rejection using skin allografts. In addition, George Snell observed that grafts shared between inbred animals were accepted but were rejected when transplanted between animals of different strains.[1]

The seminal work by early transplant researchers eventually led to the concept of histocompatibility.[1] Histocompatibility describes the process by which polymorphic genes encode cell membrane antigens that serve as targets for immune response, even within a species. Further research in transplant immunobiology led to a more accurate understanding of the alloimmune response.[1]

Joseph Murray performed the first successful organ transplant in 1954.[1] It was a kidney transplant between identical twins. This was a success in large part because no immunosuppression was necessary due to the fact that donor and recipient were genetically identical. Murray's success laid the groundwork for modern-day transplantation.

## EPIDEMIOLOGY AND ETIOLOGY
### Heart

Nearly 6 million Americans are afflicted with heart failure. Cardiac transplantation is the treatment of choice for patients with severe end-stage heart failure. Candidates for cardiac transplantation generally present with New York Heart Association (NYHA) class III or IV symptoms and have an ejection fraction of less than 20% (0.20). The general indications for cardiac transplantation include rapidly declining cardiac

function, requirement of intravenous (IV) inotropes, and having a projected 1-year mortality rate of greater than 75%. Mechanical support with an implantable left ventricular assist device may be appropriate as bridge therapy while patients await a viable organ.[1] Most heart transplants are **orthotopic**; however, in certain situations, **heterotopic** cardiac transplants have been performed. There were 2655 heart transplant procedures done in the United States in 2014.[2] Indications for heart transplant include:

- Cardiomyopathy (ie, dilated myopathy, hypertrophic cardiomyopathy, restrictive myopathy)
- Congenital heart disease
- Coronary artery disease
- Valvular heart disease

### Intestine

An intestine transplant may involve the use of an entire intestine or shortened segment. Most intestine transplants completed in the United States involve the transplant of the full organ and are often performed in conjunction with liver transplantation. Although most intestine transplants involve organs harvested from a deceased donor, recent advances in the field have made it possible for living donor intestinal segment transplants. There were 139 intestine transplants (138 deceased donors and 1 living donor) done in 2014.[2] Reasons for intestine transplant include:

- Functional bowel problems (ie, Hirschsprung disease, neuronal intestinal dysplasia, pseudoobstruction, protein-losing enteropathy, microvillous inclusion disease)
- Short gut syndrome (ie, intestinal atresia, necrotizing enterocolitis, intestinal volvulus, massive resection secondary to inflammatory bowel disease, tumors, mesenteric thrombosis)

### Kidneys

More than 26 million Americans have chronic kidney disease (CKD), with another 20 million more considered to be at increased risk for kidney disease. End-stage renal disease (ESRD) only constitutes a small portion of those patients with CKD, with more than 640,000 patients diagnosed throughout the United States as of 2012. However, the ESRD population continues to increase. All patients with ESRD should be considered for renal transplantation if they are healthy enough to undergo the surgery.

Most kidney transplants are heterotopic, where the kidney is implanted above the pelvic bone and attached to the patient's iliac artery and vein. The ureter of the transplant kidney is attached directly to the recipient's bladder or native ureter. The native kidneys are usually not removed, and data have shown that under most circumstances, removal of the native kidneys does not influence patient survival (ie, survival of the transplant patient, without regard to function or survival of the allograft) and **allograft survival**.[1] There were 17,108 (11,570 deceased donors and 5,538 living donors) kidney transplants performed in 2014.[2] Reasons for kidney transplant include:

- Congenital, familial, and metabolic disorders (ie, congenital obstructive uropathy, Fabry disease, medullary cystic disease, nephrolithiasis)
- Diabetes mellitus (DM)
- Glomerular diseases (ie, antiglomerular basement membrane disease, focal segmental glomerular sclerosis, IgA nephropathy, hemolytic uremic syndrome, systemic lupus erythematosus, Alport syndrome, amyloidosis, membranous nephropathy, Goodpasture syndrome)
- Hypertension
- Neoplasm (ie, renal cell carcinoma, Wilms tumor)
- Polycystic kidney disease
- Renovascular disease
- Tubular and interstitial diseases (ie, analgesic nephropathy, drug-induced nephritis, oxalate nephropathy, radiation nephritis, acute tubular necrosis, sarcoidosis)

### Liver

A liver transplant may involve the use of the entire organ or a segment. The majority of cases involve utilizing the full organ. In recent years, segmental transplants have been conducted using living donors. This procedure requires donation of the left hepatic lobe, which accounts for nearly 60% of the overall liver mass. This type of procedure is possible because the liver can regenerate; therefore, both the donor and recipient, in theory, will have normal liver function shortly after the transplant procedure. There were 6729 (6449 deceased donors and 280 partial lobe-living donors) liver transplants done in 2014.[2] Reasons for liver transplant include:

- Acute hepatic necrosis (ie, chronic or acute hepatitis B or C)
- Biliary atresia
- Cholestatic liver disease/cirrhosis (ie, primary biliary cirrhosis)
- Metabolic disease (ie, Wilson disease, primary oxalosis)
- Neoplasms (ie, hepatoma, cholangiocarcinoma, hepatoblastoma, bile duct cancer)
- Noncholestatic cirrhosis (ie, alcoholic cirrhosis, postnecrotic cirrhosis, drug-induced cirrhosis)

### Lungs

Lung transplants may involve deceased donation of two lungs or a single lung. More recently, lobar transplants from blood group–compatible living donors have been performed for a small segment of the population. Most of the lobar transplants have been performed on cystic fibrosis patients. On rare occasions, a simultaneous heart–lung transplant occurs. This type of procedure is reserved for patients with severe pulmonary and cardiac disease. There were 1925 (all deceased donors) lung transplants and 24 simultaneous heart–lung transplant procedures done in 2014.[2] Reasons for lung transplant include:

- α-1-Antitrypsin deficiency
- Congenital disease (ie, Eisenmenger syndrome)
- Cystic fibrosis
- Emphysema/chronic obstructive pulmonary disease
- Idiopathic pulmonary fibrosis
- Primary pulmonary hypertension

### Pancreas

The exact nationwide prevalence of all diseases of the pancreas has not been fully quantified; however DM, both types 1 and 2, affects nearly 21 million people in the United States. Some people suffering from DM may also be afflicted with ESRD. A small percentage of these patients undergo a simultaneous

pancreas-kidney (SPK) transplant, which may be accomplished using organs from deceased or living donors. Transplant of a pancreas may involve either the entire organ or a pancreas segment. Currently, whole-organ transplant is the most common procedure, with a portion of the duodenum often transplanted along with the pancreas. Living donors are often the source of segmental transplants. In recent years, isolation and transplantation of β-islet cells alone have been completed. Islet transplantation is intended to treat organ dysfunction by replacing nonfunctioning islet cells with new ones. Islet transplants are still considered experimental, and long-term benefit and/or risk of this procedure needs to be studied extensively. Future success of islet cell transplantation is dependent on identifying a nontoxic immunosuppressive combination. There were 245 pancreas transplants and 709 SPK procedures done in 2014.[2] Reasons for pancreas transplants include:

- DM (ie, type 1 and 2, DM secondary to chronic pancreatitis or cystic fibrosis)
- Pancreatic cancer

## PATHOPHYSIOLOGY
### Major Histocompatibility Complex

The primary target of the immune response after organ transplant is the major histocompatibility complex (MHC).[1,3] The MHC is a region of highly polymorphic genes located on the short arm of chromosome 6. The human MHC is referred to as human leukocyte antigen (HLA). HLA is a set of glycoproteins expressed on the surface of most cells. These proteins are involved in immune recognition, which is the discrimination of self from nonself, but are also the principal antigenic determinants of allograft rejection.[1,3]

The HLA have been classified into two major groups, class I and II:

- Class I: expressed on the surfaces of all nucleated cells and recognized by CD8+ cells (ie, cytotoxic T cells).
  - The three subclasses of MHC class I are HLA-A, HLA-B, and HLA-C.
- Class II: expressed solely on the surfaces of antigen-presenting cells (APCs). The APCs serve to stimulate CD4+ cells (ie, helper T cells).
  - The three subclasses of MHC class II are HLA-DP, HLA-DQ, and HLA-DR.

### T and B Lymphocytes

Lymphocytes are one of five kinds of white blood cells. Mature lymphocytes are astonishingly diverse in their functions. The most abundant of the lymphocytes are T lymphocytes (ie, T cells) and B lymphocytes (ie, B cells).

▶ **T Lymphocytes**

**KEY CONCEPT** *T cells play a major role in the cell-mediated immune response.* These cells are produced in the bone marrow, but mature in the thymus, hence the abbreviation "T." There are three recognized subclasses of T cells: cytotoxic T cells, helper T cells, and regulatory T cells:

- Cytotoxic T cells (CD8+) promote target cell destruction by activating cellular **apoptosis** or killing the target cell via the release of cytotoxic proteins.
- Helper T cells (CD4+) are the great communicators of the immune response. Once activated, they proliferate and

secrete cytokines that regulate **effector cell** function. Some helper T cells secrete cytokines that recruit cytotoxic T cells, B cells, or APCs, whereas others secrete cytokines that turn off the immune response.
- Regulatory T cells, or suppressor T cells, suppress the activation of an immune response.

▶ **B Lymphocytes**

B cells play a large role in the humoral immune response. In humans, B cells are produced and mature in the bone marrow. The human body produces several types of B cells. Each B cell is unique, with a distinctive cell surface receptor protein that binds to only one particular antigen. Once B cells encounter their antigen and receive a cytokine signal from helper T cells, they can further differentiate into one of two cells, plasma cells or memory B cells. Plasma cells secrete antibodies that induce the destruction of target antigens through complement recruitment and/or **opsonization**. Memory B cells play an important role in long-term immunity, as they are capable of rapidly responding to subsequent exposures to their target antigen.

### Antigen-Presenting Cells

**KEY CONCEPT** *An APC is a cell that displays a foreign antigen complexed with MHC on its cell surface.* Its major responsibility is to present these foreign antigens to T cells. T cells can identify this complex using their T-cell receptors (TCRs). There are three main types of APCs: dendritic cells (DCs), macrophages, and activated B cells. DCs are present in tissues that are in contact with the environment, such as skin and the lining of the nose, lungs, stomach, and intestines. They are responsible for **phagocytosis**. After which, they express the foreign antigen on their cell surface and then migrate to lymphoid tissues to interact with T and B cells to initiate the immune response. Macrophages' main role is removal of pathogens and necrotic debris. However, like DCs, macrophages also phagocytize antigens. The first time an antigen is encountered, the DCs and macrophages act as the primary APCs. However, if the same antigen is encountered again, memory B cells become the most important APC because they initiate the immune response quickly after antigen presentation. It appears that both the DCs and macrophages have the most activity in terms of **allorecognition**.

### Allorecognition

**KEY CONCEPT** *Recognition of the antigens displayed by the transplanted organ (alloantigens) is the prime event that initiates the immune response against the allograft.* There are currently two accepted pathways for allorecognition:

- Direct pathway: Donor APCs migrate out of the allograft into the recipient's lymph nodes and present donor MHC molecules to the recipient's T cells.
- Indirect pathway: Recipient APCs migrate into the graft and phagocytize alloantigens. The recipient's APCs present donor MHC molecules to the recipient T cells in lymph nodes.

### T-Cell Activation

**KEY CONCEPT** *Whether it is by direct or indirect pathways, in order for a T cell to become activated against the allograft, two interactions or signals must take place between the APCs and the recipient's T cells*[1,3]:

- Signal 1 is the interaction of the TCR with the foreign antigens presented by APCs.

| Table 55–1 | | |
| --- | --- | --- |
| **Organ-Specific Signs and Symptoms of an Acute Rejection Episode[1]** | | |
| **Organ** | **Clinical Symptoms** | **Laboratory Signs** |
| Heart | Fever, lethargy, weakness, SOB, DOE, hypotension, tachycardia, atrial flutter, ventricular arrhythmias | Leukocytosis, biopsy positive for mononuclear infiltrates |
| Kidney | Fever, graft tenderness, decreased urine output, malaise, hypertension, weight gain, edema | Increased SCr, BUN, leukocytosis, biopsy positive for lymphocytic infiltration |
| Intestine | Fever and GI symptoms (ie, bloating, cramping, diarrhea, increased stomal output) | There are no reliable biochemical markers for intestine transplant rejection, but biopsies may be helpful |
| Liver | Fever, lethargy, change in color or quantity of bile in patients with biliary T-tube, graft tenderness and swelling, back pain, anorexia, ileus, tachycardia, jaundice, ascites, encephalopathy | Abnormal LFTs, increased bilirubin, alkaline phosphate, transaminases, biopsy positive for mononuclear cell infiltrate with evidence of tissue damage |
| Lung | Fever, impaired gas exchange, SOB, malaise, anxiety | Decreased FEV, infiltrate on CXR, biopsy positive for lymphocytic infiltration |
| Pancreas | Fever, graft tenderness and swelling, abdominal pain, ileus, and malaise | Increased FBS, leukocytosis, decreased human C-peptide and urinary amylase levels |

BUN, blood urea nitrogen; CXR, chest x-ray; DOE, dyspnea on exertion; FBS, fasting blood sugar; FEV, forced expiratory volume; GI, gastrointestinal; LFTs, liver function tests; SCr, serum creatinine; SOB, shortness of breath.

- Signal 2 is an interaction between one of several costimulatory receptors and paired ligands on the cell surfaces of the APCs and T cells, respectively. Both interactions must occur simultaneously as Signal 1 in the absence of Signal 2 induces T-cell anergy.
- Once activated, T cells undergo clonal expansion under the influence of cytokines, specifically interleukin-2 (IL-2). These steps elicit an antidonor T-cell response that results in graft destruction.

## Mechanisms of Acute Rejection

After activation, cytotoxic T cells emerge from lymphoid organs to infiltrate the graft and trigger the immune response. These cells induce graft destruction via two mechanisms: (a) secretion of cytotoxic proteins (ie, perforin, granzyme) and (b) induction of cellular apoptosis through interaction. Besides the cytotoxic T cells, several other cell lines may play a role in allograft destruction, including B cells, granulocytes, and natural killer cells.

## Types of Rejection

### ▶ Hyperacute Rejection

Hyperacute rejection is an immediate recipient immune response against the allograft due to the presence of preformed recipient antibodies directed against the donor's HLA. This type of reaction generally occurs within minutes of transplantation. The organ must be removed immediately to prevent severe systemic responses. In the case of cardiac or lung transplantation in which the organ cannot be promptly removed, short-term mechanical circulatory support is required until an alternative organ becomes available. Those patients at highest risk for hyperacute rejection include any patients that have preformed HLA or ABO blood group antibodies, including patients with a history of previous organ transplant or multiple blood transfusions, as well as women who have had children. Hyperacute rejection has been largely eliminated due to routine pretransplant surveillance testing.

### ▶ Acute Rejection

Acute rejection is a cell-mediated process that generally occurs early posttransplant; however, it can occur at any time after transplant. This reaction is mediated through alloreactive T cells, as discussed above. Organ-specific signs and symptoms of acute rejection can be seen in Table 55–1.[1]

### ▶ Antibody-Mediated Rejection

Antibody-mediated rejection (AMR) is the process of creating graft-specific antibodies.[4] This type of rejection occurs less frequently than cell-mediated acute rejection. Histologic findings are similar to those of hyperacute rejection, but the severity of rejection is usually less with AMR. AMR is generally characterized by deposition of immunoglobulins and complement in allograft tissues. However, AMR may be diagnosed without the presence of complement. Treatment for this type of rejection is not well defined; however, several reports have shown that treatments such as plasmapheresis, immunoglobulin therapy, rituximab, bortezomib, or eculizumab may be effective.[4]

### ▶ Chronic Rejection

Chronic rejection has traditionally been thought of as a slow, insidious form of acute rejection, resulting in worsening organ function over time. The exact immunologic processes of chronic rejection are poorly understood; however, many believe that both the cell-mediated and humoral immune systems and drug-induced toxicities play a vital role in its development. Currently, retransplantation is the only effective treatment option.[1,3]

### ▶ Host–Graft Adaptation

The term "host–graft adaptation" describes the decreased immune response against the allograft over time.[1,3] This phenomenon is evident by the reduced incidence of acute rejection episodes seen months after transplantation. In theory, host–graft adaptation is thought to be secondary to a weakened T-cell response to donor antigens while patients receive maintenance immunosuppression.[1,3]

## Tolerance

Tolerance is the process that allows organ-specific antigens to be accepted as self.[1] This would mean the immune system would cease to respond to the allograft and immunosuppressive medications would not be required. Immune tolerance has been

achieved in the lab, but has yet to be successfully accomplished in humans.[1]

## Immunologic Barriers to Transplantation

One of the more common barriers to successful transplantation is the presence of preformed HLA antibodies or ABO blood group incompatibility.[4] In cases in which these antibodies exist, if they are not adequately removed prior to transplant, they are likely to result in AMR and poor graft survival. To improve outcomes, assessment of pretransplant immune risk factors plays an important role in the prevention of immune-mediated allograft injuries. The introduction of pretransplant cross-matching and the use of ABO-compatible donors has largely eliminated hyperacute rejection episodes. However, these immunologic barriers are present in several potential recipients with willing organ donors, and patients are left to wait for a deceased donor or undergo pretransplant immunomodulation in an attempt to prevent these antibodies from affecting the allograft.[4]

### ▶ ABO Incompatibility

The expanding deceased donor waiting list encouraged some centers to evaluate the use of ABO desensitization protocols in order to transplant patients with ESRD that had willing but ABO-incompatible donors.[4] The desensitization protocol most commonly used in the United States involves reducing ABO antibody titers through plasmapheresis with IV immune globulin (IVIG). Use of plasma exchange to achieve an ABO antibody titer of less than 1:8 to 1:32 has resulted in long-term renal transplant results that are comparable to those of ABO-compatible transplants, despite an incidence of acute AMR that approaches 10% to 30%.[4]

### ▶ HLA Sensitization

Evaluation of the presence or absence of alloantibodies and T-cell activities to HLA antigens plays a significant role in individualization of immunosuppression.[4] A patient's degree of sensitization is often reported as the percentage of panel-reactive antibodies (PRA), which is an estimate of the likelihood of a positive crossmatch to a pool of potential donors. Advancement in HLA antibody screening and identification through flow cytometry or solid-phase multiplex platforms has overcome many of the issues stemming from older methods of PRA calculations. Patients are considered to be highly sensitized to HLA if they have a PRA of greater than or equal to 80%, making them less likely to receive a deceased donor organ. Patients with higher PRAs and preformed antibodies have poorer long-term allograft survival. Although PRA is a sensitive test and has predictive value, lymphocytes directly obtained from the donor is a superior method of immune monitoring. The assay is aimed to detect the presence of antibodies directed against the HLA antigens of the donor. In this setting, the presence of donor-specific antibodies (DSA) is identified. In one study, allograft survival was significantly lower in patients with DSA.[5] Thus detecting DSA and the presence of high PRA may indicate the need to enhance immunosuppression to improve posttransplant outcomes and allograft survival.[4]

Like ABO incompatibilities, it is possible to desensitize patients against a willing donor despite the presence of DSA or those awaiting a deceased donor transplant with a broad array of preformed anti-HLA antibodies (PRA greater than or equal to 30%).[4] There are two general protocols used for HLA desensitization: high-dose IVIG and low-dose IVIG with plasmapheresis. Despite the relatively high degree of AMR seen in desensitized

patients, this population of patients has acceptable short-term patient and allograft survival. Unfortunately, the long-term results for graft and patient outcomes using either of these two protocols are unknown.[4]

## TREATMENT
### Desired Outcome

**KEY CONCEPT** *The major focus of pharmacotherapy in transplantation is to achieve long-term patient and allograft survival.*[1,3,5,6] Short-term outcomes (eg, acute rejection rates, 1-year graft survival) have improved significantly since the first successful transplant due to an improved understanding of the immune system and enhancements in surgical techniques, organ procurement, immunosuppression, and posttransplant care. Despite the success in improving short-term outcomes, the frequency of graft loss remains higher than desired.[1,3,5,6]

It is imperative that transplant practitioners be aware of the specific advantages and disadvantages of the available immunosuppressants, as well as their adverse reactions and drug–drug interaction (DDI) profiles. There are generally three stages of medical immunosuppression: (a) induction therapy, (b) maintenance therapy, and (c) treatment of rejection. **KEY CONCEPT** *Overall, the immunosuppressive regimens utilize multiple medications working on different targets of the immune system.* Please refer to Table 55–2 for a list of all available immunosuppressive agents.[1,5,6]

### Immunosuppressive Therapies—Induction Therapy

**KEY CONCEPT** *The goal of induction therapy is to provide a high level of immunosuppression in the early posttransplant period, when the risk of acute rejection is highest.*[5] This stage of immunosuppression is initiated intraoperatively and is concluded within the first 1 to 10 days after transplantation. Antibody induction therapy is not a mandatory stage of recipient immunosuppression and is typically predicated on immunologic risk. However, since acute rejection is a major concern in solid organ transplant recipients and its impact on chronic rejection is undeniable, induction therapy is often considered essential in some organs to optimize outcomes.[5]

### ▶ Goals of Induction Therapy

**KEY CONCEPT** *First, the induction agents are highly immunosuppressive, allowing for significant reductions in acute rejection and improved 1-year graft survival.*[5] Second, due to their unique pharmacologic effect, these agents are often considered essential in patients at high risk for poor short-term outcomes, such as patients with preformed antibodies, history of previous transplants, multiple HLA mismatches, or transplantation of organs with prolonged cold ischemic time, or from expanded-criteria donors. Specifically in renal transplantation, induction therapy plays an important role in preventing early-onset calcineurin inhibitor (CNI)–induced nephrotoxicity. With induction therapy, CNI initiation can be delayed until the graft regains some degree of function. Induction therapy is imperative when employing corticosteroid sparing or avoidance protocols.[5]

The improved short-term outcomes gained from induction therapy come with a degree of risk.[5] By using these highly immunosuppressive agents, particularly the antilymphocyte antibodies (ALA; the antithymocyte antibodies and alemtuzumab), the ability to mount a cell-mediated immune response is significantly reduced, which increases the risk of opportunistic infections and malignancy. Cytokine release syndrome is a common

**Table 55–2**

**Currently Available Immunosuppressive Agents[1,5,6]**

| Generic Name (Brand Name) | Common Dosage | Common Adverse Effects |
|---|---|---|
| *Induction Therapy Agents* | | |
| Alemtuzumab (Campath) | 20–30 mg × 1–2 doses | Flu-like symptoms, chills, rigors, fever, rash, myelosuppression |
| Antithymocyte globulin equine (ATGAM) | 15 mg/kg IV × 3–14 days | Flu-like symptoms, chills, rigors, fever, rash, myelosuppression |
| Antithymocyte globulin rabbit (Thymoglobulin) | 1.5 mg/kg IV × 3–14 days | Flu-like symptoms, chills, rigors, fever, rash, myelosuppression |
| Basiliximab (Simulect) | 20 mg IV × 2 doses | None reported compared to placebo |
| *Maintenance Immunosuppressants* | | |
| Cyclosporine (Sandimmune, Neoral, Gengraf) | 4–5 mg/kg by mouth twice a day | Neurotoxicity, gingival hyperplasia, hirsutism, hypertension, hyperlipidemia, glucose intolerance, nephrotoxicity, electrolyte abnormalities |
| Tacrolimus (Prograf, Astagraf XL, Envarsus XR) | 0.05–0.075 mg/kg by mouth twice a day or once daily if using Astagraf XL or Envarsus XR | Neurotoxicity, alopecia, hypertension, hyperlipidemia, glucose intolerance, nephrotoxicity, electrolyte abnormalities |
| Azathioprine (Imuran) | 1–2.5 mg/kg by mouth once a day | Myelosuppression, GI disturbances, pancreatitis |
| Mycophenolate mofetil (CellCept) | 0.5–1.5 gm by mouth twice a day | Myelosuppression, GI disturbances |
| Enteric-coated MPA (Myfortic) | 720 mg by mouth twice a day | Myelosuppression, GI disturbances |
| Sirolimus (Rapamune) | 1–10 mg by mouth once a day | Hypertriglyceridemia, myelosuppression, mouth sores, hypercholesterolemia, GI disturbances, impaired wound healing, proteinuria, lymphocele, pneumonitis |
| Everolimus (Zortress) | 0.75 mg by mouth twice daily | Hypertriglyceridemia, myelosuppression, mouth sores, hypercholesterolemia, GI disturbances, impaired wound healing, proteinuria, lymphocele, pneumonitis |
| Prednisone (Deltasone) | Maintenance: 2.5–20 mg by mouth once a day | Mood disturbances, psychosis, cataracts, hypertension, fluid retention, peptic ulcers, osteoporosis, muscle weakness, impaired wound healing, glucose intolerance, weight gain, hyperlipidemia |
| Belatacept (Nulojix) | 10 mg/kg on postop days 1 and 4 | GI disturbances, electrolyte abnormalities, headache |
| | 10 mg/kg at the end of postop weeks 2, 4, 8, and 12 | |
| | 5 mg/kg at the end of postop week 16 and every 4 weeks thereafter | |

GI, gastrointestinal; IV, intravenous; MPA, mycophenolic acid.

complication of T-cell depleting agents and may require premedications before infusions.[5]

▶ *Currently Available Induction Therapies*

**Basiliximab** Basiliximab is a chimeric monoclonal antibody that acts as an IL-2 receptor antagonist.[5,7] These receptors are present on almost all activated T cells. Basiliximab inhibits IL-2–mediated activation of lymphocytes, which is an important step in T-cell clonal expansion.

The dose of basiliximab is 20 mg IV given 2 hours prior to the transplant, followed by a second 20-mg dose on postoperative day 4.[5,7] This dosing schedule can be used for both children greater than or equal to 35 kg (77 lb) and adults. Two 10 mg doses with the same dosing schedule should be used for children less than 35 kg (77 lb). There are no specific dosage adjustments needed in renal or hepatic impairment.[5,7]

The incidence of all adverse reactions with basiliximab was similar to placebo in trials. There are no reported DDIs with basiliximab.[5,7]

**Antithymocyte Globulin Equine** Antithymocyte globulin equine (e-ATG) is a polyclonal antibody that contains antibodies against several T-cell surface markers. After binding to T cells,

e-ATG promotes cellular depletion through opsonization and complement-mediated T-cell lysis.[5,7] The common dosing strategy for e-ATG when used for induction therapy is 10 to 30 mg/kg/day IV for 3 to 14 days.[5,7]

After T-cell lysis there is a cytokine release. Due to this phenomenon, e-ATG is associated with several adverse reactions.[5,7] The most common of these include fever (63%), chills (43.2%), headache (34.6%), back pain (43.2%), nausea (28.4%), diarrhea (32.1%), dizziness (24.7%), malaise (3.7%), leukopenia (29.6%), and thrombocytopenia (44.4%). The overall incidence of opportunistic infections is 27.2%, with cytomegalovirus (CMV) disease occurring in 11.1% of patients. There are currently no reported pharmacokinetic DDIs with this agent.[5,7]

**Antithymocyte Globulin Rabbit** Antithymocyte globulin rabbit (r-ATG) is also a polyclonal antibody that induces T-cell clearance, but more importantly, it alters T-cell activation, homing, and cytotoxic activities.[7] Compared with e-ATG, r-ATG causes less cell lysis. It is also believed that r-ATG plays a role in inducing T-cell apoptosis. This agent is typically dosed at 1.5 mg/kg/day and is usually administered for 3 to 10 days after transplantation.[5] Many renal transplant centers aim to initiate the first dose intraoperatively to reduce organ reperfusion injury.[8]

Adverse reactions are common and may include fever (63.4%), chills (57.3%), headache (40.2%), nausea (36.6%), diarrhea (36.6%), malaise (13.4%), dizziness (8.5%), leukopenia (57.3%), thrombocytopenia (36.6%), and generalized pain (46.3%).[9,10,13] The incidence of infection is 36.6%, with CMV disease occurring in 13.4% of patients. There are no reported DDIs with the use of r-ATG at this time.[5,7]

**Alemtuzumab** Alemtuzumab is a recombinant DNA-derived monoclonal antibody that binds to CD52, which is present on most B and T lymphocytes, macrophages and natural killer (NK) cells, and a subpopulation of granulocytes.[5,7] After complexing with the CD52 cell surface marker, alemtuzumab induces an antibody-dependent cell lysis. This agent produces a rapid and extensive lymphocyte depletion that may take several months to years to return to pretransplant levels. Although it is not Food and Drug Administration (FDA) approved for use in organ transplantation, studies have demonstrated a dose of 30 mg IV or SC at the time of transplant to be effective in preventing acute rejection.[5]

Alemtuzumab has been associated with serious adverse reactions that include anemia (47%), neutropenia (70%), thrombocytopenia (52%), headache (24%), dysesthesias (15%), dizziness (12%), nausea (54%), vomiting (41%), diarrhea (22%), infusion-related reactions (15% to 89%), and infection (37%; CMV viremia occurred in 15% of patients).[7] The FDA recommends that premedication with acetaminophen and oral antihistamines is advisable to reduce the incidence of infusion-related reactions.[5]

**Comparative Efficacy—Induction Therapy Agents** Improvements in short-term outcomes gained from the use of induction therapies cannot be denied. However, despite these advances, use of induction therapy has not impacted long-term allograft function or survival. There are a few studies that help to delineate the ideal induction therapy agent. Studies comparing r-ATG and e-ATG show that r-ATG is more effective in lowering acute rejection rates and improving 1-, 5- and 10-year allograft outcomes.[9–11] Conversely, a study evaluating the use of basiliximab versus r-ATG demonstrated similar short-term efficacy between both groups.[12] However, other analyses of these two agents demonstrated similar results for allograft and patient survival, but a benefit for r-ATG in lowering incidence of acute allograft rejection.[13,14] A more recent analysis showed that alemtuzumab improved transplant outcomes when compared with basiliximab in patients with a low immunologic risk, and similar outcomes compared to r-ATG in patients with high immunologic risk.[15] When choosing an agent for induction therapy, one must weigh the risks versus benefits. Overall, the ALAs are considered to be most effective, but are associated with a higher incidence of infectious disease and malignancy.[5]

## Immunosuppressive Therapies—Maintenance Therapy

The goals of maintenance immunosuppression are to prevent rejection and optimize patient and graft survival.[6] Antirejection medications require careful selection and dose titration to balance the risks of rejection with those of toxicities.

Common maintenance immunosuppressive agents can be divided into five classes:

- Calcineurin inhibitors (CNI; cyclosporine and tacrolimus)
- Antiproliferatives (azathioprine and the mycophenolic acid [MPA] derivatives)
- Target of rapamycin (ToR) inhibitors (sirolimus and everolimus)
- Corticosteroids
- Costimulatory blockade (belatacept)

Maintenance immunosuppression is generally achieved by combining two or more medications from the different classes, specifically targeting unique components of the immune response.[6] Please refer to **Figure 55–1** for a schematic representation of these different drug mechanisms and **Figure 55–2** for an example protocol for administration of immunosuppressive medications posttransplant. This method of medication selection also minimizes toxicities by choosing agents with different adverse event profiles. Immunosuppressive regimens vary between organ types and transplant centers, but most often include a CNI with an adjuvant agent, plus or minus corticosteroids. Selection of an immunosuppressive regimen should be

---

## Patient Encounter Part 1

**HPI:** A 59-year-old woman presents to your transplant center for a living unrelated renal transplant.

**PMH:** ESRD secondary to diabetes mellitus type 2; obesity (she has lost weight in order to get her BMI less than 35 to be approved for renal transplantation); hypertension; hyperlipidemia; insomnia; gout (has had three episodes of gout in the past 12 months); secondary hyperparathyroidism

**FH:** Father died from a heart attack 3 years ago; mother is alive and living with a history of breast cancer

**SH:** Does not work due to poor health, but was formerly a dental hygienist. She admits to social alcohol use (one or two drinks per week) and denies any tobacco and IV drug use

**Admission Meds:** Diltiazem ER 120 mg by mouth once a day; irbesartan 100 mg by mouth once a day; furosemide 20 mg by mouth twice a day; atorvastatin 20 mg by mouth once a day;

zolpidem 10 mg by mouth once a day at bedtime; calcitriol 0.25 mg by mouth once a day; sevelamer carbonate 1600 mg with each meal and 800 mg with each snack; Epo 4000 units IV every hemodialysis session; insulin glargine 22 units administered in the evening; insulin aspart 4 units with each meal and a sliding scale (dependent on blood sugars)

**Allergies:** Sulfa—hives

**Labs:** CMV serostatus: donor is CMV IgG positive; CMV serostatus: recipient is CMV IgG negative; EBV serostatus: donor is EBV IgG positive; EBV serostatus: recipient is EBV IgG negative

*Identify your treatment goals for this patient.*

*Create a plan for induction therapy (ie, would you recommend induction therapy, and if so, which agent?).*
**FIGURE 55–1.** Identification of the sites of action of the various immunosuppressive medications. Allograft recognition through Signal 1 occurs when the antigen-major histocompatibility complex (MHC) molecule is recognized by the T-cell receptor (TCR). A costimulatory signal, Signal 2, initiates signal transduction with activation of second messengers, one of which is calcineurin. Together, Signal 1 and Signal 2 activate calcineurin phosphatase, which removes phosphates from the nuclear factors, allowing them to enter the nucleus, with a subsequent increase in interleukin-2 (IL-2) gene transcription. Signal 3 occurs with the interaction of IL-2, with the IL-2 receptor on the cell membrane surface. This culminates in a signal that passes through the mammalian target of rapamycin (ToR) and induces cell proliferation and production of cytokines specific to the T cell. (ATG, antithymocyte globulin; AZA, azathioprine; CsA, cyclosporine; EC-MPA, enteric-coated mycophenolic acid; EVL, everolimus; MMF, mycophenolate mofetil; NFAT, nuclear factors; SRL, sirolimus; TAC, tacrolimus.)

patient-specific, and one must take into account the patient's comorbidities, medication regimens, and preferences.[6]

### ▶ Calcineurin Inhibitors

KEY CONCEPT *Cyclosporine and tacrolimus belong to a class of immunosuppressants called calcineurin inhibitors. These agents are considered to be the cornerstone of modern immunosuppressive protocols.* The CNIs work by complexing with cytoplasmic proteins (cyclosporine with cyclophilin and tacrolimus with FK binding protein-12).[6,7] These complexes inhibit calcineurin phosphatase, which results in reduced IL-2 gene transcription and a reduction in IL-2 synthesis. This diminishes T-cell activation.[6,7]

**Cyclosporine** Cyclosporine USP was first approved in 1983, but was associated with a variable oral absorption. The development of a newer formulation, cyclosporine microemulsion USP (ie, modified), introduced in 1994, allowed for a more consistent drug exposure due to a more reliable pharmacokinetic profile.[1] Cyclosporine modified is the formulation of choice for most transplant centers utilizing cyclosporine due to the previously mentioned benefit. The two formulations are not interchangeable.[6]

The usual oral adult dose of cyclosporine ranges from 3 to 7 mg/kg/day in two divided doses.[7] The appropriate selection of the starting dose depends on the organ type, the patient's comorbidities, and other concomitant immunosuppressive agents utilized. Cyclosporine modified is available as 25-mg and 100-mg capsules and an oral solution. An IV formulation of conventional cyclosporine is also available. When converting a patient from oral to IV, the dosage should be reduced to approximately one-third of the total daily oral dose.[7]

Cyclosporine whole-blood trough concentrations ($C_0$) have traditionally been obtained to help monitor for efficacy and safety. Therapeutic $C_0$ may range from 50 to 400 ng/mL (50–400 mcg/L

or 42–333 nmol/L). Target levels should be individualized for each patient, usually depending on the organ transplanted, patient's condition, method of assay (liquid chromatography coupled to tandem mass spectrometry [LC-MS/MS], monoclonal, polyclonal), and time since transplantation.[6] Newer studies suggest that monitoring of concentrations at 2 hours postdose ($C_2$) correlates better with toxicity and efficacy when compared with $C_0$.[16]

**Tacrolimus** Tacrolimus is the second CNI and was approved in 1997. Oral starting doses of tacrolimus range from 0.1 to 0.2 mg/kg/day in two divided doses. Tacrolimus is available in 0.5-, 1-, and 5-mg capsules and as an injectable.[7] Two once daily tacrolimus formulations are also available. Tacrolimus $C_0$ should be monitored and maintained between 5 and 15 ng/mL (5 and 15 mcg/L or 6 and 18 nmol/L), again depending on the transplanted organ, patient's condition, and time since transplant.[6]

The tacrolimus IV formulation is usually avoided due to the risk of anaphylaxis, because of its castor oil component, and nephrotoxicity.[6] Doses for IV administration are recommended to start at 0.01 mg/kg/day. In an effort to avoid IV tacrolimus, many transplant centers utilize sublingual (SL) tacrolimus in their patients unable to receive the medication by mouth.[6]

**Adverse Drug Reactions** KEY CONCEPT *One of the major disadvantages of the CNIs is their ability to cause nephrotoxicity.* Acute nephrotoxicity has been correlated with high doses and is usually reversible.[7] Chronic CNI toxicity, however, is typically irreversible and is linked to chronic drug exposure. Table 55–3 expands on the more common calcineurin inhibitor–associated adverse events.[1,6]

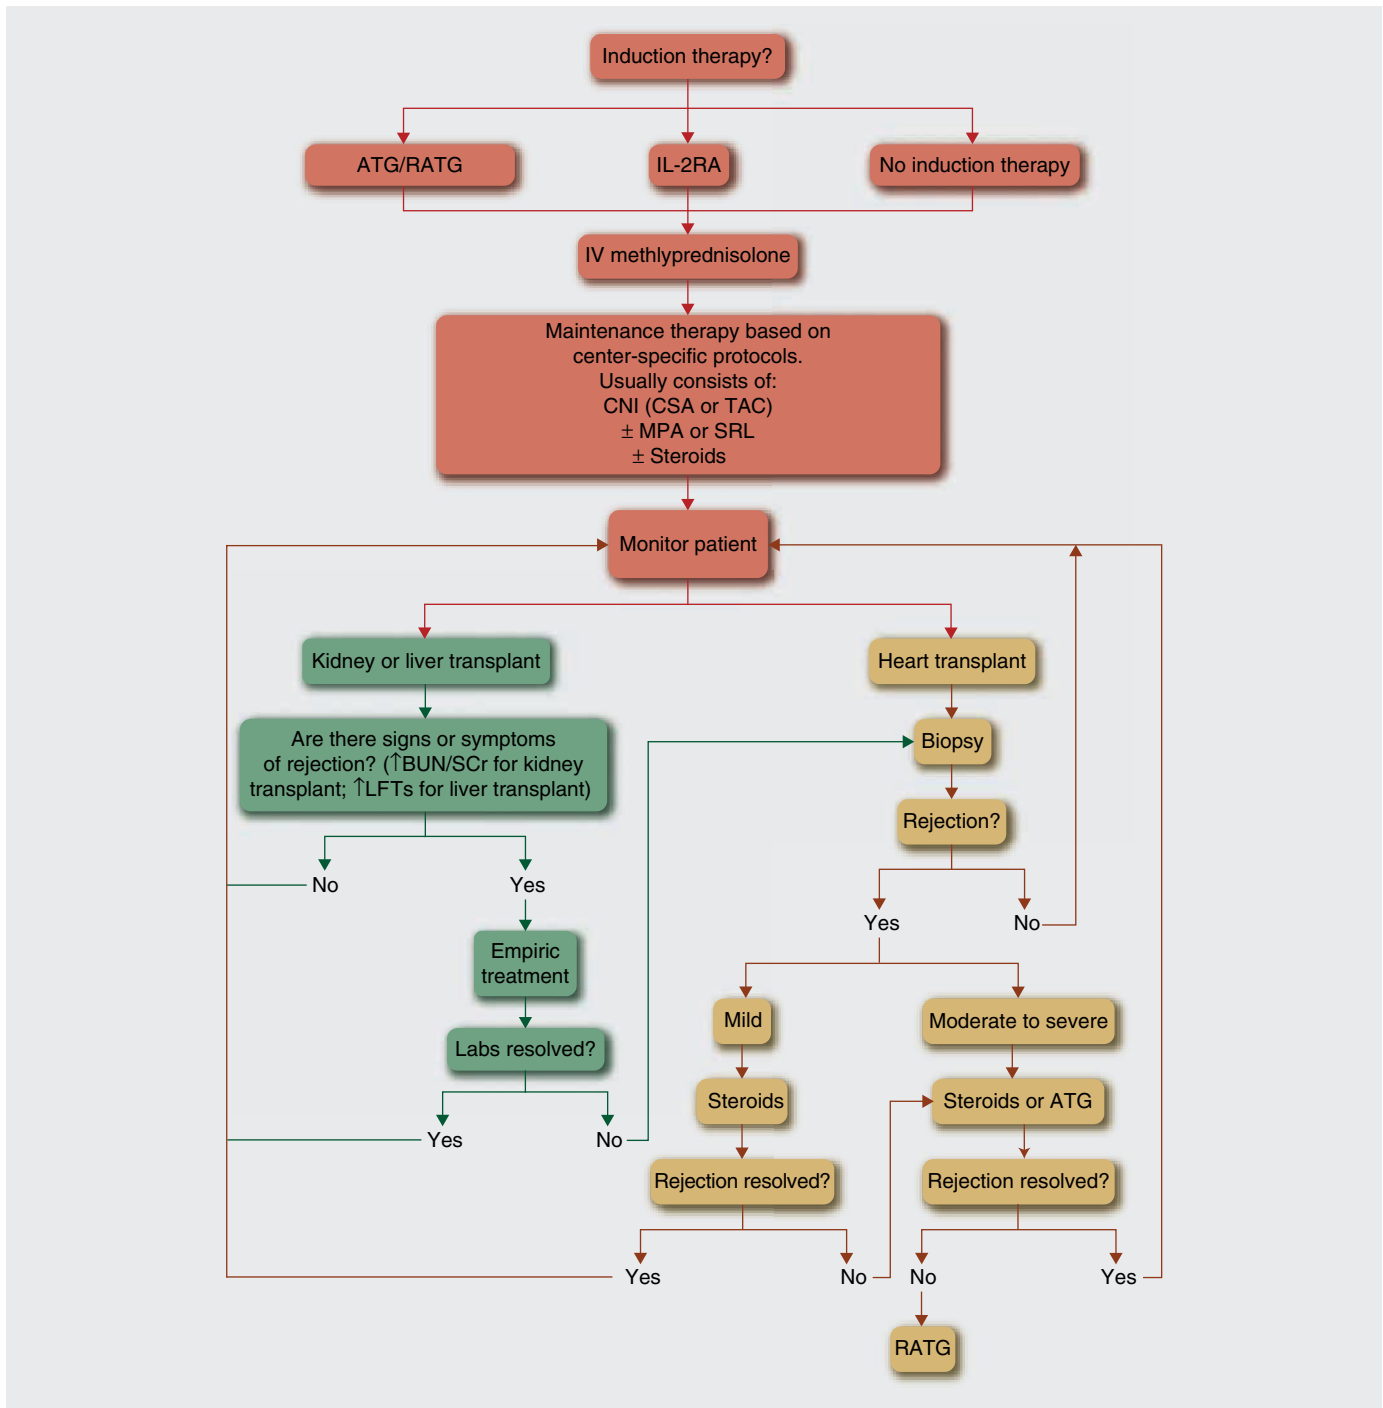
**Comparative Efficacy—Calcineurin Inhibitors** Even though cyclosporine and tacrolimus are both CNIs, there are several


**FIGURE 55–2.** Example protocol of immunosuppressive medication use in organ transplantation.[a]Center-specific protocols may use rabbit antithymocyte immunoglobulin (RATG), an interleukin-2 receptor antagonist (IL-2RA), or no induction therapy. In any situation, patients receive IV methylprednisone prior to, during, or immediately following the transplant operation. The patient then will begin the maintenance immunosuppressive regimen. The center-specific protocol will specify which calcineurin inhibitor (cyclosporine or tacrolimus) is used in combination with mycophenolate mofetil or sirolimus, with or without steroids. Patients then are monitored for signs and symptoms of rejection. If rejection is suspected, a biopsy can be done for definitive diagnosis, or the patient may be treated empirically for rejection. Empirical treatment generally involves administration of corticosteroids. If signs and symptoms of rejection are resolved with empirical therapy, the patient will continue to be monitored according to the center-specific protocol. If rejection is confirmed by biopsy, treatment may be based on the severity of rejection. High-dose corticosteroids are used most frequently for mild to moderate rejection. RATG can be used for moderate to severe rejections or steroid-resistant rejections. [a]Protocols and algorithms may differ across transplant centers. (ATG, antithymocyte globulin; BUN, blood urea nitrogen; CNI, calcineurin inhibitor; CSA, cyclosporine; IV, intravenous; LFT, liver function test; MPA, mycophenolic acid; SCr, serum creatinine; SRL, sirolimus; TAC, tacrolimus.) (From Schonder KS, Johnson HJ. Solid Organ Transplantation. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach. 9th ed. New York: McGraw-Hill; 2014:1419.)

| Table 55–3 |
|---|

**Management of Common Adverse Effects of Calcineurin Inhibitors[1,6]**

| Adverse Event | Most Likely Offending CNI | Monitoring Parameters | Therapeutic Management Options |
|---|---|---|---|
| Nephrotoxicity | Either | -SCr | -Reduce CNI dose (if possible) |
| | | -BUN | -Use of CCB for hypertension control |
| | | -Urine output | -Modify regimen (change to non-CNI containing regimen [ToR inhibitor or belatacept])[a] |
| | | -Biopsy-proven CNI-induced nephrotoxicity | |
| Hypertension[b] | Cyclosporine | -Blood pressure | -Initiate patient-specific antihypertensive therapy |
| | | -Heart rate | -Reduce cyclosporine dose (if possible) |
| | | | -Modify regimen (change to tacrolimus or non-CNI containing regimen)[a] |
| Hyperlipidemia[b] | Cyclosporine | -Fasting lipid panel | -Initiate patient-specific cholesterol-lowering therapy |
| | | | -Reduce cyclosporine dose (if possible) |
| | | | -Modify regimen (change to tacrolimus or non-CNI containing regimen)[a] |
| Hyperglycemia[c] | Tacrolimus | -Blood glucose (fasting and nonfasting) | -Lifestyle modifications |
| | | | -Reduce tacrolimus dose (if possible) |
| | | -Hemoglobin A1c | -Reduce steroids (if patient is taking them and if possible) |
| | | | -Initiate patient-specific glucose-lowering therapy (insulin or oral therapy) |
| | | | -Modify regimen (change to cyclosporine or non-CNI containing regimen)[a] |
| Neurotoxicities[c] | Tacrolimus | -Fine hand tremor | -Reduce tacrolimus dose (if possible) |
| | | -Headache | -Modify regimen (change from tacrolimus to cyclosporine or non-CNI containing regimen)[a] |
| | | -Mental status changes | |
| Hirsutism | Cyclosporine | -Patient complains of excessive hair growth or male-pattern hair growth | -Reduce cyclosporine dose (if possible) |
| | | | -Cosmetic hair removal |
| | | | -Modify regimen (change to tacrolimus or non-CNI containing regimen)[a] |
| Alopecia | Tacrolimus | -Patient complains of excessive hair loss | -Reduce tacrolimus dose (if possible) |
| | | | -Hair growth treatments (ie, minoxidil, finasteride-males only) |
| | | | -Consider use of multivitamin with thiamine and folic acid, and/or biotin 5000 mcg daily |
| | | | -Modify regimen (change to cyclosporine or non-CNI containing regimen)[a] |
| Gingival Hyperplasia | Cyclosporine | -Patient complains of excessive gum growth | -Reduce cyclosporine dose (if possible) |
| | | | -Oral surgery (gum resection) |
| | | -Discuss options for therapy with the patient's dentist | -Modify regimen (change to tacrolimus or non-CNI containing regimen)[a] |

BUN, blood urea nitrogen; CCB, calcium channel blocker; CNI, calcineurin inhibitor; SCr, serum creatinine; ToR, target of rapamycin.

[a]Modifying the immunosuppressive regimen increases risk for rejection, even in stable patients. This option should be chosen cautiously and be implemented with proper monitoring and follow-up.

[b]Tacrolimus is also associated with hypertension and hyperlipidemia, but to a much lower extent compared to cyclosporine.

[c]Cyclosporine is also associated with hyperglycemia and neurotoxicities, but to a much lower extent compared to tacrolimus.

differences between the two. A meta-analysis comprised of 30 trials and 4102 patients comparing cyclosporine to tacrolimus in kidney transplantation, showed tacrolimus was associated with significantly lower risk of allograft loss at 6 months and lower rates of acute rejection at 1 year.[17] Tacrolimus is the primary CNI in many transplant centers, due in large part to a more favorable adverse reaction profile.[6]

▶ *Antiproliferatives*

These agents are considered to be adjuvant to the CNIs or ToR inhibitors.[6]

**Azathioprine** Azathioprine was approved in 1968 as an adjunct immunosuppressant in renal transplant. It is available in oral and IV dosage forms.[7] Prior to the advent of cyclosporine, the

combination of azathioprine and corticosteroids was the mainstay of immunosuppressive therapy. Over the past 10 years, the use of azathioprine declined markedly due to the superiority of the MPA derivatives. **KEY CONCEPT** *Azathioprine is a prodrug for 6-mercaptopurine (6-MP), a purine analog. 6-MP acts as an antimetabolite and inhibits DNA replication with a resultant reduction in T-cell proliferation.*[6] *The typical oral dose of azathioprine for organ transplantation is 1 to 5 mg/kg once a day.*[7] Dose reductions due to severely impaired renal function may be necessary since 6-MP and its metabolites are renally eliminated.[7] Trough concentrations of 6-MP are not monitored; however, most clinicians often monitor for signs of myelosuppression. **KEY CONCEPT** *Myelosuppression (mainly leukopenia and thrombocytopenia) is a frequent, dose-dependent and dose-limiting complication (greater than 50% of patients) that often prompts dose reductions.*[7] *Other common adverse events include hepatotoxicity (2%–10%) and adverse gastrointestinal (GI) events (10%–15%; mostly nausea and vomiting). Importantly, pancreatitis and venoocclusive disease of the liver occur in less than 1% of patients following chronic azathioprine therapy.*[7]

**Mycophenolic Acid Derivatives** Mycophenolate mofetil was approved in 1995 and enteric-coated MPA in 2004. Both agents are considered adjunctive immunosuppressants.[6] **KEY CONCEPT** *Both mycophenolate mofetil and enteric-coated MPA are prodrugs for MPA.* MPA acts by inhibiting inosine monophosphate dehydrogenase, a vital enzyme in the de novo pathway of purine synthesis. Inhibition of this enzyme prevents the proliferation of most cells that are dependent on the de novo pathway for purine synthesis, including T and B cells.[6]

Mycophenolate mofetil is available in 250-mg and 500-mg capsules, an oral suspension (100 mg/mL; in cherry syrup), and as an injectable.[7] The recommended starting dose of mycophenolate mofetil is 1000 to 1500 mg given twice daily. The conversion between oral and IV mycophenolate mofetil is 1:1. Enteric-coated MPA is available in 180-mg and 360-mg tablets. The appropriate equimolar conversion between mycophenolate mofetil and enteric-coated MPA is 1000 mg of mycophenolate mofetil to 720 mg of enteric-coated MPA.[6] The recommended starting dose of enteric-coated MPA is 720 mg given twice daily. Conversion of mycophenolate mofetil to enteric-coated MPA has been proven safe. MPA $C_0$ can be monitored; however, it is not routinely recommended.[6]

**KEY CONCEPT** *The most common adverse events associated with these agents are GI (18%–54%; diarrhea, nausea, vomiting, and gastritis) and myelosuppression (20%–40%).*[7] Despite its enteric coating, enteric-coated MPA has the same degree of GI adverse events as mycophenolate mofetil.[6,18] However, recent data suggest there is a benefit in converting patients with documented mycophenolate-induced GI disease from mycophenolate mofetil to enteric-coated MPA.[19]

**Comparative Efficacy—Antiproliferatives** Due to the results of several studies, the MPA derivatives have replaced azathioprine as the primary antiproliferative agent.[6] The MPA derivatives are generally considered to provide a more specific immunosuppressive effect compared with azathioprine. Mycophenolate mofetil and enteric-coated MPA have similar safety and efficacy data in renal transplant recipients.[18] The decision to choose one agent over another is a purely practitioner-dependent preference.

▶ *Target of Rapamycin Inhibitors*

**Sirolimus** **KEY CONCEPT** *Sirolimus inhibits T-cell activation and proliferation by binding to and inhibiting the activation of the mammalian ToR, which suppresses cellular response to IL-2 and other cytokines (ie, IL-4, IL-15).*[6,7,20] Studies have shown that sirolimus may be used safely and effectively concomitantly with either cyclosporine or tacrolimus instead of an antiproliferative.[21] Sirolimus can also be used as an alternative agent for patients who do not tolerate CNIs due to nephrotoxicity or other adverse events.[6] **KEY CONCEPT** *At this time, the most exciting data for sirolimus point to its ability to prevent long-term allograft dysfunction when used as a substitute for the CNIs in renal transplant recipients.*[20]

Sirolimus is available in 0.5-mg, 1-mg, and 2-mg tablets and a 1-mg/mL oral solution. Although some may elect not to do a loading dose, the package insert indicates the current approved dosing regimen for sirolimus is a 6-mg loading dose followed by a 2-mg/day maintenance dose.[7] Use of a sirolimus loading dose of 5 to 15 mg/day for 1 to 3 days will allow for a more rapid achievement of adequate immunosuppression.[7] Maintenance doses of sirolimus usually range from 1 to 10 mg/day given once daily. Sirolimus blood $C_0$ should be maintained between 3 and 10 ng/mL (3 and 10 mcg/L or 3 and 11 nmol/L), depending on the institution-specific protocols.[6] Of note, sirolimus has a half-life of approximately 62 hours, which means that it will not reach steady state after dosage changes for several days.[7]

**KEY CONCEPT** *The most common adverse events reported with sirolimus are leukopenia (20%), thrombocytopenia (13%–30%), and hyperlipidemia (38%–57%).*[7] Other adverse effects include delayed wound healing, anemia, diarrhea, arthralgias, rash, proteinuria, pneumonitis, and mouth ulcers. **KEY CONCEPT** *One analysis suggests that use of sirolimus in kidney transplant recipients can reduce cardiovascular risk compared with CNI–based regimens.*[22] Sirolimus has a black-box warning in newly transplanted liver and lung recipients, due to severe and potentially life-threatening adverse events.[7] The long-term use of sirolimus in these populations may be appropriate, but not in the initial posttransplant period (ie, 3–6 months posttransplant).

**Everolimus** Everolimus is a derivative of sirolimus and has the same mechanism of action.[7,23] Everolimus is only indicated for prevention of rejection in low- to moderate-risk renal and liver transplant recipients. This agent is available in 0.25-mg, 0.5-mg, and 0.75-mg tablets. The recommended starting dose of everolimus is 0.75 to 1 mg twice daily without the need for a loading dose. Maintenance everolimus doses should be maximized to achieve a $C_0$ goal of 3 to 8 ng/mL (3–8 mcg/L or 3–8 nmol/L).[7,23] With a significantly shorter half-life compared with sirolimus, everolimus steady-state can be reached within 4 to 6 days. **KEY CONCEPT** *The adverse event profile of everolimus is similar to that of sirolimus.*[7,23]

▶ *Corticosteroids*

Traditional triple-therapy immunosuppressive regimens have consisted of a primary agent (ie, CNI, ToR inhibitor, belatacept), an antiproliferative and corticosteroids.[6] Many renal transplant protocols have focused on corticosteroid sparing or avoidance. Avoidance or sparing of corticosteroids has been supported in the literature, although more studies are needed to help better characterize which patients should follow these protocols.[6,24] A typical taper includes a bolus of IV methylprednisolone 100 to 500 mg at the time of transplant, then tapered over days to months, depending on the type of organ, to a maintenance dose of prednisone 5 to 10 mg/day. Although most centers still use low-dose steroids for immunologically high-risk patients and nonrenal transplant patients, a number of renal transplant programs have developed an immunosuppression protocol that

completely withdraws corticosteroids at some point posttransplantation.[6] Therapeutic drug monitoring of corticosteroids is not employed. **KEY CONCEPT** *Corticosteroids are associated with a variety of metabolic toxicities.* The most common adverse events have been summarized in Table 55–4.[1,6]

**KEY CONCEPT** *Corticosteroids have various effects on immune and inflammatory responses, although their exact mechanism of immunosuppression is not fully understood.* It is believed that high doses are directly lymphotoxic, and lower doses act by inhibiting the production of various cytokines that are necessary to amplify the immune response.[6,7]

The most commonly used corticosteroids are methylprednisolone (IV and oral) and prednisone (oral), although prednisolone and dexamethasone have also been shown to be effective for organ transplantation. Corticosteroid doses vary by center-specific protocols, organ type, and patient characteristics.

▶ *Costimulatory Pathway Blocker*

**Belatacept** **KEY CONCEPT** *Belatacept was approved in 2011 as the first IV biologic maintenance immunosuppressive agent in transplant.*[25] Belatacept blocks CD80 and CD86 ligands, found on APCs.[7] The CD80 and CD86 proteins are responsible for stimulating CD28 on inactive T cells, an essential costimulatory interaction (Signal 2). As detailed earlier in this chapter, Signal 1 without a complementary Signal 2 induces T-cell anergy.[25] Studies have shown that in combination with mycophenolate and corticosteroids, belatacept may be used in place of CNIs; demonstrating similar patient and allograft survival compared to a cyclosporine-based regimen.[26,27] **KEY CONCEPT** *Belatacept improved renal function; however, the incidence of acute rejection was significantly higher.* Belatacept was also associated with improvements in blood pressure and lipid levels.[25]

Belatacept is available in a 250-mg vial that requires reconstitution prior to administration.[7] The recommended dosing regimen for belatacept is 10 mg/kg on the day of transplantation, followed by an additional dose 4 days later, and again at the end of weeks 2, 4, 8, and 12, posttransplant. Beginning at the end of week 16 posttransplant, belatacept is dosed at 5 mg/kg every 4 weeks thereafter.[7,25] Belatacept requires access to an infusion center/suite, or a home infusion service to ensure appropriate administration.

The most common adverse effects associated with belatacept are infectious (urinary tract infection, 37%; upper respiratory infection, 15%), GI (diarrhea, 39%; constipation, 33%; nausea, 24%, vomiting, 22%), metabolic (hyperkalemia, 20%; hypokalemia 21%), and central nervous system (CNS; headache, 21%) complications.[7] Other adverse effects include peripheral edema, anemia, leukopenia, hypotension, arthralgia, and insomnia.[25] **KEY CONCEPT** *Belatacept has a black-box warning for increased risk of posttransplant lymphoproliferative disorders (PTLD). Due to this risk, it is recommended that belatacept only be used in patients with a proven preexisting immunity to Epstein-Barr virus (EBV).* This black-box warning has also led to the inclusion of a communication plan as part of a belatacept risk evaluation and mitigation strategy to warn practitioners that belatacept use in EBV-naive or unequivocal patients is contraindicated. An additional black-box warning advises against use of belatacept in liver transplant patients due to an increased risk of allograft loss and patient death.[7,25]

## Immunosuppressive Therapies—Treatment of Acute Rejection Episodes

Acute rejection is generally treated with a course of high-dose methylprednisolone (250 to 1000 mg/day IV for 3 days), which is usually sufficient to ameliorate the episode. If the acute rejection episode is resistant to the initial course of steroids, a second course may be administered or the patient may begin therapy with r-ATG (1.5 mg/kg/day for 4 to 14 days).[28] Cellular rejection refractory to these treatments is rare and is likely due to underlying causes such as an antibody-mediated component or other diagnosis. Treatments of refractory acute rejection may include alemtuzumab, IVIG, high-dose tacrolimus, or organ irradiation.

## Immunosuppressive Therapies—Managing Highly Sensitized Patients and Antibody-Mediated Rejection Episodes

The presence of preformed antibodies, high PRA, and DSA are major barriers to successful transplantation.[4] This is true mainly because traditional immunosuppressants do not significantly affect the humoral immune system and are ineffective at management of AMR, which is a leading cause of allograft loss in kidney and heart transplant recipients. Without some form of intervention, antibody formation and rejection can significantly impact morbidity and mortality. Two major strategies are used for reduction of DSA pretransplant: (a) high-dose IVIG and (b) plasmapheresis plus low-dose IVIG. Each approach has advantages and disadvantages.[4]

In plasmapheresis or plasma exchange, patients' plasma is removed and replaced with albumin or fresh-frozen plasma.[4] Plasmapheresis produces a rapid reduction of preformed antibodies and allows transplantation to occur. The purpose of IVIG administration is to decrease anti-HLA alloantibody synthesis. The other mechanisms of IVIG are inhibition of

| Respiratory | Epistaxis |

complement-mediated injury, reduced B-cell proliferation and NK cells, and a decrease in phagocytosis. Most patients require four to five plasmapheresis sessions with IVIG to remove DSA. In patients at risk for bleeding, the use of albumin should be limited, and fresh-frozen plasma or a combination of both agents should be considered.[4]

In patients who develop AMR posttransplant, there are limited therapeutic options, none of which are FDA-approved. The potential options include plasmapheresis and IVIG, rituximab, bortezomib, and/or eculizumab.[4] All of these agents have an effect on humoral immunity, which may provide benefit to patients with AMR. The mechanisms of plasmapheresis and IVIG were discussed earlier in this chapter.[4]

Rituximab is a chimeric monoclonal anti-CD20 antibody targeting B cells.[4,7] This agent directly inhibits B-cell proliferation and induces cellular apoptosis through complement-mediated antibody-dependent cellular cytotoxicity. In an analysis of AMR treatment, the use of rituximab in conjunction with plasmapheresis/IVIG resulted in improved 3-year graft survival (92% vs 50%) and significantly reduced DSA at 3 months compared with high-dose IVIG alone.[29] Unfortunately, plasma cells lack CD20 and are unaffected by rituximab. However, rituximab may play an important role in reducing memory B-cell response. Overall, it appears that rituximab may provide beneficial effects in managing AMR when used in combination with other therapies.[4]

Bortezomib is a proteasome inhibitor indicated for treatment of multiple myeloma.[4,7] It works by inducing cell-cycle arrest and apoptosis of plasma cells. Desensitization and treatment protocols using bortezomib have utilized doses of 1.3 mg/m$^2$ from one to four cycles. Acute hepatic dysfunction has rarely been reported; thus, bortezomib should be used cautiously in patients with moderate-to-severe hepatic impairment. Bortezomib has also been associated with significant myelosuppression and peripheral neuropathy. Bortezomib has been used in combination with plasmapheresis and IVIG or rituximab. The reported outcomes of these cases demonstrate graft survival rates of 85% to 100%. Anti-HLA antibodies are decreased by 50% within two weeks of therapy and remain suppressed for up to 5 months.[30,31] Bortezomib also seems effective in AMR refractory to plasmapheresis and IVIG.[4]

Eculizumab is a humanized monoclonal antibody directed against complement protein C5.[4,7] It inhibits the cleavage to C5a and C5b, thus preventing the generation of the membrane attack complex (MAC) and reducing antibody-dependent cell lysis. Eculizumab carries a FDA boxed warning of meningococcal infection. Meningococcal vaccination is recommended 14 days prior to eculizumab, but meningococcal infections have been reported even in vaccinated patients. There are only a few case reports demonstrating eculizumab's efficacy for treating AMR, showing fast improvement of renal function observed within a week after eculizumab use.[4]

## Maintenance Immunosuppressive Therapies— Common Drug–Drug Interactions

**KEY CONCEPT** *As the number of medications a patient takes increases, so does the potential for DDIs.* Disease severity, patient age, and organ dysfunction are all risk factors for DDIs. In general, DDIs are either pharmacokinetic or pharmacodynamic interactions:

- Pharmacokinetic interactions result when one drug alters the absorption, distribution, metabolism, or elimination of another drug.
- Pharmacodynamic interactions include additive, synergistic, or antagonistic interactions that can affect efficacy or toxicity.

### ▶ *Pharmacokinetic Interactions*

Pharmacokinetic DDIs pose a major dilemma with the maintenance immunosuppressants. Pharmacokinetic interactions can either result in: (1) increased concentrations of one or more agents, with an increased risk for drug-induced toxicities or (2) lowered (ie, subtherapeutic) drug concentrations, possibly leading to allograft rejection. These interactions can be seen during drug absorption, distribution, metabolism, and elimination.

**Interactions of Absorption**  Gut metabolism, modifications in active transport, and changes in intestinal motility and chelation interactions alter absorption of the immunosuppressants. Active transporters (ie, P-glycoprotein [P-gp]) are present in the gut, brain, liver and kidneys and play an important role in DDIs. P-gp provides a biological barrier, eliminating xenobiotics that may accumulate in these organ systems, thereby having a significant impact on the absorption and distribution of many medications. P-gp affects the absorption of the CNIs and ToR inhibitors. Medications that inhibit or induce the activity of P-gp have a significant impact on bioavailability of some of the immunosuppressive agents. For example, P-gp inhibitors, such as verapamil or quinidine, increase concentrations of cyclosporine, tacrolimus, sirolimus, and everolimus due to reduced P-gp-dependent drug elimination from the systemic circulation.[7]

There is a prominent interaction between the prokinetic agents and the CNIs seen through changes in intestinal motility. Metoclopramide increases the absorption of cyclosporine and tacrolimus by enhancing gastric motility and emptying, resulting in increased CNI concentrations.[7]

Most of the interactions with mycophenolate mofetil and enteric-coated MPA result in reductions in intestinal absorption. Proton pump inhibitors decrease the oral absorption of mycophenolate mofetil, but not enteric-coated MPA.[7] Divalent and trivalent cations (ie, aluminum, magnesium, calcium) decrease MPA absorption through chelation. These agents should be administered at least 1 hour before or 2 hours after MPA. Of note, iron does not appear to interact with the MPA preparations. The clinical implications of these DDIs are unknown, but reductions in MPA exposure can theoretically increase the rejection risk.

**Interactions of Distribution**  Interactions of distribution occur most often with highly protein bound drugs.[7] MPA is the only highly protein bound (97%) maintenance immunosuppressant with an interaction of distribution. Concomitant administration of MPA with salicylates increases MPA free concentrations. The adverse sequelae of this interaction are unknown. Drug interaction studies have not been conducted with MPA derivatives and other highly protein bound drugs.

**Interactions of Metabolism**  Oxidative metabolism by cytochrome P-450 (CYP) isozymes is the primary method of xenobiotic metabolism. The CNIs and ToR inhibitors are substrates of the CYP3A isozyme system. Most CYP-mediated metabolism takes place in the liver; however, CYP is also expressed in the intestine, lungs, kidneys, and brain. Being CYP3A substrates, it would be anticipated that cyclosporine, tacrolimus, sirolimus, and everolimus would all experience similar DDI with known substrates, inhibitors, and inducers of the CYP3A isozyme system.[6] Table 55–5 details the clinically relevant DDIs that occur with the calcineurin and ToR inhibitors due to inhibition or induction of the CYP isozyme system.[7]

Given how extensive some immunosuppressant DDIs are, in some cases empiric dose changes are necessitated when

| Lidocaine | | | Voriconazole |
| | | | Zafirlukast |

[a]Substrates of the CYP3A4 isozyme will compete with cyclosporine, tacrolimus, and sirolimus for metabolism; therefore, concentrations of both medications will be increased (usually by ≤ 20%).

[b]Inducers of the CYP3A4 isozyme will enhance the metabolism of cyclosporine, tacrolimus, and sirolimus; therefore, concentrations of these medications will be decreased.

[c]Inhibitors of the CYP3A4 isozyme will decrease the metabolism of cyclosporine, tacrolimus, and sirolimus; therefore, concentrations of these medications will be increased.

---

coadministration with an interacting medication cannot be avoided. For example, it is recommended to reduce tacrolimus doses by one-third in patients initiating voriconazole. Some clinicians utilize interactions of metabolism to reduce the dose of an immunosuppressant, such as using diltiazem to treat hypertension, which also helps reduce tacrolimus doses and decrease pill burden.

Not all metabolic DDIs occur through the CYP system. Azathioprine has a considerable interaction with allopurinol and febuxostat that is mediated through the inhibition of xanthine oxidase, which is the enzyme responsible for metabolizing 6-MP to 6-thiouricate.[7] Combining these agents can result in 6-MP accumulation and severe myelosuppression. It is recommended that concomitant therapy with azathioprine and allopurinol or febuxostat be avoided, but if necessary, azathioprine doses must be empirically reduced by 75%.[7]

**Interactions of Elimination** Mycophenolate is metabolized to MPA-glucuronide (MPAG) via hepatic glucuronosyltransferase, and then excreted in bile for gut elimination.[7] Deconjugation of MPAG to MPA by intestinal flora results in continued MPA absorption several hours after its administration. Some medications (ie, cyclosporine, bile-acid sequestrants) interfere with the biliary excretion of MPAG; thereby, eliminating MPA reabsorption in the intestines and lowering the MPA area under the curve

(AUC).[7] In this type of interaction, separation of doses is ineffective; therefore, proper patient monitoring is warranted.

▶ *Pharmacodynamic Interactions*

In addition to the numerous pharmacokinetic interactions seen with the maintenance immunosuppressants, there also exists the possibility for pharmacodynamic interactions. Pharmacodynamic interactions are the backbone of modern immunosuppressive therapies that employ multiple medications with different mechanisms of action resulting in additive immunosuppression. Unfortunately, pharmacodynamic interactions can also be problematic, such as when medications with similar adverse events are used concomitantly. For example, nephrotoxic agents, such as amphotericin B, aminoglycosides, and nonsteroidal anti-inflammatory drugs may potentiate the nephrotoxic effects of the calcineurin inhibitors.[7] The use of myelosuppressive agents, such as sulfamethoxazole-trimethoprim and valganciclovir, could enhance the myelosuppressive effects of induction therapy and the maintenance immunosuppressants.[7]

In addition to reviewing prescription medications, it is essential to question patients about the use of nonprescription agents and dietary supplements, as these products also have the potential for significant interactions, through methods discussed above. Some examples of this are St. John's wort inducing the

**Patient Encounter Part 2**

*Identify your treatment goals for the patient in terms of maintenance immunosuppressants.*

*Create a plan for maintenance therapy for the patient, making sure to compare and contrast the pros and cons of the different maintenance immunosuppressants.*

*Identify the need to continue the patient's pretransplant medications, and identify any potential DDIs that may exist with the addition of the maintenance immunosuppressants and the medications that the patient is currently taking.*

metabolism of CNIs and ToR inhibitors, and willow bark having the potential to worsen CNI-induced nephrotoxicity.

## Immunosuppressive Therapies—Management of Immunosuppressive Drug Complications

### ▶ Opportunistic Infections

KEY CONCEPT *Organ transplant recipients are at increased risk of infectious diseases, which are a chief cause of early morbidity and mortality.[32] The prevalence of posttransplant infection depends on many factors, including clinical risk factors, environmental exposures, and the degree of immunosuppression. Anti-infectives are universally prescribed in this population, and their use can be split into three different categories:*

- Prophylaxis: antimicrobials given to prevent infection
- Empiric: preemptive therapy given based on clinical suspicion of an infection
- Treatment: antimicrobials given to manage a documented infection

Posttransplant infections generally occur in a standard pattern; therefore, prevention is a key management strategy.[32] The information in this section is designed to highlight prophylaxis options routinely used in organ transplant recipients. Please refer to Table 55–6 for a list of agents used for the prevention of *Pneumocystis jiroveci* pneumonia and CMV disease.[33,34]

● ***Pneumocystis jiroveci* Pneumonia** KEY CONCEPT *Without prophylaxis, P. jiroveci pneumonia occurs in 5% to 15% of transplant recipients.[33] Antipneumocystis prophylaxis is enormously helpful and is generally used in all organ transplant recipients. The duration of prophylaxis is usually 6 to 12 months after transplant, but may be prolonged in highly immunosuppressed patients (ie, active CMV disease, treatment for rejection) or liver or*

### Table 55–6

**Prophylactic Options for *Pneumocystis jiroveci* Pneumonia and CMV[33,34]**

| Medication | Dosing | Common Adverse Events |
|---|---|---|
| *Antipneumocystis Prophylaxis* | | |
| Sulfamethoxazole-trimethoprim (Bactrim, Septra, SMZ-TMP, cotrimoxazole) | One SS tablet by mouth once a day[a] <br> One DS tablet by mouth once a day[a] <br> One DS tablet by mouth every M/W/F[a] | Hyperkalemia <br> Myelosuppression <br> Nephrotoxicity <br> Neutropenia <br> Photosensitivity <br> Rash |
| Pentamidine (NebuPent) | 300 mg inhaled every 3–4 weeks | Bronchospasm <br> Cough <br> Hypoglycemia or hyperglycemia |
| Dapsone (Avlosulfon) | 50–100 mg tablet by mouth once a day | Hepatotoxicity <br> Myelosuppression <br> Nephritis |
| Atovaquone (Mepron) | 1500 mg suspension by mouth once a day | Elevated liver transaminases <br> Nausea <br> Rash |
| *Antivirals* | | |
| Valganciclovir (Valcyte) | 450–900 mg by mouth once a day[a] | Stomach upset (8%–41%) <br> Myelosuppression (2%–27%) <br> Headache (9%–22%) |
| Ganciclovir (Cytovene) | 5 mg/kg IV every day; or 1000 mg by mouth three times a day[a] | Stomach upset (13%–40%) <br> Myelosuppression (5%–40%) <br> Rash (10%–15%) |
| Valacyclovir (Valtrex) | 1–2 g by mouth four times a day[a] | Stomach upset (1%–15%) <br> Myelosuppression (< 1%) <br> Headache (14%–35%) |
| CMV hyperimmune globulin (CytoGam) and polyvalent IVIG | The maximum recommended total dosage per infusion is 150 mg/kg beginning within 72 hours of transplantation <br> Follow-up doses and time intervals depend on the type of organ transplanted | Stomach upset (1%–6%) <br> Fevers and chills (1%–6%) <br> Flushing (1%–6%) |

CMV, cytomegalovirus; DS, double-strength (800 mg SMZ, 160 mg TMP); IVIG, intravenous immune globulin; IV, intravenous; M/W/F, Monday, Wednesday, and Friday; SS, single-strength (400 mg SMZ, 80 mg TMP); SMZ, sulfamethoxazole; TMP, trimethoprim.

[a]Dose adjustment required in renal insufficiency.

lung recipients. Sulfamethoxazole-trimethoprim is the preferred agent for prophylaxis. One of its major advantages is its broad spectrum of activity. Not only is it effective against *Pneumocystis*, but it also has activity against *Toxoplasma* and other common bacterial infections. Patients who have sulfa allergies, glucose-6 phosphate dehydrogenase (G6PD) deficiency, or are intolerant of sulfamethoxazole-trimethoprim should be given one of the second-line treatments. Unfortunately, the second-line agents are antiparasitics and have no meaningful activity against common bacteria. These agents include dapsone, atovaquone, and pentamidine.[33]

**Cytomegalovirus** CMV is a concerning opportunistic pathogen in transplantation due to its association with poor outcomes.[34] CMV infection is present in 30% to 97% of the general population, but CMV disease is typically restricted to immunocompromised hosts. The risk of CMV disease is highest among CMV-naive recipients who receive a CMV-positive organ (donor+/recipient–). Other factors that augment the risk of CMV disease include organ type (lung and pancreas recipients are highest risk) and immunosuppressive agents (ALA use increases risk). CMV disease characteristically occurs within the first 3 to 6 months posttransplantation, but delayed onset disease has been seen in patients receiving antiviral prophylaxis. Patients with CMV infection may present with flu-like symptoms, including fever, chills, aches, malaise, and fatigue. CMV infection may result in more profound symptoms in the immunosuppressed patient, including leukopenia, thrombocytopenia, and organ dysfunction.[34]

**KEY CONCEPT** *Several antivirals have proven effective in preventing and treating CMV.*[34] Valacyclovir and valganciclovir, prodrugs of acyclovir and ganciclovir, respectively, have improved bioavailability compared with their parent compounds and offer the advantage of less frequent dosing. CMV prophylaxis is typically continued for the first 200 days, or longer, after transplantation. Although valganciclovir and IV ganciclovir are considered the prophylaxis agents of choice in most organ transplant recipients, national guidelines allow for consideration of prophylaxis with CMV hyperimmune globulin in heart and lung transplant populations. Both IV ganciclovir and oral valganciclovir may be used for preemptive therapy or for treatment of established CMV disease.[34] The adverse events are similar among these agents and include myelosuppression and GI effects.[7]

**Fungal Infections** Fungal infections are an important cause of morbidity and mortality in solid organ transplant recipients.[35] Immunologic (ie, immunosuppressants, CMV infection), anatomic (ie, tissue ischemia and damage), and surgical (ie, duration of surgery, transfusion requirements) factors contribute to the risk for invasive fungal infections. Mucocutaneous candidiasis (ie, oral thrush, esophagitis) is associated with corticosteroids and ALA. **KEY CONCEPT** *Oral nystatin or clotrimazole troches are effective prophylactic options for the prevention of thrush.* However, clotrimazole inhibits the CYP3A system in the gut and can alter immunosuppressive levels.[7] The use of systemic antifungal prophylaxis, such as oral fluconazole, is controversial due to the potential for DDIs and the risk of developing resistance. The American Society of Transplantation has recommended antifungal prophylaxis in liver, lung, intestine, and pancreas transplantation.[36,37] The choice of agents depends on the fungal risk in that particular population. For example, liver, intestine, and pancreas transplant recipients are at high risk for candidiasis; therefore, the use of medications that cover *Candida* spp. is crucial, such as the triazoles (ie, fluconazole, itraconazole) or echinocandins

(ie, caspofungin, micafungin, anidulafungin). Lung transplant recipients are at high risk for aspergillosis; therefore, it is imperative to use antifungal prophylaxis that covers *Aspergillus* spp., such as the echinocandins, polyenes (ie, amphotericin B, lipid-based amphotericin B products) or new generation triazoles (ie, voriconazole, posaconazole).[36,37]

**Polyomavirus** One infection complication seen only in renal transplant recipients is polyomavirus. In humans, there are two known pathologic polyoma strains, BK and JC. These viruses are rarely associated with disease in immunocompetent individuals. During periods of immunosuppression, the virus is reactivated and can be associated with significant morbidity.[38]

In renal transplant recipients, the major diseases caused by BK virus (BKV) are tubulointerstitial nephritis and ureteral stenosis.[38] Polyomavirus-associated nephropathy (PyVAN) presents with evidence of allograft dysfunction, resulting in either an asymptomatic acute or slowly progressive rise in serum creatinine concentrations. Some studies have reported that PyVAN may affect up to 10% of renal transplant recipients, frequently resulting in permanent renal dysfunction or allograft loss.[38]

Currently, treatment options for BKV are limited, and management recommendations are generally focused on reductions in immunosuppression. There is a lack of a directed antiviral intervention; however, some centers have utilized IVIG, cidofovir, leflunomide, and the fluoroquinolone antibiotics to manage BKV infections. All of these agents have been reported to provide some benefit in managing BKV in anecdotal cases.[38]

**Vaccination** Vaccination is one of the most effective means of preventing infection and related complications.[39] However, there is a valid concern that solid organ transplant recipients may mount an inadequate response to vaccination due to immunosuppression. Required vaccinations should be administered prior to transplantation so that an appropriate antibody response can develop (Table 55–7).[39] If this strategy is pursued, the earlier a vaccine is administered, the more effective it may be, as end-stage organ failure can also contribute to a decreased immune response.[39]

In general, the weakest response to vaccine is within the first 6 months posttransplantation due to the intense level of immunosuppression during this period.[39] Vaccination within 6 months of transplant may be considered on a case-by-case basis in those patients who are at high risk of developing infection. Use of inactive vaccines is preferred in transplant recipients due to the relative risk of infection associated with live vaccines. Health care workers and family members who are in close contact with transplant recipients and have received a live vaccine should consider use of respiratory masks for at least 7 days after vaccination and adhere to strict oral and hand hygiene.[39]

### ▶ Hypertension

**KEY CONCEPT** *Cardiovascular disease has been identified as the leading cause of death in organ transplant recipients.*[40] Posttransplant hypertension is associated with increased cardiac morbidity and patient mortality in transplant patients and is also an independent risk factor for allograft dysfunction. Based on all of the available posttransplant morbidity and mortality data, it is imperative that posttransplant hypertension be identified and managed appropriately.[40]

There are several mechanisms responsible for posttransplant hypertension including renal dysfunction, increased sensitivity to endothelin-1 and angiotensin, increased density of glucocorticoid receptors in the vascular smooth muscle, and decreased

## Table 55–7

**Recommended Vaccinations Pre- and Posttransplant[39]**

| Vaccine | Before SOT | After SOT | Additional Information |
|---|---|---|---|
| Hepatitis A | X | | Immunize as soon as possible during course of disease |
| Hepatitis B | X | | Immunize as soon as possible during course of disease (before transplant, administer 40 mcg dose in a series of three to four doses) |
| Herpes Zoster | X | | Live[a] virus, administer ≥ 14 days before immunosuppressant agents are initiated (experts advise 1 month before) |
| Human Papilloma Virus | X | | Recommended for females aged 9–26, no recommendations for SOT |
| Influenza | X | X | Annual vaccination with inactivated intramuscular formulation recommended before and after SOT |
| Measles-Rubella | X | | Live[a] virus, administer to patients who are seronegative, *before* transplant, or in women of childbearing age for prevention of congenital rubella syndrome |
| Pneumococcal | X | X | 23-valent polysaccharide vaccine should be given once before transplant and boosters at 3 and 5 years after initial dose |
| Tetanus/Diptheria | X | | TDaP booster indicated for < 65 years old (may be given ≤ 2 years after last TDaP booster in SOT patients) |
| Varicella | X | | Live[a] virus, administer to patients who are seronegative, *before* transplant |

TDaP, tetanus, diphtheria, and pertussis.

[a]All live vaccines are contraindicated post solid organ transplant (SOT), as they can cause serious infection.

Live vaccines:

Bacillus Calmette-Guerin

Herpes zoster

Live intranasal attenuated influenza

Live oral typhoid

Measles-rubella

Vaccinia (smallpox)

Varicella

production of vasodilatory prostaglandins.[40] However, one of the most easily recognized causes of posttransplant hypertension is the use of corticosteroids and CNIs. Corticosteroids cause sodium and water retention, thus increasing blood pressure, whereas CNIs reduce glomerular filtration rate and renal blood flow, increase systemic and intrarenal vascular resistance, promote sodium retention, reduce concentrations of systemic vasodilators (ie, prostacyclin, nitric oxide), and increase concentrations of thromboxanes. Compared with cyclosporine, tacrolimus displays significantly less severe hypertension, and patients taking tacrolimus require significantly fewer antihypertensive medications after transplant.[40]

**Treatment** KEY CONCEPT *Controlling hypertension after transplant is essential in preventing cardiac morbidity and mortality and prolonging graft survival.* The target blood pressure in transplant recipients should be less than 130/80 mm Hg.[40] This goal blood pressure may not be suitable for all patients. Note: national guidelines for treating hypertension in the general population are often followed, despite their lack of transplant recommendations. Refer to Chapter 5, *Hypertension*, for additional information.

**Lifestyle Modifications** To achieve a goal blood pressure, lifestyle modifications including diet, exercise, sodium restriction, and smoking cessation are recommended.[40] Unfortunately, lifestyle modifications alone are often inadequate in high-risk populations, and antihypertensive medications are usually initiated early after transplant.[40]

**Immunosuppressive Regimen Modification** Because tacrolimus has shown the propensity to cause less severe hypertension compared to cyclosporine, conversion from cyclosporine-based immunosuppression to tacrolimus-based immunosuppression may be one way to reduce the severity of hypertension in transplant recipients. KEY CONCEPT *Conversion to a ToR inhibitor or belatacept, which are not associated with hypertension, may also be an alternative to the CNIs in patients with difficult-to-treat hypertension.* Corticosteroid taper or withdrawal are effective strategies for lowering blood pressure, but are not warranted in all clinical situations.[40]

**Antihypertensive Agents** There is no single class of antihypertensive medications recognized as the ideal agent. Numerous factors must be considered when determining appropriate treatment for a patient, including the safety and efficacy data of

**Patient Encounter Part 3**

*Identify your treatment goals for the patient in terms of antimicrobial prophylaxis.*

*Create a plan for her antimicrobial prophylaxis, making sure to compare and contrast the pros and cons of the different agents in this patient.*

available agents, patient-specific comorbidities, and medication cost.[40] A large majority of patients often require multiple medications to achieve goal blood pressure, and combination therapy is regarded as an appropriate first-line therapy.[40]

β-Blockers and thiazide diuretics have proven benefits in reducing cardiovascular disease–associated morbidity and mortality.[40] Tolerability permitting, these agents are to be considered first-line therapies in most transplant recipients. The angiotensin-converting enzyme (ACE) inhibitors and angiotensin receptor blockers (ARB) have definite benefits in patients with nephropathy and are believed to have renoprotective effects in most patients. However, due to their ability to cause an initial increase in serum creatinine, these agents should be used cautiously when combined with the CNIs. The dihydropyridine calcium channel blockers have demonstrated an ability to reverse nephrotoxicity associated with cyclosporine and tacrolimus. The addition of diltiazem to patients' regimens after cardiac transplant has also been shown to retard progression of cardiac allograft vasculopathy. In general, antihypertensive therapy should focus on agents with proven benefits in reducing the progression of cardiovascular disease and must be tailored to a patient's needs.[40]

### ▶ Hyperlipidemia

**KEY CONCEPT** *Hyperlipidemia is seen in as high as 60% of transplant patients.*[41] As a result of elevated cholesterol levels, transplant recipients are not only at increased risk of atherosclerotic events, but also allograft vasculopathy. Hyperlipidemia, along with other types of cardiovascular disease, is now one of the primary causes of morbidity and mortality in long-term transplant survivors.[41]

Elevated cholesterol levels in transplant patients are due to age, genetic disposition, renal dysfunction, DM, proteinuria, body weight, and immunosuppressive therapy. Many of the immunosuppressive agents can produce elevations in serum lipid levels.[41]

**Treatment** **KEY CONCEPT** *Lowering cholesterol has shown to significantly decrease severe rejection and transplant vasculopathy and improve 1-year survival in heart transplant recipients.*[42] Although these results cannot be extrapolated to other transplant populations, they do demonstrate the potential benefits of aggressive cholesterol lowering in organ transplant recipients. Due to high prevalence of cardiovascular disease among organ transplant recipients, most practitioners consider these patients to be high risk for lipid lowering. Many guidelines state a target calculated low-density lipoprotein cholesterol (LDL-C) level of less than 100 mg/dL (2.59 mmol/L) in high-risk patients.[41] Note: national guidelines for treating hyperlipidemia in the general population are often followed, despite their lack of transplant recommendations. Refer to Chapter 12, *Dyslipidemias*, for additional information.

**Lifestyle Modifications** Generally, lowering cholesterol in patients begins with therapeutic lifestyle changes. These changes are initiated either alone or in conjunction with lipid-lowering drug therapy, depending on baseline cholesterol levels and other risk factors. Therapeutic lifestyle changes entail a reduction in saturated fat and cholesterol intake and an increase in moderate physical activity.[43] As with hypertension, lifestyle modifications alone rarely allow a patient to achieve a goal LDL-C level. Modification of the immunosuppressive regimen and use of cholesterol-lowering medications are often warranted in this population.[41]

**Immunosuppressive Regimen Modifications** Tacrolimus has shown the propensity to cause less severe hyperlipidemia when compared with cyclosporine. Conversion from

cyclosporine-based immunosuppression to tacrolimus-based immunosuppression may be one way to counteract this disease in transplant recipients. Also, the ToR inhibitors have been associated with significant changes in lipids and triglycerides; therefore, conversion from a ToR inhibitor to a CNI or belatacept may be warranted in patients receiving ToR inhibitor therapy with resistant dyslipidemia.[41]

In past studies, steroid withdrawal in renal transplant patients did demonstrate moderate reductions in total cholesterol and LDL cholesterol; unfortunately, a decrease in high-density lipoprotein (HDL) levels were also noted.[41]

**Cholesterol-Lowering Agents** 3-Hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase inhibitors, or statins, are considered first-line therapy for hyperlipidemia in the general population.[41] However, there is some uncertainty about the pathogenesis of cardiovascular disease in transplant recipients and whether statin therapy will have similar effectiveness in organ transplant recipients. Statins have shown definite advantages when used in heart transplantation, including a reduction in LDL-C and major adverse cardiac events (MACE), as well as an apparent cardioprotective effect. In renal transplant recipients, statins lower LDL-C levels and reduce the incidence of some cardiac events; however, the ability to lower MACE has not been seen in this population. Despite these mixed results, statins are still considered the primary therapeutic option for hyperlipidemia in organ transplant recipients.[41] When choosing a statin for management of hyperlipidemia in the transplant patient, a focus on potential DDIs is warranted. It is recommended that doses of atorvastatin not exceed 10 mg daily when taken with cyclosporine due to an increased risk of myopathy and rhabdomyolysis. Use of cyclosporine in conjunction with simvastatin is considered a contraindication due to the risk of skeletal muscle effects.[41]

Fibric acid derivatives are an excellent choice for lowering triglycerides, but are not as effective as statins at lowering LDL-C.[41] These agents play a role in conjunction with statins in patients with both elevated cholesterol and triglycerides. Nicotinic acid is very effective at improving the lipid panel, with excellent results in lowering LDL-C, as well as increasing HDL. However, patient tolerability is a concern with this agent. The bile acid sequestrants should be avoided in transplant recipients due to their high incidence of GI adverse events, as well as their propensity for pharmacokinetic DDIs with MPA. Ezetimibe has proven safe and effective in lowering LDL-C in renal transplant recipients. Future studies are needed to establish ideal regimens involving the antihyperlipidemic and immunosuppressive medications to decrease morbidity and mortality and ultimately prevent cardiovascular events.[41]

### ▶ New-Onset DM After Transplantation

**KEY CONCEPT** *New-onset DM after transplantation (NODAT) is a serious complication that is often underestimated by transplant practitioners.*[44] Kasiske and colleagues attempted to quantify the cumulative incidence of NODAT in renal transplant recipients and found that 8.3% of patients developed NODAT at 3 months posttransplant, 12.9% at 12 months, and 22.3% at 36 months.[45] Even more alarming is that recent studies have revealed an overwhelming prevalence of impaired glucose tolerance, which is also accepted as a risk factor for long-term morbidity and mortality. NODAT is associated with a 22% higher risk of mortality. Patients with NODAT are also more likely to suffer acute rejection episodes and infectious complications than patients without NODAT.[44]

● **Prevention** KEY CONCEPT *NODAT prevention mainly consists of identifying patients at risk before transplant and controlling modifiable risk factors both before and after transplantation.*[44] The major modifiable risk factors are choice of immunosuppressive therapy and body mass index (BMI). For example:

- Immunosuppressive medications: Steroid minimization and possibly withdrawal are effective strategies for preventing NODAT. Also, patients with worsening blood glucose who are receiving tacrolimus may benefit from conversion to cyclosporine or belatacept.[44]

- Body mass index: A reduction in body weight is recommended in obese patients prior to transplant to lower their NODAT risks.[44]

● **Treatment** KEY CONCEPT *Lifestyle modifications are recommended in patients who have developed or those who are at increased risk of developing NODAT.*[44] Insulin therapy and oral hypoglycemic agents are often utilized in those patients in whom lifestyle modifications alone have not controlled blood glucose. Please refer to Chapter 43, *Diabetes Mellitus*, for proper instruction on choosing the appropriate treatment regimens in patients with DM.

▶ *Neoplasia*

● **Cancer Screening in Transplant Patients**  Transplant recipients are at increased risk for malignancies (Table 55–8).[46,48] The risk of developing Kaposi sarcoma following transplantation is over 200 times that in the general population. In addition, the risk of nonmelanocytic and melanocytic skin cancer is 10 to 20 times higher compared with the nontransplanted population. Transplant recipients are at greatest risk for the types of cancers associated with viral infections, such as PTLD, cervical, and vulvovaginal cancers. Solid organ tumors like colorectal and lung cancers are two to three times higher in transplant recipients when compared with the general population. The American Cancer Society and American Transplant Society recommend cancer screening for most adults who have undergone transplantation (Table 55–9).[46,48] Although clinical research has not yet proven that potential benefits of testing outweigh the harms of testing in transplant recipients, most believe that transplant recipients should be tested and screened very closely.[46]

### Table 55–8

**Overall Risk of Different Types of Cancer in Transplant Patients**[46,48]

| Cancer | Cumulative Incidence (/100,000) | Male | Female |
| --- | --- | --- | --- |
| Kaposi sarcoma | 140 | 17.4 | 62 |
| Kidney/ureter | 1010 | 14.1 | 14.6 |
| Lymphoma | 80 | 6.9 | 29.1 |
| Bladder | 126 | 1.6 | 3.6 |
| Esophagus | 70 | 2.4 | 2.8 |
| Cervix | 180 | – | 5.7 |
| Liver | 220 | 4.2 | 4.5 |
| Melanoma | 320 | 6.9 | 5.2 |
| Lung/bronchus/ trachea | 690 | 2.3 | 3.6 |
| Colorectal | 510 | 1.6 | 2.8 |
| Breast | 1050 | 4 | 1.1 |
| Prostate | 1740 | 1.6 | – |

● **Skin Cancer**  Skin cancer remains the most common malignancy after transplantation. The incidence of these types of cancers increases with time posttransplant, with one study showing a prevalence rate of 35% among patients within 10 years after transplant. Also, skin cancers in transplant recipients tend to grow more rapidly and are more likely to metastasize.[46]

The most common risk factors for skin cancer development after transplant include increased age; excessive ultraviolet (UV) light exposure; high degree of immunosuppression; Fitzpatrick skin types I, II, and III; history of skin cancers; and infection by human papillomavirus.[46] KEY CONCEPT *Many believe that ToR inhibitors in place of CNIs in transplant recipients can reduce the risk of nonmelanoma skin carcinomas.*[47]

Transplant practitioners must be vigilant about educating their patients about excessive exposure to the sun.[46] Patients should be warned about the risk of skin cancer and be advised on simple methods to limit risk:

- Wear protective clothing (ie, long-sleeved shirts, pants, dark-colored clothing)

- Use of sunscreen, sun protection factor (SPF) 30 or higher, daily to all sun-exposed skin

▶ *Posttransplant Lymphoproliferative Disorders*

KEY CONCEPT *PTLDs are a major complication following organ transplantation.*[46] Large series of case reports have demonstrated the incidence of PTLD is 1% for renal patients, 1.8% for cardiac patients, 2.2% for liver patients, and 9.4% for heart–lung patients. The risk of developing non-Hodgkin lymphoma is nearly 50-fold higher in organ transplant recipients compared with the general population. Another risk factor is the presence of EBV. Lymphomas are the most common form of PTLD.[46,48]

The incidence of disease depends on certain factors that include the type of organ transplanted, age of the transplant recipient, type and degree of immunosuppression, and exposure to EBV. The mortality rate in these patients is 50%, with most patients dying shortly after diagnosis. It has also been demonstrated that the risk of developing PTLD is greater in EBV seronegative patients.[46,48] Belatacept has been approved with a black box warning outlining an increased risk of PTLD, especially of the CNS. Patients who are EBV seronegative or have an unknown immunity to EBV should not receive belatacept. Also, immunosuppressive regimens utilizing the ALAs have been proven to increase the risk of PTLD.[46,48]

● **Treatment** KEY CONCEPT *Treatment for PTLD is still controversial; however, the most common treatment options include reduction of immunosuppression, chemotherapy, and anti–B cell monoclonal antibodies.*[46,48] PTLD continues to be a long-term complication of prolonged immunosuppression. Current treatment options are all associated with certain risks. Prevention is the most effective treatment for PTLD. A better understanding of the disease process and the risk factors involved with the development of PTLD will aid in the prophylaxis and treatment of this disorder.[46,48]

▶ *Pregnancy*

Females of childbearing age who do not wish to become pregnant after transplantation require adequate education on preferred forms of birth control.[49] The optimal method of birth control in this patient population is the barrier method (eg condom, diaphragm). Use of intrauterine devices and progestin-based oral contraceptives are controversial, and associated risks must be considered prior to initiating therapy. Intrauterine devices may be less effective in the setting of immunosuppression and

| Table 55–9 | | |
|---|---|---|
| **Cancer Screening Recommendations in Transplant Patients**[46,48] | | |
| **Cancer Type** | **General Populations** | **Transplant Populations** |
| Breast | Mammography every 1–2 years for all women ≥ 50 years old. Clinical breast exam every 3 years in women 20–39 years old, yearly after age 40. Monthly self-exam. | Mammography every 1–2 years for all women ≥ 50 years old. May undergo screening between 40 and 49 years old but no evidence for or against screening in this age group. |
| Cervical | Annual Pap smear and pelvic exam once sexually active; after three or more tests with normal results, may decrease frequency of exams. | Annual Pap smear and pelvic exam once sexually active. |
| Colorectal | Annual FOBT plus flexible sigmoidoscopy every 5 years for all patients ≥ 50 years old or colonoscopy and DRE every 10 years. | Annual FOBT plus flexible sigmoidoscopy every 5 years for all transplant patients ≥ 50 years old. |
| Prostate | Annual DRE and PSA for men ≥ 50 years old with 10-year life expectancy or younger men at high risk. | Annual DRE and PSA measurement in all males ≥ 50 years old. |
| Hepatocellular | Not recommended for average-risk individuals. α-Fetoprotein and ultrasound every 6 months in high-risk patients (no firm supporting data). | α-Fetoprotein and ultrasound every 6 months in high-risk patients (no firm supporting data). |
| Skin | Skin exam every 3 years between ages 20 and 40, annually thereafter. | Monthly self-exam. Total body skin exam every 6–12 months by dermatologists. |
| Renal | Insufficient evidence to support routine screening. | No firm recommendations. Regular ultrasound of native kidneys. |
| Lung | Insufficient evidence to support routine screening. | No firm recommendations. |
| Ovarian | Insufficient evidence to support routine screening. | No firm recommendations. |
| Testicular | Insufficient evidence to support routine screening. | No firm recommendations. |
| Endometrial | Insufficient evidence to support routine screening. | No firm recommendations |

DRE, digital rectal exam; FOBT, fecal occult blood test; PSA, prostate-specific antigen.

predispose patients to an increased risk of infection. Progestin-based contraceptives are considered a less effective form of birth control, but may be a safe option in those patients without hypertension.[49]

Female patients considering pregnancy after transplantation should be educated extensively regarding the potential impact of pregnancy on renal function and the risks that transplantation and medical immunosuppression may present to a fetus.[49] Risks to the infant include premature birth (50%) and intrauterine growth restriction (20%), which may result in death or long-term complications, including cerebral palsy, blindness, deafness, and learning deficiencies. Patients hoping to become pregnant should wait at least 1 year after transplantation to ensure reconstitution of gonadal function posttransplant, as well as demonstrate a 1-year freedom from acute rejection.[49]

Understanding the associated risk of immunosuppressives while pregnant is paramount considering their ability to cross the placenta as well as enter breast milk.[49] Tacrolimus and cyclosporine, both Pregnancy Category C, are the backbone of immunosuppressive therapy and have been used safely and effectively in pregnancy posttransplant for decades. Side effects associated with CNIs such as hypertension, diabetes, and nephrotoxicity should be monitored closely in the pregnant population. The ToR inhibitors are also Pregnancy Category C and have not been associated with fetal malformation but should be used cautiously in pregnant patients. Corticosteroids, pregnancy category B, are recognized to be relatively safe and have been used extensively in pregnancy after transplantation. However, they carry a risk of premature membrane rupture and newborn adrenal insufficiency. More common side effects associated with corticosteroids that may cause complications in pregnancy include hypertension, diabetes, weight gain, and poor wound healing. Due to teratogenic effects in animal studies, azathioprine is considered Pregnancy Category D; however, it has been used extensively as an antimetabolite in pregnant transplant patients without extensive evidence of harm to the fetus. 6-Mercaptopurine has not been shown to cross the placental barrier.[49]

Currently, the MPA derivatives, both Pregnancy Category D, are not considered optimal immunosuppressive agents for patients who become pregnant, and alternative therapies should be pursued.[49] These agents have a FDA-approved risk evaluation and minimization strategy to help minimize fetal exposure to MPA, prevent unplanned pregnancies in patients using MPA, collect data on MPA use in pregnancy via the Mycophenolate Pregnancy Registry, and educate patients about the risks associated with the use of this medication. A less teratogenic antimetabolite, azathioprine, should be substituted for mycophenolate mofetil or enteric-coated MPA in patients who plan on becoming pregnant. The safety of ALAs and rituximab in transplantation has yet to be fully determined; however, IVIG has been widely used without any documented adverse events. Newly available immunosuppressives, belatacept and everolimus, are pregnancy category C but are not recommended for use in pregnant patients due to inadequate human data.[49]

▶ *Immunosuppressant Therapy Adherence*

Transplant recipients require strict adherence to their medication regimens to ensure optimal outcomes. Nonadherence

## Patient Encounter Part 4

The patient continues to have her posttransplant care at your renal transplant ambulatory care clinic. She returns to your clinic 1 month after the transplant:

**Labs:** Na 147 mEq/L (147 mmol/L); K 4.5 mEq/L (4.5 mmol/L); Cl 198 mEq/L (198 mmol/L); $CO_2$ 21 mEq/L (21 mmol/L); BUN 18 mg/dL (6.4 mmol/L); SCr 0.8 mg/dL (71 μmol/L); glucose 198 mg/dL (11.0 mmol/L); lipid panel: TC = 301 mg/dL (7.78 mmol/L), direct LDL = 147 mg/dL (3.80 mmol/L), HDL = 47 mg/dL (1.22 mmol/L), TG = 522 mg/dL (5.90 mmol/L); uric acid 9.6 mg/dL (571 μmol/L); tacrolimus 9.7 ng/mL (9.7 mcg/L or 12.0 nmol/L)

**VS:** BP 155/90 mm Hg (158/88 mm Hg repeated using manual method), HR 80 beats/min

**Meds:** Tacrolimus XL 10 mg by mouth once a day; mycophenolate mofetil 1000 mg by mouth twice a day;

prednisone—no longer taking as it was completely withdrawn on postoperative day 11; atovaquone 1500 mg by mouth once a day; valganciclovir 900 mg by mouth once a day; atorvastatin 20 mg by mouth once a day; metoprolol XL 100 mg by mouth once a day; amlodipine 5 mg by mouth once a day; zolpidem 10 mg by mouth once a day at bedtime as needed; insulin glargine 32 units administered in the evening; insulin aspart 8 units with each meal and a sliding scale (dependent on blood sugars)

*Identify why the patient is taking each agent listed.*

*What are some treatment options for her elevated blood pressure?*

*What are some treatment options for her elevated cholesterol?*

*What are some treatment options for her elevated uric acid?*

*Design a monitoring plan for the patient's therapy.*

## Patient Care Process

**Early Management of Transplant Recipients**
**Patient Assessment:**

- Review all available diagnostic and laboratory data, and patient history and comorbidities to evaluate patient as a transplant recipient.

**Therapy Evaluation:**

- Evaluate medications currently being used by patient that will be continued posttransplant such as drugs to treat concomitant disease states (eg, hypertension, DM, dyslipidemia).
- For medications that are likely to be continued posttransplant, assess efficacy, safety, and patient adherence. Are there any significant drug interactions?

**Care Plan Development:**

- Propose an immunosuppressive regimen following transplantation, including:
  - Induction therapy (see Table 55–2):
    - Based on the type of organ being transplanted, recipient's history and donor characteristics, determine if the patient requires induction therapy.
    - If you decide to use induction therapy, assess for appropriate drug choice, dose, and duration of therapy.
  - Maintenance immunosuppressive agents (see Tables 55–2, 55–3, 55–4, and 55–5, and Figure 55–2):
    - Assess for appropriate choice, dose, and duration of therapy.
- Antimicrobial prophylaxis (see Table 55–6):
  - Assess suitability of chosen prophylactic agents (eg, drug allergies, CMV donor and recipient serostatus, need for antifungal prophylaxis).

- Medications used for comorbidities:
  - Assess appropriate selection of these medications for pharmacokinetic and pharmacodynamic DDIs, need, efficacy, and side effects.
- Determine if patient has insurance coverage and what agents are on formulary.
- Develop patient-specific short-term and long-term therapeutic goals.
- Provide patient education regarding the organ transplant, complications associated with transplantation, need for lifestyle modifications to reduce risk of complications (eg, wear sunscreen, low-sodium diet), and drug therapy (including importance of adherence to therapeutic regimen and insurance/payer information).
- Assess the need for therapeutic drug monitoring of any of the immunosuppressants.
- General therapeutic monitoring parameters based on organ transplanted and toxic monitoring parameters for medications prescribed.
- Continually evaluate the patient for presence of adverse drug reactions, drug allergies, or DDIs.

**Follow-Up Evaluation (Outpatient Transplant Clinic):**

- Obtain a thorough history of prescription, nonprescription, and complementary and alternative medication use.
- Monitor the patient's maintenance immunosuppression.
  - Assess for appropriate dose and duration of therapy.
- Assess for new or worsening disease states such as hypertension, DM, or dyslipidemia.
- Antimicrobial prophylaxis:
  - Does the patient need continued prophylaxis therapy?
  - When do you stop prophylaxis?

*(Continued)*

- Medications used for comorbidities:
  - Assess appropriate selection of these medications for pharmacokinetic and pharmacodynamic DDIs, need, and efficacy.
  - Assess whether new medications are needed for existing comorbidities or new diagnoses.
- Reassess your patient-specific short-term and long-term therapeutic goals.

- Continue with patient education in regard to the complications associated with transplantation, the need for lifestyle modifications to reduce risk of complications (eg, wear sunscreen, low-sodium diet), and drug therapy.
- Reemphasize the importance of adherence with therapeutic regimen.
- Assess improvement in quality-of-life measures such as physical, psychological, and social functioning, and well-being.

---

in this population can be attributed to the complexity of the regimens coupled with the variability in drug dosing, need for therapeutic drug monitoring, avoidance of potential DDIs, infectious risks, and drug toxicities. The incidence of nonadherence to immunosuppressant therapy in the first year posttransplant has been estimated to be as high as 23%.[50] This is especially alarming when one considers that 35% of all graft failures can be directly attributed to nonadherence. Risk factors associated with immunosuppressant therapy nonadherence include a history of substance abuse, personality disorders, and lack of social support. The role of the pharmacist in educating patients on the importance of their medication regimens and stressing the need for adherence is paramount in optimizing both patient and allograft survival after transplantation. Previous reports have suggested that intervention by a pharmacist posttransplant improves adherence.[50]

## OUTCOME EVALUATION

- Successful outcomes in solid organ transplantation are generally measured in terms of several separate end points: (a) preventing rejection, (b) preventing immunosuppressive drug complications, and (c) improving long-term survival.
- The short-term goals revolve around reducing the incidence of acute rejection episodes and attaining a high graft survival rate. By accomplishing these goals, transplant clinicians hope to attain good allograft function to allow for an improved quality of life. These goals can be achieved through the appropriate use of medical immunosuppression and scrutinizing over the therapeutic and toxic monitoring parameters associated with each medication employed. In addition, transplant recipients should be monitored for adverse drug reactions, DDIs, and adherence with their therapeutic regimen.
- The long-term goals after organ transplant are to maximize the functionality of the allograft and prevent the complications of immunosuppression, which lead to improved patient survival. Clinicians must play multiple roles in the long-term care of transplant recipients, as not only must the patient be followed from an immunologic perspective, but practitioners must be focused on identifying and treating the adverse sequelae associated with lifelong immunosuppression including cardiovascular disease, malignancy, infection, and osteoporosis, among others. Again, limiting drug misadventures and ensuring adherence with the therapeutic regimen are important and should be stressed.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| 6-MP | 6-Mercaptopurine |
| ACE | Angiotensin-converting enzyme |
| ALA | Antilymphocyte antibodies |
| AMR | Antibody-mediated rejection |
| APC | Antigen-presenting cell |
| ARB | Angiotensin receptor blocker |
| ATG | Antithymocyte globulin |
| AUC | Area under the curve |
| AZA | Azathioprine |
| BKV | BK virus |
| BMI | Body mass index |
| BUN | Blood urea nitrogen |
| $C_0$ | Trough concentration |
| $C_2$ | Drug concentration 2 hours postdose |
| CCB | Calcium channel blocker |
| CD4+ | Helper T cells |
| CD8+ | Cytotoxic T cells |
| CKD | Chronic kidney disease |
| CMV | Cytomegalovirus |
| CNI | Calcineurin inhibitor |

# 56 Osteoporosis

Beth Bryles Phillips and Princy A. Pathickal

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Explain the association between osteoporosis and morbidity and mortality.
2. Identify risk factors that predispose patients to osteoporosis.
3. Describe the pathogenesis of fractures.
4. List the criteria for diagnosis of osteoporosis.
5. Recommend appropriate lifestyle modifications to prevent bone loss.
6. Compare and contrast the effect of available treatment options on reduction of fracture risk.
7. Recommend an appropriate treatment regimen for a patient with osteoporosis and develop a monitoring plan for the selected regimen.
8. Educate patients on osteoporosis and drug treatment, including appropriate use, administration, and adverse effects.

## INTRODUCTION

Osteoporosis is a common and often silent disorder causing significant morbidity and mortality and reduced quality of life. It is characterized by low bone density and loss of strength in bone tissue resulting in an increased risk and rate of bone fracture. Osteoporosis is responsible for more than 2 million fractures in the United States annually. Almost 10 million Americans have osteoporosis, and an additional 43 million are classified as having low bone density.[1,2] The cost of care is expected to rise to $25.3 billion by 2025. It is estimated that postmenopausal white women have a 50% lifetime chance of developing an osteoporosis-related fracture, whereas men have a 20% lifetime chance.[1] Common sites of fracture include the spine, hip, and wrist, although almost all sites can be affected.

The fractures associated with osteoporosis have an enormous impact on individual patients, not only causing initial pain, but also chronic pain, loss of mobility, depression, nursing home placement, and death. Patients with vertebral fractures may also experience height loss, kyphosis, and decreased mobility due to limitations in bending and reaching. These patients are also at greater risk of having a future vertebral fracture. Multiple vertebral fractures may lead to restrictive lung disease and altered abdominal anatomy, while patients with hip fractures have added risks associated with surgical intervention to repair the fracture. More than 50% of patients never fully recover or regain preinjury independence. Death is common in the year after a hip fracture.[1]

## EPIDEMIOLOGY AND ETIOLOGY

Osteoporosis is the most common skeletal disorder, but only one in three patients with osteoporosis are diagnosed, and only one in seven receives treatment.[2] Osteoporosis can be classified as either primary (no known cause) or secondary (caused by drugs or other diseases). Primary osteoporosis is most often found in postmenopausal women and aging men, but it can occur in other age groups as well.[1,2]

The prevalence of osteoporosis varies by age, gender, and race/ethnicity and increases exponentially after age 50.[3] Most hip fractures occur in postmenopausal white women, who also have the highest incidence of fracture when adjusted for age. The frequency of fracture in African American and Hispanic women trail far behind that of Caucasians, although hip fracture-related mortality may be higher.[4] Although both men and women lose bone as they age, postmenopausal women have accelerated bone loss due to loss of estrogen. Men have some protection from osteoporosis due to their larger initial bone mass and size and lack of accelerated bone loss associated with menopause.[5] Secondary causes of osteoporosis, such as hypogonadism, are found more commonly in men with fragility fractures.[5]

## PATHOPHYSIOLOGY

The human skeleton contains both cortical and trabecular bone. Cortical bone comprises approximately 80% of the skeleton, and its density and compactness account for much of bone strength. It is generally found on the surfaces of long and flat bones. Trabecular (or cancellous) bone has a sponge-like appearance and is found along the inner surfaces of long bones and throughout the vertebrae, pelvis, and ribs.

Under normal circumstances, the skeleton undergoes a dynamic process of bone remodeling, responding to stress and injury through continuous replacement and repair. This process is completed by the basic multicellular unit, including both osteoblasts and osteoclasts. Osteoclasts are involved
**FIGURE 56–1.** Normal trabecular bone (left) compared with trabecular bone from a patient with osteoporosis (right). The loss of mass in osteoporosis leaves bones more susceptible to breakage. From Barnett KE, Barman SM, Boitano S. Brooks H. Ganong's Review of Medical Physiology, 24th ed. New York: McGraw-Hill; 2012: Figure 21–11; With permission. http://www.accesspharmacy.com.

with **resorption** or breakdown of bone and continuously create microscopic cavities in bone tissue. Osteoblasts are involved in bone formation and continuously mineralize new bone in the cavities created by osteoclasts. Until peak bone mass is achieved between the ages of 25 and 35, bone formation exceeds bone resorption for an overall increase in bone mass. Trabecular bone is more susceptible to bone remodeling, and therefore osteoporotic fractures, in part due to its larger surface area. **Figure 56–1** illustrates the difference between normal and osteoporotic bone.

In osteoporosis, an imbalance in bone remodeling occurs. Most commonly, osteoclastic activity is enhanced, resulting in overall bone loss. However, a reduction in osteoblastic activity and bone formation also occurs in certain types of osteoporosis. Due to a decrease in endogenous estrogen, bone remodeling accelerates during menopause, and up to 15% of bone is lost during the first 5 years postmenopause. After this initial decline, bone loss continues to occur at a slower rate of up to 1% per year. The resultant bone loss and change in bone quality predispose patients to low-impact or **fragility fractures**.

## CLINICAL PRESENTATION AND DIAGNOSIS

See accompanying text box for the clinical presentation of osteoporosis.

### Clinical Presentation of Osteoporosis

**General**

Many patients with osteoporosis are asymptomatic unless they experience a fragility fracture.

**Symptoms of Fragility Fracture**

Pain at the site of the fracture or immobility.

**Signs**

Height loss (greater than 2 cm), spinal kyphosis ("dowager's hump"), fragility fracture especially of the hip or spine.

### Table 56–1

**Risk Factors for Osteoporosis and Osteoporotic Fractures[1,2]**

| Risk Factors for Osteoporosis | Risk Factors for Falling and Fractures |
|---|---|
| Low bone mineral density[a] | Poor health/frailty |
| Female sex[a] | Impaired gait or balance |
| Advanced age[a] | Recent falls |
| Race/ethnicity[a] | Cognitive impairment |
| History of previous low trauma (fragility) fracture as an adult[a] | Impaired vision |
| Osteoporotic fracture in a first-degree relative (especially parental hip fracture[a]) | Environmental factors (eg, stairs, throw rugs, pets, poor lighting) |
| Low body weight or body mass index[a] | |
| Premature menopause (before 45 years old)[b] | |
| Secondary osteoporosis[b] (especially rheumatoid arthritis[a]) | |
| Past or present systemic oral glucocorticoid therapy[a] | |
| Current cigarette smoking[a] | |
| Alcohol intake of three or more drinks per day[a] | |
| Low calcium intake | |
| Low physical activity | |
| Minimal sun exposure | |

[a]Major risk factors used in the World Health Organization (WHO) fracture risk model.

[b]Secondary causes included in the FRAX tool question are type 1 diabetes, osteogenesis imperfecta as an adult, longstanding untreated hyperthyroidism, hypogonadism, premature menopause (before 45 years of age), chronic malnutrition, malabsorption, and chronic liver disease.

Adapted from DiPiro JT et al., eds. Pharmacotherapy: A Pathophysiologic Approach. 9th ed. New York: McGraw-Hill; 2014: Table 73–1; With permission.

**KEY CONCEPT** *The National Osteoporosis Foundation (NOF) recommends evaluating all postmenopausal women and men older than 50 years for osteoporosis risk and need for further diagnostic assessment.* Many risk factors for osteoporosis and osteoporotic fractures are predictors of low bone mineral density (BMD), such as age and ethnicity (**Table 56–1**). The risk for osteoporosis generally increases as the number of risk factors increases, and the risk of fractures increases as BMD decreases. However, the threshold at which individual patients develop a fracture varies, and other factors, such as fall risk, may play a role in fracture susceptibility. For this reason, fall history and evaluation of risk factors for falling should also be included in the initial evaluation. Because osteoporosis is commonly caused by secondary factors (**Table 56–2**), medical history, medication history, and laboratory values should be evaluated to determine if further work-up is needed.

### Diagnostic Assessment

The diagnostic assessment for osteoporosis may include an assessment of BMD, vertebral imaging, laboratory work-up, and other factors for secondary causes of osteoporosis, and

## Table 56–2[1,2]

### Medical Conditions and Drugs Associated with Osteoporosis or Low Bone Mass

| Medical Conditions | Drugs |
|---|---|
| Alcoholism | Anticoagulants (heparin, warfarin) |
| Chronic kidney disease | Anticonvulsants (phenytoin, phenobarbital) |
| Chronic obstructive pulmonary disease | Aromatase inhibitors (anastrozole, exemestane, letrozole) |
| Cushing syndrome | Cytotoxic drugs (eg, methotrexate, cisplatin) |
| Cystic fibrosis | Glucocorticoids (5 mg or more of prednisone daily or equivalent for at least 3 months) |
| Diabetes mellitus | |
| Eating disorders | |
| GI disorders (eg, gastrectomy, malabsorption syndromes) | Gonadotropin-releasing hormone analogs (leuprolide acetate, nafarelin, goserelin) |
| Hematologic disorders (eg, hemophilia) | Immunosuppressants (eg, tacrolimus) |
| Hyperparathyroidism | Lithium |
| Hyperthyroidism | Medroxyprogesterone acetate |
| Hypogonadal states | Proton pump inhibitors |
| Organ transplantation | Selective serotonin reuptake inhibitors |
| Skeletal cancer (eg, myeloma) | Thiazolidinediones |
| Vitamin D deficiency | Thyroid supplements (due to over-replacement) |
| | Total parenteral nutrition |

## Table 56–3

### World Health Organization (WHO) Definition of Osteoporosis

| Skeletal Disorder | T-Score[a] |
|---|---|
| Normal | –1 or greater |
| Osteopenia | Less than –1 to –2.5 or greater |
| Osteoporosis | Less than –2.5 |

[a]T-score is the number of standard deviations above or below the mean bone mineral density in young adults.

biochemical markers of bone turnover. **KEY CONCEPT** *Osteoporosis may be diagnosed by low bone density as determined by BMD or established history of low-trauma hip or vertebral fracture in adulthood.*[1]

### ▶ Measurement of Bone Mineral Density

Osteoporosis is characterized by weakened bone tissue, and BMD is the best measure of bone strength, representing approximately 70% of bone strength.[6] Low BMD is associated with an increased risk of fractures. BMD can be measured at various sites throughout the skeletal system and by various methods. Dual-energy x-ray absorptiometry (DXA) can be used to measure central (hip and/or spine) and peripheral (heel, forearm, or hand) sites. Quantitative ultrasound, peripheral quantitative computed tomography, radiographic absorptiometry, and single-energy x-ray absorptiometry are used to measure peripheral sites.

The World Health Organization (WHO) recommends a standardized approach to measuring BMD for diagnosis of osteoporosis using central measurement of BMD by DXA.[2] Preferred sites for central measurement include the total hip, femoral neck, and lumbar spine. Some instruments used for peripheral bone densitometry are portable, allowing bone density to be measured in pharmacies and health-fair screening booths. In addition to accessibility, peripheral measurement of BMD is generally less expensive than central DXA, making it an attractive option for many patients. Peripheral BMD testing is useful in identifying patients who are candidates for central DXA and who are at increased risk of fracture, but it should not be used for diagnosis.

Once the BMD report is available, T-scores and Z-scores are used to interpret the data. The T-score is the number of standard deviations from the mean BMD in healthy, young, white women. Osteoporosis is defined as a T-score at least –2.5

standard deviations below the mean BMD in young adults (Table 56–3). Osteopenia, or low bone mass that may eventually lead to osteoporosis, is defined as a T-score between –2.5 and –1.0. The Z-score, defined as the number of standard deviations from the mean BMD of age- and sex-matched controls, is similar to the T-score but is corrected for both age and sex of the patient. Z-scores may be more clinically relevant in evaluating BMD in premenopausal women, men younger than the age of 50, and patients who may have secondary causes for low BMD.

### ▶ Screening and Risk Factor Assessment

The NOF recommends BMD measurements in the following groups: women age 65 and older, men age 70 and older, perimenopausal women and men age 50 to 69 with risk factors, anyone with a fracture after age 50, and adults with a secondary cause for osteoporosis.[1]

FRAX (see *www.shef.ac.uk/FRAX*) is an additional tool developed by the WHO to evaluate an individual's 10-year probability of developing hip and major osteoporotic fractures based on femoral neck BMD T-score, age, and other risk factors.[1] Its intended use is for men and women older than 40 years. The FRAX tool has not been validated for patients with previous or current use of pharmacotherapy to treat osteoporosis. Although the T-score is helpful in calculating risk of fracture with FRAX, fracture risk may be calculated without it.

### ▶ Vertebral Imaging

Vertebral fractures cause significant morbidity and mortality among patients with osteoporosis. They are often clinically silent, widespread, frequently recur, and commonly go undiagnosed. For these reasons, vertebral imaging is recommended in high-risk patients: central T-score less than –1.0 in women age 70 and older and men age 80 and older; central T-score less than –1.5 in women age 65 to 69 or men age 70 to 79; and postmenopausal women and men age 50 and older who have had a fragility fracture in adulthood, height loss of 4 or more centimeters from adulthood, prospective height loss of 2 or more centimeters, or long-term glucocorticoid therapy.[1] Patients may receive vertebral imaging through traditional x-ray or lateral vertebral fracture assessment available on some DXA machines.

### ▶ Laboratory Evaluation

Laboratory assessment has little value in diagnosing osteoporosis but can be beneficial in identifying or excluding secondary causes of bone loss, or predicting patients who may be at risk for more rapid bone loss or fractures. Screening laboratory tests for the most common causes of secondary osteoporosis include complete blood cell count, serum chemistries (electrolytes with

## Patient Encounter, Part 1: Patient History

**HPI:** A frail 71-year-old white man presents to the clinic for follow-up. He reports occasional forgetfulness. His erectile dysfunction, poor libido, and fatigue have improved since starting testosterone replacement therapy. He has no complaints with his current medication regimen for COPD. He takes calcium carbonate (Tums) approximately once a week for heartburn after eating spicy meals. He usually spends his day inside the house watching television from his recliner. He states that milk upsets his stomach, so he usually drinks black coffee or diet soda, occasionally fruit juice.

**PMH:** COPD, DM type 2, HTN, hyperlipidemia, GERD, hypogonadism, lactose intolerance

**FH:** Father died at age 76 with Alzheimer disease; mother died at age 92 with history of breast cancer and osteoporotic fracture of the hip; sister alive and well at age 69

**SH**: Retired construction worker; drinks four beers per day; smoked two packs a day for 40 years, now two cigars daily

**Meds:** Albuterol inhaler two puffs as needed, metformin 500 mg twice daily; lisinopril 10 mg daily; atorvastatin 40 mg daily, omeprazole 20 mg daily; calcium carbonate (Tums) 500 mg as needed; testosterone cypionate 200 mg IM every 2 weeks; tiotropium 18 mcg daily

*Do any symptoms suggest the presence of osteoporosis?*

*What risk factors for osteoporosis does this patient have as defined by the World Health Organization?*

*What diseases or medications could contribute to osteoporosis in this patient?*

*What are the recommended daily intakes for calcium and vitamin D?*

*How could he incorporate more calcium into his diet?*

calcium, phosphorus and liver enzymes), vitamin D, and urinalysis. Biochemical markers of bone turnover such as pyridinoline, deoxypyridinoline, N-telopeptides, and C-telopeptides are not intended for widespread clinical use due to variability and limited clinical data but may be beneficial in some patients to monitor response to therapy, medication adherence, or drug absorption.[2]

## TREATMENT
### Desired Outcomes

**KEY CONCEPT** *Treatment goals for osteoporosis include: (a) preventing fractures and their complications; (b) maintaining or increasing BMD; (c) preventing secondary causes of bone loss; and (d) reducing morbidity and mortality associated with osteoporosis.* Strategies to prevent fractures include maximizing peak bone mass, reducing bone loss, and using precautions to prevent falls leading to fragility fractures.

### Nonpharmacologic Therapy
#### ▶ Modification of Risk Factors

Some osteoporosis risk factors (see Tables 56–1 and 56–2) are nonmodifiable, including family history, age, ethnicity, gender,

### Table 56–4

**Calcium-Rich Foods[a]**

1 cup[b] skim milk
1 cup soy milk (calcium-fortified)
1 cup yogurt
1½ oz[c] cheddar cheese
1½ oz jack cheese
1½ oz Swiss cheese
1½ oz part-skim mozzarella
4 tablespoonfuls[d] grated Parmesan cheese
8 oz tofu
1 cup greens (collards, kale)
2 cups broccoli
4 oz almonds
2 cups low-fat cottage cheese
3 oz sardines with bones
5 oz canned salmon
1 cup orange juice (calcium-fortified)

[a]Foods containing approximately 300 mg of elemental calcium.
[b]One cup is equivalent to approximately 240 mL.
[c]One ounce (1 oz) is equivalent to approximately 28 g.
[d]One tablespoon is equivalent to approximately 15 mL.

and concomitant disease states. However, certain risk factors for bone loss may be minimized by early intervention, including smoking, low calcium intake, poor nutrition, inactivity, heavy alcohol use, and vitamin D deficiency. To avoid certain risk factors and maximize peak bone mass, efforts must be directed toward osteoporosis prevention at an early age.

#### ▶ Nutrition

A healthy diet is essential to ensure sufficient nutrient intake and appropriate weight maintenance. Dietary calcium intake is important for achieving peak bone mass and maintaining bone density. Good dietary sources of calcium include dairy products, fortified juice, cruciferous vegetables (eg, broccoli, kale), salmon, and sardines (Table 56–4). Dietary intake generally provides 600 to 700 mg/day of calcium for men and women 50 and older. Supplementation to achieve recommended intake not attained by diet alone is important for primary prevention, as well as for those with a diagnosis of osteoporosis.

Adequate dietary intake of vitamin D is essential for calcium absorption. The most common source of vitamin D comes from exposure to sunlight. Ultraviolet rays from the sun promote synthesis of vitamin $D_3$ (cholecalciferol) in the skin, generally occurring within 15 minutes of direct sunlight exposure to exposed skin without sunscreen. However, during the winter months, patients living in northern latitudes are not able to obtain the type of exposure that results in vitamin D synthesis.[2] It is recommended that individuals receive twice weekly sun exposure to ensure optimal synthesis. Vitamin D may also be found in some dietary sources, including fortified milk, egg yolks, salt-water fish, and liver.

#### ▶ Exercise

Exercise can help prevent fragility fractures. Weight-bearing exercise such as walking, jogging, dancing, and climbing stairs can help build and maintain bone strength. Muscle-strengthening or resistance exercises can help improve and maintain strength, agility, and balance, which can reduce falls.[1] It is

important to develop and maintain a lifelong routine of weight-bearing and resistance exercise, because the benefits on bone can be lost after cessation of the exercise program.[1]

### ▶ Falls Prevention

Another crucial step in avoiding fragility fractures is prevention of falls. Patients with frailty, poor vision, hearing loss, or those taking medications affecting balance are at higher risk for falling and subsequent fragility fractures.[1,2]

A number of medications have been associated with an increased risk of falling, including drugs affecting mental status such as antipsychotics, benzodiazepines, tricyclic antidepressants, sedative/hypnotics, anticholinergics, and corticosteroids. Some cardiovascular and antihypertensive drugs can also contribute to falls, especially those causing orthostatic hypotension.[1] Efforts to decrease the risk of falling include balance training, muscle strengthening, removal of hazards in the home, installation of fall reduction measures such as handrails, and discontinuation of predisposing medications.[1,2]

## Pharmacologic Treatment (Figure 56–2)

**KEY CONCEPT** *The NOF recommends that all men and women older than 50 years be considered for pharmacologic treatment if they meet any of the following criteria: (a) history of hip or vertebral fracture, (b) T-score −2.5 or less at femoral neck or spine, or (c) osteopenia and at least a 3% 10-year probability of hip fracture or at least a 20% 10-year probability of major osteoporosis-related fracture as determined by FRAX.*[1]

### ▶ Calcium and Vitamin D

**KEY CONCEPT** *Calcium and vitamin D supplements to meet requirements should be added to all drug therapy regimens for osteoporosis to increase BMD and decrease the risk of hip and vertebral fractures.*

Calcium plays an important role in maximizing peak bone mass and decreasing bone turnover, thereby slowing bone loss. When the calcium supply is insufficient, calcium is taken from bone stores to maintain the serum calcium level. Adequate calcium consumption is essential to prevent this from occurring and may also correct secondary hyperparathyroidism in elderly patients.

The NOF recommends a daily calcium intake of 1000 mg for men between the ages of 50 to 70 and a higher intake of 1200 mg for women older than 51 and men older than 71.[1] When these requirements cannot be achieved by diet alone, appropriate calcium supplementation is recommended. Intakes over 1200 to 1500 mg/day may increase the risk of developing kidney stones,[1] and supplementation greater than 2500 mg/day may lead to hypercalciuria and hypercalcemia. Additionally, excessive calcium supplementation may be associated with an increased risk of cardiovascular events.[7,8]

Calcium supplements are available in a variety of calcium salts and dosage forms. Daily calcium requirements are reported as elemental calcium. However, many product labels list calcium content in the salt form, so the percentage of elemental calcium must be known to calculate the elemental calcium content per tablet. A number of factors, including a single large intake of calcium, can limit calcium absorption, and special consideration must be given to calcium dosing to maximize absorption. Supplement doses should be limited to 500 to 600 mg of elemental calcium per dose, and absorption parameters, elemental calcium content, and adherence should be considered when choosing an appropriate supplement (Table 56–5).

Calcium carbonate should be taken with food to maximize absorption. Elderly patients or patients receiving proton pump inhibitors or $H_2$-receptor antagonists may have difficulty absorbing calcium supplements due to reduced stomach acidity. Calcium citrate may be better absorbed in these situations because an acid environment is not needed for absorption; it may be taken with or without food.

Common adverse effects of calcium salts include constipation, bloating, cramps, and flatulence. Changing to a different salt form may alleviate symptoms for some patients. Calcium salts may reduce the absorption of iron and some antibiotics, such as tetracycline and fluoroquinolones.

Vitamin D is crucial for calcium absorption and maintenance of bone. The goal is to maintain a serum 25-hydroxyvitamin D level above 30 ng/mL (75 nmol/L).[1] The NOF recommends a daily vitamin D intake of 800 to 1000 IU daily for all adults age 50 and older. However, higher doses may be necessary in some patients to meet this goal.

Vitamin D is available as a single entity, in combination with varying amounts of calcium salts, and in many multivitamin preparations. To avoid hypercalciuria and hypercalcemia, the maximum recommended dose for chronic use in most patients is 4000 IU/day.[9] High-dose ergocalciferol (vitamin $D_2$) is available by prescription only and is generally reserved for patients with vitamin D deficiency, whereas cholecalciferol (vitamin $D_3$) is available over the counter.

Patients at risk for vitamin D deficiency include elderly patients with malabsorption syndromes, chronic renal insufficiency, other chronic diseases, and those with limited sun exposure.[1] Elderly patients in particular are at increased risk of deficiency due to decreased exposure to sunlight and subsequent decreased vitamin D synthesis in the skin, decreased GI absorption of vitamin D, and reduction in vitamin $D_3$ synthesis.

Many adults have low vitamin D levels, and vitamin D deficiency is an important secondary cause of osteoporosis.[2,12] Laboratory determination of 25-hydroxyvitamin D levels should occur prior to the start of therapy to determine whether supplementation is adequate or whether treatment of deficiency is needed. The Endocrine Society Vitamin D Deficiency clinical practice guideline recommends treatment with ergocalciferol 50,000 IU once weekly (or cholecalciferol equivalent of 6000 IU daily) for 8 to 12 weeks.[10] After 25-hydroxyvitamin D levels have risen above 30 ng/mL (75 nmol/L), cholecalciferol doses of 1500 to 2000 IU can be used to maintain 25-hydroxyvitamin D levels between 30 and 60 ng/mL (75 and 150 nmol/L).[2,10]

### ▶ Bisphosphonates

**KEY CONCEPT** *Bisphosphonates are first-line therapy for osteoporosis in both men and women due to established efficacy in preventing hip and vertebral fractures.* They decrease bone resorption by binding to the bone matrix and inhibiting osteoclast activity. They remain in the bone for several years and are released very slowly, thereby increasing BMD. Alendronate, ibandronate, risedronate, and zoledronic acid carry an FDA-approved indication for osteoporosis. All of these agents are approved for use in men and women, with the exception of ibandronate, which is only approved for use in postmenopausal osteoporosis. Ibandronate is generally considered a second-line bisphosphonate due to lack of documented efficacy in nonvertebral fractures in prospective trials.[2,11] Table 56–6 contains comparative dosing and cost information for the bisphosphonates.

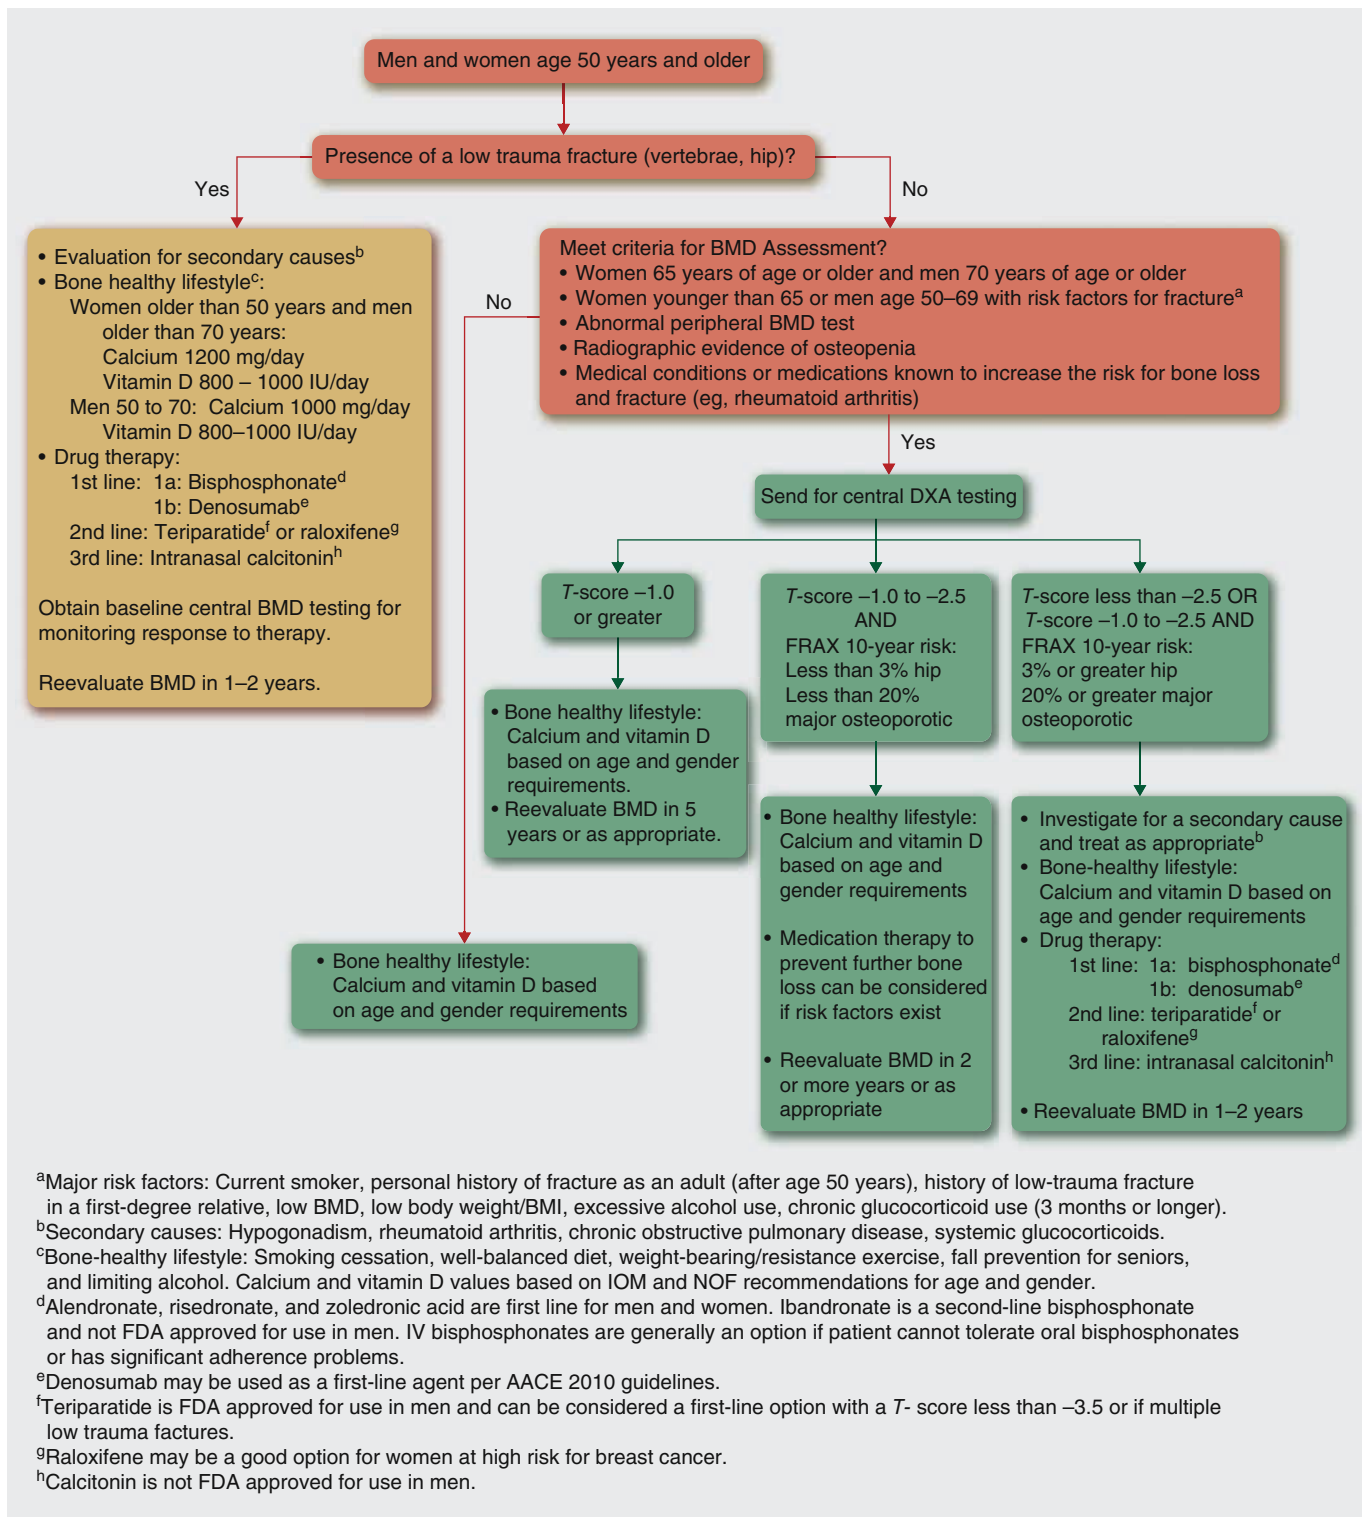
Bisphosphonates can increase BMD by up to 5% to 8% in the lumbar spine and up to 3% to 6% in the hip.[12,13] BMD continues


**FIGURE 56–2.** Algorithm for management of osteoporosis in women and in men aged 50 and older. Adapted from DiPiro JT et al., eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York: McGraw-Hill; 2014: Figure 73–3; With permission. www.accesspharmacy.com.

to increase with long-term bisphosphonate therapy of 7 to 10 years.[14,15] Although increases in BMD have been reported at other sites, most of the clinically significant increases occur in the hip or spine and are an important marker of treatment effects. Bisphosphonate therapy can also prevent vertebral and non-vertebral fractures, decreasing the vertebral fracture risk by as much as 40% to 50% with oral bisphosphonates and up to 70% with zoledronic acid.[1,16] IV zoledronic acid has also shown a 28% decrease in mortality associated with hip fracture.[17]

The most notable adverse effects associated with the oral bisphosphonates are GI, ranging from relatively mild nausea, vomiting, and diarrhea to more severe esophageal irritation and

esophagitis. Other common adverse reactions include dyspepsia, abdominal pain, nausea, and esophageal reflux. Esophageal ulceration, erosions with bleeding, perforation, stricture, and esophagitis may also occur. Upper GI adverse effects occur in up to 20% of patients and are often related to inappropriate administration. Advanced age, previous upper GI tract disease, and use of nonsteroidal anti-inflammatory drugs also increase the risk for GI adverse events, whereas once-weekly administration of oral bisphosphonates may decrease the risk.

Up to 40% of patients receiving the first dose of IV zoledronic acid may experience acute-phase reactions (flu-like symptoms) that can last for days, such as headache, arthralgia, myalgia, and fever.[1,2,17] Pretreatment with acetaminophen may prevent these symptoms.[2] Patients with moderate to severe renal impairment, severe dehydration, or taking concomitant diuretics or nephrotoxic drugs may be at higher risk of developing acute renal failure with zoledronic acid. Laboratory monitoring, including serum creatinine, alkaline phosphatase, phosphate, magnesium, and calcium, is recommended prior to administration of each zoledronic acid dose.

Long-term administration of bisphosphonates is considered beneficial in patients at high risk for fracture. However, for women who must discontinue bisphosphonate therapy due to intolerance or adverse events, improvements in BMD may be sustained.[15] Although bisphosphonates have demonstrated continued efficacy over time, there are some safety concerns with long-term use. Serious adverse events including **osteonecrosis** of the jaw (ONJ),[18,19] **subtrochanteric** fractures,[18] and nonvertebral atraumatic fractures[19] have been reported. These events may be related to oversuppression of bone turnover causing weakening of bone structure related to inhibition of osteoclastic activity.[20,21] Risk factors for development of ONJ include chemotherapy, radiotherapy, corticosteroids, infection, or preexisting

**Patient Encounter, Part 2: Physical Examination and Diagnostic Tests**

*What additional risk factors and signs of osteoporosis are present in this patient?*

*Based on the US-adapted WHO algorithm, what is the patient's 10-year probability of a hip fracture and 10-year probability of a major osteoporosis-related fracture?*

*What are the goals of pharmacologic and nonpharmacologic therapy?*

*List at least three nonpharmacologic interventions important in his treatment plan.*

*What factors support pharmacotherapy for osteoporosis in this patient?*

*What type of supplement(s) would you recommend for this patient to meet his calcium and vitamin D requirements? Why?*

dental disease. Most cases of ONJ occurred in patients receiving high doses of zoledronic acid for cancer-related indications.[18] Patients should complete major dental work prior to initiation of bisphosphonate therapy. The rate of subtrochanteric fractures also increases with more than 5 years of use.[22,23] The NOF recommends reevaluation of therapy after 3 to 5 years of use and to stop treatment in patients who are at moderate risk of fractures.[1] Esophageal cancer has also been reported with long-term therapy, but data are currently inconclusive.[24,25]

Oral bisphosphonates are poorly absorbed (less than 5%). Taking them in the presence of food or calcium supplementation further reduces absorption. After absorption, bisphosphonate uptake to the primary site of action is rapid and sustained. Once attached to bone tissue, bisphosphonates are released very slowly over several years.

Proper drug administration is important for optimal absorption and prevention of adverse effects. Oral bisphosphonates should be taken 30 to 60 minutes prior to the first meal or food in the morning after an overnight fast with 6 to 8 oz

| Table 56–6 |

CrCl, creatinine clearance; PM, postmenopausal; SC, subcutaneously.

(about 180–240 mL) of water (or 2 oz [60 mL] with the oral solution). Administration should be with water only and not combined with other fluids. Patients should remain upright and refrain from lying down for 30 to 60 minutes after administration. The tablets should be swallowed whole without chewing or sucking. Bisphosphonates should not be taken with other medications or dietary supplements. Bisphosphonates are not recommended for use in patients with esophageal abnormalities that may delay transit of the tablet, such as with severe GERD, achalasia, stricture, or Barrett esophagus. They are also not recommended in patients with hypocalcemia or renal insufficiency or

failure (creatinine clearance less than 30 to 35 mL/min [0.50–0.58 mL/s]), or in those who are pregnant. For patients who are unable to tolerate or have a contraindication to oral bisphosphonates, IV agents may be used.

▶ **Denosumab**

Denosumab is the first human monoclonal antibody FDA approved for treatment of postmenopausal osteoporosis. It is first-line therapy and should be considered in patients who are unable to tolerate bisphosphonates due to GI contraindications

or side effects and for patients with malabsorption or adherence issues.[2] Denosumab reduces nuclear factor-kappa B ligand (RANKL) action, which leads to selective inhibition of osteoclast formation, function, and survival. In contrast to bisphosphonates, the antiresorptive effects of denosumab are reversible.

Denosumab has been shown to increase BMD in the hip and spine by up to 6% and 9%, respectively; and decrease hip, vertebral, and nonvertebral fracture risk by up to 40%, 68%, and 20%, respectively.[26] Patients treated with denosumab had greater increases in hip and spine BMD than patients treated with alendronate, although fracture risk was not reported.[27-29] In a long term, open-label study use of denosumab for 6 years resulted in continued increases in BMD up to 15% in the lumbar spine and up to 7% at the hip; a reduction in fracture rates was sustained compared to denosumab use for 3 years.[30]

Common adverse effects include back pain, arthralgias, fatigue, headache, dermatologic reactions, diarrhea, and nausea. Serious adverse reactions, including hypophosphatemia, hypocalcemia, dyspnea, and skin and other infections, can also occur. Patients should seek medical attention if they experience any symptoms of infection. Denosumab can worsen hypocalcemia in predisposed patients, such as those with severe kidney disease, and preexisting hypocalcemia should be corrected before initiating therapy. Suppression of bone turnover has been associated with denosumab therapy, and ONJ has also been reported.[2]

Denosumab is part of a Risk Evaluation and Mitigation Strategy (REMS) program, in which the manufacturer is required by the FDA to inform patients and health care providers of the risks associated with its use.[31] Denosumab is administered as a subcutaneous injection once every 6 months and should be stored in the refrigerator until administration. Once at room temperature, the vial or prefilled syringe must be used within 14 days. Prescribing information recommends administration of 1000 mg of calcium and at least 400 IU of vitamin D once daily.

### ▶ *Teriparatide*

Teriparatide, recombinant human parathyroid hormone (1–34), is the first anabolic agent approved by the FDA for treatment of postmenopausal and male osteoporosis. It is generally reserved for patients with very high fracture risk or those in whom other therapies have been ineffective.[2] This agent differs from antiresorptive therapies in that it stimulates osteoblastic activity to form new bone. It is administered as a daily subcutaneous injection. Teriparatide increases BMD in the spine and hip by 9% and 3%, respectively; and reduces fracture risk by 65% and 53% in vertebral and nonvertebral fractures, respectively.[32] Significant reductions in hip fracture have not been demonstrated.

Common adverse effects include nausea, headache, leg cramps, dizziness, injection site discomfort, and hypercalcemia. Orthostatic hypotension may also occur; patients should be seated after the first several doses until drug response is predictable. Teriparatide should not be used in patients with preexisting hypercalcemia. Observations of osteosarcoma in animal studies led to the inclusion of a "black box warning" in the product labeling, but no cases have been reported in humans. Patient-related concerns regarding the use of teriparatide include cost of therapy and need for daily subcutaneous injections. The labeling recommends treatment for a maximum of 2 years because it has not been studied for longer periods.

### ▶ *Selective Estrogen Receptor Modulators (SERMs)*

Raloxifene is an SERM indicated for prevention and treatment of osteoporosis. It is recommended as alternative therapy after bisphosphonates, denosumab, or teriparatide.[2] It has estrogen-like activity on bones and cholesterol metabolism and estrogen antagonist activity in breast and endometrium. It reduces bone resorption and decreases overall bone turnover.

Raloxifene has been shown to increase BMD in the vertebra (2%–3%) and hip (1%–2%), and reduce vertebral fracture rates by as much as 55%.[33] Significant decreases in nonvertebral fractures have not been demonstrated.[2] Raloxifene has been shown to decrease the incidence of breast cancer in high-risk women. It also decreases total and low-density lipoprotein (LDL) cholesterol, which generated initial enthusiasm for additional cardiovascular benefits. However, mixed results have been seen on cardiovascular disease, stroke, and noncardiovascular mortality.[34,35]

Adverse effects of raloxifene include hot flushes, leg cramps, and increased risk of venous thromboembolism.[34] A previous history of venous thromboembolism is a contraindication to therapy. Hot flushes are very common and may be intolerable in postmenopausal women who are already predisposed to experiencing them. Raloxifene is pregnancy category X and is contraindicated in women who are pregnant or may become pregnant, and in nursing mothers.

Bazedoxifene, a third-generation estrogen agonist/antagonist, has similar effects to raloxifene. At the time of this writing, it was marketed only for short-term use as a combination product with conjugated estrogens (Duavee) for treatment of moderate to severe vasomotor symptoms associated with menopause and for prevention of postmenopausal osteoporosis.[1] A single-ingredient product, bazedoxifene acetate (Viviant), was investigational at the time of this writing.

### ▶ *Calcitonin*

Calcitonin is a naturally occurring mammalian hormone that plays a major role in regulating calcium levels. It inhibits bone resorption by binding to osteoclast receptors. Calcitonin is considered a last-line agent for the treatment of osteoporosis.[2] Calcitonin produces a modest increase in BMD at the spine of 1% to 3% and reduces vertebral fracture risk by up to 30%.[39] However, no benefit has been demonstrated in reducing nonvertebral fractures.[2] Calcitonin was previously thought to provide analgesic effects in women with back pain from vertebral fractures, but recent practice trends favor managing fracture risk and pain separately.

Although salmon calcitonin is approved and available in injectable and intranasal formulations, only the intranasal formulation has documented benefit in clinical trials for management of osteoporosis. Adverse effects associated with the intranasal formulation include rhinitis, nasal irritation, and dryness. Hypersensitivity can develop with either formulation and should be considered before administering to patients with suspected risk.[2]

### ▶ *Hormone Therapy*

Estrogen, either alone or in combination with a progestin as hormone replacement therapy (HRT), has a long history as an effective treatment of osteoporosis. The Women's Health Initiative (WHI) trial found a 34% reduction in both vertebral and hip fractures and a 23% reduction in other fractures in postmenopausal women receiving conjugated estrogens and medroxyprogesterone.[37] However, significant risks associated with long-term HRT, including breast cancer and venous thromboembolism, have limited its use in osteoporosis.[37,38]

▶ *Combination and Sequential Therapy*

Interest in combination therapy with two or more osteoporosis drugs is based on the idea that using agents with differing mechanisms would result in greater increases in BMD and reductions in fracture rates. Combination therapies with two antiresorptive agents or an anabolic agent coupled with an antiresorptive agent have shown modest benefit on BMD and markers of bone turnover. Data on fracture reduction are lacking.[1,39,40] Interest in sequential therapy (anabolic agent followed by antiresorptive therapy) stems from the limited duration (2 years) of teriparatide use and the rapid decline in beneficial effects on bone once teriparatide is discontinued.[2] Due to high cost and lack of long-term safety and efficacy data, the AACE does not recommend combination antiresorptive therapy for treating osteoporosis.[2] The NOF prefers sequential therapy over combination therapy but acknowledges that combination antiresorptive and anabolic therapies could be considered for patients with very severe osteoporosis.[1]

▶ *Investigational Agents*

Several anabolic and antiresorptive therapies are under investigation for treatment of osteoporosis. The most promising antiresorptive therapy may be odanacatib, a selective enzyme inhibitor of cathepsin-K, which prevents enzymatic bone degradation in mature osteoclasts.[41] Anabolic therapies currently under investigation include calcilytic drugs and Wnt pathway modulators.[41-43] Calcilytic drugs increase bone formation by imitating hypocalcemia and cause parathyroid hormone secretion.[42] Wnt signaling pathway modulators promote osteoblastic bone formation. Romosozumab, a monoclonal antisclerostin antibody, binds to

sclerostin, a Wnt antagonist, to increase bone formation. These agents are currently in phase 1 and 2 trials.[42,44] Other investigational therapies, strontium ranelate, PTH (1–84), and tibolone, are available outside the United States.[42]

## Treatment of Special Populations

▶ *Glucocorticoid-Induced Osteoporosis*

Glucocorticoids play a significant role in bone remodeling. Exogenous glucocorticoid administration increases bone resorption, inhibits bone formation, and changes bone quality. Glucocorticoids (eg, prednisone, hydrocortisone, methylprednisolone, and dexamethasone) promote bone resorption through reduced

---

## Patient Encounter, Part 3: Development of a Treatment Plan

Considering all of the information presented, develop a treatment plan for this patient. Include the following information:

*Recommendations for patient-specific drug therapy including dose and frequency.*

*Patient education about the chosen regimen, including administration directions.*

*Monitoring plan for efficacy and adverse effects.*

*Consideration of alternate therapies if the initial therapy fails or is intolerable.*

---

## Patient Care Process

**Patient Assessment:**

- Assess risk factors for osteoporosis and presence of secondary causes of osteoporosis.
- Assess nonpharmacologic interventions for preventing osteoporotic fractures, including nutrition and weight-bearing and muscle-strengthening exercise regimens. What is the patient's fall risk?
- Determine average calcium intake from diet (see Table 56–4) and supplements (see Table 56–5) and evaluate the patient's sources of vitamin D. Based on age, gender and laboratory values, is the patient receiving appropriate calcium and vitamin D supplementation?
- Test bone densitometry in patients at risk for having low bone mass or bone loss. If *T*-score is between –1.0 and –2.5, use FRAX to estimate fracture risk.

**Therapy Evaluation:**

- Perform a thorough medication history, including prescription, over-the-counter, and alternative therapies. Does the patient take any calcium and vitamin D supplements?
- If drug therapy is indicated, assess the patient for contraindications.

- If the patient is already receiving pharmacotherapy, assess efficacy, safety, and patient adherence. How long has the patient been on each agent? Was the patient previously trialed with other agents?
- Determine what options are available for the patient. Does the patient have prescription coverage? What agents are recommended on the formulary?

**Care Plan Development:**

- Select therapy (including agent and dose) likely to be safe and effective for the patient (see Table 56–6).
- Educate the patient on drug therapy selected, including drug name, dose, route and method of administration, common or serious adverse reactions, adherence, and monitoring.
- Educate the patient about nonpharmacologic measures to prevent osteoporotic fractures.
- Discuss therapeutic goals and expectations (eg, changes in individual *T*-scores may not necessarily correlate with benefit in fracture risk reduction).

**Follow-Up Evaluation:**

- Annually review the need for continued medication. Assess appropriate drug administration, efficacy, adverse effects, and nonpharmacologic measures to prevent fractures.

calcium absorption from the GI tract and increased renal calcium excretion. Bone formation is reduced through inhibition of osteoblasts and decreased estrogen and testosterone production.

Patients receiving long-term glucocorticoids are at increased risk of fracture, which is greater with higher doses and longer-term therapy. Most bone mass is lost during the initial 6 to 12 months of therapy but it continues to decline thereafter.[45] Due to the risk of bone loss and fractures, therapy is recommended for patients receiving long-term supraphysiologic doses of glucocorticoids.[46]

In addition to nonpharmacologic measures, the American College of Rheumatology (ACR) has specific recommendations for preventing and treating patients receiving glucocorticoids.[46] Recommendations for optimal calcium and vitamin D intake are higher and include 1200 to 1500 mg daily of elemental calcium and 800 to 1000 IU daily of vitamin D, or higher as needed to maintain adequate 25(OH)D levels, for all adults receiving glucocorticoids.

`KEY CONCEPT` *The ACR recommends bisphosphonate therapy with alendronate or risedronate for all patients who are starting treatment with glucocorticoids (prednisone 5 mg or more daily or equivalent) that will continue for 3 months or longer.* Therapy may also be started in patients with lower glucocorticoid doses or shorter duration based on risk factors for fracture. Zoledronic acid and teriparatide may also be considered for moderate- to high-risk patients. Although not FDA approved, denosumab has been studied in this population and may be considered an alternate therapy for patients nonresponsive to or intolerant of other therapies.[45]

## OUTCOME EVALUATION

- Evaluate patients for progression of osteoporosis, including signs and symptoms of new fragility fracture (eg, localized pain), loss of height, and physical deformity (eg, kyphosis). Assess patients on an annual basis or more often if new symptoms present
- Monitor for beneficial effects on bone density. The NOF recommends a follow-up DXA scan every 2 years to monitor the effects of therapy
- Assess patients for adverse effects of therapy:
  - Oral bisphosphonates: Dyspepsia, esophageal reflux, esophageal pain, or burning
  - Injectable zoledronic acid: Influenza-type symptoms related to infusion, ONJ (rare)
  - Denosumab: Arthralgias, dermatologic reactions, and hypocalcemia
  - Teriparatide: Nausea, headache, leg cramps, hypercalcemia
  - Raloxifene: Hot flushes, signs, or symptoms of thromboembolic disease (eg, pain, redness, or swelling in one extremity, chest pain, and shortness of breath)
  - Calcitonin salmon: Nasal irritation or burning

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| AACE | American Association of Clinical Endocrinologists |
| ACR | American College of Rheumatology |
| BMD | Bone mineral density |
| BMI | Body mass index |
| DXA | Dual-energy x-ray absorptiometry |
| HRT | Hormone replacement therapy |
| NOF | National Osteoporosis Foundation |
| ONJ | Osteonecrosis of the jaw |
| SERM | Selective estrogen receptor modulator |
| WHI | Women's Health Initiative |

# Rheumatoid Arthritis

Susan P. Bruce

## LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Identify risk factors for developing adult rheumatoid arthritis (RA) or juvenile idiopathic arthritis (JIA).

2. Describe the pathophysiology of RA, with emphasis on the specific immunologic components.

3. Discuss the comorbidities associated with RA.

4. Recognize the typical clinical presentation of RA or JIA.

5. Create treatment goals for a patient with RA or JIA.

6. Compare the available pharmacotherapeutic options, selecting the most appropriate regimen for a given patient.

7. Propose a patient education plan that includes nonpharmacologic and pharmacologic treatment measures.

8. Formulate a monitoring plan to evaluate the safety and efficacy of a therapeutic regimen designed for an individual patient with RA or JIA.

## INTRODUCTION

Rheumatoid arthritis (RA) is a complex systemic inflammatory condition manifesting initially as symmetric swollen and tender joints of the hands and/or feet. Some patients may experience mild **articular** disease, whereas others may present with aggressive disease and/or extraarticular manifestations. The systemic inflammation of RA leads to joint destruction, disability, and premature death. Juvenile idiopathic arthritis (JIA) is the most common form of arthritis in children.

## EPIDEMIOLOGY AND ETIOLOGY

RA has a prevalence of 0.5% to 1%.[1,2] Patients with RA have a 50% increased risk of premature death and a decreased life expectancy of 3 to 10 years compared with individuals without RA.[3] The underlying causes of increased mortality are unclear. RA arises from an immunologic reaction, perhaps in response to a genetic or infectious antigen. Risk factors associated with the development of RA include the following:

- Female gender (3:1 females to males)

- Increasing age (peak onset 35–50 years of age)

- Current tobacco smoking.[4] Tobacco users are more likely to have extraarticular manifestations and to experience treatment nonresponsiveness. This risk is reduced when a patient has remained tobacco-free for at least 10 years.

- Family history of RA. Genetic studies demonstrate a strong correlation between RA and the presence of major histocompatibility complex class II **human leukocyte antigens** (HLA), specifically HLA-DR1 and HLA-DR4.[5,6] HLA is a molecule associated with the presentation of antigens to T lymphocytes.

- Emerging evidence suggests that stress may influence RA onset and disease activity. It appears that individual major stressful life events do not play a significant role. Instead, chronic presence of minor stressors (daily hassles, work and relationship stress, financial pressures) may affect the immune response and RA disease activity.[7]

- The prevalence of JIA is approximately 1 in 1000 children.[8] There are no known risk factors for JIA.

## PATHOPHYSIOLOGY

The characteristics of a **synovium** affected by RA are: (a) the presence of a thickened, inflamed membrane lining called **pannus**; (b) development of new blood vessels; and (c) influx of inflammatory cells in the synovial fluid, predominantly T lymphocytes. The pathogenesis of RA is driven by T lymphocytes, but the initial catalyst causing this response is unknown. Understanding specific components of the immune system and their involvement in the pathogenesis of RA will facilitate understanding of current and emerging treatment options for RA. The components of most significance are T lymphocytes, cytokines, B lymphocytes, and kinases.[5,9]

### T Lymphocytes

The development and activation of T lymphocytes are important to maintain protection from infection without causing harm to the host.[5] Activation of mature T lymphocytes requires two signals. The first is the presentation of an antigen by

antigen-presenting cells to the T-lymphocyte receptor. Second, a ligand-receptor complex (ie, CD80/CD86) on antigen-presenting cells binds to CD28 receptors on T lymphocytes.

Once a cell successfully passes through both stages, the inflammatory cascade is activated.[5] Activation of T lymphocytes: (a) stimulates the release of macrophages or monocytes, which subsequently causes the release of inflammatory cytokines; (b) activates osteoclasts; (c) activates release of matrix metalloproteinases or enzymes responsible for the degradation of connective tissue; and (d) stimulates B lymphocytes and the production of antibodies.[5,9,10]

## Cytokines

Cytokines are proteins secreted by cells that serve as intercellular mediators (Table 57–1). An imbalance of proinflammatory and anti-inflammatory cytokines in the synovium leads to inflammation and joint destruction. Some of the proinflammatory cytokines are interleukin 1 (IL-1), tumor necrosis factor-$\alpha$ (TNF-$\alpha$), IL-6, and IL-17. These proinflammatory cytokines cause activation of other cytokines and adhesion molecules responsible for recruitment of lymphocytes to the site of inflammation. Anti-inflammatory cytokines and mediators (IL-4, IL-10, and IL-1 receptor antagonist) are present in the synovium, although concentrations are not high enough to overcome the effects of the proinflammatory cytokines.[5,9,10]

## B Lymphocytes

In addition to serving as antigen-presenting cells to T lymphocytes, B lymphocytes may produce proinflammatory cytokines and antibodies.[6,9] Antibodies of significance in RA are rheumatoid factors (antibodies reactive with the Fc region of IgG) and anticitrullinated protein antibodies (ACPA).[6] Rheumatoid factors are not present in all patients with RA, but their presence is indicative of disease severity, likelihood of extraarticular manifestations, and increased mortality.[11] ACPA are produced early in the course of disease. High levels of ACPA are indicative of aggressive disease and a greater likelihood of poor outcomes. Monitoring ACPA may be useful to predict the severity of disease and match aggressive treatment appropriately.

## Kinases

The role of intracellular signaling is an emerging area of interest. Kinases are enzymes involved in communication or signaling activities within and between cells. Activated kinases lead to cell activation and proliferation. Examples include Janus-associated kinases (JAKs) and spleen tyrosine kinase. Research is ongoing to identify therapeutic targets to interrupt signaling and thereby halt the inflammatory process.[12]

## Comorbidities Associated with RA

RA reduces a patient's average life expectancy, but RA alone rarely causes death. Instead, specific comorbidities contribute to premature death independent of safety issues surrounding the use of immunomodulating medications. **KEY CONCEPT** *The comorbidities with the greatest impact on morbidity and mortality associated with RA are: (a) cardiovascular disease, (b) infections, (c) malignancy, and (d) osteoporosis.*

### ▶ Cardiovascular Disease

More than half of all deaths in RA patients are cardiovascular related.[13] Because a patient with RA experiences inflammation and swelling in joints, it is likely that there is inflammation elsewhere, such as in the blood vessels, termed vasculitis. C-reactive protein (CRP), a nonspecific marker of inflammation, is associated with an increased risk of cardiovascular disease; CRP is elevated in patients with RA. Traditional cardiovascular risk factors alone cannot explain the increased cardiovascular mortality in patients with RA. Increasing evidence suggests that the presence of RA is a cardiovascular risk similar to diabetes. Aggressive management of systemic inflammation and traditional cardiovascular risk factors (eg, blood pressure, cholesterol, tobacco use) may reduce cardiovascular mortality in this population.[14]

### ▶ Infections

RA itself leads to changes in cellular immunity and causes a disproportionate increase in infections.[15] Because medications that alter the immune system increase infection risk, it is difficult to distinguish between an increased risk due to RA and the immunosuppressive therapy. Patients and clinicians must pay close attention to signs and symptoms of infection.[15]

---

### Table 57–1

**Cytokines Involved in the Pathogenesis of RA[5,9,10]**

| Cytokine | Source | Activity |
|---|---|---|
| **Proinflammatory** | | |
| TNF-$\alpha$ | Macrophages, monocytes, B lymphocytes, T lymphocytes, fibroblasts | Induces IL-1, IL-6, IL-8, GM-CSF; stimulates fibroblasts to release adhesion molecules |
| IL-1 | Macrophages, monocytes, endothelial cells, B lymphocytes, activated T lymphocytes | Stimulates fibroblasts and chondrocytes to release matrix metalloproteinases |
| IL-6 | T lymphocytes, monocytes, macrophages, synovial fibroblasts | Activates T lymphocytes, induces acute-phase response, stimulates growth and differentiation of hematopoietic precursor cells; stimulates synovial fibroblasts |
| IL-17 | T lymphocytes in synovium | Synergistic effect with IL-1 and TNF leading to increased production of proinflammatory cytokines |
| **Anti-Inflammatory** | | |
| IL-4 | CD4+ type 2 helper T lymphocytes | Inhibits activation of type 1 helper T lymphocytes, decreases production of IL-1, TNF-$\alpha$, IL-6, IL-8 |
| IL-10 | Monocytes, macrophages, B lymphocytes, T lymphocytes | Inhibits production of IL-1, TNF-$\alpha$, and proliferation of T lymphocytes |

## Table 57–2

**Comparison of RA and Osteoarthritis**

| Characteristic | RA | Osteoarthritis |
|---|---|---|
| Speed of onset | Rapid (weeks to months) | Slow (years) |
| Gender prevalence (women: men) | 3:1 | 1:1 |
| Usual age of onset | Juvenile or adult (35–50 years) | Greater than 50 years |
| Most common joints affected | Small joints of hands (MCPs, PIPs), feet | Hands (DIPs), large weight-bearing joints (hips, knees) |
| Joint symptoms | Pain, swelling, warmth, stiffness | Pain, bony enlargement |
| Presence of inflammation | Local and systemic | None or mild, local |
| Duration of morning joint stiffness | Usually 60 minutes or longer | Usually less than 30 minutes |
| Joint pattern | Symmetric | Symmetric or asymmetric |
| ESR | Elevated | Normal |
| Synovial fluid | Leukocytosis, slightly cloudy | Mild leukocytosis |
| Systemic manifestations | Yes | No |

DIPs, distal interphalangeal joints; ESR, erythrocyte sedimentation rate; MCPs, metacarpophalangeal joints; PIPs, proximal interphalangeal joints.

### ▶ Malignancy

Cancer is the second most common cause of death in RA patients. There is increased risk of developing **lymphoproliferative** malignancy (eg, lymphoma, leukemia, multiple myeloma), skin, and lung cancer but decreased risk of developing cancer of the breast and digestive tract.[15,16] The relationship between RA and cancer is not clear. To confound the issue, medications for treating RA are undergoing review to determine whether use independently increases cancer risk. Current evidence suggests that the use of biologic medications does not increase the baseline risk associated with disease alone.

### ▶ Osteoporosis

Osteoporosis associated with RA follows a multifaceted pathogenesis, but the primary mechanism likely is mediated by increased **osteoclast** activity.[15] The cytokines involved in the inflammatory process directly stimulate osteoclast and inhibit **osteoblast** activity. Additionally, arthritis medications can lead to increased bone loss. Bone mineral density should be evaluated at baseline and routinely using dual-energy x-ray absorptiometry.

## CLINICAL PRESENTATION AND DIAGNOSIS

See the box on next page for the clinical presentation of RA.

### Diagnosis

Both osteoarthritis and RA are prevalent in the U.S. population, but they differ in presentation (Table 57–2). Because management of the two conditions differs significantly, early evaluation and diagnosis are essential to maximize an individual patient's care.

In 2010, The American College of Rheumatology (ACR) and European League Against Rheumatism (EULAR) released new classification criteria for RA (Table 57–3).[1] The goal was to identify a subset of patients with undifferentiated synovitis who were at high risk for chronic and erosive disease. The criteria are intended to help identify patients earlier in the course of disease. This will allow researchers to determine whether earlier introduction of medications alters the disease process. The criteria were developed as a tool for research purposes, but they are also helpful to guide clinical diagnosis. Patients with at least one joint with definite clinical synovitis that is not explained by another disease should be tested for RA.

Several clinical features of RA are associated with a worse long-term prognosis. The presence of these poor prognostic features should be considered at the time initial treatment decisions are made; more aggressive treatment may be warranted if these features are present. **KEY CONCEPT** *The most clinically important features associated with poor long-term outcomes include: (a) functional limitation (defined by use of standard measurement scales such as the Health Assessment Questionnaire [HAQ] score),*

## Table 57–3

**ACR/EULAR 2010 Classification Criteria for Rheumatoid Arthritis[1]**

| Criteria | Score |
|---|---|
| Joint involvement | |
|     1 large joint (hips, knees, ankles, elbows, shoulders) | 0 |
|     2–10 large joints | 1 |
|     1–3 small joints (MCPS, PIPs, MTPs, wrists) | 2 |
|     4–10 small joints | 3 |
|     More than 10 joints (at least one small joint) | 5 |
| Serology (need at least one result for classification) | |
|     Negative RF and negative ACPA | 0 |
|     Low positive RF or low-positive ACPA | 2 |
|     High-positive RF or high-positive ACPA | 3 |
| Acute-phase reactants (need at least one result for classification) | |
|     Normal CRP and normal ESR | 0 |
|     Abnormal CRP or abnormal ESR | 1 |
| Duration of symptoms | |
|     Less than 6 weeks | 0 |
|     More than 6 weeks | 1 |
| TOTAL: | 6 or greater indicates definite RA |

ACPA, anticitrullinated protein antibodies; ACR, American College of Rheumatology; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; EULAR, European League Against Rheumatism; MCPs, metacarpophalangeal joints; MTPs, metatarsophalangeal joints; PIPs, proximal interphalangeal joints; RA, rheumatoid arthritis; RF, rheumatoid factor.

## Clinical Presentation of RA

**General**

- About 60% of patients develop symptoms gradually over several weeks to months.
- Patients may present with systemic findings, joint findings, or both.

**Symptoms**

- Nonspecific systemic symptoms may include fatigue, weakness, anorexia, and diffuse musculoskeletal pain.
- Patients complain of pain in involved joints and prolonged morning joint stiffness.

**Signs**

- The metacarpophalangeal (MCP), proximal interphalangeal (PIP), metatarsophalangeal (MTP), and wrist joints are involved frequently.
- Joint involvement is usually symmetric.
- There is often limited joint function.
- Signs of joint inflammation are present (tenderness, warmth, swelling, and erythema).
- Low-grade fever may be present.
- Extraarticular manifestations:
  - *Skin:* Subcutaneous nodules
  - *Ocular:* Keratoconjunctivitis sicca, scleritis

- *Pulmonary:* Interstitial fibrosis, pulmonary nodules, pleuritis, pleural effusions
- *Vasculitis:* Ischemic ulcers, skin lesions, leukocytoclastic vasculitis
- *Neurologic:* Peripheral neuropathy, Felty syndrome
- *Hematologic:* Anemia, thrombocytosis

**Laboratory Tests**

- Positive rheumatoid factor (the test is negative in up to 30% of patients)
- Elevated ESR (Westergren ESR: greater than 20 mm/hour in men; greater than 30 mm/hour in women)
- Elevated C-reactive protein (CRP) (greater than 0.7 mg/dL or 7 mg/L)
- Complete blood count: Slight elevation in WBC count with a normal differential; slight anemia; thrombocytosis
- Positive anticitrullinated protein antibodies (ACPA)

**Other Diagnostic Tests**

- *Synovial fluid analysis:* Straw colored, slightly cloudy, WBC $5–25 \times 10^3/mm^3$ ($5–25 \times 10^9/L$), no bacterial growth if cultured
- *Joint x-rays:* To establish baseline and evaluate joint damage
- *MRI:* May detect erosions earlier in the course of disease than x-rays but is not required for diagnosis

(b) extraarticular disease, (c) positive rheumatoid factor, (d) positive ACPA, and/or (e) bony erosions by radiography.

▶ *Diagnosis of Juvenile Idiopathic Arthritis*

Diagnostic criteria for JIA include: (a) age less than 16 years at disease onset, (b) arthritis in one or more joints for more than 6 weeks, (c) exclusion of other types of arthritis. JIA can be divided into three main types:

1. *Systemic (4%–17% of cases)*: Occurs equally in girls and boys. There are characteristic fever spikes twice daily (greater than 38.3°C or 101°F) and the presence of a pale, pink, transient rash. The peak onset is between ages 1 and 6 years.

2. *Polyarticular (approximately 40% of cases)*: More likely to affect girls than boys (3:1). Arthritis is present in five or more joints. The disorder resembles adult RA more than the other types of JIA.

3. *Oligoarticular (about 50% of cases)*: More likely to affect girls than boys (5:1). Uveitis is more likely to be present. Arthritis is present in four or fewer joints. The peak onset is between ages 1 and 3 years.

## TREATMENT

### Desired Outcomes

KEY CONCEPT *The goals of treatment in RA are to: (a) reduce or eliminate pain, (b) protect articular structures, (c) control systemic complications, (d) prevent loss of joint function, and (e) improve or maintain quality of life. The goals for JIA are the same, with* the added goals of maintaining normal growth, development, and activity level.[17,18] It is a common misconception that patients with JIA grow out of the disease. Many children with JIA become adults with JIA. Knowing this, it is essential that early, aggressive treatment is initiated to achieve the goals of therapy.

### General Approach to Treatment

The clinician must evaluate patient-specific factors and select appropriate treatment to maximize the care of each patient.

## Patient Encounter, Part 1

A 68-year-old woman presents to her rheumatologist with complaints of increased joint swelling in her hands and feet over the last 3 months. She is especially disturbed by daily morning joint stiffness that lasts for 90 minutes on average. She is retired but has a small business as a seamstress. She is falling behind on her business projects because of the daily limitations with her hands. She wishes to improve function in her hands as soon as possible before customers start complaining.

*What information is suggestive of RA?*

*What risk factors does she have for RA?*

*What additional information do you need before creating a treatment plan for this patient?*

*What other variables in this scenario may inhibit optimal patient care?*

Joint damage accumulates over time; therefore, early diagnosis and early aggressive treatment are necessary to reduce disease progression and prevent joint damage. Aggressive treatment is defined as one or more disease-modifying antirheumatic drugs (DMARDs) at effective doses. Delaying treatment will result in more destructive disease that is very difficult to delay or reverse to preserve joint function.

**KEY CONCEPT** *It is imperative that the initiation of one or more DMARDs occurs in all patients within the first 3 months of diagnosis to reduce joint erosion.* Depending on disease severity and whether poor prognostic features are present, combination therapy may be initiated at the time of diagnosis or after an adequate trial of a DMARD initiated as monotherapy. If a patient has more aggressive disease, a more aggressive treatment plan may be warranted. The following medication classes are prescribed commonly for treatment of RA: (a) nonsteroidal anti-inflammatory drugs (NSAIDs), (b) glucocorticoids, (c) conventional synthetic DMARDs (csDMARDs), (d) biological originator DMARDs (boDMARDs), and (e) targeted synthetic DMARDs (tsDMARDs).

An emerging drug category is biosimilar DMARDs (bsD-MARDs). This category will include biological DMARDs that are a copy of the original biologic compound and demonstrate similar efficacy and safety. boDMARDs are currently in development and not yet available for general use. The nomenclature for DMARDs was proposed by an international leader in rheumatology to distinguish the different types of DMARDs.

**Figures 57–1** and **57–2** outline the course of treatment for adult RA according to the ACR 2012 Recommendations.[19] The recommendations are based on the disease activity level, presence or absence of poor prognostic features, and duration of disease activity (early vs established). Figure 57–1 applies to patients who have had RA for less than 6 months. csDMARD monotherapy includes hydroxychloroquine, leflunomide, methotrexate, minocycline, or sulfasalazine. Examples of combination therapy for patients with moderate or high disease activity with evidence of poor prognostic features are methotrexate/hydroxychloroquine, methotrexate/sulfasalazine, or methotrexate/sulfasalazine/hydroxychloroquine.

Figure 57–2 outlines the course of treatment for patients with established RA (disease duration 6 months or longer). boDMARDs are usually considered in patients with established RA following inadequate response to csDMARDs. Figure 57–2 establishes a progression for switching from one agent to another in a patient who experiences an inadequate response or adverse event. Because of treatment expense, boDMARDs should be considered only in patients who have no limitations due to cost or insurance coverage. There is no evidence that the benefits of combination boDMARD therapy outweigh the potential risks, especially the increased risk of infections.

## Nonpharmacologic Therapy

All patients should receive education about the nonpharmacologic and pharmacologic measures to help manage RA and JIA. Empowered patients take an active role in care by participating in therapy-related decisions. Certain forms of nonpharmacologic therapy benefit all levels of severity, whereas others (ie, surgery) are reserved for severe cases only.

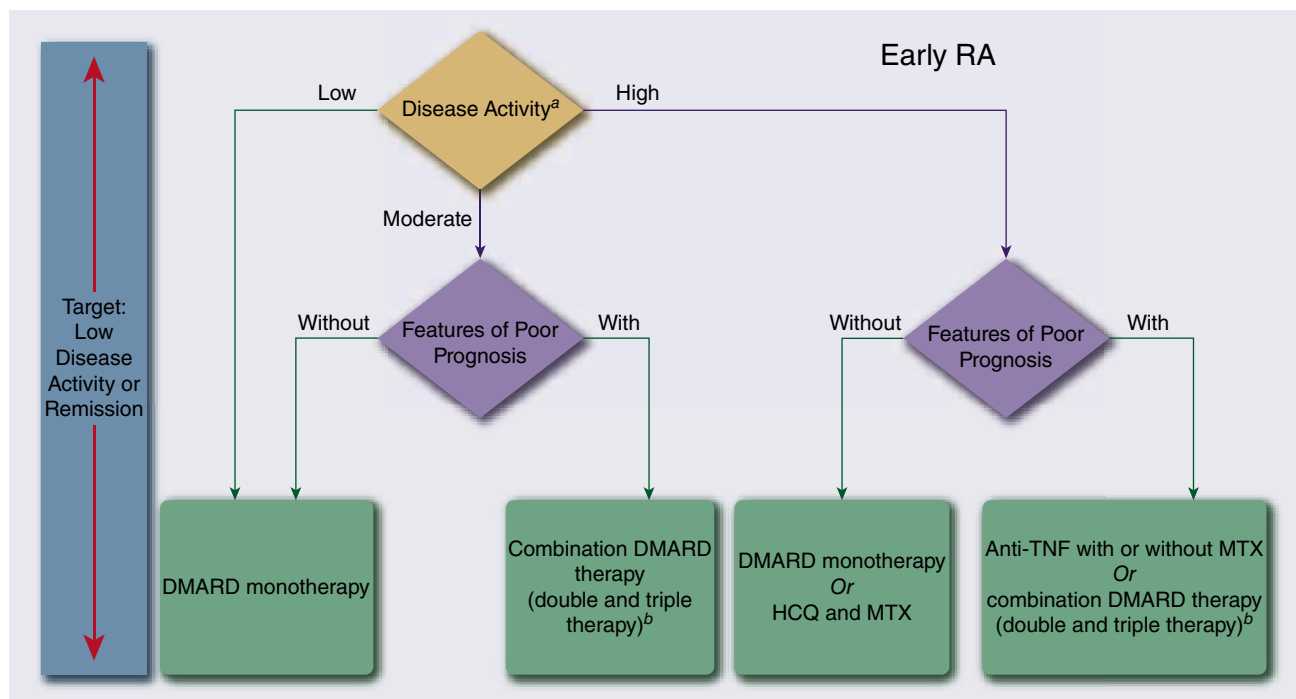

**FIGURE 57–1.** Recommendations for the treatment of early RA (disease duration < 6 months). DMARD, disease-modifying antirheumatic drug (In this figure, "DMARD" refers to conventional synthetic DMARDs or csDMARDs). [a]See Ref. 19 for definitions of disease activity. [b]Combination DMARD therapy: methotrexate + leflunomide, methotrexate + hydroxychloroquine, methotrexate + sulfasalazine, sulfasalazine + hydroxychloroquine. Triple DMARD therapy: methotrexate + hydroxychloroquine + sulfasalazine. (Reproduced, with permission, from Singh JA, Furst DE, Bharat A, et al. 2012 Update of the 2008 American College of Rheumatology recommendations for the use of disease-modifying antirheumatic drugs and biologic agents in the treatment of rheumatoid arthritis. Arthritis Care Res. 2012;64:625–639.)
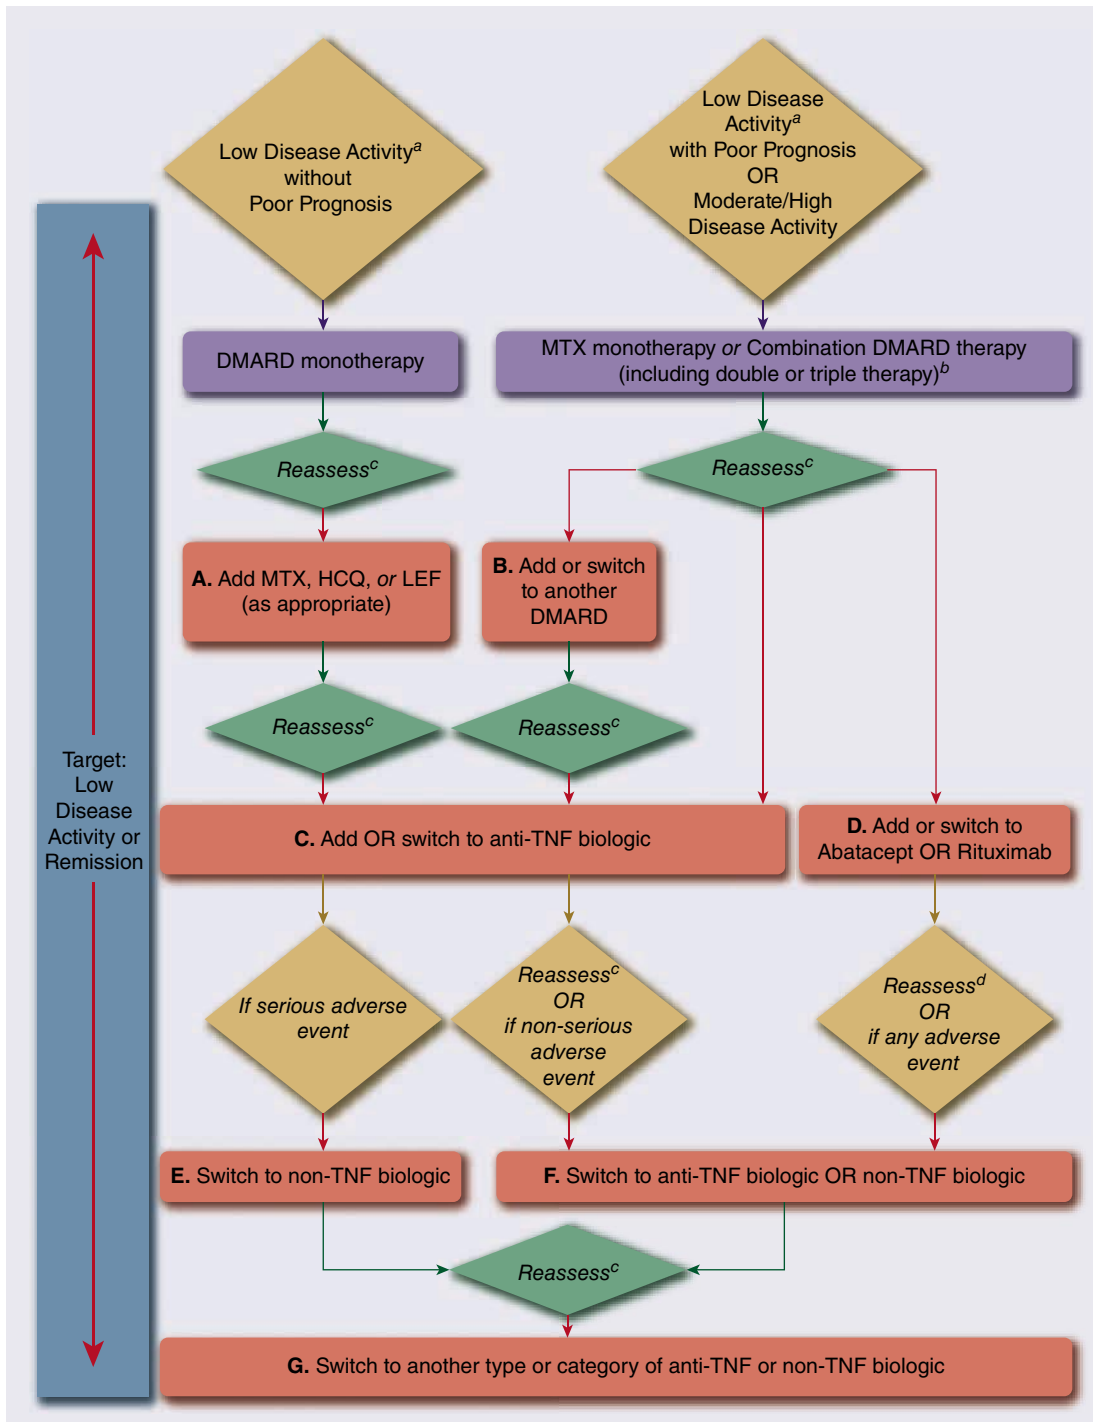

**FIGURE 57–2.** Recommendations for the treatment of established RA (disease duration 6 month or longer). Biologic, biological originator DMARD or boDMARD; DMARD, disease-modifying antirheumatic drug (In this figure, "DMARD" refers to conventional synthetic DMARDs or csDMARDs); HCQ, hydroxychloroquine; LEF, leflunomide; MTX, methotrexate; TNF, tumor necrosis factor. [a]See Ref. 19 for definitions of disease activity. [b]Combination DMARD therapy: methotrexate + leflunomide, methotrexate + hydroxychloroquine, methotrexate + sulfasalazine, sulfasalazine + hydroxychloroquine. Triple DMARD therapy: methotrexate + hydroxychloroquine + sulfasalazine. [c]Reassess after 3 months of adequate therapy. [d]Reassess after 6 months of adequate therapy. (Reproduced, with permission, from Singh JA, Furst DE, Bharat A, et al. 2012 Update of the 2008 American College of Rheumatology recommendations for the use of disease-modifying antirheumatic drugs and biologic agents in the treatment of rheumatoid arthritis. Arthritis Care Res. 2012;64:625–639.)

Occupational and physical therapy may help patients preserve joint function, extend joint range of motion, and strengthen joints and muscles through strengthening exercises. Patients with joint deformities may benefit from the use of mobility or assistive devices that help to minimize disability and allow continued activities of daily living. When appropriate, patients should also be counseled about stress management (ie, cognitive behavioral therapy, emotional disclosure, tai chi). In situations where the disease has progressed to a severe form with extensive joint erosions, surgery to replace or reconstruct the joint may be necessary.

## Pharmacologic Therapy

### ▶ Bridge Therapy/Symptomatic Relief

The current standard of care for RA treatment is to initiate disease-modifying therapy immediately. While this step is critical to control the underlying disease activity, it may take weeks to months for the patient to experience relief. It is acceptable to initiate "bridge therapy" or short-term use of certain medications to provide symptomatic relief until the disease modifying drug reaches its therapeutic effect. The most common classes used for bridge therapy are NSAIDs and glucocorticoids.

**NSAIDs** These agents provide analgesic and anti-inflammatory benefits for joint pain and swelling. However, they do not prevent joint damage or change the underlying disease. Selecting an NSAID depends on multiple patient-specific factors, including cardiovascular risk, potential for GI-related adverse events, adherence to medication regimens, and insurance coverage or lack thereof. NSAID monotherapy is recommended as initial treatment in children with JIA without prior treatment for a duration of 1 month.[17] Clinicians must carefully evaluate the potential risks of NSAID therapy against the potential benefits.[14] See Chapter 58 for additional discussion of NSAID therapy.

**Glucocorticoids** In contrast to NSAIDs, low-dose glucocorticoid treatment (equivalent to prednisone 10 mg/day or less) effectively reduces inflammation through inhibition of cytokines and inflammatory mediators and prevents disease progression.[20] However, due to the adverse effect profile, the goal of glucocorticoid use is to keep doses low and use the drugs as infrequently as possible. Patients taking more than 5 mg/day of prednisone or equivalent are at increased risk for clinically significant adverse reactions, especially bone loss leading to osteoporosis. Other glucocorticoid-related adverse reactions include Cushing syndrome, peptic ulcer disease, hypertension, weight gain, infection, mood changes, cataracts, dyslipidemia, and hyperglycemia.[20] A modified-release dosage form of prednisone is available and is intended to improve the benefit-to-risk ratio of glucocorticoid use.

Intraarticular glucocorticoid injections are recommended as initial treatment of JIA for disease affecting four or fewer joints.[17]

### ▶ Conventional Synthetic DMARDs (csDMARDs)

DMARDs are the mainstay of RA treatment because they modify the disease process and prevent or reduce joint damage. In addition to relying on safety and efficacy data, the initial DMARD choice depends on disease severity, patient characteristics (ie, comorbidities, likelihood of adherence), cost, and clinician experience with the medication.[8,19] Methotrexate alone or in combination therapy is the initial treatment of choice for patients with aggressive disease. Agents such as azathioprine, D-penicillamine, gold salts, and anakinra are used rarely today because of concerns about toxicity and reduced efficacy.[19]

**Methotrexate** `KEY CONCEPT` *Methotrexate is the csDMARD of choice in RA because of its documented efficacy and safety profile*

*when monitored appropriately.*[1,2] Methotrexate exerts its anti-inflammatory effect through inhibition of dihydrofolate reductase, which causes inhibition of purines and thymidylic acid, and by inhibiting production of certain cytokines.[2] Unless the patient has contraindications to methotrexate, once-weekly doses should be initiated within 3 months of diagnosis and increased steadily until the patient has symptomatic improvement or a maximum dose of 20 mg/wk is reached. If monotherapy does not produce complete resolution of symptoms, methotrexate may be used in combination with other csDMARDs or boDMARDs. Concomitant folic acid is given routinely to reduce the risk of folate-depleting reactions induced by methotrexate therapy (eg, stomatitis, diarrhea, nausea, alopecia, myelosuppression, and elevations in liver function tests).[1]

Methotrexate is recommended as initial treatment for JIA in patients with more than four active joints.[17] There are insufficient published data to assess the risk of serious toxicity in children receiving doses greater than 20 mg/m$^2$/week. Methotrexate therapy in children should be monitored the same way that is recommended in adults.

**Hydroxychloroquine and Sulfasalazine** The exact mechanism of action of these drugs is unknown, but both agents are fairly well tolerated. Hydroxychloroquine or sulfasalazine may be initiated on diagnosis of low disease activity. Because of their slow onset of action, each drug must be given at therapeutic doses for at least 6 months before it can be deemed a treatment failure. Hydroxychloroquine and sulfasalazine are relatively inexpensive compared to boDMARDs. If a patient does not respond to methotrexate monotherapy, adding one of these two drugs may provide the benefit necessary to reduce symptoms satisfactorily and ideally induce remission.[2,19]

Hydroxychloroquine is not associated with renal, hepatic, or bone marrow suppression and therefore may be an acceptable treatment option for patients with contraindications to other DMARDs because of their toxicities.

Starting sulfasalazine at low doses and titrating slowly will minimize the nausea and abdominal discomfort caused by the drug. Patients receiving sulfasalazine must undergo routine blood work to monitor for leukopenia.[19] Patients with a sulfa allergy should not receive sulfasalazine.

In patients with JIA, sulfasalazine is recommended only for patients with the enthesitis-related category. Enthesitis-related arthritis is a less common form of JIA that affects boys more than girls and is characterized by lower extremity joint involvement, including heel pain and enthesitis. Hydroxychloroquine is not recommended in JIA patients with active arthritis.[21]

**Leflunomide** This drug inhibits dihydroorotate dehydrogenase, an enzyme within mitochondria that supplies T lymphocytes with the necessary components to respond to cytokine stimulation.[22] Thus, leflunomide inhibits the T-lymphocyte response to various stimuli and halts the cell cycle. Its efficacy is similar to that of moderate doses of methotrexate or sulfasalazine.[22] Because of its extended half-life, leflunomide therapy begins with a loading dose followed by a maintenance dose. Leflunomide may be used in combination with methotrexate, but the added efficacy comes with a dramatic rise in the risk of hepatotoxicity. If therapy requires abrupt discontinuation (eg, due to toxicity or pregnancy), administering cholestyramine will accelerate leflunomide removal from the body.

Leflunomide is recommended as an alternative to methotrexate in patients with JIA experiencing disease activity in five or more joints.[21] However, leflunomide does not have an FDA-approved indication for this use.

### ▶ *Biological Originator DMARDs (boDMARDs)*

boDMARDs are indicated in patients who have failed an adequate trial of csDMARD therapy or in combination with csDMARDs in patients with early, aggressive disease. These agents may be added to csDMARD monotherapy (eg, methotrexate) or replace ineffective csDMARD therapy. The decision to select a particular agent generally is based on the prescriber's comfort level with monitoring the safety and efficacy of the medications, severity of disease activity, presence of factors suggestive of poor prognosis, the frequency and route of administration, the patient's comfort level or manual dexterity to self-administer subcutaneous injections, the cost, and the availability of insurance coverage. In general, boDMARDs should be avoided in patients with serious infections, demyelinating disorders (eg, multiple sclerosis), or hepatitis. TNF antagonists should be avoided in patients with heart failure.[19]

**Tumor Necrosis Factor Antagonists** Etanercept is a recombinant form of human T receptor.[22] Etanercept provides a therapeutic effect by binding to soluble TNF and preventing its binding with TNF receptors. Etanercept is very effective as monotherapy or in combination with other csDMARDs. Etanercept has an FDA-approved indication for treatment of JIA.

Adalimumab is a recombinant human IgG1 monoclonal antibody specific for human TNF.[22] Adalimumab binds to soluble and bound TNF-α. It can be administered in combination with methotrexate or other DMARDs.[2] Adalimumab has an FDA-approved indication for JIA.

Infliximab is a chimeric IgGl monoclonal antibody that binds to soluble and bound TNF-α.[22] Methotrexate typically is given with it to suppress antibody production against the mouse-derived portion of the molecule. Qualified healthcare personnel must be present during the infliximab infusion to respond to infusion-related reactions, if they occur (rash, urticaria, flushing, headache, fever, chills, nausea, tachycardia, dyspnea). These reactions may be treated by: (a) temporarily discontinuing the infusion, (b) slowing the infusion rate, or (c) administering corticosteroids or antihistamines. Patients may be pretreated with corticosteroids or antihistamines if they continue to experience infusion reactions. Infliximab was shown in clinical trials to be effective for treatment of JIA, but it has not yet received FDA approval for this indication.

Golimumab is a human monoclonal antibody that binds to membrane-bound and soluble TNF.[22] Golimumab can be administered in combination with methotrexate in patients with moderate to severe RA. One advantage of this agent over others in the class may be the once-monthly SC dosing or every-other-month IV dosing. Golimumab is not FDA approved for use in JIA.

Certolizumab is a humanized antibody Fab fragment conjugated to polyethylene glycol, which delays its metabolism and elimination.[22] Certolizumab can be administered alone or in combination with methotrexate in patients with moderate to severe RA. Certolizumab is not FDA approved for use in JIA.

**Interleukin-1 Receptor Antagonist** Anakinra is a recombinant form of human IL-1 receptor antagonist.[22] Anakinra inhibits the activity of IL-1 by binding to it and preventing cell signaling. It is indicated for adults with RA who have failed one or more csDMARDs. It may be used in combination with other csDMARDs in patients not responding to or unable to tolerate csDMARDs or TNF antagonists. Anakinra is not included in the 2012 treatment algorithms due to limited efficacy and infrequent use in RA. Regarding treatment of JIA, anakinra is recommended in the ACR treatment guidelines for patients with systemic arthritis with continued disease activity after a trial with 3 months of methotrexate or leflunomide, a 1-month trial of NSAID monotherapy, or a glucocorticoid injection.[17] Anakinra is not FDA approved for the treatment of JIA.

**Costimulation Modulators** Abatacept interferes with T-cell signaling, ultimately blocking T-cell activation and leading to anergy, or lack of response to an antigen.[22] Abatacept is indicated as monotherapy or in combination with nonbiologic DMARDs following inadequate response to methotrexate or anti-TNF agents. Abatacept is FDA approved for the treatment of moderate to severe JIA; it is recommended as an option for patients who did not respond to an adequate trial of methotrexate, leflunomide, or anakinra.[17]

**Anti-CD20 Monoclonal Antibody** Rituximab is a genetically engineered chimeric anti-CD20 monoclonal antibody that causes B-lymphocyte depletion in bone marrow and synovial tissue.[22] The exact role of rituximab in RA is not clearly defined, but it is indicated for patients with moderate to severe active RA and a history of inadequate response to one or more TNF antagonist therapies. Patients with rheumatoid factor positive RA tend to respond more favorably to rituximab than patients with rheumatoid factor negative disease. Rituximab carries a black-box warning of fatal infusion reactions and severe mucocutaneous reactions, even though these events did not occur during the RA clinical trials. The benefits of rituximab must be tempered against the safety concerns reported with use of rituximab in the oncology setting. Rituximab may be used in the treatment of JIA, though its place in therapy is not clear and the medication is not FDA approved for this purpose.[17]

**Anti–interleukin-6 Receptor Antibody** Interleukin-6 (IL-6) production is increased in patients with RA. High levels are indicative of joint damage and disease activity. In addition, IL-6 plays a significant role in the pathogenesis of anemia associated with RA.[23] Tocilizumab, an anti–IL-6 receptor monoclonal antibody, inhibits the binding of IL-6 to the IL-6 receptor.[23] Studies in patients not responding to methotrexate or TNF antagonists have demonstrated decreased disease activity and improved function and quality of life in patients with RA. In the 2012 recommendations, tocilizumab is considered after inadequate response or adverse event to anti-TNF agents, abatacept, or rituximab.[19] Tocilizumab is FDA approved for the treatment of JIA; it is recommended for patients with inadequate response to glucocorticoid monotherapy, methotrexate, leflunomide, or anakinra.[17]

### ▶ *Targeted Synthetic DMARDs (tsDMARDs)*

Tofacitinib selectively inhibits Janus kinases, with greatest affinity for JAK3.[24] Tofacitinib is indicated for the treatment of moderate to severe RA as monotherapy or in combination with csDMARDs. Combination administration with boDMARDs is inappropriate due to increased safety concerns. One distinct advantage of tofacitinib over boDMARDs is the oral dosage form. The exact place in therapy of tofacitinib is in the management of RA is not yet known. Presently, it may be initiated if a patient does not have an adequate response to or is otherwise unable to receive csDMARDs or boDMARDs.[24]

### ▶ *Selecting Disease-Modifying Therapy*

Table 57–4 highlights dosing, safety, monitoring, and patient counseling information for the common DMARDs. Developments in the treatment of RA are tempered by the lack of long-term safety and efficacy data for boDMARDs. In addition, high

**Table 57–4**

**FDA-Approved DMARDs for Treatment of RA**

| Drug | Doseª | Time to Effect (weeks) | ADRs | Dosing in Hepatic Impairment | Dosing in Renal Impairment | Monitoring | Counseling Points |
|---|---|---|---|---|---|---|---|
| **Conventional Synthetic DMARDs (csDMARDs)** | | | | | | | |
| Methotrexate | Adults: 7.5–20 mg orally or IM once weekly<br>Polyarticular-course JIA: Recommended starting dose: 10 mg/m² oral, IM, or SC once weekly; usual max dose: 20 mg/m² once weekly | 4–8 | N, D, hepatotoxicity, alopecia, new-onset cough or SOB, MYL | CI | CrCl (mL/min)ᵇ:<br>61–80: 75% of dose<br>51–60: 70% of dose<br>10–50: 50% of dose<br>Less than 10: Avoid use | CBC, creatinine, LFTs every 4–8 weeks; monitor for signs of infection | Use of folic acid concomitantly<br>Avoid alcohol<br>Use contraception if childbearing potential |
| Hydroxychloroquine | Adults: 200 mg orally twice daily | 8–24 | N, D, HA, vision changes, skin pigmentation | Use with caution | No change | Eye examination every 12 months | |
| Sulfasalazine | Adults: 1000 mg orally two to three times daily<br>Polyarticular-course JIA: Initial: 10 mg/kg/day orally; increase weekly by 10 mg/kg/day; usual dose: 30–50 mg/kg/day orally in two divided doses; max 2 g/day | 8–12 | N, D, rash, yellow-orange discoloration, photosensitivity, MYL | Avoid use | CrCl (mL/min)ᵇ:<br>10–30: Give twice daily<br>Less than 10: Give once daily | CBC every 2–4 weeks for 3 months, then every 3 months | Sunscreen use |

| Tofacitinib (Xeljanz) | Adults: 5 mg orally twice daily | | Infection, headache, HTN, elevated LFTs, D, worsening lipid profile | Mild impairment: no adjustment<br>Moderate: 5 mg once daily<br>Severe: Use not recommended | Mild: no adjustment;<br>Moderate/severe: 5 mg once daily | CBC, Hgb, lipids, LFTs, monitor for infection | |

CBC, complete blood count; CI, contraindicated; D, diarrhea; HA, headache; Hgb, hemoglobin; HTN, hypertension; IR, infusion reactions; ISR, injection site reactions; LFTs, liver function tests; MYL, myelosuppression (watch for fever, symptoms of infection, easy bruisability, and bleeding); N, nausea; SC, subcutaneous injection; SOB, shortness of breath.

[a]Geriatric patients should receive the usual adult dose unless renal or hepatic impairment is present. Pediatric doses are provided for drugs that have FDA-approved indications for juvenile idiopathic arthritis (JIA).

[b]To convert to SI units of mL/s, multiply by 0.0167.

Data From Refs. 1, 2,19,22, and 25.

costs can be a deterrent to use. Cost analyses may indicate that the increased expenses associated with these boDMARDs are offset by the costs avoided for treatment of advanced RA. **KEY CONCEPT** *The risk of infection in patients treated with boD-MARDs must be considered when selecting and monitoring therapy.*[19,26] Influencing the immune response to reduce symptoms of RA may influence the body's response to pathogens. Of particular concern is use of TNF antagonists in patients with a history of tuberculosis exposure. TNF is important in the formation of granulomas that wall off tuberculosis infection. In theory, if TNF is inhibited, patients with latent tuberculosis may have a reactivated infection. Etanercept appears to have the lowest incidence rate of tuberculosis when compared with other TNF antagonists.[22] Patients receiving any boDMARD agent should be screened for tuberculosis and other infections (hepatitis B, hepatitis C). Antituberculosis therapy should be initiated in patients with active or latent tuberculosis.[19] Patients with active tuberculosis should receive the full course of antituberculosis treatment prior to initiating boDMARDs. If there is latent infection, boDMARD therapy may be initiated after at least 1 month of antituberculosis treatment. Patients with untreated hepatitis B should not receive boDMARDs. Etanercept may be a potential treatment option in patients with RA and concomitant hepatitis C.[19] boDMARDs should not be initiated during an acute, serious infection and should be discontinued temporarily during times of infection. boDMARD therapy can be continued during nonserious infections.[27] Concomitant use of two boDMARDs or tsDMARD plus boDMARD is contraindicated due to increased infection risk.

▶ *Fertility, Pregnancy, and Fetal Development*

Women of childbearing potential should be counseled about the impact of antirheumatic drugs on fertility, pregnancy, fetal development, and lactation. Some women may experience a reduction in disease symptoms during pregnancy; however, many agents used to treat RA are known teratogens. In addition, some women may present with signs and symptoms of RA for the first time during the postpartum period. Women desiring motherhood must consult with their physicians to carefully plan for the pregnancy and reduce risks to the developing fetus.[28] Treatment plans selected must also consider the potential effects on breast-feeding babies. Low-dose corticosteroids generally are safe and effective. Certain NSAIDs, hydroxychloroquine, and azathioprine may be considered in severe disease.

Methotrexate use (FDA Pregnancy Category X) is associated with spontaneous abortion, fetal myelosuppression, limb defects, and CNS abnormalities; therefore, pregnancy must be avoided.[28] Methotrexate should be discontinued 3 months prior to attempting conception. Sulfasalazine, on the other hand, may be the drug of choice in women who are pregnant or planning to become pregnant due to its safety profile.[28] There is limited data on safety of boDMARD use in pregnant women. Case reports of pregnancy during boDMARD therapy show no increased risk of fetal toxicity, but long-term data are needed.[28] Based on available data, TNF antagonists are considered safe until the time of conception, and discontinuation during pregnancy is recommended. Rituximab should be discontinued 1 year prior to planned conception. Abatacept should be discontinued 10 weeks prior to planned conception.[28]

Male patients with RA must receive counseling about the effects of certain medications on their fertility and potential harm to the fetus. It is difficult to establish causality between use of a medication by a male and the effect on fertility or fetal development; therefore, a conservative approach must be taken. **KEY CONCEPT** *Women of childbearing potential and their partners must be counseled to: (a) use proper birth control while undergoing treatment for RA, and (b) involve health care providers in discussions regarding family planning to carefully consider all treatment options.*[28]

## Patient Encounter, Part 2: Medical History, Physical Examination, and Laboratory Tests

**PMH:** Hypertension (20 years), dyslipidemia (20 years), depression (5 years), diabetes (15 years), rheumatoid arthritis (10 years)

**FH:** Mother died age 70 from MI, also had RA, DM, HTN, dyslipidemia; father died age 82 from lymphoma

**SH:** Retired but owns a small business. She is a seamstress and relies heavily on her hands for the work of the business. She drinks alcohol occasionally and smokes a half pack of cigarettes daily.

**Allergies:** aspirin, penicillin

**Meds:** Lisinopril 10 mg once daily; hydrochlorothiazide 25 mg once daily; simvastatin 40 mg once daily; metformin 500 mg twice daily; paroxetine 20 mg once daily; methotrexate 15 mg orally once weekly; adalimumab 40 mg SC every other week; folic acid 1 mg daily; fish oil 1 g daily

**Previous Meds:** Etanercept, metoprolol, pravastatin

**ROS:** (+) Fatigue, (–) N/V/D, HA, SOB, chest pain, cough

**PE:**

**VS:** BP 186/92, P 86, RR 22, T 38.0°C (100.4°F); Ht 5′2″ (157 cm), Wt 75 kg (165 lb)

**Skin:** Warm, dry

**HEENT:** NC/AT, PERRLA, TMs intact

**CV:** RRR, normal S1 and S2, no m/r/g

**Chest:** CTA

**Abd:** Soft, NT/ND

**Neuro:** A&O × 3; CN II to XII intact

**Ext:** Bilateral tender and swollen PIPs and MCPs

**Labs:** ESR 65 mm/hour, RF (+), HLA-DR4 (+), ACPA (high +)

**Synovial fluid analysis:** Yellow, cloudy, decreased viscosity

**Hand x-rays:** Soft-tissue swelling, joint space narrowing, evidence of erosions

**Disease Activity Score 28 (DAS-28):** 6.63

*How would you categorize this patient's disease activity—low, moderate, or high? Why? How does this affect your treatment plan?*

*What nonpharmacologic and pharmacologic alternatives are appropriate for this patient?*

## OUTCOME EVALUATION

- Rheumatologists rely on standardized criteria to assess treatment interventions through measurement of disease activity. The ACR uses criteria for improvement based on percentage improvement in tender and swollen joint count and the presence of at least three or more of the following measures: (a) pain, (b) patient global assessment, (c) physician global assessment, (d) self-assessed physical disability, and (e) acute-phase reactants.[29] ACR20, ACR50, and ACR70 are common efficacy endpoints in clinical trials. The number corresponds with the percentage improvement. As drug development continues to evolve, the acceptable criteria for 20% improvement may be too low.

- Common tools to assess disease activity in patients with RA include Patient Activity Scale, Clinical Disease Activity Index, Simplified Disease Activity Index, and Disease Activity in 28 joints (DAS-28).[19] Components involved in the calculation are the number of swollen and tender joints, ESR or CRP, and a subjective measure of the patient's general health. A DAS-28 score of 3.2 or less indicates low disease activity, between 3.2 and 5.1 is considered moderate activity, and 5.1 or more is considered to be high activity. Remission as defined by DAS-28 is a score of less than 2.6.[19]

- Physical disability from RA can be measured through the Stanford Health Assessment Questionnaire (HAQ).[30,31] This patient self-assessment tool was developed to evaluate patient outcomes in five dimensions of chronic conditions: (a) disability, (b) discomfort, (c) drug adverse effects, (d) dollar costs, and (e) death. Clinicians and clinical studies in

## Patient Care Process

**Patient Assessment:**

- Determine whether physical examination findings and patient-reported symptoms are consistent with RA. Evaluate the duration of symptoms and impact on daily living.

- Review the medical history. Does the patient have comorbidities that should also be addressed? Are features of poor prognosis present?

- Review laboratory test results to establish baseline hepatic function, renal function, and blood cell status.

**Therapy Evaluation:**

- Conduct a medication history and review patient allergies. Are any of the medications causing the noted signs or symptoms?

- If the patient is already receiving pharmacotherapy for RA, assess efficacy, safety and patient adherence.

- Determine whether the patient has prescription coverage. If not, determine if the patient is eligible for prescription assistance programs.

**Care Plan Development:**

- Educate the patient on nonpharmacologic measures to improve symptoms.

- If the patient is newly diagnosed with RA, make sure s/he receives DMARD therapy immediately to minimize disease progression and joint destruction.

- Select DMARD therapy that is likely to be safe and effective. (see Figures 57–1 and 57–2)

- Ensure that drug doses are optimal (see Table 57–4).

- Screen for tuberculosis if initiation of a boDMARD is under consideration.

- Stress the importance of adherence with medications and laboratory monitoring.

- Evaluate the presence of comorbidities and implement measures to control the increased risk.

  - *Cardiovascular*: Keep doses of NSAIDs and glucocorticoids low; consider initiating folic acid, low-dose aspirin, and/or statin therapy, and encourage smokers to discontinue tobacco use.[13,14] Screen and aggressively treat elevated blood pressure.

  - *Infection*: Inform the patient to wash hands routinely, limit contact with individuals who are ill, and report signs and symptoms of infection immediately (eg, fever, weight loss, and night sweats).

  - *Malignancy*: Have the patient report new signs and symptoms (eg, fever, chills, anorexia, and night sweats) immediately.

  - *Osteoporosis*: Encourage the patient to ingest adequate amounts of calcium and vitamin D; consider initiating medications for osteoporosis if the patient is taking glucocorticoids chronically or has evidence of low bone mineral density.[32]

**Follow-Up Evaluation:**

- Assess the patient's response to initiation of DMARD therapy after allowing adequate time for the medication to achieve its therapeutic effect.

- Determine whether any adverse reactions to antirheumatic medication are present.

- Monitor laboratory parameters to ensure patient safety and reduce the risk of adverse reactions.

- Longitudinally evaluate the patient's clinical response to therapy and the impact on quality of life and mobility.

- Assess patient understanding of RA and medications they are taking. Provide additional education where appropriate.

rheumatology use the HAQ to assess longitudinal changes that influence the patient's quality of life.[30,31]

- Before starting treatment for RA, assess the subjective and objective evidence of disease. For joint findings, this includes the number of tender and swollen joints, pain, limitations on use, duration of morning stiffness, and presence of joint erosions. Systemic findings may include fatigue and the presence of extraarticular manifestations. Obtain laboratory measurements of CRP and ESR. The impact of the disease on quality of life and functional status is also important.

- At follow-up visits, compare the patient's status to baseline or previous visits using standardized criteria for improvement of disease activity and the influence on quality of life.

- **KEY CONCEPT** *In addition to designing an individualized therapeutic regimen to control the progression of RA, the clinician must evaluate the presence of comorbidities and implement measures to control the increased risk.*

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| ACPA | Anticitrullinated protein antibodies |
| ACR | American College of Rheumatology |
| boDMARD | Biological originator DMARD |
| bsDMARD | Biosimilar DMARD |
| COX-2 | Cyclooxygenase-2 |
| CRP | C-reactive protein |
| csDMARD | Conventional synthetic DMARD |
| DAS | Disease Activity Score |
| DMARD | Disease-modifying antirheumatic drug |
| ESR | Erythrocyte sedimentation rate |
| EULAR | European League against Rheumatism |
| HAQ | Health Assessment Questionnaire |
| HLA | Human leukocyte antigen |
| IL | Interleukin |
| JIA | Juvenile idiopathic arthritis |
| MCP | Metacarpophalangeal joint |
| MTP | Metatarsophalangeal joint |
| NSAID | Nonsteroidal anti-inflammatory drug |
| PIP | Proximal interphalangeal joint |
| RA | Rheumatoid arthritis |
| TNF | Tumor necrosis factor |
| tsDMARD | Targeted synthetic DMARD |

# Osteoarthritis

Nicholas Carris, Steven M. Smith, and John G. Gums

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Explain the pathophysiologic mechanisms involved in the development of osteoarthritis (OA).
2. Identify risk factors associated with OA.
3. Recognize the clinical presentation of OA.
4. Determine the goals of therapy for individual patients with OA.
5. Formulate a rational nonpharmacologic plan for patients with OA.
6. Recommend a pharmacologic plan for treating OA, taking into consideration patient-specific factors.
7. Develop monitoring parameters to assess effectiveness and adverse effects of pharmacotherapy for OA.
8. Modify an unsuccessful treatment strategy for OA.
9. Deliver effective patient counseling, including lifestyle modifications and drug therapy, to facilitate effective and safe management of OA.

## INTRODUCTION

**KEY CONCEPT** *O*steoarthritis *(OA) is the most common form of arthritis and is strongly related to age. Its incidence and cost of care will increase dramatically in the coming years due to a burgeoning senior citizenry.* Weight-bearing joints (eg, hips and knees) are most susceptible, but non–weight-bearing joints, especially the hands, also may be involved. Because of its high prevalence and involvement of joints critical for daily functioning, the disease causes tremendous morbidity and financial burden.[1] OA is the leading cause of chronic mobility disability and the most common reason for total-hip and total-knee replacement.[2]

## EPIDEMIOLOGY AND ETIOLOGY

Globally, the age-standardized prevalence of knee and hip OA is at least 3.8% and 0.85%, respectively. High-income countries, which generally have older populations, have a higher prevalence than low-income countries.[3] The National Arthritis Data Workgroup estimates that 27 million Americans have signs and symptoms of OA.[4] Approximately 7% of US adults have daily symptomatic hand OA, whereas 6% and 3% report daily symptoms affecting the knees and hips, respectively.[4] After age 60, 10% to 17% of persons report such symptoms.[4]

The prevalence of OA is greater in women by 1.5- to 2-fold, and they tend to have more generalized disease. Women are also more likely to have inflammation of the proximal and distal interphalangeal joints of the hands, which manifest as **Bouchard nodes** and **Heberden nodes**, respectively. OA of the hip occurs more frequently in men.

The prevalence of OA in whites is similar to that in African Americans, but the latter may experience more severe and disabling disease. Persons of Chinese descent rarely have hip OA; they also are less likely to develop hand OA but more likely to develop knee OA.

## PATHOPHYSIOLOGY

OA is characterized by damage to **diarthrodial** joints and joint structures (**Figure 58–1**). The pathophysiology is multifactorial and typified by progressive destruction of joint cartilage, erratic new bone formation, thickening of **subchondral** bone and the joint capsule, bony remodeling, development of **osteophytes**, variable degrees of mild **synovitis**, and other changes.[5]

The earliest stages of OA are characterized by increasing water content and softening of cartilage in weight-bearing joints. As the disease progresses, **proteoglycan** content of cartilage declines, and eventually, cartilage becomes hypocellular. Protease enzymes proliferate before changes in cartilage, suggesting that catabolic proteinases play an important role in the initiation and progression of OA.

Subchondral bone undergoes metabolic changes, including increased bone turnover, that appear to be precursors to tissue destruction. The normally contiguous bony surface becomes fissured. Persistent use of the joint eventually results in loss of cartilage, permitting bone-to-bone contact that ultimately promotes thickening and **eburnation** of exposed bone. Microfractures may appear in subchondral bone, and **osteonecrosis** may develop beneath the surface especially in individuals with advanced disease.

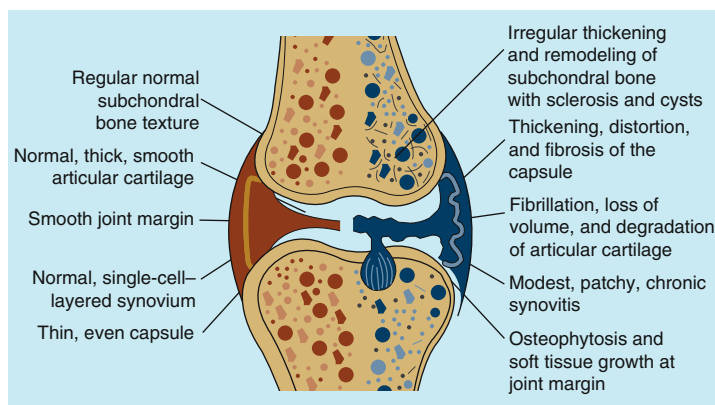
New bone is formed haphazardly, leading to the formation of osteophytes that extend into the joint capsule and ligament attachments and may encroach on the joint space. Progressive loss of joint cartilage, subchondral damage, narrowing of joint spaces, and changes in the underlying bone and soft tissues may culminate in deformed, painful joints.


**FIGURE 58–1.** Characteristics of osteoarthritis in the diarthrodial joint. (From DiPiro JT, Talbert RL, Yee GC, et al., [eds.] Pharmacotherapy: A Pathophysiologic Approach, 8th ed. New York: McGraw-Hill; 2011:1601, Fig. 101–2; With permission.)

## Classification

OA can be classified as primary (idiopathic) or secondary. *Primary OA* is the predominant form and occurs in the absence of a known precipitating event. Primary OA may assume a localized, generalized, or erosive pattern. Localized OA is distinguished from generalized disease by the number of sites involved. Erosive disease is characterized by an erosive pattern of bone destruction and marked proliferation of interphalangeal joints of the hands. Secondary OA results from congenital or developmental disorders or inflammatory, metabolic, or endocrine diseases.

## Risk Factors

OA develops when systemic factors and biomechanical vulnerabilities combine. Systemic factors include age, gender, genetic predisposition, and nutritional status. Age is the strongest predictor of OA, although advanced age alone is insufficient to cause OA.

Joints exposed to biomechanical factors are at increased risk. Occupational and recreational activities involving repetitive motion or injury can provoke OA, although most daily activities do not produce enough joint trauma to cause OA, even after decades of repeated use. However, daily activities may lead to OA if a joint is susceptible because of previous injury, joint deformity, muscle weakness, or systemic factors. Heavy physical activity is a stronger predictor of subsequent OA than light-to-moderate activities, especially for older individuals, in whom the joint structure is less capable of coping with highly stressful activities.[6] Obesity increases load-bearing stresses on hip and knee joints. The risk of OA increases by 10% for each kilogram of body weight above ideal body weight.[7]

## CLINICAL PRESENTATION AND DIAGNOSIS

See the accompanying text box for the clinical presentation of OA. No laboratory tests are specific for diagnosing OA. The erythrocyte sedimentation rate (ESR) and hematologic and chemistry panels are usually unremarkable. Synovial fluid aspirated from an affected joint should be sterile, without crystals, and with a WBC count less than $1.5 \times 10^3/mm^3$ ($1.5 \times 10^9/L$).

---

## Clinical Presentation of OA

**General**

- Patients usually are more than 50 years old.
- Presentation may range from asymptomatic to severe joint pain and stiffness with functional limitations.
- Joint involvement has an asymmetric local distribution without systemic manifestations.
- In contrast to some other arthritic conditions (eg, rheumatoid arthritis, gout), inflammation usually is absent or mild and localized when present.

**Symptoms**

- **KEY CONCEPT** *The most common symptoms are joint pain, reduced range of motion, and brief joint stiffness after periods of inactivity.*
- The cardinal symptoms are use-related joint pain, typically described as deep and aching in character, and stiffness. In advanced cases, pain may be present during rest.
- Weight-bearing joints may be unstable.

- Joint stiffness ("gelling") abates with motion and recurs with rest.
- Joint stiffness generally lasts less than 30 minutes after periods of inactivity, limits the range of joint motion, impairs daily activities, and may be related to weather.

**Signs**

- One or more joints may be involved, usually in an asymmetric pattern.
- The following sites are most often involved in primary OA:
  - Distal interphalangeal finger joints (Heberden nodes)
  - Proximal interphalangeal finger joints (Bouchard nodes)
  - First carpometacarpal joint
  - Knees, hips, and cervicolumbar spine
  - Metatarsophalangeal joint of the great toe
- Joint examination may reveal local tenderness, bony proliferation, soft tissue swelling, crepitus, muscle atrophy, limited motion with passive/active movement, and effusion.

Radiographic changes are often absent in early OA. As the disease progresses, joint-space narrowing, subchondral bone sclerosis, and osteophytes may be detected. Gross joint deformity and joint effusions may occur in late severe OA.

## TREATMENT
### Desired Outcomes

KEY CONCEPT *Goals of therapy include: (a) educating the patient and caregivers, (b) relieving pain, (c) maintaining or restoring mobility, (d) minimizing functional impairment and associated adverse outcomes (eg, falls), (e) preserving joint integrity, and (f) improving quality of life.*

### General Approach to Treatment

Treatment is individualized considering medical history, physical examination, radiographic findings, distribution and severity of joint involvement, and response to previous treatment. Comorbid diseases, concomitant medications, and allergies are integrated into a holistic treatment approach.

As shown in the treatment algorithm for OA (Figure 58–2), nonpharmacologic treatment is integral to achieving optimal outcomes. Pharmacologic therapy is an adjunctive measure to relieve pain; current treatments do not substantially modify the disease course. Surgical intervention generally is reserved for patients with advanced disease complicated by unremitting pain or severely compromised function.

### Nonpharmacologic Therapy

KEY CONCEPT *Nonpharmacologic therapy is the cornerstone of treatment: education, exercise, weight loss, and cognitive behavioral intervention are integral components.*

Educational programs include systematic educational activities designed to improve health behaviors and health status, thereby slowing OA progression. The goal is to increase patient knowledge and self-confidence in adjusting daily activities in the

### Patient Encounter, Part 1

A 67-year-old obese African American man presents to his primary care physician with right knee pain that has significantly worsened over the past several years. He describes the pain as dull and achy, and it is most severe in the morning after awakening until he "loosens up" 10 to 15 minutes later. He believes the morning stiffness is related to a previous knee surgery for his torn meniscus. He also reports feeling "down" because he is no longer able to play golf with his friends due to his knee pain. He is a retired store clerk in a position that required him to be on his feet for long hours in addition to lifting heavy boxes.

*What information is suggestive of osteoarthritis (OA)?*

*What risk factors for OA does this patient have?*

*What cultural or ethnic factors may contribute to his OA?*

*What other information will you need to differentiate OA from rheumatoid arthritis (RA)?*

*What potential comorbidities should be considered in this patient?*

*What other information will be required before formulating a treatment plan?*

face of evolving symptoms. Effective programs produce positive behavioral changes, decreased pain and disability, and improved functioning. In addition to physical outcomes, psychological outcomes such as depression, self-efficacy, and life satisfaction are positively influenced. Patients can be referred to the Arthritis Foundation (www.arthritis.org) for educational materials and information on support groups.

Lifestyle modification should be encouraged for all patients at risk for and with established OA. Low-impact exercise is advisable for most patients, especially those with knee or hip OA. Aerobic exercise and strength-training programs improve functional capacity in older adults with OA. Stretching and strengthening exercises should target affected and vulnerable joints. Isokinetic and isotonic exercises performed at least three to four times weekly improve physical functioning and decrease disability, pain, and analgesic use.

Obesity's association with both the onset and progression of OA make weight loss a pivotal treatment goal in overweight and obese patients. Women who reduce body weight by 5 kg (11 lb) can cut their risk of developing OA in half. Moreover, symptomatic relief and improved quality of life occur in people with knee OA who lose weight. Weight loss should be pursued through a combination of dietary modification and increased physical activity (see Chapter 102, Overweight and Obesity). The patient's physical capabilities should be considered when implementing an exercise program.

Application of heat or cold to involved joints improves range of motion, reduces pain, and decreases muscle spasms. Applications of heat include warm baths or warm water soaks. Heating pads should be used with caution, especially in the elderly, and patients must be warned of the potential for burns if used inappropriately.

Referral to a physical or occupational therapist may be helpful, particularly in patients with functional disabilities. Physical therapy is tailored to the patient and may include assessment of muscle strength, joint stability, and mobility; use of heat (especially prior to episodes of increased physical activity); structured exercise regimens; and assistive devices such as canes, crutches, and walkers. The occupational therapist ensures optimal joint protection and function, energy conservation, and advice on use of splints and other assistive devices.

### Pharmacologic Therapy

Simple analgesics such as acetaminophen and nonsteroidal anti-inflammatory drugs (NSAIDs) are first-line agents for treating OA (Table 58–1).

#### ▶ Acetaminophen

Acetaminophen is a centrally acting analgesic that inhibits prostaglandin production in the brain and spinal cord. KEY CONCEPT *Acetaminophen is an effective and inexpensive analgesic with a favorable risk–benefit profile. For treatment of mild-to-moderate pain, acetaminophen should be tried initially at an adequate dose and duration before considering an NSAID.*[8–11] Acetaminophen is generally considered to be as effective as NSAIDs for mild-to-moderate joint pain with a more favorable adverse effect profile.[11]

Acetaminophen should be administered initially on an as-needed basis in daily doses up to 4 g. Single doses should not exceed 1 g. Some patients may require scheduled dosing to achieve adequate pain relief. Periodic assessment of pain control should be performed to maintain the lowest effective dose. A common reason for an inadequate response to acetaminophen is failure

**FIGURE 58–2.** Treatment of osteoarthritis. (OA, osteoarthritis; CV, cardiovascular; IA, intraarticular; NSAID, nonsteroidal anti-inflammatory drug.)

| Table 58-1 | | |
|---|---|---|
| **Dosing Parameters of Agents Commonly Used to Treat OA** | | |
| **Medication** | **Dosage and Frequency** | **Maximum Dosage (mg/day)** |
| **Oral Analgesics** | | |
| Acetaminophen | 325 mg every 4–6 hours or 1 g every 6–8 hours | 4000 (consider all products utilized containing acetaminophen) |
| Tramadol | 50–100 mg every 4–6 hours | 400 (300 in elderly) |
| | CrCl < 30 mL/min (0.50 mL/s): 50–100 mg every 12 hours | 200 |
| Oxycodone | 5–15 mg every 4–6 hours (initial dose for opioid naive) | Dependent on degree of opioid tolerance and patient response |
| **Serotonin-Norepinephrine Reuptake inhibitors** | | |
| Duloxetine | 30–60 mg once daily | 60 |
| **Intraarticular Steroid Injection** | | |
| Triamcinolone hexacetonide | 2–6 mg Smaller joints; 10–20 mg Larger joints | No more often than every 3 months |
| Methylprednisolone acetate | Small joints 4–10 mg; Medium joints 10–40 mg; Large joins 20–80 mg | No more often than every 3 months |
| **Oral NSAIDs by Chemical Class** | | |
| *Carboxylic acid (salicylates)* | | |
|    Aspirin | 325–650 mg every 4–6 hours | 3600[a] |
|    Salsalate | 500–1000 mg two to three times daily | 3000[a] |
| *Acetic acid* | | |
|    Etodolac | 300–600 mg twice daily | 1200 |
| | 400–1000 mg once daily (extended-release) | |
|    Diclofenac | 50 mg two to three times daily | 150 |
| | 75 mg twice daily (delayed-release tablets) | |
| | 100 mg once daily (extended-release tablets) | |
| | 35 mg three times daily (submicron particle capsules) | |
|    Indomethacin | 25 mg two to three times daily | 200 |
| | 75 mg one to two times daily (sustained-release) | |
|    Nabumetone | 500–1000 mg one to two times daily | 2000 |
| *Propionic acid* | | |
|    Ibuprofen | 400–800 mg three to four times daily | 3200 |
|    Naproxen | 250–500 mg two times daily | 1500 |
| | 750–1000 mg once daily (controlled-release) | |
| | 275–550 mg two times daily (naproxen sodium) | 1650 |
| *Enolic acid* | | |
|    Meloxicam | 7.5–15 mg once daily | 15 |
|    Piroxicam | 20 mg once daily | 20 |
| *Coxibs* | | |
|    Celecoxib[c] | 100 mg twice daily or 200 mg once daily | 200 |
| **Topical Analgesics** | | |
| Capsaicin 0.025% or 0.075% cream | Apply to affected joint every 6–8 hours | |
| Diclofenac sodium 1% gel | Upper extremity joints: 2 g four times daily; | 8 g[b] |
| | Lower extremity joints: 4 g four times daily | 16 g[b] |
| Diclofenac sodium 1.5% solution | 40 drops per affected knee, four times per day | |
| Diclofenac sodium 2% solution | 40 mg (2 pump actuations) on each painful knee, two times a day | |
| **Dietary Supplements** | | |
| Glucosamine sulfate | 500 mg three times daily or 1500 mg once daily | |
| Chondroitin | 400–800 mg three times daily with glucosamine | |

CrCl, creatinine clearance.

[a]Serum salicylate levels should be monitored for doses greater than 3 g/day.

[b]Total daily dose of diclofenac 1% gel should not exceed 32 g for all affected joints.

[c]Celecoxib is a substrate for CYP2C9, and a 50% reduction in the initial dose should be considered in known or suspected poor metabolizers.

to use a sufficient dose for an adequate duration. A sufficient trial is defined as up to 4 g daily in divided doses for 4 to 6 weeks.

Despite being one of the safest analgesics, acetaminophen can cause significant adverse effects, including hepatic and renal toxicity.[12] Acetaminophen overdose, both intentional and unintentional, is the leading cause of acute liver injury in the United States.[13] Doses greater than 4 g are associated with an increased risk of hepatotoxicity. Total daily doses of 4 g have been associated with significant liver enzyme elevations, but such elevations do not necessarily portend hepatotoxicity.[14] Concomitant use of alcohol may increase the risk of hepatic injury; a maximum acetaminophen dose of 2.5 g daily is recommended in patients who consume more than two to three alcoholic beverages per day. Acetaminophen does not appear to exacerbate stable, chronic liver disease; it can be used with caution and vigilant monitoring of liver function in this population.[12] Prior to developing an acetaminophen regimen, a careful inventory should be taken of all concomitant prescription medications and over-the-counter products to minimize the risk of inadvertent acetaminophen overdose.

Acetaminophen may worsen kidney function and increase blood pressure.[15,16] Nevertheless, acetaminophen remains the preferred oral analgesic for mild-to-moderate pain in patients with hypertension or kidney disease because of the greater risks associated with NSAID use.[17] Monitoring specifically for these adverse effects generally is unnecessary.

▶ *Nonsteroidal Anti-inflammatory Drugs*

Prostaglandins play an important role in the function of several organ systems. These compounds are synthesized via the interaction of two isoforms of the cyclooxygenase enzyme (COX-1 and COX-2) with their substrate, arachidonic acid.

The COX-1 enzyme is expressed constitutively in various body tissues (eg, gastric mucosa, kidney, and platelets). Prostaglandins produced by the actions of the COX-1 enzyme in the gastrointestinal (GI) tract preserve the integrity of the GI mucosa by increasing mucous and bicarbonate secretion, maintaining mucosal blood flow, and decreasing gastric acid secretion. Prostaglandins associated with COX-1 also promote normal platelet activity and function. In the kidney, COX-1–mediated prostaglandins dilate the afferent arteriole, thereby maintaining intraglomerular pressure and glomerular filtration rate when renal blood flow is reduced.

In contrast, the COX-2 enzyme is normally undetectable in most tissues, but its expression can be induced rapidly in the presence of inflammation and local tissue injury. This change leads to the synthesis of prostaglandins involved in pain and inflammation. Consequently, blocking the COX-2 enzyme is thought to result in analgesic and anti-inflammatory effects. All NSAIDs inhibit both the COX-1 and COX-2 enzyme isoforms, but nonselective NSAIDs (eg, ibuprofen, diclofenac, naproxen) are not particularly selective for one isoform over the other, whereas COX-2 inhibitors (ie, celecoxib) preferentially inhibit the COX-2 isoform.

**KEY CONCEPT** *NSAIDs are a reasonable first-line therapy in patients with moderate-to-severe OA; or, as adjunctive or alternative therapy when acetaminophen fails to provide an acceptable analgesic response.* NSAIDs significantly reduce pain and improve functioning in patients with OA, although individual responses can vary widely. Some clinicians recommend NSAIDs over acetaminophen for the initial treatment of severe pain or when signs and symptoms of inflammation are present. Results from comparative trials of acetaminophen and NSAIDs have been

equivocal, but consensus guidelines support the use of NSAIDs as an alternative to acetaminophen if clinical features of peripheral inflammation or severe pain are present.[8–10] Unfortunately, no validated mechanism exists to identify patients who are more likely to respond to NSAIDs than acetaminophen. The route of administration (ie, oral or topical) should be based on affected joint(s), patient preference, ability to administer, and an assessment of risk for adverse effects of systemic NSAIDs.

Topical administration of NSAIDs minimizes systemic exposure while providing pain relief comparable to that of oral NSAIDs, but topical NSAIDs are only appropriate for patients with OA of superficial joints, including hands, wrists, elbows, knees, ankles, and feet. Currently, the only commercially available topical NSAID in the United States is diclofenac, which comes in a variety of preparations, including a solution, gel, and topical patch. These products all decrease pain and improve joint function with no demonstrated superiority for any one product over others.[18–21] Systemic absorption of topical diclofenac is significantly less than that of oral diclofenac. Thus, GI, cardiovascular, and renal adverse effects are rare and similar in incidence to placebo with proper administration. The most common adverse effects include application site dermatitis, pruritus, and phototoxicity.

For patients with OA that affects deeper joints (eg, hip), or who have not achieved an adequate response to topical NSAIDs, an oral NSAID should be considered. **KEY CONCEPT** *At equipotent doses, the analgesic and anti-inflammatory activity of all oral NSAIDs, including COX-2–selective inhibitors, are similar.* The selection of a specific oral NSAID should be based on patient preference, previous response, tolerability, dosing frequency, cost, and considering underlying GI and cardiovascular risk. Some patients respond to one NSAID better than to another. If an insufficient response is achieved with one NSAID, another agent should be tried. Pain relief occurs rapidly (within hours) with these agents, but anti-inflammatory benefits are not realized until after 2 to 3 weeks of continuous therapy. This period is the minimal duration that should be considered an adequate NSAID trial.

**KEY CONCEPT** *All NSAIDs are associated with adverse GI, renal, hepatic, cardiovascular, CNS, and blood pressure effects, particularly in the elderly.* Inhibition of the COX-1 enzyme is thought to be responsible primarily for the adverse effects on the gastric mucosa, kidney, and platelets. Direct irritant effects also may contribute to adverse GI events. Minor GI complaints, including nausea, dyspepsia, anorexia, abdominal pain, flatulence, and diarrhea, are reported by 10% to 60% of patients treated with nonselective NSAIDs. Asymptomatic gastric and duodenal mucosal ulceration can be detected in 15% to 45% of patients.[22] Perforation, gastric outlet obstruction, and GI bleeding are the most severe complications and occur in 1.5% to 4% of patients annually.[22]

**KEY CONCEPT** *COX-2 inhibitors should be reserved for patients at high risk for GI complications and low risk for cardiovascular events* (Table 58–2).[23] Several risk factors predict a greater likelihood of GI complications in NSAID-treated patients (see Chapter 18, Peptic Ulcer Disease). Detecting high-risk patients based on symptoms alone is impractical because the presence of symptoms and actual gastroduodenal damage are poorly correlated. For patients at particularly high GI risk (eg, previous history of NSAID-induced GI bleed), a selective COX-2 inhibitor combined with a proton pump inhibitor reduces risk for GI bleeds compared to a selective COX-2 inhibitor alone, which in turn has lower risk for GI bleeds compared to a nonselective NSAID combined with a proton pump inhibitor.[24–26]

### Table 58–2

**Treatment Options Based on Cardiovascular and Gastrointestinal Risk**

|  | High CV Risk[a] | Low CV Risk |
|---|---|---|
| **High GI risk[b]** | NS-NSAID[c] plus gastroprotection[d] | COX-2[e] or NS-NSAID + gastroprotection[d] |
| **Low GI risk** | NS-NSAID[c] | NS-NSAID |

COX-2, selective cyclooxygenase-2 inhibitor; CV, cardiovascular; NS-NSAID, nonselective nonsteroidal anti-inflammatory drug.

[a]Low-dose aspirin indicated for prevention of cardiovascular event.

[b]History of complicated ulcer or > 2 of the following: Age > 65 years, high dose NSAID, prior uncomplicated ulcer, and current use of aspirin, corticosteroids, or anticoagulants.

[c]Naproxen may be considered initially due to potentially lower CV risk compared with other NS-NSAIDs.

[d]Gastroprotection with either a proton pump inhibitor (preferred) or misoprostol.

[e]A COX-2 inhibitor + gastroprotection can be recommended for patients at very high GI risk (eg, previous upper GI bleed attributable to NS-NSAID therapy).

Although selective COX-2 inhibitors reduce GI events, these agents have been associated with increased risk of cardiovascular events relative to many nonselective NSAIDs.[27–29] The pharmacologic basis for this finding is not fully understood, but multiple factors may be involved, including the degree of COX-2 selectivity, dosage and dosing schedule, and potency of agents.[27] Other mechanisms for increasing cardiovascular risk have been proposed for individual agents.[30] Large scale meta-analyses suggest that COX-2 inhibitors (including celecoxib) and, to a lesser extent, diclofenac and ibuprofen, have the strongest association with major vascular events (eg, stroke, myocardial infarction).[31,32]

In patients at risk for GI events and cardiovascular disease and requiring oral NSAID therapy, a nonselective NSAID plus a proton pump inhibitor is a reasonable option. Naproxen appears to have the lowest incremental cardiovascular risk of the nonselective NSAIDs and should generally be considered first in such patients.[32] Concomitant use of low-dose aspirin mitigates some of the increased cardiovascular risk of selective COX-2 inhibitors but also obliterates the GI safety of COX-2 selectivity.[33–35] Patients treated with a selective COX-2 inhibitor plus aspirin experience GI complications at a rate commensurate with that of patients given a nonselective NSAID. Use of NSAIDs that have more relative COX-2 inhibition but are not selective COX-2 inhibitors (eg, meloxicam) to avoid cardiovascular concerns with selective COX-2 inhibitors may not be justified because neither GI nor cardiovascular safety is optimized.[36]

All NSAIDs can cause renal insufficiency when administered to patients whose renal function depends on prostaglandins. Patients with chronic renal insufficiency or left ventricular dysfunction, the elderly, and those receiving diuretics or drugs that interfere with the renin–angiotensin system are particularly susceptible. These effects may result in decreased glomerular filtration, hyperkalemia, and sodium and water retention. Therefore, both nonselective NSAIDs and selective COX-2 inhibitors should be used with caution in patients with hypertension, heart failure, or chronic renal insufficiency. NSAIDs rarely cause **tubulointerstitial** nephropathy and renal papillary necrosis.

Caution is warranted in pregnant women and women of childbearing potential because the risk of bleeding may be increased if the fetus is subjected to the antiplatelet activity of NSAIDs. Most NSAIDs are Category C before 30 weeks of gestation. After that, all NSAIDs should be avoided because they may promote premature closure of the ductus arteriosus in the fetus.

Nonselective NSAIDs and selective COX-2 inhibitors are prone to drug interactions due to high protein binding, detrimental renal effects, and antiplatelet activity. Interactions are encountered frequently with aspirin, warfarin, oral hypoglycemics, antihypertensives (ie, angiotensin-converting enzyme [ACE] inhibitors, angiotensin receptor blockers [ARBs], β-blockers, diuretics), and lithium. When potential interactions are present, vigilant monitoring is warranted for therapeutic efficacy (eg, NSAIDs blunt the antihypertensive efficacy of diuretics) and adverse effects (eg, NSAIDs increase the risk of bleeding in anticoagulated patients).

#### ▶ Tramadol

Use of opioid analgesics may be warranted when pain is unresponsive to other pharmacologic agents or when such agents are contraindicated. Tramadol is an oral, centrally acting synthetic opioid analgesic that also weakly inhibits the reuptake of serotonin and norepinephrine. Tramadol effectively treats moderate pain but is devoid of anti-inflammatory activity. Tramadol is scheduled as a controlled substance (C-IV) in the United States due to its comparatively low abuse potential.

Tramadol is a reasonable option for patients with contraindications to NSAIDs or in those who have failed to respond to other oral therapies. The addition of tramadol to NSAIDs or acetaminophen may augment the analgesic effects of a failing regimen, thereby securing sufficient pain relief in some patients.[37] Moreover, concomitant tramadol may permit the use of lower NSAID doses. However, the increased risk for side effects associated with tramadol may offset the benefits.[37]

Dizziness, vertigo, nausea, vomiting, constipation, and lethargy are all relatively common adverse events. These effects are more pronounced for several days after initiation and following upward dose titration. Seizures have been reported rarely; the risk is dose-related and appears to increase with concomitant use of antidepressants, such as tricyclic antidepressants or selective serotonin reuptake inhibitors. Tramadol should be avoided in patients receiving monoamine oxidase (MAO) inhibitors due to the potential for serotonin syndrome.

#### ▶ Other Opioid Analgesics

Opioids decrease pain, improve sleep patterns, and increase functioning in patients with OA who are unresponsive to nonpharmacologic therapy and nonopioid analgesics. Evidence suggests that patients can achieve satisfactory analgesia by using nonescalating doses of opioids with minimal risk of addiction.[38] However, clinically significant improvement in pain that is nonresponsive to NSAIDs has only been demonstrated with stronger opioids. Oxycodone is the most extensively studied of the opioids recommended for OA. However, other agents such as morphine, hydromorphone, methadone, and transdermal fentanyl are also effective.[39]

Opioid analgesics should be reserved for patients who experience pain severe enough to require opioid treatment for which alternative treatment options are inadequate. Opioids also may be appropriate in patients with severe OA and conditions that preclude the use of NSAIDs, such as renal failure, heart failure, or anticoagulation.

Opioids should be initiated at low doses in combination with acetaminophen or an NSAID when possible. Combining opioids with other analgesics reduces the opioid requirement, thereby minimizing adverse events. However, use of combination opioid products containing acetaminophen should be accompanied by clear instructions to limit additional over-the-counter acetaminophen use. Conservative initial doses of opioids are warranted, with the dose titrated to the lowest dose achieving an adequate response while minimizing adverse effects. Even with these conservative strategies, adverse effects are common. In clinical trials, more than 80% of opioid-treated patients experienced at least one adverse event, compared with approximately 50% of placebo-treated patients.[39] Common or serious adverse effects include nausea, constipation, sedation, and respiratory depression (see Chapter 34, Pain Management).

If opioid therapy is considered, there should be an initial comprehensive medical history and physical examination, documentation that nonopioid therapy has failed, clearly defined treatment goals, an understanding between the provider and the patient of the true benefits and risks of long-term opioids, use of a single provider and pharmacy whenever possible, and comprehensive follow-up.

#### ▶ Duloxetine

Duloxetine, a serotonin/norepinephrine reuptake inhibitor (SNRI), is effective as adjunctive therapy for knee OA in patients achieving a suboptimal response to acetaminophen or oral NSAIDs alone.[40] Benefits typically are observed only after several weeks of therapy with moderate doses (ie, 60 mg/day); larger doses do not provide additional benefit.[41] Duloxetine may be the preferred adjunctive treatment in patients experiencing concurrent neuropathic and musculoskeletal pain. The most common adverse events are nausea, dry mouth, somnolence, constipation, decreased appetite, and hyperhidrosis.[41] Concomitant use with tramadol should be done cautiously owing to an increased risk of serotonin syndrome.

#### ▶ Intraarticular Therapy

Intraarticular therapies represent an alternative to oral agents for treatment of joint pain. This modality is usually reserved for patients unresponsive to other treatments because of the relative invasiveness of intraarticular injections compared with oral and topical drugs, the small risk of infection, and the cost of the procedure.

**Corticosteroids**  Use of systemic corticosteroids is discouraged in patients with OA. **KEY CONCEPT** *However, in a subset of patients with an inflammatory component or knee effusion, intraarticular corticosteroids can be useful as monotherapy or as an adjunct to analgesics.*[42] Corticosteroids with reduced solubility, such as methylprednisolone and triamcinolone, are usually preferred. The affected joint can be aspirated and subsequently injected with the corticosteroid. The aspirate should be examined for the presence of crystal formation and infection. Pain relief begins within days after the injection but may wane beyond 3 weeks. Injections should be done as infrequently as possible to avoid joint damage. Specifically, a single joint should not be injected more than three to five times per year to reduce the risk of corticosteroid-induced cartilage and joint damage. Given that the recommended dosing interval greatly exceeds the typical duration of action, these agents are rarely effective as monotherapy for chronic treatment of OA.

The crystalline nature of corticosteroid suspensions can provoke a postinjection flare in some patients. The ensuing flare mimics the flare of arthritis and inflammation that accompanies infection. Cold compresses and analgesics are recommended to treat symptoms in affected patients.

**Hyaluronic Acid**  The mechanism of action of hyaluronic acid is not fully understood. Healthy cartilage and synovial fluid are replete with hyaluronic acid, a viscous substance believed to facilitate lubrication and shock absorbency under varying conditions of load bearing. Patients with OA demonstrate an absolute and functional decline in hyaluronic acid; thus, exogenous administration is referred to as viscosupplementation.

Improvement in pain and joint function following intraarticular hyaluronic acid injections has been evaluated frequently in clinical trials, most of which were of low quality. Evidence is conflicting, but these agents appear to promote only modest improvements in pain and joint function. Consequently, hyaluronic acid is generally not recommended in current treatment guidelines.[43]

Several formulations of hyaluronic acid are available in the United States for treatment of knee OA. Administration typically consists of weekly injections for 3 to 5 weeks, depending on the specific product. Most injections are well tolerated, although some patients may report local reactions. Rarely, postinjection flares and anaphylaxis have been reported. Intra-articular injection is associated with a low risk of infection (approximately 1 joint in 50,000 injections). Patients should be counseled to minimize activity and stress on the joint for several days after each injection.

#### ▶ Over-the-Counter Agents

**Glucosamine and Chondroitin**  Glucosamine is believed to function as a "chondroprotective" agent, stimulating the cartilage matrix and protecting against oxidative chemical damage. Chondroitin, often administered in conjunction with glucosamine, is thought to inhibit degradative enzymes and serve as a substrate for the production of proteoglycans. The highest quality evidence to date suggests no clinically important difference in efficacy between glucosamine, chondroitin, their combination, or placebo in patients with knee OA.[44] Consequently, these products, used alone or in combination, are generally not recommended.[45]

These agents are loosely regulated in the United States as dietary supplements, product standards are inconsistent, and the constituents are not validated by any regulatory agency. The use of glucosamine (derived from crab, lobster, or shrimp shells) and/or chondroitin (derived from cattle or shark cartilage) may warrant caution in patients with shellfish allergies, but preliminary evidence suggests little drug–allergy interaction.[46] Additionally, glucosamine may alter cellular glucose uptake, thus elevating blood glucose levels in diabetic patients.[47] Because the clinical significance of this is unclear, blood glucose levels in diabetic patients should be monitored closely after glucosamine initiation or dosage adjustments.

**Other Topical Agents**  There are limited data to support the use of salicylate-containing rubefacients (eg, methyl salicylate and trolamine salicylate) or other counterirritants (eg, menthol, camphor, and methyl nicotinate) in OA.[48] See Chapter 60 (Musculoskeletal Disorders) for more information on these products when used for musculoskeletal disorders.

Capsaicin achieves pain relief by depleting substance P from sensory neurons in the spine, thereby decreasing pain transmission. Capsaicin is not effective for acute pain; it may take up to 2 weeks of daily administration to achieve pain relief. Capsaicin may provide the greatest benefit to painful superficial joints (eg, hand OA). The lower concentration (0.025%) is typically

better tolerated. Most patients experience a local burning sensation at the site of application. The discomfort usually does not result in discontinuation and often abates within the first week. Patients should be cautioned not to allow capsaicin to come into contact with eyes or mucous membranes and to wash their hands after each application.

## Surgery

Surgery generally is reserved for patients who fail to respond to medical therapy and have progressive limitations in activities of daily living (ADL). In joint replacement surgery (arthroplasty), the damaged joint surfaces are replaced with metal or plastic prosthetic devices. Hip and knee joints are most commonly replaced, but arthroplasty may also be performed on shoulders, elbows, fingers, and ankles. Most patients achieve significant pain relief and functional restoration after arthroplasty, and it is a reasonable option in carefully selected refractory patients.

Surgical debridement may be performed arthroscopically. With this procedure, a tiny video camera is inserted into the affected joint through a small incision, and the surgeon removes torn cartilage or other debris from the joint. The long-term benefits of arthroscopic surgery for OA are unclear, and it may be no better than optimized physical and medical therapy.[49]

## OUTCOME EVALUATION

- At baseline, quantify pain using a visual analogue scale, assess range of motion of affected joints, and identify activities of daily living that are impaired.
- In patients treated with acetaminophen or oral NSAIDs, assess pain control after 2 to 3 weeks. It may take longer for the full anti-inflammatory effect of NSAIDs to occur.

---

## Patient Encounter, Part 3: Creating a Care Plan

*Based on the available information, create a care plan for this patient's OA. The plan should include:*

*(a) A statement of the drug-related needs and/or problems*

*(b) An individualized, detailed therapeutic plan*

*(c) A plan for follow-up monitoring to document the patient's response and identify adverse reactions*

- Incorporate other measures to track disease progress. Use radiography to assess severity of joint destruction, determine 50-ft (~15 m) walking time and grip strength, and administer the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and the Stanford Health Assessment Questionnaire, where appropriate, to assess activities of daily living.
- Ask patients if they are experiencing side effects or other problems with their medications and respond with more specific questions.
- In patients taking oral NSAIDs, monitor for increases in blood pressure, weight gain, edema, skin rash, and CNS adverse effects such as headaches and drowsiness.
- Evaluate serum creatinine, complete blood count, and serum transaminases at baseline and at every 6 to 12 months in patients treated with oral NSAIDs or acetaminophen.
- Perform stool guaiac in patients taking oral NSAIDs when clinically indicated.
- Monitor for drug interactions, including alcohol, at every visit.

---

## Patient Encounter, Part 2: Medical History, Physical Examination, and Diagnostic Tests

**PMH:** Obesity (BMI 30 kg/m²), HTN for 24 years, dyslipidemia, nonischemic cardiomyopathy, COPD, heat failure with reduced ejection fraction

**PSH:** Torn meniscus s/p repair on right knee 20 years ago

**FH:** Father had OA of the hip and knee; mother died of MI at age 68

**SH:** Retired clerk. Denies alcohol use; denies illicit drug use; smoked two packs of cigarettes per day for 35 years but quit 3 years ago

**Allergies:** NKDA; shellfish allergy

**Meds:** Lisinopril 40 mg once daily; metoprolol succinate 200 mg once daily; furosemide 20 mg once daily; spironolactone 25 mg once daily; atorvastatin 20 mg once daily; enteric-coated aspirin 81 mg once daily; tiotropium 18 mcg once daily; albuterol 90 mcg as needed for wheezing/shortness of breath; acetaminophen 500 mg one to two tablets two to four times per day as needed for pain

**ROS:** (+) SOB on exertion, right knee pain 5 out of 10 with movement

**PE:**

**VS:** BP 119/72 mm Hg, Pulse 61 beats/min, RR 16 breaths/min, T 98.6°F (37.0°C)

**Skin:** Warm, dry, cracked skin on feet bilaterally

**HEENT:** NC/AT, PERRLA, TMs intact

**CV:** RRR, normal $S_1$ and $S_2$, no m/r/g

**Chest:** CTA

**Abd:** Soft, NT/ND

**Neuro:** A&O × 3; CN II to XII intact

**Ext:** Bilateral ankle nonpitting edema, slight swelling of soft tissue surrounding right knee with crepitus and slight decrease in range of motion

**Labs:** ESR 12 mm/hour; basic metabolic panel within normal limits

**Knee x-rays:** Right knee shows joint space narrowing, minor osteophyte formation, and subchondral bone sclerosis

*What clinical parameters are consistent with a diagnosis of OA?*

*What are the treatment goals for this patient?*

*What nonpharmacologic options are available to treat this patient?*

*What pharmacologic options are available to treat this patient?*

*What factors are important to consider when selecting medications for this patient?*

## Patient Care Process

### Patient Assessment:

- Determine whether the patient's symptoms are consistent with OA. Review the medical history to determine whether other rheumatologic diseases may be involved.
- Assess symptoms to determine whether pain warrants additional attention. Does the pain affect quality of life or interfere with activities of daily living?
- Assess radiographs for diagnosis and disease severity (joint-space narrowing, subchondral bone sclerosis, osteophyte formation, joint deformity, joint effusion).
- Consider obtaining laboratory tests depending on degree of clinical suspicion for inflammatory etiology (eg, ESR, CRP, rheumatoid factor, ANA).

### Therapy Evaluation:

- Obtain a thorough history of previous device and drug use, including prescription drugs, over-the-counter drugs, and dietary supplements.
- Assess the effectiveness of any current or previous pharmacotherapy, including dose, frequency, and duration to determine whether an adequate trial was given.

### Care Plan Development:

- Formulate a plan for lifestyle modifications and alteration/addition of pharmacotherapy that considers risks, benefits, and patient preference given the patient's medical history, concomitant medications, and previous successful/failed OA therapies.

- Address patient concerns related to OA, its treatment, with special focus on the potential adverse effects of medications.
- Emphasize the value of adherence to medication regimens and lifestyle modifications. Facilitate adherence by implementing medication regimens and lifestyle plans that are simple and consistent with the patient's lifestyle.

### Follow-Up Evaluation:

- Schedule follow-up to assess the effectiveness of therapy and associated adverse effects; the specific time frame depends on patient factors and the treatment regimen chosen. If laboratory tests (eg, renal function) are required for monitoring drug therapy, provide the patient with an order for the laboratory tests and instructions to complete them prior to the next appointment.
- Document whether the patient has had improvements in pain, quality-of-life measures, mobility and functioning, ability to perform activities of daily living, and well-being.
- Ascertain new OTC medication use; for patients taking acetaminophen, pay particular attention to OTC sources of acetaminophen.
- Evaluate for the presence of adverse drug reactions, drug hypersensitivity, and potential drug interactions.

# Gout and Hyperuricemia

Maria Miller Thurston

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Explain the pathophysiologic mechanisms underlying gout and hyperuricemia.

2. Recognize major risk factors for developing gout in a given person.

3. Assess the signs and symptoms of an acute gout attack.

4. List the treatment goals for a patient with gout.

5. Develop a pharmacotherapeutic plan for a patient with acute gouty arthritis that includes individualized drug selection and monitoring for efficacy and safety.

6. Identify patients for whom prophylactic urate lowering therapy for gout and hyperuricemia is warranted.

7. Select an appropriate drug to reduce serum uric acid (SUA) levels in patients with gout, and outline a plan for monitoring efficacy and toxicity.

8. Formulate appropriate educational information for a patient on lifestyle modifications to help prevent gouty arthritis attacks.

## INTRODUCTION

**KEY CONCEPT** *Gout is an inflammatory condition of the arthritis-type that results from deposition of uric acid crystals in joint spaces, leading to an inflammatory reaction that causes intense pain, erythema, and joint swelling.* It is associated with hyperuricemia, defined as a serum uric acid (SUA) level of 6.8 mg/dL (404 μmol/L) or greater, but not all patients with hyperuricemia demonstrate symptoms.[1] There are presently three published guidelines that provide clinical recommendations for management of patients with gout.[2–7] This chapter will focus primarily on recommendations of the American College of Rheumatology (ACR).[5–7]

## EPIDEMIOLOGY AND ETIOLOGY

Gout is the most common inflammatory arthritis in men, with a male:female incidence of about 4:1; it affects over 3% of US adults.[1,8] The National Health and Nutrition Examination Survey (NHANES) 2007–2008 estimated the prevalence of gout among US adults to be 8.3 million.[9] Furthermore, the annual US incidence is approximately 62 cases per 100,000 persons and rising.[1] The incidence increases with age and is rising in part due to a larger number of patients with risk factors for gout.[10]

## PATHOPHYSIOLOGY

Gout is caused by an abnormality in uric acid metabolism. Uric acid is a waste product of the breakdown of purines contained in the DNA of degraded body cells and dietary protein. Uric acid is water soluble and excreted primarily by the kidneys, although some is broken down by colonic bacteria and excreted via the gastrointestinal (GI) tract.[11]

The solubility of uric acid depends on concentration and temperature. At high serum concentrations, lower body temperature causes the precipitation of **monosodium urate** (MSU) crystals. Collections of these crystals (called microtophi) can form in joint spaces in the distal extremities. Larger **tophi** may take 10 years or longer to develop.

Free urate crystals can activate several proinflammatory mediators, including tumor necrosis factor α (TNF-α), interleukin 1 (IL-1), and IL-8. Activation of these mediators signals chemotactic movement of neutrophils into the joint space that ingest MSU crystals via phagocytosis. These neutrophils then are lysed and release proteolytic enzymes that trigger the clinical manifestations of an acute gout attack such as pain and swelling. These inflammatory mechanisms in gout, especially in untreated disease, can lead to cartilage and joint destruction.

The increased SUA involves either the underexcretion of uric acid (80% of patients) or its overproduction. The cause of overproduction or underexcretion of uric acid in most gout patients is unknown; this is referred to as primary gout.[1]

The reference range for SUA is 3.6 to 8.3 mg/dL (214–494 μmol/L). The risk of gout increases as the SUA concentration increases. Approximately 30% of patients with levels greater than 10 mg/dL (595 μmol/L) develop symptoms of gout within 5 years.[12] However, most patients with hyperuricemia are asymptomatic.

Dietary risk factors involve ingestion of animal purines, fructose, and alcohol (especially beer). Patients experiencing

frequent attacks and those with poorly controlled advanced disease should be educated to avoid sweetbreads, liver, and kidney meat; high-fructose corn syrup; and alcohol use.[5] Other risk factors for gout include male gender, obesity, hypertension, dyslipidemia, and the metabolic syndrome.[8,11,13,14] Gout also occurs frequently in patients with type 2 diabetes mellitus, chronic kidney disease (CKD), and coronary artery disease; however, causal associations have not been established.[15,16] It is known that uric acid excretion is reduced in patients with CKD, putting them at risk for hyperuricemia.

Uric acid **nephrolithiasis** can occur in up to 25% of patients with persistently acidic urine and hyperuricemia. In severe cases, uric acid stones can cause nephropathy and renal failure.[17] **Tumor lysis syndrome** (TLS) involves metabolic complications resulting from extreme hyperuricemia due to rapid tumor cell destruction in patients undergoing chemotherapy for certain types of cancer.

**KEY CONCEPT** *Some drugs can cause hyperuricemia and precipitate gout, such as thiazide and loop diuretics, niacin, pyrazinamide, calcineurin inhibitors, and, occasionally, aspirin. In most cases, these drugs block uric acid secretion in the kidney.*

The effect of aspirin on uric acid is dose dependent. At very high doses (eg, 4000 mg/day), aspirin blocks uric acid reabsorption by the kidneys, increasing uric acid excretion. Smaller aspirin doses inhibit uric acid excretion and can elevate serum uric acid levels. The very low aspirin doses (75–81 mg/day) used for heart attack or stroke prevention do not substantially alter uric acid levels. For these reasons, aspirin in analgesic doses (325–650 mg several times per day) should be avoided.[2] However, patients with hyperuricemia or gout and cardiovascular risk factors should continue low-dose aspirin for cardiovascular prophylaxis because the cardiovascular benefit outweighs the minimal effect on serum urate.[5]

**KEY CONCEPT** *Long-term consequences of gout and hyperuricemia include joint destruction, tophi, nephrolithiasis, and nephropathy.*

## CLINICAL PRESENTATION AND DIAGNOSIS

Refer to the accompanying box for the clinical presentation of acute gouty arthritis.

### Diagnosis

A presumptive diagnosis is often based on presenting symptoms and may be confirmed later with laboratory and other diagnostic tests. Severe joint pain, swelling, tenderness, and erythema that rapidly peak are highly suggestive of, but not specific for, gout. For example, it is essential to distinguish between gout and septic arthritis to provide appropriate treatment. Gout is a reasonably accurate clinical diagnosis in patients with recurrent **podagra** and hyperuricemia.[3]

The serum uric acid level often is elevated but may be normal during an acute attack. In addition, an elevated SUA alone is not diagnostic for gout. The peripheral WBC count may be only mildly elevated. Other laboratory markers of inflammation (eg, increased erythrocyte sedimentation rate) are often present.

Aspiration of affected joint fluid or a tophus is essential for a definitive diagnosis. Needle-shaped negatively birefringent MSU crystals in the aspirate confirm the diagnosis (**Figure 59–1**). Joint fluid may also have an elevated white blood cell (WBC) count with neutrophils predominating. If infection is suspected, it is imperative to obtain the appropriate diagnosis and treatment.[3,18]

Radiographs of affected joints may have characteristic cystic changes, punched-out lytic lesions with overhanging bony edges,

**FIGURE 59–1.** Synovial fluid containing extracellular and intracellular needle-like, negative birefringent monosodium urate crystals. (From Schumacher H, Chen LX. Chapter 333. Gout and Other Crystal-Associated Arthropathies. In: Longo DL, Fauci AS, Kasper DL, et al., eds. Harrison's Principles of Internal Medicine, 18th ed. New York, NY: McGraw-Hill; 2012. http://accesspharmacy.mhmedical.com/content.aspx?bookid=331&Sectionid=40727136. Accessed August 25, 2014. With permission.)

and soft-tissue calcified masses. These signs may also appear in other arthropathies and are generally not apparent with the first acute gout attack. Therefore, radiographs are often reserved for patients with long-standing disease.[3,4,19]

Although rarely performed, a 24-hour urine collection can be obtained to determine whether the patient is an overproducer or an underexcretor of uric acid. Individuals who excrete more than 800 mg (4.8 mmol) of uric acid in this collection are considered overproducers. Patients with hyperuricemia who excrete less than 600 mg/day (3.6 mmol/day) are classified as underexcretors of uric acid.

---

### Clinical Presentation of Acute Gouty Arthritis

**General**

- Acute inflammatory monoarthritis.
- Patients are usually in acute distress.

**Symptoms**

- There is severe pain and swelling in the affected joint(s).
- Symptoms reach maximal intensity within 6 to 12 hours.
- The attack is usually monoarticular; the most common site is the metatarsophalangeal joint.
- In elderly patients, gouty attacks may be atypical with insidious and polyarticular onset, often involving hand or wrist joints.

**Signs**

- Affected joint(s) are warm, erythematous, and swollen.
- Mild fever may be present.
- Tophi (usually on hands, wrists, elbows, or knees) may be present in chronic, severe disease.

## Patient Encounter, Part 1

A 47-year-old obese Caucasian man presents to the emergency department with a 16-hour history of rapidly escalating excruciating pain (over 8 hours) in his left big toe unrelated to trauma. On examination, his left great toe is red, swollen, tender, and warm to the touch. During the initial patient interview, he states that this is the second time he has experienced this type of throbbing pain in his toe (last episode occurred 2 months ago and was successfully treated). He rates the pain as 10/10 (10 being the worst pain he has ever experienced). He is an unemployed, single father who did not graduate from high school. He has two young children and is concerned that he will be unable to find work and care for his children if this pain continues to occur frequently.

*What information is suggestive of acute gouty arthritis?*

*What additional information is necessary to differentiate gout from other joint abnormalities?*

*What additional information do you need before creating a treatment plan for this patient?*

*What are aspects to consider when providing care for a patient who is unemployed and with limited formal education?*

## TREATMENT OF ACUTE GOUTY ARTHRITIS

**KEY CONCEPT** *Treatment of gout involves: (a) acute relief of a gouty arthritis attack with topical application of ice and drug therapy commonly including NSAIDs, colchicine, corticosteroids or a combination thereof, and (b) in some patients, long-term prophylactic treatment with urate-lowering therapy (ULT) to prevent subsequent attacks.*

### Desired Outcomes

Treatment goals for an acute attack are to: (a) achieve rapid and effective pain relief, (b) maintain joint function, (c) prevent disease complications, (d) avoid treatment-related adverse effects, (e) provide cost-effective therapy, and (f) improve quality of life.[4] Infrequent gouty arthritis is a self-limited disease, and treatment usually focuses on symptomatic relief.

### Nonpharmacologic Therapy

Nondrug modalities play an adjunctive role and usually are not effective when used alone. Immobilization of the affected extremity speeds resolution of the attack. Applying ice packs to the joint also decreases pain and swelling, but heat application may be detrimental.[20]

### Pharmacologic Therapy

**KEY CONCEPT** *Nonsteroidal anti-inflammatory drugs (NSAIDs), colchicine, and corticosteroids are considered first-line monotherapy options for acute attacks.[6] Selection depends on number of joints affected, presence/absence of infection, clinician/patient preference, prior response, and patient factors such as comorbidities and renal function* (**Figure 59–2**). Each drug class has a unique safety and efficacy profile in gout that should be considered carefully before choosing a specific agent (**Table 59–1**). Generally, the earlier in the course of the arthritic attack these agents are employed (ie, within 24 hours), the better the outcome. Corticotropin (adrenocorticotropic hormone, ACTH) and IL-1 inhibitors are alternatives in select cases.[6] Opioid analgesics have little to no role in acute gout, which results from overwhelming inflammation.[21]

### ▶ *Nonsteroidal Anti-inflammatory Drugs*

NSAIDs have largely supplanted colchicine as the treatment of choice. These agents are most effective when given within the first 24 hours of the onset of pain. Most studies have shown similar results among agents, and no one NSAID is preferred over another as first-line treatment.[6] Doses at the higher end of the therapeutic range are often needed.[22] NSAIDs are usually continued at full doses until 24 hours after symptoms subside. Clinicians may consider tapering the dose if a patient has multiple comorbidities, including hepatic or renal failure.

Only naproxen, indomethacin, and sulindac are FDA approved for treatment of acute gout. Although indomethacin has been used traditionally, its relative cyclooxygenase-1 (COX-1) selectivity increases its gastropathy risk. Studies comparing indomethacin to other NSAIDs consistency show similar efficacy with higher side effects with indomethacin; thus, other generic NSAIDs may be preferred. The patient's overall clinical status should be evaluated prior to NSAID initiation because adverse effects include gastropathy (primarily peptic ulcers), renal dysfunction, and fluid retention.[23] NSAIDs generally should be avoided in patients at risk for peptic ulcers; those taking anticoagulants; and those with renal insufficiency, uncontrolled hypertension, or heart failure. Gastroprotective agents such as proton pump inhibitors may protect against ulcer development in patients receiving NSAIDs for acute gout.

Cyclooxygenase-2 (COX-2)–selective inhibitors (ie, celecoxib) produce results comparable with those of traditional NSAIDs.[24] However, the need for large COX-2 inhibitor doses, cardiovascular safety concerns, and high cost make the risk-benefit ratio unclear for this disorder.

### ▶ *Colchicine*

Colchicine has a long history of successful use and was the treatment of choice for many years. It is used less commonly today because of its low therapeutic index and more recently, increased cost. Colchicine is thought to exert its anti-inflammatory effects by interfering with the function of mitotic spindles in neutrophils by binding of tubulin dimers; this inhibits phagocytic activity.[25] Colchicine is not considered to be an analgesic.

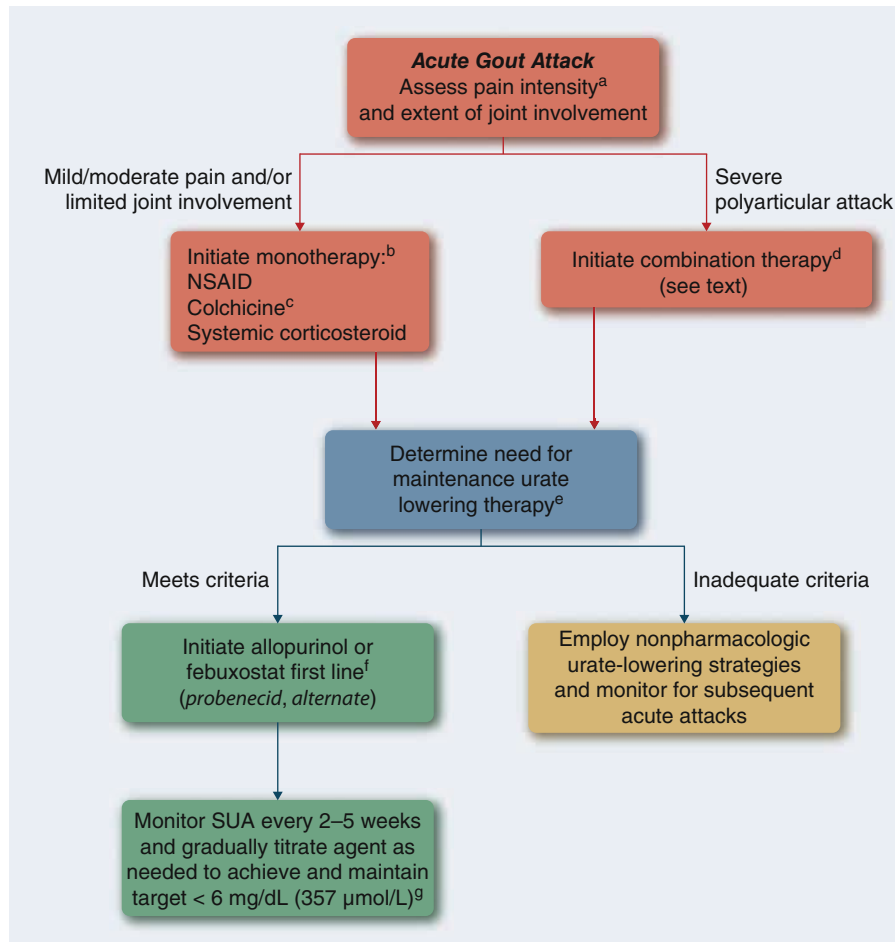
About two-thirds of patients with acute gout respond favorably if colchicine is given within the first 24 hours of symptom onset.[26] Presently, colchicine is only indicated if given within 36 hours of attack onset.[6] GI effects (eg, nausea, vomiting, diarrhea, and abdominal pain) are most common and are considered a forerunner of more serious systemic toxicity, including myopathy and bone marrow suppression (usually neutropenia). However, systemic toxicity can occur with oral colchicine without prior GI effects, especially in patients with renal insufficiency.[27,28] In the presence of severe renal impairment (creatinine clearance [CrCl] < 30 mL/min [0.5 mL/s]), dosing should be repeated no more than once every 2 weeks. Dose reductions are required when coadministered with p-glycoprotein or strong CYP3A4 inhibitors (eg, clarithromycin, verapamil, ritonavir, cyclosporine, ranolazine). Because of these problems, colchicine may be reserved for patients who are at risk for NSAID-induced gastropathy or who have failed NSAID therapy.[29]


**FIGURE 59–2.** Treatment algorithm for hyperuricemia in gout. (NSAID, nonsteroidal anti-inflammatory drug; SUA, serum uric acid.) [a]Self-reported pain score using a visual analog scale of 6 or less is considered mild/moderate pain and 7 or more is considered severe pain. [b]May consider switch to alternate monotherapy, add-on combination therapy, or off-label therapy for inadequate response (< 20% improvement in pain score within 24 hours or < 50% at 24 hours or longer). [c]Colchicine recommended only if started within 36 hours of symptom onset. [d]Intraarticular corticosteroids may be used in combination when only one or two large joints are affected. [e]Criteria for ULT initiation include: Recurrent attacks (2 or more per year), evidence of tophus or tophi, chronic kidney disease stage 2 or worse, or past urolithiasis. [f]Initiate concomitant anti-inflammatory prophylaxis and continue for indicated duration. [g]May add on uricosuric therapy if unable to achieve target SUA on maximally dosed xanthine oxidase inhibitor therapy; switch to pegloticase for refractory cases.

Colcrys is the only single-ingredient oral colchicine product FDA approved for treatment of acute gout attacks. For many years prior to its release, generic colchicine products were available without FDA approval. In 2010, the FDA ordered manufacturers to discontinue marketing these unapproved generics. Colcrys is much more expensive than the generic compounds it replaced but has proper labeling and safety data. As part of the approval process, a dosing study showed that one dose initially and a single additional dose after 1 hour was just as effective as and less toxic than continued hourly colchicine dosing.[30] Thus, the approved dosage regimen is 1.2 mg (two 0.6-mg tablets) at the onset of an acute flare, followed by 0.6 mg 1 hour later.[31] The ACR guidelines suggest it can then be continued starting 12 hours later at a dose of 0.6 mg once or twice daily (prophylaxis dosing) until the gout attack is resolved.[6] This is not part of the FDA-approved labeling but is an off-label recommendation based on pharmacokinetic data.[30] Dose adjustment is required for renal insufficiency.

Colchicine should not be used for an acute attack if the patient is currently prescribed colchicine for prophylaxis and was previously treated with colchicine for an acute attack within the last 14 days. Intravenous colchicine (no longer commercially available) should never be used in gout management.[6]

▶ *Corticosteroids*

It is important to determine the number of joints affected when considering a corticosteroid for first-line therapy. Systemic corticosteroids are a useful option in patients with contraindications to NSAIDs or colchicine (primarily renal impairment) or polyarticular attacks, especially in elderly patients. The ACR recommends initiating oral prednisone or prednisolone at a starting dose of at least 0.5 mg/kg daily for 5 to 10 days, followed by abrupt discontinuation, or full dose therapy for 2 to 5 days with a 7- to 10-day taper to discontinue.[6] Oral methylprednisolone (ie, the 6-day dose pack consisting of a 21-tablet taper of 4 mg tablets, starting with 6 tablets on day 1 [divided into three separate doses] and ending with one tablet on day 6) and naproxen have been shown to be equivalent in treating acute gout attacks.[32]

| Table 59–1 | |
|---|---|
| **Pharmacotherapy Regimens for Acute Gout Treatment** | |
| **Drug** | **Usual Dosage Range** |
| **NSAIDs**[a] | |
| Etodolac | 300–500 mg po two times daily |
| Fenoprofen | 400–600 mg po three to four times daily |
| Ibuprofen | 400–800 mg po three to four times daily |
| Indomethacin* | 50 mg po three times daily initially until pain is tolerable, then quickly taper to discontinue |
| Ketoprofen | 50 mg po four times daily or 75 mg po three times daily |
| Naproxen* | 750 mg po initially, then 250 mg po every 8 hours |
| Piroxicam | 40 mg po once daily for 5–7 days |
| Sulindac* | 150–200 mg po two times daily for 7–10 days |
| Celecoxib | 800 mg po followed by 400 mg po on day 1, then 400 mg po twice daily for 1 week |
| **Oral Colchicine[b] (Colcrys)** | 1.2 mg po at the onset of attack, then 0.6 mg po 1 hour later |
| **Corticosteroids** | |
| Local corticosteroid | |
|    Triamcinolone acetonide | 10–40 mg (large joint), 5–20 mg (small joint) for one dose by intraarticular injection |
| Systemic corticosteroid | |
|    Prednisone (example) | 30–60 mg po once daily for 3–5 days, then taper to discontinue by 5 mg decrements over 10–14 days |
|    Triamcinolone acetonide | 60 mg by IM injection for one dose[c] |
|    Methylprednisolone | 100–150 mg by IM injection once daily for 1–2 days |
| **Corticotropin[d]** | 40–80 units IM or SC every 24–72 hours |
| **Interleukin-1 Inhibitors[d]** | |
|    Anakinra | 100 mg SC once daily for 3 days |
|    Canakinumab | 150 mg SC for 1 dose |

IM, intramuscular; NSAIDs, nonsteroidal anti-inflammatory drugs; po, by mouth; SC, subcutaneous.

[a]NSAIDs that are FDA approved for treatment of gout are indicated with an asterisk.

[b]Dose reduction recommended for renal impairment.

[c]Administration of IM triamcinolone should be followed by oral prednisone or prednisolone.

[d]Not FDA approved for this indication.

Drug regimens derived from various sources.

When only one or two large joints are affected, an **intraarticular** corticosteroid injection can provide rapid relief with a relatively low incidence of side effects, and it may be used in combination with either an NSAID, colchicine, or oral corticosteroid. Joint fluid obtained by **arthrocentesis** should be examined for evidence of joint space infection and crystal identification. If uric acid crystals are present and there is no infection, intraarticular injection can proceed.

Finally, an alternative regimen consisting of a single intramuscular injection of a long-acting corticosteroid such as triamcinolone acetonide, followed by oral prednisone or prednisolone may also be used.[6]

Adverse effects from corticosteroids include fluid retention, hyperglycemia, CNS stimulation, weight gain, GI upset, and increased risk of infection. Patients with diabetes should have blood glucose levels monitored carefully during the corticosteroid course, and caution should be exercised when treating patients with a history of peptic ulcer disease.

▶ *Corticotropin (Adrenocorticotropic Hormone)*

Exogenous administration of intramuscular adrenocorticotropic hormone (ACTH) stimulates production of cortisol and corticosterone by the adrenal cortex. Clinical studies have shown efficacy similar to other agents for acute gout. Although not a first-line option (or FDA approved for this use), the ACR supports its use for patients unable to take medications orally.[6] The product is available in the United States only through specialty pharmacy distribution.

▶ *Interleukin-1 Inhibitors*

Several small clinical trials have demonstrated efficacy of IL-1 inhibitors in inhibiting inflammation associated with acute gout attacks. While their role is unclear and the available products (anakinra and canakinumab) are not FDA approved for this purpose, the ACR guidelines include off-label use as an option for severe acute attacks or for patients refractory to other agents.[6]

▶ *Combination Therapy*

In severe polyarticular attacks, particularly attacks involving multiple large joints, colchicine may be used in combination with an NSAID or oral corticosteroid. Intraarticular corticosteroid injections may be used in combination with any other first-line agent (NSAID, colchicine, oral corticosteroid).[6]

## URATE LOWERING THERAPY FOR GOUT PROPHYLAXIS

Gout is an episodic disease, and the number of attacks varies widely from patient to patient. Thus the benefit of long-term prophylaxis against acute gout flares must be weighed against the cost and potential toxicity of therapy that may not be necessary in all patients. **KEY CONCEPT** *Asymptomatic hyperuricemia generally does not require treatment.*

### Nonpharmacologic Therapy

Historically, lifestyle modifications alone have been insufficient for lowering SUA levels in gout patients. Patients should be

educated to engage in regular exercise to lose weight if obese, strictly limit or discontinue ethanol consumption, maintain hydration, and manage other comorbidities (eg, hypertension, diabetes). Low-purine diets, including avoiding organ meats, and limiting sardines, shellfish, beef, pork, and lamb are not well tolerated; instead, dietary recommendations should focus on general nutrition principles. Some studies have shown that low-fat dairy products, coffee, and vitamin C may confer a protective effect. Complementary therapies that are considered to be inappropriate for gout due to insufficient evidence of benefit include cherry juice/extract, willow bark extract, ginger, flaxseed, charcoal, strawberries, black current, burdock, sour cream, olive oil, horsetail, pears, and celery root.[6,8] Drugs that may cause or aggravate hyperuricemia should be discontinued if clinically appropriate. Few patients adhere to lifestyle modifications long term, and pharmacologic therapy usually is needed to treat hyperuricemia adequately.[33]

## Pharmacologic Therapy

**KEY CONCEPT** *Patients with recurrent attacks (2 or more per year), evidence of tophus or tophi, CKD stage 2 or worse, or past urolithiasis are candidates for* prophylactic *therapy with allopurinol, febuxostat, probenecid, or pegloticase to lower SUA levels* (see Figure 59–2). Because hyperuricemia is the strongest modifiable risk factor for acute gout, prophylactic therapy commonly involves either decreasing uric acid production or increasing its excretion (Table 59–2). The goal of therapy is to decrease SUA levels significantly, leaving less uric acid available for conversion to MSU crystals.[4]

Ideally, the selection of long-term prophylactic therapy involves determining the cause of hyperuricemia (primarily by analyzing a 24-hour urine collection for uric acid) and tailoring therapy appropriately. If less than 600 mg (3.6 mmol) of uric acid is found in the 24-hour sample, the patient is considered an underexcretor. However, this approach is not used commonly for several reasons. The urine collection is inconvenient for

### Table 59–2

**Pharmacotherapy Regimens for Urate Lowering**

| Drug | Usual Dosage Range |
|---|---|
| **Xanthine Oxidase Inhibitors** | |
| Allopurinol[a] | 100 mg po initially, then titrate to achieve SUA level < 6 mg/dL (357 µmol/L); maximum 800 mg po daily |
| Febuxostat | 40 mg po once daily initially, then increase to 80 mg po once daily if SUA does not decline to 6 mg/dL (357 µmol/L) or lower after 2 weeks of treatment |
| **Uricosurics** | |
| Probenecid | 250 mg po two times daily for 1 week, then 500 mg po twice daily; may increase by 500 mg every 4 weeks to achieve SUA level < 6 mg/dL (357 µmol/L); maximum 2 g po daily |
| **Other** | |
| Pegloticase | 8 mg given as an IV infusion over at least 2 hours once every 2 weeks, optimal duration unknown |

po, by mouth; SUA, serum uric acid.

[a]Initiation dose reduction recommended for renal impairment.

Drug regimens derived from various sources.

patients and clinicians and does not identify patients who may be both overproducers and underexcretors of uric acid. Also, drugs used to increase uric acid excretion (uricosuric agents) generally are not as well tolerated as drugs that decrease production, and uricosurics increase the risk of uric acid nephrolithiasis.[34]

Because allopurinol (which reduces uric acid production) is effective in both overproducers and underexcretors and is generally well tolerated, many clinicians forego the 24-hour urine collection and treat patients empirically with it. Both allopurinol and febuxostat are xanthine oxidase inhibitors (XOIs) and are considered to be first-line ULT agents. Probenecid, a uricosuric agent, is an alternative first-line option, whereas pegloticase is generally reserved for refractory cases.[5]

**KEY CONCEPT** *ULT should be continued in patients even during acute flares.*

### ▶ Allopurinol

Most patients in the US are treated with allopurinol, which usually is effective if the dosage is titrated appropriately. The drug and its primary active metabolite, oxypurinol, reduce SUA concentrations by inhibiting the enzyme xanthine oxidase, thereby blocking the two-phase oxidation of hypoxanthine and xanthine to uric acid.[4]

Allopurinol is well absorbed, with a short half-life of 2 to 3 hours. The half-life of oxypurinol approaches 24 hours, allowing allopurinol to be dosed once daily. Oxypurinol is cleared primarily by renal mechanisms and can accumulate in patients with reduced kidney function.

Allopurinol may be started during an acute gout attack only if anti-inflammatory treatment is also initiated, because sudden shifts in SUA levels from mobilization of tissue urate stores may precipitate or exacerbate gouty arthritis. Rapid shifts in SUA can change the concentration of MSU crystals in synovial fluid, causing more crystals to precipitate. Thus most clinicians provide anti-inflammatory prophylaxis during initiation of ULT with colchicine (0.6 mg once or twice daily or 0.3 mg daily if severe renal impairment) or a low-dose NSAID (eg, naproxen 250 mg twice daily) with acid-suppressing therapy (eg, omeprazole 20 mg once daily). If a patient is being treated with colchicine for an acute attack, the prophylactic colchicine dose may be administered 12 hours after the last treatment dose. This approach, with colchicine having a stronger evidence grade, is supported by the ACR guidelines. Guidelines recommend that all acute gout patients receive prophylaxis when ULT is started with continuation of therapy for at least 6 months or up to 3 to 6 months after no clinical evidence of gout activity is apparent and the target SUA has been achieved.[6] Patients receiving colchicine for prophylaxis should be screened for drug–drug interactions (via the cytochrome p-450 system) that may increase the risk of colchicine adverse effects. Low-dose prednisone or prednisolone (less than 10 mg/day) is an alternative for patients unable to take colchicine or NSAIDs.

The initial dose of allopurinol is based on the patient's renal function. If renal function is normal, an initial dose no greater than 100 mg daily is recommended. The initial dose should be reduced to 50 mg daily in patients with a CrCl less than 30 mL/min (0.5 mL/s).[5] The relationship between allopurinol dose and its most severe side effects, including allopurinol hypersensitivity syndrome (AHS), is controversial.[35,36] However, the dose can be adjusted upward every 2 to 5 weeks as needed and tolerated, even in patients with renal insufficiency provided that they are monitored and educated appropriately.[5,37] Historically, allopurinol was dosed according to renal function with stringent

maximum dosages. The 2012 ACR guidelines recommend titrating the dose to goal SUA regardless of renal function.

SUA levels must be monitored every 2 to 5 weeks during titration, then every 6 months after the target SUA is achieved. The target SUA level is less than 6 mg/dL (357 μmol/L) in all cases and perhaps even less than 5 mg/dL (297 μmol/L) in more severe disease involving tophi. The allopurinol dose should be titrated upward (to a maximum of 800 mg/day) or downward as these levels dictate. The typical dose prescribed is 300 mg/day in patients with normal renal function, but this dose often fails to achieve the target SUA level.[5]

Allopurinol is typically well tolerated; nausea and diarrhea occur uncommonly. A generalized, maculopapular rash occurs in about 2% of patients.[38] Although usually mild, this can progress to severe skin reactions such as Stevens-Johnson syndrome. The most serious side effect is AHS, which may involve severe desquamating skin lesions, high fever (usually greater than 39.0°C [102.2°F]), hepatic dysfunction, leukocytosis with predominant eosinophilia, and renal failure. The risk appears to be highest in the first few months of therapy, and although rare, this severe reaction has a 20% to 25% mortality rate.[5,39,40] Prior to initiating allopurinol, pharmacogenetic screening via human leukocyte antigen (HLA)-B*5801 testing is recommended for patients at an elevated risk for AHS (eg, Koreans with stage 3 or worse CKD and all individuals of Han Chinese and Thai descent). If results are positive, the patient should be provided with an alternative to allopurinol. Patients with a history of AHS should never again receive allopurinol (including desensitization) or oxypurinol (which is available outside the United States). Patients with a mild skin rash who require allopurinol can be desensitized to it using published protocols or be switched to febuxostat.[41,42]

There are several important drug–drug interactions with allopurinol. The effects of both theophylline and warfarin may be potentiated by allopurinol. Azathioprine and 6-mercaptopurine are purines whose metabolism is inhibited by concomitant allopurinol therapy; the dose of these drugs must be reduced by 75% with allopurinol cotherapy. Patients taking allopurinol who receive ampicillin are at increased risk of skin rashes.

### ▶ Febuxostat

Febuxostat is a nonpurine XOI structurally distinct from allopurinol that is FDA approved for chronic hyperuricemia associated with gout. The initial dose is 40 mg orally once daily. The dose may be increased to 80 mg orally once daily if the SUA does not decrease to 6 mg/dL (357 μmol/L) or less after 2 weeks of treatment. No dosage adjustment is necessary in patients with mild or moderate renal impairment (CrCl 30–89 mL/min [0.5–1.48 mL/s]); however, febuxostat is not recommended in patient with severe renal insufficiency (CrCl < 30 mL/min [0.5 mL/s]).[43,44] Because of its potency and rapid reduction of SUA levels, anti-inflammatory prophylaxis with low-dose colchicine or an NSAID is also recommended during initiation and titration of therapy and for at least 6 months as previously discussed for allopurinol.

Adverse effects of febuxostat include nausea, arthralgias, rash, and transient elevation of hepatic transaminases. Periodic liver function tests are recommended (eg, at baseline, 2 and 4 months after starting therapy, and then periodically thereafter). Due to differences in chemical structure, febuxostat would not be expected to cross-react in patients with a history of allopurinol hypersensitivity syndrome.

Due to cost concerns, febuxostat should generally be reserved for patients who do not tolerate allopurinol and those who

---

## Patient Encounter, Part 2

**PMH:** Obesity–120 kg (264 lb) and 5′5″ (165 cm) tall, hypertension, dyslipidemia, allergic rhinitis

**FH:** Father unknown. Mother has coronary artery disease and hypertension. No siblings

**SH:** He is currently unemployed but previously drove trucks for a local delivery company until losing his job 2 weeks ago. He drinks soda during the day and three to four beers most nights of the week. He denies use of tobacco products or illicit drugs. He admits to a poor diet consisting of many processed and fast foods and likes to snack on candy

**Allergies:** NKDA

**Meds:** Hydrochlorothiazide 25 mg once daily (adherent), amlodipine 10 mg once daily (adherent), rosuvastatin 20 mg at bedtime (nonadherent), cimetidine 300 mg at bedtime as needed (self-prescribed), loratadine 10 mg once daily (during allergy season), aspirin 325 mg twice daily as needed (self-prescribed for headaches), colchicine 1.2 mg (two 0.6-mg tablets) for one dose, followed by 0.6 mg 1 hour later and 0.6 mg once daily thereafter until gout attack resolves (completed 10-day course 2 months ago for acute gouty attack)

**ROS:** (–) Fatigue, (–) N/V/D, HA, SOB, chest pain, cough

**PE:**

**VS:** 139/92, P 72, RR 18, T 36.1°C (96.9°F)

**Skin**: Warm, dry with excessive warmth surrounding left great toe

**HEENT**: NC/AT, PERRLA, TMs intact

**CV**: RRR, normal $S_1$ and $S_2$, no m/r/g

**Chest**: CTA

**Abd**: Soft, NT/ND

**Ext**: No c/c, trace edema in both ankles

**Neuro**: A&O × 3, CN II to XII intact

**Labs:** Serum creatinine 0.9 mg/dL (80 μmol/L), SUA 8.1 mg/dL (482 μmol/L), WBC + diff WNL

**Other:** 24-hour urine collection, joint aspirate, and x-ray not performed

*What risk factors promote gout and hyperuricemia in this patient?*

*Given this additional information, what is your assessment of the patient's condition?*

*Identify your gout treatment goals for this patient.*

*What nonpharmacologic and pharmacologic alternatives are available for this patient's acute gouty attack?*

*What alternatives are available for urate-lowering therapy for gout prophylaxis in this patient?*

## Patient Encounter, Part 3

*Based on the information available, create a care plan for this patient's gout. The plan should include: (a) a statement of the drug related needs and/or problems, (b) a patient-specific detailed therapeutic plan, and (c) monitoring parameters to assess efficacy and safety.*

cannot achieve SUA levels of 6 mg/dL (357 µmol/L) or less despite maximal allopurinol therapy.[1]

### ► Probenecid

Probenecid is a uricosuric agent that blocks the tubular reabsorption of uric acid, increasing its excretion. Because of its mechanism of action, probenecid is not recommended for urate overproducers and is contraindicated in patients with a history of urolithiasis or urate nephropathy. Probenecid loses its effectiveness as renal function declines and should be avoided when the CrCl is 50 mL/min (0.83 mL/s) or less.[45] Probenecid is considered an alternate first-line agent if XOI therapy is either not tolerated or contraindicated. It may also be added to XOI therapy that has been titrated to the maximum dose without attainment of the target SUA level.[6]

Although generally well tolerated, probenecid can cause GI side effects such as nausea as well as fever, rash, and rarely, hepatic toxicity. Patients should be instructed to maintain adequate fluid intake and urine output to decrease the risk of uric acid stone formation. Some experts advocate alkalinizing the urine to decrease this risk, but no specific recommendations are provided.

### ► Other Uricosuric Agents

Other medications with mild uricosuric effects may be appropriate adjunctive therapy in some patients. Losartan increases both uric acid excretion and urine pH and may be an option in hypertensive patients with gout. Fenofibrate is also uricosuric and may be appropriate in select dyslipidemic patients with gout.[46] Either one of these agents may be combined with a XOI in patients who fail to achieve the target SUA level on maximized therapy.[5]

### ► Pegloticase

Gout does not occur in most nonprimate mammals because these species produce the enzyme uricase, which catalyzes oxidation of uric acid into the more soluble compound allantoin, which is readily excreted. Humans lack this enzyme, which allows uric acid to accumulate, leading to gout in some individuals.

Pegloticase is a recombinant form of uricase (also known as urate oxidase) conjugated to polyethylene glycol. It is FDA approved for treatment of chronic gout refractory to other therapies. The approved dose of 8 mg by IV infusion over at least 2 hours every 2 weeks rapidly (within 6 hours) decreased SUA in subjects in published trials.[47] However, pegloticase should be

## Patient Care Process

**Patient Assessment:**

- Assess patient symptoms to determine time of attack onset, joint(s) affected, pain level, and observe physical signs (joint warmth, swelling, and redness).
- Review patient history for contributing lifestyle factors (ie, alcohol use) and comorbidities including CKD that may exacerbate hyperuricemia or help to guide therapy.
- Obtain thorough medication history for prescription and nonprescription drug and dietary supplement use. Determine whether any products such as diuretic therapy may be contributing to hyperuricemia.
- Consider evaluating the SUA level to confirm presence of hyperuricemia.
- If a gout diagnosis has not been confirmed previously, consider aspiration of the affected joint or tophus to identify uric acid crystals.

**Therapy Evaluation:**

- Discontinue nonessential urate-elevating medications.
- If a patient is currently receiving pharmacotherapy, assess efficacy (ie, frequency and severity of attacks), safety/adverse reactions, adherence, and potential drug interactions.
- Ensure the patient has met criteria for ULT if already prescribed.
- Determine if the patient has prescription insurance and whether recommended agents (eg, colchicine) are included on the formulary.

**Care Plan Development: (see Figure 59–2)**

- Initiate therapy to treat acute gout attack within 24 hours (see Table 59–1).
- Select therapy based on comorbidities and potential for adverse effects.
- Assess need for continuous ULT (see Table 59–2). Use patient factors such as comorbidities to select an agent.
- Most patients need adjunctive therapy with low-dose colchicine or an NSAID during initiation or titration of ULT to prevent a rebound flare.
- Initiate ULT during an acute attack only in conjunction with effective anti-inflammatory therapy.
- Educate the patient on hyperuricemia/gout, drug therapy, and appropriate lifestyle modifications that may improve symptoms (eg, weight loss, avoidance of ethanol).

**Follow-up Evaluation:**

- Titrate ULT to achieve the target SUA; monitor the SUA concentration during ULT titration and periodically thereafter.
- Evaluate presence of adverse drug reactions, allergies, and interactions.
- Reinforce adherence with the regimen to prevent future gout attacks and long-term complications.

limited to patients with severe gout with tophi or nephropathy that has not responded to other agents because of significant adverse effects, including gout flares, infusion reactions, anaphylaxis (in up to 5% of patients) that mandates pretreatment with antihistamines and corticosteroids, the inconvenience of IV therapy, and its high cost. Pegloticase is contraindicated in patients with G6PD deficiency due to the risk of hemolysis and methemoglobinemia; therefore, patients should be screened prior to initiation of therapy.

## OUTCOME EVALUATION

### Acute Gout

- Monitor the patient for pain relief and decreased swelling of the affected joint(s). Both parameters improve significantly within 48 hours of starting therapy.

- Assess the patient's complaints and objective information for adverse effects. For NSAID therapy, be alert for new-onset epigastric pain, dark or tarry stools, blood in vomitus, dizziness or lightheadedness, development of edema, decreased urine output, or shortness of breath. For colchicine, monitor for nausea or vomiting, diarrhea, easy bruising, cold or flu-like symptoms, lightheadedness, muscle weakness, or pain. Advise the patient to inform you of any new medications started or stopped while taking colchicine.

- Monitor patients receiving intraarticular corticosteroid injections for increased swelling or pain at the injection site.

- Assess patients receiving systemic corticosteroids for mental status changes, fluid retention, increased blood glucose, muscle weakness, or development of new infections.

### Urate Lowering Therapy

- Monitor the SUA level every 2 to 5 weeks during ULT initiation and titration. Adjust the dose of ULT to achieve a target SUA level of less than 6 mg/dL (357 μmol/L) or optionally less than 5 mg/dL (297 μmol/L) in more severe disease. Then continue measurements every 6 months thereafter.

- Concomitantly initiate anti-inflammatory prophylaxis and continue for the greater of 6 months or 3 to 6 months after achieving target SUA level with no gout signs/symptoms.

- Assess for new gouty arthritis attacks or development of tophi.

- Evaluate patients taking allopurinol for development of rash, nausea, or new fever. These symptoms usually appear within the first 3 months of therapy but can occur anytime.

- Evaluate patients prescribed febuxostat for presence of nausea, arthralgias, rash, and transient elevation of hepatic transaminases.

- Assess patients receiving probenecid for fever, nausea, or skin rash. Reevaluate therapy if a significant decrease in urine output occurs.

- If pegloticase is used, monitor SUA levels before each 2-week IV infusion.

- Evaluate patients on pegloticase for development of gouty flares and infusion reactions, which may include anaphylaxis. The manufacturer recommends giving an antihistamine and perhaps low-dose methylprednisolone before the infusion to minimize reactions.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| ACR | American College of Rheumatology |
| ACTH | Adrenocorticotropic hormone |
| AHS | Allopurinol hypersensitivity syndrome |
| COX | Cyclooxygenase |
| G6PD | Glucose-6-phosphate dehydrogenase |
| HLA | Human leukocyte antigen |
| IL-1 | Interleukin-1 |
| MSU | Monosodium urate |
| SUA | Serum uric acid |
| TLS | Tumor lysis syndrome |
| ULT | Urate lowering therapy |
| XOI | Xanthine oxidase inhibitor |

# 60 Musculoskeletal Disorders

Jill S. Borchert

## LEARNING OBJECTIVES

- **Upon completion of the chapter, the reader will be able to:**
  1. Describe the pathophysiologic principles of tissue injury and inflammation.
  2. Identify the desired therapeutic outcomes for a patient with musculoskeletal injury or pain.
  3. Identify the factors that guide selection of an analgesic or counterirritant for a particular patient.
  4. Recommend appropriate nonpharmacologic and pharmacologic therapy for a patient with musculoskeletal injury or pain.
  5. Design a patient education plan, including nonpharmacologic therapy and preventative strategies.
  6. Develop a monitoring plan to assess treatment of a patient with a musculoskeletal disorder.

## INTRODUCTION

The musculoskeletal system consists of muscles, bones, joints, tendons, and ligaments. Disorders related to the musculoskeletal system often are classified by etiology. Acute soft-tissue injuries include strains and sprains of muscles and ligaments.[1] Repeated movements in sports, exercise, work, or activities of daily living can lead to repetitive strain injury, where cumulative damage occurs to the muscles, ligaments, or tendons.[2,3] Although tendonitis and bursitis can arise from acute injury, more commonly these conditions occur as a result of chronic stress.[2,4] Other forms of chronic musculoskeletal pain, such as pain from rheumatoid arthritis (see Chapter 57) or osteoarthritis (see Chapter 58), are discussed elsewhere in this textbook.

## EPIDEMIOLOGY AND ETIOLOGY

Musculoskeletal disorders are commonly self-treated, so true estimates of the incidence of both acute and chronic injury are difficult to obtain. In the United States, over 60 million musculoskeletal injuries occur each year, with 60% of episodes treated in ambulatory care offices.[3] These disorders account for a large portion of medical care expenditures and are a leading cause of work absenteeism and disability, resulting in a substantial economic burden from lost productivity and lost wages.

Some musculoskeletal disorders are induced by trauma at the workplace either via a one-time overexertion or through repetition and cumulative trauma.[3] Strains and sprains are the most common workplace injuries, representing over three-fourths of all musculoskeletal injuries. Musculoskeletal injuries are more likely to occur with heavy lifting, exposure to vibration, or working overhead.[5]

In the elderly, musculoskeletal injuries may not be related to work but to daily life. Half of all musculoskeletal injuries occur in the home with falls being the most common cause for those aged 65 and older.[3] In children and adolescents, fractures are more common than muscle and tendon injuries because growth spurts cause bones to weaken while the muscle–tendon unit tightens.[2]

Muscle injuries comprise the majority of sports-related injuries, and roughly half are related to overuse.[6,7] The ankle is the most common site of sports injury.[8] Basketball, which requires rapid acceleration and higher speeds, poses the greatest risk of muscle sprain.[9] Other sports requiring pivoting at higher speeds, such as volleyball and soccer, also pose a high risk of overuse and acute injury, especially to the knee.[7]

*Overuse musculoskeletal injury* is the phrase used to describe disorders arising from repetitive motion. This injury is common in activities such as running, particularly during periods of increased intensity or duration of training. It also can occur in the workplace with repeated, unvaried motion.[5]

## PATHOPHYSIOLOGY

Skeletal muscle consists of muscle fibers linked together by connective tissue. Tendons and ligaments are composed of collagenous fibers that have a restricted capability to stretch. Tendons connect muscle to bone, whereas ligaments connect bone to bone.

### Muscle Strains and Sprains

A **sprain** is an overstretching of supporting ligaments that results in a partial or complete tear of the ligament.[1,6,9] Although a **strain** also arises from an overstretching of the muscle–tendon unit, it is marked by damage to the muscle fibers or tendon without tearing of the ligament. The key difference is that a sprain involves damage to ligaments, whereas a strain involves damage primarily to muscle.

Overloading the muscle and connective tissue results in complete or partial tears of the skeletal muscle, tendons, or ligaments.[6,10] This usually occurs when the muscle is activated in an *eccentric contraction*, defined as a contraction in which

the muscle is being lengthened.[10] Examples of this type of contraction include putting down a large, heavy laundry basket or lowering oneself from a chin-up bar. Small tears can occur in the muscle because it is lengthening while also trying to contract to support the load. This leads to rupture of blood vessels at the site of the injury, resulting in the formation of a hematoma. Within 24 to 48 hours, an inflammatory response develops. During the inflammatory stage, macrophages remove necrotic fibers.[6,11] The activated neutrophils then release growth factors that will activate myocytes for regeneration. Finally, capillaries grow into the area, and muscle fibers regenerate during the repair and remodeling phases of healing.

### Bursitis and Tendonitis

**Bursitis** is an inflammation of the bursa, the fluid-filled sac near the joint where the tendons and muscles pass over the bone.[4] Overuse of a joint can result in an inflamed bursa. Bursitis causes stiffness and pain because the bursa serves to reduce friction within the joint space.

**Tendonitis** (or *tendinitis*) refers to inflammation of the tendon that follows incomplete tendon degeneration.[2] Repetitive overuse of a tendon can cause cellular changes in the tissues. Specifically, collagenous tendon tissue is replaced with tissue that lacks the organized collagen arrangement of a normal tendon. In fact, many patients diagnosed with chronic tendonitis may not have inflammation but instead have **tendinosis**, a condition marked by these degenerative changes. As a result of the cellular changes, the tendon progressively loses elasticity and its ability to handle stress or weight. This makes the tendon vulnerable to rupture or inflammation.

### Inflammation and Peripheral Pain Sensation

Inflammation is a common pathway in soft-tissue injury of musculoskeletal disorders. Inflammatory processes lead to two outcomes: swelling and pain. Inflammatory processes are considered to be a necessary part of the remodeling process because inflammatory cells remove damaged tissue.[12-14] However, inflammation also contributes to continued pain and swelling that limits range of motion.

The initial injury exposes membrane phospholipids to phospholipase $A_2$, leading to the formation of arachidonic acid.[12,15] Next, arachidonic acid is transformed by cyclooxygenase (COX) to thromboxanes and prostaglandins (PGs), including prostaglandin $E_2$ ($PGE_2$). $PGE_2$ is the most potent inflammatory mediator; it increases vascular permeability, leading to redness, warmth, and swelling of the affected area. The increased permeability also increases **proteolysis**, or the breakdown of proteins in the damaged tissue.

Neutrophils, lymphocytes, and monocytes are attracted to the area, and monocytes are converted to macrophages, which then stimulate additional PG production.[12] Phagocytic cells release cytokines, including interleukins, interferon, and tumor necrosis factor.

In addition to increasing vascular permeability, PGs also induce pain by sensitizing pain receptors to other substances such as bradykinin. Bradykinin, PGs, leukotrienes, and other inflammatory mediators lower the pain threshold through peripheral pain sensitization. These substances make nerve endings more excitable, and the nerve fibers are more reactive to serotonin, heat, and mechanical stimuli.[16] The increased sensitization in the damaged tissue causes tenderness, soreness, and **hyperalgesia**.[16] The process also facilitates production of additional PGs. In a cyclic fashion, the PGs then sensitize the nerves to bradykinin action.

Without interruption, the neurochemicals ultimately lead to a firing of the unmyelinated or thinly myelinated afferent neurons. This sends messages along the pain pathway in the periphery and communicates the pain message to the CNS. Interruption of this cycle may occur via the effects of anti-inflammatory agents such as aspirin and nonsteroidal anti-inflammatory drugs (NSAIDs).

Nerve receptors, or **nociceptors**, release substance P and other peptides when they are activated.[16] Substance P mediates the production and release of inflammatory mediators and acts as a potent vasodilator. This receptor activation also increases the sensitivity of nociceptors to painful stimuli. Capsaicin relieves pain by stimulating the release of substance P from sensory nerve fibers, ultimately depleting stores of substance P.[17]

## CLINICAL PRESENTATION AND DIAGNOSIS

See next page for information on the clinical presentation and diagnosis of musculoskeletal disorders.

## TREATMENT
### Desired Outcomes

**KEY CONCEPT** *The two primary goals of treating musculoskeletal disorders are to: (a) relieve pain and (b) maintain functionality.* This is accomplished by decreasing the severity and duration of pain, shortening the recovery period, and preventing acute injury pain from becoming chronic pain. If these goals are achieved, functional limitations are decreased. Ideally, a patient should be able to continue to perform activities of daily living and maintain normal functions in the workplace. Children ideally should be able to maintain usual play activities and sports schedules.

Further goals include a return to usual activity and prevention of future injury. It is also important to minimize the potential for adverse drug events during treatment.

### General Approach to Treatment

Treatment of musculoskeletal disorders involves three phases: (a) therapy of an acute injury using the rest, ice, compression, and elevation (RICE) principle; (b) pain relief using oral or topical agents; and (c) lifestyle and behavioral modifications for rehabilitation and to prevent recurrent injury or chronic pain (**Figure 60–1**).

In many cases, musculoskeletal disorders are self-treated with over-the-counter (OTC) oral or topical agents. However, further evaluation may be warranted if acute pain persists longer than

---

### Patient Encounter 1, Part 1

A 28-year-old woman presents with left ankle pain. She stepped on one of her son's toys earlier today after coming down the stairs at home and twisted her ankle. The pain occurs at rest and is worsened with weight bearing on the ankle and with rotation or movement. There is moderate swelling and bruising of the left ankle.

*What information is suggestive of a musculoskeletal disorder?*

*What is your assessment of the patient's ankle pain?*

*What additional information do you need to formulate a treatment plan?*

## Clinical Presentation and Diagnosis of Musculoskeletal Disorders

**General[2,4,7,13]**

- Clinical presentation varies based on etiology of the disorder.
- Repetitive strain or overuse injuries may have a gradual onset.
- Disorders due to acute injury may be associated with other signs of injury such as abrasion.
- Low back pain is often chronic.

**Signs and Symptoms of Acute Soft-Tissue Injury (Strains, Sprains)[8,13]**

- Discomfort ranging from tenderness to pain may occur at rest or with motion
- Swelling and inflammation of the affected area
- Bruising
- Loss of motion
- Mechanical instability

**Signs and Symptoms of Repetitive Strain or Overuse Injury (Tendonitis, Bursitis)[2,4,7]**

- Pain and stiffness that occurs either at rest or with motion
- Localized tenderness on palpation

- Mild swelling of the affected area
- Decreased range of motion
- Muscle atrophy

**Other Diagnostic Tests and Assessments[8]**

- *Radiograph (x-ray)*: Evaluate bony structures to rule out fracture, malalignment, or joint erosion as the primary cause of pain.
- *MRI*: Soft-tissue imaging to evaluate for tendon or ligament tears.
- *Ultrasound*: Superficial soft-tissue imaging to evaluate for tears in tendons or ligaments. Ultrasound does not penetrate bone, so it is of limited usefulness for assessing tendons or ligaments deep within joints.
- *Pain scale*: Patient self-rating on a scale of zero (no pain) to 10 (worst possible pain). Used to assess pain both at rest and with movement. Determined at baseline and to assess response to therapy.

7 to 10 days, symptoms worsen or subside and then return, or there are signs of a more serious condition.[8,18,19] Warning signs of more serious conditions include joint deformity, dislocation, or lack of movement in a joint. Low back pain accompanied by burning, radiating pain, or difficulty urinating requires further evaluation.

**FIGURE 60–1.** Treatment plan for musculoskeletal injury or disorder.

In children and adolescents, treatment practices are similar to the approach in adults with a focus on nonpharmacologic therapy and oral analgesics. Children younger than 2 years, elderly persons, and pregnant women also may need special care. Elderly patients may be more prone to systemic effects because of thinning of the skin and increased absorption of topical agents and drug interactions from polypharmacy.

### Nonpharmacologic Therapy: RICE

**KEY CONCEPT** *The cornerstone of nonpharmacologic therapy for acute injury in the first 48 to 72 hours is known by the acronym RICE: rest, ice, compression, and elevation*[6,13,20] (**Table 60–1**). These four methods initially minimize bleeding from broken blood vessels. Rest eases pressure on the affected area and promotes pain control during the acute inflammatory phase (the first 1–5 days after injury). Cold causes vasoconstriction, assisting in prevention of a large hematoma and providing analgesia by slowing nerve impulses. Immediately after injury, ice also helps to reduce metabolic rate and oxygen demand, thereby reducing tissue damage from hypoxia.[20] Compression, achieved by wrapping the area with an elastic bandage, also reduces the size of the developing hematoma.[6] Preventing hematoma formation is important because a large hematoma can limit mobility and range of motion. Cold and compression also decrease swelling. Elevation decreases blood flow and increases venous return from the affected area.

In addition to minimizing the acute inflammatory response, rest prevents additional injury to the affected area.[6] During acute injury, the ability of muscles and tendons to stretch is limited. Movement in the injured tissue can cause further retraction of the ruptured muscle and increase the size of the gap in the muscle to be healed. Therefore, early activity predisposes a patient to further injury, but prolonged inactivity can lengthen recovery times.

The benefits of ice following injury are well documented, but recommendations for the method of application vary widely.[13,14,20]

| Table 60–1 | | |
|---|---|---|
| **RICE Therapy** | | |
| **Therapy** | **General Guidelines** | **Therapeutic Benefit** |
| *Rest* | Rest the affected area | Analgesia |
| | Use supports such as slings and crutches as necessary | Anti-inflammatory |
| | Employ during the acute inflammatory phase, 1–5 days after injury | Prevent further injury |
| *Ice* | Cool the affected area by submersion in cool water (13°C [55°F]) or by application of crushed ice in a plastic bag covered with a thin cloth | Analgesia |
| | Cool the affected area for 15–20 minutes; repeat every 2 hours for the first 48 hours | Anti-inflammatory |
| *Compression* | Compress the affected area with an elastic bandage or support | Anti-inflammatory |
| | Begin wrapping the bandage at the point most distal to the injury (eg, at the toes for an ankle injury); bind firmly but not tightly | Adjunctive analgesia |
| | If the area distal to the injury (eg, fingers, toes) throbs or turns cold or blue, the bandage is too tight and should be loosened | |
| *Elevation* | Elevate the area (especially the extremities) above heart level | Anti-inflammatory |

Crushed ice or ice chips should be used because the area will cool more evenly than with large pieces of ice. Patients should not apply ice directly to the affected area or leave it on for longer than the recommended 20 minutes, because extreme cold can cause tissue damage.[13] Similarly, patients should wait at least 1 hour before reapplication of ice to allow the tissue to rewarm. A thin sheet or napkin will protect the skin and also allow for better cold transfer than thicker material such as a towel. Alternatively, soaking the area for 20 minutes in a cool bath (13°C [55°F]) provides effective cooling, provided the area can remain elevated.

For small areas, an ice massage for 5 to 10 minutes can cool the area and add relief.[21] This can be accomplished by freezing water in a paper cup, removing the top part of the cup to expose the ice, and rubbing the exposed ice on the affected area. Any ice application should be stopped if the area becomes white or blue.

**KEY CONCEPT** *Heat should not be applied during the acute injury phase (when edema is present) because it promotes swelling and inflammation.*[14,21] After the acute phase, many patients find that heat decreases pain and eases muscle stiffness. A heating pad, heat wrap, or warm bath can be used as long as no edema is present and no swelling develops after heat is applied. Patients should avoid sleeping with or sitting or lying on heating pads because this can result in burns. Low-level heat, such as that supplied by therapeutic heat wraps (eg, ThermaCare), may provide a safer means of heat application. However, the risk of burns increases with age, and elderly persons should be cautioned about this risk.

## Pharmacologic Therapy

**KEY CONCEPT** *There are two main approaches to pharmacologic intervention for pain relief: oral (systemic) and topical agents.* The choice between systemic or topical options is often guided by patient preference. For example, many topical products have a medicinal odor and require frequent applications. The extent of musculoskeletal pain also guides treatment choice. **KEY CONCEPT** *Localized pain may be treated effectively with local topical therapy, whereas generalized pain is best treated with systemic agents.* Factors such as alcohol use, liver function, renal function, allergies, age, and comorbid conditions should be considered when choosing among therapeutic options.

▶ *Oral Analgesics*

Nonopioid analgesics, including acetaminophen, aspirin, and NSAIDs, are used commonly for musculoskeletal disorders. These agents all provide analgesia, but aspirin and NSAIDs also work peripherally by inhibiting the enzyme COX to decrease production of $PGE_2$, the principal mediator of acute inflammation.[15,16] Although the mechanism of action of acetaminophen is less clear, it appears that acetaminophen acts as a weak inhibitor of PG production via COX-2 inhibition and exerts only a mild anti-inflammatory effect.[22]

**Acetaminophen** **KEY CONCEPT** *Acetaminophen is the drug of choice for mild-to-moderate regional musculoskeletal pain without inflammation.*[15,23] Comparative trials between acetaminophen and oral NSAIDs demonstrate equivalent analgesia in some situations, but NSAIDs may be preferred in others. Therefore, if adequate analgesia is not achieved with acetaminophen, switching to an NSAID is a reasonable alternative. Acetaminophen offers the advantage of less GI toxicity than NSAIDs. Although tolerability of acetaminophen is high at therapeutic doses, hepatotoxicity has been reported after overdose and at therapeutic doses, especially in combination with other factors.[15,23] Patients should not exceed 4 g/day of acetaminophen to minimize the risk of liver injury. Acetaminophen should be used with caution in patients who have liver disease or consume alcohol because of the risk of hepatotoxicity. Due to concern over liver injury, many nonprescription products are now labeled with a maximum recommended dose of 3 g/day. In addition, oral prescription combination products are limited by the U.S. Food and Drug Administration (FDA) to 325 mg acetaminophen per dosage unit.

**Salicylates** **KEY CONCEPT** *Aspirin is not more effective than acetaminophen, and it is not recommended for treatment of acute musculoskeletal pain because its adverse effects may be more common and severe.*[15] Gastric irritation is more common with aspirin, and bleeding risk is increased because aspirin irreversibly inhibits platelet aggregation. Patients with aspirin-induced asthma should avoid aspirin and other salicylates. Due to the risk of Reye syndrome, aspirin should be avoided in persons younger than age 19 during episodes of fever-causing illnesses.

Some salicylates are specifically marketed for musculoskeletal back pain, such as magnesium salicylate. However, no studies specifically support use of these salicylates over other systemic analgesics. Magnesium salicylate should be used with caution in patients with renal impairment due to risk of hypermagnesemia.[15]

**NSAIDs** Oral NSAIDs are used commonly for musculoskeletal pain because of their availability without a prescription and anti-inflammatory effects.[15,16] **KEY CONCEPT** *NSAIDs are a preferred choice over acetaminophen in musculoskeletal disorders in which*

*inflammation is the primary problem.*[4,15,23] As a result, NSAIDs are particularly beneficial for chronic overuse injury, in which inflammation is central to the pain and loss of motion. Although NSAIDs may be helpful in relieving pain and inflammation in tendonitis, many tendinopathies are not associated with inflammation. Therefore, use of a simple analgesic such as acetaminophen may relieve pain adequately.[2]

The analgesic effects of NSAIDs are attributed to inhibition of the COX-2 enzyme, whereas the negative GI effects are due to inhibition of COX-1.[15] Patients taking oral anticoagulants, those with a history of peptic ulcer disease, or others at high risk for GI complications may be considered candidates for a COX-2 inhibitor (eg, celecoxib) or a combination of a nonselective NSAID with a gastroprotective agent such as a proton pump inhibitor (see Chapter 58). Combination of any NSAID, including COX-2 inhibitors, with alcohol can increase GI adverse effects. Additionally, all NSAIDs should be used with caution in patients with aspirin-induced asthma.[15]

Both nonselective NSAIDs and COX-2 inhibitors are associated with nephrotoxicity.[23] Furthermore, NSAIDs, including selective COX-2 inhibitors, may increase the risk of myocardial infarction. However, this risk may be higher for the COX-2 inhibitors due to an imbalance in thromboxane $A_2$ relative to prostacyclin levels creating a prothrombotic environment. A more detailed discussion of the relative risks of nonselective NSAIDs and COX-2 inhibitors and treatment options based on the cardiovascular and GI risk of the individual patient appears elsewhere in this text (see Chapter 58).

● **Opioids** Opioid analgesics can be used for patients not responding adequately to nonopioid analgesics or for moderate-to-severe pain.[4] These agents generally are given alone or in combination with simple analgesics such as acetaminophen. Tolerance and physical dependence are considerations but less of a concern when treating acute pain. When used in equivalent doses, opioids produce similar pain relief and adverse effects such as sedation, nausea, constipation, and respiratory depression (see Chapter 34).

▶ *Topical (External) Analgesics*

Topically (or externally) applied drugs that exert a local analgesic, anesthetic, or antipruritic effect by either suppressing cutaneous sensory receptors or by stimulating these receptors in a counterirritant fashion are termed *external analgesics*.[18] These medications are applied directly to the affected area to create high local concentrations of the drug.[17,24] Formulations include gel, cream, lotion, patch, liquid, liniment, or aerosol spray. Negligible systemic concentrations are achieved with intact skin, minimizing systemic adverse effects. Topical application should not be confused with transdermal delivery, in which drug absorption into the bloodstream produces a systemic effect. Musculoskeletal disorders often are treated with topical (but not transdermal) medications.

After application, the topical medication penetrates the skin to the soft tissue and peripheral nerves.[18] At the site, topical analgesics suppress the sensitization of pain receptors, thereby reducing pain and burning. Examples include topical NSAIDs and local anesthetics such as lidocaine. In contrast, *counterirritant* products are external analgesics that stimulate cutaneous sensory receptors, producing a burning, warming, or cooling sensation that masks the underlying pain. In effect, the irritation or inflammation caused by the counterirritant distracts from the underlying pain. Menthol and capsaicin are examples of counterirritants.

Some patients prefer external analgesics to systemic analgesics because the rubbing during application can be comforting.[25] External analgesics are useful adjuvants to nonpharmacologic therapy and systemic analgesic therapy to provide additional relief. These agents are also an option in patients who cannot tolerate systemic analgesics. Because these products are not in pill form and many are available without a prescription, they may be overused or misused. This prompted the FDA to caution consumers that the agents are medicines that may also cause harm.[26] Clinicians should advise patients to read and follow directions on the labels of OTC products.

*Topical NSAIDs.* In acute soft-tissue injury such as strains and sprains, topical NSAIDs have efficacy that is superior to that of placebo and similar to that of oral NSAIDs.[24,27] Tissue concentrations of topical NSAIDs are high enough to produce anti-inflammatory effects, but systemic concentrations after application remain low.

Diclofenac is the only topical NSAID commercially available in the United States.[27–31] Diclofenac patch (Flector Patch) is indicated specifically for topical treatment of acute pain from minor sprains and strains.[28] The patch is applied to the most painful area twice daily. Diclofenac gel (Voltaren Gel) is indicated for joint pain in the knees and hands secondary to osteoarthritis; it is applied up to four times daily.[29] Diclofenac solution (Pennsaid) is indicated for osteoarthritis of the knee; it is applied to the knee and is available in a solution applied via dropper four times daily or via measured pump two times daily.[27,31] Patient education for topical NSAIDs is outlined in **Table 60–2**.[27–29,31]

**Table 60–2**

**Patient Education for Topical Diclofenac Products**

| All Topical Products | Diclofenac Gel | Diclofenac Patch | Diclofenac Solution |
|---|---|---|---|
| Do not apply to damaged or nonintact skin<br>Wash hands after application and/or removal<br>Discontinue use if rash or irritation develops<br>Do not use with oral NSAIDs | Use enclosed dosing card to determine amount for application<br>Avoid bathing or showering for 1 hour after application<br>Avoid sun exposure or tanning beds<br>Do not use with other topical agents (eg, sunscreens, lotions, moisturizers, and insect repellants) | Apply to skin at the most painful area<br>Do not wear during bathing or showering<br>Tape patch in place if it begins to peel off<br>Discard used patches away from children and pets | Apply 40 drops of 1.5% solution (10 drops at a time) four times daily or two pump actuations of 2% solution twice daily to each affected knee<br>Apply directly to knee or first into the hand, then to the knee<br>Rub evenly around front, back, and sides of the knee<br>Do not cover with clothing or apply other topical products until completely dry |

Data from Refs. 27–29 and 31.

**Table 60–3**

**Nonprescription Counterirritant External Analgesics**

| Group and Effect | Agents and Concentration | Example Products (If Applicable) | Comments |
|---|---|---|---|
| **Group A** Rubefacients: Produce redness | Allyl isothiocyanate 0.5%–5% | | Mustard derivative; pungent odor; avoid inhalation |
| | Ammonia water 1%–2.5% | | More concentrated solutions are highly caustic; avoid inhalation |
| | Methyl salicylate 10%–60% | BenGay Ultra Strength[a] Flexall Plus[a] Icy Hot Stick[a] | Caution in aspirin sensitivity May produce systemic concentrations May increase INR with warfarin |
| **Group B** Produce cooling | Camphor 3%–11% Menthol 1.25%–16% | JointFlex BenGay Patch Icy Hot Patch Mineral Ice | Medicinal odor Sensation of heat follows cooling Mild anesthetic effects at low concentrations |
| **Group C** Produce vasodilation | Methyl nicotinate 0.25%–1% | | May produce systemic vasodilation |
| **Group D** Irritate without redness | Capsaicin 0.025%–0.25% Capsicum oleoresin 0.025%–0.25% | Capzasin-HP, Zostrix | Must use regularly Burning effect subsides with regular use |

INR, international normalized ratio.

[a]Combination products that also contain menthol and/or camphor.

Theoretically, the risk of serious GI adverse events should be less than with oral NSAIDs, but long-term studies evaluating these events are lacking.[24,30] Like oral NSAIDs, topical NSAIDs should be used with caution in patients with a history of GI bleeding or ulcer.[27–29,31] Studies comparing topical NSAIDs with other topical products, including counterirritants, are also needed. Local cutaneous adverse reactions (eg, erythema, rash, pruritus, and irritation) are reported and may be due in part to the vehicle used.[27–29,31]

*Local Anesthetics.* Nonprescription topical anesthetics such as lidocaine and benzocaine are available in many types of products. Local anesthetics decrease discharges in superficial somatic nerves and cause numbness on the skin surface but do not penetrate deeper structures such as muscle where the pain often lies.[17]

However, local anesthetics are helpful when abrasion accompanies the injury. Application of an OTC antibiotic ointment containing an anesthetic provides soothing relief, promotes healing of abrasions, and prevents soft-tissue infection. Minor abrasions should be cleansed with mild soap and water before application. More severe abrasions may require removal of debris by a clinician followed by irrigation with normal saline.

*Counterirritants.* Counterirritants are categorized by the FDA into four groups (groups A through D) based on their primary actions (Table 60–3). They produce a feeling of warmth, cooling, or irritation that diverts sensation from the primary source of pain. Because these irritant effects are central to the beneficial actions, counterirritants should not be combined with topical anesthetics or topical analgesics.

Counterirritants are indicated for the temporary relief of minor aches and pains related to muscles and joints.[18] These symptoms may be associated with simple backache, arthritis, strains, sprains, or bruises. Many are available as combination products with ingredients from different counterirritant groups. Active ingredients in marketed products sometimes change;

clinicians should be aware of the current ingredients before providing a product recommendation. `KEY CONCEPT` *Patient education on proper use of counterirritants is essential to therapeutic success* (Table 60–4).[18]

Rubefacients (group A) are counterirritants that produce redness on application. Topical rubefacients containing salicylates (eg, methyl salicylate) are used most commonly. Turpentine oil is no longer judged as either safe or effective but remains in a few products.[18] Clinical trial data evaluating the effect of rubefacients on acute pain from strains, sprains, sports injuries, and chronic musculoskeletal pain are lacking.[32] A systematic review noted that topical salicylates are effective for pain from acute musculoskeletal conditions, but the low quality of the evidence

**Table 60–4**

**Patient Education for Counterirritants**

Apply up to three to five times daily to affected area.
Only for external use on the skin; do not ingest.
Do not apply to broken or damaged skin or cover large areas.
Wash hands immediately after application.
Avoid contact with the eyes and mouth.
Do not use with heating pads or other methods of heat application, because burning or blistering can occur.
Do not wrap or bandage the area tightly after application.
Consult a physician if:

- Symptoms worsen
- Symptoms persist for more than 7 days[a]
- Symptoms resolve but then recur

[a]Capsaicin may be used for chronic pain and must be applied consistently for efficacy.

From External analgesics drug products for over-the-counter human use: tentative final monograph. Fed Regist. 1983;48:5851–5869.

led authors to conclude that there are no good data supporting the efficacy of rubefacients.[32]

Methyl salicylate and trolamine salicylate are topical salicylates. Methyl salicylate is considered a counterirritant, but trolamine salicylate is not considered a counterirritant because it does not produce localized irritation after application. Application of both topical salicylates can lead to systemic effects, especially if the product is applied liberally.[33] Repeated application and occlusion with a wrap or bandage also can increase systemic concentrations. Salicylate-containing products should be used with caution in patients in whom systemic salicylates are contraindicated, such as patients with severe asthma or aspirin allergy.[33] Topical salicylates have been reported to increase prothrombin time in patients on warfarin and should be used with caution in patients on oral anticoagulants. Methyl salicylate, including oil of wintergreen, is a common source of pediatric poisonings.[34] Clinicians should advise patients to keep products out of the reach of children.

The FDA advises that there is insufficient evidence to support the effectiveness of trolamine salicylate.[18] However, many patients choose trolamine products because of the lack of medicinal odor.

The group B counterirritants menthol and camphor exert a sensation of cooling through direct action on sensory nerve endings.[33,35] A sensation of warmth follows the cooling effect. The agents also have mild anesthetic activity at low concentrations.[35] In higher concentrations, they act as counterirritants and cause a burning sensation by stimulating cutaneous nociceptors. Menthol and camphor are used often in combination with rubefacients.

Menthol, also known as peppermint oil, is used widely in toothpastes, mouthwashes, gum, lozenges, lip balms, and nasal decongestants. For topical analgesic use, it is available in creams, lotions, ointment, and patches. The patches can be trimmed to fit the affected area.

Menthol and camphor should not be used in children younger than 2 years.[18] Despite limits on the concentration of available products, camphor can be toxic to children even in small amounts, posing a seizure risk.[15] Patients should be advised to keep the products out of the reach of children.

The group C counterirritants methyl nicotinate and histamine dihydrochloride produce vasodilation.[18] Methyl nicotinate produces PG-mediated vasodilation.[36] NSAIDs and aspirin block the production of PGs and decrease methyl nicotinate–induced vasodilation. Application over a large area has been reported to cause systemic symptoms and syncope, possibly due to vasodilation and a decrease in blood pressure.[37] Patients should be educated to apply only scant amounts to the affected area.

The primary counterirritant in group D is capsaicin, a natural substance found in red chili peppers and responsible for the hot, spicy characteristic when used in foods.[15,17,25,38] Capsaicin stimulates the release of substance P from local sensory nerve fibers, depleting substance P stores over time. A period of reduced sensitivity to painful stimuli follows, and transmission of pain impulses to the CNS is reduced.

As with other counterirritants, capsaicin and its derivatives (ie, capsicum and capsicum oleoresin) exert a warming or burning sensation.[15,17] With repeated application, desensitization occurs, and the burning sensation subsides. This typically occurs within the first 1 to 2 weeks. After discontinuation, resensitization occurs gradually and returns completely within a few weeks.

Because of the lag time between initiation and effect, capsaicin is not used for treatment of acute pain from injury. Instead, topical capsaicin is used for chronic pain from musculoskeletal

and neuropathic disorders. Capsaicin preparations have been studied for treatment of pain from diabetic neuropathy, osteoarthritis, postherpetic neuralgia, and other disorders.[39] It is often used as an adjuvant to systemic analgesics in these chronic pain conditions.

Although systemic adverse effects to capsaicin are rare, local adverse effects are expected and common.[17,25] Patient education regarding consistent use of capsaicin products is essential to achieving desired outcomes. Product should be applied in a thin layer and rubbed into the skin thoroughly until little remains on the surface.[33] **KEY CONCEPT** *Patients using capsaicin should be advised to apply it regularly and consistently three to four times daily and that full effect may take 1 to 2 weeks or longer.* Patients should be assured that the burning effects will diminish with repeated application. Adherence to therapy is essential because the burning sensation persists if applications are less frequent than recommended. Because the burning sensation is enhanced with heat, patients should avoid hot showers or baths immediately before or after application. Wearing nitrile gloves during application can decrease the potential for unintended contact with eyes or mucous membranes. Dried product residue has been reported to cause respiratory effects on inhalation, and caution should be used in patients with asthma or other respiratory illnesses.

#### ▶ *Oral Muscle Relaxants*

Where pain is worsened by muscle spasm, oral muscle relaxants serve as a useful adjunct to therapy.[40] Antispasmodic agents are preferred over antispastic agents for musculoskeletal pain. The antispasmodic agents include metaxalone, methocarbamol, carisoprodol, and cyclobenzaprine. Muscle relaxants decrease spasm and stiffness associated with either acute or chronic musculoskeletal disorders. These agents should be used with caution because they all may cause sedation, especially in combination with alcohol or opioid analgesics.

### Lifestyle and Behavioral Modifications

After treatment of the acute injury with RICE and pharmacologic therapy, the final phase of therapy is rehabilitation and prevention of future injury. For most injuries, prolonged

---

**Patient Encounter 1, Part 2: Medical History, Physical Examination, and Diagnostic Tests**

**PMH/PSH:** C-section 2 years ago

**SH:** Smokes two to three cigarettes per week socially; drinks wine with dinner on Fridays

**Meds:** Women's Multivitamin one tablet by mouth daily, vitamin D 400 IU by mouth daily

**Allergies:** NKDA

**Intolerances**: NSAIDS, stomach upset

**Preferences**: Prefers topical product due to history of adverse effects with oral products

**Diagnostic Tests:** Radiographs of left ankle show no evidence of fracture

*What are your treatment goals and desired outcomes?*

*What nonpharmacologic and pharmacologic treatments options are available? Are there treatment options that should be avoided? If so, which options and why?*

**Patient Encounter 1, Part 3: Creating a Care Plan**

*Based on the information presented, create a care plan to treat this patient's ankle injury. Your plan should include the following:*

*(a) The goals of therapy and desired outcomes*

*(b) A patient-specific therapeutic plan, including nonpharmacologic therapy*

*(c) A plan to monitor the outcome of therapy to determine whether goals of therapy have been met and adverse effects avoided*

**Patient Encounter 2**

A 14-year-old boy presents with right wrist pain. On questioning, you determine that he spends more than 4 hours a day playing video games and sends text messages often throughout the day. He is right-handed and reports gradual onset of pain over the last few months. When he wakes in the morning he has minimal pain after resting overnight, but the pain intensifies throughout the day. He reports decreased range of motion compared with the left wrist. He has no significant past medical history and his only medication is a daily multivitamin.

*Given this information, what is your assessment of the patient's wrist pain? What is the likely etiology of the pain?*

*What nonpharmacologic and pharmacologic treatment options should be considered?*

*Based on the information presented, create a care plan for this patient's wrist injury. Your plan should include the following:*

*(a) The goals of therapy and desired outcomes*

*(b) A patient-specific therapeutic plan, including nonpharmacologic therapy*

*(c) A monitoring plan to determine whether goals of therapy have been met and adverse effects avoided*

immobilization can lengthen the recovery time by causing wasting of the healthy muscle fibers.[6,10,14] Rehabilitation starts with the development of range of motion via stretching exercises. The patient should warm the muscle first with light activity or moderate heat. Warmth produces relaxation and increases elasticity. Next, the patient should start general strengthening exercises.[20] Strengthening and stretching exercises should be continued beyond the healing phase to prevent future injury.

After rehabilitation, the patient should be educated about behavior changes to prevent reinjury or the development of chronic pain.[14,20] The warm-up and strengthening routines learned in the rehabilitation phase should be continued. For overuse injury, correction of biomechanical abnormalities with proper footwear and changes in technique may correct misalignments and imbalances. Repetitive trauma can be decreased with proper training (eg, by implementing a gradual increase in mileage in a running plan).[2,7]

In the workplace, repetitive motion can be decreased through proper ergonomic design and diversification of job tasks.[5] In pain of the back or lower extremity, weight loss in overweight or obese patients can assist in reduction of further inflammation and help to prevent reinjury or repetitive strain injuries.[4]

**Patient Care Process**

**Patient Assessment:**

- Assess symptoms. Determine the timing of injury (if applicable), duration, type and degree of pain, and exacerbating factors. Determine if there is interference with usual activities or range of motion.

- Assess exacerbating or alleviating factors. Ask if the patient has tried any nonpharmacologic or pharmacologic treatments.

- Obtain a complete medication history, including prescription and nonprescription drugs and dietary supplement use. Determine whether the patient has used successful or unsuccessful treatments for this condition in the past.

- Gather patient history. Inquire about social history and alcohol use. Ask the patient about drug allergies and chronic health problems such as asthma.

- Assess patient preference for systemic (oral) or local (topical) therapy including acceptability of topical medication with frequent application and/or a medicinal odor.

**Therapy Evaluation:**

- Based on assessment of symptoms, determine whether empirical care or diagnostic evaluation is appropriate.

- If pain and/or swelling are not controlled, determine if pharmacologic therapy is warranted.

**Care Plan Development:**

- Select nonpharmacologic and pharmacologic therapy appropriate for the specific patient (see Tables 60–1 and 60–3; see Figure 60–1).

- Educate the patient on nonpharmacologic therapy, including each of the steps in RICE. If swelling is no longer present, consider heat instead of ice (see Table 60–1).

- Educate on proper use of oral or topical agents selected (see Tables 60–2 and 60–4). If a counterirritant is recommended, counsel patients on the irritant effect of the product and recommend washing hands immediately after use and to avoid heating pads. For patients using a capsaicin product, emphasize adherence.

**Follow-Up Evaluation:**

- If pain is from an acute injury, assess effectiveness within 7 to 10 days. For chronic pain treated with capsaicin, begin to assess pain control in 2 weeks.

- Evaluate for adherence, adverse effects (systemic or local), and drug interactions.

Non–weight-bearing activities, such as swimming or bicycling, can be recommended for initial return to activity.[41]

## OUTCOME EVALUATION

- Use a pain scale to monitor treatment interventions to ensure that pain relief is achieved. Ask the patient to rate pain on a scale of zero (no pain) to 10 (worst possible pain) both at rest and with movement. Compare the results with baseline pain assessment to monitor the response to therapy. In pediatric patients, use a visual pain scale with facial expressions depicting various degrees of pain.

- Assess range of motion at baseline and after treatment by comparing movement with the unaffected limb and functionality before the injury. Assess functionality by asking patients if they are able to perform activities of daily living or participate in exercise as desired.

- If pain from acute injury does not decrease greatly within 7 to 10 days, further diagnostic evaluation is warranted.

- For patients using capsaicin products, assess adherence to regular application for therapeutic benefit. Assess chronic pain control in 2 weeks.

- Assess medication adverse effects on a regular basis. When NSAIDs and aspirin are used, ask about GI tolerability, bruising, and bleeding. Inquire about local adverse effects, such as burning, when topical counterirritants are used for treatment.

- Evaluate adherence to preventative rehabilitation measures such as proper footwear, warm-up before activity, strength training, and proper lifting technique.

## Abbreviations Introduced in This Chapter

COX     Cyclooxygenase
NSAIDs   Nonsteroidal anti-inflammatory drugs
PG       Prostaglandin

# Glaucoma
Mikael D. Jones

Mikael D. Jones

## LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Identify risk factors for the development of primary open-angle glaucoma (POAG) and acute angle-closure glaucoma.

2. Recommend a frequency for glaucoma screening based on patient-specific risk factors.

3. Compare and contrast the pathophysiologic mechanisms responsible for open-angle glaucoma and acute angle-closure glaucoma.

4. Compare and contrast the clinical presentation of chronic open-angle glaucoma and acute angle-closure glaucoma.

5. List the goals of treatment for patients with POAG suspect, POAG, and acute angle-closure glaucoma.

6. Choose the most appropriate therapy based on patient-specific data for open-angle glaucoma, glaucoma suspect, and acute angle-closure glaucoma.

7. Develop a monitoring plan for patients on specific pharmacologic regimens.

8. Counsel patients about glaucoma, drug therapy options, ophthalmic administration techniques, and the importance of adherence to the prescribed regimen.

## INTRODUCTION

**G**laucoma refers to a spectrum of ophthalmic disorders characterized by neuropathy of the optic nerve and loss of retinal ganglion cells, which typically leads to permanent deterioration of the visual field (peripheral vision) initially and potentially total vision loss (including central vision). It is often, but not always, eye pressure related.[1–3] **Table 61–1** describes the general classification of glaucoma. *Glaucoma Suspects* are patients with a higher than average risk of developing glaucoma because of the presence of certain clinical findings, family history, or racial background. Glaucoma suspects can be further classified as open-angle glaucoma suspects or angle-closure glaucoma suspects.

Primary open-angle glaucoma (POAG) and primary angle-closure glaucoma (PACG) represent the most common types of glaucoma and therefore are the focus of this chapter. A common presentation of PACG is acute angle-closure crisis (AACC). AACC is the sudden obstruction of the trabecular meshwork, which leads to rapid increases in IOP resulting in pressure-induced optic neuropathy if untreated.[1–4] **KEY CONCEPT** *Patients with POAG typically have a slow, insidious loss of vision. This is contrasted by the course of AACC, which can lead to rapid vision loss that develops over hours to days.*

## EPIDEMIOLOGY AND ETIOLOGY

● It is estimated that almost 65 million people had glaucoma in 2013, making it the second leading cause of blindness after cataracts. By 2040 this number may increase to greater than 110 million people worldwide[5]) In 2010, glaucoma was the second leading cause of blindness worldwide.[6] In North America it is estimated that almost 3 million people are affected by POAG, and by 2040 this number will increase to 4.2 million.[5] The prevalence varies with race and ethnicity, and it is three to five times more prevalent in African Americans than white Americans.[7] The prevalence of POAG increases with age and is rarely seen in patients younger than 40 years.[7,8] The prevalence of POAG suspects is difficult to estimate at this time, but it is estimated that 3.5% to 4.5% of white and Hispanic patients older than 40 years have ocular hypertension.[2]

Approximately 20 million people were estimated to have angle-closure glaucoma in 2013, and this is projected to increase to 32 million people by 2040.[5] The prevalence of angle-closure glaucoma is lower than POAG and varies significantly by race and ethnicity. The prevalence is lower in patients of European ancestry (0.4%) but higher in patients of Asian ancestry (1.2%).[5] PACG is also more prevalent with increasing age and among females.[4]

## PATHOPHYSIOLOGY

The pathophysiology of glaucomatous neurodegeneration has not been completely elucidated but appears to be caused by both IOP-dependent and IOP-independent factors. Elevated IOP is clearly associated with damage and eventual death of optic nerves; however, optic neuropathy still occurs in patients without elevated IOP which indicates the presence of independent factors that contribute to ganglion cell death.[9,10] The key to

| Table 61–1 | |
|---|---|
| **Glaucoma Classifications** | |
| **Classification** | **Description** |
| Primary glaucoma | Glaucoma that cannot be attributed to a preexisting ocular or systemic disease. |
| Secondary glaucoma | Glaucoma that can be attributed to preexisting ocular or systemic disease. Examples include pigment dispersion syndrome, neovascular glaucoma, and pseudoexfoliative syndrome. |
| Open-angle glaucoma | Glaucoma characterized by normal anterior-chamber angles and glaucomatous changes of the optic disc. Can be further classified as primary or secondary. |
| Angle-closure glaucoma | Glaucoma characterized by the obstruction of the anterior chamber angle resulting in either intermittent or progressive elevated IOP with subsequent damage to the optic nerve. Can be further classified as primary or secondary. |

Data from Refs. 3 and 4.

**FIGURE 61–1.** Anatomy of the eye. (From Lesar Ts, Fiscella Rg, Edward D. Glaucoma. In: Dipiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York: McGraw-Hill, 2014:1526.)

understanding the pathophysiology and treatment of glaucoma relies on an understanding of aqueous humor dynamics, IOP, and optic nerve anatomy and physiology.

## Aqueous Humor and Intraocular Pressure

IOP maintains the curvature of the cornea which is important for the refractive properties of the eye.[11] The distribution of IOP in the general population is 10 to 21 mm Hg (1.3–2.8 kPa) and is slightly skewed toward higher values. However, caution should be used in assigning this as the "normal range" for IOP because some patients may have optic neuropathy in the "normal range" while for other patients optic neuropathy may be absent at higher IOPs. Elevated IOP is generally considered greater than 21 mm Hg (2.8 kPa).[12]

Aqueous humor is an optically neutral fluid that provides oxygen and nutrition to the avascular lens and cornea. IOP is dependent on the balance between aqueous humor production and outflow from the anterior segment. (Figures 61–1 and 61–2). The anterior segment of the eye is separated by the iris into the posterior and anterior chambers. The ciliary body, a ring-like structure that surrounds and supports the lens. It also produces aqueous humor through the diffusion and ultrafiltration of plasma. The nonpigmented epithelium of the ciliary body secretes the aqueous humor into the posterior chamber. Aqueous

**FIGURE 61–2.** Anterior chamber of the eye and aqueous humor flow. (From Lesar TS, Fiscella RG, Edward D. Glaucoma. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York: McGraw-Hill, 2014:1526.

humor formation can be modified pharmacologically through the α- and β-adrenoceptors, carbonic anhydrase, and sodium and potassium adenosine triphosphatase of the nonpigmented ciliary epithelium.[13,14]

After secretion, the aqueous humor flows from the posterior chamber through the pupil into the anterior chamber. From the anterior chamber, approximately 80% of aqueous humor then exits through the trabecular meshwork while the remaining 20% exits through the uveoscleral pathway.[13,14]

The trabecular meshwork is a lattice of connective tissue that surrounds edge of the anterior chamber located in the inside intersection of the edge of the cornea and the iris insertion. The size of the trabecular meshwork can be altered by the contraction or the relaxation of the ciliary muscle. Stimulation of muscarinic receptors on the ciliary muscle causes contraction, which in turn causes the pores of the trabecular meshwork to open, increasing aqueous humor outflow into Schlemm canal and the episcleral venous system.[13] The contraction can also be decreased by inhibiting Rho Kinases which are involved in the regulation of the contractile tone of the trabecular meshwork tissue.[14]

In the uveoscleral pathway, aqueous humor exits the anterior chamber through the iris root and through spaces in the ciliary muscles, which then drain into the suprachoroidal space. Uveoscleral outflow can be pharmacologically modulated by adrenoceptors, prostanoid receptors, and prostamide receptors.[11,15]

### Optic Nerve

In the posterior segment of the eye, retinal ganglion cells are responsible for transmitting visual signaling from the retina to the brain. The axons of the retinal ganglion cells converge at the retinal nerve fiber layer to form the optic nerve. The optic nerve head (also called the optic disc) is the portion of the optic nerve that is visible on funduscopic examination. The optic nerve head is vertically oval and pink to pale yellow with a depression in the center of the optic nerve, called a physiologic cup which is formed as the axons converge and exit the eye as a bundle through the lamina cribrosa. (Figure 61–3). The optic nerve synapses at the lateral geniculate nucleus in the brain.[9,10,16,17]

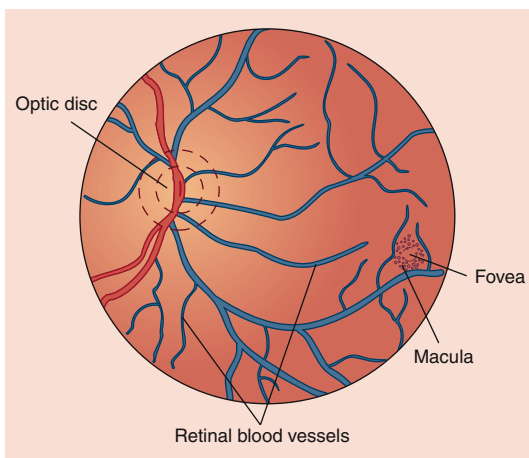

**FIGURE 61–3.** Normal fundus of the eye and optic disc and cup. (Reprinted with permission from Lesar TS, Fiscella RG, Edward D. Glaucoma. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York: McGraw-Hill, 2014:1527.)

### Pathophysiology of Open-Angle Glaucoma

● In patients with POAG, the cause of elevated IOP is not obvious, as obstruction in aqueous humor outflow is not clinically discernible. Possible causes of this increased IOP may be related to an increase in outflow resistance in the trabecular meshwork.[9,10,14,16]

● Glaucomatous optic neuropathy may also occur independent of increased IOP. Pressure independent causes of optic neuropathy include abnormal ocular perfusion, oxidative stress, and inflammation.[9,10,12,16]

Regardless of the underlying cause, elevated IOP initiates several detrimental changes to glial cells, the lamina cribrosa, and retinal ganglion cells. The increase in IOP can lead to alterations in retinal blood flow and axonal transport of neurotrophic factors, resulting in cellular stress of the retinal ganglion cells. This stress activates the glial cells in a manner that leads to inappropriate remodeling of the extracellular matrix. Elevated IOP deforms the lamina cribrosa, which places mechanical strain on the retinal ganglion cells. Chronic elevation of IOP ultimately causes the retinal ganglion cells to undergo apoptosis.[9,10,16,18,19]

Current glaucoma therapies fail to target IOP-independent glaucoma pathophysiologic factors. However, IOP reduction may still be beneficial, as the rate of visual field progression is decreased in many patients who exhibit IOP reduction via medical or surgical modalities.[3,9]

### Pathophysiology of Angle-Closure Glaucoma

● PACG involves a mechanical obstruction of aqueous humor outflow through the trabecular meshwork by the peripheral iris. Two major mechanisms of trabecular meshwork obstruction by the peripheral iris include pupillary block and an abnormality of the iris called *iris plateau*. Pupillary block is the more common mechanism of obstruction and results from a complete or functional apposition of the central iris to the anterior lens and is associated with mid-dilation of the pupil. The trapped aqueous humor in the posterior chamber increases pressure behind the iris, causing the peripheral iris to bow forward and obstruct the trabecular meshwork. Plateau iris refers to an anterior displacement of the peripheral iris caused by anteriorly positioned ciliary

---

**Patient Encounter, Part 1**

RJ, a 66-year-old African American woman with a history of COPD and hypertension, presents to your clinic for her yearly checkup. She states that she is concerned about losing her eyesight because her older sister has started losing her vision from glaucoma. She denies any changes in her vision.

**Meds**: Tiotropium 18 mcg two inhalations of powder contents of a single capsule; albuterol HFA MDI one to two puffs every 4 to 6 hours as needed; amlodipine 10 mg orally once daily; HCTZ 25 mg orally once daily.

*Based on the patient's medical and family history, what risk factors does this patient have for glaucoma?*

*How often would you recommend that this patient receive a comprehensive eye evaluation?*

*What objective assessments should be gathered in order to fully evaluate her risk factors for glaucoma?*

*How often would you recommend that this patient receive a comprehensive eye evaluation?*

| **Table 61–2** | | |

Data from Refs. 3 and 4.

processes. In this configuration the peripheral iris bunches as the eye dilates. Both of these mechanisms result in the occlusion of aqueous humor outflow, causing IOP elevation at extreme levels that can lead to vision loss in hours to days.[4,9,20] The degree of iridotrabecular contact (angle closure) can be assessed by visualizing the anatomy of the irido-corneal angle by **gonioscopy**.

## CLINICAL PRESENTATION AND DIAGNOSIS
### Risk Factor Evaluation

For POAG, only 4% to 8% of patients may progress to legal blindness. Vision loss does not occur until there has been significant loss of the retinal ganglion cells. It may take 13 to 16 years for a patient to go blind from glaucoma. A patient's quality of life may not be affected until significant visual field loss is present and the patient can no longer perform the activities of daily living.[21] **KEY CONCEPT** *Practitioners can play an important role in eye care by assessing patients for risk factors and referring to an eye care specialist for appropriate screening and evaluation.* Risk factor evaluation is essential in determining the frequency of comprehensive eye examinations for patients (**Table 61–2**).

Glaucoma risk factors are also useful in deciding when to start therapy and determining the sequence of pharmacotherapeutic or surgical treatment modalities.[2–4] **Table 61–3** lists the major risk factors associated with POAG and PACG.

The development of PACG is associated with several anatomical risk factors that lead to shallow anterior chambers. PACG patients may have a thick, anteriorly displaced lens that results from continued growth of the lens and/or cataractous changes. The anterior chamber depth is typically shallower in many individuals with PACG, which predisposes these eyes to anatomically narrower iridocorneal inlets that are a setup for developing critically narrow angles more susceptible to closure (from an enlarging cataractous lens or other insults).[4,20]

Patients with PACG are characterized by at least 180 degrees of iridotrabecular contact, elevated IOP, and ophthalmic examination characteristic of glaucomatous changes. Recurrent attacks or a prolonged acute attack can lead to the development of peripheral anterior **synechia**, which partially obstructs the flow of aqueous humor through the trabecular meshwork.[4,20]

## Clinical Presentation and Diagnosis of POAG

**General**
- Adult onset (usually greater than 40 years of age)
- Patients may be unaware that they have glaucoma and may be diagnosed during routine eye evaluation
- POAG is usually bilateral with asymmetric disease progression

**Symptoms**
- Patients with severe disease progression may report loss of peripheral vision ("tunnel vision") and may describe the presence of **paracentral**, **nasal**, and **arcuate scotoma** (blind spots) in their field of vision

**Signs**
- Ophthalmoscopic examination may reveal:
  - Optic nerve head (optic disc) cupping
  - Large cup-to-disc ratio
  - Diffuse thinning, focal narrowing, or notching of the optic nerve head rim

- Splinter hemorrhages
- Optic nerve head/nerve fiber layer changes occur before visual field changes can be detected

**Diagnostic Tests**
- Gonioscopy—anterior-chamber angles are to be open
- Applanation **tonometry**—elevated IOP (greater than 21 mm Hg [2.8 kPa]) may be present. However, patient can have signs of optic neuropathy without elevated IOP
- Pachymetry—measures central corneal thickness. Thin corneas (less than 540 μm) are considered a glaucoma risk factor
- Automated static threshold **perimetry**—evaluates visual fields. Can detect defects in the visual field before a patient may notice
- Other diagnostic tests—scanning laser polarimetry, confocal scanning laser ophthalmoscopy, and optical coherence tomography

## Clinical Presentation and Diagnosis of Acute Angle-Closure Crisis

**General**
- Medical emergency due to high risk of vision loss
- Unilateral in presentation, but fellow eye is at risk

**Symptoms**
- Ocular pain
- Red eye
- Blurry vision
- Halos around lights
- Systemic symptoms may develop:
  - Nausea/vomiting
  - Abdominal pain
  - Headache
  - Diaphoresis

**Signs**
- Cloudy cornea caused by corneal edema
- Conjunctival hyperemia
- Pupil semidilated and fixed to light
- Eye will be harder on palpation through closed eye

**Diagnostic Tests**
- Gonioscopy—anterior-chamber angles will be closed. Peripheral anterior synechiae may be present
- Applanation tonometry—elevated IOP (greater than 21 mm Hg [2.8 kPa], but when symptoms are present, IOP may be greater than 30 mm Hg [4.0 kPa])
- Slit-lamp biomicroscopy—reveals shallow anterior-chamber depth. Signs of previous attacks include peripheral anterior synechiae, iris atrophy, and pupillary dysfunction

## TREATMENT
### Primary Open-Angle Glaucoma

▶ *Desired Outcomes and Goals*

**KEY CONCEPT** *The goals of therapy are to prevent further loss of visual function; minimize adverse effects of therapy and impact on the patient's vision, general health, and quality of life; maintain IOP at or below a pressure at which further optic nerve damage is unlikely to occur; and educate and involve the patient in the management of their disease.* **KEY CONCEPT** *Current therapy is directed at altering the flow and production of aqueous humor, which is the major determinant of IOP.*

▶ *General Approach*

**KEY CONCEPT** *Because POAG is a chronic, often asymptomatic condition, the decision of when and how to treat patients is difficult, as the treatment modalities are often expensive and have potential adverse effects or complications. Currently lowering IOP is the best method to reduce the risk of visual field loss.*[22,23] *The clinician should evaluate the potential effectiveness, toxicity, and the likelihood of patient adherence for each therapeutic modality. The ideal therapeutic regimen should have maximal effectiveness and patient tolerance to achieve the desired therapeutic response.* The American Academy of Ophthalmology (AAO) publishes Preferred Practice Patterns for POAG and POAG Suspect.[2,3]

Before the selection of a therapeutic modality, the target IOP should be determined for each patient. The target IOP ideally represents an IOP range that will slow the progression of optic neuropathy and not simply obtain an IOP in the range of 10 to 21 mm Hg (1.3–2.8 kPa). Currently, the initial target IOP is an estimate, but it should be modified based on the progression of the disease at each follow-up visit. **KEY CONCEPT** *The AAO recommends an initial target IOP to be set at least 25% lower than the patient's baseline IOP. The target IOP can be set lower (30%–50% of baseline IOP) for patients who already have severe disease, risk factors for disease progression, or have normal-tension glaucoma (NTG).*[3,24] Risk factors for progression include high IOP, older age, hemorrhage of the optic disc, large cup-to-disc ratio, thinner CCT (central corneal thickness), and established glaucomatous progression (velocity of disease progression is nonlinear).

Initial IOP control can be achieved by medical, laser, surgical, or combination of these therapies. The AAO guidelines[3] do not provide a specific recommendation on which therapeutic modality should be selected first, but patients in the early stages of glaucoma should receive treatment. In general, medical and laser trabeculoplasty are preferred as early treatment options over surgical as surgical interventions are not without potential intraoperative or postoperative complications.[22] The ophthalmologist will individualize therapy based on the risk and benefits for a specific patient. **Table 61–4** describes nonpharmacologic treatment modalities for POAG.[3]

Medical treatment is the most commonly selected therapeutic modality. A well-tolerated ocular antihypertensive, at the lowest concentration, should be selected as the initial mediation (**Table 61–5**). The ocular hypotensive lipids are preferred first-line agents since they are the most effective at lowering at IOP of both peak and trough measurements by at least 25% of baseline

| Table 61–4 | |
|---|---|
| **Select Nonpharmacologic Treatment Options for POAG** | |

| Treatment Option | Description |
|---|---|
| Laser trabeculoplasty | Laser energy aimed at trabecular meshwork Improves aqueous humor outflow |
| Trabeculectomy | Surgical removal of a portion of the trabecular meshwork Improves aqueous humor outflow Mitomycin C and fluorouracil are used to decrease scarring |
| Cyclodestructive surgery | Trans-scleral laser reduces rate of aqueous humor production Reserved for patients who have failed other options |
| Aqueous shunts | Drainage device that redirects the outflow of aqueous humor through a small tube into an outlet chamber placed underneath the conjunctiva |

Data from Refs. 3, 4, and 14.

**Table 61–5**

**Pharmacologic Treatment Options for POAG**

| Drug | Pharmacologic Properties | Common Brand Names | Dose Form | Strength (%) | Usual Dose[a] | Mechanism of Action |
|---|---|---|---|---|---|---|
| **β-Adrenergic Blocking Agents** | | | | | | |
| Betaxolol | Relative $\beta_1$-selective | Generic | Solution | 0.5 | One drop twice a day | All reduce aqueous production of ciliary body |
| | | Betoptic-S | Suspension | 0.25 | One drop twice a day | |
| Carteolol | Nonselective, intrinsic sympathomimetic activity | Generic | Solution | 1 | One drop twice a day | |
| Levobunolol | Nonselective | Betagan | Solution | 0.25, 0.5 | One drop twice a day | |
| Metipranolol | Nonselective | OptiPranolol | Solution | 0.3 | One drop twice a day | |
| Timolol | Nonselective | Timoptic, Betimol, Istalol | Solution | 0.25, 0.5 | One drop every day—one to two times a day | |
| | | Timoptic-XE | Gelling solution | 0.25, 0.5 | One drop every day[a] | |
| **Nonspecific Adrenergic Agonists** | | | | | | |
| Dipivefrin | Epinephrine prodrug | Propine | Solution | 0.1 | One drop twice a day | Increased aqueous humor outflow |
| **α₂-Adrenergic Agonists** | | | | | | |
| Apraclonidine | Specific $\alpha_2$-agonists | Iopidine | Solution | 0.5, 1 | One drop two to three times a day | Both reduce aqueous humor production; brimonidine known to also increase uveoscleral outflow; only brimonidine has primary indication |
| Brimonidine | | Alphagan P | Solution | 0.15, 0.1 | One drop two to three times a day | |
| **Cholinergic Agonists Direct Acting** | | | | | | |
| Carbachol | Irreversible | Carboptic, Isopto Carbachol | Solution | 1.5, 3 | One drop two to three times a day | All increase aqueous humor outflow through trabecular meshwork |
| Pilocarpine | Irreversible | Isopto Carpine, Pilocar | Solution | 0.25, 0.5, 1, 2, 4, 6, 8, 10 | One drop two to three times a day | |
| | | | | | One drop four times a day | |
| | | Pilopine HS | Gel | 4 | Every 24 hours at bedtime | |
| **Cholinesterase Inhibitors** | | | | | | |
| Echothiophate | | Phospholine Iodide | Solution | 0.125 | Once or twice a day | |
| **Carbonic Anhydrase Inhibitors** Topical | | | | | | |
| Brinzolamide | Carbonic anhydrase type II inhibition | Azopt | Suspension | 1 | Two to three times a day | All reduce aqueous humor production of ciliary body |
| Dorzolamide | | Trusopt Generic | Solution | 2 | Two to three times a day | |
| **Systemic** | | | | | | |
| Acetazolamide | | Generic | Tablet | 125 mg, 250 mg | 125–250 mg two to four times a day | |
| | | Injection Diamox Sequels | 500 mg/vial Capsule | 250–500 mg 500 mg | 500 mg twice a day | |
| Methazolamide | | Generic | Tablet | 25 mg, 50 mg | 25–50 mg two to three times a day | |

[a]Use of nasolacrimal occlusion will increase the number of patients successfully treated with longer dosage intervals.

IOP.[25–29] Additionally, these agents lack systemic side effects and are dosed once daily. If monotherapy alone lowers IOP but does not reach target pressure or there is evidence of progression, then combination therapy or switching to another agent is appropriate. The addition of a second agent from another class generally has an additive effect on IOP reduction. The ocular hypotensive lipids, timolol, carbonic anhydrase inhibitors, or brimonidine are reasonable choices for addition as a second agent.[3,9,12] Combination eye-drops reduce the number of drops that need to be administered. Increasing the concentration or dose frequency can also be tried when possible. Adverse effects can be caused by an eye drop's therapeutic agent or inactive excipients, such as preservatives. Benzalkonium chloride is a common eye drop preservative which has been associated with superficial punctate keratitis, corneal erosion, and conjunctival allergy. Intolerances to preservatives can be resolved by changing to a preservative-free eye drop.[30] **Figure 61–4** presents an algorithm to select and optimize POAG treatment.

A uniocular trial can be used to assess the safety and effectiveness of a topical medication before initiation in both eyes; however, uniocular drug trials do not always predict the IOP response of the second eye. Ideally, the effectiveness of a medication should be assessed independently using baseline IOP measurements.

▶ *Treatment Considerations for POAG Suspects*

POAG suspects should be considered for topical medication therapy if they are at high risk for developing POAG or have a high IOP in which glaucomatous nerve damage is likely to occur. POAG suspects that develop evidence of glaucomatous damage or visual field defect have developed POAG and should be treated accordingly.[2] The Ocular Hypertension Treatment

Study (OHTS) demonstrated that a 20% decrease in IOP can reduce the progression from ocular hypertension to POAG over a 5-year period. The incidence of progression to POAG in the treatment (4.4%) and control (9.5%) groups was small, which underscores the importance of selecting patients at high risk of progressing to POAG.[31] When medical therapy is indicated, a well-tolerated agent should be selected and optimized following the POAG treatment algorithm (see Figure 61–4). The benefit of therapy should be reassessed in patients who may require third- or fourth-line agents to control IOP. Surgical or laser intervention are rarely indicated in the treatment of glaucoma suspects.[2]

## Primary Angle-Closure Glaucoma
### ▶ *Desired Outcomes and Goals*

Therapeutic modalities for PACG are targeted at decreasing IOP. The goals of therapy are to preserve visual function by controlling the elevation in IOP, prevent damage to the optic nerve, and manage or prevent an acute attack of angle closure.[4]

### ▶ *General Approach*

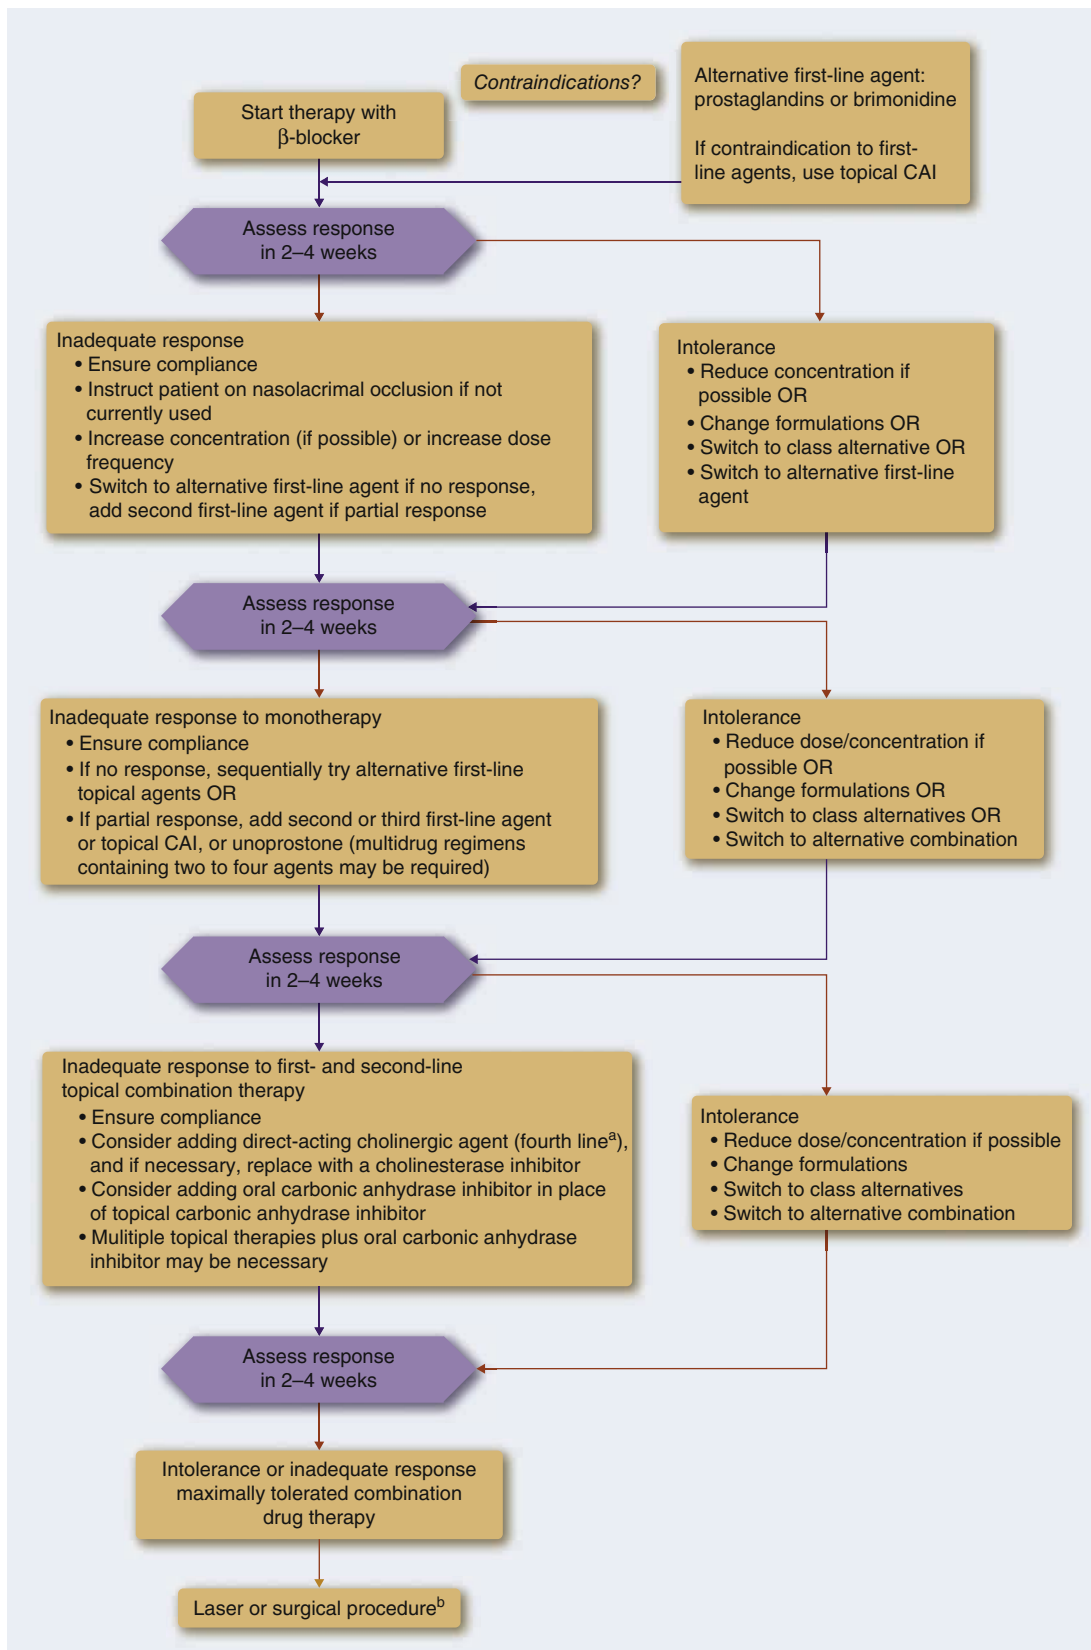
**KEY CONCEPT** *Acute angle-closure crisis is a medical emergency and requires urgent laser or surgical intervention.* The treatment of choice for PACG is peripheral laser iridotomy. Laser iridotomy uses laser energy to cut a hole into the iris to alleviate the aqueous humor buildup behind the iris, resulting in reversal of appositional angle closure. Patients currently experiencing an acute angle-closure crisis should receive medical therapy to lower IOP, reduce pain, and reverse corneal edema before the iridotomy. IOP should first be lowered with topical β-blockers, topical α-agonist, prostaglandin $F_{2\alpha}$ analogue, systemic carbonic anhydrase inhibitors, or hyperosmotic agents. Once the IOP has been controlled,


**FIGURE 61–4.** Algorithm for the pharmacotherapy of open-angle glaucoma. [a]Fourth-line agents not commonly used any longer. [b]Most clinicians believe laser procedures should be performed earlier (eg, after three-drug maximum, poorly adherent patient). CAI, carbonic anhydrase inhibitor. (From Lesar TS, Fiscella RG, Edward D. Glaucoma. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York: McGraw-Hill, 2014:1532.)

miotics (ie, pilocarpine) can be used to break the pupillary block. A topical IOP-lowering agent should be continued to control IOP until laser iridotomy can be performed. Corneal indentation with a cotton-tipped applicator or gonioscopic lens may break pupillary block. If laser iridotomy cannot be performed, then surgical incisional iridectomy is used. Incisional iridectomy is the surgical removal of a small portion of the peripheral iris to allow flow of aqueous humor trapped in the posterior chamber to migrate to the anterior chamber (bypassing the normal flow pattern through the pupil). Topical corticosteroid may be employed to decrease inflammation postoperatively. The fellow eye is at high risk to develop an acute attack and should receive prophylactic iridotomy within a reasonable interval of time. Lens extraction surgery may be another treatment modality as it increases the anterior chamber depth. PACG patients may require chronic medical therapy if the patient has PACG superimposed on preexisting POAG or if synechia formation causes reduced outflow with a continued increase in IOP.[4,9,20]

## Pharmacologic Therapy

### ▶ β-Adrenergic Antagonists

Topical β-adrenergic antagonists (β-blockers) are now considered a second-line agent after the prostaglandin analogues for the treatment of POAG unless contraindications are present.[3,9] Topical β-blockers decrease IOP by reducing the formation of aqueous humor made by the ciliary body, which results in a 20% to 35% reduction in IOP.[28,29,32,33] Timolol, levobunolol, metipranolol, and carteolol are nonselective for $\beta_1$- and $\beta_2$-adrenergic receptors, whereas betaxolol has $\beta_1$-selective properties.[32,33] Betaxolol reduces IOP to a lesser extent than the nonselective β-blockers, but part of its efficacy may be related to a neuroprotective mechanism independent of IOP reduction.[34]

Topical β-blockers are typically administered twice daily. A gel-forming solution of timolol (Timoptic-XE) can be administered once daily. Tachyphylaxis may occur in 20% to 50% of patients on monotherapy with a β-blocker, resulting in the need for a different agent or combination therapy. Patients on concurrent systemic β-blockers may experience less IOP reduction than patients on only topical β-blockers.[32,33]

β-Blockers can cause significant systemic adverse effects through nasolacrimal drainage and subsequent systemic absorption in the mucous membranes in the nasal-pharyngeal cavity. This route bypasses first-pass hepatic metabolism resulting in pharmacologically significant serum drug concentrations.[35] Bronchospasm is the most common pulmonary effect of topical β-blockers. Pulmonary edema, status asthmaticus, and respiratory arrest have been reported with β-blockers as well. Cardiovascular effects include bradycardia, hypotension, and congestive heart failure exacerbation. As with systemic β-blockers, topical β-blockers have also been reported to cause depression and hyperlipidemia and mask symptoms of hypoglycemia. The $\beta_1$-selective properties of betaxolol may cause less exacerbation of pulmonary disease. Despite the intrinsic sympathomimetic activity demonstrated by carteolol, this does not translate to a clinically significant decrease in pulmonary or cardiovascular adverse effects. Topical β-blockers are generally contraindicated in patients with asthma, chronic obstructive pulmonary disease (COPD), sinus bradycardia, second- or third-degree heart block, cardiac failure, and hypersensitivity to the product.[30,33,35]

Stinging of the eyes upon instillation is the most common adverse effect. Other local adverse effects include conjunctivitis, keratitis, dry eyes, and **uveitis**.[30,32]

Patients prescribed topical β-blockers should be counseled on the nasolacrimal occlusion technique to decrease systemic absorption.

### ▶ Ocular Hypotensive Lipids

The ocular hypotensive lipids in typical ophthalmology practice are considered first-line agents along with β-blockers because of their superior efficacy and safety profiles. Many clinicians may choose to use the ocular hypotensive lipids as first line, especially in patients who have an initial requirement to lower IOP by greater than 25%.[28,29,32,33] All four of the available agents currently have an FDA indication for both POAG and ocular hypertension. Latanoprost and travoprost have dosing aids that help patients administer each medication. Travoprost and tafluprost are available as benzalkonium chloride–free solutions.

Latanoprost, travoprost, tafluprost are analogues of prostaglandin $F_{2\alpha}$ and are agonists of the prostanoid FP receptor, which appears to lower IOP by increasing aqueous humor outflow through the uveoscleral pathway. Bimatoprost is a prostamide analogue and appears to lower IOP by activating prostamide receptors in the uveoscleral pathway and possibly through increasing outflow through the trabecular meshwork. The exact mechanism of how uveoscleral outflow is increased is still unclear, but stimulation of prostanoid FP receptors and prostamide receptors in the ciliary body cause remodeling of the extracellular matrix, making it more permeable to aqueous humor, thus increasing aqueous humor outflow through the ciliary muscles.[32,36,37]

The ocular hypotensive lipids are administered once daily at bedtime and should not be increased to twice daily, as this may decrease effectiveness. The ocular hypotensive lipids can provide a consistent reduction in IOP over a 24-hour period.[33] For patients nonresponsive to latanoprost, switching to bimatoprost may allow some patients to reach their IOP goal, presumably because of the proposed difference in the site of action of each drug.[38,39]

The ocular hypotensive lipids are well tolerated and rarely cause systemic side effects (headache has been reported). Local effects include conjunctival hyperemia, stinging on instillation, increase in iris pigmentation, deepening of the upper eyelid sulcus, **hypertrichosis**, and darkening of the eyelashes. Increases in iris pigmentation occur most commonly in patients with multicolored irides on long-term prostaglandin analogue therapy. The mechanism of this effect is by its action on melanocytes of the iris, in which the irides become darker because of increased production of melanin in the iris.[30] Increased iris pigmentation appears to be only a cosmetic effect but may affect your product selection, especially when choosing monocular therapy. Conjunctival hyperemia or engorgement of conjunctival blood vessels is a common adverse effect caused by a vasodilatory effect on scleral blood vessels. It is most prominent early in therapy and usually subsides over time. Although generally a benign adverse effect, patients may have a concern if it affects their cosmetic appearance.[30,32]

The ocular hypotensive lipids should be used with caution in patients, since they may worsen anterior uveitis and herpetic keratitis. Cystoid macular edema has been reported during treatment with the ocular hypotensive lipids; therefore, use caution in patients with intraocular inflammation, **aphakic** patients, **pseudophakic** patients with a history of intraoperative complications (eg, torn posterior lens capsule), or in patients with risk factors for macular edema.[30]

Patients prescribed ocular hypotensive lipids should be counseled on potential adverse effects and appropriate

administration. Patients receiving latanoprost or tafluprost should be instructed to refrigerate unopened medication. Once open latanoprost can stored at room temperature for 6 weeks. Tafluprost single-use containers can be stored at room temperature for up to 28 days.

### ▶ $\alpha_2$-Adrenergic Agonists

Brimonidine and apraclonidine are $\alpha_2$-adrenergic agonists that decrease IOP by reducing aqueous humor production. Brimonidine has a higher selectivity to the $\alpha_2$-receptor than apraclonidine and has a dual mechanism of action by increasing uveoscleral outflow.[32,33] Apraclonidine is often used for the prevention and treatment of postsurgical IOP elevations and is no longer commonly used for long-term treatment of POAG because of tachyphylaxis and high rate of blepharoconjunctivitis. Brimonidine lowers IOP by 14% to 25%. Peak IOP-lowering effect is similar to that of timolol, but the trough IOP-lowering effect is less than that of timolol.[27,28] Brimonidine may exhibit a neuroprotective effect and has been shown to delay visual field progression compared with timolol but there is insufficient evidence it prevents retinal ganglion cell death.[40]

Brimonidine is typically used as an adjunctive agent in combination with other agents and is usually administered every 8 hours. A 12-hour dosing schedule may be employed when used in combination therapy. Brimonidine-purite 0.1% and 0.15% solution (Alphagan-P) has similar efficacy compared with the brimonidine 0.2% solution, because the purite solution's higher pH allows for more drug to penetrate the cornea.[32,33] Brimonidine cause both local and systemic effects. Local effects include blepharoconjunctivitis, conjunctivitis, and ocular allergy. Systemic effects include headache, dry mouth, and fatigue.[30,32,33]

The frequency of dosing and local adverse effects may lead to nonadherence in some patients. Patients prescribed brimonidine should be counseled on the nasolacrimal occlusion technique to reduce systemic adverse effects and to improve efficacy.[32,33]

### ▶ Carbonic Anhydrase Inhibitors

Carbonic anhydrase inhibitors decrease aqueous humor production by inhibition of the carbonic anhydrase isoenzyme II located in the ciliary body. In the eye, carbonic anhydrase catalyzes the conversion of $H_2O$ and $CO_2$ to $HCO_3^-$ and $H^+$, which is a significant step in aqueous humor production. Carbonic anhydrase inhibitors are available in systemic and topical preparations.[32,33]

**Topical Carbonic Anhydrase Inhibitors** Dorzolamide and brinzolamide are the only topical carbonic anhydrase inhibitors available on the market. Both medications are administered every 8 hours and are used as adjunctive therapy or as monotherapy for patients who cannot tolerate first-line therapies. Nasolacrimal occlusion may allow for an every-12-hour dosing interval. They lower peak and trough IOP by 17% to 20%.[28,29,32,33]

Local side effects include burning, stinging, itching, foreign body sensation, dry eyes, and conjunctivitis. Brinzolamide may have fewer incidences of these side effects since the drug is in a neutral pH solution. Dorzolamide has been reported to cause irreversible corneal decompensation. Taste abnormalities have been reported with each agent. Both topical carbonic anhydrase inhibitors are sulfonamides and are contraindicated in patients with history of sulfonamide hypersensitivity.[30,32,33]

**Systemic Carbonic Anhydrase Inhibitors** There are three systemic carbonic anhydrase inhibitors: acetazolamide, dichlorphenamide, and methazolamide. These agents effectively lower IOP by 20% to 30% but are reserved as third-line to fourth-line agents because of their significant adverse effects. They are typically used as bridge therapy from maximal medical therapy to laser or surgical intervention or to control IOP in the perioperative period following a laser or surgical ocular procedure. The systemic carbonic anhydrase inhibitors can also be used to lower IOP in acute angle-closure glaucoma. Acetazolamide has an IV formulation that can be used in patients who are experiencing nausea due to the angle-closure attack. Acetazolamide and methazolamide are the best tolerated of the three agents.[4,32,33]

The systemic carbonic anhydrase inhibitors are associated with significant adverse effects that include paresthesias of the hands and feet, nausea, vomiting, and weight loss. Patients can develop systemic acidosis, hypokalemia, hyponatremia, and nephrolithiasis due to the inhibition of renal carbonic anhydrase. Sulfonamide allergy, renal failure, hepatic insufficiency, COPD, and decreased serum potassium and sodium levels are all contraindications of systemic carbonic anhydrase inhibitor therapy. Blood dyscrasias from bone marrow suppression have been reported and include agranulocytosis, aplastic anemia, neutropenia, and thrombocytopenia.[32,33]

### ▶ Cholinergic Agents

Cholinergic agents (also called parasympathomimetics or miotics) were the first class of agents to treat glaucoma. The class can be divided into direct-acting and indirect-acting cholinergic agents.

**Direct-Acting Cholinergic Agents** Pilocarpine directly stimulates the muscarinic ($M_3$) receptors of the ciliary body, which causes contraction of the ciliary muscle. This results in the widening of spaces in the trabecular meshwork, which causes an increase in aqueous humor outflow and reduces IOP by 20% to 30%.

Pilocarpine requires administration four times daily, since the IOP-lowering effect lasts only 6 hours. Pilocarpine is available in 1%, 2%, and 4% concentrations. Higher concentrations may be needed for patients with dark irides to obtain adequate IOP reduction. A pilocarpine 4% gel is available and allows for once-daily dosing at bedtime.[32] Pilocarpine is considered a fourth-line agent for POAG. In the treatment of PACG, it is important to delay use until IOP has been controlled, because pilocarpine could worsen angle closure by causing anterior displacement of the lens. Once IOP is controlled, pilocarpine can be given to break pupillary block by instilling one drop applied twice in an hour.

---

### Patient Encounter, Part 2

RJ was referred to an ophthalmologist for a comprehensive eye evaluation. The ophthalmology report reveals the patient has an IOP (as assessed by applanation tonometry) of 19 mm Hg (2.5 kPa) in the right eye and 23 mm Hg (3.1 kPa) in the left eye. Gonioscopic examination reveals open anterior angles in both eyes. Ophthalmoscopy reveals cupping of the optic discs in both eyes. Visual field examination reveals a nerve fiber bundle defect consistent with glaucoma in the left eye.

*What is your assessment of this patient's glaucoma type?*

*What pharmacologic and nonpharmacologic treatment modalities are available for this patient?*

The adverse effects of pilocarpine are caused by the induction of miosis. The contraction of the ciliary muscle causes the lens to displace forward, which can lead to accommodation spasm and myopia, and can lead to brow ache. Pupillary constriction can also affect night vision. Pilocarpine should be avoided in patients with severe myopia as it increases the risk of developing retinal detachment. Systemic effects may occur at higher concentrations and include nausea, vomiting and diarrhea, and bradycardia.[30]

Carbachol stimulates the same muscarinic receptor as pilocarpine and also inhibits acetylcholinesterase, the enzyme that metabolizes acetylcholine. Carbachol is more potent than pilocarpine, but it causes more accommodation spasm and brow ache and may also cause anterior uveitis. Other reported side effects include corneal clouding, persistent bullous keratopathy, and retinal detachment. Carbachol is rarely used today because of the side-effect profile.[30,32]

**Indirect-Acting Cholinergic Agents** Echothiophate iodide and demecarium bromide inhibit acetylcholinesterase. Inhibition of this enzyme increases the availability of acetylcholine at the nerve junction, thus increasing the stimulation of the muscarinic ($M_3$) receptors of the ciliary body. These products are given twice daily and have similar efficacy to pilocarpine in the degree of IOP reduction. The side-effect profile is similar to that of pilocarpine; however, they can deplete systemic cholinesterases and pseudocholinesterases and may cause the formation of cataracts. These agents should be discontinued at least 1 week before general surgical procedures. Succinylcholine and some local anesthetics are metabolized by pseudocholinesterases; therefore, depletion of this enzyme by echothiophate or demecarium may lead to toxic effects. These agents are typically used when other topical agents have failed and are limited to patients who have had their lenses removed or who have artificial lenses.[32]

#### ► Hyperosmotics

Glycerin, isosorbide, and mannitol are hyperosmotic agents that increase the osmolality of blood. These agents create an osmotic gradient that draws water from the vitreous humor, thus decreasing IOP. The resulting dehydration of the vitreous humor may cause posterior movement of the lens, which then causes the anterior chamber to deepen, thus opening the anterior angle. If the patient is not vomiting, glycerin (1–1.5 g/kg of a 50%) solution and isosorbide (1.5–2 g/kg) can be given orally. Isosorbide is preferred in patients with diabetes because it is not metabolized into glucose. If the patient has nausea or vomiting, mannitol (20%) can be given IV at a dose of 1 to 2 g/kg over 45 minutes. The hyperosmotic agents are rapid acting, reaching peak effect in 30 to 60 minutes. Headache and thirst are common complaints. Patients who are already dehydrated are at risk of developing CNS dehydration, which can lead to coma. These agents should be used with caution in patients with renal or cardiovascular disease, as extracellular water is increased.[33,41]

#### ► Nonselective Adrenergic Agonists

Epinephrine and its prodrug, dipivefrin, are rarely used for the treatment of glaucoma and are considered last-line agents because of their systemic side-effect profile. Dipivefrin increases the corneal penetration. Once it is absorbed through the cornea, it is enzymatically cleaved to epinephrine. Epinephrine has α- and β-agonist activity and is thought to increase the outflow of aqueous humor through the trabecular meshwork and the uveoscleral pathway. Both products are instilled twice daily and reduce IOP by 15% to 25%. Local adverse effects include mydriasis, conjunctival hyperemia, and ocular irritation. Aphakic patients should not use these medications because they cause a reversible cystoid macular edema. Epinephrine and dipivefrin should not be used in patients with narrow angles since these agents can cause acute angle closure. Systemic side effects include palpitations, increased blood pressure, and arrhythmia, and therefore, these drugs should be used with caution in patients with cardiovascular disease, cerebrovascular disease, and hyperthyroidism. Using the nasolacrimal technique may decrease systemic effects.[32]

## SPECIAL CONSIDERATIONS: DRUG-INDUCED GLAUCOMAS

Medications have the potential to cause or exacerbate both POAG and PACG; however, PACG is more likely to be exacerbated by medications than POAG. The use of medications with anticholinergic or sympathomimetic properties can precipitate angle closure. Medications with anticholinergic properties include first-generation antihistamines, tricyclic antidepressants, and antipsychotics. Medications with sympathomimetic properties include phenylephrine and pseudoephedrine. PACG patients who have been treated with laser iridotomy can usually use these agents without causing an exacerbation. Sulfa-based drugs, such as topiramate, acetazolamide, and hydrochlorothiazide, cause swelling of the ciliary body, which causes an anterior displacement of the lens, resulting in a decrease in anterior-chamber depth. Patients with open or closed anterior angles can experience elevated IOP from these drugs. Controlled POAG is rarely exacerbated by anticholinergics and sympathomimetics unless the patient is concomitantly at risk for angle closure. For uncontrolled or untreated POAG, the risk–benefit ratio should be considered before employing these agents. POAG can be exacerbated by any administered form of corticosteroids. Corticosteroids increase IOP by causing obstruction of the trabecular meshwork with extracellular material. The increase in IOP appears to increase with potency and intraocular penetration. Ophthalmic corticosteroid preparations carry the highest risk of increasing IOP. However, all administered routes have been shown to raise IOP in some patients. The onset and extent of IOP elevation is dependent on the specific corticosteroid, dose, route, and frequency. Generally corticosteroid-induced IOP elevation typically occurs within a few weeks of beginning steroid therapy. In most cases, the IOP lowers spontaneously to the baseline within a few weeks to months upon stopping the steroid. In rare instances, the IOP remains elevated. Some patients exhibit clinically significant and dangerously high IOP as a result of steroid use.[42]

### Patient Encounter, Part 3

The practitioner and RJ agree to start medication therapy. Develop a patient-specific care plan.

*Address the patient's (a) drug-related needs, (b) goals of therapy, (c) potential pharmacologic therapies, and (d) plan for follow-up of therapy.*

*List the monitoring parameters for effectiveness and safety for the chosen therapy.*

*Explain how you would counsel the patient on the chosen therapy, including the administration of an ophthalmic preparation.*

## Application of Ophthalmic Solutions or Suspension

1. Clean hands with soap and water.
2. Avoid touching the dropper tip with your fingers or against your eye to maintain sterility of product; shake dropper bottle if product is a suspension.
3. Tilt head back; pull down the lower eye lid with index finger.
4. Hold the dropper bottle with other hand as close as possible without touching the eye. The dropper should be pointing toward the eye with remaining fingers bracing against the face.
5. Gently squeeze the bottle so that one drop is placed into the pocket.
6. Close your eye for 2 to 3 minutes to allow for the maximum corneal penetration of drug.
7. Use a tissue to wipe away any excess liquid.
8. Replace and retighten the cap to the dropper bottle.
9. Wait at least 5 minutes before instilling another ophthalmic drug preparation.
10. Application of some ophthalmic preparations (suspension and gels) may cause blurring of vision.

## OUTCOME EVALUATION

### Primary Open-Angle Glaucoma

Evaluate patients 2 to 4 weeks after the initiation or alteration of medical therapy. The clinician should elicit the status of ocular health since the last visit, systemic medical history, medication history, and presence of local and ocular adverse effects of medications. IOP measurement, visual acuity assessment, and slit-lamp biomicroscopy at every POAG follow-up visit is necessary. The frequency of visual fields and optic nerve evaluation depends on whether IOP is controlled, the length of time IOP has been controlled, and whether there is progression of the disease. Patients who are at target IOP and have no disease progression should have optic nerve head evaluation and visual field testing every 6 to 12 months. Patients with disease progression and/or who are not at target IOP should receive follow-up evaluation every 1 to 6 months. Assess the patient's ability to use topical eye drops.[3] (See Application of Ophthalmic Solutions or Suspensions textbox.) Finally, evaluate the patient's adherence to their medical regimen. Nonadherence among patients on topical medical therapy ranges from 5% to 80%. Suspect nonadherence in patients who have visual field and optic nerve progression despite a low IOP measurement, as patients may be more adherent to their medical regimen before their visit. Pharmacy refill histories may be useful in assessing adherence but do not confirm that the patient is actually taking the regimen as prescribed.[43] Specific patient factors related to the risk of nonadherence may include health literacy, medication cost, complicated medication regimens, adverse effects, and ethnicity.[44] Using adherence aids, prescribing the least complex regimen, and educating patients about their glaucoma are ways to reduce nonadherence.[45]

**KEY CONCEPT** *Target IOP should be revised based on the course of the disease and rate of progression.* Adjust therapy if the patient fails to reach his or her target IOP. Patients who have achieved target IOP yet have progressive damage of the optic nerve or who have worsening of their visual fields should have further adjustment of their therapy. Evaluate these patients further for possible reasons of continued disease progression. Consider determining the diurnal pattern of IOP and looking for signs of poor ocular perfusion pressure. Establish a lower target IOP. Adjust therapy in patients who are intolerant, are nonadherent, or develop contraindications to their drug therapy regimen. Consider increasing the target IOP and reducing drug therapy for patients who have stable disease and who have maintained a low IOP; closely follow these patients to assess their response.[3]

## Patient Care Process

### Patient Assessment:

- Determine whether the patient is experiencing difficulty with vision.
- Review medical and family history. Does the patient have risk factors for glaucoma (Table 61–3)? Review patient's prescription, nonprescription, and natural product use. Does the patient have any causes for drug-induced glaucoma? Does the patient take any medications that interact with any glaucoma medication? Perform/review diagnostic tests (IOP, visual acuity, gonioscopy, visual fields, optic nerve evaluation, etc).

### Therapy Evaluation:

- If glaucomatous damage is present or has progressed, determine if medication therapy is indicated.
- If patient is already receiving medication therapy, assess efficacy, safety, and patient adherence. Can the patient appropriately use prescribed ophthalmic preparations? Are there factors contributing to poor adherence? Does the patient report or exhibit signs or symptoms for systemic and ocular adverse drug reactions?

### Care Plan Development:

- Select medication therapy that will likely achieve goal IOP with minimal adverse effects.
- Use combination glaucoma eye drops when possible to improve adherence.
- Address patient concerns about glaucoma and its treatment.
- Educate patient on importance of medication adherence. Instruct patient on how to instill eye drops and have them demonstrate their technique.

### Follow-Up Evaluation:

- Follow-up in 2 to 4 weeks to reassess patient for progression in glaucomatous damage, achievement of target IOP, adherence, and presence of adverse effects to medication therapy. Review interval medical history. Perform/Review ophthalmic examination findings.

## Primary Angle-Closure Glaucoma

Follow-up of acute angle-closure crisis occurs in the postoperative period. Evaluate the patency of the iridotomy and IOP in the postoperative period. Perform gonioscopy and optic nerve head evaluation if not already performed. Stable patients with PACG should be evaluated at least annually, specifically for the presence of peripheral anterior synechia and optic neuropathy. Treat patients according to POAG guidelines if they have underlying POAG or areas of peripheral anterior synechia with the presence of optic neuropathy.[4]

# Abbreviations Introduced in This Chapter

| | |
|---|---|
| AAO | American Academy of Ophthalmology |
| CCT | Central corneal thickness |
| IOP | Intraocular pressure |
| NTG | Normal tension glaucoma |
| PACG | Primary angle-closure glaucoma |
| POAG | Primary open-angle glaucoma |

# 62 Ophthalmic Disorders

Melissa L. Hunter and Michelle L. Hilaire

## LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Differentiate between the various ophthalmic disorders based on patient-specific information.

2. Choose an appropriate treatment regimen for an ophthalmic disorder.

3. Discuss the product differences that direct the selection of ophthalmic medications.

4. Assess when further treatment is required based on patient-specific information.

5. Recommend an ophthalmic monitoring plan given patient-specific information, a diagnosis, and a treatment regimen.

6. Educate patients about ophthalmic disease states and appropriate drug and nondrug therapies.

## INTRODUCTION

This chapter provides an overview of common ophthalmic disorders and their treatments. **KEY CONCEPT** *Many ophthalmic disorders are benign or self-limited, but the clinician must be able to distinguish conditions that lead to serious morbidity, including blindness.* Preserving both visual function and cosmetic appearance is the goal.[1] The clinician must understand when referral is appropriate and the proper time frame for follow-up, based on the patient-specific condition.

## OCULAR EMERGENCIES
### Etiology and Epidemiology

Ophthalmic problems encompass 3% of all emergency department visits.[2] Corneal abrasions are the most common eye injury in children. Scratches, objects and aggressive eye rubbing may damage the cornea.[3] Healthcare practitioners must know the proper treatment for ocular emergencies and the time frame for follow-up in order to prevent further morbidity (Table 62–1).

## CORNEAL ABRASIONS
### Treatment
▶ **Desired Outcomes**

- Complete healing of the corneal abrasion with no scarring or vision impairment
- Prevent infection and pain
- Prevent corneal loss or corneal transplant

▶ **General Approach to Treatment**

The five layers of the cornea contain no blood vessels but are nourished by tears, oxygen, and aqueous humor. Minor corneal abrasions heal quickly. Moderate abrasions take 24 to 72 hours to heal. Deep scratches may scar the cornea and require corneal transplant if vision is impaired. Do not use eye patches to treat uncomplicated corneal abrasion.[3]

### Corneal Abrasion Prevention[3]

- Wear eye protection during sports
- Wear industrial safety lenses
- Carefully fit and place contact lenses

▶ **Pharmacologic Therapy**

● **Topical NSAIDs** Topical nonsteroidal anti-inflammatory drugs (NSAIDs) decrease pain from corneal abrasion. Available ocular NSAIDs are bromfenac 0.09%, diclofenac 0.1%, ketorolac 0.5%, and nepafenac 0.1%. The usual dose for diclofenac and ketorolac is one drop four times daily; nepafenac is dosed three times daily, and bromfenac is dosed twice daily. Use topical NSAIDs with caution in patients with clotting disorders or those who are on systemic NSAIDs or warfarin therapy. Oral analgesics may be an option for some patients.[3]

● **Topical Antibiotics** Infection slows the healing of a corneal abrasion; therefore, prophylactic antibiotics are often used. Discontinue the use of contact lenses until the abrasion is healed and the antibiotic course complete. **KEY CONCEPT** *In contact lens wearers, choose an antibiotic that covers* Pseudomonas aeruginosa, like gentamicin ointment or solution or a fluoroquinolone.[3]

### Outcome Evaluation

● 1. Reevaluate patients in 24 hours.

2. If symptoms worsen, recheck for foreign bodies.

3. If not fully healed, evaluate again in 3 to 4 days.

4. Refer to ophthalmologist if[3]:
   - Abrasion greater than 4 mm
   - Contact lens wearers
   - Decreased vision
   - Lack of improvement or worsening symptoms

| **Table 62–1** | |
|---|---|
| **Ophthalmic Emergencies: Time to Follow Up by Ophthalmologist** | |
| **Immediate Consult Required** | **Within 24 Hours** |
| Foreign body in eye | Acute angle-closure glaucoma |
| Acute, painless loss of vision | Orbital cellulitis |
| Acute chemical burn | Blood in the eye (hyphema) |
| Blunt trauma to eye | Macular edema |
| | Retinal detachment |
| | Sudden congestive proptosis (bulging of eye forward) |
| | Corneal ulcer |
| | Corneal abrasion |

From Ref. 1, Handler JA, Ghezzi KT. General ophthalmologic examination. Emerg Med Clin North Am. 1995;13:521–538.

## OTHER OCULAR EMERGENCIES: TREATMENT
### Traumatic Injuries

Attempt to remove loose foreign bodies by gentle irrigation with artificial tears or sterile saline. If removal is successful, a topical broad-spectrum antibiotic, such as erythromycin, will prevent infection. If irrigation is unsuccessful, only ophthalmologists should complete mechanical removal of foreign objects. Protect the eye from further injury with a metal eye shield or a paper cup taped over the eye while awaiting the ophthalmologist.[2]

### Splash Injuries and Chemical Exposure

Instruct patients by phone to immediately irrigate the eye with water or saline continuously for at least 15 minutes before seeking a clinician. Irrigation dilutes and removes the chemical agent and is the best way to decrease ocular tissue damage. Patients should then seek immediate care from an ophthalmologist or emergency facility.[4]

### Clinical Presentation and Diagnosis of Corneal Abrasions[3]

**Symptoms**
- Photophobia
- Pain with extraocular muscle movement
- Foreign body sensation (or gritty feeling)
- Recent ocular trauma

**Signs**
- Excessive tearing
- Blepharospasm
- Blurred vision

**Diagnostic Test**
Use sterile fluorescein dye strips and visualize the cornea under a cobalt-blue filtered light; abrasions appear green; ensure that no foreign body remains in the eye.

## Loss of Vision

A variety of disorders may lead to rapid, painless, monocular, or binocular vision loss. These include central retinal artery occlusion, acute narrow-angle glaucoma, trauma, and others.[5] The differential diagnosis is complex and should be undertaken by an emergency department or ophthalmologist.

## CONJUNCTIVITIS
### Etiology

Conjunctivitis, also known as red eye, is one of the most common ophthalmic complaints seen by clinicians. An inflamed conjunctiva is the most common cause of red eye.[6] Conjunctivitis cases are mostly viral in nature. Use the differential diagnosis algorithm shown in Figure 62–1 to determine the proper treatment or need for referral.

## BACTERIAL CONJUNCTIVITIS
### Etiology and Pathophysiology

The primary cause of acute bacterial conjunctivitis (ABC) is gram-positive organisms, including *Streptococcus pneumoniae* and *Staphylococcus aureus*, and gram-negative *Haemophilus influenzae*.[6] **KEY CONCEPT** *Both acute and chronic bacterial conjunctivitis are self-limiting except if caused by* Neisseria.[6] The pathogens are rarely cultured unless the case is unresponsive to treatment.[6] Patients with bacterial conjunctivitis lasting 4 weeks or more should be referred to an ophthalmologist.[7]

Hyperacute bacterial conjunctivitis is associated with gonococcal (*Neisseria gonorrhoeae* or *Neisseria meningitides*) infections in sexually active patients. Prompt workup and treatment is required, as corneal perforation can occur.[6,7]

### Treatment
▶ **Desired Outcomes**
- Complete resolution of the bacterial conjunctivitis
- Prevent adverse consequences of the infection
- Preserve functionality of the eye

▶ **General Approach to Treatment**

ABC may be treated with broad-spectrum antibiotics. Although the condition is usually self-limiting, antibiotic treatment decreases the spread of disease to others and prevents extraocular infection. Additionally, treatment may help decrease the risk of corneal ulceration or other complications that affect sight. Finally, treatment speeds recovery.[6,7]

▶ **Pharmacologic Therapy**

The choice of an antibiotic agent for ABC is largely empiric. The initial treatment needs to include *Staphylococcus* coverage, and cost and side-effect profile may be pertinent.[6] In general, ointments are a good dosage form for children. Adults may prefer drops because they do not interfere with vision.

Many broad-spectrum topical antibiotics are approved to treat ABC (Tables 62–2 and 62–3).

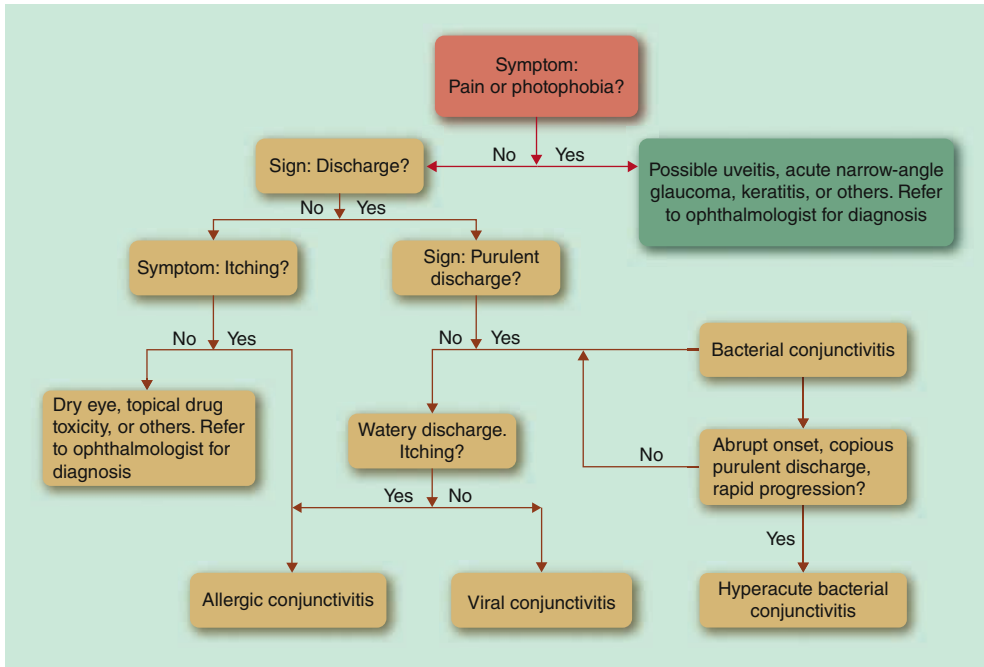
- First-line treatments include polymyxin B/trimethoprim solution, polymyxin B with bacitracin ointment, or erythromycin ointment
- The aminoglycosides (tobramycin and gentamicin) are alternatives but have incomplete gram-positive coverage and can cause corneal epithelial toxicity[7]


**FIGURE 62–1.** Differential diagnosis for red eye.

- Sulfacetamide has significant resistance
- If infection recurs or is severe, use a topical fluoroquinolone[6]
- Treat hyperacute bacterial conjunctivitis with a single dose of intramuscular ceftriaxone 1 g in combination with topical antibiotics and refer the patient to an opthalmologist[7]

- If concurrent blepharitis is present, add a lid hygiene regimen to antibiotic treatment[6]

## Outcome Evaluation

- Significant improvement of acute bacterial conjunctivitis should be seen within 1 week.[6]

### Table 62–2

**Adult Bacterial Conjunctivitis Dosing Guidelines for Topical Ophthalmic Antibiotics**

| | |
|---|---|
| Azithromycin 1% solution | Days 1 and 2: One drop twice daily, 8–12 hours apart<br>Days 3–7: 1 drop once daily |
| Ciprofloxacin 3.5 mg/mL solution | Days 1 and 2: One to two drops every 2 hours while awake<br>Days 3–7: One to two drops every 4 hours while awake |
| Ciprofloxacin 0.3% ointment | Apply a half inch (~1 cm) ribbon of ointment three times daily for 2 days, then twice daily for next 5 days |
| Erythromycin 0.5% ointment | Apply a half inch (~1 cm) ribbon of ointment up to six times daily |
| Gatifloxacin 0.3% solution | Days 1 and 2: One drop every 2 hours while awake up to eight times daily<br>Days 3–7: One drop every 4 hours while awake |
| Gatifloxacin 0.5% solution | Days 1: One drop every 2 hours while awake up to eight times daily<br>Days 2–7: One drop two to four times per day while awake |
| Gentamicin 0.3% solution | One to two drops every 4 hours. In severe infections, may use up to two drops every hour |
| Gentamicin 0.3% ointment | Apply a half inch (~1 cm) ribbon of ointment two to three times daily; up to every 3–4 hours |
| Levofloxacin 0.5% solution | Days 1 and 2: One to two drops every 2 hours while awake, up to eight times per day<br>Days 3–7: One to two drops every 4 hours while awake, up to four times daily |
| Moxifloxacin 0.5% solution | One drop two times a day for 7 days (Moxeza)<br>One drop three times a day for 7 days (Vigamox) |
| Ofloxacin 0.3% solution | Days 1 and 2: One to two drops every 2–4 hours while awake<br>Days 3–7: One to two drops four times daily |
| Polymyxin B with bacitracin ointment | Apply a half inch (~1 cm) ribbon of ointment every 3–4 hours, or two to three times per day for 7–10 days |
| Polymyxin B/trimethoprim solution | One drop every 3 hours for 7–10 days |
| Sulfacetamide 10% ointment | Apply a half inch (~1 cm) ribbon of ointment every 3–4 hours and at bedtime |
| Sulfacetamide 10% solution | One to two drops every 2–3 hours for 7–10 days |
| Tobramycin 0.3% ointment | Mild to moderate infections: Apply a half inch (~1 cm) ribbon of ointment two to three times daily; Severe infections: Apply every 3–4 hours |
| Tobramycin 0.3% solution | Mild to moderate infections: One to two drops every 2–4 hours<br>Severe infections: initially, two drops every hour |

## VIRAL CONJUNCTIVITIS

### Etiology

Viral conjunctivitis is commonly caused by adenovirus and is often called "pink-eye."[6] Adenovirus is easily spread through swimming pools, camps, and contaminated fingers and medical instruments.[7] Patients often present with an upper respiratory tract infection or recent exposure to viral conjunctivitis.[6]

**KEY CONCEPT** *Viral conjunctivitis is usually self-limiting, resolving within 2 weeks.*[6]

### Treatment

#### ▶ Desired Outcomes

- Complete resolution of the viral conjunctivitis
- Prevent adverse consequences of the infection
- Avoid spreading infection to other patients

#### ▶ Nonpharmacologic Therapy

**KEY CONCEPT** *Nonpharmacologic measures are critical to prevent the spread of viral conjunctivitis.* Cold compresses may relieve symptoms.[6,7] Patients should not share towels or other contaminated objects, should avoid close contact with other people, and avoid swimming for 2 weeks.[6,7] Take care in the medical setting to thoroughly decontaminate instruments and wash hands.[6,7]

#### ▶ Pharmacologic Therapy

Patients may obtain further symptomatic relief by using artificial tears and topical decongestants.[6,7] If artificial tear solutions sting, recommend a preservative-free formula.

Topical antivirals are not used to treat adenovirus conjunctivitis. Topical antibiotics are unnecessary and should not be used for a viral infection and to help prevent the development of antibiotic resistance.[7]

**Patient Encounter 1**

This morning, a mother brings in her 13-year-old son who has been complaining of irritation, redness, and "goop" coming out of his right eye for the past 13 hours. He woke up terrified this morning because his right eye seemed glued shut. At first, the mother was concerned because his younger sister had "pink-eye" 2 weeks ago. A warm washcloth was used to ease the eye open, and upon examination, the right eye was red and revealed a whitish discharge, whereas the left eye was just red.

*What is the probable diagnosis?*

*Please differentiate between bacterial, hyperacute bacterial, viral, and allergic causes based on physical assessment.*

*What organisms should be suspected, and what are reasonable treatment regimens?*

*If the child would have been diagnosed with viral conjunctivitis, what nonpharmacologic measures should be employed to prevent spreading?*

Patients with severe subepithelial infiltration may require a topical steroid. However, topical steroids may cause serious ocular complications, increase the period of viral shedding, and may worsen herpetic conjunctivitis, which has similar symptoms as viral conjunctivitis.[7] Only ophthalmologists should prescribe topical steroids.[6]

## Outcome Evaluation

Refer patients who do not see improvement within 7 to 10 days to an ophthalmologist to rule out herpetic and other infectious processes.[6,7]

## ALLERGIC CONJUNCTIVITIS
### Etiology and Clinical Presentation

Ocular allergy is a broad term that includes several diseases with the hallmark symptom of itching, often accompanied by tearing, conjunctival swelling, photophobia, and stringy or sticky mucoid discharge.[8] Allergic conjunctivitis affects up to 40% of patients.[9] Seasonal ocular allergy is the most common type of allergic conjunctivitis. Often, the patient's history is positive for atopic conditions, including allergic rhinitis, asthma, or eczema.[6] Perennial allergic conjunctivitis has similar but less severe symptoms and may not be tied to a specific time of year. Finally, conjunctivitis medicamentosa is a drug-induced form of allergic conjunctivitis caused by overuse of topical vasoconstricting agents.[8]

### Pathophysiology

The conjunctiva of the eye is often the initial site of contact with an environmental allergen. Mast cell degranulation occurs, and the earliest mediator is histamine, which causes itching, redness, and swelling.[9] Leukotrienes and prostaglandins cause cellular infiltration and increased mucous secretion along with chemosis, resulting in conjunctival vasodilation.

Treatment of ocular allergy is aimed at slowing or stopping these processes. Antihistamines block the histamine receptors, prevent histamine release from the mast cells and stop eosinophil activity.[9] Mast cell stabilizers inhibit the degranulation of mast cells, preventing mediator release. Some topical agents have multiple mechanisms of action, combining antihistaminic, mast cell stabilization, and anti-inflammatory properties (Tables 62–4, 62–5, and 62–6).[9]

---

### Patient Encounter 2

AZ is a 17-year-old boy presenting with swollen, teary eyes, and complains of itching. His symptoms seem to be worse in the spring months especially when he's outdoors. He has asthma and smokes (but his parents don't know). He has been using over-the-counter naphazoline for the past 2 weeks that his mother found in their medicine closet.

*What information is suggestive of allergic conjunctivitis?*

*What nonpharmacologic therapies should be recommended for this patient?*

*What pharmacologic therapies should be recommended for this patient?*

*How should the patient be monitored?*

---

### Table 62–4

**Mechanisms of Action of Ocular Allergy Drugs**

| Drug | Mechanisms |
|---|---|
| Azelastine | $H_1$-receptor antagonist |
| Cromolyn sodium | Mast cell stabilizer |
| Emedastine | $H_1$-receptor antagonist |
| Epinastine | $H_1$- and $H_2$-receptor antagonist, mast cell stabilizer |
| Ketorolac | Inhibitors prostaglandin synthesis |
| Ketotifen | $H_1$-receptor antagonist, mast cell stabilizer, eosinophil inhibitor |
| Lodoxamide | Mast cell stabilizer |
| Loteprednol | Corticosteroid |
| Nedocromil | Mast cell stabilizer, eosinophil inhibitor |
| Olopatadine | $H_1$-receptor antagonist, mast cell stabilizer |
| Pemirolast | Mast cell stabilizer |

From McEvoy GK, ed. AHFS Drug Information 2014. Bethesda, MD: American Society of Health-System Pharmacists Inc., 2014.

## Treatment
### ▶ Desired Outcomes

- Relief of current allergic symptoms
- Prevention of future allergic symptoms
- No adverse effects from treatment

### ▶ Nonpharmacologic Therapy

The primary treatment for ocular allergy is removal and avoidance of the allergen.[6,7] For conjunctivitis medicamentosa, discontinue the offending medication. Apply cold compresses several times daily to reduce redness and itching and to provide symptomatic relief.[8]

### ▶ Pharmacologic Therapy

**KEY CONCEPT** *Use a step-care approach for the treatment of allergic conjunctivitis.*

- Step 1: Nonmedicated, artificial tears solution. The solution dilutes or removes the allergen, providing relief while lubricating the eye. Solutions are applied two to four times daily as needed. Ointments may be used in the evenings to further moisturize the surface of the eye. Preservative-free formulations may be tried if other products sting or burn.

- Step 2: Topical antihistamine or antihistamine/decongestant combination. The antihistamine/decongestant combination is more effective than either agent alone. Decongestants are vasoconstrictors that reduce redness and seem to have a small synergistic effect with the antihistamine. The only topical decongestant used in combination products is naphazoline. Topical decongestants burn and sting on instillation and commonly cause mydriasis, especially in patients with lighter-colored eyes. Topical decongestant use should be limited to less than 10 days to avoid rebound congestion.

- Step 3: A mast cell stabilizer or a multiple-action agent. Use mast cell stabilizers prophylactically throughout the allergy season. Full response may take 4 to 6 weeks.

- Step 4: Short-term topical corticosteroids and immunotherapy.[8,9]

### Table 62–5

**Pediatric and Adult Dosing and Common Side Effects of Ocular Allergy Drugs**

| Drug | Dosing | Common Side Effects |
|---|---|---|
| Azelastine 0.05% | Children 3 years of age or older and adults: one drop in affected eye(s) twice daily | Ocular stinging, bitter taste, headache |
| Cromolyn sodium 4% | Children 4 years of age or older and adults: one to two drops in each eye four to six times daily | Ocular stinging |
| Emedastine 0.05% | Children 3 years of age or older and adults: one drop in affected eye up to four times daily | Ocular stinging, blurred vision, headache |
| Epinastine 0.05% | Children 3 years of age or older and adults: one drop in each eye twice daily | Ocular burning, ocular itching, cold symptoms |
| Ketorolac 0.5% | Children 3 years of age or older and adults: one drop four times a day | Ocular stinging, irritation |
| Ketotifen 0.025% | Children 3 years of age or older and adults: one drop in affected eye(s) twice daily | Red eyes, headache, rhinitis |
| Lodoxamide 0.1% | Children 2 years of age or older and adults: one to two drops in affected eye(s) four times daily, for up to 3 months | Ocular stinging, discomfort, foreign body sensation |
| Loteprednol 0.2% | Adults only: one drop in affected eye(s) four times daily | Elevated intraocular pressure, cataracts, secondary ocular infections, systemic side effects possible |
| Nedocromil 2% | Children 3 years of age or older and adults: one to two drops in each eye twice daily | Headache, ocular stinging, unpleasant taste, nasal congestion |
| Olopatadine 0.1%; 0.2% | Children 3 years of age or older and adults (0.1%): one drop in affected eye(s) two times daily with minimum 6- to 8-hour interval between doses. Children 2 years of age or older: and adults (0.2%): one drop in affected eye(s) once daily | Headache, blurred vision, ocular stinging |
| Pemirolast 0.1% | Children 3 years of age or older and adults: one to two drops in affected eye(s) four times daily | Headache, cold symptoms |

From McEvoy GK, ed. AHFS Drug Information 2014. Bethesda, MD: American Society of Health-System Pharmacists Inc., 2014.

Alomide (lodoxamide tromethamine) solution/drops 0.1%. Fort Worth(TX): Alcon Laboratories, Inc., 2003.

### Table 62–6

**Risk Factors for Bacterial Keratitis**

**Exogenous Factors**
- Contact lenses
- Loose sutures from ocular surgeries
- Previous corneal surgery
- Previous ocular or eyelid surgery
- Trauma, including foreign bodies, chemical and thermal injuries and local irradiation

**Ocular Surface Disease**
- Abnormal lid anatomy or function
- Misdirection of eyelashes
- Ocular infection (eg, conjunctivitis, blepharitis)
- Tear film deficiencies

**Systemic Conditions**
- Atopic dermatitis
- Connective tissue disease
- Debilitating illness (eg, malnourishment or respirator dependence)
- Diabetes mellitus
- Factitious disease (including anesthetic abuse)
- Gonococcal infection
- Immunocompromised
- Stevens-Johnson syndrome
- Substance abuse
- Vitamin A deficiency

**Ocular Medications**
- Anesthetics
- Antimicrobials
- Contaminated ocular medications
- Glaucoma medications
- Preservatives
- Steroids
- Topical NSAIDs

**Corneal Epithelial Abnormalities**
- Corneal epithelial edema
- Predisposition to recurrent erosion of the cornea
- Viral keratitis (eg, herpes simplex or zoster keratitis)

Data from Ref. 10, American Academy of Ophthalmology Cornea/External Disease Panel. Preferred Practice Pattern® Guidelines. Bacterial Keratitis [Internet]. San Francisco, CA: American Academy of Ophthalmology, 2013 [cited 2014 Aug 30]. www.aao.org/ppp.

Topical antihistamines are recommended before oral agents in step therapy due to the increased risk of systemic side effects with oral drugs. Topical antihistamines provide faster relief of ocular symptoms. Topical ketorolac tromethamine is approved for ocular itching.[9]

### Outcome Evaluation

Monitor patients for relief of symptoms. Ensure an adequate trial of each agent. Refer severe cases that do not respond to an ophthalmologist.

## BACTERIAL KERATITIS
### Epidemiology

Thirty thousand cases of microbial keratitis occur annually in the United States.[10] Microbial keratitis encompasses bacterial, fungal, and *Acanthamoeba* keratitis.[10] Only bacterial keratitis, the most common form, is discussed here.

## Clinical Presentation and Diagnosis of Bacterial Keratitis[6,10]

### General

The rate of progression of signs and symptoms varies depending on the infecting organism. A differential diagnosis for keratitis must include viral, fungal, and nematodal infections in addition to bacterial causes.

### Symptoms

- Photophobia
- Rapid onset of ocular pain

### Signs

- Red eye
- Conjunctival discharge
- Decreased vision

### Laboratory Tests

- Culture if keratitis is severe or sight threatening, chronic, or unresponsive to broad-spectrum antimicrobial therapy.

## Pathophysiology

Bacterial keratitis is a broad term for a bacterial infection of the cornea, including corneal ulcers and corneal abscesses. The cornea in a healthy eye has natural resistance to infection, making bacterial keratitis rare. However, many factors may predispose a patient to bacterial infection by compromising the defense mechanisms of the eye (see Table 62–6).[10]

The most common pathogens in bacterial keratitis are *Pseudomonas* (including *Pseudomonas aeruginosa*) and other gram-negative rods, Staphylococci, and Streptococci.[10] If the keratitis is related to the use of contacts, *Pseudomonas* and *Serratia marcescens* are the most common pathogens.[10] **KEY CONCEPT** *Untreated bacterial keratitis is associated with corneal scarring and potential loss of vision. Corneal perforation may occur, and the patient may lose the eye.*[10] In virulent organisms, this destruction may occur within 24 hours.[10] Central corneal scarring may result in vision loss even after successful eradication of the organism.[10]

## Treatment

### ▶ Desired Outcomes[10]

- Resolution of infection and corneal inflammation
- Reduced corneal pain
- Restored corneal integrity with minimal scarring
- Restored visual function

### ▶ General Approach to Treatment

All cases of suspected bacterial keratitis require prompt ophthalmology consultation to prevent permanent vision loss.[6]

### ▶ Pharmacologic Therapy

**Dosage Considerations** Topical antibiotic drops are preferred. Consider subconjunctival antibiotics if compliance is a concern. Systemic therapy is useful in cases of systemic infection (eg, gonorrhea) or if the sclera is infected. Reserve ointments for minor cases or adjunctive nighttime therapy.[10]

### Table 62–7

**Pharmacologic Therapies for Bacterial Keratitis**

| Organism | Drug |
|---|---|
| Unknown or multiple types of organisms | Cefazolin 50 mg/mL *and* tobramycin/gentamicin 9–14 mg/mL *or* Fluoroquinolones various strengths |
| Gram-positive cocci | Cefazolin 50 mg/mL *or* Vancomycin[a] 15–50 mg/mL *or* Bacitracin[a] 10,000 international unit *or* Moxifloxacin or gatifloxacin various strengths |
| Gram-negative rods | Tobramycin 9–14 mg/mL *or* Gentamicin 9–14 mg/mL *or* Ceftazidime 50 mg/mL *or* Fluoroquinolones various strengths |
| Gram-negative cocci | Ceftriaxone 50 mg/mL *or* Ceftazidime 50 mg/mL *or* Fluoroquinolones various strengths |
| Nontuberculous mycobacteria | Amikacin 20–40 mg/mL *or* Oral clarithromycin, adults: 500 mg every 12 hours Fluoroquinolones various strengths |
| *Nocardia* | Amikacin 20–40 mg/mL *or* Trimethoprim 16 mg/mL *and* sulfamethoxazole 80 mg/mL |

**Adult Topical Dosing**
Severe keratitis: loading dose every 5–15 minutes for the first hour, then every 15 minutes to 1 hour around the clock. Less severe keratitis may use less frequent dosing

[a]Use for resistant *Enterococcus* and *Staphylococcus* species and penicillin allergy. Due to the absence of gram-negative activity, do not use vancomycin or bacitracin for single-agent empiric therapy in bacterial keratitis.

Data from Ref. 10, American Academy of Ophthalmology Cornea/External Disease Panel. Preferred Practice Pattern® Guidelines. Bacterial Keratitis [Internet]. San Francisco, CA: American Academy of Ophthalmology, 2013 [cited 2014 Aug 30]. www.aao.org/ppp.

**Drug Choice** Start topical broad-spectrum antibiotics empirically. Use a loading dose for severe keratitis (Table 62–7). Single-drug therapy with a fluoroquinolone is as effective as combination therapy. Resistance is seen with some fluoroquinolones, choose moxifloxacin or gatifloxacin in severe keratitis cases.[10] Fortified antibiotic therapy is an option for severe or unresponsive infections but may increase toxicity to the cornea and surrounding tissues. Fortified antibiotics are compounded products that are a higher concentration than the commercially available formulation.[10]

Topical corticosteroids are employed in some cases of bacterial keratitis. The suppression of inflammation may reduce corneal scarring. However, local immunosuppression, increased ocular pressure, and reappearance of the infection are disadvantages to their use. There is no conclusive evidence that they alter clinical outcomes. If the patient is already on topical corticosteroids when the keratitis occurs, discontinue use until the infection is eliminated.[10]

## Outcome Evaluation[10]

- Symptomatic improvement is indicative of therapeutic efficacy.
- Adjust treatment based on culture and sensitivity reports.

**FIGURE 62–2.** Normal vision. (From the National Eye Institute, National Institutes of Health Ref. No. EDS01. http://www.nei.nih.gov/photo/)

- Modify the treatment regimen if the patient does not show improvement within 48 hours.
- Gram-negative keratitis will have increased inflammation in the first 24 to 48 hours, even on appropriate therapy.
- Taper therapy based on clinical response.
- Reculture if negative clinical response; discontinue antibiotics 12 to 24 hours before culturing for best results.
- Contact lenses wearers should be educated about the increased risk of infection overnight and continuous wear and the importance of adherence to contact lens hygiene.

## MACULAR DEGENERATION
### Epidemiology and Etiology

Age-related macular degeneration (AMD) is the primary cause of severe, irreversible vision impairment in developed countries (**Figures 62–2** and **62–3**). The prevalence increases with age.[11]

**FIGURE 62–3.** The scene in Figure 62–2 as it might be viewed by a person with age-related macular degeneration. (From the National Eye Institute, National Institutes of Health Ref. No. EDS05. http://www.nei.nih.gov/photo/)

| Table 62–8 | |
|---|---|
| **Risk Factors for AMD** | |
| **Definite Risk Factors** | **Potential Risk Factors** |
| Advancing age | Cardiovascular disease |
| Light pigmentation (white ethnicity) | Hypertension |
| | Low dietary intake of antioxidant vitamins or zinc |
| Cigarette smoking | |
| Family history | Increased body mass index |
| | Higher dietary fat intake |

Data from Ref. 11, American Academy of Ophthalmology Retina Panel. Preferred Practice Pattern® Guidelines. Age-Related Macular Degeneration [Internet]. San Francisco, CA: American Academy of Ophthalmology, 2008 [cited 2014 Aug 30]. www.aao.org/ppp.

In the United States, 1.75 million people age 40 or older have advanced AMD, and another 7 million people may have intermediate AMD.[11] It is projected that almost 3 million people will develop AMD by 2020.[12] The causes of AMD are not completely known (**Table 62–8**).[11]

### Pathophysiology

AMD is a deterioration of the **macula**, the central portion of the retina. The macula facilitates central vision and high-resolution visual acuity because it has the highest concentration of photoreceptors in the retina. The loss of central vision leads to irreversible loss of the ability to drive, read, and perform other fine visual tasks like recognize faces.[13] Peripheral vision is preserved, allowing mobility.[11] AMD is characterized by one or more of the following: **drusen** formation, retinal pigment abnormalities (eg, hypo- or hyperpigmentation), geographic atrophy, and **neovascular maculopathy**.[11]

## Clinical Presentation and Diagnosis of AMD[12,14]

**Symptoms**
- Mild blurry central vision
- Difficulty reading
- Trouble with color and contrast
- Painless, progressive, blurring of central vision
- Sudden loss or distortion of vision possible

**Signs**
- Drusen
- Retinal pigment epithelial mottling

**Other Diagnostic Tests**
- Amsler grid abnormalities indicate fluid in subretinal space (see Figures 62–4 and 62–5)
- Dilated fundus examination shows drusen and pigmentary abnormalities in the macula
- Rapid sequence fluorescein angiography shows leakage in the neovascular form

Based on clinical presentation, AMD is classified as early, intermediate, or advanced.[11] Early AMD is characterized by small or intermediate drusen and minimal macular pigment abnormalities. These patients generally have normal central vision. Intermediate AMD patients have medium or large drusen in one or both eyes.[11]

Advanced AMD is classified as non-neovascular (also called the atrophic, nonexudative, or dry form) or neovascular (the exudative or wet form).[11,13] In the non-neovascular form, the retina and other layers atrophy.[13] In the neovascular form, new blood vessels appear.[11,13] Generally, vision is already affected when patients progress to advanced AMD; vision loss is seen in both forms.[11] Around 10% to 20% patients with the non-neovascular form will progress to the neovascular form.[14]

## Treatment

### ▶ Desired Outcomes

The primary goal of treatment for AMD is to slow the disease progression. This includes slowing the loss of visual acuity and the progression to legal blindness, along with maintaining contrast sensitivity. The secondary goals are maintaining quality of life and minimizing the adverse effects of treatment.[13]

### ▶ General Approach to Treatment

KEY CONCEPT *There is no cure for AMD, and the efficacy of most treatments is low.* Newer drug developments show promise, but no treatment can reverse damage that has already occurred.[14] Early diagnosis is critical. High-risk patients need periodic eye examinations because some patients do not notice any changes, even when neovascularization has occurred.[11]

### ▶ Nonpharmacologic Therapy

**Non-neovascular AMD** Advise patients to stop smoking, as observational data supports a causal relationship between smoking and AMD.[11]

Drusen ablation by laser has been used however; it is not clear whether the treatment reduces progression to neovascular AMD.[14] Treatments may induce neovascularization and retinal atrophy.[13] Other nonpharmacologic therapies are in trials, but there is insufficient evidence for experts to recommend these procedures at this time.[11]

**Neovascular AMD** Thermal laser photocoagulation reduces severe visual loss 2 to 5 years after the procedure, but leads to an immediate and permanent reduction in central vision. There is a 50% chance that leakage will recur in the next 2 years after the procedure.[13]

Use of photodynamic therapy in combination with the medication verteporfin has shown success in clinical trials.[15] Verteporfin is reconstituted to achieve the desired dose of 6 mg/m² body surface area and diluted with 5% dextrose for injection to a total infusion volume of 30 mL. The drug is given intravenously, and laser light delivery is performed on the patient 15 minutes after the start of the 10-minute infusion with verteporfin. Photodynamic therapy uses nonthermal red light to activate verteporfin, which produces reactive oxygen species that locally damage the neovascular endothelium.[15] Verteporfin treatment reduces the risk of loss of visual acuity and legal blindness over 1 to 2 years. Long-term results are not yet available. Severe photosensitivity for 3 to 5 days after the procedure is common, and some patients experience a severe loss of vision. Eventually, most patients have some visual recovery. This procedure requires multiple treatments over time.[15]

### ▶ Pharmacologic Therapy

There are no approved pharmacologic treatments for non-neovascular AMD.[16] The Age-Related Eye Disease Study showed that a supplement containing ascorbic acid 500 mg, vitamin E 400 IU, β-carotene 15 mg, zinc oxide 80 mg, and cupric oxide 2 mg reduced the rate of clinical progression of all types of AMD by 28% in patients with at least intermediate macular degeneration.[16] No benefit was seen in patients with earlier stages of AMD; however, the duration of the study may have been insufficient to detect this benefit.[16] Currently, experts recommend antioxidant supplementation for intermediate AMD or advanced AMD in one eye.[11] Supplementation is not without risk.[14] For example, β-carotene supplementation in smokers may increase the risk of developing lung cancer.[11,14] At this time, it is not clear from the evidence whether a patient is at a high risk but without symptoms of AMD would benefit from supplementation.[17]

Vascular endothelial growth factor induces **angiogenesis**, increases vascular permeability, and increases inflammation, all of which are thought to contribute to neovascular AMD.[18] Pegaptanib, a vascular endothelial growth factor antagonist, binds to these growth factors in an attempt to suppress neovascularization.[11,18] In clinical studies, patients treated with pegaptanib experienced a slower rate of visual decline than patients treated with a placebo injection.[19] Vision loss continued to occur in patients, and the drug was less effective in the second year of treatment.[18]

Ranibizumab, binds to and inhibits the activity of vascular endothelial growth factor (VEGF) A, a critical protein in angiogenesis.[11] In one clinical study, 95% of patients treated with ranibizumab maintained visual acuity after 12 months compared with 62% of control patients.[11]

Aflibercept, a VEGF-A inhibitor was approved for wet age-related macular degeneration. The dosing of 2 mg every 4 weeks for the first 3 months, followed by 2 mg every 8 weeks thereafter, results in seven injections during the first year of treatment compared with 12 injections with other products.[20] Patients treated with aflibercept or other VEGF-A inhibitors are at risk for arterial thrombotic events. Specifically, stroke, nonfatal heart

---

## Patient Encounter 3, Part 1

JJ, an 82-year-old white man, presents with difficulty seeing license plates on cars while driving. He can still distinguish street signs and other cars, but smaller details seem hazy. He notes that this is only occurring in his left eye, so sometimes he closes that eye and everything is fine.

**PMH:** Hypertension, osteoporosis, hyperlipidemia, chronic kidney disease, vitamin D Deficiency

**FM:** Mother died at 70 from cardiovascular disease

Father died at 75 from cancer

**SH:** Denies drinking, or illicit drugs. Smokes half PPD

Widowed, two adult children

**PE:** BP 142/82, P 68, R 14, Ht 5′6″ (168 cm), Wt 162 lb (73.5 kg)

**Meds:** Accupril 10 mg daily; fosamax 70 mg q week (on Fridays); Zocor 20 mg daily; aspirin 81 mg daily; multivitamin daily; vitamin D 2000 IUs daily

*Does JJ have any definitive or potential risk factors for age-related macular degeneration?*

## Patient Encounter 3, Part 2

After meeting with a retinologist, JJ has been diagnosed with early non-neovascular age-related macular degeneration. He has been advised to use a magnifying glass for his left eye instead of closing it while reading. He has been advised to only drive during the day.

*What pharmacologic and nonpharmacologic treatment options are available for JJ?*

*JJ's daughter is very FRUSTRATED that her dad is not on a "medication," as a family friend is being treated for macular degeneration. What information is necessary to relay to JJ's daughter?*

*What monitoring is appropriate for JJ?*

*JJ's daughter is concerned that she will develop macular degeneration because she read that it runs in families. What symptoms should JJ's daughter watch for as she gets older?*

attack, or vascular deaths were observed were observed in 1.8% of patients in clinical trials.[20]

### Outcome Evaluation

Monitor patients for acute and chronic vision changes or loss. The Amsler grid (Figures 62–4 and 62–5) and frequent eye examinations may detect changes more quickly. The long-term prognosis for AMD is poor; therefore, it is important to work with patients and families as vision decreases. Monitor

FIGURE 62–5. Amsler grid as it might appear to someone with AMD. (From the National Eye Institute, National Institutes of Health Ref. No. EC04. http://www.nei.nih.gov/photo/)

patients for inability to drive and remove driving privileges as appropriate.

## DRY EYE

### Epidemiology and Etiology

Dry eye is a frequent cause of eye irritation. The lack of a single diagnostic test for the condition limits the available epidemiologic data. Reports of the prevalence of dry eye range from 5% to 30%, being more frequent in elderly patients.[21] The risk factors for dry eye are listed in Table 62–9. The use of caffeine is associated with a decreased risk of dry eye. Dry eye that is left untreated

FIGURE 62–4. Amsler grid distortions in the lines of the grid may be caused by subtle changes in central vision due to fluid in the subretinal space. This is the Amsler grid as it appears to someone with normal vision. (From the National Eye Institute, National Institutes of Health Ref. No. EC03. http://www.nei.nih.gov/photo/)

### Table 62–9

**Risk Factors for Dry Eye**

Androgen deficiency
Antihistamine use
Connective-tissue disease
Estrogen replacement therapy
Female gender
Hematopoietic stem cell transplantation
Hepatitis C infection
LASIK and refractive excimer laser surgery
Low dietary intake of omega-3 fatty acids
Older age
Radiation therapy
Vitamin A deficiency

Data from Ref. 22, American Academy of Ophthalmology Cornea/External Disease Panel. Preferred Practice Pattern® Guidelines. Dry Eye Syndrome [Internet]. San Francisco, CA: American Academy of Ophthalmology, 2013 [cited 30 Aug 2014]. www.aao.org/ppp.

## Clinical Presentation and Diagnosis of Dry Eye[21,22]

### General

Many other ocular diseases have similar symptoms. Patients with suggestive symptoms without signs should be placed on a treatment trial. Repeated observations may be required for a clinical diagnosis.

### Symptoms

- Dry or foreign body sensation
- Mild itching
- Burning or stinging
- Photophobia
- Ocular irritation or soreness
- Blurry vision
- Contact lens intolerance
- Diurnal fluctuation or symptoms worsening later in the day

### Signs

- Redness
- Mucous discharge
- Increased blink frequency
- Tearing

### Other Diagnostic Tests

- The tear break-up time test assesses the stability of precorneal tear film. Break-up times of less than 10 seconds are considered abnormal.
- Ocular surface dye staining assesses the ocular surface and will show blotchy areas in the dry eye.
- Schirmer test evaluates aqueous tear production but is not diagnostic. Results of 5 mm or less are considered abnormal.
- Assess corneal sensation if trigeminal nerve dysfunction is suspected.
- Consider an autoimmune disorder if significant dry eyes, other signs and symptoms, or family history are present.

---

**Table 62–10**

### Associated Conditions That Cause or Worsen Dry Eye

| Ocular Conditions | Environmental Factors |
|---|---|
| Blepharitis | Air travel |
| Eyelid malposition | Air conditioning or heating |
| Lagophthalmos | Contact lenses |
| Meibomian gland dysfunction | Exogenous irritants or allergens |
| **Systemic Diseases** | Prolonged use of computer or reading |
| Amyloidosis | Reduced humidity |
| Bell palsy | Smoke exposure |
| Epstein-Barr virus | Wind |
| Graft-versus-host disease | **Local Trauma** |
| Hemochromatosis | Injury/scarring |
| Hepatitis C infection | Orbital surgery |
| Human immunodeficiency virus infection | Radiation |
| Lymphoma | **Medications** |
| Neuromuscular diseases | Anticholinergics |
| Ocular mucous membrane pemphigoid | Antidepressants |
| Parkinson disease | Antihistamines |
| Rosacea | β-Blockers |
| Rheumatoid arthritis | Diuretics |
| Sarcoidosis | Hormone therapy |

| Systemic lupus erythematosus | |

Data from Ref. 22, American Academy of Ophthalmology Cornea/External Disease Panel. Preferred Practice Pattern® Guidelines. Dry Eye Syndrome [Internet]. San Francisco, CA: American Academy of Ophthalmology, 2013 [cited 30 Aug 2014]. www.aao.org/ppp.

---

can cause loss of vision, structural damage, an increased risk for infection, and compromised efficacy of ocular surgery.[22]

## Pathophysiology

The surface of the eye and the tear-secreting glands work together as an integrated unit that refreshes the tear supply and clears away used tears. Dry eye may be caused by impaired tear secretion and/or increased tear evaporation.[22] It has been suggested that dry eye be called "dysfunctional tear syndrome," as all the predisposing factors cause some disruption of the tear.[21]

Dysfunction may be caused by aging, systemic inflammatory diseases, a decrease in androgen hormones, surgery, ocular surface diseases, systemic diseases, or medications that affect the efferent cholinergic nerves. Dysfunctional tear film may result in an inflammatory response on the ocular surface called kerato-conjunctivitis sicca.[22]

Environmental causes (Table 62–10) and an abnormal blink reflex are common causes of increased evaporative loss of tears and worsening of dry eye.[22]

## Treatment

### ▶ Desired Outcomes[22]

- Relief of the symptoms of dry eye
- Maintain or improve visual acuity
- Prevention of long-term adverse effects from dry eye

### ▶ General Approach to Treatment

**KEY CONCEPT** *Dry eye is a chronic condition. Symptoms can be improved with treatment, but unless dry eye is secondary to a disease, it is not usually curable.* Because of this, patient education is critical, and a periodic reassessment of the efficacy of the treatment is appropriate. If the patient is unresponsive to treatment, refer to an ophthalmologist for additional options. If the dry eye is secondary to a systemic disease, the disease should be managed by the appropriate medical specialist.[22]

### ▶ Nonpharmacologic Therapy

Behavioral and environmental modifications may significantly improve dry eye, especially in mild cases. Patients should be counseled to increase their frequency of blinking, use eyelid hygiene and warm compresses, and stop smoking. Reduce air drafts and consider adding a humidifier in low-humidity areas. Schedule regular breaks from computer work or reading. Lower

the computer screen to below eye level to decrease lid aperture. Evaluate medication profile and therapeutically substitute medications that do not exacerbate dry eye. Spectacle side shields or goggles may reduce tear evaporation.[21,22]

If pharmacologic and other therapies are not sufficient, punctal occlusion or lateral tarsorrhaphy may be an option.[21,22] Punctal occlusion is the plugging of the punctal drainage sites with collagen or silicone plugs. Lateral tarsorrhaphy sutures portions of the lid margins together to decrease evaporative tear loss.

▶ *Pharmacologic Therapy*

The mainstay of treatment for dry eye is artificial tears. Artificial tears augment the tear film topically and provide symptom relief. If a patient uses artificial tears more than four times daily, or develops an allergy to ophthalmic preservatives, recommend a preservative-free formulation. Artificial tears are available in gel, ointment, and emulsion forms that provide a longer duration of relief. Ointment use is appropriate at bedtime.[21]

Preliminary data suggest dietary or supplemental intake of omega-3 fatty acids may be beneficial.[6,21,22] Omega-3 fatty acids may block the production of inflammatory cytokines and pro-inflammatory mediators.[21]

Anti-inflammatory agents may be used in conjunction with artificial tears. The only approved agent is cyclosporine emulsion. Cyclosporine emulsion increases tear production in some patients. Fifteen minutes should elapse after instillation of cyclosporine before artificial tears are instilled.[23] Use of topical corticosteroids for short periods (2 weeks) may suppress inflammation and ocular irritation symptoms.[22]

The oral cholinergic agonists pilocarpine and cevimeline are used for patients with Sjögren syndrome (combined dry eye and dry mouth) or severe dry eye. By binding to muscarinic receptors, the cholinergic agonists may increase tear production. Excessive sweating is a common side effect with pilocarpine and may limit its use (**Table 62–11**).[22]

### Outcome Evaluation[22]

- Monitor patient for relief of symptoms and ocular damage.
- Periodically reassess the patient's compliance with therapy and understanding of the disease.
- It may take 6 to 12 weeks before improvement is seen with pilocarpine therapy.[21]

---

**Patient Care Process: Patient Counseling**

Wash hands before and after instilling medication(s) into the eye

Contact lenses should be removed prior to instilling eye medication, and the patient should wait 10 minutes before reinserting contact lenses

Do not touch the tip of the container with anything

Use of nasolacrimal occlusion decreases systemic absorption up to 60% and may increase ocular bioavailability of the drug. After instilling the eye drop, the patient should close the eye and press a finger gently against the nasolacrimal duct (tear duct) for 2 to 3 minutes[24]

---

- Cyclosporine therapy may take up to 3 months for full improvement.
- If a patient presents with vision loss, moderate or severe pain, corneal ulceration, or a lack of response to therapy, refer the patient to an ophthalmologist for prompt evaluation.

## DRUG-INDUCED OCULAR DISORDERS

Many systemic medications can cause ocular adverse effects. Patients presenting with ocular complaints should have their medication profile evaluated.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| ABC | Acute bacterial conjunctivitis |
| AMD | Age-related macular degeneration |
| NSAID | Nonsteroidal anti-inflammatory drug |

# 63

# Allergic Rhinitis

David A. Apgar

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Describe the basic pathophysiology of allergic rhinitis (AR).
2. List the four typical symptoms of AR and identify the one that is usually the most troublesome.
3. List at least three reasons for referral to an allergy specialist.
4. Differentiate the categories of pharmacotherapy choices for treatment of AR.
5. Rank the pharmacotherapy choices for efficacy in treating the usual single most troublesome symptom of AR.
6. Describe an approach for treatment of mild AR with over-the-counter (OTC) drugs.
7. Create a therapy plan for treatment of moderate–severe AR.
8. Describe how to monitor patients treated for AR.
9. Identify the differences in approach to the treatment of AR for children, pregnant women, and the elderly compared with the routine approach in adults.

## INTRODUCTION

Rhinitis is inflammation of the lining of the nose and contiguous parts of the upper respiratory tract.[1–4] Allergy is only one of numerous causes of rhinitis.[1–5] The most common causes of nonallergic rhinitis are shown in Table 63–1.[1–5] Some patients suffer concurrently from both allergic rhinitis (AR) and one or more types of nonallergic rhinitis (NAR). This is sometimes called mixed rhinitis (MR).[1,3] AR will be emphasized in this chapter, but some mention will be made of NAR. Because ocular symptoms frequently occur in association with AR, some sources use the term allergic rhinoconjunctivitis. This acknowledges involvement of the bulbar and palpebral conjunctivae in the allergic process.

**KEY CONCEPT** *AR is an allergen-induced, immunoglobulin E (IgE)-mediated inflammatory condition of the lining of the nose and upper respiratory tract.*[1,6–9] This pathophysiologic feature differentiates AR from NAR. AR has traditionally been categorized as either seasonal or perennial.[7] Seasonal allergic rhinitis (SAR) is attributed to inhaled allergens (aeroallergens) that have a seasonal variation. These allergens are usually encountered outdoors and are most often grass, tree or weed pollens and substances from molds and fungi. Perennial allergic rhinitis (PAR) is attributed to aeroallergens that are present in the patient's environment almost continuously throughout the year and are usually encountered indoors. Common perennial allergens are the house dust mite, indoor molds and fungi, insects (especially cockroaches), and companion animals (pets).[7] Some patients are affected year round, but have seasonal exacerbations. These people are probably allergic to both seasonal and perennial aeroallergens. Other patients have only episodic manifestations. These people are probably allergic to aeroallergens that are only episodically encountered.

Because these traditional categories of seasonal and perennial AR are imperfect and help little with therapeutic management decisions, another system for categorizing AR has been suggested by the international group *Allergic Rhinitis and its Impact on Asthma* (ARIA).[9] This alternative system categorizes the manifestations by a combination of frequency and severity. There are two divisions of frequency: intermittent and persistent. Intermittent frequency is defined as AR manifestations occurring less often than 4 days per week or for fewer than 4 consecutive weeks. Persistent frequency is defined as AR manifestations occurring for 4 or more days per week *and* for 4 or more consecutive weeks. Severity is categorized as either mild or moderate–severe. Mild manifestations are those that do *NOT* cause interference with sleep, daily activities, or work or school performance and that are not "troublesome." Moderate–severe severity includes those patients with manifestations of AR that *DO* cause interference with sleep, impairment of daily activities, problems at work or school, or are "troublesome." The ARIA document uses IAR (for intermittent) and PER (for persistent) for the two frequency categories. It is important to realize that IAR and PER are not synonymous with the classical categories of SAR and PAR, respectively. The ARIA system results in four categories: mild intermittent, mild persistent, moderate–severe intermittent, or moderate–severe persistent. The ARIA approach was updated in 2008 and again in 2010.[9,10] See Table 63–2 for a summary of these categories of AR.

## EPIDEMIOLOGY

AR affects up to 30% of adults and 40% of children in the United States, and there is evidence that the incidence is increasing.[3,5] The total direct and indirect costs of AR in the United States were estimated to be about 11 billion dollars, annually, in 2005.[11]

### Table 63–1

**Types of Rhinitis**

**Allergic** (see Table 63–2 for details)
**Nonallergic**
    Vasomotor (also known as perennial nonallergic, idiopathic, and autonomic rhinitis) (triggered by irritants, cold air, exercise/running, or unidentified factors)
    Food/meal related (gustatory)
    Infectious
    NARES (nonallergic rhinitis with eosinophilia syndrome)
    Occupational (caused by protein allergens (IgE-mediated) or by irritants (probably non–IgE-mediated)
    Hormonally related (hypothyroidism, pregnancy, menstrual cycle related, and some drugs [see below])
    Drug-induced
        Angiotensin-converting enzyme inhibitors (ACEIs)
        $\alpha_1$-Blockers (used for treatment of BPH and HT)
        Phosphodiesterase-5 inhibitors (used for treatment of ED)
        Aspirin and other NSAIDs (as an isolated side effect of AERD)
        Oral contraceptives and hormone replacement therapy
        Miscellaneous agents have been implicated (calcium channel blockers, some diuretics, centrally acting α-2 agonists, risperidone, gabapentin)
    Atrophic rhinitis
    Rhinitis associated with inflammatory or immunologic diseases (eg, granulomatous infections, SLE, Wegener granulomatosis, sarcoidosis, Churg–Strauss syndrome)
    Malignancy
**Mixed**
    Combination of allergic and nonallergic manifestations

AERD, aspirin-exacerbated respiratory disease; BPH, benign prostatic hyperplasia/hypertrophy; ED, erectile dysfunction; HT, hypertension; NSAIDs, nonsteroidal anti-inflammatory drugs; SLE, systemic lupus erythematosus.
From Refs. 1–5.

### Table 63–2

**Categories of Allergic Rhinitis**

**Based on etiologic category**
    Seasonal—symptoms present only during specific portions of the year
    Perennial—symptoms present throughout the year
    Episodic—symptoms present only during intermittent exposure to allergen trigger
**Based on ARIA 2008 Update**
    Mild versus moderate–severe
        Mild—no interference with sleep, daily activities, work or school function and attendance, and no troublesome symptoms
        Moderate–severe—presence of any one of the following: abnormal sleep, impairment of daily activities, impairment of work or school function, troublesome symptoms
    Intermittent versus persistent
        Intermittent—symptoms are present for less than 4 days per week, or for less than 4 consecutive weeks
        Persistent—symptoms are present for 4 or more days per week and for more than 4 consecutive weeks
    Any one of the four possibilities of these variables can occur: mild intermittent, mild persistent, moderate–severe intermittent, and moderate–severe persistent

From Refs. 7 and 8.

The major risk factors for AR are a family history of atopy (AR, asthma, eczema, or food allergies); elevated serum IgE levels (especially before the age of 6 years); higher socioeconomic class; positive skin test results; exposure to particulate air pollution; maternal smoking; firstborn status; and emigration into a Western industrialized environment.[5,7,9,11,12]

Certain disorders commonly occur with AR. The most important example is asthma. While different percentages are reported, most patients with asthma have rhinitis symptoms (many of which are AR), and only somewhat fewer with AR have asthma.[5,11] In fact, there is evidence that AR can predispose to the development and/or worsening of asthma.[1,5,12] Other conditions that can occur with AR include allergic conjunctivitis, eczema, sinusitis, sleep disorders, otitis media with effusion, and the oral food allergy syndrome.[5,11,12]

## PATHOPHYSIOLOGY[1,5,7–9,12,13]

AR is an IgE-mediated disorder of people who are allergy prone. Initial contact is required to sensitize the patient to subsequent exposures. Patients with an inherited tendency to allergic disorders produce T-helper lymphocyte type 2 (Th-2)-directed responses, including production of specific IgE antibodies, to one or more allergens. Many types of cells, mediators, and intermediate substances (including cytokines) are involved. In response to subsequent exposures to the trigger antigen(s), there is an early-phase and often a late-phase allergic response. This distinction has therapeutic implications.

During the early phase, the trigger allergen becomes bound to IgE that is fixed to mast cells in the nasal mucosa. This occurs within minutes of subsequent exposure to the antigen. Mast cells degranulate and release preformed mediators, the most important of which is histamine. This stimulates more mast cells, as well as macrophages, eosinophils, and basophils to produce more substances, including cysteine leukotrienes and prostaglandin $D_2$. These mediators bind to receptors in the nose and facilitate many of the manifestations of AR. The resultant vasodilation, mucosal edema, and hypertrophy all contribute to nasal congestion. Clear, watery, and often profuse rhinorrhea is also characteristic in this early phase, a result of mucous secretion and increased vascular permeability. Sneezing and nasal itch are other prominent features of the early phase. Many patients also have ocular symptoms.

The late phase occurs in about 50% of AR sufferers. It can begin as soon as 2 hours after the early phase and usually peaks between 6 and 12 hours. The late phase involves a second release of many of the mediators of the early phase. In addition, the late phase is characterized by an inflammatory component caused by infiltration of several cell types into the nasal mucosa. The most significant manifestation during the late phase is nasal congestion that is often severe and long lasting.

A phenomenon known as the priming response or nasal hyperresponsiveness is also of importance. This means that prolonged and/or repeated allergen exposure makes it easier to stimulate mediator release and symptoms. A vicious cycle results in which smaller doses of allergen can create symptoms (ie, the threshold is lowered). Thus, even when pollen exposure is decreased, symptoms may continue. In some patients, the threshold is lowered to the degree that even irritant substances (eg, formaldehyde, tobacco smoke, perfumes, automobile exhaust, and other environmental pollutants) may cause symptoms, on a nonallergic basis.

## Clinical Presentation and Diagnosis of Allergic Rhinitis[1–3,5,6,7–9,11–14]

**Typical Symptoms**

- Rhinorrhea (usually clear and bilateral; primarily anterior but may be posterior [postnasal drip])
- Sneezing
- Itching (mostly nasal, but also palate, throat, eyes, ears)
- Nasal congestion (not in all patients, but when present, usually the most troublesome symptom)

**Other Symptoms**

- Ocular manifestations (itch, redness, tearing, chemosis, periorbital edema)
- Sleep disturbances often with fatigue, asthenia, malaise, and irritability
- Presenteeism (impaired performance at work or school)
- Absenteeism from work or school
- Quality of life impairment (including social function)
- Headache, mild facial or ear pain, or fullness
- Cough (especially in those with concurrent asthma)
- Children (especially): snorting, sniffling, clearing the throat, learning or attention problems, poor appetite

**Signs (Especially Common in Children)**

- Pale, boggy nasal mucosa
- Rubbing the nose upward (allergic salute; may create horizontal crease just above tip of nose)

- Rubbing/scratching of eyes
- Mouth breathing
- Dark circles under the eyes (allergic shiners)
- Dennie-Morgan lines or folds under the eyes

**Diagnosis**

- Typical symptoms, confirmatory signs, especially in association with exposure to allergen triggers
- Other diagnostic testing usually optional, but may be necessary to rule out nonallergic causes or if immunotherapy is considered (appropriate physical examination, specific IgE antibody testing by either skin testing or in vitro serum testing, other specialized testing)
- Several sources particularly good for differential diagnosis of nonallergic rhinitis.[3,12,14]
- Vasomotor rhinitis—sneezing and itching less common than AR; anosmia more common
- Unilateral symptoms—refer for possible obstruction, anatomic abnormality, tumor, CSF leak
- Atrophic rhinitis—older adults, history of nasal surgery

## TREATMENT
### Desired Outcomes

**KEY CONCEPT** *The goals of treatment of AR are to minimize the frequency and severity of symptoms, prevent comorbid disorders and complications, improve the patient's quality of life, improve work attendance and productivity and/or school attendance and performance, and minimize adverse effects of therapy.* Until a cure is established, these are the only realistic goals.

### Nonpharmacologic Therapy

**KEY CONCEPT** *The general approach for treatment of AR is fourfold: avoidance of allergen triggers, pharmacotherapy, immunotherapy, and patient/family education.*[8,12] Immunotherapy could be considered a type of pharmacotherapy. However, even with availability of patient-administered sublingual immunotherapy (SLIT), referral for specific diagnostic testing is required. Therefore, immunotherapy will be discussed separately.

Avoidance of allergen triggers, to the extent they have been identified and to the extent such avoidance is possible, underlies the treatment for all patients with AR (Table 63–3).[7,8]

Immunotherapy is almost always initiated by an allergist or otolaryngologist, after referral for specific allergen testing to determine individualized therapy. Historically, immunotherapy was considered for patients in three categories.[5] The first were those with severe, complicated or worsening rhinitis. This was partly for additional diagnostic testing to rule out nonallergic causes of rhinitis. The second were those patients with AR who did not tolerate or responded poorly to appropriate pharmacotherapy. The third were those patients who had a single, or one major allergen identified, for which there was an immunotherapy product available for treatment. In addition, some patients requested immunotherapy, on the basis of superior and durable effectiveness. Currently, the role of any other health care provider is limited to referral of appropriate candidates. However, this may change in the future with the introduction of several products for sublingual self-administration. As of April, 2014, three products have been approved for administration as sublingual immunotherapy (SLIT). Until that time, only subcutaneous immunotherapy (SCIT) had been available as an approved therapy in the United States.[15–17] The major advantage of SLIT over SCIT is ease of administration. The first dose is given in the prescriber's office, for purposes of safety. Subsequent doses are self-administered by the patient. Questions remain, however, about comparative efficacy and the details of optimal dosage, frequency of administration, and duration of therapy. The current cumulative wisdom is that SCIT is somewhat more effective than SLIT, but that SLIT is somewhat safer and easier to administer than SCIT.[15,18–23]

Education of the patient and the patient's support system is essential.[7] All parties need to understand the potential seriousness of AR (including complications such as asthma) and the chronic, recurrent nature of AR. All should be told about the treatment options, including their relative advantages and disadvantages. Proper understanding and use of current medication in the patient's regimen should be assured. A better educated patient and support system will result in a better relationship with health care providers and hopefully will optimize patient outcomes.

### Pharmacologic Therapy

Guideline documents have been published on AR.[7–9,10,14] They provide some of the basis for the summary that follows.

---

### Table 63–3

**Allergen Avoidance Measures**

**Allergen avoidance underlies all other treatments of AR**

*There are several limitations to allergen avoidance:*

- Allergen(s) must be identified.
- Literature support for a clinically significant improvement in symptoms from allergen avoidance is meager.
- Quality of life may be negatively impacted by forced removal of a pet from the household.

*Outdoor plant pollen and mold/fungi parts:*

- Limit outdoor exposure, especially during high pollen conditions (warm sunny days with wind and low humidity) and during mold/fungi spore release (shortly after rains).
- Wear a face mask during activities that disturb soil and decaying vegetation.
- Keep windows and doors closed.
- Use air conditioning, but maintain clean equipment.

*Indoor allergens (house dust mite, mold/fungi, cockroaches, and pets):*

- Use air-conditioning, as above.
- Maintain humidity below 50%, and maintain clean equipment.
- Clean frequently to prevent mold growth (dilute bleach with detergent).
- Avoid exposed food and garbage to deter insects.
- Clean kitchen frequently.
- Use roach traps that facilitate their removal.
- Vacuum frequently, and use a high-efficiency particulate air (HEPA) (filter).
- Minimize carpeting, fabric-covered furniture, and fabric wall/window coverings.
- Cover bedding (pillows, mattresses, box springs) with allergen-proof, zippered cases.
- Launder bedding frequently, in hot water (> 130°F or 54°C) to kill mite ova.
- Consider acaricide (eg, benzyl benzoate) treatment of carpets to kill mites and ova.
- Put items that cannot be laundered (eg, soft toys) in a plastic bag and freeze.
- Keep pets out of bedroom and bathe cats weekly, if possible.

*Irritants:*

- Avoid, as possible, all exposure to smoke, chlorine fumes, formaldehyde fumes, and other substances identified as irritant triggers (eg, perfumes, newspaper ink).

From Refs. 7 and 8.

---

### Patient Encounter 1, Part 1

Evelyn M, a regular customer in your community pharmacy, asks your advice about helping her 8-year-old son, Aaron. He has a diagnosis of "mild" asthma that is primarily exercise induced. His symptoms are usually well controlled by prophylactic use of an albuterol metered-dose inhaler. Both of his parents told the doctor that they do not want Aaron to be treated with "steroids." However, a new issue is that in recent months, he has also had frequent trouble with runny nose, sneezing, and "throat" itching.

*What additional information should you get before making any suggestions?*

---

Although guideline documents are highly regarded by many, the patients enrolled in the randomized clinical trials that are a major basis for their conclusions and recommendations are not always representative of patients in a primary practice population.[24] Other sources provide additional information for the treatment of AR.[1,2,5,6,25–27] The recommended approaches begin with allergen avoidance, emphasize patient/family education and pharmacotherapy, and include immunotherapy as an option in selected patients.

**KEY CONCEPT** *Routine first-line agents for the treatment of AR are intranasal corticosteroids and oral (or possibly intranasal) antihistamines. Secondary agents, each of which may have a first-line role in selected patients, include oral (and rarely intranasal) decongestants, the intranasal mast cell stabilizer cromone (cromolyn), the oral leukotriene receptor antagonist (LTRA) (montelukast), the intranasal antimuscarinic (ipratropium), and intranasal saline irrigation.* In all cases, therapy must be individualized, in cooperation with the patient. Considerations include frequency and severity of specific symptoms, realistic avoidance measures, patient age, patient preferences for route of administration, tolerance of side effects, adherence issues, comorbid disorders, and concurrent therapy. See **Table 63–4** for intranasal and oral medications for the treatment of AR.

---

### Table 63–4

**Intranasal and Oral Medications for AR**

**Corticosteroids**
Intranasal[a] (budesonide, beclomethasone, ciclesonide, flunisolide, fluticasone furoate, mometasone, OTC: triamcinolone, fluticasone propionate)
Oral (rarely used)

**Antihistamines**
Intranasal[a] (azelastine, olopatadine)
Oral[b]

- First generation/sedating (cautious use in selected patients) (most OTC depending on strength: diphenhydramine, chlorpheniramine, clemastine, and others)
- Second generation/low- or nonsedating (desloratadine, levocetirizine; OTC: loratadine, cetirizine, fexofenadine)[a]

**Combination antihistamine/corticosteroid**
Intranasal (azelastine and fluticasone propionate)

**Mast cell stabilizer/cromone**
Intranasal (OTC: cromolyn)

**LTRA**
Oral (montelukast)

**Antimuscarinic**
Intranasal (ipratropium)

**Decongestant**
Intranasal (short-term use) (tetrahydrozoline; OTC: phenylephrine, naphazoline, oxymetazoline)
Oral[b] (OTC: phenylephrine; BTC[c]: pseudoephedrine)

[a]First-line choices.

[b]Some products combine an antihistamine with a decongestant, sometimes with other ingredients.

[c]Behind the counter (OTC plus other requirements necessary; see the Decongestants section of text).

From Refs. 2,5,7–10,12,25–27, and 29.

## Patient Encounter 1, Part 2

Additional history from both Evelyn and Aaron reveals the following information. Aaron does have eye symptoms, including bilateral itching, watering, and redness. He thinks all his nose and eye symptoms are worse in the spring when plants are blooming. Both Evelyn and her husband have "hay fever." Aaron's symptoms have occurred most days of the week for the last 6 to 8 weeks, but he does not think they are "bad or troublesome." He denies unilateral nasal symptoms, significant decreased smell, significant nasal congestion, cough, frequent nighttime awakenings, facial pain, and ear symptoms. Evelyn is not aware of significant changes in Aaron's school performance. The family does not have animal companions (pets). Aaron has not been given any medications for these new nasal symptoms.

You notice bilateral allergic shiners, and Aaron does rub his nose and sniffle frequently during your encounter. You are not able to examine his nasal mucosa or throat.

*Explain the reasons for how you would classify Aaron's presumed allergic rhinitis.*

*What recommendations would you make for initial management of Aaron's presumed AR?*

One publication includes an action plan for AR, similar to that used for asthma.[7] The entire article, with a sample Rhinitis Action Plan, is available for universal access on the following website: *http://www.aaaai.org/Aaaai/media/MediaLibrary/PDF%20Documents/Practice%20and%20Parameters/rhinitis2008-diagnosis-management.pdf*. Many patients will benefit from having an AR action plan.

### ▶ First-Line Agents

**Corticosteroids** Corticosteroids are usually administered by the intranasal route for the treatment of AR. Occasionally, a short course of oral therapy (burst and taper) is necessary. Oral corticosteroids are best applied to overcome severe nasal congestion, particularly that due to rhinitis medicamentosa (see the section on Decongestants). Parenteral administration of corticosteroids for AR is discouraged due to side effects.[5,7,10]

Intranasal corticosteroids (INCSs) provide very good relief for sneezing, itching, and rhinorrhea, and even nasal congestion and ocular symptoms. Nasal congestion is often the most bothersome symptom of AR, and the most difficult to control. This is probably because it results from inflammation that predominates in the late phase of the allergic response. KEY CONCEPT *Intranasal corticosteroids (INCSs) are the most effective therapy for AR, especially for nasal congestion. They are first-line agents for severe manifestations and are also used for those with moderate disease not controlled with oral and/or intranasal antihistamines. Their anti-inflammatory mechanism of action probably contributes to this superiority.*[5,6,12,25,27] The majority of contemporary literature suggests that INCSs are superior to intranasal antihistamines, to oral antihistamines even when combined with a leukotriene antagonist, and to a leukotriene antagonist alone.[5,12,25]

There are currently eight intranasal corticosteroid products available in the United States, including two different salt forms of fluticasone. Most (budesonide, ciclesonide, fluticasone furoate, mometasone, and triamcinolone) are used once daily.

However, fluticasone propionate may be given either once or twice daily; beclomethasone is usually given twice daily, and flunisolide is given two or three times daily. There is no good evidence that any single product is superior in efficacy. INCSs are best given regularly, as the onset of action usually takes up to 12 hours and the maximum effects may be delayed up to 14 days.[5,25,27] In some people the onset is within 3 to 4 hours, so these agents may even be used on an as needed basis.[7,28] When nasal congestion is severe, intranasal administration may not be effective due to limited exposure to the nasal mucosa. Short-term use of intranasal decongestants may facilitate better exposure. There have been some recent additions to the marketed ICNSs. Two agents are formulated as HFA metered-dose aerosols: beclomethasone (Qnasl) and ciclesonide (Zetonna).[27] They may be better tolerated. There is a fixed-dose intranasal combination of fluticasone propionate with azelastine (an antihistamine).[26,27] Two OTC products are now available.[29] See **Table 63–5** for intranasal corticosteroid products.

The correct technique for administration of intranasal medication is important for optimum efficacy. Consult the individual product labeling for specific instructions. Also see **Table 63–6** for general instructions for the optimal administration of intranasal solutions. The technique described maximizes exposure of the drug to the nasal mucosa to optimize efficacy and minimizes both exposure to the nasal septum and loss of medication down the esophagus.

Most patients tolerate intranasal corticosteroids very well. Local side effects include nasal burning, irritation, and dryness, which may occur in 2% to 10% of patients.[5,25,27] Also, 2% to 12% of patients may experience mild **epistaxis**.[5,25] This may be partly due to administration technique. Perforation of the nasal septum is very rare. This can be minimized by proper administration technique (see Table 63–6), specifically, directing the spray laterally and away from the (medial) nasal septum.[25,27]

The older intranasal corticosteroids (beclomethasone, flunisolide, and budesonide) have significant absorption, whereas, among the newer products, fluticasone and mometasone, have bioavailability of less than 2%.[25] The decreased absorption minimizes systemic side effects. However, there is still some concern for hypothalamic–pituitary–adrenal (HPA) axis suppression (growth suppression), osteoporosis, and ocular effects (glaucoma, cataracts).[5,25,27] There is no confirmation that intranasal corticosteroids *cause* posterior subcapsular cataracts, increased intraocular pressure, or decreased bone density; however, those with risk factors for these conditions should be monitored carefully for their development.[5,25,27] Ultimately, patient preference for a specific intranasal corticosteroid may be determined more by cost, availability, and formulation differences that affect odor and aftertaste.

**Antihistamines** Antihistamines used for AR treatment are administered by either the oral or the intranasal route. These agents interact with the $H_1$ (histamine type 1) receptor. They are technically inverse agonists, not competitive antagonists; however, there may be little clinical significance to the difference.[25] These drugs bind $H_1$ receptors, keeping them in the inactive state. This downregulation of $H_1$ receptor activity results in a decrease in end organ effects.

Activation of $H_1$ receptors in the nose, upper airway mucosa, and the eye produce the common manifestations of AR (sneezing, itching, rhinorrhea, nasal congestion, and ocular symptoms). The antihistamines are very effective for the sneezing, itching, and rhinorrhea. There is some improvement of nasal congestion, but less so than for the other symptoms. There is also

**Table 63–5**

**Intranasal Corticosteroids**

| Generic (Brand) Name | mcg/dose | Usual Adult Dosage (each nostril) | Usual Pediatric Dosage (each nostril) |
|---|---|---|---|
| Beclomethasone dipropionate (Beconase AQ) | 42 | 1–2 sprays twice daily | 6 yo or more: 1–2 sprays twice daily |
| Beclmethasone dipropionate (Qnasl [HFA MDP]) | 80 | 2 sprays once daily | 12 yo or more: 2 sprays once daily |
| Budesonide (Rhinocort Aqua) | 32 | 1–4 sprays once daily | 6–11 yo or more: 1–2 sprays once daily |
| Ciclesonide (Omnaris) | 50 | 2 sprays once daily | 6 yo or more: 2 sprays once daily (seasonal AR) 12 yo or more: 2 sprays once daily (perennial AR) |
| Ciclesonide (Zetonna [HFA MDP]) | 37 | 1 spray once daily | 12 yo or more: 1 spray once daily |
| Flunisolide | 25 | 2 sprays two or three times daily | 6–14 yo or more: 1 spray three times daily or 2 sprays twice daily |
| Fluticasone furoate (Veramyst) | 27.5 | 2 sprays once daily | 2–11 yo or more: 1–2 sprays once daily |
| Fluticasone propionate (Flonase)[a] | 50 | 1–2 sprays once daily or 1 spray twice daily | 4–11 yo or more: 1–2 sprays once daily |
| Mometasone (Nasonex) | 50 | 2 sprays once daily | 2–11 yo or more: 1 spray once daily 12 yo or more: 2 sprays once daily |
| Triamcinolone acetonide (Nasacort AQ)[a] | 55 | 2 sprays once daily | 2–5 yo: 1 spray once daily 6–12 yo: 1–2 sprays once daily |

mcg, micrograms; yo, years old; HFA, hydrofluoroalkane (propellant); MDP, metered-dose pump.

Note: All products are FDA Pregnancy category C except budesonide, which is B.

[a]available OTC.

**Table 63–6**

**Administration Instructions for Intranasal Solution Medications (Not HFA MDP Products)**

1. Clear the nose of mucus and debris.
2. Consult product labeling for preadministration instructions (eg, shaking the container, priming the spray pump).
3. Do not tilt head backward. This increases drug lost down the esophagus. This decreases efficacy and increases the potential for systemic absorption and thus systemic side effects.
4. Bend the head forward (flex the chin onto the chest) so that the nose is the lowest portion of the head. This is best for nasal sprays. If possible, lie down with the stomach on a flat surface or kneel down. Then, flex chin onto neck, so that the open nostrils are pointing upward, toward the ceiling. This position may be best for nose drops (more volume than sprays). An alternate position is to lie supine on a flat surface, then bend the neck backward (extend the head), so that the open nostrils point upward toward the ceiling.
5. Use the contralateral hand to insert the spray nozzle or dropper into one nostril (ie, the left hand for right nostril).
6. Use the other hand to occlude the opposite nostril (the one not being medicated).
7. Aim the spray or drops toward the outer (lateral) inside surface of each nostril and away from the nasal septum.
8. Breath in slowly but deeply through the medicated nostril.
9. Repeat this procedure to apply medication to the other nostril.
10. Consult the product labeling for instructions on cleaning the device.
11. See the text for information about preparation and use of saline irrigation.

HFA, hydrofluoroalkane (propellant); MDP, metered-dose pump.

From Refs. 2,6, and 8.

benefit for the ocular symptoms (eg, itching, redness, tearing). Intranasal administration is more effective than oral administration for the nasal congestion, but less effective for the ocular symptoms. The onset of action by oral administration is usually within 1 to 2 hours, and for intranasal administration within 15 minutes.[5,6,12,25,27] Antihistamines probably provide better relief when used continuously during symptomatic periods, but they are also effective used only when needed.

The oral agents are divided into first- and second-generation drugs. The first-generation agents are distributed among six chemical classes, including the more sedating ethanolamine class (eg, diphenhydramine) and the least sedating alkylamine class (eg, chlorpheniramine). Most sources now discourage the routine use of the first-generation agents for AR. This is due to their CNS and antimuscarinic side effects. The CNS effects are primarily sedation and impairment of cognitive function and performance of tasks. Decision making and driving or work performance are impaired even when the patient is unaware of any overt effects.[7,25] There is also evidence of decreased performance at school and impaired learning among pediatric patients.[7,25] The major antimuscarinic effects include blurred vision, dry mouth, urinary retention, and constipation. The only possible advantage of the antimuscarinic properties is an additional effect to decrease rhinorrhea. Another disadvantage of the first-generation antihistamines is that most are administered three to four times daily. Patients who take other sedative substances may have an additive effect from the antihistamine. Those taking any other medications with antimuscarinic properties may experience additive effects from the antihistamine. The elderly are, in general, more sensitive to both types of adverse effects.

Currently available oral second-generation $H_1$ antihistamines are cetirizine, levocetirizine, loratadine, desloratadine,

fexofenadine, and acrivastine. All except acrivastine are available as a single agent, and some are marketed in combination with the decongestant pseudoephedrine. As of August, 2014, cetirizine, loratadine, and fexofenadine are available OTC. The second-generation antihistamines have less antimuscarinic activity than the first-generation agents. Based on current literature, no single $H_1$ antihistamine (first or second generation) is clearly superior in efficacy; however, very few head-to-head comparative studies have been conducted. Individual variation is likely, and patients may need to try more than one product to realize optimal benefit. The oral second-generation antihistamines are effective for the sneezing, itching, and rhinorrhea of AR, but less effective for the nasal congestion. They also improve ocular symptoms. Intranasal antihistamines are somewhat better for nasal congestion.

Fexofenadine has virtually no sedative effects, even at doses higher than recommended. Loratadine and desloratadine are not sedative at recommended doses but can be at higher doses. Cetirizine, levocetirizine, and acrivastine have some sedative effects, even at recommended doses. All the oral second-generation agents require some dosage reduction with impaired renal function, but specific recommendations vary with creatinine clearance.[30,31] Most of the oral second-generation antihistamines can be administered once daily (except for the lower dosage forms of fexofenadine and the acrivastine combination product).

There are only two intranasal antihistamine products available in the US market as of August, 2014. Both azelastine and olopatadine are considered second-generation agents, although they also have anti-inflammatory effects.[25] Both are available only by prescription. The most common side effect of these products is a bitter taste. This is more common with the original formulation of azelastine (Astelin) and less common with olopatadine.[7,25,26] A newer formulation of azelastine (Astepro) has less bitter taste.[26] Also, there is enough systemic absorption to cause sedation in some patients using azelastine (about 10%) and perhaps somewhat fewer on olopatadine.[7,25] See Table 63–7 for the single-agent second-generation antihistamine products.

**KEY CONCEPT** *Second-generation antihistamines are first-line agents, and are often effective alone, especially for mild or intermittent AR. They are preferred over first-generation antihistamines because of fewer side effects. Although effective for most symptoms of AR, they are less effective than intranasal corticosteroids for nasal congestion. Intranasal administration is more effective than oral administration for nasal congestion.* Most patients can use oral second-generation products. Others may prefer the intranasal route of administration, but they require a prescription. If nasal congestion is not relieved, addition of a decongestant is reasonable, either alone or as a combination product (see Decongestant section). Perhaps even the combination of an oral with an intranasal antihistamine is reasonable for some patients, depending on their preferences. Other pharmacologic agents can be combined with oral and/or intranasal antihistamines, as necessary for optimal control of symptoms. The new intranasal combination product of azelastine and fluticasone (Dymista) may be appropriate for some patients.

▶ *Adjunctive or Secondary Choice Agents*

**Decongestants** Decongestant drugs are useful only for nasal congestion.[7–9,25] This results from their $\alpha_1$-adrenergic agonist

### Table 63–7

**Single-Agent Second-Generation Antihistamine Products (Oral and Intranasal)**

**Oral**

| Generic (Brand) Name | Formulation | Usual Adult Dosage | Usual Pediatric Dosage |
|---|---|---|---|
| Cetirizine[a,b] (Zyrtec, generic) | 5, 10 mg tablets/chewable tablets; capsule 5 mg/5 mL syrup | 5–10 mg once daily | 6–11 mo; 2.5 mg once daily<br>12–23 mo; 2.5 mg once or twice daily<br>2–5 yo; 2.5–5 mg once daily or 2.5 mg twice daily |

| Fexofenadine[a,b] (Allegra, generic) | 30, 60, 180 mg tablets, 6 mg/mL suspension<br>30 mg orally disintegrating tablets | 60 mg twice daily or 180 mg once daily | 2–11 yo; 30 mg twice daily |
| Levocetirizine (Xyzal) | 5 mg tablets<br>2.5 mg/5 mL solution | 5 mg once daily | 6 mo–5 yo; 1.25 mg once daily<br>6–11 yo; 2.5 mg once daily |
| Loratadine[a,b] (Claritin; Alavert, generic) | 10 mg tablets and cap; 5 mg/5 mL syrup and susp; 10 mg disintegrating tablets; 5 mg chewable tablet | 10 mg once daily | 2–5 yo; 5 mg once daily |

**Intranasal Spray**

| Generic (Brand) Name | mcg/spray | Usual Adult Dosage (each nostril) | Usual Pediatric Dosage (each nostril) |
|---|---|---|---|
| Azelastine (Astelin, Astepro) | 137 | 1–2 sprays twice daily | 5–11 yo; 1 spray twice daily |
| Olopatadine (Patanase) | 665 | 2 sprays twice daily | 6–11 yo: 1 spray twice daily |

Note: Acrivastine is available only with pseudoephedrine and so is not included in this table.

mo, months old; yo, years old.

[a]Available OTC.

[b]Available in combination with pseudoephedrine (consult labeling for pediatric dosage).

From Refs. 25 and 27.

**Patient Encounter 1, Part 3**

About 6 months later, Aaron and his mother Evelyn come back to speak with you. Aaron tried using saline irrigations but he did not like the "messiness" it created, so he stopped them. He tried cetirizine but it made him sleepy during the day. Loratadine and fexofenadine just did not seem to work well. His parents still object to trying INCSs, despite your explanation. Montelukast seemed to help the AR symptoms, and even the exercise induced asthma to some extent. However, Aaron's doctor became concerned when Aaron complained of increased sleep disturbance while taking montelukast. The doctor wanted it stopped for what he called "safety" reasons. Ophthalmic ketotifen does help the ocular symptoms, but not the nasal symptoms, which he thinks are actually becoming more frequent and bothersome. They ask your advice.

*What suggestions would you offer for control of Aaron's symptoms, now?*

activity, which causes vasoconstriction in the nasal mucosa. They provide no benefit for the sneezing, itching, rhinorrhea, or the ocular manifestations. Decongestants can be given alone, either by the oral or by the intranasal route. Also, numerous combination products are available, consisting of a decongestant with an antihistamine (and sometimes other ingredients). There are some special considerations for use of decongestants in pediatric and pregnant patients (see the Special Populations section).

Oral decongestant products are currently limited to pseudoephedrine and phenylephrine.[5,25,27] Pseudoephedrine has been changed from truly OTC to a more controlled "behind the counter" (BTC) status because it is an ingredient in the illicit manufacture of methamphetamine. Some manufacturers changed the ingredients of their products by replacing pseudoephedrine with phenylephrine to maintain shelf presence in the OTC area. However, much controversy surrounds the efficacy of oral phenylephrine. Most contemporary literature suggests that the currently recommended adult dose is minimally effective as a nasal decongestant.[5,25,27]

The side effects of orally administered decongestants most often affect cardiovascular function or the CNS. The side effects are primarily due to sympathetic stimulation and are usually dose related. Some elevation of blood pressure may occur, but in normotensive and well-controlled hypertensive patients, the elevation is usually small. It is not of clinical significance in most situations, especially considering that these drugs are most appropriately used only briefly or intermittently. Insomnia, nervousness, irritability, and anxiety are relatively common CNS side effects. Some patients may have decreased appetite, tremors, headache, and even hallucinations. Men with benign prostatic hyperplasia (BPH) and other patients with disorders causing bladder outlet obstruction may have increased urinary retention due to $\alpha_1$ stimulation of the urethral sphincter.

The intranasal agents currently available include the OTC products phenylephrine, oxymetazoline, and naphazoline. Intranasal application of decongestants provides rapid and effective relief of nasal congestion. This therapy may provide relief for nasal congestion, even for those patients already on intranasal corticosteroids.[25,27] However, the continuous use of intranasal decongestants often causes a paradoxical rebound phenomenon of persistent nasal congestion, called rhinitis medicamentosa.[5,25,27] Although some patients do not develop rhinitis medicamentosa,

even after several weeks of continuous use of intranasal decongestants, the usual recommendation is to use them for no more than 3 consecutive days.[7] Intranasal decongestants can cause local side effects, including stinging, burning, dryness, and even sneezing. These are usually mild and well tolerated. Due to very limited absorption, the intranasal route rarely causes systemic side effects.[5,7] Administration technique should be optimized as described in Table 63–6. Should rhinitis medicamentosa occur, the best management is first to discontinue the decongestant, possibly with a taper to minimize worsening the situation. However, the response to withdrawal is often delayed for days. Therefore, it may be necessary to start intranasal corticosteroids and/or begin a short course of oral corticosteroid.[32]

**KEY CONCEPT** *The best applications of decongestants in AR are short-term use to overcome severe nasal congestion and to facilitate improved efficacy of other intranasal agents. The intranasal administration of decongestants should usually not exceed 3 consecutive days.* Despite the usual good tolerance of recommended doses of oral decongestants, caution is warranted when they are used in patients with cardiac disease (dysrhythmias, angina pectoris, heart failure), hypertension, cerebrovascular disease, bladder outlet obstruction (including BPH), glaucoma (especially closed angle), hyperthyroidism, and possibly diabetes.[5,25,27] The choice between the two routes of administration is based on several considerations, including cost, convenience, patient preference, speed of onset (within 30 minutes orally, within 5 to 10 minutes intranasally), and side effects.[7,12]

**Mast Cell Stabilizer/Cromone**[5–7,12,25,27] Cromolyn is the only cromone that is approved in the United States for treatment of AR. It is available as an OTC intranasal product. The mechanism of action in AR is mast cell stabilization. The drug binds to mast cells and prevents release of the mediators of AR that would otherwise result from allergen exposure. The drug is moderately effective, but less so than both intranasal corticosteroids and oral or intranasal antihistamines. It does have effects on both early and late phases of AR. Its effects begin within 4 to 7 days of use but may not be maximal for up to 2 weeks.[7] However, it can be used effectively on an as needed basis for episodic exposures to allergen.[7,27] Cromolyn is very well tolerated. The most common side effects are mild local stinging and/or burning, sneezing, unpleasant taste, and possibly nose bleed. A disadvantage is the frequency of administration. At least initially, it should be used four times daily. Some patients may need only two or three daily doses when used continuously after the first few weeks at four times daily. It is most useful for patients with mild or intermittent symptoms, especially in the pediatric population and in pregnant women.

**Leukotriene Receptor Antagonist (LTRA)** Leukotrienes are involved in the pathophysiology of AR and in particular contribute to the nasal congestion in the late phase.[1,5,7–9,12,13] There is some difference of opinion about benefits of LTRAs. Most sources indicate good benefit for nasal congestion and rhinorrhea, some benefit for ocular symptoms, but less for nasal itch and sneezing compared to INCSs and antihistamines.[5,6,25,27] Montelukast is the only LTRA approved for treatment of AR. It is marketed as oral granules and as both chewable and regular tablets. The combination of montelukast with an oral antihistamine shows improved efficacy over either agent alone, according to some sources, however, even the combination is probably not better than intranasal corticosteroids.[5,25] The onset of action of montelukast is delayed for a day or more.[7] The drug is usually considered to be very well tolerated. However, there are case reports of neuropsychiatric events, including sleep disturbances, depression and suicidal ideation, as

well as headache, GI disturbances, skin rash, and Churg-Strauss syndrome.[12,25,27] It is administered once daily, considered safe (FDA Pregnancy Category B and indicated for children as young as 6 months of age), and particularly well suited to those patients who also have asthma. It may have some benefit in vasomotor (idiopathic, autonomic) rhinitis.[4]

**Antimuscarinic Agent**[5,7,12,25,27] Ipratropium is currently the only antimuscarinic agent indicated for treatment of AR. Systemic absorption is minimal. It is available by prescription as an intranasal spray. Its use is limited to those patients whose rhinorrhea has not been controlled by other therapy (antihistamines and/or INCSs). There are two strengths available. The 0.03% product is approved for AR in children as young as 6 years of age. This agent may be particularly helpful for patients who have vasomotor (idiopathic, autonomic) rhinitis, or those who may have a mixed etiology.[5,25] Local side effects are usually limited to nasal and oral dryness, throat irritation, and mild epistaxis.[27]

**Saline** Nasal administration of saline is an alternative for treatment of AR.[5,7,25,33,34] This therapy may benefit any patient with rhinitis, including those with vasomotor rhinitis.[5] Saline may be administered as drops or a spray, but the irrigation mode of administration is popularly known by several terms, including neti pot, nasal wash, nasal douche, nose bidet, and as nasal irrigation. Although less effective than intranasal corticosteroids, it has been shown to improve sneezing and nasal congestion. It can be used either alone or as add-on therapy. The formula provided by the American Academy of Allergy, Asthma and Immunology (AAAAI) should be followed for those making their own saline nasal irrigation solution.[34] Iodized salt is not recommended as it may be irritating. Hypertonic saline seems to have no advantage over 0.9% sodium chloride. Administration can be accomplished while the patient is in the shower or leaning over a sink. The head is bent forward and downward, then tilted to the side opposite the treated nostril. Then, with a bulb syringe or similar device, slowly introduce about 4 oz (118 mL) of the warm saline solution into one nostril. Soon, the solution will run out of the opposite nostril. The position of the head should be adjusted as necessary to avoid the solution running into the ears or down the throat.

Nasal irrigation is one delivery method, although the optimal method (spray, drops, nebulizer, or irrigation) is not known. Optimal frequency of administration is also not known. Nasal irrigation is usually given twice daily, but use of smaller volumes as spray products may be given up to four times daily. Side effects are usually limited to minor local nasal irritation, but nausea has been reported.

**Omalizumab**[7,25,35] Omalizumab is a monoclonal antibody that binds to IgE. The product is approved for asthma, but not for AR as of August, 2014. It is administered by subcutaneous injection. Dosage is determined by the patient's circulating IgE levels. The cost is high compared with that of other modes of therapy. Investigational use has demonstrated efficacy in AR, although relative efficacy is unknown. Its use is best limited to those with concurrent asthma and AR.

**Complementary and Alternative Medicine Therapy** Complementary and alternative therapy for AR has been reviewed.[25,36] Consistent evidence for efficacy has not been established, and there are some safety concerns.

▶ *Special Populations*

**Children** KEY CONCEPT *Generally speaking, the treatment of AR in children is the same as it is for adults. There are, however, limitations in terms of FDA-approved products for different age groups.*

---

**Patient Encounter 2, Part 1**

Mrs. AL presents to your place of work to ask some questions. She is 32 years old, married, with no children. She does not work, but volunteers at several nonprofit organizations. This occupies several hours of her day, 4 days each week. Her husband works full time for a landscaping business. Her only chronic illness is allergic rhinitis that is caused by what her doctor calls "bad pollen allergies." She complains of "attacks" of repeated sneezing; copious watery runny nose; itchy nose and throat; often accompanied by itchy, watery eyes. Her only medications are Dymista (combination azelastine/fluticasone propionate) intranasal spray and oral fexofenadine 180 mg once daily. The dosage of Dymista is supposed to be one spray into each nostril twice daily. However, since starting it about 3 months ago, she has figured out that it makes her sleepy. She often skips the morning dose, especially, if she is volunteering that day.

*What additional information do you need to better evaluate Mrs AL's problem?*

*What preliminary suggestions would you make?*

---

*Also, depending on the age of the patient, there may be administration issues with some products.* Most children affected by AR are older than 2 years, because usually, several years of antigen exposure is required to establish sensitization.[11] Children who have rhinitis before the age of 2 should be evaluated for other etiologies.[7,25]

There has been concern about use of combination cough and cold products (many contain an antihistamine and a decongestant) in children due to side effects. Most negative outcomes have resulted from inadvertent overdosage, often by giving the same drug from more than one product concurrently. These products are discouraged in children younger than 4 years.[37]

First-generation $H_1$ antihistamines are discouraged for children as they are for adults, due to the possible detrimental effects on school performance and learning. They may also cause paradoxical CNS stimulation in the very young (< 2 years old).[25] Second-generation (less sedating) $H_1$ antihistamines (primarily for mild or intermittent symptoms) or intranasal corticosteroids (for moderate–severe or persistent manifestations) are first-line modes of therapy. Antihistamines may need to be used even for more severe and/or persistent symptoms in those children who have difficulty with use of intranasal products. If necessary, these two classes can be combined.

See Table 63–7 for dosages of second-generation antihistamines by age groups for which they are indicated. Special care should be given to avoid administration of the same medication from different (especially combination) products. The side effects of second-generation antihistamines in children are similar to those for adults.

See Table 63–5 for dosages of intranasal corticosteroids by age groups. The consensus of opinion about intranasal corticosteroids and systemic side effects, especially delay in growth, is that most products are safe. Three INCSs, mometasone, fluticasone furoate, and triamcinolone, are FDA approved for children as young as 2 years of age.[25,27]. The local side effects of intranasal corticosteroids are the same in children as for adults.

Other therapy options may be worth consideration for some pediatric patients. Montelukast provides an oral alternative, especially for those who are too young to cooperate with

intranasal administration of corticosteroids.[14] It may be used in combination with an oral antihistamine for additional efficacy. Another option for mild or intermittent symptoms is intranasal cromolyn, primarily due to its excellent safety.[25] This OTC product is labeled for use in children 2 years of age and older.[27] Intranasal ipratropium is indicated for patients 6 years of age or older and may benefit unresponsive rhinorrhea.

**Pregnant Women**[5,38]  Women who have AR may suffer an exacerbation of symptoms during pregnancy.[38] However, only minor changes in the routine approach to therapy are necessary as a result of the pregnancy. Nasal saline irrigations are safe, effective, and improve the response to most other modes of therapy. They can be the foundation of AR therapy for pregnant patients.[5,38] Physical exercise increases vasoconstriction of the nasal mucosa, decreasing congestion, and rhinorrhea.[38] External adhesive strips can be used to help keep the nares open, especially during sleep.[38] Second-generation antihistamines are generally considered safe, based on an increasing number of studies and experience.[5,38] The same generalization applies to intranasal corticosteroids. While budesonide is the only product which is FDA pregnancy category B, no evidence exists of fetal harm from either INCSs or inhaled corticosteroids used for asthma.[39] Cromolyn is also FDA Pregnancy Category B and is considered safe.[38] The disadvantages are frequent administration and less efficacy than antihistamines and INCSs. Montelukast is also FDA Pregnancy Category B, but some recommend it primarily in those with concurrent asthma or who have demonstrated a good response prior to pregnancy.[7] Ipratropium is FDA Pregnancy Category B and is useful for troublesome rhinorrhea.[14] Oral decongestants are best avoided, especially in the first trimester. If nasal congestion is severe enough to warrant a decongestant, the intranasal route of administration is preferable, due to decreased systemic exposure.[7,38] Limiting the duration of use to 2 to 3 days is wise.[7,38]

**Breast-Feeding Women**  One source has information about the relative safety of AR medication use in breast-feeding women.[40] Budesonide is probably the safest INCS and loratadine is probably the safest antihistamine. Intranasal cromolyn is also considered safe. Nasal saline irrigation could also be considered as a safe alternative in breast-feeding women.

**Elderly**  AR in elderly patients is treated generally as it is in younger adults. Therefore, first-line agents are primarily INCSs and second-generation oral or possibly intranasal antihistamines.[5,7,25] Older patients may also have a component of atrophy of nasal tissues that can result in more nasal congestion. Most will benefit from regular nasal saline irrigation.[5] The elderly are more sensitive to the sedative and antimuscarinic effects of (especially first-generation) antihistamines and to the cardiovascular and CNS-stimulant effects of decongestants. These drugs should be used cautiously if at all. An increase in cholinergic activity may result in more rhinorrhea. This may respond well to ipratropium.

▶ *Ocular Symptoms*[5,27,41,42]

Several products are available for instillation directly into the eyes for those patients with predominant or unresponsive ocular manifestations. They may be appropriate for occasional moderate–severe flares or episodic AR when other modes of therapy are not optimally effective. The combination (antihistamine and mast cell stabilizing) agents may be the most effective, and they have the advantages of rapid onset of action and (usually) only twice daily administration. Ketotifen is in this category and because it is available OTC, it can be an appropriate initial agent. See **Table 63–8** for these products.

### Summary of Treatment

Once an agent appropriate for initial therapy is chosen, ongoing management requires repeated checks to ascertain response and freedom from intolerable or adherence limiting side effects. Either "step-up" or "step-down" therapy may be appropriate, depending on individual response. See **Table 63–9** for a summary of the approach to treatment of AR. **Table 63–10** attempts

| Table 63–8 | | | | |
|---|---|---|---|---|
| **Intraocular Medications** | | | | |
| **Category** | **Generic (Brand) Name** | **Formulation** | **Frequency** | **Age** |
| Decongestant/vasoconstrictor | Naphazoline[a] (Naphcon, Privine, others) | 0.012% + 0.025% | Four times daily | Adult |
| Decongestant/vasoconstrictor + antihistamine | Naphazoline + pheniramine[a] (Visine A) | 0.025%/0.3% | Four times daily | 6 yo or more |
| Antihistamine | Emedastine (Emadine) | 0.05% | Four times daily | 3 yo or more |
| | Alcaftadine (Lastacaft) | 0.25% | Once daily | 2 yo or more |
| Mast cell stabilizer | Cromolyn (Generic) | 4% | Every 4–6 hours | 4 yo or more |
| | Lodoxamide (Alomide) | 0.1% | Four times daily | 2 yo or more |
| | Nedocromil (Alocril) | 2% | Twice daily | 3 yo or more |
| | Pemirolast (Alamast) | 0.1% | Four times daily | 3 yo or more |
| Antihistamine + mast cell stabilizer | Azelastine (Optivar) | 0.05% | Twice daily | 3 yo or more |
| | Epinastine (Elestat) | 0.05% | Twice daily | 2 yo or more |
| | Ketotifen[a] (Zaditor, Alaway, Claritin, Zyrtec, generic) | 0.025% | Every 8–12 hours | 3 yo or more |
| | Olopatadine (Patanol/Pataday) | 0.1%/0.2% | Twice daily/once daily | 3 yo or more |
| | Bepotastine (Bepreve) | 1.5% | Twice daily | 2 yo or more |
| NSAIDs | Ketorolac (Acular) | 0.5% | Four times daily | 3 yo or more |
| Corticosteroid | Loteprednol (Alrex) | 0.2% | Four times daily | Adult |

NSAID, nonsteroidal anti-inflammatory drug; yo, years old.

[a]Available OTC.

From Refs. 7,27,40, and 41.

Also, see Chapter 62, Ophthalmic Disorders for more details.

## Table 63–9

**Routine Approach to Therapy of AR**

All patients should practice avoidance of identified allergens

**Mild intermittent**
  *First line*:
    Oral antihistamine (OTC, initially; preferably second generation)
  *Adjunctive/secondary (may use more than one; no specific order intended)*:
    Add nasal saline (eg, as irrigation)
    Consider intranasal cromolyn, especially preexposure for episodic AR
    Consider OTC INCS for refractory symptoms
    Consider intraocular medications, as needed for ocular symptoms (See Table 63–8)
    Consider OTC oral decongestant for nasal congestion
    Consider OTC intranasal decongestant for refractory nasal congestion (not > 3 days)
    Consider prescription therapy for inadequate response (see below)
  *Possibly consider referral for immunotherapy*

**Persistent or moderate–severe**
  *First line*:
    Intranasal corticosteroid (could try OTC product first)
    Add oral antihistamine for possible additional benefit if necessary
  *Adjunctive/secondary (may use more than one)*:
    Add nasal saline (eg, as irrigation)
    Consider intraocular medications, as needed for ocular symptoms (See Table 63–8)
    Consider OTC oral decongestant for nasal congestion
    Consider short-term intranasal decongestant for refractory nasal congestion
    Consider replacement of one first-line agent, if poorly tolerated, with montelukast
    Consider ipratropium for inadequately controlled rhinorrhea
    Consider intranasal antihistamine
    Consider combination intranasal antihistamine with corticosteroid
  *Consider referral for immunotherapy*

**Episodic** (no order of preference intended)
    Oral antihistamine (OTC, initially; preferably second generation)
    Consider addition of or replacement with intranasal cromolyn (OTC) or intranasal antihistamine or intranasal corticosteroid

**Special situations** (children, pregnant women, elderly, ocular symptoms)
    See Special Populations section of text

From Refs. 2,5–10,12,14,25,29,33, and 34.

## Table 63–10

**Relative Efficacy (Semiquantitative) by Classes of Agents for Specific Symptoms of Allergic Rhinitis**

| Drug Class | Nasal Congestion | Sneezing | Rhinorrhea | Nasal Itch | Ocular Symptoms |
|---|---|---|---|---|---|
| Intranasal corticosteroids | 6 | 6 | 6 | 5 | 4 |
| Oral antihistamines[a] | 2 | 4 | 4 | 6 | 4 |
| Intranasal antihistamines | 3 | 4 | 4 | 5 | 0 |
| Oral decongestants[a] | 3 | 0 | 0 | 0 | 0 |
| Intranasal decongestants[a,b] | 6 | 0 | 0 | 0 | 0 |
| Oral leukotriene antagonist | 4 | 1 | 4 | 1 | 4 |
| Intranasal mast cell stabilizer[a] | 3 | 3 | 3 | 3 | 2 |
| Intranasal antimuscarinic | 0 | 0 | 5 | 0 | 0 |

Note: The information in this table is a composite from numerous sources. There are different opinions about some of the rankings, partly due to inadequate study. Individual variation may create different relative efficacy in some patients. Higher number equals greater activity.

[a]Some products in these classes are available OTC.

[b]Intranasal decongestants are best used for severe, unresponsive nasal congestion, or to facilitate mucosal contact of other intranasal medications, but in either case, should usually be limited to no more than 3 days.

From Refs. 2,5–10,12,14,25,29,33, and 34.

## Patient Encounter 2, Part 2

Mrs. AL returns in 2 weeks. She took your advice. She continued the fexofenadine. She replaced Dymista with OTC triamcinolone intranasal spray. And, she tried saline nasal irrigations. Formal allergy skin testing done by her doctor showed that she is allergic to "… just about every tree and flower that blossoms…" in this area! However, she is not allergic to animals, molds, fungi, house dust mite, or cockroaches! Her doctor made some suggestions for allergen avoidance, mostly to stay indoors, keep doors and windows closed, and use an air conditioner. She has noticed some improvement with the new regimen. She does not feel quite as sleepy, having stopped the Dymista. She thinks both the saline irrigations and the triamcinolone help. However, she still has significant symptoms while in her house, during the evening and often during the night.

Additional information gathered at this visit follows.

She is unaware of her family history. They have lived in the same city for more than 15 years. She moved to another part of town when she got married six years ago. Her current home has some plants in the yard, but her husband does all the yard upkeep. Her AR symptoms started as a child, but seem quite a bit worse in the last 5 years or so. She is not exposed to animal dander. She does not think her home is a source of mold or cockroaches. She does have symptoms during the night (while in her bedroom), but she also has symptoms in every other room of the house (see below).

She admits to some nasal congestion and mouth breathing especially at night. Other symptoms include some difficulty sleeping due to "attacks" in the evenings and even during the night. Overall, she considers her symptoms, troublesome. She has AR symptoms virtually every day even with her current regimen. Therefore, she probably has ARIA category moderate-severe persistent AR.

She thinks that her symptoms are worse when she is home and better when she is at the nonprofit organizations where she volunteers at least half a day, 4 days each week.

Before the allergy testing was done, she did not know what specific pollens she was allergic to. She had noticed more frequent and severe symptoms when plants are blooming. Now she knows what she is allergic to (see above). Curiously, however, she has symptoms both indoors and outdoors.

She tried Benadryl several years ago. It made her sleepy and caused dry mouth, so she gave up.

She has an IUD in place. It is called Mirena, which is replaced every 5 years. A new one (her third) was placed about 1 year ago. Since having this IUD, she notices that her menses are a bit lighter, although she is very regular. Her last menses started 7 days ago, and lasted the usual 2 days. She also has fewer problems with cramping. She and her husband have no plans to have children at this time.

*Explain the rationale for your plan at this time.*

## Patient Encounter 2, Part 3

After the second visit with Mrs. AL (Patient encounter 2, part 2), you had an uneasy feeling. Later that evening, you began to wonder about some of the elements in her story. You formulate a theory about the source of her symptoms, and plan to phone Mrs. AL to ask more specific information. If your

theory is correct, you may be able to significantly improve her symptom control.

*What is the theory about Mrs. AL's symptoms?*

*Presuming the theory is correct, what specific plan could be suggested?*

## Patient Encounter 3, Part 1

EM presents to your place of business to ask your advice about his "nose and eye" symptoms. EM is a 50-year-old man, who works as a tax accountant. About 25 years ago, he moved from New England to the Southwest, for employment reasons. The environment was much warmer than he was used to, but like the local people said, it was "…a dry heat!" Within a few months of the move, he began having problems with watery, sometimes profuse runny nose. At that time, the only other symptom he had was a decrease in his sense of smell.

He thought he had allergies to the new plants in the area, but the doctor he saw said that by examination his nose, throat, and ears looked normal. The doc called it "non-allergic rhinitis." He was given a prescription for intranasal flunisolide spray and told to use it three times a day. Over the years, it seemed

to work sometimes, but not always. And, he always had problems remembering to use it regularly. He added an OTC oral antihistamine years ago, but it did not help much, and it caused so much sleepiness that he couldn't work. He stopped it, and just continued irregular use of the flunisolide.

More recently, in the last year, he notices even more symptoms, including some sneezing, some nasal itch, and some eye symptoms (redness, wateriness, and itchiness). EM denies all other chronic illnesses and he takes no other medications on a regular basis. He asks your advice for treatment options for his current symptoms.

*How would you characterize EM's problem?*

*What are your recommendations for his therapy?*

## Patient Encounter 3, Part 2

EM returns 2 weeks later. He took most of your advice. He tried saline irrigations, but found them difficult to do twice every day. He switched from intranasal flunisolide to triamcinolone, which was easier to use and more effective. He tried oral cetirizine, but it seemed to make him tired, so he stopped. The major remaining problems are relatively persistent, and sometimes profuse, watery nasal discharge and itchy eyes.

*What additional advice can you suggest?*

to rank the relative effectiveness of the classes of agents for treatment of AR by specific symptoms.

## OUTCOME EVALUATION

- Confirm the patient's understanding of the disorder (see Clinical Presentation and Diagnosis).
- Confirm the patient's understanding about allergen avoidance measures (see Table 63–3).

- Assess the patient's symptom response, tolerance, and adherence.
- Assess the patient's administration technique with intranasal products.
- Recommend second-generation oral antihistamine therapy for most patients with mild or intermittent symptoms (see Clinical Presentation and Diagnosis and Table 63–9).
- Recommend intranasal corticosteroid therapy for moderate–severe or persistent symptoms (two products are OTC). Suggest additional therapy for those with incomplete control (see Clinical Presentation and Diagnosis and Table 63–9).
- Consider step-up therapy for exacerbations or incomplete response.
- Consider step-down therapy if symptoms are minimal or stable for several months.
- Consider referral to rule out nonallergic causes of rhinitis in nonresponding patients or those with an atypical presentation (see Clinical Presentation and Diagnosis).
- Consider referral for patients who request immunotherapy.
- Consider referral for patients with comorbid conditions, especially asthma.

## Patient Care Process

### Patient Assessment:

- Determine that the patient probably does not have a nonallergic type of rhinitis (see Table 63–1)
- Determine extent and severity of patient's signs and symptoms of AR. This should be done by combination of History of Present Illness (HPI), Past Medical history (PMHx) and appropriate physical assessment
- Assessment of HPI includes seven elements, using eg, the acronym LOQQSAM (location; onset; quality; quantity; setting; associated symptoms; modifying factors) (see Clinical Presentation and Diagnosis box)
- Appropriate PMHx should include conditions associated with AR and its complications (see Epidemiology section)
- Appropriate physical assessment is usually limited to observation of the patient, and sometimes examination of the nasal mucosa and oropharynx (see Clinical Presentation and Diagnosis box)
- This assessment should be expressed in terms of the frequency and severity of AR, as defined by the ARIA system (see Table 63–2)

### Therapy Evaluation:

- Determine the patient's understanding of the nature of AR.
- Determine what modes of therapy the patient has already tried (allergen avoidance, pharmacotherapy, immunotherapy).
- Assess the appropriateness of current therapy, relative to the clinical response.

- If the clinical response is inadequate or suboptimal, determine first, if poor adherence and/or administration technique (ie, with intranasal agents) are involved. See Table 63–6.
- If nonadherence and poor technique do not explain a suboptimal response, consider alternative therapeutic modes. See Table 63–9.
- If specific patient features exist (female who is currently or may become pregnant, woman who is breast-feeding, child, or elderly), see Selected Populations section.

### Care Plan Development:

- Advise allergen avoidance to the degree possible. See Table 63–3.
- Educate and counsel about optimal administration technique and adherence.
- Base subsequent, specific recommendations for therapy on symptom pattern (nasal congestion, rhinorrhea, ocular manifestations, concurrent asthma), previous response to therapy and availability (OTC, Rx, referral).

### Follow-up Evaluation:

- Follow up weekly at first, especially during worse times or seasons.
- When optimal control is approached, increase duration between follow-up visits (eg, monthly, every 2–3 months, or less frequently).

# Abbreviations Introduced in This Chapter

| | |
|---|---|
| AAAAI | American Academy of Allergy, Asthma, and Immunology |
| ACEI | Angiotensin-converting enzyme inhibitor |
| AERD | Aspirin-exacerbated respiratory disease |
| AR | Allergic rhinitis |
| ARIA | Allergic Rhinitis and its Impact on Asthma |
| BPH | Benign prostatic hyperplasia/hypertrophy |
| BTC | Behind-the-counter |
| $H_1$ | Histamine type 1 (receptor) |
| HEPA | High-efficiency particulate air (filter) |
| HFA | Hydrofluoroalkane ("green" propellant for metered-dose INCSs) |
| HPA | Hypothalamic–pituitary–adrenal (axis) |
| HPI | History of Present Illness |
| HT | (essential or primary) hypertension |
| IAR | Intermittent allergic rhinitis (ARIA system) |
| IgE | Immunoglobulin E |
| INCS(s) | Intranasal corticosteroid(s) |
| LTRA | Leukotriene receptor antagonist |
| NARES | Nonallergic rhinitis with eosinophilia (on nasal smear) syndrome |
| NSAID | Nonsteroidal anti-inflammatory drug |
| OTC | Over-the-counter |
| PAR | Perennial allergic rhinitis (AAAAI/ACAAI system) |
| PDE-5 | Phosphodiesterase (isoenzyme)-5 |
| PER | Persistent allergic rhinitis (ARIA system) |
| PMHx | Past Medical history |
| QT | Interval between the Q and T waves in an ECG |
| SAR | Seasonal allergic rhinitis (AAAAI/ACAAI system) |

# 64 Psoriasis

Miriam Ansong, Samson Amos, and Victor Padron

---

## LEARNING OBJECTIVES

● **Upon completion of this chapter, the reader will be able to:**

1. Discuss the etiology and risk factors of psoriasis.
2. Describe the pathophysiology and clinical presentations of psoriasis.
3. Evaluate the assessment strategies of patients with the disease state.
4. Recommend nonpharmacological approaches for the treatment of psoriasis.
5. Develop appropriate treatment and care plan for psoriasis patients.
6. Recommend appropriate monitoring parameters for a patient with psoriasis.
7. Propose patient education and counseling information for patients and caregivers as part of the care plan.

---

## INTRODUCTION

● **KEY CONCEPT** *P**soriasis is a chronic inflammatory condition that exhibits a normal pattern of relapse and remission. There is currently no cure for the disease and treatment is aimed toward management of signs and symptoms associated with the condition.*[1] Remission may last years in some patients, whereas, in others, exacerbations may occur every few months. Things known to exacerbate the condition are stress, seasonal changes, environmental factors, life crises, and certain medications.[2] The severity of the condition ranges from mild and moderate to severely disabling. Depression, alcohol-related problems, cardiovascular diseases, metabolic syndrome, and skin cancers are select comorbidities associated with the severe form of the disease.[1] Thus, management of patients with psoriasis is long term and management modalities may change according to the severity of illness at the time. Treatment should be individualized to meet patient needs. The disease may precipitate emotional distress that requires empathy and a caring attitude.

## EPIDEMIOLOGY AND ETIOLOGY

Psoriasis is a chronic common inflammatory skin disorder with a population prevalence of 2% to 3% worldwide. The prevalence is found in Americans and Canadians in a range of 4.6% to 4.7%. African, African American, and Asian populations have an estimated 0.4% to 0.7% prevalence of the disease.[3] Male patients tend to die at least 3.5 years earlier and females 4.5 years earlier than nonpsoriasis patients normalized for differences in mortality by gender.[3] The disease may present at any age, but peaks between age 15 and 30 and again from 50 to 60 years.[3,4] Types of psoriasis manifest as **plaque, flexural (aka inverse or intertriginous), erythrodermic, pustular, guttate, nail**, and **psoriatic arthritis (PsA)**. Eighty to ninety percent of psoriatic patients present with plaque psoriasis. Plaque psoriasis presents with red-pink lesions of varying sizes covered with silvery scales.[2] Up to 42% of patients with psoriasis have been reported to also have PsA.[1,5] PsA is mostly limited to joints, ligaments, and tendons, and manifests in the presence of psoriasis disease. Clinical presentations include pain, stiffness, swelling, and tenderness. PsA progresses from mild symptoms to the destruction of joints affecting quality of life for patients. Some patients may have deforming PsA without cutaneous involvement.[1,5]

● Recent research has shown that psoriatic patients have an increased risk of cardiovascular diseases, especially myocardial infarction.[5–7] The risk is increased in patients with both mild and severe psoriasis, with the highest risk in younger patients with severe disease.[7] These findings persist even when corrected for other cardiovascular risk factors.[7–9]

● **KEY CONCEPT** *Even though study results are inconclusive, genetic association has been documented for both psoriasis and psoriatic arthritis.*[2] The histocompatibility complex region of chromosome 6 (HLA-Cw*06) has been suspected in the disease.[2] Even though the linkage to HLA-Cw*06 has long been known, there is further support for this linkage in recent studies.[2,10,11] Studies have also shown that HLA-A2, B8, B17, and B44 are involved.[12] Women exposed to tobacco smoke have a higher risk of psoriasis than their male counterparts with the same exposure. Four life events: divorce, death of a close friend, death of a family member, and change in work environment can increase the risk of developing psoriasis. First-degree relatives with psoriasis is another risk factor, affecting males more than females. Risk is also found to be higher in urban settings versus rural settings. Additional factors exacerbating psoriasis include drugs such as lithium, NSAIDs, antimalarials, β-adrenergic blockers, and withdrawal of corticosteroids.[13] Cytokines such as interleukins and tumor necrosis factor α (TNF-α), T cells, and keratinocytes play significant roles in the inflammatory process that constitutes the disease mechanism.[2]

The emotional and psychological impact of psoriasis may not correlate with the severity of the skin presentation, and it is

important to always evaluate the psychosocial effects of psoriasis on the patient.[8,9]

## PATHOPHYSIOLOGY

The pathogenesis of psoriasis involves multiple components of the immune system. Cytokines, T cells, and keratinocytes are central to the inflammatory process associated with psoriasis. Additionally, it has been found that when keratinocytes are perturbed, the release of antimicrobial peptide LL-37 takes place. This peptide binds with DNA and RNA. This complex potentially leads to the activation of plasmacytoid and myeloid dendritic cells. These activated dendritic cells secrete interleukin IL-12 and IL-13. The production of these two interleukins eventually results in IL-17 and T helper cell type 1 differentiation.[2] The T cells then release Interleukin IL-17A, IL-17F, IL-22, and IL-23 as mediators which then subsequently activate keratinocytes. This process then generates a complex cascade including proinflammatory cytokines such as TNF-α, interferon (IFN-α and IFN-γ), and interleukin (IL-1β and IL-6). The entire process then leads to alteration of the immune system and chronic inflammation that manifests in the skin causing vascular changes and formation of psoriatic lesions.[2] Keratinocyte proliferation is central to the clinical presentation of psoriasis. Keratinocytes are skin cells producing keratin, which act as a skin barrier.[14] Hyperkeratosis that results from immune derangements causes the characteristic thick, scaly skin lesions seen in patients with psoriasis.[14] The pathologic pathway of psoriatic arthritis is the same, except that the changes that occur as a result of T-cell mediators happen in the synovial fluid within the joints. Osteoclast activation, osteolysis, and bone resorption produces the damage that occurs within the joints.[2]

## CLINICAL PRESENTATION AND DIAGNOSIS

**KEY CONCEPT** *Diagnosis of psoriasis is usually based on recognition of the characteristic plaque lesion and is not based on lab tests.*

"The severity of the disease is classified as mild/limited disease, moderate, or severe disease based on body surface area (BSA) involvement (Table 64–1)." Additionally, classification may be based on assessment tools used such as the Psoriasis Area and Severity Index (PASI) and the Dermatology Life Quality Index (DLQI).[15,16]

## TREATMENT
### Desired Outcomes and Goals

**KEY CONCEPT** *Given its manifestations, inflammation, involvement of multiple areas of the affected skin, and the chronic nature of psoriasis, treatment goals must be well targeted. The goals of treatment*

---

### Patient Encounter, Part 1

AD is a 52-year-old woman who has noticed dark, red, and smooth lesions covering the majority of her upper body. When questioned, the patient says her skin has been relatively clear, until about a month ago. Since then, the lesions have been becoming more uncomfortable, spreading from her back and abdomen to her arms. She is feeling self-conscious about what is happening and does not know what to do.

*What type of psoriasis is AD experiencing?*

---

### Clinical Presentation and Diagnosis of Plaque Psoriasis

**General characteristics**

Small, discrete lesions to generalized confluent lesions over a large BSA.

**Symptoms**

Severe itching.

**Signs**

- Raised lesion red to violet or silvery in color (commonly known as plaques).
- Sharply demarcated borders lesions, except where confluent.
- Lesions are loosely covered with silvery-white scales, which if lifted off, show small pinpoints of bleeding (Auspitz sign).
- Plaques show on the elbows, knees, scalp, umbilicus, and lumbar areas, and often extend to involve the trunk, arms, legs, face, ears, palms, soles, and nails.
- Nail involvement presents as pitting, discoloration ("oil spots"), crumbling, splinter hemorrhages, growth arrest lines, or tissue buildup around the nails.

---

*must be set based on clinical presentations, disease-related comorbidities, treatment-related morbidity, mortality, quality of life, staging of the disease, and recurrent and remission status of the disease at any given point in time.*[5,17,18] It is paramount to know

---

### Clinical Presentation and Diagnosis of Other Types of Psoriasis

- Flexural psoriasis:
  - Appears in intertriginous area
  - Scaling is minimal
- Guttate psoriasis:
  - Sudden eruption of small, disseminated erythematosquamous papules and plaques
  - Often preceded by a streptococcal infection 2 to 3 weeks prior
- Pustular psoriasis:
  - May be localized or generalized
  - May be an acute emergency requiring systemic therapy. The others are given physical descriptions, but this one is not
- Generalized pustular psoriasis:
  - Disseminated deep-red erythematous areas and pustules
  - May merge to become "lakes of pus"
- Erythrodermic psoriasis: generalized, life-threatening condition
  - Erythema, desquamation, and edema
  - May require life support measures as well as systemic therapy

**Table 64–1**

**Disease Severity Classification[15,16]**

| | |
|---|---|
| Mild or limited disease | Less than or equal to 5% BSA involvement |
| Moderate disease | PASI greater than or equal to 8 (higher in trials of biologics) |
| Severe disease | The Rule of Tens: PASI greater than or equal to 10 or DLQI greater than or equal to 10 or BSA greater than or equal to 10% (in some phototherapy trials, BSA greater than or equal to 20% is used as the lower limit |

that no cure currently exists for any type of psoriasis disease. However, evidence supports an increase in remission period and reduction in severity of the disease with current treatment options.[17] The goals must therefore include the following:

- Minimizing or eliminating the signs of psoriasis, such as plaques and scales
- Alleviating pruritus and minimizing excoriations
- Reducing flare-up frequency
- Ensuring appropriate management of associated comorbidities such as psoriatic arthritis, cardiovascular disorders, Crohn disease, clinical depression, or itching
- Avoiding or minimizing adverse effects from treatments used
- Providing cost-effective therapy
- Providing guidance or counseling as needed (eg, stress-reduction techniques)
- Maintaining or improving the patient's quality of life
- Ensuring that patients are partners in their own care
- Implementing motivational interviewing skills in all communications with the patient

### General Approach to Treatment

Management of the disease must be structured to target the type of psoriasis. Plaque, guttate, flexural, pustular, and erythrodermic are the types that currently manifest clinically in patients, with plaque psoriasis being the most common.[19] General treatment modalities must include location, the extent of BSA involvement, and lifestyle modifications. Additionally, the choice of management approach must take into consideration whether the disease is mild, moderate, or severe.[17]

For PsA, the goal of treatment is to keep the patient pain free, reduce swelling, retard or minimize joint damage and keep the joints functioning.[2,5,8,9] The goals to achieve for patients living with this skin condition are significant improvement of skin appearance and ensuring that unpleasant side effects of drugs are fairly minimized. KEY CONCEPT *Patients are managed with both pharmacologic and nonpharmacologic approaches (Figure 64–1).*[19]

### Nonpharmacologic Management

Several effective nonpharmacologic options are available to patients with psoriasis. However, considering the nature of the disease, these treatments may be used as adjunctive treatments to therapeutic agents when appropriate.[16]

KEY CONCEPT *Stress reduction techniques such as psychotherapy, guided imagery, and relaxation techniques have been shown to improve the extent and severity of psoriasis.*[20] *Oatmeal baths in tepid water may help soothe the itching associated with psoriasis.* Nonmedicated moisturizers (occlusive agents, humectants, and/or emollients) help the skin to retain moisture and reduce the scaling of the skin lesions. *Aloe vera* is a common emollient used to help manage skin dryness. These can be applied multiple times during the day to prevent skin dryness. Patients with skin sensitivities should consider the use of fragrance-free products.[21] Harsh soaps, detergents, and other skin irritants must be prohibited as they may worsen the skin condition. Skin cleansing is appropriate; however, it should be done with lipid-free cleansers. Trauma to the skin must always be avoided. Psoriasis can manifest around sites of skin trauma including surgery. The use of sun protection factor (SPF) of 30 or less is recommended to prevent sunburns, as they can induce disease flare-ups. Loose-fitting clothes are desired to help reduce skin irritation.[21]

### Pharmacologic Therapy

The pathogenesis of the disease involves a complex mechanism that disturbs the immune system, causes vascular changes, and the development of skin lesions.[2] It is paramount that therapeutic agents that antagonize these processes are well represented in the treatment of psoriasis. KEY CONCEPT *These agents are anti-inflammatory, anticytokines, and biologic therapies. They are classified into topical, phototherapy, conventional systemic therapy, and biologics.*[2,19]

#### ▶ Topical Treatment

"These agents are marked as first-line treatment for mild to moderate psoriasis (Table 64–2 and 64–3)." They are specifically known for their anti-inflammatory, antiproliferative, and anti-immunologic properties. They are classified as corticosteroids, vitamin D analogues, retinoids, calcineurin inhibitors, anthralin, and salicylic acid derivatives. Different dosage forms are available such as creams, lotions, gels, foams, ointments, shampoos, oil solutions, tapes, and sprays. KEY CONCEPT *The choice of specific dosage form or vehicle is dependent on several factors such as the surface area involved, location, thickness of the lesions, and the appearance of the plaques.*[17,19,22] Ointments are recommended for dry and thick lesions to enhance absorption and reduce loss of skin moisture. Creams are indicated for acute, but moist appearing, lesions that do not require ointment-based products. Solutions and gels are recommended for scalp lesions and foams and sprays are usually used for lesions in genital areas.[21,22]

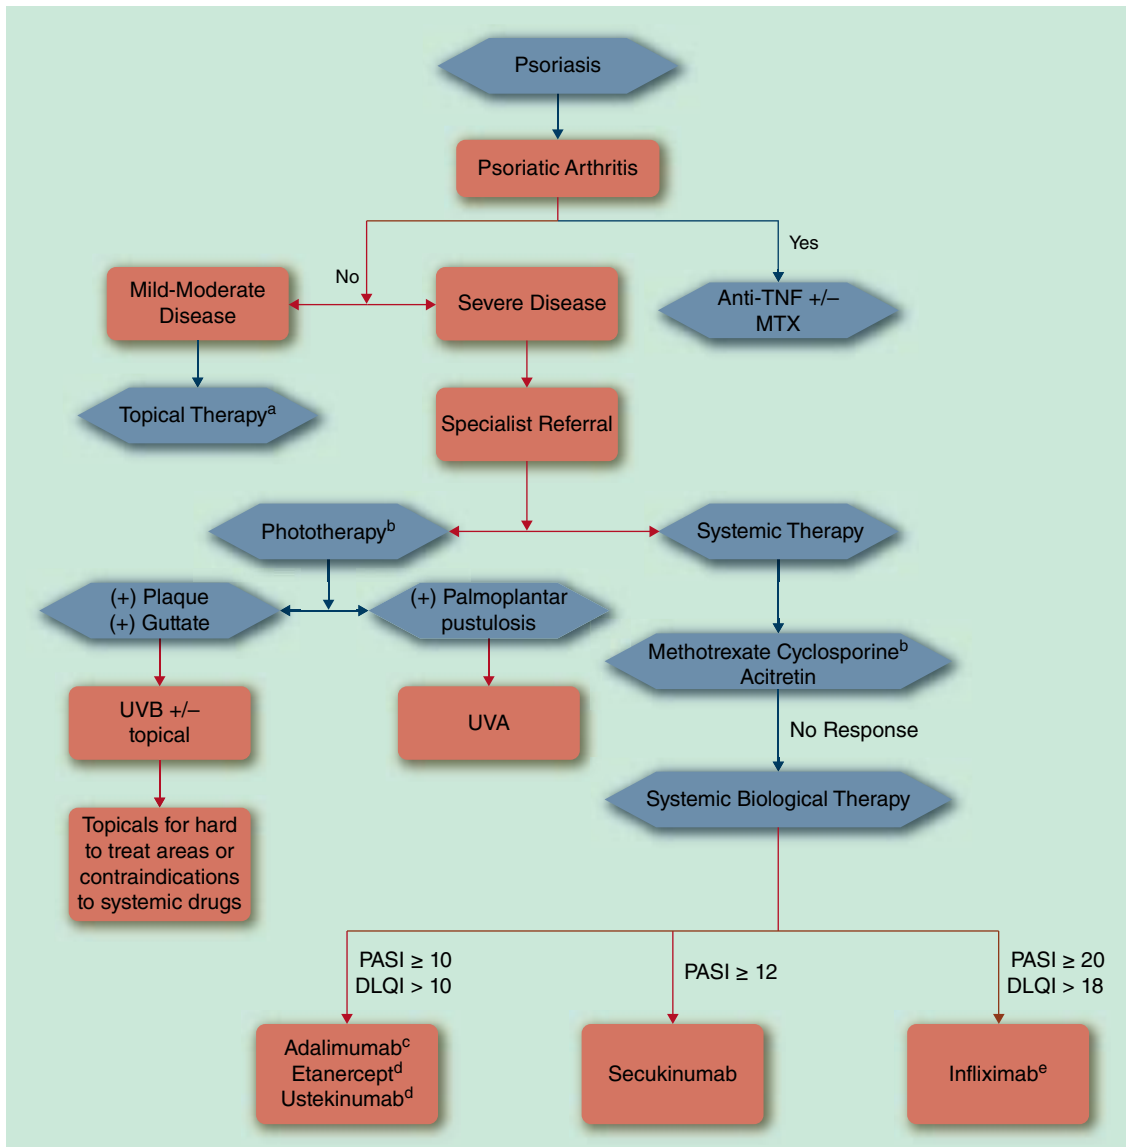
Vehicle selection is an important consideration and may vary from one body part to another. Ointments and tapes provide occlusion, enhancing drug penetration to improve efficacy. Creams and lotions are easier to spread, especially in hairy areas. Gels may have drying and cooling effects, in addition to easy spreadability. Foams may have enhanced drug delivery and/or efficacy compared to lotions or creams that can become cosmetically elegant liquids upon skin contact, providing good patient acceptance. Shampoos incorporating tar distillates or salicylic acid are useful for scalp psoriasis. Pastes, such as Lassar's paste, have an inherent stiffness, minimizing the spread of medication, and are useful for incorporating drugs such as anthralin, which, especially in higher concentrations used in short-contact methods, may cause skin irritation and burning if in contact with normal skin. It is important to remember that changing to a different vehicle may significantly alter drug potency. For example, a tape formulation (highly occlusive) is much more potent than a cream formulation. Ultimately, the optimal vehicle may be the vehicle that the patient is willing to use. Occlusive ointments may be too


**FIGURE 64–1.** Treatment algorithm for psoriasis.[5,8,9,21,22,24,27]

[a]Review appointment at 4 weeks for efficacy. [b]Relapse < 50% over 3 months, move to systemic therapy; cyclosporine: no more than
1 year.
[c]Discontinue by 16 weeks if adequate response not met.
[d]Discontinue by 12 weeks if adequate response not met.
[e]Continue treatment beyond 10 weeks if patients shows adequate response.

greasy and cosmetically unappealing, resulting in poor compliance. Sometimes using a cream formulation during the day and an ointment at night may be the best option.[18] Keratolytic agents, such as salicylic acid, are often added to bath oil or shampoos (typically 3%–4%) for scalp psoriasis.[16,21,22] Salicylic acid can also be added to topical corticosteroid preparations to enhance steroid penetration (salicylic acid breaks down keratin).[15,23]

## Diagnostic Assessment

Efficacy measurements are guided by three main instruments described as Physicians Global Assessment (PGA) scale, National Psoriasis Foundation-Psoriasis Score (NPF-PS), and PASI with PASI being the most common. Unfortunately, these tools are used predominately in clinical trials and infrequently in clinical practice. The PASI is a scoring instrument that ranges from 0 (absence of disease) to 72 (most severe form of the disease). This tool is commonly used because it takes into consideration severity of the disease and the BSA affected. Effective response to treatment in patients with psoriasis is indicated by a 75% reduction in PASI score.[17]

The National Institute for Health and Care Excellence (NICE) clinical guidelines on psoriasis outline other qualitative measures to be used in assessing the holistic approach to disease management.[1] It emphasizes evaluating the physical, psychological, and social impact of the disease on the patients' quality of life. The impact of psoriasis on the patients' daily living activities should be assessed. Depending on how the patient is coping, advice and support may be needed in the overall treatment plan for

**Table 64–2**

**Topical Medications[2,16,17,23,24]**

| Actions and Effects | Selected Agents | Criteria | Approach to Therapy | Efficacy Assessment (PGA) Scores | Dosage Form/ Strength | Place in Therapy |
|---|---|---|---|---|---|---|
| **Corticosteroids** Anti-inflammatory Vasoconstriction Immunosuppression Antiproliferative | **Very High Potency** -Bethamethasone -Clobetasol -Diflorasone | Mild to moderate | Monotherapy for acute episode | 41%–92% with increase in potency | Ointment Creams Lotions Gel Foams | First line |
| | **High Potency** -Amcinoride -Betamethasone dipropionate and valerate -Desoximetasone | | Monotherapy for acute episode | | Solutions Shampoo, spray and tape **Available Strengths:** 0.05%–2.5% | |
| | **Intermediate Potency** -Betamethasone -Desoximetasone | | Monotherapy for acute episode | | | |
| | **Low Potency** -Alclometasone -Desonide -Hydrocortisone | | Monotherapy for acute episode | | | |
| **Vitamin D Analogues** Not well-known Vitamin D receptor binding is proposed keratinocytes proliferation is attenuated | Calcipotriene | Mild to moderate | Mono or steroid sparing adjunctive therapy First consideration with steroid when rapid lesion eradication is desired | 60%–70% | Cream Scalp solution | First line with or without steroid |
| | calcitriol | | | 60%–70% | Ointment | |
| **Retinoids** Not well-known. Modifies gene transcription Decrease inflammation and proliferation due to its retinoid acid receptors binding | Tazarotene | Mild to moderate | Mono or adjunctive therapy with steroid. More effective with high potency steroids | 63% | Gel | Second line |
| **Calcineurin Inhibitors** Decrease lymphokines activity by phosphatase inhibition. Act as immunomudulators | Tacrolimus (Protopic) | Mild to Moderate | Monotherapy for more sensitive areas such as face | 65%–70% | **Ointment Strengths:** 0.03% and 0.1% | Third line |
| | Pimecrolimus (Elidel) | Mild to Moderate | Monotherapy for more sensitive areas of the skin such as face | | Cream **Strength:** 1% | |

the patient. Efficacy achievement alone may not have the overall desired effect on patients wellbeing.[1,22] Dermatology Quality of Life Scales, Dermatology Life Quality Index (DLQI), Dermatology Specific Quality of Life Instrument, and Skindex-29 are validated instruments that are used to measure these quality outcomes in patients with psoriasis by specialists.[16,22]

## Phototherapy for Psoriasis

Phototherapy and photochemotherapy are generally used in the management of moderate to severe disease. Systemic therapies are used for patients with extensive or moderate to severe disease. To minimize drug toxicities or increase efficacy, systemic therapies are sometimes used in conjunction with topical or phototherapy.[15,16]

Phototherapy is traditionally done by using ultraviolet B (UVB) radiation. It can be used as monotherapy or in combination with topical or systemic agents. The UVB disrupts the synthesis of proteins and nucleic acids in skin, which reduces epidermal keratin proliferation. Education should be provided to all patients and include information about the importance of wearing goggles for eye protection. Dosing is administered by the Fitzpatrick skin type, which deals with the skin tones of the patient. Phototherapy may be administered during pregnancy and is considered a first-line therapy.[25]

Photochemotherapy is the administration of phototherapy together with topical or systemic agents.[15,21,25] UVA has a long wavelength, and therapy with UVA is always combined with psoralens (eg, methoxsalen or trioxsalen), which are used as photosensitizers to increase efficacy. The use of psoralens + ultraviolet A (PUVA) for psoriasis causes two types of reaction: (a) an anoxic reaction that affects cellular DNA that inhibits the proliferation of epidermal cells and induces cell death (apoptosis), and (b) an oxygen dependent reaction that gives rise to the formation of free radicals and reactive oxygen that may damage membranes by lipid peroxidation.[26,27]

PUVA (psoralen ultraviolet A therapy) applies to a group of therapies utilizing psoralens to sensitize cells to UVA light.[25] Bath PUVA, topical PUVA, and oral PUVA regimens are available.[15,25] Oral PUVA consists of 8-methoxypsoralen, but in Europe 5-methoxypsoralen is more common. 5-methoxypsoralen is less toxic, but not approved in the United States. Bath PUVA involves soaking in a bath of psoralens (trimethylpsoralen) liquid for 15 minutes prior to UVA treatment and is commonly used in Scandinavian countries for generalized psoriasis to reduce systemic toxicities from psoralens.[19] Topical PUVA uses psoralens directly on the skin, then followed by UVA therapy.[25] Psoralens act much more on cells that are actively dividing than on resting cells. This explains why they are effective only in the active stage of scleroderma and not in the fibrotic stage. Their action on actively dividing or activated immune cells, especially on T cells, explains their action in immune-mediated diseases like psoriasis.

**Table 64–3**

**Topical Medications** [2,16,17,23,24]

| Drug Class | Dosing and Application | Administration Guidelines | Cautions and Side Effects |
|---|---|---|---|
| **Corticosteroid** | • Mostly once or twice daily<br>• Every other day or weekends only application may be suitable for chronic conditions<br>• Treatment is recommended for 2–3 weeks<br>• Low and intermediate potency can be used up to 3 months | • Intermediate and low potency agents are indicated for acute and mild lesions and tapering is recommended with the lowest dose when the condition improves<br>• Low potency agents are suitable for lesions in infants due to large body surface area and elderly for the sensitive and thin layer of the skin<br>• High and very high potency agents are indicated for chronic and severe lesions<br>• Palms and soles of the skin require high and very high potency agents to maximize absorption and penetration due to the thickness of the skin | • Skin irritation<br>• Dryness<br>• Withdrawal effects |
| **Vitamin D analogues** | Mostly once or twice daily for a maximum of 2 months for effective result | • Recommended to be used with topical steroids to speed up the healing process<br>• Considered less toxic than topical steroids<br>• Combination therapy with steroids has shown to be more effective than the single agent<br>• Onset of action is slow<br>• Avoid calcipotriene use with salicylic acid due to instability of calcipotriene | • Pruritus<br>• Skin irritation on facial area and skin folds<br>• Skin irritation is less with Calcitriol<br>• Skin Rashes<br>• Burning<br>• Changes in systemic vitamin D levels |
| **Retinoids** | Preferred as once daily at bedtime | • Best used to achieve better efficacy results with high potent steroids or UVB phototherapy | • Skin irritation<br>• Pruritus<br>• Dryness<br>• Photosensitivity |
| **Calcineurin inhibitors** | Mostly once or twice daily depending on the product until effective result is observed | • Comparison data to other agents or in combination is lacking<br>• Use with salicylic acid for 8 weeks showed efficacy improvement in facial lesions | • Skin irritation<br>• Pruritus<br>• Photosensitivity<br>• Risk of malignancy |
| **Other agents Salicylic acid Coal tar Anthralin** | As directed | • Decreases the scaling of the skin lesion to allow application of other agents<br>• Infrequent use of Tars and anthralins due to irritation and stain | • Skin irritation<br>• Potential salicylic acid toxicity through nausea and ringing in ears |

---

## Patient Encounter, Part 2

Additional relevant information was obtained from the patient, including the following history

**FH:** Father has psoriasis. Mother passed away 6 months ago from a stroke at the age of 65. Younger sister has Stage I HTN and hyperlipidemia

**SH:** AD is married with three children: ages 5, 3, and 1. She owns her own landscaping business and tries to join her team in the yards as often as possible. She is an occasional drinker (one to two glasses of wine per week) and admits to smoking when she has "a particularly difficult client"

**Meds:** Lisinopril 10 mg daily; ibuprofen 400 mg every 8 hours as needed (headaches)

**PE:**

**Gen:** She appears very distressed about the lesions

**VS:** BP 134/87 mm Hg, P 88 beats/min, RR 18 breaths/min, T 37.0°C (98.6°F), Ht 5′ 5″ (165 cm), Wt 175 lb (79.4 kg)

**Abd:** Soft, NTND; (+) bowel sounds; lesions on abdomen

**Exts:** Within normal limits; no joint pains; lesions spreading onto arms

**Skin:** Dark red lesions on abdomen, back, and arms

**Labs:** All within normal limits, including lipids, renal function tests, and LFTs

*What risk factors does she have for psoriasis?*

### Patient Encounter, Part 3

The diagnosis is that the patient has erythrodermic psoriasis.

Patient expresses to you at this time that she "does not have the best insurance," but she wants something that will take care of her psoriasis.

*What nonpharmacologic alternatives are appropriate for this patient?*

*What pharmacologic agents are appropriate for this patient?*

### Systemic Therapy

Systemic therapies are usually recommended for moderate to severe psoriasis.[5,15,16,28] These oral agents are classified into immunosuppressants, oral retinoids, T-cell activation inhibitors, cytokine modulators, TNF-α inhibitors, and interleukin 12 and 23 blockers.[1] See Tables 64–4 and 64–5.

Acitretin is an oral retinoid that is likely safer than methotrexate or cyclosporine since potentially serious adverse effects can usually be minimized by appropriate patient selection, careful dosing, and monitoring.[24] Acitretin given concurrently with phototherapy, acitretin +ultraviolet B (ReUVB) or oral retinoid + PUVA (RePUVA), has a synergistic treatment effect. Acitretin monotherapy is usually given for 14 days before instituting UVB or PUVA.[18] The ultraviolet light dose should be reduced by 30% to 50%.[18] ReUVB and RePUVA are well-established treatment regimens for psoriasis.[5,8,9,15,25,28,29]

Acitretin is teratogenic (Pregnancy Category X) and contraindicated in women of childbearing potential. Pregnancy must be avoided during or for 3 years after discontinuation of therapy.[8,9,16,28] Acitretin can transform spontaneously or be converted by ethanol (transesterification) into etretinate, which may take up to 3 years for body clearance.[19] Abstinence from alcoholic beverages should be observed during therapy and for at least 2 months after acitretin is discontinued. Common side effects of acitretin include mucocutaneous dryness and hyperlipidemia.[15,28] Long-term continuous use has caused diffuse idiopathic skeletal

### Patient Encounter, Part 4

The patient was started on methotrexate and has been doing well for 18 months. She reports that her condition was well controlled during this time, but recently, she and her husband have been fighting more frequently and she has noticed the lesions have reappeared. She continued her methotrexate regimen, even after the fighting had stopped and has seen no improvement.

Current Meds: Nonmedicated moisturizer after bathing and ad lib; methotrexate 2.5 mg every 12 hours for a total of three doses per week

*What is your main treatment goal for this patient?*

*What pharmacologic treatments would be appropriate for this patient at this time?*

*What are the monitoring parameters of your proposed treatment?*

hyperostosis (DISH) and periungual pyogenic granulomas.[15,25] Drug interactions include vitamin A (due to the increased risk of hypervitaminosis A), and drugs that interfere with cytochrome P-450 metabolism or have significant plasma albumin binding, which should be used with caution.[25]

Methotrexate is a folic acid antagonist that interferes with purine synthesis and thus inhibits DNA synthesis and cell replication. In addition to the antimitotic effect, it has a specific activity of T-cell suppression and, in low doses, anti-inflammatory and antiproliferative effects.[30] Compared with cyclosporine, methotrexate has a more modest effect but can be used continuously for years, with durable benefits.[15] Folic acid is added to the treatment with methotrexate to reduce gastrointestinal symptoms. It may take up to 4 weeks to see a clinical response after a dose increase.[28] Methotrexate is contraindicated in pregnancy, renal impairment, hepatitis, cirrhosis, alcoholics, unreliable patients, and patients with leukemia or thrombocytopenia.[8,9]

Cyclosporine is an immunosuppressant that specifically inhibits helper T cells and keratinocyte activation and proliferation. Cyclosporine is efficacious in both inducing remission and in maintenance therapy for patients with moderate to severe plaque psoriasis and is also effective in treating pustular, erythrodermic, and nail psoriasis.[15,16,31,32]

Mycophenolate mofetil was found useful in patients with cyclosporine-induced nephrotoxicity as a switch-over agent. Although PASI increased, patients' renal function improved.[33] As adjunctive or monotherapy, there are a few studies in relatively small groups of patients with moderate to severe psoriasis that showed some benefit (at least a 50% reduction in *PASI).*[28,33] For PsA, the systemic drugs used for rheumatoid arthritis are commonly used. This may include NSAIDS, aspirin, but also methotrexate, retinoids, corticosteroids (oral or intrasynovial injection), and cyclooxygenase inhibitors (COX-2s).[8,9]

## Biologic Response Modifiers

Biologic response modifiers (BRMs) are currently recommended for consideration as first-line therapies alongside traditional systemic agents for moderate to severe disease.[15] These are agents employed in the treatment of psoriasis that act by inhibiting various molecular signaling steps of the immunological signaling cascade that are key determinants of the pathogenesis of psoriasis. The following agents are recommended for chronic plaque psoriasis[39]:

1. Inhibitors of TNF, which includes biologic agents such as etanercept, adalimumab, infliximab
2. Inhibitors of interleukin which includes ustekinumab and secukinumab

Their safety profile in comparison with other systemic agents and relatively good acceptability by patients are all positive factors.[13] However, due to a significant cost difference, biologic agents are often reserved for cases in which traditional systemic agents provide inadequate control or for patients with comorbidities such as depression or diabetes (eg, in a patient with PsA or for whom traditional systemic agents may be inappropriate due to potential adverse effects).

Oral apremilast is one of a class of "small molecule" systemic BRMs specifically approved for PsA. It inhibits phosphodiesterase 4 (PDE4) which controls part of the inflammatory actions within cells via cAMP to decrease nitric oxide synthase, TNF-α and interleukin [IL] 23 and increase IL-10. Other BRMs may also be used.

**Table 64–4**

**Systemic Agents**[17,39,40]

| Drug | Mechanism of Action | Doses and Administration | Dosage Forms | Adverse Effects | Therapeutic Efficacy on PASI 75 | Therapeutic Application | Therapeutic Monitoring |
|---|---|---|---|---|---|---|---|
| **Immunosuppressants** | | | | | | | |
| Cyclosporine | An immunosuppressive agent that specifically inhibits helper T cell and keratinocyte activation and proliferation | 2.5 mg/kg/day in two divided doses for at least 4 weeks<br><br>This dose may be subsequently titrated and increased by 0.5 mg/kg/day every 2 weeks until there is control of plaques | Oral and IV solution | Nephrotoxicity, lowering of seizure threshold, tremor, gingival hyperplasia, hypertension, squamous cell carcinoma (cutaneous) | ~41%–71% | First-line agent | -LFTs (Baseline and routine)<br>-SCR, BUN<br>-CBC<br>-Uric acid<br>-Blood pressure<br>-Drug Interaction with cytochrome P-450 substrate and inhibitors<br>-pregnancy |
| Methotrexate | Folic acid antagonist<br><br>Act by interfering with purine synthesis, thus inhibit DNA synthesis and cell replication | -7.5 to 10 mg weekly<br>-2.5 mg Q12 hours times 3 doses | Oral and injectable | Nausea, vomiting, stomatitis, fatigue, hepatotoxicity, bone marrow suppression, pulmonary fibrosis | 24%–60% | First-line agent | -CBC<br>-SCR, BUN<br>-LFTs (baseline and Q 4 weeks)<br>-Pregnancy category X |
| **Oral Retinoids** | | | | | | | |
| Acitretin | Stimulates differentiation and normalizes epidermal cell proliferation | 10–50 mg/day | Oral capsule | Myalgia, hair loss, hepatotoxicity, pancreatitis | 70%–75% | Second-line agent | Lipids<br>-CBC<br>-SCR, BUN (baseline and every 3 months)<br>-Pregnancy category X |

**Table 64–5**

**Biological Therapy[17,34,39-43]**

| Medication | Mechanism of Action | Dose and Administration | Dosage Forms | Adverse Effects | Therapeutic Effects on PASI | Place in Therapy | Therapeutic Monitoring |
|---|---|---|---|---|---|---|---|
| **Cytokine Modulators-Tumor Necrosis Factors** | | | | | | | |
| Etanercept | Fusion protein that binds to both TNF-α and TNF-β | 50 mg SC twice weekly for 12 weeks then 50 mg SC quickly | Subcutaneous solution | Upper respiratory tract infection, nausea, vomiting, headaches Injection site reaction | 47%–59% at weeks 12 and 24 | Second-line agent | CBC LFTs PPD (tuberculosis) |
| Adalimumab | Human Monoclonal antibody that targets TNF-α | 80 mg SC, first dose then 40 mg SC on week 2, then 40 mg SC Q 2 weeks | Subcutaneous solution | Upper respiratory tract infection, pharyngitis, nausea, dyspepsia, fatigue, headaches Injection site reaction | 53%–80% at weeks 12 and 16 | First line | CBC LFTs PPD (tuberculosis) |
| Infliximab | Chimeric monoclonal antibody that targets TNF-α | 5 mg/kg IV on weeks 0, 2, 6 and then 5 mg every 8 weeks | Intravenous and subcutaneous solutions | Upper Respiratory Tract Infection, pharyngitis, diarrhea, fatigue, hypersensitivity reaction | 76%–82% at weeks 10 and 24 | First line | PPD (tuberculosis) |
| **Cytokine Modulators: Interleukin Blockers** | | | | | | | |
| Ustekinumab | Human monoclonal antibody that targets IL12/23 p40 | 45–90 mg SC on week 0 and 4, then every 12 weeks | Subcutaneous solution | Headache, upper respiratory tract infection pharyngitis, abdominal pain | 66%–78% at weeks 12 and 28 | | None |
| Secukinumab | Human monoclonal antibody that antagonizes IL17A | 300 mg SC at weeks 0, 1, 2, 3, and 4 then 300 mg every 4 weeks | Subcutaneous solution | nasopharyngitis, diarrhea, upper respiratory tract infection | 82%–86% at week 12 | | PPD (tuberculosis), Crohn Disease exacerbations, caution in patients with chronic or recurrent infection |

IV, intravenously; SC, subcutaneously.

**Table 64–6**

**Natural Plant Products[35,36,41]**

| Plant/Product | Plant Taxonomical Family | Evidence | Route of Administration/Dose | Clinical Study Model | References |
|---|---|---|---|---|---|
| *Aloe vera (AV)* | *Liliaceae* | AV improved PASI scores over triamcinolone | Administered topically three times daily for 5 consecutive days per week for 4 weeks | Randomized control trial equivalence design | Choonhakam et al 2010 |
| Avocado | | B12 cream containing avocado oil showed clinical promise in psoriasis | 12 weeks study<br>Topical cream | Randomized trial | Stucker et al 2001 |
| *Mahonia aquifolium* | *Berberidaceae* | Relieva compared to placebo | Topical cream of fruits | Randomized double blind trial | Bernstein et al 2006 |

### ▶ *Natural Health Products and Treatments*

Some patients with psoriasis are inclined to use nonmedical and synthetic preparations, such as those containing natural substances. The choice in many cases is motivated by the unwanted side effects and contraindications of conventional medications. These preparations are either used alone or in combination with the medication prescribed by the physician. KEY CONCEPT The following products have clinical evidence in the literature that is inconclusive to support their use in patients with psoriasis. Examples of these products are aloe vera, oil of avocado, and Oregon grape (*Mahonia aqulifolium*).[35–37] Some products have been tested in animal studies but their efficacy has not yet been validated in humans. Examples are capsaicin, chamomile, Indigo, and *naturalis*. A short list of plants and plant products with purported efficacy against psoriasis appears in Table 64–6.

### ▶ *Investigation Drugs*

KEY CONCEPT *There are several agents including topical, oral and biologic modifiers under investigation at various levels including the combination of topical corticosteroids with vitamin D analogues. Micellar paclitaxel, voclosporin, and pioglitazone are among the oral agents currently being studied.* Biological agents such as IL-11 inhibitor daclizumab, IL-10, protein kinase blocker AEB071, IL-12 and 23 monoclonal antibodies are all in the pipeline under various stages of investigations.[2,17]

## OUTCOME EVALUATION

- Monitor for clearance of skin lesions. Depending on the agent(s) used and site of lesions, it may take 2 to 6 weeks or longer to see a response. Complete clearance may not be achieved for all patients.
- Monitor for specific adverse effects and drug interactions, depending on agent(s) used.
- Methotrexate: Monitor CBC and liver function tests at baseline and on a regular basis. Consider liver biopsy prior to treatment and again at a cumulative dose of 1.5 g for high-risk patients.
- Cyclosporine: Monitor serum creatinine, blood urea nitrogen, serum lipids, magnesium, and blood pressure at baseline. Reassess biweekly for at least 12 weeks or until drug levels stabilize then adjust doses accordingly.

- Acitretin: Monitor serum lipids, liver function tests and perform pregnancy testing.
- Topical corticosteroids: Monitor for skin thinning, irritation telangiectasias, and possible hypothalamic–pituitary–adrenal axis suppression.
- Total clearance of skin disease is not impossible during periods of remission; remissions may be days, months, years, and even decades in length with patients being weaned from their medications entirely or have them reduced to a low maintenance dose.

## DISCUSSION

Several factors must be taken into consideration in identifying the right therapy for a patient with psoriasis. Some of these factors are the affected area of the disease, cost, availability of medication, and the preferred lifestyle of the patient. Full patient history including allergies must be collected to make therapeutic approach a success. Topical agents are recommended for mild to moderate disease due to the low cost and fewer adverse effects of the products. Low potency corticosteroids are used as first line for mild conditions. If the condition persists, it is recommended to switch to a very high potency steroid in combination with vitamin D analogue or topical retinoids. In general, a patient disease surface area should be less than 5% to qualify for topical therapy. A general recommendation after unsuccessful treatment with topical agents is to add phototherapy. PUVA was found to be more effective that UVB in the treatment of patients with moderate to severe psoriasis.[38] The traditional systemic agents should be the next in line for patients with severe diseases. Clinical trials indicate that immunosuppressants are more effective than oral retinoids. Due to the cost associated with biological agents, they are reserved as a last resort for patients with severe diseases not responding to traditional systemic agents or intolerant to the side effects of these agents. Biologics are known for their fewer adverse effects. The choice of biologic agents depends on the patient's preference. Infliximab and adalimumab are more effective than alefacept or etanercept. A disease affecting more than 5% of the BSA should be the justification for initiating systemic therapy. For patients with liver disease, kidney dysfunction, and skin cancer, it is recommended to avoid methotrexate, cyclosporine, and PUVA treatment, respectively.[17,19,24]

## SUMMARY

It should be recognized that psoriasis is a chronic disease with no current cure but requires lifelong management of the disease state. No two cases of psoriasis are identical and treatment modalities must be tailored to the patient with the help of a dermatologist. The disease can severely impact the patients' quality of life by affecting their physical, psychological, and social well-being. The NICE guidelines recommend a holistic approach in assessing all areas of life in caring for patients that live with this disease.

---

### Patient Care Process

**Patient Assessment:**

- Based on physical exam and review of systems, determine severity of disease.
- Review medical history: What risk factors does the patient have? Does the patient have any comorbid conditions?
- Conduct medication history: Include prescriptions, OTC products, herbal and dietary supplements. Does the patient have any drug allergies? Is this patient experiencing side effects from a medication? What have they tried already?

**Therapy Evaluation:**

- Is pharmacologic therapy indicated based on current presentation?
- Would patient benefit from nonpharmacologic therapy?
- If patient is already receiving treatment, assess efficacy, safety, and adherence. Are there any significant drug interactions with patients other medications?
- What kind of prescription coverage does the patient have? Determine if recommended agents are included on the institution's formulary.

**Care Plan Development:**

- Select lifestyle and nonpharmacologic therapy that are likely to be effective and safe.
- Determine if drug doses are optimal. Utilize combination therapy when appropriate to take advantage of synergistic effects and to reduce side effects.
- Address patient concerns about psoriasis.
- Discuss importance of medication adherence and lifestyle modifications to reduce psoriasis.
- Give patients an approximate time frame for improvement.
- Counsel on appropriate application techniques, administration, and potential toxicities of drug therapy.
- Interact with patient's other health care providers to discuss pertinent information about the patient's care.
- Reinforce importance of regular follow-up visits.

**Follow-up Evaluation:**

- Follow-up at appropriate intervals to assess effectiveness and safety of therapy.
- Review physical exam findings, labs, and other pertinent diagnostic tests.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| BB-UVB | Broadband ultraviolet B |
| BRM | Biologic response modifier |
| BSA | Body surface area |
| cAMP | Cyclic 3'-5'-adenosine monophosphate |
| DISH | Diffuse idiopathic skeletal hyperostosis |
| IF-γ | Interferon-γ |
| IL-2 | Interleukin-2 |
| IL-10 | Interleukin-10 |
| IL-12/23 | Interleukin-12 and interleukin-23 |
| LFT | Liver function test |
| NSAIDs | Nonsteroidal anti-inflammatory drugs |
| PASI | Psoriasis Area and Severity Index |
| PPD | Purified protein derivative |
| PUVA | Psoralen ultraviolet A therapy |
| Q | Every |
| PsA | Psoriatic arthritis |
| RePUVA | Oral retinoid + PUVA |
| ReUVB | Acitretin + ultraviolet B |
| TNF | Tumor necrosis factor |
| UVB | Ultraviolet B |

# 65    Common Skin Disorders

Laura A. Perry and Lori J. Ernsthausen

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Describe the pathophysiology of common skin disorders.

2. Assess the signs and symptoms of common skin disorders in a presenting patient.

3. List the goals of treatment for patients with common skin disorders.

4. Select appropriate nonpharmacologic and pharmacologic treatment regimens for patients presenting with common skin disorders.

5. Identify adverse effects that may result from pharmacologic agents used in the treatment of common skin disorders.

6. Develop a monitoring plan that will assess the safety and efficacy of the overall disease state management of common skin disorders.

7. Create educational information for patients about common skin disorders, including appropriate self-management, available drug treatment options, and anticipated therapeutic responses.

## INTRODUCTION

Several thousand skin disorders are currently documented, and many patients seek the assistance of a health care provider when a complication with their skin develops. Others will utilize self-care to effectively treat their symptoms.

This chapter discusses acne vulgaris, contact dermatitis (irritant and allergic), and diaper dermatitis; other common skin and soft tissue infections and superficial fungal infections are discussed in Chapters 73 and 83, respectively. Providing patients with appropriate therapy options, as well as patient education on treatment and prevention, will assist the successful management of many common skin disorders.

## ACNE VULGARIS

Acne vulgaris is an inflammatory skin disorder of the pilosebaceous units of the skin. Although most commonly seen on the face, acne can also be present on the chest, back, neck, and shoulders (**Figure 65–1**).[1] Acne is not just a self-limiting disorder of teenagers. The clinical course of acne can be prolonged or recur, resulting in long-term physical complications such as extensive scarring and psychological distress.[2]

### EPIDEMIOLOGY AND ETIOLOGY

With an estimated 40 to 50 million people affected, acne vulgaris is the number one skin disease in the United States.[3] Acne affects approximately 85% of adolescents and adults aged 12 to 25 years, with severity of acne correlating with pubertal maturity.[3,4] Additionally, acne may persist beyond puberty and has been found to affect 64% and 43% of individuals into the 1920s and 1930s, respectively. Acne is more likely to occur in males during adolescence and females during adulthood. Individuals with a positive family history of acne have been shown to develop more severe cases of acne at an earlier age. Prevalence of acne among ethnic groups is similar.[4]

While the link between diet and acne has continued to be controversial, there is evidence to suggest that high glycemic load diets may exacerbate acne.[5,6] Local irritation from occlusive clothing or athletic equipment, oil-based cosmetics or beauty products, prolonged sweating or environments of high humidity, and a variety of medications may also worsen acne.[7]

## PATHOPHYSIOLOGY

**KEY CONCEPT** *The development of acne lesions results from four pathogenic factors: excess sebum production, keratinization, bacterial growth, and inflammation.*[1,2,6]

The **pilosebaceous unit** of the skin consists of a hair follicle and the surrounding sebaceous glands. An initial acne lesion, called a comedo, forms when there is a blockage in the pilosebaceous unit.

Sebum is released by the sebaceous glands and naturally maintains hair and skin hydration. Increased androgen levels, especially during puberty, can cause an increased size of the sebaceous gland and production of abnormally high levels of sebum within those glands. This excess sebum can result in plugged follicles and acne formation.

Keratinization, the sloughing of epithelial cells in the hair follicle, is also a natural process. In acne, however, *hyper*keratinization occurs and causes increased adhesiveness of the sloughed cells. Accumulation of these cells clogs the hair follicle, blocks the flow of sebum, and forms an acne lesion called an **open comedo** or "blackhead."

**FIGURE 65–1.** Twenty-year-old man. In this case of papulopustular acne, some inflammatory papules become nodular and thus represent early stages of nodulocystic acne. (From Wolff K, Johnson RA. Disorders of sebaceous and apocrine glands. Fitzpatrick's Color Atlas & Synopsis of Clinical Dermatology. 6th ed. New York: McGraw-Hill; 2009: 3.)

*Propionibacterium acnes* (*P. acnes*), an anaerobic organism, is also found in the normal flora of the skin. This bacteria proliferates in the mixture of sebum and keratinocytes and can result in an inflammatory response producing a **closed comedo** or "whitehead." More severe acne lesions such as pustules, papules, and nodules also form with inflammatory acne and result in significant scarring if treated inadequately.

# TREATMENT
## Desired Outcomes and Goals

Although traditionally thought of as a self-limiting disorder, acne can have patterns of recurrence. Because acne cannot be cured, proper treatment must involve both short-term and long-term strategies. **KEY CONCEPT** Goals of therapy are to (1) *Reduce the number and severity of existing lesions*, (2) *Prevent the development of new lesions, and* (3) *Prevent long-term disfigurement and permanent scarring.*[6,10] Acne can cause psychological symptoms of stress, anxiety, frustration, embarrassment, and even depression.[2,6] Evaluating both physical and psychological aspects of acne is imperative.

## General Approach to Treatment

**KEY CONCEPT** *Acne treatment regimens should be based on acne severity and type of acne lesion. Other factors such as response to previous treatment, patient preference, cost and adherence should also be considered.* Topical therapy is considered first line for mild acne with oral therapies added to topical therapy in moderate to severe acne. Optimal management includes induction and maintenance therapy.[2,9] Improvement of symptoms following induction therapy occurs gradually, sometimes taking 6 to 8 weeks for results to be physically apparent.[6] Patients need to be educated on continual treatment compliance during this time and should not get discouraged if acne lesions appear to worsen before getting better. Maintenance therapy should begin after 12 weeks of induction therapy and continues for 3 to 4 months.[6,9]

## Nonpharmacologic Therapy

There is significant variance in the clinical benefit of many nonpharmacologic interventions for acne vulgaris. Patients should be counseled to avoid aggressive skin washing and to use a mild, noncomedogenic facial soap twice daily. Furthermore, discourage the use of abrasive cleansers and manipulating or squeezing

---

## Clinical Presentation and Diagnosis of Acne

Acne lesions are most often seen on the face, but can also present on the chest, back, neck, and shoulders and are described as either noninflammatory or inflammatory. Severe inflammatory lesions may lead to scarring and hyperpigmentation.

### Noninflammatory Lesions

Open comedo or "blackhead": A plugged follicle of sebum, keratinocytes, and bacteria that protrudes from the surface of the skin and appears black or brown in color. Although dark in color, blackheads do not indicate the presence of dirt, but rather, an accumulation of melanin.

   Closed comedo or "whitehead": A plugged follicle of sebum, keratinocytes, and bacteria that remains beneath the surface of the skin. Closed comedos usually appear as small white bumps about 1 to 2 mm in diameter.

### Inflammatory Lesions

Papules: Solid, elevated lesion less than 0.5 cm in diameter

Pustules: Vesicles filled with purulent fluid less than 0.5 cm in diameter

Nodules: Lesions greater than 0.5 cm in both width and depth

Cysts: Nodules filled with a fluid or semisolid that can be expressed

### Scars

Inflammatory acne can result in permanent scarring that ranges from small depressed pits to large elevated blemishes.

### Hyperpigmentation

Inflammatory acne may result in hyperpigmentation of the skin that can last for weeks to months.

### Diagnosis

The diagnosis of acne vulgaris is clinical. Lesion cultures may be warranted when treatment regimens fail to rule out other skin infections.

### Assessment

No standard acne grading scale has been identified. While several grading scale exist,[2,8,9] most clinicians describe acne as mild (few noninflammatory lesions), moderate (many inflammatory lesions) or severe (numerous severe inflammatory lesions and evidence of scarring).

lesions to minimize scarring. Use of an oil-free, noncomedogenic moisturizer may improve the tolerability of topical drug therapy.[7]

## Pharmacologic Therapy

### ▶ Topical Agents

**Benzoyl Peroxide** Benzoyl peroxide is easy to use and is recommended as an alternative to or in combination with topical retinoids or topical antibiotics in the treatment of acne of all severities.[2,9] Benzoyl peroxide has a **comedolytic** effect that increases the rate of epithelial cell turnover and helps to unclog blocked pores. It also has antibacterial activity against *P. acnes*, which appears to be the main reason for its effectiveness.[11,12]

Benzoyl peroxide is available with or without a prescription and remains the most commonly purchased over-the-counter topical treatment for acne.[7] Some data suggests that lower strengths offer similar efficacy to higher strengths. Beginning benzoyl peroxide treatment regimen with the lowest strength and titrating to higher effective strengths over several weeks, if needed, will reduce the incidence of localized adverse effects. Newer formulations of benzoyl peroxide are combined with moisturizers to help decrease skin redness and irritation.[11,12]

A typical regimen for benzoyl peroxide is to apply the product to clean, dry skin no more than two times a day. The strength and dosage form selected may vary from patient to patient depending on acne severity and the sensitivity of the patient's skin. Gel preparations are the most potent dosage form. Patients with dry or overly sensitive skin should try a cream, lotion, or facial wash first.[6] If severe irritation or an allergic reaction develops, benzoyl peroxide should be discontinued. Table 65–1 describes available products and adverse effects.

**Retinoids** Highly effective in the treatment of acne, retinoids stimulate epithelial cell turnover and aid in unclogging blocked pores. Retinoids also exhibit anti-inflammatory properties through the inhibition of neutrophil and monocyte chemotaxis.[11] Due to the ability to target multiple pathogenic features of acne, topical retinoids are recommended as first-line therapy for induction and maintenance regimens in all forms of acne. Although success is seen with monotherapy, using topical retinoids in combination with benzoyl peroxide or topical antibacterial agents is preferred for inflammatory acne lesions.[2,9]

Available topical retinoids include tretinoin, adapalene, and tazarotene. Adapalene is considered the drug of first choice because it has similar efficacy and a lower incidence of adverse effects.[9,13] Newer formulations involving a microsphere gel (Retin-A Micro) or prepolyolprepolymer-2 gel or cream (Avita) gradually release the active ingredient over time and may also cause less initial skin discomfort.[13] Table 65–1 describes available products and adverse effects of topical retinoids.

Topical retinoids should be applied once daily at bedtime, beginning with a low-potency formulation. Increased strengths are then initiated according to treatment results and tolerance. Patients should be advised that a worsening of acne symptoms generally occurs in the first few weeks of therapy, with lesion improvement occurring in 3 to 4 months.[14,15] The use of topical retinoids should be avoided in children younger than 12 years and in pregnant women.[13]

**Antibacterials** Topical antibacterials directly suppress *P. acnes* and are first-line agents used in combination with benzoyl peroxide, topical retinoids or azelaic acid for the treatment of mild to moderate inflammatory acne. To reduce the likelihood of bacterial resistance, topical antibiotics should never be used as monotherapy or as long-term maintenance therapy.[2,9]

Clindamycin and erythromycin preparations, applied once or twice daily for 3 months, have similar effects and are the most commonly prescribed topical antibacterial agents.[2,9,11] These agents are available in various formulations and combinations with benzoyl peroxide and retinoids. Table 65–1 describes the strengths, formulations, and adverse effects of the available antimicrobial agents.

**Azelaic Acid** With antibacterial and anti-inflammatory properties, and the ability to stabilize keratinization, azelaic acid is an effective alternative in the treatment of mild to moderate acne in patients who cannot tolerate benzoyl peroxide or topical retinoids.[2,9,15] It can also even out skin tone and may prove effective in patients who are prone to postinflammatory hyperpigmentation resulting from acne.[15,16] Azelaic acid 20% cream should be applied twice daily, with improvement of symptoms seen in 4 weeks.[15]

**Dapsone** Dapsone gel, a sulfone drug, has antimicrobial and anti-inflammatory properties.[17] Although approved for the treatment of mild to moderate acne, due to the lack of comparative efficacy trials, current guidelines do not comment on the place of dapsone in the treatment of acne.[2,9]

Dapsone 5% (Aczone) is a gritty gel that should be applied in a thin layer to the affected areas twice daily. If no improvement is seen after 12 weeks, treatment should be reevaluated.[18]

**Keratolytics** Sulfur, resorcinol, and salicylic acid are not as effective as other topical agents, but can be used as second-line therapies in the treatment of mild to moderate acne.[2,7]

Although these agents may cause less skin irritation than benzoyl peroxide or the topical retinoids, several disadvantages exist. Sulfur preparations produce an unpleasant odor when applied to the skin, whereas resorcinol may cause brown scaling. And although rare, the possibility of salicylism exists with continual salicylic acid use.[7,15]

### ▶ Oral Agents

**Antibacterials** Moderate to severe acne can be effectively treated with oral antibiotics, especially when treatment with topical therapy has failed.[2,9] Because of the ability to decrease *P. acnes* colonization, oral antibiotics can prevent acne lesions from developing. Use of oral antibiotics should be limited to short periods of time, ideally 3 months or less. Assessment of response to oral antibiotics after 6 to 8 weeks of therapy is recommended. As with topical antibiotics, oral antibiotics should never be used as monotherapy or as long-term maintenance therapy. Additionally, the use of topical antibiotics in combination with oral antibiotics is should be avoided.[2]

Tetracycline, doxycycline, and minocycline are the most commonly prescribed oral antibiotics for acne. Erythromycin, azithromycin, and trimethoprim (± sulfamethoxazole) are appropriate second-line agents for use when patients cannot tolerate or have developed resistance to tetracycline or its derivatives. Although effectiveness is similar to the tetracyclines, erythromycin use is often limited due to potential adverse outcomes and increased bacterial resistance.[19] (See Table 65–2 for antibiotic dosing guidelines and adverse effects.)

**Isotretinoin** Isotretinoin works on the four pathogenic factors that contribute to acne development and can produce acne remission rates of up to several years. Oral isotretinoin is Food and Drug Administration (FDA) approved for patients with severe recalcitrant nodular acne unresponsive to other topical and oral treatment regimens. Although studies are lacking, expert clinicians suggest that oral isotretinoin may be useful in treatment resistant acne of lower severity.[2,9] Contrary to some expert clinicians, the 2012 European Guidelines suggest that oral

| Table 65–1 |

**Topical Agents Used in the Treatment of Acne**

| Drug | Brand | Dosage Form | Adverse Reactions | Comments |
| --- | --- | --- | --- | --- |
| **Retinoids** | | | | |
| Tretinoin | Atralin | 0.05% gel<br>0.025% cream; 0.025% gel | Erythema, dryness, scaling, stinging/burning, pruritus, initially may worsen acne | Local adverse reactions most likely occur in first 2 to 4 weeks of use and will usually lessen with continued use. |
| | Avita | 0.025%, 0.05%, 0.1% cream | | |
| | Retin-A | 0.01%, 0.025% gel | Possibly teratogenic | Category C. Use cautiously in pregnancy. |
| | Retin-A Micro | 0.04%, 0.1% gel | | |
| | Tretin-X | 0.038%, 0.075% cream | Photosensitivity | Minimize exposure to sun light and sun lamps. Sunscreen use and protective clothing recommended. |
| Tazarotene | Tazorac | 0.05%, 0.1% cream<br>0.05%, 0.1% gel | Erythema, dryness, scaling, stinging/burning, pruritus, initially may worsen acne | Local adverse reactions most likely occur in first 2 to 4 weeks of use and will usually lessen with continued use. |
| | Fabior | 0.1% foam | | |
| | | | Teratogenic | Category X. Use in pregnancy is contraindicated. |
| | | | Photosensitivity | Minimize exposure to sun light and sun lamps. Sunscreen use and protective clothing recommended. |
| Adapalene | Differin | 0.1% cream<br>0.1%, 0.3% gel<br>0.1% lotion | Erythema, dryness, scaling, stinging/burning, pruritus, initially may worsen acne | Local adverse reactions most likely occur in first 2 to 4 weeks of use and will usually lessen with continued use |
| | | | | Less irritation compared to other retinoids. |
| | | | Photosensitivity | Minimize exposure to sun light and sun lamps. Sunscreen use and protective clothing recommended. |
| **Other topical Agents** | | | | |
| Benzoyl peroxide | 1%–10%, Various over the counter and prescription products | Lotion, gel, foam, pads | Excessive drying, peeling, erythema, allergic contact sensitization/ dermatitis | Local reactions are dose dependent. Gradually increase dose as tolerance develops. |
| | | | Bleaching of hair and colored fabric. | Minimize exposure to sun light and sun lamps. Sunscreen use and protective clothing recommended. |
| | | | Photosensitivity | Pregnancy Category C |
| Azelaic Acid | Azelex | 20% cream | Erythema, skin irritation | Alternative to benzoyl peroxide.<br>Pregnancy Category B |
| Clindamycin | Cleocin T<br>Clindagel<br>ClindaMax<br>Evoclin<br>BenzaClin | 1% solution, lotion, gel<br>1% gel<br>1% gel, lotion<br>1% foam<br>1%–5% benzoyl peroxide combination gel | Burning, itching, dryness, erythema, peeling<br>Diarrhea, colitis (pseudomembranous colitis) | Rare cases of colitis have been observed with topical use. Discontinue immediately and seek medical attention if diarrhea occurs. |
| | Duac | 1.2%–5% benzoyl peroxide combination gel | | Should be combined with topical benzoyl peroxide. |
| Erythromycin | ERYGEL<br>Ery<br>Benzamycin | 2% gel<br>2% pad<br>5%–3% benzoyl peroxide combination gel | Burning, peeling, dryness, pruritus, erythema | Should be combined with topical benzoyl peroxide. |
| Dapsone | Aczone | 5% gel | Dryness, erythema, oiliness, and peeling | Does not have a risk of phototoxicity. |

**Table 65–2**

**Oral Agents Used in the Treatment of Acne**

| Drug | Dosage form (mg) | Dosing Regimen | Adverse Reactions | Comments |
|------|-----------------|----------------|-------------------|----------|
| **Oral Antibiotics** | | | | |
| Tetracycline | 250, 500 capsule | 250–500 mg twice daily | GI upset, headache, blurry vision, vaginal candidiasis, possible teratogenic risk, tooth discoloration in children<br>Photosensitivity<br>Drug–food interactions | Avoid use in in children < 8 years. Pregnancy Category D. Avoid use in pregnancy.<br>Minimize exposure to sun light and sun lamps. Sunscreen use and protective clothing recommended.<br>Take 1 hour before or 2 hours after dairy products, antacids, vitamins, or iron supplements. |
| Doxycycline | 50, 75, 100 tablets and capsules<br>200 delayed-release tablet | Immediate release: 50–100 mg once or twice daily<br>Extended release: 200 mg once daily | GI upset, headache, blurry vision, possible teratogenic risk, tooth discoloration in children<br>Photosensitivity<br>Drug–food interactions | Avoid use in in children < 8 years. Pregnancy Category D. Avoid use in pregnancy.<br>Minimize exposure to sun light and sun lamps. Sunscreen use and protective clothing recommended.<br>Take 1 hour before or 2 hours after dairy products, antacids, vitamins, or iron supplements. |
| Minocycline | 50, 75, 100 immediate-release tablets<br>45, 55, 65, 80, 90, 105, 115, 135 extended-release tablets<br>50, 75, 100 immediate release capsules | Immediate release: 50–100 mg twice daily.<br>Extended release: 1 mg/kg daily for 12 weeks. | GI upset, headache, blurry vision, lupus-like syndrome, hepatitis, exfoliative dermatitis, possible teratogenic risk, tooth discoloration in children<br>Photosensitivity<br>Drug–food interactions | Avoid use in in children < 8 years. Pregnancy Category D. Avoid use in pregnancy.<br>Minimize exposure to sun light and sun lamps. Sunscreen use and protective clothing recommended.<br>Take 1 hour before or 2 hours after dairy products, antacids, vitamins, or iron supplements. |
| Erythromycin | 250, 500 tablets | 250–500 mg twice daily | GI upset, rash, hearing loss, hypersensitivity reactions | Highest incidence of GI intolerance and increasing bacterial resistance.<br>Possible drug interactions: CYP3A4 substrate and P-glycoprotein inhibitor<br>Alternative to tetracyclines. Drug of choice in pregnant women and children < 8 years. |
| Azithromycin | 500 tablet | 500 mg per dose 2 to 4 days a week | GI upset, rash, headache, drowsiness | Alternative if other antibiotics cannot be used. |
| Clindamycin | 75, 150, 300 capsules | 150–300 mg daily | GI upset, pruritus, rash, vaginitis, pseudomembranous colitis | Alternative if other antibiotics cannot be used.<br>Discontinue immediately and seek medical attention if diarrhea occurs. |
| Sulfamethoxazole + trimethoprim | 400/80, 800/160 tablet | 400–800/80–160 mg one to two times daily | GI upset, allergic rash, urticaria, Stevens-Johnson syndrome, possible teratogenicity<br>Photosensitivity | Alternative if other antibiotics cannot be used.<br>Pregnancy Category D. Avoid use in pregnancy.<br>Minimize exposure to sun light and sun lamps. Sunscreen use and protective clothing recommended. |
| **Hormonal Agents** | | | | |
| Oral Contraceptives | Norgestimate/ethinyl estradiol (Ortho Tri-Cyclen)<br>Norethindrone acetate/ ethinyl estradiol (Estrostep) | One tablet daily | Nausea, headache, weight gain, breast tenderness, break through bleeding, venous thromboembolism | Not for treatment of acne in men.<br>Use only in females ≥ 15 years of age.<br>Increased risk of venous thromboembolism in women who use tobacco products. |

*(Continued)*

---

**Table 65–2**

**Oral Agents Used in the Treatment of Acne (*Continued*)**

| Drug | Dosage form (mg) | Dosing Regimen | Adverse Reactions | Comments |
|---|---|---|---|---|
| Spironolactone | 25, 50, 100 | 50–200 mg daily | Menstrual irregularities, breast tenderness, nausea, dizziness, headache, transient diuretic effect, hyperkalemia | Not recommended for treatment of acne in men. Monitor serum creatinine and potassium. |
| **Oral Retinoid** | | | | |
| Isotretinoin | 10, 20, 30, 40 tablets | 0.5–1 mg/kg/day in two divided doses | Cheilitis, dryness of the nose, eyes, and mouth, peeling, pruritus, and drying of the face and skin, alopecia, acne flair up at start of therapy Teratogenicity Depression/suicidality Musculoskeletal pain Increased serum lipids, creatine phosphokinase, and blood glucose Photosensitivity | Nasal sprays, lip moisturizers, and hard candy may help to reduce drying of mucous membranes. Apply oil-free moisturizers to face to relieve drying of skin. Category X. Contraindicated in pregnancy. Monitor patient closely for changes in mood May use nonsteroidal anti-inflammatory drugs to relieve pain Monitor lipid panel, liver function tests, and blood glucose Minimize exposure to sun light and sun lamps. Sunscreen use and protective clothing recommended. |

Data from (1) Lexicomp [Internet]. Hudson (OH): Wolters Kluwer Health, Inc.1978-2014 [cited 2014 July 25]. http://online.lexi.com/lco/action/home/switch. (2) Facts & Comparisons eAnswers. St. Louis (MO) 2014: Wolters Kluwer health, Inc. 2014 [cited 2014 July 25]. http://online.factsandcomparisons.com/index.aspx

isotretinoin therapy may be used as first-line therapy in patients with severe nodular acne due to clinical effectiveness, prevention of scarring, and quick improvements in patient quality of life.[9]

Adverse effects with the use of isotretinoin are frequent and generally dose related. Table 65–2 lists common isotretinoin adverse effects and management strategies for those symptoms.

Because isotretinoin is teratogenic and classified as Pregnancy Category X, the FDA mandates an online registry program called iPLEDGE to ensure that females do not become pregnant while taking isotretinoin. Wholesalers, pharmacies, doctors, and patients must be registered in the iPLEDGE computer-based system in order to control the distribution, prescribing, and dispensing of isotretinoin. Two negative pregnancy tests prior to initiating therapy and one negative pregnancy test each month thereafter must be obtained and confirmed in the system before a prescription can be dispensed to female patients of child-bearing potential. These patients must also commit to using two effective forms of birth control 1 month prior, during, and at least 1 month after discontinuation of isotretinoin therapy. Contact the program at their website: https://www.ipledgeprogram.com/ for further details.

Initial dose ranges for treatment are 0.5 to 1 mg/kg daily in two divided doses, with beneficial results generally reported at total daily doses of 120 to 150 mg/day. Treatment with oral isotretinoin should be continued for 6 months, but may be extended for patients with an insufficient response.[2,9,20]

**Hormonal Agents** Oral contraceptives and antiandrogens (spironolactone and cyproterone acetate) are valuable second-line treatment options for moderate to severe acne in female patients. Hormonal agents primarily work by decreasing androgen production resulting in reduced sebum formation. Because sebum production occurs early in the pathogenesis of acne, it may take up to 3 to 6 months to see the full effect of hormonal agents.[10]

Although many contraceptives are effective, agents containing norgestimate with ethinyl estradiol, norethindrone acetate with ethinyl estradiol, and drospirenone with ethinyl estradiol (Yaz) have been FDA approved for the treatment of acne.[20,21,22] Spironolactone at higher doses is effective for acne through antiandrogenic properties. While not approved for use in the United States, cyproterone acetate combined with an ethinyl estradiol containing oral contraceptive has demonstrated efficacy.[2,9,20] (See Table 65–2 for hormonal agent dosing guidelines and adverse effects.)

**Other Agents** Although use is infrequent, several other agents are available as second- or third-line treatment options for acne when first-line therapies fail[2,9,20]:

- Corticosteroids
- Chemical peels
- Surgical extraction
- Phototherapy/photodynamic therapy
- Laser treatments

**Figure 65–2** shows useful algorithms for the effective treatment of the various stages of acne.

## OUTCOME EVALUATION

Depending on severity, complete resolution of acne lesions may take weeks to months. Monitor patients every 4 to 8 weeks during pharmacologic therapy to assess for efficacy.[6,8]

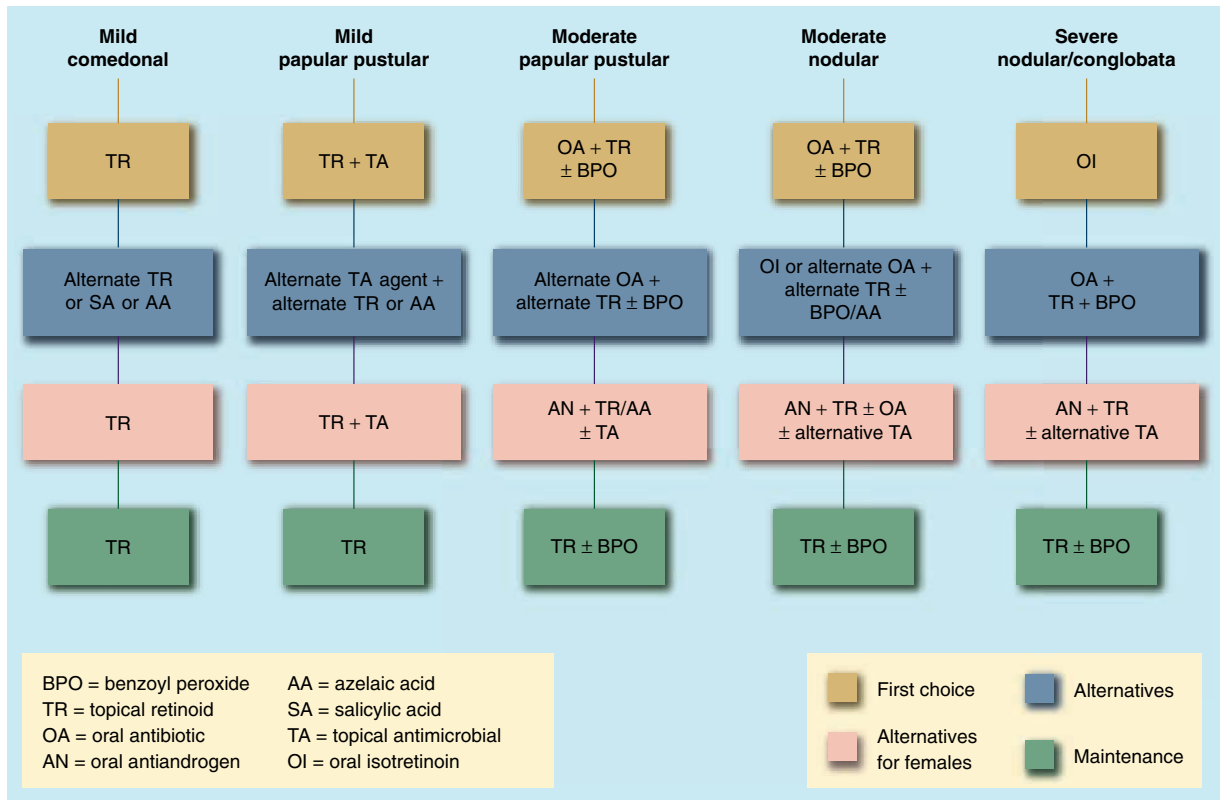
- Decreased number of lesions
- Decreased severity of lesions


**FIGURE 65–2.** Algorithms for acne treatment. (From Thiboutot D, Gollnick H, Bettoli V, et. al. New insights into the management of acne: an update from the global alliance to improve outcomes in acne group. J Am Acad Dermatol. 2009;60:S1–S50.

## Patient Care Process: Acne

### Patient Assessment:

- Assess patient symptoms and acne lesions to determine acne severity: mild, moderate, or severe.
- Determine family history of acne, including severity.
- Evaluate skin care routine, including the use of cosmetics, facial washes, moisturizers, and other possible exacerbating factors.
- Conduct a medication history (nonprescription, prescription, and herbal medications). Identify previous acne treatment regimens.
- Identify any drug allergies.

### Therapy Evaluation:

- If the patient is already receiving pharmacotherapy, assess whether active and/or previously tried therapies were effective, safe, and used as directed.
- If the patient is not well controlled, determine appropriate pharmacotherapy options for the patient's acne severity (see Figure 65–2).
- Determine whether the patient has prescription medication coverage to identify possible recommendations included in the plan formulary.

### Care Plan Development:

- Select nondrug and drug therapy likely to be effective and safe (see Tables 65–1 and 65–2).

- Address any patient concerns.
- Provide patient education on acne and its management:
  - What is acne and how does it develop?
  - Physical and psychological complications that can result from acne.
  - Proper administration technique. Topical acne therapy should be applied to acne prone areas and existing lesions.
  - Possible side effects of drug therapy.
  - Inform patient of possible initial worsening of acne and/or delay of therapeutic effectiveness of acne drug therapy.
  - Emphasize medication compliance and adherence to lifestyle modifications.

### Follow-up Evaluation:

- Follow-up every 1 to 2 months to assess effectiveness and safety of nondrug and drug therapy (see Tables 65–1 and 65–2).
- If acne lesions do not respond after 3 months of drug therapy, consider an alternative acne regimen (see Figure 65–2).
- If the patient experiences resolution of acne symptoms, transition to maintenance drug therapy.

**Patient Encounter 1**

A 15-year-old girl complains of "embarrassing zits." She began getting a few lesions when she was 14 which have now increased in number. She is starting high school and is very anxious about her appearance. Visual examination reveals numerous noninflammatory lesions and several papules and pustules on her forehead, cheeks, and nose. She is frustrated because she thinks acne means she is not a "clean person" and nothing she has tried has "cured her acne." She admits to washing her face at least three times a day with an over-the-counter face wash containing benzoyl peroxide. She also applies a salicylic acid 2% cream directly to her lesions once a day. She has never seen a dermatologist for her acne. The patient appears to be in good physical health.

*What reported symptoms support the diagnosis of acne?*

*What other information would you obtain from this patient before determining a treatment plan for her?*

*Describe your treatment goals for this patient.*

*What nonpharmacologic treatment options and lifestyle modifications would you suggest to this patient?*

*What pharmacologic treatment options are available for this patient?*

*Given the information presented, develop a treatment regimen for this patient that includes the following:*

*(a) A statement of the drug-related needs and/or problem*

*(b) A patient-specific therapeutic plan*

*(c) Monitoring parameters to assess efficacy and safety*

- Relief of pain/irritation
- Presence of scarring or pigmentation
- Psychological effects

If no improvement is reported after 6 weeks of drug therapy or if symptoms have worsened, patients should be reevaluated and a change to an alternative drug regimen may be necessary (see Figure 65–2).

Educate patients on potential adverse effects of drug therapy (see Tables 65–1 and 65–2). Consider changing therapy if a patient experiences effects that are not tolerated or are a compromise to their health.

## CONTACT DERMATITIS

Contact dermatitis is a condition in which exposure to an offending substance produces inflammation, erythema, and pruritus of the skin.[23,24] More specifically, contact dermatitis can be divided into either irritant or allergic forms.[29,30] **KEY CONCEPT** *Irritant contact dermatitis (ICD) results from first-time exposure to irritating substances such as soaps, plants, cleaning solutions, or solvents. Allergic contact dermatitis (ACD) is a delayed hypersensitivity reaction that occurs after an initial exposure to an allergen results in sensitization. With additional exposure, activation of the immune system results in dermatitis. Allergens that commonly cause ACD include poison ivy, latex, and certain types of metal.*[25,26,27] (**Figures 65–3** and **65–4**.) **Table 65–3** lists agents commonly responsible for irritant and ACD. Although generally occurring on the exposed skin, such as the hands and face, contact dermatitis can appear anywhere on the body.[29]

**FIGURE 65–3.** Acute irritant contact dermatitis on the hand due to an industrial solvent. There is massive blistering on the palm. (From Wolff K, Johnson RA. Eczema/dermatitis. Fitzpatrick's Color Atlas & Synopsis of Clinical Dermatology. 6th ed. New York: McGraw-Hill; 2009: 23.)

## EPIDEMIOLOGY AND ETIOLOGY

Contact dermatitis is the most common occupational related skin disease.[28] Although most often seen in adults, contact dermatitis can affect all age groups, with females at slightly greater risk than males due to increased risk of exposure.[26]

**FIGURE 65–4.** Allergic contact dermatitis of the hand: chromates. Confluent papules, vesicles, erosions, and crusts on the dorsum of the left hand in a construction worker who was allergic to chromates. (From Wolff K, Johnson RA. Eczema/dermatitis. Fitzpatrick's Color Atlas & Synopsis of Clinical Dermatology. 6th ed. New York: McGraw-Hill; 2009: 27.)

---

**Table 65–3**

**Common Agents Causing Contact Dermatitis**

**Irritant Contact Dermatitis**
Soaps
Detergents
Cosmetics
Solvents
Acid, mild or strong
Alkali, mild or strong

**Allergic Contact Dermatitis**
Plant resins, poison ivy, poison oak, sumac
Metals (nickel or gold in jewelry)
Latex and rubber
Cigarette smoke
Local anesthetics (lidocaine, benzocaine)

---

## PATHOPHYSIOLOGY

*Irritant* contact dermatitis is not the result of an immunologic process, but rather occurs from direct injury to the skin. An irritating agent comes into contact with the skin, damages the protective layers of the epidermis, and can cause erythema, the formation of vesicles and pruritus.[23,29,30] Symptoms occur within minutes to hours of exposure and begin to heal soon after removal of the offending substance.

---

## Clinical Presentation and Diagnosis of Contact Dermatitis

Contact dermatitis is generally confined to the area of contact, but in a highly sensitive person, a widespread or even generalized eruption may occur. Contact dermatitis is divided into two forms—irritant and allergic. Both forms may include, but are not limited to:

- Erythema
- Pruritus
- Vesicles
- Papules
- Crusts
- Burning
- Pain

### Irritant Form

The irritant form usually presents within hours of exposure and the rash is often localized. ICD may also result in fissuring and scaling.

### Allergic Form

The allergic form can take several days to present and the condition may extend beyond the borders of the region exposed. ACD may cause intense itching and include oozing pustules and skin erosion.

### Diagnosis

When the causative agent is known, the diagnosis of contact dermatitis is clinical. Patch testing is done if the allergens are unknown and is usually performed several weeks after the resolution of the original dermatitis.

---

*Allergic* contact dermatitis is a type IV hypersensitivity reaction.[25] Upon initial exposure, a substance penetrates the skin, is processed by antigen presenting cells, and subsequently activate allergen-specific T cells. Subsequent exposures to that substance will elicit a response by circulating memory T cells, resulting in an allergic reaction.[23,25,29,30] Symptoms of ACD are similar to those of the irritant type, but may take several hours to several days to develop following reexposure.[23,31]

## TREATMENT
### Desired Outcomes and Goals

KEY CONCEPT *Identifying the causative substance and eliminating its exposure is the initial treatment goal for contact dermatitis.* Although physical symptoms can develop almost immediately after contact, removal of the offending agent will improve existing symptoms and prevent further complications.[5] Removing the offending agent includes washing the skin and any clothing or objects that may have come into contact with the agent to prevent reexposure. *The second treatment goal is symptom relief.* Since inflammation and pruritus, as well as lesion formation, are likely to result from contact dermatitis, appropriate selection of nonpharmacologic and pharmacologic agents for these symptoms is necessary.

### Nonpharmacologic Therapy

In many cases, contact dermatitis may not require medical treatment. Nondrug therapy for contact dermatitis is aimed at relieving pruritus and maintaining skin hydration.[25] Effective agents used for this include the following[23,32]:

- Colloidal oatmeal baths
- Cool or tepid soapless showers
- Cool, moist compresses applied to the area for 20 to 30 minutes as often as needed
- Emollients applied to the area after bathing

### Pharmacologic Therapy
#### ▶ Astringents

The drying effect of astringents will decrease oozing from lesions and relieve itching.[23,31] Due to their ability to cause blood vessel constriction, astringents can also decrease inflammation. Aluminum acetate (Burow solution), aluminum sulfate/calcium acetate solution (Domeboro), calamine lotion, colloidal oatmeal baths/soaks, and witch hazel are safe and effective.[23] Aluminum acetate or aluminum sulfate/calcium acetate may be applied as a compress for 30 minutes at least four times daily as needed. Colloidal oatmeal baths or soaks may be applied for 15 to 20 minutes at least twice daily.

Adverse effects reported with these agents are minimal and include drying and tightening of the skin.

#### ▶ Topical Steroids

Erythema, inflammation, pain, and itching caused by ACD can be effectively treated with topically applied corticosteroids. The use of topical corticosteroids for the management of ICD is controversial, as patients with ACD generally respond better to therapy than those with ICD.[31,33] With such a wide range of products and potencies, appropriate steroid selection is based on severity and location of lesions (see Table 65–4 for a list of topical steroids and potencies.) Higher potency preparations are used in areas where

**Table 65–4**

| Potency Rating | Topical Dosage Forms |
| --- | --- |
| Class 1: Superpotent | Betamethasone dipropionate 0.05% ointment (Diprolene and Diprosone ointment)<br>Clobetasone propionate 0.05% lotion/spray/shampoo (Clobex lotion/spray/shampoo, OLUX foam)<br>Clobetasone propionate 0.05% cream and ointment (Cormax, Temovate)<br>Diflorasone diacetate 0.05% ointment (Florone, Psorcon)<br>Halobetasol propionate 0.05% cream and ointment (Ultravate)<br>Flurandrenolide tape 4 mcg/cm² (Cordran) |
| Class 2: Potent | Amcinonide 0.1% ointment (Cyclocort ointment)<br>Betamethasone dipropionate 0.05% cream/gel (Diprolene cream, gel, and Diprosone cream)<br>Desoximetasone 0.25% cream (Topicort)<br>Fluocinonide 0.05% cream, gel, ointment (Lidex)<br>Halcinonide 0.1% cream (Halog) |
| Class 3: Upper mid-strength | Amcinonide 0.1% cream (Cyclocort cream)<br>Betamethasone valerate 0.1% ointment (Betnovate/Valisone ointment)<br>Diflorasone diacetate 0.05% cream (Psorcon cream)<br>Fluticasone propionate 0.005% ointment (Cutivate ointment)<br>Mometasone furoate 0.1% ointment (Elocon ointment)<br>Triamcinolone acetonide 0.5% cream and ointment (Aristocort) |

| Class 6: Mild | Alclometasone dipropionate 0.05% cream and ointment (Aclovate)<br>Betamethasone valerate 0.05% cream and ointment<br>Desonide 0.05% cream, ointment, gel (DesOwen, Desonate, Tridesilon)<br>Desonide 0.05% foam (Verdeso)<br>Fluocinonide acetonide 0.01% cream and solution (Synalar)<br>Fluocinonide acetonide 0.01% FS oil (Derma-Smoothe) |
| Class 7: Least Potent | Hydrocortisone 0.5%, 1%, 2%, 2.5% cream, lotion, spray, and ointment (various brands) |

From Law RM, Gulliver WP. Psoriasis. In: Dipiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiological Approach. 9th ed. New York: McGraw-Hill; 2014:1583.

penetration is poor, such as the elbows and knees. Lower potency products should be reserved for areas of higher penetration, such as the face, axillae, and groin. Low-potency steroids are also recommended for the treatment of infants and children.[34,35]

Adverse effects from topical steroids are usually related to the potency of the steroid, frequency of application, duration of therapy, and the site of application. Skin atrophy, hypopigmentation, striae, and steroid-induced acne are all possible side effects associated with long-term use.[30] Ointments, because of their occlusive properties, should be avoided on weeping lesions.[23,36]

Topical steroids are typically applied two to four times daily. As improvement begins, maintenance therapy should be limited to the lowest strength steroid that continues to control the condition. Once symptoms are completely resolved, use should be discontinued and should not exceed 1 to 2 weeks.[34]

▶ *Antihistamines*

Whether due to their antihistaminic activity or their sedative side effects, pruritus caused by contact dermatitis can be relieved with the use of sedating oral antihistamines such as diphenhydramine or hydroxyzine. Topical antihistamines are available, but use is limited due to their high-sensitizing potential.[23,34] In addition to sedation, many oral antihistamines can cause hypotension, dizziness, blurred vision, and confusion.

## Outcome Evaluation

With adequate treatment, most cases of contact dermatitis should improve within 7 days. Complete resolution of symptoms may take up to 3 weeks.[23] If patients experiences severe symptoms associated with fever or difficulty breathing, they should be instructed to

## Patient Care Process: Contact Dermatitis

**Patient Assessment:**

- Assess symptoms.
- Obtain a thorough patient history. Can the agent/exposure be identified? Has there been prior exposure to that agent? If so, what treatment regimens were used to alleviate symptoms?
- Obtain patient's allergy status.

**Therapy Evaluation:**

- Determine whether the patient has ICD or ACD.
- Discuss testing needed to suggest or confirm the etiologic agent (patch testing).

**Care Plan Development:**

- Develop a treatment plan for ICD or ACD. In most cases, nondrug and nonprescription treatment options are most

appropriate. If case is severe or if the patient has ACD, the plan may also include prescription therapy.

- Provide patient education on ICD or ACD and treatment:
  - Possible adverse effects of drug therapy
  - Symptoms that warrant physician referral?
  - Importance of treatment compliance.
  - Educate on the recognition of agents that may cause contact dermatitis.

**Follow-up Evaluation:**

- Symptoms should improve within 2 to 3 days. If no improvement, the patient should be advised to follow-up with the provider.

---

seek medical attention immediately. Furthermore, patients should return to their health care provider if any of the following occur:

- Rash has not improved (increased in size or spread to other locations) after several days of treatment
- Patient is experiencing adverse effects from the treatment regimen

## Patient Encounter 2

A 25-year-old man presents to your pharmacy with complaints of intense itching and shows you a red, raised rash with papules on his arms. The patient tells you several days ago he spent the day clearing brush with his father on his family's property. He states that he was wearing gloves and work boots, but had on a T-shirt and shorts. He suspects he came into contact with poison ivy, because his rash looks similar to the one he had before when he came into contact with poison ivy while camping. The patient indicates that he took a shower several hours after exposure, but hasn't tried anything else to manage his symptoms. From the information he has presented, you conclude that he did likely come in contact with an agent while working that caused an allergic contact dermatitis to develop.

*What information supports the possibility of exposure to an allergic agent?*

*Describe the symptoms that support this diagnosis.*

*Determine what the patient has tried to relieve her symptoms.*

*Describe the differences between allergic and irritant contact dermatitis.*

*What are your treatment goals for this patient?*

*What nonpharmacologic and pharmacologic treatment options are available for this diagnosis?*

*Given the information presented, develop a treatment regimen for this patient that includes the following:*

*(a) A statement of the problem*

*(b) A patient-specific therapeutic plan*

*(c) Monitoring parameters to assess efficacy and safety*

## DIAPER DERMATITIS

### EPIDEMIOLOGY AND ETIOLOGY

Diaper dermatitis, more commonly known as diaper rash, is a form of ICD that affects the buttocks, upper thighs, lower abdomen, and genitalia of an estimated 7% to 35% of all infants.[37] Onset of occurrence is usually between 3 weeks and 2 years of age, with the most cases reported between 9 and 12 months of age.[38] The rise in the number of adults who use diapers for incontinence also increases the risk of developing diaper dermatitis.[39]

### PATHOPHYSIOLOGY

**KEY CONCEPT** *Although many factors contribute to diaper rash, it is most likely the result of prolonged contact of the skin with urine and feces in the diaper.* If a diaper is not changed soon after urination or defecation, the protective layer of the skin can break down and make the area more susceptible to irritation and infection.[40] Although most mild cases of diaper rash present as erythema, moderate to severe cases can result in the formation of papules, vesicles, and even ulceration. If these cases are not effectively treated, the likelihood of secondary fungal or bacterial infections developing is greatly increased.[39]

### TREATMENT

#### Desired Outcomes and Goals

**KEY CONCEPT** *The primary goal in the treatment of diaper rash is prevention and is most often accomplished through frequent diaper changes.* **KEY CONCEPT** *When a diaper rash is already present, repairing the damaged skin, relieving discomfort, and preventing secondary infections from occurring are important factors to consider when developing an effective treatment regimen.*[40]

#### Nonpharmacologic Therapy

Most mild cases of diaper rash can be resolved with the use of nonpharmacologic therapies. Keeping the diaper area clean and dry by changing diapers as soon as practically possible (at least every 2 hours or more frequently) is highly effective for treatment and prevention.[39,41] Other nondrug options include[31,39,41]:

## Clinical Presentation and Diagnosis of Diaper Dermatitis

### Typical Symptoms

- Erythema is the most common symptom presented with a diaper rash. The rash may begin as light to medium pink with poorly defined edges, but may become dark red and raised lesions with distinct edges.
- Rashes generally appear in the folds of the skin around the diaper area, thighs, genitals, and buttocks.
- Other typical symptoms include irritation and pruritus.

### Atypical Symptoms

Patients presenting with the following symptoms may indicate the need for more aggressive antibiotic or antifungal therapy and should be referred to a physician for further evaluation:

- Rashes not responding to typical creams and concurrent nonpharmacologic treatment
- Rashes extending beyond the diaper region (upper abdomen, back)
- Formation of papules, bullae, and ulceration
- Excessive oozing
- Presence of genital discharge
- Concurrent fever
- Rashes appearing when diapers have not been used or rashes that fail to improve upon discontinuing diaper usage for extended periods of time (several days or more)
- Bleeding or open skin

### Diagnosis

The diagnosis of diaper dermatitis is clinical. The presence of *Candida albicans* can be determined by KOH testing or culture, but is generally not necessary.

- Washing the area with lukewarm water and mild soap and allowing to completely dry before applying a new diaper
- Use water and a cotton cloth or commercial "baby wipes" without coloring, fragrances, or other additives
- Keeping diapers loose and well ventilated
- Avoiding plastic pants over diapers
- Allowing infants to take naps on an open diaper or absorbent pad to promote drying and healing

## Pharmacologic Therapy

### ▶ Protectants

Protectants form an occlusive barrier between the skin and moisture from the diaper. Cream and ointment preparations are effective in providing a sufficient barrier in mild, irritant, and noninfected diaper rashes. For more severe cases, a paste is the topical agent of choice. Pastes are thicker and often contain additional ingredients (petrolatum, moisturizers) to decrease discomfort and promote healing.[38] Zinc oxide is one of the most commonly used topical protectants. In addition to forming an effective barrier against moisture, it has astringent and antiseptic properties that provide added symptom relief.[39]

Protectants are generally applied to the affected area after every diaper change and can be discontinued when the rash resolves. Other available protectants that can be used alone or in combination for the safe and effective treatment of diaper rash include white petrolatum, Vitamins A and D, lanolin, and topical cornstarch. Many agents contain a combination of occlusive and protective agents such as Triple Paste and Calmoseptine.

### ▶ Topical Steroids

Because of the increased permeability of their skin, infants are at risk for excessive absorption and toxicity from the use of topical steroids. Although effective in decreasing inflammation and relieving pruritus, steroid use in infants for the treatment of diaper dermatitis should be limited to only low-potency preparations.[42]

A thin layer of hydrocortisone cream (0.25%–1%) applied twice a day for no more than 2 weeks is an appropriate regimen. Use of higher potency steroids or use extending beyond 2 weeks should be at the discretion of a physician only.

### ▶ Antifungals

Diaper rashes lasting longer than 48 to 72 hours are at increased risk for the development of fungal infections. These complications are most frequently caused by *Candida albicans* and will require treatment with a topical antifungal.[38] (**Figure 65–5**.)

Adverse events with the use of topical antifungals are generally limited to local irritation at the site of application.

Nystatin, clotrimazole, and miconazole creams or ointments applied two to four times daily with diaper changes have all shown to be effective in the treatment of candidal diaper rash.[43] Although some of these products are available over the counter, parents and caregivers should be advised to initiate treatment with antifungal agents only after physician recommendation.

### ▶ Antibacterials

If conventional treatment fails, unresolved diaper rash can also lead to secondary bacterial infections. *Staphylococcus aureus* and

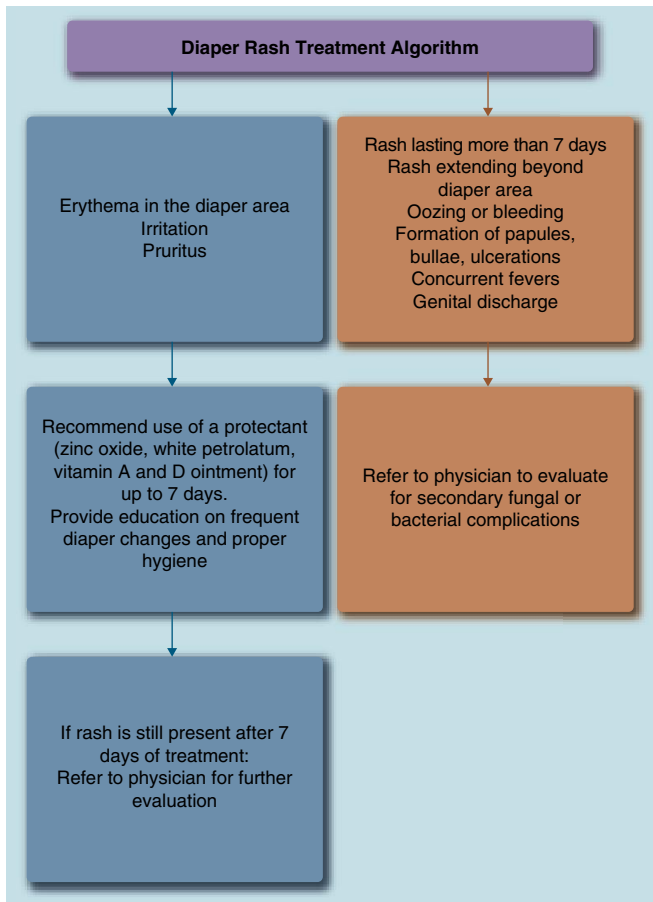
**FIGURE 65–5.** Candidiasis: diaper dermatitis. Confluent erosions, marginal scaling, and "satellite pustules" in the area covered by a diaper in an infant. (From Wolff K, Johnson RA. Cutaneous fungal infections. Fitzpatrick's Color Atlas & Synopsis of Clinical Dermatology. 5th ed. New York: McGraw-Hill; 2009: 723.)


**FIGURE 65–6.** Diaper dermatitis treatment algorithm.

*Streptococcus* are the most likely pathogens responsible for these infections and require treatment with systemic antibiotics.[38,40] While topical protectants may be used as an adjunct in treatment, suspected bacterial infections should always be referred to a physician for accurate diagnosis and the selection of an

appropriate antibacterial regimen.[39] **Figure 65–6** shows a useful algorithm for the effective treatment of diaper dermatitis.

## OUTCOME EVALUATION

Most diaper rashes can be effectively treated in less than 1 week. If symptoms do not resolve or begin to worsen, advise caregivers to seek medical attention to determine the presence of secondary fungal or bacterial infections. In addition, provide educational information on proper diaper hygiene techniques in order to prevent the development of future diaper rashes.

**Patient Encounter 3**

A woman presents to a community pharmacy inquiring about a product to purchase for her 4-month-old son who recently developed a rash in his diaper area. She says the rash has worsened from light pink to bright red. After further questioning, it is determined that the rash has lasted about 2 to 3 days, seems to be painful for her son when she cleans him with diaper wipes during changing. She has tried using white petrolatum a few times and is now concerned about the rash becoming infected.

*What reported symptoms support the diagnosis of diaper rash?*

*What additional information would aid in your assessment of this patient?*

*What are your treatment goals for this patient?*

*What nonpharmacologic and pharmacologic treatment options are available for this diagnosis?*

*Given the information presented, develop a treatment regimen for this patient that includes the following:*

*(a) A statement of the problem*

*(b) A patient-specific therapeutic plan*

*(c) Monitoring parameters to assess efficacy and safety*

## Patient Care Process: Diaper Dermatitis

**Patient Assessment:**

- Assess rash symptoms. Determine the level of severity—is there a possibility of a secondary fungal or bacterial infection?
- Identify signs and symptoms that require immediate physician referral.
- Inquire about the patient's history, including similar rashes in the past.
- Obtain patient allergy status.

**Therapy Evaluation:**

- Determine what treatment options, if any, have been tried and if they were successful.
- Discuss labs that may be necessary if a secondary infection is suspected (cultures, biopsies).

**Care Plan Development:**

- Discuss available barrier treatment options with the caregiver and develop a treatment plan.
- Include proper usage instructions and potential side effects in patient counseling.
- Educate the caregiver on the importance of frequent diaper changes and proper hygiene.
- Emphasize importance of treatment compliance and use of preventative measures

**Follow-Up Evaluation:**

- Provide any further patient education about diaper rash etiology, treatment, and prevention.
- Discuss symptoms to report to a physician (blistering, oozing, bleeding, changes in rash, or no improvement in symptoms within 2 to 3 days).

# Abbreviations Introduced in This Chapter

ACD    Allergic contact dermatitis
ICD    Irritant contact dermatitis

# 66 Anemia

Robert K. Sylvester

## INTRODUCTION

**KEY CONCEPT** *A**nemia** is a reduction in the concentration of hemoglobin (Hgb) that results in reduced oxygen-carrying capacity of the blood.* Some patients with anemia may be asymptomatic initially, but eventually, the lack of oxygen to tissues results in fatigue, lethargy, shortness of breath, headache, edema, and tachycardia. Common causes include blood loss, decreased red blood cell (RBC) production, and increased RBC destruction. Determination of the underlying cause of anemia is essential for successful management.

## EPIDEMIOLOGY AND ETIOLOGY

Anemia is a common diagnosis with a prevalence that varies widely based on age, gender, and race/ethnicity (**Table 66–1**).[1,2] Patients with specific comorbidities such as cancer and chronic kidney disease (CKD) have significantly higher rates of anemia. The incidence of anemia in cancer patients ranges from 30% to 90%.[3] Contributing factors include the underlying malignancy and myelosuppressive antineoplastic therapy.[4] The prevalence of anemia in patients with CKD ranges from 15% to 20% in patients with CKD stages 1 through 3 and up to 70% in patients with stage 5.[5]

A decrease in erythrocyte production can be multifactorial. Nutritional deficiencies (iron, vitamin $B_{12}$, and folic acid) are common causes and often easily treatable. Patients with cancer or CKD are at risk for developing anemia caused by dysregulation of iron and erythropoietin (EPO) hemostasis. Patients with chronic immune-related diseases such as rheumatoid arthritis and systemic lupus erythematosus are also at increased risk to develop anemia as a complication of their disease. Anemia related to chronic inflammatory conditions is termed anemia of chronic disease (ACD).[6]

Drug therapy is the mainstay of treatment for anemias caused by reduced RBC production and is the focus of this chapter; anemia due to destruction of erythrocytes will not be discussed.

## PATHOPHYSIOLOGY
### Erythropoiesis

Erythropoiesis begins with a pluripotent stem cell in the bone marrow undergoing differentiation and ends with the appearance of RBCs in peripheral blood. The production of RBCs is stimulated by EPO, a hormone secreted by the kidney in response to detection of decreased oxygen-carrying capacity of blood. EPO stimulates RBC production by stimulating differentiation of RBC precursors in the bone marrow to become **reticulocytes** (**Figure 66–1**). Reticulocytes become erythrocytes after 1 to 2 days in the bloodstream.[7]

### Decreased-Production Anemias
#### ▶ *Nutritional Deficiencies*

Deficiencies in folic acid and vitamin $B_{12}$ may hinder the process of erythrocyte maturation. Folic acid and vitamin $B_{12}$ are required for the formation of DNA. Significant decreases in the amount of either nutrient inhibits DNA synthesis and consequently RBC production.[7,8] Poor diet can contribute to folic acid and vitamin $B_{12}$ deficiencies. Pernicious anemia describes a severe anemia caused by the malabsorption of vitamin $B_{12}$ due to the absence of intrinsic factor, a glycoprotein produced by gastric parietal cells that binds to vitamin $B_{12}$ and facilitates its absorption in the ileum. This condition results in $B_{12}$ deficiency despite adequate dietary $B_{12}$ intake.[9]

Iron is also essential for RBC production. It is required for formation of Hgb. Lack of iron leads to a decrease in Hgb synthesis and decreased RBC production. Normal homeostasis of iron transport and metabolism is depicted in **Figure 66–2**.[10]

| Table 66–1 | |
|---|---|
| **Prevalence of Anemia[1,2]** | |
| Children (1–16 years) | 6%–9% |
| Males (16–69 years) | 2% |
| Males (85+ years) | 26% |
| Females (16–19 years) | 16% |
| Females (20–49 years, nonpregnant) | 12% |
|    White, non-Hispanic | 10% |
|    Black, non-Hispanic | 19% |
|    Mexican American | 22% |
| Females (85+ years) | 20.1% |

Approximately 1 to 2 mg of iron is absorbed through the duodenum daily, and the same amount is lost via blood loss, desquamation of mucosal cells, or menstruation.

Iron-deficiency anemia (IDA) typically occurs because of inadequate absorption of iron or excessive blood loss. Inadequate absorption may occur in patients who have congenital or acquired intestinal conditions, such as inflammatory bowel disease, celiac disease, or bowel resection. Achlorhydria and diets poor in iron, also may contribute to iron deficiency states. Iron deficiency also may occur following excessive iron loss. Common etiologies include excessive menstruation, ulcers or neoplastic lesions, and excessive bleeding following surgery or trauma.[10]

▶ *Dysregulation of Iron Homeostasis and Impaired Marrow Production*

Chronic diseases associated with ACD include infection, autoimmune disease, CKD, and cancer. A major contributing factor for development of ACD is disturbance of iron homeostasis related

**FIGURE 66–1.** The process of erythropoiesis.

**FIGURE 66–2.** The distribution of iron use in adults. (From Andrews NC. Disorders of iron metabolism. N Engl J Med. 1999;341:1986–1995.)

to activation of the immune system. Hepcidin is an acute-phase protein expressed in response to upregulation of interleukin-6 and exposure to lipopolysaccharide. Increased expression of hepcidin causes decreased iron absorption from the gastrointestinal (GI) tract and inhibition of iron release from macrophages. In addition, immune activation can cause upregulation of cytokines that impair the proliferation and differentiation of erythroid precursors. Decreased production and blunted responsiveness to EPO can also contribute to ACD; this is best documented in patients with CKD. Finally, disruption of erythropoiesis secondary to infiltration of the bone marrow by cancer can lead to anemia.[4–6]

## TREATMENT
### Desired Outcomes

KEY CONCEPT *The goal of anemia therapy is to increase Hgb to levels that improve red cell oxygen-carrying capacity, alleviate symptoms, and prevent complications from anemia.* Normal Hgb values are 14.0 to 17.5 g/dL (140–175 g/L or 8.69–10.9 mmol/L) for males and 12.3 to 15.3 g/dL (123–153 g/L or 7.63–9.50 mmol/L) for females. It is important to note that continuation of therapy should be assessed primarily by resolution of clinical symptoms. Patients who experience a resolution in their symptoms (eg, shortness of breath, tachycardia, fatigue, dizziness,) may not require aggressive therapy to maintain their Hgb values within normal limits. Hypoxia and cardiovascular sequelae due to anemia can be avoided if Hgb levels are greater than 7.0 g/dL (70 g/L or 4.34 mmol/L).[11]

### General Approach to the Anemic Patient

KEY CONCEPT *The underlying cause of anemia must be determined and used to guide therapy. A complete blood count (CBC) is the laboratory evaluation that provides objective characteristics of RBCs useful in determining etiology and appropriate treatment.*

## Clinical Presentation and Diagnosis of Anemia

### Signs and Symptoms

Generally, the signs and symptoms of anemia are nonspecific and may include the following:

- Fatigue, lethargy, dizziness
- Shortness of breath
- Headache
- Edema
- Tachycardia

Other findings that may be present in some patients include:

- Dry skin, chapped lips
- Nail brittleness
- Hunger for ice, starch, or clay (termed pica)

### Past Medical History

Inquire about the following conditions:

- History of blood loss, such as hemorrhoids, melena, or menorrhagia (IDA)
- Malnourished or recent weight loss (vitamin $B_{12}$ or folate deficiency)
- Alcoholism (folate deficiency)
- Cancer or chronic kidney disease (CKD)
- Chronic autoimmune disorders or infections, such as HIV infection or rheumatoid arthritis (anemia of chronic disease)

### Physical Examination

These findings aid the clinician in determining the severity of the anemia:

- Orthostatic hypotension and tachycardia secondary to volume depletion
- Cutaneous changes such as pallor, jaundice, and nail brittleness

### Laboratory Evaluation

Table 66–2 describes common tests used to determine the etiology of anemia. A diagnostic and treatment algorithm for anemia is outlined in Figure 66–3.

1. A CBC is a necessary first step in evaluating a patient with anemia. If the Hgb and Hct are less than the normal range, the patient is anemic. Subsequent evaluations of RBC indices and the peripheral smear often are necessary to determine the etiology (and ultimately, the treatment) of the anemia.

2. Evaluating the mean corpuscular volume (MCV) is the next step in an anemia workup. It is classified as microcytic, normocytic, or macrocytic if the MCV is below, within, or above the normal range of 80 to 96 fL/cell, respectively.

### Microcytic Anemia and Iron Evaluation

Iron studies (see Table 66–2) should be evaluated in the setting of a low MCV. These include:

- Serum iron
- Serum ferritin—the best indirect determinant of body iron stores. It is commonly decreased in patients with IDA
- Total iron-binding capacity (TIBC)—quantifies the iron-binding capacity of transferrin and is increased in IDA
- Transferrin saturation (serum iron/TIBC)—indicates the amount of transferrin that is bound with iron; it is lower in IDA

### Macrocytic Anemia

- Evaluate folic acid and vitamin $B_{12}$ levels in the setting of an elevated MCV
- Further investigation by administering radiolabeled $B_{12}$ (ie, Schilling test) to determine if lack of intrinsic factor

### Normocytic Anemia

- Evaluate reticulocytes and CBC
- High reticulocyte counts may indicate RBCs loss via acute blood loss, hemolysis, or splenic sequestration
- Low serum iron with normal to increased ferritin consistent with ACD

---

### Patient Encounter 1, Part 1

A 27-year-old African American woman scheduled a prenatal visit after a positive home pregnancy test. Previous pregnancies and deliveries were uncomplicated; she has healthy children ages 1.5 and 3 years. No other significant past medical history. Earlier this week she states feeling dizzy and short of breath after walking up stairs.

*What aspects of this patient's history suggest she may be anemic?*

*What laboratory assessments are required to make an appropriate diagnosis and therapeutic plan?*

*How would the requested laboratory parameter(s) aid your decision making?*

*The mean corpuscular volume and determination of iron, ferritin, folate, and vitamin $B_{12}$ levels are required to correctly diagnose a patient's anemia.* Figure 66–3 and Table 66–2 illustrate how laboratory test results determine the correct diagnosis.

### Nonpharmacologic Therapy

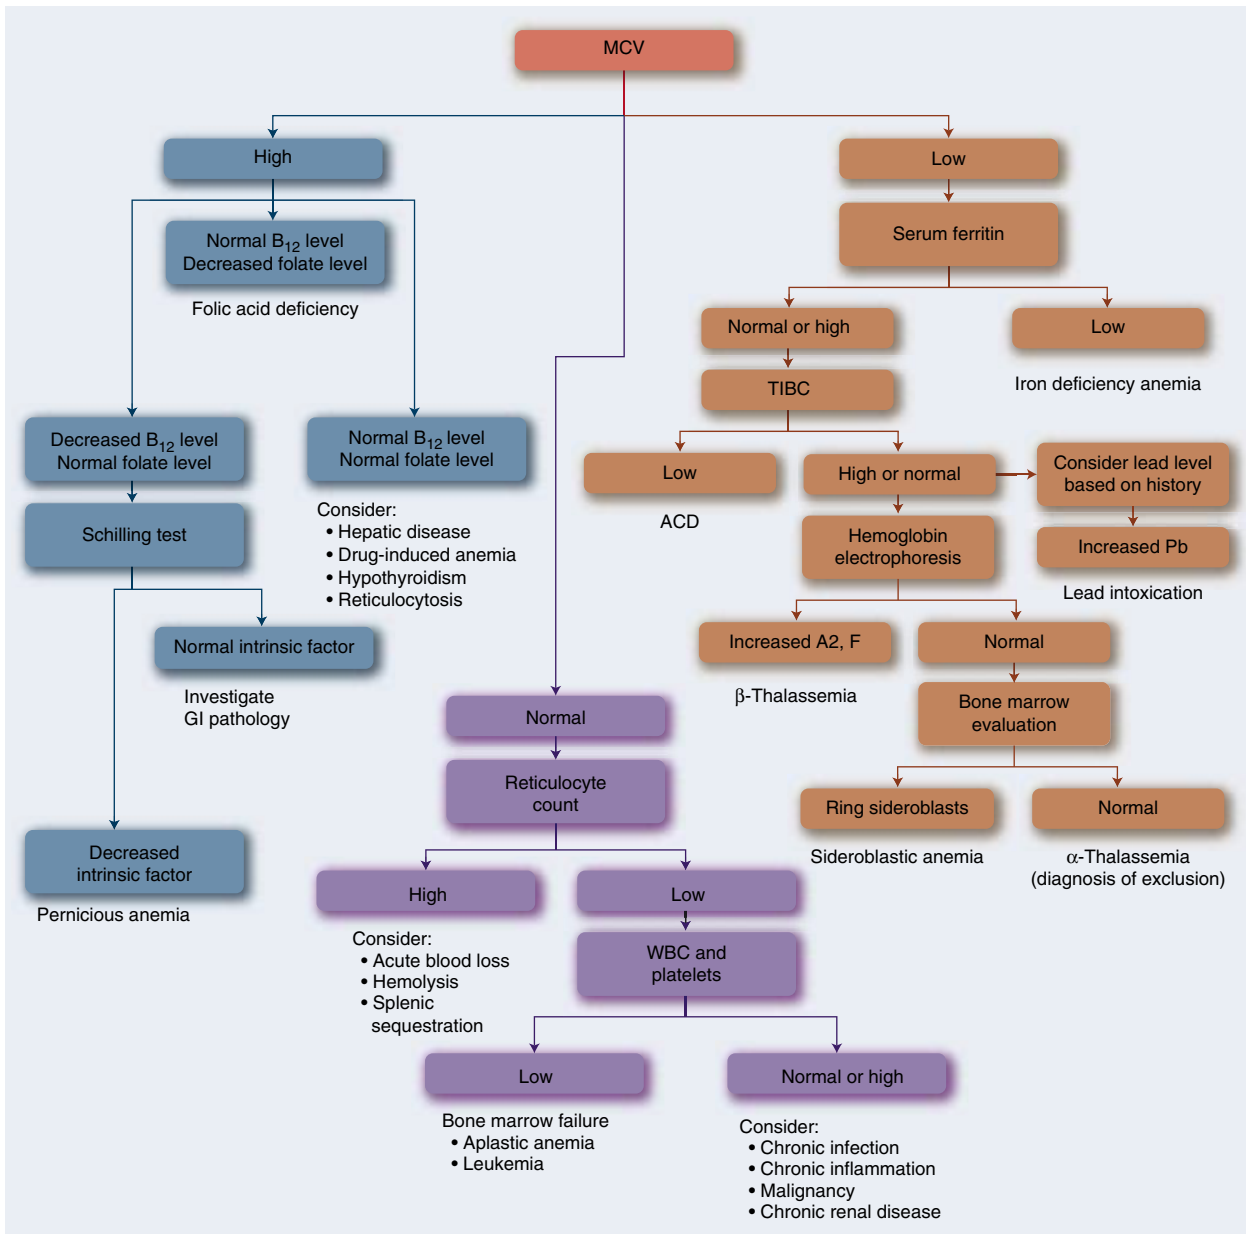
The primary nonpharmacologic treatment of anemia is transfusion of RBCs. Safety concerns, cost, and the limited availability of this therapy support efforts to establish the "optimum" threshold for administering RBC transfusions. A Cochrane review concluded it is appropriate to use "restrictive transfusion triggers in patients free of serious cardiac disease." The authors concluded a reasonable "trigger for transfusion" for patients without significant cardiovascular disease is 7.0 g/dL (70 g/L or 4.34 mmol/L).[12] The Transfusion Requirements In Critical Care trial reported no significant differences in in-hospital mortality between patients


**FIGURE 66–3.** The anemia evaluation process. ACD, anemia of chronic disease; MCV, mean corpuscular volume; Pb, lead; TIBC, total iron-binding capacity. A2, hemoglobin A2 type; F, hemoglobin F type.

randomly assigned to maintain Hgb levels of 7.0 to 9.0 g/dL (70–90 g/L or 4.34–5.59 mmol/L) and 10.0 to 12.0 g/dL (100–120 g/L or 6.21–7.45 mmol/L).[13] Typically, only patients with acute symptoms (ie, dyspnea, chest pain) and Hgb concentrations in the range of 7.0 to 9.0 g/dL (70–90 g/L or 4.34–5.59 mmol/L) require blood transfusions.

Anemia can be attributed to diets poor in iron, folic acid, or vitamin $B_{12}$. However, in the United States, nutrient-poor diets rarely cause anemia. Therefore, ingesting a diet that is rich in iron, folic acid, or vitamin $B_{12}$ should be encouraged, but is rarely the sole modality of treatment. Food sources of iron, folic acid, and vitamin $B_{12}$ are listed in Table 66–3.[8]

## Pharmacologic Therapy

### ▶ *Iron-Deficiency Anemia*

**KEY CONCEPT** *The initial treatment of IDA is oral iron therapy that provides 150 to 200 mg of elemental iron daily.* Many different

iron products and salt forms are available. Table 66–4 lists commonly prescribed oral iron products and the amount of elemental iron provided by each.

Iron supplementation resolves anemia by replenishing iron stores to levels necessary for RBC production and maturation. Reticulocytosis should occur in 7 to 10 days, and Hgb values should rise by about 1.0 g/dL (10 g/L or 0.62 mmol/L) per week. Patients should be reassessed if Hgb does not increase by 2.0 g/dL (20 g/L or 1.24 mmol/L) in 3 weeks.[14]

The preferred regimen for oral iron is 50 to 65 mg of elemental iron two to three doses daily on an empty stomach. Administration on an empty stomach (1 hour before or 2 hours after a meal) is preferred for maximal absorption. If patients develop intolerable GI side effects (ie, heartburn, nausea, bloating) after taking iron on an empty stomach, they should be advised to take it with meals. After absorption, iron binds to transferrin in the plasma and is transported to the muscles (for myoglobin), liver

**Table 66–2**

**Pertinent Laboratory Tests in the Evaluation of Anemia**

| Test Name | Normal Range | Description/Significance |
|---|---|---|
| **CBC** | | |
| Hgb | Males: 14.0–17.5 g/dL (140–175 g/L or 8.69–10.9 mmol/L)<br>Females: 12.3–15.3 g/dL (123–153 g/L or 7.63–9.50 mmol/L) | Amount of Hgb in the blood; signifies oxygen-carrying capacity of the blood and determines whether a patient is anemic |
| Hct | Males: 40.7%–50.3% (0.407–0.503)<br>Females: 36.1%–44.3% (0.361–0.44.3) | The percent of blood that the erythrocytes encompass; also indicates anemia; the Hgb is measured, and the Hct is calculated |
| RBC | Males: 4.5–5.9 × $10^6$ cells/μL (4.5–5.9 × $10^{12}$ cells/L)<br>Females: 4.1–5.1 × $10^6$ cells/μL (4.1–5.1 × $10^{12}$ cells/L) | The number of erythrocytes in a volume of blood; also indicates anemia, but seldom used |
| **RBC Indices** | | |
| MCV | 80–97.6 μm³/cell (80–97.6 fL/cell) | A widely used laboratory value to measure RBC "size"; higher values indicate macrocytosis and lower values indicate microcytosis |
| MCH | 27–33 pg/cell | Amount of Hgb per RBC; may be decreased in IDA |
| MCHC | 32–36 g/dL (320–360 g/L) | Hgb divided by the Hct; also low in IDA |
| **Iron Studies** | | |
| Serum iron | | Measures amount of iron bound to transferrin; low in IDA |
| Males | 45–160 mcg/dL (8.1–28.6 μmol/L) | |
| Females | 30–160 mcg/dL (5.4–28.6 μmol/L) | |
| Serum ferritin | | Ferritin is the protein–iron complex found in macrophages used for iron storage; low in IDA |
| Males | 20–250 ng/mL (20–250 mcg/L; 45–562 pmol/L) | |
| Females | 10–150 ng/mL (10–150 mcg/L; 22–337 pmol/L) | |
| TIBC | 220–420 mcg/dL (39.4–75.2 μmol/L) | Measures the capacity of transferrin to bind iron; high in IDA |
| TSAT | 15%–50% (0.15–0.50) | TSAT(%) = (serum iron/TIBC) × 100; a saturation of less than 15% (0.15) is common in IDA |
| **Other Tests** | | |
| RBC distribution width (RDW) | 11.5%–14.5% (0.115–0.145) | A higher value means the presence of many different sizes of RBCs; the MCV is therefore less reliable |
| Reticulocyte count | | Should be elevated in patients who are responding to treatment |
| Males | 0.5%–1.5% of RBCs (0.005–0.015) | |
| Females | 0.5%–2.5% of RBCs (0.005–0.025) | |
| Folic acid (plasma) | 3.1–12.4 ng/mL or mcg/L (7.0–28.1 nmol/L) | Used to determine folic acid deficiency |
| Folic acid (RBC) | 125–600 ng/mL (283–1360 nmol/L) | Used to determine folic acid deficiency |
| Vitamin $B_{12}$ | 180–1000 pg/mL (133–738 pmol/L) | Used to determine vitamin $B_{12}$ deficiency |
| EPO level | 2–25 mIU/mL (2–25 IU/L) | Patients may benefit from EPO therapy if they are anemic and EPO levels are normal or mildly elevated |

EPO, erythropoietin; Hct, hematocrit; Hgb, hemoglobin; IDA, iron-deficiency anemia; MCH, mean cell hemoglobin; MCHC, mean cell hemoglobin concentration; MCV, mean cell volume; RDW, RBC distribution width; TIBC, total iron-binding capacity; TSAT, transferrin saturation.

(for storage), or bone marrow (for red cell production). Common toxicities associated with oral iron include abdominal pain, nausea, heartburn, constipation, and dark stools.[14] Potentially clinically significant drug interactions involving iron products include fluoroquinolones, tetracyclines, eltrombopag, and mycophenolate mofetil. Iron decreases the absorption of these drugs. The absorption of iron is influenced by gastric acidity. Limited data support drugs that decrease gastric acidity (antacids, proton pump inhibitors, and $H_2$-receptor antagonists) may impair the absorption of iron. If concurrent administration cannot be avoided, to minimize this effect oral iron should be administered at least several hours before or after the affected drug.

**Table 66–3**

**Food Sources of Iron, Folic Acid, or Vitamin $B_{12}$**

| Nutrient | Food Sources |
|---|---|
| Iron | Red meat, organ meats, wheat germ, egg yolks, oysters |
| Folic acid | Green vegetables, liver, yeast, fruits |
| Vitamin $B_{12}$ | Animal by-products, legumes |

**Table 66–4**

[a]From FDA product labeling.

[b]From Auerbach M, Ballard H. Clinical use of intravenous iron: Administration, efficacy and safety. Hematology Am Soc Hematol Educ Program 2010:338–347.

Parenteral iron therapy is indicated when patients cannot tolerate oral formulations, are noncompliant, or fail to respond to oral iron because of malabsorption syndromes. Six parenteral iron formulations are available in the United States.[15–20] Table 66–5 provides details pertinent to the use of these products. The iron dextran products available in the United States differ markedly. As noted Dexferrum (the high-molecular-weight [HMW] product) is associated with a much higher incidence of life-threatening adverse effects, typically anaphylactic-like reactions. This significant difference in safety has resulted in recommendations that the use of HMW iron dextran (ID) be abandoned.[21,22] Although total dose infusion (TDI) is not an approved method of administration in the United States, low-molecular-weight ID is approved for TDI in Europe. TDI administration has been shown to achieve similar patient outcomes while lowering cost. Sodium ferric gluconate complex, iron sucrose, ferumoxytol, and ferric carboxymaltose received FDA labeling for the treatment of patients with anemia and CKD in the last decade.[15–20] Although the occurrence of life-threatening adverse events caused by

parenteral iron is extremely low, the absolute rate of life-threatening events is substantially higher for HMW ID.[21,22] Table 66–5 provides details pertinent to the use of these products.

The dose of iron dextran is calculated by the following equation: dose (mL) = 0.0442 (desired Hgb – observed Hgb) × body weight + (0.26 × body weight). The body weight that should be used is lean body weight for adults and children weighing more than 15 kg and actual body weight for children weighing 5 to 15 kg. Hemoglobin should be expressed units of g/dL (hemoglobin expressed in g/L × 0.10, or mmol/L × 1.61).The dose in milligrams can be calculated based on a standard concentration of 50 mg of elemental iron per milliliter.[15] Prescribing information recommends administering iron dextran in 100-mg aliquots daily until the total dose is achieved. However, anecdotal evidence reports that the total calculated dose can be administered safely over 4 to 6 hours in 1 day. Because of the risk of anaphylaxis, a test dose of iron dextran (0.5 mL over at least 30 seconds) must be administered to patients before their first dose of iron dextran. Patients should be monitored for signs of anaphylaxis

## Patient Encounter 1, Part 2

Laboratory parameters are ordered, and the following is reported

**CBC**

- WBC: $6.50 \times 10^3/\mu L$ ($6.50 \times 10^9/L$)
- Hgb: 8.3 g/dL (83 g/L; 5.15 mmol/L)
- Hct: 24.8% (0.248)
- Plt: $210 \times 10^3/\mu L$ ($210 \times 10^9/L$)

**Red Blood Cell Indices**

- MCV: $103.4 \ \mu m^3$ (103.4 fL)
- MCH: 28.4 pg/cell
- MCHC: 35.3 g/dL (353 g/L; 21.9 mmol/L)

**Others**

- RBC count: $3.6 \times 10^6/\mu L$ ($3.6 \times 10^{12}/L$)
- RDW: 22% (0.22)

**Iron Studies**

- Serum iron: 100 mcg/dL (17.9 μmol/L)
- Serum ferritin: 123 ng/L (123 mcg/L; 276 pmol/L)
- TIBC: 300 mcg/dL (53.7 μmol/L)
- Transferrin saturation: 36% (0.36)

**B$_{12}$ and Folate**

- Serum folate: 2.3 ng/mL (5.2 nmol/L)
- Serum B$_{12}$: 496 pg/mL (366 pmol/L)

*Is this a macrocytic or microcytic anemia?*

*Specifically, what is the etiology of the anemia?*

*Recommend the most appropriate drug regimen (drug, dosage form, and schedule).*

## Patient Encounter 1, Part 3

The patient is diagnosed with folic acid deficiency anemia and is started on a generic prenatal vitamin containing l mg of folic acid. Follow-up CBC 1 month later reveals Hgb of 10 g/dL (100 g/L or 6.2 mmol/L), previously 8.3 g/dL (83 g/L or 5.15 mmol/L). The patient reports no shortness of breath or dizziness in the past 2 weeks. She also states she occasionally misses doses due to her hectic days.

*What hemoglobin level would constitute a therapeutic response in this patient?*

*How can compliance be improved in this patient?*

for at least 1 hour before administering the total dose. Other adverse effects include arthralgias, arrhythmias, hypotension, flushing, and pruritus.[20]

### ▶ Vitamin B$_{12}$ and Folic Acid Anemia

KEY CONCEPT *Anemia from vitamin B$_{12}$ or folic acid deficiency is treated by replacing the missing nutrient.* Both folic acid and vitamin B$_{12}$ are essential for erythrocyte production and maturation.

Oral and parenteral vitamin B$_{12}$ (cyanocobalamin) replacement therapies are equally effective. Vitamin B$_{12}$ is absorbed completely following parenteral administration, whereas oral vitamin B$_{12}$ is absorbed poorly via the GI tract. Consequently, cyanocobalamin is commonly administered as an intramuscular or subcutaneous injection of 1000 mcg/day for 1 week, followed by 1000 mcg/week for a month or until the Hgb normalizes. Life-long maintenance therapy (1000 mcg/month) is required for patients with pernicious anemia or surgical resection of the terminal ileum. If the etiology was a dietary deficiency or reversible malabsorption syndrome, treatment can be discontinued after the underlying cause is corrected and vitamin B$_{12}$ stores normalized. A common oral dosing regimen is from 1000 to 2000 mcg/day. If parenteral cyanocobalamin is used initially, oral vitamin B$_{12}$ can be useful as maintenance therapy. Typically, resolution of neurologic symptoms, disappearance of megaloblastic RBCs, and increased Hgb levels occur within a week of therapy.

Vitamin B$_{12}$ is well tolerated. Reported adverse effects include injection-site pain, pruritus, and rash. Clinical significance of decreases in protein-bound cyanocobalamin related to proton pump inhibitor therapy has not been established.[23]

The effective dose of folic acid is 1 mg/day by mouth. Absorption of folic acid is rapid and complete. However, patients with malabsorption syndromes may require doses up to 5 mg/day. Resolution of symptoms and reticulocytosis occurs within days of commencing therapy. Typically a patient's Hgb will start to rise after 2 weeks of therapy and normalize after 2 to 4 months of therapy.

Folic acid is well tolerated. Nonspecific adverse effects include allergic reactions, flushing, and rash. A small study evaluating the effect of folic acid doses of 10 mg/day on phenytoin levels reported decreased phenytoin levels in 3 of 4 subjects. However, the occurrence of this interaction at folic acid doses of 1 mg/day has not been reported.[23]

### ▶ Anemia of Chronic Disease

KEY CONCEPT *Decreased RBC transfusion requirements is an outcome achieved in patients with ACD treated with the erythropoietin stimulating agent (ESAs). However, in 2007, the FDA product labeling for epoetin and darbepoetin were revised to include new data documenting safety concerns.* Subsequently, the Centers for Medicare and Medicaid Services (CMS) implemented more restrictive ESA coverage determination guidelines. In 2010, the FDA implemented a risk evaluation and mitigation strategy (REMS) for ESAs administered to treat patients with cancer who are undergoing chemotherapy. Table 66–6 summarizes the FDA-labeled dosing regimens for patients whose anemia is related to cancer chemotherapy, CKD, or zidovudine treatment.

**Anemia Due to Chemotherapy in Patients with Cancer** Epoetin, a recombinant human EPO, and darbepoetin, a synthetic EPO analog, bind to the EPO receptors on RBC precursor cells in the bone marrow and result in increased RBC production. Darbepoetin differs from epoetin in that it is a glycosylated protein and exhibits a longer half-life, allowing for a longer dosing interval. Clinical practice guidelines consider epoetin and darbepoetin to be therapeutic equivalents.[4,25] KEY CONCEPT *ESAs should only be used to prevent a transfusion and should not be initiated unless the hemoglobin is less than 10.0 g/dL (100 g/L, 6.21 mmol/L) and chemotherapy is planned for a minimum of two additional months.* ESA-labeled dosing regimens for treatment of patients receiving chemotherapy are summarized in Table 66–6.

Postmarketing outcome data documented that patients administered ESAs experienced increased thrombotic events and

[a]Indications and dosage regimens per FDA product labeling.

[b]for patients on dialysis.

[c]for patients not on dialysis.

[d]FDA labeled indication for Procrit (epoetin-α), not Epogen (epoetin-α) or darbepoetin.

shorter progression-free and overall survival.[24] ESAs increased on study mortality (combined hazard ratio [cHR] 1.17; 95% confidence interval [CI] 1.06–1.30) and worsened overall survival (cHR 1.06; 95% CI 1.00–1.12). This corresponds to a 17% increased risk of mortality for patients treated with ESAs while on study and a 6% increase overall. Based on these data, the FDA revised ESA product labeling, restricting their administration to patients with chemotherapy-induced anemia without a curative intent. The 2010 update of the American Society of Clinical Oncology/American Society of Hematology clinical practice guideline on the use of ESAs in patients with cancer

adopted FDA recommendations for more restrictive use of ESA in patients with cancer.[25]

CMS published more restrictive coverage criteria for ESA treatment of anemia associated with cancer chemotherapy in 2008. Patients should be monitored every 4 weeks. If Hgb has not increased by 1.0 g/dL (10 g/L, 0.62 mmol/L) after 4 weeks and remains less than 10.0 g/dL (100 g/L, 6.21 mmol/L), a one-time dose escalation of 25% is appropriate. If Hgb increases by more than 1.0 g/dL (10 g/L, 0.62 mmol/L), or is more than 10.0 g/dL (100 g/L, 6.21 mmol/L), the ESA should be discontinued. At 8 weeks if Hgb has increased by 1 g/dL (10 g/L, 0.62 mmol/L) but remains less than 10.0 g/dL(100 g/L, 6.21 mmol/L), continued ESA administration is covered. However, if after 8 weeks Hgb fails to increase by 1 g/dL (10 g/L, 0.62 mmol/L), CMS payment of therapy is not covered. CMS covers ESA therapy for up to 8 weeks after completion of chemotherapy for patients achieving respones.[26]

"Functional" iron deficiency exists when total iron stores are normal or increased but disruption of iron homeostasis prevents utilization of the stored iron for erythropoiesis.

"Functional" iron deficiency has been described in patients with ACD. Therefore, it is imperative that patients starting ESA therapy have laboratory studies performed to assess iron stores. If results document a patient has suboptimal iron stores, iron replacement therapy is indicated.

**Anemia Due to CKD**  Anemia is common in patients with CKD. Early treatment of anemia in patients with CKD on dialysis has been associated with slower disease progression and lower risk of death. It is essential to evaluate and treat anemia in patients before they progress to stage 5 CKD (glomerular filtration rate [GFR] of less than 15 mL/min/1.73 m$^2$ [0.14 mL/s/m$^2$]).[27]

Patients with CKD typically develop normocytic, normochromic anemia as a result of EPO deficiency. However, a thorough workup of anemia should be performed to rule out other etiologies.[27] Regardless, ESA therapy is effective in treating CKD anemia. The National Kidney Foundation Clinical Practice Recommendations 2007 update recommend a Hgb target range of 11.0 to 12.0 g/dL (110–120 g/L or 6.83–7.45 mmol/L) in dialysis and nondialysis patients.[27] However, in June 2011, the FDA notified health care providers that the target Hgb range in patients with CKD was lowered to 11.0 g/dL (110 g/L or 6.83 mmol/L) in patients on hemodialysis and to 10.0 g/dL (100 g/dL or 6.21 mmol/L) in CKD patients not on hemodialysis.[28] This revision was adopted to decrease the risk of serious adverse

## Patient Care Process

**Patient Assessment:**

- Based on physical exam and review of systems, determine if the patient exhibits signs or symptoms of anemia.
- Review CBC, if anemia present, assess RBC indices to determine if microcytic, normocytic, or macrocytic.
- Determine whether transfusion or pharmacotherapy is indicated.
- Assess iron, folic acid, and vitamin $B_{12}$ studies to determine etiology of anemia.
- When initiating ESAs, assess the patient's iron status.
- Initiate appropriate therapy.

**Therapy Evaluation:**

- Monitor symptoms such as fatigue, shortness of breath, lethargy, headache, edema, and tachycardia for resolution.

**Care Plan Development:**

- Discuss importance of medication adherence.

**Follow-Up Evaluation:**

- Follow up monthly to assess efficacy and tolerance of therapy until resolution of symptoms and Hgb goal achieved.
- Monitor the CBC monthly.
- Monitor side effects of therapy, such as
  - Oral iron: nausea, vomiting, abdominal pain, heartburn, constipation, and dark stools
  - Parenteral iron: anaphylaxis (test dose required for iron dextran and observe for 1 hour after), injection-site pain/irritation, arthralgias, myalgias, flushing, malaise, and fever
  - Folic acid: bad taste and nausea, rash, and allergic reactions
  - Vitamin $B_{12}$: pain and erythema at injection site
  - ESAs: hypertension (monitor blood pressure), thrombosis (eg, deep vein thrombosis/pulmonary embolism, myocardial infarction, cerebrovascular accident, and transient ischemic attack), arthralgias, and headache

cardiovascular events. ESA-labeled dosing regimens for patients with CKD are summarized in Table 66–6.

Although EPO deficiency is the primary cause of CKD anemia, iron deficiency may also exist. Iron stores in patients with CKD should be maintained so that transferrin saturation is greater than 20% (0.20) and serum ferritin is greater than 100 ng/mL (100 mcg/L or 225 pmol/L). If iron stores are not maintained appropriately, epoetin or darbepoetin will not be effective. Most CKD patients will require iron supplementation.[27]

**Anemia Due to Zidovudine in HIV-Infected Patients** Early clinical trials evaluating the efficacy of zidovudine in patients with HIV documented that nearly 50% of patients treated with zidovudine develop anemia requiring RBC transfusions. Subsequently, results from numerous clinical trials reported that epoetin resulted in statistically significant decreases in transfusion requirements for patients with serum EPO levels less than 500 mUnits/mL (500 U/L). Currently, epoetin has a labeled indication for the treatment of anemia in patients with EPO levels less than 500 mUnits/mL (500 U/L) and administered zidovudine doses less than 4200 mg/week.[32]

### OUTCOME EVALUATION

`KEY CONCEPT` *Patients should be monitored for Hgb response, symptom resolution, and adverse effects at appropriate intervals, and treatment regimens adjusted accordingly.* The goal of anemia therapy is to correct the underlying etiology of the anemia, normalize the Hgb, and alleviate associated symptoms.

- To ensure response for patients with IDA, monitor CBC with special attention to occurrence of reticulocytosis and iron studies.
- A 1.0-g/dL (10 g/L or 0.62 mmol/L) per week increase in Hgb is desirable in patients with IDA. Reevaluate patients with increases less than 2.0 g/dL (20 g/L or 1.24 mmol/L) in 3 weeks.
- For patients with folic acid deficiency, monitor Hgb periodically and reevaluate patients who fail to normalize Hgb levels after 2 months of therapy.

- For patients with vitamin $B_{12}$ deficiency, monitor for resolution of neurologic symptoms (ie, confusion and paresthesias), if applicable, and Hgb levels weekly until the levels normalize.
- For patients treated with chemotherapy, initiate ESA treatment when Hgb levels are less than 10.0 g/dL (100 g/L or 6.21 mmol/L) and monitor Hgb levels weekly. If Hgb increases exceed 1.0 g/dL (10 g/L or 0.62 mmol/L) or exceed 10.0 g/dL (100 g/L or 6.21 mmol/L), hold therapy until the level drops below 10.0 g/dL (100 g/L or 6.21 mmol/L). Restart the ESA at the lowest dose sufficient to reduce transfusions.
- For patients with CKD on dialysis, initiate ESA treatment when Hgb levels are less than 10.0 g/dL (100 g/L or 6.21 mmol/L) and monitor Hgb levels weekly. If Hgb levels approach or exceed 11.0 g/dL (110 g/L or 6.83 mmol/L), reduce or hold further doses until the level drops below 10.0 g/dL (100 g/L or 6.21 mmol/L). Restart the ESA at the lowest dose sufficient to reduce transfusions.
- For patients with CKD not on dialysis, initiate ESA treatment when Hgb levels are less than 10.0 g/dL (100 g/L or 6.21 mmol/L) and monitor Hgb levels weekly. If Hgb levels exceed 10.0 g/dL (100 g/L or 6.21 mmol/L), reduce or hold further doses until the level drops below 10.0 g/dL (100 g/L or 6.21 mmol/L). Restart the ESA at the lowest dose sufficient to reduce transfusions.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| CFU-E | Erythroid colony-forming unit |
| CKD | Chronic kidney disease |
| EPO | Erythropoietin |
| ESA | Erythropoietin stimulating agent |
| GFR | Glomerular filtration rate |
| GM-CSF | Granulocyte-monocyte colony-stimulating factor |
| Hct | Hematocrit |
| Hgb | Hemoglobin |

| IDA | Iron-deficiency anemia |
| IL-3 | Interleukin 3 |
| MCV | Mean corpuscular volume |
| MCH | Mean corpuscular hemoglobin |
| TIBC | Total iron-binding capacity |

# Coagulation and Platelet Disorders

Anastasia Rivkin and Sandeep Vansal

---

## LEARNING OBJECTIVES

**Upon completion of this chapter, the reader will be able to:**

1. Describe the basics of the regulation of hemostasis and thrombosis.
2. Select appropriate nonpharmacological and pharmacological therapy for a patient with hemophilia in a given clinical situation and patient-specific scenario.
3. Calculate an appropriate factor-concentrate dose for a product, given the percentage correction desired based on clinical situation.
4. List possible complications from hemophilia bleeding episodes.
5. Choose an appropriate treatment strategy for patients with factor VIII or IX inhibitors.
6. Devise a treatment plan for a patient with a specific variant of von Willebrand disease.
7. Describe various recessively inherited coagulation disorders (RICDs) and role of specific factor replacement in RICD management.
8. Recommend first-line and a second-line treatment approaches for immune thrombocytopenic purpura.
9. Identify basic clinical features, causes, and management of thrombotic thrombocytopenic purpura.

---

## INTRODUCTION

### Components of the Hemostatic System

Following endothelial injury, vessel-wall response involves vasoconstriction, platelet plug formation, coagulation, and **fibrinolysis** regulation. In normal circumstances, platelets circulate in the blood in an inactive form. After injury, platelets undergo activation, which consists of (a) adhesion to the subendothelium, (b) secretion of granules containing chemical mediators (eg, adenosine diphosphate, thromboxane A2, thrombin, etc), and (c) aggregation. Chemical factors released from the injured tissue and platelets stimulate the coagulation cascade and thrombin formation. In turn, thrombin catalyzes the conversion of fibrinogen to fibrin and its subsequent incorporation into the platelet plug.

The coagulation system consists of intrinsic and extrinsic pathways. Both pathways are composed of a series of enzymatic reactions that ultimately produce thrombin, fibrin, and a stable clot. In parallel with the coagulation, the fibrinolytic system is activated locally. Plasminogen is converted to plasmin, which dissolves the fibrin mesh (**Figure 67–1**).[1]

## INHERITED COAGULATION DISORDERS

### HEMOPHILIA

#### Etiology and Epidemiology

Hemophilia A and B are coagulation disorders that result from defects in the genes encoding for plasma coagulation proteins. Hemophilia A (classic hemophilia) is caused by the deficiency of factor VIII, and hemophilia B (Christmas disease) is caused by the deficiency of factor IX. The incidences of hemophilia A and B are estimated at 1 in 5000 and 1 in 30,000 male births, respectively. Both types of hemophilia are evenly distributed across all ethnic and racial groups.[1]

#### Pathophysiology

The pathophysiology of hemophilia is based on the deficiency of factor VIII or IX resulting in inadequate thrombin generation and an impaired intrinsic-pathway coagulation cascade (see Figure 67–1). Factor VIII and IX genes are located on the X chromosome. Hemophilias are recessive X-linked diseases. Generally, affected males carrying either defective allele on their X chromosome do not transmit the gene to their sons. However, their daughters are obligate carriers. More than 1000 mutations in factor VIII and IX genes have been identified to cause clinical hemophilia.[2]

Consequently, hemophilia is not a result of a single genetic mutation. However, inversion at intron 22 of the factor VIII gene accounts for 40% of severe hemophilia A cases. Owing to the high incidence, this mutation is used for carrier and prenatal testing.[3]

#### Complications of Hemophilia

The severity of bleeding associated with hemophilia correlates with the degree of factor VIII or factor IX deficiency as measured against the normal plasma standard. **Table 67–1** summarizes the age at onset and laboratory and clinical manifestations of hemophilia A and B.[4]
**FIGURE 67–1.** Cascade model of coagulation demonstrates activation via the intrinsic or extrinsic pathway. This model shows successive activation of coagulation factors proceeding from the top to the bottom where thrombin and fibrin are generated. (PK, prekallikrein; HK, high–molecular weight kininogen; TF, tissue factor.) (From Roberts HR et al. Molecular biology and biochemistry of the coagulation factors and pathways of hemostasis. ## Treatment

### ▶ *Desired Outcomes*

Currently, there is no cure for hemophilia A or B. The life expectancy of hemophiliacs was only 8 to 11 years in the 1920s and 1930s. With the development of effective treatment strategies, life expectancy is currently about 63 to 75 years, or nearly that of the normal population.[5]

The short-term goals of hemophilia treatment are to:

- Decrease the number of bleeding episodes per year or bleeding frequency
- Normalize or improve clotting factor concentrate levels

The long-term goals of hemophilia treatment are to:

- Maintain clinical joint function
- Normalize orthopedic joint score
- Normalize radiologic joint score
- Maintain quality-of-life measurements

### ▶ *General Approach to Treatment*

**KEY CONCEPT** *Intravenous factor replacement with recombinant or plasma-derived products to treat or prevent bleeding is the primary treatment of hemophilia.* Primary prophylaxis is defined as the regular administration of factor concentrates with the intention of preventing joint bleeds.[6] The rationale for primary prophylaxis is that individuals with factor levels of greater than 0.02 IU/mL (20 IU/L) rarely suffer from spontaneous bleeds and arthropathy. Therefore, to maintain a trough level above this might convert "severe" hemophilia to "moderate" disease, with the abolition of joint bleeds and the associated arthropathy.[7]

Although primary prophylaxis is expensive, historical cohorts show progressively better outcomes (joint function and radiologic appearances) with its use. The Medical and Scientific Advisory Council of the National Hemophilia Foundation of the United States recommends primary prophylaxis in patients with

---

| Table 67–1 |
| --- |

**Laboratory and Clinical Manifestations of Hemophilia**

| | Severe (< 0.01 IU/mL [10 IU/L])[a] | Moderate (0.01–0.05 IU/mL [10–50 IU/L]) | Mild (> 0.05 IU/mL [50 IU/L]) |
|---|---|---|---|
| Age at onset | 1 year or less | 1–2 years | 2 years–adult |
| Neonatal symptoms | | | |
|   PCB | Usual | Usual | Rare |
|   ICH | Occasional | Uncommon | Rare |
| Muscle/joint hemorrhage | Spontaneous | Minor trauma | Minor trauma |
| CNS hemorrhage | High risk | Moderate risk | Rare |
| Postsurgical hemorrhage (without prophylaxis) | Frank bleeding, severe | Wound bleeding, common | Wound bleeding |
| Oral hemorrhage following trauma, tooth extraction | Usual | Common | Common |

CNS, central nervous system; ICH, intracranial hemorrhage; PCB, postcircumcisional bleeding.

Normal range of factor VIII/IX activity level is 0.5–1.5 IU/mL (500–1500 IU/L). 1 IU/mL (1000 IU/L) corresponds to 100% of the factor found in 1 mL of normal plasma.

## Clinical Presentation and Diagnosis of Hemophilias A and B

Hemophilias A and B are clinically indistinguishable.

**Symptoms**

- Ecchymoses
- Hemarthrosis—bleeding into joint spaces[a] (especially knee, elbow, and ankle)
  - Joint pain, swelling, and erythema
  - Cutaneous warmth
  - Decreased range of motion
- Muscle hemorrhage
  - Swelling
  - Pain with motion of affected muscle
  - Signs of nerve compression
  - Potential life-threatening blood loss, especially with thigh bleeding
- Mouth bleeding with dental extractions or trauma
- Genitourinary bleeding
- Gastrointestinal (GI) bleeding

- Hematuria
- Intracranial hemorrhage (spontaneous or following trauma), with headache, vomiting, change in mental status, and focal neurologic signs
- Excessive bleeding with surgery

**Diagnostic Parameters/Laboratory testing**

- Family history
- Normal prothrombin time (PT)
- Normal platelet count
- Prolonged activated partial thromboplastin time (aPTT)
- Low factor VIII level (hemophilia A)
- Low factor IX level (hemophilia B)

_____

[a]Hallmark of hemophilia; recurrent inadequately managed hemarthrosis leads to deformity and chronic pain (hemophilic arthropathy).

---

severe hemophilia A and B (factor VIII or factor IX less than 1%). The optimal duration of prophylactic therapy is unknown.[8,9]

▶ *Nonpharmacologic Therapy*

**Supportive Care** Rest, ice, compression, elevation (RICE) can be used during the bleeding episode, following with casts, splints, and crutches after the bleeding has been controlled.

**Surgery** Surgical arthroscopic synovectomy reduces replacement therapy–resistant disease and repetitive hemarthrosis of a single joint. This procedure removes inflamed joint tissue. Patients may have decreased range of motion after the surgery.

**Orthotics** Joint prostheses do not deal with the deformities directly. Orthotics in hemophilia serve as an important supportive measure before or after surgery.

▶ *Pharmacologic Therapy*

**Hemophilia A**

*DDAVP* Primary therapy is based on disease severity and type of hemorrhage.[10] Most patients with mild to moderate disease and

a minor bleeding episode can be treated with 1-desamino-8-D-arginine vasopressin (desmopressin acetate [DDAVP]), a synthetic analogue of the antidiuretic hormone, vasopressin. DDAVP causes release of von Willebrand factor (vWF) and factor VIII from endothelial storage sites. DDAVP increases plasma factor VIII levels by threefold to fivefold within 30 minutes. The recommended dose is 0.3 mcg/kg IV (in 50 mL of normal saline infused over 15–30 minutes) or subcutaneously (in < 1.5 mL) or 150 to 300 mcg intranasally via concentrated nasal spray, may repeat after 24 hours. [10] Peak effect with intranasal administration

### Patient Encounter 1, Part 2: Hemophilia

Meds: None

PE:

- Swollen red joints of elbows and knees bilaterally. Wt 11.1 lb (5.04 kg)

Labs:

- Platelet count: $145 \times 10^3/mm^3$ ($145 \times 10^9$/L) (normal $140–440 \times 10^3/mm^3$ [$140–440 \times 10^9$/L])
- aPTT: 90 seconds (normal 25–40 seconds)
- INR: 1 (normal 0.8–1.2)
- Factor VIII: 5% (normal 50%–150%)
- Ristocetin cofactor activity (vWF:RCo): 150 IU/dL or 1500 IU/L (normal 50–200 IU/dL or 500–2000 IU/L)

*Given this additional information, is this patient's presentation consistent with hemophilia? Which type of hemophilia does this patient have?*

*Identify your treatment goals for this patient.*

### Patient Encounter 1, Part 1: Hemophilia

A 2-month-old boy without any significant past medical history developed mild bleeding into the joint spaces of the knees and elbows. The baby is irritable and has warm swollen joints. Patient's parents report family history significant for maternal grandfather with hemophilia.

*What additional information do you need to create a treatment plan for this patient?*

*What are this patient's risk factors for hemophilia?*

occurs 60 to 90 minutes after administration, which is somewhat later than with IV administration. Desmopressin infusion may be administered daily for up to 2 to 3 days. Facial flushing, hypertension or hypotension, GI upset, and headache are common side effects of desmopressin. Water retention and hyponatremia may occur; patients should be instructed to limit water intake while taking desmopressin. Serious side effects include seizures related to hyponatremia and myocardial infarction. Due to higher incidence of hyponatremia-related seizures in patients less than 2 years old, use of desmopressin is not recommended in this population. Tachyphylaxis, an attenuated response with repeated administration, may occur after several doses.[11]

According to the manufacturer, use of DDAVP is contraindicated in patients with creatinine clearance less than 50 mL/min (0.83 mL/s); however, it has been used off label in patients with impaired renal function.

● *Antifibrinolytic Therapy* Aminocaproic acid and tranexamic acid are antifibrinolytic agents that reduce plasminogen activity leading to inhibition of clot lysis and clot stabilization. These agents are usually used as adjuncts in dental procedures or in difficult-to-control epistaxis and menorrhagia episodes and have to be administered with appropriate factor concentrates to form a clot.[10]

*Factor VIII Replacement* Patients with severe hemophilia may receive primary (before the first major bleed) or secondary (after the first major bleed) prophylaxis. All hemophiliacs with a major bleed require factor VIII replacement.[12] The therapy may include recombinant (produced via transfection of mammalian cells with the human factor VIII gene) or plasma-derived (concentrate from pooled plasma) factor VIII (Table 67–2). The choice of product and dose are based on the overall clinical scenario because the efficacy of various preparations does not differ. Newer generation plasma-derived coagulation factor concentrates are considerably safer owing to advancements in viral testing and inactivation technology. Although original recombinant factor VIII concentrates were stabilized with human serum albumin, potentially creating a source for viral contamination, new-generation recombinant factor VIII concentrates are stabilized with sucrose, eliminating the concern for viral transmission.[10]

The severity of hemorrhage and its location are major determinants of percentage correction to target, as well as duration of therapy (Table 67–3). The normal range of factor VIII activity level is 1 IU/mL (1000 IU/L), which corresponds to 100% of the factor found in 1 mL of normal plasma. Minor bleeding may be treated with a goal of 25% to 30% (0.25–0.30 IU/mL [250–300 IU/L]) of normal activity, whereas serious or life-threatening bleeding requires greater than 75% of normal activity. Factor VIII is a large molecule that remains in the intravascular space, and its estimated volume of distribution is approximately 50 mL/kg. Generally, factor VIII levels increase by 2% (0.02 IU/mL

## Table 67–2

**Factor Concentrates**

| Brand Name | Product Type | Viral Inactivation or Exclusion Method | Other Contents |
|---|---|---|---|
| **Factor VIII Concentrates** | | | |
| Alphanate | Plasma | Solvent detergent, dry heat | Albumin, heparin, vWF |
| Advate | Recombinant | None | Trehalose |
| Bioclate | Recombinant | None | Albumin |
| Eloctate | Recombinant | None | Sucrose |
| Helixate FS | Recombinant | Solvent detergent | Sucrose |
| Hemofil M | Plasma | Solvent detergent, monoclonal antibody | Albumin |
| Humate-P | Plasma | Pasteurization | Albumin, vWF |
| Koāte-DVI | Plasma | Solvent detergent, dry heat | Albumin, vWF |
| Kogenate FS | Recombinant | Solvent detergent, monoclonal antibody | Sucrose |
| Monoclate P | Plasma | Pasteurization, monoclonal antibody | Albumin |
| Recombinate | Recombinant | Monoclonal antibody | Albumin |
| ReFacto | Recombinant B domain deleted | None | Sucrose |
| Xyntha | Recombinant B domain deleted | Solvent-detergent, nanofiltration | Sucrose |
| **Factor IX Concentrates** | | | |
| AlphaNine SD | Plasma | Solvent detergent, nanofiltration | Heparin |

APCC, activated prothrombin complex concentrate; PCC, prothrombin complex concentrate; vWF, von Willebrand factor.

**Table 67–3**

**Guidelines for Replacement Dosing with Factor VIII and Factor IX**

| Type of Hemorrhage | Desired Plasma Factor VIII Level (% of Normal) | Desired Plasma Factor XI Level (% of Normal) | Duration of Therapy (days) |
|---|---|---|---|
| CNS, intracranial, retropharyngeal, retroperitoneal, surgical prophylaxis | 80–100<br>30 | 80–100<br>20–30 | Factor VIII: every 8–12 hours over 10–14 days<br>Factor IX: every 12 hours over 10–14 days<br>Factor VIII: every 8–12 hours over 1–2 days<br>Factor IX: every 12–24 hours over 1–2 days |
| Mild hemarthrosis, mucosal (eg, epistaxis), superficial hematoma | | | |

[20 IU/L]) for every 1 unit/kg of factor VIII concentrate infused. To calculate factor VIII replacement dose, the following equation can be used:

Dose of factor VIII (units)
= weight (kg) × (desired percentage increase) × 0.5

Thus, to increase factor VIII levels by 50% (eg, from 0 to 50%) in a 70-kg (154-lb) patient, an IV dose of 1750 units is required. The median half-life of factor VIII ranges from 9.4 hours (in 1–6 year olds) to 10.4 hours (in 10–65 year olds).[13,14] Half the initial dose is given every half-life (every 8–12 hours) to maintain the desired factor VIII level. Although intermittent bolus infusions of factor VIII concentrates have been used successfully, continuous-infusion protocols are being instituted successfully in patients requiring prolonged treatment of acute hemorrhage to avoid dangerously low trough levels and decrease the overall cost of therapy. Factor VIII can be administered as a continuous infusion at 2 to 4 units/kg/hour with daily factor level monitoring to ensure appropriate rate of infusion.[15,16]

▶ *Hemophilia B*

**Factor IX Replacement** Hemophilia B therapy may include recombinant (produced via transfection of mammalian cells with the human factor IX gene) or plasma-derived (concentrate from pooled plasma) factor IX (see Table 67–2). Guidelines for choosing the factor-concentrate formulation for hemophilia B are similar to the guidelines for hemophilia A. However, older generation factor IX concentrates containing other vitamin K–dependent proteins (eg, factors II, VII, and IX), called prothrombin complex concentrates (PCCs), have been associated with thrombogenic side effects. Consequently, these products are not first-line treatment for hemophilia B. Because it is a small protein, the factor IX molecule passes into both the intravascular and the extravascular spaces. Therefore, the volume of distribution of recombinant factor IX is twice that of factor VIII. Consequently, 1 unit of factor IX administered per kilogram of body weight yields a 1% rise in the plasma factor IX level (0.01 IU/mL [10 IU/L]). To calculate the factor IX replacement dose, the following equation can be used:

Dose of factor IX (units)
= weight (kg) × (desired percentage increase) × F

Where (F = 1 for human plasma-derived products; F = 1.1 for Rixubis; F = 1.4 for Benefix in adults and 1.2 in children).

Thus, to increase factor IX levels by 50% (eg, from 0% to 50%) in a 70-kg (154-lb) patient, the required dose of factor IX is 4900

units IV (using Benefix). The half-life of factor IX ranges from 16 to 17 hours; therefore, doses are given every 18 to 24 hours. Factor IX fusion protein can be given every 1 to 2 weeks.[17]

Gene therapy for the treatment of hemophilia is currently under investigation. A recent clinical trial has shown long-term therapeutic levels of factor IX in six subjects with severe hemophilia B receiving a single infusion of a factor IX transgene vector.[18,19]

▶ *Treatment of Patients with Factor VIII or IX Inhibitors*

Factor VIII and IX inhibitors are antibodies that develop in approximately 30% and 5% of hemophilia A and hemophilia B patients, respectively, in response to replacement therapy. There is no difference between plasma-derived and recombinant products in their potential for inhibitor development. These antibodies bind to and neutralize the activity of infused factor concentrates. Although the inhibitors do not increase hemorrhage frequency, their existence challenges the treatment of bleeding episodes. Titers of inhibitors are measured and reported in Bethesda units (BU), and this measurement is used to guide therapy (Figure 67–2). Management options for acute bleeding in patients with factor inhibitors include the administration of factor VIII concentrates, PCCs, recombinant factor VIIa (rFVIIa), and porcine factor VIII (currently, recombinant porcine factor VIII is in phase II/III clinical trials in the United States). Immune tolerance induction can be attempted to prevent future bleeding episodes.

Factor VIII concentrates can be used in patients with low inhibitor levels to control acute bleeding episodes. The dose of factor VIII is determined based on clinical response (see Figure 67–2).

PCCs contain the vitamin K–dependent factors II, VII, IX, and X. These agents bypass factor VIII at which the antibody is directed (see Figure 67–2). However, PCCs carry the risk of serious thrombotic complications.

Factor VIIa (rFVIIa) is a bypassing agent designed to generate thrombin only at tissue injury sites, where it binds tissue factor. Due to its local action, rFVIIa is associated with fewer systemic thrombotic events than PCC. rFVIIa is used effectively in surgeries and spontaneous bleeds.[20]

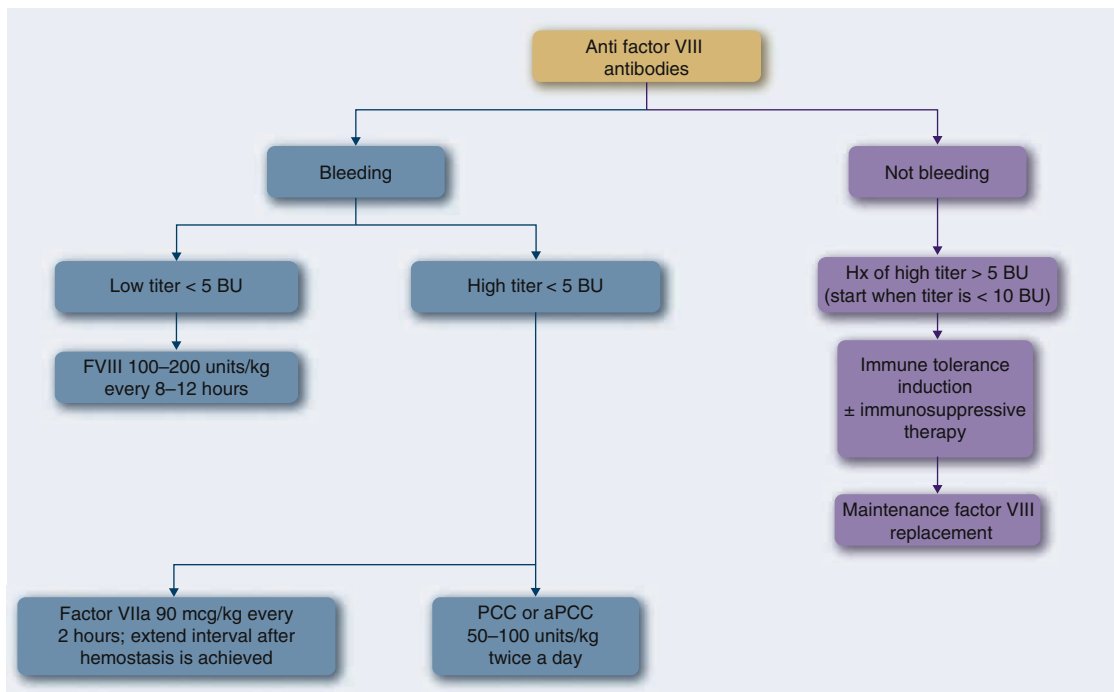
Plasma-derived porcine factor VIII participates in the coagulation cascade in place of human factor VIII. However, due to contamination with parvovirus, it is no longer available. Recombinant porcine factor VIII is currently under review and could serve as a third-line agent (only after factor VIIa and a PCC have failed) owing to the relatively high incidence of cross-reactivity with factor VIII inhibitors.


**FIGURE 67–2.** Treatment algorithm for the management of patients with hemophilia A and factor VIII antibodies. (aPCC, activated prothrombin complex concentrate; BU, Bethesda unit.) (Modified from DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach. 9th ed. New York: McGraw-Hill; 2014, Figure 81–1.)

Induction of immune tolerance is often performed with the goal of eliminating the inhibitor. Immune tolerance induction is accomplished by the administration of repetitive doses of factor VIII or IX with or without immunosuppressive therapy. It is effective in 70% of patients with hemophilia A and 30% of patients with hemophilia B.

### Pain Associated with Hemophilia

Pain commonly occurs in patients with hemophilia. Acute bleeding episodes and long-term joint destruction are common sources of pain. Acetaminophen and opioid analgesics are recommended to control mild to moderate and severe pain, respectively. Nonsteroidal anti-inflammatory drugs and aspirin should be avoided if possible, because these drugs bind to platelets and increase the risk of bleeding episodes. Cyclooxygenase-2 (COX-2) inhibitors can be used with caution.[21]

### Outcome Evaluation

The main goal of hemophilia treatment is to prevent bleeding episodes and their long-term complications. Clinicians should evaluate patients for the following:

- Musculoskeletal status, including joint range of motion and radiologic assessment, as indicated.
- Number and type of bleeding episodes to assess adequacy of prophylactic treatment and home therapy.

**Patient Encounter 1, Part 3: Hemophilia: Creating a Care Plan**

Based on the information presented, create a care plan for this patient with hemophilia.

- Use of clotting-factor concentrates to check for the development of inhibitors, especially in patients with severe disease and poor treatment responders.
- Vaccination against hepatitis A and B is recommended in all hemophiliacs without evidence of immunity.

## VON WILLEBRAND DISEASE

### Epidemiology and Etiology

von Willebrand disease (vWD) is the most common inherited bleeding disorder caused by a deficiency or dysfunction of vWF. It is classified based on the quantitative deficiency of vWF or qualitative abnormalities of vWF. The disease prevalence is estimated at 30 to 100 cases per million. In contrast to hemophilia, the majority of vWD cases are inherited as an autosomal dominant disorder, ensuing equal frequency in males and females.[22]

### Pathophysiology

vWF is a large multimeric glycoprotein with two main functions in **hemostasis**: to aid platelet adhesion to injured blood vessel walls and to carry and stabilize factor VIII in plasma. **Table 67–4** represents three main vWD phenotypes, their frequency, and genetic transmission.[23]

### Treatment

▶ **Desired Outcomes**

Unlike hemophilia, the bleeding tendency in vWD is less frequent and generally less severe. Consequently, chronic prophylaxis is usually unwarranted. The goal of two mainstay therapeutic options in vWD is:

- To stop spontaneous bleeding as necessary
- To prevent surgical and postpartum bleeding

| Table 67–4 | | | |
|---|---|---|---|
| **Classification of vWD** | | | |
| **Phenotype** | **Mechanism of Disease** | **Percentage of Cases** | **Genetic Transmission** |
| Type 1 vWD | Partial (mild to moderate) quantitative deficiency of vWF and factor VIII | 70–80 | Autosomal dominant |
| Type 2 vWD | Qualitative abnormalities of vWF | 10–30 | |
| 2A | Decreased platelet-dependent vWF function owing to lack of larger multimers | 10–20 | Autosomal dominant (or recessive) |
| 2B | Decreased vWF function due to increased affinity to platelet GP 1b and resultant sequestration or loss | 5 | Autosomal dominant |
| 2M | Defective platelet-dependent vWF functions not associated with multimer defects | Uncommon | Autosomal dominant (or recessive) |
| 2N | Defective vWF binding to factor VIII | Uncommon | Autosomal recessive |
| Type 3 vWD | Severe quantitative deficiency of vWF | Rare | Autosomal recessive |

### ▶ *Nonpharmacologic Therapy*

Local measures, including pressure and ice, may be used to control superficial bleeding.

### ▶ *Pharmacologic Therapy*

Systemic therapy is used to prevent bleeding associated with surgery, childbirth, and dental extractions and to treat bleeding that cannot be controlled with local measures. The two systemic approaches involve using desmopressin, which stimulates the release of endogenous vWF, or administering products that contain vWF. The general approach to the treatment of vWD is depicted in **Figure 67–3**. In 2008, The National Heart, Lung, and Blood Institute issued comprehensive evidence-based guidelines for the diagnosis and management of vWD.[24]

**DDAVP** Most patients with type 1 vWD (functionally normal vWF) and a minor bleeding episode can be treated successfully with desmopressin, which induces release of factor VIII and vWF from endothelial cells through interaction with vasopressin V2 receptors. The recommended dose is the same as that used to treat mild factor VIII deficiency (0.3 mcg/kg IV in 50 mL of normal saline infused over 15 to 30 min or 150 to 300 mcg intranasally via concentrated nasal spray, may repeat after 24 hours).

This therapy is generally ineffective in type 2A patients, who secrete abnormal vWF. It is recommended in type 2B patients who respond to it. It may increase the risk of postinfusion thrombocytopenia, in which case a concomitant platelet infusion is administered. Type 3 vWD patients who lack releasable stores of vWF do not respond to DDAVP therapy.[25]

The individual responsiveness to desmopressin is consistent, and a test dose administered at the time of diagnosis or prior to therapy is the best predictor of response. Generally, DDAVP is more effective in vWD than in hemophilia patients, with an average twofold to fivefold increase in vWF and factor VIII levels over baseline. In patients with an adequate response, desmopressin is first-line therapy because it allows for once-daily administration (elevates plasma levels for 8 to 10 hours), does not pose a threat in terms of viral transmission, and costs substantially less than the plasma-derived products.

**Antifibrinolytic Therapy** Fibrinolysis inhibitors and oral contraceptives are used successfully in the management of epistaxis and menorrhagia or as adjuvant treatments.[26] Fibrinolysis inhibitors include aminocaproic acid (25–60 mg/kg orally or IV (or 4–5 g) every 4 to 6 hours, to a maximum dose of 24 g/day) and tranexamic acid (10 mg/kg IV every 8 hours). Oral tranexamic

---

## Clinical Presentation and Diagnosis of vWD

Clinical manifestations vary depending on the subtype. Patients with mild disease may be asymptomatic into adulthood.

### Symptoms

- Bruising
- Mucocutaneous bleeding
  - Epistaxis
  - Oral cavity bleeding
  - Menorrhagia
  - GI bleeding
- Joint and deep tissue bleeding
- Postoperative bleeding

### Laboratory Testing

- Low or normal von Willebrand factor antigen concentration in plasma (vWF:Ag)
- Low or normal factor VIII coagulation assay (FVIII:C)[a]
- Low ristocetin cofactor activity (vWF:RCo)[b]

---

[a]Factor VIII coagulation assay measures the ability of vWF to bind and maintain adequate levels of factor VIII.

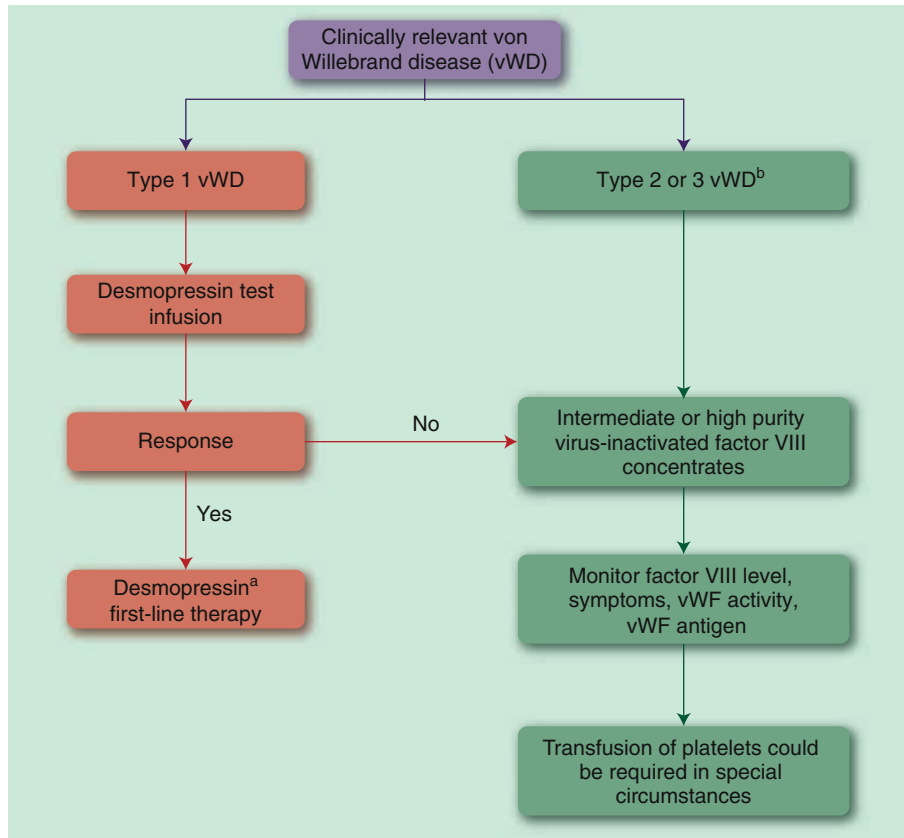
[b]Ristocetin cofactor activity (vWF:RCo) assay measures the ability of vWF to interact with intact platelets (normal 50–200 IU/dL [500–2000 IU/L]).


**FIGURE 67–3.** Guidelines for the treatment of vWD. [a]Use factor VIII concentrate for life-threatening bleeding. [b]Some patients with type 2 or 3 vWD may respond to desmopressin. (From DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach. 8th ed. New York: McGraw-Hill; 2011:1754, Figure 110–4.)

acid recently received FDA approval for the treatment of cyclic heavy menstrual bleeding; its use is currently not approved for vWD patients. The IV form of tranexamic acid given as swish and swallow or spit every 6 to 8 hours has been used as bleeding prophylaxis in dental surgery. Both aminocaproic acid and tranexamic acid are dose adjusted for patients with renal insufficiency.

● **Replacement Therapy** KEY CONCEPT *Type 1 patients unresponsive to desmopressin, patients with types 2 and 3 vWD, and major*

*surgery patients require replacement therapy with plasma-derived, intermediate- and high-purity virus-inactivated factor VIII concentrates containing vWF.*

Table 67–5 provides typical dosing guidelines and target levels of replacement therapy–concentrates to control various types of hemorrhage. Ultra-high-purity (monoclonal) plasma-derived and recombinant factor VIII concentrates do not contain vWF and should not be used in the treatment of vWD.

| Table 67–5 | | |
|---|---|---|
| **Replacement Therapy in vWD** | | |
| **Condition** | **Therapy** | **Recommended Dosage** |
| Major surgery | Maintain vWF:RCo and factor VIII levels at least 100 IU/dL (1000 IU/L) followed by 50 IU/dL (500 IU/L) for 7–14 days | 40–60 units/kg[a] loading dose, followed by 20–40 units/kg every 12–24 hours |
| | To minimize risk of thrombosis: vWF:RCo levels should not exceed 200 IU/dL (2000 IU/L), and factor VIII levels should not exceed 250 IU/dL (2500 IU/L) | DDAVP may be added after a few days |
| Minor surgery | Prophylaxis: maintain vWF:RCo and factor VIII levels at least 30 IU/dL (300 IU/L) (preferably > 50 IU/dL [> 500 IU/L]) | 30–60 units/kg loading dose, followed by 20–40 units/kg every 12–48 hours |
| | Minor surgery: maintain vWF:RCo and factor VIII levels at least 30 IU/dL (300 IU/L) (preferably > 50 IU/dL [> 500 IU/L]) for 3–5 days | DDAVP may be added after a few days |

[a]vWF concentrates are dosed based on vWF:RCo units concentration in the preparation to achieve the desired vWF:RCo levels.

**Table 67–6**

**Clotting Factor Deficiency Characteristics**

| Factor Deficient | Inheritance Pattern | Estimated Incidence | Laboratory Abnormalities | Severity and Site of Bleeding |
|---|---|---|---|---|
| II | Autosomal dominant or recessive | Extremely rare | Prolonged PT and aPTT | Mild to moderate umbilical cord, joint, and mucosal tract |
| V | Autosomal recessive | 1:1,000,000 | Prolonged PT and aPTT | Mild to moderate mucosal tract |
| VII | Autosomal recessive | 1:500,000 | Prolonged PT | Mild to severe mucosal tract and joint |
| X | Autosomal recessive | 1:1,000,000 | Prolonged PT and aPTT | Mild to severe umbilical cord, joint, and muscle |
| XI | Autosomal recessive | 4% of Ashkenazi Jews: otherwise rare | Prolonged aPTT | Mild to moderate posttraumatic bleeding |
| XII | Unknown | Unknown | Prolonged aPTT | No bleeding |
| XIII | Autosomal recessive | Less than 1:2,000,000 | Normal PT and aPTT | Moderate to severe umbilical cord, intracranial, and joint bleeding; recurrent miscarriages, impaired wound healing |

aPTT, activated partial thromboplastin time; PT, prothrombin time.

## Outcome Evaluation

The main goal of vWF treatment is to prevent bleeding with surgery or dental procedures. Clinicians should evaluate patients every 6 to 12 months for the following:

- Number and type of bleeding episodes to assess the need for prophylactic treatment.
- Ensure adequate levels of vWF and factor VIII prior to minor and major surgical procedures and for the treatment of bleeding.
- Vaccination against hepatitis A and B is recommended in all patients with vWF deficiency with no evidence of immunity.

## OTHER CLOTTING FACTOR DEFICIENCIES
### Etiology and Epidemiology

Recessively inherited coagulation disorders (RICDs) refer to relatively rare deficiencies in factor II, V, VII, and X to XIII resulting in either decreased clotting factor production or production of a dysfunctional molecule with reduced activity.[27] The clinical severity of bleeding varies and generally is poorly correlated with the factor blood levels. Table 67–6 illustrates these clotting factor deficiencies and some of their characteristics.

### Pathophysiology

The RICDs are rare genetic disorders. Mutations in the genes responsible for the respective clotting factors result in impaired functionality or production of the factor.

### Treatment
#### ▶ Desired Outcomes

Therapeutic options for RICDs improve hemostasis via replacement of deficient blood coagulation factors while minimizing the development of immune tolerance.[28]

Hemostatic levels should be maintained for the following conditions:

- Spontaneous bleeding—until bleeding stops
- Minor surgery—for 2 to 3 days
- Major surgery—until incision site has healed

#### ▶ Nonpharmacologic Therapy

● **Transfusional Therapies** KEY CONCEPT *The primary treatment of RICDs is single-donor fresh-frozen plasma (FFP) that contains all coagulation factors.* Disadvantages of FFP treatment include the risk of the patient becoming volume overloaded, especially when repeated infusions are administered to improve and maintain hemostasis; risk of infections; and risk of inhibitor development. PCCs licensed for the treatment of hemophilia B also contain significant levels of vitamin K–dependent factors and may be used off label for treatment of RICD. Table 67–7 lists the recommended RICD treatment schedules in different clinical scenarios.

#### ▶ Pharmacologic Therapy

● Less severe hemorrhages may be treated successfully with anti-fibrinolytic amino acids alone or in combination with factor replacement therapy. Tranexamic acid and aminocaproic acid may be administered IV or orally (for doses, see von Willebrand Disease, Pharmacologic Therapy mentioned earlier).

**Table 67–7**

**Treatment of Factor Deficiencies**

| Factor Deficient | Major Surgery | Spontaneous Bleeding |
|---|---|---|
| II | 1. PCC: 20–30 units/kg<br>2. FFP: 15–20 mL/kg | 1. FFP: 15–20 mL/kg |
| V | 1. FFP: 15–20 mL/kg | 1. FFP: 15–20 mL/kg |
| VII | 1. rFVIIa: 15–30 mcg/kg every 4–6 hours | 1. rFVIIa: 15–30 mcg/kg every 4–6 hours |
| X | 1. PCC: 20–30 units/kg<br>2. FFP: 15–20 mL/kg | 1. PCC: 20–30 units/kg<br>2. FFP: 15–20 mL/kg |
| XI | 1. FFP: 15–20 mL/kg | 1. FFP: 15–20 mL/kg |
| XIII | 1. Pasteurized plasma concentrate: 10–20 units/kg<br>2. FFP: 15–20 mL/kg<br>3. Cryoprecipitate (1 bag per 10 kg) | 1. FFP: 3–5 mL/kg |

Numbers indicate lines of therapy. FFP, fresh-frozen plasma; PCC, prothrombin complex concentrates.

## Patient Care Process Hemophilias, vWD disease, and RICD

**Patient Assessment:**

- Obtain a complete medical and family history.
- Evaluate CBC, vital signs, and coagulation studies. If a bleeding disorder is diagnosed, evaluate specific coagulation assays to determine the etiology of the bleeding disorder.

**Therapy Evaluation and Care Plan Development:**

- Institute nonpharmacological therapy to minimize minor bleeding.
- Depending on the specific diagnosis and disease severity, select appropriate therapy with desmopressin, antifibrinolytic medications, and/or disease-specific factor replacement therapies.
- Recommend prophylactic therapies before major and minor surgical procedures based on bleeding risk assessment.
- Evaluate pain and treat if necessary, selecting medication that do not increase the risk of bleeding.
- Review vaccination history and recommend appropriate vaccinations.

**Follow-Up Evaluation:**

- If clotting factor replacement is utilized, continuously evaluate its efficacy and test for inhibitors development if loss of efficacy is observed.
- Monitor number/severity of bleeding episodes, joint count/joint destruction, and pain associated with some coagulation/bleeding disorders.

## PLATELET DISORDERS

Platelets, in combination with several other factors such as blood vessel wall and coagulation factors, play key role in hemostasis. Normal platelet count is $150–450 \times 10^3/\text{mm}^3$ ($150–450 \times 10^9/\text{L}$). Thrombopoietin, a hormone synthesized in the liver, regulates platelet production. Several congenital and iatrogenic disorders may result in low platelet count; among them, drug-induced thrombocytopenia, infection-induced thrombocytopenia, disseminated intravascular coagulation, congenital thrombocytopenia, and idiopathic immune thrombocytopenia. Two types of thrombocytopenic disorders and their treatments are discussed below.

## IMMUNE THROMBOCYTOPENIC PURPURA

### Etiology and Epidemiology

Immune (or idiopathic) thrombocytopenic purpura (ITP) is one of the most common causes of acquired thrombocytopenia. The estimated incidence is 1.9 to 6.4 cases per 100,000 persons in children and 3.3 cases per 100,000 in adults.[29] ITP is an autoimmune disorder caused by the binding of antibodies (usually immunoglobulin G [IgG]) to platelet surface antigens, resulting in shortened platelet life span. ITP can occur as an isolated condition or secondary to an underlying disorder. Childhood-onset and adult-onset ITP present very differently. Adult-onset ITP is generally chronic (> 6 months) and affects women two to three times more often than men. By contrast, childhood-onset ITP is acute in onset and usually follows an infectious illness, and both sexes are equally affected. Childhood ITP typically resolves on its own within 4 to 6 weeks without major sequelae. In adults presenting with ITP, testing for human immunodeficiency virus (HIV) and hepatitis C virus (HCV) is recommended, because treating these infections may improve ITP course. ITP occurs in 1 to 2 of every 1000 pregnancies. In pregnant women with pre-existing ITP, both maternal and fetal complications may occur, requiring separate management.

### Pathophysiology

In ITP, IgG autoantibodies bind to platelet-antigen complex and are cleared from the blood via binding to mononuclear phagocytes by macrophage Fcγ receptor, leading to thrombocytopenia. Platelet survival time is significantly shorter in patients with ITP (from minutes to 2–3 days compared with normal 7–10 days). Sequestration in spleen, liver, and bone marrow is partially responsible for decreased platelet survival. Megakaryopoiesis may be reduced due to antibody binding to megakaryocyte precursors in the bone marrow.

## Clinical Presentation and Diagnosis of ITP

**General**

The typical patient is well with the exception of bleeding.

**Symptoms**

- Petechiae
- Purpura, wet purpura
- Ecchymoses
- Cutaneous bleeding
- Mucosal site bleeding
- Epistaxis
- Gingival bleeding
- Hematuria
- Menorrhagia
- Intracranial hemorrhage (rare)

**Diagnostic Criteria**

- Platelet count less than $100 \times 10^3/\text{mm}^3$ ($100 \times 10^9/\text{L}$)
- Otherwise normal complete blood count with differential
- Normal reticulocyte count
- Normal peripheral blood smear (no hemolysis or blast cells)
- History and physical exam ruling out other possible causes of thrombocytopenia[30]

**Other Laboratory Testing**

Laboratory testing to rule out other courses of thrombocytopenia, such as HCV, HIV, SLE, Evan syndrome, and others

## Patient Encounter 2, Part 1: ITP

A 30-year-old woman with past medical history significant for mild intermittent asthma. Presents with complaints of significant mucosal bleeding from her mouth that was slow to respond to placing ice cubes and swishing cold water. A laboratory analysis reveals platelet count of $8 \times 10^3/mm^3$ ($8 \times 10^9/L$). Her medications at home include albuterol MDI one to two inhalations every 4 hours as needed; she has no known drug allergies.

*What information is suggestive of immune thrombocytopenic purpura (ITP)?*

*What additional information do you need to create a treatment plan for this patient?*

## Treatment

▶ *Desired Outcomes*

In children, the main goal of ITP treatment is to maintain the platelet count associated with sufficient hemostasis, while awaiting spontaneous or treatment-induced remission. In adults, the main goal is to maintain platelet count greater than $30 \times 10^3/mm^3$ ($30 \times 10^9/L$), because below this count, the incidence of bleeding in increased.[31]

▶ *General Approach to Treatment*

**KEY CONCEPT** *The treatment of ITP is determined by the symptom severity. In some cases, no therapy is needed* (**Table 67–8**). The initial treatment of children with ITP is controversial because greater than 75% to 80% of cases resolve spontaneously irrespective of pharmacologic intervention. Therapy should be given to children with severe hemorrhage. Therapy may be considered in children meeting one of the following criteria: platelet counts less than $10 \times 10^3/mm^3$ ($10 \times 10^9/L$) and mucocutaneous bleeding; platelet counts less than $30 \times 10^3/mm^3$ ($30 \times 10^9/L$) and moderate

## Patient Encounter 2, Part 2: ITP

PE:

Wt 75 kg; vital signs within normal limits. Petechial rash present on lower extremities; bleeding mucous surfaces noted within oral cavity.

Labs:

- Platelet count: $8 \times 10^3/mm^3$ ($8 \times 10^9/L$) (normal 140–440 × $10^3/mm^3$ [140–440 × $10^9/L$])
- aPTT: 35 seconds (normal 25–40 seconds)
- PT: 11 seconds (normal 10–12 seconds)
- Hemoglobin 13 g/dL (130 g/L or 8.07 mmol/L) (normal 13.8–17.2 g/dL or 138–172 g/L or 8.57–10.68 mmol/L)
- HCV antibody negative
- HIV negative

*Given this additional information, is this patient's presentation consistent with ITP?*

*Identify your treatment goals for this patient.*

### Table 67–8

**Guidelines for the Management of Adult ITP**

| | |
|---|---|
| Greater than $30 \times 10^3$ platelets/mm³ ($30 \times 10^9/L$), no bleeding | No treatment |
| First line<br>  Less than $30 \times 10^3$ platelets/mm³ ($30 \times 10^9/L$), bleeding symptoms | Prednisone (1 mg/kg/day)<br>Anti-D immune globulin (50–75 mcg/kg/day, × one dose) if corticosteroids contraindicated<br>IVIg (1 g/kg/day × one dose, repeat as necessary) if corticosteroids contraindicated |
| Second line<br>  Reserved for patients with bleeding symptoms and platelets < $30 \times 10^3$ platelets/mm³ ($30 \times 10^9/L$) after an adequate trial of first-line agents | Splenectomy<br>Rituximab (375 mg/m² once weekly for four doses)<br>Eltrombopag (25–75 mg daily)<br>Romiplostim (1–10 mcg/kg)<br>Immunosuppressants |
| Hemorrhage | Platelet transfusion<br>IVIg (1 g/kg/day × one dose, repeat as necessary)<br>Methylprednisolone (1 g/day for 3 days) |

systemic or mucosal bleeding; or factors that may increase the risk of bleeding (such as participation in active contact sports increasing risk of head injury).[32] In adults, treatment is indicated when platelet counts are less than $30 \times 10^3/mm^3$ ($30 \times 10^9/L$).[31]

▶ *Nonpharmacologic Therapy*

● **Splenectomy** In adults, splenectomy is generally considered after 3 to 6 months if the patient continues to require 10 to 20 mg/day of prednisone to maintain the platelet count greater than $30 \times 10^3/mm^3$ ($30 \times 10^9/L$). Splenectomy may also be considered for urgent treatment of neurologic symptoms or for managing relapse despite an adequate trial of corticosteroids, IV immunoglobulin (IVIg), or anti-Rh(D). Even though individual patient response cannot be predicted, approximately two-thirds of refractory adult patients have a favorable response to splenectomy within several days; however, 30% to 40% will have no response or will experience a relapse sometime after splenectomy.

● In children, splenectomy is usually reserved due to the self-limited nature of ITP and fear of infectious complications of splenectomy. Splenectomy is recommended in children with ITP duration greater than 1 year with significant bleeding symptoms and unresponsive or intolerant of pharmacological therapies. Between 70% and 80% of children attain complete remission following splenectomy. Laparoscopic splenectomy is preferable to open splenectomy because it speeds the recovery and shortens the duration of hospitalization. The major drawback of splenectomy is bacterial sepsis, occurring at incidence rates of approximately 1%. Immunization with *Haemophilus influenzae* type b, pneumococcal, and meningococcal vaccines is indicated in all patients 2 weeks prior to splenectomy.[33]

● **Platelet Transfusions** Platelet transfusions are indicated if a patient has severe life-threatening bleeding, such as intracranial hemorrhage. In such situations, platelet transfusions are administered along with IV Immunoglobulin and glucocorticoids (see below).[32]

▶ *Pharmacologic Therapy*

The general approach to management of ITP in adults is summarized in Table 67–8.

**Glucocorticoids** Glucocorticoids may decrease splenic sequestration of antibody-coated platelets, diminish antibody generation by the spleen and the bone marrow, and increase platelet output by the bone marrow. In adults, the response rate to oral prednisone (1 mg/kg/day) is 50% to 75%, with patients usually responding within the first 1 to 2 weeks. The duration of therapy depends on the platelet count response; guidelines advocate longer course of prednisone therapy (21 days), followed by a taper. High-dose dexamethasone (40 mg orally or intravenously daily) administered for 4 to 8 days in 14- to 28-day cycles has also been used successfully. In children, oral or parenteral corticosteroids (prednisone, dexamethasone, methylprednisolone) can be used; various dosage regimens have been studied with no specific drug or dosage regimen showing superiority.[31]

**IV Immunoglobulin (IVIg)** IVIg impairs the clearance of platelets coated with IgG by activating inhibitory receptor FcRγIIb. Roughly 80% of adults will respond to IVIg, but remission usually is not sustained. In adults, use of IVIg (1 g/kg/day given as a single dose, repeated if necessary) is reserved for situations in which rapid increase in platelet count is necessary, such as life-threatening bleeding and very low platelet count, or for patients who have contraindications to glucocorticoids. If treatment is indicated in children, a single dose of IVIg (0.8–1 g/kg) is usually effective. IVIg use is complicated by many serious adverse effects and high cost.

**Anti-Rh(D)** Anti-Rh(D) can be used only in Rh(D)-positive patients who have not had splenectomy. It is as efficacious as IVIg and is generally less expensive. The indications for use of anti-Rh(D) are identical to those for IVIg. Anti-Rh(D) is a desirable form of treatment in chronic ITP when the goal is to circumvent long-term exposure to corticosteroids. At doses of 50 to 75 mcg/kg/day, anti-Rh(D) may increase the platelet count in about 70% to 80% of children with ITP. Dosage adjustment is recommended based on hemoglobin levels. Response to anti-Rh(D) lasts about 3 to 5 weeks, and substantial numbers of patients treated repetitively with anti-Rh(D) can postpone or avoid splenectomy. Rare fatal intravascular hemolysis has been reported with use of anti-Rh(D); special monitoring for this side effect is recommended.

**Immunosuppressants** Immunosuppressant therapy is generally utilized for patients who are refractory to or intolerant of all other ITP treatments. Rituximab, an anti-CD20 antibody, at a dose of 375 mg/m$^2$ once weekly for four doses, can induce long-term response in 21% to 27% of patients.[34] Progressive multifocal leukoencephalopathy has been rarely reported with rituximab use. Rituximab can be considered as a second- or third-line therapy in patients who have experienced treatment failure with corticosteroids, IVIg, or splenectomy. Azathioprine and cyclophosphamide produce response rates of 20% to 40% in adult patients who are treated for 2 to 6 months. Other medications used in ITP include vincristine, vinblastine, cyclosporine, danazol, and mycophenolate mofetil; due to major toxicities and lack of adequate evidence-based recommendations, their use is reserved for refractory ITP.

**Thrombopoietic Growth Factors** Additional treatment options for ITP include a thrombopoiesis-stimulating protein and a small-molecule thrombopoietin (TPO) receptor agonist. These agents stimulate the bone marrow to make enough platelets to overcome the body's premature destruction of platelets. Romiplostim and eltrombopag are two TPO mimetics that have been approved by the FDA for the treatment of thrombocytopenia in patients with chronic ITP who have had an insufficient response to corticosteroids, immunoglobulins, or splenectomy. Currently, these agents are not FDA approved for use in children; several clinical trials are underway to establish role of these agents in managing childhood ITP.

Romiplostim is a TPO peptide mimetic that binds to and activates the human TPO receptor. As a once weekly subcutaneous injection, romiplostim stimulates megakaryopoiesis, resulting in enhanced platelet production. Initial dose of romiplostim is based on the actual body weight, adjusted weekly by increments of 1 mcg/kg subcutaneously until a maximum of 10 mcg/kg and the patient achieves a platelet count greater than or equal to $50 \times 10^3$/mm$^3$ ($50 \times 10^9$/L) as necessary to reduce the risk for bleeding. Eltrombopag is a once-daily oral nonpeptide thrombopoietin receptor agonist with a low immunogenic potential that stimulates megakaryocyte proliferation and differentiation.

For most patients, the initial dose of eltrombopag is 50 mg once daily. The daily dose is subsequently adjusted to a maximum dose of 75 mg daily in order to achieve and maintain a platelet count greater than or equal to $50 \times 10^3$/mm$^3$ ($50 \times 10^9$/L) in order to reduce the risk for bleeding.

Both agents need to be discontinued if platelet counts do not increase after 4 weeks at a maximum dose.

Romiplostim and eltrombopag are effective in increasing platelet counts in patients with ITP and can be used in combination with therapies that inhibit platelet destruction. Although usually well tolerated, a number of rare but serious risks have been reported, including changes in the bone marrow, worsened thrombocytopenia and the risk of bleeding after cessation of the medication, thrombotic/thromboembolic complications (including portal vein thrombosis with eltrombopag), and worsening of blood cancers. Eltrombopag carries a "black box warning" regarding hepatic decompensation in patients with hepatitis C treated with interferon and ribavirin. It is also associated with development of cataracts and has drug–drug interactions with antacids and several minerals (calcium, iron, aluminum, magnesium, selenium, zinc).

Use of TPO-mimetic agents is reserved for refractory ITP due to cost considerations, lack of durability of response after discontinuation, and limited knowledge of long-term side effects.

## Outcome Evaluation

- Monitor platelet counts as indicated clinically.
- In adults, the goal of therapy is to maintain platelet count greater than or equal to $30 \times 10^3$/mm$^3$ ($30 \times 10^9$/L).
- Monitor for signs and symptoms of bleeding.

**Patient Encounter 2, Part 3: ITP: Creating a Care Plan**

*Based on the information presented, create a care plan for this patient. Please include whether pharmacologic therapy is indicated, and if so, please list first-line and alternative therapies.*

## Patient Care Process ITP

**Patient Assessment:**

- Conduct physical examination evaluating sites of bleeding. Obtain a complete medical and medication history.
- Evaluate CBC, peripheral blood smear, order tests to rule out other diseases commonly associated with thrombocytopenia.

**Therapy Evaluation and Care Plan Development:**

- If patient meets clinical criteria for diagnosis of ITP and is a candidate for treatment, evaluation of platelet count, occupational risks of bleeding, and actual bleeding severity dictates initial treatment approach.
- First-line treatment for patients meeting criteria for pharmacotherapy is corticosteroids for up to 21 days. Anti-D or IVIg can be considered if corticosteroids are contraindicated or rapid rise in platelet count is necessary. Alternatives to first-line agents include immunosuppressants and TPO mimetics, which are reserved for patients failing to respond after adequate trial of first-line agents. Surgical splenectomy is reserved for refractory ITP.

**Follow-Up Evaluation:**

- In adults, monitor regularly to ensure platelet counts stay above $30 \times 10^3/mm^3$ ($30 \times 10^9/L$).
- Patients should be instructed to contact their primary health care provider at new signs of bleeding.

# THROMBOTIC THROMBOCYTOPENIC PURPURA

## Etiology and Epidemiology

Thrombotic thrombocytopenic purpura (TTP) is a severe systemic disorder characterized by thrombi formation within the circulation that results in the platelet consumption and subsequent thrombocytopenia. Acute idiopathic TTP is more common in women and African Americans and most frequently occurs in people between 30 and 40 years of age. The estimated annual incidence of TTP is 4.5 cases per million.[35] Common conditions associated with TTP are summarized in Table 67–9.

## Pathophysiology

Endothelial cells normally synthesize vWF in the form of a high-molecular-weight multimer composed of smaller identical monomers. Each monomer is able to bind platelets, and the number of monomers on the vWF multimer is directly proportional to its platelet-binding capacity. Consequently, particularly adherent ultra-large molecules of the vWF (ULvWF) are broken down to smaller size by vWF-cleaving proteases such as ADAMTS13 (a disintegrin and metalloprotease with thrombospondin type 1 repeats) to avoid undesired clot formation. TTP results from genetic or acquired deficiency in the vWF-cleaving protease ADAMTS13 activity. This, in turn, elevates circulating levels of ULvWF, leading to inappropriate platelet agglutination. Thrombocytopenia develops because the rate of aggregated platelet consumption is faster than megakaryocyte bone marrow production. Microangiopathic hemolytic anemia generally follows as a consequence of red blood cell damage by platelet clumps occluding the microcirculation. Occlusive ischemia of the brain or GI tract is common, and renal dysfunction may occur.

## Clinical Presentation and Diagnosis of TTP

**Typical Pentad of Symptoms (Rare That All Five Are Present)[a]**

1. Thrombocytopenia
   - Thrombocytopenic purpura
   - Bleeding
2. Fever
3. Microangiopathic hemolytic anemia
4. Neurologic symptoms
   - Headache, confusion, difficulty speaking, transient paralysis, numbness
5. Renal abnormalities
   - Proteinuria, hematuria, mild renal insufficiency

**Laboratory Testing**

- Decreased hemoglobin, hematocrit, and platelets
- Peripheral blood smear showing schistocytes
- Decreased serum haptoglobin
- Elevated lactate dehydrogenase (LDH)
- Elevated indirect bilirubin level
- Elevated reticulocyte count
- Normal PT and aPTT
- Elevated urine protein, red blood cells, and/or serum creatinine

---

[a]TTP diagnosis can be based on the presence of thrombocytopenia and microangiopathic hemolytic anemia in the absence of other possible causes.

In patients suspected to have TTP, the differential diagnosis includes disseminated intravascular coagulation (DIC) and hemolytic uremic syndrome (HUS). Both TTP and HUS can present with thrombotic microangiopathic anemia; however, HUS is usually linked to a diarrheal illness and acute renal failure. Some sources advocate for TTP-HUS spectrum as a single disease since clinical presentation is essentially identical.

---

**Table 67–9**

**Conditions Associated with TTP**

- Infections
- Bacterial, fungal, viral, atypical
- Transplantation
- Solid organ or bone marrow
- Malignancy
- Pregnancy
- Collagen vascular diseases
- Medications
- Antineoplastic agents, ticlopidine, clopidogrel, antibiotics, immunosuppressants, others

---

## Treatment

### ▶ Desired Outcomes

The main goal of TTP treatment is to prevent end-organ damage.

### ▶ Nonpharmacologic Therapy

**KEY CONCEPT** *The present standard of treatment for TTP is urgent plasma exchange (PEX). If PEX is unavailable, treatment with plasma infusion and glucocorticoids is indicated until PEX is available.*[36]

**Plasma Exchange** The procedure involves removal of the patient's plasma and its substitution with donor plasma. In this manner, circulating antibody inhibitor of ADAMTS13 is removed and enzyme is replenished. PEX involves placement of two IV lines (cannulae) into two separate veins. Blood removed through one cannula is centrifuged to separate the blood cells from the plasma. The blood cells are mixed subsequently with donor plasma and returned to the patient via the second cannula. The goal is to exchange 1 to 1.5 plasma volumes (40–60 mL/kg). The procedure generally is repeated daily until neurologic symptoms resolve and normal lactate dehydrogenase (LDH) and platelet counts are maintained for several days. After complete remission is achieved, PEX frequency can be reduced to every other day for an additional few days, with subsequent PEX discontinuation and close patient follow-up. When PEX is started immediately upon diagnosis, remission and survival rates at 6 months are approximately 80%. Although generally considered safe, complications from catheter insertion or catheter infection may occur and include hemorrhage, pneumothorax,

---

**Patient Encounter 3, Part 1: TTP**

A 35-year-old African American woman presented to her primary care physician complaining of headache, weakness, fever, chills, nausea, vomiting, and vaginal bleeding. She was recently diagnosed with genital herpes and prescribed valacyclovir 1 g twice daily for 10 days, which she's been taking for 9 days now. Otherwise, she suffers from seasonal allergies for which she takes loratadine 10 mg by mouth daily. She is allergic to ibuprofen (rash).

*What information is suggestive of TTP?*

*What additional information do you need to create a treatment plan for this patient?*

---

**Patient Encounter 3, Part 2: TTP**

PE/ROS:

Wt 55 kg, T 100.8°F (38.2°C), patient appears lethargic and has difficulty concentrating

Labs:

- Platelet count: $9 \times 10^3$/mm³ ($9 \times 10^9$/L) (normal 140–440 × 10³/mm³ [140–440 × 10⁹/L])
- aPTT: 35 seconds (normal 25–40 seconds)
- PT: 11 seconds (normal 10–12 seconds)
- Haptoglobin 10 mg/dL (100 mg/L) (normal 30–200 mg/dL or 300–2000 mg/L)
- LDH 1900 U/L (31.7 µkat/L) (normal 100–250 U/L, or 1.67–4.17 µkat/L)
- Hemoglobin 9 g/dL (90 g/L; 5.59 mmol/L) (normal 12.1–15.1 g/dL or 121–151 g/L or 7.51–9.37 mmol/L)
- Blood peripheral smear: numerous schistocytes (10–15 per high power field)
- Serum creatinine 1.8 mg/dL (159 µmol/L) (increased from 0.8 mg/dL [71 µmol/L] on record from last year's physical exam) (normal 0.6–1.2 mg/dL [53–106 µmol/L])

*Given this additional information, is this patient's presentation consistent with TTP?*

---

sepsis, and thrombosis. Allergic reactions to plasma can cause severe hypotension and hypoxia.[37]

**Splenectomy** Splenectomy is reserved for patients with frequently relapsing disease who are refractory to PEX or immunosuppressive therapy.

### ▶ Pharmacologic Therapy

**Glucocorticoids** Glucocorticoids can be used for their immunosuppressive effect in combination with PEX; however, they are not as efficacious as monotherapy in TTP. The most commonly used agents are methylprednisolone 250 mg/day IV for or prednisone 1 mg/kg/day orally for the duration of PEX therapy and 1 to 2 weeks after normalized platelet counts are maintained.

**Immunosuppressants** TTP that fails to respond adequately to PEX can be treated with immunosuppressive agents. Cytotoxic immunosuppressive therapies with the most potential benefit in refractory TTP include cyclosporine and rituximab. Other agents that had been used include vincristine, cyclophosphamide, azathioprine, and IVIg.[36]

---

**Patient Encounter 3, Part 3: TTP: Creating a Care Plan**

*Based on the information presented, create a care plan for this patient's TTP.*

## Patient Care Process TTP

**Patient Assessment:**

- Obtain a complete medical and medication history.
- Evaluate CBC, vital signs, neurologic symptoms, chemistry 7 panel, and urinalysis for presence of thrombocytopenia, fever, anemia, and renal abnormalities. Evaluate neurologic symptoms.

**Therapy Evaluation and Care Plan Development:**

- If patient meets clinical criteria for diagnosis of TTP, start daily PEX. If ADAMTS13 deficiency is suspected, start glucocorticoids.

**Follow-up Evaluation:**

- When platelet counts stay above $150 \times 10^3/mm^3$ ($150 \times 10^9/L$) for 2 days, PEX may be discontinued; glucocorticoids may be continued for additional 1 to 2 weeks.
- Follow patients indefinitely with periodic CBC/LDH measurements to screen for possible relapse of TTP.

## Outcome Evaluation

Monitor platelet counts, hemoglobin, and LDH.

# Abbreviations Introduced in This Chapter

| | |
|---|---|
| ADAMTS13 | A disintegrin and metalloprotease with thrombospondin type 1 repeats (vWF-cleaving metalloprotease) |
| BU | Bethesda units |
| DDAVP | 1-Desamino-8-D-arginine vasopressin (desmopressin acetate) |
| DIC | Disseminated intravascular coagulation |
| FFP | Fresh-frozen plasma |
| HCV | Hepatitis C virus |
| ICH | Intracranial hemorrhage |
| ITP | Immune thrombocytopenic purpura |
| IVIg | IV immunoglobulin |
| PCC | Prothrombin complex concentrate |
| PEX | Plasma exchange |
| rFVIIa | Recombinant factor VIIa |
| RICD | Recessively inherited coagulation disorder |
| TTP | Thrombotic thrombocytopenic purpura |
| ULvWF | Ultra-large molecules of vWF |
| vWD | von Willebrand disease |
| vWF | von Willebrand factor |

# Sickle Cell Disease

Tracy M. Hagemann and Teresa V. Lewis

---

## INTRODUCTION

**KEY CONCEPT** "*Sickle cell syndrome*" refers to a collection of autosomal recessive genetic disorders that are characterized by the presence of at least one sickle hemoglobin gene (HbS).[1,2]

Sickle cell disease (SCD) is a chronic illness that is associated with frequent crisis episodes. Acute complications are unpredictable and potentially fatal. Common symptoms include excruciating musculoskeletal pain, life-threatening pneumonia-like illness, cerebrovascular accidents, and splenic and renal dysfunction.[2] As the disease progresses, patients may develop organ damage from the combination of hemolysis and infarction. Because of the complexity and severity of SCD, it is imperative that patients have access to comprehensive care with providers who have a good understanding of the countless clinical presentations and the management options of this disorder.

## EPIDEMIOLOGY AND ETIOLOGY

Sickle cell trait (SCT) is the heterozygous form (HbAS) of SCD in which a person inherits one normal adult hemoglobin (*HbA*) gene and one sickle hemoglobin (*HbS*) gene. These individuals are carriers of the SCT and are usually asymptomatic.[2] Symptomatic disease is seen in homozygous and compound heterozygous genotypes of SCD. Sickle cell anemia (SCA) is the homozygous (HbSS) state of SCD.[2] It is the most common and severe form of SCD. SCD affects both males and females equally because it is not a sex-linked disease.

**KEY CONCEPT** *Around 90,000 to 100,000 Americans have SCD and it occurs in approximately 1 out of every 500 African American births.*[3] *HbSS* (~45%) is the most common genotype, followed by HbSC (~25%), HbSβ+-thalassemia (~8%), and HbSβ0-thalassemia (~2%). Other variants account for fewer than 1% of patients.[2,4] For every infant diagnosed with SCD, 50 are identified as carriers.[4]

Having the sickle hemoglobin gene protects heterozygous carriers from succumbing to *Plasmodium falciparum* (malaria) infection.[1] The microorganism cannot parasitize abnormal red blood cells (RBCs) as easily as normal RBCs. Consequently, persons with heterozygous sickle gene (SCT) have a selective advantage in tropical regions where malaria is endemic.

The highest incidence of SCD is seen in those with African heritage, but SCD also affects persons of Indian, Saudi Arabian, Mediterranean, South and Central American, and Caribbean ancestry.[4,5]

Normal HbA is composed of two α-chains and two β-chains (α2β2).[1] A single substitution of the amino acid valine for glutamic acid at position 6 of the β-polypeptide chain is responsible for the production of a defective form of hemoglobin called HbS.[1] Different genetic mutations encode for other hemoglobin variants such as hemoglobin C (HbC).[1] The α-chains of HbS, HbA, and HbC are structurally identical. The chemical differences in the β-chain are responsible for RBC sickling and its associated sequelae.

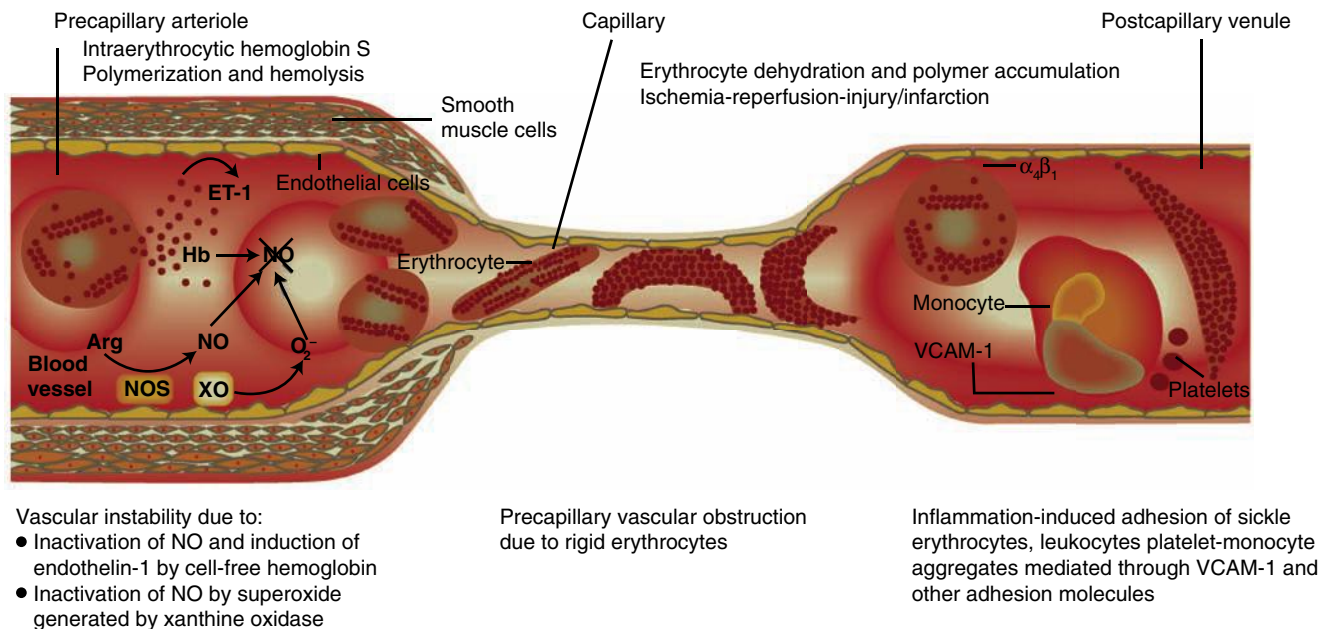
SCD is the HbSS state of SCD in which individuals inherit the mutant hemoglobin gene (*HbS*) from both parents. The progeny of two carriers will have a 25% probability of having SCD and a 50% risk of being a carrier. β-Thalassemia can be found in conjunction with HbS. Patients with HbSS and HbSβ0-thalassemia do not have normal β-globulin production and usually have a more severe course than those with HbSC and HbSβ+-thalassemia.


**FIGURE 68–1.** Pathophysiology of SCD. (Arg, arginine; ET-1, endothelin-1; Hb, hemoglobin; NO, nitric oxide; NOS, nitrous oxide synthase; VCAM-1, vascular cell adhesion molecule 1; XO, xanthine oxidase.) (From Kato GJ, Gladwin MT. Sickle cell disease. In: Hall JB, Schmidt GA, Wood LDH, eds. Principles of Critical Care. 3rd ed. New York: McGraw-Hill; 2005: 1658.)

Impaired circulation, destruction of RBCs, and vascular stasis are three known problems that are primarily responsible for the clinical manifestations of SCD (**Figure 68–1**).

## PATHOPHYSIOLOGY

**KEY CONCEPT** *SCD involves multiple organ systems, and its clinical manifestations vary greatly between and among genotypes.*

### Sickle Hemoglobin Polymerization

The primary event in the molecular pathogenesis of SCD involves polymerization of deoxygenated HbS. HbS carries oxygen normally, and when oxygenated, the solubility of HbS and HbA are the same. Once the oxygen is unloaded to the tissues, HbS solubility decreases. This promotes hydrophobic interactions between the hemoglobin molecules and polymerization, which leads to the distortion of the RBC into the characteristic crescent or sickle shape.[1]

### Viscosity of Erythrocytes and Sickle Cell Adhesion

When HbS becomes reoxygenated, the polymers within the RBCs disappear, and the cells eventually return to normal shape. Vasooclussion is caused by a combination of factors. Repeated assaults on RBCs from sickling and unsickling can lead to cell membrane damage, loss of membrane flexibility, and rearrangement of surface phospholipids. The life span of sickled RBCs is markedly shorter (10–20 days) than that of normal RBCs (100–120 days). As intracellular membrane viscosity of HbS-containing RBCs increases, blood viscosity increases, which further contributes to vasooclussion.[6] There is also increasing evidence that suggest sickle cells adhere to vascular endothelium.[1,6] The combined effects of decreased RBC deformability, slow transit through microcirculation, and adhesion to vascular endothelium contribute to obstruction of small and sometimes large blood vessels. The resulting local tissue hypoxia can accentuate the pathologic process of SCD.

### Protective Hemoglobin Types

Fetal hemoglobin (HbF) binds oxygen more tightly than HbA, and it has a decreased propensity to sickling. HbA2 also possesses this characteristic but to a lesser extent. RBCs that contain HbF sickle less readily than cells without. HbF is composed of two α chains and two β chains; therefore, it is not affected by point mutations on β chains. Irreversibly sickled cells (ISCs) are found to have low HbF concentrations. In some patients, higher HbF may ameliorate the disease.

### Other Pathophysiologic Effects

Other factors may be responsible for the pathogenesis of some of the clinical features of SCD. Sickle cells can obstruct blood flow to the spleen leading to functional asplenia. Impaired splenic function can increase the propensity to infection by encapsulated organisms, particularly *Streptococcus pneumoniae*.[1] Additionally,

---

**Clinical Presentation and Diagnosis of SCT**

**General**
- Generally asymptomatic

**Symptoms**
- Females may have frequent urinary tract infections

**Signs**
- Microscopic hematuria occurs rarely
- Gross hematuria may occur spontaneously or with heavy-intensity exercise

**Laboratory Tests**
- Normal Hgb values

## Clinical Presentation and Diagnosis of SCD

### General
- Identified by neonatal screening before 2 months of age

### Symptoms
- Painful vasoocclusive crises are the hallmark of SCD
- Dactylitis (hand–foot syndrome) before age 1 year
- May develop infarction of the spleen, liver, bone marrow, kidney, brain, and lungs
- Gallstones
- Priapism in males
- Slow-healing lower extremity ulcers after trauma or infection
- Weakness, fatigue

### Signs
- Chronic hemolytic anemia is common
- Enlargement of spleen and heart
- Scleral icterus

### Laboratory Tests
- Hgb 7.0 to 10.0 g/dL (70–100 g/L or 4.34–.21 mmol/L)
- Low HgF and increased reticulocytes, platelets, and white blood cells (WBCs)
- Presence of sickled cells on blood smear
- Neonatal screening: hemoglobin electrophoresis, isoelectric focusing, or DNA analysis

coagulation abnormalities are not uncommon since almost every component of hemostasis is altered in SCD.

## TREATMENT
### Desired Outcomes

Multidisciplinary, regularly scheduled care is required over the lifetime of the SCD patient, with the goal of reduction of complications and hospitalizations. Comprehensive care should include medical, educational, and psychosocial aspects as well as genetic and medication counseling.

Therapeutic interventions for SCD should be targeted at preventing and/or minimizing the symptoms related to the disease and its complications. The goals of treatment are to reduce or eliminate the patient's symptoms; decrease the frequency of sickle crises, including vasoocclusive pain crises; prevent the development of complications; and maintain or improve the quality of life through decreased hospitalizations and decreased morbidity. Specific therapeutic options may:

- Maintain or increase the hemoglobin level to the patient's baseline
- Increase the HbF concentration
- Decrease the HbS concentration
- Prevent infectious complications
- Prevent or effectively manage pain
- Prevent central nervous system (CNS) damage, including stroke

## General Approach to Treatment

Patients should be educated to recognize the signs and symptoms of complications that would require urgent evaluation. Patients and parents of children with SCD should be educated to seek immediate medical care when a fever develops or signs of infection occur. With acute illnesses, prompt evaluation is important, as deterioration may occur rapidly. Fluid status should be monitored to avoid dehydration or overhydration, both of which may worsen complications of SCD. Patients in acute distress should maintain oxygen saturation at 92% (0.92) or at their baseline. Any supplemental oxygen requirements should be evaluated.[4]

### Nonpharmacologic Therapy

Patients should avoid smoking and excessive alcohol intake. Patients with SCD should maintain adequate hydration in order to help decrease blood viscosity and should be educated to avoid extreme temperature changes and to dress properly in hot and cold weather. Physical exertion that leads to complications should be avoided.[4] Regular exams, including ophthalmic, dental, renal, pulmonary, and cardiac function, are required to monitor for organ damage. A treatment overview is shown in Table 68–1.

### Pharmacologic Therapy

#### ▶ Health Maintenance

**Immunizations** Children with SCD should receive the required immunizations as recommended by the American Academy of Pediatrics and the Advisory Committee on Immunization Practices.[7] Additionally, influenza vaccine should be administered yearly to SCD patients 6 months of age and older, including adult patients. All adult patients with SCD should also receive the vaccine for meningococcal disease as well as a one-time dose of *Haemophilus influenzae* type b vaccine. The quadrivalent meningococcal vaccine should be administered in two doses at least 2 months apart.[8]

Because patients with SCD have impaired splenic function, they are less adequately protected against encapsulated organisms such as *S. pneumoniae, H. influenzae,* and *Salmonella.* **KEY CONCEPT** *The use of pneumococcal vaccine in SCD patients has dramatically decreased the rates of morbidity and mortality; however, there are still groups of SCD children who continue to have high rates of invasive pneumococcal infections.*[9–11] Infection is the leading cause of death in children with SCD younger than 3 years of age.[11,12] Two pneumococcal vaccines are available. The 13-valent conjugate vaccine (PCV 13: Prevnar) is routinely administered to infants and children and provides good protection against the 13 most common isolates seen in this age range. Administer the first dose of PCV 13 between 6 weeks and 6 months of age, followed by two additional doses at 2-month intervals and a fourth dose at 12 to 15 months of age. The 23-valent polysaccharide vaccine (PPSV 23: Pneumovax 23) is indicated for children older than 2 years and adults. Because PPSV 23 is a polysaccharide vaccine, children younger than 2 years do not respond well. PPV 23 contains the 23 most common isolates of *S. pneumoniae* seen in older children and adults. Because of the different serotypes seen in the two vaccines, it is recommended that SCD children receive both vaccines, with a dose of PPSV 23 administered after the child turns 2 years of age. The dose of PPSV 23 should be separated from the last dose of PCV 13 by at least 2 months. An additional dose of PPSV 23 should be given to children 3 to 5 years of age to ensure antibody response. This second dose should be administered 5 years after the first PPSV 23 dose. All adults with

| Table 68–1 | |
|---|---|
| **Management of SCD** | |
| | **Options and Comments** |
| **Health maintenance** | |
| Infection prophylaxis | • Pneumococcal vaccines (PCV 13 and PPV 23) |
| | • Penicillin prophylaxis for children younger than 5 years of age |
| | • Annual influenza vaccine |
| Induction of fetal hemoglobin | • Hydroxyurea is the primary agent |
| | • Other agents are butyrates (arginine butyrate and sodium phenylbutyrate), decitabine, clotrimazole, and erythropoietin |
| | • Combination HbF inducers have been proposed |
| Chronic transfusion therapy | • Primary indication: stroke prevention in pediatric patients |
| | • May also reduce pain crisis and acute chest syndrome |
| | • Goal: maintain HbS less than 30% (0.30) |
| **Future prospects** | |
| Transplantation | • May potentially cure the disease |
| | • Most experience is with HLA-matched donors; umbilical cord blood transplantation is being evaluated |
| **Crises and complications** | |
| Fever and infection | • Broad-spectrum antibiotic: cefotaxime or ceftriaxone (clindamycin for cephalosporin allergy); vancomycin for staphylococcal and resistant pneumococcal organisms |
| | • Fluids |
| | • Acetaminophen or ibuprofen for fever |
| Stroke | • Exchange transfusion |
| | • Initiate chronic transfusion therapy to prevent recurrent strokes |
| Acute chest syndrome | • Broad-spectrum antibiotics (include Mycoplasma coverage) |
| | • Bronchodilator if wheezing or history of reactive airway disease |
| | • Fluids |
| | • Pain management |
| | • Transfusion |
| Pain crisis | • Hydration |
| | • Analgesics |

SCD should be vaccinated with both PCV 13 as well as PPSV 23. Adults and children who have not previously received PCV13 or PPSV 23 should receive one dose of PCV 13 followed by a single dose of PPSV 23 at a minimum of 8 weeks later.[8] If an adult or child with SCD has already received at least one dose of PPSV 23, they should additionally received on dose of PCV 13 at least 1 year after the dose of PPSV 23. When both vaccines are indicated in an unvaccinated patient with SCD, PCV 13 should be administered first, followed by a dose of PPSV 23 at least 8 weeks later.[8] A one-time revaccination with PPSV 23 should occur 5 years after the first dose of PPSV 23.[8] Because some children fall behind on their childhood vaccinations, a catch-up schedule is presented in **Table 68–2**.[7]

**Penicillin** KEY CONCEPT *Children with SCD should receive prophylactic penicillin until at least the age of 5 years, even if they have been appropriately immunized with PCV 13 against pneumococcal infections.* Penicillin V potassium is typically initiated at age 2 months, with a dose of 125 mg orally twice daily until age 3 years, then 250 mg orally twice daily until 5 years of age. The intramuscular use of benzathine penicillin 600,000 units every 4 weeks from age 6 months to 6 years is also an option for nonadherent patients. Penicillin-allergic patients may receive erythromycin 10 mg/kg twice daily. Penicillin prophylaxis usually is not continued in children older than 6 years, but may be considered in patients with a history of invasive pneumococcal infection or surgical splenectomy.[4,13,14]

**Folic Acid** Folic acid supplementation with 1 mg daily is generally recommended in adult SCD patients, women considering pregnancy, and any SCD patient with chronic hemolysis.[4]

Because of accelerated erythropoiesis, these patients have an increased need for folic acid. There are conflicting studies in the SCD population, especially among infants and children, but if the child has chronic hemolysis, supplementation is recommended.[15]

**Fetal Hemoglobin Inducers** Fetal hemoglobin (HbF) induction in patients with SCD, especially those with frequent crises, has been shown to decrease RBC sickling and RBC adhesion. A direct relationship between HbF concentrations and the severity of disease has been demonstrated in studies.[2]

**Hydroxyurea** Hydroxyurea is a ribonucleotide reductase inhibitor that prevents DNA synthesis and traditionally has been

---

**Patient Encounter 1**

A 6-year-old girl with SCD is currently taking penicillin V potassium 250 mg orally twice daily, folic acid 0.4 mg orally daily, and acetaminophen/codeine 120/12 mg per 5 mL orally every 6 hours as needed for pain. She fully completed all her routine childhood vaccinations and is up to date. She has not been hospitalized since age 2 when she had an aplastic crisis.

*What are the general prophylaxis recommendations for children with SCD?*

*What interventions do you want to make today to her medication/immunization regimens?*

*Design an infection prevention plan for this patient.*

| Table 68–2 |
|---|

**Pneumococcal Immunization for Children with SCD[7,9]**

| | Recommended Schedule |
|---|---|
| **Previously unvaccinated** | |
| Age 2–6 months | PCV 13 (Prevnar): three doses 8 weeks apart; then one dose at 12–15 months |
| Age 7–11 months | PCV 13 (Prevnar): two doses 8 weeks apart; then one dose at 12–15 months |
| Age 12–23 months | PCV 13 (Prevnar): two doses 8 weeks apart |
| Age 24–71 months | PCV 13 (Prevnar): two doses 8 weeks apart |
| | PPV 23 (Pneumovax): two doses; first dose at least 8 weeks after last PCV 13 dose; second dose 5 years after the first PPV 23 dose |
| Age 5 years or older | PCV 13 (Prevnar): one dose |
| | PPV 23 (Pneumovax): one dose at least 8 weeks after last PCV 13 dose; second dose 5 years after the first PPV 23 dose |
| **Previously vaccinated** | |
| Age 12–23 months, incomplete PCV 13 series | PCV 13 (Prevnar): two doses 8 weeks apart |
| Age 24–71 months, any incomplete schedule or completed less than three doses with PCV 13 | PCV 13 (Prevnar): two doses 8 weeks apart |
| | PPV 23 (Pneumovax): two doses; first dose at least 6–8 weeks after last PCV 13 dose; second dose 5 years after the first PPV 23 |
| Age 24–71 months, any incomplete schedule of three doses or four doses of PCV 13 | PCV 13 (Prevnar): one dose at least 8 weeks after the most recent dose |
| | PPV 23 (Pneumovax): two doses; first dose at least 6–8 weeks after last PCV 13 dose; second dose 5 years after the first PPV 23 |
| Age 24–71 months, one dose PPV 23 given | PCV 13 (Prevnar): one dose at least 8 weeks after PPV 23 dose |
| | PPV 23 (Pneumovax): second dose 5 years after first PPV 23 |
| Age 5–18 years, received one dose PPV 23 | PCV 13 (Prevnar): one dose at least 8 weeks after PPV 23 |
| | If only received one dose of PPV 23 (Pneumovax): second dose 5 years after the first PPV 23 dose |

used in chemotherapy regimens. Studies in the 1990s found that hydroxyurea increases HbF levels as well as increasing the number of HbF-containing reticulocytes and intracellular HbF. Other beneficial effects of hydroxyurea include antioxidant properties, reduction of neutrophils and monocytes, increased intracellular water content leading to increased red cell deformability, decreased red cell adhesion to endothelium, and increased levels of nitric oxide, which is a regulator involved in physiologic disturbances.[16]

**KEY CONCEPT** *Hydroxyurea reduced the frequency of hospitalizations and the incidences of pain, acute chest syndrome (ACS), and blood transfusions by almost 50% in a landmark trial in adult SCD patients with moderate to severe disease.* Hemoglobin and HbF concentrations increased and hemolysis decreased.[16] A follow-up study demonstrated a 40% reduction in mortality over a 9-year period in patients continuing to receive hydroxyurea.[17] Not all patients responded equally; therefore, hydroxyurea may not be the best option for all patients.

The use of hydroxyurea in children and adolescents with SCD has been investigated, and similar results were reported as in adult trials, with no adverse effects on growth and development.[4,18,19] Hydroxyurea is recommended as an option for children with moderate to severe SCD.[20]

The most common adverse effect of hydroxyurea is myelosuppression. Long-term adverse effects are unknown, but myelodysplasia, acute leukemia, and chronic opportunistic infections have been reported.[16] Hydroxyurea is teratogenic in high doses in animal studies and this is a concern, which should be addressed with patients. Normal pregnancies with no birth defects have been reported in some women receiving hydroxyurea, but close monitoring and weighing risk versus benefit to the patient are vitally important. Hydroxyurea is excreted in breast milk and should be avoided in lactating mothers.[16]

• Hydroxyurea should be considered in SCD with frequent vasoocclusive crises, severe symptomatic anemia, repeated history of ACS, or other history of severe vasoocclusive crisis (VOC) complications.[4] The prevention of organ damage or reversal of previous damage has not been shown to occur with chronic use of hydroxyurea.[17] The goals of therapy with hydroxyurea are to decrease the acute complications of SCD, improve quality of life, and reduce the number and severity of pain crises.

Hydroxyurea is available in 200-, 300-, 400-, and 500-mg capsules. Extemporaneous liquid preparations can be prepared for children who cannot swallow capsules. Doses should start at 10 to 15 mg/kg daily in a single oral dose, which can be increased after 8 to 12 weeks if blood counts are stable and there are no side effects. Individualize the dosage based on the patient's response and the toxicity seen. With close monitoring, doses can be increased 5 mg/kg/day up to 35 mg/kg daily.[16] In patients with renal failure, dosing of hydroxyurea will need to be adjusted according to the creatinine clearance, as shown in Table 68–3.

Closely monitor patients for efficacy and toxicity while they are receiving hydroxyurea. Monitor mean corpuscular volume (MCV), since it typically increases as the level of HbF increases. If the MCV does not increase with hydroxyurea use, the marrow may be unable to respond, the dose may not be adequate, or the patient may be nonadherent.[16] However, lack of increase in MCV or in HbF is not an indication to discontinue therapy; the clinical response to therapy may take 3 to 6 months. A 6-month trial on the maximum tolerated dose is required prior to consideration of discontinuation due to treatment failure, whether secondary to lack of adherence or failure to respond to therapy. HbF levels can also be monitored to assess response with a goal of increasing HbF to 15% to 20% (0.15–0.20). Assess blood counts every 2 weeks during dose titration and then every 4 to 6 weeks once the dose is stabilized. Temporary discontinuation of therapy is

| Table 68–3 | | |
| --- | --- | --- |
| **Dosage Adjustments for Renal and Hepatic Dysfunction** | | |
| **Medication** | **Renal Adjustment** | **Hepatic Adjustment** |
| Decitabine (Decagon) | For Scr ≥ 2 mg/dl (177 μmol/L): hold therapy until values return to baseline | For serum alanine transaminase (ALT), serum glutamic pyruvic transaminase (SGPT), or total bilirubin values more than two times the upper limit of normal: hold therapy until values return to baseline |
| Deferoxamine (Desferal) | $Cl_{cr}$ < 10 mL/min (0.17 mL/s): decrease the dose by 50% | |
| Deferasirox (Exjade) children | Greater than 33% increase in Scr (on two consecutive readings) and above the age-appropriate upper limits of normal: decrease daily dose by 10 mg/kg | Severe or persistent elevations in liver function tests: decrease the daily dose or discontinue therapy |
| Adults | Greater than 33% increase in Scr above pretreatment values on two consecutive readings: decrease daily dose by 10 mg/kg | Severe or persistent elevations in liver function tests: decrease the daily dose or discontinue therapy |
| Folic acid | No adjustment necessary | No adjustment necessary |
| Hydroxyurea | $Cl_{cr}$ < 60 mL/min (1.00 mL/s): Initial dose of 7.5 mg/kg/day | Monitor patient for bone marrow toxicity |
| | $Cl_{cr}$ 10–50 mL/min (0.17–0.83 mL/s): reduce the daily dose by 50% | |
| | $Cl_{cr}$ < 10 mL/min (0.17 mL/s): administer 20% of the usual dose | |
| | Hemodialysis: 7.5 mg/kg/day given after dialysis | |

Data from Refs. 21–26.

warranted if hemoglobin level is less than 4.5 g/dL (45 g/L or 2.79 mmol/L), absolute neutrophil count is less than $2 \times 10^3/mm^3$ ($2 \times 10^9$/L), platelets are less than $80 \times 10^3/mm^3$ ($80 \times 10^9$/L), or the reticulocytes are less than $80 \times 10^3/mm^3$ ($80 \times 10^9$/L). Monitor for increases in serum creatinine and transaminases. Once the patient's blood counts have returned to baseline, hydroxyurea may be restarted with a dose that is 2.5 to 5 mg/kg less than the dose associated with the patient's toxicity. Doses may then be increased by 2.5 to 5 mg/kg daily after 12 weeks with no toxicity.

Administer prophylactic folic acid supplementation to SCD patients receiving hydroxyurea, because folate deficiency may be masked by the use of hydroxyurea.

**5-Aza-2'-Deoxycytine (Decitabine)** For patients who do not respond to hydroxyurea, or cannot tolerate the side effects of hydroyurea, 5-azacytidine and 5-aza-2'-deoxycytidine (decitabine) may be useful. Both induce HbF by inhibiting methylation of DNA, preventing the switch from γ- to β-globin production. Decitabine appears to be safer and more potent than 5-azacytadine.

## Patient Encounter 2, Part 1

A 16-year-old African American girl with SCD is admitted to the hospital for progressive neck, shoulder, and back pain that began 2 days ago. The patient denies injury.

**PMH:** Sickle cell anemia (HbSS); admitted for vasoocclusive crises five times over the past year; acute chest syndrome at age 9, 12, and 14; multiple blood transfusions

**PSH:** Cholecystectomy, splenectomy

**FH:** Father with SC trait. Mother with SCD

**Allergies:** NKDA

**SH:** Occasional alcohol and marijuana use. Is not sexually active

**Home Meds:** Hydrocodone/acetaminophen 7.5/500 mg, one tablet every 6 hours as needed for pain; folic acid 1 mg daily by mouth

**PE:**

**VS:** T 39.0° C (102.2° F), BP 113/66, P 78, RR 22, $O_2$ Sat 99% (0.99) on 2 L nasal cannula, Ht 163 cm (5'4"), Wt 62.7 kg (138 lb)

**Gen:** Awake, alert × 3, in no acute distress, but obviously in pain

**HEENT:** Normocephalic, atraumatic. PERRLA. No lymphadenopathy

**Chest:** Normal to inspection and palpation. No rhonchi, rales, or wheezes

**CV:** RRR, no m/g/r

**Abd:** Soft, NT/ND

**Ext:** No clubbing, cyanosis, or edema. Shoulder pain with palpation

**Neuro:** Cranial nerves II through XII are grossly intact. Nonfocal

**Labs:** Hgb 7.3 g/dL (73 g/L or 4.53 mmol/L), Hct 23.1% (0.231 fraction), WBC $19 \times 10^3$/μL ($19 \times 10^9$/L), BMP WNL

Chest x-ray was within normal limits.

*What is your assessment of this patient's condition?*

*List treatment goals for this patient.*

*Devise a detailed therapeutic plan for this patient's hospital management.*

*Is the patient a candidate for hydroxyurea? Why or why not?*

**Patient Encounter 2, Part 2**

Four months later, the patient is seen on follow-up in the outpatient clinic for management of her SCD. She reports that she has a boyfriend and that they are sexually active.

*What are the concerns for using hydroxyurea in this patient? Are there any implications now that she is sexually active?*

In a small study in adults refractory to hydroxyurea, decitabine 0.2 mg/kg subcutaneously one to three times weekly was associated with an increase in HbF in all patients. Additionally, RBC adhesion was reduced. Neutropenia was the only significant toxicity reported.[27]

**Chronic Transfusion Therapy** Chronic transfusion therapy is warranted to prevent serious complications from SCD, including stroke prevention and recurrence. **KEY CONCEPT** *Especially in children, chronic transfusions have been shown to decrease stroke recurrence from approximately 50% to 10% over 3 years.* Without chronic transfusions, approximately 70% of ischemic stroke patients will have another stroke. Chronic transfusion therapy also may be used to prevent vasoocclusive pain and ACS, as well as prevent progression of organ damage.[4]

The goal of chronic transfusion therapy is to maintain the HbS level at less than 30% (0.30) of total hemoglobin concentration. Transfusions are usually administered every 3 to 4 weeks depending on the HbS concentration. For secondary stroke prevention, current studies have indicated that lifelong transfusion may be required, with increased incidence of recurrence once transfusions are stopped.[4]

The benefits of transfusion should be weighed with the risks. Risks associated with transfusions include alloimmunization (sensitization to the blood received), hyperviscosity, viral transmission, volume overload, iron overload, and transfusion reactions. Although the risk of contracting AIDS has decreased dramatically, hepatitis C remains a concern. All SCD patients should be vaccinated for hepatitis A and B and should be serially monitored for hepatitis C and other infections. Parvovirus occurs in 1 of every 40,000 units of RBCs and can be associated with acute anemia and multiple sickle cell complications.[4] Iron overload is a risk for patients maintained on chronic transfusions for more than 1 year. Counsel patients to avoid excessive dietary iron, and monitor serum ferritin regularly. Chelation therapy with deferoxamine or deferasirox should be considered when the serum ferritin level is greater than 1500 to 2000 ng/mL (1500–2000 mcg/L; 3400–4500 pmol/L). Deferoxamine should be initiated at 20 to 40 mg/kg daily (to a maximum of 1–2 g/day) over 8 to 12 hours subcutaneously and has been associated with growth failure.[4] Monitor children receiving deferoxamine for adequate growth and development on a regular basis. Deferasirox should be initiated at 20 mg/kg daily and is available in a tablet that should be dispersed in water, orange juice, or apple juice and taken orally 30 minutes before food.[28,29] Monitor all chelation patients for auditory and ocular changes on a yearly basis. Exchange transfusions may also be helpful in cases of iron overload.

Sickle cell hemolytic transfusion reaction syndrome is a unique problem in SCD patients. Due to alloimmunization, an acute or delayed transfusion reaction may occur 5 to 20 days posttransfusion. Patients may develop symptoms suggestive of a pain crisis or worsening symptoms if they are already in crisis.

A severe anemia after transfusion also may occur due to a rapid decrease in hemoglobin and hematocrit, along with a suppression of erythropoiesis. Further transfusions may worsen the clinical picture due to autoimmune antibodies. Recovery may occur only after ceasing all transfusions and is evidenced by a gradual increase in hemoglobin with reticulocytosis, which indicates the patient is now making their own RBCs.[4]

**Allogeneic Hematopoietic Stem Cell Transplant** Allogeneic hematopoietic stem-cell transplantation (HSCT) is the only potential cure for SCD. The best candidates are children with SCD who are younger than 16 years of age with severe complications, who have an identical human leukocyte antigen (HLA)-matched donor, usually a sibling. The transplant-related mortality rate is between 5% and 10%, and graft rejection is approximately 10%. Other risks include secondary malignancies, development of seizures or intracranial bleeding, and infection in the immediate posttransplant period.[4,30,31]

Experience with HSCT in adult patients with SCD is still somewhat limited. The use of less intense preparative regimens has made HSCT more available for the older patient with SCD. The best results have been seen in the use of progenitor cells (from bone marrow, cord blood, or peripheral blood stem cells) from matched sibling or related donors. The largest published trial to date in adults undergoing nonmyeloablative transplant involved 30 patients with an 87% rate of disease free survival.[5,31]

▶ *Acute Complications*

**Transfusions for Acute Complications** Red cell transfusion is indicated in patients with acute exacerbations of baseline anemia; in cases of severe vasoocclusive episodes, including ACS, stroke, and acute multiorgan failure; and in preparation for procedures that will require the use of general anesthesia or ionic contrast products. Transfusions also may be useful in patients with complicated obstetric problems, refractory leg ulcers, refractory and prolonged pain crises, or severe priapism. Hyperviscosity may occur if the hemoglobin level is increased to greater than 10.0 to 11.0 g/dL (100–110 g/L or 6.21–6.83 mmol/L). Volume overload leading to congestive heart failure is more likely to occur if the anemia is corrected too rapidly in patients with severe anemia and should be avoided.[4]

**Infection and Fever** **KEY CONCEPT** *Any fever greater than 38.5°C (101.3°F) in a SCD patient should be immediately evaluated, and the patient should have a blood culture drawn and be started on antibiotics that provide empirical coverage for encapsulated organisms.*[4]

Patients who should be hospitalized include the following:

- Infants younger than 1 year of age
- Patients with a previous sepsis or bacteremia episode
- Patients with temperatures in excess of 40°C (104°F)
- Patients with WBC counts greater than $30 \times 10^3/mm^3$ ($30 \times 10^9/L$) or less than $0.5 \times 10^3/mm^3$ ($0.5 \times 10^9/L$) and/or platelets less than $100 \times 10^3/mm^3$ ($100 \times 10^9/L$) with evidence of other acute complications
- Acutely ill-appearing individuals

Broad IV antibiotic coverage for the encapsulated organisms can include ceftriaxone or cefotaxime. For patients with true cephalosporin allergy, clindamycin may be used. If staphylococcal infection is suspected due to previous history or the patient appears acutely ill, vancomycin should be initiated. Macrolide antibiotics, such as erythromycin or azithromycin, may be

initiated if mycoplasma pneumonia is suspected. While the patient is receiving broad-spectrum antibiotics, their regular use of penicillin for prophylaxis can be suspended. Fever should be controlled with acetaminophen or ibuprofen. Because of the risk of dehydration during infection with fever, increased fluid may be needed.[1,4]

Bone infarcts or sickling in the periosteum usually is indicated by pain and swelling over an extremity. Osteomyelitis also should also be considered. *Salmonella* species are the most common cause of osteomyelitis in SCD children, followed by *Staphylococcus aureus*.[1] Select an appropriate antibiotic to cover the suspected organisms empirically.

**Cerebrovascular Accidents** Acute neurologic events, such as stroke, will require hospitalization and close monitoring. Patients should have physical and neurologic examinations every 2 hours.[4] Acute treatment may include exchange transfusion or simple transfusion to maintain hemoglobin at approximately 10.0 g/dL (100 g/L or 6.21 mmol/L) and HbS concentration at less than 30% (0.30). Patients with a history of seizure may need anticonvulsants, and interventions for increased intracranial pressure should be initiated if necessary. Children with history of stroke should be initiated on chronic transfusion therapy.[4]

Early detection of ischemic stroke can be done with the use of transcranial Doppler ultrasonography. In the Stroke Prevention Trial in Sickle Cell Anemia (STOP) study, screening with this method followed by chronic transfusion therapy significantly reduced the incidence of stroke.[32–34] Screening is recommended in all patients older than 2 years.

**Acute Chest Syndrome** ACS will require hospitalization for appropriate management of symptoms and to avoid complications. Patients should be encouraged to use incentive spirometry at least every 2 hours. Incentive spirometry helps the patient take long, slow breaths to increase lung expansion. Appropriate management of pain is important, but analgesic-induced hypoventilation should be avoided. Patients should maintain appropriate fluid balance because overhydration can lead to pulmonary edema and respiratory distress. Infection with gram-negative, gram-positive, or atypical bacteria is common in ACS, and early use of broad-spectrum antibiotics, including a macrolide, quinolone, or cephalosporin is recommended. Fat emboli, from infarction of the long bones, may lead to ACS. Oxygen therapy should be utilized in any patient presenting with respiratory distress or hypoxia. Oxygen saturations, measured by pulse oximeter, should be maintained at 92% (0.92) or above. Exchanges transfusions are often indicated when there is a rapid progression of ACS symptoms, such as increased needs for supplemental oxygen, increased respiratory distress, or progression of pulmonary infiltrates, and patients who present with wheezing may require inhaled bronchodilators.[4,35,36]

The use of corticosteroids is controversial. Although they may decrease the inflammation and endothelial cell adhesion seen with ACS, their use has also been associated with higher readmission rates for other complications.

**Priapism** By age 18, approximately 90% of SCD males will have had at least one episode of priapism. Stuttering priapism, where erection episodes last anywhere from a few minutes to less than 2 hours, resolves spontaneously. Erections lasting more than 2 hours should be evaluated promptly. Goals of therapy are to provide pain relief, reduce anxiety, provide detumescence, and preserve testicular function and fertility. Initial treatment should include aggressive hydration and analgesia. Transfusion may or

may not be helpful, but should be considered in anemic patients. Avoid the use of ice packs due to the risk of tissue damage.[4]

Both vasoconstrictors and vasodilators have been used in the treatment of priapism. Vasoconstrictors are thought to work by forcing blood out of the cavernosum and into the venous return.

**Clinical Presentation and Diagnosis of ACS in SCD**

**General**
- Occurs in 15% to 43% of patients and is responsible for 25% of deaths
- Risk factors include young age, low HbF level, high Hgb and WBCs, winter seasons, reactive airway disease
- Recurrences are up to 80% and can lead to chronic lung disease

**Symptoms**
- Patients may complain of cough, fever, dyspnea, chest pain

**Signs**
- Temperature greater than 38.5°C (101.3°F)
- Hypoxia
- New infiltrate on chest x-ray

**Laboratory Tests**
- CBC with reticulocyte count
- Blood gases
- Oxygen saturation
- Cultures (blood and sputum)

**Other**
- Closely monitor pulmonary status

**Clinical Presentation and Diagnosis of Priapism in SCD**

**General**
- Mean age of initial episode is 12 years of age
- Most males with SCD will have one episode by age 20
- Repeated episodes can lead to fibrosis and impotence

**Symptoms**
- Patients may complain of painful and unwanted erection lasting anywhere from less than 2 hours (stuttering type) to more than 2 hours (prolonged type)

**Signs**
- Urinary obstruction

**Laboratory Tests**
- CBC with reticulocyte count

**Other**
- Monitor for duration of episode
- Prolonged episodes should be considered medical emergencies

## Clinical Presentation and Diagnosis of Acute Aplastic Crisis in SCD

**General**

- Transient suppression of RBC production in response to bacterial or viral infection
- Most commonly due to infection with parvovirus B19

**Symptoms**

- Patients may complain of headache, fatigue, dyspnea, pallor, or fever
- Patients may also complain of upper respiratory or GI infection symptoms

**Signs**

- Temperature greater than 38.5°C (101.3°F) may occur
- Hypoxia
- Tachycardia
- Acute decrease in Hgb with decreased reticulocyte count

**Laboratory Tests**

- CBC with reticulocyte count
- Chest x-ray
- Parvovirus titers
- Cultures (blood, urine, and throat)

## Clinical Presentation and Diagnosis of Sequestration Crisis in SCD

**General**

- Acute exacerbation of anemia due to sequestration of large blood volume by the spleen
- More common in patients with functioning spleens
- Onset often associated with viral or bacterial infections
- Recurrence is common and can be fatal

**Symptoms**

- Sudden onset of fatigue, dyspnea, and distended abdomen
- Patients may present with vomiting and abdominal pain

**Signs**

- Rapid decrease in Hgb and Hct with elevated reticulocyte count
- Splenomegaly
- May exhibit hypotension and shock

**Evaluation**

- Vital signs
- Spleen size changes
- Oxygen saturations
- CBC with reticulocyte count
- Cultures (blood, urine, throat)

Aspiration of the penile blood followed by intracavernous irrigation with epinephrine (1:1,000,000 solution) has been effective with minimal complications.[37] In severe cases, surgical intervention to place penile shunts has been used, but there is a high failure rate, and the risk of complications, from skin sloughing to fistulas, limits its use.

Pseudoephedrine dosed at 30 to 60 mg daily taken at bedtime has been used to prevent or decrease the number of episodes of priapism.[4] Terbutaline 5 mg has been used orally to prevent priapism, with mixed results.[37,38] Leuprolide, a gonadotropin-releasing hormone, also has been used for this indication. Hydroxyurea may be helpful in some patients.[37,39] The use of antiandrogens is under investigation.[4]

### ▶ Treatment of Acute Complications

**Aplastic Crisis** Most patients in aplastic crisis will recover spontaneously and therefore treatment is supportive. If anemia is severe or symptomatic, transfusion may be indicated. Infection with human parvovirus B19 is the most common cause of aplastic crisis. Isolate infected patients because parvovirus is highly contagious. Pregnant individuals should avoid contact with infected patients because midtrimester infection with parvovirus may cause hydrops fetalis and still birth.[1,4]

**Sequestration Crisis** RBC sequestration in the spleen in young children may lead to a rapid drop in hematocrit, resulting in hypovolemia, shock, and death. Treatment is RBC transfusion to correct the hypovolemia, as well as broad-spectrum antibiotics, because infections may precipitate the crisis.[1,4]

## Clinical Presentation and Diagnosis of Vasoocclusive Crisis in SCD

**General**

- Most often involves the bones, liver, spleen, brain, lungs, and penis
- Precipitating factors include infection, extreme weather conditions, dehydration, and stresses
- Recurrent acute crises result in bone, joint, and organ damage and chronic pain

**Symptoms**

- Patients may complain of deep throbbing pain, local tenderness

**Signs**

- Erythema and swelling of painful area
- Dactylitis in young infants
- Temperature greater than 38.5°C (101.3°F)
- Leukocytosis

**Laboratory tests**

- CBC with reticulocyte count
- Urinalysis
- Abdominal studies (if symptoms exist)
- Cultures (blood and urine)
- Liver function tests and bilirubin
- Chest x-ray

---

**Table 68–4**

**Management of Acute Pain of SCD**

**Principles**
Treat underlying precipitating factors.
- Avoid delays in analgesia administration.
- Use pain scale to assess severity.
- Choice of initial analgesic should be based on previous pain crisis pattern, history of response, current status, and other medical conditions.
- Schedule pain medication; avoid as-needed dosing.
- Provide rescue dose for breakthrough pain.
- If adequate pain relief can be achieved with one or two doses of morphine, consider outpatient management with a weak opioid; otherwise hospitalization is needed for parenteral analgesics.
- Frequently assess to evaluate pain severity and side effects; titrate dose as needed.
- Treating adverse effects of opioids is part of pain management.
- Consider nonpharmacologic intervention.
- Transition to oral analgesics as the patient improves; choose an oral agent based on previous history, anticipated duration, and ability to swallow tablets; if sustained-release products are used, a fast-release product is also needed for breakthrough pain.

**Analgesic Regimens**
Mild to moderate pain:
Acetaminophen with codeine:
- Dose based on codeine—children: 1 mg/kg per dose every 6 hours; adults: 30–60 mg/dose

Hydrocodone + acetaminophen:
- Dose based on hydrocodone—children: 0.2 mg/kg per dose every 6 hours; adults: 5–10 mg/dose

Anti-inflammatory agents:
- Use with caution in patients with renal failure (dehydration) and bleeding
- Ibuprofen (oral): children: 10 mg/kg every 6–8 hours; adults: 200–400 mg/dose
- Naproxen: 5 mg/kg every 12 hours; adults: 250–500 mg/dose
- Ibuprofen + hydrocodone: Each tablet contains 200 mg ibuprofen and 7.5 mg hydrocodone per tablet; only for older children who can swallow tablets

Moderate to severe pain:
*Morphine—children:* 0.1–0.15 mg/kg per dose every 3–4 hours; adults: 5–10 mg/dose
- Continuous infusion: 0.04–0.05 mg/kg/hour; titrate to effect

*Hydromorphone—children:* 0.015 mg/kg per dose every 3–4 hours; adults: 1.5–2 mg/dose
- Continuous infusion: 0.004 mg/kg/hour; titrate to effect

IV anti-inflammatory agents:
- Ketorolac: 0.5 mg/kg up to 30 mg/dose every 6 hours

Patient-controlled analgesics:
- Morphine: 0.01–0.03 mg/kg/hour basal; demand 0.01–0.03 mg/kg every 6–10 minutes; 4 hours lockout 0.04–0.06 mg/kg
- Hydromorphone: 0.003–0.005 mg/kg/hour basal; demand 0.003–0.05 mg/kg every 6–10 minutes; 4 hours lock out 0.4–0.6 mg/kg

---

Recurrent episodes are common and can be managed with chronic transfusion and splenectomy. Observation is used commonly in adults because their episodes are milder. Splenectomy is usually delayed until after 2 years of age to lessen the risk of postsplenectomy septicemia. Patients with chronic hypersplenism should be considered for splenectomy.[4,40]

**Vasoocclusive Pain Crisis**   The mainstay of treatment for vasoocclusive crisis includes hydration and analgesia (Table 68–4). Pain may involve the extremities, back, chest, and abdomen. KEY CONCEPT *Patients with mild pain crisis may be treated as outpatients with rest, warm compresses to the affected (painful) area, increased fluid intake, and oral analgesia.* Patients with moderate to severe crises should be hospitalized. Infection should be ruled out because it may trigger a pain crisis, and any patient presenting with fever or critical illness should be started on empirical broad-spectrum antibiotics. Patients who are anemic should be transfused to their baseline. IV or oral fluids at 1.5 times maintenance is recommended. Close monitoring of the patient's fluid status is important to avoid overhydration, which can lead to ACS, volume overload, or heart failure.[4]

Aggressive pain management is required in patients presenting in pain crisis. Assess pain on a regular basis (every 2 to 4 hours), and individualize management to the patient. The use of pain scales may help with quantifying the pain rating. Obtain a good medication history of what has worked well for the patient in the past. Use acetaminophen or a nonsteroidal anti-inflammatory drug (NSAID) for treatment of mild to moderate pain. Patients with bone or joint pain who require IV medications may be helped by the use of ketorolac, an injectable NSAID. Because of the concern for side effects, including GI bleeding, ketorolac should be used only for a maximum of 5 consecutive days. Monitor for the total amount of acetaminophen given daily, because many products contain acetaminophen. Maximum daily dose of acetaminophen for adults is 4 g/day, and for children, five doses over a 24-hour period.[41] Add an opioid if pain persists or if pain is moderate to severe in nature. Combining an opioid with an NSAID can enhance the analgesic effects without increasing adverse effects.[42–45]

Severe pain should be treated with an opioid such as morphine, hydromorphone, methadone, or fentanyl. Moderate pain can be effectively treated in most cases with a weak opioid such as

codeine or hydrocodone, usually in combination with acetaminophen. Meperidine should be avoided because of its relatively short analgesic effect and its toxic metabolite, normeperidine. Normeperidine may accumulate with repeated dosing and can lead to CNS side effects including seizures.

IV opioids are recommended for use in treatment of severe pain because of their rapid onset of action and ease in titration. Intramuscular injection should be avoided. Analgesia should be individualized and titrated to effect, either by scheduled doses or continuous infusion. The use of continuous infusion will avoid the fluctuations in blood levels between doses that are seen with bolus dosing. As-needed dosing of analgesia is only appropriate for breakthrough pain or uncontrolled pain. Patient-controlled analgesia (PCA) is commonly used and allows the patient to have control over his or her analgesic breakthrough dosing. As the pain crisis resolves, the pain medications can be tapered. Physical therapy and relaxation therapy can be helpful adjuvants to analgesia.[42–45]

Tolerance to opioids is seen when patients have had continuous long-term use of the medications and can be managed during acute crises by using a different potent opioid or using a larger dose of the same medication. Adverse effects associated with the use of opioids include respiratory depression, itching, nausea and vomiting, constipation, and drowsiness. Patients on continuous infusions of opioids should be on continuous pulse oximeter to assess oxygen saturations. Monitor the patient for oxygen saturations less than 92% (0.92). Oxygen should be administered as needed to keep the saturations above 92% (0.92). Itching can be managed with an antihistamine such as diphenhydramine. Nausea and vomiting can be treated and managed with the administration of antiemetics such as promethazine or the 5HT3 antagonists, but the use of promethazine is contraindicated in children younger than 2 years of age. Assess stool frequency in all patients on a continuous opioid, and start stool softeners or laxatives as needed. Excessive sedation is difficult to control, and the concurrent use of an opioid with diphenhydramine or other sedative medications can exacerbate the drowsiness, leading to hypoxemia. A continuous very low dose of naloxone, an opioid antagonist, has been used successfully when the adverse effects such as itching are unbearable.[46]

## OUTCOME EVALUATION

SCD treatment and prevention are considered successful when complications are minimized. The major outcome parameters are a decrease in morbidity and mortality, measured by the number of hospitalizations, and the extent of end-organ damage seen over time. Today, with longer survival for SCD, chronic manifestations of the disease contribute to the morbidity later in life (Table 68–5). Thirty years ago, complications from SCD contributed to high mortality. It was estimated that approximately 50% of patients with SCD did not survive to reach adulthood.[1] Since that time, data suggest improvement in mortality rates for patients with SCD. The survival age for individuals with HbSS has increased to at least the fifth decade of life. Recent reports suggest 85% survival by 18 years of age.[4] SCD is a chronic disease and cannot be cured, except in some patients with transplant.

● Starting with birth, SCD patients should have regularly scheduled health assessments and interventions when necessary. Obtain a urine analysis, complete blood count, liver function tests, ferritin or serum iron level and total iron-binding capacity, blood urea nitrogen (BUN), and creatinine on at least a yearly basis and more often for children younger than 5 years of age to monitor for complications. All SCD patients should have regular screening of their hearing and vision.

All patients and parents of children with SCD should have a plan for what to do in the event of symptoms of infection or pain. Obtain a medication history when patients are admitted to the hospital. Assess adherence with prophylactic penicillin and childhood immunization schedules in all pediatric SCD patients.

| **Table 68–5** | |
|---|---|
| **Chronic Complications of SCD** | |

| System | Complications |
|---|---|
| Auditory | Sensorineural hearing loss due to sickling in cochlear vasculature with hair cell damage |
| Cardiovascular | Cardiomegaly, myocardial ischemia, murmurs, and abnormal ECG; patients with SCD have lower BP than the normal population; normal BP values for SCD should be used for diagnosis of hypertension ("relative" hypertension); heart failure usually is related to fluid overload |
| Dermatologic | Painful leg ulcers; failure to heal occurs in 50% of patients; recurrences are common |
| Genitourinary | Renal papillary necrosis, hematuria, hyposthenuria, proteinuria, nephrotic syndrome, tubular dysfunction, chronic renal failure, impotence |
| Growth and development | Delay in growth (weight and height) and sexual development; decreased fertility; increased complications during pregnancy; depression may be more prevalent than in general population, especially in patients with unstable disease |
| Hepatic and biliary | Cholelithiasis, biliary sludge, acute and chronic cholecystitis, and cholestasis (can be progressive and life-threatening) |
| Neurologic | "Silent" brain lesions on MRI are associated with poor cognitive and fine motor functions; pseudotumor cerebri (rare) |
| Ocular | Retinal or vitreous hemorrhage, retinal detachment, transient or permanent visual loss; central retinal vein occlusion |
| Pulmonary | Pulmonary fibrosis, pulmonary hypertension, cor pulmonale |
| Renal | Hematuria, hyposthenuria (inability to concentrate urine maximally), tubular dysfunction, enuresis during early childhood, acute renal failure can also occur |
| Skeletal | Aseptic necrosis of ball-and-socket joints (shoulder and hip); prostheses may be needed due to permanent damage; bone marrow hyperplasia resulting in growth disturbances of maxilla and vertebrae |
| Spleen | Asplenia (autosplenectomy or surgical splenectomy) |

## Patient Care Process

**Patient Assessment:**

- Based on physical exam and review of systems, determine whether the patient is experiencing any signs or symptoms of an acute or chronic SCD complication (see Tables 68–1 and 68–5)

- Review the patient's medical history. Does the patient have a history of previous complications from SCD that would necessitate chronic medication therapy? When was the patient last hospitalized for SCD complications?

- Conduct a medication history including prescriptions, OTC medications, and dietary supplements. Does the patient take any medications routinely for SCD? Does the patient take any analgesics as needed for pain? Does the patient have any medication allergies? Is the patient experiencing any side effects from their current medication therapy? Is the patient adherent with their chronic medication therapy?

- Review available laboratory tests.

- Is the patient up to date on their immunizations? Have they received their annual influenza vaccine?

**Therapy Evaluation:**

- Which analgesics have been helpful to the patient in the past? Is the patient taking appropriate doses of their pain medication to achieve the desired analgesic effect? If not, why?

- If the patient is having an acute complication of SCD, arrange for referral and/or admission to the hospital.

- If the patient is receiving hydroxyurea, review appropriate laboratory tests. Assess efficacy, safety, and patient adherence.

- If the patient is receiving chelation therapy, review appropriate laboratory tests. Assess efficacy, safety, and patient adherence.

- Determine if the patient has prescription coverage or whether recommended agents are included on the institution's formulary.

**Care Plan Development:**

- Select lifestyle modifications that are likely to be effective and safe for the patient.

- Determine whether drug doses are optimal.

- Arrange for vaccination if the patient is not up to date with recommendations.

- Address any patient concerns about SCD and its management.

- Discuss the importance of medication adherence and lifestyle modifications to reduce complications of SCD.

**Follow-Up Evaluation:**

- Follow-up at monthly intervals or more frequently to assess effectiveness and safety of therapy, to avoid complications from SCD and improve quality of life for the patient.

- Review medication history and physical exam findings, laboratory tests and results of other diagnostic tests.

- Assess for adverse effects from medications that the patient is taking.

- Stress the importance of adherence with the therapeutic regimen, including lifestyle modifications. Adjust therapeutic regimens as needed based on patient response and adverse effects.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| ACS | Acute chest syndrome |
| CNS | Central nervous system |
| HbA | Normal adult hemoglobin |
| HbAS | One normal and one sickle hemoglobin gene |
| HbC | Hemoglobin C |
| HbF | Fetal hemoglobin |
| HbS | Sickle hemoglobin |
| HbSβ$^0$-thalassemia | One sickle hemoglobin and one β$^0$-thalassemia gene |
| HbSβ$^+$-thalassemia | One sickle hemoglobin and one β$^+$-thalassemia gene |
| HbSC | One sickle hemoglobin and one hemoglobin C gene |
| HbSS | Homozygous sickle hemoglobin |
| Hgb | Hemoglobin |
| HLA | Human leukocyte antigen |
| HSCT | Hematopoietic stem cell transplantation |
| ISC | Irreversibly sickled cell |
| MCHC | Mean corpuscular hemoglobin concentration |
| MCV | Mean corpuscular volume |
| NSAID | Nonsteroidal anti-inflammatory drug |
| PCA | Patient-controlled analgesia |
| PCV 13 | 13-Valent pneumococcal conjugate vaccine |
| PPV 23 | 23-Valent pneumococcal polysaccharide vaccine |
| SCA | Sickle cell anemia |
| SCD | Sickle cell disease |
| SCT | Sickle cell trait |
| STOP | Stroke Prevention Trial in Sickle Cell Anemia |
| VOC | Vasoocclusive crisis |
| WBC | White blood cell |

# 69 Antimicrobial Regimen Selection

Catherine M. Oliphant

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Recognize that antimicrobial resistance is an inevitable consequence of antimicrobial therapy.

2. Describe how antimicrobials differ from other drug classes in terms of their effects on individual patients as well as on society as a whole.

3. Identify two guiding principles to consider when treating patients with antimicrobials, and apply these principles in patient care.

4. Differentiate between microbial colonization and infection based on patient history, physical examination, and laboratory and culture results.

5. Evaluate and apply at least six major drug-specific considerations when selecting antimicrobial therapy.

6. Evaluate and apply at least seven major patient-specific considerations when selecting antimicrobial therapy.

7. Select empirical antimicrobial therapy based on spectrum-of-activity considerations that provide a measured response proportional to the severity of illness. Provide a rationale for why a measured response in antimicrobial selection is appropriate.

8. Identify and apply five major principles of patient education and monitoring response to antimicrobial therapy.

9. Identify two common causes of patients failing to improve while on antimicrobials, and recognize other less common but potential reasons for antimicrobial failure.

## INTRODUCTION

Since 1980, infectious disease–related mortality in the United States has increased, in part owing to increases in antimicrobial resistance. The discovery of virtually every new class of antimicrobials has occurred in response to the development of bacterial resistance and loss of clinical effectiveness of existing antimicrobials. KEY CONCEPT *An inevitable consequence of exposing microbes to antimicrobials is that some organisms will develop resistance to the antimicrobial.* Today, there are many antimicrobial classes and antimicrobials available for clinical use. However, in many cases, differences in mechanisms of action between antimicrobials are minor, and the microbiologic properties of the agents are similar. KEY CONCEPT *Antimicrobials are different from other classes of pharmaceuticals because they exert their action on bacteria infecting the host as opposed to acting directly on the host.* Because antimicrobial use in one patient affects not only that patient but also other patients if they become infected with resistant bacteria, correct selection, use, and monitoring of clinical response are paramount.

KEY CONCEPT *There are two guiding principles to consider when treating patients with antimicrobials: (a) make the correct diagnosis and (b) do no harm!* Patients with infections frequently present with signs and symptoms that are nonspecific and may be confused with other noninfectious disease. Not only is it important to determine whether a disease process is of infectious origin, but it is also important to determine the specific causative pathogen of the infection. Antimicrobials vary in their **spectrum of activity**, the ability to inhibit or kill different species of bacteria. Antimicrobials that kill many different species of bacteria are called *broad-spectrum antimicrobials*, whereas antimicrobials that kill only a few species of bacteria are called *narrow-spectrum antimicrobials*. One might argue that treating everybody with broad spectrum antimicrobials will increase the likelihood that a patient will get better even without knowing the bacteria causing infection. However, counter to this argument is the principle of "Do no harm!" Broad antimicrobial coverage does increase the likelihood of empirically killing a causative pathogen; unfortunately, the development of secondary infections can be caused by selection of antimicrobial-resistant nontargeted pathogens. In addition, adverse events are thought to complicate up to 10% of all antimicrobial therapy, and for select agents, the adverse-event rates are similar to high-risk medications such as warfarin, digoxin, or insulin.[1] Therefore, the overall goal of antimicrobial therapy should be to cure the patient's infection; limit harm by minimizing patient risk for adverse effects, including secondary infections; and limit societal risk from antimicrobial-resistant bacteria.

## EPIDEMIOLOGY AND ETIOLOGY

Infectious disease–related illnesses, particularly respiratory tract infections, are among the most common reasons patients seek

medical care.[2] Antimicrobial prescribing has been associated with inappropriate use of antimicrobial agents. During the late 1990s/early 2000s, many organizations initiated campaigns to promote appropriate antimicrobial use. Recent trends in prescribing suggest a modest reduction in antimicrobial use for these infections, suggesting an increased recognition of the negative consequences of antimicrobial use.[3,4] Up to one-half of all patients receive at least one antimicrobial during hospitalization. In 2011, the number of health care–associated infections in acute care hospitals in the United States was estimated at 721,800, with approximately 75,000 deaths.[5] In 2014, the CDC reported that there were reductions in central line–associated bloodstream infections (44% reduction between 2008 and 2012) and surgical site infections (20% reduction between 2008 and 2012) as well as a slight reduction in hospital-onset MRSA bloodstream infection (4% reduction from 2011 to 2012).[6] Nosocomial infections tend be associated with antimicrobial-resistant strains of bacteria. However, there has been a shift in the etiology of some community-acquired infections. Increasingly, infections caused by antimicrobial-resistant pathogens, traditionally nosocomial in origin, are being identified in ambulatory care settings. Reasons for this change include an aging populace, improvement in the management of chronic comorbid conditions including immunosuppressive conditions, and increases in outpatient management of more debilitated patients. The majority of infections caused by antimicrobial-resistant pathogens in the ambulatory care setting occur in patients who have had recent exposure to the health care system. The converging bacterial etiologies and increasing resistance in all health care environments emphasize the need to "make the diagnosis."

## PATHOPHYSIOLOGY

### Normal Flora and Endogenous Infection

Many areas of the human body are colonized with bacteria—this is known as **normal flora**. Infections often arise from one's own normal flora (called an *endogenous infection*). Endogenous infection may occur when there are alterations in the normal flora (eg, recent antimicrobial use may allow for overgrowth of other normal flora) or disruption of host defenses (eg, a break or entry in the skin). Knowing what organisms reside where can help guide empirical antimicrobial therapy (**Figure 69–1**). In addition, it is beneficial to know what anatomic sites are normally sterile. These include the cerebrospinal fluid, blood, and urine.

### Determining Colonization versus Infection

Infection refers to the presence of bacteria that are causing disease (eg, the organisms are found in normally sterile anatomic sites or in nonsterile sites with signs/symptoms of infection). *Colonization* refers to the presence of bacteria that are not causing disease. **KEY CONCEPT** *Only bacteria that cause disease should be targeted with antimicrobial therapy, and non–disease-producing colonizing flora should be left intact.* It is important to differentiate infection from colonization because antimicrobial therapy targeting colonization is inappropriate and may lead to the development of resistant bacteria.

**Skin: $10^5$–$10^7$**
*Staphylococcus epidermidis*
*Staphylococcus aureus*
Micrococci
Diphtheroids:
*Propionibacterium spp*

**Mouth: $10^9$–$10^{11}$**
Viridans streptococci
Oral anaerobes

**Lower Respiratory Tract:**
Normally sterile

**Upper Respiratory Tract: $10^5$–$10^9$**
Oral anaerobes
*Streptococcus* sp
*Staphylococcus* sp
*Neisseria* sp
Diphtheroids
*Haemophilus* sp
*Streptococcus pneumoniae*

**Small Intestine:**
**Duodenum/jejunum: $10^3$–$10^5$**
  *Lactobacillus*
  *Streptococcus* sp
  *Enterococcus*
  Enterobacteriaceae
  Diphtheroids
  Few anaerobes

**Stomach: $<10^3$**
*Streptococcus* sp
*Lactobacillus*

**Ileum: $10^4$–$10^6$ Aerobes**
     **$10^5$–$10^7$ Anaerobes**
Enterobacteriaceae
*Enterococcus* sp
*Peptostreptococcus*
Anaerobes including:
  *Bacteroides* sp
  *Clostridium* sp

**Large Intestine: $10^4$–$10^6$ Aerobes**
              **$10^5$–$10^7$ Anaerobes**
Enterobacteriaceae
*Enterococcus* sp
*Pseudomonas* sp
*Streptococcus* sp
Anaerobes including:
  *Bacteroides* sp
  *Clostridium* sp

**FIGURE 69–1.** Normal flora and concentrations of bacteria (organisms per milliliter).

## Exogenously Acquired Bacterial Infections

Infections acquired from an external source are referred to as *exogenous infections*. These infections may occur as a result of human-to-human transmission, contact with exogenous bacterial populations in the environment, and animal contact. Resistant pathogens such as methicillin-resistant *Staphylococcus aureus* (MRSA) and vancomycin-resistant *Enterococcus* spp (VRE) may colonize hospitalized patients or patients who access the health care system frequently. It is important to know which patients have acquired these organisms because patients generally become colonized prior to developing infection, and colonized patients should be placed in isolation to minimize transmission.

## Contrasting Bacterial Virulence and Resistance

*Virulence* refers to the pathogenicity or disease severity produced by an organism. Bacteria may produce toxins or possess characteristics that contribute to their pathogenicity. Some virulence factors allow the organism to avoid the immune response of the host and cause significant disease. Virulence and resistance are different microbial characteristics. For example, *Streptococcus pyogenes*, a common cause of skin infections, produces toxins that can cause severe disease, yet it is very susceptible to penicillin. *Enterococcus faecium* is a highly resistant organism but is frequently a colonizing flora that causes disease primarily in the immunocompromised.

## CLINICAL PRESENTATION AND DIAGNOSIS
### Physical Examination

Findings on physical examination, along with the clinical presentation, can help identify the anatomic location of the infection.

Once the anatomic site is identified, the most probable pathogens associated with disease can be determined based on likely endogenous or exogenous flora.

Fever often accompanies infection and is defined as a rise in body temperature above the normal 37°C (98.6°F). Oral and axillary temperatures may underestimate core temperature by at least 0.6°C (1°F), whereas rectal temperatures best approximate core temperatures. Fever is a host response to bacterial toxins. However, bacterial infections are not the sole cause of fever. Fever also may be caused by other infections (eg, fungal or viral), medications (eg, penicillins, cephalosporins, salicylates, and phenytoin), trauma, or other medical conditions (eg, autoimmune disease, malignancy, pulmonary embolism, and hyperthyroidism). Some patients with infections may present with hypothermia (eg, patients with overwhelming infection). Elderly patients may be afebrile, as may those with localized infections (eg, urinary tract infection).[7] For others, fever may be the only indication of infection. Neutropenic patients may not have the ability to mount normal immune responses to infection (eg, infiltrate on chest x-ray, pyuria on urinalysis, or erythema or induration around catheter site), and the only finding may be fever.

### Imaging Studies

Imaging studies also may help to identify anatomic localization of the infection. These studies usually are performed in conjunction with other tests to establish or rule out the presence of an infection. Radiographs are performed commonly to establish the diagnosis of pneumonia, as well as to determine the severity of disease. Computed tomography (CT) scans are a type of x-ray that produces a three-dimensional image of the combination of soft tissue, bone, and blood vessels. In contrast, magnetic resonance imaging (MRI) uses electromagnetic radio waves to

---

## Clinical Presentation

- Review of symptoms consistent with an infectious etiology.
- Signs and symptoms may be nonspecific (eg, fever) or specific.
- Specific signs and symptoms are beyond the scope of this chapter (see disease state–specific chapters for these findings).

**Patient History**
- History of present illness
- Comorbidities
- Current medications
- Allergies
- Previous antibiotic exposure (may provide clues regarding colonization or infection with new specific pathogens or pathogens that may be resistant to certain antimicrobials)
- Previous hospitalization or health care utilization (also a key determinant in selecting therapy because the patient may be at risk for specific pathogens and/or resistant pathogens)
- Travel history
- Social history
- Pet/animal exposure
- Occupational exposure
- Environmental exposure

**Physical Findings**
- Findings consistent with an infectious etiology
- Vital signs
- Body system abnormalities (eg, rales, altered mental status, localized inflammation, erythema, warmth, edema, pain, and pus)

**Diagnostic Imaging**
- Radiographs (x-rays)
- CT scans
- MRI
- Labeled leukocyte scans

**Nonmicrobiologic Laboratory Studies**
- White blood cell count (WBC) with differential
- Erythrocyte sedimentation rate (ESR)
- C-reactive protein
- Procalcitonin

**Microbiologic Studies**
- Gram stain
- Culture and susceptibility testing

produce two- or three-dimensional images of soft tissue and blood vessels with less detail of bony structures.

## Nonmicrobiologic Laboratory Studies

Nonmicrobiological laboratory tests include the white blood cell count (WBC) and differential, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and procalcitonin levels. In most cases, the WBC count is elevated in response to infection, but it may be decreased owing to overwhelming or long-standing infection. The differential is the percentage of each type of WBC (Table 69–1). In response to physiologic stress, neutrophils leave the bloodstream and enter the tissue to "fight" against the offending pathogens (ie, leukocytosis). It is important to recognize that leukocytosis is nonspecific for infection and may temporarily occur in response to noninfectious conditions such

as acute myocardial infarction. During an infection, immature neutrophils (eg, bands) are released at an increased rate to help fight infection, leading to what is known as a "bandemia" or "left shift". Therefore, a WBC count differential is key to determining whether an infection is present. Some patients may present with a normal total WBC with a left shift (eg, the elderly). ESR and CRP are nonspecific markers of inflammation that increase as a result of the acute-phase reactant response, which is a response to inflammatory stimuli such as infection or tissue injury. These tests may be used as markers of infectious disease response because they are elevated when the disease is acutely active and usually fall in response to successful treatment. Clinicians may use these tests to monitor a patient's response to therapy in osteomyelitis and infective endocarditis. These tests should not be used to diagnose infection because they may be elevated in noninfectious inflammatory conditions. In contrast, procalcitonin, a prohormone of calcitonin, is rapidly produced in response to bacterial infection. Procalcitonin serum levels in conjunction with clinical findings are increasingly being utilized to assess both the need to initiate antibiotic therapy as well as determine when antibiotic therapy may be safely discontinued.[8,9]

## Microbiologic Studies

Microbiologic studies that allow for direct examination of a specimen (eg, sputum, blood, or urine) may aid in a presumptive diagnosis and give an indication of the characteristics of the infecting organism. Generally, microbial cultures are obtained with a Gram stain of the cultured material.

### Table 69–1

**WBC and Differential**

| Type of Cell | Normal Value % (or Fraction) | Function | Abnormalities |
|---|---|---|---|
| Neutrophil | Segs 40–60 (0.40–0.60) Bands 3–5 (0.03–0.05) | Phagocytic | Leukocytosis • Bacterial infections • Fungal infections • Physiologic stress • Tissue injury (eg, myocardial Infarction) • Medications (eg, corticosteroids) Leukopenia • Long-standing infection • Cancer • Medications (eg, chemotherapy) |
| Lymphocyte | 20–40 (0.20–0.40) | T cells (cell-mediated immunity) B cells (humoral antibody response) | Lymphocytosis • Viral infections (eg, mononucleosis) • Tuberculosis • Fungal infections Lymphopenia • HIV |
| Monocyte | 2–8 (0.02–0.08) | Phagocytic precursor to macrophage | Monocytosis • Tuberculosis • Protozoal infections • Leukemia |
| Eosinophil | 1–4 (0.01–0.04) | Antigen-antibody reactions | Eosinophilia • Hypersensitivity reactions, including medications • Parasitic infections |
| Basophil | < 1 (0.01) | | Hypersensitivity reactions |

### Patient Encounter 1

**HPI:** A 72 year old woman with a history of hypertension, diabetes, hyperlipidemia, chronic back pain, osteoarthritis, and a history of frequent urinary tract infections who began feeling poorly 48 hours prior to presenting to the emergency room. She reports extreme fatigue, chills, fever (100.6°F [38.1°C]), nausea, and headache. Her daughter, who is accompanying the patient to the emergency room, notes increasing confusion over the same time period. She has recently been treated for recurrent urinary tract infections 2 and 5 weeks ago with Bactrim DS and levofloxacin.

**PMH:** Hypertension, diabetes, hyperlipidemia, chronic back pain, osteoarthritis, and frequent urinary tract infections (5–10 per year) with the most recent being treated 2 and 5 weeks ago with Bactrim DS and levofloxacin, respectively

**FH:** Father died of colon cancer at age 72. Mother died of congestive heart failure at age 83

**SH:** Lives at home. Has 2 daughters and 1 son

**Allergies:** NKDA

**Meds:** Lisinopril 10 mg daily; hydrochlorothiazide 25 mg daily; metoprolol XL 50 mg daily; atorvastatin 20 mg daily; metformin 1000 mg twice daily; glipizide 5 mg twice daily; pregabalin 150 mg daily; oxycodone 5 mg three times; aspirin 81 mg daily; alendronate 70 mg weekly; calcium carbonate 500 mg twice daily; multivitamin 1 daily; cranberry supplement 300 mg daily

*What information in the history supports an infectious etiology?*

*Is this patient at risk for resistant pathogens? Why?*

A Gram stain of collected specimens can give rapid information that can be applied immediately to patient care. A Gram stain is performed to identify whether bacteria are present and to determine morphologic characteristics of bacteria (eg, gram-positive or gram-negative and shape—cocci, bacilli). Certain specimens do not stain well or at all and must be identified by alternative staining techniques (*Mycoplasma* spp., *Legionella* spp., *Mycobacterium* spp.). Figure 69–2 identifies bacterial pathogens classified by Gram stain and morphologic characteristics. The presence of WBCs on a Gram stain indicates inflammation and suggests that the identified bacteria are pathogenic. The Gram stain may be useful in evaluating a sputum specimen's adequacy (eg, the presence of epithelial cells on sputum Gram stain suggests that the specimen is either poorly collected or contaminated). A poor specimen can give misleading information regarding the underlying pathogen and may result in inappropriate antimicrobial use.

Culture and susceptibility testing provides additional information to the clinician to select appropriate therapy. Specimens are placed in or on culture media that provide proper growth

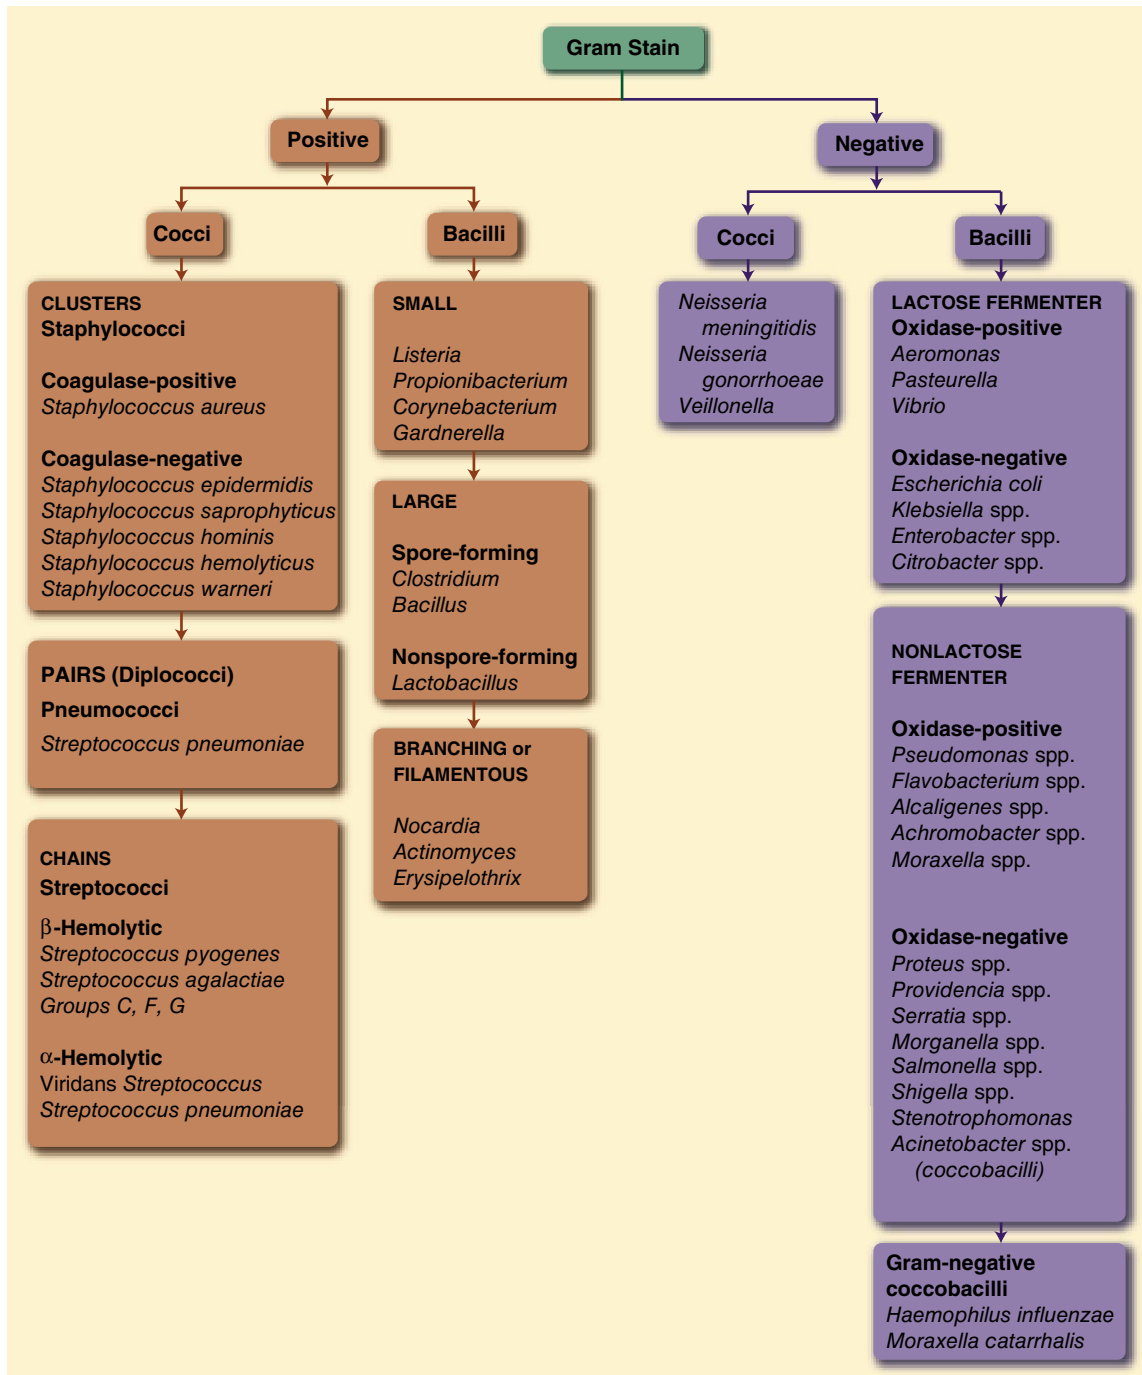

**FIGURE 69–2.** Important bacterial pathogens classified according to Gram stain and morphologic characteristics. (From Rybak MJ, Aeschlimann JR. Laboratory tests to direct antimicrobial pharmacotherapy. In: In DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach. 9th ed. New York: McGraw-Hill; 2014.)
**FIGURE 69–3.** Macrotube minimal inhibitory concentration (MIC) determination. The growth control (C), 0.5 mg/L, and 1 mg/L tubes are visibly turgid, indicating bacterial growth. The MIC is read as the first clear test tube (2 mg/L). (From Rybak MJ, Aeschlimann JR. Laboratory tests to direct antimicrobial pharmacotherapy. In: In DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach. 9th ed. New York: McGraw-Hill; 2014.)

conditions. Once the bacteria grow on culture media, they can be identified through biochemical tests. When a pathogen is identified, susceptibility tests can be performed to various antimicrobial agents. The **minimum inhibitory concentration (MIC)** is a standard susceptibility test. The MIC is the lowest concentration of antimicrobial that inhibits visible bacterial growth after approximately 24 hours (**Figure 69–3**). **Breakpoint** and MIC values determine whether the organism is susceptible (S), intermediate (I), or resistant (R) to an antimicrobial. The breakpoint is the concentration of the antimicrobial that can be achieved in the serum after a standard dose of that antimicrobial. If the MIC is below the breakpoint, the organism is considered to be susceptible to that agent. If the MIC is above the breakpoint, the organism is said to be resistant. Reported culture and susceptibility results may not provide MIC values but generally report the S, I, and R results.

**KEY CONCEPT** *In general, bacterial cultures should be obtained prior to initiating antimicrobial therapy in patients with a systemic inflammatory response, risk factors for antimicrobial resistance, or infections where diagnosis or antimicrobial susceptibility is uncertain.* The decision to collect a specimen for culture depends on the sensitivity and specificity of the physical and diagnostic findings, and whether or not the pathogens are readily predictable. Culture and susceptibility testing usually is not warranted in a young, otherwise healthy woman who presents with signs and symptoms consistent with a urinary tract infection (UTI) because the primary pathogen, *Escherichia coli*, is readily predictable. Cultures and susceptibility testing are routine for sterile-site specimens (eg, blood and spinal fluid), as well as for material presumed to be infected (eg, material obtained from joints and abscesses). Cultures need to be interpreted with caution. Poor specimen collection technique and processing speed can result in misleading information and inappropriate use of antimicrobials.

## TREATMENT

### General Approach to Treatment, Including Nonantimicrobial Treatment

While selection of antimicrobial therapy may be a major consideration in treating infectious diseases, it may not be the only therapeutic intervention. Other important therapies may

include adequate hydration, ventilatory support, and supportive medications. In addition, antimicrobials are unlikely to be effective if the source that leads to the infection is not controlled. **Source control** refers to this process and may involve removal of prosthetic materials such as catheters and infected tissue or drainage of an abscess. Source control considerations should be a fundamental component of any infectious diseases treatment. It is also important to recognize that there may be many different antimicrobial regimens that may cure the patient. While the following therapy sections provide factors to consider when selecting antimicrobial regimens, excellent and more in-depth

resources for selecting antimicrobial regimens for a variety of infectious diseases are the *Infectious Diseases Society of America Guidelines*.[10]

## Antimicrobial Considerations in Selecting Therapy

**KEY CONCEPT** *Drug-specific considerations in antimicrobial selection include spectrum of activity, effects on nontargeted microbial flora, appropriate dose, pharmacokinetic and pharmacodynamic properties, adverse-effect and drug-interaction profile, and cost* (**Table 69–2**).

### ▶ *Spectrum of Activity and Effects on Nontargeted Flora*

Most initial antimicrobial therapy is empirical because cultures have not had sufficient time for identification of a pathogen. **KEY CONCEPT** *Empirical therapy should be based on patient- and antimicrobial-specific factors such as the anatomic location of the infection, the likely pathogens associated with the presentation, the potential for adverse effects in a given patient, and the antimicrobial spectrum of activity.* Prompt initiation of appropriate therapy is paramount in hospitalized patients who are critically ill. Patients who receive appropriate initial antimicrobial therapy survive at twice the rate of patients who receive inadequate therapy.[11] Empirical selection of antimicrobial spectrum of activity should be related to the severity of the illness. Generally, acutely ill patients require broader-spectrum antimicrobial coverage, whereas less ill patients may be managed initially with narrow-spectrum therapy. While a detailed description of antimicrobial pathogen-specific spectrum of activity is beyond the scope of this chapter, this information can be obtained readily from a number of sources.[12,13]

Collateral damage is defined as the development of resistance occurring in a patient's nontargeted flora that can cause secondary infections. *Clostridium difficile* infection (CDI) is an example of a disease that occurs secondary to collateral damage. Antibiotics can increase the risk of CDI by suppressing normal intestinal flora, resulting in overgrowth of the nonsusceptible *C. difficile* bacteria. In addition, CDI is associated with the prior use of broad-spectrum antibiotics; particularly fluoroquinolones.[14] If several different antimicrobials possess activity against a targeted pathogen, the antimicrobial that is least likely to be associated with collateral damage may be preferred.

### ▶ *Single versus Combination Therapy*

A common debate involves the need for coverage with two antimicrobials for serious infections. Proponents state that double coverage may be synergistic, prevent the emergence of resistance, and improve outcome. However, there are few clinical examples in the literature to support these assertions. Examples where double coverage is considered superior are limited to infections associated with large bacterial loads and in species that are known to readily develop resistance such as active tuberculosis or enterococcal endocarditis.[15,16] A study of patients with *Pseudomonas aeruginosa* infections, an intrinsically resistant organism, demonstrated that empirical double coverage with two antipseudomonal antimicrobials improved survival.[17] Combination therapy increased the likelihood of appropriate empirical coverage; however, once organism susceptibilities were known, there was no difference in outcome between double coverage and monotherapy. Double antimicrobial coverage with two agents of similar spectra of activity may be beneficial for selected infections associated with high bacterial loads or for initial empirical coverage of critically ill patients in whom antimicrobial-resistant organisms are suspected. Monotherapy usually is satisfactory once antimicrobial susceptibilities are established.

### ▶ *Antimicrobial Dose*

Clinicians should be aware that antimicrobial dosage regimens may be different depending on the infectious process. For example, ciprofloxacin, a fluoroquinolone, has various dosage regimens based on site of infection. The dosing for uncomplicated UTIs is 250 mg twice daily for 3 days. For complicated UTIs, the dose is 500 mg twice daily for 7 to 14 days. Severe complicated pneumonia requires a dosage regimen of 750 mg twice daily for 7 to 14 days. Clinicians are encouraged to use dosing regimens designed for treatment of the diagnosed infection because they have demonstrated proven efficacy and are most likely to minimize harm.

### ▶ *Pharmacokinetic Properties*

Pharmacokinetic properties of an antimicrobial may be important in antimicrobial regimens. **Pharmacokinetics** refers to a mathematical method of describing a patient's drug exposure in vivo in terms of absorption, distribution, metabolism, and elimination. **Bioavailability** refers to the amount of antimicrobial that is absorbed orally relative to an equivalent IV dose administered. Drug-related factors that may affect oral bioavailability include the formulation of the antimicrobial, dosage form, and stability of the drug in the gastrointestinal (GI) tract. Patients with systemic signs of infection such as hypotension should receive intravenous antimicrobials to ensure drug delivery as absorption is affected by GI blood flow. In cases where patients have a functioning GI tract and are not hypotensive, antimicrobials with almost complete bioavailability (greater than 80%) such as the fluoroquinolones, fluconazole, and linezolid may be given orally. With antimicrobials with modest bioavailability (eg, many β-lactams), the decision to choose an oral product will depend more on the severity of the illness and the anatomic location of the infection. In sequestered infections, where higher systemic concentrations of antimicrobial may be necessary to reach the infected source (eg, meningitis) or for antimicrobials with poor bioavailability, IV formulations should be used.

Some antimicrobials may be bound to proteins in serum. Only unbound drug is biologically active and distributes freely between tissues. Protein binding is clinically relevant in highly protein-bound antimicrobials (greater than 50%) as the agents may not be able to penetrate sequestered compartments, such as cerebral spinal fluid, resulting in insufficient concentrations to inhibit bacteria. In addition, some drugs may not achieve

sufficient concentrations in specific compartments based on distribution characteristics. For example, *Legionella pneumophila*, an organism that causes severe pneumonia, is known to survive and reside inside pulmonary macrophages. Treatment with an antibiotic that inhibits bacterial cell wall synthesis, such as a cephalosporin, will be ineffective because it only distributes into extracellular host tissues. However, macrolide or fluoroquinolone antimicrobials, which concentrate in human pulmonary macrophages, are highly effective against this organism.

Many antimicrobials undergo some degree of metabolism once ingested. Metabolism may occur via hepatic, renal, or nonorgan-specific enzymatic processes. The route of elimination of the metabolic pathway may be exploited for infections associated with tissues related to the metabolic pathways. For example, many fluoroquinolone antimicrobials are partially metabolized and undergo renal elimination. Urinary concentrations of active drug are many times those achieved in the systemic circulation, making several of these agents good choices for complicated urinary tract infections.

#### ▶ Pharmacodynamic Properties

Pharmacodynamics describes the relationship between drug exposure and pharmacologic effect of antibacterial activity or human toxicology. Antimicrobials are categorized based on their concentration-related effects on bacteria. Concentration-dependent pharmacodynamic activity occurs where higher drug concentrations are associated with greater rates and extents of bacterial killing. Concentration-dependent antimicrobial activity is maximized when peak antimicrobial concentrations are high. In contrast, concentration-independent (or time-dependent) activity refers to a minimal increase in the rate or extent of bacterial killing with an increase in antimicrobial dose. Concentration-independent antimicrobial activity is maximized when these antimicrobials are dosed to maintain blood and/or tissue concentrations above the MIC in a time-dependent manner. Fluoroquinolones, aminoglycosides, and metronidazole are examples of antimicrobials that exhibit concentration-dependent activity, whereas β-lactam and glycopeptide antimicrobials exhibit concentration-independent activity. Pharmacodynamic properties have been optimized to develop new dosing strategies for older antimicrobials. Examples include single-daily-dose aminoglycoside or β-lactam therapy administered by continuous or extended infusion. The product labeling for many new antimicrobials takes pharmacodynamic properties into account.

Antimicrobials also can be classified as possessing bactericidal or bacteriostatic activity in vitro. Bactericidal antibiotics generally kill at least 99.9% of a bacterial population, whereas bacteriostatic antibiotics possess antimicrobial activity but reduce bacterial load by less than 3 logs (99.9%). Clinically, bactericidal antibiotics may be necessary to achieve success in infections such as endocarditis or meningitis. A full discussion of the application of antimicrobial pharmacodynamics is beyond the scope of this chapter, but excellent sources of information are available.[18]

#### ▶ Adverse-Effect and Drug-Interaction Properties

A major concern when selecting antimicrobial regimens should be the propensity for the regimen to cause adverse effects and the potential for drug interactions. In general, if several different antimicrobial options are available, antimicrobials with a low propensity to cause adverse events should be selected, particularly for patients with risk factors for a particular complication.

Risk factors for adverse events may include the coadministration of other drugs that are associated with a similar type of adverse event. For example, coadministration of the known nephrotoxin gentamicin with vancomycin increases the risk for nephrotoxicity compared with administration of either drug alone.[19] Other drug interactions may predispose the patient to dose-related toxicity through inhibition of drug metabolism. For example, erythromycin has the potential to prolong cardiac QT intervals in a dose-dependent manner, potentially increasing the risk for sudden cardiac death.[20]

#### ▶ Antimicrobial Cost

A final consideration in selecting antimicrobial therapy relates to cost. The least expensive antimicrobial is not necessarily the most cost-effective antimicrobial. Antimicrobial costs constitute a relatively small portion of the overall cost of care. Careful consideration of antimicrobial microbiologic, pharmacologic, and patient-related factors such as compliance and a variety of clinical outcomes is necessary to establish the cost versus benefit of an antimicrobial in a given patient. If there is no difference or a small difference in these factors, the least costly antimicrobial may be the best choice.

### Patient Considerations in Antimicrobial Selection

**KEY CONCEPT** *Key patient-specific considerations in antimicrobial selection include recent previous antimicrobial exposures, identification of the anatomic location of infection through physical examination and diagnostic imaging, history of drug allergies, pregnancy or breast-feeding status, organ dysfunction that may affect drug clearance, immunosuppression, compliance, and the severity of illness (see Table 69–2).*

#### ▶ Host Factors

Host factors can help to ensure selection of the most appropriate antimicrobial agent. Age is an important factor in antimicrobial selection. Populations with diminished renal function include neonates and the elderly. Hepatic function in the neonate is not fully developed, and drugs that are metabolized or eliminated by this route may produce adverse effects. For example, sulfonamides and ceftriaxone may compete with bilirubin for binding sites and may result in hyperbilirubinemia and kernicterus. Gastric acidity also depends on age; the elderly and children younger than 3 years tend to be achlorhydric. Drugs that need an acidic environment (eg, ketoconazole) are not well absorbed, and those whose absorption is enhanced in an alkaline environment will have increased concentrations (eg, penicillin G).

Disruption of host defenses due to IV or indwelling Foley catheters, burns, trauma, surgery, and increased gastric pH may place patients at higher risk for infection. Breaks in skin integrity provide a route for infection because the natural barrier of the skin is disrupted. Increased gastric pH can allow for bacterial overgrowth and has been associated with an increased risk of pneumonia.[21]

Recognizing the presumed site of infection and most common pathogens associated with the infectious source should guide antimicrobial choice, dose, and route of administration. For example, community-acquired pneumonia is caused most commonly by *Streptococcus pneumoniae*, *E. coli* is the primary cause of uncomplicated UTIs, and staphylococci and streptococci are implicated most frequently in skin and skin-structure infections (eg, cellulitis).

Patients with a history of recent antimicrobial use may have altered normal flora or harbor resistant organisms. If a patient develops a new infection while on therapy, fails therapy, or has received antimicrobials recently, it is prudent to prescribe a different class of antimicrobial because resistance to the current treatment is likely. Previous hospitalization or health care utilization (eg, residing in a nursing home, hemodialysis, and outpatient antimicrobial therapy) are risk factors for the acquisition of nosocomial pathogens, which are often resistant organisms.

Antimicrobial allergies are some of the most common drug-related allergies reported and have significant potential to cause adverse events. In particular, penicillin-related allergy is common and can be problematic because there is an approximately 4% cross-reactivity with cephalosporins as well as carbapenems.[22,23] A patient's medical history should be reviewed to determine the offending β-lactam and nature of the allergic reaction. In some cases, patients with mild or nonimmunologic reactions to penicillins may receive a β-lactam antimicrobial with low cross-reactive potential (such as cephalosporins). However, patients with a history of findings consistent with IgE-mediated reactions such as anaphylaxis, urticaria, or bronchospasm should not be administered any type of β-lactam antimicrobial, including cephalosporins, unless there are no other alternatives, and even then they should be administered with caution. Administration of potentially cross-reactive agents in this situation should occur under close observation in a health care setting prepared to treat serious reactions, and some patients may need to undergo desensitization. If the specific medical history relating to a reported allergy cannot be obtained, the patient should be assumed to have had an IgE-mediated reaction and should be managed in a similar manner. Monobactams (ie, aztreonam) may be administered to patients with IgE-mediated allergic reactions to penicillin.

Renal and/or hepatic function should be considered prior to initiation of antimicrobial therapy. Most antimicrobials undergo renal elimination and dosing adjustments are frequently necessary and recommendations for adjustment are available in the literature.[24] In contrast, dosing adjustments for antimicrobials that undergo nonrenal elimination are less well documented. Failure to adjust the antimicrobial dose or interval may result in drug accumulation and adverse effects.

Concomitant administration of other medications may influence the selection of the antimicrobial, dose, and monitoring.

Medications that commonly interact with antibiotics include, but are not limited to, warfarin, rifampin, phenytoin, digoxin, theophylline, multivalent cations (eg, calcium, magnesium, and zinc), and sucralfate. Drug interactions between antimicrobials and other medications may occur via the cytochrome P-450 system, protein-binding displacement, and alteration of vitamin K–producing bacteria. Interactions may result in increased concentrations of one or both agents, increasing the risk of adverse effects or additive toxicity. A key consideration in selecting antimicrobial regimens starts with obtaining a good patient medical and drug history, recognizing drug-specific adverse-event characteristics, and anticipating potential problems proactively. If it is necessary to use an antimicrobial with a relatively high frequency of adverse effects, informing patients of the risks and benefits of therapy, as well as what to do if an adverse effect occurs, may improve patient compliance and safety.

Antimicrobial agents must be used with caution in pregnant and nursing women. Some agents pose potential threats to the fetus or infant (eg, quinolones, tetracyclines, and sulfonamides). For some agents, avoidance during a specific trimester of pregnancy is warranted (eg, the first trimester with trimethoprim/sulfamethoxazole). Pharmacokinetic variables also are altered during pregnancy. Both the clearance and volume of distribution are increased during pregnancy. As a result, increased dosages and/or more frequent administration of certain drugs may be required to achieve adequate concentrations. This information can be obtained from a number of sources.[25,26]

Adherence is essential to ensure efficacy. Patients may stop taking their antibiotics once the symptoms subside and save them for a "future" infection. If the patient does not complete the course of therapy, the infection may not be eradicated, and resistance may emerge. Self-medication of saved antibiotics may be harmful, leading to overtreatment, which may further contribute to antibiotic resistance. Poor adherence may be due to adverse effects, tolerability, cost, and lack of patient education.

## OUTCOME EVALUATION

**Figure 69–4** provides an overview of patient- and antimicrobial agent–specific factors to consider when selecting an antimicrobial regimen. It further delineates monitoring of therapy and actions to take depending on the response to therapy. Duration of therapy depends on patient response and type of infection being treated.

After selection and initiation of an antimicrobial regimen, there are additional patient care and monitoring considerations that should be addressed to improve the likelihood of a successful outcome. **KEY CONCEPT** *Patient education,* de-escalation *of antimicrobial therapy based on culture results, monitoring for clinical response and adverse effects, and appropriate duration of therapy are important.*

## Modifying Empirical Therapy Based on Cultures and Clinical Response

If a successful clinical response occurs and culture results are available, therapy should be de-escalated. Antibiotic de-escalation generally refers to the discontinuation of antibiotics that are providing a spectrum of activity greater than necessary to treat the infection, discontinuation of duplicative spectrum antibiotics, or switching to a narrower spectrum antibiotic once a patient is clinically stable. De-escalation of empirical therapy

**Obtain patient history including clinical presentation and examination**

- Hx of present illness
- Comorbidities
- Current medications
- Allergies
- Previous antibiotic exposure
- Previous hospitalization or healthcare utilization

- Travel history
- Social history
- Pet/animal exposure
- Occupational exposure
- Environmental exposure

**Obtain appropriate diagnostic imaging and labs including cultures**

- Review of symptoms consistent with infection?
- Physical examination consistent with infection?
- Imaging consistent with infectious etiology?
- WBC, ESR, CRP elevated?
- Appropriate Gram stain culture suggests infection?

Pathogen known before starting antimicrobials? Y/N

No / Yes

Patient improving on therapy? Y/N

No / Yes

- De-escalate therapy based on culture results including discontinuation of unnecessary antimicrobials
- IV to oral conversion

- Consider alternative noninfectious diagnosis.
- Reevaluate for sources of untreated infection.
- Perform source control: remove catheters, drain abscesses, debride.
- Consider other drug- and patient-specific factors: appropriate dosing, patient compliance, and drug interactions.
**Change antimicrobial therapy based upon findings.**

Patient improving on therapy? Y/N

Yes / No

Patient cured; stop antimicrobials

**FIGURE 69–4.** Approach to selection of antimicrobial therapy.

may also include discontinuing antibiotics based on clinical criteria and negative culture results, such as the absence of antibiotic-resistant pathogens.[27] The purpose of de-escalation therapy is to minimize the likelihood of secondary infections owing to antimicrobial-resistant organisms. In cases in which a specific organism is recovered that has a known preferred antimicrobial treatment of choice, therapy might be changed to that specific agent. For example, antistaphylococcal penicillins are considered to be the agents of choice for methicillin-susceptible *S. aureus* owing to their bactericidal activity and narrow-spectrum activity and may be preferable to other antibiotic regimens. In other cases, empirical coverage might be discontinued if a specific suspected pathogen is excluded by culture or an alternative, noninfectious diagnosis is established. In addition, IV antimicrobials frequently are more expensive than oral therapy. Therefore, it is usually desirable to convert therapy to oral antimicrobials with a comparable antimicrobial spectrum or specific pathogen sensitivity as soon as the patient improves clinically.[28]

### Failure of Antimicrobial Therapy

While many infections respond readily to antimicrobials, some infections do not. A common question when a patient fails to improve relates to whether the antimicrobial therapy has failed. Changing antimicrobials generally is one of the easiest interventions relative to other options. However, it is important to remember that antimicrobial therapy comprises only a portion of the overall disease treatment, and there may be many factors that contribute to a lack of improvement. KEY CONCEPT *In general, inadequate diagnosis resulting in poor initial antimicrobial or other nonantibiotic drug selection, poor source control, or the development of a new infection with a resistant organism are relatively common causes of antimicrobial failure.* An infection-related diagnosis may be difficult to establish and generally has two components: (a) differentiating infection from noninfectious disease and (b) providing adequate empirical spectrum of activity if the cause is infectious. Failure of improvement in a patient's condition should warrant broadening the differential diagnosis to include noninfectious causes, as well as considering other potential infectious sources and/or pathogenic organisms. Another common cause of failure is poor source control. A diagnostic search for unknown sources of infection and removal of indwelling devices in the infected environment or surgical drainage of abscesses should be undertaken if the patient's condition is not improving. Less common causes of therapeutic failure include the development of secondary infections. In this case, the patient generally improves, but then develops a new infection caused by an antimicrobial-resistant pathogen and relapses. The emergence of resistance to a targeted pathogen while on antimicrobial therapy can be associated with clinical failure but usually is limited to tuberculosis, pseudomonads, or other gram-negative enterics. Drug- and patient-specific factors such as appropriate dosing, patient compliance, and drug interactions can be associated with therapeutic failure and also should be considered. A common assumption is that the correct diagnosis was made, but the patient was not treated long enough with antimicrobials. There are certain types of infections (eg, endocarditis or osteomyelitis) where the standard of care is to treat for prolonged periods of time (ie, weeks or months). However, the optimal duration of therapy for many infectious diseases is somewhat subjective. Studies of several infectious processes have suggested that shorter durations of therapy can

result in similar clinical outcomes as longer durations of therapy, frequently with fewer complications or secondary infections.[29–31] In this period of extensive antimicrobial resistance, clinicians should keep abreast of changing recommendations emphasizing shorter durations of therapy.

---

## Patient Encounter 4: Patient Care and Monitoring

**Update:** The patient was admitted to the hospital with a presumptive diagnosis of pyelonephritis, sepsis, and acute kidney injury. She received IV hydration with normal saline, 4 L oxygen, and empirical antibiotic therapy with piperacillin/tazobactam.

After 48 hours of therapy, the following parameters are obtained:

**PE:**

- VS: BP 130/70, P 70, RR 22, T 37.2°C (98.9°F), $O_2$ sat 94% (0.94) on room air

**Labs:**

- WBC $9.2 \times 10^3/mm^3$ ($9.2 \times 10^9$/L)
- WBC differential 85% (0.85) segs, 10% (0.10) lymphs, 5% (0.05) monos
- SCr 1.1 mg/dL (97 µmol/L)
- Glucose 126 mg/dL (7.0 mmol/L)
- Blood cultures × 2: *Escherichia coli (confirmed as an extended spectrum beta lactamase [ESBL] enzyme producer)*
- Urine culture: *Escherichia coli (confirmed as an extended spectrum beta lactamase [ESBL] enzyme producer)*

**Susceptibility Report:**

Cefazolin resistant (MIC greater than 16 mg/L)

Cefepime resistant (MIC greater than 16 mg/L)

Ceftriaxone resistant (MIC greater than 32 mg/L)

Piperacillin/tazo susceptible (MIC less than equal to 16 mg/L)

Meropenem susceptible (MIC less than equal to 1 mg/L)

Gentamicin susceptible (MIC less than equal to 4 mg/L)

Tobramycin resistant (MIC greater than 8 mg/L)

Nitrofurantoin susceptible (MIC less than equal to 32 mg/L)

Ciprofloxacin resistant (MIC greater than 4 mg/L)

Levofloxacin resistant (MIC greater than 4 mg/L)

Trimethoprim/sulfamethoxazole resistant (MIC greater than 2/38)

*What information suggests improvement in the patient's condition?*

*Do any of the antimicrobial doses need to be adjusted for changes in organ function?*

*Should antimicrobial therapy be modified based on the culture results?*

*Can the antimicrobial therapy be converted from IV to oral therapy?*

## Patient Care Process

**Patient Assessment:**

- Based on patient presentation, physical examination, and review of systems, determine whether the patient is experiencing signs or symptoms that are consistent with an infection.
- Review the medical history. Does the patient have risk factors for infection? Does the patient have risk factors for resistant pathogens?
- Conduct a medication history. Has the patient received recent antimicrobial therapy?
- Review available laboratory tests. Do laboratory findings suggest infection?

**Therapy Evaluation:**

- Determine whether antimicrobial therapy is indicated.
- Do no harm.
- Determine whether the patient has prescription coverage or whether recommended agents are included on institution's formulary.

**Care Plan Development:**

- Select appropriate antimicrobial therapy based on presumed site of infection, likely pathogens, supporting laboratory data, previous antimicrobial therapy (if applicable), patient's renal/hepatic function, and other pertinent patient factors (eg, age, concomitant disease states, concomitant medications, pregnant/lactating).
- For further guidance on appropriate antimicrobial therapy selection, refer to The Infectious Diseases Society of America practice guidelines (www.idsociety.org).
- Determine whether antimicrobial therapy doses are optimal.
- Address patient concerns about antimicrobial therapy and management of the infection.
- Discuss importance of medication adherence.

**Follow-Up Evaluation:**

- Follow up daily (if in-patient or at appropriate intervals if outpatient) to assess efficacy and toxicity of therapy until resolution of infection.
- Review medical history, clinical and physical examination findings, laboratory tests (including culture and susceptibility data), and results of other diagnostic tests to evaluate response to therapy.
- Follow up on culture and susceptibility reports with subsequent de-escalation of therapy, if possible.
- Reculture of specimens is not performed routinely except in few cases (eg, endocarditis) or where a secondary infection is suspected because data may be misleading and lead to the addition of broader or more powerful antimicrobials.

## Abbreviations Introduced in This Chapter

CDC     Centers for Disease Control and Prevention
CRP     C-reactive protein
ESR     Erythrocyte sedimentation rate
HPI     History of present illness
MIC     Minimum inhibitory concentration
MRSA    Methicillin-resistant *Staphylococcus aureus*
PMH     Past medical history
UTI     Urinary tract infection
VRE     Vancomycin-resistant *Enterococcus*
WBC     White blood cell count

# Central Nervous System Infections

P. Brandon Bookstaver and April Miller Quidley

## LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Discuss the pathophysiology of CNS infections and the impact on antimicrobial treatment regimens (including antimicrobial dosing and CNS penetration).

2. Describe the signs, symptoms, and clinical presentation of CNS infections.

3. List the most common pathogens causing CNS infections and identify risk factors for infection with each pathogen.

4. State the goals of therapy for CNS infections.

5. Design appropriate empirical antimicrobial regimens for patients suspected of having CNS infections caused by each of the following pathogens (taking age, vaccine history, and other patient-specific information into account), and analyze the impact of antimicrobial resistance on both empirical and definitive therapy: *Neisseria meningitidis* meningitis, *Haemophilus influenzae* meningitis, *Listeria monocytogenes* meningitis, group B *Streptococcus* meningitis, gram-negative bacillary meningitis, postneurosurgical infection, CNS shunt infection, herpes simplex encephalitis.

6. Modify empirical antimicrobial regimens based on laboratory data and other diagnostic criteria.

7. Discuss the management of close contacts of patients diagnosed with CNS infections.

8. Identify candidates for vaccines and other prophylactic therapies to prevent CNS infections.

9. Describe the role of adjunctive agents (eg, dexamethasone) in the management of CNS infections.

10. Formulate a monitoring plan to assess efficacy and adverse effects of therapy for CNS infections.

## INTRODUCTION

The term *CNS infections* describes a variety of infections involving the brain and spinal cord and associated tissues, fluids, and membranes, including meningitis, encephalitis, brain abscess, cerebrospinal fluid shunt infections, and postoperative infections. **KEY CONCEPT** *CNS infections, such as meningitis, are considered neurologic emergencies that require prompt recognition, diagnosis, and management to prevent death and residual neurologic deficits.* Improperly treated, CNS infections are associated with high rates of morbidity and mortality. Despite advances in care, the overall mortality of bacterial meningitis in the United States remains at approximately 15%, and at least 10% to 30% of survivors are afflicted with neurologic impairment, including hearing loss, **hemiparesis**, and learning disabilities.[1–3] Antimicrobial therapy and preventive vaccines have revolutionized management and improved outcomes of bacterial meningitis and other CNS infections dramatically.

## EPIDEMIOLOGY AND ETIOLOGY

CNS infections are uncommon, with an incidence 1.38 cases per 100,000 in 2006 and 2007.[3] However, the severity of these infections demands prompt medical intervention and treatment.

CNS infections can be caused by bacteria, fungi, mycobacteria, viruses, parasites, and spirochetes.

Bacterial meningitis is the most common cause of CNS infections. While vaccination has reduced the incidence of disease by many common pathogens as of 2010, *Streptococcus pneumoniae* (pneumococcus) was the most common pathogen for bacterial meningitis (0.306 cases per 100,000), followed by *Neisseria meningitidis* (meningococcus, 0.123 cases per 100,000).[4] *Haemophilus influenza was a top causative pathogen; however, its incidence has declined to 0.058 cases per 100,000*). Staphylococcal species and gram-negative bacteria account for 0.114 and 0.127 cases per 100,000 persons, respectively in the United States.[4] Group B *Streptococcus and Listeria monocytogenes* remain important causes, but current data on their incidence are lacking.[3] Vaccines directed against bacteria causing meningitis and related infections (eg, pneumonia and ear infections) have reduced the risk of infections due to *S. pneumoniae*, *N. meningitidis*, and *H. influenzae* type b (Hib) dramatically.[3,4] Prior to the availability of Hib conjugate vaccines, Hib meningitis or other invasive disease was documented in one in 200 children by the age of 5 years and due to widespread use, its incidence has decreased such that it is no longer a leading pathogen.[4] Historically, a 7-valent conjugate pneumococcal vaccine (PCV7) was administered,

but despite use of the PCV7, *S. pneumoniae* remained the most common pathogen for pediatric bacterial meningitis. In 2010, a 13-valent conjugate pneumococcal vaccine was licensed for use in the United States; however, its impact on the epidemiology of disease in the United States is still unknown. In France the 13-valent vaccine reduced the incidence of pneumococcal meningitis by 27.4%.[5]

Encephalitis may result from viral, bacterial, parasitic, or other noninfectious causes. Herpes simplex virus (HSV) is the most common cause of encephalitis in the United States, accounting for 10% of all cases.[10] The annual incidence of viral encephalitis is 3.5 to 7.4 infections per 100,000 persons.[6] Other pathogens including common bacterial meningitis causes, *Ricksettsia* species, enteroviruses, arboviruses, varicella-zoster virus, rotavirus, coronavirus, influenza viruses A and B, West Nile virus, and Epstein-Barr virus may be associated with a meningoencephalopathic presentation.[7] Approximately 20,000 hospitalizations each year are secondary to encephalitis, accounting for $650 million in health care costs.[8] Over the past 10 to 20 years, mortality secondary to encephalitis has remained constant, correlating well with the increased number of people living with human immunodeficiency virus (HIV) and acquired immune deficiency syndrome (AIDS).

Neurosurgical procedures may place patients at risk for meningitis due to bacteria acquired at the time of surgery or in the postoperative period, including *Staphylococcus aureus*, coagulase-negative staphylococci, and gram-negative bacilli. In addition to bacteria, other pathogens may cause meningitis in at-risk patients. Immunocompromised patients, such as solid-organ transplant patients and patients living with HIV infection, are at risk for fungal meningitis with *Cryptococcus neoformans* and encephalitis secondary to *Toxoplasma gondii* and JC virus. Tuberculosis can spread from pulmonary sites to cause clinical disease in the CNS. Life-threatening viral encephalitis and meningitis can occur in otherwise healthy, young individuals, as well as in patients immunocompromised by age or other factors. Risk factors for CNS infections can be classified as follows:

- *Environmental*: Recent exposures (eg, close contact with meningitis or respiratory tract infection, contaminated foods), active or passive exposure to cigarette smoke, close living conditions

- *Recent infection in the patient:* Respiratory infection, otitis media, sinusitis, mastoiditis

- *Immunosuppression:* Anatomic or functional asplenia, sickle cell disease, alcoholism, cirrhosis, immunoglobulin or complement deficiency, cancer, HIV/AIDS, uncontrolled diabetes mellitus, debilitated state of health

- *Surgery, trauma:* Neurosurgery, head trauma, CSF shunt, cochlear implant

- Noninfectious causes of meningitis include malignancy, medications (eg, sulfonamides, nonsteroidal anti-inflammatory drugs [NSAIDs], IV immunoglobulin), autoimmune disease (eg, lupus), and trauma.[6,7]

- The most common pathogens causing bacterial meningitis, by age group and other risk factors, are found in Table 70–1.

### Table 70–1

**Most Likely Pathogens and Recommended Empirical Therapy, by Risk Factor, for Bacterial Meningitis[15,25]**

| Predisposing Factor | Most Likely Pathogens | Recommended Empirical Antibiotic Therapy |
|---|---|---|
| **Age** | | |
| Less than 3 months | Group B *Streptococcus* <br> *Escherichia coli* <br> *Klebsiella pneumoniae* <br> *Listeria monocytogenes* | Ampicillin *plus* cefotaxime *or* aminoglycoside |
| 3 months to less than 18 years | *Streptococcus pneumoniae* <br> *Neisseria meningitidis* | Cefotaxime *or* ceftriaxone *plus* vancomycin |
| 18 years to less than 60 years | *S. pneumoniae* <br> *N. meningitidis* | Cefotaxime *or* ceftriaxone *plus* vancomycin |
| 60 years *or* older | *S. pneumoniae* <br> Gram-negative bacilli <br> *L. monocytogenes* | Cefotaxime *or* ceftriaxone *plus* vancomycin *plus* ampicillin |
| Immunocompromised | *S. pneumoniae* <br> *N. meningitidis* <br> *L. monocytogenes* <br> Gram-negative bacilli <br> (including *Pseudomonas aeruginosa*) | Cefotaxime *or* ceftriaxone *plus* vancomycin *plus* ampicillin (consider double antibiotic coverage against *Pseudomonas* spp. if suspected) |
| **Surgery, Trauma** | | |
| Postneurosurgical infection | *S. aureus* (including MRSA) <br> Coagulase-negative *Staphylococcus* (including MRSE) <br> Gram-negative bacilli (including *P. aeruginosa*) | Vancomycin *or* linezolid *plus* cefepime or ceftazidime *or* meropenem (consider empiric use of two active antibiotics against *Pseudomonas* spp. if suspected) |
| Penetrating head trauma | *S. aureus* (including MRSA) coagulase-negative *Staphylococcus* <br> Gram-negative bacilli (including *P. aeruginosa*) | Vancomycin *or* linezolid *plus* cefepime or ceftazidime *or* meropenem (consider empiric use of two active antibiotics against *Pseudomonas* spp. if suspected) |
| CSF shunt | Coagulase-negative *Staphylococcus (including MRSE)* <br> *S. aureus (including MRSA)* <br> Gram-negative bacilli *(including P. aeruginosa)* | Vancomycin *or* linezolid *plus* cefepime or ceftazidime or meropenem (consider empiric use of two active antibiotics against *Pseudomonas* spp. if suspected) |

MRSA, methicillin-resistant *Staphylococcus aureus*; MRSE, methicillin-resistant *Staphylococcus epidermidis*.

## Patient Encounter 1, Part 1

NB is a 57-year-old woman resident of an elderly singles living facility. She maintains her activities of daily living on her own. NB participates in group activities with coresidents on a weekly basis, with the most recent being a knitting party a week ago. She now presents to the emergency department with a 2-day history of headache, fever, and photophobia. Physical findings and laboratory values include temperature of 38.3°C (101°F) and WBC of $13.4 \times 10^3/mm^3$ ($13.4 \times 10^9/L$), with 70% (0.70) polymorphonuclear cells. Examination reveals nuchal rigidity; remainder is benign for additional findings. NB also reports occasional nausea. She has a significant history for osteoporosis for which she takes alendronate and calcium with vitamin D. She receives the influenza vaccine yearly.

*What signs and symptoms consistent with meningitis are present in NB?*

*What causative pathogens should be suspected in NB?*

*What empiric antimicrobials should be started?*

## PATHOPHYSIOLOGY

Meningitis is an inflammation of the membranes of the brain and spinal cord (meninges) and the CSF in contact with these membranes, whereas encephalitis is an inflammation of the brain tissue. CSF produced in the brain ventricles flows through the subarachnoid space and downward through the spinal cord, insulating and protecting delicate CNS tissue.

To initiate a CNS infection, pathogens must gain entry into the CNS by contiguous spread, hematogenous seeding, direct inoculation, or reactivation of latent infection. Contiguous spread occurs when infections in adjacent structures (eg, sinus cavities or the middle ear) invade directly through the blood–brain barrier. Hematogenous seeding occurs when a remote infection causes bacteremia that seeds the CSF, such as pneumococcal pneumonia. Reactivation of latent infection results from dormant viral, fungal, or mycobacterial pathogens in the spine, brain, or nerve tracts. Direct inoculation of bacteria into the CNS is the result of trauma, congenital malformations, or complications of neurosurgery.

Once through the blood–brain barrier, pathogens replicate due to limited host defenses in the CNS. Figure 70–1 depicts the pathophysiologic changes associated with meningitis. Neurologic tissue damage is the result of the host's immune reaction to bacterial cellular components, which trigger cytokine production, particularly tumor necrosis factor alpha (TNF-α) and interleukin 1 (IL-1), and other inflammatory mediators.[9] Bacteriolysis resulting from antibiotic therapy further contributes to the inflammatory process. Cytokines increase permeability of the blood–brain barrier, allowing influx of neutrophils and other host defense cells that contribute to the development of cerebral edema and increased intracranial pressure characteristic of meningitis.[10] The increase in intracranial pressure is responsible for the hallmark clinical signs and symptoms of meningitis: headache, neck stiffness, altered mental status, photophobia, and seizures. Untreated, these pathophysiologic changes may result in cerebral ischemia and death.

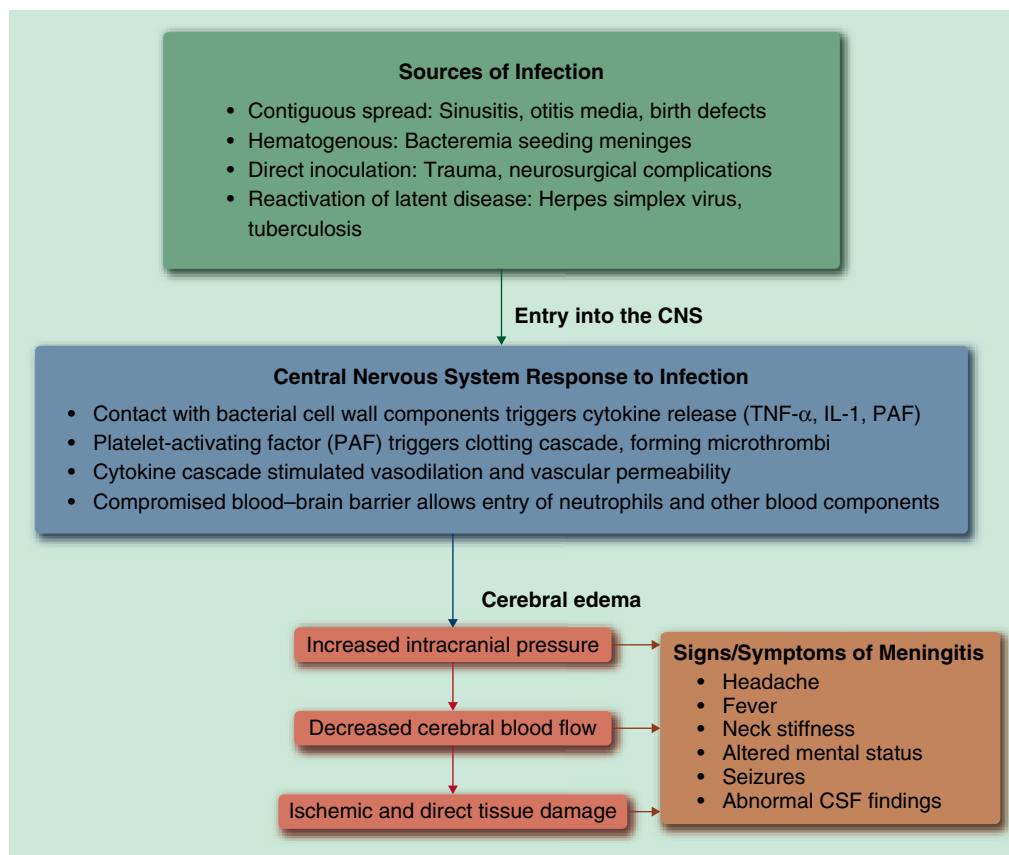

**FIGURE 70–1.** Pathophysiology of bacterial meningitis.

| Table 70–2 |
|---|

**CNS Response to Infection (CSF Findings)**

| | Normal CSF | Bacterial Infection | Viral Infection | Fungal Infection | Tuberculosis |
|---|---|---|---|---|---|
| WBC (× 10³/mm³ *or* × 10⁹/L) | < 0.005 | 1.0–greater than 5.0 | 0.1–1 | 0.1–0.4 | 50–500 |
| WBC differential (% or fraction in brackets, predominant cell type) | > 85% (0.85) monocytes | At least 80% (0.80) PMNs | 50% (0.50) lymphocytes (PMN early) | > 50% (0.50) lymphocytes | > 80% (0.80) lymphocytes (PMNs early) |
| Protein (mg/dL, mg/L) | 20–45 (200–450) | > 100 (> 1000) | 50–100 (500–1000) | 100–200 (1000–2000) | 40–150 (400–1500) |
| Glucose (mg/dL, mmol/L) | 45–80 (2.5–4.4) | 5–40 (0.3–2.2) | 30–70 (1. 7–3. 9) | < 30–70 (< 1. 7–3. 9) | < 30–70 (< 1. 7–3. 9) |
| CSF: serum glucose ratio | At least 0.6 serum glucose | < 0.4 serum glucose | At least 0.6 serum glucose | < 0.4 serum glucose | < 0.4 serum glucose |
| CSF stain | Negative | Positive Gram stain (60%–90%) | Negative | Positive India ink stain (Cryptococcus) | Positive acid-fast bacilli stain |
| Opening pressure | < 20 mm Hg | > 20 mm Hg | < 20 mm Hg | > 20 mm Hg | > 20 mm Hg |

CSF, cerebrospinal fluid; PMNs, polymorphonuclear neutrophils.

Data from Refs. 5, 11, 20, and 33.

The CNS response to infection is cellular and chemical changes in the CSF. **KEY CONCEPT** *Ideally, LP to obtain CSF for direct examination and laboratory analysis, as well as blood cultures and other relevant cultures, should be obtained before initiation of antimicrobial therapy. However, initiation of antimicrobial therapy should not be delayed if a pretreatment LP cannot be performed.*

Normal CSF has a characteristic composition in terms of protein and glucose content, as well as cell count. Table 70–2 lists CSF findings normally observed and in the setting of meningitis.

## CLINICAL PRESENTATION AND DIAGNOSIS

A high index of suspicion should be maintained for patients at risk for CNS infections. Prompt recognition and diagnosis are essential so that antimicrobial therapy can be initiated as quickly as possible. A medical history (including risk factors for infection and history of possible recent exposures) and physical examination yield important information to help guide the diagnosis and treatment of meningitis. Common signs and symptoms include fever, headache, nuchal rigidity (stiff neck), and photophobia. Infants present with nonspecific signs and symptoms, including excessive irritability or crying, vomiting or diarrhea, tachypnea, altered sleep pattern, and poor eating. Depending on involved pathogens and disease severity, patients may also present with altered mental status, stupor, and seizures.

## TREATMENT
### Goals of Therapy

Prior to antibiotic therapy and vaccination bacterial meningitis was almost universally fatal, with survivors suffering from debilitating residual neurologic deficits, such as permanent hearing loss.[1,2] Although significant improvements have been made, the fatality rate of meningitis remains above 15% in adults, likely due to its occurrence in debilitated patient populations.[2]

**KEY CONCEPT** *The treatment goals for CNS infections are to prevent death and residual neurologic deficits, eradicate or control causative micro-organisms, ameliorate clinical signs and symptoms, and implement vaccination and suppressive measures to prevent future infections.* Surgical debridement should be employed, if appropriate (as in postneurosurgical infections and brain abscess). Supportive care, consisting of hydration, electrolyte replacement, antipyretics, antiemetics, analgesics, antiepileptic drugs, and wound care (for surgical wounds), is an important adjunct to antimicrobial therapy, particularly early in the treatment course.

### Treatment Principles

**KEY CONCEPT** *Prompt initiation of IV high-dose bactericidal antimicrobial therapy directed at the most likely pathogen(s) is essential due to the high morbidity and mortality associated with CNS infections.* Although there are no prospective studies that relate timing of antibiotic administration to clinical outcome in bacterial meningitis, a longer duration of symptoms and more advanced disease before treatment initiation increase the risk of a poor outcome.[2,11] Initiation of antibiotic therapy as soon as possible after bacterial meningitis is suspected or proven (even before hospitalization) reduces mortality and neurologic sequelae.[11–13]

High-dose parenteral bactericidal antibiotic therapy is required to achieve CSF antibiotic concentrations adequate to rapidly sterilize the CSF and reduce the risk of complications. Data from animal studies and patients demonstrate better outcomes when bactericidal antibiotic therapy (vs bacteriostatic therapy) is used to sterilize the CSF.[14] However, successful treatment of meningitis has been reported with bacteriostatic agents. The presence of infection in the CSF reduces the activity of some classes of antibiotics. For example, the decreased pH of CSF associated with meningitis significantly reduces the activity of aminoglycoside antibiotics.[15]

Antimicrobial pharmacokinetics and pharmacodynamics must be considered when designing treatment regimens for CNS infections. Ability of antibiotics to reach and achieve effective concentrations at the infection site is the key to treatment success. In experimental models of meningitis, maximum bactericidal activity is achieved when CSF concentrations exceed the minimum bactericidal concentration (MBC) of the infecting pathogen by 10- to 30-fold.[16] In general, low-molecular-weight lipophilic antibiotics that are unionized at physiologic pH and not highly

## Clinical Presentation and Diagnosis of CNS Infections

### General

- Evaluate patient risk factors and recent exposures
- Evaluate other possible causes: space-occupying lesion (which may or may not be malignant), drug-induced CNS pathology autoimmune disease, and trauma[12,13]

### Signs and Symptoms[2]

- 95% of patients with bacterial meningitis have two of the following: headache, fever, neck stiffness, and altered mental status
- Headache (87%)
- Nuchal rigidity (stiff neck) (83%)
- Fever (77%)
- Nausea (74%)
- Altered mental status (ie, confusion, lethargy, and obtundation) (69%)
- Focal neurologic defects (including positive Brudzinski sign and Kernig sign) (33%)
- Seizures
- Malaise, restlessness
- Photophobia
- Skin lesions (diffuse petechial rash observed in 50% of patients with meningococcal meningitis)
- Signs and symptoms in neonates, infants, and young children: nonspecific findings, such as altered feeding and sleep patterns, vomiting, irritability, lethargy, bulging fontanel, seizures, respiratory distress, and petechial/purpuric rash[17]
- Predictors of an unfavorable outcome: seizures, focal neurologic findings, altered mental status, papilledema, hypotension, septic shock, and pneumococcal meningitis[4]

### Laboratory Tests[5,18,44]

- CSF examination via lumbar puncture (LP, spinal tap); contraindicated in patients with cardiorespiratory compromise, increased intracranial pressure and papilledema, focal neurologic signs, seizures, bleeding disorders, abnormal level of consciousness, and possible brain herniation (a CT scan should be performed before LP if there is a question of a CNS mass to avoid potential for brain herniation) (see Table 70–2 for specific CSF findings)
- Elevated opening pressure (may be decreased in neonates, infants, and children)
- Cloudy CSF
- Decreased glucose
- Elevated protein
- Elevated WBC (differential provides clues to offending pathogen)
- Gram stain (adequate for diagnosis in 60%–90% of patients with bacterial meningitis)
- Culture and sensitivity (positive in 70%–85% without prior antibiotic therapy, positive in less than 20% who have had prior therapy)
- If CSF Gram stain and/or culture is negative, rapid diagnostic tests (such as latex agglutination) may be useful; these tests are positive even if bacteria are dead
- Polymerase chain reaction (PCR; DNA amplification of the most common bacterial meningitis pathogens) may be useful to help exclude bacterial meningitis
- Elevated CSF lactate and C-reactive protein
- Blood cultures (at least two cultures, one "set"; positive in 66%)
- Scraping of skin lesions (eg, rash) for direct microscopic examination and culture
- Other cultures should be obtained as clinically indicated (eg, sputum)
- WBC with differential
- Fungal meningitis: CSF culture, CSF and serum cryptococcal antigen titers, microscopic examination of CSF specimens
- Tuberculous meningitis: CSF culture, PCR evaluation (preferred), and acid-fast stain

## Patient Encounter 1, Part 2

The 67-year-old patient with signs and symptoms of meningitis underwent lumbar puncture. Initial results from CSF studies are WBC $1.8 \times 10^3/mm^3$ ($1.8 \times 10^9/L$) with 82% (0.82) PMNs and 41% (0.41) monocytes, protein 176 mg/dL (1,760 mg/L), glucose 18 mg/dL (1.0 mmol/L). Gram stain shows gram-negative diplococci. Vital signs remain stable in the ED. First doses of antimicrobial therapy are initiated in the ED, and NB is admitted to a medicine ward for continued treatment and confirmation of final diagnosis. Culture results confirm *Neisseria meningitidis* infection. Antimicrobials are streamlined and continued for the full duration.

*What clues in the CSF results are suggestive of bacterial meningitis?*

*Would adjunctive steroids offer additional benefit in this patient?*

*How can her antibiotic regimen be streamlined at this time?*

## Patient Encounter 1, Part 3

NB has clinically improved on hospital day 3 and would like to be discharged home to continue therapy, but would prefer oral therapy if available. As her friends at the home learn of her illness, they are concerned about the possibility of getting sick and begin to follow up with the on-call physician at the group home. They wonder about medications and vaccinations to prevent the disease.

*How long should therapy be continued in NB?*

*What oral options are viable options for continuation as an outpatient in this case?*

*Who should receive antimicrobial prophylaxis for Neisseria?*

protein bound penetrate best into CSF and other body tissues and fluids.[15,17] In addition to drug characteristics, integrity of the blood–brain barrier determines antibiotic penetration into CSF. The CSF penetration of most, but not all, antibiotics is enhanced by the presence of infection and inflammation. Sulfonamides, trimethoprim, chloramphenicol, rifampin, and most antitubercular drugs achieve therapeutic CSF levels even without meningeal inflammation.[7] Most β-lactams and related antibiotics (ie, carbapenems and monobactams), vancomycin, quinolones, acyclovir, linezolid, daptomycin, and colistin achieve therapeutic CSF levels in the presence of meningeal inflammation.[7] Aminoglycosides, first-generation cephalosporins, second-generation cephalosporins (except cefuroxime), clindamycin, and amphotericin do not achieve therapeutic CSF levels, even with inflammation, but clindamycin does achieve therapeutic brain tissue levels.[7]

An adequate duration of therapy is required to treat meningitis successfully (Table 70–3). KEY CONCEPT *Parenteral (IV) therapy is administered for the full course of therapy for CNS infections to ensure adequate CSF penetration throughout the course of treatment.* Antibiotic treatment (and dexamethasone, if used as a treatment adjunct) reduces the inflammation associated with meningitis, which, in turn, reduces the penetration of some antibiotics into the CSF, and parenteral therapy must be used throughout the entire treatment course to ensure adequate concentrations. Carefully selected patients who have close medical monitoring and follow-up may be able to receive a portion of their parenteral meningitis treatment on an outpatient basis.[11,18] A management algorithm for adults with suspected bacterial meningitis, as recommended by the Infectious Diseases Society of America (IDSA), is summarized in Figure 70–2.

### Empirical Antimicrobial Therapy

After diagnosis, prompt and aggressive antimicrobial therapy with an appropriate empirical treatment is of the utmost importance in patients with suspected CNS infections. In most patients, a diagnostic LP will be performed before beginning antibiotics, but this never should delay initiation of antimicrobials. Antibiotic pretreatment may alter the CSF profile and complicate interpretation. KEY CONCEPT *Empirical therapy should be directed at the most likely pathogen(s) for a specific patient, taking into account age, risk factors for infection (including underlying disease and immune dysfunction, vaccine history, and recent exposures), CSF Gram stain results, CSF antibiotic penetration, and local antimicrobial resistance patterns.* Results of the CSF Gram stain may be used to help narrow empirical therapy for bacterial meningitis. In the absence of a positive Gram stain, empirical therapy should be continued for at least 48 to 72 hours, when meningitis may, in most cases, be ruled out by CSF findings inconsistent with bacterial meningitis, negative CSF culture, and negative polymerase chain reaction (PCR) evaluations. A repeat LP may be useful in the absence of other findings. Table 70–1 outlines recommendations for empirical antibiotic therapy for bacterial meningitis by most likely pathogen(s) and patient risk factors.

### Impact of Antimicrobial Resistance on Treatment Regimens for Meningitis

Development of resistance to β-lactam antibiotics, including penicillins and cephalosporins, has significantly impacted the management of bacterial meningitis with one-fifth of CSF isolates resistant to penicillin and 3.5% of isolates resistant to cephalosporins.[19] The Clinical and Laboratory Standards Institute (CLSI) has set a lower ceftriaxone susceptibility breakpoint for pneumococcal CSF isolates (1 mg/L) than for isolates from non-CNS sites (2 mg/L). Empirical treatment regimens now include the combination of a third-generation cephalosporin plus vancomycin. Recognition of relative and high-level resistance to *N. meningitidis* in the laboratory, as well as in clinical treatment failures, has led to greater use of third-generation cephalosporins for empirical therapy of meningococcal meningitis.[3,11] Treatment of suspected or proven β-lactamase-mediated Hib meningitis also requires a third-generation cephalosporin. Increasing rates of methicillin-resistant *S. aureus* (about one-third of staphylococcal CSF isolates) and coagulase-negative staphylococci require the use of vancomycin for empirical therapy when these pathogens are suspected.[11,18]

The emergence and continued rise of multidrug-resistant strains of gram-negative organisms such as *Pseudomonas aeruginosa*, *Acinetobacter* species, AmpC, and extended-spectrum β-lactamase (ESBL) producing strains of Enterobacteriaceae have become a recognized threat nationally, and broad-spectrum therapy taking into account local resistance patterns should be used.

### Pathogen-Directed Antimicrobial Therapy

KEY CONCEPT *Empirical antimicrobial therapy should be modified on the basis of laboratory data and clinical response.* If cultures, CSF Gram stain, or antigen/antibody testing indicate a specific pathogen, therapy should be adjusted quickly as needed to ensure adequate coverage for the offending pathogen(s). Table 70–3 outlines recommended definitive pathogen-directed treatment regimens, recommended treatment duration, and key adverse effects that should be monitored during antibiotic therapy for meningitis. Table 70–4 provides pediatric doses of selected agents used in bacterial meningitis treatment.

#### ▶ *Neisseria Meningitidis Meningitis*

*N. meningitidis* CNS infections most commonly occur in children and young adults. From 11% to 19% of survivors of meningococcal meningitis experience long-term sequelae, including hearing loss, limb loss, and neurologic deficits.[20] Nearly all meningococcal disease is caused by five serogroups: A, B, C, Y, and W-135. In the United States, serotypes B, C, and Y each are responsible for approximately 30% of cases.[3,4]

Meningococcal meningitis is observed most commonly in individuals living in close quarters (eg, college students, military personnel). Infants younger than 1 year are at highest risk, possibly because pneumococcal vaccination reduces bactericidal antibodies.[21] However, nearly 60% of cases occur in patients over 11 years of age.[20,22] *N. meningitidis* colonizes the nasopharynx and usually is transmitted via inhaled respiratory droplets from patients or asymptomatic carriers. A subclinical bacteremia typically ensues, seeding the meninges. Meningococcal disease is often (approximately 50%) associated with a diffuse petechial rash, and patients may experience behavioral changes. Patients may develop fulminant meningococcal sepsis, characterized by shock, disseminated intravascular coagulation, and multiorgan failure.[23] Meningococcal sepsis has a poor prognosis and carries a mortality rate of up to 80%, whereas the mortality rate with meningococcal meningitis alone is 13%.[23,24] Patients with suspected meningococcal infection should be kept on respiratory isolation for the first 24 hours of treatment.[20]

Increasing penicillin resistance requires that third-generation cephalosporins now be used for empirical treatment until in vitro susceptibilities are known.[11,15] Patients with a history of type I penicillin allergy or cephalosporin allergy may be treated with vancomycin. Treatment should be continued for 7 days, after which no further treatment is necessary.

| Pathogen | Recommended and Alternative Antimicrobial Therapy (Adult Doses) | Adverse Effects/Safety Monitoring | Renal and Hepatic Dose Adjustment | Duration (Days) |
|---|---|---|---|---|
| | *Alternative Therapy* Foscarnet 120–200 mg/kg IV per day in divided doses every 8–12 hours | Nephrotoxicity, electrolyte imbalances, nausea/vomiting, headache, penile ulceration, thrombophlebitis, seizures | *Renal*: CrCl: 1.0–1.4 mL/min/kg (0.017–0.023 mL/s/kg): 70 mg/kg IV every 12 hours; CrCl: 0.8–1.0 mL/min/kg (0.013–0.017 mL/s/kg): 50 mg/kg IV every 12 hours; CrCl: 0.6–0.8 mL/min/kg (0.010–0.013 mL/s/kg): 80 mg/kg IV every 24 hours; CrCl: 0.5–0.6 mL/min/kg (0.008–0.010 mL/s/kg): 60 mg/kg IV every 24 hours; CrCl: 0.4–0.5 mL/min/kg (0.007–0.008 mL/s/kg): 50 mg/kg IV every 24 hours; CrCl < 0.4 mL/min/kg (0.007 mL/s/kg) *or* < 20 mL/min (0.33 mL/s) not recommended *Hepatic*: No dose adjustment | |
| *Cryptococcus neoformans* | Amphotericin B 0.7mg/kg IV daily *plus* flucytosine 100–150 mg/kg/day in divided doses every 6 hours (induction) Fluconazole 400–800 mg (maintenance) Fluconazole 200 mg (secondary prophylaxis) | Amphotericin: nephrotoxicity, electrolyte imbalances Flucytosine: bone marrow suppression, rash Fluconazole: transaminitis; QTc prolongation | *Renal*: Caution in severe renal dysfunction; consider alternative dosing strategy or change to lipid formulation *Hepatic*: No dose adjustment Flucytosine: *Renal*: CrCl 25–50 mL/min (0.42–0.83 mL/s): every 12 hours; CrCl 10–25 mL/min (0.17–0.42 mL/s) every 24 hours; CrCl < 10 mL/min (0.17 mL/s) 12.5 mg/kg every 24 hours *Hepatic*: No dose adjustment Fluconazole: *Renal*: CrCl < 50 mL/min (0.83 mL/s) decrease dose by 50% *Hepatic*: Consider 50% reduction in mild-moderate hepatic insufficiency; risk-benefit in severe hepatic dysfunction | |
| *Toxoplasmosis gondii* | Pyrimethamine 200 mg po x 1, then 50 mg (< 60 kg) to 75 mg (≥ 60 kg) daily *plus* sulfadiazine 1000 mg (< 60 kg) to 1500 mg (≥ 60 kg) po every 6 hours plus leucovorin 10–25 mg po daily | Pyrimethamine: bone marrow suppression, high-risk for anemia Sulfadiazine: nephrotoxicity, bone marrow suppression, rash, SJS | *Renal*: No dose adjustment *Hepatic*: No dose adjustment *Renal*: CrCL 25–50 mL/min (0.42–0.83 mL/s): every 12 hours; CrCl 10–25 mL/min (0.17–0.42 mL/s) every 24 hours; CrCl less than 10ml/min (< 0.17 mL/s) caution use due to high risk of crystalluria *Hepatic*: No dose adjustment | |

LFTs, liver function tests; MIC, minimum inhibitory concentration; SJS, Stevens-Johnson Syndrome.

[a]Empiric therapy with a third-generation cephalosporin should be used until in vitro susceptibility data are known.

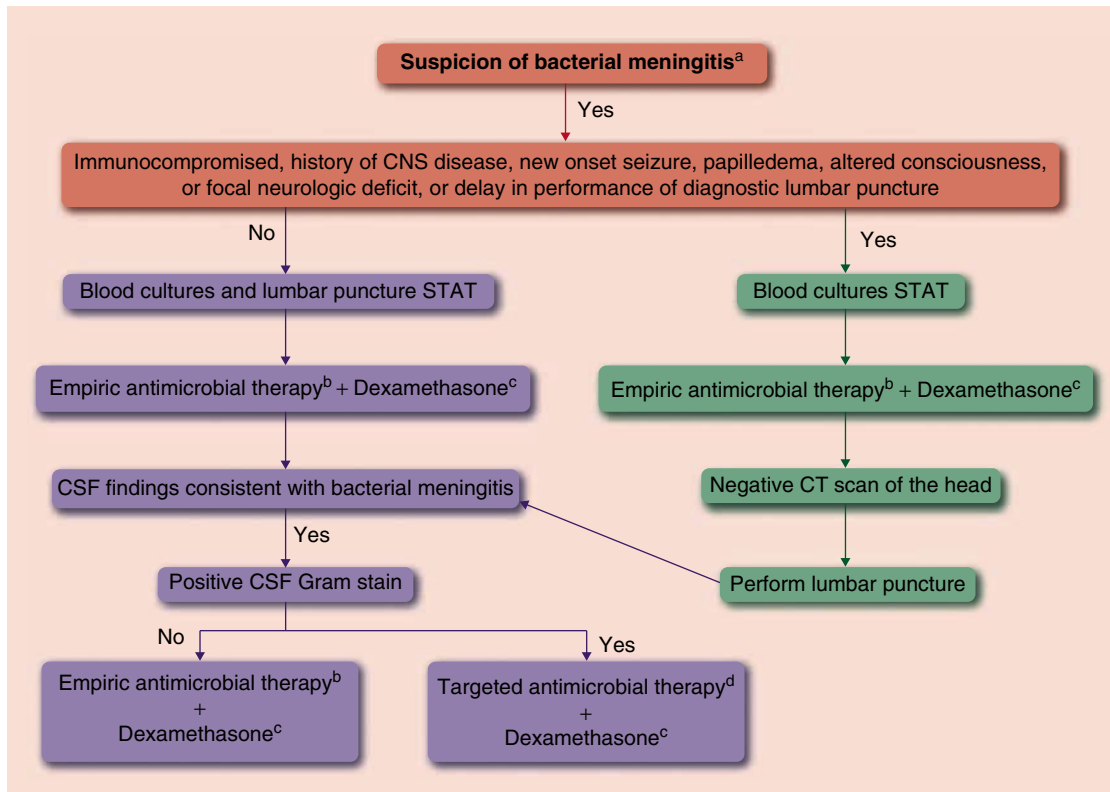
Prevention of meningococcal disease by vaccination is a key to reducing the incidence of meningococcal meningitis. Routine vaccination should be administered between ages 11 and 21 years (preferably as soon as possible), with quadrivalent vaccine that provides protection against serogroups A, C, Y, and W.[20] In addition, individuals aged 2 through 54 years who are immunocompromised (including those with complement deficiencies, who have HIV, or who have asplenia) or those with recent disease exposure during community outbreaks should receive the quadrivalent vaccine.[20] Additionally, children less than 2 years may also need quadrivalent vaccine, depending on risk factors. The quadrivalent conjugate meningococcal vaccine protects against four of the five serotypes causing invasive disease (A, C, Y, and W-135). Meningococcal vaccines do not protect against serotype B, which causes more than 50% of the cases of meningococcal meningitis in children younger than 2 years.[20]


**FIGURE 70–2.** Management algorithm for adults with suspected bacterial meningitis. [a]Management algorithm is similar for infants and children with suspected bacterial meningitis. [b]See Table 70–1 for empirical treatment recommendations. [c]See text for specific recommendations for use of adjunctive dexamethasone in adults with bacterial meningitis. [d]See Table 70–3 for pathogen-based definitive treatment recommendations. (Adapted, with permission, from Moris G, Garcia-Monco JC. The challenge of drug-induced aseptic meningitis. Arch Intern Med. 1999;159:1185–1194.)

**Pediatric Doses of Selected Agents Used in Bacterial Meningitis Treatment**

|  | Neonates, 0–7 Days | Neonates, 8–28 Days | Infants and Children |
|---|---|---|---|
| Ampicillin | 150 mg/kg IV per day in divided doses every 8 hours | 200 mg/kg IV per day in divided doses every 6–8 hours | 300 mg/kg IV per day in divided doses every 8 hours |
| Cefepime | — | — | 150 mg/kg/day in divided doses every 8 hours |
| Cefotaxime | 100–150 mg/kg IV per day in divided doses every 8–12 hours | 150–200 mg/kg IV per day in divided doses every 6–8 hours | 225–300 mg/kg/day in divided doses every 6–8 hours |
| Ceftriaxone | — | — | 80–100 mg/kg IV per day in divided doses every 12 hours |
| Gentamicin | 5 mg/kg IV per day in divided doses every 12 hours (with dosing based on serum levels) | 7.5 mg/kg IV per day in divided doses every 8 hours (with dosing based on serum levels | 7.5 mg/kg IV per day in divided doses every 8 hours based on serum levels) |
| Meropenem | — | — | 120 mg/kg IV per day in divided doses every 8 hours |
| Nafcillin/ oxacillin | 75 mg/kg IV per day in divided doses every 8–12 hours | Nafcillin: 100–150 mg/kg IV per day in divided doses every 6–8 hours; Oxacillin: 150–200 mg/kg IV per day in divided doses every 6–8 hours | 200 mg/kg IV per day in divided doses every 6 hours max, 2 g pediatrics > 3 months of age |
| Penicillin G | 0.15 million units/kg IV per day in divided doses 8–12 hours | 0.2 million units/kg IV per day in divided doses every 6–8 hours | 0.3 million units/kg IV per day in divided doses every 4–6 hours |
| Vancomycin | 20–30 mg/kg IV per day in divided doses every 8–12 hours | 30–45 mg/kg IV per day in divided doses every 6–8 hours | 60 mg/kg IV per day in divided doses every 6 hours |

LFTs, liver function tests; MIC, minimum inhibitory concentration.

Adapted, with permission, from Scheld WM, Koedel U, Nathan B, Pfister HW. Pathophysiology of bacterial meningitis: mechanism(s) of neuronal injury. J Infect Dis. 2002;186(Suppl 2):S225–S233.

Meningococcal vaccines can be used in outbreak situations, with protective antibodies measurable within 7 to 10 days. **KEY CONCEPT** *Close contacts of patients with meningococcal infections should be evaluated for antimicrobial prophylaxis.* Close contacts include members of the same household, individuals who share sleeping quarters, daycare contacts, and individuals exposed to oral secretions of meningitis patients. After consultation with the local health department, close contacts should receive prophylactic antibiotics to eradicate nasopharyngeal carriage of the organism. Household contacts of patients with meningococcal meningitis have a 400- to 800-fold increased risk of developing meningitis.[23] Prophylactic antibiotics should be started as soon as possible, preferably within 24 hours of exposure and within 14 days. Recommended regimens, all of which are 90% to 95% effective, for adults include rifampin 600 mg orally every 12 hours for 2 days, ciprofloxacin 500 mg orally for one dose, or ceftriaxone 250 mg intramuscularly for one dose. Regimens for children include rifampin 5 mg/kg orally every 12 hours for 2 days (less than 1 month of age), rifampin 10 mg/kg orally every 12 hours for 2 days (greater than 1 month of age), or ceftriaxone 125 mg intramuscularly for one dose (less than 12 years of age).[11,20,23] It is not known whether close contacts who have been vaccinated will benefit from prophylaxis. Patients with meningococcal meningitis who are treated with antibiotics other than third-generation cephalosporins also should be considered for prophylaxis to eradicate the nasopharyngeal carrier state.[22]

### ▶ Streptococcus Pneumoniae Meningitis

*S. pneumoniae* is the most common cause of meningitis in adults and in children younger than 2 years of age. Pneumococcus is associated with the highest mortality observed with bacterial meningitis in adults (14%–18%), and coma and seizures are more common in pneumococcal meningitis.[1–3] Patients at high risk for pneumococcal meningitis include the elderly, alcoholics, splenectomized patients, patients with sickle cell disease, and patients with cochlear implants. At least 50% of pneumococcal meningitis cases are due to a primary infection of the ears, sinuses, or lungs.

Due to increases in pneumococcal resistance to high-dose penicillin G, the preferred empirical treatment now includes a third-generation cephalosporin in combination with vancomycin.[11]

---

### Patient Encounter 2, Part 1

BB is a 4-year-old boy who is brought to the ED with a 3-day history of fever and irritability. In the past 24 hours, he has become more lethargic, sleeping for 18 hours, and is difficult to arouse. Vital signs and laboratory values include a rectal temperature of 39.4°C (103°F), respirations 40 per minute, heart rate 145 beats/min, and peripheral WBC of $15.9 \times 10^3/mm^3$ ($15.9 \times 10^9/L$), with 68% (0.68) PMNs. Physical examination reveals that the patient is more comfortable when lying flat and has some nuchal rigidity. BB also has a 9-year-old brother with autism and therefore he has not received any routine vaccinations.

*What signs and symptoms consistent with meningitis are present in BB?*

*What clues to causative pathogen are present in BB?*

*What empiric antimicrobial regimen should be started?*

---

All CSF isolates should be tested for penicillin and cephalosporin resistance by methods endorsed by the CLSI. Once in vitro sensitivity results are known, therapy may be tailored (see Table 70–3). Patients with a history of type I penicillin or cephalosporin allergy may be treated with vancomycin. Treatment should be continued for 10 to 14 days, after which no further maintenance therapy is required. Antimicrobial prophylaxis is not indicated for close contacts.

Administration of vaccines to high-risk individuals is a key strategy to reduce the risk of invasive pneumococcal disease. However, 2013 reports note only 82% of children aged 35 months completed the full series of the pneumococcal conjugate vaccine.[25] The 23-valent pneumococcal vaccine targets serotypes that account for more than 90% of invasive disease in high-risk patients. However, the 23-valent vaccine does not produce a reliable immunologic response in children younger than 2 years, nor does it reduce pneumococcal carriage. The 7-valent pneumococcal protein-polysaccharide conjugate vaccine used between 2000 and 2010 targeted the seven most common serotypes in children and provided protection (94% reduction) against invasive pneumococcal disease (such as sepsis and meningitis) in children younger than 5 years.[4,26,27] Widespread administration of the 7-valent conjugate vaccine to children has also contributed to a 28% reduction in invasive pneumococcal disease in adults.[4] PCV13, a 13-valent vaccine introduced in 2010, confers protection against serotypes 1, 3, 4, 5, 6A, 6B, 7F, 9V, 14, 18C, 19A, 19F, and 23F. It is intended for use in children younger than 18 years in the same schedule as the 7-valent conjugate vaccine.[27] PCV13 is specifically recommended for immunocompromised children aged 6 to 18 years.[28] Immunization schedules provided by CDC are updated at least annually and should be consulted for additional details.

### ▶ Haemophilus Influenzae Meningitis

Prior to the introduction of the Hib conjugate vaccine, *H. influenzae* type b was the most common cause of bacterial meningitis in the United States.[3,4] Routine inoculation of pediatric patients against Hib has significantly reduced the incidence of Hib meningitis between 1998 and 2007.[3,4] The Hib vaccine is also recommended for patients undergoing splenectomy. Hib meningeal disease is often associated with a parameningeal focus such as a sinus or middle ear infection. Due to β-lactamase–mediated resistance, the empirical treatment of choice is third-generation cephalosporins (eg, ceftriaxone and cefotaxime). Treatment should be continued for 7 days, after which no further maintenance therapy is required.

**KEY CONCEPT** *Close contacts of patients with H. influenzae type B meningitis should be evaluated for antimicrobial prophylaxis.* The risk of Hib meningitis in close contacts may be up to 200- to 1000-fold higher than in the general population.[7] Invasive Hib disease, including meningitis, should be reported to the local health department and the CDC. Prophylaxis to eliminate nasal and oropharyngeal carriage of Hib in exposed individuals should be initiated after consultation with local health officials. Rifampin (600 mg/day for adults; 20 mg/kg/day for children, maximum of 600 mg/day) is administered for 4 days.[11,16] Rifampin prophylaxis is not necessary for individuals who have received the full Hib vaccine series. Exposed, unvaccinated children between 12 and 48 months of age should receive one dose of vaccine, and unvaccinated children 2 to 11 months of age should receive three doses of vaccine, as well as rifampin prophylaxis.[11,16] According to the CDC, up to 18% of children at 35 months have not completed the HiB vaccine series.[25]

## Patient Encounter 2, Part 2

BB underwent lumbar puncture. Initial results from CSF studies are WBC $1.76 \times 10^3/mm^3$ ($1.76 \times 10^9$/L) with 79% (0.79) PMNs, protein 265 mg/dL (2650 mg/L), glucose 30 mg/dL (1.7 mmol/L), with a concurrent serum glucose of 110 mg/dL (6.1 mmol/L). Gram stain shows gram-negative rods and culture results identify *H. influenzae* infection. The patient is admitted to an acute care unit and remains clinically stable.

*What complications is BB at risk for acutely? What potential long-term complications may result?*

*How can his antibiotic regimen be streamlined at this time?*

*How long should the antibiotics be continued?*

### ▶ Listeria monocytogenes Meningitis

*L. monocytogenes* is an intracellular gram-positive bacillus that contaminates foods, such as soft cheese, unpasteurized milk, raw meats and fish, processed meats, and raw vegetables. Bacteria from contaminated foods colonize the GI tract, pass into the bloodstream, and overcome natural cellular immune responses to cause infection. *L. monocytogenes* meningitis, usually observed in patients at extremes of age and in immunocompromised patients with depressed cellular immunity (including patients with leukemia, solid-organ transplants, and HIV/AIDS) has an overall mortality rate of up to 30%.[29,30]

Only a limited number of antibiotics show bactericidal activity against *Listeria*. The combination of high-dose ampicillin or penicillin G and an aminoglycoside is synergistic and bactericidal against *Listeria*. A total treatment course of at least 3 weeks is required. Because of concerns about the risk of nephrotoxicity with an extended treatment course of aminoglycosides, patients are treated with combination therapy for 10 days and may finish out the remainder of their treatment with ampicillin or penicillin alone.[30] In penicillin-allergic patients, trimethoprim-sulfamethoxazole is the agent of choice due to documented in vitro bactericidal activity against *Listeria*, as well as good CNS penetration. Vancomycin and cephalosporins are not effective treatments for *Listeria* meningitis. Prophylaxis is not needed for close contacts, nor is suppressive therapy indicated. Patients with severe depression of cell-mediated immunity should be advised to avoid foods that may be contaminated with *Listeria.*

### ▶ Group B Streptococcus Meningitis

Infection with group B *Streptococcus* (eg, *S. agalactiae*) is the most common cause of neonatal sepsis and meningitis. Around 15% to 35% of pregnant women are a carrier of group B *Streptococcus* in the vagina or rectum. Group B streptococci can be acquired during childbirth after exposure to infected secretions from the mother's birth canal or rectum. Neonates born to women who are carriers are at very high risk (1 of every 100–200 babies) of developing invasive group B streptococcal disease.[31] Neonatal meningitis is associated with significant morbidity and mortality. Synergistic treatment with penicillin or ampicillin, plus gentamicin, for 14 to 21 days is recommended for group B streptococcal meningitis.[11]

To reduce the risk of clinical group B streptococcal disease in neonates, pregnant women should be screened at 35 to 37 weeks' gestation to determine whether they are carriers of group B streptococci.[31] Intrapartum antibiotics (eg, penicillin or ampicillin) are recommended for pregnant women with the following characteristics: group B streptococcal carrier state detected at screening, history of group B streptococcal bacteriuria at any time during pregnancy, and history of delivery of infant with invasive group B streptococcal disease.[31]

### ▶ Gram-Negative Bacillary Meningitis

Meningitis caused by enteric gram-negative bacilli is an important cause of morbidity and mortality in populations at risk, including those with diabetes, malignancy, cirrhosis, immunosuppression, advanced age, parameningeal infection, and/or a defect allowing communication from skin to CNS (eg, neurosurgery, congenital defects, cranial trauma).[7]

The optimal treatment for gram-negative bacillary meningitis is not well defined. The introduction of extended-spectrum cephalosporins has improved patient outcomes significantly. Although the third-generation cephalosporins ceftriaxone and cefotaxime provide good coverage for most Enterobacteriaceae, these antibiotics are not active against *P. aeruginosa*. Ceftazidime, cefepime, and carbapenems are effective in pseudomonal meningitis.[15,17] Addition of an aminoglycoside may improve treatment results; however, CNS penetration of aminoglycosides is extremely poor, even in the setting of inflamed meninges. Intrathecal or intraventricular administration of aminoglycosides may be useful, but intraventricular antibiotics have been associated with increased mortality in neonates.[15,32] Intrathecal therapy is accomplished by administering the antibiotic into the CSF via LP, whereas intraventricular therapy is usually administered into a reservoir implanted in the ventricles of the brain.

Initial therapy of suspected or documented pseudomonal meningitis should include an antipsuedomonal β-lactam (eg, cefepime, meropenem) plus an aminoglycoside (eg tobramycin, amikacin). Although the carbapenem imipenem-cilastatin has similar activity to these β-lactams, its use is not recommended in meningitis because of the risk of seizures. Aztreonam, high-dose ciprofloxacin, and colistin are alternative treatments for pseudomonal meningitis, although local susceptibility rates should be considered before initiating alternative therapy. Local therapy (ie, intrathecal or intraventricular therapy) may be indicated in patients with multidrug-resistant gram-negative bacillary meningitis or in patients who fail to improve on IV antibiotics alone. In cases of multidrug-resistant pathogens, alternative pharmacodynamic dosing strategies such as continuous or extended infusion of β-lactam antimicrobials may be considered to optimize target attainment (time greater than minimum inhibitory concentration). Given the differences in local hospital resistance patterns, administration of pathogen-directed treatment is very important after microbiology results become available. Therapy for gram-negative bacillary meningitis should be continued for at least 21 days.

### ▶ Postoperative Infections in the Neurosurgical Patient and Shunt Infections

Patients who undergo neurosurgical procedures or have invasive or implanted foreign devices (eg, CSF shunts, intraspinal pumps or catheters, epidural catheters) are at risk for CNS infections. Key pathogens in postneurosurgical infections include coagulase-negative staphylococci, *S. aureus*, streptococci, propionibacteria, and gram-negative bacilli, including *P. aeruginosa*. Clinical signs and symptoms may be similar to those of other CNS infections, and there also may be evidence of malfunction of implanted hardware or visible signs of a postoperative wound infection.

Empirical therapy for postoperative infections in neurosurgical patients (including patients with CSF shunts) should include vancomycin in combination with either cefepime, ceftazidime, or meropenem. Linezolid reaches adequate CSF concentrations and resolves cases of meningitis refractory to vancomycin.[30,33] However, data with linezolid are limited. The addition of rifampin may be considered for treatment of shunt infections. Removal of infected devices is desirable; aggressive antibiotic therapy (including high-dose IV antibiotic therapy plus intraventricular vancomycin and/or tobramycin) may be effective for patients in whom hardware removal is not possible.[34] If methicillin-resistant *S. aureus* is identified as the causative organism, daptomycin may be considered an alternative therapy.[35]

The use of prophylactic antibiotics against meningitis postcraniotomy remains controversial.[36,37] One meta-analysis suggests that prophylaxis reduces rates of postoperative meningitis by nearly one-half.[36] Breakthrough meningitis that does occur may be a result of drug-resistant pathogens.[37]

Brain abscesses are localized collections of pus within the cranium. These infections are difficult to treat due to the presence of walled-off infections in the brain tissue reducing antibiotic penetration. In addition to appropriate antimicrobial therapy (a discussion of which is beyond the scope of this chapter), surgical debridement is often required as an adjunctive measure. Surgical debridement may also be required in the management of neurosurgical postoperative infections.

▶ *Viral Encephalitis and Meningitis*

Viral encephalitis and meningitis may mimic bacterial meningitis on clinical presentation but often can be differentiated by CSF findings (see Table 70–2). The most common viral pathogens are enteroviruses, which cause approximately 85% of cases of viral CNS infections.[7] Other viruses that may cause CNS infections include arboviruses, HSV, cytomegalovirus, varicella-zoster virus, rotavirus, coronavirus, influenza viruses A and B, West Nile virus, and Epstein-Barr virus. Viral CNS infections are acquired through hematogenous or neuronal spread.[7] Most cases of enteroviral meningitis or encephalitis are self-limiting with supportive treatment.[38] However, arbovirus, West Nile virus, and Eastern equine virus infections are associated with a less favorable prognosis.

In contrast to other viral encephalitides, HSV type 1 and 2 encephalitis are treatable. Although rare (one case per 250,000 population per year in the United States), HSV encephalitis is a serious, life-threatening infection.[39] More than 90% of HSV encephalitis in adults is due to HSV type 1, whereas HSV type 2 predominates in neonatal HSV encephalitis (greater than 70%).[40] HSV encephalitis is the result of reactivation of a latent infection (two-thirds of cases) or a severe case of primary infection (one-third). Without effective treatment, the mortality rate may be as high as 85%, and survivors often have significant residual neurologic deficits. In accordance with 2008 IDSA guidelines, high-dose IV acyclovir is the drug of choice, given for 2 to 3 weeks at a dose of 10 mg/kg IV every 8 hours in adults, based on ideal body weight, and for 3 weeks at a dose of 20 mg/kg IV every 8 hours in neonates.[41] Patients receiving acyclovir should maintain adequate hydration (consider continuous IV hydration) to help prevent acute kidney injury secondary to crystal nephropathy.[41] Foscarnet 120 to 200 mg/kg/day divided every 8 to 12 hours for 2 to 3 weeks is the treatment of choice for acyclovir-resistant HSV.[41]

▶ *Opportunistic CNS Infections*

**Cerebral Toxoplasmosis**   Across the globe, cerebral toxoplasmosis represents the most common focal brain infection in HIV-infected patients. Infection rates in the United States vary but are reported to be approximately 15% among patients with AIDS.[42] The majority of cases occur in patients with CD4+ cell counts less than 100 cells/mm³ ($100 \times 10^6$/L). Potent antiretroviral therapy and primary prophylaxis (first-line option is sulfamethoxazole-trimethoprim) in IgG-positive patients has greatly reduced the disease burden.[43] First-line therapy in toxoplasmosis encephalitis is pyrimethamine plus sulfadiazine, given concomitantly with leucovorin to prevent severe hematologic adverse effects secondary to pyrimethamine (see tables for dosing).[43] Clindamycin may be substituted for sulfadiazine in cases of contraindications to sulfa-based therapy. Sulfamethoxazole-trimethoprim may also be an option, specifically in patients unable to take oral therapy. Adjunctive corticosteroids and anticonvulsant therapy should be considered to reduce sequelae from the inflammatory process and control active seizures, respectively.[43]

**Cryptococcal Meningitis**   CNS disease secondary to *Cryptococcus neoformans* is primarily observed in severely immunocompromised hosts, such as those with HIV infection. Potent antiretroviral therapy has significantly reduced the disease burden from preantiretroviral therapy rates of 5% to 8% in developed countries. The majority of disease occurs in patients with CD4+ cell counts less than 50 cells/mm³ ($50 \times 10^6$/L). First-line therapy is considered amphotericin B deoxycholate 0.7 mg/kg IV daily plus flucytosine 100 mg/kg/day orally in four divided doses for a minimum of 2 weeks.[43] Therapeutic drug monitoring may be considered for flucytosine to help reduce the risk of adverse effects. Development of renal dysfunction as a result of disease and/or drug toxicity should be closely monitored and may prompt dose reduction or possible switch to alternative lipid formulations of amphotericin, which may be less nephrotoxic. High-dose fluconazole is considered an alternative first-line therapy, especially in resource-limited areas. Secondary prophylaxis with fluconazole for an indefinite period is recommended following the completion of at least 2 weeks of induction therapy and 8 weeks of maintenance therapy with fluconazole.[43]

▶ *Adjunctive Dexamethasone Therapy*

The adjunctive agent dexamethasone improves outcomes in selected patient populations with bacterial meningitis. Dexamethasone inhibits the release of proinflammatory cytokines and limits the CNS inflammatory response stimulated by infection and antibiotic therapy.

Clinical benefit in reducing neurologic deficits (primarily by reducing hearing loss) has been observed in infants and children, if dexamethasone is initiated prior to antibiotic therapy.[1,44] The American Academy of Pediatrics recommends dexamethasone (0.15 mg/kg IV every 6 hours for 2 to 4 days) for infants and children at least 6 weeks of age with Hib meningitis and consideration of dexamethasone in pneumococcal meningitis.[11,45] In contrast to this recommendation, a large multicenter cohort study failed to show any mortality benefit of adjunctive dexamethasone therapy regardless of age or responsible pathogen (*S. pneumoniae* or *N. meningitidis*).[46] Dexamethasone should be initiated 10 to 20 minutes before or no later than the time of initiation of antibiotic therapy; it is not recommended for infants and children who have already received antibiotic therapy because

it is unlikely to improve treatment outcome in these patients. There are insufficient data to make a recommendation regarding the use of adjunctive dexamethasone therapy in neonatal meningitis.

In adults, a significant benefit was observed with dexamethasone in reducing meningitis complications, including death, particularly in patients with pneumococcal meningitis.[47] The IDSA recommends dexamethasone 0.15 mg/kg IV every 6 hours for 2 to 4 days (with the first dose administered 10 to 20 minutes before or with the first dose of antibiotics) in adults with suspected or proven pneumococcal meningitis.[11] Dexamethasone is not recommended for adults who have already received antibiotic therapy. Some clinicians would administer dexamethasone to all adults with meningitis pending results of laboratory tests. Benefit of dexamethasone in bacterial meningitis in a HIV-positive population has not been clearly established.[48]

There is controversy regarding the administration of dexamethasone to patients requiring vancomycin for pneumococcal meningitis. Animal models indicate that concurrent steroid use reduces vancomycin penetration into the CSF by 42% to 77% and delays CSF sterilization.[15] A prospective evaluation in patients with pneumococcal meningitis receiving vancomycin and adjunctive dexamethasone demonstrated that adequate concentrations of vancomycin (nearly 30% of serum concentrations) were achievable in the CSF, provided appropriate vancomycin dosage was utilized.[49] Treatment failures have been reported in adults with resistant pneumococcal meningitis who were treated with dexamethasone, but the risk–benefit of using dexamethasone in these patients cannot be defined at this time. Animal models indicate a benefit of adding rifampin in patients with resistant pneumococcal meningitis whenever dexamethasone is used.[15,17]

## OUTCOME EVALUATION

Monitor patients with CNS infections continuously throughout their treatment course to evaluate their progress toward achieving treatment goals, including relief of symptoms, eradication of infection, and reduction of inflammation to prevent death and the development of neurologic deficits. These treatment goals are best achieved by appropriate parenteral antimicrobial therapy, including empirical therapy to cover the most likely pathogens, followed by directed therapy after culture and sensitivity results are known. **KEY CONCEPT** *Components of a monitoring plan to assess efficacy and safety of antimicrobial therapy of CNS infections include clinical signs and symptoms and laboratory data (eg, CSF findings, culture, sensitivity data).*

### Patient Encounter 2, Part 3

As noted, BB had not received any vaccinations since birth. The parents are concerned and inquire about the need for antibiotic prophylaxis for the family and now are considering vaccination for BB.

*Who should receive antimicrobial prophylaxis for H. influenzae?*

*Who should receive vaccination against Hib disease?*

*How is vaccination important in the prevention of Hib disease, especially for BB?*

### Patient Care Process

**Patient Assessment:**

- Assess patient allergies, including severity of reactions
- Determine if patient has received recent antibiotics that may influence LP results or treatment decisions
- Determine from a medication history if any medicines may be associated with drug-induced aseptic meningitis

**Therapy Evaluation:**

- Assess LP results, results of antigenic testing, and culture and susceptibility for additional data to help streamline therapy
- Monitor patient for any antimicrobial-related adverse events. Provide recommendations for necessary prophylaxis based on causative pathogen and exposure history

**Care Plan Development:**

- Based on patient-specific factors and local susceptibility patterns, determine appropriate empirical antimicrobial treatment plan
- Collaborate with treatment team to ensure timely administration of antibiotic in relation to performing LP and obtaining blood cultures
- Collaborate with treatment team to determine appropriate administration of adjunctive corticosteroid therapy

**Follow-up Evaluation:**

- Determine appropriate length of therapy for diagnosed CNS infection
- Provide recommendations for outpatient parenteral therapy as needed upon discharge from acute care facility

During the patient's treatment course, monitor clinical signs and symptoms at least three times daily. Trends are more important than one-time assessments. Expect fever, headache, nausea and vomiting, and malaise to begin to improve within 24 to 48 hours of initiation of antimicrobial therapy and supportive care. Evaluate the patient for resolution of neurologic signs and symptoms, such as altered mental status and nuchal rigidity, as the infection is eradicated and inflammation is reduced within the CNS. Expect improvement and subsequent resolution of signs and symptoms as the treatment course continues. At the time of hospital discharge, arrange outpatient follow-up for several weeks to months depending on the causative pathogen, clinical treatment course, and patient's underlying comorbidities.

Monitoring of laboratory tests is important in patients receiving treatment for CNS infections. Monitor CSF and blood cultures so that antimicrobial therapy can be tailored to the etiologic organisms. Follow-up cultures may be obtained to prove eradication of the organism(s) or treatment failure. Although repeat LP generally is not performed, consider repeat LP for patients who do not respond clinically after 48 hours of appropriate antimicrobial therapy, especially those with resistant pneumococcus who receive dexamethasone.[11] Other candidates for repeat LP include those with infection with gram-negative bacilli, prolonged fever, and recurrent meningitis. Repeat the

LP in neonates to determine the duration of therapy. Repeat LP also may be performed to relieve elevated intracranial pressure. Expect repeat blood cultures to become negative quickly during therapy and the serum WBC count to improve and normalize with appropriate antimicrobial therapy.

Evaluate antimicrobial dosing regimens to ensure efficacy of the treatment regimen. Trough vancomycin concentrations of 15 to 20 mg/L (10–14 μmol/L) are recommended for the treatment of CNS infections.[44] Monitor patients for drug adverse effects, drug allergies, and drug interactions. The specific safety monitoring plan will depend on the antibiotic(s) used (Table 70–3). Pay close attention to concomitant medications in patients on rifampin for treatment or prophylaxis. Rifampin is a potent inducer of hepatic metabolism and may reduce the efficacy of other drugs metabolized by the cytochrome P-450 enzyme pathway.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| CDC | Centers for Disease Control and Prevention |
| CLSI | Clinical and Laboratory Standards Institute |
| CNS | Central nervous system |
| CSF | Cerebrospinal fluid |
| DIC | Disseminated intravascular coagulation |
| ESBL | Extended spectrum beta-lactamase |
| GBS | Group B *Streptococcus* |
| Hib | *Haemophilus influenzae* type B |
| HSV | Herpes simplex virus |
| IDSA | Infectious Diseases Society of America |
| IL-1 | Interleukin 1 |
| LP | Lumbar puncture |
| MBC | Minimum bactericidal concentration |
| MIC | Minimum inhibitory concentration |
| MRSA | Methicillin-resistant *Staphylococcus aureus* |
| MRSE | Methicillin-resistant *Staphylococcus epidermidis* |
| NSAIDs | Nonsteroidal anti-inflammatory drugs |
| PCR | Polymerase chain reaction |
| PMN | Polymorphonuclear cell |
| SJS | Stevens-Johnson Syndrome |
| TNF-α | Tumor necrosis factor-alpha |

Diane M. Cappelletty

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. List the common pathogens that cause community-acquired pneumonia (CAP), aspiration pneumonia, ventilator-associated pneumonia (VAP; early versus late onset), and health care–associated pneumonia.

2. Explain the host defenses that protect against infection.

3. Explain the pathophysiology of pneumonia.

4. List the signs and symptoms associated with CAP and VAP.

5. Identify patient and organism factors required to guide the selection of a specific antimicrobial regimen for an individual patient.

6. Design an appropriate empirical antimicrobial regimen based on patient-specific data for an individual with CAP, aspiration pneumonia, and VAP or health care–associated pneumonia (early vs late onset).

7. Design an appropriate antimicrobial regimen based on both patient- and organism-specific data.

8. Develop a monitoring plan based on patient-specific information for a patient with CAP and health care–associated pneumonia or VAP.

9. Formulate appropriate educational information to be provided to a patient with pneumonia.

## INTRODUCTION

Pneumonia is inflammation of the lung with consolidation. The cause of the inflammation is infection, which can be caused by a wide range of organisms. **KEY CONCEPT** *There are five classifications of pneumonia: community-acquired, aspiration, hospital-acquired, ventilator-associated, and health care-associated.* Patients who develop pneumonia in the outpatient setting and have not been in any health care facilities, which include wound care and hemodialysis clinics, have community-acquired pneumonia (CAP). Pneumonia can be caused by aspiration of either oropharyngeal or gastrointestinal contents. Hospital-acquired pneumonia (HAP) is defined as pneumonia that occurs 48 hours or more after admission.[1,2] Ventilator-associated pneumonia (VAP) requires endotracheal intubation for at least 48 to 72 hours before the onset of pneumonia.[2] Health care–associated pneumonia (HCAP), which is defined as pneumonia occurring in any patient hospitalized for at least 2 days within 90 days of the onset of the infection; residing in a nursing home or long-term care facility; received IV antibiotic therapy, wound care, or chemotherapy within the last 30 days prior to the onset of the infection; or having attended a hemodialysis clinic.[2,3]

## EPIDEMIOLOGY AND ETIOLOGY
### Etiology and Mortality Rates

**KEY CONCEPT** *The etiology of bacterial pneumonia varies in accordance with the type of pneumonia.* **Table 71–1** lists the more common pathogens associated with the various types or classifications of pneumonia. *Streptococcus pneumoniae* colonizes the nasopharyngeal flora in up to 50% of healthy adults and may colonize the lower airways in individuals with chronic bronchitis.[4,5] It possesses many virulence factors, enhancing its ability to cause infection in the respiratory tract. **KEY CONCEPT** Therefore, *it is not surprising that S. pneumoniae is the predominant bacterial pathogen associated with CAP.* The second most common pathogen is one of the atypical organisms, *Mycoplasma pneumoniae*. Nontypeable *Haemophilus influenzae* intermittently colonizes about 80% of the population, and the incidence of permanent colonization increases in chronic obstructive pulmonary disease (COPD) patients and those with cystic fibrosis. Therefore, the likelihood of nontypeable *H. influenzae* causing pneumonia increases in COPD patients. *Moraxella catarrhalis* is a more common cause of pneumonia in the very young and the very old. *Chlamydophila pneumoniae* and *Legionella pneumophila* are less frequent causes than the other bacterial and atypical organisms. Community-acquired methicillin-resistant *Staphylococcus aureus* (CA-MRSA) is associated with necrotizing and severe pneumonia in healthy children and young adults. Less than 2% of all CA-MRSA infections are pneumonia (most are skin and soft tissue); however, the number of reports of pneumonia are increasing.[6]

Viruses are a common cause of CAP in children (about 65%) and in adults ranges from 12% to 29%.[7–9] Mixed infections of viruses and bacteria have been increasingly identified in 11% to 56% of cases.[8–10] Viruses most often associated with pneumonia in adults include influenza A and B and rhinoviruses, but can be caused by adenoviruses, enteroviruses, cytomegalovirus,

| Table 71–1 | |
|---|---|
| **Common Pathogens by Type of Pneumonia** | |
| **Type of Pneumonia** | **Common Pathogens** |
| Community | Aerobic bacteria: *S. pneumoniae, H. influenzae, M. catarrhalis* |
| | Atypical: *M. pneumoniae, C. pneumoniae, L. pneumophila,* respiratory viruses (rhinoviruses and influenza most common) |
| Aspiration | Oral contents: Anaerobes, *Viridans* streptococci |
| | GI contents with pH increase |
| | Enteric gram-negative bacilli |
| Hospital | (Early onset, no risk factors for resistant pathogens) |
| Ventilator health care | *S. pneumoniae,* MSSA, *E. coli, K. pneumoniae, (M. pneumoniae, C. pneumoniae* are rare) |
| Hospital | (Late onset and/or risk factors for resistant pathogens) |
| Ventilator health care | MRSA, extended-spectrum β-lactamase-producing *K. pneumoniae, P. aeruginosa, Acinetobacter* spp. |

MRSA, methicillin-resistant *Staphylococcus aureus*; MSSA, methicillin-susceptible *S. aureus.*

varicella-zoster virus, herpes simplex virus, and others. In children, viral pneumonia is more commonly caused by respiratory syncytial virus, influenza A, and parainfluenza, and less commonly those listed previously for adults. Influenza is associated with seasonal local outbreaks (epidemics) and global outbreaks (pandemics). Influenza viruses are characterized and named for the hemagglutinin (H) and neuraminidase (N) proteins on the surface of the viruses. There are 16 hemagglutinin and 9 neuraminidase subtypes of influenza A, and H1–3 and N1 and 2 are the principal antigenic types found in humans.[11]

Mortality associated with CAP is dependent on the severity of the illness and the age of the patient. In elderly patients admitted to the hospital with severe pneumonia, the mortality rate is up to 40%.[12–15] In the outpatient setting (mild to moderate disease), the mortality rate is less than 5%.[16] Mortality among case reports of CA-MRSA necrotizing pneumonia is 42%.[6] Pneumonia owing to aspiration of oral contents is caused by a variety of anaerobes (*Bacteroides* spp., *Fusobacterium* spp., *Prevotella* spp., and anaerobic gram-positive cocci) as well as *Streptococcus spp. Moraxella catarrhalis,* and *Eikenella corrodens* may be involved but much less frequently.[17,18] When gastric contents are aspirated, enteric gram-negative bacilli and *Staphylococcus aureus* are more commonly the pathogens.[18]

HAP, VAP, and HCAP may be caused by a wide spectrum of organisms. HCAP, early onset HAP and VAP are commonly caused by enteric gram-negative bacilli in addition to the bacteria listed previously for CAP. Late-onset HAP and VAP are more likely to be caused by more resistant enteric gram-negative bacilli, *Pseudomonas aeruginosa, Acinetobacter* spp., or *S. aureus.* Rarely are viruses or fungi a cause of HAP, VAP, or HCAP. The number of infections caused by multidrug-resistant (MDR) bacteria is increasing significantly in hospitalized patients.[3,15,19–21]

## PATHOPHYSIOLOGY
### Local Host Defenses

Local host defenses of both the upper and lower respiratory tract along with the anatomy of the airways are important in preventing infection. Upper respiratory defenses include the mucociliary apparatus of the nasopharynx, nasal hair, normal bacterial flora, IgA, and complement. Local host defenses of the lower respiratory tract include cough, mucociliary apparatus of the trachea and bronchi, antibodies (IgA, IgM, and IgG), complement, and alveolar macrophages. Mucous lines the cells of the respiratory tract, forming a protective barrier for the cells. This minimizes the ability of organisms to attach to the cells and initiate the infectious process. The squamous epithelial cells of the upper respiratory tract are not ciliated, but those of the columnar epithelial cells of the lower tract are. The cilia beat in a uniform fashion upward, moving particles up and out of the lower respiratory tract.

Particles greater than 10 microns (μm) are efficiently trapped by mechanisms of the upper airway and are removed from the nasopharynx either by swallowing or by expulsion. The mucociliary apparatus of the trachea and bronchi along with the sharp angles of the bronchi often are effective at trapping and eliminating particles that are 2 to 10 μm in size. Particles in the range of 0.5 to 1 μm may consistently reach the alveolar sacs of the lung. Microorganisms fall within this size range, and if they reach the alveolar sacs, then infection may result if alveolar macrophages and other defenses cannot contain the organisms.

### Aspiration

Aspiration of the oropharyngeal or gastric contents may lead to aspiration pneumonia or chemical (acid) pneumonitis. Risk factors for aspiration include dysphagia, change in oropharyngeal colonization, gastroesophageal reflux (GER), and decreased host defenses.

Dysphagia can be caused by stroke or other neurologic disorders, seizures, alcoholism, and aging.[17] Oropharyngeal colonization may be altered by oral/dental disease, poor oral hygiene, tube feedings, or medications. This could result in a higher number

### Patient Encounter 1

A 65-year-old man, who only speaks Spanish, presents to your ED complaining of difficulty breathing and shortness of breath. He is accompanied by his daughter and she serves as his translator. His physical examination reveals that he is alert and oriented ×3, has decreased breath sounds on the left side compared with the right, and has rales and crackles in the left lower lobe. His temperature is 38.3°C (100.9°F), respiratory rate is 16 breaths/min, and blood pressure is 120/80 mm Hg. She indicates he is a bit confused and this is not normal for him.

*What are his signs and symptoms of pneumonia?*

*What are the top two bacterial organisms that could be causing the pneumonia?*

*What are the top two atypical organisms and top two viruses that could be causing the pneumonia?*

*What are the advantages and disadvantages of having a family member serve as an interpreter for the patient?*

of anaerobic organisms in the oral cavity or colonization with enteric gram-negative bacilli.[17] Acid suppression is an important factor in the treatment of GER disease, which may allow enteric gram-negative bacilli to colonize the gastric contents. Finally, impaired mucous production or cilia function, decreased immunoglobulin in secretions, and altered cough reflex may increase the likelihood of infection following an aspiration. The infection can result in a necrotizing pneumonia or lung abscess.

### HAP, VAP, HCAP

Risk factors for the development of HAP fall into four general categories: intubation and mechanical ventilation, aspiration, oropharyngeal colonization, and hyperglycemia.

Intubation and mechanical ventilation increase the risk of HAP/VAP 6- to 21-fold.[2,22] VAP may also be related to colonization of the ventilator circuit.[22] Risk of aspiration is increased in these patients due to the supine positioning of the patient, the presence of the endotracheal tube preventing the closure of the epiglottis over the glottis, enteral feedings, GER, and medications.[22] Oropharyngeal colonization is affected by the use of antibiotics, oral antiseptics, and poor infection control measures, which may decrease normal commensal flora and allow pathogenic organisms to colonize the oral cavity. Hyperglycemia may directly or indirectly promote infection; two proposed mechanisms are inhibiting phagocytosis and providing additional nutrients for bacteria.

Once breakdown of the local host defenses occurs and organisms invade the lung tissue, an inflammatory response is generated either by the organisms causing tissue damage or by the immune response to the presence of the organisms. This inflammatory response either can remain localized in the infected tissue or can become systemic. The role of the alveolar macrophages is twofold. First, to engulf the organisms and to contain the infection, and second, to process the antigens for presentation in order to generate a specific immune response by either the cell-mediated or humoral system, or both. The macrophages release cytokines in the area of the infection, which result in increased mucous production, constricting the local vasculature, and lymphatic vessels and attraction of other immune cells to the site. The increase in mucus is associated with symptoms such as cough and sputum production. If tumor necrosis factor alpha (TNF-α) and interleukins-1 and -6 are released systemically,

then the symptoms become more severe and include hypotension, organ dysfunction, and/or a septic or septic-shock clinical presentation.

## CLINICAL PRESENTATION AND DIAGNOSIS

Several scoring systems are available for assessing the severity of the pneumonia: the Pneumonia Severity Index (PSI); confusion, uremia, respiratory rate, blood pressure (CURB); CURB-65 (for those greater than equal to 65 years of age), and systolic BP, oxygenation, age, and respiratory rate (SOAR).[12,15,23] PSI or CURB-65 scores less than or equal to 70 and less than 2 respectively, correlate with mild disease that should be treated in the outpatient setting. These models are used by physicians to help determine the severity of illness, prognosis (mortality risk), and the need for hospitalization and then to help guide in the selection of antimicrobial therapy, along with the use of published guidelines.[12,15,16]

## TREATMENT

**KEY CONCEPT** *The goal of antibiotic therapy is to eliminate the patient's symptoms, minimize or prevent complications, and decrease mortality.* Potential complications secondary to pneumonia include further decline in pulmonary function in patients with underlying pulmonary disease, prolonged mechanical ventilation, bacteremia/sepsis/septic shock, and death. Use of an antimicrobial agent with the narrowest spectrum of activity that covers the suspected pathogen(s) without having activity against organisms not involved in the infection is preferred to minimize the development of resistance.

### General Approach to Treatment

Designing a therapeutic regimen for any patient with any type of pneumonia begins with three general categories of consideration:

1. Patient-specific factors that will impact therapy.
2. The top two to three organisms likely causing the infection and resistance issues associated with each organism.
3. The antimicrobials that will cover these organisms. The spectrum should not be too broad or narrow; they should penetrate into the site of infection and be the most cost effective.

Patient factors that need to be considered include age, renal function, drug allergies and/or drug intolerances, immune status (diabetes, neutropenia, or immunocompromised host), cardiopulmonary disease, pregnancy, medical insurance and prescription coverage, exposure to resistant organisms, and prior antibiotic exposure(s).

- The most common pathogens vary with the type of pneumonia, and they are listed in Table 71–1.
  *M. pneumoniae* lack a cell wall; therefore, β-lactam drugs have no activity against this organism. The atypical organisms have not changed in recent years with respect to antibiotic resistance. β-Lactamase production in *H. influenzae* has remained relatively steady over the last 5 to 10 years, and the rate is approximately 25%.[24] *S. pneumoniae* has developed resistance mechanisms against many classes of antimicrobials, and the mechanisms include the following:
- Alteration of the penicillin-binding proteins (PBPs), inactivating β-lactams
- Efflux or methylation of the ribosome-inactivating macrolides

---

**Patient Encounter 2**

A 68-year-old woman was admitted to the hospital secondary to a motor vehicle accident. One day after admission she developed respiratory failure and was intubated. She has remained intubated and on day 9 the chest x-ray revealed bilateral lower lobe infiltrates. She is sedated but does respond to commands. Her temperature is 38.9°C (102°F), her blood pressure is 110/75 mm Hg, and her WBC is $20.4 \times 10^3/mm^3$ ($20.4 \times 10^9$/L) with a cell differential of 75% (0.75) neutrophils, 7% (0.07) bands, 15% (0.15) lymphocytes, and 3% (0.03) monocytes.

*What are her signs and symptoms of pneumonia?*

*What are the top three bacterial organisms that could be causing the pneumonia?*

## Clinical Presentation of CAP or Aspiration Pneumonia

### General

Patients may experience nonrespiratory symptoms in addition to respiratory symptoms. With increasing age, both respiratory and nonrespiratory symptoms decrease in frequency.

`KEY CONCEPT` *Symptoms*

- Respiratory—cough (productive or nonproductive), shortness of breath, and difficulty breathing
- Nonrespiratory—fever, fatigue, sweats, headache, myalgias, mental status changes

`KEY CONCEPT` *Signs*

- Temperature may increase or decrease from baseline, but most often it is elevated. The temperature may be sustained or intermittent.
- Respiratory rate is often increased. Cyanosis, increased respiratory rate, and use of accessory muscles of respiration are suggestive of severe respiratory compromise.
- Breath sounds may be diminished. Rales or rhonchi may be heard.
- Confusion, lethargy, and disorientation are relatively common in elderly patients.

### Diagnostic Tests

- Chest x-ray should reveal single or multiple infiltrates.
- Oxygen saturation should be more than 90% (0.90), as determined by pulse oximetry.
- Arterial blood gases are beneficial primarily in patients with severe pneumonia.

### Laboratory Tests

- The WBC may or may not be elevated. In elderly patients, a drop in WBCs also can be a sign of infection. The differential should show a predominance of neutrophils if a bacterial infection is present. The presence of bands also could be an indicator of bacterial infection. Elevated lymphocytes are an indication of viral infection.
- Blood urea nitrogen (BUN) and serum creatinine are needed to dose antibiotics appropriately and to minimize or prevent drug toxicity (especially in the elderly patient).

### Microbiology Tests

- Sputum Gram stain should demonstrate the presence of WBCs and the absence of squamous epithelial cells. It may or may not show a predominance of one type of organism.
- Sputum culture and susceptibility are not obtained in the outpatient setting. The value of culturing is debated owing to the rapidity in which *S. pneumoniae* dies in transport media and the inability to reliably or routinely culture atypical organisms.
- Bronchoscopy may be performed to improve the ability to diagnose pneumonia. Tracheal secretions often are better specimens than sputum owing to the lack of oral contamination.
- Serology (IgM and IgG) is useful in determining the presence of atypical organisms such as *Mycoplasma* and *Chlamydia*.
- Urinary Legionella antigen is used to diagnose *L. pneumophila*.
- Polymerase chain reaction (PCR) is being used more frequently to detect the DNA of respiratory pathogens.
- Blood cultures should be obtained in all patients admitted to the ICU with pneumonia. Positive blood cultures are present in about 1% to 20% of patients with CAP.

## Clinical Presentation of Severe CAP or Aspiration Pneumonia

### General

In approximately 10% of patients, CAP will be severe enough to require intensive care or mechanical ventilation.

`KEY CONCEPT` *Symptoms*

- Respiratory—cough (productive or nonproductive), shortness of breath, difficulty breathing
- Nonrespiratory—fever, fatigue, sweats, headache, myalgias, mental status changes

### Signs

- Temperature may increase or decrease from baseline, but most often it is elevated. The temperature may be sustained or intermittent.
- Respiratory rate greater than 30 breaths/min. Cyanosis and use of accessory muscles of respiration along with the increased respiratory rate are suggestive of severe respiratory compromise.
- Hypotension (systolic blood pressure less than 90 mm Hg or diastolic blood pressure less than 60 mm Hg).
- Requirement for vasopressors.
- Breath sounds may be diminished. Rales or rhonchi may be heard.
- Urine output less than 20 mL/hour or less than 80 mL over 4 hours.
- Confusion, lethargy, and disorientation are relatively common in elderly patients.

### Diagnostic Tests

As stated in the clinical presentation of community-acquired or aspiration pneumonia.

### Laboratory Tests

As stated in the clinical presentation of community-acquired or aspiration pneumonia.

### Microbiology Tests

As stated in the clinical presentation of community-acquired or aspiration pneumonia.

## Diagnosis of VAP

### Clinical Strategy

- Chest x-ray should reveal a new infiltrate *plus* two of the following:
  - Temperature greater than 38.0°C (100.4°F)
  - Leukocytosis or leukopenia
  - Purulent secretions
  - Semiquantitative cultures are obtained to identify the pathogen(s)
- Tracheal aspirates grow more organisms than invasive quantitative cultures and often result in overuse of antibiotics
- The major limitation of the clinical strategy is the consistent overprescribing of antibiotics

### Bacteriologic Strategy

- Uses quantitative culture of endotracheal aspirates, bronchoalveolar lavage (BAL), or protected specimen brush (PSB)
- Greater than or equal to $10^6$ cfu/mL ($10^9$ cfu/L) for endotracheal aspirates
- Greater than or equal to $10^4$ to $10^5$ cfu/mL ($10^7$–$10^8$ cfu/L) for BAL
- Greater than or equal to $10^3$ cfu/mL ($10^6$ cfu/L) for PSB
- The advantage of this method is that it separates colonization from infection better than culturing tracheal aspirates

- The limitation is the potential misinterpretation of negative culture results. These samples should be obtained prior to antibiotics being started

### Recommended Diagnostic Strategy

- Combination of the preceding two methods:
  - Obtain either a quantitative or semiquantitative culture of a lower respiratory sample. Initiate empirical broad-spectrum antibiotic therapy
  - Days 2 and 3: Check culture results, and assess clinical response to therapy: temperature, WBCs, chest x-ray, oxygenation, purulent sputum, hemodynamic changes, and organ function
- Assess clinical improvement at 48 to 72 hours:
  - Improvement and culture negative—stop antibiotics
  - Improvement and culture positive—narrow antibiotic therapy
  - No improvement and culture negative—consider other pathogens, complications, or other diagnosis
  - No improvement and culture positive—change antibiotic therapy and consider other pathogens, complications, or other diagnosis

## Patient Encounter 3, Part 1: Medical History, Physical Examination, and Diagnostic Tests

A 65-year-old man presents to your ED complaining of difficulty breathing and shortness of breath.

**PMH:** Hypertension for 8 years, COPD for 5 years, currently controlled

**FH:** Father died of lung cancer at the age of 68 years; mother died of natural causes

**SH:** Denies alcohol use, smokes 1 pack per day for 15 years. Lives alone and has 2 children. He is 5′8″ (173 cm) and weighs 140 lb (63.6 kg)

**Allergies:** NKDA

**Meds:** Hydrochlorothiazide 25 mg orally once daily; fluticasone propionate/salmeterol 250/50 mcg one inhalation twice daily; albuterol inhaler 1 to 2 inhalations every 4 hours as needed for shortness of breath

**ROS:** (+) difficulty breathing and shortness of breath; (–) chest pain, N/V/D, change in appetite

**PE:**

**VS:** BP 120/80, P 82, RR 22, T 38.6°C (101.5°F)

**CV:** RRR, normal $S_1$, $S_2$; no murmurs, rubs, or gallops

**Lungs:** Decreased breath sounds on the left side compared with the right with rales and crackles in the left lower lobe

**Abd:** Soft, nontender, nondistended; (+) bowel sounds, no hepatosplenomegaly, heme (–) stool

**Neuro:** Oriented to name and place, confused

**Diagnostic Tests:** Chest x-ray: left lower lobe infiltrates; oxygen saturation 84% (0.84) on room air

**Labs:** WBCs $14.2 \times 10^3$/mm³ ($14.2 \times 10^9$/L) with a cell differential of 70% (0.70) neutrophils, 2% (0.02) bands, 20% (0.20) lymphocytes, and 8% (0.08) monocytes; BUN 9 mg/dL (3.2 mmol/L), SCr 0.9 mg/dL (80 μmol/L), glucose 90 mg/dL (5.0 mmol/L); sputum Gram stain: moderate gram-positive cocci, few gram-negative bacilli, many WBCs; sputum culture is pending

*Given this additional information, what is your assessment of the patient's condition?*

*Identify your treatment goals for the patient.*

*What organisms should you include in your list of potential pathogens?*

*What pharmacologic agents are available for treating this patient?*

- Ribosome protection (tetM gene) inactivating tetracyclines
- Alteration of DNA gyrase or topoisomerase IV inactivating fluoroquinolones

*S. pneumoniae* resistance to commonly prescribed antimicrobials such as the penicillins and macrolides/azalides dramatically increased in the late 1980s through the mid- to late 1990s and has remained relatively flat in the 2000s. Resistance information collected nationally along with susceptibility testing for a new antimicrobials, demonstrates that average national rates of resistance to penicillin and macrolides were approximately 13% and 38%, respectively.[25,26] Resistance to trimethoprim/sulfamethoxazole is approximately 25%, and fluoroquinolone resistance remains less than 0.5%.[26]

For HCAP, HAP, and VAP, the risk of infection from an MDR pathogen is relatively high. The number and type of organisms that are MDR vary from hospital to hospital, making it more difficult to generate guidelines for treatment. Therefore, the treatment recommendations may be too broad or too narrow for any given institution. Treating patients with HCAP, HAP, or VAP is more complex than treating patients with CAP. There are many factors to consider, and one of those relates to the timing of infection to the most likely pathogens. Early-onset infection is less likely to be caused by MDR pathogens than late-onset infection. In early-onset infection, community pathogens such as pneumococcus, *Legionella*, and *Mycoplasma* need to be considered as well as some of the hospital pathogens. Patients developing late-onset pneumonia are at increased risk for resistant pathogens or MDR pathogens such as MRSA, enteric gram-negative bacilli, *Pseudomonas*, and *Acinetobacter*. Risk factors for developing infection caused by a resistant pathogen are as follows:

- Antimicrobial therapy in preceding 90 days
- Current hospitalization of at least 5 days
- High occurrence of antibiotic resistance in the community or in the specific hospital unit
- Immunosuppressive disease and/or therapy

- Presence of risk factors for HCAP:
  - Hospitalization for 2 days or more in the preceding 90 days
  - Residence in a nursing home or extended-care facility
  - Home infusion therapy (including antibiotics)
  - Peritoneal or hemodialysis within 30 days
  - Home wound care
  - Close contact family member with MDR pathogen

Once these issues are addressed, antimicrobial therapy can be selected and initiated. The patient- and drug-related categories are common to all types of pneumonia, but the organisms vary with the type of pneumonia. Guidelines have been generated by experts in the field for all types of pneumonia. These guidelines were generated to provide practitioners with evidence-based therapeutic options for the management of patients with pneumonia. The evidence-based guidelines generated by the American Thoracic Society and Infectious Diseases Society of America were derived from VAP and applied to HCAP and HAP.

### Pharmacologic Therapy for CAP

**KEY CONCEPT** *Treatment of CAP is predominantly empiric, that is, treatment is started without knowing the causative pathogen.* The most recent guidelines are the result of a collaboration between the Infectious Diseases Society of America and the American Thoracic Society.[27] The approach to patient care is based on the classification of patients into two broad categories, outpatient and inpatient, and then further dividing the groups by comorbid conditions and location in the hospital, respectively. These guidelines use patient-specific data along with predominant pathogen information to design appropriate empirical antimicrobial regimens. Table 71–2 summarizes these therapeutic options.

#### ▶ Adult Outpatient Previously Healthy

First-line therapeutic options for treating previously healthy adults include use of a macrolide (erythromycin, clarithromycin)

---

### Patient Encounter 3, Part 2: Medical History, Physical Examination, and Diagnostic Tests

A 68-year-old woman was admitted to the hospital secondary to a motor vehicle accident. One day after admission she developed respiratory failure and was intubated. She has remained intubated and on day 9 the chest x-ray revealed bilateral lower lobe infiltrates. She is sedated but does respond to commands.

**PMH:** Hypertension for 15 years, currently controlled

**FH:** Father and mother deceased from natural causes. Both had hypertension, mother had hypothyroidism

**SH:** Denies tobacco, social alcohol one to two glasses of wine per week. She lives with her husband; retired teacher. She is 5′6″ in (168 cm) and weighs 68.2 kg (150 lb)

**Allergies:** Penicillin—hives

**Meds:** Losartan 50 mg orally once daily

**PE:**

**VS:** BP 100/70, P 78, T 38.7°C (101.6°F)

**CV:** RRR, normal $S_1$, $S_2$; no murmurs, rubs, or gallops

**Abd:** Soft, nontender, nondistended; (+) bowel sounds, no hepatosplenomegaly

**Diagnostic Tests:** Chest x-ray: bilateral lower lobe infiltrates; oxygen saturation 98% (0.98) on ventilator

**Labs:** WBC is $20.4 \times 10^3/mm^3$ ($20.4 \times 10^9/L$) with a cell differential of 75% (0.75) neutrophils, 7% (0.07) bands, 15% (0.15) lymphocytes, and 3% (0.03) monocytes; BUN 10 mg/dL (3.6 mmol/L), SCr 0.9 mg/dL (80 μmol/L); BAL Gram stain: many gram-negative bacilli, moderate gram-positive cocci in clusters, many WBCs; culture is pending

*Given this additional information, what is your assessment of the patient's condition?*

*Identify your treatment goals for the patient.*

*What organisms should you include in your list of potential pathogens?*

*What pharmacologic agents are available for treating this patient?*

## Table 71–2

**Summary of CAP Treatment**

| | |
|---|---|
| *Adult outpatient otherwise healthy* Empirical coverage against *S. pneumoniae, M. pneumoniae, C. pneumoniae,* and *H. influenzae* | *Monotherapy* Azithromycin, clarithromycin, erythromycin, doxycycline |
| *Adult outpatient comorbidities* Empirical coverage against *S. pneumoniae, M. pneumoniae, C. pneumoniae,* and *H. influenzae* | *Combination therapy* High-dose amoxicillin, or high-dose amoxicillin-clavulanate (alternatives are cefpodoxime, or cefuroxime, or ceftriaxone) *plus* azithromycin, or clarithromycin or, doxycycline |
| | *Monotherapy* Gemifloxacin, levofloxacin, moxifloxacin |
| *Adult inpatient (non-ICU)* Empirical coverage against *S. pneumoniae, H. influenzae, M. pneumoniae,* and *C. pneumoniae* | *Combination therapy* Cefotaxime, or ceftriaxone, or ampicillin-sulbactam, or ertapenem *plus* azithromycin, or clarithromycin, or doxycycline |
| | *Monotherapy* Gemifloxacin, levofloxacin, moxifloxacin |
| *Adult inpatient ICU (no Pseudomonas)* Empirical coverage against *S. pneumoniae, L. pneumophila, H. influenzae,* enteric GNB, and *S. aureus* | *Combination therapy* Cefotaxime or ceftriaxone *plus* azithromycin, or levofloxacin, or moxifloxacin |
| *Adult inpatient ICU (Pseudomonas is a concern)* Empirical coverage against *P. aeruginosa, S. pneumoniae, L. pneumophila, H. influenzae,* enteric GNB, and *S. aureus* | *Combination therapy* Cefepime, or ceftazidime, or piperacillin-tazobactam, or imipenem, or meropenem *plus* or ciprofloxacin or levofloxacin or an aminoglycoside If an aminoglycoside is chosen, then add azithromycin or levofloxacin or moxifloxacin |
| *Adult inpatient non-ICU or ICU (MRSA is a concern)* Empirical coverage against *S. pneumoniae, L. pneumophila, H. influenzae,* enteric GNB, and *S. aureus (Pseudomonas* if ICU) | Add vancomycin or linezolid to the regimens listed above |
| *Pediatric outpatient* Empirical coverage against *S. pneumoniae, M. pneumoniae,* and *C. pneumoniae* | *Monotherapy* High-dose amoxicillin, or high-dose amoxicillin-clavulanate, or intramuscular ceftriaxone, or azithromycin, or clarithromycin |
| *Pediatric inpatient (non-ICU)* Empirical coverage against *S. pneumoniae* | *Monotherapy* Fully immunized child—ampicillin or penicillin G Partially immunized child—ceftriaxone or cefotaxime |
| Empirical coverage against *S. pneumoniae, H. influenzae, M. pneumoniae,* and *C. pneumoniae* | *Combination therapy* IV cefuroxime, or cefotaxime, or ceftriaxone, or ampicillin-sulbactam plus azithromycin, or clarithromycin |
| *Pediatric inpatient ICU* Empirical coverage against *S. pneumoniae, L. pneumophila, H. influenzae,* enteric GNB, and *S. aureus* | *Combination therapy* Cefotaxime, or ceftriaxone plus azithromycin, or clarithromycin |

CA-MRSA, community-acquired methicillin-resistant *Staphylococcus aureus;* GNB, gram-negative bacteria; ICU, intensive care unit.

or an azalide (azithromycin) or doxycycline.[27] If a patient has failed therapy with a macrolide, azalide, or doxycycline, one has to consider why the patient failed. The most common reasons are either medication adherence issues or the presence of resistant organisms. If a resistant organism is suspected, then use of one of the respiratory fluoroquinolones active against *S. pneumoniae* (gemifloxacin, levofloxacin, or moxifloxacin) is warranted.

▶ **Adult Outpatient with Comorbid Conditions**

The comorbid conditions that can impact therapy and outcomes in patients with CAP include diabetes mellitus, COPD, chronic heart, liver, or renal disease, alcoholism, malignancy, asplenia, and immunosuppressive condition or use of immunosuppressive drugs.[27] If the patient did not receive antibiotics in the last 3 months, then either a respiratory fluoroquinolone alone or a combination of an oral β-lactam agent plus a macrolide or azalide is recommended. If the patient received an antibiotic in the last 3 months, the recommendation is to use an agent from a different class. Doxycycline is an acceptable alternative to a macrolide or azalide.

The preferred β-lactam antimicrobial agents are high-dose (3 g daily) amoxicillin or high-dose (4 g daily) amoxicillin-clavulanate. Alternative β-lactams are second- and third-generation cephalosporins such as cefuroxime, cefpodoxime, or ceftriaxone.

▶ **Adult Inpatient Not in the ICU**

For patients admitted to the hospital with CAP, the severity of illness is generally increased (caused either by the organism itself

**Patient Encounter 4, Part 1: Creating a Care Plan**

*Based on the information presented, create a care plan for this patient's pneumonia. Your plan should include:*

*(a) A statement of drug-related needs and/or problems*

*(b) A patient-specific detailed therapeutic plan*

*(c) Monitoring parameters to assess efficacy and safety*

or underlying comorbidities in the patient), and the pathogens are essentially the same as in the outpatient setting. Recommendations are to use either a respiratory fluoroquinolone alone or a combination of an IV β-lactam antimicrobial agent plus an advanced macrolide/azalide (clarithromycin/azithromycin) or doxycycline. The recommended β-lactams include cefotaxime, ceftriaxone, ampicillin-sulbactam, or ertapenem.[27] The first antibiotic dose should be administered within the first 24 hours of admission. Conversion to oral therapy should occur when the patient is hemodynamically stable, improving clinically, and able to take oral medications, which often is within 48 to 72 hours for most patients. Discharge from the hospital should be as soon as the patient is stable and without other medical complications. The need to observe the patient in the hospital on their oral antibiotic is not necessary.[27]

### ▶ Adult Inpatient in the ICU

Patients admitted to the ICU have severe pneumonia, and the likely etiology includes *S. pneumoniae* and *H. influenzae* as in the other categories; however, the incidence of *L. pneumophila* increases in this setting and should be considered a potential pathogen. In addition, enteric gram-negative bacilli and *S. aureus* are more frequently the cause of the pneumonia in these patients. The recommendations are to treat with an IV β-lactam plus either azithromycin or a respiratory fluoroquinolone. These combination therapies minimize the risk of treatment failure due to a resistant pathogen as well as provide broad coverage.[27] The β-lactams are the same as for inpatient non-ICU treatment. If the patient is allergic to β-lactams, then aztreonam plus a respiratory fluoroquinolone are preferred.

If *P. aeruginosa* is suspected, then the antimicrobial treatment must be broadened to cover *Pseudomonas* as well as the organisms listed previously. Owing to the high resistance rates observed with *Pseudomonas*, the recommended regimens empirically double cover the *Pseudomonas* to ensure at least one of the antibiotics is active against it. The regimens include the use of an antipneumococcal, antipseudomonal β-lactam (cefepime, ceftazidime, piperacillin/tazobactam, imipenem, or meropenem), plus either ciprofloxacin or levofloxacin or an aminoglycoside. If the aminoglycoside is chosen, then either IV azithromycin or a respiratory fluoroquinolone should be added to cover *S. pneumoniae* and the atypical bacterial organisms.[27]

If CA-MRSA is suspected in the patient, then the addition of vancomycin or linezolid to the preceding regimen should be considered. Daptomycin cannot be used because surfactant in the lung inactivates the drug, thus rendering it ineffective for pneumonia. CA-MRSA can cause a necrotizing pneumonia, and the cause is believed to be due to its many virulence factors, including the Panton-Valentine leukocidin toxin.[6] In these patients the use of an agent that decreases toxin production may be beneficial. Linezolid decreases toxin production; the other recommended agents to decrease toxin production and added to vancomycin therapy are clindamycin or a respiratory fluoroquinolone.[27]

### ▶ Influenza

Influenza viruses A and B can cause pneumonia in pediatric and adult patients. Amantadine and rimantadine are available oral agents with activity against influenza virus type A. If started within 48 hours of the onset of the first symptoms, they reduce the duration of the illness by about 1.3 days. Oseltamivir and zanamivir are oral agents active against both type A and B

---

> ## Patient Encounter 4, Part 2: Creating a Care Plan
>
> *Based on the information presented, create a care plan for this patient's pneumonia. Your plan should include:*
> *(a) A statement of drug-related needs and/or problems*
> *(b) A patient-specific detailed therapeutic plan*
> *(c) Monitoring parameters to assess efficacy and safety*

influenza that reduce the duration of the illness by about 1.3 days if initiated within 40 to 48 hours of the first symptoms.[28] For active infection beyond the first 48 hours, none of these agents are effective in treating infection, and supportive care is the best treatment for these patients.

### ▶ Aspiration

Anaerobes and *Streptococcus* spp. are the primary pathogens if a patient aspirates their oral contents and develops pneumonia. Antibiotics active against these organisms include penicillin G, ampicillin/sulbactam, and clindamycin. If the patient aspirates oral and gastric contents, then anaerobes and gram-negative bacilli are the primary pathogens. The preferred treatment regimen is a β-lactam/β-lactamase inhibitor combination (ampicillin/sulbactam, amoxicillin/clavulanate, piperacillin/tazobactam, or ticarcillin/clavulanate).[27]

### ▶ Pediatric Outpatient

Guidelines have been published for treating CAP in children. The most predominant pathogens in preschool children in the outpatient setting are viruses, and often supportive therapy (maintaining hydration, antipyretics) is all that is needed.[29] For appropriately immunized infants, children, and adolescents with mild-to-moderate pneumonia in an area lacking high-level penicillin-resistant pneumococcus, high-dose amoxicillin is the recommended first-line therapy. If atypical organisms are considered likely, then a macrolide is recommended. If moderate to severe CAP is diagnosed and it is during influenza season, then treatment with oseltamivir, zanamivir (Relenza), amantadine, or rimantadine is recommended.[29] Fluoroquinolones and tetracyclines should not be used in children younger than 5 years. Dosing of antibiotics for pediatric patients is presented in Table 71–3.

### ▶ Pediatric Inpatient

If the infant or child is fully immunized, then the guidelines recommend the use of IV penicillin G or ampicillin. Alternative β-lactams include IV cefotaxime or ceftriaxone. If the infant or child is not fully immunized, then the third-generation cephalosporins (cefotaxime or ceftriaxone) should be administered.[29] If atypical organisms are suspected, add azithromycin to the β-lactam. If community-acquired MRSA is suspected, then vancomycin or clindamycin should be added to the regimen.[29]

### Pharmacologic Therapy for HCAP/HAP/VAP

*Nosocomial pneumonia* has since been replaced by the terms *health care–associated pneumonia*, *hospital-associated pneumonia*, and *ventilator-associated pneumonia*. **KEY CONCEPT** *Empirical selection of antimicrobial therapy for ventilator-, health care–, and hospital-associated pneumonia is broad spectrum; however, once culture and susceptibility information are available, the therapy should be narrowed (de-escalation) to cover the identified*

**Table 71–3**

**CAP Antimicrobial Dosing in Pediatric Patients**

| Drug (Route) | Body Weight < 2000 g | | Body Weight > 2000 g | | |
| --- | --- | --- | --- | --- | --- |
| | 0–7 Days Old | 7–28 Days Old | 0–7 Days Old | 7–28 Days Old | > 28 Days Old |
| Amoxicillin (po) | | | | 15 mg/kg every 12 hours | 17 mg/kg every 8 hours |
| Amoxicillin-clavulanate (po) | | | 15 mg/kg every 12 hours | 15 mg/kg every 12 hours | 45 mg/kg every 12 hours |
| Cefotaxime (IV) | 50 mg/kg every 12 hours | 50 mg/kg every 8 hours | 50 mg/kg every 12 hours | 50 mg/kg every 8 hours | 50 mg/kg every 8 hours |
| Ceftriaxone (IM/IV) | 25 mg/kg every 24 hours | 50 mg/kg every 24 hours | 25 mg/kg every 24 hours | 50 mg/kg every 24 hours | 50 mg/kg every 24 hours |
| Cefuroxime (po) | | | | | 15 mg/kg every 12 hours |
| Azithromycin (po/IV) | 5 mg/kg every 24 hours | 10 mg/kg every 24 hours | 5 mg/kg every 24 hours | 10 mg/kg every 24 hours | 10 mg/kg every 24 hours |
| Clarithromycin (po) | | | | | 7.5 mg/kg every 12 hours |

● *pathogen(s)*. Two factors important to the empirical selection of antibiotics for these types of pneumonia are onset time after admission and risk factors for MDR organisms. If it is early onset (less than equal to 5 days since admission), and there are no risk factors for MDR organisms, then the most frequent pathogens include *S. pneumoniae, H. influenzae*, methicillin-susceptible *Staphylococcus aureus* (MSSA), and enteric gram-negative bacilli. Recommendations for therapy include third-generation cephalosporins such as ceftriaxone or cefotaxime; a respiratory fluoroquinolone such as gemifloxacin, levofloxacin, or moxifloxacin; ampicillin/sulbactam; or ertapenem.[2] If it is late-onset pneumonia and/or there are risk factors for MDR organisms, then the pathogen list includes *P. aeruginosa*, extended-spectrum β-lactamase–producing *K. pneumoniae*, *Acinetobacter* spp., and MRSA. Empirical antibiotic selection must cover *P. aeruginosa*, which often then covers the other gram-negative pathogens. Available antibiotics include cefepime, ceftazidime, imipenem, meropenem, piperacillin/tazobactam, ticarcillin/clavulanate, levofloxacin, ciprofloxacin, gentamicin, tobramycin, and amikacin. Empirical therapy for late-onset pneumonia (listed in **Table 71–4**) could include any of the β-lactams, carbapenems, or fluoroquinolones alone or in combination with one of the aminoglycosides. If MRSA is suspected, then either vancomycin or linezolid should be added to the regimen. Recommendations for vancomycin trough concentrations of 15 to 20 mcg/mL (15–20 mg/L; 10–14 μmol/L) were based on expert opinion, not evidence from clinical trials.[2]

Currently there is debate over whether or not double coverage for *Pseudomonas* is required. In vitro studies have shown that aminoglycosides exhibit synergistic killing against gram-negative bacilli when combined with β-lactams. Dosing of the aminoglycosides is dependent on the patient's renal function. A high-dose once-daily regimen (eg, 4–7 mg/kg gentamicin or tobramycin or 15–20 mg/kg amikacin) can be utilized in patients with good renal function. Most of the studies enrolled patients with estimated creatinine clearances of at least 70 mL/min (1.17 mL/s). Meta-analyses have shown high-dose once-daily regimens to be as efficacious as and less toxic than divided daily dosing.[30–34] Divided daily dosing (eg, 1 to 2 mg/kg gentamicin or tobramycin or 7.5 mg/kg amikacin) has been utilized since the 1970s, and the dosing interval is based on the patient's renal function to achieve a trough concentration of less than 2 mcg/mL (2 mg/L; 4 μmol/L)

for gentamicin and tobramycin and less than 5 mcg/mL (5 mg/L; 9 μmol/L) for amikacin.

In addition to obtaining a synergistic effect, another reason for double coverage when treating VAP, HAP, or HCAP is to broaden the coverage empirically to increase the likelihood of covering the majority of resistant pathogens. VAP is the most studied of these types of pneumonias and is often the most severe. There is an increase in mortality when inadequate therapy is initiated for VAP. Crude mortality ranges are quite large (35%–92%) compared with estimates of attributable mortality (approximately 9%); however, attributable mortality studies are limited by the large sample size needed to accurately measure this outcome.[35–37]

**KEY CONCEPT** *Once a pathogen or pathogens have been identified, therapy should be narrowed (de-escalated) to cover only those*

**Table 71–4**

**Empirical Therapy for Late-Onset HAP, HCAP, or VAP in Adults**

| Antibiotic (Route) | Dosage[a] |
| --- | --- |
| Cefepime (IV) | 2 g every 8–12 hour |
| Ceftazidime (IV) | 2 g every 8 hour |
| Imipenem (IV) | 500 mg every 6 hour |
| Meropenem (IV) | 1 g every 8 hour |
| Piperacillin-tazobactam (IV) | 4.5 g every 6 hour |
| Ticarcillin-clavulanate (IV) | |
| Levofloxacin (IV/po) | 750 mg every 24 hour |
| Ciprofloxacin (IV) | 400 mg every 8 hour |
| Ciprofloxacin (po) | 500 mg every 8 hour |
| Gentamicin or Tobramcyin[b] (IV) | 5–7 mg/kg every 24 hour |
| Amikacin[b] (IV) | 20 mg/kg every 24 hour |
| Vancomycin (IV) | 15–20 mg/kg every 12 hour |
| Linezolid (IV/po) | 600 mg every 12 hour |

[a]Dosages are based on normal renal and hepatic function and should be adjusted as appropriate for each patient.

[b]Trough concentrations ideally should be nondetectable; less than 1 mcg/mL for gentamicin and tobramycin (1 mg/L; 2 μmol/L) and less than 4 to 5 mcg/mL (4–5 mg/L; 7–9 μmol/L) for amikacin.

*pathogens.* Use of broad-spectrum antibiotics for prolonged durations increases the risk of colonization with MDR pathogens.

## Duration of Antimicrobial Therapy

**KEY CONCEPT** *The duration of therapy for pneumonia should be kept as short as possible* and depends on several factors: type of pneumonia, inpatient or outpatient status, patient comorbidities, bacteremia/sepsis, and the antibiotic chosen. If the duration of therapy is too prolonged, then it can have a negative impact on the patient's normal flora in the respiratory and gastrointestinal tracts, vaginal tract of women, and on the skin. This can result in colonization with resistant pathogens, *Clostridium difficile* colitis, or overgrowth of yeast. In addition, the longer antibiotics are administered, the greater the chance for toxicity from the agent, as well as an increase in cost.

For treating adult outpatient CAP, two antibiotics are approved for a 5-day duration of therapy, levofloxacin (the 750-mg dose) and azithromycin. The recommended duration of therapy for all other therapies is 7 to 10 days. For treatment of CAP in adult patients admitted to the hospital, the duration is dependent on whether or not blood cultures were positive. In the absence of positive blood cultures, the duration of therapy is 7 to 10 days. If blood cultures were positive, the duration of therapy should be 2 weeks from the day blood cultures first became negative. The duration of therapy in pediatric patients is 10 days for uncomplicated CAP, with the exception of azithromycin, which is approved for 5 days.[29]

The duration of therapy cited in the literature for HCAP, HAP, or VAP ranges from 10 to 21 days. Efforts should be made to shorten the duration of therapy from the traditional 14 to 21 days to periods as short as 7 days, provided that the etiologic pathogen is not *P. aeruginosa* and that the patient has a good clinical response with resolution of clinical features of infection. Shortening the duration of therapy is beneficial because of the colonization, toxicity, and cost issues. Several studies evaluated mortality, clinical success, recurrence, or the development of resistance with shorter courses of therapy for VAP and found no differences when compared with longer courses of therapy.[36,38] The Clinical Pulmonary Infection Score (CPIS) has been used to determine when to end therapy for VAP. Using CPIS, patients who survived VAP and were treated with adequate therapy clinically improved within 3 to 5 days.[39] This study was instrumental in recommending a shortened duration of therapy of 6 days.

## OUTCOME EVALUATION

For CAP, outcomes include preventing hospitalization, shortening the duration of hospitalization, and minimizing mortality. Improvement of symptoms should occur within 24 to 72 hours after initiation of therapy for most patients with CAP. Response to therapy could be slowed in patients with underlying pulmonary disease such as moderate to severe asthma, COPD, or emphysema. In patients not responding to therapy consider patient comorbid conditions, other infectious and noninfectious reasons, and a drug-resistant pathogen must be considered. Noninfectious reasons to consider include pulmonary embolus, congestive heart failure, carcinoma, lymphoma, intrapulmonary hemorrhage, and certain inflammatory lung diseases.

Outcome parameters for VAP, HAP, and HCAP are similar to those with CAP. Clinical improvement should occur within 48 to 72 hours of the start of therapy. If a patient is not responding to therapy, then, again, consider infectious and noninfectious reasons. Infectious explanations are the same as for CAP stated above, but noninfectious are not. They include atelectasis, acute respiratory distress syndrome (ARDS), pulmonary embolism or hemorrhage, cancer, empyema, or lung abscess.

## PREVENTION

**KEY CONCEPT** *Prevention of both pneumococcal and influenza pneumonia by use of vaccination is a national goal.* Vaccination is used to prevent or minimize the severity of pneumonia caused by *S. pneumoniae* or the influenza virus.

The influenza vaccine is available in two forms, injectable and nasal inhalation. There are two forms of the injectable inactivated vaccine (containing killed virus). The regular influenza vaccine is approved for use in people older than 6 months of age, including healthy people and people with chronic medical conditions. Fluzone intradermal vaccine is indicated for adults 18 through 64 years of age against influenza disease caused by virus subtypes A and type B. The high-dose influenza vaccine

---

## Patient Care Process

**KEY CONCEPT** *Monitoring response to therapy is essential for determining efficacy, identifying adverse reactions, and determining the duration of therapy.*

**Patient Assessment:**

- Symptoms and status (ie, inpatient, outpatient, or intubated) to determine the type of pneumonia.
- Comorbid conditions of asthma, COPD, or emphysema, smoking history.
- Chest x-ray, pulse oximetry.
- Allergies and drug intolerances, noting the severity of the reaction.

**Therapy Evaluation:**

- What are the top two to three organisms associated with the type of pneumonia the patient has?

- Select an appropriate empirical antibiotic regimen for the patient and type of pneumonia, ensuring that the doses are correct for renal function (see Tables 71–2 and 71–3).

**Care Plan:**

- Assess the effectiveness of the antibiotic therapy after 24 to 72 hours looking for improvement in signs and symptoms.
- If the patient is not improving, then reevaluate the diagnosis and pathogen list, and make appropriate changes to therapy.
- Assess the patient for conversion from IV to oral therapy.
- Assess the patient for the presence of adverse drug reactions, drug allergies, and drug interactions.

**Follow-up Evaluation:**

- If the patient responds to therapy within the first 72 hours consider a short course of therapy.

is recommended for those 65 years of age and older. The nasal-spray influenza vaccine is made with live, weakened influenza viruses that do not cause the influenza (live attenuated influenza vaccine). This formulation is approved for use in healthy people 2 to 49 years of age who are not pregnant. The ability of influenza vaccine to protect a person depends on two key factors: the age and health status of the person getting the vaccine, and the similarity or "match" between the virus strains in the vaccine and those in circulation. Protective antibodies are detected approximately 2 weeks after vaccination. In February 2010, the Centers for Disease Control and Prevention (CDC) adopted a universal influenza vaccination policy, thus recommending all persons 6 months of age and older to be vaccinated annually. The CDC indentified high risk groups in whom vaccination is especially important[40]:

1. Pregnant women

2. Children younger than 5, but especially children younger than 2 years old

3. People 50 years of age and older

4. People of any age with certain chronic medical conditions

5. People who live in nursing homes and other long-term care facilities

6. People who live with or care for those at high risk for complications from flu, including:

   • Health care workers

   • Household contacts of persons at high risk for complications from the flu

   • Household contacts and out-of-home caregivers of children less than 6 months (these children are too young to be vaccinated)

The 13-valent conjugated pneumococcal vaccine (PCV13) is recommended for children younger than 5 years (6 years if chronic health conditions are present) and the 23-purified-capsular polysaccharide antigen vaccine (PPSV23) for children 5 years of age and older and adults. The serotypes in the PCV13 are the most common disease-causing strains of pneumococcus.[41,42] The minimum age to receive the PCV is 6 weeks, and the recommended age range is between 12 and 15 months. A reliable immunologic response to the PCV13 has been demonstrated, along with a favorable safety profile.[42,43] The PCV13 is also recommended for adults aged 19 years or older with immunocompromising conditions, functional or anatomic asplenia, cerebrospinal fluid (CSF) leaks, or cochlear implants in addition to receiving the PPSV23 vaccine.[40] The 23 capsular types in the PPSV23 represent at least 85% to 90% of the serotypes that cause invasive pneumococcal infections among children and adults in the United States. Ten years after vaccination, a sample of elderly individuals demonstrated significant quantity of protective antibodies.[44] Those who should receive the polysaccharide vaccine include the following[40]:

1. *All adults 65 years or older should receive one dose.*

2. *Anyone older than 6 years who has a long-term health* problem such as heart disease, lung disease, sickle cell disease, diabetes, alcoholism, cirrhosis, and leakage of cerebrospinal fluid.

3. *Anyone older than 6 years who has a disease or condition* or *is taking any drug that lowers the body's resistance to infection*, such as Hodgkin disease, lymphoma, leukemia, kidney failure, multiple myeloma, nephrotic syndrome, HIV infection or AIDS, damaged spleen or no spleen, organ transplant, long-term steroids, certain cancer drugs, or radiation therapy.

For patients who meet the qualifications, discuss the value of vaccination against *S. pneumoniae* and/or influenza.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| ARDS | Acute respiratory distress syndrome |
| ATS | American Thoracic Society |
| BUN | Blood urea nitrogen |
| CA-MRSA | Community-acquired methicillin-resistant *Staphylococcus aureus* |
| CAP | Community-acquired pneumonia |
| CDC | Center for Disease Control and Prevention |
| COPD | Chronic obstructive pulmonary disease |
| CPIS | Clinical Pulmonary Infection Score |
| DFA | Direct fluorescence antigen |
| GER(D) | Gastroesophageal reflux (disease) |
| H | Hemagglutinin |
| HAP | Hospital-acquired pneumonia |
| HCAP | Health care–associated pneumonia |
| IDDM | Insulin-dependent diabetes mellitus |
| IDSA | Infectious Diseases Society of America |
| MDR | Multidrug resistant |
| MRSA | Methicillin-resistant *Staphylococcus aureus* |
| MSSA | Methicillin-susceptible *Staphylococcus aureus* |
| N | Neuraminidase |
| $Pao_2/Fio_2$ | Arterial oxygen pressure/fraction of inspired oxygen |
| PBP | Penicillin-binding protein |
| PCR | Polymerase chain reaction |
| PCV13 | Pneumococcal 13-valent conjugated vaccine |
| PPSV23 | Purified-capsular polysaccharide 23 antigen vaccine |
| TNF-α | Tumor necrosis factor alpha |
| VAP | Ventilator-associated pneumonia |

# Upper Respiratory Tract Infections

Heather L. Girand

## LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. List common bacteria that cause acute otitis media (AOM), acute bacterial rhinosinusitis (ABRS), and acute pharyngitis.

2. Explain the pathophysiology of and risk factors for AOM, bacterial rhinosinusitis, and streptococcal pharyngitis.

3. Identify clinical signs and symptoms associated with AOM, bacterial rhinosinusitis, streptococcal pharyngitis, and the common cold.

4. List treatment goals for AOM, bacterial rhinosinusitis, streptococcal pharyngitis, and the common cold.

5. Develop a treatment plan for a patient with an upper respiratory tract infection (URI) based on patient-specific information.

6. Create a monitoring plan for a patient being treated for a URI using patient-specific information and prescribed therapy.

7. Educate patients about URIs and proper antibiotic use.

## INTRODUCTION

Upper respiratory tract infection (URI) is a comprehensive term for upper airway infections, including otitis media, sinusitis, pharyngitis, laryngitis, and the common cold. Over 1 billion URIs occur annually in the United States, triggering millions of ambulatory care visits and antibiotic prescriptions each year.[1] KEY CONCEPT *Most URIs are caused by viruses, have non-specific symptoms, and resolve spontaneously.*[2] Antibiotics are not effective for viral URIs, and their excessive use has contributed to resistance, which has prompted development of clinical guidelines to reduce inappropriate prescribing. This chapter focuses on acute otitis media (AOM), sinusitis, and pharyngitis which are frequently caused by bacteria. Proper management of the common cold is also reviewed.

## OTITIS MEDIA

Otitis media, or middle ear inflammation, is the most common childhood illness treated with antibiotics. It usually results from a nasopharyngeal viral infection and can be subclassified as AOM or otitis media with effusion (OME). AOM is a rapid, symptomatic infection with effusion, or fluid, in the middle ear. OME is not an acute illness but is characterized by middle ear effusion. Antibiotics are only useful for the treatment of AOM.

## EPIDEMIOLOGY AND ETIOLOGY

AOM occurs in all ages but is most common between 6 months and 2 years of age. By 3 years of age, more than 80% of children have at least one episode, and up to 65% have recurrent infections by 5 years of age.[3,4] Many risk factors (Table 72–1) predispose children to otitis media.[4,5] While the use of antibiotics for otitis media has declined since the mid-1990s, the proportion of health care visits resulting in antibiotic prescriptions remains close to 60%.[6–8]

Although AOM occurs frequently with viral URIs, bacteria are isolated from middle ear fluid in up to 90% of children with AOM.[9] Historically, *Streptococcus pneumoniae* was the most common organism, responsible for up to half of bacterial cases.[9,10] *Haemophilus influenzae* and *Moraxella catarrhalis* caused up to 30% and 20% of cases, respectively. Routine childhood pneumococcal vaccination has altered the microbiology such that the prevalence of *H. influenzae* and *S. pneumoniae* is now nearly equal.[9–11] Viruses are isolated from middle ear fluid with or without concomitant bacteria in up to half of cases.[5,12] Lack of improvement with antibiotics is usually a result of viral infection and subsequent inflammation rather than antibiotic resistance.

KEY CONCEPT *Antibiotic resistance heavily influences the treatment options for AOM.* Penicillin-resistant *S. pneumoniae* (PRSP) exhibit intermediate resistance (minimum inhibitory concentrations between 0.12 and 1.0 mcg/mL [0.12 and 1.0 mg/L]) or high-level resistance (minimum inhibitory concentration of 2.0 mcg/mL [2.0 mg/L] and higher). Altered penicillin-binding proteins cause resistance in approximately 44% of pneumococci, where one-third are highly penicillin-resistant.[13] Amoxicillin resistance is less common, occurring in approximately 19% of pneumococci.[13] PRSP are frequently resistant to other drug classes, including sulfonamides, macrolides, and clindamycin, but are usually susceptible to levofloxacin. Treatment should be aimed at *S. pneumoniae* because pneumococcal AOM is unlikely to

| Table 72–1 |  |
| --- | --- |
| **Risk Factors for Otitis Media[4,8]** |  |
| Allergies | Native American or Inuit ethnicity |
| Anatomic defects such as cleft palate | Pacifier use |
| Daycare attendance | Positive family history/genetic predisposition |
| Gastroesophageal reflux | Siblings |
| Immunodeficiency | Tobacco smoke exposure |
| Lack of breast-feeding | Viral respiratory tract infection/ winter season |
| Low socioeconomic status | Young age at first diagnosis |
| Male sex |  |

resolve spontaneously and commonly results in recurrent infections.[5,9] β-Lactamase production occurs in nearly 30% and 90% of *H. influenzae* and *M. catarrhalis*, respectively.[14] Although infections caused by these organisms are more likely to resolve without treatment, they should be considered when failure occurs.

## PATHOPHYSIOLOGY

AOM is caused by an interplay of factors. Viral URIs impair eustachian tube function and cause mucosal inflammation, impairing mucociliary clearance and promoting bacterial proliferation and infection. Children are predisposed because they have shorter, more flaccid, and more horizontal eustachian tubes than adults, which are less functional for middle ear drainage and protection. Clinical manifestations of AOM result from host immune response and cellular damage from inflammatory mediators released by bacteria.

Viscous effusions caused by allergy or irritant exposure contribute to impaired mucociliary clearance and AOM in susceptible individuals. Effusions can persist for up to 6 months after an episode of AOM. Atopic children experience chronic OME that may require tympanostomy tube placement to reduce complications such as hearing and speech impairment and recurrent AOM.

## TREATMENT

The goals of treatment are to alleviate ear pain and fever, if present; eradicate infection; prevent complications; and avoid unnecessary antibiotic use.

---

### Patient Encounter 1, Part 1

A 13-month-old boy presents to the pediatric clinic with 2 days of fever (maximum temperature of 39.3°C [102.7°F]), rhinorrhea, and fussiness. His mother reports that he was rubbing his left ear throughout the day yesterday. She states that he is irritable and he was crying intermittently throughout the night last night. He has not eaten much today. He attends daycare 3 days a week and has a 5-year-old sister who recently had a cold.

*What information is suggestive of acute otitis media (AOM)?*

*What risk factors does this child have for AOM?*

*Is there any additional information you need to know before recommending a treatment plan?*

---

## General Approach to Treatment

**KEY CONCEPT** *The majority of uncomplicated cases resolve spontaneously.* Untreated AOM improves in over 80% of children between days 2 and 7 of illness without increasing complications.[15] Antibiotics improve otalgia in only 5% of children between days 2 and 7 of therapy while *increasing* the risk of adverse events by 7%.[15] Antibiotics significantly improve recovery in children younger than 2 years with bilateral AOM and in those with AOM and otorrhea.[15] Children younger than 2 years have a higher incidence of PRSP infections, and children between 6 months and 3 years have higher clinical and bacteriologic failure rates and complications without initial antibiotic treatment as compared with older children.[9,16] Patients with severe AOM have lower spontaneous recovery rates than those with less severe disease, particularly in children less than 2 years.[9,17] **KEY CONCEPT** *Therefore, antibiotics should be reserved for patients most likely to benefit, which is dependent on proper diagnosis, patient age, and illness severity.* Current guidelines stratify patients using these criteria in order to identify those most likely to benefit from antibiotics.[9]

## Nonpharmacologic Therapy

Watchful waiting and "safety-net" antibiotic prescriptions (prescription given to the patient but only filled if symptoms persist or worsen within 48–72 hours after diagnosis) are approaches used to attenuate microbial resistance and avoid unnecessary antibiotic adverse events and costs. Initial observation and use of delayed prescriptions in older children and those with less severe disease can reduce antibiotic use by 67% without increasing complications.[15,18] These approaches should only be considered in otherwise healthy children (Figure 72–1) as a joint decision between the clinician and the parent/caregiver and only if close follow-up and good communication exist.[3,9,18]

Children with recurrent AOM or chronic OME with impaired hearing or speech may benefit from surgery (tympanostomy tube placement with or without adenoidectomy).

## Pharmacologic Therapy

### ▶ Antibiotic Therapy

When antibiotics are necessary, clinicians must consider drug factors (eg, antimicrobial spectrum, likelihood of response, middle ear fluid penetration, side effects, drug interactions, cost) and patient factors (eg, risk factors for resistance, allergies, regimen complexity, medication palatability, and presence of other medical conditions). Studies in uncomplicated AOM have not revealed significant differences between antibiotics in clinical response rates, but most were confounded by spontaneous resolution in children likely to have had viral URIs. Bacteriologic response varies among antibiotics and does not always correlate well with clinical response but is considered important when selecting therapy.[5,9]

The American Academy of Pediatrics (AAP) developed clinical guidelines for healthy children between 6 months and 12 years of age with uncomplicated AOM (Figure 72–2).[9] **KEY CONCEPT** *Amoxicillin is the drug of choice in most patients because of its proven effectiveness, high middle ear concentrations, excellent safety profile, low cost, good-tasting suspension, and relatively narrow spectrum* (Table 72–2). High-dose amoxicillin (80–90 mg/kg/day) is preferred over conventional doses (40–45 mg/kg/day) because higher middle ear fluid concentrations can overcome pneumococcal penicillin resistance without substantially increasing adverse effects.[19] **KEY CONCEPT** *High dose amoxicillin-clavulanate is preferred for children who received amoxicillin in the previous*

## Clinical Presentation and Diagnosis of AOM

Patients with AOM usually have cold symptoms, including rhinorrhea, cough, or nasal congestion, before or at diagnosis.

**Symptoms**

- Young children: ear tugging or rubbing, irritable, poor sleeping and eating
- Older patients: ear pain, ear fullness, hearing impairment

**Signs[5,9]**

- Fever: present in fewer than 25% of patients; often in younger children
- Middle ear effusion
- Otorrhea with tympanic membrane perforation
- Bulging tympanic membrane
- Limited or absent mobility of tympanic membrane
- Distinct erythema of tympanic membrane
- Opaque tympanic membrane that obscures middle ear visibility

**Laboratory Tests**

- Gram stain, culture, and sensitivities of ear fluid if draining spontaneously or obtained via tympanocentesis (not performed routinely in practice)

**Complications**

- Infectious: mastoiditis, meningitis, osteomyelitis, intracranial abscess
- Structural: perforated eardrum, cholesteatoma
- Hearing and/or speech impairment

**Diagnosis[9]**

AOM should be diagnosed if any of the following are met:

- Moderate to severe bulging of tympanic membrane (usually with impaired mobility as assessed by pneumatic otoscopy)
- Mild bulging of tympanic membrane *and* recent onset (less than 48 hours) of otalgia (or ear rubbing/tugging in nonverbal child) or intense erythema of tympanic membrane
- New onset otorrhea not caused by acute otitis externa

Severe AOM: Moderate to severe otalgia or otalgia for at least 48 hours *or* temperature of 39.0°C (102.2°F) or greater

---

*30 days, have concurrent purulent conjunctivitis, have a history of recurrent AOM unresponsive to amoxicillin, and when coverage for β-lactamase-producing organisms is desired.* Patients with penicillin allergies require alternative therapy (see Figure 72–2). There is limited cross-reactivity between penicillins and

newer cephalosporins which supports AAP recommendations to use cephalosporins in penicillin-allergic patients because they are more effective than alternatives.[9,20] Trimethoprim-sulfamethoxazole and macrolides have limited efficacy against *S. pneumoniae* and *H. influenzae*, making them less desirable for most

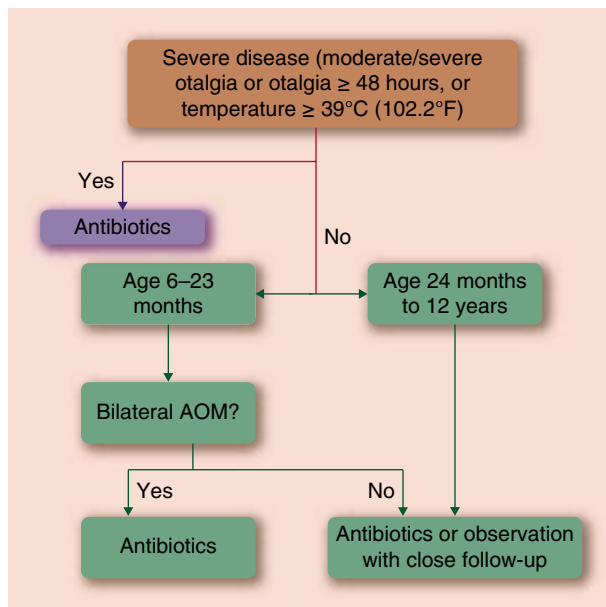

**FIGURE 72–1.** Treatment algorithm for initial antibiotics or observation in children 6 months to 12 years of age with uncomplicated AOM. (Data from Lieberthal AS, Carroll AE, Chonmaitree T, et al. The diagnosis and management of acute otitis media. Pediatrics. 2013;131(3):e964–e999.)

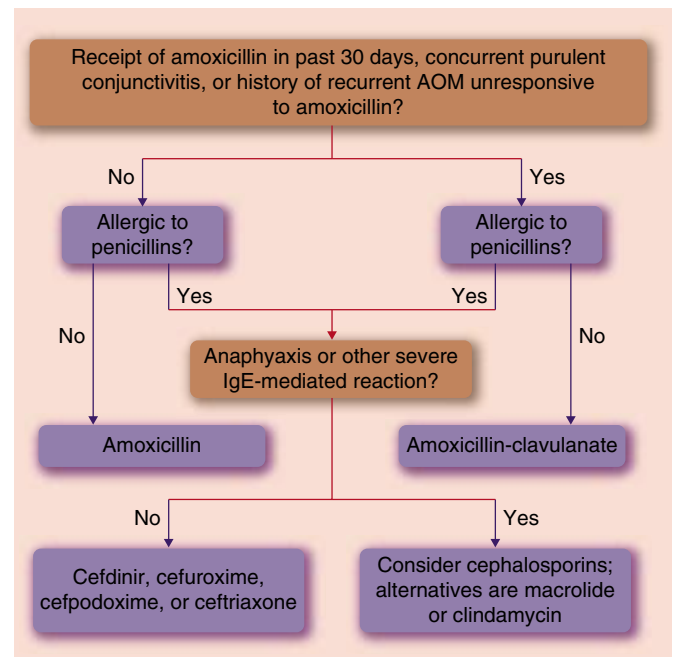

**FIGURE 72–2.** Treatment algorithm for uncomplicated AOM in children 6 months to 12 years of age. (Data from Lieberthal AS, Carroll AE, Chonmaitree T, et al. The diagnosis and management of acute otitis media. Pediatrics 2013;131(3):e964–e999.)

| Table 72–2 |
|---|

**Antibiotics[a] for the Treatment of Acute Otitis Media**

| Drug | Usual Dose and Schedule | Common Adverse Effects | Relative Cost[b] | Comments |
|---|---|---|---|---|
| Amoxicillin | 80–90 mg/kg/day in two doses (adult: 875 mg twice daily) | Nausea, vomiting, diarrhea, rash | $ | Drug of choice for AOM; experts recommend high dose to overcome penicillin resistance |
| Amoxicillin-clavulanate | 90 mg/kg/day in two doses (adult: 875 mg twice daily) | Nausea, vomiting, diarrhea, rash, diaper rash | $$$–$$$$ | More diarrhea than amoxicillin; amoxicillin:clavulanate ratio of 14:1 preferred because of lower daily clavulanate component |
| Cefuroxime axetil | 30 mg/kg/day in two doses (max 1 g/day with suspension; adult: 250 mg twice daily) | Nausea, vomiting, diarrhea, rash, diaper rash | $$–$$$ | Suspension gritty and bitter tasting; not interchangeable with tablets (less bioavailable) |
| Cefdinir | 14 mg/kg/day in one to two doses (adult: 300 mg twice daily or 600 mg once daily) | Diarrhea, rash, vomiting, diaper rash, yeast infections | $$$–$$$$ | Preferred oral cephalosporin (good taste); separate from Fe supplements by 3 hours |
| Cefpodoxime proxetil | 10 mg/kg/day in two doses (adult: 200 mg twice daily) | Diarrhea, diaper rash, vomiting, rash, yeast infections | $$$–$$$$ | Suspension is bitter tasting |
| Ceftriaxone | 50 mg/kg IM or IV for 1 or 3 days (max 1 g/dose) | Injection site pain, swelling, or erythema, diarrhea, rash | $$$–$$$$ | 3-day regimen preferred for PRSP |
| Clindamycin | 30–40 mg/kg/day in three doses (adult: 300–450 mg 3 times daily) | Nausea, diarrhea, *C. difficile* colitis, anorexia | $$ | Oral liquid poor tasting; only for pneumococcal infection |

[a]Other FDA-approved antibiotics for AOM not recommended in AAP guidelines: azithromycin, cefaclor, cefixime, cefprozil, ceftibuten, cephalexin, clarithromycin, erythromycin-sulfisoxazole, and trimethoprim-sulfamethoxazole.

[b]Approximate cost per course: $ (under $25), $$ ($25–$50), $$$ ($50–$100), $$$$ (over $100).

AOM, acute otitis media; Fe, iron; IM, intramuscular; IV, intravenous, PRSP, penicillin-resistant *S. pneumoniae.*

Data from Lieberthal AS, Carroll AE, Chonmaitree T, et al. The diagnosis and management of acute otitis media. Pediatrics 2013;131(3):e964-e999.

patients.[9,13,14] Single-dose intramuscular ceftriaxone is effective for children who cannot tolerate oral medications, but a 3-day course may be preferred because of increasing pneumococcal resistance and reports of treatment failure with single doses.[21] Ototopical antibiotics are an alternative to systemic agents for patients with otorrhea or tympanostomy tubes.[22]

If there is no improvement or worsening with initial therapy during the first 48 to 72 hours, proper diagnosis and antibiotic selection must be reassessed.[9] Tympanocentesis can assist with guiding therapy in difficult cases.

Duration of antimicrobial therapy depends on antibiotic selection, patient characteristics, and acceptability of failure if a short treatment course is used. Failure rates with short-course therapy (less than 10 days) are significantly higher in children with perforated eardrums and in children less than 2 years treated with azithromycin.[23] Short-course antibiotics may result in fewer gastrointestinal side effects but only when compared with 10-day courses of amoxicillin-clavulanate.[23] Standard 10-day regimens are recommended for all severe infections and for children less than 2 years.[9] Seven-day regimens and five- to seven-day regimens can be considered for mild to moderate AOM in children 2 to 5 years and children 6 years and older, respectively.[9]

▶ *Adjunctive Therapy*

Pain is a central feature of AOM but it is often overlooked. Analgesics provide relief within 24 hours and should be used regardless of antibiotic therapy.[9] Acetaminophen and ibuprofen are commonly used for mild to moderate pain.

Ibuprofen provides longer relief than acetaminophen but should be avoided in children younger than 6 months because of increased toxicity concerns. Alternating ibuprofen with acetaminophen is not recommended because of the potential for dosing error in ambulatory settings and a lack of safety and efficacy data. Topical anesthetic drops provide pain relief within 30 minutes of administration but their effects are short lived. **Myringotomy**, an incision made in the tympanic membrane, provides immediate relief but is rarely performed. Decongestants, antihistamines, and corticosteroids have no role in AOM treatment and can prolong effusion duration.[9,24] Data are lacking on the safety and efficacy of complementary and alternative treatments.

▶ *Prevention*

Vaccinations may prevent AOM in certain patients. Influenza vaccine is more effective in children older than 2 years because of impaired immune responses and immature host defenses in infants and toddlers.[25] The live attenuated influenza vaccine is more effective than the injectable inactivated vaccine for protecting children older than 2 years against influenza-associated AOM.[26] Pneumococcal conjugate vaccine is most protective against infection from pneumococcal serotypes contained in the vaccine and in infants at low-risk for AOM.[27] Antibiotic prophylaxis is not recommended because of antibiotic resistance trends. Exclusive breast-feeding for the first 6 months of life and avoidance of tobacco smoke are advised, but the effects of these interventions remain unproven.

## Patient Encounter 1, Part 2

On further questioning, his mother states that he is "allergic" to trimethoprim/sulfamethoxazole. He was treated for a urinary tract infection 7 months ago and experienced diarrhea while taking this antibiotic. He has not received antibiotics since that time, and this is his first ear infection.

Immunizations: up-to-date

**Meds:** Acetaminophen drops 120 mg orally every 4 to 6 hours as needed for fever

**ROS:** (+) rhinorrhea and fever, (−) vomiting, diarrhea, or cough

**PE:**

**Gen:** Irritable child but consolable

**VS:** BP 100/64 mm Hg, P 130 beats/min, RR 22 breaths/min, T 39.1°C (102.4°F)

**HEENT:** Erythema and severe bulging of the left tympanic membrane with the presence of middle ear fluid; the right tympanic membrane is obscured with cerumen.

*Identify your treatment goals for this child.*

*Given this information, what nonpharmacologic and pharmacologic therapy do you recommend?*

## OUTCOME EVALUATION

Improvement of signs and symptoms (ie, pain, fever, and tympanic membrane inflammation) should be evident by 72 hours of proper therapy. Children can appear clinically worse during the first 24 hours but often stabilize during the second day. If symptoms persist or worsen, reevaluate the patient for the proper diagnosis and treatment. Counsel patients and caregivers regarding common antibiotic adverse effects such as rash, diarrhea, and vomiting that may prompt additional medical attention.

Presence of middle ear effusion in the absence of symptoms is not an indicator of treatment failure. Evaluate hearing in children who are otherwise healthy and have persistent effusion lasting 3 months in duration. Preschool-aged and younger children or those at risk for developmental difficulties may need reexamination earlier because speech and hearing impairment is more difficult to assess in these populations.

## SINUSITIS

Sinusitis, or paranasal sinus inflammation, is often described as rhinosinusitis because it involves contiguous nasal mucosa and occurs in nearly all viral URIs. Acute rhinosinusitis is characterized by symptoms that persist for up to 4 weeks, whereas chronic rhinosinusitis lasts for more than 12 weeks. Acute bacterial rhinosinusitis (ABRS) refers to an acute bacterial sinus infection that occurs independently of or is superimposed on chronic sinusitis. This section will focus on ABRS.

## EPIDEMIOLOGY AND ETIOLOGY

Rhinosinusitis affects about 1 billion people annually in the United States.[1] It is caused mainly by respiratory viruses but can also be triggered by allergies or environmental irritants. Viral rhinosinusitis is complicated by secondary bacterial infection in 0.2% to 2% of adults and 5% to 13% of children.[1,28] URIs of less

## Patient Care Process for Acute Otitis Media

**Patient Assessment:**

- Based on patient history, review of systems, and physical examination (including pneumatic otoscopy findings), determine if the patient has AOM and if it is severe.
- Perform a medical review and conduct a medication history (including prescription and nonprescription medications and natural products). Does the patient have any medication allergies or adverse reactions? Is the patient up-to-date on immunizations?

**Therapy Evaluation:**

- If the patient is receiving pharmacotherapy, assess efficacy, safety, and adherence.
- Determine if antibiotic therapy is indicated or if observation can be employed (see Figure 72–1).
- Determine whether the patient has prescription coverage and if the desired antibiotic is covered by their insurance.

**Care Plan Development:**

- If appropriate, select analgesic therapy that will provide optimal pain relief.
- If appropriate, select antibiotic therapy that is likely to be effective and safe (see Figure 72–2).
- Select an optimal antibiotic dose (see Table 72–2) and an appropriate duration of treatment based on patient age and illness severity.
- Discuss potential adverse effects and how to manage them.
- Discuss importance of medication adherence to treat infection and pain.
- Determine the need for influenza and pneumococcal vaccinations to reduce risk for future infection.

**Follow-up Evaluation:**

- Reevaluate patient within 48 to 72 hours if symptoms persist or worsen.
- Monitor for middle ear effusion resolution at an appropriate interval based on age and presence of conditions that interfere with recognition of hearing impairment.

than 7 days' duration are usually viral, whereas more prolonged or severe symptoms are often caused by bacteria. Risk factors for ABRS include prior viral URI, allergic rhinitis, and anatomic defects (Table 72–3).[29,30]

Bacteria that cause sinusitis are similar to those in AOM. *S. pneumoniae* and *H. influenzae* cause more than half of ABRS cases, with an additional 8% to 16% of cases caused by *M. catarrhalis*.[29,30] Similar to AOM, an increased prevalence of *H. influenzae* has been reported in ABRS, and certain factors predict the presence of drug-resistant pathogens.[1,30]

## PATHOPHYSIOLOGY

Rhinosinusitis is caused by mucosal inflammation and mucociliary dysfunction from viral infection or allergy. Increased mucous production and reduced clearance lead to blockage of the sinus

**Table 72–3**

**Risk Factors for Acute Bacterial Rhinosinusitis[29,30,31]**

| | |
|---|---|
| Allergic or nonallergic rhinitis | Intranasal medications or illicit drugs |
| Anatomic defects (eg, septal deviation) | Mechanical ventilation |
| Aspirin allergy, nasal polyps, and asthma | Nasogastric tubes |
| Cystic fibrosis or ciliary dyskinesia | Swimming or diving |
| Dental infections or procedures | Tobacco smoke exposure |
| Female sex | Traumatic head injury |
| Gastroesophageal reflux | Viral respiratory tract infection or winter season |
| Immunodeficiency | |

ostia. This environment is ideal for bacterial growth and promotes a cycle of local inflammation and mucosal injury characterized by increased concentrations of interleukins, histamine, and tumor necrosis factor.[31] Damage to the host defense system perpetuates bacterial overgrowth and persistence of infection.

## TREATMENT

The goals of treatment are to relieve symptoms, promote sinus drainage, use antibiotics when appropriate that minimize resistance, and prevent development of chronic disease or complications.

### General Approach to Treatment

Initial management focuses on symptom relief. Clinicians often inappropriately prescribe antibiotics for rhinosinusitis, which usually is viral and self-limited. Studies in adults with clinically diagnosed nonsevere sinusitis report cure rates of nearly 50% by day 10 with no differences between antibiotics and placebo but significantly more adverse events with antibiotics.[33] Studies in children with persistent nasal discharge for at least 10 days report

modest benefits with antibiotic therapy.[34] **KEY CONCEPT** *Antibiotics should be prescribed only when ABRS is most likely: persistent symptoms for greater than 10 days with no improvement; sudden worsening of symptoms within 5 to 10 days of initial improvement; and severe symptoms for 3 to 4 days at illness onset.*[28,30,32] In patients with mild persistent illness for at least 10 days, observation for another 3 days can be employed if there is adequate follow-up.[28,30]

### Nonpharmacologic Therapy

Humidifiers and saline nasal sprays or drops moisturize the nasal canal, impair crusting of secretions, and promote ciliary function. Although many patients report benefit from such therapies, there are no controlled studies that support their efficacy. Nasal irrigation with isotonic or hypertonic saline may reduce medication use and improve symptoms, especially in patients with recurrent or chronic sinusitis.[28,35]

### Pharmacologic Therapy

#### ▶ Adjunctive Therapy

Medications that target symptoms are commonly used in rhinosinusitis despite a lack of evidence demonstrating their efficacy. Analgesics/antipyretics should be used to treat facial pain and fever. Oral decongestants relieve congestion but should be avoided in children younger than 4 years and patients with ischemic heart disease or uncontrolled hypertension. Intranasal decongestants can be used for severe congestion in patients 6 years of age or older, but use should be limited to 3 days to avoid rebound nasal congestion. Avoid antihistamines because they thicken mucus and impair clearance, but they may be useful in patients with allergic rhinitis or chronic sinusitis. Similarly, intranasal corticosteroids usually are reserved for patients with allergies or chronic sinusitis, but they may be beneficial as monotherapy or with antibiotics in ABRS.[28,36]

#### ▶ Antibiotic Therapy

No randomized, double-blind, placebo-controlled antibiotic studies have used pre- and posttreatment sinus aspirate cultures as an outcome measure. In some studies, antibiotics resulted in

## Clinical Presentation and Diagnosis of Acute Bacterial Rhinosinusitis

**KEY CONCEPT** *It is important to differentiate between viral sinusitis and ABRS to avoid inappropriate antibiotic use.*

**Signs and Symptoms[28,30,31]**

- *Adults:* Nasal congestion or obstruction, purulent nasal or postnasal discharge, facial pain or pressure (especially unilateral), diminished sense of smell, fever, cough, maxillary tooth pain, fatigue, ear fullness or pain
- *Children:* Persistent nasal or postnasal drainage, nasal congestion, mouth breathing, persistent cough (particularly at night) or throat clearing, fever, pharyngitis, ear discomfort, halitosis, morning periorbital edema or facial swelling, fatigue, facial or tooth pain

**Complications**

Orbital cellulitis or abscess, periorbital cellulitis, meningitis, cavernous sinus thrombosis, ethmoid or frontal sinus erosion, chronic sinusitis, and exacerbation of asthma or bronchitis

**Diagnosis[28,30,32]**

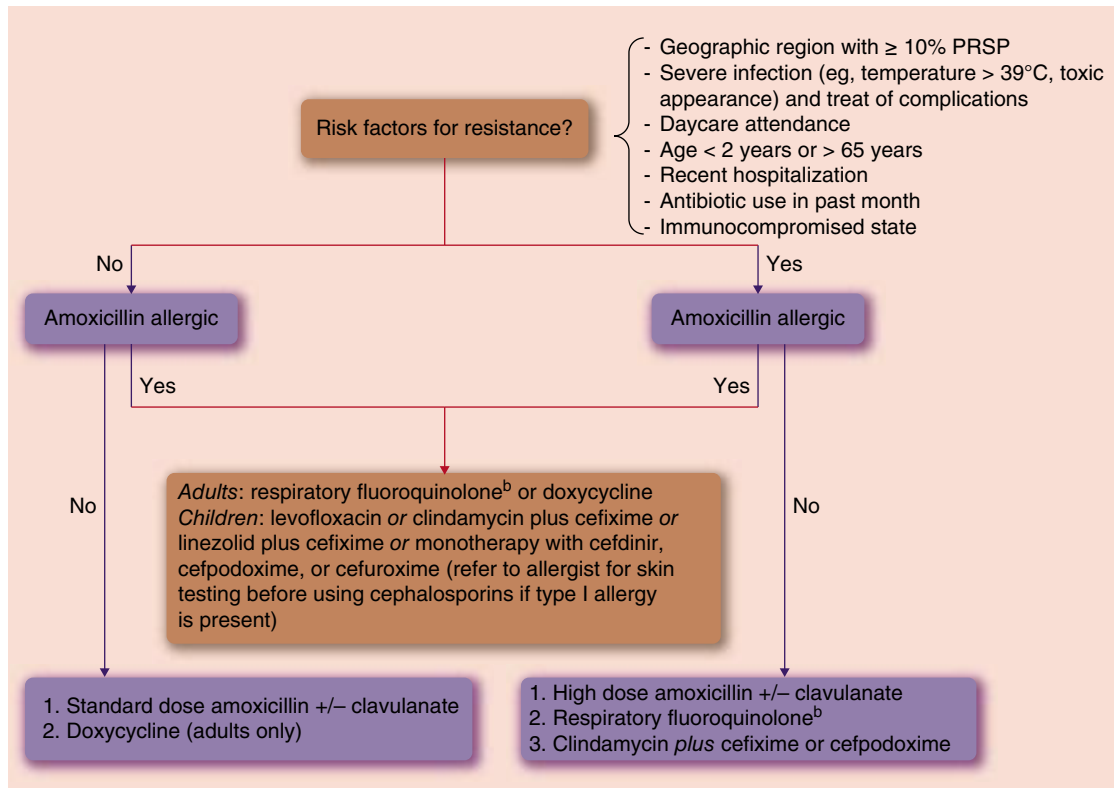
- *Clinical diagnosis:* Most common method; signs and symptoms that persist for more than 10 days with no improvement *or* that worsen after initial improvement, *or* severe symptoms (fever greater than or equal to 39.0°C [102.2°F] and purulent nasal discharge) for at least 3 to 4 days at illness onset. Respiratory secretion color is unreliable for diagnosis because neutrophil presence causes color and is found in viral sinusitis.[32]
- *Radiographic studies:* Useful for assessing presence of complications
- *Paranasal sinus puncture*: "Gold standard"; not routine but can be useful in complicated or chronic cases
- *Laboratory studies/nasopharyngeal cultures:* not recommended


**FIGURE 72–3.** Treatment algorithm[a] for ABRS. [a]Antibiotics are listed in order of preference based on predicted clinical and bacteriologic efficacy rates, clinical studies, safety, and tolerability. Doses can be found in Table 72–4. [b]Respiratory fluoroquinolone = levofloxacin, moxifloxacin.[28,30]

faster symptom resolution with lower failure rates compared with no treatment, particularly with more severe infection.[28,30,32] Because diagnosis is usually based on clinical presentation, clinicians must differentiate ABRS from viral rhinosinusitis in order to minimize inappropriate antibiotic use. Empiric antibiotic selection is usually used and should target commonly infecting bacteria. **KEY CONCEPT** *Treatment guidelines outline antibiotic choices that are likely to result in favorable clinical and bacteriologic outcomes based on causative pathogens and nationwide resistance patterns (Figure 72–3).*[28,30] Severe disease should be treated in conjunction with specialists such as otolaryngologists or infectious disease physicians.

Antibiotics (Table 72–4) should target *S. pneumoniae* and *H. influenzae*, but consideration must also be given to other bacteria and local resistance patterns. **KEY CONCEPT** *Standard dose amoxicillin or amoxicillin-clavulanate is recommended for most patients.*[28,30] Amoxicillin is effective for most infections and is less expensive and better tolerated than amoxicillin-clavulanate, which provides expanded coverage against β-lactamase–producers. High-dose amoxicillin or amoxicillin-clavulanate is recommended for patients who are at risk for infection from resistant bacteria, such as those who attend daycare, and when PRSP and other resistant bacteria are frequent in a community (see Figure 72–3). Patients with penicillin allergies can be treated with an appropriate cephalosporin, doxycycline, or a respiratory fluoroquinolone depending on age and allergy severity. Cephalosporin monotherapy is less desirable because of increased pneumococcal resistance, so combination therapy may be required to optimize coverage for PRSP and β-lactamase producers.[28] Macrolides and trimethoprim-sulfamethoxazole are not recommended because

of high pneumococcal and *H. influenzae* resistance. For uncomplicated infections, treatment duration ranges from 5 to 10 days in adults and 10 to 14 days in children.[28,30] While short-course therapy with some fluoroquinolones and β-lactams are as effective as longer courses in adults with uncomplicated acute maxillary sinusitis, data are lacking to support shorter courses in more severe infections or in children.[37]

Failure to improve within 3 to 5 days of therapy or worsening at any time requires reevaluation to confirm the diagnosis, consider changing antibiotics, and examine for complications.[28,30]

## OUTCOME EVALUATION

Clinical improvement (eg, defervescence, reduced nasal congestion and discharge, improvements in pain or facial pressure) should be evident within 5 days of therapy. Monitor for common adverse effects and refer to a specialist if clinical response is not obtained with first- or second-line therapy. Referral is also important for severe, recurrent, or chronic infection. Surgery may be indicated in complicated cases.

## PHARYNGITIS

Pharyngitis is an inflammation of the throat often caused by infection. Acute pharyngitis is responsible for 1% to 2% of physician visits in adults and 6% to 8% of pediatric visits, but it is generally self-limited.[38,39] Antibiotics are frequently prescribed because it can be difficult to clinically distinguish between viral and bacterial infection and the fear of untreated streptococcal illness.

**Table 72–4**

**Antibiotics$^a$ for the Treatment of Acute Bacterial Rhinosinusitis[28,30]**

| Drug | Adult Dose | Pediatric Dose$^b$ | Comments |
|------|-----------|---------------------|----------|
| Amoxicillin | 1.5–4 g/day in two to three doses | 45–90 mg/kg/day in two doses | Lacks coverage against β-lactamase producers |
| Amoxicillin-clavulanate | 1.5–4 g/day in two to three doses | 45–90 mg/kg/day in two doses | Broad coverage particularly with high doses; Augmentin XR (2 g every 12 hour) targeted toward PRSP |
| Cefdinir | 600 mg/day in one to two doses | 14 mg/kg/day in one to two doses | Preferred oral liquid cephalosporin owing to good palatability |
| Cefixime | 200 mg twice daily | 8 mg/kg/day in two doses | IDSA recommends use only in combination with clindamycin |
| Cefpodoxime proxetil | 200 mg twice daily | 10 mg/kg/day in two doses | IDSA recommends use only in combination with clindamycin |
| Cefuroxime axetil | 250–500 mg twice daily | 15–30 mg/kg/day in two doses | |
| Ceftriaxone | 1 g IM/IV every 24 hours | 50 mg/kg IM/IV every 24 hours | Experts recommend a 5-day treatment course; useful for patients who are vomiting and cannot tolerate oral therapy |
| Doxycycline | 100 mg twice daily | Avoid in children < 8 years | Can cause photosensitivity, GI problems, tooth staining in young children; many drug–drug interactions (antacids, iron, calcium) |
| Levofloxacin | 500–750 mg once daily (750 mg × 5 days) | 10 mg/kg/dose every 12–24 hours | Common fluoroquinolone side effects are nausea, vaginitis, diarrhea, dizziness; many drug–drug interactions (antacids, iron, calcium); tendon rupture, photosensitivity, QT prolongation possible; cost similar to amoxicillin/clavulanate |
| Moxifloxacin | 400 mg once daily | Not available | |
| Clindamycin | 300–450 mg three times daily | 30–40 mg/kg/day in three doses | No gram-negative coverage; use only in combination with cephalosporin |
| Linezolid | 600 mg twice daily | 10 mg/kg/dose every 8–12 hours | No gram-negative coverage; use only in combination as an alternative to clindamycin |

$^a$Refer to Table 72–2 for more information on antibiotics. Other FDA-approved antibiotics for ABRS not included in the Infectious Diseases Society of America or American Academy of Pediatrics guidelines: azithromycin, cefaclor, cefprozil, clarithromycin, ciprofloxacin, erythromycin, and trimethoprim-sulfamethoxazole.

$^b$Maximum dose not to exceed adult dose.

ABRS, acute bacterial rhinosinusitis; IDSA, Infectious Diseases Society of America; PRSP, penicillin-resistant *S. pneumoniae*; IM, intramuscular.

## EPIDEMIOLOGY AND ETIOLOGY

Pharyngitis is a common manifestation of viral URIs. *Streptococcus pyogenes* (Group A streptococci) is the most common bacterial cause, responsible for 20% to 30% of cases in children and 5% to 15% of adult infections.[40,41] It is most common in late winter and early spring and spreads easily through direct contact with contaminated secretions. Clusters of infection are common within families, classrooms, and other crowded settings.

## PATHOPHYSIOLOGY

Group A streptococci colonize the pharynx in up to 20% of children and is a risk factor for developing pharyngitis if there is disruption in mucosal integrity.[40] Symptoms of streptococcal pharyngitis usually are self-limited and resolve within a few days of onset *without* antibiotic treatment.[40] Historically, untreated or inappropriately treated infection caused acute rheumatic fever, heart valve damage, and other infectious complications. Delayed antibiotic therapy given up to 9 days after symptom onset can prevent these sequelae, so **KEY CONCEPT** *proper diagnosis is important to minimize unnecessary antibiotic use for viral pharyngitis and prevent complications of untreated streptococcal infection.*[39–41]

## TREATMENT

**KEY CONCEPT** *The goals of therapy for streptococcal pharyngitis are to shorten the disease course, reduce spread, and prevent complications, including peritonsillar or retropharyngeal abscesses, cervical lymphadenitis, and rheumatic fever.* Immune-mediated, nonsuppurative complications such as **glomerulonephritis** and reactive arthritis are not impacted by antibiotics.[38]

### Pharmacologic Therapy

Pain is a key feature of pharyngitis. Oral analgesics provide pain relief and can allow patients to maintain normal eating and drinking habits. **KEY CONCEPT** *Antibiotics should be used only in cases of laboratory-confirmed streptococcal pharyngitis with associated clinical symptoms* (**Figure 72–4**).[38,40,41] Effective therapy (**Table 72–5**) reduces the infectious period from approximately 10 days to 24 hours and shortens symptom duration by 1 to 2 days.[2,38,40] **KEY CONCEPT** *Penicillin is the drug of choice because of its narrow spectrum, documented safety and efficacy in nasopharyngeal streptococcal eradication, and low cost.*[40,41] Amoxicillin is an alternative agent, particularly for children because of its improved taste and its enhanced adherence with once-daily dosing.[40,41]

## Patient Encounter 2

A 45-year-old man presents to his primary care physician with purulent postnasal discharge, nasal congestion, headache, and fatigue. He reports that his symptoms began 6 days ago and have worsened over the past 2 days. He states that his "head hurts" when he bends forward and he noticed that his upper molars ache when he eats or brushes his teeth. He tried acetaminophen and phenylephrine but received no relief. He has sinus infections every few years. His last course of antibiotics was 8 months ago when he received penicillin for streptococcal pharyngitis. He has two daughters (9 years and 13 years of age).

**Immunizations:** Up-to-date; he has not received his influenza vaccine this season

**Allergies:** Grass and tree pollens; ragweed

**Meds:** Fexofenadine 60 mg orally twice daily during allergy season; intranasal fluticasone one spray each nostril twice daily; acetaminophen 500 mg orally as needed; phenylephrine 10 mg orally every 4 hours as needed

**PE:**

**Gen:** Tired-appearing, moderate distress, appears uncomfortable

**VS:** BP 132/74 mm Hg, P 88 beats/min, RR 14 breaths/min, T 38.2°C (100.8°F), Wt 95.5 kg (210 lb)

**HEENT:** Thick, purulent brown postnasal discharge; nasal mucosal edema; right maxillary facial pain and right upper molar hypersensitivity upon tapping; no oral lesions; erythematous pharynx with mild tonsillar hypertrophy

*What information is suggestive of acute bacterial rhinosinusitis (ABRS)?*

*What risk factors are present?*

*What other diagnostic studies, if any, should be performed?*

*What are the treatment goals for this patient?*

*Create a care plan for this patient that includes nonpharmacologic and pharmacologic therapies and a monitoring plan.*

## Patient Care Process for Acute Bacterial Rhinosinusitis

**Patient Assessment:**

- Based on patient history, review of systems, and physical examination, determine if the patient has ABRS and its severity.
- Perform a medical review and conduct a medication history (including prescription and nonprescription medications and natural products). Does the patient have any medication allergies or adverse reactions? Is the patient up-to-date on immunizations?

**Therapy Evaluation:**

- If the patient is receiving pharmacotherapy, assess efficacy, safety, and patient adherence.
- Determine if antibiotic therapy is indicated or if observation can be used.
- Determine whether the patient has prescription coverage and if the desired antibiotic is covered by their insurance.

**Care Plan Development:**

- Select analgesic therapy that will provide optimal pain relief and appropriate adjunctive therapies to relieve symptoms.
- If appropriate, select antibiotic therapy that is likely to be effective and safe (see Figure 72–3).
- Select an optimal antibiotic dose (see Table 72–4) and an appropriate duration of treatment based on patient age and severity of illness.
- Discuss potential adverse effects and how to manage them.
- Discuss importance of medication adherence to treat infection and clinical symptoms.

**Follow-up Evaluation:**

- Reevaluate patient if symptoms persist beyond 5 days or worsen at any time.
- If recurrent infections or chronic sinusitis develop, refer to a specialist.

---

Cephalosporins may be more effective than penicillin for relapse prevention and nasopharyngeal eradication, particularly in asymptomatic carriers.[41,42] Usual duration of therapy is 10 days, but 5-day courses of some cephalosporins are as effective for streptococcal eradication as 10 days of penicillin.[43]

Resistance plays a smaller role in pharyngitis treatment compared with other URIs. **KEY CONCEPT** *Penicillin resistance has not been documented in group A streptococci, but resistance and clinical failures occur more frequently with tetracyclines, trimethoprim-sulfamethoxazole, and to a lesser degree macrolides.* Patients with penicillin allergies should be treated with a first-generation cephalosporin (if non–type I allergy), a macrolide/azalide, or clindamycin.[40,41] Recurrent infections or treatment failures can be retreated with the same initial antibiotic or treated with amoxicillin-clavulanate, a first-generation cephalosporin, clindamycin, or penicillin G benzathine.[40,41]

## OUTCOME EVALUATION

Antibiotics relieve symptoms of streptococcal pharyngitis within 3 to 5 days, and patients can return to work or school if improved after the first 24 hours of therapy. Lack of improvement or worsening after 72 hours of therapy requires reevaluation. Follow-up throat cultures are not recommended unless symptoms persist or recur. Recurrent symptoms following an appropriate treatment course should prompt reevaluation for possible retreatment.

## COMMON COLD

The common cold is a viral URI associated with significant health care resource utilization, including physician office and emergency department visits and nearly universal use of cough and cold medication for treatment or prevention.[44,45] Clinicians

---

## Clinical Presentation and Diagnosis of Streptococcal Pharyngitis

Children between 5 and 15 years have the highest incidence of streptococcal pharyngitis.

**Signs and Symptoms of Streptococcal Pharyngitis[40,41]**

- Sudden sore throat with severe pain while swallowing
- Fever
- Headache, abdominal pain, nausea, or vomiting (especially children)
- Tonsillopharyngeal erythema with or without exudates
- Tender, anterior cervical lymphadenitis
- Swollen red uvula
- Halitosis
- Soft palate petechiae
- Scarlatiniform rash

- Absence of conjunctivitis, hoarseness, cough, rhinorrhea, discrete ulcerations, and diarrhea (suggestive of viral etiology)

**Diagnosis[38,40,41]**

- Rapid antigen detection test (RADT): 70% to 90% sensitivity; results available within minutes.
- Throat culture: "gold standard"; results available within 24 to 48 hours. Should be performed after all negative RADTs in children and adolescents, and adults with significant pediatric contact. Also recommended in outbreaks and to monitor for resistance.
- Tests should be performed *only* when there is clinical suspicion for streptococcal pharyngitis. Pharyngeal carriage occurs in up to 20% of healthy children.

---

must be aware of evidence regarding the use of cough and cold products in order to make appropriate recommendations for this commonly encountered condition.

## EPIDEMIOLOGY AND ETIOLOGY

Many viruses cause the common cold, including rhinoviruses (most common), coronaviruses, parainfluenza viruses, respiratory syncytial virus, and adenoviruses. Infection rates increase during the fall through spring seasons and are highest in the winter months. Adults experience 2 to 4 colds each year, whereas children have 6 to 10 colds per year.[46] Colds usually resolve over 10 to 14 days but can be complicated by bacterial superinfections, including AOM and ABRS. Factors associated with an increased incidence of colds are young age, contact with school-age children, crowded conditions and poorly ventilated areas, and cigarette smoking. Children are more likely than adults to transmit viruses because of poorer hand hygiene, closer casual contacts, and sharing of toys.[45] Viral antigenic drifts and host immune system evasion contribute to the persistence of URIs in the community.

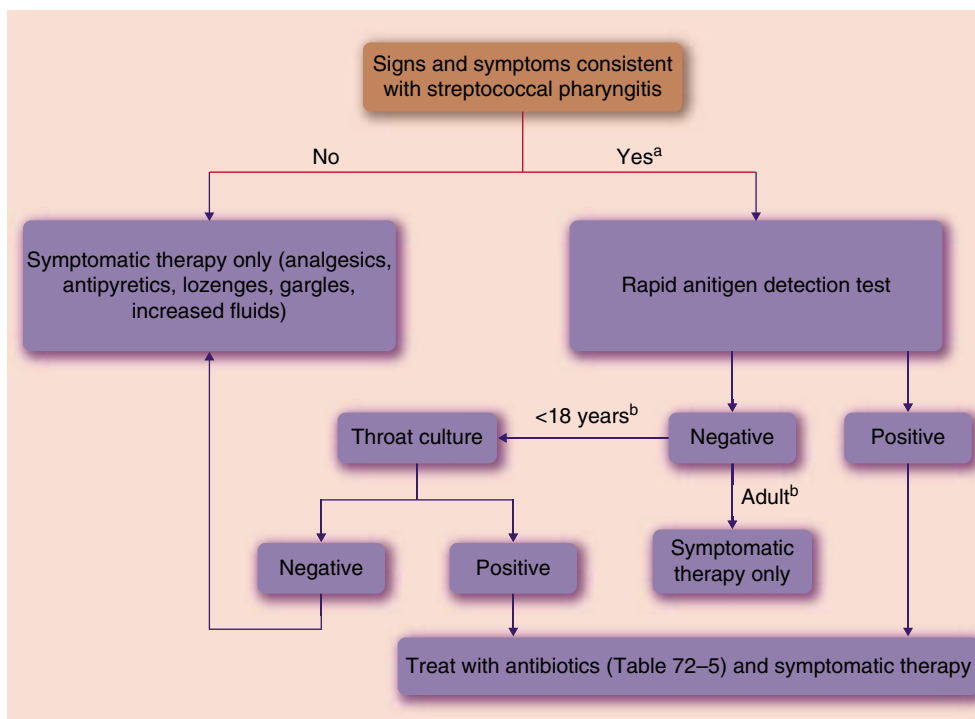

**FIGURE 72–4.** Treatment algorithm for management of pharyngitis in children and adults. [a]Rapid antigen detection tests (RADTs) are preferred if the test sensitivity exceeds 80%. [b]It is the clinician's discretion to perform a throat culture in adults who have a negative RADT.[40,41]

### Table 72–5

**Antibiotics$^a$ for the Treatment of Streptococcal Pharyngitis[40,41]**

| Drug | Adult Dose | Pediatric Dose | Duration | Comments |
|---|---|---|---|---|
| Penicillin V | 500 mg two to three times daily | 250 mg two to three times daily (if ≤ 27 kg), 500 mg two to three times daily (if > 27 kg) | 10 days | Drug of choice but increasing reports of treatment failures |
| Penicillin G benzathine | 1.2 million units | 600,000 units (if ≤ 27 kg); 1.2 million units (if > 27 kg) | 1 IM dose | Useful for patients with poor adherence or emesis; painful injection but pain can be reduced if warmed to room temperature prior to administration |
| Amoxicillin | 775 mg to 1 g once daily (Moxatag 775 mg is a time-released formulation given once daily for patients 12 years of age and older) | 50 mg/kg once daily; max 1 g | 10 days | Preferred drug for young children because of improved palatability and once daily dosing |
| Cephalexin | 500 mg twice daily | 25–50 mg/kg/day in two doses | 10 days | Recommended in non–type I penicillin allergy |
| Cefadroxil | 1 g once daily | 30 mg/kg once daily | 10 days | Recommended in non–type I penicillin allergy |
| Cefuroxime axetil | 250 mg twice daily | 20 mg/kg/day in two doses | 10 days | |
| Cefdinir | 300 mg twice daily or 600 mg once daily | 14 mg/kg/day in one to two doses | 5–10 days | Broad spectrum; expensive |
| Azithromycin | 500 mg once daily | 12 mg/kg once daily | 5 days | Recommended in immediate-type penicillin hypersensitivity; increasing resistance |
| Clindamycin | 300 mg 3 times daily | 20 mg/kg/day in three doses | 10 days | Recommended in immediate-type penicillin hypersensitivity; useful for recurrent infections |

$^a$Other FDA-approved agents include amoxicillin-clavulanate, cefixime, cefaclor, cefprozil, cefpodoxime, erythromycin, clarithromycin, and others.

IM, intramuscular.

## PATHOPHYSIOLOGY

Viruses enter the respiratory tract mucosa via inhalation of aerosols or infected droplets or direct contact with contaminated secretions. After cell entry, viral replication and shedding occur for several days to weeks. Symptoms arise from epithelial cell damage, inflammation, vasodilation, local tissue edema, increased mucous production, and impaired mucociliary clearance. Tracheobronchial inflammation and irritation induce cough via afferent nerve impulse transmission to the medulla.[45] Antibody production halts viral replication and inflammation as symptoms diminish.

## TREATMENT

The treatment goal is to minimize discomfort from symptoms to allow patients to function as normally as possible. Preventative measures are also important to limit the spread of infection.

Antibiotics are not effective, but they are often prescribed to patients with viral URIs and purulent secretions, which have contributed to increased resistance.[2] Treatment should focus on symptom relief.

Supportive measures include air humidification, intranasal saline drops or sprays with or without bulb suctioning, increased fluid intake, throat lozenges or saline gargles, and rest. Nasal strips may relieve congestion by lifting the nares and opening the anterior nasal passages. These nondrug measures are particularly important for children younger than 6 years and pregnant women, for whom medication safety is a significant concern. Although studies proving their benefits are lacking, these non-drug treatments are safe.

Nonprescription cough and cold preparations are used frequently despite a lack of evidence to support their safety and efficacy. Reports of serious adverse events and deaths led to efforts to eliminate use of these medications in young children.[47] Manufacturers have removed product labeling for all children younger than 4 years. Hundreds of products are available to manage cold symptoms. **KEY CONCEPT** *Choice of therapy is influenced by patient age, presence of comorbid conditions, and balance of effectiveness and safety.* Single-ingredient agents are preferred to target only symptoms that are present and to minimize toxicity that can result from confusion and lack of knowledge about active ingredients in multiple ingredient formulations. Cautious use of nonprescription products is warranted in certain patient populations: pregnant or lactating women, elderly, and patients with cardiovascular disease, diabetes, or glaucoma. Table 72–6 summarizes some of the available agents used for cold symptoms. Antipyretics and analgesics can be used for fever, pain, and discomfort. Local anesthetics (eg, benzocaine, dyclonine) relieve throat pain and are available in lozenges and sprays. Decongestants cause vasoconstriction that can improve congestion, but use of intranasal products should be limited to 3 days to avoid rebound congestion.[44,49]

## Patient Care Process for Streptococcal Pharyngitis

**Patient Assessment:**

- Based on patient history, review of systems, and physical examination, determine if streptococcal pharyngitis is likely. If so, perform a rapid antigen detection test and/or follow-up throat culture to confirm the diagnosis.
- Perform a medical review and conduct a medication history (including prescription and nonprescription medications and natural products). Does the patient have any medication allergies or adverse reactions?

**Therapy Evaluation:**

- If the patient is receiving pharmacotherapy, assess efficacy, safety, and patient adherence.
- Determine if antibiotic therapy is indicated (see Figure 72–4).
- Determine whether the patient has prescription coverage and if the desired antibiotic is covered by their insurance.

**Care Plan Development:**

- If appropriate, select analgesic therapy that will provide optimal pain relief.
- If appropriate, select antibiotic therapy that is likely to be effective and safe (Table 72–5). Select an optimal dose and appropriate duration of treatment.
- Discuss potential adverse effects and how to manage them.
- Discuss importance of medication adherence to treat infection, minimize spread, and reduce chances of recurrence.
- Discuss the need to avoid close contact with others for 24 hours to minimize spread.

**Follow-up Evaluation:**

- Reevaluate patient if symptoms persist after 72 hours or worsen.
- Reevaluate patient if infection recurs after completion of therapy.

## Clinical Presentation and Diagnosis of the Common Cold

Symptoms begin 24 to 72 hours after infectious contact. They peak at day 3 to 4, begin to wane by day 7, and resolve by day 10 to 14.

**Signs and Symptoms[44,45]**

- *Onset:* Malaise, fatigue, headache, pharyngitis, low-grade fever (can be higher in infants and children)
- *Secondary:* Nasal and/or postnasal drainage (often clear at onset, but can become thick and purulent); congestion; cough and/or throat clearing; sneezing; conjunctivitis; irritability; impaired smell or taste

**Complications**

- AOM, ABRS, chronic bronchitis, bronchiolitis (in infants and children less than 2 years), pneumonia, asthma exacerbation

**Diagnosis**

- *Clinical diagnosis:* Most common method; based on history, presence of symptoms, and physical examination
- *Radiographic studies:* Useful for assessing complications such as pneumonia
- *Laboratory studies:* Rapid viral antigen tests and nasopharyngeal cultures helpful for epidemiology and diagnosis in acutely ill young infants

## Patient Encounter 4

A 20-year-old woman presents to the university health center clinic with a "sinus infection." Three days ago, she developed a sore throat and a "runny nose." Today, her nasal discharge is thicker and yellow in color, she is congested, and she has a headache. She took acetaminophen 500 mg this morning, which provided some relief. She has exercise-induced asthma. She attends college and lives in an apartment with two friends who also have similar symptoms.

**Immunizations:** Up-to-date; needs influenza vaccine this season

**Meds:** Ortho Tri-Cyclen orally daily, albuterol inhaler as needed before exercise

**Allergies:** Cephalexin (rash)

**PE:**

**Gen:** No apparent distress

**VS:** BP 118/66 mm Hg, P 66 beats/min, RR 16 breaths/min, T 37.3°C (99.2°F), Wt 54.5 kg (120 lb)

**HEENT:** Conjunctiva clear; no photophobia; yellow nasal discharge with swollen nasal mucosa; erythematous pharynx; no facial pain upon palpation; tympanic membranes normal appearing

**Lungs:** Clear to auscultation; no crackles

*What signs and symptoms are suggestive of the common cold? Which are suggestive of ABRS?*

*What diagnostic studies should be performed?*

*Create a care plan that includes nonpharmacologic and pharmacologic therapies and a monitoring plan. Include preventative measures in your plan.*

## Patient Encounter 3

A 7-year-old girl presents to the pediatrician with a sore throat and fever of 39.1°C (102.4°F) for the past 12 hours. She has pain while swallowing, so she is unable to eat or drink as much as usual. She also complains of a "belly ache." She has no other symptoms and takes no medications. She is allergic to amoxicillin (rash). Her mother reports that two children in her daughter's class had "strep throat" recently. Physical examination reveals halitosis, pharyngeal and tonsillar erythema with exudates, and cervical lymphadenopathy.

*Does this child have streptococcal pharyngitis?*

*Is antibiotic therapy indicated? If so, what agent should be initiated and for how long?*

*What education should be provided to her mother regarding treatment?*

| Table 72–6 |
|---|

**Select Nonprescription Medications for the Common Cold for Patients 6 Years of Age and Older[44,47,48]**

| Class/Drug | Adult Dose[a] | Pediatric Dose[b] | Comments |
|---|---|---|---|
| **Analgesics/Antipyretics** | | | |
| Acetaminophen[c,d] | 325–1000 mg every 4–6 hours (max 4 g/day) | 10–15 mg/kg/dose every 4–6 hours (max 5 doses/day) | Use with caution in preexisting liver disease |
| Ibuprofen[e] | 200–400 mg every 6–8 hours (max 1200 mg/day) | 5–10 mg/kg/dose every 6–8 hours (max 4 doses/day) | Use with caution in cardiovascular disease; avoid use in elderly, renal impairment, and heart failure; avoid in third trimester of pregnancy |
| **Decongestants** | | | |
| *Intranasal:* | | | |
| Oxymetazoline 0.05%[d] | Two to three sprays every 12 hours (max 2 doses/ 24 hours) | One to two sprays every 12 hours (max 2 doses/24 hours) | Limit use of intranasal decongestants to 3–5 days to minimize risk of rebound congestion; use with caution in patients with cardiovascular disease |
| Phenylephrine 0.25%, 0.5%, 1% | Two to three sprays no more than every 4 hours | Two to three sprays no more than every 4 hours (0.25% only) | |
| *Systemic:* | | | |
| Pseudoephedrine | 60 mg every 4–6 hours (max 240 mg/day) | 30 mg every 4–6 hours (max 120 mg/day) | Avoid use in patients with cardiovascular disease; children and elderly have increased risk of adverse effects (cardiovascular or CNS stimulation); use with caution in patients with diabetes, hyperthyroidism, prostatic hypertrophy; avoid in first trimester of pregnancy |
| Phenylephrine | 10 mg every 4 hours (max 60 mg/day) | 5 mg every 4 hours (max 30 mg/day) | |
| **Cough Suppressants** | | | |
| Dextromethorphan[d] | 10–20 mg every 4 hours or 30 mg every 6–8 hours or 60 mg every 12 hours (max 120 mg/day) | 5–10 mg every 4 hours or 15 mg every 6–8 hours or 30 mg every 12 hours (max 60 mg/day) | Increased adverse effects in children and poor metabolizers (5%–10% of white patients); can cause dysphoria and serotonin syndrome; use caution in those taking psychotropic medications |
| **Expectorants** | | | |
| Guaifenesin | 200–400 mg every 4 hours or 600–1200 mg every 12 hours (max 2.4 g/day) | 100–200 mg every 4 hours (max 1.2 g/day) | May cause nausea and abdominal pain, particularly in higher doses |
| **Anticholinergics** | | | |
| Intranasal ipratropium 0.06%[d] | Two sprays three to four times/day | Two sprays three times/day | Used for rhinorrhea only; does not improve congestion, postnasal drip, or sneezing |

[a]Also for children older than 12 years.

[b]For children 6 to 12 years of age.

[c]Preferred antipyretic/analgesic for children; can be used in newborns.

[d]Safe to use in pregnancy.

[e]Can be used in children older than 6 months of age.

Antihistamines should be avoided: first-generation agents may dry secretions through their anticholinergic effects, but they impair mucociliary clearance of thick mucus, which can worsen congestion, and there is not a clear benefit for cough or cold symptoms when these agents are used alone.[44,49] Cough suppressant use is not supported by strong evidence showing benefit. They can cause significant neurologic adverse effects and have been linked to abuse by teens for their euphoric effects in high doses.[44–46,49] Guaifenesin, an expectorant, may reduce sputum thickness in adults, but it has been poorly studied in children.[49] High-dose vitamin C (greater than 200 mg/day) supplementation does not significantly impact cold severity or duration, but it may be useful for prevention in patients exposed to severe physical exercise or cold stress.[49] Echinacea has limited benefit for treatment in adults, and its use is discouraged for prevention and in all children because of adverse effects.[50] Zinc lozenges are not consistently effective, and concerns exist regarding the loss of smell with intranasal preparations, so they should be avoided.

## PREVENTION

Prevention of the common cold is best achieved by minimizing contact with infected people and secretions. Frequent hand-washing with soap and water or use of alcohol-based products is vital. Coughing and sneezing into the arm sleeve should be taught rather than using tissues or covering the mouth and nose with hands. Other methods that are advocated for preventing the spread include smoking cessation, maintenance of a healthy lifestyle through diet and exercise, and minimizing stress.

## Patient Care Process for Common Cold

**Patient Assessment:**

- Based on patient history, review of systems, and physical examination, determine if the presentation is consistent with the common cold.
- Perform a medical review and conduct a medication history (including prescription and nonprescription medications and natural products). Does the patient have any medication allergies or adverse reactions? Is the patient up-to-date on immunizations?

**Therapy Evaluation:**

- If the patient is receiving pharmacotherapy, assess efficacy, safety, and patient adherence.
- Determine if pharmacologic therapy is indicated or if nonpharmacologic measures alone can be employed.

**Care Plan Development:**

- Select nonpharmacologic and/or nonprescription therapies that will provide optimal relief of symptoms and that are safe for the patient.
- Discuss importance of medication adherence to provide symptom relief and minimize adverse effects.
- Discuss preventative measures for minimizing spread and future illnesses.

**Follow-up Evaluation:**

- Reevaluate patient if symptoms persist beyond 10 to 14 days or worsen at any time.

## OUTCOME EVALUATION

Most colds resolve within 7 to 10 days. Monitor patients for persistent symptoms lasting longer than 10 to 14 days, worsening symptoms, and complications such as wheezing, difficulty breathing, significant facial or ear pain, and high fevers. If complications are suspected, refer to a clinician for evaluation.

## Abbreviations Introduced in This Chapter

ABRS     Acute bacterial rhinosinusitis
AOM     Acute otitis media
OME     Otitis media with effusion
PRSP     Penicillin-resistant *S. pneumoniae*
RADT     Rapid antigen detection test
URI     Upper respiratory tract infection

# 73  Skin and Soft Tissue Infections

Jaime R. Hornecker

Jaime R. Hornecker

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Discuss characteristics of the skin that render it resistant to infection.
2. Describe the epidemiology, etiology, pathogenesis, clinical manifestations, diagnostic criteria, and complications associated with skin and soft tissue infections (SSTIs).
3. Identify the desired therapeutic outcomes for patients with SSTIs.
4. Recommend appropriate empirical and definitive antimicrobial regimens when given a diagnosis, patient history, physical examination, and laboratory findings.
5. Monitor chosen antimicrobial therapy for safety and efficacy.

## INTRODUCTION

Skin and soft tissue infections (SSTIs) are frequently encountered in both acute and ambulatory care settings. They can range in severity from mild, superficial, and self-limiting, to life-threatening deep tissue infections that require intensive care, surgical intervention, and IV broad-spectrum antibiotics. Gram-positive pathogens, primarily *Staphylococcus aureus* and *Streptococcus* species, are the most common causative bacteria.[1–4] Polymicrobial infections are more likely in complicated infections involving deeper layers of the skin, fascia, or muscle in persons with immune suppression, diabetes, and vascular insufficiency, and in postsurgical patients.[1,4]

The role of methicillin-resistant *S. aureus* (MRSA), particularly community-acquired methicillin-resistant *S. aureus* (CA-MRSA), in SSTI is of increasing importance. In many US cities, MRSA is the most frequently isolated pathogen from patients presenting to emergency departments with SSTI, and antimicrobial prescribing has largely shifted to empiric use of MRSA-active agents.[2,5] MRSA infections were historically associated with exposures to health care settings and more defined populations such as injection drug users or athletes; however, the prevalence of MRSA in the community and its rise in otherwise healthy individuals means that historical high-risk groups have little clinical relevance in most areas. In areas with high rates of CA-MRSA, and in those with recurrent infections or infections that persist despite appropriate antimicrobial therapy, empiric therapy including antibiotics active against this pathogen must be considered.[1,6] This chapter covers the epidemiology, pathogenesis, clinical manifestations, and pharmacologic management of the more common and severe bacterial SSTIs.

Intact skin generally is resistant to infection. In addition to providing a mechanical barrier, its relative dryness, slightly acidic pH, colonizing bacteria, frequent desquamation, and production of various antimicrobial defense chemicals, including sweat (which contains IgG and IgA), prevent invasion by various microorganisms.[7] Conditions that predispose a patient to SSTIs include: (a) high bacterial load (greater than $10^5$ microorganisms); (b) excessive skin moisture; (c) decreased skin perfusion; (d) availability of bacterial nutrients; and (e) damage to the corneal layer of the skin.[8]

## IMPETIGO

### EPIDEMIOLOGY AND ETIOLOGY

**KEY CONCEPT** *Impetigo is a common skin infection worldwide that can occur in any age group, but most frequently affects children between 2 and 5 years.*[9] β-Hemolytic streptococci and *S. aureus* are the most common causative pathogens.[4] Impetigo is a superficial infection and spreads easily, especially in settings of poor hygiene and crowding, and particularly during the summer months. The offending microorganisms colonize the skin surface and invade through abrasions, insect bites, or other small traumas. The scabby, crusty eruption of impetigo ensues. These lesions may occur anywhere on the body, but are most common on the face and extremities.[10]

### CLINICAL PRESENTATION AND DIAGNOSIS

Impetigo lesions are numerous, well localized, and **erythematous**. **KEY CONCEPT** *They begin as small, thin-walled blisters that can quickly evolve into ruptured lesions, with the dried discharge forming a honey-colored crust reminiscent of cornflakes.*[4] *S. aureus* and β-hemolytic Strep is most often implicated in impetigo.[4] The lesions of impetigo are rarely painful, but are **pruritic**. Scratching the lesions can spread the infection to other areas of the body. Scarring is rarely problematic, unless ulceration occurs, as in ecthyma.[4]

In order to avoid further spread and complications, antibiotic therapy is usually indicated. Sequelae of impetigo are uncommon, but rarely, glomerulonephritis secondary to group A

*Streptococcus* (GAS) may occur.[4] Development of impetigo into more serious infections such as cellulitis or sepsis is another rare, but serious consequence.

## TREATMENT

The primary goals of therapy for impetigo include preventing the spread of infection within the patient and to others, resolution of infection, and preventing recurrence. Secondarily, relief of symptoms associated with impetigo, such as itching, and improving cosmetic appearance are also important. Prevention of the rare, but serious complications of impetigo is an alternative goal.[11]

### Nonpharmacologic Treatment

Because impetigo is rarely painful, there is often a delay in seeking medical attention. Lesions may improve with time and increased hygiene, and soaking and cleansing the lesions with mild soap and water and the use of skin emollients to dry skin areas may reduce spread.[11]

### Pharmacologic Treatment

Antibiotic therapy is recommended to achieve the desired outcomes of preventing the spread of infection and complications. Although GAS historically has been the primary causative organism and penicillin is recommended when cultures yield streptococci alone, KEY CONCEPT *the incidence of* S. aureus *impetigo is common, and oral penicillinase-stable penicillins* (such as dicloxacillin) *or first-generation cephalosporins* (such as cephalexin) *are preferred.* Clindamycin, sulfamethoxazole-trimethoprim, or doxycycline is preferred when MRSA is suspected, or as alternative choices when penicillin allergy is a concern; however, tetracyclines should be avoided in children younger than 8 years. KEY CONCEPT *Topical mupirocin or retapamulin twice daily for 5 days may be used alone in mild cases with few lesions or in individual outbreaks.*[4,6]

## FOLLICULITIS, FURUNCLES, AND CARBUNCLES

See Table 73-1 for summary.

## CELLULITIS AND ERYSIPELAS

### EPIDEMIOLOGY AND ETIOLOGY

Cellulitis and erysipelas are bacterial infections involving the skin. KEY CONCEPT *Cellulitis is an infection of the dermis and subcutaneous tissue, whereas erysipelas is a more superficial infection of the upper dermis and superficial lymphatics. Although both can occur on any part of the body, many infections involve the leg.*[13,14] These infections develop after a break in skin integrity, resulting from trauma, surgery, ulceration, burns, tinea infection, or other skin disorder. However, they may occur after an inapparent break in the skin, and the skin may appear previously intact. In rare cases, cellulitis develops from bloodborne or contiguous spread of pathogens.[4,14]

Etiologic microorganisms vary according to the area involved, host factors, and exposures. KEY CONCEPT *The predominant pathogens associated with cellulitis are streptococci, mainly group A, and less frequently S. aureus, including methicillin-resistant strains. Persons who are immunocompromised have diabetes or vascular insufficiency, or use injection drugs, are at risk for polymicrobial cellulitis.*[4]

## CLINICAL PRESENTATION AND DIAGNOSIS

The manifestations of and diagnostic criteria for erysipelas and cellulitis are presented in Table 73–2.

With early diagnosis and appropriate therapy, the prognoses for cellulitis and erysipelas are excellent. Severe or repeated episodes can cause lymphedema. Rare complications include the spread of infection to deeper skin and soft tissue layers, bacteremia, and sepsis.[4] Although rates of bacteremia were traditionally low, prevalence may be increasing and associated with increased length of hospitalization and costs, and higher readmission rates.[15]

Recurrent cellulitis can be problematic. Annual recurrence rates, especially for cellulitis of the leg, can be as high as 20%. Vascular and lymphatic insufficiencies increase the risk of recurrences; obesity, tobacco use, history of cancer, and homelessness also increase risk.[4]

## TREATMENT

The goals of therapy for cellulitis and erysipelas are rapid and successful eradication of the infection and prevention of related complications.

### Nonpharmacologic Treatment

Nonpharmacologic treatment includes elevating the involved limb to decrease swelling. Sterile saline dressings may be placed on any open lesions to cleanse them of purulent materials. Surgical débridement may be indicated for severe infection and to rule out any necrotizing process. Drainage of abscesses is imperative to achieving clinical cure and may be the only treatment necessary if the abscess is small (less than 5 cm) with limited cellulitis.[4,14]

### Pharmacologic Treatment

Most patients with erysipelas or cellulitis are effectively treated with outpatient therapy. Hospitalization and treatment with IV antibiotics is recommended in the presence of systemic inflammatory response syndrome (SIRS) (eg, temperature greater than 38°C or less than 36°C, tachypnea greater than 24 breaths/min, tachycardia greater than 90 beats/min, or white blood cell count greater than $12 \times 10^3/mm^3$ [$12 \times 10^9/L$] or less than 400/mm³ [$0.4 \times 10^9/L$]), altered mental status, or hemodynamic instability. Outpatient treatment should also be avoided when deep or necrotizing infection is present, in severe immunocompromise, or when outpatient treatment is failing or adherence to therapy is poor.[4]

Antibiotic choices for typical cases of cellulitis should have activity against streptococci, and include penicillin, amoxicillin, amoxicillin-clavulanate, dicloxacillin, cephalexin, or clindamycin. In uncomplicated cases, a 5-day course is as effective as a 10-day course.[4] Monotherapy with a β-lactam is appropriate in uncomplicated cases[16]; however, when purulent drainage, abscess, or ulcer is present, or in cases of penetrating trauma, particularly IV drug use, coverage for MRSA should be initiated.

Vancomycin continues to be the drug of choice for severe cellulitis due to MRSA because of its efficacy, safety, and low cost. Daptomycin, linezolid, telavancin, or ceftaroline are also acceptable and should be considered over vancomycin when the isolated organism has a minimum inhibitory concentration (MIC) of greater than 2 mcg/mL (greater than 2 mg/L) (eg, vancomycin-intermediate *S. aureus* [VISA] or vancomycin-resistant *S. aureus* [VRSA]).[6] Tigecycline is an alternative; however, due to its broad spectrum of activity, it is best reserved for patients with intolerances to the aforementioned drugs or in those with polymicrobial infections. Several new agents for SSTI, including tedizolid,

**Table 73–1**

**Folliculitis, Furuncles, and Carbuncles**

| | Folliculitis | Furuncles | Carbuncles |
|---|---|---|---|
| Epidemiology/ etiology | KEY CONCEPT *Folliculitis is a superficial inflammatory reaction involving the hair follicle. The most familiar form of folliculitis is acne.* It can be infectious, caused by microorganisms such as *S. aureus, Pseudomonas, and Candida.* Folliculitis can also be chemically induced. | Also known as boils, furuncles might be described as a deep form of folliculitis. A furuncle is a bacterial infection that has spread into the subcutaneous skin layers but still only involves individual follicles. Furuncles occur primarily in young men. Diabetes and obesity are other predisposing factors. Staphylococci are the most common cause. | Carbuncles share all the characteristics of furuncles. However, a carbuncle is larger and involves several adjacent follicles and may extend into the subcutaneous fat. Carbuncles are more likely to occur in patients with diabetes and tend to form on the back of the neck. |
| Presentation and diagnosis | Folliculitis presents as small, pruritic, erythematous papules. Location of the lesions and a good patient history are often all that are required in the diagnosis of folliculitis. Although Gram stain and culture of the papules may be considered to help determine the causative agent, they are not generally required as folliculitis typically resolves spontaneously. | Furuncles most commonly develop on the face, neck, axilla, and buttock. A furuncle typically starts as a small, red, tender nodule. Within a few days, the nodule becomes painful and pustular. Typically, a furuncle will spontaneously discharge pus, heal, and leave a small scar. | Carbuncles are similar to furuncles; only they are larger and exquisitely painful. |
| Desired outcomes | The goals of therapy for folliculitis, furuncles, and carbuncles are resolution of infection with no or minimal scarring. A secondary goal of therapy for larger furuncles and all carbuncles is to minimize the risk of endocarditis or osteomyelitis by reducing bloodstream invasion. | | |
| Nonpharmacologic treatment | KEY CONCEPT *Warm compresses are generally sufficient.* | *Moist heat is indicated to facilitate drainage. Large furuncles require incision and drainage.* | *Incision and drainage are indicated.* |
| Pharmacologic treatment | KEY CONCEPT *Often resolves spontaneously. A topical antibiotic or antifungal may be used to control the spread of infection but generally is unnecessary.* For staphylococcal or streptococcal folliculitis, antibiotic ointments such as mupirocin might be administered. Antifungal shampoo can be used for dermatophytes. | *Carbuncles and furuncles that are purulent with signs of infection (ie, fever) should be treated systemically with an antibiotic that will cover S. aureus, such as dicloxacillin or cephalexin. Trimethoprim-sulfamethoxazole or doxycycline is preferred if CA-MRSA is suspected or if the patient has a severe allergy to penicillin.* Treatment should continue until acute inflammation has resolved, usually a 5- to 10-day course. Immunocompromised patients and severe infections or abscesses in patients who fail incision and drainage plus oral antibiotics should be treated empirically with vancomycin, daptomycin, linezolid, televancin, or ceftaroline. Prevention for recurrent episodes may be warranted, including adequate skin hygiene with the use of soap and water, and handwashing after contact with lesions. Proper care of clothing and dressings is also recommended to prevent autoinoculation. | |

Data from Refs. 4, 10, and 12.

## Patient Encounter 1, Part 1: Cellulitis

A 57-year-old man presents to the ambulatory care clinic with a 3-day history of progressively worsening pain and swelling of his left lower extremity. Upon examination, you notice that in addition to the patient's complaints, the area is visibly erythematous. Poorly defined areas of redness and streaking extend from just below the knee up toward his hip. A small, nonpurulent scabbed area is present over the kneecap. He reports running a low-grade fever and some feelings of fatigue, but otherwise feels fine. When questioned, he indicates that he recently fell from a ladder while working on the gutters of his home and landed primarily on his left side. His vitals at the clinic reveal a temperature of 38.8°C, pulse 90 beats/min, blood pressure 128/89 mm Hg, and respiratory rate 18 breaths/min. The physician diagnoses the patient with cellulitis.

*What subjective and objective clinical manifestations are suggestive of cellulitis?*

*What additional information do you need before developing a therapeutic plan for this patient?*

## Table 73–2

### Presentation of Erysipelas and Cellulitis

**Symptoms**

- The infected area is described as painful or tender. In the case of erysipelas, the patient may complain of "burning pain" at the lesion site. CA-MRSA infections often start as a localized skin lesion and may be described by the patient as looking like a "spider bite."

**Signs**

- Both erysipelas and cellulitis are manifested by rapidly spreading areas of redness, edema, warmth, and tenderness. Lymphangitis and regional lymphadenopathy may be observed.
- The affected area may have an "orange peel" appearance due to superficial skin edema causing skin dimpling around the hair follicles.
- Low-grade fever, flu-like illness, and other systemic symptoms may occur prior to development of the lesion.

**Laboratory Tests**

- Leukocytosis may be present.
- Cultures and sensitivities:
  - Blood cultures should be obtained for complicated or severe cases, although their yield is often low as bacteremia is an infrequent, but growing, occurrence; facial cellulitis may increase risk. Cultures aspirated from the lesion have a low organism isolation rate, but also may be considered.
  - Abscess drainage and débrided tissue, if obtainable, should be cultured and will frequently yield the causative organism(s).

**Imaging Studies**

- Imaging studies may identify abscess formation, gas in the soft tissues, or osteomyelitis.

dalbavancin and oritavancin, may have advantages over traditional therapy in terms of duration of activity and administration.[17,18] For less severe, uncomplicated infections, many CA-MRSA strains can be treated with clindamycin (isolates resistant to erythromycin should be evaluated with a **D-test**), doxycycline, or trimethoprim-sulfamethoxazole.[4,6] Trimethoprim-sulfamethoxazole and doxycycline should be empirically combined with a β-lactam if GAS is also a suspected causative organism, since the activity of these agents against β-hemolytic streptococci is unknown.[4]

**KEY CONCEPT** *In addition to coverage for staphylococcal and streptococcal cellulitis, patients with severe infections should receive treatment for gram-negative bacilli such as Escherichia coli and Pseudomonas aeruginosa, with or without* **anaerobic** *coverage. Empirical broad-spectrum antimicrobial coverage, including coverage for resistant organisms such as health care-associated MRSA (HA-MRSA) and P. aeruginosa, is appropriate for severe cellulitis and/or severe systemic illness.* Vancomycin plus piperacillin/tazobactam is recommended in these cases. Therapy continuation is recommended in polymicrobial infections, whereas more defined therapy is recommended when a causative pathogen is isolated.[4]

**Table 73–3** lists some recommended antibiotic regimens for the treatment of cellulitis. Because antimicrobial susceptibilities vary considerably between geographic locations, clinicians should select empirical treatment based on the antibiograms at their respective institutions. To decrease the spread of resistance, antibiotic therapy should be narrowed based on culture and sensitivity results whenever possible. The duration of therapy for uncomplicated cellulitis typically ranges from 5 to 10 days. For complicated cellulitis, therapy with IV antibiotics is generally initiated, and a switch to oral therapy can be made once the patient is afebrile and skin findings begin to resolve. Typically, this is done after 3 to 5 days. The complete duration of therapy can range from 10 to 14 days and longer in cases in which abscess, tissue necrosis, underlying skin wounds, or delayed response to therapy are involved.[4,14]

## Patient Encounter 1, Part 2: Cellulitis: Medical History, Physical Examination, and Diagnostic Tests

**PMH:** Hypertension, dyslipidemia, GERD.

**FH:** Father (age 79) and mother (age 77) are both alive. Father has hypertension and CAD; mother is otherwise healthy. One brother, age 54, also has hypertension.

**SH:** Denies alcohol or illicit drug use. Married, with two sons who attend the local community college. Works full-time in construction.

**Meds:** Lisinopril 20 mg daily; simvastatin 20 mg daily; omeprazole 20 mg daily as needed.

**Allergies:** No known drug allergies.

**ROS:** (+) pain, edema, and erythema in the left lower extremity; (-) headache, chest pain, shortness of breath, cough, nausea, vomiting, diarrhea, and weight loss.

**PE:**

**Gen:** Patient is in no acute distress. Wt 88.2 kg (194 lb); Ht 5'11" (180 cm).

**Chest:** Lungs bilaterally clear to auscultation.

**CV:** Regular rate, rhythm. No murmurs/rubs/gallops.

**Ext:** Left lower extremity with erythema and edema from the knee to just below the hip. Warm to the touch. RLE within normal limits.

**Labs:** WBC $15.8 \times 10^3/mm^3$ ($15.8 \times 10^9/L$), serum creatinine 0.8 mg/dL (71 μmol/L).

*What are the most likely causative organisms in this case of cellulitis?*

*What are the goals of therapy for this patient?*

*What nonpharmacologic interventions would you recommend for him?*

*What antimicrobial therapy would you recommend? Include drug, dosage, route, interval, and duration of therapy.*

*How would you monitor your selected regimen for safety and efficacy?*

*How would your initial choice of an antimicrobial agent change if this patient was at high risk for MRSA?*

| Table 73–3 |
| --- |

**Empirical Antimicrobial Therapy for Cellulitis**

| Host Factors | Probable Etiologic Bacteria | Mild Infection or Step-Down Therapy[a] (Oral Antibiotic Therapy) | Moderate–Severe Infection[a] (IV Antibiotic Therapy) |
| --- | --- | --- | --- |
| Previously healthy | MSSA<br>GAS<br>CA-MRSA | Dicloxacillin 500 mg every 6 hours<br>Cephalexin 500 mg every 6 hours<br>Clindamycin 300–600 mg every 6–8 hours<br>CA-MRSA suspected or allergy to PCNs: Clindamycin[b] 300–600 mg every 6–8 hours<br>Trimethoprim-sulfamethoxazole DS[c] one to two tablets every 12 hours<br>Doxycycline[c] 100 mg every 12 hours | Nafcillin 1–2 g every 4 hours<br>Cefazolin 1–2 g every 8 hours<br>Clindamycin 600–900 mg every 8 hours<br>CA-MRSA suspected or allergy to PCNs:<br>Vancomycin 15–20 mg/kg every 8–12 hours (individualize dose to achieve a trough of 15–20 mcg/mL [15–20 mg/L; 10.4–13.8 μmol/L])<br>Linezolid 600 mg every 12 hours<br>Daptomycin 4 mg/kg every 24 hours<br>Telavancin 10 mg/kg every 24 hours<br>Ceftaroline[f] 600 mg every 12 hours |
| Immunocompromise, diabetes mellitus, vascular insufficiency, pressure ulcer infection, or other polymicrobial infection suspected | MSSA<br>HA-MRSA<br>CA-MRSA<br>Enterobacteriaceae<br>*P. aeruginosa*<br>Anaerobes | Amoxicillin-clavulanate[d] 875 mg every 12 hours<br>Levofloxacin[e] 750 mg every 24 hours + clindamycin 300–600 mg every 6 hours<br>Moxifloxacin[d] 400 mg every 24 hours | Vancomycin, daptomycin, linezolid, or telavancin[g]<br>In combination with one of the following choices:<br>Piperacillin-tazobactam[e] 3.375 g every 6 hours<br>Ampicillin-sulbactam 3 g every 6 hours<br>Imipenem-cilastatin[e] 500 mg every 6 hours<br>Ertapenem 1 g every 24 hours<br>Meropenem 500 mg every 8 hours<br>Cefepime[e] 2 g every 12 hours ± metronidazole 500 mg every 8 hours<br>Ceftazidime[e] 2 g every 8 hours + clindamycin 600–900 mg every 8 hours<br>OR<br>Ceftaroline 600 mg every 12 hours + clindamycin 600–900 mg every 8 hours or metronidazole 500 mg every 8 hours<br>OR<br>Tigecycline 100 mg load, then 50 mg every 12 hours |

[a]Doses given are for adults with normal renal function. IV therapy can be switched to oral therapy (as for mild infection) when the patient is afebrile and signs of infection are resolving.

[b]CA-MRSA isolates resistant to erythromycin should be evaluated for inducible clindamycin resistance via a D-test.

[c]Limited clinical data exist for the treatment of MRSA infections. Poor activity against GAS; consider using in combination with clindamycin or cephalexin if empirical coverage for GAS is desired.

[d]If CA-MRSA suspected, clindamycin, trimethoprim-sulfamethoxazole, or doxycycline must be added to this regimen.

[e]*P. aeruginosa* generally is susceptible to this agent.

[f]Use caution in patients with known hypersensitivity to β-lactam antibiotics.

[g]MRSA coverage indicated for patients with severe cellulitis or systemic illness, who have risk factors for HA-MRSA or CA-MRSA infection, or reside in areas with high CA-MRSA prevalence. Otherwise, the broad-spectrum regimens listed below, without MRSA coverage, are appropriate.

Data from Refs. 4, 10 and 14.

Recurrent cellulitis can be problematic, especially in the lower extremities. Reducing risk factors may help with preventing recurrences.[4] Low-dose antibiotic prophylaxis with penicillin may reduce recurrences, but the benefit subsides when therapy is discontinued.[4,13]

## NECROTIZING FASCIITIS

### EPIDEMIOLOGY AND ETIOLOGY

Necrotizing fasciitis (NF) is an uncommon, rapidly progressive, life-threatening infection that causes necrosis of the subcutaneous tissue and fascia. When due to GAS infection, its associated mortality rate approaches 25%.[19] NF can affect any age group.

**Patient Encounter 1, Part 3: Cellulitis: Clinical Course**

Three days later, the patient returns to the clinic with moderate improvement of his cellulitis, but with a new presentation of a maculopapular skin rash. It is presumed that he has developed an allergy to penicillin.

*What would you suggest for modification of his antimicrobial regimen?*

*How would you monitor his new regimen for safety and efficacy?*

*How would your choice of an agent change if this patient's cellulitis was severe enough to warrant hospitalization?*

Although the risk of NF is higher in injection drug users and in patients with diabetes or vascular insufficiency, healthy hosts can become infected as well.[4]

NF typically erupts after an initial trauma, which can range from a small abrasion to a deep penetrating wound. The infection begins in the fascia, where bacteria replicate and release toxins that facilitate their spread.[4]

NF may be monomicrobial, most often involving *S. pyogenes, S. aureus, Vibrio vulnificus, Aeromonas hydrophilia*, and anaerobic streptococci (*Peptostreptococcus*). Polymicrobial NF develops in the following clinical settings: after surgery or deep penetrating wounds involving the bowel; from decubitous ulcer, perianal, or vulvovaginal infection; or from the injection site in an IV drug user.[4]

## CLINICAL PRESENTATION AND DIAGNOSIS

Patient outcomes rely on the clinician's ability to recognize NF early in the course of disease. This is often difficult because early disease tends to be indistinguishable from cellulitis. The clinical presentation of NF is presented in Table 73–4.

NF is perhaps the most devastating SSTI. Left untreated, it can invade the muscles and circulation, resulting in myonecrosis and septic shock, respectively. Half of the cases caused by GAS are accompanied by GAS toxic shock–like syndrome. The syndrome is endotoxin mediated, manifested by hypotension and multiorgan dysfunction, and highly lethal.[20] Amputation is common in patients with extremity infections. Once the patient recovers from acute NF, he or she often requires skin and/or

---

**Table 73–4**

**Presentation of Necrotizing Fasciitis**

**Symptoms**
- Early: Severe pain that is disproportionate to clinical signs and extends beyond the margins of the infected area.
- Late: Area may become numb secondary to muscle and nerve involvement.

**Signs**
- Early: Skin is erythematous, edematous, and warm; the clinical presentation is similar to that of cellulitis.
- Intermediate (within 24–48 hours): Blisters and bullae indicate severe skin and tissue ischemia.
- Late: The skin becomes violaceous and progressively gangrenous, and subcutaneous tissues have wooden-hard induration; hemorrhagic bullae may be present. Systemic signs may include fever, tachycardia, hypotension, and shock.

**Laboratory Tests**
- White blood count, serum creatinine, and C-reactive protein may be elevated.
- Deep tissue specimens obtained during surgical irrigation and débridement should be sent for Gram stain, culture, and sensitivity.

**Imaging Studies**
- MRI and CT scans may reveal fluid and gas along fascial planes.
- Typically, imaging studies are avoided when making a diagnosis because they may delay surgical intervention and increase mortality.

NF, Necrotizing fasciitis.

Data from Refs. 4 and 20.

---

muscle grafting and consequent physical rehabilitation depending on the amount and types of tissues removed during surgical intervention and the duration of hospital stay.[21]

## TREATMENT

The goals of therapy for NF include eradication of infection and reduction of related morbidity and mortality.

### Nonpharmacologic Treatment

KEY CONCEPT *After resuscitation and hemodynamic stabilization, prompt surgical intervention is key in the treatment of NF. Delayed operative débridement increases mortality, and most patients should return to the operating room frequently until debridement is no longer indicated.*[4,22]

### Pharmacologic Treatment

As an adjunct to surgery, high-dose, broad-spectrum IV antibiotic therapy should be initiated immediately in patients with NF until the patient has improved clinically and is afebrile for 48 to 72 hours, and no further need for debridement exists. Piperacillin-tazobactam, a carbapenem, or ceftriaxone or a fluoroquinolone plus metronidazole is appropriate for empiric therapy. These agents should be used in combination with vancomycin, daptomycin, or linezolid until MRSA infection is ruled out.[4] The protein synthesis inhibitors clindamycin or linezolid are often utilized to decrease bacterial toxin production, thereby limiting tissue damage. This is particularly beneficial in streptococcal or clostridial infection.[20]

IV immunoglobulin (IVIG) dosed at 2 g/kg may also be a useful adjunctive treatment in patients with GAS NF who present with shock. Anecdotal evidence and data from small studies strongly support its use in improving 30-day survival and reducing mortality, although additional evidence is needed for a definitive recommendation.[4]

## DIABETIC FOOT INFECTIONS

### EPIDEMIOLOGY AND ETIOLOGY

Foot ulcers and related infections are among the most common, severe, and costly complications of diabetes mellitus. For the approximately 25 million patients with diabetes in the United States, the lifetime risk of developing at least one foot ulcer is estimated at 25%.[22] In addition to significant morbidity, the health care costs associated with treating infected foot ulcers are enormous.

Infected diabetic foot ulcers typically contain a multitude of microorganisms. KEY CONCEPT *Aerobic gram-positive cocci, such as* S. aureus *and β-hemolytic streptococci, are the predominant pathogens in acutely infected diabetic foot ulcers. However, severe, or more extensive chronically infected wounds are subject to polymicrobial infection.* The clinician should suspect the involvement of gram-negative (such as *P. aeruginosa*) and possibly low-virulence pathogens (including enterococci and *S. epidermidis*) in polymicrobial infections. Foul-smelling, necrotic, or gangrenous wounds are also commonly infected with anaerobic bacteria. Patients recently hospitalized or treated with broad-spectrum antibiotics, or those with a previous history of MRSA infection are at risk for MRSA as a causative agent.[23]

## Patient Encounter 2, Part 1: Diabetic Foot Infection

A 66-year-old man with type 2 diabetes mellitus presents to the emergency department with complaints of soreness and swelling of his right foot, accompanied by difficulty walking. Upon examination, you see a purulent lesion on the plantar aspect of his right great toe approximately 3 cm (1.2 in) in diameter. His foot is erythematous, warm, and foul-smelling, and cellulitis and lymphangitic streaking extend beyond his ankle. The patient indicates that his doctor told him at his last visit 8 months ago that his feet had some areas of redness that should be watched, especially with his history of a prior amputation, but because of ongoing chronic back pain and diabetic neuropathy, the patient admits to poor foot hygiene at home. The patient is afebrile, and other vital signs are within normal limits.

*What signs and symptoms present in this patient are indicative of a diabetic foot infection?*

*Based on presentation, classify this patient's diabetic foot infection using the PEDIS grading scale.*

*What additional information do you need before developing a therapeutic plan for this patient?*

## PATHOPHYSIOLOGY

**KEY CONCEPT** *The pathogenesis of diabetic foot infection stems from two key factors:* peripheral *neuropathy and ischemia from peripheral vascular disease.*[22] Neuropathy, the most prominent risk factor for diabetic foot ulcers, develops when continuously high blood glucose levels damage motor, autonomic, and sensory nerves. Damage to motor neurons that supply the small intrinsic muscles of the foot causes deformation, resulting in altered muscular balance, abnormal areas of pressure on tissues and bone, and repetitive injuries. Damage to autonomic neurons results in the shunting of blood through direct arteriole-venous communications, thereby decreasing capillary flow. The secretion of sweat and oil is also diminished, producing dry, cracked skin that is more prone to infection. Finally, damage to sensory neurons produces a loss of protective sensation so that the patient becomes unaware of injury or ulceration.[22]

Dysfunction of the endothelial cells and abnormalities of the smooth muscles of the peripheral vessels is also the result of high blood glucose concentrations. Vasoconstriction can occur due to decreased levels of endothelium-derived vasodilators, as well as in the presence of other risk factors, including hypertension, dyslipidemia, and smoking. Together, ischemia and skin breakdown can occur as a cumulative result.[22]

Finally, persons with diabetes have altered immune function that predisposes them to infection. Leukocyte function, and cell-mediated and humoral immunity are compromised in poorly controlled disease.[23] Achieving and maintaining controlled blood glucose levels should be a component of the prevention and management of diabetic foot infections.

## CLINICAL PRESENTATION AND DIAGNOSIS

Not all diabetic foot ulcers are infected. However, infection is often difficult to detect when perfusion and the inflammatory response are limited in the patient with diabetes. The common signs and symptoms (ie, pain, erythema, and edema) of infection

## Patient Encounter 2, Part 2: Diabetic Foot Infection: Medical History, Physical Examination, and Diagnostic Tests

**PMH:** Type 2 diabetes mellitus for 21 years, hypertension, hypertriglyceridemia, peripheral neuropathy, and chronic back pain. Left second toe amputation secondary to diabetic foot infection.

**FH:** Father died of an MI at age 69; mother (age 87) is living with Alzheimer dementia, type 2 diabetes mellitus. One sister alive with type 2 diabetes mellitus.

**SH:** Married, three grown children. Retired truck driver. Denies alcohol and tobacco use.

**Meds:** Lantus 35 units at bedtime; Humalog 12 units with meals; losartan 100 mg daily; hydrochlorothiazide 25 mg daily; gemfibrozil 600 mg twice daily; gabapentin 600 mg three times daily; hydrocodone/acetaminophen 5/500 mg every 6 hours as needed; aspirin 81 mg daily.

**Allergies:** Sulfa (rash), lisinopril (cough).

**ROS:** (+) right foot findings per HPI; (–) headache, chest pain, shortness of breath, cough, nausea, vomiting, diarrhea, and weight loss.

**PE:**

**Gen:** Patient is in no acute distress. Wt 107.7 kg (237 lb); Ht 5′9″ (175 cm).

**Chest:** CTAB.

**CV:** RRR. No murmurs/rubs/gallops.

**Ext:** 3-cm purulent, erythematous lesion present on the plantar aspect of the right great toe. 1+ edema in the right foot; diminished sensation bilaterally. Lymphangitic streaking present; wound probe 1.5 cm deep.

**Labs:** Most recent laboratory test results were drawn at last visit 8 months ago: BUN 14 mg/dL (5.0 mmol/L), SCr 1.2 mg/dL (106 μmol/L), Glu 154 mg/dL (8.5 mmol/L), A1C 8.8% (0.088; 73 mmol/mol hemoglobin).

The patient is diagnosed with a diabetic foot infection and is admitted to the local hospital.

*Explain the role of neuropathy, ischemia, and immunopathy in the development of this patient's diabetic foot infection.*

*What are the best preventative strategies for diabetic foot infections and complications such as lower extremity amputation?*

*Antimicrobial therapy for this patient's infection should provide coverage for which microorganisms?*

*What antimicrobial therapy would you recommend? Include drug, dosage, route, interval, and duration of therapy.*

*How would you monitor your selected regimen for safety and efficacy?*

**Table 73–5**

**Clinical Classification of a Diabetic Foot Infection**

| Infection Severity | PEDIS Grade | Clinical Manifestations of Infection |
|---|---|---|
| Uninfected | 1 | Wound lacking purulence or any manifestations of inflammation |
| Mild | 2 | Presence of at least two manifestations of inflammation (purulence or erythema, pain, tenderness, warmth, or induration), but any cellulitis/erythema extends no more than 2 cm around the ulcer, and infection is limited to the skin or superficial subcutaneous tissues; no other local complications or systemic illness |
| Moderate | 3 | Infection (as above) in a patient who is systemically well and metabolically stable but who has at least one of the following characteristics: cellulitis extending > 2 cm, lymphangitic streaking, spread beneath the superficial fascia, deep tissue abscess, gangrene, and involvement of muscle, tendon, joint, or bone |
| Severe | 4 | Infection in a patient with systemic toxicity or metabolic instability (eg, fever, chills, tachycardia, hypotension, confusion, vomiting, leukocytosis, acidosis, severe hyperglycemia, or azotemia) |

From Lipsky BA, Berendt AR, Cornia PB, et al., 2012 Infectious Diseases Society of America clinical practice guideline for the diagnosis and treatment of diabetic foot infections. Clin Infect Dis 2012;54(12)132–173.

---

may be absent.[24] Still, the diagnosis of diabetic foot infection depends mostly on clinical evaluation.

Purulent drainage from the ulcer is indicative of infection. When pus and inflammatory symptoms are not present, the clinician must be astute to more subtle findings. These include delayed healing, increase in lesion size, prolonged exudate production, malodor, and tissue friability. Abnormal granulation tissue also may be present, as evidenced by color change (from bright red to dark red, brown, or gray) and increased bleeding. The ability to probe the ulcer to the underlying bone is highly indicative of osteomyelitis.[24]

Diabetic foot infections are classified into four categories based on clinical presentation using the PEDIS scale (perfusion, extent/size, depth/tissue loss, infection, sensation). Grade 1 signifies no infection; grade 2, involvement of skin and subcutaneous tissue only; grade 3, extensive cellulitis or deeper infection; and grade 4, presence of systemic inflammatory response syndrome.[23] Table 73–5 provides detailed information regarding these grades.

Imaging studies, such as x-ray and magnetic resonance imaging (MRI), can identify osteomyelitis. Blood cultures should be obtained from all patients with signs and symptoms of systemic illness. Deep tissue cultures may help to direct therapy. Bone also may be sent for culture in cases of osteomyelitis. Superficial cultures of ulcers are unreliable and should be avoided.[23]

Spreading soft tissue infection and osteomyelitis are often the first complications that develop from diabetic foot infection. Some patients develop bacteremia and sepsis.

---

**Patient Encounter 2, Part 3: Diabetic Foot Infection: Clinical Course**

The patient received the empiric therapy you recommended for his diabetic foot infection. Two days later, deep wound cultures were reported positive for *P. aeruginosa*. Blood cultures revealed no growth. The patient remained hospitalized for an additional week, during which time his cellulitis improved on directed antimicrobial therapy. He was discharged to complete his antibiotic therapy and to follow up as an outpatient in 1 week.

*What modifications would you make to this patient's antimicrobial regimen knowing that the causative agent is P. aeruginosa?*

*What individualized foot care strategies can you suggest to this patient to prevent further infections?*

---

The most feared complication of infected diabetic foot ulcers is lower extremity amputation. More than 80% of all nontraumatic lower extremity amputations performed each year in the United States are linked to diabetic foot infections, about half of which could be potentially avoided.[22]

## TREATMENT

The goals of therapy for diabetic foot infection are eradication of the infection and avoidance of soft tissue loss and amputation.

### Prevention

Comprehensive foot care programs and the utilization of multidisciplinary care teams can improve outcomes and decrease amputation rates.[23] Periodic foot examinations with monofilament testing and patient education regarding proper foot care, optimal glycemic control, and smoking cessation are key preventative strategies.

### Nonpharmacologic Treatment

The nonpharmacologic treatment of diabetic foot ulcers may include débridement of necrotic or nonviable tissue, wound dressings, vascular or orthopedic surgery, and off-loading pressure from the wound.[23]

### Pharmacologic Treatment

The severity of a patient's infection, based on the PEDIS scale, can help guide the selection of empirical antimicrobial therapy. Although most patients with grade 2 diabetic foot infections can be treated as outpatients with oral antimicrobial agents, all grade 4 and many grade 3 infections require hospitalization, stabilization of the patient, and broad-spectrum IV antibiotic therapy.[23]

Multiple antibiotic options exist for the treatment of diabetic wound infections. Table 73–6 provides both general treatment strategies and specific, although not all-inclusive, antibiotic recommendations. The duration of therapy correlates with infection severity. Antibiotics should be continued until the infection has resolved, but not necessarily until the ulcer has healed. Milder infections generally require 7 to 14 days of therapy, whereas more severe infections may necessitate longer treatment durations. Patients with osteomyelitis may require days to weeks of

**Table 73–6**

**Empirical Pharmacologic Treatment of Diabetic Foot Infection**

| Infection Severity | PEDIS Grade | General Approach to Empirical Pharmacologic Treatment | Examples of Appropriate Empirical Antibiotics[a] |
|---|---|---|---|
| Uninfected | 1 | None. Avoid treating uninfected diabetic foot ulcers. | Not applicable |
| Mild | 2 | Oral, narrow-spectrum antibiotic therapy with activity against *S. aureus* and streptococcal species. Include coverage for MRSA according to patient history and resistance patterns in the area. | MRSA not suspected: cephalexin, dicloxacillin, clindamycin, amoxicillin-clavulanate<br><br>MRSA suspected: clindamycin[b], trimethoprim-sulfamethoxazole[c], or doxycycline[c] |
| Moderate | 3 | Difficult to define a general approach. In many patients, highly bioavailable oral therapy is appropriate. IV therapy should be initiated in patients with more extensive or chronic infections, or those with abscess, deep tissue or bone involvement, or gangrene. | Oral options for grade 3 infections: amoxicillin-clavulanate, levofloxacin[d] + clindamycin, or moxifloxacin<br><br>MRSA suspected: clindamycin[b], trimethoprim-sulfamethoxazole[c] or doxycycline[c] |
| Severe | 4 | Parenteral, broad-spectrum antibiotic therapy should be initiated. Ideally, drugs with activity against gram-positive, gram-negative, and anaerobic bacteria (especially if wound is malodorous) should be selected. Include coverage for MRSA. | IV options for grade 3–4 infection: MRSA not suspected: ampicillin-sulbactam, ertapenem, imipenem-cilastatin[d], moxifloxacin, levofloxacin[d] + clindamycin<br><br>MRSA suspected: vancomycin, daptomycin, or linezolid<br><br>*P. aeruginosa:* piperacillin-tazobactam |

[a]Please refer to Table 73–3 for dosing in adults with normal renal function.

[b]CA-MRSA isolates resistant to erythromycin should be evaluated for inducible clindamycin resistance via a D-test.

[c]Poor activity against GAS; consider using in combination with clindamycin or cephalexin if empirical coverage for GAS is desired.

[d]*P. aeruginosa* generally is susceptible to this agent.

From Williams DT, Hilton JR, Harding KG. Diagnosing foot infection in diabetes. Clin Infect Dis 2004;39(2):S83–S86.

antibiotic therapy depending on whether infected and necrotic bone is surgically debrided.[23]

## INFECTED PRESSURE SORES

### EPIDEMIOLOGY AND ETIOLOGY

Pressures sores, also known as *decubitus ulcers* or *bedsores*, affect approximately 3 million adults, with an annual prevalence in the United States of about 12.5%. Patients of advanced age and those with spinal cord or orthopedic injuries are at highest risk.[25]

A pressure sore is a chronic wound that results from continuous pressure on the tissue overlying a bony prominence. This pressure impedes blood flow to the dermis and subcutaneous fat, resulting in tissue damage and necrosis.[26] Pressure sore infections develop from breaks in skin integrity and contamination from dirty areas of close proximity, and are often polymicrobial.[27]

### CLINICAL PRESENTATION AND DIAGNOSIS

Approximately two-thirds of all pressure sores occur on the sacrum and heels.[27] Pressure sores are classified according to the extent of tissue destruction.[28] The most commonly used system for staging of pressure sores is presented in Table 73–7.

Bacterial colonization of pressure sores is common. Because infection impairs wound healing and may require systemic antimicrobial therapy, the clinician must be able to distinguish it from colonization. Table 73–8 describes the clinical presentation of infected pressure sores.

Most complications are infectious. The most common is osteomyelitis; less frequently, NF, clostridial myonecrosis, and sepsis can occur.

### TREATMENT

The goals of therapy for infected pressure sores include resolution of infection, promotion of wound healing, and establishment of effective infection control.[30]

#### Prevention

**KEY CONCEPT** *Prevention is the most humane and cost-effective component for the management of pressure sores.* Key prevention strategies include monitoring of high-risk patients, reducing skin exposure to pressure and moisture, and promoting good nutritional status.

Careful monitoring and preventative care of high-risk patients can begin once these patients are identified. Intrinsic or host-related risk factors for the development of pressure sores include age more than 75 years, limited mobility, loss of sensation, unconsciousness or altered sense of awareness, and malnutrition. Extrinsic or environmental risk factors include pressure, friction, shear stress, and moisture.[31]

Turning and repositioning the patient at least every 2 hours can reduce skin pressure and prevent pressure sores. However, because this level of care is difficult to achieve in most hospital and nursing home environments, multitudes of pressure-reducing mattresses have been manufactured. Although these can help to decrease pressure on susceptible areas, they do not negate the need for position changes.[31]

Maintaining a clean, dry environment can prevent skin maceration and subsequent tissue damage. This can be accomplished with

---

**Table 73–7**

**Staging of Pressure Ulcers**

**Suspected Deep Tissue Injury**

- Intact skin with localized area of purple or maroon discoloration or presence of a blood-filled blister.
- The area may be preceded by tissue that is painful, firm, mushy, boggy, and warmer or cooler as compared with adjacent tissue.

**Stage I**

- Intact skin with localized area of nonblanchable redness, usually over a bony prominence.
- May be difficult to detect in darkly pigmented skin; its color may differ from the surrounding area.

**Stage II**

- Partial-thickness loss of dermis presenting as a shallow open ulcer with a red-pink wound bed or an intact or ruptured serum-filled blister.
- This stage should not be used to describe skin tears, tape burns, perineal dermatitis, maceration, or excoriation.

**Stage III**

- Full-thickness tissue loss. Subcutaneous fat may be visible, but bone, tendon, or muscle is not exposed. Slough may be present but does not obscure the depth of tissue loss. May include undermining and tunneling.

**Stage IV**

- Full-thickness tissue loss with exposed bone, tendon, or muscle. Slough or eschar may be present on some parts of the wound bed. Often include undermining and tunneling.

**Unstageable**

- Full-thickness tissue loss in which the base of the ulcer is covered by slough (yellow, tan, gray, green, or brown) and/or eschar (tan, brown, or black) in the wound bed.
- Until enough slough and/or eschar is removed to expose the base of the wound, the true depth, and therefore stage, cannot be determined. Stable (dry, adherent, intact without erythema or fluctuance) eschar on the heels serves as "the body's natural (biological) cover" and should not be removed.

From National Pressure Ulcer Advisory Panel. Updated staging system [online]. 2007. [cited 2014 September 1]. Available from: http://www.npuap.org/resources/educational-and-clinical-resources/npuap-pressure-ulcer-stagescategories/

---

**Table 73–8**

**Presentation of Infected Pressure Sores**

**Symptoms**

- Because many high-risk patients lack sensation, pain may not be a primary symptom.

**Signs**

- Infection generally is diagnosed when erythema and edema of the surrounding skin, purulent drainage, malodor, or delayed wound healing are present.

Patients with bacteremia often develop fever, chills, confusion, and/or hypotension.

**Laboratory Tests**

- Deep tissue cultures may help to direct therapy. Bone also may be sent for culture in cases of osteomyelitis. Superficial cultures are unreliable and should be avoided.

**Imaging Studies**

- Imaging studies, such as CT, MRI, or bone scan, can be used to detect osteomyelitis and to determine the depth and extent of tissue destruction.

From Refs. 29 and 30.

---

Mild superficial infections, such as those that present clinically with delayed wound healing or minimal cellulitis, may be treated with topical antimicrobial agents such as silver sulfadiazine 1% cream or combination antibiotic ointments.[26] Systemic options for more extensive cellulitis are available in Table 73–3.

## INFECTED BITE WOUNDS

### EPIDEMIOLOGY AND ETIOLOGY

Many Americans will be bitten by an animal at least once during their lifetimes. Although most of these injuries are minor, some will require medical treatment.

Dogs cause most animal bites, typically open lacerations, of which approximately 20% become infected. Cat bites are the second most common animal bite, most often puncture wounds involving the hand. Because cat bites are deep and penetrating, up to 80% may become infected.[32]

Human bites are the third most common and the most serious. Before the availability of antibiotics, up to 20% resulted in amputation. Currently, human bite–associated amputation rates remain at 5%, secondary to vascular compromise and infectious complications.[33]

There are two types of human bite injuries. Occlusal injuries are inflicted by actual biting, whereas clenched-fist injuries are sustained when a person's closed fist hits another's teeth. Of the two, clenched-fist injuries typically are more prone to infectious complications.[32,33]

**KEY CONCEPT** *Bite wound infections generally are polymicrobial.*[4] Both the normal flora of the biter's mouth and that of the bite recipient's skin can be implicated. The bacteriology of the cat and dog mouth is quite similar. *Pasteurella multocida*, a gram-negative aerobe, is one of the predominant pathogens. Viridans streptococci are the most frequently cultured bacteria from human bite wounds, although empiric treatment should also provide coverage for *Eikenella corrodens*.[4,33] Table 73–9 provides a comprehensive list of cat-, dog-, and human bite-wound pathogens.

frequent changes of bed sheets and clothing, thorough drying of skin after bathing, and prompt disposal of incontinent stool or urine.

Malnutrition is a significant but reversible risk factor. High-protein diets improve wound healing in patients with pressure sores.[31]

### Nonpharmacologic Treatment

Pressure relief, adequate nutrition (high-protein diet), and surgical débridement or abscess drainage are the mainstays of nonpharmacologic treatment.[30]

### Pharmacologic Treatment

Systemic antibiotics are indicated for serious pressure ulcer infections, including those associated with spreading cellulitis, osteomyelitis, or bacteremia.[30] Pressure ulcer infections are generally polymicrobial; thus, antimicrobial agents with a broad spectrum of activity should be initiated and narrowed according to the results of cultures obtained surgically. The duration of treatment is generally 10 to 14 days, unless osteomyelitis is present.[30]

## Table 73–9

**Etiology and Presentation of Infected Bite Wounds**

**Bacterial Pathogens**

- *Dog and cat: Pasteurella multocida,* staphylococci, streptococci *Moraxella* spp., *Eikenella corrodens, Capnocytophaga canimorsus, Actinomyces, Fusobacterium, Prevotella,* and *Porphyromonas* spp.
- *Human:* Viridans streptococci, *S. aureus, E. corrodens, Haemophilus influenzae,* and β-lactamase–producing anaerobic bacteria.

**Signs and Symptoms**

- The onset of infectious symptomatology is typically 12–24 hours after the bite.
- Pain at the wound site is common.
- Erythema, edema, and purulent or malodorous drainage at the wound site are manifestations of infected wounds. The patient may be febrile.
- Limited range of motion may be present, especially if the hand is bitten.

**Laboratory Tests**

- Leukocytosis may be present.
- The clinician should obtain anaerobic and aerobic wound cultures only if the wound appears clinically infected.

**Imaging Studies**

- Radiographs should be obtained if the bite is on the hand, could have damaged bone or joints, or if an embedded object or tooth fragment is suspected.

Data from Refs. 4 and 33.

## CLINICAL PRESENTATION AND DIAGNOSIS

The clinical presentation of infected bite wounds is presented in Table 73–9.

Complications of infected bite wounds include lymphangitis, abscess, septic arthritis, tenosynovitis, and osteomyelitis. Bites to the hand are particularly complication-prone.[33]

## TREATMENT

The goals of therapy for an infected bite wound are rapid and successful eradication of infection and prevention of related complications.

### Nonpharmacologic Treatment

Thorough irrigation with normal saline is the first step in the care of an infected bite wound. The wound should be elevated and immobilized. Surgical closure may be advocated, especially for facial wounds. Wounds that are infected, at higher risk for infection, or older than 24 hours should be left open because premature closure can lead to disastrous infectious complications.[33]

### Pharmacologic Treatment

Most bite wounds require antibiotic therapy only when clinical infection is present. *However, prophylactic therapy is recommended for wounds at higher risk for infection and bites requiring surgical repair.*[33] Bites to the hand and human bites may benefit the most from prophylaxis.[32]

*The most effective agent for the treatment (and prophylaxis) of human and animal bite-wound infections is amoxicillin-clavulanate.*

Alternatives include second-generation cephalosporins, such as cefuroxime, plus coverage for anaerobes, such as clindamycin or metronidazole. Moxifloxacin, doxycycline, or a carbapenem may also be used. The durations of prophylaxis and treatment are generally 3 to 5 days.[4]

If the wound is associated with significant cellulitis and edema, systemic signs of infection, or possible joint or bone involvement, hospitalization and IV antibiotics (typically ampicillin-sulbactam 3 g IV every 6 hours) should be initiated. Bone and joint infections will require longer durations of therapy of up to 6 weeks.[4,33]

## OUTCOME EVALUATION

Education of the patient, caregivers, and household members is important to limit further spread of infection and is a key component in SSTI case management. Table 73–10 lists several key prevention messages for patients with SSTIs.

Patients receiving antibiotic therapy for SSTIs require monitoring for efficacy and safety. Efficacy typically is manifested by reductions in temperature, white blood cell count, erythema, edema, and pain. Initially, signs and symptoms of infection may worsen owing to toxin release from certain organisms (ie, GAS); however, they should begin to resolve within 48 to 72 hours of treatment initiation. If no response or worsening infection is noted after the first 3 days of antibiotics, reevaluate the patient.[4] Lack of response may be due to a noninfectious or nonbacterial diagnosis, a pathogen not covered by or resistant to current antibiotic therapy, poor patient adherence, drug or disease interactions causing decreased antibiotic absorption or increased clearance, immunodeficiency, or the need for surgical intervention. To ensure the safety of the regimen, dose antibiotics according to renal and hepatic function as appropriate, and monitor for or minimize adverse drug reactions, allergic reactions, and drug interactions.

## Table 73–10

**Prevention Education for Patients with SSTIs**

1. Draining wounds should be covered with clean, dry bandages.
2. Hands should be cleaned regularly with soap and water (or with alcohol-based hand gel if not visibly soiled) and immediately after touching infected skin or any item directly contacting a draining wound.
3. General hygiene should be maintained with regular bathing.
4. Items that may become contaminated with wound drainage or that directly touch the skin should not be shared.
5. Wash and dry thoroughly any clothing that has come in contact with wound drainage after each use.
6. If the wound is unable to be covered with a clean, dry bandage at all times, avoid activities with skin-to-skin contact until the wound is healed.
7. Equipment and environmental surfaces with bare skin contact should be cleaned with *S. aureus*–active detergents or disinfectants.

From Gorwitz RF, Jernigan DB, Powers JH, et al. Strategies for clinical management of MRSA in the community: Summary of an experts' meeting convened by the Centers for Disease Control and Prevention [online]. 2006. [cited 2011 Oct 10]. http://www.cdc.gov/ncidod/dhqp/ar_mrsa_ca.html.50

## Patient Care Process

**Patient Assessment:**

- Based on physical examination and review of systems, determine whether the patient is experiencing signs or symptoms of an SSTI and if so, its severity.
- Review the medical history. Does the patient have any risk factors or chronic conditions that lend to the diagnosis of an SSTI or a particular causative pathogen?
- Conduct a medication history (including prescriptions, OTC medications, and dietary supplements). Does the patient have any drug allergies? Is the patient experiencing side effects from therapy?
- Review available laboratory tests, especially white blood cell counts and renal function.

**Therapy Evaluation:**

- Determine whether oral or IV therapy is indicated based on severity of infection.
- If the patient is already receiving pharmacotherapy, assess efficacy, safety, and patient adherence. Are there any significant drug interactions?
- Determine whether the patient has prescription coverage or whether recommended agents are included on the institution's formulary.

**Care Plan Development:**

- Select an empirical antibiotic agent based on patient assessment that is likely to be effective and safe.
- Determine whether drug doses, dosing frequency, and duration of therapy are optimal.
- Address any patient concerns about SSTIs and their management.
- In pediatric patients especially, consider method and ease of administration, and palatability and tolerability of oral formulations.

**Follow-Up Evaluation:**

- Ensure that antimicrobial therapy is effective by monitoring for resolution of local and systemic signs and symptoms of infection.
- Monitor for laboratory evidence of infection resolution.
- Narrow antibiotic coverage when possible with the use of culture and sensitivity data.
- Determine whether patient is experiencing any adverse reactions or drug interactions.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| CA-MRSA | Community-acquired methicillin-resistant *S. aureus* |
| GAS | Group A *Streptococcus* (also known as *Streptococcus pyogenes*, one of the β-hemolytic streptococci) |
| GERD | Gastroesophageal reflux disease |
| HA-MRSA | Health care-associated methicillin-resistant *S. aureus* |
| IVIG | Intravenous immunoglobulin |
| MIC | Minimum inhibitory concentration |
| MRI | Magnetic resonance imaging |
| MRSA | Methicillin-resistant *S. aureus* |
| MSSA | Methicillin-sensitive *S. aureus* |
| NF | Necrotizing fasciitis |
| SIRS | Systemic inflammatory response syndrome |
| SSTI | Skin and soft tissue infection |
| VISA | Vancomycin-intermediate *S. aureus* |
| VRE | Vancomycin-resistant enterococci |
| VRSA | Vancomycin-resistant *S. aureus* |

# 74 Infective Endocarditis

Ronda L. Akins and Katie E. Barber

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Differentiate the causes and development of infective endocarditis (IE).

2. Identify the clinical presentation and laboratory evaluation for IE.

3. Assess diagnostic criteria used to evaluate a patient suspected of having IE.

4. Describe the most likely causative pathogens of IE, particularly in specific patient populations.

5. Develop appropriate pharmacologic treatment recommendations for patients with IE.

6. Define appropriate patient populations requiring prophylactic treatment, and differentiate appropriate drug regimens.

7. Devise a monitoring plan for patients with IE to determine treatment efficacy and discern any adverse effects.

## INTRODUCTION

Infective endocarditis (IE) is a serious infection affecting the lining and valves of the heart. Although this disease is mostly associated with infection of the heart valves, septal defects may become involved in some cases. Infections also occur in patients with prosthetic or mechanical devices or who are intravenous drug users (IVDUs). Bacteria are the primary cause of IE; however, fungi and atypical organisms may also be responsible pathogens.

Typically IE is classified into two categories: acute or subacute. Differences between the two categories are based on the progression and severity of the disease. Acute disease is more aggressive, characterized by high fevers, leukocytosis, and systemic toxicity, with death occurring within a few days to weeks. This type of IE is often caused by more virulent organisms, particularly *Staphylococcus aureus*. Subacute disease is typically caused by less virulent organisms, such as viridans group streptococci, producing a slower and more subtle presentation. It is characterized by weakness, fatigue, low-grade fever, night sweats, weight loss, and other nonspecific symptoms, with death occurring in several months.

Successful management of patients with IE is based on proper diagnosis, treatment with appropriate therapy, and monitoring for complications, adverse events, or development of resistance. The treatment and management of IE are best determined through identification of the causative organism. IE has varied clinical presentations; therefore, patients with this infection may be found in any medical subspecialty (ie, medicine, surgery, critical care, etc).

## EPIDEMIOLOGY AND ETIOLOGY

Despite IE being a fairly uncommon infection, in the United States, there are about 10,000 to 20,000 new cases annually, accounting for an incidence of approximately five to seven cases per 100,000 persons-years.[1] Although the exact number of cases is often difficult to determine, owing to the diagnostic criteria and reporting methods for this disease, it continues to rise. IE is now considered the fourth leading cause of serious infectious diseases syndromes following sepsis secondary to urinary tract infection, pneumonia, and intraabdominal sepsis.[2] Although IE occurs at any age, more than 50% of cases occur in patients older than 50 years.[1] IE in children continues to be uncommon and is mainly associated with underlying structural defects, surgical repair of the defects, or nosocomial catheter-related bacteremia.[1] With the increased use of mechanical valves, prosthetic-valve endocarditis (PVE) now accounts for approximately 10% to 30%.[3] Patients who are IVDUs are also at an increased risk for IE, with 150 to 2000 cases per 100,000 persons per year, most being younger adults.[4] Additionally, others at high risk for IE include patients with any congenital or structural cardiac defects, including valvular disease, long-term hemodialysis, diabetes mellitus; poor oral hygiene, major dental treatment, previous endocarditis, hypertrophic cardiomyopathy, and mitral valve prolapse with regurgitation.[5-7]

Although almost any type of microorganism is capable of causing IE, the majority of cases are caused by gram-positive organisms. These consist primarily of streptococci, staphylococci, and enterococci. Consideration of gram-negative, fungal, and other atypical organisms must be taken into account, particularly in certain patient populations. In **Table 74–1**, approximate percentages are given for each organism based on the type of IE, including native valve (community-acquired vs health care–associated), prosthetic valve (grouped by months post-surgery), and IVDUs.

**Table 74–1**

**Etiologic Organisms of Infective Endocarditis**

| | Native-Valve IE | | PVE (Indicated in Months After Valve Surgery) | | IVDU (Right- and Left-Sided) | |
| | Community-Acquired | Health Care-Associated | < 2 | 2–12 | > 12 | Total |
|---|---|---|---|---|---|---|
| Streptococci[a] | 40 | 9 | 1 | 9 | 31 | 12 |
| Pneumococci | 2 | — | — | — | — | — |
| Enterococci | 9 | 13 | 8 | 12 | 11 | 9 |
| *Staphylococcus aureus* | 28 | 53[b] | 22 | 12 | 18 | 57 |
| CNS | 5 | 12 | 33 | 32 | 11 | — |
| HACEK group | 3 | — | — | — | 6 | — |
| Gram-negative bacilli | 1 | 2 | 13 | 3 | 6 | 7 |
| Fungi (*Candida* spp.) | < 1 | 2 | 8 | 12 | 1 | 4 |
| Polymicrobial/ miscellaneous | 3 | 4 | 3 | 6 | 5 | 7 |
| Diphtheroids | — | < 1 | 6 | — | 3 | 0.1 |
| Culture-negative | 9 | 5 | 5 | 6 | 8 | 3 |

CNS, coagulase-negative staphylococci; HACEK, *Haemophilus* spp. (primarily *H. paraphrophilus, H. parainfluenzae*, and *H. aphrophilus*), *Aggregatibacter actinomycetemcomitans, Cardiobacterium hominis, Eikenella corrodens*, and *Kingella kingae*.

[a]Includes viridans group streptococci; *S. bovis*; other nongroup A, groupable streptococci; and nutritionally variant streptococci.

[b]Methicillin resistance is common among these *S. aureus* strains.

Modified from Karchmer AW. Infective endocarditis. In: Fauci AS, Braunwald E, Kasper DL, Hauser SL, Longo DL, Jameson JL, Loscalzo J, eds. Harrison's Principles of Internal Medicine. 18th ed. New York: McGraw Hill; 2012: Chap. 124.

## Patient Encounter, Part 1

A 62-year-old woman with a history of end-stage renal disease (ESRD) on hemodialysis presents to the emergency department with complaints of weakness, fever, and chills. Her current weight is 105 kg (231 lb). On interviewing the patient, you determine she has had type 2 diabetes for 25 years and has been receiving dialysis Monday, Wednesday, and Friday for the past 6 months. She denies any use of alcohol, illicit drugs, or tobacco.

*What information would make you suspect IE?*

*Does she have any risk factors for IE?*

*What additional information would you like to know before deciding on an empirical treatment for this patient?*

## PATHOPHYSIOLOGY

**KEY CONCEPT** *For IE to develop, the occurrence of several factors is required. Typically, there must be an alteration of the endothelial surfaces of the heart valves to allow for organism attachment and colonization.* These alterations may be produced by an inflammatory process such as rheumatic heart disease or by injury from turbulent blood flow. Platelets and fibrin are then capable of depositing on the damaged valves, forming a nonbacterial thrombotic endocarditis (NBTE). At this point, bacteria, through hematogenous spread (ie, bacteremia), adhere to and colonize the **nidus**, forming a vegetation. Further deposits of platelets and fibrin cover the bacteria, providing a protective coating that allows for development of a suitable environment for continued

organism and vegetation progression, often producing an organism density of $10^9$ to $10^{10}$ **colony-forming units** (CFU) per gram.

Acquisition of PVE differs in early stages, where direct inoculation may occur during surgery rather than through hematogenous seeding. In addition, causative organisms in early PVE are typically nosocomial, with increased likelihood of being drug resistant.[7,8] The prosthetic valve also has a greater propensity for organism colonization than native valves.[8] However, in late PVE, the process of colonization and vegetation formation is similar to that of native-valve IE, as described earlier.[7,8]

Typically, vegetations are located on the line along valve closure on the atrial surface of the atrioventricular valves (tricuspid and mitral) or on the ventricular surface of the semilunar valves (pulmonary and aortic). The vegetations can vary significantly in size, ranging from millimeters to several centimeters and may be single or multiple masses. Often, destruction of underlying tissue occurs and may cause perforation of the valve leaflet or rupture of the chordae tendineae, interventricular septum, or papillary muscle. Valve ring abscesses may occur, resulting in fistulas penetrating into the myocardium or pericardial sac, particularly with staphylococcal endocarditis.

Embolic events are also common. Embolization occurs as portions of the friable vegetation break loose and enter the bloodstream. These infected pieces are called *septic emboli*. Pulmonary abscesses are commonly formed as a result of septic emboli from right-sided IE (tricuspid and pulmonary valves). However, left-sided IE (mitral and aortic valves) is more likely to have an embolus travel to any organ, especially kidneys, spleen, and brain. Along with emboli, immune complex deposition may occur in organ systems, causing extracardiac manifestations of the disease. This commonly occurs in the kidneys, producing

abscesses, infarction, or glomerulonephritis. Immune complexes or emboli may also produce skin manifestations of the disease, as seen with petechiae, Osler nodes, and Janeway lesions, or within the eye (eg, Roth spots).

## CLINICAL PRESENTATION AND DIAGNOSIS

The clinical presentation for IE is quite variable and often non-specific. **KEY CONCEPT** *A fever is the most frequent and persistent symptom in patients but may be blunted with previous antibiotic use, congestive heart failure, chronic liver or renal failure, or infection caused by a less virulent organism (ie, subacute disease).*[1,3,4] Other signs and symptoms that may also occur are listed below, with some discussed in further detail.

Heart murmurs are heard frequently on auscultation (greater than 85% of cases), but a new murmur or change in murmurs is only found in 3% to 5% or 5% to 10%, respectively.[1] Additionally, more than 90% of patients who have a new murmur will develop congestive heart failure, which is a major cause of morbidity and mortality. Splenomegaly and mycotic aneurysms are also noted in many cases of IE.

This disease is also characterized by the following peripheral manifestations. Some of these clinical findings are found in up to one-half of adult patients with IE, although recently the prevalence has been decreasing and is rarely seen in children.[1,3]

- **Skin:** *Petechiae* are very small (usually less than 3 mm), pinpoint, flat red spots beneath the skin surface caused by microhemorrhaging. They occur in 20% to 40% of patients with chronic IE and are often found on the buccal mucosa, conjunctivae (**Figure 74–1A**), and extremities.[1] *Splinter hemorrhages* appear as small dark streaks beneath the fingernails or toenails and occur most commonly proximally with IE, typically as a result of local vasculitis or microemboli in about 20% of patients (**Figure 74–1B**). *Osler nodes* are small (usually 2–15 mm), painful, tender subcutaneous nodules located on the pads of the fingers and toes (**Figure 74–1D**) caused primarily by either septic emboli or vasculitis. These nodes are rare in acute disease but are also nonspecific for IE despite occurring in 10% to 25% of all patients.[1] *Janeway lesions* are small, painless, hemorrhagic macular plaques on the palms of the hands or soles of the feet due to septic emboli (in ~5% of patients) and more commonly associated with acute *S. aureus* IE (**Figure 74–1E**).

- **Extremities:** *Clubbing* of the finger tips typically occurs in long-standing illness and is present in approximately 10% to 20% of patients (**Figure 74–1C**).[1]

- **Eye:** *Roth spots* occur rarely (less than 5% of IE cases) and are oval-shaped retinal hemorrhages with a pale center near the optic disc (**Figure 74–1F**).

### Laboratory Studies

**KEY CONCEPT** *Blood cultures are the essential laboratory test for the diagnosis and treatment of IE. Typically, patients with IE have a low-grade consistent bacteremia, with approximately 80% of cases having less than 100 CFU/mL (100,000 CFU/L) in the bloodstream.*[1] *Blood culture results are critical for determining the most appropriate therapy.* Three blood culture sets should be drawn within the initial 24 hours to determine the etiologic agent. Approximately 90% of the first two cultures will yield a positive result. If a positive blood culture is not obtained from a patient with suspected IE, the microbiology laboratory should be notified to monitor cultures for growth of fastidious organisms (eg, HACEK) for up to 1 month.

**KEY CONCEPT** *Another important tool aiding in the diagnosis of IE is the* **echocardiogram**. *This imaging tool is used to visualize vegetations. Two methods of the echocardiogram are used: the transthoracic echocardiogram (TTE) and the transesophageal*

---

## Clinical Presentation and Diagnosis of IE  KEY CONCEPT

### General

Patients typically present with nonspecific and variable signs or symptoms.

### Symptoms

Complaints from patients may include:

- Fever
- Chills
- Night sweats
- Weakness
- Dyspnea
- Weight loss
- Myalgia or arthralgias

### Signs

- Fever is the most common sign of IE
- New or changing heart murmur
- Embolic phenomena (emboli affect the kidneys, spleen, brain, lung, or extremities)

- Skin manifestations (eg, petechiae, splinter hemorrhages, Osler nodes, Janeway lesions)
- Splenomegaly
- Clubbing of extremities

### Laboratory Tests

- Blood cultures are the most important laboratory assessment for persistent bacteremia, which occurs commonly in IE. A minimum of three blood culture sets should be collected during the initial 24 hours
- Hematologic tests for anemia (normochromic, normocytic)
- WBC count may be elevated in acute disease but could be normal in subacute IE
- Nonspecific findings such as thrombocytopenia, elevated erythrocyte sedimentation rate or C-reactive protein, and abnormal urinalysis (ie, proteinuria or microscopic hematuria)

### Other Diagnostic Tests

An echocardiogram (TTE or TEE) should be performed on any patient with suspected IE to detect the presence of vegetations.
**FIGURE 74–1.** (A) Conjunctival petechiae. (From Wolff K, Johnson R, Saavedra AP. In: Fitzpatrick's Color Atlas & Synopsis of Clinical Dermatology. 7th ed. New York: McGraw Hill. Copyright 2013.) (B) Splinter hemorrhage. (From Knoop KJ, Stack LB, Storrow AB, Thurman AB. In: Atlas of Emergency Medicine. 3rd ed. New York: McGraw Hill. Copyright 2010.) (C) Clubbing of finger. (From Tosti A, Piraccini BM. In: Fitzpatrick's Dermatology in General Medicine. 7th ed. New York: McGraw Hill. Copyright 2007.) (D) Osler nodes. (From Knoop KJ, Stack LB, Storrow AB, Thurman AB. In: Fitzpatrick's Color Atlas & Synopsis of Clinical Dermatology. 7th ed. New York: McGraw Hill. Copyright 2013.) (F) Roth spots. (From Effron D, Forcier BC, Wyszynski RE. In: Atlas of Emergency Medicine. 3rd ed. New York: McGraw Hill. Copyright 2010.)

*echocardiogram (TEE)*. The TTE has been used since the 1970s; however, it is less sensitive (45%–65%) than the TEE (85%–95%).[3] Despite the TEE being more sensitive, use of the TTE for patients with suspected native-valve IE is usually sufficient.[9,10] The TEE may be used as a secondary test for patients whose TTE was negative when a high clinical suspicion of IE exists. On the other hand, a TEE is often preferred in patients who have complicated disease, including left-sided IE, prosthetic valves, or perivalvular extension of the vegetation.[2,10,11] Echocardiograms may also be employed to assess the need for surgical intervention or to determine the possible source of emboli.[10]

Additional nonspecific tests for IE may be performed. These include hematologic parameters to determine whether the patient is anemic, which occurs in the majority of patients. The white blood cells (WBCs) may be elevated, particularly in acute disease. However, in a subacute infection, WBCs may be normal.

An **erythrocyte sedimentation rate** (ESR) may also be obtained to determine the presence of inflammation, although this test is highly nonspecific and almost always elevated in IE.

## Diagnostic Criteria

A definitive diagnosis of IE would consist of a biopsy or culture directly from pathologic specimens from the endocardium. However, this would be a highly invasive test. Therefore, diagnosis of IE relies on clinical presentation as well as laboratory and echocardiographic results. To guide the clinical diagnosis of IE, major and minor criteria have been established (Table 74–2A).[12] Depending on the number of major or minor criteria a patient demonstrates, leads to a classification of definite, possible, or rejected diagnosis of IE (Table 74–2B).

## Causative Organisms

Gram-positive bacteria are the most common causative organisms to produce IE. Streptococci and staphylococci species account for the majority of cases at more than 80%.[1,7] Viridans group streptococci have been considered the primary pathogens in IE. However, staphylococci have been increasing in prevalence and are now the dominant causative organisms in some reports (see Table 74–1).[12,13] Other gram-positive, gram-negative, atypical, and fungal organisms are less common but still must be considered in certain patient populations.

### ▶ Streptococci

Streptococci causing IE are typically a group of species called viridans group streptococci. The most common of this group are *Streptococcus salivarius, Streptococcus mutans, Streptococcus mitis*, and *Streptococcus sanguis*. This group of bacteria, considered normal flora in the human mouth, is α-hemolytic, with most clinical microbiology laboratories not differentiating to the exact species. These organisms may cause bacteremia after dental procedures, which can lead to the development of IE in at-risk patients. Viridans group streptococci are also the predominant pathogen of IE associated with mitral valve prolapse, native valves and in children.[14] Another streptococcal species commonly associated with IE is *Streptococcus bovis*, classified as group D streptococci and is frequently found in the GI tract. However, owing to the similarities of these streptococci, including microbiologic susceptibility, treatment is similar regardless of species.

IE caused by these streptococci typically have a subacute clinical course. The current cure rate is often greater than 90% unless complications arise, which do occur in more than 30% of patients.[14,15] The majority of viridans group streptococci remain very susceptible to penicillin, with most strains having a *minimum inhibitory concentration* (MIC) of less than 0.125 mcg/mL (0.125 mg/L).[16] However, isolation of organisms with decreased susceptibilities is increasing. Therefore, antibiotic susceptibilities need to be assessed in order to determine the most appropriate treatment regimen.

### ▶ Staphylococci

Staphylococcal endocarditis continues to increase in prevalence, causing 30% or more of all cases of IE, with the majority (80%–90%) being due to *S. aureus* (coagulase-positive staphylococci).[17,18] This increase in staphylococci has been primarily attributed to expanded use of venous catheters, more frequent valve replacement, and increased IVDU.[17] Coagulase-negative

**Table 74–2**

**Modified Duke Criteria for IE**

**2A. Definitions of Modified Duke Criteria**

**Major Criteria**

*Blood culture positive for IE:*

Typical microorganisms consistent with IE from two separate blood cultures:

Viridans streptococci, *S. bovis*, HACEK group, *S. aureus,* or community-acquired enterococci in the absence of a primary focus, or

Microorganisms consistent with IE from persistently positive blood cultures, defined as follows:

At least two positive cultures of blood samples drawn greater than 12 hours apart, or

All of three or a majority of four separate cultures of blood (with first and last sample drawn at least 1 hour apart)

Single positive blood culture for *C. burnetii* or antiphase I IgG antibody titer greater than 1:800

*Evidence of endocardial involvement:*

Echocardiogram positive for IE (TEE recommended in patients with prosthetic valves, rated at least "possible IE" by clinical criteria, or complicated IE [paravalvular abscess] TTE as first test in other patients), defined as follows:

Oscillating intracardiac mass on valve or supporting structures, in the path of regurgitant, or on implanted material in the absence of an alternative anatomic explanation, or

Abscess, or

New partial dehiscence of prosthetic valve

New valvular regurgitation (worsening or changing of preexisting murmur not sufficient)

**Minor Criteria**

Predisposition: predisposing heart condition or injection drug use

Fever: temperature greater than 38°C (100.4°F)

Vascular phenomena: major arterial emboli, septic pulmonary infarcts, mycotic aneurysm, intracranial hemorrhage, conjunctival hemorrhages, and Janeway lesions

Immunologic phenomena: glomerulonephritis, Osler nodes, Roth spots, and rheumatoid factor

Microbiologic evidence: positive blood culture but does not meet a major criterion as noted above[a] or serologic evidence of active infection with organism consistent with IE

**2B. Modified Duke Criteria for the Diagnosis of IE**

**Definite IE**

*Pathologic criteria:*

(1) Microorganisms demonstrated by culture or histologic examination of a vegetation that has embolized, or an intracardiac abscess specimen, or

(2) Pathologic lesions; vegetation or intracardiac abscess confirmed by histologic examination showing active endocarditis

*Clinical criteria[b]:*

(1) Two major criteria, or

(2) One major criterion and three minor criteria, or

(3) Five minor criteria

**Possible IE**

(1) One major criterion and one minor criterion, or

(2) Three minor criteria

**Rejected**

(1) Firm alternate diagnosis explaining evidence of IE, or

(2) Resolution of IE syndrome with antibiotic therapy for less than or equal to 4 days, or

(3) No pathologic evidence of IE at surgery or autopsy, with antibiotic therapy for less than or equal to 4 days, or

(4) Does not meet criteria for possible IE, as above

TEE, transesophageal echocardiography; TTE, transthoracic echocardiography.

[a]Excludes single positive cultures for CNS and organisms that do not cause endocarditis.

[b]See above for definitions of major and minor criteria.

From Li JS, Sexton DJ, Mick N, et al. Proposed modifications to the Duke criteria for the diagnosis of infective endocarditis. Clin Infect Dis 2000;30:633–638; by permission of Oxford University Press, 2000 by the Infectious Diseases Society of America.

staphylococci (CNS) also cause IE; however, these organisms typically infect prosthetic valves or indwelling catheters.[19]

Patients with *S. aureus* bacteremia are at an increased risk of developing IE. *S. aureus* may infect "normal" heart valves (no prior detected valvular disease) in one-third of cases.[1,17] Therefore, it is imperative to assess these patients adequately for the presence of vegetations. Any heart valve may be affected; however, when the mitral or aortic valve is involved, it often results in extensive systemic infection with a mortality rate of approximately 20% to 65%.[1,17] When treating *S. aureus* IE, one must consider whether the isolate displays methicillin-resistance, the location of infection (right or left side), presence of prosthetic valves, and history of IVDU. Despite significant resistance to penicillinase-resistant penicillins (eg, methicillin and nafcillin), most isolates remain susceptible to vancomycin. However, there is an increasing incidence of *S. aureus* with an elevated MIC of 2 mcg/mL (2 mg/L) which may require use of an alternative agent such as daptomycin.[20] Additionally, strains that are intermediately-resistant or fully resistant to vancomycin have been reported.[21–23] Fortunately, these strains are not widespread enough to affect empirical antibiotic selection. Susceptibility reports along with clinical response should be assessed to ensure appropriate antimicrobial coverage.

Over the past decade, there has been an increasing emergence of community-acquired methicillin-resistant *S. aureus* (CA-MRSA) that differs from healthcare-associated MRSA. This organism tends to be less resistant to many antibiotics, with sensitivity to clindamycin, trimethoprim-sulfamethoxazole, and minocycline, as well as vancomycin, linezolid, and daptomycin. In addition, this organism has a virulence gene (Panton-Valentine-leukocidin), which produces a toxin that causes necrosis. To date, this organism primarily causes skin/skin-structure infections or pneumonias (see Chapter 73: Skin and Soft Tissue Infections). There have been a limited number of cases of IE caused by CA-MRSA.[24] If CA-MRSA is suspected, treatment with vancomycin with or without gentamicin and/or rifampin remains standard of care.

The predominant coagulase-negative organism causing IE has been *S. epidermidis*. However, in the past few years there has been an increase in isolation of another coagulase-negative species, *S. lugdunensis*.[25,26] Typically, coagulase-negative staphylococcal IE has a subacute course with numerous complications. Treatment (with or without surgical intervention) is usually successful. On the other hand, *S. lugdunensis* produces a more virulent infection and, despite similar antibiotic susceptibilities, has a much higher mortality rate.[25,26]

#### ▶ Enterococci

Enterococci are normal flora of the human GI tract and sometimes found in the anterior urethra. Affected patients are typically older males who have undergone genitourinary manipulations or younger females who have had obstetric procedures. Although enterococci are a less common cause of IE, there are two predominant species: *Enterococcus faecium* and *Enterococcus faecalis*. *E. faecalis* is the most common and more susceptible of the strains. However, enterococci overall are more intrinsically resistant, with enterococcal IE representing one of the most problematic gram-positive infections to treat and cure. Frequently, enterococci display resistance to multiple antibiotics, including penicillins, vancomycin, aminoglycosides, as well as being described in some of the newer agents (eg, linezolid, quinupristin/dalfopristin, or daptomycin).[27]

#### ▶ Gram-Negative Organisms

Gram-negative IE is much less common (~2%) but is typically much more difficult to treat than gram-positive infections.[1,28] Fastidious organisms, such as the HACEK group, tend to be seen most commonly, causing approximately 3% of all IE.[4,29,30] This group consists of *Haemophilus* spp. (primarily *H. paraphrophilus, H. parainfluenzae*, and *H. aphrophilus*), *Aggregatibacter actinomycetemcomitans, Cardiobacterium hominis, Eikenella corrodens*, and *Kingella kingae*. The clinical presentation of IE by these organisms is subacute, with approximately 50% of patients developing complications. These complications are primarily due to the presence of large, friable vegetations and numerous emboli along with development of acute congestive heart failure often requiring valve replacement.[30,31] It is important to allow cultures sufficient incubation time (often 2–3 weeks) in order to isolate these organisms. Despite prolonged incubation, these organisms may not be isolated on culture and thus present as culture-negative IE.

Other gram-negative organisms, such as *Pseudomonas* spp., cause IE, especially in IVDUs and patients with prosthetic valves. Additionally, IE may be caused by *Salmonella* spp., *Escherichia coli, Citrobacter* spp., *Klebsiella* spp., *Enterobacter* spp., *Serratia marcescens, Proteus* spp., and *Providencia* spp.[1,28]

Historically, gram-negative IE typically had a poor prognosis with high mortality rates. However, as nondrug therapy advances to include cardiac surgery in more than half of patients, in-hospital mortality has improved to 24%.[1,28] Treatment usually consists of high-dose combination antimicrobial therapy, with valve replacement often necessary in many patients.

#### ▶ Culture Negative

Negative blood cultures are reported in approximately 5% of confirmed IE cases, often delaying diagnosis and treatment.[1,4,32] Cultures that do not grow bacteria may be the result of previous antibiotic use, subacute right-sided disease, slow growth of fastidious organisms, nonbacterial endocarditis (eg, fungal or intracellular parasitic infections), noninfective endocarditis, or improper collection of blood cultures. If nonbacterial or fastidious organisms are suspected, additional testing is essential. The choice of treatment regimen depends on patient history and risk factors.

#### ▶ Other Organisms

Numerous bacteria, including gram-positive bacilli, unusual gram-negative bacteria, atypical bacteria, and anaerobes, as well as spirochetes, may be a rare cause IE.[29] Some of the more common organisms include *Legionella, Coxiella burnetii* (Q fever), and *Brucella*. These rare organisms occur primarily in at-risk patients such as those with prosthetic valves or IVDUs. A comprehensive discussion of these organisms is not feasible for this chapter; for further information, other references sources (particularly references 1–5) should be examined. Treatment of these organisms is difficult, and cure rates are low. Therefore, consulting an infectious diseases specialist is warranted.

#### ▶ Fungi

Fungal endocarditis is quite uncommon but has significant mortality, typically affecting patients who have had cardiovascular surgery, received total parenteral nutrition (TPN) or prolonged course of broad-spectrum antibiotics, have long-term catheter placement, immunocompromised, or IVDUs.[3,33] Survival rates remain poor, at approximately 15%, but improvements (survival rates ~30%) have been reported owing to advances in diagnosis

and treatment.[33] Poor prognosis has been attributed to large vegetations, propensity for organism invasion into the myocardium, extensive septic emboli, poor antifungal penetration into vegetations, and low toxic-to-therapeutic ratio and lack of cidal activity of certain antifungals.[30,33] The two most commonly associated organisms are *Candida* spp. and *Aspergillus* spp. Lack of clinical studies makes treatment decisions difficult. Typically, combination and/or high-dose therapy in conjunction with surgery is required.

## TREATMENT

### Therapeutic Considerations

Treatment of IE often is complicated and difficult. Numerous factors involving vegetations influence the effectiveness of antimicrobial agents. Vegetations consist of a fibrin matrix (as discussed earlier) that provides an environment where organisms are relatively free to replicate unimpeded, allowing the microbial density to reach very high concentrations ($10^9$–$10^{10}$ CFU/g). Once organism density has reached this level, the organisms are virtually in a static growth phase. These factors hinder host defenses, as well as the ability of antimicrobials to produce sufficient kill. This is often seen with β-lactams and glycopeptides as their effectiveness can be significantly affected by bacterial inoculum and stationary growth phase.

**KEY CONCEPT** *Selection of an appropriate antimicrobial agent must combine characteristics such as the ability to penetrate into the vegetation, the ability to achieve adequate drug concentrations, and the ability to be minimally affected by high bacterial inoculum in order to achieve adequate kill rates.*

**KEY CONCEPT** *To accomplish this, antimicrobials typically have to be given parenterally at high doses, with an extended treatment course of 4 to 6 weeks (in most cases).* Other desirable drug characteristics include bactericidal and synergistic activity.

### Empirical Therapy

**KEY CONCEPT** *The overall goal of therapy is to eradicate the infection and minimize/prevent any complications.* Patients with suspected IE should be evaluated for risk factors that may provide some indication of the most likely causative organism. If no risk factors can be determined, empirical therapy should primarily cover gram-positive organisms. Generally, if streptococci are suspected, empirical treatment should consist of penicillin plus gentamicin. However, if staphylococci or enterococci are suspected, empirical treatment should consist of vancomycin plus gentamicin. It is important to monitor the patient's response to therapy closely until cultures and susceptibilities are determined to ensure adequate treatment.

### Specific Therapy

The American Heart Association (AHA) has published guidelines for the management of IE, including specific treatment recommendations.[5] A summary of these treatments for the most common organisms (streptococci, staphylococci, and enterococci) is provided in Tables 74–3 through 74–6. However, for more detailed information, refer to the complete guidelines.[5]

#### ▶ Streptococci

Most isolates are highly susceptible to penicillin; therefore, penicillin G remains the regimen of choice. However, ceftriaxone may be used as an alternative agent if the patient is allergic or penicillin resistance is suspected. Typically, length of treatment is 4 weeks and remains the most common duration. However, a

## Patient Encounter, Part 2: Medical History, Physical Examination, and Diagnostic Tests

**PMH:** ESRD on hemodialysis (MWF), type 2 diabetes

**FH:** Mother had a history of hypertension and died at the age of 70 from a stroke; father's history is unknown

**SH:** She began dialysis 6 months ago. She denied alcohol, illicit drug, and tobacco usage

**Meds:** Novolog (insulin aspart) 90 units/24 hour basal rate with 20 units bolus prior to each meal via an insulin pump; sevelamer 800 mg three times daily; epogen 10,000 units post-HD

**Allergies:** No known allergies

**ROS:** Fatigue, decreased appetite

**PE:**

**VS:** BP 105/65 mm Hg, P 115 beats/min, RR 22 breaths/min, T 39.5°C

**Cardiovascular:** Tachycardia, positive new murmur

**Abd:** Normal weight, soft, nontender, nondistended; (–) bowel sounds

**Labs:** Within normal limits, except WBC = 18.6 × 10³/μL (18.6 × 10⁹/L), SCr = 4.2mg/dL (371 μmol/L)

*Given this additional information, what is your assessment of the patient's condition?*

*Identify your empirical treatment recommendations for this patient.*

*What other information would be beneficial to obtain?*

shorter course (ie, 2 weeks) may be employed for a patient with uncomplicated IE due to highly penicillin-susceptible strains with no extracardiac infection or whose creatinine clearance is greater than 20 mL/min (0.33 mL/s). If the shorter length of therapy is chosen, gentamicin should be added to the previous regimens for the entire course (ie, 2 weeks). Recommended therapies for highly penicillin-susceptible viridans streptococci are summarized in Table 74–3.

When penicillin MICs for viridans group streptococci are greater than 0.12 mcg/mL [0.12 mg/L] but less than or equal to 0.5 mcg/mL [0.5 mg/L], antimicrobial doses should be increased with 4 weeks therapy suggested. In addition, combination therapy with gentamicin is recommended during the first 2 weeks. In patients who are allergic or intolerant to β-lactams, vancomycin is an alternative treatment option. In patients with resistant strains of viridans group streptococci (MIC greater than 0.5 mcg/mL [0.5 mg/L]), treatment should include antimicrobial agents for enterococcal IE (precise agents determined by the susceptibility report).

Patients with PVE caused by penicillin-susceptible strains of viridans streptococci require treatment for 6 weeks with penicillin G or ceftriaxone with or without gentamicin during the initial 2 weeks of therapy. However, if the organism demonstrates less susceptibility to penicillin (MIC greater than > 0.12 mcg/mL [0.12 mg/L]), combination therapy with penicillin G or ceftriaxone plus gentamicin should be given for the entire 6 weeks. Vancomycin remains the primary alternative for β-lactam (eg, penicillins, cephalosporins) allergic patients.

▶ *Staphylococci*

It is important to determine (a) whether the isolate is methicillin-susceptible versus methicillin-resistant and (b) whether the patient has a native versus prosthetic valve. For patients with no prosthetic material, methicillin-susceptible staphylococcal treatment should consist of a penicillinase-resistant penicillin (eg, nafcillin or oxacillin) or cefazolin with or without gentamicin, and for methicillin-resistant strains, therapy should consist of vancomycin (see Table 74–4). Combination therapy with aminoglycosides, when used in these patients, typically is given only during the first 3 to 5 days of therapy to decrease bacterial burden. In the absence of prosthetic material, some treatment guidelines do not recommend combination therapy against MRSA. However, many clinicians may combine either gentamicin or rifampin with vancomycin if the patient is unresponsive to monotherapy.

Increasing resistance of staphylococci necessitates the expanded use of alternative therapies. Daptomycin demonstrated similar efficacy when compared with standard therapy (ie, penicillinase-resistant penicillin for methicillin-sensitive *S. aureus* [MSSA] or vancomycin for MRSA) in patients with staphylococcal IE and is FDA approved for the treatment of right-sided IE or bacteremia caused by *S. aureus*.[34] Recommended daptomycin dosing for these indications is 6 mg/kg/day (unless renal adjustments are necessary); although dosages of 8 to 10 mg/kg/day have been suggested in IE.[20,34] Daptomycin was shown to be safe and well tolerated.[34,35] Additionally, other antibiotics, such as ceftaroline, linezolid, quinupristin/dalfopristin, telavancin, or tigecycline alone or in combination, have been used in patients who were unresponsive to standard therapy, although they have had variable response rates.[36–39] These therapies often are reserved for patients who have been unresponsive to traditional therapy (eg, β-lactams or vancomycin) or for organisms that remain susceptible to these agents when resistant to traditional therapy.

**Table 74–6**

**Therapy for Native-Valve or Prosthetic-Valve Enterococcal Endocarditis Caused by Strains Susceptible to Penicillin, Gentamicin, and Vancomycin**

| Regimen | Dosage[a] and Route | Duration (weeks) | Strength of Recommendation[b] | Comments |
|---|---|---|---|---|
| Ampicillin sodium *OR* | 12 g/24 hour IV in six divided doses | 4–6 | IA | Native valve: 4-week therapy recommended for patients with symptoms of illness ≤ 3 months; 6-week therapy recommended for patients with symptoms > 3 months |
| Aqueous crystalline penicillin G sodium *plus* gentamicin sulfate[c] | 18–30 million units/24 hour IV either continuously or in six equally divided doses | 4–6 | IA | Prosthetic valve or other prosthetic cardiac material: minimum of 6 weeks of therapy recommended |
| | 3 mg/kg/24 hour IV/IM in three equally divided doses *Pediatric dose*[d]: ampicillin 300 mg/kg/24 hour IV in four to six equally divided doses; penicillin 300,000 units/kg/24 hour IV in four to six equally divided doses; gentamicin 3 mg/kg/24 hour IV/IM in three equally divided doses | 4–6 | | |
| Vancomycin hydrochloride[e] | 30 mg/kg/24 hour IV in two equally divided doses | 6 | IB | Vancomycin therapy recommended only for patients unable to tolerate penicillin or ampicillin |
| *plus* gentamicin sulfate | 3 mg/kg/24 hour IV/IM in three equally divided doses *Pediatric dose:* vancomycin 40 mg/kg/24 hour IV in two or three equally divided doses; gentamicin 3 mg/kg/24 hour IV/IM in three equally divided doses | 6 | | 6 weeks of vancomycin therapy recommended because of decreased activity against enterococci |

[a]Dosages recommended are for patients with normal renal function.

[b]IA, condition with evidence and/or general agreement that a procedure or treatment is useful and effective, based on data from multiple randomized clinical trials; IB, condition with evidence and/or general agreement that a procedure or treatment is useful and effective, based on data from a single randomized trial or nonrandomized studies.

[c]Dosage of gentamicin should be adjusted to achieve peak serum concentration of 3 to 4 mcg/mL (3–4 mg/L; 6.3–8.4 μmol/L) and a trough concentration of less than 1 mcg/mL (1 mg/L; 2.1 μmol/L). Patients with a creatinine clearance of less than 50 mL/min (0.83 mL/s) should be treated in consultation with an infectious diseases specialist.

[d]Pediatric dose should not exceed that of a normal adult.

[e]See Table 74–3 for appropriate dosage of vancomycin.

Reprinted with permission from Baddour LM, Wilson WR, Bayer AS, et al. American Heart Association Scientific Statement. Infective endocarditis: Diagnosis, antimicrobial therapy, and management of complications. Circulation 2005;111:e394–e433. ©2005, American Heart Association, Inc.

For staphylococcal PVE, treatment length increases significantly, typically requiring a minimum of 6 weeks (see Table 74–5). For MSSA, a penicillinase-resistant penicillin should still be used, as well as vancomycin for MRSA. However, with either regimen, addition of gentamicin for first 2 weeks and rifampin for the entire length of treatment is recommended. Infectious Diseases consultation is recommended for all patients with *S. aureus* IE, irrespective of methicillin-susceptibility, due to an observed reduction in mortality in this patient population.

▶ *Enterococci*

For enterococci, it is imperative to determine species and antibiotic susceptibilities. If the organism is susceptible to penicillin and vancomycin, treatment may consist of high-dose penicillin G, ampicillin, or vancomycin plus an aminoglycoside (gentamicin [see Table 74–6] or streptomycin for gentamicin-resistant strains). Treatment length is usually 4 to 6 weeks, with the aminoglycoside used over the entire course. As resistance develops to penicillin, ampicillin and vancomycin remain treatment options. If the isolate becomes resistant to ampicillin, vancomycin is considered the treatment of choice.

If the isolate is determined to be vancomycin-resistant, it is crucial to know the exact species because some treatment options, such as quinupristin/dalfopristin, are not active against *E. faecalis*. Treatment options for vancomycin-resistant enterococci (VRE) have not been well established. Currently,

recommendations for treating vancomycin-resistant *E. faecium* include linezolid or quinupristin/dalfopristin for a minimum of 8 weeks. However, newer agents, such as daptomycin, provide another option for treatment for either enterococci species (*E. faecium* and *E. faecalis*). The guidelines also suggest the use of imipenem/cilastatin plus ampicillin or ceftriaxone plus ampicillin for the treatment of *E. faecalis*, with a minimum of 8 weeks of therapy; although these regimens are not commonly used. Even with newer agents, combination therapy is often warranted; therefore, consultation with an infectious diseases specialist is recommended if VRE is identified.

### ▶ Gram-Negative Organisms

Identification of the exact pathogen is crucial in gram-negative IE as treatment decisions depend on which organism is isolated. Therapy is usually targeted to the most susceptible antibiotics. Combination therapy (usually the addition of an aminoglycoside) is commonly used. For example, *Pseudomonas* spp. are treated with an antipseudomonal β-lactam (eg, piperacillin/tazobactam, cefepime, imipenem/cilastatin) plus high-dose aminoglycoside (typically tobramycin 8 mg/kg/day). However, exact dosing of antibiotics depends on the organism isolated. Length of treatment is usually a minimum of 6 weeks.

### ▶ HACEK Group

The HACEK group bacteria are difficult to isolate, often taking weeks for identification. If one of these organisms is suspected, it is important to initiate appropriate empirical treatment. The preferred regimen is ceftriaxone (or another third- or fourth-generation cephalosporin), followed by ampicillin-sulbactam. However, for patients who are intolerant of these treatments, ciprofloxacin may be used. The length of treatment typically is 4 weeks for these organisms.

### ▶ Culture-Negative

Treatment for culture-negative IE presents a significant dilemma. Therapeutic regimens are guided by isolated organisms. When cultures fail to identify a specific organism, decisions regarding treatment should cover the most common causative pathogens. If the patient is unresponsive to this initial treatment, additional coverage for less common organisms becomes warranted. An infectious diseases specialist should be consulted for managing culture-negative IE.

### ▶ Fungi

Treatment of fungal IE is exceptionally difficult. There is a significant lack of evidence to identify the most appropriate therapy. Currently, amphotericin B is the most common treatment. However, valve replacement surgery is often considered a necessary adjunctive therapy. Intravenous antifungal therapy requires high doses for a minimum of 8 weeks of treatment. Oral azoles (eg, fluconazole) are used as long-term suppressive therapy to prevent relapse. Newer antifungals may be effective options, including the echinocandins (eg, caspofungin) and voriconazole, depending on the organism and susceptibilities.[33]

## Surgery

Surgical intervention has become an integral therapy in combination with pharmacologic management of IE. Valve replacement is the predominant intervention, and is used in almost one-half of all cases of IE.[1] Surgery may be indicated if the patient has unresolved infection, ineffective antimicrobial therapy, more than one episode of serious emboli, refractory congestive heart failure, significant valvular dysfunction, mycotic aneurysm requiring resection, local complications (perivalvular or myocardial abscesses), or prosthetic-valve infection associated with a pathogen demonstrating higher antimicrobial resistance.[40,41] Often a patient's hemodynamic status (ie, blood pressure, heart rate, pulmonary artery pressure, etc) is used to determine when surgical intervention is warranted.[1] Despite appropriate medical management and cure, a significant number of people who develop native-valve endocarditis require valve replacement surgery. Involvement of the aorta or development of IE complications is considered an indication for surgery in the majority of patients with PVE.[42,43]

## Antimicrobial Dosing Considerations

The majority of antibiotic and antifungal agents used for the treatment of IE require dosing modifications based on renal or hepatic function. However, the most closely monitored are vancomycin and aminoglycosides. This is due in part because (a) serum levels are normally monitored to guide therapy, and (b) there is an increased likelihood of developing toxicities (ie, nephrotoxicity, ototoxicity) if the level is too high or adverse outcomes (ie, clinical failure or resistance development) if level is too low. General dosing considerations are included in for

**Table 74–7**

**Dosage Considerations for Standard Antibiotics for Treatment of IE[a]**

| Drug | Renal Adjustments | Hepatic Adjustments | Comments |
|---|---|---|---|
| Penicillin G | Required | None | Extension of dosing interval primarily used for adjustment |
| Ampicillin | Required | None | Seizures most common AE if dosing not adjusted |
| Nafcillin | None | Severe (see comment) | Adjustments necessary ONLY in patients with severe hepatic AND renal impairment |
| Oxacillin | Severe (see comment) | None | Adjustments for CrCl < 10 mL/min (0.17 mL/s) to lower range of normal dose |
| Cefazolin | Required | None | Dose and/or dosing interval require adjustment. Based on patient's CrCl |
| Ceftriaxone | Severe (see comment) | None | Do not exceed 2 g/day if patient has BOTH severe renal AND hepatic impairment |
| Vancomycin | Required | None | Monitor therapeutic levels to guide dosage adjustments (see treatment guidelines for target ranges) |
| Gentamicin | Required | None | Used for synergy only with gram-positives. Therapeutic levels vary for gram-negative organisms<br>Monitor therapeutic levels to guide dosage adjustments<br>Synergy target levels: peak 3–4 mcg/mL (3–4 mg/L; 6.3–8.4 µmol/L) and trough < 1 mcg/mL (1 mg/L; 2.1 µmol/L) |
| Rifampin | None | Required | Adjustment based on hepatic dysfunction |
| **Newer and Salvage Drugs** | | | |
| Ceftaroline | Required | None | Adjustments in dose (33%–67% reduction) are based on patient's CrCl. Suggested dosages in off-label use for IE are higher than standard dosing (ie, 600 mg every 8 hours) |
| Daptomycin | Required | None | Adjustment in dosing interval CrCl < 30 mL/min (0.50 mL/s)<br>CPK should be monitored prior to and during therapy |
| Linezolid | None | None | Metabolites may accumulate in severe renal impairment<br>Monitor for hematologic AE<br>Use in severe hepatic impairment not established |
| Quinupristin/ dalfopristin | None | Possibly | Adjustments suggested based on pharmacokinetic data. However, no specific recommendations are described |
| Telavancin | Required | None | Decrease daily dose by 25% if CrCl 30–50 mL/min (0.50–0.83 mL/s) or if CrCl < 30 mL/min (0.50 mL/s)—extend interval to every 48 hours |
| Tigecycline | None | Severe (see comment) | In severe hepatic impairment (Child-Pugh class C)—decrease maintenance dose 50% |
| Streptomycin | Required | None | Used for synergy only with gram-positives. Therapeutic levels vary for gram-negative organisms<br>Monitor therapeutic levels to guide dosage adjustments<br>Synergy target levels: peak 20–35 mcg/mL (20–35 mg/L; 34–60 µmol/L) and trough < 10 mcg/mL (10 mg/L; 17 µmol/L) |

AE, adverse event; CPK, creatinine phosphokinase; CrCl, creatinine clearance.

[a]Gram-negative bacteria, fungal, or atypical treatments are not listed. It is suggested that an Infectious Diseases Consult be obtained if a patient has IE caused by one of these organisms due to the complexity and difficulty in managing these patients.

the most commonly used drugs for treating IE. However, specific dosing adjustments for individual patients should be determined by referring to an appropriate drug dosing reference.

## Prophylaxis

KEY CONCEPT *Certain conditions have been associated more commonly with IE due to preexisting cardiac disease in the presence of a transient bacteremia. In an effort to prevent the development of IE, prophylactic treatment is generally considered appropriate for these at-risk patients.* Although there are no well-controlled clinical studies of these recommendations, it is thought that if antibiotics are given just prior to a procedure, the number of bacteria may be decreased in the bloodstream and prevent the bacteria from adhering to the valves.

Cardiac conditions in which prophylaxis is reasonable include presence of prosthetic valves or material, prior IE, congenital cardiac disease (specific forms only), and cardiac transplant patients with cardiac valvulopathy (Table 74–8).[6] Although many patients have other cardiac dysfunction, only patients with these conditions are considered to be at a high risk of developing IE. No prophylaxis is advised in other patients.

Transient bacteremia may occur due to many types of dental and surgical procedures. However, the AHA guidelines significantly limit the types of procedures where prophylaxis is appropriate. Only dental procedures involving manipulation of gingival tissue or periapical region of teeth or perforation of the oral mucosa are considered to increase the likelihood that high-risk patients will develop IE.[6] Viridans group streptococci are the primary bacteria targeted for prophylaxis in this circumstance. On the other hand, prophylaxis for GI or genitourinary surgeries primarily targets enterococci.

The AHA guidelines include suggested antibiotic regimens for dental procedures for which prophylaxis is warranted.[6] Recommended regimens for dental procedures are listed in Table 74–9.

**Table 74–8**

**Cardiac Conditions Associated with the Highest Risk of Adverse Outcome from Endocarditis for Which Prophylaxis with Dental Procedures Is Reasonable[a]**

Prosthetic cardiac valve or prosthetic material used for cardiac-valve repair

Previous IE

Congenital heart disease[b]

Unrepaired cyanotic congenital heart disease, including palliative shunts and conduits

Completely repaired congenital heart defect with prosthetic material or device, whether placed by surgery or by catheter intervention, during the first 6 months after the procedure[c]

Repaired congenital heart disease with residual defects at the site or adjacent to the site of a prosthetic patch or prosthetic device (which inhibit endothelialization)

Cardiac transplantation recipients who develop cardiac valvulopathy

[a]*All dental procedures* that involve manipulation of gingival tissue or the periapical region of teeth or perforation of the oral mucosa is reasonable to give prophylaxis in the patient conditions listed above.

[b]Except for the conditions listed above, antibiotic prophylaxis is no longer recommended for any other form of CHD.

[c]Prophylaxis is reasonable because endothelialization of prosthetic material occurs within 6 months after the procedure.

These guidelines recommend a single oral or intramuscular/intravenous dose initiated shortly before the procedure. The regimen for dental procedures consists primarily of a penicillin as first choice, with a cephalosporin for penicillin-allergic patients who have not had an anaphylactic reaction and clindamycin or a macrolide for penicillin-allergic patients. A second prophylactic dose is not recommended. However, if an infection develops

**Patient Encounter, Part 5: Create a Care Plan**

Based on this patient's information, create a care plan for the management of her IE. Be sure to include:

*(a) A statement regarding treatment requirements and/or possible problems*

*(b) Goals of therapy*

*(c) A patient-specific plan, including preventive plans*

*(d) A follow-up plan to assess whether the goals have been met and to determine whether the patient experienced any adverse effects*

at the procedure site, additional antibiotics (ie, a therapeutic course) may be required.

## OUTCOME EVALUATION

KEY CONCEPT *Monitoring for successful therapy is critical for this serious infection to prevent complications, prevent development of resistance, and decrease mortality.* Routine assessment of clinical signs and symptoms, as well as laboratory tests (ie, repeat blood cultures), microbiologic testing, and serum drug concentrations (if appropriate), must be performed.

Resolution of signs and symptoms typically occurs within a few days to a week in most cases. Monitor the patient daily for febrile episodes, as well as other vital signs, with expected normal values within 2 to 3 days of initiating antimicrobial therapy.[4] Persistent signs or symptoms could be indicative of inadequate treatment or development of resistance.

Blood cultures are the primary laboratory evaluation to assess response to therapy. Typically, with appropriate treatment, they should become negative within 3 to 7 days. Perform additional blood cultures if the patient appears unresponsive to current therapy or upon treatment completion to confirm eradication of infection. Evaluate all susceptibility reports to assess for appropriateness of antimicrobial therapy.

**Table 74–9**

**Prophylactic Regimens for Dental Procedure**

| Situation | Agent | Regimen: Single Dose 30–60 Minutes Before Procedure | |
|---|---|---|---|
| | | **Adults** | **Children** |
| Oral | Amoxicillin | 2 g | 50 mg/kg |
| Unable to take oral medications | Ampicillin or Cefazolin or Ceftriaxone | 2 g IM or IV | 50 mg/kg IM or IV |
| Allergic to penicillins or ampicillin—oral | Cephalexin[a,b] or Clindamycin or Azithromycin or Clarithromycin | 2 g<br>600 mg<br>500 mg | 50 mg/kg<br>20 mg/kg<br>15 mg/kg |
| Allergic to penicillins or ampicillin and unable to take oral medications | Cefazolin or Ceftriaxone[b] or Clindamycin | 1g IM or IV<br>600 mg IM or IV | 50 mg/kg IM or IV<br>20 mg/kg IM or IV |

IM, intramuscular.

[a]Or other first- or second-generation oral cephalosporin in equivalent adult or pediatric dosage.

[b]Cephalosporins should not be used in an individual with a history of anaphylaxis, angioedema, or urticaria with penicillins or ampicillin.

Reprinted with permission from Wilson W, Taubert KA, Gewitz M, et al. Prevention of infective endocarditis: Guidelines from the American Heart Association. Circulation 2007;116:1736–1754. © 2007, American Heart Association, Inc.

## Patient Care Process

**Patient Assessment:**

- Review patient history (social, medical, and surgical), physical exam, laboratory tests (especially blood cultures) and diagnostic imaging (particularly echocardiogram results), assess whether patient has clinical features of IE utilizing modified Duke criteria (see Table 74–2).
- Review patient past medical and medication history. Does patient have any allergies which could limit antimicrobial therapy? Does patient have any risk factors for resistant-pathogens (prior use of broad-spectrum antibiotics, multiple hospital admissions, hemodialysis patient, etc)?
- Conduct a personal history to identify possible causes of IE.

**Therapy Evaluation:**

- Once blood culture identification/susceptibility reported, determine if patient is on appropriate antimicrobial therapy.
- If bacteremia not cleared after repeat blood cultures, reassess appropriateness of antimicrobial(s) including new cultures/susceptibility and drug dosage and/or frequency.
- Monitor subsequent blood cultures for growth. Determine end of therapy based on first negative blood culture.
- Monitor vital signs/symptoms for return to baseline. If continued to be abnormal, reassessment of therapy/other diagnostic testing is necessary.

- Is patient experiencing any adverse effects from their antimicrobial(s)? Are there any potential drug–drug interactions from this medication?
- Determine whether recommended agent is on institution's formulary. If not, is there a formulary alternative? If no alternative, is there anything specific to institution to utilize nonformulary agent?
- Determine whether patient has prescription coverage. Is patient able to afford medication if completing therapy as an outpatient?

**Care Plan Development:**

- Determine whether drug doses are optimal. Change therapy if pathogen not susceptible to current antimicrobial(s) or if patient not improving on current therapy.
- Address any patient concerns about IE and its management.
- Discuss importance of lifestyle modifications if applicable.

**Follow-Up Evaluation:**

- Follow-up with blood cultures and physical exam. Review medical history and any other pertinent laboratory tests and results of other diagnostic tests.
- Discuss with patient preventative antibiotics prior to future invasive dental procedures.

---

Additionally, counsel patients at risk on the necessity of prophylactic antibiotics prior to major dental treatments in order to prevent recurrent infections. This is critical in patients with risk factors that predispose them to developing IE, such as prosthetic heart valves, other valvular defects, or previous IE.

Develop a follow-up plan to determine whether the patient has achieved a cure, which includes a clinical evaluation of signs/symptoms, repeat blood cultures, and possibly a repeat echocardiogram. The patient should also be assessed for any adverse events. This should be performed usually within a few weeks after the completion of therapy.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| AHA | American Heart Association |
| CFU | Colony-forming units |
| CNS | Coagulase-negative staphylococci |
| ESR | Erythrocyte sedimentation rate |
| HACEK | Group of bacteria consisting of *Haemophilus* spp., *Aggregatibacter actinomycetemcomitans*, *Cardiobacterium hominis*, *Eikenella corrodens*, and *Kingella kingae* |
| IE | Infective endocarditis |
| IVDUs | Intravenous drug users |
| MIC | Minimum inhibitory concentration |
| MRSA | Methicillin-resistant *S. aureus* |
| MSSA | Methicillin-sensitive *S. aureus* |
| NBTE | Nonbacterial thrombotic endocarditis |
| PVE | Prosthetic-valve endocarditis |
| TEE | Transesophageal echocardiogram |
| TTE | Transthoracic echocardiogram |
| VRE | Vancomycin-resistant enterococci |

# 75 Tuberculosis

Rocsanna Namdar, Michael Lauzardo, and Charles Peloquin

## LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Compare the risk for active tuberculosis (TB) disease among patients based on their age, immune status, place of birth, and time since exposure to an active case.

2. Design an appropriate therapeutic plan for a patient with active TB disease.

3. Distinguish among the diagnostic tests used for patients potentially infected with TB.

4. Assess the effectiveness of therapy in TB patients.

5. Describe the common and important adverse drug effects caused by TB drugs.

6. Select patients for whom therapeutic drug monitoring (TDM) may be valuable and identify the necessary laboratory monitoring parameters for patients on antituberculosis medications.

7. Design appropriate antimicrobial regimens for the treatment of latent TB infection.

## INTRODUCTION

Tuberculosis (TB) remains one of the leading infectious causes of death worldwide. In 2012, about 8.6 million people developed TB and 1.3 million people died from the disease.[1] Most deaths are preventable if access to health care for diagnosis and correct treatment are provided.

## EPIDEMIOLOGY AND ETIOLOGY

**KEY CONCEPT** *Roughly one-third of the world's population is infected and drug resistance is increasing in many areas.[1] The majority of cases worldwide are found in South-East Asia and Africa. In the United States, about 13 million people have latent TB infection (LTBI), evidenced by a positive skin test (*purified protein derivative *[PPD]) but no signs or symptoms of disease.* The PPD is the antigen derived from *Mycobacterium tuberculosis* used to determine the presence of an immune response in patients with previous exposure. Patients testing positive have roughly a 1 in 10 chance of active disease during their lives, with the greatest risk in the first 2 years after infection. In 2013, 9588 new TB cases were reported in the United States; a 4.2% decline from 2012.[2]

The most recent data from the Centers for Disease Control and Prevention (CDC) indicate that TB deaths in the United States have increased slightly to 7.6%, from 529 deaths in 2009 to 569 deaths in 2010.[3] (For details, visit the CDC website at www.cdc.gov/nchstp/tb.)

### Risk Factors for Infection

#### ▶ Location and Place of Birth

California, New York, Florida, and Texas accounted for approximately 50% of all TB cases in 2013.[2] These higher numbers may reflect the high immigration rates into these states.[2] Mexico, the Philippines, Vietnam, India, and China account for the largest numbers of these immigrants.[2] TB is most prevalent in large urban areas and is exacerbated by crowded living conditions.[2] Those in close contact with patients with active pulmonary TB are most likely to become infected.[2,3]

#### ▶ Race, Ethnicity, Age, and Gender

● *In 2012, Asians accounted for 30% of new TB cases, followed by Hispanics (28%) and African Americans (22%), whereas non-Hispanic whites accounted for 16% of new TB cases in the United States.[3] TB is most common among people 25 to 44 years of age, and those 45 to 64 years of age.[3]*

### Risk Factors for Disease

● *Once infected, a person's lifetime risk of active TB is about 10%, with about half this risk during the first 2 years.[2–4] Young children, the elderly, and immunocompromised patients have greater risks.* **KEY CONCEPT** *HIV is the most important risk factor for active TB because the immune deficit prevents patients from containing the initial infection.[1–4] HIV-infected patients with M. tuberculosis infection are roughly 100 times more likely to develop active TB than normal hosts.[1,3,4]*

TB is caused by *M. tuberculosis*, a rod-shaped thin aerobic bacterium. It presents either as LTBI or as progressive active disease.[4] The latter typically causes progressive destruction of the lungs, leading to death in most patients who do not receive treatment. *M. tuberculosis* are acid-fast bacilli (AFB). Acid-fast organisms are characterized by wax-like nearly impermeable cells walls which often do not stain with Gram stain and cannot be decolorized by acid alcohol. The cell wall contains a high amount of mycolic acids, long-chain fatty acids, and cell wall lipids which make the wall difficult to attack with conventional antibiotics. The acid-fast stain is a differential stain used to identify acid-fast organisms.

## Culture and Susceptibility Testing

**KEY CONCEPT** *Microscopic examination of infected material ("sputum smear" of material on a glass slide) is the most rapid and readily available test to detect AFB in clinical specimens.* Three sputum specimens should be collected in patients suspected of pulmonary TB to increase the likelihood of finding AFB. *The sensitivity of the sputum smear is only about 40%, so culture based TB diagnosis is the current gold standard.*[5] Unfortunately, culture is much slower due to the roughly 20-hour doubling time of the bacilli. Furthermore, microscopic examination for AFB through sputum smear alone cannot determine which of over 100 mycobacterial species is present. Depending on the presence of epidemiological risk factors, the usual practice is to isolate the patient and treat empirically until presence of *M. tuberculosis* is confirmed by genetic probe or positive culture.

Antimicrobial susceptibility testing is essential for directing proper treatment. The most common method utilizing solid growth media, known as the *proportion method,* takes 3 to 8 weeks to produce results. Growth in liquid media is faster and can detect live mycobacteria in about 2 weeks.[5,6] Rapid-identification tests include nucleic acid amplification tests utilizing the polymerase chain reaction (PCR).[7-9] Three nucleic acid amplification tests have been approved for use in the United States to detect *M. tuberculosis* in respiratory secretions. These tests are highly sensitive and specific for smear positive patients and somewhat less sensitive in smear negative patients, but only need as few as 1 to 10 organisms/mL ($10^3$–$10^4$/L) to give a positive result.[7-9]

---

### Patient Encounter, Part 1

**HPI:** AF is a 43-year-old man who presents to the medical clinic complaining of a 2-month history of a persistent cough that has become productive over the past 3 weeks. He also complains of fever, malaise and a 6-kg (13-lb) weight loss over the past 2 months.

**PMH:** Type 2 diabetes mellitus (NIDDM)—not well controlled; hypertension (HTN) × 5 years—not controlled, rheumatoid arthritis

**FH:** Mother and father died in an MVA 10 years ago; one brother, age 50, lives with the patient; one sister, age 53, is alive and currently undergoing chemotherapy treatment for breast cancer

**SH:** Born and raised in Mexico city until the age of 19 when he moved to Los Angeles, California. Single, one daughter. He reports IV drug use but last use was 5 years ago. He had a 20-year history of alcohol abuse but has been sober for 5 years. He owns his own import/export business and travels internationally to Mexico and parts of South America

**Meds:** Lisinopril 20 mg daily; amlodipine 5 mg daily; metformin 500 mg twice daily, adalimumab 40 mg every other week. Patient reports that he tries to be compliant with his therapies and takes them regularly except when he is unable to get his refills; over the past 2 months, he has only gone 3 to 4 days without medication

*What information is suggestive of TB?*

*What factors place this patient at increased risk for acquiring TB?*

---

The Cepheid MTB/RIF Assay performed on the Xpert System is a qualitative test designed for rapid detection of *M. tuberculosis* and rifampin resistance.[10] New tests looking for specific mutations such as the katG gene associated with isoniazid resistance may facilitate rapid drug therapy decisions in the future. Nitrate reductase assays and porous ceramic support systems are among other rapid drug susceptibility testing techniques currently being investigated.[11] DNA fingerprinting is performed to assist surveillance programs and contact investigations. Various techniques are employed including restriction fragment length polymorphism (RFLP) analysis, spoligotyping, and mycobacterial interspersed repeat units. These techniques exploit conserved fragments in the TB genome that change gradually over time and allow investigators to determine if strains are related to one another. Strains that are related to one another are referred to as clusters. Clusters generally indicate recent transmission and are then targeted for interventions by TB programs.[12]

## PATHOPHYSIOLOGY

### Primary Infection

**KEY CONCEPT** *M. tuberculosis* is transmitted from person to person by coughing or any other aerosol producing activities.[4,13] This produces small particles known as *droplet nuclei* that float in the air for long periods of time. Primary infection usually results from inhaling droplet nuclei that contain *M. tuberculosis*.[4,13] The progression to clinical disease depends on three factors: (1) the number of *M. tuberculosis* organisms inhaled (infecting dose), (2) the virulence of these organisms, and (3) the host's cell-mediated immune response.[4,13,14] If pulmonary macrophages inhibit or kill the bacilli, the infection is aborted.[13] If not, *M. tuberculosis* eventually spreads throughout the body through the bloodstream.[4,13] *M. tuberculosis* most commonly infects the posterior apical region of the lungs, where conditions are most favorable for its survival.

T lymphocytes become activated over the course of 3 to 4 weeks, producing interferon-γ (IFN-γ) and other cytokines. These stimulate microbicidal macrophages to surround the tuberculous foci and form granulomas to prevent further extension.[13] A granuloma is a nodular aggregation of mononuclear inflammatory cells formed when the immune system attempts to wall off foreign substances. At this point, the infection is largely under control, and bacillary replication falls off dramatically. Any remaining mycobacteria are believed to reside primarily within granulomas or within macrophages that have avoided detection and lysis. Over 1 to 3 months, tissue hypersensitivity occurs, resulting in a positive tuberculin skin test.[4,13] Approximately 95% of individuals with an intact immune system will enter into this latent phase. **KEY CONCEPT** *Progressive primary disease occurs in roughly 5% of patients, especially children, the elderly, and immunocompromised patients.*[15] *This presents as a progressive pneumonia and frequently spreads, leading to meningitis and other severe forms of TB, often before patients develop positive skin tests or interferon-γ release assays.*[15]

### Reactivation Disease

About 10% of infected patients develop reactivation TB, with half occurring in the first 2 years after infection.[4,8] Reactivation TB results when a previously "dormant" focus is reactivated and causes disease. Progression involves the development of caseating granulomas as a result of a vigorous immune response. Liquefaction leads to local spread and a pulmonary cavity results. This provides a portal to the airways and subsequently ambient

air that enhances person-to-person spread. Bacterial counts in the cavities can be as high as $10^8$/mL ($10^{11}$/L) of cavitary fluid.[4,13] Prior to the chemotherapy era, pulmonary TB usually was associated with hypoxia, respiratory acidosis, and eventually death related to asphyxia; a fate that remains all too common in poor countries where patients do not have access to effective therapy.

### Extrapulmonary and Miliary Tuberculosis

Caseating granulomas, regardless of location, can spread tubercle bacilli, and cause symptoms.[4] Because of muted or altered symptoms, the diagnosis of TB is difficult and often delayed in immunocompromised hosts.[4,13] HIV-infected patients may present with only extrapulmonary TB, which is uncommon in HIV-negative persons. A widely disseminated form of the disease called *miliary TB* can occur, particularly in children and immunocompromised hosts. It can be rapidly fatal and immediate treatment is required.[13]

### Influence of HIV Infection on Pathogenesis

HIV infection is the most important risk factor for active TB.[13] As CD4+ lymphocytes multiply in response to the mycobacterial infection, HIV multiplies within these cells and selectively destroys them, gradually eliminating the TB-fighting lymphocytes.[16,17] HIV-positive patients often have negative skin tests and fail to produce cavitary lesions, and fever may be absent.' Cavitary lesions are present in a wide variety of pathological processes involving the lung and are observed radiographically as gas or fluid filled areas of the lung in the center of a nodule. Approximately 5% of HIV-infected patients with pulmonary TB who are not being treated effectively with antiretroviral medications will have positive results on acid-fast staining, yet have a normal chest radiograph. Patients coinfected with HIV and TB have a substantially higher risk of early mortality compared with HIV-negative patients with TB.[17]

## CLINICAL PRESENTATION AND DIAGNOSIS

Fever, night sweats, weight loss, fatigue, and a productive cough are the classic symptoms of TB.[4,13,14] Onset may be gradual, and the diagnosis is easily missed if the symptoms are muted.[4,13,14] Progressive pulmonary disease leads to cavitary lesions visible on x-ray. Physical examination is nonspecific but may be consistent with pneumonia. Dullness to chest percussion, rales, and increased vocal fremitus may be observed on examination. Laboratory data often are uninformative, but a modest increase in the white blood cell (WBC) count with a lymphocytic predominance can be seen. Frequently however, the physical exam is largely unremarkable.

Atypical presentations are common in patients coinfected with HIV.[4,13,17] Symptoms for these patients range from classic pulmonary to muted and nonspecific. Extrapulmonary TB typically presents either as a slowly progressive decline in the effected organ's function or commonly as a mass lesion. Lymphadenopathy is relatively common.[13,14] Abnormal behavior, headaches, or convulsions suggest tuberculous meningitis, although other acute central nervous system (CNS) infections must be excluded.[4,14]

### The Elderly

*Positive skin tests, fevers, night sweats, sputum production, or hemoptysis may be absent, making TB hard to distinguish from other bacterial or viral infections or chronic lung diseases.*[4,18,19] In contrast, mental status changes are twice as common in the

elderly, and CNS disease must be considered when TB is entertained. Mortality is six times higher in the elderly, in part owing to delays in diagnosis.[4,18,19]

### Children

*TB in children may present as atypical bacterial pneumonia, and often involves the lower and middle lobes.*[4,14,19] Extrapulmonary TB is more common in children. The Bacille Calmette-Guérin (BCG) is a vaccine made from strains of tubercle bacilii and is used to produce immunity against human TB. It is administered in countries where TB remains common appears to stimulate children's immune systems to ward off the most serious forms of the disease. In fact, BCG is most effective in reducing infant mortality from TB meningitis and miliary disease. BCG does not block infection, and these same children often experience reactivation TB as young adults.

### Skin Testing

TB skin testing with PPD (commercially available as Tubersol or Aplisol) is one of the oldest diagnostic tests still in clinical use.[4,14,16] Also known as the tuberculin skin test, the product is injected into the skin (not subcutaneously) with a fine (27-gauge) needle, a technique referred to as the Mantoux method, and produces a small, raised, blanched wheal to be read by an experienced professional in 48 to 72 hours. The chance of a false-negative result is increased when the patient is immunosuppressed. The CDC does not recommend the routine use of anergy panels to determine if a patient's T-cell immune system reacts to common antigens.[16,20]

Criteria for interpretation are listed in Table 75–1.[14]

The "booster effect" occurs in patients who do not respond to an initial skin test but show a positive reaction if retested 1 to 3 weeks later.[14,20] In order to reduce the likelihood that a boosted reaction is misinterpreted as a new infection, the two-step method is recommended at the time of initial testing for individuals such as health care workers or nursing home residents who may be tested periodically. If the first PPD skin test is negative, repeat the test in 1 to 3 weeks. If the second test is positive, it is most likely a boosted reaction, and the person should be classified as previously infected.

### Newer Diagnostic Tests

Newer technology has led to the development of blood tests or interferon-γ release assays (IGRAs) that may replace the PPD test.[20] These methods measure the release of interferon-γ in blood in response to TB antigens. The sensitivity of IGRAs ranges from 80% to 90%, and specificity of 95% for diagnosis of latent TB. The IGRAs do not cause the booster phenomenon and are unaffected by BCG, or infection by most nontuberculosis mycobacteria. Results of the IGRAs are available in less than 24 hours, versus the 3 days required for the traditional PPD skin test. Data are limited for use of IGRAs in children younger than 5 years of age, persons recently exposed to TB, health care workers, and immunodeficient patients.[20] **KEY CONCEPT** *The CDC has endorsed the use of IGRA tests in all circumstances where the PPD is used.* IGRAs are approved for the diagnosis of LTBI in HIV-infected patients, but sensitivity is diminished.[20] *IGRAs are preferred for testing patients who have received BCG and in patients who have poor rates of return for PPD skin test reading.* Testing with both PPD and IGRA generally is not recommended, but may be useful in certain situations (eg, if the initial PPD test is negative and the risk for infection, clinical suspicion, or the

---

**Table 75–1**

**Criteria for Tuberculin Positivity, by Risk Group**

| Reaction ≥ 5 mm of Induration | Reaction ≥ 10 mm of Induration | Reaction ≥ 15 mm of Induration |
|---|---|---|
| HIV-infected persons | Recent immigrants (ie, within the last 5 years) from high-prevalence countries | Persons with no risk factors for TB |
| A recent contact of a person with TB disease | Injection drug users | |
| Fibrotic changes on chest radiograph consistent with prior TB | Residents and employees[a] of the following high-risk congregate settings: prisons and jails, nursing homes and other long-term facilities for the elderly, hospitals and other health care facilities, residential facilities for patients with AIDS, and homeless shelters | |
| Patients with organ transplants and other immunosuppressed patients (receiving the equivalent of 15 mg/day or more of prednisone for 1 month or longer, taking TNF-α antagonists)[b] | Mycobacteriology laboratory personnel, persons with the following clinical conditions that place them at high risk: silicosis, diabetes mellitus, chronic renal failure, some hematologic disorders, other specific malignancies, gastrectomy, and jejunoileal bypass | |
| | Children younger than 4 years of age or infants, children, and adolescents exposed to adults at high risk | |

[a]For persons who are otherwise at low risk and are tested at the start of employment, a reaction of 15 mm or more of induration is considered positive.

[b]Risk of TB in patients treated with corticosteroids increases with higher dose and longer duration.

---

risk for poor outcome is high; or if the initial PPD test is positive and additional evidence of infection is required; or the patient has a low risk of infection or progression).[20,21] IGRAs, and for that matter the PPD, should not be used to rule in or rule out the diagnosis of active TB disease.[21]

## TREATMENT

### General Approaches to Treatment

The primary treatment approach is the use of antimicrobials active against *M. tuberculosis*. Monotherapy can be used only for patients with LTBI, as evidenced by a positive skin test or positive IGRA in the absence of signs or symptoms of disease. Once active disease is present, typically *three or four drugs* must be used simultaneously from the outset of treatment.[4,13,20,16] The shortest duration of treatment is 4 months in the unusual case of smear and culture negative clinical cases of pulmonary TB, and up to 2 years of treatment may be necessary for advanced cases of Multidrug-resistant tuberculosis (MDR-TB).[20,22] Directly observed treatment (DOT) is a method used to ensure adherence in which patients are directly observed by a health care worker while taking their antituberculosis medication.[23] This also is a cost-effective way to ensure completion of treatment.

### Desired Outcomes

*Steps should be taken to (a) prevent the spread of TB (respiratory isolation); (b) find where TB has already spread (contact investigation); and (c) return the patient to a state of normal weight and well-being.* Items (a) and (b) are performed by public health departments. Clinicians involved in the treatment of TB should verify that the local health department has been notified of all new cases of TB. In rare instances, surgery may be needed.[16]

### Pharmacologic Therapy

#### ▶ Treating LTBI

KEY CONCEPT *Isoniazid is used for treating LTBI. Typically, isoniazid 300 mg daily (5–10 mg/kg of body weight) is given alone for 9 months. Lower doses usually are less effective.*[16] *In some instances, a 6 month duration of treatment with isoniazid alone is an acceptable alternative. Pyridoxine (25–50 mg/day in adults) can reduce the risk of peripheral neuropathy.*[16,24] Treatment of LTBI reduces a person's lifetime risk of active TB from about 10% to about 1%.[16,24] Rifampin 600 mg daily for 4 months can be used when isoniazid resistance is suspected or when the patient cannot tolerate isoniazid.[16,24] Rifabutin 300 mg daily might be substituted for rifampin in patients at high risk of drug interactions.[25] The combination of pyrazinamide and rifampin is no longer recommended.[25,26] Once-weekly doses of isoniazid 900 mg and rifapentine 900 mg given as DOT for 3 months are as effective as 9 months of self-administered isoniazid 300 mg daily.[27] When resistance to isoniazid and rifampin is suspected, there is no regimen proven to be effective (Table 75–2).[24] Note that patients with LTBI are not infectious and there is no isolate on which to perform susceptibility testing. Susceptibility patterns must be inferred based on the most likely source of infection.

#### ▶ Treating Active Disease

In the United States, TB patients can receive free treatment through the local health department. Treating active TB disease requires combination chemotherapy. KEY CONCEPT *Generally, four drugs are started. In particular, isoniazid and rifampin should be included because they are the best drugs available for preventing drug resistance.*[16,24] *Drug susceptibility testing should be done on the initial isolate for all patients.*[16,24] Susceptibility testing is repeated if the patient remains culture-positive 8 weeks or more into therapy.[22]

*The standard TB treatment regimen for susceptible TB is isoniazid, rifampin, pyrazinamide, and ethambutol for 2 months, followed by isoniazid and rifampin for 4 months, for a total of 6 months of treatment.*[16,24] *Extending treatment to 9 months of isoniazid and rifampin treatment is recommended for patients at greater risk of failure and relapse, including those with cavitary lesions on initial chest radiograph and positive cultures at the completion of the initial 2-month phase of treatment, as well as for patients treated initially without pyrazinamide. Ideally, treatment should be continued for at least 6 months from the time*

**CXR:** Bilateral upper lobe infiltrates with cavitary lesions on left; small left pneumothorax

**Clinical Course:** The patient was admitted and placed on respiratory isolation. Three separate sputum AFB stain specimens were reported to contain 3+ AFB. IFN-γ was sent and a PPD tuberculin skin test was placed. Sputum samples were sent for AFB, fungi, and bacterial cultures and sensitivities. After 48 hours, the PPD skin test was read as a 7-mm area of induration

**Assessment:** Active pulmonary TB; pneumothorax; hypertension; type 2 diabetes mellitus; rheumatoid arthritis

*Which signs, symptoms, and other findings are consistent with active TB infection?*

---

*that patients convert to a negative culture.*[16,24] When the patients' sputum smears convert to negative, the risk of infecting others is greatly reduced, but it is not zero.[10,24] Such patients can be removed from respiratory isolation if they are responding clinically. The decision to discontinue isolation should be done by medical providers experienced in TB control. **Table 75–3** shows the recommended treatment regimens. When intermittent therapy is used, DOT is essential. Doses missed during an intermittent TB regimen decrease the efficacy of the regimen and increase the relapse rate.

Adjustments to the regimen should be based upon susceptibility data.[8,24] Drug resistance should be suspected in patients who have been treated previously for TB. If adjustments are needed, two or more drugs with in vitro activity against the patient's isolate and that were not used previously should be added to the regimen.[8,24] When isoniazid and rifampin cannot be used, either because of drug resistance or intolerance, treatment durations typically become 2 years or more, regardless of immune status.[8,24,28] TB specialists should be consulted regarding cases of drug-resistant TB, or whenever treatment is uncertain.[8,24] Therapeutic drug monitoring (TDM) can direct dosing for such patients. One of the proven reasons for treatment failure is malabsorption of orally administered drugs.[24,28,29] **KEY CONCEPT** *Due to the risk of further drug resistance, it is critical to avoid adding only a single drug to a failing regimen.*[8,24]

| Table 75–2 | | | | | |
|---|---|---|---|---|---|
| **Recommended Drug Regimens for Treatment of LTBI in Adults** | | | | | |
| **Drug** | **Interval and Duration** | **Comments** | | **Rating[a] HIV−** | **Evidence HIV+** |
| Isoniazid | Daily for 9 months[c,d] | In HIV-infected patients, isoniazid may be administered concurrently with nucleoside reverse transcriptase inhibitors (NRTIs), protease inhibitors, or non-NRTIs (NNRTIs) | | A (II) | A (II) |
| | Twice weekly for 9 months[c,d] | Preferred regimen in children 2–11 years | | B (II) | B (II) |
| | | Directly observed treatment (DOT) must be used with twice-weekly dosing | | | |
| Isoniazid and Rifapentine | Once weekly | Equal alternative to 9 months of daily isoniazid for otherwise healthy patients age > 12 years | | B(I) | B(I) |
| | | DOT is recommended | | | |
| | | Not recommended for children < 2 years HIV-infected patients taking antiretroviral therapy, presumed resistance, pregnant women or women expecting to become pregnant during the treatment period | | | |
| Isoniazid | Daily for 6 months[d] | Not indicated for HIV-infected persons, those with fibrotic lesions on chest radiographs, or children | | B (I) | C (I) |
| | Twice weekly for 6 months[d] | DOT must be used with twice-weekly dosing | | B (II) | C (I) |
| Rifampin | Daily for 4 months | For persons who are contacts of patients with isoniazid-resistant rifampin-susceptible TB | | B (II) | B (III) |
| | | In HIV-infected patients, protease inhibitors or NNRTIs generally should not be administered concurrently with rifampin; rifabutin can be used as an alternative for patients treated with indinavir, nelfinavir, amprenavir, ritonavir, or efavirenz, and possibly with nevirapine or soft-gel saquinavir[e] | | | |

[a]Strength of recommendation: A = preferred; B = acceptable alternative; C = offer when A and B cannot be given.

[b]Quality of evidence: I = randomized clinical trial data; II = data from clinical trials that are not randomized or were conducted in other populations; III = expert opinion.

[c]Recommended regimen for children younger than 18 years.

[d]Recommended regimens for pregnant women. Pyrazinamide should be avoided during the first trimester.

[e]Rifabutin should not be used with hard-gel saquinavir or delavirdine. When used with other protease inhibitors or NNRTIs, dose adjustment of rifabutin may be required.

## Special Populations

Treatment for extrapulmonary TB is the same as for pulmonary disease. Patients with CNS TB usually are treated for 12 months.[8,24] Isoniazid and pyrazinamide cross the blood–brain barrier well, but rifampin, ethambutol, and streptomycin can penetrate inflamed meninges. TB osteomyelitis typically is treated for 9 months, occasionally with surgical débridement.[8,24] TB of the soft tissues can be treated with conventional regimens.[8,24] Patients with diabetes mellitus have been shown to have low 2-hour peak serum concentrations of antimicrobials. TDM can be considered to optimize treatment response.[30] TB in children may be treated with regimens similar to those used in adults, although some physicians extend treatment to 9 months.[8,14,15,16,24] Pediatric doses of isoniazid and rifampin on a milligram per kilogram basis are higher than those used in adults (**Table 75–4**).[24]

Pregnant women receive the usual treatment of isoniazid, rifampin, and ethambutol for 9 months.[24] Pyrazinamide has not been studied in large numbers of pregnant women, but anecdotal data suggest that it may be safe.[24,31] The clinician should always determine risk versus benefit and determine if a drug is safe to administer in pregnancy.

▶ *Human Immunodeficiency Virus*

● *HIV-infected adults may receive a 6-month regimen of phase of isoniazid, a rifamycin, pyrazinamide, and ethambutol for the first 2 months followed by isoniazid and a rifamycin for 4 months.[8,24,32] Some clinicians recommend extending treatment to 9 months. Rifabutin is used to reduce drug interactions with protease inhibitors and some non-nucleoside reverse transcriptase inhibitors.* Integrated antiretroviral therapy (ART) is superior to sequential ART in the treatment of naïve HIV seropositive patients with TB.[33] The optimal timing of integrated HIV and TB therapy is influenced by the patient's immune status.[33] It is recommended to start integrated ART therapy 2 to 12 weeks after initiating anti-TB therapy.[31] TB-HIV experts should manage such patients. Highly intermittent regimens (twice or once weekly) are not recommended for HIV-positive TB patients.[24,32] Some patients with AIDS malabsorb their oral medications, and drug interactions are common, so TDM can be useful.[24,28,29]

## Table 75–3

### Drug Regimens for Culture-Positive Pulmonary Tuberculosis Caused by Drug-Susceptible Organisms

| | | Initial Phase | | Continuation Phase | |
|---|---|---|---|---|---|
| Regimen | Drugs | Interval and Doses[a] (Minimal Duration) | Drugs | Interval and Doses[a,b] (Minimal Duration) | Range of total doses (minimum duration) |
| 1 | Isoniazid Rifampin Pyrazinamide Ethambutol | 7 days per week for 56 doses (8 weeks) or 5 days per week for 40 doses (8 weeks)[c] | Isoniazid/Rifampin Isoniazid/Rifampin Isoniazid/Rifapentine | 7 days per week for 126 doses (18 weeks) or 5 days per week for 90 doses (18 weeks)[c] Twice weekly for 36 doses (18 weeks)[d] Once weekly for 18 doses (18 weeks)[e] | 182–130 (26 weeks) 92–76 (26 weeks)[d] 74–58 (26 weeks) |
| 2 | Isoniazid Rifampin Pyrazinamide Ethambutol | 7 days per week for 14 doses (2 weeks)[c], *then* twice weekly for 12 doses (6 weeks) or 5 days per week for 10 doses (2 weeks), *then* twice weekly for 12 doses (6 weeks) | Isoniazid/Rifampin Isoniazid/Rifapentine | Twice weekly for 36 doses (18 weeks)[d] Once weekly for 18 doses (18 weeks)[e] | 62–58 (26 weeks) 44–40 (26 weeks) |
| 3 | Isoniazid Rifampin Pyrazinamide Ethambutol | three times weekly for 24 doses (8 weeks) | Isoniazid/Rifampin | Three times weekly for 54 doses (18 weeks) | 78 (26 weeks) |
| 4 | Isoniazid Rifampin Ethambutol | 7 days per week for 56 doses (8 weeks) or 5 days per week for 40 doses (8 weeks)[c] | Isoniazid/Rifampin | 7 days per week for 217 doses (31 weeks) or 5 days per week for 155 doses (31 weeks)[c] | 273–195 (39 weeks) |
| | | | Isoniazid/Rifampin | Twice weekly for 62 doses (31 weeks) | 118–102 (39 weeks) |

[a]When DOT is used, drugs may be given 5 days per week and the necessary umber of doses adjusted accordingly. Although there are no studies that compare five with seven daily doses. Extensive experience indicates this would be an effective practice.

[b]Patients with cavitation on initial chest radiograph and positive cultures at completion of 2 months of therapy should receive 7-month continuation phase

[c]Five days a week administration is always given by DOT.

[d]Not recommended for HIV infected patients with CD4 counts < 100 cells/μl (100 × 10$^6$/L).

[e]Once weekly options with rifapentine should be used only in HIV negative patients who have negative sputum smears at the time of completion of 2 months of therapy and who do not have cavitation on initial chest radiograph. For patients started on this regimen and found to have a positive culture form the 2-month specimen, treatment should be extended an extra 3 months. Centers for Disease Control and Prevention. Treatment of Tuberculosis, American Thoracic Society, CDC, and Infectious Diseases Society of America. MMWR 2003;52(No. RR-11):[inclusive page numbers].

For complete recommendations on management of TB and HIV visit the CDC website: www.cdc.gov/tb/publications/guidelines/HIV_AIDS.htm.

#### ▶ Multidrug-Resistant TB

If drug-resistant TB is suspected, the empiric regimen should be modified based on patterns of suspected resistance. Once susceptibilities are confirmed, regimens can be modified appropriately. Patients with MDR-TB are at high risk of failure and should be treated by specialists or centers with experience treating drug resistant TB.

#### ▶ Renal Failure

Isoniazid and rifampin usually do not require dose modification in renal failure.[27,34,] Pyrazinamide and ethambutol typically are reduced to three times weekly to avoid accumulation of the parent drug (ethambutol) or metabolites (pyrazinamide).[28,29] Renally cleared TB drugs include the aminoglycosides, ethambutol, cycloserine, and levofloxacin.[28,29] With renal impairment, dosing

intervals need to be extended for these drugs. TB drugs should be administered after hemodialysis; three times weekly regimens may be more convenient. Serum concentration monitoring should be performed for cycloserine and ethambutol to avoid dose-related toxicities in renal failure patients.[29,34,35]

### Patient Encounter, Part 3

*Based on the information provided, what are the goals of therapy for this patient?*

*Select and recommend a therapeutic plan for treatment of this patient's TB infection. What drugs, dose, schedule, and duration of therapy are best for this patient?*

*Who else should be tested? How should any contacts infected by this patient be evaluated and treated?*

**Table 75–4**

**Antituberculosis Drugs for Adults and Children**

| Drug | Daily Doses[a,b,c] | Adverse Effects | Monitoring |
|---|---|---|---|
| Isoniazid | *Adults*: 5 mg/kg (300 mg)<br><br>*Children*: 10–15 mg/kg (300 mg) | Asymptomatic elevation of aminotransferases, clinical hepatitis, fatal hepatitis, peripheral neurotoxicity, CNS system effects, lupus-like syndrome, hypersensitivity, monoamine poisoning, diarrhea | LFT monthly in patients who have preexisting liver disease or who develop abnormal liver function that does not require discontinuation of drug<br><br>Dosage adjustments may be necessary in patients receiving anticonvulsants or warfarin |
| Rifampin[d] | *Adults*: 10 mg/kg (600 mg)<br><br>*Children*: 10–20 mg/kg (600 mg) | Cutaneous reactions, GI reactions (nausea, anorexia, abdominal pain), flu-like syndrome, hepatotoxicity, severe immunologic reactions, orange discoloration of bodily fluids (sputum, urine, sweat, tears), drug interactions owing to induction of hepatic microsomal enzymes | Rifampin causes many drug interactions. For a complete list of drug interactions and effects, refer to CDC website: www.cdc.gov/nchstp/tb/tb |
| Rifabutin[d] | *Adults*: 5 mg/kg (300 mg)<br><br>*Children*: Appropriate dosing unknown | Hematologic toxicity, uveitis, GI symptoms, polyarthralgias, hepatotoxicity, pseudojaundice (skin discoloration with normal bilirubin), rash, flu-like syndrome, orange discoloration of bodily fluids (sputum, urine, sweat, tears) | Drug interactions are less problematic than rifampin |
| Rifapentine[d] | *Adults*: 10 mg/kg (continuation phase) (600 mg) dosed weekly<br><br>*Children*: The drug is not approved for use in children | Similar to those associated with rifampin | Drug interactions are being investigated and are likely similar to rifampin |
| Pyrazinamide | *Adults*: Based on IBW: 40–55 kg: 1000 mg; 56–75 kg: 1500 mg; 76–90 kg: 2000 mg<br><br>*Children*: 15–30 mg/kg | Hepatotoxicity, GI symptoms (nausea, vomiting), nongouty polyarthralgia, asymptomatic hyperuricemia, acute gouty arthritis, transient morbilliform rash, dermatitis | Serum uric acid can serve as a surrogate marker for compliance<br><br>LFTs in patients with underlying liver disease |

| | *Children:* Not recommended | | |

[a]Dose per weight is based on ideal body weight. Children weighing more than 40 kg should be dosed as adults.

[b]For purposes of this document adult dosing begins at age 15 years.

[c]The authors of this chapter do not agree with the use of maximum doses, since this arbitrarily caps doses for patients who otherwise might need larger doses. These maximum doses were not based on prospective studies in large or overweight individuals, and do not consider patients with documented malabsorption of their medications. Clinical judgment should be used in such circumstances.

[d]Higher doses of rifampin and rifapentine are being studied. Rifabutin dose may need to be adjusted when there is concomitant use of protease inhibitors or nonnucleoside reverse transcriptase inhibitors.

[e]The drug can likely be used safely in older children but should be used with caution in children less than 5 years of age, in whom visual acuity cannot be monitored. In younger children, ethambutol at the dose of 15 mg/kg/day can be used if there is suspected or proven resistance to isoniazid or rifampin.

[f]It should be noted that, although this is the dose recommended generally, most clinicians with experience using cycloserine indicate that it is unusual for patients to be able to tolerate this amount. Serum concentration measurements are often useful in determining the optimal dose for a given patient.

[g]The single daily dose can be given at bedtime or with the main meal.

[h]Dose: 15 mg/kg/day (1 g), and 10 mg/kg in persons older than 59 years of age (750 mg). Usual dose: 750–1000 mg administered intramuscularly or intravenously, given as a single dose 5–7 days/week and reduced to two or three times per week after the first 2 to 4 months or after culture conversion, depending on the efficacy of the other drugs in the regimen.

[i]The long-term (more than several weeks) use of levofloxacin in children and adolescents has not been approved because of concerns about effects on bone and cartilage growth. However, most experts agree that the drug should be considered for children with tuberculosis caused by organisms resistant to both isoniazid and rifampin. The optimal dose is not known.

[j]The long-term (more than several weeks) use of moxifloxacin in children and adolescents has not been approved because of concerns about effects on bone and cartilage growth. The optimal dose is not known.

Data from Centers for Disease Control and Prevention. Treatment of tuberculosis. MMWR 2003;52 (RR-11).

▶ *Hepatic Failure*

Hepatically cleared TB drugs include isoniazid, rifampin, pyrazinamide, ethionamide, and *p*-aminosalicylic acid.[22] Ciprofloxacin and moxifloxacin are about 50% cleared by the liver. Isoniazid, rifampin, pyrazinamide, and to a lesser degree ethionamide, *p*-aminosalicylic acid, and rarely ethambutol may cause hepatotoxicity.[26,28,] These patients require close monitoring, and serum concentration monitoring may be the most accurate way to dose them.[29]

## TB Drugs

Detailed information regarding TB drugs can be accessed at the following references.[22,24,28,29] A summary is provided in Table 75–4.[23] Isoniazid, rifampin, and pyrazinamide are the key drugs. Other drugs are used in selected circumstances. Quinolones eventually may be used as first-line drugs, but currently are

not.[36,37] In 2012, the Food and Drug Administration approved bedaquiline for the treatment of MDR-TB.[38] It should be used with three or more drugs that are active against the patient's isolate. Bedaquiline carries a black-box warning due to prolongation of QTc interval. Baseline and follow-up electrocardiograms are recommended. Other new therapies include investigational vaccines, and investigational drugs such as PA-824, OPC-67683, and SQ109, which are in clinical trials.[39]

## OUTCOME EVALUATION

● *Effectiveness of TB therapy is determined by AFB smears and cultures. Send sputum samples for AFB staining and microscopic examination (sputum smears) every 1 to 2 weeks until two consecutive smears are negative. This provides early evidence of a response to treatment.*[24] *Once on maintenance therapy,* sputum

cultures *can be performed monthly until two consecutive cultures are negative, which generally occurs over 2 to 3 months. If sputum cultures continue to be positive after 2 months, repeat drug susceptibility testing and check serum concentrations of the drugs.*

KEY CONCEPT *The most serious problem with TB therapy is patient nonadherence.[24,40] There is no reliable way to identify such patients a priori, therefore DOT should be used.[8,24,40]* DOT also provides increased opportunities to observe the patient for any apparent toxicities, thus improving overall care.[40]

Check serum chemistries, including blood urea nitrogen (BUN), creatinine, aspartate transaminase (AST), and alanine transaminase (ALT) and a complete blood count with platelets at baseline and periodically thereafter depending on the presence of other factors that may increase the likelihood of toxicity (eg, advanced age, alcohol abuse, pregnancy).[24] Suspect hepatotoxicity in patients whose transaminases exceed five times the upper limit of normal (ULN) or whose total bilirubin exceeds 3 mg/dL (51 μmol/L), and in patients with symptoms such as nausea, vomiting, and jaundice with liver enzyme elevations of more than three times ULN. At this point, discontinue the offending agents. Typically, all TB drugs are stopped, followed by the sequential reintroduction of the drugs, along with frequent testing of liver enzymes. This usually is successful in identifying the offending agent; other agents may be continued (see Table 75–4).[24]

### Therapeutic Drug Monitoring

TDM is the use of serum drug concentrations to optimize therapy.[24,28,29] Patients with uncomplicated, drug-susceptible TB generally do well. Pharmacokinetic variability of anti-TB drugs can contribute to poor outcomes despite adherence. TDM can be used to shorten the time to response and to treatment completion. The evidence to support the use of TDM in the treatment of TB is growing.[29] *TDM can assist in patients failing appropriate DOT (no clinical improvement after 2 to 4 weeks or smear-positive after 4 to 6 weeks). Patients with AIDS, diabetes, and various GI disorders often fail to absorb these drugs properly and also are candidates for TDM. Drug levels in patients with hepatic or renal disease should be monitored, given their potential for toxicities. In the treatment of MDR-TB, TDM may be particularly useful.[22] Finally, TDM of the TB and HIV drugs is perhaps the most logical way to untangle the complex drug interactions that take place.*

For a complete list of drug interactions, visit the CDC website: www.cdc.gov/tb/publications/guidelines/TB_HIV_DRUGS/default.htm.[41] In particular, interactions between the rifamycins (eg, rifampin, rifapentine, rifabutin) and the HIV protease inhibitors and non-nucleoside reverse transcriptase inhibitors are common and require dose and frequency modifications in many cases. Because these are constantly being updated, the preceding link is an excellent way to keep current.

---

### Patient Encounter, Part 4

*Based on the information provided, which clinical and laboratory parameters should be monitored in this patient to determine efficacy and avoid toxicity?*

*Is this patient a candidate for therapeutic drug monitoring? Why or why not?*

---

### Patient Care Process

- Rapidly identify a new TB case.
- Assess the patient's risk factors and signs and symptoms to determine whether the patient might be infected with TB.
- Isolate the patient with active disease to prevent the spread of the disease.
- Collect appropriate samples for smears and cultures.

**Therapy Evaluation:**

- Obtain a thorough medication history.
- Select and recommend appropriate antituberculosis treatment. Consider HIV status, type of TB infection, renal function, liver function, etc.

**Care Plan Development:**

- Ensure adherence to the treatment regimen by the patient.
- Obtain AFB stains to evaluate the effectiveness of treatment.
- Consider TDM if no clinical improvement.

**Follow-up Evaluation:**

- Continue treatment for at least 6 months from the time that the patient converts to a negative culture.
- Identify the index case that infected the patient, identify of all persons infected by both the index case and the new case of TB, and the complete of appropriate treatments for those individuals.

---

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| AFB | Acid-fast bacillus |
| AIDS | Acquired immunodeficiency syndrome |
| ALT | Alanine transaminase |
| ART | antiretroviral therapy |
| AST | Aspartate transaminase |
| BCG | Bacille Calmette-Guérin |
| CDC | Centers for Disease Control and Prevention |
| CNS | Central nervous system |
| DOT | Directly observed therapy |
| HIV | Human immunodeficiency virus |
| HTN | Hypertension |
| IGRA | Interferon-γ release assay |
| INF | Interferon |
| LTBI | Latent tuberculosis infection |
| MDR-TB | Multidrug-resistant tuberculosis |
| MGIT | Mycobacterial growth indicator tube |
| NIDDM | Noninsulin-dependent diabetes mellitus |
| PCR | Polymerase chain reaction |
| PPD | Purified protein derivative |
| RFLP | Restriction fragment length polymorphism |
| TB | Tuberculosis |
| TDM | Therapeutic drug monitoring |
| ULN | Upper limit of normal |
| WBC | White blood cell |

# Gastrointestinal Infections

Bradley W. Shinn and Sharon Ternullo

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Describe the epidemiology and clinical presentation of commonly encountered gastrointestinal (GI) infections.
2. Summarize common risk factors associated with the development of a GI infection.
3. Given a patient with a GI infection, develop an individualized treatment plan.
4. Outline the impact of widespread antimicrobial resistance on current treatment recommendations for GI infections.
5. Discuss the effect of host immunosuppression on the risk of disease complications and treatment strategies associated with GI infections.
6. Educate patients on appropriate prevention measures of GI infections.
7. Describe the role of antimicrobial prophylaxis and/or vaccination for GI infections.

## INTRODUCTION

One of the primary concerns related to gastrointestinal (GI) infection, regardless of the cause, is dehydration, which is the second leading cause of worldwide morbidity and mortality.[1] Dehydration is especially problematic for children younger than age 5; however, the highest rate of death in the United States occurs among the elderly.[1] **KEY CONCEPT** *Rehydration is the foundation of therapy for GI infections, and oral rehydration therapy (ORT) is usually preferred* (**Table 76–1**).[2] Single-dose oral ondansetron should be considered the first-line antiemetic in children who are dehydrated with significant vomiting.[3] In non-immunocompromised hospitalized pediatric patients, *Lactobacillus* supplementation may reduce the length of hospitalization.[4]

In the United States, each year 31 major pathogens cause about 9 million episodes of foodborne illness, almost 56,000 hospitalizations, and 1350 deaths. Most illnesses are caused by norovirus, nontyphoidal *Salmonella* (NTS), *Clostridium perfringens*, and *Campylobacter*.[5] **KEY CONCEPT** *The indiscriminate use of proton-pump inhibitor (PPI) therapy leads to GI-tract bacterial colonization and increased susceptibility to enteric bacterial infections.*[6]

## BACTERIAL INFECTIONS

### SHIGELLOSIS
#### Epidemiology

*Shigella* causes bacillary dysentery, which refers to diarrheal stool containing pus and blood. Worldwide, there are an estimated 165 million annual cases of shigellosis, with 1 million associated deaths, and approximately 450,000 infections each year in the United States, which results in more than 6000 hospitalizations.[7]

Shigellosis usually affects children 6 months to 10 years of age. In the United States, shigellosis is a serious problem in daycare centers and in areas with crowded living conditions or poor sanitation. Most cases of shigellosis are transmitted through the fecal–oral route. Activities that may lead to shigellosis include handling toddlers' diapers, ingesting pool water, or consuming vegetables from a sewage-contaminated field. *Shigella* transmission from contaminated food and water, although less common, is associated with large outbreaks.

#### Pathogenesis

*Shigella* organisms are nonmotile, nonlactose-fermenting, gram-negative rods and are members of the Enterobacteriaceae family. *S. sonnei* (serogroup D) is responsible for most shigellosis cases in the United States. Infection with Shigella occurs after ingestion of as few as 10 to 100 organisms, which may explain the ease of person-to-person spread. Symptoms develop in about 3 days (range, 1–7) after contracting the bacteria.[8]

*Shigella* strains invade intestinal epithelial cells, with subsequent multiplication, inflammation, and destruction. This organism only rarely invades the bloodstream; but, bacteremia can occur in malnourished children and immunocompromised patients and is associated with a mortality rate as high as 20%.[9]

#### Treatment and Monitoring

Although infection with *Shigella* is generally self-limited and responds to supportive care, antibiotic therapy is indicated because it shortens the duration of illness and reduces the risk of transmission.[10] Several antimicrobial agents are available for the treatment of shigellosis, although options are increasingly limited due to globally emerging drug resistance. If antimicrobial susceptibility results are not available, the recommended

| Table 76–1 | | | |
|---|---|---|---|
| **Clinical Assessment of Degree of Dehydration in Children Based on Percentage of Body Weight Loss** | | | |
| **Variable** | **Mild (3%–5%)** | **Moderate (6%–9%)** | **Severe (10% or More)** |
| Blood pressure | Normal | Normal | Normal to reduced |
| Quality of pulses | Normal | Normal to slightly decreased | Moderately decreased |
| Heart rate | Normal | Increased | Increased (bradycardia in severe cases) |
| Skin turgor | Normal | Decreased | Decreased |
| Fontanelle | Normal | Sunken | Sunken |
| Mucous membranes | Slightly dry | Dry | Dry |
| Eyes | Normal | Sunken orbits/decreased tears | Deeply sunken orbits/decreased tears |
| Extremities | Warm, normal capillary refill | Delayed capillary refill | Cool, mottled |
| Mental status | Normal | Normal to listless | Normal to lethargic to comatose |
| Urine output | Slightly decreased | < 1 mL/kg/hour | < 1 mL/kg/hour |
| Thirst | Slightly increased | Moderately increased | Very thirsty |
| Fluid replacement | ORT 50 mL/kg over 2–4 hours | ORT 100 mL/kg over 2–4 hours | Lactated Ringer 40 mL/kg in 15–30 minutes, then 20–40 mL/kg if skin turgor, alertness, and pulse have not returned to normal *or* Lactated Ringer or normal saline 20 mL/kg, repeat if necessary, and then replace water and electrolyte deficits over 1–2 days, followed by ORT 100 mL/kg over 4 hours |

From Martin S, Jung R. Gastrointestinal infections and enterotoxigenic poisonings. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach. 9th ed. New York: McGraw-Hill; 2014:1951–1967.

first-line drugs are ciprofloxacin or levofloxacin. Alternative agents include azithromycin and ceftriaxone.[11] However, the choice of antibiotic should also be influenced by periodically updated local antimicrobial susceptibility patterns. Treatment should be continued for a total of 5 days. Antimotility agents are not recommended because they can worsen dysentery and may be related to the development of toxic megacolon. No vaccines are available for the prevention of shigellosis.

## SALMONELLOSIS
### Epidemiology

*Salmonella* are gram-negative facultative rods that cause a wide variety of disease manifestations. *Salmonella typhi* and *Salmonella paratyphi* cause typhoid (or enteric) fever. Although typhoid fever is now a rare disease in the United States with approximately 300 clinical cases reported per year, these infections cause an estimated 20 million cases and 200,000 deaths annually worldwide.[12] Nontyphoidal *Salmonella* (NTS) are important causes of reportable food-borne infection. There are an estimated 1.4 million cases of NTS illness annually in the United States, and almost 94 million worldwide.[13] The highest incidence is in those younger than 1 year of age and older than 65 years of age or in those with HIV/AIDS. Exotic pets, especially reptiles, are an increasing source of human salmonellosis. NTS strains may also result in bacteremia and focal disease, such as endovascular infections, osteomyelitis, meningitis, and septic arthritis. Antimicrobial-resistant strains are associated with excess bloodstream infections and hospitalizations.[14] Recurrent *Salmonella* bacteremia is an AIDS-defining illness.

Risk factors for salmonellosis include extremes of age; alteration of endogenous GI flora due to antimicrobial therapy, surgery, or acid-suppressive therapy[5]; diabetes; malignancy; rheumatologic disorders; HIV infection; and therapeutic immunosuppression.

## Clinical Presentation and Diagnosis of Shigellosis

- Biphasic illness
  - Early—high fever, watery diarrhea without blood
  - Later—after approximately 48 hours, colitis develops with urgency, **tenesmus**, and dysentery
  - Low-grade fever
  - More frequent small-volume stools ("fractional stools")
  - Vomiting (35%)
- Complications of shigellosis
  - **Proctitis** or rectal prolapse—more common in infants and young children
  - Intestinal obstruction
- Colonic perforation
- Bacteremia—more common in children
- Metabolic disturbances
- Neurologic disease—most commonly seizures (approximately 10% of patients)
- Hemolytic-uremic syndrome (HUS)
- Microscopic examination of stool is extremely useful and reveals multiple polymorphonuclear leukocytes and red blood cells (RBCs). Diagnosis is usually confirmed by stool culture

## Patient Encounter 1

A 3-year-old child who attends daycare four days each week complains that his "stomach hurts" and that he does not want to eat anything. His mother notes that his stools are loose and that the child has a low-grade fever. The next day, his mother notices blood and some pus in his stools.

*By what method did this child most likely acquire this infection?*

*What is the most likely microorganism to be causing this infection?*

*What antibiotic (if any) should be recommended to treat this child's infection?*

Proper food handling and storage can help prevent *Salmonella* gastroenteritis. Effective handwashing is important, especially when handling eggs and poultry.

## Treatment and Monitoring

### ▶ Gastroenteritis

*Salmonella* gastroenteritis is usually self-limited, and antibiotics have no proven value. Patients respond well to ORT. Symptoms typically diminish in 3 to 7 days without sequelae. Antibiotic use may result in a higher rate of chronic carriage and relapse. Antimicrobial use should be limited to preemptive therapy among patients at higher risk for extraintestinal spread or invasive disease (Table 76–2). Antimotility agents should not be used.

### ▶ Enteric Fever

The current drug of choice for typhoid fever in adults is a fluoroquinolone, such as ciprofloxacin. Azithromycin or ceftriaxone are preferred in children. The recommended adult dose of ciprofloxacin for uncomplicated typhoid fever is 500 mg orally twice daily for 5 to 7 days; however, decreased susceptibility to ciprofloxacin is a significant problem in many parts of the world. In the United States, *S. typhi* with decreased ciprofloxacin susceptibility is associated with travel to the Indian subcontinent.[12] If ciprofloxacin resistance is present, ceftriaxone may be used; however, this agent may be less suitable in some low- and middle-income countries due to cost and route of administration. Azithromycin is an effective alternative for uncomplicated typhoid fever.[15]

### Table 76–2

**Antimicrobial Indications for Nontyphoidal Salmonellosis (NTS)**

Age 3 months or less or 65 years or more
Fever and systemic toxicity
HIV/AIDS
Other immunodeficiency (eg, steroid use, organ transplantation)
Uremia or hemodialysis or renal transplant
Malignancy
Sickle cell anemia or hemoglobinopathy
Inflammatory bowel disease
Aortic aneurysm, prosthetic heart valve, vascular or orthopedic prosthesis

## Clinical Presentation and Diagnosis of Salmonellosis

### Gastroenteritis

- Onset 8 to 48 hours after ingestion of contaminated food.
- Fever, diarrhea, and cramping.
- Stools are loose, of moderate volume, and without blood.
- Headache, myalgias, and other systemic symptoms can occur.
- Certain underlying conditions (eg, AIDS, inflammatory bowel disease, and prior gastric surgery) predispose the patient to more severe disease.

### Enteric Fever

- Febrile illness 5 to 21 days after ingestion of contaminated food or water, which may be persistent and high-grade. A relative bradycardia may be noted at the fever peak.
- Chills, diaphoresis, headache, anorexia, cough, weakness, sore throat, dizziness, muscle pain, and diarrhea may be present before onset of fever.
- Rose spots, a coated tongue, and/or hepatosplenomegaly may be noted.
- Intestinal hemorrhage or perforation, leukopenia, anemia, and subclinical disseminated intravascular coagulopathy may occur.
- Culture of stool, blood, or bone marrow for *Salmonella* species is helpful.

Two typhoid vaccines are available for use in the United States. Immunization is recommended for travelers going to endemic areas such as Latin America, Asia, and Africa; household contacts of a chronic carrier; and laboratory personnel who frequently work with *S. typhi*.

### ▶ Bacteremia and Focal Infections

Treatment of *Salmonella* bacteremia should be initiated with either a fluoroquinolone (eg, levofloxacin, ciprofloxacin) or a third-generation cephalosporin (eg, ceftriaxone).[11] Given increasing antimicrobial resistance, life-threatening infections should be treated with both agents until susceptibilities are available.[13] If there is no evidence of an endovascular infection, therapy for bacteremia should continue for 10 to 14 days. For patients with suspected meningitis, high-dose ceftriaxone is preferred because of its optimal penetration of the blood–brain barrier. Osteomyelitis and joint infections, often associated with sickle-cell anemia, are difficult to eradicate and require longer durations of antimicrobial therapy (at least 4–6 weeks), as do patients who are infected with HIV.[13]

### ▶ Chronic Carrier State

A chronic carrier state, defined as positive stool or urine cultures for more than 12 months, develops in 1% to 4% of adults with typhoid fever. Effective agents for eradication of chronic carriage include amoxicillin (3 g orally divided three times a day in adults for 3 months), trimethoprim-sulfamethoxazole (one double-strength tablet orally twice a day for 3 months), or ciprofloxacin (750 mg orally twice daily for 4 weeks). Surgery in combination with antibiotic therapy is indicated in patients with biliary tract abnormalities.

## CAMPYLOBACTERIOSIS
### Epidemiology

*Campylobacter jejuni* is the most commonly identified cause of bacterial diarrhea worldwide. In the United States, this organism accounts for an estimated 1.4 million infections, 13,000 hospitalizations, and 100 deaths annually.[16] Risk factors for *Campylobacter* infection include consumption of contaminated foods of animal origin, especially undercooked poultry or other foods that are cross-contaminated by raw poultry meat during food preparation; unpasteurized milk; contaminated water; foreign travel; contact with farm animals and pets; and the use of antimicrobial therapy.[17] People should be instructed to wash their hands after contact with raw meats and animals.

In developed countries, there are two distinct age peaks for Campylobacter infection: younger than 1 year of age and 15 to 44 years of age, with a mild male predominance. In developing countries, *Campylobacter* diarrhea is primarily a pediatric disease.

### Pathophysiology

*Campylobacter* spp. are gram-negative bacilli that have a curved or spiral shape. *Campylobacter* are sensitive to stomach acidity; as a result, diseases or medications that buffer gastric acidity may increase the risk of infection. The infectious inoculum for *C. jejuni* is low, similar to that for *Salmonella* spp. After an incubation period, infection is established in the jejunum, ileum, colon, and rectum.

### Treatment

Effective fluid and electrolyte replacement is the cornerstone of therapy for patients with *Campylobacter* infection. In most cases, this can be accomplished with the use of oral glucose–electrolyte solutions. Antibiotic therapy should be considered in patients with high fevers, bloody stools, symptoms lasting longer than 1 week, pregnancy, infection with HIV, and other immunocompromising conditions.

Macrolides are the recommended first-line drug class for the treatment of *Campylobacter* infections.[11] A fluoroquinolone or a tetracycline are alternatives; however, the widespread use of these agents in food animals has resulted in fluoroquinolone-resistant *Campylobacter* strains worldwide.[17] *Campylobacter fetus*

---

### Clinical Presentation and Diagnosis of Campylobacteriosis

- Incubation period of 1 to 7 days.
- A brief prodrome of fever, headache, and myalgias is followed by crampy abdominal pain, a high fever, and several bowel movements per day, which may be watery or bloody.
- The abdominal pain and tenderness may be localized, and pain in the right lower quadrant may mimic acute appendicitis. Abdominal pain is more prevalent in *Campylobacter* infection than in either *Shigella* or *Salmonella* infections.
- Tenesmus occurs in approximately 25% of patients.
- Fecal leukocytes and red blood cells (RBCs) are detected in the stools of 75% of infected individuals. Diagnosis of *Campylobacter* is established by stool culture.

---

is the most commonly identified species in patients with bacteremia, which primarily occurs in patients who are elderly or immunocompromised. In addition, focal infections such as cellulitis, vascular infections, meningitis, and abscesses may be present. *C. fetus* has a predilection for the vascular endothelium and implanted medical devices.[18] For these serious infections, treatment with a third-generation cephalosporin, gentamicin, ampicillin, or a carbapenem is recommended.[11] Antimotility agents should be avoided because they may prolong the duration of symptoms and have been associated with worse outcomes. Postinfectious complications associated with *Campylobacter* infection include reactive arthritis (1%) and Guillain-Barré syndrome (0.1%).

## ENTEROHEMORRHAGIC *ESCHERICHIA COLI*
### Epidemiology

**KEY CONCEPT** *Blood in the stool indicates the possibility of inflammatory mucosal disease of the colon such as enterohemorrhagic Escherchia coli (EHEC), a pathogenic subgroup of shiga toxin–producing organisms and an important cause of bloody diarrhea in the United States.* Acute hemorrhagic colitis has been primarily associated with the O157:H7 serotype. This serotype has been responsible for large outbreaks of infection, has higher rates of complications, and appears to be more pathogenic than non-EHEC STEC strains. The spectrum of disease associated with *E. coli* O157:H7 includes bloody diarrhea, which is seen in up to 95% of patients; nonbloody diarrhea; hemolytic-uremic syndrome (HUS); and thrombotic thrombocytopenic purpura (TTP). The incidence of HUS has declined in recent years and NSAIDs are increasingly recognized as an important contributor to acute kidney injury in children, especially if volume depleted.[19]

Approximately 70,000 cases of EHEC illness occur every year in the United States and lead to more than 2000 hospitalizations. The highest incidence is in patients aged 5 to 9 years and 50 to 59 years. Both young and old patients are at risk to develop postinfectious complications, TTP, and HUS.[20] Outbreaks of diarrhea due to *E. coli* O157:H7 and other STECs have occurred following ingestion of contaminated beef, unpasteurized milk, vegetables (eg, alfalfa sprouts, coleslaw, and lettuce), and apple juice. The most important reservoir for *E. coli* O157:H7 is the GI tract of cattle. Person-to-person transmission also occurs,

---

### Patient Encounter 2

A 55-year-old man with a 20-year history of HIV infection has recently purchased a pet snake. About two months after getting the snake, he presents to his local emergency center with a 3-day history of nausea, several episodes of vomiting, abdominal pain, and nonbloody diarrhea. He also complains of episodes of chills and nightsweats over the past two days. Upon further questioning, it is noted that he recently lost his health insurance coverage and he has been unable to refill his HIV medications the past two months. STAT blood cultures are positive for nontyphoidal *Salmonella* (NTS).

*What risk factors does this patient have for a disseminated Salmonella infection?*

*What treatment do you recommend? Are there any special considerations due to this patient's HIV infection?*

and swimming in infant pools or contaminated lakes or drinking municipal water are additional risk factors. The incidence of diagnosed *E. coli* O157:H7 infections in the United States are greater among rural populations and usually occur in summer and autumn months.

### Pathophysiology

The infectious inoculum of EHEC is very low, between 1 and 100 colony-forming units (CFUs). The major virulence factor for EHEC is the production of two Shiga-like cytotoxins (Shiga toxin [Stx] I and II), which are responsible for vascular damage and systemic effects such as HUS. Adhesion mediates initial attachment of EHEC to intestinal epithelial cells. Following attachment, these organisms produce lesions on individual intestinal epithelial cells in the small or large intestine resulting in diarrhea.

### Treatment

The only recommended treatment of EHEC infection is supportive, including fluid and electrolyte replacement, usually in the form of ORT. Most illnesses resolve in 5 to 7 days. Patients should be monitored for the development of HUS. Antibiotics are currently contraindicated because they can induce the expression and release of toxin. Antimotility agents should be avoided because they delay clearance of the pathogen and toxin, which increases the risk of systemic complications. The use of narcotics and nonsteroidal anti-inflammatory drugs (NSAIDs) should also be avoided in acutely infected patients.[21]

Prevention of EHEC infection is especially important because no therapeutic interventions are available to lessen the risk of the development of HUS.[20] Hamburgers should be cooked thoroughly until the temperature of the thickest part of the patty is 72°C. All surfaces and utensils that contact raw meat should be washed thoroughly before reuse. Fruits and vegetables should be washed thoroughly, especially those that will not be cooked. Handwashing is also very important and should include the supervision of handwashing by children in daycare centers.

## CHOLERA
### Epidemiology

Cholera is an intestinal infection that is caused by the bacterium *Vibrio cholerae* that leads to a massive loss of fluid through the

GI tract and often results in life-threatening dehydration and shock. The biotypes of *V. cholerae* responsible for pandemics are serogroup O1 (El Tor) and serogroup O139. Worldwide this infection affects 3 to 5 million people and causes more than 100,000 deaths per year. Cholera can be transmitted by water or by food tainted with contaminated water, particularly undercooked seafood.[22] Research on cholera has led to the refinement of general rehydration therapy, including the proper use of IV and oral rehydration solutions.

### Pathophysiology

*V. cholerae* is a gram-negative bacillus. Vibrios pass through the stomach to colonize the upper small intestine. They possess filamentous protein extensions that attach to receptors on the intestinal mucosa, and their motility assists with penetration of the mucus layer. The cholera enterotoxin consists of two subunits, one of which (subunit A) is transported into the cells and causes an increase in cyclic adenosine monophosphate (cAMP), which leads to the secretion of fluid into the small intestine. This large volume of GI fluid results in the watery diarrhea that is characteristic of cholera. The stools consist of an electrolyte-rich isotonic fluid that is highly infectious.[22]

### Treatment

The cornerstone of cholera treatment is fluid replacement. Without treatment, the case-fatality rate for severe cholera is approximately 50%. For cholera, rice-based ORT is better than glucose-based ORT because it reduces the number of stools.[23] Antibiotic prophylaxis is not warranted. The current WHO treatment protocol recommends antibiotics for only "severe" symptoms; however, this is controversial and some expert groups argue that antibiotics should be used more liberally in significant outbreaks.[24] With effective antibiotic therapy, the illness is shortened by about 50%, and the duration of excretion of *V. cholerae* in the stool is shortened to 1 or 2 days.[25] A tetracycline (eg, doxycycline) is recommended as first-line therapy; however, some

---

## Clinical Presentation and Diagnosis of Cholera

- Incubation period of 18 hours to 5 days
- Abrupt, painless onset of watery diarrhea and vomiting. The diarrheal fluid is usually clear and may be as much as 10 to 20 liters per day
- Large volumes of rice-water stools, which may have fishy odor
- Dehydration is often severe and puts patients at risk for death within hours of disease onset. Symptoms of severe dehydration include low blood pressure, poor skin turgor, sunken eyes, and rapid pulse
- Severe muscle cramps in extremities are due to electrolyte imbalances caused by fluid loss. These cramps should resolve with treatment
- Metabolic acidosis

---

strains are resistant. Other therapeutic options include a fluoroquinolone, trimethoprim-sulfamethoxazole, and azithromycin,[11] which is increasingly utilized in areas where multidrug-resistant strains are prevalent.[26]

Primary preventive strategies include ensuring a safe water supply and safe food preparation, improving sanitation, and patient education. Safe and effective oral vaccines for cholera are available; however, cholera vaccination is not recommended by the Centers for Disease Control and Prevention (CDC) for most people traveling from the United States to endemic areas. The WHO recommends immunization of high-risk groups, such as children and patients infected with HIV, in countries where the disease is endemic.[24]

## TRAVELER DIARRHEA
### Epidemiology
Traveler diarrhea (TD) commonly occurs when visitors from developed countries travel to developing countries. More than 50 million people are at risk for TD each year.[27] These infections arise following the consumption of food or water contaminated with bacteria, viruses, or parasites. **KEY CONCEPT** *Bacteria such as Shigella, Salmonella, Campylobacter, and enterotoxigenic E. coli (ETEC) are responsible for 60% to 85% of TD cases.[27] Noroviruses are increasingly recognized as a significant cause of TD as well.[28]* Most of these illnesses occur during the first 2 weeks of travel and last about 4 days without therapy.[29] Protozoans are an uncommon cause but should be suspected if diarrhea lasts for more than 2 weeks.

Food and water contaminated with fecal matter are the main sources of pathogens that lead to TD. Particularly problematic foods and beverages include salads, unpeeled fruits, raw or poorly cooked meats and seafood, unpasteurized dairy products, and tap water (including ice).[29] Food from street vendors and buffet-style meals are particularly risky. The consumption of more than five alcoholic drinks per day is a risk factor for TD, especially in males.[30] Providing effective education about the types of foods and activities to avoid during travel may decrease the number of cases of TD.

---

## Clinical Presentation and Diagnosis of Traveler Diarrhea

- Frequent, loose stools
- Nausea and vomiting
- Abdominal pain
- Fecal urgency
- Dysentery
- Signs and symptoms related to specific causative pathogen

---

### Pathophysiology
Enterotoxigenic *E. coli*, which is responsible for up to 70% of TD cases in Mexico, produces both heat-labile enterotoxins (LT) and heat-stable enterotoxins (ST). Both toxins demonstrate cellular mechanisms similar to those of cholera toxins and lead to a great increase in both fluid and electrolyte secretion. These *E. coli* strains are not invasive, as are the Shiga-toxin–producing EHEC strains. These organisms lead to a profuse, watery diarrhea without blood, leukocytes, or abdominal cramping.

### Treatment
The goal of treatment is to maintain hydration and functional status and to prevent disruption of travel plans. For travelers with mild cases of diarrhea, oral rehydration salts can prevent and treat dehydration and may be particularly important for children and the elderly.[31] Loperamide (to a maximum dose of 16 mg/day) may be used for milder diarrhea; however, this agent is not recommended if bloody diarrhea or fever is present. Antibiotics are effective at reducing the duration of illness to 1 or 2 days. Providing the traveler with a means for empiric self-treatment is an effective method of treating this illness without promoting the inappropriate use of antibiotics. Therapy should be initiated after the first episode of diarrhea that is uncomfortable or interferes with activities.[32] In general, levofloxacin or ciprofloxacin are recommended as first-line agents for travel to most parts of the world.[29,31] Azithromycin is an alternative and is preferred in areas where quinolone-resistant *Campylobacter* is prevalent (eg, Thailand, India).[29] Azithromycin can also be used in pregnant women and children (10 mg/kg/day orally for 3 days).[31] Rifaximin, a nonabsorbed oral antibiotic, is approved for treatment of TD caused by ETEC in persons at least 12 years old and has been used off-label in younger children at a dose of 20 to 40 mg/kg/day for 4 days. This agent may be a good choice for persons traveling to destinations where ETEC is the predominant pathogen, such as Mexico. Many clinicians will recommend the use of loperamide in dysentery if it is combined with an antibiotic.[29]

**KEY CONCEPT** *The education of travelers about high-risk food and beverages is an important component in the prevention of TD.* Slogans such as "peel it, boil it, cook it, or forget it" can help to remind travelers of the foods that may be contaminated. However, many travelers find it difficult to follow dietary recommendations. In a study of American travelers, almost 50% developed diarrhea despite receiving advice on preventive dietary measures.[33] Antibiotic prophylaxis is not recommended by the CDC because it can lead to drug-resistant organisms and may give travelers a false sense of security.[29] However, some health care professionals do prescribe prophylactic antibiotics for those who are at high risk of developing TD (eg, immunocompromised persons, patients with impaired gastric acid production) or for

those who cannot risk temporary incapacitation (eg, athletes, diplomats, business people). A fluoroquinolone antibiotic, such as levofloxacin or ciprofloxacin, is usually used first line for this purpose at a dose of one tablet daily during travel and for 2 days following return.[31] Although not approved for prophylaxis, rifaximin may be an option for travelers to Mexico because it is not absorbed and should be less likely to select out resistant organisms than are the fluoroquinolones. Bismuth subsalicylate (Pepto-Bismol; 525 mg orally four times daily for up to 3 weeks) provides a rate of protection of about 60% against TD.[29] However, this agent should not be used in persons taking anticoagulants or other salicylates. Probiotics colonize the GI tract and may prevent pathogenic organisms from causing infections. These agents may provide protection rates as high as 50%, but additional studies are needed, and these products suffer from lack of standardization. No effective vaccines are available for TD.

## *CLOSTRIDIUM DIFFICILE* INFECTION
### Epidemiology

*C. difficile* is the primary cause of hospital-acquired infectious diarrhea in hospitalized patients, including children. Both the incidence and severity of *C. difficile* infection (CDI) have been increasing in the United States.[34] The number of *C. difficile* cases that were reported in 2005 (84 per 100,000) was nearly three times higher than the 1996 rate.[35] There has also been a significant increase in severe cases, colectomies, and death related to CDI.[36] A more virulent, epidemic strain (NAP1/B1/027) was initially identified in the 1980s and is now commonly associated with outbreaks. These strains are associated with an increased production of toxins A and B, which are the primary virulence determinants for *C. difficile*.[35] An increasing proportion of CDI patients have a community-acquired infection. These patients are often younger, lack traditional risk factors, and generally have less severe disease compared with those with hospital-acquired infections.[34] A primary risk factor for these community-acquired infections appears to be therapeutic gastric acid suppression.[37] Common risk factors for hospital-acquired CDI include increasing age, severe underlying illness, intensive care unit admission, gastric acid suppression,[38] and exposure to antimicrobials, especially broad-spectrum, multiple-drug regimens.[39] **KEY CONCEPT**
*Nosocomial Clostridium difficile-associated diarrhea (CDAD) is almost always associated with antimicrobial use; therefore, unnecessary and inappropriate antibiotic therapy should be avoided. Clindamycin, cephalosporins, and penicillins are the antibiotics most commonly associated with CDAD, but almost all antibiotics except aminoglycosides have been implicated.[40]* Fluoroquinolones are also strongly associated with CDAD, especially in community-acquired infections.[41]

### Pathophysiology

*C. difficile*, a gram-positive, spore-forming anaerobe, is spread by the fecal–oral route, and patient-to-patient spread is an important mode of transmission within the hospital. The organism is ingested either as the vegetative form or spores, which can survive for long periods in the environment and can traverse the acidic stomach. In the small intestine, spores germinate into the vegetative form. Once the GI tract is colonized with spores, disruption of the gut flora, which occurs with antibiotic therapy, allows *C. difficile* to proliferate. Toxin production is essential for the disease to occur and is responsible for the inflammation, fluid and mucus secretion, and mucosal damage that lead to diarrhea or colitis.

### Treatment

Patients who develop CDI while receiving an antibiotic should have the antibiotic discontinued, if possible. If antimicrobial therapy must continue, an attempt should be made to switch the patient to an agent with a lower risk of CDI.[42] The use of concurrent antibiotics during CDI therapy, or soon thereafter, lowers the chances of a clinical cure. Clinical practice guidelines recommend that initial antimicrobial therapy should be based on the severity of illness.[43]

Metronidazole (500 mg orally three times daily for 7–14 days; or, 30 mg/kg/day divided into four daily doses for children) is the recommended first-line drug for initial treatment of mild-to-moderate CDI. Oral vancomycin (125 mg four times daily for 7 to 14 days; or, 40 to 50 mg/kg/day divided into four daily doses for children) is the recommended first-line drug therapy for initial treatment of severe CDI,[43] which is usually defined as a serum creatinine increase to more than 1.5 times baseline or a white blood cell count greater than 15,000 cells/mm$^3$($15 \times 10^9$/L). Other risk factors for severe disease include age more than 65 years, hypoalbuminemia, immunosuppression, and severe underlying disease.[39] For the treatment of severe, complicated CDI (refractory hypotension, ileus, and/or toxic megacolon), a higher dose of vancomycin (500 mg orally four times daily) may be combined with IV metronidazole (500 mg every 8 hours). Vancomycin may be given as a retention enema (500 mg in 100 mL of normal saline every 6 hours) if a complete ileus is present.[43] The use of antimotility agents should be avoided because they may precipitate toxic megacolon. Surgical intervention may be lifesaving, particularly in cases complicated by toxic megacolon or colonic perforation. Antimicrobial stewardship programs can decrease the incidence of CDIs and better assure appropriate initial therapy.[44]

The cost of oral vancomycin capsules (~$1,000 for a 10-day course) is much higher than metronidazole; however, vancomycin for IV use can be prepared for oral use at a much lower cost.[39] The FDA has also approved fidaxomicin, an oral macrolide antibiotic, for the treatment of CDI in patients who are at least 18 years old. This drug is minimally absorbed and has no activity against organisms other than clostridia, which allows for preservation of normal gut flora. The recommended dose of fidaxomicin is 200 mg orally twice daily for 10 days. In clinical trials, fidaxomicin resulted in clinical cure rates that were similar to those achieved with oral vancomycin, but there were significantly fewer recurrences in those treated with fidaxomicin. However, recurrence rates were similar among patients infected with the more virulent NAP1/B1/027 strain.[45] Fidaxomicin is expensive (~$3000 for a 10-day course) and its place in therapy has not been clearly established.

The recurrence rate after an initial episode of CDI is approximately 20% to 25%, with the highest risk within the first 2 weeks.[39] This rate is independent of which agent is used initially. Treatment of the first recurrence of CDI is usually treated with the same regimen used for the initial episode; however, this choice should also depend on the clinical condition of the patient, as recommended for the initial therapy choice.[43] Metronidazole should not be used beyond the first recurrence or for long-term chronic treatment due to the risk of neurotoxicity. The treatment of second or later recurrences of CDI should be undertaken with vancomycin using a tapered and/or pulse regimen.[35,43] Fidaxomicin may be superior to vancomycin at preventing CDAD recurrences secondary to non-NAP1/B1/027 strains. Rifaximin, administered directly following a course of metronidazole or vancomycin, may be an option for the prevention of recurrent

## Clinical Presentation and Diagnosis of CDAD

- Symptoms can start as early as the first day of antimicrobial therapy or several weeks after antibiotic therapy is completed.
- Asymptomatic carriage.
- Diarrhea:
  - Acute watery diarrhea with lower abdominal pain, low-grade fever, and mild or absent leukocytosis.
  - Mild, with only three or four loose watery stools per day.
  - *C. difficile* toxins are present in stool, but sigmoidoscopic examination is normal.
- Colitis:
  - Profuse, watery diarrhea with 5 to 15 bowel movements per day, abdominal pain, abdominal distention, nausea, and anorexia.
  - Left or right lower quadrant abdominal pain and cramps that are relieved by passage of diarrhea.
  - Dehydration and low-grade fever.
  - Sigmoidoscopic examination may reveal a nonspecific diffuse or patchy erythematous colitis with or without pseudomembranes.
- Toxic megacolon: Suggested by acute dilation of the colon to a diameter greater than 6 cm, associated systemic toxicity, and the absence of mechanical obstruction. It carries a high mortality rate.
- Fulminant colitis: Acute abdomen and systemic symptoms such as fever, tachycardia, dehydration, and hypotension.

- Some patients have marked leukocytosis (up to $40 \times 10^3$ white blood cells/mm$^3$ [$40 \times 10^9$/L]). Diarrhea is usually prominent but may not occur in patients with paralytic ileus and toxic megacolon.
- Recurrent disease:
  - Risk factors include increased age, recent abdominal surgery, increased number of *C. difficile* diarrheal episodes, and leukocytosis.
  - 20% to 25% of patients develop a second episode of CDAD within 2 months of the initial diagnosis.
- In most cases, *C. difficile* toxin testing of a single unformed stool specimen effectively establishes the diagnosis. Stool culture is the most sensitive test, but it is not clinically practical due to slow turnaround time. Enzyme immunoassay (EIA) testing for toxin A and B is used in most labs. This test is rapid, but less sensitive, and repeat testing may be necessary if the initial test is negative. Newer tests, such as EIA detection of glutamate dehydrogenase or use of polymerase chain reaction technology, may ultimately improve diagnostic testing for CDI.
- Leukocytosis, hypoalbuminemia, and fecal leukocytes are nonspecific but suggestive of *C. difficile* infection.
- In selected patients, sigmoidoscopy, colonoscopy, or abdominal CT scan can provide useful diagnostic information.

episodes of CDI in some patients. Fecal microbiota transplantation (FMT) has a reported efficacy of about 90% in preventing recurrent CDI, and this therapy is emerging as a first-line option for patients with multiple recurrent episodes of CDI.[46]

Strict infection control measures, including contact precautions, should be instituted for all patients with CDAD. Environmental cleaning with chlorine-containing agents should be used to eliminate *C. difficile* spores. Because alcohol is ineffective in killing spores, it is essential that health care workers wash their hands with soap and water rather than using alcohol-based hand sanitizers. Meticulous handwashing is the single most important strategy to decrease the patient-to-patient transmission of *C. difficile*. The administration of currently available probiotic agents is not recommended to prevent primary CDI or to treat recurrences.[43]

## Patient Encounter 4

A 58-year-old man presents to his local medical clinic complaining of new-onset diarrhea, which he describes as watery and "constant." He also states that he has some lower abdominal pain. Upon physical examination, the patient is noted to have a low-grade fever and initial lab studies show a mild leukocytosis. Upon further review of this patient's electronic medical record, you note that he was hospitalized about two months earlier for an acute small bowel obstruction which required surgery. Following surgery, he developed a ventilator-associated pneumonia and was treated with broad-spectrum antibiotics for ten days. Shortly after finishing this course of antibiotics, he was diagnosed with a moderately severe *C. difficile* infection (CDI) and completed a 10-day course of oral metronidazole (500 mg). About one month ago, he was diagnosed with recurrent CDI that was described as "mild."

At that time he completed a second 10-day course of oral metronidazole. About 2 weeks before this presentation, this patient was treated with a 10-day course of oral levofloxacin for an episode of acute bacterial rhinosinusitis. He now presents with what is presumed to be a third episode of CDI. His current outpatient medications include lisinopril, carvedilol, citalopram, esomeprazole, albuterol (prn), and ibuprofen (prn).

*What was the primary risk factor that led to this patient's initial episode of CDI?*

*What risk factors are present for this patient's recurrent infections?*

*What drug and/or nondrug therapies could be considered for this patient's third C. difficile infection?*

## CRYPTOSPORIDIOSIS

### Epidemiology

Cryptosporidiosis has been recognized as a human disease since the 1970s, with increasing importance in the 1980s and 1990s because of its relationship with HIV/AIDS. *Cryptosporidium* accounts for 2.2% and 6.1% of diarrhea cases in immunocompetent people in developed and developing countries, respectively.[47] In the United States, the number of reported cases of cryptosporidiosis increased from 6479 in 2006 to 10,500 in 2008. This increase was partially attributed to multiple large recreational water outbreaks and likely reflects increased use of communal swimming venues (eg, lakes, swimming pools, and water parks) by young children.[48]

Cryptosporidiosis is spread person-to-person, usually via the fecal–oral route; by animals, particularly cattle and sheep; and through the environment, especially water.

### Pathophysiology

*Cryptosporidium* is an intracellular protozoan parasite that is capable of completing its entire life cycle within one host. Humans become infected upon ingestion of the oocysts, and autoinfection and persistent infections are possible owing to repeated life cycles within the GI tract. As few as 10 to 100 oocysts can cause infection.[47]

### Treatment

In general, immunocompetent persons and those with asymptomatic infection do not require antimicrobial therapy. In patients with HIV/AIDS, the optimal therapy is restoration of immune function through the use of antiretroviral therapy (ART). In persons in whom antimicrobial therapy is deemed necessary or in HIV/AIDS patients in whom ART is ineffective, a combination of an antimicrobial and an antidiarrheal agent is recommended.[47]

Nitazoxanide is the only FDA-approved agent for the treatment of cryptosporidiosis in adults and children 1 year and older. This agent has demonstrated efficacy in cryptosporidiosis in immunocompetent persons, malnourished children, and HIV/AIDS patients. Patients who are infected with both HIV and *Cryptosporidium* usually require longer therapy durations and higher doses than immunocompetent patients. Alternative agents include paromomycin, azithromycin, and clarithromycin.

Prevention of cryptosporidiosis can prove difficult because the oocysts are resilient to many disinfectants and antiseptics, including ammonia, alcohol, and chlorine. Routine screening

of drinking water should be considered for water-treatment plants, and severely immunocompromised individuals should be advised to avoid water in lakes and streams and contact with young animals.[47]

## VIRAL GASTROENTERITIS

**KEY CONCEPT** *Viruses are the most common cause of diarrheal illness in the world and, in the United States, account for 450,000 illnesses and 160,000 hospitalizations for adults and children, respectively, and more than 4000 deaths.* Many viruses may cause gastroenteritis, including rotaviruses, noroviruses, astroviruses, enteric adenoviruses, and coronaviruses (Table 76–3). This chapter focuses on rotaviruses.

---

**Clinical Presentation and Diagnosis of Cryptosporidiosis**

**General**

- 7- to 10-day incubation period.
- Profuse, watery diarrhea with mucus but not blood or leukocytes that lasts for approximately 2 weeks.
- Nausea, vomiting, fever, and abdominal cramps may accompany the diarrhea.
- Simplest method of diagnosis is detection of oocysts by modified acid-fast staining of a stool specimen. Standard ova and parasite test does not include *Cryptosporidium*.

**Immunocompetent**

- May manifest as asymptomatic disease, acute diarrhea, or persistent diarrhea lasting for several weeks.
- Usually self-limiting.

**Immunocompromised**

- May manifest as asymptomatic disease, chronic diarrhea lasting at least 2 months, or fulminant infection with at least 2 L of watery stool per day.
- In HIV-infected individuals, asymptomatic disease is more common in those with a CD4+ cell count greater than 200 cells/mm³ (200 × 10⁶/L), and fulminant infection is more common in those with a CD4+ cell count of less than 50 cells/mm³ (50 × 10⁶/L).

---

**Table 76–3**

**Agents Responsible for Acute Viral Gastroenteritis and Diarrhea**

| Virus | Peak Age | Peak Time | Duration | Transmission | Symptoms |
|---|---|---|---|---|---|
| Rotavirus | 6 months–2 years | Winter | 3–8 days | Fecal–oral, water, food | Diarrhea, vomiting, fever, abdominal pain |
| Enteric adenovirus | < 2 years | Year-round | 7–9 days | Fecal–oral | Diarrhea, respiratory symptoms, vomiting, fever |
| Astrovirus | < 7 years | Winter | 1–4 days | Fecal–oral, water, shellfish | Vomiting, diarrhea, fever, abdominal pain |
| Noroviruses | > 5 years | Variable | 12–24 hours | Fecal–oral, food, aerosol | Nausea, vomiting, diarrhea, abdominal cramps, headache, fever, chills, myalgia |

Modified from Martin S, Jung R. Gastrointestinal infections and enterotoxigenic poisonings. In: DiPiro JT, Talbert RL, Yee GC, et al., eds. Pharmacotherapy: A Pathophysiologic Approach. 8th ed. New York: McGraw-Hill; 2011:1951–1967.

## Clinical Presentation and Diagnosis of Rotavirus Infection

- Incubation period of 2 days.
- 2- to 3-day **prodrome** of fever and vomiting.
- Profuse diarrhea without blood or leukocytes (up to 10 to 20 stools per day).
- Severe dehydration.
- Anorexia.
- Fever may be present.
- Presentation in adults may vary from asymptomatic to nonspecific symptoms of headache, malaise, and chills to severe diarrhea, nausea, and vomiting.
- Diagnosis can be made by polymerase chain reaction (PCR) of the stool.

## Patient Encounter 5

A 28-year-old woman who has an occasional prescription filled in your community pharmacy, now comes in to ask if she needs to get a flu shot. Since you know she has a 4-month-old child, you ask if her child has started the vaccine series for rotavirus. The mother tells you that she doesn't believe in giving her child a lot of vaccines because she is concerned that there are a lot of potential long-term effects from vaccines that we don't know about.

*What scientific findings could you discuss with this mother to persuade her to get all recommended vaccinations for her child, especially the rotavirus vaccine?*

## ROTAVIRUS

Rotavirus causes between 600,000 and 875,000 deaths each year, with the highest rates in the very young and in developing countries. Rotavirus is the leading cause of childhood gastroenteritis and death worldwide. Most infections occur in children between 6 months and 2 years of age, typically during the winter season, but adults may be infected as well. Worldwide, rotavirus causes more than 2 million hospitalizations and 600,000 deaths per year in children younger than 5 years of age and approximately 60,000 hospitalizations in the United States each year. Almost all children will experience at least one episode of rotavirus infection before 5 years of age. Person-to-person transmission occurs through the fecal–oral route.

The mechanism of diarrhea has not been clearly elucidated, but theories include a reduction in the absorptive surface along with impaired absorption owing to cellular damage, enterotoxigenic effects of a rotavirus protein, and stimulation of the enteric nervous system.

The cornerstone of rotavirus treatment is supportive care and rehydration with ORT or IV fluids. Antimotility and antisecretory agents should not be used owing to their potential side effects in children and the self-limited nature of the disease. **KEY CONCEPT** Two oral rotavirus vaccine products are currently approved by the FDA and, since their introduction, these vaccines have reduced diarrhea-related health care use in children by as much as 94% and has conferred protection on unvaccinated children (herd immunity). This reduction in health care usage has saved an estimated $1 billion over a 4-year period.[49,50] The CDC Advisory Committee on Immunization Practices recommends vaccination at 2, 4, and 6 months.

## FOOD POISONING

Each year in the United States, approximately 76 million food-borne illnesses occur, leading to 325,000 hospitalizations and more than 5000 deaths. Many bacterial and viral pathogens that have been discussed previously in this chapter (eg, *Salmonella, Shigella, Campylobacter, E. coli*, and noroviruses) can cause food poisoning. Other bacteria that can cause food-borne illness include *Staphylococcus aureus, C. perfringens, Clostridium botulinum*, and *Bacillus cereus* (Table 76–4). Food poisoning should be suspected if at least two individuals present with similar symptoms after the ingestion of a common food in the prior 72 hours.

## Table 76–4

**Food Poisonings**

| Organism | Onset (Hours) | Associated Foods | Duration | Symptoms | Treatment |
|---|---|---|---|---|---|
| *Staphylococcus aureus* | 1–6 | Salad, pastries, ham, poultry | 12 hours | Nausea, vomiting | Supportive |
| *Bacillus cereus*—emetic | 0.5–6 | Rice, noodles, pasta, pastries | 24 hours | Vomiting | Supportive |
| *Bacillus cereus*—diarrheal | 8–16 | Meats, vegetables, soups, sauces, milk products | 24 hours | Diarrhea, abdominal pain | Supportive |
| *Clostridium perfringens* (type A) | 8–12 | Meats, poultry | 24 hours | Nausea; abdominal cramps; profuse, watery diarrhea | Supportive |
| *Clostridium botulinum* | 18–24 | Canned fruits, vegetables, meats, honey, salsa, relish | Weeks | Acute GI symptoms followed by symmetric, descending, flaccid paralysis; death is possible | Supportive (including mechanical ventilation); trivalent antitoxin |

## Patient Care Process

**Patient Assessment:**

- Based on physical examination, review of systems, and laboratory findings, determine the degree of fluid and electrolyte depletion and estimate current renal function.
- Review the medical history with particular attention to risk factors or medical conditions associated with more severe infection outcomes, such as immunosuppression.
- Conduct a medication history focusing on holding drugs that may worsen the current fluid status or renal function, immunosuppressive therapies, and antibiotic allergies.

**Therapy Evaluation:**

- Review all available tests to determine the etiology and antimicrobial susceptibilities of the suspected pathogen.
- Based on suspected pathogen, patient age, assessment of immune status, and other risk factors for severe complications, determine if antibiotic therapy is indicated.

**Care Plan Development:**

- Determine that appropriate fluids and other supportive measures have been initiated.

- If indicated, select an antibiotic that is appropriate for the pathogen, not unnecessarily broad in its coverage, and is cost-effective for the patient and the health care system.

**Follow-Up Evaluation:**

- Determine that signs of fluid depletion and electrolyte imbalances have been corrected. If acute renal dysfunction was initially present, assess for clinical improvement and reassess medication doses.
- Assess for increase in stool consistency and decrease in stool frequency.
- Assure that all indicated chronic medications that were initially held have been restarted, as appropriate.
- Provide patient counseling on measures to avoid gastrointestinal pathogens and vaccinations, as appropriate.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| ART | Antiretroviral therapy |
| CDAD | *Clostridium difficile*–associated diarrhea |
| CDC | Centers for Disease Control and Prevention |
| CDI | *Clostridium difficile* infection |
| CFUs | Colony-forming units |
| EHEC | Enterohemorrhagic *Escherichia coli* |
| ETEC | Enterotoxigenic *Escherichia coli* |
| FMT | Fecal microbiota transplant |
| HUS | Hemolytic-uremic syndrome |
| ORT | Oral rehydration therapy |
| LT | Heat-labile enterotoxin |
| MIC | Minimum inhibitory concentration |
| NSAID | Nonsteroidal anti-inflammatory drug |
| NTS | Nontyphoidal *Salmonella* |
| PPI | Proton-pump inhibitor |
| ST | Heat-stable enterotoxin |
| STEC | Shiga toxin-producing *E. coli* |
| TD | Traveler diarrhea |
| TTP | Thrombotic thrombocytopenic purpura |
| WHO | World Health Organization |

# 77 Intra-Abdominal Infections

Joseph E. Mazur and Joseph T. DiPiro

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Define and differentiate between primary and secondary intra-abdominal infections (IAIs).
2. Describe the microbiology typically seen with primary and secondary IAIs.
3. Describe the clinical presentation typically seen with primary and secondary IAIs.
4. Describe the role of culture and susceptibility information for diagnosis and treatment of IAIs.
5. Recommend the most appropriate drug and nondrug measures to treat IAIs.
6. Recommend an appropriate antimicrobial regimen for treatment of a primary and a secondary IAIs.
7. Describe the patient-assessment process during the treatment of IAIs.

## INTRODUCTION

Intra-abdominal infections (IAIs) are those contained within the peritoneal cavity or retroperitoneal space. The peritoneal cavity extends from the undersurface of the diaphragm to the floor of the pelvis and contains the stomach, small bowel, large bowel, liver, gallbladder, and spleen. The duodenum, pancreas, kidneys, adrenal glands, great vessels (aorta and vena cava), and most mesenteric vascular structures reside in the retroperitoneum. IAIs may be generalized or localized. They may be contained within visceral structures, such as the liver, gallbladder, spleen, pancreas, kidney, or female reproductive organs. Two general types of IAI are discussed throughout this chapter: peritonitis and abscess. (*Peritonitis* is defined as the acute inflammatory response of the peritoneal lining to microorganisms, chemicals, irradiation, or foreign-body injury.)

An *abscess* is a purulent collection of fluid separated from surrounding tissue by a wall consisting of inflammatory cells and adjacent organs. It usually contains necrotic debris, bacteria, and inflammatory cells. Peritonitis and abscess differ considerably in presentation and approach to treatment.

## EPIDEMIOLOGY AND ETIOLOGY

Peritonitis may be classified as primary, secondary, or tertiary. Primary peritonitis, also called *spontaneous bacterial peritonitis*, is an infection of the peritoneal cavity without an evident source of bacteria from the abdomen.[1,2] In secondary peritonitis, a focal disease process is evident within the abdomen. Secondary peritonitis may involve perforation of the gastrointestinal (GI) tract (possibly because of ulceration, ischemia, or obstruction), postoperative peritonitis, or posttraumatic peritonitis (eg, blunt or penetrating trauma). Tertiary peritonitis occurs in critically ill patients, and it is an infection that persists or recurs at least 48 hours after apparently adequate management of primary or secondary peritonitis.

**KEY CONCEPT** Most IAIs are secondary infections that are caused by a defect in the GI tract that must be treated by surgical drainage, resection, and/or repair. *Primary peritonitis develops in 10% to 30% of hospitalized patients with alcoholic cirrhosis.*[3] Patients undergoing continuous ambulatory peritoneal dialysis (CAPD) average one episode of peritonitis every 2 years.[4] Secondary peritonitis may be caused by perforation of a peptic ulcer; traumatic perforation of the stomach, small or large bowel, uterus, or urinary bladder; appendicitis; pancreatitis; diverticulitis; bowel infarction; inflammatory bowel disease; cholecystitis; operative contamination of the peritoneum; or diseases of the female genital tract such as septic abortion, postoperative uterine infection, endometritis, or salpingitis. Appendicitis is one of the most common causes of IAI. In 2010, approximately 305,000 appendectomies were performed in the United States for suspected appendicitis.[5]

Primary peritonitis in adults occurs most commonly in association with alcoholic cirrhosis, especially in the end stage, or with ascites caused by postnecrotic cirrhosis, chronic active hepatitis, acute viral hepatitis, congestive heart failure, malignancy, systemic lupus erythematosus, and nephrotic syndrome. It also may result from the use of a peritoneal catheter for dialysis with renal failure or central nervous system ventriculoperitoneal shunting for hydrocephalus. Abscesses are the result of chronic inflammation and may occur without preceding generalized peritonitis. They may be located within the peritoneal cavity or in a visceral organ and may vary in size, taking a few weeks to years to form.

## PATHOPHYSIOLOGY

IAI results from bacterial entry into the peritoneal or retroperitoneal spaces or from bacterial collections within intra-abdominal organs. In primary peritonitis, bacteria may enter the abdomen via the bloodstream or the lymphatic system by transmigration through the bowel wall, through an indwelling peritoneal dialysis (PD)

---

## Patient Encounter 1, Part 1

A 32-year-old woman with a history of sickle cell disease presents to the surgery clinic with chief complaints of abdominal pain. She had an appendectomy 4 weeks ago and had an uneventful course. Her current medications are oxycodone 10 mg orally every 12 hours, zolpidem 5 mg orally at bedtime, and two herbals (ginseng and ginko biloba). On the previous hospital course, she was treated with a 2-day course of fluconazole.

**PMH:** Sickle cell disease and early onset ESRD for the last 7 years

**Meds:** Oxycodone 10 mg orally every 12 hours, zolpidem 5 mg orally every 12 hours, plus herbals

**SOC:** Single, no alcohol, smoking, or illicit drugs

**PE:**

Tender, hard, distended abdomen, negative bowel sounds. Rest of the physical exam is noncontributory

**VS:** T 100°F (37.8°C), BP 75/35 mm Hg, P 136 beats/min, RR 22 breaths/min, Wt 115 lb (52.3 kg), Ht 5'5" (165 cm)

**Labs:** Hct 15.0% (0.150), Hgb 5.1 g/dL (51 g/L; 3.17 mmol/L), WBC $20 \times 10^3/mm^3$ ($20 \times 10^9$/L), serum creatinine 3.2 mg/dL (283 μmol/L), BUN 30 mg/dL (10.7 mmol/L), Na 140 mEq/L (140 mmol/L), K 4.9 mEq/L (4.9 mmol/L), Cl 95 mEq/L (95 mmol/L), $CO_2$ 20 mEq/L (20 mmol/L), total bilirubin 1.8 mg/dL (30.8 μmol/L), aPTT 32.0 seconds

*Comment on the diagnostic approach which should be taken in this patient in order to determine a diagnosis.*

*What are the top two diagnoses that could be made for this patient?*

*Based on your assessment of her medication history, are there any of her medications or herbals that could be potentiating her clinical condition?*

*What pharmacotherapeutic treatments should the pharmacy clinician focus on?*

---

catheter, or via the fallopian tubes in females. Hematogenous bacterial spread (through the bloodstream) occurs more frequently with tuberculosis peritonitis or peritonitis associated with cirrhotic ascites. When peritonitis results from PD, skin-surface flora are introduced via the peritoneal catheter. In secondary peritonitis, bacteria most often enter the peritoneum or retroperitoneum as a result of perforation of the GI or female genital tracts caused by diseases or traumatic injuries.

If bacteria that enter the abdomen are not contained by cellular and humoral defense mechanisms, bacterial dissemination occurs throughout the peritoneal cavity, resulting in peritonitis. This is more likely to occur in the presence of a foreign body, hematoma, necrotic tissue, large bacterial inoculum, continuing bacterial contamination, and contamination involving a mixture of synergistic organisms.

The fluid and protein shift into the abdomen (called *third spacing*) may be so dramatic that circulating blood volume is decreased, which causes decreased cardiac output and hypovolemic shock. Accompanying fever, vomiting, or diarrhea may worsen the fluid imbalance. A reflex sympathetic response, manifested by sweating, tachycardia, and vasoconstriction, may be evident. With an inflamed peritoneum, bacteria and endotoxins are absorbed easily into the bloodstream (*translocation*), and this may result in septic shock.[1] Other foreign substances present in the peritoneal cavity potentiate peritonitis, notably feces, dead tissues, barium, mucus, bile, and blood.

Many of the manifestations of IAIs, particularly peritonitis, result from cytokine activity. Inflammatory cytokines are produced by macrophages and neutrophils in response to bacteria and bacterial products or to tissue injury, resulting from the

---

## Patient Encounter 2, Part 1

A 65-year-old man with a recent history of gastric cancer (diagnosed 1 year back) presents to the emergency room with a 3-day history of fevers and night sweats. He has just completed an 8-week course of chemotherapy that ended 1 week ago. His surgical history comprises a subtotal gastrectomy done at the onset of his diagnosis. His lab values are as follows:

**PE:**

The patient is tender to palpation and winces in pain

**VS:** T 101°F (38.3°C), BP 110/75 mm Hg, P 99 beats/min, RR 12 breaths/min, Wt 250 lb (dry weight on admission [114 kg]), Ht 6'2" (188 cm)

**Labs:** Na 142 mEq/L (142 mmol/L), K 4.5 mEq/L (4.5 mmol/L), Cl 95 mEq/L (95 mmol/L), $CO_2$ 22 mEq/L (22 mmol/L), glucose 250 mg/dL (13.9 mmol/L), BUN 42 mg/dL (15.0 mmol/L), serum creatinine 1 mg/dL (88 μmol/L), total bilirubin 1.2 mg/dL

(20.5 μmol/L), lactate 4.0 mg/dL (0.44 mmol/L), Hct 30% (0.30), Hgb 10 g/dL (100 g/L; 6.21 mmol/L), WBC $1.5 \times 10^3/mm^3$ ($1.5 \times 10^9$/L) with an absolute neutrophil count (ANC) of $1050/mm^3$ ($1.050 \times 10^9$/L).

The patient's blood pressure is dropping, and the patient is still hypotensive.

*What test(s) should be done to ascertain the cause of his continued fevers and night sweats?*

*Comment on the monitoring parameters that should be displayed in assisting this patient through the next 24 to 48 hours?*

*What pharmacological treatment should be used for this patient focusing on empiric antibiotics, doses, and addressing any toxicity that may result?*

*List the most likely resistance patterns than can result from overuse of antimicrobials for intra-abdominal processes.*

surgical incision.[1] The outer membrane components of gram-negative and gram-positive organisms contribute to the cascade of proinflammatory cytokines, ultimately leading to end-organ dysfunction (lungs, heart, kidneys) and septic shock.[6] Peritonitis may result in death because of the effects on major organ systems.

An abscess occurs if peritoneal contamination is localized but bacterial elimination is incomplete. The location of the abscess often is related to the site of primary disease. For example, abscesses resulting from appendicitis tend to appear in the right lower quadrant or the pelvis; those resulting from diverticulitis tend to appear in the left lower quadrant or pelvis. A mature abscess may have a fibrinous capsule that isolates bacteria and the liquid core from antimicrobials and immunologic defenses.

### Microbiology of Intra-Abdominal Infection

**KEY CONCEPT** *Primary bacterial peritonitis is often caused by a single organism.* In children, the pathogen is usually *Streptococcus pneumoniae* or a group A *Streptococcus*, *Escherichia coli*, *S. pneumoniae*, or *Bacteroides* species.[4,7] When peritonitis occurs in association with cirrhotic ascites, *E. coli* and *Klebsiella* are isolated most frequently.[8] Other potential pathogens are *Haemophilus pneumoniae*, *Klebsiella*, *Pseudomonas*, anaerobes, and *S. pneumoniae*.[9] Occasionally, primary peritonitis may be caused by *Mycobacterium tuberculosis*. Peritonitis in patients undergoing PD is caused most often by common skin organisms ranging from *S. aureus* to *S. epidermidis*, to *Pseudomonas aeruginosa*.[10] Occasionally, aerobic gram-negative bacilli may cause infections, particularly in patients undergoing dialysis during hospitalization.

**KEY CONCEPT** *Because of the diverse bacteria present in the GI tract, secondary IAIs are often polymicrobial.*[2,11]

### Bacterial Synergism and Other Factors

A combination of aerobic and anaerobic organisms appears to increase the severity of infection (synergism). Facultative bacteria (eg, *E. coli*) may provide an environment conducive to the growth of anaerobic bacteria.[2] Although many bacteria isolated in mixed infections are nonpathogenic by themselves, their presence may be essential for the pathogenicity of the bacterial mixture.[3]

Complicating the clinical picture for treatment are polymicrobial IAIs with certain bacterial species being isolated such as enterococci or *P. aeruginosa*. Depending on the patients' immune system (immunocompromised host), targeting these organisms may be necessary to avoid treatment failure or mortality.[12]

## CLINICAL PRESENTATION AND DIAGNOSIS

IAIs have a wide spectrum of clinical features. Peritonitis usually is easily recognized, but intra-abdominal abscess often may continue unrecognized for long periods of time. Patients with primary and secondary peritonitis present quite differently.

## TREATMENT

The primary goals of treatment are correction of the intra-abdominal disease processes or injuries that have caused infection and drainage of collections (source control) of purulent material (abscess). A secondary objective is to resolve the infection without major organ system complications (eg, pulmonary, hepatic, cardiovascular, or renal failure) or adverse drug effects. Ideally, the patient should be discharged from the hospital with full function for self-care and routine daily activities.

### General Approach to Treatment

The treatment of IAI most often requires the coordinated use of three major modalities: (a) prompt drainage; (b) support of vital functions; and (c) appropriate antimicrobial therapy to treat infection not eradicated by surgery.[13] Antimicrobials are an important adjunct to drainage procedures in the treatment of secondary IAIs; however, the use of antimicrobial agents without surgical intervention usually is inadequate. For most cases of primary peritonitis, drainage procedures may not be required, and antimicrobial agents become the mainstay of therapy.

**KEY CONCEPT** *In the early phase of serious IAIs, attention should be given to preserving major organ system function.* With generalized peritonitis, large volumes of IV fluids are required to maintain intravascular volume, to improve cardiovascular function, and to ensure adequate tissue perfusion and oxygenation. Adequate urine output should be maintained to ensure appropriate fluid resuscitation and to preserve renal function. A common cause of early death is hypovolemic shock caused by inadequate intravascular volume expansion and tissue perfusion.

An additional important component of therapy is nutrition. IAIs often involve the GI tract directly or disrupt its function

---

## Clinical Presentation of Primary Peritonitis

**General**

Patients may not be in acute distress, particularly with peritoneal dialysis.

**Symptoms**

Patient may complain of nausea, vomiting (sometimes with diarrhea), and abdominal tenderness.

**Signs**

- Temperature may be only mildly elevated or not elevated in patients undergoing peritoneal dialysis.
- Bowel sounds are hypoactive.

- Cirrhotic patients may have worsening encephalopathy.
- There may be cloudy dialysate fluid with peritoneal dialysis.

**Laboratory Tests**

- The WBC may be only mildly elevated.
- Ascitic fluid usually contains more than $0.3 \times 10^3/mm^3$ ($0.3 \times 10^9/L$) leukocytes, and bacteria may be evident on Gram stain of a centrifuged specimen.

**Other Diagnostic Tests**

Culture of peritoneal dialysate or ascitic fluid should be positive.

<div style="border:1px solid; background:#f2d0cc; padding:1em;">

## Clinical Presentation of Secondary Peritonitis

**General**

Patients may be in acute distress.

**Symptoms**

- Patients may complain of nausea, vomiting, and generalized abdominal pain.
- Patients may demonstrate abdominal guarding and a "boardlike abdomen."

**Signs**

- Tachypnea and tachycardia are present.
- Temperature is normal initially, then may increase to 100°F to 102°F (37.8°C–38.9°C) within the first few hours, and may continue to rise for the next several hours.
- Hypotension and shock may develop if intravascular volume is not restored.

- Decreased urine output may develop owing to dehydration.
- Bowel sounds are faint initially and eventually cease.

**Laboratory Tests**

- The WBC is high (WBCs $15$–$20 \times 10^3/mm^3$ [$15$–$20 \times 10^9$/L]), with neutrophils predominating and an elevated percentage of immature neutrophils (bands).
- The hematocrit and blood urea nitrogen increase because of dehydration.
- Hyperventilation and vomiting result in early alkalosis, which changes to acidosis and lactic academia to reduced intravascular volume and diminished tissue perfusion.

**Other Diagnostic Tests**

Abdominal radiographs may be useful because free air in the abdomen (indicating intestinal perforation) or distension of the small or large bowel is often evident.

</div>

(paralytic ileus). The return of GI motility may take days, weeks, and occasionally, months. In the interim, enteral or parenteral nutrition as indicated facilitates improved immune function and wound healing to ensure recovery.

## Nonpharmacologic Therapy

### ▶ Drainage Procedures

Primary peritonitis is treated with antimicrobials and rarely requires drainage. Secondary peritonitis requires surgical removal of the inflamed or gangrenous tissue to prevent further bacterial contamination. If the surgical procedure is suboptimal, attempts are made to provide drainage of the infected or gangrenous structures.

The drainage of purulent material is the critical component of management of an intra-abdominal abscess. This may be performed surgically or with percutaneous image-guided techniques.[14] Without adequate drainage of the abscess, antimicrobial therapy and fluid resuscitation can be expected to fail. The most valuable microbiologic information may be obtained at the time of percutaneous or operative abscess drainage.

### ▶ Fluid Therapy

In patients with peritonitis, hypovolemia is often accompanied by acidosis, and large volumes of an intravenous solution such as lactated Ringer may be required initially to restore intravascular volume. Maintenance fluids should be instituted (after intravascular volume is restored) with 0.9% sodium chloride and potassium chloride (20 mEq/L [20 mmol/L]) or 5% dextrose and 0.45% sodium chloride with potassium chloride (20 mEq/L [20 mmol/L]). The administration rate should be based on estimated daily fluid loss through urine and nasogastric suction, including 0.5 to 1.0 L for insensible fluid loss. Aggressive fluid therapy often must be continued in the postoperative period because fluid will continue to sequester in the peritoneal cavity, bowel wall, and lumen.

## Pharmacologic Therapy

### ▶ Antimicrobial Therapy

The goals of antimicrobial therapy are as follows:

- To control bacteremia and prevent the establishment of metastatic foci of infection

<div style="border:1px solid; background:#cfe6f2; padding:1em;">

## Patient Encounter 1, Part 2: Physical Examination and Diagnostic Tests

**PE:**

The patient is becoming more encephalopathic and somnolent, and she is still having a lot of pain (7/10 pain scale) the attending physician decides to perform an invasive test.

Ascitic fluid analysis is reported as following: hazy yellow color with 2125 cu/mm³ ($2.125 \times 10^9$/L) WBC, (38% [0.38] neutrophils, 5% [0.05] lymphocytes, 57% [0.57] macrophages). Urinalysis is not significant because the patient is oliguric and almost anuric. Other physical exam findings are nonsignificant.

**VS:** As noted previously

**Labs:** As noted previously

**Serum:** As noted previously

**KUB:** Negative findings

**DPL (diagnostic peritoneal lavage):** 2125 cu/mm³ ($2.125 \times 10^9$/L)

Microbiological cultures: 2/2 bottles from the blood positive for gram-positive pairs in chains and gram-negative bacilli cultured the small amount of urine collected.

*Discuss the most appropriate pharmacologic course of treatment, outlining medications, dosing, and monitoring parameters.*

*List the goals of treatment and follow-up plan that should be developed by the clinician to ensure positive patient outcomes.*

</div>

## Patient Encounter 2, Part 2

The patient's clinical status grows worse over the next couple of hours despite the efforts of the team. He is now placed on vasopressor therapy combined with fluid, antibiotics are begun emergently, and steroids are also begun. His urine output is less than 15 mL/hour and the patient is still mechanically ventilated.

*What are your next steps in terms of a care plan as well as monitoring parameters for this patient?*

*What is the overall goal of treatment in patients with intra-abdominal infections?*

*How do the pharmacologic versus nonpharmacologic goals compare in this patient?*

- To reduce suppurative complications after bacterial contamination
- To prevent local spread of existing infection

After suppuration has occurred (eg, an abscess has formed), a cure by antibiotic therapy alone is difficult to achieve; antimicrobials may serve to improve the results with surgery.

**KEY CONCEPT** *An empirical antimicrobial regimen should be started as soon as the presence of IAI is suspected and before identification of the infecting organisms is complete.* Therapy must be initiated based on the likely pathogens, which vary depending on the site of IAI and the underlying disease process. Cultures of secondary IAI sites generally are not useful for directing antimicrobial therapy. Table 77–1 lists the likely pathogens against which antimicrobial agents should be directed.

### ▶ Antimicrobial Experience

Important findings from the last 25 years of clinical trials regarding selection of antimicrobials for IAIs are as follows:

- Antimicrobial regimens for secondary IAIs should cover a broad spectrum of aerobic and anaerobic bacteria from the GI tract. Worrisome is the development of hospital-acquired IAIs with bacteria such as *P. aeruginosa, Acinetobacter* spp., *Proteus* spp., B-lactamase producing bacteria, methicillin-resistant *S. aureus* (MRSA), *Enterobacteriaceae*, *Candida* spp., and Enterococci that make the clinical management of these patients challenging.
- Single-agent regimens (such as antianaerobic cephalosporins, extended-spectrum penicillins with β-lactamase inhibitors, or carbapenems) are as effective as combinations of aminoglycosides or fluoroquinolones with antianaerobic agents. This is also true for antimicrobial treatment of acute bacterial contamination from penetrating abdominal trauma.
- Newer agents such as tigecycline and ertapenem may offer some theoretical advantages in the treatment of IAIs, but have some limitations. Tigecycline has a broad spectrum of activity against both aerobic and anaerobic gram negative rods, but lacks sufficient anti-*Pseudomonal* activity. Ertapenem is an example of a carbapenem that has a favorable pharmacokinetic profile (once daily dosing) and, like the other agents, lacks MRSA activity.
- Clindamycin and metronidazole appear to be equivalent in efficacy when combined with agents effective against aerobic gram-negative bacilli (eg, gentamicin or aztreonam).

**Table 77–1**

**Likely Intraabdominal Pathogens**

| Type of Infection | Aerobes | Anaerobes |
|---|---|---|
| **Primary (Spontaneous) Bacterial Peritonitis** | | |
| Children | Group A *Streptococcus, E. coli*, pneumococci | — |
| Cirrhosis | *E. coli, Klebsiella*, pneumococci (many others) | — |
| Peritoneal dialysis | *Staphylococcus, Streptococcus, E. coli, Klebsiella, Pseudomonas* | — |
| **Secondary Bacterial Peritonitis** | | |
| Gastroduodenal | *Streptococcus, E. coli* | — |
| Biliary tract | *E. coli, Klebsiella*, enterococci | *Clostridium* or *Bacteroides* (infrequent) |
| Small or large bowel | *E. coli, Klebsiella, Proteus* | *B. fragilis* and other *Bacteroides, Clostridium* |
| Appendicitis | *E. coli, Pseudomonas* | *Bacteroides* |
| Abscesses | *E. coli, Klebsiella, Streptococcus*, enterococci | *B. fragilis* and other *Bacteroides, Clostridium*, anaerobic cocci |
| Liver | *E. coli, Klebsiella, Streptococcus*, enterococci, *Staphylococcus*, amoeba | *Bacteroides* (infrequent) |
| Spleen | *Staphylococcus, Streptococcus, E. coli, Salmonella* | |

- For most patients, antimicrobial treatment can be completed orally with moxifloxacin, ciprofloxacin and metronidazole, levofloxacin plus metronidazole, or amoxicillin–clavulanate or the combination of ciprofloxacin and metronidazole.
- Four to 7 days of antimicrobial treatment are sufficient for most IAIs of mild to moderate severity.

IAI presents in many different ways and with a wide spectrum of severity. The antibiotic regimen employed and duration of treatment depends on the specific clinical circumstances (ie, the nature of the underlying disease process and the condition of the patient).

### Recommendations

**KEY CONCEPT** *For most IAIs, the antimicrobial regimen should be effective against both aerobic and anaerobic bacteria.*[15] Although it is impossible to provide antimicrobial activity against every possible pathogen, agents with activity against enteric gram-negative bacilli, such as *E. coli* and *Klebsiella*, and anaerobes, such as *B. fragilis* and *Clostridia* spp., should be administered.

Table 77–2 presents the recommended agents for treatment of community-acquired and complicated IAIs from the Infectious Diseases Society of America and the Surgical Infection Society.[15] These recommendations were formulated using an

**Recommended Agents for the Treatment of Community-Acquired Complicated Intraabdominal Infections in Adults**

| Agents Recommended for Mild-to-Moderate Infections | Agents Recommended for High Risk or High Severity Infections |
|---|---|
| **Single Agent** | |
| Cefoxitin[a] | Piperacillin–tazobactam |
| Ticarcillin–clavulanate | |
| Moxifloxacin[b] | Imipenem–cilastatin,[c] |
| Ertapenem[c] | Meropenem,[c] doripenem[c] |
| **Combination Regimens** | |
| Cefazolin,[a] cefuroxime,[a] ceftriaxone, cefotaxime each in combination with metronidazole | Cefepime or ceftazidime each in combination with metronidazole |
| Ciprofloxacin[b] or levofloxacin[b] each in combination with metronidazole | Ciprofloxacin[b] or levofloxacin[b] each in combination with metronidazole |

[a]Empiric first- and second-generation cephalosporin use should be avoided unless local antibiograms show > 80% to 90% susceptibility of *E. coli* to these agents.

[b]Use of quinolones may be associated with treatment failure due to increasing resistance of enteric pathogens including *E. coli*. Empiric quinolone use should be avoided unless local antibiograms show > 80% to 90% susceptibility of *E. coli* to quinolones.

[c]Carbapenems should typically be reserved for settings where there is a high risk of resistance to other agents.

Data from Pharmacotherapy: A Pathophysiologic Approach, 9th edition Adapted from Solomkin et al.

evidence-based approach. Most community-acquired infections are "mild to moderate," whereas health care-associated infections tend to be more severe and difficult to treat. Table 77–3 presents guidelines for treatment and alternative regimens for specific situations. These are general guidelines; there are many factors that cannot be incorporated into such a table.

When used for IAI, aminoglycosides should be combined with agents that are effective against the majority of *B. fragilis*; however, their side-effect profile may prohibit use secondary to nephrotoxicity. Clindamycin or metronidazole is the agent of first choice, but others, such as antianaerobic cephalosporins (eg, cefoxitin, cefotetan, or ceftizoxime), piperacillin, mezlocillin, and combinations of extended-spectrum penicillins with β-lactamase inhibitors would be suitable alternative. Preemptive antifungal therapy should maybe be indicated with either an azole antifungal (fluconazole) or an echinocandin (caspofungin) in patients who are immunocompromised or postsurgical with recurrent infection.

In immunocompromised patients or patients with valvular heart disease or a prosthetic heart valve, there is justification to provide specific antimicrobial activity against enterococci. Ampicillin or other penicillins that are active against enterococci (eg, penicillin, piperacillin, and mezlocillin) should be used in patients at high-risk, patients with persistent or recurrent IAI, or patients who are immunosuppressed, such as after organ transplantation. Ampicillin remains the drug of choice for this indication because it is most active in vitro against enterococci and is relatively inexpensive. Vancomycin is active against most

enterococci; however, resistance is increasing, and this agent should be reserved for established infections when first-line therapies cannot be used.

Intraperitoneal (IP) administration of antibiotics is preferred over IV therapy in the treatment of peritonitis that occurs in patients undergoing CAPD.[16] The International Society of Peritoneal Dialysis guidelines for the diagnosis and pharmacotherapy of PD-associated infections provide dosing recommendations for intermittent and continuous therapy based on the modality of dialysis (CAPD or automated PD [APD]) and the extent of the patient's residual renal function.[10]

**KEY CONCEPT** *Antimicrobial agents effective against both gram-positive and gram-negative organisms should be used for initial IP empirical therapy for peritonitis in PD patients.* The most important factors to take into consideration for initial antimicrobial selection are the dialysis center's and the patient's history of infecting organisms and their sensitivities. The use of cefazolin (loading dose [LD] 500 mg/L, maintenance dose [MD] 125 mg/L) plus ceftazidime (LD 500 mg/L, MD 125 mg/L) or cefepime (LD 500 mg/L, MD 125 mg/L) or an aminoglycoside (gentamicin-tobramycin LD 8 mg/L, MD 4 mg/L) is suitable for initial empirical therapy; if patients are allergic to cephalosporin antibiotics, vancomycin (LD 1000 mg/L, MD 25 mg/L) or an aminoglycoside should be substituted. Aztreonam is an alternative to ceftazidime or cefepime in this patient population. Another option is monotherapy with imipenem-cilastin (LD 750 mg/L, MD 50 mg/L) or cefepime. Antimicrobial doses should be increased empirically by 25% in patients with residual renal function (greater than 100 mL/day urine output).[10] Antimicrobial therapy should be continued for at least 1 week after the dialysate fluid is clear and for a total of at least 14 days. The reader is referred to these guidelines for additional information.[10]

After acute bacterial contamination, such as with abdominal trauma where GI contents spill into the peritoneum, combination antimicrobial regimens are not required. If the patient is seen soon after injury (within 2 hours) and surgical measures are instituted promptly, antianaerobic cephalosporins (eg, cefoxitin or cefotetan) or extended-spectrum penicillins are effective in preventing most infectious complications. Antimicrobials should be administered as soon as possible after injury.[17]

For appendicitis, the antimicrobial regimen used should depend on the appearance of the appendix at the time of operation, which may be normal, inflamed, gangrenous, or perforated. Because the condition of the appendix is unknown preoperatively, it is advisable to begin antimicrobial agents before the appendectomy is performed. Reasonable regimens would be antianaerobic cephalosporins or, if the patient is seriously ill, a carbapenem or β-lactam–β-lactamase-inhibitor combination. If, at operation, the appendix were normal or inflamed, postoperative antimicrobials would not be required. If the appendix is gangrenous or perforated, a treatment course of 5 to 7 days with the agents listed in Table 77–2 is appropriate.

**KEY CONCEPT** *Acute intra-abdominal contamination, such as after a traumatic injury, may be treated with a short course (24 hours) of antimicrobials.[17] For established infections (ie, peritonitis or intra-abdominal abscess), an antimicrobial course limited to 4 to 7 days is justified.* Under certain conditions, therapy for longer than 7 days would be justified, for example, if the patient remains febrile or is in poor general condition, when relatively resistant bacteria are isolated, or when a focus of infection in the abdomen still may be present. For some abscesses, such as pyogenic liver abscess, antimicrobials may be required for a month or longer.

**Table 77–3**

**Guidelines for Empiric Antimicrobial Agents for Intraabdominal Infections [39,49]**

| | Primary Agents | Alternatives |
|---|---|---|
| **Primary (Spontaneous) Bacterial Peritonitis** | | |
| Cirrhosis | Ceftriaxone, cefotaxime | 1. Piperacillin–tazobactam, carbapenems<br>2. Aztreonam combined with an agent active against *Streptococcus* spp. (e.g., vancomycin) or quinolones with significant *Streptococcus* spp. activity (levofloxacin, moxifloxacin) |
| Peritoneal dialysis | Initial empiric regimens should be active against both gram-positive (including *S. aureus*) and gram-negative pathogens: Gram-positive agent (first-generation cephalosporin or vancomycin) plus a gram-negative agent (third-generation cephalosporin or aminoglycoside)<br>1. *Staphylococcus* spp.:oxacillin/nafcillin or first-generation cephalosporin | 1. Cefepime or carbapenems may be used alone<br>2. Aztreonam or an aminoglycoside may be used in place of ceftazidime or cefepime as long as combined with a gram-positive agent<br>3. Quinolones may be used in place of gram-negative agents if local susceptibilities allow<br>1. Vancomycin should be used if concern for methicillin-resistant *Staphylococcus* spp.<br>2. Add rifampin for 5–7 days with vancomycin for methicillin-resistant *Staphylococcus aureus* |
| | 2. *Streptococcus* or *Enterococcus*: ampicillin | 1. An aminoglycoside may be added for *Enterococcus* spp.<br>2. Linezolid, daptomycin, or quinupristin/dalfopristin should be used to treat vancomycin-resistant *Enterococcus* spp. not susceptible to ampicillin |
| | 3. Aerobic gram-negative bacilli: ceftazidime or cefepime<br>4. *Pseudomonas aeruginosa*: two agents with differing mechanisms of action, such as an oral quinolone plus ceftazidime, cefepime, tobramycin, or piperacillin | 1. The regimen should be based on in vitro sensitivity tests |
| **Secondary Bacterial Peritonitis** | | |
| Perforated peptic ulcer | First-generation cephalosporins | 1. Ceftriaxone, cefotaxime, or antianaerobic cephalosporins[a] |
| Other | Third- or fourth-generation cephalosporin with metronidazole, piperacillin–tazobactam or ticarcillin–clavulanate, carbapenem | 1. Ciprofloxacin[b] or levofloxacin[b] each with metronidazole or *moxifloxacin*[b] alone<br>2. Aztreonam with vancomycin and metronidazole<br>3. Antianaerobic cephalosporins[a] |
| **Abscess** | | |
| General | Third- or fourth-generation cephalosporin with metronidazole, piperacillin–tazobactam, or ticarcillin–clavulanate | 1. Imipenem–cilastatin, meropenem, doripenem, or ertapenem<br>2. Ciprofloxacin[b] or levofloxacin[b] each with metronidazole or moxifloxacin alone |
| Liver | As above | Use metronidazole if amoebic liver abscess is suspected |
| Spleen | Ceftriaxone or cefotaxime | Moxifloxacin[b] or levofloxacin[b] |
| **Other Intraabdominal Infections** | | |
| **Appendicitis** | Same management as for community-acquired complicated intraabdominal infections as listed in Table 92-6[39] | |
| **Community-Acquired Acute Cholecystitis** | Ceftriaxone or cefotaxime | Severe infection, piperacillin/tazobactam, antipseuodomonal carbapenem, aztreonam with metronidazole |
| **Cholangitis** | Ceftriaxone or cefotaxime each with or without metronidazole | Vancomycin with aztreonam with or without metronidazole |
| **Acute Contamination from Abdominal Trauma** | Antianaerobic cephalosporins[a] or metronidazole with either ceftriaxone or cefotaxime | 1. Piperacillin/tazobactam or a carbapenem<br>2. Ciprofloxacin[b] or levofloxacin[b] each with metronidazole or moxifloxacin alone |

[a]Cefoxitin or ceftizoxime; these agents should be avoided empirically unless local antibiograms show > 80% to 90% susceptibility of *E. coli* to these agents.

[b]Use of quinolones may be associated with treatment failure due to increasing resistance of enteric pathogens including *E. coli*. Empiric quinolone use should be avoided unless local antibiograms show > 80% to 90% susceptibility of *E. coli* to quinolones.

## OUTCOME EVALUATION

● Whether diagnosed with primary or secondary peritonitis, monitor the patient for relief of symptoms. Once antimicrobials are initiated and the other important therapies described earlier are used, most patients should show improvement within 2 to 3 days.

Successful antimicrobial therapy with resolution of infection will result in decreased pain, manifested as resolution of abdominal guarding and decreased use of pain medications over time. The patient should not appear in distress, with the exception of recognized discomfort and pain from incisions, drains, and a nasogastric tube.

Monitor vital signs and WBC count with differential; each should normalize as the infection resolves. At 24 to 48 hours, aerobic bacterial culture results should be available. If a suspected pathogen is not sensitive to the antimicrobial agents being given, the regimen should be changed if the patient has not shown sufficient improvement. If the isolated pathogen is extremely sensitive to one antimicrobial and the patient is progressing well, concurrent antimicrobial therapy often may be discontinued.

With anaerobic culturing techniques and the slow growth of these organisms, anaerobes often are not identified until 4 to 7 days after culture, and sensitivity information is difficult to obtain. For this reason, anaerobic culture information generally is not helpful for selection of the antianaerobic component of the antimicrobial regimen.

Once the patient's temperature is normal for 48 to 72 hours and the patient is eating, consider changing the IV antibiotic to an oral regimen for the duration of antibiotic treatment. Monitor the serum creatinine level to evaluate for renal complications as well as potential drug toxicity, especially if an aminoglycoside is a component of the antibiotic regimen. Bowel sounds should return to normal. Evaluate the patient daily for development of rash or other drug-related adverse effects.

For patients with primary peritonitis, if peritoneal dialysate cultures were positive initially, repeat cultures should be negative. For patients with secondary peritonitis, monitor the amount of fluid draining if a drain was placed. The volume of drainage should lessen as the infection resolves. Repeat abdominal radiographs should return to normal.

If symptoms do not improve, the patient should be evaluated for persistent infection. There are many reasons for poor patient outcome with IAI; improper antimicrobial selection is only one. The patient may be immunocompromised, which decreases the likelihood of successful outcome with any regimen. It is impossible for antimicrobials to compensate for a nonfunctioning immune system. There may be surgical reasons for poor patient outcome. Failure to identify all intra-abdominal foci of infection or leaks from a GI anastomosis may cause continued IAI. Even when IAI is controlled, accompanying organ system failure, most often renal or respiratory, may lead to patient demise.

**KEY CONCEPT** *Health care-associated infections are becoming more common for IAIs secondary to acute care hospital admissions or admissions from chronic care settings. The major pathogens include more resistant gram-negative flora,* Candida *infections causing peritonitis, and Enterococcal species.*

The outcome from IAI is not determined solely by what transpires in the abdomen. Unsatisfactory outcomes in patients with IAIs may result from complications that arise in other organ systems. Infectious complications commonly associated with mortality after IAI are urinary tract infections and pneumonia.[18] Reasons for antimicrobial failure may not always be apparent. Even when antimicrobial susceptibility tests indicate that an organism is susceptible in vitro to the antimicrobial agent, therapeutic failures may occur. Possibly there is poor penetration of the antimicrobial agent into the focus of infection, or bacterial resistance may develop after initiation of antimicrobial therapy. Also, it is possible that an antimicrobial regimen may encourage the development of infection by organisms not susceptible to the regimen being used. Superinfection in patients being treated for IAI can be caused by *Candida*; however, Enterococci or opportunistic gram-negative bacilli such as *Pseudomonas* and *Serratia* may be involved.

Treatment regimens for IAI can be judged as successful if the patient recovers from the infection without recurrent peritonitis or intra-abdominal abscess and without the need for additional antimicrobials. A regimen can be considered unsuccessful if a significant adverse drug reaction occurs, reoperation or percutaneous drainage is necessary, or patient improvement is delayed beyond 1 or 2 weeks.

## Patient Care Process

### Patient Assessment:

- You should do a thorough patient medication history at the time of admission to document all recent medication use, including nonprescription medications and use of complementary or alternative medicines. You should also document any drug allergies or intolerances for your patient you are working up.

### Therapeutic Evaluation:

- Be cognizant for the initial antimicrobial regimen conforming to standard guidelines (unless an appropriate justification for an alternative regimen is evident). See Table 77–3.

### Care Plan Development:

- You need to review the dosages of all medications to be sure that they are appropriate for age, weight, and major organ function.
- You should also verify that the drugs selected are not contraindicated in the patient with allergies or other intolerances.
- You should select antimicrobials that are appropriate based on the susceptibility information, while reviewing the results of the obtained both preoperatively or during the surgical procedure.
- On the fifth day of antimicrobial treatment or when GI function returns, determine whether parenteral antimicrobial agents can be switched to oral agents to complete therapy.
- Assess nutritional needs and recommend appropriate supplementation. When the patient is tolerating an oral diet, determine whether any parenteral medications can be switched to the oral route.

### Follow-Up Evaluation:

- You should monitor the patient for the development of potential complications of treatment such as delayed hypersensitivity reactions, antibiotic-induced diarrhea, pseudomembranous colitis, or fungal superinfections (manifested as oral thrush).
- You should also provide information to the patient concerning the medications administered in the hospital as well as any new medications prescribed for use at home.
- You should also advise the patient to contact his or her doctor or pharmacist if he or she experiences any adverse effects from medications.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| ANC | Absolute neutrophil count |
| APD | Automated peritoneal dialysis |
| CAPD | Continuous ambulatory peritoneal dialysis |
| DPL | Diagnostic peritoneal lavage |
| IAIs | Intra-abdominal infections |
| IP | Intraperitoneal |
| LD | Loading dose |
| MD | Maintenance dose |
| MRSA | Methicillin-resistant *S. aureus* |
| PD | Peritoneal dialysis |

# 78 Parasitic Diseases

J. V. Anandan

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Identify the primary reasons why some parasitic diseases may be more prevalent in the US population.
2. Describe the treatment algorithm for giardiasis and amebiasis.
3. List one effective therapy for nematodes and select the drugs of choice for strongyloidiasis and tapeworms.
4. List three major reasons why travelers are infected with malaria.
5. Describe the presenting signs and symptoms of malaria.
6. List some specific toxicities of mefloquine.
7. Identify the monitoring parameters for quinidine gluconate in severe malaria.
8. Define the major complications of falciparum malaria.
9. Discuss the cardiovascular complications of chronic South American trypanosomiasis.
10. Describe the steps to take to eradicate lice infestation and scabies.

## INTRODUCTION

The increased desire of large segments of the US population to travel to Asia, Africa, and other parts of the world can expose them to parasitic infections that are endemic in those areas. The influx of refugees and new immigrant populations from Asia and other parts of the world have brought new parasitic infections to our shores. Migrant farm workers, the large and growing Central and South American immigrant population, and the presence of immunosuppressed populations (eg, those with the AIDS and transplant patients) represent significant sources of parasitic infections in the United States.[1–5]

Terms that are frequently used when discussing parasitic diseases are as follows.[6] *Symbiosis* means "living together," when two species are dependent on each other for food and protection. The term *commensalism*, implies a mutual association in which both organisms may benefit, or at least one benefits but does no harm to the other. In contrast, *parasitism*, although resembling symbiosis in that it is also an intimate relationship between two species does not represent a mutually beneficial association. One species (the host) does not benefit from the relationship, and in fact the relationship may be detrimental to its survival.

Parasites have made metabolic and other defensive adaptations over time to increase their ability to survive host defenses and have allowed them to utilize the host's biochemical systems to synthesize necessary cellular components. Beef and pork tapeworms (cestodes) possess highly developed reproductive systems that allow them to transfer easily to new hosts. Because of the lack of digestive systems, cestodes are completely host-dependent for all nutrients. Cestodes (tapeworms) (*Taenia saginata* and *Taenia solium*) use specialized suckers that enable them to obtain blood

and vital nutrients from their host. *Entamoeba histolytica*, once it has gained access to the human colon or large intestine is able to invade and utilize its specialized proteolytic enzyme to erode the GI mucosa. *E. histolytica* is also able to survive in adverse conditions by walling itself off and forming cysts; this protects the parasite from environmental conditions until it is ready to infect the next host.

Although acquired immunity to some parasitic diseases may lower the level of infection, absolute immunity as seen in bacterial and viral infections is seldom seen in parasitic diseases. Since parasitic infections produce a wide variety of antigens because of the many life cycle phases, it is more difficult to identify a constant antigenic protein against which specific antibodies are protective. However, malaria remains a likely candidate for a vaccine and there are ongoing studies to develop one.

For more detailed discussions of the world of parasites, clinicians and students are directed to some excellent resources on parasites and parasitic diseases.[5,6] Discussion in this chapter includes parasitic diseases more likely seen in the United States and includes GI parasites (primarily giardiasis and amebiasis), protozoan infections (malaria and South American trypanosomiasis), some common helminthic diseases (specifically those caused by nematodes and cestodes), and ectoparasites (lice and scabies).

## GIARDIASIS
### Epidemiology and Etiology

*Giardia lamblia* (*G. intestinalis* or *G. duodenalis*), is the most common intestinal parasite responsible for diarrheal syndromes throughout the world and is the most frequently identified

## Patient Encounter 1: Giardiasis

LA is a 29-year-old recently returned US resident who had traveled to Texcoco in Mexico to visit a friend he had met at a meeting in Mexico city. Although the majority of his meals were in his friend's house, the night before returning home he had a meal at a local restaurant. Three days after his return from Texcoco he developed severe nausea, diarrhea, alternating with constipation. When he is seen at the travel clinic at a local hospital, he reports nausea and crampy, watery diarrhea with foul-smelling stools for four days. LA also reported that his stool was "light-colored."

*Are his symptoms characteristic of parasitic-associated diarrhea?*

*How would you differentiate giardiasis from an Escherichia coli–induced diarrhea?*

intestinal parasites in the United States, with a prevalence rate of 5% to 15% in some areas. *G. lamblia* has been identified as the first enteric pathogen in children in developing countries, with prevalence rates between 15% and 30%.[7,8]

There are two stages in the life cycle of *G. lamblia*: the trophozoite and the cyst. *G. lamblia* is found in the small intestine, the gallbladder, and in biliary drainage.[7,8] The distribution of giardiasis is worldwide, with children being more susceptible than adults.

### Pathophysiology

Giardiasis is caused by ingestion of *G. lamblia* cysts in fecally contaminated water or food.[7,8] The protozoan excysts in the low gastric pH to release the trophozoite. Colonization and multiplication of the trophozoite lead to mucosal invasion, localized edema, and flattening of the villi, resulting in malabsorption states in the host. Achlorhydria, hypogammaglobulinemia, or deficiency in secretory immunoglobulin A (IgA) predispose to giardiasis.[7] Individuals with HIV infection and AIDS may have higher carriage rates than the general population. Some patients may develop lactose intolerance after chronic giardiasis.

### Pharmacologic Therapy

**KEY CONCEPT** *All symptomatic adults and children over the age of 8 years with giardiasis should be treated with metronidazole 250 mg three times daily for 7 days, or tinidazole 2 g as a single dose, or nitazoxanide (Alina) 500 mg twice daily for 3 days.*[9] The pediatric dose of metronidazole is 15 mg/kg/day three times daily for 7 days. Alternative drugs include furazolidone 100 mg four times daily or paromomycin 25 to 35 mg/kg/day in divided doses daily for 7 days. Paromomycin may be used in pregnancy instead of metronidazole. Pediatric patients can also be treated with suspensions of furazolidone 6 mg/kg/day in four divided doses for 7 days.

Quinacrine 100 mg three times in adults or 5 mg/kg/day in pediatric patients for 5 to 7 days, is available from a specialized pharmacy (eg, Panorama Compounding Pharmacy).[9]

### Outcome Evaluation

Patients with symptomatic giardiasis and positive stool samples or positive enzyme-linked immunosorbent assay (ELISA) tests should be treated with metronidazole for 7 days. Patients who

## Clinical Presentation and Diagnosis of Giardiasis

**Acute Onset**

- Diarrhea, cramp-like abdominal pain, bloating, and flatulence
- Malaise, anorexia, nausea, and belching

**Chronic Symptoms**

- Diarrhea: Foul-smelling, copious, light-colored, and greasy stools
- Weight loss, steatorrhea, and vitamin $B_{12}$ and fat-soluble vitamin deficiencies
- Constipation alternating with diarrhea

**Diagnosis**

- Diagnosis is made by examination of fresh stool or a preserved specimen during acute diarrheal phase
- Fresh stool may show trophozoites, whereas preserved specimens yield cysts. (*Note:* stool for ova may show the presence of other parasites [eg, *Cryptosporidium parvum, E. histolytica*, or *E. hartmanni*]; multiple stool samples may be needed.)
- Stool examination for ova and parasites is the major means of diagnosis, and other diagnostic tests include enzyme-linked immunosorbent assay (ELISA), which is considered to be between 85% and 98% sensitive and almost 100% specific (ProSpec T, Giardia Microplate Assay, Remel, Lenexa, KS.)

## Patient Care Process: Giardiasis

**Patient Assessment:**

- Evaluate patient medical history, recent travel, signs, and symptoms.
- Conduct a medication history, review laboratory findings and consider if stool for O/P and other tests may be necessary for diagnosis of giardiasis.

**Therapy Evaluation:**

- Based on symptoms and laboratory findings, consider the appropriate pharmacotherapy for the patient.
- Discuss expected side effects, any drug interactions and availability of the prescribed medication in the community or hospital.

**Care Plan Development:**

- Consider any dietary or other considerations for giardiasis—fluids and replacements for deficiencies if warranted.
- Address patient concerns about the infection and the therapy.

**Follow-Up Evaluation:**

- Decide when patient should come back for follow-up.
- Inform patient for repeat stool for O/P and the need for reevaluation at the end of therapy.

fail initial therapy with metronidazole should receive a second course of therapy. Pregnant patients can receive paromomycin 25 to 35 mg/kg/day in divided doses for 7 days. Giardiasis can be prevented by good hygiene and by using caution in food and drink consumption.

## AMEBIASIS
### Epidemiology and Etiology

Amebiasis remains one of the most important parasitic diseases because of its worldwide distribution and serious GI manifestations. The major causative agent in amebiasis is *E. histolytica*, which invades the colon and must be differentiated from *Entamoeba dispar*, which is associated with an asymptomatic carrier state and is considered nonpathogenic.[10,11] Invasive amebiasis is almost exclusively the result of ingesting *E. histolytica* cysts found in fecally contaminated food or water. Approximately 50 million cases of invasive disease result each year worldwide, leading to an excess of 100,000 deaths. In the general population, the highest incidence is found in institutionalized mentally retarded patients, sexually active homosexuals, AIDS patients, the Native American population, and new immigrants from endemic areas (eg, Mexico, South and Southeast Asia, West and South Africa, and portions of Central and South America).[10,11]

### Pathophysiology

*E. histolytica* invades mucosal cells of colonic epithelium, producing the classic flask-shaped ulcer in the submucosa. The trophozoite toxin has a cytocidal effect on cells. If the trophozoite gets into the portal circulation, it will be carried to the liver, where it produces abscess and periportal fibrosis. Liver abscesses are more common in men than women and are rarely seen in children.[11,12] Amebic ulcerations can affect the perineum and genitalia, and abscesses may occur in the lung and brain.

Erosion of liver abscesses can result in peritonitis. Liver abscesses that are located in the right lobe can spread to the lungs and pleura. Pericardial infection, although rare, may be associated with extension of the amebic abscesses from the liver.[11,12]

---

### Patient Encounter 2: Amebiasis

DR is a 32-year-old computer programmer who, on returning from visiting Angkor Wat in Siem Reap, Cambodia, is seen in the emergency department at Detroit Receiving Hospital with complaints of a 3-day history of severe diarrhea, cramps, and postprandial abdominal pain. The abdominal pain is over the right lower quadrant and associated with nausea and flatulence. DR indicates that he had some diarrhea the night after he had visited a local restaurant in Siem Reap. The diarrhea subsided after treatment from a local physician. However, 5 days later after his return to the States, his symptoms came back.

*What specific findings in this patient suggest that he may have giardiasis, amebiasis or an E. coli-associated diarrhea?*

*What specific laboratory or diagnostic test will confirm a diagnosis of amebiasis?*

*Describe some of the complications associated with amebiasis.*

---

### Clinical Presentation and Diagnosis of Amebiasis

Review of the patient's history should include the following: recent travel, type of foods ingested (eg, salads or unpeeled fruit), the nature of water and fluid consumed, and description of any symptoms of friends or relatives who ate the same food

#### Intestinal Disease

- Vague abdominal discomfort
- Symptoms may range from malaise to severe abdominal cramps, flatulence, and nonbloody or bloody diarrhea (heme-positive in 100% of cases) with mucus
- May have low-grade fever, but this may be absent in many patients
- Eosinophilia is usually absent, although mild leukocytosis is not unusual

*Note:* Fecal screening may show other intestinal parasites, including *Cryptosporidium* spp., *Balantidium coli, Dientamoeba fragilis, Isospora belli, G. lamblia,* or *Blastocystis hominis.*

#### Amebic Liver Abscess

- May present with high fever with significant leukocytosis with **left shift**, anemia, elevated alanine aminotransferase, and dull abdominal pain on palpation
- *Physical findings:* Right upper quadrant pain, hepatomegaly, and liver tenderness, with referred pain to the left or right shoulder (*Note*: Erosion of liver abscesses may present as peritonitis.)

**KEY CONCEPT** Diagnosis

- *Intestinal amebiasis is diagnosed by demonstrating E. histolytica cysts or trophozoites (may contain ingested erythrocytes) in fresh stool or from a specimen obtained by sigmoidoscopy*
- *Microscopy may not differentiate between the pathogenic E. histolytica and the nonpathogenic (commensal) E. dispar or E. moshkovskii in stools*
- *Sensitive techniques are available to detect E. histolytica in stool: antigen detection, antibody test (ELISA) and polymerase chain reaction (PCR)*
- **Endoscopy** with scrapings or biopsy and stained slides (iron hematoxylin or trichrome) may provide more definitive diagnosis of amebiasis
- Diagnosis for liver abscess includes serology and liver scans (using isotopes by ultrasound or computed tomography [CT]) or MRI; however, none of these are specific for liver abcess. In rare instances, needle aspiration of hepatic abscess may be attempted using ultrasound guidance

### Pharmacologic Therapy

Metronidazole (Flagyl), dehydroemetine, and chloroquine (Aralen) are tissue-acting agents, and iodoquinol (Yodoxin), diloxanide furoate (Furamide), and paromomycin (Humatin) are well absorbed that the amounts of the drug remaining in the bowel may be insufficient to have luminal or local effects. A agent active in the GI lumen, on the other hand, may not attain effective enough

levels in the tissue to be efficacious. Asymptomatic cyst passers (identified by stool examinations, and who may develop invasive disease) and patients with mild intestinal amebiasis should receive a luminal agent: paromomycin 25 to 35 mg/kg/day three times daily for 7 days, or iodoquinol 650 mg three times daily for 20 days. These regimens have cure rates of between 84% and 96%. The pediatric dose of paromomycin is the same as that used in adults, whereas the pediatric dose of iodoquinol is 30 to 40 mg/kg (maximum: 2 g) per day in three doses for 20 days, and the pediatric dose of diloxanide furoate is 20 mg/kg/day in three doses for 10 days. Paromomycin is the preferred agent in pregnant patients.[9,11]

Patients with severe intestinal disease or liver abscess should receive metronidazole 750 mg three times daily for 10 days, followed by the luminal agents indicated previously. The pediatric dose of metronidazole is 50 mg/kg/day in divided doses, which should be followed by a luminal agent.[11–14] An alternative regimen of metronidazole is 2.4 g/day for 2 days in combination with the luminal agent.[9,11,12] Tinidazole administered in a dose of 2 g daily for 3 days (pediatric dose: 50 mg/kg for 3 days; can be crushed and added to cherry syrup) is an alternative to metronidazole.[9] If there is no prompt response to metronidazole or aspiration of the abscess, an antibiotic regimen should be added. Patients who cannot tolerate oral doses of metronidazole should receive an IV dose of metronidazole.[11,12]

## Outcome Evaluation

Follow-up in patients with amebiasis should include repeat stool examinations, serology, colonoscopy (in colitis), or CT scan a month after the end of therapy. Serial liver scans have demonstrated healing of liver abscesses over 4 to 8 months after adequate therapy.[12,14]

## Patient Care Process: Amebiasis

**Patient Assessment:**
- Based on physical exam, review of systems and travel history, determine if these findings are consistent with giardiasis or amebiasis.
- Address what specific diagnostic tests would be required to make a definitive diagnosis for amebiasis.
- Conduct a medication history and check for allergies.

**Therapy Evaluation:**
- Determine, based on the results of the diagnostic tests, whether this is amebic colitis or colitis with liver abscess.
- Verify whether the drug or drugs you intend to use is on the hospital formulary or readily available at a local pharmacy.

**Care Plan Development:**
- Select pharmacotherapy and appropriate regimen and check for any potential drug interactions.
- Address any patient concerns and discuss the need for medication adherence and dietary restrictions.

**Follow-Up Evaluation:**
- Follow-up in 10 days and repeat tests to evaluate therapy.
- Monitor for efficacy and toxicity.

## HELMINTHIC DISEASES

Helminthic infections include three groups of organisms: roundworms or nematodes, flukes (trematodes), and tapeworms (cestodes). Brief descriptions of some of the helminthic infections most commonly seen in North America and their treatments are provided here. Although helminthic infections may not produce clinical manifestations, they can cause significant pathology. One factor that determines the pathogenicity of helminthic infections is their population density; a high-density population ("worm burden") results in predictable disease presentation. In the United States, these infections are reported most frequently in recent immigrants from Southeast Asia, the Caribbean, Mexico, and Central America.[1,15–17] Populations at risk include institutionalized patients (both young and elderly), preschool children in daycare centers, residents of Native American reservations, and homosexuals.[15,16] Certain conditions and drugs (anesthesia and corticosteroids) can cause atypical localization of worms. Immunocompromised hosts can be overwhelmed by some helminthic infections, such as *Strongyloides stercoralis*.

## Nematodes

### ▶ Hookworm Disease

Hookworm infection is caused by *Ancylostoma duodenale* or *Necator americanus*. *N. americanus* is found in the southeastern United States.[15–17] Infective larvae enter the host in contaminated food or water or penetrate the skin and migrate to the small intestine. The adult worm attaches to GI mucosa and causes injury by lytic destruction of the tissue. Over a period of time, the adult worm can cause anemia and hypoproteinemia in the host.[18–20]

### ▶ Treatment

**KEY CONCEPT** *The drug of choice is mebendazole (Vermox), which is also active against ascariasis, enterobiasis, trichuriasis, and hookworm.*[9,21] The adult and pediatric (age greater than 2 years) oral dose of mebendazole for hookworm is 100 mg twice daily for 3 days. An alternative agent that can be used in both pediatric and adult patients is albendazole (Zentel), 400 mg as a single oral dose. Diagnosis is by detection of eggs or larvae in stool. Stool examination for eggs and the larvae should be repeated in 2 weeks and the patient retreated if necessary.

## Ascariasis

The causative agent in ascariasis is the giant roundworm *Ascaris lumbricoides,* which is found worldwide and is responsible for about 4 million infections in the United States (it primarily affects residents of the Appalachian mountain range and the Gulf Coast states).[15–17] Migration of the worm into the lungs usually produces pneumonitis, fever, cough, eosinophilia, and pulmonary infiltrates. *Ascaris* infection can also cause abdominal discomfort, intestinal obstruction, and appendicitis. Diagnosis is made by detection of the characteristic eggs in the stool or passed worms.

### ▶ Treatment

In both adults and pediatric patients older than 2 years of age, mebendazole 100 mg orally twice daily for 3 days is the treatment to use. An alternative agent is pyrantel pamoate (Antiminth).[9] The stool should be checked within 2 weeks and the patient retreated when warranted.

## Enterobiasis

Enterobiasis, or pinworm infection, is caused by *Enterobius vermicularis*. It is the most widely distributed helminthic infection in the world.[15–17] There are approximately 42 million cases in the United States, primarily affecting children. The most common manifestation of the infection is cutaneous irritation in the perianal region, resulting from the migrating female or the presence of eggs. The intense pruritus may lead to dermatitis and secondary bacterial infections. Diagnosis is made by the use of a perianal swab and cellophane tape sampling, which will aid in egg identification.

### ▶ Treatment

The three agents that are administered for enterobiasis include pyrantel pamoate, mebendazole, and albendazole.[9] The oral dose of pyrantel pamoate is 11 mg/kg (maximum: 1 g) as a single dose that can be repeated in 2 weeks. The oral dose of mebendazole for both adults and children older than 2 years of age is 100 mg as a single dose. This may be repeated in 2 weeks.[9] Following treatment, to eradicate the eggs, all bedding and underclothing should be sterilized by steaming or washing in the hot cycle of the washing machine.

## Strongyloidiasis

Strongyloidiasis is caused by *Strongyloides stercoralis,* which has a worldwide distribution and is predominantly prevalent in South America (Brazil and Columbia) and in Southeast Asia.[33–38] Strongyloidiasis is primarily seen among institutionalized populations (those in mental hospitals and children's hospitals) and immunocompromised individuals (those with HIV infection, AIDS, and patients with hematologic malignancies).[22–24] The worm is usually found in the upper intestine, where the eggs are deposited and hatch to form the rhabditiform larvae. The rhabditiform larva (male and female) migrate to the bowel where they may be excreted in the feces. If excreted in the feces, the larva can evolve into either one of two forms after copulation: a free-living noninfectious rhabditiform larvae, or an infectious filariform larvae. The filariform larva can penetrate host skin and migrate to the lungs and produce progeny, a process called **autoinfection**. This can result in hyperinfection (ie, an increased number of larva in the intestine, lungs, and other internal organs), especially in an immunocompromised host.

Patients with acute infection may develop a localized pruritic rash, but heavy infestations can produce eosinophilia (10%–15% eosinophils [0.10–0.15]), diarrhea, abdominal pain, and intestinal obstruction. Administration of corticosteroids or other immunosuppressive drugs to an infected individual can result in hyperinfections and disseminated strongyloidiasis.[23,24] Diagnosis of strongyloidiasis is made by identification of the rhabditiform larva in stool, sputum, or duodenal fluid, or from small bowel biopsy specimens. Even though antigen testing (ELISA essay) remains the most sensitive method, stool examinations and other body fluids should also be utilized in the diagnosis.[22,24]

### ▶ Treatment

**KEY CONCEPT** *The drug of choice for strongyloidiasis is oral ivermectin 200 mcg/kg/day for 2 days, whereas albendazole 400 mg twice daily is given for 7 days as an alternative.*[9] With hyperinfection or disseminated strongyloidiasis, immunosuppressive drugs should be discontinued and treatment should be initiated with ivermectin 200 mcg/kg/day until all symptoms are resolved. Patients should be tested periodically to ensure the elimination of the larva.

Individuals from an endemic area who are candidates for organ transplantation must be screened for *S. stercoralis*.[24]

## Cestodiasis

Cestodiasis (tapeworm infection) is caused by species of the phylum Platyhelminthes (flatworms) and include, among others, the pork tapeworm (*Taenia solium*) and the beef tapeworm (*T. saginata*).[6,25] The tapeworm attaches itself to the mucosal wall of the upper jejunum by the scolex (mouth parts) and by two to four cup-shaped suckers and a structure called a rostellum, which may have hooks in some species. Since the parasite lacks a digestive system, it obtains all nutrients directly from the host. The scolex, proglottids (segments), and eggs are specific for each species and used for identification of tapeworms. Tapeworm infections are caused by ingestion of poorly cooked meat that contains the larva or cysticerci. Cysticerci, when released from the contaminated meat by host digestive juices, mature in the host jejunum. Cystericercosis is a systemic disease caused by the larva of *T. solium* (oncosphere or hexacanth) and is usually acquired by ingestion of eggs in contaminated food or by autoinfection.[6,25] The larvae can penetrate the bowel and migrate through the bloodstream to infect different organs, including the central nervous system (CNS) (neurocysticercosis). Diagnosis of both *T. saginata* and *T. solium* is accomplished by recovery of the gravid proglottids and the scolex in the stool. Newer diagnostic tools for neurocysticercosis include serum and cerebrospinal antigen and antibody testing.[25]

### ▶ Treatment

**KEY CONCEPT** *Tapeworm infections (T. saginata and T. solium) are treated with praziquantel 5 to 10 mg/kg as a single dose (use the same dose for adults and pediatric patients).*[9] The treatment for cysticercosis and neurocysticercosis may include surgery, anticonvulsants (neurocysticercosis can cause seizures), and anthelmintic therapy. The anthelmintic therapy of choice is albendazole 400 mg twice daily for 5 to 30 days.[25–29] The pediatric dose of albendazole is 15 mg/kg (maximum: 800 mg) in two divided doses for 8 to 30 days. The doses for both adults and pediatric subjects can be repeated if necessary. Praziquantel is an alternative therapy.[9]

## Outcome Evaluation

Morbidity and disease due to helminthic infections is related to the intensity of infection. The major adverse effects of helminthic infections are malnutrition, fatigue, and diminished work capacity. Unlike other helminthic infections, strongyloidiasis can cause autoinfection, and in the presence of immunosuppression, it can cause CNS and disseminated infections, which have high mortality.[23,24]

The most serious complication of cysticercosis is neurocysticercosis that can cause strokes and seizures.[26,27] Treatment of neurocysticercosis with anthelmintic treatment remains controversial.

## MALARIA

Malaria is one of the most devastating parasitic diseases, affecting a population in excess of 500 million and causing in excess of 660,000 deaths a year worldwide.[2,3] In the year 2000, approximately 27 million US travelers visited countries where malaria is endemic. In 2011, the Centers for Disease Control and Prevention indicated that there were 1925 cases of malaria, an increase of 14% over 2010 and the highest number reported since 1971.[3] There were five fatalities, three due to *Plasmodium falciparum*

## Patient Encounter 3, Part 1: Malaria

AR is a 52-year-old West African man who had returned recently from Cameroon. He was well since returning from Cameroon until 2 days ago, when he developed a temperature as high as 39.0°C (102.2°F), with anorexia, headache, chills, sweats, myalgias, and abdominal pain. AR comes to the emergency department with high fever (greater than 39.8°C [greater than 103.6°F]), headache, abdominal pain, nausea, stiffness of the neck, and back pain. AR indicates that he took some antimalarials but missed some days and is not able to name the exact medication or doses taken.

*What are the symptoms in this patient that are consistent with malaria?*

*Why is this patient at risk for malaria?*

*Are there any additional information you like to have, to be able to develop a pharmacotherapy plan for this patient?*

*and one due P. vivax* (the malaria species in one case was not reported).[3] **KEY CONCEPT** *The primary reasons for morbidity and death in malaria are failure to take recommended chemoprophylaxis, inappropriate chemoprophylaxis, delay in seeking medical care or in initiating therapy promptly, and misdiagnosis.*[3] Evaluation of a patient should include specific travel history, details of chemoprophylaxis, and physical findings (eg, splenomegaly).

Malaria is transmitted by the bites of the *Anopheles* mosquitoes, which introduce into the bloodstream one of five species of sporozoites of the plasmodia (*Plasmodium falciparum, P. ovale, P. vivax, P. malariae, and P.knowlesi*).[30–33] Initial symptoms of malaria are nonspecific and may resemble influenza and include chills, headache, fatigue, muscle pain, rigors, and nausea. The onset of the symptoms is between 1 and 3 weeks following exposure. Fever may appear 2 to 3 days after initial symptoms and may follow a pattern and occur every 2 or 3 days (*P. vivax, P. ovale,* and *P. malariae*). Fever with *P. falciparum* can be erratic and may not follow specific patterns. It is not unusual for patients to have concomitant infections with *P. vivax* and *P. falciparum.* Falciparum malaria (or *P. knowlesi*) must always be regarded as a life-threatening medical emergency.

### Epidemiology and Etiology

The distribution of the various species of malaria is not well defined, but *P. vivax* is reported to be prevalent in the Indian subcontinent, Central America, North Africa, and the Middle East, whereas *P. falciparum* is predominantly in Africa (including sub-Saharan Africa), both East and West Africa, Haiti, the Dominican Republic, the Amazon region of South America, Southeast Asia, and New Guinea.[3,30,31] Most *P. ovale* infections occur in Africa, whereas the distribution of *P. malariae* is worldwide.[3,30] Most infections in the United States are reported in American travelers, recent immigrants, or immigrants who have visited friends and family in an endemic area.[3,30] Placental transmission and blood transfusions are also sources of malaria.

### Pathophysiology

Within minutes after the bite of the *Anopheles* mosquito, the sporozoites invade hepatocytes and begin an asexual phase called schizonts (exoerythrocytic stage or schizogony). The patient may be asymptomatic during this period. After a lapse of between 5 and 15 days (depending on the species), schizonts rupture to release daughter cells (merozoites) into the blood, which then invade erythrocytes. In erythrocytes, the merozoites undergo a number of sequential forms: a ring form, trophozoite, schizont, and merozoite, which then invade new erythrocytes. This asexual phase is about 48 hours for *P. falciparum, P. vivax,* and *P. ovale,* and 72 hours for *P. malariae.* Subsequently, the merozoites develop into gametocytes and undergo a sexual phase (sporogony) in the *Anopheles* mosquito. In the mosquito, the gametocytes undergo a number of stages: zygote, ookinete, and oocyst, and finally transform into sporozoites in the salivary glands, where it is again able to infect the next host. Unlike *P. falciparum* and *P. malariae,* which only remain in the liver for about 3 weeks before invading erythrocytes, *P. ovale* and *P. vivax* can remain in the liver for extended periods in a latent stage (as hypnozoites); this can result in the recurrence of the infection after weeks or months. Primaquine therapy is necessary to eradicate this stage of the infection.[9]

### Clinical Presentation and Diagnosis

The clinical presentation of malaria can be quite variable. Normally, the appearance of a prodrome with headache, abdominal pain, fatigue, fever, and chills, which coincides with the erythrocytic phase of malaria, occurs frequently between 10 and 21 days after being exposed.[3,30,31] This phase causes extensive hemolysis, which results in anemia and splenomegaly. The most serious complications are caused by *P. falciparum* infections. Infants and children younger than 5 years and nonimmune pregnant women are at high risk for severe complications with falciparum infections.[30,31,34] The complications associated with falciparum malaria are related to two unique features of *P. falciparum*: (a) its ability to produce high parasitism (up to 80%) of red cells of all ages; and (b) the propensity to be sequestered in postcapillary venules of critical organs such as brain, liver, heart, lungs, and kidneys.[30,34] It has been postulated that tissue hypoxia from anemia, together with *P. falciparum*–parasitized red blood cell adherence to endothelial cells in capillaries, contributes to severe ischemia and metabolic derangements.[34] *P. malariae* is implicated in immune-mediated **glomerulonephritis** and nephrotic syndrome.[35]

### Clinical Presentation and Diagnosis

Innovations for detecting malaria include DNA or RNA probes by PCR and monoclonal antibody testing.[3,30] These, however, are not widely available for clinical use. A *P. falciparum*–specific monoclonal antibody test, histidine-rich protein 2 (HRP-2), is fairly sensitive for *P. falciparum* and is recommended by the World Health Organization as an alternative for microscopic test (the "gold standard"). However, the rapid malaria diagnostic tests (MRDTs) are restricted from wide use by cost, regulatory standards, operative expertise, and availability.[2,3,30]

### Treatment

The primary goal in the management of malaria is the rapid identification of the *Plasmodium* species by blood smears (both thick and thin smears repeated every 12 hours for 3 days). Antimalarial therapy should be initiated promptly to eradicate the infection within 48 to 72 hours and avoid complications such as hypoglycemia, pulmonary edema, and renal failure.[3,31,34,36]

### Pharmacologic Therapy

In an uncomplicated attack of malaria (for all plasmodia except chloroquine-resistant *P. falciparum and P. vivax*), the

## Patient Encounter 3, Part 2: Falciparum Malaria

TW presents with fever, nausea, headache, myalgias, chills, and body aches including back pain.

**PMH:** Otherwise healthy 52-year-old man

**FH:** Father died of colon cancer at age 62 years; mother, who is 82-year-old, has osteoarthritis and lives with an unmarried daughter

**SH:** Works for an office supply company; infrequently drinks a beer

**Meds:** Amlodipine 10 mg; furosemide 40 mg

**ROS:** In addition to the complaints noted previously, he complains of severe nausea and fatigue

**PE:**

**Gen:** Patient is slightly agitated and febrile

**VS:** BP 170/98 mm Hg; P 120 beats/min, RR 36 breaths/min, T 40.1°C (104.2°F)

**Skin:** Warm and dry to touch

**HEENT:** Slightly dry oral mucosa

**ABD:** Splenomegaly

Rest of the systems were WNL

**Labs:** Sodium 148 mEq/L (148 mmol/L), hemoglobin 10.2 g/dL (102 g/L or 6.33 mmol/L), potassium 4.1 mEq/L (4.1 mmol/L), hematocrit 31% (0.31), chloride 96 mEq/L (96 mmol/L), WBC $14.8 \times 10^3/mm^3$ ($14.8 \times 10^9$/L), BUN 28 mg/dL (10.0 mmol/L), total bilirubin 1.8 mg/dL (30.8 μmol/L), Scr 1.4 mg/dL (124 μmol/L), platelets $110 \times 10^3/mm^3$ ($110 \times 10^9$/L), glucose 77 mg/dL (4.3 mmol/L), aspartate aminotransferase 87 U/L (1.45 μkat/L), albumin 3.2 g/dL (32 g/L), alanine aminotransferase 94 U/L (1.57 μkat/L), blood smear (Giemsa stain): *P. falciparum*.

*As a result of above findings, what is your approach in the management of TW?*

*Describe the specific steps one need to take to ensure a good outcome and minimize the associated complications with P. falciparum infection.*

---

recommended oral regimen is chloroquine 600 mg (base) initially, followed by 300 mg (base) 6 hours later, and then 300 mg (base) daily for 2 days.[9,36] **KEY CONCEPT** *In severe illness or falciparum malaria, patients should be admitted to an acute care unit, and quinidine gluconate 10 mg salt/kg as a loading dose (maximum 600 mg) in 250 mL normal saline should be administered IV slowly over 1 to 2 hours. This should be followed by continuous infusion of 0.02 mg/kg/min of quinidine for at least 24 hours until oral therapy can be started. In patients who have received either quinine or mefloquine, the loading dose of quinidine should be omitted. Oral quinine salt (650 mg every 8 hours) plus doxycycline 100 mg twice daily should follow the IV dose of quinidine to complete 7 days of therapy.*[9,36] The pediatric dose of IV quinidine gluconate is the same as the dose for adults. The pediatric dose of oral quinine is 25 mg/kg/day in three divided doses, whereas the dose of doxycycline (children greater than 8 years) is 4 mg/kg in two divided doses for 7 days. An alternative to doxycycline is clindamycin 900 mg (20 mg/kg/day) three times daily for 3 days. The pediatric dose of clindamycin is the same as in adults. *(In patients who cannot tolerate quinidine or if quinidine is not readily available, IV artesunate 2.4 mg/kg/dose for 3 days, at 0, 12, 24, 48, and 72 hours may be used, followed by oral therapy. Artesunate is available from the Centers for Disease Control and Prevention [CDC] under an investigational new drug application. The pediatric dose of artesunate is same as in adults. Oral therapy may include atovaquone/proguanil, doxycycline, mefloquine or clindamycin.)*[9,36]

## Clinical Presentation and Diagnosis of Malaria

**Initial Presentation**

Include a careful travel history of patient and physical findings (eg, splenomegaly) and details of antimalarial chemoprophylaxis, when obtainable

**Erythrocytic Phase**

1. Prodrome: Headache, anorexia, malaise, fatigue, and myalgia
2. Nonspecific complaints include abdominal pain, diarrhea, chest pain, and arthralgia
3. Paroxysm: High fever, chills, and rigor
4. Cold phase: Severe pallor, cyanosis of the lips and nail beds
5. Hot phase: Fever between 40.5°C (104.9°F) and 41.0°C (105.8°F) (seen more frequently with *P. falciparum*)
6. Sweating phase: Follows the hot phase by 2 to 6 hours
7. When fever resolves, it is followed by marked fatigue and drowsiness, warm dry skin, tachycardia, cough, headache,

nausea, vomiting, abdominal pain, diarrhea and delirium, anemia, and splenomegaly

**KEY CONCEPT** *P. falciparum malaria is a life-threatening emergency. Complications include hypoglycemia, acute renal failure, pulmonary edema, severe anemia (high parasitism), thrombocytopenia, heart failure, cerebral congestion, seizures, coma, and adult respiratory distress syndrome*

**Diagnostic Procedures for Malaria**

1. To ensure a positive diagnosis, blood smears (both thick and thin films) should be obtained every 12 to 24 hours for 3 consecutive days
2. The presence of parasites in the blood 3 to 5 days after initiation of therapy suggests resistance to the drug regimen

In *P. falciparum, P. vivax, P. ovale,* or *P. malariae* (chloroquine-resistant) infections, a dose of 750 mg of mefloquine followed by 500 mg 12 hours later is recommended.[9,36] The pediatric dose of mefloquine is 15 mg/kg (less than 45 kg) followed by 10 mg/kg 8 to 12 hours later. Mefloquine is associated with sinus brady-cardia, confusion, hallucinations, and psychosis and should be avoided in patients with a history of epilepsy, cardiovascular problems or depression. IV quinidine gluconate followed by qui-nine plus doxycycline or clindamycin should be administered for severe illness as indicated previously. The IV quinidine regimen requires close monitoring of the ECG (QT-segment) and other vital signs (hypotension and hypoglycemia). An alternative oral treatment for *P. falciparum* infections in adults, especially those with history of seizures, psychiatric disorders, or cardiovascular problems, is the combination of atovaquone 250 mg and pro-guanil 100 mg (Malarone) (two tablets twice daily for 3 days).[12] The pediatric dose of Malarone is as follows: it is not indicted for children less than 5 kg; 9 to 10 kg: three pediatric tablets per day for 3 days; 11 to 20 kg: one adult tablet per day for 3 days; 21 to 30 kg: two adult tablets per day for 3 days; 31 to 40 kg: three adult tablets per day for 3 days; greater than 40 kg: two adults tab-lets twice daily for 3 days. **KEY CONCEPT** *Since falciparum malaria is associated with serious complications, including pulmonary edema, hypoglycemia, jaundice, renal failure, confusion, delirium, seizures, coma, and death, careful monitoring of fluid status and hemody-namic parameters is mandatory.* Exchange transfusion that may be required in patients with *P. falciparum* malaria in whom parasitemia may be between 5% and 15% remains a controversial modality.[3,36] Either peritoneal or hemodialysis may be indicated in renal failure.

### Outcome Evaluation

Acute *P. falciparum* malaria resistant to chloroquine should be treated with IV quinidine and the loading dose of quinidine should be omitted in patients who have received quinine or mefloquine. Hypoglycemia, that is associated with both *P. falciparum* and quinidine administration, should be checked every 6 hours and when necessary, corrected with dextrose (5%–10%) infusions. Quinidine infusions should be slowed or stopped if the QT inter-val is greater than 0.6 second, the increase in the QRS complex is greater than 25%, or hypotension unresponsive to fluid challenge results. Quinidine levels should be maintained at 3 to 7 mg/dL (9.2–21.6 μmol/L). If quinidine is not readily available, artesunate

(investigational protocol) should be obtained from the Cen-ters for Disease Control and Prevention (www.cdc.gov/malaria/features/artesunate_now available.htm).[9,36]

When advising potential travelers on prophylaxis for malaria, be aware of the incidence of chloroquine-resistant *P. falciparum* malaria and the countries where it is prevalent.[36,37] In patients who have *P. vivax* or *P. ovale* malaria (note that some patients can have *P. falciparum* and one of these species), following the treatment of the acute phase of malaria and screening for glucose-6-phosphate dehydrogenase deficiency, patients should receive a regimen of primaquine for 14 days to ensure eradica-tion of the hypnozoite stage of *P. vivax* or *P. ovale*.[9,36] For detailed recommendations for prevention of malaria, go to www.cdc.gov/travel/. *Vaccines for malaria are under investigation.*[37]

## AMERICAN TRYPANOSOMIASIS
### Etiology

Two distinct forms of the genus *Trypanosoma* occur in humans. One is associated with African trypanosomiasis (sleeping sickness) and the other with American trypanosomiasis (Chagas disease). *Trypanosoma brucei gambiense* and *Trypanosoma brucei rhod-esiense* are the causative organisms for the East African and West African trypanosomiasis, respectively. *T. brucei rhodesiense* causes the acute disease and is the more virulent of the two species. Both East and West African trypanosomiasis are transmitted by vari-ous species of tsetse fly belonging to the genus *Glossina*. Further discussion of this subject will focus on American trypanosomiasis.

*Trypanosoma cruzi* is the agent that causes American trypano-somiasis. American trypanosomiasis is transmitted by a number of species of reduviid bugs (*Triatoma infestans* and *Rhodium prolixus*) that live in wall cracks of houses in rural areas of North, Central, and South America.[38–41] The reduviid bug is infected by sucking blood from animals (eg, opossums, dogs, and cats) or humans infected with circulating trypomastigotes. American trypanosomiasis is endemic in all Latin American countries and can be transmitted congenitally, by blood transfusion, and by organ transplantation.[42]

### ▶ Pharmacologic Therapy

The drugs used for *T. cruzi* include nifurtimox (Lampit) and benznidazole (Rochagan). Oral nifurtimox is available from

---

## Patient Care Process: Malaria

**Patient Assessment:**
- Based on the physical exam and review of systems, determine whether patient has acute malaria.
- Review all laboratory tests and take note of blood work that identifies the species of plasmodia reported.
- Conduct a medication history and identify any allergies.

**Therapy Evaluation:**
- Determine, based on patient presentation and previous therapy, if acute malaria is chloroquine sensitive or chloroquine-resistant.
- Assess the efficacy of present therapy and patient adherence.
- Recheck blood smears and parasite load.

**Care Plan Development:**
- Determine what modification in therapy is warranted.
- Review new regimen, consider whether a combination therapy is needed and check for any drug interactions.
- Check the CDC Malaria Website for recommended therapy.

**Follow-Up Evaluation:**
- Monitor patient for efficacy and toxicity.
- Review physical exam findings, lab tests, and diagnostic tests.

## Clinical Presentation and Diagnosis of Trypanosomiasis

### Acute
- Unilateral orbital edema (Romana sign)
- Granuloma (chagoma)
- Fever, hepatosplenomegaly, and lymphadenopathy

**KEY CONCEPT** ### Chronic
- *Cardiac: cardiomyopathy and heart failure*
- *ECG: first-degree heart block, right bundle-branch block, and arrhythmias*
- *GI: enlargement of the esophagus and colon ("mega" syndrome)*
- *CNS: meningoencephalitis, strokes, seizures, and focal paralysis*

### Diagnosis
Positive history of exposure and use of serology: indirect hemagglutination test, ELISA (Chagas EIA, Abbott Labs, Abbott Park, IL), and complement fixation (CF) test. (*Note:* CF may produce false-positive reactions in those exposed to leishmaniasis, syphilis, and malaria. PCR may be more definitive for diagnosis.)

---

the CDC, whereas benznidazole is only available in Brazil.[9,42–44] The adult dose of nifurtimox is 8 to 10 mg/kg/day in divided doses for 120 days. Since children seem to tolerate the dose better than adults, the pediatric dose of nifurtimox for 1- to 10-year-old children is 15 to 20 mg/kg/day, and for 11- to 16-year-old children is 12.5 to 15 mg/kg/day in divided doses.[9] Symptomatic treatment for heart failure associated with Chagas disease should be initiated. The GI complications may require surgical revisions and reconstruction.

### Outcome Evaluation

Treatment of the acute phase of the disease (ie, fever, malaise, edema of the face, and hepatosplenomegaly) is nifurtimox. The congestive heart failure associated with cardiomyopathy of Chagas disease is treated the same way as cardiomyopathy from other causes.[38,39]

## ECTOPARASITES

A parasite that lives outside the body of the host is called an ectoparasite. Approximately 6 to 12 million subjects become infested with pediculosis (lice infestation) yearly in the United States. Pediculosis is usually associated with poor hygiene, and infections are passed from person to person through social and sexual contact.

### Lice

The two species that belong to this group include *Pediculus humanus capitis* (head louse) and *Pediculus humanus corporis* (body louse).[45–47] The eggs (or nits) remain firmly attached to the hair, and in about 10 days the lice hatch to form nymphs, which mature in 2 weeks. The lice become attached to the base of the hair follicle and feed on the blood of the host.[10] Pubic or crab lice is found on the hairs around the genitals but may occur in other parts of the body (eg, eyelashes or axillae). Hypersensitivity to the secretions from lice can produce macular swellings and lead to secondary bacterial infections.

### ► Treatment

**KEY CONCEPT** *The agent of choice for all three infections (body, head, and crab lice) is 1% permethrin (Nix).*[9,45–47] Permethrin has both pediculicidal and ovicidal activity against *P. humanus capitis*. The cure rate is reported to be between 90% and 97%. A cream rinse of permethrin 1% (Nix-Crème Rinse) is also available. Individuals with a history of hypersensitivity to ragweed or chrysanthemum may react to permethrin and should avoid this preparation. An alternative agent is oral ivermectin 100 mcg/kg for 3 days (days 1, 2, and 10). Permethrin can cause itching, burning, stinging, and tingling with application. Permethrin 1% should be applied to the dry scalp after shampooing and be left on the scalp for 10 minutes. The application may need to be repeated. Because of the reports of resistance to permethrin, an alternative agent is 0.5% malathion (Ovide), which has to be left on the scalp for 90 minutes and has also been found to be effective. Two applications of malathion, 7 days apart, may be necessary to eradicate the infection.[9] An alternative for head lice is Spinosad 0.9% Creme which became available for patients who may not tolerate permethrin.[47] Benzyl alcohol 5% (Ulesfia) is a recently available lice therapy for subjects over 6 months. For the relief of pruritus, calamine lotion with 0.1% menthol or an equivalent agent may be used. *All individuals, including immediate family members and sexual*

---

## Patient Care Process: Trypanosomiasis (Chagas Disease)

**Patient Assessment:**
- Review medical history and laboratory tests including serology to establish the diagnosis for *T. cruzi*.
- Identify common complications associated with *T. cruzi*.

**Therapy Evaluation:**
- Determine if patient needs to be treated for primary disease and any secondary complications.
- Assess efficacy, safety, and potential drug interactions.

**Care Plan Development:**
- Determine the doses and regimen for pharmacotherapy.

- Address patient concerns and discuss the importance of adherence.

**Follow-Up Evaluation:**
- Review medical history, physical exam findings, and lab tests monthly.
- Determine, after assessing efficacy and toxicities of pharmacotherapy, if changes in regimen are necessary.

*partners of the primary host, should be treated. All bedding and clothes should be sterilized as previously indicated for enterobiasis.*

## SCABIES

**KEY CONCEPT** *Scabies is caused by the itch mite Sarcoptes scabiei hominis, which affects both humans and animals. Infection usually affects the interdigital and popliteal folds, axillary folds, the umbilicus, and the scrotum.* The infection causes severe itching and excoriations in the interdigital web spaces, buttocks, groin, and scalp.[48–50] *Diagnosis is made by identifying the mite from skin scrapings on a wet mount.*

### Treatment

**KEY CONCEPT** *The agent of choice for scabies is permethrin 5% (Elimite) cream.*[9] Alternative agents in subjects who cannot use permethrin are crotamiton 10% (Eurax) and oral ivermectin (Stromectol) 200 mcg/kg as a single dose. To initiate the treatment with permethrin, the skin should be scrubbed in a warm soapy bath to remove the scabs. The permethrin lotion should then be applied to the whole body, avoiding the face, mucous membranes, and eyes, and left on for 8 to 14 hours. A single application eradicates 97% of scabies. However, in subjects with poor response, permethrin application can be combined with oral ivermectin therapy.[48–50] All close contacts should be treated appropriately. The pruritus associated with scabies may persist for 2 to 4 weeks because of the remnants of mite parts in the skin.

### Outcome Evaluation

Infections due to arthropods can be controlled by preventing their access to the host. Improving living conditions and avoiding sharing common personal items like hats and hair brushes may minimize these infections due to arthropods. Permethrin (1%–5%) is an effective agent for all these infections.

## Abbreviations Introduced in This Chapter

CDC   Centers for Disease Control and Prevention
CF    Complement fixation
ELISA Enzyme-linked immunosorbent assay
IgA   Immunoglobulin A
PCR   Polymerase chain reaction

# 79 | Urinary Tract Infections

Warren E. Rose

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Determine the diagnostic criteria for significant bacteriuria.
2. Interpret the signs and symptoms of urinary tract infections (UTIs) and differentiate those of upper versus lower urinary tract disease.
3. Identify the organism responsible for the majority of uncomplicated UTIs.
4. Assess the laboratory tests that help in diagnosing patients with UTI.
5. Recommend appropriate drug, dose, and duration for uncomplicated and complicated UTI prophylaxis and empiric treatment.
6. Evaluate and select therapy for uncomplicated and complicated UTIs based on specific urine culture results and patient characteristics.
7. Formulate appropriate monitoring and education information for patients with UTIs.

## INTRODUCTION

Urinary tract infections (UTIs) are comprised of a diverse array of syndromes depending on the location of the infection within the urinary tract.[1–3] UTIs are one of the most common infectious diseases accounting for approximately 10.5 million annual ambulatory patient visits.[4] In hospitalized patients, UTIs are also common and are reported in 3.7% of catheterized and 0.9% of non-catheterized patients.[5] A UTI is defined by microorganism(s) in the urinary tract, which does not represent contamination.

## EPIDEMIOLOGY AND ETIOLOGY

The prevalence and type of UTIs generally vary by age and gender.[7,8] Premature infants have a higher rate than full-term infants, and neonatal boys are five to eight times more likely to have UTIs than neonatal girls. In young children 1 to 5 years of age, significant **bacteriuria** occurs more in girls than boys, 4.5% compared with 0.5%, respectively.[9] Once adulthood is reached, bacteriuria increases in young, nonpregnant women (range, 1%–3%), yet remains low in men (up to 0.1%).[10] Symptomatic UTI affects 30% of women between 20 and 40 years of age, which represents a prevalence that is 30 times greater than that of men in the same age group. The lifetime risk of UTIs in women is as high as 50% based on symptomatic reporting.[11]

The etiology of UTIs has remained relatively unchanged over the past several decades. **KEY CONCEPT** *UTIs are either uncomplicated or complicated.* There is a lack of consensus regarding the definition of what makes a UTI complicated (specifically in postmenopausal women or patients with diabetes mellitus), but in general, a complicated UTI refers to a structural or functional abnormality of the urinary tract.[1] Patients with complicated UTIs are typically given longer treatment durations than those patients with uncomplicated infections. Those with complicated UTIs by definition are also prone to more frequent infections. It is important to note that an upper UTI does not necessarily imply complicated UTI, nor does lower UTI imply uncomplicated UTI.

## PATHOPHYSIOLOGY

There are three potential ways for bacteria to enter into the urinary tract and cause infection: the ascending, hematogenous, and lymphatic pathways.

### Ascending Pathway

The ascending pathway is involved when bacteria colonizing the urethra subsequently travel upwards, or ascend, the urethra to the bladder and cause **cystitis** (**Figure 79–1**). Women have a shorter urethra than men, and colonization of the female urethra is likely due to its proximity to the perirectal area.[12–14] Once in the bladder, bacteria are not limited to causing cystitis. These bacteria may continue to ascend the urinary tract via the ureters and cause more complicated infections, such as **pyelonephritis**.

### Hematogenous Pathway

The hematogenous route is involved through the seeding of the urinary tract with pathogens carried by the blood supply. These pathogens represent an infection at some other primary site in the body. *Staphylococcus aureus* **bacteremia** can cause renal abscesses via the hematogenous route,[15] and pyelonephritis can be experimentally produced in rabbits by intravenous (IV) injection of *Salmonella* spp., *Mycobacterium tuberculosis*, or even yeast (*Candida* spp.).[16] *E. coli* and *P. aeruginosa* are less likely to seed the kidneys via hematogenous spread.[16]
**FIGURE 79–1.** Anatomy and associated infection of the urinary tract. (From Sprandel KA, Lesch CA, Rodvold KA. Lower urinary tract infection. IN: Schwinghammer TL (ed). 6th ed. New York: McGraw-Hill; 2005; 315; with permission.)

## Host Defense Mechanisms

Urine possesses characteristics that are not ideal for bacterial metabolism and growth such as low pH, high urea concentration, and high osmolality. Bacteria in the bladder can stimulate an urge to urinate and increase bacterial voiding. In men, prostatic fluid secretions in can inhibit bacterial growth, whereas normal vaginal flora in women such as *Lactobacillus* spp. can secrete lactic acid that further lowers the pH of the enviroment.[17–19]

Innate host response and adaptive immunity are a primary defense against bacterial infections including UTIs.[20] Several other secreted host factors specifically inhibit bacterial virulence factors. Virulence factors are mechanisms that bacteria utilize to cause infection and/or ensure their survival. Glycosaminoglycan is compound produced by the bladder that coats the epithelial cells. This separates the bladder from the urine by forming a protective layer against bacterial adhesion.[21] Tamm-Horsfall protein is also secreted into the urine and prevents *E. coli* from binding to receptors present on the surface of the bladder.

## Risk Factors

There are several risk factors for development of UTIs.[10] Common risk factors for UTIs in women include sexual intercourse, use of a cervical diaphragm, use of spermicidal jellies, diabetes, and pregnancy.[22–24] In men, the risks are increased in uncircumcised males and older age men with prostatic hyperplasia. Common risk factors for both men and women include urologic

---

| Table 79–1 |
| --- |

**Diagnostic Criteria for Significant Bacteriuria**

- Greater than or equal to $10^2$ CFU coliforms/mL ($10^5$ CFU/L) or greater than or equal to $10^5$ CFU noncoliforms/mL ($10^8$ CFU/L) in a symptomatic female
- Greater than or equal to $10^3$ CFU organisms/mL ($10^6$ CFU/L) in a symptomatic male
- Greater than or equal to $10^5$ CFU same organisms/mL ($10^8$ CFU/L) in asymptomatic individuals on two consecutive specimens
- Any growth of bacteria on suprapubic catheterization in a symptomatic patient
- Greater than or equal to $10^2$ CFU organisms/mL ($10^5$ CFU/L) in a catheterized patient

instrumentation, urethral catheterization, renal transplantation, neurogenic bladder, and urinary tract obstruction.[25,26]

## CLINICAL PRESENTATION AND DIAGNOSIS

Bacteriuria, or bacteria in the urine, does not always represent infection. For this reason, quantitative diagnostic criteria have been created (Table 79–1) to identify the amount of bacteria in

---

**Clinical Presentation and Diagnosis of UTIs**

**General**

- Most women present with hematuria; however, this is not a presentation restricted only to UTIs.
- Elderly patients frequently will not present with common signs and symptoms of UTI, but may present with altered mental status.
- More than 95% of uncomplicated UTIs are caused by a single organism.
- Patients may present with urosepsis.

**KEY CONCEPT** *Signs and Symptoms of Lower UTI*

- *Dysuria, gross hematuria, suprapubic heaviness, nocturia, increased urinary frequency and urgency*

**KEY CONCEPT** *Signs and Symptoms of Upper UTI*

- *Fever, nausea, vomiting, malaise, and often severe flank pain*

**Laboratory Tests**

Urinalysis should show:

- **Pyuria** typically greater than 10 white blood cells/mm³ urine ($10 \times 10^6$/L)
- Bacteriuria, usually greater than $10^5$ CFU organisms/mL ($10^8$ CFU/L)
- Nitrites present
- Leukocyte esterase present

**Other Diagnostic Tests**

- Bacterial urine culture
- Presence of costovertebral tenderness (upper UTI only)

## Patient Encounter, Part 1

AC is a 30-year-old woman who presents to an acute care clinic with complaints of a 3-day history of dysuria and urgency. She has had three prior UTI episodes in the last 6 months each treated with oral trimethoprim/sulfamethoxazole 800/160 mg daily for 3 days. Her last antibiotic course finished 6 days ago. She denies vomiting, fever, nausea, or flank pain. Urine culture information is not available from previous UTI episodes.

*What signs and symptoms are suggestive of a lower urinary tract infection (UTI)?*

*Would you classify this patient as noncomplicated or complicated UTI?*

*How does this change your treatment approach?*

*What additional patient information is required before creating an appropriate treatment plan for this patient?*

the urine that most likely represents true infection. Clinically this is referred to as significant bacteriuria.[6] UTIs are classified as lower tract or upper tract disease. Lower tract urinary infections are usually less severe and are treated in the outpatient setting. Cystitis, a common lower tract syndrome, involves inflammation of the bladder and is associated with symptoms of dysuria, nocturia, gross hematuria, and occasional suprapubic tenderness. Upper tract disease such as pyelonephritis is generally more severe infection, and patients more often present with symptoms of systemic response such as fever, chills, and elevated white blood cell count. Patients with upper tract infection are more likely to be admitted to the hospital for treatment.

## TREATMENT

KEY CONCEPT *The goals of treatment are to eradicate the causative pathogen, prevent or treat consequences of infection, administer targeted antimicrobial therapy for the identified or most likely pathogen, minimize unnecessary exposure to noncausative organisms, and prevent, if possible, recurrence of infection.* Therapy is directed at microbiologic eradication of the offending organism through antibiotics with a defined duration of treatment based on the UTI classification.

Antimicrobial therapy is the cornerstone of treatment in symptomatic UTIs. The selected antimicrobial should ideally be well tolerated, lend itself to patient compliance (low total number of doses), have adequate concentrations at the site of the infection in the urinary tract, have good oral bioavailability, and be narrow in antimicrobial spectrum to limit collateral damage and resistance development in human flora not affiliated with the infection.[1]

### Nonpharmacologic Therapy

Several nonpharmacologic therapies have been proposed for prevention of UTIs. The intake of large volumes of cranberry juice has been associated with a decrease in the number of UTIs over a year period in patients with recurrent UTIs in small randomized controlled trials. The efficacy is uncertain in the general population and with smaller intake volumes.[27–29] Probiotics such as *Lactobacillus* spp. lower urinary pH and may reduce the growth of pathogenic bacteria[18,19], and the agents have demonstrated promise in preventing recurrent UTIs in women.[30] Topical estrogen replacement therapy significantly decreases the incidence of UTIs in postmenopausal women as compared with placebo.[31] Methenamine hippurate and methenamine mandelate are hydrolyzed in acidic urine to the antimicrobial formaldehyde and are effective in preventing UTIs in patient without renal tract abnormalities.[32] Patient education of common risk factors is important.

### Pharmacologic Therapy

Table 79–2 reviews oral and IV antibiotics frequently used to treat UTIs with comments on their use, and Table 79–3 reviews frequency, duration, and doses of oral antibiotics used commonly for outpatient treatment of UTIs.

#### ▶ Uncomplicated UTIs

**Cystitis** Uncomplicated cystitis is frequently managed in the outpatient setting and occurs mostly in women of childbearing age.[1]

### Table 79–2

**Commonly Used Antimicrobial Agents for the Treatment of UTIs**

| Agent | Comments |
| --- | --- |
| **Oral Therapy** | |
| *Penicillins* | |
| Amoxicillin | Increasing *E. coli* resistance has limited amoxicillin use in acute cystitis despite broad-spectrum activity. |
| Amoxicillin-clavulanic acid | Amoxicillin-clavulanic acid is empirically preferred due to resistance. Ampicillin is the drug of choice for enterococci-sensitive to penicillin, but oral bioavailability is approximately 50%. |
| Pivmecillinam | Pivmecillinam is a prodrug of mecillinam and is recommended for treatment of acute cystitis. It should be avoided in patients with suspected pyelonephritis. Neither pivmecillinam nor mecillinam are currently approved for use by the US FDA. |
| *Cephalosporins* | |
| Cefaclor | There are no major advantages of these agents over other oral agents in the treatment of UTIs, and they may |
| Cefadroxil | have inferior efficacy as compared with other oral agents such as fluoroquinolones. They may be useful in |
| Cefixime | cases of resistance to amoxicillin and trimethoprim-sulfamethoxazole, but concern exists for use as a first- |
| Cefpodoxime | line agent for uncomplicated cystitis therapy due to potential selection of cephalosporin resistant organisms |
| Cefuroxime | (collateral damage). These agents are not active against enterococci. Susceptibility of cephalexin cannot be |
| Cephalexin | accurately predicted based on cefazolin susceptibility testing. |
| Cephradine | |

*(Continued)*

| Table 79–2 | |
|---|---|
| **Commonly Used Antimicrobial Agents for the Treatment of UTIs (*Continued*)** | |
| **Agent** | **Comments** |
| *Tetracyclines* | |
| Doxycycline<br>Minocycline<br>Tetracycline | These agents have been effective for initial episodes of UTI; however, resistance can develop rapidly. Avoid during pregnancy. |
| *Fluoroquinolones* | |
| Ciprofloxacin<br>Levofloxacin<br>Norfloxacin<br>Ofloxacin | The newer quinolones have a greater spectrum of activity; rates of resistance are increasing. Concern for use as a first-line agent for uncomplicated UTI therapy exists due to potential selection of multidrug resistant organisms (collateral damage). These agents are often effective for pyelonephritis. Avoid in pregnancy and children. Moxifloxacin is not listed due to limited urinary excretion. |
| *Miscellaneous* | |
| Trimethoprim-<br>sulfamethoxazole | This combination is highly effective against most aerobic enteric bacteria except *P. aeruginosa*. High urinary tract tissue levels and urine levels are achieved, which may be important in complicated UTI treatment. Also effective as prophylaxis for recurrent infections. Generally well tolerated and low cost but increasing resistance rates above 20% in certain regions has limited empiric use. Its use may be precluded in patients with sulfa allergies. |
| Nitrofurantoin | This agent is effective in treatment and prophylaxis in patients with uncomplicated or recurrent lower tract UTIs. Should not be used in patients with low estimated CrCl (< 40–60 mL/min [0.67–1.00 mL/s]) due to limited urine concentrations and potential increased risk of neuropathy. |
| Azithromycin | Commonly used for sexually transmitted diseases (ie, chlamydia infections) rather than for UTIs. |
| Fosfomycin | Single-dose therapy for uncomplicated cystitis. Has been recommended for empiric therapy since resistance rates are low but may have inferior efficacy when compared with short courses of other oral antibiotic agents. |
| **Parenteral Therapy** | |
| *Aminoglycosides* | |
| Amikacin<br>Gentamicin<br>Tobramycin | Gentamicin and tobramycin are generally equally effective, whereas tobramycin has slightly better coverage of certain *Pseudomonas* spp. Amikacin generally is reserved for multidrug-resistant bacteria. Typically used as a short course of therapy followed by a switch to an oral agent. Concern for neurotoxicity and ototoxicity generally limit use, especially in patients with impaired renal function. |
| *Penicillins* | |
| Ampicillin<br>Ampicillin-sulbactam<br>Piperacillin<br>Piperacillin-tazobactam | These agents are generally effective for susceptible bacteria. The extended-spectrum penicillins are active against certain strains of *Pseudomonas* spp. They are very useful in renally impaired patients since urine concentration can remain adequate or when an aminoglycoside is avoided. Empiric use of ampicillin with an aminoglycoside is recommended only in patients with suspected infection due to *Enterococcus* spp. |
| *Cephalosporins* | |
| First-, second-, third-, and fourth-generation | Second- and third-generation cephalosporins have a broad spectrum of activity against gram-negative bacteria, but are not active against enterococci. Only ceftazidime and cefepime have activity against certain strains of *Pseudomonas* spp. They are useful for nosocomial infections and urosepsis due to susceptible pathogens. A single ceftriaxone dose could be used in lieu of an IV fluoroquinolone for acute uncomplicated pyelonephritis. |
| *Carbapenems* | |
| Doripenem<br>Ertapenem<br>Imipenem-cilastatin<br>Meropenem | These agents have broad-spectrum activity, including gram-positive, gram-negative, and anaerobic bacteria. Ertapenem is not active against *Pseudomonas* spp. All may be associated with *Candida* spp. superinfections. Rarely used for UTIs. |
| *Fluoroquinolones* | |
| Ciprofloxacin<br>Levofloxacin | These agents have broad-spectrum activity against both gram-negative and gram-positive bacteria. They provide high urine and tissue concentrations and are actively secreted in reduced renal function. Switch to oral therapy when possible due to excellent bioavailability. |
| *Monobactam* | |
| Aztreonam | Only active against gram-negative bacteria, including some strains of *P. aeruginosa*. Generally useful for nosocomial infections when aminoglycosides are to be avoided and in patients with type 1/immediate hypersensitivity to penicillins. |
| *Glycopeptide* | |
| Vancomycin | May be considered in combination for empiric therapy based on patient risk factors for multidrug-resistant organisms and gram-positive cocci shown in urinalysis. |

**KEY CONCEPT** *E. coli represent the vast majority of causal organisms in this setting, but Staphylococcus saprophyticus, Klebsiella pneumoniae, Proteus mirabilis, Enterococcus spp. are also known pathogens.*[33–36] Treatment in the outpatient setting is frequently relegated to a urinalysis and empiric therapy without a urine culture.[1,37,38] Patients are subsequently monitored for resolution of signs and symptoms. **KEY CONCEPT** *Uncomplicated UTIs may be managed with a short-course antimicrobial therapy with one-dose, 3-day, or 5-day regimens depending on the clinical factors involved.*

**Table 79–3**

**Overview of Outpatient, Oral Antimicrobial Therapy for Lower and Upper Tract UTIs**

| Indications | Antibiotic | Adult Dose[a] | Frequency | Duration |
|---|---|---|---|---|
| **Lower Tract UTIs** | | | | |
| Uncomplicated | Nitrofurantoin macrocrystals | 100 mg | Every 12 hours | 5–7 days |
| | Nitrofurantoin monohydrate | 100 mg | Every 12 hours | 5–7 days |
| *Alternative options:* | Trimethoprim-sulfamethoxazole | One DS[b] tablet | Every 12 hours | 3 days |
| | Trimethoprim | 100 mg | Every 12 hours | 3 days |
| | Fosfomycin | 3000 mg | Single dose | 1 day |
| | Pivmecillinam[c] | 400 mg | Every 12 hours | 3–7 days |
| | Ciprofloxacin | 250 mg | Every 12 hours | 3 days |
| | Levofloxacin | 250 mg | Every 24 hours | 3 days |
| | Ofloxacin | 200 mg | Every 12 hours | 3 days |
| | Amoxicillin-clavulanic acid | 500 mg | Every 8 hours | 3 days |
| | Cefdinir | 100 mg | Every 12 hours | 7 days |
| | Cefaclor | 250–500 mg | Every 8 hours | 7 days |
| | Cefpodoxime-proxetil | 100 mg | Every 12 hours | 7 days |
| Complicated | Trimethoprim-sulfamethoxazole | One DS[b] tablet | Every 12 hours | 7–10 days |
| | Trimethoprim | 100 mg | Every 12 hours | 7–10 days |
| | Ciprofloxacin | 500 mg | Every 12 hours | 7–10 days |
| | Norfloxacin | 400 mg | Every 12 hours | 7–10 days |
| | Levofloxacin | 250 mg | Every 24 hours | 7–10 days |
| | Amoxicillin-clavulanic acid | 500 mg | Every 8 hours | 7–10 days |
| Recurrent infections—continuous prophylaxis | Trimethoprim-sulfamethoxazole | ½ SS[d] tablet | Every 24 hours | 6 months |
| | Trimethoprim | 100 mg | Every 24 hours | 6 months |
| | Ciprofloxacin | 125 mg | Every 24 hours | 6 months |
| | Nitrofurantoin | 50 *or* 100 mg | Every 24 hours | 6 months |
| | Cefaclor | 250 mg | Every 24 hours | 6 months |
| | Cephalexin | 125 mg | Every 24 hours | 6 months |
| **Upper Tract UTIs** | | | | |
| Uncomplicated Acute pyelonephritis[e] | Ciprofloxacin | 500 mg | Every 12 hours | 7 days |
| | Ciprofloxacin (extended release) | 1000 mg | Every 24 hours | 7 days |
| | Levofloxacin (extended release) | 750 mg | Every 24 hours | 5 days |
| | Trimethoprim-sulfamethoxazole | One DS[b] tablet | Every 12 hours | 14 days |

[a]Majority of listed antimicrobial agents require dosage adjustment in patients with significant renal dysfunction.

[b]DS, double strength (160 mg trimethoprim/800 mg sulfamethoxazole).

[c]Not approved for use by the US FDA as of November 2011.

[d]SS, single strength (80 mg trimethoprim/400 mg sulfamethoxazole).

[e]Doses listed for acute pyelonephritis are for oral regimens.

For acute uncomplicated UTIs, it is reasonable to pursue oral empiric therapy with one dose (3000 mg) of fosfomycin, a 3-day course of trimethoprim-sulfamethoxazole (one double-strength tablet twice daily), or a 5-day course of nitrofurantoin (100 mg twice daily) depending on the patient's characteristics and risk factors.[1] For treatment of multidrug resistant organisms, multiple doses of fosfomycin (given every other day) have been used.[39] The antibiotic selection for empiric therapy partly depends on known resistance rates in the geographic region, particularly *E. coli* resistance to trimethoprim-sulfamethoxazole.[33,40] Empiric therapy with trimethoprim-sulfamethoxazole should be considered only if the local resistance rates in *E. coli* is less than 20%, due to poor UTI treatment responses with trimethoprim-sulfamethoxazole when resistance rates are above this threshold.[1,40] Although fluoroquinolone antibiotics and certain β-lactam agents can be highly active and efficacious against *E. coli*, these agents should be considered alternative agents in uncomplicated UTIs due to their broad-spectrum activity and risk of resistance development in bacteria unaffiliated with the infection.[1]

▶ **Complicated UTIs**

🔵 **KEY CONCEPT** *Complicated UTIs including acute pyelonephritis should be treated for at least 7 days and sometimes 2 weeks or longer.*

▶ **Acute Pyelonephritis**

Patients who present with pyelonephritis usually have high-grade fever (greater than 38.3°C [100.9°F]) and severe flank pain. Select patients with pyelonephritis may be treated in the outpatient setting; however, patients with infection-related vomiting, decreased food intake, and dehydration may need to be treated in the hospital. These patients will often receive IV antibiotics initially before being switched to oral therapy depending on susceptibility testing.

Patients with pyelonephritis are traditionally given 14 days of therapy. Shorter course fluoroquinolone therapy for 7 days has been successful in women with acute pyelonephritis[41], but further studies are needed for validation.[1] Gram stain and culture are important in ensuring that appropriate antimicrobial coverage is selected. Women who present with mild cases of pyelonephritis

## Patient Encounter, Part 2 of Patient AC: Medical History, Physical Exam, and Diagnostic Tests

**PMH:** Obesity (body mass index 32); history of UTI with three episodes in last 6 months

**FH:** Mother living with hypertension; father living with chronic obstructive pulmonary disease, hypertension, and dyslipidemia

**SH:** Unmarried, sexually active with two partners in last 6 months, occupation: store clerk

**Allergies:** None

**Meds:** Norethindrone 0.5 mg/ethinyl estradiol daily

**ROS:** (+) dysuria, urinary frequency; (–) fever, nausea, vomiting, flank pain

**VS:** BP 125/77 mm Hg, P 70 beats/min, RR 16 breaths/min, T 37.0°C

**CV:** RRR, normal S1, S2; normal findings

**Abd:** Soft, nontender, nondistended; (+) bowel sounds, no hepatosplenomegaly, heme (–) stool

**Lab:** Within normal limits including blood glucose; (–) pregnancy test

**Urinalysis:** Greater than 200 white blood cells/mm$^3$ (200 × 10$^6$/L); urine nitrates positive; leukocyte esterase positive

**Urine Gram Stain:** Gram-negative rods, more than 10$^5$ CFU/mL (10$^8$ CFU/L)

*Given this additional information, what is your assessment of the patient's condition?*

*Identify your treatment goals for the patient.*

*What nonpharmacologic and pharmacologic alternatives are available for the patient?*

*What duration of antibiotic therapy is appropriate for this patient?*

---

(defined as low-grade fever and a normal to slightly elevated peripheral white blood count, without nausea or vomiting) may be treated as outpatients. Outpatient antibiotic therapy with trimethoprim-sulfamethoxazole, fluoroquinolones, or even β-lactam/β-lactamase inhibitor, such as amoxicillin-clavulanic acid is recommended.[1] In cases where an initial, one-time IV antibiotic is used as supplemental therapy, a single ceftriaxone dose or single high-dose aminoglycoside therapy could be used in lieu of an IV fluoroquinolone. This practice is a recommended addition to therapy if local prevalence of fluoroquinolone resistance exceeds 10%.[1] Those patients who exhibit more severe signs and symptoms will need to be admitted to an acute care setting for appropriate treatment. The same holds true for antibiotic selection in these patients. Hospitalized patients, suspected of having bacteremia or **urosepsis**, typically receive IV therapy such as a fluoroquinolone or a β-lactam plus an aminoglycoside.[1,42] When selecting fluoroquinolone antibiotics, ciprofloxacin may be ideal due to its relatively narrow spectrum of activity directed against gram-negative organisms.[1]

### Special Populations

#### ▶ Pregnant Women

Changes to the urinary tract in pregnant women predispose them to an increased incidence of bacteriuria and subsequent UTIs that may follow. These changes include alterations in amino acid and other nutrient concentrations in the urine along with physiologic changes such as reduced bladder tone and dilation of the renal pelvis and ureters.[43,44]

An association exists between maternal UTI during pregnancy and fetal death, labor complications, mental retardation, and developmental delay.[45,46] Therefore, screening for UTI during pregnancy is necessary.[22,47] In pregnant patients with significant bacteriuria, whether symptomatic or asymptomatic, treatment is recommended to avoid these complications. In the majority of patients, a sulfonamide (with the exception of use during the third trimester due to concerns for kernicterus), amoxicillin-clavulanic acid, cephalexin, or nitrofurantoin are effective treatment options. Tetracyclines and fluoroquinolones should be

avoided due to risk of teratogenicity and ability to inhibit cartilage and bone development, respectively. Follow-up usually consists of a urine culture 1 to 2 weeks after completion of therapy and then subsequent monthly urine cultures until birth.

#### ▶ Catheterized Patients

An indwelling catheter is commonly used in various health care settings and is associated with UTIs.[25,48] Bacteria may be introduced into the bladder via the catheter by colonization and direct introduction during catheterization. UTIs as a result of an indwelling catheter are common and occur at a rate of 3% to 8% per day of catheter presence.[48]

The approach to management of a patient with bacteriuria and an indwelling urinary catheter follows two paths.[48] **KEY CONCEPT** *The first, in asymptomatic patients with catheterization, is to hold antibiotics and remove the catheter if possible. The second, in symptomatic patients with catheterization, is to initiate antibiotic therapy and remove the catheter if possible.* In both of the above situations, if discontinuation of the catheter is not possible, the patient should be recatheterized with a new urinary catheter if the previous catheter is greater than 2 weeks old.[48]

#### ▶ UTIs in Men

**KEY CONCEPT** *Although UTIs in men are not always complicated by definition, due to the relative infrequency of UTIs in men compared*

---

## Patient Encounter, Part 3: Creating a Care Plan for AC

*Based on the information presented, create a care plan for this patient's UTI. Your plan should include:*

*(a) A statement of the drug-related needs and/or problems*

*(b) A patient-specific detailed therapeutic plan*

*(c) Monitoring parameters to assess efficacy and safety*

| Table 79–4 |
| --- |

**Monitoring Parameters for Select Antibiotics Used in the Treatment of UTIs**

| Drug Class or Drug | What to Monitor | Frequency | Endpoint |
| --- | --- | --- | --- |
| Aminoglycosides | SCr, urine output | Every 24 hours | Prevention of nephrotoxicity manifested by a rise in SCr |
|  | Aminoglycoside serum concentrations | Depends on duration of therapy. At least once weekly; more frequently if evidence of changing renal function | Trough serum concentrations < 2 mg/L (< 4.2 μmol/L for gentamicin and < 4.3 μmol/L for tobramycin) or < 8 mg/L (13.7 μmol/L) for amikacin,[a] to decrease risk of nephrotoxicity and ototoxicity |
| Nitrofurantoin | SCr | Only if renal function changing or unstable | Nitrofurantoin metabolites may accumulate in renal insufficiency and lead to neuropathy; avoid if CrCl < 40 mL/min (0.67 mL/s) |
|  | Liver profile | Periodic monitoring | Prevention of cholestasis |
| Aminoglycosides Nitrofurantoin Tetracyclines Sulfonamides | SCr | Only if renal function changing or unstable | Decreases in glomerular filtrate rate can significantly decrease the urine concentration of these agents |

[a]Streptomycin concentrations are different than those listed here; because streptomycin is not used to treat UTIs, monitoring for this agent is not included.

*with women, an abnormality (structural or functional) should be suspected and therefore treated as a probable complicated infection until proven otherwise.*[49] For this reason, men should not be treated with a single dose or short course of therapy if diagnosed with a UTI. Typically, these patients will receive 2 weeks of therapy and in situations of failure may be treated up to 6 weeks, particularly if a prostatic source of infection is suspected.

## Outcome Evaluation

- Monitor the patient for resolution of symptoms with the goal of 48 to 72 hours to resolution after start of antimicrobial therapy

- If possible, follow-up on susceptibilities of the infecting organism detected by the urine culture
- Repeat urine culture is necessary only if symptoms do not acutely abate or reinfection or recurrence occurs. Resistance rates to *E. coli* are increasing to antibiotics commonly prescribed for UTI, and certain isolates are multidrug resistant.[50]
- Depending on the chosen antibiotic therapy, evaluate the patient based on drug therapy monitoring parameters including those presented in Table 79–4 to optimize therapy and decrease incidence of adverse events.

## Patient Care Process

**Patient Assessment:**

- Based on physical exam, review of systems, and urinalysis, determine whether the patient is experiencing signs and symptoms of UTI.
- Assess patient medication history and risk factors for the potential of an antibiotic resistant infection.
- Assess patient renal function and other laboratory tests for antibiotic dosing and systemic complications.
- Identify potential sources of infection such as urinary catheters.

**Therapy Evaluation:**

- Based on urinalysis and Gram stain (if available), determine whether the empiric antibiotic selection is appropriate.
- Based on culture and susceptibility data (if available), determine whether any changes should be made from your initial empiric antimicrobial selection (ie, resistance to the regimen initially selected).
- Evaluate the patient's symptoms to determine response to the antimicrobial regimen you have chosen.

- Evaluate the patient for the presence of adverse drug reactions, drug allergies, and potential drug interactions.

**Care Plan Development:**

- Determine the optimal antibiotic dose and duration of therapy based on the patient and infection type (complicated vs uncomplicated).
- Determine whether the patient may benefit from prophylactic therapy (ie, recurrent UTIs secondary to chronic urinary catheterization due to paraplegia).
- Recommend lifestyle modifications as needed to minimize UTI recurrence.
- Discuss the importance of medication adherence throughout the entire recommended treatment duration.

**Follow-Up Evaluation:**

- Stress the importance of complying with the prescribed antimicrobial regimen and to follow up with the health care provider if signs and symptoms recur.

## Abbreviations Introduced in This Chapter

CFU  Colony-forming units
CrCl  Creatinine clearance
IV  Intravenous
SCr  Serum creatinine
UTI  Urinary tract infection

# 80 Sexually Transmitted Infections

Marlon S. Honeywell and Evans Branch III

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Analyze the behavioral considerations and assess the importance of contraception with regard to the contributing factors of sexually transmitted infections (STIs).

2. Apply the "expedited partner treatment" method when recommending treatment for STIs.

3. Identify the patient populations that are typically affected by specific STIs.

4. Identify causative organisms for STIs.

5. Devise a list of the clinical signs and symptoms corresponding to each type of STI and classify patients based on recommended criteria.

6. Select appropriate diagnostic procedures for STIs.

7. Identify STI treatment regimens and recommend therapy when appropriate.

8. Design a patient care plan based on the monitoring parameters.

## INTRODUCTION

Though we have made progress in medicine, age-old problems of infectious disease continue to plague us.[1] Even with the discovery of newly improved antibiotics, sexually transmitted infections (STIs) have not been eradicated. Many have reemerged secondary to modern social trends of sexual activity, and some as a result of the HIV epidemic, socioeconomic concerns, and the global lack of preventive education. **KEY CONCEPT** *Optimal detection and treatment of sexually transmitted diseases depends on counseling by a patient-friendly and knowledgeable clinician who can establish open communication with the patient.*

The correlation between risky sexual behavior and STIs is well documented.[2] Inconsistent and incorrect condom use increases the incidence of new STIs. **KEY CONCEPT** However, counseling patients on the consistent use of condoms, spermicides, or diaphragms is an important component in reducing the overall incidence of STIs.[3] Health care providers who manage persons at risk for STIs should counsel women concerning the option for emergency contraception, if indicated, and provide it in a timely fashion if desired by the woman or the couple. Plan B (two 750 mcg levonorgestrol) is approved in the United States for the prevention of unintended pregnancy.[4]

In addition to the increasing number of adolescents engaging in unsafe sexual practices is a high incidence of men who have sex with men (MSM) and women who have sex with women (WSW). Many MSM do not disclose their HIV status. This "don't ask, don't tell" practice has been linked to an upsurge in newly diagnosed HIV infections and STIs among previously noninfected people.[5] Although limited data are available with regard to STIs in WSW, risk of transmission probably varies by the specific STI and sexual techniques. Sharing penetrative items or employing practices involving digital vaginal or digital anal contact most likely represent common modes of transmission. This possibility is supported by reports of metronidazole-resistant trichomoniasis and genotype-specific HIV transmitted sexually between women who reported such behaviors and an increased prevalence of bacterial vaginosis (BV) among monogamous WSW.[6]

Sexual abuse in adolescents and children is becoming prevalent in the United States. Any child or adolescent with a STI should be evaluated for sexual abuse.[7] In cases of abusive contact, commonly found infections include *Neisseria gonorrhoeae* or *Chlamydia trachomatis*. Abusive cases should be reported to Child Protective Services.

Defined as a person who engages in the exchanging of spouses for sexual activities, the emergence of "swingers" as a new category of at-risk patients has been seen in STI clinics throughout the world. In fact, in one Canadian clinic, swingers composed 40.8% of patients that rarely accessed STI health services.[8] To this end, although little data exists, swingers now represent a group with risky behaviors that must be identified and treated, when necessary.

**KEY CONCEPT** *Optimally, both sex partners should be treated simultaneously for a STI; however, this is difficult to accomplish. Clinics and health departments often proactively attempt dual treatment by providing a prescription for the partner to the index patient (the patient who is evaluated by a clinician), a practice commonly known as patient-delivered partner therapy. Medications or prescriptions should be accompanied by treatment instructions and appropriate warnings.* Counseling regarding the appropriate use of condoms, cervical diaphragms, spermicides, and emergency contraception is also important to mitigate the occurrence of reinfection.

Accurate reporting of STIs is imperative to the evaluation of trends in sexual behaviors; reporting may be provider- or laboratory-based. State and local health departments may assist with the mechanism by which STIs are reported and cases must be conveyed in accordance with statutory requirements. Confidentiality should always be exercised in such cases.[9,10]

## GONORRHEA

Gonorrhea is a curable STI caused by the gram-negative diplococcus *Neisseria gonorrhoeae*. Gonorrhea may be the second most commonly reported bacterial STI. Proper therapeutic management with antimicrobial agents is essential to eradicate this infection and prevent the development of associated sequelae such as a urethritis, cervicitis, or dysuria.

In the United States, the highest rate of gonococcal infection is seen within the 15- to 24-year-old age groups for both sexes; although more cases are reported in men. Approximately 700,000 new cases occur annually in the United States.[9,10] Factors associated with an increased risk of infection include ethnicity, low socioeconomic status, illicit drug use, and age. Targeted screening of young women, less than 25 years of age, who are at an increased risk has been correlated to gonorrhea control in the United States.[9] In fact, the risk of a cervical infection after a single episode of vaginal intercourse is approximately 50% and increases with multiple exposures. Furthermore, rates of reinfection are significantly higher among ethnic minorities.

### PATHOPHYSIOLOGY

Attachment to mucosal epithelium, mediated in part by pili and opa (outer membrane opacity proteins), is followed by penetration of *N. gonorrhoeae* through epithelial cells to the submucosal tissue within 24 to 48 hours. A vigorous response by neutrophils begins with sloughing of the epithelium, development of submucosal microabscesses, and exudation of pus. Stained smears usually reveal large numbers of gonococci within a few neutrophils, whereas most cells contain no organisms.[11]

### DIAGNOSIS

Several laboratory tests are available to aid in the diagnosis of gonorrhea and include Gram-stained smears, endocervical or vaginal specimens, culture, or the DNA hybridization probe. A Gram stain of a male urethral specimen that demonstrates polymorphonuclear leukocytes with intracellular gram-negative

---

**Clinical Presentation of Gonorrhea[9,10]**

**General**
- Purulent discharge

**Signs**
- Painful or swollen testicles
- Tubal scarring

**Symptoms**
*Men:*
- May be asymptomatic, though acute urethritis is the predominant manifestation
- Urethral discharge and dysuria, usually without urinary frequency or urgency
- When compared with nongonococcal urethritis, the discharge in gonococcal urethritis is generally more profuse and purulent
- Pain during urination

*Women:*
- Cervicitis, urethritis, increased vaginal discharge, dysuria, and intermenstrual bleeding
- Pain during urination
- Abdominal pain

---

**Patient Encounter 1, Part 2**

**PMH:** Hypertension, diabetes, hyperlipidemia; no prior history of STIs; no drug allergies noted

**Meds:** Amlodipine 10 mg by mouth daily; furosemide 40 mg by mouth daily; metformin 500 mg by mouth three times daily; glipizide XL 5 mg by mouth daily; simvistatin 40 mg by mouth at bedtime

**FH:** Mother has diabetes and hypertension. Father is deceased

**SH:** Admits to having unprotected sex with wife and another woman. Does not smoke; drinks alcohol occasionally

**ROS:** C/o urethral discharge and swollen testicles

**PE:**

**VS:** BP 145/88 mm Hg, post prandial glucose 132 mg/dL (7.3 mmol/L), total cholesterol 188 mg/dL (4.86 mmol/L), P 70 beats/min, T 37.0°C (98.6°F)

**Lab:** Urethral discharge swab revealed *N. gonorrhoeae*; rapid plasma reagin (RPR) test was positive

*Given this additional information, what is your assessment of the patient's condition?*

*What consideration should be given to other STIs?*

*Identify your treatment goals for this patient.*

*What pharmacologic alternatives are available for this patient?*

---

**Patient Encounter 1, Part 1**

BJ is a 52-year-old man who visits a clinic complaining of profuse urethral discharge and swollen testicles for the past several days. The patient admits to having sexual intercourse with his wife and with another woman without barrier contraception (condoms). He also admits to having sexual intercourse with the other woman for more than 6 months.

*What information is suggestive of gonorrhea?*

*What potential risk factors for STIs are present?*

*What other diagnostic tests should be ordered?*

diplococci may be considered diagnostic in symptomatic men. A gram-negative stain should not be considered sufficient for ruling out infection in asymptomatic men.[9] Additionally, Gram stain of endocervical, pharyngeal, or rectal specimens are also insufficient to detect infections. All patients who test positive for gonorrhea should be tested for other STIs, including chlamydia, syphilis, and HIV.

## TREATMENT

The desired outcome is complete eradication of *N. gonorrhoeae* and avoidance of sequelae.

### Pharmacologic Therapy[4,9,12,13]

**KEY CONCEPT** *Patients infected with gonorrhea often are coinfected with C. trachomatis and should receive therapy to eradicate both organisms concurrently.* To mitigate the probability of resistance, the combination of doxycycline and azithromycin have been prescribed.[9] Cephalosporins are now a secondary treatment option; if used, dual treatment may increase efficacy for pharyngeal infections. However, treatment failures involving cephalosporins have been noted in Hawaii and Asian countries. As such, clinicians should determine whether sexual activity may have occurred in these countries before recommending antibiotic therapy. Fluoroquinolones should not be prescribed for infections in MSM, in those with a history of recent foreign travel or partners' travel, or for infections acquired in California, Hawaii, and in Asian countries or for infections in other areas with increased gonococcal resistance.[14]

Gonoccocal resistance to some cephalosporins has emerged.[15] The recommended first-line treatment for gonorrhea in most countries is third generation cephalosporins, and in some cases, spectinomycin, doxycycline, and azithromycin.[16] The mechanism of resistance appears to be associated with a mosaic penicillin-binding protein in addition to other chromosomal mutations previously found to confer resistance to β-lactam antimicrobials. To mitigate the prevalence of cephalosporin resistance, strong antimicrobial management programs, expanding surveillance networks and procedures, and STI control and prevention is warranted.

Oral hormonal contraception has been evaluated to determine if it deters the acquisition of gonnococal infections in women. Though transmission of *N. gonorrhea* is poorly understood, one study suggested that oral hormonal contraception may lessen the probability of infection.[17] More studies are required to support this theory as a viable option for prevention.

Treatment of gonorrhea may vary according to clinical presentation and is indicated as follows[9]:

**Uncomplicated Gonococcal Infection of the Cervix, Urethra, and Rectum**\*: Ceftriaxone 250 mg intramuscularly *or* cefixime 400 mg orally *or* single-dose injectable cephalosporin regimens *plus* azithromycin 1 g orally *or* doxycycline 100 mg orally twice daily for 7 days. Several alternative agents possess notable activity; however, they should not be used if pharyngeal infection is suspected. Alternatives include cefpodoxime 400 mg orally or cefuroxime axetil 1 g orally or azithromycin 2 g. Though unavailable in the United States, spectinomycin has also been prescribed.

**MSM or Heterosexuals with a History of Recent Travel**\* Ceftriaxone 250 mg intramuscularly *or* cefixime 400 mg orally *plus* treatment for chlamydial infection if it has not been ruled out.

**Uncomplicated Gonococcal Infection of the Pharnyx, Cervix, Urethra, or Rectum** Ceftriaxone 250 mg intramuscularly plus azithromycin 1 g orally or doxycycline 100 mg orally twice daily for 7 days.

**Coverage for Coinfection with *C. trachomatis*** Azithromycin 1 g orally as a single dose *or* doxycycline 100 mg orally twice daily for 7 days. Since most gonococcal infections in the United States are susceptible to azithromycin and doxycycline, routine cotreatment might hinder the development of resistance.

### Treatment of Gonorrhea in Special Situations

Uncomplicated infections of the cervix, urethra, and rectum can be treated with one of the following regimens in adults:

▶ **Recommendations During Pregnancy**

- Pregnant women should be treated with a recommended or alternative cephalosporin. For women who cannot tolerate a cephalosporin, azithromycin 2 g orally may be prescribed. For treatment of presumptive or diagnosed *C. trachomatis*, azithromycin or amoxicillin is recommended.
- Doxycycline and fluoroquinolones are contraindicated.

**Recommendations for Disseminated Gonococcal Infection (Regimens Should Be Continued for 24 to 48 Hours)** Ceftriaxone 1 g intramuscularly or IV every 24 hours *or* cefotaxime 1 g IV every 8 hours *or* ceftizoxime 1 g IV every 8 hours. Continue regimens for 24 to 48 hours after improvement is noted. Once improvement begins, therapy should be converted to Cefixime 400 mg orally twice daily for at least one week.

**Uncomplicated Infections of the Cervix, Urethra, and Rectum in Children Less Than 45 kg** Ceftriaxone 250 mg intramuscularly as a single dose *or* spectinomycin 40 mg/kg intramuscularly as a single dose (not to exceed 2 g).

**Gonococcal Conjunctivitis** Ceftriaxone 1 g intramuscularly once for adults has demonstrated excellent response rates. Lavage of the infected eye(s) once with saline solution should also be considered. Patients treated for gonococcal conjunctivitis should also be treated prophylactically for *C. trachomatis* infection.

---

## Patient Encounter 1, Part 3

Unprotected sex is a major risk factor for contracting STIs. Although the purulent discharge is consistent with gonorrhea infection, a positive urethral swab coupled with an incubation period consistent with gonorrhea confirms the diagnosis. A serologic test for HIV should be performed. Although gonorrhea has been confirmed in this patient, infection with *C. trachomatis* occurs commonly in this setting. The expedited partner treatment approach should be employed and treatment should effectively cover gonorrhea and chlamydia.

*If this patient has an allergy to penicillin, how would the therapeutic management of the identified problems change?*

---

\*Regimens are given for one dose only.

**Ophthalmic Neonatorum or Prophylactic Treatment for Infants Whose Mothers Have Gonococcal Infection** Ceftriaxone 25 to 50 mg/kg IV or intramuscularly in a single dose, not to exceed 125 mg.

**Gonococcal Scalp Access in Newborns** Ceftriaxone 25 to 50 mg/kg/day IV or intramuscularly in a single daily dose for 7 days or cefotaxime 25 mg/kg IV or intramuscularly every 12 hours for 7 days may be used. If meningitis is noted, treatment duration of both medications should be extended for a total of 10 to 14 days.

**Ophthalmic Neonatorum Prophylaxis** Erythromycin (0.5%) ophthalmic ointment in a single application to the eyes *or* ceftriaxone 25 to 50 mg/kg IV or intramuscularly, not to exceed 125 mg in a single dose.

### Outcome Evaluation

- Order diagnostic test for gonorrhea. If positive, recommend antibiotics that cover gonorrhea and chlamydia.
- Subsequent to treatment, expect the eradication of organisms responsible for gonorrhea and chlamydia.
- Monitoring is generally not required.

## CHLAMYDIA

### Epidemiology

Infection with *C. trachomatis* has increased dramatically in recent years. This bacterium is the most common cause of nongonococcal urethritis, accounting for as many as 40% of cases. Worldwide, this intracellular, gram-negative bacterium produces around 92 million new genital infections. The prevalence is highest in individuals less than or equal to 25 years. Associated sequelae include pelvic inflammatory disease (PID), ectopic pregnancy, and infertility.

### PATHOPHYSIOLOGY

*C. trachomatis* possesses characteristics resembling both bacteria and viruses. Its major membrane is comparable to that of gram-negative bacteria, although it lacks a peptidoglycan cell wall and requires cellular components from the host for replication. Chlamydia transmission risk is thought to be less than that of gonorrhea.

### CLINICAL PRESENTATION AND DIAGNOSIS

Common tests used to diagnose *C. trachomatis* include culture, enzyme immunoassay, DNA hybridization probe, or the direct fluorescent monoclonal antibody test. Diagnosis has been confirmed in women through urine or swab specimen collected from the endocervix and in men using a urethral swab or urine specimen. Most women are asymptomatic; therefore, an annual screening or physical is necessary, as early detection may reduce rates of transmission.

### TREATMENT[9,18]
### Uncomplicated Urethral, Endocervical, or Rectal Infection in Adults

The recommended adult regimen is azithromycin 1 g orally in a single dose *or* doxycycline 100 mg orally twice daily for 7 days. An alternate regimen *is* erythromycin ethylsuccinate 800 mg orally four times daily for 7 days *or* erythromycin base 500 mg orally four times daily for 7 days *or* levofloxacin 500 mg orally once daily for 7 days *or* ofloxacin 300mg orally twice daily for 7 days.

The recommended regimen for pregnant patients is azithromycin 1 g orally in a single dose *or* amoxicillin 1 g orally in a single dose *or* amoxicillin 500 mg orally three times daily for 7 days.

Alternate regimens include erythromycin base 500 mg orally four times daily for 7 days *or* 250 mg orally four times daily for 14 days *or* erythromycin ethylsuccinate 800 mg orally four times daily for 7 days *or* 400 mg orally four times daily for 14 days.

### *C. trachomatis* Infection in Infants

Treatment of ophthalmia neonatorum or infant pneumonia should be with erythromycin base or ethylsuccinate 50 mg/kg/day orally divided into four doses daily for 14 days. An association between oral erythromycin and infantile hypertrophic pyloric stenosis (IHPS) has been reported in infants aged less than 6 weeks

---

### Patient Care Process

**Patient Assessment:**

- Review the patient's medical history and determine whether the patient's symptoms are consistent with gonorrhea.
- Order a culture to identify whether *N. gonorrhea* is present.

**Therapy Evaluation:**

- Recommend therapy consistent with the treatment of gonorrhea and chlamydia.
- Ensure that the patient and partner receive adequate treatment for both organisms.

**Care Plan Development:**

- Counsel the patient on effective methods of contraception and on the possibility of side effects or of an allergy to the drug.

---

### Clinical Presentation of Chlamydia[9,10,13]

**General**

- Asymptomatic

**Signs**

- Beefy red cervix that bleeds easily (women)

**Symptoms**

- When present, the urethral discharge is watery and less purulent than that seen with acute gonococcal urethritis. Complications resulting from lack of treatment or inadequate treatment include: epididymitis (in males), and PID including associated complications in women.

**Other Diagnostic Tests**

- Culture is usually positive for both chlamydia and gonorrhea.

who were treated with this drug. Infants treated with erythromycin should be monitored for signs and symptoms of IHPS.

### ▶ Infant Pneumonia Caused by C. Trachomatis

Erythromycin base or ethylsuccinate 50 mg/kg/day orally divided into four doses daily for 14 days.

## Outcome Evaluation

- Order diagnostic test for chlamydia. If positive, recommend antibiotics that cover gonorrhea and chlamydia.
- Subsequent to treatment, expect the eradication of organisms responsible for gonorrhea and chlamydia.
- Monitoring is generally not required.

## SYPHILIS

Syphilis, attributed to the spirochete *Treponema pallidum*, can have numerous and complex manifestations. Clinician familiarity, stage-specific diagnosis, and effective treatment are vital. Missed or inappropriately treated syphilis may result in cardiovascular complications, neurologic disease, or congenital syphilis.

## EPIDEMIOLOGY AND ETIOLOGY

Since the 1940s, the incidence of syphilis declined drastically following the introduction of penicillin, but rose when HIV arrived from obscurity in the 1980s. In 2009, rates of primary and secondary syphilis increased for the tenth consecutive year, reaching the highest rate reported since 1995. Although increases have occurred mostly among men, in 2013, the rate of reported primary and secondary syphilis in the United States was 5.3 cases per 100,000 population. Additionally, from 2005 to 2013, the number of primary and secondary cases nearly doubled. The primary and secondary syphilis rate among black men was 5.2 times that among white men; the rate among black women was 13.3 times that among white women, emphasizing the need for enhanced preventive measures among blacks and MSM. The disparity among men and women has been observed across racial and ethnic groups and is highest in the South and among non-Hispanic blacks.[19]

## PATHOPHYSIOLOGY

*T. pallidum* rapidly penetrates intact mucous membranes or microscopic dermal abrasions, and within a few hours, enters the lymphatics and blood to produce systemic illness. During the secondary stage, examinations commonly demonstrate abnormal findings in the cerebrospinal fluid (CSF). As the infection progresses, the parenchyma of the brain and spinal cord may subsequently be damaged.

## Diagnosis and Clinical Presentation

### ▶ Stages of Syphilis

**Primary Syphilis**  Usually manifests as a solitary, painless chancre. Primary syphilis develops at the site of infection approximately 3 weeks after exposure to *T. pallidum*; the chancre is highly infectious.[9,20]

**Secondary Syphilis**  Without appropriate treatment, primary syphilis will advance to secondary syphilis, a stage usually apparent from its clinical symptomatology. Symptoms include fatigue, diffuse rash, fever, lymphadenopathy, and genital or perineal condyloma latum. Additionally, the skin is most often affected and a rash may present as macular, macropapular, or pustular lesions or may involve skin surfaces including the palms of the hands and soles of the feet.

**Latent Syphilis**

*Early Latent*  Usually occurs during the first year after infection and may be established in patients who have seroconverted, who had symptoms of primary or secondary syphilis, or who had sex with a partner with primary, secondary, or latent syphilis.

*Late Latent*  Patients should be considered to have late latent syphilis if the aforementioned criteria (early latent) are not met. In both stages, patients are usually asymptomatic and the lesions noted in the primary and secondary phase usually resolve; however, individuals are still seropositive for *T. pallidum*.

*Tertiary Syphilis*  Develops years after the initial infection and may involve any organ in the body.

## Congenital Syphilis

Congenital syphilis is a condition in which the fetus is infected with *T. pallidum* as a result of the hematogenous spread from an infected mother, although transmission may also occur from direct contact with the infectious genitalia of the mother. Since the primary stage of syphilis is characterized by spirochetemia, infectious rates of the fetus are nearly 100% if the mother has primary syphilis.[20,21]

Diagnostic procedures include dark-field microscopy, nontreponemal exams[9,20] (ie, the Venereal Disease Laboratory [VDRL] and the rapid plasma reagin [RPR] test), and treponemal exams (ie, enzyme immunoassay, the *T. pallidum* hemagglutination test, the fluorescent treponemal antibody test, and the enzyme-linked immunosorbent assay).

## TREATMENT

After confirming the diagnosis of syphilis, the desired outcome is a fourfold decrease in quantitative nontreponemal titers over a 6-month period and within 12 to 24 months after treatment of

## Patient Encounter 2

RM is a HIV-positive male who complains of first observing the appearance of a "sore" on his penis. He admits to disregarding the lesion; however, he is now experiencing fatigue, diffuse rash, fever, and perineal condyloma latum. He reports having unprotected sexual intercourse with two male partners. He denies pain or itching at the original site of the lesion, dysuria, or frequent urination. Additionally, there appears to be no vesicles in the genital area.

*What information is suggestive of syphilis?*

*What stage of syphilis is present?*

*What potential risk factors for STIs are present?*

*How should the diagnosis of syphilis be confirmed in this patient?*

*If the diagnosis of syphilis is confirmed, what therapeutic options exist for this patient?*

latent or late syphilis. An algorithm for the treatment of syphilis is shown in **Figure 80–1**.

With regard to neurosyphilis, a reduction in neurologic manifestations is desired, which may include seizures, paresis, meningitis, stroke, hyperreflexia, visual disturbances, hearing loss, neuropathy, or loss of bowel and bladder function. In late neurosyphilis, vascular lesions (meningovascular neurosyphilis) may also be observed; thus, a reduction in the number of observed lesions is warranted. A diminution in CSF WBC (less than $10 \times 10^3/\text{mm}^3$ [$10 \times 10^9/\text{L}$]) or protein levels (0.05 g/dL [0.5 g/L]) is also preferred.

### Pharmacologic Therapy

**KEY CONCEPT** *Parenterally administered penicillin is recommended for all stages of syphilis (Table 80–1).* Although penicillin is the drug of choice, combinations of benzathine penicillin with procaine penicillin or oral penicillin preparations are not considered appropriate treatment regimens. Several reports demonstrated the misuse of the benzathine–procaine combination (Bicillin C-R) instead of the standard benzathine penicillin (Bicillin L-A) for treatment of syphilis.[20,22] Clinicians and purchasing agents should be aware of the similarities in product names to avoid errors in the prescribing and administration of these agents. Pertinent information germane to benzathine penicillin G is found in Table 80–1.

Alternative agents may be used in allergic individuals and include doxycycline, minocycline, tetracycline, or erythromycin base or stearate. Some patients (such as young children or pregnant women) may not respond favorably to alternative modalities or should not receive tetracyclines. Therefore, in patients who must be administered penicillin (ie, patients who are pregnant or have central nervous system [CNS] involvement) or are allergic, **desensitization** should be performed before the drug is initiated.

Patients may experience fever, chills, tachycardia, and tachypnea, a condition commonly known as the Jarisch-Herxheimer reaction, an acute febrile reaction accompanied by headache, myalgia, fever, and other symptoms within the first 24 hours after the initiation of therapy. This reaction is postulated to occur secondary to spirochete lysis and proinflammatory cytokine cascades. Treatment is supportive and may include antipyretic and anti-inflammatory agents, as well as fluid resuscitation and bed rest.

### ▶ Primary Syphilis

**Drug of Choice**

*Adults* Benzathine penicillin, 2.4 million units intramuscularly as a single dose. Additional doses of benzathine penicillin or other antibiotics do not enhance efficacy, regardless of HIV status.[9]

*Children* Benzathine penicillin 50,000 units/kg intramuscularly, up to the adult dose of 2.4 million units in a single dose. Infants less than 1 month of age diagnosed with syphilis should have a CSF test to determine if asymptomatic neurosyphilis is present. Patient records should be reviewed to decipher whether syphilis is congenital or acquired.

**Alternatives** Oral doxycycline 100 mg twice daily for 2 weeks *or* tetracycline 500 mg by mouth four times daily for 2 weeks. Limited literature also supports the use of ceftriaxone 1 g intramuscularly or IV once daily for 10 days *or* oral azithromycin as a single 2 g dose.[9,21]

### ▶ Secondary and Early Latent Syphilis

Treatment modalities administered in primary syphilis are also effective in secondary syphilis and early latent syphilis (less than 1 year duration).

Children with early latent syphilis should receive benzathine pencillin G 50,000 units/kg intramuscularly, up to the adult dose of 2.4 million units in a single dose.

### ▶ Late Latent Syphilis

Benzathine penicillin, 7.2 million units total, administered as three doses of 2.4 million units intramuscularly each at 1-week intervals.

Children with late latent syphilis should be treated with benzathine penicillin G 50,000 units/kg intramuscularly, up to the adult dose of 2.4 million units, administered as three doses at 1-week intervals (total 150,000 units/kg up to the adult dose of 7.2 million units)

### ▶ Tertiary Syphilis

**Drug of Choice** Benzathine penicillin 2.4 million units administered intramuscularly once weekly for 3 weeks. A total of 7.2 million units should be administered.

**Alternatives** In nonpregnant patients with a penicillin allergy, alternative regimens include doxycycline 100 mg orally two times daily for 4 weeks *or* tetracycline 500 mg orally four times daily for 4 weeks.

### ▶ Gummatous and Cardiovascular Syphilis

As long as no evidence of CNS involvement exists, antibiotic therapy for **gummatous** and cardiovascular syphilis is identical to that for tertiary syphilis.

### ▶ Neurosyphilis

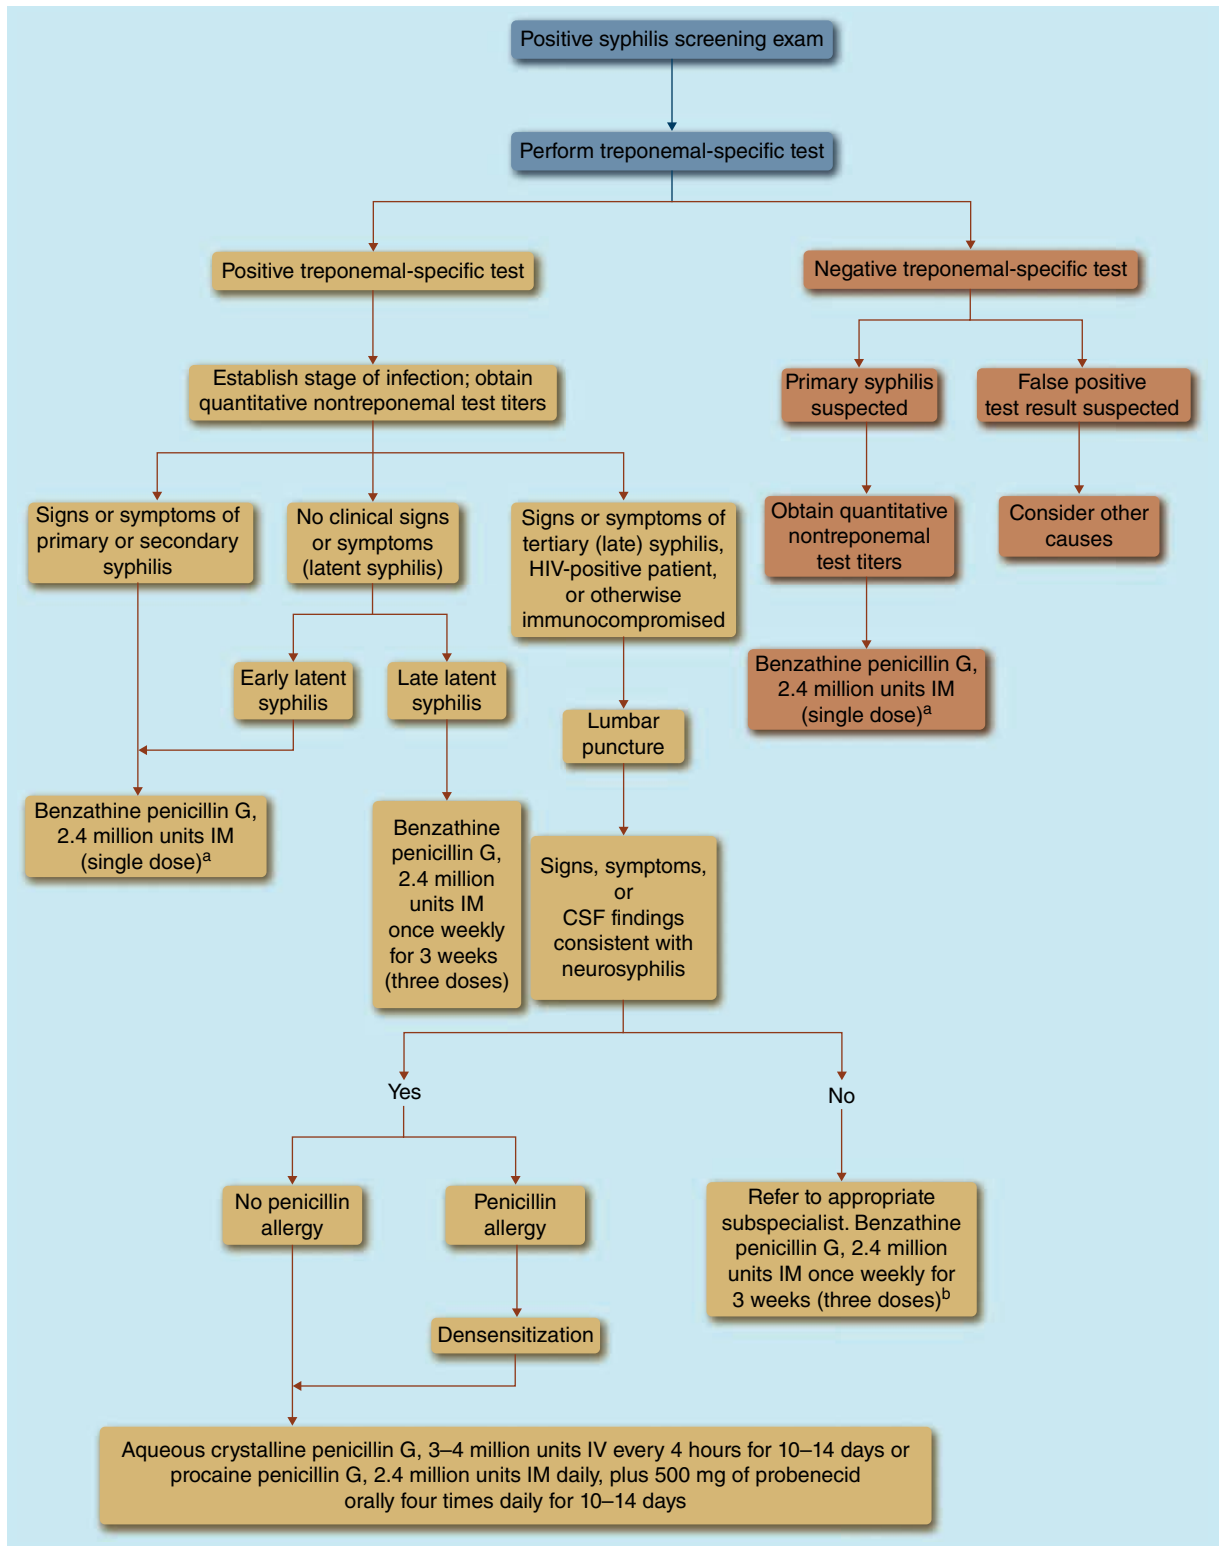
As an effective treatment for neurosyphilis, the Centers for Disease Control and Prevention (CDC) endorse two regimens of penicillin. Alternatively, ceftriaxone may also be prescribed.[25]


**FIGURE 80–1.** Treatment of syphilis. (CSF, cerebrospinal fluid; IM, intramuscularly.) (From Brown D, Frank J. Diagnosis and management of syphilis. Am Fam Physician. 2003;68(2):283–290.) [a]Alternative treatments for nonpregnant penicillin-allergic patients: doxycycline 100 mg orally twice daily for 2 weeks, or tetracycline 500 mg four times daily for 2 weeks; limited data support ceftriaxone 1 g once daily IM or IV for 8 to 10 days; or azithromycin, 2 g orally (single dose). [b]Alternative treatments for nonpregnant penicillin-allergic patients: doxycycline, 100 mg orally twice daily for 4 weeks, or tetracycline 500 mg orally four times daily for 4 weeks.

CNS, central nervous system; IM, intramuscular.

Data from Lacy C, Armstrong L, Goldman M, Lance L. Lexi-Comp's Drug Information Handbook, 19th ed. Hudson, OH: Lexi-Comp; 2010:1128–1132.

The regimens of choice are aqueous penicillin G 3 to 4 million units administered IV every 4 hours or continuous infusion for 10 to 14 days *or* procaine penicillin G 2.4 million units administered intramuscularly once daily, plus probenecid 500 mg orally four times daily, both for 10 to 14 days.

## Congenital Syphilis[23–25]

The decision to treat an infant should be based on a diagnosis of syphilis in the mother and confirmation of adequacy of maternal treatment. Clinical, laboratory, or radiographic evidence of syphilis in the infant should be documented. Maternal nontreponemal titers (at delivery) should be compared with the infant's nontreponemal titers. Since diagnosis based on neonatal serologic testing is complicated by the transplacental transfer of maternal IgG antibodies, which can cause a positive test in the absence of infection, neonatal titers are assessed. A titer greater than four times the maternal titer would not generally result from passive transfer and diagnosis is considered confirmed or highly probable.

The following regimens are recommended for treatment of maternal syphilis: benzathine penicillin G 2.4 million units or 7.2 million units intramuscularly over 3 weeks if the duration of syphilis has been at least a year. An alternative regimen is procaine penicillin 0.6 to 0.9 million units intramuscularly for 10 to 14 days, or ceftriaxone 1 g daily intramuscularly or IV for 8 to 10 days.

In women who experience uterine cramping, pelvic pain, or fever, administer acetaminophen to combat these symptoms. Additionally, the patient should be well hydrated and rested.

Treatment of asymptomatic neonates is with 50,000 units/kg of benzathine penicillin G in a single intramuscular dose. Symptomatic neonates should receive 50,000 units/kg of aqueous crystalline penicillin G every 12 hours intramuscularly for the first 7 days of life, then every 8 hours for 3 days *or* procaine penicillin G 50,000 IU/kg intramuscularly as a single dose daily for 10 days.

## Outcome Evaluation

The CDC has provided patient care monitoring guidelines for syphilis (**Figure 80–2**).[9,11,20]

## Primary and Secondary Syphilis

- After 6, 12, and 24 months of treatment, reexamine the patient and recommend a follow-up quantitative nontreponemal titer. More frequent assessment might be sensible if follow-up is uncertain. If the patient is asymptomatic, yet has a fourfold increase in nontreponemal titer or persistent or recurrent symptoms are observed, order an HIV test and a lumbar puncture; if the patient is HIV-positive, suggest an infectious disease consult.

- In patients who are both negative for HIV and the lumbar puncture, administer benzathine penicillin G 2.4 million units intramuscularly once weekly for three additional weeks. Perform a patient follow-up in 6 months including a clinical examination and another nontreponemal titer. In HIV-negative patients with lumbar puncture findings compatible with neurosyphilis, treat the patient accordingly for neurosyphilis.

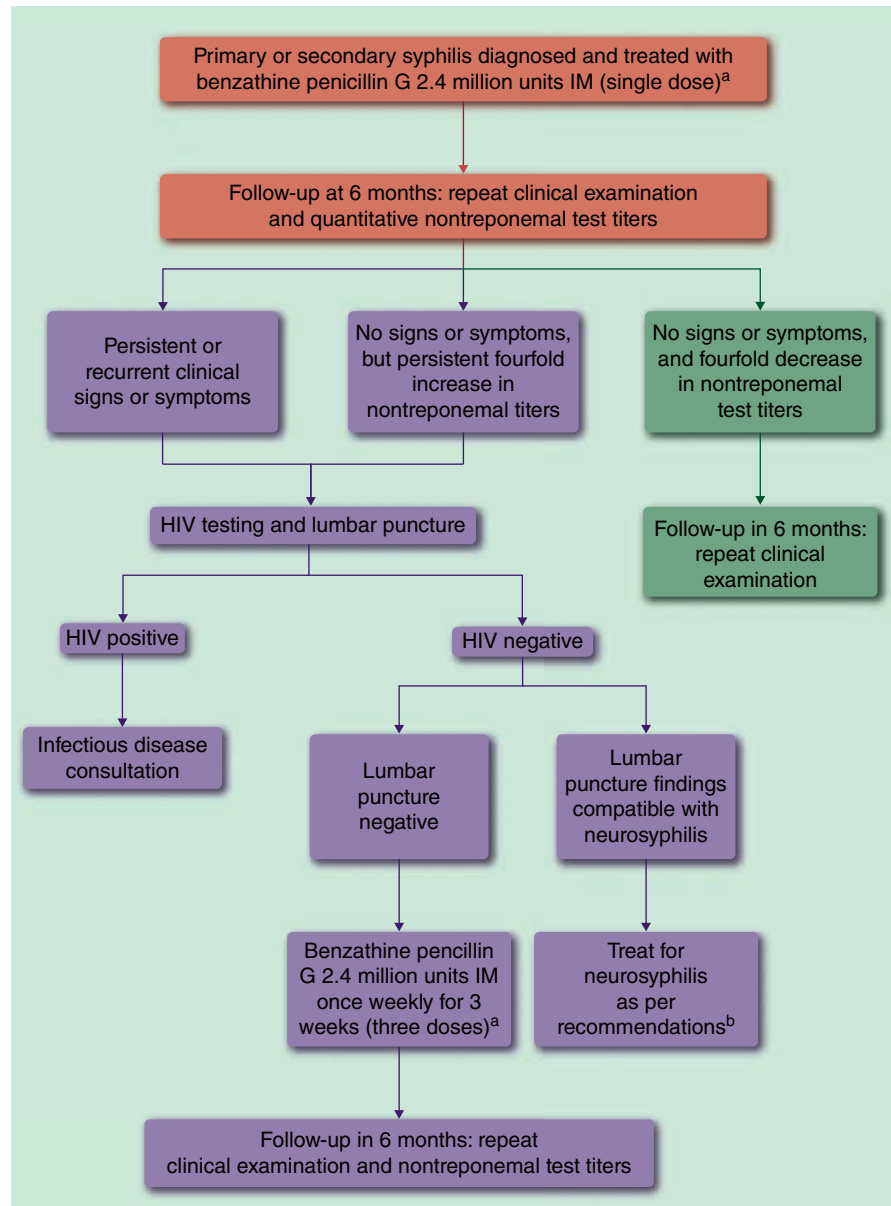
- Six months after the original diagnosis, institute a standard clinical follow-up exam in patients who show no symptomatology and a fourfold decrease in nontreponemal titers. By testing and observing the patient for signs of remission, you may be able to initiate proper treatment or recommend a consult in a timely fashion, thereby decreasing the propensity of the patient's condition to advance to a higher stage.


**FIGURE 80–2.** Patient care monitoring for syphilis. (From Brown D, Frank J. Diagnosis and management of syphilis. Am Fam Physician. 2003;68(2):283–290.) (ªSee text for alternative treatment recommendations for nonpregnant penicillin-allergic patients. ᵇSee text for treatment recommendations for neurosyphilis.)

- If serologic titers do not decline despite a negative CSF examination and a repeated course of therapy, it is unclear whether additional therapy or CSF examinations are needed; additional testing or repeated therapy is not generally recommended.

## Early and Late Latent Syphilis

- Order nontreponemal titers 6, 12, and 24 months after instituting treatment for early or late latent syphilis. Neurosyphilis should be strongly considered in patients who show a fourfold increase in titers, patients who have an initially high titer (1:32 or greater) that fails to decline at least fourfold within 12 to 24 months of therapy, HIV-infected patients, and patients who develop signs or symptoms associated with neurosyphilis.

## Neurosyphilis

- Follow-up is dependent on the CSF findings. If **pleocytosis** is present, reexamine the CSF every 6 months until the WBC count normalizes. Consider recommending a second course of treatment if the CSF white count does not decline after 6 months or completely normalize after 2 years.[4,9,20] Failure to normalize may require retreatment; most treatment failures occur in immunocompromised patients.

## Congenital Syphilis

- Observe the patient for changes in clinical features; hepatomegaly, jaundice, and bone changes will usually resolve in 3 months.
- Monitor elevated serologic markers (nontreponemal tests) for reduction in titer levels. Given effective treatment, clinical

---

## Patient Care Process

**Patient Assessment:**

- Review the patient's medical history. Evaluate patient for HIV infection.
- Order darkfield examinations to detect *T. pallidum* in lesion exudate or tissue.
- If positive, a positive treponemal test is observed, order nontreponemal titers as they correlate closely with disease activity. Titers generally decline subsequent to treatment initation.
- If a negative treponemal test is observed, perform a different treponemal test to confirm initial results. If second treponemal test is positive, do not recommend further management unless a likelihood of reexposure is suspected.
- Offer treatment to those without prior exposure to *T. pallidum.*

**Therapy Evaluation:**

- Recognize that treatment failure may occur with any regimen.
- Evaluate response to treatment by reviewing the nontreponemal titers. Failed treatment or reexposure is consistent with persistent or recurrent signs and symptoms or a sustained fourfold increase in nontreponemal titers over a 6- to 12-month period.

- If treatment failure is observed, analyze CSF for neurosyphilis and test patient for HIV infection. Additional serologic tests may be required.

**Care Plan Development:**

- Test patient for possible HIV infection.
- Test patient for an allergy to pencillin. If allergic, recommend desensitization.
- Recommend treatment for the appropriate stage of syphilis.
- Perform clinical and serologic evaluation at 6 and 12 months after treatment to assess for treatment success of failure.
- Evaluate treatment success or failure and the necessity of retreatment based on serologic and clinical exams.

**Follow-Up Evaluation:**

- Order quantitative nontreponemal and CSF tests to determine patient response to therapy. Adjust doses and treatment accordingly.
- Evaluate patient for signs of advancement in stages of syphilis and treat appropriately.
- When neurosyphilis is present, order CSF exams and leukocyte count to evaluate effectiveness of treatment.

---

features will usually disappear after 6 months. On this basis, evaluate seropositive infants periodically for at least 6 months.[24]

## TRICHOMONIASIS

Trichomoniasis is caused by the protozoan *Trichomonas vaginalis* and is far more prevalent than *C. trachomatis* or *N. gonorrhoeae*. In the United States, approximately 5 million new cases appear annually, compared with 3 million chlamydial and 650,000 gonococcal cases annually.[26]

### PATHOPHYSIOLOGY

*T. vaginalis*, a protozoa, may be isolated from the vagina, urethra, and Bartholin or Skene glands. After attachment to the host cells, it ignites an inflammatory response exhibited as a discharge containing elevated levels of polymorphonuclear leukocytes. The pathogen causes direct damage to the epithelium, leading to microulcerations.

### Clinical Presentation and Diagnosis

Diagnosis is usually performed with a wet mount or Papanicolaou smear. In women, symptoms are characterized by diffuse, malodorous, yellow-green vaginal discharge with vulvar irritation. Some women may be asymptomatic.

### Treatment

The desired outcome is the complete eradication of *T. vaginalis* in both partners and elimination of the signs and symptoms observed.

▶ *Pharmacologic Therapy*

KEY CONCEPT *The 5-nitroimidazoles (metronidazole and tinidazole) have been the standard therapy for trichomoniasis for over 45 years.* When using these agents advise patients to avoid the consumption of alcohol.

---

## Clinical Presentation of Trichomoniasis[9,26]

**General**

- Asymptomatic

**Signs**

- Strawberry cervix (women)
- Colpitis macularis (women)
- Prostatitis or epididymitis (men)

**Symptoms**

- Vaginal/vulvar erythema
- Excessive yellow-green discharge
- Vulvar itching
- Vaginal odor
- Urethral discharge or irritation
- Dysuria
- Vaginal pH greater than 4.5

**Metronidazole** Metronidazole may be administered orally as a single 2 g dose or 500 mg twice daily for 7 days.[9,26] Pregnant women should be prescribed the single dose of metronidazole. Cure rates are greater than 90% when metronidazole is administered as either a single 2 g dose or a 7-day regimen. Possible adverse effects include an unpleasant metallic taste, reversible neutropenia, urticaria, rash, flushing, dry mouth, darkened urine, and a disulfiram-like reaction.

**Tinidazole** Tinidazole, a second-generation nitroimidazole with protozoal and anaerobic activity.[27] As a single 2 g dose, tinidazole has an efficacy equivalent to a 2 g dose of metronidazole. Tindazole also has a longer half-life than metronidazole, 14 and 7 hours, respectively, and penetrates into male reproductive tissue better than metronidazole.

Tinidazole is effective for metronidazole-resistant trichomoniasis.[26,27] Possible side effects include an unpleasant metallic taste, dizziness, loss of coordination, seizures, severe diarrhea, darkened urine, nausea, vomiting, and a swollen or discolored tongue.

### Outcome Evaluation

- Order diagnostic test for trichomoniasis. If positive, recommend antibiotics that cover *T. vaginalis*.
- Subsequent to treatment, expect the eradication of the protozoa.
- Monitoring is generally not required.

## GENITAL WARTS

Genital warts, caused by the human papillomavirus (HPV), usually appear in the genital area as very contagious, small bumps. Responsible for various visible, keratotic, and nonkeratotic manifestations, HPV has more than 120 noted strains, some of which have been linked to squamous cell carcinoma.[28] More than 40 strains have been linked to the genital area.[9]

### EPIDEMIOLOGY AND ETIOLOGY

Genital warts are caused by several strains of HPV and are spread by skin-to-skin contact during sexual activity.[29] Affecting over 20 million Americans, HPV is the most common newly diagnosed STI in the United States, with prevalence just about 15.2%. Approximately 6.2 million new HPV infections occur every year in the United States.[30] Condoms offer incomplete (grade B, level II [fair research-based evidence to support the recommendation]) protection against HPV.[29]

The frequency of cervicovaginal HPV infection among sexually active women has been observed at 43%, with the greatest incidence noticed in men with three or more sex partners and women whose most recent regular sexual partner had two or more lifetime partners. Most people with HPV do not develop symptoms. At least half of sexually active persons will become infected at least once in their lifetime. In 90% of the cases, the body immune system clears HPV naturally within 2 years. Routine testing for HPV infection is not recommended. HPV types 16 and 18 cause 99.7% of all cervical cancer while HPV types 6 and 11 are responsible for about 90% of genital warts.[31]

### PATHOPHYSIOLOGY

HPV replicates in terminally differentiated squamous cells in the intermediate layers of the genital mucosa. Hence, these effects of the viral early region genes on DNA synthesis are critical for viral survival. Genital warts are the clinical manifestation of active viral replication and virion production at the infection site.

### Clinical Presentation and Diagnosis

- A definitive diagnosis of HPV is based on DNA or RNA or capsid protein detection.
- Diagnosis is generally made from the clinical presentation and may be classified into several categories: classic condyloma acuminata, which are pointed or cauliform; keratotic warts with a thick, horny surface resembling common skin warts; and flat warts, frequently observed on the surface.
- Tissue biopsy or viral typing is only indicated if the diagnosis is uncertain and is not recommended for patients with routine or typical lesions.
- Since HPV is highly associated with cervical cancer and has more than 20 different cancer-associated HPV types, patients who are diagnosed with HPV should be tested for cervical cancer.

**Table 80–2**

**Comparison of Adverse Effects Seen With Treatments for Genital Warts**

| Treatment | Adverse Effects |
|---|---|
| Podofilox | Burning at site of application, pain, inflammation |
| Imiquimod | Erythema, irritation, ulceration, pain, burning, edema, pigmentary changes |
| Sinecatechins | Burning at site of application, erythema, pruritus, edema |
| Podophyllin resin | Local irritation, erythema, burning, soreness at application site; possibly oncogenic |
| Bichloroacetic and trichloroacetic acid | Local irritation and pain, minimal systemic effects |
| Cryotherapy | Pain or blisters at application site |
| Surgical excision | Pain, bleeding, scarring; possible burning or allergic reaction to local anesthetic |
| Vaporization | Pain, bleeding, scarring; risk of HPV spreading via smoke plumes |
| Intralesional interferon | Burning, itching, irritation at injection site, systemic myalgia, headache, fever, chills, leukopenia, elevated liver enzymes, and thrombocytopenia |

HPV, human papillomavirus.

Data from Refs. 9, 28, and 31.

## Treatment

Approximately 40% to 60% of untreated warts will spontaneously resolve in 9 to 12 months if left untreated.[29] Treatment of benign, symptomatic genital warts is aimed at alleviation of physical symptoms and cosmetic improvement. Removal of visible warts and reduction of infectivity are the goals of treatment.

A comparison of adverse effects related to treatment options may be found in Table 80–2.[32]

### ▶ Patient-Applied Treatment

**Podofilox**  Available as a 0.5% gel or solution containing purified extract of the most active compound of podophyllin, podofilox arrests the formation of the mitotic spindle, prevents cell division, and may also induce damage in blood vessels within the warts. The surface area treated must not exceed 10 cm$^2$, and a maximum of 0.5 mL should be used on a daily basis.

Apply podofilox twice daily for 3 consecutive days followed by 4 consecutive days without treatment. This cycle may be repeated until there are no visible warts or for a maximum of 4 weeks. Side effects are generally local and may include erythema, swelling, and erosions. Podofilox is not recommended for use in the vagina, anus, or during pregnancy.

**Imiquimod**  Imiquimod is a cell-mediated immune-response modifier, available as a topical 5% cream in single-dose application packets. There are two recommended dosage regimens:

a.  Apply at bedtime, three times a week for up to 16 weeks.
b.  Apply every other day for three applications.

The treatment area should be washed with soap and water 6 to 10 hours after application. Mild to moderate erythema has been noted with imiquimod use; however, this generally suggests that the drug is reaching a therapeutic range and may be clearing the lesion.[33,34]

**Sinecatechins**  A green tea extract with an active product (catechins), is available as a 15% ointment. Apply a thin layer (0.5 cm) using a finger to each wart, three times a day until complete clearance of warts. Do not wash off after use and all sexual contact should be avoided while ointment is on the skin. This product should not be continued for longer than 16 weeks.[9]

### ▶ Physician-Applied Treatments

**Podophyllin Resin**  A 10% to 25% solution of podophyllin resin has been the standard in-office treatment for genital warts. Because podophyllin is neurotoxic and easily systemically absorbed, only a small amount (no more than 0.5 mL) should be applied, avoiding normal tissue. Application should be limited to less than 0.5 mL of podophyllin on an area of less than 10 cm$^2$ of warts per session and no open lesions or wounds should exist in the area to which treatment is administered. The affected area will likely become erythematous and painful within 48 hours of application.[34]

Topical podophyllin is applied once weekly and the area should be allowed to dry. Immediately following treatment, the dried drug should be removed using alcohol or soap and water. It is contraindicated in pregnant patients.

**Bichloroacetic (BCA) and Trichloroacetic (TCA) Acids**  These products are available in 80% to 90% concentrations and are not systemically absorbed. The products are effective when used to treat a few, small, moist lesions. Apply once a week until wart is resolved. They may be applied to both keratinized epithelial and mucosal surfaces and may be used in pregnancy.

A noted reaction to these medications is transient burning; contact with surrounding epithelium may prove to be painful, producing significant local erythema and swelling. To avoid these effects, place petroleum jelly around the external lesion, including unaffected skin, and carefully apply the agent with a small applicator. If an excess amount of acid is used, talc or sodium bicarbonate (baking soda) may be administered to neutralize unreacted acid.

**Other Treatments**  Other treatments may include fluorouracil/epinephrine/bovine collagen gel, an intralesional injection that has been proven effective in clinical trials for refractory patients or an intralesional injection of interferon.[31]

### ▶ Ablative Therapy

Several ablative options have been employed in the treatment of genital warts and include cryotherapy, surgical removal, and vaporization.

### ▶ Special Therapeutic Issues [32–35]

**Large Warts**  Treat warts greater than 10 mm in diameter with surgical excision. Use imiquimod for three to four treatment cycles to reduce the number of warts and improve surgical outcomes. Fifty percent reduction in wart size after four treatment cycles warrants continued use of imiquimod until warts clear or eight cycles have been completed; less than 50% reduction warrants surgical excision or other ablative therapy.

**Subclinical Warts**  Subclinical warts may be identified through colonoscopy, biopsy, acetic acid application, or laboratory serology. However, early treatment has not been linked to a favorable effect during the course of therapy in the index patient or the partner with regard to reduction of the transmission rate.

**Pregnancy**  Agents contraindicated in pregnancy include podofilox, sinecatechins, fluorouracil, and podophyllin. Imiquimod is not approved for use in pregnancy, although it has been

## Patient Care Process

**Patient Assessment:**

- Physical examination should be done.
- Order a pregnancy test.
- Review symptoms.
- Verify sexual history.
- Determine if lesions are a first episode or reoccurrence.
- Review all medical conditions and medications.

**Therapy Evaluation:**

- Discuss the treatment options with the patient including observation without active treatment.
- Determine the choice of therapy based on the size, site, and morphology of the lesion.
- Include patient preference, treatment cost, adverse effects, and convenience before making a decision.

**Care Plan Development:**

- Emphasize to the patient that sexually active people can lower the chance of getting HPV by limiting the number of partners.
- Order oral contraception for fertile women.
- Start patient treatment and continue for the recommended duration.
- Switch to an alternate therapy if there has been no response after two to three treatment cycles.

**Follow-up Evaluation:**

- Follow-up every 2 to 3 months for a reduction in lesions or disease remission.
- Monitor patient compliance, disease remission, and benign or cancerous tumors.

considered after signed consent has been obtained. Bichloroacetic and trichloroacetic acids have been used without problems. Ablative therapy is also a viable option.

### Outcome Evaluation

- Monitor the patient for any visible warts and relief of symptoms.
- Apply powder with talc, baking soda, or liquid soap to remove unreacted trichloracetic or bichloroacetic acid.
- Dry area before contact with normal mucosa after application of podophyllin.
- Repeat TCA, BCA, podophyllin treatment weekly if necessary.
- Administer a different agent if warts persist after one type of therapy.
- Refer all recalcitrant patients to local STI clinic, gynecologists, dermatologists, or urologists.

### Vaccinations

Several HPV genotypes have been linked to the development of cervical cancer. Gardasil, developed to protect against HPV genotypes 6, 11, 16, and 18, was the first vaccine employed to prevent cervical cancer, precancerous genital lesions, and genital warts due to HPV. Cervarix vaccine prevents cervical cancer and precancers caused by HPV types 16 and 18. The CDC recommends the HPV vaccine for all 11- and 12-year-old females and males. Vaccination is also recommended for females aged 13 through 26 years and males 13 to 21 years old who have not been previously vaccinated or who have not completed the full series of shots.[36] The quadrivalent vaccine Gardasil is FDA-approved for females and males 9 to 26 years old.[37]

Both inactivated vaccines are given in a series of three injections over a 6-month period. The second and third doses should be given at 2 and 6 months (respectively) after the first dose. HPV vaccine may be given at the same time as other vaccines. Vaccines are efficacious in preventing genital warts; however, they will not clear those that are already present.

## GENITAL HERPES

Genital herpes (GH) is caused by herpes simplex virus (HSV) types 1 and 2. HSV is a chronic, lifelong viral infection, for which there is no cure. Once latency is established, neither competent host immunity nor therapeutic agents can eradicate the virus.[9] Currently, there is no vaccine available for HSV, and it seems that the development of one is unlikely in the near future.

### EPIDEMIOLOGY AND ETIOLOGY

Approximately 50 million Americans have GH. HSV-2 is the most common cause of recurrent genital herpes. Roughly 1 in 6 people in the United States (16.2%) aged 14–49 is infected with HSV-2. Prevalence of HSV-2 infection has grown by approximately slightly since the late 1970s (16.4%–17.2%), and currently over 500,000 new cases of HSV-2 occur annually.

### PATHOPHYSIOLOGY

Nearly all HSV-2 infections are sexually acquired. Since HSV is only found in humans, infection may only be transmitted from infectious secretions onto mucosal surfaces (ie, cervix or urethra) or direct contact with an active lesion (abraded skin). The virus may survive for a limited amount of time on environmental surfaces. Most sexual transmission occurs while the source case is asymptomatic. Most patients with asymptomatic or unrecognized genital HSV infections will still shed virus intermittently in the genital tract. Patients will have small, painful blisters that are filled with fluid. The first outbreak takes 2 to 4 weeks to heal, with later attacks being less severe. Because there is no cure for this illness, treatment will only help reduce the signs, symptoms, and number of attacks.

### Clinical Presentation and Diagnosis

Ulcerative or multiple vesicular lesions are absent in many infected persons. Laboratory confirmation is vital to effective treatment of HSV, especially in individuals in whom a clinical diagnosis cannot be obtained. There are several methods by which a definitive diagnosis may be acquired, and these include virologic typing, serologic diagnosis, rapid point-of-care antigen detection, enzyme-linked immunosorbent assay (ELISA), immunoblot, and DNA polymerase chain reaction.[38] Glycoprotein G-based assays may also be used to aid in the diagnosis of HSV.

### Treatment

The desired outcome is to curtail the number of episodic prodromes and to minimize any side effects experienced due to the

## Clinical Presentation of Genital Herpes[9,38,39]

**General**
- Asymptomatic

**Classic Sign**
- A cluster of painful vesicles on an erythematous base

**Symptoms**
- Itching
- Burning
- Tingling
- Groin lump
- Dysuria
- Dyspareunia
- Increased urinary frequency

**Other Symptoms**
- Ulcerative lesions, fissures, cervicitis

antivirals. Counseling of infected persons and their partners is vital to the management of HSV.

### ▶ First Episode

The first episode is a systemic illness associated with the vesicular lesions, may last up to 21 days, usually has an uncomplicated course of infection, and in severe cases may require hospitalization. Several agents are effective during this period (Table 80–3).[39–41] At the cited dosages, these agents have had excellent outcomes with regard to lesion healing time, viral shedding, and loss of pain. Common adverse effects are nausea, headache, and diarrhea. It is important to note that the first episode does not necessarily indicate recent infection and the genital symptoms may develop several years after the infection was acquired. Condom use in new or uninfected partners particularly in the 12 months after the first attack is recommended.

### ▶ Episodic Therapy

In a patient with a previous diagnosis of genital herpes, the appearance of new vesicular lesions is synonymous with HSV reactivation. For most patients, genital herpes recurrence is self-limiting and short-lived, lasting approximately 6 to 7 days.

### ▶ Suppressive Therapy

Suppressive therapy is effective for controlling all symptoms related to the disease and may impact troublesome complications of infection. Before beginning suppressive therapy, discuss patient expectations. Encourage patients to record any breakthrough episodes, as this may require treatment reevaluation and adjustment.

### ▶ Preventive Therapy

Valacyclovir 500 mg orally once daily has been used to prevent the sexual transmission of HSV to an uninfected partner. In addition to pharmacologic therapy, counsel patients regarding safe sex practices.

### ▶ Drug Resistance

All acyclovir resistant strains are resistant to valacyclovir and the majority are resistant to famciclovir. Foscarnet, cidofovir, and trifuridine have been administered in acyclovir-resistant patients.[42] These agents are usually reserved for use after other medications have failed because of their associated toxicities.

### ▶ Pregnancy

Women who are pregnant may transmit the virus to the neonate during delivery. There are two management strategies: caesarean section and antiviral therapy. Acyclovir 200 to 400 mg every 8 hours has been administered from 38 weeks' gestation until delivery. Acyclovir, famciclovir, and valcyclovir are all classified as category B (no evidence of risk in humans) for use during pregnancy. Suppressive treatment includes the use of acyclovir or valacyclovir from week 36 until delivery. The goal of therapy is to reduce the number of lesions and asymptomatic shedding at delivery.

### ▶ Neonates

The risk for transmission from an infected mother to a neonate is high among women who acquired GH near time of delivery. HSV infections should be considered in all neonates who present with nonspecific symptoms such as fever, poor feeding, lethargy, or seizures in the first month of life. Infants suspected to have or who are diagnosed with an HSV infection should be treated parenterally. Acyclovir 20 mg/kg/day in three divided doses IV for 21 days for disseminated and CNS disease or 14 days for disease limited to skin, eyes, and mucous membranes.

## Outcome Evaluation

- Monitor for systemic symptom improvement and a decrease in viral shedding in initial HSV treatment.
- Take lukewarm baths three to four times a day to ease itching and pain. Pat dry infected areas.
- Wear loose-fitting underwear to help the sore dry.
- Avoid sexual contact until treatment is finished.
- Consider stopping suppressive therapy after 1 year to assess recurrence rate.
- Compound topical 1% cidofovir gel in acyclovir-resistant strains where IV foscarnet is not preferred.

## PELVIC INFLAMMATORY DISEASE

Pelvic inflammatory disease (PID) usually affects young, sexually active, reproductive-age women. PID includes a spectrum of inflammatory disorders of the upper female genital tract. In the majority of cases, the pathogens responsible are *C. trachomatis* and *N. gonorrhoeae*; although anaerobes, enteric gram-negative rods, and cytomegalovirus have also been implicated in the pathogenesis.[43] PID has been correlated with ectopic pregnancy, infertility, tubo-ovarian abscess, and chronic pelvic pain.[44]

## Epidemiology and Etiology

PID is most common in women younger than 25 years of age, who have more than one sex partner. More than 750,000 women are affected by PID each year in the United States. The highest rates of PID occur in teenagers and first time mothers. Up to 10% to 15% of these women may become infertile as a result of PID. The CDC estimates that more than 1 million women experience

**Table 80–3**

**Comparison of Antiviral Agents Used for Herpes Simplex Infection**

| Agent | Dose | Side Effects |
|---|---|---|
| **First Episode** | | |
| Acyclovir | *200 mg orally five times a day × 7–10 days* <br> *Or* <br> 400 mg orally three times daily × 7–10 days | Headache, confusion, nausea, vomiting, thrombocytopenia, renal insufficiency, rash, pruritus, fever, arthralgias, myalgia, thrombotic thrombocytopenic purpura, hallucinations, somnolence, depression |
| Valacyclovir | *1 g orally two times daily × 7–10 days* | Refer to acyclovir |
| Famciclovir | 250 mg orally three times daily × 7–10 days | Refer to acyclovir |
| **Episodic** | | |
| Acyclovir | *200 mg orally five times daily × 5 days* <br> *Or* <br> 400 mg orally every 8 hours × 5 days <br> *Or* <br> 800 mg orally two times daily × 5 days <br> *Or* <br> 800 mg orally three times daily × 2 days | Refer to acyclovir (WHO) |
| Valacyclovir | *500 mg orally two times daily × 3 days* <br> *Or* <br> 1 g orally once daily × 5 days | Refer to acyclovir |
| Famciclovir | 125 mg orally two times daily × 5 days <br> *Or* <br> 1000 mg orally twice daily × 1 day | Refer to acyclovir |
| **Suppressive** | | |
| Acyclovir | 400 mg orally two times daily continuously <br> *Or* | Refer to acyclovir |
| Valacyclovir | 500 mg orally once daily continuously <br> *Or* | Refer to acyclovir |
| Valacyclovir | 1000 mg orally once daily continuously <br> *Or* | Refer to acyclovir |
| Famciclovir | 250 mg orally two times daily continuously | Refer to acyclovir |
| **Reserved Agents** | | |
| Foscarnet | 40 mg/kg IV every 8 hours until clinical resolution is attained | Renal insufficiency, metabolic disturbances, hypophosphatemia |
| Cidofovir | 1% topical agent (gel) used daily on a compassionate basis for acyclovir-resistant herpes lesions for 5 days | Application site reactions, lesion recrudescence |
| Imiquimod | Topical alternative used daily on a compassionate basis for acyclovir-resistant herpes lesions for 5 days | Application site reactions, lesion recrudescence |

*Italicized* data indicate recommended dosages.

Data from Refs. 9 and 33.

---

**Patient Encounter 3**

LS is a 27-year-old female model who decides to visit her gynecologist because of a 1-month history of vaginal burning, vaginal bleeding, and rough thick lesions around her perianal area. Currently, LS is not in a monogamous relationship. Upon questioning, LS stated she was treated twice before for STIs in the past decade. Her last sexual encounter was 2 weeks ago and stated they did not utilize protection.

*What information is suggestive of genital herpes?*

*What potential risk factors for STIs are present?*

*What additional information is required to initiate a treatment plan? What is your opinion about the use of the Gardasil vaccine in this patient?*

---

**Patient Encounter 4**

BC is the father of patient 1 (LS) only child. BC is a 33-year-old former NBA player that was forced to retire 4 years ago due to a long history of substance abuse. BC has three other children from two different women. BC became mentally and emotionally stress after hearing of LS's diagnosis. BC has experienced symptoms of painful urination, enlarged lymph nodes, and small blisters in his genital area 3 days ago. BC was initially informed of his HSV-2 status during his rookie year in the NBA.

*Given this information, what is your assessment of the patient?*

*Identify the treatment goals for this patient?*

*BC subsequently states that acyclovir did not work during his last episode. What are his options?*

## Patient Care Process

**Patient Assessment:**

- Based on physical exam, ask a series of questions: Do you have sores in the genital area or anywhere else on your body? Do the sores come and go? Do you have frequent urination or burning/stinging with urination? If discharge is present, does it smell or have color? Do you use condoms or birth control? Have you or your partner ever been treated for a STI in the past? Is this your first outbreak?
- Review all medical conditions and medications including dosing.
- Review available laboratory test if available of definitive diagnosis.

**Therapy Evaluation:**

- Base treatment on likelihood of patient compliance, whether it is first or a recurrent episode, host immunity, and pregnancy.
- Remind patient that response has been linked to the time it takes to initiate treatment with acyclovir, or its analogues, after symptom onset.

**Care Plan Development:**

- Immediately initiate therapy (within one day of onset) in episodic treatment of systematic recurrent lesions for patient to experience benefit from agent.
- Emphasize that sexually active people can lower their chances of spreading HSV by using condoms.
- Evaluate and educate all sex partners of infected persons.

**Follow-up Evaluation:**

- Reevaluate the patient's psychosocial and psychosexual status.
- Order tests to detect malignant changes of the female genital tract.
- Order yearly testing for HIV status.
- Review side effects of drugs with the patient.
- Frequently reassess all recurrent episodes and therapy adjustments.

an episode of PID every year. The disease leads to approximately 2.5 million office visits annually. Since many cases of PID go unrecognized and some episodes are asymptomatic, the potential for damage to the reproductive health of women has increased. There is an increased risk for women with past STIs and with partners who have more than one partner.

## PATHOPHYSIOLOGY

PID is an infection that occurs when bacteria move upward from a woman's vagina into her reproductive organs. Normally, the cervix prevents bacteria from entering the vagina and spreading to the reproductive organs. However, when the cervix is exposed to STI's such as chlamydia and gonorrhea, the bacteria is disseminated to the female internal organs. Chlamydia may produce a heat-shock protein that causes tissue damage through a delayed hypersensitivity reaction. *C. trachomatis* may also possess DNA

evidence of toxin-like genes that code for high-molecular-weight proteins with structures similar to *Clostridium difficile* cytotoxins, enabling inhibition of immune activation. This may explain the observation of a chronic *C. trachomatis* infection in subclinical PID.

## Clinical Presentation and Diagnosis[43,46]

Because many women with PID have subtle or mild symptoms, delays in diagnosis and treatment probably led to inflammatory sequelae in the upper reproductive tract. To be diagnosed with PID, patients must have uterine tenderness, cervical motion tenderness, painful urination, lower abdominal pain, painful intercourse, and adnexal tenderness with no other cause of these signs. Additional criteria include:

- Oral temperature greater than 38.3°C (101°F)
- Abnormal cervical or vaginal discharge or that has an unusual color (green or yellow)
- WBC presence on saline microscopy of vaginal secretions
- Elevated erythrocyte sedimentation rate
- Elevated C-reactive protein
- Laboratory documentation of cervical infection with *N. gonorrhoeae* or *C. trachomatis*

## Treatment

The removal of causative bacteria and reduction of any related sequelae are the desired goals of treatment. Resolution of infection (ie, *N. gonorrhoeae*, *C. trachomatis*, *Streptococcus* spp., and gram-negative facultative bacteria) and mitigation of sequelae should be the main goal of pharmacologic therapy. Treatment regimens for PID must provide empiric, broad-spectrum coverage of likely pathogens. CDC-approved treatment regimens are shown in Table 80–4.[9,43]

Though outpatient management remains contentious, many feel that outpatient management should be limited to individuals who: remain afebrile, have a WBC counts less than $11 \times 10^3/mm^3$ ($11 \times 10^9/L$), have minimal evidence of peritonitis, have active bowel sounds, and can tolerate oral nourishment. Nonetheless, outpatient therapy with a parenteral cephalosporin followed by doxycycline and metronidazole is recommended.

## OUTCOME EVALUATION

- Reevaluate any patient who does not respond significantly within 72 hours of parenteral/oral treatment.
- Initiate parenteral therapy (inpatient or outpatient) for patients that do not respond to oral treatment.
- Continue parenteral therapy for 14 days; however, it may be stopped 24 hours after clinical improvement and doxycycline continued to complete 14 days of therapy.
- Hospitalization and reassessment of the antimicrobial regimen and diagnostics are recommended in women without clinical improvement.
- Repeat testing of all women who have been diagnosed with chlamydia or gonorrhea is recommended 3 to 6 months after treatment, regardless of whether their sex partners were treated.
- Inform the patient that an alteration in sexual behavior should be the first concern, as promiscuous sexual activity augments the probability of infection.

## Table 80–4

### Treatment Regimens for Pelvic Inflammatory Disease

**Parenteral Option A**

Cefotetan 2 g IV every 12 hours

Or

Cefoxitin 2 g IV every 6 hours plus doxycycline 100 mg orally or IV every 12 hours

**Parenteral Option B**

Clindamycin 900 mg IV every 8 hours plus gentamicin, loading dose IV or IM (2 mg/kg) followed by maintenance dose (1.5 mg/kg) every 8 hours. A single daily dose of gentamicin (3–5mg/kg) may be used

**Alternative Parenteral treatment**

Ampicillin-sulbactam 3 g IV every 6 hours plus doxycycline 100 mg orally or IV every 12 hours

**Oral**

Ceftriaxone 250 mg intramuscular single dose plus doxycycline 100 mg orally twice daily for 14 days with or without metronidazole 500 mg orally twice daily for 14 days

Or

Cefoxitin 2 g intramuscular single dose and probenecid 1 g single dose, plus doxycycline 100 mg orally twice daily for 14 days with or without metronidazole 500 mg orally twice daily for 14 days

Or

Third-generation cephalosporin (ceftizoxime or cefotaxime) plus doxycycline 100 mg orally twice daily for 14 days with or without metronidazole 500 mg orally twice daily for 14 days

Data from Refs. 9, 45, and 46.

Abstinence is the best course of action, especially in patients with herpes during lesional episodes. However, compliance in some may be minimal, in which case, appropriate condom use should always be recommended. To alleviate any possible misconceptions about condom application, either demonstrate how to apply a condom or ask the patient to demonstrate. During

## Clinical Presentation of Pelvic Inflammatory Disease[9,46]

**General**

- Signs and symptoms may vary from mild to severe

**Signs**

- Vague

**Symptoms**

- Lower abdominal or pelvic pain
- Malodorous vaginal discharge
- Abnormal uterine bleeding
- Dyspareunia
- Dysuria
- Nausea and/or vomiting
- Fever

## Patient Care Process

**Patient Assessment:**

- Based on a physical exam that includes a pelvic exam, determine if the patient is experiencing and pain in the lower belly or back, vagina discharge with or without color, painful sex, fever, or burning during urination.
- Test for pregnancy, complete blood count, gonorrhea, chlamydia, and bacterial vaginosis.

**Therapy Evaluation:**

- Optimal management of PID should be individualized based on clinical setting and patient characteristics.
- For some patients, hospitalizations, IV antibiotics, and surgical treatment of complications may be needed.

**Care Plan Development:**

- If no clinical improvement has occurred within 3 days after parenteral or outpatient oral therapy, perform further assessment.
- Educate the patient about the goals of monitoring patients with PID are related to reducing long-term complications.
- Examine the male sex partners of women with PID if the patient's onset of symptoms occurred within the previous 60 days. Remind women that numerous sex partners increase the risk of developing PID.

**Follow-up Evaluation:**

- Advise a combination of prevention efforts.
- The primary approach should be prevention and education of at-risk women.
- Secondary prevention includes screening by conducting a pelvic exam during a routine check-up.
- Verify substantial clinical improvement within 72 hours after initiation of therapy.

## Patient Encounter 5

**PMH:** History of chlamydia 2 years ago. Allergy to clindamycin

**FH:** Noncontributory

**SH:** 18-year-old college freshman and current girlfriend of BC. Admits that she has a secretive sexual relationship with the starting football quarterback

**ROS:** Unpleasant vaginal odor, painful sex, and pain in her lower abdomen

**PE:**

**VS:** BP 135/85, Ht 5'4" (163 cm), Wt 117 lb (53.2 kg) T 97.8°F (36.6°C)

In the past, the patient utilized condoms frequently; but states they cause her to have yeast infections and has since discontinued their use.

*What consideration should be given to other STIs?*

*What oral treatment options are available for this patient?*

*What non-pharmacologic therapy should be recommended for this patient?*

the demonstration, explicitly educate the patient with regard to application, storage, and the use of lubricants.[46]

# 81 Osteomyelitis

Melinda M. Neuhauser and Susan L. Pendland

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. List common risk factors for osteomyelitis.
2. Discuss the pathophysiology of osteomyelitis.
3. Compare and contrast the classic signs and symptoms of acute and chronic osteomyelitis.
4. Evaluate microbiology culture data and other laboratory tests and imaging studies utilized for diagnosis of osteomyelitis.
5. List the most common pathogens isolated in acute and chronic osteomyelitis.
6. Develop a treatment plan for osteomyelitis.
7. Recommend parameters to monitor antimicrobial therapy for effectiveness and toxicity.
8. Educate patients regarding disease state and drug therapy.

## INTRODUCTION

**KEY CONCEPT** *Osteomyelitis is an infection of the bone that can be an acute or chronic process.* The inflammatory response associated with acute osteomyelitis can lead to bone necrosis and subsequently chronic infections.[1] Bacterial pathogens, particularly *Staphylococcus aureus*, are the most common microorganisms implicated in these infections.[1–8] Diagnosis and treatment are often difficult due to the heterogeneous nature of osteomyelitis.[1,2] Medical management is the mainstay of treatment for acute infections; however, surgical intervention is necessary for chronic infections that involve bone necrosis.[1,2] Outcomes may vary based on patient-specific risk factors, duration of disease, and site of infection.[1,2]

**KEY CONCEPT** *Osteomyelitis is most often classified by duration of disease and route of infection.*[1,2,9] Historically, osteomyelitis has been classified as acute or chronic based on duration of disease.[1,2,9] However, there are no established definitions for acute and chronic infections.[1,9,10] Acute infection has been defined as first episode or recent onset of symptoms (within 2 weeks).[2,9–11] Chronic osteomyelitis is generally defined as relapse of the disease or symptoms persisting beyond 2 months.[2,9] Because there is no abrupt demarcation, but rather a gradual shift from acute to chronic infection, others describe chronic osteomyelitis as the presence of necrotic bone.[1,2,10,11]

In the Waldvogel classification scheme, the route of infection is categorized as either hematogenous or contiguous.[9] Osteomyelitis secondary to a contiguous focus is further subdivided into infections with or without vascular insufficiency. Typical bone involvement in osteomyelitis depends on the route of infection.

- Hematogenous: long bones (femur, tibia) in children and vertebra in the elderly[2–5,10]
- Contiguous with vascular insufficiency: lower extremities[2,11,12]
- Contiguous without vascular insufficiency: bones affected by trauma, surgery, or adjacent to soft-tissue infection[1,5]

A single pathogen is most often isolated in hematogenous osteomyelitis, whereas multiple organisms are often isolated in contiguous osteomyelitis.[7,10,11,13]

## EPIDEMIOLOGY AND ETIOLOGY

Hematogenous osteomyelitis is the most common type of osteomyelitis in children while osteomyelitis due to contiguous spread is most common in adults.[1–4,6] Hematogenous osteomyelitis is reported in older adults and IV drug users, with the spine (vertebral osteomyelitis) being the most common site of infection.[1,2,5]

**KEY CONCEPT** *S. aureus is the predominant pathogen seen in all types of osteomyelitis, with methicillin-resistant S. aureus (MRSA) being increasingly reported.*[1–4,6,10] However, the spectrum of potential causative pathogens varies with patient-specific risk factors including the following:

- Patients with uncontrolled diabetes and/or peripheral vascular disease have poor wound healing and often present with nonhealing skin ulcers. These wounds are typically colonized with a mixture of aerobic and anaerobic microorganisms, which can lead to polymicrobial osteomyelitis.[1,11,13,14] Common aerobic pathogens in this setting may include MRSA, Enterobacteriaceae, and *Pseudomonas aeruginosa*.[11,14] Therefore, if a wound is deep or extensive, these patients should be evaluated for underlying osteomyelitis.[11,14]
- Sickle cell patients (*Salmonella* spp)[1,2,7]

- Individuals with prosthetic implants (coagulase-negative staphylococci)[7]
- Neonates (*E. coli* or group B streptococci)[2]
- Patients with pressure sores (polymicrobial)[2,7]

## PATHOPHYSIOLOGY

Both microbial and host factors are important determinants in the development of osteomyelitis.[1] Healthy bone tissue is normally resistant to infection but may become susceptible under certain conditions.[1,2] Bone can become infected: (a) via the presence of bacteria in the bloodstream, (b) by direct inoculation from trauma or surgery, and (c) by spread from an adjacent site (eg, soft-tissue infection).[1] The latter is particularly problematic in patients with foreign body implants (eg, hip replacement) and chronic skin ulcers.[1,11]

*Staphylococcus* species possess bacterial adhesins, which promote their attachment to tissues and foreign devices.[1] Microbial adherence to bone elicits an inflammatory response.[1] The subsequent release of leukocytes and cytokines leads to edema and ischemia. In some cases, these processes can lead to bone necrosis.[1] Pieces of dead bone may become separated, forming sequestra.[1] These areas typically cannot be penetrated by antimicrobials and phagocytic cells and thus require surgical intervention to eradicate the bacterial nidus.[1,11]

## CLINICAL PRESENTATION AND DIAGNOSIS
### General

The clinical presentations of osteomyelitis may vary depending on route and duration of infection, as well as patient-specific factors such as infection site, age, and comorbidities.[1–4,7,11,14]

**KEY CONCEPT** *The gold standard for diagnosis of osteomyelitis is a bone biopsy with isolation of microorganism(s) from culture and the presence of inflammatory cells and osteonecrosis on histologic exam.[1,2,11–14] Due to the invasive nature of the bone biopsy, the diagnosis of osteomyelitis is often based on clinical findings, laboratory tests, and imaging studies rather than bone biopsy.[1,12,13]*

**KEY CONCEPT** *Typical signs and symptoms of osteomyelitis include local pain and tenderness over the affected bone, as well as inflammation, erythema, edema, and decreased range of motion.[1,3,4,6,9] Patients with acute hematogenous osteomyelitis may also present with fever, chills, and malaise.[1,3,4,9] A cardinal sign of chronic osteomyelitis is the formation of sinus tracts (a channel from the infected site to the skin) with purulent drainage.[1]*

### Laboratory Tests

No single noninvasive laboratory test is currently available for the diagnosis of osteomyelitis.[1] Despite low specificity, several tests are commonly used to aid in the diagnosis and to monitor response to therapy.

Nonspecific inflammatory markers for infection include:[1,2,4–6]

- White blood cell count (WBC)
- Erythrocyte sedimentation rate (ESR)
- C-reactive protein (CRP)
- Procalcitonin

WBC, ESR, and CRP are often elevated, but may also be within normal limits. An elevated WBC is mostly seen in patients with acute osteomyelitis.[1,3,6,9] CRP rises faster than ESR during early stages of infection and also returns to normal levels more quickly than ESR. This makes CRP a more useful tool for both diagnosis

and monitoring of therapeutic response.[4–6] Similar to CRP, procalcitonin may be useful for both diagnosis and monitoring of therapeutic response; however, it is often more expensive and may not be as readily available.[4]

### Microbiologic Evaluation

Isolation of causative pathogen from bone biopsy samples is essential for targeted antimicrobial therapy.[1–3,5,7,11,12] If bone biopsy is not done, quality specimens (eg, two consecutive samples with bone contact [deep samples] in patients with contiguous osteomyelitis[12,15] or blood cultures in patients with acute hematogenous osteomyelitis[1,3,5] may assist in pathogen identification. Superficial swabs often represent colonization rather than infecting organism(s).[1,7,12,14]

### Imaging Studies

- Imaging tests are used to assist in the diagnosis of osteomyelitis.[1,3,12,14,16,17]
- Plain film radiographs (x-rays) are the initial imaging study of choice for skeletal infections.[1,5,6,12,16] Although changes in soft tissue may appear within 3 days of infection, bone lesions may not be visible for 10 to 21 days.[1,4,6,11,12,16] Advantages of radiographs are accessibility, cost, low radiation exposure, and they are readily repeatable.[5,16] A disadvantages is the inability to detect early bone infections.[1,3,4,6,11,16]
- Magnetic resonance imaging (MRI) is considered the best overall imaging modality for the diagnosis of osteomyelitis.[1,3,4,11,13,14,16,17] Advantages include early detection (ie, 3–5 days after onset of infection), no radiation exposure, and high resolution.[1,6,16,17] Disadvantages include expense, inconvenience to patients (long examination time), movement artifacts, and the limitations to scanning patients with pacemakers and other implantable metal devices.[3,17]
- Computed tomography (CT) scans have high resolution and reproducibility.[17] CT scans have reduced sensitivity compared to MRI and should not be routinely used to diagnose osteomyelitis.[1,5,16] Advantages are that it is useful for the identification of sequestra, and it is less expensive than MRI.[3,16,17] Disadvantages are the exposure of the patient to radiation and inability to use contrast medium to enhance images in patients with impaired renal function or previous allergic reactions.[3,4,17]
- Radionuclide imaging is also used for the early diagnosis of bone infections.[16] The most widely used nuclear medicine test is the three-phase bone scan.[16,17] An advantage is early detection within 24 to 48 hours after onset of symptoms.[5,6,16] Disadvantages include low specificity (increased risk of false positives) in patients with recent trauma, surgery, orthopedic prosthesis, diabetes, and ischemia, and high radiation dose required.[1,16] Using a labeled WBC scan in combination with the three-phase bone scan can increase sensitivity and specificity.[14,16]

## TREATMENT

**KEY CONCEPT** *The treatment goals for osteomyelitis are to eradicate the infection and prevent recurrence.[6–8,14,18]* In comparison to acute hematogenous osteomyelitis, chronic osteomyelitis is associated with higher failure rates, largely due to the presence of necrotic bone.[1,8,14,19] These patients typically require surgical intervention to remove the necrotic bone and tissue, and if applicable, to

## Patient Encounter, Part 1

A 42-year-old man limps into the emergency department complaining of pain and swelling in his left lower leg. He states that he also has a fever and feels tired. After questioning him, you discover that he was recently discharged from the hospital following surgery for an open fracture of his left tibia. He had undergone debridement and irrigation, followed by internal fixation and treatment with IV cefazolin. He was discharged home on oral cephalexin. On physical examination, the area above the fracture is red and swollen (erythematous and inflamed).

*What information is suggestive of osteomyelitis?*

*What risk factors, if any, does he have for osteomyelitis?*

replace infected hardware.[7] Comorbidities such as vascular insufficiency can further contribute to the poor outcomes seen with chronic osteomyelitis.[1,7] Due to the high failure rates, treatment in this patient population may require prolonged therapy, with the primary goal of preventing amputation of infected areas.[1,11,14]

### General Approach to Treatment

**KEY CONCEPT** *Antimicrobial therapy alone is the mainstay of treatment for acute osteomyelitis.[3–5,7] In comparison, treatment for chronic osteomyelitis typically requires a combination of antimicrobial therapy and surgical intervention.[7,11,14]* If the patient is not a candidate for surgical intervention, prolonged antimicrobial therapy is generally necessary.[11–14]

#### ▶ Nonpharmacologic Therapy

In addition to medical and surgical management, nonpharmacologic interventions for health promotion such as smoking cessation, weight-control and good nutrition should be communicated to the patient. Additionally, a diabetic patient should be counseled regarding the necessity of controlled blood glucose, routine care and self-examination of lower extremities, and aggressive wound care.[14] Patients with chronic immobility should be counseled on skin care and techniques to prevent the development of pressure ulcers.[7]

#### ▶ Pharmacologic Therapy

**KEY CONCEPT** *Empiric antimicrobial therapy should target likely causative pathogen(s) based on patient-specific risk factors and route of infection.[6]* Empiric antimicrobial coverage against *S. aureus* should be considered for all classifications of osteomyelitis.[2,6] With MRSA increasingly being reported in the hospital and community

## Patient Encounter, Part 2

The medical team suspected osteomyelitis and ordered laboratory tests and imaging studies and consulted orthopedic surgery service.

*How would you classify the infection in this patient?*

*What laboratory test(s) should be ordered for this patient?*

*What imaging study(s) should be ordered for this patient?*

settings, the use of anti-MRSA antimicrobials (eg, vancomycin) should be considered as first-line therapy for empiric coverage of suspected staphylococcal osteomyelitis.[1,2,6,7,20,21] In addition to anti-MRSA coverage, patients with contiguous osteomyelitis with vascular insufficiency (eg, diabetic) should also receive empiric antimicrobial therapy to cover Enterobacteriaceae, *P. aeruginosa,* and anaerobes.[11,14] Specific recommendations may vary based on factors such as patient allergies, potential for harboring a resistant organism, institution formulary, and cost considerations.[2,3,11]

Antimicrobial therapy should be modified based on culture and sensitivity data of appropriately collected specimens (**Table 81–1**).[4,6,11,14] If MRSA is isolated, vancomycin is considered first-line therapy unless the minimum inhibitory concentration is greater than 2 mcg/mL (2 mg/L).[10,22,23] Alternate agents include daptomycin, linezolid, clindamycin, and trimethoprim-sulfamethoxazole in combination with oral rifampin.[22] Other anti-MRSA agents (tigecycline, telavancin, ceftaroline, dalbavancin, tedizolid, oritavancin) lack clinical data to support their routine use in osteomyelitis.[10,24] Clindamycin is commonly used in pediatric patients.[3,4,8,22] However, microbiology laboratories must screen with a disk diffusion test (D-test) for inducible resistance via the macrolide-lincosamide-streptogramin gene, as clindamycin failures have been associated with infections caused by isolates that are D-test positive.[3,25] If methicillin-sensitive *S. aureus* is isolated and the patient has no β-lactam allergy, therapy should be changed to nafcillin/oxacillin or cefazolin.[1,2,5–7]

Treatment is initiated with IV antimicrobials in the inpatient or outpatient setting to optimize drug concentrations in bone.[16,7,14] Following initial IV therapy, a switch to oral antibiotics may be considered in patients with good clinical response, strict adherence, and outpatient follow-up.[3,4,6,8,11,14,22] Oral agents should possess such characteristics as high bioavailability, good bone penetration, and long half-life (ie, extended dosing interval).[1,3,5–7,10,11,19,22] Antimicrobials commonly used as oral therapy for osteomyelitis include fluoroquinolones, clindamycin, linezolid, and trimethoprim-sulfamethoxazole.[1,6,7,19,22] Additionally, oral rifampin may be used in combination with another antibiotic in patients with foreign devices or MRSA osteomyelitis.[1,7,11,19,22] For chronic osteomyelitis, some clinicians recommend placement of antibiotic impregnated beads or cement.[3,7,11,14] This enables antibiotics such as aminoglycosides and vancomycin to be delivered in high concentrations at the site of infection.[3,7]

**KEY CONCEPT** *The duration of treatment is typically 4 to 6 weeks for acute and chronic osteomyelitis.[1–5,8,14,22]* Shorter regimens (3 weeks) are often recommended for uncomplicated acute hematogenous infections due to *S. aureus* in children greater than 3 months of age.[4,6,8] *Infectious Diseases Society of America (IDSA) MRSA guidelines recommend a minimum of 8 weeks for treatment of MRSA osteomyelitis in adults.[22]* Prolonged therapy (greater than 3 months) may be necessary for certain populations such as patients with vascular insufficiency or patients with recalcitrant infections that do not respond to 4 to 6 weeks of therapy.[1,5,11,14,22]

## OUTCOME EVALUATION

Therapeutic success is measured by the extent to which the care plan (a) resolves signs and symptoms, (b) eradicates the microorganism(s), (c) prevents relapses, and (d) prevents complications such as amputation.[8,11,14] Patients should be evaluated for resolution of clinical signs and symptoms and normalization of laboratory tests (WBC, CRP, ESR, procalcitonin, and cultures).[3–6,8,10,14] Improvement in clinical manifestations may be

| Table 81–1 | | | |
|---|---|---|---|
| **Pathogen-Targeted Antimicrobial Therapy and Dosing Recommendations in Adults and Pediatrics** | | | |
| **Microorganism** | **Antimicrobial Agent** | **Adult Dose** | **Pediatric Dose[a]** |
| ***S. aureus*** | | | |
| MRSA | Vancomycin[b] | 15–20 mg/kg IV every 8–12 hours | 15 mg/kg IV every 6 hours |
| | Daptomycin[b] | 6 mg/kg IV every 24 hours | 6–10 mg/kg IV every 24 hours |
| | Linezolid | 600 mg IV/oral every 12 hours | 10 mg/kg IV/oral every 8 hours (< 12 years old) |
| | Clindamycin[c] | 600 mg IV/oral every 8 hours | 10–13 mg/kg/dose IV/oral every 6–8 hours |
| | Trimethoprim-sulfamethoxazole[b] (+ rifampin[c] 600 mg oral daily) | 3.5–4.0 mg/kg of trimethoprim component IV/oral every 8–12 hours (trimethoprim-sulfamethoxazole single strength tablet is 80 mg/400 mg; double strength tablet is 160 mg/800 mg) | — |
| MSSA | Nafcillin[d]/oxacillin[b] | 1–2 g IV every 4–6 hours | 100–200 mg/kg/day IV in divided doses every 4–6 hours |
| | Cefazolin[b] | 1–2 g IV every 6–8 hours | 50–100 mg/kg/day IV in divided doses every 6–8 hours |
| ***Enterococcus* spp.** | | | |
| Ampicillin-sensitive | Ampicillin[b] | 2 g IV every 4–6 hours | 100–400 mg/kg/day IV in divided doses every 6 hours |
| Ampicillin-resistant | Vancomycin[b] | 15–20 mg/kg IV every 8–12 hours | 15 mg/kg IV every 6 hours |
| Vancomycin-resistant | Daptomycin[b] | 4–6 mg/kg IV every 24 hours | — |
| | Linezolid | 600 mg IV/oral every 12 hours | 10 mg/kg IV/oral every 8 hours (< 12 years old) |
| ***Streptococcus* spp.** | Penicillin G[b] | 2–4 million units IV every 4–6 hours | 250,000–400,000 units/kg/day IV in divided doses every 4–6 hours |
| ***P. aeruginosa*** | | | |
| | Doripenem[b] | 500 mg IV every 8 hours | — |
| | Imipenem/cilastatin[b] | 500 mg IV every 6 hours | 25 mg/kg IV every 6 hours |
| | Meropenem[b] | 1 g IV every 8 hours | 10–20 mg/kg IV every 8 hours |
| | Ceftazidime[b] | 2 g IV every 8 hours | 50 mg/kg IV every 8 hours |
| | Cefepime[b] | 2 g IV every 12 hours | 50 mg/kg IV every 8–12 hours |
| | Piperacillin/tazobactam[b] | 4.5 g IV every 6 hours | 100 mg/kg IV piperacillin component every 8 hours |
| | Ciprofloxacin[b,e] | 400 mg IV every 8–12 hours; 750 mg oral every 12 hours | — |
| | Levofloxacin[b,e] | 750 mg IV/oral every 24 hours | — |
| **Enterobacteriaceae** (in addition to antipseudomonal agents listed above) | Ceftriaxone[d] | 1–2 g IV every 24 hours | 50–100 mg/kg/day IV in divided doses every 12–24 hours |
| | Cefotaxime[b,d] | 1–2 g IV every 8 hours | 50–200 mg/kg/day IV in divided doses every 6–8 hours |
| | Ertapenem[b] | 1 g IV every 24 hours | — |
| | Moxifloxacin[c,e] | 400 mg IV/oral every 24 hours | — |
| Anaerobes[f] | Clindamycin[c] | 600–900 mg IV every 8 hours; 300–450 mg oral every 6–8 hours | 25–40 mg/kg/day IV in divided doses every 6–8 hours |
| | Metronidazole[b,c] | 500 mg IV/oral every 6–8 hours | 30 mg/kg/day IV/oral in divided doses every 6–8 hours |

[a]Refer to specialized pediatric reference for maximum neonatal and pediatric dosing recommendations.

[b]Dosage adjustment necessary in renal dysfunction.

[c]Dosage adjustment necessary in severe hepatic dysfunction.

[d]Dosage adjustment necessary in patients with concomitant renal and hepatic dysfunction.

[e]Fluoroquinolones: Not approved by the US FDA for use in children except for anthrax (ciprofloxacin, levofloxacin) and complicated UTI and pyelonephritis (ciprofloxacin).

[f]May consider β-lactam/β-lactamase inhibitor or carbapenem for broad-spectrum activity including anaerobes.

Data from Refs. 1, 3, 4, 7, 8, 10, 11, 19, 20, and 22–26.

seen within 2 to 4 days of initiation of IV antimicrobial therapy in patients acute osteomyelitis.[4,8] A reduction in CRP should be seen within 1 week of therapy and should be monitored weekly throughout therapy for a continued downward trend.[3,4,6] ESR can also be monitored weekly, although normalization will be slower than for CRP.[3,6] Patients should also be monitored for antimicrobial tolerability and toxicity[2] (**Table 81–2**). If poor response is noted, the following should be evaluated: (a) patient adherence, (b) significant drug–drug or drug–food interactions, (c) appropriate dosage to achieve therapeutic concentrations,

---

**Table 81–2**

**Monitoring Considerations for Select Antistaphylococcal Agents**

| Antimicrobial | Monitoring Considerations |
|---|---|
| Daptomycin | Muscle pain or weakness particularly of the distal extremities; monitor CPK weekly with more frequent monitoring in patients with renal insufficiency or receiving (or recent discontinuation) of HMG-CoA reductase inhibitors; Consider temporarily discontinuing HMG-CoA reductase inhibitors while patient receiving daptomycin. |
| | Peripheral neuropathy: Monitor for neuropathy |
| | Decreased efficacy was observed in patients with moderate baseline renal impairment. |
| Linezolid | Myelosuppression: Monitor CBC once weekly |
| | MAO inhibitors; evaluate for potential drug–drug interactions. Linezolid should not be used concomitantly or within 2 weeks of medications that inhibit monoamine oxidases A or B. |
| | Serotonin syndrome; evaluate for potential drug–drug and drug-food interactions. Patients taking serotonergic antidepressants should receive linezolid only if no other therapies are available. Discontinue serotonergic antidepressants and monitor patients for signs and symptoms of both serotonin syndrome and antidepressant discontinuation. |
| | Peripheral and/or optic neuropathy has been reported with long-term therapy; perform routine neurologic and ophthalmic evaluations in these patients. |
| | Elevation of blood pressure in certain patients (eg, uncontrolled hypertension): monitor blood pressure. |
| | Hypoglycemia in patients with diabetes mellitus receiving insulin or oral hypoglycemic agents: monitor glucose. |
| Vancomycin | Targeted steady state trough is 15–20 mcg/mL (15–20 mg/L; 10–14 μmol/L) for serious infections such as osteomyelitis. |
| | Renal dysfunction: monitor weekly renal function (BUN/SCr) and troughs in stable patients; more often in nonstable patients. |
| | Potential for additive renal toxicity if being coadministered with a nephrotoxic agent (eg, aminoglycoside). |

BUN, blood urea nitrogen; CBC, complete blood count; CPK, creatine phosphokinase; MAO, monoamine oxidase; SCr, serum creatinine.

Data from Refs. 1, 7, 11, 20, and 22–26.

**Patient Encounter, Part 3: The Medical History, Physical Exam, and Diagnostic Tests**

**PMH:** Type 2 diabetes mellitus, dyslipidemia, depression

**SH:** Tobacco smoker (one pack per day for 10 years), two to three cans of beer daily. Employed as mechanic

**Allergies:** NKDA

**Meds:** Cephalexin 500 mg orally four times a day; rosuvastatin 20 mg orally at bedtime; metformin 500 mg orally twice daily; fluoxetine 20 mg orally daily

**PE:**

**Gen:** Moderate distress with pain and tenderness in lower left leg; limps

**Skin:** Erythema and inflammation

**VS:** BP 120/70 mm Hg, P 85 beats/min, RR 20 breaths/min, T 38.4°C (101.2°F), Ht 5′ 7″ (170 cm), Wt 73 kg (161 lb)

**Labs:** WBC $16.4 \times 10^3/mm^3$ ($16.4 \times 10^9$/L), hemoglobin 13.0 g/dL (130g/L; 8.07 mmol/L), hematocrit 37.0% (0.37), platelets $220 \times 10^3$/uL ($220 \times 10^9$/L), BUN 23 mg/dL (8.2 mmol/L), serum creatinine (Scr) 1.3 mg/dL (115 μmol/L), total bilirubin 1.1 mg/dL (18.8 μmol/L), alkaline phosphatase 82 U/L (1.37 μkat/L), AST 28U/L (0.47μkat/L), ALT 13 U/L (0.22 μkat/L), albumin 3.7g/dL (37 g/L), fasting blood glucose 180 mg/dL (10.0 mmol/L), ESR 110 mm/h, CRP 14 mg/dL (140 mg/L)

**Microbiology:** Culture from bone aspirate grew *S. aureus* (sensitive to daptomycin, linezolid, rifampin, trimethoprim-sulfamethoxazole, and vancomycin but resistant to clindamycin, erythromycin, and oxacillin)

*Based on the information presented, create a care plan for this patient's osteomyelitis. Your plan should include:*

*(a) Goals of therapy*

*(b) Patient-specific detailed therapeutic plan*

*(c) Nonpharmacologic interventions*

*(d) Follow-up plan to determine whether outcomes have been achieved*

(d) development of antimicrobial resistance necessitating a change in the treatment regimen, (e) need for additional imaging studies, and (f) diagnostic reevaluation.[8,14] Treatment is considered successful if all clinical signs and symptoms are resolved and all laboratory tests have returned to normal

**Patient Encounter, Part 4**

The patient received 2 weeks of IV antimicrobial therapy following debridement. The patient has shown clinical and laboratory improvement. The multidisciplinary medical team plans to complete therapy with an oral antibiotic.

*What oral antimicrobial therapy would you recommend for this patient?*

*Evaluate the patient's medication profile for drug–drug interactions.*

*Counsel the patient regarding this drug therapy.*

## Patient Care Process

**Patient Assessment:**

- Review the medical history to assess risk factors for osteomyelitis.
- Based on physical exam and review of systems, determine whether the patient is experiencing signs or symptoms of osteomyelitis.
- Review available imaging studies and laboratory tests, especially WBC, ESR, and CRP.
- Obtain a thorough history of prescription, nonprescription, and natural drug product use.

**Therapy Evaluation:**

- Determine the appropriateness of current antibiotic therapy based upon patient-specific factors and microbiology data (if available).

**Care Plan Development:**

- Determine whether the antibiotic dosage regimen is optimal based upon patient-specific factors and site of infection.
- Provide patient education with regard to disease state and drug therapy. Stress the importance of adherence to the therapeutic regimen.

**Follow-Up Evaluation:**

- Patients should be monitored for clinical and laboratory response, development of adverse drug reactions, and potential drug–drug interactions. Patients should also be closely monitored for adherence in the outpatient setting.

following 4 to 8 weeks of appropriate treatment. Due to high rates of relapse, patients should have medical follow-up for at least 1 year following resolution of symptoms.[4] Patients should be evaluated at predefined follow-up intervals (3- to 6- to 12-months) for any clinical manifestations of recurring infection and continued normalization of laboratory tests.[8,11] Follow-up imaging studies at 1 to 2 years may be useful in some patients to confirm therapeutic success.

# Sepsis and Septic Shock

Trisha N. Branan, Christopher M. Bland, and S. Scott Sutton

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Compare and contrast the definitions of syndromes related to sepsis.
2. Identify the pathogens associated with sepsis.
3. Discuss the pathophysiology of sepsis as it relates to pro- and anti-inflammatory mediators.
4. Identify patient symptoms as early or late sepsis and evaluate diagnostic and laboratory tests for patient treatment and monitoring.
5. Assess complications of sepsis and discuss their impact on patient outcomes.
6. Design desired treatment outcomes for septic patients.
7. Formulate a treatment and monitoring plan (pharmacologic and nonpharmacologic) for septic patients.
8. Evaluate patient response and devise alternative treatment regimens for nonresponding septic patients.

## INTRODUCTION

**KEY CONCEPT** *Sepsis occurs across a continuum of physiologic stages in response to infection which manifests as systemic inflammation, coagulation, and tissue hypoperfusion, potentially leading to organ dysfunction known as severe sepsis.*[1] The American College of Chest Physicians and the Society of Critical Care Medicine have defined the nomenclature to standardize sepsis terminology. (**Table 82–1**).[2,3] Physiologic parameters categorize patients as having systemic inflammatory response syndrome (SIRS), sepsis, severe sepsis, or septic shock.[2]

## EPIDEMIOLOGY AND ETIOLOGY

Sepsis is the leading cause of morbidity and mortality for critically ill patients and the tenth leading cause of death overall.[4,5] Mortality rates remain high for patients with severe sepsis and septic shock with septic shock and multiorgan failure as the most common causes of death.[1] There are approximately 750,000 cases of sepsis diagnosed every year in the United States which continues to increase.[1]

Risk factors for sepsis include increased age, cancer, immunodeficiency, chronic organ failure, genetic factors (male gender and nonwhite ethnic origin in North America), and bacteremia.[5–9] Pulmonary infections cause approximately half of all cases, followed by intra-abdominal and genitourinary infections.[2] In approximately one-third of cases of sepsis a pathogen is not identified making de-escalation from broad spectrum to a more narrowed antimicrobial regimen difficult.[2]

**KEY CONCEPT** *Gram-positive and gram-negative bacteria, fungal species, and viruses may cause sepsis (***Table 82–2***). Gram-positive infections account for 30% to 50% of sepsis and septic shock cases.[5–7] The percentages of gram-negative, polymicrobial, and viral sepsis cases are 25%, 25%, and 4%, respectively.[5–7,10] A multinational study of 14,000 critically ill patients showed an increase in gram-negative bacterial causes of sepsis compared to gram-positive bacterial and fungal causes.[2] Multidrug-resistant (MDR) bacteria are responsible for approximately 25% of sepsis cases, are difficult to treat, and increase mortality.[6,7] The rate of fungal infections has significantly increased with *Candida albicans* as the most common fungal species identified; however, non-albicans species (*C. glabrata, C. krusei,* and *C. tropicalis*) have increased from 24% to 46%.[5,10,11] Other fungi identified as causes of sepsis include species of *Cryptococcus, Coccidioides, Fusarium*, and *Aspergillus*.

## PATHOPHYSIOLOGY

The development of sepsis is complex and multifactorial. The normal host response to infection is designed to localize and control bacterial invasion and initiate repair of injured tissue through phagocytic cells and inflammatory mediators.[4] **KEY CONCEPT** *Sepsis results when the interplay between the host's immune, inflammatory, and coagulant responses becomes exaggerated extending to normal tissue distant from the initial tissue site.*

### Pro- and Anti-inflammatory Mediators

The key factor in the development of sepsis is inflammation, which is intended to be a local and contained response to infection or injury. Infection or injury is controlled through proinflammatory and anti-inflammatory mediators. Proinflammatory mediators facilitate clearance of the injuring stimulus, promote resolution of injury, and are involved in processing of damaged tissue.[4,14–17] To control the intensity and duration of the inflammatory response, anti-inflammatory mediators are released that act to regulate proinflammatory mediators.[16,17] The balance between pro- and anti-inflammatory mediators localizes

**Table 82–1**

**Diagnostic Criteria for Sepsis, Severe Sepsis, and Septic Shock**

**Sepsis (documented or suspected infection plus ≥ 1 of the following)**
General variables
    Hyperthermia (core temperature > 38.3°C)
    Hypothermia (core temperature < 36°C)
    Tachycardia (heart rate > 90 beats/min)
    Tachypnea
    Altered mental status
    Substantial edema or positive fluid balance (> 20 mL/kg of body weight over 24 hours)
    Hyperglycemia (plasma glucose > 120 mg/dL [6.7 mmol/L]) in absence of diabetes
Inflammatory variables
    Leukocytosis (white blood cell count > 12,000/mm$^3$ [12 × 10$^9$/L])
    Leukopenia (white blood cell count < 4000/mm$^3$ [4 × 10$^9$/L])
    Normal white blood cell count with > 10% (0.10) immature forms (bands)
    Elevated plasma C-reactive protein
    Elevated plasma procalcitonin
Hemodynamic variables
    Arterial hypotension (systolic pressure < 90 mm Hg; mean arterial pressure < 70 mm Hg (9.3 kPa); or decrease in systolic pressure of > 40 mm Hg)
    Organ dysfunction variables
    Arterial hypoxemia (Pao$_2$/Fio$_2$ < 300 mm Hg [39.9 kPa])
    Acute oliguria (urine output < 0.5 mL/kg/hour or 45 mL/hour for at least 2 hours)
    Increase in serum creatinine level of > 0.5 mg/dL (> 44 µmol/L)
    Coagulation abnormalities (INR > 1.5; or aPTT > 60 seconds)
    Paralytic ileus (absence of bowel sounds)
    Thrombocytopenia (platelet count < 100,000/mm$^3$ [100 × 10$^9$/L])
    Hyperbilirubinemia (plasma total bilirubin > 4 mg/dL [68.4 µmol/L])
Tissue-perfusion variables
    Hyperlactatemia (lactate > 1 mmol/L)
    Decreased capillary refill or mottling
**Severe sepsis (sepsis plus organ dysfunction)**
**Septic shock (sepsis plus either hypotension [refractory to fluid resuscitation] or hyperlactatemia)**

Pao$_2$, partial pressure of oxygen; Fio$_2$, fraction of inspired oxygen.

---

**Table 82–2**

**Pathogens in Sepsis**

| Organism | Frequency (%) |
|---|---|
| Gram-positive bacteria | 30–50 |
|     Methicillin-susceptible *Staphylococcus aureus* | 14–24 |
|     Methicillin-resistant *Staphylococcus aureus* | 5–11 |
|     Other *Staphylococcus* species | 1–3 |
|     *Streptococcus pneumoniae* | 9–12 |
|     Other *Streptococcus* species | 6–11 |
|     *Enterococcus* species | 3–13 |
|     Anaerobes | 1–2 |
|     Other gram-positive bacteria | 1–5 |
| Gram-negative bacteria | 25–30 |
|     *Escherichia coli* | 9–27 |
|     *Pseudomonas aeruginosa* | 8–15 |
|     *Klebsiella pneumoniae* | 2–7 |
|     Enterobacter species | 6–16 |
|     *Haemophilus influenzae* | 2–10 |
|     Anaerobes | 3–7 |
|     Other gram-negative bacteria | 3–12 |
| Fungi | |
|     *Candida albicans* | 1–3 |
| Other *Candida* species | 1–2 |
| Parasites | 1–3 |
| Viruses | 2–4 |

Data from Refs. 5, 6, 12, and 13.

A physical examination should be performed rapidly and efficiently when sepsis is suspected, with efforts directed toward uncovering the most likely cause of sepsis. The patient may not provide any medical history; therefore, historical data may be obtained from medical records and/or family. The patient's medical condition, recent illnesses, infections, or activities may provide valuable information about the cause of sepsis.

### Diagnostic and Laboratory Tests

Microbiologic cultures should be obtained before antimicrobial therapy is initiated as long as this does not significantly delay

infection/injury of host tissue.[14–17] However, systemic responses ensue when equilibrium in the inflammatory process is lost.

The inflammatory process in sepsis is linked to the coagulation system. Proinflammatory mediators may have procoagulant and antifibrinolytic effects, whereas anti-inflammatory mediators may have fibrinolytic effects. A key factor in the inflammation of sepsis is activated protein C, which enhances fibrinolysis and inhibits inflammation. Protein C levels are decreased in many septic patients.

## CLINICAL PRESENTATION AND DIAGNOSIS

The clinical presentation of sepsis varies, and the rate of development of clinical manifestations may differ from patient to patient.

---

**Physical Examination Results in Sepsis**

**HEENT:** Scleral icterus, dry mucous membranes, pinpoint pupils, dilated and fixed pupils, nystagmus

**Neck:** Jugular venous distention, carotid bruits

**Lungs:** Crackles (rales), consolidation, egophony, absent breath sounds

**CV:** Irregular rhythm, S$_3$ gallop, murmurs

**Abd:** Tense, distended, tender, rebound, guarding, hepatosplenomegaly

**Rectal:** Decreased tone, bright red blood

**Exts:** Swollen calf, disparity of blood pressure between upper extremities

**Neurologic:** Agitation, confusion, delirium, obtundation, coma

**Skin:** Cold, clammy, or warm; hyperemic skin; rashes

## Clinical Presentation and Diagnosis of Sepsis

The signs and symptoms of septic patients are referred to as early and late sepsis.

### Signs and Symptoms

The initial clinical signs and symptoms represent early sepsis, and they include fever, chills, and change in mental status. Other signs and symptoms include:

- Tachycardia
- Tachypnea
- Nausea and vomiting
- Hyperglycemia
- Myalgias
- Lethargy and malaise
- Proteinuria
- Leukocytosis
- Hypoxia
- Hyperbilirubinemia

Septic patients may have an elevated, low, or normal temperature. The absence of fever is common in neonates and elderly patients. Hypothermia is associated with a poor prognosis. Hyperventilation may occur before fever and chills and may lead to respiratory alkalosis. Disorientation and confusion may develop early in septic patients, particularly in the elderly and patients with preexisting neurologic impairment. Disorientation and confusion may be related to the infection or due to sepsis signs and symptoms (eg, hypoxia).

Late sepsis represents a slow process that develops over several hours of hypoperfusion. Signs and symptoms of late sepsis include:

- Lactic acidosis
- Oliguria
- Leukopenia
- Thrombocytopenia
- Myocardial depression
- Pulmonary edema
- Hypotension
- Hypoglycemia
- Gastrointestinal hemorrhage

Oliguria often follows hypotension because of decreased renal perfusion. Metabolic acidosis ensues because of diminished clearance of lactate by the kidneys and liver.

---

the start of therapy. However, cultures take 6 to 48 hours for results to be completed and often are negative (no growth of bacterial organisms). Negative cultures do not rule out the presence of infection. Administering antimicrobials before obtaining cultures may lead to a false-negative culture. Rapid diagnostics of blood cultures allows for identification of specific pathogens within as little as 20 minutes to 3 hours after initial growth is identified. However not all health care systems have this technology available.

At least two sets of blood cultures should be obtained to rule out contamination with at least one set drawn percutaneously and one set drawn through each vascular access device present for greater than 48 hours.

Cultures of urine (with urinalysis), respiratory secretions, cerebrospinal fluid, and wounds should be obtained if the clinical presentation suggests infection of these specific fluids, tissues, or organs. Laboratory tests should be performed to evaluate infection or complications of sepsis, including complete blood count (CBC) with differential, coagulation parameters, comprehensive metabolic panel (CMP), serum lactate concentration, arterial blood gas (ABG), and appropriate diagnostic radiographic imaging studies.

The use of biomarkers of sepsis has been controversial. Measurement of endotoxin, procalcitonin, or other markers in blood or serum is not routinely recommended. Concentrations of procalcitonin in serum are usually increased in sepsis, but fail to differentiate between infection and inflammation. However, procalcitonin has a high negative predictive value and may allow for the discontinuation of antibiotics.

### Complications of Sepsis

KEY CONCEPT *Recognition and treatment of sepsis complications, particularly organ failure, is essential to improve outcomes.*

*The cumulative burden of sepsis complications is the leading factor of mortality. The risk of death increases 20% with failure of each additional organ. Severe sepsis averages two failed organs, with a mortality rate of 40%.* The most common complications are respiratory and cardiovascular compromise, usually seen as **acute respiratory distress syndrome** (ARDS), hemodynamic compromise, and elevated serum lactate levels. Other complications include altered mentation, acute kidney injury (AKI) which may require renal replacement therapy, paralytic ileus, **disseminated intravascular coagulation** (DIC), and adrenal insufficiency.[2]

## TREATMENT AND OUTCOME EVALUATION
### Desired Outcomes

KEY CONCEPT *The primary treatment goal of sepsis is to prevent morbidity and mortality through rapid recognition and intervention.* Treatment is aimed at early implementation of therapies, such as fluid

## Patient Encounter, Part 1

A 35-year-old woman with history of asthma presents to the emergency department with complaints of several days of high fevers, chills, cough, and increased purulent sputum production. The patient appears to be in severe respiratory distress and is becoming increasingly lethargic.

*What information is suggestive of infection and/or sepsis?*

*What information do we need in order to confirm or diagnose sepsis in this patient?*

resuscitation and antimicrobials, reducing or eliminating organ dysfunction, eliminating the source of infection, avoiding adverse reactions of treatment, and providing cost-effective therapy.[18–24]

### General Approach to Treatment

Similar to the emphasis placed on the expedited treatment of patients with acute myocardial infarction and cerebrovascular accidents, quick, quantitative intervention with appropriate therapies to achieve specific, measurable endpoints once a diagnosis of sepsis has been made is crucial to decrease morbidity and mortality.[18,20]

Pertinent approaches in the management of septic patients are as follows (**Figure 82–1**)[24]:

1.  Prompt recognition of the septic patient and early implementation of therapies.

2.  Fluid therapy, using crystalloids initially, to achieve quantitative therapeutic endpoints.

3.  Early administration of broad-spectrum antimicrobial therapy.

4.  Vasopressor therapy, using norepinephrine initially, to maintain hemodynamic stability (on average a mean arterial pressure of 65 mm Hg [8.6 kPa]) in patients with septic shock refractory to fluid resuscitation.

5.  Intravenous (IV) hydrocortisone may be considered for patients who remain hemodynamically unstable despite adequate fluid resuscitation and vasopressor support.

6.  Glycemic control via infusion of regular insulin to maintain glucose levels between 140 and 180 mg/dL (7.8 and 10.0 mmol/L).

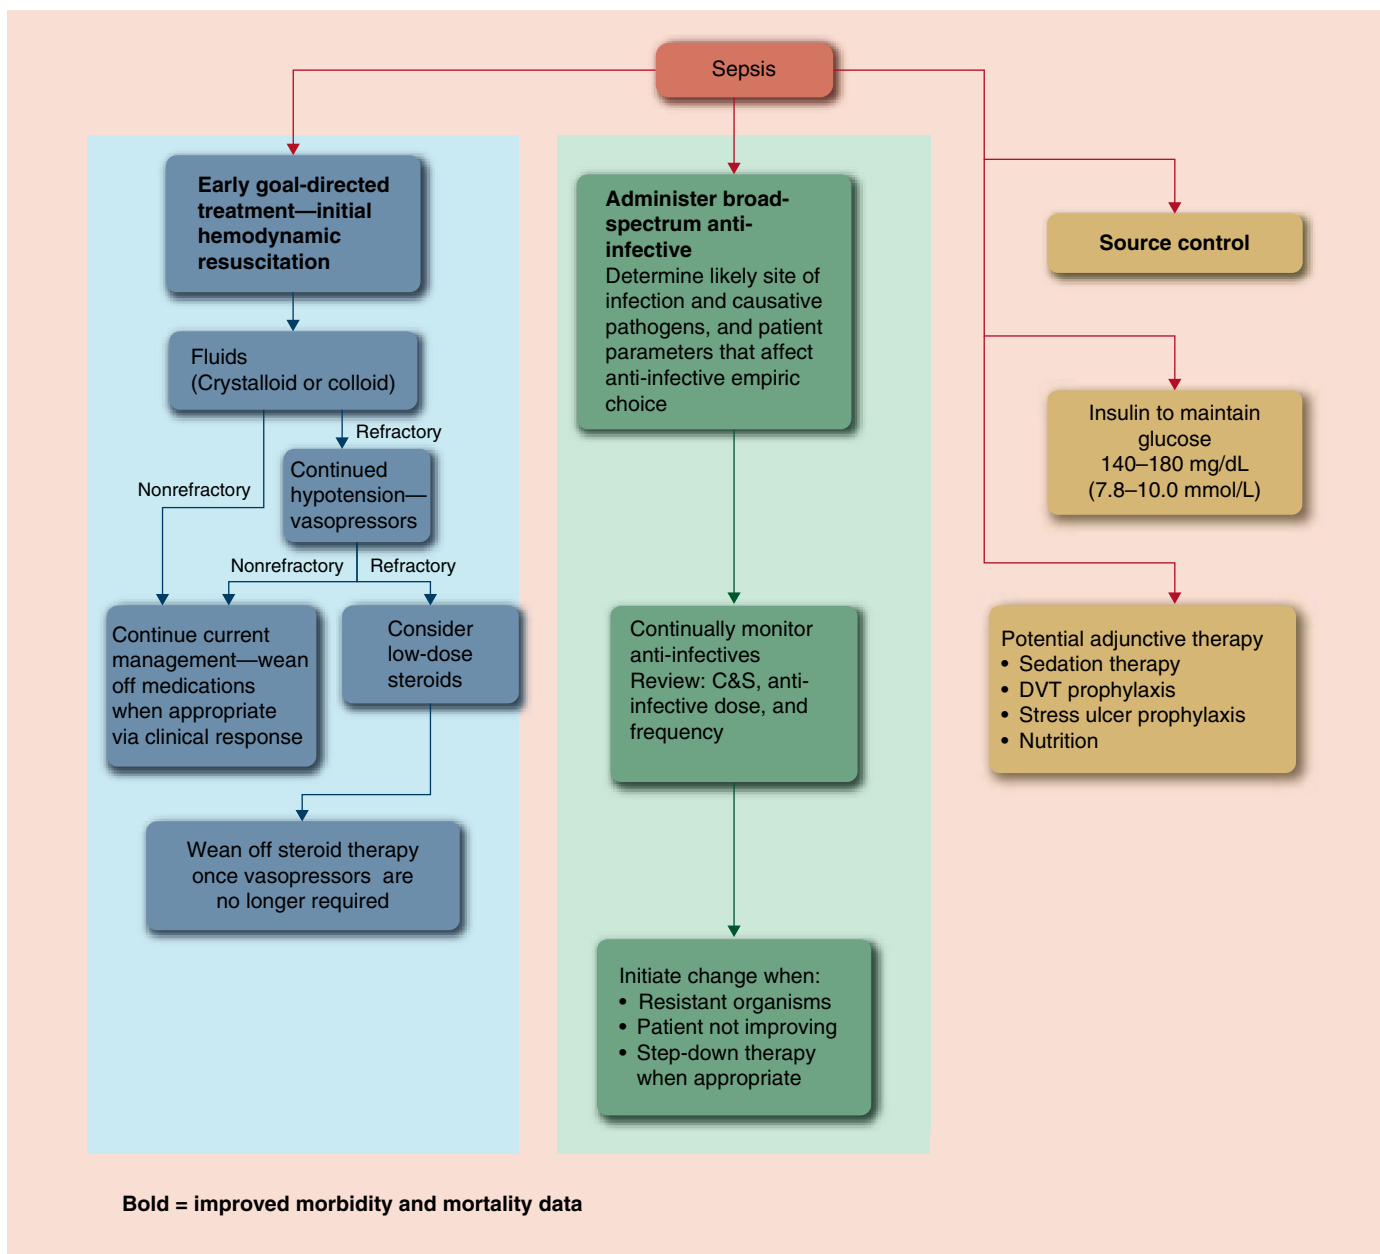

**FIGURE 82–1.**  Therapeutic approach to sepsis. (C&S, culture and sensitivity.)

7. Adjunctive therapies: blood product administration, sedation, analgesia, neuromuscular blockade, renal replacement therapy, deep vein thrombosis (DVT) prophylaxis, stress ulcer prophylaxis, and nutrition.

Treatment for sepsis focuses on infection, inflammation, hypoperfusion, and widespread tissue injury. Septic patients may require multiple simultaneous treatment regimens to achieve desired outcomes of decreased morbidity and mortality.

### Initial Resuscitation

A landmark study of early goal directed therapy (EGDT) using a standardized protocol that required the use of a special catheter for central venous oxygen saturation monitoring decreased 28-day mortality in septic patients by approximately 16%.[23] Three subsequent randomized controlled studies comparing EGDT to groups of patients receiving contemporary care (with or without the use of protocols) found no differences in mortality.[25–27] These results may demonstrate that continued focus on early recognition and treatment of these patients may play a more important role than protocol-based therapy. Specifically the placement of central venous catheters for mixed venous oxygen saturation monitoring as well as administration of inotrope therapy and blood transfusions did not improve outcomes compared to standard care. The most current treatment goals of sepsis-induced hypoperfusion (hypotension or blood lactate level greater than or equal to 4 mEq/L [4 mmol/L]) during the first 6 hours include[20,23,24,28]:

- Central venous pressure (CVP) 8 to 12 mm Hg (1.1–1.6 kPa)
- Mean arterial pressure (MAP) greater than or equal to 65 mm Hg (8.6 kPa)
- Urine output greater than or equal to 0.5 mL/kg/h

Emerging noninvasive techniques, such as the use of cardiac ultrasound, have recently shown reliability in assessing intravascular volume status through measuring inferior vena cava diameter changes and collapsibility.[29,30] Resuscitation should also target the normalization of blood lactate levels in patients with an initially elevated blood lactate as a marker of improved tissue perfusion.[20]

### Fluid Therapy

Crystalloid fluids (such as 0.9% sodium chloride or lactated Ringer solutions) or colloids (albumin products) are used for resuscitation, and clinical studies comparing the fluids have found them to be equivalent.[28,31,32] Crystalloids require more fluid volume, which may lead to more edema (utilize caution in patients at risk for fluid overload, eg, congestive heart failure and ARDS); however, albumin is significantly more expensive. Hydroxyethyl starches (HES), another type of colloid, should not be used due to studies demonstrating increased morbidity and mortality rates.[33,34] A large, multicenter, randomized controlled trial comparing HES to Ringer acetate in patients with severe sepsis showed an increased 90-day mortality rate and a higher need for renal replacement therapy in patients administered HES for fluid resuscitation.[33] For these reasons, crystalloids are preferred versus colloids for initial resuscitation, except in cases where large amounts of crystalloids are needed and hypervolemia may be harmful to the patient.[20]

Administer an initial fluid challenge in patients with suspected sepsis-induced tissue hypoperfusion and hypovolemia with 30 mL/kg of crystalloid fluid. Most patients require aggressive fluid resuscitation during the first 24 hours because of persistent venodilation and capillary leak.[20,24]

### Anti-infective Therapy

**KEY CONCEPT** *Appropriate empiric antimicrobial therapy decreases 28-day mortality compared with inappropriate empiric therapy (24% vs 39%).*[18,19,35] Additionally, appropriate therapy administered within 1 hour of sepsis recognition also decreases complications and mortality.[18,19,35] Empiric antimicrobial therapy should include multiple agents for most cases, depending on the likely site of infection and causative pathogens. Anti-infective clinical trials in sepsis and septic shock patients are scarce and have not demonstrated differences among agents; therefore, factors that determine selection are:

- Site of infection
- Causative pathogens
- Community- or nosocomial-acquired infection
- Immune status of patient
- Antibiotic susceptibility and resistance profile for the institution and local community. Clinicians should be cognizant of growing prevalence of bacterial resistance in community and health care settings.

---

## Patient Encounter, Part 2: Medical History, Physical Exam, and Diagnostic Tests

**PMH:** Asthma diagnosed at 3 years of age

**FH:** Father had stroke at age 62; mother has history of hypertension and diabetes mellitus

**SH:** Teacher; nonsmoker; rare alcohol intake

**Allergies:** NKDA

**Meds:** Fluticasone/Salmeterol 250/50 mg one puff twice daily; albuterol 90 mcg inhaler two puffs every 4 hours as needed for shortness of breath

**ROS:** Unable to obtain; patient has become more confused

**PE:**

Within normal limits except as noted below

**VS:** BP 79/44 mm Hg, P 124 beats/min, RR 29 breaths/min, T 39.3°C (102.7°F)

**Lungs:** Decreased breath sounds, bilateral crackles

**Labs:** Serum creatinine 2.7 mg/dL (239 μmol/L); glucose 298 mg/dL (16.5 mmol/L); white blood cells: leukocytosis (15,000/mm³ [15 × 10⁹/L]) with left shift.; lactic acid 5.1 mEq/L (5.1 mmol/L)

**Cultures:** Blood, urine, and respiratory cultures pending

**Radiology:** Bilateral pulmonary infiltrates seen on chest x-ray

*According to the patient's parameters, what does she have (ie, systemic inflammatory response syndrome, sepsis, or septic shock)?*

*Identify treatment goals.*

*Formulate an initial plan for therapy.*

- Patient history (underlying disease, previous cultures or infections including any recent antibiotic therapy, and drug allergy/intolerance)
- Adverse reactions
- Cost

Anti-infective regimens should be broad-spectrum since delays in appropriate therapy result in increased mortality.

## Monitoring and Treatment Strategies to Maximize Efficacy and Minimize Toxicity for Antimicrobials

- Administer broad-spectrum antimicrobials for initial therapy, as early as possible and within first hour of recognition of sepsis.
- Appropriate cultures should be obtained before initiating antibiotic therapy, but should not prevent prompt administration.
- Administer antibiotics that concentrate at the site of infection.
- Monitor patient parameters to ensure adequate dosing.
- Abnormal renal and hepatic function will increase drug concentration and predispose the patient to toxicity.
  - Ensure antibiotic dosing is changed to normal doses once renal dysfunction has resolved to limit the development of treatment failure, antimicrobial resistance, or both.
- Septic patients may have increased volume of distribution due to initial large volume resuscitation.
- Reevaluate the initial dosing regimen daily to optimize activity, prevent development of resistance, reduce toxicity, and decrease costs.
- Initiate step-down therapy based on microbiologic cultures to: prevent resistance, reduce toxicity, and cost.
- Monotherapy is equivalent to combination therapy once a causative pathogen has been identified in the vast majority of cases. Empiric therapy should include combination regimens to ensure appropriate coverage of causative organisms.

## Duration of Anti-Infective Therapy

Average duration of antimicrobial therapy for septic patients is 7 to 10 days. However, durations vary depending on the site of infection and response to therapy. Step-down therapy from IV to oral antimicrobials is recommended in most patients whom are hemodynamically stable, afebrile for 48 to 72 hours, have a normalized WBC, and able to take oral medications.

## Source Control

Evaluate septic patients for the presence of a localized infection amenable to source control measures. Common source control

---

### Patient Encounter, Part 3

#### Treatment and Outcome Evaluation

The patient remains hypotensive despite previous intervention. Continued hypoxia has led to mechanical ventilation. The patient's serum creatinine has risen to 6.8 mg/dL (601 μmol/L) and she has minimal urine output.

*What additional therapies will you consider adding to this patient?*

---

measures include drainage and debridement, device removal, and prevention.[20–22] Implementation of source control methods should be instituted as soon as possible following initial fluid resuscitation. The selection of optimal source control methods must weigh benefits and risks of the intervention. Source control measures may cause complications (bleeding, fistulas, and organ injury); therefore, the method with the least risk should be employed.[20]

## HEMODYNAMIC SUPPORT

### Vasopressors and Inotropic Therapy

**KEY CONCEPT** *When fluid resuscitation does not provide adequate arterial pressure and organ perfusion, vasopressors and/or inotropic agents should be initiated.* Vasopressors are recommended in patients with a systolic blood pressure less than 90 mm Hg or MAP lower than 60 to 65 mm Hg (8.0–8.6 kPa), after failed treatment with crystalloids.[20,23,24] Vasopressors and inotropes are effective in treating life-threatening hypotension and improving cardiac index, but complications such as tachycardia and myocardial ischemia require slow titration of the adrenergic agents to restore MAP without impairing stroke volume. Vasopressor therapy may also be required transiently to sustain life and maintain perfusion in the face of life-threatening hypotension, even when fluid resuscitation is in progress and hypovolemia has not yet been corrected. Agents commonly considered for vasopressor or inotropic support include norepinephrine, epinephrine, dopamine, phenylephrine, vasopressin, and dobutamine. Norepinephrine is the first-line vasopressor to correct hypotension in septic shock.[20]

Norepinephrine is a potent α-adrenergic agent with less pronounced β-adrenergic activity. Doses of 0.01 to 3 mcg/kg/min can reliably increase blood pressure through vasoconstriction with small changes in heart rate or cardiac index. Norepinephrine is a more potent agent than dopamine in refractory septic shock.[20,23,24] Norepinephrine induces less arrhythmias compared with dopamine.[36]

Dopamine is an α- and β-adrenergic agent with dopaminergic activity. Low doses of dopamine (1–5 mcg/kg/min) maintain renal perfusion; higher doses (greater than 5 mcg/kg/min) exhibit α- and β-adrenergic activity and are frequently utilized to support blood pressure and to improve cardiac function, mainly through increasing stroke volume and heart rate. Because of the effects on heart rate, dopamine causes more tachycardia and thus increases potential for arrhythmias versus norepinephrine. Based on these data, dopamine should not be used routinely in the management of septic shock.[20,36] Low doses of dopamine should not be used for renal protection as part of the treatment of severe sepsis.[20,23,24]

Epinephrine is a nonspecific α- and β-adrenergic agonist that can increase cardiac index and produce significant peripheral vasoconstriction. Some human and animal studies suggest it can also increase lactate levels and impair blood flow to the splanchnic system; however, studies comparing norepinephrine to epinephrine show no difference in mortality rates. Epinephrine should be considered the first alternative to norepinephrine in patients with persistent hypotension.[20,23,24]

Phenylephrine is a fast-acting, short-acting pure $\alpha_1$-agonist. Phenylephrine is the least likely vasopressor to cause tachycardia, but may decrease stroke volume. Phenylephrine should be reserved for use in patients with high cardiac output in whom tachycardia or ischemia limits the use of other vasopressors or as salvage therapy.[20,23,24]

Vasopressin levels are increased during hypotension to maintain blood pressure by vasoconstriction. However, there is

a vasopressin deficiency in septic shock. Low, fixed doses of vasopressin increase MAP, leading to the discontinuation of vasopressors. However, routine use of vasopressin with nor-epinephrine is not recommended because of no difference in mortality compared with norepinephrine monotherapy.[37] Vaso-pressin is a direct vasoconstrictor without inotropic or chrono-tropic effects and may result in decreased cardiac output and hepatosplanchnic flow. Vasopressin use may be considered in patients with refractory shock despite adequate fluid resuscita-tion and high-dose vasopressors.[20,23,24]

Dobutamine is recommended as the first-line inotropic agent. Dobutamine is a β-adrenergic inotropic agent that can be uti-lized for improvement of cardiac output and oxygen delivery. Doses of 2 to 20 mcg/kg/min increase cardiac index; however, heart rate increases significantly. Dobutamine should be consid-ered in septic patients with adequate filling pressure and blood pressure, but low cardiac index. If used in hypotensive patients, dobutamine should be combined with vasopressor therapy.[20,23,24]

## Corticosteroids

Stress-induced adrenal insufficiency complicates 9% to 24% of septic patients and is associated with increased mortality. The role of steroid use in septic shock remains unclear. Previous studies have demonstrated a mortality benefit or quicker reversal of shock in patients with sepsis-induced adrenal insufficiency treated with hydrocortisone.[38] However, a large, multicenter, randomized controlled trial (CORTICUS) showed no difference in mortality rates in septic shock patients treated with hydrocor-tisone.[39] **KEY CONCEPT** *For these reasons, the use of IV hydrocortisone at a dose of 200 mg/day should be reserved for patients who remain hemodynamically unstable despite fluid and vasopressor therapy.*[20] Patients should be weaned from steroid therapy when vasopressors are no longer required.

## Glucose Control

The optimal blood glucose range in septic patients is unknown. Tight glycemic control (80–110 mg/dL [4.4–6.1 mmol/L]) improved survival in postoperative surgical patients, but did not show a benefit in medical critically ill patients.[40,41] More recent studies, including the large NICE-SUGAR trial, do not demon-strate a mortality benefit in favor of tight glycemic control, but actually a higher incidence of severe hypoglycemia and increased mortality rates.[42] **KEY CONCEPT** *Following initial stabilization of septic patients, current guidelines recommend initiating insulin therapy when two consecutive blood glucose measurements are greater than 180 mg/dL (10.0 mmol/L) and then maintaining a blood glu-cose range of 140 to 180 mg/dL (7.8–10.0 mmol/L).* Blood glucose levels should be monitored frequently, every 1 to 2 hours, until glucose values and insulin infusion rates are stable, then every 4 hours thereafter.[20]

## Patient Encounter, Part 4

Three days later, the patient's blood pressure begins to respond to therapy with a MAP remaining greater than 65 mm Hg (8.6 kPa) on minimal vasopressor support.

*What changes to the patient's medication regimen do you recommend?*

## Adjunctive Therapies

### ▶ *Blood Product Administration*

There are no trials showing the optimal hemoglobin concen-tration in patients with severe sepsis. However, based on other studies which included subgroups of septic patients, with the exception of myocardial ischemia, severe hypoxemia, acute hem-orrhage, or ischemic coronary artery disease, it is recommended to target a hemoglobin concentration of 7 to 9 g/dL (70–90 g/L; 4.34–5.59 mmol/L) and red blood cell transfusion should occur when the hemoglobin concentration is less than 7 g/dL (70 g/L; 4.34 mmol/L).[20,43] Erythropoietin stimulating agents, fresh frozen plasma, and antithrombin should not be adminis-tered, unless other compelling indications exist, to treat sepsis-induced abnormalities.[20]

### ▶ *Sedation, Analgesia, and Neuromuscular Blockade*

It is common for severe sepsis patients to require mechanical ventilation during their course of therapy. These patients may require analgesic or sedative agents to facilitate mechanical ven-tilation. Historically, concerns for patient safety and posttrau-matic stress disorder emphasized the need for sedation in these patients. However, there continue to be ample data indicating that, while sedation is necessary, limiting exposure to certain sedative medications may improve morbidity and mortality rates. When sedation is needed, a standardized protocol targeting specific endpoints should be utilized.[20,44]

Neuromuscular blockade usually is reserved for patients in whom sedation alone does not improve the effectiveness of mechanical ventilation. Neuromuscular blockers may lead to prolonged skeletal muscle weakness and should be avoided if possible especially if receiving concomitant corticosteroid therapy which can increase the risk of critical illness polyneu-ropathy. Patients requiring neuromuscular blockade should be monitored, and intermittent bolus doses or continuous infusion should be utilized. Monitor depth of neuromuscular blockade with either train-of-four stimulation or other forms of clinical assessment when using continuous infusion. Patients with early, sepsis-induced ARDS with a $Pao_2/Fio_2$ less than 150 mm Hg (20.0 kPa), may benefit from a short course of a neuromuscular blocking agent to not exceed 48 hours.[20]

## Renal Replacement Therapy

Patients who develop acute kidney injury as a manifestation of severe sepsis may require some type of renal replacement therapy. There are no data currently that suggest superiority for either continuous or intermittent modalities of hemodialysis as both have demonstrated similar mortality rates. In patients who are hemodynamically unstable, continuous renal replacement therapy may be more beneficial due to less overall hypotension during therapy.

## Deep Vein Thrombosis Prophylaxis

Combination pharmacologic and mechanical prophylaxis against venous thromboembolism is recommended for septic patients when possible. Low-dose unfractionated heparin, low-molecular-weight heparin (eg, enoxaparin or dalteparin), or pentasac-charide therapy (eg, fondaparinux) may be utilized. Graduated compression stockings or an intermittent compression device is recommended for patients with a contraindication to heparin products (thrombocytopenia, severe coagulopathy, active bleed-ing, or recent intracerebral hemorrhage).[20]

## Patient Care Process

**Patient Assessment:**

- Based on physical exam and review of systems, determine whether the patient meets criteria for suspected sepsis.
- Review available diagnostic and laboratory data, especially CBC with differential, CMP, lactic acid, and patient specific factors including previous antimicrobial history and microbiologic cultures.
- Measure vital signs, including temperature, heart rate, respiratory rate, and blood pressure.

**Therapy Evaluation:**

- Institute early intervention initially with crystalloid fluids. Understand which parameters indicate effective/ineffective therapy. Recommend additional resuscitation therapy if the patient remains hypotensive.
- Initiate appropriate, broad-spectrum antimicrobials that cover the most likely pathogens within the first hour of diagnosis.

- Evaluate the source of infection and make recommendations to remove potential sources.
- If patient remains hemodynamically unstable despite fluid administration, start vasopressor therapy and/or corticosteroids with potential inotropic therapy if required.

**Care Plan Development:**

- Formulate appropriate dosing regimens of medications involved in therapy and revise as needed.
- Patient parameters may change frequently, thus requiring modifications of therapy. This may include the addition or deletion of adjunctive medications, such as antimicrobial agents, analgesics, sedatives, neuromuscular blockers, insulin, blood products, and renal replacement therapy.

**Follow-Up Evaluation:**

- Continually monitor patient parameters to ensure optimal therapy to minimize morbidity and mortality.

### Stress Ulcer Prophylaxis

Patients with severe sepsis are at increased risk for developing a stress ulcer bleeding event. Stress ulcer prophylaxis using either a histamine-receptor antagonist (H-2 blocker) or proton pump inhibitor (PPI) is recommended in septic patients. Patients at greatest risk for stress ulcers include those who are coagulopathic, mechanically ventilated (greater than 48 hours), or hypotensive. Histamine-2 receptor antagonists (eg, ranitidine) are more efficacious than sucralfate. There is ongoing debate to determine if PPIs (eg, omeprazole) are more efficacious than H-2 blockers with low-quality data showing conflicting outcomes.[20,45] Both, however, demonstrate equivalence in the ability to increase gastric pH.[20] The benefit of prophylaxis must be weighed against the potential effect of increased stomach pH and development of infectious complications, such as hospital-acquired pneumonia and/or *Clostridium difficile* infection.

### Nutrition

Meeting the nutritional needs of septic patients can be challenging, especially in patients who are hemodynamically unstable. When possible, early initiation of enteral nutrition should be considered to maintain gut mucosa and potentially decrease the risk of bacterial translocation leading to infection. Patients who are hemodynamically unstable may not tolerate enteral nutrition and are at risk for gut ischemia. Parenteral nutrition alone or in conjunction with enteral nutrition should not be initiated in the first 7 days as this has not been shown to improve outcomes.[20]

### Prognosis

There are various factors that influence outcome. Gram-negative bacteria are more likely to produce septic shock than gram-positive bacteria (50% vs 25%) and have a higher mortality rate than other pathogens. This may be related to the severity of the underlying condition. Patients with rapidly fatal conditions, such as leukemia, aplastic anemia, and burns, have a worse prognosis than patients with nonfatal underlying conditions, such as diabetes mellitus or chronic renal insufficiency. Other factors that worsen the prognosis of septic patients include advanced age, malnutrition, resistant bacteria, utilization of medical devices, and immunosuppression. Data for long-term mortality are lacking (it is estimated that the mortality for sepsis survivors within the first year is 20%).[12] Patients may have prolonged physical disability related to muscle weakness and posttraumatic stress.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| ABG | Arterial blood gas |
| AKI | Acute kidney injury |
| ARDS | Acute respiratory distress syndrome |
| CBC | Complete blood count |
| CMP | Comprehensive metabolic panel |
| CVP | Central venous pressure |
| DIC | Disseminated intravascular coagulation |
| DVT | Deep vein thrombosis |
| $Fio_2$ | Fraction of inspired oxygen |
| HES | Hydroxyethyl starch |
| IV | Intravenous |
| MAP | Mean arterial pressure |
| MDR | Multidrug resistant |
| $Pao_2$ | Partial pressure of oxygen |
| SIRS | Systemic inflammatory response syndrome |

# 83 Superficial Fungal Infections

Lauren S. Schlesselman

## LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Explain the underlying pathophysiology of vulvovaginal candidiasis, oropharyngeal candidiasis, esophageal candidiasis, and fungal skin infections.

2. Identify symptoms of vulvovaginal candidiasis, oropharyngeal candidiasis, esophageal candidiasis, and fungal skin infections.

3. Identify the desired therapeutic outcomes for patients with uncomplicated and complicated vulvovaginal candidiasis, oropharyngeal candidiasis, esophageal candidiasis, and fungal skin infections.

4. Recommend appropriate lifestyle modifications and pharmacotherapy interventions for patients with vulvovaginal candidiasis, oropharyngeal candidiasis, esophageal candidiasis, and fungal skin infections.

5. Recognize when long-term suppressive therapy is indicated for a patient with vulvovaginal candidiasis.

6. Recognize when topical versus oral treatment is indicated for a patient with oropharyngeal candidiasis, esophageal candidiasis, vulvovaginal candidiasis, and fungal skin infections.

7. Educate patients about the disease state, appropriate lifestyle modifications, and medication therapy required for effective treatment of vulvovaginal candidiasis, oropharyngeal candidiasis, esophageal candidiasis, and fungal skin infections.

## INTRODUCTION

Superficial fungal infections, also referred to as mycoses, are common and treatable conditions seen in everyday practice. Treatment largely depends on the use of azole and allyl-amine antifungal agents, either topically or orally, depending on the site, severity, and immune status of the patient.

## VULVOVAGINAL CANDIDIASIS

Vulvovaginal candidiasis (VVC), whether symptomatic or asymptomatic, refers to infections in women whose vaginal cultures are positive for *Candida* species.

### EPIDEMIOLOGY AND ETIOLOGY

Vulvovaginal candidiasis, also known as moniliasis, is a common form of vaginitis, accounting for 20% to 25% of vaginitis cases. Although VVC is uncommon prior to menarche, an estimated 75% of women will have at least one occurrence of VVC.[1]

According to the treatment guidelines of the Centers for Disease Control and Prevention (CDC),[1] VVC can be classified as uncomplicated or complicated. Uncomplicated infections occur sporadically, cause mild to moderate symptoms, and occur in nonimmunocompromised women. Uncomplicated infections, most often caused by *Candida albicans*, often have no identifiable precipitating cause. Complicated infections, including recurrent, severe infections, and those in women with uncontrolled diabetes, debilitation, or immunosuppression, may be caused by nonalbicans or azole-resistant fungal organisms. Recurrent VVC, defined as four or more infections per year, occurs in less than 5% of women, is distinguishable from a persistent infection by the presence of a symptom-free interval between infections.[1]

**KEY CONCEPT** *Candida albicans is the primary pathogen responsible for VVC, accounting for 66% of cases.*[2] Other cases are caused by nonalbicans species, including *Candida glabrata, Candida tropicalis, Candida krusei*, and *Candida parapsilosis.*[2]

### PATHOPHYSIOLOGY

The normal vaginal environment protects women against vaginal infections. Under the influence of estrogen, vaginal epithelium cornifies to reduce the risk of infection. Vaginal discharge, composed of exfoliated cells, cervical mucus, and colonized bacteria, cleans the vagina. The normal pH of vaginal secretions, near 4.0, is toxic to many pathogens and is maintained by *Lactobacillus acidophilus*, diphtheroids, and *Staphylococcus epidermidis*. Alterations in the vaginal environment, including pH changes, allow for overgrowth of organisms that are normally suppressed, increasing the risk of vulvovaginitis.

### RISK FACTORS

**KEY CONCEPT** *Although no risk factors are consistently associated with conversion to symptomatic infection, a variety of factors may increase the risk of developing symptomatic VVC in certain women* (Table 83–1).

## Clinical Presentation and Diagnosis of VVC

Patients with VVC may present with vulvar and/or vaginal symptoms. Symptoms often develop the week before menses and resolve with the onset of menses.

### Symptoms

- Vaginal itching
- Vaginal soreness
- Vaginal burning
- Irritation
- External dysuria
- Dyspareunia

### Signs

- Nonodorous vaginal discharge (may vary from watery to curd-like)
- Yellow or yellowish green discharge
- Erythema and edema of the labia and vulva
- Fissures
- Pustulopapular lesions
- Normal cervix

### Diagnostic Testing

- Microscopic investigation for the presence of blastospores or pseudohyphae; saline wet mount has a sensitivity of 40% to 50%, whereas a potassium hydroxide (KOH) preparation has a sensitivity of 50% to 70%.[7] *Asymptomatic vaginal colonization of* Candida albicans *is not diagnostic of VVC since 10% to 20% of women are asymptomatic carriers of* Candida *species. Asymptomatic vaginal colonization does not require treatment; therefore, the presence alone of* Candida *should not determine care.*
- Vaginal pH less than or equal to 4.5; pH should remain normal in cases of fungal infection, whereas an elevated pH suggests bacterial infection.
- *Candida* cultures should be obtained only if signs and microscopy are inconclusive or in cases of recurrent VVC.

## TREATMENT

The goals of treatment of VVC are as follows:

- Relief of symptoms
- Eradication of infection
- Reestablishment of normal vaginal flora
- Prevention of recurrent infections in complicated infections

### Nonpharmacologic Treatments

In combination with pharmacologic treatment, the practitioner should recommend basic nonpharmacologic approaches to treatment and prevention of VVC:

- Keep the genital area clean and dry
- Avoid prolonged use of hot tubs
- Avoid constrictive clothing
- Avoid vaginal douching

### Table 83–1

**Possible Risk Factors Associated with VVC**

| Risk Factor | Proposed Mechanism |
| --- | --- |
| Broad-spectrum antibiotic use | Altered vaginal flora allowing overgrowth of *Candida* organisms; risk increases with duration of antibiotic use |
| Systemic corticosteroid or immunosuppressant use | Reduced vaginal protection by immunoglobulins |
| Sexual activity | VVC is often associated with the onset of sexual activity; partners may have penile or oral colonization; use of vaginal irritants or devices, including diaphragms and intrauterine systems, can irritate vaginal mucosa |
| Tight-fitting and nonabsorbent clothing | Promotes warm, moist environment for fungus growth |
| Elevated estrogen levels, hormonal contraceptives, and pregnancy | Estrogen enhances *Candida* adherence to vaginal epithelial cells and yeast-mycelial transformation; this is supported by the fact that infection rates are lower before menarche and after menopause (except in women taking hormone replacement therapy), whereas rates are higher during pregnancy |
| Vaginal pH | Changes in glycogen and lactic acid levels |
| Gastrointestinal reservoir of *Candida* organisms | Transfer of organism from rectum to vagina; irritation of the vulvovaginal area during sexual intercourse may enhance invasion of organisms |
| Diabetes | Enhanced binding of *Candida* to epithelial cells due to hyperglycemia; asymptomatic colonization is more common in patients with diabetes; elevated sugar levels may cause conversion to symptomatic infection |

## Patient Encounter 1

A teenaged girl and her mother present to your clinic. The mother reports that her daughter has been complaining of itching in her vaginal area and a white discharge. After questioning the daughter, you determine that she has vaginal burning, soreness, and itching, accompanied by a curd-like discharge. She has never had a vaginal infection before. Upon further questions, you determine that the girl is a lifeguard and on the high school swim team, along with a long-distance runner. Despite the daughter's denial of sexual activity, the mother is concerned that her daughter has contracted a sexually transmitted disease "from the water in the pool." On examination, she has erythema of the labia and a nonodorous discharge.

*What information is suggestive of VVC?*

*What additional information do you need to know before creating a treatment plan for this patient?*

- Wear underwear made of breathable materials, such as cotton
- Avoid soaps and perfumes in the genital area
- Although study results are conflicting, possibly due to the strain or concentration studied, the daily consumption of active *Lactobacillus* may reduce recurrence. Newer studies have found ingestion of *Lactobacillus rhamnosus* and *Lactobacillus reuteri* suppressed metabolic activity and killed *C. albicans*,[3] whereas older studies found no difference in infection rates in women who ingested yogurt.[4]

### Pharmacologic Treatment of Uncomplicated VVC

For most cases of uncomplicated VVC, the CDC guidelines recommend a short course of therapy (1–3 days) with an oral or vaginal antifungal agent, either prescription or nonprescription.[1] Nonprescription azole antifungal products are available as 1-night, 3-night, and 7-night regimens in a variety of formulations, including cream, suppository, and vaginal tablets (Table 83–2). Oral fluconazole offers the option of treatment with one dose administered without regard to time of day. Some practitioners opt to retreat with a second dose of fluconazole 3 days later. Due to the risk of severe hepatotoxicity, the use of oral ketoconazole should be reserved for severe fungal infections resistant to other antifungal options.

Inability to resolve an infection may indicate a mixed infection, infection owing to a nonalbicans strain, an infection that is not fungal, or indicative of serious underlying conditions, such as diabetes or human immunodeficiency virus (HIV) infection. For these reasons, if infection does not resolve with a single antifungal course or if symptoms return within 2 months, practitioners should check cultures and further evaluate the patient's health status.

**KEY CONCEPT** *Due to the numerous treatment options available, a variety of factors can influence product selection, with patient preference playing a significant role.* To improve adherence with therapy, the practitioner should discuss with the patient what options are available and what her preferences are.

Adherence rates are greater with oral treatment than with vaginal therapy, possibly due to ease of administration, short duration, and administration flexibility. Vaginal creams provide rapid relief of itching and burning, while symptom resolution may take 1 to 2 days with oral treatment. The practitioner may wish to recommend applying a vaginal cream externally to reduce itching and burning when using an oral agent, although this increases the cost of therapy. Most OTC products cost $10 to $20 per course of therapy. The cost of prescription products can vary based on insurance coverage. If the patient does not have prescription coverage, nonprescription products may prove less expensive than even one or two fluconazole tablets.

#### ▶ Risk of Adverse Effects and Interactions

Systemic adverse effects associated with vaginally administered azoles are less frequent than with oral products. With topical products, local discomfort such as burning, itching, stinging, and redness may occur, particularly with the first application. In contrast, common adverse effects associated with fluconazole include headache, diarrhea, nausea, dizziness, abdominal pain, and taste alterations. Around 15% of patients experience gastrointestinal side effects with orally administered fluconazole.[5]

Oral azoles are associated with significant drug interactions, particularly due to potent inhibition of cytochrome P-450 (CYP) 2C9 and moderate inhibition of CYP 3A4. For patients receiving only a few doses, these interactions do not pose a significant risk but may pose a risk with long-term suppressive therapy for recurrent infections.

### TREATMENT OF RECURRENT VVC

The goal of treating recurrent VVC is control of the infection, rather than cure. First, any acute episodes are treated, followed by maintenance therapy. Although acute episodes of recurrent VVC will respond to azole therapy, some patients may require prolonged therapy to achieve remission. To achieve remission, 14 days of topical azole therapy or a second dose of oral fluconazole 150 mg repeated 3 days after the first dose can be used. The practitioner should consider that nonalbicans infections are more common in recurrent VVC; therefore, fluconazole and itraconazole resistance may make these agents less effective.

**KEY CONCEPT** *After achieving remission, recurrent VVC requires long-term suppressive therapy for 6 months* (Table 83–3). Per CDC

---

**Table 83–2**

**Treatment Options for Uncomplicated VVC**

**1-Day Therapies**
Butoconazole 2% sustained-release cream, 5 g intravaginally as a single application
Fluconazole 150 mg, one tablet orally as a single dose
Tioconazole 6.5% ointment, 5 g intravaginally as a single application

**3-Day Therapies**
Butoconazole 2% cream, 5 g intravaginally for 3 nights
Clotrimazole 100-mg vaginal tablet, two tablets for 3 nights
Miconazole 200-mg vaginal suppository, one suppository for 3 nights
Terconazole 0.8% cream, 5 g intravaginally for 3 nights
Terconazole 80-mg vaginal suppository, one suppository for 3 nights

**7- to 14-Day Therapies**
Boric acid 600-mg vaginal suppository, one suppository intravaginally twice daily for 14 days
Clotrimazole 1% cream, 5 g intravaginally for 7–14 nights
Clotrimazole 100-mg vaginal tablet, one tablet for 7 nights
Miconazole 2% cream, 5 g intravaginally for 7 nights
Miconazole 100-mg vaginal suppository, one suppository for 7 nights
Nystatin 100,000-unit vaginal tablet, one tablet for 14 nights
Terconazole 0.4% cream, 5 g intravaginally for 7 nights

---

**Table 83–3**

**Treatment Options for Maintenance Therapy**

**Daily**
Boric acid 600 mg in gelatin capsule vaginally daily during menses (5 days)
Itraconazole 100 mg orally once daily
Ketoconazole 100 mg orally once daily

**Weekly**
Clotrimazole 500 mg vaginal suppository once weekly
Fluconazole 100 or 150 mg orally once weekly
Terconazole 0.8% cream 5 g vaginally once weekly

**Monthly**
Fluconazole 150 mg orally once monthly
Itraconazole 400 mg orally once monthly

guidelines, oral fluconazole 100-, 150-, or 200-mg weekly for 6 months is first-line treatment.[1] Cessation of suppressive therapy is associated with resurgence of symptomatic infection in 30% to 50% of women.[1]

## TREATMENT OF NONALBICANS INFECTIONS

Treatment response rates are lower for nonalbicans infections. Although an optimal regimen is unknown, use of nonfluconazole azole therapy for 7 to 14 days is recommended.[1] For second-line therapy, boric acid 600 mg in a gelatin capsule administered vaginally daily for 2 weeks is recommended.[1] This regimen provides mycologic cure rates of 40% to 100%,[6] although local irritation often limits its use. Oral itraconazole 200-mg twice daily one day per month for 6 months is also effective.[7] Topical 4% flucytosine is also effective, but use should be limited due to the potential for resistance.

## VVC DURING PREGNANCY

During pregnancy, VVC may prove difficult to treat due to elevated estrogen levels, lower response rates, and frequent recurrences, accompanied by concern for the fetus. Vaginal antifungals remain the preferred treatment during pregnancy, although therapy should continue for 1 to 2 weeks to ensure effectiveness.[8] Most topical antifungals are classified as risk category C, whereas clotrimazole is classified as risk category B. Fluconazole's risk category classification for the single 150-mg dose is risk category C but category D for all other doses due to case studies of congenital limb deformities with doses of 400 to 800 mg daily during the first trimester.[9]

## CULTURAL AWARENESS DURING TREATMENT OF VVC

As with all gynecologic issues, the practitioner is faced with cultural perceptions of female genitalia. In particular, practitioners are treating an increased number of patients who have undergone female genital mutilation. Female genital mutilation, formerly known as female circumcision, describes the intentional alteration or injury of female genitalia. More than 100 million women and girls, particularly in Africa and the Middle East, have undergone such procedures for cultural and religious reasons.[10] Some authorities suggest using the term "genital cutting" when dealing with patients to avoid appearing judgmental.[11] Women who have undergone this procedure suffer acute and chronic complications. Patients with female genital mutilation may suffer from recurrent VVC due to inadequate drainage of vaginal fluids. Regardless of the practitioner's opinion on female genital mutilation, the practitioner must be sensitive to the patient's feeling and cultural values.

## OUTCOME EVALUATION

Whether using a topical or an oral agent, patients should notice relief of itching and discomfort within 1 to 2 days. The volume of discharge should also begin to decrease within a few days. The entire course of therapy should be continued even if symptoms have resolved. If the condition recurs within 4 weeks or more than four times per year, the patient should be further evaluated for possible non-*Candida* infections, resistant organism, or other complicating factors, along with assessment of need for long-term suppressive therapy.

---

## Patient Care Process for VVC

**Patient Assessment:**

- Assess the patient's symptoms to determine whether self-treatment with OTC antifungal therapy is appropriate. OTC preparations should only be recommended for patients who have previously been diagnosed with VVC.
- Review any available diagnostic data, including cultures and KOH preps.
- Obtain a thorough history of prescription, nonprescription, and natural drug product use. Is the patient taking any medications, such as steroids, antibiotics, or immunosuppressants, that may contribute to VVC? Is the patient taking any medications that may interfere with treatment? Any allergies?

**Therapy Evaluation:**

- Determine whether self-treatment with OTC antifungal therapy is appropriate.
- If the patient has had VVC previously, determine what treatments were helpful to the patient in the past.
- Determine whether long-term maintenance therapy is necessary.
- Evaluate the patient for the potential for adverse drug reactions, drug allergies, and drug interactions.
- Determine whether patient has prescription coverage.

**Care Plan Development:**

- Stress the importance of adherence with the antifungal regimen, including lifestyle modifications.
- Educate the patient on lifestyle modifications that may prevent recurrence, including wearing loose clothing, increased consumption of yogurt containing live cultures, and wearing cotton underwear.
- Provide patient education pertaining to vulvovaginal candidiasis and antifungal therapy, including causes, medication administration, adverse effects of vaginal agents on latex condoms, and potential adverse effects.
- Discuss warning signs to report to a practitioner such as recurrent or difficult-to-cure infections or infections with malodorous discharge.

**Follow-Up Evaluation:**

- Follow-up only necessary of treatment failure or recurrence.

---

# OROPHARYNGEAL AND ESOPHAGEAL CANDIDIASIS

Oropharyngeal candidiasis (OPC) is a common fungal infection, often associated with immune suppression. If left untreated, it will progress to more serious oral disease, such as esophageal candidiasis.

## EPIDEMIOLOGY AND ETIOLOGY

KEY CONCEPT *The occurrence of oropharyngeal and esophageal candidiasis is an indicator of immune suppression, often developing in infants, the elderly, and the immunocompromised.* One-third to

one-half of geriatric inpatients develop oropharyngeal candidiasis. Denture stomatitis is present in approximately 40% of denture wearers,[12] more commonly in women than men. Oral candidiasis is the most commonly reported adverse drug event reported by patients receiving inhaled corticosteroids,[13] with the prevalence of esophageal candidiasis reaching 37% among patients treated with inhaled corticosteroids.[14] The incidence of esophageal candidiasis is highest among patients receiving high doses of corticosteroids or with diabetes.

The prevalence of HIV infection plays a significant role in the incidence of oropharyngeal and esophageal candidiasis. In the 1980s, the incidence of oropharyngeal candidiasis increased five-fold, in association with the spread of HIV infections.[15] Although HIV infection remains a risk factor for candidiasis, the introduction of highly active antiretroviral therapy precipitated a decline in the incidence of oral candidiasis to 45.9% to 79.1%, varying by geographic location, race, and therapy.[16]

Oropharyngeal candidiasis remains the most common opportunistic infection in patients with HIV. For the majority of patients, it is the first manifestation of HIV infection.[28] The incidence of oropharyngeal infection increases with decreasing CD4$^+$ lymphocyte counts, with an incidence of 59% in patients with a CD4$^+$ count less than 350 cells/mm$^3$ ($350 \times 10^6$/L).[17]

Although esophageal candidiasis represents the first manifestation of HIV infection in less than 10% of cases, it is the most common acquired immunodeficiency syndrome (AIDS)–defining disease.[18] The CDC classifies esophageal candidiasis as a Stage 3-defining opportunistic infection in HIV.[19] As with oropharyngeal candidiasis, the incidence of esophageal candidiasis increases with decreasing CD4$^+$ counts, therefore is a measure of declining CD4$^+$ count or treatment failure.

*Candida albicans* accounts for 80% of cases of OPC and esophageal candidiasis. Over the last 20 years, an increasing incidence of *C. albicans* resistance has been accompanied by an increased incidence of nonalbicans species infections, including *Candida glabrata, Candida tropicalis, Candida krusei*, and *Candida parapsilosis*. In patients with cancer and HIV, the prevalence of *Candida glabrata* infections or mixed *Candida albicans* and *Candida glabrata* infection has been increasing.[20] Such infections tend to be more severe and require larger doses of antifungal agents for treatment.

## PATHOPHYSIOLOGY

Similar to VVC, the development of OPC occurs when the normal environment is altered. *Candida* organisms frequently colonize the oropharynx and mucous membranes. These organisms do not become pathogenic until the environmental balance is disturbed. This occurs in the setting of broad-spectrum antibiotic use, tissue damage (due to chemotherapy, catheter tubing, trauma, or smoking), hyposalivation, or immune deficiency.

## RISK FACTORS

Risk factors for OPC can be found in Table 83–4.

## CLINICAL PRESENTATION AND DIAGNOSIS

See text boxes for clinical presentation and diagnosis of OPC and esophageal candidiasis.

## TREATMENT

Along with selecting an effective treatment, selection of an appropriate antifungal agent requires consideration of location

---

**Table 83–4**

**Risk Factors for Oropharyngeal and Esophageal Candidiasis**

| Factor | Proposed Mechanism |
|---|---|
| Extremes of age | Immature immunity in infants and reduced immunity in the elderly |
| Impaired mucosal integrity | Breaks in the protective barrier allows fungal invasion; often due to radiation, surgery, or mucositis |
| Dentures | Adherence of fungus to dentures, along with reduced salivary flow under dentures; ill-fitting dentures may impair mucosal integrity |
| Xerostomia | Reduced cleansing and defense factors of saliva |
| Use of antibiotics | Altered flora of mucosa allowing fungal overgrowth |
| Use of steroids | Suppression of immunity |
| Use of immunosuppressants | Suppression of immunity |
| HIV infection | Decreased CD4 T lymphocytes |
| Diabetes mellitus | Elevated glucose levels and defense factors in saliva |
| Nutritional deficiencies | Altered defense mechanisms, impaired mucosal integrity, or enhanced pathogenic potential of fungus |

---

and severity of infection, medication adherence, potential drug interactions, concomitant medical conditions, and presence of sucrose or dextrose. Topical agents require frequent dosing and prolonged contact time with oral mucosa. Rough surfaces of tablets and troches may irritate sensitive mucosa. Patients with xerostomia may have inadequate saliva to dissolve troches. Topical agents containing sucrose or dextrose may increase the risk of caries or cause elevated blood sugar in patients with diabetes. Along with being expensive, oral azoles exhibit an increased risk of toxicity and drug interactions due to inhibition of CYP-450.

Because oropharyngeal and esophageal candidiasis are signs of immunocompromise, the immune status of the patient should be considered in the therapeutic care plan. For HIV-infected patients, this should also include an evaluation of the patient's antiretroviral therapy because fungal infections may represent immune status deterioration.

**KEY CONCEPT** *For low-risk patients, topical agents are first-line therapy for oropharyngeal candidiasis, although systemic agents may be used for severe or unresponsive cases.* Infectious Disease Society of America (ISDA) guidelines recommend nystatin suspension four times per day or clotrimazole troches 10 mg five times per day for mild infections.[21] Once-daily oral fluconazole is reserved for moderate-to-severe cases.[21] Two weeks of oral itraconazole 200-mg or posaconazole 400-mg daily, voriconazole 200-mg twice daily, or amphotericin-B suspension are alternatives, typically reserved for refractory cases.

For non–HIV-infected patients who have suppressed immune systems, the practitioner must consider the patient's risk of dissemination. Patients with cell-mediated immune deficiency but near-normal granulocyte function, such as patients with diabetes, solid organ transplant, or solid tumors, are at low risk for dissemination. The risk of dissemination is higher in patients who develop neutropenia, including patients with leukemia or bone

## Clinical Presentation and Diagnosis of Oropharyngeal Candidiasis

OPC is often a presumptive diagnosis based on signs and symptoms, along with the resolution of them after treatment with antifungal agents.

**Symptoms**

- Sore, painful mouth and tongue
- Burning tongue
- Dysphagia
- Metallic taste

**Signs**

Signs vary depending on the type of oropharyngeal candidiasis.

- Diffuse erythema on the surface of buccal mucosa, throat, tongue, and gums
- White patches on tongue, gums, or buccal mucosa; removal of patches reveals erythematous and bloody tissue; ability to remove patches distinguishes OPC from oral hairy leukoplakia
- Angular cheilitis presents with small cracking lesions, erythema, and soreness at the corners of the mouth; associated with vitamin and iron deficiency

- Denture stomatitis presents with flat, red lesions on mucosa beneath dentures; signs of chronic erythema and edema on mucosa
- Hyperplastic OPC presents with discrete, transparent raised lesions on the inner mucosa of the cheek; typically found in men who smoke
- Pseudomembranous OPC presents with yellow-white plaques that may be small and discrete or confluent; most common form found in HIV patients

**Diagnostic Testing**

Diagnosis is primarily based on identification of characteristic lesions. Although rarely necessary, diagnostic testing is possible if a definitive diagnosis is required.

- Cytology, although presence of *Candida* is not diagnostic because colonization is common
- Culture to identify species of yeast or presence of resistance
- Biopsy

---

marrow transplant. These patients should be treated aggressively to prevent invasive fungal infection.

For the treatment of OPC in HIV-infected individuals, initial episodes can be adequately controlled with topical agents, such as clotrimazole troches, so long as symptoms are not severe and no esophageal involvement is suspected. Topical clotrimazole appears to be the most effective topical antifungal, exhibiting clinical responses equivalent to oral fluconazole and itraconazole solution, but mycological cure rates are lower and relapse rates higher with clotrimazole.[18]

**KEY CONCEPT** *Representing a severe extension of oropharyngeal candidiasis, esophageal candidiasis requires systemic antifungal therapy.*

The significant morbidity associated with esophageal candidiasis warrants aggressive treatment.

The ISDA recommends 2 to 3 weeks of fluconazole 200 to 400 mg for esophageal candidiasis, with an echinocandin or amphotericin-B as alternatives in patients unable to tolerate oral therapy, or with resistant or refractory disease.[21] Itraconazole 200-mg daily, posaconazole 400-mg twice daily, or voriconazole 200-mg twice daily are considered second-line therapy. If immunocompromised patients experience frequent or severe recurrences, particularly of esophageal candidiasis, chronic maintenance therapy with fluconazole 100 to 200 mg daily should be considered.

---

## Clinical Presentation and Diagnosis of Esophageal Candidiasis

**Symptoms**

- Fever
- Odynophagia
- Dysphagia
- Retrosternal pain

**Signs**

- Fever
- Hyperemic or edematous white plaques
- Ulceration of esophagus
- Increased mucosal friability
- Narrowing of lumen

**Diagnostic Testing**

Unlike OPC, diagnosis of esophageal candidiasis is not based solely on clinical presentation, instead requiring endoscopic visualization of lesions and culture confirmation. Due to the invasive nature of these procedures, most practitioners opt to treat the infection presumptively, reserving endoscopic evaluation for patients who fail therapy.

- Cytology and culture to identify species of yeast or presence of resistance
- Barium esophagogram
- Endoscopy revealing whitish plaques with progression to superficial ulceration of the esophageal mucosa
- Mucosal biopsy

### OUTCOME EVALUATION

- Patients should notice symptomatic relief within 2 to 3 days of initiating therapy. Complete resolution typically occurs within 7 to 10 days. The entire course of therapy should be continued even if symptoms have resolved. If the condition does not resolve or worsens, the patient should be referred to a specialist for aggressive therapy.

- Short courses of oral azoles are associated with gastrointestinal upset, whereas courses lasting longer than 7 to 10 days are associated with increased risk of hepatotoxicity and CYP-450 drug interactions. In patients receiving prolonged therapy lasting more than 3 weeks, periodic monitoring of liver function tests should be considered.

- Immunocompetent patients generally do not require reassessment after treatment. Patients with neutropenia exhibit an increased risk of dissemination of infection and therefore should be monitored for signs of systemic fungal infection. Due to an increased risk of recurrence, HIV-positive patients should routinely be evaluated for recurrence at each visit.

## MYCOTIC INFECTIONS OF THE SKIN, HAIR, AND NAILS

Tinea infections are superficial fungal infections in which the pathogen remains within the keratinous layers of the skin or nails (Table 83–5). Typically these infections are named for the affected body part, such as tinea pedis (feet), tinea cruris (groin), and tinea corporis (body). Tinea infections are commonly referred to as ringworm due to the characteristic circular lesions. In actuality, tinea lesions can vary from rings to scales and single or multiple lesions.

### EPIDEMIOLOGY AND ETIOLOGY

Tinea infections are second only to acne in frequency of reported skin disease. The common tinea infections are tinea pedis, tinea corporis, and tinea cruris. Tinea pedis, the most prevalent cutaneous fungal infection, afflicts more than 25 million people annually in the United States.

| Table 83–5 |
| --- |

**Signs, Symptoms, and Risk Factors of Superficial Fungal Infections**

| Infection | Symptoms, Signs, and Risk Factors |
| --- | --- |
| Tinea pedis | • Involves plantar surface and interdigital spaces of foot<br>• Interdigital infections produce itching; presents as fissures, scaling, or macerated skin; can occur between any toes but most often between fourth and fifth toes; may cause foul smell due to superinfection with *Pseudomonas* or diphtheroids<br>• Hyperkeratotic infections present with slivery white scales on a thickened, red base; usually covers entire foot; occasionally may also affect hand<br>• Vesiculobullous tinea pedis presents as pustules or vesicles on soles of feet; associated with maceration, itching, and thickening of sole; may cause lymphangitis and cellulitis; most common during summer months<br>• Ulcerative tinea pedis presents as macerated, denuded, and weeping ulcers on soles; may produce extreme pain and erosion of interdigital spaces; typically complicated by opportunistic gram-negative infections<br>• Risk factors include occlusive footwear, foot trauma, and use of public showers |
| Tinea manuum | • Infection of the interdigital and palmar surfaces<br>• Presents as white scales in palmar folds; may also develop scales on remainder of palm; may present as singular plaque<br>• More commonly affecting only one hand<br>• Presents with hyperkeratotic skin |
| Tinea cruris | • Presents with follicular papules and pustules on the medial thigh and inguinal folds<br>• Ringed lesions may extend from inguinal fold over adjacent inner thigh<br>• Lesions usually spare the penis and scrotum, in contrast to candidiasis<br>• Frequency increases during summer<br>• Primarily develops in young men<br>• Risk factors include tight-fitting clothing, excessive sweating, poor hygiene, increased humidity and temperatures<br>• Commonly referred to as "jock itch" |
| Tinea corporis | • Presents with circular, scaly patch with enlarged border<br>• Lesions may have red papules or plaque in center that clears, leaving hypopigmentation or hyperpigmentation<br>• Itching may be present<br>• Commonly referred to as ringworm of the body<br>• Risk factors include animal to human contact |
| Tinea versicolor | • Characterized by skin depigmentation but can present as hyperpigmentation, particularly in dark-skinned patients<br>• Typically occurs in areas with sebaceous glands, including neck, trunk, and arms<br>• Depigmentation may persist for years<br>• Primarily develops in young and middle-aged adults<br>• Risk factors include application of oil, greasy skin, high ambient temperature, high relative humidity, tight-fitting clothing, immunodeficiency, malnutrition, hereditary predisposition |
| Tinea barbae | • Infection of beard area |
| Tinea capitis | • Infection of the head and scalp<br>• May be asymptomatic initially, then progresses to inflammatory alopecia<br>• "Black dot" alopecia may develop due to breakage of hair at the root<br>• May form kerions (nodular swellings)<br>• Scaling or favus may develop on scalp<br>• Cervical lymphadenopathy is common<br>• Primarily found in infants, children, and young adolescents, often in African American and Hispanic populations<br>• Can be spread from person to person or animal to person |
| Onychomycosis (tinea unguium) | • Infection of nail plate and bed<br>• Nail becomes opaque, thick, rough, yellow or brownish, and friable; nail may separate from bed<br>• Toenails affected more frequently than fingernails<br>• Prevalence increases with advanced age |

Fungal skin infections are primarily caused by **dermatophytes** such as *Trichophyton*, *Microsporum*, and *Epidermophyton*. *Trichophyton rubrum* accounts for more than 75% of all cases in the United States.[22] To a lesser extent, *Candida* and other fungal species cause skin infections. With tinea infections, the causative dermatophyte typically invades the stratum corneum without penetration into the living tissues, leading to a localized infection.

## PATHOPHYSIOLOGY

The primary mode of transmission of tinea infections is direct contact with other persons or surface reservoirs. Upon contact, the dermatophytes attach to the keratinized cells, leading to thickening of the cells. Although infection remains localized, bacterial superinfections may develop.

The pathophysiology of onychomycosis depends on the clinical type. With the most common form of onychomycosis, distal

## Clinical Presentation and Diagnosis of Mycotic Infections

**Symptoms and Signs**

(see Table 83–5)

**Diagnostic Testing**

- KOH prep
- Wood's ultraviolet lamp
- Microscopic examination
- Fungal cultures
- Periodic acid-Schiff (PAS) staining of nail

**Treatment of Skin and Hair Infections**

The goals of treatment include the following:

- Providing symptomatic relief
- Resolution of infection
- Preventing spread of infection

---

### Patient Encounter 3

A middle-aged man presents to the clinic complaining of painful red areas on his feet, particularly between his toes. He said this has been going on for a few weeks and he thought it might be athlete's foot so he sprayed antifungal powder inside his running shoes, rather than on his feet "since my feet are in those shoes for hours each day when I run anyway." When that did not work, the raw skin became so painful that he had to stop training for his next ultra-marathon.

*What information is suggestive of tinea pedis?*

*What risk factors are present for tinea pedis?*

*What nonpharmacologic approaches can be recommended to prevent recurrence?*

---

lateral subungual, the fungus spreads from the plantar skin. The fungus invades the underside of the nail through the distal lateral nail bed, leading to inflammation of the area. In cases of white superficial onychomycosis, the fungus invades the surface of the nail plate directly. With white superficial onychomycosis, the nail bed and hyponychium are infected secondarily. Proximal subungual onychomycosis infections begin in the cuticle and the proximal nail fold, then penetrate the dorsum of the nail plate.

### RISK FACTORS

- Prolonged exposure to sweaty clothing
- Excessive skin folds
- Sedentary lifestyle
- Warm, humid climate
- Use of public pools
- Walking barefoot in public areas
- Skin trauma
- Poor nutrition
- Diabetes mellitus
- Immunocompromise
- Impaired circulation

### TREATMENT
#### Nonpharmacologic Therapy

- Because fungi thrive in warm, moist environments, the practitioner should encourage patients to wear loose-fitting clothing and socks, preferably garments made of cotton or other fabrics that wick moisture away from the body. Avoid clothing made with synthetic fibers or wool.
- Sweaty or wet clothing should be removed as soon as possible.
- Clean the infected area daily with soap and water.
- The infected area should be dried completely prior to dressing, paying particular attention to skin folds.
- To allow circulation of air, the infected area should not be bandaged.
- For foot infections, cotton socks are recommended, although these should be changed two to three times a day to reduce moisture.
- To prevent spread, towels, clothing, and footwear should not be shared with other persons.
- Wear protective footwear in public showers and pool areas.

### Pharmacologic Therapy of Tinea Infections

**KEY CONCEPT** *Since dermatophyte hyphae seldom penetrate into the living layers of the skin, instead remaining in the stratum corneum, most infections can be treated with topical antifungals. Infections covering large areas of the body, infections involving nails or hair, chronic infections, or infections not responding to topical therapy may require systemic therapy.* Treatment is typically initiated based on symptoms, rather than on microscopic evaluation. For infections accompanied by inflammation, combination therapy with a topical steroid can be considered (Tables 83–6, 83–7, and 83–8).

Typically, tinea pedis requires treatment one to two times daily for 4 weeks, whereas tinea corporis and tinea cruris require topical treatment one to two times daily for 2 weeks. When applying treatment, the medication should be applied at least 1 in beyond the affected area. Treatment of infection should continue at least 1 week after resolution of symptoms. Many practitioners opt to initiate therapy with nonprescription clotrimazole, tolnaftate, miconazole, or terbinafine, reserving prescription topical agents, such as naftifine, ciclopirox, and butenafine, for second-line therapy or refractory cases and systemic therapy for refractory cases.

When recommending topical therapy, the selection of vehicle is based on the type of lesion and location of the infection. Solutions and lotions are recommended for hairy areas and oozing lesions, whereas creams and ointments should be avoided in these areas. Creams are better for moderately scaling and nonoozing lesions. For hyperkeratotic lesions, ointments can be considered. The selected formulation should be applied to the affected area after it is cleaned and dried. The medication should be rubbed into the infected area for improved penetration. Because most patients do not rub in sprays and powders, penetration of the epidermis is minimal, making them less effective than other formulations. Sprays and powders should

**Table 83–6**

**Available Topical Antifungal Agents**

| Medication | Rx/OTC | Cream/Ointment | Gel | Lotion | Spray/Solution | Powder |
|---|---|---|---|---|---|---|
| Butenafine | OTC | X | | | | |
| Ciclopirox | Rx | X | | x | Lacquer and shampoo | |
| Clotrimazole | OTC | X | | x | X | x |
| Econazole | Rx | x | | | | |
| Efinaconazole | Rx | | | | X | |
| Haloprogin | Rx | x | | | X | |
| Ketoconazole | Rx/OTC | x | | | Shampoo | |
| Miconazole | OTC | x | | x | X | x |
| Naftifine | Rx | x | X | | | |
| Nystatin | Rx | x | | x | | x |
| Oxiconazole | Rx | x | | x | | |
| Sertaconazole | Rx | x | | | | |
| Sulconazole | Rx | x | | | | |
| Tavaborole | Rx | | | | X | |
| Terbinafine | OTC | x | X | | X | |
| Tolnaftate | OTC | x | | x | X | |

be considered as adjuvant therapy with a cream or lotion or as prophylactic therapy to prevent recurrence.[7]

Due to the severity of infection and inflammation, tinea capitis does not adequately respond to topical agents; therefore, oral agents for 6 to 8 weeks are recommended. Griseofulvin has long been considered the treatment of choice due to its ability to achieve high levels within the stratum corneum. Itraconazole has also demonstrated effectiveness. Due to its lipophilicity, itraconazole achieves high dermal concentrations that are maintained for 4 weeks after discontinuation of therapy.

## Treatment of Onychomycosis

For onychomycosis, a chronic infection that rarely remits spontaneously, adequate treatment is essential to prevent spread to other sites, secondary bacterial infections, cellulitis, or gangrene. **KEY CONCEPT** *Due to the chronic nature and impenetrability of nails, topical agents have low efficacy rates for treating onychomycosis.* Oral agents that can penetrate the nail matrix and nail base,

such as itraconazole and terbinafine, are more effective than ciclopirox lacquer, efinaconazole solution, or tavaborole solution. Itraconazole (200 mg twice daily for 1 week per month or 200 mg daily for 12 weeks) and terbinafine (250 mg daily for 12 weeks) demonstrate mycological cure rates of 71% and 77%, respectively, whereas the cure rate range from 29% to 36% for ciclopirox, approximately 55% for efinaconazole, and 35% for tavaborole.[23] For patients with liver disease or who are unable to use oral agents, ciclopirox lacquer, efinaconazole solution, and tavaborole solution remain reasonable alternatives, despite requiring 48 weeks of therapy. Due to low efficacy, griseofulvin should only be considered as second-line therapy with therapy continued for 4 months for fingernail infections or 6 months for toenail infections.

The FDA has released warnings pertaining to itraconazole and terbinafine as there is a small but real risk of developing congestive heart failure with itraconazole therapy due to its negative inotropic effects. Itraconazole should not be administered to patients with ventricular dysfunction such as congestive heart failure. The FDA also released warnings that itraconazole and terbinafine are associated with serious hepatic toxicity, including liver failure and death. Liver failure associated with these medications has occurred in patients with no preexisting living disease or serious underlying medical conditions. Treatment with itraconazole or terbinafine for prolonged periods requires laboratory monitoring of liver function tests before initiation of therapy and at monthly intervals.

**Table 83–7**

**Dosing of Topical Agents for Tinea Infections and Onychomycosis**

| Agents | Topical Dosing Frequency |
|---|---|
| Butenafine | Once daily |
| Ciclopirox | Twice daily; at bedtime (lacquer) |
| Clotrimazole | Twice daily |
| Econazole | Once daily |
| Efinaconazole | Once daily (nail solution) |
| Haloprogin | Twice daily |
| Ketoconazole | Once daily |
| Miconazole | Twice daily |
| Naftifine | Once daily (cream); twice daily (gel) |
| Oxiconazole | Twice daily |
| Sertaconazole | Twice daily |
| Sulconazole | Twice daily |
| Tavaborole | Once daily (nail solution) |
| Terbinafine | Twice daily |
| Tolnaftate | Two to three times daily |

**Table 83–8**

**Dosing of Systemic Therapy for Tinea Infections**

| Medication | Adult Dosing | Pediatric Dosing |
|---|---|---|
| Fluconazole | 150 mg/week | 6 mg/kg/week |
| Griseofulvin | 0.5–1 g/day | 10–20 mg/kg/day |
| Itraconazole | 200 mg twice daily | Not studied |
| Ketoconazole | 200–400 mg/day | 3.3–6.6 mg/kg/day |
| Terbinafine | 250 mg/day | < 25 kg: 125 mg/day; 25–35 kg: 187.5 mg/day; > 35 mg: 250 mg/day |

## Patient Care Process for Mycotic Infections

**Patient Assessment:**

- Assess the patient's symptoms to determine whether self-treatment with OTC antifungal therapy is appropriate. Exclusions for self-treatment include infection of nails or hair, unsuccessful initial treatment, worsening condition, signs of secondary bacterial or systemic infection, large infected areas, or chronic medical conditions such as diabetes, immunosuppression, or impaired circulation.

- Review any available diagnostic data, including cultures and KOH preps.

- Obtain a thorough history of prescription, nonprescription, and natural drug product use. Any allergies?

**Therapy Evaluation:**

- If the patient has had a mycotic infection previously, determine what treatments were helpful to the patient in the past.

- Determine whether long-term prophylactic therapy is necessary to prevent recurrence.

- Determine whether the patient has prescription coverage.

**Care Plan Development:**

- Evaluate the patient for the potential for adverse drug reactions, drug allergies, and drug interactions.

- Educate the patient on lifestyle modifications that will prevent recurrence, including keeping the area dry, wearing shower shoes, washing clothing in hot water, using drying powders, avoiding sharing towels or clothing, and wearing loose-fitting clothing.

- Provide the patient education pertaining to mycotic infections and antifungal therapy, including causes, medication application or administration, length of therapy, how to avoid spread of infection or recurrence, and potential adverse effects.

- Discuss dietary modifications that are necessary with oral agents.

- Discuss medications that may interact with antifungal therapy, particularly with oral agents used for nail infections.

- Discuss warning signs to report such as recurrent or difficult-to-cure infections, infections with malodorous discharge or bleeding.

- Stress the importance of adherence with the antifungal regimen.

**Follow-Up Evaluation:**

- Follow-up if unresolved or worsens with treatment.

### Cultural Awareness When Treating Mycotic Infections

Awareness of cultural beliefs related to feet and hands is essential when treating patients with fungal infections. In Arab countries, showing the bottom of the foot is a grave insult. The foot is considered the dirtiest part of the body. As such, patients from these countries may be hesitant to show their feet to the practitioner. In other countries, the open palm "high five" gesture is considered insulting. When treating patients with infections on the hand, the practitioner should refrain from making this gesture while discussing the patient's hand infection.

### OUTCOME EVALUATION

For infections of the skin, patients should notice relief of symptoms, including pruritus, scales, and inflammation, within 1 to 2 weeks. Therapy should be continued at least 1 week after complete resolution of symptoms. If the condition worsens on topical therapy, the patient should be treated with oral therapy.

For onychomycosis, relief of symptoms is slow. The infected nail will need months to grow out. The practitioner should advise the patient not to become frustrated by the slow resolution. Despite the slow progress, the antifungal agent is curing the infection. The practitioner should also advise the patient that even after the infection is cured, the nail may not look "normal."

## Abbreviations Introduced in This Chapter

AIDS    Acquired immunodeficiency syndrome
CDC    Centers for Disease Control and Prevention
HIV    Human immunodeficiency virus
KOH    Potassium hydroxide
OPC    Oropharyngeal candidiasis
OTC    Over the counter
PAS    Periodic acid-Schiff test
VVC    Vulvovaginal candidiasis

# 84 Invasive Fungal Infections

Russell E. Lewis and P. David Rogers

## LEARNING OBJECTIVES

Upon completion of the chapter, the reader will be able to:

1. Differentiate epidemiologic differences and host risk factors for acquisition of primary and opportunistic invasive fungal pathogens.

2. Recommend appropriate empiric or targeted antifungal therapy for the treatment of invasive fungal infections.

3. Describe the components of a monitoring plan to assess effectiveness and adverse effects of pharmacotherapy for invasive fungal infections.

4. Evaluate the role of antifungal prophylaxis in the prevention of opportunistic fungal pathogens.

## INTRODUCTION

Invasive fungal infection or invasive mycoses are general terms for diseases caused by invasion of living tissue by fungi. In contrast to superficial mycoses (see Chapter 83), invasive fungal infections are much less common, but are of greater medical concern because of their disproportionately higher severity and mortality. Approximately 1.5 million people die each year from the 10 most common invasive fungal infections, which is higher than World Health Organization mortality estimates for tuberculosis (1.4 million) or malaria (1.2 million).[1] However, these numbers probably underestimate the actual mortality burden of invasive fungal disease considering that the four most common infections (cryptococcosis, invasive candidiasis, invasive aspergillosis, and *Pneumocystis jiroveci* pneumonia) are often underdiagnosed and not reportable diseases to public health agencies (Table 84–1).

Invasive fungal infections are broadly categorized as either primary or opportunistic mycoses. Primary invasive fungal infections develop following exposure to fungal spores or conidia in the soil that, when disturbed, can become aerosolized and inhaled leading to infection, even in an immunocompetent patient exposed to a sufficient inoculum. Because these fungi are in specific soil types in select geographic areas, they are also referred to as endemic fungi. In the United States, three Genera (*Histoplasma capsulatum*, *Blastomyces dermatitidis*, and *Coccidioides immitis/Coccidioides posadasii*) account for most of these infections (see Table 84–1).

In contrast, opportunistic fungal infections are most frequently encountered in setting of compromised host immune defenses, and are caused by a wider spectrum of less virulent fungal species that rarely cause infection in healthy patients (see Table 84–1). Hence, the spectrum, severity, and outcome of opportunistic fungal infections are strongly influenced by the degree, type, and severity of host immunosuppression. As a general rule, opportunistic fungal infections are difficult to diagnose, but often fatal if not diagnosed early and treated aggressively.

Occasionally, opportunistic fungal pathogens may be associated with outbreaks of invasive disease in otherwise nonimmunocompromised patients, especially if they are inadvertently inoculated into patients from contaminated drug solutions or medical devices. For example, in 2012 an outbreak of fungal meningitis and articular infections (n=751 cases) in 20 states was eventually traced by the Centers for Disease Control and state health departments to contaminated preservative-free methylprednisolone solution used for epidural and articular injections in patients with chronic back or joint pain. The dematiaceous mold eventually linked to the fungal meningitis cases, *Exserohilum rostratum*, had rarely been described as a human pathogen prior to the outbreak.[2]

## EPIDEMIOLOGY AND ETIOLOGY

Endemic mycoses are capable of infecting otherwise healthy individuals. In immunocompromised patients, endemic fungal infections present with a more fulminant course (in the case of primary infections, or reactivate to cause life-threatening infection). Because initial symptoms of an endemic fungal infection are nonspecific and produce symptoms indistinguishable from other slowly progressing infections (eg, tuberculosis), a careful patient history concerning travel and activities that may have resulted in exposure to endemic fungi is essential for early diagnosis.

Two of the most common endemic fungal infections (histoplasmosis and North American blastomycosis) are found in overlapping regions in the eastern and central river basins of the United States (Figure 84–1).[3,4] *H. capsulatum* var. *capsulatum*, the causative fungus of histoplasmosis, grows heavily in soil contaminated with bird or bat excreta, which serve to enhance sporulation of the fungus. Infections have been associated with activities that disturb soil contaminated with this excreta, including cave exploration (spelunking), working in or demolishing chicken coops or older buildings, or cleaning working in

campsites in heavily wooded areas. For blastomycosis, decaying organic matter, warm humid conditions, and proximity to water or frequent rainfall support growth of this fungus. Outbreaks of blastomycosis have been most frequently associated with

occupational or recreational activities around the major water-ways such as the Great Lakes region, where soil concentrations of *B. dermatitidis* are elevated.[4]

Coccidioidomycosis differs from histoplasmosis and blastomycosis, as the fungus is associated with arid to semiarid climates, hot summers, low altitude, alkaline soil, and sparse flora. Hence the fungus is found in the southwestern regions of the United States stretching from western Texas to southern California (see Figure 84–1).[5] Epidemics of coccidioidomycosis have been reported in California following dust storms and earthquakes, including cycles of intense drought and rain, which favor the growth of the fungus and enhance dispersion of its specialized spore forms, called arthroconidia.

## PATHOPHYSIOLOGY

Endemic fungi share several key biologic and ecologic characteristics that contribute to their pathogenicity in humans. All endemic fungi exhibit temperature-dependent dimorphism, meaning they can propagate as either yeast (single cells that reproduce by budding into daughter cells) or molds (multicellular filamentous fungi that reproduce through production of conidia or spores). At environmental temperatures (25–30°C [77–86°F]), *H. capsulatum, B. dermatitidis,* and *C. immitis* grow in the mold form, producing 2- to 10-μm round- to oval-shaped (*Histoplasma* and *Blastomyces*) or barrel-shaped conidia (*Coccidioides*) that are dispersed throughout the environment and in air currents. At physiologic temperatures, the conidia germinate into yeast (*Histoplasma* and *Blastomyces*) or in specialized cell forms called spherules (*Coccidioides*) that are resistant to killing by alveolar macrophages and neutrophils in the host lung.

Control of infection by the host requires the development of antigen-specific T-lymphocyte response that enhances macrophage fungicidal activity and formation of a granuloma to contain the

fungus.[6] Not surprisingly, patients with T-cell–mediated immune deficiency (eg, AIDS patients and transplant recipients) or suppressed cellular immunity due to drug therapy (eg, chemotherapy, high-dose corticosteroids, or tumor necrosis-α blockers such as infliximab) are especially prone to severe reactivation of fungal disease.

The most common route of infection for endemic fungi is the respiratory tract, where conidia aerosolized from contaminated soil are inhaled into the lung. Once in the lung, conidia are phagocytosed but not destroyed by macrophages and neutrophils in the alveoli and bronchioles. Within 2 to 3 days, conidia germinate into facultative yeast resistant to phagocytosis and killing by macrophages and neutrophils (Figure 84–2A and B). For *C. immitis*, germination of the arthroconidia results in the formation of a sac-like structure called a spherule filled with endospores (Figure 84–2C). Spherules then rupture to release large numbers of endospores, which are the propagating form of the infection. Control of infection in the lungs is typically accomplished through formation of **granulomas** that contain the infection. However, in patients exposed to an overwhelming inoculum, or lower inocula in the setting of suppressed T-cell–mediated immunity, dissemination outside the lung to the skin and oral mucosa, adrenal glands, bone, spleen, thyroid, GI tract, heart, and central nervous system (CNS) is possible and uniformly fatal if left untreated.

## CLINICAL PRESENTATION AND DIAGNOSIS

Histoplasmosis and coccidioidomycosis are frequently asymptomatic infections in immunocompetent patients or present as a self-limiting, influenza-like or mild lower-respiratory tract illness 1 to 3 weeks after inhalation of conidia. The clinical presentation of blastomycosis can range from asymptomatic infection, to acute or chronic pneumonia that develops 30 to 40 days after exposure, to full-blown disseminated disease.

More severe endemic fungal disease presents as persistent pneumonia despite antibiotic therapy that is accompanied by fever, chills, cough, arthralgia, night sweats, and weight loss that may be indistinguishable from other chronic infections such as pulmonary tuberculosis. **KEY CONCEPT** *The diagnosis of endemic fungal infection is often prompted by a patient history of prolonged infectious symptoms, travel or residence in an endemic area, and/or participation in activities that result in exposures to soil contaminated by endemic fungi.*

### Radiographs

- Chest radiographs often reveal either diffuse or nodular infiltrates in the lung, accompanied by enlargement of the hilar and/or mediastinal lymph nodes.

- Fulminant pneumonia may be seen with high inoculum exposures, resulting in diffuse lung infiltrates that precede to acute respiratory distress syndrome (ARDS) and respiratory failure.

## Signs and Symptoms

- Rheumatologic symptoms such as severe arthritis, pericarditis, and erythema nodosum may be seen in 10% to 30% of patients with endemic fungi.[3–5]
- Dissemination outside the lung is common in patients with suppressed cellular immunity and frequently produces signs of progressing infection.
- Ulcerative oral and cutaneous lesions may also arise with any endemic fungal infections.
- Verrucose (wart-like) skin lesions on sun-exposed areas on the face are particularly suggestive of progressing blastomycosis and are frequently mistaken for cutaneous malignancy.[4]
- Dissemination of the fungi to bone marrow may result in anemia or thrombocytopenia.
- Hepatomegaly, splenomegaly, and adrenal insufficiency can also occur with dissemination of the endemic fungi to these internal organs.
- Seizures, meningeal signs, and hydrocephalus are common findings with dissemination of the infection to the CNS and portend an especially poor prognosis in the setting of disseminated coccidioidomycosis.

Definitive diagnosis of an endemic fungal infection requires growth of the fungus from body fluids or tissue, or evidence of cellular or tissue invasion in clinical samples by histopathology. However, cultures may only be positive in the setting of high inoculum exposures, pneumonia, or disseminated disease.[7] Serologic testing is helpful in the diagnosis and management of patients with histoplasmosis or coccidioidomycosis, but lacks specificity for diagnosis of *B. dermatitidis*.[4] In general, a fourfold rise in antibody or complement fixation titers of *Histoplasma* or *Coccidioides* or any titer greater than 1:16 suggests active infection. However, many clinicians still consider titers as low as 1:8 as evidence of active disease because undetectable titers may

**Patient Encounter 1, Part 1: Endemic Fungal Infection**

A 54-year-old African American woman from Phoenix Arizona with a history of steroid-refractory Crohn disease presents with a 3-week history of cough, fever, night sweats, and 7-kg weight loss. Approximately 6 weeks before this presentation, she was treated with infliximab and a 7-day course of amoxicillin-clavulanate. The patient complains of fatigue but is afebrile (37°C), with a normal resting respiratory rate. Laboratory studies revealed anemia (hemoglobin less than 8.7 g/dL [87 g/L or 5.40 mmol/L]). A chest x-ray taken 1-week ago is reported as normal.

*What information is suggestive that this patient may have an endemic fungal infection?*

*What is the most likely endemic fungal pathogen based on this patient's area of residence?*

be present in one-third of all active infections.[5] Enzyme-linked immunosorbent assays (ELISAs) have been developed for direct detection of *Histoplasma* antigens in serum and urine. Serial antigen testing can also provide a means for assessing response of histoplasmosis to antifungal therapy and detection of relapsing disease.[3]

## TREATMENT

**KEY CONCEPT** *The approach to antifungal therapy in patients with endemic fungal infections is determined by the severity of clinical presentation, the patient's underlying immunosuppression, and potential toxicities and drug interactions associated with antifungal treatment.* Immunocompetent patients with mild disease following exposure to *H. capsulatum* or *C. immitis* often experience a benign course of infection that does not require antifungal therapy. Persons of Filipino or African descent have a higher risk for dissemination with *C. immitis*, and this may

also be taken into consideration for more aggressive treatment.[5] Approximately 9% of patients exposed to coccidioidomycosis (defined by positive IgM or IgG serology) develop pneumonia requiring hospitalization, and 1% may develop infections of the CNS, which are difficult to treat if not incurable.[5]

Patients with mild disease may be initially followed in the outpatient setting with serial antigen or serologic studies to confirm resolving infection. Patients without clinical improvement within the first month can be treated with oral itraconazole for 6 to 12 weeks (Table 84–2).[3,5] Broader-spectrum triazoles such as voriconazole and posaconazole, and in the future possibly isavuconazole, appear to have clinically-useful activity against endemic fungi; but have limited data to recommend their routine first-line use. Fluconazole (400–800 mg/day) is somewhat less effective than itraconazole (higher relapse rates), but has fewer GI adverse effects and drug interactions versus itraconazole. Echinocandins and flucytosine are not clinically useful agents for the treatment of endemic mycoses.
