### Table 84–2

**Common Treatment Regimens for Endemic Fungal Infections**

| Mycosis | Recommended Treatment Regimens | Comments |
|---|---|---|
| **Histoplasmosis** | | |
| Mild to moderate | Observation or itraconazole 200 mg three times daily for 3 days, then two times daily for 6–12 weeks. | Fluconazole has a higher rate of relapse than itraconazole but is better tolerated by many patients than itraconazole. Echinocandins are not clinically effective against endemic mycoses. |
| | | Lipid formulations better tolerated than conventional formulations, especially for CNS disease. |
| | Fluconazole 12 mg/kg/day PO for 6–12 weeks adjusted for renal function.[a] | Patients initially treated with amphotericin B–based regimens are transitioned to itraconazole or fluconazole once they are clinically stable. |
| | | Corticosteroid therapy should be considered in hypoxic patients with acute pulmonary infection. |
| Severe including CNS disease or immunocompromised host | Amphotericin B 0.7 mg/kg/day IV or liposomal. Amphotericin B 3–5 mg/kg/day for 12 weeks or until clinically stable. | Itraconazole is less effective for CNS infections. |
| **Blastomycosis** | | |
| Mild to moderate | Itraconazole 200 mg three times daily for 3 days, then two times daily for 6–12 months. | Relapses are common in immunocompromised host. |
| Severe including CNS disease or immunocompromised host | Amphotericin B 0.7 mg/kg/day IV until patient is clinically stable, then Itraconazole (non-CNS) or fluconazole 12 mg/kg/day orally adjusted for renal function.[a] | |
| **Coccidioidomycosis** | | |
| Mild to moderate | Observation or itraconazole 200 mg three times daily for 3 days, then two times daily for 3–6 months. OR Fluconazole 6–12 mg/kg/day PO daily adjusted for renal function[a] for 3–6 months. | Itraconazole demonstrated trend toward superiority over fluconazole in a randomized controlled trial for progressive, nonmeningeal coccidioidomycosis; however, fluconazole is better tolerated than itraconazole. |
| Diffuse pneumonia or disseminated infection | Amphotericin B 1–1.5 mg/kg/day with dose and frequency decreased as improvement occurs. Patient then transitioned to triazole therapy. OR Lipid Amphotericin B formulations 3–5 mg/kg/day. Patient then transitioned to triazole therapy. | Fluconazole 800–1000 mg/day adjusted for renal function[a] is often recommended after initial AMB therapy for meningitis. |

CNS, central nervous system; IV, intravenous; PO, oral.

[a]CrCl more than 50–90 mL/min (0.83–1.50 mL/s), 100% of dose; CrCl 10–50 mL/min (0.17–0.83 mL/s), 50% of dose; CrCl less than 10 mL/min (0.17 mL/s) 50%.

Patients with progressive symptoms for longer than 2 weeks, greater than 10% weight loss, extensive pneumonia, or serologic titers greater than 1:8 of histoplasmosis or coccidioidomycosis are candidates for immediate antifungal therapy. Any patient with underlying immunosuppression should also receive immediate antifungal therapy. The following signs and symptoms are considered to be indicators of severe disease that require hospitalization and initial treatment with systemic amphotericin B (see Table 84–2).[3–5]

- Hypoxia indicated by a partial pressure of oxygen less than 80 mm Hg (10.6 kPa)
- Hypotension (systolic blood pressure less than 90 mm Hg)
- Impaired mental status
- Anemia (hemoglobin less than 10 g/dL [100 g/L or 6.2 mmol/L])
- Leukopenia (less than $1 \times 10^3/mm^3$ [$1 \times 10^9/L$])
- Elevated hepatic transaminases (greater than five times upper limit of normal) or bilirubin (greater than 2.5 times upper limit of normal)
- Coagulopathy
- Evidence of dissemination, including cutaneous manifestations
- Meningitis

All patients with blastomycosis require antifungal treatment, even though patients with mild disease can be managed as outpatients with oral itraconazole.[4] Patients with evidence of severe pulmonary disease or dissemination require initial treatment in the hospital with amphotericin B–based regimens until they are clinically stable, whereupon they can complete a 6- to 12-month treatment course as outpatients with oral triazoles.[4] Methylprednisolone (0.5–1 mg/kg daily IV) may be administered during the first 1 to 2 weeks of antifungal therapy if the patient develops respiratory complications, including hypoxemia or significant respiratory distress.

## OUTCOME EVALUATION

Response to antifungal therapy may be slow in patients with a prolonged history of infection or severe manifestations. However, gradual improvements in symptoms and reduction in fever are indicators of response to treatment. For histoplasmosis and coccidioidomycosis, decreasing antigen titers or serology are indicative of response to antifungal therapy.[3,5]

Antifungals used for the treatment of endemic mycoses can be associated with clinically significant drug interactions and toxicities, especially with the prolonged treatment courses that are often required for endemic mycoses. Itraconazole is available as a capsule formulation and as a cyclodextrin-solubilized solution.

---

**Patient Encounter 1, Part 2: Endemic Fungal Infection**

**Patient management**

The patient's serum titer for coccidiodiodomycosis returns as greater than 1:8. Based on the information presented, select an appropriate treatment plan for the patient's infection.

*Should the patient receive antifungal therapy at this time? What factors need to be considered?*

---

The liquid formulation of itraconazole has several advantages over the capsule: It has a better oral bioavailability and does not require the low gastric pH that is required for dissolution and absorption of the capsule. However, the oral solution is somewhat dilute, has an unpalatable aftertaste (an issue when taking months of therapy), and has a much higher rate of GI intolerance. Therefore, the capsule formulation is often preferred provided patients are not on acid-suppression therapy (ie, proton pump inhibitors, histamine antagonists, or antacids).

Posaconazole is formulated as a micronized suspension that is best absorbed when taken with high-fat meals and when taken in divided doses up to 800 mg/day. A delayed-release tablet formulation with improved bioavailability and fewer gastric pH-associated drug interactions has been introduced, and is probably the preferred oral treatment formulation in most patients unless the patient cannot swallow the tablet.[8] Absorption of voriconazole is not affected by gastric pH, but is generally administered 1 hour prior to or 2 hours after eating.

Drug interactions are an important concern in patients taking long-term triazole therapy. Itraconazole and voriconazole are substrates of the cytochrome P450 (CYP) 3A4 enzyme.[9] Coadministration of itraconazole, voriconazole, and to lesser extent fluconazole and posaconazole, with inducers of this CYP 3A4 (eg, rifampin, phenytoin, and phenobarbital) increases drug clearance resulting in ineffective plasma and tissue concentrations of the drug.[9] In general, coadministration of the broader spectrum triazoles (itraconazole, voriconazole, posaconazole) with these inducers must be avoided. Itraconazole, voriconazole, and posaconazole are also potent inhibitors of CYP 3A4, which predisposes these agents to a large number (estimated greater than 2000) of clinically significant pharmacokinetic drug–drug interactions.[9]

Posaconazole is also a substrate and inhibitor of P-glycoprotein, although the impact of this pathway on drug absorption or distribution into some anatomically protected sites such as the CNS is unknown.[10] Consequently, all patients should have their medication profile carefully reviewed prior to initiating and stopping triazole antifungals, preferably with the aid of a computerized drug-interactions database. Even in the absence of drug interactions, serum drug levels of the broader spectrum triazoles (itraconazole, voriconazole, posaconazole) are often unpredictable.[11] Serum drug concentration monitoring has been recommended in patients receiving triazole antifungals for documented infections, or when inadequate serum concentrations are suspected because of altered absorption, drug interactions. Suspected toxicities, especially CNS toxicity during voriconazole therapy, may also be indicative of excessive drug levels that can be detected by therapeutic drug monitoring (Table 84–3).

All azole antifungals carry the potential for rash, photosensitivity, and hepatotoxicity. In general, hepatotoxicity is mild and reversible, presenting as asymptomatic increases in liver transaminases, and less frequently increases in total bilirubin. Fulminant hepatic failure is less common and typically mediated by immunologic mechanisms. Therefore, serial monitoring of liver function is recommended in all patients receiving triazole antifungals. Long-term therapy with itraconazole has also been associated with reversible adrenal suppression and cardiomyopathy due to negative inotropic effects of the drug. Long-term therapy with voriconazole can be associated with severe phototoxic reactions and cutaneous erythema in sun-exposed skin, which may not be preventable with sunscreen alone. These reactions have been linked to development of squamous cell carcinoma or melanoma.[12] Patients should be instructed to avoid sun exposure while on voriconazole therapy and have frequent

**Table 84–3**

**Recommendations for Antifungal Therapeutic Drug Monitoring**

| Drug | Indication for Monitoring | Time of First Measurement | Target Conc. for Efficacy (mcg/mL or mg/L) | Target Conc. for Safety (mcg/mL or mg/L) |
|---|---|---|---|---|
| Flucytosine | Routine during first week of therapy, renal insufficiency, or poor clinical response | 3–5 days | Peak > 20 (155 μmol/L) | Peak < 50 (387 μmol/L) to reduce risk of marrow toxicity |
| Itraconazole | Routine during first week of therapy, GI dysfunction, suspected drug interactions | 4–7 days | Prophylaxis > 0.5 (0.7 μmol/L); therapy trough > 1–2 (1.4–2.8 μmol/L) | Some evidence to suggest trough greater than 4 (5.7 μmol/L) increased cardiac toxicity |
| Voriconazole | Lacking response, GI dysfunction, suspected drug interactions, pediatrics,[a] IV to oral switch, unexplained neurological changes | 4–7 days | Prophylaxis trough > 0.5 (1.4 μmol/L); therapy trough 1–2 (2.9–5.7 μmol/L) | Trough < 6 (17.2 μmol/L) to reduce risk of CNS toxicities |
| Posaconazole | Lacking response, GI dysfunction, potent acid suppression therapy (ie, proton pump inhibitor) therapy, suspected drug interactions | 4–7 days | Prophylaxis trough greater than 0.5 (0.7 μmol/L); therapy trough 0.5–1.5 (0.7–2.1 μmol/L) | Not established Delayed-release tablet formulation preferred for most patients because fewer pH drug interactions and improved bioavailibility |

[a]Pediatric patients display accelerated linear clearance of voriconazole. Therefore, higher daily voriconazole dosing (7 mg/kg every 12 hours) without a loading dose are recommended to achieve similar exposures to adults. Some children may require doses as high as 12 mg/kg every 12 hours to achieve similar serum drug exposures to adults. Therefore, therapeutic drug monitoring is recommended.

skin examinations by a dermatologist. Long-term voriconazole therapy may also predispose patients to periostitis (fluoride toxicity) that presents with nonspecific joint, shoulder and limb pain that can be diagnosed radiographically and with serum fluoride levels.[13] Alopecia, chapped lips and brittle nails, and cognitive difficulties have also been reported with longer-term voriconazole therapy, especially at higher doses.[14] Peripheral neuropathy may develop in 3% to 17% of patients on long-term triazole therapy, and is most frequently reported with itraconazole and voriconazole.[15]

Amphotericin B remains the mainstay of treatment of patients with severe endemic fungal infections. The conventional deoxycholate formulation of the drug can be associated with substantial infusion-related adverse effects (eg, chills, fever, nausea, rigors, and in rare cases hypotension, flushing, respiratory difficulty, and arrhythmias). As-needed premedication with low doses of hydrocortisone, acetaminophen, nonsteroidal anti-inflammatory agents, and meperidine are used to reduce acute infusion-related reactions. Venous irritation associated with the drug can also lead to thrombophlebitis; hence, central venous catheters are the preferred route of administration in patients receiving more than a week of therapy.

The most severe adverse effect associated with amphotericin B therapy is nephrotoxicity, which occurs through the renal vascular effects of the drug (constriction of the afferent arterioles in the kidney tubule) and direct toxicity to the kidney tubular membrane.[11] Generally, nephrotoxicity with amphotericin B is reversible provided the drug is stopped. However, treatment interruptions can be problematic in patients with severe infections. Precipitous decreases in glomerular filtration may occur in patients with marked dehydration or during aggressive diuresis. Infusion of normal saline before and after amphotericin B, a practice known as "sodium loading," can blunt precipitous decreases in renal perfusion pressure and slow the rate of decline in the glomerular filtration rate but may not be tolerated in patients with poor cardiac function. Administration of amphotericin B by continuous infusion reduces the nephrotoxicity of the drug but is generally not advocated because of unproven efficacy. Toxicity can be delayed by avoiding the use of other drugs with known tubular toxicity such as aminoglycosides, cyclosporine, cisplatin, or foscarnet. Generally, tubular toxicity manifests in patients with severe wasting of potassium and magnesium in the urine. Therefore, patient electrolytes must be carefully monitored and potassium and magnesium supplementation is always necessary. Hypokalemia and hypomagnesaemia frequently precede decreases in glomerular filtration (increased serum creatinine), especially in patients who are adequately hydrated.[16] Continued tubular damage eventually results in decreases in renal blood flow and glomerular filtration through tubuloglomerular feedback mechanisms that further constrict the afferent arteriole.

During the 1990s, amphotericin B was reformulated into three different lipid-based formulations (Abelcet, AmBisome, and Amphotec) that have reduced rates of nephrotoxicity compared with the conventional deoxycholate formulation (Fungizone). Two of the formulations (Abelcet and AmBisome) have lower rates of infusion-related reactions. Although these lipid formulations are generally considered to be as effective as conventional amphotericin B deoxycholate, they are not dosed equivalently to the standard formulation (see Table 84–2).

## PROPHYLAXIS

Primary prophylaxis, before development of infection, is generally not recommended for endemic fungi, but may be considered in specific situations, including the following:

1. Patients with HIV infection with CD4+ cell counts less than 150 cells/mm³ (150 × 10⁶/L) (histoplasmosis) or less than 250 cells/mm³ (250 × 10⁶/L)(coccidioidomycosis) living in regions with high endemic case rates (more than 10 cases per 100 patient-years), or in any patient with positive IgM or IgG antibodies. The recommended regimen is itraconazole 200 mg daily.

2. Secondary prophylaxis or suppressive therapy with itraconazole 200 mg daily is recommended to prevent recurrence of blastomycosis in immunosuppressed patients if immunosuppression cannot be reversed.[4]

3. In patients with prior CNS disease, fluconazole or voriconazole are preferred over itraconazole and posaconazole due to the lower penetration of itraconazole and posaconazole into the CNS.[5]

## OPPORTUNISTIC MYCOSES

**KEY CONCEPT** *Commensal or environmental fungi that are typically harmless can become invasive mycoses when the host immune defenses are impaired. Host immune suppression and risk for opportunistic mycoses can be broadly classified into three categories:*

1. *Quantitative or qualitative deficits in neutrophil function*

2. *Deficits in cell-mediated immunity*

3. *Disruption of the integument and/or microbiologic barriers*

Quantitative defects in neutrophils (neutropenia) resulting from neoplastic diseases, cytotoxic chemotherapy, marrow transplantation, or bone marrow aplasia are among the most common risk factors for opportunistic mycoses. Qualitative defects may be seen in certain disease states (eg, advanced diabetes mellitus and chronic granulomatous disease) or with high-dose corticosteroid therapy. Deficits in T-cell–mediated immunity associated with HIV infection, high-dose corticosteroid therapy, calcineurin inhibitors or other immunosuppressive drugs, chemotherapy, transplantation, bone marrow failure, and other immunodeficiencies have become increasingly prevalent with the prolonged survival of transplant patients or other chronically-immunosuppressed populations.

Immune deficits arising from disruption of the integument or GI/genitourinary barriers can also predispose patients to fungal infections. The most common types of barrier disruptions include surgery or infections/perforation of the abdominal viscus, use of central venous and urinary catheters, parenteral nutrition, and mucositis associated with cytotoxic chemotherapy and antibiotic therapy. Broad-spectrum antibacterial therapy disrupts the protective microbiologic flora of the gut, which allows overgrowth of *Candida* species that can translocate to the bloodstream and invade internal organs..

All of the opportunistic mycoses are difficult to diagnose and often must be treated empirically before diagnosis is proven. Deciding when to initiate antifungal therapy and what opportunistic pathogens to cover is a decision governed largely by the *cumulative* immune deficits of the host, local epidemiology and experience, or clinical or diagnostic clues suggestive of incipient infection.

## INVASIVE CANDIDIASIS

### EPIDEMIOLOGY AND ETIOLOGY

*Candida* species are the most common opportunistic fungal pathogens encountered in hospitals, ranking as the third to fourth most common cause of nosocomial bloodstream infections in the United States.[17] The incidence of nosocomial candidiasis has increased steadily since the early 1980s, with the widespread use of central venous catheters, broad-spectrum antimicrobials, and other advancements in the supportive care of critically ill patients. In the 1980s, *C. albicans* accounted for more than 80% of all bloodstream yeast isolates cultured from patients. By the late 2000s, this relative frequency of *C. albicans* had decreased to less 50% in national surveys of bloodstream infections with increasing proportion of infections caused by non-*albicans* species.[17,18] Because of the inherent resistance (eg, *C. krusei*) or diminished susceptibility (eg, *C. glabrata*) of many the non-*albicans* species, the introduction of fluconazole in the early 1990s is often cited as the key element driving the shift in the microbiology of invasive candidiasis. Nevertheless, other factors, including central venous catheters, higher intensity of cytotoxic/mucotoxic chemotherapy, and broad-spectrum antibiotic therapy have also contributed to this trend. **KEY CONCEPT** *Familiarity with the local epidemiology and frequency of non-albicans Candida species in the institution or intensive care unit (ICU) is essential before selecting empiric antifungal therapy for invasive candidiasis, as fluconazole is not recommended for the treatment of C. glabrata and C. krusei infections, and echinocandin-resistance among* C. glabrata *is increasing in some centers.*

### CLINICAL PRESENTATION AND DIAGNOSIS

Invasive candidiasis encompasses several infectious syndromes broadly categorized as candidemia or deep-seated infections (infections of tissue sites beneath mucosal surfaces).[19] Approximately one-third of all patients with invasive candidiasis fall within three groups at the time of diagnosis: (1) patients with uncomplicated candidemia in the absence of deep-seated candidiasis; most frequently arising from an infected catheter; (2) candidemia associated with deep-seated candidiasis, most frequently arising from the gastrointestinal tract or secondary seeding from a separate infection site; and (3) deep-seated candidiasis without candidemia.[20]

Focal deep-seated invasive candidiasis can involve virtually any organ, even following apparently uncomplicated catheter-related bloodstream infections. The most common sites of infection are the kidney, eye, and bone. *Candida* in the urine can be an indication of renal candidiasis or an obstructing fungus ball; however, it must be distinguished from more benign colonization of the urinary tract, especially in patients with chronic indwelling urinary catheters.[21] Similarly, *Candida* species isolated for respiratory samples (sputum, bronchoalveolar lavage) are indicative of colonization, and almost never reflect true pneumonia, which is an uncommon clinical entity. All patients with candidemia should undergo an eye examination to rule out *Candida* endophthalmitis, which can be sight threatening if not recognized early and may require direct installation of antifungal therapy for adequate treatment.[21]

Invasive candidiasis is most frequently diagnosed by blood culture, which probably identifies the majority of patients with candidemia alone, fewer patients with mixed of deep-seated disease and intermittent candidemia, and virtually no patients who have infection limited to deep tissues at the time of culture.[20] As a result, half of all episodes of invasive candidiasis are not detected by blood cultures alone. Therefore, a negative blood culture cannot rule out the possibility of invasive candidiasis, especially in patients with multiple underlying risk factors for the infection. The development of new diagnostic tools that do not exclusively rely on microbiological isolation of *Candida* has become a major research focus for improving diagnosis of the infection, especially deep-seated disease.[20]

Novel serodiagnostic tests have been developed for the detection *Candida* cell wall antigens, or nucleic acids of *Candida*

species, in the hope of improving the detection of invasive disease missed by blood cultures. Currently, the most frequently used test is the Fungitell (1→3)-β-D-glucan test, Associates of Cape Cod Inc.). False-positive results may occur, however, in patients with gram-negative bacteremia, certain gauze dressing or dialysis membranes, or patients heavily colonized with *Candida* species.

Laboratory identification of *Candida* in clinical samples must be performed to the species level whenever possible, as *Candida* species differ considerably in their susceptibility to antifungal agents.[21] Rapid discrimination of *C. albicans* from common non-albicans *Candida* species can be accomplished by the germ-tube test, which presumptively identifies *C. albicans* by the early formation (less than 4 hours) of a hyphae-like structure when the yeast is incubated in serum at 37°C (98.6°F). Definitive species identification, however, may require an additional 48 to 72 hours after the organism is isolated on agar, but can be accelerated with fluorescent in situ hybridization (FISH) of *Candida* species-specific DNA sequences. Matrix-assisted laser desorption/ionization time of flight (MALDI-TOF) and magnetic-resonance based technologies have shown some promise in the early identification of *Candida* species in whole blood specimens in as little as 3 hours, which could shorten the time to earlier diagnosis.

*C. albicans* remains the most common cause of invasive candidiasis and is the most virulent of *Candida* species, but is the most susceptible to commonly used antifungals including fluconazole.[17,21] Like *C. albicans*, *C. tropicalis* is a relatively virulent species associated with the highest mortality rates,[17,22] but has similar susceptibility profiles as *C. albicans*. *C. parapsilosis* is a less virulent species seen frequently in neonates and in adults with central venous catheters. However, many *C. parapsilosis* isolates form thick biofilms on prosthetic materials and catheters that make the organism difficult to eradicate.[17] *C. parapsilosis* is generally susceptible to most antifungals, including fluconazole, although mean inhibitory concentrations (MICs) for echinocandins are higher than for other *Candida* species. *C. krusei* is considered to be uniformly resistant to fluconazole, although most isolates retain susceptibility to voriconazole and posaconazole.

### Patient Encounter 2, Part 1: Invasive Candidiasis

A 44-year-old man recovering in the surgical ICU following a ruptured appendix and diffuse peritonitis develops fever while receiving broad-spectrum antibacterial therapy (meropenem 1 g every 8 hours and linezolid 600 mg every 12 hours). The patient has a central venous catheter and a Foley catheter. Blood cultures are negative at the time, but the patient has yeast growing in the sputum and urine. A serum (1→3)-β-D-glucan test is positive at 80 pg/mL (80 ng/L). Laboratory studies reveal a white blood cell count of 11,500 cells/mm³ (11.5 × 10⁹/L).

*What are this patient's risk factors for developing an invasive fungal infection?*

*What evidence suggests this patient has an invasive fungal infection despite negative blood cultures?*

*If antifungal therapy is empirically started in this patient, what information should be considered?*

*C. glabrata* has become a common cause of breakthrough infection on fluconazole prophylaxis, and increasingly during treatment with echinocandins. Although *C. glabrata* is generally less virulent than other *C. albicans*, infections with this organism are typically seen in older patients with poor performance status, and therefore mortality remains high. The marginal susceptibility of *C. glabrata* to fluconazole and increasing echinocandin resistance fueled a growing clinical need for susceptibility testing of this species, as some isolates may demonstrate resistance to multiple antifungal classes.[23,24] Generally, fluconazole-resistant strains of *C. glabrata* should be assumed to be cross-resistant to other triazoles.

## TREATMENT

Six antifungals (amphotericin B, fluconazole, voriconazole, caspofungin, micafungin, and anidulafungin) have been studied as monotherapy in prospective, randomized comparative clinical trials for the treatment of invasive candidiasis. In a patient-level meta-reanalysis of these trials, increasing patient age, increasing APACHE II score, use of immunosuppressive therapy, and infection with *Candida tropicalis* were independent risk factors for patient mortality.[25] On the other hand, removal of central venous catheters in patients with candidemia and treatment with an echinocandin were variables associated with reduced patient mortality. Based on these findings and treatment guidelines endorsed by the Infectious Diseases Society of America,[21] echinocandins are recommended as the preferred initial treatment for invasive bloodstream candidiasis, even less "critically-ill" patients.[26] Timely initiation of antifungal therapy for invasive candidiasis is critical, as any delay in the initiation of antifungal therapy once a patient has a positive blood culture increases the potential for metastatic seeding of organs and mortality. Clinically stable patients can be transitioned to oral fluconazole or other triazoles once the infecting isolate has been identified and susceptibility is known.[27]

The efficacy of echinocandins for deep-tissue candidiasis is less well established compared to bloodstream infections, and higher failure rates have been reported for infections located in anatomical sites where echinocandin penetration is limited (ie, meninges, endophthalmitis, urine).[10] For other forms of deep tissue candidiasis, triazoles or lipid amphotericin B formulation may be preferable as initial therapy until diagnosis and culture results are available, depending on the suspected organs involved and the clinical severity of illness.[21] Frequently patients are transitioned to oral triazole therapy once stable because of the long-treatment courses that are often required (4–6 weeks minimum) for deep-seated infections.

Another important caveat for empiric use of echinocandins is that cryptococcosis, endemic fungi, or other rare yeast (eg, *Trichosporon* species) occasionally produce fungemia in lymphopenic patients that may initially be mistakenly assumed to be *Candida*. Therefore, initial treatment with a lipid amphotericin B formulation may be judicious in profoundly lymphopenic patients (i.e., CD4⁺ less than 250/mm³ [250 × 10⁶/L]) with yeast in blood cultures until fungal identification is confirmed, as echinocandins have poor activity against non-*Candida* yeast.

Echinocandins (ie, caspofungin, micafungin, or anidulafungin); voriconazole; or lipid amphotericin B formulation are often administered as empiric treatment for *Candida* spp in patients with prolonged neutropenia (ie, absolute neutrophil count less than 500 PMN/mm³ [500 × 10⁶/L] for greater than 7 days) with fever.[21,28] Fluconazole may be an acceptable option

| Table 84–4 |
| --- |

**Therapeutic Approach to Opportunistic Invasive Fungal Infections**

| Mycoses | Recommended Treatment Regimens | Comments |
| --- | --- | --- |
| **Candidiasis** | | |
| Catheter-related and acute hematogenous | Fluconazole 12 mg/kg loading dose, then 6–12 mg/kg/day IV every 24 hours adjusted for renal function[a] OR Echinocandin[b] OR Voriconazole 6 mg/kg every 12 hours IV for 1 day, then 3 mg/kg every 12 hours IV *Second line:* Lipid amphotericin B formulation 3–5 mg/kg /day[c] OR Amphotericin B 0.7 mg/kg/day IV OR Amphotericin B + fluconazole | Treat for 14 days after the last positive blood culture and resolution of signs and symptoms; catheter should be removed whenever possible Patients can be switched to oral fluconazole when clinically stable if isolate is susceptible Echinocandins and amphotericin B are preferred agents for fluconazole-resistant species. Voriconazole appears to be effective against fluconazole-resistant *C. krusei* |
| Empirical therapy in neutropenic patient | Fluconazole 6–12 mg/kg/day (low risk) adjusted for renal function[a] OR Liposomal amphotericin B 3 mg/kg every 24 hours OR Echinocandin OR Amphotericin B 0.7 mg/kg every 24 hours | Antifungals with coverage of *Aspergillus* should be used in higher risk patients or prolonged neutropenia (ie, longer than 2 weeks) |
| Urinary candidiasis | Fluconazole 200 mg IV or orally for 7–14 days OR Amphotericin B 0.3 mg/kg/day IV for 1–7 days | Asymptomatic candiduria does not require therapy |
| **Cryptococcosis** | | |
| **Pulmonary-Isolated** | Fluconazole 6 mg/kg/day IV or PO for 6–12 months adjusted for renal function[a] | |
| **Severe Pulmonary Infection and Meningitis** | *Induction:* Amphotericin B 1 mg/kg/day + flucytosine 100 mg/kg/day orally divided every 6 hours for 2 weeks adjusted for renal function[c] *Consolidation:* Fluconazole 6–12 mg/kg/day for 10 weeks adjusted for renal function[a] *Second line:* Fluconazole + flucytosine for 2 weeks, then fluconazole for 10 weeks adjusted for renal function[a,c] OR Amphotericin + fluconazole for 2 weeks, then fluconazole for 10 weeks adjusted for renal function[a] OR Liposomal amphotericin B 5 mg/kg/day for 2 weeks, then fluconazole for 10 weeks adjusted for renal function[a] | Therapeutic drug monitoring is required for safe use of flucytosine, see Table 84–3 Echinocandins have no activity against cryptococci Use of flucytosine-amphotericin B combination therapy was associated with faster CSF sterilization and improved survival. Similar benefits were not observed with combination fluconazole-amphotericin B regimens |

[a]Fluconazole renal dosing adjustments: CrCl greater than 50–90 mL/min (0.83–1.50 mL/s), 100% of dose; CrCl 10–50 mL/min (0.17–0.83 mL/s), 50% of dose; CrCl less than 10 mL/min (0.17 mL/s) 50%.

[b]Anidulafungin 200 mg loading dose day 1, then 100 mg daily, caspofungin 70 mg loading dose day 1, then 50 mg daily; or micafungin 100 mg daily.

[c]Flucytosine renal dosing adjustments: CrCl greater than 50–90 mL/min (0.83–1.50 mL/s), 25 mg/kg every 12 hours; CrCl 10–50 mL/min (0.17–0.83 mL/s), 25 mg/kg every 12–24 hours; CrCl less than 10 mL/min (0.17 mL/s) 25 mg/kg every 24 hours. Therapeutic drug monitoring is required for safe use of flucytosine (see Table 84–3).

in patients expected to have short duration of neutropenia (less than 2 weeks) not receiving systemic antifungal prophylaxis with a triazole. Lipid amphotericin B formulations, an echinocandin, or voriconazole are preferred if the patient has or is expected to have prolonged neutropenia (ie, greater than 2 weeks) because of the increased risk for mold infections. If patients are receiving fluconazole prophylaxis, breakthrough infections with *C. glabrata,* and less frequently *C. krusei,* are possible and should be initially treatable with an echinocandin or amphotericin B.

Urinary candidiasis is a term for an ill-defined group of syndromes that can range from benign colonization (candiduria) in the bladder to invasive disease of the renal parenchyma. Asymptomatic candiduria in nonneutropenic patients does not require antifungal therapy, as transient clearance of *Candida* from the urine of asymptomatic patients has no demonstrable clinical benefit.[21] Patients should receive 7 to 14 days of antifungal therapy for urinary candidiasis if they are (a) symptomatic, (b) have clinical or laboratory evidence of infection, (c) are neutropenic, (d) are low-birth-weight infants; (e) will undergo urologic manipulations, or (f) have renal allografts. Removal of urinary tract instruments, including Foley catheters and stents, is essential to prevent relapse. The preferred therapy is fluconazole 200 mg daily, although IV amphotericin B deoxycholate 0.3 to 1 mg/kg/day is also effective. Other antifungal agents (with the exception of flucytosine) do not achieve appreciable concentrations in the urine and therefore should not be considered first-line treatments for urinary candidiasis.[10] Irrigation with amphotericin B is not effective for infections above the bladder and should not be used in higher risk patients with the exception of its use as a diagnostic tool for confirming a localized infection of the bladder. *Candida* infections of the renal parenchyma secondary to metastatic seeding from the bloodstream are treated in a similar fashion to candidemia.

Mucocutaneous candidiasis is not invasive and can be treated with topical azoles (clotrimazole troches), oral azoles (fluconazole, ketoconazole, or itraconazole), or oral polyenes (such as nystatin or oral amphotericin B). Orally administered and absorbed azoles (ketoconazole, fluconazole, or itraconazole solution), amphotericin B suspension, IV echinocandins, or IV amphotericin B are recommended for refractory or recurrent infections.[17]

Although more severe than mucocutaneous candidiasis, esophageal candidiasis typically does not evolve into a life-threatening infection unless the esophagus is ruptured. However, topical

**Patient Encounter 2, Part 2: Invasive Candidiasis**

The patient was started on fluconazole 400 mg/day, but 4 days later has persistent fever and develops hypotension and decreased urine output. Blood cultures are now growing a germ tube–negative yeast. Laboratory studies revealed a white blood cell count of 14,200/mm³ (14.2 × 10⁹/L), aspartate aminotransferase 68 IU/L (1.13 μkat/L), alanine aminotransferase 75 IU/L (1.25 μkat/L), alkaline phosphatase 168 IU/L (2.80 μkat/L), and normal bilirubin. Serum creatinine has increased from 1.2 to 1.8 mg/dL (106–159 μmol/L) over the last 3 days.

*What factors suggest empiric antifungal therapy should be changed in this patient?*

*What other procedures should be recommended in this patient to improve management and response to antifungal therapy?*

therapy is ineffective. Triazole antifungals (fluconazole, itraconazole solution, or voriconazole), echinocandins, or IV amphotericin B (in cases of unresponsive infections) are effective treatment options. Parenteral therapy should be used in patients who are unable to take oral medications.[17]

## OUTCOME EVALUATION

Response to antifungal therapy in invasive candidiasis is often more rapid than for endemic fungal infections. Resolution of fever and sterilization of blood cultures are indications of response to antifungal therapy with the caveat that the growth of *Candida* from blood cultures is often delayed by 48 to 72 hours. Adverse effects associated with antifungal therapy are similar in these patients as described earlier, except some toxicities may be more pronounced in critically ill patients with invasive candidiasis. Nephrotoxicity and electrolyte disturbances with amphotericin B can be especially problematic and may not be avoidable even with lipid amphotericin B formulations. Therefore, current treatment guidelines favor less-toxic treatment options, such as the echinocandins, especially in higher-risk patients. Decisions to use one class of antifungal agents over the other are principally driven by concerns of non-*albicans* species, patient tolerability, or history of prior fluconazole exposure (risk factor for non-*albicans* species.) and local susceptibility patterns; especially institutional rates of fluconazole (triazole) and echinocandin-resistance.

## PROPHYLAXIS

Fluconazole (400 mg/day) has been studied as a prophylactic regimen to prevent invasive candidiasis in patients with prolonged (greater than 2 weeks) neutropenia.[21] Placebo-controlled, prospective randomized trials performed in the 1990s demonstrated that fluconazole was effective in reducing the frequency, morbidity, and, in some trials, mortality due to invasive candidiasis in neutropenic patients if administered until marrow recovery. However, the major limitation with fluconazole is its lack of mold coverage needed for high-risk patients with prolonged (ie, greater than 3 weeks) neutropenia.[28] Itraconazole, voriconazole, posaconazole, and the echinocandin micafungin have demonstrated a benefit in reducing the incidence of invasive candidiasis when used for prophylaxis in hematopoietic cell transplant recipients until engraftment; however, all of the drugs have limitations with respect to prolonged administration in high-risk patients. Therefore, the approach toward antifungal prophylaxis is highly institution-specific depending on the patient population, epidemiology of invasive fungal infections, and options for outpatient IV drug therapy.

Use of antifungal prophylaxis for invasive candidiasis in non-neutropenic patients remains an area of controversy. Fluconazole prophylaxis can reduce the incidence but not necessarily mortality associated with invasive candidiasis in select high-risk transplant populations (eg, liver, pancreatic, or small-bowel transplantation) or subsets of ICU patients at high risk for infection (ie, neonatal intensive care).[21] However, prophylaxis can result in excessive antifungal use in lower-risk patients; therefore, many experts have advocated preemptive (ie, starting therapy based on biomarkers of infection such as serum β-glucan) or empirical (symptoms of infection) treatment approaches in this population in lieu of prophylaxis.

Nevertheless, a multi-institutional prospective randomized trial of administering empirical fluconazole (800 mg/day versus placebo) in ICU patients with persistent fever, did not demonstrate significant benefits in reducing the incidence or mortality associated with invasive candidiasis.[29] Similarly, a recent multi-institutional study that focused on ICU patients identified as "high risk" for invasive candidiasis using a validated clinical risk prediction score failed to demonstrate significant reductions in the incidence or mortality of invasive candidiasis with caspofungin prophylaxis.[30] However, patients who were treated with an echinocandin after developing a positive serum β-glucan appeared to have lower rates of progression to documented invasive candidiasis. Therefore, many questions persist regarding the optimal approach for preventing or preemptive treating invasive candidiasis in non-neutropenic ICU patients.

## CRYPTOCOCCOSIS

### EPIDEMIOLOGY

*Cryptococcus neoformans* is an encapsulated yeast that can infect apparently normal hosts but is more frequently associated with severe infections in immunocompromised patients. *C. neoformans* is divided into two varieties based on serotype: *C. neoformans* var. *neoformans* (serotypes a and d) that is associated with infections in immunocompromised patients, and *C. neoformans* var. *gattii* (serotypes b and c) that is associated with infections in healthy hosts. *C. neoformans* var. *gattii* is found predominantly in tropical and subtropical climates with eucalyptus trees, and has been linked to infectious outbreaks around Vancouver Island and the US Pacific Northwest. *C. neoformans* var. *neoformans* is found worldwide and is associated with pigeon droppings and other avian excreta. Before the AIDS pandemic, cryptococcosis was a relatively uncommon disease, but became a leading cause of meningitis among HIV-infected patients. Although the incidence of this infection has declined in developed countries with the widespread use of highly active antiretroviral therapy (HAART), *C. neoformans* remains an important pathogen in the developing regions with high rates of AIDS and also in immunocompromised patients, including transplant and cancer patients who may present with initially indolent pulmonary forms of the infection.

### CLINICAL PRESENTATION AND DIAGNOSIS

*C. neoformans* is acquired primarily through inhalation of the desiccated yeast particles found in the environment. Inhaled cells reach distal alveolar spaces where they gradually rehydrate and form their characteristic polysaccharide capsules that enable resistance to phagocytosis. Defects in cellular immunity allow reconstitution of the protective capsule and multiplication of yeast in the lungs. Although alveolar macrophages phagocytose the yeast, containment and killing require a coordinated response between innate and adaptive humoral (complement and anti-cryptococcal antibodies) and T-cell–mediated host responses.[6] Deficiencies in cell-mediated immunity allow the yeast to survive as a facultative intracellular pathogen in macrophages as they migrate from the lung to draining lymph nodes, leading to dissemination via the bloodstream to the meninges.

Unlike most opportunistic fungi, true virulence factors have been identified for *C. neoformans*. The capsules, including the soluble polysaccharides released from the yeast cells during infection, impair phagocytosis and binding of anticryptococcal antibodies. Primary cryptococcal infection begins in the lung, presenting as a mildly symptomatic or asymptomatic infection

that resolves spontaneously or undergoes encapsulation in non-calcified lung nodules. It is common for these isolated nodules to be detected on chest x-rays during routine workup. Diagnosis of primary cryptococcosis is only made if the nodule is aspirated or removed because of concerns of primary lung cancer.

In the immunocompromised host, infection of the lung may present with more diffuse, bilateral, and interstitial disease that mimics the presentation of *P. jiroveci (carinii)* pneumonia (PCP). Dissemination to other organs, particularly the CNS, eye, and possibly the skin, is more likely to occur in patients with severe deficits in cell-mediated immunity. Fever, cough, dyspnea, and pleural pain are common at presentation, with accompanying hypoxemia that can rapidly evolve to acute respiratory failure. Because the features of diffuse pulmonary cryptococcosis overlap with other opportunistic pathogens, early diagnosis requires bronchoalveolar lavage or transbronchial biopsy, which can effectively diagnose 80% to 100% of cases.[31] The clinical course of diffuse cryptococcal pneumonia can be as severe as PCP, with mortality rates approaching 100% in untreated patients by 48 hours.

*C. neoformans* readily disseminates from the lung to the CNS, specifically the leptomeninges, and occasionally the parenchyma of the brain. The clinical characteristics of cryptococcal meningitis differ somewhat, however, between patients with and without underlying AIDS. In patients without AIDS, disease presentation is more insidious, and symptoms such as dizziness, irritability, decreased comprehension, and unstable gait may present many weeks to months before the diagnosis is established.[31] Patients with AIDS generally present much later in the course of disease with severe meningoencephalitis.[31] The most common signs and symptoms on presentation are fever, headache, **meningismus**, photophobia, mental status changes, and seizures. CT or more sensitive MRI may reveal cerebral edema, multiple areas of enhanced nodules, or a single mass lesion (cryptococcoma). Examination of the cerebrospinal fluid (CSF) often reveals increased opening pressure upon lumbar puncture, but glucose, protein, and leukocyte levels can be normal.[31]

## LABORATORY DIAGNOSIS

Clinical diagnosis is confirmed by cultures from the blood, CSF, or other clinically relevant fluids or tissue. *C. neoformans* can be directly visualized in the CSF when stained with India Ink, which is excluded by the yeast capsule (**Figure 84-3B**). However, infection is most frequently diagnosed (Figure 84–3B), by detection of cryptococcal antigen in either serum or CSF, which has high sensitivity and specificity (greater than 95%) and correlated with fungal burden.[31] A positive serum antigen test of greater than 1:4 strongly suggests cryptococcal infection, and greater than or equal to 1:8 is indicative of active disease. Antigen titers in serum are positive in 99% of patients with cryptococcal meningitis and typically exceed titers of 1:2048 in patients with AIDS.[31] However, the time course of cryptococcal antigen elimination is unknown, and a positive test result can persist for many years. Changes in the CSF cryptococcal antigen titers have limited value in the monitoring of drug therapy for cryptococcal meningitis, although it is expected that a decrease should be seen after 2 or more weeks of antifungal therapy.[31]

## TREATMENT

Cryptococcal meningitis is fatal if left untreated. Because pneumonia frequently precedes dissemination of disease and

**FIGURE 84–3.** Opportunistic mycoses in clinical samples. **(A)** Candidiasis (tissue). **(B)** Cryptococcosis (India ink stain of CSF). **(C)** Aspergillosis (tissue). **(D)** Mucormycosis (tissue).

subsequent meningitis, all patients with culture-, histopathology-, or serology-proven disease should receive antifungal therapy. In patients with isolated pulmonary cryptococcosis, fluconazole is generally considered to be the therapy of choice (see Table 84–2).[31] Alternatively, itraconazole, voriconazole, or combination therapy (fluconazole plus flucytosine) has also been used with some success, but these regimens are generally considered inferior to amphotericin B and are recommended only for persons unable to tolerate or unresponsive to standard treatment. Echinocandins do not have activity against *C. neoformans*.

Disseminated or CNS cryptococcosis requires a more aggressive treatment approach. Pretreatment predictors of poor outcome with antifungal therapy include the following:

- Progressive underlying disease or immune dysfunction
- Abnormal mental status at the time of presentation
- Increased opening pressure on lumbar puncture (greater than 260 mm $H_2O$ [2.55 kPa])
- High fungal burden as reflected by a CSF antigen titer (in AIDS patients) of greater than 1:2048

Clinical trials performed by the National Institute of Allergy and Infectious Diseases (NIAID) Mycoses Study Group defined the standard treatment regimen for cryptococcal meningitis consisting of 2 weeks of induction antifungal therapy with combination amphotericin B (0.7 mg/kg/day) plus flucytosine (100 mg/kg/day) for cryptococcal meningitis, followed by consolidation therapy with fluconazole (400 mg daily) for 8 weeks (see Table 84–2).[31] However, other combinations of either fluconazole plus flucytosine, or fluconazole plus amphotericin B were sometimes recommended due difficulties in obtaining flucytosine (especially in developing countries) and toxicity (see Table 84–2).

**KEY CONCEPT** *In a landmark study addressing which combination is best for cryptococcal meningitis, there were significantly fewer deaths in patients receiving amphotericin B plus flucytosine versus patients receiving amphotericin B alone or a combination of amphotericin B plus fluconazole.*[32] Notably, the amphotericin B–flucytosine combination was associated with more rapid clearance of yeast from the CSF versus other regimens.

## PROPHYLAXIS

Fluconazole (200 mg/day) is recommended as maintenance therapy for life in patients with persistent underlying immune dysfunction to prevent recurrent cryptococcal meningitis.[31] Available data suggest it is safe to discontinue maintenance therapy in AIDS patients who have had a sustained immunologic response on effective antiretroviral therapy (ie, CD4+ count greater than 100 cells/microliter ($100 \times 10^6$/L) with undetectable or very low viral RNA) if they have received at least 12 months of antifungal therapy.[31] Occasionally, initiation of HAART can result in the reactivation of a subclinical, immunologic manifestation of cryptococcal infection (or other opportunistic infections). Manifestations of this *immune reconstitution inflammatory syndrome* (IRIS) may include exacerbations of meningitis or necrotizing pneumonia. Antifungal therapy plus a nonsteroidal anti-inflammatory agent or prednisone has been used successfully in patients with cryptococcal-associated immune reconstitution syndrome.[33] However, the optimal management of this recently defined clinical entity remains unknown.

## INVASIVE ASPERGILLOSIS

### EPIDEMIOLOGY

Invasive molds, particularly *Aspergillus* species, are a common complication of intensive cancer chemotherapy required for hematologic malignancies, and prolonged immunosuppression following hematopoietic and solid organ transplantation. Four species are commonly associated with invasive infection: *Aspergillus fumigatus*, *Aspergillus flavus*, *Aspergillus terreus*, and *Aspergillus niger*. Of these four species, *A. fumigatus* accounts for

most of human infections. However, identification of *Aspergillus* mold in culture to the species level is still essential because the incidence of amphotericin B–resistant *Aspergillus terreus* and *Aspergillus flavus* have increased in some centers over the last 10 years. Additionally, less common mold infections such as fusariosis and mucormycosis often present with similar clinical features aspergillosis, but require different treatment approaches due to their inherent resistance to many antifungal agents. Early and accurate diagnosis of invasive aspergillosis (IA) improves the outcome of infection, reducing mortality rates by 30% to 50% with the timely administration of effective antifungal therapy.[34]

### CLINICAL PRESENTATION AND DIAGNOSIS

The pathogenesis of IA is defined largely by the underlying immune dysfunction of the host. The most common route of acquisition for *Aspergillus* is through the respiratory tract. Conidia dispersed in air currents are continuously inhaled through the sinuses and mouth and penetrate down to distal alveolar spaces (see **Figure 84–4**). Most conidia are rapidly phagocytosed and removed by resident macrophages and neutrophils in the upper and lower respiratory tract.[6] However, macrophage function may be suppressed following transplantation, cytotoxic chemotherapy, or in patients who have received high-dose corticosteroid therapy. Conidia that escaped phagocytosis begin to germinate into hyphal forms that invade blood vessels or contiguous tissues or bone (in sinuses), resulting in hemorrhage and/or infarction and coagulative necrosis. Once in the bloodstream, viable hyphal fragments can break off and disseminate to distal organs including the brain. Control of the infection at this stage requires development of an adaptive TH1 or TH17 response to enhance the fungicidal activity of professional effector cells (ie, neutrophils) against hyphal elements.[6]

Hyphae break off and disseminate via the bloodstream

**FIGURE 84–4.** Pathogenesis of invasive aspergillosis (IA).

Patients with dysregulated, suppressed T-cell–mediated immunity or prolonged neutropenia are unable to control fungal growth and are at high risk for dissemination of the infection. Without early diagnosis and antifungal therapy, IA in persistently immunosuppressed patients is uniformly fatal.

Signs and symptoms of IA are predictably muted in the immunocompromised host. Fever is common but nonspecific for infection and may be accompanied by pleuritic chest pain, cough, hemoptysis, and/or friction rub.[34] Neurologic signs, including seizures, hemiparesis, and stupor, may be present in patients with dissemination to the brain. Cutaneous plaques or papules characterized by a central necrotic ulcer or eschar occur in up to 10% of patients with disseminated disease; however, concomitant blood cultures are often negative. Chest radiographs cannot detect early forms of disease and may remain negative in up to 10% of patients within 1 week of death. Nodular lesions detected by high-resolution computed tomography (HRCT) scans, along with fever, are often the first indication of invasive pulmonary aspergillosis in severely immunocompromised patients. Typically these radiographs reveal wedge-shaped or nodular lesions, surrounded by intermediate attenuation called the "halo sign" (**Figure 84–5**). These early lesions on CT scans represent hemorrhage and edema surrounding an infarcted blood vessel. Despite "effective" antifungal therapy, lesions on CT scan may continue to increase in size in neutropenic patients until neutrophil counts recover, at which time they begin to cavitate, forming the "air-crescent sign" on chest radiographs, indicative of resolving infection. **KEY CONCEPT** *Immunocompromised patients on fluconazole with progressive sinus or pulmonary disease by radiography should be considered to have a possible mold infection and receive empiric antifungal therapy directed (at minimum) against Aspergillus species.*[40]

## LABORATORY DIAGNOSIS

Like other invasive mycoses, definitive diagnosis of aspergillosis requires histopathologic evidence of hyphal invasion in tissue (see Figure 84–3). However, procedures needed to establish a definitive diagnosis by sampling of suspicious lesions (eg, fine-needle aspiration or thoracoscopic lung biopsy) are not feasible in many patients with underlying thrombocytopenia secondary to hematologic malignancies or chemotherapy. Even if hyphae are observed in tissue, histopathology alone cannot distinguish *Aspergillus* from other angioinvasive septate molds, such as *Fusarium*, which have different patterns of antifungal susceptibility (see Table 84–1). Therefore, respiratory and/or wound

---

**Patient Encounter 3: Invasive Mold Infection**

A 52-year-old man with acute myeloid leukemia who received a matched-allogeneic donor hematopoietic stem-cell transplantation presents to the clinic 70 days after transplant with complaints of fever. On laboratory examination, he is noted to have an alanine aminotransferase of 119 IU/L (1.98 μkat/L), aspartate aminotransferase 107 IU/L (1.78 μkat/L), and total bilirubin of 1.8 mg/dL (31 μmol/L). The patient has an absolute neutrophil count of 970 (970 × 10^6/L). His current medications include tacrolimus 5 mg twice daily (most recent level: 9 ng/mL [9 mcg/L; 11 nmol/L]), prednisone 10 mg daily, levofloxacin 500 mg daily, fluconazole 200 mg/day, valacyclovir 500 mg twice daily. A CT scan of the chest reveals a single dense pleural-based lung nodule in the left lung. A serum galactomannan test is reported to be negative (index 0.4, positive when greater than 0.5). The primary service wishes to start voriconazole.

*What are the patient's risk factors and signs that suggest he has an invasive fungal infection?*

*What problems need to be anticipated in this patient if voriconazole is started?*

*If the patient's infection appears to resolve and he continues to take voriconazole for months while tapering immunosuppression, what are some of the toxicities potentially associated with prolonged voriconazole therapy?*

---

cultures (if cutaneous or sinus/hard palate lesions are present) are important factors in the modification of empiric antifungal therapy.

Respiratory cultures, including sputum, bronchial washings, or bronchoalveolar lavage have a low sensitivity for diagnosis of IA but a high positive predictive value in immunocompromised patients. Therefore, a negative bronchoalveolar lavage culture does not rule out invasive pulmonary aspergillosis, but a positive culture in a high-risk patient (eg, allogeneic hematopoietic cell transplant patients) indicates pulmonary aspergillosis in at least 60% of such patients. Blood cultures have little diagnostic value for IA, but may reflect true disease with *A. terreus.* Patients with limited lung involvement or on prophylactic or empiric antifungal therapy may continue to be culture-negative for *Aspergillus* species, despite the appearance of progressing disease.[34] Therefore, negative cultures are never the sole indication for stopping antifungal therapy in patients with suspected or proven aspergillosis.

In the past, antifungal susceptibility testing was not routinely recommended for *Aspergillus* spp. in treatment guidelines because of limited data to support the recommendation. *Aspergillus terrreus* and *A. flavus* were considered to be the major concerns because of their intrinsic resistance to amphotericin B. Multitriazole-resistant *Aspergillus fumigatus* spp. have been reported in China, Canada, the United States, and several European countries, with especially high levels in the Netherlands and United Kingdom. These trends suggest that MIC testing (when isolates can be grown from patient) may be increasingly necessary to confirm susceptibility to first-line antifungal treatments.

Considerable effort has been focused in the last decade to develop non–culture-based laboratory methods (antigen detection, polymerase chain reaction [PCR], and antigen detection)

for the diagnosis of IA. The hope is that these surrogate tests could detect early evidence of *Aspergillus* infection before significant target organ damage eventually detected by CT scans occurs. Currently, most centers use an ELISA–based assay for the detection of a polysaccharide component of the *Aspergillus* cell wall called galactomannan. Although several large prospective studies have found that the sensitivity and specificity of the assay exceeded 90% in neutropenic patients with hematologic malignancies, the median time span between galactomannan detection and clinical signs and symptoms of IA averages less than 6 days. The sensitivity of the galactomannan may be enhanced if the test is performed on bronchial lavage fluid. Other factors such as patient immune status (neutropenia vs graft-versus-host disease), antibacterial therapy, antifungal prophylaxis, and diet may affect the sensitivity and specificity of the galactomannan test.[34] For example, false-positive results have been reported to be higher in the pediatric population, patients receiving piperacillin-tazobactam for neutropenic fever, and following the ingestion of certain cereals, pastas, nutritional supplements, or soy sauce. Accumulating clinical data suggest that rising galactomannan levels are a harbinger of breakthrough infection, and declining galactomannan concentrations are an early indicator of response to treatment. However, antifungal therapy is rarely stopped in patients once the serum galactomannan becomes negative, especially in persistently immunosuppressed patients. Hence, the galactomannan test and other non–culture-based strategies, such as serum β-glucan, which can also be detected during *Aspergillus* infection, serve as complementary methods to confirm results from microbiologic, histopathologic, and radiographic investigations directed toward diagnosing IA.

## TREATMENT

Four comparative randomized controlled clinical trials have evaluated antifungal therapies for the treatment of diagnosis-proven IA. Voriconazole is considered by many experts and consensus treatment guidelines to be the preferred antifungal for IA (see Table 84–2).[34] However, patients who are intolerant to voriconazole, have ongoing hepatotoxicity issues, or have received voriconazole prophylaxis in the recent past may initially be treated with a liposomal amphotericin B formulation. Lipid amphotericin B formulations are recommended over other antifungal classes because of their better coverage of Mucorales molds, which are intrinsically resistant to voriconazole, but often present as a breakthrough infection indistinguishable from IA. Once the infection has stabilized and diagnosis is clarified, patients can be transitioned back to an intravenous or oral triazole for the completion of their therapy.

Isavuconazole is a newer triazole unique from other agents because it is administered as a prodrug, isavuconazonium, which is rapidly cleaved in vivo to the active drug (isavuconazole) and an inactive prodrug cleavage product (BAL8728). In a phase 3 trial, patients with proven or probable aspergillosis treated with isavuconazole achieved similar clinical response rates as a standard voriconazole regimen, but with significantly fewer hepatic, skin, and visual adverse effects.[35] Therefore, isavuconazole appears to be a promising alternative to voriconazole for the treatment of IA.

Echinocandins are clinically active against *Aspergillus* spp. and have demonstrated efficacy in the treatment of probable or proven aspergillosis. However, their lack of fungicidal activity and possibly lower response rates reported with monotherapy regimens in noncomparative studies[36] makes them less appealing

as a frontline treatment regimen for documented infections, despite their excellent safety profile.

Multiple studies in vitro and in animal models, as well small clinical studies have suggested that administration of an echinocandin with a triazole such as voriconazole may be synergistic and improve survival in IA over monotherapy, but prospective clinical studies, until recently, have been lacking. A multicenter, randomized clinical trial comparing voriconazole-anidulafungin combination therapy to to voriconazole monotherapy for proven or probable aspergillosis reported a trend in improved 6-week survival for patients randomized to combination therapy, that was significant among a post-hoc analyzed group of patients whose disease was diagnosed with galactomannan antigen but not culture (reflecting patients with earlier-diagnosed disease).[37] Nevertheless, the failure of the study to meet its primary endpoint objective raises lingering questions about the efficacy of combination therapy, and many clinicians reserve the use of combination regimens for patients with extensive disease (ie, multifocal or bilateral pneumonia, disseminated infection) or in cases of suspected breakthrough infection.

## PROPHYLAXIS

Although published guidelines for preventing opportunistic infections in hematopoietic cell transplant recipients do not provide concrete recommendations for antifungal prophylaxis against *Aspergillus*, prophylaxis should be considered in certain high-risk subgroups with rates of IA exceeding 10%. These groups include (a) patients with prolonged pre-engraftment periods (eg, cord-blood transplant recipients), (b) patients with a history of IA prior to transplantation, (c) patients receiving transplants with a high risk of graft-versus-host disease (eg, haploidentical allogeneic transplant) or infection (eg, T-cell–depleted transplant), any patient with graft-versus-host disease on high-dose corticosteroid therapy (greater than 1 mg/kg prednisone equivalent) with or without antithymocyte globulin or tumor necrosis factor blockade (ie, infliximab), and (d) any transplant recipient with active cytomegalovirus disease, which is associated with an increased risk of subsequent mold infections due to the immunosuppressive effects of the virus. Posaconazole was shown in two prospective randomized trials to reduce *Aspergillus*-associated death in patients with acute high-risk leukemia and reduce mold infections in patients with graft-versus-host disease following hematopoietic stem cell transplantation. Similar data are available for voriconazole, for HSCT[38,39] but less benefit was observed versus standard fluconazole prophylaxis plus intensive galactomannan monitoring in the hematopoietic stem cell transplant patients. Prophylactic approaches, however, are often individualized to institution and patient-specific risk factors.

## OUTCOME EVALUATION

Response to antifungal therapy in invasive molds is slow and difficult to judge by clinical signs alone. Resolution of fever and eventual clearing of CT scans (in the case of lung infections) are indications of response to antifungal therapy. Toxicity associated with antifungal therapy is similar in these patients as in those described earlier. Patients who develop breakthrough infections on voriconazole should also undergo a careful clinical workup for other invasive mold pathogens such as mucormycosis (see Table 84–1), which are not susceptible to voriconazole. In most cases, antifungal therapy may be continued until immunosuppression has resolved.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| AIDS | Acquired immunodeficiency syndrome |
| ARDS | Acute respiratory distress syndrome |
| CNS | Central nervous system |
| CrCl | Estimated creatinine clearance |
| CSF | Cerebrospinal fluid |
| CT | Computed tomography |
| CYP | Cytochrome P-450 isoenzyme |
| ELISA | Enzyme-linked immunosorbent assay |

# 85 Antimicrobial Prophylaxis in Surgery

Mary A. Ullman and John C. Rotschafer

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Describe the impact of surgical site infections (SSIs) on patient outcomes and health care costs.
2. Name and differentiate the four different types of wound classifications.
3. Recognize at least three risk factors for postoperative SSIs.
4. Identify likely pathogens associated with different surgical operations.
5. Compare and contrast antimicrobials used for surgical prophylaxis and identify potential advantage and disadvantages for each antimicrobial.
6. Discuss the importance of β-lactam allergy screening and how this could impact resistance and health care costs.
7. Identify nonantimicrobial methods that can reduce the risk of postoperative infection.
8. Discuss the importance of antimicrobial timing, duration, and redosing in relation to antimicrobial prophylaxis in surgery.
9. Recommend appropriate prophylactic antimicrobial(s) given a surgical operation.

## INTRODUCTION

**KEY CONCEPT** *Surgical site infections (SSIs) are a significant cause of morbidity and mortality.* Approximately 2% to 5% of patients undergoing clean extra-abdominal operations and 20% undergoing intra-abdominal operations will develop an SSI.[1] SSIs have become the second most common cause of nosocomial infection, and these data are likely underestimated due to a large number of surgical procedures being performed on an outpatient basis.[1,2]

SSIs negatively affect patient outcomes and increase health care costs. Patients who develop SSIs are five times more likely to be readmitted to the hospital and have twice the mortality of patients who do not develop an SSI.[1] A patient with an SSI is also 60% more likely to be admitted to an ICU.[1] SSIs lengthen hospital stays and increase costs.[1,3,4] Deep SSIs, involving organs or spaces, result in longer durations of hospital stay and higher costs compared with incisional SSIs.[5] Additionally, since 2008, Medicare and Medicaid Services no longer reimburses hospitals for any cost incurred from treating certain hospital-acquired infections, including SSIs.[6]

SSIs are defined and reported according to Centers for Disease Control and Prevention (CDC) criteria.[5] SSIs are classified as either incisional or organ/space. Incisional SSIs are further divided into superficial incisional SSI (skin or subcutaneous tissue) and deep incisional SSI (deeper soft tissues of the incision). Organ/space SSIs involve any anatomic site other than the incised areas (eg, meningitis after brain tumor removal). An infection is considered an SSI if any of the above criteria is met and the infection occurs within 30 days of the operation. If a prosthetic is implanted during the operation, the timeline extends out to 1 year.

## EPIDEMIOLOGY AND ETIOLOGY

Risk factors for SSIs can be divided into two categories: patient and operative characteristics.[5,7,8] Patient risk factors for SSI include age, comorbid disease states (especially chronic lung disease and diabetes), malnutrition, immunosuppression, nicotine or steroid use, and colonization of the nares with *Staphylococcus aureus*. Modifying risk factors prior to planned operations may decrease the threat of SSI.

Operative characteristics are based on the actions of both the patient and the operating staff. Shaving of the surgical site prior to operating can produce microscopic lacerations and increase the chance of SSI and is, therefore, not accepted as a method of hair removal.[5] Maintaining aseptic technique and proper sterilization of medical equipment is effective in preventing SSI. Surgical staff should wash their hands thoroughly. In clean operations, most bacterial inoculums introduced postoperatively are generally small. However, subsequent patient contact between contaminated areas (such as the nares or rectum) and the surgical site can lead to SSI. Finally, the appropriate use of antimicrobial prophylaxis can have a significant impact on decreasing SSIs.

## PATHOPHYSIOLOGY
### Prophylaxis Versus Treatment

Properly identifying the site of an infection is important when using antimicrobial prophylaxis in surgery. Antimicrobial prophylaxis begins with the premise that no infection exists but that during the operation there can be a low-level inoculum of

bacteria introduced into the body. However, if sufficient antimicrobial concentrations are present, bacteria can be controlled without infection developing. This is the case when surgery is done under controlled conditions, there are no major breaks in sterile technique or spillage of GI contents, and perforation or damage to the surgical site is absent. An example would be an elective hysterectomy done with optimal surgical technique.

If an infection is already present, or presumed to be present, then antimicrobial use is for treatment, not prophylaxis, and the goal is to resolve the infection. This is the case when there is spillage of GI contents, gross damage or perforation is already present, or the tissue being operated on is actively infected (pus is present and cultures are positive). An example would be a patient undergoing surgery for a ruptured appendix with diffuse peritonitis.

**KEY CONCEPT** *The distinction between prophylaxis and treatment influences the choice of antimicrobial and duration of therapy.* Appropriate antimicrobial selection, dosing, and duration of therapy differ significantly between these two situations. A regimen for antimicrobial prophylaxis ideally involves one agent and lasts less than 24 hours. Treatment regimens can involve multiple antimicrobials with durations lasting weeks to months depending on desired antimicrobial coverage and the surgical site.

## Types of Surgical Operations

**KEY CONCEPT** *Surgical operations are classified at the time of operation as clean, clean-contaminated, contaminated, or dirty.* Antimicrobial prophylaxis is appropriate for clean, clean-contaminated, and contaminated operations. Dirty operations take place in situations of existing infection and antimicrobials are used for treatment, not prophylaxis (**Table 85–1**).

## Microbiology

**KEY CONCEPT** *Appropriate prophylactic antimicrobial selection relies on anticipating which organisms will be encountered during the*

| Table 85–2 | |
|---|---|
| **Major Pathogens in Surgical Wound Infections[9]** | |

| Pathogen | Percentage of Infections |
|---|---|
| *Staphylococcus aureus* | 30.4 |
| Coagulase-negative Staphylococci | 11.7 |
| *Escherichia coli* | 9.4 |
| *Enterococcus faecalis* | 5.9 |
| *Pseudomonas aeruginosa* | 5.5 |
| *Streptococcus* spp. | 4.9 |
| *Enterobacter* spp. | 4 |
| *Klebsiella (pneumonia/oxytoca)* | 4 |
| *Enterococcus* spp. | 3.2 |
| *Proteus* spp. | 3.2 |
| *Enterococcus faecium* | 2.5 |
| *Serratia* spp. | 1.8 |
| *Candida albicans* | 1.3 |
| *Acinetobacter baumannii* | 0.5 |

*operation.* SSIs associated with extra-abdominal operations are the result of skin flora organisms in nearly all cases. These organisms include gram-positive cocci, with *S. aureus* and *Staphylococcus epidermidis* being among the most frequently isolated SSI pathogens[5,6,9] (**Table 85–2**). *Streptococcus* spp. may also be implicated.

Intra-abdominal operations involve a diverse flora with the potential for polymicrobial SSIs. *Escherichia coli* make up a large portion of bowel flora and are frequently isolated as pathogens.[5,6] Other enteric gram-negative bacteria, as well as anaerobes (especially *Bacteroides* spp.), may be encountered during intra-abdominal operations.

*Candida albicans* continues to be an increasing cause of SSIs.[6] Increased use of broad-spectrum antimicrobials and

|---|---|---|---|
| **National Red Cross Wound Classification, Risk of SSI, and Antimicrobial Indication** | | | |

| Classification | Description | SSI Risk | Antimicrobial Prophylaxis |
|---|---|---|---|
| Clean | No acute inflammation or transection of GI, oropharyngeal, GU, biliary, or respiratory tracts; elective case, no technique break | Low | Indicated |
| Clean-contaminated | Controlled opening of aforementioned tracts with minimal spillage or minor technique break; clean procedures performed emergently or with major technique breaks | Medium | Indicated |
| Contaminated | Acute, nonpurulent inflammation present; major spillage or technique break during clean-contaminated procedures | High | Indicated |
| Dirty | Obvious preexisting infection present (abscess, pus, or necrotic tissue present) | — | Not indicated; antimicrobials used for treatment |

GU, genitourinary.

Data from Refs. 7 and 11.

rising prevalence of immunocompromised and human immunodeficiency virus-infected individuals are factors in fungal SSIs. Despite this increase, antifungal prophylaxis for surgery is not currently recommended.

## Choosing an Antibiotic

Ideal criteria for an antimicrobial in surgical prophylaxis include the following:

- Spectrum that covers expected pathogens
- Inexpensive
- Parenteral
- Easy to use
- Minimal adverse-event potential
- Longer half-life to minimize need for redosing during procedure

Operations can be separated into two basic categories: extra-abdominal and intra-abdominal. SSIs resulting from extra-abdominal operations are frequently caused by gram-positive aerobes. Thus an antimicrobial with strong gram-positive coverage is useful. Cefazolin provides a benign adverse-event profile, simple dosing, and low cost, making cefazolin the mainstay for surgical prophylaxis of extra-abdominal procedures. For patients with a β-lactam allergy, clindamycin or vancomycin can be used as an alternative.

Intra-abdominal operations necessitate broad-spectrum coverage of gram-negative organisms and anaerobes. Antianaerobic cephalosporins, cefoxitin and cefotetan, are widely used. Fluoroquinolones or aminoglycosides, paired with clindamycin or metronidazole, should provide adequate coverage for intra-abdominal operations; these regimens are recommended as appropriate regimens for use in patients with β-lactam allergies.

Guidelines do not recommend routine use of vancomycin for surgical procedures.[10,11] Vancomycin should be considered when a cluster of methicillin-resistant *S. aureus* (MRSA) or coagulase-negative staphylococci have been identified. Additionally, vancomycin is appropriate to use in patients with known MRSA colonization or at high risk for MRSA colonization. However, vancomycin use in institutions where MRSA rates are "high" may not translate into a lower incidence of SSI. The incidence of SSI for patients on cefazolin or vancomycin did not differ despite a high MRSA rate at the study institution.[12] However, patients who received cefazolin were more likely to develop an SSI due to MRSA.[11] The increasing prevalence of community-associated methicillin-resistant *S. aureus* (CA-MRSA) in patients admitted to the hospital creates an added concern, although this pathogen is often sensitive to clindamycin. Responsibility for determining appropriate use of vancomycin falls on each institution and interpretation of institutional resistance data.

Newer antimicrobials may be alternative agents for surgical prophylaxis, especially as drug shortages limit availability of routinely used antimicrobials. Ertapenem was superior to standard cefotetan in the prevention of SSIs after elective colorectal surgery.[13] However, the ertapenem treatment group had a larger proportion of *Clostridium difficile* infections than those in the cefotetan treatment group. Ertapenem has been included as an approved antimicrobial for colon surgery.[10] At this time, it is not considered appropriate to routinely use newer antimicrobials for surgical prophylaxis; overuse of these antimicrobials may contribute to collateral damage and the development of bacterial resistance.

## β-Lactam Allergy

Allergy to β-lactam antimicrobials such as penicillin is one of the most common reported drug allergies. Concerns over cross-reactivity between antimicrobials may limit the use of β-lactams for surgical prophylaxis. KEY CONCEPT *A thorough drug allergy history should be taken to discern true allergy (eg, anaphylaxis) from medication intolerance (eg, upset stomach).* Allergy testing may be helpful in confirming penicillin allergy and could spare vancomycin. However, practitioners should be aware that penicillin allergy testing may be difficult to perform due to the removal of a major component (penicilloyl-polylysine) of the testing from the commercial market.[14] If a practitioner desires to perform allergy testing, the individual reagents required for penicillin allergy testing must be prepared at the health care facility, on a case-by-case basis. Cross-allergenicity between penicillins and cephalosporins is low. The increased risk of cephalosporin allergy in patients with a history of penicillin allergy may be as low as 0.4% for first-generation cephalosporins and nearly zero for second- and third-generation agents.[14] Other studies also found the risk of cross-reactivity to be very low.[16] However, in the case of severe penicillin allergy (anaphylaxis), cephalosporins should be avoided.

## Alternative Methods to Decrease SSI

Several nonantimicrobial methods have been studied for reducing the risk of SSI.[18–34] Supplemental warming of patients (36.7°C [98.0°F]) during the intraoperative period reduced infection rates compared with control patients (34.7°C [94.5°F]).[19] Intensive glucose control (maintaining blood glucose to 80–110 mg/dL [4.4–6.1 mmol/L]) versus conventional control (blood glucose < 220 mg/dL [12.2 mmol/L]) reduced operative site infections and improved outcomes in cardiac patients who received intensive insulin control in the ICU after surgery.[20] Also, patients randomized to 80% (0.80) inspired oxygen had lower SSI rates compared with patients on 30% (0.30) oxygen after colorectal resection.[21] Despite these findings, there are insufficient data to make definitive recommendations on the use of these approaches.

Alternative topical routes of antimicrobial prophylaxis such as antimicrobial-impregnated bone cement, implantable antimicrobial collage sponges, antimicrobial irrigations, and topical administration of antimicrobial powders have not been well studied. Studies demonstrating an advantage often lack rigorous design and only show superiority when compared to placebo.[10,20–21] Irrigation with detergent solutions, rather than antimicrobials, appears to provide the same results but with less wound-healing problems encountered with antimicrobial irrigation.[25] Confounding this issue is the lack of standards for topical administration routes. An array of drugs, from aminoglycosides to macrolides, is used in these preparations. Some bone cements are produced commercially, whereas others are made in the operating room. The long-term durability of impregnated cements is also unknown, as the addition of antimicrobials may reduce the tensile strength of bone cement. Irrigation solutions may be compounded in the surgical suites and result in variable concentrations. High concentrations can results in local irritation, systemic absorption, and toxicity. Alternatively, low concentrations can contribute to the development of resistant organisms may occur. Further study is required before topical administration is recommended for use in surgical prophylaxis.

With the increase of CA-MRSA, increased importance has been placed on screening for *S. aureus*, especially MRSA and decolonization. Surgical patients with nasal colonization of

*S. aureus* have a higher risk of an SSI due to *S. aureus*, and decolonization leads to a lower incidence of SSIs.[25–27] Guidelines endorse the use of mupirocin for *S. aureus* decolonization, especially in cardiac and orthopedic surgery. The most studied approach to eradication of methicillin-sensitive *S. aureus* (MSSA) and/or MRSA has been mupirocin applied to the anterior nares for 5 days prior to surgery.[10,30] Additionally, skin decolonization with 4% chlorhexidine for 5 days prior to surgery has also been recommended. Although decolonization of the anterior nares is the most common and most studied, some controversy exists because patients may be colonized elsewhere (rectum, throat, vagina, etc) and often do not receive complete decolonization.[30] Furthermore, decolonization usually does not lead to lifelong eradication. Other drugs, both topical and systemic, have been studied for decolonization/eradication of MRSA, but a review of randomized controlled trials for the eradication of MRSA found insufficient evidence for the use of any agent for eradication of MRSA.[31] A significantly lower incidence of infections was demonstrated in surgical patients who were nasal colonized with *S. aureus* and completed a 5-day treatment of intranasal mupirocin twice daily and chlorhexidine wash daily. Although no MRSA infections were noted in the patients included in this study, the authors suggest that this treatment strategy would be beneficial in MRSA-colonized patients as long as those strains were susceptible to mupirocin. Although MRSA screening has gained more acceptance, less than 10% of centers screen for mupirocin and/or chlorhexidine resistance.[10,33] Mupirocin resistance rates have varied from 1.9% to 5.6% of *S. aureus* isolates.[34] Further studies are needed to elucidate this area of surgical prophylaxis, including cost-effectiveness.

## Principles of Antimicrobial Prophylaxis

### ▶ Route of Administration

IV antimicrobial administration is the most common delivery method for surgical prophylaxis. IV administration ensures complete bioavailability while minimizing the impact of patient-specific variables. Oral administration is also used in some bowel operations. Nonabsorbable compounds such as erythromycin base and neomycin are given during the 24 hours prior to surgery to reduce microbial concentrations in the bowel. Note that oral agents are used adjunctively and do not replace IV agents.

### ▶ Timing of First Dose

**KEY CONCEPT** *For prevention of SSIs, correct timing of antimicrobial administration is imperative so as to allow the persistence of therapeutic concentrations in the blood and wound tissues during the entire course of the operation.* The National Surgical Infection Prevention Project recommends infusing antimicrobials for surgical prophylaxis within 60 minutes of the first incision. Exceptions to this rule are fluoroquinolones and vancomycin, which can be infused 120 minutes prior to avoid infusion-related reactions.[1] No consensus has been reached on whether the infusion should be complete prior to the first incision. However, if a proximal tourniquet is used, antimicrobial administration should be complete prior to inflation.

Administration of the intravenous antimicrobial should begin as close to the first incision as possible. This is important for antimicrobials with short half-lives so that therapeutic concentrations are maintained during the operation and reduce the need for redosing. Beginning the antimicrobial infusion after the first incision is of little value in preventing SSI. Administration

of the antimicrobial after the first incision had SSI rates similar to patients who did not receive prophylaxis.[35]

### ▶ Dosing and Redosing

**KEY CONCEPT** *The goal of antimicrobial dosing for surgical prophylaxis is to optimize the pharmacodynamic parameter of the selected agent against the suspected organism for the duration of the operation.* Dosing recommendations can vary between institutions and guidelines. Clinical judgment should be exercised regarding dose modifications for renal function, age, and especially weight. Obese patients often require higher antimicrobial doses than do nonobese patients. The newest guidelines recommended higher doses of cefazolin based on population pharmacokinetic/pharmacodynamics data: 2 g for all patients less than 120 kg; 3g for patients more than or equal to 120 kg.[10] Clindamycin should be given as a 900-mg preoperative intravenous dose[10].

If an operation exceeds two half-lives of the selected antimicrobial, then another dose should be administered.[1,10] Repeat dosing reduces rates of SSI. For example, cefazolin has a half-life of about 2 hours, thus another dose should be given if the operation exceeds 4 hours. The clinician should have extra doses of antimicrobial ready in case an operation lasts longer than planned.

### ▶ Duration

The National Surgical Infection Prevention Project and published evidence suggest that the continuation of antimicrobial prophylaxis beyond wound closure is unnecessary.[1,10] **KEY CONCEPT** *The duration of antimicrobial prophylaxis should not exceed 24 hours (48 hours for cardiac surgery); additional doses of antimicrobial past this time point do not demonstrate added benefits.* Antimicrobial prophylaxis does not need to be continued until all drains and catheters have been removed. Longer durations of antimicrobial prophylaxis are advocated by some guidelines and will be discussed later.

## PROPHYLAXIS REGIMENS

## Antimicrobial Prophylaxis in Specific Surgical Procedures

### ▶ Gynecologic and Obstetric

- Possible pathogens: enteric gram-negative bacilli, anaerobes, group B streptococci, enterococci
- Prophylaxis for hysterectomy: cefazolin, cefotetan, cefoxitin, ampicillin-sulbactam
  - Alternatives for β-lactam allergy: clindamycin or vancomycin combined with aminoglycoside, aztreonam, or fluoroquinolone; metronidazole combined with aminoglycoside or fluoroquinolone
- Prophylaxis for Cesarean section: cefazolin
  - Alternatives for β-lactam allergy: clindamycin and aminoglycoside

Cesarean sections are stratified into low- and high-risk groups. Patients who undergo emergency operations or have cesarean sections after the rupture of membranes and/or onset of labor are considered high risk. Prophylactic antimicrobials are most beneficial for high-risk patients but are used in both groups. Antimicrobials should not be administered until after the first incision and the umbilical cord has been clamped. This practice prevents potentially harmful antimicrobial concentrations from reaching the newborn.

**Table 85–3**

**Recommended Regimens for Antimicrobial Prophylaxis of Specific Surgical Procedures[a]**

| Type of Operation | Recommended Prophylaxis Regimen (Duration is for a total of 24 hours unless specified) | Alternative Regimen for β-Lactam Allergy (Duration is for a total of 24 hours unless specified) |
|---|---|---|
| Vascular | Cefazolin 2–3 g[b] IV every 8 hours | Clindamycin 900 mg IV every 6–8 hours *or* vancomycin 15 mg/kg every 8–12 hours |
| Neurosurgery | Cefazolin 2–3 g[b] IV every 8 hours | Clindamycin 900 mg IV every 6–8 hours *or* vancomycin 15 mg/kg IV every 8–12 hours |
| Head and neck (clean with prosthesis placement excluding tympanostomy tubes) | Cefazolin 2–3 g[b] IV every 8 hours *or* cefuroxime 1.5 g every 8 hours | Clindamycin 900 mg IV every 6–8 hours |
| Head and neck (clean-contaminated) | (Cefuroxime 1.5 g every 8 hours and metronidazole 500 mg every 8 hours) *or* amipicillin-sulbactam 3 g every 6 hours | Clindamycin 900 mg IV every 6–8 hours |
| Urologic (clean) | Cefazolin 2–3 g[b] IV × 1 | Clindamycin 900 mg IV × 1 *or* vancomycin 15 mg/kg × 1 |
| Urologic (lower tract instrumentation with risk factors for infection, transrectal prostate biopsy) | Ciprofloxacin 400 mg IV × 1 *or* levofloxacin 500 mg IV × 1 *or* trimethoprim-sulfamethoxazole *or* cefazolin 2–3 g[b] × 1 | Gentamicin 5 mg/kg × 1 with or without clindamycin 900 mg × 1 |
| Cesarean section | Cefazolin 2–3 g[b] IV × 1 | See hysterectomy |
| Hysterectomy | Cefazolin 2–3 g[b] IV × 1 *or* cefotetan 2 g × 1 *or* cefoxitin 2 g × 1 *or* ampicillin-sulbactam 3 g × 1 | (Clindamycin 900 mg × 1 *or* vancomycin 15 mg/kg × 1) and (gentamicin 5 mg/kg × 1 *or* aztreonam 2 g *or* ciprofloxacin 400 mg *or* levofloxacin 500 mg) |
| Gastroduodenal (high-risk only: obstruction, acid suppression, morbid obesity, hemorrhage, malignancy) | Cefazolin 2–3 g[b] IV × 1 | (Clindamycin 900 mg × 1 *or* vancomycin 15 mg/kg × 1) and (gentamicin 5 mg/kg × 1 *or* aztreonam 2 g *or* ciprofloxacin 400 mg *or* levofloxacin 500 mg) |
| Biliary tract (open procedure or high-risk laprascopic only: age > 70 years, acute cholecystitis, obstructive jaundice, duct stones, nonfunctioning gallbladder) | Cefazolin 2–3 g[b] IV × 1 *or* cefotetan 2 g × 1 *or* cefoxitin 2 g × 1 *or* ceftriaxone 2 g × 1 *or* ampicillin-sulbactam 3 g × 1 | [(Clindamycin 900 mg × 1 *or* vancomycin 15 mg/kg × 1] and gentamicin 5 mg/kg × 1 *or* aztreonam 2 g *or* ciprofloxacin 400 mg *or* levofloxacin 500 mg)] or ([metronidazole 500 mg × 1 AND [gentamicin 5 mg/kg × 1 *or* ciprofloxacin 400 mg *or* levofloxacin 500 mg]) |
| Colorectal | [c]Oral: neomycin 1 g plus erythromycin base 1 g (give 19, 18, and 9 hours prior to procedure) | |
| | IV: (Cefazolin 2–3 g[b] × 1 and metronidazole 500 mg × 1) *or* cefoxitin 2 g × 1 *or* cefotetan 2 g × 1 *or* ampicillin-sulbactam 3 g × 1 *or* (ceftriaxone 2 g × 1 AND metronidazole 500 mg × 1) *or* ertapenem 1 g × 1 | See biliary tract |
| Appendectomy | Cefoxitin 2 g IV × 1; cefotetan 2 g IV × 1; cefazolin 2–3g[b] × 1 and metronidazole 500 mg × 1 | Metronidazole 0.5–1 g IV *plus* gentamicin 1.5 mg/kg IV × 1 |
| Orthopedic | Cefazolin 2–3 g[b] IV every 8 hours | Vancomycin 15 mg/kg every 8–12 hours *or* clindamycin 900 mg every 6–8 hours |
| Cardiothoracic | Cefazolin 2–3 g[b] IV every 8 hours for a total of 48 hours *or* cefuroxime 1.5 g IV every 12 hours for a total of 48 hours | Vancomycin 15 mg/kg every 8–12 hours for a total of 48 hours *or* clindamycin 900 mg every 6–8 hours for a total of 48 hours |

[a]Dosing recommendations are based on common clinical doses for adult patients with normal renal function; dosing for individual patients and institutions may vary.

[b]3 g dose for weight more than or equal to 120 kg.

[c]Oral regimens should be used in conjunction with IV prophylaxis.

Data from Refs. 10, 11, and 15.

▶ *Orthopedic Surgery*

- Possible pathogens: gram-positive cocci, mostly staphylococci
- Prophylaxis for total joint arthroplasty (hip or knee): cefazolin
  - Alternatives for β-lactam allergy: clindamycin, vancomycin

Antimicrobial-impregnated bone cement can be useful in lowering infection rates in orthopedic surgery but has not been approved for prophylaxis.

▶ *Cardiothoracic and Vascular Surgery*

- Possible pathogens: gram-positive cocci, mostly staphylococci
- Prophylaxis for cardiac surgeries: cefazolin, cefuroxime
- Prophylaxis for noncardiac thoracic surgeries: cefazolin, ampicillin-sulbactam
- Prophylaxis for vascular surgeries: cefazolin
- For all cardiothoracic and vascular surgeries alternatives for β-lactam allergy: clindamycin, vancomycin

Debate exists on the duration of antimicrobial prophylaxis for cardiothoracic operations. SSIs are rare after cardiothoracic operations, but the potentially devastating consequences lead some clinicians to support longer periods of prophylaxis. The National Surgical Infection Prevention Project cites data that extending prophylaxis beyond 24 hours does not decrease SSI rates and may increase bacterial resistance.[1,10] However, the Society of Thoracic Surgeons issued practice guidelines in 2006 to extend the duration of antimicrobials to 48 hours following cardiac surgeries.[37] Duration of therapy should be based on patient factors and risk of development of an SSI.

▶ *Colorectal Surgery*

- Possible pathogens: gram-positive, gram-negative, and anaerobic organisms

---

### Patient Encounter Part 1

RP is a 61-year-old woman with a history of rectal bleeding and recent diagnosis of sigmoid colon cancer. She presents today for a colon resection (colorectal surgery). She has a history of nausea with cephalexin. You have been asked for recommendation for surgical prophylaxis.

**VS:** BP 127/83 mm Hg, HR 63 beats/min, RR 21 breaths/min, T 98.6°F (37.0°C), Ht 62′ (157 cm), Wt 186 lb (84.5 kg)

**Labs:** WBC $7 \times 10^3$ mm³ ($7 \times 10^9$/L), serum creatinine 0.7 mg/dL (62 μmol/L), glucose 95 mg/dL (5.3 mmol/L)

*What organisms are likely to be encountered for this operation and why?*

*What agents need to be avoided considering this patient's previous reaction with cephalosporins?*

*What drug would you choose for this operation and why?*

*The surgeon agrees with your decision and wants to begin infusing the antimicrobial 3 hours prior to the first incision. Comment on this.*

*What other interventions besides antimicrobial use could prove useful in lowering RP's risk of SSI?*

---

### Patient Encounter Part 2

RP is transferred to the oncology ward after completion of her surgery. In the procedure notes, the surgeon notes that part of the small bowel was nicked and possible intra-abdominal contamination may have occurred.

*Does this patient still require surgical site prophylaxis?*

*The surgeon asks for your opinion for which antimicrobial the patient should receive. Which antimicrobial do you recommend?*

*How long should this patient remain on antimicrobials?*

---

- Parenteral prophylaxis: cefazolin and metronidazole; cefoxitin; cefotetan; ampicillin-sulbactam; ceftriaxone and metronidazole; ertapenem
  - Alternatives for β-lactam allergy**:** clindamycin combined with aminoglycoside, aztreonam, or fluoroquinolone; metronidazole combined with aminoglycoside or fluoroquinolone

Oral routes for prophylaxis include the combination of neomycin with either erythromycin or metronidazole and are administered at 19, 18, and 9 hours prior to surgery. These oral routes should be given with mechanical bowel preparation. For most patients, this oral regimen should be combined with a parenteral regimen.

Appendectomy is one of the most common intra-abdominal operations. Antimicrobial prophylaxis used for appendectomy is similar to that used for colorectal regimens. In the case of ruptured appendix, antimicrobials are used for treatment, not prophylaxis.

## OUTCOME EVALUATION

The clinician should consistently follow up postoperative patients and screen for any sign of SSI. **KEY CONCEPT** *According to CDC criteria, SSIs may appear up to 30 days after an operation and up to 1 year if a prosthesis is implanted.*[5] This period often extends beyond hospitalization, so educate patients on warning signs of SSI and be encouraged to contact a clinician immediately if necessary. The presence of fever or leukocytosis in the immediate postoperative

---

### Patient Encounter Part 3

RP was treated appropriately for her surgical complications based on your recommendations following her surgery. She presents to a 3-week follow-up appointment to the surgical clinic. She notes that her wound site has been increasing in redness over the past 1 to 2 days, accompanied by a slight discharge that started this morning prior to the clinic visit.

**VS:** BP 104/78 mm Hg, P 82 beats/min, RR 21 breaths/min, T 101.7°F (38.7°C)

**Labs:** WBC $19 \times 10^3$/mm³ ($19 \times 10^9$/L) serum creatinine 1.4 mg/dL (124 μmol/L)

*Based on the available data, does RP have an SSI?*

*What further steps should be taken in regard to this possible SSI?*

## Patient Care Process

**Patient Assessment:**

- Conduct thorough medication history.
- Obtain serum creatinine and weight.
- Document allergies and the type of reaction.

**Therapy Evaluation:**

- Consider penicillin allergy testing in patients with unclear documentation of penicillin allergy.
- Document type of operation patient is to receive.
- Start antimicrobials within 1 hour of surgical incision (2 hours for vancomycin, fluoroquinolones).

**Care Plan Development:**

- Monitor patient for signs of allergic reaction.
- Document any major breaks in surgical technique and adjust length of antimicrobial therapy if surgical classification changes.

**Follow-Up Evaluation:**

- Monitor for signs and symptoms of postoperative infection (30 days postoperation, up to 1 year if prosthesis involved).
- Draw cultures to further guide therapy if SSI suspected.

period does not constitute SSI and should resolve with proper patient care. Distal infections, such as pneumonia, are not considered SSIs even if these infections occur in the 30-day period. Check the appearance of the surgical site regularly and document any changes (eg, erythema, drainage, or pus). The presence of pus or other signs suggestive of SSI must be treated accordingly. Any wound requiring incision and drainage is considered an SSI regardless of appearance. Collect prompt cultures and initiate appropriate antimicrobial therapy to reduce any chance of morbidity and mortality.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| ASHP | American Society of Health-System Pharmacists |

# Vaccines and Toxoids

Marianne Billeter

---

## LEARNING OBJECTIVES

- **Upon completion of the chapter, the reader will be able to:**
  1. Define vaccination and immunization.
  2. Recommend an immunization schedule for a child, including immunocompromised children.
  3. Recommend an immunization schedule for an adult based on comorbid conditions and lifestyle choices.
  4. Evaluate an adverse reaction and its probable association with a vaccine.

## INTRODUCTION

The development and widespread use of vaccines is one of the greatest public health achievements of the 20th century. Other than safe drinking water, no other modality has had a greater impact on reducing mortality from infectious diseases.[1] The first accounts of deliberate inoculation to prevent disease date back as far as the 10th century. However, it wasn't until 1798 that Edward Jenner published his work on inoculation of natural cowpox as a means to prevent infection with smallpox that documented the first scientific attempt to prevent infection by inoculation. Since 1900, the widespread use of vaccines has resulted in the eradication of smallpox worldwide and wild-type poliovirus from the Western hemisphere. There have also been dramatic declines in the incidence of diphtheria, pertussis, tetanus, measles, mumps, rubella, and *Haemophilus influenzae* type b infections. In the United States, there are immunization recommendations against 17-vaccine preventable diseases affecting all age groups.

**KEY CONCEPT** *Vaccines have traditionally been preparations of killed or attenuated microorganisms that provide active immunity against a variety of viral and bacterial infections.* Most vaccines are designed to prevent acute infections that can be rapidly controlled and cleared by the immune system. Successful immunization involves activation of antigen-presenting cells with processing of the antigen by lysosomal or cytoplasmic pathways. T and B lymphocytes will be activated to replicate and differentiate to form large pools of memory cells for protection against subsequent exposure to the antigen.[2]

Vaccines against viral infections may be **attenuated** live viruses or inactivated viral particles. Attenuation may be accomplished by several methods to decrease the viruses' virulence while retaining their **immunogenicity**. Bacterial vaccines utilize antigenic particles of the outer membrane to elicit an immune response. **KEY CONCEPT** *Outer membrane polysaccharides are poorly immunogenic in children younger than 2 years* unless conjugated with a carrier protein. Also, bacterial toxins may undergo chemical treatment to render them nontoxic to form **toxoids** against infectious agents.

Often the terms *vaccination* and *immunization* are used interchangeably even though they are distinct concepts. Vaccination refers to the act of administering a vaccine, whereas immunization refers to the development of immunity to a pathogen. The delivery of a vaccine does not imply that the individual mounted an adequate immune response to the vaccine to elicit protection. However, immunization implies that the act of vaccination resulted in the development of protective immunity.

**Herd immunity** refers to high levels of immunization in one population, resulting in protection of another unvaccinated population. For example, concentrated vaccination of children with the pneumococcal conjugate vaccine resulted in decreased invasive *Streptococcus pneumoniae* infection not only in the vaccinated children, but also in elderly persons within the same community.

**Cocoon immunization** is a strategy used to immunize all persons surrounding another high-risk individual, such as vaccinating parents, siblings, and grandparents of a new infant who is too young to be vaccinated. This strategy is used to protect individuals who are not able to be vaccinated themselves.

## THE ROUTINE VACCINES
### Diphtheria, Tetanus, and Pertussis Vaccines

Diphtheria is a contagious bacterial respiratory infection characterized by membranous pharyngitis. The impact of diphtheria is not from the causative bacteria, *Corynebacterium diphtheriae*, but rather from complications attributed to its exotoxin, such as **myocarditis** and peripheral **neuritis**. Diphtheria is rarely reported in the United States since the introduction of vaccination with diphtheria toxoid; however, diphtheria continues to be a major problem in developing countries.

The tetanus vaccine differs from others in that it does not protect against a contagious disease such as diphtheria, but rather against an environmental pathogen. *Clostridium tetani* is widely found in the environment, especially in dirt and soils. Tetanus is rarely seen in developed countries.

Pertussis is a highly contagious respiratory tract infection caused by the bacteria *Bordetella pertussis*. Pertussis is characterized by a protracted severe cough with or without posttussive vomiting, whoop, difficulty breathing, difficulty sleeping, and rib fractures. It is often referred to as "whooping cough" or the 100-day cough.

### ▶ Use of Diphtheria, Tetanus, and Acellular Pertussis Vaccine

Diphtheria and tetanus toxoids and acellular pertussis vaccine should be administered in a five-shot series to all children beginning at 2 months of age. The shots are given at 2, 4, 6, and 15 to 18 months, and 4 to 6 years. Immunity to diphtheria, tetanus, and pertussis is achieved after the third vaccination.

### ▶ Use of Tetanus and Diphtheria Toxiod Vaccine

Immunity to tetanus and diphtheria wane with increasing age necessitating the need for booster doses every 10 years. The preferred agent to use in adults is tetanus and diphtheria toxoid in order to also give a booster for diphtheria. Tetanus immunization status should be assessed in the management of moderate and severe wounds or contaminated wounds in individuals seeking medical care. A tetanus booster should be administered if necessary.

### ▶ Use of Tetanus Toxiod, Reduced Diphtheria, and Acellular Pertussis Vaccine

Pertussis continues to be reported in adolescents and adults of all ages indicating a waning immunity following primary immunization. Additionally, adults with pertussis may infect young infants who have not received the first three doses of primary vaccination resulting in hospitalizations and death. A tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine is recommended for use in adolescents and adults.

Tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine should be administered to adolescents 11 through 18 years as a single booster. Ideally it should be given at 11 to 12 years of age. Tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine is also recommended for adults 19 years and older as a single booster dose in individuals who have not already received it. This may be given as a routine vaccination or for wound management.[3]

Tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine is also used as part of cocoon immunization strategy to protect young infants. The vaccine should be administered to pregnant women during the third trimester (27–36 weeks preferred) of each pregnancy in order for transfer of maternal antibodies to the newborn infant. Additionally, individuals with close contact to infants less than 12 months of age, such as fathers, grandparents, health care workers, and child care workers, should also be vaccinated. Tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccine may be given at any interval following a tetanus vaccine.[4]

### *Haemophilus Influenzae* Type b Vaccine

*H. influenzae* is a bacterial respiratory pathogen that causes a wide spectrum of disease ranging from upper respiratory infections to bacterial meningitis. *H. influenzae* type b was the leading cause of invasive disease in children younger than 5 years. Approximately two-thirds of the cases were meningitis that resulted in a high degree of hearing loss among survivors.[5] Since the introduction of the vaccine, invasive disease due to *H. influenzae* type b has been nearly eliminated.

The *H. influenzae* type b vaccine is a protein conjugate that illicits T-lymphocyte-dependent immunity. The T-dependent antigens induce an enhanced immune response in younger children including infants. *H. influenzae* type b conjugate vaccine is a recommended routine childhood vaccination beginning at 2 months of age. There are currently three licensed monovalent *H. influenzae* type b conjugate vaccines and three combination vaccines containing *H. influenzae* type b conjugate. Each vaccine has a different dosing schedule and age range for use. Vaccine providers need to be aware of the brand being used and related dosing schedule. The immune response to *H. influenzae* type b is similar among the different vaccines. The different brands are interchangeable without affecting the primary immune response or booster response.[5]

A booster dose of *H. influenzae* type b vaccine is also recommended in adolescents and adults at high risk for becoming infected with *H. influenzae*. The currently available vaccines are labeled for pediatric use, but can be used in adults when vaccination is indicated.

*H. influenzae* type b and influenza vaccines have the potential for confusion and medication errors because of the similarity of the names. Care should be taken when ordering, dispensing, and administering these vaccines.

## Hepatitis A Vaccine

Hepatitis A virus continues to be a frequent cause of illness despite the availability of a highly effective vaccine. Frequently, children younger than 6 years are asymptomatic with primary infection and play a pivotal role in spreading disease to adults. The economic burden of hepatitis A is greater than $300 million annually in combined direct and indirect costs. Widespread use of the Hepatitis A vaccine significantly decreases the disease burden caused by hepatitis A infection.[6]

Hepatitis A vaccine was licensed in the United States in 1995. It is an inactivated whole virus vaccine that is administered in a two-dose series. More than 94% of children, adolescents, and adults will have protective antibodies 1 month after receiving the first dose and 100% following the second dose. The hepatitis A vaccine is recommended for all children following the first birthday, with the second dose administered 6 months later. Adults who are at high risk for hepatitis A should receive two doses at least 6 months apart. High-risk adults include persons with clotting disorders or chronic liver disease, men who have sex with men, illicit drug users, and international travelers going to areas with high to intermediate endemicity of hepatitis A, persons with anticipated close contact with an international adoptee, or any other person who wishes to become immune.[6]

## Hepatitis B Vaccine

Hepatitis B virus is transmitted following exposure to infected blood and body fluids. Individuals with chronic hepatitis B infection are at risk for cirrhosis, liver cancer, liver failure and death. Vaccination with hepatitis B vaccine is the most effective way to prevent hepatitis B infection.[7]

Hepatitis B vaccine is manufactured using recombinant DNA technology to express hepatitis B surface antigen (HBsAg) in yeast. Hepatitis B vaccine is available as a single component or in combination vaccines.

Hepatitis B vaccine is recommended for routine use in infants and children in a three-dose series. The first dose should be given prior to discharge following birth. The remaining two doses should be administered with other routine infant vaccinations during the

first 6 months of life. The dosing schedule will depend on the use of single component or combination vaccines. Adolescents should receive the three-dose series if not previously vaccinated.[7]

Hepatitis B vaccine is recommended for adults at high risk for hepatitis B infection and those requesting protection from hepatitis B. The vaccine is administered in a three-dose series over 4 to 6 months.[8] Frequently, individuals do not follow through with the complete three-dose series and questions arise about restarting the series. Hepatitis B vaccine produces an amnesic response; therefore, the series may be continued at any time in order to complete the three doses.

Following vaccination with hepatitis B vaccine, hepatitis B virus serologic markers will remain negative, with the exception of antibody to hepatitis B surface antigen (anti-HBs), which will be positive indicating immunity. Persons with anti-HBs concentration greater than 10 mIU/mL (10 IU/L) after vaccination will have complete protection against acute and chronic infection.[8] There is no need for booster doses in immunocompetent individuals when anti-HBs concentrations fall below 10 mIU/mL (10 IU/L), since a good memory response will occur following exposure to hepatitis B virus. However, a booster dose may be warranted in immunocompromised individuals.

### Human Papillomavirus Vaccine

Human papillomavirus (HPV) is the most common sexually transmitted virus and is associated with a wide range of diseases, including cervical cancer and genital warts. More than 150 HPVs have been identified and classified on their ability to cause malignant disease. HPV 16 and 18 are highly associated with causing cervical cancer, as well as anal, oropharyngeal, penile, vaginal, and vulval cancers. HPV 6 and 11 are associated with 90% of genital warts.

There are two HPV vaccines on the market. The bivalent vaccine is effective against HPV 16 and 18, while the quadravalent vaccine is effective against HPV 6, 11, 16, and 18. These vaccines are unique in that preventing infection by HPV will translate into prevention of cancer. Countries with high uptake of HPV vaccine have started to see declines in HPV infections and related diseases such as genital warts and high-grade cervical disease.[9]

HPV vaccination is recommended for females aged 11 or 12 in a three-dose series. Females aged 13 through 26 years should also be vaccinated if they have not previously received the full three-dose series. There is no preference to administering the bivalent or quadravalent vaccine in females.[10]

The HPV quadravalent vaccine is recommended for routine vaccination in males aged 11 or 12 years. Vaccination is also recommended for males 13 through 21 years who have not received the full three-dose series.[10]

The overall rate of HPV vaccination is low among 13 year olds, with 57% of girls and 34% of boys having initiated the HPV series in 2013. The main reasons cited for not vaccinating teens is related to knowledge gaps among clinicians and parents regarding recommendations for use and safety concerns. With over 68 million doses distributed, the adverse event profile is similar to other vaccines administered to adolescents.[10]

### Influenza Vaccine

Influenza is a contagious viral respiratory infection that usually occurs during the winter months in the Northern Hemisphere and all year round in the Southern Hemisphere. All age groups are affected by influenza; however, children have the highest rate of infection. Serious illness and death due to influenza usually occurs in extremes of age, those older than 65 years or younger than 2 years.

Influenza A and B viruses are responsible for causing human disease. Both influenza A and B undergo frequent antigenic drift, creating new influenza variants. Immunity to the surface antigens decreases the likelihood of infection. Unfortunately, antibody to one influenza subgroup does not give complete protection against other influenza subtypes.

The best way to protect against seasonal influenza is through vaccination. The current trivalent influenza vaccine contains two A strains, 1 A(H1N1), 1 A(H3N2), and one B strain. The quadravalent influenza vaccine contains the same components of the trivalent and an additional B strain. Inactivated influenza vaccine is available in both trivalent and quadravalent presentations. The live attenuated vaccine is only quadravalent.[11]

All individuals 6 months of age and older should receive yearly seasonal influenza vaccination. There is no preference for vaccine presentation when multiple types are available within an approved age range, except for the following groups. The live attenuated influenza vaccine should preferentially be administered to healthy children aged 2 through 8 years. Live attenuated influenza vaccine is more effective than inactivated influenza vaccine in this age group. However, in adults inactivated influenza vaccine is more effective than live attenuated influenza vaccine.[12] In person 65 years and older, the high-dose trivalent-inactivated influenza vaccine produced increased immunity and protection against confirmed influenza when compared to regular dose influenza vaccine, and should be used for older adults.[13] The recombinant influenza vaccine is used in persons with severe egg allergy.

### Measles, Mumps, and Rubella Vaccine

Measles, mumps, and rubella are acute viral infections that can cause serious disease and complications. Aggressive vaccination programs have made these infections uncommon in the United States. Measles and rubella have been eliminated from the United States. Recent outbreaks have been caused from importation of infected persons from other parts of the world where measles are still circulating. Some outbreaks also occur in communities with high levels of unvaccinated individuals.

Measles, mumps, and rubella vaccine is a live attenuated vaccine. It causes a mild subclinical infection producing long-term immunity. Measles, mumps, and rubella vaccine is recommended for routine vaccination after the first birthday and a second dose administered at 4 through 6 years of age. Measles, mumps, and rubella vaccine is available in combination with varicella vaccine. This vaccine is not recommended for the first dose due to the increased risk of febrile seizures when compared to giving measles, mumps, and rubella and varicella separately at the same visit.[14] Measles, mumps, and rubella vaccine should also be given to adults older than 18 years who are found to be nonimmune.

Measles, mumps, and rubella vaccine should be avoided in immunocompromised persons because of the risk of acquiring measles from the vaccine. However, HIV-infected persons, who are not severely immunocompromised, including those on antiretroviral therapy, can be vaccinated if not immune.[14]

Measles, mumps, and rubella vaccine is a safe vaccine and rarely associated with severe reactions. The most common reaction is fever which usually occurs more than a week after vaccination. Children with a personal or family history of febrile seizures or epilepsy are at increased risk for measles, mumps, and rubella vaccine associated febrile seizures.[14]

**Patient Encounter 1**

A mother brings her 1-year boy to the pediatrician's office with his first yearly check-up. The child is healthy with no chronic health problems. The mother has researched childhood vaccines on the Internet and is reluctant to have any vaccines administered because of the risks of seizures and autism.

*What routine vaccines should the child receive?*

*How should the mother's concerns regarding autism be addressed?*

*The mother is concerned about the number of shots, and wants to use combination vaccines. What combinations can be administered?*

## Meningococcal Vaccines

*Neisseria meningitidis* is a significant cause of meningitis and bacteremia. Invasive meningococcal disease is associated with a high morbidity and mortality rate. Morbidity in survivors is substantial, with approximately 20% having loss of limb or neurologic sequelae. The highest rates of meningococcal disease are among young children; however, rates have been increasing in adolescents and young adults. Thirteen meningococcal serogroups have been identified; however, five serogroups, A, B, C, Y, and W-135, are responsible for epidemic and endemic disease worldwide. Despite the availability of highly active antibacterial agents against *N. meningitidis*, there has been little impact on decreasing the morbidity and mortality due to invasive meningococcal disease.[15]

The meningococcal vaccine is recommended for routine vaccination of adolescents. The first dose should be administered at 11 to 12 years with a booster dose at age 16 years. Meningococcal vaccine is also recommended for high-risk individuals older than 2 months.[15] There are three quadravalent and a bivalent vaccine available for use. The quadravalent vaccines contain serogroups A, C, Y, and W-135. The bivalent contains serogroups C and Y, and is conjugated to *H. influenzae* type B vaccine. Each vaccine is approved for different age groups. The vaccine provider should be cognizant to use the appropriate vaccine for the age of the patient. The quadravalent conjugated vaccines should preferentially be used. The polysaccharide vaccine should be reserved for high-risk individuals older than 55 years.

## Pneumococcal Vaccines

*S. pneumoniae* is the most common bacterial cause of community-acquired respiratory tract infections. *S. pneumoniae* causes approximately 3000 cases of meningitis, 50,000 cases of bacteremia, 500,000 cases of pneumonia, and more than 1 million cases of otitis media each year. The increasing prevalence of drug-resistant *S. pneumoniae* has highlighted the need to prevent infection through vaccination. Pneumococcal vaccines are highly effective in preventing disease from the common *S. pneumoniae* serotypes that cause human disease.

The 13-valent pneumococcal conjugate vaccine contains the serotypes that most commonly cause disease in children. The 23-valent pneumococcal polysaccharide vaccine contains 23 serotypes that are responsible for causing more than 80% of invasive *S. pneumoniae* infections in adults. The pneumococcal vaccines have demonstrated good immunogenicity and prevention of invasive pneumococcal disease.

The 13-valent pneumococcal vaccine is part of the routine childhood immunization schedule beginning at 2 months of age. Children older than 6 years who are at high risk of invasive pneumococcal disease should receive a single 23-valent pneumococcal polysaccharide vaccine, with a booster dose given in 5 years.[16]

Both the 13-valent pneumococcal conjugate and 23-valent pneumococcal polysaccharide vaccines are recommended for routine use in all adults 65 years of age or older. The 13-valent vaccine should be administered first followed by the 23-valent vaccine 6 to 12 months later. If an individual has already received the 23-valent pneumococcal vaccine, the 13-valent vaccine should be administered at least 12 months after the 23-valent vaccine. Adults 19 through 64 years who are at increased risk for invasive pneumococcal disease are recommended to receive a single vaccination with the 13-valent pneumococcal conjugate vaccine. This is followed in 8 weeks with a 23-valent pneumococcal polysaccharide vaccine, and a booster dose in 5 years.[17]

Revaccination with the 23-valent pneumococcal polysaccharide vaccine is recommended for adults older than 65 years if the first dose was administered when they were younger than 65 years and at least 5 years have passed. A dose of the 13-valent pneumococcal vaccine should be administered prior to receiving the 23-valent vaccine.[17]

## Poliovirus Vaccine

Poliomyelitis is a highly contagious disease that is often asymptomatic; however, approximately 1 in every 100 to 1000 cases will develop a rapidly progressive paralytic disease. Polio is caused by poliovirus. Since the introduction of the first poliovirus vaccine, there has been a significant reduction in the number of polio cases. Today, polio caused by wild-type poliovirus has been eradicated from the Western hemisphere with the goal of eradicating it from the world.[18]

The oral poliovirus vaccine has been routinely used in the United States. Unfortunately, the oral poliovirus vaccine has the risk of vaccine-associated paralytic poliomyelitis occurring in approximately 1 case of every 2.4 million doses distributed. The risk with the first dose of oral poliovirus vaccine is 1 case in 750,000 doses.[18]

The last reported case of indigenous wild-type poliovirus in the United States was in 1979; subsequent cases were all vaccine associated. In 1997, a transition period to the inactivated poliovirus vaccine was begun to reduce the risk of vaccine-associated paralytic poliomyelitis. By January 2000, the oral vaccine was no longer recommended for routine use. Currently, the inactivated poliovirus vaccine is recommended for routine use in the United States. It is available as a single component or in combination vaccines. A booster dose should be given after age 4 years, no matter how many doses were given in the infant vaccination series.[19]

## Rotavirus Vaccine

Rotavirus is the most common cause of severe diarrheal disease in children younger than 5 years. It is a major cause of diarrhea hospitalizations for dehydration worldwide. Rotavirus G1 is the most prevalent strain found in the United States. However, in any given year, other strains (G2, G3, G4, and G9) may predominate.

There are two rotavirus vaccines available for use. They are a pentavalent human-bovine reassortant vaccine that contains outer capsid proteins for G1, G2, G3, G4, and P1, and a monovalent, G1 vaccine. The exact mechanism by which these vaccines produce an immune response is unknown; however, these live virus vaccines replicate in the small intestine and induce immunity.

The rotavirus vaccine is administered in either a two-dose or a three-dose series that is orally administered. The first dose is

given to infants between 6 and 12 weeks of age. The impact of the rotavirus vaccine has been dramatic with a significant decrease in rotavirus hospitalizations and all-cause diarrhea hospitalizations in children younger than 5 years. The vaccine has also offered protection to children too old to receive the vaccine and young adults.[20] The most severe adverse events associated with rotavirus vaccine is intrussusception, a telescoping of the intestines on to itself. Post-licensure monitoring has shown a minimal risk of the vaccine with 1 to 5 excess cases of intrussusception per 100,000 vaccinated children.

### Varicella Vaccine

Varicella zoster virus is a highly contagious herpes virus. Primary infection with varicella zoster causes chickenpox and was one of the most common childhood diseases in the prevaccine era. Following primary infection, varicella becomes latent in cranial nerve, dorsal routes, and autonomic ganglia where it may reactivate to cause shingles (Zoster) in older adults. Since the introduction of the varicella virus vaccine in 1995, there has been a 90% reduction in varicella infections and hospitalization in all age groups.[21]

The varicella vaccine is a live attenuated vaccine. Children younger than 12 years will have a 97% seroconversion rate following a single vaccination. Adolescents and adults older than 13 years will only have 78% seroconversion after a single inoculation, but will have 99% conversion following a second dose. Therefore, varicella vaccine is recommended to be administered in a two-dose series. The first dose should be administered after 12 months of age and a second dose at 4 years of age. Adolescents and adults without evidence of immunity to varicella zoster should receive two doses of varicella vaccine given 4 to 8 weeks apart. Antibody titers appear to persist for at least 20 years following immunization.

Varicella vaccine is well tolerated with tenderness at the injection site and mild rash the most common adverse events. Rashes due to the vaccine strain typically occur more than 20 days following vaccination. A few cases of secondary transmission to household contacts have been reported.[21]

### Zoster Vaccine

Later in life, approximately 15% of the population will develop herpes zoster (shingles). Zoster is the reactivation of latent varicella zoster virus in the sensory ganglia. Zoster most frequently occurs in the elderly and immunocompromised individuals who have decreased circulating antibodies to varicella zoster virus.

Zoster vaccine is a more concentrated form of the varicella vaccine. It is FDA approved for use in individuals 50 years and older. However, ACIP recommends its use in individuals 60 years and older even with a previous episode of shingles.[22] Use of the zoster vaccine has shown a reduction in the incidence of zoster and postherpetic neuralgia.

---

### Patient Encounter 2

A 65-year-old patient presents to the pharmacy to pick-up his prescription for blood pressure medication. The pharmacist asks the patient if he would like to receive his vaccines, and the patient accepts.

*What vaccines should the patient receive?*

*What warnings should be given to the patient?*

---

## VACCINE ADMINISTRATION SCHEDULES

Most vaccines are administered in two- to four-shot series in order to elicit the best protection. Childhood and adult immunization schedules are revised frequently and published annually by the CDC Advisory Committee on Immunization Practices (ACIP). Current immunization schedules can be found at www.cdc.gov/vaccines/. Recommendations will be published throughout the year in the *Morbidity and Mortality Weekly Report* (*MMWR*) as new vaccines are licensed or new information necessitates a change in previous recommendations.[23] See Table 86-1 for vaccine dosing.

The childhood immunization schedule is complex and requires a large number of injections. In small infants, the number of injections can be intolerable to the infant, parent, and health care provider. Limiting the number of injections at each visit can lead to missed vaccinations and increased expense for return visits. KEY CONCEPT *Use of combination vaccines decreases the number of injections and increases the likelihood that the immunization schedule will be completed.* Using combination vaccine does not adversely affect the immunity or increase adverse effects. Vaccine administration should not be delayed for mild to moderate respiratory tract illnesses or fevers.[23]

## VACCINE SAFETY

Vaccination is one of the most powerful tools used to prevent disease. As with all drugs, most vaccines have been reported to cause adverse reactions. The reactions are either acute or are related to the risk of developing another disease. Health care professionals should discuss the risks versus benefits of vaccines with individuals or caregivers prior to vaccination. Vaccine information sheets (VIS) provide written information about each vaccine and are required to be given individuals prior to vaccination.[23]

Vaccine safety is monitored by the FDA and CDC through a passive reporting system that allows anyone, health professionals or lay public, to report any event through the Vaccine Adverse Event Reporting System (VAERS). KEY CONCEPT *Health care professionals are mandated to report certain events through VAERS.* Additionally, any serious, life-threatening or unusual reactions should also be reported.

The VAERS database is continually monitored to determine whether the prevalence of reactions is changing and to identify previously unreported reactions to a particular vaccine. Large epidemiologic safety studies are conducted through the Vaccine Safety Datalink; a partnership between the CDC and 9 large health care organizations.

Pain at the injection site is one of the most commonly reported adverse effects of vaccination. The reaction is usually mild, with complaints of pain and tenderness at the injection site that may or may not be accompanied by erythema. Local reactions tend to be more frequent with repeated doses or booster doses of vaccine.[23] Tetanus-containing vaccines are well known for causing localized reactions.

Fever is the most frequently reported adverse effect in children. Elevated temperature is usually self-limiting and resolves in a few days. Rarely febrile seizures may occur following vaccination with measles, mumps, and rubella vaccine.

Reports of syncope following vaccination have been increasing since the approval of human papillomavirus and tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccines. Syncope most commonly occurs in adolescent girls and young adults. Health care professionals should implement measures to mitigate secondary injuries when vaccinating this age group.[23]

| Table 86–1 | | | | |
|---|---|---|---|---|
| **Vaccine Dosing** | | | | |
| **Vaccine** | **Common Abbreviation** | **Dose** | **Route** | **Cautions and Adverse Effects** |
| Diphtheria and tetanus toxoid | DT | 0.5 mL | Intramuscular | History of arthus-type hypersensitivity reaction |
| Diphtheria, tetanus, acellular pertussis | DTaP | 0.5 mL | Intramuscular | Systemic neurologic reaction from previous vaccine |
| | | | | History of arthus-type hypersensitivity reaction Temperature greater than 40.6°C (105°F) |
| *Haemophilus influenzae* type b | HIB | 0.5 mL | Intramuscular | |
| Hepatitis A | HepA | C: 0.5 mL A: 1 mL | Intramuscular | Pregnant women |
| Hepatitis B | HepB | C: 0.5 mL A: 1 mL | Intramuscular | |
| Human papillomavirus | HPV (HPV2, HPV4) | 0.5 mL | Intramuscular | Pregnant women |
| Inactivated influenza | IIV3, IIV4 | 0.5 mL 0.1 mL | Intramuscular Intradermal | Severe egg allergy History of Guillain-Barré syndrome |
| Live attenuated influenza | LAIV | 0.2 mL | Intranasal | Severe egg allergy Asthma Chronic health problems Immunocompromised host Pregnant women History of Guillain-Barré syndrome |
| Measles, mumps, rubella | MMR | 0.5 mL | Subcutaneous | Pregnant women Immunocompromised host |
| Meningococcal polysaccharide | MPSV4 | 0.5 mL | Subcutaneous | |
| Meningococcal conjugate | MCV4 | 0.5 mL | Intramuscular | |
| Pneumococcal 13-valent conjugate | PCV13 | 0.5 mL | Intramuscular | |
| Pneumococcal polysaccharide | PPV23 | 0.5 mL | Intramuscular route preferred; subcutaneous | Children < 2 years |
| Poliovirus, inactivated | IPV | 0.5 mL | Intramuscular, subcutaneous | |
| Rotavirus vaccine | RV (RV1, RV5) | 1 or 2 mL | Oral | Immunocompromised host |
| Tetanus and diphtheria toxoid | Td | 0.5 mL | Intramuscular | History of arthus-type hypersensitivity reaction |
| Tetanus, reduced diphtheria, acellular pertussis | Tdap | 0.5 mL | Intramuscular | Systemic neurologic reaction from previous vaccine |
| | | | | History of arthus-type hypersensitivity reaction |
| Varicella | VAR | 0.5 mL | Subcutaneous | Pregnant women Immunocompromised host |
| Zoster | ZOS | 0.65 mL | Subcutaneous | Immunocompromised host |

A, adult; C, children.

## Autism

Thimerosal is a preservative used in vaccines that has been purported to cause autism in children. The assumption is that thimerosal, also known as ethyl mercury, causes similar effects as methyl mercury, which has neurotoxic and nephrotoxic effects at high doses. Numerous epidemiologic studies have not shown a higher rate of autism among children receiving thimerosal-containing vaccines when compared with the normal background rate of autism. Additionally, the mercury exposure with vaccination is much lower than through many other environmental exposures.[24]

## Guillain-Barré Syndrome

Guillain-Barré syndrome is a transient neurologic disorder causing flaccid paralysis. It is thought to be caused from the development of autoimmune antibodies that cause damage to the peripheral nerves. Guillain-Barré syndrome has been temporally associated with several bacterial and viral infections as well as vaccinations.

The association with vaccination and Guillain-Barré syndrome was first recognized with the Swine flu vaccine of 1976. Since that time a clear association of influenza vaccination and Guillain-Barré syndrome has not been clearly established. Caution is still recommended with influenza vaccines since the influenza strains contained in the vaccine has the potential to change each year.[25]

Several large epidemiologic studies have sought to establish a temporal association of Guillain-Barré syndrome and other routine vaccines. The evidence is inconclusive in determining a cause-and-effect relationship. Overall the risk of Guillain-Barré syndrome following vaccination is minimal with 1 to 2 cases per 100,000 vaccines administered. The benefits of vaccination far outweigh the risk of Guillain-Barré syndrome.[25]

## Patient Encounter 3

A 12-year-old girl is being seen at a school-based clinic with complaints of a common cold. The girl has significant nasal congestion, but no fever. The health provider takes the opportunity to review her vaccination records and finds she is due for her routine adolescent vaccines.

*Should this patient wait 2 weeks before being vaccinated?*

*What vaccines should this patient receive?*

*What precautions should be taken with this patient when administering vaccines?*

## SPECIAL POPULATIONS

### Immunocompromised Host

The number of immunocompromised persons is continually increasing as advances are made in medicine. The life expectancy for persons with cancer, HIV infection, and solid organ or bone marrow transplantation is increasing. Vaccination provides one tool to prevent infection in the immunocompromised host. However, the individual's immunosuppressed state will alter the response to the vaccine. In general, all vaccinations should be updated prior to the person becoming immunosuppressed. **KEY CONCEPT** *Once a person becomes significantly immunosuppressed, live virus vaccines should be avoided.*

Infants, children, and adults with HIV should receive all routine vaccinations according to the recommended immunization schedule as long as T-lymphocyte CD4 count is more than 200 cells/mm³ ($200 \times 10^6$/L). Live vaccines should be used with caution when T-lymphocyte CD4 counts are less than 200 cells/mm³ ($200 \times 10^6$/L). All HIV-infected persons should receive yearly inactivated influenza vaccination.[26]

Following hematopoietic stem-cell transplantation, the patient will need most routine vaccines to be administered 6 to 12 months following transplantation. Diphtheria, tetanus, acellular pertussis, *H. influenzae* type b, hepatitis B, meningococcal, pneumococcal, and inactivated poliovirus should be given. Inactivated influenza vaccine is given yearly, starting 6 months after transplant. Measles, mumps, and rubella can be given 2 years after transplant and varicella and zoster vaccines are contraindicated.[26]

Solid organ transplant recipients have a blunted immune response to vaccines because the immunosuppressive regimens used to prevent organ rejection inhibit both T- and B-cell proliferation. Prior to transplant, children should complete primary immunization schedules if possible. Otherwise primary immunization schedule with inactivated vaccines may continue 2 months following transplantation. Adults should have all vaccinations updated prior to transplantation. Yearly seasonal inactivated influenza vaccination may be given 6 months following transplantation.[26]

Household contacts of immunocompromised persons should have all routine vaccines as scheduled, including yearly influenza vaccination. Children in the household may receive live virus vaccines without special precautions; however, if a rash develops following varicella vaccination, contact should be avoided with the immunocompromised host until the rash resolves.

### Pregnancy

Vaccination during pregnancy has the ability to protect not only the mother but also the newborn infant. A fully immunized mother is less likely to infect their infant with critical diseases such as influenza, tetanus, and pertussis. Mothers who are vaccinated in the second half of the pregnancy will have maternal transfer of antibodies through the placenta giving protection to the newborn infant. Pregnant women should be vaccinated with inactivated influenza and tetanus toxoid, reduced diphtheria toxoid, and acellular pertussis vaccines during each pregnancy. Ideally the vaccines should be administered after 20-week gestation, but can be administered at any time during the pregnancy.[27]

Live virus vaccines should be avoided during pregnancy due to the theoretical concern of the virus being transported across the placenta and infecting the fetus. Women found to be nonimmune to rubella or varicella may be vaccinated soon after delivery, but not during the pregnancy. The live attenuated influenza vaccine should also be avoided.[27]

### Health Care Professionals

Health care professionals are in a unique position to protect themselves and their patients by receiving immunizations against vaccine preventable diseases. Health care professionals should have documented immunity to measles, mumps, rubella, and varicella. The vaccine series should be administered if found nonimmune. Health care professionals with direct patient contact should also receive the Hepatitis B vaccine series and have proven immunity following the series. As concerns regarding the rise of pertussis among adults, it is now recommended that all health care professionals receive at least one dose of tetanus, reduced diphtheria, and acellular pertussis vaccine to protect against pertussis. This dose may be administered at any interval following a tetanus booster.[28]

The Centers for Diseases Control recommends all health care professionals receive yearly influenza vaccination; there is no preference to the type of influenza vaccine that is given. Many health care facilities are now mandating that employees receive yearly influenza vaccination or wear masks during influenza season.[28]

## OUTCOME MEASURES

**KEY CONCEPT** *Vaccines are a cost-effective means for disease prevention.* From a societal perspective, for every dollar spent on routine childhood vaccines, there will be a $10 savings in direct and indirect costs.[29] The rates of vaccination for young children are 90% or more for most recommended vaccines. This has been attributed to the requirements for proof of vaccination by States for enrollment into daycare centers and school. For vaccines not required by schools, the rate of vaccination is lower.

Adolescents present a unique challenge for vaccinating because they do not have as many encounters with health care professionals as young children do. However, the constantly changing immunization schedules makes this population vulnerable to missing newly approved vaccines and catch-up doses of vaccines that were not recommended when they were younger. Every encounter with a health care establishment should be viewed as an opportunity to evaluate and vaccinate if necessary. Adolescents may also have incomplete medical records due to changes in health care providers. Therefore, it is important for health professionals to regularly utilize universal State immunization databases that document pediatric and adult vaccinations. This eliminates the problems of lost immunization records if a child changes health care providers.[23]

The vaccination rate in adults is much lower than that in children. Only 50% to 60% of adults who meet criteria have received pneumococcal vaccination, and less than 40% have received seasonal influenza vaccine. Comprehensive initiatives need to be implemented to increase the adult vaccination rate.

Some proven concepts are providing reminders to patients that vaccines are due and implementation of standing orders for vaccines. This latter concept allows nurses and pharmacists to screen patients to determine whether pneumococcal, influenza, or other vaccines are needed and to vaccinate without a direct physician's order.

## Abbreviations Introduced in This Chapter

# 87

# Human Immunodeficiency Virus Infection

Emily L. Heil, Christine Trezza, and
Amanda H. Corbett

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Explain the routes of transmission for HIV and its natural disease progression.
2. Identify typical and atypical signs and symptoms of acute and chronic HIV infection.
3. Identify the desired therapeutic outcomes for patients with HIV infection.
4. Recommend appropriate first-line pharmacotherapy interventions for patients with HIV infection.
5. Recommend appropriate second-line pharmacotherapy interventions for patients with HIV infection.
6. Describe the components of a monitoring plan to assess effectiveness and adverse effects of pharmacotherapy for HIV infection.
7. Educate patients about the disease state, appropriate lifestyle modifications, and drug therapy required for effective treatment.

## INTRODUCTION

Human immunodeficiency virus type is the major cause of AIDS. HIV primarily targets CD4$^+$ lymphocytes, which are critical to proper immune system function. If left untreated, patients experience a prolonged asymptomatic period followed by rapid, progressive immunodeficiency. Therefore, most complications experienced by patients with AIDS involve opportunistic infections and cancers. AIDS occurs when a patient with HIV has a CD4 cell count below 200 cells/mm$^3$ ($200 \times 10^6$/L), a CD4 cell percentage of total lymphocytes less than 14% (0.14), or one of the Centers for Disease Control (CDC) AIDS defining conditions.[1]

## EPIDEMIOLOGY AND ETIOLOGY

HIV is primarily transmitted by sexual contact, by contact with blood or blood products, and from mother to child during gestation, delivery, or breast-feeding. Although the global incidence of HIV has fallen 33% since 2001, HIV prevalence has increased, largely due to life-extending antiretroviral therapy. Combination antiretroviral therapy (cART) has increased both the length and quality of life for HIV-infected patients, however, to date, there are no treatments that eradicate HIV from the body.[2]

As of 2012, approximately 35.3 million people are infected with HIV worldwide. Approximately 70% of these cases are in Sub-Saharan Africa, with a prevalence of approximately 5%. Central Asia, Eastern Europe, North Africa, and the Middle East are also seeing rapidly rising infection rates.[2]

In 2012 alone, approximately 1.6 million people worldwide died from AIDS and 2.3 million people were newly infected with HIV. Most of these infections were acquired through heterosexual transmission. As of December 2012, women accounted for 45.6% of all people living with HIV worldwide. Young adults, aged 15 to 24 years, accounted for approximately 39% of new HIV infections worldwide.[2]

In the United States, at the end of 2011, an estimated 1.2 million persons (aged 13 years or older) were living with HIV/AIDS. Approximately 14% of these are undiagnosed and unaware of their HIV infection and could be unknowingly transmitting the virus to others.[3]

In 2010, HIV/AIDS rates for African American men were six times those for white men and twice that for Hispanic males, representing 44% and 21% of cases, respectively. Although HIV/AIDS rates in African American women dropped by 21% in 2010, incidence in this population is 20 times the rate for white females and five times the rate for Hispanic females.[3]

Risk factors for HIV/AIDS infection include men who have sex with men (MSM), history of or current IV drug use (needle or equipment sharing), unprotected sexual intercourse with high-risk individuals, the presence of other sexually transmitted infections (eg, *Chlamydia trachomatis* or *Neisseria gonorrhoeae*), persons with coagulation/hemophilia disorders, and previous blood product recipients.

## PATHOPHYSIOLOGY

HIV-1 is a retrovirus and member of the genus *Lentivirus*. There are two molecularly and serologically distinct but related types of HIV: HIV-1 and HIV-2. These viruses have a prolonged latency period. HIV-2 is a less common cause of the epidemic and is found primarily in West Africa. HIV-1 is categorized by phylogenetic lineages into three groups (M [main or major], N [new], and O [outlier]). HIV-1 group M can be further categorized into nine subtypes: A through D, F through H, and J and K. HIV-1 subtype B is primarily responsible for the North American and Western European epidemic.

HIV infection occurs through three primary modes of transmission: sexual, parenteral, and perinatal. The most common method for transmission is receptive anal and vaginal

intercourse, with the probability of transmission highest, 138 infections per 10,000 exposures, with receptive anal intercourse.[4] The probability of transmission increases when the infected partner has a high level of viral replication (which occurs at the beginning of infection or late in disease) or when the uninfected partner has ulcerative disease or compromised mucosal surfaces or (in the case of men) has not been circumcised.

Parenteral transmission of HIV primarily occurs through injection drug use by sharing contaminated needles or injection-related supplies. Less than 1% of all cases of HIV infection occur as a result of transfusions of contaminated blood or blood products, or infected transplant organs.[3] Health care workers have a 0.3% estimated risk of acquiring HIV infection through percutaneous needlestick injury.

Perinatal infection (also known as vertical transmission or mother-to-child transmission [MTCT]) can occur during gestation, at or near delivery, and during breast-feeding. In the absence of specific intervention including medications, the risk of MTCT up to and including delivery is approximately 25%, whereas the risk of transmission during breast-feeding is approximately 15% to 20% within the first 6 months of life.[5] Because a high rate of HIV replication in the blood is a significant risk factor for transmission of HIV, it is important to treat women for their HIV infection during pregnancy. After delivery, mothers are strongly recommended not to breast-feed if safe alternatives are available.

Understanding the life cycle of the virus is important to know how antiretroviral drugs are combined for optimal therapy (Figure 87–1). Once HIV enters the body, an outer glycoprotein called gp120 binds to CD4 receptors found on the surface of dendritic cells, T lymphocytes, monocytes, and macrophages. This allows further binding to other chemokine receptors on the cell surface called CCR5 and/or CXCR4. Greater than 95% of newly infected patients have viruses that preferentially use CCR5 to enter the cell, and most patients with advanced disease have viruses that preferentially use CXCR4 to enter the cell.

After the virus has attached to CD4 and chemokine receptors, another viral glycoprotein (gp41) assists with viral fusion to the cell and internalization of the viral contents. The viral contents include single-stranded RNA, an RNA-dependent DNA polymerase (also known as **reverse transcriptase**), and other enzymes. Using the single-stranded viral RNA as a template, reverse transcriptase synthesizes a complementary strand of DNA. The single-stranded viral RNA is removed from the newly formed DNA strand by ribonuclease H, and reverse transcriptase completes the synthesis of double-stranded DNA. The viral reverse transcriptase enzyme is highly error-prone, and many mutations occur in the conversion of RNA to DNA. This inefficient reverse transcription activity is responsible for HIV's ability to rapidly mutate and develop drug resistance.

A chronic infection is established when the double-stranded DNA migrates to the host cell nucleus and is integrated into the host cell chromosome by an HIV enzyme called **integrase**. Once the cell becomes activated by antigens or cytokines, HIV replication starts: Host DNA polymerase transcribes viral DNA into messenger RNA, and messenger RNA is translated into viral

**FIGURE 87–1.** Life cycle of HIV and targets for antiretroviral drugs. (From Fletcher CV, Kakuda TN. Human immunodeficiency virus infection. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach. 9th ed. New York: McGraw-Hill; 2005: 2258; With permission.)

proteins. These proteins assemble beneath the bilayer of the host cell, a nucleocapsid forms containing these proteins, and the virus buds from the cell. After budding, the virus matures when an HIV protease enzyme cleaves large polypeptides into smaller functional proteins. Without this process, the virus is unable to infect other cells.

During the early stages of infection, approximately 10 billion virions can be produced each day. Most of the cells containing these viruses will be lysed as a result of budding virions, cytotoxic T-lymphocytes, or undergoing apoptosis. However, HIV will be protected within some cells (macrophages, T cells in lymph nodes), which can stay dormant for years.

The initial immune response against HIV is relatively effective, but it is unable to completely clear the infection, and the patient enters a latent, asymptomatic, or mildly symptomatic stage lasting 5 to 15 years. During this time, a high rate of viral replication can be seen in the lymph nodes. Eventually immune deficiency occurs when the body is no longer able to replenish helper T cells at a rate equal to that at which HIV is destroying them.

**KEY CONCEPT** *The goal of therapy is to maximally and durably suppress HIV replication to restore and preserve immune system function and minimize morbidity and mortality.* Because HIV replication has been found in all areas of the body, it is important to use potent combination drug therapy that can achieve adequate concentrations in all tissues, including protected sites such as the brain and genital tract.

## CLINICAL PRESENTATION AND DIAGNOSIS

Patients who are acutely infected with HIV may be asymptomatic or present with signs and symptoms associated with any viral infection, such as fever, myalgias, lymphadenopathy, pharyngitis, or rash. Taken together, these are the "acute retroviral syndrome," and 40% to 90% of acutely infected individuals will have symptoms.[8] Providers should consider the possibility of HIV infection in any patient with these findings and inquire about recent high-risk sexual encounters or other modes of high-risk exposures. In the United States, 1 in 6 HIV-infected individuals are not aware of their status, thus identifying acutely infected patients and providing referral into HIV care is critical for preventing HIV transmission.[3] In acute infection, HIV RNA concentrations in blood and the genital tract are very high, increasing the risk of transmission to others.[6] Increased infectiousness coupled with undiagnosed HIV infection in these patients may account for a substantial proportion of sexual HIV transmission.

If patients are not identified during acute infection, they may later present with nonspecific symptoms such as myalgias, fatigue, weight loss, thrush, or symptoms associated with opportunistic infections. The U.S. CDC recommends that patients aged 13 to 64 years in all health care settings undergo opt-out HIV testing, meaning that a separate consent form for testing is not needed after the patient has been informed that testing will be performed. For those patients in the high-risk groups mentioned above, HIV testing should be performed on an annual basis, and pregnant women should be tested with each pregnancy.[7]

Diagnosis of HIV is made either by a positive HIV enzyme-linked immunosorbent assay (ELISA) or rapid test (these tests may be positive as soon as 3–6 weeks after infection) and then confirmed by a positive test, usually the HIV western blot (WB) (Table 87–1). At-home HIV-1 test kits (Home Access Systems, OraQuick), allows patients to self-collect blood or oral swab samples, and obtain confidential results in the privacy of their home. Positive results require confirmation by WB.

If the WB is the gold standard confirmatory test and is commonly used. The WB is considered reactive if two of the three major bands (p24, gp41, and/or gp120/160) change color. The test is nonreactive if no viral bands are visible. If the test is indeterminate (one band visible), patients are retested in 2 to

---

**Table 87–1**

**HIV Diagnostic Tests**

| Test | Minimum Time to Detection after Exposure | Sample(s) Tested | Comments |
|---|---|---|---|
| **Initial Screening Tests** | | | |
| ELISA | 3–6 weeks | Plasma | If nonreactive, no further testing is required, unless acute infection suspected |
| HIV RNA assay | Up to 14 days | Plasma | Obtain if recent high-risk exposure; if initially negative, repeat at months 1, 3, and 6 |
| *Rapid tests (currently FDA-approved products):* | Detects HIV antibodies within minutes of sample application | | |
| OraQuick ADVANCE | 3–6 weeks | Oral fluid | Detects HIV-1 and HIV-2 |
| SURE CHECK HIV 1/2 | 3–6 weeks | Whole blood, plasma, or serum | Detects HIV-1 and HIV-2 |
| Multispot HIV-1/HIV-2 Rapid Test | 3–6 weeks | Plasma or serum | Detects HIV-1 and HIV-2 |
| Reveal Rapid HIV-1 Antibody Test | 3–6 weeks | Plasma or serum | Detects HIV-1 |
| Uni-Gold Recombigen HIV Test | 3–6 weeks | Whole blood, plasma, or serum | Detects HIV-1 |
| INSTI™ HIV-1/HIV-2 Rapid Antibody Kit | 3–6 weeks | Plasma or whole blood | Detects HIV-1 and HIV-2 |
| **Confirmatory Tests** | | | |
| Western blot (WB) | 3–6 weeks | Plasma | Gold standard confirmatory test |
| Indirect immunofluorescence assay (IFA) | 3–6 weeks | Plasma | Simple to perform, but requires expertise to interpret results |

ELISA, enzyme-linked immunosorbent assay.

## Clinical Presentation and Diagnosis of HIV

Patients with acute HIV infection may display symptoms described as acute retroviral syndrome. Patients with chronic HIV infection may present with these same nonspecific symptoms and/or opportunistic infections.

### Acute Retroviral Syndrome

The majority of patients may present with fever, lymphadenopathy, pharyngitis, and/or rash. Other symptoms include the following:

- Myalgia or arthralgia
- Diarrhea
- Headache
- Nausea and vomiting
- Hepatosplenomegaly
- Weight loss
- Thrush
- Neurologic symptoms (meningoencephalitis, aseptic meningitis, peripheral neuropathy, facial palsy, or cognitive impairment or psychosis)

### Opportunistic Infections

Depending on the severity of immunosuppression (the CD4$^+$ count), patients may present with the following opportunistic infections (grouped by CD4$^+$ count):

- *Any CD4$^+$ count*
  - *Mycobacterium tuberculosis* disease
  - Bacterial pneumonia (commonly *Streptococcus pneumoniae, Haemophilus influenzae, Pseudomonas aeruginosa,* and *Staphylococcus aureus*)

- Herpes simplex virus disease
- Varicella zoster virus disease
- Bacterial enteric disease (most commonly *Salmonella, Campylobacter,* and *Shigella*)
- Syphilis
- Bartonellosis
- *Less than 200 cells/mm$^3$ (200 × 10$^6$/L)*
  - Coccidioidomycosis
  - *Pneumocystis jiroveci* (formerly *carinii*) pneumonia (PCP or PJP)
  - Oropharyngeal and esophageal candidiasis
  - Kaposi sarcoma or human herpesvirus-8 disease
- *Less than 150 cells/mm$^3$ (150 × 10$^6$/L)*
  - Disseminated histoplasmosis
- *Less than 100 cells/mm$^3$ (100 × 10$^6$/L)*
  - *Toxoplasma gondii* encephalitis
  - Cryptosporidiosis
  - Microsporidiosis
- *Less than 50 cells/mm$^3$ (50 × 10$^6$/L)*
  - Disseminated *Mycobacterium avium* complex disease
  - Cytomegalovirus disease (CMV)
  - Cryptococcosis, aspergillosis

---

3 months. This is most likely if a recent (ie, less than 3–6 weeks) infection has occurred, and HIV antibodies have not yet been fully formed. In this case, a plasma HIV RNA concentration (reverse transcriptase polymerase chain reaction [RT-PCR]) should be evaluated. Patients with acute infection will generally have HIV RNA concentrations greater than 10$^6$ copies/mL (10$^9$ copies/L). **KEY CONCEPT** *HIV treatment response and disease progression is determined by following: (a) the CD4$^+$ lymphocyte count (CD4$^+$ count) and percentage and (b) HIV RNA (viral load).* The CD4$^+$ percentage is followed because the absolute count may fluctuate and does not necessarily indicate a change in the patient's condition.

## TREATMENT

**KEY CONCEPT** *The goals of treatment are to maximally and durably suppress viral replication, avoid the development of drug resistance, restore and preserve immune function, prevent opportunistic infections, minimize drug adverse effects, and prevent disease transmission.* Elimination or cure of HIV is not possible with currently available therapies. Instead, maximal suppression of viral replication (defined as HIV RNA concentrations undetectable by the most sensitive assay available) is desired. After the initiation of antiretroviral therapy, a rapid decline to undetectable HIV RNA in 16 to 24 weeks is a predictor of improved clinical outcomes.[8]

**KEY CONCEPT** *Degree of immune function preservation is also correlated with decreased viral replication and is measured by CD4$^+$ T-cell counts. CD4$^+$ measures are the best predictor of progression to AIDS and help clinicians determine when to initiate treatment.* At CD4$^+$ T-cell counts of 200 cells/mm$^3$ (200 × 10$^6$/L) and lower, patients require drug prophylaxis for opportunistic infections. Table 87–2 details the monitoring points of HIV treatment for HIV RNA and CD4$^+$ T-cell counts. In addition to these parameters, basic blood chemistry tests, liver function tests, complete blood counts, and lipid profiles should be monitored every 3 to 6 months in patients receiving antiretroviral therapy.[8]

Six classes of drugs are available to treat HIV infection: nucleoside (NRTI)/nucleotide (NtRTI) reverse transcriptase inhibitor, protease inhibitor (PI), nonnucleoside reverse transcriptase inhibitor (NNRTI), fusion inhibitors, CCR5 inhibitors, and integrase strand transfer inhibitors (INSTI). **KEY CONCEPT** *Currently, combination antiretroviral drug therapy with three or more active drugs is the standard of care, which increases the durability of viral suppression and decreases the potential for the development of resistance. Two nucleoside (nucleotide) reverse transcriptase inhibitors AND an NNRTI OR a ritonavir-boosted PI OR an INSTI are the mainstay regimens of combination therapy in initial treatment.* Combination regimens decrease HIV RNA to less than 50 copies/mL (50 × 10$^3$ copies/L) in 80% to 90% of patients in clinical trials.[8] Therefore, monotherapy with any agent or the use of NRTIs without another drug class are not recommended

**Table 87–2**

**Monitoring End Points for CD4⁺ T-Cell Counts and HIV RNA**

| CD4⁺ T Cell Counts | | | HIV RNA Concentration | | |
|---|---|---|---|---|---|
| When to Monitor? | Why? | Goal | When to Monitor? | Why? | Goal |
| Initial diagnosis | Assess immune function<br>Assess need for OI chemoprophylaxis | Start therapy in appropriate patients<br>Start prophylaxis when counts < 200 cells/mm³ (200 × 10⁶/L) | Initial diagnosis/ evaluation<br>2–8 weeks after starting or changing ART[a] | Establish baseline<br>Early assessment of regimen efficacy | Start ART in appropriate patients<br>Undetectable concentrations |
| Every 3–6 months | Receiving ART: monitor success of treatment[b] | Average increase of 100–150 cells/ mm³/year (100 × 10⁶–150 × 10⁶/L/year) | Every 3–6 months | Receiving ART: assess success and durability of virologic suppression and adherence with current regimen | Steadily decreasing and/or consistently undetectable concentrations |
| | Not receiving ART: assess urgency to begin therapy<br>Assess need for OI chemoprophylaxis | Start ART in appropriate patients<br>Start prophylaxis when counts < 200 cells/ mm³ (200 × 10⁶/L) | Optional[c] | Not receiving ART: monitor changes in viral load | Start therapy in appropriate patients |

ART, antiretroviral therapy; OI, opportunistic infection.

[a]If viral load is detectable, repeat every 4 to 8 weeks until less than 200 copies/mL (200 × 10³/L), then resume every 3- to 6-month schedule.

[b]In clinically stable patients with viral loads less than 50 copies/mL (50 × 10³/L) for more than 2 years, monitoring can be extended to every 6 to 12 months.

[c]For patients who choose to delay therapy, repeat viral load testing while not on therapy is optional. HIV RNA concentration should be determined prior to initiating therapy.

## Patient Encounter 1, Part 1: Treatment Initiation

A 32-year-old white man presents to the clinic requesting to be tested for HIV. He reports having unprotected receptive anal intercourse with multiple male partners in the past year. Last week, he presented to the urgent care clinic with complaints of fever, malaise, and pharyngitis. He was prescribed azithromycin for a presumed bacterial infection.

**PMH:** Seizure disorder, Allergic rhinitis, obesity

**FH:** Mother—HTN, CAD; father—Type II DM, dyslipidemia, prostate cancer

**SH:** Financial advisor; reports multiple sexual partners in the past 12 months with condom use about 50% of the time. He denies illicit drugs, but drinks about 10 alcoholic drinks weekly

**Meds:** Carbamazepine 200 mg by mouth twice daily; azithromycin 500 mg by mouth on day 1, 250 mg by mouth days 2 to 5 (completed 2 days ago); fexofenadine by mouth once daily; multivitamin by mouth once daily

**All:** Penicillin (anaphylaxis)

**ROS:** Negative for weight loss, decreased appetite, shortness of breath, and cough, chest pain, nausea, vomiting, diarrhea

**PE:**

Within normal limits

**VS:** BP 124/84 mm Hg, P 73 beats/min, RR 18 breaths/min, T 39.3°C

**HEENT:** Within normal limits

**CV:** RRR, normal S1, S2; no murmurs, rubs, gallops

**Abd:** Soft, nontender, nondistended; (+) bowel sounds, no hepatosplenomegaly

**Rectal:** Deferred

**Labs:** Sodium 135 mEq/L (135 mmol/L), potassium 3.6 mEq/L (3.6 mmol/L), chloride 100 mEq/L (100 mmol/L), bicarbonate 24 mEq/L (24 mmol/L), blood urea nitrogen 14 mg/dL (5 mmol/L), creatinine 1.0 mg/dL (88 μmol/L), WBC 5.2 × 10³/mm³ (5.2 × 10⁹/L), hemoglobin 11.5 g/dL (115 g/L or 7.14 mmol/L), hematocrit 34.1% (0.341), platelets 151 × 10³/mm³ (151 × 10⁹/L), neutrophils 58% (0.58), bands 9% (0.09), lymphocytes 32% (0.32), monocytes 1% (0.01), eosinophils 0% (0.00), basophils 0% (0.00)

*What information is suggestive of HIV?*

treatment options. Fusion inhibitors are only FDA approved for use in treatment experienced patients with drug resistance to NRTIs, NNRTIs, and/or PIs. Figure 87–1 details the mechanisms of action of the drug classes within the life cycle of HIV.

## Nonpharmacologic Interventions

**KEY CONCEPT** *Patient adherence is a key component in treatment success.* Drug therapy is required for a lifetime, as the virus begins to replicate at high levels when medications are stopped. HIV combination therapy used in the past was exceedingly complicated for patients, with multiple daily doses, varying food restrictions, and large pill burdens. Advances in delivery and formulations now make possible once- or twice-daily dosing with fewer pills per day. Currently, two combination tablets providing one pill, once daily NNRTI-containing regimens are available: tenofovir + emtricitabine + efavirenz (Atripla) and tenofovir + emtricitabine + rilpivirine (Complera). Additionally, two fixed dose INSTI-containing combination tablets are available: elvitegravir + cobicistat + tenofovir + emtricitabine (Stribild) and dolutegravir + abacavir + lamivudine (Triumeq), both once daily regimens. The use of low-dose ritonavir or cobicistat to enhance the concentrations of other PIs or elvitegravir, respectively (known as pharmacokinetic enhancement, or "boosting" agents) allows for significantly fewer daily doses and lower pill burdens. Cobicistat, unlike ritonavir, does not exert antiviral activity. Atazanavir or darunavir with ritonavir boosting are potent, once-daily PI options; once-daily lopinavir/ritonavir may be used in selected treatment-naïve patients. These advances, however, do not replace the need for patient counseling by a trained pharmacist and a multidisciplinary approach to promoting adherence.

All patients should be counselled initially and repeatedly on ways to prevent viral transmission. Preventing the spread of resistant virus is particularly important. Patients receiving antiretroviral therapy can still transmit virus to sexual partners and to those with whom they share needles or other drug equipment. Where both partners are HIV-positive, safe sex and needle practices reduce the risk of superinfection with differing strains of HIV and the transmission of other sexually transmitted diseases. General guidelines for preventing viral transmission include using condoms with a water-based lubricant for vaginal or anal intercourse, using condoms without lubricant or dental dams for oral sex, and not sharing equipment used to prepare, inject, or inhale drugs. Treating other sexually transmitted infections (STIs), particularly genital herpes, in HIV-infected patients may help to prevent HIV transmission. The presence of STIs increases genital tract HIV viral load and, correspondingly, the risk of HIV transmission to sexual partners.

**KEY CONCEPT** *Nutrition and dietary counseling should also be included in the care of the HIV patient, as poor nutrition leads to poorer outcomes and complicates treatment.* Antiretroviral therapy itself introduces a host of nutritional issues, including drug–food interactions, GI adverse effects that may affect appetite and limit dietary intake, lipid abnormalities, and fat redistribution. The American Dietetics Association currently recommends assessing HIV-infected patients for their level of nutritional risk and involving a registered dietician as part of the clinical team for optimal nutrition care.[9]

## Pharmacologic Therapy for Antiretroviral-Naïve Patients

Two expert panels publish guidelines for the treatment of HIV-infected individuals. Although the recommendations are quite similar, slight differences do exist between the Department of Health and Human Services (DHHS) Guidelines[8] and the International AIDS Society–USA (IAS-USA) Panel Recommendations.[10] The DHHS Guidelines are updated frequently, and current and archived versions are available online at www.aidsinfo.nih.gov. Due to the intense research and constant modifications to therapeutic approaches in the treatment of HIV, the majority of the treatment algorithms and recommendations presented herein follow the most up-to-date information found in the May 2014 DHHS recommendations.

**KEY CONCEPT** *The decision of when to begin antiretroviral therapy is complex. Initiating highly active antiretroviral therapy should be considered in all HIV-infected individuals willing to adhere to lifelong therapy. The strength of this recommendation is based on the CD4+ T-cell count and other comorbid conditions.* Other factors to consider include the patient's viral load, decline in CD4+ counts over time, hepatitis C status, risk for cardiovascular disease, risk of transmission to sex partners, willingness to begin therapy and maintain medication adherence, and the risk versus benefit of treating an asymptomatic patient. The DHHS guidelines recommend initiating antiretroviral therapy in all HIV-infected individuals to reduce the risk of disease progression. The strength and evidence to support this recommendation depends on pretreatment CD4+ T lymphocyte count. The clinical evidence is strongest for beginning treatment at CD4+ counts less than 350 cells/mm³ ($350 \times 10^6$/L), but more recent evidence from long-term studies and the availability of potent drugs with improved tolerability support earlier treatment at higher CD4+ counts. Once the decision is made to initiate treatment, the regimen is selected based on patient-specific factors. **KEY CONCEPT** *All recommended regimens for initial treatment contain an NNRTI, a ritonavir-boosted PI, or an INSTI in combination with two NRTI (tenofovir + emtricitabine or abacavir + lamivudine).* The recommended agents are shown in Table 87–3.

---

### Table 87–3

**Recommended Initial ART Regimen Options for All Patients, Regardless of Pre-ART Viral Load or CD4+ Cell Count[8]**

**NNRTI-Based Regimens:**
Efavirenz + tenofovir + emtricitabine
Efavirenz + abacavir + lamivudine *(Only for patients with pre-ART plasma HIV RNA < 100,000 copies/mL [100 x 10⁶/L] AND HLA-B\*5701 negative)*
Rilpivirine + tenofovir + emtricitabine *(Only for patients with pre-ART plasma HIV RNA < 100,000 copies/mL [100 x 10⁶/L] AND CD4+ count > 200 cells/mm³ [200 × 10⁶/L])*

**PI-Based Regimens:**
Atazanavir/ritonavir + tenofovir + emtricitabine
Atazanavir/ritonavir + abacavir + lamivudine *(Only for patients with pre-ART plasma HIV RNA < 100,000 copies/mL [100 × 10⁶/L] AND HLA-B\*5701 negative)*
Darunavir/ritonavir + tenofovir + emtricitabine

**INSTI-Based Regimens:**
Dolutegravir + abacavir + lamivudine *(Only for patients who are HLA-B\*5701 negative)*
Dolutegravir + tenofovir + emtricitabine
Elvitegravir + cobicistat + tenofovir + emtricitabine *(Only for patients with pre-ART CrCL > 70 mL/min [1.17 mL/s])*
Raltegravir + tenofovir + emtricitabine

The decision to choose an NNRTI-, PI-, or INSTI-based regimen as initial therapy is based on many patient- and clinician-specific factors. Drug resistance testing should be performed at diagnosis and again prior to initiating treatment if time has elapsed between diagnosis and treatment (see Pharmacologic Therapy for Antiretroviral-Experienced Patients for further discussion of drug resistance testing). The results of resistance testing may dictate which drug class is preferred; a minimum of 10% to 17% of newly diagnosed patients will have drug-resistant virus.[11] This initial resistance pattern often involves the NNRTIs, but may involve other drug classes. NNRTI-based regimens have low pill burdens and may have decreased incidences of long-term adverse effects (eg, dyslipidemia) in comparison with some PI-based regimens. However, this class also has a low threshold for drug resistance (the K103N mutation causes high level cross-class resistance), and patient adherence is a critical consideration. In pregnant women, or women with the potential to become pregnant, a PI-based regimen is preferred due to the potential teratogenicity of efavirenz in early pregnancy (Pregnancy Category D). INSTI-based regimens have the advantage of avoiding many complex drug–drug interactions and toxicities seen with NNRTIs and PIs. However, raltegravir must be dosed twice daily, elvitegravir must be coadministered with cobicistat which is associated with many cytochrome (CYP)-450-mediated drug interactions and should not be initiated in patients with a creatinine clearance less than 70 mL/min (1.17 mL/s). Transmitted INSTI resistance is not yet a major clinical concern, but may develop as integrase inhibitors come into wider use. If transmitted INSTI resistance is a concern, integrase resistance testing must be ordered separately from standard HIV genotyping, which only includes the protease and reverse transcriptase genes.

In patients who cannot tolerate the preferred first-line therapies, or have a compelling reason to choose a different agent, the following alternative regimens are recommended.[8]

1. PI based:
   a. Darunavir/ritonavir + abacavir/lamivudine
   b. Lopinavir/ritonavir (dosed once or twice daily) + either tenofovir/emtricitabine OR abacavir/ lamivudine
2. INSTI:
   a. Raltegravir + abacavir/lamivudine

If abacavir is included in a regimen, patients should undergo human leukocyte antigen (HLA)-B*5701 testing prior to initiation to assess the risk of abacavir hypersensitivity. Patients who test positive for the allele are at high risk (approximately 50%–67%) of developing this reaction and should not be given abacavir.[8] An abacavir allergy should also be documented in the patient's medical record to prevent future administration. Those patients with a negative test may receive abacavir, but should still be counseled and monitored for the development of hypersensitivity.

Regimens with demonstrated efficacy but less desirable, including the CCR5 antagonist maraviroc, the NNRTI nevirapine, unboosted atazanavir, and boosted saquinavir are no longer recommended as first-line therapy for treatment-naïve patients. One of these regimens should only be selected if a first-line regimen is intolerable or the patient has a compelling reason to avoid drugs in a first-line regimen. If maraviroc is under consideration, viral tropism testing should be performed to ensure CCR5-tropic virus for optimal efficacy.

Therapies *not recommended* for initial treatment due to poor potency or significant toxicity include triple-NRTI regimens, delavirdine, nevirapine in patients with moderate to high CD4[+]

### Patient Encounter 1, Part 2

After receiving the diagnosis of HIV and assessing his laboratory values and willingness to initiate therapy, the patient from Part 1 and his medical team decide to start antiretrovirals.

*What is the guidance for when to start therapy in a treatment-naïve patient?*

*What are the recommended regimens according to the DHHS Guidelines?*

*What is the potential for drug interactions with each of the recommended regimens?*

*Which concomitant medication complicates initiating therapy in this patient and what are possible ways to manage such drug interactions?*

*What adverse effects does the patient need to be counseled on with each of the recommended regimens?*

T-cell counts, indinavir ± ritonavir, darunavir, saquinavir or fosamprenavir used without ritonavir ("unboosted"), ritonavir used without another PI, nelfinavir, tipranavir/ritonavir, and tenofovir, lamivudine, or emtricitabine with didanosine. Because of limited data in antiretroviral naïve patients, etravirine is not recommended in the DHHS Guidelines at this time.

Drugs that should *not be combined* due to overlapping toxicities include atazanavir plus indinavir (due to enhanced hyperbilirubinemia), two NNRTIs, and didanosine plus stavudine. Emtricitabine and lamivudine should not be combined because of their similar chemical structures, and antagonism can result when stavudine is combined with zidovudine.

## Pharmacologic Therapy for Antiretroviral-Experienced Patients

**KEY CONCEPT** *Ongoing viral replication, whether at low levels in the face of adequate drug concentrations or at higher levels due to inconsistent systemic concentrations (or low concentrations in sanctuary sites, eg, male and female genital fluids, cerebrospinal fluid, or lymph nodes), will eventually lead to resistance to the prescribed medications.* To avoid further progression of resistant mutations, a failing regimen should be discontinued as soon as possible. *Virologic failure is defined as the inability to obtain or maintain an HIV RNA less than 200 copies/mL* ($200 \times 10^3$ copies/L), *whereas incomplete virologic suppression is defined as two consecutive HIV RNA greater than 200 copies/mL* ($200 \times 10^3$ copies/L) *after 24 weeks of therapy.*[8] Immunologic failure is defined as the failure to achieve and/or maintain an adequate CD4[+] count in the setting of virologic suppression. A typical CD4[+] count should increase at least 150 cells/mm³ ($150 \times 10^6$/L) over the first year of therapy. The goal of therapy for patients with antiretroviral resistance is to reestablish virologic suppression or HIV RNA lower than the limit of detection of the assay (typically less than 40 *copies/mL* [$40 \times 10^3$ copies/L]).

Treatment considerations for antiretroviral-experienced patients are much more complex than for patients who are naïve to therapy. Prior to changing therapy, the reasons for treatment failure should be identified. A comprehensive review of the patient's severity of disease, antiretroviral treatment history, adherence to therapy, intolerance or toxicity, concomitant drug

therapies, comorbidities, and results of current and past HIV resistance testing should be performed. If patients fail therapy due to poor adherence, the underlying reasons must be determined and addressed prior to initiation of new therapy. Reasons for poor adherence include problems with medication access, active substance abuse, depression and/or denial of the disease, and a lack of education on the importance of 100% adherence to therapy. Medication intolerance or toxicity can be remedied with therapy for the adverse event, exchanging the drug causing the toxicity with another in the same class, or changing the entire regimen. Pharmacokinetics or systemic drug exposure can be optimized by ensuring maximal drug absorption (taking the drug with or without food can alter exposure by up to 30%) and avoiding interactions with concomitant prescription or nonprescription medications and dietary supplements. When causes for treatment failure are identified, appropriate strategies for therapy can be determined.

An additional consideration when stopping or changing therapy is a staggered discontinuation of antiretrovirals with different half-lives. For example, in patients taking Atripla (tenofovir, emtricitabine, and efavirenz), tenofovir and emtricitabine should be continued for at least 4 to 7 days after discontinuation of the Atripla combination pill due to the much prolonged half-life of efavirenz as compared with tenofovir and emtricitabine. Without continued dosing of tenofovir and emtricitabine, patients will have prolonged exposure of only efavirenz resulting in efavirenz monotherapy, which has demonstrated antiretroviral resistance. If new antiretroviral therapy is to be initiated immediately, no overlap is necessary; however, it should be noted that efavirenz concentrations will persist for some period of time.[8]

Drug interactions between antiretrovirals and between antiretrovirals and concomitant medications should be evaluated for each patient to avoid under- and/or overexposure of either therapy. **KEY CONCEPT** *NNRTIs, PIs, certain INSTIs, and maraviroc are metabolized by CYP-450 enzymes. In addition, NNRTIs, PIs, and cobisistat are inhibitors and/or inducers of this enzyme system.* In addition, some of the antiretrovirals are substrates, inhibitors, and/or inducers of transporters such as P-glycoprotein (P-gp) and therefore may lead to drug interactions. Information provided in **Table 87–4** describes the drug interaction potential of each antiretroviral. Due to the ever-changing drug interactions with this class of medications, the regularly updated DHHS Guidelines for the Use of Antiretroviral Agents in HIV-1–Infected Adults and Adolescents are a recommended source of specific drug interactions.[8]

The goals of therapy differ for antiretroviral-experienced patients who have limited drug exposure (ie, developing resistance to their first antiretroviral regimen) versus those with extensive exposure (ie, developing resistance to their third or fourth antiretroviral regimen). It is reasonable to expect maximal viral suppression in those with limited drug exposure. However, this may not be feasible for patients with prior exposure to multiple medications. In antiretroviral-experienced patients, a reasonable goal is to simply preserve immune function and prevent clinical progression.

Several issues need to be considered in choosing a salvage regimen for HIV infection. Knowing prior medication exposure can assist in identifying which drugs to avoid. However, direct HIV resistance testing can better identify the resistance and susceptibility patterns of the major viral strains. Because HIV may be susceptible to certain components of the failing antiretroviral regimen, these drugs can be recycled into future regimens. Resistance testing should be used when all patients enter into care, in patients with virologic failure on an antiretroviral regimen, or with suboptimal suppression after initiation of antiretroviral therapy. Testing is generally preferred for antiretroviral naïve patients. For resistance testing to be useful, the patient should have a plasma HIV RNA of at least 1000 copies/mL ($1 \times 10^6$ copies/L) and should be currently taking their antiretroviral medications (or be within 4 weeks of discontinuing antiretroviral therapy). This viral concentration is necessary to yield reliable amplification of the virus, and the antiretroviral medications are needed because the dominant viral species reverts to **wild-type** within 4 to 6 weeks after medications are stopped.

Two types of HIV resistance testing are available, an HIV **genotype** and an HIV **phenotype**. Genotyping involves detecting mutations by genetically sequencing the virus, whereas phenotyping determines the ability of the virus to replicate in the presence of varying antiretroviral concentrations. Genotyping is more rapid and less costly than phenotyping, but results in a list of mutations that may be more difficult to interpret than phenotyping. An HIV virtual phenotype report may also be obtained when genotypes are ordered.[8] This compares the patient's viral sequence to a database of matched genotypes and drug susceptibilities. Web-based tools are available to assist with interpretation of resistance mutations (eg, Stanford University's HIV Drug Resistance Database; http://hivdb.stanford.edu/index.html). However, expert interpretation of genotype and phenotype reports is recommended.

Management of antiretroviral-experienced patients is complex, and expert opinion is advised before selecting therapy. **KEY CONCEPT** *As with antiretroviral-naïve patients, three or more active drugs should be prescribed.*[8] Since considerable cross-resistance can occur between medications within an antiretroviral class, simply using drugs to which the patient has not been exposed may be insufficient. Complete cross-resistance occurs within the first generation of NNRTIs, whereas the NRTIs and PIs have variable overlapping resistance patterns. For this reason, HIV resistance assays are important tools for choosing subsequent effective therapies. The use of antiretrovirals with unique mechanisms of action like enfuvirtide (fusion inhibitor) or maraviroc (CCR5 antagonist) may be warranted as salvage therapy.

If patients fail therapy with resistance to only one drug, one or two active agents may be substituted for this drug while retaining the remaining drugs in the regimen. If patients fail therapy with resistance to more than one drug, changing classes of antiretrovirals and/or adding new active drugs is warranted. New NRTIs should be selected from resistance testing. If this is not available, the assumption should be made that resistance has developed to all NRTIs used in the failing regimen. In general, HIV that is resistant solely to lamivudine and/or emtricitabine will be susceptible to other NRTIs. If HIV develops resistance solely to tenofovir, then it may have reduced susceptibility to didanosine and likely abacavir but should remain susceptible to zidovudine, stavudine, lamivudine, and emtricitabine. Cross-resistance occurs between zidovudine and stavudine.[8]

If a patient appears to fail an antiretroviral regimen without detectable HIV resistance, adherence should be investigated, and the adequacy of the plasma HIV RNA concentration in the resistance sample confirmed. Options include continuing the current regimen or starting a new regimen and repeating the resistance test 2 to 4 weeks after adherence is verified. The availability of new potent antiretrovirals has resulted in a decrease in the number of patients with multiclass drug resistance. Although rare, such patients have very limited treatment options, making it impossible to construct a regimen with two to three active agents.

**Table 87–4**

**Summary of Currently Available Antiretroviral Agents**

| Generic Name [Abbreviation] (Trade Name) | Dosage Forms | Commonly Prescribed Doses | Dose Adjustments | | | Food Restrictions | Significant Adverse Events | Drug Interaction Potential |
|---|---|---|---|---|---|---|---|---|
| **Nucleoside (Tide) Reverse Transcriptase Inhibitors** | | | | | | | | |
| Abacavir (Ziagen) | 300-mg tablet; 20 mg/mL oral solution | 300 mg twice daily or 600 mg once daily | None | | | None (alcohol increases abacavir conc. by 41%) | Potentially fatal hypersensitivity reaction (rash, fever, malaise, nausea, vomiting, shortness of breath, sore throat, loss of appetite)—HLA B*5701 test before treatment | Alcohol dehydrogenase and glucuronyl transferase, 82% renal excretion of metabolites |
| Didanosine (Videx EC) | 125-, 200-, 250-, 400-mg capsules; 10 mg/mL oral Powder for Suspension: | > 60 kg: 400 mg daily < 60 kg: 250 mg daily | CrCl (mL/ min[mL/s]): 30–59 [0.50–0.99] 10–29 [0.17–0.49] less than 10 [0.17] | Greater than 60 kg: 200 mg 125 mg 125 mg | Less than 60 kg: 125 mg 100 mg 75 mg | Take 30 minutes prior or 2 hours after meal (conc. decrease 55% with food) | Pancreatitis; peripheral neuropathy; nausea; diarrhea | Renal excretion |
| Emtricitabine (Emtriva) | 200-mg capsule; 10 mg/mL oral solution | 200 mg daily; 240 mg (24 mL) oral solution daily | CrCl (mL/ min[mL/s]): 30–49 [0.50–0.82] 15–29 [0.25–0.49] < 15/HD [0.25/HD] (Dose after dialysis on dialysis days) | Capsule: 200 mg every 48 hours 200 mg every 72 hours 200 mg every 96 hours | Solution: 120 mg every 24 hours 80 mg every 24 hours 60 mg every 24 hours | None | Minimal | Renal excretion |
| Lamivudine (Epivir) | 150-mg and 300-mg tablets or 10 mg/mL oral solution | 150 mg twice daily or 300 mg once daily | CrCl (mL/ min[mL/s]): 30–49 [0.50–0.82] 15–29 [0.25–0.49] 5–14 [0.08–0.24] < 5/HD [0.08/HD] (Dose after dialysis on dialysis days) | Dose: 150 mg every day 150 mg, then 100 mg every day 150 mg, then 50 mg every day 50 mg, then 25 mg every day | | None | Minimal | Renal excretion |

**Summary of Currently Available Antiretroviral Agents (*Continued*)**

| Generic Name [Abbreviation] (Trade Name) | Dosage Forms | Commonly Prescribed Doses | Dose Adjustments | | | Food Restrictions | Significant Adverse Events | Drug Interaction Potential |
|---|---|---|---|---|---|---|---|---|
| Stavudine (Zerit) | 15-, 20-, 30-, 40-mg capsules or 1 mg/mL for oral solution | > 60 kg: 40 mg twice daily < 60 kg: 30 mg twice daily | **CrCl (mL/ min[mL/s]):** 26–50 [0.43–0.83] 10–25/HD [0.17–0.42/HD] | **Greater than 60 kg:** 20 mg every 12 hours 20 mg every 24 hours | **Less than 60 kg:** 15 mg every 12 hours 15 mg every 24 hours | None | Peripheral neuropathy; lipodystrophy; rapidly progressive ascending neuromuscular weakness (rare); pancreatitis; lactic acidosis with hepatic steatosis (higher incidence with stavudine than with other NRTIs); hyperlipidemia | Renal excretion |
| Tenofovir disoproxil fumarate (Viread) | 150, 200, 250-, 300-mg tablet Oral powder for suspension 40 mg per 1g powder | 300 mg daily | **CrCl (mL/ min[mL/s]):** 30–49 [0.50–0.82] 10–29 [0.17–0.49] ESRD/HD (Dose after dialysis on dialysis days) | **Dose:** 300 mg every 48 hours 300 mg twice weekly 300 mg every 7 days | | Powder taken with food | Asthenia, headache, diarrhea, nausea, vomiting, and flatulence; renal insufficiency | Renal excretion |
| Zidovudine (Retrovir) | 100-mg capsule, 300-mg tablet, 10 mg/mL IV solution, 10 mg/mL oral solution | 600 mg daily in two to three divided doses | 100 mg 3 times daily or 300 mg once daily in severe renal impairment (CrCl < 15 mL/min [0.25 mL/s]) or HD | | | None | Bone marrow suppression: macrocytic anemia or neutropenia; GI intolerance, headache, insomnia, asthenia | Glucuronyl transferase and renal |
| Zidovudine + lamivudine (Combivir) | Zidovudine 300 mg + Lamivudine 150-mg tablet | One tablet twice daily | Do not use with CrCl < 50 mL/min (0.83 mL/s) | | | None | See adverse events for zidovudine and lamivudine | See zidovudine and lamivudine |
| Abacavir + lamivudine + zidovudine (Trizivir) | Abacavir 300 mg + lamivudine 150 mg + zidovudine 300-mg tablet | One tablet twice daily | Do not use with CrCl < 50 mL/min (0.83 mL/s) | | | None | See adverse events for zidovudine, lamivudine, and abacavir | See zidovudine, lamivudine, and abacavir |
| Abacavir + lamivudine (Epzicom) | Abacavir 600 mg + lamivudine 300-mg tablet | One tablet daily | Do not use with CrCl < 50 mL/min (0.83 mL/s) | | | None | See adverse events for abacavir and lamivudine | See abacavir and lamivudine |
| Tenofovir + emtricitabine (Truvada) | Tenofovir 300 mg + emtricitabine 200-mg tablet | One tablet daily | **CrCl (mL/ min[mL/s]):** 30–49 [0.50–0.82] < 30 [0.50] | **Dose:** One tablet every 48 hours Not recommended | | None | See adverse events for tenofovir and emtricitabine | See tenofvir and emtricitabine |

**Nonnucleoside Reverse Transcriptase Inhibitors**

| | | | | | | |
|---|---|---|---|---|---|---|
| Delavirdine (Rescriptor) | 100-, 200-mg tablets | 400 mg 3 times daily (100-mg tablet can be dispersed in 3 oz or more of water to produce slurry); 200-mg tablet should be administered whole; separate dosing from buffered didanosine or antacids by 1 hour | Use with caution in patients with hepatic impairment | None | Rash; increased LFTs, headaches | Metabolized by cytochrome P-450 (CYP); CYP3A inhibitor; 51% excreted in urine (< 5% unchanged); 44% in feces |
| Efavirenz (Sustiva) | 50-, 200-mg capsules or 600-mg tablet | 600 mg daily at or before bedtime | Use with caution in patients with hepatic impairment | Take on an empty stomach high-fat/calorie meals increases $C_{max}$ of capsule 39% and $C_{max}$ of tablet 79% | Rash; CNS symptoms (insomnia, irritability, lethargy, dizziness, vivid dreams) usually resolve in 2 weeks; increased LFTs; false-positive cannabinoid test; teratogenic in monkeys | Metabolized by CYP2B6 and CYP3A (3A mixed inducer/ inhibitor); 14–34% excreted in urine (glucuronidated metabolites, < 1% unchanged); 16%–61% in feces |
| Etravirine (Intelence) | 100-, 200-mg tablets | 200 mg twice daily following a meal | No dosage adjustment for Child Pugh Class A or B. Has not been evaluated for Class C | Take following a meal. Fasting decreases by 50% | Rash, nausea | Metabolized by CYP3A, 2C9, and 2C19; Induces 3A4 and inhibits 2C9 and 2C19 |
| Nevirapine (Viramune, Viramune XR) | 200-mg tablet, 100 and 400mg XR tablet or 50 mg/5 mL oral suspension, | 200 mg once daily for 14 days; then 200 mg twice daily, For XR tablet, lead-in with 200 mg once daily of IR tablet followed by 400 mg daily XR tab | Use with caution in patients with hepatic impairment; avoid use with moderate to severe hepatic impairment | No food restrictions | Rash including Stevens-Johnson syndrome; symptomatic hepatitis, including fatal hepatic necrosis | Metabolized by CYP2B6 and CYP3A (3A inducer); 80% excreted in urine (glucuronidated metabolites; less than 5% unchanged); 10% in feces |
| Rilpivirine (Edurant) | 25-mg tablet | 25 mg daily | No dosage adjustment for Child Pugh Class A or B. Has not been evaluated for Class C; Use with caution in severe or end-stage renal impairment | Take with a normal- to high-calorie meal Absorption dependent on gastric pH-special considerations needed when coadministered with antacids | Rash; depressive disorders; | Metabolized by CYP3A4 |

Table 87–4

**Summary of Currently Available Antiretroviral Agents (*Continued*)**

| Generic Name [Abbreviation] (Trade Name) | Dosage Forms | Commonly Prescribed Doses | Dose Adjustments | | Food Restrictions | Significant Adverse Events | Drug Interaction Potential |
|---|---|---|---|---|---|---|---|
| Tenofovir + emtricitabine + efavirenz [tenofovir/ emtricitabine/ efavirenz] (Atripla) | Tenofovir 300 mg Emtricitabine 200 mg Efavirenz 600 mg | One tablet daily | Do not use in patients with CrCl < 50 mL/min (0.83 mL/s) | | High-fat/high-caloric meals increase peak plasma concentrations of efavirenz capsules by 39% and efavirenz tablets by 79%; take on empty stomach | See adverse events of tenofovir, emtricitabine, and efavirenz | See tenofovir, emtricitabine, and efavirenz |
| Tenofovir + emtricitabine + rilpivirine [tenofovir/ emtricitabine/ rilpivirine] (Complera) | Tenofovir 300 mg Emtricitabine 200 mg Rilpivirine 25mg | One tablet daily | Do not use in patients with CrCl < 50 mL/min (0.83 mL/s) | | Take with a meal (preferrably high fat), avoid acid suppression | See adverse events of tenofovir, emtricitabine, and rilpivirine | See tenofovir, emtricitabine, and rilpivirine |
| **Protease Inhibitors** | | | | | | | |
| Atazanavir (Reyataz) | 100-, 150-, 200-, 300-mg capsules | Atazanavir 300mg + ritonavir 100mg or atazanavir 400 mg daily If taken with tenofovir use the following: atazanavir 300 mg daily + ritonavir 100 mg daily If taken with efavirenz in treatment of naïve patients only: atazanavir 400 mg daily + ritonavir 100 mg daily (do not use efavirenz in treatment of experienced patients) | Child-Pugh Class 7–9 > 9 | Dose 300 mg daily Not recommended; Treatment-naïve patients on hemodialysis: atazanavir 300 mg + ritonavir 100 mg daily; treatment-experienced patients on hemodialysis: Not recommended | Take with food (AUC increases 30%); pH-sensitive dissolution— special considerations needed when coadministered with antacids | Indirect hyperbilirubinemia; prolonged PR interval (asymptomatic first-degree AV block); use with caution in patients with underlying conduction defects or on concomitant medications that can cause PR prolongation; hyperglycemia; fat maldistribution; increased bleeding episodes in patients with hemophilia | CYP3A4 inhibitor and substrate; UGT1A1 inhibitor |

| Darunavir (Prezista) | 75-g, 150-mg, 600-mg, 800-mg tablets, 100 mg/mL oral suspension | Darunavir 600 mg + ritonavir 100 mg twice daily in treatment experienced patients Darunavir 800 mg daily + ritonavir 100 mg daily in treatment naïve patients | Use with caution in patients with hepatic impairment | | Should be given with food | Skin rash (has a sulfonamide moiety, Stevens-Johnson and erythema multiforme have been reported); diarrhea, nausea; headache; hyperlipidemia; transaminase elevation; hyperglycemia; fat maldistribution; possible increased bleeding episodes in patients with hemophilia | CYP3A4 inhibitor and substrate |
|---|---|---|---|---|---|---|---|
| Fosamprenavir (Lexiva) | 700-mg tablet; 50 mg/mL oral suspension | ARV-naïve patients: fosamprenavir 1400 mg twice daily, Fosamprenavir 700 mg + ritonavir 100 mg twice daily, or fosamprenavir 1400 mg + ritonavir 200 mg once daily; PI-experienced *patients:* fosamprenavir 700 mg + ritonavir 100 mg twice daily | Child-Pugh Class 5–8 9–12 | Dose 700 mg twice daily Not recommended | None | Skin rash; diarrhea, nausea and vomiting; headache; hyperlipidemia; LFT elevation; hyperglycemia; fat maldistribution; increased bleeding episodes in patients with hemophilia | CYP3A4 inhibitor, inducer, and substrate |
| | | Coadministration with efavirenz: fosamprenavir 700 mg + ritonavir 100 mg twice daily or fosamprenavir 1400 mg + ritonavir 300 mg once daily | Ritonavir should not be used in patients with hepatic impairment | | | | |

Table 87–4

**Summary of Currently Available Antiretroviral Agents (*Continued*)**

| Generic Name [Abbreviation] (Trade Name) | Dosage Forms | Commonly Prescribed Doses | Dose Adjustments | Food Restrictions | Significant Adverse Events | Drug Interaction Potential |
|---|---|---|---|---|---|---|
| Indinavir (Crixivan) | 200-, 400-mg capsules | 800 mg every 8 hours; indinavir 800 mg + ritonavir 100 twice daily; indinavir 800 mg + ritonavir 200 mg twice daily | Mild to moderate hepatic insufficiency due to cirrhosis: 600 mg every 8 hours | *For unboosted indinavir:* Take 1 hour before or 2 hours after heavy meals, or concomitantly with low-fat meal. No restrictions when used with ritonavir | Nephrolithiasis; GI intolerance, nausea; indirect hyperbilirubinemia; hyperlipidemia; headache, asthenia, blurred vision, dizziness, rash, metallic taste, thrombocytopenia, alopecia, hemolytic anemia; hyperglycemia; fat maldistribution; increased bleeding episodes in patients with hemophilia | CYP3A4 inhibitor (less than ritonavir) |
| Lopinavir + ritonavir (Kaletra) | Lopinavir 100 mg + ritonavir 25 mg tablet, Lopinavir 200 mg + ritonavir 50-mg tablet, lopinavir 400 mg + ritonavir 100 mg/5 mL oral solution (contains 42% alcohol) | two 200/50 mg tablets or 5 mL twice daily four 200/50 mg tablets once daily; with efavirenz or nevirapine: 3 tablets or 6.5 mL twice daily | Use with caution in patients with hepatic impairment | Take with food (AUC increases 48%–80%) | Nausea, vomiting, diarrhea; asthenia; hyperlipidemia; LFT elevation; hyperglycemia; fat maldistribution; increased bleeding episodes in hemophiliacs | CYP3A4 inhibitor and susbstrate CYP2C9, 2C19, 1A2 inducer |
| Nelfinavir (Viracept) | 250- to 625-mg tablets, 50 mg/g oral powder | 1250 mg twice daily or 750 mg three times daily | Use with caution in patients with hepatic impairment | Take with meal or snack | Diarrhea; hyperlipidemia; hyperglycemia; fat maldistribution; increased bleeding in hemophiliacs; LFT elevation | CYP3A4 inhibitor and substrate |

| Drug | Formulation | Dosage | Hepatic Impairment | Food | Adverse Effects | Metabolism |
|---|---|---|---|---|---|---|
| Ritonavir (Norvir) | 100-mg tablet or capsule, 600 mg/7.5-mL solution | 100–200 mg/dose when used as pharmacokinetic enhancer | No dosage adjustment in mild hepatic impairment<br>No data for moderate to severe impairment; use with caution | Take with food to improve tolerability | GI intolerance, nausea, diarrhea; paresthesias; hyperlipidemia; hepatitis; asthenia; taste perversion; hyperglycemia; fat maldistribution; increased bleeding in hemophiliacs | CYP3A4 inhibitor (potent) and substrate; CYP2D6 substrate; mixed dose-dependent induction and inhibition of other phase I and II enzymes |
| Saquinavir (Invirase) | 200-mg capsule, 500-mg tablet | Unboosted saquinavir not recommended<br>*With* ritonavir*:*<br>(ritonavir 100 mg + saquinavir 1000 mg) twice daily | Use with caution in patients with hepatic impairment | Take within 2 hours of a meal when taken with ritonavir | Nausea, diarrhea; headache; LFT elevation; hyperlipidemia; hyperglycemia; fat maldistribution; increased bleeding in hemophiliacs | CYP3A4 inhibitor and substrate |
| Tipranavir (Aptivus) | 250-mg capsules, oral solution 100 mg/mL | 500 mg twice daily with ritonavir 200 mg twice daily | Contraindicated in patients with moderate to severe hepatic insufficiency | Take with food | Hepatotoxicity; skin rash; hyperlipidemia; hyperglycemia; fat maldistribution; possible increased bleeding in hemophiliacs | Tipranavir/ritonavir mixed CYP inhibitor/inducer; Tipranavir is CYP3A4 substrate |
| **Fusion Inhibitors** | | | | | | |
| Enfuvirtide (Fuzeon) | Injectable, in lyophilized powder<br>Each single-use vial contains 108 mg of enfuvirtide to be reconstituted with 1.1 mL of sterile water for injection for delivery of approximately 90 mg/1 mL | 90 mg (1 mL) subcutaneously twice daily | No dosage recommendation | N/A | Local injection site reaction (pain, erythema, induration, nodules and cysts, pruritus, eachymosis) in most patients; increased rate of bacterial pneumonia; less than 1% hypersensitivity reaction (rash, fever, nausea, vomiting, chills, rigors, hypotension, or elevated serum transaminases); do not rechallenge | Catabolism to amino acids, with subsequent recycling in the body pool |

| Generic Name [Abbreviation] (Trade Name) | Dosage Forms | Commonly Prescribed Doses | Dose Adjustments | Food Restrictions | Significant Adverse Events | Drug Interaction Potential |
|---|---|---|---|---|---|---|
| **Chemokine Receptor Antagonists (CCR5 Antagonists)** | | | | | | |
| Maraviroc (Selzentry) | 150-mg and 300-mg tablets | 150 mg twice daily when given with strong CYP3A inhibitors (with or without CYP3A inducers) including PIs (except tipranavir/ritonavir) 300 mg twice daily when given with NRTIs, enfuvirtide, tipranavir/ritonavir, nevirapine and other drugs that are not potent P450 inhibitors 600 mg twice daily when given with CYP3A inducers, including efavirenz, rifampin, etc. (without a CYP3A inhibitor) | Patients with CrCl < 30 mL/min (0.83 mL/s) should receive maraviroc with a CYP3A inhibitor only if benefit outweighs the risk | No food restrictions | Abdominal pain; cough; dizziness; musculoskeletal symptoms; pyrexia; rash; upper RTI; hepatotoxicity; orthostatic hypotension | CYP3A substrate |
| **Integrase Inhibitors** | | | | | | |
| Dolutegravir (Tivicay) | 50-mg tablet | 50 mg daily if treatment naïve 50 mg twice daily if coadministered with efavirenz, fosamprenavir, tipranavir/ritonavir, rifampin OR if INSTI-experienced with known or suspected INSTI resistance | Use with caution if CrCl < 30 mL/min (0.83 mL/s) No dosage adjustment for Child Pugh Class A or B Not recommended in Class C/has not been studied | Separate dose from polyvalent cations (eg, Ca, Mg, Al, Fe, Zn) | Insomnia, headache, increased serum creatinine | UGT1A1/3/9 and CYP3A4 (minor) substrate |

| Drug | Formulation | Dosing | Dosage Adjustment | Administration | Adverse Events | Metabolism |
|---|---|---|---|---|---|---|
| Elvitegravir + cobicistat + tenofovir + emtricitabine (Stribild) | Elvitegravir 150 mg + cobicistat 150 mg + tenofovir 300 mg + emtricitabine 200-mg tablet | One tablet daily | CrCl < 70 mL/min (1.17 mL/s) at initiation of therapy: Not recommended<br>CrCl < 50 mL/min (0.83 mL/s) during therapy: Continued use is not recommended | Take with food<br>Separate dose from polyvalent cations (eg, Ca, Mg, Al, Fe, Zn) | Nausea; diarrhea; proteinuria; increased serum creatinine | Elvitegravir: UGT1A1/3 and CYP3A substrate<br>Cobicistat: CYP3A inhibitor<br>See tenofovir and emtricitabine |
| Raltegravir (Isentress) | 400-mg tablet, 25 mg and 100 mg chewable tablets, 100 mg packets for oral suspension | 400 mg twice daily<br>800 mg twice daily if coadministered with rifampin | No dosage adjustment | Separate dose from polyvalent cations (eg, Ca, Mg, Al, Fe, Zn) | Nausea; headache; diarrhea; pyrexia; CPK elevation | UGT1A1 substrate (glucuronidation) |
| Abacavir + lamivudine + Dolutegravir (Triumeq) | Abacavir 600 mg Lamivudine 300 mg Dolutegravir 50 mg | One tablet daily | Do not use if CrCl < 50 mL/min (0.83 mL/s)<br>No dosage adjustment for Child Pugh Class A or B.<br>Not recommended in Class C/has not been studied | | See adverse events of abacavir, lamivudine, and dolutegravir | See abacavir, lamivudine, and dolutegravir |

ARV, antiretroviral; AUC, area under the time-concentration curve; AV, atrioventricular; $C_{max}$, maximum concentration; CrCl, creatinine clearance; ESRD, end-stage renal disease; HD, hemodialysis; INSTI, integrase strand transfer inhibitor; LFT, liver function test; NRTI, nucleoside reverse transcriptase inhibitor; UGT, uridine diphosphate-glucuronsyltransferase.

Adapted from the DHHS Guidelines for the Use of Antiretroviral Agents in HIV-1-Infected Adults and Adolescents, May 1, 2014.

For these patients, continuing the current regimen may be beneficial because drug-resistant virus may have a compromised replication capacity. Other strategies may be considered for this type of patient, including pharmacokinetic enhancement with ritonavir, retreatment with prior antiretroviral agents, treatment with multidrug regimens (four or more antiretroviral drugs), and the use of new agents through expanded access programs or clinical trials.

## Treatment Considerations in Special Populations

### ▶ Acute HIV Infection

Diagnosis of acute HIV infection is difficult, since many patients are asymptomatic or have nonspecific clinical symptoms similar to other common respiratory infections. If acute HIV infection is suspected, HIV antibody tests and a plasma HIV RNA concentration should be obtained. A clear diagnosis is made when an HIV antibody test is negative and the plasma HIV RNA concentration is detected or p24 antigen is present.

There is limited outcome data for treating acutely infected patients. Treatment of acute infection can decrease the severity of acute disease and decrease the viral set point; this may decrease progression rates and reduce the rate of viral transmission.[5] Limitations include an increased risk of chronic drug-induced toxicities and the development of viral resistance. Resistance testing should be performed prior to initiation of therapy due to an increase in resistance of antiretroviral naïve patients.[8]

### ▶ Adolescent and Young Adult Patients

As a result of similar modes of HIV transmission, adolescents infected after puberty are treated as adults. In this population, dosing of antiretroviral drugs should not be based on age, but on the Tanner stage (which considers external primary and secondary sexual characteristics).[8] Adolescents in early puberty should be dosed according to pediatric guidelines, whereas those in late puberty should be dosed as adults. During growth spurts, adolescents should be monitored closely for drug efficacy and toxicity, since rapid changes in weight can lead to altered drug concentrations. Adherence is of concern in this population due to denial of the disease, misinformation, distrust of health care professionals, low self-esteem, and lack of family and/or social support. Additionally, asymptomatic patients this age find it more difficult to adhere to therapy while feeling well.

### ▶ Pediatric Patients

There are unique considerations in the treatment of HIV-infected children. Specific treatment guidelines exist,[12] but a thorough review is outside the scope of this chapter. Most children acquire HIV infection through perinatal transmission either in utero, intrapartum, or postpartum through breast-feeding, although antiretroviral interventions have dramatically reduced transmission rates.[8] Antiretroviral therapy research is limited in pediatric patients, as some drugs have no dosing recommendations for this population or are not available in a formulation that can be easily administered to children. Additionally, drug exposures can change dramatically during early childhood development due to altered drug-metabolizing enzyme and drug transporter activities.

### ▶ Pregnancy and Women of Reproductive Potential

The goals of antiretroviral therapy for women of reproductive age and pregnant women are the same as for other adult patients. Specific guidelines for HIV-infected pregnant women

are available.[13] If a woman is already virally suppressed on an antiretroviral regimen at the time she becomes pregnant, it is recommended that she remain on that regimen unless it contains efavirenz, which is pregnancy category D. However, because the risk of neural tube defects with efavirenz is highest during the first 5 to 6 weeks of pregnancy, and pregnancy is often not detected before 4 to 6 weeks, it is reasonable for women virologically suppressed on an efavirenz-containing regimen to continue that regimen rather than switch regimens and risk viral rebound. If not already on antiretroviral therapy, recommended therapies in pregnancy include zidovudine, lamivudine, lopinavir/ritonavir, atazanavir/ritonavir, and, if greater than 8 weeks of gestation, efavirenz. Nevirapine may be considered an alternative NNRTI for ARV-naive pregnant women if the CD4+ count is less than 250 cells/mm³ (250 × 10⁶/L). Although data on the use of raltegravir in pregnancy is limited, it may be considered as an alternative agent if first-line therapies are to be avoided. A dual nucleoside reverse transcriptase inhibitor (NRTI) backbone that includes one or more NRTIs with high levels of transplacental passage, if possible, is recommended. Drugs to be avoided include efavirenz (in the first 8 weeks of pregnancy due to potential teratogenicity), the combination of didanosine and stavudine (due to a high incidence of lactic acidosis), and nevirapine in patients with a CD4+ count greater than 250 cells/mm³ (250 × 10⁶/L) (due to an increased risk of hepatotoxicity). The goal of therapy is to reduce plasma HIV RNA below detectable levels and prevent MTCT of HIV. Limited data are available on antiretroviral pharmacokinetics in pregnancy, and standard doses of antiretroviral drugs are currently recommended, with close HIV RNA and CD4+ monitoring in the third trimester of pregnancy.

Women of reproductive potential prescribed efavirenz should be counseled on its potentially teratogenic effects and the importance of birth control. Additionally, efavirenz, nevirapine, ritonavir, atazanavir/ritonavir, lopinavir/ritonavir, and tipranavir/ritonavir, darunavir/ritonavir, fosamprenavir/ritonavir, and saquinavir/ritonavir decrease the concentrations of different estrogens and/or progestins in oral contraceptives, which could lead to failure.[8] For patients prescribed these drugs, barrier forms of contraception are preferred to prevent pregnancy. Atazanavir may be taken with oral contraceptives with extreme caution, as it can increase or decrease the exposure to estrogen and progesterone, depending on whether it is used in combination with ritonavir. Depo-Provera is likely the safest alternative, as studies have shown no significant interactions between depot medroxyprogesterone acetate and antiretrovirals.[14] Maraviroc, raltegravir, elvitegravir/cobicistat, and dolutegravir have not shown clinically significant effects when used with oral contraceptives and are safe to use in combination.

### ▶ Hepatitis B Coinfection

HIV-infected patients coinfected with hepatitis B virus (HBV) have higher concentrations of DNA and hepatitis B early antigen (HBeAg) and higher rates of HBV-associated liver disease. Indications to initiate therapy for HBV/HIV coinfected patients are the same as in HIV-negative patients and is based on the HBV DNA level, serum ALT, and severity of liver disease. Options include interferon-α 2a or 2b and nucleoside/tide analogs. Nucleoside/tide analogs that treat HBV but not HIV are adefovir and entecavir. Entecavir, however, exhibits minimal antiviral activity against HIV, and should never be administered to coinfected patients who are not concurrently receiving fully suppressive HIV therapy. If given without suppressive antiretrovirals, entecavir can select for M184 resistance, leading to HIV resistance to

emtricitabine and lamivudine. Nucleoside/tide analogs that are used to treat HBV and HIV are lamivudine, emtricitabine, and tenofovir. Combinations of tenofovir + emtricitabine or tenofovir + lamivudine should comprise the NRTI backbone of a fully suppressive regimen.[15] When changing HIV therapy in a patient with HBV viral suppression, the lamivudine, emtricitabine, or tenofovir should be continued for treatment of HBV in addition to the new HIV regimen.[8] Abrupt discontinuation of these antiretrovirals may result in significant hepatic injury due to the exacerbation of hepatitis B.

Vaccination against HBV can effectively prevent transmission. Currently in the United States, all infants should get their first HBV vaccination at birth. If there is no record of vaccination, or immunization history is unknown, HIV-infected patients and adults with high-risk sexual behavior or occupational exposure to HBV should be vaccinated.

▶ *Hepatitis C Coinfection*

All HIV-infected patients should be screened for hepatitis C infection. Patients coinfected with hepatitis C virus (HCV) and HIV have an increased rate of progression to cirrhosis, decompensated liver disease, hepatocellular carcinoma, and death compared with monoinfected HCV alone.[15] All HCV/HIV coinfected patients should be considered for therapy, taking into consideration the HCV genotype, stage of liver disease, as well as patient specific factors that may contraindicate therapy (eg, nonadherence, depression, substance abuse). The goal of HCV treatment is to achieve sustained virologic response (absence of detectable viremia greater than or equal to 3 months after discontinuation of treatment) and to decrease the progression of liver injury and likelihood of end-stage liver disease. Comprehensive treatment guidelines for HIV/HCV-coinfected patients are available and have recently been updated to reflect the rapidly evolving treatment options for HCV.[16] Recommended treatment regimens for HCV consist of pegylated interferon-α 2a or 2b, ribavirin, sofosbuvir, and simeprevir, with the combinations and duration of treatment determined by HCV genotype. Sofosbuvir and simeprevir are novel direct acting antivirals that exhibit potent antiviral activity and minimal toxicity. However, simeprevir, an HCV protease inhibitor, is metabolized primarily by CYP3A4 and is a substrate for the drug transporter P-glycoprotein (P-gp) and organic anion transporting polypeptide 1B1. Due to the potential for significant drug interactions, simeprevir is not recommended for use with HIV protease inhibitors, cobicistat, or the non-nucleoside reverse transcriptase inhibitors efavirenz, nevirapine, and etravirine. Coadministration of ribavirin with didanosine, and stavudine (due to increased risk of pancreatitis and/or lactic acidosis) and ribavirin with zidovudine (due to increased risk of anemia) should also be avoided. The first-generation protease inhibitors, telepravir and boceprevir, are associated with relatively increased toxicities and extensive drug-drug interactions, and are no longer recommended by the guidelines.[16] With many potent direct-acting antivirals in the HCV pipeline, the landscape of HCV treatment is rapidly evolving, with the hope of multiple curative, interferon-free, regimens to come in the near future.

### Preexposure Prophylaxis (PrEP)

Multiple large-scale clinical trials in populations at highest risk for acquiring HIV have demonstrated that antiretrovirals, particularly tenofovir + emtricitabine, in combination with effective risk-reduction services (counseling, access to condoms, treatment of STI, etc.), reduce the rate of HIV transmission. Data from these trials has led to the FDA approval of Truvada

---

**Patient Encounter 2**

A 29-year-old African American man presents to your clinic requesting medication to prevent the transmission of HIV. He had heard from his HIV-infected partner that the FDA approved a prescription medication for the prevention of HIV and he wanted to learn more about it. He reports engaging in MSM with an HIV-infected partner and uses condoms about 75% of the time.

*What additional information do you need to know before creating a treatment plan for this patient?*

*What laboratory tests do you recommend?*

*What pharmacologic and nonpharmacologic options are available for this patient to protect himself from acquiring HIV?*

*What monitoring assessments and follow-up would you recommend?*

---

(fixed-dose combination of tenofovir disoproxil fumarate 300 mg and emtricitabine 200 mg), as preexposure prophylaxis (PrEP) to reduce the risk of HIV-1 in adult homosexual men who have sex with men, heterosexually active men and women, and injection drug users who are at substantial risk of HIV acquisition.[17] The use of daily Truvada as PrEP should be in combination with effective risk-reduction interventions, as well as, very close follow-up and monitoring. Patients must be tested for HIV at baseline, and minimally every 3 months while taking PrEP. Additionally, due to the potential toxicities associated with tenofovir, renal function must be assessed at baseline and at 6-month intervals in patients taking Truvada as PrEP. Patient counseling, stressing the importance of medication adherence, should be routinely provided, as medication adherence has been linked to PrEP efficacy.[17]

## OUTCOME EVALUATION

**KEY CONCEPT** *The success of antiretroviral therapy is measured by the degree to which the therapy (a) restores and preserves immunologic function, (b) maximally and durably suppresses HIV RNA, (c) improves quality of life, (d) reduces HIV-related morbidity and*

---

**Patient Encounter 3**

A 43-year-old woman presents to your clinic with complaints that she has noticed yellowing of the whites of her eyes. Four months ago, she initiated a regimen consisting of emtricitabine, tenofovir, and atazanavir/ritonavir. She is very upset because colleagues from work have noticed and as a result she would like to switch therapy.

*Which medication is responsible for this adverse event?*

**Table 87–5**

**Serious Adverse Effects and Management**

| Adverse Effects | Drug | Signs and Symptoms | Risk Factors | Prevention/Monitoring | Management |
|---|---|---|---|---|---|
| Hepatotoxicity | Nevirapine | **Onset:** Up to 18 weeks postinitiation **Symptoms:** Abrupt onset of flu-like symptoms, abdominal pain, jaundice, fever ± rash | Increased CD4$^+$ count at initiation Female Elevated baseline AST/ALT Any liver disease High nevirapine concentration | 2-week dose escalation Avoid starting nevirapine in women with CD4$^+$ > 250 cells/mm$^3$ (250 × 10$^6$/L), men with CD4$^+$ > 400 cells/mm$^3$ (400 × 10$^6$/L) AST/ALT every 2 weeks for 1st month, monthly for 3 months, then every 3 months | D/C antiretrovirals; D/C all hepatotoxic agents; rule out other causes; do not rechallenge with nevirapine |
| | Other NNRTIs, PIs, most NRTIs, and MVC | **Onset:** NNRTI—60% within first 12 weeks PI—weeks to months NRTI—months to years **Symptoms:** NNRTI—asymptomatic to nonspecific symptoms, such as anorexia, weight loss, or fatigue PI—generally asymptomatic, some with anorexia, weight loss, jaundice Didanosine NRTI—zidovudine, didanosine, stavudine may cause hepatotoxicity associated with lactic acidosis; lamivudine, emtricitabine, or tenofovir may cause HBV flare when these drugs are withdrawn | HBV or HCV coinfection Alcoholism Concomitant hepatotoxic drugs | Monitor LFTs at least every 3–4 months | Rule out other causes. For symptomatic patients: D/C all antiretrovirals and other potential hepatotoxic agents; after symptoms and LFTs normalize, begin new antiretroviral regimen (without the potential offending agents). For asymptomatic patients: If ALT > 5–10 × ULN, may consider D/C antiretrovirals or continue with close monitoring; after symptoms and LFTs normalize, begin new antiretroviral regimen (without the potential offending agents) |
| Lactic acidosis/ hepatic steatosis ± pancreatitis | NRTIs (esp. stavudine, didanosine, zidovudine) | **Onset:** Months after initiation **Symptoms:** Nonspecific GI (nausea, anorexia, abdominal pain, vomiting, weight loss, fatigue) Laboratory values: ↑ lactate, ↓ arterial pH, ↓ serum bicarbonate, ↑ AST/ALT, ↑ PT, ↑ T.bili, ↓ serum albumin, ↑ amylase/lipase (with pancreatitis) | Stavudine + didanosine Female sex Obesity Pregnancy Didanosine + hydroxyurea or ribavirin ↑ Duration of NRTI use | None unless symptoms present Consider lactate concentrations in patients with ↓ serum bicarbonate or ↑ anion gap | D/C all antiretrovirals; symptomatic support with fluids; some patients require IV bicarbonate, hemodialysis, parenteral nutrition, or mechanical ventilation; once syndrome resolves, consider using NRTIs with ↓ mitochondrial toxicity (abacavir, tenofovir, lamivudine, or emtricitabine); monitor lactate after restarting NRTIs; some clinicians use NRTI-sparing regimens |

| | | | | | |
|---|---|---|---|---|---|
| Stevens-Johnson syndrome/toxic epidermal necrosis | Nevirapine greater than efavirenz, delavirdine, etravirine; also, amprenavir, abacavir, zidovudine, didanosine, indinavir lopinavir/r, atazanavir, darunavir, rilpivirine, raltegravir | **Onset:** First day–weeks after therapy start **Symptoms:** Skin eruption with mucosal ulcerations; fever, tachycardia, malaise, myalgia, arthralgia; for nevirapine may also have hepatic toxicity | Nevirapine—female, black, Asian, Hispanic | Nevirapine: use 2-week lead in 200 mg daily, then 200 mg twice a day Avoid corticosteroid use during dose escalation— may increase rash incidence Educate patients to report symptoms as soon as they appear | D/C all antiretrovirals as well as any other possible cause; aggressive symptom support; do not rechallenge patient with offending agent; if caused by nevirapine, avoid NNRTI class, if possible |
| Hypersensitivity reaction (HSR) | Abacavir | **Onset:** Median = 9 days; 90% within first 6 weeks **Symptoms:** Acute onset of symptoms (most frequent to least): high fever, diffuse skin rash, malaise, nausea, headache, myalgia, chills, diarrhea, vomiting, abdominal pain, dyspnea, arthralgia, respiratory symptoms | HLA-B*5701, HLA-DR7, HLA-DQ3 Antiretroviral-naïve patients Higher incidence with 600 mg every day compared with twice a day dosing | HLA-B*5701 screening prior to abacavir if (+), label as abacavir allergic in medical chart Educate patients about signs and symptoms of HSR and the need of prompt report | D/C abacavir and other antiretrovirals; rule out other causes of symptoms, most signs and symptoms resolve 48 hours after abacavir/D/C; do not rechallenge with abacavir after suspected HSR |
| Lactic acidosis/ rapidly progressive ascending neuromuscular weakness | Stavudine | **Onset:** Months, then striking motor weakness within days–weeks **Symptoms:** Rapidly progressive ascending demyelinating polyneuropathy (similar to Guillain-Barré); respiratory paralysis | Prolonged stavudine use | Early recognition and D/C of offending agent to avoid progression | D/C antiretrovirals; supportive care; recovery may take months, sometimes irreversible; do not rechallenge with offending agent |
| Bleeding events | Tipranavir/ritonavir: intracranial hemorrhage (ICH); other PIs: ↑ bleeding in hemophiliacs | **Onset:** ICH: median = 525 days on tipranavir/ ritonavir Hemophiliacs: Few weeks **Symptoms:** ↑ Spontaneous bleeding tendency (in joints, muscles, soft tissues, and hematuria) | ICH: CNS lesions, head trauma, recent neurosurgery, coagulopathy, alcohol abuse, or on anticoagulant or antiplatelet agents Hemophiliac patients: PI use | ICH: Avoid tipranavir/ritonavir use in high risk patients Hemophiliacs: Consider using an NNRTI-based regimen; monitor for spontaneous bleeding | ICH: D/C tipranavir/ritonavir; supportive care Hemophiliacs: May require increased use of factor VIII products |
| Bone marrow suppression | Zidovudine | **Onset:** Few weeks–months **Symptoms:** Fatigue, risk of ↑ bacterial infections due to neutropenia; anemia, neutropenia | Advanced HIV High-dose zidovudine Preexisting anemia or neutropenia Concomitant use of bone marrow suppressants | Avoid in patients at high risk for bone marrow suppression; avoid other suppressing agents; monitor CBC with differential at least every 3 months | Switch to another NRTI; D/C concomitant bone marrow suppressant, if possible; for anemia: Identify and treat other causes; consider erythropoietin treatment or blood transfusion, if indicated; for neutropenia: Identify and treat other causes; consider filgrastim treatment, if indicated |

*(Continued)*

**Table 87–5**

**Serious Adverse Effects and Management (*Continued*)**

| Adverse Effects | Drug | Signs and Symptoms | Risk Factors | Prevention/Monitoring | Management |
|---|---|---|---|---|---|
| Nephrolithiasis/ urolithiasis/ crystalluria | Indinavir Atazanavir | **Onset:** Any time after initiation of therapy, especially if ↓ fluid intake **Symptoms:** Flank pain and/or abdominal pain, dysuria, frequency; pyuria, hematuria, crystalluria; rarely, ↑ serum creatinine and acute renal failure | History of nephrolithiasis Patients unable to maintain adequate fluid intake High peak indinavir concentration ↑ duration of exposure | Drink at least 1.5–2 L of noncaffeinated fluid per day; ↑ fluid intake at first sign of darkened urine; monitor urinalysis and serum creatinine every 3–6 months | Increased hydration; pain control; may consider switching to alternative agent; stent placement may be required |
| Nephrotoxicity | Indinavir, tenofovir | **Onset:** Indinavir—months after therapy Tenofovir—weeks to months after therapy **Symptoms:** Indinavir—asymptomatic; rarely develop end-stage renal disease; ↑ serum creatinine, pyruria; hydronephrosis, renal atrophy Tenofovir—asymptomatic to symptoms of nephrogenic diabetes insipidus, Fanconi syndrome; ↑ serum creatinine, proteinuria, hypophosphatemia, glycosuria, hypokalemia, non–anion gap metabolic acidosis | History of renal disease Concomitant use of nephrotoxic drugs | Avoid use of other nephrotoxic drugs; adequate hydration if on indinavir; monitor creatinine, urinalysis, serum potassium and phosphorus in patients at risk | D/C offending agent, generally reversible; supportive care; electrolyte replacement as indicated |
| Pancreatitis | Didanosine; didanosine + stavudine; didanosine + hydroxyurea or ribavirin; tenofovir | **Onset:** Usually weeks to months **Symptoms:** Postprandial abdominal pain, nausea, vomiting; ↑ serum amylase and lipase | High intracellular and/or serum Didanosine concentrations History of pancreatitis Alcoholism Hypertriglyceridemia Concomitant use of didanosine with stavudine, hydroxyurea, or ribavirin Use of didanosine + tenofovir without Didanosine dose reduction | Didanosine should not be used in patients with history of pancreatitis; avoid concomitant use of didanosine with stavudine, hydroxyurea, or ribavirin; ↓ didanosine dose when used with tenofovir | D/C offending agents; symptomatic management of pancreatitis—bowel rest, IV hydration, pain control, gradual resumption of oral intake |

ALT, alanine aminotransferase; AST, aspartate aminotransferase; CBC, complete blood cell count; CPK, creatine phosphokinase; D/C, discontinue; HBV, hepatitis B virus; HCV, hepatitis C virus; LFT, liver function tests; NNRTI, nonnucleoside reverse transcriptase inhibitor; NRTI, nucleoside reverse transcriptase inhibitor; PI, protease inhibitor; PT, prothrombin time; T.bili, total bilirubin; ULN, upper limit of normal.

**Table 87–6**

**Other Adverse Effects and Management**

| Adverse Effects | Drug | Signs and Symptoms | Risk Factors | Prevention/Monitoring | Management |
|---|---|---|---|---|---|
| **Potential Long-Term Complications** | | | | | |
| Cardiovascular | Potentially all PIs and other antiretrovirals (efavirenz, stavudine—unfavorable lipid effect; abacavir, didanosine—unknown) | **Onset**: months to years after therapy initiation **Symptoms**: premature CVD | Other risk factors for CVD | Consider non–PI-based regimen; lifestyle modification, counseling | Early diagnosis, prevention, and pharmacologic therapy for hyperlipidemia, HTN, insulin-resistance/diabetes mellitus; assess cardiac risk factors; switch to NNRTI- or atazanavir-based regimen; avoid stavudine |
| Hyperlipidemia | All PIs (except atazanavir); stavudine; efavirenz (to a lesser extent) | **Onset**: weeks to months after therapy initiation **Symptoms**: all PIs except atazanavir—↑ LDL and total cholesterol (TC), ↓↑ HDL; lopinavir/r and ritonavir—disproportionate ↑ TG; stavudine—↑ TG; may also ↑ LDL and TC; efavirenz or nevirapine—↑ HDL, slight ↑ TG | Underlying hyperlipidemia PI: Tipranavir/r greater than lopinavir/r and ritonavir greater than nelfinavir and amprenavir greater than indinavir and saquinavir greater than atazanavir NNRTI: less than PIs; efavirenz greater than nevirapine, etravirine, or rilpivirine NRTI: stavudine greater than zidovudine and tenofovir most common | Use non-PI, non–stavudine-based regimens; use atazanavir-based regimen; monitor fasting lipid profile at baseline, 3–6 months after new regimen, then at least annually | Assess cardiac risk factor; lifestyle modification; switch to antiretrovirals with fewer lipid effects; Consider statin therapy |
| Insulin resistance/ diabetes mellitus | All PIs | **Onset**: weeks to months after therapy initiation; **Symptoms**: polyuria, polydipsia, polyphagia, fatigue, weakness; exacerbation of hyperglycemia in patients with underlying diabetes | Underlying hyperglycemia, family history of diabetes mellitus | Use PI-sparing regimens; monitor fasting blood glucose 1–3 months after starting new regimen, then at least every 3–6 months | Diet and exercise; consider switching to an NNRTI-based regimen; if need for pharmacologic therapy, consider metformin, sulfonylurea, "glitazones," or insulin, where indicated |
| Osteoporosis/ Osteonecrosis | All PIs Tenofovir | **Onset**: insidious; **Symptoms:** mild to moderate periarticular pain; 85% of cases involve one or both femoral heads | Diabetes Prior steroid use Advanced age Alcohol use Hyperlipidemia | Risk reduction (limit steroid and alcohol use): for asymptomatic cases with < 15% bony head involvement, monitor with MRI every 3–6 months × 1 year, then every 6 months × 1 year, then annually | Conservative: reduce weight-bearing activity on affected joint; reduce risk factors; analgesics as needed; surgical: core decompression ± bone grafting (early disease); total joint arthroplasty (severe disease) |

*(Continued)*

**Table 87–6**

**Other Adverse Effects and Management (*Continued*)**

| Adverse Effects | Drug | Signs and Symptoms | Risk Factors | Prevention/Monitoring | Management |
|---|---|---|---|---|---|
| **Quality-of-Life Complications** | | | | | |
| CNS effects | Efavirenz | **Onset**: first few doses; **Symptoms**: one or more of the following: drowsiness, insomnia, abnormal dreams, dizziness, impaired concentration, depression, hallucination; exacerbation of psychiatric disorders; psychosis; suicidal ideation | Preexisting or unstable psychiatric illness. Use of other drugs with CNS effects. May be more common in African Americans due to genetic predisposition of ↓ clearance | Take no earlier than 2–3 hours before bedtime; take on an empty stomach; counsel patients to avoid operating machinery during first 2–4 weeks of therapy | Symptoms usually diminish or resolve after 2–4 weeks; may consider discontinuing therapy if symptoms persist and significantly impair daily function or exacerbate psychiatric illness |
| Fat maldistribution | PIs, thymidine analogs (stavudine more common than zidovudine) | **Onset**: gradually, months after therapy initiation; **Symptoms**: lipoatrophy—peripheral fat loss (facial thinning, thinning of extremities and buttocks); lipohypertrophy—increase in abdominal girth, breast size, and dorsocervical fat pad (buffalo hump) | Lipoatrophy—low baseline body mass index | DEXA scan; lipoatrophy: avoid thymidine analogs or switch from zidovudine or stavudine to abacavir or tenofovir | Switching to other agents may slow or stop progression, but may not reverse effects; injectable poly-L-lactic acid for facial lipoatrophy, human growth hormone |
| GI intolerance | All PIs, zidovudine, didanosine | **Onset**: first few doses; **Symptoms**: nausea, vomiting, abdominal pain; diarrhea commonly seen with nelfinavir, lopinavir/ritonavir, and didanosine-buffered formulations | All patients | Taking with food may reduce symptoms (not for didanosine or unboosted indinavir); may preemptively need antiemetics or antidiarrheals | May spontaneously resolve or become tolerable with time; nausea and vomiting: consider antiemetic prior to dosing; switch to less emetogenic agent; diarrhea: consider antimotility agents, calcium tablets, bulk-forming agents, and/or pancreatic enzymes |
| Injection site reactions | Enfuvirtide | **Onset**: first new doses; **symptoms**: pain, pruritus, erythema, ecchymosis, warmth, nodules, rarely injection site infection | All patients | Educate regarding use of sterile technique, solution at room temperature, rotation of injection sites, avoidance of sites with little subcutaneous fat or existing reactions | Massaging the area vigorously before and after injection may reduce pain; wear loose clothing around injection site areas; take warm shower or bath prior to injection; rarely, warm compact or analgesics may be necessary |
| Peripheral neuropathy | Didanosine, stavudine | **Onset**: weeks to months after therapy initiation; **Symptoms**: begins with numbness and paresthesias of toes and feet; may progress to painful neuropathy; upper extremities less frequently involved; may be irreversible despite drug discontinuation | Preexisting peripheral neuropathy. Combined use of these NRTIs or other drugs which may cause neuropathy. Advanced HIV. High dose of offending drugs or drugs that may increase didanosine intracellular activities (hydroxyurea, ribavirin) | Avoid using these agents in patients at risk, if possible; avoid combined use of these agents; ask patient at each encounter | Consider D/C offending agent prior to onset of disabling pain; pharmacologic treatment (variable effectiveness): gabapentin, tricyclic antidepressants, lamotrigine, oxcarbamazepine, topiramate, tramadol, narcotic analgesics, capsaicin cream, topical lidocaine |

CVD, cardiovascular disease; D/C, discontinue; DEXA, dual-energy x-ray absorptiometry; HTN, hypertension; LDL, low-density lipoprotein; NNRTI, nonnucleoside reverse transcriptase inhibitor; NRTI, nucleoside reverse transcriptase inhibitor; PI, protease inhibitor; TG, triglyceride.

*mortality, and (e) prevents opportunistic infections.* **KEY CONCEPT** *The major outcome parameters are CD4$^+$ lymphocyte absolute count and percentage and plasma HIV RNA.* Adequate immunologic response in antiretroviral-naïve patients consists of an increase in CD4$^+$ cell count that averages 50 to 150 cells/mm$^3$ (50 × 10$^6$ to 150 × 10$^6$/L) (with a faster response in the first 3 months), and a 1-log decrease in HIV RNA by 2 to 8 weeks after starting medications, followed by concentrations less than 50 copies/mL (50 × 10$^3$ copies/L) by 12 to 16 weeks (if HIV RNA less than 100,000/mL [100 × 10$^6$/L] or by 16 to 24 weeks if HIV RNA greater than 100,000/mL [100 × 10$^6$/L]). Upon initiating or changing antiretroviral therapy, HIV RNA should be measured after 2 to 8 weeks and every 4 to 8 weeks until undetectable. Once stable, HIV RNA and CD4$^+$ count are monitored generally every 3 to 6 months. In highly treatment-experienced patients, adequate immunologic response may be only a stable, or slightly increased, CD4$^+$ count and a stable HIV RNA. This may be enough to prevent clinical progression. However, with the new agents and new therapeutic classes of antiretrovirals available for treatment-experienced patients, the goal of treatment should be to reestablish maximal viral suppression to less than 50 HIV RNA copies/mL (50 × 10$^3$ copies/L).[8]

There should be a plan for each patient to assess the effectiveness of antiretroviral therapy after initiation. At each clinic visit, patients should be evaluated for the presence of adverse drug reactions, drug allergies, medication adherence, and potential drug interactions. Antiretrovirals have both class-associated and drug-specific adverse effects (see Table 87–4). If the patient experiences any of the serious, life-threatening effects (Table 87–5), the offending agent should be discontinued promptly, and in most cases the patient cannot be rechallenged. Potential long-term complications that may reduce the quality of life are listed in Table 87–6. For drugs with a high likelihood of intolerability (such as nelfinavir-associated diarrhea), patients should be counseled to anticipate these effects and have concomitant prescriptions available for preemptive management (such as an antidiarrheal agent). Patients should have follow-up within the first week after initiating a new drug regimen. If the patient does not tolerate a medication despite all efforts to the contrary, consider changing the drug.[8]

**KEY CONCEPT** *Treatment of HIV infection is lifelong.* Unplanned short-term treatment interruptions may be necessary due to drug toxicity or illness that precludes administration of oral therapy. If a patient must interrupt therapy due to toxicity, all drugs of the regimen should be stopped at the same time, regardless of half-life. The strategy of scheduling elective treatment interruptions (where patients stop and start antiretroviral therapy based on CD4$^+$ T-cell count criteria) has been evaluated in several clinical trials. Viral rebound occurs quickly after stopping therapy and worsens immune function, causes clinical progression, and may even result in death. If either short-term (less than 7 days) or long-term treatment interruption is needed, drug half-life must be taken into consideration to assure that monotherapy with longer-acting antiretrovirals is avoided as was described previously for tenofovir/emtricitabine/efavirenz combination. For regimens in which all components have similar half-lives, all drugs can be stopped simultaneously. If the regimen contains components with significantly different half-lives (eg, Atripla), stopping all drugs at the same time could result in the drug with the longest half-life (usually NNRTIs) lingering in the body and functioning as monotherapy. The ideal time to stop the NNRTIs (efavirenz, etravirine, or nevirapine) is unknown, as these drugs can continue to be detectable 1 to 3+ weeks in patients. Options include either (a) stopping the NNRTI first and continuing the

## The Patient Care Process: Newly Diagnosed

**Patient Assessment:**

- Confirm HIV infection (see Table 87–1), screen for additional sexually transmitted infections, and assess the risk for opportunistic infections and need for prophylaxis.
- Create a safe and comfortable environment to obtain a thorough medical and medication history (prescription, nonprescription, and natural drug product use). Review and update patient allergies.
- Acquire baseline laboratory data (see Table 87–2) to stage HIV disease and to assist in the selection of ARV drug regimens (genotypic resistance testing, HLA-B*5701).
- Assess patient's readiness for initiating ART.

**Therapy Evaluation:**

- Evaluate comorbid conditions (eg, mental illness, substance abuse) and social issues (economic stability, lack of social support, insurance coverage) that may impair medication adherence.
- Utilize results of genotype in conjunction with patient specific factors to construct a recommended ART regimen.
- Assess the potential for clinically significant drug–drug, drug–food, drug–disease interactions.

**Care Plan Development:**

- Provide patient with basic information regarding HIV infection, progression of HIV/prognosis, treatment options, and support services available.
- Inform patient of the benefits of initiating ART, stressing the importance of strict medication adherence.
- Educate patient on regimen-specific administration and the common adverse drug effects (see Table 87–4). Warn patient of the key signs and symptoms of severe toxicity (ie, jaundice and abacavir hypersensitivity reaction).
- Provide risk reduction counseling on effective strategies to prevent HIV transmission and disclosure to sexual and/or needle-sharing partners.

**Follow-up Evaluation:**

- Assess response to ARV therapy by drawing plasma HIV RNA within 2 to 4 weeks (no later than 8 weeks) after initiation of ART and every 4 to 8 weeks until viral load is suppressed.
- Monitor immune reconstitution by measuring CD4$^+$ count 3 months after initiation of ART.
- Evaluate tolerability of regimen by assessing for adverse events and medication adherence.

other drugs in the regimen for up to 4 weeks or (b) substituting the NNRTI with a PI and continuing the PI with dual NRTIs for up to 4 weeks. In this situation, therapeutic drug monitoring of the long half-life drug can be useful in determining when to stop the NRTI ± PI coverage.[8]

# Abbreviations Introduced in This Chapter

| | |
|---|---|
| AIDS | Acquired immunodeficiency syndrome |
| ALT | Alanine aminotransferase |
| ART | Antiretroviral therapy |
| AST | Aspartate aminotransferase |
| CPK | Creatine phosphokinase |
| CVD | Cardiovascular disease |
| CYP | Cytochrome P-450 isoenzyme |
| D/C | Discontinue |
| DEXA | Dual-energy x-ray absorptiometry |
| DHHS | Department of Health and Human Services |
| ELISA | Enzyme-linked immunosorbent assay |
| GERD | Gastroesophageal reflux disease |
| gp | Glycoprotein |
| HAART | Highly active antiretroviral therapy |
| HBeAg | Hepatitis B early antigen |
| HBV | Hepatitis B virus |
| HCV | Hepatitis C virus |
| HDL | High-density lipoprotein |
| HIV | Human immunodeficiency virus |
| HLA | Human leukocyte antigen |
| HSR | Hypersensitivity reaction |
| HTN | Hypertension |
| IAS-USA | International AIDS Society–USA |
| ICH | Intracranial hemorrhage |
| IFA | Indirect immunofluorescence assay |
| LDL | Low-density lipoprotein |
| LFT | Liver function tests |
| MSM | Men who have sex with men |
| MTCT | Mother-to-child transmission |
| NNRTI | Nonnucleoside reverse transcriptase inhibitor |
| NRTI | Nucleoside reverse transcriptase inhibitor |
| NtRTI | Nucleotide reverse transcriptase inhibitor |
| P-gp | P-glycoprotein |
| PCP | *Pneumocystis jiroveci* (formerly *carinii*) pneumonia |
| PI | Protease inhibitor |
| PrEP | Pre-Exposure Prophylaxis |
| PT | Prothrombin time |
| RT-PCR | Reverse transcriptase polymerase chain reaction |
| SIV | Simian immunodeficiency virus |
| STI | Sexually transmitted infection |
| T.bili | Total bilirubin |
| TDF | Tenofovir disoproxil fumarate |
| TG | Triglyceride |
| ULN | Upper limit of normal |
| WB | Western blot |

# Cancer Chemotherapy and Treatment

Amy Robbins Williams

## INTRODUCTION

**KEY CONCEPT** *T*he word cancer covers a diverse array of tumor types that affect a significant number of Americans and individuals worldwide and are a major cause of mortality. The term *cancer* actually refers to more than 100 different diseases. What is common to all cancers is that the cancerous cell is uncontrollably growing and has the potential for invading local tissue and spreading to other parts of the body, a process called **metastases**. Cancer is now the leading cause of death in Americans younger than 85 years.[1] In 2015, it was projected that just over 1.6 million Americans will be diagnosed with cancer, and that an estimated 589,430 Americans will die from the cancer.[2] **Figure 88–1** describes cancers by gender, new cases, and deaths.

Although cancer in children and adolescents is less common when compared to older adults, it is estimated that about 1 in 285 children in America will be diagnosed before age 20. It is the second leading cause of death in children ages 5 to 14.[2]

Once diagnosed, a cancer patient may encounter many different health professionals. All health professionals need to collaborate to ensure safe and appropriate prescribing, preparation, administration, and monitoring of anticancer agents; management of toxicities; resolution of reimbursement issues; and participation in clinical trials.[3]

As a result of advances in research and technology, available cancer treatments have increased dramatically in the last couple of decades. The fields of radiation therapy, surgery, and drug development have made enormous progress over the years; therefore, patients may not only be receiving less toxic treatments but also treatments that have better outcomes than in the past. Supportive care therapies have improved, and patients now may be at less risk for toxicity and have a better **quality of life** than patients in the past. Twenty years ago, most patients received chemotherapy in the hospital because of side effects. Today, most patients are able to receive chemotherapy in the outpatient clinics and/or take oral anticancer agents at home.

### Cancer Prevention

Because most cancers are not curable in advanced stages, cancer prevention is an important and active area of research. Both lifestyle modifications and chemoprevention agents may significantly reduce the risk of developing cancer. Although still an active area of investigation, the Food and Drug Administration (FDA) has approved three vaccines that can help prevent cancer. There are two approved vaccines that prevent infection with human papillomavirus, which can cause cancers of the cervix, vulva, vagina, and anus. Another approved vaccine prevents infection with hepatitis B virus, which can cause liver cancer. In addition to vaccines, there are other medications that can be taken orally and have been used for cancer prevention. An example is the selective estrogen receptor modulator (SERM) tamoxifen, which reduces the risk of breast cancer in premenopausal women. Another SERM, raloxifene and the aromatase inhibitor exemestane both have shown a reduction in breast cancer in high-risk postmenopausal women. Because these agents will have adverse effects and possible long-term complications (eg, an increased risk of endometrial cancer with the use of tamoxifen), benefits versus risks needs to be weighed when making a recommendation.

### Tobacco

Tobacco smoking increases the risk of developing not only lung cancer but also many other types of cancer, including cancer of the bladder, mouth, pharynx, larynx, and esophagus as well as renal cell cancer. Smoking cessation is associated with a gradual decrease in the risk of cancer, but more than 5 years is needed before a major decline in risk is detected. In addition, most
**FIGURE 88−1.** Cancer Incidences (left) and deaths (right) in the United States for males and females—2014 estimates. Reproduced with permission from American Cancer Society. Cancer facts and figures-2014.

studies have found that passive smoking (ie, secondhand smoke) also increases a person's risk of developing lung cancer.[4]

## Ultraviolet Radiation

Ultraviolet light (sunlight or tanning booths and lamps) and increased skin exposure may increase the risk of melanoma and other skin cancers, especially in individuals who have a positive family history, fair skin, light-colored eyes, high degrees of freckling, and a tendency to burn instead of tan. Practitioners can counsel patients on proper sun protection, including minimizing sun exposure, using sunscreens with a sun protection factor (SPF) of 15 or greater on exposed areas, wearing protective clothing and sunglasses, avoiding tanning beds and sun lamps, and the importance of early detection.

## CARCINOGENESIS

The exact cause of cancer remains unknown and is probably very diverse given the vast array of diseases called cancer. It is thought that cancer develops from a single cell in which the normal mechanisms for control of growth and proliferation are altered. Current evidence indicates that there are four stages in the cancer development process. The first step, **initiation**, occurs when a carcinogenic substance encounters a normal cell to produce genetic damage and results in a mutated cell. The environment is altered by carcinogens or other factors to favor the growth of the mutated cell over the normal cell during **promotion**, the second step. The main difference between initiation and promotion is that promotion is a reversible process. Third, **transformation** (or **conversion**) occurs when the mutated cell becomes malignant. Depending on the type of cancer, up to 20 years may elapse between the carcinogenic phases and the development of a clinically detectable tumor. Finally, **progression** occurs when cell proliferation takes over and the tumor spreads or develops metastases.

There are substances known to have carcinogenic risks, including chemicals, environmental factors, and viruses. Chemicals in the environment, such as aniline and benzene, are associated with the development of bladder cancer and leukemia, respectively. Environmental factors, such as excessive sun exposure, can result in skin cancer, and smoking is widely known as a cause of lung cancer. Viruses, including human papillomavirus (HPV), Epstein-Barr virus, and hepatitis B virus, have been linked to cervical cancers, lymphomas, and liver cancers, respectively. Anticancer agents such as the alkylating agents (eg, melphalan), anthracyclines (eg, doxorubicin), and epipodophyllotoxins (eg, etoposide) can cause secondary malignancies (eg, leukemias) years after therapy has been completed. Additionally, factors such as the patient's age, gender, family history, diet, and chronic irritation or inflammation may be considered to be promoters of carcinogenesis.

## Cancer Genetics

Because the human genome has been sequenced and with the great improvements in genetic technology, there is growing knowledge regarding the genetic changes of cancer. There are two major classes of genes involved in carcinogenesis, **oncogenes** and **tumor suppressor genes**. **Protooncogenes** are normal genes that, through some genetic alteration caused by carcinogens, change into oncogenes. Protooncogenes are present in all normal cells and regulate cell function and replication. Genetic damage of the protooncogene may occur through point mutation, chromosomal rearrangement, or an increase in gene function, resulting in the oncogene. The genetic damage may either be inherited from an individual's parents (germline mutations) or by way of carcinogenic agents (eg, smoking). The oncogene produces abnormal or excessive gene product that disrupts normal cell growth and proliferation.[5] As a result, this may cause the cell to have a distinct growth advantage, increasing its likelihood of becoming cancerous. **Table 88–1** provides examples of oncogenes by their cellular function and associated cancer.

Tumor suppressor genes inhibit inappropriate cellular growth and proliferation by gene loss or mutation. This results in loss

### Table 88–1

**Examples of Oncogenes and Tumor Suppressor Genes**

| Gene | Function | Associated Human Cancer |
|---|---|---|
| **Oncogenes** | | |
| **Genes for growth factors or their receptors** | | |
| EGFR or Erb-B1 | Codes for epidermal growth factor (EGFR) receptor | Glioblastoma, breast, head and neck, and colon cancers |
| HER-2/neu or Erb-B2 | Codes for a growth factor receptor | Breast, salivary gland, prostate, bladder, and ovarian cancers |
| RET | Codes for a growth factor receptor | Thyroid cancer |
| **Genes for cytoplasmic relays in stimulatory signaling pathways** | | |
| K-RAS and N-RAS | Code for guanine nucleotide-proteins with GTPase activity | Lung, ovarian, colon, pancreatic binding cancers |
| | | Neuroblastoma, acute leukemia |
| **Genes for transcription factors that activate growth-promoting genes** | | |
| c-MYC | | Leukemia and breast, colon, gastric, and lung cancers |
| N-MYC | | Neuroblastoma, small cell lung cancer, and glioblastoma |
| **Genes for cytoplasmic kinases** | | |
| BCR-ABL | Codes for a nonreceptor tyrosine kinase | Chronic myelogenous leukemia |
| **Genes for other molecules** | | |
| BCL-2 | Codes for a protein that blocks apoptosis | Indolent B-cell lymphomas |
| BCL-1 or PRAD1 | Codes for cyclin D$_1$, a cell-cycle clock stimulator | Breast, head, and neck cancers |
| MDM2 | Protein antagonist of p53 tumor suppressor protein | Sarcomas |
| **Tumor-Suppressor Genes** | | |
| **Genes for proteins in the cytoplasm** | | |
| APC | Step in a signaling pathway | Colon and gastric cancer |
| NF-1 | Codes for a protein that inhibits the stimulatory Ras protein | Neurofibroma, leukemia, and pheochromocytoma |
| NF-2 | Codes for a protein that inhibits the stimulatory Ras protein | Meningioma, ependymoma, and schwannoma |
| **Genes for proteins in the nucleus** | | |
| MTS1 | Codes for p16 protein, a cyclin-dependent kinase inhibitor | Involved in a wide range of cancers |
| RB1 | Codes for the pRB protein, a master brake of the cell cycle | Retinoblastoma, osteosarcoma, and bladder, small cell lung, prostate, and breast cancers |
| p53 | Codes for the p53 protein, which can halt cell division and induce apoptosis | Involved in a wide range of cancers |
| **Genes for protein whose cellular location is unclear** | | |
| BRCA1 | DNA repair, transcriptional regulation | Breast and ovarian cancers |
| BRCA2 | DNA repair | Breast cancer |
| VHL | Regulator of protein stability | Renal cell cancer |
| MSH2, MLH1, PMS1, PMS2, MSH6 | DNA mismatch repair enzymes | Hereditary nonpolyposis colorectal cancer |

From DiPiro JT, Talbert RL, Yee GC, et al. (eds.) Pharmacotherapy: A Pathophysiologic Approach, 8th ed. New York: McGraw-Hill; 2011: Table 135–2.

of control over normal cell growth. The *p53* gene is one of the most common tumor suppressor genes, and mutations of *p53* may occur in up to 50% of all malignancies. This gene stops the cell cycle to enable "repairs" of the cell. If *p53* is inactivated, then the cell allows the mutations to occur. Although mutations of the *p53* gene are found in many tumors, such as breast, colon, and lung cancer, it is also associated with drug resistance of cancer cells. DNA repair genes fix errors in DNA that occur because of environmental factors or errors in replication and can be classified as tumor suppressor genes. Mutations in DNA repair genes have been reported in hereditary nonpolyposis colon cancer and in some breast cancer syndromes.

**KEY CONCEPT** *Numerous cellular changes occur in the genetic material of the cancer cell so that programmed cell death, or apoptosis, does not occur. Proliferation of cancer cells goes unregulated.* If mutations persist and cells are not repaired or suppressed, cancer may develop. **Apoptosis**, or programmed cell death, may prevent the mutated cell from becoming cancerous. Loss of *p53* and overexpression of *bcl-2* are two examples of changes within the cell that occur to result in enhanced cell survival. Cellular

senescence refers to cell death that occurs after a preset number of cell doublings. Telomeres are DNA segments at the ends of chromosomes that shorten with each replication to the point where senescence is triggered.

Identification of genes involved in cancer may be conducted for various reasons, including cancer screening to determine if an individual is at an increased risk of cancer, to develop new anticancer agents, to aid in diagnosis, and to predict response and/or the toxicity of the agents used in individual patients.

## Principles of Tumor Growth

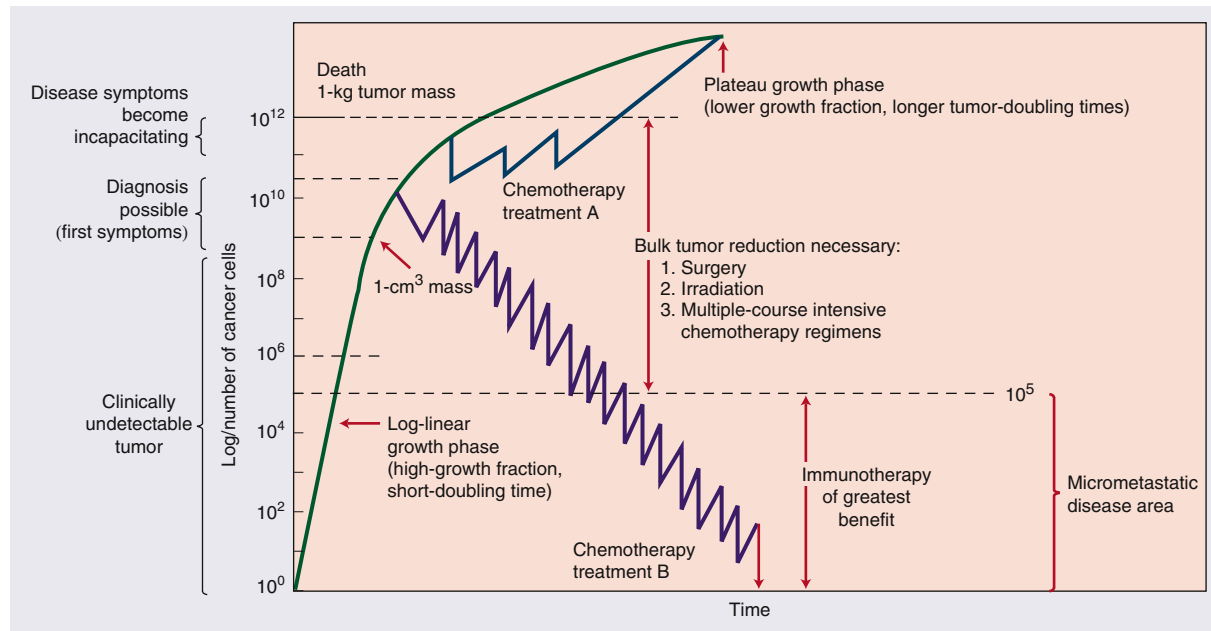
It takes about $10^9$ cancer cells to be clinically detectable by palpation or radiography. **Figure 88–2** demonstrates the classic Gompertzian kinetics tumor growth cycle. From the diagram, one can see that malignant cell growth occurs many times before a mass may be detected. The number of malignant cells may decrease drastically because of surgery or in decreasing steps by each administration of chemotherapy. One dosing round, or cycle, of


**FIGURE 88−2.** The Gompertzian growth curve demonstrating symptoms and treatments versus tumor volume.

chemotherapy does not eliminate all malignant cells; therefore, repeated cycles of chemotherapy are administered to eliminate tumor cell burden. The cell kill hypothesis states that a fixed percentage of tumor cells will be killed with each cycle of chemotherapy. According to this hypothesis, the number of tumor cells will never reach zero. This theory assumes that all cancers are equally responsive and that anticancer drug resistance and metastases do not occur, which is not the case.[6]

## Metastases

A metastasis is a growth of the same cancer cell found at some distance from the primary tumor site.[7] The metastasis may be large, or it may be just a few cells that may be detected through polymerase chain reaction (PCR); however, the presence of metastasis at staging usually is associated with a poorer prognosis than the patient with no known metastatic disease. As the technology to detect malignant cells evolves, the dilemma exists on how to treat patients based on current guidelines that were not based on cellular detection technology.

Cancers spread usually by two pathways: hematogenous (through the bloodstream) or through the lymphatics (drainage through adjacent lymph nodes). The malignant cells that split from the primary tumor find a suitable environment for growth. It is believed that malignant cells secrete mediators that stimulate the formation of blood vessels for growth and oxygen, the process of angiogenesis. The usual metastatic sites for solid tumors are the brain, bone, lung, and liver.

## PATHOPHYSIOLOGY
### Tumor Origin

Tumors may arise from the four basic tissue types: epithelial, connective (ie, muscle, bone, and cartilage), lymphoid, or nerve tissue. The suffix *-oma* is added to the name of the cell type if

the tumor cells are benign. A *lipoma* is a benign growth that resembles fat tissue.

Precancerous cells have cellular changes that are abnormal but not yet malignant and may be described as *hyperplastic* or *dysplastic*. Hyperplasia occurs when a stimulus is introduced and reverses when the stimulus is removed. Dysplasia is an abnormal change in the size, shape, or organization of cells or tissues.

Malignant cells are divided into categories based on the cells of origin. Carcinomas arise from epithelial cells, whereas sarcomas arise from muscle or connective tissue. Adenocarcinomas arise from glandular tissue. *Carcinoma* in situ refers to cells limited to epithelial origin that have not yet invaded the basement membrane. Malignancies of the bone marrow or lymphoid tissue, such as leukemias or lymphomas, are named differently.

## Tumor Characteristics

Tumors are either benign or malignant. Benign tumors often are encapsulated, localized, and indolent; they seldom metastasize; and they rarely recur once removed. Histologically, the cells resemble the cells from which they developed. Malignant tumors are invasive and spread to other locations even if the primary tumor is removed. The cells no longer perform their usual functions, and their cellular architecture changes. This loss of structure and function is called *anaplasia*. Despite improvements in screening procedures, many patients have metastatic disease at the time of diagnosis. Usually, once distant metastases have occurred, the cancer is considered incurable.[8]

## DIAGNOSIS OF CANCER

Cancer can present as a number of different signs and symptoms. Unfortunately, many people fear a diagnosis of cancer and may not seek medical attention at the first warning signs

when the disease is at its most treatable stage. After the initial visit with the clinician, a variety of tests will be performed, which are somewhat dependent on the initial differential diagnoses. Appropriate laboratory tests, radiologic scans, and tissue samples are necessary. The sample of tissue may be obtained by a biopsy, fine-needle aspiration, or exfoliative cytology. No treatment of cancer should be initiated without a pathologic diagnosis of cancer. During the pathologic workup, genetic analysis may be done. Depending on the type of cancer, the genetic analysis can provide the additional information on prognosis of the malignancy and whether certain therapies may be appropriate.

Once the pathology of cancer is established, then staging of the disease is done before treatment is initiated. **KEY CONCEPT** *Cancer staging is usually done according to the primary tumor size, extent of lymph node involvement, and the presence or absence of metastases, also referred to as the tumor, nodes, metastases (TNM) system (Table 88–2). The stage of the disease is a compilation of the primary tumor size, the nodal involvement, and metastases and is usually referred to as stages I, II, III, or IV.* Not all cancers can be staged according to this system, but many of the solid tumors are.

Staging of the disease is an important part of determining the prognosis of the cancer. Staging also allows comparison of

---

### Table 88–2

**Tumor (T), Node (N), Metastasis (M) Staging for Non–Small Cell Lung Cancer**

| Primary Tumor | | Description |
|---|---|---|
| $T_1$ | | Tumor 3 cm or less diameter, surrounded by lung or visceral pleura, without invasion more proximal than lobar bronchus |
| | $T_{1a}$ | Tumor 2 cm or less in diameter |
| | $T_{1b}$ | Tumor greater than 2 cm but 3 cm or less in diameter |
| $T_2$ | | Tumor greater than 3 cm but 7 cm or less, or tumor with any of the following features: <br>–Involves main bronchus, 2 cm or less distal to carina <br>–Invades visceral pleura <br>–Associated with atelectasis or obstructive pneumonitis that extends to the hilar region but does not involve the entire lung |
| | $T_{2a}$ | Tumor greater than 3 cm but 5 cm or less |
| | $T_{2b}$ | Tumor greater than 5 cm but 7 cm or less |
| $T_3$ | | Tumor greater than 7 cm or any of the following: <br>–Directly invades any of the following: chestwall, diaphragm, phrenic nerve, mediastinal pleura, parietal pericardium, main bronchus less than 2 cm from carina (without involvement of carina) <br>–Atelectasis or obstructive pneumonitis of the entire lung <br>–Separate tumor nodules in the same lobe |
| $T_4$ | | Tumor of any size that invades the mediastinum, heart, great vessels, trachea, recurrent laryngeal nerve, esophagus, vertebral body, carina, or with separate tumor nodules in a different ipsilateral lobe |
| **Regional lymph nodes (N)** | | |
| $N_0$ | | No regional lymph node metastases |
| $N_1$ | | Metastasis in ipsilateral peribronchial and/or ipsilateral hilar lymph nodes and intrapulmonary nodes, including involvement by direct extension |
| $N_2$ | | Metastasis in ipsilateral mediastinal and/or subcarinal lymph node(s) |
| $N_3$ | | Metastasis in contralateral mediastinal, contralateral hilar, ipsilateral or contralateral scalene, or supraclavicular lymph node(s) |
| **Distant metastasis (M)** | | |
| $M_0$ | | No distant metastasis |
| $M_1$ | | Distant metastasis |
| | $M_{1a}$ | Separate tumor nodule(s) in a contralateral lobe; tumor with pleural nodules or malignant pleural or pericardial effusion |
| | $M_{1b}$ | Distan metastasis |

| Stage | T | N | M | 5-Year Survival |
|---|---|---|---|---|
| Stage IA: | $T_{1a}$-$T_{1b}$ | $N_0$ | $M_0$ | 73% |
| Stage IB: | $T_{2a}$ | $N_0$ | $M_0$ | 58% |
| Stage IIA: | $T_{1a}$, $T_{1b}$, $T_{2a}$, $T_{2b}$ | $N_1$, $N_0$ | $M_0$, $M_0$ | 46% |
| Stage IIB: | $T_{2b}$, $T_3$ | $N_1$, $N_0$ | $M_0$, $M_0$ | 36% |
| | $T_{1a}$, $T_{1b}$, $T_{2a}$, $T_{2b}$ | $N_2$ | $M_0$ | |
| Stage IIIA: | $T_3$ | $N_1$, $N_2$ | $M_0$ | 24% |
| | $T_4$ | $N_0$, $N_1$ | $M_0$ | |
| Stage IIIB: | $T_4$ | $N_2$ | $M_0$ | 9% |
| | Any T | $N_3$ | $M_0$ | |
| Stage IV: | Any T | Any N | $M_{1a}$ or $M_{1b}$ | 13% |

From DiPiro JT, Talbert RL, Yee GC, et al. (eds.) Pharmacotherapy: A Pathophysiologic Approach. 8th ed. New York: McGraw-Hill; 2011: Table 137–2.

patient groups when examining data from clinical trials; staging reflects the extent of disease. Finally, the clinician uses it as a guide to treatment and may use restaging after treatment to guide further treatment.

Some cancers produce substances (eg, proteins) that are detected by a blood test, that may be useful in following response to therapy or detecting a recurrence; these are referred to as tumor markers. An example of a clinically used tumor marker is the prostate-specific antigen (PSA). The PSA serum level is used to monitor response to treatment. Unfortunately, some tumor markers are nonspecific and may be elevated from nonmalignant causes. In the case of PSA, nonmalignant causes such as prostatitis, trauma, surgery, ejaculation, some medications, benign prostatic hypertrophy, or riding on an exercise bicycle can all cause increased PSA levels.[9] Some tumors may express a marker in some patients and not in others. The full role of tumor markers has not been fully elucidated.

## TREATMENT
### Desired Outcome
Surgery may be able to remove all macroscopic disease; however, microscopic cells may still be present near the surgical site or may have traveled to other parts of the body. When malignant cells have traveled to other parts of the body and become established there and are able to grow in this new environment, they are called metastatic cancer cells. Thus, for chemotherapy-sensitive diseases, systemic therapies may be administered after surgery to destroy these microscopic malignant cells; this is called **adjuvant chemotherapy**. The goals of adjuvant chemotherapy are to decrease the recurrence of the cancer and to prolong survival. Chemotherapy may also be given before surgical resection of the tumor; this is referred to as **neoadjuvant chemotherapy**. Chemotherapy given before surgery should decrease the tumor burden to be removed (which may result in a shorter surgical procedure or less physical disfigurement to the patient) and make the surgery easier to perform because the tumor has shrunk away from vital organs or vessels. Neoadjuvant chemotherapy also gives the clinician an idea of the responsiveness of the tumor to that particular chemotherapy.

Chemotherapy may be given to cure cancers that are curable, or it may be given to help control the symptoms of an incurable cancer, which is referred to as **palliative therapy**.

### Response
The responses to chemotherapy may be referred to as **complete response (CR)**, **partial response (PR)**, **stable disease (SD)**, or **disease progression**. A cure in oncology implies that the cancer is completely gone, and the patient will have the same life expectancy as a patient without cancer. The Response Evaluation Criteria in Solid Tumors (RECIST) was developed in 2000 and revised in 2009 and is considered to be the standard criteria to evaluate a response to therapy (**Table 88–3**). The term **overall objective response rate** refers to the combination of PR and CR. Some cancers, such as leukemia, cannot be measured by size, so biopsy of the bone marrow provides a cellular indication of the absence or presence of disease.[10]

Anticancer treatments can be thought of as being analogous to antiinfectives treatments. Cancer cells may be **sensitive** to certain chemotherapy agents, but then with repeated exposure, the cells may become **resistant** to treatment. The resistant cells then may grow and multiply. A number of genetic mutations, including *EGFR*, *KRAS*, and *BRAF*, predict sensitivity to

| Table 88–3 | |
|---|---|
| **RECIST 1.1 Criteria** | |
| **Term** | **Description** |
| Complete response (CR) | Disappearance of all targeted lesions |
| Partial response (PR) | At least a 30% decrease in the sum of the longest diameter of target lesions from baseline |
| Progressive disease (PD) | At least a 20% increase in the sum of the longest diameter of target lesions from baseline, including new lesions discovered during treatment |
| Stable disease (SD) | Neither sufficient shrinkage to qualify for PR nor sufficient increase to qualify for PD |

Adapted from Eisenhauer E, Therasse P, Bogaerts J, et al. New response evaluation criteria in solid tumours: Revised RECIST guideline (version 1.1). Eur J Cancer. 2009;45:228–247.

chemotherapy agents that target these mutations. These mutations will be discussed in depth in the following cancer-specific chapters.

### Nonpharmacologic Therapy
The four primary treatment modalities of cancer are surgery, radiation, biotherapy, and pharmacologic therapy. Surgery is useful to gain tissue for diagnosis of cancer and for treatment, especially those cancers with limited disease. Radiation plays a key role not only in the treatment and possible cure of cancer but also in palliative therapy. Together, surgery and radiation therapy may provide local control of symptoms of the disease. However, when cancer is widespread, surgery may play little or no role, but radiation therapy localized to specific areas may palliate symptoms.

### Pharmacologic Therapy
Chemotherapy of cancer started in the early 1940s when nitrogen mustard was first administered to patients with lymphoma. Since then, numerous agents have been developed for the treatment of different cancers.

### Dosing of Chemotherapy
Chemotherapeutic agents typically have a very narrow therapeutic index. If too much is administered, the patient may suffer from fatal toxicities. If too little is given, the desired effect on cancer cells may not be achieved. Many chemotherapy agents have significant organ toxicities that preclude using steadily increasing doses to treat the cancer. The doses of chemotherapy must be given at a frequency that allows the patient to recover from the toxicity of the chemotherapy; each period of chemotherapy dosing is referred to as a cycle. Each cycle of chemotherapy may have the same dosages; the dosages may be modified based on toxicity; or a chemotherapy regimen may alternate from one set of drugs given during the first, third, and fifth cycles to another set of different drugs given during the second, fourth, and sixth cycles. The **dose density** of chemotherapy refers to shortening of the period between cycles of chemotherapy. This can accomplish two things: First, the tumor has less time between cycles of chemotherapy to grow, and second, patients receive the total

## Clinical Presentation and Diagnosis: Cancer Chemotherapy and Treatment

**Signs and Symptoms**

**The seven warning signs of cancer are:**

- Change in bowel or bladder habits
- A sore that does not heal
- Unusual bleeding or discharge
- Thickening or lump in breast or elsewhere
- Indigestion or difficulty in swallowing
- Obvious change in a wart or mole
- Nagging cough or hoarseness

**The eight warning signs of cancer in children are:**

- Continued, unexplained weight loss
- Headaches with vomiting in the morning
- Increased swelling or persistent pain in bones or joints
- Lump or mass in abdomen, neck, or elsewhere
- Development of a whitish appearance in the pupil of the eye
- Recurrent fevers not caused by infections
- Excessive bruising or bleeding
- Noticeable paleness or prolonged tiredness

**Diagnostic Procedures**

- Laboratory tests: CBC, lactate dehydrogenase (LDH), renal function, and liver function tests
- Radiologic scans: x-rays, CT scans, MRI, position emission tomography (PET)
- Biopsy of tissue or bone marrow with pathologic evaluation
- Cytogenetics
- Tumor markers

Staging determination of the primary tumor size, extent of lymph node involvement, and the presence or absence of metastases, referred to as the TNM system (see Table 88–2). Most solid tumors are staged according to the TNM classification system. The size of the primary tumor, extent of nodal involvement, and presence of metastases are used to determine the stage. Metastases are cancer cells that have spread to sites distant from the primary tumor site and have started to grow. The most frequently occurring sites of metastases of solid tumors are the brain, bone, liver, and lungs.

---

number of required cycles in a shorter time period. Administration of dose-dense chemotherapy regimens often requires the use of colony-stimulating factors (eg, filgrastim or granulocyte colony-stimulating factor [G-CSF]) to be administered. These agents shorten the duration and severity of neutropenia. The chemotherapy regimens that are dose dense tend to be adjuvant regimens, and the goal of therapy is cure.

When a chemotherapy regimen is used as palliative therapy (to control symptoms), the dosages of chemotherapy may be decreased based on toxicity or the interval between cycles may be lengthened to maintain quality of life.

Patient and tumor biology also affect how cancer therapy is dosed. Patients with a uridine diphosphate–glucuronosyltransferase 1A1 enzyme (UGT1A1* 28) deficiency can have life-threatening diarrhea and complications from irinotecan related to a decreased ability to metabolize the parent drug. The patient may have a blood test before irinotecan therapy to determine if this genetic mutation is present. In the case of some monoclonal antibodies, flow cytometry results reveal whether the tumor has the receptor where the drug will bind and exert the pharmacologic effect.[11] The therapeutic uses of oncology drugs with valid genomic biomarkers will be discussed briefly in this chapter and in more detail in the following chapters.

Another consideration of chemotherapy administration is the patient. Factors that affect chemotherapy selection and dosing are age, concurrent disease states, and performance status. Performance status can be assessed through either the Eastern Cooperative Oncology Group (ECOG) Scale or the Karnofsky Scale (Table 88–4). Performance status is a very important prognostic factor for many types of cancer. If a patient has renal dysfunction and the chemotherapy is eliminated primarily by the kidney, dosing adjustments will need to be made. If a patient has had a myocardial infarction recently or preexisting heart disease, the clinician will weigh the risks of anthracycline therapy against the benefit of the treatment of the cancer.

Another important consideration for treatment of cancers is reimbursement by third-party payers for compendia off-label use. Off-label use is when a medication is used to treat a cancer that is not an FDA-labeled indication. Because of rapid advancements in oncology, it is estimated that up to 75% of chemotherapy agents are prescribed "off-label." Drugs used according to FDA-approved indications are usually reimbursed. If sufficient supportive literature exists and the use is supported by one of the Medicare-approved compendia (eg, AHFS-DI, Clinical Pharmacology, DRUGDEX, NCCN, others), an insurer should cover the cost of the anticancer treatment that does not have an FDA indication.

During the time of chemotherapy administration, patients will likely experience various toxicities. The National Cancer Institute (NCI) has provided a standardized system for evaluating and grading the toxicity from chemotherapy to provide uniform grading of toxicity and evaluation of new agents and new regimens (Table 88–5).

### Combination Chemotherapy

The underlying principles of using combination therapy are to use (1) agents with different pharmacologic actions, (2) agents with different organ toxicities, (3) agents that are active against the tumor and ideally synergistic when used together, and (4) agents that do not result in significant drug interactions (although these can be studied carefully and the interactions addressed). When two or more agents are used together, the risk of development of resistance may be lessened, but toxicity may be increased.

**KEY CONCEPT** *Traditional chemotherapy agents have some similar side effects, usually manifested on the most rapidly proliferating cells of the body. However, there are unique toxicities of various pharmacologic categories of antineoplastic agents. Anthracyclines (eg, doxorubicin) have the potential to cause cardiac toxicity, which is related to the cumulative dose. Microtubule-targeting agents (eg, vincristine) are associated with various forms of*

**Table 88–4**

**Performance Status Scales**

| Description: Karnofsky Scale | Karnofsky Scale (%) | Zubrod Scale (ECOG) | Description: ECOG Scale |
|---|---|---|---|
| No complaints; no evidence of disease | 100 | 0 | Fully active; able to carry on all predisease activity |
| Able to carry on normal activity; minor signs or symptoms of disease | 90 | | |
| Normal activity with effort; some signs or symptoms of disease | 80 | 1 | Restricted in strenuous activity but ambulatory and able to carry out work of a light or sedentary nature |
| Cares for self; unable to carry on normal activity or to do active work | 70 | | |
| Requires occasional assistance but is able to care for most personal needs | 60 | 2 | Out of bed more than 50% of time; ambulatory and capable of self-care but unable to carry out any work activities |
| Requires considerable assistance and frequent medical care | 50 | | |
| Disabled; requires special care and assistance | 40 | 3 | In bed more than 50% of time; capable of only limited self-care |
| Severely disabled; hospitalization indicated, although death not imminent | 30 | | |
| Very sick; hospitalization necessary; requires active supportive treatment | 20 | 4 | Bedridden; cannot carry out any self-care; completely disabled |
| Moribund; fatal processes progressing rapidly | 10 | | |
| Dead | 0 | | |

ECOG, Eastern Cooperative Oncology Group.

**Table 88–5**

**Selected National Cancer Institute Common Toxicity Criteria**

| Toxicity | Grade 1 | Grade 2 | Grade 3 | Grade 4 | Grade 5 |
|---|---|---|---|---|---|
| General Neutropenia | Mild Lowest baseline: 1500/mm³ (1.5 × 10⁹/L) | Moderate Less than 1500–1000/mm³ (1.5–1 × 10⁹/L) | Severe Less than 1000–500/mm³ (1–0.5 × 10⁹/L) | Life threatening Less than 500/mm³ (0.5 × 10⁹/L) | Death |
| Thrombocytopenia | Lowest baseline: 75,000/mm³ (75 × 10⁹/L) | Less than 75,000–50,000/mm³ (75–50 × 10⁹/L) | Less than 50,000–25,000/mm³ (50–25 × 10⁹/L) | Less than 25,000 mm³ (25 × 10⁹/L) | Death |
| Diarrhea | Increase of less than four stools per day over baseline or mild increase in ostomy output | Increase of four to six stools per day over baseline; IV fluids indicated less than 24 hours of moderate increase in ostomy output compared with baseline; not interfering with ADLs | Increase of greater than or equal to seven stools per day over baseline; incontinence; IV fluids greater than or equal to 24 hours; hospitalization; severe increase in ostomy output compared with baseline; interfering with ADLs | Life-threatening consequences (eg, hemodynamic collapse) | Death |
| Esophagitis | Asymptomatic pathologic, radiographic, or endoscopic findings only | Symptomatic altered eating or swallowing; IV fluids indicated less than 24 hours | Symptomatic and severely altered eating or swallowing; IV fluids, tube feedings, or TPN indicated 24 hours or more | Life-threatening consequences | Death |
| Nausea | Loss of appetite without alteration in eating habits | Oral intake decreased without significant weight loss, dehydration, or malnutrition; IV fluids indicated less than 24 hours | Inadequate oral caloric or fluid intake; IV fluids, tube feedings, or TPN indicated greater than 24 hours | Life-threatening consequences | Death |
| Vomiting | One episode in 24 hours | Two to five episodes in 24 hours; IV fluids indicated less than 24 hours | Six episodes or more in 24 hours; IV fluids or TPN indicated greater than or equal to 24 hours | Life-threatening consequences | Death |

ADL, activity of daily living; IV, intravenous; TPN, total parenteral nutrition.

In: Brunton LL, Chabner BA, Knollman BC (eds). Goodman & Gilman's The Pharmacologic Basis of Therapeutics, 12th ed. New York: McGraw-Hill, 2010.

neurotoxicity. *Alkylating agents (eg, melphalan) are associated with secondary malignancies.*

Currently, anticancer agents are categorized by the mechanism of action. As depicted in **Figure 88–3**, different agents work in different parts of the cell.

## Antimetabolites: Pyrimidine Analogues

### ▶ *Fluorouracil*

5-Fluorouracil (5-FU) is a fluorinated analogue of the pyrimidine uracil. Once administered, this prodrug is metabolized by dihydropyrimidine dehydrogenase. 5-FU ultimately is metabolized to fluorodeoxyuridine monophosphate (FdUMP), which interferes with the function of thymidylate synthase (TS), which is required for synthesis of thymidine. The triphosphate metabolite of 5-FU is incorporated into RNA to produce the second cytotoxic effect of 5-FU. Inhibition of thymidylate synthesis occurs with the continuous infusion regimens, whereas the triphosphate form is associated with bolus administration. Patients with a low activity of dihydropyrimidine dehydrogenase appear to be at risk for life-threatening toxicities. Folates increase the stability of FdUMP–TS inhibition, which enhances the activity of the drug in certain cancers. 5-FU is metabolized extensively by the liver, but up to 15% of a dose may be found unchanged in the urine.

Age does not appear to alter the pharmacokinetics. 5-FU has shown clinical activity in several solid tumors, and is frequently used to treat both breast and colon cancer. Adverse effects may include stomatitis, diarrhea, esophagitis, gastric ulcerations, cardiac abnormalities, and rarely reported cerebellar toxicities. Some alopecia may occur, but hair regrowth may occur with subsequent doses. Cryotherapy (using ice chips in the mouth) for 30 minutes while receiving bolus 5-FU may decrease the severity of mucositis.[12] Neurotoxicity may consist of headaches, visual disturbances, and cerebellar ataxia. Cardiac toxicity may consist of ST-segment elevation, which appears to be more common in patients with a history of coronary artery disease.

▶ *Capecitabine*

Capecitabine is an orally active prodrug of 5-FU and has shown to be active in tumors of the colon, rectum, and breast. It not only shares the same mechanism but the toxicity profile is also similar to that of 5-FU. There appears to be a higher level of thymidine phosphorylase intracellularly, which is the enzyme responsible for converting capecitabine into 5-FU. This is believed to make the agent more selective against malignant cells. Toxicities include diarrhea, mucositis, palmar-plantar erythrodysesthesia, nausea, and myelosuppression. Palmar-plantar erythrodysesthesia, also called hand–foot syndrome, refers to redness, itching, and blistering of the palms of the hands and soles of the feet. Patients should be counseled to notify the prescriber when this adverse effect occurs. Significant increases in international normalization ratio (INR) and prothrombin time may occur within several days when capecitabine is initiated in patients concomitantly receiving warfarin. The INR should be monitored closely or the patient may be switched to a low-molecular-weight heparin. Phenytoin levels may become elevated related to possible CYP2C9 inhibition by capecitabine; therefore, plasma levels of phenytoin should be monitored. Patients should be instructed to take capecitabine within 30 minutes of a meal to increase absorption of the drug.

▶ *Cytarabine*

Cytarabine is a structural analogue of cytosine and is phosphorylated intracellularly to the active triphosphate form, which inhibits DNA polymerase. The triphosphate form also may be incorporated into DNA to result in chain termination to prevent DNA elongation. The drug may be administered as a low-dose continuous infusion, high-dose intermittent infusion, and into the subdural space via intrathecal or intraventricular administration. There is also a liposomal formulation available for less frequent administration into the central nervous system (CNS). Cytarabine is eliminated by the kidneys with a renal clearance of 90 mL/min (1.5 mL/s). Cytarabine has shown efficacy in the treatment of acute leukemias and some lymphomas. The toxicities of cytarabine in high doses include myelosuppression; cerebellar syndrome (ie, nystagmus, dysarthria, and ataxia); and chemical conjunctivitis, an eye irritation that requires prophylaxis with steroid eye drops. The risk of neurotoxicity is increased with high doses (greater than 1 g/m$^2$), advanced age, and renal dysfunction. If cerebellar toxicity does occur, the drug needs to be discontinued immediately, and decisions regarding further therapy need to be carefully considered.[13]

▶ *Gemcitabine*

Gemcitabine is a deoxycytidine analogue that is structurally related to cytarabine. Gemcitabine inhibits DNA polymerase activity and ribonucleotide reductase to result in DNA chain elongation. Gemcitabine has shown activity in several solid

**Patient Encounter 1, Part 1**

The patient is 64-year-old previously healthy man who has had symptoms of an upper respiratory tract infection for about 4 weeks. He has been treated with two courses of antibiotics without improvement of symptoms. He has also noticed an increase in bruising and frequent nose bleeds. He reports feeling extraordinarily tired recently. Today, he presents to an urgent care center with worsening cough. His complete blood count (CBC) reveals a high white blood cell (WBC) count (38 × 10$^3$/mm$^3$ [38 × 10$^9$/L]) and peripheral blasts (40% [0.40]). He is emergently admitted to the hospital for further evaluation.

After a bone marrow biopsy and further cytogenetic testing, a diagnosis of AML is made and treatment is planned to start as soon as possible.

*What signs and symptoms in this patient are consistent with a cancer presentation?*

*What is your desired outcome when treating this patient?*

tumors and some lymphomas. The toxicities include myelosuppression; flu-like syndrome with fevers during the first 24 hours after administration; rash that appears 48 to 72 hours after administration; and hemolytic uremic syndrome, a rare but life-threatening adverse effect. Patients should be counseled to use acetaminophen to treat the fevers during the first 24 hours; however, fevers occurring 7 to 10 days after gemcitabine are likely to be febrile neutropenias and need prompt treatment with broad-spectrum antibiotics.

▶ *Azacitidine and Decitabine*

Azacitidine and decitabine are nucleoside analogues approved for the treatment of patients with myelodysplastic syndrome, a hematopoietic disorder that can transform into acute myeloid leukemia (AML). Both of these agents cause cytotoxicity by directly incorporating in the DNA and inhibiting DNA methyltransferase, which causes hypomethylation of DNA. Hypomethylation of DNA appears to normalize the function of the genes that control cell differentiation and proliferation to promote normal cell maturation. The major side effects reported are myelosuppression and infections.

▶ *Nelarabine*

Nelarabine is indicated for the treatment of patients with T-cell acute lymphoblastic leukemia and T-cell lymphoblastic lymphoma, whose disease has been already treated with at least two other chemotherapy regimens. Nelarabine is a prodrug that accumulates as the active 5'-triphosphate form in leukemic blasts to result in inhibition of DNA synthesis and cell death. The most common adverse effects are hematologic toxicities, neutropenic fever, headaches, and gastrointestinal toxicities. Severe neurologic toxicities, including mental status change, convulsions, peripheral neuropathies, and effects similar to Guillain–Barré syndrome, have been reported.

## Antimetabolites: Purine Analogues

▶ *Mercaptopurine and Thioguanine*

6-Mercaptopurine (6-MP) and thioguanine are oral purine analogues that are converted to ribonucleotides that inhibit purine synthesis. Mercaptopurine is converted into thiopurine

nucleotides, which are catabolized by thiopurine *S*-methyl-transferase (TPMT), which is subject to genetic polymorphisms and may cause severe myelosuppression. TPMT status may be assessed before therapy to reduce drug-induced morbidity and the costs of hospitalizations for neutropenic events. Both of these agents are used in the treatment of acute lymphocytic leukemia (ALL) and chronic myeloid leukemia (CML). Because the agents are similar structurally, cross-resistance is observed. Significant side effects include myelosuppression, mild nausea, skin rash, cholestasis, and rarely, veno-occlusive disease. Mercaptopurine is metabolized by xanthine oxidase, an enzyme that is inhibited by allopurinol. This represents a major drug–drug interaction. To avoid toxicities of mercaptopurine when these drugs are used concomitantly, the dose of mercaptopurine must be reduced by 66% to 75%.

#### ▶ *Fludarabine*

Fludarabine is an analogue of the purine adenine. It interferes with DNA polymerase to cause chain termination and inhibits transcription by its incorporation into RNA. Fludarabine is dephosphorylated rapidly and converted to 2-fluoro-Ara-AMP (2-FLAA), which enters the cells and is phosphorylated to 2-fluoro-Ara-ATP, which is cytotoxic. Fludarabine is used in the treatment of chronic lymphocytic leukemia (CLL), some lymphomas, and refractory AML. This drug is given intravenously (IV) usually daily for 5 days every 4 weeks. Significant and prolonged myelosuppression may occur, along with immunosuppression, so patients are susceptible to opportunistic infections. Prophylactic antibiotics and antivirals are recommended until CD4 counts return to normal. Mild nausea and vomiting and diarrhea have been observed. Rarely, interstitial pneumonitis has occurred.

#### ▶ *Cladribine*

Cladribine is a purine nucleoside that is a prodrug. It is activated via phosphorylation to a 5′-triphosphate derivative, which is incorporated into DNA, resulting in inhibition of DNA synthesis and chain termination. It may be administered as a continuous 7-day IV infusion or as a 2-hour infusion daily for 5 days; both regimens deliver the same total dose of drug. The primary indication for cladribine is hairy cell leukemia. Although fairly well tolerated, patients may experience myelosuppression and opportunistic infections. Fever, which is thought to be as a result of cell lysis and endogenous pyrogens being released into the bloodstream, can prompt the clinician to consider initiation of antibiotics. Even though it is likely drug induced, it may be difficult to rule out an infectious cause. Rash occurs in approximately 50% of patients.

#### ▶ *Clofarabine*

Clofarabine was developed based on the structures of fludarabine and cladribine with the hope it would be resistant to deamination by adenosine deaminase. Clofarabine has shown activity in myeloid leukemia and myelodysplastic syndrome.[14] Side effects include bone marrow suppression, severe but transient liver dysfunction in 15% to 25% of patients, skin rashes, and hand–foot syndrome.

#### ▶ *Pentostatin*

Pentostatin is an inhibitor of adenosine deaminase, an enzyme important in purine base metabolism. Pentostatin irreversibly inhibits adenosine deaminase, which blocks DNA synthesis through inhibition of RNA ribonucleotide reductase. Side effects include bone marrow suppression, myalgias, conjunctivitis, and rash.

### Antimetabolites: Folate Antagonists

Folates carry one-carbon groups in transfer reactions required for purine and thymidylic acid synthesis. Dihydrofolate reductase is the enzyme responsible for supplying reduced folates intracellularly for thymidylate and purine synthesis.

#### ▶ *Methotrexate*

Methotrexate inhibits dihydrofolate reductase of both malignant and nonmalignant cells. When high doses of methotrexate are given, the "rescue drug" leucovorin, a reduced folate, is administered to bypass the methotrexate inhibition of dihydrofolate reductase of normal cells and is usually initiated 24 hours after methotrexate administration. This is done to prevent potentially fatal myelosuppression and mucositis. For safety purposes, the term folinic acid, another term used for leucovorin, should not be used because of the potential for a medication error in which folic acid might be given instead. Methotrexate concentrations should be monitored to determine when to stop leucovorin administration. Generally, leucovorin administration may be stopped when methotrexate concentrations decrease to $5 \times 10^{-8}$ M, although this may vary by the chemotherapy regimen. High dosages of methotrexate may cause methotrexate to crystallize out in the kidney, which may result in acute renal failure and decreased methotrexate clearance. Administration of IV hydration with sodium bicarbonate to maintain urinary pH greater than or equal to 7 is necessary to prevent methotrexate-induced renal dysfunction. Methotrexate is eliminated by tubular secretion; therefore, concomitant drugs (eg, probenecid, salicylates, penicillin G, and ketoprofen) that may inhibit or compete for tubular secretion should be avoided. Methotrexate doses must be adjusted for renal dysfunction and close monitoring of methotrexate concentrations is advised. Side effects of methotrexate include myelosuppression, nausea and vomiting, and mucositis. Methotrexate also may be administered via the intrathecal route or via an Ommaya reservoir in very low doses as small as 12 mg, so it is crucial for the clinician to know the correct dose by the correct route in order to avoid substantial toxicity. The methotrexate used for intrathecal and intraventricular injection must be preservative-free to prevent CNS toxicity.

#### ▶ *Pemetrexed*

Pemetrexed inhibits four pathways in thymidine and purine synthesis. Pemetrexed has shown activity in the treatment of mesothelioma and non–small cell lung cancer (NSCLC). Side effects include myelosuppression, rash, diarrhea, and nausea and vomiting. Patients should receive folic acid and cyanocobalamin to reduce bone marrow toxicity and diarrhea. Doses of folic acid of at least 400 mcg/day starting 5 days before treatment and continuing throughout therapy, as well as for 21 days after the last pemetrexed dose, have been used. Cyanocobalamin 1000 mcg is given intramuscularly the week before pemetrexed and then every three cycles thereafter. Dexamethasone 4 mg twice daily the day before, the day of, and the day after pemetrexed administration helps to decrease the incidence and severity of rash.[15]

#### ▶ *Pralatrexate*

Pralatrexate is a folate analogue metabolic inhibitor that is transported into tumor cells via the reduced folate carrier (RFC-1) and competitively inhibits dihydrofolate reductase. It also competitively inhibits polyglutamylation by the enzyme folylpolyglutamyl

synthetase, resulting in the depletion of thymidine and other molecules. It is an intravenously administered agent indicated for the treatment of patients with refractory or relapsed peripheral T-cell lymphoma. Pralatrexate was approved based on overall response rates, not survival benefits. Common adverse reactions include mucositis, thrombocytopenia, nausea, and fatigue. In an effort to reduce the treatment-related mucositis and hematologic toxicity associated with pralatrexate, patients should be counseled to take low-dose oral folic acid on a daily basis and vitamin $B_{12}$ intramuscular injections every 8 to 10 weeks.

## Microtubule-Targeting Agents

### ▶ Vinca Alkaloids (Vincristine, Vinblastine, and Vinorelbine)

The vinca alkaloids (vincristine, vinblastine, and vinorelbine) are derived from the periwinkle (vinca) plant and cause cytotoxicity by binding to tubulin, disrupting the normal balance between polymerization and depolymerization of microtubules, and inhibiting the assembly of microtubules, which interferes with the formation of the mitotic spindle. As a result, cells are arrested during the metaphase of mitosis. The vinca alkaloids are used in several malignancies, primarily hematologic. Even though these agents have similar structures, the incidence and severity of toxicities vary among the agents. The dose-limiting toxicity of vincristine is neurotoxicity, which can consist of depressed tendon reflexes, paresthesias of the fingers and toes, toxicity to the cranial nerves, or autonomic neuropathy (constipation or ileus, abdominal pain, and/or orthostatic hypotension.) In contrast, the dose-limiting toxicity associated with vinorelbine and vinblastine is myelosuppression. All of the vinca alkaloids are **vesicants** and can cause tissue damage; therefore, the clinician must take precautions to avoid extravasation injury. Biliary excretion accounts for a significant portion of elimination of vincristine and its metabolites, so doses need to be adjusted for obstructive liver disease.

Vincristine, vinblastine, and vinorelbine have similar sounding names, which is a potential cause of medication errors. As with all chemotherapy prescribing, dispensing, and administration, the clinician must be very careful with sound-alike, look-alike medications. Unfortunately, vincristine has been involved in numerous cases of fatal chemotherapy errors, including inadvertent intrathecal administration. Because the drug is a vesicant, intrathecal administration of the drug can cause widespread tissue damage in the brain and death. An example of a strategy that health systems can use to decrease the likelihood of an error such as this is for the pharmacy to only dispense vincristine in a minibag for IV administration. Many clinicians cap IV vincristine doses at 2 mg to prevent severe neuropathic side effects; however, if the intent of chemotherapy is curative, the vincristine dose may be dosed above the 2-mg cap.[16]

### ▶ Taxanes (Paclitaxel, Nanoparticle Albumin-Bound Paclitaxel, Docetaxel, and Cabazitaxel)

Paclitaxel and docetaxel are taxane plant alkaloids that, similar to the vinca alkaloids, exhibit cytotoxicity during the M phase of the cell cycle by binding to tubulin. Unlike the vinca alkaloids, however, the taxanes do not interfere with tubulin assembly. Rather, the taxanes promote microtubule assembly and inhibit microtubule disassembly. Once the microtubules are polymerized, the taxanes stabilize against depolymerization.

Hepatic metabolism and biliary excretion account for the majority of paclitaxel's elimination. Paclitaxel has demonstrated activity in several solid tumors. Considerable variability exists in paclitaxel dosing, from weekly 1-hour infusions to 24-hour infusions administered every 3 weeks. The diluent for paclitaxel, Cremophor EL, is composed of ethanol and castor oil. Infusions must be prepared and administered in non–polyvinyl chloride–containing bags and tubings, and solutions must be filtered. Patients receive dexamethasone, diphenhydramine, and an $H_2$ blocker to prevent hypersensitivity reactions caused by Cremophor EL. Patients also may have asymptomatic bradycardia during the infusion. Approximately 3 to 5 days after administration, patients may complain of myalgias and arthralgias that may last several days. Myelosuppression, flushing, neuropathy, ileus, and total-body alopecia are other common side effects. Because paclitaxel is a substrate for CYP 3A4, steady-state concentrations of paclitaxel were 30% lower in patients receiving phenytoin than in patients not receiving phenytoin. Paclitaxel clearance was decreased by 33% when it was administered after cisplatin, so paclitaxel is administered before cisplatin.

A nanoparticle albumin-bound nab-paclitaxel product is also available for the treatment of metastatic breast cancer resistant to conventional chemotherapy or progressing within 6 months of receiving a regimen containing an anthracycline. The nab-paclitaxel formulation uses nanotechnology to combine human albumin with paclitaxel allowing for the delivery of an insoluble drug in the form of nanoparticles. This unique formulation allows for an increased bioavailability and higher intracellular concentrations of the drug. It does not have the serious hypersensitivity reactions encountered with paclitaxel solubilized in Cremophor EL, so premedication with $H_1$ and $H_2$ blockers and steroids is not necessary. There is also a significantly lower incidence of severe neutropenia when compared to paclitaxel. The dose is infused over 30 minutes and does not require a special IV bag, tubing, or filter. The dosing of this product is different from that of the original paclitaxel, so practitioners need to be aware of which product is being prescribed. The pharmacokinetics of the albumin-bound paclitaxel displays a higher clearance and larger volume of distribution than paclitaxel. The drug is eliminated primarily via fecal excretion.[17] Bone marrow suppression, neuropathy, ileus, arthralgias, and myalgias still occur.

Docetaxel has activity in the treatment of several solid tumors also. Dexamethasone, 8 mg twice daily for 3 days starting the day before treatment, is used to prevent the fluid-retention syndrome associated with docetaxel and possible hypersensitivity reactions. The fluid-retention syndrome is characterized by edema and weight gain that is unresponsive to diuretic therapy and is associated with cumulative doses greater than 800 mg/m². Myelosuppression, alopecia, and neuropathy are other side effects associated with docetaxel treatment.

Cabazitaxel is a newer taxane used in combination with prednisone for the treatment of metastatic hormone-refractory prostate cancer in patients previously treated with a docetaxel-containing treatment regimen. Cabazitaxel has shown to have similar adverse effects as paclitaxel and docetaxel. Premedication with an antihistamine, corticosteroid, and $H_2$ antagonist to prevent hypersensitivity reactions is required.

### ▶ Halichondrins

Eribulin mesylate is a nontaxane microtubule dynamics inhibitor. It is a synthetic analogue of halichondrin B, which is a product isolated from the sea sponge *Halichondria okadai*. While taxanes inhibit cell division by stabilizing microtubules, eribulin arrests the cell cycle through inhibition of the growth phase of microtubules without interfering with microtubule

shortening. The cytotoxicity results from its effects via a tubulin-based antimitotic mechanism, resulting in $G_2$/M cell-cycle arrest and mitotic blockage. Apoptotic cell death results from prolonged mitotic blockage. Eribulin mesylate is an IV medication that is specifically indicated for the treatment of patients with metastatic breast cancer who have received at least two previous chemotherapy regimens (containing an anthracycline and taxane) for metastatic disease. The most common adverse effects reported are neutropenic fever, anemia, asthenia or fatigue, alopecia, peripheral neuropathy, nausea, and constipation. Eribulin has been reported to cause significant neutropenia and QT interval prolongation. It has vesicant properties. Dosages should be adjusted in renal and hepatic impairment.[18]

#### ► *Estramustine*

Estramustine, an oral drug, also inhibits microtubule assembly and has weak estrogenic activity at the estradiol hormone receptors of the cell. This drug is used primarily for the treatment of prostate cancer, but its use is limited by the side effects, which include nausea and vomiting, diarrhea, thromboembolic events, and gynecomastia.

#### ► *Ixabepilone*

Ixabepilone, an epothilone analogue, binds to β-tubulin subunits on microtubules, which results in suppression of microtubule dynamics. Ixabepilone is primarily eliminated by the liver by oxidation through the CYP3A4 system. Ixabepilone, in combination with capecitabine or alone if resistant to capecitabine, is indicated for the treatment of metastatic or locally advanced breast cancer after failures of anthracyclines and a taxane. Studies have shown a possible synergy when used in combination with capecitabine. Side effects include hypersensitivity reactions, myelosuppression, and peripheral neuropathy. To minimize the occurrence of hypersensitivity reactions, patients must receive both $H_1$ and $H_2$ antagonists before therapy. If a reaction still occurs, corticosteroids should be added to the premedications.

### Topoisomerase Inhibitors

Topoisomerase is responsible for relieving the pressure on the DNA structure during unwinding by producing strand breaks. Topoisomerase I produces single-strand breaks, whereas topoisomerase II produces double-strand breaks.

#### ► *Epipodophyllotoxins (Etoposide and Teniposide)*

Etoposide and teniposide are semisynthetic podophyllotoxin derivatives that inhibit topoisomerase II, causing multiple DNA double-strand breaks. Etoposide has shown activity in the treatment of several types of lymphoma, testicular and lung cancer, retinoblastoma, and carcinoma of unknown primary. Oral bioavailability is approximately 50%, so oral dosages are approximate two times those of IV doses. Teniposide has shown activity in the treatment of ALL, neuroblastoma, and non-Hodgkin lymphoma. Both of these agents should be slowly administered to prevent hypotension. Side effects of these agents include mucositis, myelosuppression, alopecia, phlebitis, hypersensitivity reactions, and secondary leukemias. Hypersensitivity reactions may be life threatening.

#### ► *Camptothecin Derivatives (Irinotecan and Topotecan)*

Irinotecan and topotecan, both camptothecins, inhibit the topoisomerase I enzyme to interfere with DNA synthesis through the active metabolite SN38. Topoisomerase I enzymes stabilize DNA single-strand breaks and inhibit strand resealing. Irinotecan has shown activity in the treatment of cancers of the colon, rectum, cervix, and lung. Irinotecan-induced diarrhea is a serious complication and may be life threatening. One form of diarrhea (acute) can occur during or immediately after the infusion. This is a result of a cholinergic process in which the patient may experience facial flushing, diaphoresis, and abdominal cramping. IV atropine should be administered to treat diarrhea that occurs any time during the first 24 hours of administration. Another form of diarrhea (chronic) can occur several days after administration and can result in severe dehydration. This adverse effect should be treated immediately with loperamide at a dosage of 2 mg every 2 hours or 4 mg every 4 hours until diarrhea has stopped for 12 hours. Other side effects include myelosuppression, fatigue, and alopecia. Individuals homozygous for *UGT1A1\* 28* have an increased risk of febrile neutropenia and diarrhea and should be considered for an empiric dose reduction of one level; heterozygotes should receive closer monitoring, including more frequent complete blood counts (CBCs) to detect myelosuppression.

Topotecan has shown clinical activity in the treatment of ovarian and lung cancer, myelodysplastic syndromes, and AML. The IV infusion may be scheduled daily for 5 days or once weekly. Side effects include myelosuppression, mucositis, and diarrhea. Diarrhea is less common than with irinotecan.

### Anthracene Derivatives

#### ► *Daunorubicin, Doxorubicin, Idarubicin, and Epirubicin*

Anthracyclines (daunorubicin, doxorubicin, idarubicin, and epirubicin) are also referred to as antitumor antibiotics or topoisomerase inhibitors when considering their mechanism of action. All of the anthracyclines contain a four-membered anthracene ring, a chromophore, with an attached sugar portion. Free radicals formed from the anthracyclines combine with oxygen to form superoxide, which can make hydrogen peroxide. These agents are able to insert between base pairs of DNA to cause structural changes in DNA. However, the primary mechanism of cytotoxicity appears to be the inhibition of topoisomerase II. These drugs are widely used in a variety of cancers.

Oxygen-free-radical formation is a cause of cardiac damage and extravasation injury, which is common with these drugs. The anthracyclines can cause cardiac toxicity as manifested by a congestive heart failure or cardiomyopathy symptomatology, alopecia, nausea or vomiting, mucositis, myelosuppression, and urinary discoloration. These drugs are vesicants. Dosage alterations should be made in the presence of biliary dysfunction.[19]

To reduce the risk of cardiotoxicity associated with doxorubicin, the maximum lifetime cumulative dose is 550 mg/m². Ventricular ejection fractions should be measured before therapy and periodically if therapy is continued. Therapy should be halted if there is a 10% to 20% decrease from baseline in ejection fraction. Patients at increased risk of cardiotoxicity include patients reaching the upper limit of cumulative lifetime dose; those taking concomitant or previous cardiotoxic drugs, concurrent paclitaxel, or bolus administration; patients with preexisting cardiac disease or mediastinal radiation; and the very young and elderly. Cardioprotectants (eg, dexrazoxane) have been used to decrease risk in some cases. Clinical guidelines exist recommending when cardioprotective agents are warranted.[20]

Liposomal doxorubicin is an irritant, not a vesicant, and is dosed differently from doxorubicin, so clinicians need to be very careful when prescribing these two drugs. Liposomal doxorubicin has shown significant activity in the treatment of breast and

ovarian cancer along with multiple myeloma and Kaposi sarcoma. Side effects include mucositis, myelosuppression, alopecia, and palmar-plantar erythrodysesthesia. The liposomal doxorubicin may be less cardiotoxic than doxorubicin.

### ▶ *Mitoxantrone*

This royal blue–colored drug is an anthracenedione that inhibits DNA topoisomerase II. Mitoxantrone has shown clinical activity in the treatment of acute leukemias, breast and prostate cancer, and non-Hodgkin lymphomas. Myelosuppression, mucositis, nausea and vomiting, and cardiac toxicity are side effects of this drug. The total cumulative dose limit is 160 mg/m$^2$ for patients who have not received prior anthracycline or mediastinal radiation. Patients who have received prior doxorubicin or daunorubicin therapy should not receive a cumulative dose greater than 120 mg/m$^2$ of mitoxantrone. Patients should be counseled that their urine will turn a blue–green color.[21]

## Alkylating Agents

Although still widely used for many malignancies, the alkylating agents are the oldest class of anticancer drugs. The agents cause cytotoxicity via transfer of their alkyl groups to nucleophilic groups of proteins and nucleic acids. The major site of alkylation within DNA is the N7 position of guanine, although alkylation does occur to a lesser degree at other bases. These interactions can either occur on a single strand of DNA (monofunctional agents) or on both strands of DNA through a cross-link (bifunctional agents), which leads to strand breaks. The major toxicities of the alkylating agents are myelosuppression, alopecia, nausea or vomiting, sterility or infertility, and secondary malignancies.

### ▶ *Nitrogen Mustards (Cyclophosphamide and Ifosfamide)*

Cyclophosphamide and ifosfamide are commonly used bifunctional alkylating agents, therefore, causing cross-linking of DNA. They each share similar adverse effects and spectrum of activity, being used in a variety of solid and hematologic cancers. Cyclophosphamide and ifosfamide are both prodrugs, requiring activation by mixed hepatic oxidase enzymes to get to their active forms, phosphoramide and ifosfamide mustard, respectively. During the activation process, additional byproducts (acrolein and chloroacetaldehyde) are formed. Acrolein has no cytotoxic activity but is responsible for the hemorrhagic cystitis associated with ifosfamide and high-dose cyclophosphamide. Acrolein produces cystitis by directly binding to the bladder wall. Prophylaxis is necessary with aggressive hydration, administration of 2-mercaptoethane sulfonate sodium (MESNA, which binds

***

**Patient Encounter 1, Part 2**

The decision to treat the patient with a systemic chemotherapy regimen is made. He will be receiving the standard induction regimen of 7 + 3 (idarubicin 12 mg/m$^2$/day IV every day for 3 days + cytarabine 100 mg/m$^2$/day continuous IV infusion for 7 days).

*Before initiating this chemotherapy regimen in the patient, what patient specific issues need to be addressed?*

*What adverse effects will the patient likely experience with these two chemotherapy drugs?*

***

**Patient Encounter 1, Part 3**

The patient goes into complete remission (or a complete response), and now consolidation therapy with high-dose cytarabine (2 g/m$^2$/dose IV every 12 hours for six doses) will be initiated.

*What is the mechanism of action of cytarabine?*

*How do the toxicities of high-dose cytarabine differ from those of conventional (low-dose) cytarabine? What are the risk factors, prophylaxis recommendations, and treatment recommendations for these toxicities?*

***

to and inactivates acrolein in the bladder), frequent voiding, and monitoring in patients receiving ifosfamide and high-dose cyclophosphamide. Patients should be counseled to drink plenty of fluids; void frequently; and report any hematuria, irritation, or flank pain. Dosing regimens of MESNA range from an equal milligram dose to the ifosfamide mixed in the same IV bag to 20% of the dose before ifosfamide and 20% of the dose repeated at 4 and 8 hours after the dose.

Chloroacetaldehyde, a metabolite of ifosfamide, can result in encephalopathy, especially in patients receiving ifosfamide that exhibit risk factors such as renal dysfunction or advanced age. This adverse effect can occur within 48 to 72 hours of administration and is usually reversible.

### ▶ *Busulfan*

Busulfan is an alkylating agent that forms DNA–DNA and DNA–protein cross-links to inhibit DNA replication. Oral busulfan is well absorbed, has a terminal half-life of 2 to 2.5 hours, and is eliminated primarily by metabolism. It is also available in an IV formulation, which is useful when using the high doses required in blood and marrow transplantation. Busulfan has shown significant clinical activity in the treatment of AML and CML and has been used as a conditioning regimen prior to stem cell transplant. Side effects include bone marrow suppression; hyperpigmentation of skin creases; and rarely, pulmonary fibrosis. High doses used for bone marrow transplant preparatory regimens result in severe nausea and vomiting, tonic–clonic seizures, and sinusoidal obstruction syndrome. Patients receiving high-dose busulfan should receive anticonvulsant prophylaxis. Toxicities associated with busulfan dosing along with a discussion on adaptive dosing of busulfan can be found in Chapter 98.

### ▶ *Nitrosoureas (Carmustine and Lomustine)*

Carmustine (BCNU) and lomustine (CCNU) are nitrosoureas that are lipophilic in nature and therefore able to cross the blood–brain barrier. Carmustine, which is reconstituted with ethanol, crosses the blood–brain barrier when given IV. It also comes as a biodegradable wafer formulation that may be implanted to treat residual tumor tissue after surgical resection of brain tumors. Lomustine is available in an oral formulation. Carmustine has shown clinical activity in the treatment of lymphoma, melanoma, and brain tumors. Lomustine has shown clinical activity in the treatment of non-Hodgkin lymphoma and melanoma. Patients should receive only enough lomustine for one cycle at a time to prevent confusion with their drug regimens and the prolonged neutropenia that can occur. Side effects include myelosuppression, severe nausea and vomiting, and pulmonary fibrosis with long-term therapy.

### ▶ Nonclassic Alkylating Agents (Dacarbazine and Temozolomide)

Although the exact mechanism of action remains unclear, dacarbazine and temozolomide appear to inhibit DNA, RNA, and protein synthesis. Dacarbazine has shown clinical benefit in the treatment of patients with melanoma, Hodgkin lymphoma, and soft tissue sarcomas. Side effects include myelosuppression, severe nausea and vomiting, and a flu-like syndrome that starts about 7 days after treatment and lasts 1 to 3 weeks.

Temozolomide is an orally active agent that is well absorbed and crosses the blood–brain barrier. Temozolomide is converted via pH-dependent hydrolysis to the active metabolite 5-(3-methyltriazeno)-imidazole-4-carboxamide. Temozolomide may be used in the treatment of melanoma, refractory anaplastic astrocytoma, and glioblastoma multiforme. Nausea may be minimized by administering the drug at bedtime. Because patients receiving temozolomide may have confusion secondary to their brain tumors and because dosing can consist of multiple capsule sizes, care must be taken by all providers to simplify regimens to prevent chemotherapy overdose.[22]

### ▶ Procarbazine

Although the exact mechanism of action of procarbazine is unknown, it does inhibit DNA, RNA, and protein synthesis. Procarbazine is used most often in the treatment of lymphoma. Myelosuppression is the major side effect. Nausea, vomiting, and a flu-like syndrome occur initially with therapy. Patients must be counseled to avoid tyramine-rich foods because procarbazine is a monoamine oxidase inhibitor. Patients should be provided a list of foods and beverages to avoid a hypertensive crisis. A disulfiram-like reaction can occur with the ingestion of alcohol.

### ▶ Bendamustine

Bendamustine has three chemically active groups: a 2-chlorethyl group, a butyric acid side chain, and a benzimidazole ring. Bendamustine has shown activity in chronic lymphocytic leukemia and non-Hodgkin lymphoma. It is usually given in combination with rituximab as first-line therapy. Side effects include nausea, vomiting, bone marrow suppression, headache and dyspnea.

### ▶ Thiotepa

Thiotepa is an alkylating agent that reacts with DNA phosphate groups to produce chromosomal cross-linkage. Thiotepa has shown clinical activity in the treatment of breast, bladder, and ovarian cancer, along with carcinomatous meningitis and malignant effusions, and usually is administered IV or as an intravesicular infusion. It also may be used intrathecally. Side effects include myelosuppression, nausea and vomiting, and venous irritation.

## Heavy Metal Compounds

Platinum drugs form reactive platinum complexes that bind to cells, so the pharmacokinetics of the individual drug may be of the platinum, both free and bound, rather than of the parent drug.

### ▶ Cisplatin

Cisplatin forms inter- and intrastrand DNA cross-links to inhibit DNA synthesis. Cisplatin has shown clinical activity in the treatment of numerous tumor types, from head and neck cancers to anal cancer, including many types of lymphoma and carcinoma of unknown primary. Cisplatin is highly emetogenic, even when low doses are given daily for 5 days, and causes delayed nausea and vomiting as well; patients require aggressive antiemetic regimens for both delayed and acute emesis. Significant nephrotoxicity and electrolyte abnormalities can occur if inadequate hydration occurs. Ototoxicity, which manifests as a high-frequency hearing loss, and a glove-and-stocking neuropathy may limit therapy.

### ▶ Carboplatin

Carboplatin has the same mechanism of action as cisplatin, however, its side effects are similar but less intense than those of cisplatin. Many chemotherapy regimens dose carboplatin based on an area under the curve (AUC), which is also called the Calvert equation. According to the Calvert equation, the dose in milligrams of carboplatin = (CrCl + 25) × AUC desired, where CrCl is expressed in mL/min.[23] Carboplatin has shown clinical activity in the treatment of several solid tumors and lymphoma. Thrombocytopenia, nausea and vomiting, and hypersensitivity reactions are adverse effects.

### ▶ Oxaliplatin

Oxaliplatin has shown clinical activity in the treatment of colorectal cancer. Oxaliplatin, although similar in action to cisplatin and carboplatin in terms of adverse effects, also, causes a cold-induced neuropathy. Patients should be counseled to avoid cold beverages, to use gloves to remove items from the freezer, and to wear protective clothing in cold climates for the first week after treatment. A glove-and-stocking neuropathy also occurs with long-term dosing. Hypersensitivity reactions and moderate nausea and vomiting are also adverse effects.[24]

## mTOR Inhibitors

### ▶ Temsirolimus and Everolimus

The mammalian target of rapamycin (mTOR) is a downstream mediator in the phosphatidylinositol 3-kinase/Akt signaling pathway that controls translation of proteins that regulate cell growth and proliferation but also angiogenesis and cell survival. The mTOR is an intracellular component that stimulates protein synthesis by phosphorylating translation regulators, and contributes to protein degradation and angiogenesis.

Temsirolimus is approved for the treatment advanced renal cell carcinoma. Temsirolimus and its metabolite sirolimus are substrates of the cytochrome CYP3A4/5 isoenzyme system. The primary side effects of temsirolimus include mucositis, diarrhea, maculopapular rash, nausea, leucopenia, thrombocytopenia, and hyperglycemia.

Everolimus is an oral inhibitor of mTOR that is approved for the treatment of patients with advanced renal cell cancer after failure of treatment with sunitinib or sorafenib and most recently for the treatment of advanced pancreatic neuroendocrine tumors. Drug interactions and adverse reactions are similar to those of temsirolimus.

## Miscellaneous Agents

### ▶ Altretamine

Altretamine, formerly known as hexamethylmelamine, is similar in structure to alkylating agents but is known to have anticancer activity in cancer cells resistant to alkylating agents. Altretamine has shown activity in the treatment of ovarian and lung cancer. This orally administered drug has the dose-limiting side effects of anorexia, nausea, vomiting, diarrhea, and abdominal cramping. Other side effects include neuropathy, agitation, confusion, and depression.

### ► *Bleomycin*

Bleomycin is a mixture of peptides with drug activity expressed in units, where 1 unit equals to 1 mg. Bleomycin causes DNA strand breakage. Bleomycin has shown clinical activity in the treatment of patients with testicular cancer and malignant effusions, squamous cell carcinomas of the skin, and Kaposi sarcoma. Hypersensitivity reactions and fever may occur, so premedication with acetaminophen may be required. The most serious side effect is the pulmonary toxicity that presents as a pneumonitis with a dry cough, dyspnea, rales, and infiltrates. Pulmonary function studies show decreased carbon monoxide diffusing capacity and restrictive ventilatory changes. "Bleomycin lung" is associated with cumulative dosing greater than 400 units and occurs rarely with a total dose of 150 units. The pulmonary toxicity is potentiated by thoracic radiation and by hyperoxia. Additional side effects include fever with or without chills, mild to moderate alopecia, and nausea and vomiting. Bleomycin has been used to manage malignant plural effusions at doses of 15 to 60 units through installation into the affected area. The drainage tube of the effusion is clamped off for some period of time after administration of bleomycin and then the amount of drainage is monitored to determine efficacy of the treatment.[25]

### ► *Hydroxyurea*

Hydroxyurea is an oral drug that inhibits ribonucleotide reductase, which converts ribonucleotides into the deoxyribonucleotides used in DNA synthesis and repair. Hydroxyurea has shown clinical activity in the treatment of CML, polycythemia vera, and thrombocytosis. The major side effects are myelosuppression, nausea and vomiting, diarrhea, and constipation. Rash, mucositis, and renal tubular dysfunction occur rarely.

### ► *L-Asparaginase*

L-Asparaginase is an enzyme that may be produced by *Escherichia coli*. Asparaginase hydrolyzes the reaction of asparagine to aspartic acid and ammonia to deplete lymphoid cells of asparagine, which inhibits protein synthesis. L-Asparaginase has shown clinical activity in the treatment of ALL and childhood AML. Severe allergic reactions may occur when the interval between doses is 7 days or greater, so while a skin test result may be negative, patients should be observed closely after asparaginase administration. Pancreatitis and fibrinogen depletion may also occur during therapy. Repletion of fibrinogen should be done to prevent disseminated intravascular coagulation and fatal bleeding. If the patient suffers an allergic reaction to L-asparaginase, pegaspargase, which is L-asparaginase modified through a linkage with polyethylene glycol, which extends the half-life and allows for lower doses and less frequent administration, may be given. Cost and limited availability are some reasons pegaspargase may not be used first.

### ► *Arsenic Trioxide*

Arsenic trioxide, which is approved for the treatment of acute promyelocytic leukemia (APL), induces the growth of cancer cells into mature, more normal cells and induces programmed cell death, or apoptosis. Arsenic trioxide causes QT-interval prolongation, so frequent electrocardiograms need to be done before each dose, and other drugs that may prolong the QT interval need to be avoided during therapy. Monitoring of potassium and magnesium should be performed and active replacement undertaken to prevent QT prolongation. Other side effects include dry skin with itching, nausea and vomiting, loss of appetite, and elevations of serum hepatic enzymes. A serious side effect is APL differentiation syndrome, which appears similar to pneumonia but is related to the arsenic therapy.[26]

### ► *Mitomycin C*

Mitomycin C forms cross-links with DNA to inhibit DNA and RNA synthesis. Mitomycin C has shown clinical activity in the treatment of several solid tumors. Side effects consist of myelosuppression and mucositis, and it is a vesicant.

### ► *Tretinoin*

Tretinoin, also referred to *ATRA*, which stands for all-trans-retinoic acid, is a retinoic acid that is not cytotoxic but promotes the maturation of early promyelocytic cells and is specific to the t(15;17) cytogenetic marker. The most significant side effect is the APL differentiation syndrome, which may occur anywhere from the first couple of days of therapy until the end of therapy and consists of symptoms of fever, respiratory distress, and hypotension. Chest radiographs are consistent with a pneumonia-like process. The syndrome can be confused easily with pneumonia in a patient with possible neutropenia. The treatment for retinoic acid syndrome is dexamethasone 10 mg IV every 12 hours; the syndrome may resolve within 24 hours of the start of dexamethasone therapy. However, the use of steroids in a febrile neutropenic patient may further compromise the treatment of infection.[27]

### ► *Immunomodulatory Agents (Thalidomide, Lenalidomide, and Pomalidomide)*

Thalidomide was introduced into the market in Europe on October 1, 1957, as a sedative–hypnotic, and when it was taken by pregnant women, it resulted in severe limb deformities (phocomelia) and its withdrawl from use. Thalidomide is an angiogenesis inhibitor, but the full mechanism of action is still unknown. Possible mechanisms of action include free radical oxidative damage to DNA, inhibiting tumor necrosis factor α production, altering the adhesion of cancer cells, and altering cytokines that affect the growth of cancer cells.[28,29] Thalidomide has shown clinical activity in the treatment of multiple myeloma. Because of thalidomide's potential to cause phocomelia, each patient must be enrolled in the STEPS program and counseled on the risks of thalidomide not only for the patient but also the patient's reproductive partner. Clinicians must be registered to prescribe thalidomide. Common adverse effects include somnolence, constipation, peripheral neuropathy, and deep vein thrombosis (DVT). Recommendations for DVT prophylaxis include standard dose warfarin or low-molecular-weight heparins.

Lenalidomide is approved for the treatment of myelodysplastic syndrome when the 5q deletion is present and multiple myeloma. Because lenalidomide is an analogue of thalidomide, all of the same precautions must be taken to prevent phocomelia. However, lenalidomide has fewer adverse effects than thalidomide. Dosing adjustments are necessary for renal dysfunction. Lenalidomide is used in the treatment of myelodysplastic syndrome and multiple myeloma. Other side effects are neutropenia, thrombocytopenia, deep vein thrombosis (DVT), and pulmonary embolus.

Pomalidomide was approved for the treatment of refractory or progressive multiple myeloma in February 2013. Adverse effects include myelosuppression and infections. The use of

the immunomudulatory agents in the treatment of multiple myeloma is discussed thoroughly in Chapter 96.

### ▶ Bexarotene

Bexarotene is a retinoid that selectively activates retinoid X receptors, which affects cellular differentiation and proliferation. Bexarotene is eliminated primarily by the hepatobiliary system. Bexarotene is indicated for the treatment of cutaneous manifestations of cutaneous T-cell lymphoma in patients who are refractory to other therapy. Side effects include hypercholesterolemia, elevations in triglycerides, pancreatitis, hypothyroidism, and leukopenia, headache, and dry skin.

### ▶ Proteasome Inhibitors (Bortezomib and Carfilzomib)

The proteasome is an enzyme complex that exists in all cells and plays an important role in degrading proteins the control the cell cycle. When the proteasome is inhibited, the numerous pathways that are necessary for the growth and survival of cancer cells are disrupted. Bortezomib specifically inhibits the 26S proteasome, which is a large protein complex that degrades ubiquitinated proteins. This pathway plays an essential role in regulating the intracellular concentration of specific proteins, causing the cells to maintain homeostasis. Inhibition of the 26S proteasome prevents this to occur, ultimately causing a disruption in the homeostasis and cell death.

Bortezomib is approved for the treatment of multiple myeloma (MM), mantle cell lymphoma, and in some cases of relapsed/refractory AML. It is administered as an IV injection. The most commonly reported adverse effects are asthenia, gastrointestinal disturbances (nausea, diarrhea, decreased appetite, constipation, vomiting), thrombocytopenia, peripheral neuropathy, anemia, headache, insomnia, and edema. Prophylactic anticoagulation is not routinely required. Reactivation of varicella zoster infection is also common with bortezomib, and antiviral prophylaxis with acyclovir should be considered.

Carfilzomib is a newer second-generation proteasome inhibitor and is used in the treatment of refractory cases of MM.

### ▶ Omacetaxine Mepesuccinate

Omacetaxine mepesuccinate, an alkaloid from *Cephalotaxus harringtonia*, was granted accelerated approval by the FDA in October 2012. The agent reversibly inhibits protein synthesis, causing cell death. It affects both malignant and nonmalignant cells. It is a subcutaneous injection and is indicated for the treatment of CML patients (including those patients with the T315I mutation) showing resistance and/or intolerance to two or more TKIs. The most common nonhematological adverse effects are gastrointestinal disruption, fatigue, and hyperglycemia. Rare but serious adverse reactions include febrile neutropenia, infections, and cerebral hemorrhage.

### ▶ Ziv-aflibercept

Ziv-aflibercept is a recombinant fusion protein that consists of vascular endothelial growth factor (VEGF)-binding portions from the extracellular domains of human VEGF receptors 1 and 2 fused to the Fc portion of the human IgG1 immunoglobulin. It is an intravenously administered and approved for the treatment of metastatic colorectal cancer in combination with FOLFIRI after progression on an oxaliplatin-based regimen. Ziv-aflibercept has black-box warnings, which include hemorrhage, gastrointestinal perforation, and compromised wound healing. Other adverse effects include neutropenia, diarrhea, and a reversible posterior leukoencephalopathy syndrome.

---

**Patient Encounter 2**

A 48-year-old man is receiving doxorubicin and ifosfamide for a newly diagnosed osteosarcoma. While receiving chemotherapy, he begins to complain of flank pain and hematuria. His serum creatinine has risen from 0.8 mg/dL to 2.1 mg/dL (71 to 186 μmol/L) in the last 3 days.

*What is the likely diagnosis?*

*What medication should always be included as part of this regimen?*

*What should patients be counseled to do while receiving ifosfamide therapy?*

---

### ▶ HDAC Inhibitors (Vorinostat and Romidepsin)

Vorinostat is indicated for the treatment of cutaneous T-cell lymphoma in patients with progressive, persistent, or recurrent disease after treatment with two systemic therapies. Romidepsin is approved for the treatment of cutaneous or peripheral T-cell lymphoma in patients who have received at least one systemic therapy. These agents catalyze the removal of acetyl groups from acetylated lysine residues in histones, resulting in the modulation of gene expression. Vorinostat is an orally available agent, and romidepsin is only available in an IV formulation. These drugs are metabolized by CYP3A4, so caution should be exercised with monitoring for drug–drug interactions. Side effects include diarrhea, fatigue, nausea and anorexia, hypercholesterolemia, hypertriglyceridemia, and hyperglycemia. Despite anemia, thrombocytopenia, and neutropenia, patients have developed pulmonary embolism and DVT while on therapy.[30]

## Immune Therapies

### ▶ Interferons

The categories of α, β, and γ interferons exist; the α-interferons are used in the treatment of cancer. Interferon enhances the immune system's attack on cancer cells, can decrease new blood vessel formation, and can augment expression of antigen on tumor cell surfaces. Interferon has shown clinical activity in the treatment of melanoma, kidney cancer, Kaposi sarcoma, and CML and CLL. Unfortunately, interferon is not well tolerated by patients because it causes a flu-like syndrome that consists of fevers and chills; depression, malaise, and fatigue are other side effects. Premedication with acetaminophen helps alleviate the flu-like symptoms, which decrease with chronic administration.

### ▶ Aldesleukin

Aldesleukin, which is a human recombinant *interleukin-2 (IL-2)*, is a lymphokine that promotes B- and T-cell proliferation and triggers a cytokine cascade to attack the tumor. Aldesleukin has shown clinical activity in the treatment of kidney cancer and melanoma. Side effects of IL-2 vary by dose and route. IV high-dose IL-2 causes a drug-induced shock-like picture. Patients may develop hypotension despite aggressive IV hydration. Patients develop a red, itchy skin; liver and kidney function tests change; via immune complex formation in the kidneys, fluid and electrolyte imbalances occur; and high fevers occur while receiving scheduled acetaminophen and nonsteroidal anti-inflammatory agents. Severe rigors and chills may require symptom control. All the side effects reverse within 24 hours of stopping the drug. The

toxicity profile is much less with subcutaneous administration. However, with subcutaneous administration, nodules form at the injection site and may take months to resolve. Corticosteroids should not be administered to patients while they are receiving aldesleukin unless a life-threatening emergency occurs. Steroids reverse all the symptoms and the antitumor effect even with topical administration. The itching, red skin may be treated with topical creams and antihistamines.

▶ *Denileukin Diftitox*

Denileukin diftitox is a combination of the active moieties of IL-2 and diphtheria toxin. It binds to high-affinity IL-2 receptors on the cancer cell (and other cells), and the toxin portion of the molecule inhibits protein synthesis to result in cell death. Denileukin diftitox is used for the treatment of persistent or recurrent cutaneous T-cell lymphoma whose cells express the CD25 receptor. Side effects include vascular leak syndrome, fevers or chills, hypersensitivity reactions, hypotension, anorexia, diarrhea, and nausea and vomiting.

▶ *Peginterferon α-2b*

Sylatron is a covalent conjugate of recombinant α-2b interferon with monomethoxy polyethylene glycol (PEG). The mechanism of cytotoxicity in patients with melanoma is unknown. This agent is specifically indicated for the adjuvant treatment of melanoma with microscopic or gross nodal involvement up to 84 days after definitive surgical resection (including complete lymphadenectomy). Adverse effects include fatigue, increased liver enzymes, pyrexia, headache, anorexia, myalgia, nausea, chills, and pain at the injection site.[31]

▶ *Sipuleucel-T*

Sipuleucel-T is a novel autologous cellular immunotherapy approved for the treatment of asymptomatic or minimally symptomatic metastatic hormone refractory prostate cancer. Sipuleucel-T is designed to induce an immune response targeted at prostatic acid phosphatase (PAP), which is an antigen expressed in greater than 95% of prostate cancers. Patients receiving sipuleucel-T undergo leukapheresis to collect their own antigen-presenting cells. These cells are then sent to a manufacturing facility and cultured with a recombinant antigen (PAP-GM-CSF, composed of PAP and GM-CSF, an immune cell activator). The cellular product, which is made specifically for each patient, is then delivered to the patient's clinic and infused intravenously into the patient on day 3 or 4. Each course consists of three infusions of activated cells given at 2-week intervals. Adverse effects include chills, fatigue, fever, back pain, nausea, joint pain, and headache.[32]

## Monoclonal Antibodies

The cell surface contains molecules, which are referred to as *CD*, which stands for "cluster of differentiation." The antibodies are produced against a specific antigen. When administered, usually by an IV injection, the antibody binds to the antigen, which may trigger the immune system to result in cell death through complement-mediated cellular toxicity, or the antigen–antibody cell complex may be internalized to the cancer cell, which results in cell death. Monoclonal antibodies also may carry radioactivity, sometimes referred to as *hot antibodies*, and are referred to as *radioimmunotherapy*, so the radioactivity is delivered to the cancer cell. Antibodies that contain no radioactivity are referred to as *cold antibodies*.

All monoclonal antibodies end in the suffix -*mab*. The syllable before -*mab* indicates the source of the monoclonal antibody

| Table 88–6 |  |
| --- | --- |
| **Syllable Source Indicators for Monoclonal Antibodies**[a] | |
| U | Human |
| O | Mouse |
| A | Rat |
| E | Hamster |
| I | Primate |
| Xi | A cross between humanized and animal source |

[a]These letters appear before mab, which stands for monoclonal antibody.

From Programme on International Nonproprietary Names (INN) Division of Drug Management and Policies, World Health Organization, Geneva. 1997.

(Table 88–6). When administering an antibody for the first time, one should consider the source. The less humanized an antibody, the greater the chance for the patient to have an allergic-type reaction to the antibody. The more humanized the antibody, the lower the risk of a reaction. The severity of the reactions may range from fever and chills to life-threatening allergic reactions. Premedication with acetaminophen and diphenhydramine is common before the first dose of any antibody. If a severe reaction occurs, the infusion should be stopped and the patient treated with antihistamines, corticosteroids, or other supportive measures.

▶ *Bevacizumab*

Bevacizumab is a humanized monoclonal antibody that binds to vascular endothelial growth factor (VEGF), which prevents it from binding to its receptors, ultimately resulting in inhibition of angiogenesis. Bevacizumab has shown clinical activity in the treatment of colorectal, kidney, lung, breast, and head and neck cancer. Patients may develop hypertension requiring chronic medication during therapy. Impaired wound healing, thromboembolic events, proteinuria, bleeding, and bowel perforation are serious side effects that occur with this drug.

▶ *Brentuximab*

Brentuximab vedotin is a CD30-directed antibody–drug conjugate (ADC) that consists of the antibody specific for CD30, a microtubule disrupting agent called monomethyl auristatin E (MMAE), and a protease-cleavable linker that covalently attaches MMAE to the antibody. It is reported that the cytotoxic activity is a result of the binding of the ADC to CD30-expressing cells followed by internalization of the ADC–CD30 complex, and then proteolytic cleavage and release of MMAE into the cell. Binding of MMAE to tubulin disrupts the microtubule network, resulting in cell cycle arrest and apoptosis. This IV agent is indicated for Hodgkin lymphoma patients after failure of autologous stem cell transplant (ASCT) or after failure of at least two multidrug regimens in patients who are not eligible for ASCT and for patients with systemic anaplastic large cell lymphoma who have failed at least one systemic chemotherapy regimen. In vitro data suggests that MMAE is a substrate and an inhibitor of CYP3A4/5; therefore, patients need to be monitored for drug–drug interactions. The most common adverse effects are neutropenia, peripheral neuropathy, fatigue, nausea and vomiting, diarrhea, anemia, thrombocytopenia, and upper respiratory infection. Dosing modifications guidelines for peripheral neuropathy can be found in the prescribing information.[33]

### ▶ Cetuximab

Cetuximab is a chimeric antibody that binds to the epidermal growth factor receptor (EGFR) to block its stimulation. Tumors that have *KRAS* mutations do not respond to treatment with cetuximab; therefore, tumors should be tested for *KRAS* mutations before initiating therapy. Cetuximab has shown clinical activity in the treatment of colorectal and head and neck cancers. An acne-like rash may appear on the face and upper torso 1 to 3 weeks after the start of therapy. Other side effects include hypersensitivity reactions, interstitial lung disease, fever, malaise, diarrhea, abdominal pain, and nausea and vomiting.

### ▶ Ipilimumab

Ipilimumab is a recombinant, human monoclonal antibody that binds to the cytotoxic T lymphocytic–associated antigen 4 (CTLA-4), which is a molecule on T cells that causes a suppression of the immune response. CTLA-4 is a negative regulator of T-cell activation. Ipilimumab binds to CTLA-4 and blocks the interaction of CTLA-4 with its ligands. This blockage has been reported to enhance T-cell activation and proliferation. Ipilimumab is approved for patients with unresectable or metastatic melanoma. The antitumor effects appear to be T-cell–mediated immune responses. Ipilimumab administration can result in severe and fatal immune-mediated adverse reactions, including enterocolitis, hepatitis, toxic epidermal necrolysis, neuropathy, and endocrine abnormalities. These symptoms can occur during treatment or weeks to months after discontinuation of the drug. Liver and thyroid function tests should be performed at baseline and before each dose. If this occurs, treatment should be initiated with systemic corticosteroids and the drug should be discontinued permanently. Progressive multifocal leukoencephalopathy has been reported. Additional less serious adverse effects include fatigue, diarrhea, pruritus, rash, and colitis.

### ▶ Panitumumab

Panitumumab binds to the EGFR to prevent receptor autophosphorylation and activation of receptor-associated kinases, which results in inhibition of cell growth and induction of apoptosis. Panitumumab has demonstrated activity against tumors of the colon and rectum. However, panitumumab is not recommended for the treatment of colorectal cancer with *KRAS* mutations in codon 12 or 13. Retrospective subset analyses have not shown a treatment benefit for these mutations. Side effects include dermatitis, pruritus, exfoliative rash, infusion reactions, pulmonary fibrosis, diarrhea, hypomagnesemia, hypocalcemia, and photosensitivity.

### ▶ Rituximab

Rituximab is a monoclonal antibody to the CD20 receptor expressed on the surface of B lymphocytes; the presence of the antibody is determined during flow cytometry of the tumor cells. Cell death results from antibody-dependent cellular cytotoxicity. Rituximab has shown clinical activity in the treatment of B-cell lymphomas that are CD20 positive. Side effects include infusion-related reactions, hypotension, fevers, chills, rash, headache, and mild nausea and vomiting. Premedication with diphenhydramine and acetaminophen is recommended to minimize the first-dose infusion reaction.

### ▶ Tositumomab and Ibritumomab Tiuxetan

Tositumomab, a "hot antibody," is linked to radioactive iodine and binds to the CD20 receptor present on B lymphocytes (see Rituximab). Tositumomab has shown activity in non-Hodgkin lymphoma. Hematologic toxicity occurs several weeks after administration and may persist for months. Because radioactive iodine may have adverse effects on the thyroid, all patients must receive thyroid-blocking agents.

Ibritumomab Tiuxetan, a "hot antibody," is linked to yttrium and binds to the CD20 receptor of B lymphocytes. Similarly, hematologic toxicity may occur several weeks after administration and may take weeks to resolve.

### ▶ Ofatumumab and Obinutuzumab

Ofatumumab and obinutuzumab are two newer monoclonal antibodies that are directed at the CD20 antigen in patients with chronic lymphocytic leukemia that is refractory to fludarabine and alemtuzumab therapy. Obinutuzumab was approved recently for the combination treatment with chlorambucil in patients that have previously untreated CLL. The most common adverse effects include infusion-related reactions, neutropenia, infections, pyrexia, anemia, diarrhea, and nausea. Serious adverse events, including fatal infections, progressive multifocal leukoencephalopathy, and reactivation of hepatitis B, have been reported.

### ▶ Alemtuzumab

Alemtuzumab is an antibody to the CD52 receptor present on B and T lymphocytes. Alemtuzumab has shown clinical activity in the treatment of chronic lymphocytic leukemia. Severe and prolonged (6 months) immunosuppression may result, which necessitates pneumocystis carinii pneumonia (PCP) prophylaxis and antifungal and antiviral prophylaxis to prevent opportunistic infections. Infusion-related reactions typically occur with the first dose and can be severe. Premedication with antihistamines and acetaminophen is recommended. Subcutaneous administration will also alleviate the severity of infusion reactions.

### ▶ Ramucirumab

Ramucirumab is a humanized monoclonal antibody that binds with high affinity to the extracellular domain of vascular endothelial growth factor receptor 2 (VEGFR2, preventing the binding of VEGF-A, VEGF-C, and VEGF-D. This agent was approved in 2014 for the treatment of advanced gastric cancer with disease progression after fluoropyrimidine- or platinum-containing chemotherapy. The most common grade 3 or 4 adverse effects are hypertension, most commonly occurring in patients with preexisting hypertension. There is also a risk of hemorrhage, and the drug should be permanently discontinued in patients experiencing a severe bleeding episode.

### ▶ Trastuzumab

Trastuzumab is a humanized monoclonal antibody directed against human epidermal receptor 2 (HER-2), which is amplified or overexpressed by 15% to 20% of all breast cancers and is associated with aggressive disease and decreased survival. Breast cancer tissue must be tested for the presence of HER-2 because patients who do not express HER-2 do not respond to trastuzumab. It can be used as single agent or in combination with an anthracycline or taxane-based combination chemotherapy. Trastuzumab is also indicated for the treatment of gastric cancer. Severe congestive heart failure may occur with concurrent anthracycline administration. Cardiac toxicity may be seen when the drug is administered months after anthracycline administration, so patients must be counseled on the signs and symptoms of heart failure. A common side effect associated with trastuzumab

is a first-dose infusion-related reaction which includes chills. The patient may be given acetaminophen and diphenhydramine and/or the infusion may be slowed. Other side effects which are rare include hypersensitivity reactions and pulmonary reactions.[34] A more detailed discussion of the use of trastuzumab in breast cancer can be found in Chapter 89.

### ▶ *Trastuzumab-DM1 (T-DM1, Trastuzumab Emtansine)*

Trastuzumab-DM1 or ado-trastuzumab emtansine was approved by the FDA in February 2013. In this compound, trastuzumab is used as a drug vehicle to deliver an anticancer agent known as emtansine (a maytansine derivative). Phase 3 clinical data evaluating the use in progressive HER-2-positive breast cancer patients will be discussed in Chapter 89. The most common serious adverse effect reported in clinical trials was thrombocytopenia. The platelet nadir usually occurred about 7 days after treatment and recovered within a week. Other adverse effects included abnormal liver function tests, fatigue, nausea, headache, and hypokalemia. Cardiac toxicity was not a reason for study withdrawal.

### ▶ *Pertuzumab*

The FDA approved the new HER-2-targeted pertuzumab in June 2012. When compared to trastuzumab, pertuzumab recognizes different extracellular epitopes, binds uniquely which causes structural changes and therefore interrupts receptor dimerization. These differences were thought to be able to provide greater inhibition of HER-2 when compared to trastuzumab. This has not been proven to be the case, but based on clinical studies is indicated for first-line treatment in combination with trastuzumab and docetaxel for HER-2-positive metastatic breast cancer. Adverse effects seen in clinical trials were diarrhea and a similar incidence of cardiac toxicity as trastuzumab. When used in combination with trastuzumab, it does not appear to increase the incidence of cardiac toxicity.

## Tyrosine Kinase Inhibitors

There are more than 100 different types of tyrosine kinases present in the body. Tyrosine kinase inhibitors (TKIs) are also referred to as small-molecule inhibitors. Each of the following drugs was developed to block either several or a specific tyrosine kinase.

### ▶ *Imatinib*

Imatinib was the first FDA-approved TKI and is considered to be first-generation. Imatinib inhibits phosphorylation during cell proliferation. The drug was designed to block the breakpoint cluster region tyrosine kinase (BCR-ABL) produced by the Philadelphia chromosome associated with CML and ALL. Imatinib also has shown activity against gastrointestinal stromal tumors (GIST) that are positive for c-kit (CD117). Imatinib is usually well tolerated, but common adverse effects include myelosuppression, rash, GI upset, edema, fatigue, arthalgias, myalgias, and headaches. A cumulative cardiotoxicty is a serious but rare adverse effect therefore it is recommended to closely monitor patients with preexisting cardiac conditions. Numerous drug interactions have been reported for imatinib. CYP3A4 inducers, such as rifampicin and St. John's wort, increase the clearance of imatinib.[35,36] Ketoconazole, a CYP3A4 inhibitor, has been shown to decrease imatinib clearance by almost 30%.[37] Imatinib also may increase the exposure of simvastatin, a CYP3A4 substrate.[38] These are various examples of how drug–drug interactions can occur and how important monitoring for these reactions is for the health professionals.

### ▶ *Advanced-Generation BCR-ABL TKIs*

Advanced generation BCR-ABL TKIs were developed in an effort to overcome the resistance or intolerance to imatinib. These agents are more potent than imatinib and can overcome most BCR-ABL mutations that lead to imatinib resistance. Dasatinib and nilotinib are second-generation TKI that share the same binding site on the BCR-ABL cluster region as imatinib but maintains activity despite imatinib resistance, with higher potency than imatinib. Dasatinib also inhibits SRC kinases, which are tyrosine kinases that mediate cellular differentiation, proliferation, and survival. Dasatinib and nilotinib are used front line in the treatment of CML and in CML with resistance or intolerance to imatinib. Side effects of dasatinib and nilotinib are similar to imatinib and include myelosuppression, nausea and vomiting, headache, fluid retention, and hypocalcemia. Pleural effusions have been reported with dasatinib and imatinib but not with nilotinib. QT prolongation can occur with dasatinib and nilotinib. Abnormalities in indirect bilirubin have been reported with nilotinib.

Nilotinib is a competitive inhibitor of UGT1A1 in vitro, which could increase the concentrations of nilotinib. In a pharmacogenetic analysis, patients with (TA)7/(TA)7 genotype (UGT1A1*28) had a statistically significant increase in bilirubin over other genotypes.[39] Nilotinib should be administered on an empty stomach or 2 hours after a meal.

Bosutinib is indicated for the second-line treatment of CML in cases of resistance or intolerance to prior TKI therapy. With the exception of *T315I*, Bosutinib overcomes most BCR-ABL domain mutations. Gastrointestinal disturbances and rash are common. Bosutinib appears to have a milder side effect profile than other TKIs.

Ponatinib is a third-generation multikinase inhibitor and the only advanced generation TKI that overcomes the *T315I* mutation. Serious adverse effects reported included thrombosis, hepatotoxicity (rare) and death (rare). These are included as black-box warnings. Less serious adverse effects include abdominal pain, dry skin, and rash.

### ▶ *Ibrutinib and Idelalisib*

Two small molecule inhibitors that target the B-cell receptor pathway have been recently approved. Ibrutinib inhibits Bruton tyrosine kinase and has shown activity in mantle cell lymphoma and CLL. Idelalisib, in combination with rituximab, is approved for relapsed CLL and targets phosphatidylinositol-3-kinase (PI3-K), an essential lipid kinase. Adverse effects associated with these agents are GI disturbances, rash, hematological side effects, fatigue and musculoskeletal pain. Idelalisib has hepatotoxicity, colitis, pneumonitis, and intestinal perforation as black-box warnings.

### ▶ *Epidermal Growth Factor Receptor Pathway Inibitors (Erlotinib, Afatinib, and Lapatinib)*

Patients with malignancies (eg, non-small cell lung cancer or NSCLC) in which the tumors have mutations in exon 19 and/or 21 in the epidermal growth factor receptor (EGFR) pathway will likely respond to EGFR tyrosine kinase inhibitors such as erlotinib. These agents are believed to inhibit the intracellular phosphorylation of the EGFR. Erlotinib is about 60% absorbed after oral administration. Food increases bioavailability to almost 100%, but this is variable, and experts recommend administering erlotinib on an empty stomach. Erlotinib is eliminated predominately by CYP3A4. Smoking increases the clearance of erlotinib by 24%, which may result in treatment failure.[40] Erlotinib is used

in the treatment of NSCLC and cancer of the pancreas. Side effects include interstitial lung disease, rash, diarrhea, anorexia, pruritus, conjunctivitis, and dry skin. Again, significant drug interactions have been documented with CYP3A4 inducers and inhibitors.

Afatinib is an oral, selective EGFR-TKI approved for the treatment of metastatic NSCLC in patients with EGFR exon 19 deletions or exon 21 (L858R) substitution mutations. It is taken on an empty stomach at a dose of 40 mg orally once daily. Adverse effects are similar to those reported with erlotinib.

Lapatinib inhibits the intracellular kinase domains of both EGFR and HER-2 and has been shown to retain activity against breast cancer cells that have become resistant to trastuzumab. Lapatinib is indicated for the treatment of patients with breast cancer whose tumors overexpress HER-2. When used in combination with capecitabine, the adverse effects of lapatinib include decreased left ventricular ejection fraction and QT prolongation, diarrhea, dyspepsia, rash, and hepatotoxicity. When not used as a doublet with capecitabine, the cardiac events and adverse effects were not as common.

### ▶ Multikinase Inhibitors (Sorafenib, Sunitinib, Pazopanib)

Sorafenib is a multikinase inhibitor that inhibits both intracellular and extracellular kinases to decrease renal cell cancer proliferation. Sorafenib is metabolized primarily by the liver by CYP3A4. Sorafenib is used for the treatment of renal cell cancer. The primary side effects of sorafenib include rash, hand–foot skin reaction, diarrhea, pruritus, and elevations in serum lipase.

Sunitinib blocks several tyrosine kinases, including platelet-derived growth factor, VEGF receptor, stem cell factor receptor, fms-like receptor growth factor, colony-stimulating growth factor receptor type 1, and glial cell line–derived neurotrophic factor receptor. The active metabolite of sunitinib blocks these same enzymes with similar potency. Significant side effects include left ventricular dysfunction, hemorrhage, asthenia, hypertension, nausea and vomiting, and diarrhea. Approximately one-third of patients may develop a yellow color of the skin along with dryness and cracking of the skin. Also, hair may become depigmented with doses of 50 mg/day or more; the depigmentation is reversible when therapy is stopped. Clinically significant drug interactions exist with inducers and inhibitors of CYP3A4; ketoconazole has been shown to increase concentrations of sunitinib, whereas rifampin has been shown to decrease concentrations of sunitinib.

Pazopanib is a vascular epidermal growth factor receptor (VEGFR) TKI that acts at VEGFR-1, VEGFR-2, and VEGFR-3. It is specifically indicated for the treatment of patients with advanced renal cell carcinoma. Pazopanib is metabolized through CYP3A4; therefore, drug–drug interactions should be monitored. Pazopanib is an orally administered agent that should be taken on an empty stomach. Common adverse effects include diarrhea, hypertension, hair color change, nausea and vomiting, fatigue, and anorexia. Serious toxicities that have been observed are increased in liver enzymes and bilirubin, including fatal hepatotoxicity, prolonged QT intervals and torsades de pointes, hemorrhagic events, arterial thrombotic events, gastrointestinal perforation, and proteinuria.

### ▶ Regorafenib

Regorafenib is a small molecule inhibitor of multiple membrane-bound and intracellular kinases. It is approved for the treatment of metastatic colorectal cancer in patients who have

been previously received fluoropyrimidine-, oxaliplatin-, and irinotecan-based chemotherapy, anti-VEGF therapy, and an anti-EGFR therapy if KRAS wild-type. The proposed mechanism of action is through inhibition of vascular endothelial receptors involved in angiogenesis. It was recently approved for the treatment of gastrointestinal stromal tumor that had been previously treated with imatinib mesylate and sunitinib malate. GI effects, hypertension, mucositis, infection, rash, and fever are commonly occurring adverse effects. Hepatoxicity is listed as a black-box warning; therefore hepatic function should be monitored closely. It is an orally administered agent given for the first 21 days per 28-day cycle and should be taken with a low-fat breakfast.

### ▶ Vemurafenib, Trametinib, Dabrafenib

Vemurafenib is a potent inhibitor of mutated *BRAF* and is indicated for the treatment of unresectable or metastatic melanoma in patients with documented *BRAFV600E* mutation as determined by an FDA-approved test. Vemurafenib produced improved rates of overall and progression-free survival in a phase III trial when compared with dacabarazine. Vemurafenib is not indicated for patients with wild-type *BRAF*. The orally administered vemurafenib is dosed at 960 mg twice daily without regards to meals. Common adverse effects include arthralgia, rash, fatigue, alopecia, keratoacanthoma or squamous cell cancer, photosensitivity, nausea, and diarrhea. Approximately 40% of patients require dosage modifications because of adverse effects.[41]

Trametinib is a reversible inhibitor of mitogen-activated extracellular kinases (MEK)-1 and MEK-2 that is also active against *BRAF V600*-mutated forms of BRAF kinases in melanoma cells. It is indicated as monotherapy and in combination with dabrafenib for unresectable or metastatic malignant melanoma. It is not indicated in patients previously treated with a BRAF inhibitor. Rash, diarrhea, and lymphedema were commonly reported. Cardiomyopathy (defined as heart failure) and bleeding have also been reported.

Dabrafenib is a kinase inhibitor that has activity against BRAF kinases. It is indicated for the treatment of unresectable or metastatic malignant melanoma as monotherapy in patients with *BRAF V600E* mutation or in combination with trametinib in patients with *BRAF V600E* or V600K mutations. Adverse effects associated with this agent include arthralgias, alopecia, headache, palmar-plantar erythrodysesthesia syndrome, elevated liver enzymes, pyrexia, and papilloma.

### ▶ Crizotinib and Ceritinib

Crizotinib is a small-molecule inhibitor of the anaplastic lymphoma kinase gene (ALK) and mesenchymal epithelial transition growth factor (*c-MET*). This orally available agent is approved for the treatment of locally advanced or metastatic NSCLC that is ALK positive (about 2%–7% of NSCLC patients) as detected by an FDA-approved test. Adverse effects reported include mild gastrointestinal symptoms, edema, and visual disturbances, which have been described as trails of light following objects as they move.[42] Ceritinib is newly approved for ALK-positive NSCLC patients who have progressed on or are intolerant to crizotinib. Ceritinib, which has shown to be 20 times more potent than crizotinib in enzymatic assays, primarily targets ALK along with additional targets, including insulin-like growth factor 1 (IFG-1) receptor, insulin receptor (InsR), and ROS1. In comparison with crizotinib, ceritinib does not inhibit the kinase activity of c-MET. GI toxicities and elevated liver function tests

were the most common adverse reactions. Visual changes, pulmonary disease, and QT prolongation were also seen in clinical trials.

### ▶ *Vandetanib*

Vandetanib is an orally available receptor TKI that blocks both the VEGF and EGF receptor kinase. This agent is indicated for the treatment of symptomatic or progressive medullary thyroid cancer in patients with unresectable locally advanced or metastatic disease. Common adverse effects include diarrhea, rash, acne, nausea, hypertension, headache, fatigue, decreased appetite, and abdominal pain.

## Hormonal Therapies

A patient's hormonal receptor status (eg, estrogen and progesterone receptor status) can be used clinically as a prognostic indicator and can help predict a response to hormonal therapy. Hormonal or endocrine therapies have shown activity in the treatment of cancers whose growth is affected by gonadal hormonal control. Hormonal treatments either block or decrease the production of endogenous hormones. You will learn more about these treatments and outcomes in chapters 89 and 91, including the breast and prostate cancer chapters.

### ▶ *Antiandrogens: Bicalutamide, Flutamide, and Nilutamide*

The antiandrogens block androgen receptors to inhibit the action of testosterone and dihydrotestosterone in prostate cancer cells. Unfortunately, prostate cancer cells may become hormone refractory.

Side effects common to these agents are hot flashes, gynecomastia, and decreased libido. Flutamide tends to be associated with more diarrhea and requires three times daily administration, whereas bicalutamide is dosed once daily. Nilutamide may cause interstitial pneumonia and is associated with the visual disturbance of delayed adaptation to darkness.

### ▶ *Pure Androgen Receptor Antagonist: Enzalutamide*

Enzalutamide is an androgen receptor (AR) antagonist that works by competitively inhibiting androgen binding to androgen receptors and by inhibiting androgen receptor nuclear translocation and coactivator recruitment of the ligand-receptor complex. This agent has shown to competitively inhibit androgen binding to androgen receptors and inhibit androgen receptor nuclear translocation and interaction with DNA. Enzalutamide is indicated for the treatment of metastatic castration-resistant prostate cancer. The oral dosage is 160 mg orally once daily. Adverse effects associated with the agents are musculoskeletal effects, hot flashes, diarrhea, peripheral edema, hypertension, infections, headache, spinal cord compression, and hematuria.

### ▶ *Luteinizing Hormone–Releasing Hormone Agonists: Goserelin and Leuprolide*

Initially, luteinizing hormone–releasing hormone (LHRH) agonists increase levels of luteinizing hormone and follicle-stimulating hormone, but testosterone and estrogen levels are decreased because of continuous negative-feedback inhibition. Major side effects are testicular atrophy, decreased libido, gynecomastia, and hot flashes. Goserelin is injected as a pellet under the skin, therefore, subcutaneous injection of lidocaine around the injection site before administration helps to decrease the pain associated with goserelin administration. Numerous dosage forms are available for leuprolide with varying strengths and dosing intervals. Antiandrogens may be administered during initial therapy to decrease symptoms of tumor flare (eg, bone pain and urinary tract obstruction).

### ▶ *Luteinizing Hormone–Releasing Hormone Antagonist: Degarelix*

Degarelix is a gonadotropin-releasing hormone (GnRH) receptor antagonist that works by binding reversibly to the pituitary GnRH receptors, thereby reducing the release of gonadotropins and consequently testosterone. Degarelix is indicated for the treatment of advanced prostate cancer. Adverse events include hot flashes, injection site reactions, and an increase in liver enzymes. An advantage of degarelix over LHRH agonists is the lack of the tumor flare.[43]

### ▶ *Abiraterone*

Abiraterone is an orally available androgen biosynthesis inhibitor that inhibits 17α-hydroxylase/C17,20-lyase (CYP17), which is expressed in testicular, adrenal, and prostatic tumor tissues. Abiraterone is indicated in combination with prednisone for the treatment of metastatic castration–resistant prostate cancer who has received prior chemotherapy containing docetaxel. Adverse effects include joint swelling, hypokalemia, edema, muscle discomfort, hot flashes, diarrhea, urinary tract infections, nocturia, urinary frequency, dyspepsia, cough, hypertension, and arrhythmia. The patient must be counseled to take the oral medication on an empty stomach because food increases absorption and results in adverse reactions.[44]

### ▶ *Aromatase Inhibitors*

There are three aromatase inhibitors (AI) currently available, anastrozole, letrozole, and exemestane. Anastrozole and letrozole are selective nonsteroidal aromatase inhibitor that lowers estrogen levels. Anastrozole is a standard adjuvant treatment of postmenopausal women with hormone-positive breast cancer. The length of therapy is usually 5 years; however, evidence exists that suggests a benefit of prolonged treatment in certain situations. Exemestane, a steroidal compound, is an irreversible aromatase inactivator that binds to the aromatase enzyme to block the production of estrogen from androgens. This difference in activity does not appear to translate into improved clinical outcomes when compared to other AI therapies. When compared to tamoxifen, there are less endometrial and uterine cancers, vaginal bleeding, and thrombosis with AI therapy. Common adverse effects associated with the AI therapy include hot flashes and arthralgias. Serious adverse effects include osteoporosis, skeletal-related events, and atherosclerotic cardiovascular disease. The AIs are used exclusively for postmenopausal women. More information on the pharmacology and clinical use of AI therapy can be found in Chapter 89.

### ▶ *Antiestrogens*

Antiestrogens bind to estrogen receptors and block the effect of estrogen on tissue. There are two classes of antiestrogens: selective estrogen-receptor modulators (SERMs, tamoxifen, raloxifene) and selective estrogen-receptor downregulators (SERDs, Fulvestrant). SERDs were developed in an effort to eliminate the unwanted estrogenic side effects from the SERMs. Tamoxifen is used for the treatment of estrogen receptor (ER) positive premenopausal or postmenopausal metastatic hormone receptor–positive breast cancer, as adjuvant and primary treatment of

breast cancer, and in the prevention of breast cancer in high-risk women. It is associated with a significant decrease in disease recurrence and mortality. The agent has a beneficial effect on bone density and the lipid profile. Unwanted side effects include hot flashes, fluid retention, and mood swings. Thrombosis, endometrial and uterine cancer, corneal changes, and cataracts are harmful adverse effects that occur more frequently with this agent. Although uncommon, there is a disease/tumor flare which can occur during the initiation of therapy in metastatic breast cancer patients with bone metastases. Because tamoxifen is a substrate of CYP3A4, decreased tamoxifen levels have occurred with use of St. John's wort and rifampin. Tamoxifen is also a substrate for CYP450 2D6, and evidence suggests that those who are *CYP2D6*4/*4* may have a poorer response and more toxicity with tamoxifen.[45] Routine pharmacogenomics screening of these patients is not currently recommended. Significant drug interactions exist and drug–drug interactions affecting this enzyme should be avoided if possible.

Raloxifene is another SERM and is used for the treatment of osteoporosis in postmenopausal women and is the chemopreventative agent of choice for the prevention of breast cancer in high-risk women. When compared head to head with tamoxifen for breast cancer prevention, it was demonstrated to have equal efficacy with less toxicity. Raloxifene was not studied in premenopausal women; therefore, tamoxifen is still the preventative agent of choice in these women. Hot flashes, arthralgias, and peripheral edema occur frequently with raloxifene, but thrombosis and endometrial cancer is less common than with tamoxifen.

Fulvestrant is used as second-line treatment in hormone receptor–positive metastatic breast cancer, postmenopausal women with disease progression following antiestrogen therapy. Fulvestrant is given as a monthly intramuscular injection, which might be a deterrent to some patients.

Other antiestrogen agents that are used in the treatment of breast cancer include toremifene (SERM) and megestrol acetate. Megestrol acetate can cause fluid retention, hot flashes, vaginal bleeding and spotting, breast tenderness, and thrombosis.

## ADMINISTRATION ISSUES

### Extravasation

One issue of chemotherapy safety is extravasation. Antineoplastic agents that cause severe tissue damage when they escape from the vasculature are called vesicants. The tissue damage may be severe, with tissue sloughing and loss of mobility, depending on the area of extravasation. Patients need to be educated to notify the nurse immediately if there is any pain on administration. If extravasation of a vesicant occurs, the injection should be stopped and any fluid aspirated out of the injection site. The prevention, risk factors, signs and symptoms, causative agents, and treatment will be discussed thoroughly in Chapter 99.

### Hypersensitivity Reactions

Hypersensitivity reactions of cancer treatments is problematic because of cross-reactivity between agents and the desire to continue active therapies against the cancer.[46] For documented immediate hypersensitivity reactions to a particular agent, further administration of the agent may be achieved through extensive premedication with $H_1$ and $H_2$ antihistamines and corticosteroids and through use of escalating doses of the offending agent given at doses of one-hundredth, one-tenth, and the balance of the dose (so the total dose administered is equivalent to the normally prescribed dose) administered over a much longer

period of time. These treatments must be given in an environment where resuscitation is readily available in case of medical emergency.

## Secondary Malignancies

Chemotherapy and radiation therapy treatments may cause cancers later in life; these are referred to as secondary cancers. The most common type of secondary cancer is myelodysplastic syndrome, or AML. The antineoplastic agents most commonly associated with secondary malignancies are alkylating agents, etoposide, teniposide, topoisomerase inhibitors, and anthracyclines. Although the risk for secondary cancers is extremely low, it must outweigh the risk of survival produced by treatment of the primary malignancy. Because secondary malignancies may not occur for several years after treatment, patients with relatively short-term survival owing to the primary malignancy should consider the more immediate benefits of chemotherapy. Radiation therapy rarely may cause solid tumors as secondary cancers decades after treatment. The most common example of radiation therapy–induced secondary malignancy is breast cancer, which rarely occurs after mantle field radiation therapy for Hodgkin disease.

## CHEMOTHERAPY SAFETY

One of the first Institute of Medicine reports, the health arm of the National Academy of Sciences, starts out with a patient who died from an overdose of chemotherapy; the patient did not have an immediately life-threatening cancer, so her death was hastened by a medication error. Chemotherapy agents may cause harm to patients, health professionals, and the environment if not handled correctly.

**KEY CONCEPT** *Because of the risk of severe toxicities associated with many of the chemotherapy agents, safety precautions must be in place to prevent chemotherapy errors or accidental chemotherapy exposures of health professionals or patients.* The Oncology Nursing Society and the American Society of Health-System Pharmacists have information to assist in the safe handling of chemotherapy agents.[16] National, state, and local regulations regarding the safe disposal of chemotherapy agents and the equipment used to administer them need to be followed to protect the environment.

**KEY CONCEPT** *Each organization should have chemotherapy safety checks built into the prescribing, preparation and administration of chemotherapy.*[16] Dosing based on patient-specific information should be included on every order for chemotherapy, whether it is oral or parenteral. Many chemotherapy regimens are referred to by acronyms (eg, AC, which is doxorubicin cyclophosphamide); these should not be allowed as the only reference to drugs in the prescribing of chemotherapy. Also, abbreviations for the names of chemotherapy agents should be avoided because one abbreviation may stand for two different drug entities. For drugs such as doxorubicin and liposomal doxorubicin, the names should be written out fully, and in this case, the addition of the brand name may help to prevent a mistake.

The measured height and weight, along with the body surface area (BSA), if applicable, should be readily available, along with the dosage in milligrams per meter squared or kilogram, so that the dosage may be checked. If a chemotherapy regimen is a continuous infusion of 800 mg/m$^2$/day for 4 days, an added safety feature would be to include the total dosage of 3200 mg in order to prevent any ambiguity. In cases where the clinician wants to decrease the dosage based on a laboratory value or side effect, it

| Table 88–7 |
| --- |

**Empiric Dose Modifications in Patients with Renal Dysfunction**

| Agent | Organ Dysfunction | Dose Modification |
| --- | --- | --- |
| Bleomycin | CrCl = 30–60 mL/min (0.50–1.0 mL/s) | 25%–50% decrease |
| | CrCl = 10–30 mL/min (0.17–0.50 mL/s) | 25%–50% decrease |
| | CrCl < 10 mL/min (0.17 mL/s) | 50% decrease |
| Bosutinib | CrCl < 30 ml/min (0.50 mL/s) | Decrease dose to 300 mg daily |
| Capecitabine | CrCl = 30–50 mL/min (0.50–0.83 mL/s) | 25% decrease |
| | CrCl < 30 mL/min (0.50 mL/s) | Do not use |
| Carboplatin | Renal insufficiency | Total Dose = AUC × (CrCl [in mL/min] + 25) |
| Cisplatin | CrCl < 50 mL/min (0.83 mL/s) | Decrease dose by 50% |
| Crizotinib | CrCl < 30 ml/min (0.50 mL/s) | Use with caution. Decrease dose to 250 mg daily |
| Cyclophosphamide | Renal failure | Decrease dose 25% |
| Eribulin | CrCl 30–60 ml/min(0.50–1.00 mL/s) | Decrease dose to 1.1 mg/m$^2$ |
| | CrCl < 30 ml/min (0.50 mL/s) | Do not use |
| Etoposide | CrCl: 15–50 mL/min (0.25–0.83 mL/s) | Decrease dose 25% |
| Fludarabine, hydroxyurea | CrCl < 60 mL/min (1.00 mL/s) | Decrease dose in proportion to CrCl |
| Ifosfamide | CrCl = 10–50 mL/min (0.17–0.83 mL/s) | Decrease dose 25% |
| | CrCl = < 10 mL/min (0.17 mL/s) | Decrease dose 50% |
| Lenalidomide | CrCl < 60 ml/min (1.00 mL/s) | Dose modification varies depending on diagnosis |
| Methotrexate[a] | 80 mL/min (1.33 mL/s) | Full dose |
| | 80 mL/min (1.33 mL/s) | 75% |
| | 60 mL/min (1.00 mL/s) | 63% |
| | 50 mL/min (0.83 mL/s) | 56% |
| | < 50 mL/min (0.83 mL/s) | Use alternative chemotherapy |
| Pentostatin | Renal insufficiency | Dose in proportion to CrCl |
| Pomalidomide | Serum Creatinine ≥ 3.0 mg/dL (265 μmol/L) | Do not use |
| Streptozocin | Renal Failure | Decrease dose 50%–75% |
| Topotecan | CrCl 20–39 mL/min (0.33–0.65 mL/s) | Decrease dose 50% |
| | CrCl < 20 ml/min (0.33 mL/s) | Do not use |
| Vandetanib | CrCl < 50 ml/min (0.83 mL/s) | Decrease dose 200 mg daily |

[a]Monitor levels closely in all patients receiving high-dose therapy (eg, 150 mg/m$^2$ or greater).

is recommended that the clinician include that information with the order so that everyone understands what the correct dosage is for that patient. Chemotherapy dosages should be checked for route and dose to determine that the dosages prescribed are correct according to the regimen and do not exceed dosing guidelines. Appropriate laboratory values should be checked to verify that dosages are correct for any organ dysfunction present, and drug interactions should be scrutinized closely (Tables 88–7 and 88–8). Health professionals administering chemotherapy should check the dosage calculation for the patient's weight or BSA along with the five Rs of administering medication (ie, right patient, right medication, right dose, and right route, at the right time). If there is any question about the safe dosage or safe administration of a chemotherapy agent, the chemotherapy should not be administered until the question is resolved.

An area of controversy with chemotherapy dosing: What weight should be used for patients who are morbidly obese currently? Based on clinical practice guidelines published by the American Society of Clinical Oncology, it is recommended that clinicians routinely use an obese patient's actual body weight, instead of an ideal body weight or other measurement.

## ORAL CHEMOTHERAPY

KEY CONCEPT *Over the past decade, self-administration of oral chemotherapy has increased because of the availability of oral, novel anticancer agents. Although oral chemotherapy has many advantages, such as convenience for the patient, potential increase in quality of life, and decreased treatment-associated costs, it also comes with an increased risk of medication errors, less monitoring of adverse effects and drug, dietary supplements, OTC medication and/or food interactions and accidental exposure to other individuals.* Health professionals have an important role in ensuring safe handling of oral anticancer agents, and should be properly trained and perform competently within guidelines for the storage, handling, and disposal of oral agents. The health professionals are also expected to provide proper training and education on safe handling and proper administration ( See Table 88-9) for the patient and caregivers.[47]

## CANCER SURVIVORSHIP

KEY CONCEPT *As early detection of cancers and effective therapies have improved over the last several years, the number of cancer survivors has increased. A cancer survivor by definition, according to the National Coalition for Cancer Survivorship, starts at the point of diagnosis. It is estimated that two out of every three people with cancer live at least 5 years after diagnosis.* In 2005, the Institute of Medicine (IOM) released a report, "From Cancer Patient to Cancer Survivor: Lost in Transition," which emphasized that a lack of definitive guidance in this area and identified that increased efforts were needed to raising awareness. In addition to facing a risk of a cancer recurrence, secondary malignancy, and an increased risk of developing other health

**Table 88–8**

**Empiric Dose Modifications for Patients with Hepatic Dysfunction**

| | | |
|---|---|---|
| Abiraterone acetate | Child-Pugh Class B | Decrease dose to 250 mg daily |
| | Child-Pugh Class C | Do not give |
| Anthracyclines | Bilirubin 1.2–3.0 mg/dL (20.5–51.3 µmol/L) | Decrease dose 50% |
| | Bilirubin 3.1–5.0 mg/dL (53.0–85.5 µmol/L) | Decrease dose 75% |
| | Bilirubin > 5.0 mg/dL (85.5 µmol/L) | Do not give |
| Axitinib | Child-Pugh Class A | No modification needed |
| | Child-Pugh Class B | Decrease dose 50% |
| | Child-Pugh Class C | Has not been studied |
| Bosutinib | Any baseline hepatic impairment | Decrease dose 200 mg daily |
| Cabozantinib | Moderate/severe hepatic impairment | Do not give |
| Carfilzomib | ALT/AST ≥ 3 × ULN and Bilirubin ≥ 2 × ULN | Do not give |
| Crizotinib | Bilirubin > 1.5 × ULN or AST/ALT > 2.5 × ULN | Use caution |
| Docetaxel | Bilirubin greater than ULN | Do not give |
| | AST or ALT > 1.5 ULN and | Do not give |
| | Alk Phos > 2.5 ULN | |
| Eribulin | Child-Pugh A | Decrease dose to 1.1 mg/m$^2$ |
| | Child-Pugh B | Decrease dose to 0.7 mg/m$^2$ |
| Etoposide | Bilirubin 1.5–3.0 mg/dL (25.7– 51.3 µmol/L) | Decrease dose 50% |
| | Bilirubin 3.1–5.0 mg/dL (53.0– 85.5 µmol/L) | Do not give |
| Everolimus | Child-Pugh Class A | Decrease dose to 7.5 mg daily |
| | Child-Pugh Class B | Decrease dose to 5 mg daily |
| | Child-Pugh Class C | Decrease dose to 2.5 mg daily |
| Imatinib | Bilirubin greater than 3 × ULN | Withhold until less than 1.5 ULN |
| Ixabepilone | As a monotherapy agent if AST or ALT greater than 10 × ULN or bilirubin greater than 3 × ULN | Contraindicated |
| | In combination with capecitabine AST or ALT greater than 2.5 × ULN or bilirubin greater than 1 × ULN | |
| Lapatinib | Child–Pugh class C hepatic dysfunction | Dose reduction to 750 mg/day |
| Paclitaxel | Use with caution in hepatic failure | |
| Albumin-bound paclitaxel (Abraxane) | Bilirubin > 1.26 × ULN and elevated AST level | Dose modifications recommended (varies by diagnosis) |
| | Bilirubin > 5 × ULN or SGOT (AST) level > 10 × ULN | Do not give |
| Pazopanib | Bilirubin > 1.5–3 × ULN | Decrease to 200 mg daily |
| | Bilirubin > 3 × ULN | Do not give |
| Pomalidomide | Bilirubin > 2.0 mg/dL (34.2 µmol/L) and AST/ALT greater than 3.0 × ULN | Do not give |
| Ponatinib | Any baseline hepatic dysfunction (Child-Pugh Class A, B, or C) | Decrease dose 30 mg daily |
| Thiotepa | Use with caution in hepatic failure | |
| Vandetanib | Moderate-Severe hepatic impairment | Do not give |
| Vinblastine, vincristine | Bilirubin 1.5–3.0 mg/dL (25.7–51.3 µmol/L) | Decrease dose 50% |
| | Bilirubin 3.1–5.0 mg/dL (53.0–85.5 µmol/L) | Do not give |
| Vinorelbine | Bilirubin 2.1–3.0 mg/dL (35.9–51.3 µmol/L) | Decrease dose 50% |
| | Bilirubin > 3 mg/dL (51.3 µmol/L) | Decrease dose 75% |

ULN, upper limit of normal.

---

**Patient Encounter 3**

A 63-year-old woman with a stage IV NSCLC (adenocarcinoma) and a mutation in exon 19 of the EGFR gene presents to the clinic. She will be receiving a new prescription for afatanib 40 mg orally, once daily.

*What education and training should be provided to the patient to ensure their understanding of safe handling procedures as well as thorough knowledge of proper administration?*

*How should the patient be instructed to take this medication, in regards to meals or the time of day?*

*What adverse reactions would require that a holding treatment or a dose modification be made in therapy?*

---

conditions, cancer survivors often face physical, emotional, financial, and social challenges as a result of the cancer diagnosis and treatment.[48] Agencies such as the American Cancer Society (ACS), National Cancer Institute (NCI), Centers for Disease Control (CDC), and American Society of Clinical Oncology (ASCO) are implementing strategies to meet the needs of these individuals who experience the long-term effects of cancer and its treatment.

## OUTCOME EVALUATION

Once a pathologic diagnosis of cancer is made, the patient may be evaluated by a radiation oncologist, a surgical oncologist, and a medical oncologist. Options for treatment are presented that may include surgery, radiation, chemotherapy biotherapy, or some combination of these modalities. The goals of treatment vary by the cancer and the stage of disease. For example, the

patient who has metastatic kidney cancer could be presented with several options. They may have a possible cure with high-dose aldesleukin or receive palliative therapy with sorafenib or sunitinib, or the patient may decline any therapy because of fears of significant toxicity that would decrease quality of life. In this case, if the patient's performance status is poor, such as an ECOG performance status 3, then the patient would not be a candidate for aldesleukin therapy because of significant toxicity or even death from treatment. The patient with the poor performance status will receive palliative therapy to control symptoms of the disease to improve the quality of life at the end of life. For the patient with a poor performance status and extensive metastatic disease, no treatment of the cancer may be appropriate, and the patient may be enrolled in a hospice program or provided comfort care.

## Patient Care Process

**Patient Assessment:**

- Based on workup, confirm cancer diagnosis and stage of disease before initiating anticancer treatment.
- Determine treatment goals (ie, cure) considering type of cancer, stage of disease, patient characteristics (eg, age, performance status, etc).
- Review the medical history. Does the patient have any special population precautions (eg, pregnancy, breastfeeding, dialysis, renal/hepatic dysfunction, pharmacogenomic information, etc) or specific concerns that would change your approach with standard of care treatments?
- Ensure that weight and height is accurate and recent. Calculate the BSA (if applicable). Determine if actual, ideal, or adjusted weights are to be used, based on treatment goals and discussion with health care team.
- Check patient laboratory values, physical assessment and any other work-up to ensure that the CBC and organ function studies are normal or within acceptable limits before administering chemotherapy. Does the patient need a measure of ejection fraction or a chest x-ray, for example? Does the patient need a central line (if receiving a vesicant)?
- Conduct a medication history (including prescriptions, OTC medications, herbals and dietary supplements) and nutrition history. Identify any possible drug–drug or drug–food interactions. Does the patient have any allergies or previous treatment with an anticancer agent? For example, has a patient received an anthracycline in the past?

**Therapy Evaluation:**

- Evaluate the chemotherapy regimen to ensure the correct dose and route of administration.
- If a patient has hematologic, renal or hepatic, or other toxicities, recommend adjustments in chemotherapy and/or doses if necessary.
- Ensure appropriate antiemetic therapy, hydration, and ancillary medications (antihistamines, steroids, folate, anti-infectives, etc) along with any rescue medications (leucovorin, mesna, etc) are ordered for patient.
- Assess the regimen to determine if primary prophylaxis with colony-stimulating factors is needed.

**Care Plan Development**

- Counsel patient and caregivers on the treatment plan, short- and long-term adverse effects, precautions, supportive care plans.
- Use safe handling and disposal methods.
- For oral chemotherapy, provide specific recommendations to patients and caregivers to ensure their understanding of safe handling procedures as well as thorough knowledge of proper administration of the medication.

**Follow-up Evaluation:**

- Monitor CT scans or other imaging studies, and categorize patient with a CR, PR, SD, or progressive disease.
- Monitor CBC, renal function, liver function, and other laboratory or diagnostic tests as needed.
- Monitor patient for other known toxicities of the chemotherapy regimen and hold or modify the dose or discontinue the regimen if necessary.
- Ensure that cancer survivorship needs are being met.

# Abbreviations Introduced in This Chapter

| | |
|---|---|
| 2-FLAA | 2-Fluoro-Ara-AMP |
| 5-FU | Fluorouracil |
| 6-MP | 6-Mercaptopurine |
| 6-TG | 6-Thioguanine |
| ADC | Antibody–drug conjugate |
| AI | Aromatase inhibitor |
| ALK | Anaplastic lymphoma kinase gene |
| ALL | Acute lymphocytic leukemia |
| AML | Acute myeloid leukemia |
| APL | Acute promyelocytic leukemia |
| Ara-C | Cytarabine |
| ASCT | Autologous stem cell transplant |
| ATRA | All-trans-retinoic acid |
| AUC | Area under the-curve |
| c-MET | Mesenchymal epithelial transition growth factor |
| CD | Cluster of differentiation |
| CLL | Chronic lymphocytic leukemia |
| CML | Chronic myeloid leukemia |
| CTC | Common toxicity criteria |
| CTLA-4 | Cytotoxic T-lymphocytic-associated antigen 4 |
| ECOG | Eastern Cooperative Oncology Group |
| EGFR | Epidermal growth factor receptor |
| ER | Estrogen receptor |
| FdUMP | Fluorodeoxyuridine monophosphate |
| GIST | Gastrointestinal stromal tumor |
| GnRH | Gonadotropin-releasing hormone receptor |
| HER-2 | Human epidermal receptor-2 |
| HPV | Human papillomavirus |
| IL | Interleukin |
| LHRH | Luteinizing hormone releasing hormone |
| MEK | Mitogen-activated extracellular kinases |
| MM | Multiple myeloma |
| MMAE | Monomethyl auristatin E |
| mTOR | Mammalian target of rapamycin |
| NCI | National Cancer Institute |
| NSCLC | Non–small cell lung cancer |
| PCR | Polymerase chain reaction |
| PEG | Polyethylene glycol |
| PSA | Prostate specific antigen |
| SERDs | Selective estrogen-receptor downregulators |
| SERMs | Selective estrogen receptor modulator |
| TKI | Tyrosine kinase inhibitor |
| TNM | Tumor, nodes, metastases |
| TPMT | Thiopurine S-methyltransferase |
| TS | Thymidylate synthase |
| VEGF | Vascular epidermal growth factor |
| VEGFR | Vascular epidermal growth factor receptor |

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Explain the relative importance of various risk factors.
2. Summarize the features of the four intrinsic breast cancer subtypes.
3. Articulate some of the reasons for improved patient survival.
4. Recognize signs and symptoms related to early and late stages of the disease.
5. Distinguish between good and poor prognostic factors.
6. Describe the roles of hormone and HER2 receptors.
7. Determine treatment goals for early stage, locally advanced, and metastatic breast cancers.
8. State the rationale for inclusion of adjuvant and neoadjuvant therapies.
9. Discuss the benefits and risks associated with various endocrine therapies.
10. List relevant factors that guide management and treatment of early and metastatic breast cancers.

## INTRODUCTION

Two breast cancer trends, the modest decline in new diagnoses and improvement of 5-year survival rates, have continued over the past decade. One factor that could be associated with both the former and latter findings is screening. The link to screening is plausible as detection of more patients with non-invasive (ie, in situ) disease could impact the number of new invasive breast cancer cases, while diagnosis of early-stage disease should translate to improved overall survival.

## EPIDEMIOLOGY AND ETIOLOGY

Breast cancer is the most common type of cancer and second only to lung cancer as a cause of cancer death in American women. In 2015, female breast cancer will account for 99% of the projected 235,000 new cases; the median age at diagnosis will be 61 years; and approximately 40,000 deaths will occur as a result of the disease.[1] **KEY CONCEPT** Even *though the disease occurs more frequently in white women than any other ethnic group, the mortality rate is highest among African Americans.*

Tumor size of most breast cancers at diagnosis is usually small (less than 2 cm); and early-stage disease predominates in all racial and ethnic groups. However, African American women have proportionally more cases of advanced disease compared with white women. It has been suggested that reduced access to proper medical care, including breast cancer screening programs, as well as certain biological factors, contribute to late diagnoses.

**KEY CONCEPT** *The etiology of breast cancer remains largely unknown though a number of factors have been associated with risk of developing the disease. Evidence also strongly suggests that breast cancer biology involves very complex interactions between sex hormones, genetic factors, environment, and lifestyle.* The intrinsic and extrinsic components associated with the disease are discussed further.

### Intrinsic Components

**KEY CONCEPT** *Aside from gender, the variable most strongly associated with breast cancer is age as disease risk and incidence increase with age.* One of the most frequently quoted breast cancer statistic is the probability that one in eight will develop the disease. However, a more instructive way of explaining the age-related factor is shown in **Table 89–1**. Although the probability of developing breast cancer increases with age, more than half the risk occurs after 60 years of age.

Both personal and family history can influence the risk of developing breast cancer. For example, a woman who has a history of breast cancer has a fivefold increase in risk of developing contralateral breast cancer. Prior histories of cancers involving the uterus and ovary also appear to be associated with an increased risk of developing breast cancer. Breast tissue with atypical changes appears to be a premalignant lesion. Even though family history is often linked to disease risk, the percentage of familial breast cancer, in reality, is quite low (ie, ~10%). **KEY CONCEPT** *Nonetheless, clarification of several key elements related to family history includes findings that:*

- A first-degree relative (ie, mother or sister) with breast cancer is associated with a 3-fold increase in risk.
- A first-degree relative diagnosed with breast cancer younger than 45 years is associated with a more than threefold increase in risk.

| Table 89–1 | |

| **Risk of Developing Breast Cancer: SEER Areas, Women, All Races, 2008 to 2010** | |
| **Age Interval (years)** | **Probability (%) of Developing Invasive Breast Cancer during the Interval** |
| 30–40 | 0.44 or 1 in 227 |
| 40–50 | 1.45 or 1 in 69 |
| 50–60 | 2.31 or 1 in 43 |
| 60–70 | 3.49 or 1 in 29 |
| From birth to death | 12.15 or 1 in 8 |

SEER, Surveillance, Epidemiology and End Results.

Probability derived by Devcan 6.7.0, June 2013 (http://surveillance.cancer.gov/devcan).

- Multiple first-degree relatives with breast cancer have not been consistently shown to be associated with risk greater than one first-degree relative.

- A second-degree relative with breast cancer is associated with 1.5-fold increase in risk.

- Family members on the paternal side contribute to risk similar to the maternal side.

KEY CONCEPT *A number of endocrine factors have been linked to an increased risk for breast cancer.* Many of the risks relate to the total duration of estrogen exposure. Hence, early menarche (before age 12 years) and late menopause (after age 55 years) are associated with an increased risk of the disease. Support for this association is the finding that bilateral oophorectomy before age 35 years decreases the relative risk of developing breast cancer. Nulliparity and late age at first birth (30 years or older) have been reported to double the lifetime risk of developing breast cancer.

Long-term use of hormone replacement therapy and concurrent use of progestins appear to contribute to breast cancer risk. Use of postmenopausal estrogen replacement therapy in women with a history of breast cancer is generally contraindicated. However, most experts believe that the safety and benefits of low-dose oral contraceptives currently outweigh the potential risks and that changes in the prescribing practice for the use of oral contraceptives are not warranted. Moreover, oral contraceptives are known to reduce the risk of ovarian cancer by about 40% and the risk of endometrial cancer by about 60%.

KEY CONCEPT *In the early 1990s, the BRCA1 gene (locus 17q21) was found to be mutated in a large percentage of hereditary breast and ovarian cancer patients. A second breast cancer gene, called BRCA2, has been mapped to chromosome 13.* Since *BRCA1* and *BRCA2* are tumor suppressor genes, mutations or functional aberrations result in loss of key inhibitory activities of both proteins.[2] Compelling evidence of their critical importance is the observation that women who carry germline mutations of *BRCA1* are at high risk for breast and ovarian cancers (85% and 60% over their lifetimes, respectively). Carriers of the *BRCA2* mutation have similar risks for breast cancer but much lower risks for ovarian cancer. Jewish people of Eastern European descent (Ashkenazi Jews) have an unusually high (2.5%) carrier rate of germline mutations in *BRCA1* and *BRCA2* compared with the rest of the US population. Women with strong family histories of breast cancer are candidates for *BRCA1* and *BRCA2* mutation analysis. If performed, genetic testing should be done under the guidance of a professional genetic counselor.

## Extrinsic Components

KEY CONCEPT *Experimental and epidemiologic evidence suggest an association between breast cancer and a diet high in calories, fat, and cooked meats. Obesity in postmenopausal women and distribution of body fat around the abdominal region also appear to increase the risk of breast cancer.* This risk factor may be related, in part, to peripheral conversion of androgens to estrogens in adipose tissue. More dramatic evidence of the negative impact of obesity was presented at the 2014 meeting of American Society of Clinical Oncology (ASCO). In a large-scale analysis investigators reported that among premenopausal women with early-stage, ER positive breast cancer, obesity raised the risk of dying by 34% compared with the other breast cancer patients. Evidence also indicates a modest ingestion-dependent relationship between alcohol and breast cancer. While exercise may have a modest protective effect against breast cancer, neither cigarette smoking nor breast augmentation appears to modify disease risk

Radiation is also associated with an increased risk of breast cancer. Even though the risk appears to be dosage-related, the minimal level of exposure is not well defined. Overt environmental exposure such as that which occurred in survivors of the atomic bomb is associated with an increased risk. However, even radiation exposure during therapeutic management of patients with postpartum mastitis, tuberculosis, and certain hematologic malignancies appears to increase breast cancer risk. Interestingly, this risk appears to be confined to exposure before 40 years of age, which suggests that a "window of initiation" for breast cancer occurs relatively early. On the other hand, it is currently accepted that exposure to radiation doses utilized in diagnostic x-rays, including screening mammography, are not of clinical concern.

Despite what is known to confer risk, the majority of women diagnosed with breast cancer do not have any of the identified factors (other than age). A number of calculators now accessible through the Internet can be used to estimate breast cancer risk. The National Cancer Institute (NCI) has an online version of the Breast Cancer Risk Assessment Tool that is considered to be the most authoritative and accurate (www.cancer.gov/bcrisk-tool). This tool was designed for health professionals to project individualized 5-year and lifetime risks for invasive breast cancer.

## Prevention of Breast Cancer

Even though breast cancer is not the most lethal malignancy, disease-related morbidity and mortality is still significant. Current efforts at breast cancer prevention are directed toward the identification and removal of risk factors. Unfortunately, a number of risk factors such as age, family or personal history of the disease or other gynecologic malignancies cannot be modified.

The idea that prevention can be achieved pharmacologically is based on clinical trials of tamoxifen, an antiestrogen used as **adjuvant therapy** for certain women with early breast cancer. These trials demonstrated a reduction of contralateral breast cancer events as well as a survival advantage in this subset of patients who received the drug for 2 to 5 years following mastectomy.[3] Several clinical trials conducted with this antiestrogen provided proof of principle that breast cancer risk reduction could be achieved through chemoprevention.[4,5] A meta-analysis of these trials indicated a consistent (and significant) benefit in reducing the risk of developing estrogen receptor (ER) positive breast cancers in premenopausal and postmenopausal women.

Results of these trials also confirmed the carcinogenic and thrombogenic effects of tamoxifen. Unfortunately, the increased

## Patient Encounter, Part 1

A 45-year-old woman who is part owner of a local dry cleaning business comes to clinic. Except for hypertension (controlled with lisinopril + hydrochlorothiazide) and being slightly overweight, she has been in good health. She is happily married with two grown children in college. She has one paternal aunt who died from breast cancer. There is no other breast or gynecologic cancer history in the family. On routine self-examination, she detected a very small lump in her left breast. No other breast changes were noted. Although she had screening mammography nearly a year ago which was officially read as normal, she is still very concerned and makes an appointment to see her personal physician as soon as possible. The following week her doctor also notes the abnormality on clinical examination and orders a mammogram.

*Compile a list of considerations integral to screening programs.*

*Explain why the currently ordered mammogram is not a screening mammogram.*

incidence of endometrial cancers and thrombotic events had a negative impact on both patient acceptance and physician willingness to prescribe tamoxifen in this setting. However, studies with another antiestrogen known as raloxifene demonstrated that this agent not only reduced spinal fractures in postmenopausal women, but also decreased the incidence of breast cancer without adversely affecting the endometrium. The latter finding led to a head-to-head clinical study of tamoxifen and raloxifene (STAR), which involved postmenopausal women considered to be at increased risk for developing breast cancer.[6] Although the reduction in the incidence of breast cancer was similar, raloxifene had a superior safety profile with regards to cancer and thromboembolic events. Thus, raloxifene is considered the chemopreventive agent of choice for high-risk postmenopausal women. Because premenopausal women were not included in the STAR trial, tamoxifen is the only agent approved for reducing the risk of breast cancer in young women.

Despite these important findings, the role of tamoxifen in *BRCA* mutation carriers is still not clear. Surgical prophylaxis for these individuals includes bilateral mastectomy or oophorectomy at completion of childbearing. Importantly, the risk of developing breast and ovarian cancer following prophylactic surgery is significantly, but not absolutely, reduced. For those foregoing elective surgical options semiannual mammograms are recommended.

The impressive data of the aromatase inhibitors (AIs) in the adjuvant setting provided the impetus for studying their potential as breast cancer chemopreventive agents. The steroidal AI, exemestane, has been reported to be more effective than placebo in reducing the risk of breast cancer in high risk postmenopausal women.[7] Although exemestane has not been compared directly with either tamoxifen or raloxifene, the superior results of AIs compared to tamoxifen in the adjuvant setting suggest that the AIs could outperform the antiestrogens in reducing breast cancer risk with lower endometrial and thrombotic events.

## PATHOPHYSIOLOGY

Histologic evaluation of breast lesions serves to establish a pathologic diagnosis and confirm the presence or absence of other factors believed to influence prognosis. These **prognostic factors** are discussed later.

### Invasive Breast Cancer

Breast cancer typically arises in the ducts or lobules of the mammary gland. When tumor cells infiltrate surrounding breast tissue, a diagnosis of invasive breast cancer is made. Even though the vast majority of tumors are adenocarcinomas, this does not imply that breast cancer is one disease. *Substantial progress has been made to further refine the way four intrinsic subtypes of breast cancer are classified. When defined by clinical and pathological features, the classification system also provides a guide to treatment (Table 89–2).*

### Noninvasive Carcinoma

The annual breast cancer incidence does not include thousands of cases of carcinomas in situ (ie, noninfiltrating tumors confined to the ducts and lobules). Ductal carcinoma in situ (DCIS) accounts for approximately 85% of all in situ breast cancers;

---

**Table 89–2**

**Intrinsic Subtypes of Breast Cancer**

| Subtype | Tumor Features | Treatment Approach | Added Comment |
|---|---|---|---|
| Luminal A | All of the following: ER and PR positive, HER2 negative, and low Ki-67 (proliferation marker) | Endocrine only (usually) | May add chemotherapy if 4 or more positive nodes, grade 3 disease, Oncotype Dx recurrence score higher than 25, or age younger than 35 years |
| Luminal B (HER2 negative) | ER positive, HER2 negative, and either high Ki-67 or PR negative | Endocrine | Add chemotherapy for most patients |
| Luminal B (HER2 positive) | ER positive, HER2 positive | Endocrine, HER2 targeted therapy and chemotherapy | |
| HER2 amplified or overexpressed (nonluminal) | HER2 positive | HER2 targeted and chemotherapy | Opinion differs regarding use of anti-HER2 therapy in tumors |
| Basal (triple-negative) | ER, PR, and HER2 negative | Chemotherapy only | Less than 5 mm |

while lobular carcinoma in situ (LCIS) may not be a true cancer, but rather a high-risk premalignant lesion. The overwhelming majority of cases can be cured by surgery alone. Although there is no proven role for the application of cytotoxic chemotherapy, patients with **hormone receptor-positive** tumors may benefit from the addition of tamoxifen.[8]

## CLINICAL PRESENTATION AND DIAGNOSIS

### Early Detection

The rationale for early detection of breast cancer is based on the clear relationship between early stage disease at diagnosis and greater probability of long-term survival. Thus, patients with tumors less than 2 cm and negative lymph nodes have a higher likelihood of being cured. **KEY CONCEPT** *Screening guidelines for early detection of breast cancer have been put forward by the American Cancer Society, the United States Preventive Services Task Force (USPSTF), and the NCI (Table 89–3).* All include recommendations for women at average risk, with some general statements regarding screening for high-risk women as well. Nearly 80% of all breast cancers occur in women 50 years of age or older, and regular use of screening mammography can reduce mortality from breast cancer by 20% to 40% in this age group. Controversy regarding the use of screening mammography is largely confined to women younger than 50 years. After many years of debate,

three organizations recommended mammograms in this age group of women every 1 to 2 years except for the USPSTF, which modified its recommendation in 2009.[9]

### Diagnosis

Unless following up on abnormalities found during screening, the initial workup for women presenting with signs or symptoms (see Clinical Presentation and Diagnosis) suggestive of breast cancer should include a careful history, physical examination of the breast, three-dimensional mammography, and possibly other imaging techniques such as magnetic resonance imaging. Most (80%–85%) breast cancers are visualized on a mammogram as a

**Estimated Stage at Presentation and 5-Year Disease-Free Survival (DFS): Breast Cancer**

| | Percentage of Total Cases | 5-Year DFS[a] (%) |
|---|---|---|
| Stage I | 40 | 70–90 |
| Stage II | 40 | 50–70 |
| Stage III | 15 | 20–30 |
| Stage IV | 5 | 0–10[b] |

[a] With current conventional local and systemic therapy.

[b] Patients in stage IV are rarely free of disease; however, 10% to 20% of these patients may survive with minimal disease for 5 to 10 years.

mass, a cluster of calcifications, or a combination of both. A breast biopsy is indicated for a mammographic abnormality that suggests malignancy or for a palpable mass on physical examination.

### Clinical Staging

Stage is determined by primary tumor size (T), axillary lymph node involvement (N), and presence or absence of distant metastases (M). See Table 88–2 for an example of TMN staging. Aside from carcinoma in situ (stage 0) multiple combinations of T and N are possible within a given stage. Simplistically, stage I disease is represented by tumors less than 2 cm in diameter and usually no lymph node involvement. **KEY CONCEPT** *Stage I and II disease is referred to as early breast cancer, which carries a relatively good prognosis and correlates with the highest probability of cure (Table 89–4).* Stage III, or locally advanced breast cancer, has poorer disease features, including larger tumor size, positive node involvement, and tumor invasion of the chest wall. Stage IV disease is characterized by the presence of metastases ($M_1$) to organs or tissue distant from the primary tumor and is often referred to as advanced or metastatic breast cancer.

### Prognostic Factors

Prognostic factors are biological or clinical indicators associated with survival independent of therapy. Poor prognostic factors for breast cancer include:

- Age younger than 35 years
- Large tumor size
- High nuclear grade (correlates with tumor growth)
- Lymph node involvement
- Triple-negative disease (ie, absence of ER, PR, and HER2 receptors)
- Overexpression of HER2 alone

## EARLY BREAST CANCER

### TREATMENT
### Desired Outcome

**KEY CONCEPT** *Most patients presenting with invasive breast cancer today have small tumors with negative lymph nodes (stage I), or a stage II cancer. The goal of therapy for early breast cancer is cure.* While surgery alone may be able to cure approximately one-third to one-half of all patients with early stage breast cancer, certain tumor features warrant addition of systemic therapy.

### Patient Encounter, Part 3

Two years after this patient's initial diagnosis, routine follow-up chest x-ray showed two 3-cm nodules in the right upper lobe of the lung. Pulmonary consultants perform a transbronchial lung biopsy of one lung lesion. Pathologic examination reveals recurrent breast cancer. Tumor tissue indicates the same receptor pattern. Imaging of the chest, abdomen, and pelvis is negative for other sites of metastasis.

*Formulate a list of clinical factors that should be considered when deciding on therapy.*

*Conclude what treatment would be appropriate at this time.*

### Local-Regional Therapy

Surgical procedures have changed drastically over the past 50 years. **KEY CONCEPT** *Less aggressive surgical options for early invasive breast cancer include total mastectomy and breast conserving surgery (BCS) such as lumpectomy.* The reason for favoring the latter is based on findings that BCS achieves similar survival outcomes as more extensive surgical procedures and is cosmetically superior.[10] Additionally, breast conservation aids in preserving the emotional and psychological well-being of the patient.[11] Only two contraindications to BSC considered absolute (or nearly absolute) include persistence of tumor on surgical margins and inability to perform postsurgery radiation, if indicated.

**KEY CONCEPT** *Equally important is the issue related to complete axillary lymph node dissection (CALND). Because of the morbidity associated with the procedure, clinical trials were conducted to determine when biopsy of the sentinel lymph nodes was sufficient.* Results of these studies indicated that CALND can be avoided in patients with microscopic disease in the sentinel nodes as well as in patients undergoing BCS with postsurgery radiation to the breast.[12,13]

Except for the elderly and patients with substantial comorbid medical conditions, radiation therapy is an integral adjunct to BCS. However, radiation therapy should also be considered in certain postmastectomy situations, especially in patients with more than three positive nodes or patients with positive sentinel nodes without CALND. What used to entail 4 to 6 weeks of external-beam radiation, newer clinical evidence supports the efficacy of a shorter 3-week course of whole breast irradiation.[14] Complications associated with radiation therapy are usually minor and include erythema of the breast tissue and shrinkage of total breast mass beyond that predicted on the basis of surgical resection alone.

### Systemic Adjuvant Therapy

Breast cancer cells can spread by contiguity, lymphatic channels, and blood to distant sites. Tumor cells often metastasize early in cancer growth. Because these deposits cannot be detected with current diagnostic techniques, they are referred to as micrometastases. Systemic adjuvant therapy is treatment that follows definitive local therapy when there is no evidence of disease beyond the axillary nodes but a high likelihood of disease recurrence. Hence, administration of systemic therapy (at a time when the tumor burden is low) should theoretically increase the likelihood of cure and minimize the emergence of drug-resistant tumor cell clones. **KEY CONCEPT** *Most published results confirm that chemotherapy (in selected patients), hormonal therapy (in patients with hormone receptor–positive disease), anti-HER2*

*therapy (in tumors with amplification or overexpression of HER2) or appropriate combinations of these therapies improved disease-free survival (DFS) and/or overall survival (OS) in patients with early-stage breast cancer (see Table 89–2).*

Among the most influential groups that provide treatment recommendations is the St. Gallen International Expert Consensus panel. Convened every 2 years to review new evidence related to therapies for early breast cancer, the most recent conference was held in 2013.[15] In the 2 years since their previous meeting, additional evidence has emerged to support the various types of systemic therapies (see Table 89–2).

▶ *Adjuvant Chemotherapy*

Cytotoxic drugs that have been used most frequently as adjuvant therapy of breast cancer include cyclophosphamide, anthracyclines, taxanes, methotrexate, and fluorouracil. The most common chemotherapy regimens used in the adjuvant setting are listed in Table 89–5. Dose-limiting and other significant toxicities have been previously described in Chapter 88 and are discussed in Table 89–6.

Chemotherapy is usually initiated within 3 weeks of the surgical procedure. Traditionally, treatment consisted of four to six

cycles; and completed in less than 6 months. Dose reduction for standard chemotherapy regimens should be avoided in the absence of severe acute toxicity because of the negative impact on DFS and OS.[16] Even though most patients are able to maintain a reasonable level of functional, emotional, and social well-being during treatment, there are some compelling data indicating that some toxicities can have chronic debilitating effects on quality of life.[17] Various forms of supportive therapy including antiemetics and hematopoietic growth factors for patients receiving systemic adjuvant chemotherapy are discussed in Chapter 99.

As mentioned previously, the usefulness of the intrinsic subtype classification also extends to treatment strategies (see Table 89–2). Since the magnitude of the 10-year survival benefit with cytotoxic agents appears to be only 5% and 10% for patients with negative and positive nodes, respectively, there has been intensive research to identify patients with low-risk disease that could avoid treatment with chemotherapy. One validated multigene assay known as Oncotype DX is used to identify patients with luminal A disease, regardless of nodal involvement, who can be treated with endocrine therapy alone.[18]

**KEY CONCEPT** *It is generally agreed that patients with luminal B, HER2-positive, and basal-like subtypes should receive*

---

### Table 89–5

**Common Chemotherapy Regimens for Breast Cancer**

#### Adjuvant Chemotherapy Regimens

**AC**
Doxorubicin 60 mg/m$^2$ IV, day 1
Cyclophosphamide 600 mg/m$^2$ IV, day 1
Repeat cycles every 21 days for four cycles[a]

**FAC[w]**
Fluorouracil 500 mg/m$^2$ IV, days 1 and 4
Doxorubicin 50 mg/m$^2$ IV continuous infusion over 72 hours[w]
Cyclophosphamide 500 mg/m$^2$ IV, day 1
Repeat cycles every 21–28 days for six cycles[c]

**CAF**
Cyclophosphamide 600 mg/m$^2$ IV, day 1
Doxorubicin 60 mg/m$^2$ IV bolus, day 1
Fluorouracil 600 mg/m$^2$ IV, day 1
Repeat cycles every 21–28 days for six cycles[e]

**FEC**
Fluorouracil 500 mg/m$^2$ IV, day 1
Epirubicin 100 mg/m$^2$ IV bolus, day 1
Cyclophosphamide 500 mg/m$^2$ IV, day 1
Repeat cycle every 21 days for six cycles[g]

**CEF**
Cyclophosphamide 75 mg/m$^2$ orally on days 1–14
Epirubicin 60 mg/m$^2$ IV, days 1 and 8
Fluorouracil 500 mg/m$^2$ IV, days 1 and 8
Repeat cycles every 28 days for six cycles (requires prophylactic antibiotics or growth factor support)[i,j]

**AC → Paclitaxel (CALGB 9344)**
Doxorubicin 60 mg/m$^2$ IV, day 1
Cyclophosphamide 600 mg/m$^2$ IV, day 1
Repeat cycles every 21 days for four cycles
Paclitaxel 175 mg/m$^2$ on day 1

**TAC (BCIRG 001)**
Docetaxel 75 mg/m$^2$ IV, day 1
Doxorubicin 50 mg/m$^2$ IV bolus, day 1

Cyclophosphamide 500 mg/m$^2$ IV, day 1
(doxorubicin should be given first)
Repeat cycles every 21–28 days for six cycles[d]

**Paclitaxel→ FAC[f,w]**
Paclitaxel 80 mg/m$^2$/week IV over 1 hour every week for 12 weeks
Followed by:
Fluorouracil 500 mg/m$^2$ IV, days 1 and 4
Doxorubicin 50 mg/m$^2$ IV continuous infusion over 72 hours
Cyclophosphamide 500 mg/m$^2$ IV, day 1
Repeat cycles every 21–28 days for four cycles[n]

**CMF**
Cyclophosphamide 100 mg/m$^2$/day orally, days 1–14
Methotrexate 40 mg/m$^2$ IV, days 1 and 8
Fluorouracil 600 mg/m$^2$ IV, days 1 and 8
Repeat cycles every 28 days for six cycles[h,j]
*or*
Cyclophosphamide 600 mg/m$^2$ IV, day 1
Methotrexate 40 mg/m$^2$ IV, day 1
Fluorouracil 600 mg/m$^2$ IV, days 1 and 8
Repeat cycles every 28 days for six cycles[i]

**Dose-Dense AC → Paclitaxel**
Doxorubicin 60 mg/m$^2$ IV bolus, day 1
Cyclophosphamide 600 mg/m$^2$ IV, day 1
Repeat cycles every 14 days for four cycles (must be given with growth factor support)
Followed by:
Paclitaxel 175 mg/m$^2$ IV over 3 hours
Repeat cycles every 14 days for four cycles (must be given with growth factor support)[k]
Followed by:
Paclitaxel 175 mg/m$^2$ IV over 3 hours
Repeat cycles every 21 days for four cycles[b]

IV, intravenous.

*chemotherapy (both anthracycline and taxane) with hormonal and/or HER2-targeted therapy if indicated.*[19]

#### ▶ Adjuvant Anti-HER2 Therapy

*HER-2* amplification or overexpression is found in approximately 15% to 20% of all breast cancers. Because of its aggressive features, trastuzumab (plus chemotherapy) is usually indicated in this subset of patients, especially for tumors greater than or equal to 0.5 cm in size. Most experts also agree that HER2-positive tumors appear to derive greater benefit from anthracycline or taxane-based chemotherapy regimens.[20] When used with these agents, trastuzumab is given either following completion of the anthracycline or concurrently with the taxane. Current

evidence indicates that the duration of trastuzumab therapy is 12 months.[21]

#### ▶ Adjuvant Endocrine Therapy

**KEY CONCEPT** *Hormone receptors are used clinically as indicators of prognosis, predictors of response to endocrine therapies, and more recently, discriminators of luminal breast cancer subtypes.* Estrogen and progesterone receptors (PR) are cytoplasmic proteins that bind to nuclear DNA and function as transcription factors. Approximately 50% to 70% of patients with primary and metastatic breast cancer have hormone receptor–positive tumors. However, receptor-positivity refers to tumors expressing both ER and PR, as well as either ER or PR alone. Furthermore,

**Table 89–6**

**Toxicities of Common Chemotherapies Used for Breast Cancer**

| Class | Drug | Dose-Limiting Toxicities | Other Toxicities |
|---|---|---|---|
| Anthracyclines | Doxorubicin, epirubicin | Myelosuppression, cardiomyopathy | Alopecia, nausea, vomiting, stomatitis, ulceration, and necrosis with extravasation, red-colored urine, radiation-recall effect |
| | Liposomal doxorubicin | Myelosuppression, palmar-plantar erythrodysesthesia (hand–foot syndrome) | Alopecia, infusion reactions, stomatitis, fatigue, nausea, vomiting |
| Taxanes | Paclitaxel | Neutropenia, peripheral neuropathy, hypersensitivity reactions | Alopecia, fluid retention, myalgia, skin reactions, ulceration, and necrosis with extravasation, bradycardia, stomatitis |
| | Docetaxel | Myelosuppression, severe fluid retention | Alopecia, fatigue, stomatitis, nausea, vomiting, diarrhea, peripheral neuropathy, nail disorder, skin reactions, hypersensitivity reactions |
| Antimetabolites | Capecitabine | Diarrhea, palmar-plantar erythrodysesthesia (hand–foot syndrome) | Myelosuppression, stomatitis, nausea, vomiting |
| | Gemcitabine | Myelosuppression (especially thrombocytopenia) | Flulike syndrome (fever, chills, myalgias, and arthralgias), nausea |
| | Fluorouracil | Myelosuppression | Stomatitis, diarrhea, alopecia |
| | Methotrexate | Myelosuppression, stomatitis | Diarrhea, nausea, vomiting, renal toxicity |
| Vinca alkaloids | Vinorelbine | Neutropenia | Fatigue, nausea, vomiting, ulceration, and necrosis with extravasation |
| Alkylating agents | Cyclophosphamide | Myelosuppression, hemorrhagic cystitis | Alopecia, stomatitis, amenorrhea, aspermia |

"ER positive" tumors traditionally refer to ERα only. Although it is beyond the scope of this discussion, it is noteworthy to mention the existence, and accumulating data regarding the roles of ERβ and the ERα/ERβ heterodimer in breast cancer.[22,23] Tumors with high expression of both ER and PR (ie, luminal A subtype) are associated with favorable prognoses, superior responses to endocrine therapy, and longer disease-free intervals following initial treatment. Hormone receptor–positive tumors are more common in postmenopausal patients. Many experts also believe that the premenopausal breast cancer is biologically more aggressive than breast cancers diagnosed after menopause.

**KEY CONCEPT** *Hormonal therapies that have been studied in the treatment of early breast cancer include selective estrogen receptor modulators (SERMs, tamoxifen), ovarian suppression (surgical and pharmacologic), and the aromatase inhibitors (AIs).*

Tamoxifen, has been used in the adjuvant setting for nearly four decades. Analysis of long-term data indicates the drug's antagonist (anti-estrogen) effect was associated with a significant reduction in disease recurrence and mortality. This observation, coupled with evidence of the drug's beneficial agonist activity on the lipid profile and bone density supported tamoxifen's role as standard endocrine therapy. However, the agonist properties are also associated with detrimental effects on endometrial tissue and blood coagulation.

In premenopausal women, tamoxifen alone is considered the adjuvant hormonal therapy of choice. Some disagreement exists among experts regarding the utility of combining ovarian function suppression with tamoxifen in women younger than 40 years. Tamoxifen is initiated shortly after surgery or as soon as pathology results are known. However, when chemotherapy is also indicated, tamoxifen is given after all cytotoxic agents have been completed. The rationale for sequential therapy is supported by some data which show a small negative effect on disease-free survival (DFS) when tamoxifen and chemotherapy are given concurrently.

Treatment with adjuvant tamoxifen (20 mg/day) has historically been for 5 years. However, results of a recent clinical trial indicate a survival benefit associated with extending therapy to a total of 10 years.[24] While these data are noteworthy, it should also be noted that the additional 5 years of treatment may not apply to all women. Other issues that make the longer duration of therapy less appealing relate to drug-related toxicities and medication compliance.

Other new evidence of note relates to women who were premenopausal when starting, and postmenopausal at completion, of tamoxifen therapy. In this subset of women, continuation of endocrine therapy with an aromatase inhibitor was associated with a significant improvement in breast cancer-related events, including new primaries in the contralateral breast, disease recurrence, and disease-free survival.[25] So compelling were the results, the clinical trial had to be stopped after a median follow-up of only 2.4 years.

**Patient Encounter, Part 4**

Four months after beginning treatment for the lung metastasis, repeat imaging indicates a complete response (ie, no radiographic evidence of disease) to therapy. However, the patient now states that she has been having more frequent headaches and some problems with balance. An MRI of the head shows several small ring-enhancing lesions in the cerebellum. Biopsy of one of the lesions indicates brain metastasis.

*Explain your choice of therapy in this patient with brain-only metastasis.*

## Patient Encounter, Part 5

Routine mammography in your patient, a 62-year-old grandmother indicates an area on the right breast that appears to be consistent with atypical changes but not highly suspicious for cancer. However, because of her family history (sister with breast cancer), a fine-needle aspirate of the breast tissue was obtained for histologic examination. Molecular markers show great promise as an adjunct to a tissue diagnosis of cancer. On the other hand, we must ensure that these tests are accurate indicators of malignant disease. Pathology used a new molecular test with modest sensitivity (ie, 80%) but very high specificity (ie, 99%) on the tissue sample to further analyze the radiographic abnormality. Although the test was negative, the tissue findings were consistent with atypical hyperplasia.

*Summarize what would be appropriate to tell this 62-year-old woman regarding the needle aspirate findings.*

*Formulate a follow-up plan for this patient.*

Finally, the issue regarding the role of pharmacogenomics in tailoring tamoxifen therapy is both persuasive and controversial.[26,27] As such, routine screening for germline variants of CYP2D6 has not been endorsed. Nonetheless, drugs that do inhibit the enzyme should be avoided if possible.

In postmenopausal women, the use of adjuvant AIs has been studied in three different ways: (a) direct comparison with tamoxifen, (b) after 5 years of tamoxifen therapy, and (c) sequentially after 2 to 3 years of tamoxifen.[28] Based on the positive results of several studies, expert panels strongly recommend AIs for postmenopausal women with hormone-dependent breast cancer.[29] Although 5 years of adjuvant AI therapy is considered standard, there is also strong support for continuing hormonal therapy (beyond 5 years) if tamoxifen was used initially, especially in patients with high-risk features such as node-positive disease. Further support of extended endocrine therapy that includes an AI has been noted previously.[25] While these recommendations can be applied to most postmenopausal patients, tamoxifen can still be used first line or as an alternative in those who do not tolerate AI therapy.

AI therapy is associated with several adverse effects, including hypercholesterolemia, atherosclerotic cardiovascular disease, and skeletal-related events. The three available AIs are anastrozole, letrozole, and exemestane (Table 89–7).

# LOCALLY ADVANCED BREAST CANCER (STAGE III)

## TREATMENT
### Desired Outcome

Locally advanced breast cancer is defined by tumors greater than or equal to 5 cm and a high likelihood of nodal involvement in the absence of demonstrable distant metastasis. A wide variety of clinical scenarios can be seen within this group of patients, including tumors that have been neglected for a period of time and inflammatory breast cancer, which is a unique clinical entity. Inflammatory breast cancer has, at times, been misdiagnosed as cellulitis.

Treatment of stage III breast cancer consists of all modalities used in the management of early breast cancer. The goal of therapy is to achieve optimal systemic control of the disease. However, despite treatment, systemic relapse and death are common even when local-regional control is accomplished. One major difference related to the systemic therapies is the use of chemotherapy plus ant-HER2 therapy (if indicated) or hormonal therapy before surgery. This approach, referred to as neoadjuvant therapy, can render initially inoperable tumors resectable, even with the possibility of BCS. It is also conceivable that earlier administration of systemic therapy could have therapeutic benefits beyond surgical

---

### Table 89–7

**Endocrine Therapies Used for Metastatic Breast Cancer**

| Class | Drug | Dose | Side Effects |
|---|---|---|---|
| **Aromatase inhibitors** | | | |
| Nonsteroidal | Anastrozole | 1 mg/day PO | Hot flashes, arthralgias, myalgias, headaches, diarrhea, mild nausea |
| | Letrozole | 2.5 mg/day PO | |
| Steroidal | Exemestane | 25 mg/day PO | |
| **Antiestrogens** | | | |
| SERMs | Tamoxifen | 20 mg/day PO | Hot flashes, vaginal discharge, mild nausea, thromboembolism, endometrial cancer |
| | Toremifene | 60 mg/day PO | |
| SERDs | Fulvestrant | 250 mg IM every 28 days | Hot flashes, injection site reactions, possibly thromboembolism |
| **LHRH analogues** | Goserelin | 3.6 mg SC every 28 days | Hot flashes, amenorrhea, menopausal symptoms, injection site reactions |
| | Leuprolide | 7.5 mg IM every 28 days | |
| | Triptorelin | 3.75 mg IM every 28 days | |
| **Progestins** | Megestrol acetate | 40 mg PO 4 for a day | Weight gain, hot flashes, vaginal bleeding, edema, thromboembolism |
| | Medroxyprogesterone | 400–1000 mg IM every week | |
| **Androgens** | Fluoxymesterone | 10 mg PO twice a day | Deepening voice, alopecia, hirsutism, facial or truncal acne, fluid retention, menstrual irregularities, cholestatic jaundice |

IM, intramuscular; LHRH, luteinizing hormone–releasing hormone; PO, oral; SC, subcutaneous; SERD, selective estrogen receptor downregulator; SERM, selective estrogen receptor modulator.

resection. Other potential advantages include in vivo assessment of treatment response, and an opportunity to evaluate the biologic effects of the systemic therapy. However, nodal status will not be assessable.

## Pharmacologic Therapy

For patients with inoperable breast cancer, including inflammatory breast cancer, one of the treatment objectives is to obtain tumor resectability. The guidelines for selection and duration of systemic neoadjuvant chemotherapy are similar to the adjuvant setting. Available data support the use of anthracycline-containing regimens, incorporation of the taxanes, and approaches to improve dose-density or dose-intensity. Neoadjuvant endocrine therapy may be an option for patients who have unresectable, strongly hormone receptor–positive tumors, low risk factors, or are unable to receive chemotherapy because of comorbid medical conditions. When endocrine therapy is used, treatment is continued to maximal response. Even though not an approved indication, several clinical studies have demonstrated the efficacy of neoadjuvant trastuzumab in combination with chemotherapy in patients with HER2-overexpressing tumors. Interestingly, pertuzumab is the only HER2-targeted agent approved in the neoadjuvant setting when used in combination with trastuzumab and docetaxel. Regardless of therapeutic approach, about two-thirds of the tumors can be downstaged.

In terms of local therapy, the extent of surgery will be determined by tumor response to neoadjuvant therapy, patient wishes, and cosmetic results likely to be achieved. To minimize local recurrence, adjuvant radiation therapy should be administered to all patients with locally advanced breast cancer who undergo mastectomy or BCS. Inoperable tumors that are unresponsive to systemic chemotherapy may require radiation for local management; however, these tumors may be ineligible for subsequent surgical resection. This situation is associated with a very poor prognosis though not commonly seen.

## METASTATIC BREAST CANCER (STAGE IV)

### TREATMENT
#### Desired Outcome

**KEY CONCEPT** *The goals of therapy for patients with metastatic breast cancer are maintaining or improving quality of life and prolonging survival, if possible. In order to achieve these goals, an important consideration is selecting therapy with good activity and tolerability.*

#### General Approach to Treatment

**KEY CONCEPT** *The choice of therapy for metastatic disease is based on receptor expression status (ie, hormone and HER2) and distant disease sites. In many instances, age and comorbid medical problems will also be considered. While the choice between endocrine and cytotoxic chemotherapy is usually the hormone receptor status of the tumor, sites of metastatic disease may also influence treatment decisions.* For example, in patients with ER positive breast cancer with soft tissue or bone-only metastasis (without impending fracture), endocrine therapy alone is usually warranted. Hormonal therapy can even be considered in patients with asymptomatic visceral involvement. In contrast, chemotherapy is usually the initial treatment option for hormone-dependent breast cancer in patients who present with significant life-threatening metastasis to liver and/or lung. When

### Patient Encounter, Part 6

The patient missed her next two mammograms and returned to the clinic 30 months later than originally scheduled. Imaging studies performed at this time showed definite changes and an irregular lesion measuring 1.6 × 1.9 cm at its greatest diameters. Core biopsy of the mass lesion was interpreted by pathology as malignant adenocarcinoma of the breast. Further testing indicated an ER-positive/PR-negative, HER2-negative, well-differentiated tumor. Staging indicated several "hot spots" in the femur and pelvis consistent with metastatic disease. There is no tumor involvement of visceral organs, lungs, or brain.

*Outline the most appropriate way to manage this patient's breast cancer. Appraise the patient's overall prognosis.*

used, chemotherapy is continued to maximal response. Patient encounters, part 6 and part 7 illustrate these concepts further. Patients with tumors responding initially to endocrine therapies are often treated with chemotherapy when endocrine options are exhausted or symptomatic visceral metastasis develops. Approximately 75% to 80% of tumors positive for both ER and PR respond to initial hormonal therapy; responses decrease to 50% to 60% for ER positive/PR negative tumors. The best predictor of response to second- and, possibly, third-line endocrine therapies is extent and duration of the initial response. Nevertheless, tumor responses are frequently lower and durations shorter with subsequent hormonal therapies.

**KEY CONCEPT** *Endocrine therapy is not indicated for tumors that do not express at least one of the hormone receptors. Patients with receptor negative tumors should be treated with cytotoxic chemotherapy. Objective responses are achieved in 50% to 60% of patients who have not received prior chemotherapy though less than 20% of the responses are complete.* The duration of response to first-line therapy is usually less than 12 months. Although very uncommon, responses to initial treatment can be extremely durable with patients living years without evidence of disease. The response rate to second- and third-line chemotherapy varies from 20% to 40%. Combinations of different hormonal therapies or chemotherapy plus endocrine therapy are not used in the metastatic disease setting because of increased toxicity without added benefit.

In general, the duration of overall survival of patients with advanced breast cancer ranges between 14 and 33 months.

### Pharmacologic Systemic Therapy
#### ▶ Endocrine Therapy

The operative mode of all endocrine therapies is estrogen deprivation. The pharmacologic goals of treatment include decreasing the levels of circulating estrogen and/or preventing the effects of estrogen on tumor tissue through hormone receptor blockade or downregulating receptor expression. Achievement of these goals is independent of menopausal status. Many available endocrine therapies can accomplish these goals. Combined endocrine therapies also have been studied in an attempt to improve patient outcomes with negative results. As such, patients usually receive sequential endocrine therapies before chemotherapy is considered.

Until the turn of the century, evidence did not support the superiority of one type of endocrine therapy with regards to

response or survival. Because of the similarity in efficacy, selection of endocrine therapy was based primarily on their toxicity prolife (see Table 89–7), which favored tamoxifen. The only exception to this choice of therapy occurred in patients who received adjuvant tamoxifen and subsequently developed metastatic disease within 1 year of drug cessation.

Over the past 15 years, accumulating evidence related to the AIs has changed the way postmenopausal women with hormone-dependent metastatic breast cancers are treated. After menopause, estrogens continue to be produced by extragonadal conversion of androstenedione and testosterone to estrone and estradiol. This biosynthetic process, which is dependent on aromatase, occurs in peripheral tissue, including muscle, adipose, and even the breast itself. Therefore, AIs effectively reduce the level of circulating estrogens, as well as estrogens in the target gland. Their toxicity profile has been described in Chapter 88 and Table 89-7. Anastrozole and letrozole are nonsteroidal compounds that competitively inhibit aromatase. Exemestane is a steroidal compound that binds irreversibly (by forming a covalent bond) to aromatase. However, this biochemical distinction does not translate into clinical superiority with exemestane.

The AIs are used as first-line therapy for ER-positive advanced breast cancer in postmenopausal women.[30] Large trials have compared these agents with tamoxifen and have found similar response rates and a longer median time to progression for patients receiving the selective AIs. A consistent observation in these trials was a lower incidence of thromboembolic events, endometrial cancer, and vaginal bleeding in patients treated with an AI. Collectively, these findings led to the recommendation that AI therapy be used as first-line therapy for advanced breast cancer in postmenopausal women. Of note also, several small studies indicate that regardless of which subclass of AI is used initially, approximately 50% of the patients will have further antitumor benefit after switching to the other subclass suggesting that cross-resistance is incomplete. Therefore, postmenopausal patients may receive two AIs as first- and second-line therapies.

The AIs are only used in postmenopausal women. Even though ovarian estrogen production relies on the same enzymatic pathway discussed earlier, premenopausal or perimenopausal women with functioning ovaries are not appropriate candidates for these therapies. The reason is physiologic as evidence indicates that negative endocrine feedback will overcome aromatase inhibition. Early clinical data also suggested that the strategy of combining an AI with ovarian suppression (ie, oophorectomy or LHRH agonists) may be a therapeutic option in premenopausal women. Currently, this option is considered inappropriate unless a strict contraindication to tamoxifen exists.

The use of AIs in men with advanced breast cancer should be avoided. Available data suggest the use of these agents in men increases circulating levels of testosterone, which may negate the therapeutic effects of the drug.

Antiestrogens bind to ERs, preventing receptor-mediated gene transcription, and therefore are used to block the effect of estrogen on the end target. This class of agents is subdivided into two pharmacologic categories, SERMs and SERDs (selective estrogen-receptor downregulators). SERMs like tamoxifen have tissue-specific estrogenic and antiestrogenic activities. The effort to minimize or eliminate the adverse estrogenic effects led to the development of SERDs, which are pure estrogen receptor antagonists. The distinguishing feature of SERDs is their ability to degrade the ligand–ER complex.

Tamoxifen can be used in both premenopausal and postmenopausal women with ER positive, metastatic breast cancer. Toxicities associated with tamoxifen have been previously described. The only additional acute adverse effect, which occurs in about 5% of the patients with bone metastasis is tumor flare or hypercalcemia following initiation of tamoxifen. Generally, this acute reaction is not an indication to discontinue treatment. Conversely, this finding appears to correlate with subsequent response to endocrine therapy.

Fulvestrant is the only SERD approved for clinical use in the United States. The drug is approved as second-line therapy of postmenopausal patients with hormone-dependent advanced breast cancer. Clinical studies conducted in postmenopausal patients with disease progressing on tamoxifen compared fulvestrant against anastrozole. Results of these trials indicated similar efficacy and acceptable tolerability. The side effect observed with fulvestrant only was dermal reactions at the injection site. Even though fulvestrant is a good option for patients who are unable to take an oral medication, some patients may be averse to the drug because it must be given intramuscularly. There is no biological reason why fulvestrant should not produce similar outcomes in premenopausal women; however, safety or efficacy data are lacking.

Estrogen production in premenopausal women can be effectively achieved by surgery, pharmacologic agents, or radiation. Results of two randomized clinical trials evaluating the overall response rate between oophorectomy and tamoxifen were not significantly different. Interestingly, secondary response rates to oophorectomy after tamoxifen treatment were somewhat higher than response rates to tamoxifen after oophorectomy (33% versus 11%). Interpretation of these findings suggests that tamoxifen does not completely antagonize available estrogen, particularly in premenopausal women. Ovarian ablation (surgically or chemically) is still commonly performed in parts of the United States and is considered by some to be the endocrine therapy of choice in premenopausal women with advanced disease. The mortality rate with surgical oophorectomy is less than 3% in appropriately selected patients.

Castration can also be achieved pharmacologically with LHRH agonists. An initial surge in luteinizing hormone (LH) and estrogen production during the first few weeks of treatment can cause a tumor flare reaction similar to tamoxifen. With continued therapy, this strategy induces remission in about one-third of unselected patients. LHRH agonists purportedly downregulates LHRH receptors in the pituitary resulting in decreased LH release and castrate levels of estrogens. Of the three agents available in the United States (ie, leuprolide, goserelin, and triptorelin), only goserelin is approved for the treatment of metastatic breast cancer.

In randomized trials, progestins such as megestrol acetate and medroxyprogesterone acetate have been shown to induce noninferior response rates when compared with tamoxifen. Megestrol acetate is used more frequently in the United States. Despite their efficacy, these agents are generally used after patients have received an AI and/or tamoxifen. The most common side effects are listed in Table 89-7. One side effect, weight gain, occurs in 20% to 50% of patients. Patients experiencing weight gain may have fluid retention, but fluid retention is not responsible for all of the weight gain. In cachectic cancer patients, the weight gain may be desirable, but this is not uniformly true of all patients with metastatic breast cancer.

High-dose estrogens and androgens are rarely used because they are more toxic than other hormonal agents and in some cases less effective. About one-third of patients placed on high-dose estrogens will discontinue the use of these agents because

side effects, the most important of which are thromboembolic events, vomiting, and fluid retention.

#### ▶ *Cytotoxic Chemotherapy*

Except for brain and spine (with impending cord compression), chemotherapy is given as initial treatment of metastasis in patients with hormone receptor–negative tumors. The median time to an objective response is 2 to 3 months, but this period depends largely on the site of measurable disease. For example, time to response is 3 to 6 weeks for disease localized primarily to skin and lymph nodes; 6 to 9 weeks lung lesions; 15 weeks for liver metastasis; and 18 weeks for bone involvement. Once chemotherapy has been initiated, it is usually continued until maximal response, disease progression, or intolerable toxicity.

Unlike endocrine therapy, no clinical characteristic or established test has been shown to predict benefit from chemotherapy. However, a number of factors are associated with likelihood of tumor response, including good performance status, limited number (one or two) of disease sites, treatment naïve status, and previous response to chemotherapy with a long disease-free interval. Tumors that progress while being treated may respond to different agents. Importantly, tumors that do not respond to endocrine therapy are as likely to respond to chemotherapy as tumors treated with cytotoxic agents first. If not used initially, chemotherapy is eventually required in most patients with advanced breast cancer.

Although many chemotherapeutic agents have demonstrated activity in the treatment of breast cancer, the most frequently used agents include all of the agents used in the adjuvant setting plus nab-paclitaxel, capecitabine, gemcitabine, ixabepilone, and vinorelbine. **KEY CONCEPT** *The most active classes of chemotherapy in metastatic breast cancer are the anthracyclines and the taxanes with response rates as high as 50% to 60% in patients who have not received prior chemotherapy for metastatic disease.* A brief discussion of some chemotherapy-related issues specific to breast cancer extends upon what is described in Chapter 88.

#### Taxanes

In the metastatic setting the most effective weekly dose of paclitaxel appears to be 80 mg/m$^2$/week with no breaks in therapy. With this approach, the toxicity profile of paclitaxel changes with less myelosuppression and delayed onset of peripheral neuropathy but slightly more fluid retention and skin and nail changes.

A dose-response relationship has been demonstrated with docetaxel. However, at 100 mg/m$^2$ every 21 days, the positive impact was limited to ORR. Therefore, asymptomatic patients who may not require a rapid clinical response, dosages in the range of 60 mg/m$^2$ to 75 mg/m$^2$ are appropriate. While less neuropathy, myalgia, and hypersensitivity reactions are observed with docetaxel (compared to paclitaxel), the incidence of febrile neutropenia, fluid retention, and skin reactions is higher. A weekly schedule of docetaxel, 35 mg/m$^2$, six doses of an 8-week cycle is also very active and more tolerable than the 3-weekly schedule.

Nanoparticle albumin-bound (nab)-paclitaxel exhibits some advantages over conventional paclitaxel. Comparatively, treatment with nab-paclitaxel, 260 mg/m$^2$, produced significantly better ORRs and median TTP than standard dose paclitaxel, 175 mg/m$^2$. Despite the higher dosage, the incidence of severe neutropenia was significantly lower with nab-paclitaxel. Nab-paclitaxel is indicated for patients with metastatic breast cancer resistant to conventional chemotherapy or progressing within 6 months of receiving an adjuvant anthracycline-containing chemotherapy regimen.

### Antimetabolites

Capecitabine has activity against tumors progressing on anthracycline-and taxane-containing regimens. Moreover, the drug exhibits somewhat selective activity against cancer cells. This belief is supported by the presence of higher tumor cell levels of thymidine phosphorylase, the enzyme which catalyzes the final step in the conversion of capecitabine to 5-FU. In previously treated patients, capecitabine produced response rates of about 25%, which was impressive compared with other tested chemotherapy agents.

Gemcitabine is another agent that is used frequently in patients with advanced breast cancer. This nucleotide analogue has a unique mechanism of action and a favorable toxicity profile. As a single agent, response rates of nearly 40% have been achieved in the first-line setting. However, ORRs up to 90% have been obtained when gemcitabine was combined with doxorubicin or epirubicin and paclitaxel as first-line treatment. Response rates to gemcitabine monotherapy in the second- and third-line settings are approximately 18% to 26%. When combined with one other agent such as a taxane, vinorelbine, cisplatin, or an anthracycline, results of clinical studies consistently demonstrated higher efficacy than either single agent. In patients who have been exposed to an anthracycline and a taxane, gemcitabine appears to provide similar benefit to capecitabine.

### Epothilone

In vitro studies show that the antimicrotubule activity of ixabepilone is similar to the taxanes. The results of a phase 3 clinical trial demonstrated that the combination of ixabepilone plus capecitabine significantly improved PFS by 38% while the ORR was more than twice as high with the combination compared with capecitabine alone (35% vs 14%, respectively).[31] Even in patients with disease intrinsically resistant to previous taxane therapy, response rates were twice as high with the combination. The findings from this study support preclinical data that the antitumor activity between ixabepilone and capecitabine are at least additive and, possibly, synergistic. However, the improved outcomes must be balanced against a much higher incidence of adverse effects involving the bone marrow and peripheral nervous system. Five infection-related deaths occurred with combination therapy. In addition, two-thirds of the patients developed variable grades of sensory neuropathy; 21% of the all patients discontinued treatment because of this adverse effect. Ixabepilone is approved for use in combination with capecitabine for patients with advanced breast cancer resistant to or progressing on previous anthracycline and taxane therapy or for patients

---

#### Patient Encounter, Part 7

Unfortunately, this patient's disease progresses after 11 months of treatment. She now complains of right abdominal quadrant pain. Her liver exhibits rebound tenderness. She is nauseated and weak from dehydration. CT of her abdomen indicates multiple lesions in both lobes of the liver, which are consistent with recurrent disease. Liver function tests are two times the upper limit of normal. A month ago, her performance status was 1; now it is 3 and metastasis related.

*Propose a plan to manage the patient.*

in whom anthracyclines are contraindicated. The use of single-agent ixabepilone is approved for use in patients with disease resistant to capecitabine.

## Vinca alkaloid

Although not approved for breast cancer, activity has been observed with vinorelbine therapy in patients with advanced disease. However, some of the more intriguing data are associated with the combination of vinorelbine and trastuzumab. In a small cohort of patients with HER2-positive, metastatic breast cancer, an ORR of 68% was achieved; 38% of patients were progression-free after 1 year. Importantly, none of the antimicrotubule agents appears to be cross-resistant with the anthracyclines.

## General Comments

Combination chemotherapy regimens are usually associated with higher response rates than are single-agent therapies, but the higher response rates do not necessarily translate into significant differences in OS. The use of sequential single-agent therapy versus combination chemotherapy regimens has been debated widely for metastatic breast cancer. In fact, current consensus regarding first-line chemotherapy is the use of single agents or combination chemotherapy.[32] In the palliative metastatic setting, the least toxic approach is preferred when efficacy is considered equal. In clinical practice, patients who require a rapid response to chemotherapy (eg, those with symptomatic bulky metastases) often receive combination therapy despite the added toxicity. This decision is complex and should be made on an individual patient basis.

Because many patients receive adjuvant chemotherapy, regimens chosen for first-line use in the metastatic setting often are different from those used in the adjuvant setting with the following caveat. If the patient's cancer recurs more than 1 year after the end of adjuvant chemotherapy, the same agents may have activity in the metastatic disease setting.

### ▶ Targeted Biologic Therapy

All breast cancers are tested for HER2 by immunohistochemistry (IHC) and/or fluorescence in-situ hybridization (FISH). Notably, an IHC score of 2+ (on a 0–3+ scale) for HER2 is associated with little to no benefit with trastuzumab therapy. Moreover, the 2+ IHC score is often negative by the more sensitive and specific FISH technique. As such, targeted anti-HER2 therapies are only indicated for breast cancers that overexpress the receptor at the 3+ level by IHC and/or demonstrate gene amplification by FISH.

Trastuzumab is a humanized monoclonal antibody that recognizes a specific extracellular epitope of HER2. Single-agent treatment with trastuzumab produces responses in approximately 15% to 20% of patients; the clinical benefit rate, which includes CRs, PRs, and stable disease is nearly 40%. Trastuzumab has additive and perhaps synergistic activity with chemotherapeutic agents.[33] Because cardiac toxicity is associated with the antibody, trastuzumab is given after all cycles of the anthracyclines have been completed. A non–anthracycline-containing regimen with excellent activity is the combination of docetaxel and carboplatin with concurrent trastuzumab.[34] Other chemotherapy agents that are being evaluated in combination with trastuzumab include vinorelbine, gemcitabine, capecitabine, and the platinum agents (eg, cisplatin and carboplatin).

Trastuzumab is reasonably well tolerated. The most common adverse effects are first dose infusion-related chills which occur in about 40% of patients. To alleviate the symptoms, acetaminophen and diphenhydramine may be given and/or the infusion rate may be reduced. Rare severe adverse effects including hypersensitivity and/or pulmonary reactions have also been reported. It is important to educate patients regarding the pulmonary reactions because they may occur up to 24 hours after the infusion and can be fatal if not treated promptly. Trastuzumab may increase the incidence of infection, diarrhea, and/or other adverse events when given with chemotherapy. When trastuzumb is given with an anthracycline, the rates of heart failure are unacceptably high; even as a single agent, cardiac events have approached 5%. Fortunately, this toxicity is usually reversible though patients may require pharmacologic management. Some patients have even continued therapy with trastuzumab after their left ventricular ejection fraction has returned to normal. Close monitoring for clinical signs and symptoms of heart failure is important in order to intervene with appropriate cardiac treatments.

Lapatinib is a dual inhibitor of HER2 and the epidermal growth factor receptor (EGFR, HER1). In contrast to the extracellular recognition site of trastuzumab, the specific targets of lapatinib are the receptors' intracellular kinase domain. A pivotal phase 3 clinical trial was conducted to assess the efficacy and safety of lapatinib plus capecitabine versus capecitabine alone in patients with disease progressing on trastuzumab. The trial was terminated early when a preplanned interim analysis indicated a significant reduction in risk of disease progression that favored the combination arm. Of note, the incidence of brain metastasis was significantly lower in the lapatinib-treated group.[35]

The side-effect profile of lapatinib is described in Chapter 88. A few side effects such as diarrhea, dyspepsia, and rash occurred more frequently when lapatinib was combined with capecitabine. Importantly, the lapatinib doublet was not associated with cardiac events resulting in subject withdrawal.

In May 2014, the American Society of Clinical Oncology (ASCO) issued two clinical practice guidelines related to lapatinib for the treatment of advanced, HER2-positive breast cancer. First, depending on hormone receptor status, third-line therapy may include hormonal therapy or chemotherapy with trastuzumab and in some cases with lapatinib or the combination of trastuzumab and lapatinib; and second, in patients with brain metastases systemic therapies with lapatinib and capecitabine is one option that can be considered for patients with a poor prognosis for survival.

A new HER2-targeted agent called pertuzumab received FDA approval in June 2012. Although both pertuzumab and trastuzumab are monoclonal antibodies that inhibit HER2-mediated signaling, a number of differences exist. First, each agent recognizes different extracellular epitopes, a finding that could have important therapeutic ramifications. Second, the unique binding site of pertuzumab induces structural changes that hinder receptor dimerization. Theoretically, by inhibiting HER2 signaling initiated by ligand-activated HER1 or HER3, pertuzumab could provide even greater inhibition of HER2 than trastuzumab. However, this does not appear to be case. In fact, compared to trastuzumab, pertuzumab has exhibited less activity. Based on results of a phase 3 clinical trial, pertuzumab is indicated for use as first-line therapy (in combination with trastuzumab and docetaxel) for HER2-positive metastatic breast cancer.[36] The most frequently reported adverse observed in clinical trials involving pertuzumab was diarrhea; cardiac toxicity was similar to, but does not appear to be increased when used concurrently with, trastuzumab.

One of the most significant limitations of cytotoxic chemotherapy is the lack of tumor specificity. Coupling target selectivity with the observation that trastuzumab's modest antitumor

effect was substantially improved by the addition of chemotherapy led to the idea that antibodies could be used to deliver chemotherapy rather specifically to tumor cells. However, the efficacy of antibody-chemotherapy (drug) conjugates (ADCs) has historically been limited by variable expression of the target antigen, defective tumor cell uptake mechanisms, and unreliable linkers used in the conjugation process.

A novel therapeutic compound known as trastuzumab-DM1 (T-DM1, trastuzumab emtansine) has been developed that appears to have resolved all of the above issues. Because HER2 is overexpressed in approximately 20% of breast cancers, trastuzumab was identified as a reasonable vehicle for drug delivery. In order to improve the therapeutic index of the attached chemotherapeutic agent, a maytansine derivative was synthesized. The resulting maytansinoid, emtansine, was configured to have an easily cleavable linker to trastuzumab. The resulting ADC has the potential not only of retaining the antitumor properties of the individual agents but also maintaining a tolerable side-effect profile.

The most significant results were reported in a phase 3 clinical trial which compared T-DM1 against the combination of lapatinib plus capecitabine as second-line therapy for patients with HER2-positive breast cancer progressing on trastuzumab and a taxane.[37] Primary end points were PFS, OS, and tolerability. Compared to the capecitabine/lapatinib arm, T-DM1 significantly reduced the risk of disease progression or death by 35%. Median OS at the second interim analysis crossed the prespecified efficacy stopping boundary. The most common grade more than or equal to 3 toxicity observed in patients receiving T-DM1 arm was thrombocytopenia. Platelet nadirs occurred 7 days after drug administration and recovered within a week. Other frequently occurring side effects included liver function test abnormalities, hypokalemia, fatigue, nausea, and headache. However, none of these adverse events were greater than grade 2. Cardiac toxicity requiring treatment discontinuation was not observed. The results of this study led to FDA approval in February 2013.

Two noteworthy phase 3 clinical trials involving this novel ADC are in progress. The first compares T-DM1 with or without pertuzumab against trastuzuamb plus a taxane as first-line treatment of HER2-positive, progressive or recurrent locally advanced or metastatic breast cancer; the second, T-DM1 versus trastuzumab as adjuvant therapy for patients with HER2 positive primary breast cancer who have residual tumor present pathologically in the breast or axillary lymph nodes following preoperative therapy.

▶ *Bisphosphonates*

For women whose breast cancer has metastasized to bone, bisphosphonates are recommended, in addition to chemotherapy or endocrine therapy, to reduce bone pain and fractures. Pamidronate (90 mg) and zoledronate (4 mg) can be given IV once each month. These bisphosphonates are given in combination with calcium and vitamin D.

## Local-Regional Control

▶ *Radiation Therapy*

Radiation is an important modality in the treatment of symptomatic metastatic disease. The most common indication for treatment with radiation therapy is painful bone metastases or other localized sites of disease refractory to systemic therapy. Approximately 90% of patients who are treated for painful bone metastases experience significant pain relief with radiation therapy. Additionally, radiation is an important modality in the palliative treatment of metastatic brain lesions and spinal cord lesions, which respond poorly to systemic therapy, as well as eye or orbit lesions and other sites where significant accumulation of tumor cells occurs. Open or painful skin wounds and/or lymph node metastases confined to the chest wall area may also be treated with radiation therapy for palliation.

## Patient Care Process: Breast Cancer

**Patient Assessment:**

- Detail key aspects of the patient's history related to the breast cancer diagnosis. Describe the circumstances (ie, screening or physical findings) underlying the cancer diagnosis. Determine patient risk factors for the disease.
- Summarize disease stage, prognosis, and treatment goals.

**Therapy Evaluation:**

- Formulate rational treatment plans for premenopausal and postmenopausal women with early breast cancer in each of the following situations: (1) luminal A; (2) luminal B; (3) HER2 positive; and (4) basal subtype. Determine surgical options, radiation therapy, and systemic therapies as indicated.
- Formulate rational treatment plan for a patient with locally advanced breast cancer (including surgical options, radiation therapy, and systemic therapies as indicated).
- Formulate rational treatment plans for premenopausal and postmenopausal women with metastatic breast cancer in each of the following situations: (1) luminal A; (2) luminal B; (3) HER2 positive; and (4) basal subtype. Determine systemic therapies as indicated.

**Care Plan Development:**

- Articulate components of the overall management plan with a focus on pharmacologic agents, their relevant side effects especially with regard to probability and timing of occurrence, and appropriate prophylaxis and/or management.
- Propose a plan for the supportive care of the patient.
- Identify and assess key endpoints (especially with regards to quality of life issues) related to pharmacotherapeutic management of the patient.

**Follow-Up Evaluation:**

- Address adverse events and modify the treatment plan accordingly.
- Reeducate the patient regarding any change(s) to the treatment plan.
- Explain the importance of patient reporting of adverse events and adherence with the prescribed medication regimen.

## OUTCOME EVALUATION

Early breast cancer is resected completely with curative intent and adjuvant chemotherapy and/or hormonal therapy with trastuzumab in selected patients are initiated to prevent recurrence. During adjuvant chemotherapy, laboratory values to monitor chemotherapy toxicity are obtained before each cycle of treatment. After completion of adjuvant therapy, patients are monitored every 3 months for the first few years after diagnosis, with intervals between examinations extended as time from diagnosis lengthens. Evaluation includes:

- Physical examination to detect breast cancer recurrence
- Annual mammography
- Symptom-directed workup

Patients with locally advanced breast cancer are often treated with neoadjuvant therapy to make the tumor surgically resectable. However, many believe that neoadjuvant therapy may have benefits that extend beyond downstaging. During neoadjuvant chemotherapy, laboratory values to monitor chemotherapy toxicity are obtained before each cycle and weekly thereafter while on treatment; physical and ultrasound examinations to determine the size of the tumor are performed following a complete course of neoadjuvant therapy. Generally, no further chemotherapy is given after surgery. After complete surgical resection, monitoring proceeds as described for early breast cancer.

Metastatic breast cancer is not curable, and therapy is intended to palliate symptoms and prolong survival. In most cases, hormonal therapy is the mainstay for tumors that are ER positive. While on therapy, patients are monitored monthly for signs of disease progression or metastasis to common sites, such as the bones, brain, or liver. Evaluations include:

- Pain
- Mental status or other neurologic findings
- Laboratory tests
- Liver function tests
- Complete blood count
- Calcium, electrolytes

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| AI | Aromatase inhibitor |
| DFS | Disease-free survival |
| ER | Estrogen receptor |
| HER2 | Human epidermal growth factor receptor 2 |
| LHRH | Luteinizing hormone-releasing hormone |
| ORR | Overall response rate |
| OS | Overall survival |
| PFS | Progression-free survival |
| PR | Progesterone receptor |
| SERD | Selective estrogen-receptor downregulators |
| SERM | Selective estrogen receptor modulator |
| TNM | Tumor, node, metastasis (staging system) |
| TTP | Time to progression |

# Lung Cancer

Val Adams and Justin Balko

## LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Identify major risk factors for the development of lung cancer.

2. Explain the pathologic progression of lung cancer and its relationship with signs and symptoms of the disease.

3. Make appropriate recommendations for screening or preventive measures in high-risk patients.

4. Understand staging of lung cancer patients and how it influences treatment decisions.

5. List the rationale, advantages, disadvantages, and place in therapy for adjuvant and neoadjuvant chemotherapy.

6. Identify the chemotherapeutic or molecularly targeted regimens of choice for limited and extensive small cell lung carcinoma, as well as local, locally advanced, and advanced non–small cell lung carcinoma.

7. Monitor patients for treatment-associated toxicity and recommend appropriate management.

8. Distinguish the treatment goals of palliative care versus those of first-line treatment.

## INTRODUCTION

Lung cancer has a major health impact both in the United States and worldwide. Before 1930, lung cancer was a relatively rare disease, but a sharp incline in industrialization and smoking in the early 1900s has bred an epidemic. Lung cancer has a high mortality rate, and although treatment can cure some patients, most therapies only prolong survival for months. Recent advances in lung cancer research provide good reason for optimism but antismoking campaigns still appear to offer the best opportunity to reduce lung cancer incidence and mortality.

## EPIDEMIOLOGY AND ETIOLOGY

### Incidence and Mortality

Cancers of the lung and bronchus rank first in cancer-related mortality, comprising more than 28% of cancer-related deaths.[1] In 2015, more than 1,500 new cases of lung cancer are expected. A close correlation exists between incidence and mortality of lung cancer, reflecting the reality that approximately 70% of lung cancer patients ultimately die of the disease.

### Clinical Risk Factors

#### ▶ Smoking

**KEY CONCEPT** *The most important risk factor for the development of lung cancer is smoking.* One of the most predictive factors on lung cancer epidemiology is prevalence of cigarette smoking. Because lung cancer is a fatal disease in most cases, both incidence and mortality strongly reflect the smoking prevalence of the population on a 20- to 30-year lag. In other words, decreases

in tobacco use now would be expected to affect lung cancer incidence in 2040. With this knowledge, the current expectation is that lung cancer incidence and mortality will decrease steadily until 2020, reflecting decreases in cigarette smoking between 1970 and 1990. Because smoking prevalence has been constant since 1990, lung cancer incidence is expected to plateau.[2] Correlation between smoking and lung cancer continues to drive antismoking and clean indoor air campaigns and should be considered an investment in the future health care of the nation. Furthermore, smoking cessation plays an important role in reducing lung cancer risk on a patient-to-patient basis, and appropriately guiding such therapy is a crucial part of preventing lung cancer in at-risk patients.[3] Both total smoke exposure and current use correlate with the individual's risk of developing malignancy. The risk of lung cancer decreases to near-normal levels 10 to 15 years following successful smoking cessation. Total smoke exposure is reported as pack-years. One pack-year is the equivalent of smoking one pack per day for 1 year. A patient who smokes 40 cigarettes per day (two packs) for 5 years would have a 10 pack-year history (2 packs/day for 5 years).

#### ▶ Other Air-Related Risks

In addition to direct inhalation of cigarette smoke, other environmental factors have been identified as risks for the development of primary lung tumors. Environmental tobacco smoke (ETS) presents a significant occupational hazard for nonsmokers working in environments that have a high smoking population, such as bars or restaurants. Each year approximately 3000 cases of lung cancer in nonsmokers are caused by ETS. In response, the majority of states have enacted clean indoor air acts. Other

environmental factors linked to lung cancer include radon, arsenic, nickel, and chloromethyl ethers. Those who live in an urban environment are also at an increased risk for lung cancer owing to exposure to high concentrations of combustion fumes.[4] Asbestos exposure increases the risk of developing a distinct but rare type of lung cancer called mesothelioma.

### ▶ *Nutrition*

Diet and nutrition are suspected to play a role in cancer susceptibility, and many studies have sought to define specific foods or nutrients that influence cancer risk. Because not all heavy smokers develop lung cancer, nutritional factors may explain part of this variation. Epidemiologic studies focusing on diet and nutrition in lung cancer have shown reduced rates of lung cancer in smoking individuals who report higher fruit and vegetable consumption. However, studies attempting to identify specific chemical components of fruits and vegetables that are responsible for this effect have not been successful.[5] **KEY CONCEPT** *Recommendations to patients who are at risk owing to smoking or other factors or those who are simply interested in reducing their risk of cancer should include an increase in dietary intake of fruits and vegetables.*

### Hereditary or Genetic Risk Factors

Although smoking is a key risk factor for lung cancer, the majority of people who smoke never develop lung cancer. Genetic risk factors may predispose certain smokers to lung cancer. After adjustments for age, smoke exposure, occupation, and gender, relatives of a lung cancer patient have approximately a twofold risk of developing lung cancer. The degree of inherited risk inversely correlates with the age of the relative at the time of diagnosis. First-degree relatives of a lung cancer patient diagnosed between the ages of 40 and 59 years have a sixfold relative risk for lung cancer. Familial lung cancer that develops at an early age in nonsmokers fits a Mendelian codominant inheritance model. However, a lung cancer gene has not been identified.

### Chemoprevention

Chemoprevention refers to the use of prophylactic medications to prevent the development of cancer. Many studies have been conducted testing potential chemopreventatives, including nonsteroidal anti-inflammatory drugs, retinoids, inhaled glucocorticoids, vitamin E, selenium, and green tea extracts, but none have been successful. A large randomized trial testing the effects of selenium, previously considered a promising chemopreventative agent for lung cancer, was stopped early due to lack of any observable effect at its first interim analysis.[6]

Interestingly, data from a placebo-controlled double blind study demonstrated that selective cyclooxygenase-2 (COX-2) inhibition with celecoxib reduces the proliferation of bronchial epithelial cells, lowers inflammatory markers, and may resolve benign or premalignant lung nodules in former smokers.[7] Existing data suggest that bronchial epithelial cell proliferation may be a surrogate endpoint for chemopreventative lung cancer trials. However, at this time, routine use of celecoxib as a chemopreventative agent is not warranted.

### Screening and Early Detection

Overall 5-year survival in lung cancer is only 15%, but those who are diagnosed at a localized stage exhibit a 5-year survival rate of 50%. Currently, more than three quarters of newly diagnosed lung cancers present with locally advanced or metastatic disease,

and therefore, very few patients are able to undergo surgical resection.[1] In an attempt to identify tumors when they are localized and have higher cure rates, many studies have evaluated different screening modalities, which have led to screening recommendations.

The landmark trial, the National Lung Screening Trial (NLST) randomized more than 53,000 patients at high risk for lung cancer to three annual low-dose spiral computed tomography (CT) scans or chest x-ray. Chest x-ray has been shown in large trials to be equivalent to no screening and can be considered a placebo control for mortality. In the CT arm 6.9% of patients were diagnosed with lung cancer and 63% were diagnosed with stage Ia or Ib disease with over 90% having surgery with curative intent. Screening by CT reduced lung cancer mortality by 20% and was subsequently approved and recommended for high-risk patients. High-risk patients are defined by the following criteria:

1. Age greater than or equal to 55 years

2. Smoking within the last 15 years

3. A 20 pack-year history plus an additional risk factor or greater than a 30 pack-year history

The challenge with utilizing low-dose CT scans in screening is the high sensitivity, which translates into frequent detection of nonmalignant lesions. In the NLST, the CT screening arm had positive findings in 24.2% of patients with 96.4% of the lesions being benign (false positives). Due to this high false positive rate, screening should be perceived as a two-step process in order to prevent excessive patient workup and anxiety. The plan for a patient (biopsy, PET scan evaluation, or repeat CT scan at 3, 6, or 12 months) with a positive finding on spiral CT is determined by an algorithm that evaluates the number, size, and characteristics of lesions.

The United States Preventative Services Task Force guidelines provide lung cancer screening a grade B recommendation, which means the magnitude of benefit is moderate. The proposed action for grade B recommendations is to offer or provide this service for qualifying patients.

## PATHOPHYSIOLOGY

Most lung cancers arise from the epithelium of the airways and are classified as carcinomas. There are four major and several rare histologic types of lung cancer. They appear to form through different mutagenic pathways; however, they all appear to transition through a premalignant state. The presence of a transitional state from normal tissue to cancerous tissue is important because the premalignant cells contain damage that is generally thought to be reversible. Researchers are currently trying to develop methods to identify people with premalignant lesions as well as drugs that can reverse the damage.

Continued damage to premalignant cells can lead to cancer. The first appearance of cancer cells that have not yet become invasive is referred to as carcinoma in situ. Patients are rarely diagnosed with this early stage of cancer owing to a lack of symptoms and relatively rapid progression from this state to larger invasive tumors. As the tumor grows, cells may become dislodged from the tumor bulk and enter the hematologic or lymphatic circulatory systems, where they can travel to either local or distant parts of the body. Hematologic spread usually results in metastatic sites in the bones, liver, and central nervous system (CNS). Lymphatic spread is more orderly in nature, with the hilar and mediastinal lymph nodes in the pleural cavity commonly being involved. Once the tumor has spread to multiple

**Table 90–1**

**Lung Tumor Histopathology[32]**

| Tumor Type | Percent of Tumors | Approximate Cell Doubling Time (days) | Sensitivity to Chemotherapy and Radiotherapy | Relative Risk of Metastasis |
|---|---|---|---|---|
| Small cell | 15–20 | 30 | High | High |
| Non–small cell | | | | |
|   Adenocarcinoma | 35–40 | 180 | Low | Medium |
|   Large cell (giant) | 10 | 100 | Low | Low |
|   Squamous (epidermoid) | 25–30 | 180 | Low | Low |

locations, curative treatment is rare because surgical excision and radiotherapy cannot remove all or nearly all of the cancer cells.

## Histologic Classification

Histologic classification of lung cancer involves determining the cellular origin of the tumor. Knowing the histology of the tumor influences treatment decisions as well as prognosis.

There are four major histologic types of lung cancer that are divided into three classes based on response to treatment and prognosis: small cell lung cancer (SCLC), squamous cell non–small cell lung cancer (NSCLC) and non–squamous NSCLC. The four major types of lung cancer are outlined by class in Table 90–1. However, it is important to note that certain other rare malignancies can be seen and many lung cancers may consist of multiple histologic subtypes. Furthermore, a recent phenomenon has been observed where pharmacologic treatments may selectively kill different components of the tumor, resulting in a conversion of the remaining tumor to a different subtype (ie, NSCLC becomes SCLC after treatment). Therefore, repeat biopsies of lung tumors before each line of treatment may become a standard of care, although it is not routinely performed at this time.

## Clinical Staging

Once the diagnosis of lung cancer is confirmed through visualization and biopsy, the extent of disease must be determined. NSCLC (squamous and non–squamous subsets) are staged using the American Joint Committee on Cancer (AJCC) tumor, node, and metastasis (TNM) staging system. SCLC is typically staged using the Veterans Administration Lung Cancer Study Group method. Clinical staging serves two primary purposes: predicting prognosis and guiding therapy.

### ▶ Non–Small Cell Lung Cancer

● Clinical staging of NSCLC with the TNM system evaluates the size of the tumor (T), extent of nodal involvement (N), and presence of metastatic sites (M). The combination of these three evaluations determines the stage. Clinical stages and associated survival rates are outlined in Table 90–2. Local disease includes tumors that are confined to a single **hemithorax** and those cancers which have spread to the ipsilateral hilar lymph nodes. Once malignancy invades the mediastinal lymph nodes or contralateral hilar nodes, the disease becomes locally advanced. When signs of cancer are detected outside the pleural cavity, it is classified as advanced disease. Local disease is associated with the highest cure and survival rates, whereas those with advanced disease have a 5-year survival rate of less than 5%.

Mutation (genetic) testing plays a key role in the treatment plan for NSCLC. Tumors bearing mutations or rearrangements of the EGFR or ALK genes have specific treatment options that offer improved response rates over traditional therapies. In non–squamous NSCLC histology, mutational testing should always be performed to further guide therapy.

### ▶ Small Cell Lung Cancer

● The most common system for staging SCLC was developed originally by the Veterans Administration Lung Cancer Study Group. This system categorizes SCLC into two classifications, limited and extensive disease.[8]

- Limited disease: evidence of the tumor is confined to a single hemithorax and can be encompassed by a single radiation port
- Extensive disease: any progression beyond limited disease

**Patient Encounter, Part 1**

A 61-year-old woman presents at your clinic complaining of new-onset cough. She has had several upper respiratory infections in the last 2 months, with occasional hemoptysis. She smoked about a pack of cigarettes per day beginning in her early 30s, but quit about 10 years later, and has not smoked since. She lives downtown in the city and has worked at her own restaurant/bar since she bought the establishment 10 years ago.

*What risk factors for lung cancer are present?*

*Calculate this patient's pack-year history.*

**Table 90–2**

**Clinical Stage and Prognosis[8]**

## Clinical Presentation and Diagnosis

### Pulmonary Symptoms

Symptoms related to the direct effects of the primary tumor often appear first and are the most common. These include the following:

- Cough
- Chest pain
- Shortness of breath
- Dysphagia
- Hemoptysis

### Extrapulmonary Symptoms

Once the tumor invades tissues outside the pleural cavity, it can produce a wide array of symptoms, including:

- General bone pain
- Adrenal insufficiency
- Confusion
- Personality changes
- Enlarged lymph nodes
- Weight loss
- Seizures
- Nausea and vomiting
- Focal neurologic symptoms
- Horner syndrome
- Fatigue
- Headache
- Pancoast syndrome
- Subcutaneous skin nodules

### Paraneoplastic Syndromes

Symptoms that are not a result of the direct effects of the tumor are termed paraneoplastic syndromes. They may be caused by substances secreted by the tumor or in response to the tumor and often occur in tissues far from the site of malignancy. Paraneoplastic syndromes are numerous and affect a wide variety of systems, including the endocrine, neurologic, skeletal, renal, metabolic, vascular, and hematologic systems.

### Diagnosis

Diagnosis requires visualization of one or more lesions as well as biopsy of the lesion to confirm malignancy. Both visualization and sampling can be performed by invasive or noninvasive methods. These methods are summarized in Table 90–3.

## CLINICAL PRESENTATION AND DIAGNOSIS

**KEY CONCEPT** *Signs and symptoms of lung cancer can be classified into three subdivisions: pulmonary, extrapulmonary, and paraneoplastic syndromes. Distinguishing among these classes of symptoms is important because it can aid in determining the severity of the disease, guide treatment options, and affect prognosis.*

## TREATMENT

### Desired Outcome and General Approach to Patient

The treatment of lung cancer depends on tumor histology, genetic alterations; stage of disease; and patient characteristics such as age, gender, history, and performance status (PS). All these aspects must be assessed before appropriate treatment can

### Table 90–3

**Diagnostic Tools**

| | Technique | Description |
|---|---|---|
| Visualization | Chest x-ray | The least expensive visualization method in the diagnosis of lung cancer. Readily accessible and does not require systemic administration of contrast dye. However, it often detects lesions that are not cancerous and is not capable of assessing lymph node status. |
| | CT | More accurate when providing information on size, location, and invasion than chest radiography. It is recommended as part of the standard workup in most cases. |
| | PET scanning | Uses a substance called 5-FDG to produce a functional image of the lungs. Cells that are actively growing and dividing use greater amounts of glucose and therefore take up more 5-FDG. Focal regions of fluorescence can be visualized in cancerous lesions. PET scanning combined with a CT scan is more accurate than CT scan alone; however, the exact role of PET scanning in staging and monitoring is unclear. The apparent benefit and common role in staging is to evaluate mediastinal disease when it can influence the tumor resectability. |
| Tumor sampling | Fine-needle aspiration | A method of aspirating cells from the tumor via insertion of a small-bore needle into the lesion and aspirating. Commonly used to evaluate lymph nodes or other poorly accessible sites, it has the advantage of being faster and less invasive than other biopsy methods; however, it does not preserve the architecture of the tumor and may return cells that are undergoing cell death, which negates histologic analysis. |
| | Bronchoscopy | A fiberoptic camera is inserted through the airways to examine the site of the suspected lesion. Once the lesion is visualized, a tool attached to the camera allows for a tissue biopsy. Newer technologies incorporate fluorescence to differentiate malignant tissue from premalignant lesions. |
| | Core needle biopsy | A method of obtaining tissue and preserving the tumor architecture. A large-bore needle is inserted into a lesion, where it cuts a core of tissue out that then can be evaluated. |
| | Thoracentesis | Involves removal of fluid in the pleural cavity via a needle. The fluid then is assayed for presence cancerous cells. This procedure has low sensitivity and depends on the presence of a pleural effusion. |
| | Sputum cytology | Detects cancerous cells that become dislodged from the airways into the sputum. Sputum cytology is useful because it is not invasive, but it has much lower sensitivity for detecting cancer. |

CT, computed tomography; 5-FDG, 5-fluorodeoxyglucose; PET, positron emission tomography.

## Patient Encounter, Part 2

**Medical History, Physical Examination, and Diagnosis**

**PMH:** GERD (controlled with PPIs), and moderate hypertension (controlled)

**FH:** Father recently diagnosed with colorectal cancer, but alive, mother living and healthy

**Meds:** Lisinopril 20 mg daily; lansoprazole 30 mg daily

**ROS:** (+) Chest pain, shortness of breath, hemoptysis; (–) recent weight loss

**PE**

**VS:** BP 125/69, RR 26, P 80, T 99°F (37.2°C)

**CV:** RRR

**Labs:** Slightly elevated ionized calcium and LFTs; all others WNL; CXR reveals a solitary nodule in right lower lobe; fine-needle aspiration confirms adenocarcinoma of the lung; further evaluation with CT and PET scans reveal a 3-cm mass, with possible ipsilateral lymph node involvement.

*What clinical stage is this patient's disease?*

*What is the estimated survival time for this stage of NSCLC?*

*Does this patient have any factors that may negatively or positively influence survival?*

be recommended. In the development of a patient care plan, keep in mind the ultimate goals of therapy. Treatment modality based on histology and stage is outlined in **Figure 90–1**. KEY CONCEPT *In general patients with early stage disease, a definitive cure is the primary goal of treatment, although this end point is* *not always met. Additional goals of treating lung cancer patients include prolongation of survival and improvement of quality of life through alleviation of symptoms.* The goals of treatment must be considered when selecting a therapeutic plan. Some treatments may prolong survival by a few months but at the expense of

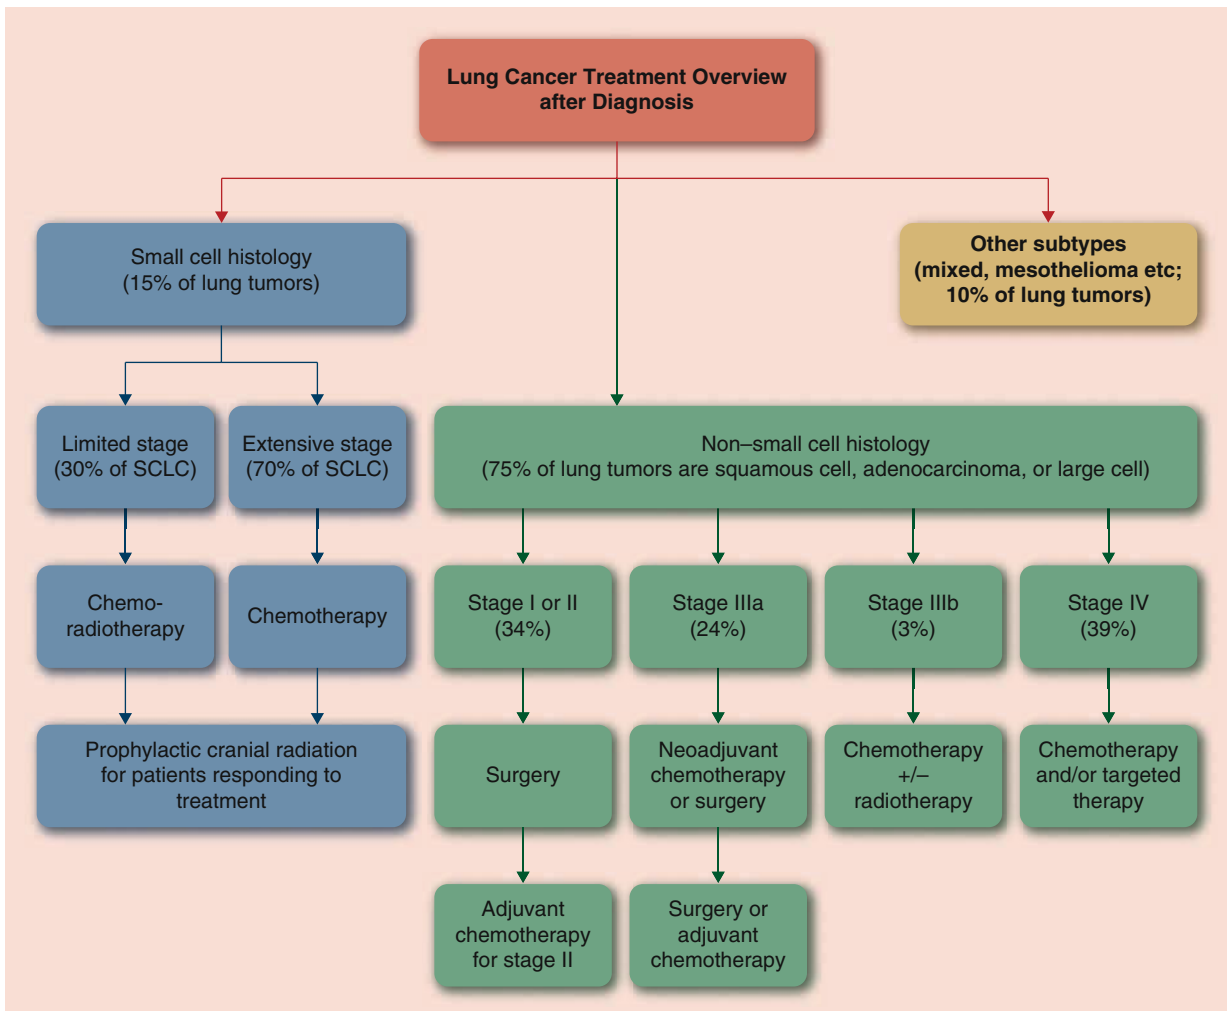

**FIGURE 90–1.** Overview of lung cancer epidemiology and treatment modality. [a]See text for specific treatment recommendations.

significant decreases in patient quality of life. Treatment decisions must include both the health care team and an informed and well-counseled patient.

### ▶ Performance Status

The performance status (PS) of an individual patient predicts response and likelihood of toxicity to chemotherapy as well as overall survival. The PS evaluation system used most frequently was developed by the Eastern Cooperative Oncology Group (ECOG) (see Chapter 88). KEY CONCEPT *Categorizing patients by their ECOG PS allows for an objective measure of capability to tolerate systemic therapies that may severely compromise the patient's health. Patients with a good PS (0–1) are more likely to tolerate intense therapy. PS 2 may receive chemotherapy, and PS 3 to 4 may receive supportive therapy or treatment with targeted therapies if they have targetable activating mutations.* Patients with localized disease may be treated more aggressively in this scenario because the intent of treatment is curative.

### Treatment Modality

#### ▶ Surgery (NSCLC)

KEY CONCEPT *Of all treatment modalities, surgical resection of the affected lobe or lung leads to the greatest improvement in survival for patients with early stage and locally advanced NSCLC tumors (clinical stage IA, IB, or IIA).* In patients with advanced disease NSCLC, surgery is not curative and as a general approach does not prolong survival. However, surgery for advanced disease is an important palliative treatment that can improve quality of life in some patients. In this respect, surgery is limited to local sites where the tumor is causing significant morbidity (eg, spinal cord compression).

#### ▶ Surgery (SCLC)

Patients with SCLC are rarely treated with surgery because the results of a randomized trial published in 1969 showed that surgery did not result in any 5- or 10-year survivors, but radiation produced a 4% survival rate at 5 and 10 years.[9] With improved imaging and surgical techniques as well as the use of effective adjuvant therapy, some clinicians believe that surgery does have a role in early stage SCLC. However, this has yet to be proven in a clinical trial.

#### ▶ Radiotherapy (NSCLC)

Patients with localized NSCLC are best treated with surgery; however, many of these patients are inoperable because of comorbidities (eg, lung disease from smoking). In these situations, radiation therapy can be used with curative intent in place of surgery, and the success rate is approximately 50% that of surgery.[10] Patients with locally advanced (stage IIIB, nonsurgically resectable) disease have prolonged survival with combined chemotherapy and radiotherapy. Patients with late stage NSCLC can receive radiation therapy to palliate symptomatic metastases. Although radiation is less invasive than surgery, it can have marked toxicity on normal tissue, and patients may experience esophagitis, pneumonitis, cardiac abnormalities, myelopathies, and skin irritation. These adverse events can be decreased by using stereotactic radiation and/or hyperfractionated administration.[11]

Postoperative radiotherapy (PORT) is thought to eliminate remnants of the resected tumor that might be deposited in nearby tissue, but is only recommended for patients with positive margins after surgical resection, when a local recurrence is of concern.

#### ▶ Radiotherapy (SCLC)

Radiotherapy (concurrent with chemotherapy) is the treatment of choice for limited-stage SCLC. Limited- and extensive-stage SCLC patients who respond to therapy should also receive prophylactic cranial irradiation (PCI), which treats micrometastatic disease in the CNS. This improves cure rates for limited-stage disease and prolongs survival for extensive stage disease.

## Pharmacologic Therapy

Traditional chemotherapy has been the mainstay for most lung cancer patients and will be administered to the large majority of patients, despite recent advances with targeted therapy for patients with EGFR and ALK mutations. Cisplatin and carboplatin are arguably the most effective traditional chemotherapy agents regardless of histology. KEY CONCEPT *Doublet chemotherapy regimens offer superior response rates compared with single-agent chemotherapy regimens and should be used when the patient can tolerate the increased toxicity.* The effective chemotherapy agents that are added to the platinum include etoposide, paclitaxel, docetaxel, gemcitabine, vinorelbine, and pemetrexed (see **Table 90–4** for regimen details).

Monoclonal antibodies targeting vascular endothelial growth factor (VEGF) signaling (bevacizumab and ramucirumab), and epidermal growth factor receptor (EGFR; cetuximab and necitumumab) have been combined with traditional chemotherapy to improve outcomes. Tyrosine kinase inhibitors (TKI) targeting EGFR such as afatinib and erlotinib can be appropriate as monotherapy (usually in those patients with an EGFR-activating mutation in exons 19 or 21). Similarly, tyrosine kinase inhibitors targeting an anaplastic leukemia kinase (ALK) gene rearrangement (gene fusions and translocations) can be treated with crizotinib or ceritinib as monotherapy. Selecting the best regimen for a specific patient is aided by patient characteristics (PS, comorbid conditions, etc), extent of tumor spread, histology, and genetics as discussed in more detail below. Preventing and managing therapy induced toxicity (see Chapter 88) is crucial to optimizing patient outcomes (eg, curing, prolonging life, or palliating symptoms). Furthermore, decisions to start chemotherapy must include the full consent and understanding of risks by the patient. Counseling on the therapeutic regimen and risk of toxicity is imperative before dosing. Lung cancer regimens and their associated toxicities are shown in Table 90–4. Refer to Chapter 88 for dosing recommendations in renal and hepatic failure.

## Treatment of Small Cell Lung Cancer

SCLC typically presents as extensive disease (approximately 60%–70% of new cases) and progresses very quickly. SCLCs are very responsive to chemotherapy and radiation but have a short duration of response. Radiotherapy became the standard in 1969, when a randomized trial showed that it offered the potential for

cure, whereas surgery did not.[12] In the vast majority of patients, chemotherapy with or without radiotherapy is the treatment of choice. Even after a complete response to therapy, the cancer usually recurs within 6 to 8 months, and the survival time following recurrence is typically short (~ 4 months). This yields an average survival rate of 14 to 20 months for limited disease and 8 to 13 months for extensive disease.[13] **Figure 90–2** illustrates the general treatment path of SCLC.

#### ▶ Limited Disease

The regimen of choice for limited-disease SCLC is etoposide–cisplatin (EP). In patients who are able to tolerate combined modality therapy, concomitant chemoradiotherapy offers the greatest survival benefit. Carboplatin may be substituted for cisplatin in patients who cannot tolerate cisplatin toxicity. Cisplatin is preferred over carboplatin because of a small study that randomized patients to cisplatin or carboplatin plus etoposide. There was a numerically higher complete response rate with cisplatin, which is believed to be requisite for cure. Consequently, the guidelines recommend that the EP regimen be used with concurrent radiotherapy.[13]

Because patients with SCLC commonly have a recurrence in the CNS, trials have been performed to evaluate the benefit of PCI. A pivotal study showed that PCI reduces the incidence of brain metastasis and increases the 3-year survival rate from 15% to 21%.[14] Patients with limited stage SCLC who achieve a complete response with treatment should be offered PCI.

#### ▶ Extensive Disease

Platinum regimens, particularly EP, are the treatment of choice in extensive disease. In one Japanese study, a combination of irinotecan and cisplatin demonstrated an increased median survival time by approximately 3 months over the EP regimen. This irinotecan–cisplatin regimen also had a lower incidence of severe neutropenic side effects but exhibited higher rates of middle- to high-grade diarrhea. However, this study was repeated in the United States and did not show a similar improvement over the EP regimen.[15] Therefore, EP remains the regimen of choice for treating extensive SCLC in the United States. Because of the high sensitivity of treatment-naïve SCLC to chemotherapy, it is imperative that these patients be monitored for signs of tumor lysis syndrome and possibly treated with prophylactic therapy.

Concurrent radiotherapy is not used routinely in extensive disease; however, PCI provides significant benefit in patients responding to chemotherapy. A pivotal study demonstrated that median survival from the time of randomization increased from 5.4 to 6.7 months and 1-year survival rates increased from 13.3% to 27.1% with PCI. An additional benefit was a lower rate of brain metastases (14.6% vs 40.4%).[16]

#### ▶ Recurrent Disease

The treatment of recurrent SCLC depends on the time to recurrence. If the time to recurrence is less than 6 months, second-line therapy should be considered if the patient has an acceptable PS (see Patient Care Process). The most widely accepted second-line therapies in SCLC are topotecan alone or CAV (cyclophosphamide, doxorubicin [Adriamycin], and vincristine). Relapses occurring more than 6 months after treatment warrant a repeat of the initial regimen. Patients with a poor PS (3–4) are typically managed with best supportive care, including palliative care therapies.

### Treatment of Non–Small Cell Lung Cancer

The first step in treatment of NSCLC involves confirmation of the clinical stage and determination of likelihood of resection of the tumor. When the histology results are not of squamous cell histology (adenocarcinoma and large cell), tissue should be sent for genetic analysis of EGFR mutations and ALK rearrangement. Treatment options depend on the stage of disease (ie, eligibility for resection), PS, histology, and genetic findings.

#### ▶ Local Disease (Stages 1A, 1B, and IIA)

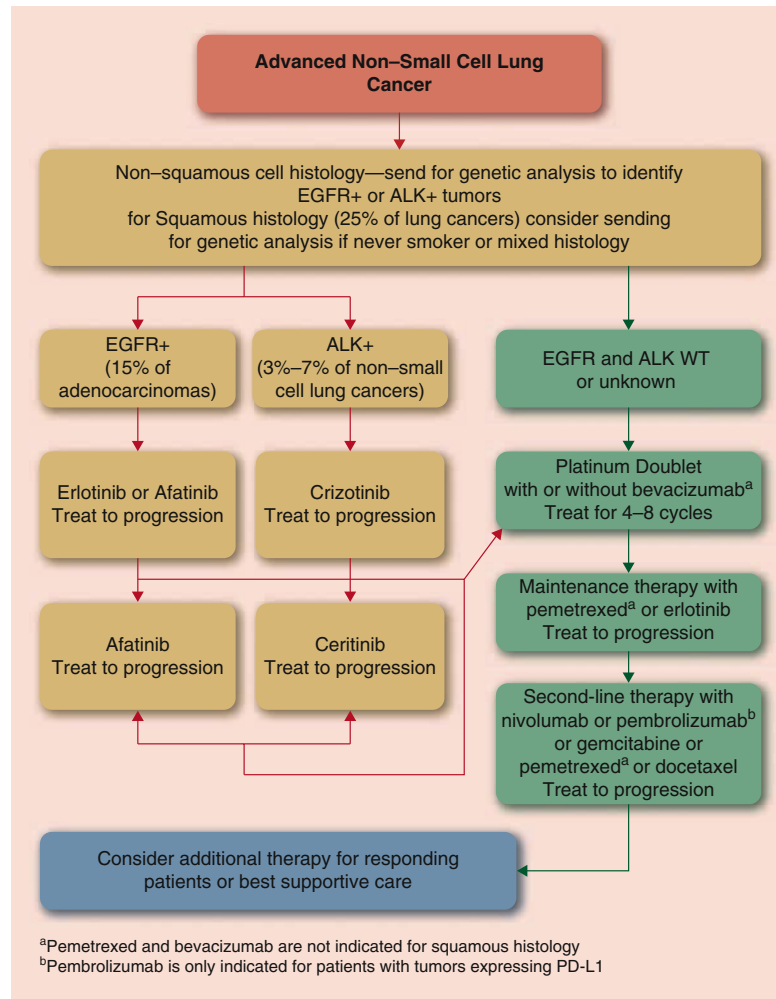
Local disease encompasses stages IA through IIA and is associated with a favorable prognosis because approximately 40% to 60% of patients are expected to live more than 5 years from diagnosis. Goals of therapy are curative in local disease, and surgery is the mainstay of treatment regardless of histology or genetics. Stage IA tumors are rarely seen clinically and may be treated with surgery alone. If surgical margins are positive, radiotherapy or re-resection is recommended.[17] Stage IB, IIA, and locally advanced IIB NSCLC are treated with adjuvant chemotherapy. The rationale behind adjuvant chemotherapy is to eradicate micrometastases or other tumor cells that may have been missed during removal of the primary tumor. The recent results of five relatively large prospective trials suggest that there is benefit


**FIGURE 90–2.** Advanced stage non–small cell lung cancer treatment algorithm.[13] Reproduced, with permission, from NCCN Practice Guidelines in Oncology: Non-Small Cell Lung Cancer. National Comprehensive Cancer Network; 2015; v.1.2016. www.nccn.org. Accessed November 9, 2015.

from adjuvant (postsurgical) chemotherapy leading to a survival advantage of 4% to 15%.[18,19] Consequently, adjuvant therapy has become the standard of care in resectable NSCLC and should be offered to patients after resection, particularly those with stage II or III disease.

Although the regimen of choice is unclear, studies evaluating pemetrexed in squamous cell histology demonstrate that it has minimal to no activity in this subtype. Thus, regimens containing pemetrexed should be avoided in patients with squamous cell histology. Based on prospective randomized trials, cisplatin–vinorelbine appears to be the regimen with the most evidence regardless of histology and genetics.

### ▶ *Locally Advanced Disease (Stages IIB and IIIA)*

Patients with locally advanced disease should also be considered for surgery, which would be followed with adjuvant treatment as outlined in local disease. However, neoadjuvant (aka. induction) chemotherapy could also be considered before surgery. The rationale behind neoadjuvant therapy is to decrease the size of the tumor so that it can be extracted more easily with clean margins, as well as to eliminate distant micrometastases before invasive local treatment. Meta-analysis of neoadjuvant trials suggests that neoadjuvant chemotherapy in all early stages improves 5-year survival by 5%.[20] However, the methods used

in many of these studies did not give adjuvant chemotherapy, which could also improve survival by about the same degree. One concern of giving neoadjuvant therapy is that the toxicity of induction regimens may delay surgery, and if the tumor does not respond to the treatment, there is a risk of disease progression. Nonetheless, current data suggest that more than 90% of patients who are treated with neoadjuvant therapy maintain their scheduled surgery.[21] The utilization of neoadjuvant chemotherapy is inconsistent, but is most common in patients with locally advanced tumors (stage III).[22] Neoadjuvant chemotherapy regimens are platinum-based doublets that do not include a targeted therapy (see Table 90–4). None of the large studies prospectively controlled/individualized therapy choices based on histology or genetics, which could improve results. Three cycles of carboplatin and paclitaxel administered on a 3-week schedule is a common and supported approach. The benefit of combining neoadjuvant therapy and surgery with additional adjuvant therapy is being investigated but is of unknown value at this time. Relatively small studies have evaluated using three treatment modalities (chemotherapy, radiation, and surgery) to two treatment modalities (chemotherapy and radiation). Improvements have been shown for progression-free survival, but not overall survival. Consequently, the value of trimodal therapy is unknown and does not have a clear role.

▶ *Advanced or Metastatic Disease (Stages IIIB and IV)*

Advanced disease is treated with systemic therapy if the patient has an acceptable ECOG PS score (0–1). Historically, patients with NSCLC received the same treatment and had a similar prognosis regardless of tumor characteristics. With that approach platinum-containing doublets given for four to eight cycles produced the highest overall response rates (25%–35%) and survival times (30%–40% 1-year survival) in well-performing patients with advanced disease. A number of different platinum doublet treatment regimens have been used in this setting. In some patients with stage IIIB disease, cisplatin and etoposide may be given concurrently with radiotherapy. However, treating unresectable stage III patients with a platinum-containing doublet regimen and omitting the radiation is common. NSCLC chemotherapy doublets that are considered generally equivalent include:

- Paclitaxel–cisplatin
- Paclitaxel–carboplatin
- Cisplatin–gemcitabine
- Cisplatin–docetaxel
- Carboplatin–docetaxel
- Cisplatin–vinorelbine
- Gemcitabine–paclitaxel
- Gemcitabine–docetaxel
- Cisplatin–pemetrexed
- Carboplatin-nab-paclitaxel

A large randomized trial comparing the first four regimens reported similar response rates and survival with all treatments, although there were less life-threatening toxicity and treatment-related deaths associated with paclitaxel–carboplatin.[23] Consequently, some argued that paclitaxel–carboplatin was the treatment of choice.

Individualized treatment is now the standard approach. Beyond patient characteristics, tumor histology and genetic analysis (in non–squamous cell histology) for activating EGFR mutations and ALK rearrangements guide treatment selection (see Figure 90–2).

**Drug Considerations for Squamous Cell NSCLC** There are specific drug considerations that must be made with squamous histology. In squamous NSCLC, pemetrexed is associated with decreased efficacy. This is true for combination studies as well as monotherapy studies and the inactivity with this histology is reflected in current treatment guidelines. Furthermore, bevacizumab is associated with an increased risk of fatal hemorrhage in squamous NSCLC. In the randomized phase II study that included 13 patients with squamous cell histology, four had a life-threatening bleeds, which led to the exclusion of this population in the phase III trial. Tumor EGFR activating mutations and ALK rearrangements can identify patient most likely to respond to TKI-targeted therapy. Since the incidence of these mutations in squamous cell histology is so low, current guidelines do not recommend testing squamous cell tumors for these mutations. Although these guiding factors are well established, the best combination is still unclear. Based on subset analysis of randomized controlled trials, it appears that gemcitabine and albumin-bound nanoparticle paclitaxel (nab-paclitaxel) have greater activity in squamous histology. The recent randomized trial comparing carboplatin with nab-paclitaxel versus carboplatin with traditional paclitaxel did not find a difference in overall survival (including the squamous histology subset); however, the response rate in patients with squamous cell histology was 41% with nab-paclitaxel and 24% with traditional paclitaxel. Based on this subset analysis, patients who have a symptomatic tumor might preferentially be treated with carboplatin and nab-paclitaxel. Alternatively, cisplatin and gemcitabine appear to be an acceptable option in squamous NSCLC, although no randomized clinical trials have proven an overall survival advantage in this histology, meaning that any platinum doublet is acceptable for advanced squamous cell lung cancer.

Squamous cell NSCLC frequently overexpresses the EGFR protein. Thus, there has been interest in adding an EGFR-targeted monoclonal antibody with chemotherapy for advanced squamous cell NSCLC. The anti-EGFR monoclonal antibody cetuximab has been shown to improve survival when combined with cisplatin and vinorelbine. The FLEX trial demonstrated a 1.2-month survival advantage of cetuximab when added to cisplatin and vinorelbine in recurrent or metastatic NSCLC (stages IIIB–IV all histologies).[24] However, despite the small survival advantage shown, cetuximab was not approved by the FDA for this indication.

**Drug considerations for non–squamous cell NSCLC** Treatment options for non–squamous histology are broader than squamous histology and targeted therapies are making a significant impact, particularly for patients with a genetic alteration that can be targeted with drug therapy.

Approximately 10% to 15% of NSCLC patients have tumors with mutations in exon 19 and/or 21 in the EGFR gene. These mutations define a population likely to respond to treatment with EGFR TKIs (erlotinib or afatinib). In this population, first-line therapy progression-free survival is approximately 4 to 6 months longer with EGFR TKIs than platinum-doublet chemotherapy. Since afatinib and erlotinib have not been compared in a randomized trial, it is not possible to determine which one is better. However, there is evidence that afatinib works in EGFR-mutant tumors in patients who fail erlotinib or have an exon 20 T790M mutant (which predicts resistance to erlotinib). Based on these data, patients who are started on erlotinib, respond, and then progress can be treated with afatinib although going straight to chemotherapy may still be considered the standard. Since there are no data showing that patients who recur after afatinib will respond to erlotinib, patients failing afatinib first line should then go on to treatment with chemotherapy like genetic wild-type adenocarcinoma patients (see Figure 90–2).

Crizotinib is a new targeted therapy that was designed for a subset of patients with an ALK rearrangement (ALK+; ∼ 5% of patients). It received accelerated approval based on a single-arm trial in the salvage setting that resulted in a 55% survival rate at 2 years.[25] Despite the lack of data in the first-line setting, the NCCN guidelines recommend that patients with a known ALK rearrangement can be treated with crizotinib in the first-line setting. Response rates are approximately 60% with a progression free survival of 8 to 10 months, and most patients have a recurrence within 12 months. Ceritinib was recently approved for patients who fail crizotinib. In this setting about half of patients respond and the duration of response is approximately 7 months. Although neither have been tested in a randomized trial as first-line therapy or against each other, based on the data and guidelines; ALK+ patients should receive first-line crizotinib, then ceritinib, and then start treatment with chemotherapy like genetic wild-type adenocarcinoma patients (see Figure 90–2).

| Table 90–5 | | | | | | |
|---|---|---|---|---|---|---|
| **Molecularly Targeted Agents in Lung Cancer** | | | | | | |
| **Agent** | **Target** | **FDA-Approved in Lung Cancer** | **Genetic or Histologic Indication** | **Contraindication** | **Dosage** | **Regimen** |
| Erlotinib | EGFR | Yes | EGFR mutations in exons 19 and 21 | EGFR mutations in exon 20 | 150 mg orally daily | Single agent |
| Cetuximab | EGFR | No, used off-label | EGFR expression | | 400 mg/m² IV day 1, then 250 mg m² weekly thereafter | Cisplatin and vinorelbine |
| Afatinib | EGFR | Yes | EGFR mutations (all) | | 40 mg orally daily | Single agent |
| Bevacizumab | VEGF | Yes | | Squamous cell histology | 15 mg/kg IV day 1 of a 3 week cycle | Carboplatin and paclitaxel |
| Necitumumab | EGFR | No, investigational drug | Squamous cell histology | | 800 mg IV days 1 and 8 of a 3-week cycle | Gemcitabine and cisplatin |
| Ramucirumab | VEGFR2 | Yes | Can be used in squamous cell histology | | 10 mg/kg IV day 1 of a 3-week cycle | Docetaxel |
| Crizotinib | ALK, cMET, ROS1 | Yes | ALK-rearranged (translocations and fusions) | | 250 mg orally twice daily | Single agent |
| Ceritinib | ALK | Yes | ALK-rearranged (translocations and fusions) can be used in crizotinib-resistant patients | | 750 mg orally daily | Single agent |

In summary, targeted therapy as monotherapy or in combination with chemotherapy has become a mainstay in first-line treatment of advanced NSCLC. Targeted agents utilized in NSCLC are presented in Table 90–5.

## Special Populations

Patients who cannot tolerate platinum can be treated with gemcitabine–paclitaxel or gemcitabine–docetaxel. Randomized trials have produced response durations and survival times similar to the platinum-containing doublet regimens. However, these regimens are only recommended for patients who are unlikely to tolerate the toxicity of platinum regimens owing to comorbidities or other factors.[26]

Poorly performing patients, defined as those with a PS of 2 is a subject of debate. Although patients with a PS of 2 typically have inferior survival rates and higher toxicity to platinum chemotherapy than higher performing patients, low-toxicity single-agent regimens may offer a survival advantage in this subset. Use of these regimens also presents a method of providing symptomatic care for advanced stage patients. Agents such as pemetrexed, gemcitabine, and docetaxel may be used in this scenario. In patients with a PS of 3 or 4, chemotherapy typically results in high rates of toxicity and fails to convey a survival benefit. Consequently, treatment should be aimed at relief of symptoms instead of a definitive cure. Because targeted agents typically have lower rates of severe toxicity, they also have been used in appropriate subsets of patients with a poor PS (ECOG PS of 2 or 3). Unfortunately, we do not adequate clinical trial data regarding the efficacy and toxicity of targeted agents in these patients. In summary, debilitated patients should not be treated with combination chemotherapy with or without targeted agents because of historically high rates of toxicity without benefit. Single-agent therapy with less toxicity can be used to help palliate symptoms.

## Duration of Therapy

Because advanced stage NSCLC is not curable, an argument can be made that the goal is to extend the number of quality days, rather than just overall survival. With this goal in mind and an assumption that quality of life is lower during chemotherapy treatment, it is important to consider the duration of therapy. Over the last decade, treatment has moved toward fewer chemotherapy cycles. Typical therapy regimens have decreased from planning eight cycles to six cycles, to four cycles, which was the standard until several years ago. It was at this time that positive data were reported from two studies using pemetrexed, erlotinib, and bevacizumab as maintenance therapy. Both key studies included patients who had a response or stable disease after four cycles of a platinum-based doublet who were then randomized to placebo or treatment.[27] The pemetrexed study reported a 3-month survival advantage with maintenance therapy. A subgroup analysis of this study demonstrated that patients with squamous histology did not benefit from therapy leaving an overall survival benefit of 5 months for the non–squamous cell group. Similarly, the erlotinib maintenance study reported a 1-month overall survival advantage, which does not appear as robust; however, the subset analysis showed benefit was much more likely in nonsmokers and those with adenocarcinoma histology and particularly in patients who had an activating mutation (exon 19 or 21). Similar to the pemetrexed study, patients whose tumor was of squamous cell histology did not appear to benefit from maintenance. In summary, the duration of therapy depends highly on histology; patients with squamous cell histology will likely be treated for four cycles, but patients with non–squamous cell histology will be treated until progression.[27]

### ▶ Recurrent and Progressive Disease

Although patients frequently experience a response to initial therapy, disease recurs in most cases. If the recurrence is

## Patient Encounter, Part 4

The patient undergoes surgery for her disease, which is successful, with negative margins. After 1 year, however, the patient returns for routine follow-up and is found to have recurrent disease, with metastases present in both the brain and in the liver. Molecular diagnostics reveals an ALK rearrangement (ALK-EML4 translocation/fusion).

*What is the patient's new clinical stage?*

*Discuss the significance of the genetic alteration identified in the tumor.*

*Based on the information provided, develop a care plan for this patient. Include (a) treatment goals, (b) monitoring parameters for anticipated toxicities, and (c) a follow-up plan to determine response to treatment and surveillance.*

## Patient Care Process

**Patient Assessment:**

- Determine stage and histology of cancer.
- Perform mutation analysis if clinically indicated.

**Therapy Evaluation:**

- Evaluate the appropriateness of a patient's regimen at every visit (every week, 3 weeks, or 4 weeks).
- Inquire about toxicity or issues.
- Include a medication reconciliation process.
- Laboratory and/or radiology evaluations can be prompted by the initial assessment or at a scheduled interval for the treatment regimen.
- Findings of tumor growth or significant toxicity should prompt a change in the therapeutic plan.

**Care Plan Development:**

- Grade and monitor toxicity—Grade 3 or 4 toxicity (see Chapter 88) requires a change in therapy with the next cycle of treatment. Common changes include a chemotherapy dose reduction or pharmacologic intervention to prevent or treat the toxicity.
- Manage toxicity— **KEY CONCEPT** *Knowing when and how to treat adverse events from chemotherapy is an important aspect of patient care. Unmanaged events may cause delays in chemotherapy administration and reduced chemotherapy doses and may contribute to treatment failure.* This includes managing neutropenic episodes (See Chapter 99) and chemotherapy-induced nausea and vomiting (see Chapter 99). The emetogenic potential of selected chemotherapy regimens are listed in Chapter 99.
- Counsel patients on appropriate use and adherence of oral medications.

**Follow-Up Evaluation:**

- Monitor for recurrence. Follow recommendations of the NCCN, as outlined in Outcome Evaluation.
- Smoking cessation plans. For NSCLC patients, all long-term care plans should include options and recommendations for smoking cessation (see Chapter 36).

localized, surgery options may be assessed. If the patient's PS remains acceptable (0–1), second-line systemic chemotherapy has been shown to improve survival. Although platinum doublets may be used at this point in care, a single-agent therapy with docetaxel, pemetrexed, erlotinib, or crizotinib is recommended, depending on the tumor genotype.[25,28] A recent phase III trial tested the addition of ramucirumab (a VEGFR2-targeted monoclonal antibody) to docetaxel as second-line therapy regardless of histology. The results show that ramucirumab increases overall survival and progression-free survival by approximately 1.5 months.[29] Currently ramucirumab is not approved for lung cancer, but is approved for gastric cancer and might be used off label with docetaxel.

Recurrences in poorly performing patients (3–4) usually are not treated with chemotherapy and are instead treated with supportive care. Additional recurrences (eg, third-line therapy) may be treated with single-agent therapy not previously used or best supportive care.

Progression on targeted TKIs such as erlotinib or crizotinib in appropriately (genetically) selected patients after an initial response occurs frequently. This phenomenon is a sign of acquired resistance of the tumor to the molecular effects of the agent. Order of therapy for TKIs is discussed previously in "Drug considerations for non–squamous cell NSCLC." An overwhelming amount of clinical and preclinical data suggests that patients with molecularly targetable tumors should never lose the opportunity to be treated with TKIs, and perhaps the best opportunity of maintaining quality of life and survival is to enroll in clinical trials testing these second-generation agents. Furthermore, it is important to note that patients who initially benefit from erlotinib and acquire resistance to therapy may benefit from retreatment with erlotinib after other lines of therapy.

## OUTCOME EVALUATION

Evaluating outcomes is a goal-oriented process and should begin from that perspective. Patients with localized disease are treated with localized therapy with or without systemic therapy with curative intent as the goal. Monitoring for toxicity and recurrence on a regular basis is essential.

Following surgery or pharmacologic treatment, the patient should be monitored regularly to detect recurrence or progression of disease. Methods include a physical examination and chest x-ray every 3 to 4 months for 2 years. If no disease is detected during this time, follow-up frequency can be prolonged to every 6 months for 3 years and then annually. Low-dose spiral CT scanning is also recommended annually.

Smoking cessation counseling with or without pharmacologic treatment should be a priority. Although studies have shown that patients who continue to smoke through treatment in NSCLC do not perform more poorly compared with those that quit before treatment, those who respond to treatment and continue to smoke probably have an increased risk of developing secondary malignancies.[30] In contrast to NSCLC, some data suggest that SCLC patients with limited stage disease have poorer outcomes if they continue to smoke during treatment.[31]

For those with advanced disease, the goal of treatment is to prolong the duration of life, particularly the number of quality

days. Ultimately, most lung cancer patients succumb to their disease. Palliative care involves management of symptoms and improvement of quality of life when curative treatment options are no longer available. Often, problematic metastases can be removed by surgery (depending on location) or can be treated with radiotherapy to reduce tumor size. In selecting options at this point in treatment, it is important to keep the goals of therapy (ie, maximizing the duration and quality of life) in mind. Low-toxicity single-agent chemotherapy, targeted therapy, and best supportive care (including fatigue and pain management) are commonly the mainstays of palliative care.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| 5-FDG | 5-Fluorodeoxyglucose |
| ALK | Anaplastic lymphoma kinase |
| CAV | Cyclophosphamide, doxorubicin [Adriamycin], vincristine |
| CT | Computed tomography |
| ECOG | Eastern Cooperative Oncology Group |
| EGF | Epidermal growth factor |
| EGFR | Epidermal growth factor receptor |
| EML4 | Echinoderm microtubule-associated protein-like 4 |
| EP | Etoposide, cisplatin |
| ETS | Environmental tobacco smoke |
| NSCLC | Non–small cell lung cancer |
| PCI | Prophylactic cranial irradiation |
| PET | Positron-emission tomography |
| PS | Performance status |
| SCLC | Small cell lung cancer |
| TNM | Tumor, node, and metastasis staging |
| VEGF | Vascular endothelial-derived growth factor |
| VEGFR | Vascular endothelial-derived growth factor receptor |

# Colorectal Cancer

Emily B. Borders and Patrick J. Medina

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Identify the risk factors for colorectal cancer.
2. Recognize the signs and symptoms of colorectal cancer.
3. Describe the treatment options for colorectal cancer based on patient-specific factors, such as stage of disease, age of patient, genetic mutations, and previous treatment received.
4. Outline the pharmacologic principles for agents used to treat colorectal cancer.
5. Develop a monitoring plan to assess the efficacy and toxicity of agents used in colorectal cancer.
6. Educate patients about the adverse effects of chemotherapy that require specific patient counseling.
7. Outline preventive and screening strategies for individuals at average and high risk for colorectal cancer.

## INTRODUCTION

**C**olorectal cancer is one of the four most common cancers diagnosed in the United States and includes cancers of the colon and rectum. In 2015, an estimated 139,970 new cases of colon cancer with an estimated 50,710 deaths, making colorectal cancer the second leading cause of cancer-related deaths in the United States.[1] The prognosis is primarily determined by the stage of disease with the majority of patients with early stage (I or II) disease cured. Treatment options for colorectal cancer include surgery, radiation, chemotherapy, and targeted molecular therapies.

## EPIDEMIOLOGY AND ETIOLOGY

Colorectal cancer occurs more frequently in industrialized regions such as North America and Europe, while the lowest rates are seen in less-developed areas, suggesting that environmental and dietary factors influence the development of colorectal cancer. In addition to environmental factors, colorectal cancers develop more frequently in certain families, and genetic predisposition to this cancer is well known.

The incidence of colorectal cancer in men is approximately 1.5 times greater than observed in women. Overall, colon and rectal cancers make up approximately 12% of all cancer diagnoses in men and women in the United States. The median age at diagnosis is 68 years with very few cases occurring in individuals younger than 45 years of age.[2] **KEY CONCEPT** *Age appears to be the biggest risk factor for the development of colorectal cancer with 70% of cases diagnosed in adults older than 65 years of age.*

Although still the second leading cause of cancer death, mortality rates for colorectal cancer have declined over the past 30 years as a result of better, and increasingly used screening modalities, and more effective treatments.

## RISK FACTORS

In addition to age, dietary or environmental factors, inflammatory bowel disease, and genetic susceptibility increase the risk of colorectal cancer. Table 91–1 lists well-known risk factors for developing colorectal cancer.

**KEY CONCEPT** *Diets high in fat and low in fiber are associated with increased colorectal cancer risk.* While data is not entirely consistent, long-term consumption of red and processed meats is associated with an increased risk of colorectal cancer. A large pooled analysis of 13 prospective cohort studies found dietary fiber intake to be inversely associated with the risk of colorectal cancer; however, upon multivariate analysis for other dietary risk factors, the benefit was no longer observed.[3] This analysis does not consider for the known benefits of a fiber-rich diet for noncancerous conditions such as diabetes and coronary artery disease.

Foods that are high in fiber include vegetables, fruit, grains, and cereals. The protective effects of fiber may be a result of reduced absorption of carcinogens in the bowel, reduced bowel transit time, or a reduction in dietary fat intake associated with high-fiber diets.[3]

Physical inactivity and elevated body mass index (BMI) are associated with up to a twofold increase in the risk of colorectal cancer. Decreased bowel transit time and exercise-induced alterations in body glucose, insulin levels, and other hormones may reduce tumor cell growth.[4,5] Type 2 diabetes mellitus, independent of body mass size and physical activity level, is also associated with an increased risk of colorectal cancer in women and supports a role for hyperinsulinemia as a possible link between obesity, sedentary lifestyle, diabetes mellitus, and colorectal cancer.[5] Additional lifestyle choices that increase the risk of colorectal cancer include alcohol consumption and smoking that may increase the risk of colorectal cancer by generating carcinogens or their direct toxic effects on bowel tissue.[4]

| Table 91–1 |
|---|
| **Risk Factors for Colorectal Cancer** |
| **General** |
| Age is the primary risk factor |
| **Dietary** |
| High-fat, low-fiber diets |
| **Lifestyle** |
| Alcohol |
| Smoking |
| Obesity or physical inactivity |
| **Comorbid Conditions** |
| Inflammatory bowel disease (ulcerative colitis and Crohn disease) |
| **Hereditary or Genetic** |
| FAP and HNPCC |
| Family history |

FAP, familial adenomatous polyposis; HNPCC, hereditary nonpolyposis colorectal cancer.

Inflammatory bowel diseases, such as chronic ulcerative colitis, particularly when it involves the entire large intestine, and to lesser extent Crohn disease, confer increased risk for colorectal cancer. Overall, individuals with inflammatory bowel disease account for about 1% to 2% of all new cases of colorectal cancer each year.

Finally, as many as 10% of cases are thought to be hereditary. The two most common forms of hereditary colorectal cancer are familial adenomatous polyposis (FAP) and hereditary non-polyposis colorectal cancer (HNPCC). FAP is a rare autosomal dominant trait that is caused by mutations of the **adenomatous polyposis coli (APC)** gene and accounts for 1% of all colorectal cancers. The disease is manifested by hundreds to thousands of **polyps** arising during adolescence.[6] The risk of developing colorectal cancer for individuals with untreated FAP is virtually 100%, and patients require early screening for the disease and likely prophylactic total colectomy. HNPCC, also an autosomal dominant syndrome, accounts for up to 5% of colorectal cancer cases.[6] In contrast to FAP, juvenile polyps occur rarely, and the average age of colorectal cancer in these patients is closer to that of average risk patients, with most patients diagnosed in their 40s. Testing for HNPCC mutations is available but reserved for individuals who meet strict diagnostic criteria.

Up to 25% of patients who develop colorectal cancer have a family history of colorectal cancer unrelated to a mutation described earlier.[7] First-degree relatives of patients diagnosed with colorectal cancer have an increased risk of the disease that is at least two to four times that of persons in the general population without a family history.

## Summary of Risk Factors

In summary, the true association between most dietary factors and the risk of colorectal cancer is unclear. The protective effects of fiber and a diet low in fat are not completely known at this time. Physical inactivity, alcohol use, and smoking appear to increase the risk of colorectal cancer. Clinical risk factors and genetic mutations are well-known risks for colorectal cancer.

## SCREENING

**KEY CONCEPT** *Effective colorectal cancer screening programs incorporate annual fecal occult blood testing in combination with regular examination of the entire colon starting at age 50 years*

*for average-risk individuals and should be recommended by all health care providers.* Appropriate screening of patients at normal and high risk for colorectal cancer leads to the detection of smaller, localized lesions and higher cure rates.[8] Screening techniques include fecal occult blood tests (FOBTs) and imaging of the colon. The use of FOBTs annually in combination with digital rectal examinations has led to diagnosis of early stages of disease and may reduce colorectal cancer mortality by up to one-third.[8] However, FOBT using a single stool sample collected during a digital rectal examination is not a recommended option for screening because this method has a decreased sensitivity for detecting advanced disease.[7] Recommendations for adequate FOBT require the patient to collect two stool samples from three consecutive specimens using at-home testing procedures.[8] Two main methods are available to detect occult blood in the feces: guaiac dye and immunochemical methods. The Hemoccult II is the most commonly used FOBT in the United States and is a guaiac-based test. Proper counseling by health care providers is required to receive accurate test results. Consumption of red meat, blood sausages, peroxidase-containing vegetables, iron products, or NSAIDS may result in false-positive results. Vitamin C and dehydrated samples may lead to false-negative results. These products should be avoided for 3 days prior to testing. Fecal immunochemical tests (FITs) (InSure and others), which use antibodies to detect hemoglobin, are also available for use. Though more expensive, an advantage of FITs is that they do not react with dietary factors or medications. Both FOBTs can be recommended in screening protocols for patients.

In addition, imaging of the colon with a sigmoidoscopy, colonoscopy, or double-contrast barium enema is required every 5 to 10 years in most individuals. Colonoscopy is the preferred procedure as it allows for greater visualization of the entire colon and simultaneous removal of lesions found during screening.[8] A sigmoidoscopy only examines the lower half of the colon, and a double-contrast barium enema requires a supplemental colonoscopy to remove any lesions found during the screening process. Several revisions to the colorectal cancer screening guidelines have been made in an attempt to increase the compliance to screening guidelines. These include the use of computed tomographic colonography (CTC) and stool DNA testing as acceptable screening methods. CTC, also known as "virtual colonoscopy," uses integrated two- and three-dimensional images

---

**Patient Encounter, Part 1**

A 66-year-old woman presents to your clinic with a chief complaint of abdominal discomfort and changes in her bowel habits with up to six loose stools per day. She also states she has felt tired and has had a reduced appetite over the past month. She has a medical history positive for hypertension, type 2 diabetes mellitus, peripheral neuropathy from her diabetes, and obesity. She states that she consumes a moderate amount of alcohol (two or three beers most days of the week after work), is a current smoker (one pack per day for 32 years), and does not follow any particular diet.

*What risk factors does this patient have for colon cancer?*

*Does she have clinical symptoms suggestive of colon cancer?*

*What additional tests need to be ordered to diagnosis colon cancer?*

| Table 91–2 | |
|---|---|
| **Colon Cancer Screening Guidelines** | |

| | CTC every 5 years |
| Family history | Screening at ages 40 years or 10 years before the youngest case in the immediate family, whichever is earlier |
| HNPCC | Screening at age 20–25 years or 10 years before the youngest case in the immediate family, whichever is earlier |
| FAP | Screening at ages 10–12 years |
| IBD | 8 years after the onset of pancolitis; 12–15 years after onset of left-sided colitis |

CTC, computed tomographic colonography; FAP, familial adenomatous polyposis; FIT, fecal immunochemical tests; FOBT, fecal occult blood tests; HNPCC, hereditary nonpolyposis colorectal cancer; IBD, inflammatory bowel disease.

to detect and characterize polyps. Although noninvasive compared with colonoscopy, adequate bowel preparation, which is often cited as the reason for noncompliance, is still required. In addition, any lesions found on examination require a follow-up colonoscopy.

Stool DNA testing detects molecular markers associated with advanced colorectal cancer. Because this test is not dependent on the detection of bleeding, which can be sporadic, it requires only a single stool collection. How often and what molecular markers to test for are undergoing further evaluation. **KEY CONCEPT** *Table 91–2 is a summary of the current American Cancer Society guidelines for screening and surveillance for early detection of colorectal polyps and cancer.*[8]

## COLORECTAL CANCER PREVENTION

There are currently no pharmacologic agents approved for colorectal cancer prevention. Strategies under investigation to prevent colorectal cancer include pharmacologic and surgical interventions and involve either preventing the initial development of colorectal cancer (primary prevention) or preventing cancer in patients who demonstrate early signs of colorectal cancer (secondary prevention).

The most widely studied agents for the chemoprevention of colorectal cancer are agents that inhibit COX-2 (aspirin, NSAIDs, and selective COX-2 inhibitors) and calcium supplementation.[9] Individual studies have demonstrated that regular (at least two doses per week) nonsteroidal anti-inflammatory drug (NSAID) and aspirin use is associated with a 20% to 40% reduction in risk of colorectal cancer in individuals at average risk.[10,11] However, a meta-analysis of over 40 trials suggests the benefit of these agents may be limited to individuals at high risk for developing colorectal cancer.[12] Chronic use of aspirin and other NSAIDs are associated with significant potential adverse effects, including gastrointestinal (GI) and cardiovascular toxicities. These risks limit health care professionals from routine recommendations for use in patients of average risk for colorectal cancer.

The risk of colorectal cancer appears to be inversely related to calcium and folate intake. Calcium supplementation appears to be associated with a moderate reduction in risk of recurrent colorectal adenomas with prospective studies demonstrating a nonstatistical decrease in adenoma recurrence, its role as a chemoprevention agent in the average-risk patient remains under investigation.[9,12]

Additional agents, including selenium and folic acid, show promise as chemopreventive agents in colorectal cancer and preliminary, and confirmatory studies evaluating their effectiveness have been completed or are ongoing.[9] Exogenous hormone use, particularly postmenopausal hormone replacement therapy, is associated with a significant reduction in colorectal cancer risk in most studies with the greatest benefit in women who are on current hormone replacement therapy.[13] Unfortunately, the known risks of hormone replacement therapy outweigh this benefit, and routine use of hormone replacement therapy to prevent colorectal cancer is not recommended.

Surgical resection remains an option to prevent colorectal cancer in individuals at extremely high risk for its development such as patients diagnosed with FAP. Individuals with FAP who are found to have polyps on screening examinations require total abdominal colectomy. In addition, removal of noncancerous polyps detected during screening colonoscopy is considered the standard of care to prevent the progression of premalignant polyps to cancer.

## PATHOPHYSIOLOGY
### Anatomy and Bowel Function

The large intestine consists of the cecum; ascending, transverse, descending, and sigmoid colon; and rectum (**Figure 91–1**).

Four major tissue layers, from the lumen outward, form the large intestine: the mucosa, submucosa, muscularis externa, and serosa. Complete replacement of surface epithelial cells occurs every 7 to 10 days with the total number of epithelial cells remaining constant in normal colonic tissue. As patients age, abnormal cells accumulate on the surface epithelium and

**FIGURE 91–1.** Colon and rectum anatomy. (From DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York: McGraw-Hill, 2014; Figure. 107–2.)

protrude into the stream of fecal matter; their contact with fecal mutagens can lead to further cell mutations and eventual adenoma formation.[6]

## Colorectal Tumorigenesis

The development of a colorectal neoplasm is a multistep process of several genetic and phenotypic alterations of normal bowel epithelium leading to unregulated cell growth, proliferation, and tumor development. A genetic model has been proposed for colorectal tumorigenesis that describes a process of transformation from adenoma to carcinoma. This model of tumor development reflects an accumulation of mutations within colonic epithelium that gives a selective growth advantage to the cancer cells.[6] Genetic changes include activating mutations of oncogenes, mutations of tumor suppressor genes, and defects in DNA mismatch repair genes.

Additional genes and protein receptors are believed important in colorectal tumorigenesis. COX-2, which is induced in colorectal cancer cells, influences apoptosis and other cellular functions in colon cells, and overexpression of the EGFR, a transmembrane glycoprotein involved in signaling pathways that affect cell growth, differentiation, proliferation, and angiogenesis, occurs in the majority of colon cancers.[14] These mechanisms are potentially important because of the availability of pharmacologic agents targeted to inhibit these processes.

More than 90% of colorectal cancers that develop are adenocarcinomas and are assigned a grade of I to III based on how similar they are compared with normal colorectal cells. Grade I tumors most closely resemble normal cellular structure, but grade III tumors have frequently lost the characteristics of mature normal cells. Grade III tumors are associated with a worse prognosis than grade I tumors.[15]

---

### Clinical Presentation and Diagnosis of Colorectal Cancer

**General**

Patients are often asymptomatic in early stages of disease

**Symptoms**

Changes in bowel habits, abdominal pain, anorexia, nausea and vomiting, weakness (if anemia is severe), and tenesmus

**Signs**

Blood in stool and weight loss

**Laboratory Tests**

- Patients may have a low hemoglobin level from blood loss
- Positive FOBT
- Liver function tests (INR, activated partial thromboplastin time, and bilirubin) may be abnormal if disease has metastasized to the liver
- CEA level may be high; normal level is less than 2.5 ng/mL (2.5 mcg/L) in nonsmokers and less than 5 ng/mL (5 mcg/L) in smokers

**Imaging Tests**

Chest x-ray, CT scan, or PET scan results may be positive if cancer has spread to the lungs, liver, or peritoneal cavity

---

## CLINICAL PRESENTATION AND DIAGNOSIS

The signs and symptoms associated with colorectal cancer can be extremely varied, subtle, and nonspecific. Most patients are asymptomatic but may develop changes in bowel or eating habits, fatigue, abdominal pain, and blood in the stool.

## TREATMENT
### Desired Outcomes

Patients are staged with the tumor, node, metastasis (TNM) classification system (TNM) (See Chapter 88) to determine treatment options and assess prognosis. Figure 91–2 depicts how the three categories are used in combination to determine the stage of disease. **KEY CONCEPT** *The stage of colorectal cancer upon diagnosis is the most important prognostic factor for survival and disease recurrence. Stages I, II, and III disease are considered potentially curable and are aggressively treated in an attempt to cure these patients. Patients who develop stage IV disease are treated to reduce symptoms, avoid disease-related complications, and prolong survival.*

### General Approach to Treatment

The treatment approaches for colorectal cancer reflect two primary treatment goals: curative therapy for localized disease (stages I–III) and palliative therapy for metastatic cancer (stage IV). Surgical resection of the primary tumor is the most important part of therapy for patients in whom cure is possible.[16] Depending on the stage of disease and whether the tumor originated in the colon or rectum, further adjuvant chemotherapy or chemotherapy plus radiation may be needed after surgery to cure these patients. In the metastatic setting, pharmacologic intervention is the main treatment option.

Pharmacogenetic and pharmacogenomic testing has become an integral component to designing the optimal pharmacologic intervention for patients with colorectal cancer. The choice of treatment agents is largely dictated by individualized patient and tumor-specific factors. For example, data have demonstrated specific tumor characteristics that may assist clinicians in predicting who will respond to EGFR inhibitors. Early immunohistochemical staining for EGFR status is not useful in predicting response because both EGFR-positive and EGFR-negative patients respond at the same rate. However, *RAS* gene mutation status has demonstrated predictive value. Patients should be tested for both *KRAS* and *NRAS*, patients with mutated *RAS* are unlikely to benefit from cetuximab or panitumumab therapy.[15] In particular, testing for *RAS* mutational status is now part of the disease workup to define patients who may derive benefit from cetuximab or panitumumab. Characteristics of the tumor are also vital in making treatment decisions for patients with stages II and III disease. The degree of microsatellite instability (MSI) within a tumor tells clinicians information about both prognosis and treatment options. More detail on specific pharmacogenetic and pharmacogenomic information is provided the pertinent pharmacologic therapy sections.

### Nonpharmacologic Therapy
#### ▶ *Operable Disease (Stages I–III)*

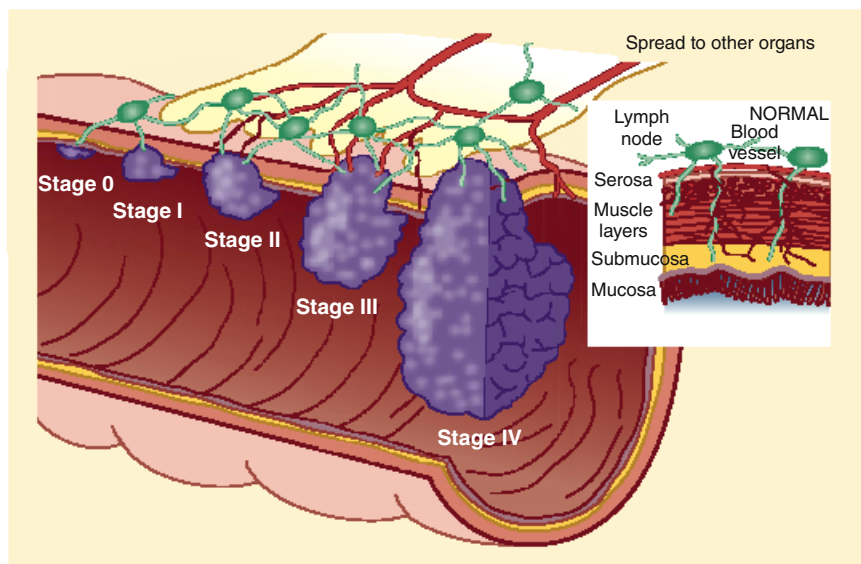
**Surgery** Individuals with stages I to III colorectal cancer should undergo a complete surgical resection of the tumor mass with removal of regional lymph nodes as a curative approach for their disease.[16] Surgery for rectal cancer depends on the region of tumor involvement with attempts to retain rectal


**FIGURE 91-2.** Stage I: cancer is confined to the lining of the colon. Stage II: cancer may penetrate the wall of the colon into the abdominal cavity but does not invade any local lymph nodes. Stage III: cancer invades one or more lymph nodes but has not spread to distant organs. Stage IV: cancer has spread to distant locations in the body, which may include the liver, lungs, or other sites. (From http://www.cancer.gov/cancertopics/pdq/treatment/colon/Patient/page2.)

function as a goal of the surgical procedure. Overall, surgery for colorectal cancer is associated with low morbidity and mortality rates. Common complications include infection, anastomotic leakage, obstruction, adhesion formation, and malabsorption syndromes.

**Radiation Therapy** There is currently no role for adjuvant radiation in colon cancer. However, patients who receive surgery for rectal cancer receive radiation therapy to reduce local tumor recurrence. Adjuvant radiation plus chemotherapy is considered standard treatment for patients with stage II or III rectal cancer after the surgical procedure is complete.[17] Preoperative radiation may be used to reduce the initial size of rectal cancers to make the surgical procedure easier.

▶ *Metastatic Disease (Stage IV)*

**Surgery** Unlike stages I to III disease, the benefit of surgical resection in most patients with metastatic disease is limited to symptomatic improvement. Select patients who have from one to three small nodules isolated to the liver, lungs, or abdomen may

have a prolongation of survival, although cure is rare. Five-year survival for patients who undergo surgical resection of metastases isolated to the liver is approximately double that of patients who are not surgical candidates with approximately 33% of patients alive at 5 years.[18] Alternatives to surgery include destroying the tumor through freezing and thawing (cryoablation), heat (radiofrequency), or alcohol injection, although these appear to be less successful than surgical resection.[16,18] Because the majority of these patients will relapse, many practitioners offer adjuvant chemotherapy to select patients following potentially curative resection, but further studies are needed to determine an optimal treatment regimen.[18]

**Radiation** Symptom reduction is the primary goal of radiation for patients with advanced or metastatic colorectal cancer.

## Pharmacologic Therapy

Table 91–3 lists common chemotherapy regimens used in colorectal cancer and the abbreviations used in the literature to describe them.

---

## Patient Encounter, Part 2

**PMH:** Hypertension since age 40 years; obesity; the patient is 55% over her ideal body weight

**FH:** Father died at age 60 years after a stroke. Mother died at age 75 years with breast cancer; older sister with breast cancer; maternal aunt died at age 47 years from rectal cancer

**SH:** Works in a department store. Married with three grown children

**Meds:** Atenelol 50 mg daily; glyburide 10 mg daily; gabapentin 300 mg three times a day; aspirin 81 mg daily

**ROS:** (+) Abdominal cramping, loss of appetite, diarrhea, and fatigue

**PE:**

**VS:** 154/88 mm Hg, P 80, RR 17, T 37.1°C (98.8°F), Ht 168 cm (66 in), Wt 89 kg (196 lb)

**Abd:** Distended and tender to touch, (+) bowel sounds

**Labs:** Positive hemoglobin 11.8 g/dL (118 g/L or 7.32 mmol/L) decreased from 13.4 g/dL (134 g/L or 8.32 mmol/L) last year

**Imaging and Diagnostic Studies**

- Colonoscopy revealed multiple polyps in her transverse colon
- Biopsy revealed four polyps positive for adenocarcinoma of the colon
- Staging CT scan negative for disease outside of her colon.
- Three lymph nodes positive for disease

*Because the patient has stage III colon cancer, how does this affect the goal of your treatment plan compared with stage IV disease?*

*What nonpharmacologic and pharmacologic options are available to this patient?*

**Table 91–3**

**Dosing Schedules of Chemotherapy Regimens for Colon Cancer[a]**

| Regimen | Dosing |
|---|---|
| 5-FU + leucovorin (continuous infusion) | Leucovorin 200 mg/m² IV<br>5-FU 400 mg/m² IV bolus and then 600 mg/m² of 5-FU as a 22-hour continuous infusion on days 1 and 2; repeat every 2 weeks |
| FOLFIRI | Irinotecan 180 mg/m² IV day 1<br>Folinic acid (leucovorin) 400 mg/m² IV day 1<br>5-FU 400–500 mg/m² IV bolus after folinic acid; then 2400–3000 mg/m² of 5-FU IV over 46 hours<br>Repeat every 14 days |
| FOLFOX4 | Oxaliplatin 85 mg/m² IV + leucovorin 200 mg/m² IV followed by 5-FU 400 mg/m² IV bolus and then 5-FU 600 mg/m² IV over 22 hours day 1<br>Leucovorin 200 mg/m², followed by 5-FU 400 mg/m² IV bolus and then 5-FU 600 mg/m² IV over 22 hours day 2<br>Repeat every 2 weeks |
| mFOLFOX6 | Oxaliplatin 85 mg/m² IV day 1<br>Leucovorin 400 mg/m² IV over 2 hours, followed by 5-FU 400 mg/m² IV bolus day 1 followed by 2400 mg/m² IV over 48 hours<br>Repeat every 2 weeks |
| FOLFOXIRI | Irinotecan 165 mg/m² IV day 1<br>Oxaliplatin 85 mg/m² IV day 1<br>Leucovorin 200 mg/m² IV over 2 hours, followed by 5-FU 3200 mg/m² IV over 48 hours<br>Repeat every 2 weeks |
| Bevacizumab + 5-FU regimen | Bevacizumab 5 mg/kg every 2 weeks + a 5-FU–containing regimen (FOLFOX, FOLFIRI, or 5-FU + leucovorin)<br>Bevacizumab 7.5 mg/kg every 3 weeks with CapeOX |
| Cetuximab ± irinotecan | Cetuximab 400 mg/m² first infusion, then 250 mg/m² weekly ± irinotecan 125 mg/m² every week for 4 weeks<br>Repeat irinotecan every 6 weeks (after a 2-week break) |
| Panitumumab | 6 mg/kg every 2 weeks |
| Capecitabine | 1250 mg/m² twice a day orally for 14 days<br>Repeat every 3 weeks |
| CapeOX | Capecitabine 1000 mg/m² twice a day orally for 14 days<br>Oxaliplatin 130 mg/m² IV on day 1<br>Repeat every 3 weeks |

5-FU, 5-fluorouracil; CapeOX, capecitabine–oxaliplatin; IV, intravenous.

[a]Note that many variations exist, and current literature should be checked before administering any chemotherapy regimen.

▶ *Operable Disease (Stages I–III)*

KEY CONCEPT *Adjuvant chemotherapy is administered after tumor resection to decrease relapse rates and improve survival in patients with colon cancer by eliminating micrometastatic disease that is undetected on imaging studies. Patients diagnosed with stage I colon or rectal cancer are usually cured by surgical resection, and adjuvant chemotherapy is not indicated in these patients.[16] The role of adjuvant chemotherapy for stage II colon cancer is controversial but may benefit certain high-risk groups. Adjuvant chemotherapy is standard therapy for patients with stage III colon cancer.* Table 91–4 lists adjuvant treatment regimens based on stage and performance status (PS). Adjuvant chemotherapy for patients with stage II disease has not been shown to be superior to surgery alone with the possible exception of high-risk patients, including those with inadequate nodes sampled for staging, bowel perforation upon diagnosis, T4 lesions, and those with unfavorable histology.[15] The risks and benefits of adjuvant chemotherapy should be discussed with medically fit patients who have stage II disease with high-risk features. However, the American Society of Clinical Oncology does not recommend the routine use of adjuvant chemotherapy in the general patient population unless part of a clinical trial.[19]

There is currently insufficient data to recommend the use of tumor gene profiling to determine need for adjuvant therapy in stage II disease, but it is an area of active research.[15] An additional consideration for deciding on adjuvant therapy is

the status of MSI within the tumor. MSI results from defective DNA mismatch repair (dMMR) genes leading to damaged DNA. Patient' with tumors that display high levels of MSI may have better prognosis than patients with microsatellite-stable

**Table 91–4**

| **Low Risk[b]** | **Poor Performance Status** |
| • Observation or clinical trial<br>• Capecitabine or 5-FU plus leucovorin | • Capecitabine |

5-FU, 5-fluorouracil.

[a]Individualized assessment of patient risk is necessary to determine if treatment is required. Clinical trials or observation may be an appropriate option.

[b]T3 lesions may be considered high risk by some clinicians.

(MSS) tumors. Despite being associated with a better prognosis, tumors that display high levels of MSI do not respond as well to certain chemotherapy, including 5-fluorouracil (5-FU).[20] It is recommended that stage II patients should be tested for the status of MSI if 5-FU is being considered for therapy, and an alternative therapy should be considered if high levels of MSI are displayed.[15] In general, patients with stage II colon cancer should be enrolled into clinical trials to assess the impact of new agents and prognostic models.

Adjuvant chemotherapy is standard therapy for patients with stage III colon cancer. The presence of lymph node involvement in the resected specimen places patients with stage III colon cancer at high risk for relapse; the risk of death within 5 years of surgical resection alone is as high as 70%.[16] In this population of patients, adjuvant chemotherapy significantly decreases the risk of cancer recurrence and death and is considered the standard of care.

**KEY CONCEPT** *5-FU, leucovorin, and oxaliplatin (FOLFOX)–based chemotherapy is the standard regimen used in adjuvant colon cancer. It is usually given for 6 months.* Refer to Tables 91–3 and 91–4 for recommended treatment regimens and schedules. 5-FU alone results in a small improvement in survival that can vary based on the method of 5-FU administration and the status of MSI.[20]

The combination of 5-FU plus leucovorin has undergone extensive study in the adjuvant setting with decreased rates of recurrence and improved survival seen in patients receiving 5-FU plus leucovorin compared with surgery alone. Though various schedules of 5-FU and leucovorin can be administered, continuous infusions may be less toxic and have improved response rates (although no survival advantage) compared with bolus regimens. Capecitabine is an oral prodrug of 5-FU that is also effective in the adjuvant setting and is being used as a replacement in certain regimens for 5-FU. Data suggest that capecitabine is at least equivalent to bolus 5-FU and leucovorin in efficacy and is better tolerated by patients in the adjuvant setting.[21] An increase in hand–foot syndrome and decreased mucositis and neutropenia are seen with capecitabine compared with bolus 5-FU.

More often, 5-FU or capecitabine is administered as part of a combination regimen with oxaliplatin and leucovorin (FOLFOX or CapeOx). FOLFOX is considered standard of care for patients with stage III disease unless their PS is so poor that clinicians do not believe the patients could tolerate intensive combination therapy. Every effort should be made to minimize adverse treatment effects and use this regimen in patients with stage III colon cancer because this is the only regimen demonstrated to improve overall survival in these patients.[16,22] Several variations on the original FOLFOX regimen have been studied with mFOLFOX6 being the most routinely used in clinical practice (Refer to Table 91–4). CapeOx resulted in improved DFS compared with bolus 5-FU–leucovorin, but no overall survival benefit in stage III patients and is considered an acceptable adjuvant regimen in this patient population.[15,23]

Targeted therapies, including cetuximab and bevacizumab, have been evaluated for their role in their adjuvant treatment of colon cancer. At this time, no targeted agents are approved for use as adjuvant therapy in stage II or III colorectal cancer patients. Additionally, irinotecan should not be used in the adjuvant setting because its addition to 5-FU–based regimens has increased toxicity without therapeutic benefit.[15]

▶ *Metastatic Disease (Stage IV)*

Traditional chemotherapy and targeted biological therapies are the mainstay of treatment for metastatic colon or rectal cancer

and have improved the median survival time of these patients to more than 2 years.[16] Most often, a combination of chemotherapy agents with biological therapies is administered to these patients. Currently, metastatic colorectal cancer is incurable, and treatment goals are to reduce patients' symptoms, improve quality of life, and extend survival. Combination chemotherapy regimens have been demonstrated to result in prolongation of survival with tolerable adverse effects. Similar to the adjuvant setting, 5-FU plus leucovorin continues to be in most first-line chemotherapy regimens used for metastatic colorectal cancer. A variety of continuous intravenous (IV) infusion 5-FU and bolus regimens can be used; however, compared with IV bolus 5-FU, response rates with continuous infusion 5-FU are approximately doubled. In a large meta-analysis of patients with advanced colorectal cancer, continuous infusions of 5-FU had a significantly higher tumor response rate, a small increase in survival, and lower incidence of myelosuppression, diarrhea, and mucositis when compared with bolus regimens.[24]

Additional agents including irinotecan and oxaliplatin have been added to the 5-FU and leucovorin regimen with superior response and survival rates compared to the two drugs used alone.[25,26] A large European study compared a combined bolus and infusional 5-FU regimen plus irinotecan (FOLFIRI) with the FOLFOX regimen (using a slightly different schedule) with crossover to the opposite arm upon relapse.[27] No difference in patient survival was seen with either regimen, and toxicity was as expected. Neuropathy and neutropenia were more common with FOLFOX, while diarrhea, nausea, vomiting, dehydration, and febrile neutropenia were more common with FOLFIRI. Based on improved survival data with the FOLFOX and FOLFIRI regimens, irinotecan-based regimens should only be administered outlined as described in Table 91–3.

Capecitabine also has activity in the metastatic setting. When combined with oxaliplatin in regimens known as CapeOx or XELOX, capecitabine appears to be as safe as 5-FU–based regimens.[15] Additionally, **progression-free survival** (PFS) with capecitabine and oxaliplatin is similar to that of FOLFOX and is considered noninferior to the FOLFOX regimen as first-line therapy in advanced disease.[28] This noninferiority with capecitabine may be specific to its use with oxaliplatin because capecitabine in combination with irinotecan (CAPIRI) demonstrated decreased PFS compared with FOLFIRI and the routine substitution of 5-FU with capecitabine in irinotecan-based regimens is not recommended.[15,29]

5-FU plus leucovorin, or capecitabine alone, is appropriate first-line treatment options for individuals for whom three-drug combination regimens are believed to toxic. The site(s) of tumor involvement, history of prior chemotherapy, and patient-specific factors help define the appropriate management strategy. **KEY CONCEPT** *The most important factor in patient survival is not the initial regimen but whether or not patients receive all three active chemotherapy drugs (5-FU, irinotecan, and oxaliplatin) at some point in their treatment course.*[30] Some clinicians choose to use all three agents in combination in the first-line setting in a regimen termed FOLFOXIRI, although only in patients who are able to tolerate intensive therapy.

Targeted or biologic agents have been approved for use in metastatic colorectal cancer. Bevacizumab in combination with IV 5-FU–based chemotherapy (either FOLFOX or FOLFIRI) is approved by the FDA for initial treatment of patients with metastatic colorectal cancer. Results from randomized trials show increased benefit compared with chemotherapy alone.[15] The efficacy of bevacizumab in this patient population shows

the relevance of **angiogenesis** as an important target for the treatment of metastatic colorectal cancer. The addition of bevacizumab to first-line oxaliplatin-based chemotherapy has also been demonstrated to improve PFS but did not positively impact response rates or overall survival.[31] Similar results were demonstrated with bevacizumab in combination with capecitabine and oxaliplatin.[42]

Based on these results, bevacizumab is recommended as part of 5-FU–based chemotherapy regimens used for the first-line treatment of metastatic colorectal cancer unless contraindicated. Bevacizumab is contraindicated in patients with GI perforation or fistulas involving a major organ, recent (within 28 days) major surgeries or open wounds, wound dehiscence requiring medical intervention, hypertensive crisis or uncontrolled severe hypertension, hypertensive encephalopathy—serious bleeding, a severe arterial thromboembolic event, moderate or severe proteinuria (urine protein excretion 2 g/24 hours or more), nephrotic syndrome, and reversible posterior leukoencephalopathy syndrome.

The EGFR inhibitors, cetuximab and panitumumab, demonstrate improved PFS as first-line therapy in the metastatic setting when individually combined with either the FOLFOX or FOLFIRI regimens in *KRAS* wild-type individuals.[32–35] **KEY CONCEPT** *Before using these agents, testing for KRAS mutation status should occur. Extensive literature exists demonstrating poor response rates of EGFR inhibitors in patients whose tumors have a mutation in codon 12 or codon 13 of the KRAS gene.*[15, 36] Consequently, cetuximab or panitumumab may be used in the first-line setting in combination with traditional chemotherapy agents in *KRAS* WT patients only.[15]

Attempts to combine the vascular endothelial growth factor (VEGF) inhibitor bevacizumab with cetuximab and panitumumab as part of traditional chemotherapy regimens have resulted in inferior outcomes to regimens with bevacizumab alone.[37] Based on these results, the use of bevacizumab with either EGFR inhibitor is not recommended.[15]

**KEY CONCEPT** *In summary, most practitioners select first-line treatment for metastatic colorectal cancer from among these treatments: oxaliplatin plus 5-FU plus leucovorin (FOLFOX); irinotecan plus 5-FU plus leucovorin (FOLFIRI); capecitabine plus oxaliplatin (CapeOx or XELOX); oxaliplatin plus irinotecan plus 5-FU plus leucovorin (FOLFOXIRI); bevacizumab plus 5-FU– or capecitabine-based chemotherapy (FOLFIRI or FOLFOX or CapeOx or FOLFOXIRI); or cetuximab or panitumumab plus 5-FU–based chemotherapy (FOLFOX or FOLFIRI) in KRAS WT patients.*[15]

▶ *Second-Line Therapy*

**KEY CONCEPT** *Treatment of relapsed or refractory metastatic disease uses agents not given in the first-line setting. Patients who receive all effective chemotherapy options have improved outcomes compared with those who do not.* Because most patients will have received a combination of 5-FU or capecitabine with either irinotecan or oxaliplatin, second-line therapy with the alternate regimen should be considered.[15] For example, a patient who received FOLFOX plus bevacizumab as first-line therapy for metastatic disease should be offered FOLFIRI as part of their second-line regimen. EGFR inhibitors are an additional option for use in the second-line setting in patients with WT *KRAS* only. Patients who did not have an EGFR inhibitor in their first-line regimens are candidates for single-agent cetuximab or panitumumab or either agent in combination with 5-FU and irinotecan (FOLFIRI + EGFR inhibitor). Additionally cetuximab plus irinotecan can

be used without the inclusion of 5-FU. The use of EGFR inhibitors may be beneficial as monotherapy, but response rates and PFS appear to be increased in combination with irinotecan-based chemotherapy.[38–42] The results appear to be best when irinotecan is continued because of synergy demonstrated between the two classes of agents.[15,38]

If targeted agents such as bevacizumab were not part of the initial regimen, addition to the second-line regimen should be strongly considered. The addition of bevacizumab to FOLFOX has been shown to increase overall survival.[43] Bevacizumab as monotherapy was shown to be inferior to FOLFOX4 in efficacy and should not be considered as a treatment option in the second-line setting. In patients receiving bevacizumab as part of first-line therapy, continuation of bevacizumab with second-line therapy is associated with increased survival.[44] Based on these findings, continuation of bevacizumab in combination with traditional second-line chemotherapy regimens (5-FU-irinotecan or 5-FU-oxaliplatin based) can be considered in patients treated with a first-line bevacizumab containing regimen. A second agent targeting VEGF, ziv-aflibercept, in combination with FOLFIRI can also be considered for use in the second-line setting in patients who have progressed following an oxaliplatin-based first-line regimen. A modest increase in overall and PFS was found in patients receiving FOLFIRI plus ziv-aflibercept compared to FOLFIRI alone.[45] Adverse events and warnings for use with ziv-aflibercept are similar to those with bevacizumab and described in the section of specific agents. **Table 91–5** lists treatment options for first- and second-line treatment of metastatic colorectal cancer. Patients with good PS are treated more aggressively than those with poor PS because of their ability to better tolerate chemotherapy.

---

### Table 91–5

**Treatment Options for Metastatic Colon Cancer[a]**

| First-Line Therapy | Second-Line Therapy |
|---|---|
| **Good Performance Status** | **If First-Line Irinotecan** |
| • FOLFOX or FOLFIRI with bevacizumab | • FOLFOX with or without bevacizumab[b] |
| • FOLFOX or FOLFIRI with cetuximab or panitumumab[c] | • Irinotecan with or without cetuximab[c,d] |
| • FOLFOXIRI with or without bevacizumab | • Capecitabine or 5-FU plus leucovorin |
| • 5-FU + leucovorin or capecitabine with or without bevacizumab | |
| **Poor Performance Status** | **If First-Line Oxaliplatin** |
| • Capecitabine or 5-FU plus leucovorin with or without bevacizumab | • FOLFIRI with or without bevacizumab |
| | • FOLFIRI with ziv-aflibercept |
| | • Irinotecan with ziv-aflibercept |
| | • FOLFIRI or irinotecan with or without cetuximab or panitumumab[c,d] |

5-FU, 5-fluorouracil.

[a]CapeOX may replace FOLFOX in selected patients.

[b]Bevacizumab may be given if not part of the first-line therapy.

[c]If KRAS wild type.

[d]Cetuximab or panitumumab may be given if not part of first-line therapy.

## Patient Encounter, Part 3

Based on the information presented, create a care plan for this patient's colon cancer.

*Your plan should include:*

*(a)  The patient's drug- and nondrug-related needs and problems.*

*(b)  The goals of therapy.*

*(c)  A treatment plan specific to HB that includes strategies to prevent adverse effects of chemotherapy.*

*(d)  A follow-up plan to determine whether the goals have been achieved and the adverse effects of chemotherapy have been minimized.*

*(e)  A plan for treatment options when the initial therapy is no longer achieving the goals of therapy.*

▶ *Salvage Therapy*

Third-line options for patients with metastatic colorectal cancer are limited. Panitumumab is approved for patients who have progressed after 5-FU, oxaliplatin, and irinotecan. Compared with best supportive care, it improves time to disease progression.[15] Based on improvement in PFS compared to best supportive care, the multiple tyrosine kinase inhibitor, regorafenib, was approved as a single agent for metastatic colorectal cancer in the third- or fourth-line setting.[46] Patients who fail standard treatment for metastatic colorectal cancer should be encouraged to participate in a clinical trial evaluating new treatment approaches for this incurable disease.

## SPECIFIC AGENTS USED IN COLORECTAL CANCER

Table 91–6 lists all FDA-approved drugs used in colorectal cancer along with their mechanisms of action, common toxicities, and recommended dose adjustments for hepatic and renal dysfunction as well pharmacogenetic considerations.

### 5-Fluorouracil

5-Fluorouracil (5-FU) acts as a "false" pyrimidine inhibiting the formation of the DNA base thymidine as described in Chapter 88.[16]

5-FU is commonly used in the adjuvant and metastatic treatment of colon and rectal cancers with common regimens listed in Table 91–3. Clinical studies comparing efficacy of bolus and continuous infusion schedules generally favor continuous infusion of 5-FU. This is consistent with evidence that suggests that the duration of infusion may be an important determinant of the biologic activity of 5-FU, particularly because of its short plasma half-life, S-phase specificity, and relatively slow growth of colon tumors.[16,47]

Clinically significant differences in toxicity also differ based on the dose, route, and schedule of 5-FU administration. Leukopenia and mucositis are the primary dose-limiting toxicities of bolus 5-FU, whereas palmar-plantar erythrodysesthesia ("hand–foot syndrome") and diarrhea occur most frequently with continuous infusions of 5-FU.[16,47] Health care practitioners can offer valuable patient advice to decrease the impact of these adverse effects. Patients can be informed to suck on ice chips before and for up to 30 minutes after 5-FU boluses to decrease the incidence

of mucositis. Hand–foot syndrome, characterized by painful swelling and redness of the soles of the feet and palms of the hand, can be minimized with loose-fitting clothing and keeping skin moist. Additional toxicities include moderate nausea and vomiting, skin discoloration, nail changes, photosensitivity, and neurologic toxicity.

An additional determinate of 5-FU toxicity, regardless of the method of administration, is related to its catabolism and pharmacogenomic factors. Dihydropyrimidine dehydrogenase (DPD) is the main enzyme responsible for the catabolism of 5-FU to inactive metabolites.[48] A number of polymorphisms in DPD have been identified in which patients have a complete or near-complete deficiency of this enzyme. This results in unusually severe toxicity, including death, after the administration of 5-FU. Approximately 3% of patients have a complete lack of DPD activity with other patients demonstrating a partial deficiency in enzyme activity. Although patients may be tested for level of DPD activity, it is not routinely done but may be considered in patients who develop severe toxicity after 5-FU administration. The response to 5-FU is also influenced by the status of MSI within the tumor. Tumors with high levels of MSI are generally more resistant to 5-FU despite being associated with better prognosis.

Leucovorin is commonly given with 5-FU. Leucovorin acts to increase the affinity of 5-FU to thymidine synthase, thus increasing the pharmacologic activity of 5-FU.[16] Leucovorin is most effective when administered before 5-FU and can be given by IV bolus or as a continuous infusion. Health care practitioners can also expect an increase in 5-FU toxicities (leukopenia, mucositis, and diarrhea) when leucovorin is given in combination with 5-FU.

### Capecitabine

Capecitabine (Xeloda) is an oral prodrug of 5-FU that is designed to be selectively activated by tumor cells. Capecitabine undergoes a three-step conversion to 5-FU, the last step being phosphorylation by thymidine phosphorylase (TP). TP levels are reported to be higher in tumor cells than normal tissues; therefore, the systemic exposure of active drug is minimized, and tumor concentrations of the active drugs are optimized.[16,22] After the drug is converted to 5-FU, it has the same mechanism of action. The current FDA-approved indication for capecitabine is for use in metastatic and adjuvant colorectal cancer when monotherapy is desired, although it is actively being investigated as a replacement for 5-FU in most combinations of colon and rectal cancer regimens. Capecitabine has been demonstrated to be at least equivalent to bolus IV 5-FU in the metastatic and adjuvant setting with improved patient tolerability.[22,49] Hand–foot syndrome and diarrhea are common with capecitabine because its toxicities (and pharmacologic activity) appear to mimic those of continuous infusions of 5-FU. Both irinotecan and oxaliplatin have been combined with capecitabine. Capecitabine in combination with oxaliplatin appears to be as safe and effective as IV-based 5-FU in the treatment of patients with colorectal cancer.[15,47] Combinations with irinotecan have had mixed results and are not routinely recommended.[15,29]

The dose of capecitabine ranges from 1000 to 1250 mg/m$^2$ twice a day when used by itself; lower doses are often used when it is given in combination with irinotecan or oxaliplatin or in patients with renal insufficiency. The dose should be taken on a full stomach with breakfast and dinner. Capecitabine administered with warfarin can result in significant increases in patients' international normalized ratio (INR) and requires close monitoring.

**Table 91–6**

**FDA-Approved Drugs Used in Colon Cancer**

| Generic Name (Trade Name) | Mechanism of Action | Common Toxicities | Dosing Adjustments for Renal or Hepatic Dysfunction or Pharmacogenetic Considerations |
|---|---|---|---|
| 5-FU | Inhibition of the enzyme thymidylate synthase, the rate-limiting step in thymidine formation | *Dose limiting:* Myelosuppression and mucositis with bolus administration Diarrhea and hand–foot syndrome with continuous infusion *Additional toxicities:* Skin discoloration, nail changes, photosensitivity, and neurologic toxicity | Do not give if bilirubin greater than 5 mg/dL (86 μmol/L) DPD deficiency may result in increased toxicity. Testing not routine, but may be considered in those with excessive toxicity |
| Capecitabine (Xeloda) | Orally active prodrug of 5-FU. Once activated, the mechanism of action is the same | Similar to continuous infusion 5-FU | CrCl 30–50 mL/min (0.50–0.83 mL/s) decrease starting dose to 75% of the original dose Do not give if CrCl < 30 mL/min (0.50 mL/s) |
| Irinotecan (Camptosar) | Topoisomerase inhibitor that forms a complex with the covalently bound DNA topoisomerase enzyme and interferes with the DNA breakage-resealing process | *Dose limiting:* Early and late diarrhea *Additional toxicities:* Neutropenia, nausea, and vomiting | Decrease dose one level in patients with a homozygous UGT1A1*28 allele. Having this allele decreases the hepatic metabolism of irinotecan and increases the toxicity |
| Oxaliplatin (Eloxatin) | Similar to other platinum analogues (cisplatin) in that it binds to the N-7 position of guanine, which results in cross-linking of DNA and double-stranded DNA breaks | *Dose limiting:* Acute (within first 2 days) and persistent (> 14 days) neuropathies *Additional toxicities:* Anaphylactic-like reactions, dyspnea, nausea, vomiting | No formal dose adjustment, though use with caution in patients with mild to moderate renal dysfunction |
| Bevacizumab (Avastin) | Monoclonal antibody that binds to VEGF and inhibits angiogenesis | *Dose limiting:* Hypertension, bleeding episodes, thrombotic events *Additional toxicities:* Rare perforation of the bowel, proteinuria | None |
| Ziv-aflibercept (Zaltrap) | Recombinant fusion protein that binds to VEGF and inhibits angiogenesis | *Dose limiting:* Hypertension, bleeding episodes, thrombotic events, infection, diarrhea *Additional toxicities:* Rare perforation of the bowel, proteinuria | None |
| Regorafenib (Stivarga) | Multiple protein kinase inhibitor, including VEGF KIT, PDGFR, RET, FGFR, TIE2, DDR2, TrkA, Eph2A, RAF-1, BRAF, SAPK2, PTK5, and Abl | *Dose limiting:* Hypertension, hand-foot skin reaction *Additional toxicities:* GI perforation, impaired wound healing, hemorrhage, RPLS, fatigue, electrolyte imbalance, hepatotoxicity | Do not use if Child-Pugh Class C hepatic impairment; Specific recommendations exist for hepatotoxicity developing while on therapy |
| Cetuximab (Erbitux) | Binds to the cell surface EGFR, preventing EGF and TGF-α binding. This decreased cell proliferation of cancer cells | *Dose limiting:* Infusion-related reactions, acneiform skin rash *Additional toxicities:* Diarrhea, hypomagnesemia, hypocalcemia, interstitial lung disease | *KRAS* WT only |
| Panitumumab (Vectibix) | Similar to cetuximab | *Dose limiting:* Acneiform skin rash *Additional toxicities:* Infusion-related reactions, diarrhea, hypomagnesemia, hypocalcemia, interstitial lung disease | *KRAS* WT only |

5-FU, 5-fluorouracil; CrCl, creatinine clearance; EGF, epidermal growth factor; EGFR, epidermal growth factor receptor; RPLS, Reversible posterior leukoencephalopathy syndrome; TGF, transforming growth factor; VEGF, vascular endothelial growth factor; WT, wild type.

The convenience of oral administration, potentially requiring fewer clinic visits, and an improvement in toxicity make capecitabine a useful alternative to IV 5-FU both by itself and incorporated into other regimens used in colorectal cancer.

### Irinotecan

Irinotecan (Camptosar) is a topoisomerase-I inhibitor that forms a complex with the covalently bound DNA topoisomerase I enzyme and interferes with the DNA breakage–resealing process.[49] Binding permits uncoiling of the double-stranded DNA, but it prevents subsequent resealing of the DNA, resulting in double-stranded DNA breaks. Irinotecan is a prodrug that is converted by carboxylesterases to its active form, SN-38. Irinotecan is indicated for the first-line treatment of metastatic colorectal cancer in combination with 5-FU and leucovorin or as a single agent in patients who fail first-line therapies. Irinotecan is not recommended as part of the adjuvant treatment of colorectal cancer at this time.

The major toxicity of irinotecan is diarrhea, which can occur both early and late in therapy.[15,47] The early diarrhea is a cholinergic reaction that occurs in the first 24 hours (often during the infusion) in up to 10% of patients and responds to atropine 0.25 to 1 mg IV. The late diarrhea seen in a larger percent of patients occurs 7 to 14 days after the irinotecan infusion. Health care practitioners have to be diligent in counseling patients on this adverse reaction and counseling them on the proper use of antidiarrheals. At the first change in bowel habits, an intensive loperamide regimen should be started by patients (4 mg initially followed by 2 mg every 2 hours until diarrhea free for 12 hours). If diarrhea does not stop or if it worsens, patients should be instructed to call their health care provider immediately. Late-onset diarrhea may require hospitalization or discontinuation of therapy, and fatalities have been reported. Additional toxicities with irinotecan include leukopenia (including neutropenic fever) and moderate nausea and vomiting. Toxicities of irinotecan appear to be greater when the drug is given weekly compared with other administration schedules.

Similar to 5-FU, a pharmacogenomic abnormality is associated with irinotecan toxicity. UDP-glucuronosyltransferase (UGT1A1) is an enzyme that is responsible for the glucuronidation of SN-38 to inactive metabolites, and reduced or deficient levels of this enzyme correlate with irinotecan-induced diarrhea and neutropenia.[15,47] The FDA approved a blood test that detects variations in this gene. This test may assist health care providers in predicting which patients may develop severe toxicities from "normal" doses of irinotecan and can be ordered before patients receive irinotecan.[15] The package insert recommends dose reductions of one level in patients who are UGT1A1 homozygous variants. Irinotecan is administered as an IV bolus over 60 to 90 minutes in a variety of dosing schedules.

### Oxaliplatin

Oxaliplatin (Eloxatin) is similar to other platinum analogues (cisplatin) in that it binds to the N-7 position of guanine that results in cross-linking of DNA and double-stranded DNA breaks.[47] Oxaliplatin differs from cisplatin in that the DNA damage induced by oxaliplatin may not be as easily recognized by DNA repair genes often seen in colorectal cancer. Oxaliplatin, in combination with 5-FU-based regimens, is indicated for the first- and second-line treatment of metastatic colorectal cancer as well as the adjuvant treatment of colorectal cancer.

The dose-limiting toxicity of oxaliplatin is acute and chronic neuropathy.[16] Acute neuropathies occur within 1 to 2 days of dosing, resolve within 2 weeks, and usually occur peripherally. These acute neuropathies occur in almost all patients to some degree and are exacerbated by exposure to cold temperature or cold objects. Health care providers should instruct patients to avoid cold drinks, avoid use of ice, and cover skin before exposure to cold or cold objects. In addition, carbamazepine, gabapentin, amifostine, and calcium and magnesium infusions have been used to both prevent and treat oxaliplatin-induced neuropathies, although use of these agents is not widely accepted.[16] Persistent neuropathies generally occur after eight cycles of oxaliplatin and are characterized by defects that can interfere with daily activities (eg, writing, buttoning, swallowing, and walking). Patients may receive predefined breaks from oxaliplatin to decrease the onset of these toxicities with reinitiation of therapy.[26] This strategy varies among protocols but involves administering a certain number of predefined oxaliplatin cycles and then stopping. Maintenance therapy with another agent is usually administered and then the oxaliplatin-based regimen is restarted based on the protocol. These neuropathies occur in up to half of patients receiving oxaliplatin but usually resolve with dosage reductions or after oxaliplatin is stopped.[16] A recent phase III trial in the adjuvant setting demonstrated a decrease in greater than grade 2 chronic sensory neuropathies in patients receiving IV calcium and magnesium infusions before and after oxaliplatin infusion.[47] Oxaliplatin has minimal renal, myelosuppressive effects, and nausea and vomiting when compared with other platinum drugs. Oxaliplatin is given IV in a variety of dosing schedules with a typical dose of 85 mg/m$^2$ IV every 2 weeks.

### Bevacizumab

Bevacizumab (Avastin) is a recombinant, humanized monoclonal antibody that inhibits VEGF. VEGF is a proangiogenic growth factor found in many cancers, including colorectal, and is thought to promote blood vessel formation and metastasis of the tumor by binding to VEGF receptors on tumors. Bevacizumab inhibits circulating VEGF, preventing it from binding to receptors and decreasing the formation of new blood vessels.[15,16] Additionally, bevacizumab may allow for increased concentrations of traditional chemotherapy such as irinotecan to reach the tumor to exert its pharmacologic effect. Bevacizumab is not effective alone and must be used in combination with other agents effective in colorectal cancer. It is indicated for first-line and second-line treatment of patients with metastatic colorectal cancer in combination with IV 5-FU–based regimens. Bevacizumab is also approved for use in combination with 5-FU-irinotecan or 5-FU-oxaliplatin-based chemotherapy for treatment of patients with metastatic colorectal cancer whose disease has progressed on a first-line bevacizumab-containing regimen.

Adverse effects associated with bevacizumab include hypertension, which is common but easily managed with oral antihypertensive agents. Thrombotic events (including myocardial infarctions, pulmonary embolisms, and deep vein thrombosis) occur more frequently in the elderly patients with cardiovascular risk factors and need to be monitored routinely. Because bevacizumab interferes with normal wound healing, it should not be given shortly before or after surgical procedures.[15] Initiation within 28 days of surgery is not recommended to allow for proper wound healing and decrease the risk of bleeding. The amount of time needed after bevacizumab discontinuation to perform elective surgical procedures is less clear, but health care providers should take into consideration bevacizumab's half-life of approximately 20 days when making clinical decisions.[33] Patients should have their urine checked for protein

before each dose of bevacizumab to check for potential kidney damage. Patients who have developed 2+ protein on the urinalysis require additional testing before receiving therapy. These patients will have their 24-hour urine collected and assessed for protein. Therapy is interrupted if urine protein excretion exceeds 2 g/24 hours or more and resumed when urine protein excretion decreases to less than 2 g/24 hours.

Finally, there is a risk of GI perforation that is rare but potentially fatal. Patients complaining of abdominal pain associated with vomiting or constipation should be counseled to call their physician immediately. Bevacizumab is commonly given at a dose of 5 mg/kg IV every 14 days until disease progression. Once disease progresses and salvage chemotherapy is initiated, the benefit of continuing bevacizumab is unclear.

### Ziv-aflibercept

Ziv-aflibercept (Zaltrap) is a soluble recombinant fusion protein developed by fusing sections of the VEGFR-1 and VEGFR-2 immunoglobulin domains to the $F_c$ portion of human IgG1 antibody. This results in trapping the VEGF-A, VEGF-B, and PIGF ligands before they get to the native transmembrane receptors, and therefore, inhibiting the angiogenic process.[49] It is FDA approved for the treatment of metastatic colorectal cancer in combination with FOLFIRI after progression on an oxaliplatin-based regimen. The dose is 4 mg/kg as an IV infusion over 1 hour every 2 weeks in combination with FOLFIRI.

Toxicities include severe and potentially fatal hemorrhage, GI perforation, and compromised wound healing for which the FDA has given ziv-aflibercept a black-box warning. Other adverse effects common to VEGF inhibition (thromboembolic events, hypertension, proteinuria) are seen. As a result ziv-aflibercept shares similar monitoring parameters and warnings to those mentioned in the bevacizumab section. Finally additional warnings for neutropenia, diarrhea and dehydration, and reversible posterior leukoencephalopathy syndrome (RPLS) require monitoring patients for signs and symptoms of these toxicities.

### Regorafenib

Regorafenib (Stivarga) is an oral medication that inhibits multiple protein kinases. Its main mechanism of action in colorectal cancer appears to be related to inhibition of vascular endothelial receptors involved in angiogenesis. The importance of additional protein kinase inhibited by regorafenib is unknown in colorectal cancer. Regorafenib is FDA approved as a single agent for metastatic colorectal cancer in the third- or fourth-line setting.[46] The dose of regorafenib is 160 mg orally, once daily for the first 21 days of each 28-day cycle and it must be taken with a low-fat breakfast to improve absorption.

Adverse effects for regorafenib include those typical for VEGF inhibition (hemorrhage, hypertension, wound healing complications, GI perforation) mentioned with bevacizumab and ziv-aflibercept. Regorafenib has a black-box warning for hepatotoxicity that requires baseline liver function tests (ALT, AST, and bilirubin), then every 2 weeks during the first 2 months of therapy, and then monthly. In patients with elevated liver function tests holding doses, dose reductions, or permanent discontinuation of regorafenib may be necessary. Also, asthenia, fatigue, decreased appetite, hand-foot syndrome, diarrhea, mucositis, weight loss, infection, and dysphonia occurred in over 30% of patients. Refer to chapter 99 on supportive care for management. Finally, regorafenib is a substrate of CYP3A4 and patients should be screened for potential drug interactions.

### Cetuximab and Panitumumab

Cetuximab (Erbitux) and panitumumab (Vectibix) are monoclonal antibodies directed against the EGFR. Cetuximab is a chimeric antibody, whereas panitumumab is a fully human monoclonal antibody. EGFR is overexpressed in colorectal cancers and leads to an increase in tumor proliferation and growth.[47] Cetuximab received FDA approval for use in EGFR-expressing metastatic colorectal cancer in irinotecan-relapsed or irinotecan-refractory patients. Cetuximab should be administered in combination with irinotecan but can be used as a single agent in patients who cannot tolerate irinotecan-based chemotherapy. Panitumumab is approved as monotherapy agent and as first-line therapy in combination with FOLFOX in metastatic colorectal cancer.

Both agents are well tolerated with infusion-related reactions being the dose-limiting toxicity of cetuximab and rash most commonly seen with panitumumab. Patients receiving cetuximab require premedication with acetaminophen and diphenhydramine and may require modifications to their administration schedule or permanent discontinuation if they develop severe allergic toxicity. A skin rash and diarrhea are also commonly seen with both agents, and health care practitioners should provide counseling to patients about these adverse effects. Treatment options include common medications used to treat acne (doxycycline), topical and systemic steroids, and general skin care. Patients may be offered these agents prophylactically, upon initiation of therapy, to decrease the potential impact the rash has on their quality of life. Development of rash may be a surrogate marker of response, and clinicians should attempt to minimize the complications of the rash before discontinuing therapy.[15] Other toxicities common to both agents include low magnesium, calcium, and potassium levels that require checking levels and replacement therapy as clinically indicated. A rare adverse effect (less than 1%), interstitial lung disease is seen with all agents that inhibit EGFR, and patients should be instructed to report any new-onset shortness of breath. Cetuximab has an initial loading dose of 400 mg/m$^2$ IV infusion. Weekly doses of 250 mg/m$^2$ are then administered starting the following week. Panitumumab is given 6 mg/kg every 2 weeks.

## RECTAL CANCER

Although often treated similarly to colon cancer, there are some important differences in the treatment of rectal cancer, especially in the adjuvant setting. Rectal cancer involves tumors found in the distal 15 cm of the large bowel and, as such, is very distinct from colon cancer in that it has a propensity for both local and distant recurrence. The higher incidence of local failure and poorer overall prognosis associated with rectal cancer are attributable to limitations in surgical techniques.

---

### Patient Encounter, Part 4

Despite completing six cycles of adjuvant chemotherapy, the patient's disease progresses, and a CT scan reveals metastases to her bone and liver. The tumor is sent for pharmacogenomic profiling and is found to be positive for the wild-type *KRAS* gene (no mutation detected).

*What pharmacologic treatment options are available for the treatment of her metastatic disease?*

Therefore, multimodality therapies with a combination of chemotherapy, radiation, and surgery are at the forefront in the treatment of rectal cancer with the main goal of survival and quality of life by preserving the function of the anal sphincter. In addition, because treatment with surgery, radiation, or systemic chemotherapy at the time of the recurrence is often suboptimal, adjuvant therapy after tumor resection is an important aspect of treatment of the primary tumor. Similar to adjuvant therapy for colon cancer, 5-FU provides the basis for chemotherapy regimens for rectal cancer.

**KEY CONCEPT** *Adjuvant therapy consisting of 5-FU–based chemotherapy in combination with radiation therapy should be offered to patients with stage II or III cancer of the rectum.*[50] Radiation therapy decreases the rate of local recurrences, but 5-FU decreases the risk of distant tumor recurrence as well as acting as a radiosensitizer. Toxicities from combined modality therapy include severe hematologic toxicity, enteritis, and diarrhea. Additional trials have sought to determine optimal combinations of concurrent radiation and 5-FU. Similar to tumors in the colon, continuous infusions of 5-FU appear to be superior to bolus doses. However, leucovorin does not appear to improve efficacy of adjuvant treatment for rectal cancer. Use of oral alternatives to 5-FU that are also known to enhance radiation effects, such as capecitabine, are under investigation with preliminary data suggesting the combination of capecitabine and radiation is likely to be safe and effective. In addition, based on the efficacy in colon cancer, FOLFOX regimens have moved into clinical trials in the adjuvant setting.

Another unique aspect of rectal cancer is the use of neoadjuvant therapy. Preoperative radiation (with or without chemotherapy) is given to downstage the tumor before surgical resection to improve sphincter preservation.[50]

**KEY CONCEPT** *Metastatic rectal cancer is treated with similar regimens as outlined in the colon cancer section are used for palliation of symptoms.*[50]

## OUTCOME EVALUATION

The goals of monitoring are to evaluate whether the patient is receiving any benefit from the management of the disease, detect recurrence, and minimize the adverse effects of treatment. During treatment for active disease, patients should undergo monitoring for measurable tumor response, progression, or new metastases; these tests may include chest CT scans or x-rays, abdominal or pelvic CT scans or x-rays, depending on the site of disease being evaluated for response; and carcinoembryonic antigen (CEA) measurements every 3 months if the CEA level is or was previously elevated.[17] A PET scan can be considered to identify localized sites of metastatic disease when a rising CEA level suggests metastatic disease but results of CT scans and other imaging studies are negative. Symptoms of recurrence such as pain, changes in bowel habits, rectal bleeding, pelvic masses, anorexia, and weight loss develop in fewer than 50% of patients. Patients who undergo curative surgical resection, with or without adjuvant therapy, require close follow-up because early detection and treatment of recurrence could still result in patient cures. In addition, early treatment for asymptomatic metastatic colorectal cancer appears superior to delayed therapy. Colorectal cancer surveillance guidelines published by the American Society of Clinical Oncology recommend against routinely monitoring liver function tests, complete blood count (CBC), FOBT, CT scans, annual chest x-rays, or pelvic imaging in asymptomatic patients.[55]

In addition, a CBC should be obtained before each course of chemotherapy administration to ensure that hematologic values are adequate. In particular, white blood cell counts and absolute neutrophil counts can be decreased in patients receiving chemotherapy such as irinotecan and 5-FU. Baseline liver function tests and an assessment of renal function should be evaluated

---

## Patient Care Process

### Patient Assessment:

- Based on a review of symptoms and presenting signs and symptoms, determine what signs and symptoms the patient is experiencing are related to their colon cancer diagnosis.
- Review the medication history (including prescription and OTC medications) to identify agents that may worsen the patient's symptoms of colon cancer. Identify agents that effect bowel function (resulting in diarrhea or constipation) or agents such as NSAIDs that may cause GI bleeding.
- Review all laboratory and imaging studies, focus on the CBC, serum creatinine, and hepatic function.
- Determine performance status of the patient (see Chapter 88).

### Therapy Evaluation:

- Determine if the patient requires chemotherapy to treat the colon cancer. If you determine they need therapy, evaluate treatment options for the patient.
- Review the chemotherapy order and assess efficacy, dosages, drug-interactions, and possible adverse effects from the regimen (see Tables 91–3 and 91–5).

### Care Plan Development:

- Discuss lifestyle modifications that may assist in symptom and disease management.
- Calculate the body surface area (BSA) and determine if doses are optimal and correct for this patient. Evaluate laboratory values to assist in this process.
- Review supportive care options to decrease the impact of adverse effects for this patient (see Chapters 88 and 99).
- Counsel patient on potential adverse effects of the regimen.

### Follow-up Evaluation:

- Follow up when the patient is scheduled for their next round of chemotherapy. Assess the patient for adverse effects of the regimen or other supportive care measures that may need to be added (eg, pain management).
- Review medication history, physical examination, laboratory results, and other imaging and diagnostic tests to evaluate if the patient should continue on their current chemotherapy regimen.

before and periodically during therapy. Other selected laboratory tests include checking for the presence of protein in the urine in patients receiving bevacizumab and monitoring of magnesium, calcium, and potassium in patients receiving cetuximab or panitumumab.

Patients should be evaluated during every treatment visit for the presence of anticipated side effects from their treatment, and health care practitioners should anticipate these adverse reactions and aggressively treat and prevent them from occurring. These generally include loose stools or diarrhea from irinotecan, 5-FU, and capecitabine; hand–foot syndrome from 5-FU and capecitabine; nausea or vomiting from irinotecan, 5-FU, and oxaliplatin; mouth sores from 5-FU; neuropathies from oxaliplatin; bleeding and hypertension from bevacizumab; and skin rash associated with cetuximab and panitumumab.

## SUMMARY

Recent advances in the treatment of cancer of the colon and rectum now offer the potential to improve patient survival, but for many patients, improved DFS and PFS represent equally important therapeutic outcomes. In the absence of the ability of a specific treatment to demonstrate improved survival, important outcome measures should include the effects of the treatment on patient symptoms, daily activities, PS, and other quality-of-life indicators. Individualized patient care to balance the risks associated with treatment and benefits of a specific treatment regimen is necessary to optimize patient outcomes.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| APC | Adenomatous polyposis coli |
| CapeOX | Capecitabine and oxaliplatin |
| CBC | Complete blood count |
| CEA | Carcinoembryonic antigen |
| COX-2 | Cyclooxygenase-2 |
| CTC | Computed tomographic colonoscopy |
| DFS | Disease-free survival |
| DPD | Dihydropyrimidine dehydrogenase |
| EGFR | Epidermal growth factor receptor |
| FAP | Familial adenomatous polyposis |
| FIT | Fecal immunochemical test |
| FOBT | Fecal occult blood test |
| FOLFIRI | Folinic acid, fluorouracil, and infusional irinotecan |
| FOLFOX | Folinic acid, fluorouracil, and oxaliplatin |
| GI | Gastrointestinal |
| HNPCC | Hereditary nonpolyposis colorectal cancer |
| INR | International normalized ratio |
| MSI | Mircrosatellite instability |
| NSAID | Nonsteroidal anti-inflammatory drug |
| PET | Positron emission tomography |
| PFS | Progression-free survival |
| TNM | Tumor, node, metastasis |
| TP | Thymidine phosphorylase |
| UGT | UDP-glucuronosyltransferase |
| VEGF | Vascular endothelial growth factor |

# Prostate Cancer

Trevor McKibbin

## LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. List the risk factors associated with the development of prostate cancer.
2. Discuss the benefits and risks associated with screening for prostate cancer.
3. Determine the prognostic- and patient-specific data needed to determine appropriate treatment options.
4. Recommend an initial treatment for prostate cancer on the basis of stage, Gleason score, prostate-specific antigen, patient age, and symptoms.
5. State adverse effects associated with androgen deprivation therapy.
6. List adverse effects associated with treatment options for castrate-resistant prostate cancer.
7. Determine an appropriate treatment for a patient with metastatic castrate-resistant prostate cancer.
8. Understand the role of immunotherapy in the treatment of metastatic castrate-resistant prostate cancer.

## INTRODUCTION

Prostate cancer is the most commonly diagnosed cancer in US men and the second leading cause of cancer-related death in men.[1] The disease course varies from a slow growing, asymptomatic tumor that may not require treatment to a rapidly progressing, aggressive tumor resulting in distant metastasis, morbidity, and mortality.

## EPIDEMIOLOGY AND ETIOLOGY

**KEY CONCEPT** *Prostate cancer is the most frequently diagnosed cancer among US men and represents the second leading cause of cancer-related deaths in all men.[1]* In the United States alone, it was predicted that more than 280,000 new cases of prostatic cancer will be diagnosed and more than 27,000 men would die from this disease in 2015.[1] Although prostate cancer incidence increased during the late 1980s and early 1990s, owing to widespread prostate-specific antigen (PSA) screening, deaths from prostate cancer have been declining since 1995.[2] In the United States, 1 in 6 men will be diagnosed with prostate cancer, with 1 in 35 eventually succumbing to the disease.

The widely accepted risk factors for prostate cancer are age, race, and family history of prostate cancer (**Table 92–1**). Age is the greatest predictor of risk, the disease is rare under the age of 40, but the incidence sharply increases with each subsequent decade of life.[2] In an evaluation of autopsies from men in Michigan dying of unrelated causes, prostate cancer was identified in 2%, 29%, 32%, 55%, and 64% of men in their third, fourth, fifth, sixth, and eighth decades of life, respectively.[3] Men of older age have had a greater lifetime exposure to testosterone, a known growth signal for the prostate.

## Race

The incidence of clinical prostate cancer varies across geographic regions. Scandinavian countries and the United States report the highest incidence of prostate cancer, but the disease is less common in Japan and other Asian countries.[2] African American men have the highest rate of prostate cancer in the world, and prostate cancer mortality in African Americans is approximately twice that seen in the white population. Hormonal, dietary, and genetic differences, as well as differences in access to health care, may contribute to the variability in incidence and mortality in these populations.[2] Testosterone, commonly implicated in the pathogenesis of prostate cancer, is 15% higher in African American men compared with white men. Activity of 5-α-reductase, the enzyme that converts testosterone to its more active form, dihydrotestosterone (DHT), in the prostate is decreased in Japanese men compared with African Americans and whites.[2,3] In addition, genetic variations in the androgen receptor exist. Activation of the androgen receptor is inversely correlated with trinucleotide (CAG) repeat length. Shorter CAG repeat sequences have been found in African Americans. The combination of increased testosterone and increased androgen receptor activation may account for the increased risk of prostate cancer in African American men.[2]

## Family History

Men with a brother or father with prostate cancer have twice the risk for prostate cancer compared to the rest of the population.[2] Genome-wide scans have identified potential prostate cancer susceptibility candidate genes, and there appears to be a familial clustering of a prostate cancer syndrome. Common exposure

**Table 92–1**

**Risk Factors Associated with Prostate Cancer**

| Factor | Possible Relationship |
|---|---|
| **Probable Risk Factors** | |
| Age | More than 70% of cases are diagnosed in men older than 65 years |
| Race | African Americans have a higher incidence and death rate |
| Genetic | Familial prostate cancer inherited in an autosomal dominant manner |
| | Mutations in *p53*, *Rb*, E-cadherin, α-catenin, androgen receptor, *KAI1*, and microsatellite instability; loss of heterozygosity at 1, 2q, 12p, 15q, 16p, and 16q; *BRCA1* and *BRCA2* mutations |
| | Candidate prostate cancer gene locus identified on chromosome 1 |
| **Possible Risk Factors** | |
| Environmental | Clinical carcinoma incidence varies worldwide |
| | Latent carcinoma similar between regions' nationalized men adopt intermediate incidence rates between that of the United States and their native country |
| Occupational | Increased risk associated with cadmium exposure |
| Dietary | Increased risk associated with high-meat and high-fat diets |
| | Decreased intake of 1,25-dihydroxyvitamin D, lycopene, and β-carotene increases risk |
| Hormonal | Does not occur in castrated men |
| | Low incidence in cirrhotic patients |
| | Up to 80% are hormonally dependent |
| | African Americans have 15% increased testosterone |
| | Japanese have decreased 5-α-reductase activities |
| | Polymorphic expression of the androgen receptor |

to environmental and other risk factors may also contribute to increased risk among patients with first-degree relatives with prostate cancer.[2] Male carriers of germline mutations of *BRCA1* and *BRCA2* are known to have an increased risk for developing prostate cancer, although sequencing of these genes is not commonly performed.[4] However, as evidence has accumulated that several additional germline DNA sequence variants may be associated with prostate cancer, the possibility that genetic testing might be used to aid in prostate cancer screening, detection, diagnosis, or risk stratification has emerged. In one analysis, five such sequence variants, three single nucleotide polymorphisms (SNPs) at 8q24 and one each at 17q12 and 17q24.3, were found to have a marked association with prostate cancer, especially for men with a family history of the disease, showing a 9.46-fold increased risk (with 95% confidence interval of 3.62–24.72) for a prostate cancer diagnosis.

### Diet

A number of epidemiologic studies support an association between high fat intake and risk of prostate cancer.[5] A strong correlation between national per capita fat consumption and national prostate cancer mortality has been reported, and prospective case-control studies suggest that a high-fat diet doubles the risk of prostate cancer. Dietary factors that are potentially protective for prostate cancer include retinol, carotenoids, lycopene, calcium, and vitamin D consumption.[5] Tomatoes, pink grapefruit, and watermelon are rich in lycopenes, antioxidants that help prevent damage to DNA. Studies suggest that lycopenes may help lower prostate cancer risk, but prospective clinical trials are needed. A large trial of selenium and vitamin E supplementation to prevent prostate cancer failed to show any benefit.[6]

### Other Factors

Benign prostatic hyperplasia (BPH) is a common problem among elderly men, affecting more than 40% of men older than the age of 70 years. BPH results in the urinary symptoms of hesitancy and frequency. Because prostate cancer affects a similar age group and often has similar presenting symptoms, the presence of BPH often complicates the diagnosis of prostate cancer, although it does not appear to increase the risk of prostate cancer.[2,9]

Smoking has been associated with an increased risk of aggressive prostate cancer and smokers with prostate cancer have an increased mortality resulting from the disease compared with nonsmokers with prostate cancer.[2]

### PATHOPHYSIOLOGY

The prostate gland is a solid, round, walnut-shaped organ positioned between the neck of the bladder and the urogenital diaphragm (Figure 92–1). Adenocarcinoma, the major pathologic cell type, accounts for more than 95% of prostate cancer cases.[7] Much rarer tumor types include small cell neuroendocrine cancers, sarcomas, and transitional cell carcinomas.

Prostate cancer can be graded systematically according to the histologic appearance of the malignant cell and then grouped into categories of well, moderately, or poorly differentiated grades.[7] Gland architecture is examined and then rated on the Gleason scale of 1 (well differentiated) to 5 (poorly differentiated). Two different specimens are examined, and the score for

**FIGURE 92–1.** The prostate gland. (From DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 6th ed. New York: McGraw-Hill, 2005:1856.)

each specimen is added. Groupings for total Gleason score are 2 to 4 for well differentiated, 5 or 6 for moderately differentiated, and 7 to 10 for poorly differentiated tumors. Poorly differentiated tumors grow rapidly (poor prognosis), while well-differentiated tumors grow slowly (better prognosis).

Metastatic spread can occur by local extension, lymphatic drainage, or hematogenous dissemination.[7,8] Lymph node metastases are more common in patients with large, undifferentiated tumors that invade the seminal vesicles. The pelvic and abdominal lymph node groups are the most common sites of lymph node involvement (see Figure 92–1). Skeletal metastases from hematogenous spread are the most common sites of distant spread. Typically, the bone lesions are osteoblastic or a combination of osteoblastic and osteolytic. The most common site of bone involvement is the lumbar spine. Other sites of bone involvement include the proximal femurs, pelvis, thoracic spine, ribs, sternum, skull, and humerus. The lung, liver, brain, and adrenal glands are the most common sites of visceral involvement, although, these organs usually are not involved initially. About 25% to 35% of patients have evidence of lymphangitic or nodular pulmonary infiltrates at autopsy.

Normal growth and differentiation of the prostate depends on the presence of androgens, specifically DHT.[8,9] The testes and the adrenal glands are the major sources of circulating androgens. Hormonal regulation of androgen synthesis is mediated through a series of biochemical interactions among the hypothalamus, pituitary, adrenal glands, and testes (**Figure 92–2**).

Testosterone, the major androgenic hormone, accounts for 95% of the androgen concentration.[9] The primary source of testosterone is the testes; however, 3% to 5% of testosterone is derived from direct adrenal cortical secretion of testosterone or C19

**Table 92–2**

**Hormonal Manipulations in Prostate Cancer**

steroids such as androstenedione. In the prostate 5-α-reductase converts testosterone to a more active form, DHT.[10]

In early stage prostate cancers, aberrant tumor cell proliferation is promoted by the presence of androgens, namely testosterone and dihydrotestosterone. Blockade and reduction in the level of circulating androgens induces tumor regression in most patients. Hormonal manipulations to reduce circulating androgens can occur through several mechanisms (**Table 92–2**).[8–10] The testes, the organs primarily responsible for androgen production, can be removed surgically (orchiectomy). Hormonal pathways that modulate prostatic growth can be interrupted at several steps (see Figure 92–2). Interference with gonadotropin-releasing hormone (GnRH) or LH (by estrogens, GnRH agonists, direct GnRH antagonists, progesterones, and cyproterone acetate) can reduce testosterone secretion by the testes. Estrogen administration reduces androgens by directly inhibiting LH release, acting directly on the prostate cell, or decreasing free androgens by increasing steroid-binding globulin levels.[11]

The physiologic response to GnRH depends on both the dose and the mode of administration. Intermittent pulsed GnRH administration, which mimics the endogenous release pattern, causes sustained release of both LH and FSH, but high dose or continuous administration of GnRH inhibits gonadotropin release via receptor downregulation.[11] Structural modification of the naturally occurring GnRH and innovative delivery have produced a series of GnRH agonists that cause a similar downregulation of pituitary receptors and a decrease in testosterone production.[12]

Androgen synthesis can also be inhibited in the testes or adrenal gland.[11] Aminoglutethimide inhibits the desmolase–enzyme complex in the adrenal gland, thereby preventing the conversion of cholesterol to pregnenolone. Pregnenolone is the precursor substrate for all adrenal-derived steroids, including androgens, glucocorticoids, and mineralocorticoids. Abiraterone is a specific and potent inhibitor of CYP17A1, decreasing the conversion of pregnenolone to dihydroepiandrosterone (DHEA), a

required precursor for testosterone. Ketoconazole, an imidazole antifungal agent, causes a dose-related reversible reduction in serum cortisol and testosterone concentration through a similar mechanism. Megestrol is a synthetic derivative of progesterone that exhibits a secondary mechanism of action by inhibiting the synthesis of androgens. This inhibition appears to occur at the adrenal level, but circulating levels of testosterone also are reduced, suggesting that inhibition at the testicular level also may occur.[10,11]

Antiandrogens inhibit the formation of the DHT–receptor complex and thereby interfere with androgen-mediated action at the cellular level. Megestrol acetate, a progestational agent, also is available and has antiandrogen actions.[11] Finally, the conversion of testosterone to DHT may be inhibited by 5-α-reductase inhibitors.

In advanced stages of the disease, prostate cancer cells may be able to survive and proliferate without the signals normally provided by circulating androgens.[9,11] When this occurs, these tumors are referred to as **castrate resistant** and were formally known as hormone refractory or androgen independent. Because tumors remain amenable to secondary hormonal manipulations, and because the reintroduction of androgens can continue to promote tumor growth, the term castrate resistant more accurately reflects the clinical picture.

## PREVENTION AND EARLY DETECTION
### Chemoprevention

Significant decreases in the risk of prostate cancer have been demonstrated by the 5-α-reductase inhibitors finasteride and dutasteride.[13,14] Finasteride selectively inhibits the 5-α-reductase type-II isoenzyme, whereas dutasteride inhibits both type I and type II. Both finasteride and dutasteride lower the PSA by approximately 50%.[9,13] This lowering may vary across individuals or within the same individual over time. Although no prospective studies have validated a specific threshold for PSA monitoring in patients receiving a 5-α-reductase inhibitor, common clinical practice is to lower the PSA threshold by one-half, for example, a PSA of 4 ng/mL (4 mcg/L) for a man on dutasteride would be considered the same as a PSA of 8 ng/mL (8 mcg/L) for a man not on dutasteride.

The Prostate Cancer Prevention Trial compared 5 mg/day of finasteride for 7 years with placebo for the prevention of prostate cancer in men 55 years of age or older with normal digital rectal examination findings and a PSA of 3.0 ng/mL (3.0 mcg/L) or less. When compared with placebo, the prevalence of prostate cancer was reduced for those on finasteride by 24.8%. However, in those who did develop prostate cancer, there was an increase in the number of high-grade (Gleason grade, 7–10) tumors detected at biopsy in the finasteride group. Overall, finasteride did reduce the frequency of prostate cancer; however, the prostate cancers that were diagnosed in the finasteride group were more aggressive. There were no differences in overall survival. Common adverse events included decreased libido, erectile dysfunction, and gynecomastia.[13]

Dutasteride was evaluated in a different population of men.[19] The study randomized men that were 50 to 75 years of age with PSA levels of 2.5 to 10 ng/mL (2.5–10 mcg/L) and a recent negative prostate biopsy result to dutasteride 0.5 mg/day or placebo. Treatment with dutasteride resulted in a significant reduction in the risk for prostate cancer (RR reduction of 22.8%) as well as a reduction in acute urinary retention. There were no significant differences in overall survival.[15]

5-α-Reductase inhibitors decrease the period prevalence of for-cause prostate cancer by approximately 26% (RR, 0.74; 95% CI, 0.67–0.83). The absolute risk reduction is about 1.4%, although this may vary with the age of the treated population. On the basis of these outcomes, the ASCO and AUA guidelines recommend that asymptomatic men with a PSA less than or equal to 3 ng/mL (3 mcg/L) who are regularly screened with PSA may benefit from a discussion of both the benefits of 5-α-reductase inhibitors for 7 years for the prevention of prostate cancer and the potential risks (including adverse effects and the possibility of high-grade prostate cancer). Men who are taking 5-α-reductase inhibitors for benign conditions such as lower urinary tract symptoms may benefit from a similar discussion.[16]

### Screening

Early detection of potentially curable prostate cancers is the goal of prostate cancer screening. For cancer screening to be beneficial, it must reliably detect cancer at an early stage, and identify those cancers that would benefit from an early intervention and decrease mortality. Whether prostate cancer screening fits these criteria has generated considerable controversy.[17,18] Digital rectal examination (DRE) has been recommended since the early 1900s for the detection of prostate cancer. The primary advantage of DRE is its specificity, reported at greater than 85%, for prostate cancer. Other advantages of DRE include low cost, safety, and ease of performance. However, DRE is relatively insensitive and is subject to interobserver variability. DRE as a single-screening method has poor compliance and had little effect on preventing metastatic prostate cancer in one large case-control study.

**KEY CONCEPT** *Prostate-specific antigen (PSA) is a useful marker for detecting prostate cancer at early stages, predicting outcome for localized disease, monitoring disease-free status, and monitoring response to treatment of advanced-stage disease.* PSA is a member of the human kallikrein gene family of serine proteases. PSA is produced by columnar secretory cells in the prostate and plays a role in the liquefaction of seminal fluid. Periodic PSA monitoring is used widely for prostate cancer screening in the United States, with simplicity as its major advantage and low specificity as its primary limitation.[19] Although PSA is often elevated in men with prostate cancer, the PSA may also be elevated in men who are smokers or with acute urinary retention, acute prostatitis, and prostatic ischemia or infarction, as well as BPH, a common condition in men at risk for prostate cancer. PSA elevations between 4.1 ng/mL (4.1 mcg/L) and 10 ng/mL (10 mcg/L) cannot distinguish between BPH and prostate cancer, limiting the utility of PSA alone for the early detection of prostate cancer. Additionally, not all men with clinically significant prostate cancer have a serum PSA outside the reference range.[17]

---

**Patient Encounter 1: Prevention and Screening**

A 56-year-old man comes into the pharmacy for a refill of his finasteride, which he is taking for BPH. He wants to know what he can do to reduce his risk of prostate cancer.

This patient does not have a family history of prostate cancer. He has never been screened for prostate cancer.

*What do you recommend for prostate cancer screening?*

*What do you recommend for prostate cancer chemoprevention?*

The benefit of prostate cancer screening is controversial. PSA measurements can identify small, subclinical prostate cancers, in which no intervention may be required. Detecting prostate cancer in those not needing therapy subjects some patients to unnecessary workups and psychological stress related to a cancer diagnosis.[18] Currently, the American College of Physicians recommends that rather than screening all men for prostate cancer as a matter of routine, physicians should describe the potential benefits and known risks of screening, diagnosis, and treatment; listen to the patient's concerns; and then decide on an individual's screening method.[17] The US Preventative Task Force rates PSA screening for prostate cancer a grade D, intended to "discourage the use of the service."[20]

## CLINICAL PRESENTATION AND DIAGNOSIS (Table 92–3)

KEY CONCEPT *The prognosis for patients with prostate cancer depends on the histologic grade and stage of the prostate cancer*[20,2,23] Details of staging is discussed in Chapter 88. One of the most important prognostic criteria appears to be the histologic grade, assessed by Gleason score. Poorly differentiated tumors are highly associated with both regional lymph node involvement and distant metastases. Once the tumor has spread into locoregional lymph nodes, there is a significantly increased risk of recurrence of disease after curative intent therapy.[23]

## TREATMENT

### Desired Outcome

The desired outcome in early stage prostate cancer is to minimize morbidity and mortality from prostate cancer with consideration that some degree of morbidity may be caused by the toxicity of treatment.[23] Early stage disease may be treated with surgery, radiation, or observation. Although surgery and radiation are curative, they are associated with significant morbidity and a low rate of mortality. Because the overall goal is to minimize

---

morbidity and mortality associated with the disease, observation is appropriate in selected individuals with a low risk of rapid disease progression. Advanced prostate cancer (metastatic spread) is not curable, and treatment of advanced disease should focus on providing symptom relief and maintaining quality of life.

### General Approach to Treatment

The initial treatment for prostate cancer depends on the disease stage, Gleason score, presence of symptoms, and life expectancy of the patient.[22] For asymptomatic patients, determining risk for disease progression and recurrence are critical for determining treatment options. Asymptomatic patients with a low risk of recurrence, those with a $T_1$ or $T_{2a}$ tumor, with a Gleason score of 2 through 6, and a PSA of less than 10 ng/mL (10 mcg/L) may be managed by active surveillance. However, radiation or radical prostatectomy may also be offered (Table 92–4). Because patients with asymptomatic, early stage disease generally have an excellent 10-year survival rate, immediate morbidities of prostatectomy or radiation must be balanced with the lower likelihood of dying from prostate cancer. In general, more aggressive treatments of early stage prostate cancer are reserved for younger men, although patient preference is a major consideration in all treatment decisions. In a patient with a life expectancy of less than 10 years, observation or radiation therapy alone may be preferred. In those with a life expectancy of equal to or greater than 10 years, radiation (external beam or brachytherapy), or radical prostatectomy with a pelvic lymph node dissection may be offered; however, observation can still be used.[23]

Radical prostatectomy and radiation therapy generally are considered therapeutically equivalent for localized prostate cancer.[23] Complications from radical prostatectomy include blood loss, stricture formation, incontinence, lymphocele, fistula formation, anesthetic risk, and impotence. Nerve-sparing radical prostatectomy can be performed in many patients; 50% to 80% regain sexual potency within the first year. Acute complications from radiation therapy include cystitis, proctitis, hematuria, urinary retention, penoscrotal edema, and impotence (30% incidence).[23] Chronic complications include proctitis, diarrhea, cystitis, enteritis, impotence, urethral stricture, and incontinence. Because radiation and prostatectomy have significant and immediate morbidity compared with observation alone, some patients may elect to postpone therapy.[23]

**Table 92–4**

**Management of Prostate Cancer with Low and Intermediate Recurrence Risk**

| Recurrence Risk | Expected Survival (years) | Initial Therapy |
|---|---|---|
| **Low** | | |
| $T_1$-$T_{2a}$ and Gleason 2–6 and PSA < 10 ng/mL (10 mcg/L) and < 5% tumor in specimen | < 10<br>10 or more | Expectant management or radiation therapy<br>Expectant management or radical prostatectomy with or without pelvic lymph node dissection or radiation therapy |
| **Intermediate** | | |
| $T_{2b}$ or Gleason 7 or PSA 10–20 ng/mL (10–20 mcg/L) | < 10 | Expectant management or radical prostatectomy with or without pelvic lymph node dissection or radiation therapy with or without 4–6 months of androgen deprivation therapy |
| | 10 or more | Radical prostatectomy with or without pelvic lymph node dissection or radiation therapy with or without 4–6 months of androgen deprivation therapy |

PSA, prostate-specific antigen.

Individuals with $T_{2b}$ disease or a Gleason score of 7 or a PSA ranging from 10 to 20 ng/mL (10 to 20 mcg/L) are considered at intermediate risk for prostate cancer recurrence. Individuals with less than a 10-year expected survival may be offered observation, radiation therapy, or radical prostatectomy with or without a pelvic lymph node dissection, and those with a greater than or equal to 10-year life expectancy may be offered either radical prostatectomy with or without a pelvic lymph node dissection or radiation therapy (see Table 92–4).

The patients at high risk of recurrence (stages $T_{2c}$, a Gleason score ranging from 8 to 10, or a PSA value greater than 20 ng/mL [20 mcg/L]) should be treated with androgen deprivation therapy for 2 to 3 years combined with radiation therapy (**Table 92–5**).[24] Selected individuals with a low tumor volume may receive a radical prostatectomy with or without a pelvic lymph node dissection.

Patients with $T_{3b}$ and $T_4$ disease have a very high risk of recurrence and are usually not candidates for radical prostatectomy because of extensive local spread of the disease.[23]

---

**Table 92–5**

**Management of Prostate Cancer with High and Very High Recurrence Risk**

| Recurrence Risk | Initial Therapy[a] |
|---|---|
| **High** | |
| $T_{2c}$ or $T_{3a}$, Gleason 8–10, PSA > 20 ng/mL (20 mcg/L) | Androgen ablation[b] (2–3 years) and radiation therapy, or radiation therapy or radical prostatectomy with or without pelvic lymph node dissection |
| **Locally Advanced, Very High** | |
| $T_{3b–T4}$ | Androgen ablation[b] (2–3 years) or radiation therapy + androgen ablation (2–3 years) |
| **Very High** | |
| Any T, $N_1$ | Androgen ablation[b] or radiation therapy + androgen ablation |
| Any T, Any N, $M_1$ | Androgen ablation[b] |

[a]Androgen ablation = serum testosterone levels less than 50 ng/dL (1.74 nmol/L).

[b]Luteinizing hormone–releasing hormone agonist (medical castrations or surgical are equivalent).

**KEY CONCEPT** *Androgen deprivation with a GnRH agonist should be used with radiation therapy for patients with locally advanced prostate cancer to improve outcomes over radiation therapy alone.*

**KEY CONCEPT** *Androgen deprivation therapy, with either orchiectomy, a GnRH agonist alone or a GnRH agonist plus an antiandrogen (combined androgen blockade), can be used to provide palliation for patients with advanced prostate cancer.* Secondary hormonal manipulations, cytotoxic chemotherapy, immunotherapy, or supportive care is used for patients who progress after initial therapy.[26]

## Nonpharmacologic Therapy

### ▶ *Observation*

Observation or active surveillance involves monitoring the course of disease and initiating treatment if the cancer progresses or the patient becomes symptomatic. A PSA and a DRE are performed every 6 months with a repeat biopsy at any sign of disease progression. The advantages of observation are avoiding the adverse effects associated with definitive therapies such as radiation and radical prostatectomy and minimizing the risk of unnecessary therapies. The major disadvantage of observation is the risk that the cancer progresses and requires a more intensive therapy or metastasizes, making the disease incurable.

---

**Patient Encounter 2: Initial Presentation and Treatment**

A 58-year-old man presents to the clinic for follow-up of routine screening with DRE and PSA.

Physical examination is positive for a 1-cm nodule in the prostate, and his laboratory study results reveal the following: PSA, 22 ng/mL (22 mcg/L); PSA from 2 years ago was 2.4 ng/mL (2.4 mcg/L).

A prostate biopsy by TRUS reveals adenocarcinoma of the prostate with a Gleason score of 7. CT scanning and bone scan reveal disease that is metastatic to regional lymph nodes and the lumbar vertebrae.

*Based on his metastatic disease, what are treatment options for this patient?*

### ▶ *Orchiectomy*

Bilateral orchiectomy, or removal of the testes, rapidly reduces circulating androgens to castrate levels (ie, serum testosterone levels less than 50 ng/dL [1.74 nmol/L]).[23] However, many patients find this procedure psychologically unacceptable, and others are not surgical candidates. Orchiectomy may be preferred in the initial treatment of patients with impending spinal cord compression or ureteral obstruction.

### ▶ *Radiation*

The two commonly used methods for radiation therapy are external-beam radiotherapy and brachytherapy.[23,25] In external-beam radiotherapy, doses of 70 to 75 Gy are delivered in 35 to 41 fractions in patients with low-grade prostate cancer and 75 to 80 Gy for those with intermediate- or high-grade prostate cancer. Brachytherapy involves the permanent implantation of radioactive beads of 145 Gy 125-iodine or 124 Gy of 103-palladium and is generally reserved for individuals with low-risk cancers. Radiation therapy may be used to treat local or locally advanced prostate cancer with curative intent. In later stages of disease short courses of external beam radiation therapy can be used to palliate symptoms.[25]

### ▶ *Radical Prostatectomy*

Radical prostatectomy is performed in patients who are surgical candidates with disease that requires definitive therapy based on risk factors and patient preference; additionally, the disease must be amenable to complete surgical resection. Complications from radical prostatectomy include blood loss, stricture formation, incontinence, lymphocele, fistula formation, anesthetic risk, and impotence. Nerve-sparing radical prostatectomy can be performed in many patients; 50% to 80% regain sexual potency within the first year. Acute complications from radical prostatectomy and radiation therapy include cystitis, proctitis, hematuria, urinary retention, penoscrotal edema, and impotence (30% incidence).[23] Chronic complications include proctitis, diarrhea, cystitis, enteritis, impotence, urethral stricture, and incontinence. Because radiation and prostatectomy have significant and immediate mortality when compared with observation alone, many patients may elect to postpone therapy until symptoms develop.

## Pharmacologic Therapy

### ▶ *Gonadotropin-Releasing Hormone Agonists*

GnRH agonists are a reversible method of androgen deprivation and are as effective as orchiectomy in treating prostate cancer.[23] Currently available GnRH agonists include leuprolide, leuprolide depot, leuprolide implant, triptorelin depot, triptorelin implant, and goserelin acetate implant. Leuprolide acetate is administered once daily, whereas leuprolide depot and goserelin acetate implant can be administered once monthly, once every 12 weeks, or once every 16 weeks (leuprolide depot). The leuprolide depot formulation contains leuprolide acetate in coated pellets. The dose is administered intramuscularly, and the coating dissolves at different rates to allow sustained leuprolide levels throughout the dosing interval. Goserelin acetate implant contains goserelin acetate dispersed in a plastic matrix of D,L-lactic and glycolic acid copolymer and is administered subcutaneously. Hydrolysis of the copolymer material provides continuous release of goserelin over the dosing period. Another formulation of leuprolide is a miniosmotic pump implanted intramuscularly that delivers 120 mcg of leuprolide daily for 12 months. After 12 months, the implant is removed, and a different implant can be placed. Triptorelin LA is administered as an intramuscular injection of 11.25 mg every 84 days. Triptorelin depot is administered once every 28 days as a 3.75-mg dose.

Several randomized trials have demonstrated that leuprolide, goserelin, and triptorelin are effective agents when used alone in patients with advanced prostate cancer. Response rates around 80% have been reported, with a lower incidence of adverse effects compared with estrogens. The choice between the three GnRH agonists is usually made on the basis of cost and patient and physician preference for a dosing schedule.

The most common adverse effects reported with GnRH agonist therapy include vasomotor symptoms such as hot flashes, erectile impotence, decreased libido, and injection site reactions. Long-term adverse effects include decreased bone mineral density and metabolic syndrome.[29] Disease flare-up in the first weeks of therapy can be caused by an initial induction of LH and FSH by the GnRH agonist, leading to an initial phase of increased testosterone production.[23] It manifests clinically as an exacerbation of disease-related symptoms, usually increased bone pain or urinary symptoms. This flare reaction usually resolves after 2 weeks and has a similar onset and duration pattern for the depot GnRH products. Initiating an antiandrogen before the administration of the GnRH agonist and continuing for 2 to 4 weeks is a frequently used strategy to minimize this initial tumor flare.

GnRH agonist monotherapy can be used as initial therapy of advanced prostate cancer, with response rates similar to orchiectomy.[23] They are preferred to orchiectomy for the adjuvant treatment of locally advanced prostate cancer as they are reversible. There is a lower incidence of cardiovascular-related adverse effects associated with GnRH therapy than with estrogen administration. A short course of concomitant antiandrogen therapy may need to be considered before initiating the GnRH agonist. Caution should be exercised if initiating GnRH agonist monotherapy in patients with widely metastatic disease involving the spinal cord or having the potential for ureteral obstruction because irreversible complications may occur.

Another potentially serious complication of androgen deprivation therapy is a resultant decrease in bone-mineral density, leading to an increased risk for osteoporosis, osteopenia, and an increased risk for skeletal fractures.[27] Most clinicians recommend that men starting long-term androgen deprivation therapy should have a baseline bone mineral density test and be initiated on a calcium and vitamin D supplement.

### ▶ *Gonadotropin-Releasing Hormone Antagonists*

An alternative to GnRH agonists is the GnRH antagonist, degarelix.[12] Degarelix reversibly binds to GnRH receptors on cells in the pituitary gland, reducing the production of testosterone to castrate levels. The major advantage of direct GnRH agonists is the speed at which they can achieve the drop in testosterone levels; castrate levels are achieved in 7 days or less with degarelix, compared with 28 days with leuprolide, eliminating the tumor flare seen and need for antiandrogens with GnRH agonists. Degarelix is equivalent to leuprolide in lowering testosterone levels for up to 1 year and is approved by the Food and Drug Administration for the treatment of advanced prostate cancer. Degarelix is available as 40-mg/mL and 20-mg/mL vials for subcutaneous injection, and the starting dose is 240 mg followed by 80 mg every 28 days. The starting dose should be split into two injections of 120 mg.

The most frequently reported adverse reactions are injection site reactions, including pain (28%), erythema (17%), swelling (6%), induration (4%), and nodule (3%). Most adverse effects were transient and mild to moderate, leading to discontinuation

GI, gastrointestinal.

in fewer than 1% of study subjects. Other adverse effects included elevations in lever function tests, which occurred in approximately 10% of study subjects. Similar to other methods of androgen deprivation therapy, osteoporosis may develop, and calcium and vitamin D supplementation should be considered. Degarelix is not approved in combination with antiandrogens.

## Antiandrogens

The first generation of nonsteroidal antiandrogens include flutamide, bicalutamide, and nilutamide (Table 92–6). Monotherapy with first-generation antiandrogens is less effective than GnRH agonist therapy. Therefore, for advanced prostate cancer, all currently available antiandrogens are indicated only in combination with androgen-deprivation therapy, flutamide and bicalutamide are indicated in combination with a GnRH agonist, and nilutamide is indicated in combination with orchiectomy. Enzalutamide is a second-generation antiandrogen that is indicated in metastatic castrate-resistant prostate cancer.

The most common antiandrogen-related adverse effects are listed in Table 92–6. Diarrhea is reported more frequently with flutamide than bicalutamide.[21, 28] Few clinical trials have made direct comparisons among the first-generation antiandrogens.

## Combined Androgen Blockade

Although up to 80% of patients with advanced prostate cancer respond to initial hormonal manipulation, almost all patients progress within 2 to 4 years after initiating therapy.[12, 29] Multiple mechanisms have been proposed to explain this tumor resistance. The tumor could be heterogeneously composed of cells that are hormone dependent and hormone independent, or the tumor could be stimulated by extratesticular androgens that are converted intracellularly to DHT. The rationale for combination

GnRH agonists and first-generation antiandrogens is to interfere with multiple hormonal pathways to more completely eliminate androgen action. In clinical trials, combination hormonal therapy, also referred to as **combined androgen blockade** (CAB), has been used. The combination of GnRH agonists or orchiectomy with antiandrogens is the most extensively studied CAB approach.

Many studies comparing CAB with conventional medical or surgical castration have been performed.[29] CAB likely results in a small extension in overall survival compared to GnRH agonist alone or orchiectomy. However, adverse effects such as diarrhea, elevated liver function test results, and anemia are more common in those patients who receive CAB. Because the benefits of CAB are relatively small and the increased adverse effects are not insignificant, it is appropriate to use either GnRH agonist monotherapy or CAB as initial therapy for metastatic prostate cancer.[23] CAB may be most beneficial for improving survival in patients with minimal disease and for preventing tumor flare. All other patients may be started on GnRH monotherapy, and an antiandrogen may be added after several months if androgen ablation is incomplete, or if disease progression occurs despite a castrate level of testosterone.[32]

There is considerable debate concerning when to start hormonal-deprivation therapy in patients with advanced prostate cancer. The original recommendation to start therapy when symptoms appeared was based on trials in which no overall survival difference was demonstrated in patients who either started DES initially or crossed over to active treatment when symptoms appeared; the excess mortality rate was attributed to estrogen administration. Because GnRH agonists and antiandrogens have less cardiovascular toxicity, it is not clear whether delaying therapy is justified with these agents.[32] Thus, early intervention before symptoms appear is appropriate.

## Secondary Therapies

Secondary or salvage therapies for patients who progress after their initial therapy depend on what was used for initial management. For patients initially diagnosed with localized prostate cancer, radiotherapy may be used for local disease recurrence after radical prostatectomy. Alternatively, androgen deprivation therapy can be used in patients who progress after either radiation therapy or radical prostatectomy.[32]

In patients treated initially with one hormonal modality, secondary hormonal manipulations may be attempted. This may include adding an antiandrogen for a patient who either incompletely suppresses testosterone secretion with a GnRH agonist or experiences disease progression while a castrate level of testosterone is maintained. In patients who have progression while receiving CAB, withdrawing antiandrogens, or using agents that inhibit androgen synthesis may be attempted.[32]

For patients who initially received a GnRH agonist alone, castration testosterone levels should be documented. Patients with inadequate testosterone suppression more than 20 ng/dL [0.7 nmol/L]) can be treated by adding an antiandrogen or performing an orchiectomy. If castration testosterone levels have been achieved, the patient is considered to have castrate-resistant disease, and palliative salvage therapy can be used. Supportive care, enzalutamide, abiraterone, radium-223, chemotherapy, immunotherapy, and local radiotherapy can be used in patients who have failed androgen deprivation.[26, 30, 31]

**KEY CONCEPT** *Antiandrogen withdrawal for patients having progressive disease while receiving combined hormonal blockade with a GnRH agonist plus an antiandrogen can provide additional*

*symptomatic relief.* If the patient initially received CAB with a GnRH agonist with an antiandrogen, then anti androgen withdrawal is the first salvage manipulation.[32] Objective and subjective responses have been reported following the discontinuation of flutamide, bicalutamide, or nilutamide in patients receiving these agents as part of CAB. Patient responses to androgen withdrawal manifest as significant PSA reductions and improved clinical symptoms. Androgen withdrawal responses lasting 3 to 14 months have been reported in up to 35% of patients, and predicting response seems to be most closely related to longer antiandrogen exposure times. Incomplete cross-resistance has been noted in some patients who received bicalutamide after they had progressed while receiving flutamide, suggesting that patients who fail one antiandrogen may still respond to another agent.[32]

**KEY CONCEPT** *Once advanced prostate cancer progresses despite castrate levels of testosterone, it is known as castration-resistant prostate cancer.*[32] Previously, this was termed hormone refractory or androgen-independent prostate cancer. Castration resistant more accurately describes the cancer because it may continue to respond to treatments inhibiting the androgen pathways such as enzalutamide or abiraterone. Further, androgens remain a growth signal for the cancer and androgen deprivation therapy is continued throughout the treatment course of castrate-resistant prostate cancer.

## Enzalutamide

Despite initial responses to androgen deprivation therapy and first-generation antiandrogens, disease resistance eventually develops. Enzalutamide is a second-generation antiandrogen that is effective in castrate-resistant prostate cancer, even when first-generation antiandrogens have failed.[3] This may be because enzalutamide prevents the androgen receptor from entering the cell nucleus, further inhibiting androgen signaling. Enzalutamide improves overall survival in castrate-resistant prostate cancer compared to placebo.[10,11] Primary adverse effects include fatigue, diarrhea, hot flashes, and musculoskeletal pain.[33] A rare incidence of seizures was also noted. Enzalutamide is effective in patients that have failed previous chemotherapy, or in patients that are chemotherapy naive.[26] Like other therapies for castrate-resistant prostate cancer, androgen deprivation therapy is continued. Enzalutamide is a strong CYP3A4 inducer and a moderate CYP2C9 and CYP2C19 inducer. Enzalutamide is known to decrease exposure and effect of multiple CYP enzyme substrates, including midazolam (CYP3A4 substrate), warfarin (CYP2C9 substrate), and omeprazole (CYP2C19 substrate).

## Abiraterone

Despite androgen deprivation therapy with GnRH agonists, direct antagonists, or orchiectomy. Androgen synthesis can continue to occur in the periphery (namely the adrenal glands) or within the tumor. The family of cytochrome P450 of enzymes plays a critical role in the synthesis of androgens. CYP17A1 inhibition prevents the conversion of pregnenolone to DHEA, a requisite precursor for testosterone. Abiraterone acetate is a potent and specific inhibitor of CYP17A1 resulting in further reduction of testosterone when combined with continued androgen deprivation. Inhibition of CYP17A1 results in mineral corticoid excess, which contributes to the primary adverse effects of abiraterone. These include fluid retention, hypokalemia, and hypertension.[34] Less common significant adverse effects include hepatotoxicity. Abiraterone should be administered on an empty stomach either 2 hours after or 1 hour before a meal, as food significantly increases absorption. Abiraterone is effective in castration-resistant prostate cancer in chemotherapy naïve patients, as well as in patients with disease progression on docetaxel, not previously treated with abiraterone.[25,26,34]

Androgen synthesis inhibitors, such as aminoglutethimide 250 mg orally every 6 hours or ketoconazole 400 mg orally three times a day, can provide symptomatic relief for a short time in approximately 50% of patients with progressive disease despite previous androgen-ablation therapy.[26] Adverse effects during aminoglutethimide therapy occur in approximately 50% of patients. Central nervous system effects that include lethargy, ataxia, and dizziness are the major adverse reactions. A generalized morbilliform, pruritic rash has been reported in up to 30% of patients treated. The rash is usually self-limiting and resolves within 5 to 8 days with continued therapy. Adverse effects from ketoconazole include diarrhea, transient rises in liver and renal function tests, and hypoadrenalism. Additionally, ketoconazole is a strong inhibitor of CYP1A2 and CYP3A4. Absorption of ketoconazole requires gastric acidity; therefore, ketoconazole should not be administered with $H_2$-blockers, proton pump inhibitors, or antacids. Ketoconazole should be combined with replacement doses of hydrocortisone to prevent symptomatic hypoadrenalism.

## Zoledronic Acid and Denosumab

Skeletal metastases from hematogenous spread are the most common sites of distant spread of prostate cancer. Typically, the bone lesions are osteoblastic or a combination of osteoblastic and osteolytic. Bisphosphonates may prevent skeletal-related events and improve bone mineral density. Zoledronic acid at a dose of 4 mg every 3 weeks reduces the incidence of skeletal-related (such as the need for palliative radiation or pathologic fracture) events by 25% compared with placebo.[35]

Denosumab, a monoclonal antibody targeted against the receptor activator of nuclear factor kappa-B (NF-$\kappa B$), also

### Patient Encounter 3: Progressive Disease

A 66-year-old man who was initially diagnosed with metastatic prostate cancer 5 years ago presents to the clinic. He was initially started on leuprolide and has progressed through treatment as described in the treatment summary below.

#### Treatment Summary

| Date | PSA | Intervention |
|------|-----|--------------|
| 1/10/14 | 25 ng/mL (25 mcg/L) | Started leuprolide 7.5 mg IM every month |
| 3/10/14 | 2 ng/mL (2 mcg/L) | Continued leuprolide |
| 6/2/14 | 22 ng/mL (22 mcg/L) | Added bicalutamide 50 mg orally daily |
| 9/2/14 | 5 ng/mL (5 mcg/L) | Continued leuprolide and bicalutamide |
| 10/2/14 | 32 ng/mL (32 mcg/L) | Continued leuprolide; stopped bicalutamide |
| 11/1/14 | 7 ng/mL (7 mcg/L) | Continued leuprolide |

Today he presents to the clinic with bone pain and a serum PSA of 67 ng/mL (67 mcg/L).

*Why was bicalutamide discontinued on 10/2/14?*

*How would you characterize the patient's disease?*

*What treatments are options for him?*

decreases the incidence of skeletal-related events in patients with castrate-resistant prostate cancer with bone metastasis. Denosumab is a subcutaneous injection administered at a dose of 120 mg every 4 weeks. While it may cause a higher incidence of hypocalcemia compared to zoledronic acid, it also provides greater protection against skeletal-related events, such as fracture. Similar to zoledronic acid, patients should be counseled to take calcium and vitamin D supplementation.[35] Both denosumab and zoledronic acid also associated with a low but significant rate of osteonecrosis of the jaw.[36] Dental procedures should be avoided while receiving these agents and dental screening prior to initiation is recommended.[37]

**KEY CONCEPT** *Chemotherapy with docetaxel and prednisone improves survival in patients with castrate-resistant prostate cancer.*

Docetaxel 75 mg/m$^2$ every 3 weeks combined with prednisone 5 mg twice a day improves survival in hormone-refractory metastatic prostate cancer.[38] The most common adverse events reported with this regimen are nausea, alopecia, and bone marrow suppression. In addition, fluid retention and peripheral neuropathy, known effects of docetaxel, are observed. Docetaxel is hepatically eliminated; patients with hepatic impairment may not be eligible for treatment with docetaxel because of an increased risk for toxicity.[38]

The combination of estramustine (280 mg three times a day, days 1 to 5) and docetaxel 60 mg/m$^2$ on day 2 every 3 weeks also improves survival in hormone-refractory metastatic prostate cancer.[39] Estramustine causes a decrease in testosterone and a corresponding increase in estrogen; therefore, the adverse effects of estramustine include an increase in thromboembolic events, gynecomastia, and decreased libido (Table 92–7). Estramustine is an oral capsule and should be refrigerated. Calcium inhibits the absorption of estramustine. Although both the docetaxel–prednisone and the docetaxel–estramustine regimens are effective in hormone-refractory prostate cancer, the docetaxel/prednisone regimen reported similar efficacy without the cardiovascular adverse effects associated with estramustine.[25,26] In addition, androgen deprivation is continued when chemotherapy is initiated.

The regimen of mitoxantrone plus prednisone has been shown to be effective in reducing pain from bone metastasis and was a standard therapy before the development of docetaxel and prednisone.[26] Now, therapy with mitoxantrone is relegated to a salvage therapy after failure of other therapies.

**KEY CONCEPT** *Chemotherapy with cabazitaxel and prednisone improves survival in patients with castrate-resistant prostate cancer who have either progressed or are intolerant to docetaxel.*

Cabazitaxel is an antimicrotubule taxane with demonstrated activity in docetaxel-resistant cell lines and animal models of human cancer. A partial explanation is that docetaxel is a substrate for P-glycoprotein multidrug resistance transporter while cabazitaxel has low affinity. In patients previously treated with docetaxel and prednisone, treatment with cabazitaxel 25 mg/m$^2$ every 3 weeks with prednisone 10 mg/day significantly improved progression-free survival and overall survival compared with mitoxantrone and prednisone.[40] Neutropenia, febrile neutropenia, neuropathy, and diarrhea are the most significant toxicities. Hypersensitivity reactions may occur, and premedication with an antihistamine, a corticosteroid, and an H$_2$ antagonist is recommended. Cabazitaxel is extensively hepatically metabolized and should be avoided in patients with hepatic dysfunction (Table 92–8).

**KEY CONCEPT** *Immunotherapy with sipuleucel-T improves survival in patients with castrate-resistant prostate cancer with minimally symptomatic disease.*

Sipuleucel-T is a patient-specific anticancer vaccine.[41] Patients eligible for treatment first undergo leukapheresis to collect dendritic cells, which are sent to a central processing laboratory. These are then cultured and stimulated with a fusion protein of prostatic phosphatase and granulocyte macrophage colony-stimulating factor. The cultured cells are then returned and injected into the patient. This procedure is performed three times—at 0, 2, and 4 weeks. Treatment is well tolerated with common adverse effects of moderate and transient chills, fever, and transient influenza-like symptoms. Although disease progression was not improved by sipuleucel-T, overall survival was significantly improved from 21.7 months with placebo to 25.8 months with sipuleucel-T.[41] Because disease progression was not slowed by sipuleucel-T, it does not offer significant relief from disease-related symptoms. In symptomatic patients, or those with rapidly progressing disease an alternative treatment that delays tumor progression is more appropriate.

### Radium-223

Radium-223 is an alpha particle emitting, calcium-mimetic, radiopharmaceutical that provides significant palliation to patients with castrate-resistant prostate cancer with bone metastasis.[42] Radium is taken up into the osseous metastatic loci of prostate cancer, where it emits primarily alpha irradiation. Alpha irradiation, as opposed to beta, consists of higher energy, dispersed into a smaller radius of approximately 1 cell length. Radium-223 results in lower rates of myelosuppression compared to alpha emitting radiopharmaceuticals. When given to patients with a high bone disease burden and limited visceral

**Second-Line Therapy for Metastatic Castrate Resistant Prostate Cancer**

| Chemotherapy | Usual Dose | Adverse Effects | Dose Adjustments |
|---|---|---|---|
| Cabazitaxel | 25 mg/m² every 3 weeks | Myelosuppression, neuropathy, diarrhea | *Hepatic*<br>Extensively hepatically metabolized, usage should be avoided in hepatic dysfunction (ALT/AST > 1.5 × ULN or bilirubin > ULN)<br>*Hematologic*<br>Ensure CBC recovered |
| Abiraterone | 1000 mg once daily | Edema, hypokalemia, hypertension, hepatotoxicity | *Hepatic*<br>Moderate hepatic impairment (Child-Pugh class B), reduce the starting dose to 250 mg once daily; for development of hepatotoxicity during treatment, hold until recovery; retreatment may be initiated at a reduced dose |
| Enzalutamide | 160 mg once daily | Edema, hypertension fatigue, hot flashes, seizures | Strong CYP2C8 inhibitors, avoid or reduce dose to 80 mg once daily |

ALT, alanine aminotransferase; AST, aspartate aminotransferase; CBC, complete blood count.

disease, Radium-223 can significantly improve survival and improve palliation of pain. Primary adverse effects include moderate myelosuppression; exposure to radiation to caregivers is minimal. Plastic gloves are sufficient for shielding personnel from the radiation during administration to the patient.

Other radiopharmaceuticals that have been used for the treatment of bone metastases include strontium 89.[43] While palliation can be achieved, no survival benefit has been proven and a higher rate of hematologic adverse events is reported compared to Radium-223.

## OUTCOME EVALUATION

Monitoring of prostate cancer depends on the stage of the cancer. When definitive, curative therapy is attempted, objective parameters to assess tumor response include assessment of the tumor size, evaluation of involved lymph nodes, and the response of tumor markers such as PSA to treatment. Following definitive therapy, the PSA level is checked every 6 months for the first 5 years and then annually.[23] Local recurrence in the absence of a rising PSA may occur, so the DRE and radiologic studies are also performed. In the metastatic setting, clinical benefit responses can be documented by evaluating performance status changes, weight changes, quality of life, and analgesic requirements, in addition to the PSA or and radiologic studies to objectively measure tumor response.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| BPH | Benign prostatic hyperplasia |
| CAB | Combined androgen blockade |
| DES | Diethylstilbestrol |
| DHT | Dihydrotestosterone |
| DRE | Digital rectal examination |
| FSH | Follicle-stimulating hormone |
| GnRH | Gonadotropin-releasing hormone |
| IM | Intramuscular |
| LH | Luteinizing hormone |
| LHRH | Luteinizing hormone–releasing hormone |
| NCI | National Cancer Institute |
| PSA | Prostate-specific antigen |

## Patient Care Process

**Patient Assessment:**

- Obtain complete past medical history, family history, and social history.
- Obtain complete list of any concomitant prescription and over-the-counter medications; be sure to include herbal, vitamin, and mineral supplements.
- Verify completion of prostate cancer workup and staging.

**Therapy Evaluation:**

- Using information obtained, identify appropriate treatment options.

**Care Plan Development:**

- Discuss the benefits and risks of appropriate treatment options with the health care team and patient.
- If drug therapy is selected, review patient medical history for drug–drug and drug–herbal interactions.
- Initiate therapy.

**Follow-up Evaluation:**

- If patient is asymptomatic, monitor PSA and circulating androgens for castration level of testosterone. If patient is symptomatic, monitor symptoms for improvement or worsening.
- Monitor for any new symptoms and adverse events from therapy.

# 93 Skin Cancer

Kenneth Lin and Jill Kolesar

## LEARNING OBJECTIVES

● **Upon completion of this chapter, the reader will be able to:**

1. Identify the risk factors associated with skin cancer.

2. Devise a plan of lifestyle modifications for the prevention of skin cancer.

3. Discuss the role of mutation testing in patients with newly diagnosed metastatic melanoma and the impact of the test on choosing drug therapy.

4. Explain the goals of therapy for the treatment of the different stages of nonmelanoma and melanoma skin cancer.

5. Compare and contrast the pharmacologic treatment options that are available for patients diagnosed with nonmelanoma and melanoma skin cancer.

6. Suggest management options for patients experiencing adverse effects of pharmacologic therapy.

## INTRODUCTION

Skin cancer is the most prevalent of all malignancies occurring in humans, and in the United States, it accounts for more than 50% of all cancers.[1] The most common cutaneous malignancies are basal cell carcinoma (BCC), squamous cell carcinoma (SCC), and malignant melanoma (MM). BCC and SCC are categorized as nonmelanoma skin cancer (NMSC). It is estimated that more than 3.5 million cases (in more than 2 million people) of BCC and SCC and more than 100,000 cases of melanomas are diagnosed in the United States each year.[1] NMSC and MM differ with regard to prognosis, metastatic potential, mortality, curability, and treatment options.[2]

## MELANOMA

### EPIDEMIOLOGY AND ETIOLOGY

MM is the most common serious form of skin cancer, and the lifetime risk of developing it is 1 in 37 for men and 1 in 56 for women.[1] Approximately 73,870 new cases of melanoma are predicted to occur in 2015.[3] Melanoma represents about 2% of all skin cancers in the United States, but it accounts for 75% of all skin cancer deaths.[1] The incidence of melanoma is not evenly distributed among all populations; race, gender, and age confer different rates. The annual incidence rate per 100,000 is 1 for blacks, 4 for Hispanics, and 25 for non-Hispanic whites.[3] While women are more likely to develop melanoma than men before the age of 50, the converse occurs after the age of 50, with men having double the incident rate at age 65 and triple the rate at age 80 compared to women.[4] The change in risk may be due to the different level of sun exposure, be it occupational or recreational, through the lifetime of a particular sex. Even though incidence rates have significantly increased in the last 30 years, the rate among young age groups has leveled off; the incidence rate for men and women 50 years of age or older increased 2.6% per year from 2007 to 2011 but was relatively stable for those below age 50.

## RISK FACTORS

### Environmental

● The risk factors for developing MM can be categorized as environmental factors and host factors. **KEY CONCEPT** *Exposure to ultraviolet radiation (UVR) from the sun is recognized as one of the primary triggers for skin carcinogenesis.* UV radiation (specifically UVB) is absorbed by DNA in the cells in the epidermal layer and may induce DNA damage. Gene mutations, such as UVR-induced mutation to the p53 tumor suppressor gene, may occur, resulting in dysregulation of apoptosis, expansion of mutated keratinocytes, and initiation of skin cancer.[2] Other mechanisms of UV radiation–induced DNA damage include the generation of reactive oxygen species, which create breaks in DNA, leading to genetic mutations and skin cancer.[2] It is estimated that 65% to 90% of MMs are attributable to UV exposure, particularly when a person has a history of intense and blistering sunburns in childhood. If a person experienced more than one severe sunburn in childhood, the risk of developing melanoma is increased twofold.[2] Exposure to sources of artificial UV radiation such as tanning beds has also been linked to increased risk of skin cancer.[2]

### Host Factors

Host risk factors for developing MM include individuals with phenotypic characteristics of red hair, light skin, blue eyes, sun sensitivity, and freckling. Family history of MM in a first-degree relative is another risk factor for developing MM, with a twofold likelihood compared with patients with no family history.[2] In individuals without a family history of MM (sporadic

## Patient Encounter, Part 1

A 55-year-old woman presents to her dermatologist with a pigmented skin lesion on her left shoulder that she noticed had enlarged and changed color recently in the past few months.

**History:** She has the lesion since youth, and it was measured at 3 mm. She noticed the change in color and size in the past few months.

The woman reports being a "sun worshiper" all her life; she spends her weekends outdoors or at the pool and vacations at the beach. She notes that she burns initially and then eventually tans with excessive freckling. She reports using an indoor tanning bed 3 to 5 days a week for the past 20 years. She does not use sunscreen or practice sun protection measures.

*What are this patient's risk factors for developing malignant melanoma?*

*What primary prevention measures are recommended to prevent skin cancer?*

*What is the recommendation to detect melanoma early in a patient?*

MM), the presence of benign melanocytic nevi (benign moles) is consistently identified as the strongest risk factor for the future development of MM. The greater the number of benign nevi a person possess, the greater the susceptibility to MM growth. A personal history of MM or NMSC also increases the risk of developing subsequent MM.[5] The dysplastic nevus syndrome is another risk factor. A person with five or more dysplastic nevi has six times the risk of developing MM than a person with no dysplastic nevi.[5] Larger nevi, as in the case of congenital melanocytic nevi (larger than 20 cm), is also associated with a greater risk of developing MM.[5]

The median age of MM diagnosis is 62 years in men and 54 years in women, and as a person ages, the risk increases further, especially in men.[6] The risk of MM is also increased in patients with immunosuppression due to cancer, AIDS, a history of chronic lymphocytic leukemia, non-Hodgkin lymphoma, and after organ transplants.[2] Rare genetic syndromes such as xeroderma pigmentosum (XP) increases the risk of developing MM and NMSC 100-fold compared with the general population.[6] MM has been reported in breast-ovarian cancer families with a 2.6-fold risk in carriers of *BRCA2* mutations.[6] An association has been found between pancreatic cancer and MM with mutation in *CDKN2A*.[6]

## PRIMARY PREVENTION OF SKIN CANCER

UVR exposure from the sun is the major cause of NMSC and MM. **Primary prevention** strategies for skin cancer aim at educating people against excessive exposure to the sun and are spearheaded by the American Academy of Dermatology, American Cancer Society, Environmental Protection Agency, and Centers for Disease Control and Prevention. The aims of these programs are to increase public awareness about the harmful effects of sun exposure and the risk of skin cancer, change attitudes about the social norms related to sun protection and tanned skin, and decrease the incidence of skin cancer and deaths related to this

malignancy. The National Council on Skin Cancer Prevention recommends a variety of simple strategies to minimize exposure to UV rays:[7]

- Seek shade when outdoors, especially between the hours of 10 AM and 4 PM when UV rays are most intense.
- Wear hats with a broad enough brim to shade the face, ears, and neck.
- Wear protective clothing (especially tightly woven apparel) that covers as much as possible the arms, legs, and torso.
- Cover skin with a sunscreen lotion with a skin protection factor (SPF) of at least 30, protecting against UV radiation (both UVA and UVB).
- Apply sunscreen 15 minutes before going outdoors and reapply sunscreens every 2 hours (especially if sweating or swimming).
- Avoid intentional tanning and tanning beds.
- Take extra caution near water, sand, and snow.

The use of chemical sunscreen is only one of many strategies, and it should not be the sole agent used for cancer prevention. Sunscreen protective agents have been proven only to reduce the risk of actinic keratosis (AK) and SCC. There is no convincing evidence that sunscreen application has protective effect against BCC or MM.[8]

## SECONDARY PREVENTION OF SKIN CANCER

**Secondary prevention** of skin cancer involves early detection of premalignant cancers for early intervention with the hope that it will reduce mortality and increase cure. Regular screening for melanoma either by skin self-examination or total skin examination performed by health care providers consistently identify smaller and thinner lesions in high-risk patients.[9] However, recommendations for melanoma screening are conflicting because there are no randomized, controlled, prospective melanoma trials demonstrating that routine screening reduces mortality.

## PATHOPHYSIOLOGY

MM is a cancer that arises from melanocytes, which are cells that synthesize melanin and contribute to hair and skin pigmentation. The overwhelming majority of MMs originate from the skin, although they may also arise less commonly from mucosal epithelial tissues such as the conjunctiva, oral cavity, esophagus, vagina, female urethra, penis, and anus. Exposure to UVR is an important factor in MM development. MM may occur in individuals with either inherent genetic susceptibility or low genetic susceptibility for melanocyte proliferation. The distinguishing characteristic is that MM may develop with less solar damage and on intermittent sun exposed body sites such as the trunk for individuals with high genetic susceptibility. Conversely, in individuals with low genetic susceptibility, melanoma occurs with chronic UV exposure on commonly exposed areas such as the face and neck.[10]

### Genetic Pathway to the Development of Melanoma

Recent advances in molecular profiling and genome sequencing have enabled the identification of oncogenic mutations that drive MM progression. Much attention has been focused on the BRAF melanoma oncogene and its role in MM. BRAF is a serine/threonine protein kinase that is a member of the RAF kinase

family, which is a part of the RAF/MEK/ERK serine threonine cascade (also known as ERK/MAP kinase pathway or "classical" MAPK pathway).[11] Mutations in *BRAF* activates the ERK/MAP pathway and thus trigger melanocyte proliferation and clonal expansion. BRAF mutation is found in approximately one half of all MM, and *BRAF* mutant melanomas tend to occur on intermittent sun-exposed skin areas, skin phenotypes that have poor UV protection (eg, pale skin, poor tanning response, red hair, and freckling), and younger individuals (younger than 55 years) with lower cumulative UV exposure.[12] There are more than 50 mutations in *BRAF* described, but the valine to glutamic acid (*BRAF V600E*) substitution accounts for over 75% of all *BRAF* mutations. Furthermore, this *V600E* mutation is the most common BRAF mutation in MM.[11] Potent and selective BRAF kinase inhibitors are now a mainstay for treating BRAF mutation positive metastatic MM.

## CLINICAL PRESENTATION, DIAGNOSIS, AND STAGING

There are four major subtypes of cutaneous MM: superficial spreading, nodular, lentigo maligna melanoma, and acral lentiginous (Table 93–1). They each vary in clinical and growth characteristics.[13,14]

Data from Surveillance, Epidemiology, and End Results (SEER) show that 84% of diagnosed MM are locally confined, 9% are diagnosed after the cancer has spread regionally, 4% are diagnosed with distant metastasis, and the remaining 3% are not staged.[15] **KEY CONCEPT** *Once skin cancer is diagnosed, the cancer is staged to determine if the cancer is confined to the original tumor site or has spread to other sites, such as the lymph nodes, liver, brain, lungs, or bone. The purpose of staging is to determine prognosis, categorize patients with regard to metastatic potential and survival probability, and aid in clinical decision making.* As with most solid tumors, the tumor, node, metastasis (TNM) classification is used to stage MM.[16] Staging of solid tumors is described in Chapter 88.

**KEY CONCEPT** *Determination of lymph node status is important in melanoma staging because it is an independent prognostic factor, and it provides guidance for therapy decisions.* For patients with MM that are at risk of spreading to the lymph nodes, a sentinel lymph node (SLN) biopsy is performed. The SLN, the first lymph node to receive lymph draining from the tumor, is identified by injecting a radioactive material, technetium-99m-labeled radiocolloids, and vital blue dye into the skin next to the tumor and tracing the flow of lymph from the tumor site to the nearest lymph node chain. Once the SLN is located, it is removed and analyzed for the presence of MM cells. If it is positive for the presence of MM, then the whole lymph node basin in that area is dissected; this is also known as lymphadenectomy. An SLN biopsy is the initial procedure to assess the status of lymph node involvement to prevent the morbidity associated with a total lymphadenectomy.

In addition to the stage of the disease and the status of disease involvement in the lymph nodes, other prognostic factors for outcome in MM include primary tumor thickness (Figure 93–1), the presence of ulceration in the primary melanoma, mitotic activity, the presence of tumor infiltrating lymphocytes (TIL), and gender. Tumor thickness is defined as thin (less than 1 mm), intermediate (1–4 mm), and thick (more than 4 mm). The 10-year survival rate is 92% for thin tumors and 63% to 80% for intermediate tumors and decreases further to 50% in patients with thick tumors.[16] Ulceration is defined as the lack of an intact dermis overlying the primary tumor on histologic evaluation. Survival rates for patients with an ulcerated melanoma are proportionately lower than those with a nonulcerated melanoma of equivalent thickness, but the survival rate is similar for a nonulcerated melanoma of the next highest level of thickness. The male sex is associated with poor prognosis and adverse outcome in MM.[17]

### Skin Examination

The *ABCDE* acronym is a helpful mnemonic for recognizing the signs and symptoms of early MM (Figure 93–2). It was devised in 1985 by clinicians working in the Melanoma Clinical Cooperative Group at New York University School of Medicine and is used to educate health care professionals who are not dermatologists in differentiating common moles from cancer.[9] It is also a useful tool to educate patients to assess pigmented lesions and screen for suspicious moles. This may help identify the MM in its early stage when it is curable. Not all MMs, including nodular melanoma, have all ABCDE characteristics, and it is not meant to provide a comprehensive list of all MM features. The characteristics for each of the letters are described in the Clinical Presentation and Diagnosis box. It should be noted that evolution of a lesion is one of the most important warning signs of danger in the assessment of moles for MM.

## TREATMENT

Early diagnosis of skin cancer is the key to improved prognosis. On presentation to a clinician's office, patients may offer a history of a new growth or an area of irritation. Conversely, the skin cancer may have been present for years undetected by the patient. The definitive diagnosis of any suspected cutaneous malignancy should be confirmed by a biopsy before treatment.

The modality of treatment for skin cancer depends on the size, location, and stage of the tumor; the age of the patient; and the type of skin cancer. Treatment options for skin cancer include surgery, radiation, chemotherapy, immunotherapy, and targeted therapy.

### Desired Outcome

The primary goals of therapy for MM are to completely eradicate the tumor and minimize the risk of tumor recurrence and metastasis. Secondary goals of therapy include preserving normal tissue, maintaining function, and providing optimal cosmetic outcomes. Patients with local disease MM (stages I and IIA) are curable with surgical resection of the tumor. Thus, the aim is to diagnose patients at the earliest stage to increase the probability of cure. Patients with regional disease (stages IIB, IIC, and III) have a high recurrence risk, and the goal of therapy is to prevent relapse of the disease. Disseminated, metastatic MM is not curable, and the goal of therapy is local control of the disease and palliation of symptoms.

The outcome of patients diagnosed with MM depends on the stage of the disease at diagnosis. The overall 5-year survival rate for patients with localized disease (stages I and IB) is the best at 89% to 95%.[16] For patients with stage IIA to IIIA disease, the 5-year survival rate ranges from 63% to 79%.[16] In patients with more advanced regional metastatic disease (stage IIIB to IIIC), the 5-year survival rate ranges from 24% to 59%. Patients with stage IV distant metastatic disease have the worst 5-year survival rate at only 7% to 19%.[16]

**Table 93–1**

**Characteristics of Different Types of Skin Cancer**

| | Malignant Melanoma | | | | Nonmelanoma Skin Cancer | |
|---|---|---|---|---|---|---|
| | **Superficial Spreading** | **Nodular** | **Lentigo Maligna Melanoma** | **Acral Lentiginous** | **Basal Cell Carcinoma** | **Squamous Cell Carcinoma** |
| Frequency | 70% | 10%–15% | 10% | Less than 10% | 75% | 20% |
| Location | Head, neck | Trunk, head, neck | Sun-exposed areas, face, head, neck | Palms of the hands, soles of feet, nailbeds | Head and neck | Face, hands, forearms |
| | Legs in women | | | | | |
| | Trunk in men | | | | | |
| Age | Fifth decade | Seventh decade | Eighth decade | Sixth decade | Incidence increases after age 40 | Incidence increases after age 40 |
| Ethnicity | White | White | White | Most frequent type in ethnic groups of color | Similar between whites and African Americans | Most common in African Americans |
| Clinical features | Long horizontal growth phase (5–7 years); better prognosis | Very aggressive without identifiable horizontal growth phase; deeply invasive at the time of diagnosis; associated with poor prognosis | Long horizontal growth phase (10 years); lentigo maligna is the in situ form of lentigo maligna melanoma (only 5% transform to malignant melanoma) | Aggressive, rapid progression from horizontal to vertical growth; poorer prognosis | Rarely metastasize<br><br>Circumscribed types:<br>A: Nodular BCC, most common subtype<br>B: Adenoid BCC<br>C: Fibroepithelioma<br>D: Basosquamous (metatypical)<br>Diffuse types: plaque-like with horizontal spread and poorly defined margins<br>A: Superficial BCC; second most common type of BCC, least aggressive<br>B: Morpheaform, most aggressive<br>C: Micronodular | Metastasize to lymph nodes and blood<br><br>Have premalignant precursors and in situ variant; usually presents as raised pink papule or plaque, often scaly and sometimes ulcerated |

Data from Refs. 14 and 15.
**FIGURE 93–1.** Skin anatomy: Breslow microstaging and Clark levels. Clark level refers to the level of penetration into the dermis. Breslow classification measures tumor thickness in millimeters from the epidermis to the deepest depth of penetration into the dermis. (From Langley RGB, Barnhill RL, Mihm Jr MC, et al. Neoplasms: Cutaneous melanoma. In: Freedberg IM, Eisen AZ, Wolff K, et al., eds. Fitzpatrick's Dermatologyin General Medicine, 6th ed. New York: McGraw-Hill; 2003:938.)

## Treatment Options for Malignant Melanoma

### ▶ *Surgery*

**KEY CONCEPT** *The primary treatment modality for local/regional (stage I to III) MM is surgical excision of the tumor and a lymph-adenectomy for patients with positive lymph nodes.* The goals of therapy are to optimize local control, achieve potential cure, and minimize morbidity. Achieving adequate surgical margins for the primary tumor is important in preventing local recurrence and improving overall survival. The thickness of the tumor dictates the extent of the surgical margin.[18] The most common first site of recurrence in primary melanoma after excision of the tumor is in the lymph nodes. **KEY CONCEPT** *For patients with metastatic MM, surgical excision is not curative. The primary goal*

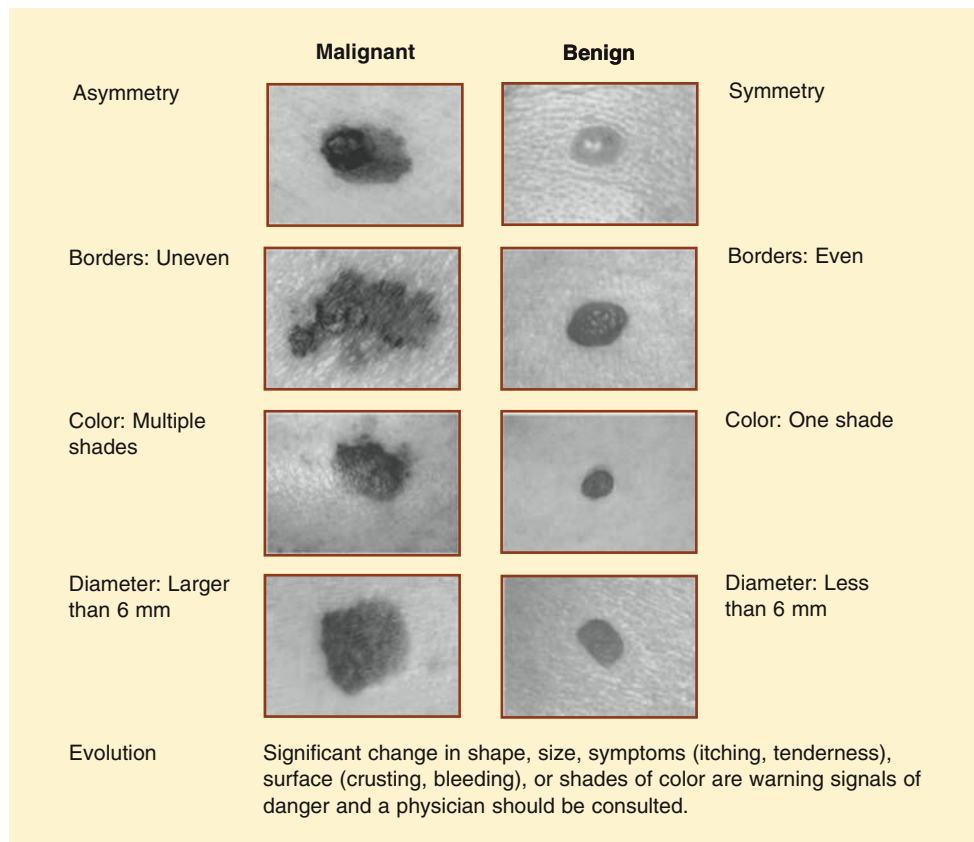

**FIGURE 93–2.** ABCDE features of early melanoma. (Images courtesy of the Skin Cancer Foundation, New York, www.skincancer.org.)

## Patient Encounter, Part 2

**PMH:** Otherwise healthy

**FH:** Father experienced multiple SCCs but no melanoma. Mother has diabetes and hypertension

**SH:** Patient is an administrative assistant. Married with two children

**Examination:** Reveals an asymmetric pigmented lesion of 6 mm on the left shoulder with no other suspicious lesions noted. Lymph nodes are not palpable

**Biopsy:** Excisional biopsy of lesion reveals melanoma, Breslow thickness 5.4 mm, positive for ulceration, and mitosis 3/mm²

**CT Scan:** No distant metastases

**Laboratory Data:** Normal

She underwent a surgical wide excision of the lesion with a 2-cm margin and sentinel lymph node biopsy. Pathology revealed negative margins and one of three nodes positive for melanoma. Her melanoma is diagnosed as stage IIIB. She underwent a lymphadenectomy of the left axilla

*What is the treatment goal for this patient at this stage of her disease?*

*Should this patient receive adjuvant therapy?*

---

*of therapy is local control of the disease and relief of identifiable symptoms.* In highly selected patients, such as those with good performance status, less aggressive tumor biology, prolonged period of disease-free interval from the time of primary tumor treatment, and limited disease that is contained within a single location, complete surgical resection results in a median survival time of 2 years and a 5-year survival rate of 10% to 25%. For most other patients with stage IV MM, unfortunately, the survival rate is measured in months rather than years, with an overall median survival of 5 to 8 months and a 5-year survival rate of less than 5%.[19]

Surgical resection is sometimes an option for patients with a brain metastases. It is most often used for a solitary brain lesion without systemic disease or a single metastatic brain lesion. For patients with symptomatic or life-threatening brain lesions, surgical resection allows for relief of symptoms such as intracranial hypertension, seizures, and a reduction of neurologic deficits.[20]

### ► Radiation

Radiation is generally not indicated for the treatment of primary melanoma except when surgery is impossible or not reasonable. It also may be administered as adjuvant therapy in areas where complete excision of the tumor is difficult, such as the face. It is indicated for the lymph nodes only when a lymph node dissection is not complete. For patients with bone metastasis, radiation may be indicated as palliative therapy for pain, fracture risks, or spinal cord compression.[21]

Melanoma commonly metastasizes to the central nervous system (CNS), with 10% to 40% of melanoma patients presenting with cerebral metastasis.[22] Patients with brain metastasis have a life expectancy of 3 to 5 months, and 1-year survival is less than 10% to 15%. Headaches and seizures are the most common presenting symptoms. Radiation therapy is indicated for palliation of CNS symptoms and as adjuvant therapy after resection of the CNS metastasis.[21]

Whole-brain radiation therapy (WBRT) is indicated for patients with multiple (more than three) CNS metastases, surgically inaccessible lesions, and extensive systemic disease. WBRT for metastatic CNS MM does not improve survival or provide a cure; however, it is effective in relieving neurologic symptoms,[22] preventing new metastasis, reducing symptomatic recurrence, and decreasing the need for salvage therapy.[21] It improves neurologic deficits in 50% to 75% of cases and relieves headaches in 80% of patients.[23] There are some data to suggest that surgical resection followed by WBRT in patients with a single CNS metastasis decreases the risk of local recurrence compared with resection alone.[21]

Stereotactic radiosurgery (SRS) delivers high doses of focused ionizing external-beam radiation to a well-defined target area in one session of radiation therapy. This technique maximizes the dose of radiation to the tumor with a rapid dose falloff outside the target area, resulting in sparing of the surrounding normal tissue. SRS may be considered over surgery for patients with fewer than three metastatic CNS lesions that are deep, nonsymptomatic, and smaller than 3 cm in size.[22]

### ► Chemotherapy

In general, cytotoxic chemotherapy is not considered a standard of care for metastatic melanoma. The major indication for systemic chemotherapy is in patients with metastatic or inoperable MM who are not candidate for immunotherapy or targeted therapy. The goal of chemotherapy is to reduce tumor size, and it is an accepted palliative therapy for stage IV melanoma. Dacarbazine, an alkylating agent, is the most active single-agent chemotherapy against MM, achieving response rates of 15% to 25% in older clinical trials.[24] More recent large-scale clinical trials have shown response rates of 5% to 12%.[25] It is the only chemotherapy agent approved by the Food and Drug Administration (FDA) for the treatment of metastatic MM.

### ► Immunotherapy

**KEY CONCEPT** *Melanoma is an immunogenic tumor and strategies to enhance the patient's immune response to treat the cancer are an area of active research.* The relationship between melanoma and the immune system was also established after spontaneous regression of melanoma was observed, and spontaneous serologic and cellular immunity can be documented in a high proportion of patients with advanced melanoma.[26] Strategies to enhance patients' immune response for the treatment of MM have focused on cytokine therapy, immune-modulating therapy, adoptive T-cell therapy, and vaccines.

**Interferon-α-2b** Interferon-α-2b (IFN-α-2b) has diverse mechanisms of action, including antiviral activity, impact on cellular metabolism and differentiation, and antitumor activity. The antitumor activity is attributable to a combination of direct antiproliferative effect on tumor cells and indirect immune-mediated effects.[27] **KEY CONCEPT** *IFN and pegylated IFN (peginterferon-α-2b) are both approved by the FDA as adjuvant therapy for patients who are free of disease after curative surgical resection but are at high risk of MM recurrence.* This includes patients with bulky disease or regional lymph node involvement such as stage IIB, IIC, or III disease.

The optimum dose, schedule, and duration of IFN-α-2b in high-risk melanoma remain to be defined. A recent meta-analysis of clinical trials of IFN in patients at high risk of recurrence after surgical resection showed improvements in relapse-free survival and overall survival.[28] However, IFN is associated with

## Clinical Presentation of MM

Patients with skin cancer generally present with a lesion that may be located anywhere on the body. The most common sites are the head, neck, trunk, and extremities. Changes in any characteristics of a lesion are important danger warning signals. Abnormal presentations of a mole or lesion indicate the need for further assessment.

- **Asymmetry:** Half the lesion does not mirror the other half
- **Border:** Sharp, ragged, uneven, and irregular borders
- **Color:** Multiple colors of various hues of light brown, dark brown, black, red, blue, or gray
- **Diameter:** Larger than 6 mm or the size of a pencil head eraser
- **Evolving:** Significant change in shape, size, symptoms, surface, or shades of color

Other signs and symptoms to monitor for in a lesion, in addition to ABCDE, include:

- Sudden or continuous enlargement of a lesion or elevation of a lesion
- Changes in the skin surrounding the nevus
- Redness, swelling, itching, tenderness, or pain
- Ulceration: friability of the lesion with bleeding or oozing. This is a danger signal

### Less Common Sites and Manifestations of MM

It is important to examine these sites for "hidden" MM:

- Nailbed
- Mucosal tissue
- Scalp
- Eye

In the nailbed, a black streak or wide variegated brown streak, elevation of nailbed, skin next to nail becomes darker, nail looks deformed or is being destroyed; size of nail streak increases over time.

### Diagnostic Tests

- Dermoscopy
- Biopsy

### Staging Tests (Depending on Patient's Presentation)

- Baseline chest radiography
- LDH level
- CT of chest, abdomen, pelvis
- SLN biopsy: **KEY CONCEPT** *The status of the SLN is one of the most powerful independent prognostic factors predicting survival. It also provides the clinician with guidance for therapy decisions and accurate staging.*
- PET
- MRI

Data from Rigel D, Russak J, Friedman R. The evolution of melanoma diagnosis: 25 years and beyond the ABCDs. CA Cancer J Clin. 2010;60(5):301–316.

---

substantial toxicities, and the decision for IFN therapy should be made on an individual basis after explaining to the patient the potential benefits and side effects of the therapy. The duration of high-dose IFN is for 1 year if in stage IIB to III, or peginterferon-α-2b for up to 5 years if in stage III when the decision has been made to initiate IFN; low-dose or intermediate-dose IFN is not recommended (Table 93–2).[29] Encouragement to participate in clinical trials is also reasonable for eligible patients.

HDI has substantial side effects that can be divided into acute and chronic manifestations and categorized into four major side effect groups: constitutional, neuropsychiatric, hematologic, and hepatic.[30] Patients should be educated on the side effects to expect and counseled of the interventions available to minimize the toxicities. Peginterferon-α-2b has a longer duration of action than IFN-α-2b and may be administered once a week. The side effects are similar to IFN-α-2b, although the incidence may be less. The monitoring recommendations for peginterferon-α-2b are the same as for IFN.

**Interleukin 2** Interleukin-2 (IL-2) therapy is approved by the FDA for the treatment of metastatic MM. IL-2 indirectly causes tumor cell lysis by proliferating and activating cytotoxic T lymphocytes (CTLs). The overall objective response rate for patients with metastatic MM receiving high-dose IL-2 is 16%, with a complete response in 6% of patients and a partial response in 10% of patients. The median duration of response is 8.9 months for all responding patients and 5.9 months for patients with a partial response.[31] The median duration of complete response has not been reached but is at least 59 months. Disease progression is not observed in any patient responding for longer than

30 months. The data are encouraging because for the small number of patients who responded to therapy, the effect is of a long duration, and some patients may be considered to be cured of the disease. (Refer to Table 93–2 for dosing.)

High-dose IL-2 therapy is associated with significant severe toxicities and morbidity.[32] This treatment option is generally only considered in patients with good performance status who will have a better chance of tolerating and completing the therapy. With the availability of new therapies, IL-2 is no longer the primary option for patients with metastatic melanoma. Table 93–3 lists the most common side effects experienced by patients receiving IL-2 therapy and recommendations for management. All clinicians involved with the care of patients receiving IL-2 should be well educated on the monitoring and management of IL-2–specific side effects.

### Immune Checkpoint Inhibitors

#### ▶ *Ipilimumab*

T-cell activation involves two different signals: (a) the binding of the T-cell receptor to a peptide presented by the major histocompatibility complex on the antigen-presenting cell (APC) and (b) the interaction of a costimulatory receptor (CD28) on the T-cell surface with a costimulatory ligand (B7) on the APC. The costimulatory molecules enhance the immune response by promoting T-cell activation and proliferation.[33]

CTLA-4 is expressed in CD4+ and CD8+ T cells and regulatory T cells. It is a member of the immunoglobulin (Ig) super family. After T-cell activation occurs, CTLA-4 migrates to the surface of the T cell, where it has higher affinity for the B7 ligand

| Table 93–2 |
|---|

**Dosing[a] Recommendations**

**Interferon[a] Dosing Regimens**
**High dose:** 20 million units/m$^2$ IV daily × 5 days per week for 4 weeks followed by 10 million units/m$^2$ SC three times per week for 48 weeks
**Peginterferon:** 6 mcg/kg/week SC for 8 weeks followed by 3 mcg/kg/week for up to 5 years

**Interleukin-2[a] Dosing Regimen**
**IL-2:** 600,000 International Units/kg (0.037 mg/kg) dose administered every 8 hours by an IV 15-minute infusion for a maximum of 14 doses. Following 9 days of rest, the schedule is repeated for another 14 doses, for a maximum of 28 doses

**Immune Checkpoint Inhibitor[a] Dosing Regimens**
**Ipilimumab:** 3 mg/kg IV infusion over 90 minutes every 3 weeks for four doses; permanently discontinue if treatment cannot be completed within 16 weeks
**Nivolumab:** 3 mg/kg IV infusion over 1 hour every 2 weeks until disease progression or unacceptable toxicity; prior to administration, evaluate liver and thyroid function and serum creatinine, and monitor periodically during treatment
**Pembrolizumab:** 2 mg/kg IV infusion over 30 minutes every 3 weeks; continue treatment until disease progression or unacceptable toxicity occurs

**RAF-MEK-ERK (MAPK) Pathway Inhibitors[a] Dosing Regimens**
**Vemurafenib:** 960 mg by mouth twice daily every 12 hours. Continue treatment until disease progression or unacceptable toxicity occurs Caution should be used in patients with severe renal or hepatic impairment; no dose adjustment needed for mild to moderate renal or hepatic impairment
**Dabrafenib:** 150 mg by mouth every 12 hours, at least 1 hour before or at least 2 hours after a meal; continue treatment until disease progression or unacceptable toxicity occurs
**Trametinib:** 2 mg by mouth once daily; take at least 1 hour before or 2 hours after a meal; continue treatment until disease progression or unacceptable toxicity occurs

**Chemotherapy[a] Dosing**
**Dacarbazine:** 250 mg/m$^2$/day IV, days 1 to 5, every 21 days

[a]The doses presented here are general. Clinicians should refer to clinical trials to determine the specific dose based on the regimen the patient is receiving.

IV, intravenous; SC, subcutaneous.

From U.S. Food and Drug Administration. Drugs@FDA FDA Approved Drug Products [Internet]. [cited 2015 Feb 22]. http://www.accessdata.fda.gov/scripts/cder/drugsatfda/.

than CD28 and preferentially binds to B7. This results in an inhibitory signal to the T cell and causes a downregulation on the immune response; in other words, CTLA-4 acts as a "brake" on the activation of the immune system.[33]

Ipilimumab is a fully human monoclonal IgG1 specific for CTLA-4. It has a high affinity for CTLA-4 and impedes binding of CTLA-4 to B7, preventing downregulation of the immune response. This results in increased proliferation of activated T cells and increases the interactions of T cells and cancer cells.[33] Ipilimumab was approved by the FDA for the treatment of unresectable or metastatic melanoma based on a phase III study demonstrating improved survival.[34] Pooled analysis of long-term survival in advanced melanoma patients found median overall survival to be 13.5 months with ipilimumab treatment-naive group compared to 10.7 months in previous treated group; 3-year survival rates were 26% and 20%, respectively.[35] Common side effects may include pruritus, rash, gastrointestinal upset, and fatigue. Because T-cell activation can lead to enterocolitis, hepatitis, dermatitis including toxic epidermal necrolysis, neuropathy, and endocrinopathy, both providers and patients are enrolled in the FDA Risk Evaluation and Mitigation Strategy (REMS) that includes a communication plan.[36] No formal studies have been done to assess cytochrome P-450 (CYP) interactions, and none are expected. Corticosteroids are the treatment of choice for ipilimumab-induced adverse events. The administration of steroids to treat the side effects did not appear to result in decreased effectiveness of ipilimumab. Interestingly, there may

be a correlation between immune-related adverse events and treatment success.[37] (see Table 93–4 for adverse effects and their management).

▶ **Nivolumab**

Many tumor cells express programmed death-ligand 1 (PD-L1) that can interact with programmed death-1 (PD-1) receptor on T cells and B cells to diminish the body's immune response. Nivolumab is an IgG4 fully humanized antibody that targets PD-1 to interfere with the binding with PD-L1 and thus allow T cells to remain active to mount an immune response. The FDA-approved indication includes unresectable and metastatic MM following ipilimumab and, if BRAF V600 mutation positive, a BRAF inhibitor. Patient with confirmed, unresectable, previously treated stage III or IV melanoma without BRAF mutation in a phase III trial showed an overall rate of survival at 1 year of 72.9% in the nivolumab group compared to 42.1% in the dacarbazine group.[38] Common side effects may include rash, purities, peripheral edema, and cough while rare but serious adverse events may include ventricular arrhythmia, infection, hepatotoxicity, and neuropathy. No formal studies have been done to assess CYP interactions.[32]

▶ **Pembrolizumab**

Pembrolizumab (previously known as lambrolizumab) is an IgG4 engineered humanized antibody that is also a PD-1 inhibitor. The FDA approved indication includes unresectable

## Table 93–3

### IL-2 Toxicities

| Toxicity (% of Patients) | Management |
|---|---|
| **Cardiovascular**<br>Hypotension (64%), supraventricular tachycardia (17%) | Discontinue antihypertensive medications; IV fluids to maintain systolic blood pressure > 80–90 mm Hg or vasopressor support with an α-agonist such as phenylephrine as indicated; be judicious in use of IV fluids for hypotension |
| **GI**<br>Vomiting and diarrhea (55%), nausea (24%), stomatitis (14%) | 5-HT$_3$ antagonist, prochlorperazine for emesis (avoid corticosteroids), H$_2$-blocker for gastritis, antidiarrheal as needed (loperamide, diphenoxylate/atropine, codeine) |
| **Neurologic**<br>Confusion (30%), somnolence agitation, anxiety, insomnia | Haldol for agitation, lorazepam for anxiety, zolpidem for insomnia |
| **Pulmonary**<br>Dyspnea (31%), pulmonary edema, and ARDS | Advise smokers to quit 2 weeks before therapy; discontinue therapy if requiring > 4 L O$_2$ or 40% O$_2$ mask for saturation > 95% (0.95) |
| **Hepatic**<br>Elevated bilirubin (51%), transaminase (39%), ALP | Consider discontinuing therapy if severe |
| **Renal**<br>Oliguria (49%), elevated serum creatinine (35%), anuria (8%) | Normal saline or dopamine at renal perfusion dose of 2 mcg/kg/min for oliguria; monitor for electrolyte abnormalities and replace as indicated |
| **Hematologic**<br>Thrombocytopenia (43%), anemia (29%), leukopenia (21%) | Transfuse with packed red blood cells and platelets as needed |
| **Skin**<br>Rash (27%), exfoliative dermatitis (15%), pruritus | Hydroxyzine, diphenhydramine, oatmeal powder baths, Lubriderm lotion |
| **General**<br>Fever and or chills (47%), malaise (34%), infection (15%) | Acetaminophen and NSAIDs around the clock for fever and chills; add meperidine if chills are severe; clindamycin or cefazolin to prevent infection |
| Hypothyroidism | May occur in one-third of patients; thyroid function tests |

ALP, alkaline phosphatase; ARDS, adult respiratory distress syndrome; 5-HT$_3$, serotonin; IV, intravenous; NSAID, nonsteroidal anti-inflammatory drug.

Data from Refs. 38 and 39.

and metastatic MM following ipilimumab and, if *BRAF* V600 mutation positive, a BRAF inhibitor. A study of patients with measurable metastatic locally advanced unresectable melanoma with adequate organ function and performance score found that overall response rate from investigator-assessed immune response criteria was 37% for all examined doses; response Evaluation Criteria in Solid Tumors (RECIST) confirmed response rate was 38%.[39] Common side effects may include arthralgia and constipation/diarrhea while rare but serious adverse events may include colitis, hepatitis, pancreatitis, pneumonitis, and hypophystitis. No formal studies have been done to assess cytochrome p450 interactions interactions.[32]

### RAF-MEK-ERK Pathway Targeted Therapy

#### ▶ *Vemurafenib*

BRAF is an intermediary in signal transduction through the RAF-MEK-ERK (MAPK) pathway. Activation of *BRAF* is associated with downstream activation of ERK, elevation of cyclin D1, and an increase in cellular proliferation.[41] *BRAF* is mutated in approximately 50% of melanomas, and over 75% of these mutations are the *BRAF V600E* mutation.[11] Vemurafenib is an oral competitive small molecule serine threonine kinase inhibitor that functions by binding to the adenosine triphosphate binding domain of mutant *BRAF*.[40] **KEY CONCEPT** *Vemurafenib selectively targets the mutated BRAF V600E isoform and was approved by the FDA for unresectable stage IIIC or metastatic melanoma that is BRAF V600 mutation positive.* The Cobas 4800 *BRAF* V600

Mutation Test is the companion FDA-approved diagnostic tool used to test for the *BRAF* V600 Mutation (see Table 93–2 for dosing).

A phase III clinical trial compared vemurafenib with dacarbazine in patients with previously untreated, unresectable stage IIIC or metastatic melanoma possessing the *BRAF V600E* mutation.[41] Data analysis at 6 months showed that overall survival was 84% and median progression-free survival (PFS) was 5.3 months for patients receiving vemurafenib compared with 64% overall survival and 1.6 months PFS for patients receiving dacarbazine. Common side effects associated with vemurafenib may include photosensitivity, rash, arthralgia, and alopecia. Rare but serious side effects may include prolonged QT interval, foot-hand syndrome, vision changes, and SCC though the latter can be excised without discontinuation of the agent.[41] Vemurafenib is metabolized by CYP3A4 and thus may interact with its inducers or inhibitors. It may increase the serum concentration of substrates of CYP1A2 and 2D6. It may decrease the serum concentration of substrates of CYP3A4.[32]

#### ▶ *Dabrafenib*

Similar to vemurafenib, dabrafenib is also a selective inhibitor of BRAF V600E kinase. The FDA-approved indications include monotherapy for unresectable and metastatic MM with *BRAF V600E* mutation and combination therapy with trametinib for unresectable and metastatic MM with BRAF *V600E* or *V600K* mutation. Dabrafenib is unique in its activity to treat melanoma

| Table 93–4 | |
|---|---|
| **Ipilimumab Toxicities[a]** | |
| **Toxicity (% of patients)** | **Management** |
| **Dermatologic (47%–68%)** | |
| Maculopapular rash | Do not need to stop or dose reduce ipilimumab |
| Pruritus | Topical corticosteroid |
| Vitiligo | Urea-containing cream |
| | Antipruritic agent such as hydroxyzine |
| | For grade 3 or 4: oral corticosteroid with prednisone 1 mg/kg or dexamethasone 4 mg every 4 hours with a 4-week taper |
| **GI (31%–46%)** | |
| Mild diarrhea, severe diarrhea, or colitis | Loperamide, hydration, electrolyte replacement |
| | Budesonide 9 mg/day or prednisone 1 mg/kg |
| | or high-dose IV steroids: methylprednisolone 2 mg/kg once or twice daily or dexamethasone 4 mg every 4 hours; then taper over 4 weeks after symptom resolution; some patients may require 6 to 8 weeks; taper; too rapid taper may result in recrudescence or worsening of symptoms |
| | **If no response to steroids in 48 to 72 hours:** |
| | Infliximab 5 mg/kg every 2 weeks. NOTE: infliximab is contraindicated in patients with bowel perforation or sepsis |
| | Discontinue ipilimumab for severe symptoms such as colitis |
| **Inflammatory hepatoxicity (3%–9%)** | Methylprednisolone 2 mg/kg/day one to two times daily for LFT greater 8 × ULN or total bilirubin greater 5 × ULN |
| | Mycophenolate 1 g IV or 1.5 g orally two times daily if symptoms persist |
| **Endocrine (4%–6%)** | |
| Hypophysitis | Obtain thyroid function tests, serum cortisol levels, ACTH, testosterone, FSH, LH, prolactin |
| | Dexamethasone 4 mg every 4 hours for 7 days and taper over at least 4 weeks |
| | Hormone substitution as needed |
| | Endocrinologist consult |
| **Neurologic (1%)** | |
| Guillain–Barré syndrome | If symptoms persist for more than 5 days, evaluate for neurologic disorders |
| Sensory or motor neuropathy | Corticosteroids |
| Myasthenia gravis | May need to interrupt or discontinue therapy if symptoms are severe |

[a]In general, for severe grade 3 or 4 ipilimumab toxicities, therapy should be discontinued permanently.

ACTH, adrenocorticotropic hormone; FSH, follicle-stimulating hormone; LH, luteinizing hormone; ULN, upper limit of normal.

Data from Kähler C, Hauschild A. Treatment and side effect management of CTLA-4 antibody therapy in metastatic melanoma. J Dtsch Dermatol Ges. 2011;9:277–285.

metastasis in the brain. A phase I trial (BREAK-I) showed patients with asymptomatic untreated brain metastasis (3 mm size or smaller) decreased brain tumor size in nine out of ten patients with *BRAF V600* mutation and previously untreated

brain metastasis, with four patient achieving complete elimination. A phase II trial (BREAK–MB) showed that investigator-assessed intracranial response rate in untreated compared to previously treated but relapsed *BRAF V600E* patients were 39% and 31%, respectively.[11] Common side effects may include hypoglycemia, arthralgia, and neutropenia while rare but serious adverse events may include prolong QT interval, serious febrile reactions, uveitis, iritis, and SCC. Similar to vemurafenib, SCC can be excised without discontinuation of the agent. Dabrafenib is metabolized by CYP3A4 and 2C8 and thus may interact with its inducers or inhibitors. It may decrease the serum concentration of substrates of CYP3A4 and 2C9.[32]

▶ *Trametinib*

Trametinib is a MEK 1/2 kinase inhibitor that works directly downstream of BRAF in the MAPK pathway. The FDA approved indications include monotherapy or combination therapy with dabrafenib for unresectable and metastatic MM with *BRAF V600E* or V600K mutation. Patients in a Phase III trial with metastatic melanoma with a *BRAF V600E* or V600K mutation showed a response of median PFS of 4.8 months with trametinib compared to PFS of 1.4 months with chemotherapy (dacarbazine or paclitaxel).[42] Common side effects may include dry skin and nail changes while rare but serious adverse events may include

**Patient Encounter, Part 3**

This patient presents 3 years later after treatment of her stage III melanoma with high-dose interferon. At her routine follow-up visit, a chest x-ray showed bilateral lung metastases. This patient also reports a history of increasing nonproductive cough and exertional shortness of breath in the past few weeks.

Laboratory Data: LDH two times above normal level; all other lab data are normal

CT Scan: Confirms metastasis in lung and paraaortic lymph nodes

*What is the treatment of choice for this patient?*

*What test is used to determine if the patient should receive a BRAF inhibitor?*

vision changes and rhabdomyolysis. No formal studies have been done to assess CYP interactions.[32]

### ▶ *Dabrafenib and Trametinib Combination Therapy*

Favorable synergistic effects have been found when comparing BRAF and MEK inhibitor combination to BRAF inhibitor mono-therapy. A Phase III trial comparing dabrafenib and trametinib to dabrafenib alone in patients with previously untreated, unre-sectable stage IIIC or metastatic melanoma and either *BRAF* V600K or *V600E* mutation found an estimated median PFS of 9.3 months in the former versus 8.8 months in the latter.[43] In another phase III trial comparing dabrafenib and trametinib to vemurafenib alone in patients with metastatic melanoma and either *BRAF* V600K or *V600E* mutation found median overall survival to be 17.2 months in the vemurafenib group and was not reached for the combination group. The rate of overall survival at 12 months was 72% in the combination group compared to 65% in the vemurafenib group.[44]

Treatment options for metastatic MM include immunothera-pies; ipilimumab, nivolumab, or pembrolizumab; targeted thera-pies; dabrafenib in combination with trametinib or vemurafenib monotherapy, or a clinical trial. Only patients determined to have mutated BRAF V600 isoform can be effectively treated with vemurafenib, dabrafenib, and/or trametinib. Even though ipili-mumab and BRAF inhibitors (for *BRAF V600* mutation positive patients) are indicated before treatment with pembrolizumab or nivolumab, the latter two drugs have been shown to have higher response rate and less toxicity compared to ipilimumab and are considered part of first-line therapy. Trametinib monotherapy is only recommended for *BRAF V600* mutation positive patients who cannot tolerate BRAF inhibitor monotherapy.[29]

## OUTCOME EVALUATION

After diagnosis and treatment of skin cancer, the next phase of management is appropriate follow-up with the purpose of detecting recurrent disease or new MMs.[29]

Recurrence of MM occurs after complete resection in 30% of patients diagnosed with stage I to III disease, and 80% of the patients develop recurrence within 3 years of their diagnosis of primary MM. Among patients whose melanoma recurred, the site of recurrence is local in 20% to 28% of patients; in 26%

---

### Patient Encounter, Part 4

This patient was negative for *BRAF* mutation with analysis using the Cobas 4800 *BRAF V600* Mutation Test.

The decision was made to initiate her on ipilimumab. She is scheduled to receive 3 mg/kg every 3 weeks for a total of four cycles. At week 4, it was noted that this patient has new subcutaneous lesions and enlargement of the preexisting lesions. Furthermore, a few days after she received her second dose of ipilimumab, she experienced severe grade 3 diarrhea. She reports mild abdominal pain with no fever and no blood in her stool.

*What are the most common side effects associated with ipilimumab?*

*What should be done to manage the side effects of ipilimumab?*

---

to 60%, recurrence is in regional lymph nodes; and 15 to 50% experience distant recurrence. The rate of recurrence detection by patients is reported to be 33% to 99%; thus, patients should be educated on how to perform self-examination of the skin and lymph nodes and the importance of ongoing sun protection measures.[45]

Patients who received immunotherapy for stage III or IV MM may experience fatigue and other chronic side effects. Develop a plan to order laboratory tests such as liver function tests, thyroid-stimulating hormone, and white blood cell count at baseline and on a weekly or monthly basis as indicated. Monitor and evaluate patients for side effects of IL-2, IFN, immune check-point inhibitors, and MAPK inhibitors and educate patients on what to expect and how the side effects will be managed. Assess patients' psychological, physical, and social functioning. Coun-sel patients to contact the hospital's social service department or the American Cancer Society for assistance in dealing with the disease emotionally and recommend that patients consider attending support group meetings or talking to a counselor if or before they become overwhelmed with the diagnosis.

## NONMELANOMA SKIN CANCER

### EPIDEMIOLOGY AND ETIOLOGY

Nonmelanoma skin cancer (NMSC) accounts for more than half of all newly diagnosed cancers in the United States each year, and it was estimated that more than 3.5 million new cases of BCC and SCC (in more than 2 million people) would be diagnosed in 2011.[1] The true prevalence of NMSC may be underestimated because it is treated in outpatient settings, and no formal report-ing to cancer registries is required. The incidence rate of NMSC is increasing worldwide with a yearly rise of 3% to 8% since 1960.[46] BCC is the most common form of NMSC and comprises 75% of NMSC with SCC accounting for 20%.[14] The majority of NMSCs are curable, and the mortality rate is low; cure rates approach 98%, and the overall 5-year survival rate is greater than 95%.[47] Metastasis occurs in fewer than 0.1% of BCCs com-pared with an average of 3.6% of SCCs. Seventy-five percent of all NMSC deaths are attributed to SCC.[47] NMSC is associated with considerable morbidity related to functional and cosmetic deformity. In addition, it is an economic burden to the health care system because costs associated with NMSC treatment are estimated at approximately $426 million per year.[14]

### RISK FACTORS

The risk of developing NMSC is multifactorial (Table 93–5). The most important risk factor for NMSC is UV radiation exposure, and data from epidemiologic studies indicate that greater cumulative lifetime sun exposure is associated with a higher risk of developing SCC, but intermittent and childhood sun-exposure correlates more with BCC.[46] Most cases of BCC are sporadic; however, it occurs frequently in the rare individu-als with hereditary disorders such as basal cell nevus syndrome (also known as Gorlin syndrome). It is also common in patients with genetic syndromes such as XP. The *patched* gene (*PTCH*), a tumor-suppressor gene, has been shown to be mutated in 68% of sporadic BCCs.[46] There is clear evidence linking defects of the immune system to the development of NMSC. For example, it is observed that patients receiving chronic immunosuppressant therapy for organ transplantation have a 65-fold increase in developing SCC and 10-fold increase in developing BCC.[48]

## PATHOPHYSIOLOGY

NMSCs arise from epidermal keratinocytes and involve primarily squamous cells and basal cells of the epidermis and dermis skin layers. BCCs arise from interfollicular basal cells or keratinocytes in hair follicles or sebaceous glands.[48]

## CLINICAL PRESENTATION AND PROGNOSIS

BCC is characterized as circumscribed or diffuse, and within these two groups, it is further classified according to type, degree of differentiation, and depth of invasion (see Table 93–1).[14] Nodular BCC is the most common type of BCC followed by superficial BCC. The morpheaform BCC is the most aggressive subtype.[13] BCC has indolent growth characteristics with a very low metastatic and mortality rate.[46] Paradoxically, BCCs can cause extensive local destruction and significant disfigurement. Approximately 80% of BCCs occur on the head and neck. Superficial BCC occurs predominantly on the trunk. Early-stage BCC is usually small, translucent or pearly with raised telangiectatic edges.[46] BCC may also appear as raised, yellowish-reddish lesions with a border resembling a string of pearls and telangiectasia. Dermatoscopy may distinguish between a benign and malignant lesion; however, clinical examination is usually sufficient for diagnosis of BCC. Depending on the size of the tumor, subtype, and treatment planned, a biopsy may be needed.

SCC usually presents on sun-exposed sites because of UVR damage to the skin. Unlike BCC, SCCs are preceded by premalignant lesions such as leukoplakia, actinic keratosis (AK) (a small papule that appears on areas of sun damage on the skin), or SCC in situ (Bowen disease).[46] The rate of AK progression to SCC is 1% to 10% in 10 years and may be higher if a patient has more

than five AKs.[46] Patients with a Bowen lesion present with slowly enlarging erythematous scaly or crusted plaques and have a 3% to 5% risk of progressing to SCC. A typical SCC lesion has an adherent crust and ill-defined edges; the first sign of malignant SCC is induration of the lesion. The rate of metastasis for SCC is 2% to 6% and may be as high as 10% to 14% in high-risk sites such as the ear and lip and 30% in the genital area.[47] Metastasis most commonly presents 1 to 2 years after diagnosis of the primary SCC with 80% of metastasis involving the regional lymph nodes.[49]

Risk factors for NMSC are outlined in Table 93–5. If a patient possesses these factors, he or she is at high risk for disease recurrence and subsequent metastasis. Patients with NMSC have a 10-fold increased risk of developing subsequent NMSC compared with the general population.[46]

Staging for NMSC uses the TNM staging system recommended by the American Joint Committee on Cancer. It is seldom done for patients with BCC because nodal and visceral metastasis is rare for this disease.[46]

## TREATMENT

**KEY CONCEPT** *In patients diagnosed with BCC and SCC, the primary goal of therapy is to cure the patient and to prevent recurrence.* Although NMSC has a low mortality rate, morbidity related to tissue destruction, functional impairment, and disfigurement is a significant issue. Therefore, secondary goals of therapy for NMSC are preservation of function and restoration of cosmesis. The treatment options for NMSC involve surgery, pharmacologic therapy, or a combination of both. The choice of treatment depends on factors such as tumor size, the site of the lesion, patient comorbidities, and the histologic and clinical nature of the cancer.

### Nonpharmacologic Therapy

▶ *Surgery*

Surgery is the primary treatment modality for all patients diagnosed with either BCC or SCC. Full-thickness ablative procedure in the form of surgical excision of the tumor along with a margin of normal tissue surrounding the tumor is the preferred method for high-risk tumors. Obtaining negative surgical margins is critical for cure and decreasing the risk of tumor recurrence. A margin of 4 to 5 mm in well-defined BCC and SCC ensures peripheral clearance in 95% of cases. Depending on the tumor size, degree of differentiation, and invasion of surrounding structures, larger margins of resection may be necessary.[46] The two most common surgical techniques used are electrodessication and curettage (ED&C) and Mohs micrographic surgery (MMS). The indications of each of these procedures are described below.

Low-risk tumors defined as small, well-differentiated, and slow growing can be treated with superficial ablative techniques, including ED&C and cryotherapy.[46] ED&C is a simple, cost-effective technique that uses repeated cycles of using a curette to cut through malignant tissue followed by electrodesiccation, which involves the application of high voltage, low current to the skin, causing drying or desiccation of the tissue. ED&C is most appropriate for well-defined superficial lesions that are not located in areas with increased risk for metastasis. The disadvantage of this technique is that histologic confirmation of complete tumor removal is not possible.[48] This procedure is not recommended for treatment of recurrent disease, tumors of the face, and high-risk tumors.[48]

For high-risk NMSC or for tumors located in cosmetically or anatomically sensitive areas, MMS is the procedure of choice. The goal of this therapy is complete removal of the cancer with preservation of as much surrounding normal tissue as possible. MMS involves careful dissection, staining of frozen sections, and anatomic mapping of the tumor specimen. Sections are assessed immediately under the microscope by the surgeon, and the process is repeated until a tumor-free margin is attained. MMS cures 93% of primary NMSC and 90% to 94% of recurrent disease compared with 92% and 77% cure rate with standard excision for primary and recurrent disease, respectively.[49]

Cure rates for all modalities decrease with the presence of high-risk features but are still superior with MMS.[49]

Cryotherapy is a procedure used primarily for smaller, low-risk NMSCs with clearly defined margins. It involves delivering liquid nitrogen at subzero temperatures as a spray or with a supercooled metal probe to destroy the malignant tissue in a single cycle or multiple cycles.[48] This technique can achieve comparable results to conventional surgery for well differentiated, not too large, superficial tumors in older patients with BCC.[48] The procedure is contraindicated in the hair-bearing scalp, upper lip, and distal portion of lower leg because of delayed healing and high rates of recurrence.[48]

#### ▶ Radiation

Radiation is not standard therapy for the treatment of skin cancer; however, there are circumstances in which radiation may be preferred. It may be offered to patients in whom surgery is not possible because the tumor is inoperable or surgery would lead to unacceptable cosmetic or functional impairment.[49] Radiation to the lip, ear, and nasal entrance for SCC may provide the best cosmetic and functional result. On the other hand, some patients may develop dyspigmentation, radiodystrophy, or telangiectasia at the site of radiation, resulting in poorer cosmetic outcomes. Radiation is contraindicated in treating BCC that recurred after radiotherapy. It should be used with caution in patients younger than 65 years because latent NMSC can develop after 15 to 20 years of radiation exposure.[46]

#### ▶ Photodynamic Therapy

Photodynamic therapy (PDT) involves the topical application of a photosensitizing agent that is activated after exposure to a light source and causes tumor cell damage and death. The photosensitizer is converted to protoporphyrin IX after it is preferentially taken up by active tumor cells. Damage to cell membranes, organelles, and surrounding vasculature occurs when protoporphyrin IX is activated after exposure to a light source. Protoporphyrin IX has absorption bands at 408, 510, 543, 583, and 633 nm; therefore, blue light (corresponding to 408-nm band) and red light (corresponding to 633-nm band) are the most commonly used light source.[48] Blue light is used for superficial lesions because of its shorter wavelength and because it does not penetrate the skin as well as red light.[48]

δ-Aminolevulinic acid (ALA) and methyl aminolevulinate (MAL) are two photosensitizing agents that have FDA approval for the treatment of AK (see Table 93–6 for dosing).[29] PDT has also been shown to be effective in the treatment of SCC in situ, but it is not indicated for SCC because of its extensive invasiveness and metastatic potential.[29] In patients with superficial BCC, MAL-PDT may be considered when surgery may result in suboptimal cosmetic outcomes or complications.[29] For patients with nodular BCC, MAL-PDT may be considered but not ALA-PDT.[29,48]

---

| **Table 93–6** |
| --- |
| **Topical Therapy for Nonmelanoma Skin Pre-Cancer** |

**Methyl Aminolevulinate Hydrochloride**
**Actinic keratosis:** apply up to 1 g (half tube) of cream topically on lesion(s) during PDT session (two sessions 1 week apart) followed by occlusive dressing for 3 hours (at least 2.5 hours and no more than 4 hours in duration) and then red light illumination for 7–10 minutes; maximum, 1 g (half tube) per treatment session.

**Aminolevulinic Acid**
**Actinic keratosis:** apply topically to target lesion(s) on face or scalp and let dry and then repeat once; 14–18 hours later, gently rinse area with water and pat dry; follow by illumination from the BLU-U(R) Blue Light Photodynamic Therapy Illuminator; may retreat a second time after 8 weeks.

Protect treated lesions from sunlight or prolonged or intense light for at least 40 hours by covering with light-opaque material; sunscreen will not protect against photosensitivity reactions caused by visible light.

**Topical Fluorouracil**
**Actinic keratosis:** cover lesions topically with 2% or 5% solution or cream twice daily for 2–6 weeks or with 0.5% microsphere formulation once daily for up to 4 weeks.

**Imiquimod**
**Actinic keratosis:** Imiquimod 5% apply topically formulation once daily five times per week for 6 weeks; apply at bedtime and leave on skin for 8 hours

The doses presented here are general. Clinicians should refer to reference materials to determine the specific dose based on the regimen the patient is receiving.

PDT, photodynamic therapy.

## Pharmacologic Therapy

#### ▶ Fluorouracil

Nonsurgical treatment is used frequently for superficial NMSCs. Topical 5-fluorouracil has been used for the treatment of dermatologic disorders for approximately 45 years, and it has FDA approval for the treatment of AK and superficial BCC. Fluorouracil is available as solution and cream with strengths ranging from 1% to 5%. There is also a microsphere-encapsulated 0.5% cream that has reduced systemic absorption with enhanced skin retention to reduce systemic side effects. The microsphere formulation is applied only once a day, providing patient preference and convenience over the twice-daily application with the other formulations. The optimal strength of fluorouracil is still under investigation, but the FDA has approved 2% to 5% cream or solution and 0.5% microsphere formulation for AK. For superficial BCC, only the 5% strength is FDA approved for this indication. The most common side effects with topical fluorouracil are expected to occur within the initial 5 to 10 days of treatment, and it presents as erythema, irritation, burning sensation, pruritus, and pain along with hypo- or hyperpigmentation. Patients also experience inflammatory reactions that include crusting, edema,

and oozing. If the reactions are severe, the fluorouracil strength or frequency of application may be reduced. To reduce inflammation, topical steroids may be used concurrent with fluorouracil application and for 1 to 2 weeks after treatment.[29] Caution should be used in administering fluorouracil to patients with dihydropyrimidine dehydrogenase deficiency, an enzyme critical in the metabolism of fluorouracil, because increased toxicity may be observed.

### ► *Imiquimod*

Imiquimod is an immune-modulating agent that works by stimulating innate and cell-mediated immune responses. It has FDA approval for the treatment of AK and for when surgical procedure is not appropriate for superficial BCC located on the trunk, neck, or extremities and when follow-up is assured. Imiquimod has been shown to have complete clearing of AK in 50% of patients and partial clearing in 75% of patients with AK compared with 5% for those treated with placebo. Cure rates for imiquimod 5% in patients with superficial BCC are greater than 90%. The response rate is much lower for nodular BCC at 75%; therefore, it should be used in these patients only if they are not able to undergo surgery, radiation, or cryotherapy and the tumor is small and in a low-risk area. Imiquimod is not recommended for the treatment of invasive SCC, but data for SCC in situ showed a 93% cure rate; thus, it may be considered for this patient population.

Imiquimod is available in 3.75% strength, which may be applied daily on larger areas of skin, the balding scalp, or the full face, and 5% strength, which may be used on areas of skin that are 25 cm$^2$ or smaller (see Table 93–4). Imiquimod should be applied before bedtime and left on the skin for 6 to 10 hours. The most common side effects with imiquimod involve the area of application and present as erythema, pruritus, a burning or stinging sensation, and tenderness. Less commonly, hypopigmentation, fever, diarrhea, and fatigue may also occur. Temporary discontinuation of imiquimod and application of topical steroids may be necessary to alleviate the irritation symptoms. Imiquimod may be resumed at a decreased frequency after the symptoms have resolved.[29]

### ► *Vismodegib*

Genetic alterations in hedgehog signaling pathway cause loss of function of patch homolog 1 (PTCH1), which normally acts to inhibit signaling activity of Smoothened, a transmembrane protein involved in Hedgehog signal transduction. Vismodegib is a first-in-class, oral small molecule inhibitor of the Hedgehog signaling pathway; it binds to and inhibits Smoothened (SMO). Vismodegib is approved by the FDA for the treatment of adults with metastatic BCC or locally advanced BCC that has recurred following surgery or who are not candidates for surgery or radiation.

## OUTCOME EVALUATION

BCC and SCC have excellent outcomes, with cure rates approaching 98%.[47] Recurrence of NMSC is around 30% to 50% during a 5-year follow-up, and 70% to 80% of recurrence develops within the first 2 years after initial therapy.[47] Therefore, it is crucial to advise patients to schedule routine follow-up visits with their dermatologist and to educate them about the value of sun protection and total-body skin self-examination.[29]

Patients receiving topical agents such as fluorouracil or imiquimod should be educated to wash the treatment area with mild soap and water before applying the cream, use gloves to apply enough to cover the area with a 1-cm margin, and wash their hands thoroughly after each application. They should avoid sun exposure and be counseled to monitor for side effects such as pain, itching, and inflammation. They should consult their dermatologist if the side effects are intolerable.

---

## Patient Care Process

**Patient Assessment:**
- Take a thorough medication history with particular attention to nonprescription or herbal medications.
- Assess sun exposure and advise patient regarding sun exposure prevention.

**Therapy Evaluation:**
- Determine the optimal treatment regimen for the patient incorporating diagnosis, stage, and mutation status.
- Verify regimen doses with a standardized reference and assess for dose adjustment based on height, weight, and body surface area and organ dysfunction (renal or hepatic).
- Assess appropriateness of supportive care for the regimens including need for prophylactic antiemetics.

**Care Plan Development:**
- Enroll patient in REMS program if they will receive ipilimumab.
- Provide patient education regarding common toxicities associated with immunotherapy such as rash, diarrhea, and hepatotoxicity.
- Provide patient education regarding common toxicities associated with targeted therapy such as hypoglycemia, arthralgia, and neutropenia.
- Advise patients receiving targeted therapies of the risk of new skin cancers.

**Follow-up Evaluation:**
- Schedule regular laboratory tests and skin exams to monitor for toxicities.
- Monitor patient for to therapy.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| AK | Actinic keratosis |
| APC | Antigen-presenting cell |
| BCC | Basal cell carcinoma |
| CNS | Central nervous system |
| CTL | Cytotoxic T lymphocyte |
| CTLA-4 | Cytotoxic T-lymphocyte antigen-4 |
| CYP | Cytochrome P-450 |
| ED&C | Electrodessication and curettage |
| IFN | Interferon-α-2b |
| Ig | Immunoglobulin |
| IL-2 | Interleukin 2 |
| LFT | Liver function test |

MM        Malignant melanoma
MMS       Mohs micrographic surgery
NMSC      Nonmelanoma skin cancer
PFS       Progression-free survival
REMS      Risk Evaluation and Mitigation Strategy
SCC       Squamous cell carcinoma
SEER      Surveillance, Epidemiology, and End Results
SLN       Sentinel lymph node
SPF       Skin protection factor
SRS       Stereotactic radiosurgery
TNM       Tumor, node, metastasis
UVR       Ultraviolet radiation
WBRT      Whole-brain radiation therapy
XP        Xeroderma pigmentosum

# Ovarian Cancer

Judith A. Smith

## LEARNING OBJECTIVES

● **Upon completion of the chapter, the reader will be able to:**

1. Demonstrate understanding of the etiology and risk factors associated with the development of ovarian cancer.

2. Justify the risk and benefits of the surgical and chemoprevention options available for decreasing the potential risk of developing ovarian cancer.

3. Interpret and understand the utility of the screening tests and serologic markers for diagnosing ovarian cancer.

4. Distinguish the nonspecific physical signs and symptoms of ovarian cancer.

5. Recommend the appropriate surgical and chemotherapy treatment options for newly diagnosed, persistent, and recurrent ovarian cancer patients.

6. Discuss the role of consolidation treatment for improving overall survival for ovarian cancer patients.

7. Compare and contrast chemotherapy options for women with recurrent platinum-resistant ovarian cancer.

## INTRODUCTION

Ovarian cancer is relatively uncommon but is the most incurable of the gynecologic cancers. Ovarian cancer is often denoted as the "silent killer." KEY CONCEPT *The primary reason for the high mortality rate associated with ovarian cancer is the nonspecific symptoms and difficulty for early detection or screening that result in patients presenting with advanced disease.* The majority of ovarian cancers are of epithelial origin. Each time ovulation occurs, the epithelium of the ovary is broken followed by occurrence of cell repair. The incessant ovulation hypothesis proposes that the increasing number of times the ovary epithelium undergoes cell repair is associated with the increasing risk of mutations and ultimately ovarian cancer. Although the majority of patients will achieve a complete response (CR) to primary surgery and chemotherapy, disease recurs in more than 50% of patients in the first 2 years after completion of primary treatment. KEY CONCEPT *Ovarian cancers often cause metastasis via the lymphatic and blood systems to the liver, and/or lungs.* Common complications of advanced and progressive ovarian cancer include **ascites** and small bowel obstruction (SBO), which often are associated with the end of life.

## EPIDEMIOLOGY AND ETIOLOGY

In 2015, there were an estimated 21,290 new cases of ovarian cancer diagnosed with an associated 14,180 deaths.[1] Ovarian cancer remains the number one gynecologic killer and the fifth leading cause of cancer-related death in women. Despite great efforts and extensive research, addition of new agents and routes of administration, there has been little change in the mortality rate associated with ovarian cancer over the past five decades. Again, this high mortality rate associated with ovarian cancer can be attributed to its insidious onset of nonspecific symptoms, resulting in the majority of patients not presenting until the cancer has progressed to stages III to IV disease.

As with many other disease states, a significant risk factor associated with ovarian cancer is aging. Risk of ovarian cancer increases from age 40 to 79 years, with the mean age at diagnosis being 63 years and the majority of women being diagnosed between 55 and 64 years.[2]

Ovarian cancer is a sporadic disease; fewer than 10% of ovarian cancers can be attributed to heredity. KEY CONCEPT *The majority of cases of ovarian cancer occur sporadically, thus making it difficult to screen and prevent.* Although hereditary accounts for fewer than 10% of all ovarian cancer cases, when there is a family history, it appears to be an important risk factor in the development of ovarian cancer in some patients.[3] If one family member has a diagnosis of ovarian cancer, the associated risk is about 9%, but this risk increases to greater than 50% if there are two or more first-degree relatives (ie, mother and sister) with a diagnosis of ovarian cancer or multiple cases of ovarian and breast cancer.[3] Both breast cancer activator gene 1 (*BRCA1*) and breast cancer activator gene 2 (*BRCA2*) mutations have been associated with ovarian cancer. However, *BRCA1* is more prevalent, being associated with 90% of hereditary and 10% of sporadic cases of ovarian cancer.[3] Hereditary breast and ovarian cancer (HBOC) syndrome is one of the two different forms of hereditary ovarian cancer and is associated with germline mutations in *BRCA1* and *BRCA2*.[3,4] The hereditary nonpolyposis colorectal cancer (HNPCC) or Lynch syndrome is a familial syndrome with germline mutations causing defects in enzymes involved in DNA

## Patient Encounter 1, Part 1

The patient is a 66-year-old active woman, who has been in good health up until recently (about 6 weeks or so). At Thanksgiving, she mentioned to her daughter that she has had not been able to have a bowel movement in over 6 days despite use of OTC laxative medications. The following Monday she saw her gastroenterologist that completed CT scan that suggests minor colitis but no obvious reason for inability to have bowel movement. One week later, her symptoms persisted, so her physician did an exploratory laparoscopic surgery, which came back positive for an abdominal mass and thickening of the peritoneal lining and mass on right ovary extending to outside of colon wall which was removed by general surgeon and required temporary ostomy. Of note, she has been married for 41 years with only one sexual partner in her lifetime. They have three children who are all grown adults. Her first menses was when she was 11 years old and menopause was at age 54 years. She has had infrequent alcohol on social occasions only and denies any tobacco use.

*Based on the results from exploratory surgery, what additional diagnostic tests would be recommended to complete her workup?*

*In the context of this patient, discuss why ovarian cancer is often denoted the "silent killer" and what needs to be done for earlier diagnosis of ovarian cancer.*

*Compare and contrast the treatment options for RH after her initial surgery.*

## Patient Encounter 2

A 37-year-old professional, single woman who has been in good health, presents to your clinic complaining of constipation and abdominal bloating. She explains to you that she is concerned about her cancer risk because her 64-year-old mother was recently diagnosed breast cancer and then last month, her step-sister was diagnosed with stage I ovarian cancer and underwent TAH-BSO and had genetic testing completed that revealed she was *BRCA1* positive. She is requesting to check her CA-125 level today in clinic.

*Explain the association between hereditary and ovarian cancer risk.*

*Discuss why monitoring CA-125 is not used as a screening tool for ovarian cancer.*

*Describe the potential advantages and disadvantages of using oral contraceptives for prevention of ovarian cancer for this patient.*

---

mismatch repair, which has been associated with up to 12% of hereditary ovarian cancer cases.[4]

Although it is not clearly defined, hormones and reproductive history are associated with the risk of developing ovarian cancer. Nulliparity, infertility, early menarche, or late menopause is associated with an increased risk of ovarian cancer.[5]

Ovarian cancer is associated with certain dietary and environmental factors as well. A diet that is high in galactose and animal fat and meat increases the risk of ovarian cancer, whereas a vegetable-rich diet is suggested to decrease the risk.[6,7] Although still somewhat controversial, exogenous factors such as asbestos and talcum powder use on the perineal area have also been suggested to increase the risk of ovarian cancer.[6]

### Screening and Prevention

#### ▶ Screening

Currently, there is no standard effective screening tool that is adequately specific or sensitive for early detection.

Pelvic examinations are effective for detecting obvious tumors present with a sensitivity of 67% for detecting all tumors; however, minimal or microscopic disease cannot be detected on physical examination.[8] Pelvic examinations are noninvasive and well accepted, but they do not usually detect ovarian cancer until it is in advanced stage. Transvaginal ultrasound (TVUS) is a component of current screening practices. Typically, it is used in combination with cancer antigen-125 (CA-125) or could be used as a single modality. TVUS releases sonic sound waves that create an image of the ovary to evaluated the size and shape and detect the presence of cystic or solid masses. Limitations of this

technique are lack of specificity and an inability to detect peritoneal cancer or cancer in normal size ovaries.[2,9] Most prevention clinics use this multimodality approach to screen high-risk women and recommend yearly ultrasound in combination with CA-125 blood test every 6 months.

Serum CA-125 is the most extensively evaluated tumor marker for ovarian cancer. **KEY CONCEPT** *Because CA-125 is a nonspecific marker, it is not a standard recommendation for routine screening for prevention of ovarian cancer.* Unfortunately, CA-125 is nonspecific, and elevated levels can be associated with a number of other gynecologic and GI-related diseases. CA-125 levels in a woman without ovarian cancer are static or tend to decrease over time, but levels associated with malignancy continue to rise.[9,10]

#### ▶ Prevention

Ovulation is considered a hostile event to the ovarian epithelium, making it more susceptible to damage and cancer. Interventions or conditions that limit the number of ovulations in a woman's reproductive history, including multiparity, have a protective effect.

**Chemoprevention** Investigational chemoprevention strategies used for ovarian cancer include oral contraceptives (OCs), aspirin and nonsteroidal anti-inflammatory agents, and retinoids, although none of these is currently accepted as standard treatment for the prevention of ovarian cancer. The theory that OCs reduce the number of ovulatory events is a basic explanation of its protective effect. Recent studies have suggested that progestin-induced apoptosis of the ovarian epithelium is responsible for the chemopreventive effect of OCs. The theory is that cells that have genetic damage but are not yet neoplastic have an increased chance of undergoing apoptosis.[11] OCs decrease the relative risk to less than 0.4% in women that use OCs for longer than 10 years.[12] However, the maximum protective effect of OC use in women with *BRCA* mutations has been reported to be between 3 and 5 years.[12] At the same time, OC use has been associated with an increased risk of breast cancer.[11,13] Thus, women with a family history of breast cancer would not be ideal candidates for this preventive measure.

Nonsteroidal anti-inflammatory agents, aspirin, and acetaminophen have been suggested for use in the prevention of different cancers, especially hereditary nonpolyposis colon cancer.[13] Although observational studies have linked these to a reduction of ovarian carcinoma risk, evidence is still lacking. Potential mechanisms include effects on normal ovulation shed and inhibition of ovulation.[13] Other pharmacologic interventions that have been suggested but are still being evaluated include vitamin A, lutein, and other carotenoids.[14,15] The protective effect of these agents is associated with inhibition of cell growth as well as promotion of cellular differentiation.[14]

**Prophylactic Surgery** Surgical strategies are also used in the prevention of ovarian cancer. The goal is to remove healthy, at-risk organs and ultimately reduce the risk of developing cancer. These surgeries include prophylactic bilateral salpingo-oophorectomy (BSO) or tubal ligation (Figure 94–1).

Prophylactic oophorectomy should be considered in any woman with a high risk of developing ovarian cancer.[16] The criteria for defining high risk includes any woman with two or more first-degree relatives with epithelial ovarian carcinoma; a family history of multiple occurrences of nonpolyposis colon cancer, endometrial cancer, and ovarian cancer; and a family history of multiple cases of breast and ovarian cancer.[17] Patients undergoing prophylactic oophorectomy need to be made aware that complete protection is not guaranteed.[17–19] Although a 67% reduction in risk has been shown, a potential 2% to 5% risk of peritoneal carcinomatosis remains.[18–20]

Tubal ligation is another procedure that has shown potential for risk reduction. However, it is not recommended as a sole procedure in prophylaxis. The protective effect may be attributable to limiting exposure of the ovary to environmental carcinogens. A case-control study conducted by Narod and colleagues[19] found that a history of tubal ligation in *BRCA*-positive women was associated with a statistically significant 63% reduction in risk.

**Genetic Screening** Genetic screening is another option available for high-risk patients. Patients can be screened for genes such as *BRCA1* and *BRCA2* or other genes such as those associated with HNPCC or the HBOC syndrome.[3,21] Patient and family counseling and genetic counseling should be available for the patient and family to prepare and deal with the health and psychosocial implications of the genetic test results. Before this decision, the potential preventive options should be discussed, such as prophylactic BSO and/or total hysterectomy. Cancer risk and patient's health need to be balanced, but typically surgery can be held off until after the childbearing years.[20,21]
## PATHOPHYSIOLOGY

The three current theories are the incessant ovulation hypothesis, the pituitary gonadotropin hypothesis, and the chronic inflammatory processes hypothesis.[2] The incessant ovulation hypothesis proposes that the pathogenesis of ovarian cancer is connected to continual ovulation. Ovulation is considered a "hostile" event to the ovaries, perhaps with not enough time for adequate repair. Each time ovulation occurs, the ovary epithelium is disrupted, and cell damage occurs. Thus, repeated ovulations may lead to a greater number of repairs of the ovarian epithelium and increase the possibility of aberrant repairs, mutation, and carcinogenesis.[22] The pituitary gonadotropin hypothesis associates the disease with elevations in gonadotropin and estrogen levels.[2] This leads to an increase in the number of follicles and therefore an increased risk of malignant changes. Finally, the chronic inflammatory processes may be involved with various environmental carcinogens to cause cancer.[2,13]

The three major pathologic categories of ovarian tumors include sex-cord stromal, germ cell, and epithelial. About 85% to 90% of ovarian cancers are of epithelial origin. Epithelial ovarian tumors are composed of cells that cover the surface of the ovary such as serous, mucinous, endometrioid, clear cell, and poorly differentiated adenocarcinomas. Germ cell tumors involve the precursors of ova with the most common type being dysgerminoma, which are most commonly diagnosed in women younger than the age of 40 years and generally have a better prognosis.[2] Sex-cord stromal tumors are indolent tumors that produce excess estrogen and androgens but also have a better overall prognosis.[2] Although the histologic type of the tumor is not a significant prognostic factor, it is important to know the histopathologic grade. Undifferentiated tumors are associated with a poorer prognosis than lesions that are considered to be well or moderately differentiated.

## TREATMENT
### Desired Outcomes

Health care providers use a multimodality approach, including surgery and chemotherapy, in initial treatment of patients with ovarian cancer with a curative intent, or restoring a normal life span. **KEY CONCEPT** *Although the majority of patients initially achieve a CR, disease will recur within the first 2 years in more than 50% of patients.*[2,23] CR to treatment is defined as no evidence of disease can be detected by physical examination or diagnostic tests and patient has a normalized CA-125.

The stage of disease at the time of diagnosis is the most important prognostic factor affecting overall survival in ovarian cancer patients.[24] The estimated 5-year survival rates of patients with localized, regional, distant, and unstaged ovarian cancer are 92.7%, 71.1%, 30.6%, and 26%, respectively.[24] The histology of the disease is another predominant prognostic factor influencing treatment outcomes. Clear cell and undifferentiated tumors do not respond as well to chemotherapy.[2] The extent of residual disease and tumor grade are also predictive of response to chemotherapy and overall survival.[2] There are other prognostic factors that may predict how well a patient will respond to adjuvant chemotherapy.

The treatment goals shift when a patient presents with recurrent ovarian cancer. The desired outcomes focus on relief of

**FIGURE 94–1.** Diagram of female reproductive tract (uterus, fallopian tubes, ovaries, vagina). The *dashed line box* outlines what is removed during the total abdominal hysterectomy with bilateral salpingo-oophorectomy (TAH/BSO).

## Clinical Presentation and Diagnosis of Ovarian Cancer

### General

Ovarian cancer typically has delay in diagnosis due to the common nonspecific signs and symptoms often initially suggesting GI-related complications. By the time symptoms become unrelenting and bothersome, patients most likely have advanced stage disease.

### Symptoms

Patients may experience episodes or persistent symptoms such as abdominal pain, constipation or diarrhea, flatulence, urinary frequency, or incontinence.

### Signs

The degree of abdominal swelling secondary to fluid accumulation may present like "pregnant abdomen" and irregular vaginal bleeding.

### Laboratory Test

- CA-125. The normal level is less than 35 U/mL (35 kU/L). Note: This test is associated with a lack of specificity. CA-125 can be elevated in a number of other states such as different phases of the menstrual cycle, endometriosis, and nongynecologic cancers.
- NOTE: It is important to rule out other cancers associated with the abdominal cavity.
- Carcinoembryonic antigen (CEA). CEA is a marker for colon cancer. A normal value is less than 3 ng/mL (3 mcg/L).
- CA-19–9 is a marker for many GI tumors such as cholangiocarcinomas.

### Chemistries with Liver Function Tests (LFTs)

- LFTs and serum creatinine might be suggestive of extent of disease. The majority of this information is needed to determine if patient is a surgical candidate. Laboratory study results should be within normal limits.

### Complete Blood Count (CBC)

- Abnormalities in CBC are not associated with ovarian cancer; however, this information is needed to determine if patient is a surgical candidate. Laboratories should be within normal limits.

### Other Diagnostic Tests

To characterize local disease, one or both of the following are completed:

- TVUS
- Abdominal ultrasound

To evaluate the extent of disease, only one of the following is completed:

- CT scan
- MRI
- PET scan

Chest x-ray is also often done as part of clearance for surgery.

Ovarian cancer is usually confined to the abdominal cavity, but spread can occur to the lung and liver and less commonly to the bone or brain. Disease is spread by direct extension, peritoneal seeding, lymphatic dissemination, or bloodborne metastasis. Lymphatic seeding is the most common pathway and frequently causes ascites.

---

symptoms such as pain or discomfort from ascites, slowing disease progression, and prevention of serious complications such as SBO. When a patient relapses, the prognostic factors are similar as after initial surgery except that the amount of time that has lapsed since the completion of chemotherapy should be considered to determine if drug resistance is emerging in the tumor. Recurrent platinum-sensitive ovarian cancer patients generally have a better prognosis than platinum-resistant patients.

### Nonpharmacologic Therapy

**KEY CONCEPT** *Surgery is the primary treatment intervention for ovarian cancer.*[25–27] A total hysterectomy with BSO (TH-BSO) (see Figure 94–1), omentumectomy, and lymphonectomy (or lymph node dissection) is the standard initial surgical treatment of ovarian cancer.[25] The objective of the surgery is to debulk the patient to less than 1 cm of residual disease remains. Residual disease less than 1 cm correlates with better CR rates to chemotherapy and better overall survival compared with patients with bulky residual disease (larger than 1 cm).[26,27] Indeed, the size of residual tumor masses after primary surgery is found to be another important prognostic factor in patients with advanced ovarian cancer.[27]

A thorough exploratory laparotomy is essential for the accurate staging of the patient.[25–27] **KEY CONCEPT** *Ovarian cancer is staged surgically using the International Federation of Gynecology and*

*Obstetrics (FIGO) staging algorithm.* For certain patients with limited stage disease, surgery may be curative.

Other surgical procedures have been evaluated to improve overall survival. Debulking surgery is intended to relieve symptoms associated with complications such as SBO and help improve the patient's quality of life but does not have a curative intent. Interval debulking that is completed after two to three cycles of chemotherapy has not translated to an improved survival benefit. Often debated, the benefit of the "second-look laparotomy" to evaluate residual disease after the patient has completed chemotherapy remains controversial because it has been difficult to establish any impact on patients' overall survival. It has questionable benefit because although approximately 40% of patients with advanced disease have a negative second look, 50% still relapse.[2] The role of laparoscopic surgery is somewhat controversial for initial surgery but is more often considered in debulking of recurrent or advanced disease when the intent is palliative rather than curative.[25]

### Pharmacologic Therapy

#### ▶ First-Line Chemotherapy

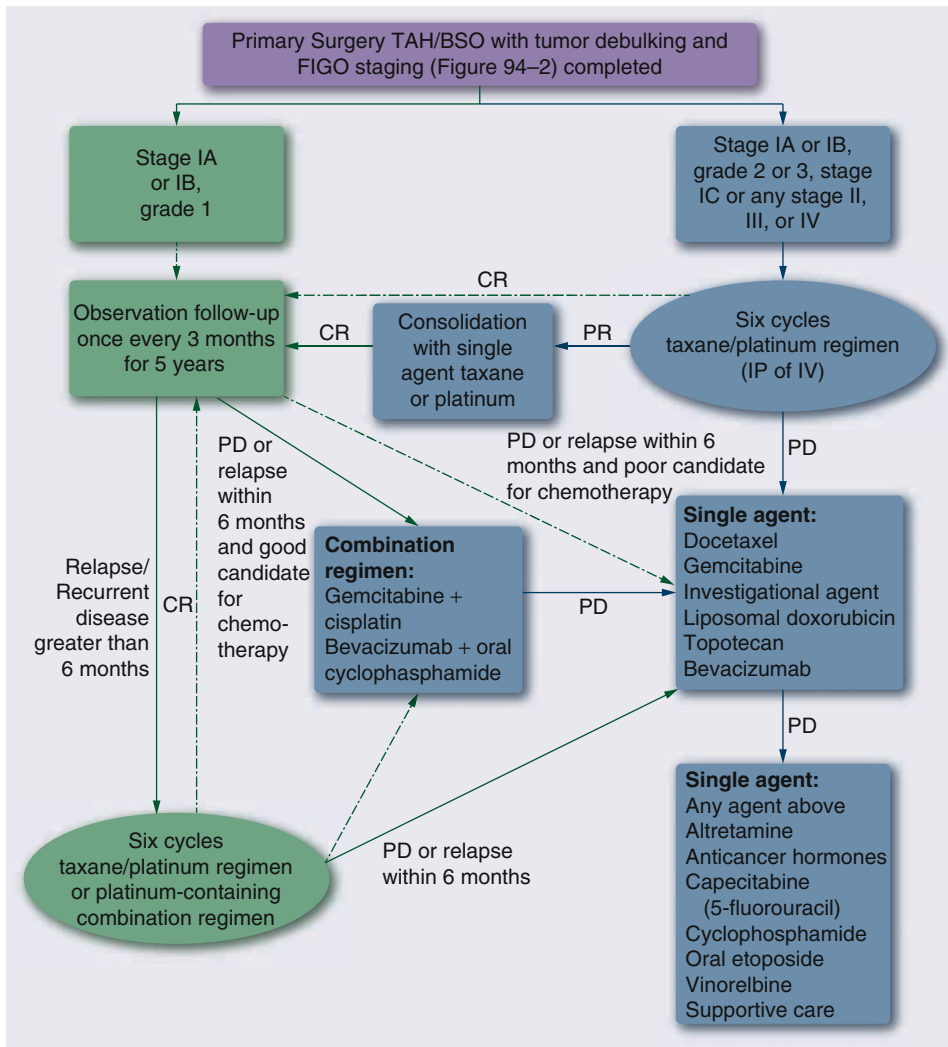
**KEY CONCEPT** *After initial surgery, the gold standard of care is six cycles of taxane/platinum-containing regimen for patients with advanced ovarian cancer.*[28–30] Patients with limited disease, ie, stage IA, will have observation alone after surgery


**FIGURE 94–2.** Summary of a chemotherapy treatment algorithm for epithelial ovarian cancer. (CR, complete response; FIGO, Federation of Gynecology and Obstetrics; PD, progressive disease; PR, partial response; TAH-BSO, total abdominal hysterectomy with bilateral salpingo-oophorectomy.)

(Figure 94–2). Most often, paclitaxel is the taxane agent used in combination with carboplatin as the preferred platinum agent.[28–30] Depending on patients' preexisting comorbidities and how well they tolerate chemotherapy regimens, substitution with docetaxel or cisplatin might be considered. The route of administration should also be discussed. Although intravenous (IV) administration is often used, **intraperitoneal** (IP) administration has been shown to improve overall survival and should be considered for first-line treatment; however, patient selection for IP therapy is critical[31] (Table 94–1). Close monitoring of organ function, nausea/vomiting, myelosuppression, and neuropathies is necessary for all taxane/platinum regimens (Table 94–2).

#### ▶ Intraperitoneal Chemotherapy

For more than four decades, numerous investigators have evaluated the IP route for administration of chemotherapy; however, it was not until the third report of an improvement in overall survival that brought its use to the forefront in the first-line setting.[32] The principal theory supporting IP administration is to increase drug concentration in the site of disease, specifically the abdominal cavity. Patient characteristics greatly influence response and tolerability of IP chemotherapy. To be selected to receive IP chemotherapy for first-line treatment of ovarian cancer, the patient should have tumor optimally debulked and no bowel resection

with primary surgery, normal renal and liver function, younger age, and no significant comorbidities.

When IP therapy is administered, the placement of an IP catheter should occur at the time of surgery unless otherwise contraindicated. During IP administration, chemotherapy is delivered to the peritoneal space in 1 L of normal saline (NS) that has been warmed followed by another liter of NS to enhance drug distribution as tolerated.[33,34] The current standard IP regimen includes the administration of paclitaxel IV on day 1 followed by cisplatin IP on day 2 and then paclitaxel IP on day 8 given on a 21-day cycle for a total of six cycles (see Table 94–2). The most common toxicities associated with IP administration include abdominal pain, myelosuppression, neurotoxicity, and catheter-related infections. The substitution of carboplatin IP in place of cisplatin remains investigational and should not be recommended outside a clinical trial protocol.

#### ▶ Neoadjuvant Chemotherapy

Neoadjuvant chemotherapy is first-line treatment for patients who are poor surgical candidates or patients with bulky or significant tumor burden.[23] For patients who are poor surgical candidates because of significant comorbidities, a combination of taxane with platinum agent is administered every 21 to 28 days as tolerated with the intent to relieve symptoms and

| **Table 94–1** |
| --- |

**Summary of First-Line Chemotherapy Regimens for Advanced Ovarian Cancer**

Gold standard first-line chemotherapy after initial surgery for treatment of ovarian cancer:
Paclitaxel 175 mg/m$^2$ IV infused over 3 hours + carboplatin AUC = 5 IV infused over 1 hour. Regimen is given once every 21 days × 6 cycles
   {+/– bevacizumab 7.5 mg/kg once every 3 weeks × 6 cycles followed by additional 12 cycles after completion of primary chemotherapy}
Alternative first-line regimen: Paclitaxel IV with substitution of carboplatin IV with cisplatin IP and addition of paclitaxel IP therapy:
Patient selection is critical: must have optimally debulked disease (< 1 cm) and no significant comorbidities; younger patients tolerate better
Day 1: paclitaxel 135 mg/m$^2$ IV infused over 24 hours + day 2: cisplatin 100 mg/m$^2$ IP infused over 1 hour + day 8: paclitaxel 60 mg/m$^2$
   IP infused over 1 hour. Regimen is given once every 21 days × 6 cycles
Alternative first-line regimen: Dose density. Consider for patients with optimal debulking, no comorbidities, good performance status:
Paclitaxel 80 mg/m$^2$ IV infused over 1 to 3 hours once a week with carboplatin AUC = 6 IV infused over 1 hour on day 1 only of 21-day cycle.
Alternative first-line regimen: Substitution of cisplatin in place of carboplatin. Consider for patients experiencing difficulty with
   maintaining platelet counts:
Paclitaxel 135 mg/m$^2$ IV infused over 24 hours + day 2: cisplatin 75 mg/m$^2$ IV infused over 4 hours. Regimen is given once every 21 days ×
   6 cycles
Alternative first-line regimen: Substitution of docetaxel in place of paclitaxel. Consider for patients with preexisting or increased risk of
   neuropathies:
Docetaxel 75 mg/m$^2$ IV infused over 1 hour + carboplatin AUC = 5 IV infused over 1 hour. Regimen is given once every 21 days × 6 cycles

AUC, area under the curve; IV, intravenous.

**Summary of Chemotherapy Agents Used for First-Line Treatment of Advanced Ovarian Cancer**

**Mechanism of Action of First-Line Agents**

**Platinum analogues:** Produce intra- and interstrand cross-links and DNA adducts to disrupt DNA replication

**Taxanes agents:** Stabilize microtubules and prevents depolymerization of tubulin

| Agent | Common Adverse Effects | Monitoring/Comments |
| --- | --- | --- |
| **Paclitaxel** | Peripheral neuropathy (DLT), nausea/vomiting, alopecia, hypersensitivity reactions | 1. Use caution with any elevation in AST (SGOT) <br> 2. Give proper dosing for liver dysfunction. At least a 50% dose reduction generally recommended <br> 3. Do not give if total bilirubin is > 5 mg/dL (86 μmol/L) <br> 4. Premedicate for hypersensitivity reactions: dexamethasone, diphenhydramine, and cimetidine |
| **Docetaxel** | Neutropenia (DLT) hyperlacrimation, fluid retention, nail disorders, myelosuppression | 1. Use with caution in liver dysfunction. Patients with bilirubin greater than the ULN and/or liver transaminases > 1.5 times, the ULN should not receive docetaxel <br> 2. Do not give if biliary tract is obstructed <br> 3. Premedicate for hypersensitivity reactions: dexamethasone |
| **Carboplatin** | Myelosuppression (DLT), nephrotoxicity, nausea/vomiting, electrolyte wasting, diarrhea, stomatitis, hypersensitivity reactions | 1. Prehydration not required <br> 2. If using BSA dosing, then give proper dosing for renal dysfunction <br>    CrCl ≥ 60 mL/min (1.00 mL/s): no dosage adjustment needed. <br>    CrCl 41–59 mL/min (0.68–0.99 mL/s): give 250 mg/m$^2$ <br>    CrCl 16–40 mL/min (0.26–0.67 mL/s): give 200 mg/m$^2$ <br>    CrCl ≤ 15 mL/min (0.25 mL/s): do not give <br>    NOTE: Calvert formula (AUC dosing) is based on renal function, so no additional dose adjustment is needed <br> 3. Premedicate for hypersensitivity reactions: dexamethasone, diphenhydramine, and cimetidine <br> 4. Appropriate antiemetic regimen for prevention of acute and delayed nausea |
| **Cisplatin** | Neurotoxicity (DLT), nausea/vomiting, ototoxicity, nephrotoxicity, myelosuppression, electrolyte wasting, diarrhea | 1. Prehydration and posthydration with electrolyte replacement (ie, potassium chloride 10 mEq [10 mmol] and magnesium sulfate 16 mEq [8 mmol]) required <br> 2. Do not use if SrCr > 1.5 mg/dL (133 μmol/L) or BUN > 25 mg/dL (8.9 mmol/L) <br> 3. Give proper dosing for renal dysfunction CrCl 46–60 mL/min (0.77–1.00 mL/s): decrease dose by 50%. CrCl 31–50 mL/min (0.51–0.83 mL/s): decrease dose by 75%. CrCl ≤ 30 mL/min (0.50 mL/s): do not use <br> 4. Appropriate antiemetic regimen for prevention of acute and delayed nausea |
| **Bevacizumab** | Hypertension, proteinuria, infusion-related reactions, fluid retention, increase risk of thrombosis, myelosuppression | 1. Monitor urine-to-creatinine baseline and every two cycles; hold therapy if ratio > 2 or measure urine protein every cycle and addition testing if positive for proteinuria <br> 2. Use caution in patients with a history of thrombosis |

AST, aspartate aminotransferase; AUC, area under the curve; BSA, body surface area; BUN, blood urea nitrogen; CrCl, creatinine clearance;
DLT, dose-limiting toxicity; SrCr, serum creatinine; ULN, upper limit of normal.

slow progression of disease. In some cases, especially in elderly patients, single-agent carboplatin is used as palliative treatment instead. Chemotherapy alone has not been curative for patients with advanced ovarian cancer.[23]

In patients with bulky disease or significant tumor burden, neoadjuvant chemotherapy can be used to decrease tumor burden to increase the likelihood of optimal tumor debulking during surgery.[31] Typically, three cycles of the standard combination taxane/platinum regimen is administered once every 21 days. After surgery, patient will receive another three to six cycles depending on their response to chemotherapy.

▶ *Consolidation and Maintenance Chemotherapy*

Consolidation chemotherapy is the addition of cycles of the taxane/platinum regimen or the addition of single-agent platinum or single taxane after completion of first-line chemotherapy.[36] If the tumor has a partial response (PR) to first-line chemotherapy evident by a significant decline in CA-125 by greater than 50% presurgery level and/or tumor regression or decrease in size, then cancer is still considered taxane/platinum sensitive. Additional cycles of chemotherapy are given until CR is achieved (see Figure 94–2). In 2014, bevacizumab was finally approved to be added to the primary treatment and as consolidation treatment for ovarian cancer based on the improved overall survival observed in the ICON-7 study.[37]

Maintenance chemotherapy is similar to consolidation chemotherapy except maintenance chemotherapy is given to patients who have achieved a clinically CR.[38] Maintenance chemotherapy is used to hopefully extend progression-free and overall survival by eliminating any microscopic disease present after completion of primary chemotherapy.

For an extensive description of the common agents used in first-line, consolidation, and maintenance chemotherapy of ovarian cancer, please see Chapter 88. A brief overview of the regimens is provided in Table 94–1 and adverse effects are provided in Table 94–2.

## Recurrent Chemotherapy

In the recurrent setting, platinum sensitivity of the tumor is assessed first. If recurrence occurs in less than 6 months or disease progresses while the patient is receiving a platinum-based regimen, the cancer is considered platinum resistant (see Figure 94–2). These parameters are also used to determine if tumors are taxane sensitive or resistant. However, patients resistant to paclitaxel may still respond to docetaxel.[39] If the treatment goal is palliative care, then often single therapy will be used, but curative care typically is an aggressive combination regimen (see Figure 94–2 and Table 94–3). Sometimes an investigational agent may achieve responses equivalent or surpassing standard therapy, and should be considered for most patients.

## Table 94–3

**Summary of Combination Chemotherapy Regimens Used for Treatment of Recurrent Ovarian Cancer**

| Drug(s) | Regimen Dosing | Drug Monitoring Comments[b] |
|---|---|---|
| **Combination Regimens** | | |
| **Platinum Sensitive** | | |
| Paclitaxel and carboplatin | 175 mg/m² IV (3-hour infusion) AUC 5–7.5 IV every 21 days | • Monitor closely for hypersensitivity reactions |
| Paclitaxel and cisplatin | 135 mg/m² IV (24-hour infusion) 75 mg/m² IV | • Monitor closely for hypersensitivity reactions |
| Docetaxel and carboplatin | 75 mg/m² IV AUC 5 IV every 21 days | • Monitor closely for hypersensitivity reactions |
| Gemcitabine and carboplatin | 800 mg/m² IV days 1 and 8 AUC 5 IV day 1 every 21 days | • Monitor platelet counts closely<br>• Monitor closely for hypersensitivity reactions |
| Liposomal doxorubicin and carboplatin | 30 mg/m² IV over 1–3 hour AUC 5 IV every 28 days | • Monitor closely for hypersensitivity reactions<br>• Liposomal doxorubicin infusion start over 3 hour and decrease to 1 hour as tolerated<br>• Counsel patient for PPE prevention |
| **Platinum-Resistant[a]** | | |
| Gemcitabine and cisplatin | 1000 mg/m² IV days 1 and 8 40 mg/m² IV days 1 and 8 every 21 days | • Monitor renal function closely<br>• Monitor ANC closely, consider primary use of growth factor<br>• Monitor closely for hypersensitivity reactions |
| Cyclophosphamide and bevacizumab | 50 mg PO once daily 10 mg/kg IV once every 2 weeks every 28 days (continuous) | • Monitor for hypertension; hold therapy blood pressure greater than 140/90 mm Hg<br>• Monitor urine-to-creatinine baseline and every two cycles; hold therapy if the ratio is greater than 2 or measure urine protein every cycle and addition testing if positive for proteinuria<br>• Use caution in patients with history of thrombosis |

[a]*Platinum resistance* = disease progression while on platinum agent or recurrence within 6 months of completion of platinum-based therapy.

[b]See Table 94–2 for specific monitoring parameters.

ANC, absolute neutrophil count; AUC, area under the curve; IV, intravenous; PO, oral; PPE, palmar-plantar erythrodysesthesia.

### ▶ Platinum Sensitive

In patients who experienced a CR to first-line chemotherapy and have had greater than a 6-month platinum-free interval, retreatment with a platinum-containing regimen is appropriate. The combination of carboplatin with gemcitabine, liposomal doxorubicin, or paclitaxel for the treatment of platinum-sensitive recurrent ovarian cancer with a curative intent is recommended.[31,40,41] (see Table 94–3). However, in patients who are unable to tolerate additional combination chemotherapy regimens, carboplatin alone or any one of the second-line agents would be appropriate[42] (see Table 94–2).

### ▶ Platinum Resistant

Recurrent or persistent ovarian cancer after platinum-based regimens has a discouraging prognosis. Second-line agents have not been successful to date, but any active agent that has not been used during initial treatment is available to use. KEY CONCEPT

*Single-agent chemotherapy is standard practice for recurrent platinum-resistant ovarian cancer.* However, two combination regimens have demonstrated promising activity in the recurrent setting: (a) gemcitabine plus cisplatin because gemcitabine modulates platinum resistance allowing it to regain its cytotoxic activity, and (b) bevacizumab with metronomic oral cyclophosphamide.[43,44] Active agents include altretamine (formerly hexamethylmelamine), anastrozole, capecitabine (5-fluorouracil), cyclophosphamide, docetaxel, gemcitabine, liposomal doxorubicin, oral etoposide, vinorelbine, topotecan, bevacizumab, or investigational agents. Numerous ongoing investigational studies are evaluating the benefit of addition of bevacizumab with other cytotoxic agent to improve outcomes in the recurrent ovarian cancer setting (see Figure 94–2). KEY CONCEPT *Because the efficacy of the agents is similar, the selection of agent for treatment of recurrent platinum-resistant ovarian cancer is dependent upon residual toxicities, clinician preference, and patient convenience.* Table 94–4 gives a short summary of the adverse effects and

---

**Table 94–4**

**Summary of Chemotherapy Single-Agent Regimens Used for Treatment of Progressive and Recurrent Platinum-Resistant Ovarian Cancer**

| Agent | Dose | Response Rate (%) | Common Adverse Effects | Monitoring/Comments |
|---|---|---|---|---|
| Docetaxel | 75 mg/m² IV over 1 hour repeat every 21–28 days vs. 30–40 mg/m² IV over 1 hour once every week | 22<br><br>NR | Neutropenia (DLT) hyperlacrimation, fluid retention, nail disorders, myelosuppression | 1. Premedicate for hypersensitivity reactions with dexamethasone<br>2. Use with caution in liver dysfunction. Patients with bilirubin greater than the ULN and/or liver transaminases greater than 1.5 times the ULN should not receive docetaxel<br>3. Do not give if the biliary tract is obstructed |
| Gemcitabine | 800 mg/m² IV infused over 30 minutes once a week on days 1, 8, and 15 followed by 1 week of rest | 13.9–27 | Myelosuppression (DLT), flulike symptoms, headache, somnolence, nausea/vomiting, stomatitis, diarrhea, constipation, rash | 1. Use with caution in renal or liver dysfunction. No specific guidelines available |
| Liposomal doxorubicin | 40 mg/m² IV infused over 3 hours cycle 1 and 2; then infused over 1 hr; thereafter repeat every 28 days | 12.3–18 | Myelosuppression, stomatitis, mucositis, alopecia, flushing, shortness of breath, hypotension, headaches, cardiotoxicity, hand–foot syndrome | 1. Give proper dosing for liver dysfunction; total bilirubin 1.2–3 mg/dL (21–51 μmol/L): reduce dose by 50%; total bilirubin ≥ 3 mg/dL (51 μmol/L): reduce dose by 75%<br>2. Do not give if total bilirubin is > 5 mg/dL (86 μmol/L) |
| Topotecan | 1.5 mg/m² IV infused over 30 minutes on days 1, 2, 3, 4, and 5; repeat every 21 days OR 4 mg/m² IV infused over 30 minutes once a week for 3 consecutive weeks followed by 1-week rest | 6.5–17<br><br>31 | Myelosuppression (DLT), nausea/vomiting, diarrhea, stomatitis, abdominal pain, alopecia, AST/ALT elevation | 1. Give proper dosing for renal dysfunction; CrCl 40–60 mL/min (0.67–1.00 mL/s): no dosage adjustment needed; CrCl 20–39 mL/min (0.33–0.66 mL/s): reduce dose by 50%<br>2. Do not give if CrCl < 20 mL/min (0.33 mL/s) |
| Altretamine (Hexalen) | 260 mg/m² PO daily for 14–21 days; repeat every 28 days | 9.7 | Nausea/vomiting, diarrhea, abdominal cramping, myelosuppression | 1. Monitor for potential CYP450 drug interactions |
| Capecitabine | 1800–2500 mg/m² PO as divided dose twice daily for 14 consecutive days followed by 1 week of rest | 29 | Myelosuppression, hand–foot syndrome, nausea/vomiting, edema, stomatitis, diarrhea, cardiotoxicity, rash | 1. Monitor for PPE and recommend regular use of lotions on hands and feet<br>2. Use with caution in renal dysfunction; CrCl ≥ 51 mL/min (0.84 mL/s): no dose adjustment; CrCl 30–50 mL/min (0.50–0.83 mL/s): reduce dose by 25%; CrCl < 30 mL/min (0.50 mL/s): do not give<br>3. Use with caution in liver dysfunction; no specific guidelines available |

monitoring parameters for chemotherapy agents commonly used for the treatment of recurrent ovarian cancer.

## OUTCOME EVALUATION

Overall survival is impacted by success of initial surgery to debulk tumor to less than 1 cm of disease and response to first-line chemotherapy. The CA-125 level should be monitored with each cycle, and at least a 50% reduction in CA-125 after four cycles of taxane/platinum chemotherapy is related to an improved prognosis. Patients who achieve CR should have follow-up examinations once every 3 months, including CA-125, physical examination, and pelvic examination, and appropriate diagnostic scans (ie, computed tomography [CT], magnetic resonance imaging [MRI], or positron emission tomography [PET] scan) should be evaluated for the detection of disease. While evaluating patient specifically assess resolution of any residual chemotherapy-related adverse effects including: neuropathies, nephrotoxicity, ototoxicity, myelosuppression, or nausea/vomiting. Younger patients with an active menstrual cycle before surgery will encounter "surgical menopause" and often experience intense hot flushes. Because there are concerns about potential of hormones in the pathogenesis of ovarian cancer, the use of hormone replacement therapy is controversial. The use of phytoestrogen supplements, such as black cohosh or soy, is also controversial. Alternative nutritional supplements with less controversy may include: omega3 (fish oil), fiber supplement, or maca root. An effective alternative has been the use of the class of serotonin reuptake inhibitors such as venlafaxine controlled-released once daily.

In the PD or recurrent setting, CA-125 levels should still be monitored with each cycle, but no change in therapy is recommended until after minimum of three cycles of chemotherapy.

### Patient Encounter 1, Part 2: Completion of Primary Treatment

Your patient completed six cycles of paclitaxel 175 mg/m$^2$ IV plus carboplatin AUC 6 IV. Her CT scan findings suggest minimal residual disease and CA-125 has decreased but still above the normal range (38 U/mL [38 kU/L]) upon completion of her chemotherapy. She feels great and has no obvious symptoms of ovarian cancer at this time.

*Discuss the advantages and disadvantages of treatment options for consolidation treatment with chemotherapy verses bevacizumab for this patient.*

*Describe the role of second-look surgery for this patient.*

## Patient Care Process

**Patient Assessment:**

- Assess patient history of nonspecific symptoms and signs to determine if patient has newly diagnosed or potential recurrence of ovarian cancer.
- Review available laboratory tests, specifically CA-125, CBC, electrolytes, LFTs and calculate estimated creatinine clearance.
- Review any recent diagnostic scans (ie, CT scan, MRI, or PET scan)
- Complete medication history (prescriptions, OTC medications and nutritional supplements) to identify any potential interactions, therapy duplication. Does patient have any new drug allergies? Any residual drug-related side effects?
- Assess patient pain to determine need for acute or chronic pain medications.

**Therapy Evaluation:**

- If patient is a surgery candidate, evaluate patient comorbidities and medications to determine if additional workup is necessary before tumor debulking surgery. Do any medications need to be stopped or changed before surgery (ie, aspirin, warfarin, nonsteroidal anti-inflammatory agents)?
- If patient is a chemotherapy candidate (neoadjuvant, adjuvant or recurrent) evaluate patient medications, residual toxicities, renal function and liver function to determine if any potential dose adjustments ought to be recommended for the selected chemotherapy regimen. (see Figure 94–2)
- Determine whether patient has insurance coverage for planned chemotherapy regimen and prescription coverage for supportive care medications. Assist patient in locating pharmacy to fill opioid prescription medications when needed.

**Care Plan Development:**

- Provide appropriate patient education on respective chemotherapy agents that will be given for treatment of ovarian cancer. What each chemotherapy agent is, route, frequency, and duration it will be administered and how it works to treat cancer.
- Explain the plan and frequency for monitoring response to treatment and treatment intent- curative verses palliative (relief of symptoms).
- What side effects to expect during chemotherapy? Precautions to take to prevent infection and how to monitor for signs and symptoms of infection; neuropathy, electrolyte wasting and bowel habits.
- Develop appropriate plan for prevention and treatment of nausea and vomiting based on emetogenic potential of regimen. Discuss nonpharmacologic interventions such as diet choices and frequency of meals. Also provide information on any drug or food interactions with chemotherapy to avoid
- Review pharmacological and non-pharmacological recommendations for blood clot prevention postsurgery.

**Follow-up Evaluation:**

- Patient should be evaluated 5 to 6 weeks after surgery. Evaluate wound healing, pain control/resolution, and determine if adjuvant chemotherapy required.
- Review laboratory values prior to each new cycle of chemotherapy. Recommend appropriate dose adjustments or changes for altered organ function, prolonged myelosuppression, or unacceptable toxicity.
- Assess tumor response to chemotherapy once every 3 months. Evaluate potential for recurrence or response to treatment with CT Scan/MRI once every 3 to 4 months.

In addition, appropriate diagnostic scans (ie, CT scan, MRI, or PET scan) should be evaluated once every three cycles. Patients should also have routine physical examinations with each cycle of chemotherapy to evaluate for any physical toxicity associated with chemotherapy such as neuropathies, fluid retention, palmar-plantar erythrodysesthesia, myelosuppression, or nausea/vomiting.

Unfortunately, most patients will eventually progress through all chemotherapy options, and supportive care measures should be provided to maintain patient comfort and quality of life. Common complications while developing a plan for treatment of advanced or progressive ovarian cancer include ascites, uncontrollable pain, and SBO. Precaution should be used in removal of ascites because of the potential complications associated with rapid fluid shifts. Liberal use of opioids to control pain is appropriate as ovarian cancer patients cope with PD and approaching end of life. Appropriate bowel regimens with laxatives and stool softeners should be used to prevent constipation. However, when a patient with a well-controlled bowel regimen presents with new onset of constipation, additional workup is required before altering the bowel regimen. **KEY CONCEPT** *In ovarian cancer patients, SBO is a common complication of progressive disease.*

*In general, laxatives should not be used in patients with SBOs.* Before treating constipation, patients should have a physical examination and abdominal x-ray to rule out SBO. Often, palliative surgery is required to correct SBO and alleviate patient pain. Patients should not eat any solid or liquids until resolution of SBO. If inoperable SBO exists, then parenteral nutrition can be considered but weighed against ultimate treatment objectives. Overall, providing any measures needed to maintain patient comfort is the priority for patients with progressive ovarian cancer.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| AUC | Area under the curve |
| BRCA1 | Breast cancer activator gene 1 |
| BRCA2 | Breast cancer activator gene 2 |
| BSO | Bilateral salpingo-oophorectomy |
| CA-125 | Cancer antigen 125 |
| CA-19 | Cancer antigen 19 |
| CEA | Carcinoembryonic antigen |
| CR | Complete response |
| CrCl | Creatinine clearance |

| DLT | Dose-limiting toxicity |
| FIGO | International Federation of Gynecology and Obstetrics |
| GFR | Glomerular filtration rate |
| GST | Glutathione S-transferase |
| HBOC | Hereditary breast and ovarian cancer |
| HNPCC | Hereditary nonpolyposis colorectal cancer |
| IP | Intraperitoneal |
| LFT | Liver function test |
| NCCN | National Comprehensive Cancer Network |
| NS | Normal saline |
| OC | Oral contraceptive |
| PD | Progressive disease |
| PET | Positron emission tomography |
| PR | Partial response |
| SBO | Small bowel obstruction |
| SXR | Steroid xenobiotic receptor |
| TAH | Total abdominal hysterectomy |
| TVUS | Transvaginal ultrasound |

# Acute Leukemia

Nancy Heideman and Shirley Abraham

## LEARNING OBJECTIVES

- **Upon completion of the chapter, the reader will be able to:**
  1. Describe the pathogenesis of acute leukemia.
  2. Compare the classification systems for acute lymphocytic leukemia and acute myelogenous leukemia.
  3. Identify the risk factors associated with a poor outcome for the acute leukemias.
  4. Explain the importance of minimal residual disease and its implication on early bone marrow relapse.
  5. Explain the role of induction, consolidation, and maintenance phases for acute leukemia.
  6. Define the role of central nervous system preventive therapy for acute leukemia.
  7. Recognize the treatment complications associated with therapy for acute leukemias.
  8. Describe the late effects associated with the treatment of long-term survivors of acute leukemias.

## INTRODUCTION

**KEY CONCEPT** *T*he acute leukemias are hematologic malignancies of bone marrow precursors characterized by excessive production of immature hematopoietic cells. *This proliferation of "blast" cells eventually replaces normal bone marrow and leads to the failure of normal hematopoiesis and the appearance in peripheral blood as well as infiltration of other organs.* These blast cells proliferate in the marrow and inhibit normal cellular elements, resulting in anemia, neutropenia, and thrombocytopenia. Leukemia also may infiltrate other organs, including the liver, spleen, bone, skin, lymph nodes, testis and central nervous system (CNS). Virtually anywhere there is blood flow, the potential for extramedullary (outside the bone marrow) leukemia exists.

**KEY CONCEPT** *Acute leukemias are classified according to their cell of origin. Acute lymphocytic leukemia (ALL) arises from the lymphoid precursors. Acute nonlymphocytic leukemia (ANLL) or acute myelogenous leukemia (AML) arises from the myeloid or megakaryocytic precursors.* As a result of clinical trials defining various prognostic (risk) factors that helped guide treatment modifications, the outcomes of acute leukemias, especially ALL, has improved dramatically over the past 30 years.[1] Risk-based treatment strategies that consider multiple **phenotypic** and biological risk factors and attempt to match the aggressiveness of therapy with the presumed risk of relapse and death are now the standard of care. Despite the overall success in treating patients with acute leukemias, the long-term survival for patients who relapse remains dismal.

## EPIDEMIOLOGY AND ETIOLOGY
### Epidemiology

Leukemia is a relatively uncommon disease. The current overall age-adjusted annual incidence of acute leukemia in the United States has remained relatively stable at 10 per 100,000 in children and 1 to 2 per 100,000 in adults.[2] In 2015, it is estimated that there will be 54,270 new cases of leukemia, or 3.1% of all new cancer cases.[3]

In the pediatric population, leukemia is a common cancer, accounting for almost one-third of all childhood malignancies. ALL accounts for 75% to 80% of all cases of childhood leukemia, whereas AML accounts for no more than 20%. Males generally are affected more often than females in all but the infant age group, and its incidence is higher in whites than among other racial groups.

The incidence of AML in children is bimodal: It peaks at 2 years of age, decreases steadily thereafter to age 9 years, and then increases again at around age 16.[4] The average age of diagnosis for AML is about 65 years and is a result of an increasing incidence of AML with age.

### Etiology

The causes of the acute leukemias is unknown; multiple influences related to genetics, socioeconomics, infection, environment, hematopoietic development, and chance all may play a role.[4] **Table 95–1** lists the major conditions that have been associated with the acute leukemias. In most cases, however, there is no identifiable cause of the leukemia.

Although leukemia is rarely a hereditary disease, some genetic associations are evident. For example, among identical twins, the concordance for ALL in the initially unaffected twin is 20% to 25% within 1 year. Although the incidence in fraternal twins is much less, there is still a fourfold increase in the risk of leukemia in the initially unaffected twin compared with the normal population. One explanation for this association may be a shared placental circulation, which allows for transmission of disease from one twin to the other. Additionally, leukemia is known to have an increased incidence in several chromosomally abnormal populations. Patients with Down syndrome have a 20 times

increased risk of developing leukemia compared with the rest of the population. Patients with Klinefelter syndrome and Bloom syndrome also have an increased incidence of leukemias.[4]

Exposure to environmental agents such as agricultural chemicals, pesticides, and radiation have also been periodically associated with leukemia, but none is conclusively related to the development of leukemia. An increased frequency of ALL is associated with higher socioeconomic status. It is postulated that less social contact in early infancy and thus a late exposure to some common infectious agents may have some impact.[4]

Risk factors for the development of AML include exposure to environmental toxins, Hispanic ethnicity, and genetics.[5] Of greater concern is the increased prevalence of AML as a secondary malignancy, resulting from chemotherapy and radiation treatment for other cancers. Alkylating agents, such as ifosfamide and cyclophosphamide, and topoisomerase inhibitors, such as etoposide, are linked to an increased risk of AML and **myelodysplastic syndrome** (MDS).[5]

## PATHOPHYSIOLOGY

Hematopoiesis is defined as the development and maturation of blood cells and their precursors. In utero, hematopoiesis may occur in the liver, spleen, and bone marrow; after birth, this process occurs exclusively in the bone marrow. All blood cells are generated from a common hematopoietic precursor, or stem cell. These stem cells are self-renewing and pluripotent and thus are able to commit to any one of the different lines of maturation that give rise to platelet-producing megakaryocytes, lymphoid, erythroid, and myeloid cells. The myeloid cell line produces monocytes, basophils, neutrophils, and eosinophils, whereas the lymphoid stem cell differentiates to form circulating B and T lymphocytes, natural killer (NK) cells, and dendritic cells. In contrast to the ordered development of normal cells, the development of leukemia seems to represent an arrest in differentiation at an early phase in the continuum of stem cell to mature cell.[1]

Both AML and ALL are presumed to arise from clonal expansion of these "arrested" cells. As these cells expand, they acquire

one and often more chromosomal aberrations, including translocations, inversions, deletions, point mutations, and amplifications.[4] The translocation t(12;21) or *TEL–AML1* is found in approximately 25% of cases of pediatric ALL and is associated with a favorable prognosis.[6] This translocation is uncommon in adults. Another example is the t(9;22) translocation (Philadelphia chromosome, Ph$^+$), which results in the *BCR–ABL* fusion protein. This translocation produces a novel kinase that leads to uncontrolled proliferation, survival, and self-renewal of cells. It is uncommon in childhood ALL and commonly found in adult ALL, especially in older patients.

Patients with MDS or AML as a secondary neoplasm are often characterized by having had prior alkylator-based or etoposide-based chemotherapy. Patients who have received treatment for Hodgkin disease or solid tumors are most at risk for this problem because they often treated with these agents. Patients with MDS have an abnormal bone marrow and a variety of cytopenias involving one or more of their marrow cell lines. They are at high risk of converting to overt leukemia over time. A variety of complex cytogentic findings and monosomies of chromosome 5 or 7, and 11q23 translocations are often present in this population.[5]

### Leukemia Classification

Classification methods for leukemia have evolved from simple schemes that were largely phenotypic and considered only age, gender, white blood cell (WBC) count, and blast morphology to now-complex methods that include biological features such as cell-surface receptors, DNA content (ploidy; more or less than normal chromosomal DNA content), and a variety of cytogenetic abnormalities.

For all newly diagnosed patients with leukemia, an aspirate of the liquid marrow and a bone marrow core biopsy are obtained. Analysis of the leukemic cell surface markers (immunophenotyping) establish three types of ALL, pre-B, mature B, and T-cell precursor ALL. There are eight subtypes of AML (M0 to M7) as classified by the French-American-British (FAB) scheme (**Tables 95–2** and **95–3**).

**Immunophenotyping** by **flow cytometry** has taken on an increasingly important role in the diagnosis of leukemia. Owing to the ease of application, sensitivity, and quantifiable results, flow cytometry is the preferred method for leukemic lineage as well as prognostic assignment.[7] This approach takes advantage of the development of diagnostic monoclonal antibodies (MABs) to many cell-surface antigens that are differentially expressed during hematopoietic differentiation. The antigens are referred to as antibody cluster determinants (CDs) that define cells at various stages of development and can easily separate ALL from AML and T-cell from pre–B-cell ALL.[4,7] The combined approach of flow cytometric identification and cytogenetic DNA content, much of which is also revealed by flow cytometry and fluorescent in situ hybridization (**FISH**; microscopic, fluorescence identification of chromosomal features) has facilitated diagnosis and delineation of specific subtypes of the acute leukemias. Common immunophenotypic markers seen in AML and ALL are provided in **Table 95–4**.

### Prognostic Factors

**KEY CONCEPT** *The goal of treatment is to match treatment to risk and minimize overtreatment or undertreatment. Patients with leukemia are sorted into prognostic categories based on clinical and biological features that mirror their risk of relapse. Risk assessment is an important factor in the selection of treatment. Age, WBC, leukemic cell-surface markers, DNA content, and specific*

AML, acute myeloid leukemia.

### ▶ *Prognostic Factors in ALL*

In both children and adults with ALL, clinical trials have identified several risk factors that correlate with outcome (Table 95–5). Prognostic features include age, WBC count, cytogenetic abnormalities, ploidy (DNA content), leukemic cell immunophenotype, and degree of initial response to therapy, and minimal residual disease (MRD; the degree of subclinical disease remaining at various times after starting treatment)[4,7,8] When these factors are combined, they predict groups of patients with varying degrees of risk for treatment failure.

The importance of age is evident in both children and adults. Children younger than 1 year or older than 10 years of age have a poorer outcome than others. Likewise, in adults, there is a steady decline in the rate of survival with increasing age.

Similar to age, the WBC count at presentation is a reliable indicator of complete response (CR) rate and outcome. The WBC count is indicative of tumor burden, although the underlying biological mechanisms that account for the unfavorable outcomes associated with an elevated WBC count are unclear. Patients with WBC counts of less than $50 \times 10^3/\text{mm}^3$ ($50 \times 10^9/\text{L}$) are considered being at standard risk and have a better outcome than those with a higher WBC counts at presentation, which is associated with higher risk of treatment failure (see Table 95–5).

Specific chromosomal abnormalities in leukemic cells also possess prognostic significance. Blast cells with a translocation of parts of chromosome 12 and 21 (the *TEL–AML1* fusion) or trisomies of 4, 10, and 17 are considered to have favorable genetic features.[4] The presence of the Philadelphia chromosome (Ph+), the result of a specific translocation between chromosome 9 and

## Patient Encounter 1, Part 1

An 8-year-old boy presents to the pediatric emergency department with his father with a history of aches, chills, and fevers for the past 4 to 5 days. He has had several colds over the past few weeks that do not seem to be improving. He has also had diffuse body and bone pain in his legs over the past couple of weeks. Physical examination reveals pallor, cervical lymphadenopathy, and hepatosplenomegaly. Electrolytes and uric acid are within normal limits. A complete blood count (CBC) shows a normochromic, normocytic anemia with a hemoglobin of 7.0 g/dL (70 g/L, 4.34 mmol/L; reference range, 11.7 to 15.7 g/dL, 7.26 to 9.74 mmol/L), hematocrit of 21% (0.21; reference range, 35%–47% or 0.35–0.47), and WBC count of $4.1 \times 10^3/mm^3$ ($4.1 \times 10^9$/L). The differential on the WBC count reveals 65% (0.65) lymphocytes (reference range, 20%–40% or 0.2–0.4), 13% (0.13) neutrophils (reference range, 55%–62% or 0.55–0.62), and 22% (0.22) lymphoblasts (normal amount, 0%). Flow cytometry from the peripheral blood is consistent with pre–B-cell ALL.

*What information is consistent with the diagnosis of ALL?*

*What are the prognostic factors for this patient?*

*What is the role of flow cytometry in identifying ALL?*

22, t(9;22)(q34;q11.2), is a high-risk feature, which is present in about 3% of children but is much more common in adults with ALL. This translocation results in a novel tyrosine kinase that drives cell proliferation.[7,8]

Among children younger than 1 year of age, as many as 70% possess a poor prognostic genotype represented by the presence of the *MLL* (11q22) gene rearrangement. This finding is rare among older patients. Leukemias with the *MLL* gene rearrangement are highly resistant to the key antileukemic drugs such as glucocorticoids and L-asparaginase.[9]

The DNA content of blast cells, hyper-, hypo-, or diploid, corresponding to increased, decreased, or normal chromosome

### Table 95–5

**Prognostic Factors in ALL**

| Factor | Risk for Leukemic Relapse | |
| --- | --- | --- |
| | Standard/Low | High |
| Immunologic phenotype | pre–B cell | Null cell, T cell, pre–B cell, mature B cell |
| WBC count at diagnosis | $< 50 \times 10^3\ mm^3$ | $> 50 \times 10^3/mm^3$ ($50 \times 10^9$/L) |
| Patient age | 1–10 years | < 1 year or > 10 years |
| Cytogenetics | Normal karyotype, t(12;21), trisomy 4,10,17 | t(9;22); t(4;11); t(17;19), iAmp21, ph-like |
| Ploidy | Hyperdiploidy | Hypodiploidy, near haploid |
| CNS leukemia | Absent | Present |
| MRD at end of induction | < 0.01% | > 0.01% |

WBC, white blood cell.

numbers, has been considered prognostic. Lower risk patients with hyperdiploidy (greater than 50 chromosomes per leukemic cell) generally include approximately 25% of children who have B-cell lineage ALL.[6] These children are between the ages of 1 and 9 years, but the higher risk patients with normal diploidy (50 chromosomes) generally are older. Hypodiploid ALL with less than 44 chromosomes occurs in 1% to 5% of pediatric patients with ALL and is an independent risk factor for poor prognosis with declining prognosis with decreased chromosome number.[10]

Patients with cell-surface markers indicating that the blasts are early in the B-cell lineage (CD markers) are considered favorable and standard risk, whereas those with mature B-cell and T-cell blasts are considered high risk. T-cell ALL is found in approximately 15% of childhood ALL. Compared with B-lineage ALL, T-cell ALL is relatively resistant to different classes of drugs, including methotrexate and cytarabine.

Patients completing induction treatment and in apparent remission still harbor malignant cells in their bone marrow even though they appear disease free by peripheral blood and bone marrow morphology. Assuming that most patients present with about a $10^{11}$ leukemic cell burden at diagnosis, at least $10^9$ cells remain after initial treatment. These residual leukemic cells are below the limits of detection using standard morphologic examination. Measurement of this population of cells has become an increasingly significant prognostic factor and a determinant of the aggressiveness of postinduction therapy. Through flow cytometric analysis and polymerase chain reaction, it is possible to detect one leukemic cell among $10^6$ normal cells, representing 1000-fold greater sensitivity than morphologic examination.[11,12]

**KEY CONCEPT** *Minimal residual disease (MRD) is a quantitative assessment of subclinical remnant of leukemic burden remaining at the end of the initial phase of treatment (induction) when a patient may appear to be in a complete morphologic remission. This measure has become one of the strongest predictors of outcome for patients with acute leukemia. The elimination of MRD is a principal objective of postinduction leukemia therapy.* Several studies in children, in whom ALL is common, have evaluated disease levels at the end of induction and correlated these values with event-free survival (EFS). For a patient with detectable MRD less than 0.1% at the end of induction, EFS is 88% at 3 years. Conversely, a patient with high MRD (greater than 1%) has a 3-year EFS of only 30%.[13] Assessment of MRD is also emerging as an important indicator of disease recurrence in the adult population and in patients with AML.

### ▶ Prognostic Factors in AML

The major prognostic factors in newly diagnosed AML are age, subtype, chromosome status, ethnicity, and body mass index.

Older adults with AML (greater than 60 years), compared with younger patients with the same disease, have a dismal prognosis and represent a distinct population in terms of disease biology, treatment-related complications, and overall survival (OS). These older patients have a higher incidence of unfavorable chromosomal abnormalities, such as aberrations of chromosomes 5, 7, or 8, $FLT_3$-internal tandem duplication (ITD) and fewer abnormalities that are associated with a more favorable outcome, such as t(8;21) or inv(16) (Table 95–6).[5,13]

Recent studies suggest that ethnicity may be an important predictor of outcome in children with AML. Investigators found that African Americans treated with chemotherapy had a significantly worse outcome than whites, perhaps suggesting race-related pharmacogenetic differences. Body mass index may also affect the prognosis of children with AML. Underweight patients and

**Table 95–6**

**Risk Category According to Cytogenetic Abnormalities Present**

| Disease | Risk Category | | |
| --- | --- | --- | --- |
| | Good Risk | Intermediate Risk | High Risk |
| **AML** | t(8;21) (q22;q22); inv(16); t(15;17); t(9;11) trisomy 21 | Normal karyotype; trisomy 8; 11q23; del(7q); del(9q); trisomy 22 | Complex karyotype; –5; –7; del (5q); inv(3P) |
| Probability of relapse | 25% or less | 50% | 70% or more |
| 4-Year survival | 70% or more | 40%–50% | 20% or less |
| **ALL** | Hyperdiploidy; t(12;21), trisomy 4, 10, 17 | | t(9;22); t(8;14); t(4;11); t(17;19), hypodiploid, near haploid |
| Probability of relapse | Less than 10% | Less than 20% | 30-40% |
| 4-Year survival | More than 80% | More than 60% | 40-50% |

ALL, acute lymphocytic leukemia; AML, acute myelogenous leukemia.

overweight patients were less likely to survive than normal weight patients because of a greater risk of treatment-related deaths.[15] Current clinical trials in adults and pediatrics strongly suggest that patients with detectable MRD at the end of induction therapy or consolidation is strongly associated with the risk of relapse.[14]

## TREATMENT
### Desired Outcome

The primary objective in treating patients with acute leukemia is to achieve a continuous complete remission (CCR). Remission is defined as the absence of all clinical evidence of leukemia with the restoration of normal hematopoiesis. For both ALL and AML, remission induction is achieved with the use of myelosuppressive chemotherapy that initially induces a state of bone marrow aplasia as the leukemic cells die followed by a slow return and proliferation of normal cells. After this period, hematopoiesis is restored. Failure to achieve remission in the first 7 to 14 days of therapy is highly predictive of later disease recurrence. This again represents the growing importance of MRD in prognosis and treatment.

### Nonpharmacologic Therapy

This year, roughly 1.6 million people will be diagnosed with cancer in the United States and Canada. With improvements in detection and treatment, approximately two-thirds of those diagnosed with the disease can expect to be alive in 5 years. With improving longevity, the cumulative adverse effects of both the disease and treatment are becoming an increasingly important issue. "Late-effects" data show that both adult and pediatric cancer survivors are at greater risk for developing second malignancies, cardiovascular disease, diabetes, and osteoporosis than those in the general population. With respect to the growing population of pediatric cancer survivors, data confirm that they are eight times more likely than their siblings to have a severe or life-threatening chronic health condition. For example, the survivors of pediatric ALL have an increased risk of obesity, osteopenia, and associated comorbidities. Thus, it is important to provide supportive care and intervention and counseling related to nutrition, smoking cessation, and exercise as a part of their active treatment. Health care professionals should think beyond the immediate treatment-related issues of their patients and provide appropriate, active assistance to promote healthy lifestyles and encourage patients to take active roles in pursuing general preventive health strategies.[15]

### Pharmacologic Therapy: ALL

The treatment for ALL consists of four main elements: remission induction (the initial tumor reduction leading to morphologic remission), CNS-directed treatment, intensive postremission consolidation regimens, followed by a prolonged maintenance phase (Table 95–7).

#### ▶ Remission Induction

KEY CONCEPT *The initial treatment for acute leukemias is called induction. The purpose of induction is to induce a remission, a state in which there is no identifiable leukemic cells in the bone marrow or peripheral blood with light microscopy.*

KEY CONCEPT *Current induction therapy for ALL typically consists of vincristine, L-asparaginase, and a steroid (prednisone or dexamethasone). An anthracycline is added for higher risk patients.* Although induction treatment produces 95% CR in children, it declines to no more than 60% in patients older than 60 years of age.

Adults, unlike children, are universally considered to be at high risk for relapse; therefore, their induction regimens include an anthracycline (daunorubicin or doxorubicin) in addition to the standard steroid and vincristine treatment that have been the backbone of treatment for this disease for the last 40 years.[16,17]

## Patient Encounter 1, Part 2

The patient is admitted to the pediatric oncology service. A bone marrow biopsy and aspirate is done, which shows 85% replacement with precursor B-cell blasts. FISH analysis performed on the peripheral blood is positive for the BCR/ABL translocation (Ph⁺) in 5.5% of the cells examined. He is started on intravenous hydration with sodium bicarbonate and allopurinol. A diagnostic lumbar puncture (LP) is performed, which is negative for CNS leukemia. During the LP, the patient receives IT cytarabine.

*What is the role of CNS prophylaxis for this patient?*

*What is the BCR/ABL translocation?*

*How does the presence of this chromosomal abnormality change this patient's risk status?*

## Clinical Presentation and Diagnosis of ALL[3,6,11]

### General

- Typically, patients have symptoms for 1 to 3 months before presentation. These include fatigue, fever, and pallor, but patients generally are in no obvious distress.

### Symptoms

- The patient may present with weakness, malaise, bleeding, and weight loss.
- Neutropenic patients are often febrile and highly susceptible to infection.
- Anemia usually presents as pallor, tiredness, and general fatigue.
- Patients with thrombocytopenia usually present with bruising, petechiae, and ecchymosis.
- Patients often present with bone pain secondary to expansion of the marrow cavity from leukemic infiltration.
- CNS involvement is common at diagnosis.

### Signs

- Temperature may be elevated secondary to an infection associated with a low WBC count.
- Petechiae and bleeding are indicative of thrombocytopenia.
- Patients may present with organ involvement, such as peripheral adenopathy, hepatomegaly, and splenomegaly.
- T-lineage ALL may present with a mediastinal mass.

### Laboratory Tests

- CBC with differential is performed.
- The anemia is usually normochromic and normocytic. Approximately 50% of children present with platelet counts of less than $50 \times 10^3/mm^3$ ($50 \times 10^9/L$). The WBC count may be normal, decreased, or high. About 20% of patients have WBC counts over $100 \times 10^3/mm^3$ ($100 \times 10^9/L$), which places them at risk for leukostasis.
- Uric acid is increased in approximately 50% of patients secondary to rapid cellular turnover.
- Electrolytes: Potassium and phosphorus often are elevated. Calcium usually is low.
- Coagulation disorders: Elevated prothrombin time, partial thromboplastin time, D-dimers; hypofibrinogenemia.

### Other Laboratory Tests

Flow cytometric evaluation of bone marrow and peripheral blood is performed to characterize the type of leukemia as well as to detect specific chromosomal rearrangements. The bone marrow at diagnosis usually is hypercellular, with normal hematopoiesis being replaced by leukemic blasts. At diagnosis, a LP is performed to determine if CNS leukemia is present.

---

Dexamethasone often replaces prednisone as the steroid of treatment because of its longer half-life and better CNS penetration.[17] Although dexamethasone possesses more favorable pharmacologic characteristics than prednisone, its use may be associated with more aseptic osteonecrosis of the femoral and humoral heads as well as an increase in life-threatening infections and septic deaths.[17]

### ▶ CNS Prophylaxis

KEY CONCEPT *Leukemic invasion of the CNS is considered to be an almost universal event in patients even in those whose cerebrospinal fluid (CSF) cytology shows no apparent disease. Thus, all patients with ALL and AML leukemia receive intrathecal (IT) chemotherapy. Although this is often referred to as "prophylaxis," it more realistically represents treatment.* CNS prophylaxis relies on IT chemotherapy (eg, methotrexate, cytarabine, and corticosteroids), systemic chemotherapy with dexamethasone and high-dose methotrexate, and craniospinal irradiation (XRT) in selected high-risk patients.[16] Cranial radiation use diminished substantially after the efficacy of IT treatment was evident, and the toxicities associated with radiation; learning disabilities, growth retardation, and secondary malignancies (particularly with the use of 6-mercaptopurine), were recognized. IT therapy has replaced cranial XRT as CNS prophylaxis for all except the very high-risk patients and those with T-cell ALL who are at higher risk of CNS disease.

Inexplicably, the treatment of CNS leukemia has not impacted the OS of adults as it has for childhood ALL. With IT chemotherapy alone, the incidence of CNS relapse in adults is 9% to 13% compared with less than 3% in children.[5,12]

### ▶ Postremission Consolidation Regimens

**Consolidation**  After completion of induction and restoration of normal hematopoiesis, patients begin consolidation. The goal of consolidation is to administer dose-intensive chemotherapy in an effort to further reduce the burden of residual leukemic cells. It is in this and subsequent treatment phases that the remaining leukemic burden is eliminated. Several regimens use agents and schedules designed to minimize the development of drug cross-resistance. Studies have demonstrated that consolidation is an effective strategy in the prevention of relapse in children with ALL, but its benefits in adults are less clear.

In children, the intensity of the consolidation treatment is now determined not only by the child's risk classification but also by the degree of cytoreduction during induction (MRD). Patients who respond slowly to induction therapy (as determined by bone marrow examination early in induction) are at higher risk of relapse and are treated with more aggressive regimens.[18]

**Delayed Intensification**  The Berlin-Frankfurt-Munster (BFM) Study Group introduced a treatment element called delayed intensification (or reinduction) therapy. This therapy consisted of repetition of the initial remission induction therapy administered approximately 3 months after remission. This, similar to consolidation, has been adopted as a component of treatment for children by virtually all institutions.[15]

Intensification regimens may vary in their aggressiveness and the drugs they use depending on the patient's risk group and immunophenotype. For example, the use of high-dose methotrexate ($5$ g/m$^2$) appears to improve outcome in patients with T-cell ALL. The use of intensive asparaginase treatment in T-cell ALL patients also has improved outcomes significantly.[17]

## Table 95–7

**Representative Chemotherapy Regimens for Adult ALL**

▶ *Maintenance*

The purpose of maintenance therapy is to further eliminate leukemic cells and produce an enduring CCR. The two most important agents in maintenance chemotherapy are a combination of oral methotrexate and 6-mercaptopurine. Improved outcome is associated with increasing 6-mercaptopurine doses to the limits of individual tolerance based on absolute neutrophil count (ANC). The benefit of adding intermittent "pulses" of vincristine and a steroid (usually dexamethasone) to the antimetabolite backbone remains unclear, but it is common practice in most modern treatment regimens.[17] The goal is to induce a moderate immunosuppression and leukemic cell kill.

6-Mercaptopurine is a key agent in maintenance therapy. It has a complex metabolism and is initially cleared by thiopurine methyltransferase (TPMT). TPMT activity is variable with about 90% of patients having normal activity, about 10% having intermediate activity, and fewer than 1% having very low or no activity. These enzymatic polymorphisms are inherited in an autosomal recessive fashion and have a profound influence on 6-mercaptopurine tolerance.[20,21]

TPMT screening is recommended for children starting therapy with 6-mercaptopurine. Children who possess alleles that have diminished activity require 6-mercaptopurine dose reductions of 50% to 90% to prevent severe immunosuppression and infection. Despite these reductions, these children have equivalent OS when compared with those receiving full-dose 6-mercaptopurine. The optimal duration of maintenance therapy in both children and adults is unknown, but most regimens are given for 2 to 3 years; extension of the regimen beyond 3 years has not shown any additional benefit.

## ALL in Infants and Young Children

Infants and children younger than 1 year of age account for approximately 5% of all children with ALL and have the worst outcome of any group with this disease. These patients have several poor prognostic features at diagnosis, including hyperleukocytosis, hepatomegaly, splenomegaly, and CNS leukemia.[9]

A characteristic finding in up to 70% in this group is a chromosomal translocation involving the *MLL* gene located at 11q23. There are multiple possible rearrangements of this gene with other chromosomes, and all confer a poor prognosis. In vitro, blasts of these patients showed greater drug resistance to prednisolone and L-asparaginase than those from other patients, although they are more sensitive to cytarabine.[22] Based on this information, several studies are testing the efficacy of intensified chemotherapy that includes high-dose cytarabine. Another achievement is the prevention of CNS relapse using IT cytarabine in conjunction with high-dose systemic cytarabine. This combination has eliminated the need for cranial XRT in this young population. Even with major advances in cure rates for the general pediatric ALL population, in whom survival is 80% or more, the long-term survival of infants is only about 40% (**Tables 95–8**).

## ALL in Adolescents and Young Adults

As noted previously, age is an important prognostic factor in ALL. Adolescents and adult patients have generally been shown to have poorer survival than children. However, the group of patients between late adolescence and age 30 years (adolescents and young adults) have a substantially better outcome than older adult patients, most likely because of the use of using

---

### Table 95–8

**Representative Chemotherapy Regimens for Pediatric ALL**

**Induction (1 month)**
IT cytarabine on day 0
Prednisone 40 mg/m$^2$/day or dexamethasone 6 mg/m$^2$/day po for 28 days
Vincristine 1.5 mg/m$^2$/dose (maximum, 2 mg) IV weekly for four doses
Pegaspargase 2500 units/m$^2$/dose IM for one dose or asparaginase 6000 units/m$^2$/dose IM Monday, Wednesday, and Friday for six doses
IT methotrexate weekly for two to four doses

**Consolidation (1 month)**
Mercaptopurine 50–75 mg/m$^2$/dose po at bedtime for 28 days
Vincristine 1.5 mg/m$^2$/dose (maximum, 2 mg) IV on day 0
IT methotrexate weekly for one to three doses
Patients with CNS or testicular disease may receive radiation

**Interim Maintenance (one or two cycles) (2 months)**
Methotrexate 20 mg/m$^2$/dose po at bedtime weekly
Mercaptopurine 75 mg/m$^2$/dose po daily on days 0–49
Vincristine 1.5 mg/m$^2$/dose (maximum, 2 mg) IV on days 0 and 28
Dexamethasone 6 mg/m$^2$/day po on days 0–4 and 28–32

**Delayed Intensification (one or two cycles) (2 months)**
Dexamethasone 10 mg/m$^2$/day po on days 0–6 and 14–20
Vincristine 1.5 mg/m$^2$/dose (maximum, 2 mg) IV weekly for three doses
Pegaspargase 2500 units/m$^2$/dose IM for one dose
Doxorubicin 25 mg/m$^2$/dose IV on days 0, 7, and 14
Cyclophosphamide 1000 mg/m$^2$/dose IV on day 28
Thioguanine 60 mg/m$^2$/dose po at bedtime on days 28–41
Cytarabine 75 mg/m$^2$/dose SC or IV on days 28–31 and 35–38
IT methotrexate on days 0 and 28

**Consolidation Option (2- to 3-week intervals for six courses on weeks 5–24)**
Mercaptopurine 50 mg/m$^2$/dose po at bedtime
Prednisone 40 mg/m$^2$/day for 7 days on weeks 8 and 17
Vincristine 1.5 mg/m$^2$/dose (maximum, 2 mg) IV on the first day of weeks 8, 9, 17, and 18
Methotrexate 200 mg/m$^2$/dose IV + 800 mg/m$^2$/dose over 24 hours on day 1 of weeks 7, 10, 13, 16, 19, and 22
IT methotrexate on weeks 5, 6, 9, 12, 15, and 18

**Late Intensification (weeks 25–52)**
Methotrexate 20 mg/m$^2$/dose IM weekly or 25 mg/m$^2$/dose po every 6 hours for four doses every other week
Mercaptopurine 75 mg/m$^2$/dose po at bedtime
Prednisone 40 mg/m$^2$/day po for 7 days on weeks 25 and 41
Vincristine 1.4 mg/m$^2$w/dose (maximum, 2 mg) IV on the first day of weeks 25, 26, 41, and 42
IT methotrexate on day 1 of weeks 25, 33, 41, and 49

**Maintenance (12-week cycles)**
Methotrexate 20 mg/m$^2$/dose po at bedtime or IM weekly with dose escalation as tolerated
Mercaptopurine 75 mg/m$^2$/dose po at bedtime on days 0–83
Vincristine 1.5 mg/m$^2$/dose (maximum, 2 mg) IV on days 0, 28, and 56
Dexamethasone 6 mg/m$^2$/day po on days 0–4, 28–32, and 56–60
IT methotrexate on day 0

IM, intramuscular; IT, intrathecal; po, oral; SC, subcutaneous.

Adapted from Leather HL, Bickert B. Acute Leukemias. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 6th ed. New York: McGraw-Hill; 2005:2458–2511.

**Patient Encounter 1, Part 3**

This patient begins induction therapy with vincristine, prednisone, daunorubicin, and asparaginase. According to his protocol, he will begin dasatinib in the middle of his induction treatment, on day 15. He has a bone marrow on day 29 showing a morphologic remission, and his MRD on day 29 was less that 0.1%. He is now ready to begin consolidation.

*What is the role of dasatinib for Ph+ ALL?*

*What is the significance of an MRD of 0.1%?*

*What is the purpose of consolidation therapy?*

**Patient Encounter 2**

The patient is a 6-year-old boy who had completed his treatment for standard risk preB-ALL 1 year ago. For the past 3 weeks, he has been complaining of worsening headaches. A CT scan was done which was within normal limits. CBC at this visit shows WBC 6.6 K/mm³, hemoglobin 10.1 g/dL, hematocrit 30%, platelet 75K, differential 14% neutrophils, 52% lymphocytes, 3% variant lymphocytes, 1% metamyelocyte, 30% blasts. Uric acid is 3.7 mg/dL, LDH 1947 Units/L. On examination, patient is well appearing, no significant lymphadenopathy, no hepatosplenomegaly, testicular and neurologic exam is normal.

*What is the principal form of treatment failure in patients with ALL?*

*What are the important predictors of second remission?*

pediatric ALL regimens. Retrospective studies show that survival is improved from 30% to 40% with standard adult therapy to as high as 65% with pediatric protocols.[2,23] The reasons for this are not entirely clear, and multiple factors are likely to play a role. Among the likely explanations is that pediatric protocols use more aggressive and prolonged postremission consolidation therapy before maintenance. Other proposed explanations are the potential differences in disease biology in this versus older age patients, more intense CNS prophylaxis, and the greater degree of social support and better compliance fostered in a pediatric environment. Current and planned trials are focusing on the potential of extending this treatment approach to patients age 40 years and possibly older.

### ALL in Adults

The incidence of ALL in adults ages 30 to 60 years is only 2 per 100,000 persons per year compared with almost 10 per 100,000 in children. The conventional risk factors such as high WBC counts, older age, and CNS disease hold true in adults as in children. However, the significance of cytogenetic and molecular markers that are so important in children seems to be less predictive of outcome in adults. An exception is the adverse prognostic factor, the presence of the *BCR-ABL* translocation (Ph⁺) just as in childhood ALL. This occurs in 15% to 30% of adults and is even more common in patients older than 60 years of age.[23] The use of imatinib or dasatinib, both potent inhibitors of the Ph⁺-associated BCR-ABL tyrosine kinase, has now become a standard of practice for all patient groups with Ph⁺ disease.[7] Results show that the combination of these agents with conventional chemotherapy improves remission rates as well as OS compared with the use of conventional chemotherapy alone.[7,8,23]

Currently, the induction and consolidation regimens in adults is similar to the regimens in pediatric patients, but the more aggressive postinduction regimens are not as well tolerated in this population, particularly in elderly patients (age greater than 60 years) and are associated with a much higher incidence of toxicity and treatment-related deaths.[7] Some investigators are studying "moderate-dose" consolidation regimens that are better tolerated, although long-term efficacy data is lacking. Even though remissions are achieved in 80% to 90% of adult patients, 5 years disease-free survivals are only in the 30% to 40% range. Among elderly patients, the outcome is even poorer with no more than 20% having long-term survival.

### Relapsed ALL

Relapse is the recurrence of leukemic cells at any site after remission has been achieved. **KEY CONCEPT** *Bone marrow relapse is the*

*major form of treatment failure in 15% to 20% of patients with ALL. Most relapses have the same immunophenotype and cytogenetic changes seen of the original disease.* Extramedullary sites of relapse include the CNS and the testicles.[24] Extramedullary relapse, although once common, has decreased to 5% or less because of effective prophylaxis. Site of relapse and the length of the first remission are important predictors of second remission and OS. Marrow relapses occurring less than 18 to 24 months into first remission are associated with a poor survival, but longer periods of remission (greater than 36 months) have a much higher chance of survival.[24] Treatment strategies for relapsed ALL include chemotherapy or allogeneic hematopoietic stem cell transplant (allo-HSCT). Even though patients undergoing allo-HSCT are less likely to relapse, treatment-related toxicity leads to a higher incidence of morbidity and mortality compared with chemotherapy alone.[6] Clofarabine, a next-generation deoxyadenosine analogue, has shown considerable activity in children and adults with refractory acute leukemias. Of interest, this is the only anticancer drug to receive primary indication for use in pediatrics in the past 10 years.[23]

### Treatment of AML

As with ALL, the primary aim in treating patients with AML is to induce remission and thereafter prevent relapse. Treatment of AML is conventionally divided into two phases: induction and consolidation. The prognosis of children with AML has improved dramatically over the past 30 years. Rates of complete remission as high as 80% to 90% and overall survival rates of 60% now are reported. This improvement is a result of better understanding of the biology of AML and the development of molecular targets that are used in combination with conventional chemotherapy.[14]

**KEY CONCEPT** *The current induction therapy for AML usually consists of a combination of cytarabine, daunorubicin, and etoposide. The second phase of treatment for AML is called* consolidation. *The purpose of this phase is to further enhance remission with more cytoreduction.*[14]

### ▶ Remission Induction

The goal of induction chemotherapy in AML is essentially identical to that in ALL—"empty" the bone marrow of all hematopoietic precursors and allow repopulation with normal cells. The combination of an anthracycline (eg, daunorubicin, doxorubicin,

## Clinical Presentation and Diagnosis of AML[3,6,11]

**General**

- Patients may have symptoms of AML for 1 to 3 months before presentation. These include fatigue, fever, and pallor, but patients generally are in no obvious distress.

**Symptoms**

- The patient may present with weakness, bone pain, malaise, bleeding, and weight loss.
- Neutropenic patients are often febrile and highly susceptible to infection.
- Anemia usually presents as pallor, tiredness, and general fatigue.
- Patients with thrombocytopenia usually present with bruising, petechiae, and ecchymosis.
- Chloromas (localized leukemic deposits named after their color) may be seen, especially in the periorbital regions and as skin infiltrates.
- Gum hypertrophy is indicative of AML M4 and AML M5 subtypes.
- Disseminated intravascular coagulation may be present in all AML subtypes, but is common in AML M3 and is associated with generalized bleeding or hemorrhage.
- Lymphadenopathy, massive hepatosplenomegaly, and bone pain are not as common in AML as in ALL.

**Signs**

- Temperature may be elevated secondary to an infection associated with a low WBC count.
- Petechiae and bleeding are indicative of thrombocytopenia.

**Laboratory Tests**

- CBC with differential is performed.
- The anemia is usually normochromic and normocytic.
- Approximately 50% of children present with platelet counts of less than $50 \times 10^3/mm^3$ ($50 \times 10^9$/L).
- The WBC count may be normal, decreased, or high. About 20% of patients have WBC counts of over $100 \times 10^3/mm^3$ ($100 \times 10^9$/L), which places them at risk for leukostasis.
- Uric acid is increased in approximately 50% of patients secondary to rapid cellular turnover.
- Electrolytes: Potassium and phosphorus are often elevated. Calcium is usually low.
- Coagulation disorders: Elevated prothrombin time, partial thromboplastin time, D-dimers; hypofibrinogenemia.

**Other Diagnostic Tests**

Flow cytometric evaluation of bone marrow and peripheral blood to characterize the type of leukemia, as well as to detect specific chromosomal rearrangements. The bone marrow at diagnosis usually is hypercellular, with normal hematopoiesis being replaced by leukemic blasts. The presence of greater than 20% blasts in the bone marrow is diagnostic for AML. At diagnosis, a LP is performed to determine if CNS leukemia is present. The CNS is involved at diagnosis in approximately 15% of patients.[14]

or idarubicin) and the antimetabolite cytarabine forms the backbone of AML induction therapy. The most common induction regimen (7 + 3) combines daunorubicin for 3 days with cytarabine on days 1 to 7.[13] The remission rate for this combination is approximately 80% in children and younger adults but declines to 40% to 50% in patients older than 60 years of age.[5,13] Paving the way for more innovative therapies, gemtuzumab ozogamicin, a humanized anti-CD33 antibody, has shown it improved the outcome of pediatric and younger adults patient (age less than 60 years) when added to conventional 7 + 3 chemotherapy.[26,27] Sorafenib, a tyrosine kinase inhibitor, has shown promise in adults with $FLT_3$ positive ITD. Bortezomib, a proteasome inhibitor, has shown to selectively reduce the leukemic stem cells that are a cause of resistance for AML.[14]

▶ *Postremission Chemotherapy*

In AML, postremission chemotherapy is often referred to as consolidation therapy. Several cycles of intensive postremission chemotherapy combining non–cross-resistant agents given every 4 to 6 weeks substantially improves DFS. Without postremission treatment, all patients would relapse within several weeks. This is analogous to the consolidation and other phases of postremission chemotherapy in ALL. The use of high-dose cytarabine in postremission therapy seems to be important for improving survival, but the most effective dose has yet to be determined.[14] Although the optimal number of courses remains to be determined, at least four are probably required.[13]

**Allogeneic Hematopoietic Stem Cell Transplantation** Hematopoietic stem cell transplantation (HSCT) is the most effective treatment for AML. Its promising benefit must be weighed against the potential risk of transplantation related sequelae. HSCT has become a less attractive option as the results of increasingly intensive chemotherapy and postrelapse salvage therapy have improved.[14]

The availability of HLA-matched sibling donors determines whether patients undergo HSCT as postremission treatment. To facilitate this process, it is important to obtain HLA typing on all younger patients and siblings shortly after diagnosis. Patients who do not have an HLA-matched sibling proceed to postremission therapy with chemotherapy alone.

Complications and benefits of allogeneic HSCT are described in Chapter 98. Transplant-related mortality following matched-sibling allo-HSCT is 20% to 30% in most series. Complications from transplantation increase with age; therefore, patients older than 60 years of age are uncommonly considered to receive a myeloablative allo-HSCT. Because the average age of AML patients is 65 years, most patients with this disease are not candidates for this form of therapy. For older patients up to 70 years of age, a reduced-intensity (mini or nonmyeloablative allogeneic) transplant may be an option. These transplants use less intensive preparative regimens and rely on the allogeneic graft-versus-leukemia (GVL) effect to eliminate their disease.[13]

The role of HSCT, particularly whether it should be performed during the first CR or reserved for second remission, remains

the most controversial issue in pediatric AML. In certain institutions, HSCT is often reserved for patients that are considered high risk.[14] Some types of AML patients may be curable with conventional-dose chemotherapy alone.

### Autologous Hematopoietic Stem Cell Transplantation

Because the majority of AML patients lack a HLA-identical donor, investigators began to consider the use of the patient's own bone marrow, obtained while in CR, as a source of hematopoietic regeneration. However, relapse continues to be a problem secondary to the presence of residual disease in the graft. Despite the reduced morbidity and mortality associated with auto-HSCT, this type of transplant does not compare favorably to standard postremission chemotherapy.[13]

### ▶ CNS Therapy

The prevalence of CNS disease at diagnosis of AML is approximately 15%.[14] Features associated with the risk of CNS leukemia include hyperleukocytosis, monocytic, or myelomonocytic leukemia (FAB M4 or M5), and young age. Adequate CNS prophylaxis is an essential component of therapy. Studies have shown that patients with CNS disease at diagnosis can be cured with IT therapy alone without the use of cranial XRT. In most cases, IT cytarabine with or without methotrexate and systemic high-dose cytarabine provide effective treatment.

## AML in Infants

AML in infants younger than 12 months of age shows clinical and biological characteristics different from those of older children. The disease phenotype is more commonly monoblastic or myelomonoblastic (M4, M5), and the patients usually present with hyperleukocytosis. Extramedullary involvement is common, often involving skin and other organs. As in infant ALL, there is a high incidence of translocations involving the *MLL* gene in infant AML. The number of infant AML trials reported is limited, but the EFS of this population is similar to that of older children with AML. This is in marked contrast to the outcomes for infants with ALL for whom the EFS is much lower than in older children.[28]

## AML in the Elderly

AML is the most common acute leukemia in the elderly. Compared with younger patients with the same disease, older adults have a poor prognosis and represent a distinct population with regard to the biology of their disease. Older adults have a lower incidence of favorable chromosomal aberrations and a higher incidence of unfavorable aberrations.[5,13] Fms-like tyrosine kinase 3 ($FLT_3$) which is an AML oncogene plays an important role in AML pathogenesis and was associated with a poor outcome. $FLT_3$-ITD is common in adults, but is only found in 12% of the pediatric population.[14] The elderly also have a much higher incidence of comorbidities, such as type 2 diabetes, obesity, and other physiologic limitations. Thus, the poor prognosis of AML in the elderly is only partly the result of unfavorable biology.

In older adults, in contrast to children, AML is more likely to arise from a proximal bone marrow–stem cell disorder, such as MDS, or present as a secondary, prior treatment-related leukemia. These forms of AML are notoriously poorly responsive to conventional chemotherapy and thus have a lower CR rate and poorer survival.[29]

As previously noted, age is an important prognostic factor. Older adults are not as tolerant of or as responsive to remission induction and consolidation chemotherapy as younger patients.

Furthermore, long-term survival for patients older than 60 years is only 5% to 15% compared with 30% DFS for younger adults.[5,13]

## Relapsed AML

Even though 75% to 85% of patients with AML achieve a remission, only about 50% survive. Patients who relapse usually respond poorly to additional treatment and have a shorter duration of remission. This is probably related to drug resistance induced during induction and certain chromosomal abnormalities.

Even though there is no standard therapy for relapse, most studies have shown that high-dose cytarabine-containing regimens have considerable activity in obtaining a second remission. Cytarabine has been used in combination with mitoxantrone, etoposide, fludarabine, 2-chlorodeoxyadenosine, and (more recently) clofarabine.[5,13] The targeted immunotherapy agent gemtuzumab has induced remissions who have recurrent CD33+ AML alone or in combination with standard chemotherapy.[14]

After a patient has achieved a second remission with conventional chemotherapy, allo-HSCT is the therapy of choice. For patients without an HLA-matched sibling, a matched unrelated donor (MUD) or cord blood transplant may be a reasonable alternative. The combination of myeloablative high-dose chemotherapy and the GVL effect is thought to offer the best chance of survival in AML.

## Complications of Treatment

### ▶ Tumor Lysis Syndrome

Tumor lysis syndrome (TLS) is an oncologic emergency that is characterized by metabolic abnormalities resulting from the death of blast cells and the release of large amounts of purines, pyrimidines, and intracellular potassium and phosphorus. Uric acid, the ultimate breakdown product of purines, is poorly soluble in plasma and urine. Deposition of uric acid and calcium phosphate crystals in the renal tubules can lead to acute renal failure. Many patients with acute leukemia, especially those with a high tumor burden, are at risk for TLS during the first several days of chemotherapy. Measures to prevent TLS include aggressive hydration, alkalinization to help solubilize uric acid, and allopurinol to reduce uric acid production. Hyperhydration and alkalinization is generally an effective method of dealing with this issue. However, on some occasions, the use of rasburicase is indicated. Rasburicase is a urate oxidase that catalyzes the oxidation of uric acid to allantoin, which is much more soluble than uric acid and excreted more easily.[30,31] Given its high cost, rasburicase generally is restricted to patients with high WBC counts (greater than $50 \times 10^3/mm^3$, $50 \times 10^9/L$) and uric acid levels greater than 8 mg/dL (476 µmol/L).

### ▶ Infection

Infection is a primary cause of death in acute leukemia patients. Both the disease and aggressive chemotherapy cause severe myelosuppression, placing the patient at risk for sepsis.

The therapy for AML is extremely myelosuppressive. Children with AML have a 10% to 20% induction mortality rate secondary to infection and bleeding complications. Therefore, patients receiving induction therapy usually are hospitalized for the first 4 to 6 weeks of therapy. The induction therapy for ALL is far less myelosuppressive, and these patients recover their neutrophil counts quicker and usually do not require prolonged hospitalizations.[6]

It is important to recognize that symptoms and signs of infection may be absent in a severely immunosuppressed or neutropenic patient. Fever (greater than 38.3°C [100.9°F]) in a

neutropenic patient is a medical emergency. Because the progression of infection in neutropenic patients can be rapid, empirical antibiotic therapy should be administered quickly when fever is documented. Currently, the most commonly used initial antibiotic agent is cefepime, a fourth-generation cephalosporin that has good antipseudomonal coverage as well as adequate coverage against *Streptococcus viridans* and pneumococci.[32]

Disseminated fungal infections most commonly caused by Candida and Aspergillus species can be life threatening in children with AML. From the results of clinical trials in adults, many pediatric institutions recommend antifungal prophylaxis with voriconazole, posaconazole, micafungin, or caspofungin. Fluconazole and itraconazole are not considered ideal, because they are not effective against aspergillus species and other molds.[32]

Trimethoprim–sulfamethoxazole is started in all patients with any acute leukemia for the prevention of *Pneumocystis jiroveci* pneumonia (PJP). Patients normally continue this therapy for 6 months after completion of treatment. The use of additional antibiotic prophylaxis is not encouraged because of concerns for antibiotic resistance.

Of note is that up to 10% of patients seem to exhibit excessive myelosuppression with trimethoprim–sulfa antibiotics (presumably the result of the antifolate trimethoprim in combination with other systemic cytotoxic agents). Changing to another anti-PJP agent such as dapsone or inhaled pentamidine may help to alleviate this problem.

### ▶ Secondary Malignancies

Secondary malignancies are a risk of the successful treatment of a prior cancer or the use of cytotoxic agents in a variety of autoimmune diseases. The chemotherapy agents used, especially alkylating agents and topoisomerase II inhibitors, predispose patients to secondary hematopoietic neoplasms. As the aggressiveness of treatment and the number of survivors of AML increase, the risk of secondary neoplasms also may rise. There are two different types of second malignancies: acute leukemia, which is generally myeloid in origin, or MDS. There are also reports of secondary solid tumors, especially within regions of prior radiation exposure. The latency period between the end of treatment and the development of a secondary leukemia is generally in the range of 5 to 10 years. For those patients who develop secondary solid malignancies, the latency may be as long as 10 to 20 years.

The incidence of second cancers attributed to alkylators peaks 4 to 6 years after exposure and plateaus after 10 to 15 years. Higher cumulative doses and older age at the time of treatment are risk factors for this type of cancer.

Epipodophyllotoxins (etoposide and others) can induce a second malignancy characterized by balanced chromosomal translocations and short latency periods (2–4 years). The risk of this leukemia is related to schedule (dose intensity) and the concomitant use of other agents (ʟ-asparaginase, alkylating agents, and possibly antimetabolites). The prognosis for topoisomerase II inhibitor–related secondary leukemia is extremely poor. Only about 10% of these patients survive after salvage chemotherapy, and only 20% survive after HSCT.

Ionizing radiation therapy is also a cause of secondary malignancies. These secondary tumors generally develop within or adjacent to the previous radiation field. These cancers often have a prolonged latency, typically 15 or more years, but shorter latencies (5–14 years) are known. Higher doses of radiation and younger age are associated with an increased risk of secondary malignancy.

Unlike children, adults may have other factors that predispose them to secondary malignancies. Lifestyle choices such as tobacco use, alcohol use, and diet have been implicated in influencing the development of secondary neoplasms in the adult population.

Now that 80% or more of children survive their primary cancers, the incidence of secondary neoplasms may increase. Recognizing this potential, many treatment regimens for children are being modified appropriately to reduce exposure to alkylators, topoisomerase inhibitors, and radiation. Late effects clinics screen for secondary malignancies and other disease and treatment-related disabilities that accompany childhood cancer. Similar screening and educational opportunities are not as established in adult survivors.

### ▶ Late Effects

With increased success in pediatric clinical trials, the OS rate for pediatric cancers has increased markedly over the last 35 years. For some diseases (acute lymphoblastic leukemia, Wilms tumor, low-grade and common germ cell tumors), the OS rate is now at or above 80%. **KEY CONCEPT** *Despite this significant increase in survival, many patients, particularly pediatric cancer survivors, have disease-related or treatment-related disabilities. As many as 50% to 60% of these survivors are estimated to have at least one chronic or late-occurring complication of treatment.*[33] In leukemia, the intensified use of methotrexate may be responsible for some sporadic neurotoxicity seen in children and adults. Likewise, the use of pharmacologic doses of glucocorticoids has been associated with avascular necrosis of bone in older children and adults. High cumulative doses of anthracyclines can cause irreversible cardiomyopathy. Cranial XRT is now less frequently used for CNS leukemia prophylaxis but can cause neuropsychological and neuroendocrine abnormalities that may lead to obesity, short stature, or precocious puberty.[4] As newer and more intensive treatments enter clinical trials, close observation for long-term side effects will assume even greater importance.

## Supportive Care

Because of the need for repeated venous access, a central venous catheter or infusion port is placed before starting treatment. These devices are useful not only for delivery of chemotherapy but also to support patients during periods of myelosuppression. Infection and bleeding complications are the primary causes of mortality in patients with leukemia.

Platelet transfusions are a common tool to prevent hemorrhage. Patients with uncomplicated thrombocytopenia can be transfused when the platelet count falls below $10 \times 10^3/mm^3$ ($10 \times 10^9/L$). Patients who are either highly febrile or actively bleeding may require transfusions at higher levels. Red blood cell transfusions generally are not necessary for a hemoglobin concentration greater than 8 g/dL (80 g/L, 4.97 mmol/L).

There is much controversy regarding the routine use of colony-stimulating factors (eg, granulocyte colony-stimulating factor [G-CSF] and granulocyte-macrophage colony-stimulating factor [GM-CSF]) in neutropenic patients. Even though several clinical trials have shown the time to ANC recovery is decreased with a colony-stimulating factor, none have demonstrated that CSFs statistically influence infection-related mortality. At present, the use of colony-stimulating factors (G-CSF most commonly) generally is limited to those chemotherapy regimens that place the patient at highest risk for prolonged neutropenia.

## OUTCOME EVALUATION

Developing strategies for the treatment and monitoring of acute leukemias begins with risk stratification. Understanding the likely risk of relapse determines the aggressiveness and length

## Patient Care Process

**Patient Assessment:**

- Based on the physical exam and review of systems does the patient have the symptoms and physical findings of acute leukemia?
- Review the medical history. Is the patient receiving any medications that would be contraindicated or cause adverse effects prior to starting induction therapy?
- Review the laboratory features especially serum electrolytes and uric acid.
- Measure serum electrolytes and uric acid every 6 to 8 hours during the first 3 to 4 days of therapy. Patient may require frequent blood and platelet transfusions.

**Therapy Evaluation:**

- Evaluate the response to treatment by performing a bone marrow and LP.
- Does the patient demonstrate any residual leukemia as defined by the presence of blasts in the bone marrow or CSF?
- Determine the significance of the presence MRD at the end of induction.

**Care Plan Development:**

- Provide patient education on the potential side effects of the drug therapy for acute leukemia.
- Address the importance of medication compliance.
- Discuss the warning signs to report immediately to the health care provider (eg, fever, bruising, or bleeding).

**Follow-up Evaluation:**

- Follow-up with weekly CBCs and electrolytes to assess the effectiveness of therapy for any adverse effects associated with treatment.
- Provide education regarding the long-term sequelae associated with the treatment for acute leukemia.

indicate appropriate treatment response. Based on response to prior phases of treatment, the clinician should recognize potential toxicities in subsequent phases of treatment with the same or different drugs at similar or different doses.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| ALL | Acute lymphocytic/lymphoblastic leukemia |
| allo-HSCT | Allogeneic hematopoietic stem cell transplantation |
| AML | Acute myelogenous leukemia |
| ANC | Absolute neutrophil count |
| ANLL | Acute nonlymphocytic leukemia |
| BFM | Berlin-Frankfurt-Munster |
| CCR | Continuous complete remission |
| CD | Cluster determinants |
| CR | Complete remission |
| CSF | Cerebrospinal fluid |
| CSF | Colony-stimulating factor |
| DFS | Disease-free survival |
| EFS | Event-free survival |
| FISH | Fluorescent in situ hybridization |
| G-CSF | Granulocyte colony-stimulating factor |
| GM-CSF | Granulocyte-macrophage colony-stimulating factor |
| GVL | Graft-versus-leukemia |
| HLA | Human leukocyte antigen |
| HSCT | Hematopoietic stem cell transplantation |
| ITD | Internal tandem duplication |
| MAB | Monoclonal antibody |
| MDS | Myelodysplastic syndrome |
| MRD | Minimal residual disease |
| MUD | Matched unrelated donor |
| OS | Overall survival |
| Ph$^+$ | Philadelphia chromosome |
| TLS | Tumor lysis syndrome |
| XRT | Irradiation |

of therapy. Remission status and MRD after the induction phase of treatment must be closely observed. Failure to obtain morphologic bone marrow remission by day 28 is a very adverse prognostic sign and dictates further induction treatment. For those who have a morphologic remission, quantification of MRD has become an increasingly important prognostic factor. Levels of residual less than 0.01% appear to be associated with better outcomes.

A clinician is generally charged with developing a plan to educate patients and families about their drugs and doses. This is a critical responsibility; it is imperative that the patients and their families understand why they are receiving their medications and how to take them. Frank, open discussion (with the family or patient in possession of their prescriptions) go a long way toward preventing errors that occur as a result of "assuming" that they understand their medications. If modifications are necessary secondary to toxicity or inadequate response, establish a plan for treatment change. Remember that individual patients often do not fit the "average" patient profile, and dose modifications are frequently needed. The practitioner should be familiar with dosing ranges, WBC count, and other parameters that

# Chronic Leukemias and Multiple Myeloma

Amy M. Pick

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Explain the role of the Philadelphia chromosome in the pathophysiology of chronic myelogenous leukemia (CML).

2. Describe the natural history of CML.

3. Identify the clinical signs and symptoms and laboratory findings associated with CML.

4. Discuss treatment options for CML with special emphasis on tyrosine kinase inhibitors.

5. Describe the clinical course of chronic lymphocytic leukemia (CLL).

6. Describe patients who may be observed without treatment and those who receive aggressive treatment for CLL.

7. Discuss the various treatment options available for CLL.

8. Describe the clinical presentation of multiple myeloma.

9. Discuss the treatment options available for multiple myeloma.

## INTRODUCTION

Several diseases comprise chronic leukemia. The two most common forms are chronic myelogenous leukemia (CML) and chronic lymphocytic leukemia (CLL). The slower progression of the disease contrasts it from acute leukemia, with the survival of chronic leukemia often lasting several years without treatment. This chapter covers CML and CLL. The chapter also discusses the hematologic cancer multiple myeloma.

## CHRONIC MYELOGENOUS LEUKEMIA

CML is a hematologic cancer that results from an abnormal proliferation of an early myeloid **progenitor** cell. The clinical course of CML has three phases: chronic phase, accelerated phase, and **blast** crisis.[1] Criteria for these phases is largely based on the percent blasts in the peripheral blood or bone marrow. Chemotherapy can be used to control white blood cell (WBC) counts in the chronic phase, but as CML slowly progresses, the cancer becomes resistant to treatment. Blast crisis resembles acute leukemia, and immediate aggressive treatment is required.

## EPIDEMIOLOGY AND ETIOLOGY

It was estimated that 6660 new cases of CML would be diagnosed in 2015, accounting for 15% of all adult leukemias.[2] The incidence of CML increases with age, the median age being 67 years.[3,4] In most newly diagnosed cases, the etiology cannot be determined, but high doses of ionizing radiation and exposure to solvents such as benzene are recognized risk factors.

## PATHOPHYSIOLOGY

### Cell of Origin

CML arises from a defect in an early progenitor cell. The pluripotent (noncommitted) stem cell is implicated as the origin of the disease; therefore, multiple cell lineages of hematopoiesis may be affected, including myeloid, erythroid, megakaryocyte, and (rarely) lymphoid lineages. These cells remain functional in chronic phase CML, which is why patients in this phase are at low risk for developing infections.

### Ph Chromosome

**KEY CONCEPT** *The Philadelphia chromosome (Ph) results from a translocation between chromosomes 9 and 22, leaving a shortened chromosome 22. The Ph results in the formation of an abnormal fusion gene between the breakpoint cluster region and the Abelson proto-oncogene (BCR-ABL), which encodes an overly active tyrosine kinase. The loss of control of tyrosine kinase activity causes abnormal cellular proliferation and inhibition of apoptosis.*[1,4] Molecular tools such as quantitative and qualitative polymerase chain reaction (Q-PCR) and fluorescence in situ hybridization (FISH) are used in detection and monitoring of CML.[5]

## TREATMENT

### Desired Outcome

The primary goal in the treatment of CML is to eradicate the Ph positive clones. Elimination of the Ph is termed a complete cytogenetic response. International standardization of molecular

**Signs and Symptoms**

- 30%–50% are asymptomatic at diagnosis
- Symptoms may include fatigue, fever, weight loss, and bleeding
- Organomegaly consisting of splenomegaly and hepatomegaly

**Diagnostic Procedures**

- Peripheral blood smear
- Bone marrow biopsy (percentage of blasts)
- Cytogenetic studies
- Molecular testing (Q-PCR and FISH to detect *BCR-ABL* transcripts)

**Laboratory Findings**

Peripheral blood smear

- Leukocytosis (most present with WBC count > 100 × $10^9$/L [$100 × 10^3$/mm³])
- Thrombocytosis (~50% of patients in chronic phase)
- Anemia
- Basophilia
- Presence of blasts

Bone marrow

- Hypercellularity with presence of blasts
- Cytogenetics including the presence of Ph

**Poor Prognostic Factors**

- Older age
- Splenomegaly
- High percent blasts in the blood
- High or low platelet count

response has been updated to reflect a percentage of *BCR-ABL1* compared to control gene.[3] A complete molecular response is undetectable *BCR-ABL* transcripts by the international scale. An early goal of therapy is to achieve a complete hematologic response or to normalize peripheral blood counts. A cure from CML can only come from complete eradication of the Ph clone.

## General Approach to Treatment

There have been significant advances in the treatment of CML since the discovery of the Ph in 1960. The success of therapy is largely dependent on the clinical phase of the disease. Treatment decisions are based on patient's age, phase of CML, and comorbidities. Nearly all patients with CML are initially treated with a tyrosine kinase inhibitor (TKI). Depending on the clinical phase, newer TKIs or omacetaxine may be options for patients who fail to respond or do not tolerate initial TKI therapy. Hydroxyurea may be used after diagnosis to rapidly reduce high WBC counts and prevent potentially serious complications (respiratory and neurologic) associated with large numbers of circulating neutrophils. Hydroxyurea, though, does not alter the disease process. TKIs can also reduce peripheral WBC counts over several weeks;

therefore, many patients are started on a TKI alone. Although allogeneic stem cell transplant is the only curative therapy for CML, transplantation is reserved for patients with TKI resistance. Figure 96–1 illustrates one approach for clinically managing newly diagnosed CML patients.

## Nonpharmacologic Therapy

### ▶ *Hematopoietic Stem Cell Transplantation*

**KEY CONCEPT** *Allogeneic stem cell transplantation is the only curative treatment option for CML, however the TKIs have diminished the role of transplant.* Allogeneic stem cell transplant may be considered for the rare patient with BCR-ABL mutations that are resistant to or who fail TKI therapy. Transplant should also be considered for patients who present in blast crisis or who progress on a TKI in accelerated phase or blast crisis.[3] There are significant risks and long-term complications with allogeneic stem cell transplantation including early mortality and graft-versus-host disease. For patients who do not achieve a complete molecular response or have a relapse, the infusion of donor lymphocytes may place the patient back into a durable remission.[3]

## Pharmacologic Therapy (Table 96–1)

The treatment of CML has dramatically changed since the introduction of TKIs. **KEY CONCEPT** *Nearly all patients with CML are initially treated with a TKI. These oral agents do not cure CML but are able to produce long-term disease control in the vast majority of patients.*

### ▶ *Imatinib mesylate (Gleevec)*

Imatinib mesylate (STI-571; Gleevec) is a first-generation TKI and was the first TKI to show efficacy in the treatment of CML. Imatinib inhibits phosphorylation of various proteins involved in cell proliferation. In CML, imatinib works by binding to the adenosine triphosphate–binding pocket of *BCR-ABL*.[4] The 8-year follow-up data show that the use of imatinib in chronic phase CML results in an overall survival of 85% and an estimated event-free survival of 81%.[6] As expected with more aggressive disease, lower response rates are reported in accelerated phase and blast crisis.[7] Disease progression is typically attributed to imatinib primary or secondary resistance.[8] The *ABL* mutation T315I is one mechanism of secondary resistance that results in reactivation of BCR-ABL activity. The T315I mutation renders imatinib and the second-generation TKIs ineffective; therefore, alternative therapy with agents that overcome this mutation must be selected.[3,8]

Imatinib may be used as first-line therapy in patients with CML. Standard dosing of imatinib is 400 mg/day in chronic phase CML. Studies have investigated the use of higher doses of imatinib in all phases of CML. Although these higher doses produced rapid responses compared to standard imatinib dosing, they were also associated with more serious adverse effects.[3,9]

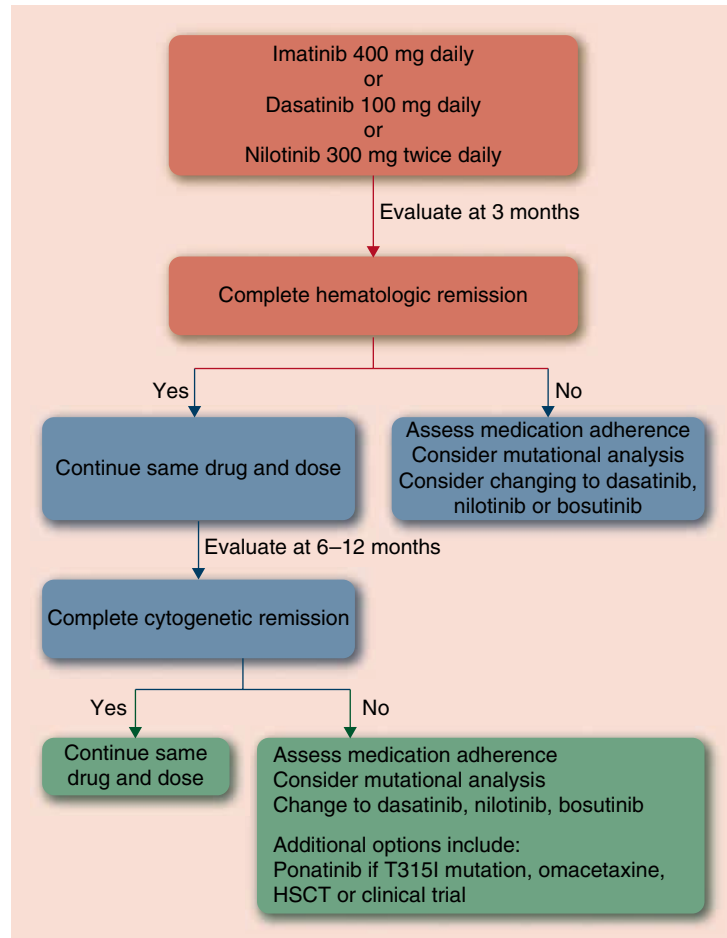
Therapy with imatinib is generally well tolerated. Common side effects include myelosuppression (phase and dose related), rash, gastrointestinal disturbances, edema, fatigue, arthralgias, myalgias, and headaches. Congestive heart failure is a rare but serious side effect and requires careful monitoring in patients with preexisting cardiac conditions.[3,10,11] Imatinib is metabolized by CYP450 3A4, and possible drug interactions include agents that inhibit or induce 3A4, such as erythromycin, ketoconazole, and phenytoin.[3]


**FIGURE 96–1.** Algorithm for tyrosine kinase inhibitor therapy in newly diagnosed chronic myeloid leukemia (CML) patients. (HSCT, hematopoietic stem cell transplantation.)

**Table 96–1**

**Drugs Used in CML**

| Drug | Adverse Effects | Comments | Renal Dosing | Hepatic Dosing |
|------|-----------------|----------|--------------|----------------|
| Bosutinib (Bosulif) | Diarrhea, nausea vomiting, thrombocytopenia, neutropenia, increased liver function tests, fluid retention | Dose: 500 mg po once daily<br>Dose may be increased to 600 mg po once daily if complete hematologic response not seen at 8 weeks or complete cytogenetic response by 12 week<br>Take with food<br>Drug interactions: metabolized by CYP 3A4; inhibitor and substrate of P-glycoprotein | CrCl 30–50 mL/min (0.50–0.83 mL/s): 500 mg daily and may decrease to 400 mg if cannot tolerate<br>CrCl < 30 ml/min (0.50 mL/s): 300 mg daily | Any baseline liver impairment: 200 mg daily |
| Dasatinib (Sprycel) | Thrombocytopenia, neutropenia, headache, rash, edema, pleural effusions | Dose: 100 mg po once daily for chronic phase CML or 140 mg po daily for accelerated phase or blast crisis<br>Avoid concomitant medications that prolong the QT-interval; low levels of potassium and magnesium should be corrected before initiating therapy<br>Drug interactions: metabolized by CYP 3A4<br>Dasatinib exhibits pH-dependent absorption; avoid medications that alter gastric pH (eg, H2 antagonists and PPIs) | No reductions | No reductions |

| **Drugs Used in CML** *(Continued)* | | | | |
| **Drug** | **Adverse Effects** | **Comments** | **Renal Dosing** | **Hepatic Dosing** |
| Imatinib mesylate (Gleevec, STI 571) | Neutropenia, thrombocytopenia, diarrhea, rash, nausea, edema, fatigue, arthralgias, myalgias, headache, increased liver function tests, congestive heart failure (rare) | Dose range: 400–800 mg po per day depending on phase<br>Take with meals and a full glass of water<br>Drug interactions: metabolized by CYP 3A4; weak inhibitor of CYP 2D6 and 2C9<br>Avoid taking with acetaminophen to reduce hepatic toxicity<br>Diarrhea usually responds to loperamide | CrCl 20–39 mL/min (0.33–0.66 mL/s): 50% reduction in dose<br>CrCl < 20 mL/min (0.33 mL/s): use with caution | Mild to moderate impairment: no adjustment<br>Severe impairment: reduce dose by 25%<br>Discontinue imatinib if liver transaminases are > 5 × upper limit of normal or if serum bilirubin > 3 × upper limit of normal |
| Nilotinib (Tasigna) | Thrombocytopenia, neutropenia, elevated bilirubin, elevated serum lipase | Dose: 400 mg po twice daily<br>Take on an empty stomach<br>Black-box warning for QT prolongation; avoid concomitant medications that prolong the QT interval; low levels of potassium and magnesium should be corrected before initiating therapy<br>Drug interactions: metabolized by CYP 3A4; competitive inhibitor of CYP 2C8, 2C9, 2D6, and UGT1A1<br>Pharmacogenomic testing of UGT1A1 polymorphisms can be used to identify patients who may have hyperbilirubinemia | No reductions | Child-Pugh class A, B, or C: 200 mg po twice daily for chronic phase CML; may increase to 300 mg if tolerating nilotinib therapy; discontinue nilotinib if experiencing grade 3 or 4 elevations in bilirubin or liver transaminases |
| Omacetaxine mepesuccinate (Synribo) | Myelosuppression, hyperglycemia | Dose: 1.25 mg/m$^2$ subcutaneous injection twice daily × 14 days, repeat every 28 days until hematologic response achieved<br>Maintenance therapy: 1.25 mg/m$^2$ subcutaneous injection twice daily × 7 days every 28-day cycle<br>Drug interactions: P-glycoprotein substrate | No reductions | No reductions |
| Ponatinib (Iclusig) | Arterial and venous thromboembolisms, hepatotoxicity, congestive heart failure, pancreatitis, gastrointestinal bleeding, fluid retention, myelosuppression, fatigue, headaches | Dose: 45 mg daily<br>Black-box warnings for thromboembolism stroke, myocardial infarction, hepatotoxicity and heart failure<br>Monitor CBC, lipase and liver function tests.<br>Drug interactions: metabolized by CYP 3A4,2C8, 2D6 competitive inhibitor of P-glycoprotein | No reductions | Child-Pugh class A, B, or C: 30 mg daily<br>Hold ponatinib if liver transaminases are > 3 × upper limit of normal. May resume but reduce dose when < 3 × upper limit of normal |

CML, chronic myeloid leukemia; CrCl, creatinine clearance; po, oral; PPI, proton pump inhibitor.

▶ *Advanced-Generation TKIs*

There are four advanced-generation BCR-ABL TKI inhibitors. KEY CONCEPT *Dasatinib (Sprycel), nilotinib (Tasigna), bosutinib (Bosulif), and ponatinib (Iclusig) are advanced generation TKIs that may overcome imatinib resistance or intolerance.* These inhibitors are anywhere from 10 to 325 times more potent than imatinib in inhibiting BCR-ABL and are able to overcome most *BCR-ABL* mutations that lead to imatinib resistance.[12] Of the four, only ponatinib can overcome the *T315I* mutation.[13]

Dasatinib and nilotinib were initially indicated for use in CML when patients failed imatinib therapy. Their indication has now expanded to include first-line therapy based on results of trials comparing these drugs to imatinib. These study results suggest that dasatinib and nilotinib are comparable to, if not better than, imatinib in achieving faster and deeper cytogenetic and molecular responses.[6,10,14,15] These studies suggest that fewer patients may progress to accelerated or blast phase on dasatinib or nilotinib compared to imatinib. Common side effects are similar to those of imatinib.

A significant and potentially severe side effect of pleural effusions has been reported with the use of imatinib and dasatinib but not with the use of nilotinib.[6] Additional side effects include QT prolongation (dasatinib and nilotinib) and increases in indirect bilirubin (nilotinib).[3,12]

Bosutinib is used in the second-line treatment of CML when patients are resistant or intolerant to prior TKI therapy. Bosutinib overcomes most *BCR-ABL* domain mutations with the exception of the *T315I* mutation. Bosutinib is not recommended as first-line therapy since the Phase III trial comparing the efficacy of bosutinib to imatinib did not meet its primary endpoint of complete cytogenetic response at 12 months.[16] The side effects of bosutinib appear to be less severe and less common than many of the other TKIs. Gastrointestinal disturbances and rash are some of the most common nonhematologic side effects.[16]

Ponatinib is a third-generation multikinase inhibitor that overcomes the *BCR-ABL* domain mutation *T315I*. Ponatinib was initially approved for the treatment of patients in all phases that were resistant or intolerant to prior TKI therapy. In postmarketing analysis, an increase in serious arterial thrombotic events was shown in 24% of patients.[3,13] The revised label indicates the use of ponatinib in patients harboring the *T315I* mutation or have failed multiple prior TKIs. Nonhematologic side effects include rash, dry skin, and abdominal pain. Rare yet serious adverse effects include liver failure and death, which are both black-box warnings.[3,13]

### ▶ *Omacetaxine Mepesuccinate*

Omacetaxine mepesuccinate (Synribo) is a semisynthetic formulation of homoharringtonine. Omacetaxine reversibly inhibits protein synthesis thereby causing cell death.[17] Unlike TKIs, the mechanism of action affects both normal and malignant hematopoietic cells. Omacetaxine is a subcutaneous injection indicated for patients in chronic or accelerated phase CML who are resistant or intolerant to two or more TKIs.[3] It may be used in patients with the *T315I* mutation. Nonhematologic adverse reactions include gastrointestinal disturbances, fatigue and hyperglycemia. Febrile neutropenia, infections, and cerebral hemorrhage are a few of the serious adverse reactions.[17]

## OUTCOME EVALUATION

Successful treatment for CML depends on the elimination of the Ph. Nearly all newly diagnosed CML patients will be placed on a TKI. First-line treatment options include imatinib, dasatinib, and nilotinib. Which agent to use depends on several factors, including mutational status, disease risk score, age, comorbid conditions, and medication safety profile. Patients should be counseled on the importance of medication adherence. Patients should understand that poorer outcomes may result if they are not adherent to daily TKI therapy. Historically, if patients fail to obtain a cytogenetic response within 6 to 12 months, a change in therapy is recommended. Research is evaluating the use of early molecular responses in the treatment management of CML. If TKI treatment failure occurs, patients should undergo *BCR-ABL* domain mutation testing. Second-line chronic phase CML therapy should be determined based on mutational analysis with second-generations TKIs (including bosutinib). These agents may also be used in patients who have accelerated phase CML. Ponatinib may be considered if the *T315I* mutational status is present with an understanding that it is associated with serious vascular effects. Omacetaxine, allogeneic stem cell transplantation and clinical trials are options for those patients that do not respond to a TKI.

---

### Patient Encounter 1

A 48-year-old man presents to his primary care physician with complaints of worsening fatigue and left upper quadrant pain. His medical history consists of type 2 diabetes managed with metformin and gastroesophageal reflux disease treated with omeprazole. A CBC is drawn and shows the following:

**Total WBC:** $70 \times 10^9$/L ($70 \times 10^3$/mm³), (4% [0.04] blasts, 86% [0.86] segs, 10% [0.10] lymphs)

**Hgb/Hct:** 8.3 g/dL (83 g/L; 5.15 mmol/L)/25% (0.25)

**Platelets:** $489 \times 10^9$/L ($489 \times 10^3$/mm³)

The patient is referred to an oncologist for further workup. A bone marrow biopsy is performed and reveals hypercellular marrow with 5% (0.05) blasts. FISH analysis is positive for *Ph*.

*What information is suggestive of CML?*

*What are the first-line treatment options for chronic phase CML patient?*

*Which specific treatment do you recommend for this patient and why?*

*Identify your treatment goals for this patient.*

*Assuming this patient has suboptimal response to your initial therapy, what would you recommend for second-line therapy?*

*What factors may contribute to this patient's having a suboptimal response?*

---

Some patients will not respond to treatment and will progress to blast crisis where they will receive treatment for acute leukemia. Although its use is limited, allogeneic transplant offers the only cure for CML and may be useful in patients with advanced disease.

## CHRONIC LYMPHOCYTIC LEUKEMIA

CLL is a cancer that results in the accumulation of functionally incompetent lymphocytes.[18] CLL is usually considered an indolent, incurable disease, and treatment should only be initiated when patients have symptoms. However, a subset of patients will have aggressive disease, and these individuals need to be treated aggressively.

## EPIDEMIOLOGY AND ETIOLOGY

CLL is the most common type of leukemia diagnosed in adults, accounting for 30% of all adult leukemias. It was estimated that in 2015, 14,620 new cases would be diagnosed in the United States.[2] The median age at diagnosis is the sixth decade of life with the incidence increasing with age. The etiology of CLL is unknown, but hereditary factors may have a role, with family members of CLL patients having a twofold to sevenfold increased risk of CLL.[18]

## PATHOPHYSIOLOGY
### Cell of Origin

CLL is characterized by small, relatively incompetent B lymphocytes that accumulate in the blood and bone marrow over time. The lack of apoptotic mechanisms leads to the persistence and accumulation of B lymphocytes. The exact cell of origin is controversial but has been described as an antigen-activated B

lymphocyte.[18] Chromosomal abnormalities have been identified in 40% to 50% cases of CLL and often correlate with progressive disease. Numerous tyrosine kinases appear to be involved in CLL, including the activation of Bruton tyrosine kinase (BTK).[19] Detection of some of these markers may predict clinical course and prognosis and may influence treatment decisions.[18,19]

### Clinical Course

**KEY CONCEPT** *CLL can have a variable clinical course with survival ranging from months to decades. Low-risk disease is asymptomatic, and median survival times exceed 10 years. Intermediate risk is associated with lymphadenopathy and has median survival times of about 7 years.* High-risk patients with anemia have median survival times of only 3 years.[20] The typical low-risk patient is an asymptomatic elderly patient who is diagnosed on routine blood draw. The typical high-risk patient is a symptomatic middle-aged patient.

### PROGNOSTIC FACTORS

Two staging systems, Rai's and Binet's, have been developed to help practitioners determine the overall prognosis of patients with CLL. They are comparable systems and are useful to broadly determine good, intermediate, and poor prognostic disease.[20] Risk stratification criteria included in these systems are lymphadenopathy, splenomegaly, hepatomegaly, and cytopenias. Increasingly, a number of biological markers of the disease such as deletions of chromosome 17p and 13q and mutational status of immunoglobulin heavy chain variable region gene (IgVH) are being used to predict the likely clinical course.[21] These biological markers are not included in the Rai's or Binet's staging systems.

### TREATMENT
#### Desired Outcomes

The primary goals in the treatment of CLL are to provide palliation of symptoms and improve overall survival. Because the current treatments for CLL are not curative, reduction in tumor burden and improvement in disease symptoms are reasonable end points, particularly in older patients. A complete response (CR) to therapy can be defined as a resolution of lymphadenopathy and organomegaly, normalization of peripheral blood counts, and elimination of lymphoblasts in the bone marrow.

#### Nonpharmacologic Therapy

**KEY CONCEPT** *Asymptomatic early stage CLL can be observed without treatment until evidence of disease progression.* Past studies with chlorambucil suggest that chemotherapy does not improve overall survival in early stage CLL although there is question whether this remains true with the development of newer therapies. In addition, deferring therapy until a patient becomes symptomatic does not alter overall survival.[20] For this reason, the notion of "watch and wait" is considered reasonable for older patients with low risk disease. Several factors will influence this approach, including life expectancy, disease characteristics, and ability to tolerate therapy.[20,22]

##### ▶ *Hematopoietic Stem Cell Transplantation*

The use of hematopoietic stem cell transplantation (HSCT) in CLL is limited. Allogeneic transplantation offers longer disease-free remissions than **autologous** transplantation but is associated with high treatment morbidity and mortality. Several factors must be considered before allogeneic stem cell transplantation. The lack of a donor, older age, and poor performance status make transplant an uncommon procedure in this population. Allogeneic transplantation remains an option for younger patients with aggressive disease who have failed prior therapies. Although its use is currently limited, HSCT may someday be an important component in achieving a cure for CLL.[20,22]

#### Pharmacologic Therapy (Table 96–2)

CLL treatment is typically initiated in the symptomatic patient. Numerous agents can be used as initial therapy in the treatment of symptomatic or advanced CLL. Many of the chemotherapy regimens have not been compared directly with one another, so

---

## Clinical Presentation and Diagnosis of CLL

**Signs and Symptoms (50% are asymptomatic at diagnosis)[16]**

- Lymphadenopathy
- Organomegaly consisting of splenomegaly and hepatomegaly
- Fatigue, weight loss, night sweats, fevers
- Chronic infections caused by immature lymphocytes

**Diagnostic Procedures**

- Peripheral blood smear
- Bone marrow biopsy
- Cytogenetic studies
- Molecular testing

**Laboratory Findings**

Peripheral-blood

- Leukocytosis (WBC count > $100 \times 10^9$/L [$100 \times 10^3$/mm³])
- Lymphocytosis (absolute lymph count > $5 \times 10^9$/L [$5 \times 10^3$/mm³])
- Anemia
- Thrombocytopenia
- Hypogammaglobinemia

Bone marrow

- Must have at least 30% (0.30) lymphocytes

Molecular markers

- Cytogenetic abnormalities

**Poor Prognostic Factors**

- Lymphocytosis with accompanying:
  - Anemia (hemoglobin ≤ 11.0 g/dL [110 g/L; 6.83 mmol/L])
  - Thrombocytopenia (platelets < $100 \times 10^9$/L [$100 \times 10^3$/mm³])
- ZAP-70 and CD38 antigen expression
- Cytogenetics such as deletions of chromosomes 17p and 11q (deletion of 13q is favorable)

| Table 96–2 |
| --- |

**Drugs Used in CLL**

| Drug | Adverse Effects | Comments | Renal Dosing | Hepatic Dosing |
| --- | --- | --- | --- | --- |
| Alemtuzumab (Campath) | Infusion reactions: fever, chills, nausea, vomiting; hypotension; prolonged immunosuppression (resulting in infectious complications) | Antiviral and PCP prophylaxis should be initiated during treatment<br>Consider antifungal prophylaxis<br>Premedicate with acetaminophen, diphenhydramine with or without a steroid to alleviate infusion-related reactions<br>SC dosing may lessen acute toxicity | No reductions | No reductions |
| Bendamustine (Treanda) | Myelosuppression, fever, nausea, vomiting, infusion reactions, tumor lysis syndrome | Consider using allopurinol for tumor lysis syndrome during first few cycles of therapy | CrCl < 40 mL/min (0.67 mL/s): do not use | Mild impairment: use with caution<br>Moderate to severe impairment: do not use |
| Chlorambucil (Leukeran) | Myelosuppression; allergic reactions (skin rash); secondary malignancies | Take on an empty stomach because food decreases absorption<br>Dose range: 4–10 mg po daily | No reductions | No reductions |
| Fludarabine (Fludara) | Myelosuppression; prolonged immunosuppression, resulting in secondary infectious complications; edema; neurotoxicity | Dose: 20 mg/m$^2$ IV daily for 5 days<br>Often given in combination | CrCl 30–70 mL/min (0.50–1.17 mL/s): 20% reduction of dose (IV and po)<br>CrCl < 30 mL/min (0.50 mL/s): do not use IV; reduce dose of oral by 50% | No reductions |
| Ibrutinib (Imbruvica) | Risk of bleeding, neutropenia, thrombocytopenia | Dose: 420 mg po once daily<br>Avoid the use of concomitant CYP 3A4 inhibitors/inducers<br>Drug metabolism: CYP 3A4 and 2D6 | No reductions in CrCl > 25 ml/min (0.42 mL/s)<br>Insufficient data in < 25 ml/min (0.42 mL/s) | Insufficient data exists |
| Idelalisib (Zydelig) | Black-box warnings: Severe hepatotoxicity, diarrhea, colitis, pneumonitis, intestinal perforation<br>Serious allergic reactions | Dose: 150 mg po twice daily<br>Drug metabolism: CYP 3A4; strong inhibitor of 3A4, 2C8, 2C9, 2C19 | No reductions in CrCl > 15 ml/min (0.25 mL/s)<br>Insufficient data in < 15 ml/min (0.25 mL/s) | Insufficient data exists |
| Obinutuzumab (Gazyva) | Infusion reactions, reactivation of hepatitis B, progressive multifocal encephalopathy, tumor lysis syndrome, neutropenia | Premedicate with acetaminophen, IV antihistamine, and an IV steroid to alleviate infusion-related reactions<br>Consider antimicrobial, antiviral and antifungal prophylaxis<br>Hold antihypertensives 12 hours prior, during and after due to the risk of hypotension | No reductions in CrCl > 30 ml/min (0.50 mL/s)<br>Insufficient data in < 30 ml/min (0.50 mL/s) | No reductions |
| Ofatumumab (Arzerra) | Severe infusion-reactions: bronchospasm, edema, fever, chills, rigors, hypotension; prolonged myelosuppression | Premedicate with acetaminophen, IV antihistamine, and an IV steroid to alleviate infusion-related reactions<br>Rate of infusion should be increased gradually to minimize reactions<br>Monitor for reactivation of hepatitis B | No reductions | No reductions |
| Pentostatin (Nipent) | Myelosuppression; infectious complications | Fatal pulmonary toxicity when given with fludarabine | Hold dose if serum creatinine increases | No reductions |
| Rituximab (Rituxan) | Infusion reactions: fever, chills, rigors, hypotension | Premedicate with acetaminophen, diphenhydramine with or without a steroid to alleviate infusion related reactions<br>Rate of infusion should be increased gradually to minimize reactions<br>Monitor for reactivation of hepatitis B | No reductions | No reductions |

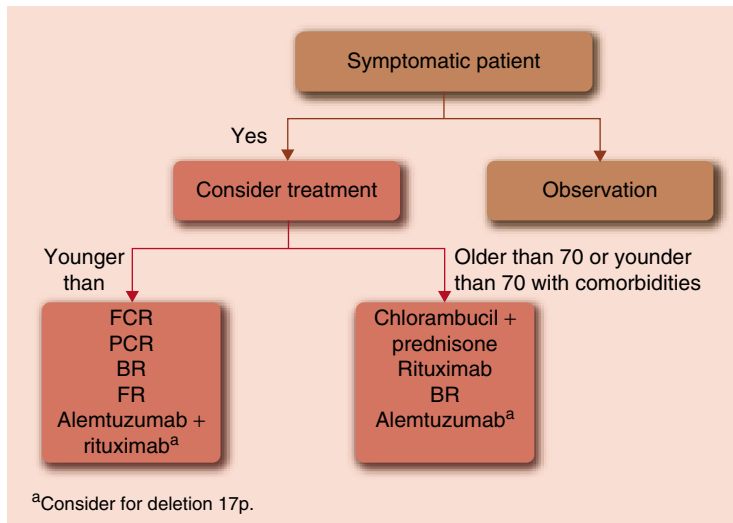
CrCl, creatinine clearance; IV, intravenous; po, oral; PCP, pneumocystits pneumonia; SC, subcutaneous.


**FIGURE 96–2.** Algorithm for initial therapy in newly diagnosed chronic lymphocytic leukemia (CLL) patients. B, bendamustine; C, cyclophosphamide; F, fludarabine; P pentostatin; R, rituximab.

there is not one preferred regimen. Selection of the appropriate chemotherapy depends on the individual patient and practitioner's preference. Figure 96–2 illustrates one approach for initial therapy in newly diagnosed patients with CLL.

▶ *Cytotoxic Chemotherapy*

Historically, chlorambucil (Leukeran), an oral alkylating agent, was considered the standard treatment for CLL. Today, the treatment for CLL has changed with the development of the purine analogs. There are three purine analogs used in the treatment of CLL: fludarabine (Fludara), pentostatin (Nipent), and cladribine (Leustatin) with fludarabine being the most studied. **KEY CONCEPT** *Fludarabine-based chemoimmunotherapy is commonly used as first-line therapy for younger patients with CLL.* Randomized clinical trials have shown that fludarabine is superior to chlorambucil in achieving higher response rates and producing a longer duration of response.[20,22] Fludarabine is effective in previously untreated patients as well as patients who have chlorambucil-resistant disease. Although fludarabine is one of the most effective agents in the treatment of CLL, it is rarely used as a sole agent. Instead fludarabine is given in combination with other drugs to improve response rates.[19,20,22]

Fludarabine is associated with more toxicities than chlorambucil, including myelosuppression and prolonged immunosuppression.[23] Resultant infectious complications may occur during the periods of prolonged immunosuppression. Clinicians should consider antibacterial and antiviral prophylaxis for *Pneumocystis* and varicella zoster when using fludarabine-based therapy.[22] Today, chlorambucil remains a practical option for symptomatic elderly patients who require palliative therapy because of the ease of oral administration, low cost and limited side-effect profile.

Bendamustine (Treanda) is an alkylating agent used in the treatment of CLL. As first-line therapy for CLL, bendamustine was shown to have superior overall response rates, CRs, and longer progression-free survival than chlorambucil.[22] Bendamustine is usually given in combination with rituximab as first-line therapy.[19,22]

▶ *Monoclonal Antibodies*

**KEY CONCEPT** *Combination chemoimmunotherapy with anti-CD20 monoclonal antibodies are widely used in the treatment of CLL.*

Rituximab (Rituxan) is a naked chimeric monoclonal antibody directed against the CD20 antigen on B-lymphocytes.[19,20] Similar to other B-cell malignancies, CLL expresses CD20 antigens. Dose escalation studies suggest that higher doses are required than those used in non-Hodgkin lymphoma.[24] The higher dose required in CLL is probably a combined effect of lower CD20 antigen expression and higher concentrations of soluble CD20 antigen than in non-Hodgkin lymphoma.[24] Rituximab is given in combination with other therapies since these combinations result in higher CRs than rituximab alone.[19] The most common side effects of rituximab include infusion reactions consisting of fever, chills, hypotension, nausea, vomiting, and headache.[18] Premedication with diphenhydramine and acetaminophen is recommended to minimize infusion reactions.

Ofatumumab (Arzerra) and obinutuzumab (Gazyva) are two newer biologics in this class. Ofatumumab is a CD20 antigen-directed monoclonal antibody that is approved in CLL patients who fail fludarabine and alemtuzumab.[25] Obinutuzumab is different than the other two having a higher binding affinity to the CD20 epitope and causing direct cell death.[25] It is approved in combination with chlorambucil for the treatment of previously untreated CLL. Premedications are similar to rituximab with the addition of a corticosteroid to reduce the incidence of infusion reactions. The rate of infusion and titration depends on patient tolerability of the medication. Table 96-2 lists some of the adverse effects seen with the anti-CD20 monoclonal antibodies.

Alemtuzumab (Campath) is a humanized monoclonal antibody directed against the CD52 antigen.[20] CD52 antigen is expressed on the majority of B and T lymphocytes. Alemtuzumab may be used as single agent or combination therapy in the treatment of CLL. Studies have shown alemtuzumab to be effective in fludarabine-resistant disease, in patients with the deletion of 17p, and as front-line therapy.[22] Infusion-related reactions can be significant and typically occur with the initial dose and lessen in severity with subsequent doses. To limit acute allergic reactions, subcutaneous administration may be given instead of IV dosing.[18,22] Premedication with oral antihistamines and acetaminophen is recommended. Alemtuzumab also suppresses the T cells, resulting in prolonged immunosuppression. Infectious complications may occur from the reactivation of

cytomegalovirus and herpes virus and from infection with *Pneumocystis*. These infections have been shown to occur with both the IV and subcutaneous routes of administrations. Patients should receive trimethoprim–sulfamethoxazole and acyclovir or an equivalent antiviral to prevent these infections.[18,20]

#### ► *Small-Molecule Inhibitors*

An understanding of the B-cell receptor signaling pathways of CLL has led to the approval of newer oral targeted therapies.[26] Ibrutinib (Imbruvica) is an inhibitor of BTK which is an essential enzyme in the B-cell receptor pathway. Ibrutinib has been shown to have an improved progression free survival, response rate and overall survival compared to ofatumumab in previously treated patients with CLL.[27] Ibrutinib has also been studied in previously untreated patients with CLL and in patients with the del 17p.[22] Idelalisib (Zydelig) targets phosphatidylinositol-3-kinase (PI3-K), an essential lipid kinase that is a regulator of the B-cell receptor pathway and involved in cellular survival and proliferation. Idelalisib has been studied as monotherapy as well as combination therapy with rituximab in patients with relapsed disease.[28] Nonhematologic side effects for both drugs may be found in Table 96-2. Black-box warnings for idelalisib include hepatotoxicity, colitis, pneumonitis, and intestinal perforation.

#### ► *Chemoimmunotherapy*

Chemoimmunotherapy is the standard for younger patients with symptomatic CLL. The regimen is often selected based on age and cytogenetics. Combination therapy generally consists of an anti-CD20 antibody in combination with chemotherapy. The combination of fludarabine, cyclophosphamide, and rituximab improves CR rates compared with fludarabine alone (70% vs 20%, respectively) but at the expense of increased infections.[19,22] Rituximab is often added to bendamustine, lenalidomide, and alemtuzumab.[22] A recent multiple-treatment meta-analysis was not able to show a significant survival benefit of one regimen compared to another.[29]

### OUTCOME EVALUATION

Successful outcomes depend on the appropriate treatment selection for a specific patient. Risk-versus-benefit should be determined in the treatment of older CLL patients. Because CLL is incurable, watch and wait is a reasonable approach for those with indolent disease. Treatment can then begin when the patient becomes symptomatic. Aggressive chemoimmunotherapy with fludarabine is often reserved for younger patients with high-risk CLL, with the goal being prolonged disease-free survival. A desirable response to therapy includes a reduction in lymphocytes, decrease in stage of the disease, and resolution of symptoms.

## MULTIPLE MYELOMA

Multiple myeloma (MM) is a malignancy of the **plasma cell** and is characterized by an abnormal production of a monoclonal protein in the bone marrow. Features of the disease include bone lesions, anemia, and renal insufficiency.[30] Multiple myeloma is an incurable disease; however, advancements in the treatment of myeloma have significantly extended survival.

### EPIDEMIOLOGY AND ETIOLOGY

Multiple myeloma (MM) is the second most common hematologic malignancy. It is estimated that approximately 26,850 new cases of MM would be reported in 2015, accounting for 1% to 2% of all cancers.[2] The median age at diagnosis is 70 years, and fewer than 2% are diagnosed before the age of 40 years.[30,31] The incidence of myeloma is highest in African Americans, lowest in Asians, and occurs more frequently in men than women.[31] The etiology of MM remains largely unknown although a exposure to ionizing radiation and genetic factors have been implicated.[31]

### PATHOPHYSIOLOGY

The pathogenesis of MM is quite complex with multiple-step models created to postulate the process. Myeloma must be distinguished from a condition called monoclonal gammopathy of unknown significance (MGUS), which is characterized by a monoclonal immunoglobulin without malignant plasma cells. Yearly, about 1% of patients with MGUS will develop MM. Chromosomal abnormalities and changes in gene expression lead to cell cycle dysregulation and appear to be involved early in the disease process.[30] The pathophysiology of MM involves complex bone marrow microenvironment, and cytokine interactions. Interleukin-6, tumor necrosis factor, vascular endothelial growth factor, and stromal-derived factor-1 support the establishment and proliferation of myeloma cells.[30,31] The understanding of these interactions has led to novel agents used in the treatment of MM.

### PROGNOSTIC FACTORS

Prognostic factors for myeloma include tumor, treatment, and patient related factors. The International Staging System is used to predict outcomes after therapy. Staging is stratified based on the levels of serum $\beta_2$-microglobulinemia and serum albumin. High $\beta_2$-microglobulinemia and low albumin are poor prognostic factors and are indicative of high tumor load.[32] Although cytogenetic abnormalities are not included in the International Staging System, many abnormalities are associated with poor outcomes. The Mayo Stratification for Myeloma and Risk-Adapted

### Patient Encounter 2

A 42-year-old man presents to his health care provider for his annual well-check. Physical exam reveals cervical lymph node enlargement and splenomegaly. Blood work reports the following:

**WBC:** $85 \times 10^9$/L ($85 \times 10^3$/mm³)

**Hgb:** 10.9 g/dL (109 g/L; 6.77 mmol/L)

**Platelets:** $200 \times 10^9$/L ($20 \times 10^3$/mm³)

**Peripheral Smear:** Lymphocytosis with small, mature-appearing cells suggestive of chronic lymphocytic leukemia

**Prognostic Markers:** Positive for CD38 expression, negative for ZAP-70, deletion 11q

*What information supports the diagnosis of CLL?*

*Identify your treatment goals for this patient.*

*What treatment approach do you recommend?*

*Would your treatment options change if this patient were asymptomatic? If so, what would be your new treatment?*

*Would your treatment options change if this patient were a symptomatic, 86-year-old man?*

## Clinical Presentation and Diagnosis of Multiple Myeloma

### Signs and Symptoms

- "CRAB"
  - "C"—hyper**C**alcemia
  - "R"—**R**enal failure (serum creatinine > 2 mg/dL [177 μmol/L])
  - "A"—**A**nemia (fatigue)
  - "B"—**B**one disease (pain, lesions, fractures)
- Weight loss
- Recurrent infections

### Diagnostic Procedures

- Laboratory
  - CBC, chemistry panel, $\beta_2$-microglobulin
  - Peripheral blood smear
  - Serum protein electrophoresis and immunofixation
  - Urine protein electrophoresis and immunofixation
  - Serum free light chains
- Radiologic evaluation (MRI, bone densitometry)
- Bone marrow biopsy
  - Cytogenetic studies
  - Molecular testing

### Laboratory Findings

- Peripheral blood
  - Monoclonal protein in serum (usually IgG or IgA)
  - High $\beta_2$-microglobulin
  - Low platelets and hemoglobin
  - High creatinine, urea, lactate dehydrogenase, C-reactive protein, and calcium
  - Rouleaux formation
- Urinalysis
  - Urinary free light chains (Bence-Jones Protein)
- Bone marrow
  - Plasma cells (10% or more)
  - Abnormal cytogenetics
- Radiologic findings
  - Bone lesions, fractures, osteoporosis

### Poor Prognostic Factors

- High serum $\beta_2$-microglobulin and low serum albumin
- Elevated C-reactive protein
- Elevated lactate dehydrogenase
- IgA isotype
- Low platelet count
- Chromosome 13 deletions and other cytogenetic abnormalities

## Patient Encounter 3

A 58-year-old woman presents to her health care provider with complaints of extreme fatigue and severe right and left hip pain. Her past medical history includes controlled hypertension. Workup reveals:

**Radiology:** X-ray of right and left hips: Osteolytic lesions

**Labs:** Hemoglobin: 7.2 g/dL (72 g/L; 4.47 mmol/L); platelets: $220 \times 10^9$/L ($220 \times 10^3$/mm³); corrected calcium: 11.8 mg/dL (2.95 mmol/L); serum creatinine: 1.8 mg/dL (159 μmol/L); serum IgG: 4200 mg/dL (42 g/L) (normal: 620–1500 mg/dL (6.2–15 g/L); serum IgM: 80 mg/dL (8 g/L) (normal: 50–200 mg/dL (0.5–2 g/L); bone marrow: 83% plasma cell infiltrates

*What information is suggestive of multiple myeloma?*

*What treatment options are available for this patient?*

*Assuming this patient is a candidate for autologous stem cell transplantation, what would be an appropriate induction regimen?*

*Assuming this patient is a not a candidate for autologous stem cell transplantation, what would be an appropriate induction regimen?*

*What may be used for maintenance therapy after an autologous stem cell transplantation?*

Therapy classification incorporates tumor biology to stratify patients according to their disease risk.[33] Chromosomal changes are being used to predict high-risk patients with perhaps the most important being deletions of the long arm of chromosome 13 and translocation of chromosomes 4 and 14.[30,34] Older patients, renal impairment, and other comorbidities also predict for poorer outcomes.[31]

## TREATMENT

### Desired Outcomes

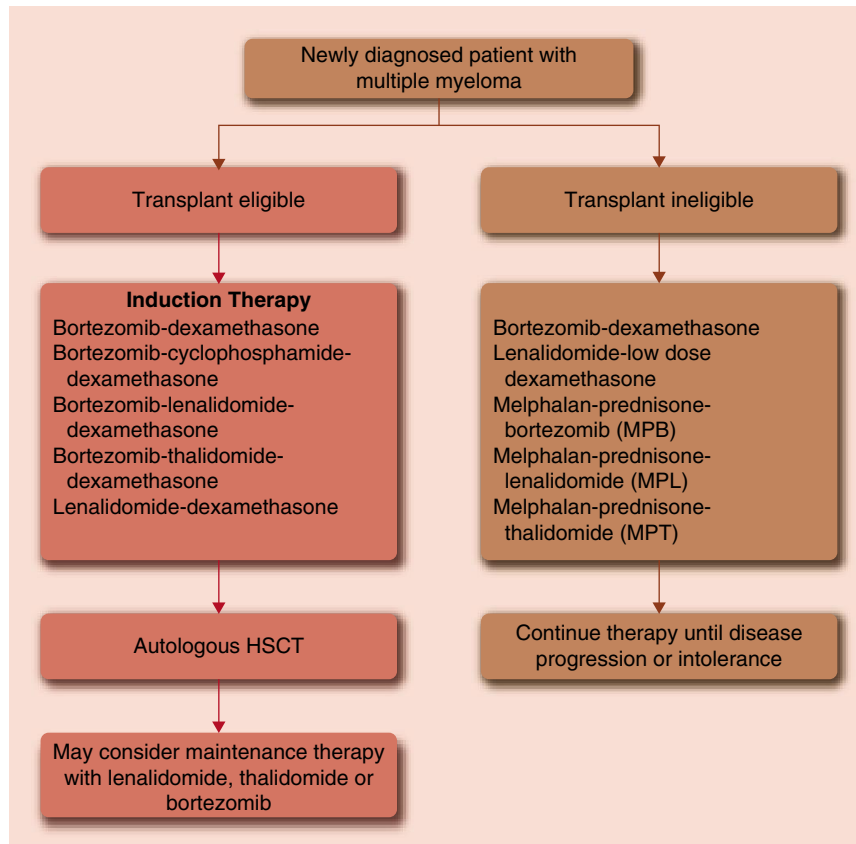
The primary goal in the treatment of MM is to prolong progression free and overall survival while minimizing complications associated with the disease. A watch and wait approach is an option for asymptomatic patients (smoldering myeloma) who have no lytic lesions in the bone. When symptoms occur, treatment is required. The treatment of MM often includes induction, transplantation, and maintenance therapy. All patients should be evaluated early on to see if they are transplant eligible candidates. Autologous stem cell transplantation prolongs overall survival in patients who can tolerate high-dose chemotherapy. Regardless of transplant eligibility, all patients will be placed on initial induction therapy to reduce tumor burden. Maintenance therapy following transplant with immunomodulators or proteasome inhibitors is being used to prolong the duration of response. Almost all patients become refractory to initial treatment and require the use of salvage therapies. **Figure 96–3**


**FIGURE 96–3.** Possible approach for treatment in newly diagnosed patients with multiple myeloma. (HSCT, hematopoietic stem cell transplantation.)

illustrates possible treatment approaches for transplant-eligible and transplant-ineligible patients.

## Nonpharmacologic Therapy

### ▶ Autologous Stem Cell Transplantation

**KEY CONCEPT** *Autologous stem cell transplantation results in higher response rates and extends progression-free survival compared with those who receive conventional chemotherapy.* Although these initial trials did not include the immunomodulators, stem cell transplant remains the standard of care and should be considered in all patients who can tolerate high-dose chemotherapy.[34–36] High-dose melphalan is the most common preparative regimen. Two sequential transplants (tandem transplants) improve overall survival in patients who do not have a good partial response after one transplant.[31] The use of maintenance therapy after autologous transplantation with lenalidomide or bortezomib may be used in select patients to extend progression-free survival.[34,35] Since the studies supporting the use of transplant were conducted prior to the development of many of the novel agents used in the treatment of myeloma; the future role of stem cell transplantation may evolve.

## Pharmacologic Therapy (Table 96–3)

Symptomatic MM requires treatment. There are five main classes of drugs used in the treatment of multiple myeloma: alkylating agents, anthracyclines, corticosteroids, immunomodulatory agents, and proteasome inhibitors. Drugs from these classes are used in combination and are the backbone for numerous chemotherapeutic regimens.

### ▶ Conventional-Dose Chemotherapy

The use of conventional-dose chemotherapy with alkylating agents or anthracyclines has declined with the advent of immunomodulators and proteasome inhibitors. The combination of melphalan and prednisone (MP) was once the most common initial treatment combination for myeloma. Today, melphalan-based therapy may be considered as initial therapy in transplant-ineligible patients.[34] Melphalan is toxic to progenitor cells and should be avoided in transplant eligible patients.[31,34] The anthracycline doxorubicin is also incorporated into treatment regimens. Currently, the combination of doxorubicin, bortezomib, and dexamethasone may be selected for induction therapy in patients who are transplant eligible. This regimen minimizes the risk of secondary malignancies that are associated with chronic alkylating therapy.[34]

### ▶ Immunomodulatory Drugs

**KEY CONCEPT** *Thalidomide (Thalomid), lenalidomide (Revlimid), and pomalidomide (Pomalyst) are used in the treatment of MM. Depending on the agent, they may be used as monotherapy or combination therapy.* The precise mechanism of action is unknown, but its antimyeloma activity may be attributable to its antiangiogenic and anticytokine properties.[37] Response rates are improved when an immunomodulatory agent is added to a treatment regimen. Thalidomide and steroid combinations produce

**Table 96–3**

**Drugs Used in Multiple Myeloma**

| Drug | Adverse Effects | Comments | Renal Dosing | Hepatic Dosing |
|---|---|---|---|---|
| Bortezomib (Velcade) | Constipation; decreased appetite; asthenia; fatigue; fever; thrombocytopenia; dose related, reversible peripheral neuropathy | Dose: 1.3 mg/m² IV bolus or SC twice weekly for 2 weeks; week 3 off; repeat Concentration for IV is 1mg/mL and 2.5mg/mL for SC Consider herpes zoster prophylaxis with daily acyclovir | No reductions | Bilirubin > 1.5 × the upper limit of normal: reduce dose to 0.7 mg/m² |
| Carfilzomib (Kyprolis) | Neutropenia, thrombocytopenia, cardiac toxicity including cardiac arrest, congestive heart failure, infusion-reactions, tumor lysis syndrome | Dose: 20 mg/m² IV bolus on days 1, 2, 8, 9, 16 and 16; days 17–28 off; repeat every 28 days Patients with a BSA greater than 2.2 m² should have dose calculated based on 2.2 m² Premedicate with dexamethasone 4 mg prior to reduce infusion-related reactions Hydration with normal saline prior to carfilzomib is recommended | No reductions | May need to dose reduce or hold dose depending on degree of hepatic dysfunction |
| Dexamethasone | Hyperglycemia, edema, adrenal cortical insufficiency | Dose given po once daily | No reductions | No reductions |
| Doxorubicin (Adriamycin) | Myelosuppression; alopecia; cumulative dose-limiting toxicity: myocardium damage | Given in combination with VAD | No reductions | Bilirubin 1.2–3 mg/dL (21–51 μmol/L): 50% reduction in dose Bilirubin 3.1–5 mg/dL (53–85 μmol/L): 75% reduction in dose Bilirubin > 5 mg/dL (85 μmol/L): use with caution |
| Lenalidomide (Revlimid) | Possible birth defects neutropenia, thrombocytopenia, DVT, PE, pruritus, fatigue | Dose: 25 mg taken with water once daily Women of childbearing age must use two forms of contraception Pregnancy test must be taken before and during use Enrollment into monitoring program required | CrCl 30–60 mL/min (0.50–1.00 mL/s): 10 mg/day CrCl < 30 mL/min (0.50 mL/s): 15 mg every 48 hours Dialysis and CrCl < 30 mL/min (0.50 mL/s): 5 mg every 24 hours given after dialysis | No reductions |
| Melphalan (Alkeran) | Myelosuppression, secondary malignancies, pulmonary fibrosis, sterility, alopecia | Dose given po once daily IV formulation used for stem cell transplantation | No recommendation but may consider an initial dose reduction | No reductions |
| Pomalidomide (Pomalyst) | Severe birth defects, DVT, neutropenia | Dose: 4 mg po daily on days 1–21; off 21–28 and repeat Drug metabolism: CYP 1A2 and 3A4 | Do not use if SCr > 3 mg/dL (265 μmol/L) | Do not use if bilirubin > 2 mg/dL (34 μmol/L) and AST/ALT > 3 × the upper limit of normal |
| Thalidomide (Thalomid) | Severe birth defects, peripheral neuropathy, DVT, somnolence, constipation | Titrate initial doses; doses are taken nightly Women of childbearing age must use two forms of contraception Pregnancy test must be taken before and during use Enrollment into monitoring program required | No reductions | No reductions |
| Vincristine (Oncovin) | Dose-limiting toxicity: peripheral neuropathies; paresthesias, constipation, alopecia | Given in combination with doxorubicin and dexamethasone (VAD) | No reductions | Bilirubin > 3 mg/dL (51 μmol/L): 50% reduction in dose |

DVT, deep venous thrombosis; IV, intravenous; PE, pulmonary embolism; po, oral; SC, subcutaneous; VAD, vincristine–dexamethasone.

responses in 60% to 80% of previously untreated patients.[31,34] Responses can be improved to 94% with the addition of a third agent, bortezomib, but adding a fourth agent does not further improve responses.[38,39] The addition of thalidomide to MP also improves overall response and overall survival in newly diagnosed patients.[40] This combination (MPT) can be used as initial therapy in patients who are not transplant eligible. Thalidomide is also used as maintenance therapy as an attempt to control disease posttransplant although the studies have not shown a consistent OS benefit.[41] Common side effects of thalidomide therapy include somnolence, constipation, peripheral neuropathy, and deep venous thrombosis (DVT). Standard dose warfarin

or low-molecular-weight heparins are recommended to prevent DVT.[34,42] There are substantial teratogenic effects of thalidomide if it is used during pregnancy, so distribution of the drug is closely monitored through the STEPS program.

Lenalidomide is more potent and has a more favorable safety profile over thalidomide.[34] The combination of lenalidomide, bortezomib, and dexamethasone has emerged as the one of the most commonly used induction regimens in the treatment of transplant-eligible patients with myeloma. Phase III trials showed that lenalidomide in combination with dexamethasone produced higher response rates and a longer time to progression than dexamethasone alone in relapsed and refractory

---

## Patient Care Process

### CHRONIC MYELOID LEUKEMIA

**Patient Assessment:**

- Review laboratory values and determine the stage of CML depending on the percent blasts in the peripheral blood or bone marrow.
- Review medical history, including patient's age, comorbid conditions and current medications to avoid drug–drug interactions.

**Therapy Evaluation:**

- If hematologic, cytogenetic and molecular goals are not achieved, determine whether a change in medication is warranted.
- If the patient experiences intolerance to therapy including any severe adverse effects, a change in medication may be warranted.
- Determine whether one of the first-line TKIs may be more cost-effective than the other agents.

**Care Plan Development:**

- Discuss the importance of medication adherence and long-term outcomes.
- Address any concerns about the selected medication including cost and management of adverse effects.

**Follow-up Evaluation:**

- TKI therapy should be frequently monitored. Follow-up may be scheduled every 3 months to determine whether goals of therapy are being met.
- Out of office follow up (ie, phone calls) may be helpful to reinforce the importance of adherence and to identify and manage any adverse effects.

### CHRONIC LYMPHOCYTIC LEUKEMIA

**Patient Assessment:**

- Review history of present illness, physical exams, and laboratory values to determine whether immediate treatment is necessary.

**Therapy Evaluation:**

- Depending on the therapy, assess efficacy, adverse effects, and patient adherence.
- If patients continue to have disease progression, another regimen may be utilized.

- Monitor WBC count and signs of infection if the patient is receiving aggressive chemoimmunotherapy.

**Care Plan Development:**

- Address any concerns about the selected medication including cost and management of adverse effects.
- Supportive care medication such as remedications for the prevention of infusion reactions, prophylactic trimethoprim–sulfamethoxazole and an antiviral (acyclovir, famciclovir, or valacyclovir) may be recommended for certain medications.

**Follow-up Evaluation:**

- Asymptomatic patients will be routinely follow-up to determine when they require treatment.
- Routine follow-ups during and postchemotherapy will be needed to assess treatment efficacy.

### MULTIPLE MYELOMA

**Patient Assessment:**

- Review medical history, including patient's age, comorbid conditions and current medications to determine whether the patient is transplant eligible.

**Therapy Evaluation:**

- If patients continue to have disease progression or have relapsed disease, another regimen may be utilized.
- Monitor myeloma monoclonal protein in urine and serum, renal function, hemoglobin, and platelets.
- Assess safety of medications including the monitoring of peripheral neuropathy. Dose reduction may be necessary to prevent permanent neurologic damage.
- Supportive care including bisphosphonates, pain medications and prophylactic anticoagulation may be required depending on the medication selected.

**Care Plan Development:**

- Discuss the importance of medication adherence if oral therapy is chosen.

**Follow-up Evaluation:**

- Frequent follow-up is needed to determine efficacy or if another regimen should be used.
- Maintenance therapy posttransplantation requires additional follow-up and monitoring of adverse effects.

myeloma.[34,43] Low-dose dexamethasone with lenalidomide offers improved overall survival compared with high-dose dexamethasone.[43] The combination of melphalan, prednisone, and lenalidomide (MPL) may be used as initial therapy in transplant ineligible patients. The response rate appears to be quite high at 81% with 24% achieving a CR.[44] Lenalidomide lacks many of the common side effects seen with thalidomide. Significant adverse effects of lenalidomide include myelosuppression and DVTs. DVT prophylaxis is recommended with lenalidomide–dexamethasone combinations.[34,42] Stem cells should be collected shortly after starting lenalidomide because CD34-positive stem cell counts tend to decrease with prolonged lenalidomide exposure.[34] Maintenance lenalidomide after stem cell transplantation has been associated with an increase in progression free survival, however, with an increase in the incidence of secondary malignancies.[34]

Pomalidomide is the newest immunomodulatory agent used in the treatment of refractory or progressive MM. It was shown to increase PFS and OS when used in combination with dexamethasone in patients that were refractory to bortezomib and lenalidomide.[45] Adverse effects for pomalidomide include myelosuppression and an increase in infections.

▶ *Proteasome Inhibitors*

Bortezomib (Velcade) and carfilzomib (Kyprolis) are **proteosome** inhibitors approved for the treatment of MM. Proteosome inhibitors induce myeloma cell death by modulating **nuclear factor kappa-B** products, including inflammatory cytokines and adhesion molecules that support myeloma cell growth. These drugs also disrupt the myeloma microenvironment by inhibiting the binding of myeloma cells to the bone marrow stromal cells.[31] **KEY CONCEPT** *Bortezomib-based regimens are frequently used as induction therapy in transplant-eligible patients.* The response rates have been reported as high as 97% in newly diagnosed myeloma.[30] Bortezomib can also be given in combination with a corticosteroid and melphalan (MPB) in patients who are not transplant eligible. Superior response rates and survival are seen with the combination MPB compared MP.[44] Side effects of bortezomib include fatigue, nausea, peripheral neuropathy, and hematologic effects.[44] The incidence of DVT is lower than the immunomodulators; thus, bortezomib does not routinely require prophylactic anticoagulation. However, prophylactic acyclovir should be considered to reduce the risk of herpes zoster reactivations.[34] Carfilzomib is a newer second-generation proteasome inhibitor that is used in the treatment of refractory MM. Studies are also examining carfilzomib as primary therapy in combination regimens with an immunomodulator and dexamethasone.[46]

▶ *Bisphosphonates*

Bone disease is a common manifestation of MM. Bisphosphonates should be initiated in symptomatic patients with bone lesions to slow osteopenia and reduce the fracture risk associated with the disease. Pamidronate 90 mg and zolendronic acid 4 mg have equivalent efficacy in the management of osteolytic lesions.[47] The use of zolendronic acid decreases pain and bone-related complications and improves quality of life. Osteonecrosis of the jaw is a major concern with bisphosphonate therapy. Risk factors are unclear, but osteonecrosis of the jaw is more common in patients receiving IV administration of bisphosphonates and having dental procedures performed. It is recommended that patients have dental restoration work before starting bisphosphonate therapy. Several consensus guidelines have been published on the use of bisphosphonates and myeloma. Recommendations on the duration of therapy and which bisphosphonate to use have largely been left up to the practitioner.[34,48]

## OUTCOME EVALUATION

Newly diagnosed, asymptomatic patients with MM may be observed without treatment. This asymptomatic period may last for months to a couple years. All patients with MM become symptomatic, and when this occurs, treatment is required. All patients should be evaluated for an autologous stem cell transplant. For patients who are eligible for transplant, induction therapy often consists of thalidomide or lenalidomide, bortezomib, and dexamethasone. Maintenance therapy with an immunomodulatory agent may be used posttransplant. There are numerous treatment options for transplant ineligible patients including MPT, MPB, or MPL. Nearly all patients progress at some point, and second-line therapy usually includes bortezomib. Monthly bisphosphonates should be given to patients who have bone lesions with the hope of reducing pain and fractures.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| CLL | Chronic lymphocytic leukemia |
| CML | Chronic myelogenous leukemia |
| CR | Complete response |
| DVT | Deep venous thrombosis |
| FISH | Fluorescence in situ hybridization |
| HSCT | Hematopoietic stem cell transplantation |
| MGUS | Monoclonal gammopathy of unknown significance |
| MP | Melphalan–prednisone |
| MPB | Melphalan–prednisone–bortezomib |
| MPL | Melphalan–prednisone–lenalidomide |
| MPT | Melphalan–prednisone–thalidomide |
| Ph | Philadelphia chromosome |
| Q-PCR | Qualitative and quantitative polymerase chain reaction |
| TKI | Tyrosine kinase inhibitor |
| WBC | White blood cell |

# Malignant Lymphomas

Keith A. Hecht and Susanne E. Liewer

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Discuss the underlying pathophysiologic mechanisms of the lymphomas and how they relate to presenting symptoms of the disease.

2. Differentiate the pathologic findings of Hodgkin lymphoma (HL), follicular indolent non-Hodgkin lymphoma (NHL), and diffuse aggressive NHL and how this information yields a specific diagnosis.

3. Describe the general staging criteria for the lymphomas and how it relates to prognosis; evaluate the role of the prognostic systems such as the International Prognostic Score for HL, the Follicular Lymphoma International Prognostic Index, and the International Prognostic Index for diffuse, aggressive NHL.

4. Compare and contrast the treatment algorithms for early and advanced stage disease for HL.

5. Delineate the clinical course of follicular indolent and diffuse aggressive NHL and the implications for disease classification schemes and treatment goals.

6. Outline the general treatment approach to follicular indolent and diffuse aggressive NHL for localized and advanced disease.

7. Interpret the current role for monoclonal antibody therapy in NHL.

8. Assess the role of autologous hematopoietic stem cell transplantation for relapsed lymphomas.

## INTRODUCTION

The malignant lymphomas are a clonal disorder of hematopoiesis with the primary malignant cells consisting of lymphocytes of B-, T-, or natural killer (NK) cell origin. Lymphoma cells predominate in the lymph nodes; however, they can infiltrate lymphoid and nonlymphoid tissues, such as the bone marrow, central nervous system (CNS), gastrointestinal (GI) tract, liver, mediastinum, skin, and spleen. An overview of the lymph node regions is depicted in **Figure 97–1**. KEY CONCEPT *There are two broad classifications of lymphoma, Hodgkin lymphoma (HL) and non-Hodgkin lymphoma (NHL), and both contain numerous histologic subtypes that are pathologically distinct disease entities.*

The clinical course varies widely among histologies of lymphoma. More aggressive lymphoma subtypes are highly proliferating tumor cells that require aggressive therapeutic intervention with chemotherapy, radiation therapy, or both. By contrast, certain subtypes of NHL are characterized by a disease course that flares and remits intermittently over a period of years regardless of treatment.

## HODGKIN LYMPHOMA

### EPIDEMIOLOGY AND ETIOLOGY

Approximately 9050 new cases of HL were estimated to be diagnosed in the United States in 2015, with 1150 deaths attributed to the disease.[1] The incidence of HL is bimodal, with its peaks occurring in the third decade of life and in patients older than 50 years of age.[2] The precise cause of HL is unknown, but certain associations have been reported and provide insight about possible etiologic factors. Epstein-Barr virus (EBV) has been associated with HL, its viral genome is detected in Reed-Sternberg (RS) cells in up to 40% of cases in developed countries. Other viruses (cytomegalovirus, human herpes viruses, HIV, and adenoviruses) have been associated with HL; however, data is conflicting.[2] Other possible risk factors identified include woodworking and a familial history of HL.

## PATHOPHYSIOLOGY

Pluripotent stem cells in the bone marrow are able to differentiate to both lymphoid and myeloid progenitor cells. Lymphoid progenitor cells undergo normal gene rearrangement to yield either B-cell or T-cell lineage precursor cells. Normal maturation for naive B cells includes expression of cell surface antibody or the cells typically undergo **apoptosis**. These cells are differentiated from other B cells, such as memory cells, by virtue of cell surface antigen (CD5$^+$ or CD5$^-$ and CD27$^-$) and bound antibody (IgM+ and IgD+). When naive B cells recognize antigen with their cell surface antibody, they accumulate in the lymph nodes, spleen, or other lymphoid tissue. The DNA of these B cells is susceptible to three different types of genetic modification: **receptor editing, somatic hypermutation,** and class switching within the germinal center of the lymph node. Germinal centers are microanatomic structures located within lymph nodes that develop

**WHO Classification of Lymphoid Neoplasms**

**B-Cell Neoplasms**
Precursor B-cell neoplasm
Precursor B-lymphoblastic leukemia/lymphoma
Mature (peripheral) B-cell neoplasms
B-cell chronic lymphocytic leukemia/small lymphocytic lymphoma
B-cell prolymphocytic leukemia
Lymphoplasmacytic lymphoma
Splenic marginal zone B-cell lymphoma (+/– villous lymphocytes)
Hairy cell leukemia
Plasma cell myeloma/plasmacytoma
Extranodal marginal zone B-cell lymphoma of MALT type
Nodal marginal zone B-cell lymphoma (+/– monocytoid B cells)
Follicular lymphoma
Mantle cell lymphoma
Diffuse large B-cell lymphoma
Mediastinal large B-cell lymphoma
Primary effusion lymphoma
Burkitt lymphoma/Burkitt cell leukemia

**T-Cell and NK-Cell Neoplasms**
Precursor T-cell neoplasm
Precursor T-lymphoblastic lymphoma/ALL
Mature (peripheral) T-cell neoplasms
T-cell prolymphocytic leukemia
T-cell granular lymphocytic leukemia
Aggressive NK cell leukemia
Adult T-cell lymphoma/leukemia (HTLV1+)
Extranodal NK/T-cell lymphoma, nasal type
Enteropathy-type T-cell lymphoma
Hepatosplenic gamma-delta T-cell lymphoma
Subcutaneous panniculitis-like T-cell lymphoma
Mycosis fungoides/Sézary syndrome
Anaplastic large-cell lymphoma, T/null cell, primary cutaneous type
Peripheral T-cell lymphoma, not otherwise characterized
Angioimmunoblastic T-cell lymphoma
Anaplastic large-cell lymphoma, T/null cell, primary systemic type

**HL**
Nodular lymphocyte-predominant HL
Classical HL
    Nodular sclerosis HL
    Lymphocyte-rich classical HL
    Mixed cellularity HL
    Lymphocyte depletion HL

ALL, acute myeloid leukemia; HL, Hodgkin lymphoma;

MALT, mucosa-associated lymphoid tissue; NK, natural killer.

with clonal B-cell expansion secondary to antigen stimulation. Under normal circumstances, these genetic changes allow for adaptation of the immune system to the repeated exposure to environmental antigens.

The pathophysiology of HL is defined by the presence of the RS cell in a grouping of lymph nodes. The RS cell is a morphologically large cell with a multinucleated structure possessing pronounced eosinophilic nucleoli, thought to be B- cell in origin.[3] In the affected lymph nodes, the RS cells are contained within an inflammatory background that is believed to be essential for their survival.

RS cells have lost the expression of most B-cell markers. Common cell-surface antigens expressed by RS cells include CD30 and CD15, but other common B-cell antigens, such as CD20 are inconsistently expressed.[4] The Janus kinase-signal transduction and transcription (JAK-STAT) signaling pathway has also been found to be active in HL. Additionally, the overexpression of nuclear factor kappa-B (NF-κB), a proliferative and antiapoptotic transcription factor nuclear factor is believed to contribute to the expansion and survival of RS cells.[5]

HL is classified into disease subtypes based on the number and morphologic appearance of RS cells and the background cellular milieu. These are listed in the World Health Organization (WHO) classification of lymphoid neoplastic diseases in Table 97–1.[6] Nodular sclerosing (70%) is the most common

form of HL. It is more common in young adults and is marked by the presence of the RS variant cell, the lacunar cell. The second most common form of HL is the mixed-cellularity variant (20%), with others accounting for the remainder of cases.[4] Factors identified as negative disease prognostic indicators are listed in Table 97–2.

## TREATMENT OF HL
### Desired Outcome

Staging of HL with a standard classification is necessary to guide treatment. The extent and location of involvement, localized or disseminated extranodal disease, and B symptoms are factors in assignment of stage. The Cotswold staging system,

## Table 97–2

**Negative Prognostic Factors for HL**

**International Prognostic Score—Advanced HL**
Albumin < 4 g/dL (40 g/L)
Hemoglobin < 10.5 g/dL (105 g/L; 6.52 mmol/L)
Male sex
Age > 45 years
Stage IV disease
WBC ≥ 15,000/mm³ (15 × 10⁹/L)
Lymphocytopenia (count < 600/mm³ [0.6 × 10⁹/L], < 8% [0.08] of WBC count, or both)

WBC, white blood cell.

a revision of the original Ann Arbor classification, is outlined in **Table 97–3**.[7]

**KEY CONCEPT** *The principal goal in treating HL is to cure the patient of the primary malignancy.* HL is sensitive to both radiation and chemotherapy, resulting in an 80% rate of cure with modern therapy. Treatment strategy is generally divided into approaches for early stage I/II localized disease and stage III/IV advanced disease. Patients with early stage I/II disease are further classified into favorable, unfavorable with bulky disease, and unfavorable with nonbulky disease. Regardless of stage, all patients are treated with curative intent. Other goals during treatment include:

- Complete resolution of disease symptoms
- Incorporation of supportive care measures to optimize quality of life during therapy
- Minimization of acute and long-term treatment-related toxicity

## Table 97–3

**Cotswold Staging Classification for Hodgkin Disease (1989 Revision of Ann Arbor Staging)[a]**

| Stage | Description |
|---|---|
| I | Involvement of a single lymph node region or lymphoid structure (eg, spleen, thymus, Waldeyer ring) |
| II | Involvement of two or more lymph node regions on the same side of the diaphragm; the number of anatomic sites is indicated by a subscript |
| III | Involvement of lymph node regions or structure on both sides of the diaphragm<br>$III_1$: With or without involvement of splenic, hilar, celiac, or portal nodes<br>$III_2$: Involvement of para-aortic, iliac, or mesenteric |
| IV | Involvement of extranodal site(s) beyond that designated E |
| **Designations Applicable to All Stages** | |
| A | No symptoms |
| B | Fever, night sweats, and weight loss |
| X | Bulky disease: greater than one-third the width of the mediastinum or > 10 cm maximal dimension of nodal mass |
| E | Involvement of a single extranodal site, contiguous or proximal to a known nodal site |
| CS | Clinical stage |
| PS | Pathologic stage |

[a]Also used for non-Hodgkin lymphoma.

## Clinical Presentation and Diagnosis of Malignant Lymphomas

**General**

Nonspecific; can range from an asymptomatic patient with a less aggressive lymphoma to a patient who is gravely ill with advanced disease.

**KEY CONCEPT** **Symptoms**

- *Lymphadenopathy, generally in the cervical, axillary, supraclavicular, or inguinal lymph nodes*
- *Splenomegaly*
- *Shortness of breath, dry cough, chest pressure (patients with mediastinal mass)*
- *GI complications (nausea, vomiting, early satiety, constipation, and diarrhea)*
- *Back, chest, or abdominal pain*

**Signs**

- Fever[a]
- Night sweats[a]
- Weight loss greater than 10% within last 6 months[a]
- Pruritus

**Laboratory Tests**

- LDH
- ESR
- Serum chemistries
- CBC with differential

**KEY CONCEPT** **Other Diagnostic Tests**

- *Physical examination with careful attention to lymph node inspection.*
- *Imaging—chest x-ray, chest CT, abdominal or pelvic CT; integrated PET and CT is recommended as part of the initial workup.*
- *Bone marrow biopsy.*
- *Biopsy of suspected lymph node(s)—either open lymph node biopsy (preferred) or core biopsy; fine-needle aspiration should only be performed if preferred biopsy methods are unobtainable.*
- *Hematopathology evaluation of biopsy specimen—morphologic inspection, immunohistochemistry for cell surface antigens to characterize lymphoma cells, cytogenetic analysis.*

[a]Known collectively as B symptoms.

CBC, complete blood count; CT, computed tomography; ESR, erythroid sedimentation rate; LDH, lactate dehydrogenase; PET, positron emission tomography.

## Patient Encounter, Part 1: Initial Evaluation

A 52-year-old woman with a medical history of hypertension and hypothyroidism presents to the oncologist upon recommendation of her primary care provider for suspicion of new onset lymphoma. She was in her usual state of health until 2 months ago when she started experiencing fevers and night seats. Upon physical examination the oncologist notes palpable lymph nodes in the left and right inguinal areas as well as the right axilla area. The patient reports that she has reduced exercise tolerance but no other impairments of his activities of daily living. Complete blood count revealed a WBC of 16, 000/mm³ (16 × 10⁹/L), hemoglobin of 9 g/dL (90 g/L; 5.59 mmol/L) and platelets were 165,000/mm³ (165 × 10⁹/L). The chemistry panel was unremarkable.

*What tests should be performed to confirm a diagnosis of lymphoma and determine its overall stage?*

*Based on the information provided, what is her International Prognostic Score, and how does it impact treatment selection?*

### Nonpharmacologic Therapy

Radiation therapy is effective in the treatment of HL and has cured patients of their disease. Historically, patients with favorable early stage I/II disease were treated with radiation alone. However, long-term toxicities associated with this practice have precluded this approach. Current treatment strategies combine radiation with chemotherapy. This has been reported to reduce the irradiated volume and dose as well as the number of cycles of chemotherapy.

Historically in the treatment of HL, the radiation fields were large and often included the lungs, liver, heart, and breast. Today, the use of involved-field radiotherapy (IFRT) limits radiation to the involved area. In addition to the smaller radiation volumes, other organs such as the breast, heart, and lungs have reduced exposure.[8]

Treatment with radiotherapy produces significant toxicity of acute and delayed onset. Acute effects of irradiation include nausea, vomiting, anorexia, xerostomia, dysgeusia, pharyngitis, dry cough, fatigue, diarrhea, and rash. These effects are typically transient, resolving shortly after completion of treatment. Delayed effects from radiotherapy are concerning in as they may be permanent and present months to years after therapy. Pneumonitis, pericarditis, hypothyroidism, infertility (with pelvic field irradiation), coronary artery disease, deformities in bone and muscle growth in children, herpes zoster reactivation, and Lhermitte sign are not uncommon. Patients cured with radiotherapy are at increased risk for new cancers of the breast, lung, and stomach, as well as melanoma and new NHL, depending on the radiation field.

### Pharmacologic Therapy

▶ *Early Stage Disease*

KEY CONCEPT *Initial treatment of HL includes combination chemotherapy, these regimens are effective and have acceptable long-term toxicities.* Combined modality therapy of two to four cycles ABVD (doxorubicin, bleomycin, vinblastine, and dacarbazine) plus 20 to 30 Gy (Gray, the absorbed radiation dose) of IFRT or two cycles Stanford V chemotherapy plus 30 Gy of IRFT is the preferred treatment of patients with favorable stage I/II HL. Patients with favorable disease have:

an erythrocyte sedimentation rate less than 50 mm/hour, no extralymphatic lesions, and one or two lymph nodes involved. Restaging should occur after a minimum of two cycles of chemotherapy. IFRT should be initiated within 3 weeks for patients who achieve a complete response (CR) or a partial response (PR). After completion of IFRT, no further treatment is necessary for patients with a CR, further restaging is required for patients with PR to therapy.

ABVD or Stanford V followed by IFRT is recommended for patients with unfavorable, bulky disease. Four cycles of ABVD are given before restaging. For patients with a CR, IFRT is administered alone or in combination with two more cycles of ABVD. Patients with a PR will receive two additional cycles of chemotherapy. If there is response, patients then receive IFRT followed by end of treatment assessment to determine disease response. Patients with unfavorable, nonbulky disease receive ABVD for two cycles followed by interim staging. Two to four more cycles are recommended guided by the response to chemotherapy. The use of the Stanford V regimen should be considered for patients with mediastinal disease, bulky disease, B symptoms, or unfavorable nonbulky disease.[9] A listing of chemotherapy regimens used in HL is presented in Table 97–4.

## Table 97–4

**Common Treatment Regimens in HL**

**MOPP—Every 28 Days**
Mechlorethamine 6 m/m² IV × 1, days 1 and 8
Vincristine 1.4 mg/m² IV × 1, days 1 and 8
Procarbazine 100 mg/day po, days 1–14
Prednisone 40 mg/day po, days 1–14

**ABVD—Every 28 Days**
Doxorubicin 25 mg/m² IV × 1, days 1 and 15
Bleomycin 10 units IV × 1, days 1 and 15
Vinblastine 6 mg/m² × 1, days 1 and 15
Dacarbazine 375 mg/m² IV × 1, days 1 and 15

**Stanford V**
Doxorubicin 25 mg/m² IV weeks 1, 3, 5, 7, 9, and 11
Vinblastine 6 mg/m² IV weeks 1, 3, 5, 7, 9, and 11
Mechlorethamine 6 mg/m² IV weeks 1, 5, and 9
Etoposide 60 mg/m² IV weeks 3, 7, and 11
Vincristine 1.4 mg/m² IV weeks 2, 4, 6, 8, 10, and 12
Bleomycin 5 mg/m² IV weeks 2, 4, 6, and 8
Prednisone 40 mg po every other day for 12 weeks, start taper at week 10

**BEACOPP (Escalated)—Every 21 Days**
Bleomycin 10 mg/m² IV, day 8
Etoposide 200 mg/m² IV daily × days 1–3
Doxorubicin 35 mg/m², day 1
Cyclophosphamide 1200 mg/m² IV, day 1
Vincristine 1.4 mg/m² IV, day 8
Procarbazine 100 mg/m² po daily, days 1–7
Prednisone 40 mg po daily, days 1–14

**BEAM (High-Dose With Autologous SCT)a**
Carmustine 300 mg/m² IV × 1 day
Etoposide 100–200 mg/m² IV every 12 hours × 4 days
Cytarabine 100–200 mg/m² IV every 12 hours × 4 day
Melphalan 140 mg/m² IV × 1 day

aUsed for both Hodgkin lymphoma and non-Hodgkin lymphoma.

IV, intravenous; po, oral; SCT, stem cell transplantation.

### ▶ Advanced Disease

Patients with advanced disease can be further classified into two groups based on IPS. (see Table 97–2) Patients with three or fewer poor prognostic factors are considered to have favorable disease while patients with four or more factors have unfavorable disease. Patients who have at least four of the criteria may warrant more aggressive treatment.

Trials have focused on the use of multiagent chemotherapy for six to eight total cycles. The combination chemotherapy regimen MOPP (mechlorethamine, vincristine, procarbazine, and prednisone) is of historical significance because it was the first chemotherapy regimen to cure HL in the 1960s. However, significant toxicity, including sterility and secondary leukemia led to the development of new regimens. ABVD was compared with MOPP or ABVD–MOPP alternating.[10] This pivotal phase III trial comparing these regimens in patients with stage III/IV HL documented a higher CR in the ABVD arms. A recent update of the data shows superior 18-year freedom from progression in the ABVD arms compared to MOPP though a survival advantage has yet to be demonstrated.[11] ABVD is now considered standard therapy for initial treatment of stage III or IV HL. Further information on ABVD may be found in Table 97–5.

Additional regimens such as Stanford V and BEACOPP were developed to improve the outcomes of patients with advanced HL. Except in patients with high risk disease (IPS greater than 3) the Stanford V regimen has demonstrated similar response rates to ABVD reported for event-free survival, overall survival, and toxicity.[12] A dose-escalated regimen of BEACOPP (with colony-stimulating factor [CSF] support) was compared with a standard-dose BEACOPP and also COPP (cyclophosphamide substituted for mechlorethamine in MOPP) alternating with ABVD. The dose-escalated BEACOPP was superior to the other arms in both freedom from treatment failure and overall survival at 10 years.[13] However, the escalated BEACOPP regimen is associated with more toxicity including infertility and more cases of secondary leukemia. Currently, neither BEACOPP regimen is widely used in the United States but is considered for advanced HL with a high number of poor prognostic factors.

Despite the high success rate in treating HL, approximately 5% to 10% of patients will be refractory to initial treatment and 10% to 30% will relapse after initial response. Patients relapsing after treatment should be offered additional therapy as durable responses have been reported. The duration of remission after chemotherapy remains a vital prognostic factor for likelihood of response to future treatment.[14] For healthy patients, the definitive therapy after relapse is high-dose chemotherapy with autologous stem cell transplantation (SCT).[15] This treatment offers a cure rate of approximately 40%.

Several studies have reported the importance of giving conventional chemotherapy before SCT. The purpose of the initial treatment after relapse is to decrease the tumor bulk before high-dose chemotherapy. The safety profile of autologous SCT continues to improve as refinements in supportive care are realized. Current estimates of mortality from autologous SCT for HL are approximately 5%. Morbidity commonly associated with preparative regimens in HL, aside from infectious and bleeding complications, includes the additive pulmonary toxicity of bleomycin coupled with carmustine, inducing potentially fatal pulmonary pneumonitis.

Patients who are not candidates for autologous SCT may receive standard salvage chemotherapy, such as etoposide, methylprednisolone, cytarabine, and cisplatin (ESHAP) or dexamethasone, cytarabine, and cisplatin (DHAP). Newer regimens such as GVD (gemcitabine, vinorelbine, and pegylated liposomal doxorubicin), IGEV (ifosfamide, gemcitabine, and vinorelbine) and GCD (gemcitabine, carboplatin, and dexamethasone) have also been effective for relapsed refractory HL. Brentuximab vedotin is a monoclonal antibody approved for the treatment of relapsed or refractory HL. It targets CD-30 and is linked to a microtubule-disrupting agent, monomethylauristatin E.[16] This agent has been effective in heavily pretreated HL patients. Clinical trials are currently ongoing to further define the role of brentuximab.

## NON-HODGKIN LYMPHOMA

### EPIDEMIOLOGY AND ETIOLOGY

Approximately 71850 cases of NHL were estimated to be diagnosed in the United States in 2015, with an estimated 19,790 deaths. These figures represent a stabilization in the incidence of

---

**Table 97–5**

**Practical Information for ABVD and CHOP**

| Regimen | Drug Class | Pharmacokinetics | Unique Toxicities |
|---|---|---|---|
| **ABVD** | | | |
| Doxorubicin | Anthracycline | Hepatic metabolism[a] | Highly emetogenic<br>Cardiomyopathy<br>Maximum cummulative lifetime dose, 550 mg/m$^2$ |
| Bleomycin | Antitumor antibiotic | Renal clearance[a] | Pulmonary fibrosis<br>Maximum cummulative lifetime dose, 400 mg |

[a]See dose adjustments (Chapter 88).

NHL since 1998 that follows a dramatic increase that had nearly doubled the number of cases in the United States since 1950.[2,17] The increase may be related to the development of aggressive NHL in patients with HIV, although the overall increase is independent of HIV disease, particularly for patients older than 65 years of age. The median age for diagnosis is 50 years, although children and young adults may also be affected. The etiology of certain aggressive NHL subtypes is related to specific endemic geographic factors. Follicular or low-grade lymphoma is more common in the United States and Europe and is relatively uncommon in the Caribbean, Far East, Middle East, or Africa. The human T-cell leukemia virus I induces T-cell lymphoma or leukemia in both Japan and the Caribbean. Human herpes virus 8, and hepatitis C have been implicated in inducing NHL. Lymphomas of the GI tract are more prevalent in patients with celiac sprue, inflammatory bowel disease, or *Helicobacter pylori* infection. The incidence of Burkitt NHL is 7 cases per 100,000 people in Africa compared with 0.1 per 100,000 in the United States. Malaria or EBV is thought to contribute to the chronic B-lymphocyte stimulation that leads to malignant transformation in Burkitt NHL. EBV has been shown to transform lymphocytes in vitro to a monoclonal malignant population, which is believed to drive the development of disease in patients who are in a chronically immunosuppressed state. Patients with congenital diseases such as Wiskott-Aldrich syndrome, common variable hypogammaglobinemia; X-linked lymphoproliferative syndrome.[18] Environmental factors have been identified as contributing to the development of NHL. Certain occupations such as wood and forestry workers, butchers, exterminators, grain millers, machinists, mechanics, painters, printers, and industrial workers have a higher prevalence of disease. Industrial chemicals such as pesticides, herbicides, organic chemicals (eg, benzene), solvents, and wood preservatives are also associated with NHL.

## PATHOPHYSIOLOGY

The pathophysiology of NHL is governed by numerous environmental and genetic events culminating with a monoclonal population of malignant lymphocytes. B cells represent the cells of origin in excess of 90% of cases. **Figure 97–2** outlines normal B-cell

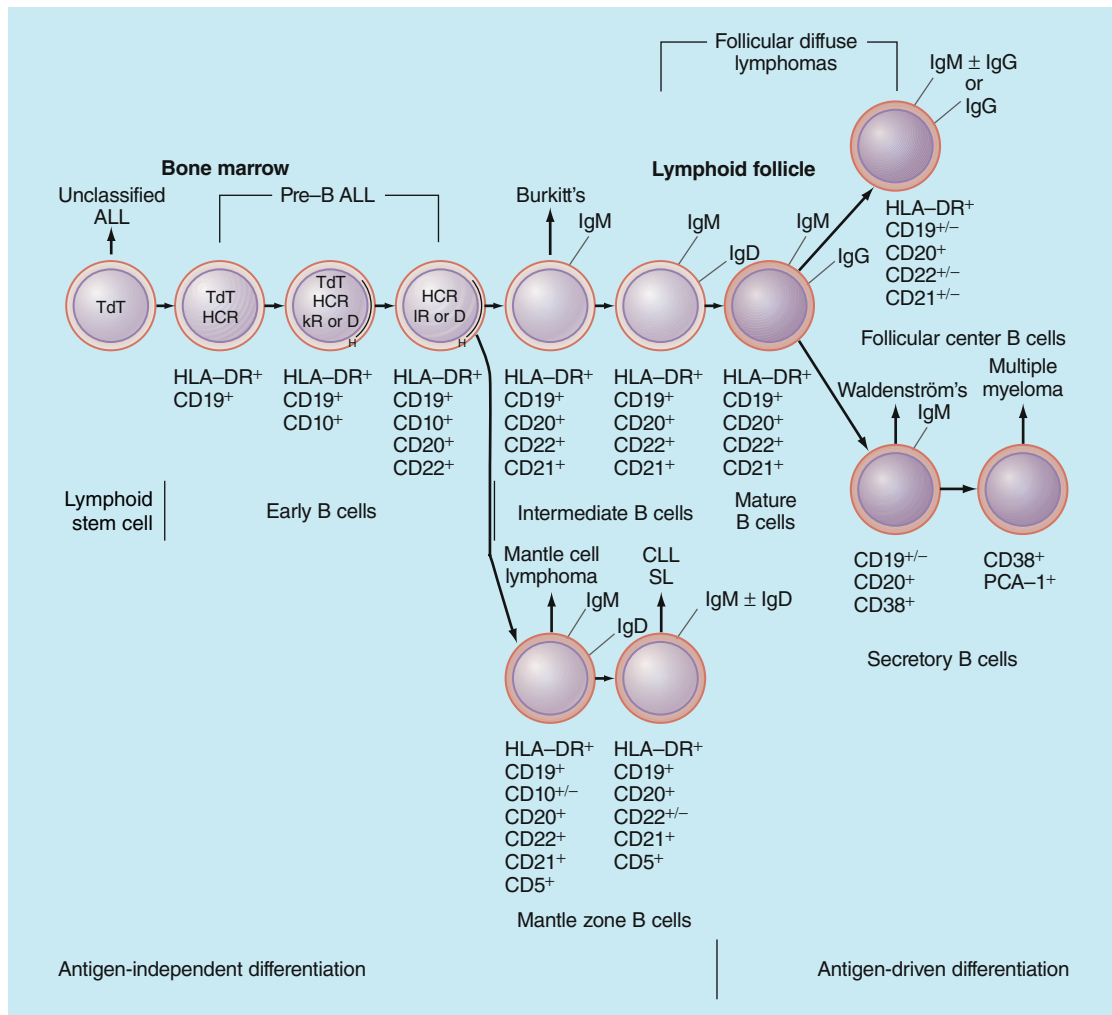

**FIGURE 97–2.** Pathway of normal B-cell differentiation and relationship to B-cell lymphocytes. (ALL, acute lymphoblastic leukemia; HLA, human leukocyte antigen; HCR, human chemokine receptor; Ig, immunoglobulin; TdT, terminal deoxynucleotidyl transferase.) (From Longo DL. Longo D.L. Chapter 110. Malignancies of Lymphoid Cells. In: Longo DL, Fauci AS, Kasper DL, Hauser SL, Jameson J, Loscalzo J. Longo D.L., Fauci A.S., Kasper D.L., Hauser S.L., Jameson J, Loscalzo J eds. *Harrison's Principles of Internal Medicine, 18e.* New York, NY: McGraw-Hill; 2012.)

maturation with accompanying cell-surface antigens. Evolving data are correlating chromosomal mutations with specific disease subtypes. Cytogenetic abnormalities involving translocations of antigen receptor genes are prevalent in NHL. These include T-cell receptor genes in T-cell lymphomas and immunoglobulin genes in B-cell lymphomas. The principal defect appears to be an error in the assembly of the regulatory gene segment of an antigen receptor gene, resulting in inappropriate binding to an oncogene. This results in dysregulation of cell growth and proliferation, leading to the malignant clone of lymphocytes. Oncogenes identified in different lymphomatous diseases include *c-myc, bcl-1, bcl-2, bcl-3, NF-κB,* and *bcl-6.*[19] Classic translocations for NHL include t(8;14) in Burkitt lymphoma, t(14;18) in follicular lymphomas, t(11;14) mantle cell lymphoma, and t(11;18)/t(1;14) in mucosa-associated lymphoid tissue (MALT).

KEY CONCEPT *Characterization of the morphology of the lymphocytes, the reactivity of the other cells in the lymph node, and the lymph node architecture are essential in obtaining a diagnosis and predicting disease course.* The nodal presentation of NHL is divided into two main categories: follicular, corresponding to low-grade disease, and diffuse, corresponding to aggressive disease. A follicular disease pattern in the inspected lymph node is indicative of a more indolent or low-grade progression that has survival measured in years if left untreated. In contrast, a diffuse pattern of lymph node infiltration is a marker of highly aggressive disease, resulting in death within weeks to months if untreated. Follicular NHL is the most common indolent subtype, comprising 22% of NHL. Diffuse, large B-cell lymphoma is the most common aggressive histology, comprising 31% of NHL. The cells of origin for follicular NHL tend to be more mature, nondividing lymphocytes, whereas aggressive NHL is derived from rapidly dividing lymphoid precursors. A unique feature of the biology of NHL is that follicular low-grade histologies can undergo further malignant transformation, transforming further into a diffuse, large B-cell lymphoma population. This syndrome, called Richter transformation, may occur in up to 20% of follicular low-grade lymphoma patients and involves multiple genetic events, including abnormalities of chromosomes 11 and 12 and tumor suppressor genes. Richter transformation may also occur in patients with chronic lymphocytic leukemia, which results in a transformation to diffuse lymphoma.[20]

The classification of NHL has undergone several revisions as the histology, molecular biology, and clinical course have been more precisely defined. Classification schemes such as the Working Formulation categorize disease on aggressiveness into three categories: low grade—survival estimated in years without treatment, intermediate grade—survival estimated in months without treatment, and high grade—survival measured in days to weeks for untreated disease (Table 97–6). This scheme is limited in its clinical applicability because the large number of distinct diseases that are not categorized by this classification. The WHO has updated a classification scheme published in 1994 by the International Lymphoma Study Group called the *Revised European American Classification of Lymphoid Neoplasms* (REAL) that broadly categorizes histologic subtypes into B- and T-cell subtypes. This newer classification incorporates immunologic morphologic and genetic and clinical attributes of various NHL histologies.

Prognostic factors present at diagnosis have been identified for NHL. Age, the presence of B symptoms, performance status, number of nodal and extranodal sites, lactate dehydrogenase level, bulky disease (greater than 10 cm), advanced stage, and $\beta_2$-microglobulin concentration have been shown to be important prognostic features in NHL. Table 97–7 shows the International

| Table 97–6 | |
|---|---|
| **Working Formulation for NHL** | |
| **Classification** | **Immunophenotype** |
| **Low Grade** | |
| Small lymphocytic | 100% B cell |
| Follicular, small cleaved cell | 100% B cell |
| Follicular, mixed small cleaved cell and large cell | 100% B cell |
| **Intermediate Grade** | |
| Follicular, large cell | 100% B cell |
| Diffuse, small cleaved cell | 75% B cell, 20% T cell, 5% null cell |
| Diffuse, mixed small and large cell | 75% B cell, 20% T cell, 5% null cell |
| Diffuse, large cell | 70% B cell, 20% T cell, 10% null cell |
| Diffuse, large cell | 70% B cell, 20% T cell, 10% null cell |
| **High Grade** | |
| Immunoblastic | 50% B cell, 50% T cell |
| Lymphoblastic | 5% B cell, 95% T cell |
| Diffuse, small noncleaved cell | 100% B cell |

<sup>a</sup>Lymphomas not included in the working formulation: *Mycosis fungoides*, mantle cell lymphoma, monocytoid B-cell lymphoma, mucosa-associated lymphoid tissue, anaplastic large cell lymphoma, angiocentric lymphoma, angioimmunoblastic lymphadenopathy, Castleman disease, adult T-cell leukemia/lymphoma.

Prognostic Index (IPI), a predictive model for aggressive NHL to be treated with doxorubicin-containing chemotherapy regimens.[21] This index is used as a tool to identify patients who may benefit from a more intense treatment regimen. Additionally, patients with diffuse aggressive B-cell lymphoma that is of germinal center type carry a better prognosis than other patients.[22] A model similar to the IPI, the Follicular Lymphoma International Prognostic Index (FLIPI), is used to help guide treatment decisions in follicular lymphoma.[23]

## TREATMENT OF NHL
### Desired Outcome

Treatment of NHL depends primarily on histologic subtype (follicular low grade versus diffuse aggressive) and staging (local stage I/II versus advanced stage III/IV) to guide treatment with observation, chemotherapy, radiation, or chemotherapy and radiation. The Cotswold modification of the Ann Arbor staging system for HL is used in NHL as well.

Treatment goals depend on the patient's specific subtype of NHL. For follicular low-grade NHL, the disease is considered to be incurable with standard therapies. Many patients with follicular lymphoma are older than 60 years of age, making allogeneic SCT impractical due to high treatment-related mortality for older patients.

KEY CONCEPT *The treatment goals for low-grade NHL include:*

- *Observation of the disease until the patient exhibits obvious progression that limits functional capacity or is life threatening*
- *Treatment that induces remission with manageable toxicity*
- *Judicious selection of treatment options to avoid long-term toxicity*
- *Prevention of infectious complications*

| Table 97–7 |
| --- |

**Negative Prognostic Factors for NHL**

**International Prognostic Index—Diffuse, Aggressive NHL**

| Criteria | Risk Group | Number of criteria |
| --- | --- | --- |
| Age 60 years or older | | |
| Stage III/IV disease | Low | 0–1 |
| Extranodal disease greater than one site | Low-intermediate | 2 |
| ECOG performance status 2 or greater | High-intermediate | 3 |
| Serum LDH > 1 × normal limit | High | 4–5 |

**Follicular Lymphoma International Prognostic Index**

| Criteria | Risk Group | Number of criteria |
| --- | --- | --- |
| Age 60 years or older | | |
| Stage III/IV disease | Low | 0–1 |
| Hemoglobin < 12.0 g/dL (120 g/L; 7.45 mmol/L) | Intermediate | 2 |
| Serum LDH > 1 × normal limit | High | 3 or more |
| Number of nodal sites ≥ 5[a] | | |

[a]The nodal map used in the Follicular Lymphoma International Prognostic Index is different than the nodal map used in conventional staging.

The intent of treatment for patients with aggressive histologies is cure of the malignancy. Some histologic subtypes exhibit an aggressive clinical course and are not considered to be curable. These patients are still treated with curative-intent chemotherapy or may be considered for a clinical trial.

## Nonpharmacologic Therapy

For patients with low-grade follicular NHL, deferring initiation of therapy until progression of disease is a standard approach. The median survival time is 6 to 10 years. Some patients may be asymptomatic for several years after initial diagnosis, making observation a reasonable approach. Radiation therapy has a limited role in NHL relative to HL. NHL is more often a systemic disease, and radiation typically has been reserved for consolidation after chemotherapy in patients presenting with a large extranodal mass. However, IFRT without systemic therapy is a treatment option for patients with stage I/II follicular lymphoma.

For early-stage diffuse, aggressive NHL, combined-modality therapy was tested versus a longer course of chemotherapy.[24] Overall survival favored the CHOP–radiation arm for 5 years (82% vs 72%). There was a trend toward increased toxicity, particularly hematologic and cardiac toxicity, in the CHOP alone arm. The results of this trial have established combined-modality therapy as first-line treatment for early stage NHL.

## Pharmacologic Therapy

### ▶ Follicular Low-Grade NHL

The management of low-grade lymphomas is an area of controversy, especially in patients presenting with early stage disease.

| Table 97–8 |
| --- |

**Chemotherapy Regimens for Low-Grade, Follicular NHL**

**Fludarabine/Rituximab**
Fludarabine 25 mg/m² IV days 1–5 every 28 days
Rituximab 375 mg/m² IV, days 1 and 5 of week 1 and 26; single dose 72 hours before fludarabine cycles 2, 4, and 6

**Bendamustine/Rituximab—Every 28 Days**
Bendamustine 90 mg/m² IV days 1 and 2
Rituximab 375 mg/m² IV, day 1

**rCVP—Every 21 Days**
Rituximab 375 mg/m² IV, day 1
Cyclophosphamide 750 mg/m² IV, day 1
Vincristine 1.4 mg/m² IV, day 1
Prednisone 40 mg/m² po daily, days 1–5

**rCHOP—Every 21 Days**
Rituximab 375 mg/m² IV, day 1
Cyclophosphamide 750 mg/m² IV, day 1
Doxorubicin 50 mg/m² IV, day 1
Vincristine 1.4 mg/m² IV, day 1
Prednisone 100 mg/day po, days 1–5

IV, intravenous; po, oral.

Typical indications for treatment include cytopenias, recurrent infections, threatened end-organ function, disease progression over at least 6 months, or patient preference. In these patients, chemotherapy such as fludarabine or bendamustine is typically offered initially. In patients in whom a more rapid response is desired, such as patients with advanced disease, multiagent chemotherapy such as CVP (cyclophosphamide, vincristine, and prednisone) or CHOP may be used. These regimens, detailed in Table 97–8, have not been associated with an improvement in overall survival, making it impossible to select an unequivocal first-line regimen.[25–27]

Rituximab is also an integral component in drug therapy for this disease. Rituximab is a chimeric monoclonal antibody that binds specifically to CD20 expressed on B lymphocytes.[28] NHL of B-cell origin expresses CD20 in greater than 90% of cases. The initial clinical experience with rituximab involved 166 patients with CD20+ low-grade lymphoma treated with four doses of 375 mg/m² of rituximab weekly.[29] The overall response rate was 48%, with CR in 6% of patients. The median follow-up of 12 months demonstrated a median time to progression of 13 months. This established rituximab as a viable treatment option in patients with indolent follicular NHL, typically added to chemotherapy in most patients. Additionally, rituximab was examined as maintenance therapy administered every 8 weeks for 2 years after rituximab-containing multiagent chemotherapy. Compared with observation, rituximab increased 3-year PFS (74.9 vs 57.6 months).[30]

Other strategies for treatment of low-grade lymphomas include the combination of monoclonal antibodies directed against CD20 with a radiopharmaceutical attached and a new kinase inhibitor active against B-cells. Ibritumomab-yttrium 90 is a monoclonal antibody targeting CD20 that delivers radioactive yttrium. It is indicated for the treatment of relapsed follicular lymphoma or as consolidation after response to initial chemotherapy. Idelalisib is a small molecule that inhibits PI3Kδ kinase found in B-cells, inducing apoptosis and inhibiting chemotaxis. It was approved for follicular lymphoma based on a phase I study in patients who had failed multiple prior therapies. These heavily pretreated patients had an overall response

rate of 45%.[31] High-dose chemotherapy is being evaluated for low-grade follicular NHL, but its role is currently limited to clinical trials.

### ▶ Diffuse, Aggressive NHL

**KEY CONCEPT** *The mainstay of therapy for diffuse, aggressive NHL has been anthracycline-based combination chemotherapy, generally consisting of four or more drugs.* Therapy options for intermediate- and high-grade NHL generally are segregated between localized (stage I/II) and advanced (stage III/IV) disease. Combined-modality therapy with an abbreviated course of CHOP and local radiation is considered a standard of care for stage I/II disease.

The standard therapy for disseminated disease since the 1970s has been CHOP. This regimen conferred a response of 50% to 60%, with long-term survival of approximately 30%. However, the 1980s were notable for the development of newer combination chemotherapy regimens that incorporated increasing numbers of agents with varying schedules. A phase III clinical trial compared CHOP to three more intensive regimens in patients with intermediate or high-grade NHL (Working Formulation Classification).[32] There were no significant differences in response rate or overall survival between the groups. Severe toxicity and death were higher in the advanced-generation treatment programs relative to CHOP. This pivotal trial has cemented CHOP as first-line chemotherapy in diffuse NHL.

Rituximab is also routinely used to treat diffuse, aggressive NHL. Another study randomized patients 60 to 80 years of age with newly diagnosed disease to either CHOP for eight cycles or CHOP plus rituximab for eight cycles.[33] Two-year follow-up showed rituximab improved CR (76% vs 63%) and median event-free survival (57% vs 38%) and long-term follow-up confirmed benefit was with an increase in 10-year survival (43% vs 27.6%). Similar findings have been reported in younger patients, making CHOP plus rituximab first-line therapy for advanced-stage diffuse, aggressive NHL (Table 97–9).

### ▶ Special Populations

There are histologic subtypes of diffuse, aggressive NHL that respond less well to treatment with conventional regimens such as CHOP. Burkitt lymphoma, lymphoblastic lymphoma, mantle cell lymphoma, and primary CNS lymphoma are examples of disease that benefit from more intensive therapy. Regimens such as hyper-CVAD, which alternate cycles of hyperfractionated cyclophosphamide, doxorubicin, vincristine, and dexamethasone with high-dose cytarabine and methotrexate, may be substituted for CHOP.

Patients with CNS NHL have disease that is poorly responsive to therapy because of inadequate penetration of standard doses of chemotherapy across the blood–brain barrier. High-dose methotrexate, ranging from 2500 to 8000 $mg/m^2$ is a mainstay of therapy. Treatment may also include intrathecal chemotherapy. Drugs that are commonly instilled intrathecally include

---

**Table 97–9**

**Treatment Regimens for Diffuse, Aggressive NHL**

**rCHOP—Every 21 Days[a]**

**EPOCH-Rituximab—Every 21 Days**
Rituximab 375 $mg/m^2$ IV, day 1
Etoposide 50 $mg/m^2$/day CIVI days 1–4
Prednisone 60 $mg/m^2$/day po, days 1–5
Vincristine 0.4 $mg/m^2$/day CIVI days 1–4
Cyclophosphamide 750 $mg/m^2$ IV day 5
Doxorubicin 10 $mg/m^2$/day CIVI days 1–4

**RCEOP—Every 21 Days[b]**
Rituximab 375 $mg/m^2$ IV, day 1
Cyclophosphamide 750 $mg/m^2$ IV, day 1
Etoposide 50 $mg/m^2$ IV, day 1
Etoposide 100 $mg/m^2$ po days 2–3
Vincristine 1.4 $mg/m^2$ IV, day 1
Prednisone 100 mg/day po, days 1–5

**CNOP-Rituximab—Every 21 Days[b]**
Rituximab 375 $mg/m^2$ IV, day 1
Cyclophosphamide 750 $mg/m^2$ IV, day 1
Mitoxantrone 10 $mg/m^2$ IV, day 1
Vincristine 1.4 $mg/m^2$ IV, day 1
Prednisone 100 mg/day po, days 1–5

**Hyper-CVAD**
Part A: The following drugs given on course 1, 3, 5 and 7
Cyclophosphamide 300 $mg/m^2$ IV every 12 hours, days 1–3 (with Mesna)
Doxorubicin 50 $mg/m^2$ IV, day 1
Vincristine 1.4 $mg/m^2$ IV, days 1,11

Dexamethasone 40 mg/day po, days 1–4 and 11–14
Methotrexate 15 mg intrathecal, day 2
Cytarabine 30 mg intrathecal, day 2
Hydrocortisone 15 mg intrathecal, day 2

Part B: The following drugs are given on courses 2, 4, 6, and 8
Methotrexate 1000 $mg/m^2$ IV over 24 hours, day 1
Cytarabine 3000 $mg/m^2$ IV every 12 hours, days 2 and 3
Leucovorin 25 mg IV × 1; then 25 mg po every 6 hours for seven doses
Methotrexate 15 mg intrathecal, day 2

**Bendamustine/Rituximab—Every 28 Days[a]**

**ESHAP**
Etoposide 40 $mg/m^2$ IV per day continuous infusion, days 1–4
Cisplatin 25 $mg/m^2$ IV per day continuous infusion, days 1–4
Cytarabine 2000 $mg/m^2$ IV × 1, day 5
Methylprednisone 250 mg IV every 12 hours, days 1–4

**DHAP**
Dexamethasone 40 mg po or IV daily, days 1–4
Cisplatin 100 $mg/m^2$ IV continuous infusion, day 1
Cytarabine 2000 $mg/m^2$ IV every 12 hours for two doses on day 2

**ICE**
Etoposide 100 $mg/m^2$ IV daily, days 1–3
Carboplatin AUC 5 (maximum dose, 800 mg) IV, day 2
Ifosfamide 5000 $mg/m^2$ IV continuous infusion × 1 on day 2 (with 100% replacement with Mesna)

[a]Refer to Table 97–8 for regimen.

[b]Data is limited, use only for patients who are unable to receiving an anthracycline.

AUC, area under the curve; CIVI, continuous intravenous infusion; IV, intravenous; po, oral.

**Patient Encounter, Part 2: Treatment Selection**

Complete evaluation revealed stage IV Hodgkin lymphoma and therapy is scheduled to begin immediately.

*What therapy (or therapies) is (are) most appropriate for this patient?*

*At this time is this patient an appropriate candidate for stem cell transplant?*

*What other information (eg, laboratory studies, diagnostic tests) is needed prior to initiating chemotherapy?*

**Patient Encounter, Part 3: Creating a Care Plan**

*Based on the information presented, create a care plan for this patient, including the goals of therapy, antineoplastic therapy plan, and necessary supportive care.*

methotrexate, cytarabine (conventional formulation and liposomal products), and corticosteroids.

The recent appreciation of *H. pylori* colonization and MALT has spurred the more aggressive treatment of this organism with antibiotics. In patients with localized disease, aggressive, combination therapy for *H. pylori* has been shown to induce MALT remission. Patients with advanced disease may require combination chemotherapy, such as CHOP.

Mantle cell lymphoma, which comprises 6% of NHL cases, is defined by a chromosomal translocation of t(11;14)(q13;32). This translocation results in the overexpression of cyclin D1 coupled with NF-κB, which plays a critical role in intracellular protein regulation and protranscription factors leading to increased cell survival. Bortezomib, a proteasome inhibitor, disrupts the regulation and degradation of proteins required for cell cycle regulation. It is approved by the FDA for the treatment of patients with mantle cell lymphoma who have failed prior chemotherapy. A study conducted in 155 patients demonstrated that bortezomib resulted in 31% overall response rate with a median survival of 9.3 months.[34] Bortezomib is well tolerated, with peripheral neuropathy, thrombocytopenia, neutropenia, and nausea reported most frequently.

With more than half of patients with NHL expected to relapse, salvage therapy plays a major role in the attempt to cure recurrence. Multiple drug regimens such as ESHAP and DHAP can induce a CR, but the long-term cure rate with these regimens is less than 10%. Salvage therapy can induce remissions with subsequent relapses; however, the chance for a CR and the duration of remission is further diminished.

High-dose chemotherapy with autologous SCT has been studied as an alternative to standard dose regimens in the setting of first relapse.[35] The best-studied indication for SCT is for patients with intermediate- or high-grade disease that fails to respond to first-line therapy. A 3- to 5-year survival of greater than 40% is achieved in patients who have good performance and disease that demonstrates a significant response to one or two cycles of salvage chemotherapy. The procedure-related mortality rate has ranged from 5% to 10% in published reports. However, as with HL, with more broad application of peripheral blood stem cells and improved supportive care, the mortality rate continues to decline. The role of allogeneic SCT in this setting is limited because of donor availability, the older age of patients, and the high treatment-related morbidity and mortality. Additionally, outcomes between autologous and allogeneic transplant appear similar.

Patients with HIV-related lymphoma represent a therapeutic dilemma considering many have high-grade NHL. A common presentation is that of extranodal disease, frequently in the GI tract, CNS, or bone marrow. Therapy for this population thus far has fared poorly, with a median survival time of 6 to 12 months, which decreases to 3 months with CNS involvement.[36] The addition of rituximab to chemotherapy has failed to improve overall survival in this patient population and is associated with increased infectious complications.[37]

## OUTCOME EVALUATION

Treatment response in lymphomas is measured using the response evaluation criteria in solid tumors (RECIST), a uniform criteria assessing tumor response developed by the National Cancer Institute. Lymphomas may have residual masses after completion of treatment, adding to the difficulty in establishing a definitive remission from treatment. Clinical trials with limited numbers of patients have been published suggesting the value of positron emission tomography (PET) scans to rule out whether residual tumor masses after treatment contain viable tumor.[38] Integrated PET–computed tomography (CT) scanning is recommended as part of the initial workup and to evaluate for residual disease at the end of treatment.[39]

Long-term follow-up monitors patients for continued disease remission or relapse with careful examination of the original areas of involvement and imaging studies including chest x-rays and CT scans to detect recurrence. Patients also require long-term monitoring for toxicities of their treatment.

Most patients treated for lymphoma with chemotherapy or radiation notice a regression of palpable lymphadenopathy within days. This is because of the high sensitivity of the rapidly proliferating malignant lymphocytes to chemotherapy and radiotherapy. This necessitates implementation of tumor lysis syndrome precautions with aggressive intravenous hydration and allopurinol. Rasburicase should be considered for patients with moderate to high tumor burdens. Most chemotherapy treatments for lymphoma have a significant risk of infectious complications. Combination regimens for both HL and NHL are associated with rates of severe leukopenia and/or neutropenia ranging from 20% to 100% of patients. Consideration must be given to supportive care with prophylactic antibiotics and CSFs. Most chemotherapy regimens discussed in this section are highly emetogenic. Antiemetic regimens are available to control chemotherapy-induced nausea and vomiting well for most standard-dose regimens.[40]

Advances in the treatment of lymphoma have increased the number of long-term survivors. Identification of long-term complications of lymphoma therapy is vital to patient follow-up and may influence treatment decisions in newly diagnosed patients. Outcomes associated with the treatment of HL make up the majority of data. However, advances in NHL treatment have provided more information regarding long-term toxicities. Two leading causes of death associated with lymphoma treatment are secondary malignancies and cardiovascular disease.

The use of combined modality of irradiation with doxorubicin-based therapy has been reported to increase the risk of cardiac dysfunction. Treatment-related pulmonary toxicity, hypothyroidism, and infertility have been associated with lymphoma therapy as well. Lymphoma survivors have an increased risk for developing myelodysplasia, acute myelogenous leukemia, and various solid tumors.[41]

A limitation of rituximab is severe, potentially fatal infusion-related reactions. Deaths have been reported resulting from the profound hypotension and circulatory collapse seen with the drug, particularly on the first dose. The package labeling recommends premedication with acetaminophen and diphenhydramine before each infusion. The initial infusion should be given slowly, at 50 mg/hour. The infusion rate may be increased as tolerated to a maximum of 400 mg/hour. In the absence of infusion reactions, subsequent doses may be started at a higher rate and titrated more aggressively. Reactivation of hepatitis B infections has occurred in patients treated with rituximab. Patients at high risk for hepatitis B should be screened and monitored carefully for reactivation of hepatitis. If hepatitis occurs, rituximab should be discontinued, and patients should be treated appropriately. Other associated toxicities of rituximab include fever, chills, headache, asthenia, nausea, vomiting, angioedema, bronchospasm, and skin reactions. **KEY CONCEPT** *Rituximab is an effective treatment option for patients with various forms of NHL in combination with chemotherapy or as a single agent as long as patients are monitored appropriately.* The radiolabeled CD-20 antibody causes more myelosuppression than rituximab alone and has a long-term risk of inducing secondary leukemias.[42]

## Patient Care Process

**Patient Assessment:**
- Take a thorough medication history with particular attention to nonprescription or herbal medications.
- Before initiation of treatment assess patient for risk of tumor lysis syndrome.

**Therapy Evaluation:**
- Determine the optimal treatment regimen for the patient incorporating diagnosis, stage, and prognostic indicators.
- Verify chemotherapy regimen doses with a standardized reference and assess for dose adjustment based on height, weight, and body surface area and organ dysfunction (renal or hepatic).
- Assess appropriateness of supportive care for the chemotherapy regimens including need for prophylactic antiemetics and use of colony-stimulating factors.

**Care Plan Development:**
- Provide patient education regarding common toxicities associated with chemotherapy such as nausea/vomiting, mucositis, myelosuppression, and alopecia.
- For doxorubicin-containing regimens, maintain records of the cumulative doxorubicin dosage received by the patient to monitor for cardiac toxicity risk.
- For bleomycin-containing regimens, maintain records of the cumulative bleomycin dosage received by the patient to monitor for pulmonary fibrosis.
- Educate patients regarding the short- and long-term complications associated with radiation therapy.
- Provide contact numbers for patient in the event of a fever and a response plan if the patient is considered to be at risk for neutropenic fever.

**Follow-Up Evaluation:**
- Schedule regulatory laboratory tests including complete blood count and blood chemistries to monitor for chemotherapy toxicities.
- Monitor patient for signs and symptoms of response of tumor to chemotherapy.
- Develop a plan to monitor for long term complications of chemotherapy such as cardiotoxicity and secondary malignanacies.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| *Bcl-1* | Important in the regulation of mitosis |
| *Bcl-2* | A regulator of apoptosis |
| *Bcl-3* | A regulator of nuclear transcription factor |
| *Bcl-6* | Regulates cell differentiation |
| *c-myc* | Regulator of gene transcription |
| ABVD | Doxorubicin, bleomycin, vinblastine, and dacarbazine |
| CHOP | Cyclophosphamide, doxorubicin, vincristine, and prednisone |
| CSFs | Colony-stimulating factors |
| CVP | Cyclophosphamide, vincristine, and prednisone |
| EBV | Epstein-Barr virus |
| FLIPI | Follicular lymphoma international prognostic index |
| HL | Hodgkin lymphoma |
| IFRT | Involved field radiation therapy |
| IPI | International Prognostic Index |
| LDH | Lactate dehydrogenase |
| MALT | Mucosa-associated lymphoid tissue |
| MOPP | Mechlorethamine, vincristine, procarbazine, and prednisone |
| NHL | Non-Hodgkin lymphoma |
| PET | Positron emission tomography |
| RECIST | Response evaluation criteria in solid tumors |
| RS | Reed-Sternberg |
| SCT | Stem cell transplant |

# 98 Hematopoietic Stem Cell Transplantation

Christina Carracedo and Amber P. Lawson

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Explain the rationale for using hematopoietic stem cell transplant (HSCT) to treat cancer.

2. Compare the different types of HSCTs, specifically (a) the types of donors (ie, autologous and allogeneic), (b) the source of hematopoietic cells (ie, umbilical cord, peripheral blood progenitor cells, and bone marrow), and (c) the type of preparative regimen (ie, myeloablative and nonmyeloablative).

3. List the nonhematologic toxicity to high-dose chemotherapy used in myeloablative preparative regimens, specifically busulfan-induced seizures, hemorrhagic cystitis, gastrointestinal toxicities, and sinusoidal obstruction syndrome.

4. Develop a plan for monitoring and managing engraftment of hematopoiesis.

5. Explain graft-versus-host disease (GVHD).

6. Recommend a prophylactic and treatment regimen for GVHD.

7. Choose an appropriate regimen to minimize the risk of infectious complications in HSCT patients.

8. Evaluate the long-term health care of HSCT survivors.

## INTRODUCTION

**KEY CONCEPT** *Hematopoietic stem cell transplantation (HSCT) is a procedure used mainly to treat hematologic malignancies via high-dose chemotherapy and/or a graft-versus-tumor effect.* HSCT may be either autologous; where a patient receives their own bone marrow or allogeneic; where the patient receives bone marrow from a donor. As an alternative to bone marrow, hematopoietic stem cells may be obtained from the peripheral blood progenitor cells (PBPCs) or umbilical cord blood. Bone marrow and PBPCs contain pluripotent stem cells and postthymic lymphocytes, which are responsible for long-term hematopoietic reconstitution, called engraftment and immune recovery.[1]

The rationale of an autologous transplant is to administer **myeloablative preparative regimen** and eradicate the patient's malignancy. Collecting the bone marrow or PBPCs prior to administering high dose chemotherapy essentially protects the collected PBPCs from the effects of chemotherapy and can restore hematopoiesis. Allogeneic transplants use donor PBPCs to rescue the patient after myeloablative chemotherapy with of an added advantage of the donor cells generating an immunologic response towards the recipient's residual tumor, called the **graft-versus-tumor** effect. Unfortunately, **graft-versus-host disease** (GVHD) where the donor cells generate an immunologic response toward the recipient's normal tissue also occurs.

The type of HSCT performed depends on a number of factors, including the type and status of disease, availability of a compatible donor, patient age, performance status, and organ function. Examples of diseases treated with HSCT are listed in **Table 98–1**.

## EPIDEMIOLOGY AND ETIOLOGY

Worldwide, approximately 35,000 autologous HSCTs and 25,000 allogeneic HSCTs are performed per year, with approximately one-third of allogeneic HSCTs using reduced-intensity preparative regimens. In the late 1990s, the number of allogeneic HSCTs reached a plateau, most likely related to the introduction of effective oral therapies for the treatment of newly diagnosed chronic-phase chronic myelogenous leukemia (CML), a disease that was historically managed with allogeneic HSCT. Furthermore, the limited availability of suitable donors may have also contributed to the plateau effect.[2]

The use of allogeneic PBPCs is increasing; from years 2007 through 2011, almost 80% of allogeneic HSCTs performed worldwide used PBPCs as the source of hematopoietic cells rather than bone marrow in adult patients.[2]

Autologous PBPC use has increased and essentially has replaced bone marrow as a graft source in many transplant centers. From years 2007 through 2011, approximately 99% of autologous HSCTs in adults and 94% in children used PBPCs as the source of hematopoietic cells.[2]

## PATHOPHYSIOLOGY

**KEY CONCEPT** *Autologous HSCT, or infusion of a patient's own hematopoietic cells, allows for the administration of higher doses of chemotherapy, radiation, or both to treat the malignancy or autoimmune disorder.* In this setting, the hematopoietic cells "rescue" the recipient from otherwise dose-limiting hematopoietic toxicity. Autologous HSCT is used to treat intermediate- and

| Table 98–1 | | |
|---|---|---|
| **Diseases Commonly Treated with HSCT** | | |
| | **Autologous Graft** | **Allogeneic Graft** |
| Cancers | Multiple myeloma | Acute myeloid leukemia |
| | Non-Hodgkin lymphoma | Acute lymphoblastic leukemia |
| | Hodgkin disease | Chronic myeloid leukemia |
| | Neuroblastoma | Myelodysplastic syndrome |
| | Germ cell tumors | Myeloproliferative disorders |
| | | Non-Hodgkin lymphoma |
| | | Hodgkin disease |
| | | Chronic lymphocytic leukemia |
| | | Multiple myeloma |

| | | Severe combined immunodeficiency |
| | | Inborn errors of metabolism |

high-grade non-Hodgkin lymphoma (NHL), multiple myeloma (MM), autoimmune diseases, and relapsed or refractory Hodgkin disease.[1] Patients do not benefit from an immunologic graft-versus-tumor effect while undergoing an autologous transplant; instead, the administration of high-dose chemotherapy followed by an autologous stem cell transplant in chemotherapy-sensitive malignancies relies on the preparative regimen alone to eradicate the malignant disease. Autologous HSCT circumvents the need for histocompatible donors, is associated with a lower mortality rate, and is not restricted to younger patients.[2]

**KEY CONCEPT** *Allogeneic HSCT involves the transplantation of hematopoietic cells obtained from a different person's (donor) bone marrow, peripheral blood, or umbilical cord blood to the recipient.* Unless the donor and the recipient are identical twins (referred to as a *syngeneic HSCT*), they are dissimilar genetically.

The transplanted donor stem cells or bone marrow is immunologically active, and thus there is potential for bidirectional graft rejection. When host-versus-graft reactions occur, cytotoxic T cells and natural killer (NK) cells belonging to the host (recipient) recognize minor histocompatibility (MHC) antigens of the graft (donor hematopoietic stem cells) and lead to a rejection response. When GVHD occurs, immunologically active cells in the graft recognize host MHC antigens and elicit an immune response. When host-versus-graft effects occur in allogeneic HSCT, they are referred to as *graft failure* or *rejection,* which results in ineffective hematopoiesis (ie, adequate absolute neutrophil count [ANC] and/or platelet counts were not obtained). Allogeneic HSCT is used to treat both nonmalignant conditions and hematologic malignancies such as acute and chronic leukemias.[1]

For both allogeneic and autologous transplants, hematopoietic cells are infused after the administration of a combination of chemotherapy and/or radiation, termed the conditioning or preparative regimen. **KEY CONCEPT** *A myeloablative preparative regimen involves the administration of sublethal doses of chemotherapy to the recipient to eradicate residual malignant disease. The recipient will not regain his or her own hematopoiesis and will be at risk for substantial life-threatening nonhematologic toxicity.* For those undergoing an autologous HSCT, their hematopoietic

cells must be harvested and stored before the myeloablative preparative regimen is administered. After the administration of the myeloablative preparative regimen, these hematopoietic cells serve as a rescue intervention to reestablish bone marrow function and avoid long-lasting, life-threatening bone marrow aplasia. In the setting of an allogeneic HSCT, the preparative regimen is designed to suppress the recipient's immunity, eradicate residual malignancy, or create space in the marrow compartment. Improved survival outcomes have been observed with both autologous and allogeneic HSCT when the hematologic malignancy is in complete remission at the time of HSCT.[2] At most HSCT centers, age younger than 65 years and normal renal, hepatic, pulmonary, and cardiac function are considered eligibility requirements for myeloablative allogeneic HSCT.

The recognition of graft-versus-tumor effect, which likely is caused by cytotoxic T lymphocytes in the donor stem cells in those undergoing a allogeneic HSCT transplant, led to investigations with nonmyeloablative transplants, in which less toxic preparative regimens are used in the hope of expanding the availability of HSCT to recipients whose medical condition or age prohibits use of myeloablative regimens.

A myeloablative or **nonmyeloablative preparative regimen** may be used for allogeneic HSCT; only myeloablative preparative regimens are used for autologous HSCT.

## Histocompatibility

**Histocompatibility** differences between the donor and the recipient necessitate immunosuppression after an allogeneic HSCT because considerable morbidity and mortality are associated with graft failure and GVHD. Rejection is least likely to occur with a syngeneic donor. In patients without a syngeneic donor, initial HLA typing is conducted on family members because the likelihood of complete histocompatibility between unrelated individuals is remote. Siblings are the most likely individuals to be histocompatible within a family. The chance for complete histocompatibility occurring in an individual with only one sibling is 25%. Approximately 40% of patients with more than one sibling will have an HLA-identical match. Having a matched-sibling donor is no longer a requirement for allogeneic HSCT because improved immunosuppressive regimens and the National Marrow Donor Program have allowed an increase in the use of unrelated or related matched or mismatched HSCTs. The use of alternative sources of allogeneic hematopoietic cells, such as related donors mismatched at one or more HLA loci or phenotypically (ie, serologically) matched unrelated donors, has been evaluated.[5] Establishment of the National Marrow Donor Program has helped to increase the pool of potential donors for allogeneic HSCT. Through this program, an HLA-matched unrelated volunteer donor might be identified. Recipients of an unrelated graft are more likely to experience graft failure and acute GVHD relative to recipients of a matched-sibling donor. Determination of histocompatibility between potential donors and the patient is completed before allogeneic HSCT. Initially, HLA typing is performed using blood samples and compatibility for class I MHC antigens (ie, HLA-A, HLA-B, and HLA-C) is determined through serologic and DNA-based testing methods. In vitro reactivity between donor and recipient also can be assessed in mixed-lymphocyte culture, a test used to measure compatibility of the MHC class II antigens (ie, HLA-DR, HLA-DP, and HLA-DQ). Currently, most clinical and research laboratories are also performing molecular DNA typing using polymerase chain reaction (PCR) methodology to determine the HLA allele sequence.[3]

The preparative regimen or GVHD prophylaxis may be altered based on the mismatch between the donor and the recipient. The risk of graft failure decreases with better matches such that those with a class I (ie, HLA-A, HLA-B, or HLA-C) antigen mismatch have the highest risk of rejection; those with just one class I allele mismatch have a minimal risk. Graft failure does not appear to be associated with mismatch at a single class II antigen or allele. GVHD and survival have been associated with disparity for classes I and II antigens and alleles.[4]

## Stem Cell Sources

**KEY CONCEPT** *Bone marrow, PBPCs, and umbilical cord blood can serve as the source of hematopoietic cells. The optimal cell source differs based on the donor and recipient characteristics.*

Hematopoietic stem cells are obtained from bone marrow or peripheral blood. The technique for harvesting hematopoietic cells depends on the anatomic source (ie, bone marrow or peripheral blood). A surgical procedure is necessary for obtaining bone marrow. Multiple aspirations of marrow are obtained from the anterior and posterior iliac crests until a volume with a sufficient number of hematopoietic stem cells is collected (ie, 600–1200 mL of bone marrow). The bone marrow then is processed to remove fat or marrow emboli and usually is infused intravenously into the patient similar to a blood transfusion.

The shift to the use of PBPCs over bone marrow for HSCT is primarily because of the more rapid engraftment and decreased health care resource use. For an autologous transplant, the harvest occurs before administering the preparative regimen; therefore, autologous hematopoietic cells must be cryopreserved and stored for future use.

Allogeneic cells are usually harvested just prior to the HSCT and administered to the recipient without cryopreservation; however, they are sometimes collected and cryopreserved as well. The bone marrow may need additional processing if the donor and recipient are ABO incompatible, which occurs in up to 30% of HSCTs. Red blood cells (RBCs) may need to be removed before infusion into the recipient to prevent immune-mediated hemolytic anemia and thrombotic microangiopathic syndromes.

Transplantation with PBPCs essentially has replaced bone marrow transplantation (BMT). PBPCs are obtained by administering a mobilizing agent(s) followed by apheresis, which is an outpatient procedure similar to hemodialysis. Hematopoietic growth factors (HGFs) alone or in combination with myelosuppressive chemotherapy are used for mobilization of autologous PBPCs with similar results.[5] HGFs are also used to mobilize donor PBPCs for allogeneic transplants, although chemotherapy is not used in this setting.

Transplant with umbilical cord blood offers an alternative stem cell source to patients requiring an allogeneic transplant who do not have an acceptable matched related or unrelated donor. When allogeneic hematopoietic cells are obtained from umbilical cord blood, the cord blood is obtained from a consenting donor in the delivery room after birth and delivery of the placenta. The cord blood is processed, a sample is sent for HLA typing, and the cord blood is frozen and stored for future use. Numerous umbilical cord blood registries exist, with the goal of providing alternative sources of allogeneic stem cells. One potential limitation to the use of umbilical cord blood transplants is the inability to use donor-lymphocyte infusions in the event of relapse. Engraftment is slower in umbilical cord blood transplants, with a potential lower risk of GVHD and similar survival rates relative to BMT.[1,6] In children receiving an umbilical cord blood graft from an unrelated donor, cell dose (eg, nucleated cells) is related to engraftment, transplant-related morbidity, and survival.[7] Although there were initial concerns regarding whether a umbilical cord blood transplant could provide enough nucleated cells to engraft adequately within an adult, there is growing experience to indicate that a umbilical cord blood transplant is feasible when at least $1 \times 10^7$ nucleated cells per kilogram of recipient body weight are administered.[11] The prospective use of dual umbilical cord units and *ex vivo* expansion of umbilical cord units to obtain adequate engraftment are methods currently under exploration.

## TREATMENT

### Desired Outcome

**KEY CONCEPT** *Engraftment is defined as the point at which a patient can maintain a sustained ANC of greater than 500 cells/mm³ ($0.5 \times 10^9$/L) and a sustained platelet count of 20,000/mm³ ($20 \times 10^9$/L) or more lasting 3 or more consecutive days without transfusions[8] and is the desired short term outcome in a transplant.* The desired long-term outcome with HSCT is to cure the patient of his or her underlying disease while minimizing the short- and long-term morbidity associated with HSCT.

## Nonpharmacologic Therapy

▶ ***Harvesting, Preparing, and Transplanting Autologous and Allogeneic Hematopoietic Cells***

**Autologous Transplants** The HGFs granulocyte-macrophage colony-stimulating factor (sargramostim, Leukine) and granulocyte colony-stimulating factor (filgrastim, Neupogen) are used as mobilizing agents. The use of pegylated granulocyte colony-stimulating factor (pegfilgrastim, Neulasta) for mobilization of PBPCs appears more convenient and is promising as a mobilization agent; however, further data are needed regarding graft composition, HSCT outcomes, and donor safety in allogeneic donations before widespread use of this agent can be recommended.

The combination of chemotherapy with an HGF enhances PBPC mobilization relative to HGF alone.[1] In addition to treating the underlying malignancy, this approach lowers the risk of tumor cell contamination and the number of apheresis collections required, but there is a greater risk of neutropenia and thrombocytopenia. The HGF is initiated after completion of chemotherapy and is continued until apheresis is complete. Many centers monitor the number of cells that express the CD34 antigen (ie, CD34+ cells) to determine when to start apheresis. The CD34 antigen is expressed on almost all unipotent and multipotent colony-forming cells and on precursors of colony-forming cells but not on mature peripheral blood cells. Apheresis is continued daily until the target number of PBPCs per kilogram of the recipient's weight is obtained. For adult recipients, the number of CD34+ cells correlates with time to engraftment. Lower yield of CD34+ cells is associated with administration of stem cell toxic drugs (eg, carmustine and melphalan) and intensive prior chemotherapy or radiotherapy, which should be avoided prior to transplant if possible.

If patients are unable to obtain an adequate yield of CD34+ cells per kilogram after mobilization attempts fail, then allogeneic transplant may be considered as an alternative. Additionally, plerixafor (Mobozil) is approved by the Food and Drug Administration (FDA) for use in combination with granulocyte colony-stimulating factor to mobilize PBPCs for collection

and subsequent autologous transplantation in patients with NHL and MM. Plerixafor is an inhibitor of the CXCR4 chemokine receptor that results in more circulating PBPCs in the peripheral blood because of the inability of CXCR4 to assist in anchoring hematopoietic stem cells to the bone marrow matrix. Because administration of plerixafor with granulocyte colony-stimulating factor results in increased yield of CD34+ cells per kilogram compared to granulocyte colony-stimulating factor alone, this combination serves as an alternative mobilization strategy in patients deemed to be at risk for mobilization failure with conventional methods.

**Allogeneic Transplants**    The allogeneic donor first undergoes mobilization therapy with an HGF to increase the number of hematopoietic cells circulating in the peripheral blood. The most commonly used regimen to mobilize allogeneic donors is a 4- to 5-day course of filgrastim, 10 mcg/kg/day, administered subcutaneously followed by apheresis on the fourth or fifth days when peripheral blood levels of CD34+ cells peak. An adequate number of hematopoietic cells usually are obtained with one to two apheresis collections, with the optimal number of CD34+ collected being a minimum of $4\text{-}8 \times 10^6$ cells/kg of recipient body weight. Higher numbers of CD34+ cells are associated with more rapid neutrophil and platelet engraftment; patients who receive less than $2 \times 10^6$/kg CD34+ cells are at risk for delayed engraftment.[5] Hematopoietic stem cells obtained from the peripheral blood are processed like bone marrow–derived stem cells and may be infused immediately into the recipient or frozen for future use. Compared with bone marrow donation, allogeneic PBPC donation leads to quicker hematopoietic recovery. Neutrophil engraftment occurs 2 to 6 days earlier, and platelet engraftment occurs approximately 6 days earlier with PBPC grafts than bone marrow grafts.[9] The donor may experience musculoskeletal pain, headache, and mild increases in hepatic enzyme or lactate dehydrogenase levels related to filgrastim administration. Hypocalcemia may also occur owing to citrate accumulation, which decreases ionized calcium concentrations during apheresis.

Allogeneic PBPC grafts contain approximately 10 times more T and B cells than bone marrow grafts. Historically, there has been significant concern that the greater T- and B-cell content of PBPCs could increase the risk of acute and/or chronic GVHD. In patients with a hematologic malignancy who have an HLA-matched sibling donor, a PBPC graft is optimal relative to bone marrow graft because the PBPC graft is associated with quicker neutrophil and platelet engraftment and potentially improved disease-free survival rates.[10] Grafts from PBPCs are likely associated with a higher incidence of acute GVHD and an approximately 20% increase in the incidence of extensive-stage and overall chronic GVHD.[10] Similar trends for engraftment and GVHD have been found with unrelated donors.[11]

**T-Cell Depletion**    Immunocompetent T lymphocytes may be depleted from the donor bone marrow *ex vivo* before infusion (referred to as T-cell–depleted hematopoietic cells) into the recipient as a means of preventing GVHD. Depletion of T lymphocytes in donor hematopoietic cells is completed *ex vivo* using physical (eg, density-gradient fractionation) and/or immunologic (eg, antithymocyte globulin [ATG] antibodies) methods. Functional recovery of T cells in the recipient is delayed, and the risk of Epstein-Barr virus–associated lymphoproliferative disorders is higher with the use of T-cell–depleted bone marrow. The use of T-cell–depleted grafts reduces the incidence of GVHD, but graft failure and relapse are more common. The use of donor lymphocyte infusion in patients who relapse after receiving a T-cell–depleted HSCT is being investigated.

**Engraftment**    After chemotherapy and radiation, pancytopenia lasts until the infused stem cells reestablish functional hematopoiesis. The median time to engraftment is a function of several factors, including the source of stem cells such as PBPCs, which can result in earlier engraftment than bone marrow. Myeloablative preparative regimens have significant regimen-related toxicity and morbidity and thus usually are limited to healthy, younger (ie, usually less than 50 years) patients. Alternatively, nonmyeloablative transplants are being performed with the hope of curing more patients with cancer by increasing the availability of HSCT with less regimen-related toxicity and by using the graft-versus-tumor effect.[1]

A delicate balance exists between host and donor effector cells in the bone marrow environment. Residual host-versus-graft effects may lead to graft failure, which is also known as graft rejection. Graft failure is defined as the lack of functional hematopoiesis after HSCT and can occur early (ie, lack of initial hematopoietic recovery) or late (ie, in association with recurrence of the disease or reappearance of host cells after initial donor cell engraftment). Engraftment usually is evident within the first 30 days in patients undergoing an HSCT; however, rejection can occur after initial engraftment. Therapeutic options for the treatment of graft rejection are limited; a second HSCT is the most definitive therapy, although the toxicities are formidable.[12]

▶ *Graft-Versus-Tumor Effect*

A graft-versus-tumor effect caused by the donor lymphocytes occurs after transplant. This results in lower relapse rates in patients with GVHD relative to those who did not have GVHD; a higher rate of leukemia relapse after T-cell–depleted, autologous, or syngeneic HSCT; and the effectiveness of donor lymphocyte infusions in reinducing a remission in patients who relapsed after allogeneic HSCT. Rapid taper of immunosuppression in patients with residual disease may induce a graft-versus tumor effect. In donor lymphocyte infusion, lymphocytes are collected from the peripheral blood of the donor and administered to the recipient. Eradication of the recurrent malignancy is caused by either specific targeting of the tumor antigens or GVHD, which may affect cancer cells preferentially. Patients with hematologic

---

## Patient Encounter, Part 1

A 55-year-old woman is diagnosed with acute myeloid leukemia with complex cytogenetics. The patient achieved complete remission with induction therapy and is now being evaluated for an allogeneic stem cell transplant with a peripheral blood stem cell graft from a full HLA-matched unrelated donor. She has no siblings. Her preparative regimen consists of cyclophosphamide and TBI and her GVHD prophylaxis consists of tacrolimus, methotrexate, and ATG.

*What nonhematologic toxicities are associated with the preparative regimen?*

*What are the advantages and disadvantages of obtaining and infusing hematopoietic stem cells from a peripheral blood stem cell source as opposed to a bone marrow source?*

*What are the implications for this patient of an unrelated stem cell donor?*

malignancies (eg, CML and acute myelogenous leukemia [AML]) and certain solid tumors (eg, renal cell carcinoma) appear to benefit from a graft-versus-tumor effect. These data gave rise to the use of nonmyeloablative preparative regimens.

## Pharmacologic Therapy

### ▶ *Preparative Regimens for HSCT*

Examples of commonly used preparative regimens are included in Table 98–2.

**Myeloablative Preparative Regimens** In both autologous and allogeneic HSCT, infusion of stem cells circumvents dose-limiting myelosuppression, maximizing the potential value of the steep dose–response curve to alkylating agents and radiation, suppressing the host immune system, and creating space in the marrow compartment to facilitate engraftment. The preparative regimen is designed to eradicate immunologically active host tissues (lymphoid tissue and macrophages) and to prevent or minimize the development of host-versus-graft reactions. Most allogeneic preparative regimens for the treatment of hematologic malignancies contain cyclophosphamide, radiation, or both. The combination of cyclophosphamide and total-body irradiation (TBI) was one of the first preparative regimens developed and is still used widely today. This regimen is immunosuppressive and has inherent activity against hematologic malignancies (eg, leukemias and lymphomas). TBI has the added advantage of being devoid of active metabolites that might interfere with the activity of donor hematopoietic cells. In addition, TBI eradicates residual malignant cells at sanctuary sites such as the central nervous system. Modifications of the cyclophosphamide–TBI preparative regimen include replacing TBI with other agents (eg, busulfan) or adding other chemotherapeutic or monoclonal

agents to the existing regimen in hopes of minimizing long-term toxicities. In the case of a mismatched allogeneic HSCT with a substantially increased chance of graft rejection, ATG also may be added to the preparative regimen to further immunosuppress the recipient.

The optimal myeloablative preparative regimen remains elusive. Busulfan–cyclophosphamide (BU-CY) and cyclophosphamide–TBI (CY-TBI) are prescribed in patients with AML and CML, which represent the more common indications for allogeneic HSCT. Intravenous busulfan with pharmacokinetic monitoring may improve outcomes when utilized with BU-CY compared to Cy-TBI in AML patients although preparative regimens should be tailored to the primary disease and to the degree of HLA compatibility.[17]

**Nonmyeloablative Preparative Regimens** KEY CONCEPT *A nonmyeloablative preparative regimen is less toxic than a myeloablative regimen in the hope of being able to offer the benefits of an allogeneic HSCT to more patients. A nonmyeloablative HSCT is based on the concept of donor immune response having a graft-versus-tumor effect.*

Because of the severe regimen-related toxicity of a myeloablative preparative regimen, the use of HSCT traditionally was limited to younger patients with minimal comorbidities. Most patients diagnosed with cancer are elderly; therefore, myeloablative HSCT could not be offered to a substantial portion of cancer patients. The concept of donor immune response having a graft-versus-tumor effect gave rise to the theory that a strongly immunosuppressive, but not myeloablative, preparative regimen (ie, a nonmyeloablative transplant may result in a state of chimerism in which the recipient and donor are coexisting). The toxicity and efficacy of nonmyeloablative transplants are being evaluated

## Table 98–2

**Commonly Used Preparative Regimens for HSCT[a]**

| Type of HSCT | Preparative Regimen | Dose and Schedule for Adults | Dose and Schedule for Pediatric Patients |
|---|---|---|---|
| Allogeneic[13] | Myeloablative CY-TBI | CY 60 mg/kg/day IV on 2 consecutive days before TBI 1000–1575 rads (10–15.75 Gy) fractionated over 1–7 days | CY 60 mg/kg/day IV on 2 consecutive days before TBI 1000–1575 rads (10–15.75 Gy) fractionated over 1–7 days |
| Allogeneic, autologous[14] | Myeloablative BU-CY | BU 1 mg/kg per dose po or 0.8 mg/kg per dose IV every 6 hours × 16 doses CY 60 mg/kg/day IV daily × 2 days after BU | BU 1 mg/kg per dose po or 0.8 mg/kg per dose IV every 6 hours × 16 doses CY 120–200 mg/kg IV given over 2–4 days after BU |
| Autologous[15] | Myeloablative BEAM (carmustine/etoposide/-cytarabine/melphalan) | Carmustine 300 mg/m² IV Etoposide 400–800 mg/m² IV given over 4 days Cytarabine 400–1600 mg/m² IV given over 4 days Melphalan 140 mg/m² IV | Carmustine 300 mg/m² IV Etoposide 400–800 mg/m² IV given over 4 days Cytarabine 400–1600 mg/m² IV given over 4 days Melphalan 140 mg/m² IV |
| Allogeneic[16] | Nonmyeloablative BU-FLU | Fludarabine 30 mg/m²/day IV on day −10 to day −5 followed by busulfan 1 mg/kg/dose po every 6 hours × 8 doses on days −6 and −5 | Fludarabine 30 mg/m²/day IV on day −10 to day −5 followed by busulfan 1 mg/kg/dose po every 6 hours × 8 doses on days −6 and −5 |

[a]BEAM, carmustine, etoposide, cytarabine, and melphalan; BU-CY, busulfan and cyclophosphamide; BU-FLU, busulfan and fludarabine; CY-TBI, cyclophosphamide–total-body irradiation; IV, intravenous; po, oral; TBI, total-body irradiation.

in patients with malignant and nonmalignant conditions who are not eligible for a myeloablative HSCT.

A nonmyeloablative preparative regimen allows for development of mixed chimerism (defined as 5%–95% peripheral donor T cells) between the host and recipient to allow for a graft-versus-tumor effect as the primary form of therapy (**Figure 98–1**). Chimerism is assessed within peripheral blood T cells and granulocytes and bone marrow using conventional (eg, using sex chromosomes for opposite-sex donors) and molecular (eg, variable number of tandem repeats) methods for same-sex donors.

The nonmyeloablative preparative regimen does not completely eliminate host normal and malignant cells. Donor cells eradicate residual host hematopoiesis, and the graft-versus-tumor effects generally occur after the development of full donor T-cell chimerism. After engraftment, mixed chimerism should be present and is shown by the presence of both donor- and recipient-derived cells. Autologous recovery should occur promptly if the graft is rejected. The intensity of immunosuppression required for engraftment depends on the immunocompetence of the recipient and the histocompatibility and composition of the HSCT.[18] More intensive conditioning regimens that are required for engraftment in the setting of unrelated-donor- or HLA-mismatched-related HSCT have been termed reduced-intensity myeloablative transplants. After chimerism develops, donor-lymphocyte infusion can be administered safely in patients without GVHD to eradicate malignant cells.

Nonmyeloablative preparative regimens typically consist of a purine analog (eg, fludarabine) in combination with an alkylating agent or low-dose TBI. Adverse effects in the early post-transplant period are decreased because of the lower intensity preparative regimen, thus making HSCT available to patients who in the past were not healthy or young enough to receive a myeloablative preparative regimen. The risk of GVHD remains with nonmyeloablative transplant; the GVHD prophylaxis regimens are reviewed in the GVHD section below. Presently, non-myeloablative transplant is not indicated as first-line therapy for any malignant or nonmalignant conditions, although research is ongoing. Nonmyeloablative transplantation is being evaluated for cancers sensitive to a graft-versus-tumor effect (eg, CML and AML), in older patients, or for those with comorbidities who would not be able to tolerate a myeloablative HSCT.

**Toxicities and Management of Preparative Regimens** Myelo-suppression is a frequent dose-limiting toxicity for antineoplastics when administered in the conventional doses used to treat cancer. However, because myelosuppression is circumvented with hematopoietic rescue in the case of patients receiving HSCT, the dose-limiting toxicities of these myeloablative preparative regimens are nonhematologic and vary with the preparative regimen used. Most patients undergoing HSCT experience toxicities commonly associated with chemotherapy (eg, alopecia, mucositis, nausea and vomiting, and infertility), albeit these toxicities are magnified in the HSCT population.

**◉ Busulfan Seizures** Seizures have been reported in both adult and pediatric patients receiving high-dose busulfan for HSCT preparative regimens. Anticonvulsants are used to minimize the risk of seizures. Anticonvulsants are begun shortly before busulfan, with the loading dose completed at least 6 hours before the first busulfan dose. Oral loading and maintenance regimens generally are sufficient because target phenytoin concentrations of 10 to 20 mcg/mL (10–20 mg/L; 40–79 μmol/L) can be achieved by the peak time of seizure risk. If patients are experiencing

**FIGURE 98–1.** Schema for nonmyeloablative transplantation. Recipients (R) receive a nonmyeloablative preparative regimen and an allogeneic hematopoietic stem cell transplantation (HSCT). Initially, mixed chimerism is present with the coexistence of donor (D) cells and recipient-derived normal and leukemia or lymphoma ($R_L$) cells. Donor-derived T cells mediate a graft-versus-host hematopoietic effect that eradicates residual recipient-derived normal and malignant hematopoietic cells. Donor-lymphocyte infusions (DLIs) may be administered to enhance graft-versus-tumor effects. (From Champlin R, Khouri I, Anderlini P, et al. Nonmyeloablative preparative regimens for allogeneic hematopoietic transplantation. Biology and current indications. Oncology (Williston Park). 2003;17:94–100; discussion 103–107.)

significant vomiting or have difficulty maintaining therapeutic phenytoin concentrations, intravenous (IV) phenytoin should be substituted. Benzodiazepines such as lorazepam or clonazepam also have been used for seizure prophylaxis during high-dose busulfan therapy before HSCT. Antiseizure medications usually are discontinued 24 to 48 hours after administration of the last dose of busulfan. Seizures still can occur despite the use of prophylactic anticonvulsants and usually do not result in permanent neurologic deficits.

**Adaptive Dosing of Busulfan** The considerable interpatient variability in the clearance of both oral and IV busulfan along with the identified concentration–effect relationships, has led to the adaptive dosing of busulfan. Adjusting the oral busulfan dose to achieve a target concentration minimizes the toxicities of the BU-CY regimen, particularly hepatic sinusoidal obstruction syndrome (SOS; formerly referred to as veno-occlusive disease) while improving engraftment and relapse rates. Complete reviews of these relationships after oral busulfan administration are available elsewhere.[19] An IV busulfan product, Busulfex, was approved by the FDA in February 1999 in combination with cyclophosphamide as a preparative regimen before allogeneic HSCT for CML. In combination with either cyclophosphamide or fludarabine, the data available with busulfan suggests that therapeutic drug monitoring may be needed to optimize patient outcome with regards to efficacy and toxicity.[20]

**Hemorrhagic Cystitis** High-dose cyclophosphamide causes moderate to severe hemorrhagic cystitis; acrolein, a metabolite of cyclophosphamide, is the putative bladder toxin. Preventive measures to lower the risk of hemorrhagic cystitis include vigorous hydration, continuous bladder irrigation, or concomitant use of the uroprotectant mesna. The American Society of Clinical Oncology (ASCO) Guidelines for the Use of Chemotherapy and Radiotherapy Protectants recommends the use of Mesna (2-mercaptoethane sulfonate) plus saline diuresis or forced saline diuresis to lower the incidence of urothelial toxicity with high-dose cyclophosphamide in the setting of HSCT.[21]

**Chemotherapy-Induced Gastrointestinal Effects** Preparative regimens for myeloablative HSCT result in other end-organ toxicities, such as renal failure and idiopathic pneumonia syndrome. In addition, recipients of myeloablative preparative regimens are at risk for severe gastrointestinal (GI) toxicity, specifically chemotherapy-induced nausea and vomiting (CINV), diarrhea, and mucositis. CINV can be caused by administration of highly emetogenic chemotherapy over several days, TBI, and poor control of CINV before HSCT. Thus, patients who are undergoing a myeloablative HSCT should receive a prophylactic corticosteroid with a serotonin antagonist, with higher doses of serotonin antagonists potentially being needed in this patient population. In addition, these patients are at high risk for delayed CINV in the immediate posttransplant period, and these issues should be addressed accordingly as per published clinical practice guidelines.[22]

Diarrhea is also an adverse effect experienced by a majority of patients undergoing HSCT. Chemotherapy-induced diarrhea occurs because of the effects of the preparative regimen, which results in inflammation and damage to the cells lining the GI tract. Diarrhea caused by the preparative regimen is usually apparent within the first week after the initiation of chemotherapy and/or radiation. Treatment strategies for chemotherapy-induced diarrhea include the administration of antidiarrheals after excluding infectious causes of diarrhea and the prevention of dehydration.

Virtually all patients receiving a myeloablative preparative regimen experience severe mucositis owing to its effects on rapidly dividing cells of the oral epithelium and subsequent inflammation of the oropharyngeal cavity. Routine oral care protocols are indicated to reduce the severity of mucositis, which may onset within the first week of HSCT and persist for up to approximately 2 weeks. Palifermin, a keratinocytic growth factor, may be considered for patients undergoing myeloablative HSCT with TBI-based preparative regimens.[23] Patients may require parenteral opioid analgesics for pain relief owing to mucositis, and total parenteral nutrition may be necessary to prevent the development of nutritional deficiencies.

**Sinusoidal Obstruction Syndrome** Hepatic SOS is a life-threatening complication that may occur secondary to preparative regimens or radiation. The pathogenesis of SOS is not understood completely, but several mechanisms have been proposed. The key event appears to be endothelial damage caused by the preparative regimen. The primary site of the toxic injury is the sinusoidal endothelial cells; the endothelial damage initiates the coagulation cascade, induces thrombosis of the hepatic venules, and eventually leads to fibrous obliteration of the affected venules.[24]

The clinical manifestations of SOS are hyperbilirubinemia, jaundice, fluid retention, weight gain, and right upper quadrant abdominal pain. To make a clinical diagnosis of SOS, these features must occur in the absence of other causes of posttransplant liver failure, including GVHD, viral hepatitis, fungal abscesses, or drug reactions. Most cases of SOS occur within 3 weeks of HSCT, and the clinical diagnosis can be confirmed histologically via liver biopsy.

Patients with mild SOS have an excellent prognosis, but those with more severe disease (ie, bilirubin greater than 20 mg/dL [342 μmol/L] or weight gain greater than 15%) have a high mortality rate. Pretransplant risk factors for SOS include a mismatched or unrelated graft, increased age, prior abdominal radiation or stem cell transplant, and increased transaminases before HSCT.[24] Interpatient variability in the metabolism and clearance of the chemotherapy (ie, busulfan and cyclophosphamide) used within the preparative regimen also may be associated with a poor outcome, although the relationships vary within the various preparative regimens. The association of SOS with busulfan concentrations is discussed in the section on adaptive dosing of busulfan. Use of ursodiol, unfractionated heparin, or low-molecular-weight heparin has been associated with a lower incidence of SOS in a limited number of small, randomized studies and may be recommended for SOS prophylaxis.[24]

The mainstay of treatment for established SOS is supportive care aimed at sodium restriction, increasing intravascular volume, decreasing extracellular fluid accumulation, and minimizing factors that contribute to or exacerbate hepatotoxicity and encephalopathy. Recombinant tissue plasminogen activator administered with or without heparin has been investigated for treatment of SOS, but the life-threatening risk of bleeding precludes any potential benefit.[24] Defibrotide, an oligonucleotide with antithrombotic, anti-ischemic, and anti-inflammatory activity, is not FDA approved in the United States but has shown promising results in the treatment of SOS in clinical trials.[24]

**Myelosuppression and Hematopoietic Growth Factor Use** HGFs may be administered to mobilize PBPCs before an HSCT, to hasten hematopoietic recovery during the period of aplasia after an autologous HSCT, and to stimulate hematopoietic recovery when the patient fails to engraft.[25]

Autologous HSCT is associated with profound aplasia owing to the myeloablative preparative regimen. Aplasia typically lasts 7 to 14 days after an autologous PBPC transplant. During this period of aplasia, patients are at high risk for complications such as bleeding and infection. Filgrastim and sargramostim exert their effects by stimulating the proliferation of committed progenitor cells and accelerating recovery on hematopoiesis. Once engraftment occurs, HGFs may be discontinued. The anatomic source of hematopoietic cells predicts the degree of benefit, with the greatest benefit reached when bone marrow is the graft source. With autologous PBPC transplant, the effect of HGF on neutrophil recovery is variable.

The use of HGF after allogeneic HSCT—whether from bone marrow or PBPC grafts—is controversial. The amount of data with sargramostim is limited in this setting; data with filgrastim have shown more rapid neutrophil but slower platelet engraftment in those receiving grafts from bone marrow or PBPCs.[26] The effects of post-HSCT filgrastim use on acute and chronic GVHD have been conflicting, with either no effect or increases in both the incidence of acute and chronic GVHD and treatment-related mortality.[26] Thus, there is little reason to treat allogeneic BMT with filgrastim as prophylaxis after HSCT.

**Graft Failure**   A delicate balance between host and donor effector cells in the bone marrow is necessary to ensure adequate engraftment because residual host-versus-graft effects may lead to graft rejection. The incidence of graft rejection is higher in patients with aplastic anemia and those undergoing HSCT with histoincompatible marrow or T-cell–depleted marrow.[1] Graft rejection is uncommon in leukemia patients receiving myeloablative preparative regimens with a histocompatible allogeneic donor.

Therapeutic options for the treatment of graft rejection or graft failure are limited. A second HSCT is the most definitive therapy, although the associated complications and toxicities may preclude its use. Graft rejection is best managed with immunosuppressants such as ATG. Primary graft failure occasionally can be treated successfully using HGFs, although patients who received purged autografts are less likely to respond.

▶ *Graft-Versus-Host Disease*

**KEY CONCEPT** *GVHD is caused by the activation of donor lymphocytes, leading to immune damage to the skin, gut, and liver in the recipient.* Immune-mediated destruction of tissues, a hallmark of GVHD, disrupts the integrity of protective mucosal barriers and thus provides an environment that favors the establishment of opportunistic infections. **KEY CONCEPT** *An immunosuppressive regimen is administered to prevent GVHD in recipients of an allogeneic graft; this regimen is based on the type of preparative regimen and the source of the graft.* The combination of GVHD and

---

## Clinical Presentation and Diagnosis of Sinusoidal Obstructive Syndrome

**General**

- Sinusoidal obstructive syndrome (SOS) usually occurs within the first 3 weeks after HSCT.
- Busulfan, cyclophosphamide, pretransplant exposure to gemtuzumab, TBI-containing preparative regimens, and pretransplant abnormalities in liver function tests may increase the risk for SOS.

**Symptoms**

- Patients may complain of weight gain and abdominal pain.

**Signs**

- Fluid retention: Weight gain caused by ascites greater than 2% compared with pretransplant weight
- Hepatomegaly: May result in right upper quadrant pain
- Hepatic: Jaundice caused by hyperbilirubinemia defined as a bilirubin greater than 2 mg/dL (34.2 μmol/L)

**Laboratory Tests**

- Hepatic: Elevation of bilirubin, alkaline phosphatase, and γ-glutamyltransferase (GGT)
- Hematologic: Complete blood count with differential may reveal thrombocytopenia, elevated plasminogen activator-1 levels, decreased antithrombin III, protein C, and protein S

**Other Diagnostic Tests**

- Reversal of blood flow in portal and hepatic veins on Doppler ultrasonography
- Liver biopsy for pathologic review

---

## Patient Encounter, Part 2

**PMH:** Hypertension, type 2 diabetes, hyperlipidemia, hypothyroidism, sleep apnea, and gout

**FH:** Father died at age of 56 years of myocardial infarction. Mother has history of hypertension. One younger sister with a history of hypertension

**SH:** She is a high school teacher and is married with no children. She drinks alcohol occasionally and does not smoke or use illicit drugs

**Allergies:** NKDA

**Meds:** Metformin 500 mg by mouth twice daily; lisinopril 20 mg by mouth once daily; carvedilol 12.5 mg by mouth twice daily; aspirin 81 mg by mouth once daily; atorvastatin 40 mg by mouth once nightly at bedtime; levothyroxine 75 μg by mouth once daily; allopurinol 300 mg by mouth once daily

**ROS:** (+) Fatigue

**PE:**

**VS:** BP 134/82, P 69, RR 18, T 37.6°C

Physical exam reveals no acute findings.

Laboratory analysis is within normal limits except for serum creatinine of 1.3 g/dL (115 μmol/L) and hemoglobin of 10.2 g/dL (102 g/L; 6.33 μmol/L).

*Given this additional information, what is your assessment of the planned preparative regimen?*

*What infectious complications are of a concern for this patient during the early transplant period?*

infectious complications are leading causes of mortality for allogeneic HSCT patients. GVHD is divided into two forms (ie, acute and chronic) based on clinical manifestations. Traditionally, the boundary between acute and chronic GVHD was set at 100 days after HSCT; however, more recent definitions hinge upon different clinical symptoms rather than the time of onset.[27,28]

**Acute GVHD** The degree of histocompatibility between donor and recipient is the most important factor associated with the development of acute GVHD. The pathophysiology for acute GVHD is a multistep phenomenon, including the development of an inflammatory milieu that results from host tissue damage induced by the preparative regimen; both recipient and donor antigen-presenting cells and inflammatory cytokines triggering activation of donor-derived T cells; and the activated donor T cells mediate cytotoxicity through a variety of mechanisms, which leads to tissue damage characteristic of acute GVHD.[28]

Despite prophylaxis, 20% to 80% of patients will develop acute GVHD.[29] Other factors that increase the risk of acute GVHD include increasing recipient or donor age (older than 20 years), female donor to a male recipient, and mismatches in minor histocompatibility antigens in HLA-matched transplants.[28] T-cell depletion or receipt of an umbilical cord blood graft appears to lower the risk of acute GVHD.[1]

**Clinical Presentation and Staging of Acute GVHD** Acute GVHD targets the skin, liver and GI tract; it must be distinguished accurately from other causes of skin, liver, or GI toxicity in HSCT patients. Other causes of toxicities affecting the skin, liver, or GI tract may include a drug reaction or an infectious process. A staging system based on clinical criteria is used to grade acute GVHD (**Figure 98–2**). The severity of organ involvement is scored on an ordinal scale from 0 (no symptoms) to IV (severe symptoms), and then an overall grade is established based on the number and extent of involved organs.

**Immunosuppressive Prophylaxis of Acute GVHD** GVHD is a leading cause of morbidity and mortality after allogeneic HSCT and thus, efforts have focused on preventing acute GVHD. The donor graft and preparative regimen influence the prophylactic regimen for acute GVHD, with two approaches having been taken by clinicians over time. One approach involves T-cell depletion, which was discussed more fully in the section on T-cell depletion earlier. The more common method is to use two-drug immunosuppressive therapy that typically consists of a calcineurin inhibitor (ie, cyclosporine or tacrolimus) with methotrexate after myeloablative HSCT. Prophylaxis of acute GVHD for nonmyeloablative preparative regimens is varied, but a calcineurin inhibitor with either methotrexate or mycophenolate mofetil is used.[16]

The calcineurin inhibitors (ie, cyclosporine and tacrolimus) should be initiated before donor cell infusion (eg, day –1) when used for GVHD prophylaxis. This schedule is recommended because of the known mechanism of action of calcineurin inhibitors, which entails blocking the proliferation of cytotoxic T cells by inhibiting production of T helper cell–derived interleukin-2 (IL-2). Administering calcineurin inhibitors before the donor cell infusion allows inhibition of IL-2 secretion to occur before a rejection response has been initiated. Studies comparing cyclosporine and tacrolimus in combination with methotrexate have shown that tacrolimus administration is associated with a lower incidence of grade II to IV acute GVHD and a similar incidence of chronic GVHD but variable effects on overall survival.[30,31]

**Adaptive Dosing of the Calcineurin Inhibitors** Most HSCT centers have their own standardized approach to dose adjust the calcineurin inhibitors cyclosporine and tacrolimus to target concentration ranges. Cyclosporine and tacrolimus trough concentrations are associated with acute GVHD and nephrotoxicity. Cyclosporine trough concentrations usually are maintained between 150 and 400 ng/mL (125 and 333 nmol/L) in patients undergoing allogeneic HSCT. Tacrolimus trough concentrations are targeted to a range of 10 to 20 ng/mL (10–20 mcg/L; 12.4–24.8 nmol/L).[32] Dosage adjustments to either calcineurin inhibitor also should be made for elevated serum creatinine regardless of their serum concentrations. Nephrotoxicity can occur despite low or normal concentrations of the calcineurin

| Grading by Organ System | | | Overall Clinical Grade | | | | |
|---|---|---|---|---|---|---|---|
| **Organ** | **Extent of Involvement** | **Code** | **I** | **II** | **III** | **IV** | |
| **Skin** | Rash (% of body surface) < 25 | 1+ | | | | | |
| | 25–50 | 2+ | | | | | |
| | > 50 | 3+ | | | | | |
| | Desquamation | 4+ | | | | | |
| **Liver** | Bilirubin (mg%) 2–3 | 1+ | | | | | |
| | 3–6 | 2+ | | | | | |

inhibitor cyclosporine and may be a consequence of other drug- or disease-related factors known to influence the development of nephrotoxicity (eg, genetic risk factors, concurrent use of other nephrotoxic agents, and sepsis). Careful monitoring for drug interactions via CYP 3A4 and P-glycoprotein is also warranted. The calcineurin inhibitor doses are adjusted based on serum drug levels and the calculated creatinine clearance. Common adverse effects to these agents include neurotoxicity, hypertension, hyperkalemia, hypomagnesemia, and/or nephrotoxicity (which may lead to an impaired clearance of methotrexate).

Tapering schedules for the calcineurin inhibitors after myeloablative HSCT vary widely. In patients without GVHD, the calcineurin inhibitor doses usually are stable to day +50 and then are tapered slowly with the intent of discontinuing all immunosuppressive agents by 6 months after HSCT. By this time, immunologic tolerance has developed, and patients no longer require immunosuppressive therapy. There is a paucity of information regarding the optimal duration of GVHD prophylaxis after nonmyeloablative HSCT, with data suggesting that a 2-month duration of cyclosporine with a 4-month taper lowers the rate of severe acute GVHD.[33]

**Treatment of Acute GVHD** The most effective way to treat GVHD is to prevent its development. Corticosteroids, usually in combination with a calcineurin inhibitor, are the first-line therapy for treatment of established acute GVHD. Corticosteroids indirectly halt the progression of immune-mediated destruction of host tissues by blocking macrophage-derived

IL-1 secretion. IL-1 is a primary stimulus for T helper cell–induced secretion of IL-2, which, in turn, is responsible for stimulating proliferation of cytotoxic T lymphocytes. The recommended dosage of methylprednisolone in this setting is 2 mg/kg/day; there is no advantage to higher corticosteroid doses (ie, 10 mg/kg/day).[28] A partial or complete response is seen in approximately 50% of patients treated with corticosteroids. Once a clinical improvement occurs, there is no consensus on the optimal method for tapering the corticosteroids. Patients with steroid-refractory acute GVHD have a poor prognosis, and a number of medications are being studied for salvage therapy.

**Chronic GVHD** Occurring in 20% to 70% of HSCT recipients surviving longer than 100 days, chronic GVHD is the most frequent and serious late complication of allogeneic HSCT.[34] Chronic GVHD is the major cause of nonrelapse mortality and morbidity. The clinical course of chronic GVHD is multifaceted, involving almost any organ in the body, and its symptoms resemble autoimmune and immunologic disorders (eg, scleroderma). Chronic GVHD symptoms usually present within 3 years of allogeneic HSCT and often are preceded by acute GVHD.[27] Traditionally, the boundary between acute and chronic GVHD was set at 100 days after HSCT; however, more recent definitions hinge on different clinical symptoms rather than the time of onset.[34] A consensus document regarding the diagnosis and scoring of chronic GVHD has been published that proposes a clinical scoring system to describe chronic GVHD as opposed to historical descriptions of chronic GVHD, which described the phenomenon as being "limited" versus "extensive" in nature.[29] The diagnosis of chronic GVHD requires distinction from acute GVHD; the presence of at least one diagnostic clinical sign of chronic GVHD or presence of at least one distinctive manifestation confirmed by pertinent biopsy or other relevant tests; and exclusion of other possible diagnoses.

**Prevention and Treatment of Chronic GVHD** Chronic GVHD is not a continuation of acute GVHD, and separate approaches are needed for its prevention and management. Prevention of chronic GVHD through prolonged use of immunosuppressive medications has been unsuccessful.[34] Thus, its prevention is focused on minimization of factors associated with higher rates of chronic GVHD. Several recipient, donor, and transplant factors are relevant. Recipient risk factors that are not modifiable include older age, certain diagnoses (eg, chronic myeloid leukemia), and lack of an HLA-matched donor. Modifiable factors that may lower the risk of chronic GVHD include selection of a younger donor, avoidance of a multiparous female donor, use of umbilical cord blood or bone marrow grafts rather than PBPCs, and limitation of CD34+ and T-cell dose infused.[34] Development of acute GVHD is a major predictor for chronic GVHD, with 70% to 80% of those with grade II to IV acute GVHD developing chronic GVHD.[34]

Relative to no treatment, survival in those with chronic GVHD is improved by extended corticosteroid therapy; however, multiple long-term adverse effects are associated with corticosteroid use. The prednisone dosage is 1 mg/kg/day administered orally in divided doses for 30 days and then slowly converted to an alternate-day therapy. One to two months may pass before an improvement in clinical symptoms is noted, and therapy usually is continued for 9 to 12 months. Therapy can be tapered slowly after resolution of signs and symptoms of chronic GVHD. If a flare of chronic GVHD occurs during the tapering schedule or after therapy is discontinued, immunosuppressive therapy

is restarted. Other potential approaches for patients who are refractory to initial therapy include etanercept (Enbrel), infliximab (Remicade), mycophenolate mofetil (Cellcept), rituximab (Rituxan), extended use of calcineurin inhibitors, or extracorporeal photochemotherapy.[34] When immunosuppressive therapy is administered for long periods, the patient must be monitored closely for chronic toxicity. Cushingoid effects, aseptic necrosis of the joints, and diabetes can develop with long-term corticosteroid use. Other severe complications include a high incidence of infection with encapsulated organisms and atypical pathogens such as *Pneumocystis jiroveci*, cytomegalovirus (CMV), and varicella zoster virus (VZV).

### ▶ Infectious Complications

**KEY CONCEPT** *Recipients of HSCT are at higher risk of bacterial, viral, and fungal infections and usually receive a prophylactic or preemptive regimen to minimize the morbidity and mortality associated with infectious complications.* After myeloablative and nonmyeloablative HSCT, opportunistic infections are a major source of morbidity and mortality. There are three periods of infectious risks, preengraftment (from 15 days prior and to 45 days after HSCT), postengraftment (engraftment to day 100 days post engraftment), and late 100 days after engraftment. From days 0 to 30 after HSCT, particularly for patients undergoing myeloablative HSCT, the primary pathogens are aerobic bacteria, *Candida* spp., and herpes simplex virus (HSV). Respiratory viruses such as respiratory syncytial virus (RSV), influenza, adenovirus, and parainfluenza virus are recognized increasingly as pathogens causing pneumonia, particularly during community outbreaks of infection with these organisms. Because of the need to administer chemotherapy, blood products, antibiotics, and other adjunctive medications, the placement of a semipermanent double- or triple-lumen central venous catheter is necessary before HSCT. However, the indwelling IV central catheters put HSCT recipients at increased risk for *Staphylococcus* infections.

The second period of infectious risk occurs after engraftment to post transplant day 100. Bacterial infections are still of concern, but pathogens such as CMV, adenovirus, and *Aspergillus* spp. are common. A common manifestation of infection is interstitial pneumonitis (IP), which can be caused by CMV, adenovirus, *Aspergillus,* and *P. jiroveci.* Suppression of the immune system from acute GVHD and corticosteroids contributes to the risk of such infections during this period. Therefore, patients undergoing nonmyeloablative transplant who are receiving corticosteroids to treat GVHD can be expected to have a similar risk for infection as those undergoing myeloablative HSCT.[35] Invasive fungal infections over the first year after HSCT occur at a similar rate in nonmyeloablative transplant compared with historical control participants receiving a myeloablative preparative regimen.[36]

During the late period (100 days after engraftment), the predominant organisms are the encapsulated bacteria (eg, *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Neisseria meningitidis*), fungi, and VZV. The encapsulated organisms commonly cause sinopulmonary infections. The risk of infection during this late period is increased in patients with chronic GVHD as a result of prolonged immunosuppression.

**Prevention and Treatment of Bacterial and Fungal Infections** Between the time of administration of the preparative regimen and successful engraftment, allogeneic myeloablative HSCT patients undergo a period of pancytopenia that can last

from 2 to 6 weeks. The risk of infection is also reduced by aggressive use of antibacterial, antifungal, and antiviral therapy both prophylactically and for the treatment of documented infection. The antibacterial prophylactic regimens vary substantially among HSCT centers. Some HSCT centers use a prophylactic fluoroquinolone (eg, levofloxacin) on admission for HSCT and then switch to a broad-spectrum IV antibiotic (eg, cefepime) when the patient experiences his or her first neutropenic fever. Although fluoroquinolones reduce the incidence of gram-negative bacteremia, they have not been shown to affect mortality; the possibility of developing clostridium difficile-associated diarrhea exists with fluoroquinolone use and infectious causes should be ruled out if diarrhea occurs. Concerns with fluoroquinolone use in the prophylactic setting during HSCT include the emergence of resistant organisms and an increased risk for streptococcal infection. Broad-spectrum IV antibiotics should be initiated immediately at the time of the first neutropenic fever under the treatment guidelines endorsed by the Infectious Disease Society of America for management of fever of unknown origin in the neutropenic host.[37]

**Prevention of HSV and VZV** Patients who are HSV antibody seropositive before HSCT are at high risk for reactivation of their HSV infection. Acyclovir is highly effective in preventing HSV reactivation, and thus, prophylactic acyclovir is used commonly in HSV-seropositive patients who are undergoing an allogeneic or autologous HSCT. In the setting of HSV prophylaxis, dosing regimens for prophylactic acyclovir vary widely and most centers discontinue acyclovir at the time of hematopoietic recovery.[38] Valacyclovir (Valtrex), a prodrug of acyclovir with improved bioavailability, may allow for adequate serum concentrations to prevent HSV in patients undergoing HSCT as well.

In those with a history of VZV infection, VZV disease occurs in 30% of allogeneic HSCT recipients.[39] The appropriate duration of VZV prophylaxis is controversial. Although VZV infections are reduced by prophylactic acyclovir administered from 1 to 2 months until 1 year after HSCT, the risk of VZV persists in those on continued immunosuppression.[38]

**Prevention and Preemptive Therapy of CMV Disease** After allogeneic HSCT, CMV disease is common and has high morbidity and mortality rates. Allogeneic patients are at greater risk than autologous recipients primarily because the latter more efficiently reconstitute their immune system after transplantation. However, autologous HSCT recipients who are CMV seropositive before HSCT are at risk for CMV infection, and prophylaxis should be considered in a select minority of patients.[38] Infection caused by CMV is usually asymptomatic and develops when CMV replication occurs. Replication occurs primarily in body fluids such as the blood (viremia), bronchoalveolar fluid, or urine (viruria). CMV disease is symptomatic and occurs when the virus invades an organ or tissue. Pneumonia and gastritis are the most common types of CMV disease after allogeneic HSCT. The presence of a CMV infection substantially increases the risk for developing invasive CMV disease. Strategies to prevent CMV infection have resulted in dramatic reductions in the incidence of CMV disease.

Primary CMV can be prevented with CMV seromatching, which includes transplanting PBPCs or bone marrow from CMV-seronegative donors and infusing CMV-negative blood products to CMV-negative recipients. Antivirals are important in those who are CMV seropositive or have a CMV-seropositive graft, with two available approaches to minimize the morbidity associated with CMV. The first is universal prophylaxis, in which

ganciclovir is begun at the time of engraftment and is continued until approximately 100 days after engraftment. The second approach is called preemptive therapy, for which ganciclovir is selectively administered based on detection of CMV reactivation.

Preemptive therapy is the most commonly used strategy for preventing CMV disease after allogeneic HSCT because ganciclovir is used only in patients at highest risk for developing CMV disease. This approach minimizes administration of ganciclovir, thus lowering the risk of ganciclovir-induced neutropenia with its subsequent increased risk of invasive bacterial and fungal infections. Preemptive strategies typically use an induction course of ganciclovir for 7 to 14 days followed by a maintenance course until 2 or 3 weeks after the last positive antigenemia result or until 100 days after HSCT.[38] Oral valganciclovir (Valcyte) is an orally bioavailable prodrug of ganciclovir that is converted to ganciclovir in vivo after intestinal absorption and has been used for preemptive therapy. Foscarnet may be given as an alternative to ganciclovir to prevent CMV disease, although its use is complicated by nephrotoxicity and electrolyte wasting.

### Fungal Infections

***Prevention of Fungal Infections.*** The widespread use of fluconazole prophylaxis since the early 1990s has led to a significant decline in the morbidity and mortality associated with invasive candidiasis in HSCT recipients. However, invasive aspergillosis (IA); zygomycetes; and fluconazole-resistant *Candida* spp., such as *Candida krusei* and *Candida glabrata,* have increased markedly in incidence.[40] Itraconazole, another azole antifungal agent, has better *in vitro* activity against fluconazole-resistant fungi (eg, *Aspergillus* and some *Candida* spp.) and is more effective than fluconazole for long-term prophylaxis of invasive fungal infections after allogeneic HSCT; however, itraconazole is used less often because of frequent GI side effects and concern for potential drug interactions.[41] Posaconazole (Noxafil) is a triazole antifungal that has been approved by the FDA for prophylaxis against IA in HSCT patients with GVHD and is now the recommended prophylactic agent for this subset of HSCT patients on immunosuppression. Posaconazole oral suspension should be given with food for adequate absorption. The posaconazole tablet can be administered without regard to food. Micafungin (Mycamine), an agent of the newer class of antifungals known as the echinocandins, has been FDA approved for prophylaxis of *Candida* infections in patients undergoing HSCT.

***Risk Factors for Invasive Mold Infections.*** Invasive mold infections (eg, *Aspergillus* spp., *Fusarium* spp., *Zygomycetes*, and *Scedosporium* spp.) are an increasing cause of morbidity and death after allogeneic and autologous HSCT. It has been estimated that up to one-third of febrile neutropenic patients who do not respond to antibiotic therapy after 1 week are harboring a fungal infection.[37] In HSCT recipients, risk factors for invasive fungal infections include previous history of IA; recipient factors, including older age, CMV seropositivity, and type of stem cell transplant; treatment factors (eg, a fludarabine-based preparative regimen); transplant complications (eg, prolonged neutropenia, graft failure, and higher grade GVHD); and host factors (eg, diabetes, iron overload).[42] Infections with *Aspergillus* spp. remain the most common mold infections diagnosed in the HSCT population and optimal treatment must be promptly initiated if indicated.

***Treatment of Invasive Aspergillosis.*** Early diagnosis and initiation of appropriate therapy may reduce the high mortality rate of IA. Outcomes also depend on recovery of the recipient's immune system and reduction of immunosuppression. Diagnosis is difficult

with the use of computed tomography scans and cultures. Research is ongoing to evaluate the benefit of using nonculture-based methods, such as galactomannan and $(1,3)$-β-D-glucan antigen detection, which are components of the fungal cell wall that can be detected by commercially available assays.

Practice guidelines are available for the treatment of invasive *Aspergillus* infections in immunocompromised patients.[43] Available mold-active agents include triazole antifungals (itraconazole, voriconazole, and posaconazole), echinocandins (caspofungin, micafungin, and anidulafungin), and amphotericin B formulations.

Historically, conventional amphotericin B (c-AmB) was considered the "gold standard" antifungal therapy for any IA infection; however lipid analogs of amphotericin have shown equivalent efficacy and a reduction in side effects, albeit at a higher acquisition cost. With significant toxicity limiting the overall utility of conventional amphotericin B, voriconazole (Vfend) was compared with c-AmB for treatment of IA. For initial therapy of IA, voriconazole had higher response and survival rates than c-AmB and is now considered the primary option for patients with IA.[44]

In patients who have failed initial therapy (ie, salvage), lipid formulations of amphotericin products, itraconazole, posaconazole or an agent from the echinocandin class may be used.

The optimal duration of appropriate antifungal therapy for treating IA is individualized to the reconstitution of the patient's immune system and his or her response to antifungal treatment. Most clinicians continue aggressive antifungal therapy until the infection has stabilized radiographically and may continue with less aggressive "maintenance" therapy (eg, oral voriconazole) until immunosuppression is lessened or completed. In general, it is common to require several months of antifungal therapy to treat IA.

***Pneumocystis jiroveci.*** After allogeneic HSCT, prophylaxis for *P. jiroveci* (formerly *P. carinii*) pneumonia (PCP) is used because *Pneumocystis* is a serious infection with a high mortality rate if left untreated. Most centers use sulfamethoxazole/trimethoprim for 6 to 12 months after HSCT;[38] aerosolized or IV pentamidine and oral dapsone are alternatives for patients who are allergic to sulfa drugs or who do not tolerate cotrimoxazole. Because PCP most often occurs after engraftment, cotrimoxazole usually is begun after neutrophil recovery because of its myelosuppressive effects. Patients receiving prophylactic cotrimoxazole should be monitored closely for rash and unexplained neutropenia or thrombocytopenia. Cotrimoxazole usually is avoided on days of methotrexate administration because the sulfonamides can displace methotrexate from plasma binding sites and decrease renal methotrexate clearance, resulting in higher methotrexate concentrations. Autologous HSCT patients do not receive posttransplant immunosuppression, and thus, their risk of developing PCP is lower.[38] PCP prophylaxis is used often after autologous HSCT in patients with a hematologic malignancy.

### ▶ Issues of Survivorship After HSCT

The number of long-term HSCT survivors is increasing as 5-year disease-free survival rates improve. Because nonmyeloablative preparative regimens were developed over the past decade, the late effects reported in HSCT survivors describe those resulting from myeloablative preparative regimens.[45] HSCT recipients—with either an autologous or an allogeneic graft—have a higher mortality rate than the general population.[46] KEY CONCEPT *Long-term survivors of HSCT should be monitored closely, particularly for infections and secondary malignant neoplasms.*

Survivors of HSCT are at higher risk for secondary malignant neoplasms.[45] Long-term impairment of end-organ function,

## Patient Encounter, Part 3

The patient is admitted for allogeneic HSCT with a reduced-intensity preparative regimen consisting of fludarabine and busulfan. Her hospital course was complicated for neutropenic fever and gastrointestinal toxicities. Neutrophil engraftment occurred on day +12 after HSCT, and the patient was discharged from the hospital on day +14 with minimal complaints. She presents to the transplant clinic on day +22 complaining of a skin rash on her palms and trunk. She does not report diarrhea, nausea, vomiting, or any other symptoms.

*What is the differential diagnosis for the patient's current condition?*

*How should this patient be monitored for progression of GVHD?*

including the kidneys, liver, and lungs, may be caused by the preparative regimen, infectious complications, and/or post-transplant immunosuppression. Many HSCT recipients experience endocrine dysfunction, such as hypothyroidism from TBI, adrenal insufficiency from long-term corticosteroids to treat GVHD, and infertility from radiation and/or high doses of alkylating agents in myeloablative preparative regimens. Osteopenia has been found in more than half of HSCT recipients, most likely from gonadal dysfunction and/or corticosteroid administration.

Close monitoring of HSCT recipients for infections is necessary because recovery of immune function is slow, sometimes requiring more than 2 years, even in the absence of immunosuppressants.[45] Fevers should be assessed and treated rapidly to minimize the likelihood of a fatal infection. HSCT recipients—both autologous and allogeneic—lose protective antibodies to vaccine-preventable diseases; international guidelines been published regarding recommendations for reimmunization of HSCT recipients.[38]

Survivors of HSCT should be monitored routinely for signs of relapse and, if an allogeneic graft was used, chronic GVHD. They should be advised regarding revaccination and obtaining prompt medical care for fevers or signs of infection. Routine evaluations of organ function (ie, renal, hepatic, thyroid, and ovarian) and osteopenia should occur and the appropriate management strategies initiated if necessary.

## OUTCOME EVALUATION

Monitor for symptoms and signs of the disease that is being treated by HSCT to assess the effectiveness of the HSCT. For example, the monitoring plan for a patient with CML would be to monitor disease response by PCR of the *BCR-ABL* transcript. The actual clinical outcome monitored, along with the frequency of monitoring, is based on the underlying disease.

Monitor for nonhematologic toxicity of the preparative regimen during its administration. Monitor these symptoms at least daily, with more frequent monitoring if the patient is experiencing these nonhematologic effects. The goal is to prevent or minimize these adverse effects. Specifically:

- *Busulfan:* Seizures, busulfan concentrations if being used with the BU-CY preparative regimen, number of vomiting episodes, and nausea by patient self-report, total bilirubin, and sudden weight changes (SOS)
- *Cyclophosphamide:* Electrocardiography during IV administration, RBCs in urine, frequency of urination, pain on urination, urinary output, number of vomiting episodes, and nausea by patient self-report, total bilirubin, and SOS
- *Etoposide:* Blood pressure, respiratory rate, serum pH, serum bicarbonate with arterial blood gases, and evaluation of anion gap if necessary

## Patient Care Process

**Patient Assessment:**

- Assess the patient regarding the indication for HSCT, the type of preparative regimen and the type of donor.
- Review the patient's medical history and available laboratory tests. Is the preparative regimen appropriate based on this information?
- Determine the nonhematologic toxicity of the preparative regimen, the expected timing of engraftment after the graft is infused, and the need for GVHD prophylaxis.
- Conduct a medication history. Identify medications that should be continued and medications that should be stopped during the transplant period.

**Therapy Evaluation:**

- Determine the supportive care needs during administration of the preparative regimen, including use of indwelling central venous catheters and blood product support.
- Assess pharmacologic management of CINV, mucositis, and pain daily; adjust according to efficacy. Review new medications for drug interactions.

**Care Plan Development:**

- After the graft is infused, monitor the complete blood count with differential at least daily to evaluate engraftment.
- Determine the need for prophylaxis or treatment of infection during the patient's prolonged period of immunosuppression following engraftment.
- Counsel the patient regarding adherence to prophylactic antibiotic, antifungal, and antiviral regimens. Ensure that the patient is appropriately immunized after recovery from HSCT.
- Counsel the patient regarding adherence to GVHD prophylaxis and treatment. Monitor and manage for adverse drug reactions.

**Follow-Up Evaluation:**

- Assess the effectiveness of the HSCT for the patient's disease. Continue to monitor for nonhematologic toxicity of the preparative regimen, signs and symptoms of GVHD, and infection.
- Follow allogeneic HSCT patients closely for the first year post HSCT for long term effects of the preparative regimen and altered immunity.

- *Total-body irradiation:* Number of vomiting episodes, nausea by patient self-report, SOS, total bilirubin, and skin assessment for the presence of irritation or blister formation

Until the patient has achieved engraftment, monitor the patient for engraftment with at least daily complete blood counts with differentials; these tests may be needed more often if the patient is critically ill or had a prior low hemoglobin. Patients will require transfusion support with blood products and platelets until engraftment occurs if hemoglobin and/or platelets drop below unsafe levels.

Until engraftment has occurred, monitor the patient's temperature every 4 to 8 hours for signs of infection. Also guide monitoring signs of focal point of infection based on clinical symptoms. For example, if the patient develops shortness of breath, then imaging of the lungs should occur to assess pulmonary infection. Monitor for the toxicity of prophylaxis and/or treatment of bacterial, fungal, or viral infections.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| AML | Acute myelogenous leukemia |
| ANC | Absolute neutrophil count |
| ASCO | American Society of Clinical Oncology |
| ATG | Antithymocyte globulin |
| BMT | Bone marrow transplantation |
| BU-CY | Busulfan–cyclophosphamide |
| c-AmB | Conventional amphotericin B |
| CINV | Chemotherapy-induced nausea and vomiting |
| CML | Chronic myelogenous leukemia |
| CMV | Cytomegalovirus |
| CY-TBI | Cyclophosphamide–total-body irradiation |
| GVHD | Graft-versus-host disease |
| HGF | Hematopoietic growth factors |
| HLA | Human leukocyte antigen |
| HSCT | Hematopoietic stem cell transplant |
| IA | Invasive aspergillosis |
| IL-2 | Interleukin-2 |
| MHC | Minor histocompatibility |
| MM | Multiple myeloma |
| NHL | Non-Hodgkin lymphoma |
| NK | Natural killer |
| PBPC | Peripheral blood progenitor cells |
| PCP | Pneumocystis pneumonia |
| SOS | Sinusoidal obstruction syndrome |
| SCr | Serum creatinine |
| TBI | Total-body irradiation |
| VZV | Varicella zoster virus |

# Supportive Care in Oncology

Sarah L. Scarpace

## LEARNING OBJECTIVES

- **Upon completion of the chapter, the reader will be able to:**

1. Describe the impact of various supportive care interventions on the prognosis of patients with cancer.
2. Discuss the scientific basis for providing various supportive care interventions in the oncology patient population.
3. Identify patient-related and disease-related risk factors in defining a population for whom supportive care interventions would be of benefit.
4. Recognize typical presenting signs and symptoms of common complications and emergencies that require supportive care interventions.
5. Outline appropriate prevention and management strategies for various supportive care interventions.
6. Prepare a monitoring plan to evaluate the efficacy and toxicity of pharmacotherapy interventions for supportive care problems.

## INTRODUCTION

Patients with cancer are at risk for serious adverse events that result from their treatment, the cancer, or both. The management of these complications is generally referred to as supportive care (or symptom management). Examples of treatment-related complications include chemotherapy-induced nausea and vomiting (CINV), myelosuppression, febrile neutropenia (FN), hemorrhagic cystitis, mucositis, and tumor lysis syndrome (TLS). Tumor or cancer-related complications include superior vena cava (SVC) obstruction, spinal cord compression, hypercalcemia, and brain metastases. In some cases, these events can be life threatening. SVC obstruction, spinal cord compression, TLS, and hypercalcemia have traditionally been defined as oncologic emergencies. Treatment- and disease-related complications in the oncology population require rapid assessment and supportive care interventions. The onset of oncologic emergencies may herald the onset of an undiagnosed malignancy or progression or relapse of a preexisting malignancy. Optimal management of patients with various oncologic emergencies and complications requiring supportive care interventions can significantly decrease morbidity and mortality in patients with cancer. This chapter provides an overview of these issues. First, an overview of the management of common side effects of treatment is given. Later, a summary of common oncologic emergencies is presented.

## CHEMOTHERAPY-INDUCED TOXICITIES: NAUSEA/VOMITING

Nausea and vomiting are among the most commonly feared toxicities by patients undergoing chemotherapy.[1] **KEY CONCEPT** *The optimal method of managing CINV is to provide adequate pharmacologic prophylaxis given a patient's risk level for emesis. Insufficient control during the first cycle of chemotherapy leads to more difficulty in controlling emesis for subsequent cycles.*[2]

## EPIDEMIOLOGY AND ETIOLOGY

Although it is widely known that chemotherapy causes nausea and vomiting, the rate of emesis varies depending on individual patient risk factors and drug therapy regimen. Therefore, cancer treatments are stratified into varying risk levels: high, moderate, low, and minimal. Agents with a "high" emetic risk cause emesis in more than 90% of cases if not given any prophylaxis. The rates of emesis for "moderate," "low," and "minimal" are 30% to 90%, 10% to 30%, and less than 10%, respectively. **Table 99–1** lists the individual agents and their risk category.[3]

## PATHOPHYSIOLOGY

The pathophysiology of nausea and vomiting is described in Chapter 20. Specific to CINV, the key receptors include serotonin ($5\text{-HT}_3$) receptors (located in the chemoreceptor trigger zone, emetic center of the medulla, and gastrointestinal [GI] tract) and neurokinin-1 (NK1) receptors (located in the emetic center of the medulla). Serotonin plays an important role in the genesis of acute vomiting, occurring within the first 24 hours of chemotherapy, because some cancer drug therapies can stimulate a release of serotonin from enterochromaffin cells in the GI tract. Serotonin then activates the emetic response by binding to $5\text{HT}_3$ receptors in the emetic center. This short-lived release of serotonin likely explains why serotonin antagonists are more beneficial for preventing acute versus delayed vomiting.[4] Other sites that are targeted by antiemetics include dopamine, muscarinic (acetylcholine), histamine, and cannabinoid receptors.

## CLINICAL PRESENTATION AND DIAGNOSIS

CINV, although frequently discussed as one syndrome, includes two distinct clinical entities, including both nausea and vomiting. Nauseous patients may present with general GI upset and reflux and may report a sensation or desire to vomit without being able to do so.[3] In all cases, it is important that other etiologies of nausea and vomiting are ruled out before diagnosing chemotherapy as the cause.[5] Other causes of nausea and vomiting may include bowel obstruction, opioid intolerance, electrolyte imbalances, brain metastases, and vestibular dysfunction.[5]

## TREATMENT
### Desired Outcomes

The desired outcome is to completely prevent or minimize the severity of nausea, vomiting, and the use of breakthrough antiemetic medications. In clinical trials, a common end point is "complete response," defined as having no emesis and no breakthrough medication use within a defined period of time. If patients experience nausea or emesis, the goal is to quickly relieve the episode and prevent future nausea or vomiting, whether in the next few days or for the next cycle of chemotherapy.

### General Approach to Treatment

Treatment-related factors and patient-related factors can help define a patient population at risk for developing CINV. Treatment-related factors include those chemotherapy agents with high levels of emetogenicity (see Table 99–1 for a complete listing). CINV is typically a cyclical occurrence. Although this section focuses on CINV, it can be helpful for practitioners to remember that patients undergoing concomitant radiation therapy and chemotherapy are at risk for more severe nausea and vomiting. Radiation (particularly total-body irradiation as part of a conditioning regimen for stem cell transplant) can cause a more cumulative (versus cyclical) nausea/vomiting phenomenon.

Specific patient-related factors such as female gender, age less than 50, history of motion sickness, pregnancy-induced nausea or vomiting, and poor emetic control in previous chemotherapy cycles increase the risk of emesis. Interestingly, patients

## Clinical Presentation and Diagnosis of CINV

**Acute Nausea/Vomiting**
- Occurs within the first 24 hours after chemotherapy administration

**Delayed Nausea/Vomiting**
- Occurs between 24 hours and 5 days after chemotherapy administration

**Anticipatory Nausea/Vomiting**
- A learned, conditioned reflex response to a stimulus (sight, sound, smell) often associated with poor emetic control in a previous cycle of chemotherapy

**Breakthrough Nausea/Vomiting**
- Occurs despite prophylaxis with an appropriate antiemetic regimen

**Differential Diagnosis**
- Surgery, radiation
- Gastric outlet or bowel obstruction, constipation
- Hypercalcemia, hyperglycemia, hyponatremia, uremia
- Other drugs (opioids)

**Table 99–2**

**Recommended Therapy by Emetic Risk**

| Emetic Risk Category (Incidence of Emesis without Antiemetics) | Antiemetic Regimens and Schedules |
|---|---|
| High (> 90%) | 5-HT$_3$ serotonin receptor antagonist: day 1<br>Dexamethasone: days 1–4<br>Aprepitant: days 1–3 or fosaprepitant 150 mg IV day 1 only<br>Or<br>Olanzapine: Days 1–4<br>Palonosetron: Day 1<br>Dexamethasone: Day 1 |
| Moderate (30%–90%) | 5-HT$_3$ serotonin receptor antagonist: days 1–3<br>Dexamethasone: day 1<br>Or<br>5-HT$_3$ serotonin receptor antagonist: day 1<br>Dexamethasone: days 1–3 |
| Low (10%–30%) | Dexamethasone: day 1<br>Or<br>5-HT$_3$ serotonin receptor antagonist: Day 1 |
| Minimal (< 10%) | As needed |

Data from Kris MG, Hesketh PJ, Somerfield MR, et al. American Society of Clinical Oncology Guidelines for Antiemesis in Oncology: Update 2006. J Clin Oncol. 2006;24:2932–2947.

with a history of alcohol abuse have a reported decreased risk of emesis.[3] It is important to design an antiemetic regimen with consideration of these patient-specific risk factors.[6] A well-designed regimen includes a prophylactic regimen and a breakthrough antiemetic drug "as needed." Although many drugs are recommended as "breakthrough" drugs, choose a drug with a different mechanism of action compared with the drugs used for prophylaxis.[5]

### ▶ Nonpharmacologic Therapy

Nonpharmacologic therapy for nausea and vomiting can be useful adjuncts to drug therapy, particularly in the setting of anticipatory nausea and vomiting. Behavior therapies such as relaxation, guided imagery, and music therapy as well as acupuncture or acupressure as useful in this setting.[5] Other general measures that can be taken include ensuring adequate sleep before treatment, eating smaller meals, and avoiding greasy foods and foods with strong odors.[5]

### ▶ Pharmacologic Therapy

Nonprescription medications such as antacids, histamine-2 receptor blockers, and proton pump inhibitors can be helpful in reducing gastroesophageal reflux associated with some cancer treatments that may trigger or exacerbate CINV.[5] Nonprescription antihistamines marketed for nausea associated with motion sickness are not usually helpful in managing CINV.

Four drug classes are highly effective in preventing CINV: corticosteroids (dexamethasone), serotonin receptor antagonists, NK1 receptor antagonists (aprepitant or fosaprepitant), and the thienobenzodiazepine, olanzapine.[7] Drugs with differing mechanisms of action are combined, depending on the emetic risk level of the chemotherapy regimen. (Table 99–2).

Intravenous (IV) antiemetics are usually administered 30 minutes before chemotherapy, and oral antiemetics are administered 60 minutes before chemotherapy. Dexamethasone is the

preferred agent to prevent CINV in the delayed setting (days 2–4 after chemotherapy administration) for moderately and highly emetogenic chemotherapy and is given at dose of 4 mg orally twice daily (or 8 mg once daily) for 3 to 4 days. In some cases, the serotonin antagonists may also be continued orally for 3 to 4 days after chemotherapy or be used in place of dexamethasone. When oral aprepitant is used prechemotherapy, the aprepitant is continued as 80 mg orally once daily on days 2 and 3 of the chemotherapy cycle. No oral aprepitant is necessary when fosaprepitant is given on day 1.

Concerns of QT prolongation have resulted in the IV formulation of dolasetron to be removed from the market and dosing of ondansetron has been reduced to 16 mg IV as the 32 mg IV was reported to extend the QT interval.[8]

The other classes of antiemetics are usually prescribed "as needed" for breakthrough nausea or vomiting. The dopamine antagonists prochlorperazine and metoclopramide are usually recommended because they antagonize a different receptor than the drugs already given for prophylaxis. Other medications, including serotonin receptor antagonists, cannabinoids, dexamethasone, scopolamine, or olanzapine, may be used as alternatives to dopamine antagonists for breakthrough nausea and vomiting.[5] Breakthrough medications should have different mechanisms of action than the medications a patient is taking to prevent nausea and vomiting. For those in any risk group who experience anticipatory nausea and vomiting, the addition of lorazepam for prophylaxis and breakthrough is recommended for its antiemetic and antianxiety properties. Table 99–3 lists the doses of the antiemetic agents for prophylaxis and breakthrough use.

**Table 99–3**

**Antiemetic Dosing**

| Antiemetic | Single Dose Administered Before Chemotherapy | Daily Schedule |
|---|---|---|
| **5-HT$_3$ Serotonin Receptor Antagonists** | | |
| Dolasetron | po: 100 mg | 100 mg po daily |
| Granisetron | po: 2 mg<br>IV: 1 mg or 0.01 mg/kg<br>Topical: 34.3-mg patch (apply 24–48 hours before chemotherapy, leave on for 7 days) | 1–2 mg po daily or 1 mg two times a day |
| Ondansetron | po: 16–24 mg<br>IV: 8–16 mg | 8 mg po two times a day or 16 mg po daily |
| Palonosetron | IV: 0.25 mg | |
| **Others** | | |
| Aprepitant | po: 125 mg | 80 mg po days 2 and 3 |
| Fosaprepitant | IV: 150 mg | No aprepitant on days 2 or 3 |
| Dexamethasone | po: 12 mg if given with aprepitant, otherwise 20mg<br>IV: 12mg if given with aprepitant, otherwise 20mg | 8 mg po days 2–4 |
| Olanzapine | po: 10mg | 10mg po daily |

Data from Kris MG, Hesketh PJ, Somerfield MR, et al. American Society of Clinical Oncology Guidelines for Antiemesis in Oncology: Update 2006. J Clin Oncol. 2006;24:2932–2947.

A prophylactic antiemetic regimen for high emetic risk levels of IV chemotherapy should be with a triple-drug combination using dexamethasone, aprepitant, and 5-HT$_3$ antagonist to prevent both acute and delayed emesis. Dexamethasone should be continued until day 4, and aprepitant is also administered on days 2 and 3 if the oral formulation is used. When fosaprepitant 150 mg IV is administered on day 1, no oral aprepitant is needed on days 2 and 3 of therapy. Alternatively, olanzapine in combination with palonosetron and dexamethasone can be used. A phase 3 trial of 241 patients comparing aprepitant, palonosetron, and dexamethasone to olanzapine with a palonosetron and dexamethasone for patients treated with highly emetogenic chemotherapy had similar

rates of CINV control (87%–97% prevention of acute CINV, 73%–77% prevention of delayed CINV), though nausea was better controlled by the olanzapine-based regimen (69% overall vs 38% overall).[9]

For moderately emetogenic regimens, acute emesis is still of major concern, but the incidence of delayed emesis is less.

## Patient Care Process: CINV

**Patient Assessment:**
- Evaluate patient's chemotherapy regimen and assess emetic potential.
- Using a visual analogue or numerical rating scale (0–10), have the patient rate the severity of nausea (assess nausea first; then move on to emesis).
- Daily, ask about the number of emesis episodes in the last 24 hours.
- Assess scheduled and breakthrough medication adherence.
- Assess patient for risk factors for CINV such as history of motion sickness, pregnancy-induced nausea/vomiting, anxiety, lack of sleep, etc.
- Evaluate patient's outpatient medications and determine if there are drug interactions, precautions, or other contraindications to intended antiemetic therapy.
- On subsequent cycles, evaluate continued effectiveness of initial antiemetic regimen and assess the need for breakthrough antiemetics.

**Therapy Evaluation:**
- Evaluate patient for complete response to therapy, especially after the first cycles—no vomiting and no nausea.
- Monitor patient diary of recording of breakthrough antiemetic use.

**Care Plan Development:**
- Counsel the patient on how to take the antiemetic regimen, side effects, drug interactions. Emphasize the need to take the regimen regardless of whether the patient feels nauseous or not—the goal is prevention.
- Explain which drugs are taken as prophylaxis to prevent nausea and vomiting and which are taken as needed to treat it.
- Counsel patient on nonpharmacological management of CINV—adequate sleep, small meals, stress management, etc.
- Have the patient journal when a dose is taken in relation to the chemotherapy. Encourage journaling the severity and frequency of nausea, vomiting, diet, and antiemetic adherence.

**Follow-Up Evaluation:**
- Ensure no episodes of nausea or vomiting at each chemotherapy visit.

## Patient Encounter 1: CINV

A 73-year-old man with non–small cell lung cancer (NSCLC) presents today for initiation of chemotherapy with cisplatin 75 mg/m$^2$ and paclitaxel 175 mg/m$^2$.

*What category of emetic risk should this dose regimen fall under?*

*What do you recommend for preventing nausea and vomiting in this patient?*

Therefore, dexamethasone plus a 5-HT$_3$ antagonist should be given on day 1. On days 2 to 4, choose to continue either the dexamethasone or the 5-HT$_3$ antagonist to prevent delayed emesis. One exception is when palonosetron is given as the 5-HT$_3$ antagonist on day 1. Because its half-life is long, no redosing is necessary on subsequent days. Aprepitant and fosaprepitant 115 mg IV are also approved by the Food and Drug Administration (FDA) for the prevention of CINV in the moderate setting. While an NK1 receptor antagonist is not routinely used for moderately emetogenic chemotherapy, if patients have clinical risk factors or if they experienced uncontrolled emesis with previous chemotherapy cycles, the same regimen for "high-" risk levels may be used.

For low emetic risk IV chemotherapy regimens, single antiemetic prophylaxis with either dexamethasone or a dopamine antagonist is recommended. For minimal emetic risk groups, guidelines do not recommend routine prophylaxis with antiemetics; instead, patients should be provided with a drug to take as needed for nausea and vomiting. Table 99–2 summarizes regimens for antiemetic prophylaxis for the different risk levels of IV chemotherapy.

Many oral anticancer agents are now available and are typically administered daily. For highly and moderately emetogenic oral anticancer therapy, an oral 5HT$_3$-antagonist is administered before each dose with or without lorazepam and/or an H$_2$-blocker or proton pump inhibitor.[5] Low-minimal risk oral anticancer agents are given in conjunction with "as needed" antiemetics similar to the approach for IV chemotherapy.[5]

## OUTCOME EVALUATION

It is often difficult to evaluate nausea and vomiting when chemotherapy is given as an outpatient. After drug administration, patients return home and may or may not report inadequate control of emesis. Subsequent chemotherapy cycles may also be poorly controlled, especially if patients do not state their experience with the previous cycle. To ameliorate this problem, patients' experiences with CINV should be assessed, particularly after the first and second cycles of chemotherapy. Patients should be asked about their previous emesis control with subsequent cycles of chemotherapy, and a prophylactic regimen may need to be adjusted. Patients should also be encouraged to self-report poor control of emesis while at home. Side effects of the antiemetic regimen should also be assessed and reported.

## MUCOSITIS

Mucositis is the degradation of mucosal lining in the oral cavity and GI tract caused by damage from radiation or chemotherapy.[10] Mucositis is a common supportive care issue that deserves attention and is associated with many negative health consequences, including pain, inadequate nutritional intake, and risk for infection. Patients with mucositis often require parenteral analgesics, nutrition supplementation, and antiinfectives to treat concomitant bacterial, fungal, or viral infections. Furthermore, mucositis is associated with economic consequences, primarily increased lengths of hospital stay.[11] An understanding of the current guidelines for prevention and treatment of mucositis can help improve patient outcomes.

## EPIDEMIOLOGY AND ETIOLOGY

The incidence of chemotherapy or radiation-induced mucositis depends mostly on the type of chemotherapy, the type and area of radiation, and the specific cancer. Studies have reported an incidence of about 85% in head and neck cancer patients receiving chemoradiation.[10] The World Health Organization estimates that approximately 75% of patients who are treated with high-dose chemotherapy for stem cell transplantation developed oral mucositis.[10] Specific chemotherapy agents associated with moderate-severe mucositis include taxanes, anthracyclines, platinum analogues, methotrexate, and the fluoropyrimidines.

## PATHOPHYSIOLOGY

The classical concept of mucositis pathophysiology asserts that direct cytotoxicity from chemotherapy or radiation to basal epithelial cells results in ulcerative lesions caused by a lack of regeneration. These lesions are further complicated by trauma or microorganism growth. However, the most recent theory of mucositis pathophysiology is more detailed and involves a multistage, dynamic process that builds upon the historical model.[11] According to this theory, there are five stages of mucositis: initiation, primary damage response, signal amplification, ulceration, and healing. It is important to note that these stages do not occur sequentially. Rather, they are dynamic and may overlap. Prevention of mucositis or treatment in early stages results in the best outcomes for patients.

## CLINICAL PRESENTATION AND DIAGNOSIS

Patients with mucositis may present along a continuum of mild, painless, erythematous ulcers to those that are painful and/or bleeding that may interfere with eating and swallowing or that may require treatment with hydration, antibiotics, or even parenteral nutrition in its most severe forms.[11]

## TREATMENT

### Nonpharmacologic Treatment

The goal of nonpharmacologic measures to prevent mucositis is to reduce the bacterial load. **KEY CONCEPT** *The fundamental approach to lessen the severity of mucositis begins with basic, good oral hygiene (brushing with a soft-bristled toothbrush at least twice daily, flossing, bland rinses, and saliva substitutes).*[10–12] Cryotherapy with ice chips is also helpful for almost all patients at risk for mucositis.[10] Low-level laser therapy (in centers that have the resources to offer it) is also helpful to prevent mucositis in the hematopoietic cell transplant (HCT) setting.[10]

### Pharmacologic Treatment

In the setting of radiation therapy, amifostine, a free radical scavenger, at doses equal to or greater than 340 mg/m$^2$ intrarectal before each dose of radiation therapy for rectal cancer may be considered to prevent gastrointestinal mucositis.[10] Gelclair, Caphosol, and Biotene are gels that provide a protective barrier between damaged oral mucosa and the environment, lessening pain and irritation and are also sometimes used as part of the overall treatment of patients with mucositis.[10] Antimicrobial lozenges, sucralfate and chlorhexidine rinses, and "magic-mouthwash" compounded rinses are not generally recommended by clinical practice guidelines for mucositis prevention even though they are sometimes used in practice.[12] Ranitidine or omeprazole orally are recommended to prevent pain associated with mucositis and reflux following offending chemotherapy.[10]

Unfortunately, little evidence is available to recommend specific treatments for mucositis. Pain assessment and appropriate management are important.[10,12] Pain management may be achieved with oral morphine, topical anesthetic products, and compounded rinses that incorporate lidocaine.[10,12] In more severe cases in which infection of the oral mucosa is suspected, appropriate antibiotic therapy is necessary to prevent systemic infection.[10,12]

## Clinical Presentation and Diagnosis of Mucositis

- Painful, erythematous ulcers develop on the lips, cheeks, soft palate, floor of mouth, and throughout the entire gastrointestinal (GI) tract.
- Assess mucositis using validated scales, either oral mucositis assessment scale (OMAS) or University of Nebraska oral assessment score (MUCPEAK).
- Symptoms appear within 5 to 7 days after chemotherapy and resolve in 2 to 3 weeks.
- Pain may affect ability to swallow and eat.
- The patient may have concomitant localized or systemic infection.
- Diarrhea is a symptom of mucositis in the lower GI tract can lead to electrolyte imbalances.

Palifermin is FDA approved for the prevention and treatment of mucositis in patients receiving high-dose chemotherapy as part of stem cell transplant or induction regimens for leukemia. Palifermin is administered as an IV bolus injection at a dosage of 60 mcg/kg/day for 3 consecutive days before and 3 consecutive days after myelotoxic therapy for a total of six doses. Administering palifermin within 24 hours of chemotherapy can result in an increased sensitivity of rapidly dividing epithelial cells to the cytotoxic agent. For this reason, palifermin should not be administered for 24 hours before, 24 hours after, or during the infusion of myelotoxic chemotherapy to avoid increasing the severity and the duration of oral mucositis.

### OUTCOME EVALUATION

The goal of therapy is to prevent or decrease the severity and duration of mucositis. Outcomes measured in clinical trials often assess the incidence, duration, and severity of mucositis with a given intervention intended to prevent or treat mucositis. Agents that are intended to palliate the symptoms of mucositis are usually assessed by measures in pain scales and the ability to eat or drink.

## HEMATOLOGIC COMPLICATIONS: FEBRILE NEUTROPENIA (FN)

### INTRODUCTION

FN is a common adverse effect after administration of cytotoxic chemotherapy. The mortality rate in neutropenic patients caused by infectious complications currently remains between 5% and 10%; therefore, FN is considered a true oncologic emergency. Patients frequently require hospitalization for prompt administration of broad-spectrum antibiotics that are critical to avoid morbidity and mortality.

### EPIDEMIOLOGY AND ETIOLOGY

The microorganisms responsible for infections in neutropenic patients have changed significantly in the last 50 years. From the 1960s through the mid-1980s, gram-negative organisms were the most common bacteria isolated. This pattern shifted to the gram-positive organisms in the late 1980s, which remain the most common isolates. Recent data indicate that gram-positive organisms account for 62% to 76% of all bloodstream infections.[13]

### Table 99–4

**Commonly Isolated Pathogens in Patients with FN**

| Type of Organism | Comments |
| --- | --- |
| **Bacteria** | |
| Gram-positive organisms | Most common isolates in FN |
| Coagulase-negative staphylococci (ie, *Staphylococcus epidermidis*) | Between 70% and 90% resistant to methicillin; indolent course with low mortality |
| *Staphylococcus aureus* | Some centers report greater than 50% resistance to methicillin |
| *Enterococcus* spp | Resistance to vancomycin ≥ 30% |
| *Viridans streptococci* | Increasing resistance to penicillin; result of fluoroquinolone prophylaxis; associated with mucositis |
| Gram-negative organisms | Infections rapidly fatal |
| *Pseudomonas aeruginosa* | High mortality rate; increasing resistance to quinolones |
| *Escherichia coli* | Increased incidence of β-lactamase–producing strains |
| *Klebsiella* spp | |
| *Enterobacter* spp | Increased incidence of β-lactamase–producing strains |
| **Fungi** | Occur primarily after prolonged neutropenia (longer than 1 week) |
| Yeasts | |
| *Candida albicans* | Increasing incidence (~10%); high mortality rate |
| Non-*albicans Candida* (*Candida krusei*, *Candida glabrata*) | Resistant to fluconazole; high mortality rate |
| Molds | Resistant to fluconazole; high mortality |
| *Aspergillus* spp | Pulmonary infection common |
| *Fusarium* spp | Emerging pathogen |
| *Scedosporium* spp | Emerging pathogen |

FN, febrile neutropenia.

The causes of this change are attributed to the widespread use of central venous catheters and more aggressive chemotherapy regimens as well as the use of prophylactic antibiotics with relatively poor gram-positive coverage (quinolones). Commonly isolated pathogens are shown in Table 99–4. Although gram-negative infections are less common, they cause the majority of infections in sites other than the blood and are particularly virulent. It should be noted that isolates vary considerably among institutions; thus, attention to institutional isolation patterns is prudent.

## Patient Encounter 2: FN

A 63-year-old woman receiving treatment for metastatic breast cancer presents today, 8 days after chemotherapy, for follow-up and laboratory check. Relevant laboratory study results include WBC count, $0.7 \times 10^3$/mL ($0.7 \times 10^9$/L); HgB 9.0 g/dL (90 g/L; 5.59 mmol/L)); HCT 26.6% (0.266); PLT, $6 \times 10^3$/mL ($6 \times 10^9$/L); serum chemistries within normal limits except; SCr, 1.3 mg/dL (115 µmol/L); and estimated GFR 54 mL/min/1.73m². Vitals: T 98.2°F (36.8°C); P 71 beats/min; RR 18 breaths/min; BP 116/64 mm Hg. The patient has no known drug allergies.

*What risk factors for FN does this patient have?*

*How would you approach this patient?*

Fungal infections caused by *Candida* spp. (especially *Candida albicans*) have emerged as significant pathogens, especially in patients with hematologic malignancies and those undergoing bone marrow transplantation (BMT). In addition, *Aspergillus* spp. are important pathogens in patients with prolonged and severe neutropenia.

## PATHOPHYSIOLOGY

The neutrophils are the primary defense mechanism against bacterial and fungal infection. Most infections in neutropenic patients are a result of organisms contained in endogenous flora, both on the skin and within the GI tract. These organisms are provided access to the bloodstream through breakdowns in host defense barriers (mucositis, use of central venous catheters).

Neutropenia is defined as an absolute neutrophil count (ANC) less than 500/μL (0.50 × 10⁹/L) cells or an ANC less than 1000/μL (1.00 × 10⁹/L) cells with a predicted decrease to less than 500/μL (0.50 × 10⁹/L) cells over the next 48 hours. The ANC is calculated by multiplying the total WBC by the percentage of neutrophils (segmented neutrophils plus "bands"). Fever is defined as a single oral temperature greater than or equal to 38.3°C (101°F) or a temperature greater than or equal to 38.0°C (100.4°F) for at least 1 hour. The combination of these two factors defines FN.[14] The risk of infection during the period of neutropenia depends primarily on two factors:

- The duration of the neutropenia (time period of ANC less than 500/μL [0.50 × 10⁹/L] cells)

- The severity of the neutropenia (lowest ANC level reached [nadir])

A multitude of other risk factors for FN have been identified[15] (Table 99–5). Many of these are also risk factors for poor outcome in patients who experience FN. Cancer drug therapy regimens are also categorized as being high risk (greater than 20% incidence of FN reported in clinical trials) or intermediate risk (10%–20% risk of FN reported in clinical trials). Similar to the approach to the prevention of CINV, it is important to consider both the regimen and patient-specific risk factors when determining whether a patient should receive prophylactic therapy for FN.

---

**Table 99–5**

**Risk Factors for FN**

| Patient Related | Therapy Related |
|---|---|
| Age 60 years or older | History of extensive chemotherapy |
| Poor performance status | Planned full dose intensity of chemotherapy |
| Bone marrow involvement by tumor | High-dose chemotherapy (ie, bone marrow transplant) |
| Poor nutritional status | > 20% incidence of FN reported in clinical trials with treatment regimen |
| Hematologic malignancy | |
| Elevated LDH | |
| Decreased hemoglobin level | 10%–20% incidence of FN reported in clinical trials with treatment regimen plus presence of patient-specific risk factors |
| Baseline or first-cycle low neutrophil counts | |
| History of previous FN | |
| Uncontrolled or advanced stage cancer | |

FN, febrile neutropenia; LDH, lactate dehydrogenase.

**Table 99–6**

**MASCC Risk-Index for Identifying Low-Risk Patients with FN[a]**

| Characteristic | Score |
|---|---|
| Burden of illness[b] | |
| No symptoms | 5 |
| Mild symptoms | 5 |
| Moderate symptoms | 3 |
| No hypotension | 5 |
| No COPD | 4 |
| Solid tumor or hematologic malignancy without fungal infection | 4 |
| No dehydration | 3 |
| Outpatient onset of fever | 3 |
| Age < 60 years[c] | 2 |

[a]Note: A risk-index score of 21 or higher indicates that the patient is likely to be at low risk for complications and morbidity.

[b]Choose one symptom assessment.

[c]Does not apply to patients 16 years of age or younger.

COPD, chronic obstructive pulmonary disease; FN, febrile neutropenia; MASCC, Multinational Association for Supportive Care in Cancer.

From Klastersky J, Paesmans M, Rubenstein EB, et al. The Multinational Association for Supportive Care in Cancer risk index: A multinational scoring system for identifying low-risk febrile neutropenic patients. J Clin Oncol. 2000;18:3038–3051.

---

It is clear that patients with FN represent a heterogenous group. Some patients are at lower risk and could potentially be treated as outpatients, thereby avoiding the risk and cost of hospitalization. The Multinational Association for Supportive Care in Cancer (MASCC) has validated a risk assessment tool that assigns a risk score to patients presenting with FN (Table 99–6).[16] Patients with a risk-index score greater than or equal to 21 are identified as low risk and are candidates for outpatient therapy (discussed under section Treatment).

## PREVENTION

Three primary modalities for preventing infection in patients who are expected to become neutropenic have been utilized, the first of which is the least expensive and simplest:

- Vigilant hand hygiene
- Prophylactic antibiotics
- Colony-stimulating factors (CSFs)

The advantages and disadvantages of these strategies are discussed individually in the following sections.

### Hand Hygiene

As previously discussed, most infections in neutropenic patients are a result of endogenous flora; however, prevention of further acquisition of environmental pathogens is also important. Patients who are or will become neutropenic should practice careful handwashing and avoid contact with people who neglect hand hygiene. In addition, ingestion of certain fresh fruits and vegetables as well as unprocessed dairy products should be avoided during the neutropenic period. Practitioners should also engage in vigilant hand hygiene after each patient encounter to limit the spread of infections between patients.[18]

## Prophylactic Antibiotics

Routine antibacterial prophylaxis is controversial and has been attempted primarily with sulfamethoxazole–trimethoprim (SMZ-TMP) and quinolones. SMZ-TMP offers improved prophylaxis against gram-positive organisms compared with quinolones; quinolones are more effective prophylaxis against gram-negative infections. The 2010 Infectious Diseases Society of America (IDSA) guidelines recommend fluoroquinolone prophylaxis in patients who are at high risk for "prolonged and profound" neutropenia.[14] The IDSA does not recommend routine antibiotic prophylaxis for low-risk patients because of the lack of a clear benefit on mortality rates and concerns regarding increasing antibiotic resistance. One exception is that SMZ-TMP is recommended for prophylaxis of *Pneumocystis jiroveci* (formerly *Pneumocystis carinii*) pneumonitis (PCP) in all at-risk patients (ie, hematopoietic cell transplant recipients, AIDS), regardless of the presence of neutropenia.

Two meta-analyses add fuel to the controversy of routine antibiotic prophylaxis.[19,20] Decreases in infection-related mortality and gram-negative bacteremia were demonstrated with the use of quinolones; however, overall adverse events were higher, and most of the studies were conducted in patients with hematologic malignancies (an inherently high-risk group). Although two additional randomized trials in patients with both solid tumors and hematologic malignancies demonstrated lower rates of FN, infection, and hospitalization with oral prophylactic levofloxacin compared with placebo, both the NCCN and IDSA only recommend prophylactic levofloxacin for patients with expected duration of neutropenia (defined as an ANC less than 1000/μL [1.00 × 10^9/L]) for more than 7 days because of the:

- Unknown long-term consequences on the development of resistant organisms
- Emergence of *Clostridium difficile* and methicillin-resistant *Staphylococcus aureus* (MRSA) from fluoroquinolone overuse

- Ability to treat lower-risk patients on an outpatient basis, reducing the need for prophylactic antibiotics.[18]

Therefore, the use of prophylactic quinolones in patients who are at high risk for infection (ie, hematologic malignancies) is reasonable; however, use should not be routine for low-risk patients. If prophylactic quinolone use is adopted, changes in local patterns of resistance should be closely monitored.

## Colony-Stimulating Factors

The CSFs stimulate the maturation and differentiation of neutrophil precursors. Four agents are currently approved for use in the United States (Table 99–7). The prophylactic use of these agents decreases days of hospitalization and use of empiric antibiotics by shortening the duration of severe neutropenia (defined as ANC less than 500/μL [0.50 × 10^9/L]). There is little to no effect on the depth of neutrophil nadir. A recent meta-analysis found that the use of prophylactic granulocyte CSF (either filgrastim or pegfilgrastim) results in a 46% risk reduction of FN and a 48% risk reduction in infectious mortality, although absolute differences are small (3.3% vs 1.7%).[21,22] It is critical to note that patients who receive these agents may still experience FN despite the risk reduction. The primary limitation of the use of these agents is cost. CSFs are recommended beginning with the first cycle (primary prophylaxis) of chemotherapy when the risk of FN is greater than or equal to 20%, regardless if the goal of therapy is curative or palliative.[20] This is the point where the use of CSFs is cost effective when balanced against the cost of hospitalization and antimicrobials. Secondary prophylaxis refers to the subsequent prophylactic use of a CSF after a patient has had an episode of FN. This strategy should be used especially when the chemotherapy is being given in patients with the intention of cure (ie, Hodgkin lymphoma, early breast cancer). In this circumstance, administration of full doses of chemotherapy on time without delays has been shown to improve patient outcomes.

Although generally well tolerated, CSFs may cause bone pain in around 25% of patients. This may be managed with acetaminophen or nonsteroidal anti-inflammatory drugs (NSAIDs), although attention to the platelet count is warranted with the use of NSAIDs. Sargramostim in particular may result in low-grade fever and myalgias, perhaps as a result of its wider pattern of effector cell stimulation.[20]

## TREATMENT

### Desired Outcomes

Because rapid death may occur with certain infections in neutropenic patients, prompt and emergent treatment is indicated. The primary goal is to prevent morbidity and mortality during the neutropenic period. This is accomplished by effectively treating subclinical or established infections.

### General Approach to Treatment

**KEY CONCEPT** *A risk assessment should be performed at presentation of FN to identify low-risk patients for potential outpatient treatment (see Table 99–6). Patients who do not meet low-risk criteria should be hospitalized for parenteral administration of broad-spectrum antibacterials.* The IDSA has published evidence-based guidelines for the management of FN (Figure 99–1).[14] The choice of initial antimicrobial agent(s) depends on the following factors:

- Presence of a central venous catheter
- Drug allergies
- Concurrent renal dysfunction or use of nephrotoxic agents

| Table 99–7 | | | | |
|---|---|---|---|---|
| **Overview of CSF** | | | | |
| **Agent** | **Effector Cell(s)** | **Dosage** | **Common Adverse Effects** | **Comments[a]** |
| Filgrastim (Neupogen GCSF, tbo-filgrastim, Granix) | Neutrophil | 5 mcg/kg/day SC or IV or round to 300- *or* 480-mcg vial size | Bone pain (~25%) | Begin 1–3 days after chemotherapy |
| Pegfilgrastim (Neulasta) | Neutrophil | 6 mg SC once | Bone pain (~25%) | Self-mediated clearance via neutrophils<br>Once per cycle dosing<br>Administer 1–3 days after chemotherapy |
| Sargramostim (Leukine GM-CSF) | Neutrophil, eosinophil, macrophage | 250 mcg/m²/day SC or IV or round to 250- or 500-mcg vial size | First dose effect (hypotension, flushing)<br>Low-grade fever<br>Bone pain<br>Injection site skin reaction | Indicated for use after induction chemotherapy in older patients with AML<br>Limited experience and lack of FDA approval for prevention of FN |

AML, acute myeloid leukemia; FDA, Food and Drug Administration; FN, febrile neutropenia; GC-SF, granulocyte-colony stimulating factor; GM-CSF, granulocyte-macrophage colony stimulating factor; SC, subcutaneous.

[a]No renal or hepatic dose adjustments are required for any product listed in this table.

- Use of prophylactic antibiotics
- Institutional and/or community susceptibility patterns
- Cost

**KEY CONCEPT** *The administration of empiric therapy should begin immediately after cultures are taken. Therapy should not be withheld until after culture results are obtained.*

As illustrated in Figure 99–1, specific criteria exist for the addition of vancomycin for coverage of resistant gram-positive organisms or agents for coverage of fungal infections. Additional agents are necessary in the setting of continued fever or declining clinical status in neutropenic patients. In general, all empiric therapy is continued until recovery of the ANC to levels above 500 cells/μL (0.500 × 10⁹/L) in patients with negative culture results. If a specific etiology is identified, appropriate therapy should be continued until 7 days after neutropenia resolves. Specific regimens with recommended dosages are summarized in **Table 99–8**.

▶ *Nonpharmacologic Therapy*

Prevention of infection is key. Handwashing is critical in the prevention of disease transmission.[18,23] It is also important to ensure that patients receive annual influenza vaccines and have had a pneumonia and meningococcal vaccine, and neutropenic patients should avoid individuals with active respiratory infections.[22,23] Indwelling catheters are often sources of infection; however, the IDSA acknowledges that catheters do not always need to be removed.[14] Catheters should be removed in the following circumstances: established tunnel infection (subcutaneous tunnel or periport infection, septic emboli, hypotension associated with catheter use, or a nonpatent catheter), recurrent infection, or no response to antibiotics within 2 or 3 days.[14] Wound debridement should also be performed upon catheter removal. In the setting of peripheral blood stem cell or bone marrow transplant, the Centers for Disease Control and Prevention recommends the use of high-efficiency particulate air (HEPA) filtration systems in patient rooms, and the NCCN suggests that HEPA filters are reasonable to be considered for other patients who experience prolonged neutropenia.[18] HEPA filters are likely to be most useful in preventing mold infections. Although several small studies have attempted to evaluate the effectiveness of isolation of neutropenic patients as a mechanism for infection prevention, no clear data are available to support this practice.[18]

▶ *Pharmacologic Therapy*

There are two primary choices for the initial management of high-risk FN: monotherapy and dual therapy (see Figure 99–1) when vancomycin is not needed. Both regimens have been shown to be equivalent in randomized studies and meta-analyses. Monotherapy avoids the nephrotoxicity of the aminoglycosides and is potentially less expensive but lacks significant gram-positive coverage and may increase selection of resistant organisms. Dual therapy provides synergistic activity, decreased resistance, and dual coverage of *Pseudomonas aeruginosa* but requires therapeutic monitoring for aminoglycosides. The choice between monotherapy and dual therapy is usually provider and institution preference, although dual therapy may be preferred in an acutely symptomatic patient (eg, hypotensive).

Vancomycin adds broad-spectrum gram-positive coverage; however, the increasing emergence of vancomycin-resistant organisms (ie, *Enterococcus* spp.) prompts conservative use of this medication. Vancomycin should only be included as part of the initial therapy if the following are present:

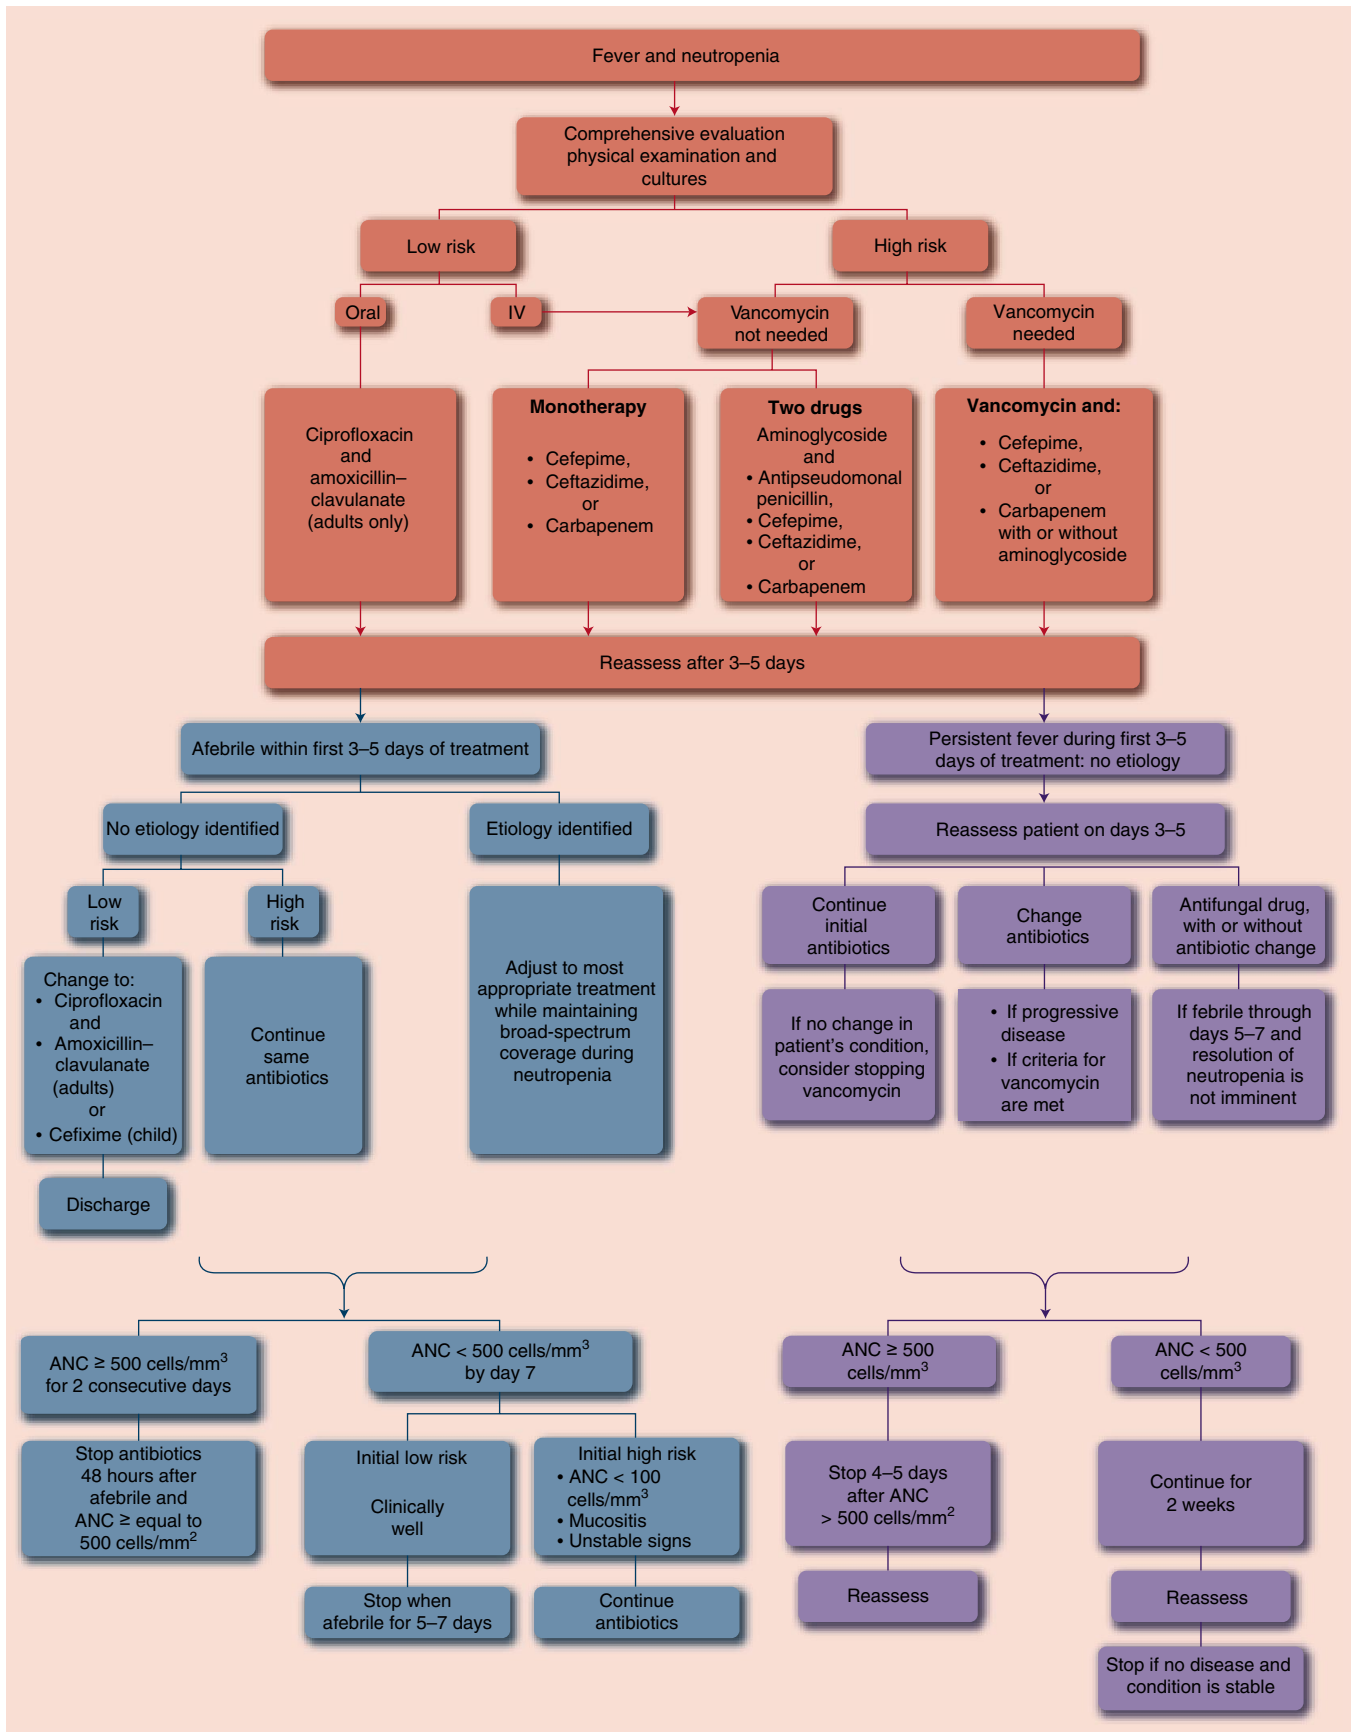
- Severe mucositis
- Soft tissue infection


**FIGURE 99–1.** Management of febrile episodes in neutropenic cancer patients. (ANC, absolute neutrophil count.)

**Table 99–8**

**Dosing Guidelines for Empiric Antimicrobial Agents in FN**

| Regimen Type | Agents and Dosing[a] | Comments |
|---|---|---|
| **Antibacterial** | | |
| β-Lactam monotherapy | Cefepime 2 g IV every 8 hours<br>Ceftazidime 2 g IV every 8 hours<br>Imipenem 500 mg IV every 6 hours<br>Meropenem 1 g IV every 8 hours<br>Piperacillin–tazobactam 4.5 g IV every 6 hours | Although piperacillin–tazobactam is not recommended in the IDSA guidelines, recent data demonstrate equivalence to other monotherapy and dual therapy regimens. All these agents require renal dose adjustment, and none requires adjustment in hepatic dysfunction. All except meropenem require adjustment during dialysis. |
| Dual therapy with antipseudomonal β-lactam plus aminoglycoside | Cefepime, ceftazidime, imipenem, meropenem, piperacillin–tazobactam (above dosages), ticarcillin–clavulanic acid 3.1 g IV every 6 hours and gentamicin or tobramycin | Gentamicin or tobramycin 2 mg/kg loading dose followed by doses adjusted by serum concentrations; once-daily dosing of aminoglycosides may be used. Both gentamicin and tobramycin require renal dose adjustment but are dosed based on serum levels. Neither gentamicin nor tobramycin requires hepatic dose adjustment. |
| Empiric regimens containing vancomycin | Cefepime, ceftazidime, imipenem, meropenem (above dosages) and vancomycin 0.5–1 g every 6–12 hours with or without aminoglycoside | Vancomycin dosages may be adjusted based on serum levels and are adjusted for renal disease and dialysis. No dose adjustment is recommended for hepatic dysfunction. |
| Dual therapy containing fluoroquinolone | Ciprofloxacin 400 mg IV every 8 hours and piperacillin–tazobactam, ceftazidime (above dosages) | Cannot be used in patients who receive fluoroquinolone prophylaxis. Dose adjusted in renal disease and dialysis but not for hepatic dysfunction. |
| Low-risk po regimen | Ciprofloxacin 750 mg po every 12 hours and amoxicillin–clavulanate 500–875 mg po every 12 hours | For patients with MASCC scores ≥ 21 not receiving fluoroquinolone prophylaxis. Amoxicillin–clavulanate is adjusted in renal disease and dialysis but not hepatic dysfunction. |
| **Antifungal** | | |
| Amphotericin B deoxycholate | 0.5–1 mg/kg IV daily | Premedication with acetaminophen and diphenhydramine; 500 mL normal saline boluses before and after. No dose adjustments are recommended for renal or hepatic dysfunction or during dialysis. |
| Liposomal amphotericin B | 3 mg/kg IV daily | Lower incidence of nephrotoxicity and infusion reactions; more expensive. No dose adjustments are recommended for renal or hepatic dysfunction or during dialysis. |
| Caspofungin | 70 mg/kg IV loading dose on day 1 followed by 50 mg/kg IV daily | Dosage adjustment in hepatic dysfunction but not for renal disease or dialysis. |
| Voriconazole | 6 mg/kg IV loading dose every 12 hours on day 1 followed by 4 mg/kg po or IV every 12 hours | Dosage adjustment in hepatic dysfunction; IV formulation contraindicated if creatinine clearance < 50 mL/min (0.83 mL/s); multiple drug interactions. |
| Posaconazole | Prophylactic: 200 mg po three times a day with food<br>300 mg IV twice a day on day 1, then 300 mg IV daily<br>Salvage: 200 mg po four times a day with food; then 400 mg po two times a day when stable | Not FDA approved for primary or salvage therapy for invasive fungal infections but used clinically; no dose adjustments required for renal or hepatic dysfunction or during dialysis. |

AML, acute myeloid leukemia; FDA, Food and Drug Administration; IDSA, Infectious Diseases Society of America; IV, intravenous; MDS; myelodysplastic syndrome; NCCN, National Comprehensive Cancer Network; po, oral.

[a]Dosing for adult patients; adjust doses for renal dysfunction.

- Quinolone or TMP-SMX prophylaxis
- Hypotension or septic shock
- Colonization with resistant gram-positive organisms (ie, MRSA)
- Evidence of central venous catheter infection[14]

Vancomycin may be added to the empiric regimen after 3 to 5 days in persistently febrile patients or if cultures reveal gram-positive organisms. Vancomycin should be changed if the gram-positive organism is susceptible to other antibacterials or discontinued in patients with persistent fever after 3 days with negative culture results. Linezolid, quinupristin–dalfopristin, tigecycline, and daptomycin may be used in cases of vancomycin-resistant organisms or if vancomycin is not an option because of drug allergy or intolerance.[14]

Empiric antifungal agents are typically added in persistently febrile patients after 5 to 7 days, especially if continued neutropenia is expected. Amphotericin B has historically been the drug of choice because of its broad-spectrum activity against both yeast (*Candida* spp.) and mold (*Aspergillus* spp.) infections. Because frequent toxicity (nephrotoxicity, infusion reactions) limits the use of amphotericin B, less toxic alternatives have been studied. Lipid formulations of amphotericin provide decreased toxicity, and liposomal amphotericin B (AmBisome) has been shown to be equivalent to conventional amphotericin B as empiric therapy but is significantly more expensive.;

Caspofungin is equivalent with less toxicity compared with liposomal amphotericin B in a randomized trial and is FDA approved for this indication.[14,18] Voriconazole is equivalent to liposomal amphotericin in mortality, but response was improved in those receiving liposomal amphotericin. Voriconazole does not have an indication, but it is sometimes used. Itraconazole has also been used in some institutions, but its use is complicated by poor bioavailability of oral preparations and numerous drug interactions. Posaconazole is a newer azole that is sometimes used prophylactically in neutropenic patients with acute myeloid leukemia or myelodysplastic syndrome and for patients with graft-versus-host disease while receiving intensive immunosuppressive therapy. It is not FDA approved as primary or salvage therapy for the treatment of invasive fungal infections but it is approved by the European Union for invasive aspergillosis and other fungal infections that are refractory to standard antifungal agents.

As stated earlier, low-risk patients fulfilling the MASCC criteria (see Table 99–6) may be treated empirically as an outpatient with a regimen combining amoxicillin–clavulanic acid and ciprofloxacin. Ciprofloxacin and clindamycin are reasonable alternatives for penicillin-allergic patients.

The CSF should not routinely be used for treatment of FN in conjunction with antimicrobial therapy.[14,18] However, the use of CSFs in certain high-risk patients with hypotension, documented fungal infection, pneumonia, or sepsis is reasonable. A meta-analysis demonstrated that hospitalization and neutrophil recovery are shortened and infection-related mortality is marginally improved with CSF prophylaxis in high-risk patients.[24] As with prophylactic use of these agents, cost considerations limit their use to high-risk patients.

## OUTCOME EVALUATION

The success of the treatment of FN depends on the adequate recovery of the ANC and either optimal antimicrobial coverage of identified organisms or empiric coverage of unidentified organisms. Monitor the complete blood count (CBC) with differential and $T_{max}$ (maximum temperature during previous 24 hours) daily. Assess renal and hepatic function at least twice weekly, especially in patients receiving nephrotoxic agents. Vital signs should be taken every 4 hours. Follow-up on blood and urine culture results daily because many cultures do not become positive for several days. Assess the patient daily for pain that may indicate an infectious source. Conduct daily physical examination of common sites of infection. Repeat cultures and chest x-ray in persistently febrile patients and culture developing sources of infection (ie, stool cultures for diarrhea).

---

## Patient Care Process: FN

**Patient Assessment:**

- Review patient history for cytotoxic chemotherapy.
- Evaluate risk of FN with cytotoxic chemotherapy using NCCN practice guideline for myeloid growth factors.
- Obtain a complete patient history:
  a. What chemotherapy did the patient receive and when? Is the ANC on the way down (before nadir) or on the way up (after nadir)? Was the patient receiving prophylactic antibiotics, filgrastim, sargramostim, or pegfilgrastim?
  b. Did the patient have previous episodes of FN? What were the previous culture results to determine colonization status?
- Evaluate patient-specific risk factors.
- Evaluate other sources of infection, such as catheters and surgery sites.
- Assess patient for temperature, onset of fever, duration of fever.
- Ensure patient has not taken NSAIDs, acetaminophen, or other therapies which may give a false impression of a lower temperature/lack of fever.
- Assess patient for severe signs/symptoms of systemic infection such as chills, headache, disorientation, etc.
- Determine patient allergies, especially to antibiotics, antifungals, and antivirals.

**Therapy Evaluation:**

- Select empiric antibiotic therapy if patient meets criteria for prophylactic treatment. Do not wait for culture results. Verify patient allergies.
- Change antimicrobials once culture results are obtained, if applicable. Verify antimicrobial effectiveness against institutional nomogram.

**Care Plan Development:**

- Discuss with interprofessional team advantages/disadvantages of treating patient as an outpatient, if applicable.
- Counsel patients receiving cytotoxic chemotherapy or alemtuzumab to promptly report fever. Provide patients with a diet to use during the neutropenic period. Counsel patients to avoid close contact with sick friends and relatives and remind patients and caregivers of the importance of handwashing.

**Follow-Up Evaluation:**

- Assess the patient daily for any new signs or symptoms of infection. Evaluate the patient for adverse drug reactions, drug allergies, and interactions. Have all antibiotics been dose adjusted for renal or hepatic dysfunction?
- For patients receiving oral antibiotics either prophylactically or as treatment of FN: Counsel patients that initial or persistent fever should be promptly reported and that compliance with the regimen is critical. Patients should also have easy access to medical care and adequate caregiver support. Provide information on drug interactions and adverse effects.

## CARDIOVASCULAR COMPLICATIONS: SUPERIOR VENA CAVA SYNDROME (SVCS)

### INTRODUCTION

Superior vena cava syndrome (SVCS) is a relatively rare complication that, although nonmalignant, may occur in patients with cancer. SVCS is rarely immediately life threatening except in patients with airway compromise and/or laryngeal or cerebral edema. However, rapid recognition of typical presenting symptoms facilitates referral for tissue diagnosis (if unknown) and treatment.

### EPIDEMIOLOGY AND ETIOLOGY

SVCS occurs in around 15,000 patients per year, 90% of which are caused by malignancy. Specific cancers most commonly associated with SVCS are listed in Table 99–9. Lung cancer is the most frequent cause, of which small cell lung cancer (SCLC) is the most frequent subtype associated with SVCS. This is thought to be because of its predilection for the central and perihilar areas of the lung. Interestingly, right-sided lung cancers are four times more likely than left-sided lesions to cause SVCS. Mediastinal masses from lymphomas are the second most common cause.

The most common nonmalignant etiology of SVCS is catheter-related thrombosis, primarily caused by the increasing use of central access devices. Other causes include benign teratoma, tuberculosis, silicosis, and sarcoidosis.

### PATHOPHYSIOLOGY

The SVC is the primary drainage vein for blood return from the head, neck, and upper extremities. It is a relatively thin-walled vein that is particularly vulnerable to obstruction from adjacent tumor invasion or thrombosis. The obstruction leads to elevated venous pressure, although collateral veins partially compensate. This is one reason for the relatively slow onset of the classic symptoms of SVCS. In fact, 75% of patients have signs and symptoms for more than 1 week before seeking medical attention.[25]

#### Table 99–9

**Tumors Most Commonly Associated with SVCS**

| Cause | Frequency (%) |
|---|---|
| Non–small cell lung cancer | 50 |
| Small cell lung cancer | 22 |
| Lymphoma | 12 |
| Metastatic cancer (especially breast) | 9 |
| Germ cell tumor | 3 |
| Thymoma | 2 |
| Mesothelioma | 1 |

From Wilson LD, Detterbeck FC, Yahalom J. Superior vena cava syndrome with malignant causes. N Engl J Med. 2007;356(8):1862–1869.

### Clinical Presentation and Diagnosis of SVCS[25]

**General**
- Presentation depends on the degree of SVCS obstruction
- Almost complete obstruction is necessary to demonstrate classic symptoms

**Signs and Symptoms**
- Most common: swelling of face, neck, and upper extremity edema; dyspnea; cough; dilated upper extremity veins; orthopnea
- Less common: hoarseness, dysphagia, dizziness, headache, lethargy, chest pain
- Patients with elevated ICP may have mental status changes
- Patients with airway obstruction may have shortness of breath

**Diagnostic Tests**
- Tissue biopsy to determine underlying malignancy (if unknown), chest x-ray, CT scan, bronchoscopy, mediastinoscopy

### CLINICAL PRESENTATION AND DIAGNOSIS

### TREATMENT

#### Desired Outcomes

KEY CONCEPT *The primary goal of treatment of SVCS is to relieve the obstruction of the SVC by treating the underlying malignancy.* In the case of SVCS caused by thrombosis, the goal is to eliminate the thrombus and prevent further clot formation. Resolution of the obstruction will rapidly relieve symptoms and restore normal SVC function. The final goal of therapy is to avoid potentially fatal complications of SVCS such as cerebral edema from rapid increases in intracranial pressure (ICP) and intracranial thrombosis or bleeding.

#### General Approach to Treatment

Because the majority of SVCS is not immediately life threatening, a tissue diagnosis (if malignancy is unknown) to specifically identify the cancer origin is critical because treatment approaches vary considerably according to tumor histology. Thus, therapy can typically be withheld until a definitive tissue diagnosis is established. While biopsy results are pending, supportive measures such as head elevation, diuretics, corticosteroids, and supplemental oxygen may be used.

#### ▶ Nonpharmacologic Therapy

Radiation therapy is the treatment of choice for chemotherapy-resistant tumors such as NSCLC or in chemotherapy-refractory patients with SVCS. Between 70% and 90% of patients experience relief of symptoms. Radiation therapy may also be combined with chemotherapy for chemotherapy-sensitive tumors such as SCLC and lymphoma. In the rare emergency situations of airway obstruction or elevated ICP, empiric radiotherapy before tissue diagnosis should be used. In most patients, symptoms resolve within 1 to 3 weeks.

## Patient Care Process: SVCS

**Patient Assessment:**

- Evaluate patient for sign/symptoms of SVCS and determine severity and duration.
- Evaluate patient for risk factors for SVCS, especially cancers known to cause SVCS and central access devices.
- Obtain head and chest CT scan to diagnose presence of obstruction.
- If possible, obtain biopsy of mass to determine cause of SVCS.
- Depending on diagnosis of cause of SVCS, evaluate appropriateness of therapy (ie, antithrombolytics if source is a thrombus vs radiation therapy and steroids if cancer is the cause).
- Determine patient's candidacy for surgery if applicable.

**Therapy Evaluation:**

- Verify tissue diagnosis of SVCS.
- Monitor the patient for relief of symptoms by:
  a. Daily physical assessment of signs and symptoms
  b. Daily monitoring of fluid status
    - For corticosteroid use: Monitor daily serum glucose, insomnia, fluid retention, GI upset, mental status changes, and signs and symptoms of infection.

**Care Plan Development:**

1. Treat underlying malignancy to relieve obstruction.
2. Consider corticosteroids.

**Follow-Up Evaluation:**

- Surgery provides rapid relief of symptoms within 1 to 7 days of stent placement.
- Patients who receive chemotherapy and/or radiotherapy generally experience symptom relief within 1 to 2 weeks.
- Repeat CT scans of the chest after the first cycle of chemotherapy, surgical stenting, or radiotherapy to assess tumor response.

Surgical options for the management of SVCS include stent placement and surgical bypass. SVC stenting may provide longer-term relief of symptoms than radiotherapy, so it is often used in the palliative care setting when chemotherapy has failed.[36] One disadvantage of SVC stenting is the need for anticoagulation, especially in patients at high risk for thrombosis. The role of surgical bypass is limited to patients with complete SVC obstruction or patients who are refractory to chemotherapy and radiotherapy; thus, it is rarely indicated.

▶ *Pharmacologic Therapy*

Cytotoxic chemotherapy is the treatment of choice for chemotherapy-sensitive tumors such as SCLC and lymphoma. As indicated earlier, chemotherapy may also be combined with radiotherapy, especially in patients with lymphoma who have bulky mediastinal lymphadenopathy.

Corticosteroids play a key role in the management of SVCS, particularly in cases of lymphoma, because these tumors inherently respond to corticosteroid therapy. They are also helpful in the setting of respiratory compromise. Corticosteroids benefit patients who are receiving radiation therapy by reduction of local radiation-induced inflammation and patients with increased ICP. Dexamethasone 4 mg IV or by mouth every 6 hours is a frequently used regimen. The dosage should be tapered upon completion of radiation therapy or resolution of symptoms.

The role of diuretics in the management of SVCS is controversial. Although patients may derive symptomatic relief from edema, complications such as dehydration and reduced venous blood flow may exacerbate the condition. If diuretics are used, furosemide is most frequently used with diligent monitoring of the patient's fluid status and blood pressure.

In the case of thrombosis-related SVCS, anticoagulation is controversial because there is a lack of survival benefit. However, thrombolytics (ie, alteplase) and anticoagulation with heparin and warfarin may be beneficial in patients with thrombosis caused by indwelling catheters if used within 7 days of onset of symptoms, although catheter removal may be required.[25]

## OUTCOME EVALUATION

The major measure of outcome of treatment of SVCS is the relief of symptoms, regardless of the therapy used.

# NEUROLOGIC COMPLICATIONS: SPINAL CORD COMPRESSION

## INTRODUCTION

Although not typically life threatening, spinal cord compression is a true oncologic emergency because delays in treatment by mere hours may lead to permanent neurologic dysfunction. Practitioners must quickly recognize the signs and symptoms of this condition to facilitate rapid management strategies.

## EPIDEMIOLOGY AND ETIOLOGY

Around 20,000 cancer patients experience spinal cord compression in the United States every year, most of which involves the thoracic spine (~70%). Cancers that inherently metastasize to the bone (ie, breast, prostate, and lung) are the most frequent underlying malignancies associated with this complication. Most spinal cord compression occurs in patients with a known malignancy; however, 8% to 34% of cases occur as the initial presentation of cancer, especially in patients with non-Hodgkin lymphoma, multiple myeloma, and lung cancer.[26] Recently, predictive models have been developed to predict survival from SCC from myeloma and NSCLC.[27,28]

## PATHOPHYSIOLOGY

The spinal cord emerges from the brain stem at the base of the skull and terminates at the second lumbar vertebra. The thoracic spine is most vulnerable to cord compression because of natural kyphosis and because the width of the thoracic spinal canal is the smallest among the vertebrae. Most spinal cord compression is caused by adjacent vertebral metastases that compress the spinal cord or from pathologic compression fracture of the vertebra. This results in significant edema and inflammation in the affected area.

Patients with spinal cord compression are in acute, severe back and/or neck pain and may present to the emergency department

## Clinical Presentation and Diagnosis of Spinal Cord Compression

### General

- Once neurologic deficits appear, progression to irreversible paralysis may occur within hours to days
- Around 10% to 38% of patients present with multiple sites of spinal involvement

### Signs and Symptoms

- Back pain is present in more than 90% of patients
- Initially localized and increases in intensity over several weeks
- Aggravated by movement, supine positioning, coughing, sneezing, neck flexion, straight leg raise, Valsalva maneuver, palpation of spine
- Sensory deficit
- Cervical spine compression: quadriplegia
- Thoracic spine compression: paraplegia
- Upper lumbar spine compression: bowel and bladder dysfunction (constipation and urinary retention) and abnormal extensor plantar reflexes
- Weakness

### Diagnostic Tests

- MRI with gadolinium enhancement is the gold standard
- X-rays may be helpful to identify bone abnormalities

for evaluation. Diagnosis is made based on symptoms and imaging studies that show fractured vertebrae.

## TREATMENT

### Desired Outcomes

KEY CONCEPT *Because patients with spinal metastases are generally incurable, the primary goal of treatment of spinal cord compression is palliation. The most important prognostic factor for patients presenting with spinal cord compression is the degree of underlying neurologic dysfunction.* Only around 10% of patients who present with paralysis are able to ambulate after treatment.[26] Therefore, the goals of treatment are recovery of normal neurologic function, local tumor control, pain control, and stabilization of the spine. Therapeutic options depend primarily on the following factors:

- Underlying malignancy
- Prior therapies
- Stability of the spine at presentation
- Overall patient prognosis

### ▶ Nonpharmacologic Therapy

Radiation therapy is generally considered to be the treatment of choice for most patients. Exceptions to this include patients with prior radiation to the treatment site and patients with inherently radio-resistant tumors (ie, melanoma, renal cell carcinoma). The radiation field should include two vertebral bodies above and below the involved area.

Surgery for spinal cord compression typically involves either laminectomy for posterior lesions or decompression with fixation. Surgery is the treatment of choice for the following patients: (a) patients with unstable spine requiring stabilization, (b) immediately impending sphincter dysfunction requiring rapid spinal decompression, (c) patients who do not respond to or have received their maximum dose of radiotherapy, and (d) direct compression of the spinal cord caused by spinal bony fragments.[26] Recent evidence suggests that surgery followed by radiation therapy may be superior to radiotherapy alone in terms of increased ambulation time after treatment, maintenance of continence, and rates of nonambulatory patients becoming ambulatory.[29] Surgery is also useful for establishing a tissue diagnosis in cases of unknown malignancy. Overall, the risks and benefits of surgery must be weighed against the expected prognosis of the patient in light of the significant rehabilitation required after surgery.

### ▶ Pharmacologic Therapy

Corticosteroids play a vital role in the management of spinal cord compression. Dexamethasone is most frequently used to reduce edema, inhibit inflammation, and delay the onset of

## Patient Care Process: Spinal Cord Compression

### Patient Assessment:

- Take patient history of signs/symptoms of SCC.
- Obtain pain score from patient.
- Obtain imaging studies to diagnose bone fractures.
- Evaluate patient for history of radiation therapy to affected areas.

### Therapy Evaluation:

- Improved symptoms of sensory loss, using physical examination every 4 hours until symptoms improve then daily
- Improved autonomic system function, including urine and bowel control, every 4 hours until symptoms improve; then daily
- Improved pain control using detailed pain assessment every 2 to 4 hours during initial titration then daily thereafter
- For corticosteroid use: serum glucose, insomnia, fluid retention, GI upset, mental status changes, signs and symptoms of infection daily

### Care Plan Development:

- Treat underlying malignancy to relieve spinal cord compression
- Corticosteroids
- Pain relief

### Follow-Up Evaluation:

- Evaluate patient's ability to carry out activities of daily living with minimal or no pain.
- Monitor closely for signs of compression and paralysis.

neurologic complications. Dexamethasone has been shown to improve ambulation in combination with radiation compared with radiation alone.[30] Significant controversy exists regarding the optimal dosing of dexamethasone. Oral loading doses of 10 to 100 mg followed by 4 to 24 mg orally four times daily have been used. Higher doses may be used in cases of rapidly progressing symptoms, but adverse effects, including GI bleeding and psychosis, are more severe. Steroids should be continued during radiation therapy and then tapered appropriately.

Pain management is also of critical importance in patients with spinal cord compression. Although dexamethasone will provide some benefit, opioid analgesics should also be used and titrated rapidly to achieve adequate pain control.

## OUTCOME EVALUATION

Patients who receive definitive treatment with radiation and/or surgery generally derive benefit within days.

## COMPLICATIONS OF BRAIN METASTASES

### INTRODUCTION

Brain metastases are among the most feared complications of cancer and generally carry a poor prognosis. One serious consequence of brain metastases is elevated ICP, which can rapidly lead to fatal intracranial herniation and death. Rapid identification of the signs and symptoms of brain metastases is critical to improve long-term outcome and avoid mortality. The signs and symptoms of brain metastasis can be confused with common psychological distress or other neurologic problems (eg, headaches) that may go unrecognized. It is important that patients

---

### Clinical Presentation and Diagnosis of Brain Metastasis

**General**

- Almost all patients with brain metastases are symptomatic.
- New cerebral neurologic symptoms in a cancer patient should initiate evaluation for brain metastases.
- Other causes of brain lesions, including hemorrhage, infection, and infarct, should be ruled out.

**Signs and Symptoms**

- Mental status changes (most common): loss of consciousness, irritability, confusion
- Hemiparesis, aphasia, papilledema, weakness, seizure, nausea, and vomiting
- Headache: may be of gradual onset or sudden in the case of hemorrhage

**Diagnostic Tests**

- MRI with contrast enhancement is the gold standard.
- CT scans may be used in patients with pacemakers, but may miss small metastases.

---

who are suspected to have brain metastasis are quickly referred for appropriate management.[31]

## EPIDEMIOLOGY AND ETIOLOGY

Brain metastasis is the most common neurologic complication seen in patients with cancer. Approximately 170,000 patients develop brain metastases in the United States each year.[31] Many malignancies are frequently associated with brain metastases (Table 99–10). Although melanoma is the tumor type most likely to metastasize to the brain, brain metastases caused by lung and breast cancer are seen more often because they are among the most common cancers. In addition, brain metastases may be diagnosed at the same time as the primary malignancy in around 20% of cases.[31] Around 80% of brain metastases occur in the cerebral hemispheres, 15% in the cerebellum, and 5% in the brain stem.

## PATHOPHYSIOLOGY

A delicate balance of normal pressure is maintained in the brain and spinal cord by brain, blood, and cerebrospinal fluid. Because the brain is contained within a confined space (skull), any foreign mass contained within that space causes adverse sequelae. This results in either destruction or displacement of normal brain tissue with associated edema. Most brain metastases occur through hematogenous spread of the primary tumor and around 80% of patients have multiple sites of metastases within the brain.

## TREATMENT
### Desired Outcomes

Therapeutic modalities used for the management of brain metastases may be divided into symptomatic management and definitive management. **KEY CONCEPT** *The goals of treatment of brain metastases are to manage symptoms by reducing cerebral edema, treat the underlying malignancy both locally and systemically, and improve survival.*

### General Approach to Treatment

Patients with brain metastases have a poor prognosis. Untreated patients generally have a median survival of 1 month. The choice of treatment depends primarily on the status of the patient's underlying malignancy and the number and sites of brain metastases. The primary definitive treatments for brain metastases are surgery and radiation therapy. Pharmacologic modalities are primarily used to control symptoms, although cytotoxic chemotherapy plays a limited role in the management.

---

**Table 99–10**

**Cancers Most Frequently Associated with Brain Metastases**

| Type of Cancer | Frequency (%) |
| --- | --- |
| Lung cancer | 18–64 |
| Breast cancer | 2–21 |
| Melanoma | 4–16 |
| Colorectal cancer | 2–11 |
| Hematologic malignancies (ie, leukemia) | ~10 (primarily caused by leptomeningeal spread) |

From Lassman AB, DeAngelis LM. Brain metastases. Neurol Clin North Am. 2003;21:1–23.

▶ *Nonpharmacologic Therapy*

Radiation therapy is the treatment of choice for most patients with brain metastases. Most patients receive whole-brain radiation because the majority of brain metastases are multifocal. Another method known as stereotactic radiosurgery provides intense focal radiation, typically using a linear accelerator or gamma knife, in patients who cannot tolerate surgery or have lesions that are surgically inaccessible (ie, brain stem). Because brain metastases can occur in up to 50% of patients with small cell lung cancer, prophylactic cranial irradiation is recommended in patients with good performance status who at least partially respond to chemotherapy to both prevent the development of brain metastases and to prolong survival.[32] Although other cancers can metastasize to the brain, the benefits of routine prophylactic cranial irradiation have only been demonstrated in studies conducted in patients with small cell lung cancer.[32] In fact, a recent meta-analysis reported that prophylactic cranial irradiation may reduce overall survival when used in NSCLC patients even though it reduced brain metastases in these patients.[33]

## Patient Care Process: Brain Metastasis

**Patient Assessment:**

- Determine onset and duration of signs/symptoms such as headache, nausea, visual changes, mental status changes, depression, etc.
- Evaluate the patient for drug interactions, allergies, and adverse effects with phenytoin or corticosteroid therapy.
- Obtain head CT scan to diagnose brain metastasis.

**Therapy Evaluation:**

- Assess the patient's symptoms for prompt referral for radiation or surgery.
- For patients receiving corticosteroids, monitor for adverse effects and drug interactions. Does the patient need GI prophylaxis for long-term treatment? Slowly taper once symptoms improve and/or radiation or surgery is completed.
- Instruct patients receiving phenytoin about symptoms of elevated serum concentrations (nystagmus, blurred vision, dizziness, drowsiness, lethargy).
- Provide patient education regarding when to take medications and the importance of compliance and to promptly report symptoms of recurrence (mental status changes, seizures).

**Care Plan Development:**

- Initiate treatment for underlying malignancy
- Provide symptomatic relief with mannitol and corticosteroids
- Manage seizure with phenytoin or diazepam if they develop

**Follow-Up Evaluation:**

- Monitor patients for improvements in presenting signs/symptoms.
- Monitor patients for response to chemotherapy.

Surgery plays a key role in the management of patients with brain metastases, particularly in patients whose systemic disease is well controlled and in patients with solitary lesions. Surgery may also benefit patients with multiple metastatic sites who have a single dominant lesion with current or impending neurologic sequelae.

In cases of elevated ICP caused by cerebral herniation, mechanical hyperventilation to decrease the arterial $PCO_2$ down to 25 mm Hg (3.33 kPa) acutely decreases ICP by causing cerebral vasoconstriction. Elevation of the patient's bed may also quickly reduce the ICP. It should be noted that these strategies only relieve symptoms, and definitive therapy is still required.

▶ *Pharmacologic Therapy*

Corticosteroids are a mainstay in the management of brain metastases. They reduce edema that typically surrounds sites of metastases thereby reducing ICP. A loading dose of dexamethasone 10 mg IV followed by 4 mg by mouth or IV every 6 hours is typically used. Symptom relief may occur shortly after the loading dose, although the maximum benefit may not be seen for several days (after definitive therapy).[31]

Mannitol is an agent that may be used in patients with impending cerebral herniation. Mannitol is an osmotic diuretic that shifts brain osmolarity from the brain to the blood. Doses of 100 g (1–2 g/kg) as an IV bolus should be used. Repeated doses are typically not recommended because mannitol may diffuse into brain tissue, leading to rebound increased ICP.[31]

Around 20% patients with brain metastases may present with seizures and require anticonvulsant therapy. Phenytoin is the most frequently used agent with a loading dose of 15 mg/kg followed by 300 mg by mouth daily (titrated to therapeutic levels between 10 and 20 mcg/mL [40 and 79 μmol/L]). Diazepam 5 mg IV may be used for rapid control of persistent seizures. Prophylactic anticonvulsants have frequently been used; however, a systematic review did not support their use.[32] Thus, because adverse effects and drug interactions are common, the routine use of prophylactic anticonvulsants is not recommended.

## OUTCOME EVALUATION

The success of therapy is based on the ability to decrease symptoms, treat the underlying sites of disease within the brain, and prolong survival.

## UROLOGIC COMPLICATIONS: HEMORRHAGIC CYSTITIS

### INTRODUCTION

Hemorrhagic cystitis is defined as acute or insidious bleeding from the lining of the bladder. Although therapy with certain medications is the most common cause, it is also the most preventable. Once it occurs, hemorrhagic cystitis causes significant morbidity and mortality rates between 2% and 4%. This section focuses on preventive strategies for chemotherapeutic causes of hemorrhagic cystitis.

### EPIDEMIOLOGY AND ETIOLOGY

Numerous etiologies have been linked to hemorrhagic cystitis (Table 99–11).[34] Of these, the oxazaphosphorine alkylating agents (cyclophosphamide and ifosfamide) are most

| Table 99–11 |  |
|---|---|
| **Primary Causes of Hemorrhagic Cystitis** |  |
| **Pharmacologic** | **Nonpharmacologic** |
| Cyclophosphamide | Pelvic irradiation |
| Chronic low doses | Viral infection |
| High-doses used in BMT | CMV |
| Ifosfamide | Papovavirus |
| Intravesicular thiotepa | Herpes simplex virus |
| Chronic oral busulfan | Adenovirus |
| Anabolic steroids | |

frequently implicated. Hemorrhagic cystitis is the dose-limiting toxicity of ifosfamide and predisposes patients with bladder cancer. Incidence rates vary considerably but generally range between 18% and 40% with ifosfamide and 0.5% to 40% with high-dose (300 mg/m$^2$ or more) cyclophosphamide in the absence of prophylactic measures.[35] Chronic, low-dose oral cyclophosphamide as typically used in autoimmune disorders and chronic lymphocytic leukemia is infrequently associated with hemorrhagic cystitis.

Around 20% patients receiving pelvic irradiation may experience hemorrhagic cystitis, especially with concurrent cyclophosphamide. Viral infections commonly associated with this condition most frequently occur in bone marrow transplant recipients who may also receive cyclophosphamide.

## PATHOPHYSIOLOGY

Cyclophosphamide- or ifosfamide-induced damage to the bladder wall is primarily caused by their shared metabolite known as acrolein. Acrolein causes sloughing and inflammation of the bladder lining, leading to bleeding and hemorrhage. This is most common when urine output is low because higher concentrations of acrolein come into contact with the bladder urothelium for longer periods of time.

## PREVENTION

**KEY CONCEPT** *The use of effective prevention strategies can decrease the incidence of hemorrhagic cystitis to fewer than 5% in patients receiving cyclophosphamide or ifosfamide. Three methods are used to reduce the risk: administration of Mesna (2-mercaptoethane sulfonate), hyperhydration, and bladder irrigation with catheterization.* Mesna is the primary method used with ifosfamide; all three strategies are used with cyclophosphamide.

Mesna is a thiol compound that is rapidly oxidized in the bloodstream after administration to dimesna, which is inactive. However, after being filtered through the kidneys, dimesna is reduced back to Mesna, which binds to acrolein, leading to its inactivation and excretion. ASCO has published evidence-based guidelines for the dosing and administration of Mesna (Table 99–12).[35] The dose of oral Mesna must be double the IV dose because of its oral bioavailability between 40% and 50%. Because the half-life of Mesna (~1.2 hours) is much shorter than

**● Clinical Presentation and Diagnosis of Hemorrhagic Cystitis**

**General**
- Presentation may be mild (microscopic hematuria) or severe (massive hemorrhage) and develops during or shortly after chemotherapy infusion

**Signs and Symptoms**
- Suprapubic pain and cramping, urinary urgency and frequency, dysuria and burning, hematuria
- Urinary retention leading to hydronephrosis and renal failure may occur if large blood clots obstruct the ureters or bladder outlet.

**Laboratory Tests**
- Urine dipsticks for blood
- Urinalysis reveals more than three RBCs per high-power field: microscopic hematuria
- CBC with differential, prothrombin time or international normalized ratio, activated partial thromboplastin time, blood urea nitrogen, creatinine

that of ifosfamide or cyclophosphamide, prolonged administration of Mesna beyond the end of the chemotherapy infusion is critical (Figure 99–2). Patients should receive at least 2 L of IV fluids beginning 12 to 24 hours before and ending 24 to 48 hours after the last dose of chemotherapy.[34,35]

Hyperhydration with normal saline at 3 L/m$^2$/day with IV furosemide to maintain urine output greater than 100 mL/hour has also been used with cyclophosphamide. Continuous bladder irrigation by catheterization uses normal saline at 250 to 1000 mL/hour to flush acrolein from the bladder. Mesna is equivalent to both strategies in patients receiving high-dose cyclophosphamide and avoids the discomfort and infection risk with catheterization and the intensity of hyperhydration. Thus, Mesna is the preventive method of choice.[35]

## TREATMENT
### Desired Outcomes

If hemorrhagic cystitis occurs, the goals of treatment are to decrease exposure to the offending etiology, establish and maintain urine outflow, avoid obstruction and renal compromise, and maintain blood and plasma volume. Restoration of normal bladder function is the ultimate goal following acute treatment.

### General Approach to Treatment

The treatment of hemorrhagic cystitis first involves discontinuation of the offending agent. Agents such as anticoagulants and inhibitors of platelet function should also be discontinued. IV fluids should be aggressively administered to irrigate the bladder. Blood and platelet transfusions may be necessary to maintain normal hematologic values. Pain should be managed with opioid analgesics. Local intravesicular therapies may be necessary if hematuria does not resolve (Figure 99–3).

## Table 99–12

**ASCO Guidelines for the Use of Mesna with Ifosfamide and High-Dose Cyclophosphamide**

| Chemotherapy Schedule | Dosing Schedule for Mesna | Comments |
|---|---|---|
| Low-dose ifosfamide < 2 g/m²/day | Oral: 100% of total daily dose of ifosfamide given 20% IV 15 minutes before and 40% po 2 and 6 hours after start of ifosfamide | Available in 400-mg tablets Peak urinary thiol concentrations with oral Mesna is at 3 hours If patient vomits within 2 hours of administration, repeat dose po or IV |
| Standard-dose ifosfamide equal to 2.5 g/m²/day | Bolus: 60% of total daily dose of ifosfamide given IV in 20% increments 15 minutes before and 4 and 8 hours after start of ifosfamide Infusion: 60% of total daily dose of ifosfamide given 20% IV 15 minutes before and 40% by continuous infusion during and for 12–24 hours after end of ifosfamide | Peak urinary thiol concentrations with IV Mesna is at 1 hour Compatible with ifosfamide and cyclophosphamide by Y-site administration or when admixed in the same bag |
| High-dose ifosfamide > 2.5 g/m²/day | Lack of evidence for dosing, but higher doses for longer duration recommended based on longer half-life of ifosfamide at high doses | |
| Standard-dose cyclophosphamide | Use of Mesna is not routinely necessary | Should be combined with saline diuresis (1.5 L/m²/day of normal saline) |
| High-dose cyclophosphamide (BMT) | Bolus: 40% of cyclophosphamide dose given IV at hours 0, 3, 6, and 9 after cyclophosphamide Infusion: 100% of cyclophosphamide dose given by continuous infusion until 24 hours after cyclophosphamide | |

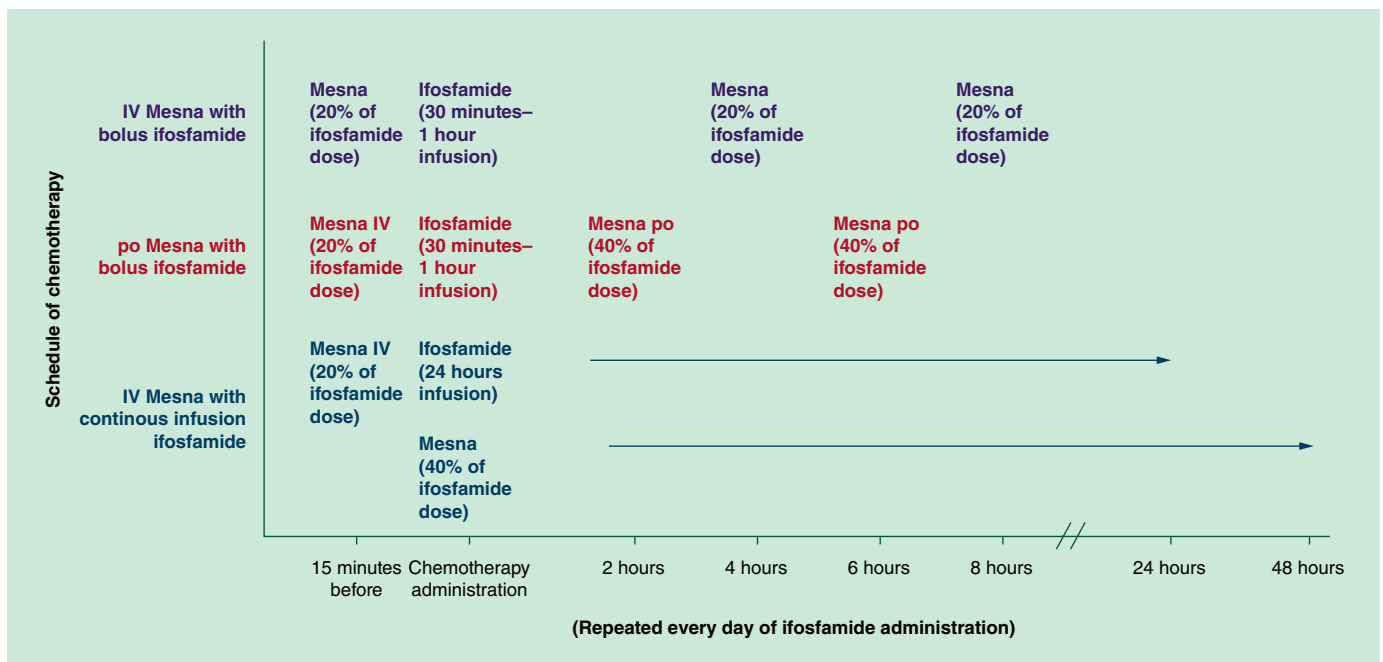

**FIGURE 99–2.** Examples of Mesna (2-mercaptoethane sulfonate) administration with ifosfamide. (IV, intravenous; po, oral.)
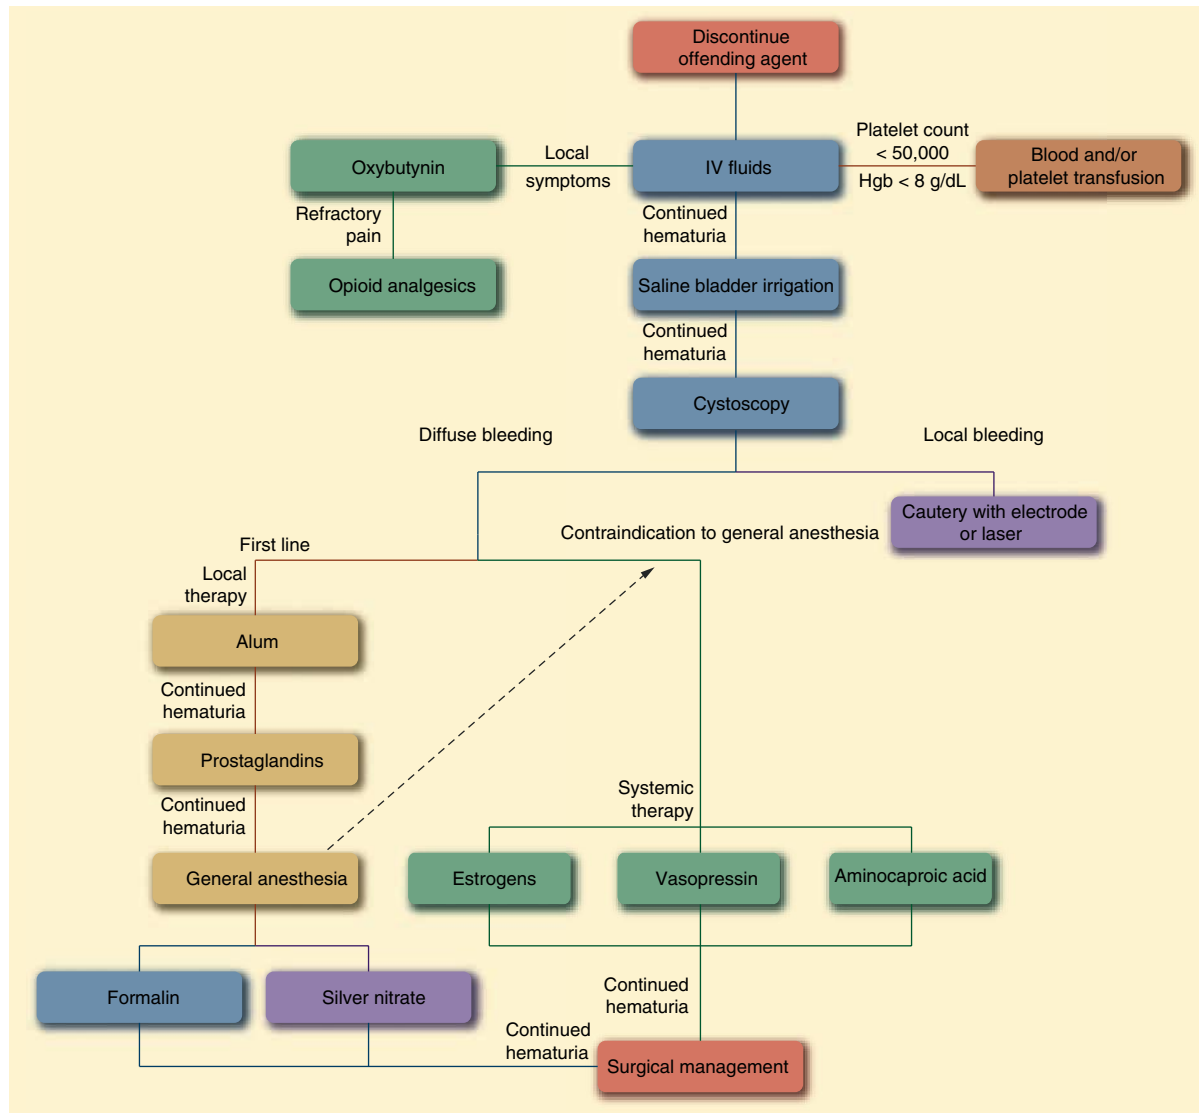

**FIGURE 99–3.** Treatment of hemorrhagic cystitis. (From Bucavene G, Micuzzi A, Menichetti F, et al. Levofloxacin to prevent bacterial infection in patients with cancer and neutropenia. N Engl J Med. 2005;353:977–987.)

▶ *Nonpharmacologic Therapy*

A large-diameter, multihole urethral catheter should be inserted to facilitate saline lavage and evacuation of blood clots. Surgical removal of blood clots under anesthesia may be required if saline lavage is ineffective. Active bleeding from isolated areas may be cauterized with an electrode or laser. In severe cases that are unresponsive to local or systemic pharmacologic intervention, urinary diversion with percutaneous **nephrostomy** or surgical removal of the bladder may be required.

▶ *Pharmacologic Therapy*

A number of local or systemic agents are used in the treatment of hemorrhagic cystitis.[34] Local (direct instillation into the bladder), one-time administration of hemostatic agents such as alum, prostaglandins, silver nitrate, and formalin may be used; however, general anesthesia is required, especially with formalin, because of pain. Systemic agents, including estrogens, vasopressin, and aminocaproic acid, may be used in patients who are refractory to local therapy, although they introduce the risk of systemic side effects. These agents should be continued until bleeding stops.

Antispasmodic agents such as oxybutynin 5 mg by mouth two to three times daily may be used for bladder spasms. In patients with refractory pain, opioid analgesics should be titrated to adequate pain control.

## OUTCOME EVALUATION

The goal of treatment is resolution of bladder symptoms and appropriate pain management.

Monitor the patient for resolution of hematuria after each successive therapeutic intervention. The frequency of monitoring is based on the severity of hemorrhaging. Monitor urinary output and serum chemistries (including sodium, potassium, chloride, blood urea nitrogen, and serum creatinine) daily for renal dysfunction. Check the CBC at least daily to monitor hemoglobin and platelet count.

# METABOLIC COMPLICATIONS: HYPERCALCEMIA OF MALIGNANCY

## INTRODUCTION

Hypercalcemia is the most common metabolic abnormality experienced by patients with cancer. A small percentage of as yet undiagnosed patients present with hypercalcemia. Once hypercalcemia occurs, it is associated with a very poor prognosis because of the frequent association with advanced or metastatic disease.[36]

## EPIDEMIOLOGY AND ETIOLOGY

Hypercalcemia occurs in 10% to 30% of patients with cancer during the course of their disease. The most common tumor types associated with hypercalcemia are breast cancer; squamous cell carcinomas of the head, neck, and lung; and renal cancer. Hematologic malignancies such as multiple myeloma and, rarely, lymphomas are other underlying malignancies associated with hypercalcemia.

## PATHOPHYSIOLOGY

Around 99% of calcium is contained in the bones; the other 1% resides in the extracellular fluid. Of this extracellular calcium, approximately 40% is bound to albumin, and the remainder is in the ionized, physiologically active form. Normal calcium levels are maintained by three primary factors: parathyroid hormone (PTH), 1,25-dihydroxyvitamin D, and calcitonin. PTH increases renal tubular calcium resorption and promotes bone resorption. The active form of vitamin D, 1,25-dihydroxyvitamin D, regulates absorption of calcium from the GI tract. Calcitonin serves as an inhibitory factor by suppressing osteoclast activity and stimulating calcium deposition into the bones.[36]

The delicate balance maintained by these factors is altered in patients with cancer by two principal mechanisms: tumor production of humoral factors that alter calcium metabolism (humoral hypercalcemia) and by local osteolytic activity from bone metastases.[37] Humoral hypercalcemia causes around 80% of all hypercalcemia cases and is primarily mediated by systemic secretion of PTH-related protein (PTHrP). This protein mimics the action of endogenous PTH on bones. Local osteolytic activity causes 20% to 30% of hypercalcemia cases, although local osteolytic activity may also have a humoral component. Local production of various factors directly stimulates osteoclastic bone resorption, which releases growth factors and cytokines (ie, transforming growth factor-β) that are necessary for tumor growth. Thus, these metastatic tumors perpetuate their own growth through this mechanism. Calcium is also released by the osteolytic activity, resulting in hypercalcemia).[37] A third and less common mechanism is production of 1,25-dihydroxyvitamin D by tumor cells (usually lymphoma), which increases GI absorption of calcium and enhances osteoclastic bone resorption.

## TREATMENT
### Desired Outcomes

**KEY CONCEPT** *The primary goal of treatment for hypercalcemia is to control the underlying malignancy. Therapies directed at lowering the calcium level are temporary measures that are useful until anticancer therapy begins to work.* The goals of calcium-lowering therapy are to (a) lower the corrected calcium to normal levels, (b) regain fluid and electrolyte balance, (c) relieve symptoms, and (d) prevent life-threatening complications. Patients who are refractory to available therapies may have calcium-lowering therapy withheld (usually resulting in coma and death), which may be a humane approach.[36]

### General Approach to Treatment

Therapeutic options for the treatment of hypercalcemia should be directed toward the level of corrected serum calcium and the presence of symptoms (**Figure 99–4**). Hypercalcemia may be classified as mild (corrected calcium equal to 10.5–11.9 mg/dL [2.63–2.98 mmol/L]), moderate (12–13.9 mg/dL [3.00–3.49 mmol/L]), and severe (greater than 14 mg/dL [3.50 mmol/L] or more).[36] Adequate treatment of mild or asymptomatic hypercalcemia may be achieved on an outpatient basis with nonpharmacologic measures. Moderate to severe or symptomatic hypercalcemia almost always requires pharmacologic intervention.

#### ▶ Nonpharmacologic Therapy

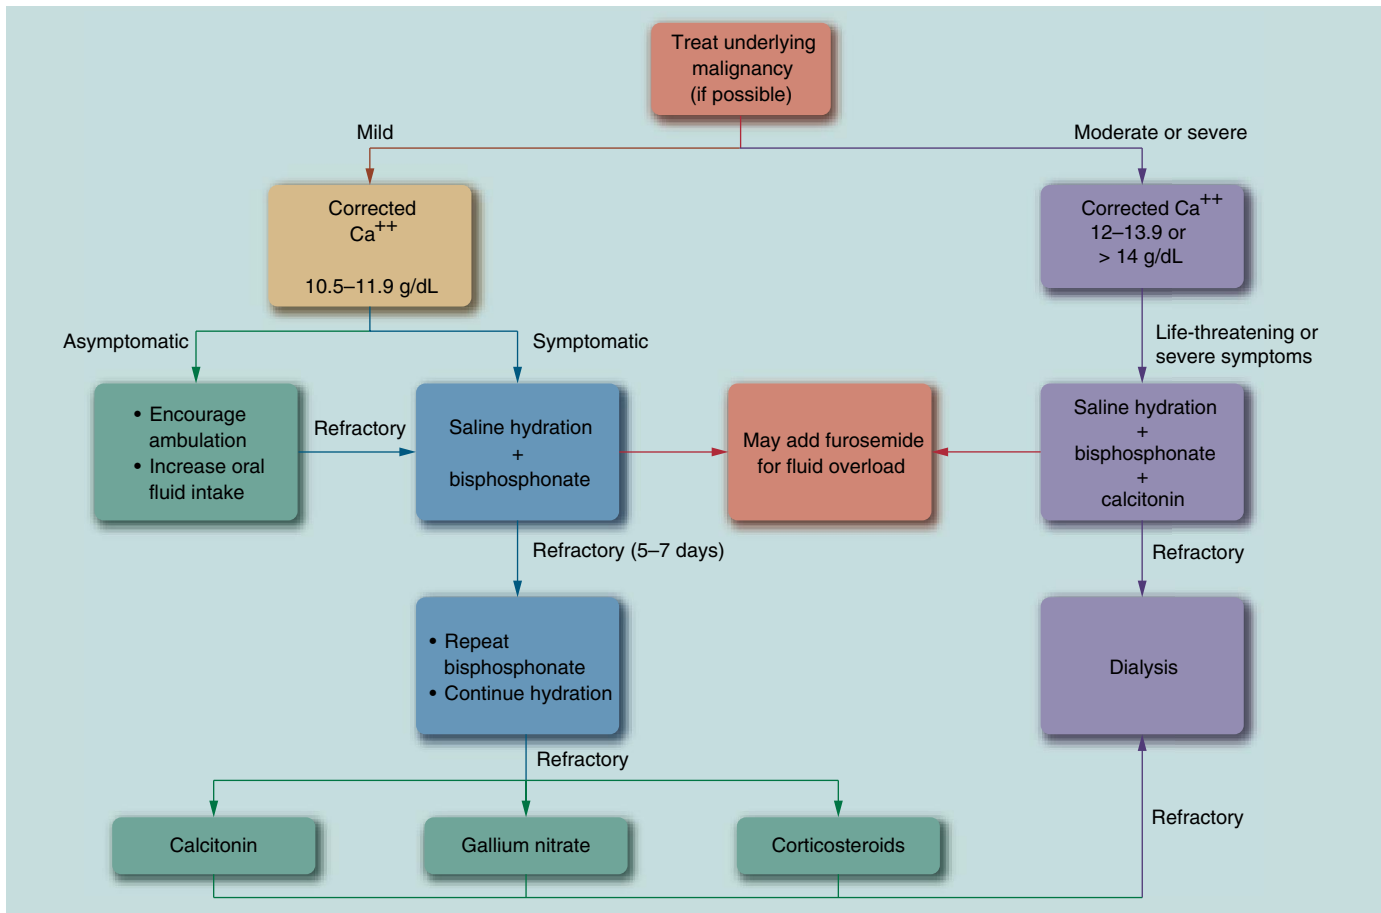
Calciuric therapy in the form of hydration is a key component in the treatment of hypercalcemia, regardless of severity or presence of symptoms.[36] Mild or asymptomatic patients may be encouraged to increase their oral fluid intake (3–4 L/day). Patients with moderate to severe or symptomatic hypercalcemia should receive normal saline at 200 to 500 mL/hour according to their dehydration and cardiovascular status. Patients should


**FIGURE 99–4.** Treatment algorithm for the hypercalcemia of malignancy.

## Clinical Presentation and Diagnosis of Hypercalcemia[36]

### General

- Presence of symptoms depends not only on the calcium level but the rapidity of onset
- Normal calcium level is 8.5 to 10.5 mg/dL (2.13–2.63 mmol/L) (varies by laboratory)
- Serum calcium level *must* be corrected for albumin level using the following formula:

Corrected calcium (mg/dL) = Serum calcium + 0.8 (4 – Serum albumin) for serum calcium expressed in mg/dL and albumin in g/dL.

or

Corrected calcium (mmol/L) = Serum calcium + 0.02 (40 – serum albumin) for serum calcium expressed in mmol/L and albumin in g/L.

### Signs and Symptoms

- Five primary organ systems may be affected:
- GI: anorexia, nausea, vomiting, constipation
- Musculoskeletal: weakness, bone pain, fatigue, ataxia

- CNS: confusion, headache, lethargy, seizures, coma
- Genitourinary: polydipsia, polyuria, renal failure
- Cardiac: Bradycardia, ECG abnormalities, arrhythmias

### Laboratory Tests

- Elevated corrected serum calcium level (≥ 10.5 mg/dL [2.63 mmol/L]), serum albumin, low to normal serum phosphate
- Patient may have elevated blood urea nitrogen and serum creatinine
- Elevated alkaline phosphatase may indicate bone destruction
- ECG may indicate prolonged PR interval, shortened QT interval, widened T wave

### Other Diagnostic Tests

- Rule out other causes of hypercalcemia, including primary hyperparathyroidism, hyperthyroidism, vitamin D intoxication, chronic renal failure

be encouraged to ambulate as much as possible because immobility enhances bone resorption. Although calcium should be discontinued from parenteral feeding solutions, oral calcium supplementation minimally contributes to hypercalcemia unless it is mediated by vitamin D. In these cases, oral calcium should be discontinued. Finally, agents that may contribute to hypercalcemia (thiazide diuretics, vitamin D, lithium) or decrease renal function (NSAIDs) should be discontinued. Dialysis may be used in refractory cases or patients who cannot tolerate aggressive saline hydration.[36]

▶ *Pharmacologic Therapy*

Multiple pharmacologic interventions are available for the treatment of hypercalcemia (Table 99–13). Furosemide 20 to 40 mg/day may be added to hydration after rehydration has been achieved to avoid fluid overload and enhance renal excretion of calcium. Although effective in relieving symptoms, hydration and diuretics are temporary measures that are useful until the onset of antiresorptive therapy; thus, hydration and antiresorptive therapy should be initiated simultaneously.[36]

The antiresorptive therapy of choice for hypercalcemia of malignancy is a bisphosphonate. Because of poor oral bioavailability, only IV agents should be used. Pamidronate and zoledronic acid are most commonly used and are potent inhibitors of osteoclast activity.[35] The bisphosphonates should be administered at diagnosis of hypercalcemia because of their delayed onset of action.

Calcitonin is the drug of choice in cases of emergent hypercalcemia (patients with life-threatening electrocardiographic [ECG] changes, arrhythmias, or central nervous system [CNS] effects) because of its rapid onset of action. Calcitonin inhibits osteoclast activity and decreases renal tubular calcium resorption. Corticosteroids are useful in patients with steroid-responsive malignancies, such as lymphomas or multiple myeloma, and may delay tachyphylaxis to calcitonin. Gallium nitrate is another treatment option, although the 5-day

---

**Table 99–13**

**Treatment Options for Hypercalcemia of Malignancy**

| | Agent | Dosage | Onset | Duration | Reduction in Serum Calcium Concentration | Comments |
|---|---|---|---|---|---|---|
| Calciuric therapy | IV normal saline<br>Furosemide | 200–500 mL/hour<br>20–40 mg IV | 24–48 hours<br>4 hours | 2–3 days<br>2–3 days | 0.5–2 mg/dL (0.13–0.50 mmol/L) | Avoid fluid overload, monitor electrolytes<br>Monitor for hypokalemia, dehydration |
| Antiresorptive therapy | Pamidronate | 60–90 mg IV over 2–24 hours[a] | 24–72 hours | 3–4 weeks | > 1 mg/dL (0.25 mmol/L) | Nadir not seen until after 4–7 days; may cause fever, renal dysfunction; pamidronate less expensive |
| | Zoledronic acid | 4 mg IV over 15 minutes | 24–48 hours | 4+ weeks | > 1 mg/dL (0.25 mmol/L) | |
| | Corticosteroids | Prednisone (or equivalent) 50–100 mg/day | 5–7 days | 3–4 days | 0.5–3 mg/dL (0.13–0.75 mmol/L) | Monitor for hyperglycemia, insomnia, immunosuppression |
| | Calcitonin | 4–8 IU/kg SC or IM every 6–12 hours | 2–4 hours | 1–3 days | 2–3 mg/dL (0.50–0.75 mmol/L) | Salmon-derived formulation preferred; 1-unit test dose recommended; can be given in renal failure; may cause flushing, nausea |
| | Gallium nitrate | 100–200 mg/m² CIV daily for 5 days | 24–48 hours | | | Do not administer if creatinine > 2.5 mg/dL (221 μmol/L); may cause renal failure |
| | Denosumab | 120 mg SQ days 1, 8, and 15 the first month, then day 1 only | 48–96 hours | 4+ weeks | > 1 mg/dL (0.25 mmol/L) | Not renally cleared, may be used in patients with renal dysfunction, but reduce dose as increased risk of hypocalcemia in renally impaired |

CIV, continuous intravenous infusion; IM, intramuscular; IV, intravenous; SC, subcutaneous.

[a]60 mg of pamidronate may be used in smaller patients or in patients with mild hypercalcemia or renal dysfunction. May use longer infusion time in patients with renal dysfunction.

Data from Refs. 47 and 49.

administration regimen and risk of nephrotoxicity limit its use. Denosumab 120 mg subcutaneously, a RANKL inhibitor, was successful in correcting hypercalcemia in 12/15 patients with persistent hypercalcemia despite treatment with bisphosphonates and may be considered in those with bisphosphonate-resistant hypercalcemia.[37]

## OUTCOME EVALUATION

The long-term success of therapy for hypercalcemia is determined primarily by the success of treatment of the underlying malignancy. The goal of treatment is to reduce serum calcium levels to normal range and to relieve patient symptoms if present.

## METABOLIC COMPLICATIONS: TLS

### INTRODUCTION

Although not as common as hypercalcemia, TLS may cause significant morbidity and mortality if adequate prophylaxis and treatment are not instituted. TLS is the result of rapid destruction of malignant cells with subsequent release of intracellular contents into the circulation.

### EPIDEMIOLOGY AND ETIOLOGY

The overall incidence of TLS is unknown but has been linked to a number of patient- and tumor-related risk factors (Table 99–14).[38] TLS typically occurs in malignancies with high tumor burdens or high proliferative rates. Because of this, children are most

### Table 99–14

**Risk Factors for TLS**

**Disease Related**

**High risk**
Acute lymphoblastic leukemia
High-grade non-Hodgkin lymphoma (ie, Burkitt lymphoma)

**Intermediate risk**
Chronic lymphocytic leukemia (especially bulky lymphadenopathy)
Acute myeloid leukemia (especially WBC count > 50,000 $10^3/\mu L$ [$50 \times 10^9$/L])
Multiple myeloma

**Low risk**
Low- and intermediate-grade non-Hodgkin lymphoma
Hodgkin disease
Chronic myeloid leukemia (blast crisis)

**Rare**
Breast cancer
Small cell lung cancer
Testicular cancer

**Patient Related**

Decreased urinary output, dehydration, or renal failure
Preexisting hyperuricemia
Acidic urine
WBC count > 50,000 $10^3/\mu L$ ($50 \times 10^9$/L)
LDH levels > 1500 IU/L (25.0 μkat/L)
High tumor sensitivity to treatment modalities

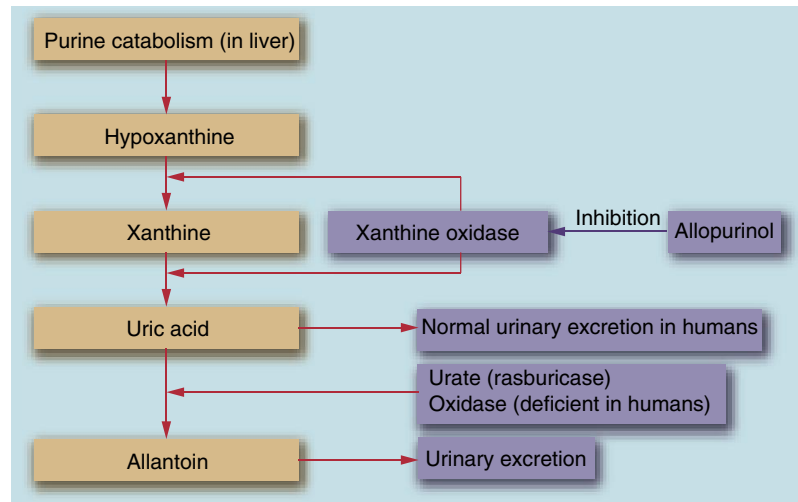
LDH, lactate dehydrogenase; WBC, white blood cell.


**FIGURE 99–5.** The role of allopurinol and rasburicase in the enzymatic degradation of purine nucleic acids.

frequently affected because they frequently have aggressive malignancies. TLS is typically induced by cancer treatment modalities, including chemotherapy, hormonal therapy, radiation, biologic therapy, or corticosteroids, although some patients may present spontaneously before treatment.[38]

## PATHOPHYSIOLOGY

Patients with TLS experience a wide range of metabolic abnormalities. The massive cell lysis that occurs leads to the release of intracellular electrolytes, resulting in hyperkalemia and hyperphosphatemia. High concentrations of phosphate bind to calcium, leading to hypocalcemia and calcium phosphate precipitation in the renal tubule. Purine nucleic acids are also released, which are subsequently metabolized to uric acid through multiple enzyme-mediated steps (**Figure 99–5**). Uric acid is poorly soluble at urinary acidic pH, leading to crystallization in the renal tubule. The precipitation of uric acid and calcium phosphate leads to metabolic acidosis, facilitating further uric acid crystallization. Acute renal failure may be the end result.[38]

## TREATMENT
### Desired Outcomes

KEY CONCEPT *The primary goals of management of TLS are (a) prevention of renal failure and (b) prevention of electrolyte imbalances. Thus, the best treatment for TLS is prophylaxis to enable delivery of cytotoxic therapy for the underlying malignancy.* For patients who present with or develop TLS despite prophylaxis, treatment goals include (a) decreasing uric acid levels, (b) correcting electrolyte imbalances, and (c) preventing compromised renal function. These goals should be achieved in a cost-effective manner.

### General Approach to Treatment

Prevention of TLS is generally achieved by increasing the urine output and preventing accumulation of uric acid. Prophylactic strategies should begin immediately upon presentation,

preferably 48 hours prior to cytotoxic therapy. Treatment modalities primarily increase uric acid solubility, maintain electrolyte balance, and support renal output.[38]

#### ▶ *Nonpharmacologic Therapy*

Vigorous IV hydration with dextrose 5% in water with half normal saline at 3 L/m$^2$/day to maintain a urine output greater than or equal to 100 mL/m$^2$/hour is necessary unless the patient presents with acute renal dysfunction. Alkalinization of the urine to a pH greater than or equal to 7.0 with 50 to 100 mEq/L (50–100 mmol/L) of sodium bicarbonate has been used to promote uric acid solubility for excretion. This measure is controversial because xanthine and hypoxanthine are less soluble at alkaline pH, potentially leading to crystallization, especially during and after allopurinol therapy (see Figure 99–5).[38] Medications that increase serum potassium (angiotensin-converting enzyme inhibitors, spironolactone) or block tubular resorption of uric acid (probenecid, thiazides) should be discontinued. Nephrotoxic agents such as amphotericin B or aminoglycosides should also be avoided. Hemodialysis may be required in patients who develop anuria or uncontrolled hyperkalemia, hyperphosphatemia, hypocalcemia, acidosis, or volume overload.[38]

#### ▶ *Pharmacologic Therapy*

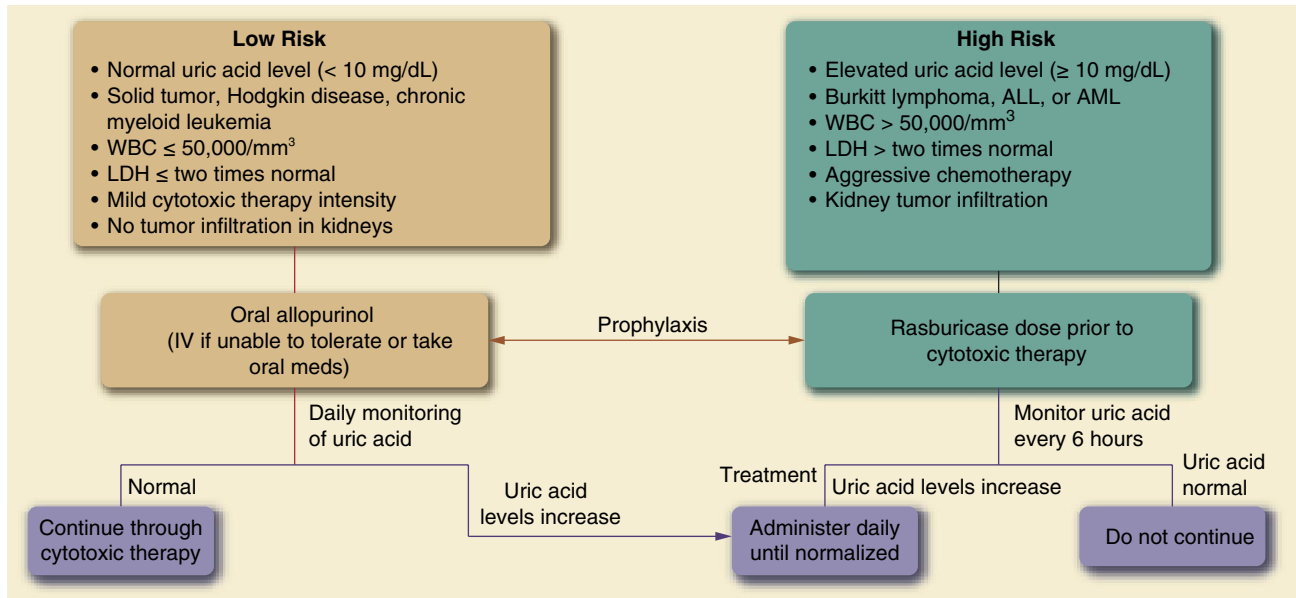
Pharmacologic prevention strategies for TLS are aimed at low- and high-risk patients (**Figure 99–6**). Allopurinol is an xanthine oxidase inhibitor that is used for prevention only because it has no effect on preexisting elevated uric acid. Rasburicase is a recombinant form of urate oxidase that is useful for both prevention and treatment, but is expensive (**Table 99–15**). Although the approved dose is 0.2 mg/kg/day for 5 days, recent studies using abbreviated courses (1–3 days) and/or lower doses (0.05–0.1 mg/kg/day) may be equally efficacious with significantly reduced cost.[39] Because uric acid levels generally fall within 4 hours of the first dose, one dose may be administered with frequent, serial monitoring of the uric acid level for repeat dosing if necessary (see Figure 99–6). Of note, rasburicase continues to break down uric acid in blood samples drawn from patients. This can be avoided by immediately placing the sample in an ice bath for processing to avoid falsely lowered uric acid levels.[39]


**FIGURE 99–6.** Prophylaxis and treatment of hyperuricemia associated with tumor lysis syndrome. (ALL, acute lymphoblastic leukemia; AML, acute myelogenous leukemia; IV, intravenous; LDH, lactate dehydrogenase; WBC, white blood cell.) (Data from Refs. 35 and 36.)

**Table 99–15**

**Comparison of Allopurinol and Rasburicase in TLS**

| Drug | Dosing | AWP[a] | Comments |
|---|---|---|---|
| Oral allopurinol (Zyloprim) | Adult: 600–800 mg/day in two to three divided doses<br>Pediatric: 10 mg/kg/day or 200–300 mg/m$^2$/day | $0.48/day (generic) | Adjust dose for renal impairment<br>Avoid drug interactions (mercaptopurine)<br>Monitor for skin rash |
| IV allopurinol (Aloprim) | Adult: 200–400 mg/m$^2$/day<br>Pediatric: 200 mg/m$^2$/day | $625–$1,250/day | As above<br>Reserve for patients who cannot tolerate or take oral medications<br>Maximum dose = 600 mg/day |
| Rasburicase (Elitek) | 0.2 mg/kg/day for up to 5 days | $12,000/day | Lower doses and abbreviated schedules may be used to decrease cost (0.05–0.1 mg/kg/day)<br>May rarely cause nausea and vomiting<br>Contraindicated in patients with G6PD deficiency → hemolytic anemia<br>Rare cases of hypersensitivity and antibody formation |

AWP, average wholesale price; G6PD, glucose-6-phosphate dehydrogenase; po, oral.

[a]Normalized for 70-kg patient or body surface area = 1.73 m$^2$; all costs are estimated and may vary.

## Clinical Presentation and Diagnosis of TLS[38]

### General
- Patients present primarily with laboratory abnormalities.
- Normal uric acid is equal to 2 to 8 mg/dL (119–476 µmol/L).
- Most often occurs within 12 to 72 hours of initiation of cytotoxic therapy

### Signs and Symptoms
- Most patients are asymptomatic
- Patients may develop edema, fluid overload, and oliguria, which may progress to anuria with acute renal failure
- Some patients with hyperuricemia may have nausea, vomiting, and lethargy
- Hyperkalemia: lethargy, muscle weakness, paresthesia, ECG changes, bradycardia
- Hypocalcemia: muscle cramps, tetany, irritability, paresthesias, arrhythmias

### Laboratory Tests (Adults)
- Serum uric acid level greater than 8 mg/dL (476 µmol/L)
- Serum potassium greater than 6 mEq/L (6 mmol/L)
- Serum phosphorus greater than 4.5 mg/dL (1.45 mmol/L)
- Serum calcium less than 7 mg/dL (1.75 mmol/L)
- Elevated blood urea nitrogen and creatinine once renal dysfunction develops

*or*

- A change of greater than 25% from baseline in the above laboratory values[35]

## Patient Care Process: TLS

### Patient Assessment:
- Assess patient's medical history for risk factors of TLS, including cancer and chemotherapy history.
- Assess patient for signs/symptoms of TLS, including uremia, visual disturbances, muscle cramping, etc.
- Order laboratory tests: Uric acid, potassium, phosphate, calcium, electrolytes, renal function tests.

### Therapy Evaluation:
- Monitor daily at-risk patients who present with normal laboratory values daily for serum uric acid, electrolytes (Na, K, Ca, Mg, Cl, $PO_4$), blood urea nitrogen, creatinine, and urine output.
- Monitor for signs of fluid overload during aggressive hydration.

### Care Plan Development:
- Initiate allopurinol

### Follow-Up Evaluation:
- Continue hydration and prophylaxis until 2 to 3 days after cytotoxic therapy.
- In patients undergoing urinary alkalinization with sodium bicarbonate, assess the urine pH every 6 hours and maintain above 7.

Electrolyte disturbances that develop in patients with TLS should be aggressively managed to avoid renal failure and cardiac sequelae. One exception pertains to the use of IV calcium for hypocalcemia. Adding calcium may cause further calcium phosphate precipitation in the presence of hyperphosphatemia and should be used cautiously.

## OUTCOME EVALUATION

The most successful outcome in TLS is prevention. If the condition is not able to be prevented, the goal of therapy is to avoid renal failure and quickly return electrolytes to normal.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| ANC | Absolute neutrophil count |
| AWP | Average wholesale price |
| BMT | Bone marrow transplantation |
| BUN | Blood urea nitrogen |
| CIV | Continuous intravenous infusion |
| CSF | Colony-stimulating factor |
| G6PD | Glucose-6-phosphate dehydrogenase |
| ICP | Intracranial pressure |
| IV | Intravenous |
| LDH | Lactate dehydrogenase |
| NSAID | Nonsteroidal anti-inflammatory drug |
| NSCLC | Non–small cell lung cancer |
| PCP | *Pneumocystis jiroveci* pneumonitis (formerly *Pneumocystis carinii*) |
| PTHrP | Parathyroid hormone–related protein |
| SCLC | Small cell lung cancer |
| SVCS | Superior vena cava syndrome |

# 100   Parenteral Nutrition

Michael D. Kraft and Melissa R. Pleva

**Upon completion of the chapter, the reader will be able to:**

1. List appropriate indications for parenteral nutrition (PN) in adult patients.
2. Describe the components of PN and their role in nutrition support therapy.
3. List key elements of nutrition assessment and factors considered in assessing an adult patient's nutritional status and nutritional requirements.
4. Explain the pharmaceutical and compounding issues with PN admixtures.
5. Develop a plan to design, initiate, and adjust a PN formulation for an adult patient based on patient-specific factors.
6. Describe the etiology and risk factors for PN macronutrient-associated complications in adult patients receiving PN.
7. Describe the etiology and risk factors for refeeding syndrome.
8. Design a plan to assess the efficacy and monitor for safety, as well as fluid, electrolyte, vitamin, and trace element abnormalities in adult patients receiving PN.

## INTRODUCTION

Malnutrition in hospitalized patients is associated with significant complications (eg, increased infection risk, poor wound healing, prolonged hospital stays, increased mortality), especially in surgical and critically ill patients.[1] Maintaining adequate nutritional status, especially during periods of illness and metabolic stress, is an essential part of patient care. *Nutrition support therapy* refers to the administration of nutrients via the oral, enteral, or parenteral route for therapeutic purposes.[1] KEY CONCEPT *Parenteral nutrition (PN), also called total parenteral nutrition (TPN), is the intravenous (IV) administration of fluids, macronutrients, electrolytes, vitamins, and trace elements for the purpose of weight maintenance or gain, to preserve or replete lean body mass and visceral proteins, and to support anabolism and nitrogen balance when the oral or enteral route is not feasible or adequate.* PN is a potentially lifesaving therapy in patients with intestinal failure but can be associated with significant complications.

### Desired Outcomes and Goals

The goals of nutrition support therapy include:

- Correction or avoidance of nutritional deficiencies
- Weight maintenance (or weight gain in malnourished patients and growing children)
- Preservation or repletion of lean body mass and visceral proteins
- Support of anabolism and nitrogen balance and improvement of healing

- Correction or avoidance of fluid and electrolyte abnormalities
- Correction or avoidance of vitamin and trace element abnormalities
- Improving clinical outcomes

### Indications for PN

PN can be a lifesaving therapy in patients with intestinal failure, but the oral or enteral route is preferred when providing nutrition support therapy. Compared with PN, enteral nutrition is associated with a lower risk of hyperglycemia and fewer infectious complications (eg, pneumonia, intra-abdominal abscess, catheter-related infections).[1–3] However, if used appropriately PN can be safe and effective and can improve nutrient delivery. Indications for PN are listed in **Table 100–1**.[1,2] PN should be reserved for patients with altered intestinal function or absorption or when the gastrointestinal (GI) tract cannot be used. The anticipated duration of adequate PN therapy should be at least 5 to 7 days because shorter durations are unlikely to have a beneficial effect on a patient's clinical and nutritional outcomes but may increase infection risk.[1,2]

## PN COMPONENTS

PN should provide a *balanced* nutrition formula, including macronutrients, micronutrients, fluids, and electrolytes. Macronutrients, including amino acids, dextrose, and IV fat emulsions (IVFE), are important sources of structural and energy-yielding substrates. In a balanced PN formulation for adult patients, total daily calories are typically provided as 10% to 20% from amino

---

**Table 100–1**

**Indications for Parenteral Nutrition in Adults[1,2]**

- Bowel obstruction
  - Physical or mechanical (eg, tumor compressing intestinal lumen)
  - Functional (eg, ileus, colonic pseudo-obstruction)
- Major small bowel resection (eg, short-bowel syndrome)
  - Adult patients with < 100 cm of small bowel distal to the ligament of Treitz without a colon
  - Adult patients with < 50 cm of small bowel if the colon is intact
- Diffuse peritonitis
- Intestinal fistulas if EN cannot be provided above or below the fistula
- Pancreatitis—if patients have failed EN beyond the ligament of Treitz or cannot receive EN (eg, because of intestinal obstruction)
- Severe intractable vomiting
- Severe intractable diarrhea
- Preoperative nutrition support in patients with moderate to severe malnutrition who cannot tolerate EN and in whom surgery can be delayed safely for at least 7 days
- In critically ill patients without malnutrition who cannot receive oral or EN in the first 7 days of ICU admission, PN should only be initiated after the first 7 days of admission and if oral or EN is still not feasible

---

acids, 50% to 60% from dextrose, and 15% to 30% from IVFE. Amino acids may provide more than 20% of the total daily calories in patients with conditions that increase protein requirements (eg, severe thermal injury, healing wounds, cachexia, treatment with continuous renal replacement therapy, hypocaloric feeding). Electrolytes and micronutrients, including vitamins and trace elements, are required to support essential biochemical reactions. Patients require individual adjustments of PN components based on their nutritional status, nutritional requirements, underlying disease state(s), level of metabolic stress, clinical status, and organ functions.

## Macronutrients

### ▶ Amino Acids

Amino acids, the building blocks of proteins, are an essential component of PN admixtures. **KEY CONCEPT** *Amino acids are provided to preserve or replete lean body mass and visceral proteins, to promote protein anabolism and wound healing, and as a source of energy.* Amino acids have a caloric value of 4 kcal/g (17 kJ/g).

Parenteral crystalline amino acid solutions are supplied by various manufacturers in various concentrations (eg, 7%, 8%, 8.5%, 10%, 15%, and others). Different formulations are tailored for specific age groups (eg, adults, infants) and disease states (eg, kidney or liver dysfunction). Specialized formulations for

## Patient Encounter, Part 1

PG is a 59-year-old man with a history of hypertension and colon cancer, status post colon resection and colostomy, followed by chemotherapy, and subsequent colon reanastomosis. He was admitted approximately 2 weeks ago with signs and symptoms consistent with a bowel obstruction. He was taken to the OR for an exploratory laparotomy and found with multiple adhesions causing small bowel obstructions in two locations. He underwent a small bowel resection (jejunum) and extensive lysis of adhesions, and he was discharged 8 days ago. PG is readmitted with foul-smelling drainage from his surgical incision for 2 days along with nausea, decreased appetite, and decreased oral intake for the past 2 to 3 days. Since his diagnosis of colon cancer he has had weight loss, poor oral intake, and malnutrition. Most recently with his bowel obstructions and current symptoms, he reports an unintentional weight loss of about 10 lb (4.5 kg) over the past 4 to 5 weeks.

**PMH:** Hypertension × 10 years

Colon cancer diagnosed 2 years ago, status post colectomy, chemotherapy, and reanastomosis

Malnutrition since diagnosis of colon cancer

**Past Surgical History**

Colon resection with colostomy, colostomy takedown with reanastomosis 2 years ago

Exploratory laparotomy with small bowel resection and lysis of adhesions due to small bowel obstruction (greater than 100 cm of small intestine remaining, ileocecal valve intact, part of the colon remaining)

**FH:** Mother and father: hypertension; grandmother: chronic constipation

**SH:** 30 pack–year smoking history, quit 2 years ago; patient reports only occasional alcohol; no recreational drugs

**Medications Prior to Admission:** Hydrochlorothiazide 50 mg po daily; docusate 100 mg po twice daily

**Allergies:** NKDA

**PE:**

Ht, 178 cm (~5'10"); actual body weight, 61 kg (134 lb); ideal body weight, 73 kg (160 lb); alert and oriented × 3; mucous membranes and skin appear cool and dry; lungs clear

**VS:** T 37.2°C (99.0°F); HR 87 beats/min; BP 138/82 mm Hg; RR 14 breaths/min

**Abd:** Soft, tender around incision, faint bowel sounds, drainage of apparent enteric contents from surgical incision

Physical examination otherwise unremarkable

**Diagnoses:** Likely enterocutaneous fistula, probably from small bowel/jejunum (most recent surgery/small bowel resection), mild dehydration, and malnutrition

**Plan:** The patient was admitted to the hospital (non-ICU) for evaluation of a possible enterocutaneous fistula. The team performed a fistulogram and confirmed presence of an enterocutaneous fistula apparently originating in the proximal- to mid-jejunum. Given the patient's recent surgery, surgical intervention was deemed to not be an appropriate option at this time. A drain was placed into the fistula to control drainage and quantify output; the fistula drained approximately 600 mL in the first 24 hours. Against medical orders, the patient drank approximately 1 L of water, and the following day his fistula drained approximately 1500 mL of fluid. It is now hospital day #2

*Is PN therapy indicated in this patient? Why or why not?*

patients with acute kidney injury contain higher proportions of essential amino acids. Formulations for patients with hepatic encephalopathy contain higher amounts of branched-chain and lower amounts of aromatic amino acids. However, these specialized formulations have not been clearly shown to improve patient outcomes and therefore are not routinely used in clinical practice. Crystalline amino acid solutions have an acidic pH (pH ≈ 5–7) and may contain inherent electrolytes (eg, sodium, potassium, acetate, phosphate).

### ▶ Dextrose

**KEY CONCEPT** *Dextrose (D-glucose) is the major energy source, and it is vital for cellular metabolism, body protein preservation, and cellular growth.* The central nervous system, red blood cells, and the renal medulla depend primarily on dextrose as a source of energy.

Typically a 70% (70 g/100 mL) parenteral dextrose (hydrous dextrose) stock solution is used in PN compounding (a 50% stock solution is also available). Hydrous dextrose provides 3.4 kcal/g (14.2 kJ/g). A dextrose infusion rate of 2 mg/kg/min in adult patients is typically sufficient to suppress gluconeogenesis and spare body proteins from being used for energy.[4] Dextrose infusion rate in hospitalized adult patients generally should not exceed 4 to 5 mg/kg/min.[5,6] Use adjusted body weight (AdjBW) rather than actual weight in obese patients when calculating the dextrose infusion rate.

### ▶ Intravenous Fat Emulsions

**KEY CONCEPT** *Intravenous fat emulsions (IVFE) are provided to prevent or treat essential fatty acid deficiency (EFAD) and as an energy source.* IVFE particles consist of a triglyceride core surrounded by a layer of egg phospholipids (emulsifiers). These particles carry a negative charge on their surface that creates repulsive electrostatic forces between droplets and maintains the stability of the emulsion. Glycerol is added to adjust the tonicity, and water is the solvent. The negative charges on the surface of lipid particles can be disrupted by cations, especially divalent cations such as calcium, magnesium, and iron[7] and extreme pH changes, particularly acidic pH. Creaming, coalescence, and oiling out are signs of a destabilized IVFE. If there is any apparent disruption to IVFE, it should *not* be infused into a patient.

IVFEs differ in their concentration (10%, 20%, and 30%), caloric density by volume, natural source of fats/triglycerides, and ratio of phospholipids to triglycerides (PL:TG ratio). Table 100–2 shows a comparison of standard commercially available IVFEs in the United States. Most standard IVFEs marketed in the United States contain long-chain triglycerides derived from soybean oil. Because of the addition of phospholipid emulsifiers and glycerol, the caloric density of IVFEs by weight is approximately 10 kcal/g (42 kJ/g; dietary fat is ~9 kcal/g [38 kJ/g]). Compared with the 10% IVFE, 20% and 30% IVFEs have a lower PL:TG ratio and lower phospholipid content, and this translates to better plasma clearance compared to the 10% IVFE.[8] The 30% IVFE is only approved by the Food and Drug Administration (FDA) for infusion in a total nutrient admixture (TNA) and should not be infused directly into patients nor via Y-site injection.

IVFE particles are hydrolyzed in the bloodstream by lipoprotein lipase to release free fatty acids and glycerol. Fatty acids are taken up into adipose tissue for storage (triglycerides), oxidized to energy in various tissues (eg, skeletal muscles), or recycled in the liver to make lipoproteins.

The essential fatty acids that cannot be produced endogenously in humans are linoleic acid (C18:2 n-6) and α-linolenic acid (C18:3 n-3) (long-chain triglycerides). Arachidonic acid (C20:4 n-6) is also essential but can be synthesized *in vivo* from linoleic acid. Adult patients should receive a minimum of 2% to 4% of total daily calories as linoleic acid and 0.25% to 0.5% of total daily calories as α-linolenic acid to prevent essential fatty acid deficiency.[6] This can be achieved by providing a minimum of ~500 mL of 20% (100 g) IVFE per week (in a single dose, or divided doses [eg, 250 mL twice a week]) for most adult patients. The typical daily dose of IVFE in adults is about 0.5 to 1 g/kg/day (or ~15%–30% of total daily calories). The maximum dose is 2.5 g/kg/day[6] or 60% of total daily calories, although doses this high are rarely used in practice and should be avoided to prevent complications.

Biochemical evidence of essential fatty acid deficiency (eg, decreased serum linoleic acid, α-linolenic acid, and arachidonic acid concentrations; elevated mead acid concentrations; elevated

| Approximate osmolarity (mOsm/L) | 284 | 292 | 293 | 300 | 350 | 310 | 260 |
| Approximate mean pH (range) | 8.3 (6.0–9.0) | 8.4 (6.0–9.0) | | 8.0 (6.0–8.9) | | | (6.0–9.0) |

PL, phospholipid; TG, triglyceride.

[a]1 kcal/mL is equivalent to 4.19 kJ/mL.

triene-to-tetraene ratio) can develop in well-nourished adult patients within about 2 to 4 weeks of receiving PN without IVFE, and clinical manifestations (eg, dry skin, skin desquamation, hair loss, hepatomegaly, anemia, thrombocytopenia, poor wound healing) may appear after an additional 1 to 2 weeks, although skin changes may take longer to develop.[9]

Complications and safety concerns related to the administration of IVFE include severe hypertriglyceridemia, infection, anaphylactic reactions, and infusion-related reactions. Patients with a history of hypertriglyceridemia, acute kidney injury, chronic kidney disease, hepatic dysfunction, severe metabolic stress, or pancreatitis (particularly if caused by hypertriglyceridemia) may have reduced lipid clearance and be at risk of developing hypertriglyceridemia. IVFE should be withheld in adult patients with serum triglyceride concentrations exceeding 400 mg/dL (4.52 mmol/L).

IVFEs support the growth of bacterial and fungal pathogens, but bacterial growth is slower in TNAs than in IVFE alone[10,11] due to the acidic pH of amino acid solutions and higher osmolarity of PN formulations. Because of this, the Centers for Disease Control and Prevention (CDC) recommends that TNA infusions be completed within 24 hours of initiation. Recent guidelines suggest that IVFE infusion should be completed within 12 to 24 hours if administered from the original manufacturer container, but completed within 12 hours if repackaged/transferred to another container and infused separately from a 2-in-1 PN admixture (although repackaging/transfer to another container was not recommended).[12] There is still debate about the optimal approach when infusing IVFE separately from a 2-in-1 PN admixture.

PN infusion lines must contain an appropriate filter (a 0.22-μm filter or a 1.2-μm filter). A 0.22-μm filter cannot be used on the TNA or IVFE infusion line because the average size of IVFE particles is approximately 0.4- to 0.5-μm (which cannot pass through the smaller filter intact and will clog the filter).

Patients with an allergy to eggs or specific legumes (eg, soy beans, broad beans, lentils) may develop cross-allergic reactions to IVFE. Rarely, infusion-related adverse effects may occur with rapid infusion, including fever, chills, headache, palpitations, dyspnea, chest tightness, and nausea. Extending the IVFE infusion time (eg, over 12–24 hours) can minimize infusion-related adverse events and improves IVFE clearance. Infusion rate of IVFE should not exceed 0.12 g/kg/hour.[6]

Recently the FDA approved Clinolipid for use in adult patients. Clinolipid is a mixture of refined olive and soybean oils in a 4:1 ratio. This combination reduces the amount of omega-6 fatty acids in the IVFE. This may have a positive impact on immune function and inflammation, but this is theoretical and this product has not been demonstrated to improve patient outcomes. The exact role of this IVFE product in patient care is not yet known.

▶ **Fluid**

KEY CONCEPT *Parenteral nutrition should not be used to treat acute fluid abnormalities. PN should be adjusted to provide maintenance fluid requirements and to minimize worsening of underlying fluid disturbances, taking into account other fluids the patient is receiving.* Daily maintenance fluid requirements for adults can be estimated with the following equation:

$$\text{Total daily fluid requirements} = 1{,}500 \text{ mL} + (20\text{mL/kg} \times [\text{Wt (kg)} - 20])^*$$

---

*For elderly patients (eg, greater than 60 years old), use 15 mL/kg for every kilogram above 20 kg.

For patients with significant fluid deficits, it is safer and more cost effective to correct fluid abnormalities using standard IV fluids (eg, 0.9% sodium chloride in water, dextrose 5% and sodium chloride 0.45% in water, lactated Ringer solution). Minimizing PN fluid volume may be indicated in patients with fluid overload, patients with oliguric or anuric acute kidney injury, or those with congestive heart failure or symptomatic pleural effusion. It is reasonable to provide total daily fluid requirements (maintenance requirements and replacement for GI or other abnormal losses) in the PN admixture in patients who require long-term PN. However, diluting a PN admixture can affect its physical and chemical properties (eg, IVFE stability, calcium–phosphate solubility/compatibility); therefore, stability and compatibility data must be confirmed before diluting a PN admixture.

## Micronutrients

KEY CONCEPT *Electrolytes, vitamins, and trace elements are essential for numerous biochemical and metabolic functions and should be added to PN daily unless otherwise not indicated.*

▶ **Electrolytes**

KEY CONCEPT *Electrolytes are essential for many metabolic and homeostatic functions, including enzymatic and biochemical reactions, maintenance of cell membrane structure and function, neurotransmission, hormone function, muscle contraction, cardiovascular function, bone composition, and fluid homeostasis.* The causes of electrolyte abnormalities in patients receiving PN may be multifactorial, including altered absorption and distribution; excessive or inadequate intake; altered hormonal, neurologic, and homeostatic mechanisms; altered excretion and losses via the GI tract (eg, gastric, diarrhea, ostomy, enterocutaneous fistula) and kidneys; changes in fluid status and fluid shifts; and medication therapies. PN should not be used to treat acute electrolyte abnormalities but should be adjusted to meet maintenance requirements and to minimize worsening of underlying electrolyte disturbances.

Electrolytes that are included routinely in PN admixtures include sodium, potassium, phosphorus (as phosphate), calcium, magnesium, chloride, and acetate. Always assess the patient's kidney function when determining electrolyte doses in PN admixtures. Typical daily electrolyte maintenance requirements for adults with normal kidney function are listed in Table 100–3.[6,13] For additional details regarding management of fluid, electrolyte and acid–base disorders refer to Chapters 27 and 28.

▶ **Calcium-Phosphate Solubility**

The FDA published a safety alert in response to two deaths from microvascular pulmonary emboli associated with calcium–phosphate precipitation in PN.[14] Because calcium and phosphate can bind and precipitate in solution, caution must be exercised when mixing these two electrolytes in PN admixtures. Several factors can affect calcium–phosphate solubility, including:

- *Amino acid concentration.* Primary factor that affects pH of the PN admixture. The pH of amino acid stock solutions may vary between commercial products. In general, the higher the final amino acid concentration, the lower the pH of the final admixture. Phosphates can also bind with amino acids, leaving fewer phosphates available to bind with calcium.

- *pH.* Largely affected by the amino acid brand and concentration, to a lesser extent by the dextrose concentration; the lower the solution pH, the less chance for calcium–phosphate precipitation. Monobasic phosphates

**Table 100–3**

**Approximate Daily Maintenance Electrolyte Requirements for Adults[6,13]**

| Electrolyte | Approximate Daily Maintenance Requirements[a] | Electrolyte Salts Used in PN | Maximum Concentration in PN |
|---|---|---|---|
| Sodium | 1–2 mEq/kg (1–2 mmol/kg) | Chloride, acetate, phosphate | 154 mEq/L (154 mmol/L, equivalent to normal saline) |
| Potassium | 1–2 mEq/kg (1–2 mmol/kg) | Chloride, acetate, phosphate | 120 mEq/L (120 mmol/L) (central PN) |
| Phosphorus | 20–40 mmol (~10–15 mmol per 1000 kcal [2.4–3.6 mmol per 1000 kJ]) | Sodium phosphate, potassium phosphate | See text section on calcium-phosphate solubility |
| Calcium | 10–15 mEq (5–7.5 mmol) | Gluconate | |
| Magnesium | 8–20 mEq (4–10 mmol) | Sulfate | 20 mEq/L (10 mmol/L) |
| Chloride | [b] | Sodium, potassium | Linked to limitations of sodium and potassium. Usual ratio of chloride to acetate ~1:1–1.5:1 |
| Acetate | [b] | Sodium, potassium | |
| Conversions | 1 mmol potassium phosphate = 1.47 mEq potassium<br>1 mmol sodium phosphate = 1.33 mEq sodium<br>1 g of calcium gluconate = 4.65 mEq (2.32 mmol) calcium<br>1 g of magnesium sulfate = 8.1 mEq (4 mmol) magnesium | | |

[a]Electrolyte requirements are adjusted based on serum electrolyte concentrations and vary depending on kidney function, gastrointestinal losses, nutritional status, specific metabolic and endocrine functions, and medication therapy that affect electrolyte losses or retention.

[b]As needed to maintain acid–base balance; linked to amounts of sodium and potassium provided (as chloride and acetate salts).

predominate at low pH, leaving fewer free dibasic phosphates for precipitation with divalent calcium; monobasic calcium phosphate is more soluble than dibasic calcium phosphate.

- *Calcium salt.* Calcium gluconate is the preferred calcium salt in PN because it has a lower dissociation constant in solution with less free calcium available at a given time to bind phosphate.
- *Time.* The longer calcium and phosphate are in solution, the more calcium and phosphate will dissociate over time and increase the risk for calcium–phosphate precipitation.
- *Temperature.* As temperature increases, more calcium and phosphate dissociate and increase the risk of calcium-phosphate precipitation.
- *Order of mixing.* Calcium and phosphate should not be added simultaneously or consecutively when compounding PN admixtures (eg, add phosphate first, then add other PN components, and then add calcium near the end of compounding). The volume in the PN admixture at the time calcium is added (not necessarily the final volume) must be used to determine the maximum calcium that can be added.

When compounding PN admixtures, use calcium–phosphate solubility curves (based on the specific brand and final concentration of amino acids and dextrose) to determine safe and appropriate calcium and phosphate concentration limits.

▶ **Acetate**

Acetate is converted to bicarbonate at a 1:1 molar ratio, and this conversion appears to occur mostly outside the liver. Bicarbonate should *never* be added to or coinfused with PN admixtures. This can lead to the release of carbon dioxide and result in the formation of insoluble calcium or magnesium carbonate salts.

▶ **Vitamins**

Water-soluble and fat-soluble vitamins in the parenteral multivitamin products are essential cofactors for numerous biochemical reactions and metabolic processes. Parenteral multivitamins are added daily to the PN admixture. Water-soluble vitamins, with the exception of vitamin B$_{12}$, are generally readily excreted and not stored in the body in significant amounts. Deficiencies of water-soluble vitamins can occur rapidly in the absence of adequate vitamin supplementation in PN. Severe refractory lactic acidosis and deaths were reported in patients who received PN without added thiamine. Thiamine is an essential cofactor in carbohydrate metabolism (via the tricarboxylic acid cycle). Deficiency of thiamine pyrophosphate prevents the formation of acetyl-CoA from pyruvate, which is instead converted to lactate via anaerobic metabolism, resulting in lactic acidosis. Parenteral multivitamin products contain 150 mcg of vitamin K in accordance with FDA recommendations. A parenteral adult multivitamin formulation is available without vitamin K, but standard compounding of PN formulations should include a product that contains vitamin K unless otherwise indicated. Patients with chronic kidney disease are at risk for vitamin A accumulation and potential toxicity. Serum vitamin A concentrations should be measured in patients with chronic kidney disease when vitamin A accumulation is a concern. Not all vitamins are available individually in injectable form, so restricting vitamin A may compromise provision of other vitamins.

▶ **Trace Elements**

Trace elements are essential cofactors for numerous biochemical processes. Trace elements added routinely to PN include zinc, selenium, copper, manganese, and chromium (Table 100–4). Various individual and multi-ingredient parenteral trace element formulations can be added to PN admixtures. Trace element supplementation in PN should be individualized, especially for long-term PN-dependent patients, rather than using a fixed dose of multitrace element products.[15] Zinc is important for wound healing, and patients with high-output enterocutaneous fistulas, diarrhea, burns, and large open wounds may require additional zinc supplementation. Patients may lose as much as 12 to 17 mg zinc/L of GI output (eg, diarrhea, enterocutaneous

| Table 100–4 | | | | |
|---|---|---|---|---|
| **Approximate Daily Maintenance Trace Element Requirements for Adults[6,a]** | | | | |
| **Zinc (Zn)** | **Selenium (Se)** | **Copper (Cu)** | **Manganese (Mn)** | **Chromium (Cr)** |
| 2.5–5 mg | 20–60 mcg | 0.3–0.5 mg | 0.06–0.1 mg | 10–15 mcg |

[a]Requirements may vary based on patients' kidney function, liver function, gastrointestinal losses, nutritional status, specific metabolic and endocrine functions, serum levels, and medication therapy. Contamination of some PN ingredients with trace elements (eg, chromium, manganese) can contribute significantly to the total amount the patient receives. Monitor serum trace element levels in patients receiving long-term PN therapy.

fistula); however, 12 mg/day may be adequate to maintain positive zinc balance in these patients.[16] Patients with chronic severe diarrhea, malabsorption, high-output enterocutaneous fistula, or short-bowel syndrome may also have increased selenium losses and may require additional selenium supplementation. Chromium is a cofactor for glucose metabolism, and patients with chromium deficiency may exhibit glucose intolerance; however, chromium deficiency is a rare cause of hyperglycemia. Patients who are chronically dependent on PN may accumulate chromium[6] and manganese, resulting in high serum levels because these are known contaminants of parenteral products that are used in the making of PN, and manganese content of multitrace element products is higher than the recommended daily dose.[6,15] Patients with cholestasis (serum direct bilirubin concentrations that exceed 2 mg/dL [34.2 μmol/L]) should have manganese and possibly copper restricted to avoid accumulation and possible toxicity because both elements undergo biliary elimination. However, copper deficiency resulting in anemia, pancytopenia, and death has occurred in PN-dependent patients when copper was omitted from the PN admixture. Because copper deficiency has been reported to occur anywhere between 6 weeks and 12 months after copper elimination from PN,[17] serum copper concentrations must be regularly monitored (eg, every 6 weeks at first and then every 2–3 months thereafter) when copper is omitted from PN admixtures. Trace element status should initially be monitored periodically (eg, every 3 months) in patients at risk for trace element deficiency or accumulation. When stable, serum trace element concentrations can be monitored less frequently (eg, every 6–12 months).

## PN Additives

### ▶ Regular Insulin

Regular insulin may be added to PN admixtures for glycemic control. The dose depends on the patient's clinical condition, severity of hyperglycemia, predisposing factors for hyperglycemia, renal function, and daily insulin requirements. Generally, after the patient is receiving his or her goal dextrose dose in PN, about 50% to 70% of the total insulin doses administered over the previous 24 hours as sliding scale or continuous infusion can be added to the next PN admixture. In patients with diabetes, IV insulin doses in the PN admixture to maintain euglycemia range from 0.05 to 0.2 unit of insulin per each gram of dextrose in PN (adjusted based on frequent capillary blood glucose evaluation). Caution should be used when insulin is added to PN to avoid hypoglycemia, especially when reversible causes of hyperglycemia have resolved (eg, stress, acute pancreatitis, corticosteroids therapy) or more than one form of insulin therapy is used concurrently. Adding insulin to PN (vs a continuous IV infusion) does not provide the flexibility of frequent titration.

### ▶ Histamine-2 Receptor Antagonists

Intravenous histamine-2 receptor antagonists such as ranitidine, famotidine, and cimetidine are compatible with PN admixtures and can be added when indicated.

### ▶ Heparin

Heparin (0.5–1 unit/mL of final PN volume) has been added to PN admixtures for three reasons:

- Maintain catheter patency (although this effect is debated)
- Reduce thrombophlebitis (with PPN infusion)
- Enhance lipid particle clearance as a cofactor for the lipoprotein lipase enzyme (temporary effect, and data are limited)

The benefits and necessity of adding heparin to PN are unclear, and this practice is becoming less common in adult patients. There are also concerns about the stability and compatibility of IVFE with heparin. Heparin should be omitted in patients with active bleeding, thrombocytopenia, heparin-induced thrombocytopenia (HIT), or heparin allergy.

### ▶ Human Albumin

Human albumin is a colloid used as a plasma volume expander and *not* a source of nutrition. Albumin should not be added to the PN admixture and should be administered separately from PN.

### ▶ Parenteral Iron

Chronic PN-dependent patients are at risk for iron-deficiency due to underlying clinical conditions and the lack of regular iron supplementation in PN. Parenteral iron dextran should be used with caution due to its infusion-related adverse effects. Iron dextran is compatible with 2-in-1 PN formulations, but is not commonly added to PN admixtures due to incompatibility with IVFE; Other parenteral iron formulations (eg, iron sucrose, ferric gluconate) should NOT be added to PN admixtures due to a lack of compatibility data.

## NUTRITION ASSESSMENT AND NUTRIENT REQUIREMENTS

A nutrition assessment is used to determine a patient's nutritional status, identify patients with malnutrition, identify risk factors for nutrition-related problems, identify or rule out specific nutrient deficiencies, and determine nutrient requirements.[1] A complete description of nutrition assessment is beyond the scope of this chapter, and a nutrition assessment should be completed by a health care professional with appropriate training and expertise (eg, dietitian, nutrition-certified pharmacist). Briefly, key components of a nutrition assessment include[1,18]:

- Patient history
- Physical assessment, including height, weight, ideal body weight (IBW), body mass index (BMI = weight [kg]/height [m²]), and recent weight changes (intentional or unintentional)
  - BMI is a vague indicator of total body fat mass in adults and is not an indicator of body nutrient stores. BMI categories do not account for frame size, muscle mass, bone, and water weight. Classifications of BMI:
    - Underweight, less than 18.5 kg/m²
    - Normal, 18.5 to 24.9 kg/m²
    - Overweight, 25 to 29.9 kg/m²
    - Obese, more than or equal to 30 kg/m²
- Degree of malnutrition can be classified by assessing the percentage of unintentional weight loss or percentage of usual weight. For example:
  - Severe malnutrition: greater than 5% weight loss within 1 month or greater than 10% weight loss over 6 months;
  - Moderate malnutrition: 5% to 10% weight loss over 6 months;
  - Mild malnutrition/well-nourished: less than 5% weight loss over less than or equal to 6 months
- Anthropometrics and physical examination of the musculoskeletal system (eg, biceps, triceps, quadriceps, temporalis, deltoid, and interosseus muscles) for loss of muscle mass or decreased grip strength, and examination of the skin and mucous membranes for abnormalities (eg, dry or flaky skin, bruising, edema, ascites, poorly healing wounds) and loss of subcutaneous fat
- Changes in eating habits, GI function, and associated GI symptoms
- Presence and severity of underlying and concurrent disease(s)
- Serum visceral protein concentrations (eg, albumin, prealbumin). Hypoalbuminemia at baseline or before hospitalization may indicate malnutrition, and severe hypoalbuminemia may be associated with poor outcomes. Serum albumin and prealbumin are negative acute phase proteins and therefore are not sensitive or specific indicators of nutritional status and protein stores in patients under metabolic stress or with evidence of inflammatory response (eg, postsurgery, organ failure, severe burns, trauma, sepsis). Measuring serum C-reactive protein (CRP) may help assess inflammatory response (eg, CRP greater than 2.5 mg/dL [25 mg/L]). Synthesis and distribution of albumin and prealbumin may be altered, and serum concentrations are affected by non-nutritional factors, including hydration status, kidney function, and liver function. Because prealbumin has a shorter half-life (~2 days) than albumin (~20 days), serum prealbumin concentrations may be measured usually once weekly to help evaluate the net anabolism in response to nutrition support therapy in the absence of acute stress/inflammation
- Serum concentrations of vitamins, trace elements, and iron studies as indicated

After performing a nutrition assessment, estimate the patient's daily energy and protein requirements (Table 100–5). Indirect calorimetry involves measuring the volumes of oxygen consumption ($VO_2$) and carbon dioxide production ($VCO_2$) to determine the resting metabolic rate (RMR) or resting energy expenditure (REE) and respiratory quotient (RQ = $VCO_2/VO_2$).

The REE or RMR is the amount of calories required during 24 hours by the body in a nonactive state and is approximately 10% higher than the basal energy expenditure (BEE, metabolic activity required to maintain life) as it adjusts for the thermic effect of food and awake state. Critically ill patients may have variable energy expenditure (EE), and indirect calorimetry is a valuable tool in assessing EE in these patients. Indirect calorimetry requires specific equipment and trained personnel and therefore is not feasible in all settings.

More than 200 equations and derivations have been developed to predict EE for adults. The Harris-Benedict equations, Penn State equations (for nonobese critically ill patients receiving mechanical ventilation), and Mifflin-St. Jeor equations (for nonobese and obese noncritically ill patients) are some of the most widely used, and they take into account several variables (depending on the equation) including a patient's sex, weight, height, age, and mechanical ventilation data to determine the BEE. A "stress" or "injury" factor is sometimes applied to estimate the daily total EE (TEE), although there is debate about the appropriateness and validity of this approach. Daily energy requirements are about 100% to 130% of the RMR with adequate protein intake. Alternatively, EE can be estimated based on EE per body weight (ie, kilocalories per kilogram or in kilojoules per kilogram). However, dry weight or hospital admission weight should be used, and this estimation may not be appropriate in obese or elderly patients. There is debate over the best method to estimate energy requirements for obese patients. Indirect calorimetry would be the preferred method but may not always be available. Several equations have been developed to estimate EE in obese patients. Although there is no consensus on the weight used to estimate EE in obese patients, it is reasonable to use an AdjBW in obese patients to avoid overfeeding. AdjBW can be calculated with 25% to 50% of the difference between the actual weight and IBW added to the IBW. Using a 25% difference in calculating the AdjBW further avoids overfeeding when estimating energy requirements:

$$AdjBW = IBW + (0.25 \times [Actual\ weight - IBW])$$

Hypocaloric feeding is another approach for nutrient dosing in obese critically ill patients (discussed as follows).

Amino acid requirements are based on the patient's nutritional status, clinical condition(s), kidney function, and liver function. Amino acids are needed in adequate amounts to facilitate anabolism, restore lean body mass, or promote wound healing while avoiding adverse effects from excessive amino acid loading (eg, azotemia). No evidence-based data are available confirming the optimal body weight (actual, ideal, or adjusted) to use for dosing amino acids in adult patients. It is suggested to dose amino acids based on actual body weight for normal body sized or malnourished adult patients (ie, when actual weight is at or below IBW) and based on IBW or AdjBW for obese patients.

Hypocaloric nutrition support is an approach to dosing nutrition therapy for obese patients (BMI greater than or equal to 30 kg/m² or actual weight greater than 130% of IBW). Hypocaloric feeding involves providing high doses of protein (greater than or equal to 2–2.5 g/kg IBW/day) to support anabolism with lower amounts of total calories (average ~11–14 kcal/kg actual weight/day [~46–59 kJ/kg actual weight/day] or ~22–25 kcal/kg IBW/day [~92–105 kJ/kg IBW/day]) with primary goals to promote net protein anabolism and avoid hyperglycemia or exacerbation of metabolic stress in critically ill patients.[2,19] Other benefits could include avoiding fat weight gain

| Table 100–5 | |
|---|---|
| **Estimating Daily Nutritional Requirements in Adults[1,6,18–20]** | |
| **Determining Energy Expenditure:** | |
| **Harris-Benedict equations** | Men: BEE = 66.42 + 13.75 (W) + 5 (H) – 6.78 (A) |
| | Women: BEE = 655.1 + 9.65 (W) + 1.85 (H) – 4.68 (A) |
| | W = weight in kg, H = height in cm, A = age in years |
| | Energy expenditure then multiplied by a stress factor |
| | To estimate the TEE: |
| | Bed rest ≈ 1.2 × BEE |
| | Ambulatory ≈ 1.3 × BEE |
| | Anabolic ≈ 1.5 × BEE |
| | Energy requirements should also be increased ~12% with each degree of fever above 37°C (98.6°F) |
| **Penn State equations (for critically ill nonobese adult patients receiving mechanical ventilation.)** | RMR = (0.85 × BEE$^a$) + (33 × $V_E$) + (175 × $T_{max}$) – 6433 |
| | RMR = (0.96 × BMR$^b$) + (31 × $V_E$) + (167 × $T_{max}$) – 6212 |
| **Mifflin-St. Jeor equations (for nonobese, overweight, and obese noncritically ill adult patients)** | Men BMR = (10 × Wt) + (6.25 × Ht) – (5 × Age) + 5 |
| | Women BMR = (10 × Wt) + (6.25 × Ht) – (5 × Age) – 161 |
| **Energy expenditure per body weight (ie, kcal/kg)$^c$** | Range of ~20–30 kcal/kg/day, possibly up to 35 kcal/kg/day |
| | Maintenance ~20–25 kcal/kg/day |
| | Repletion, postoperative wound healing, critical illness, sepsis, severe trauma, severe burns ~25–30 kcal/kg/day, possibly up to 35 kcal/kg/day |
| **Determining Amino Acid Requirements:** | |
| **Patient Clinical Condition** | **Daily Amino Acid Requirements$^d$ (g/kg)** |
| Maintenance or nonstressed | 0.8–1 |
| Repletion | 1.3–2 |

| Hepatic failure with encephalopathy | 0.8–1 |
| Acute kidney injury, predialysis | 0.8–1 |
| Acute kidney injury receiving IHD | 1.2–1.5 |
| Chronic kidney disease receiving CAPD | 1.2–1.5 |
| Acute kidney disease receiving CRRT | 1.5–2.5 |

BMR, basal metabolic rate; CAPD, continuous ambulatory peritoneal dialysis; CRRT, continuous renal replacement therapy; Ht, height (cm); IHD, intermittent hemodialysis; RMR, resting metabolic rate; TEE, total energy expenditure; $T_{max}$, maximum body temperature in degrees Celsius; $V_E$, minute ventilation in liters per minute; Wt, weight (kg).

$^a$BEE calculated using the Harris-Benedict equation.

$^b$BMR calculated using Mifflin-St. Jeor equation.

$^c$One kcal/kg is equivalent to 4.184 kJ/kg.

$^d$Amino acid requirements are based on actual body weight for normal body sized or malnourished adult patients and on ideal body weight (IBW) for obese patients.

or promoting fat weight loss. Most data with hypocaloric feeding are in critically ill adult patients, but this approach has been used in other patients. Hypocaloric feeding should not be used in patients with kidney or liver dysfunction. Also, the optimal safe duration of hypocaloric feeding is unknown.

Permissive underfeeding refers to providing a lower calorie nutrition support regimen to critically ill adult patients for a short period of time during the initial phase of high metabolic stress. The aims of permissive underfeeding are to avoid the burden of caloric intake on worsening metabolic stress and the negative effects of carbohydrate loading and associated hyperglycemia, increased carbon dioxide production, and fat accumulation. Typically, a permissive underfeeding PN regimen provides about 60% to 80% of daily energy requirements. Because the optimal amounts of calories for critically ill patients is not well defined, strong clinical evidence to support the use of permissive underfeeding is also lacking. Furthermore, severe underfeeding should be avoided because it can result in energy deficit to the patient with the consequences of increased infectious complications with negative outcomes.

## PARENTERAL NUTRITION SAFETY

Serious and sometimes fatal adverse events have occurred with inappropriate use of PN. Shortages of key PN components have also presented challenges to meet nutritional needs of patients requiring PN therapy. The American Society for Parenteral and Enteral Nutrition (A.S.P.E.N.) has published several key PN safety documents, including comprehensive safe practice guidelines,[6] PN safety recommendations,[21] and revised guidelines that address PN ordering, order review, compounding, labeling, and dispensing.[12] A.S.P.E.N. has also provided guidance for managing shortages of PN components. These are essential resources for pharmacists and other health care professionals for the safe and efficacious use of PN therapy, and they represent the standards of practice as related to PN prescribing, compounding, stability, compatibility, labeling, administration, and quality assurance. There are several key points and recommendations

in these documents to improve the safety of the PN use process, including:

- Adopting published guidelines and literature.
- Developing standardized processes for PN prescribing, order verification, compounding, labeling, dispensing, administering, and monitoring.
- Developing PN-specific policies and procedures.
- Develop education and competency assessments at least annually for all health care professionals involved in the PN use process.
- Optimizing computerized prescriber order entry (CPOE) and clinical decision support for PN orders.
- Build, test, and heed clinical decision support warnings in CPOE systems and in automated compounding devices.
- Avoiding use of handwritten PN orders and eliminate transcription of PN orders.
- Matching templates between ordering/CPOE, compounding software/automated compounding devices, and PN labels .
- PN use process and development policies, procedures, education, and competencies should include health care professionals with expertise in nutrition support, preferably from multiple disciplines.

Although application of these guidelines is voluntary, health care professionals who are involved in prescribing, compounding, dispensing, administering, and monitoring PN therapy should review and apply them to their practice.

## PREPARING THE PN PRESCRIPTION: ADMINISTRATION, COMPOUNDING, AND PHARMACEUTICAL ISSUES

After performing a nutrition assessment and estimating nutritional requirements, determine the optimal route to provide nutrition support therapy (eg, oral, enteral, or parenteral). If PN is indicated, venous access for PN infusion must be obtained.

Finally, formulate a PN prescription and administer PN according to safety guidelines.

### Route of PN Administration: Peripheral versus Central Vein Infusion

**KEY CONCEPT** *PN can be administered via a smaller peripheral vein or via a larger central vein* (**Figure 100–1**). Peripheral PN (PPN) is generally is reserved for short-term administration (up to 7 days) when central venous access is not available. PN formulations are hyperosmolar, and PN infusion via a peripheral vein can cause thrombophlebitis. Factors that increase the risk of **phlebitis** include high solution osmolarity, extreme pH, rapid infusion rate, vein properties, catheter properties (eg, diameter, material), and infusion time via the same vein.[22] The osmolarity of PPN admixtures should be limited to less than or equal to 900 mOsm/L to minimize the risk of phlebitis. The approximate osmolarity of a PN admixture can be calculated from the osmolarity of the individual components:

- Amino acids ~10 mOsm/g (or 100 mOsm/L% final concentration in PN)
- Dextrose ~5 mOsm/g (or 50 mOsm/L% final concentration in PN)
- Sodium (chloride, acetate, and phosphate) = 2 mOsm/mEq (or 2 mOsm/mmol)
- Potassium (chloride, acetate, and phosphate) = 2 mOsm/mEq (or 2 mOsm/mmol)
- Calcium gluconate = 1.4 mOsm/mEq (2.8 mOsm/mmol)
- Magnesium sulfate = 1 mOsm/mEq (2 mOsm/mmol)

PPN admixtures should be coinfused with IVFE when using 2-in-1 PN because the iso-osmolarity and near-neutral pH of IVFE may decrease the risk of phlebitis (see Table 100–2). Infectious and mechanical complications may be lower with PPN compared with central venous PN administration. However, because of the risk of phlebitis, severe soft tissue damage if extravasation occurs, and osmolarity limit, PPN admixtures have

**FIGURE 100–1.** Selected vascular anatomy. (Reprint from Krzywda EA, Andris DA, Edmiston CE, Wallace JR. Parenteral Access Devices. In: Gottschlich MM, ed. The A.S.P.E.N. Nutrition Support Core Curriculum: A Case-Based Approach—The Adult Patient. Silver Spring, MD: American Society for Parenteral and Enteral Nutrition, 2007:300–322.)

low macronutrient concentrations and therefore usually require large fluid volumes to meet a patient's nutritional requirements. Given these limitations, every effort should be made to obtain central venous access and initiate central PN in patients who have an appropriate indication (see Table 100–1).

Central PN refers to the administration of PN via a large central vein, and the catheter tip must be positioned in the superior vena cava (Figure 100–2). Central PN allows the infusion of a highly concentrated, hyperosmolar nutrient admixture. The typical osmolarity of a central PN admixture is about 1500 to 2000 mOsm/L. Central veins have much higher blood flow and the PN admixture is diluted rapidly on infusion, so phlebitis is usually not a concern. Patients who require PN therapy for longer periods of time (greater than 7 days) should receive central PN. Central PN requires placement of a central venous catheter and an x-ray to confirm placement of the catheter tip. A commonly used central catheter for PN infusion is a peripherally inserted central venous catheter (PICC), which is inserted into a peripheral vein but the catheter tip is placed in the superior vena cava (Figure 100–3). Central venous catheter placement may be associated with complications, including pneumothorax, arterial injury, air embolus, venous thrombosis, infection, chylothorax, and brachial plexus injury.[1,22]

## Types of PN Formulations: 3-in-1 versus 2-in-1

**KEY CONCEPT** *PN admixtures can be prepared by mixing all components into one bag, or IVFE may be infused separately (via a Y-site infusion or through a separate IV catheter or lumen). When all components are mixed together, it is referred to as a 3-in-1 admixture or TNA.[23] When dextrose, amino acids, and all other PN components are mixed together without IVFE, this is referred to as a 2-in-1 PN admixture.* There are various advantages and disadvantages to using either TNA or 2-in-1 PN admixtures (Table 100–6). With a 2-in-1 PN admixture, IVFE can be infused separately on a daily or intermittent basis. When IVFE is mixed in the PN, the TNA becomes an emulsion with respect to physical and chemical characteristics. The final concentration of IVFE in a 3-in-1 admixture should be greater than or equal to 2%

**FIGURE 100–3.** Peripherally inserted central venous catheter. (Reprint from Krzywda EA, Andris DA, Edmiston CE, Wallace JR. Parenteral Access Devices. In: Gottschlich MM, ed. The A.S.P.E.N. Nutrition Support Core Curriculum: A Case-Based Approach— The Adult Patient. Silver Spring, MD: American Society for Parenteral and Enteral Nutrition, 2007:300–322.)

(20 g/L) to prevent compromising the stability of the emulsion.[23] Electrolyte, dextrose, and amino acid concentrations may also be more limited in a 3-in-1 admixture.

Safety is a primary concern with PN therapy. The FDA has provided recommendations for safe infusion of PN admixtures containing calcium and phosphate:

- A 0.22- μm air-eliminating in-line filter should be used for infusion of non–IVFE-containing PN.
- A 1.2- μm in-line filter should be used for the infusion of a TNA because it can remove large and unstable fat droplets and particulate matter.[24]

Another safety concern is the coinfusion of IV medications with PN admixtures. For safety reasons, medications should not be admixed or coinfused with PN unless necessary, and it should only be done if reasonable and safe (based on toxicity profile, pharmacokinetic and pharmacodynamic considerations).[21] *Always* consult compatibility data before adding a medication to or coinfusing with a PN admixture. Many IV medications have limited compatibility with 3-in-1 formulations but may be coinfused with a 2-in-1 formulation.[25,26] Some medications can be coinfused at the Y-site, few medications can be mixed directly into the PN admixture or coinfused with IVFE, and some cannot be mixed or coinfused with the PN admixture.[25,26]

## Standardized, Commercially Available (Premixed) PN Formulations

A standardized, commercially available PN formulation (also referred to as premixed PN) is a product available from a manufacturer that requires fewer compounding steps before administration.[27] These products usually contain amino acids and dextrose in a two-chamber bag, with or without electrolytes. Vitamins and trace elements must be manually added. IVFE can be added to create a TNA or infused separately. Potential advantages of premixed

**FIGURE 100–2.** Percutaneous nontunneled catheter. (Reprint from Krzywda EA, Andris DA, Edmiston CE, Wallace JR. Parenteral Access Devices. In: Gottschlich MM, ed. The A.S.P.E.N. | | Decreased vein irritation (with PPN) | |
| **Disadvantages** | Decreased stability compared to 2-in-1 PN | Increased labor and costs (if IV lipid emulsion infused |
| | Cannot use 0.22- μm bacterial retention filter; must use | separately) |
| | 1.2- μm filter | Increased vein irritation, especially if PPN is not coinfused |
| | Increased bacterial growth compared with 2-in-1 PN | with IV lipid emulsion |
| | Visual inspection is difficult | |
| | Limited compatibility with medications | |

PN, parenteral nutrition; PPN, peripheral parenteral nutrition; TNA, total nutrient admixture.

PN include improvements in safety (both decreased compounding errors and microbiologic contamination) and reduced costs.[27] The safety advantages are logically related to fewer manual manipulations of the system, but clinical trial data are lacking. Cost advantages have been demonstrated in some trials, with others finding no difference or increased costs. Limitations with the use of pre-mixed PN in the United States are related to the limited number of products available, including a lack of formulations containing IVFE (in a three-chamber bag), relatively low amino acid concentration, only 1- and 2-L volumes, limited variability in electrolyte content, and no formulations available for neonates and infants. These limitations may make premixed PN less appropriate for some patients (eg, critically ill, obese, those with organ dysfunction or who require fluid restriction).

## Formulating a PN Admixture and Regimen

After completing a full nutrition assessment; estimating the patient's daily fluid, energy, and protein requirements (see Table 100–5); and determining if PN is indicated (see Table 100–1), develop an appropriate PN prescription.

### Initiating PN

Exercise caution when initiating PN to avoid hyperglycemia and fluid and electrolyte abnormalities. After the goal daily PN volume has been determined, initiate PN at a lower infusion rate (eg, ~50% of goal for anywhere from ~6 to 24 hours) on day 1 with no more than 150 to 200 g of dextrose per day (or a maximum dextrose infusion rate of ~2 mg/kg/min for the first 6–24 hours). Then increase PN to goal over the following 18 to 24 hours, provided that glycemic control is maintained and the patient does not experience significant fluid or electrolyte abnormalities. Monitor electrolytes daily and correct as needed. Advance PN more slowly and cautiously in patients with severe malnutrition and monitor for refeeding syndrome (see Complications of PN).

### Cycling PN

PN should be administered over 24 hours in most hospitalized patients to minimize glucose, fluid, and electrolyte abnormalities. However, administering PN via an infusion over less than 24 hours, or *cycling PN*, may be advantageous in certain patients and situations. Cycling PN typically involves administering the same PN volume over a goal infusion time, usually over 12 to 18 hours, rather than over 24 hours. Begin with PN infusion over

---

**Patient Encounter, Part 2**

It is now hospital day #3. Given that PG has malnutrition, an enterocutaneous fistula originating from the jejunum with high output (greater than 500 mL/day, increased when the patient drank water), and had recent abdominal surgery, the surgery team decided to manage PG conservatively: control fistula drainage, NPO status, and begin parenteral nutrition (PN) support today. A peripherally inserted central catheter (PICC) was placed for PN therapy.

Labs: Na 134 mEq/L (134 mmol/L); K 3.3 mEq/L (3.3 mmol/L); Cl 91 mEq/L (91 mmol/L); $HCO_3$ 26 mEq/L (26 mmol/L); BUN 12 mg/dL (4.3 mmol/L); serum creatinine 0.8 mg/dL (71 μmol/L); blood glucose 91 mg/dL (5.1 mmol/L); total Ca 8.4 mg/dL (2.10 mmol/L); ionized Ca 2.38 mEq/L (1.19 mmol/L); Mg 1.5 mg/dL (0.62 mmol/L); phosphorus 2.5 mg/dL (0.81 mmol/L); TG 129 mg/dL (1.46 mmol/L); albumin 2.9 g/dL (29 g/L); WBC count 6300/mm³ ($6.3 \times 10^9$/L); hemoglobin 12.4 mg/dL (124 g/L or 7.70 mmol/L); hematocrit 35.1% (0.35); platelets 204,000/mm³ ($204 \times 10^9$/L)

*Determine appropriate nutritional goals for PG (calorie and protein requirements).*

*What other patient data should be collected to help formulate a PN prescription?*

## Patient Encounter, Part 3

The surgical team asks for your recommendations for PN therapy for PG.

*Develop a plan for a complete and balanced PN prescription (including fluid, total calories, dextrose, amino acids, IVFE, electrolytes, vitamins, trace elements, and any additives) and explain the rationale supporting your PN formulation and plan.*

*How should this PN admixture be initiated and titrated to goal?*

*Would you recommend any other treatments before initiating PN? (Hint: Is this patient at risk for refeeding syndrome?)*

24 hours; then taper the PN infusion to the goal cycle over 2 to 4 days (eg, 24 hours, then 18–20 hours the next day, then 14–16 hours the next day, and then 12 hours the next day). A longer goal cycle (eg, 18 hours) may limit adverse effects related to rate of fluid and dextrose administration (hyper- and hypoglycemia). Titrate the PN infusion rate up over 1 to 2 hours to goal rate to avoid hyperglycemia and taper down over 1 to 2 hours at the end of the cycle to avoid reactive hypoglycemia. Most home infusion pumps can be programmed to cycle a given PN volume automatically over a given time. However, the pharmacist may have to develop an appropriate PN cycle if the infusion pump cannot be programmed for an automatic cycle.

Cyclic PN has the following potential advantages:

- It may improve the quality of life of patients receiving home PN by allowing the patient time off of PN to engage in normal activities of daily living.
- While data are limited, it may help prevent and alleviate PN-associated liver disease by avoiding continuous compulsive nutrient overload on the liver.[28]

Concerns with cycling PN include hyperglycemia with high infusion rates, reactive hypoglycemia when PN infusion is stopped, and fluid and electrolyte abnormalities. Random capillary blood glucose concentrations should be checked approximately 4 hours into the PN cycle (~2 hours after reaching goal rate), 15 to 60 minutes after PN stops, and intermittently during the PN cycle as needed for glycemic control. During cyclic PN infusion, the potassium infusion rate should not exceed 10 mEq/hour (10 mmol/hour) if the patient is not on a cardiac monitor. If nocturnal cyclic PN infusion interferes with patient's sleep pattern by causing overdiuresis, the PN cycle can be extended over a longer infusion time or PN can be infused during other times of the day that are most convenient to the patient.

### Transition to Oral or Enteral Nutrition

The goal is to transition the patient to enteral or oral nutrition and taper off PN as soon as indicated. After initiation of enteral or oral nutrition, monitor the patient for glucose, fluid, and electrolyte abnormalities. When oral nutrition intake is inconsistent, perform calorie counts to determine the adequacy of nutrition via the oral route. When the patient is tolerating more than 50% of total estimated daily calorie and protein requirements via the oral or enteral route, decrease PN by about 50%. PN can be stopped when the patient is tolerating at least 75% of total daily calorie and protein requirements via the oral or enteral route, assuming that intestinal absorption is maintained.

### Table 100–7

**Complications Associated with Parenteral Nutrition**

| Short Term | Long Term |
|---|---|
| Hyperglycemia | Infectious complications |
| Hypoglycemia | Liver toxicity |
| Electrolyte abnormalities | Vitamin abnormalities |
| Refeeding syndrome | Trace element abnormalities |
| Acid–base disturbances | Metabolic bone disease |
| Hyperlipidemia | Catheter/mechanical |
| Hypercapnia |    complications |
| Infectious complications | |
| Catheter/mechanical | |
|    complications | |

## COMPLICATIONS OF PN

KEY CONCEPT *PN therapy is associated with significant complications, both with short- and long-term therapy (Table 100–7). Many complications are related to overfeeding (Table 100–8).*

### Hyperglycemia

Hyperglycemia is one of the most common complications associated with PN therapy. The rate of dextrose oxidation may be reduced in patients with stress and hypermetabolism, patients with diabetes or acute pancreatitis, and patients receiving certain medications (eg, corticosteroids, vasopressors, octreotide, and tacrolimus).[29,30] Uncontrolled hyperglycemia can lead to fluid and electrolyte disturbances, hyperglycemic hyperosmolar nonketotic syndrome, hypertriglyceridemia, and an increased risk of infection.[31] Hyperglycemia in critically ill patients may be more a reflection of illness severity than from dextrose infusions, provided that the patient is not being overfed with dextrose.[32] Critical illness is associated with increased endogenous glucose production (caused by increased glycogenolysis and gluconeogenesis) and insulin resistance. Therefore, critically ill patients have lower tolerance for dextrose infusion compared with nonstressed patients. A portion of daily calories (~20%–30%) can be administered via IVFE to help decrease hyperglycemia, provided that the patient does not have hypertriglyceridemia. Overfeeding (with dextrose and with total calories) must always be avoided. Most recent data suggest that moderate glucose control is

### Table 100–8

**Consequences of Overfeeding**

| Source of Overfeeding | Consequences |
|---|---|
| Dextrose | Hyperglycemia, hypertriglyceridemia, hepatic steatosis, hypercapnia; hyperglycemia may cause fluid and electrolyte disturbances and increased infection risk |
| IV lipid emulsions | Hypertriglyceridemia, hyperlipidemia, hepatic steatosis |
| Amino acids | Azotemia |
| Total calories | Hepatic steatosis, cholestasis, hypercapnia |

indicated in critically ill patients (eg, capillary glucose concentrations between ~140 and 180 mg per dL [7.8 and 10.0 mmol/L]).[33] Refer to the section on "PN Additives: Regular Insulin" regarding management of hyperglycemia with insulin.

### Hypoglycemia

Hypoglycemia can occur in patients when PN is interrupted suddenly (reactive hypoglycemia), especially when patients are treated with insulin or as a result of insulin overdosing in PN.[1] It is essential to prevent hypoglycemia and, if it occurs, identify and treat it promptly. Reactive hypoglycemia typically is rare and usually can be avoided by tapering PN over 1 to 2 hours before discontinuation rather than abruptly stopping the infusion (especially if the patient is receiving insulin in PN or if the patient is not receiving oral or enteral nutrition). Reactive hypoglycemia generally occurs within 15 to 60 minutes after stopping PN (especially in neonatal patients), although it can occur later than this after discontinuing PN.[1] Capillary blood glucose concentrations should be monitored about 15 to 60 minutes after stopping PN infusion to detect any potential hypoglycemia. If PN is interrupted abruptly (eg, because of lost IV access), infusing dextrose 10% in water or dextrose 10% NaCl 0.45% in water (to avoid excessive free water) at the same rate as PN should prevent hypoglycemia. In patients with poor venous access, reduce the PN infusion rate by 50% for 1 hour before discontinuing. Another alternative to prevent reactive hypoglycemia is to provide a glucose source via the oral route (by mouth or sublingually) when feasible.

### Hyperlipidemia/Hypertriglyceridemia

Patients receiving IVFE may be at risk for hyperlipidemia and hypertriglyceridemia. Hyperlipidemia in patients receiving PN may lead to a reduction in pulmonary gas diffusion and pulmonary vascular resistance.[34] Severe hypertriglyceridemia (especially serum triglyceride concentrations exceeding 1000 mg/dL or 11.30 mmol/L) can precipitate acute pancreatitis.[35] Hypertriglyceridemia may develop as a result of increased fatty acid synthesis caused by hyperglycemia, impaired IVFE clearance, in patients with history of hyperlipidemia, obesity, diabetes, alcoholism, kidney failure, liver failure, multiorgan failure, sepsis, or pancreatitis, or as a result of medications (eg, propofol, corticosteroids, cyclosporine, and sirolimus).[36,37] Hyperglycemia is probably the most common cause of hypertriglyceridemia in patients receiving PN. A higher PL:TG ratio has been proposed to cause the appearance of the abnormal lipoprotein X particles in the blood.[8,36] Lipoprotein X may compete with IVFE particles for metabolism by lipoprotein lipase. It is preferred to use IVFE with a lower PL:TG ratio, especially in patients with hypertriglyceridemia, because they have improved clearance compared with emulsions with a higher PL:TG ratio (see Table 100–2).[8,36]

Monitor serum triglyceride concentrations regularly during PN therapy (see Table 100–8). If a patient develops hypertriglyceridemia, identify and correct the underlying cause(s) if possible. Prolonging the infusion of IVFE may improve lipid clearance. If a patient is receiving propofol, IVFE should be withheld and the calories from the 10% IVFE in propofol should be taken into account (see Table 100–2). IVFE should be held when the serum is lipemic or when serum triglyceride concentrations are greater than 400 mg/dL (4.52 mmol/L). When this occurs, restart IVFE when the serum triglyceride concentration is approximately 200 to 400 mg/dL (2.26–4.52 mmol/L) (or less) and administer only two to three times per week to prevent EFAD. Avoid completely holding IVFE for more than 3 to 4 weeks due to risk of EFAD.

### Hypercapnia

Hypercapnia can develop as a result of overfeeding with dextrose and/or total calories.[1,38] Excess carbon dioxide production and retention can lead to acute respiratory acidosis. Excess carbon dioxide will also stimulate an increase in respiratory rate, and this increase in respiratory workload could cause respiratory insufficiency that may require mechanical ventilation. Reducing total calorie and dextrose intake would result in resolution of hypercapnia if due to overfeeding.

### Liver Complications

The incidence of liver complications associated with PN ranges from approximately 7% to 84%, and end-stage liver disease develops in as many as 15% to 40% of adult patients on long-term PN.[36] Patients may develop a mild increase in liver transaminases within 1 to 2 weeks of initiating PN, but this generally resolves as PN continues, provided overfeeding is avoided. Severe liver complications include hepatic steatosis, steatohepatitis, cholestasis, and cholelithiasis.[36]

Hepatic steatosis is usually a result of excessive administration of carbohydrates or fats, but deficiencies of carnitine, choline, and essential fatty acids also may contribute. Hepatic steatosis can be minimized or reversed by avoiding overfeeding, especially from dextrose and IVFE.[36] Cholestasis is a common and potentially serious complication in PN-dependent patients. Factors that predispose PN patients to cholestasis include overfeeding, bowel rest, long duration of PN, short-bowel syndrome, bacterial overgrowth and translocation, and sepsis.[36] Patients may exhibit increased liver transaminases, increase alkaline phosphatase and gamma-glutamyl transferase concentrations, and mainly increased bilirubin concentrations with jaundice. The most sensitive marker of cholestasis is increased serum conjugated bilirubin concentration of greater than 2 mg/dL (34.2 μmol/L).[36] Cholestasis generally is reversible if PN is discontinued before permanent liver damage occurs. Serum liver function tests may take up to 3 months to return to normal after discontinuing PN. Steps to prevent cholestasis associated with PN include early enteral or oral feedings, using a balanced PN formulation, avoiding overfeeding, using cyclic PN infusion, and treating and avoiding sepsis.[36] Limiting soy-based IVFE infusion to one or two times weekly at a dose adequate to prevent essential fatty acid deficiency may also decrease serum bilirubin concentrations and improve cholestasis.[39] Pharmacologic treatments include ursodeoxycholic acid (ursodiol), which may improve bile flow and reduce the signs and symptoms of cholestasis. However, ursodiol is only available in an oral dosage form, and absorption may be limited in patients with intestinal resections.

Cholelithiasis can develop as a result of decreased gallbladder contractility, especially in the absence of enteral or oral intake. Lack of intestinal stimulation reduces secretion of cholecystokinin, a peptide hormone secreted in the duodenum that induces gallbladder contractility and emptying. The best prevention of cholelithiasis is early initiation of enteral or oral feeding.

Monitor liver function tests, including serum aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase, total bilirubin, conjugated bilirubin, unconjugated bilirubin, and γ-glutamyl transferase at the initiation of PN therapy and regularly thereafter during PN therapy. The frequency of monitoring liver function tests depends on the presence or absence of liver disease. This varies from one to two times weekly in the acute setting to once weekly, once monthly, or even one to two times per year in stable home PN patients.

## Manganese Toxicity

Manganese accumulation can occur in patients with cholestasis or in patients receiving long-term PN therapy. Neurotoxicity is the most common manifestation (headache, somnolence, weakness, confusion, tremor, muscle rigidity, altered gait, and mask-like face [a Parkinson-like syndrome]), but liver toxicity also may occur.[36] Periodically monitor blood manganese concentrations in patients on long-term PN. Patients with cholestasis receiving PN may require restriction of manganese in PN to prevent accumulation and possible toxicity.

## Metabolic Bone Disease

Metabolic bone disease (MBD) is a condition of bone demineralization leading to osteomalacia, osteopenia, or osteoporosis in patients receiving long-term PN. MBD may occur in as many as 40% to 100% of patients receiving long-term PN.[36] Often patients are asymptomatic, although symptoms can include bone pain, back pain, and fractures. Patients often have increased serum alkaline phosphatase concentrations, low to normal parathyroid hormone (PTH) concentrations, normal 25-hydroxyvitamin D and low 1,25 dihydroxyvitamin D concentrations, hypercalcemia or hypocalcemia, and hypercalcuria.[40] Because patients may be asymptomatic, diagnosis can be incidental. Radiographic techniques commonly used in diagnosing bone disease include quantitative computed tomography (CT) and bone mineral density.[40]

Factors that can predispose patients to developing MBD include deficiencies of phosphorus, calcium, and vitamin D; aluminum toxicity; amino acids and hyperosmolar dextrose infusions; chronic metabolic acidosis; corticosteroid therapy; and lack of mobility.[36,40] Calcium deficiency (caused by decreased intake or increased urinary excretion) is one of the major causes of MBD in patients receiving PN. Provide adequate calcium and phosphate with PN to improve bone mineralization and help to prevent MBD. Administration of amino acids and chronic metabolic acidosis also appear to play an important role. Provide adequate amounts of acetate in PN admixtures to maintain acid–base balance.

Aluminum toxicity appears to play a role in the development of MBD in patients on long-term PN, possibly by impairing calcium bone fixation, inhibiting the conversion of 25-hydroxyvitamin D to the active 1,25-dihydroxyvitamin D, and/or reducing PTH secretion.[36,40] The FDA issued a rule specifying acceptable aluminum concentrations in large-volume parenterals,[41] indicating that products contains no more than 25 mcg/L (0.93 μmol/L) of aluminum and defined a safe upper limit for parenteral aluminum intake at less than 4 to 5 mcg/kg/day. Pharmacies should use products with the lowest labeled aluminum content for the making of PN. Patients who are chronically dependent on PN should have their serum aluminum concentrations routinely monitored or whenever MBD is suspected or diagnosed.

Encourage patients on long-term PN to engage in regular low-intensity exercise. Yearly bone density measurements also should be performed on patients on long-term PN and when MBD is suspected.

## Refeeding Syndrome

Refeeding syndrome describes the metabolic derangements that occur during nutritional repletion of patients who are starved, underweight, or severely malnourished.[42] Hypophosphatemia and hypokalemia (along with associated complications) are the classic signs and symptoms, but refeeding syndrome encompasses a constellation of fluid and electrolyte abnormalities affecting neurologic, cardiac, hematologic, neuromuscular, and pulmonary systems. The most severe cases of refeeding syndrome have resulted in cardiac failure, seizures, coma, and death.[42] The reintroduction of energy substrates, especially carbohydrates, increases metabolism and utilization of glucose as the predominant fuel source. This increases insulin secretion and demand for phosphorylated intermediates of glycolysis (eg, ATP and 2,3-diphosphoglycerate [2,3-DPG]), inhibits fat metabolism, and causes an intracellular shift of phosphorus, potassium, and magnesium. These changes, in combination with preexisting low total body stores of phosphorus, potassium, and magnesium and enhanced cellular uptake of phosphorus during anabolic refeeding, result in hypophosphatemia, hypokalemia, and hypomagnesemia. Vitamin deficiencies (eg, thiamine) also may exist or be precipitated during refeeding. High carbohydrate intake increases the demand for thiamine, which can precipitate thiamine deficiency and cause lactic acidosis and neurologic abnormalities,[42] as well as myocardial dysfunction and congestive heart failure. Other metabolic alterations that may occur include expansion of the extracellular water compartment and fluid intolerance.

The primary goal is preventing refeeding syndrome when initiating PN in high-risk patients (eg, prolonged lack of adequate nutritional intake, significant weight loss, or moderate to severe malnutrition). When initiating nutrition support, the rule of thumb to prevent refeeding syndrome is to "start low and go slow." Initiate PN cautiously (eg, ~25%–33% of estimated nutritional requirements on day 1) and gradually increase to goal over 3 to 5 days. Correct electrolyte abnormalities before initiating PN and provide supplemental phosphate, potassium, and magnesium in and/or outside of PN. Doses of IV phosphate up to 0.64 to 1 mmol/kg may be used to treat severe hypophosphatemia (in patients with normal kidney function), and doses can be repeated as needed until serum phosphorus concentration has normalized.[43] Provide supplemental oral or IV thiamine 100 mg/day and folic acid 1 mg/day for about 1 week in addition to the standard multivitamin in PN. Assess patients for fluid balance, signs of edema, fluid overload, and weight gain, and consider minimizing fluid and sodium intake during the first few days of PN.[42] Monitor patients closely for signs and symptoms of refeeding syndrome until they are tolerating PN at goal for a few days:

- Vital signs, mental status, and neurologic and neuromuscular function at least every 4 to 8 hours.

- Pulse oximetry and any electrocardiographic changes when indicated.

- Serum laboratory values (including sodium, potassium,, phosphorus, and magnesium) at least once a day.

## Infectious Complications

Patients receiving central PN are at increased risk of developing infectious complications caused by bacterial and fungal pathogens.[1,44] Patients without malnutrition who receive early PN (eg, within 48 hours of ICU admission) may have a higher incidence of infectious complications than patients who do not receive PN or receive late PN initiation (eg, greater than 7 days after ICU admission).[2,10,45] Strict aseptic techniques must be used when placing the catheter along with continuous care of the catheter and infusion site. Catheter-related bloodstream infections are a common complication in long-term PN patients, often requiring hospital admission for parenteral antimicrobial therapy and/or removal of the catheter. Contamination of the PN admixture is

**Table 100–9**

**Suggested Frequency of Monitoring Parameters in Hospitalized Patients Receiving PN**

| Parameters | Initial | Daily (Unstable) | 2–3 × Weekly (Stable) | Weekly | As Indicated |
|---|---|---|---|---|---|
| BUN, creatinine | X | X | X | | |
| Sodium, potassium, chloride, bicarbonate | X | X | X | | |
| Glucose | X | X | X | | |
| Calcium, phosphorus, magnesium albumin, AST, ALT, LDH, alkaline phosphatase, total bilirubin | X | X | X | | |
| Conjugated bilirubin | X | | | X | X |
| Prealbumin[a] | X | | | X | X |
| Triglycerides | X | | | X | X |
| RBC count, hemoglobin, hematocrit, WBC count ± differential, platelets, PTT | X | | | | X |
| PT or INR | | | | X | X |
| Nitrogen balance | | | | | X |
| Zinc, selenium, chromium, copper, manganese, iron | | | | | X |
| TIBC, ferritin | | | | | X |

| Blood cultures | | | | | X |
| Body weight | X | X | X | | |

ALT, alanine aminotransferase; AST, aspartate aminotransferase; BUN, blood urea nitrogen; INR, international normalized ratio; LDH, lactate dehydrogenase; PT, prothrombin time; PTT, partial thromboplastin time; RBC, red blood cell; TIBC, total iron-binding capacity; WBC, white blood cell.

[a]Only recommended/indicated in the absence of inflammatory response.

possible but rare if protocols are followed for aseptic preparation of PN admixtures.

## Mechanical Complications

Mechanical complications of PN are related to venous catheter placement and the equipment used to administer PN. A central venous catheter must be placed by a trained professional, and risks associated with placement include pneumothorax, arterial puncture, bleeding, hematoma formation, venous thrombosis, and air embolism.[1] Over time, the venous catheter may require replacement. Problems with the equipment include malfunctions of the infusion pump, IV tubing sets, and filters.

## MONITORING PN THERAPY

**KEY CONCEPT** *When initiating PN, patients should have important baseline laboratory values checked to assess electrolyte status, organ function, and nutritional status. Thereafter, these and other nutritional parameters should be monitored routinely or as indicated (Table 100-9).* Random capillary blood glucose concentrations also should be monitored every 6 to 8 hours when initiating PN, and regular insulin should be administered to control blood glucose concentrations as needed.

## SUMMARY AND CONCLUSION

PN is an effective and potentially lifesaving method of administering nutrition support to patients who cannot receive adequate oral or enteral nutrition. Administration of PN can be associated with significant adverse effects and metabolic, infectious, and mechanical complications. Optimal design, compounding, and administration of a PN regimen are essential to minimize the risk of adverse effects and complications, and patients must be monitored closely while receiving PN to optimize outcomes.

### Patient Encounter, Part 4

The surgical team plans to initiate PN for PG per your recommendations. Laboratory data were listed previously.

*What monitoring parameters related to PN therapy should you follow in PG after initiating PN? List monitoring parameters and frequency.*

*What potential complications of PN should you monitor for in PG?*

*What special considerations must be made when developing a plan for nutrition support therapy and a PN formulation for patients with severe malnutrition?*

## Abbreviations Introduced in This Chapter

## LEARNING OBJECTIVES

● **Upon completion of this chapter, the reader will be able to:**

1. Discuss how gut structure and function impact choice of feeding route and outcome of feeding.
2. Estimate kilocalorie and protein requirements of an enteral feeding candidate and design an enteral nutrition (EN) regimen to meet these.
3. Evaluate patient-specific parameters to determine whether EN is appropriate.
4. Compare clinical efficacy, complications, and costs of EN versus parenteral nutrition (PN).
5. Formulate a monitoring plan for an EN patient.
6. Select appropriate medication administration techniques for an EN patient.

---

## INTRODUCTION

*E*nteral nutrition (EN) is broadly defined as delivery of nutrients via the gastrointestinal (GI) tract. The terms *enteral nutrition* and *tube feedings* are often used synonymously. Formulas for EN usually are delivered in the form of commercially prepared liquid preparations, although some products are produced as powders for reconstitution. Nonvolitional feedings in patients who cannot meet nutritional requirements by oral intake include EN and **parenteral nutrition** (PN), which are collectively known as *specialized nutrition support* (SNS).

Several organizations have issued clinical guidelines on the use of EN. These include the American Society for Parenteral and Enteral Nutrition (A.S.P.E.N.), European Society for Clinical Nutrition and Metabolism (ESPEN), and a Canadian team known as Critical Care Nutrition.[1–4] A.S.P.E.N. and the Society for Critical Care Medicine (SCCM) have jointly issued guidelines for SNS in critically ill patients.[5]

## GI TRACT STRUCTURE AND FUNCTION
### Anatomy and Absorptive Function

With normal volitional feeding, food is ingested via the mouth. There, the process of breaking down complex foodstuffs into simpler forms that can be absorbed by the small bowel begins. Solid food is chewed in the mouth, and enzymes begin digestion. The trigger for release of many enzymes and GI hormones is the presence of food in specific regions of the GI tract. Food is swallowed and passes through the esophagus and the esophageal sphincter to the stomach, where additional digestive enzymes and acids further break it down. The stomach also serves a mixing and grinding function.

The food, now in a liquid form known as *chyme*, passes through the pyloric sphincter into the duodenum, where stomach acid is neutralized. Most absorption of digested carbohydrate and protein occurs within the jejunum. Most fat absorption occurs within the jejunum and ileum. In the small bowel, breakdown of macronutrients (ie, carbohydrate, protein, and fat) occurs both within the lumen and at the intestinal mucosal membrane surface. The absorptive units on the intestinal mucosal membrane are infoldings known as *villi*. These villi are made up of epithelial cells called *enterocytes*. Projections from these enterocytes called *microvilli* increase the surface area of the small bowel and make up the *brush-border membrane*.

Digestive substances secreted by the pancreas play a role in food breakdown. The pancreas secretes large amounts of sodium bicarbonate that neutralize stomach acid. Substances flow from the pancreas through the pancreatic duct. The pancreatic duct typically joins the hepatic duct to become the common bile duct that empties through the **sphincter of Oddi** into the duodenum. Bile secreted by the liver does not contain digestive enzymes, but bile salts help to emulsify fat and facilitate fat absorption. Bile flows through bile ducts into the hepatic duct and common bile duct. Bile is stored in the gallbladder until needed in the gut to aid fat digestion, at which time it empties through the cystic duct to the common bile duct to the duodenum. Pathways through which carbohydrate, protein, and fat are digested and absorbed through the small bowel are illustrated in **Figure 101–1**.

Remaining undigested food passes from the ileum through the ileocecal valve to the colon. A major role of the colon is fluid absorption. Some of the water and sodium absorption achieved by the colon is facilitated by short-chain fatty acids (SFCAs) formed from digestion of certain dietary fibers by colonic bacterial enzymes.

### Gut Immune Function

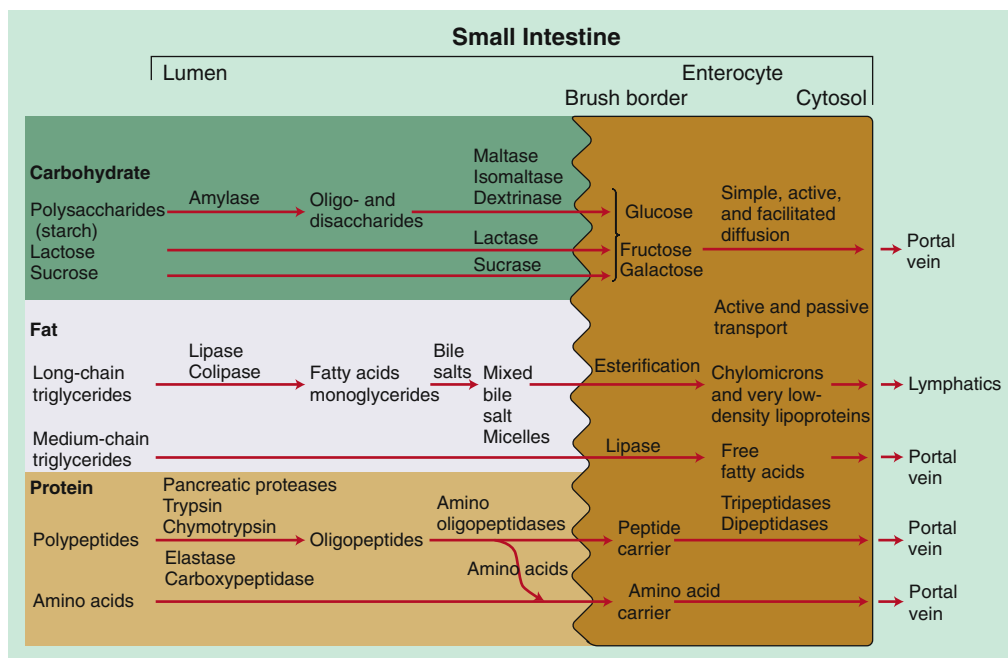
The gut plays significant immune roles. The distal small bowel and colon host many bacteria and their endotoxins, and it is important that these organisms not gain access to the internal systems of the body. This function is known globally as the *gut barrier function*.[6] Normal flora of the gut comprises one component. The normal flora, particularly some anaerobes, helps to prevent overgrowth of potential pathogens. A second component involves


**FIGURE 101−1.** Schematic of carbohydrate, fat, and protein digestion. (From Kumpf VJ, Chessman KH. Enteral nutrition. In: DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York: McGraw-Hill, 2014:2428.)

mechanical factors. These include a mucous layer that prevents adherence of bacteria. Peristalsis of the small bowel prevents stasis of bacteria. Gut-associated lymphoid tissue (GALT), prominent in small bowel, serves as a local immune system. Secretory immunoglobulin A produced at the mucosal surface in response to food in the gut prevents bacteria from invading the surface.

## PATIENT SELECTION

In general, **KEY CONCEPT** *EN is the preferred route if the gut can be used safely in patients who cannot meet nutritional requirements by oral intake.* If the gut functions, EN is usually preferred over PN. The timing of SNS (either EN or PN) is controversial, but definitive guidelines for these therapies state that SNS should be started when intake has been inadequate for 7 to 14 days or if inadequate oral intake is anticipated for at least 7 to 14 days.[1] Prior nutritional status of the patient should be considered. Previously well-nourished patients can better afford not being fed for longer periods than previously poorly nourished patients. Patients in the intensive care unit (ICU) probably benefit from early EN started within 24 to 48 hours of admission to the ICU.[3,5] Ethical questions come into play when consideration is given to starting (or stopping) EN in seemingly futile situations. Methods for assessing nutritional status and designing SNS regimens are covered in Chapter 100. Generally, nonobese hospitalized patients require 20 to 35 total kcal/kg of body weight/day (84–147 kJ/kg body weight/day) and 1 to 2 g protein/kg of body weight/day. Obese patients are often fed hypocaloric, high-protein diets; guidelines state to start feedings at 1.2 g protein per kg and less than 14 kcal/kg actual body weight (59 kJ/kg actual body weight).[7]

## Indications

Many potential indications for EN exist (Table 101–1). PN was used extensively in the past for many of these conditions.

| Table 101–1 |
| --- |
| **Potential Indications for EN** |

| | |
| --- | --- |
| **Neoplastic Disease** | **GI Disease** |
| Chemotherapy | Inflammatory bowel disease |
| Radiation therapy | Short-bowel syndrome |
| Upper GI tumors | Esophageal motility disorder |
| Cancer cachexia | Pancreatitis |
| **Organ Dysfunction** | Fistulas |
| Liver disease/failure | Gastroesophageal reflux disease (severe) |
| Kidney insufficiency/failure | Esophageal or intestinal atresia |
| Cardiac cachexia | **Neurologic Impairment** |
| ARDS/ALI | Comatose state |
| Bronchopulmonary dysplasia | Cerebrovascular accident |
| Congenital heart disease | Demyelinating disease |
| Organ transplantation | Severe depression |
| **Hypermetabolic States** | Cerebral palsy |
| Closed head injury | **Other Indications** |
| Burns | AIDS |
| Trauma | Anorexia nervosa |
| Postoperative major surgery | Complications during pregnancy |
| Sepsis | Failure-to-thrive |
| | Geriatric patients with multiple chronic diseases |
| | Extreme prematurity |
| | Inborn errors of metabolism |
| | Cystic fibrosis |

AIDS, acquired immune deficiency syndrome; ALI, acute lung injury; ARDS, acute respiratory distress syndrome.

**Table 101–2**

**Contraindications and Precautions for EN**

Severe hemorrhagic pancreatitis
Severe necrotizing pancreatitis
Necrotizing enterocolitis
Diffuse peritonitis
Small bowel obstruction
Paralytic ileus
Severe hemodynamic instability
Enterocutaneous fistulae
Severe diarrhea
Severe malabsorption
Severe GI hemorrhage
Intractable vomiting

---

Advances in EN technology now allow many patients with these conditions to receive EN. EN is administered in both institutional and home settings.

## Contraindications and Precautions

EN should not be used or should be used with extreme caution in certain conditions (Table 101–2). It is possible to use EN in some patients with these conditions depending on severity of illness, location of abnormality, and experience of practitioners delivering care. Feeding in the setting of hemodynamically instability is particularly controversial; some clinicians avoid enteral feedings in this setting for fear of worsening intestinal ischemia, whereas others believe early feeding may facilitate intestinal perfusion and be beneficial.[5,8–9] Others might avoid jejunal feedings in this setting but would proceed with cautious gastric feedings.

## Enteral versus Parenteral Feeding

With advent of the technique of PN by large central vein in the late 1960s, this modality quickly became popular. PN was incorporated quickly into care of patients such as critically ill patients. The relative ease of PN administration, along with the perception that critically ill patients had prolonged high-energy expenditures, led to complications of overfeeding. Dextrose overfeeding led to complications, including hyperglycemia, carbon dioxide overproduction leading to delays in weaning from mechanical ventilation, and liver abnormalities owing to hepatic steatosis.

The pendulum began to swing toward EN in the late 1980s and early 1990s as clinical studies showed better clinical outcomes with EN compared to PN. Some potential advantages of EN over PN are included here. First, EN is expected to preserve the gut barrier function better than PN. This could prevent translocation of bacteria and endotoxin from the gut lumen into the lymphatic system and systemic circulation, thus preventing infections. Some studies support that KEY CONCEPT *EN is associated with fewer infectious complications than PN.* EN is cited frequently as having a better overall safety profile than PN. Whereas PN is associated with more severe complications, such as pneumothorax and catheter sepsis, EN is associated with more nuisance complications, such as GI side effects. Another frequently cited advantage of EN over PN is that EN is less expensive. EN formulas typically are cheaper and less labor intensive to prepare than PN, although some specialty EN formulas approach the cost of PN formulas. Depending on the method of feeding tube placement, EN costs can mount if the tube must be placed by a radiologist or gastroenterologist rather than a nurse or if the tube must be replaced.

Arguments in support of EN over PN have been questioned. Part of this questioning relates to the question of whether EN is beneficial compared with PN or whether PN as commonly administered may be detrimental. Overfeeding and hyperglycemia occur easily with PN, and the potential harm of hyperglycemia, especially in critical care populations, has been demonstrated, although the exact range optimal for glycemic control in ICU patients remains controversial.[10,11] A study published in 1991 demonstrated in a mildly malnourished perioperative population that there were more infectious complications in patients randomized to receive PN compared with those randomized to receive no SNS; there was no difference in noninfectious complications between the two groups.[12] Only in severely malnourished perioperative patients were fewer noninfectious complications seen with PN; in these patients, no difference in infectious complications was seen between groups. Whether EN truly prevents infections and improves clinical outcomes or whether PN is detrimental continues to be debated and probably depends upon specific patient population. At present, EN is preferred by most experts over PN when the gut is functional. In Europe (more so than in North America), PN has been used to supplement EN during the first week of intensive care therapy when EN is not yet being tolerated at full rates.[2] This approach is currently discouraged by American and Canadian ICU guidelines.[3,5] Recent randomized controlled trials relating to this topic have yielded disparate results.[13–17]

## ROUTES OF ACCESS[18]

There are several access sites for EN (Figure 101–2). Nasogastric (NG), orogastric (OG), nasoduodenal (ND), and nasojejunal (NJ) routes generally are for short-term use (less than 1 month), whereas gastrostomy, percutaneous endoscopic gastrostomy (PEG), jejunostomy, and percutaneous endoscopic jejunostomy (PEJ) tubes are preferred for longer-term treatment. Both advantages and disadvantages exist for each EN route (Table 101–3).

### Gastric Feeding

Gastric feedings are used commonly. They require an intact gag reflex and normal gastric emptying for safety and success. Certain patients, such as those who have suffered head trauma, may not empty their stomachs efficiently and therefore may not be good candidates for gastric feedings. In these patients, it may be impossible to achieve a gastric tube feeding rate to provide adequate nutrients. In addition, pooling of formula in the stomach could increase risk of aspirating feeding formula into the lungs.

The NG route is used most commonly for short-term enteral access. The major advantage of this route is that the tube can be placed quickly and inexpensively by the nurse at the bedside.

Gastrostomy tubes, in which an incision is made directly through the abdominal wall, are indicated for patients who can tolerate gastric feedings but in whom long-term feedings are anticipated. The most commonly placed gastrostomy tubes are either placed by interventional radiology or are PEG tubes placed endoscopically. Gastrostomy tubes also can be placed laparoscopically or during an open procedure by a surgeon. Placement of a gastrostomy tube either endoscopically or surgically is more expensive than bedside OG or NG placement but can result in placement of a larger bore tube.

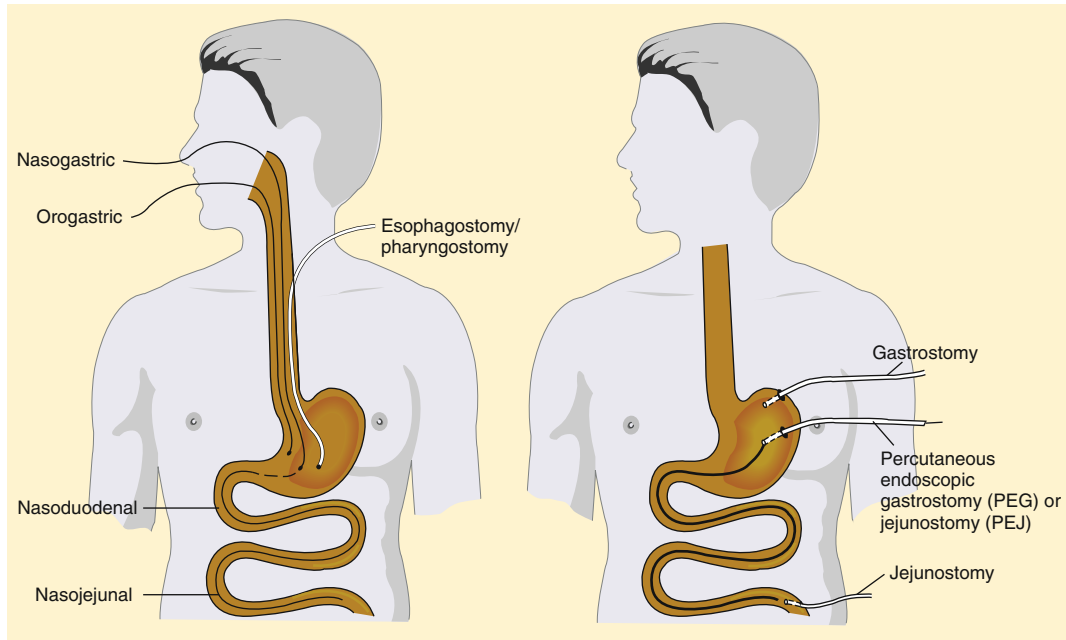
An advantage of feeding into the stomach is that feedings can be delivered either intermittently or continuously. When feeding directly into the small bowel continuous feedings must be used. Intermittent feedings into the small bowel result in GI intolerance in most patients.


**FIGURE 101–2.** Access sites for tube feeding. (From Kumpf VJ, Chessman KH. Enteral nutrition. In DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed, New York: McGraw-Hill, 2014:2431.)

### Table 101–3

**Options and Considerations in the Selection of Enteral Access**

| Access | EN Duration/Patient Characteristics | Tube Placement Options | Advantages | Disadvantages |
|---|---|---|---|---|
| Nasogastric or orogastric | Short term<br>Intact gag reflex<br>Normal gastric emptying | Manually at bedside | Ease of placement<br>Allows for all methods of administration<br>Inexpensive<br>Multiple commercially available tubes and sizes | Potential tube displacement<br>Potential increased aspiration risk |
| Nasoduodenal or nasojejunal | Short term<br>Impaired gastric motility or emptying<br>High risk of GER or aspiration | Manually at bedside<br>Fluoroscopically<br>Endoscopically | Potential reduced aspiration risk<br>Allows for early post injury or postoperative feeding<br>Multiple commercially available tubes and sizes | Manual transpyloric passage requires greater skill<br>Potential tube displacement or clogging<br>Bolus or intermittent feeding not tolerated |
| Gastrostomy | Long term<br>Normal gastric emptying | Surgically<br>Endoscopically<br>Radiologically<br>Laparoscopically | Allows for all methods of administration<br>Low-profile buttons available<br>Large-bore tubes less likely to clog<br>Multiple commercially available tubes and sizes | Attendant risks associated with each type of procedure<br>Potential increased aspiration risk<br>Risk of stoma site complications |

EN, enteral nutrition; GER, gastroesophageal reflux.

From Kumpf VJ, Chessman KH. Enteral nutrition. In DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York: McGraw-Hill, 2014.

## Postpyloric Feedings

**KEY CONCEPT** *For patients intolerant of gastric feedings or in whom the risk of aspiration is high, feedings delivered with the tip of the tube in the jejunum are preferred.* This bypasses the problem of poor gastric emptying and adds another barrier (pyloric sphincter) through which tube feedings must traverse before aspiration into the lungs. However, postpyloric feedings do not preclude the possibility of aspiration. Many patients with this complication are aspirating their own nasopharyngeal secretions.

Nasoduodenal and NJ feeding tubes can be placed by trained, experienced nurses at the bedside. Although such placements typically take more time than NG or OG placements, this is still a relatively inexpensive method of placement. Bedside electromagnetic transmitter devices (eg, CORTRAK, Corpak Medsystems) may be helpful in achieving postpyloric tube placement. In some institutions, ND or NJ placements are done in radiology by a radiologist using fluoroscopy to visualize tube advancement. This procedure increases cost of EN therapy. NJ tubes generally are preferred over ND tubes; placement of the tube tip distal to the ligament of Treitz (located near the junction of the duodenum and the jejunum) may reduce risk of aspiration. Alternatively, during a laparotomy, the surgeon can place an ND or NJ tube.

Surgically placed jejunostomy tubes are placed through an incision in the abdominal wall, precluding the need for a tube down the nose or mouth. These tubes frequently are placed during laparotomy following abdominal trauma. Alternatively, jejunal access can be obtained by placing a jejunal extension through a PEG tube; the resulting tube is sometimes referred to as a *PEGJ tube* or *G-J tube*. Another option is to place a PEJ tube directly; this is more technically difficult than PEG placement. Tubes with both gastric and jejunal lumens are sometimes used, the gastric lumen for suctioning stomach contents and the jejunal lumen for delivery of feedings.

## METHODS OF DELIVERY

Enteral feedings are delivered by several different methods. Continuous infusion must be used when duodenal or jejunal feedings are administered. For gastric feedings, bolus or intermittent feedings could be administered instead of continuous feedings. Each method has advantages and disadvantages.

In many hospitals, EN is delivered most commonly as a continuous infusion at a constant rate regulated by an infusion pump. A variation of continuous infusion is cyclic feeding, in which a constant rate is maintained over a certain number of hours daily; this method of administration is used commonly in long-term care or home settings. Sometimes EN is administered overnight.

Intermittent feedings are used commonly in long-term care or home settings. Patients frequently are started with continuous feedings; transitioned to intermittent feedings given several times a day over about 30 to 45 minutes for each feeding; and eventually changed to bolus feedings administered over less than 10 minutes per feeding. An advantage of intermittent feedings is that they may be administered by gravity flow adjusted with a roller clamp, although some institutions may use an infusion pump. Bolus feedings can be administered using a 60-mL syringe, although in some circumstances, an infusion set and pump may be used. Intermittent and bolus feedings often are given in amounts of 240 to 480 mL per feeding, corresponding to one to two cans of formula.

## EN FORMULAS

One advantage of EN over PN is the availability in the United States of certain nutrients in some EN formulations (eg, glutamine, fish oils) that are not available for parenteral use. A number of EN formulas are marketed commercially. Hospitals and long-term care facilities usually limit formularies of EN formulas, stocking only a limited number of products.

## Polymeric versus Oligomeric Formulas

A major criterion for categorizing EN products is whether macronutrients (particularly protein) are more intact (polymeric) or present in simpler forms (oligomeric). **KEY CONCEPT** *Standard EN formulas are polymeric; these are appropriate for most patients.* Oligomeric formulas should be reserved for patients with GI dysfunction.

Polymeric formulas typically contain intact proteins (most commonly casein). They have low osmolality of 300 to 500 mOsm/kg. These usually supply essential vitamins and minerals in amounts similar to the Adequate intakes (AI) or Recommended Dietary Allowances (RDA) for these nutrients when the formula is delivered in amounts adequate to meet macronutrient requirements of most patients. Many polymeric formulas are inexpensive relative to oligomeric formulas. Most modern formulas are lactose and gluten free. Products designed for use as oral supplements generally are polymeric and often have sucrose or other simple sugars added to improve taste.

Oligomeric formulas are also known as *chemically defined formulas*. These can be subcategorized based on whether the formula contains all free amino acids (elemental formulas) or peptides (peptide based) as the protein source. Some formulas contain a combination of free amino acids and small peptides. Dipeptides and tripeptides are absorbed more efficiently than free amino acids. Oligomeric formulas may be better tolerated than polymeric formulas for patients with defects in GI function and may be particularly useful with severe pancreatic dysfunction or significantly decreased GI surface area. However, adaptation of the bowel is better when intact nutrients are supplied to patients with short bowel syndrome, so those patients should be transitioned to intact nutrients as soon as possible.

Oligomeric formulas typically are more expensive than polymeric formulas and have higher osmolality. However, osmolality of these products usually does not exceed 700 mOsm/kg, a value less than that of many oral medications or a regular diet. Sometimes enteral feedings are diluted to deliver extra water required by the patient; this practice generally is discouraged because of potential risk of formula contamination. Instead, it is better to give extra water as boluses through the tube. If medications are administered through the feeding tube, generous amounts of water should be used to flush the tube before and after each medication; this practice helps provide extra fluid and prevent problems with tube occlusion.

Oligomeric formulas are less palatable than polymeric formulas and are not designed for use as oral supplements. Many oligomeric formulas provide some fat calories as medium-chain triglycerides (MCTs), a fat source that is more readily absorbed and metabolized than long-chain triglycerides (LCTs) typically found in polymeric formulas. The MCTs do not require bile salts or pancreatic enzymes for absorption. Some elemental formulas contain a low proportion of fat (less than 10% of total calories), which makes them useful in certain situations where fat needs to be restricted. The carbohydrate source in oligomeric formulas

is also less complex than in polymeric formulas, consisting of oligosaccharides rather than hydrolyzed starch.

## Fiber Content

Another distinguishing factor of enteral formulas is whether or not they contain fiber. Both soluble and insoluble fibers may be included. Insoluble fiber exerts an effect on gut motility by drawing water into the intestine and decreasing transit time, thus preventing constipation. Soluble fiber can help to lower blood cholesterol levels, regulate blood sugar, and prolong gastric emptying. Soluble fiber may also help control diarrhea. Cellulose gum is an example source of insoluble fiber. Oat fiber and guar gum provide primarily soluble fiber. Soy fiber provides primarily insoluble fiber but also some soluble fiber and is the most commonly used fiber source in tube feeding products. Fiber has been useful for regulating gut motility in some but not all clinical studies; it certainly can be useful in selected patients.[19] Some patients may experience GI discomfort secondary to gas production with introduction of fiber.

Fructooligosaccharides (FOS) are a form of fiber that pass through the stomach and small bowel undigested and are fermented by colonic bacteria to the SCFAs butyrate, propionate, and acetate. The SCFAs serve as a fuel source for colonocytes and also serve other important functions.[20] The FOS are thus *prebiotics* that serve as fermentable substrates for normal flora of the colon. The SCFAs are not added directly to EN products because they would be absorbed completely before reaching the colon; rather, FOS are added, allowing bacterial degradation to form SCFAs. Products containing FOS are often avoided postoperatively due to increased gas, bloating, and abdominal distention with these products.

## Caloric Density

Enteral feeding formulas can be categorized based on caloric density. Standard caloric density is 1 to 1.3 kcal/mL (4.2–5.4 kJ/mL). More calorically dense formulas containing 1.5 to 2 kcal/mL (6.3–8.4 kJ/mL) are available and have a higher osmolality. Fluid-overloaded patients may benefit from more calorically dense formulas. As caloric content of a formula increases, the amount of free water decreases.

## Protein Content

Protein content is an important factor in choosing an EN formula. Standard protein content in EN formulas is up to about 20% of total calories as protein. High-protein formulas containing 25% or more of total calories as protein are available for highly stressed patients with elevated protein needs. So are low-nitrogen formulas containing less than 10% of total calories as protein for use in patients requiring protein restriction. A wide range of protein is available, from about 35 to 95 g/L.

## Carbohydrate Content

The most common carbohydrate source in tube feeding products is maltodextrin, a partially hydrolyzed starch that is easily digestible. Corn syrup solids are another hydrolyzed starch found in many products. Products containing simple sugars (often those intended for oral use) tend to be higher in osmolality.

## Fat Content

Both MCTs and LCTs are used in tube feeding products. Corn, soy, and safflower oils are standard sources of fat, providing mainly ω-6 polyunsaturated fatty acids (PUFAs). Some newer EN products contain higher quantities of ω-3 PUFAs from sources such as fish oil (ie, docosahexanoic acid [DHA] and eicosapentaenoic acid [EPA]). Other formulas contain higher quantities of monounsaturated fatty acids (MUFAs) from canola oil and high-oleic safflower or sunflower oils. The essential fatty acid (EFA) content (mainly linoleic acid) of EN formulas is important because EFA deficiency can be induced if at least 1% to 4% of total calories are not supplied as EFAs. MCT oil does not contain EFAs.

## Vitamin, Mineral, and Electrolyte Content

Most EN products contain vitamins and minerals, including major electrolytes, in amounts adequate to deliver the RDA or AI when a standard volume of formula is delivered daily. Some specialty formulas (eg, renal formulas) may have altered amounts of certain micronutrients.

## Specialty Formulas

Specialty formulas designed for use in specific clinical situations generally are more expensive than standard polymeric formulas. **KEY CONCEPT** *Robust clinical trial data supporting use of specialty formulas in niche populations typically remain lacking in terms of improved patient outcomes.*

## Stress and Trauma Formulas

Historically, formulas aimed specifically for highly stressed, critically ill patients, were enriched with branched-chain amino acids (BCAAs). The rationale was that skeletal muscle BCAAs are preferentially used for energy in critical illness. Provision of BCAAs might limit breakdown of muscle in these patients. Clinical data failed to support or refute benefit of these formulas unequivocally in terms of clinical outcomes.[3]

The newer generation of enteral feeding formulas marketed for use in these populations covers a broad spectrum of characteristics (Table 101–4). Whereas some are polymeric, others are oligomeric to address malabsorption that may accompany high stress. Some formulas marketed for use in critical illness are calorically dense (1.5–2 kcal/mL [6.3–8.4 kJ/mL]) to address fluid restrictions seen in this population, and others are less calorically dense. Most products contain generous amounts of protein to address requirements of highly stressed patients (nonprotein kilocalorie to nitrogen ratios typically between 75:1 and 125:1 [nonprotein energy to nitrogen ratio between about 300 and 500 kJ/g N]). Many products contain ingredients purported to increase immune function; the term *immunonutrition* is sometimes attached to these products.

Immune-enhancing ingredients present in some enteral feeding products include arginine, glutamine, ω-3 fatty acids, nucleic acids, and antioxidants. Few products contain all of these (see Table 101–4). Arginine is an important substrate for nitric oxide (NO) synthesis, and small amounts of NO have beneficial effects on immune function under certain conditions. Arginine has been purported to have a positive influence on lymphocyte and macrophage function. Glutamine is considered to be conditionally essential in critical illness and is a preferred fuel source for enterocytes of the small bowel. Supplementation with glutamine, either parenterally or enterally, may help maintain integrity of gut mucosa, preventing translocation of bacteria and endotoxin from the gut lumen into the lymphatic system and systemic circulation. However, a recent trial showed increased mortality with glutamine supplementation

CI, critical illness; HS, high stress; MCT, medium-chain triglycerides; PD, pulmonary disease/ventilator dependent; TR, trauma.

[a] kcal is equivalent to 4.186 kJ.

[b]Formula considered enriched if following criteria met: arginine—greater than 10 g/1500 kcal (6,279 kJ); glutamine—greater than 10 g/1500 kcal (6279 kJ); MCT—greater than 30% of total fat; and ω-3 fatty acid—ratio of ω-6 to ω-3 less than or equal to 2:1 or greater than 1.5 g/L ω-3 fatty acids.

of patients with multiorgan failure.[21] The ω-3 fatty acids, primarily from fish oils, are included in many immunonutrition products. Metabolites of ω-6 fatty acids include mediators such as prostaglandins, leukotrienes, and thromboxanes that are primarily proinflammatory and increase coagulation. Conversely, mediators produced from ω-3 fatty acids are less proinflammatory and decrease coagulation. Limited data support nucleic acids as immunomodulators. Quantities of antioxidants (particularly vitamin C, vitamin E, and β-carotene) higher than traditionally found in standard enteral formulas are added to some immunonutrition formulas to protect body systems, including the immune system, from damage by oxygen-free radicals. **KEY CONCEPT** *Use of enteral immunonutrition in certain clinical settings is now widely accepted.* Commercial immunonutrition products and/or specific ingredients found in these products have generally been found to have no benefit in terms of mortality rates.[3,22,23] However, infection rates, length of stay, and length of time on a ventilator may be decreased with these products. The 2009 A.S.P.E.N./SCCM ICU Guidelines support use of these formulas in major elective surgery, trauma, burns, head and neck cancer, and mechanically ventilated patients.[5] The best timing (initiation and duration) of delivery remains to be determined. There is some concern that supplementation with arginine may be detrimental in septic patients.[3]

## Pulmonary Formulas

Enteral feeding formulas designed for use in patients with chronic obstructive pulmonary disease or receiving mechanical ventilation contain higher amounts of fat (40%–55% of total kilocalories) than most formulas. The rationale for high fat content is that burning of fat for energy is associated with less carbon dioxide production compared with burning of carbohydrate. Less carbon dioxide production theoretically would be advantageous in patients with retention of this substance and might facilitate weaning from mechanical ventilation. Because part of the market targeted by the manufacturers of these products comprises mechanically ventilated patients, these products are included in Table 101–4. Carbon dioxide retention owing to carbohydrate administration was a problem previously when feeding was overzealous. However, at conservative calorie levels, standard enteral formulas usually can be given without fear of excess carbon dioxide production.

One formula, Oxepa (Nestle), has been studied specifically in critically ill patients with acute respiratory distress syndrome (ARDS), acute lung injury (ALI), and sepsis. This formula contains high quantities of the ω-3 fatty acids (EPA) and γ-linolenic acid (GLA). GLA is metabolized to a prostaglandin with vasodilatory properties. EPA is converted to prostaglandins and leukotrienes that are less proinflammatory than those derived from ω-6 fatty acids. This formula contains large quantities of antioxidants. Patients receiving this formula had improved outcomes, including fewer days of mechanical ventilation, compared with patients receiving a high-fat enteral feeding product as a control.[24] Another study using a standard enteral feeding product as a control did not show clear benefit in septic patients with ARDS or ALI.[25] However, a third study demonstrated benefit from Oxepa in patients with early sepsis even when using a standard enteral feeding control product.[26] Timing and duration of use for optimum benefit remain to be determined.

**Table 101–5**

**Selected Enteral Feeding Formulas Marketed for Use in Diabetes and Stress-Induced Hyperglycemia[a]**

| Product Name/Manufacturer | kcal/mL | % kcal as Fat | % kcal as Carbohydrate | Fiber (g/L) |
|---|---|---|---|---|
| Glytrol/Nestle | 1 | 42 | 40 | 15.2 |
| Glucerna 1.0 Cal/Abbott | 1 | 49 | 34.3 | 14.3 |
| Glucerna 1.2 Cal/Abbott | 1.2 | 45 | 35 | 16 |
| Glucerna 1.5 Cal/Abbott | 1.5 | 45 | 33 | 16 |

[a]One kcal is equivalent to 4.186 kJ.

## Diabetic Formulas

Similar to pulmonary formulas, formulas designed for patients with diabetes or stress-induced hyperglycemia are relatively high in fat and low in carbohydrates (Table 101–5). These formulas typically contain fiber (primarily soluble) because it plays some role in glycemic control. They also may contain fructose and MUFAs. Data support improved blood sugar control with use of these formulas in patients with diabetes.[27] Whether or not a diabetic EN formula is chosen, avoidance of overfeeding and maintenance of good glycemic control with insulin or other hypoglycemic medications are important in these populations.

## Renal Formulas

Products designed for use in renal failure have high caloric density (1.8–2 kcal/mL [7.5–8.4 kJ/mL]) to decrease administered fluid (Table 101–6). The products vary in amounts of nutrients of interest in renal failure patients such as protein, potassium, phosphorus, and magnesium. Products low in protein (20–35 g/L) may be appropriate in chronic renal failure patients not yet receiving dialysis. On the other hand, removal of nitrogen by dialysis, coupled with the hypercatabolic, hypermetabolic condition seen in many acute renal failure patients, makes use of higher protein formulas (80–90 g/L) appropriate in these situations. Potassium, phosphorus, and magnesium contents of EN formulas designed for use in renal failure tend to be lower than standard formulas because these renally excreted electrolytes accumulate during renal failure.

Historically, elemental formulas designed for renal failure were enriched with essential amino acids (EAAs) and contained lesser amounts of nonessential amino acids (NEAAs) than standard formulas. Theoretically, EAAs could combine with urea nitrogen in the synthesis of NEAAs, leading to a decrease in blood urea nitrogen (BUN). The only situation in which such formulas may be appropriate is in patients with chronic renal failure who are not candidates for dialysis. Even in this setting, use of these products should be limited to no more than 2 or 3 weeks.[1] These formulas have been supplanted largely by polymeric formulas with protein content similar to standard EN formulas. Many dialysis patients tolerate standard, high-protein EN formulas, although electrolytes must be monitored closely.

## Hepatic Formulas

Specialized formulas for patients with hepatic insufficiency are limited in number. These are enriched with BCAAs while containing a reduced quantity of aromatic amino acids (AAAs) and methionine compared with standard formulas. These changes address high levels of AAAs and low levels of BCAAs found in the blood of patients with hepatic insufficiency. Theoretically,

these products might help patients with hepatic encephalopathy (HE). Hepatic formulas have low AAA content, and this distinguishes them from the BCAA-enriched formulas historically used in patients with critical illness and stress. Improvement in mortality attributable to these products has not been consistent.[1]

The A.S.P.E.N./SCCM guidelines for the ICU recommend against the use of protein restriction to reduce risk of development of HE.[5] These guidelines recommend use of standard EN formulas for ICU patients with acute or chronic liver disease but state that the hepatic specialty formulas may be useful in improving coma grade in HE patients refractory to standard treatment with locally acting antibiotics and lactulose. An example of a specialized hepatic formula is Hepatic-Aid II (Hormel Health Labs), a product supplied as a powder for reconstitution that requires vitamin, mineral, and electrolyte supplementation. A second product is NutriHep (Nestle), supplied as a liquid formula containing the recommended amounts of key vitamins, minerals, and electrolytes.

## Wound Healing Formulas

Tube feeding and oral supplement formulas designed for use in patients with wounds or decubitus ulcers typically supply high

**Table 101–6**

**Selected Enteral Feeding Products Designed for Use in Renal Failure**

| Product Name/Manufacturer | Protein/L | Characteristics |
|---|---|---|
| Nepro with Carb Steady/Abbott | 80.6 | Complete formula[a] similar to Novasource Renal for patients on dialysis |
| Novasource Renal/Nestle | 91.1 | Complete formula similar to Nepro with Carb Steady for patients on dialysis |
| Suplena with Carb Steady/Abbott | 44.7 | Complete formula with low amounts of protein for patients not yet receiving dialysis |

[a]Complete formula—contains all nutrients in amounts sufficient to meet needs of most patients in a volume equal to or less than that usually administered.

## Patient Encounter, Part 1

LT is an obese 55-year-old woman with a history of diabetes mellitus and chronic obstructive pulmonary disease admitted with multiorgan failure and septic shock with a suspected pulmonary source. She meets criteria for acute respiratory distress syndrome (ARDS) and prerenal azotemia. She is placed on mechanical ventilation; started on aggressive fluid resuscitation, vasopressor therapy, and antibiotics; and systemic corticosteroid therapy. She is started on propofol for sedation while on the ventilator.

LT responds somewhat slowly to the sepsis protocol and on day 3 is still requiring both norepinephrine and vasopressin for blood pressure support. The dietitian assesses her nutritional needs. Her dry weight is 102 kg; height is 64 inches (163 cm); body mass index is 38 kg/m$^2$.

*Is there any concern regarding starting EN at this time?*

*If EN is not appropriate at this time, should PN be initiated?*

amounts of protein and calories. The antioxidant vitamins A, C, and E are frequently also found in high quantities as is zinc.

### Modular Components

Single nutrient components are frequently administered through feeding tubes to augment the composition of the EN formula. Protein modules are probably the most commonly used. These may be supplied by the manufacturer as a powder that must be reconstituted with water or as a liquid product. Another modular component is fiber. These components are typically given as a bolus through the feeding tube rather than being added to the feeding formula.

### MONITORING AND COMPLICATIONS

Although complications of EN generally are considered less serious than those of PN, some complications nevertheless can be dangerous or can lead to impaired delivery of desired nutrient load. Complications can be divided into four categories: GI, technical, infectious, and metabolic. The first three categories, along with common causes, are listed in Table 101–7. Patients on EN must be monitored for prevention of complications (Table 101–8). Monitoring of many parameters can become less frequent as patient condition stabilizes. Monitoring for efficacy of EN is also important.

### GI Complications

KEY CONCEPT *GI complications are the most common complications of EN limiting the amount of feeding that patients receive.* Although diarrhea frequently is blamed on feeding formula or the method of EN administration, other possible causes usually exist (see Table 101–8). In the inpatient setting, patients receiving EN frequently are very sick. Along these lines, *Clostridium difficile* colitis must be considered as a possible cause of diarrhea, especially in patients receiving antimicrobial therapy or proton pump inhibitors.[28–30] Antibiotic therapy is a major cause of diarrhea in acutely ill patients, including those receiving EN. A medication-related cause of diarrhea is the sorbitol content of medications.[31] Large quantities of sorbitol present in oral liquid medications

### Table 101–7

**Complications of Tube Feeding**

| Complication | Causes |
|---|---|
| **GI** | |
| Diarrhea | Drug related |
| |     Antibiotic-induced bacterial overgrowth |
| |     Hyperosmolar medications administered via feeding tubes |
| |     Antacids containing magnesium |
| | Malabsorption |
| |     Hypoalbuminemia or gut mucosal atrophy |
| |     Pancreatic insufficiency |
| |     Inadequate GI tract surface area |
| |     Rapid GI tract transit |
| |     Radiation enteritis |
| | Tube feeding related |
| |     Rapid formula administration |
| |     Formula hyperosmolality |
| |     Low residue (fiber) content |
| |     Lactose intolerance |
| |     Bacterial contamination |
| Nausea and vomiting | Gastric dysmotility (surgery, anticholinergic drugs, diabetic gastroparesis) |
| | Rapid infusion of hyperosmolar formula |
| Constipation | Dehydration |
| | Drug induced (anticholinergics) |
| | Inactivity |
| | Low residue (fiber) content |
| | Obstruction or fecal impaction |
| Abdominal distention or cramping | Too rapid formula administration |
| **Technical** | |
| Occluded feeding tube lumen | Insoluble complexation of enteral formula and medication(s) |
| | Inadequate flushing of feeding tube |
| | Undissolved feeding formula |
| Tube displacement | Self-extubation |
| | Vomiting or coughing |
| | Inadequate fixation (jejunostomy) |
| Aspiration | Improper patient position |
| | Gastroparesis or atony causing regurgitation |
| | Feeding tube malpositioned |
| | Compromised lower esophageal sphincter |
| | Diminished gag reflex |
| Peristomal excoriation | Improper skin and tube care |
| | GI tract secretions leaking peristomally |
| **Infectious** | |
| Aspiration pneumonia | Same as technical—aspiration comments |
| | Prolonged use of large-bore polyvinylchloride tube |

GI, gastrointestinal.

From Janson DD, Chessman KH. Enteral nutrition. In DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 5th ed. New York: McGraw-Hill, 2005.

(often considered the dosage form of choice for administration through a feeding tube) can cause diarrhea. Unfortunately, sorbitol content of many medications is not listed on their labeling, and manufacturers frequently reformulate preparations to contain varying amounts of excipients, such as sorbitol.

Determining cause of diarrhea is important to know how to address the problem. Whereas *C. difficile* colitis should be treated

| Liver function tests | Weekly | Every 1–3 months |
| Trace elements, vitamins | If deficiency/toxicity is suspected | If deficiency/toxicity is suspected |

EN, enteral nutrition.

From Kumpf VS, Chessman KH. Enteral nutrition. In DiPiro JT, Talbert RL, Yee GC, et al, eds. Pharmacotherapy: A Pathophysiologic Approach, 9th ed. New York: McGraw-Hill, 2014.

with an appropriate antibiotic, medication-related diarrhea can be addressed by removal of the offending agent. Likewise, diarrhea secondary to malabsorption sometimes can be addressed by changing to an oligomeric EN formula. Antiperistaltic agents (eg, loperamide) may be useful in some noninfectious diarrhea.

On the other hand, constipation may occur in patients receiving EN, especially the elderly. Increased provision of fluid or fiber may be useful. Constipation may be drug related, in which case discontinuation or replacement of the offending drug may be beneficial.

Impaired gastric emptying is seen commonly in EN patients receiving gastric feedings and may be associated with nausea and vomiting. Impaired emptying may be related to disease process (eg, diabetic gastroparesis or sequelae to head injury) or to drug therapy, most notably narcotics. Gastric residual checks

frequently are measured in patients receiving gastric feedings (see Table 101–8). To accomplish this, a syringe is attached to the feeding device, and as much liquid as possible is aspirated into the syringe. Debate is ongoing as to what constitutes a significant gastric aspirate, with numbers between 200 and 500 mL most commonly defended; a recent study indicated that residual checks are not necessary.[4,32–34] Approaches to the patient with delayed gastric emptying might include changing to a formula containing less fat because dietary fat is associated with slower gastric emptying. Metoclopramide often is given to patients receiving gastric feedings to facilitate gastric emptying. Erythromycin is an alternative medication that may be useful, although it is associated with drug–drug interactions. Patients with consistently high residuals are considered to be at higher risk of aspirating feedings into their lungs and should be considered for transition to postpyloric feedings. Postpyloric feedings may help relieve EN-related nausea and vomiting and are preferred for patients without an intact gag reflex. An important practice to help prevent aspiration is elevation of the head of the bed to at least 30 degrees during continuous feedings and during and for 30 to 60 minutes after intermittent and bolus feedings.

## Technical Complications

Technical or mechanical complications are encountered frequently in EN patients. Tube occlusion most commonly is related to formula occlusion or medication administration through the tube. **KEY CONCEPT** *An important practice to help prevent medication-related occlusion is adequate water flushing of the tube before, between, and after each medication is given through the tube.* If intermittent feedings are used, water flushing after each feeding is recommended. Tube occlusion can increase cost of EN if the tube has to be removed and replaced. Clearing of occlusions using water or pancreatic enzymes plus sodium bicarbonate can be attempted, and special devices and kits (eg, DeClogger, Bionix) are available.[35]

Tube displacement is a potentially significant complication. This may be seen in an agitated patient pulling at the tube, or in some cases, the tube tip migrates spontaneously. If the tip of the tube is positioned in the tracheobronchial tree and feeding is delivered to this area, pneumonia, pneumothorax, and other problems could potentially occur. Location of the feeding tube tip should be confirmed initially by chest radiograph after placement and before use. For ongoing assessment of tube placement, auscultation and measurement of aspirate pH can be used.

Endoscopic and surgical feeding tubes can cause erosion of the exit site caused by leakage of gastric or intestinal contents onto the skin. This complication must be addressed by good wound care and repair or replacement of the access device. Similarly, NG, ND, and NJ tubes can be complicated by nasopharyngeal irritation or necrosis. This is one reason why such tubes should be considered for short-term use only.

## Infectious Complications

Infectious complications of EN include aspiration pneumonia and infections related to delivery of contaminated EN formula. Although GI infections owing to industrial contamination of enteral formulas have been reported uncommonly, these formulas are more commonly seeded with organisms during the processes of transferring from can to delivery bag with ready-to-use formulas and during the process of reconstitution with powdered formulas. The so-called closed systems of delivery, wherein the formulas come from the manufacturer premixed

in a delivery bag, should help decrease possibility of formula contamination. Practice recommendations from A.S.P.E.N. state that sterile water should be used for formula reconstitution, medication dilution, tube flushing, and additional water provision in acute or chronically ill patients requiring EN.[4] This recommendation can be difficult to implement, especially in home care.

## Metabolic Complications

Metabolic complications of EN most commonly include disorders of fluid and electrolyte homeostasis and hyperglycemia. More severely ill patients require more frequent monitoring (see Table 101–8). Both dehydration and fluid overload can occur. Careful monitoring of fluid inputs and outputs as well as body weight is important. Dehydration may be caused by either excessive fluid losses or inadequate fluid intake. The trend in the ratio of BUN to serum creatinine can be useful in helping monitor fluid status; a ratio greater than 15:1 (60:1 for SI mmol/L:mmol/L) may be an indicator of dehydration; high ratios may also be a result of high protein provision by the feeding. Attention should be paid to free-water content of EN formulas. Free-water content varies from about 65% to 85%; percentage-free water typically drops as caloric density of the formula rises. If dehydration develops, switching to a less calorically dense formula or using larger water flushes is appropriate. Fluid overload is reflected by increases in weight, lower extremity edema, and pulmonary rales and particularly may be a problem in patients with renal or cardiac insufficiency. Use of a more calorically dense EN formula may be helpful, and diuretic therapy may be necessary. Fluid imbalances often are associated with abnormalities of sodium homeostasis that should be addressed in concert with fluid imbalance.

Hypokalemia, hypomagnesemia, and hypophosphatemia are some of the most common electrolyte abnormalities in sick, hospitalized patients. These can occur in context of the refeeding syndrome which occurs in chronically malnourished patients aggressively started on feeding. Although classically associated with PN, refeeding syndrome can also occur with aggressive EN. Careful monitoring of electrolytes, coupled with a feeding regimen increased gradually to goal rate over a period of several days, should help protect at-risk patients from this complication. Hypokalemia and hypomagnesemia also are associated with excessive losses through the GI tract or urine and are associated with various medications, including diuretics. Repletion may be accomplished enterally in nonsymptomatic patients or parenterally if the patient is symptomatic or the abnormality is severe. Enteral repletion with magnesium and phosphate can cause diarrhea. Hyperkalemia, hypermagnesemia, and hyperphosphatemia are less common and usually are associated with renal insufficiency. Hyperkalemia also is associated with medications, including potassium-sparing diuretics, angiotensin-converting enzyme inhibitors, and angiotensin receptor blockers.

Although hyperglycemia is less common with EN than PN, it can occur. Many severely ill patients (eg, septic, highly stressed) receiving EN have a metabolic milieu promoting hyperglycemia. For ICU patients with hyperglycemia receiving continuous EN, an IV insulin drip may be the most effective way to achieve good glycemic control. Scheduled intermediate or long-acting insulin plus correctional regular or rapid acting insulin is preferred after stabilization on the feeding regimen.[36,37] Administration of a higher fat, lower carbohydrate EN formula may be useful in selected patients.

## Monitoring for Efficacy and Outcome Evaluation

A useful physical measurement of EN efficacy in the long-term patient is body weight. Depending on the clinical situation, the goal may be weight gain, weight maintenance, or weight loss. Whereas day-to-day fluctuations in weight generally reflect fluid changes, week-to-week variations are more useful in determining if caloric provision is appropriate.

The amount of EN actually administered is often less than the amount ordered owing to interruptions in therapy. It is imperative to monitor volume of feedings actually received and to make adjustments in rates or amounts of EN as necessary.

Biochemical markers have been used historically to help interpret EN adequacy. Use of visceral proteins such as albumin or prealbumin is limited by the effects of inflammation on serum levels of these biomarkers.[38] In the acute phase of illness characterized by a proinflammatory state, proteins known as *acute-phase reactants* are preferentially synthesized. One of these measured clinically is C-reactive protein (CRP). In some patients with significant illness, prealbumin may not rise, even though the patient is receiving appropriate EN, until CRP begins to fall. Collection of urine to measure nitrogen balance can help analyze adequacy of caloric and protein provision.

In patients with wounds (eg, decubitus ulcers), a goal of therapy is to facilitate wound healing. Monitoring status of the wound becomes part of ongoing nutritional assessment. In debilitated patients, particularly on long-term EN, measures of functional status such as grip strength and ability to perform activities of daily living become important components of nutritional assessment.

## MEDICATION ADMINISTRATION IN PATIENTS RECEIVING EN

### Medication Administration Through Feeding Tubes

If a patient receiving EN is alert and can swallow oral medications, then medications should be given by mouth. Many patients are not able to receive medications by this route, and the feeding tube may be considered as a delivery route. Effects of medication administration through feeding tubes on the delivery of both the drug and the EN formula nutrients have been inadequately studied.[39]

---

### Patient Encounter, Part 2

On day 4, vasopressor requirements are minimal and enteral feeding is initiated at a low rate via nasogastric tube. Propofol is changed to dexmedetomidine on day 5. Gastric residuals range from 0 to 20 mL over the next 2 days as the tube feeding is advanced to goal rate. Blood sugar readings rise to above 200 mg/dL (11.1 mmol/L), necessitating initiation of an insulin drip on day 7; on day 9, insulin glargine subcutaneous is added as the insulin drip is titrated off.

*How does propofol affect the initial EN prescription?*

*Design an enteral feeding regimen, including choice of formula and goal rate, appropriate for this patient at this time.*

*What are this patient's risk factors for hyperglycemia, and is the approach to blood sugar management rational?*

**KEY CONCEPT** *Compatibility of medication with EN formula is of concern when administering medications through feeding tubes.* An important technical complication of EN is tube occlusion, related most commonly to medication administration. Not only must compatibility of medication and EN formula be considered, but interactions between medications and the feeding tube itself must be considered. Strict protocols for flushing the tube before, between, and after administration of medications are important.[4] The best fluid for flushing is warm water. Between 10 and 30 mL of water should be used as a flush before and after any medication administration through a feeding tube. Medications should be administered one at a time sequentially rather than being mixed together for simultaneous administration down the tube; about 5 mL of water should be used as a flush between medications. This should help prevent interactions between drugs within the tube itself that could lead to occlusion.

Different dosage forms present unique challenges for administration through feeding tubes. Certain solid dosage forms should not be crushed because crushing would alter release characteristics.[40] For example, controlled-release, extended-release, and sustained-release preparations should not be crushed, nor should sublingual dosage forms. Enteric-coated dosage forms generally are designed to protect acid-labile medications from stomach acid; when these dosage forms reach the small bowel with its higher pH, the drug is released into an environment in which it is more stable. Alternatively, enteric-coated dosage forms protect the stomach from medications that could cause irritation. Thus, crushing the enteric coating defeats the purpose of the dosage form and could lead to decreased efficacy or increased adverse events.

Medications available commercially as compressed tablets can be crushed for administration through tubes. After crushing, the fine powder should be mixed with 10 to 30 mL of fluid (usually warm water) for administration. A powdered dosage form inside a hard-gelatin capsule can be poured out and mixed with water for administration through tubes. Soft-gelatin capsules can be dissolved in warm water. Some enteric-coated and delayed-release microencapsulated products can be opened and individually coated particles administered through the tube without crushing if the tube has a large enough diameter.

If a liquid dosage form of a medication exists, it would seem rational to use this for administration through a feeding tube. This may decrease potential for tube clogging but may in some instances decrease tolerability of medication administration. Sorbitol is an excipient found in many liquid medications in amounts sufficient to cause diarrhea. If diarrhea secondary to sorbitol is suspected, contact with the manufacturer to ascertain sorbitol content may be necessary.

Another potential problem with administration of liquid medications through feeding tubes is high osmolality of some products. Dilution of hypertonic medications with 30 to 60 mL of water or administration of smaller dosages more frequently may help prevent diarrhea. Although administration of IV medications through feeding tubes may be entertained, these dosage forms frequently are hypertonic and contain problematic excipients when given via the GI tract.

It is generally not recommended to mix medications directly into EN formula because physical incompatibilities might lead to tube occlusion. Limited data currently available indicate that acidic syrups and elixirs may be most harmful, causing physical incompatibility when admixed with EN formulas. It would seem logical that medications considered absorbed better in the fasted state either should be given between feedings on an intermittent feeding schedule or feedings should be held before and after medication administration. However, not all studies have supported this notion; therefore, this issue deserves further study.[41]

Location of feeding tube tip is important when considering medication administration. This is particularly true if the medication acts locally in the GI tract. For example, sucralfate and antacids act locally in the stomach; therefore, administration through a duodenal or jejunal tube is illogical. Likewise, for medications requiring acid for best absorption, administration directly into the duodenum or jejunum may result in suboptimal absorption. Absorption of drugs when administered directly into the small bowel, especially the jejunum, is a topic where more research would be useful.

## Problem Medications

### ▶ Phenytoin

Certain medications present challenges when administered through feeding tubes. The medication studied most thoroughly is phenytoin. Most studies have shown significant decreases in phenytoin absorption when administered enterally to patients receiving EN. Several mechanisms have been proposed for this interaction. Liberal dilution of phenytoin suspension before its administration down the tube may improve its delivery. Many institutions hold tube feedings for 1 or 2 hours before and after administration of phenytoin, although some EN patients subjected to this routine still require high dosages of phenytoin to achieve therapeutic serum concentrations. Holding feeding around medication administration can make meeting nutritional requirements difficult with continuous feedings, especially if phenytoin is administered several times daily. Diligent monitoring of phenytoin serum concentrations is necessary for the patient on EN receiving this medication. In some cases, use of IV phenytoin or another anticonvulsant medication may be prudent.

### ▶ Warfarin

EN formulas contain vitamin K, which can antagonize the pharmacologic activity of warfarin. Vitamin K content of EN formulas has been adjusted down over several decades, resulting in products that contain amounts of vitamin K unlikely to affect anticoagulation by warfarin significantly. However, inadequate warfarin anticoagulation in EN patients receiving formulas containing minimal vitamin K has been reported. A component of certain tube feedings, perhaps protein, may bind warfarin and result in suboptimal activity. One small study indicated a better response in terms of the international normalized ratio (INR) when feedings were held for 1 hour before and after warfarin compared with administration of the drug without

---

**Patient Encounter, Part 3**

LT is extubated on day 13. Concern regarding her swallowing strength leads to a speech pathology consult. She is switched to a standard formula tube feeding. On day 14, an order to advance oral diet as tolerated is written following the speech pathology assessment.

*Was the switch to a standard tube feeding formula rational?*

*How should the transition from EN to oral feedings be accomplished?*

## Patient Care Process

**Patient Assessment:**

- Based on patient's disease states and severity, estimate the amount of time until adequate oral intake resumes (see Table 101–1).
- Are there any contraindications or precautions regarding use of EN (see Table 101–2)? When the GI tract is nonfunctional, either PN or no SNS is indicated.
- If inadequate intake has occurred or is anticipated for 7 to 14 days, start SNS. The threshold for starting SNS is lower for previously malnourished patients. Critically ill patients should generally be started on EN within 24 to 48 hours of ICU admission.
- Choose the appropriate type of enteral access device based upon the expected duration of use and upon whether any condition exists which precludes gastric feeding (see Table 101–3).
- Choose the method of feeding administration (eg, intermittent or continuous) based on the feeding access type (ie, gastric versus postpyloric) and other patient factors.

**Therapy Evaluation:**

- Adjust formula, rate of administration, and/or route of administration if intolerance develops or nutritional

goals (eg, weight loss, weight maintenance, weight gain, maintenance of muscle mass, slowing of functional decline) are not met.
- Are medications being administered down the feeding tube? If so, assess the appropriateness of this route.

**Care Plan Development:**

- Start tube feeding at full strength and low rate and increase rate as tolerated to goal that will meet patient's nutritional requirements.
- Develop plan to include monitoring at appropriate intervals for metabolic, GI, technical, or infectious complications (see Table 101–8).
- Develop monitoring plan for adequacy of nutritional regimen. This may include serial weights, intakes and outputs, and a measure of functional status.

**Follow-Up Evaluation:**

If patient is to be discharged home on EN, educate patient or caregiver on enteral access device care, feeding delivery, troubleshooting, and complications to observe for (see Table 101–7).

---

holding feedings.[42] When tube feedings are started, changed, or discontinued, INR should be monitored closely.

▶ *Fluoroquinolones*

Absorption of antimicrobial agents such as fluoroquinolones and tetracyclines that can be bound by divalent and trivalent cations potentially could be compromised by administration with EN formulas containing these cations. Fluoroquinolones (eg, levofloxacin and ciprofloxacin) have been best studied in this regard, and results of studies are not consistent.[41] Some institutions hold tube feedings for 1 to 2 hours or more before and after enteral dosages of fluoroquinolones. Not all fluoroquinolones are affected by the interaction, suggesting that a mechanism other than chelation by divalent cations may also be significant. Because ciprofloxacin absorption has been shown to be decreased with jejunal administration, this drug probably should not be given by jejunal tube.

## SUMMARY AND CONCLUSION

EN is an important method of feeding patients who cannot or should not eat enough to meet nutrient requirements for a prolonged time. When the GI tract can be used safely, EN is preferred over PN. Various types of enteral access devices are available. Whereas tubes inserted through the nose often are adequate for patients expected to receive EN for a short time, more permanent devices are preferred for longer-term patients. Choice of whether to feed into the stomach or postpylorically is patient specific. Although numerous EN formulas are available, many products are very similar, making a limited formulary feasible.

Data supporting many specialized types of EN formulas are limited. Although complications of EN tend to be less serious than those of PN, adverse effects encountered can be significant, and diligent ongoing monitoring is necessary. Although medications can be administered through feeding tubes, various factors must be taken into account in each individual patient.

## Abbreviations Introduced in This Chapter

| | |
|---|---|
| AAA | Aromatic amino acid(s) |
| AI | Adequate intake |
| ALI | Acute lung injury |
| ARDS | Acute respiratory distress syndrome |

# Overweight and Obesity

Maqual R. Graham and Daniel S. Aistrope

## LEARNING OBJECTIVES

**Upon completion of the chapter, the reader will be able to:**

1. Explain the underlying causes of overweight and obesity.
2. Identify parameters used to diagnose obesity and other objective information that indicates the severity of disease.
3. Identify desired therapeutic goals for patients who are overweight or obese.
4. Recommend appropriate nonpharmacologic and pharmacologic therapeutic interventions for overweight or obese patients.
5. Implement a monitoring plan that will assess both the efficacy and safety of therapy initiated.
6. Educate patients about the disease state and associated risks, comprehensive lifestyle interventions, drug therapy, and surgical options necessary for effective treatment.

## INTRODUCTION

Overweight and obesity are terms used to describe weight measurements greater than what is considered healthy for a given height.[1] **KEY CONCEPT** *Body mass index (BMI), waist circumference (WC), comorbidities, and readiness to lose weight are used in the assessment of overweight or obese patients.* The primary modality in defining overweight and obesity is the BMI, a measure of body fat based on height and weight. BMI should be used to identify adults at increased risk for cardiovascular disease (CVD) and other obesity-related disorders. Evaluation of the patient's risk status involves not only calculation of the BMI but also the measurement of WC and determination of obesity-related comorbidities and presence of CVD risk factors. **KEY CONCEPT** *The presence of comorbidities (CVD, type 2 diabetes mellitus, and sleep apnea) and cardiovascular risk factors (cigarette smoking, hypertension, elevated low-density lipoprotein cholesterol, low high-density lipoprotein cholesterol, impaired fasting glucose) requires identification and aggressive management for overall effective treatment of the overweight or obese patient.* Obese patients may be at very high risk for mortality if concomitant risk factors exist; therefore, high-risk patients require aggressive modification of risk factors in addition to obesity treatment.[2]

## ETIOLOGY AND EPIDEMIOLOGY

Obesity is a multifactorial, complex disease that occurs because of an interaction between genotype and the environment. Although the etiology is not completely known, it involves overlapping silos of social, behavioral, and cultural influence; pathophysiology; metabolism; and genetic composition.[3] The majority of overweight or obese individuals are adults, but these diseases are also prevalent in children between 2 and 19 years of age. While the prevalence of obesity appears to be leveling off, approximately 35% of US adults 20 years of age and older are currently considered obese. The prevalence of obesity in men and women of various racial and ethnic origins differ. Thirty-six percent of non-Hispanic white adults are considered obese, where approximately 40% of Mexican Americans and 50% of non-Hispanic black Americans are obese.[4]

Thirty-two percent of children and adolescents aged 2 through 19 years are considered either overweight or obese. The prevalence of obesity among this age group remains unchanged at 17%.[5] Overweight children typically mature to overweight adults, but most obese adults were not overweight as children.[6] Overweight and obesity, when present in young adults, may be a better predictor of prevalence.[6] Adulthood overweight and obesity contribute to an increased risk of death in the presence of hypertension, dyslipidemia, diabetes mellitus, CVD, stroke, sleep apnea, gallbladder disease, osteoarthritis, and certain cancers.[2] Psychosocial functioning also may be hindered because obese patients may be at risk for discrimination if negatively stereotyped.[2] Pediatric obesity is also associated with significant health-related problems and is therefore considered a risk factor for much of the adult obesity-related morbidity and mortality.[7,8] Cardiovascular (eg, dyslipidemia and hypertension), endocrine (eg, hyperinsulinemia, impaired glucose tolerance, type 2 diabetes mellitus, and menstrual irregularities), and mental (eg, low self-esteem and depression) health problems exist for obese patients.[9]

## PATHOPHYSIOLOGY

The key factor in the development of overweight and obesity is the imbalance that occurs between energy intake and energy expenditure. The extent of obesity is determined by the length of time this imbalance has been present. Energy intake is affected

by environmental influences, including social, behavioral, and cultural factors, whereas genetic composition and metabolism affect energy expenditure.[10]

### Energy Intake

Food intake is regulated by various receptor systems. Stimulation of the following receptors increases and decreases food intake, respectively.

▶ *Increase Food Intake*

- Serotonin 1A subtype ($5\text{-HT}_{1A}$)
- Noradrenergic $\alpha_2$
- Cannabinoid 1 ($CB_1$)

▶ *Decrease Food Intake*

- Serotonin 2C subtype ($5\text{-HT}_{2C}$)
- Noradrenergic $\alpha_1$ or $\beta_2$
- Histamine subtypes 1 and 3 ($H_1$ and $H_3$)
- Dopamine 1 and 2 (D1 and D2)

Identification of appetite-associated receptors is useful in the development of pharmacologic agents, however not all are targeted by currently approved anti-obesity medications. In addition to receptor-modulated food consumption, higher levels of the protein leptin are associated with decreased food intake.[11] In contrast, elevated levels of neuropeptide Y increase food intake.[11]

It is debatable whether obesity is related to total calorie intake or composition of macronutrients. Of the three macronutrients (ie, carbohydrate, protein, and fat), fat has received the most attention, given its desirable texture and its ability to augment the flavor of other foods. Food high in fat promotes weight gain, in comparison with the other macronutrients, because fat is more energy dense. When compared with carbohydrate and protein, more than twice as many calories per gram are contained in fat. In addition, fat is stored more easily by the body compared with protein and carbohydrate.[12]

### Energy Expenditure

A person's metabolic rate is the primary determinant of energy expenditure. The metabolic rate is enhanced after food consumption and is directly related to the amount and type.[13] Physical inactivity may predispose an individual to overweight and obesity. In addition, endocrine-related disorders (eg, hypothyroidism and Cushing syndrome) may lower the metabolic rate, further contributing to the development of overweight and obesity.

## CLINICAL PRESENTATION AND DIAGNOSIS

**KEY CONCEPT** *BMI, WC, comorbidities, and readiness to lose weight are used in the assessment of overweight or obese patients.* Any interaction between a patient and a health care provider presents an opportunity to evaluate the patient's height and weight; however, these parameters should be measured no less than annually. The BMI should then be calculated and classified based on current cut points for overweight and obesity. The BMI is calculated using the measured weight in kilograms divided by the height in meters squared ($kg/m^2$) for all adult patients regardless of gender. The greater the BMI in overweight and obese individuals, the greater the risk of CVD, type 2 diabetes mellitus and all-cause mortality.[14] The BMI distribution changes with age for children

| Table 102–1 | |
|---|---|
| **BMI Classification** | |
| **Adult** | |
| Underweight | < 18.5 kg/m² |
| Normal weight | 18.5–24.9 kg/m² |
| Overweight | 25–29.9 kg/m² |
| Obesity (Class 1) | 30–34.9 kg/m² |
| Obesity (Class 2) | 35–39.9 kg/m² |
| Extreme obesity (Class 3) | ≥ 40 kg/m² |
| **Children (Does Not Pertain to Those Less Than 2 Years of Age[a])** | |
| Underweight | < 5th percentile |
| Healthy weight | 5th–84th percentile |
| Overweight | 85th–94th percentile |
| Obesity | ≥ 95th percentile |

[a]Weight for height values should be plotted and monitored over time for children younger than 2 years.

Data from Refs. 2 and 14.

just as height and weight. Percentiles specific for age and gender are used to classify pediatric patients as overweight and obese as well as healthy and underweight. The BMI is classified according to Table 102–1. WC should also be determined no less than annually for adult patients by placing a measuring tape at the top of the right iliac crest and proceeding around the abdomen, ensuring that the tape is tight but not constricting the skin. The value is measured after normal expiration.[2] Table 102–2 defines high-risk WC.[2] Measurement of WC is not recommended for children and adolescents because reference values identifying risk are unavailable.[15] After obtaining patient appropriate parameters, further assess the adult patient for the presence of obesity-related comorbidities and cardiovascular risk factors. **KEY CONCEPT** *The presence of comorbidities (CVD, type 2 diabetes mellitus, and sleep apnea) and cardiovascular risk factors (cigarette smoking, hypertension, elevated low-density lipoprotein cholesterol, low high-density lipoprotein cholesterol, impaired fasting glucose) requires identification and aggressive management for overall effective treatment of the overweight or obese patient.* A patient is at very high absolute risk if diagnosed with CVD, type 2 diabetes mellitus, or sleep apnea or if three or more of the risk factors listed in Table 102–3 are present.[2] Aggressive disease management should be initiated and not limited to weight loss. If the patient is a child or adolescent and the BMI is greater than the 85th percentile, determine the patient's risk for future obesity-related problems or presence of obesity-related medical conditions such as sleep, respiratory, gastrointestinal (GI), endocrine, cardiovascular, and psychiatric disorders.[15,16]

## TREATMENT
### Desired Outcome

**KEY CONCEPT** *The treatment goals for overweight and obesity are to prevent additional weight gain, reduce and maintain a lower body weight, and control related risks.* A 5% to 10% weight loss as derived from the patient's current weight is the initial goal of obesity management because favorable outcomes on the negative effects of obesity have been documented.[14] A sustained loss in weight of 5% will likely reduce triglyceride and blood glucose values as well as risk for the development of type 2 diabetes mellitus.[14] Greater reductions in weight will reduce blood pressure and improve both low-density and high-density lipoprotein cholesterol. **KEY CONCEPT** *Weight loss is indicated for patients with a BMI of 25 to 29.9 kg/m² with one or more indicators of increased CVD risk (eg, elevated WC, prediabetes or type 2 diabetes, hypertension, dyslipidemia, current cigarette smoker) or for any patient with a BMI of 30 kg/m² or greater.* Weight loss should occur at a rate of 0.45 to 0.9 kg (1–2 lb) per week, meeting the initial weight loss goal within the first 6 months of therapy. If the patient achieves a 5% to 10% loss in weight, weight loss maintenance strategies should be considered. **KEY CONCEPT** *Weight maintenance occurs after successful achievement of weight loss.*

It is desirable to achieve a goal of improved long-term physical health for a child or adolescent. A BMI below the 85th percentile is warranted but is difficult to assess in frequent or short time periods. Serial weight measurements may better quantify energy balance. Goals are most likely accomplished through adaptation of lifelong healthy lifestyle habits. In doing so, weight loss or maintenance can be attained for some children. Others may need to incorporate changes that result in a negative energy balance or energy input less than energy output.[15,16]

### General Approach to Treatment

**KEY CONCEPT** *Treatment of obesity includes comprehensive lifestyle intervention (caloric restricted diet, increased physical activity, and behavioral therapy to facilitate compliance with diet and exercise), pharmacologic treatment, surgical intervention, or a combination of modalities.* Before initiating therapy, secondary causes of obesity (eg, hypothyroidism and Cushing syndrome) must be considered. Current treatment with medications that negatively alter weight should be determined and, if present, alternative therapies should be suggested.[17,18] Table 102–4 provides a list of drugs commonly associated with weight gain. If no secondary cause exists, the presence of other cardiovascular risk factors and

---

### Patient Encounter 1, Part 1

A 54-year-old woman presents to your weight loss clinic for an initial evaluation. She reports that her glucose was elevated upon screening while attending a community health fair. She followed up with her primary care provider who recommended weight loss as patient is unwilling to start metformin. She is not currently following any specific diet. She admits to eating foods high in sugar content, especially for breakfast. She routinely skips lunch and then snacks on potato chips, nuts, and sweetened beverages in the late afternoon. She frequently eats fast food for dinner as it is quick and requires no clean-up. Patient is recently divorced (1 year ago) and doesn't enjoy making dinner for one. This patient is not currently exercising but has adhered to a daily walking regimen in the past. The patient does not smoke or consume alcohol. Her BMI is 30.8 kg/m² and her waist circumference is 39 in (99 cm).

*What classification of overweight and obesity is appropriate for this patient?*

*Does this patient have a high-risk waist circumference?*

*Does she have other risk factors that may contribute to morbidity or mortality?*

*What are the treatment goals for the patient?*

*What additional information do you need to know before creating a treatment plan for this patient?*

---

| Table 102–4 |

| **Drugs Contributing to Weight Gain** |

Anticonvulsants/mood stabilizers
    Carbamazepine
    Gabapentin
    Pregabalin
    Valproic acid
    Lithium
Antidepressants
    Monoamine oxidase inhibitors (phenelzine)
    Presynaptic $\alpha_2$ antagonist (mirtazapine)
    Selective serotonin reuptake inhibitors (citalopram, escitalopram, fluvoxamine)
    Serotonin and norepinephrine reuptake inhibitors (duloxetine)
    Tricyclics (amitriptyline, imipramine)
Antidiabetics
    Insulin
    Meglintinides
    Sulfonylureas (glipizide, glyburide)
    Thiazolidinediones
Antipsychotics
    Atypical (clozapine, olanzapine, paliperidone, quetiapine, risperidone, ziprasidone)
    Conventional (haloperidol)
Others
    Antihistamines
    Corticosteroids
    Hormonal Contraceptives (depot injections)

Data from Refs. 17 and 18.

comorbidities must be determined to guide clinical decisions. Therapy implemented to minimize associated risk(s) may not enhance weight loss, but weight loss will positively address risk factors. Weight loss therapy should not be initiated in pregnant or lactating patients, decompensated psychiatric patients, or patients in whom reduced caloric intake can exacerbate an acute, serious illness.[2]

Four stages have been suggested for the treatment of obesity in children and adolescents. Stage 1 or Prevention Plus is the first step and includes adherence to healthy eating and activity habits. Patients should be encouraged to eat more than or equal to five servings of fruits and vegetables daily, limit consumption of sweetened drinks, decrease television or other screen time behaviors, and increase physical activity to greater than or equal to 1 hour/day. Stage 2 or Structured Weight Management incorporates Prevention Plus habits while setting specific eating and activity goals. Responsibilities include meal planning, observed physical activity or play daily for 1 hour, and documentation of energy consumption and expenditure. Comprehensive Multidisciplinary Interventions (Stage 3) is directed at increasing the intensity of healthy behaviors. To accomplish goals, the child or adolescent should work closely with the primary care provider, registered dietician, exercise specialist, and behavioral counselor. Stage 4, Tertiary Care Intervention, may be needed for severely obese adolescents. A very low-calorie diet, medication or weight control surgery may be warranted.[15]

## Nonpharmacologic Therapy

Given that the imbalance between energy intake and energy expenditure is key factor for developing overweight and obesity, weight loss therapy requires the creation of an energy deficit. This may be achieved through daily caloric restriction and increased physical activity. Both therapeutic strategies are part of a comprehensive lifestyle intervention program as well as behavioral therapy to facilitate compliance diet and exercise. Comprehensive lifestyle intervention is foundational to weight loss and should be recommended for patients who have never participated in such a program. In addition, a comprehensive lifestyle intervention program is recommended for patients even when adjunctive therapy with medications or bariatric surgery have been implemented.[14]

### ▶ Reduced-Calorie Diet

Overall energy consumption and expenditure will determine the amount of weight alteration. Techniques to reduce dietary energy intake include adoption of a target energy intake less than that required for energy balance. This can usually be accomplished by reducing the energy intake by 500 kcal/day (2093 kJ/day) or greater. Recommend 1200–1500 or 1500–1800 kcals/day (5023–6279 or 6279–7534 kJ/day) for women and men, respectively. The choice of calorie-restricted diet is based on patient preference and current health status. A variety of diets, including but not limited to high protein, low carbohydrate, low fat, Mediterranean and American Heart Association (AHA) Step-1 diet, can result in weight loss if reduction in dietary intake is achieved.[14] The AHA Step-1 diet restricts daily calories to a range of 1000 to 1200 kcal (4186–5023 kJ/day) for women weighing less than 75 kg (165 lb) and 1400 to 1600 kcal (5860–6697 kJ/day) for all others. This daily limit should be considered after assessing a patient's normal daily caloric intake and ensuring that the initial caloric restriction does not exceed 500 to 1000 kcal (2093–4186 kJ/day). For example, a male patient who consumes 3000 kcal (12,557 kJ/day) should not reduce his daily

caloric intake to less than 2000 kcal (8372 kJ/day) when initially implementing a dietary program. Further reduction to the target of 1600 kcal (6697 kJ/day) can be attempted when the patient has reduced calories successfully as initially recommended for a period agreeable by the practitioner and the patient.[2] Diets that are too restrictive in calorie reduction are successful initially but fail in the long term because compliance is difficult to sustain.[19] Therefore, this less aggressive approach promotes gradual weight loss and weight maintenance. Consultation with a dietician is recommended when implementing a healthy meal plan tailored to the individual's nutritional needs.

### ▶ Increased Physical Activity

Although diet and exercise contribute to weight loss, combining a reduced-calorie diet with increased physical activity results in greater weight loss compared with either therapy alone.[20] In addition, physical activity can help prevent weight regain and reduce related cardiovascular risks.[14] Slow titration of both the amount and intensity of aerobic physical activity is recommended for most patients.[2] A program that incorporates brisk walking daily is a viable option for most patients (Table 102–5). Suggest 10 minutes of physical activity 3 days/week with a target of no less than 30 minutes most days, if not every day.[2,14] Two hundred to 300 minutes per week of aerobic physical activity are recommended for weight maintenance or prevention of weight regain.[14]

### ▶ Behavioral

Nonadherence with recommended lifestyle changes may result in unsuccessful weight loss for adults.[14,20] Eliminating barriers through behavior modification is necessary to gain maximal benefit from both dietary modification and exercise. Successful behavioral therapy includes regular self-monitoring of food intake, physical activity, and weight.[14]

Targeted behaviors should be recommended to pediatric patients and their families because healthy habits help prevent excessive weight gain. These include, but are not limited to[15,16]:

- Limit the consumption of sugar-sweetened beverages.
- Limit the amount of screen time (television, computer, etc) to 2 hours or less per day.

### Table 102–5

**Summary of Approved Long-Term Pharmacologic Weight-Loss Agents**

| Drug | Class | Daily Dose (mg) |
|---|---|---|
| Orlistat[a] | Lipase inhibitor | 360 |
| Lorcaserin[b] | Serotonin 2C agonist | 20 |
| Phentermine-Topiramate[c] | Noradrenergic agent-antiepileptic | 15/92 |
| Naltrexone-Bupropion[d] | Opioid antagonist-antidepressant | 8/90 |

[a]Efficacy and safety have not been determined beyond 4 years of use.

[b]Efficacy and safety have not been determined beyond 2 years of use.

[c]Efficacy and safety have not been determined beyond 1 years of use.

[d]Efficacy and safety have not been determined beyond 56 weeks of use.

Data from Refs. 23, 28, 30, and 31.

- Limit the number meals eaten at restaurants, especially those serving fast food.
- Parents should limit portion size when preparing and serving meals.

## Pharmacologic Therapy

KEY CONCEPT *Pharmacotherapy in addition to comprehensive lifestyle intervention can be considered for patients with a BMI of 30 kg/m² or greater, or a BMI of 27 kg/m² or greater with other obesity-related risk factors*. Pharmacologic products promoting weight loss are classified according to their mechanisms of action, including the suppression of appetite and the suppression of fat absorption. Pharmacotherapy was indicated previously for short-term use; however, because obesity-related risks resurface with weight regain, long-term treatment may be necessary to minimize these sequelae. KEY CONCEPT *Weight will likely be regained if lifestyle changes are not continued indefinitely*. Four drugs are currently approved for long-term use in promoting weight loss and preventing weight regain.

### ▶ Orlistat

Orlistat promotes and maintains weight loss by acting locally in the GI tract. It inhibits pancreatic and gastric lipases, as well as triglyceride hydrolysis. As a result, undigested triglycerides are not absorbed, causing a caloric deficit and weight loss.[21]

Several studies have reported significant weight loss for adult patients receiving orlistat 120 mg three times a day compared with placebo.[22,23] Weight maintenance or prevention of weight regain has also been documented with continued orlistat use.[22,24]

Orlistat (120 mg three times daily) in combination with diet, exercise, and behavior modification resulted in a significant reduction in BMI and WC in adolescents. In addition, orlistat-treated subjects exhibited minimal weight increase after 1 year.[25]

The safety and efficacy of orlistat have not been determined beyond 4 years of use. Because orlistat acts locally in the GI tract, common side effects reported include oily spotting, flatus with discharge, fecal urgency, fatty or oily stools, oily evacuation, increased defecation, and fecal incontinence.[21] Other adverse events include bloating, abdominal pain, dyspepsia, nausea, vomiting, diarrhea, and headache.[26] Liver injury information is contained within orlistat's product label and includes signs, symptoms, and when to seek medical attention for severe liver disease. Signs and symptoms include itching, yellowing of the eyes or skin, dark urine, decreased appetite and light-colored stools. Orlistat should be stopped if the patient complains of these signs and symptoms. In addition, liver function tests, including aspartate transaminase (AST) and alanine aminotransferase (ALT), should be assessed.[27]

Orlistat reduces the absorption of some fat-soluble vitamins and β-carotene. Daily intake of a multivitamin containing fat-soluble vitamins, as well as β-carotene, is recommended. Patients should take the multivitamin 2 hours before or after the dose of orlistat.[21] Because the availability of vitamin K may decline in patients receiving orlistat therapy, close monitoring of coagulation status should occur with concomitant administration of warfarin.[21] Hypothyroidism has been observed in patients taking both orlistat and levothyroxine. Patients should take levothyroxine 4 hours before or after the orlistat dose and be monitored for changes in thyroid function. Administration of orlistat in conjunction with cyclosporine can result in decreased cyclosporine plasma levels. To avoid this interaction, cyclosporine should be taken 2 hours before or after the dose of orlistat. Additionally, cyclosporine levels should be monitored more frequently.[21]

Pregnant or lactating women should not take orlistat because no data exist to establish safety. Orlistat is contraindicated in patients with chronic malabsorption syndrome or cholestasis.[21]

Initiate orlistat 120 mg three times a day with a well-balanced but reduced-caloric meal containing no more than 30% of calories from fat. Orlistat may be taken during or up to 1 hour after the meal. If a meal is missed or contains little fat, the dose of orlistat may be omitted. Doses above 360 mg/day provide no greater benefit and thus are not recommended.[21]

### ▶ Lorcaserin

Lorcaserin, a 5-HT$_{2C}$ agonist, promotes satiety and decreases food consumption; however, the exact mechanism is unknown. The safety and effectiveness of lorcaserin has been established in adults, however, no data exists for patients under the age of 18; therefore, pediatric use is not recommended.[28,29]

Common adverse reaction noted in the trials include headache, dizziness, fatigue, nausea, dry mouth, and constipation. Almost 30% of diabetic patients taking lorcaserin experienced hypoglycemia. Blood glucose should be monitored closely in patients taking an antidiabetic medication and lorcaserin.[28]

Because lorcaserin is a serotonergic drug, serotonin syndrome may occur if taken with other drugs affecting the serotonergic neurotransmitter systems including triptans, monoamine oxidase inhibitors (MAOI), selective serotonin reuptake inhibitors, serotonin-norepinephrine reuptake inhibitors, tricyclic antidepressants, bupropion, lithium, antipsychotics, St. John's wort, tryptophan, and dextromethorphan. If serotonin syndrome symptoms occur (agitation, hallucinations, tachycardia, hyperthermia, muscle rigidity, nausea/vomiting and diarrhea), discontinue lorcaserin immediately and initiate supportive care.[28]

Lorcaserin is contraindicated during pregnancy (Pregnancy Category X). Because it is unknown whether lorcaserin is excreted in human milk, the nursing mothers should avoid use while nursing or decide not to nurse.[28]

Initiate lorcaserin 10 mg twice daily in addition to a calorie-restricted diet and increased physical activity. The drug should be discontinued if the patient has not achieved a 5% weight loss by week 12 of treatment. Doses greater than 20 mg daily are not recommended and may result in the development of euphoria, altered mood, and hallucinations. Due to the potential for psychic dependence and abuse, lorcaserin is a federally controlled substance (CIV).[28]

### ▶ Phentermine-topiramate

Phentermine-topiramate is an extended-release combination product approved for weight loss. Phentermine decreases food intake by increasing norepinephrine and dopamine release in the central nervous system (CNS). Topiramate is an antiepileptic drug whose exact mechanism of action is unknown. It is thought to increase satiety and suppress appetite through multiple pathways.[30]

The safety and effectiveness of phentermine-topiramate have not been established in pediatric patients; therefore, its use is not recommended.[30]

Common adverse reactions include paresthesias, dizziness, dysgeusia, insomnia, constipation, and dry mouth. Phentermine-topiramate use is associated with increased heart rate. Monitor resting heart rate frequently and have patients report the presence of palpitations. Topiramate can increase a patient's risk for suicidal thoughts and behaviors. Patients should be monitored for worsening depression, thoughts of suicide, and unusual mood or behavior. Topiramate is also associated with acute myopia and secondary angle closure glaucoma. Patients should

report decreased visual acuity and/or ocular pain. Phentermine-topiramate can cause mood disorders (depression and anxiety) and insomnia. Most resolve spontaneously but dose reduction or discontinuation of drug may be necessary. Cognitive impairment is also associated with use of phentermine-topiramate; patients should proceed with caution when operating hazardous machinery including driving a car until the extent of impairment is known. An increase in serum creatinine and decrease in both potassium and bicarbonate have been reported. Monitoring of serum electrolytes and creatinine are recommended at baseline and during therapy.[30]

Because topiramate is a known teratogen, use of phentermine-topiramate during pregnancy is contraindicated. All women of childbearing potential should have a documented negative pregnancy result before this drug is initiated and monthly while on therapy. Phentermine-topiramate may be excreted in human milk; nursing mothers should avoid use or discontinue nursing.[30]

Coadministration of phentermine-topiramate and MAOI could result in a hypertensive crisis. Do not initiate phentermine-topiramate within 14 days of MAOI discontinuation. Phentermine-topiramate used in patients taking an oral contraceptive may cause irregular bleeding but not an increased risk of pregnancy. Advise patients to not discontinue the oral contraceptives if spotting occurs. Alcohol can potentiate the CNS depressant effect; avoid concomitant use.[30]

Initiate phentermine-topiramate at a dose of 3.75 mg/23 mg daily for 14 days then increase to 7.5 mg/46 mg daily. Discontinue drug or increase the dose of phentermine-topiramate if a 3% weight loss is not achieved in 12 weeks. If the decision is made to increase the dose, recommend 11.25 mg/69 mg daily for 14 days then increase to 15 mg/92 mg daily. Discontinue drug if a 5% weight loss is not achieved after 12 weeks at the highest drug dose. Due to the potential for drug abuse, phentermine-topiramate is a federally controlled substance (CIV).[30]

### ▶ Naltrexone-Bupropion

Naltrexone-bupropion is an extended-release combination product approved for chronic weight management. The exact mechanisms by which this opioid antagonist/antidepressant combination product decreases food intake and weight are not fully known but involve two separate areas of the brain (hypothalamus and mesolimbic dopamine circuit).[31]

The safety and effectiveness of naltrexone-bupropion have not been established in patients less than 18 years; therefore, its use is not recommended.[31]

Patients taking this combination weight loss product should be monitored for emergence or worsening of suicidal thoughts and behaviors and neuropsychiatric reactions. Common adverse reactions include nausea, constipation, headache, vomiting, dizziness, and insomnia. This combination product is contraindicated in patients with elevated blood pressure, seizure disorders or in patients taking antiepileptics, in patients taking chronic opioids and in patients taking MAOI or discontinued MAOI use within 14 days. Bupropion inhibits CYP2D6 and can therefore increase the concentration of antidepressants, antipsychotics and β-blockers. When taken with a CYP2B6 inhibitor (eg, clopidogrel), the concentration of bupropion increases. Reduce maximum daily dose by half in these patients. CYP2B6 inducers may reduce bupropion efficacy.[31]

Naltrexone-bupropion is contraindicated during pregnancy as weight loss offers no benefit during pregnancy and potential for fetal harm (Pregnancy Category X). This drug is not recommended for nursing mothers.[31]

Each extended-release tablet contains 8 mg of naltrexone and 90 mg of bupropion. Patients should be advised to not cut, crush, or chew tablets. Patients should also avoid taking naltrexone-bupropion with high-fat meals to minimize the risk of enhanced bupropion absorption and subsequent seizure occurrence. To further reduce the risk of seizures, the dose must be titrated slowly. Initiate drug at one tablet every morning for 1 week, then one tablet twice daily (morning and evening) for 1 week, then two tablets in the morning and one tablet in the evening for 1 more week and then two tablets twice a day thereafter. If the patient has not lost 5% of baseline body weight following 12 weeks of maintenance therapy, naltrexone-bupropion should be discontinued.[31]

### ▶ Phentermine

As monotherapy, this drug is indicated for short-term use—no more than a few weeks—in addition to lifestyle modifications.[32] An average weight loss of 3.6 kg (7.9 lb) was demonstrated for patients treated with phentermine compared with placebo.[26]

Safety and efficacy have not been determined in pediatric patients less than 16 years of age.[32]

Common adverse reactions seen with phentermine use include heart palpitations, tachycardia, elevated blood pressure, stimulation, restlessness, dizziness, insomnia, euphoria, dysphoria, tremor, headache, dry mouth, constipation, and diarrhea. Phentermine should be avoided in patients with CVD, hypertension, hyperthyroidism and agitated states. Because phentermine is related to the amphetamines, the potential for abuse is high.[32]

Phentermine use should be avoided in patients concomitantly receiving or having received a MAOI within the preceding 14 days due to the potential for causing hypertensive crisis. Alcohol is not recommended for patients prescribed phentermine.[32]

The use of phentermine is contraindicated in pregnant patients as weight loss offers no benefit during pregnancy and risk of fetal harm (Pregnancy Category X). Owing to the potential for severe adverse effects in nursing infants, a decision to stop the drug or discontinue nursing must be made.[32]

Phentermine is available as an immediate- and a sustained-release product. In conjunction with a healthy lifestyle, 30 to 37.5 mg of phentermine is administered once daily, typically before breakfast or 1 to 2 hours after the morning meal. The dosage should be individualized; some patients may be managed adequately at 15 to 18.75 mg/day, but a dose of 18.75 mg twice daily may be used to minimize side effects, excluding insomnia. To lessen the risk of insomnia, dosing phentermine in the evening should be avoided.[32]

### ▶ Diethylpropion

This sympathomimetic amine exhibits similar pharmacologic activity as the amphetamines, resulting in CNS stimulation and appetite suppression and is indicated for short-term use in conjunction with a reduced-calorie diet and physical exercise.[33] The safety and effectiveness of diethylpropion have not been established in patients younger than 16 years; therefore, its use is not recommended.[33]

Use of diethylpropion for a period longer than 3 months is associated with an increased risk for development of pulmonary hypertension. When used as directed, reported common CNS adverse effects included overstimulation, restlessness, dizziness, insomnia, euphoria, dysphoria, tremor, headache, jitteriness, anxiety, nervousness, depression, drowsiness, malaise, mydriasis, and blurred vision. In addition, diethylpropion can decrease

the seizure threshold. Other organ systems also can adversely be affected, resulting in tachycardia, elevated blood pressure, palpitations, dry mouth, abdominal discomfort, and constipation. Diethylpropion is contraindicated in patients with pulmonary hypertension, advanced arteriosclerosis, severe hypertension, hyperthyroidism, agitated states, or glaucoma. Because diethylpropion is related to the amphetamines, the potential for abuse is high.[33]

Use of diethylpropion should be avoided in patients receiving or having received an MAOI within the preceding 14 days to prevent hypertensive crisis. Combination with other anorectic agents should be avoided.[33]

No adequate studies have been conducted using diethylpropion in pregnant women; therefore, the drug should be used only if the benefit outweighs potential fetal risk. Use with caution in nursing mothers because the drug is excreted in breast milk.[33]

Diethylpropion is available as both an immediate- and a controlled-release product. In conjunction with a reduced-calorie diet and/or exercise, dose diethylpropion (immediate release) 25 mg three times a day before meals or 75 mg (controlled release) once a day, usually midmorning.[33]

### ▶ Phendimetrazine

Phendimetrazine's activity is similar to amphetamine. It suppresses appetite through stimulation of the CNS. Studies to determine efficacy were conducted over a few weeks and therefore

---

long-term use is not indicated. Use in pregnancy has not been established; phendimetrazine should not be taken by women who are or may become pregnant. Phendimetrazine is not recommended for use in children younger than 12 years.[34]

Common adverse reactions observed in studies include heart palpitation, tachycardia, elevated blood pressure, overstimulation, restlessness, insomnia, agitation, dizziness, headache, psychotic state, blurred vision, mouth dryness, nausea, diarrhea, and constipation. Contraindications for use include advanced arteriosclerosis, symptomatic CVD, hypertension, hyperthyroidism, and glaucoma. Phendimetrazine is not recommended for patients taking other CNS stimulants including MAOI.[34]

If use is warranted, dose phendimetrazine (105 mg) in the morning, 30 to 60 minutes before the morning meal. Phendimetrazine is a federally controlled substance (CIII).[34]

### ▶ Surgical Intervention

**KEY CONCEPT** *Weight loss (bariatric) surgery is warranted when other treatment attempts have failed in severely obese patients (BMI of 40 kg/m² or greater, or 35 kg/m² or greater with obesity-related comorbidities).*[2,35] Several surgical techniques exist, however three are currently recognized as contemporary procedures: **gastric bypass**, which induces weight loss through both malabsorptive and restrictive mechanisms, **sleeve gastrectomy** and **laparoscopic adjustable gastric banding (LAGB)**, which achieves weight loss through restriction of food intake only.[2,35]

Surgical options for obesity may produce a loss of two-thirds of excessive weight after 2 years that is sustained long term.[2] Additionally, favorable outcomes for obesity-related comorbid conditions are observed after surgery. When evaluating the various types of surgery available, long-term data suggests the average weight loss from gastric bypass after 15 years is 27%, which is significantly higher than banding (around 14%) and conventional therapy (2%).[36] Risk versus benefit must be considered as complications are inherent to any surgical procedure. The more common bariatric surgery complications are respiratory problems, wound formation, wound infections, hernia development, deep venous thrombosis, and pulmonary embolism. No differences were observed in mortality rates among various surgical procedures. Postoperative weight loss is much greater compared with pharmacologic therapies, but no comparative trials exist.[37]

Bariatric surgery is an alternative offered to adolescents because it results in substantial weight loss and medical health improvement, but also has the potential for serious complications.[38] Patients with a BMI greater than or equal to 40 kg/m² and an associated medical condition or BMI greater than or equal to 50 kg/m² at or after the age of 13 and 15 years for girls and boys, respectively; display emotional and cognitive maturity; and have implemented a behavioral-based weight-loss program are candidates for surgery.[16]

All patients undergoing bariatric surgery should be part of a comprehensive program of health education, diet, exercise, and behavioral modification before and after surgery.[2] Patients must understand and commit to a substantial change in eating patterns to maintain long-term weight reduction.[16,37]

Postoperatively, health care providers should also make considerations for medication management as these procedures may alter drug and nutrient absorption.[39]

- Medications should be transitioned to crushed or liquid formulations initially and until appropriate to restart solid dosage forms (likely variable).

---

## Patient Encounter 1, Part 2: Medical History, Physical Exam, and Diagnostic Tests

**PMH:** Occasional lower back pain, occasional heartburn

**FH:** Father alive and 68 years of age. Mother also alive (age 65) with history of obesity

**SH:** (–) Tobacco, (–) alcohol

**Meds:** Ibuprofen 400 mg orally as needed, ranitidine 75 mg orally as needed

**ROS:** (+) Heartburn; (–) chest pain, nausea, vomiting, diarrhea, change in appetite, shortness of breath, or cough

**PE:**

**VS:** BP 120/84 mmHg, P 72 beats/min, RR 16 respirations/min, T 98.6° F (37.0°C), Wt 174 lb (79 kg), Ht 63 in (160 cm)

**Waist Circumference:** 39 in (99 cm)

**CV:** Normal $S_1S_2$; no murmurs, rubs, gallops

**Abd:** Obese, soft, nontender, nondistended; (+) bowel sounds

**Ext:** (–) Edema

**Labs:** All values are within normal limits except glucose (118 mg/dL [6.5 mmol/L]) and HgbA$_{1C}$ (6.0% [0.06 or 42 mmol/mol Hgb])

**ECG:** No evidence of past ischemia

*Given this additional information, do you recommend weight loss? If so, how much weight should the patient lose and how fast?*

*What nonpharmacologic and pharmacologic alternatives are available for the patient?*

- Certain medications should be avoided or used with caution (eg, NSAIDs, extended- or delayed-release products, oral bisphosphonates).
- Certain medications may be indicated (eg, fat soluble vitamins, iron, vitamin $B_{12}$).
- Alternative routes of administration may be considered.

## OUTCOME EVALUATION

Successful management of overweight and obesity is determined by the ability the treatment plan has to (a) prevent weight gain, (b) reduce and maintain a lower body weight, and (c) decrease the risk of obesity-related comorbidities. Because weight is necessary to calculate the BMI, measure the patient's weight and WC. Obesity management may encompass more than weight loss or maintenance in the presence of other conditions; assess other pertinent parameters at baseline. This includes presence of hypertension, type 2 diabetes mellitus, hyperlipidemia, CVD, sleep apnea, hypothyroidism, osteoarthritis, gallbladder disease, gout, or cancer. Measure blood pressure and heart rate before implementation of any therapy, and assess basic metabolic panel, liver function tests, complete blood count, fasting lipid profile, full thyroid function tests, and other laboratory studies at baseline and as clinically indicated. Additionally, obtain an electrocardiogram if recent results are unknown.[2]

When considering various approaches to behavioral therapy for weight loss, in-person, high-intensity (defined as a minimum of 14 sessions within 6 months) behavioral therapy is the most effective. Sessions can be conducted by a pharmacist or **trained interventionist** for an individual or groups of patients. During each session, assess compliance with comprehensive lifestyle intervention, as well as measure weight, blood pressure, and heart rate. Measure WC intermittently. Identify presence of adverse drug reactions or drug interactions if weight loss medications have been initiated.[2,14]

### Patient Encounter 2, Part 1

A 44-year-old white man presents to your CVD Risk Reduction Clinic. The patient currently denies chest pain, shortness of breath, dizziness, and lightheadedness. Upon review of previous progress notes, you discover that the patient's blood pressure has been elevated during the past three office visits. As a computer programmer, he finds himself sitting more than engaging in physical activity. He frequently eats fast food for lunch because the other guys in the office like to eat out. Evenings are spent watching TV and eating ice cream. The patient's BMI is 37.9 kg/m², and his waist circumference is 47 in (119 cm).

*What classification of overweight and obesity is appropriate for this patient?*

*Does this patient have a high-risk waist circumference?*

*Does he have other risk factors that may contribute to morbidity or mortality?*

*What are the treatment goals for the patient?*

*What additional information do you need to know before creating a treatment plan for this patient?*

### Patient Encounter 2, Part 2: Medical History, Physical Exam, and Diagnostic Tests

**PMH:** Occasional headache

**FH:** Father alive and 78 years of age. Mother also alive and 77 years of age

**SH:** Drinks alcohol most days (socially) but denies any alcohol-related problems

**Meds:** None

**ROS:** (–) Heartburn, regurgitation; (–) chest pain, nausea, vomiting, diarrhea, change in appetite, shortness of breath, or cough

**VS:** BP 154/92 mmHg, P 92 beats/min, RR 15 respirations/min, T 98.7°F (37.1°C), Wt 228 lb (103.4 kg), Ht 65 in (165 cm)

**Waist Circumference:** 47 in (119 cm)

**10-year CVD Risk:** 5.3%

**PE:**

**General:** Well developed, in no acute distress

**HEENT:** Conjunctiva clear

**CV:** Regular rhythm, no $S_3$ or $S_4$ noted

**Lungs:** Clear to auscultation (CTA) bilaterally

**Abd:** Obese, soft, nontender, nondistended; (+) bowel sounds

**Neuro:** Normal gait, normal speech

**Ext:** (–) Edema

**Labs:** Na 142 mEq/L (142 mmol/L); K 4.6 mEq/L (4.6 mmol/L); Cl 107 mEq/L (107 mmol/L); $CO_2$ 23 mEq/L (23 mmol/L); BUN 18 mg/dL (6.4 mmol/L); creatinine 0.9 mg/dL (80 μmol/L); glucose 72 mg/dL (4.0 mmol/L); TC 213 mg/dL (5.51 mmol/L); LDL 153 mg/dL (3.96 mmol/L); HDL 30 mg/dL (0.78 mmol/L); TG 152 mg/dL (1.72 mmol/L); AST 24 U/L (0.40 μkat/L); ALT 30 U/L (0.50 μkat/L)

*Given this additional information, do you recommend weight loss? If so, how much weight should the patient lose and how fast?*

*What nonpharmacologic and pharmacologic options are available for the patient?*

When the patient has achieved the recommended weight loss, he or she then enters the weight maintenance phase, which includes continued contact for education (no less than monthly), guidance, and risk factor assessment. Self-weighing, at least weekly, is associated with better weight maintenance over time. Counsel patient to address small weight gains before they become larger.[14]

If weight loss is not attained, further assess why the goals of therapy are unmet. Direct the interaction toward determining the motivation to lose weight, balance between caloric intake and physical activity, adherence to behavioral therapy, and determination of psychological stressors present.[2] Refer patient to a nutrition professional or for evaluation for bariatric surgery. If adjunctive pharmacotherapy has not been initiated, consider antiobesity drugs approved for long-term use.[2,14]

## Patient Encounter 2, Part 3: CVD Risk Reduction 12-Week Follow-up Clinic Visit

The patient present for his 12-week follow-up visit in the CVD Risk Reduction Clinic. He states that he has been adhering to the Step-1 diet and currently jogs on a treadmill 30 minutes a day 2 days a week.

**SH:** Continues to drink three to four beers nightly

**Meds:** Lisinopril 10 mg orally every morning

**ROS:** (–) Heartburn, regurgitation; (–) chest pain, nausea, vomiting, diarrhea, change in appetite, shortness of breath, or cough

**VS:** BP 126/74 mmHg, P 84 beats/min, RR 16 breaths/min, T 98.5°F (36.9°C), Wt 221 lb (100.2 kg), Ht 65 in (165 cm)

**Waist Circumference:** 45 in (114)

**PE:**

**General:** Well developed, in no acute distress

**HEENT:** Conjunctiva clear

**CV:** Regular rhythm, no $S_3$ or $S_4$ noted

**Lungs:** CTA bilaterally

**Abd:** Obese, soft, nontender, nondistended; (+) bowel sounds

**Neuro:** Normal gait, normal speech

**Ext:** (–) Edema

**Labs:** Na 142 mEq/L (142 mmol/L); K 4.7 mEq/L (4.7 mmol/L); Cl 107 mEq/L (107 mmol/L); $CO_2$ 23 mEq/L (23 mmol/L); BUN 18 mg/dL (6.4 mmol/L); creatinine 1.0 mg/dL (88 μmol/L); glucose 84 mg/dL (4.7 mmol/L); TC 218 mg/dL (5.64 mmol/L); LDL 155 mg/dL (4.01 mmol/L); HDL 34 mg/dL (0.88 mmol/L); TG 145 mg/dL (1.64 mmol/L); AST 20 U/L (33 μkat/L); ALT 32 U/L (0.53 μkat/L)

*Calculate the patient's BMI.*

*What is the best weight loss option for the patient?*

## Patient Care Process

**Patient Assessment:**

- Measure weight and height.
- Calculate BMI.
- Classify BMI to identify patients at increased risk for CVD/other obesity-related conditions.
- Review medical history for secondary causes of weight gain.
- Conduct a medication history to identify drug therapy contributing to weight gain.
- Review laboratory data to identify secondary causes of weight gain, identify CVD risks and obesity-related comorbidities and to ensure safe use of medication.
- Assess current lifestyle and history of weight gain/loss over time.
- Assess need to lose weight (candidates include obese patients or overweight patients with at least one indicator of increased CVD risk:
  - Elevated WC, prediabetes or diabetes, hypertension, dyslipidemia, current cigarette smoker
- Assess readiness to make lifestyle changes.
- Determine weight loss goals.

**Therapy Evaluation:**

- Implement comprehensive lifestyle intervention strategies (restricted caloric-diet, increased physical activity, and behavioral therapy) with or without adjunctive therapies.

- If patient is already receiving an antiobesity medication, assess efficacy, safety, adherence, and potential drug interactions.
- Manage CVD risk factors such as hypertension, dyslipidemia, etc.

**Care Plan Development:**

- Implement comprehensive lifestyle intervention. If antiobesity drug is warranted, choose a medication for chronic obesity management that is deemed safe based on patient-specific parameters.
- Educate the patient regarding a comprehensive lifestyle intervention program, one that includes a balance between caloric intake and energy expenditure as well as suggest methods to modify behavior.
- Encourage self-weighing, at least weekly, for better weight loss and maintenance over time.

**Follow-Up Evaluation:**

- In 2 weeks, assess weight, blood pressure, heart rate, and adherence with comprehensive lifestyle intervention. Assess weight log.
- Patients should be reassessed in person no less than 14 times within a 6-month period.
- Once weight loss is achieved, continue contact with patient no less than monthly. Address small weight gains and continued adherence with comprehensive lifestyle intervention. Continually assess risk for CVD and address when necessary.

# Abbreviations Introduced in This Chapter

| | |
|---|---|
| ALT | Alanine aminotransferase |
| AST | Aspartate transaminase |
| BMI | Body mass index |
| $CB_1$ | Cannabinoid receptor |
| CNS | Central nervous system |
| CVD | Cardiovascular disease |
| D1 | Dopamine 1 |
| D2 | Dopamine 2 |
| GI | Gastrointestinal |
| $5\text{-}HT_{1A}$ | Serotonin 1A subtype |
| $H_1$ | Histamine subtype 1 |
| $H_3$ | Histamine subtype 3 |
| $5\text{-}HT_{2C}$ | Serotonin 2C subtype |
| MAOI | Monoamine oxidase inhibitor |

# Appendix A: Conversion Factors and Anthropometrics*

## CONVERSION FACTORS

### SI Units

SI (*le Systéme International d'Unités*) units are used in many countries to express clinical laboratory and serum drug concentration data. Instead of using units of mass (eg, micrograms), the SI system uses moles (mol) to represent the amount of a substance. A molar solution contains 1 mole (the molecular weight of the substance in grams) of the solute in 1 L of solution. The following formula is used to convert units of mass to moles (mcg/mL to $\mu$mol/L or, by substitution of terms, mg/mL to mmol/L or ng/mL to nmol/L).

▶ *Micromoles per Liter*

Micromoles per liter ($\mu$mol/L)

$$= \frac{\text{drug concentration (mcg/mL)} \times 1000}{\text{molecular weight of drug (g/mol)}}$$

▶ *Milliequivalents*

An equivalent weight of a substance is the weight that will combine with or replace 1 g of hydrogen; a milliequivalent is 1/1000 of an equivalent weight.

**Milliequivalents per Liter**

Milliequivalents per liter (mEq/L)

$$= \frac{\text{weight of salt (g)} \times \text{valence of ion} \times 1000}{\text{molecular weight of salt}}$$

$$\text{Weight of salt (g)} = \frac{\text{mEq/L} \times \text{molecular weight of salt}}{\text{valence of ion} \times 1000}$$

### Approximate Milliequivalents: Weight Conversions for Selected Ions

| Salt | mEq/g Salt | mg Salt/ mEq |
|------|-----------|--------------|
| Calcium carbonate ($CaCO_3$) | 20.0 | 50.0 |
| Calcium chloride ($CaCl_2 \cdot 2H_2O$) | 13.6 | 73.5 |
| Calcium gluceptate ($Ca[C_7H_{13}O_8]_2$) | 4.1 | 245.2 |
| Calcium gluconate ($Ca[C_6H_{11}O_7]_2 \cdot H_2O$) | 4.5 | 224.1 |
| Calcium lactate ($Ca[C_3H_5O_3]_2 \cdot 5H_2O$) | 6.5 | 154.1 |
| Magnesium gluconate ($Mg[C_6H_{11}O_7]_2 \cdot H_2O$) | 4.6 | 216.3 |
| Magnesium oxide (MgO) | 49.6 | 20.2 |
| Magnesium sulfate ($MgSO_4$) | 16.6 | 60.2 |
| Magnesium sulfate ($MgSO_4 \cdot 7H_2O$) | 8.1 | 123.2 |
| Potassium acetate ($K[C_2H_3O_2]$) | 10.2 | 98.1 |
| Potassium chloride (KCl) | 13.4 | 74.6 |
| Potassium citrate ($K_3[C_6H_5O_7] \cdot H_2O$) | 9.2 | 108.1 |
| Potassium iodide (KI) | 6.0 | 166.0 |
| Sodium acetate ($Na[C_2H_3O_2]$) | 12.2 | 82.0 |
| Sodium acetate ($Na[C_2H_3O_2] \cdot 3H_2O$) | 7.3 | 136.1 |
| Sodium bicarbonate ($NaHCO_3$) | 11.9 | 84.0 |
| Sodium chloride (NaCl) | 17.1 | 58.4 |
| Sodium citrate ($Na_3[C_6H_5O_7] \cdot 2H_2O$) | 10.2 | 98.0 |
| Sodium iodide (NaI) | 6.7 | 149.9 |
| Sodium lactate ($Na[C_3H_5O_3]$) | 8.9 | 112.1 |
| Zinc sulfate ($ZnSO_4 \cdot 7H_2O$) | 7.0 | 143.8 |

### Valences and Atomic/Molecular Weights of Selected Ions

| Substance | Electrolyte | Valence | Atomic/ Molecular Weight |
|-----------|-------------|---------|--------------------------|
| Calcium | $Ca^{2+}$ | 2 | 40.1 |
| Chloride | $Cl^-$ | 1 | 35.5 |
| Magnesium | $Mg^{2+}$ | 2 | 24.3 |
| Phosphate | $HPO_4^{2-}$(80%) | 1.8 | 96.0[a] |
| (pH = 7.4) | $H_2PO_4^-$(20%) | | 97.0 |
| Potassium | $K^+$ | 1 | 39.1 |
| Sodium | $Na^+$ | 1 | 23.0 |
| Sulfate | $SO_4^-$ | 2 | 96.0[a] |

[a]The atomic/molecular weight of phosphorus is only 31; that of sulfur is only 32.1.

## Anion Gap

The anion gap is the concentration of plasma anions not routinely measured by laboratory screening. It is useful in the evaluation of acid–base disorders. The anion gap is greater with increased plasma concentrations of endogenous species (eg, phosphate, sulfate, lactate, and ketoacids) or exogenous species (eg, salicylate, penicillin, ethylene glycol, ethanol, and methanol). The formulas for calculating the anion gap are as follows:

$$\text{Anion gap} = (Na^+ + K^+) - (Cl^- + HCO_3^-)$$

or

$$\text{Anion gap} = Na^+ - (Cl^- + HCO_3^-)$$

where the expected normal value for the first equation is 11 to 20 mmol/L and for the second equation is 7 to 16 mmol/L. Note that there is a variation in the upper and lower limits of the normal range.

## Temperature

Fahrenheit to Centigrade: (°F – 32) × 5/9 = °C
Centigrade to Fahrenheit: (°C × 9/5) + 32 = °F
Centigrade to Kelvin: °C + 273 = °K

## Weights and Measures

### ► Metric Weight Equivalents

1 kilogram (kg) = 1000 grams
1 gram (g) = 1000 milligrams
1 milligram (mg) = 0.001 gram
1 microgram (mcg, μg) = 0.001 milligram
1 nanogram (ng) = 0.001 microgram
1 picogram (pg) = 0.001 nanogram
1 femtogram (fg) = 0.001 picogram

### ► Metric Volume Equivalents

1 liter (L) = 1000 milliliters
1 deciliter (dL) = 100 milliliters
1 milliliter (mL) = 0.001 liter
1 microliter (μL) = 0.001 milliliter
1 nanoliter (nL) = 0.001 microliter
1 picoliter (pL) = 0.001 nanoliter
1 femtoliter (fL) = 0.001 picoliter

### ► Apothecary Weight Equivalents

1 scruple (ᴐ) = 20 grains (gr)
60 grains (gr) = 1 dram (ℨ)
8 drams (ℨ) = 1 ounce (℥)
1 ounce (℥) = 480 grains (gr)
12 ounces (℥) = 1 pound (lb)

### ► Apothecary Volume Equivalents

60 minims (m) = 1 fluidram (fl ℨ)
8 fluidrams (fl ℨ) = 1 fluid ounce (fl ℥)
1 fluid ounce (fl ℥) = 480 minims (m)
16 fluid ounces (fl ℥) = 1 pint (pt)

### ► Avoirdupois Equivalents

1 ounce (oz) = 437.5 grains
16 ounces (oz) = 1 pound (lb)

### ► Weight/Volume Equivalents

1 mg/dL = 10 mcg/mL
1 mg/dL = 1 mg%
1 ppm = 1 mg/L

### ► Conversion Equivalents

1 gram (g) = 15.43 grains (gr)
1 grain (gr) = 64.8 milligrams (mg)
1 ounce (℥) = 31.1 grams (g)
1 ounce (oz) = 28.35 grams (g)
1 pound (lb) = 453.6 grams (g)
1 kilogram (kg) = 2.2 pounds (lb)
1 milliliter (mL) = 16.23 minims (m)
1 minim (m) = 0.06 milliliter (mL)
1 fluid ounce (fl oz) = 29.57 milliliters (mL)
1 pint (pt) = 473.2 milliliters (mL)
1 US gallon = 3.78 liters (L)
1 Canadian gallon = 4.55 liters (L)
0.1 milligram = 1/650 grain
0.12 milligram = 1/540 grain
0.15 milligram = 1/430 grain
0.2 milligram = 1/320 grain
0.3 milligram = 1/220 grain
0.4 milligram = 1/160 grain
0.5 milligram = 1/130 grain
0.6 milligram = 1/110 grain
0.8 milligram = 1/80 grain
1 milligram = 1/65 grain

### ► Metric Length Conversion Equivalents

2.54 cm = 1 inch
30.48 cm = 1 foot
1 m = 3.28 feet
1.6 km = 1 mile

## ANTHROPOMETRICS

## Creatinine Clearance Formulas

### ► Formulas for Estimating Creatinine Clearance in Patients with Stable Renal Function

**Cockcroft-Gault Formula**

Adults (age 18 years and older)[1]:

$$CrCl\,(men) = \frac{(140 - age) \times weight}{SCr \times 72}$$

$$CrCl\,(women) = 0.85 \times \text{above value}^*$$

*Some studies suggest that the predictive accuracy of this formula for women is better *without* the correction factor of 0.85.

where CrCl is creatinine clearance (in mL/min), SCr is serum creatinine (in mg/dL [or µmol/L divided by 88.4]), age is in years, and weight is in kilograms.

### Traub-Johnson Formula

Children (age 1–18 years)[2]:

$$CrCl = \frac{0.48 \times height \times BSA}{SCr \times 1.73}$$

where BSA is body surface area (in $m^2$), CrCl is creatinine clearance (in mL/min), SCr is serum creatinine (in mg/dL [or µmol/L divided by 88.4]), and height is in centimeters.

### ▶ *Formula for Estimating Creatinine Clearance From a Measured Urine Collection*

$$CrCl\,(mL/min) = \frac{U \times V}{P \times T}$$

where $U$ is the concentration of creatinine in a urine specimen in mg/dL, $V$ is the volume of urine in mL, $P$ is the concentration of creatinine in serum at the midpoint of the urine collection period in mg/dL, and $T$ is the time of the urine collection period in minutes (eg, 6 hours = 360 minutes; 24 hours = 1440 minutes). Procedures for obtaining urine specimens should stress the importance of complete urine collection during the collection time period.

### ▶ *IDMS-Traceable MDRD Equation (Used for Creatinine Methods with Calibration Traceable to IDMS)*

For creatinine in mg/dL:

$$X = 175 \times creatinine^{-1.154} \times age^{-0.203} \times constant$$

For creatinine in µmol/L:

$$X = 175 \times (creatinine/88.4)^{-1.154} \times age^{-0.203} \times constant$$

where $X$ is the glomerular filtration rate, constant for white men is 1 and for women is 0.742, and constant for African Americans is 1.212.

## Ideal Body Weight

IBW is the weight expected for a non-obese person of a given height. The IBW formulas below and various life insurance tables can be used to estimate IBW. Dosing methods described in the literature may use IBW as a method in dosing obese patients.

**Adults (age 18 years and older)[3]:**

IBW (men) = 50 + (2.3 × height in inches over 5 ft)

IBW (women) = 45.5 + (2.3 × height in inches over 5 ft)

where IBW is in kilograms.

**Children (age 1–18 years)[2] under 5-feet tall:**

$$IBW = \frac{height^2 \times 1.65}{1000}$$

where IBW is in kilograms and height is in centimeters.

**Children (age 1–18 years) 5 feet or taller:**

IBW (males) = 39 + (2.27 × height in inches over 5 ft)

IBW (females) = 42.2 + (2.27 × height in inches over 5 ft)

where IBW is in kilograms.

# Appendix B: Common Medical Abbreviations

These are the abbreviations used commonly in medical practice both in verbal communication and in the medical record.

| | |
|---|---|
| A&O | alert and oriented |
| A&O×3 | awake (or alert) and oriented to person, place, and time |
| A&O×4 | awake (or alert) and oriented to person, place, time, and situation |
| A&P | active and present; anterior and posterior; assessment and plans; auscultation and percussion |
| A&W | alive and well |
| A1c | hemoglobin A1c |
| AA | aplastic anemia; Alcoholics Anonymous |
| AAA | abdominal aortic aneurysm |
| AAO | awake, alert, and oriented |
| AAO×3 | awake and orientated to time, place, and person |
| ABC | absolute band counts; absolute basophil count; apnea, bradycardia, and cytology; aspiration, biopsy, and cytology; artificial beta cells |
| Abd | abdomen |
| ABG | arterial blood gases |
| ABO | blood group system (A, AB, B, and O) |
| ABP | arterial blood pressure |
| ABW | actual body weight |
| ABx | antibiotics |
| AC | before meals (*ante cibos*) |
| ACE | angiotensin-converting enzyme |
| ACE-I | angiotensin-converting enzyme inhibitor |
| ACLS | advanced cardiac life support |
| ACS | acute coronary syndromes |
| ACTH | adrenocorticotropic hormone |
| AD | Alzheimer disease; right ear (*auris dextra*) |
| ADA | American Diabetes Association; adenosine deaminase |
| ADE | adverse drug effect (or event) |
| ADH | antidiuretic hormone |
| ADHD | attention-deficit hyperactivity disorder |
| ADL | activities of daily living |
| ADR | adverse drug reaction |
| AF | atrial fibrillation |
| AFB | acid-fast bacillus; aortofemoral bypass; aspirated foreign body |
| AFEB | afebrile |
| AI | aortic insufficiency |
| AIDS | acquired immune deficiency syndrome |

| | |
|---|---|
| AKA | above-knee amputation; alcoholic ketoacidosis; all known allergies; also known as |
| AKI | acute kidney injury |
| ALFT | abnormal liver function test |
| ALL | acute lymphoblastic leukemia; acute lymphocytic leukemia |
| ALP | alkaline phosphatase |
| ALS | amyotrophic lateral sclerosis |
| ALT | alanine transaminase (SGPT); alanine aminotransferase |
| AMA | against medical advice; American Medical Association; antimitochondrial antibody |
| AMI | acute myocardial infarction |
| AML | acute myelogenous leukemia |
| Amp | ampule |
| ANA | antinuclear antibody |
| ANC | absolute neutrophil count |
| ANLL | acute nonlymphocytic leukemia |
| AODM | adult-onset diabetes mellitus |
| AOM | acute otitis media |
| AP | anteroposterior |
| APAP | acetaminophen (acetyl-*p*-aminophenol) |
| aPTT | activated partial thromboplastin time |
| ARB | angiotensin receptor blocker |
| ARC | AIDS-related complex |
| ARD | acute respiratory disease; adult respiratory disease; antibiotic removal device; aphakic retinal detachment |
| ARDS | adult respiratory distress syndrome |
| ARF | acute renal failure; acute respiratory failure; acute rheumatic fever |
| AROM | active range of motion |
| AS | left ear (*auris sinistra*) |
| ASA | aspirin (acetylsalicylic acid) |
| ASCVD | arteriosclerotic cardiovascular disease |
| ASD | atrial septal defect |
| ASH | asymmetric septal hypertrophy |
| ASHD | arteriosclerotic heart disease |
| AST | aspartate transaminase (SGOT); aspartate aminotransferase |
| ATG | antithymocyte globulin |
| ATN | acute tubular necrosis |
| AU | each ear (*auris uterque*) |
| AV | arteriovenous; atrioventricular; auditory visual |

| | | | |
|---|---|---|---|
| AVR | aortic valve replacement | C/O | complains of |
| BBB | bundle branch block; blood–brain barrier | CO | cardiac output; carbon monoxide |
| BC | blood culture | COLD | chronic obstructive lung disease |
| BCOP | Board Certified Oncology Pharmacist | COPD | chronic obstructive pulmonary disease |
| BCP | birth control pill | CP | chest pain; cerebral palsy |
| BCPP | Board Certified Psychiatric Pharmacist | CPAP | continuous positive airway pressure |
| BCPS | Board Certified Pharmacotherapy Specialist | CPK | creatine phosphokinase (BB, MB, and MM are isoenzymes) |
| BE | barium enema | | |
| BG | blood glucose | CPP | cerebral perfusion pressure |
| bid | twice daily (*bis in die*) | CPR | cardiopulmonary resuscitation |
| BKA | below-knee amputation | CrCl | creatinine clearance |
| BM | bone marrow; bowel movement; an isoenzyme of creatine phosphokinase | CRF | chronic renal failure; corticotropin-releasing factor |
| BMC | bone marrow cells | CRH | corticotropin-releasing hormone |
| BMD | bone mineral density | CRI | chronic renal insufficiency; catheter-related infection |
| BMI | body mass index | | |
| BMP | basic metabolic panel | CRNA | Certified Registered Nurse Anesthetist |
| BMR | basal metabolic rate | CRNP | Certified Registered Nurse Practitioner |
| BMT | bone marrow transplantation | CRP | C-reactive protein |
| BP | blood pressure | CRTT | Certified Respiratory Therapy Technician |
| BPD | bronchopulmonary dysplasia | CSF | cerebrospinal fluid; colony-stimulating factor |
| BPH | benign prostatic hyperplasia | CT | computed tomography; chest tube |
| bpm | beats per minute | cTnI | cardiac troponin I |
| BR | bed rest | CTZ | chemoreceptor trigger zone |
| BS | bowel sounds; breath sounds; blood sugar | CV | cardiovascular |
| BSA | body surface area | CVA | cerebrovascular accident |
| BUN | blood urea nitrogen | CVC | central venous catheter |
| Bx | biopsy | CVP | central venous pressure |
| C&S | culture and sensitivity | Cx | culture; cervix |
| CA | cancer; calcium | CXR | chest x-ray |
| CABG | coronary artery bypass grafting | CYP | cytochrome P450 |
| CAD | coronary artery disease | D&C | dilatation and curettage |
| CAH | chronic active hepatitis | $D_5W$ | 5% dextrose in water |
| CAM | complementary and alternative medicine | DBP | diastolic blood pressure |
| CAPD | continuous ambulatory peritoneal dialysis | D/C | discontinue; discharge |
| CBC | complete blood count | DCC | direct-current cardioversion |
| CBD | common bile duct | DI | diabetes insipidus |
| CBG | capillary blood gas; corticosteroid-binding globulin | DIC | disseminated intravascular coagulation |
| | | Diff | differential |
| CC | chief complaint | DJD | degenerative joint disease |
| CCA | calcium channel antagonist | DKA | diabetic ketoacidosis |
| CCB | calcium channel blocker | dL | deciliter |
| CCE | clubbing, cyanosis, edema | DM | diabetes mellitus |
| CCK | cholecystokinin | DNA | deoxyribonucleic acid |
| CCU | coronary care unit | DNR | do not resuscitate |
| CF | cystic fibrosis | DO | Doctor of osteopathy |
| CFS | chronic fatigue syndrome | DOA | dead on arrival; date of admission; duration of action |
| CFU | colony-forming unit | | |
| CHD | coronary heart disease | DOB | date of birth |
| CHF | congestive heart failure; chronic heart failure | DOE | dyspnea on exertion |
| CHO | carbohydrate | DOT | directly observed therapy |
| CI | cardiac index | DPGN | diffuse proliferative glomerulonephritis |
| CIWA | Clinical Institute Withdrawal Assessment | DPI | dry powder inhaler |
| CK | creatine kinase | DRE | digital rectal examination |
| CKD | chronic kidney disease | DRG | diagnosis-related group |
| CLL | chronic lymphocytic leukemia | DS | double strength |
| CM | costal margin | d/t | due to |
| CMG | cystometrogram | DTP | diphtheria–tetanus–pertussis |
| CML | chronic myelogenous leukemia | DTR | deep tendon reflex |
| CMV | cytomegalovirus | DVT | deep vein thrombosis |
| CN | cranial nerve | Dx | diagnosis |
| CNS | central nervous system | EBV | Epstein-Barr virus |

| | | | | |
|---|---|---|---|---|
| EC | enteric coated | | gr | grain |
| ECF | extracellular fluid | | GT | gastrostomy tube |
| ECG | electrocardiogram | | gtt | drops (*guttae*) |
| ECHO | echocardiogram | | GTT | glucose tolerance test |
| ECT | electroconvulsive therapy | | GU | genitourinary |

| EPO | erythropoietin | | HBIG | hepatitis B immune globulin |
| EPS | extrapyramidal symptoms | | HBP | high blood pressure |
| ER | emergency room | | HBsAg | hepatitis B surface antigen |
| ERCP | endoscopic retrograde cholangiopancreatography | | HBV | hepatitis B virus |
| | | | HC | hydrocortisone, home care |
| ERT | estrogen replacement therapy | | HCG | human chorionic gonadotropin |
| ESKD | end-stage kidney disease | | $HCO_3$ | bicarbonate |
| ESLD | end-stage liver disease | | Hct | hematocrit |
| ESR | erythrocyte sedimentation rate | | HCTZ | hydrochlorothiazide |
| ESRD | end-stage renal disease | | HCV | hepatitis C virus |
| ET | endotracheal | | HD | Hodgkin's disease; hemodialysis |
| EtOH | ethanol | | HDL | high-density lipoprotein |
| FB | finger breadth; foreign body | | HEENT | head, eyes, ears, nose, and throat |
| FBS | fasting blood sugar | | HF | heart failure |
| FDA | Food and Drug Administration | | HFA | hydrofluoroalkane |
| FEF | forced expiratory flow rate | | H flu | *Hemophilus influenzae* |
| $FEV_1$ | forced expiratory volume in 1 second | | HGH | human growth hormone |
| FFP | fresh-frozen plasma | | HH | hiatal hernia |
| FH | family history | | Hib | *Hemophilus influenzae* type b |
| $FiO_2$ | fraction of inspired oxygen | | HIT | heparin-induced thrombocytopenia |
| FOBT | fecal occult blood test | | HIV | human immunodeficiency virus |
| FPG | fasting plasma glucose | | HJR | hepatojugular reflux |
| FPIA | fluorescence polarization immunoassay | | HLA | human leukocyte antigen; human lymphocyte antigen |
| FSH | follicle-stimulating hormone | | | |
| FTA | fluorescent treponemal antibody | | HMG-CoA | hydroxy-methylglutaryl coenzyme A |
| $FT_4$ | free thyroxine | | H/O | history of |
| F/U | follow-up | | HOB | head of bed |
| FUO | fever of unknown origin | | HPA | hypothalamic–pituitary axis |
| Fx | fracture | | hpf | high-power field |
| g | gram | | HPI | history of present illness |
| G-CSF | granulocyte colony-stimulating factor | | HR | heart rate |
| G6PD | glucose-6-phosphate dehydrogenase | | $H_2RA$ | $H_2$ receptor antagonist |
| GB | gallbladder | | HRSD | Hamilton Rating Scale for Depression |
| GBS | group B *Streptococcus*; Guillain-Barré syndrome | | HRT | hormone-replacement therapy |
| | | | HS | at bedtime (*hora somni*) |
| GC | gonococcus | | HSV | herpes simplex virus |
| GDM | gestational diabetes mellitus | | HTN | hypertension |
| GE | gastroesophageal; gastroenterology | | Hx | history |
| GERD | gastroesophageal reflux disease | | I&D | incision and drainage |
| GFR | glomerular filtration rate | | I&O, I/O | intake and output |
| GGT | γ-glutamyl transferase | | IBD | inflammatory bowel disease |
| GGTP | γ-glutamyl transpeptidase | | IBW | ideal body weight |
| GI | gastrointestinal | | ICD | implantable cardioverter defibrillator |
| GM-CSF | granulocyte-macrophage colony-stimulating factor | | ICP | intracranial pressure |
| | | | ICS | intercostal space; inhaled corticosteroid |
| GN | glomerulonephritis; graduate nurse | | ICU | intensive care unit |

| | | | |
|---|---|---|---|
| ID | identification; infectious disease | LPN | Licensed Practical Nurse |
| IDDM | insulin-dependent diabetes mellitus | LPT | Licensed Physical Therapist |
| IFN | interferon | LR | lactated Ringer's |
| Ig | immunoglobulin | LS | lumbosacral |
| IgA | immunoglobulin A | LT$_4$ | levothyroxine |
| IgD | immunoglobulin D | LUE | left upper extremity |
| IHD | ischemic heart disease | LUL | left upper lobe |
| IJ | internal jugular | LUQ | left upper quadrant |
| IM | intramuscular; infectious mononucleosis | LUTS | lower urinary tract symptoms |
| INH | isoniazid | LVH | left ventricular hypertrophy |
| INR | international normalized ratio | MAP | mean arterial pressure |
| IOP | intraocular pressure | MAR | medication administration record |
| IP | intraperitoneal | MB-CK | a creatine kinase isoenzyme |
| IPG | impedance plethysmography | mcg | microgram |
| IPN | interstitial pneumonia | MCH | mean corpuscular hemoglobin |
| IRB | institutional review board | MCHC | mean corpuscular hemoglobin concentration |
| ISA | intrinsic sympathomimetic activity | MCV | mean corpuscular volume |
| ISH | isolated systolic hypertension | MD | Medical Doctor |
| IT | intrathecal | MDI | metered-dose inhaler |
| ITP | idiopathic thrombocytopenic purpura | MDRD | modification of diet in renal disease |
| IU | international units (this can be dangerous abbreviation because it may be read as "IV" for "intravenous") | MEFR | maximum expiratory flow rate |
| | | mEq | milliequivalent |
| | | mg | milligram |
| IUD | intrauterine device | MHC | major histocompatibility complex |
| IV | intravenous; Roman numeral four; symbol for class 4 controlled substances | MI | myocardial infarction; mitral insufficiency |
| | | MIC | minimum inhibitory concentration |
| IVC | inferior vena cava; intravenous cholangiogram | mL | milliliter |
| IVDA | intravenous drug abuse | MM | multiple myeloma; an isoenzyme of creatine phosphokinase |
| IVDU | injection drug use; intravenous drug use | | |
| IVF | intravenous fluids | MMR | measles–mumps–rubella; midline malignant reticulosis |
| IVIG | intravenous immunoglobulin | | |
| IVP | intravenous pyelogram; intravenous push | MOM | milk of magnesia |
| JODM | juvenile-onset diabetes mellitus | MPV | mean platelet volume |
| JRA | juvenile rheumatoid arthritis | m/r/g | murmur/rub/gallop |
| JVD | jugular venous distension | MRI | magnetic resonance imaging |
| JVP | jugular venous pressure | MRSA | methicillin-resistant *Staphylococcus aureus* |
| K | potassium | MRSE | methicillin-resistant *Staphylococcus epidermitis* |
| kcal | kilocalorie | MS | mental status; mitral stenosis; musculoskeletal; multiple sclerosis; morphine sulfate |
| KCl | potassium chloride | | |
| KOH | potassium hydroxide | MSE | mental status exam |
| KUB | kidney, ureter, and bladder | MSW | Master of Social Work |
| KVO | keep vein open | MTD | maximum tolerated dose |
| L | liter | MTX | methotrexate |
| LABA | long-acting beta agonist | MVA | motor vehicle accident |
| LAD | left anterior descending; left axis deviation | MVI | multivitamin |
| LAO | left anterior oblique | MVR | mitral valve replacement; mitral valve regurgitation |
| LBBB | left bundle branch block | | |
| LBP | low-back pain | MVS | mitral valve stenosis; motor, vascular, and sensory |
| LDH | lactate dehydrogenase | | |
| LDL | low-density lipoprotein | N&V | nausea and vomiting |
| LE | lower extremity | NAD | no acute (or apparent) distress |
| LES | lower esophageal sphincter | N/C | noncontributory; nasal cannula |
| LFT | liver function test | NG | nasogastric |
| LHRH | luteinizing hormone-releasing hormone | NGT | nasogastric tube; normal glucose tolerance |
| LLE | left lower extremity | NIDDM | non–insulin-dependent diabetes mellitus |
| LLL | left lower lobe | NIH | National Institutes of Health |
| LLQ | left lower quadrant (abdomen) | NKA | no known allergies |
| LMD | local medical doctor | NKDA | no known drug allergies |
| LMP | last menstrual period | NHDA | nonketotic hyperosmolar acidosis |
| LMWH | low-molecular-weight heparin | NL | normal |
| LOS | length of stay | NOS | not otherwise specified |
| LP | lumbar puncture | NPN | nonprotein nitrogen |

| | | | | |
|---|---|---|---|---|
| NPO | nothing by mouth (*nil per os*) | | pH | hydrogen ion concentration |

| PAC | premature atrial contraction | | | |
| $Paco_2$ | arterial carbon dioxide tension | | PTCA | percutaneous transluminal coronary angioplasty |
| $Pao_2$ | arterial oxygen tension | | | |
| PAOP | pulmonary artery occlusion pressure | | PTE | pulmonary thromboembolism |
| PC | after meals (*post cibum*) | | PTH | parathyroid hormone |
| PCA | patient-controlled analgesia | | PTSD | posttraumatic stress disorder |
| PCI | percutaneous coronary intervention | | PTT | partial thromboplastin time |
| PCKD | polycystic kidney disease | | PUD | peptic ulcer disease |
| PCN | penicillin | | PVC | premature ventricular contraction |
| PCP | *Pneumocystis carinii* pneumonia (also known as *Pneumocystis jirovecii* pneumonia); pneumocystis pneumonia; primary care physician; phencyclidine | | PVD | peripheral vascular disease |
| | | | PVR | peripheral vascular resistance |
| | | | PVT | paroxysmal ventricular tachycardia |
| | | | q | every (*quaque*) |
| PCWP | pulmonary capillary wedge pressure | | QA | quality assurance |
| PDE | paroxysmal dyspnea on exertion | | qday | every day (*quaque die*) |
| PE | physical examination; pulmonary embolism | | QI | quality improvement |
| PEEP | positive end-expiratory pressure | | qid | four times daily (*quater in die*) |
| PEFR | peak expiratory flow rate | | QNS | quantity not sufficient |
| PEG | percutaneous endoscopic gastrostomy; polyethylene glycol | | qod | every other day |
| | | | QOL | quality of life |
| Peg-IFN | pegylated interferon | | QS | quantity sufficient |
| PERL | pupils equal, reactive to light | | QTc | corrected QT interval |
| PERRLA | pupils equal, round, and reactive to light and accommodation | | R&M | routine and microscopic |
| | | | R&R | rate and rhythm |
| PERRRLA | pupils equal, round, regular, and reactive to light and accommodation | | RA | rheumatoid arthritis; right atrium |
| | | | RAAS | renin–angiotensin–aldosterone system |
| PET | positron emission tomography | | RBC | red blood cell |
| PFT | pulmonary function test | | RCA | right coronary artery |

| | | | |
|---|---|---|---|
| RCM | right costal margin | SMA-12 | sequential multiple analyzer for glucose, BUN, uric acid, calcium, phosphorous, total protein, albumin, cholesterol, total bilirubin, alkaline phosphatase, SGOT, and LDH |
| RDA | recommended daily allowance | | |
| RDS | respiratory distress syndrome | | |
| RDW | red blood cell distribution width | | |
| REM | rapid eye movement; recent event memory | SMA-23 | includes the entire SMA-12 plus sodium, potassium, $CO_2$, chloride, direct bilirubin, triglyceride, SGPT, indirect bilirubin, R fraction, and BUN/creatinine ratio |
| RES | reticuloendothelial system | | |
| RF | rheumatoid factor; renal failure; rheumatic fever | | |
| Rh | rhesus factor in blood | SMBG | self-monitoring of blood glucose |
| RHD | rheumatic heart disease | SNF | skilled nursing facility |
| RLE | right lower extremity | SNS | sympathetic nervous system |
| RLL | right lower lobe | SOB | shortness of breath; see order book; side of bed |
| RLQ | right lower quadrant | S/P | status post |
| RML | right middle lobe | SPF | sun protection factor |
| RN | Registered Nurse | SQ | subcutaneous |
| RNA | ribonucleic acid | SSKI | saturated solution of potassium iodide |
| R/O | rule out | SSRI | selective serotonin reuptake inhibitor |
| ROM | range of motion | STAT | immediately; at once |
| ROS | review of systems | STEMI | ST-segment elevated myocardial infarction |
| RPh | Registered Pharmacist | STD | sexually transmitted disease |
| RR | respiratory rate; recovery room | SV | stroke volume |
| RRR | regular rate and rhythm | SVC | superior vena cava |
| RRT | Registered Respiratory Therapist | SVRI | systemic vascular resistance index |
| RSV | respiratory syncytial virus | SVR | supraventricular rhythm; systemic vascular resistance |
| RT | radiation therapy | | |
| RUE | right upper extremity | SVT | supraventricular tachycardia |
| RUL | right upper lobe | SW | social worker |
| RUQ | right upper quadrant | Sx | signs |
| RVH | right ventricular hypertrophy | T | temperature |
| $S_1$ | first heart sound | $T_3$ | triiodothyroxine |
| $S_2$ | second heart sound | $T_4$ | thyroxine |
| $S_3$ | third heart sound (ventricular gallop) | T&A | tonsillectomy and adenoidectomy |
| $S_4$ | fourth heart sound (atrial gallop) | T&C | type and crossmatch |
| SA | sinoatrial | TB | tuberculosis |
| SABA | short-acting beta agonist | TBG | thyroid-binding globulin |
| SAD | seasonal affective disorder | TBI | total-body irradiation; traumatic brain injury |
| SAH | subarachnoid hemorrhage | TBW | total body weight |
| $Sao_2$ | arterial oxygen percent saturation | T bili | total bilirubin |
| SBE | subacute bacterial endocarditis | TCA | tricyclic antidepressant |
| SBFT | small bowel follow-through | TCN | tetracycline |
| SBGM | self-blood glucose monitoring | Tdap | tetanus, diphtheria, acellular pertussis vaccine |
| SBO | small bowel obstruction | TEE | transesophageal echocardiogram |
| SBP | systolic blood pressure | TFT | thyroid function test |
| SC | subcutaneous; subclavian | TG | triglyceride |
| SCr | serum creatinine | TIA | transient ischemic attack |
| SEM | systolic ejection murmur | TIBC | total iron-binding capacity |
| SG | specific gravity | tid | three times daily (*ter in die*) |
| SGOT (AST) | serum glutamic oxaloacetic transaminase (aspartate transaminase) | TLC | therapeutic lifestyle changes |
| | | TMJ | Temporomandibular joint |
| SGPT (ALT) | serum glutamic pyruvic transaminase (alanine transaminase) | TMP-SMX | trimethoprim–sulfamethoxazole |
| | | TNTC | too numerous to count |
| SH | social history | TOD | target organ damage |
| SIADH | syndrome of inappropriate antidiuretic hormone secretion | TPN | total parenteral nutrition |
| | | TPR | temperature, pulse, respiration |
| SIDS | sudden infant death syndrome | T PROT | total protein |
| SJS | Stevens-Johnson syndrome | TSH | thyroid-stimulating hormone |
| SL | sublingual | TURP | transurethral resection of the prostate |
| SLE | systemic lupus erythematosus | Tx | treat, treatment |
| SMA-6 | sequential multiple analyzer for sodium, potassium, $CO_2$, chloride, glucose, and BUN | UA | urinalysis, uric acid |
| | | UC | ulcerative colitis |
| SMA-7 | sequential multiple analyzer for sodium, potassium, $CO_2$, chloride, glucose, BUN, and creatinine | UE | upper extremity |

# Appendix C: Glossary

**2,3-Diphosphoglycerate:** A compound in red blood cells that affects oxygen binding to and release from hemoglobin.

**Ablation:** Destruction of part or all of an organ or structure.

**Abscess:** A purulent collection of fluid separated from surrounding tissue by a wall consisting of inflammatory cells and adjacent organs. It usually contains necrotic debris, bacteria, and inflammatory cells.

**Absence:** A primary-generalized seizure characterized by sudden and brief (i.e., several seconds in duration) loss of consciousness without muscle movements.

**Acanthosis nigricans:** Increased thickness and hyperpigmentation of the outer cell layers of the skin; typically observed at areas of flexure.

**Acaricide:** A chemical that kills mites and ticks.

**Acetaldehyde:** A hepatotoxic metabolic by-product of alcohol.

**Acetylcholine:** The neurotransmitter responsible for transmitting messages between certain nerve cells in the brain.

**Achalasia:** Disorder in which the esophageal sphincter is impaired, preventing normal swallowing and often causing reflux of contents and a feeling that something is caught in the throat.

**Achlorhydria:** Absence of free hydrochloric acid in the stomach.

**Acidemia:** An increase in the hydrogen ion concentration of the blood or a fall below normal in pH.

**Acidosis:** Any pathologic state that leads to acidemia.

**Acinar cells:** Exocrine glands of the pancreas that secrete digestive enzymes.

**Acromegaly:** A pathologic condition characterized by excessive production of growth hormone during adulthood after epiphyseal (long bone) fusions have completed.

**Action potential:** A rapid change in the polarity of the voltage of a cell membrane from negative to positive and back to negative; a wave of electrical discharge that travels across a cell membrane.

**Acute acid-base disorder:** An acid-base disturbance that has been present for minutes to hours.

**Acute coronary syndrome (ACS):** Ischemic chest discomfort at rest most often accompanied by ST-segment elevation, ST-segment depression, or T-wave inversion on the 12-lead electrocardiogram; caused by plaque rupture and partial or complete occlusion of the coronary artery by thrombus. Acute coronary syndromes include myocardial infarction and unstable angina.

**Acute kidney injury:** Characterized by a rapid decrease in kidney function and the resultant accumulation of nitrogenous waste products (e.g., creatinine and blood urea nitrogen or BUN), with or without a decrease in urine output.

**Acute otitis media:** Inflammation of the middle ear accompanied by fluid in the middle ear space and signs or symptoms of an acute ear infection.

**Acute respiratory distress syndrome (ARDS):** Occurs when fluid builds up in the alveoli of the lungs, reducing amount of oxygen delivered to other organs.

**Acute tubular necrosis:** Form of acute kidney injury that results from toxic or ischemic injury to the cells in the proximal tubule of the kidney.

**Addiction:** A primary, chronic, neurobiologic disease, with genetic, psychosocial, and environmental factors influencing its development and manifestations. It is characterized by behaviors that include one or more of the following: impaired control over substance use, compulsive use, continued use despite harm, and craving.

**Adenoma:** A non-malignant tumor of the epithelial tissue that is characterized by glandular structures.

**Adenomatous polyposis coli (APC):** A gene associated with familial adenomatous polyposis (FAP), an inherited disorder characterized by the development of myriad polyps in the colon, often occurring in adolescents and young adults ages 15 to 25.

**Adjuvant chemotherapy:** Treatment given after the primary surgical treatment and designed to eliminate any remaining cancer cells that are undetectable, with the goal of improving survival.

**Adjuvant therapy:** Treatment which follows the primary modality with the intent of reducing the risk of disease relapse and prolonging survival. The ultimate goal is to cure patients who would not otherwise be cured by the primary modality alone.

**Adrenalectomy:** Surgical removal of an adrenal gland.

**Adrenocorticotropic hormone:** A hormone secreted by the anterior pituitary that controls secretion of cortisol from the adrenal glands. Also referred to as corticotropin.

**Adverse drug reaction (ADR):** Any unexpected, unintended, undesired, or excessive response to a medication that requires discontinuing or changing the medication, or modifying the dose (except for minor dosage modifcations). May necessitate hospital admission and/or supportive treatment; prolong stay in a health care facility; significantly complicate diagnosis; negatively affect prognosis; or result in temporary or permanent harm, disability, or death.

**Aeroallergen:** An airborne substance that causes an allergic response.

**Afterload:** The force against which a ventricle contracts that is contributed to by the vascular resistance, especially of the arteries, and by the physical characteristics (mass and viscosity) of the blood.

**Ageism:** Discrimination against aged persons.

**Air embolus:** An obstruction in a small blood vessel caused by air that is introduced into a blood vessel and is carried through the circulation until it lodges in a smaller vessel.

**Akathisia:** Motor or subjective feelings of restlessness, often characterized by the urge to move limbs and inability to sit still.

**Akinesia:** Lack of movement.

**Albuminuria:** The presence of albumin (greater than 30 mg/day) in the urine, which is an early sign of chronic kidney disease (CKD).

**Aldosterone:** A hormone produced in and secreted by the zona glomerulosa of the adrenal cortex. Aldosterone acts on the kidneys to reabsorb sodium and excrete potassium. It is also a part of the renin-angiotensin-aldosterone system that regulates blood pressure and blood volume.

**Alkalemia:** A decrease in the hydrogen ion concentration of the blood or a rise above normal in pH.

**Alkalosis:** Any pathologic state that leads to alkalemia.

**Allodynia:** Pain that results from a stimulus that does not normally cause pain.

**Allogeneic hematopoietic stem cell transplant:** A procedure in which a person receives blood-forming stem cells (cells from which all blood cells develop) from a genetically similar, but not identical, donor.

**Allogeneic transplant:** Procedure by which cells from one person are transferred to another.

**Allograft:** Tissue or organ transplanted from a donor of the same species but different genetic makeup; recipient's immune system must be suppressed to prevent rejection of the graft.

**Allograft survival:** After the transplant procedure, the transplanted organ continues to have some degree of function, from excellent to poor.

**Allorecognition:** Recognition of the foreign antigens present on the transplant organ or the donor's antigen presenting cells.

**Alopecia:** Hair loss.

**Alzheimer disease:** Type of dementia with insidious onset and gradual progression that causes problems with memory, learning, thinking, and behavior. Symptoms eventually become severe enough to interfere with daily tasks, including self-care.

**Ambulatory esophageal reflux monitoring:** A telemetry capsule containing a tiny camera is swallowed, or a transnasal catheter is inserted to determine how often reflux is occurring as well as the incidence of abnormal esophageal acid exposure. The telemetry capsule provides about 48 hours of data, whereas the transnasal catheter provides about 24 hours of data.

**Amenorrhea:** Abnormal cessation or absence of menses.

**Ampulla of Vater:** Dilation of the duodenal wall at the opening of the fused pancreatic and common bile ducts.

**Amylin:** A 37-amino acid polypeptide hormone that is secreted from the β cells of the pancreas in response to nutrients. Mechanisms of action include slowing gastric emptying, suppressing postmeal glucagon secretion, and suppressing appetite.

**Amyloid:** Any of a group of chemically diverse proteins that are composed of linear non-branching aggregated fibrils.

**Anaphylactic/anaphylaxis:** Immediate, severe, potentially fatal hypersensitivity reaction induced by an antigen.

**Anaphylactoid:** An anaphylactic-like reaction, similar in signs and symptoms but not mediated by IgE. The drug causing this reaction produces direct release of inflammatory mediators by a pharmacological effect.

**Anastomosis:** The connection of two hollow organs to restore continuity after resection.

**Anemia:** Reduction in the concentration of hemoglobin that results in reduced oxygen-carrying capacity of the blood.

**Anemia of chronic kidney disease:** A decline in red blood cell production caused by a decrease in erythropoietin production by the progenitor cells of the kidney. As kidney function declines in chronic kidney disease, erythropoietin production also declines, resulting in decreased red blood cell production. Other contributing factors include iron deficiency and decreased red blood cell lifespan, caused by uremia.

**Anergy:** A reduction or lack of an immune response to a specific antigen.

**Aneurysm:** A blood-filled bulge which forms in the wall of a weakened blood vessel; if ruptured, may result in bleeding, shock, and/or other negative health outcome including mortality.

**Angina:** Discomfort in the chest or adjacent areas caused by decreased blood and oxygen supply to the myocardium (myocardial ischemia).

**Angioedema:** Swelling similar to urticaria (hives), but the swelling occurs beneath the skin instead of on the surface. Characterized by deep swelling around the eyes and lips and sometimes of the hands and feet. If it proceeds rapidly, it can lead to airway obstruction and suffocation, and should therefore be treated as a medical emergency.

**Angiogenesis:** The formation of new blood vessels. Increased blood flow to deliver nutrients is required for tumor growth.

**Angiography:** Examination of the blood vessels using x-rays after injection of a radiopaque substance.

**Anosmia:** Loss of smell.

**Anterior circulation:** Blood supply to the anterior section of the brain supplied by the internal carotid arteries, anterior cerebral artery, and middle cerebral artery.

**Anterograde amnesia:** Memory loss affecting the transfer of new information or events to long-term storage.

**Antiangiogenic:** Preventing or inhibiting the formation and differentiation of blood vessels.

**Anticoagulant:** Any substance that inhibits, suppresses, or delays the formation of blood clots. These substances occur naturally and regulate the clotting cascade. Several anticoagulants have been identified in a variety of animal tissues and have been commercially developed for medicinal use.

**Antiproteinase:** A substance that inhibits the enzymatic activity of a proteinase.

**Anuria:** Urine output of less than 50 mL over 24 hours.

**Aphakic:** The absence of a lens in the eye.

**Aphasia:** Impairment of language affecting the ability to speak and to understand speech.

**Aphthous ulcer:** A small superficial area of ulceration within the gastrointestinal mucosa, typically found in the oral cavity.

**Apoptosis:** Programmed cell death as signaled by the nuclei in normally functioning cells when age or state of cell health and condition dictates.

**Arcuate scotoma:** An arc-shaped area of blindness in the field of vision.

**Arteriovenous malformation:** A tangle of blood vessels, usually in the brain, that results in abnormal connections between arteries and veins; if ruptured, may result in hemorrhage.

**Arthrocentesis:** Puncture and aspiration of a joint. Certain drugs can be injected into the joint space for a local effect.

**Articular:** Related to a joint or joints.

**Ascites:** Accumulation of fluid within the peritoneal cavity.

**Asterixis:** A flapping tremor of the arms and hands that is seen in patients with end-stage liver disease.

**Astringent:** A substance that causes tissues to constrict, resulting in a drying effect of the skin.

**Atelectasis:** Decreased or absent air in a partial or entire lung, with resulting loss of lung volume.

**Atherosclerosis:** Accumulation of lipids, inflammatory cells, and cellular debris in the subendothelial space of the arterial wall.

**Atherosclerotic cardiovascular disease:** Disease in which plaque builds up in vessels.

**Atonic seizure:** A primary-generalized seizure characterized by loss of consciousness and muscle tone.

**Atopy:** A genetic predisposition to develop type I hypersensitivity reactions against common environmental antigens. It is seen commonly in patients with allergic rhinitis, asthma, and atopic dermatitis.

**Atresia:** Congenital absence of a normal opening or normally patent lumen.

**Atrophic urethritis:** An inflammation of the vagina (and the outer urinary tract) due to a lack of estrogen.

**Attenuation:** Loss of intensity or virulence.

**Aura:** Visual, but sometimes sensory, motor or verbal disturbance usually occurring before a migraine or seizure.

**Auspitz sign:** Pinpoint bleeding that occurs when a psoriatic scale or lesion is peeled off of the skin.

**Autologous:** A transplant using one's own stem cells.

**Autologous hematopoietic stem cell transplant:** A procedure in which blood-forming stem cells (cells from which all blood cells develop) are removed, stored, and later given back to the same person.

**Automaticity:** Ability of a cardiac fiber or tissue to spontaneously initiate depolarizations.

**Avolition:** Inability to initiate and persist in goal-directed activities.

**Azoospermic:** Having no living spermatozoa in the semen, or failure of spermatogenesis.

**B2 microglobulin:** A low-molecular weight protein that may be elevated in multiple myeloma.

**Bacille Calmette-Guérin vaccine:** A tuberculosis vaccine prepared from an attenuated strain of the closely related species *Mycobacterium bovis*, used for immunization against tuberculosis in many countries, but not in the United States.

**Bacteremia:** Bacteria in the bloodstream.

**Bacteriuria:** Presence of bacteria in urine.

**Barium enema:** A diagnostic test using an x-ray to view the lower gastrointestinal tract (colon and rectum) after rectal administration of barium sulfate, a chalky liquid contrast medium.

**Barrett esophagus:** Disorder in which the cells of the lower esophagus are damaged, most often a result of longstanding reflux.

**Basal ganglia:** Cluster of nerve cells deep in the brain that coordinate normal movement.

**β-hydroxybutyric acid:** A ketone body that is elevated in ketosis, is synthesized in the liver from acetyl-CoA, and can be used as an energy source by the brain when blood glucose is low.

**Bence-Jones proteins:** Light chained immunoglobulins found in the urine.

**Bilateral salpingo-oophorectomy:** Surgical excision (removal) of both ovaries.

**Bile acids:** The organic acids in bile. Bile is the yellowish-brown or green fluid secreted by the liver and discharged into the duodenum where it aids in the emulsification of fats, increases peristalsis, and retards putrefaction.

**Biliary sludge:** A deposit of tiny stones or crystals made up of cholesterol, calcium bilirubinate, and other calcium salts. The cholesterol and calcium bilirubinate crystals in biliary sludge can lead to gallstone formation.

**Bioavailability:** The amount of an agent that is absorbed orally relative to an equivalent dose administered intravenously.

**Biopsy:** The removal of cells or tissue for examination.

**Bladder hypotonicity:** Low elastic tension of the bladder.

**Blast:** An immature cell.

**Blastospores:** An asexual reproductive sphore formed by budding, often seen with yeast.

**Blood urea nitrogen (BUN):** A waste product in the blood produced from the breakdown of dietary proteins. The kidneys filter blood to remove urea and maintain homeostasis; a decline in kidney function results in an increase in BUN.

**Body mass index (BMI):** A calculation utilized to correct weight changes for height and is a direct calculation regardless of gender. It is the result of the weight in kilograms divided by the height in meters squared. If nonmetric measurements are used, it is the result of the weight in pounds multiplied by 703 and then that quantity divided by the product of height in inches squared.

**Bone remodeling:** The constant process of bone turnover involving bone resorption followed by bone formation.

**Bouchard nodes:** Hard, bony enlargement of the proximal interphalangeal (middle) joint of a finger or toe.

**Brachial plexus:** Collection of nerves that arises from the spine at the base of the neck from nerves that supply parts of the shoulder, arm, forearm, and hand.

**Brachytherapy:** A form of radiotherapy where a sealed radiation source is placed inside or next to the area requiring treatment.

**Bradycardia:** Slower than normal heart rate.

**Bradykinesia:** Slow movement.

**Breakpoint:** The concentration of an antimicrobial agent that can be achieved in serum after a normal or standard dose of that antimicrobial agent.

**Bronchiectasis:** Chronic dilation of bronchi or bronchioles as a result of inflammatory disease or obstruction associated with heavy sputum.

**Bronchoalveolar lavage:** Diagnostic procedure in which a scope is passed through the nose or mouth into the lungs and fluid is squirted into an area of lung then recollected for examination.

**Bullectomy:** Surgical removal of one or more bullae (air spaces in the lung measuring more than one centimeter in diameter in the distended state).

**Bursitis:** An inflammation of the bursa, the fluid-filled sac near the joint where tendons and muscles pass over bone.

**Cancer survivorship:** The process of living with, throughout, and beyond cancer. Begins at cancer diagnosis and includes people who are/are not receiving treatment to manage disease or to decrease the risk of recurrence.

**Capillary leak:** Loss of intravascular volume into the interstitial space within the body.

**Carcinogenesis:** The actual formation of a cancer, whereby normal cells are transformed into cancer cells.

**Carcinoma:** A malignant growth that arises from epithelium, found in skin or the lining of body organs. Carcinomas tend to infiltrate into adjacent tissue and spread to distant organs.

**Carcinomatosis:** Condition of having widespread dissemination of carcinoma (cancer) in the body.

**Cardiac cachexia:** Physical wasting with loss of weight and muscle mass caused by cardiac disease; a wasting syndrome that causes weakness and a loss of weight, fat, and muscle.

**Cardiac index:** Cardiac output normalized for body surface area (cardiac index = cardiac output/body surface area).

**Cardiac output:** The volume of blood ejected from the left side of the heart per unit of time [cardiac output (L/min) = stroke volume × heart rate].

**Cardiac remodeling:** Genome expression resulting in molecular, cellular, and interstitial changes and manifested clinically as

changes in size, shape, and function of the heart resulting from cardiac load or injury.

**Carotid bruit:** Abnormal sound heard when auscultating a carotid artery caused by turbulent blood flow, usually due to the presence of atherosclerotic plaques.

**Carotid endarterectomy:** Removal of a thrombus from the carotid artery.

**Carotid intima-media thickness:** A measurement of the surface between the intima and media. This is a well-validated measure of the progression of atherosclerosis. Increasing measurements over time correlate with increasing atherosclerosis, whereas a decrease in the measurement is indicative of atherosclerotic regression.

**Carotids:** The two main arteries in the neck.

**Castrate resistant:** Prostate cancers resistant to hormonal therapy.

**Cataplexy:** A sudden loss of muscle control with retention of clear consciousness that follows a strong emotional stimulus (e.g., elation, surprise, or anger) and is a characteristic symptom of narcolepsy.

**Causalgia:** Persistent burning pain, allodynia, and hyperpathia following a traumatic nerve lesion.

**Cavitary lesions:** A spherical, air-containing lesion found on radiograph or computed tomography. The lesion usually has a thick wall and can be found within an area of a surrounding infiltrate or mass.

**CD4 and CD8:** Proteins predominately found on the surface of T cells.

**Central pain:** Pain that results from a lesion or dysfunction in the central nervous system.

**Cephalic:** Of or relating to the head.

**Cervicitis:** Inflammation of the cervix.

**Chemoprevention:** The use of drugs, vitamins, or other agents to reduce the risk or delay the development or recurrence of cancer.

**Chemoreceptor trigger zone (CTZ):** Located in the area postrema of the fourth ventricle of the brain. It is exposed to cerebrospinal fluid and blood and is easily stimulated by circulating toxins to induce nausea and vomiting.

**Chemosis:** Edema of the bulbar conjunctiva.

**Cheyne-Stokes respiration:** Pattern of breathing with gradual increase in depth (and sometimes in rate) to a maximum, followed by a decrease resulting in apnea; the cycles ordinarily are 30 seconds to 2 minutes in duration, with 5 to 30 seconds of apnea.

**Chimeric:** An individual, organ, or substance composed of substances with different genetic origins.

**Chloasma:** Melasma characterized by irregularly shaped brown patches on the face and other areas of the skin, often seen during pregnancy or associated with the use of oral contraceptives.

**Chlorpromazine equivalents:** Approximate dose equivalent of a first-generation antipsychotic to 100 mg of chlorpromazine (relative potency).

**Cholecystitis:** Inflammation of the gallbladder.

**Cholelithiasis:** Formation of stones in the gallbladder (gallstones).

**Cholestasis:** Reduced or lack of flow of bile, or obstruction of bile flow.

**Cholesteatoma:** A mass of keratinized epithelial cells and cholesterol resembling a tumor that forms in the middle ear or mastoid region.

**Cholinesterase inhibitor:** Medication class that inhibits the acetylcholinesterase enzyme from breaking down acetylcholine,

thereby increasing both the level and duration of action of the neurotransmitter acetylcholine.

**Chorea:** A type of dyskinesia with rhythmic dance-like movement. The increase in motor activity may be associated with fidgetiness, twitching, or flinging movements.

**Chronic acid-base disorder:** An acid-base disturbance that has been present for hours to days.

**Chronic kidney disease (CKD):** A progressive, irreversible decline in kidney function that occurs over a period of several months to years.

**Chronic stable angina:** Manifestation of ischemic heart disease that typically results when an atherosclerotic plaque progresses to occlude at least 70% of a major coronary artery. Patients typically present with a sensation of chest pressure or heaviness that is provoked by exertion and relieved with rest or sublingual nitroglycerin.

**Chronotropic:** Pertaining to the heart rate.

**Chvostek sign:** Noted when a tap on the patient's facial nerve adjacent to the ear produces a brief contraction of the upper lip, nose or side of the face.

**Chylothorax:** The presence of lymphatic fluid (chyle) in the pleural cavity.

**Circadian rhythm:** 24-hour cycles of behavior and physiology that are generated by endogenous biologic clocks (pacemakers).

**Circulatory shock:** A condition wherein the circulatory system is inadequately supplying the oxygen and vital metabolic substrates to cells throughout the body.

**Cirrhosis:** Hepatic fibrosis and regenerative nodules that have destroyed the architecture of the liver, scarring the liver tissues. Progressive scarring of the liver resulting in nonfunctional hepatocytes.

**Clonal expansion:** An immunologic response in which lymphocytes stimulated by antigen proliferate and amplify the population of relevant cells.

**Closed comedo:** A plugged hair follicle of sebum, keratinocytes, and bacteria that remains beneath the surface of the skin. Also referred to as a "whitehead."

**Clotting cascade:** A series of enzymatic reactions by clotting factors leading to the formation of a blood clot. The clotting cascade is initiated by several thrombogenic substances. Each reaction in the cascade is triggered by the preceding one and the effect is amplified by positive feedback loops.

**Clotting factor:** Plasma proteins found in the blood that are essential to the formation of blood clots. Clotting factors circulate in inactive forms but are activated by their predecessor in the clotting cascade or a thrombogenic substance. Each clotting factor is designated by a Roman numeral (e.g., factor VII) and by the letter "a" when activated (e.g., factor VIIa).

**Clubbing:** Proliferation of soft tissues, especially in the nail bed, which results in thickening and widening of finger and toe extremities.

**Coalescence:** Fusion of smaller lipid emulsion particles forming larger particles, resulting in destabilization of the emulsion.

**Cognitive function:** Executive function and mental processing such as understanding, perception, reasoning, language, and awareness. Executive function involves organization, self-regulation, attention, and problem solving.

**Coitus:** Sexual intercourse.

**Collateral damage:** The development of resistance occurring in a patient's nontargeted flora that can cause secondary infections.

**Colloids:** Intravenous fluids composed of water and large-molecular weight molecules used to increase volume in

patients with hypovolemic shock via increased intravascular oncotic pressure.

**Colonoscopy:** Visual examination of the colon using a lighted, lens-equipped, flexible tube (colonoscope) inserted into the rectum.

**Colony-forming units:** Number of viable colonies of bacteria, yeast, or mold per unit of measurement (e.g., milliliter or gram).

**Colorectal cancer:** The development of malignant cells in the lining or epithelium of the first and longest portion of the large intestine.

**Combined androgen blockade:** The combination of both androgen receptor (AR) antagonism and inhibition or suppression of androgen production.

**Comedolytic:** An agent that is able to break up or destroy a comedo.

**Comorbidities:** Multiple disease states occurring concurrently in one patient.

**Complete response:** In cancer, disappearance of all targeted lesions.

**Complex partial seizures:** Seizures that are localized in a specific area of the brain, but there is an alteration in the patient's level of consciousness.

**Complex regimen:** Taking medications 3 or more times per day, or 12 or more doses per day.

**Complicated acid-base disorder:** The presence of two or more distinct acid-base disorders.

**Concreteness:** Inability to think in abstract terms. It may be a primary developmental defect or secondary to organic mental disorder or schizophrenia.

**Congenital adrenal hyperplasia:** A rare inherited condition resulting from a deficiency in cortisol and aldosterone synthesis with resulting excess androgen production. The clinical presentation depends on the variant of the condition but typically manifests as abnormalities in sexual development and/or adrenal insufficiency.

**Conjunctival injection:** Erythema of the conjunctiva.

**Conjunctivitis:** Inflammation of the conjunctiva.

**Conjunctivitis medicamentosa:** A drug-induced form of allergic conjunctivitis resulting from overuse of topical ocular vasoconstrictors.

**Consolidation:** Cancer treatment given after induction therapy to consolidate the gains obtained, further reduce the number of cancer cells, and enhance the likelihood of a durable complete remission.

**Contiguous spread:** Infection that involves bone that has come from adjacent tissues.

**Continuous positive airway pressure:** A technique of assisting breathing by maintaining the air pressure in the lungs and air passages constant and above atmospheric pressure throughout the breathing cycle.

**Convection:** The movement of dissolved solutes across a semipermeable membrane by applying a pressure gradient to the fluid transport.

**Conversion (transformation):** Mutated cell becomes malignant.

**Cor pulmonale:** Right-sided heart failure caused by lung disease.

**Corneal arcus:** Accumulation of lipid on the cornea.

**Coronary artery bypass graft:** Surgical intervention to improve coronary blood flow by removing a vein from the leg and attaching one end to the aorta and the other end to the coronary artery distal to the atherosclerotic plaque. Alternatively, an artery from the inside of the chest wall may be used to bypass the coronary occlusion.

**Coronary artery disease:** Narrowing of one or more of the major coronary arteries, most commonly by atherosclerotic plaques. May be referred to as coronary heart disease.

**Coronary heart disease:** Narrowing of one or more of the major coronary arteries, most commonly by atherosclerotic plaques. May be referred to as coronary artery disease.

**Corpus luteum:** The small yellow endocrine structure that develops within a ruptured ovarian follicle and secretes progesterone and estrogen.

**Corticotropin-releasing hormone:** A hormone released by the hypothalamus that stimulates release of adrenocorticotropic hormone by the anterior pituitary gland.

**Cortisol:** An adrenal gland hormone responsible for maintaining homeostasis of carbohydrate, protein, and fat metabolism.

**Cosyntropin:** A synthetic version of adrenocorticotropic hormone.

**Counterirritant:** A substance that elicits a superficial inflammatory response with the objective of reducing inflammation in deeper, adjacent structures.

**C-peptide:** A peptide which is made when proinsulin is split into insulin and C-peptide. They split before proinsulin is released from endocytic vesicles within the pancreas, one C-peptide for each insulin molecule. C-peptide is the abbreviation for "connecting peptide." It is used to determine if a patient has type 1 or type 2 diabetes mellitus.

**Creaming:** Aggregation of lipid emulsion particles that then migrate to the surface of the emulsion; can be reversed with mild agitation.

**Creatinine:** A waste product in the blood produced from the breakdown of protein by-products generated by muscle in the body or ingested in the diet. The kidneys filter blood to remove creatinine and maintain homeostasis; a decline in kidney function results in an increase in creatinine.

**Creatinine clearance:** Rate at which creatinine is filtered across the glomerulus; estimate of glomerular filtration rate.

**Crepitus:** A grating sound or sensation typically produced by friction between bone-on-cartilage or bone-on-bone contact.

**Cretinism:** Obsolete term for congenital hypothyroidism.

**Cross-allergenicity:** Sensitivity to one drug and then reacting to a different drug with a similar chemical structure.

**Crypt abscess:** Neutrophilic infiltration of the intestinal glands (crypts of Lieberkühn); a characteristic finding in patients with ulcerative colitis.

**Cryptogenic (cause unknown) epilepsies:** A seizure disorder that results from an underlying neurologic disorder that is often ill-defined, and other neurologic functions are often abnormal or developmentally delayed.

**Crystalloids:** Intravenous fluids composed of water and electrolytes (e.g., sodium, chloride, etc.) used as intravascular volume expanders for patients with hypovolemic shock.

**Cutis laxis:** Hypereflacidity of the skin with loss of elasticity.

**Cyanosis:** A dark blue or purple discoloration of the skin and mucous membranes due to deficient oxygenation of the blood.

**Cyclic citrullinated peptide (CCP):** A circular peptide (a ring of amino acids) containing the amino acid citrulline. Autoantibodies directed against cyclic citrullinated peptide provide the basis for a test of importance in rheumatoid arthritis.

**Cyclooxygenase:** An enzyme that catalyzes the conversion of arachidonic acid to prostaglandins and consists of two isoforms, generally abbreviated COX-1 and COX-2.

**Cystitis:** Inflammation of urinary bladder.

**Cystocele:** Hernial protrusion of the bladder, usually through the vaginal wall.

**Cytokines:** Regulatory proteins, such as interleukins and lymphokines, that are released by cells of the immune system and act as intercellular mediators in the generation of an immune response. Soluble glycoproteins released by the immune system which act through specific receptors to regulate immune responses.

**Cytomegalovirus (CMV) disease:** The term used when patients who are already infected with CMV present with the classically associated symptoms that resemble a viral infection and may include fever, malaise, arthralgias, and others.

**Cytomegalovirus (CMV) infection:** The term used when a patient has anti-CMV antibodies in the blood, when CMV antigens are detected in infected cells, or when the virus is isolated from a culture.

**Decolonization:** Eradication of targeted bacterial species normally found on a person's body but which have the potential to cause invasive disease.

**Deep vein thrombosis:** A disorder of thrombus formation causing obstruction of a deep vein in the leg, pelvis, or abdomen.

**De-escalation:** Decreasing antimicrobial regimen spectrum of activity to provide coverage against specific antimicrobial-sensitive pathogens recovered from culture.

**Delayed peak response:** The peak effects of a dose of medication take longer than expected to manifest.

**Delirium:** Transient brain syndrome presenting as disordered attention, cognition, psychomotor behavior, and perception.

**Delirium tremens (DTs):** Symptom of alcohol withdrawal characterized by hallucinations, delirium, severe agitation, fever, elevations of blood pressure and heart rate, and possible cardiac arrhythmias.

**Denervation:** Loss of nerve supply.

**Dennie-Morgan line:** A line or fold below the lower eyelids;

**Dermatophyte:** Any microscopic fungus that grows on the skin, scalp, and nails. May cause infections.

**Desensitization:** A process in which a drug to which a patient is allergic is administered in small, incremental doses to induce a state of temporary tolerance.

**Desquamation:** Peeling or shedding of the epidermis (superficial layer of the skin) in scales or flakes.

**Detumescence:** The return of the penis to a flaccid state.

**Diabetes insipidus:** Polyuria due to the failure of renal tubules to reabsorb water in response to antidiuretic hormone.

**Diabetic ketoacidosis:** A reversible but life-threatening short-term complication primarily seen in patients with type 1 diabetes caused by the relative or absolute lack of insulin that results in marked ketosis and acidosis.

**Dialysate:** The physiologic solution used during dialysis to remove excess fluids and waste products from the blood.

**Dialysis:** The process of removing fluid and waste products from the blood across a semi-permeable membrane to maintain fluid, electrolyte, and acid-base balance in patients with kidney failure.

**Diaphoresis:** Sweating or profuse perspiration, generally as a symptom of a disease or an adverse drug effect.

**Diarthrodial joint:** A freely moveable joint (e.g., knee, shoulder). Contrast with amphiarthrodial joint (a slightly movable joint; e.g., vertebral joint) and synarthrodial joint (an unmovable joint; e.g., fibrous joint).

**Diastolic dysfunction:** Abnormal filling of the ventricles during diastole.

**Diffusion:** The movement of a solute across the dialyzer membrane from an area of higher concentration (usually the blood) to a lower concentration (usually the dialysate).

**Dilated cardiomyopathy:** Ability of the heart to pump blood is decreased because the left ventricle is enlarged and weakened.

**Diphasic dyskinesia:** The motor fluctuations occur while the plasma levodopa concentrations are rising and when they are falling. In each dosing interval, the patient may experience improvement, dyskinesia and improvement (IDI) or dyskinesia, improvement, dyskinesia (DID).

**Direct current cardioversion:** The process of administering a synchronized electrical shock to the chest, the purpose of which is to simultaneously depolarize all of the myocardial cells, resulting in restoration of normal sinus rhythm.

**Disease-free survival:** Length of time after treatment during which no disease is found.

**Disease progression:** In cancer, at least a 20% increase in the sum of the longest diameter of target lesions from baseline, including new lesions discovered during treatment.

**Disseminated erythrosquamous papules:** Widespread or whole body red, scaly psoriatic lesions.

**Disseminated intravascular coagulopathy:** Abnormal overactivity of proteins in the blood that form blood clots; over time, clotting proteins are reduced which then increases risk for serious bleeding.

**DNA mismatch repair (*dMMR*) genes:** Genes that control an intrinsic intracellular mechanism which corrects nucleotide insertion errors made during DNA replication, by excising the mismatched base pairs that escaped correction by the proofreading activities of DNA polymerases and replacing the mismatched bases with the correct ones.

**Door-to-needle time:** Time from arrival in hospital to administration of treatment in appropriate patients.

**Downregulation:** The process of reducing or suppressing a response to a stimulus.

**Drusen:** Tiny yellow or white deposits of extracellular material in the eye.

**D-test:** Double disk diffusion microbiological testing which indicates the presence or absence of macrolide-induced resistance to clindamycin.

**Ductus arteriosus:** Shunt connecting the pulmonary artery to the aortic arch that allows most of the blood from the right ventricle to bypass fetal lungs.

**Duodenal enterocyte:** Cells lining the duodenum, which is the first of three parts of the small intestine.

**Dysarthria:** Speech disorder due to weakness or incoordination of speech muscles; speech is slow, weak, and imprecise.

**Dysesthesia:** An unpleasant abnormal sensation.

**Dysgeusia:** Taste disturbance or dysfunction of the sense of taste.

**Dyskinesia:** Abnormal involuntary movements, which include dystonia, chorea, and akathisia.

**Dyslipidemia:** Elevation of the total cholesterol, low-density lipoprotein cholesterol, or triglyceride concentrations, or a decrease in high-density lipoprotein cholesterol concentration in the blood.

**Dysmenorrhea:** Crampy pelvic pain occurring with or just prior to menses. "Primary" dysmenorrhea implies pain in the setting of normal pelvic anatomy, while "secondary" dysmenorrhea is secondary to underlying pelvic pathology.

**Dyspareunia:** Painful sexual intercourse due to medical or psychological causes.

**Dysphagia:** Difficulty in swallowing.

**Dysphonia:** Impairment of the voice or difficulty speaking.

**Dysphoria:** An unhappy or depressed feeling.

**Dyspnea:** Shortness of breath or difficulty breathing.

**Dystonia:** A type of dyskinesia. The movement is slow and twisting. It may be associated with painful muscle contractions or spasms.

**Dysuria:** Difficulty or pain in urination.

**Ebstein anomaly:** Congenital heart defect in which the opening of the tricuspid valve is displaced toward the apex of the right ventricle of the heart.

**Eburnation:** A condition in which bone or cartilage becomes hardened and denser.

**Ecchymosis:** Passage of blood from ruptured blood vessels into subcutaneous tissue causing purple discoloration of the skin.

**Echocardiogram:** An ultrasound test with high-frequency sound waves to produce a graphic image of the interior heart to evaluate the heart's structures and movement.

**Ectopic pregnancy:** Presence of a fertilized ovum outside of the uterine cavity.

**Effector cells:** Cells that become active in response to initiation of the immune response.

**Ejection fraction:** The fraction of the volume present at the end of diastole that is pushed into the aorta during systole.

**Electrocardiogram:** A noninvasive recording of the electrical activity of the heart.

**Electroconvulsive therapy:** Administration of electric current to the brain through electrodes placed on the head to induce seizure activity in the brain; used in the treatment of certain mental disorders.

**Electroencephalograph:** A diagnostic test where electrodes are placed on the scalp and electrical activity in the brain is measured and recorded.

**Electroencephalography:** The recording of brain waves via electrodes placed on the scalp or cortex.

**Embolism:** The sudden blockage of a vessel caused by a blood clot or foreign material which has been brought to the site by the flow of blood.

**Embolization:** The process by which a blood clot or foreign material dislodges from its site of origin, flows in the blood, and blocks a distant vessel.

**Emesis:** Vomiting; a reflexive rapid and forceful oral expulsion of upper gastrointestinal contents due to powerful and sustained contractions in the abdominal and thoracic musculature.

**Endometritis:** Inflammation of the endometrium.

**Endoscopic evaluation:** Visual inspection of the inside of hollow organs with an endoscope; used mainly for diagnostic purposes; refers to procedures such as gastroscopy, duodenoscopy, colonoscopy, and sigmoidoscopy.

**Endoscopy:** A diagnostic tool used to examine the inside of the body using a lighted, flexible instrument called an endoscope.

**Endothelial cell:** A single layer of cells surrounding the lumen of arteries.

**End-stage liver disease:** Liver failure that is usually accompanied by complications such as ascites or hepatic encephalopathy.

**Enteral nutrition:** Delivery of nutrients via the gastrointestinal tract, either by mouth or by feeding tube.

**Enthesitis:** Inflammation of the sites where tendons, ligaments, or fascia attach to bone.

**Enuresis:** Incontinence at night.

**Epilepsy:** A neurological disorder characterized by recurring motor, sensory, or psychic malfunction with or without loss of consciousness or convulsive seizures.

**Epistaxis:** Nasal hemorrhage with blood drainage through the nostrils; a nosebleed.

**Erectile dysfunction:** Condition defined as the inability to achieve or maintain an erection sufficient for sexual intercourse.

**Erythema multiforme:** A rash characterized by papular (small raised bump) or vesicular lesions (blisters), and reddening or discoloration of the skin often in concentric zones about the lesion.

**Erythematous:** Flushing of the skin caused by dilation of capillaries. Erythema is often a sign of inflammation and infection.

**Erythrocyte sedimentation rate:** Non-specific test to indirectly measure degree of inflammation in the body due to conditions such as infections, cancers, or autoimmune diseases.

**Erythrodermic psoriasis:** Generalized erythema covering nearly the entire body surface area. Fever and malaise are common but, while quite rare, can be severe and even fatal; it is usually associated with a worsening of other forms of psoriasis.

**Erythropoiesis stimulating agents:** Agents developed by recombinant DNA technology that have the same biological activity as endogenous erythropoietin to stimulate erythropoiesis (red blood cell production) in the bone marrow. The currently available agents in the United States are epoetinalfa and darbepoetinalfa.

**Erythropoietin:** A hormone primarily produced by the progenitor cells of the kidney that stimulates red blood cell production in the bone marrow. Lack of this hormone leads to anemia.

**Esophageal varices:** Dilated blood vessels in the esophagus.

**Essential fatty acid deficiency:** Deficiency of linoleic acid, linolenic acid, and/or arachidonic acid, characterized by hair loss, thinning of skin, and skin desquamation. Long-chain fatty acids include trienes (containing 3 double-bonds [e.g., 5,8, 11-eicosatrienoic acid {or Mead acid}, trienoic acids]) and tetraenes (containing 4 double-bonds [e.g., arachidonic acid]). Biochemical evidence of essential fatty acid deficiency includes a triene:tetraene greater than 0.2 and low linoleic or arachidonic acid plasma concentrations.

**Euphoria:** A feeling of happiness and excitement.

**Euthymia:** Normal mood.

**Euthyroid:** State of normal thyroid function or hormone activity.

**Euvolemia:** The state of proper fluid balance.

**Exanthem:** Eruption of the skin.

**Exfoliative dermatitis:** Severe inflammation of the entire skin surface due to a reaction to certain drugs.

**Exophthalmos:** Abnormal protrusion of the eyeball, seen in Graves disease.

**Exploratory laparotomy:** Surgical incision into the abdominal cavity, performed to examine the abdominal organs and cavity in search of an abnormality and diagnosis.

**External beam:** An external source of radiation is pointed at a particular part of the body.

**Extraction ratio:** Fraction of the drug entering the liver in the blood which is irreversibly removed.

**Extrapyramidal symptoms (EPS):** Adverse drug effects of medications such as phenothiazines. EPS include dystonia (involuntary muscle contractions), tardive dyskinesia (repetitive, involuntary movements), and akathisia (motor restlessness or anxiety).

**Extravasation:** Movement of fluid from inside a blood vessel into the surrounding tissues.

**Facultative anaerobe:** An organism that makes adenosine triphosphate by aerobic respiration if oxygen is present, but switches to fermentation under anaerobic conditions.

**Felty syndrome:** An extra-articular manifestation of rheumatoid arthritis associated with splenomegaly and neutropenia.

**Ferritin:** A protein in the body that binds to iron; most of the iron stored in the body is bound to ferritin.

**Festination:** Walking with short, rapid, shuffling steps.

**Fibrin:** An insoluble protein that is one of the principal ingredients of a blood clot. Fibrin strands bind to one another to form a fibrin mesh. The fibrin mesh often traps platelets and other blood cells.

**Fibrinolysis:** A normal ongoing process that dissolves fibrin and results in the removal of small blood clots; hydrolysis of fibrin.

**Fibrinolytic:** Possessing the property of preventing blood clot formation.

**Fibroadenoma:** A benign neoplasm that commonly occurs in breast tissue and is derived from glandular epithelium.

**FISH:** A laboratory technique used to look at genes or chromosomes in cells and tissues. Pieces of DNA that contain a fluorescent dye are made in the laboratory and added to cells or tissues on a glass slide. When these pieces of DNA bind to specific genes or areas of chromosomes on the slide, they light up when viewed under a microscope with a special light. Also called fluorescence in situ hybridization.

**Fistula:** Abnormal connection between two internal organs (e.g., arteriovenous fistula is a connection between an artery and a vein), or between an internal organ and the exterior or skin (e.g., enterocutaneous fistula is a connection between the intestine and the skin).

**Fistulogram:** X-ray photograph (or radiograph) taken after injection of a contrast material or radiopaque material (material that will not allow passage of x-rays and will be visible in an x-ray photograph [or radiograph]).

**Flexural psoriasis:** Characterized by lesions found in skin folds. These lesions tend to be erythematous plaques and are often found in the axillary, genital, perineal, intergluteal, and inframammary regions. While shiny, smooth, and deep red in color, there may be skin fissures and the absence of the silvery scales.

**Flight of ideas:** A nearly continuous flow of rapid speech and thought that jumps from topic to topic, usually loosely connected.

**Floppy iris or small pupil syndrome:** The iris of the eye becomes flaccid and cannot become dilated.

**Flow cytometry:** A method of measuring the number of cells in a sample, the percentage of live cells in a sample, and certain characteristics of cells, such as size, shape, and the presence of tumor markers on the cell surface. The cells are stained with a light-sensitive dye, placed in a fluid, and passed in a stream before a laser or other type of light. The measurements are based on how the light-sensitive dye reacts to the light.

**Foam cell:** Lipid-laden white blood cell.

**Forced expiratory volume in 1 second:** The volume of air that a patient can forcibly exhale in the first second of forced exhalation after taking a maximal breath.

**Forced vital capacity:** The maximum volume of air that can be forcibly exhaled after taking a maximal breath.

**Fragility fracture:** A fracture resulting from a fall from standing height or less amount of trauma.

**Frailty:** Excess demand imposed upon reduced capacity; a common biological syndrome in the elderly.

**Frank-Starling mechanism:** Increase in stroke volume in response to an increase in volume of blood filling the heart (i.e., end-diastolic, volume) when all other factors remain constant.

**Freelite™ assay:** A highly sensitive assay that determines the ratio of serum free light chain kappa to lambda.

**Freezing:** A sudden but temporary inability to move.

**Fremitus:** A palpable vibration, as felt by the hand placed on the chest during coughing or speaking.

**Friction:** Risk factor for pressure ulcers that is created when a patient is dragged across a surface, which can lead to superficial skin damage.

**Fructooligosaccharides:** Polymers of fructose that reach the colon undigested and are broken down to short chain fatty acids by bacterial enzymes.

**Functional gastrointestinal disorder:** A term used to describe symptoms occurring in the gastrointestinal tract in the absence of a demonstrated pathologic condition; the clinical product of psychosocial factors and altered intestinal physiology involving the brain–gut interrelationship.

**Gadolinium:** An intravenous contrast agent used with magnetic resonance imaging.

**Gallstone (cholelithiasis):** A solid formation in the gallbladder or bile duct composed of cholesterol and bile salts.

**γ-Aminobutyric acid:** An inhibitory neurotransmitter.

**Gamma knife:** A treatment using gamma rays, a type of high-energy radiation that can be tightly focused on small tumors or other lesions in the head or neck, so very little normal tissue receives radiation.

**Gastrectomy:** Surgical excision of part or all of the stomach.

**Gastric bypass:** A surgical procedure for weight loss that elicits its effectiveness through malabsorption and gastric volume limitation. The procedure involves full partitioning of the proximal gastric segment into a jejunal loop.

**Gastritis:** Chronic or acute inflammation of the lining of the stomach.

**Gastroparesis:** A form of autonomic neuropathy involving nerves of the stomach. It may include nausea, vomiting, feeling full, bloating, and lack of appetite. It may cause wide fluctuations in blood sugars due to insulin action and nutrient delivery not occurring at the same time.

**Gastroschisis:** Congenital abdominal wall defect in which the intestines, and sometimes other organs, develop outside the fetal abdomen through an opening in the abdominal wall.

**Gastrostomy:** Operative placement of a new opening into the stomach, usually associated with feeding tube placement.

**Geniculate nucleus:** The portion of the brain that processes visual information from the optic nerve and relays it to the cerebral cortex.

**Genotype:** The genetic constitution of an individual. May be used to examine the genetic structure of HIV to identify genetic mutations known to cause resistance to certain drugs.

**Geriatric syndrome:** Age specific presentations or differential diagnoses, including visual and hearing impairment, malnutrition and weight loss, urinary incontinence, gait impairment and falls, osteoporosis, dementia, delirium, sleep problems, and pressure ulcers; commonly seen conditions in elderly patients.

**Gestational diabetes mellitus:** Diabetes that occurs during pregnancy which may or may not end at delivery.

**Gigantism:** A condition of abnormal size or overgrowth of the entire body or of any of its parts.

**Glomerular filtration rate:** The volume of plasma that is filtered by the glomerulus per unit time, usually expressed as mL/min or mL/min/1.73 m$^2$ (and in some areas, in SI units of mL/s or mL/s/m$^2$), which adjusts the value for body surface area. This is the primary index used to describe overall renal function.

**Glomerulonephritis:** Glomerular lesions that are characterized by inflammation of the capillary loops of the glomerulus.

These lesions are generally caused by immunologic, vascular, or other idiopathic diseases. Leads to high blood pressure and possible loss of kidney function.

**Glucagon:** Hormone involved in carbohydrate metabolism that is produced by the pancreas and released when glucose levels in the blood are low. When blood glucose levels decrease, the liver converts stored glycogen into glucose, which is released into the bloodstream. The action of glucagon is the opposite of insulin.

**Gluconeogenesis:** Formation of glucose from precursors other than carbohydrates especially by the liver and kidney using amino acids from proteins, glycerol from fats, or lactate produced by muscle during anaerobic glycolysis.

**Glutamate:** An excitatory amino acid found in the central nervous system.

**Glycogenolysis:** The process by which glycogen is broken down to glucose in body tissues.

**Goiter:** An enlargement of the thyroid gland, causing a swelling in the front part of the neck.

**Gonioscopy:** Examination of the anterior chamber angle. A gonioprism or Goldman lens is used to perform gonioscopic evaluation.

**Graft-versus-host disease:** Disease caused when cells from a donated stem cell graft attack the normal tissue of the transplant patient. Symptoms include jaundice, skin rash or blisters, a dry mouth, or dry eyes. Also called GVHD.

**Graft-versus-tumor:** An immune response to a person's tumor cells by immune cells present in a donor's transplanted tissue, such as bone marrow or peripheral blood.

**Grandiosity:** Exaggerated sense of self-importance, ideas, plans, or abilities.

**Granuloma:** Unique inflammatory response composed of macrophages, giant cells, and other cells of the immune response to wall off infectious pathogens perceived as foreign but cannot be eliminated.

**Gross hematuria:** Visible blood in the urine.

**Gummatous tumor:** A soft, gummy tumor which occurs in the later stages of syphilis.

**Gut-associated lymphoid tissue:** Lymphoid tissue, including Peyer patches, found in the gut that are important for providing localized immunity to pathogens.

**Guttate psoriasis:** Psoriasis characterized a heavy or light sprinkling of teardrop-like, salmon-pink papules covered with a fine scale. These lesions are found primarily on the trunk and proximal extremities.

**Haptenation:** The process where a drug, usually of low molecular weight, is bound to a carrier protein or cell and becomes immunogenic.

**Hashimoto disease:** Condition in which the immune system attacks the thyroid gland; may result in hypothyroidism. Symptoms may include fatigue, weight gain, pale or puffy face, feeling cold, joint and muscle pain, constipation, dry and thinning hair, heavy menstrual flow or irregular periods, depression, a slowed heart rate, and problems getting pregnant and maintaining pregnancy. Occurs more commonly in women than in men.

**Health literacy:** Degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions.

**Heberden nodes:** Hard, bony enlargement of the distal interphalangeal (terminal) joint of a finger or toe.

**Hemarthrosis:** Blood in the joint space.

**Hematemesis:** Vomiting of blood.

**Hematochezia:** Passage of stool that is bright red or maroon, usually because of bleeding from the lower gastrointestinal tract.

**Hematogenous:** Spread through the blood.

**Hematoma:** A localized swelling in an organ or soft tissue that is filled with clotted or partially clotted blood resulting from a break in a blood vessel wall.

**Hematuria:** Presence of blood or red blood cells in urine.

**Hemiparesis:** Weakness on one side of the body.

**Hemisensory deficit:** Loss of sensation on one side of the body.

**Hemithorax:** A single side of the trunk between the neck and the abdomen in which the heart and lungs are situated.

**Hemoptysis:** The expectoration of blood or blood-tinged sputum from the larynx, trachea, bronchi, or lungs.

**Hemorrhagic conversion:** Conversion of an ischemic stroke into a hemorrhagic stroke.

**Hemostasis:** Cessation of bleeding through natural (clot formation or construction of blood vessels), artificial (compression or ligation), or surgical means.

**Heparin-induced thrombocytopenia:** A clinical syndrome of IgG antibody production against the heparin-platelet factor 4 complex occurring in approximately 1% to 5% of patients exposed to either heparin or low-molecular weight heparin. Results in excess production of thrombin, platelet aggregation, and thrombocytopenia (due to platelet clumping), often leading to venous and arterial thrombosis, amputation of extremities, and death.

**Hepatic encephalopathy:** Confusion and disorientation experienced by patients with advanced liver disease due to accumulation of ammonia in the bloodstream.

**Hepatic steatosis:** Accumulation of fat in the liver.

**Hepatocellular carcinoma:** Cancer of the liver.

**Hepatojugular reflex:** Distention of the jugular vein induced by pressure over the liver; it suggests insufficiency of the right heart.

**Hepatorenal syndrome:** Acute kidney injury resulting from decreased perfusion in cirrhosis.

**Hepatotoxicity:** Toxicity to the liver causing damage to liver cells.

**Herniation:** Protrusion of the brain through the cranial wall.

**Heterotopic:** Placing a transplanted organ into an abnormal anatomic location.

**Heterozygous:** Having different alleles at a gene locus.

**Hirsutism:** Excess body hair, especially in females, appearing on the lower abdomen, around the nipples, around the chin and upper lip, between the breasts, and on the lower back.

**Histocompatibility:** Compatibility between the tissues of different individuals, so that one accepts a graft from the other without having an immune reaction.

**Homeostenosis:** Impaired capability to withstand stressors and decreased ability to maintain physiological and psychosocial homeostasis; a state commonly found in the elderly.

**Homozygous:** Having identical alleles at a gene locus.

**Hormone receptor-positive:** Tumors that appear to grow in the presence of estrogens; likewise, antiestrogen therapy or estrogen deprivation strategies lead to tumor regression.

**Hospice:** The provision of palliative care during the last six months of life as defined by federal guidelines.

**Hot flashes:** A feeling of warmth that is commonly accompanied by skin flushing and mild to severe perspiration.

**Human leukocyte antigens (HLA):** Groups of genes found on the major histocompatibility complex that contain cell-surface antigen presenting proteins. The body uses HLA to distinguish between self cells and non-self cells.

**Humoral:** Pertaining to or derived from a body fluid. The humoral part of the immune system includes antibodies and immunoglobulins in blood serum.

**Hydramnios:** Increased amniotic fluid.

**Hyperalgesia:** An exaggerated intensity of pain sensation.

**Hypercalcemia:** Excessive amount of calcium in the blood.

**Hypercalciuria:** Excessive amount of calcium in the urine.

**Hypercapnia:** Abnormally high concentration of carbon dioxide in the blood.

**Hypercoagulable state:** A disorder or state of excessive or frequent thrombus formation; also known as thrombophilia.

**Hyperemesis gravidarum:** A rare disorder of severe and persistent nausea and vomiting during pregnancy that can result in dehydration, malnutrition, weight loss, and hospitalization.

**Hyperglycemic hyperosmolar nonketotic syndrome:** Severe increase in serum glucose concentration without the production of ketones, leading to an increase in serum osmolality and symptoms such as increased thirst, increased urination, weakness, fatigue, confusion, and in severe cases, convulsions and/or coma.

**Hyperopia:** Farsightedness.

**Hyperosmolar hyperglycemic state:** Blood glucose levels greater than 600 mg/dL (33.3 mmol/L) without significant ketones where extreme dehydration, insulin deficiency, hyperosmolarity, and electrolyte deficiency are common.

**Hyperpigmentation:** A common darkening of the skin that occurs when an excess of melanin forms deposits in the skin.

**Hyperprolactinemia:** A medical condition of elevated serum prolactin characterized by prolactin serum concentrations greater than 20 ng/mL (20 mcg/L; 870 pmol/L) in men or 25 ng/mL (25 mcg/L; 1087 pmol/L) in women.

**Hyperthyroidism:** State caused by excess production of thyroid hormone.

**Hypertrichosis:** Excessive growth of hair.

**Hypocretin:** A wake-promoting hypothalamic neuropeptide, a deficiency of which is involved in the pathophysiology of narcolepsy.

**Hypogammaglobinemia:** Reduced levels of antibodies.

**Hypogonadism:** A medical condition resulting from or characterized by abnormally decreased functional activity of the gonads, with retardation of growth and sexual development. Associated with testosterone deficiency resulting from either testicular or pituitary/hypothalamic diseases. Presenting symptoms differ according to the timing of disease onset in relation to puberty.

**Hypomania:** Abnormal mood elevation that does not meet the criteria for mania.

**Hypomimia:** Lack of facial expression. Often termed masked face.

**Hypophonia:** Decreased voice volume.

**Hypopituitarism:** A clinical disorder characterized by complete or partial deficiency in pituitary hormone production.

**Hypothalamic-pituitary-adrenal axis:** A neuroendocrine feedback loop that controls response to stress.

**Hypothyroidism:** State caused by inadequate production of thyroid hormone.

**Hypovolemic shock:** Circulatory shock caused by severe loss of blood volume and/or body water.

**Hypoxemia:** Deficiency of oxygen in the blood.

**Hypoxia:** Deficiency of oxygen in body tissues.

**Hysterectomy:** An operation to remove a woman's uterus.

**Idiopathic (genetic) epilepsies:** Epilepsy syndromes thought to be due to genetic alterations. Neurologic functions are completely normal apart from the occurrence of seizures.

**Immunogenicity:** Ability of a substance to provoke an immune response.

**Immunoglobulin G index:** The ratio of immunoglobulin G to protein in the serum or cerebrospinal fluid.

**Immunophenotyping:** A process used to identify cells, based on the types of antigens or markers on the surface of the cell. This process is used to diagnose specific types of leukemia and lymphoma by comparing the cancer cells to normal cells of the immune system.

**Immunotherapy:** A type of biological therapy that uses substances to stimulate or suppress the immune system to help the body fight cancer, infection, and other diseases.

**Impedance pH monitoring:** Detects gastroesophageal reflux based on changes in resistance to electrical current flow between two electrodes when a liquid and/or gas bolus moves between them. It can detect both acid and nonacid reflux.

**Implantable cardioverter defibrillator:** A device implanted into the heart transvenously with a generator implanted subcutaneously in the pectoral area that provides internal electrical cardioversion of ventricular tachycardia or defibrillation of ventricular fibrillation.

**Incretrin effect:** A greater insulin stimulatory effect after an oral glucose load than that caused by an intravenous glucose infusion. The majority of the effect is thought to be due to glucose-dependent insulinotropic peptide (GIP) and glucagon like peptide-1 (GLP-1). Patients with type 2 diabetes have a significant reduction of the incretin effect, implying that these patients either have decreased concentration of the incretin hormones, or a resistance to their effects. GLP-1 concentrations are reduced in patients with type 2 diabetes in response to a meal, while GIP concentrations are either normal or increased, suggesting a resistance to the actions of GIP, thus making GLP-1 a more logical target for therapeutic intervention.

**Induction:** The first treatment given for a disease. It is often part of a standard set of treatments, such as surgery followed by chemotherapy and radiation.

**Infantile spasms (West syndrome):** A seizure syndrome in infants younger than 1 year of age. It is characterized by a specific EEG pattern and spasms or jitters.

**Initiation:** In cancer, occurs when a carcinogenic substance encounters a normal cell to produce genetic damage, and results in a mutated cell.

**Inotropic:** Relating to or influencing the force of muscular contractions.

**Insulin resistance:** A decreased response to insulin found before or early in the diagnosis of type 2 diabetes mellitus.

**Insulin-like growth factor-I (IGF-I):** An anabolic peptide that acts as a direct stimulator of cell proliferation and growth in all body cells.

**Integrase:** Enzyme produced by HIV that enables its genetic material to be integrated into the DNA of the infected host cell.

**International normalized ratio (INR):** The ratio of the patient's clotting time to the clinical laboratory's mean reference value; normalized by raising it to the international sensitivity index (ISI) power to account for differences in thromboplastin reagents. Therefore, INR = (Patient's prothrombin time/laboratory's mean normal prothrombin time)$^{ISI}$.

**Intima:** The inner layer of the wall of an artery or vein.

**Intraarticular:** Administered to or occurring in the space within joints.

**Intraperitoneal:** Within the peritoneal cavity.

**Intrathecal:** Within the meninges of the spinal cord.

**Intravesicular:** Administration directly into the bladder through the urethra.

**Intussusception:** The enfolding of one segment of the intestine within another.

**Iontophoresis:** Introduction of a medication into tissue through use of an electric current.

**Ipsilateral:** Occurring on the same side.

**Ischemic heart disease:** Imbalance between myocardial oxygen supply and oxygen demand.

**Ischemic penumbra:** Ischemic, but still viable cerebral tissue. Typically a rim of mild to moderately ischemic tissue in between normally perfused tissue and the area of evolving infarction; may remain viable for several hours.

**Jejunal enterocyte:** Cells lining the jejunum, which is a section of the small intestine connecting the duodenum to the ileum.

**Jejunostomy:** Operative placement of a new opening into the jejunum, usually associated with feeding tube placement.

**Juvenile myoclonic epilepsy:** An epilepsy syndrome that typically occurs during teenage years and consists of generalized tonic-seizures and myoclonic jerks. Absence seizures may also occur with this syndrome.

**Kegel exercises:** Specific exercises that strengthen the pelvic floor muscles and help to prevent and treat stress incontinence.

**Keratinization:** The sloughing of epithelial cells in the hair follicle.

**Keratinocytes:** The predominant cell type in the outermost layer of the skin.

**Keratitis:** Infection of the cornea.

**Keratoconjunctivitis sicca:** An eye disease caused by eye dryness, which results from either decreased tear production or increased tear film evaporation. Also known as dry eye syndrome.

**Ketosis:** An abnormal increase of ketone bodies present in conditions of reduced or disturbed carbohydrate metabolism.

**Korotkoff sounds:** The noise heard over an artery by auscultation when pressure over the artery is reduced below the systolic arterial pressure.

**Kyphosis:** Abnormal curvature of the spine resulting in protrusion of the upper back; hunchback.

**Lactose intolerance:** Inability to digest milk and some dairy products, resulting in bloating, cramping, and diarrhea; caused by enzymatic lactase deficiency.

**Lag-ophthalmos:** Poor closure of the upper eyelid.

**Lamina cribrosa:** A series of perforated sheets of connective tissue that the optic nerve passes through as it exits the eye.

**Laminectomy:** A surgical procedure to remove the back of one or more vertebrae, usually to give access to the spinal cord or to relieve pressure on nerves.

**Laparoscopic adjustable gastric banding:** A surgical procedure for weight loss that elicits its effectiveness through gastric volume limitation. The procedure involves inserting a silicone band lined with an inflatable donut-shaped balloon around the neck of the stomach to be filled with isotonic liquid thereby limiting food intake.

**Laparoscopy:** Abdominal exploration or surgery employing a type of endoscope called laparoscope.

**Laparotomy:** Surgical opening of the abdominal cavity

**Latent autoimmune diabetes in adults (LADA):** A slow, progressive form of type 1 diabetes mellitus for which a patient does not require insulin for a number of years. In its early stages, LADA typically presents as type 2 diabetes mellitus and

is often misdiagnosed as such. However, LADA more closely resembles type 1 diabetes mellitus and shares common physiological characteristics of type 1 diabetes mellitus for metabolic dysfunction, genetics, and autoimmune features. LADA does not affect children and is classified distinctly as being separate from juvenile diabetes.

**Left shift:** Refers to an increase in the number of immature neutrophils (also referred to as bands). A left shift usually indicates infection or inflammation. The term originated in the days in which lab reports were written by hand and the bands were written on the left-hand side of the lab report. Also known as bandemia.

**Lennox-Gastaut syndrome:** An epilepsy syndrome that often appears early in life that consists of a distinct EEG pattern, mild to severe developmental delay, and multiple seizure types.

**Leukocytoclastic vasculitis:** Acute cutaneous vasculitis characterized by purpura (especially of the legs) and histologically by exudation of neutrophils and sometimes fibrin around dermal venules, with extravasation of red blood cells.

**Leukopenia:** A condition in which the number of circulating white blood cells are abnormally low due to decreased production of new cells, possibly in conjunction with medication toxicities.

**Lewy bodies:** Abnormal masses inside nerve cells. Their structure and composition vary depending on location.

**Lhermitte sign:** Tingling or shock-like sensation passing down the arms or trunk when the neck is flexed.

**Libido:** Conscious or unconscious sexual desire.

**Ligament of Treitz:** Landmark in the proximal portion of the jejunum beyond which it is preferred that postpyloric feedings be delivered for minimization of aspiration.

**Linea nigra:** Dark vertical line that appears on the abdomen during pregnancy.

**Linear accelerator:** An accelerator in which particles travel in straight lines, not in closed orbits.

**Lipophilic:** Having affinity for fatty substances.

**Lipoprotein lipase:** Enzyme located in the capillary endothelium involved in the breakdown of intravenous lipid emulsion particles.

**Livedo reticularis:** Purple mottling of the skin.

**Liver biopsy:** A procedure whereby tissue is removed from the liver and used to determine the severity of liver damage.

**Locus ceruleus:** Nucleus of norepinephrine containing neurons located in the brainstem that are responsible for physiological response to stress and panic.

**Lower esophageal sphincter:** A manometrically defined zone of the distal esophagus with an elevated basal resting pressure that prevents the reflux of gastric material from the stomach. It relaxes on swallowing to permit the free passage of food into the stomach.

**Luteolysis:** Death of the corpus luteum.

**Lymphadenectomy:** A surgical procedure in which the lymph nodes are removed and a sample of tissue is checked under a microscope for signs of cancer.

**Lymphangitis:** Inflammation of lymphatic channels.

**Lymphatic:** The network of vessels carrying tissue fluids.

**Lymphoproliferative:** Of or related to the growth of lymphoid tissue.

**Maceration:** The softening or breaking down of a solid by leaving it immersed in a liquid.

**Macrophages:** Large scavenger cells.

**Macrovascular:** Complications contributed to by diabetes that include myocardial infarctions, strokes, or peripheral vascular disease.

**Macula:** The central portion of the retina.

**Maculopapular:** A rash that contains both macules and papules. A macule is a flat discolored area of the skin, and a papule is a small raised bump. A maculopapular rash is usually a large area that is red and has small, confluent bumps.

**Magnetic resonance imaging:** A test that uses strong magnet fields to create a high resolution image of body parts.

**Major malformation:** A defect that has either cosmetic or functional significance to the child.

**Manometry:** Measurement of pressures and muscle contractions in the esophagus. It helps to localize the lower esophageal sphincter for ambulatory pH monitoring, evaluates peristaltic function in patients considering surgery, and identifies possible motor disorders.

**Macrocytosis:** Enlargement of red blood cells with near-constant hemoglobin concentration.

**Mastalgia:** Tenderness of the breast.

**Matrix metalloproteinase:** Any of a group of enzymes, normally located in the extracellular space of tissue, that function to break down proteins (e.g., collagen) and require zinc or calcium atoms as cofactors for enzymatic activity. Responsible for the degradation of connective tissue.

**Meatal stenosis:** Narrowing in the opening of the urethra.

**Meconium:** First intestinal discharge ("stool") of a newborn infant, usually green in color and consisting of epithelial cells, mucus, and bile.

**Melasma:** Dark skin discoloration. Patchy skin pigmentation, often seen during pregnancy.

**Melena:** Abnormally dark black, tarry feces containing blood (usually from gastrointestinal bleeding).

**Menarche:** The first menstrual cycle.

**Meninges:** Covering of the brain consisting of three layers.

**Menopause:** Permanent cessation of menses following the loss of ovarian follicular activity.

**Menorrhagia:** Menstrual blood loss of greater than 80 mL per cycle; a more practical definition is heavy menstrual flow associated with problems of containment of flow, unpredictably heavy flow days, or other associated symptoms.

**Mesial temporal lobe epilepsy:** A common epilepsy syndrome manifested by seizures arising from the mesial temporal lobe of the brain, and is often associated with an anatomical change, described as hippocampal sclerosis.

**Mesocortical pathway:** A neural pathway that connects the ventral tegmentum to the cortex, particularly the frontal lobes. It is one of the major dopamine pathways in the brain.

**Mesothelioma:** A benign or malignant tumor affecting the lining of the chest or abdomen. Commonly caused by exposure to asbestos fibers.

**Metabolic acidosis:** A condition in the blood and tissues that is a consequence of an accumulation of lactic acid resulting from tissue hypoxia and anaerobic metabolism. It may also be caused by a decrease in the concentration of alkaline compounds (typically bicarbonate).

**Metabolic alkalosis:** Alkalosis that is caused by an increase in the concentration of alkaline compounds (typically bicarbonate).

**Metabolic syndrome:** Constellation of cardiovascular risk factors related to hypertension, abdominal obesity, dyslipidemia, and insulin resistance diagnosed by the presence of at least three of the following criteria: increased waist circumference, elevated triglyceride concentrations, decreased high-density lipoprotein (HDL) cholesterol or active treatment to raise HDL cholesterol, elevated blood pressure, or active treatment with antihypertensive therapy, or elevated fasting glucose or active treatment for diabetes.

**Metastasis:** Cancer that has spread from the original site of the tumor.

**Micelles:** Microscopic particles of digested fat and cholesterol.

**Microalbuminuria:** Urinary excretion of small but abnormal amounts of albumin. Confirmed spot urine albumin to creatinine ratio of 30 to 300 mg/g (3.4 to 34 mg/mmol creatinine) is consistent with microalbuminuria. Considered an early sign of chronic kidney disease.

**Microcytosis:** A condition in which the erythrocytes are smaller than normal.

**Micrognatia:** Abnormal smallness of the jaws.

**Micrographia:** Small handwriting, often seen in patients with Parkinson disease.

**Micrometastases:** Deposits of tumor cells in distant organs that cannot be detected by any imaging techniques available.

**Microsatellite instability (MSI):** The condition of genetic hypermutability that results from impaired DNA mismatch repair (MMR). The presence of MSI represents phenotypic evidence that MMR is not functioning normally.

**Microvascular pulmonary emboli:** An obstruction in the small blood vessels in the lung caused by material (e.g., blood clot, fat, air, foreign body) that is carried through the circulation until it lodges in another small vessel.

**Microvascular:** Complications contributed to by diabetes that include retinopathy, neuropathy, nephropathy.

**Micturition:** Urination.

**Minimum inhibitory concentration:** The lowest concentration of an antimicrobial agent that inhibits visible bacterial growth after approximately 24-hour incubation.

**Minor malformation:** A defect that has neither cosmetic nor functional significance to the child.

**Miosis:** Pupil constriction.

**Mixed acid-base disorder:** See Complicated disorder.

**Mixed mood episodes:** Symptoms of mania and depression occurring simultaneously or in close juxtaposition.

**Mobilization:** Process of encouraging stem cells to emerge from the bone marrow into the peripheral blood where they can be harvested.

**Mobitz type I:** A type of second degree AV nodal block.

**Mobitz type II:** A type of second degree AV nodal block.

**Möbius syndrome:** Rare congenital neurological disorder characterized by facial paralysis and affects eye movement.

**Monocytes:** A variety of white blood cells.

**Monoparesis:** Slight or incomplete paralysis affecting a single extremity or part of one.

**Monosodium urate:** A crystallized form of uric acid that can deposit in joints leading to an inflammatory reaction and the signs and symptoms of gout.

**Morphology:** The science of the form and structure of organisms (plants, animals, and other forms of life).

**Motor tics:** An involuntary brief spasmodic muscular movement or contraction, usually of the face or extremities.

**Mucositis:** Inflammation of mucous membranes, typically within the oral and esophageal mucosa. Usually associated with certain chemotherapy agents and radiation therapy involving mucosal area.

**Mucous colitis:** A condition of the mucous membrane of the colon characterized by pain, constipation, or diarrhea (sometimes alternating), and passage of mucus or mucous shreds.

**Multiparity:** Condition of having given birth to multiple children.

**Muscularis mucosa:** The thin layer of smooth muscle found in most parts of the gastrointestinal tract.

**Mydriasis:** Pupil dilation.

**Myelin:** A protein and phospholipid sheath that surrounds the axons of certain neurons. Myelinated nerves conduct impulses more rapidly than non-myelinated nerves.

**Myeloablative preparative regimen:** A regimen consisting of a single agent or combination of agents expected to destroy the hematopoietic cells in the bone marrow and resulting in profound pancytopenia within one to three weeks from the time of administration. The resulting pancytopenia is long-lasting, usually irreversible, and in most instances fatal, unless hematopoiesis is restored by infusion of hematopoietic stem cells.

**Myelodysplastic syndrome:** One of a group of disorders characterized by abnormal development of one or more of the cell lines that are normally found in the bone marrow.

**Myeloproliferative disorder:** A group of diseases of the bone marrow in which excess cells, usually lymphocytes, are produced.

**Myelosuppression:** Reduction in white blood cells, red blood cells, and platelets.

**Myocardial infarction:** The formation of an infarct, an area of tissue death, due to a local lack of oxygen. Myocardial cell death secondary to prolonged ischemia.

**Myocarditis:** Inflammation of the heart muscle.

**Myoclonic:** A primary-generalized seizure characterized by a single and very brief (< 1 sec) jerk of the body, head, or arms.

**Myoglobinuria:** The presence of myoglobin in urine.

**Myonecrosis:** Necrotic damage to muscle tissue.

**Myopathy:** Any disease of the muscle causing weakness, pain, and tenderness.

**Myringotomy:** A surgical incision in the tympanic membrane to relieve pressure and drain fluid from the middle ear.

**Myxedema:** Hypothyroidism characterized by a relatively hard edema of subcutaneous tissue, with increased content of proteoglycans in the fluid; characterized by somnolence, slow mentation, dryness and loss of hair, increased fluid in body cavities such as the pericardial sac, subnormal temperature, hoarseness, muscle weakness, and slow return of a muscle to the neutral position after a tendon jerk.

**Nail psoriasis:** Nail psoriasis can be characterized by pitting, oncholysis, hyperkeratosis, and an oil-drop sign.

**Nasal scotoma:** An area of blindness in the nasal portion of peripheral vision.

**Nascent:** Immature.

**Nasolacrimal occlusion:** The closing of the tear duct to decrease systemic absorption of a drug.

**Nausea:** The subjective feeling of a need to vomit.

**Necrosectomy:** Surgical excision of necrotic tissue; debridement.

**Necrotizing enterocolitis:** Medical condition seen in premature infants, where portions of the bowel undergo necrosis.

**Negative feedback:** A self-regulating process that responds to influences of an original signal resulting in stabilization or reductions in the effect of fluctuations.

**Nelson syndrome:** A condition characterized by the aggressive growth of a pituitary tumor and hyperpigmentation of the skin.

**Neoadjuvant therapy:** Therapeutic strategy that precedes primary treatment modality (usually surgery). The goals are to "down-stage" tumors so that the surgical field is smaller or to transform a patient from a nonsurgical candidate to one that is surgical. Neoadjuvant therapy may improve overall survival. Strategies usually involve the use of systemic therapy with or without radiation.

**Neovascular maculopathy:** Proliferation of blood vessels in the macula.

**Nephrolithiasis:** A condition marked by the presence of renal calculi (stones) in the kidney or urinary system.

**Nephron:** The working unit of the kidney that filters blood to remove fluid, toxins, and drugs. Each kidney contains approximately 1 million nephrons.

**Nephrostomy:** Surgery to make an opening from the outside of the body to the renal pelvis (part of the kidney that collects urine). This may be done to drain urine from a blocked kidney or blocked ureter into a bag outside the body. It may also be done to look at the kidney using an endoscope (thin, lighted tube attached to a camera), to place anticancer drugs directly into the kidney, or to remove kidney stones.

**Neuritic plaques:** Extracellular deposits of beta amyloid in the gray matter of the brain.

**Neuritis:** Inflammation of a nerve.

**Neurofibrillary tangles:** Aggregates of hyperphosphorylated tau protein; commonly known as a primary marker of Alzheimer disease.

**Neuropathic pain:** Pain resulting from a lesion or dysfunction of the nervous system.

**Neuropathy:** An abnormal and usually degenerative state of the nervous system or nerves. Damage to the small and large nerves due to glycation end products, lack of blood and nutrients to the nerves, or chemical imbalances.

**Neurotransmitters:** Chemicals in the brain that allow the passage of a message between neurons or nerve cells.

**Neutralizing antibodies:** Antibodies that develop in response to a therapeutic agent that decrease the efficacy of the agent.

**Nidus:** A site of origin in which bacteria have multiplied or may multiply; a focus of infection.

**Nitric oxide:** An endogenous vasodilator.

**NMDA antagonist:** Class of medications that work to antagonize the N-methyl-D-aspartate receptor.

**Nociception:** Encoding and processing of noxious stimuli to the nervous system.

**Nociceptors:** Receptors for pain caused by injury from physical stimuli (mechanical, electrical, or thermal) or chemical stimuli (toxins); located in the skin, muscles, or in the walls of the viscera.

**Nocturia:** Excessive urination at night.

**Nocturnal polysomnography:** Electrophysiologic assessment of human sleep minimally composed of electroencephalogram, electrooculogram, and electromyogram that allows determination of sleep stage, breathing events, and muscle movements.

**Nodules:** An abnormal small swelling or aggregation of cells in the body. When seen with rheumatoid arthritis, nodules are subcutaneous knobs over bony prominences or extensor surfaces.

**Nonmyeloablative preparative regimen:** A nonmyeloablative regimen is one that will cause minimal cytopenia (but significant lymphopenia) by itself and does not require stem cell support.

**Nonpolyposis:** Absence of polyps.

**Nonprotein kilocalorie to nitrogen ratio:** Numerical value derived from dividing kilocalories from carbohydrate plus fat by the number of grams of nitrogen in the diet.

**Non-REM sleep:** A state of usually dreamless sleep that occurs regularly during a normal period of sleep with intervening periods of REM sleep and that consists of four distinct substages and low levels of autonomic physiological activity.

**Non-ST-segment elevation myocardial infarction:** A type of myocardial infarction that is limited to the sub-endocardial myocardium and is smaller and less extensive than an ST-segment elevation myocardial infarction.

**Normal flora:** Normal colonizing bacteria of a human host.

**Nuchal rigidity:** Neck stiffness.

**Nuclear factor kappa-light-chain-enhancer of activated B cells (Nf-kappa-B):** A protein complex that controls transcription of DNA, cytokine production, and cell survival.

**Nulliparity:** Condition of not having given birth to a child.

**Nystagmus:** Rapid, involuntary movements of the eyes.

**Off time:** The time when a Parkinson disease patient has poor control of his or her symptoms.

**Off-label use:** Use of a medication outside the scope of its approved, labeled use.

**Oiling out:** Continued coalescence of lipid emulsion particles, resulting in irreversible separation of the emulsion (also called "breaking" or "cracking" of the emulsion).

**Oligoanovulation:** The condition of having few to no ovulatory menstrual cycles.

**Oligoclonal immunoglobulin G bands:** Small discrete bands in the gamma globulin region of fluid electrophoresis.

**Oligohydramnios:** Decreased amniotic fluid.

**Oligomenorrhea:** Abnormally light or infrequent menstruation.

**Oliguria:** Reduced urine output; usually defined as less than 400 mL in 24 hours or less than 0.5 mL/kg/hour.

**Omentumectomy:** Excision of the double fold of the peritoneum attached to the stomach and connecting it with abdominal viscera (omentum).

**On time:** The time when the Parkinson disease patient has good control of his or her symptoms.

**Oncogenes:** Genes, when activated, that cause transformation of normal cells into cancer cells by promoting uncontrolled cell growth and multiplication leading to tumor formation.

**Open comedo:** A plugged hair follicle of sebum, keratinocytes, and bacteria that protrudes from the surface of the skin and appears black or brown in color. Also referred to as a "blackhead."

**Opsonization:** The process by which an antigen is altered so as to become more readily and more efficiently engulfed by phagocytes.

**Optic neuritis:** Usually monocular central visual acuity loss and ocular/periorbital pain caused by demyelination of the optic nerve.

**Oral glucose tolerance test:** Used to measure the body's response to glucose; may be used to screen for type 2 diabetes and gestational diabetes.

**Oral rehydration solution (ORS):** A liquid preparation, commercially prepared or made at home using common ingredients according to a formula developed by the World Health Organization, designed to replace fluid loss in persons with diarrhea.

**Organification:** Binding of iodine to tyrosine residues of thyroglobulin.

**Orthopnea:** Difficulty in breathing that occurs when lying down and is relieved upon changing to an upright position.

**Orthostasis:** Characterized by a drop in blood pressure when standing up from sitting or lying down, often causing lightheadedness and dizziness.

**Orthotopic transplantation:** Placing a transplanted organ into the normal anatomic location.

**Osmolality:** A measure of the number of osmotically active particles per unit solution, independent of the weight or nature of the particle.

**Osmolar gap:** The difference between the measured serum osmolality and the calculated serum osmolality.

**Osteoblast:** Cells that secrete the matrix for bone formation.

**Osteoclasts:** Cells involved in bone resorption.

**Osteomalacia:** Softening of the bones.

**Osteonecrosis:** Death of bone tissue.

**Osteopenia:** Reduced bone density or mass.

**Osteophytes:** Bony outgrowths (also called bone spurs) into the joint space.

**Osteoporosis:** Disease of the bones characterized by a loss of bone tissue, resulting in brittle, weak bones that are susceptible to fracture (porous bones).

**Ostomy:** Surgical operation by which part of the abdominal wall is opened and part of the intestine is connected to the opening for intestinal draining (e.g., colostomy, ileostomy).

**Otalgia:** Ear pain or earache.

**Otitis media with effusion:** Fluid in the middle ear space with no signs or symptoms of an acute infection.

**Ovulation:** Periodic ripening and rupture of mature follicle and the discharge of ovum from the cortex of the ovary.

**Pacemaker:** A mass of fibers that possess actual or potential automaticity which initiates and determines the rate of spontaneous depolarizations.

**Palliative care:** The active, total care of patients whose disease is not responsive to curative treatment.

**Palliative chemotherapy:** Treatment given to control the symptoms of an incurable cancer.

**Pancolitis:** Inflammation that involves the majority of the colon in patients with inflammatory bowel disease; often used interchangeably with extensive disease.

**Pancreatic pseudocysts:** A cyst-like space not lined by epithelium and contained within the pancreas.

**Pancreatitis:** Inflammation of the pancreas.

**Panhypopituitarism:** A clinical disorder characterized by complete deficiency in pituitary hormone production.

**Pannus:** Inflamed synovial tissue that invades and destroys articular structures.

**Papilledema:** Swelling around the optic disk, the area where the optic nerve (the nerve that carries messages from the eye to the brain) enters the eyeball.

**Paracentesis:** Removal of ascitic fluid from the peritoneal space.

**Paracentral scotoma:** Blind spots near the center of the visual field.

**Parasomnia:** Undesirable physical or behavioral phenomena that occur predominantly during sleep. The most common parasomnias include sleepwalking, sleeptalking, bruxism, enuresis, and REM sleep behavior disorder.

**Parenchyma:** Specific cells or tissue of an organ.

**Parenteral nutrition:** Delivery of nutrients via the intravenous route.

**Paresthesia:** An abnormal touch sensation, such as burning or prickling, that occurs without an outside stimulus.

**Paroxysmal:** Intermittent occurrence, initiating suddenly and spontaneously, lasting minutes to hours, and terminating suddenly and spontaneously.

**Partial response:** In cancer, at least a 30% decrease in the sum of the longest diameter of target lesions from baseline.

**Partial seizures:** Seizures that begin in a localized area of the brain.

**Peak expiratory flow:** The maximum flow rate of air leaving the lungs upon forced exhalation. Individualized best measurements are established for each patient using a handheld peak flow meter.

**Pelvic inflammatory disease:** Inflammation of the endometrium, uterine tubes, and pelvic peritoneum; often due to a sexually transmitted infection.

**Percutaneous coronary intervention:** A minimally invasive procedure whereby access to the coronary arteries is obtained through either the femoral or radial artery up the aorta to the coronary ostia. Contrast media is used to visualize the coronary artery stenosis using a coronary angiogram. A guidewire is used to cross the stenosis and a small balloon is inflated to break up atherosclerotic plaque and restore coronary artery blood flow. A stent is often deployed at the site to prevent acute closure and restenosis of the coronary artery. Newer stents are coated with antiproliferative drugs, such as paclitaxel, sirolimus, zotarolimus, or everolimus, which further reduce the risk of restenosis of the coronary artery.

**Percutaneous endoscopic gastrostomy:** Gastric feeding tube placed via endoscopic technique.

**Percutaneous endoscopic jejunostomy:** Jejunal feeding tube placed via endoscopic technique.

**Perihilar:** Around the root or hilum of the lung.

**Perimenopause:** Also known as the climacteric, is the period of time prior to menopause when hormonal and biological changes and physical symptoms begin to occur and usually lasts for one year after the last menstrual period. The perimenopausal period may last for an average of three to five years.

**Perimetry:** Measurement of the field of vision.

**Peripheral artery disease:** Atherosclerosis of the peripheral arteries.

**Peripheral resistance:** The sum of resistance to blood flow by systemic blood vessels.

**Peritonitis:** An acute inflammatory reaction of the peritoneal lining to microorganisms or chemical irritation.

**Petechiae:** Tiny localized hemorrhages from the small blood vessels just beneath the surface of the skin.

**Phagocytosis:** The process of engulfing and ingesting an antigen by phagocytes.

**Pharmacogenomics:** The study of inherited genetic variations that dictate different drug responses. Pharmacogenomics explores the ways such variations can be used to predict responses to investigational products and plays an increasingly important role in drug discovery.

**Phenotype:** The visible or observable properties of an organism that are produced by the interaction of the genotype and the environment. May be used to evaluate the growth of HIV compared to "wild type" virus in the presence of drug to directly measure the amount of drug necessary to suppress viral replication in vitro.

**Pheochromocytoma:** A tumor arising from chromaffin cells, most commonly found in the adrenal medulla. The tumor causes the adrenal medulla to hypersecrete epinephrine and norepinephrine resulting in hypertension and other signs and symptoms of excessive sympathetic nervous system activity. The tumor is usually benign but may occasionally be cancerous.

**Phlebitis:** Inflammation of a blood vessel (e.g., vein).

**Photochemotherapy:** The use of psoralens in addition to ultraviolet rays for patients with a significant amount of body surface area affected (greater than 10%).

**Photodynamic therapy:** Treatment with drugs that become active when exposed to light.

**Photophobia:** Intolerance to bright light.

**Phototherapy:** The use of ultraviolet rays for patients with a significant amount of body surface area affected (greater than 10%).

**Physical dependence:** A state of adaptation that is manifested by a drug-class specific withdrawal syndrome that can be produced by abrupt cessation, rapid dose reduction, decreasing blood level of the drug, and/or administration of an antagonist.

**Pilosebaceous unit:** A hair follicle and the surrounding sebaceous glands.

**Plaque psoriasis:** Plaque psoriasis is the most common form of psoriasis and manifests as well-defined, sharply demarcated, erythematous plaques typically covered with silvery scales. These plaques are irregular, round to oval in shape, and are almost always found on the scalp, trunk, buttocks, and limbs.

**Plasma cell:** Antibody producing cells.

**Plasmapheresis:** A process of separating cells out from the plasma. This process is used to remove the monoclonal antibodies from the blood.

**Pleocytosis:** An increased white blood cell count in a bodily fluid, such as cerebrospinal fluid.

**Pleuritis:** Inflammation of the lining (pleura) around the lungs.

**Pneumatic otoscopy:** A diagnostic technique involving visualization of the tympanic membrane for transparency, position, and color, and its response to positive and negative air pressure to assess mobility.

**Pneumothorax:** The presence of air in the pleural cavity, often causing part of the lung to collapse.

**Podagra:** Gout involving the first metatarsophalangeal joint (great toe).

**Polycythemia:** An abnormal increase in the number of erythrocytes in the blood.

**Polydipsia:** Excessive thirst.

**Polymerase chain reaction:** A laboratory method used to make many copies of a specific DNA sequence.

**Polyphagia:** Eating excessively large amounts of food at a meal.

**Polypharmacy:** Taking multiple medications concurrently.

**Polyps:** Any growth or mass protruding from a mucous membrane.

**Polyuria:** Excessive excretion of urine resulting in profuse micturition.

**Portal hypertension:** Increased pressure in blood vessels leading to the liver; usually a result of cirrhosis.

**Posterior circulation:** Blood supply to the posterior section of the brain through the vertebral, basilar, and posterior cerebral arteries (i.e., brainstem, cerebellum, occipital lobe).

**Postpyloric feeding:** Delivery of nutrients via a tube placed with its tip past the pyloric sphincter separating the stomach from the duodenum.

**Prader-Willi syndrome:** A genetic disorder characterized by short stature, mental retardation, low muscle tone, abnormally small hands and feet, hypogonadism, and excessive eating leading to extreme obesity.

**Prediabetes:** An asymptomatic but abnormal state that precedes the development of clinically evident diabetes.

**Preload:** The stretched condition of the heart muscle at the end of diastole just before contraction; volume in the left ventricle at the end of diastole estimated by the pulmonary artery occlusion pressure (also known as the pulmonary artery wedge pressure or pulmonary capillary wedge pressure).

**Priapism:** A prolonged, painful erection lasting more than 4 hours. Considered a medical emergency.

**Primary amenorrhea:** Absence of menses by age 15 in the presence of normal secondary sexual development or within 5 years of thelarche (if occurs before age 10).

**Primary generalized seizures:** A seizure where the entire cerebral cortex is involved from the onset of the seizure.

**Primary prevention:** A program of activities directed at improving general well-being while also involving specific protection for selected diseases.

**Prinzmetal angina:** Vasospasm or contraction of the coronary arteries in the absence of significant atherosclerosis. Also referred to as variant angina.

**Probiotics:** Dietary supplements containing potentially beneficial bacteria that promote health by stimulating optimal mucosal immune responses.

**Proctitis:** Inflammation confined to the rectum in patients with inflammatory bowel disease.

**Proctosigmoiditis:** Inflammation involving the sigmoid colon and rectum in patients with inflammatory bowel disease.

**Progenitor:** A primitive cell.

**Prognostic factors:** Biologic or clinical indicators associated with survival independent of therapy (e.g., over-expression of HER2 is associated with increased risk of relapse and shorter survival).

**Progression:** In cancer, cell proliferation takes over and the tumor spreads or develops metastases.

**Prolapse:** A condition whereby organs fall down or slip out of place.

**Promotion:** Reversible process in cancer; the environment is altered by carcinogens or other factors to favor the growth of the mutated cell over the normal cell.

**Proptosis:** Forward displacement of the eyeball.

**Prostaglandin:** Any of a large group of biologically active, carbon-20, unsaturated fatty acids that are produced by the metabolism of arachidonic acid through the cyclooxygenase pathway.

**Prostatectomy:** An operation to remove the prostate gland and tissues surrounding it.

**Prostatic hyperplasia:** Enlargement of the prostate.

**Protease:** Enzyme that cleaves newly synthesized polyproteins into functional units of an infectious HIV virion.

**Protectant:** An agent that forms an occlusive barrier between the skin and surrounding moisture.

**Proteinase:** Any of numerous enzymes that catalyze the breakdown of proteins (also called protease).

**Proteinuria:** The presence of measurable amounts of protein in the urine, which is often indicative of glomerular or tubular damage in the kidney.

**Proteoglycan:** Any one of a class of glycoproteins of high molecular weight that are found in the extracellular matrix of connective tissue. They are made up mostly of carbohydrate consisting of various polysaccharide side chains linked to a protein and resemble polysaccharides rather than proteins with regard to their properties.

**Proteolysis:** Degradation of proteins in damaged tissue.

**Proteosome:** An enzyme complex that degrades intracellular proteins.

**Prothrombin:** A clotting factor that is converted to thrombin; also known as Factor II.

**Prothrombin time:** A measure of coagulation representing the amount of time required to form a blood clot after the addition of thromboplastin to the blood sample; also known as Quick test.

**Prothrombotic state:** A state of high coagulation of the blood.

**Protooncogenes:** Normal genes that are present in all normal cells and regulate cell function and replication, and through some genetic alteration caused by carcinogens, change into oncogenes.

**Pruritis:** Localized or generalized itching due to irritation of sensory nerve endings.

**Pseudoaddiction:** A term used to describe patient behaviors (e.g., "drug-seeking," "clock watching", or illicit drug use) that may occur when pain is undertreated. Pseudoaddiction can be distinguished from true addiction in that the behaviors resolve when pain is effectively treated.

**Pseudohyphae:** Chains of easily disrupted fungal cells; not a true hypha.

**Pseudophakic:** Refers to presence of a lens after cataract extraction.

**Pseudopolyp:** An area of hypertrophied gastrointestinal mucosa that resembles a polyp and contains non-malignant cells.

**Psoralens:** Compounds that act as photosensitizing compounds.

**Psoriatic arthritis:** Inflammatory arthropathy associated with psoriasis. This condition is characterized by stiffness, pain, swelling, and tenderness around the joints and ligaments.

**Pulmonary artery catheter:** An invasive device used to measure hemodynamic parameters directly, including cardiac output and pulmonary artery occlusion pressure; calculated parameters include stroke volume and systemic vascular resistance.

**Pulmonary artery occlusion pressure:** A hemodynamic measurement obtained via a catheter placed into the pulmonary artery used to evaluate patient volume status within the left ventricle.

**Pulmonary embolism:** A disorder of thrombus formation causing obstruction of a pulmonary artery or one of its branches and resulting in pulmonary infarction.

**Pulsus paradoxus:** A large fall in systolic blood pressure and pulse volume during inspiration or an abnormal variation in pulse volume during respiration in which the pulse becomes weaker with inspiration and stronger with expiration.

**Punding:** Stereotyped behavior with repetitive movement or actions. An adverse reaction to dopaminergic therapy.

**Purkinje fibers:** Specialized myocardial fibers that conduct impulses from the atrioventricular node to the ventricles.

**Purpura:** A small hemorrhage of the skin, mucous membrane, or serosal surface.

**Purulent:** Containing, consisting of, or being pus.

**Pustular psoriasis:** Collection of neutrophils is great enough to be seen clinically. May be generalized or localized. Often characterized by widespread sterile pustules and erythema.

**Pyelonephritis:** Inflammation of a kidney.

**Pyuria:** Presence of pus in urine when voided.

**Quality indicators:** A list of indicators used by long-term care facility administrators and government overseers to identify potential problems in patient care.

**Quality of life:** Perceived physical and mental health over time.

**Radiofrequency catheter ablation:** Procedure by which radio-frequency energy is delivered through a catheter positioned at the atrioventricular node for the purpose of destroying one pathway of a reentrant circuit.

**Raphe nuclei:** Bed of serotonin containing neurons that extend to the hypothalamus, septum, hippocampus, and cingulate gyrus.

**Receptor editing:** A process that occurs during the maturation of B cells, which are part of the adaptive immune system. This process forms part of central tolerance to attempt to change the specificity of the antigen receptor of self reactive immature B-cells, in order to rescue them from programmed cell death, called apoptosis.

**Recombinant activated factor VII:** A clotting factor manufactured via recombinant technology used off-label (not Food and Drug Administration approved) to foster clotting in

hemorrhagic shock patients with massive hemorrhage refractory to conventional therapies such as fresh frozen plasma.

**Rectal prolapse:** Externally visible sinking of the rectum through the anal sphincter.

**Recurrence:** A relapse that occurs after a clear-cut recovery.

**Reentry:** Circular movement of electrical impulses, a mechanism of many arrhythmias.

**Refractory period:** The period of time after an impulse is initiated and conducted during which cells cannot be depolarized again.

**Regurgitation:** A passive process without involvement of the abdominal wall and the diaphragm wherein gastric or esophageal contents move into the mouth.

**Relapse:** The return of symptoms, satisfying the full syndrome criteria, after a patient has responded, but prior to recovery.

**REM sleep:** A state of sleep that recurs cyclically several times during a normal period of sleep and is characterized by increased neuronal activity of the forebrain and midbrain, depressed muscle tone, and especially dreaming, rapid eye movements, and vascular congestion of the sex organs.

**Remission:** Patient has no or minimal symptoms of disease. In the case of cancer, in partial remission, some but not all signs and symptoms of cancer have disappeared. In complete remission, all signs and symptoms of cancer have disappeared, although cancer still may be in the body.

**Renal osteodystrophy:** Altered bone turnover that results from sustained metabolic conditions that occur in chronic kidney disease, including secondary hyperparathyroidism, hyperphosphatemia, hypocalcemia, and vitamin D deficiency. The disease can be characterized by high bone turnover, low bone turnover, or adynamic disease, or may be a mixed disorder.

**Renin-angiotensin-aldosterone system:** The hormonal system controlled mainly by the kidneys and adrenal glands that regulates blood pressure, blood volume, and electrolyte balance.

**Resorption:** The process of bone breakdown by osteoclasts.

**Respiratory acidosis:** Acidosis that is caused by an accumulation of carbon dioxide.

**Respiratory Disturbance Index:** A summary measure that quantifies the number of apneas, hypopneas, and respiratory effort-related arousals per hour of sleep.

**Response:** Refers to a pre-defined reduction of symptoms from baseline that generally result in significant functional improvement.

**Response inhibition:** Ability to stay on task or the ability to think before acting.

**Restenosis:** Renarrowing of the coronary artery after a percutaneous intervention.

**Restriction fragment length polymorphism:** Variation in the length of a restriction fragment produced by a specific restriction enzyme acting on DNA from different individuals that usually results from a genetic mutation and that may be used as a genetic marker.

**Retching:** A process that follows nausea and consists of diaphragm, abdominal wall, and chest wall contractions and spasmodic breathing against a closed glottis.

**Reticulocytes:** Immature blood cells that mature into erythrocytes.

**Retinopathy:** Occurs when the microvasculature nerve layer that provides blood and nutrients to the retina is damaged, and can cause blindness.

**Retrograde ejaculation:** Semen flows to the bladder instead of the urethra.

**Reverse transcriptase:** Enzyme that generates complementary DNA from an RNA template used in the replication of HIV.

**Rhabdomyolysis:** Destruction of skeletal muscle.

**Rheumatoid factors:** Antibodies reactive with the Fc region of IgG.

**Rhinosinusitis:** Inflammation of the mucous membranes in the nose and sinuses.

**Rhonchi:** Abnormal, rumbling sounds heard on auscultation of an obstructed airway. They are more prominent during expiration and may clear somewhat on coughing.

**Rouleaux formation:** The stacking or aggregation of red blood cells on a peripheral smear when diluted.

**Rubefacient:** A substance that produces redness of the skin.

**Salicylism:** A toxic syndrome caused by excessive doses of acetylsalicylic acid (aspirin), salicylic acid, or any other salicylate product. Signs and symptoms may include severe headache, nausea, vomiting, tinnitus (ringing in the ears), confusion, increased pulse, and increased respiratory rate.

**Scleritis:** Inflammation of the outer layer of the eyeball (sclera).

**Scotoma:** A spot in the visual field in which vision is absent or deficient.

**Secondarily generalized seizure:** A partial seizure (simple or complex) that spreads to the entire brain.

**Secondary amenorrhea:** Absence of menses for 3 cycles or 6 months in a previously menstruating woman.

**Secondary hyperparathyroidism:** Increased secretion of parathyroid hormone from the parathyroid glands caused by hyperphosphatemia, hypocalcemia, and vitamin D deficiency that result from decreased kidney function. Secondary hyperparathyroidism can lead to bone disease (renal osteodystrophy).

**Secondary prevention:** Interruption of any disease process before the emergence of recognized signs or diagnostic findings of the disorder.

**Seizure:** A sudden electrical disturbance of the cerebral cortex, when a population of neurons fires rapidly and repetitively for seconds to minutes and electrical discharges are excessively rapid, rhythmic, and synchronous.

**Sentinel lymph node:** The first lymph node to which cancer is likely to spread from the primary tumor.

**Septic emboli:** A detached, traveling intravascular mass of infected tissue.

**Seropositive:** Showing a positive reaction to a test on blood serum for a disease.

**Serum sickness:** A group of symptoms caused by a delayed immune response to certain medications. Arthralgias, fever, malaise, and urticaria may develop usually 7 to 14 days after exposure to the causative antigen.

**Shear stress:** Risk factor for pressure ulcers that is generated when the head of a patient's bed is elevated and can cause deeper blood vessels to crimp, leading to ischemia.

**Sialorrhea:** Drooling.

**Sick sinus syndrome:** Idiopathic sinus node dysfunction leading to symptomatic sinus bradycardia.

**Sigmoidoscopy:** Visual inspection of the sigmoid colon and rectum with a flexible tube called a sigmoidoscope.

**Simple acid-base disorder:** The presence of a single acid-base disorder, with or without compensation.

**Simple partial seizures:** Seizures in which the patient has a sensation or uncontrolled muscle movement of a portion of their body without an alteration in consciousness.

**Sleep apnea:** The temporary stoppage of breathing during sleep; can be caused by narrowing of the airways resulting from swelling of soft tissue.

**Sleep latency:** The amount of time it takes to fall asleep.

**Sleeve gastrectomy:** A surgical treatment for weight loss that involves constructing a small pouch in the stomach that empties through a narrow opening into the distal stomach and duodenum.

**Slit-lamp biomicroscope:** An instrument that allows for the microscopic examination of the cornea, anterior chamber lens and posterior chamber.

**Somatic hypermutation:** A cellular mechanism by which the immune system adapts to the new foreign elements that confront it (e.g., microbes), as seen during class switching.

**Source control:** Removal of the primary cause of an infection such as contaminated prosthetic materials (e.g., catheters), necrotic tissue, or drainage of an abscess. Antimicrobials are unlikely to be effective if the process or source that led to the infection is not controlled.

**Spastic colon:** A synonym for irritable bowel syndrome.

**Spasticity:** A motor disorder characterized by an increase in muscle tone with exaggerated tendon jerks, resulting from hyperexcitability of the stretch reflex.

**Spectrum of activity:** A qualitative term that describes the number of different bacterial species that are susceptible to an antimicrobial regimen. Generally, broad spectrum activity refers to regimens that possess activity against many bacterial species, whereas narrow-spectrum therapy refers to activity against a few bacterial species.

**Sphincter of Oddi:** Structure through which the common bile duct empties bile and pancreatic secretions into the duodenum.

**Spirometry:** Measurement by means of a spirometer of the air entering and leaving the lungs.

**Sprain:** An overstretching of supporting ligaments that results in a partial or complete tear of the ligament.

**Stable disease:** In cancer, neither sufficient shrinkage to qualify for partial response nor sufficient increase to qualify for progressive disease.

**Stage:** Estimate of tumor burden, which is not only of prognostic importance, but also has important implications regarding appropriate treatment options.

**Status epilepticus:** Continuous seizure activity lasting more than 5 minutes or two or more seizures without complete recovery of consciousness.

**Steatohepatitis:** A severe form of liver disease caused by fat deposition in the liver, characterized by hepatic inflammation that may rapidly progress to liver fibrosis and cirrhosis.

**Steatorrhea:** Excessive loss of fat in stool.

**Steatosis:** Infiltration of liver cells with fat.

**Stenosis:** Blockage of an artery.

**Stenting:** Placement of a stent to allow blood flow through an artery.

**Stereotactic radiosurgery:** A type of external radiation therapy that uses special equipment to position the patient and precisely give a single large dose of radiation to a tumor.

**Stevens-Johnson syndrome:** A severe expression of erythema multiforme (also known as erythema multiforme major). It typically involves the skin and the mucous membranes, with the potential for severe morbidity and even death.

**Stimulant:** Any amphetamine or amphetamine-like substance (methylphenidate) that causes an increase in dopaminergic and norepinephrine activity in the brain resulting in lessening of hyperactivity, impulsiveness, and/or inattentiveness.

**Stomatitis:** Inflammation of mucous membranes in the mouth.

**Strain:** Damage to the muscle fibers or tendon without tearing of the ligament.

**Stricture:** An abnormal narrowing of a body passage, especially a tube or a canal.

**Stroke volume:** The amount of blood ejected from the heart during systole.

**ST-segment elevation myocardial infarction:** A type of myocardial infarction that typically results in an injury that transects the thickness of the myocardial wall.

**Subchondral:** Situated beneath and supporting cartilage.

**Substantia nigra:** The area in the brainstem with highly pigmented cells that make dopamine.

**Subtrochanteric:** Below the trochanter (the bony protrusion at the end of the femur where the hip and thigh muscles attach).

**Surgical site infection:** Infections occurring at or near the surgical incision within 30 days of the operation; up to 1 year if a prosthesis is implanted.

**Suspending agent:** An additive used in the compounding of oral liquid medications to suspend drug particles throughout a liquid; enables resuspension of particles by agitation (eg, shaking well).

**Symptomatic epilepsies:** A seizure disorder with an identifiable cause for the seizures, such as trauma or hypoxia.

**Synechia:** Adhesions or the abnormal attachment of the iris to another structure. Peripheral anterior synechia refers to occurrence of synechia with the trabecular meshwork.

**Synergism:** Interaction between two or more factors or substances that produces an effect greater than the sum of their individual effects.

**Synovitis:** Inflammation of the synovial membrane, often in combination with pain and swelling of the affected joint.

**Synovium:** The membrane lining the internal surfaces of joints.

**Systolic dysfunction:** An abnormal contraction of the ventricles during systole.

**T2 weighted magnetic resonance imaging:** A setting of the magnetic resonance imaging machine that shows water as a bright signal.

**Tachycardia:** An abnormally rapid heart rate.

**Tachyphylaxis:** A rapidly decreasing response to a drug following its initial administration.

**Tachypnea:** Faster than normal respiratory rate.

**Tachysystole:** More than five contractions in 10 minutes, averaged over a 30-minute window.

**Tangentiality:** Abandoning one's ideational objective in pursuit of thoughts peripheral to the original goal. Used to describe a thought and speech pattern wherein the individual never gets to the point or answers the question.

**Tardive dyskinesia:** A chronic disorder of the nervous system characterized by involuntary jerky or writhing movements of the face, tongue, jaws, trunk, and limbs, usually developing as a late occurring side effect of prolonged treatment with antipsychotic drugs.

**Targeted therapy:** A type of treatment that uses drugs or other substances to identify and attack specific types of cancer cells with less harm to normal cells.

**Tendinosis:** Tendon degeneration without accompanying inflammation.

**Tendonitis:** Inflammation of the tendon.

**Tenesmus:** Difficulty with bowel evacuation despite the urgency to defecate.

**Teratogenic:** Causing malformations in a fetus.

**Terminal secretions:** The noise produced by the oscillatory movements of secretions in the upper airways in association with the inspiratory and expiratory phases of respiration. It is also known as "death rattle."

**Thelarche:** Onset of breast development.

**Third spacing:** Fluid accumulation in the interstitial space disproportionate to the intracellular and extracellular fluid spaces.

**Thoracentesis:** Removal of fluid that is present in the pleural space. Common procedure to determine what caused the fluid accumulation.

**Thought-blocking:** Speech is halted, often in mid-sentence, and then picked up later, usually at another point in the thought process.

**Thrombin:** An enzyme formed from prothrombin which converts fibrinogen to fibrin. It is the principal driving force in the clotting cascade.

**Thrombocytopenia:** A condition whereby the number of circulating platelets are abnormally low due to decreased production of new cells, possibly secondary to medication toxicities.

**Thrombocytosis:** Increased number of platelets in the blood.

**Thrombogenesis:** The process of forming a blood clot.

**Thrombolysis:** The process of enzymatically dissolving or breaking apart a blood clot.

**Thrombolytic:** An enzyme that dissolves or breaks apart blood clots.

**Thrombophlebitis:** Inflammation of a blood vessel (e.g., vein) associated with the stimulations of clotting and formation of a thrombus (or blood clot).

**Thromboplastin:** A substance that triggers the coagulation cascade. Tissue factor is a naturally occurring thromboplastin and is used in the prothrombin time test.

**Thrombosis:** A condition in which blood changes from a liquid to a solid state and produces a blood clot.

**Thrombotic thrombocytopenic purpura:** Condition characterized by formation of small clots within the circulation resulting in the consumption of platelets and a low platelet count.

**Thrombus:** Blood clot attached to the vessel wall and consisting of platelets, fibrin, and clotting factors. A thrombus may partially or completely occlude the lumen of a blood vessel compromising blood flow and oxygen delivery to distal tissue.

**Thyroglobulin:** A thyroid hormone-containing protein, usually stored in the colloid within the thyroid follicles.

**Thyroid peroxidase:** Enzyme that catalyzes the organification and coupling steps of thyroid hormone synthesis.

**Thyroiditis:** Inflammation of the thyroid gland.

**Thyrotoxicosis:** State caused by excess amount of thyroid hormone.

**Tocolytic:** Medication used to suppress premature labor.

**Tolerance:** A state of adaptation in which exposure to a drug induces changes that result in a diminution of one or more of the drug's effects over time.

**Tonic-clonic seizure:** A primary-generalized seizure characterized by a sudden loss of consciousness accompanied by tonic extension and rhythmic clonic contractions of all major muscle groups.

**Tonometry:** Method by which the cornea is indented or flattened by an instrument. The pressure required to achieve corneal indentation or flattening is a measure of intraocular pressure.

**Tophi:** Collections of monosodium urate crystals that develop in tissues and generally appear as firm nodules under the skin.

**Topoisomerase-I:** Enzymes that cut one of the two strands of double-stranded DNA, relax the strand, and reanneal the strand.

**Torsade de pointes:** Very rapid ventricular tachycardia characterized by a gradually changing QRS complex in the ECG; may change into ventricular fibrillation.

**Toxic epidermal necrolysis:** A life-threatening skin disorder characterized by blistering and peeling of the top layer of skin.

**Toxoid:** Bacterial toxin which has been inactivated.

**Trained interventionist:** Includes mostly health professionals such as registered dieticians, psychologists, exercise specialists, health counselors, and professionals in training who adhere to weight management protocols.

**Transesophageal echocardiogram:** Procedure used to generate an image of the heart via sound waves, via a probe introduced into the esophagus (rather than the traditional transthoracic view) in order to obtain a better image of the left atrium.

**Transferrin saturation:** The ratio of serum iron and total iron-binding capacity, multiplied by 100.

**Transformation (conversion):** Mutated cell becomes malignant.

**Transient ischemic attack (TIA):** A transient episode of neurological dysfunction caused by focal brain, spinal cord, or retinal ischemia without acute infarction. TIAs have a rapid onset and short duration, typically lasting less than 1 hour and often less than 30 minutes. The symptoms vary depending on the area of the brain affected; however, no deficit remains after the attack.

**Translocation:** Movement of bacteria and endotoxin from the intestinal lumen through the gut mucosa and into the lymphatic and systemic circulation.

**Transmural:** Existing or occurring across the entire wall of an organ or blood vessel.

**Transsphenoidal pituitary microsurgery:** Surgery through the nasal cavity to access the pituitary gland through the sphenoid bone.

**Traveler's diarrhea:** An acute infectious diarrhea that afflicts travelers during or immediately upon return from visits to other countries.

**Trigeminal neuralgia:** A disorder of the fifth cranial (trigeminal) nerve characterized by excruciating paroxysms of pain in the face.

**Troponins T or I:** Proteins found predominately in the myocardium. Troponin I and T are released into the blood from the myocytes at the time of myocardial cell necrosis secondary to infarction. These biochemical markers become elevated and are used in the diagnosis of myocardial infarction.

**Trousseau sign:** Noted when a blood pressure cuff is applied to a patient's upper arm and inflated.

**Trypsin:** A proteolytic enzyme formed in the small intestine from trypsinogen by the action of enteropeptidase, which once activated hydrolyzes peptides, amides, and esters.

**Tuberoeruptive xanthomas:** Small yellow-red raised papules usually presenting on the elbows, knees, back, and buttocks.

**Tubulointerstitial:** Involving the tubules or interstitial tissue of the kidneys.

**Tumor lysis syndrome:** A syndrome resulting from cytotoxic therapy, occurring generally in aggressive, rapidly proliferating lymphoproliferative disorders. It is characterized by combinations of hyperuricemia, lactic acidosis, hyperkalemia, hyperphosphatemia, and hypocalcemia.

**Tumor suppressor genes:** A gene that suppresses growth of cancer cells.

**Tympanocentesis:** Puncture of the tympanic membrane with a needle to aspirate middle ear fluid.

**Tympanostomy tube:** Small plastic or metal tube inserted in the eardrum to keep the middle ear aerated and improve hearing in patients with chronic middle ear effusion.

**Uhthoff phenomenon:** Acute worsening of multiple sclerosis symptoms on exposure to heat because high body temperatures

may exceed the capacitance of the demyelinated nerve and conduction may fail.

**Ultrafiltration:** The movement of plasma water across a semi-permeable membrane.

**Uncomplicated acid-base disorder:** See simple disorder.

**Unstable angina:** Pathogenically similar to non-ST segment myocardial infarction but without muscle damage, therefore, troponins are not elevated.

**Uremia:** A condition that results from accumulation of metabolic waste products and endogenous toxins in the body resulting from impaired kidney function. Symptoms of uremia include nausea, vomiting, weakness, loss of appetite, and mental confusion.

**Urethral structure:** Narrowing of the urethra.

**Uricosuric:** Pertaining to, characterized by, or promoting renal excretion of uric acid.

**Urosepsis:** Sepsis resulting from a urinary source.

**Urticaria:** Itchy, raised, swollen areas on the skin. Also known as hives.

**Uveitis:** An inflammation of the uvea. Uveal structures include the iris, the ciliary body, and the choroid.

**Vagal maneuvers:** Stimulate the activity of the parasympathetic nervous system, which inhibits atrioventricular nodal conduction. Examples of vagal maneuvers include cough, carotid sinus massage, and Valsalva.

**Vagotomy:** A surgical procedure that blocks vagal (cholinergic) stimulation to the stomach.

**Valsalva maneuver:** Vagal maneuver; patient bears down against a closed glottis, as if they were having a bowel movement.

**Variceal bleeding:** Varices are weak collateral blood vessels that are friable and rupture easily; often observed in the esophagus or stomach.

**Vasculitis:** Inflammation of the walls of blood vessels.

**Vasomotor symptoms:** Menopausal symptoms that include both hot flashes and night sweats.

**Vasopressors:** Medications that cause constriction of blood vessels, increase in vascular resistance, and increase in blood pressure.

**Vasospasm:** Narrowing (constriction) of a blood vessel causing a reduction in blood flow.

**Ventilation/perfusion ratio ($V_A/Q$):** A comparison of the proportion of lung tissue being ventilated by inhaled air to the rate of oxygenation of pulmonary blood.

**Ventricular depolarization:** Change in the membrane potential of a ventricular myocyte, resulting in loss of polarization. Under normal conditions, depolarization of ventricular myocytes is followed by ventricular contraction.

**Vertigo:** Sensation of spinning or feeling out of balance.

**Vesicants:** Chemotherapy drugs that cause significant tissue damage if extravasation occurs.

**Virilization:** Production or acquisition of virilism, which is masculine characteristics.

**Volvulus:** Twisting of the intestine causing obstruction and possible necrosis.

**Vomiting:** A reflexive rapid and forceful oral expulsion of upper gastrointestinal contents due to powerful and sustained contractions in the abdominal and thoracic musculature.

**Waist circumference:** A practical tool to measure the abdominal fat in patients with a BMI of less than 35.

**Wernicke syndrome:** Neurologic condition caused by thiamine deficiency and characterized by classic triad of symptoms (mental confusion, ataxia, and ophthalmoplegia).

**Wheeze:** A high-pitched whistling sound caused by air moving through narrowed airways. Wheezes are usually heard at the end of expiration but may be heard during inspiration and expiration in acute severe asthma.

**White coat hypertension:** A persistently elevated average office blood pressure of greater than 140/90 mm Hg and an average awake ambulatory reading of less than 135/85 mm Hg.

**Wild-type virus:** Refers to natural form of HIV virus without any genetic mutations.

**Wilson disease:** A disorder of copper metabolism, characterized by cirrhosis of the liver and neurological manifestations.

**Xanthomas:** Firm raised nodules composed of lipid-containing histocytes.

**Xerostomia:** Unusual dryness of the mouth.

**ZAP-70 expression:** An intracellular tyrosine kinase found in CLL B-cells.

**Zymogen:** An inactive protein precursor of an enzyme that is converted into an active form.

# Appendix D: Prescription Writing Principles

Kim Hawkins, Jill Isaacs, Emily Knezevich, and Jon Knezevich

According to the International Monetary Systems (IMS) Health Report, 4 billion prescriptions were written and dispensed in the United States in 2011. This reflects a need for prescribers and dispensers to fully understand prescriptive privileges and rational prescribing.[1] The following outlines principles of pharmacotherapy, including general considerations of prescribing, rational prescribing of medications, types of prescription orders, safe prescribing practices including the importance of handwriting, adverse event reporting, and medication education.

It is essential that the prescriber and dispenser familiarize themselves with the professional guidelines, state laws, and federal laws. In addition, they must also understand the components of rational prescribing. Table D–1 below provides key elements a prescriber should understand as well as useful resources.

## TYPES OF PRESCRIPTION ORDERS

Prescription orders can be provided in a variety of ways by authorized prescribers. Outpatient prescriptions may be written, verbally authorized by phone, faxed, or provided via electronic means. All outpatient prescriptions are subject to federal regulations and contain the same basic components. Laws and regulations for outpatient prescription requirements can vary from state to state, so prescribers should be knowledgeable of all applicable laws. The basic components of a prescription are listed below as well as numbered in Figure D–1.[2]

1. Prescriber information: name, address, and phone number
2. Prescriber's signature and prescriptive authority number or Drug Enforcement Administration (DEA) number (if applicable)
3. Patient information: full name and address, and weight and age if appropriate
4. Date the prescription was written
5. Superscription (Rx symbol), meaning "you take" or "recipe"
6. Inscription: medication being prescribed (name of medication, strength, and dose)
7. Signa, sig, or signature: directions to the patient (eg, take one tablet daily)
8. Subscription: dispensing instructions to the pharmacist (number, quantity, or volume to dispense)
9. Number of refills allowed
10. Generic substitution requirement: "DAW (dispense as written)" or "no substitution" if brand name medication only is desired

Further regulations are in place for prescriptions written for controlled substances. In addition to the aforementioned elements, prescriptions for controlled substances must also include the patient's full name and address as well as the full name, address, and DEA number of the prescriber. Stricter regulations exist for Schedule II controlled substances compared with Schedule III-V. Schedule II prescriptions must be written and can only be provided orally in an emergency situation. Refills are prohibited with Schedule II prescriptions.[3] Schedule II and IV prescriptions may be refilled up to five times within 6 months of when the prescription was issued.

Chart orders, orders written for hospital inpatients, are not considered prescriptions and are not subject to the same requirements. Typically chart orders include:

- Patient identifiers including name and account number
- Physician name
- Medication name, dose, route, and frequency of administration
- Date and time of order
- Physician signature
- If the order was given verbally, the person reducing the order to writing must sign the order and the ordering physician countersign

Electronic prescribing has become common practice because of government incentives aimed at moving health records to electronic databases.[4] Principles discussed previously in regard to requirements of a prescription hold true for electronic orders; however, additional considerations must be taken to ensure safe prescribing habits occur. A brief list of potential barriers and benefits is summarized in Table D–2.

Electronic prescribing is no longer a projection of the future but instead is becoming the norm. With appropriate use of this technology, patients are provided ultimately with safer and more efficient care.

Omission of any of the earlier discussed elements on a prescription order can be considered erroneous and poses a danger to patient care. Responsibility lies with the prescriber as well as the pharmacist dispensing the medication to ensure the prescriptions are not only accurate but also appropriate for the given patient.

## SAFE PRESCRIBING PRACTICES

Safe prescribing should be a priority of all health care providers. To avoid inappropriate use of medications in patients, prescribers

## Table D-1

**Pharmacotherapy Principles**

| Pharmacotherapy Principle | Description | Online Resources |
|---|---|---|
| Prescriptive privileges | Dictated by federal and state law<br>Scope of practice and formularies vary by profession. Physicians, nurse practitioners, physician assistants, and dentists all have varying scopes of practice, which may include formularies or supervising prescribers. Each provider must become familiar with his or her profession's scope of practice.<br>Pharmacology courses in program of study and Continuing Education required<br>Prescribing legend drugs requires board examination and National Provider Identifier (NPI)<br>Prescribing controlled substances requires DEA registration number | https://nppes.cms.hhs.gov/NPPES/Welcome.do<br>http://www.dea.gov/index.shtml |
| Rational prescribing | Ensure necessity of medication<br>Obtain pertinent history<br><br>• Health history: comorbidities or contraindications (ie, pregnancy, hepatic failure, or renal failure)<br>• Medication history: prior and current prescription, OTC, or herbal use; drug allergies or sensitivities; compliance issues<br>• Family and social history<br><br>Select correct medication<br>• It is important to know the following components of each medication when prescribing or dispensing:<br>• Pharmacokinetics<br>• Pharmacodynamics<br>• Drug interactions<br>• Drug-disease interactions<br>• Interdisciplinary collaboration when necessary | http://www.jointcommission.org/ |

DEA, Drug Enforcement Administration; OTC, over the counter.

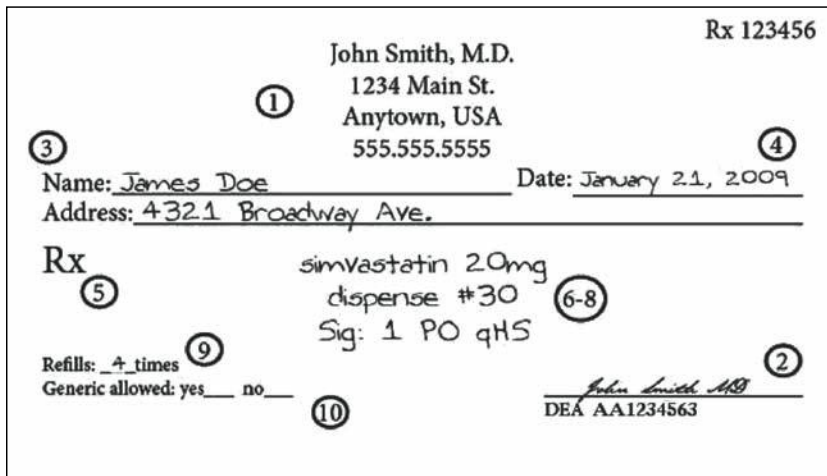

**FIGURE D-1.** Example of a prescription.

## Table D-2

**Electronic Prescribing[4-6]**

| Benefits | Barriers |
|---|---|
| Reduce medication errors | Cost of software programs |
| Reduce adverse drug events | Lack of financial benefit seen immediately |
| Improves efficiency | Lack of software standardization |
| Improved recognition of drug–drug and drug–disease interactions | Indirect costs: training personnel, reduced patient visits during training period |
| Improved recognition of medication allergy cross-sensitivity | Clinician resistance: worry of worsening relationship with patient, negative impact on workflow, and fears of restrictions on prescribing habits |
| Enhanced prescriber knowledge of patient adherence | |
| Enhanced prescriber knowledge of insurance coverage for medications | |

## Table D–3

### Sound-Alike/Look-alike Medications[7,a]

| Medication Name | Misinterpreted Medication Name |
|---|---|
| acetoHEXAMIDE | aceta**ZOLAMIDE** |
| chlordiazePOXIDE | chlorpro**MAZINE** |
| CISplatin | **CARBO**platin |
| ePHEDrine | **EPINEPH**rine |
| hydrALAZINE | hydr**OXY**zine |
| LORazepam | **ALPRAZ**olam |
| NIFEdipine | ni**CAR**dipine |
| RABEprazole | **ARIP**iprazole |
| risperiDONE | r**OPINIR**ole |
| sulfADIAZINE | sulfa**SALA**zine |
| valACYclovir | val**GAN**ciclovir |
| Zantac | Xanax |

[a]For additional information, please see http://www.ismp.org/tools/confuseddrugnames.pdf.

should take careful consideration in writing clear and descriptive prescriptions. This ensures appropriate communication among all interdisciplinary health care providers.

A thorough understanding of the medication prescribed, including its expected risks and benefits, should be realized by the prescriber ensuring appropriate drug selection. Providers should be aware of common errors related to prescription writing. These errors include: sound-alike/look-alike medications and inappropriate use of shorthand language and abbreviations. The Joint Commission, as well as the Institute for Safe Medication Practices (ISMP), has collected common examples of these errors seen during the ordering process. Common examples are described in Tables D–3 and D–4.

Other abbreviations are commonly used medical abbreviations used in prescription writing can be found in Appendix B: Common Medical Abbreviations.

### Adverse Event Reporting

Adverse events may occur related to inappropriate prescribing, dispensing, or administrating medications. Inappropriate prescribing may be avoided by ensuring care is taken to determine

## Table D–4

### Error-Prone Abbreviations[8,a]

| Abbreviation | Anticipated Meaning | Misinterpretation | Correction |
|---|---|---|---|
| μg | Microgram | Mistaken as "mg" | Use "mcg" |
| IJ | Injection | Mistaken as "IV" or "intrajugular" | Use "injection" |
| qd or QD | Every day | Mistaken as qid, especially if the period after the "q" or the tail of the "q" is misunderstood as an "i" | Use "daily" |
| U | Units | May appear as a μ or 0 | Use "units" |
| IU | International Units | IV (intravenous) | Use "units" |
| bid, tid, qid | Twice daily, three times daily, four times daily | Depending on handwriting, may be misinterpreted a number of ways. | Write out the words "twice daily", etc |
| biw, tiw, qiw | Twice weekly, three times weekly, four times weekly | Two times per day, three times per day, four times per day | Write out the words "twice weekly", etc |
| **Dose Designation** | **Anticipated Meaning** | **Misinterpretation** | **Correction** |
| Trailing zero after decimal point (eg, 4.0 mg) | 4 mg | Mistaken as 40 mg if the decimal point is not seen | Do not use trailing zeros for doses expressed in whole numbers |
| No leading zero before a decimal point (eg, .8 mg) | 0.8 mg | Mistaken as 8 mg if the decimal point is NOT seen | Use zero before a decimal point when the dose is less than a whole unit |
| Large doses without properly placed commas(eg, 100,000 units;1,000,000 units) | 100,000 units 1,000,000 units | 100,000 has been mistaken as 10,000 or 1,000,000; 1,000,000 has been mistaken as 100,000 | Use commas for dosing units at or above 1000 or use words such as 100 "thousand" or 1 "million" to improve readability |
| **Drug Name Abbreviation** | **Anticipated Meaning** | **Misinterpretation** | **Correction** |
| AZT | Zidovudine (Retrovir) | Mistaken as azathioprine or aztreonam | Use complete drug name |
| MS, MSO$_4$ | Morphine sulfate | Mistaken as magnesium sulfate | Use complete drug name |
| PCA | Procainamide | Mistaken as patient-controlled analgesia | Use complete drug name |
| T3 | Tylenol with codeine No. 3 | Mistaken as liothyronine | Use complete drug name |
| **Stemmed Drug Names** | **Anticipated Meaning** | **Misinterpretation** | **Correction** |
| "Nitro" drip | Nitroglycerin infusion | Mistaken as sodium nitroprusside infusion | Use complete drug name |
| "IV Vanc" | Intravenous vancomycin | Mistaken as Invanz | Use complete drug name |
| **Symbol** | **Anticipated Meaning** | **Misinterpretation** | **Correction** |
| × 3d | For 3 days | Mistaken as three doses | Use "for 3 days" |
| & | And | Mistaken as "2" | Use "and" |
| ° | Hour | Mistaken as a zero (eg, q2° seen as q 20) | Use "hr," "h," or "hour" |

[a]For additional information, please see ISMP/Joint Commission List of Error-Prone Abbreviations.

all pertinent patient related issues are discussed during the encounter. Additionally, appropriate interdisciplinary care where multiple health care providers are evaluating the patient's problem and its treatment may help avoid adverse events from occurring. Inappropriate dispensing and administration may be avoided through use of clear order entry that undergoes multiple checks by a variety of providers before it reaches the patient. Movement to electronic prescribing has helped eliminate many issues with misinterpreting hand written orders, however, should they still be encountered, providers should take care to very legibly write prescriptions. If any questions remain upon receipt of a questionable order should be verified with the writing provider by the dispensing pharmacist. If adverse events related to medication use are determined, the health care provider who discovers the event is responsible for reporting it. The Food and Drug Administration's reporting system for such adverse events is MedWatch http://www.fda.gov/Safety/MedWatch/default.htm.[9] This online database archives medication-related adverse events, and providers are able to report errors seen in clinical practice.

## Medication Education

After a prescription has been written, counseling patients on newly prescribed therapies is an essential responsibility of the prescriber and pharmacist. The patient should be made aware of the rationale for drug use, the dose, route, and frequency at which they should administer the medication and expectations of the prescribed drug. Expectations should include risks and benefits to avoid patient confusion about side effects or efficacy measures. Thorough discussion of medication therapy selected with the patient may identify contraindications previously unknown or a patient history of failure or success with the selected agent in the past.

## CONCLUSION

Multiple principles must be exercised for appropriate drug delivery from the bedside to the patient. As a health care provider, understanding these processes helps to ensure safe medication prescribing.

# INDEX

Page numbers followed by *f*, *t*, and *a*, indicate figures, tables, and algorithms, respectively.

## Common Laboratory Tests

The following table is an alphabetical listing of some common laboratory tests and their reference ranges for adults as measured in plasma or serum (unless otherwise indicated). Reference values differ among laboratories, so readers should refer to the published reference ranges used in each institution. For some tests, both the Système International Units and Conventional Units are reported.

| Laboratory Test | Conventional Units | Conversion Factor | Système International Units |
|---|---|---|---|
| Acid phosphatase | | | |
|   Male | 2–12 U/L | 16.7 | 33–200 nkat/L |
|   Female | 0.3–9.2 U/L | 16.7 | 5–154 nkat/L |
| Activated partial thromboplastin time (aPTT) | 25–40 seconds | | |
| Adrenocorticotropic hormone (ACTH) | 15–80 pg/mL or ng/L | 0.2202 | 3.3–17.6 pmol/L |
| Alanine aminotransferase (ALT, SGPT) | 7–53 U/L | 0.01667 | 0.12–0.88 μkat/L |
| Albumin | 3.5–5.0 g/dL | 10 | 35–50 g/L |
| Albumin:creatinine ratio (urine) | | 0.113 | |
|   Normal | < 30 mg/g creatinine | | < 3.4 mg/mmol creatinine |
|     Microalbuminuria | 30–300 mg/g creatinine | | 3.4–34 mg/mmol creatinine |
|     Proteinuria | > 300 mg/g creatinine | | > 34 mg/mmol creatinine |
|   or | or | | |
|   Normal | | | |
|     Male | < 18 mg/g creatinine | 0.113 | < 2.0 mg/mmol creatinine |
|     Female | < 25 mg/g creatinine | 0.113 | < 2.8 mg/mmol creatinine |
|   Microalbuminuria | | | |
|     Male | 18–180 mg/g creatinine | 0.113 | 2.0–20 mg/mmol creatinine |
|     Female | 25–250 mg/g creatinine | 0.113 | 2.8–28 mg/mmol creatinine |
|   Proteinuria | | | |
|     Male | > 180 mg/g creatinine | 0.113 | > 20 mg/mmol creatinine |

| Trimester 1 | 4–5 × 10⁶/mm³ | 10⁶ | 4–5 × 10¹²/L |
| Trimester 2 | 3.2–4.5 × 10⁶/mm³ | 10⁶ | 3.2–4.5 × 10¹²/L |
| Trimester 3 | 3–4.9 × 10⁶/mm³ | 10⁶ | 3–4.9 × 10¹²/L |
| Postpartum | 3.2–5 × 10⁶/mm³ | 10⁶ | 3.2–5 × 10¹²/L |

(Continued)

| Laboratory Test | Conventional Units | Conversion Factor | Système International Units |
|---|---|---|---|
| Red blood cell distribution width (RDW) | 11.5%–14.5% | 0.01 | 0.115–0.145 |
| Reticulocyte count | | | |
|   Male | 0.5%–1.5% of total RBC count | 0.01 | 0.005–0.015 |
|   Female | 0.5%–2.5% of total RBC count | 0.01 | 0.005–0.025 |
| Retinol-binding protein (RBP) | 2.7–7.6 mg/dL | 10 | 27–76 mg/L |
| Rheumatoid factor (RF) titer | Negative | | |
| Salicylate, therapeutic | 150–300 mcg/mL or mg/L | 0.00724 | 1.09–2.17 mmol/L |
| | 15–30 mg/dL | 0.0724 | 1.09–2.17 mmol/L |
| Sirolimus (renal transplant) | 4–20 ng/mL | 1 | 4–20 mcg/L |
| | | 1.094 | 4–22 nmol/L |
| Sodium | 135–145 mEq/L | 1 | 135–145 mmol/L |
| Tacrolimus | | | |
|   Renal, cardiac, liver, or pancreatic transplant | 5–20 ng/mL | 1 | 5–20 mcg/L |
| | | 1.24 | 6.2-24.8 nmol/L |
| Testosterone (total) | | | |
|   Men | 300–950 ng/dL | 0.0347 | 10.4–33.0 nmol/L |
|   Women | 20–80 ng/dL | 0.0347 | 0.7–2.8 nmol/L |
| Testosterone (free) | | | |
|   Men | 9–30 ng/dL | 0.0347 | 0.31–1.04 nmol/L |
|   Women | 0.3–1.9 ng/dL | 0.0347 | 0.01–0.07 nmol/L |
| Theophylline | | | |
|   Therapeutic | 5–15 mcg/mL or mg/L | 5.55 | 28–83 μmol/L |
|   Toxic | 20 mcg/mL or mg/L or more | 5.55 | 111 μmol/L or more |
| Thiocyanate | Toxic level unclear; units are mcg/mL or mg/L | 17.2 | μmol/L |
| Thrombin time | 20–24 seconds | | |
| Thyroglobulin | < 42 ng/mL | 1 | < 42 mcg/L |
| Thyroglobulin antibodies | Negative | | |
| Thyroxine-binding globulin (TBG) | 1.2–2.5 mg/dL | 10 | 12–25 mcg/L |
| Thyroid-stimulating hormone (TSH) | 0.35–6.20 μIU/mL | 1 | 0.35–6.20 mIU/L |
| TSH receptor antibodies (TSHRab) | 0–1 units/mL | | 0-1 kU/L |
| Thyroxine ($T_4$) | | | |
|   Total | 4.5–12.0 mcg/dL | 12.87 | 58–154 nmol/L |
|   Free | 0.7–1.9 ng/dL | 12.87 | 9.0–24.5 pmol/L |
| Thyroxine index, free ($FT_4I$) | 6.5–12.5 | | |
| TIBC—see Iron binding capacity (total) | | | |
| Tobramycin, therapeutic | | | |
|   Peak | 4–10 mcg/mL or mg/L | 2.14 | 8.6–21.4 μmol/L |
|   Trough | ≤ 2 mcg/mL or mg/L | 2.14 | ≤ 4.3 μmol/L |
| Transferrin | 200–430 mg/dL | 0.01 | 2.0–4.3 g/L |
| Transferrin saturation | 30–50% | 0.01 | 0.30–0.50 |
| Triglycerides (fasting) | < 160 mg/dL | 0.0113 | < 1.81 mmol/L |
| Triiodothyronine ($T_3$) | 45–132 ng/dL | 0.0154 | 0.69–2.03 nmol/L |
| Triiodothyronine ($T_3$) resin uptake | 25–35% | | |
| Uric acid | 3–8 mg/dL | 59.48 | 178–476 μmol/L |
| Urinalysis (urine) | | | |
|   pH | 4.8–8.0 | | |
|   Specific gravity | 1.005–1.030 | | |
|   Protein | Negative | | |
|   Glucose | Negative | | |
|   Ketones | Negative | | |
|   RBC | 1–2 per low-power field | | |
|   WBC | < 5 per low-power field | | |
| Valproic acid, therapeutic | 50–100 mcg/mL or mg/L | 6.93 | 346–693 μmol/L |
| Vancomycin, therapeutic | | | |
|   Peak | 20–40 mcg/mL or mg/L | 0.690 | 14–28 μmol/L |
|   Trough | 10–20 mcg/mL or mg/L | 0.690 | 7–14 μmol/L |
|   Trough for central nervous system infections | 15–20 mcg/mL or mg/L | 0.690 | 10–14 μmol/L |
| Vitamin A (retinol) | 30–95 mcg/dL | 0.0349 | 1.05–3.32 μmol/L |
| Vitamin $B_{12}$ | 180–1000 pg/mL | 0.738 | 133–738 pmol/L |
| Vitamin $D_3$, 1,25-dihydroxy | 20–76 pg/mL | 2.4 | 48–182 pmol/L |
| Vitamin $D_3$, 25-hydroxy | 10–50 ng/mL | 2.496 | 25–125 nmol/L |
| Vitamin E (a-tocopherol) | 0.5–2.0 mg/dL | 23.22 | 12–46 μmol/L |
| WBC count | $4–10 \times 10^3/mm^3$ | $10^6$ | $4–10 \times 10^9/L$ |
| WBC differential (peripheral blood) | | | |
|   Polymorphonuclear neutrophils (PMNs) | 50%–65% | 0.01 | 0.50–0.65 |
|   Bands | 0%–5% | 0.01 | 0–0.05 |
|   Eosinophils | 0%–3% | 0.01 | 0–0.03 |
|   Basophils | 1%–3% | 0.01 | 0.01–0.03 |
|   Lymphocytes | 25%–35% | 0.01 | 0.25–0.35 |
|   Monocytes | 2%–6% | 0.01 | 0.02–0.06 |
| WBC differential (bone marrow) | | | |
|   PMNs | 3%–11% | 0.01 | 0.03–0.11 |
|   Bands | 9%–15% | 0.01 | 0.09–0.15 |
|   Metamyelocytes | 9%–25% | 0.01 | 0.09–0.25 |
|   Myelocytes | 8%–16% | 0.01 | 0.08–0.16 |
|   Promyelocytes | 1%–8% | 0.01 | 0.01–0.08 |
|   Myeloblasts | 0%–5% | 0.01 | 0–0.05 |
|   Eosinophils | 1%–5% | 0.01 | 0.01–0.05 |
|   Basophils | 0%–1% | 0.01 | 0–0.01 |
|   Lymphocytes | 11%–23% | 0.01 | 0.11–0.23 |
|   Monocytes | 0%–1% | 0.01 | 0–0.01 |
| Zinc | 60–150 mcg/dL | 0.153 | 9.2–23.0 μmol/L |

[a]Hemoglobin A1c (mmol/mol hemoglobin) = (Hemoglobin A1c (%) − 2.15) × 10.929.
