This disulfide (FW = 612.60 g/mol; CAS = 70-18-8), frequently referred to as oxidized glutathione and abbreviated GSSG, is produced in many oxidation/reduction reactions. (See *Glutathione for details on redox chemistry*) Oxidized glutathione binds to and inhibits numerous intracellular enzymes that normally require thiol groups for full catalytic activity. **Target(s):** acid phosphatase (1); S-adenosylmethionine synthetase (2); adenylyl-sulfate kinase (3); arylamine glucosyltransferase, weakly inhibited (85); ATP:citrate lyase, or ATP:citrate synthase (4,5,87); cadmium-transporting ATPase (6); calpains (7); creatine kinase (8); deoxycytidine kinase (9); deoxyribo-pyrimidine photo-lyase (10); DNA-binding activity of c-Jun (11); DNA-directed DNA polymerase (12); DNA polymerase  $\delta$  (12); eukaryotic initiation factor-2, or eIF-2 (4); S formylglutathione hydrolase (13); fructose-1,6-bisphosphatase (14,15); fructose-1,6-bisphosphate aldolase (16); 1,4- $\alpha$ -glucan branching enzyme (86); glucan endo- $\beta$ -D-glucosidase (17); glutamine amino-transferase (18);  $\gamma$ -glutamyl cyclotransferase (19);  $\gamma$ -glutamylcysteine synthase (20); glutathione synthetase (21-23); glutathione S-transferase (24,83); glyceraldehyde-3-P dehydrogenase (25-28); glycogen synthase (4); guanidinoacetate N-methyltransferase (89,90); guanylate cyclase (4,29); hexokinase (4,30-33); cytomegalovirus protease (34); 3-hydroxy-3-methylglutaryl-CoA reductase (4,35,36); 15-hydroxyprostaglandin dehydrogenase (37); 3 $\alpha$ -hydroxy-steroid dehydrogenase (38); indoleamine N-acetyl-transferase (4); isocitrate lyase (5); maleylacetoacetate isomerase (39,40); methionine S-adenosyltransferase (84); 2-methyleneglutarate mutase (41); methylitaconate  $\Delta$ -isomerase (41); 5-methyltetrahydropteroyltriglutamate: homocysteine S-methyl-transferase (88); methylumbelliferyl-acetate deacetylase (42); myosin ATPase (43); nucleotide diphosphatase (44); ornithine decarboxylase (45); pantetheine hydrolase (46, but ref. 47 reports no inhibition); peptidyl-dipeptidase A, or angiotensin-converting enzyme (48); 1-phosphatidylinositol 4-phosphate 5-kinase (49); phosphoadenylyl-sulfate reductase (93); phosphofructokinase (4); phosphoglucoc-mutase (50); phospho-inositide 5-phosphatase (51); phospholipase D (52); phospho-protein phosphatase types 1 and 2A (4,53-56); phospho-ribulokinase (57,58); [phosphorylase] phosphatase (4,54,59,60); phosphotyrosine protein phosphatase (61); prostaglandin  $\Delta^1$  reductase (62); pyrophosphatase (63,64); pyruvate kinase (65); saccharolysin (66); sedoheptulose-bisphosphatase (15); sphingomyelin phosphodiesterase (67,68); stizolobate synthase (92); stizolobinate synthase (92); succinate dehydrogenase (27,69-73); succinyl-CoA synthetase (74); sucrose synthase (4); sulfur reductase (75); thiol oxidase (94,95); thiosulfate:thiol sulfurtransferase, product inhibition (76); transglutaminase (77); UDP-glucose dehydrogenase (78); xanthine dehydrogenase (91); xenobiotic transporting ATPase, multidrug-resistance protein (79-82). 1. ### Glyceraldehyde

This aldotriose (FW = 90.08 g/mol; CAS = 56-82-6), of which the D-enantiomer is the form most commonly encountered in Nature, reacts with lysyl residues of many proteins to form imine adducts. **Target(s):** N-acetylneuraminase lyase, inhibited by DL-glyceraldehyde (1); aldose 1 epimerase, or mutarotase, inhibited by DL-glyceraldehyde (2); N-(5-amino-5-carboxypentanoyl)-L-cysteiny-D-valine synthetase (3); formaldehyde transketolase, also an alternative substrate (4); galactonolactone dehydrogenase (5); glycerone kinase, inhibited by DL-glyceraldehyde, also weak alternative substrate (6); hemoglobin S polymerization, by DL-

glyceraldehyde (7-9); phosphoribulokinase, inhibited by DL-glyceraldehyde (10); Cu,Zn-superoxide dismutase (11); transaldolase, inhibited by L-glyceraldehyde (12). 1. ### D-Glyceraldehyde 3-Phosphate

This key metabolic intermediate (FW<sub>free-acid</sub> = 170.06 g/mol; CAS = 9001-50-7; Water-soluble; pK<sub>a</sub> values of 1.42 and 6.45; Decomposes rapidly under basic pH conditions) is the structural isomer of dihydroxyacetone phosphate (*i.e.*, glycero phosphate). Even neutral or acidic solutions should always be freshly prepared and used within 24 hours. May be stored frozen at -15°C. It is often advisable to generate D-glyceraldehyde 3-phosphate *in situ* from a protected precursor (*e.g.*, D-glyceraldehyde 3-phosphate diethyl acetal is stable at 4°C for at least a year). D-Glyceraldehyde 3-phosphate is a product of the reactions catalyzed by fructose-1,6 biphosphate aldolase, triosephosphate isomerase, transketolase, transaldolase, formaldehyde transaldolase, triokinase, deoxyribose-phosphate aldolase, phosphoketolase, tryptophan synthase, glycerol-3-phosphate 1-dehydrogenase, and several other aldolases. It is a substrate for glyceraldehyde-3-phosphate dehydrogenases and glyceraldehyde-3-phosphate dehydrogenases (phosphorylating). It is reportedly a regulator of glucose-6-phosphate dehydrogenase (1). **Target(s):** acetyl-CoA synthetase, *or* acetate:CoA ligase, weakly inhibited (3); adenylate kinase (4); *N*-(5-amino-5-carboxypentanoyl)-L-cysteinyl-D-valine synthetase (5); aspartate aminotransferase (2,6); enolase (7); formate C-acetyltransferase, *or* pyruvate formate-lyase (18,30-32); D-glucosaminatase dehydratase (8); glucose-6-phosphate isomerase (9); glutamine:fructose-6-phosphate aminotransferase (10); glycerol-3-phosphate acyltransferase, by the DL-mixture (11); glycerol-3-phosphate dehydrogenase (12,13); glycero kinase, inhibited by the racemic mixture (14); methylglyoxal synthase (15); phosphoenolpyruvate phosphatase (16); 6-phosphogluconate dehydrogenase (17); pyruvate,water dikinase (19,20); ribose-phosphate diphosphokinase, *or* phosphoribosyl-pyrophosphate synthetase (21); ribose-5-phosphate isomerase (22,23); ribulose-biphosphate carboxylase (24-26); ribulose-5-phosphate kinase (27); starch synthase (28); thymidylate synthase (29). 1. ### D-Glycerate (D-Glyceric Acid)

This (*R*)-hydroxy acid (FW<sub>free-acid</sub> = 106.08 g/mol; CAS = 6000-40-4; pK<sub>a</sub> = 3.52), also known as (*R*)-2,3-dihydroxypropanoic acid, is very soluble in water and ethanol. Note that glyceric acid will polymerize and produce an insoluble anhydride upon long standing. **Target(s):** acid phosphatase (1,2); phosphoenolpyruvate carboxykinase (GTP), weakly inhibited (3); phosphonate dehydrogenase, *or* phosphite dehydrogenase (4). 1. Hollander (1971) *The Enzymes*, 3rd ed., **4**, 449. 2. Kilsheimer & Axelrod (1957) *J. Biol. Chem.* **227**, 879. 3. Guidinger & Nowak (1990) *Arch. Biochem. Biophys.* **178**, 131. 4. Costas, White & Metcalf (2001) *J. Biol. Chem.* **276**, 17429.

### DL-Glycerate (DL-Glyceric Acid)

This racemic hydroxy acid (FW<sub>free-acid</sub> = 106.08 g/mol; pK<sub>a</sub> = 3.55), also known as (*R,S*)-2,3-dihydroxypropanoic acid, is very soluble in water and ethanol. Surprisingly, the racemic mixture is less soluble in water than the pure enantiomer. Note that glyceric acid will polymerize to produce an insoluble anhydride upon long standing. **Target(s):** acid phosphatase (1,2); fructose-1,6-bisphosphatase (3); isocitrate lyase (4); L-lactate dehydrogenase (5); L-lactate dehydrogenase, *or* cytochrome (6); phosphoenolpyruvate carboxykinase (GTP), weakly inhibited (7); phosphoenolpyruvate carboxylase (8); phosphoglycerate phosphatase (9,10); sedoheptulose-bisphosphatase (3). 1. ### Glycerol

This viscous water-soluble polyol (FW = 92.09 g/mol; CAS = 56-81-5; Density = 1.261 g/cm<sup>3</sup>; Melting Point = 17.8 °C) is a major component of saponifiable fats (mainly as mono-, di-, and tri-fatty acyl esters). Glycerol is often used as a cryoprotectant, stabilizing cells and many proteins and enzymes. Indeed, it often promotes protein oligomerization and polymerization. For example, the presence of 2-4 M glycerol greatly promotes polymerization of chromatographically pure tubulin, enhancing microtubule self-assembly even in the absence of microtubule-stabilizing proteins like MAP2 and Tau. In glycerol-water mixtures (10-40 vol %), proteins give clear evidence that they are preferentially hydrated in ways that stabilize the native structure of globular proteins (1,2). Glycerol and other vicinal diols also react with propanediol dehydratase, typically resulting in conversion of enzyme-bound adenosylcobalamin to cob(II)alamin and formation of aldehyde or ketone derivatives from substrate (3,4). All are capable of effecting the irreversible inactivation of the enzyme. Glycerol is a very good diol dehydratase substrate as well as a

potent inactivator, but does not induce cob(II)alamin formation to any detectable extent. In the presence of glycerol, diol dehydratase inactivation process accompanied by conversion of enzyme-bound adenosylcobalamin to an alkyl or thiol cobalamin, probably by substitution of an amino acid chain near the active site for the 5'-deoxy-5'-adenosyl ligand on the cobalamin (3). The inactivation reaction with glycerol exhibits a sizable deuterium isotope effect ( $k_D/k_H = 14$ ), suggesting that hydrogen transfer is an important step in the inactivation mechanism. 1. ### sn-Glycerol 1-Phosphate

This phosphorylated metabolite (FW<sub>free-acid</sub> = 172.07 g/mol; CAS = 57-03-4), also called (S)-glycerol 1-phosphate, L-glycerol 1-phosphate, D-α-glycerophosphate, and D-glycerol 3-phosphate; is a structural isomer of the common component of many phospholipids, one that is only rarely encountered in the free form. Salts of sn-glycerol 1-phosphate are quite soluble in water. Solutions are relatively stable at 4°C. While chiral, glycerol-P has a barely measurable optical activity:  $[\alpha]_D = -1.45^\circ$  for the free acid (1). (See also sn-Glycerol 3-Phosphate) **Target(s):** 1-deoxy-D-xylulose-5-phosphate synthase, inhibited by DL-α-glycerophosphate (2); fructose-2,6-bisphosphate 2-phosphatase (3); glyceraldehyde-3-phosphate dehydrogenase (4); glycerol-1,2-cyclic-phosphate phosphodiesterase (5); 6-phosphogluconate dehydratase (6); ribulose-phosphate 3-epimerase, inhibited by DL-α-glycerophosphate (7); triose phosphate isomerase (8). 1. ### Glycerol 2-Phosphate

This phosphorylated metabolite (FW<sub>free-acid</sub> = 172.07 g/mol; CAS = 17181-54-3), also known as β-glycerophosphate, is a structural isomer of the common component of many phospholipids. Salts of glycerol 2-phosphate are quite soluble in water. **Target(s):** [acetyl-CoA carboxylase] kinase (1,2); 1-deoxy-D-xylulose-5-phosphate synthase (3); glycerol-1,2-phosphate-cyclic-phosphate phosphodiesterase (4); glycogen phosphorylase (5,6); glycogen synthase (7); 3-phosphoglycerate kinase (8); pyridoxamine:oxaloacetate aminotransferase (9); *Ustilago sphaerogena* ribonuclease (10); *Xenopus* ribosomal protein S6 kinase II (11). 1. ### sn-Glycerol 3-Phosphate

This phosphorylated metabolite (FW<sub>free-acid</sub> = 172.07 g/mol; CAS = 57-03-4), also called (R)-glycerol 1-phosphate, L-glycerol 3-phosphate, and D-glycerol 1-phosphate, is a component of many phospholipids. Salts of sn-glycerol 3-phosphate are quite soluble in water. **Target(s):** [acetyl-CoA carboxylase] kinase (1); diglycosyl diacylglycerol synthase (2); fructose-1,6-bisphosphate aldolase, inhibited by DL-α-glycerophosphate (3); α-galactosidase (4); D-glucosaminatase dehydratase (5); glucose-1,6-bisphosphate synthase (6); glutamine:fructose-6 phosphate transaminase (7); glyceraldehyde-3-phosphate dehydrogenase (8); glycerol-1,2-cyclic-phosphate phosphodiesterase (9); glycerone-phosphate O-acyltransferase, or dihydroxyacetone-phosphate O-acyltransferase (10,36-39); glycerol-phosphocholine phosphodiesterase (11); glycerophospho-inositol glycerophosphodiesterase (12); NADH peroxidase, inhibited by racemic mixture (13); 6-phosphofructo-2-kinase/fructose 2,6-bisphosphatase (14-27); 6-phospho-β-glucosidase, inhibited by DL-α-glycerophosphate (28); 3-phosphoglycerate kinase (29); pyridoxamine:oxaloacetate aminotransferase (30); ribulose-phosphate 3-epimerase, inhibited by DL-α-glycerophosphate (31); triose-phosphate isomerase (32-35). 1. ### sn-Glycerol-3-phosphocholine

This substituted glycerol (FW = 258.23 g/mol) is a component of many complex lipids, most notably phosphatidylcholine (i.e., the diacylated derivative). Note that choline esters of glycerophosphate also isomerize in acid and alkaline solutions, resulting in partial racemization. **Target(s):** cholinesterase, acetylcholine esterase (1); Lysophospholipase (2); phosphatidylcholine desaturase (3); phosphatidylinositol transfer protein α (4); phosphoserine phosphatase (5); 4-phytase (6). 1. Kravica (1950) *Enzymologia* **14**, 39. 2. Fallbrook, Turenne, Mamalias, Kish & Ross (1999) *Brain Res.* **834**, 207. 3. Slack, Roughan & Browne (1979) *Biochem. J.* **179**, 649. 4. Maiti, Majumder & Biswas (1974) *Phytochemistry* **13**, 1047.

### Glycerophosphoinositol 4-Phosphate

This phosphoinositol metabolite (FW = 416.21 g/mol) inhibits the adenyllyl cyclase activity ( $K_i = 1-4 \mu\text{M}$ ) in FRTL5 membranes, when stimulated by the GTP-binding protein activator fluoroaluminate. Glycerophosphoinositol 4-phosphate exerts an inhibitory effect on the GTP-binding protein that stimulates the cyclase and serves as a Ras cascade messenger. **Target(s):** adenylate cyclase (1); glycerophosphoinositol glycerophospho-diesterase (2); inositol-polyphosphate 5-phosphatase, or inositol-1,4,5-trisphosphate 5-phosphatase (3); phosphoinositide phospholipase C (4). 1. ### Glycidol Phosphate

This epoxide-containing glycerol-P/glyceraldehyde-P analogue (FW<sub>free-acid</sub> = 154.06 g/mol), also known as 1,2-epoxypropanol 3-phosphate, has *R* and *S* stereoisomers, and both inhibit enolase (1-3), 3-phosphoglycerate phosphatase (4), and triose-phosphate isomerase (3,5). **Primary Mode of Action:** Although similar concentrations of *D*- and *L*-glycidol-P give half-maximal rates of inactivation for triose phosphate isomerase, the maximum  $V_{\text{inact}}$  values is 10-times higher for *D*-glycidol-P. Although the same catalytic glutamate residue is esterified by addition to the C1 carbon of both enantiomers, the rate differences agree with inferences about active-site stereospecificity. 1. ### Glycine

This  $\alpha$ -amino acid (FW = 75.07 g/mol; CAS = 56-40-6; Symbols: Gly or G;  $pK_a$  values of 2.35 and 9.78 at 25°C), itself the simplest of the twenty proteogenic amino acids, has four codons: GGG, GGU, GGC, and GGA. Glycine residues are frequently found in reverse turns. They also tend to destabilize  $\alpha$ -helical structures. Homologous proteins often have glycyl residues interchanged with alanyl, seryl, aspartyl, or asparaginyl residues. Because glycine is a cheap and widely used zwitterionic buffer, it should not be surprising that numerous papers report enzyme inhibition by glycine *in vitro*. Most studies are conducted at 50 mM glycine, and the inhibition is of dubious significance. **Target(s):** acetylcholinesterase, weakly inhibited (1);  $N^5$ -( $\beta$ -*N*-acetylglucosaminy)-*L*-asparaginase (2); agaritine  $\gamma$ -glutamyl-transferase (3); alanine aminotransferase, weakly inhibited (4); *L*-alanine dehydrogenase (5); *D*-alanyl-*D*-alanine synthetase, or *D*-alanine-*D*-alanine ligase (6); alkaline phosphatase (7-12); 2-aminohexano-6-lactam racemase (13); aminomalonate decarboxylase, *now*: aspartate  $\beta$ -decarboxylase (14); 8-amino-7-oxononanoate synthase (15-17); 5-aminovalerate aminotransferase (18); Arginase, weakly inhibited (19); asparaginase (20); asparagine:oxo-acid aminotransferase (21,22); asparagine synthetase,

weakly inhibited (23); bile acid acyl glucuronosyltransferase (24); carbamoyl-phosphate synthetase, glutamine-hydrolyzing (25); carbonic anhydrase (26,27); cystalysin (28); cystathionine  $\beta$ -lyase (29); cystathionine  $\gamma$  lyase, or cysteine desulfhydrase (28,30); 2-dehydro-3-deoxyglucurate aldolase, or 2-keto-3 deoxyglucurate aldolase (31); 2,2-dialkylglycine decarboxylase (pyruvate) (32); diphosphate:serine phosphotransferase, or pyrophosphate:serine phosphotransferase, weakly inhibited (33); formyltetrahydrofolate deformylase (34); fumarase (35); gelatinase A, matrix metalloproteinase 2 (36); glutamine synthetase (23,38-52);  $\gamma$ -glutamyl transpeptidase, or  $\gamma$ -glutamyltransferase (53-56); *D*-glycerate dehydrogenase (57); glycerol-2-phosphatase (58); polygalacturonase (59); haloacetate dehalogenase, weakly inhibited (60); histidine ammonia-lyase (61-65); formyltetrahydrofolate hydrolase (66,67); linoleate diol synthase (68); nucleotide diphosphatase (69); ornithine carbamoyltransferase (70); ornithine decarboxylase (71); pancreatic ribonuclease (72); pantothenase (73); phenylalanine ammonia-lyase, greater inhibition in the presence of phenol, *o*-cresol, or *m* cresol (74,75); phosphodiesterase I, 5'-exonuclease (76,77); 3-phosphoglycerate dehydrogenase (57); phosphoglycolate phosphatase (78); phosphoserine phosphatase (79-81); procollagen C endopeptidase, weakly inhibited (82); serine *O*-acetyltransferase (83-86); *D*-serine ammonia lyase (87,88); *L*-serine ammonia-lyase (89,90); serine hydroxymethyltransferase (91); tryptophan synthase (92); tyrosine decarboxylase, weakly inhibited (93); UDP-*N*-acetylmuramate:*L*-alanine ligase (6, 94). 1. ### Glycocholate (Glycocholic Acid)

This bile acid conjugate (FW<sub>free-acid</sub> = 465.63 g/mol; FW<sub>sodium-salt</sub> = 523.64 g/mol (monohydrate); CAS = 207614-05-9), also known as cholyglycine, is the main bile constituent of herbivorous mammals. Its critical micelle

concentration (cmc) is 7.1 mM. **Target(s):** acetylcholinesterase, moderately inhibited (1); 1-acylglycerophosphocholine *O*-acyltransferase, or lysophosphatidylcholine *O*-acyltransferase (2); alkaline phosphatase (3); ATPase, Mg<sup>2+</sup>-dependent (4); bile-acid-CoA:amino acid *N*-acyltransferase (5,6); carbonic anhydrase (7); β-carotene,15'-monooxygenase (8); esterase (9); γ-glutamyl transpeptidase (10,11); lipase, or triacylglycerol lipase (12,13); lysozyme (14); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (4); steryl-sulfatase, or arylsulfatase C, mildly inhibited (15). 1. ### Glycocyamine

This substituted guanidine (FW = 117.11 g/mol; CAS = 352-97-6), also known as *N*-amidinoglycine and guanidinoacetic acid, is very soluble in water. The *N*-phosphorylated derivative is a phosphagen in polychaete worms. **Target(s):** arginase (1); arginine decarboxylase (2,3); arginine deaminase (4); glycine amidinotransferase, product inhibition (5); 5-guanidino-2-oxopentanoate decarboxylase, or α-ketoarginine decarboxylase, weakly inhibited (6); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase, possibly as a consequence of changes to membrane (7,8). 1. ### Glycodeoxycholate (Glycodeoxycholic Acid)

This conjugated bile salt (FW<sub>free-acid</sub> = 449.63 g/mol; CAS = 360-65-6; c.m.c. = 2.1 mM), also known as deoxy-cholyglycine, induces apoptosis in hepatocytes. **Target(s):** bile-acid-CoA:amino acid *N*-acyltransferase (1); β-glucuronidase (2); γ-glutamyl transpeptidase (3); lipase, or triacylglycerol lipase (4). 1. Kimura, Okuno, Inada, Ohyama & Kido (1983) *Hoppe-Seyler's Z. Physiol. Chem.* **364**, 637. 2. Ho (1985) *Biochim. Biophys. Acta* **827**, 197. 3. Abbott & A. Meister (1983) *J. Biol. Chem.* **258**, 6193. 4. Desnuelle (1972) *The Enzymes*, 3rd ed., **7**, 575.

actin-bound nucleotide in the absence or presence of profilin. **Target(s):** *Listeria* motility; profilin binding to vasodilator-stimulated phosphoprotein (VASP) and neural-Wiskott-Aldrich Syndrome protein (N-WASP). 1. Kang, Laine, Bubb, Southwick & Purich (1997) *Biochemistry* **36**, 8384.

### 18 $\beta$ -Glycyrrhetic Acid

This sweet, pentacyclic triterpene (FW<sub>free-acid</sub> = 470.69 g/mol), also known as enoxolone, is the active pharmacological ingredient of licorice (*Glycyrrhiza glabra*). It is the aglycon of glycyrrhizin and a number of saponins. **Target(s):** cAMP-dependent protein kinase (1); cAMP phosphodiesterase (2); complement component C2 (3);  $\beta$ -glucuronidase (4); glycogen phosphorylase (5); 3 $\alpha$ -hydroxysteroid dehydrogenase (6); 3 $\beta$ -hydroxysteroid dehydrogenase (7); 3 $\alpha$ /20 $\beta$ -hydroxysteroid dehydrogenase (8,9); 11 $\beta$ -hydroxysteroid dehydrogenase (7,10-14); 17 $\beta$ -hydroxysteroid dehydrogenase (15); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (16); protein kinase C (17); steroid 5 $\beta$ -reductase (10,18). 1. ### Glycyrrhizin

This intensely sweet glycoside (FW<sub>free-acid</sub> = 822.94 g/mol; CAS = 1405-86-3), also known as glycyrrhizic acid, from licorice (*Glycyrrhiza glabra*) is amphiphilic and inhibits many enzymes. **Target(s):** arylamine N-acetyltransferase (1,2);  $\beta$ -glucuronidase (3-6); glycogen phosphorylase (7); HIV-1 reverse transcriptase (8,9); hyaluronoglucaninidase, *or* hyaluronidase (10); 3 $\alpha$ /20 $\beta$ -hydroxysteroid dehydrogenase (11); 11 $\beta$ -hydroxysteroid dehydrogenase (12); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (13); phospholipase A<sub>2</sub> (14,15); polypeptide-dependent protein kinase, *or* protein kinase P, *or* casein kinase II (16-18); RNA-directed DNA polymerase, *or* reverse transcriptase (8,9); thrombin (19). GL also exerts a protective effect on ischemia-reperfusion injury in rat brains through the inhibition of inflammation, oxidative stress and apoptotic injury by antagonising the cytokine activity of High Mobility Group Box 1, *or* HMGB1 (20). 1. ### Glyoxal

This, the simplest of all dialdehydes (FW = 58.04 g/mol; CAS = 107-22-2; M.P. = 15°C; B.P. = 51°C) reacts under alkaline conditions with arginyl and lysyl residues in peptides and proteins. Extreme care should be exercised with this reagent, inasmuch as mixtures with air are known to explode. Glyoxal polymerizes quickly upon standing and reacts violently upon contact with water. Aqueous solutions of glyoxal (*i.e.*, three mol glyoxal per two mole of H<sub>2</sub>O) are commercially available and relatively stable. **Target(s):** alcohol dehydrogenase (1); D-amino-acid oxidase (2); aminolevulinic aminotransferase (3); argininosuccinate synthetase (4); bacterial leucyl aminopeptidase (5); glutamate dehydrogenase (6); glutamine: fructose-6-phosphate aminotransferase (7); glutathione peroxidase (8); 4-hydroxy-2-oxoglutarate aldolase, *or* 2-keto-4-hydroxyglutarate aldolase (9); malate synthase (10); methylglyoxal reductase (NADPH-dependent) (11); propanediol dehydratase (12); 3-propylmalate synthase (13); pyruvate carboxylase (14); ribonuclease T<sub>1</sub> (15); subtilisin (16); Cu,Zn-superoxide dismutase (17); tartronate-semialdehyde reductase, *or* 2-hydroxy-3-oxopropionate reductase (18). 1. ### Glyoxylate

This naturally occurring carboxylic acid (FW = 74.04 g/mol; CAS = 298-12-4), also known as oxoacetic acid, glyoxalic acid, and oxoethanoic acid, is a key intermediate of the glyoxylate cycle occurring in some plants and microorganisms. The anhydrous acid is hygroscopic and has a melting point of 98°C. The hemihydrate melts at 70-75°C and will deliquesce rapidly, forming a syrup when exposed to the atmosphere. The common form of glyoxylic acid is the monohydrate which is also hygroscopic and melts at about 50°C. Glyoxylic acid is a relatively strong acid (pK<sub>a</sub> = 3.18 at 30°C) that is very soluble in water. The sodium salt is stable in neutral or slightly acidic conditions.

### Glyphosate

This broad-spectrum herbicide (FW<sub>free-acid</sub> = 169.07; CAS = 1071-83-6; IUPAC Name: *N*-(phosphonomethyl)glycine), marketed in the U.S. as Round-Up™ and Tumbleweed™, is an extraordinarily potent homogentisate pathway inhibitor that is used on the farm and in the garden to eradicate weeds and other nuisance plants. Entire fields have been cleared and maintained in a weed-free state that facilitates highly efficient farming. Development of genetically modified (GM) cultivars that metabolize glyphosate allows farmers to suppress weeds without damaging the crop. Glyphosate's plant-killing power stems from its inhibitory action on 5-enolpyruvyl-shikimate-3-phosphate synthetase (EPSPS), an essential enzyme for the formation of aromatic amino acids and plant vitality. The latter are precursors for certain secondary metabolites, including folates, ubiquinones and naphthoquinones. While the shikimate pathway is absent in mammals and humans, glyphosate blocks phosphoenol pyruvate (PEP) binding to EPSPS, raising the concerning possibility that glyphosate may affect PEP-dependent reactions in other organisms. **Primary Mode of Action:** Various studies report glyphosate forms a tight ternary complex with EPSP synthase and shikimate 3-phosphate, prompting to the suggestion that in this complex, glyphosate functions as a transition-state analogue of the putative phosphoenolpyruvyl oxonium ion (1,2). Despite this attractive suggestion, later studies (3) convincingly demonstrated that glyphosate is an uncompetitive inhibitor *versus* EPSP,  $K_{ii} = 54 \mu\text{M}$ . **Target(s):** adenosine kinase (4,5); 3-deoxy-7-phosphoheptulonate synthase, or 3-deoxy-D-arabino-heptulosonate-7-phosphate synthase (6,7); 3-phosphoshikimate 1-carboxyvinyltransferase, or 5-enolpyruvylshikimate-3-phosphate synthase (1-3,8-27); ribokinase (28). 1. ### GLYX-13

This NMDAR partial agonist (FW = 413.47 g/mol; CAS = 117928-94-6; Sequence: TPPT-NH<sub>2</sub>) is a nootropic tetrapeptide that interacts at the receptor's glycine binding site and enhances learning and memory in young adult and learning-impaired aging rats (1,2). GLYX-13 readily crosses the

blood brain barrier and increases long-term potentiation. It also induces gene expression of the NR1 subunit of *N*-methyl-D-aspartate receptor (NMDAR) within the hippocampus. GLYX-13 has a therapeutic index of 500 or more, onset within 20 minutes of administration, and produces antidepressant-like effects lasting approximately two weeks following administration (1). **Discovery:** The monoclonal antibody B6B21, which acts as a partial agonist at the glycine site of the NMDAR facilitated the discovery of a unique hippocampal neuron surface antigen (3). To create novel NMDAR-targeted drugs, the hyper-variable region of B6B21's light chain was cloned and sequenced, followed by screening of those peptides promoting binding of the NMDA-binding anticonvulsant MK-801 in the presence of 7-chlorokynurenic acid, a glycine site-specific competitive inhibitor of NMDAR (4). Peptides increasing MK-801 binding in a dose-dependent manner under such conditions were collectively termed "Glyxins". **Pharmacodynamics:** Inhibition of NMDA-mediated neurotransmission is known to provide anti-nociceptive actions in a number of animal models, and both partial agonists and antagonists of the NMDA-associated glycine site often exert antinociceptive actions at doses that are not ataxic. GLYX-13 is one such glycine site-specific, partial agonist NMDA receptor. Direct two-photon imaging of Schaffer collateral burst-evoked increases in [Ca<sup>2+</sup>] within individual dendritic spines revealed that GLYX-13 selectively enhances burst-induced NMDAR-dependent spine Ca<sup>2+</sup> influx (5). Examining the rate of MK-801 block of synaptic *versus* extra-synaptic NMDAR-gated channels revealed that GLYX-13 selectively enhances activation of burst-driven extra-synaptic NMDA receptors, an action that was blocked by the NR2B-selective NMDAR antagonist Ifenprodil. These findings suggest that GLYX-13 possesses unique a therapeutic potential, both as a learning-enhancing and memory-enhancing drug in view of its ability to simultaneously enhance long-term potentiation, while suppressing long-term depression, or LTD (5). 1. **GM-1489**, See *N*-[(2*R*)-2-(Carboxymethyl)-4-methylpentanoyl]-*L*-tryptophan-(*S*)-methyl-benzylamide

### GM6001

This broad-spectrum matrix metalloprotease inhibitor (FW = 388.46 g/mol; CAS = 142880-36-2), also known as Galardin, Ilomastat, and *N*<sup>1</sup>-hydroxy-*N*<sup>1</sup>-[(1*S*)-1-(1*H*-indol-3-ylmethyl)-2-(methylamino)-2-oxoethyl]-2-(2-methylpropyl)-(2*R*)-butanediamide, targets MMP-1 ( $K_i = 0.4 \text{ nM}$ ), MMP-2 ( $K_i = 0.5 \text{ nM}$ ), MMP-3 ( $K_i = 27 \text{ nM}$ ), MMP-7 ( $K_i = 3.7 \text{ nM}$ ), MMP-8 ( $K_i = 0.1 \text{ nM}$ ), MMP-9 ( $K_i = 0.2 \text{ nM}$ ), MMP-12 ( $K_i = 3.6 \text{ nM}$ ), MMP-14 ( $K_i = 13.4 \text{ nM}$ ), and MMP-26 ( $K_i = 0.36 \text{ nM}$ ). Hydroxamate-containing inhibitors rely on the hydroxamate moiety to interact with the active-site Zn<sup>2+</sup> in matrix metalloprotease inhibitor, with specificity conferred by other side-chain groups. Penetration of epithelial cells into the submucosa, a process that requires digestion of the basal lamina and the surrounding extracellular matrix, is strongly inhibited by GM6001 (2). Compared to placebo, GM6001 significantly inhibited intimal hyperplasia and intimal collagen content, and it increased lumen area in stented arteries without effects on proliferation rates (3). 1. Coll. Cardiol.* **39**, 1852.

**GMX1778**

This nicotinamide phosphoribosyltransferase-specific inhibitor (FW = 371.90 g/mol; CAS = 200484-11-3), also known as CHS 828 and *N*-[6-(4-chlorophenoxy)hexyl]-*N'*-cyano-*N''*-4-pyridinylguanidine targets a rate-limiting enzyme required for NAD<sup>+</sup> synthesis from nicotinamide and 5'-phosphoribosyl-1'-pyrophosphate (1). GMX1778 increases intracellular reactive oxygen species (ROS) in cancer cells, while elevating the superoxide level and decreasing the cellular NAD<sup>+</sup> content. GMX1778-mediated ROS induction is p53-dependent, suggesting that the status of both p53 and NAPRT1 might affect tumor apoptosis (2). Significantly, GMX1778 is without effect on untransformed cells. GMX1778-induced ROS accumulation can be reduced by supplying cells with nicotinic acid, with the extent of reduction depending on active NAPRT1. Teglarinad chloride (FW = 672.60 g/mol; CAS = 432037-57-5; *Abbreviation*: GMX1777; *IUPAC/Chemical name*: (*Z*)-4-(3-(6-(4-chlorophenoxy)hexyl)-2-cyanoguanidino)-1-(3-oxo-2,4,7,10,13,16-hexaoxaheptadecyl)pyridin-1-ium chloride) is the water-soluble, intravenously administered pro-drug (IC<sub>50</sub> = 5-10 nM) that is taken up and rapidly converted into active drug (GMX1778) through hydrolytic cleavage of its carbonate ester bond (3). **1.** Hjarnaa, Jonsson, Latini, *et al.* (1999) *Cancer Res.* **59**, 5751. **2.** Cerna, Li, Flaherty, *et al.* (2012) *J. Biol. Chem.* **287**, 22408. **3.** Fuchs, Rodriguez, Eriksson, *et al.* (2010) *Int. J. Cancer* **126**, 2773.

**GNF-7**

This third-generation imatinib-based antineoplastic agent (FW = 547.54 g/mol; CAS = 839706-07-9; Solubility: 20 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named *N*-[3-[1,4-dihydro-1-methyl-7-[(6-methyl-3-pyridinyl)amino]-2-oxopyrimido[4,5-*d*]pyrimidin-3(2*H*)-yl]-4-methylphenyl]-3-(trifluoromethyl)-benzamide, targets the protein kinase activity of Bcr-Abl<sup>wild-type</sup> (IC<sub>50</sub> < 5 nM), Bcr-Abl<sup>M351T</sup> (IC<sub>50</sub> < 5 nM), Bcr-Abl<sup>T315I</sup> (IC<sub>50</sub> = 61 nM), Bcr-Abl<sup>E255V</sup> (IC<sub>50</sub> = 122 nM), Bcr-Abl<sup>G250E</sup> (IC<sub>50</sub> = 136 nM), and c-Abl (IC<sub>50</sub> = 133 nM). Synthesized with the goal of bridging the ATP and allosteric binding sites with a linker that accommodates a larger gatekeeper residue, GNF-7 is among the first type-II PKI's to inhibit the T315I mutant. GNF-7 also displays excellent growth inhibitory activity against human colon cancer cell lines Colo205 and SW620, while having weaker action against the non-cancer HEK293T cell line. (**See also** *Imatinib*; *Nilotinib*; *Dasatinib*, and *Bosutinib*) **1.** Choi, Ren, Adrian, *et al.* (2010) *J. Med. Chem.* **53**, 5439.

**GNF-6702**

This broad-spectrum antiprotozoal drug (FW = 429.42 g/mol), systematically named *N*-[4-fluoro-3-(6-pyridin-2-yl-[1,2,4]triazolo[1,5-*a*]pyrimidin-2-yl)phenyl]-2,4-dimethyl-1,3-oxazole-5-carboxamide, targets the kinetoplastid proteasomes of *Trypanosoma cruzi*, *Leishmania* spp. and *Trypanosoma brucei* spp., parasites now shown to share a common druggable target. GNF6702 inhibits the kinetoplastid proteasome noncompetitively, but does not inhibit the mammalian proteasome or the growth of mammalian cells. It is well-tolerated in mice. **1.** Khare, Nagle, Biggart, *et al.* (2016) *Nature* **537**, 229.

**Gö 6976**

This indolocarbazole (FW = 378.43 g/mol; CAS = 136194-77-9; IUPAC name: 12-(2-cyanoethyl)-6,7,12,13-tetrahydro-13-methyl-5-oxo-5*H*-indolo(2,3-*a*)pyrrolo(3,4-*c*)carbazole) inhibits protein kinase C (IC<sub>50</sub> = 7.9 nM). At higher concentrations, Gö 6976 will also inhibit protein kinase G (IC<sub>50</sub> = 6.2 μM) and [myosin light-chain] kinase (IC<sub>50</sub> = 5.8 μM). With respect to protein kinase C, Gö 6976 also exhibits some selectivity: the α-isozyme has an IC<sub>50</sub> value of 2.3 nM and PKCβ1 IC<sub>50</sub> = 6.2 nM. The δ-, ε-, and ζ-isozymes are not inhibited, even at micromolar levels. Protein kinase Cγ has an IC<sub>50</sub> value of 20 nM. **Target(s)**: polo kinase (1); protein kinase C (2-8). **1.** Johnson, Stewart, Woods, Giranda & Luo (2007) *Biochemistry* **46**, 9551. **2.** Martiny-Baron, Kazanietz, Mischak, *et al.* (1993) *J. **Gonadotropin-Inhibitory Hormone**

This hypothalamic neuropeptide (FW = 1390.66; Quail Sequence: SIKPSAYLPLRF-NH<sub>2</sub>; Symbol: GnIH), which is secreted by the anterior hypophysial gland, inhibits gonadotropin secretion from the pituitary and plays a crucial role in vertebrate gonadal development and function. Its wide distribution within the brain also suggested roles in regulation of behavior. Melatonin acts directly on GnIH neurons through its receptor; to induce GnIH expression. In the quail, GnIH is also located in neurons of the paraventricular nucleus (*or* PVN) that terminate in the median eminence (*or* ME) (1-3). **1.** Tsutsui, Saigoh, Ukena, *et al.* (2000) *Biochem. Biophys. Res. Commun.* **275**, 661. **2.** Ukena, Ubuka & Tsutsui (2003) *Cell Tissue Res.* **312**, 73. **3.** Ubuka, Ueno, Ukena & Tsutsui (2003) *J. Endocrinol.* **178**, 311.

**Gonadotropin-Releasing Hormone**

This peptide amide (FW = 1182.29 g/mol; CAS = 9034-40-6), also known as luteinizing hormone-releasing hormone (LHRH), luliberin, and gonadoliberin, stimulates the release of luteinizing hormone and follicle-stimulating hormone from the anterior pituitary. Human peptide sequence: L-pyroGlu-L-His-L-Try-L-Ser-L-Tyr-Gly-L-Leu-L-Arg-L-Pro-Gly-NH<sub>2</sub>.

**Target(s)**: carboxypeptidase E (1); pyroglutamyl-peptidase II, *K<sub>i</sub>* = 8.1 μM, with the salmon peptide (2-6). **1.** Hook & LaGamma (1987) *J. Biol. ## Gossypol

This toxic yellow secondary metabolite (FW = 518.56 g/mol; CAS = 303-45-7) from cotton (*Gossypium* sp.) inhibits sperm production in humans. Gossypol functions as a part of the cotton plant's defense system against pathogenic fungi and insects. **Target(s):** acid phosphatase (1); acrosomal proteinase, or acrosin (1,2); alcohol dehydrogenase (3); aldehyde dehydrogenase (3); aldose reductase (4,5); alkaline phosphatase (6); apyrase, or ATP diphosphohydrolase (7,8); arylsulfatase (1); azocoll proteinase (1); calcineurin (9); catechol *O*-methyltransferase (10); cathepsin L (11); cholesterol monooxygenase, side-chain cleavage (12); cytochrome *c* oxidase (13); DNA-directed DNA polymerase (14); DNA polymerase  $\alpha$  (14); DNA topoisomerase II (15); glucose-6-phosphate dehydrogenase (16);  $\beta$ -glucuronidase (1); glutamate dehydrogenase (16,17); glutathione *S*-transferase (18); HIV-1 replication (19); hyaluronidase (1);  $\alpha$ -hydroxyacid dehydrogenase (16,20);  $3\beta$ -hydroxysteroid dehydrogenase (21);  $11\beta$ -hydroxysteroid dehydrogenase (22,23);  $17\beta$ -hydroxysteroid dehydrogenase, *potently* (41); inositol-polyphosphate multikinase (15); inositol-trisphosphate 3-kinase (15); lactate dehydrogenase (17,18), with  $K_i$  values of 1.9, 1.4, and 4.2  $\mu$ M for LDH-A<sub>4</sub>, LDH-B<sub>4</sub>, and LDH-C<sub>4</sub>, respectively (24); lactate dehydrogenase X (18,25,26); lipoxygenase (27); 5-lipoxygenase, or arachidonate 5-lipoxygenase (28); 12-lipoxygenase, or arachidonate 12-lipoxygenase (28); malate dehydrogenase (16,17,20,25); malic enzyme (16); maltase (6); [myosin light-chain] kinase (29); neuraminidase (1); phospholipase A<sub>2</sub> (30-32); procathepsin L self-processing, acrosomal (33); prostaglandin synthase (28); protein kinase C (29,34-36); ribonucleotide reductase (37); steroid  $\Delta^5$ - $\Delta^4$  isomerase (21); steroid  $5\alpha$ -reductase (38); steroid  $11\beta$ -monooxygenase (21,12); succinate dehydrogenase (13); sucrose (6); telomerase (39); tubulin polymerization, microtubule assembly (40). 1. ## Gougerotin

This nucleoside antibiotic (FW = 443.42 g/mol; CAS = 2096-42-6), also known as aspiculamycin and asteromycin, is produced by *Streptomyces gougerotii* and inhibits both prokaryotic and eukaryotic protein biosynthesis (1-7) Gougerotin perturbs the relative positioning of the 3'-end of the P/P' site-bound tRNA and the peptidyltransferase loop region of 23S rRNA. **Target(s):** peptidyltransferase (1-10); peptidyl-tRNA hydrolase, or aminoacyl-tRNA hydrolase (11). 1. Fernandez-Muñoz, Monro & Vazquez (1971) *Meth. Enzymol.* **20**, 481. 2. Gottesman (1971) *Meth. Enzymol.* **20**, 490. 3. Pestka (1974) *Meth. Enzymol.* **30**, 261. 4. ## GP 683

This diaryltubercidin analogue (FW = 402.44 g/mol), also named (2*R*,3*R*,4*S*,5*R*)-2-(4-anilino-5-phenylpyrrolo[2,3-*d*]pyrimidin-7-yl)-5-methylxolane-3,4-diol, is a potent adenosine kinase inhibitor (ED<sub>50</sub> = 1.1 mg/kg) that maintains the adenosine concentration at seizure foci, thereby favoring activation of A<sub>1</sub> adenosine receptors and providing a measure of relief against further seizure. Because the use of adenosine receptor agonists is plagued by dose-limiting cardiovascular side effects, there is great interest in developing adenosine kinase inhibitors (AKIs) as a means for raising steady-state adenosine concentrations. GP683 also reduced epileptiform discharges induced by removal of Mg<sup>2+</sup> in a rat neocortical preparation. This anti-seizure activity of GP683, both in *in vivo* and *in vitro* preparations, was markedly reversed by the adenosine receptor antagonists, such as theophylline and 8-(*p*-sulfophenyl)theophylline. GP683's ability to stabilize adenosine concentration surges promises to provide a measure of anti-seizure relief akin to 5'-amino-5'-deoxyadenosine, 5-iodotubercidin, and 5'-deoxy-5-iodotubercidin, but with fewer dose-limiting side effects. 1. Wiesner, Ugarkar, Castellino (1999) *J. Pharmacol. Exp. Ther.* **289**, 1669.

## GQ-177

This thiazolidinedione-based PPAR $\gamma$  partial agonist (FW = 452.34 g/mol) targets Peroxisome Proliferator-Activated Receptor- $\gamma$  (or PPAR $\gamma$ ), which regulates multiple pathways involved in the pathogenesis of obesity and atherosclerosis. GQ-177 improves obesity-associated insulin resistance and dyslipidemia with atheroprotective effects in LDLR<sup>-/-</sup> mice. In atherosclerosis mouse model, GQ-177 inhibits atherosclerotic lesion progression, increases plasma HDL and mRNA levels of PPAR $\gamma$  and ATP-binding cassette A1 in atherosclerotic lesions. **See also Rosiglitazone 1.** Silva, César, de Oliveira, *et al.* (2016). *Pharmacol Res.* **104**, 49.

**GR-20263, See Ceftriaxime**

## GR 231118

This cyclic peptide amide (FW = 2352.77 g/mol; CAS = 158859-98-4; where Dpr = 2,3-Diaminopropionic acid), also known as I229U91 and GW-1229, is a selective neuropeptide Y (NPY) Y<sub>1</sub>-receptor antagonist ( $K_d = 5 \times 10^{-9}$  M) and an NPY Y<sub>4</sub> receptor agonist ( $K_d = 1 \times 10^{-6}$  M). *In vitro*, GR-231118 also binds to neuropeptide FF (NPFF) receptors ( $K_i = 43$ -73 nM). **1.** Hegde, Bonhaus, Stanley, *et al.* (1995) *J. Pharmacol. Exp. Ther.* **275**, 1261. **2.** Parker, Babij, Balasubramaniam, *et al.* (1998) *Eur. J. Pharmacol.* **349**, 97. **3.** Ishihara, *et al.* (1998) *Am. J. **GR38032F, See Ondansetron**

## Grazoprevir

This second generation, nonpeptide macrocycle and HCV protease inhibitor (FW = 766.90 g/mol; CAS = 1350514-68-9), also known by the code name MK-6170 and as 1*R*,18*R*,20*R*,24*S*,27*S*-*N*-{[(1*R*,2*S*)-1-[(cyclopropylsulfonyl)carbamoyl]-2-vinylcyclopropyl]-7-methoxy-24-(2-methyl-2-propyl)-22,25-dioxo-2,21-dioxo-4,11,23,26-tetraaza-pentacyclo[24.2.1.0<sup>3,12</sup>.0<sup>5,10</sup>.0<sup>18,20</sup>]nonacos-3,5,7,9,11-pentaene-27-carboxamide, targets the Hepatitis C virus NS3/4a protease, exhibiting good activity against a range of HCV genotype variants, including some that are resistant to most currently used antiviral medications. Grazoprevir is used in combination with elbasvir, the resulting formulation, known as Zepatier<sup>®</sup>, is a highly effective, FDA-approved treatment of chronic HCV genotypes 1 or 4. A molecular modeling-derived strategy led to the design of this protease inhibitor which contains a conformationally constrained structure. This design arose from an analysis of the crystal structure of full-length NS3/4A with and without inhibitors docked in the active site. That strategy, when coupled with a modular synthetic approach exploiting key ring-closing metathesis reaction, allowed for the rapid exploration of these molecules. **1.** Harper S, McCauley JA, Rudd, *et al.* (2012) *ACS Med Chem Lett.* **3**, 332. **2.** Ali, Aydin, Gildemeister, *et al.* (2013) *ACS Chem. Biol.* **8**, 1469.

## Gramicidins

These linear membrane-penetrating antibiotics (FW<sub>Val-GR-A</sub> = 1882.30 g/mol; FW<sub>Ile-GR-A</sub> = 1896.40 g/mol; FW<sub>Val-GR-B</sub> = 1843.30 g/mol; FW<sub>Ile-GR-B</sub> = 1857.30 g/mol; FW<sub>Val-GR-C</sub> = 1859.30 g/mol; FW<sub>Ile-GR-C</sub> = 1873.3 g/mol; CAS 1393-88-0 and 1405-97-6) are channel-forming ionophores that are active against Gram-positive microorganisms, hence their name (1-6). They efficiently uncouple oxidative phosphorylation and photophosphorylation by blocking formation of both the membrane potential and  $\Delta\text{pH}$ . Truncated derivatives stimulate the ATPase without collapsing the membrane potential. Such findings suggest gramicidins interact directly with the H<sup>+</sup>-ATPase (7). **Structural Features:** GRA, GRB, and GRC are linear 15-residue peptides. Key features: N-terminus = Formyl (H<sub>2</sub>C(=O)-); Residue-X = Val and Ile residues in all three; Residue-Y = W in GRA, F in GRB, and Y in GRC; C-terminus = Ethanolamine (-OCH<sub>2</sub>CH<sub>2</sub>NH<sub>2</sub>). They are formulated at the N-terminus and contain ethanolamine at the C-terminus. Each gramicidin consists of two chains, differing only in the residue at position one, where it is either an L-valyl residue or an L-isoleucyl residue. Note that the alternating stereochemical configurations of amino acid residues is an essential property for  $\beta$ -helix formation. The valine-containing ionophore is the principal form in Gramicidins A, B, and C, roughly amounting to 80-95%. Gramicidin D is a minor and more hydrophilic form. Commercial formulations from *Bacillus aneurinolyticus* (*Bacillus brevis*) consist of GRA (87.5%), GRB (7.1%), GRC (5.1%), and GRD (0.3% w/w). **1.** Dubos (1939) *J. Exp. ## Gramine

This alkaloid (FW<sub>free-base</sub> = 174.25 g/mol; CAS = 87-52-5), formed from L-tryptophan and found in relatively large amounts in barley, is a vasorelaxant and 5-HT<sub>2A</sub> receptor antagonist. **Target(s):** acetylcholinesterase (1); adenylate cyclase activity, dopamine-stimulated (2); 5-hydroxytryptamine 2A (5-HT<sub>2A</sub>) receptor (3,4); NADH dehydrogenase, or Complex I (5); octopamine receptor (3,4). **1.** Lockhart, Closier, Howard, Steward & Lestage (2001) *Naunyn Schmiedebergs Arch. Pharmacol.* **363**, 429. **2.** Capasso, Creti, De Petrocellis, De Prisco & Parisi (1988) *Biochem. Biophys. Res. ## Granisetron

This serotonin 5-HT<sub>3</sub> receptor antagonist and anti-emetic (FW = 312.41 g/mol; CAS = 109889-09-0), also known as BRL 43694, Sancuso<sup>®</sup>, Kytril<sup>®</sup>, and 1-methyl-*N*-((1*R*,3*r*,5*S*)-9-methyl-9-azabicyclo[3.3.1]nonan-3-yl)-1*H*-indazole-3-carboxamide, is a FDA-approved drug (often administered as a transdermal patch) for the treatment nausea and vomiting associated with cancer chemotherapy. Often used in combination with other antiemetics, granisetron is specifically indicated for the prevention of both acute and delayed nausea and vomiting that attend the use of emetogenic chemotherapeutic agents, such as anthracycline and cyclophosphamide. **Primary Mode of Inhibitor Action:** Granisetron affects both peripheral and central nervous systems, reducing vagus nerve activity and thereby deactivating the 5-HT<sub>3</sub> receptor-dense vomiting center located in the medulla oblongata. It is without effect on dopamine receptors or muscarinic receptors. BRL-43694 forms a high-affinity complex ( $K_d = 0.30$  nM) with 5-HT<sub>3</sub> receptors, similar to that of quipazine. Scatchard analysis suggests binding occurs at a single population of receptors (1). There is also

a direct correlation ( $r = 0.98$ , slope = 0.95) between BRL 43694 binding and observed inhibition of the 5-HT-evoked BJR, the so-called Bezold-Jarisch chemoreflex associated with combined bradycardia, hypotension, and peripheral vasodilation. (Other similarly acting 5-HT<sub>3</sub> antagonists include: tropisetron, ondansetron, dolasetron, and palonosetron. The effectiveness of each depends on particular variants of 5-HT<sub>3</sub> receptors expressed by the patient, including changes in promoters for the receptor genes.) 1. Nelson & Thomas (1989) *Biochem. Pharmacol.* **38**, 1693.

### Grepafoxacin

This orally bioavailable fluoroquinolone-class antibiotic (FW = 359.40 g/mol; CAS = 119914-60-2), also named Raxar<sup>®</sup> and (R,S)-1-cyclopropyl-6-fluoro-5-methyl-7-(3-methylpiperazin-1-yl)-4-oxoquinoline-3-carboxylate, is a broad-spectrum systemic antibacterial agent that targets Type II DNA topoisomerases (gyrases), which are required for bacterial replication and transcription. Despite its effectiveness against Gram-positive and -negative bacteria (especially *Haemophilus influenzae*, *Streptococcus pneumoniae*, and *Moraxella catarrhalis*), grepafoxacin was withdrawn from the market, because it lengthens the QT interval, resulting in cardiac events and sudden death. For the prototypical member of this antibiotic class, See *Ciprofloxacin*

### Griseofulvin

This orally active microtubule-directed antifungal agent from *Penicillium griseofulvum* and *P. janczewskii* (FW = 352.77 g/mol; CAS = 126-07-8; Solubility 50 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O; IUPAC: (2*S*,6'*R*)-7-chloro-2',4,6-trimethoxy-6'-methyl-3*H*,4'*H*-spiro[1-benzofuran-2,1'-cyclohex[2]ene]-3,4'-dione) targets tubulin and microtubules (MTs), interfering with mitosis in *Trichophyton rubrum* and *Trichophyton mentagrophytes*, two pathogenic dermatophytes. Griseofulvin also targets centrosomal clustering that enables bipolar mitosis in cancer cell lines harboring supernumerary centrosomes. Griseofulvin induces multipolar spindles by inhibiting centrosome coalescence and mitotic arrest, with subsequent cell death in tumor cell lines, but not in diploid fibroblasts and keratinocytes having normal centrosome content. Inhibition of centrosome clustering by griseofulvin was not restricted to mitotic cells and occurs during interphase (1). While multipolar-spindle formation is dynein-independent, interphase MT depolymerization appears to be mechanically involved in centrosomal declustering. SAR studies with the parent compound and 53 griseofulvin analogues strongly suggest that the mode-of-action of the compound class toward fungi and mammalian cancer cells is different (2). Treatment of *T. rubrum* fungal cells with griseofulvin decreased  $\beta$ -tubulin gene expression in a dose-dependent manner (3). Griseofulvin is used mainly to treat skin infections such as jock itch, athlete's foot, and ringworm; as well as fungal infections of the scalp, fingernails, and toenails. (See also GF-15) **Target(s):** ferrocyclase (rodent) (4); tubulin polymerization (microtubule assembly) (5-9); UDP-glucuronosyltransferase (10). 1. Rebacz, Larsen, Clausen, *et al.* (2007) *Cancer Res.* **67**, 6342. 2. Rønneest, Raab, Anderhub, *et al.* (2012) *J. Med. Chem.* **55**, 652. 3. Zomorodian, Uthman, Tarazooie & Rezaie (2012) *J. Golovinsky (2001) *Arch. Toxicol.* **75**, 609.

### Griseoviridin

This antibiotic (FW = 477.53; CAS = 53216-90-3;  $\lambda_{\max} = 221$  nm (in methanol);  $\epsilon_{(1\%1\text{cm})} = 870$ ), obtained from a strain of *Streptomyces*, binds to the large subunit of *Escherichia coli* ribosomes, blocking the interaction of the 3' terminal end of peptidyl tRNA with the donor site of the peptidyltransferase. Note revised structure. **Target(s):** peptidyltransferase (1); prokaryotic protein biosynthesis (initiation and elongation) (2,3). 1. Spirin & Asatryan (1976) *FEBS Lett.* **70**, 101. 2. Jiménez (1976) *Trends Biochem. Sci.* **1**, 28. 3. Barbacid, Contreras & Vazquez (1975) *Biochim. Biophys. Acta* **395**, 347.

### GRN163L, See Imetelstat

### GS 143

This  $\beta$ -TrCP1 ligase inhibitor (FW = 466.46 g/mol; CAS = 916232-21-8; Soluble to 100 mM in DMSO), systematically named 4-[4-[[5-(2-fluorophenyl)-2-furanyl]methylene]-4,5-dihydro-5-oxo-3-(phenylmethyl)-1*H*-pyrazol-1-yl]benzoic acid, blocks I $\kappa$ B $\alpha$  ubiquitination ( $IC_{50} = 5.2$   $\mu$ M) without affecting proteasome activity. The inducible transcription factor NF- $\kappa$ B regulates divergent signaling pathways including inflammatory response and cancer development. NF- $\kappa$ B is canonically activated by preferential disposal of its inhibitory protein; I $\kappa$ B, which suppresses the nuclear translocation of NF- $\kappa$ B. Itself a major member of I $\kappa$ B family proteins, I $\kappa$ B $\alpha$  is phosphorylated by an I $\kappa$ B kinase (IKK) and subsequently undergoes polyubiquitylation by SCF( $\beta$ TrCP1) ubiquitin-ligase in the presence of E<sub>1</sub> and E<sub>2</sub> and subsequent proteasomal degradation. GS143 suppresses I $\kappa$ B $\alpha$  ubiquitylation, markedly suppressing its destruction. The latter is stimulated by TNF $\alpha$  and a set of downstream responses coupled to NF- $\kappa$ B signaling, but not those of p53 and  $\beta$ -catenin *in vivo*. GS-143 also inhibits LPS-induced expression of inflammatory cytokines in human myelomonocytic cells. It suppresses antigen-induced NF $\kappa$ B expression, inflammation and mucus production in airways of OVA-sensitized mice. (Note: GS143 does not inhibit I $\kappa$ B $\alpha$  phosphorylation, MDM2-directed p53 ubiquitylation, and proteasome activity *in vitro*.) 1. Hirose *et al.* (2008) *Biochem. Biophys. Res. Commun.* **374** 507. 2. Nakajima, Fujiwara, Furuichi, Tanaka & Shimbara (2008) *Biochem. Biophys. Res. Commun.* **368**, 1007.

### GS-1101

This orally bioavailable PI3K $\delta$  inhibitor (FW = 415.43 g/mol), also known as CAL-101, Idelalisib<sup>®</sup>, and 5-fluoro-3-phenyl-2-([S]-1-[9H-purin-6-ylamino]propyl)-3H-quinazolin-4-one, targets the  $\delta$ -isoform of the 110-kDa catalytic subunit of Class I phosphoinositide-3 kinase, showing potent immunomodulating and antineoplastic activities by through the inhibition of phosphatidylinositol-3,4,5-trisphosphate (PIP<sub>3</sub>) formation. GS-1101 exhibits 40–300x selectivity over other PI3K isoforms (1-3). By preventing the activation of the PI3K signaling pathway, GS-1101 inhibits tumor cell proliferation, motility, and survival. Unlike other isoforms of PI3K, PI3K- $\delta$  is expressed primarily in hematopoietic lineages. GS-1101 also synergistically potentiates histone deacetylase inhibitor-induced proliferation inhibition and apoptosis through the inactivation of PI3K and extracellular signal-regulated kinase pathways (4). GS-1101 may also enjoy added therapeutic potential by targeting the infiltrative capacity of tumor-associated macrophages that is critical for their enhancement of tumor invasion and metastasis (5). 1. Herman, Gordon, Wagner, *et al.* (2010) *Blood* **116**, 2078. 2. Meadows, Vega, Kashishian *et al.* (2012) *Blood* **119**, 1897. 3. Castillo, Furman & Winer (2012) *Expert Opin. Investig. Drugs* **21**, 15. 4. Bodo, Zhao, Sharma, *et al.* (2013) *Brit. J. Haematol.* **163**, 72. 5. Mouchemore, Sampaio, Murrey, *et al.* (2013) *FEBS J.* **280**, 5228.

#### GS-7977

This antiviral pro-drug (FW = 387.44 g/mol; CAS = 1190307-88-0), also known as PPI-7977, Sofosbuvir<sup>®</sup>, and isopropyl (2S)-2-[[[(2R,3R,4R,5R)-5-(2,4-dioxypyrimidin-1-yl)-4-fluoro-3-hydroxy-4-methyltetrahydrofuran-2-yl]methoxyphenoxyphosphoryl]amino]propanoate, is metabolized into the active agent, 2'-deoxy-2'- $\alpha$ -fluoro- $\beta$ -C-methyluridine-5'-monophosphate, which in turn inhibits Hepatitis C virus RNA-dependent RNA polymerase. Clinical trials suggest Sofosbuvir plus Ribavirin for twelve weeks may be effective in previously untreated patients with HCV genotype 1, 2, or 3 infection (2). 1. Sofia, Bao, Chang, *et al.* (2010) *J. Med. Chem.* **53**, 7202. 2. Gane, Stedman, Hyland, *et al.* (2013) *New Engl. J. Med.* **368**, 34.

#### GS-8374

This prototypical phosphonate-containing protease inhibitor (FW = 728.79 g/mol), also named (3R,3aS,6aR)-hexahydrofuro[2,3-b]furan-3-yl-(2S,3R)-1-(4-((diethoxyphosphoryl)methoxy)-phenyl)-3-hydroxy-4-(N-isobutyl-4-methoxyphenylsulfonamido)butan-2-ylcarbamate, inhibits wild type HIV-1 protease (EC<sub>50</sub> = 0.01 nM) and antiviral-resistant forms (1). This diethylphosphonate derivative of TMC-126 (MW = 562.68 g/mol) (2,3) has a resistance profile that is superior to all clinically approved protease inhibitors. 1. Grantz Šašková, Kozišek, Stray, *et al.* (2014) *J. Virol.* **88**, 3586. 2. Ghosh, Chapsal, Weber & Mitsuya (2008) *Acc. Chem. Res.* **41**, 78. 3. Ghosh, Pretzer, Cho, Hussain & Duzgunes (2002) **54**, 29.

#### GS-9137, See Elvitegravir

#### GS-9350

This potent mechanism-based inhibitor and pharmacoenhancer (FW = 776.02 g/mol; CAS = 1004316-88-4; Abbreviation: COBI), also known as Cobicistat<sup>®</sup>, targets human CYP3A (or cytochrome P450 3A) isoforms (IC<sub>50</sub> = 30-285 nM), thereby boosting systemic exposure to co-administered agents that are otherwise deactivated by CYP3A (1). GS-9350 also displays weak action as an HIV proteinase inhibitor (IC<sub>50</sub> > 40-50  $\mu$ M), allowing it to boost the action of higher-affinity anti-HIV drugs without risking selection of potential cobistat-resistant HIV variants. Cobistat also inhibits the intestinal efflux transporters P-glycoprotein and breast cancer resistance protein, thereby boosting the efficacy of HIV protease inhibitors atazanavir and darunavir and the lymphoid cell- and tissue-targeted pro-drug of the nucleotide analogue tenofovir (2). 1. Mathias, German, Murray, *et al.* (2010) *Clin. Pharmacol. Ther.* **87**, 322. 2. Lepist, Phan, Roy, *et al.* (2012) *Antimicrob. Agents Chemother.* **56**, 5409.

#### GSI-IX, See DAPT

#### GSK591

This PRMT5 inhibitor (FW = 380.49 g/mol; CAS = 1616391-87-7; Solubility: 79 mg/mL DMSO; < 1mg/mL H<sub>2</sub>O), also known as (S)-2-(cyclobutylamino)-N-(3-(3,4-dihydroisoquinolin-2(1H)-yl)-2-hydroxypropyl)isonicotinamide, EPZ015866, GSK-3203591, GSK-591, and GSK 591, selectively targets Protein arginine methyltransferase-5 (IC<sub>50</sub> = 11 nM), an enzyme that catalyzes the symmetrical dimethylation of arginine residues in the small nuclear ribonucleoproteins Smd1 (SNRPD1) and Smd3 (SNRPD3), a step that is required in snRNP core particle assembly. PRMT5 also methylates SUPT5H and is likely to regulate its transcriptional elongation properties. PRMT5 also catalyzes the mono- and di-methylation of arginyl residues in myelin basic protein (MBP) *in vitro* and may play a role in cytokine-activated transduction pathways. PRMT5 also attenuates EGF signaling by monomethylating EGFR, RAF1 and probably BRAF. PRMT5 interacts with a number of binding partners that influence its substrate specificity. In an *in vitro* assay, GSK591 potently inhibits the PRMT5/MEP50 complex from methylating (histone) H4 (IC<sub>50</sub> = 11 nM). In Z-138 cells, GSK591 inhibits the symmetric arginine methylation of Smd3 (EC<sub>50</sub> = 56 nM). GSK591 is selective for PRMT5 (up to 50  $\mu$ M) relative to a panel of methyltransferases. Reference-1 describes the design and optimization strategies using an initial hit compound with poor *in vitro* clearance to yield the *in vivo* tool compound EPZ015666 (GSK3235025) in addition to the potent *in vitro* tool molecule EPZ015866 (GSK-591). 1. Duncan, Rioux, Boriak-Sjodin (2016) *ACS Med. Chem. Lett.* **7**, 162.

**GSK621**

This AMPK activator (FW = 489.91 g/mol; CAS 1346607-05-3; Solubility: 97 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 6-chloro-5-(2'-hydroxy-3'-methoxy[1,1'-biphenyl]-4-yl)-3-(3-methoxy-phenyl)-1H-pyrrolo[3,2-d]pyrimidine-2,4(3H,5H)-dione, potently and specifically targets Adenosine Monophosphate Kinase, doubling its basal activity at 1-2  $\mu$ M and reaching nearly three-fold higher than basal at 8  $\mu$ M. (Compare to corresponding values of 10 and 27  $\mu$ M for A-769662) AMPK is a signal transduction kinase that acts either as a tumor suppressor or oncogene, depending on the context. GSK621 induces cytotoxicity by activating autophagy, independently of mTORC1 inhibition. Unexpectedly, activation of AMPK and constitutive mTORC1 signaling results in a synthetic lethal interaction across a range of acute myeloid leukemia (AML) primary samples and cell lines. **1.** Sujobert, Poulain, Paubelle, *et al.* (2015) *Cell Rep.* 11, 1446.

**GSK 2033**

This potent cell-permeable LXR antagonist (FW = 591.66 g/mol; CAS = 1221277-90-2; Solubility: 20 mM in DMSO), also known as 2,4,6-Trimethyl-N-[[[3'-(methylsulfonyl)[1,1'-biphenyl]-4-yl]methyl]-N-[[5-(trifluoromethyl)-2-furanyl]methyl]benzenesulfonamide, targets liver X receptor ( $K_i = 30$  nM), a member of the nuclear receptor family of transcription factors that is closely related to nuclear receptors such as the PPARs, FXR and RXR (1,2). LXRs are important regulators of cholesterol, fatty acid, and glucose homeostasis. A ligand-bound cocrystal structure was determined which elucidated key interactions for high binding affinity (1). T-helper-17 (T<sub>H</sub>17) cells, which are a subset of CD4<sup>+</sup> T cells characterized by the secretion of IL-17A, IL-17F, IL-21, and IL-22, play an important role in the regulation of immune responses against bacterial and fungal infections. These cells require the expression of both retinoic acid receptor-related orphan receptors  $\alpha$  and  $\gamma$  (ROR $\alpha$  and ROR $\gamma$ t) for full differentiation. Although the LXR agonist T0901317 also displays high-affinity ROR $\alpha$  and ROR $\gamma$ t inverse activity, GSK-2003 was useful in demonstrating that it is T0901317's activity at ROR $\alpha$  and  $\gamma$ t, but not at LXR, that facilitates the inhibition of T<sub>H</sub>17 cell differentiation and function (2). **1.** Zuercher, Buckholz, Campobasso, *et al.* (2010) *J. Med. Chem.* 53, 3412. **2.** Solt, Kamenecka & Burris (2012) *PLoS One* 7, e46615.

**GSK3787**

This orally available PPAR $\delta$  antagonist (FW = 392.78 g/mol; CAS = 188591-46-0; Solubility: 79 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O) selectively targets Peroxisome Proliferator-Activated Receptor  $\delta$  (PPAR $\delta$ ), IC<sub>50</sub> of 2.2  $\mu$ M, without measurable affinity for hPPAR $\alpha$  or hPPAR $\gamma$ . Mass spectral analysis confirms covalent binding to Cys249 within the PPAR $\delta$  binding pocket (1). GW0742 induces up-regulation of Angptl4 as well as Adrp mRNA expression in wild-type mouse colon, but not in PPAR $\beta/\delta$ -null mouse colon, correlating well with reduced promoter occupancy of PPAR $\beta/\delta$  on genes for Angiopoietin-like 4, or Angptl4, and Adipose differentiation-related protein, Adrp. **1.** Shearer, Wiethe, Ashe, *et al.* (2010) *J. Med. Chem.* 53, 1857. **2.** Palkar, Borland, Naruhn, *et al.* (2010) *Mol. Pharmacol.* 78, 419.

**GSK256066**

This quinolone-based PDE inhibitor (FW = 518.55 g/mol), also named 6-({3-[(dimethylamino)carbonyl]phenyl}sulfonyl)-8-methyl-4-[[3-methoxyphenyl]amino]-3-quinolinecarboxamide, shows exceptionally high affinity (apparent IC<sub>50</sub> = 3.2 pM; steady-state IC<sub>50</sub> < 0.5 pM) for phosphodiesterase PDE4, and exhibits >380,000-fold selectivity toward PDE4 over PDE1, PDE2, PDE3, PDE5, and PDE6, and >2500-fold against PDE7. **1.** Woodrow, Ballantine, Barker, *et al.* (2009) *Bioorg. Med. Chem. Lett.* 19, 5261.

**GSK-3203591, See GSK591****GSK 429286A**

This potent PKI and vasodilator (FW = 432.37 g/mol for the monohydrochloride; CASs = 864082-47-3; Solubility: 90 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known as N-(6-fluoro-1H-indazol-5-yl)-2-methyl-6-oxo-4-(4-(trifluoromethyl)phenyl)-1,4,5,6-tetra-hydropyridine-3-carboxamide, targets ROCK1 and ROCK2, with IC<sub>50</sub> values of 14 nM and 63 nM, respectively. RhoA/Rho kinases (abbreviated ROCK) play important roles in mediating vasoconstriction and vascular remodeling in the pathogenesis of pulmonary hypertension. GSK429286A slightly inhibits RSK and p70S6K with IC<sub>50</sub> values of 0.78  $\mu$ M and 1.94  $\mu$ M, respectively. **1.** Goodman, *et al.* (2007) *J. Med. Chem.* 50, 6. **2.** Nichols, *et al.* (2009) *Biochem. J.* 424, 47.

**GSK461364**

This protein kinase inhibitor (FW<sub>free-acid</sub> = 543.60 g/mol; CASs = 929095-18-1 and 1000873-97-1; Solubility: 30 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known systematically as 5-(6-((4-methylpiperazin-1-yl)-methyl)-1H-benzo[d]imidazol-1-yl)-3-((R)-1-(2-(trifluoromethyl)-phenyl)ethoxy)thio-phenyl-2-carboxamide, targets the Polo-like kinase Plk1 ( $K_i$  = 2.2 nM), bringing about G<sub>2</sub>/M cell-cycle arrest and cell death. RNA silencing of WT p53 increases the antiproliferative activity of GSK461364, suggesting that cancers with defective p53 would likewise be sensitive to co-administration of GSK461364 and DNA-damaging drugs. 1. Gilmartin, et al. (2009) *Cancer Res.* **69**, 6969. 2. Degenhardt, et al. (2010) *Mol. Cancer Ther.* **9**, 2079. 3. Olmos, et al. (2011) *Clin. Cancer Res.* **17**, 3420.

**GSK525762, See I-BET-762****GSK525762A, See I-BET-762****GSK690693**

This pan-Akt inhibitor (F.W. = 425.48; CAS = 937174-76-0; Solubility (25°C): 39 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), known systematically as 4-(2-(4-amino-1,2,5-oxadiazol-3-yl)-1-ethyl-7-((S)-piperidin-3-ylmethoxy)-1H-imidazo[4,5-c]pyridin-4-yl)-2-methylbut-3-yn-2-ol, targets Akt1, Akt2 and Akt3 Protein Kinases (or PKB) with IC<sub>50</sub> of 2 nM, 13 nM, and 9 nM, respectively. 1. Rhodes, et al. (2008) *Cancer Res.* **68**, 2366. 2. Levy, et al. (2009) *Blood* **113**, 1723. 3. Altomare, et al. (2010) *Clin. Cancer Res.* **2010**, **16**, 486.

**GSK1059615**

This potent and selective PI3K $\alpha$ /PI4KIII $\beta$  inhibitor (F.Wt. = 333.36; CAS = 958852-01-2, 1356195-42-0 (monohydrate, Na); Solubility (25°C): 2 mg/mL DMSO, <1 mg/mL Water), also known as (Z)-5-((4-(pyridin-4-yl)quinolin-6-yl)methylene)thiazolidine-2,4-dione, has the following inhibitory profile: PI3K $\alpha$ , IC<sub>50</sub> = 0.4 nM; PI3K $\beta$ , IC<sub>50</sub> = 0.6 nM; PI3K $\delta$ , IC<sub>50</sub> = 2 nM; and PI3K $\gamma$  mTOR, IC<sub>50</sub> = 0.4 nM. 1. Carnero (2009) *Expert Opin. Investig. Drugs* **18**, 1265. 2. Knight, et al. (2010) *ACS Med. Chem. Lett.* **1**, 39.

**GSK1120212, See Trametinib****GSK1265744**

This orally available strand-transfer inhibitor and potent antiviral (FW = 405.36 g/mol; CAS: 1051375-10-0), also known as GSK-1265744, S-265744, targets HIV integrase (with a low-nM IC<sub>50</sub>), an essential enzyme that splices a viral DNA (vDNA) replica of its genome into host cell chromosomal DNA (hDNA) and is a promising druggable target for anti-AIDS agents. GSK1265744 monotherapy significantly reduces plasma HIV-1 RNA >100x below baseline to day-11 in HIV-1-infected subjects receiving 5 or 30 mg *versus* placebo. The mean plasma half-life is 31.5 hours, and a nanoparticle-based formulation has a half-life of 21–50 days. 1. Spreen, Min, Ford, et al. (2013) *HIV Clin. Trials* **14**, 192.

**GSK1322322**

This first-in-class, orally bioavailable antibiotic (FW = 479.55 g/mol; CAS = 1152107-25-9) targets bacterial peptide deformylase (EC 3.5.1.88; *Reaction*: N-Formyl-L-methionyl peptide + H<sub>2</sub>O  $\rightleftharpoons$  Formate + Methionyl peptide) which is required for protein maturation in prokaryotes. Intended for the treatment of complicated bacterial skin infections and hospitalized community-acquired pneumonia, GSK1322322 is active against such multidrug-resistant, Gram-negative pathogens as *Staphylococcus aureus* ATCC 29213 (MIC, 1-4  $\mu$ g/mL), *Haemophilus influenzae* ATCC 49247 (MIC, 0.5-4  $\mu$ g/mL), and *Streptococcus pneumoniae* ATCC 49619 (MIC, 0.12-0.5  $\mu$ g/mL) (1). Upon single-dose administration, GSK1322322 is absorbed rapidly, with median time-to-maximum plasma concentration of 0.5 to 1.0 h (2). 1. Ross, Scangarella-Oman, Miller, Sader & Jones (2011) *J. Clin. Microbiol.* **49**, 3928. 2. Naderer, Dumont, Zhu, Kurtinecz & Jones (2005) *Antimicrob. Agents Chemother.* **57**, 2005.

**GSK1363089, See Foretinib****GSK1562590**

This orally active, high-affinity UT receptor antagonist (FW<sub>HCl-salt</sub> = 617.95 g/mol; CAS = 1003878-07-6; Soluble to 100 mM in DMSO; N-[(1R)-1-[3'-(aminocarbonyl)-[1,1'-biphenyl]-4-yl]-2-(1-pyrrolidinyl)ethyl]-6,7-dichloro-2,3-dihydro-N-methyl-3-oxo-4H-1,4-benzoxazine-4-acetamide) selectively targets recombinant urotensin II receptors in monkey (pK<sub>i</sub> = 9.14), human (pK<sub>i</sub> = 9.28), mouse (pK<sub>i</sub> = 9.34), cat (pK<sub>i</sub> = 9.64) and rat (pK<sub>i</sub> 9.66). GSK1562590 exhibits selectivity for UT receptors over a range of G protein-coupled receptors, ion channels, enzymes and neurotransmitter transporters. GSK1562590 also inhibits the hU-II-induced systemic pressor

playing a key role in HCV replication, decreases the antiviral activity of GSK2336805. Such mutations in the genotype 1b replicon show modest shifts in compound activity (<13x), whereas mutations identified in the genotype 1a replicon have a more dramatic impact on potency. Combination and cross-resistance studies demonstrated that GSK2336805 could be used as a component of a multi-drug HCV regimen employing compounds with different mechanisms of action. **1.** Walker, Crosby, Wang, *et al.* (2013) *Antimicrob. Agents Chemother.* **58**, 38.

**GSK2118436**, See *Dabrafenib*

**GSK2578215A**

This potent, brain-penetrating Leucine-Rich Repeat Kinase-2, or LRRK2 inhibitor (FW = 399.42 g/mol; CAS = 1285515-21-0; Soluble to 100 mM in DMSO), also named 5-(2-fluoro-4-pyridinyl)-2-(phenylmethoxy)-N-3-pyridinylbenzamide, has IC<sub>50</sub> values of 10 and 8 nM, respectively, for the wild type enzyme and its [Gly-2019-Ser]-mutant. GSK2578215A displays selectivity for LRRK2 versus 460 other protein kinases. GSK2578215A blocks Ser-910 and Ser-935 phosphorylation of both wild-type LRRK2 and G2019S mutant at a concentration of 0.3-1.0 μM in cells and in mouse spleen and kidney, but not in brain, following intraperitoneal injection of 100mg/kg. **1.** Reith, Bamborough & Jandu, *et al.* (2012) *Bioorg. Med. Chem. Lett.* **22**, 5625.

**GSK 2606414**

This orally available PERK inhibitor (FW = 451.44 g/mol; CAS = 1337531-36-8; Solubility: 100 mM in DMSO; 20 mM in H<sub>2</sub>O for mono-HCl with gentle warming), also named 1-[5-(4-amino-7-methyl-7H-pyrrolo[2,3-d]pyrimidin-5-yl)-2,3-dihydro-1H-indol-1-yl]-2-[3-(trifluoromethyl)phenyl]ethanone, potently and selectively targets protein kinase R-like ER kinase, or PERK (IC<sub>50</sub> = 0.4 nM), inhibiting thapsigargin-induced PERK phosphorylation in lung carcinoma A549 cells and attenuating subcutaneous pancreatic human tumor xenograft growth in mice.

**GSK 2656157**

This ATP-competitive protein kinase inhibitor (FW = 416.45 g/mol; CAS = 1337532-29-2; Solubility: 37 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also named 1-(5-(4-amino-7-methyl-7H-pyrrolo[2,3-d]pyrimidin-5-yl)-4-fluorindolin-1-yl)-2-(6-methylpyridin-2-yl)ethanone, targets Protein kinase RNA-like Endoplasmic Reticulum Kinase (PERK), IC<sub>50</sub> = 0.9 nM, showing 500x greater selectivity versus a panel of 300 kinases. PERK is an enzyme within the Unfolded Protein Response (UPR) signal transduction cascade that coordinates cellular adaptation to microenvironmental stresses that include hypoxia, nutrient deprivation, and change in redox status. GSK2656157 inhibits PERK activity in cells with an IC<sub>50</sub> values of 10-30 nM, as shown by inhibition of stress-induced PERK autophosphorylation, eIF2α substrate phosphorylation, together with corresponding decreases in ATF4 and CAAT/enhancer binding protein homologous protein (CHOP) in multiple cell lines. Oral administration to mice shows both dose- and time-dependent pharmacodynamic responses in pancreas, as measured by PERK autophosphorylation. Twice daily dosing of GSK2656157 results in dose-dependent inhibition of multiple human tumor xenografts growth in mice. **1.** Atkins, Liu, Minthorn, *et al.* (2013) *Cancer Res.* **73**, 1993.

**GSK J1**

This JMJD3-selective inhibitor (FW<sub>free-acid</sub> = 388.45 g/mol; CAS = 1373422-53-7; λ<sub>max</sub> = 253 nm), also named 3-((6-(4,5-dihydro-1H-benzo[d]azepin-3(2H)-yl)-2-(pyridin-2-yl)pyrimidin-4-yl)amino)propanoate, targets the histone H3 lysine-27 (or H3K27) demethylase known as JMJD3 (1). Jumonji family histone demethylases are Fe<sup>2+</sup>/α-ketoglutarate-dependent oxygenases in regulatory transcriptional chromatin complexes. They play critical roles in transcriptional control of cell differentiation, development, inflammation, and cancer by silencing through the polycomb-repressive complex PRC1 or PRC2. GSK-J1's polar carboxylate restricts its cellular permeability, but its prodrug ethyl ester GSK-J4 is cell-penetrating. GSK-J1 shows significant activity (IC<sub>50</sub> = 60 nM for human JMJD3) *in vitro* and in cells using an ester derivative (GSK-J4: 1 μM < IC<sub>50</sub> < 10 μM). Another pyridine regio-isomer, known as GSK-J2, displays significantly less on-target activity (IC<sub>50</sub> > 100 μM for human JMJD3) and can be used as control for target effects *in vitro*, and as ester derivative (GSK-J5) in cells. GSK-J1 also shows some activity (IC<sub>50</sub> = 950 nM for Jarid1b, IC<sub>50</sub> = 1.8 μM for Jarid1c) versus H3K4me3/2/1 demethylases. GSK-J1 has no effect on more than 100 different kinases or other unrelated proteins, including other chromatin-modifying enzymes such as histone deacetylases. See also references 2-4 for comments on the selectivity of GSK-J1. **1.** Kruidenier, Chung, Cheng, *et al.* (2012) *Nature* **488**, 404. **2.** Heinemann, Nielsen, Hudlebusch, *et al.* (2014) *Nature* **514**, E1. **3.** Kruidenier, Chung, Cheng, Liddle, *et al.* (2014) *Nature* **514**, E2. **4.** <http://www.thesgc.org/chemical-probes/GSKJ1>

**GSK J4**

This GSK J1 pro-drug (FW<sub>free-base</sub> = 417.51 g/mol; CAS = 1373423-53-0; λ<sub>max</sub> = 253 nm) that is cell-permeable and, once within cells, readily transformed into GSK J1 (See GSK J1), the first selective inhibitor of the H3K27 histone demethylase JMJD3 and UTX (IC<sub>50</sub> = 60 nM), but is otherwise inactive against a panel of JMJD family demethylases. The jumonji (JMJD) family of histone demethylases are Fe<sup>2+</sup>- and α-ketoglutarate-dependent oxygenases that are essential components of regulatory

transcriptional chromatin complexes. These enzymes demethylate lysine residues in histones in a methylation-state and sequence-specific context. 1. Kruidenier, Chung, Cheng, *et al.* (2012) *Nature* **488**, 404.

### GSK-LSD1

This selective LSD1 inhibitor (FW<sub>free-base</sub> = 216.33 g/mol; FW<sub>2HCl</sub> = 289.24 g/mol; CAS = 1431368-48-7 (free-base)), also named *N*-((1*R*,2*S*)-2-phenylcyclopropyl)piperidin-4-amine, targets Lysine-Specific Demethylase 1, or LSD1 (IC<sub>50</sub> = 16 nM), showing > 1000 fold selective over other closely related FAD utilizing enzymes (*i.e.*, LSD2, and monoamine oxidases MAO-A, MAO-B). LSD1 belongs to the flavin adenine dinucleotide (FAD)-dependent amine oxidase family that also includes monoamine oxidases (MAOs) and polyamine oxidase (PAO). LSD1 demethylates mono- and dimethylated histone H3 at Lysine-4, resulting in transcriptional repression and controls p53 tumor suppressor activity of p53 by demethylation at Lysine-370. 1. Shi, Lan, Matson, *et al.* (2004) *Cell* **119**, 941. 2. Forneris, Binda, Vanoni, *et al.* (2005) *J. Biol. Chem.* **280**, 41360. 3. Huang, Sengupta, Espejo, *et al.* (2007) *Nature* **449**, 105. 4. See also <http://www.thesgc.org/chemical-probes/LSD1>

### GsMTx4

This first-in-class, 35-residue peptide toxin (FW = 4095.86 g/mol; Soluble to 1 mg/mL in H<sub>2</sub>O), first isolated from the venom of the tarantula *Grammostola spatulata*, is a cysteine knot family member that exploits its amphipathic structure to block cation-selective stretch-activated channels (SACs), *K<sub>d</sub>* = 0.63 μM, based on the ratio of experimentally determined dissociation and association rate constants (1). The ability to bind to and burrow into phospholipid membranes is most likely a key to its mechanism of action, bending boundary lipids toward the channel and making the membrane appear thinner (2). In hypotonically swollen astrocytes, GsMTx-4 produces approximately 40% reduction in swelling-activated whole-cell current (1). Quite remarkably, a peptide (*en*GsMTx-4) of similar sequence, but containing D-amino acids, shows a similar *K<sub>d</sub>* suggesting the binding of GsMTx4 is unlikely rely on stereochemical recognition (3). 1. Suchyna, Johnson, Hamer, *et al.* (2000) *J. Gen. Physiol.* **115**, 583. (Erratum in: *J. Gen. Physiol.* (2001) **117**, 371.) 2. Bowman, Gottlieb, Suchyna, Murphy & Sachs (2007) *Toxicol.* **49**, 249. 3. Suchyna, Tape, Koeppel, 2nd, *et al.* (2004) *Nature* **430**, 235.

### GTS-21

This orally bioavailable anabaseine analogue and partial nicotinic acetylcholine receptor agonist (FW<sub>free-base</sub> = 308.38 g/mol; FW<sub>dihCl-Salt</sub> = 381.31 g/mol; CAS = 156223-05-1), also named 3-[(2,4-dimethoxyphenyl)methylene]-3,4,5,6-tetrahydro-2,3'-bipyridine and DMXBA, targets α<sub>7</sub>-nicotinic acetylcholine receptors, showing cognition-enhancing effects in mammals including humans (1-4). Although GTS-21 selectively activates the α<sub>7</sub>-nicotinic receptor, at higher concentrations, it is also an antagonist at α<sub>4</sub>β<sub>2</sub> and 5-HT<sub>3</sub> receptors. GTS-21 dose-dependently facilitates the induction of long-term potentiation (LTP) in the hippocampus (5). Sustained administration of GTS-21 improves deficient sensory inhibition

of repetitive auditory stimuli, a biomarker common in schizophrenics, without causing tachyphylaxis or receptor up-regulation in DBA/2 mice (6). The benzylidene substituent provides an extended π-electron bond system that suppresses dehydropiperidine ring opening (as occurs in anabaseine) and thereby maximizes the fraction of its pharmacologically active closed-ring form (7) (See *Anabasine & Anabaseine*). 1. Zoltewicz, Prokai-Tatrai, Bloom, Kem (1993) *Heterocycles* **35**, 171.

### Guaiaicol

This photosensitive phenol (FW = 124.14 g/mol; CAS = 90-05-1), also known as 2-methoxyphenol and *o*-hydroxyanisole, has been used as a hydrogen donor in assays of peroxidases. It is also an alternative substrate for laccase. Guaiaicol is also produced as a pheromone within the gut of the desert locust, *Schistocerca gregaria*. (This compound should not be confused with the similarly named sesquiterpene, guaiol.) **Target(s):** acetaldehyde dehydrogenase (1); catalase (2); catechol 2,3-dioxygenase (3,4); linoleate diol synthase (5); 5-lipoxygenase, or arachidonate 5-lipoxygenase (6); 15-lipoxygenase, or arachidonate 15-lipoxygenase (6); prostaglandin H synthase (7); shikimate dehydrogenase (8,9). 1. Gupta, Mat-Jan, Latifi & Clark (2000) *FEMS Microbiol. Lett.* **182**, 51. 2. Garcia, Kaid, Vignaud & Nicolas (2000) *J. Agric. Food Chem.* **48**, 1050. 3. ### Guaifenesin

This over-the-counter expectorant (FW = 198.22 g/mol; CAS = 93-14-1), also known as guaifenesin, glyceryl guaiacolate, Mucinex<sup>®</sup>, and (*RS*)-3-(2-methoxyphenoxy)propane-1,2-diol, loosens mucus in the lungs, making it easier to cough up otherwise congestive mucus associated with chest colds. Guaifenesin increases the analgesic effects of acetaminophen and aspirin and increases the sedative effects of alcohol, tranquilizers, sedative, and anesthetics.

### Guangxitoxins

These peptide toxins (Symbol: GxTX) from the venom of the tarantula *Plesiophrictus guangxiensis* primarily inhibit outward voltage-gated K<sub>v</sub>2.1 potassium channel currents. GxTX-1D (Sequence: DGECCGGFWWKCGSGKPACCPYVCSFKWGLCNFMP; MW = 3922 g/mol). GxTX-1E (Sequence: EGEGGGFWWKCGSGKPACCPYVCSFKWGLCNFMP; MW = 3936 g/mol). GxTX-2 (Sequence: ECRKMFGGCVSDSCAHLGCKPTLKCAWDGT; MW = 3582 g/mol). The molecular structure of GxTX-1E is similar to those of tarantula toxins that target voltage sensors in Kv channels in that it contains an ICK motif, composed of beta-strands, and contains a prominent cluster of solvent-exposed hydrophobic residues surrounded by polar residues. Notably, inhibition of Kv2.x channels by

GxTX-1E or the small molecule inhibitor RY796 enhances glucose-stimulated insulin secretion in isolated wild-type mouse and human islets, but not in islets from Kv2.1(-/-) mice (1). In wild-type mice, neither inhibitor improved glucose tolerance *in vivo*. GxTX-1E and RY796 also enhance somatostatin release in isolated human and mouse islets and *in situ* perfused pancreata from WT and Kv2.1(-/-) mice (1). The NMR structure of the toxin reveals an amphipathic part and an inhibitor cystine knot motif (2). The structural architecture of GxTX-1E is also similar to that of JZTX-III, a tarantula toxin that interacts with Kv2.1 with low affinity (2). The most striking structural differences between GxTX-1E and JZTX-III are found in the orientation between the first and second cysteine loops and the C-terminal region of the toxins, suggesting that these regions of GxTX-1E are responsible for its high affinity (2). 1. Li, Herrington, Petrov, *et al.* (2013) *J. Pharmacol. Exp. Ther.* **344**, 407. 2. Lee, Milescu, Jung, *et al.* (2010) *Biochemistry* **49**, 5134.

#### $\gamma$ -Guanidinobutyrate ( $\gamma$ -Guanidinobutyric Acid)

This guanidine-containing metabolite (FW = 145.16 g/mol; CAS = 463-00-3), which arises in marine invertebrates by amino acid oxidase action on arginine and in mammals by transamidation involving  $\gamma$ -aminobutyrate and an amidine donor, such as arginine, inhibits carboxypeptidase B, arginine 2-monooxygenase, and arginase. **Target(s):** Arginase (1,2); arginine decarboxylase (3); arginine deaminase (4); arginine 2-monooxygenase (5); carboxypeptidase B (6); guanidinoacetate kinase, weakly inhibited (7); 5-guanidino 2-oxopentanoate decarboxylase, or  $\alpha$ -ketoarginine decarboxylase,  $K_i = 4.2$  mM (8); putrescine carbamoyltransferase (9). 1. #### 2-Guanidinoethylmercaptosuccinic Acid

This arginine isostere and potent enkephalin convertase inhibitor (FW = 235.26 g/mol; CAS = 77482-44-1), often abbreviated GEMSA), binds reversibly to membrane-bound and soluble forms. **Target(s):** carboxypeptidase B (1-6); carboxypeptidase D (7); carboxypeptidase E, or carboxypeptidase H, or enkephalin convertase,  $K_i = 8.8$  nM (3,5,8-19); carboxypeptidase M (5,12,20-22); carboxypeptidase U (5,23-29); carboxypeptidase Z (5,30); lysine carboxypeptidase, or lysine(arginine) carboxypeptidase, or carboxypeptidase N (3,5,31-34); metalloproteinase D (8,35-40); thrombin activatable fibrinolysis inhibitor (41,42). 1. #### Guanine

This purine base (FW = 151.13 g/mol; CAS = 73-40-5; Solubility: 4 mg/100 mL H<sub>2</sub>O (more under alkaline or acidic solutions);  $\lambda_{max} = 246$  nm at pH 7;  $\epsilon = 10700$  M<sup>-1</sup>cm<sup>-1</sup>; Symbol = G or Gua), systematically named 2-amino-6-hydroxypurine and 2-amino-1,7-dihydro-6H-purin-6-one, is one of the principal bases found in RNA and DNA. Guanine is an important structural element in nucleosides, nucleotides, and certain metabolites. Guanine derivatives are precursors in pterin, folate, and riboflavin biosynthesis. Spiders excrete guanine as their principal urotelic metabolite. **Target(s):** acid phosphatase (1); adenine phosphoribosyltransferase, weakly inhibited (2,3); dihydrofolate reductase, weakly inhibited (4); hydroxyacylglutathione hydrolase, glyoxalase II (5); 3-hydroxyanthranilate oxidase (6); lactoylglutathione lyase, glyoxalase I (5); S-methyl-5' thioadenosine phosphorylase (7,8); purine-nucleoside phosphorylase, or guanosine phosphorylase, by product inhibition (9,10); sepiapterin deaminase, weakly inhibited (11); starch phosphorylase (12,13); thiol oxidase (14); urate-ribonucleotide phosphorylase, weakly inhibited (15); xanthine dehydrogenase (16,17); xanthine oxidase (18); xanthine phosphoribosyltransferase, also alternative substrate (19-21). 1. #### Guanine Nucleotide Dissociation Inhibitor

These GoLoco (GL) motif-containing proteins regulate G-protein signaling by binding to G<sub>α</sub> subunit and acting as guanine nucleotide dissociation

inhibitors. GDI's bind to the GDP-bound form of Rho and Rab small GTPases, preventing exchange and keeping Rho or Rab in its off-state) and by blocking its localization to the membrane. Its inhibition can be reversed by the action of GDI displacement factors. GDI also inhibits cdc42 by binding to its tail, preventing cdc42 insertion into membrane and reducing its ability to trigger WASP-mediated nucleation of F-actin and associated motile events. The  $\alpha$ -isoform of bovine Rab-GDI is a 50-kDa protein. (Note: The GoLoco motif is a 19-residue structural element within multi-domain signaling regulators, such as Loco, RGS12, RGS14, and Rap1GAP, as well as in tandem arrays in proteins, such as AGS3, G18, LGN, Pcp-2/L7, and Partner of Inscuteable/Discs-large complex, the latter required to establish planar polarity during asymmetric cell division in *Drosophila*.) 1. Hall (1994) *Ann. Rev. Cell Biol.* **10**, 31.

## Guanosine

This ribonucleoside (FW = 283.24 g/mol; CAS = 118-00-3;  $\lambda_{\max}$  = 253 nm at pH 6;  $\epsilon$  = 13600 M<sup>-1</sup>cm<sup>-1</sup>), also known as 9- $\beta$ -D-ribofuranosylguanine, is found in both the free form and as a component of nucleic acids and several enzyme cofactors. Guanosine is a substrate or product for a number of enzymes: for example, guanosine phosphorylase, guanosine deaminase, purine-nucleoside phosphorylase, purine nucleosidase, and diphosphate:purine nucleoside kinase. **Target(s):** adenosine deaminase (1-4); adenosine kinase (5,6); adenylylhomocysteinase (7); adenylosuccinate synthetase (8); alcohol dehydrogenase, yeast (9); cytidine deaminase, weakly inhibited (10); cytosine deaminase (11,12); deoxycytidine kinase, weakly inhibited (13); deoxyguanosine kinase (14); dihydroorotase (15); galactoside 2- $\alpha$ -L-fucosyltransferase, weakly inhibited (29);  $\beta$ -galactoside  $\alpha$ -2,3-sialyltransferase (16); guanylate kinase (17); hydroxyacylglutathione hydrolase, or glyoxalase II (18); lactoylglutathione lyase, glyoxalase I (18); S-methyl-5'-deoxyadenosine phosphorylase (28); NMN nucleosidase (19); 5'-nucleotidase (20,21); 1-phosphatidylinositol 4-kinase (22); purine nucleosidase (23); ribonuclease T<sub>2</sub> (24); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (25); ribosylpyrimidine nucleosidase (26); starch phosphorylase (30); urate-ribonucleotide phosphorylase, weakly inhibited (27). 1. ## Guanosine 2',3'-Cyclic Monophosphate

This guanosine phosphodiester (FW<sub>free-acid</sub> = 345.21 g/mol), also called 2',3'-cyclic GMP and 2',3'-cGMP, is produced as an intermediate in the alkaline hydrolysis of RNA and in the enzyme-catalyzed hydrolysis of RNA by several ribonucleases (e.g., ribonuclease T<sub>1</sub>, ribonuclease T<sub>2</sub>, ribonuclease U<sub>2</sub>, *Bacillus subtilis* ribonuclease). 2',3'-cGMP is also a substrate for 2',3' cyclic-nucleotide 2'-phosphodiesterase and 2',3'-cyclic-nucleotide 3'-phosphodiesterase. A 2',3'-cyclic nucleoside phosphate termini is produced in the endonucleolytic cleavage of pre tRNA by tRNA-intron endonuclease. **Target(s):** 3',5'-cyclic-GMP phospho-diesterase, or cGMP phosphodiesterase (1); dCMP deaminase (2-4); galactoside 2- $\alpha$ -L-fucosyltransferase, weakly inhibited (5). 1. Morishima (1975) *Biochim. Biophys. Acta* **410**, 310. 2. Scarano, Bonaduce & de Petrocellis (1960) *J. Biol. Chem.* **235**, 3556. 3. J.* **125**, 1157.

## Guanosine 3',5'-Cyclic Monophosphate

This key second messenger (FW<sub>free-acid</sub> = 345.21 g/mol; CAS = 7665-99-8;  $\lambda_{\max}$  = 254 nm at pH 7;  $\epsilon$  = 12950 M<sup>-1</sup>cm<sup>-1</sup>), also called 3',5'-cyclic GMP and 3',5'-cGMP, participates in many signal transduction pathways, including rhodopsin-mediate phototransduction, by means of cGMP-dependent protein kinases, cGMP-regulated channels, and cGMP-regulated cyclic nucleotide phosphodiesterases. 3',5'-cyclic GMP is produced from GTP by the action of guanylate cyclases and is hydrolyzed to GMP via cyclic-nucleotide phosphodiesterases. There is food evidence for accelerated cyclic nucleotide metabolic flux without changes in cell content of cGMP or cAMP in response to excitatory cellular stimuli. Sodium, potassium, and ammonium salts of cGMP are soluble in water, but the free acid is barely soluble. Its glycosidic bond is more stable in mineral acids than GMP. **Target(s):** adenylosuccinate synthetase (1-3); *Bacillus subtilis* ribonuclease (4); 3',5'-cyclic nucleotide phosphodiesterase, types 3A and 3B (5-12); cystinyl aminopeptidase (oxytocinase)13-15; glutaminase, phosphate-activated (16); poly(ADP-ribose) glycohydrolase (17,18). 1. ### Guanosine 5'-Diphosphate

This purine nucleotide (FW<sub>free-acid</sub> = 443.20 g/mol; CAS = 146-91-8; pK<sub>a</sub> for GDP are < 1, 2.9, 6.3, and 9.6) is a substrate for eukaryotic ribonucleotide reductases as well as nucleoside 5'-diphosphokinase (NDPK). It is found in either the free form or, more commonly, as a one-to-one complex with a divalent cation (*e.g.*, MgGDP). GDP is also a component of guanosinediphosphoguanos. GDP is the product of many GTP-dependent enzymes and is a regulatory agent in many cellular processes. **Target(s):**  $\alpha$ -N-acetylgalactosaminide  $\alpha$ -2,6-sialyltransferase (1); N-acetylneuraminatyl-transferase (2);  $\alpha$ -N-acetylneuraminatyl  $\alpha$ -2,8-sialyltransferase (97); adenine phosphoribosyltransferase (3,116-118); adenylosuccinate synthetase (4-11); adenylyl-sulfate kinase (12); alcohol dehydrogenase (13); amidophosphoribosyltransferase (14-17,102-114); D-amino-acid oxidase (18); AMP nucleosidase (19-22); asparagine synthetase, weakly inhibited (23); ATP diphosphatase (24); *Basidiobolus haptosporus* nuclease, or nuclease Bh1 (25,26); bis(5'-nucleosyl) tetraphosphatase, asymmetrical (27); CDP-diacylglycerol diphosphatase (28); cellulose synthase (141); chitobiosyldiphosphodolichol  $\beta$ -mannosyltransferase (29,125,126); [citrate lyase] deacetylase (30); cytosine deaminase (31,32); dCMP deaminase (4,33-35); deoxyguanosine kinase (36); diacylglycerol cholinephosphotransferase (37); dolichyl-phosphate  $\beta$ -D-mannosyltransferase (129-133); ethanolaminephosphotransferase (37); N-formylglutamate deformylase, or N- $\beta$ -citrylglutamate deacylase (38); fructose-1,6-bisphosphatase (39); galactoside 2- $\alpha$ -L-fucosyltransferase (40,134,135); galactoside 3(4)-L-fucosyltransferase (1);  $\beta$ -galactoside  $\alpha$ -2,3-sialyltransferase (1); 3-galactosyl-N-acetylglucosaminide 4- $\alpha$ -L-fucosyltransferase (138); GDP-mannose 4,6-dehydratase (41); GDP-mannose 6-dehydrogenase (42); glucokinase (43); glucosamine N-acetyltransferase (144); glucose-1-phosphate adenylyltransferase, or ADPglucose pyrophosphorylase (44,45); glucose-6-phosphate dehydrogenase (46); glycolipid 2- $\alpha$ -mannosyltransferase (128); glucomannan 4- $\beta$ -mannosyltransferase (140); glycolipid 3- $\alpha$ -mannosyltransferase (47,127); glycoprotein 3- $\alpha$ -L-fucosyl-transferase (120-124); glycoprotein 6- $\alpha$ -L-fucosyltransferase (136,137); GTP cyclohydrolase I (48); GTP cyclohydrolase IIa (49); hexokinase (50); hydroxyacylglutathione hydrolase, or glyoxalase II (51); IMP cyclohydrolase (52); IMP dehydrogenase (4,53-55); lactoylglutathione lyase, or glyoxalase I (51); mannose-1-phosphate guanylyltransferase (56); m<sup>7</sup>G(5')pppN diphosphatase, slightly inhibited (57); micrococcal nuclease (58); *Neurospora* glutamate dehydrogenase (59); nicotinate phosphoribosyltransferase (115); NMN nucleosidase (60); nucleoside deoxyribosyltransferase (119); nucleoside-diphosphate kinase (61); 3'-nucleotidase (62); nucleotide diphosphatase (63,64); oligonucleotidase (65); orotate phosphoribosyltransferase (66); orotidylate decarboxylase (66); 1-phosphatidylinositol 4-kinase (67); phosphoenolpyruvate carboxykinase (GTP) (68,69); phosphoglycerate kinase (70); phosphomannan mannose-phosphotransferase (71); phosphoprotein phosphatase (72); 5-phosphoribosylamine synthetase, or ribose-5-phosphate:ammonia ligase (73,74); phosphoribosyl-pyrophosphate synthetase, or ribose-5-phosphate pyrophosphokinase (75); [phosphorylase] phosphatase (76); poly(A)-specific ribonuclease, weakly inhibited (77); poly(A) polymerase (78); polypeptide N-acetylgalactosaminyltransferase (139); polyphosphate kinase (79,80); protein-glutamine  $\gamma$ -glutamyltransferase, or transglutaminase (142,143); [protein-PII] uridylyltransferase (81); pyruvate,orthophosphate dikinase (82); ribonuclease, pancreatic, or ribonuclease A (83-85); ribonuclease T<sub>1</sub> (86); ribonuclease T<sub>2</sub> (87); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (88,89); ribose-5-phosphate isomerase (90); succinate dehydrogenase (14); threonine synthase, weakly inhibited (91); UDP-glucuronate 4-epimerase (92-94); undecaprenyl-phosphate galactose phosphotransferase, weakly inhibited

(95); uridine nucleosidase (96); xanthine phosphoribosyltransferase (98,99); 1,4- $\beta$ -D-xylan synthase (100,101). **1.** Sadler, Beyer, Oppenheimer, *et al.* (1982) *Meth. #### Guanosine 3'-Diphosphate 5'-Diphosphate (or, ppGpp)

This bacterial alarmone (FW = 588.17 g/mol), frequently abbreviated ppGpp and also called Magic Spot I, is elevated in microorganisms (*e.g.*, *Escherichia coli*) exhibiting the stringent response (*i.e.*, a metabolic stress response linked to poor nutrient and growth conditions such as a lack of

amino acids). ppGpp is an alternative product of the reaction catalyzed by GTP diphosphokinase (utilizing GDP as the acceptor substrate). Note that the 3'-substituent is more susceptible to hydrolysis than the 5'-pyrophosphate. ppGpp should be stored at  $-70^{\circ}\text{C}$ . The half-life in 0.3 M KOH at  $37^{\circ}\text{C}$  is only 6.5 minutes. **For stability, concentration determinations, and metal ion binding properties, see Guanosine 5'-triphosphate.** **Target(s):** acetyl-CoA carboxylase (1); adenylosuccinate synthetase (2); ADPglucose pyrophosphorylase (3); ATP phosphoribosyltransferase, in the presence of L-histidine (4-6); 3 fructose-1,6-bisphosphatase (7); glycerol-3-phosphate dehydrogenase (8); hydroxydecanoyl-[acyl carrier-protein] dehydratase (9); hypoxanthine phosphoribosyltransferase (10); ornithine decarboxylase (11); phosphatidylglycerophosphate synthase (12); protein biosynthesis (elongation) (4,13,14); protein-synthesizing GTPase, elongation factor (4,13,14); RNA-directed RNA polymerase, or Q $\beta$  replicase (15,16); RNA polymerase (4). **1.** Polakis, Guchhait & Lane (1973) *J. #### Guanosine 5'-[ $\beta,\gamma$ -Imido]triphosphate

This GTP analogue (FW<sub>free-acid</sub> = 522.20 g/mol), also called GMPPNP, p(NH)ppG, and  $\beta,\gamma$ -imidoguanosine 5'-triphosphate, is an inhibitor of many GTP-dependent enzymes. It also serves as an alternative substrate for enzymes that hydrolyze GTP between the  $\alpha$  and  $\beta$  phosphorus atoms: *e.g.*, snake venom phosphodiesterase hydrolyzes GMPPNP to produce GMP and imidodiphosphate (PNP). *Escherichia coli* alkaline phosphatase will hydrolyze the nucleotide to orthophosphate and the corresponding nucleoside diphosphate derivative. GMPPNP often bind to and reversibly activates G proteins. GMP-PNP is very soluble in water and binds metal ions with a greater affinity than GTP. It is unstable in acidic solutions, producing the corresponding phosphoramidate and orthophosphate. **Target(s):** adenylate cyclase (1); adenylosuccinate synthetase (2); dynamin GTPase (3); F<sub>1</sub> ATPase (4); GTPase (5); guanylate cyclase (6-8); [3-methyl-2-oxobutanoate dehydrogenase, or 2 methylpropanoyl-transferring] phosphatase, or [branched-chain  $\alpha$ -keto-acid dehydrogenase] phosphatase (9,10); phosphoprotein phosphatase (11); protein-synthesizing GTPase, elongation factor (12,13); ribosomal translocation (5); minor effect on tubulin polymerization, but substantial inhibition of depolymerization of p(NH)ppG-containing microtubule (13). **1.** Kirkham & Henley (1993) *Biochem. **Guanosine 2'-Monophosphate**

This nucleotide (FW<sub>free-acid</sub> = 363.22 g/mol), also known as 2'-guanylate and abbreviated 2'-GMP, is produced from hydrolysis of guanosine 2',3'-cyclic monophosphate (as is 3'-GMP). The cyclic nucleotide is an intermediate in the alkaline hydrolysis of RNA. 2'-GMP is soluble in water and the *N*-glycosidic bond can be hydrolyzed at elevated temperatures in acidic conditions (guanine, ribose, and orthophosphate is produced in one hour in 1 M HCl at 100°C). **Target(s):** adenylosuccinate synthetase (1); 2',3'-cyclic-nucleotide 3'-phosphodiesterase (2); phosphogluconate dehydrogenase, decarboxylating (3); ribonuclease M (4); ribonuclease, pancreatic, ribonuclease A (5); ribonuclease T<sub>1</sub> (6-8); ribonuclease T<sub>2</sub> (4,9); ribonuclease Rh4, *or* ribonuclease U2 (10). 1. Biophys. Acta* **383**, 168.

**Guanosine 3'-Monophosphate**

This nucleotide (FW<sub>free-acid</sub> = 363.22 g/mol), also called 3'-guanylate, is readily produced by the alkaline hydrolysis of RNA (*e.g.*, by 0.3 M KOH at 37°C for 16 hours) and by the action of a number of ribonucleases (*e.g.*, spleen exonuclease, yeast ribonuclease, and ribonuclease T1). It is also a product of the reaction catalyzed by 2',3'-cyclic-nucleotide 2' phosphodiesterase. 3'-GMP is soluble in water. Note that the *N*-glycosidic bond can be hydrolyzed at elevated temperatures in acidic conditions. The ultraviolet spectrum has a  $\lambda_{\max}$  of 252 nm ( $\epsilon = 13,400 \text{ M}^{-1}\text{cm}^{-1}$ ) at pH 7. **Target(s):** adenylosuccinate synthetase (1); ribonuclease, pancreatic, *or* ribonuclease A (2); ribonuclease T<sub>1</sub> (3); ribonuclease T<sub>2</sub> (4); ribose-5-phosphate isomerase (5). 1. Spector, Jones & Elion (1979) *J. Biol. Chem.* **254**, 8422. 2. Richards & Wyckoff (1971) *The Enzymes*, 3rd ed., **4**, 647. 3. Takahashi & Moore (1982) *The Enzymes*, 3rd ed., **15**, 435. 4. **Guanosine 5'-Monophosphate**

This common nucleotide (FW<sub>free-acid</sub> = 363.22 g/mol), abbreviated GMP and also known as guanylic acid, is produced from XMP via GMP synthases.

GMP can be hydrolyzed to guanine, orthophosphate and ribose in 1 M HCl at 100°C. GMP has a  $\lambda_{\max}$  at pH 7 of 252 nm ( $\epsilon = 13700 \text{ M}^{-1}\text{cm}^{-1}$ ).

**Guanosine 5'-O-(2-Thiodiphosphate)**

This nucleotide analogue (FW = 443.27 g/mol), abbreviated GDP- $\beta$ -S, is a non-hydrolyzable GDP analogue that inhibits G-protein activation and the stimulation of adenylate cyclase by GTP and GTP analogues. **Target(s):** adenylate cyclase (1,2); diacylglycerol kinase (3); G protein (4,5). 1. Svoboda, Furnelle, Eckstein & Christophe (1980) *FEBS Lett.* **109**, 275. 2. Eckstein, Cassel, Levkovitz, Lowe & Selinger (1979) *J. Biol. Chem.* **254**, 9829. 3. **Guanosine 5'-O-(3-Thiotriphosphate)**

This nucleotide (FW = 522.24 g/mol; Abbreviated: GTP- $\gamma$ -S) is a non-hydrolyzable GTP analogue that inhibits many GTP-dependent reactions. It is also G-protein activator, stimulates adenyl cyclase, and will induce actin polymerization. **Target(s):** acetyl-CoA carboxylase (1); diacylglycerol kinase (2); DNA topoisomerase II (3); dynamin GTPase (4); GTP cyclohydrolase IIa (5); NAD<sup>+</sup> ADP-ribosyltransferase, *or* poly(ADP-ribose) polymerase (6); phospholipase A<sub>1</sub> (7); protein-glutamine  $\gamma$ -glutamyltransferase, *or* transglutaminase (8-11); protein-synthesizing GTPase, elongation factor (12,13); Rho ADP-ribosyltransferase (14); tubulin polymerization, microtubule assembly (15). 1. **Guanosine 5'-Triphosphate**

This purine nucleotide (FW<sub>free-acid</sub> = 523.18 g/mol; Abbreviation: GTP) is second only to ATP in its role as a phosphoryl-donor and source of Gibbs energy to drive mechanoenzyme (*or* energase) reactions. GTP is also a prominent metabolic regulator inasmuch as it binds to G-proteins. GTP is also a required substrate for RNA synthesis. GTP is produced by many

substrate-level phosphorylation reactions, including nucleoside-diphosphate kinase (*Reaction*:  $\text{MgATP}^{2-} + \text{GDP} \rightleftharpoons \text{MgGTP}^{2-} + \text{ADP}$ ;  $K_{\text{eq}} \approx 1$ ). **Stability**: Solid sodium and potassium salts of GTP are stable for months at  $-15^{\circ}\text{C}$  and about a week at  $0^{\circ}\text{C}$ . However, it is always good procedure to freshly prepare solutions of GTP. In alkaline solutions, GTP degrades to pyrophosphate (or, diphosphate) and GMP even at  $0^{\circ}\text{C}$ . The phosphoanhydride bonds are very labile to acids (e.g., 66% of total phosphorus produces orthophosphate in fifteen minutes at  $100^{\circ}\text{C}$  in 0.5 N  $\text{H}_2\text{SO}_4$ ); the phosphate ester bond is not as labile. More drastic treatment (0.5 N  $\text{H}_2\text{SO}_4$  at  $100^{\circ}\text{C}$  for one hour) will produce guanine, ribose 5-phosphate, ribose, and orthophosphate. Treatment with nitrous acid converts GTP xanthine 5'-triphosphate (XTP), via diazotization and hydrolysis of the diazonium salt. **Standardization of GTP Solutions**: Direct weighing is an unreliable way to calibrate GTP solutions. The actual concentration should be determined with the aid of a UV/visible spectrophotometer using a suitably diluted sample at a defined pH. At pH 7,  $\lambda_{\text{max}}$  is 253 nm ( $\epsilon = 13,700 \text{ M}^{-1}\text{cm}^{-1}$ ). At pH 11,  $\lambda_{\text{max}}$  is 256 nm ( $\epsilon = 12,400 \text{ M}^{-1}\text{cm}^{-1}$ ). At pH 11,  $\lambda_{\text{max}}$  is 257 nm ( $\epsilon = 11,900 \text{ M}^{-1}\text{cm}^{-1}$ ). **Metal Ion Binding**: GTP forms tight complexes with many metal ions. The stability constants are substantially the same as that for ATP. The stability constants for  $\text{MgATP}^{2-}$ ,  $\text{CaATP}^{2-}$ , and  $\text{MnATP}^{2-}$  are 73000, 35000, and 100000  $\text{M}^{-1}$ , respectively. Metal ion-free ATP is usually an inhibitor for  $\text{MgATP}$ -utilizing enzymes, and the same is undoubtedly true for GTP-utilizing enzymes. **Target(s)**:  $\alpha$ -*N*-acetylgalactosaminide  $\alpha$ -2,6-sialyltransferase (1); *N*-acetylneuraminidase cytidylyltransferase (2,3); adenine phospho-ribosyltransferase (4,184); adenylate cyclase (5,6); adenylate dimethylallyltransferase (7); adenylylsulfatase (8-10); aldose-1-phosphate nucleotidyl-transferase (11); amidophosphoribosyl-transferase (12,180,181); 4-aminobutyrate aminotransferase (13); 5-aminolevulinic synthase (227); AMP deaminase (14-23); arylsulfate sulfotransferase (24); asparagine synthetase (25); aspartate ammonia-lyase (26); aspartate carbamoyltransferase (27-29,230-234); aspartate racemase (30); ATP:citrate lyase, or ATP:citrate synthase (211); *Bacillus subtilis* ribonuclease (31); *Basidobolus haptosporus* nuclease Bh1 (32); bis(5'-nucleosyl)-tetrakisphosphate (asymmetrical) (33); casein kinase II (34); CDP-diacylglycerol:inositol 3-phosphatidyltransferase (35,36); cellulose synthase (UDP-forming) (210); chitobiosyldiphosphodolichol  $\beta$ -mannosyltransferase (37,191); chloroplast protein-transporting ATPase (38); citrate (*sr*)-synthase, weakly inhibited (212); 3',5'-cyclic-GMP phosphodiesterase, or cGMP phosphodiesterase, slightly inhibited (39); 3'.5'-cyclic-nucleotide phosphodiesterase (40); cysteinyl-tRNA synthetase (41); cytidine deaminase (42); cytosine deaminase (42,43); deoxycytidine kinase (44); deoxyguanosine kinase (45,46); dGTPase (47); diacylglycerol kinase (48-51); DNA topoisomerase II (52); dolichol kinase (53); dolichyl-phosphate  $\beta$ -D-mannosyltransferase (194-196); exopoly-phosphatase (54); 5' $\rightarrow$ 3' exoribonuclease (55); exoribonuclease H (56); *N*-formylglutamate deformylase, or *N*- $\beta$ -citryl-glutamate deacylase (57,58);  $\beta$ -fructofuranosidase, or invertase (59); fructose-1,6-bisphosphatase (60,61); fucokinase (62); fumarase (63); galactoside 2- $\alpha$ -L-fucosyltransferase (197-199);  $\beta$ -galactoside  $\alpha$ -2,3-sialyltransferase (1,176); GDP-mannose 4,6-dehydratase (64,65); 1,3- $\beta$ -glucan synthase (204,205); glucokinase, also weak alternative substrate (66,67); glucomannan 4- $\beta$ -mannosyltransferase (206); glucosamine *N*-acetyltransferase (228); glucose-1 phosphatase (68); glucose-1-phosphate adenylyl-transferase (69); glucose-1-phosphate cytidylyltransferase (70); glucose-6-phosphate dehydrogenase (71,72); glucuronokinase (73); glutamate dehydrogenase (74-77); glutamine synthetase, *Neurospora crassa* (78); glycogen phosphorylase *b* (79); glycogen synthase (80-82); glycolipid 2- $\alpha$ -mannosyltransferase (193); glycolipid 3- $\alpha$ -mannosyltransferase (83, 192); glycoprotein 3- $\alpha$ -L-fucosyltransferase (187-189); glycoprotein 6- $\alpha$ -L-fucosyl-transferase (200,201); guanylate kinase (84,85); hexokinase (86); hydroxyacylglutathione hydrolase, or glyoxalase II (87); 3-hydroxyanthranilate oxidase, weakly inhibited (238); 5-hydroxypentanoate CoA-transferase, weakly inhibited (88); hypoxanthine(guanine) phosphoribosyltransferase (184-186); inosine kinase, or guanosine-inosine kinase (89); *myo*-inositol oxygenase (90,236,237); insulin (91); D-lactate dehydrogenase (92,93); lactoylglutathione lyase, or glyoxalase I (87); membrane Dipeptidase, or renal Dipeptidase, or dehydropeptidase I (94,95); methionine *S*-adenosyltransferase (96-102); [3-methyl-2-oxobutanoate dehydrogenase, or 2-methylpropanoyl-transferring] phosphatase, or [branched-chain  $\alpha$ -keto-acid dehydrogenase] phosphatase (103-106);  $m_7\text{G}(5')\text{pppN}$  diphosphatase, slightly inhibited (107); mitochondrial processing peptidase (108); multiple inositol-polyphosphate phosphatase, or inositol-1,3,4,5-tetrakisphosphate 3-phosphatase (109);

NAD<sup>+</sup> diphosphatase (110); NADH peroxidase (111); NAD(P)H dehydrogenase (quinone) (112); nicotinate-nucleotide diphosphorylase (carboxylating) (178,179); nucleotidases (54); 3'-nucleotidase (54); 5'-nucleotidase (54,113-115); 2',5'-oligoadenylate synthetase (116); oligonucleotidase (117); ornithine carbamoyltransferase (229); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (118); phytanoyl-CoA dioxygenase (235); phosphatidate cytidylyl-transferase (119); phosphatidate phosphatase (120); 1-phosphatidylinositol 4 kinase (121-124); phosphodiesterase I, or 5'-exonuclease (125-127); phosphoenolpyruvate carboxylase (128-132); 1-phosphofructokinase (133,134); 6-phosphofructokinase (135-138); phosphoglucomutase (139); phosphogluconate dehydrogenase (140); 3-phosphoglycerate dehydrogenase (141); phosphoprotein phosphatase types 1 and 2A (106,142-147); phosphoribosyl-pyrophosphate synthetase, or ribose-5-phosphate pyrophosphokinase (148); phosphorylase kinase (149); phytoene synthase (150); polygalacturonate 4- $\alpha$  galacturonosyltransferase (202); polynucleotide adenylyltransferase, or poly(A) polymerase (151-157); polynucleotide 5'-hydroxyl-kinase (158,159); poly-peptide *N*-acetylgalactosaminyltransferase (203); porphobilinogen synthase ( $\delta$ -aminolevulinic dehydratase) (160); protein-glutamine  $\gamma$  glutamyltransferase (transglutaminase) (161,213-226); [protein-PII] uridylyltransferase (162); pyruvate carboxylase (163); pyruvate dehydrogenase complex (164); pyruvate kinase (165-168); Rho ADP ribosyltransferase (169); ribonuclease H (56); ribose-phosphate diphosphokinase (phosphoribosyl pyrophosphate synthetase) (170,171); sterol 3 $\beta$ -glucosyltransferase (190); sucrose-phosphate synthase (207,208); sucrose synthase (209); thiamin-phosphate diphosphorylase (172,173); UDP-*N* acetylglucosamine:dolichyl-phosphate *N*-acetylglucosamine-phosphotransferase (174); uracil phosphoribosyltransferase, weakly inhibited (GTP is an activator in many organisms) (182,183); xanthine phosphoribosyltransferase (177). 1. #### (±)-Guatambuine

This alkaloid (FW = 264.37 g/mol; CAS = 2744-45-8) from *Aspidosperma subincanum* bark inhibits cyclopropane-fatty acyl-phospholipid synthase, IC<sub>50</sub> = 4 μM, with the inhibition patterns indicating that *Escherichia coli* CFAS operates via an ordered Bi Bi mechanism with S-adenosyl-L-methionine binding first. **1.** Gulanvarc'h, Guangqi, Drujon, Rey, Wang & Ploux (2008) *Biochim. Biophys. Acta* **1784**, 1652.

#### Guggulsterone

**E-Guggulsterone**

**Z-Guggulsterone**

This plant steroid and FXR antagonist (FW = 312.45 g/mol; CASs = 95975-55-6 (*E/Z*-isomer), 39025-24-6 (*E*-isomer), 39025-23-5 (*Z*-isomer)), also named pregna-4,17-diene-3,16-dione, from the resin of the guggul tree, *Commiphora mukul*, targets the Farnesoid X Receptor, acting as an antagonist in coactivator association assays, while enhancing FXR agonist-induced transcription of bile salt export pump (BSEP), a major hepatic bile acid transporter (**1**). Guggulipid, from which guggulsterone is derived, has been widely used in Asian folk medicine to treat hyperlipidemia. In HepG2 cells, in the presence of an FXR agonist, such as chenodeoxycholate or GW4064, GS enhances endogenous BSEP expression with a maximum

induction of 400-500% that induced by an FXR agonist alone. This enhancement is also readily observed in FXR-dependent BSEP promoter activation using a luciferase reporter construct. GS is thus a selective bile acid receptor modulator that regulates expression of a subset of FXR targets. In rats, guggulipid treatment lowers serum triglyceride and raises serum high density lipoprotein levels. These data suggest that guggulsterone defines a novel class of FXR ligands characterized by antagonist activities in coactivator association assays but with the ability to enhance the action of agonists on BSEP expression *in vivo*. (See also Dy 268) **1.** Cui, Huang, Zhao, *et al.* (2003) *J. Biol. Chem.* **278**, 10214.

#### GW2016, See Lapatinib

#### GW2580

This oral cFMS kinase inhibitor (FW = 366.42 g/mol; CAS = 870483-87-7; Solubility: 48 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 5-[[[3-methoxy-4-[(4-methoxyphenyl)methoxy]phenyl]methyl]-2,4-pyrimidinediamine, selectively targets monocyte growth and bone degradation by targeting cFMS kinase (**1**). Notably, GW-2580 inhibits the cellular homolog of the *V-FMS* oncogene product of the Susan McDonough strain of feline sarcoma virus, or c-FMS (IC<sub>50</sub> = 30 nM), about 150x to 500x lower concentration than its inhibition of b-Raf, CDK4, c-KIT, c-SRC, EGFR, ERBB2/4, ERK2, FLT-3, GSK3, ITK, and JAK2 kinases. GW-2580 selectively inhibits cFMS kinase compared with 186 other kinases *in vitro* and completely inhibited CSF-1-induced growth of rat monocytes (IC<sub>50</sub> = 0.2 μM) (**2**). At 1 μM, GW 2580 completely inhibits CSF-1-induced growth of mouse M-NFS-60 myeloid cells and human monocytes and completely inhibits bone degradation in cultures of human osteoclasts, rat calvaria, and rat fetal long bone (**1**). In contrast, GW2580 did not affect the growth of mouse NS0 lymphoblastoid cells, human endothelial cells, human fibroblasts, or five human tumor cell lines. GW2580 also did not affect lipopolysaccharide-(LPS-) induced TNF, IL-6, and prostaglandin E2 production in freshly isolated human monocytes and mouse macrophages. After oral administration, GW2580 blocked the ability of exogenous CSF-1 to increase LPS-induced IL-6 production in mice, inhibited the growth of CSF-1-dependent M-NFS-60 tumor cells in the peritoneal cavity, and diminished the accumulation of macrophages in the peritoneal cavity after thioglycolate injection (**1**). Use of GW2580 as a selective pharmacologic inhibitor of CSF1R signaling demonstrated that CSF-1 regulates the tumor recruitment of CD11b<sup>+</sup>Gr-1(Lo)Ly6C(hi) mononuclear Myeloid-Derived Suppressor Cells, or MDSCs (**3**). **1.** Conway, McDonald, Parham, *et al.* (2005) *Proc. Natl. Acad. Sci. U.S.A.* **102**, 16078. **2.** Conway, Pink, Bergquist, *et al.* (2008) *J. Pharmacol. Exp. Ther.* **326**, 41. **3.** Priceman, Sung, Shaposhnik, *et al.* (2010) *Blood* **115**, 1461.

#### GW5074

This potent signal transduction inhibitor (FW = 520.94 g/mol; CAS = 220904-83-6; Solubility: 100 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), systematically named 3-[(3,5-dibromo-4-hydroxyphenyl)-methylene]-1,3-dihydro-5-iodo-2H-indol-2-one, selectively targets the proto-oncogene serine/threonine-protein kinase known as c-Raf (IC<sub>50</sub> = 9 nM), stimulating the Raf-MEK-ERK pathway, with little or no effect on the activities of JNK1, JNK2, JNK1, MEK1, MKK6, MKK7, CDK1, CDK2, c-Src, p38

MAP, VEGFR2 or c-Fms. GW5074 protects against the neurotoxic effects of MPP<sup>+</sup> and methylmercury in cerebellar granule neurons, and glutathione depletion-induced oxidative stress in cortical neurons (1). GW-5074 also prevents neurodegeneration and improves behavioral outcome in an animal model of Huntington's disease (1). GW 5074 treatment (10 μM, 60 min) completely abolishes chronic morphine-mediated AC superactivation, suggesting that Raf-1 may have a crucial role in compensatory feedback regulation of cellular cAMP levels by clinically important opioid analgesics (2). Intraperitoneal administration of GW5074 significantly suppresses hyperresponsiveness of the airway contraction, whereas the airway epithelium-dependent relaxation is unaffected (3). 1. Chin, Liu, Morrison, *et al.* (2004) *J. Neurochem.* **90**, 595. 2. Yue, Varga, Stropova, *et al.* (2006) *Eur. J. Pharmacol.* **540**, 57. 3. Lei, Cao, Xu, *et al.* (2008) *Respir. Res.* **9**, 71.

**GW572016**, See *Lapatinib*

**GW788388**

This orally active ALK5 inhibitor (FW = 425.28 g/mol; CAS = 452342-67-5; Solubility: 33 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O or Ethanol), also known as 4-(4-(3-(pyridin-2-yl)-1H-pyrazol-4-yl)pyridin-2-yl)-N-(tetrahydro-2H-pyran-4-yl)benzamide, potently and selectively targets the Activin receptor-Like Kinase activities of Transforming Growth Factor-β (TGF-β) type I receptor (*or* ALK5), with an IC<sub>50</sub> of 18 nM, thereby blocking both TGF-β type II receptor and activin type II receptor kinase activities, but not that of the Bone Morphogenic Protein type II (BMP type II) receptor (1). When administered orally at 10 mg/kg once daily in a model of puromycin aminonucleoside-induced renal fibrosis, GW-788388 significantly reduces expression of Collagen IA1 (1). With db/db mice, which develop diabetic nephropathy, GW788388 (given orally for 5 weeks) significantly reduces renal fibrosis and decreases mRNA levels of key mediators of extracellular matrix deposition (2). Cardiomyocyte hypertrophy in MI hearts was likewise attenuated upon ALK5 inhibition by GW 788388 (3). In the bleomycin-induced fibrosis mouse model, treatment with GW788388 and bosentan prevents the fibrotic response, supporting the idea that the TGF-β/ET-1 axis has a role in wound repair and skin fibrosis (4). 1. Gellibert, de Gouville, Woolven, *et al.* (2006) *J. Med. Chem.* **49**, 2210. 2. Petersen, Thorikay, Deckers, *et al.* (2008) *Kidney Int.* **73**, 705. 3. **Gyromitrin**

This toxin/carcinogen (FW = 100.12 g/mol; CAS = 16568-02-8), also known as acetaldehyde methylformylhydrazone, from the false morel *Gyromitra esculenta* hydrolyzes readily to form N-methyl-N-formylhydrazine, which then reacts with pyridoxal 5-phosphate, thereby depleting this cofactor within glutamic acid decarboxylase and reducing γ-aminobutyrate formation (1). Gyromitrin is a non-competitive inhibitor of human intestinal diamine oxidase, ID<sub>50</sub> = 1.6 × 10<sup>-5</sup> M (2). 1. List & Luft (1968) *Arch. Pharm. Ber. Deutsch Pharm. Ges.* **301**, 294. 2. Biegański, Braun & Kusche (1984) *Agents Actions* **14**, 351.

**GZ-793A**

This potent VMAT<sub>2</sub> inhibitor (FW = 464.04 g/mol; CAS = 1356447-90-9), also named (*R*)-3-[2,6-cis-di(4-methoxyphenethyl)piperidin-1-yl]propane-1,2-diol, selectively targets dopamine uptake by the vesicular monoamine transporter-2, inhibiting methamphetamine-evoked release of dopamine from striatal slices and methamphetamine self-administration in rats (1). (See *N-Methyl-amethylphenethylamine* (*or* *methamphetamine*)). GZ-793A shows ~50x selectivity for VMAT<sub>2</sub> over the serotonin or dopamine transporters. GZ-793A's ability to evoke [<sup>3</sup>H]dopamine release and inhibit methamphetamine-evoked [<sup>3</sup>H]dopamine release from isolated striatal synaptic vesicles fit a two-site model, with high- and EC<sub>50</sub> values of 15.5 nM and 29.3 μM (1). Tetrabenazine and reserpine completely inhibit GZ-793A-evoked [<sup>3</sup>H]dopamine release, but only at the High-affinity site. Low concentrations of GZ-793A that interact with the extra-vesicular dopamine uptake site and the High-affinity intra-vesicular DA release site also inhibited methamphetamine-evoked [<sup>3</sup>H]dopamine release from synaptic vesicles. These results support a hypothetical model of GZ-793A interaction at more than one site on the VMAT<sub>2</sub> protein, explaining its potent inhibition of dopamine uptake, dopamine release via a high-affinity tetrabenazine- and reserpine-sensitive site, dopamine release via a low-affinity tetrabenazine- and reserpine-insensitive site, and a low-affinity interaction with the dihydrotrabenazine binding site on VMAT<sub>2</sub> (1). GZ-793A specifically decreases METH self-administration, without the development of tolerance (2). Increasing the unit dose of METH did not surmount the inhibition produced by GZ-793A on METH self-administration. GZ-793A did not serve as a substitute for self-administered METH. GZ-793A and related VMAT<sub>2</sub> inhibitors may be promising leads for reducing the risk of relapse to METH use following exposure to drug-associated cues (3). 1. Horton, Nickell, Zheng, Crooks & Dwoskin (2013) *J. Neurochem.* **127**, 177. 2. Beckmann, Denehy, Zheng, *et al.* (2012) *Psychopharmacol.* (Berlin). **220**, 395. 3. Alvers, Beckmann, Zheng, *et al.* (2012) *Psychopharmacol.* (Berlin). **224**, 255.

**GZD824**

This novel, oral bioavailable Bcr-Abl inhibitor (FW<sub>free-base</sub> = 532.57 g/mol; FW<sub>dimesylate-salt</sub> = 724.77 g/mol; CAS = 1421783-64-3; Solubility: 100 mg/mL DMSO or H<sub>2</sub>O), known systematically as 4-methyl-N-[4-[(4-methyl-1-piperazinyl)methyl]-3-(trifluoromethyl)phenyl]-3-[2-(1H-pyrazolo[3,4-b]pyridin-5-yl)ethynyl]benzamide, methanesulfonate (1:2) targets both wild type Bcr-Abl (IC<sub>50</sub> = 0.34 nM) and mutant Bcr-Abl<sup>T315I</sup> (IC<sub>50</sub> = 0.34 nM), the oncogenic kinases formed by fusion of the Breakpoint cluster (Bcr) and Abelson (Abl) genes and resulting in formation of the so-called Philadelphia chromosome found in more than 90% of chronic myelogenous leukemia (CML) cases. The Bcr-Abl<sup>T315I</sup> mutant confers resistance to all FDA-approved Bcr-Abl inhibitors prior to ponatinib (See *Ponatinib*). GZD824 likewise potently suppresses proliferation of Bcr-Abl-positive K562 and Ku812 human CML cells with IC<sub>50</sub> values of 0.2 and 0.13 nM, respectively. GZD824 displays an *in vivo* half-life of 10.6 hours. 1. Ren, Pan, Zhang, *et al.* (2013) *J. Med. Chem.* **56**, 879.

## H, See Histidine

### H-77

This peptidomimetic (FW = 1011.24 g/mol; *Sequence*: D-His-L-Pro-L-Phe-L-His-L-Leu(CH<sub>2</sub>NH)-L-Leu-L-Val-L-Tyr) inhibits canine (IC<sub>50</sub> = 24 nM), human (IC<sub>50</sub> = 1 μM), and rat renin (IC<sub>50</sub> = 0.6 μM) *in vitro*. This analogue corresponds to a sequence in the renin substrate, angiotensinogen, except that the peptide bond between Leu-5 and Leu-6 is replaced by a -CH<sub>2</sub>NH-moiety. **Target(s)**: cathepsin E, K<sub>i</sub> = 50 nM (1-3); endothiapepsin, mildly inhibited (4); renin (5,6). 1. Jupp, Richards, Kay, *et al.* (1988) *Biochem. J.* **254**, 895. 2. Robinson, Lees, Kay & Cook (1992) *Biochem. J.* **284**, 407. 3. Hill, Montgomery & Kay (1993) *FEBS Lett.* **326**, 101. 4. ### H 89

This Ser/Thr protein kinase inhibitor (FW = 519.28 g/mol; CAS 130964-39-5; Solubility: 25 mM in H<sub>2</sub>O; 100 mM in DMSO), also named *N*-[2-[[[3-(4-bromophenyl)-2-propenyl]amino]ethyl]-5-isoquinoline sulfonamide]-HCl, targets ribosomal protein S6 kinase 1, or S6K1 (K<sub>i</sub> = 80 nM), mitogen- and stress-activated protein kinase-1, or MSK1 (K<sub>i</sub> = 120 nM), cAMP-stimulate protein kinase, or PKA (K<sub>i</sub> = 135 nM), Rho-associated protein kinase, or ROCKII (K<sub>i</sub> = 270 nM), Akt/PKBα (K<sub>i</sub> = 2.6 μM), and Mitogen-Activated Protein Kinase-Activated protein kinase-2, or MAPKAP-K1b (K<sub>i</sub> = 2.8 μM). On the unwarranted assumption that H-89 effect is mainly directed against PKA, H-89 has been widely used (in >1000 reports!) to evaluate the role of PKA in the heart, osteoblasts, hepatocytes, smooth muscle cells, neuronal tissue, epithelial cells, etc. Even so, H89 targets at least eight other kinases, a fact that compromises interpretation of earlier results (1). **Target(s)**: forskolin-induced neurite outgrowth (2); phosphatidylcholine biosynthesis in HeLa cells (3); protein kinase A in LPS-induced activation of NF-κB proteins of J774 mouse macrophage-like cell line (4); incorporation of choline into phosphatidylcholine via inhibition of choline kinase (5); forskolin-stimulated cardiac L-type calcium current (6); protein kinase-mediated acetylcholine release from myenteric plexus of guinea pig ileum (7); collagenase induction by phorbol ester through a mechanism that does not involve protein kinase A (8). 1. ### H-189

This synthetic peptidomimetic and human renin inhibitor (FW = 1268.53 g/mol; *Sequence*: Pro-His-Pro-Phe-His-Sta-(statinyl)-Val-Ile-His-Lys), itself an analogue of human angiotensinogen, inhibits endothiapepsin (K<sub>i</sub> = 1 nM) and renin (K<sub>i</sub> = 10 nM). Note that a tetrahedral statine moiety substitutes for the leucyl residue at the scissile bond. **Target(s)**: cathepsin D, mildly inhibited (1); endothiapepsin (2-5); renin (1). 1. Tree, Atrash,

Donovan, *et al.* (1983) *J. Hypertens.* **1**, 399. 2. Coates, Erskine, Crump, Wood & Cooper (2002) *J. Mol. Biol.* **318**, 1405. 3. Bailey, Cooper, Veerapandian, *et al.* (1993) *Biochem. ### H-1152 & glycyl-H-1152

This cell-permeable isoquinoline (FW = 319.43 g/mol; CAS 871543-07-6; Photosensitive; Solubility: 100 mM in H<sub>2</sub>O; 50 mM in DMSO), also named (S)-(+)-2-methyl-1-[(4-methyl-5-isoquinolyl)sulfonyl]homopiperazine, inhibits G-protein Rho-associated kinase (K<sub>i</sub> = 1.6 nM). The related Glycyl-H-1152 (FW = 449.40 g/mol; CAS 913844-45-8) displays improved ROCKII selectivity (*e.g.*, IC<sub>50</sub> values are 0.0118, 2.35, 2.57, 3.26, >10 and >10 μM for ROCKII, Aurora A, CAMKII, PKG, PKA and PKC respectively). **Target(s)**: ROCKII (IC<sub>50</sub> = 0.012 μM); CAMKII (IC<sub>50</sub> = 0.180 μM); PKG (IC<sub>50</sub> = 0.360 μM); Aurora A (IC<sub>50</sub> = 0.745 μM); PKA (IC<sub>50</sub> = 3.03 μM); PKC (IC<sub>50</sub> = 5.68 μM); and MLCK (IC<sub>50</sub> = 28.3 μM); polo kinase (1); protein kinase A (2,3); Rho-associated kinase (2,3). The structurally related Glycyl-H 1152 (FW = 319.43 g/mol; CAS 913844-45-8; Photosensitive), also named (S)-(+)-4-glycyl-2-methyl-1-[(4-methyl-5-isoquinolyl)sulfonyl]hexahydro-1H-1,4-diazepine, displays improved selectivity toward ROCKII (4). **Target(s)**: ROCKII (IC<sub>50</sub> = 0.0118 μM); Aurora A (IC<sub>50</sub> = 2.35 μM); CAMKII (IC<sub>50</sub> = 2.57 μM); PKG (IC<sub>50</sub> = 3.26 μM); PKA (IC<sub>50</sub> >10 μM); PKC (IC<sub>50</sub> >10 μM); and MLCK (IC<sub>50</sub> = 28.3 μM). 1. ## HA14-1

This cell-permeable Bcl-2 inhibitor (FW = 409.24 g/mol; CAS 65673-63-4; Soluble to 100 mM in DMSO and to 100 mM in Ethanol), also named 2-amino-6-bromo- $\alpha$ -cyano-3-(ethoxycarbonyl)-4H-1-benzopyran-4-acetic acid ethyl ester, disrupts Bax/Bcl-2 interactions ( $IC_{50} \sim 9 \mu M$ ), thereby inducing apoptosis of tumor cells. *In vitro* binding studies demonstrated that HA14-1 interacts with a Bcl-2 surface pocket that is essential for its biological function (1). HA14-1 induces apoptosis of human acute myeloid leukemia (HL-60) cells overexpressing Bcl-2 protein associated with the decrease in mitochondrial membrane potential and activation of caspase-9, followed by caspase-3. Cytokine response modifier A, a potent inhibitor of Fas-mediated apoptosis, did not block apoptosis induced by HA14-1 (1). In acute myelogenous leukemia (AML) cell lines with constitutively activated MAPK, MAPK kinase (MEK) blockade by PD184352 strikingly potentiates apoptosis induced HA14-1 or by Bcl-2 antisense oligonucleotides (2). HA14-1 also binds to the antiapoptotic Bcl-2 proteins, Bcl-XL and Bcl-w (3). 1. Wang, Liu, Zhang, *et al.* (2000) *Proc. Natl. Acad. Sci. U.S.A.* **97**, 7124. 2. Milella, Estrov, Kornblau, *et al.* (2002) *Blood* **99**, 3461. 3. Doshi, Tian & Xing (2006) *J. Med. Chem.* **49**, 7731.

## HA 130

This lipase inhibitor (FW = 463.29 g/mol; CAS 1229652-21-4; Solubility: 100 mM in DMSO), also named *B*-[3-[[4-[[3-[(4-fluorophenyl)methyl]-2,4-dioxo-5-thiazolidinylidene]methyl]phenoxy]methyl]phenyl]boronic acid, targets ( $IC_{50} = 28 \text{ nM}$ ) ectonucleotide pyrophosphatase/phosphodiesterase-2, or E-NPP-2, or autotaxin (ATX), an extracellular enzyme catalyzes the conversion of lysophosphatidylcholine into the lipid mediator, lysophosphatidic acid (LPA) (1). Although autotaxin itself was mistakenly thought to be a tumor cell-motility-stimulating factor, its reaction product, LPA, is the actual signal molecule. ATX-LPA signaling has been implicated in angiogenesis, chronic inflammation, fibrotic diseases and tumor progression, making this system an attractive druggable target for therapy (2). The boronic acid moiety interacts with the active-site threonine in ATX, thereby increasing its affinity. 1. Albers, van Meeteren, Egan, *et al.* (2010) *J. Med. Chem.* **53**, 4958. 2. Albers, Dong, van Meeteren, *et al.* (2010) *Proc. Natl. Acad. Sci. USA* **107**, 7257.

## (R)-(+)-HA-966

This brain-penetrant NMDA receptor antagonist/partial agonist (FW = 116.12 g/mol; CAS 123931-04-4; Soluble to 100 mM in H<sub>2</sub>O), also named (R)-(+)-3-amino-1-hydroxypyrrolidin-2-one, is a centrally- and peripherally-acting antagonist ( $IC_{50} \sim 150 \mu M$ ), binding at the strychnine-insensitive glycine allosteric site of the *N*-methyl-D-aspartate receptor

ionophore complex (1) and reducing the affinity of glutamate for its recognition site on the NMDA receptor by 5x (2). By contrast, the *S*-enantiomer of HA-966 is much less potent,  $IC_{50} > 1 \text{ mM}$ . The  $IC_{50}$  of (R)-HA-966 for displacing glycine binding is decreased in the presence of spermine, suggesting that spermine increases the affinity of (R)-HA-966 at the glycine binding site (3). 1. Pullan, *et al.* (1990) *J. Neurochem.* **55**, 1346. 2. Kemp & Priestley (1991) *Mol. Pharmacol.* **39**, 666. 3. Pullan, *et al.* (1991) *Eur. J. Pharmacol.* **208**, 25.

## HA-1077, See Fasudil

## Hadacidin

This glycine derivative (FW<sub>free-acid</sub> = 119.08 g/mol; CAS 689-13-4), also called *N*-formyl-*N*-hydroxyglycine and *N*-formyl-*N* hydroxyaminoacetic acid, from *Penicillium frequentans* and *P. aurantio-violaceum* exhibits antitumor properties, inhibiting the growth of human adenocarcinoma (1,2). Hadacidin also inhibits bacterial and mammalian purine nucleotide biosynthesis. **Target(s)**: adenylosuccinate synthetase (3-9); aspartate aminotransferase (10). 1. Kaczka, Gitterman, Dulaney & Folkers (1962) *Biochemistry* **1**, 340. 2. Stevens & Emery (1966) *Biochemistry* **5**, 74. 3. Gale & Smith (1968) *Biochem. Pharmacol.* **17**, 2495. 4. ## Haemadin

This 57-residue exosite II-binding polypeptide (MW  $\approx 5 \text{ kDa}$ ) from the land-living Indian leech *Haemadipsa sylvestris* has a mechanism of thrombin inhibition that is similar to that of hirudin (1,2). The *N*-terminal segment of haemadin binds within the thrombin active site, forming a parallel  $\beta$ -strand with residues Ser214-Gly216 of the proteinase. In contrast to hirudin, however, haemadin's markedly acidic C-terminal peptide does not bind the fibrinogen-recognition exosite, and interacts instead with the heparin-binding exosite of thrombin (3). (See also *Hirudin*) 1. Strube, Kroger, Bialojan, Otte & Dodt (1993) *J. Biol. Chem.* **268**, 8590. 2. Richardson, Fuentes-Prior, Sadler, Huber & Bode (2002) *Biochemistry* **41**, 2535. 3. Richardson, Kröger, Hoeffken, *et al.* (2000) *EMBO J.* **19**, 5650.

## Halichondrin B

This naturally occurring marine toxin (FW = 1125.36 g/mol; CAS 103614-76-2) from the marine sponge *Halichondria okadai*, is a tubulin-directed anti-mitotic agent with powerful anticancer properties (1). Its structurally less complicated analogue, eribulin, has already advanced to clinical trials, showing great promise as an antineoplastic agent that interrupts mitosis and induces apoptosis (See *Eribulin*). Halichondrin B is highly cytotoxic ( $IC_{50} = 0.3 \text{ nM}$  for L1210 murine leukemia cells), with arrest in mitosis (2). It also inhibits polymerization of purified brain tubulin in the absence or presence of microtubule-associated proteins (2). The total synthesis of Halichondrin B was accomplished in Kishi's laboratory at Harvard (3). 1. Hirata & Uemura (1986) *Pure Appl. Chem.* **58**, 701. 2. Bai, Paull, Herald, *et al.* (1991) *J. Biol. Chem.* **266**, 15882. 3. Aicher, Buszek, Fang *et al.* (1992) *J. Am. Chem. Soc.* **114**, 3162.

**Halofantrine**

This antimalarial agent (FW<sub>free-base</sub> = 500.43 g/mol; CAS 69756-53-2), also known as 1,3-dichloro- $\alpha$ -[2-(dibutylamino)ethyl]-6-(trifluoromethyl)-9-phenanthrenemethanol, is effective against asexual forms of multidrug-resistant *Plasmodium falciparum* malaria. **Target(s):** cAMP-dependent protein kinase, or protein kinase A (1); CYP2D6, also as alternative substrate (2); hERG K<sup>+</sup> current (3-5). 1. Wang, Ternai & Polya (1994) *Biol. Chem. Hoppe Seyler* **375**, 527. 2. Halliday, Jones, Smith, Kitteringham & Park (1995) *Brit. J. Clin. Pharmacol.* **40**, 369. 3. Traebert, Dumotier, Meister, et al. (2004) *Eur. J. Pharmacol.* **484**, 41. 4. Mbai, Rajamani & January (2002) *Cardiovasc. Res.* **55**, 799. 5. Tie, Walker, Singleton, et al. (2000) *Brit. J. Pharmacol.* **130**, 1967.

**Haloperidol**

This powerful antipsychotic agent (FW<sub>free-base</sub> = 375.87 g/mol; CAS 52-86-8), also known as 4-[4-(4-chlorophenyl)-4-hydroxy-1-piperidinyl]-1-(4-fluoro-phenyl)-1-butanone, is a dopamine antagonist at D<sub>1</sub> (K<sub>i</sub> = ~ 80 nM), D<sub>2</sub> (K<sub>i</sub> = 8 nM), D<sub>3</sub> (K<sub>i</sub> = ~ 7 nM), D<sub>4</sub> (K<sub>i</sub> = 2 nM), and D<sub>5</sub> (K<sub>i</sub> = ~ 100 nM) receptors and is frequently used to treat acute and chronic schizophrenia. While its precise mechanism of therapeutic action remains to be established, haloperidol appears to depress the CNS at the subcortex, midbrain, and brain stem. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** Ca<sup>2+</sup>-dependent cyclic-nucleotide phosphodiesterase (1); cholesterol  $\Delta$  isomerase, or sterol  $\Delta^{7,8}$ -isomerase (2); dopamine receptors (3,4); glycine transporter (5); monamine oxidase (6). 1. Hidaka, Inagaki, Nishikawa & Tanaka (1988) *Meth. Enzymol.* **159**, 652. 2. Moebius, Reiter, Bermoser, et al. (1998) *Mol. Pharmacol.* **54**, 591. 3. **Haloxypop**

This aryloxyphenoxypropionate herbicide (FW<sub>free-acid</sub> = 361.70 g/mol; CAS 69806-34-4), also known as (R*S*)-2-[4-[3-chloro-5-(trifluoromethyl)-2-pyridyloxy]phenoxy]propionic acid, is a strong inhibitor of wheat acetyl-CoA carboxylase (IC<sub>50</sub> = 0.28  $\mu$ M), an important target of aryloxyphenoxypropionate-class herbicides. Analysis of the interaction between the active site residues and (R)-haloxypop shows the van der Waals interactions play a key role in binding. Note that the (R)-enantiomer is often referred to as haloxypop-P. 1. Burton, Gronwald, Somers, et al. (1987) *Biochem. Biophys. Res. Commun.* **148**, 1039. 2. Rendina, Felts, Beaudoin, et al. (1988) *Arch. Biochem. Biophys.* **265**, 219. 3. Zhang, Tweel & Tong (2004) *Proc. Natl. Acad. Sci. U.S.A.* **101**, 5910. 4. Rendina, Craig-Kennard,

Beaudoin & Breen (1990) *J. Agric. Food Chem.* **38**, 1282. 5. Egli, Gengenbach, Gronwald, Somers & Wyse (1993) *Plant Physiol.* **101**, 499. 6. U.S.A.* **98**, 6617.

**Halysin**

This cysteine-rich, 71-residue disintegrin and hemorrhagic agent (MW = 7500 (SDS gel electrophoresis); CAS 137544-79-7) from the venom of the snake *Agkistrodon halys* contains an RGD loop that facilitates tight binding to integrins, resulting in the potent inhibition of platelet aggregation stimulated by ADP, thrombin, and collagen (IC<sub>50</sub> = 160–360 nM), without affecting platelet secretion. It was active in inhibiting platelet aggregation of platelet-rich plasma and whole blood. Halysin had no effect on thromboxane B<sub>2</sub> formation of platelets or intracellular Ca<sup>2+</sup> mobilization of Quin 2-AM loaded platelets stimulated by thrombin. It inhibited the fibrinogen-induced aggregation of elastase-treated platelets. 1. Huang, Liu, Ouyang & Teng (1991) *Biochem. Pharmacol.* **42**, 1209.

**HAMI3379**

This potent receptor antagonist (FW = 595.70 g/mol; CAS 712313-35-4; IUPAC: 3-[[[3-carboxycyclohexyl]amino]carbonyl]-4-[3-[4-[4-(cyclohexyloxy) butoxy]phenyl]propoxy]benzoic acid) targets the G-protein-coupled leukotriene LTD<sub>4</sub>- and LTC<sub>4</sub> receptor-mediated mobilization of intracellular calcium ion, with IC<sub>50</sub> values of 3.8 and 4.4 nM, respectively, with a far weaker effect on the Cys-LT<sub>1</sub> receptor (IC<sub>50</sub> = >10  $\mu$ M) (1). Intracerebroventricular injection of HAMI 3379 protects against acute brain injury after focal cerebral ischemia in rats (2). 1. Wunder, Tinel, Kast, et al. (2010) *Br. J. Pharmacol.* **160**, 399. 2. Shi, Xiao, Zhao, et al. (2012) *Brain Res.* **1484**, 57.

**Hammerhead Ribozyme-Mediated mRNA Knockdown**

The smallest RNA endonucleases, hammerhead *trans*-acting ribozymes specifically bind and cleave RNA sequences at defined targets, often discriminating between those differing by a single nucleotide (1,2). Values for  $k_{cat}$  range from 3-15 min<sup>-1</sup>, indicating an acceptable rate cleavage rate, and  $k_{cat}/K_m$  typically reaches values of 10<sup>6</sup> min<sup>-1</sup> M<sup>-1</sup>, a value comparable with those described for other biologically active ribozymes Mercatanti et al. (3) describe a method for predicting accessible target sites for hammerhead ribozymes within a given RNA sequence. Their approach maps all putative NUH cleavage sites (where N = A, C, G, U and H = A, C, U) and picks out short flanking regions as the binding domain for the corresponding ribozyme. The probabilistic level of unfolding, accessibility score (AS), is then calculated for each target region on the basis of a comparison of all folding structures obtained for the target RNA and arranged according to the Boltzmann's distribution. Application of a series of imposed limits then gives the best target sequences (*i.e.*, those endowed with likely accessibility and with a potentially active catalytic structure of the hammerhead sequence). 1. Phylactou, Tsipouras & Kilpatrick (1998) *Biochem Biophys Res Commun* **249**:804 2. Citti & Rainaldi (2005) *Curr. Gene Ther.* **5**, 11. 3. Mercatanti, Rainaldi, Mariani, Marangoni & Citti (2009) *J. Comput. Biol.* **9**, 641.

**Hanatoxin-1**

This 34-residue channel-gating modifier (FW = 4120.71 g/mol; Sequence: ECRYLFGGCLTSDCCCKHLGCKFRDKYCAWDFS; CAS 170780-00-4) from the venom of the Chilean rose tarantula (*Grammostola spatulata*) inhibits voltage-gated K<sup>+</sup> channels (*i.e.*, Kv2.1 voltage-activated K<sup>+</sup> channels) not by blocking the pore, but by altering the energetics of gating (1,2). HaTx1 adopts an inhibitor-cystine-knot motif, composed of two  $\beta$ -strands, presenting a hydrophobic patch and its surrounding charged

residues that are principally responsible for the binding of this gating modifier toxins to the voltage-gated channel (3). 1. Swartz & MacKinnon (1995) *Neuron* **15**, 941. 2. ### Harmaline

This psychoactive alkaloid (FW<sub>free-base</sub> = 214.27 g/mol; CAS 304-21-2), also known as 3,4-dihydroharmine and harmidine, is found in a wide variety of plant groups, but was isolated from *Peganum harmala* in 1841 (1). Harmaline is a central nervous system stimulator that inhibits monoamine oxidase A, an enzyme that inactivates monoaminergic neurotransmitters, such as serotonin, melatonin, noradrenalin, and adrenalin. In view of their vital role in the inactivation of neurotransmitters, MAO dysfunctions are thought to underlie a number of psychiatric and neurological disorders. Harmaline also acts as a general inhibitor of Na<sup>+</sup>-dependent transporters. **Target(s):** *N*-acetyltransferase (2); alanine transport, Na<sup>+</sup>-dependent (3); aryl acylamidase (4); calcium ion channels (5); choline uptake (6); dicarboxylic acid transporter (7); DNA topoisomerase I (8);  $\beta$ -fructofuranosidase, *or* invertase (9); glutamine transport (10); histamine *N*-methyltransferase (11); *N* hydroxyarylamine *O*-acetyltransferase (12);  $\gamma$ -hydroxybutyrate transport (13); Mg<sup>2+</sup>-dependent ATPase (14); monoamine oxidase, *or* amine oxidase (15-22); Na<sup>+</sup>-dependent transport (6,23-26); Na<sup>+</sup>/HCO<sub>3</sub><sup>-</sup> cotransporter (27); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (14,28,29); NhaB, a Na<sup>+</sup>/H<sup>+</sup> antiporter (30); phenylalanine transport (23,25,31,32); sucrase (33); taurine transport (34). 1. ### Harman

This antioxidant and lipid peroxidation inhibitor (FW<sub>free-base</sub> = 182.22 g/mol; CAS 486-84-0), also known as 1-methyl-9H-pyrido[3,4-*b*]indole and 2-methyl- $\beta$ -carboline, is an alkaloid first isolated from the seeds of

*Peganum harmala*, but is also formed in cooked foods and cigarette smoke. Harman is also an I<sub>1</sub> imidazoline receptor agonist. Mammalian brain possesses a  $\beta$ -carboline 2-*N*-methyltransferase (perhaps phenylethanolamine *N*-methyl-transferase) that converts  $\beta$ -carbolines, such as norharman and harman, into 2-*N*-methylated  $\beta$ -carbolinium cations that are structural and functional analogs of the Parkinson Disease-inducing toxin 1-methyl-4-phenylpyridinium cation, *or* MPP<sup>+</sup> (1). **Target(s):** acetylcholinesterase (2); benzodiazepine receptor (3); cholesterol-5,6-oxide hydrolase (4); DNA- (apurinic or apyrimidinic site) lyase activity of the UV endonuclease induced by phage T<sub>4</sub> (5); DNA topoisomerase I (6,7); DNA topoisomerase II, weakly inhibited (7); monoamine oxidase A, amine oxidase (8-10); soluble epoxide hydrolase (11). 1. Gearhart, Neafsey & Collins (2002) *Neurochem. Int.* **40**, 611. 2. Skup, Oderfeld-Nowak & Rommelspacher (1983) *J. Neurochem.* **41**, 62. 3. ### Harringtonine

This alkaloid (FW<sub>free-base</sub> = 531.60 g/mol; CAS 26833-85-2), from the plum yew (*Cephalotaxus hainanensis*) indigenous to Hainan Island, is an antitumor agent has been used to treat acute or chronic myeloid leukemia. Harringtonine inhibits protein biosynthesis in HeLa cells, rabbit reticulocytes, and reticulocyte lysates. DNA synthesis is partially inhibited at 200 nM, but RNA synthesis is unaffected (1). These inhibitory effects on protein and DNA synthesis are partially reversible. Harringtonine induces breakdown of polyribosomes to monosomes with concomitant release of completed polypeptides. Its main effect is retarding the initiation of protein synthesis. **Target(s):** DNA biosynthesis (2); protein biosynthesis (1,3,4); telomerase (5). 1. Huang (1975) *Mol. Pharmacol.* **11**, 511. 2. ### HBI-8000, See Chidamide

### HCT, See Hydrochlorothiazide

### HC Toxin

This cyclopeptide mycotoxin (FW = 436.51 g/mol; CAS 83209-65-8) from the pathogenic plant fungus *Cochliobolus carbonum* (previously *Helminthosporium carbonum*, hence the "HC", named systematically as cyclo[D-prolyl-L-alanyl-D-alanyl-L-2-amino-8-oxo-9,10-epoxydecanoyl], is very toxic to plants, including maize, and is a potent histone deacetylase inhibitor (HDACi). The anti-neuroblastoma activity of HC toxin is superior to that of retinoic acids and all other HDACi tested. Structurally, HC toxin adopts a rigid conformation that serves as a scaffold to mimic reverse-turns.

#### Helenalin

This antitumor agent (FW = 262.31 g/mol; CAS 6754-13-8), first isolated from the sneezeweed *Helenium autumnale*, inhibits 5-lipoxygenase, undergoing Michael-type addition with the sulfhydryl groups of reduced glutathione and cysteine. **Target(s):** aminopyrine demethylase, cytochrome P450 (1); aniline hydroxylase, cytochrome P450 (1); ethoxyresorufin deethylase, cytochrome P450 (1); leukotriene C<sub>4</sub> synthase (2); 5-lipoxygenase, or arachidonate 5-lipoxygenase (2,3); NF-κB (4); oxidative phosphorylation (5); telomerase (6).

#### Heliquinomycin

This antibiotic (FW = 714.59 g/mol; CAS 178182-49-5) from *Streptomyces* inhibits DNA helicase as well as the growth of HeLa S3, KB, LS180, K562, and HL60 human tumor cell lines (1). **Primary Mode of Action:** Heliquinomycin inhibits cellular DNA replication (IC<sub>50</sub> = 2.5 μM), without affecting level of chromatin-bound MCM4 (a DNA replication licensing factor) and without activating the DNA replication-stress checkpoint system, suggesting that the antibiotic perturbs DNA replication mainly by inhibiting the activity of replicative DNA helicase that unwinds DNA duplex at replication forks. Heliquinomycin inhibits the DNA helicase activity of MCM4/6/7 complex by stabilizing its interaction with single-stranded DNA.

2. Sugiyama, Chino, Tsurimoto, Nozaki & Ishimi (2012) *J. Biochem.* **151**, 129.

#### Helvolic Acid

This steroid antibiotic (FW<sub>free-acid</sub> = 568.71 g/mol; CAS 29400-42-8), independently isolated from *Aspergillus fumigatus* in the early 1940s by Nobelists Waksman and Chain, is structurally related to fusidic acid and is effective against Gram-positive organisms. Helvolic acid forms a host-guest complex with γ-cyclodextrin. **Target(s):** elongation factor-2 (1); cholesterol ester accumulation in macrophages (2).

2. Shinohara, Hasumi & Endo (1993) *Biochim Biophys Acta* **1167**, 303.

#### Hematin

This Fe(III) porphyrin complex (FW<sub>free-acid</sub> = 633.51 g/mol; CAS 15489-90-4), also known as haematin, ferriprotoporphyrin IX hydroxide, and ferriheme hydroxide, is an oxidized form of heme that is the prosthetic group found in methemoglobin, metmyoglobin, catalase, cytochrome *b*, and plant peroxidases. Hematin also binds cooperatively to β<sub>1</sub>-glycoglobulin and albumin, the latter a reservoir for excess heme that may enter the plasma. Hematin also activates the extra-hepatic P450 mono-oxygenases in tissue homogenates. Less stable than hemin (*i.e.*, ferriprotoporphyrin IX chloride), hematin can be reduced to heme by sodium dithionite (Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub>). Hematin is especially prone to self-assembly into dimers, oligomers and aggregates, depending on pH, solvent, temperature, concentration, ionic strength. This biocrystallization process converts hematin into insoluble and chemically inert paracrystals known as hemozoin, which consists of a centrosymmetric triclinic unit cell comprised of reciprocal head-to-tail dimeric units of heme bound through propionate O-Fe(III) (1). **Oligomerization in Plasmodium-infected Red Cells:** During its intraerythrocytic stages of infection, the malaria parasite consumes >80% of the red cell's hemoglobin, using the latter as a foodstuff for amino acids and releasing hematin, the latter in turn provoking membrane disruption and lysis. Left undeterred, the latter property would limit the parasite burden; however, to offset this effect, the parasite blocks hematin-induced lysis by oligomerization and paracrystal formation. Quinoline-type antimalarials (including chloroquine and amodiaquine) owe their antimalarial effects to the ability to inhibit hemozoin formation. (See also *Hemin*) **Target(s):** 5-aminolevulinic synthase (2,3); L-dopachrome isomerase (4); fatty-acid binding protein (5); glutathione S-transferase (6-19); 3-hydroxy-3-methylglutaryl-CoA reductase (20); malate dehydrogenase (acceptor) (21); porphobilinogen synthase, or 5-aminolevulinic dehydratase (22); prostaglandin-D synthase (23); succinate dehydrogenase (24-26).

### Heme

This iron(II)-protoporphyrin IX complex (FW<sub>free-acid</sub> = 616.50 g/mol; CAS 15489-90-4), also known as ferroprotoporphyrin IX and ferroheme, is the prosthetic group of myoglobin, hemoglobin, catalase, erythrocyruorins, certain peroxidases, and cytochromes *b*. Absent the stabilizing effects of its protein binding partner, heme rapidly oxidizes; hence, heme solutions must be prepared under oxygen-free conditions. Heme iron can be removed by treatment with HCl. The presence of heme in blood samples is a confounding factor in the use of PCR in assays of bacterial and yeast sepsis, because heme inhibits Taq polymerase. Such variability can be minimized through the appropriate choice of another DNA polymerase (1). **Target(s)**: aminolevulinatase aminotransferase (2,3);  $\delta$ -aminolevulinatase synthase (4-7); fatty-acid binding protein (8); ferrochelatase (9-12); glutamyl-tRNA synthetase, plant (13); magnesium protoporphyrin IX methyltransferase (14); nitric-oxide synthase (15); porphobilinogen synthase, or  $\delta$  aminolevulinatase dehydratase (16); protoporphyrinogen oxidase (17). 1. ### Hemisterlin

This cytotoxic oligopeptide (FW = 526.72 g/mol), isolated from the sponge genus *Auleta* and two collections of *Siphonochalina* sp., target tubulin, and, at low nanomolar toxic concentrations, produces abnormal mitotic spindles resembling those formed in the presence of taxol, nocodazole and vinblastine. At higher concentrations, hemisterlin A does not cause microtubule bundling, as does taxol, but instead promotes microtubule depolymerization, much like nocodazole and vinblastine (1). Hemisterlin induces the formation of ring-like tubulin aggregates with a diameter of about 40 nm, without producing any turbidity (2). A total synthesis of (-)-hemisterlin has been accomplished in nine steps, with an overall yield of >35% (3). 1. Anderson, Coleman, Andersen & Roberge (1997) *Cancer Chemother. ### Hemicholinium-3 Dibromide

This symmetrical quaternary ammonium salt (FW = 574.35 g/mol; CAS 312-45-8; *Abbreviation*: HC-3) is a strong inhibitor of the Na<sup>+</sup>-dependent choline uptake, resulting in an inhibition of acetylcholine synthesis. HC-3 is frequently used to deplete acetylcholine stores, and [<sup>3</sup>H]-HC-3 has found use in locating HC-3 sites in rat brain. **Target(s)**: acetylcholinesterase (1); carnitine *O*-octanoyltransferase (2); choline kinase (3-12); choline transport (13-16); ethanolamine kinase (6,8). 1. ### Hemin

This porphyrin complex (FW<sub>free-acid</sub> = 651.95 g/mol; CAS 16009-13-5), also known as ferroprotoporphyrin IX chloride and ferriheme chloride, is an oxidized form of heme, in which the iron is in the +3 oxidation state. Hemin is more stable than hematin (*i.e.*, ferroprotoporphyrin IX hydroxide), and the iron ion can be removed upon treatment with sulfuric acid. Hemin also regulates protein biosynthesis, by activation of a protein kinase (*i.e.*, the hemin-controlled translational repressor). The latter phosphorylates eIF-2,

resulting in inhibition of polypeptide chain initiation and protein biosynthesis. (See also *Hematin*; *Heme*) **Target(s):** actin polymerization (1); aminolevulinatase aminotransferase, or L-alanine:4,5-dioxovalerate aminotransferase (2,3,39-45); 5-aminolevulinatase synthase (4-8,48-61); calpain (9); Ca<sup>2+</sup>/Mg<sup>2+</sup>-dependent ATPase (10); cAMP-dependent protein kinase, protein kinase A (11); casein kinase II (12); coproporphyrinogen III oxidase (13); cowpea mosaic virus 24-kDa proteinase (14,15); CYP1A2 (16); CYP3A4 (16); CYP2D6 (16); DNA polymerase (17); fatty-acid binding protein (18); ferrochelatase (19,20); glutamate racemase (21); glutathione S-transferase (22,46,47); guanylate cyclase (23); hemin-controlled repressor protein kinase (12); holocytochrome-c synthase (24); 3-hydroxy-3-methylglutaryl-CoA reductase (25); lactoylglutathione lyase, or glyoxalase I (26); lipoamidase (27); magnesium protoporphyrin IX methyltransferase (62,63); murine leukemia virus reverse transcriptase, or RNA-directed DNA polymerase (28); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (29); porphobilinogen synthase, or 5-aminolevulinatase dehydratase (8,30); protein kinase (31); proteasome endopeptidase complex (32); protoporphyrinogen oxidase (33); pyruvate decarboxylase (34); ribonuclease (35); RNA-directed DNA polymerase (28); succinyl-CoA synthetase (36,37); uroporphyrinogen decarboxylase (38).

### Heparan Sulfate

This mucopolysaccharide (MW = 5-50 kDa for the indefinite biopolymer; CAS 9050-30-0; Note: X = H or SO<sub>3</sub><sup>-</sup>, and Y = SO<sub>3</sub><sup>-</sup> or CH<sub>3</sub>CO), also known as heparitin sulfate, consists of repeating units of D-glucosamine and D-glucuronate (the latter predominating over L-iduronate), linked 1,4 and containing O- and N-sulfate groups. Heparan sulfate contributes to cell-cell adhesion. There are fewer sulfate groups in heparan sulfate compared to heparin: an average of one sulfate group per disaccharide unit is present in heparan sulfate. There is greater variability in structure and the polysaccharide tends to be longer in length: molecular weights vary between 5 and 50 kDa. In addition, heparan sulfate is typically found linked to a core protein. **Target(s):** N-acetylgalactosamine-6-sulfatase (1); α-N-acetylglucosaminidase (2); [β-adrenergic-receptor] kinase (3); casein kinase II (4); cathepsin G (5); cruzipain (6); β-glucuronidase (7); granzyme A (8); histone acetyltransferase, inhibited by heparan sulfate proteoglycan (9); hyaluronoglucosaminidase, or hyaluronidase (10-14); L-iduronidase (15); iduronate-2-sulfatase (16); nucleotide diphosphatase (17); phospholipase A<sub>2</sub> (18); procollagen N-endopeptidase (19-21).

### Heparin

This acid mucopolysaccharide and an anti-clotting agent (MW range = 5-40 kDa, MW<sub>average</sub> = 15 kDa, where R = H or SO<sub>3</sub><sup>-</sup>, and R' = SO<sub>3</sub><sup>-</sup> or CH<sub>3</sub>CO) CAS 9005-49-6; Average Net Charge Per Polymer = -75) consists of repeating units of D-glucosamine and either D-glucuronate or L-iduronate (with L-iduronate comprising 90% of the uronic acids), joined by 1,4

linkages and containing *O*- and *N*-sulfate groups. On average, there are 2.7 sulfate groups per disaccharide unit, making heparin the most negatively charged polyelectrolyte in mammalian tissues. In addition, the amino group on D-glucosamine residues can be acetylated. Heparin inhibits the conversion of prothrombin to thrombin, activating antithrombin III. (**See also Antithrombin; Antithrombin III; Deltaparin; Heparan Sulfate; Tinzaparin**) **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** *N*-acetylgalactosamine-4-sulfatase, or arylsulfatase B (1); *N*-acetylgalactosamine 6-sulfatase (2,3);  $\alpha$ -*N*-acetyl-glucosaminidase (4); ADAMTS-4 endopeptidase, or aggrecanase (5); adenosine deaminase (RNA-adenosine deaminase) (6); adenylate cyclase (7); [ $\beta$ -adrenergic-receptor] kinase (8-17); alcohol dehydrogenase (18); alkaline phosphatase (19);  $\alpha$ -amylase (20,21);  $\beta$ -amylase (20,21); arginyltransferase (199); Arylsulfatase (22); bovine spleen ribonuclease (23); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (24-27); [branched-chain- $\alpha$ -keto-acid dehydrogenase] phosphatase, or [3-methyl-2-oxobutanoate dehydrogenase] phosphatase (28-30); casein kinase-1 (31-33); casein kinase-2 (34-44); cathepsin G, also inhibited by low-molecular-weight heparin derivatives (45-47); chondroitin AC lyase (48); chondroitin 4-sulfotransferase (49); chondroitin 6-sulfotransferase (50); chymase (51); coagulation factor IXa (52); coagulation factor Xa (53); coagulation factor Xia (54); 2',3'-cyclic-nucleotide 3'-phosphodiesterase (55-57); deoxyribonuclease I (58); DNA-directed DNA polymerase (59,60); DNA-directed RNA polymerase (59,61-64); DNA topoisomerase I (65-70); endopeptidase La (71); endopeptidase So (72); exopolyphosphatase (73-79); exo- $\alpha$ -sialidase, or neuraminidase, or sialidase (80,81); ferredoxin:NADP<sup>+</sup> reductase (82);  $\beta$ -fructofuranosidase, or invertase, inhibited below pH 4.5 (20,83,84); fumarate (20,85);  $\beta$ -D-galactoside 2,3-sialyltransferase (86);  $\beta$ -glucuronidase (20,87-91);  $\gamma$ -glutamyl hydrolase (92,93); glycerophosphocholine phosphodiesterase (94); [glycogen synthase] kinase-I, or casein kinase I (31,32); [G-protein-coupled receptor] kinase (95-97); guanylate cyclase (98); [heparan sulfate]-glucosamine 3-sulfotransferase 1, inhibited by low affinity heparin (99); histone acetyltransferase (200); hyaluronoglucosaminidase, or hyaluronidase (20,100-116); L-iduronidase (117); inositol-trisphosphate 3 kinase (118); inositol-1,3,4-trisphosphate 5/6-kinase (119); leukocyte elastase (45,120,121); lipoprotein lipase (20,122); [low-density-lipoprotein receptor] kinase (123); lysozyme (20,124,125); myosin ATPase, competitively inhibited by heparins of molecular weights 1.75 to 11.6 kDa (126); [myosin heavy chain] kinase (127); nicotinamide phosphoribosyltransferase (128); non-specific serine/threonine protein kinase (31-44); nucleotide diphosphatase (129); pancreatic ribonuclease, or ribonuclease A (20,130-135); pappalysin-1 (136); 1-phosphatidylinositol-4-phosphate 5-kinase (137,138); phospholipase A<sub>2</sub> (139-141); phosphoprotein phosphatase (30,142-144); phosphorylase kinase (145); [phosphorylase] phosphatase (142-144); polynucleotide adenyllyltransferase, or poly(A) polymerase (146); polynucleotide 5'-hydroxyl-kinase (147-150); polynucleotide phosphorylase, or polyribonucleotide nucleotidyl-transferase (151); procollagen N-endopeptidase (152-154); protein kinase C (155); protein tyrosine kinase (156); protein-tyrosine-phosphatase (157-167); protein xylosyltransferase (194-198); rhodopsin kinase (168-170); RNA-directed DNA polymerase, or reverse transcriptase (59,171); RNA directed RNA polymerase (172,173); [RNA-polymerase]-subunit kinase (174); RNA uridylyltransferase (175,176); *Schizophyllum commune* nuclease (177); simian immunodeficiency virus reverse transcriptase (171); squid ribonuclease (23); sterol esterase, or cholesterol esterase (178); thrombin (179-187); tRNA-pseudouridine synthase I (188); trypsin (20,189,190); tubulin-tyrosine carboxypeptidase (191); Vaccinia RNA polymerase (192); *Xenopus* ribosomal protein S<sub>6</sub> kinase II (193). 1. ### Heparin Cofactor II

This human liver serpin and anticoagulant (MW = 65.6 kDa) is a natural serine protease with high specificity towards thrombin. HCII inactivates thrombin rapidly in the presence of dermatan sulfate (*i.e.*, heparin cofactor II is activated upon binding to cell surface glycosaminoglycans). The inhibition occurs by formation of a stable binary complex between the plasma glycoprotein and thrombin. Unlike antithrombin, which also inhibits other proteases (*e.g.*, coagulation factors IXa, Xa, XIa, XIIa, plasmin, and kallikrein), heparin cofactor II is highly selective. (*For a discussion of the likely mechanism of inhibitory action, See Serpins; also  $\alpha$ -Antichymotrypsin*) **Target(s):** cathepsin G, weakly inhibited (1); chymotrypsin (2); thrombin (3-9). **1.** Parker & Tollefsen (1985) *J. ### Hepatocyte Growth Factor Activator Inhibitor-1

This multidomain Type-I transmembrane glycoprotein (MW = 66 kDa; Symbol: HAI-1; Accession Number: AB000095) and its splice variant (HAI-1B) are novel Kunitz-type serine protease inhibitors, the latter containing an extra 16 residues adjacent to the C-terminus of its Kunitz-type domain (1). Its main target (IC<sub>50</sub> = 30.5 nM) is Hepatocyte Growth Factor Activator (HGFA), a serum serine proteinase that specifically converts the inactive proform of Hepatocyte Growth Factor/Scatter Factor (*or* pro-HGF/SF) to its active form, HGF/SF, in response to tissue injury. Because HGF/SF is a pleiotropic factor with multifunctional roles in a variety of cells via its high-affinity receptor, c-Met receptor tyrosine kinase, HGFA is likely to play roles in a number of pathophysiological phenomena *in vivo*. HAI-1 inhibits other serine proteases and has been shown to be essential for placental development by modulating the activities of extracellular proteases (1). **Structural Features:** The primary translation product consists of 513 residues, with the NH<sub>2</sub>-terminal 35 residues serving as a signal peptide. The mature protein appears to be membrane-bound, because a hydrophobic region of about 20 amino acids is present at the COOH-terminal region. HAI has two well defined Kunitz domains, which contain around 60 residues and three disulfide bonds, thus resembling the functional domain of bovine pancreatic trypsin inhibitor. One or both of the Kunitz domains in HAI appear to be responsible for the inhibitory activity of the protein. **Secondary Targets:** matriptase (IC<sub>50</sub> = 16.5 nM); plasma kallikrein (IC<sub>50</sub> = 690 nM); plasmin (IC<sub>50</sub> = 400 nM); and trypsin (IC<sub>50</sub> = 2.4 nM). Attesting to its physiologic significance is the finding that HAI-1-deficient mice die *in utero*, resulting from undifferentiated chorionic trophoblasts (1-3). HAI-1 plays a role in maintaining postnatal tissue homeostasis (*e.g.*, keratinization of the epidermis, hair development, and the

integrity of the colonic epithelium integrity (4-6). Genetic studies in mice have established that improper inhibition of matriptase activity by HAI-1 can give rise to carcinogenesis (7). HAI-1 was first identified as an inhibitor co-purifying with hepatocyte growth factor activator, or HGFA-2 (8) and was later purified from human milk in complex with matriptase (9). Simultaneous genetic ablation of matriptase in mice rescues the placental defect caused by a lack of HAI-1 (3). HAI-1 also inhibits the glycoposphatidyl-inositol membrane-anchored serine protease known as prostasin (10). 1. Tanaka, Nagaike, Takeda, *et al.* (2005) *Molec. Cellular Biol.* **25**, 5687. 2. ### Hepcidin

This iron entry inhibitor and master regulator of iron homeostasis (FW = 2868.48 g/mol; Sequence: DTHFPICFCCGCCHRSKQCQMCCKT; Uniprot: P81172) binds to the iron export channel ferroportin on the outer basolateral surface of gut enterocytes and the plasma membrane of reticuloendothelial cells (macrophages). By inhibiting ferroportin, hepcidin prevents iron entry into the hepatic portal system, thereby reducing dietary iron absorption and maintaining plasma iron concentrations in humans at 10-30  $\mu\text{M}$ . Hepcidin is first expressed as its 84-residue pre-prohormone, which is processed into a 60-residue prohormone, and ultimately to the active 25-residue hormone. Hepatic hepcidin synthesis is transcriptionally regulated by extracellular and intracellular iron concentrations through a molecular complex of bone morphogenetic protein receptors and their iron-specific ligands, modulators and iron sensors. The hepcidin-ferroportin axis controls both extracellular iron concentrations and total body iron levels. It limits the size of the extracellular iron pool by binding ferroportin and mediating its degradation, thus preventing iron release from intracellular sources. 1. Richardson (2005) *Curr. Med. Chem.* **12**, 2711. 2. Ganz & Nemeth (2012) *Biochim. Biophys. Acta* **823**, 1434.

### D-manno-2-Heptulose

This seven-carbon reducing monosaccharide (FW = 210.18 g/mol), most often isolated from the pulp of the avocado (1), is soluble in water and has a melting point of 151-152°C. More than 99% of the sugar is in the  $\alpha$ -pyranose form at 22°C. **Target(s):** glucokinase (2,6); ketohexokinase, hepatic fructokinase, also as an alternative substrate (3); mannokinase, also as a weak alternative substrate (4); hexokinase (5). 1. ### 2-n-Heptyl-4-hydroxyquinoline-N-oxide

This quinoline derivative (FW = 259.35 g/mol; Stock solutions prepared in 10 mM NaOH), often abbreviated HQNO and HOQNO, and also known as 2 heptyl-4-quinolinol 1-oxide, inhibits NADH and succinate oxidation and mitochondrial electron transport (at cytochrome  $bc_1$  (1-5)). It also inhibits

chloroplast electron transport (6). HQNO is also a streptomycin antagonist (7,8). **Target(s):** cytochrome  $d$  complex (9); cytochrome  $o$ -type oxidase (9-13); electron transport, chloroplast, and photosynthetic phosphorylation (6,14); electron transport, mitochondrial (2-5,7,15-19); hydrogen:quinone oxidoreductase (30); 5-lipoxygenase, or arachidonate 5-lipoxygenase (20); menaquinol oxidase21; methane monooxygenase (22); NADH dehydrogenase (1,15,23); plastoquinol:plastocyanin reductase (31); sulfur reductase (24); taurine dehydrogenase (25); ubiquinol:cytochrome- $c$  reductase (Complex III) (2-4,18,19,26-28,32-34); ubiquinol oxidase, *Escherichia coli* (29). 1. ### Herbimycin A

This ansamycin-class macrocyclic antibiotic (FW = 574.67 g/mol; CAS 70563-58-5; photosensitive; hygroscopic) was first isolated from species of *Streptomyces* (e.g., *S. Hygroscopicus*). In view of its ability to bind to and inhibit Hsp90, treatment of cells with herbimycin A activates a heat shock response, even in the absence of heat shock. Pretreatment of cells with the Hsp90 inhibitors also delayed the rate of restoration of normal protein synthesis following a brief heat shock. Herbimycin also selectively inactivates cytoplasmic tyrosine kinases by reacting irreversibly with the reactive SH group(s) and blocking ATP access to the active site. It profoundly decreases the total cellular activity of transmembrane tyrosine kinase receptors (including insulin-like growth factor, insulin, and epidermal growth factor receptors). This enhanced degradation is prevented by inhibitors of the 20S proteasome, whereas neither lysosomotropic agents nor general serine- and cysteine-protease inhibitors prevent receptor degradation. Herbimycin also inhibits p60v-src (IC<sub>50</sub> = 12  $\mu\text{M}$ ) and PDGF-induced ([platelet-derived growth factor]-induced) phospholipase D activation (IC<sub>50</sub> = 8  $\mu\text{g/mL}$ ). It is also reported to inhibit c-src related bone resorption (IC<sub>50</sub> = 70 nM). (See also Geldanamycin, Radicol, Deguelin, Derrubone, Macbecin) 1. Sepp-Lorenzino, Ma, Lebwohl, Venitsky & Rosen

### Heroin

This often highly abused morphine derivative (FW = 369.41 g/mol; CAS 561-27-3), also known diacetylmorphine, morphine diacetate or diamorphine, is an opioid analgesic that is only occasionally administered in the U.S. and regularly in the UK (by subcutaneous, intramuscular, intrathecal or intravenous routes) for the treatment for acute pain associated with myocardial infarction, post-surgical pain as well as chronic pain, especially that associated with certain end-stage cancers. **Pharmacokinetics** Once within circulation, heroin is rapidly hydrolyzed to monoacetylmorphine by serum cholinesterase (EC 3.1.1.8), or acylcholine acylhydrolase, or butyrylcholine esterase (See Morphine). The kinetics for 6-monoacetylmorphine formation coincide with the period over which users report experiencing a "rush", meaning an acute sense of a transcendent state of euphoria. Blood heroin and 6-acetylmorphine reach their maximal concentrations within minutes and are cleared rapidly. Upon intravenous injection or infusion, the mean half-life of heroin is only 3 min, and the mean clearance rate for heroin from the blood at apparent steady-state is 31 mL per kilogram of body weight per minute (1). Morphine levels rise more gradually, and morphine is cleared much more slowly. Oral administration of heroin results in measurable blood levels of morphine but not of heroin or 6-acetylmorphine. **Addictive Power:** Words alone cannot convey heroin's extreme addictiveness. The relative potency of heroin and its active metabolites (e.g., 6-acetylmorphine and morphine) in lowering the threshold for reward stimulation of the medial forebrain bundle and raising the threshold for aversive stimulation of the mesencephalic reticular formation. Heroin is some 40-times more potent than morphine in lowering the reward threshold and approximately 6.5x more potent in raising the escape threshold (2). 6-Acetylmorphine and heroin were approximately equipotent in producing significant effects on the threshold in both rewarding and aversive brain stimulation. **1.** Inturrisi, Max, Foley, *et al.* (1984) *New Engl. J. Med.* **310**, 1213. **2.** Hubner & Kornetsky (1992) *J. Pharmacol. Exp. Ther.* **260**, 562.

### Hesperadin

This ATP-competitive Aurora kinase inhibitor (FW = 553.12 g/mol; CAS 422513-13-1; Solubility: 100 mM in DMSO; Desiccate at Room Temperature), also named *N*-[2,3-dihydro-2-oxo-3-[(3*Z*)-phenyl][4-(1-piperidinylmethyl)phenyl]amino]methylene]-1*H*-indol-5-yl]ethanesulfonamide hydrochloride, targets Aurora B kinase (IC<sub>50</sub> = 250 nM), blocking an inhibitor of chromosome alignment and segregation (1). Mammalian cells

treated with Hesperadin enter anaphase in the presence of numerous monooriented chromosomes, many of which may have both sister kinetochores attached to one spindle pole (syntelic attachment). Hesperadin also causes cells arrested by taxol or monastrol to enter anaphase within <1 h, whereas cells in nocodazole stay arrested for 3-5 h. Such findings suggest that Aurora B is required to generate unattached kinetochores on monooriented chromosomes, which in turn could promote bipolar attachment as well as maintain checkpoint signaling (1). (See **similarly-sounding flavanones Hesperetin; Hesperidin**) **1.** Hauf, Cole, LaTerra, *et al.* (2003) *J. Cell Biol.* **161**, 281.

### Hesperetin

This flavanone (FW = 302.28 g/mol; CAS 520-33-2), also known as 3',5,7-trihydroxy-4-methoxyflavanone, is a potent antioxidant that is particularly effective against peroxynitrite. Hesperetin stimulates muscle phosphorylase kinase and is also demethylated by CYP1A1 and CYP1B1. (See **similarly-sounding flavanone Hesperidin; also similarly-sounding Aurora Kinase inhibitor Hesperadin**) **Target(s):** acid phosphatase, plant (1); aromatase, or CYP19 (2); 3',5'-cyclic-nucleotide phosphodiesterase (3); estrone sulfotransferase (4); fatty-acid synthase (5); flavanone 7-*O*-glucoside 2''-*O*-β-L-rhamnosyltransferase (6); 15-lipoxygenase, or arachidonate 15-lipoxygenase (7); phenol sulfotransferase (4); phosphodiesterase- 4 (3); xanthine oxidase (8). **1.** Axelrod (1947) *J. Biol. Chem.* **167**, 57. **2.** Jeong, Shin, Kim & Pezzuto (1999) *Arch. Pharm. Res.* **22**, 309. **3.** Ko, Shih, Lai, Chen & Huang (2004) *Biochem. ### Hesperidin

This flavone glycoside (FW = 610.57 g/mol), also known as cerantin, is abundant in lemons and sweet oranges (e.g., approximately 8% of the dry weight of orange peel is hesperidin). Upon ingestion, hesperidin releases its aglycone, hesperetin (See Hesperetin; See also **similarly-sounding Aurora Kinase inhibitor Hesperadin**), which induces heme oxygenase. **Target(s):** Cyclooxygenase (1); β-glucuronidase, weakly inhibited (2); hyaluronidase, inhibited by acetylated, sulfonated, or phosphorylated hesperidin (3); lipase, or triacylglycerol lipase (4); 15-lipoxygenase, soybean (5); [myosin light-chain] kinase (6); nitric-oxide synthase (1); tyrosinase, or monophenol monooxygenase (7); xanthine oxidase, mildly inhibited, also inhibited by phosphorylated hesperidin (8). **1.** Sakata, Hirose, Qiao, Tanaka & Mori (2003) *Cancer Lett.* **199**, 139. **2.** Rodney, Swanson, Wheeler, Smith & Worrel (1950) *J. ## Heteropodatoxins

DCGTIWHYCGTDQSECCEGWKCSRQLCKYVIDW  
Heteropodatoxin-1

DDCGKLFSGCDTNADCCCEGYVCRWLWCKLDW  
Heteropodatoxin-2

ECGTLFSGCSTHADCCCEGFICKLWCRYERTW  
Heteropodatoxin-3

These oligopeptides (Heteropodatoxin-1:  $FW_{H1} = 3917.41$  g/mol;  $FW_{H2} = 3419.85$  g/mol; Heteropodatoxin-3:  $FW_{H3} = 3606.11$  g/mol) from venom of the spider *Heteropoda venatoria* inhibit Kv4.x potassium channels.

**Target(s):** Ito1 (transient outer current; inhibited by heteropodatoxin-3 (1,2); potassium channel Kv4.x, inhibited by heteropodatoxins-1,-2, and -3 (2-4). 1. Himmel, Wettwer, Q. Li & U. Ravens (1999) *Amer. J. Physiol.* **277**, H107. 2. Sanguinetti, Johnson, Hammerland, *et al.* (1997) *Mol. Pharmacol.* **51**, 491. 3. Ramakers & Storm (2002) *Proc. Natl. Acad. Sci. U.S.A.* **99**, 10144. 4. Wang, Cheng, Tandan, *et al.* (2006) *J. Cardiovasc. Electrophysiol.* **17**, 298.

## Hexachlorobiphenyls

These polychlorinated aromatics ( $FW = 360.88$  g/mol), of which there are many isomer forms, are highly stable industrial chemicals that exert harmful effects on the environment. Their lipophilicity assures that they will readily penetrate tissues and will concentrate in fat-rich tissues and organs.

**CAUTION:** PCB exposure gives rise to liver damage, nausea, jaundice, and decreased birth weight in the children of exposed pregnant women. Great care should be exercised in handling these and related compounds. Although some inhibitory targets are listed here, use of PCBs as metabolic inhibitors should be avoided. There are many better and safer alternatives.

**Target(s):** L-aromatic amino acid decarboxylase (1); glycogen phosphorylase *a* and *b* (2); Ah receptor (3); uroporphyrinogen decarboxylase (4). 1. Aarts, Denison, Cox, *et al.* (1995) *Eur. J. Pharmacol.* **293**, 463. 2. Kawanishi, Seki & Sano (1983) *J. Biol. Chem.* **258**, 4285. 3. Angus, Mousa, Vargas, *et al.* (1997) *Neurotoxicology* **18**, 857. 4. Mead, Hart & Gamble (1982) *Biochim. Biophys. Acta* **701**, 173.

## Hexachlorophene

This hexachlorinated bisphenol ( $FW = 406.91$  g/mol; CAS 70-30-4), also known as 2,2'-methylenebis(3,4,6-trichlorophenol), is used as a disinfectant and flukicide. Because neurotoxic effects can occur upon hexachlorophene overexposure, wider use of this disinfectant was abandoned in the 1970s. In rats, the oral  $LD_{50}$  is ~60 mg/kg, further evidence that it is relatively toxic.

**Target(s):** acetylcholinesterase (1,2); adenylate cyclase (3); ATPase (3); chitin synthase (4); 3CL protease (5); cystathionine  $\beta$ -synthase, or serine sulfhydrylase (6-8); enoyl-[acyl-carrier protein] reductase (9,10); glucose-6-phosphate dehydrogenase (11); glutathione *S*-transferase (12); homocysteine desulfhydrylase (6); 3-oxoacyl-[acyl-carrier-protein] reductase (13); succinate dehydrogenase (14). 1. 3-[[*cis,cis*-7,10-Hexadecadienyl]-4-hydroxy-2-butenolide

This synthetic monoalide analogue ( $FW = 320.47$  g/mol) inhibits lysophospholipase and phospholipase  $A_2$ . The closed and open forms of the  $\alpha,\beta$ -unsaturated  $\gamma$ -lactone ring are in rapid equilibrium over the pH range from 4 to 9, with the cyclic form preferred at acidic pH values and the open *cis* form preferred at pH 9.5. When the pH is raised above 12, the  $\alpha,\beta$  double bond isomerizes to form the *trans* butenolide. This *trans* isomer is stable at all pH values and does not recyclize to the  $\gamma$ -lactone ring.

**Target(s):** lysophospholipase (1); phospholipase  $A_2$  (2). 1. Zhang & Dennis (1988) *J. Biol. Chem.* **263**, 9965. 2. Deems, Lombardo, Morgan, Mihelich & Dennis (1987) *Biochim. Biophys. Acta* **917**, 258.

## Hexadecylsulfonyl Fluoride

This long-chain alkyl sulfonyl fluoride ( $FW = 308.50$  g/mol), also known as hexadecanesulfonyl fluoride and cetyl sulfonyl fluoride, is an active-site directed irreversible inhibitor of a number of serine esterases. **Target(s):** acylglycerol lipase, or monoacylglycerol lipase (1-3); lipase, or triacylglycerol lipase (4,5); lipoprotein lipase (6-8); palmitoyl-protein thioesterase (9); phospholipase A, *Escherichia coli* (10,11). 1. Dinh, Freund & Piomelli (2002) *Chem. Phys. Lipids* **121**, 149. 2. Dinh, Carpenter, Leslie, *et al.* (2002) *Proc. Natl. Acad. Sci. U.S.A.* **99**, 10819. 3. 1-Hexadecyl-3-trifluoroethylglycero-*sn*-2-phosphomethanol

This highly selective phospholipase inhibitor ( $FW = 493.50$  g/mol (lithium salt)), also known as MJ33, targets Type-1B phospholipase  $A_2$  (1-7) as well as 1-Cys peroxiredoxin (1). nt. MJ 33 has poor affinity for the Type II human synovial PLA $_2$  and has only moderate affinity toward macrophage lysosomal PLA $_2$ . 1. Chen, Dodia, Feinstein, Jain & Fisher (2000) *J. Biol. Chem.* **275**, 28421. 2. Jain, Tao, Rogers, *et al.* (1991) *Biochemistry* **30**, 10256. 3. Sekar, Eswaramoorthy, Jain & Sundaralingam (1997) *Biochemistry* **36**, 14186. 4. ### 1-Hexanol

This primary alcohol (FW = 102.18 g/mol; M.P. = -51.6°C; B.P. = 157.5 °C), also known as *n*-hexyl alcohol, is a component of naturally occurring esters in certain fruits and seeds. **Target(s):** aryldialkylphosphatase, *or* paraoxonase, *or* arylesterase (1); arylesterase (1); bacterial luciferase, alkanal monooxygenase (FMN-linked),  $K_i = 0.369$  mM (2); choline transport (3); cutinase (4); cytochrome *c* oxidase (5); diacylglycerol *O*-acyltransferase (6); esterase (7); firefly luciferase, *or* *Photinus*-luciferin 4-monooxygenase (8); glutaconyl-CoA decarboxylase (9); leucyl aminopeptidase (10,11); *N*-methyl-D-aspartate (NMDA) receptor (12); oxidative phosphorylation, uncoupling (13); peroxidase, horseradish (14); protein kinase C (15); pyroglutamyl-peptidase I (16). 1. Debord, Dantoine, Bollinger, *et al.* (1998) *Chem. Biol. Interact.* **113**, 105. 2. Curry, Lieb & Franks (1990) *Biochemistry* **29**, 4641. 3. Deves & Krupka (1990) *Biochim. Biophys. Acta* **1030**, 32. 4. Maeda, Yamagata, Abe, *et al.* (2005) *Appl. Microbiol. Biotechnol.* **67**, 778. 5. Hasinoff & Davey (1989) *Biochem. J.* **258**, 101. 6. Coleman & Bell (1976) *J. Biol. ### Hexathionine Sulfoximine & Hexathionine Sulfoximine Phosphate

These derivatives (FW<sub>Hsx</sub> = 250.36 g/mol; FW<sub>Hsx-P</sub> = 330.34 g/mol) are tightly bound mechanism-based *reversible* inhibitors of  $\gamma$ -glutamylcysteine synthetase, which catalyzes the first step in glutathione biosynthesis. By mimicking the tetrahedral reaction intermediate, hexathionine sulfoximine is held firmly within the active site of glutamylcysteine synthetase. In contrast to buthionine sulfoximine, however, hexathionine sulfoximine causes substantial depletion of mitochondrial GSH. Hexathionine sulfoximine most likely perturbs mitochondrial membranes in such a way as to facilitate loss of GSH. Significantly, hexathionine sulfoximine produces substantial toxicity, whereas buthionine sulfoximine is relatively nontoxic and does not produce extensive loss of mitochondrial GSH (See also *Buthionine Sulfoximine*) **Target(s):**  $\gamma$ -glutamylcysteine synthetase (1,2). 1. Seelig & Meister (1985) *Meth. Enzymol.* **113**, 379. 2. Griffith (1987) *Meth. Enzymol.* **143**, 286.

### Hexestrol

This diphenol (FW = 270.37 g/mol; CAS 5776-72-7), also known as dihydrodiethylstilbestrol and *meso*-3,4-bis(*p*-hydroxyphenyl) *n*-hexane, is a synthetic nonsteroidal estrogen. **Target(s):** ATPase (1,2); Ca<sup>2+</sup>-transporting ATPase (3); 3 $\alpha$ -hydroxysteroid dehydrogenase (4-6); 3-(or 17- $\beta$ -hydroxysteroid dehydrogenase (7-11); 3(20) $\alpha$ -hydroxysteroid dehydrogenase, indanol dehydrogenase (12,13); testosterone 17 $\beta$ -dehydrogenase (6); tyrosinase, monophenol monooxygenase (14); tubulin polymerization (microtubule assembly) (15,16). 1. ### 2-Hexylthioether- $\beta$ , $\gamma$ -methylene-ATP

This nonhydrolyzable ATP analogue (FW = 618.41 g/mol) targets NTPDase 2 (IC<sub>50</sub> = 20  $\mu$ M), an ectonucleotidase catalyzing ATP hydrolysis and forming extracellular ADP, which binds to Type-2 purinergic receptors and controls multiple biological responses. The origin of inhibitor selectivity is its thiohexyl moiety, which is favorably located within a hydrophobic pocket of NTPDase 2, but, when bound to NTPDase 1, is exposed to solvent. 1. Gillerman, Lecka, Simhaev, *et al.* (2014) *J. Med. Chem.* **57**, 5919.

### 5-Hexyne-1,4-diamine

This putrescine analogue (FW<sub>free-base</sub> = 112.17 g/mol; CAS 69355-11-9) is a potent irreversible inhibitor of ornithine decarboxylase. Prolonged incubation with dithiothreitol is ineffective in reactivating the enzyme. Kinetic isotope measurements using 4-deuterio-5-hexyne-1,4-diamine suggest covalent bond formation is rate-limiting. 5-Hexyne-1,4-diamine is also an alternative substrate of monoamine oxidase, producing 4-aminohex-5-ynoate, an irreversible inhibitor of 4-aminobutyrate aminotransferase. 1. Metcalf, Bey, Danzin, *et al.* (1978) *J. Amer. Chem. Soc.* **100**, 2551. 2. Danzin, Jung, Metcalf, Grove & Casara (1979) *Biochem. Pharmacol.* **28**, 627.

### Higenamine

This benzyltetrahydroisoquinoline alkaloid (FW<sub>free-base</sub> = 271.32 g/mol; CAS 5843-65-2 (racemate), 106032-53-5 (R-enantiomer), 22672-77-1 (S-enantiomer)), also known as 1-[(4-hydroxyphenyl)methyl]-1,2,3,4-

tetrahydroisoquinoline-6,7-diol and isolated from the roots of *Aconitum japonicum*, inhibits dihydropteridine reductase. It also mediates cardiotoxic, vascular relaxation and bronchodilator effects. It is also a pharmacologically active metabolite in *Nandina domestica Thunberg*, a plant long known to improve cough and breathing difficulties. Indeed, the isolated agent and chemically pure higenamine have equal potency in relaxing isolated guinea pig trachea (2). This action is the consequence of higenamine's actions as an agonist of  $\alpha_2$  adrenoceptors. Higenamine also inhibits iNOS expression by inhibiting nuclear factor  $\kappa_B$  activation by LPS + IFN- $\gamma$  and may be beneficial in inflammatory diseases in which enhanced formation of NO is the main causative factor (3). Due to its positive inotropic action, higenamine may be more effective in conditions, where myocardial contractility is likely to be depressed, such as in septic shock and/or endotoxin-induced inflammatory disorders (3). It is also a new lead compound for treating erectile dysfunction (4). **1.** Shen, Smith, Davis, Brubaker & Abell (1982) *J. Biol. Chem.* **257**, 7294. **2.** Tsukiyama, Ueki, Yasuda, et al. (2009) *Planta Med.* **75**, 1393. **3.** Kang, Lee, Lee, et al. (1999) *J. Pharmacol. Exp. Ther.* **291**, 314. **4.** Kam, Do, Choi, et al. (2012) *Int. J. Impot. Res.* **24**, 77.

### Himbacine

This alkaloid (FW = 345.53 g/mol; CAS 6879-74-9), also named (3*S*,3*aR*,4*R*,4*aS*,8*aR*,9*aS*)-4-[(1*E*)-2-[(2*R*,6*S*)-1,6-dimethyl-2-piperidinyl]-ethenyl]decahydro-3-methylnaphtho[2,3-*c*]furan-1(3*H*)-one, is a selective antagonist of M<sub>2</sub> and M<sub>4</sub> muscarinic acetylcholine receptors, with lower affinity for M<sub>1</sub> and M<sub>3</sub> forms. Its derivative, SCH 530348, is a thrombin receptor antagonist with potent anticoagulant properties. **1.** Dorje, Wess, Lambrecht, et al. (1991) *J. Pharmacol. Exp. Ther.* **256**, 727. **2.** Gilani & Cobbin (1987) *Arch. Int. Pharmacodyn. Ther.* **290**, 46.

### Hippurate (Hippuric Acid)

This modified amino acid (FW<sub>free-acid</sub> = 179.18 g/mol; CAS 495-69-2; pK<sub>a</sub> = 3.62), also known as *N*-benzoylglycine, can be found in the urine of herbivores and humans. As an oxidation product in toluene metabolism, high circulating levels of hippurate are a useful index of toluene toxicity.

**Target(s):** acetylcholinesterase (1); adenylosuccinate synthetase, weakly inhibited (2);  $\gamma$ -glutamyl transpeptidase, transfer activity (3,4); glycine *N*-acyltransferase, product inhibition (5,6); glycine *N*-benzoyltransferase, product inhibition (5-7); lysine carboxypeptidase, or lysine(arginine) carboxypeptidase, or carboxypeptidase N (8); papain (9); peptidylglycine monooxygenase, also alternative substrate (10). **1.** Bergmann, Wilson & Nachmansohn (1950) *J. Biol. Chem.* **186**, 693. **2.** Jahngen & Rossomando (1984) *Arch. Biochem. Biophys.* **229**, 145. **3.** Gardell & Tate (1983) *J. Biol. Chem.* **258**, 6198. **4.** Thompson & Meister (1979) *J. Chem.* **363**, 51. **9.** Sluyterman (1964) *Biochim. Biophys. Acta* **85**, 316. **10.** Francisco, Blackburn & Klinman (2003) *Biochemistry* **42**, 1813.

### Hirudin

This direct thrombin inhibitor and anticoagulant (MW  $\approx$  7 kDa; Sequence: VVYTDCTESGQNLCLGNSVCGQGKNCILGSDGKNCQCVTGEGTP GPQSHNDGDFEPEEYL; CAS 8001-27-2) from the saliva of the medicinal leech *Hirudo medicinalis* potently inhibits thrombin ( $K_i$  = 0.2

pM) by simultaneously occupying the fibrinogen site and the anionic exosite (1). Hirudin inhibits both free thrombin and fibrin clot-bound thrombin. X-ray structural analysis shows that, while thrombin's active site is blocked by hirudin, none of hirudin's residues are embedded at the S<sub>1</sub> subsite (2,3); its C-terminal residues bind to the fibrinogen's exosite.

**Target(s):** coagulation factor IXa (4); complement component I (5); thrombin (1-4,6-15). **1.** Markwardt (1994) *Thromb. Res.* **74**, 1. **2.** Grütter, Priestle, Rahuel, et al. (1990) *EMBO J.* **9**, 2361. **3.** Rydel, Ravichandran, Tulinsky, et al. (1990) *Science* **249**, 277. **4.** Bagby, Barabas, Gráf, Petersen & Magnusson (1976) *Meth. Enzymol.* **45**, 669. **5.** Tsiptsoglou & Sim (2004) *J. Immunol.* **173**, 367. **6.** Stone & Le Bonniec (1998) in *Handb. Res.* **109** Suppl. 1, S17.

### Hispidin

This naturally occurring pyrone and antioxidant (FW = 246.22 g/mol; CAS 56070-89-4), also known as 6-(3,4-dihydroxystyryl)-4-hydroxy-2-pyrone, is a trypanocide that inhibits protein kinase C $\beta$ , IC<sub>50</sub> = 2  $\mu$ M (1). Hispidin also inhibits  $\beta$ -secretase,  $K_i$  = 8.4  $\mu$ M (1) and prolyl endopeptidase,  $K_i$  = 24  $\mu$ M (1). **1.** Gonindard, Bergonzi, Denier, et al. (1997) *Cell Biol. Toxicol.* **13**, 141. **2.** Park, Jeon, Lee, Kim & Song (2004) *Planta Med.* **70**, 143.

### Histamine

This naturally occurring histidine metabolite (FW<sub>free-base</sub> = 111.15 g/mol; CAS 51-45-6; MP<sub>free-base</sub> = 83-84°C; Soluble in water and ethanol; pK<sub>a</sub> values of 6.04 and 9.75), systematically named 1*H*-imidazole-4-ethanamine, is a potent vasodilator and H<sub>1</sub>, H<sub>2</sub>, H<sub>3</sub>, and H<sub>4</sub> receptor agonist. Most histamine in the body is generated in the granules of mast cells and in basophils and eosinophils. Histamine release occurs when allergens bind to mast-cell-bound IgE antibodies. When released into circulation (or when injected intravenously), histamine causes most blood vessels to dilate, reducing blood pressure. This mechanism is a key process in anaphylaxis.

**Metabolism:** Histamine is formed by decarboxylation of the L-histidine, as catalyzed by the pyridoxal 5-phosphate-dependent histidine decarboxylase (HDC). Histamine is inactivated either by methylation of the imidazole ring, catalyzed by histamine *N*-methyltransferase (HMT) or by oxidative deamination of the primary amino group, catalyzed by diamine oxidase (DAO). Histamine also activates nitric-oxide synthase, causing smooth muscle and playing a role in controlling gastric secretions. Histamine is transported by the organic cation transporter (OCT), the plasma membrane monoamine transporter (PMAT), the vesicular monoamine transporter (VMAT), and the endo/exocytotic uptake/release in/from cellular vesicles or granules. **Histamine Receptors:** The H<sub>1</sub> receptor is a member of the family of Rhodopsin-like G-protein-coupled receptors and is expressed in smooth muscles, on the surface of vascular endothelial cells, as well as in the heart and central nervous system. (See **H<sub>1</sub>-antagonists:** Diphenhydramine; Loratadine; Cetirizine; Fexofenadine; Clemastine) Histamine H<sub>2</sub> receptors are coupled to adenylate cyclase via G<sub>s</sub>, forming CyclicAMP, which in turn activates Protein Kinase A. (See **H<sub>2</sub>-antagonists:** Ranitidine; Cimetidine; Famotidine; Nizatidine) Histamine H<sub>3</sub> receptors are expressed in the CNS and to a lesser extent the peripheral nervous system, where they act as autoreceptors in presynaptic histaminergic neurons. They also control histamine turnover via feedback inhibition of histamine synthesis and release. (See **H<sub>3</sub>-antagonists:** Ciproxifan; Clobenpropit; Thioperamide) Histamine H<sub>4</sub> receptors are highly expressed in bone marrow and white blood cells

(also in colon, liver, lung, small intestine, spleen, testes, thymus, tonsils, and trachea) and regulates neutrophil release from bone marrow. It also acts on the histamine-gated chloride channel, producing fast inhibitory postsynaptic potentials in brain. (See **H<sub>1</sub>-antagonists**: *Thioperamide*; JNJ 7777120) **Target(s)**: amine oxidase, inhibited by elevated histamine concentrations (1); aminoimidazole (2); chitinase (3,4); dipeptidyl-peptidase II (5); fibrin polymerization (6); glutamyl peptide cyclotransferase (7); glycopeptide *N*-tetradecanoyltransferase, or protein *N* myristoyltransferase (21,24); histidine ammonia-lyase (8-10); histidyl-tRNA synthetase (11);  $\beta$ -lactamase (penicillinase) (12); lysozyme (13-15); NAD<sup>+</sup>-diphthamide ADP-ribosyltransferase (16); ornithine decarboxylase (17); poly(ADP-ribose) polymerase (18); protein-glutamine  $\gamma$ -glutamyltransferase (or transglutaminase) (19,20); pyridoxal kinase (22); tryptase (23). 1. ### Histargin

This fungal metabolite (FW = 355.40 g/mol; CAS 93361-66-1), also known as *N*-(2-((4-(amino(imino)methyl)amino)-1(*S*) carboxybutyl)amino) ethyl)-L-histidine, first isolated from a strain of *Streptomyces roseoviridis*, consists of L-histidine and L-arginine, with their  $\alpha$  amino groups linked by an ethylene diamine bridge. **Target(s)**: carboxypeptidase A and B (1,2); lysine carboxypeptidase (lysine(arginine) carboxypeptidase, or carboxypeptidase N (1); neprilysin (3); peptidyl-dipeptidase A, or angiotensin-converting enzyme (1,3,4). 1. ### L-Histidine

This proteogenic amino acid (FW<sub>neutral-species</sub> = 155.16 g/mol; FW<sub>HCl-Salt</sub> = 191.62; CAS 71-00-1; pK<sub>a</sub> values of 1.80 (-COOH), 6.04 (imidazole), and 9.33 (-NH<sub>2</sub>) at 25°C), named systematically as (*S*)-2-amino-3-(1*H*-imidazol-4-yl)propanoic acid and symbolized by His and H, is the source of catalytic imidazole groups in many enzymes. L-Histidine is one of ten essential amino acids in mammals, and its two codons are CAU and CAC. Histidine is a dibasic amino acid that is frequently found on the surface of proteins and, because the imidazole ring has a pK<sub>a</sub> value close to neutrality, often found as a proton acceptor/donor within the active sites of enzymes. They are often found in some  $\alpha$ -helices and are more so in  $\beta$ -pleated sheets. Homologous proteins often have histidyl residues interchanged with asparaginyl or glutaminyl residues. The carbon atom situated between the two nitrogens in the ring can exchange its hydrogen atom slowly with the aqueous solvent. This exchange renders histidyl residues useful probes of protein structure in NMR experiments. Imidazole nitrogen atoms also have an affinity for metal ions and are often associated with iron, zinc, or copper ions. **Target(s)**: acrosin (1); alkaline phosphatase (2-4); alkylglycerol-phosphoethanolamine phospho-diesterase, or lysophospholipase D (5); 2-aminohexano 6-lactam racemase (6,7); 8-amino-7-oxononanoate synthase (8,69,70); aminopeptidase B (9); D-arabinose isomerase, activates in presence of Mn<sup>2+</sup>; inhibits in absence of Mn<sup>2+</sup> or presence of other ions (10); arginine kinase (11,12); argininosuccinate synthetase (13); aspartate aminotransferase (50); ATP phosphoribosyltransferase (14-16,51-67); brachyuran, or *Novoden modestrus* collagenolytic protease (17); catalase (76); DNA nucleotidylexotransferase, or terminal deoxynucleotidyl transferase (18); dopamine  $\beta$  monoxygenase (72,73); L-fucose isomerase, activates in presence of Mn<sup>2+</sup>; inhibits in absence of Mn<sup>2+</sup> or presence of

other ions (10); gametolysin (19,20); gelatinase A, or matrix metalloproteinase-2 (21); gelatinase B, or matrix metalloproteinase-9 (21);  $\alpha$ -glucosidase (22-24); glutamate decarboxylase, weakly inhibited (25); glutamine synthetase (26-31); glutaminyl-peptide cyclotransferase (68);  $\gamma$ -glutamyl transpeptidase (32,33); histidinol-phosphatase (34,35); homoserine kinase (36); iodide peroxidase, or thyroid peroxidase (74); kynureninase (37); microbial collagenase (38,39); ornithine carbamoyltransferase (71); ornithine decarboxylase (40); pancreatic ribonuclease (41); peroxidase (75); phenylalanine ammonia-lyase (42); phosphoprotein phosphatase (43); poly(ADP-ribose) polymerase (44); ribonuclease T<sub>1</sub> (45); L-serine ammonia-lyase, L-serine dehydratase (46); serine:pyruvate aminotransferase (47); *Streptomyces griseus* aminopeptidase (48); *Vibrio* collagenase (49). 1. ### L-Histidinol

This amino alcohol (FW = 141.17 g/mol; CAS 501-28-0), also known as 4-(2-amino-3-hydroxypropyl)imidazole, is an L-histidine precursor that strongly inhibits protein biosynthesis by targeting histidyl-tRNA synthetase,  $K_i = 1.3 \mu\text{M}$  for the *Salmonella typhimurium* enzyme (1-4). Quantitative structure-activity analysis, based on  $K_i$  values from the kinetics of ATP-PP<sub>i</sub> exchange and tRNA aminoacylation, led to the following conclusions: (a) the enzyme is stereospecific in its formation of aminoacyl-tRNA complexes, with D-histidine unable to influence either reaction; (b) the -COOH group is not required for binding, but bulky carboxy derivatives prevent binding to the enzyme; (c) the -NH<sub>2</sub> group is needed for good binding affinity; (d) the length of the side-chain plays a very important role in binding interactions; and (e) the heteroatoms within the five-membered ring also determine the inhibitory properties of L-histidine analogues (4). L-Histidinol has been gainfully employed in X-ray crystallographic studies as a nonreactive histidine analogue for exploring the active sites of Class II aminoacyl-tRNA synthetases. L-Histidinol dehydrogenase (HDH) appears to be essential for the survival of bacteria responsible for brucellosis and tuberculosis, suggesting that HDH-selective histidinol analogues may prove to be therapeutically useful. **Target(s):** glutaminyl-peptide cyclotransferase (5); glycylpeptide *N*-tetradecanoyltransferase, or protein *N*-myristoyltransferase (6,7); histidine ammonia-lyase (8,9); histidine decarboxylase (10); histidinol-phosphatase, weakly as a product inhibitor (11). 1. ### Histogranin

This bioactive pentadecapeptide (FW = 1718.97 g/mol; CAS 150045-04-8; Sequence: MNYALKGQGR<sup>T</sup>LYGF), which co-purifies with bombesin-like immunoreactive peptides from bovine adrenal medulla, is concentrated within the pituitary (5.1 nmol/g) and adrenal glands (0.27 nmol/g), but it is also present in other tissues including the brain (1.6 pmol/g) and blood plasma (24 fmol/ml). A neuropeptide function for the adrenal peptide is suggested by its relative high concentration in chromaffin granules (42 fmol/mg protein as compared with 1 fmol/mg protein in cytosol) and its release from perfused bovine adrenal glands. In rat brain membrane preparations, synthetic histogranin displaces [<sup>3</sup>H]CGP-39653, a specific ligand of *N*-methyl-D-aspartate (NMDA) receptor. The displacement curve was biphasic with IC<sub>50</sub> of 0.6 and 3955 nM, representing 33% and 67% of the binding sites, respectively. Intracerebroventricular (i.c.v.) injection of the peptide (5-100 nmol) in mice produced a dose-dependent protection against NMDA (0.5-1.0 nmol) -induced convulsions but not against (*R,S*)- $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionate (AMPA, 0.25-2.0 nmol), kainate (0.25-0.75 nmol) and bicuculline (1-10 nmol)-induced convulsions. Histogranin has 80% homology with residues 86-100 of histone H4 (2). However, because the structure of histone H4 is highly conserved, it is presumed that histogranin possesses its own precursor and that its gene is distinctly expressed (2). 1. Lemaire, Shukla, Rogers, et al. (1993) *Eur. J. Pharmacol.* **193** **245**, 247. 2. Lemaire, Rogers, Dumont, et al. (1995) *Life Sci.* **56**, 1233.

## HLM 006474

This E2F inhibitor (FW = 399.48 g/mol; CAS 353519-63-8; Soluble to 20 mM in DMSO; IUPAC: 7-[(4-ethoxy-3-methylphenyl)(2-pyridinylamino)methyl]-2-methyl-8-quinolinol), identified by computer-based virtual screen based on the crystal structure of the DNA-bound E2F4/DP2 heterodimer, reduces intracellular E2F4 DNA-binding activity in several cell lines, as measured by electrophoretic mobility shift assay. The E2F/Rb is critical in regulating the initiation of DNA replication, making it a reasonable target for developing chemotherapeutic agents for blocking the mammalian cell cycle. Overnight exposure to HLM006474 results in down-regulation of total E2F4 protein as well as known E2F targets. E2F4-null mouse embryonic fibroblasts are less sensitive than wild-type counterparts to the apoptosis-inducing activity of the compound, revealing its biological specificity. A375 cells, for example, are exquisitely sensitive to the apoptosis-inducing activity of HLM006474 in two-dimensional culture. It is also a potent inhibitor of melanocytes proliferation and subsequent invasion in a three-dimensional tissue culture model system. Importantly, HLM006474 is predicted to make hydrogen bonds with three residues that are absolutely conserved within the E2F family, suggesting that there is no reason to expect that HLM006474 is specific to E2F4 heterodimers. **1.** Ma, Kurtyka, Boyapalle, *et al.* (2008) *Cancer Res.* **68**, 6292.

## HM30181

This P-gp inhibitor (FW = 688.74 g/mol; CAS 849675-66-7 (free base) and 849675-88-3 (hydrochloride)), targets Multi-Drug Resistance-1 (MDR1, ABCB1), also known as P-glycoprotein, thereby increasing the oral bioavailability and efficacy of paclitaxel. HM30181 is the most potent ( $IC_{50} = 0.63$  nM) of several MDR1 inhibitors (including cyclosporin A, XR9576, and GF120918), and blocks ( $IC_{50} = 35$  nM) transepithelial transport of paclitaxel in MDCK monolayers (1). HM30181 does not inhibit MRP1 (ABCC1), MRP2 (ABCC2), and MRP3 (ABCC3), and only partially inhibits BCRP (ABCG2) at nonpharmacological levels (1). In humans, plasma concentrations peak at 14-42 hours and decline with  $t_{1/2}$  of 76-169 hours after single administration; however, after multiple administrations peaks at 5.5-8 hours and declines with  $t_{1/2}$  of 150-220 hours (2). After single administration,  $C_{max}$  and  $AUC_T$  (*i.e.*, area under the concentration curve within dosing intervals) increase in a dose-dependent manner; however, after multiple administrations,  $C_{max}$  and  $AUC_T$  dose-dependent increases were not observed (2). HM30181 does inhibit Pgp at the murine blood-brain barrier at clinically feasible doses, making [ $^{14}C$ ]-HM30181 unsuitable as a PET tracer for visualise cerebral Pgp expression levels (3). **1.** Kwak, Lee, Lee, *et al.* (2010) *Eur. J. Pharmacol.* **627**, 92. **2.** Kim, Gu, Yoon, *et al.* (2012) *Clin. Ther.* **34**, 482. **3.** Bauer, Wanek, Mairinger, *et al.* (2012) *Eur. J. Pharmacol.* **696**, 18.

## HMN-214

This protein kinase inhibitor (FW<sub>free-acid</sub> = 543.60 g/mol; CAS 173529-46-9; Solubility: 12 mg/mL DMSO; <1 mg/mL Water), also known as VX-214 and systematically as 5-(6-((4-methylpiperazin-1-yl)methyl)-1H-benzo[d]imidazol-1-yl)-3-((R)-1-(2-(trifluoromethyl)-phenyl)-ethoxy)-thiophene-2-carboxamide, targets the Polo-like kinase Plk1 ( $IC_{50} = 118$  nM), bringing about G<sub>2</sub>/M cell-cycle arrest and cell death. RNA silencing of WT p53 increases the antiproliferative activity of HMN-214, suggesting that cancers with defective p53 would likewise be sensitive to co-administration of HMN-214 and DNA-damaging drugs. **1.** Takagi, *et al.* (2003) *Invest. New Drugs*, **21**, 387. **2.** Tanaka, *et al.* (2003) *Cancer Res.* **63**, 6942. **2.** DiMaio, *et al.* (2009) *Mol. Cancer Ther.* **8**, 592.

HMR-1275, See *Flavopiridol*

## HMR 1556

This potent channel blocker (FW = 411.44 g/mol; CAS 223749-46-0; Solubility: 100 mM in DMSO), also named *N*-[(3*R*,4*S*)-3,4-Dihydro-3-hydroxy-2,2-dimethyl-6-(4,4,4-trifluorobutoxy)-2*H*-1-benzopyran-4-yl]-*N*-methylmethanesulfonamide, targets the slowly activating, delayed I<sub>Ks</sub> rectifier potassium current ( $IC_{50} = 10.5$  and 34 nM, respectively, in canine and guinea pig ventricular myocytes). HMR-1556 selectively inhibits I<sub>Ks</sub> currents over I<sub>Kr</sub>, I<sub>K1</sub>, I<sub>to</sub> and L-type Ca<sup>2+</sup> channel currents, with little or no effect on K<sub>v</sub>11.1, K<sub>v</sub>1.5, K<sub>v</sub>1.3, K<sub>v</sub>2.1 and HCN2 channel currents (1,2). While HMR1556 alone does not cause Torsade de pointes (TdP), a polymorphic ventricular tachycardia commonly associated with prolongation of the QT interval in ECGs, it does increase E-4031-induced TdP from 25 to 80% (3). **1.** Gerlach, Brendel, Lang, *et al.* (2001) *J. Med. Chem.* **44**, 3831. **2.** Thomas, Gerlach, & Antzelevitch (2003) *J. Cardiovasc. Pharmacol.* **41**, 140. **3.** Michael, Dempster, Kane & Coker (2007) *Brit. J. Pharmacol.* **152**, 1215.

## HO-3867

This curcumin-like synthetic antioxidant (FW = 468.59 g/mol), also named 1-[(1-oxyl-2,2,5,5-tetramethyl-2,5-dihydro-1*H*-pyrrol-3-yl)methyl]-(3*E*,5*E*)-3,5-bis(4-fluorobenzylidene)piperidin-4-one, exhibits potent anticancer

efficacy towards human ovarian cancer cells and xenograft tumors, while exhibiting substantially lower toxicity towards noncancerous cells. In aerated solutions and cells, HO-3867 induced G<sub>2</sub>/M cell-cycle arrest in A2780 cells as evidenced by a significant increase in the p53, p21, and p27 protein levels, but also a significant reduction in Cdk2 and cyclin A levels (1). HO-3867-mediated downregulation of *STAT3* gene expression, in both *in vitro* and *in vivo*, as a putative mechanism for increased Fas/CD95 expression. This is obvious from the substantial decrease in the level of Tyr705-phosphorylated STAT3, a major active form of activated STAT3. It is noteworthy that the expression level of Ser727-phosphorylated STAT3 was also clearly decreased *in vivo* (1). Ser727 phosphorylation is known to regulate the transcriptional activity of STAT3, and the attenuated phosphorylation is likely to account for the down-regulated transcriptional activity of STAT3 in the xenograft tumor treated with HO-3867. This agent also causes substantial inhibition of phospho-JAK1 (Tyr-1022/1023), suggesting it also inhibits constitutive activation of STAT3, which may be caused, at least in part, by pJAK1 inhibition. Depending on cell type, HO-3867 is also likely to inhibit STAT3 activation through JAK2, Src, Erb2, and EGFR, which are known to be implicated in STAT3 activation as well (1). Notably, the DAP compound HO-3867 selectively inhibited STAT3 phosphorylation, transcription and DNA binding without affecting the expression of other active STATs (2). Pharmacological analysis revealed higher bioabsorption/bioavailability of the active (cytotoxic) metabolites by cancer cells compared to normal cells. The selective cytotoxicity of HO-3867 appeared to be multifaceted, eliciting differential activation of the Akt pathway in normal versus cancer cells. RNAi attenuation experiments confirmed the requirement of STAT3 for HO-3867-mediated apoptosis in ovarian cancer cells. 1. Selvendiran, Tong, Bratasz, *et al.* (2010) *Mol. Cancer Ther.* **9**, 1169. 2. Rath, Naidu, Lata, *et al.* (2014) *Cancer Res.* **74**, 2316.

#### HOE-140

This peptidomimetic (FW = 1304.52 g/mol; Systematic Name: D-arginyl-L-arginyl-L-prolyl-(*trans*-4-hydroxy)-L-prolyl-glycyl-3-(2-thienyl)-L-alanyl-L-seryl-D-1,2,3,4-tetrahydro-3-isoquinolinecarboxyl-L-(2 $\alpha$ ,3 $\beta$ ,7 $\alpha$ )-octahydro-1*H*-indole-2-carboxyl-L-arginine), is a selective and longlasting B<sub>2</sub> bradykinin receptor antagonist, IC<sub>50</sub> = 1 nM (1-3). Deletion of its C-terminal L-arg residue yields a potent B<sub>2</sub> bradykinin receptor antagonist (4,5). (**For its cyclized form, see MEN 11270**) 1. Hock, Wirth, Albus, *et al.* (1991) *Brit. #### L-Homocysteic Acid

This oxidized L-homocysteine metabolite (FW = 183.18 g/mol; CAS 1001-13-4; Abbreviation: L-HCA) is an L-glutamate analogue that inhibits a number of glutamate-dependent reactions, including the glutamate:cystine transport system. L-HCA occurs naturally in the mammalian CNS and is released from K<sup>+</sup>-stimulated brain slices in a calcium-dependent manner. L-HCA is present in nerve terminals located in brain regions having a high density of NMDA receptors. L-HCA also appears to be an endogenous excitotoxic ligand at NMDA receptors. With the hypothesis that a high homocysteic acid level is a brain biomarker in Alzheimer's Disease brain and that increased levels may induce the accumulation of intraneuronal amyloid- $\beta$  peptides, a recent study demonstrated a neuroprotective effect by anti-homocysteic acid antibodies in 3xTg-AD mouse model (1). Homocysteic acid is also an alternative substrate for folylpoly- $\gamma$ -glutamate synthetase, and homocysteate is likely to prevent the incorporation of additional glutamate moieties, thereby reducing intracellular folate retention. **Note:** D-Homocysteic acid (CAS 56892-03-6) is likely to be a useful experimental control or reference molecule when probing the stereoselectivity of L-homocysteic acid. **Target(s)**: acetylserotonin O-methyltransferase, *or* hydroxyindole O-methyltransferase (2); glutamate dehydrogenase (3); glutamate synthase (4);  $\gamma$ -glutamyl transpeptidase, *or*  $\gamma$ -glutamyltransferase; inhibited by the DL-mixture, K<sub>i</sub> = 11 mM (5); kynurenine:oxoglutarate aminotransferase (6); methionine  $\gamma$ -lyase (7); methylaspartate mutase, *or* glutamate mutase (8); Na<sup>+</sup>-dependent L-glutamate:L-cystine antiport exchanger (9); serine-sulfate ammonia-lyase, weakly inhibited by DL-mixture (10); sulfinoalanine decarboxylase, *or* cysteinesulfinate decarboxylase (11); tetrahydrofolate synthetase, chain termination inhibitor (12,13); UDP-N-acetylmuramoylalanine:D-glutamate

ligase, inhibited by the DL-mixture; also an alternative substrate (14). 1. Hasegawa, Mikoda, Kitazawa & LaFerla (2010) *PLoS ONE* **5**, e8593. 2. Karahasanoglu & Ozand (1972) *J. ### L-Homocysteine

This nonproteogenic thiol-containing L-amino acid (FW = 135.19 g/mol; CAS 6027-13-0; Symbol = Hcy;  $pK_a$  are 2.22 (–COOH), 8.87 (–SH), and 10.86 (–NH<sub>3</sub><sup>+</sup>) is a key intermediate in methionine metabolism as well as a proximal precursor in cysteine biosynthesis. Homocysteine is readily oxidized to homocystine. Homocystine thiolactone forms within a few minutes in hot 20% HCl. **Target(s):** adenosylhomocysteinase (1-5); adenylylsulfatase (6); 1-aminocyclopropane-1 carboxylate synthase (7); 5-aminolevulinatase aminotransferase (8,9,33); butyrylcholinesterase (10,11); carbamoyl-phosphate synthetase (12,13); catechol *O* methyltransferase (41); L-3-cyanoalanine synthase (14); cyclooxygenase (15); cystathionine β-lyase (16,17); cystathionine γ-lyase, *or* cysteine desulfhydrase (18); cystathionine γ-synthase (34); cysteine synthase, *or* *O*-acetylserine sulfhydrylase (16); cysteinyl-tRNA synthetase (19,20); cystine lyase (17); gelatinase A, *or* matrix metalloproteinase 2 (21); gelatinase B, *or* matrix metalloproteinase 9 (21); glutathione peroxidase (22,42); histidine ammonia-lyase (23); homoserine *O*-acetyltransferase (35); homoserine kinase (24); K<sup>+</sup> channels (25); methionine adenosyltransferase (26); methionyl-tRNA synthetase (27); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (10,28); serine *O*-acetyltransferase, weakly inhibited (36-38); L-serine ammonia-lyase, *or* L-serine dehydratase (29,30); *O*-succinylhomoserine (thiol)-lyase (31); thiopurine *S*-methyltransferase (39); tRNA (guanine-*N*<sup>2</sup>-)-methyltransferase, weakly inhibited (40); tyrosine decarboxylase (32). 1. ### Homogentisic Acid

This metabolite (FW<sub>free-acid</sub> = 168.15 g/mol; CAS 451-13-8), also known as 2,5-dihydroxyphenylacetate, is an intermediate in the degradation of phenylalanine and tyrosine. Note that homogentisate will slowly oxidize to its quinone upon standing, particularly in alkaline pH, and this quinone will polymerize to produce a dark colored polymer. Alcaptonuria is an inborn error in metabolism in which there is a deficiency of homogentisate 1,2-dioxygenase and this dark polymer can be seen in the urine of individuals having this disorder. In addition, homogentisate can readily form the lactone (*i.e.*, 5-hydroxy-2-oxocoumaran). **Target(s):** imidazoleacetate 4-monooxygenase (1); tyrosine aminotransferase (2,3). 1. Watanabe, Kambe, Imamura, *et al.* (1983) *Anal. Biochem.* **130**, 321. 2. Ohisalo, Andersson & Pispala (1977) *Biochem. J.* **163**, 411. 3. Schepartz (1970) *Enzymologia* **39**, 211.

### Homoharringtonine

This toxic alkaloid (FW = 545.63 g/mol; CAS 26833-87-4), isolated from *Cephalotaxus hainanensisanti*, is an anticancer agent that has been used to treat acute or chronic myeloid leukemia. Homoharringtonine inhibits protein biosynthesis by blocking chain elongation. (See also Harringtonine) 1. Tujebajeva, Graifer, Matasova, *et al.* (1992) *Biochim. Biophys. Acta* **1129**, 177. 2. Tujebajeva, Graifer, Karpova & Ajtkhozina (1989) *FEBS Lett.* **257**, 254. 3. Fresno, Jimenez & Vazquez (1977) *Eur. J. Biochem.* **72**, 323.

### Homoserine

This γ-hydroxy amino acid (FW = 119.12 g/mol; CAS 672-15-1), a component in the antibiotics tolaasin and syringostatin, is an intermediate in the biosynthesis of L-threonine, L-methionine, and cystathionine. It is also the principal free amino acid in pea plants. Homoserine converts to the lactone upon standing at room temperature under acidic conditions. Solutions should always be freshly prepared. **Target(s):** *O*-acetylhomoserine aminocarboxypropyltransferase, *or* *O*-acetylhomoserine sulfhydrylase (1-4); *O*-acetylserine/*O*-acetylhomoserine sulfhydrylase (5); 1-aminocyclopropane-1 carboxylate deaminase (6,7); asparagine:oxo-acid aminotransferase (8,9); aspartate kinase (10); cystathionine γ-lyase (11);

cysteine synthase (12,13); dihydrodipicolinate synthase, weakly inhibited by the L-enantiomer (14); diphosphate:serine phosphotransferase (15); hemoglobin S polymerization (16,17); hydroxylysine kinase (18); kynureninase, weakly inhibited by racemic mixture (19); methionine adenosyltransferase (20); methionine  $\gamma$ -lyase (21); methionyl-tRNA synthetase (22); muramoyltetrapeptide carboxy-peptidase, inhibited by D-homoserine,  $K_i = 43$  mM (23); serine O-acetyltransferase, weakly inhibited (24,25); serine-phosphoethanolamine synthase (26); thetin:homocysteine methyltransferase, inhibited by the racemic mixture (27,28); threonine ammonia-lyase, or threonine dehydratase (29). 1. #### trans-HR22C16

This cell-permeable, non-tubulin-interacting mitotic inhibitor (FW = 389.46 g/mol; CAS 462630-41-7) blocks mitosis ( $IC_{50} = 800$  nM) by binding to Eg5, a mitotic kinesin motor protein that plays an essential role in centrosome separation and formation of bipolar mitotic spindles. HR22C16 inhibits cell survival in both Taxol-sensitive and -resistant ovarian cancer cells with at least 15-fold greater efficacy than monastrol, the first generation Eg5 inhibitor (2). 1. Hotha, Yarrow, Yang, et al. (2003) *Angew. Chem. Int. Ed. Engl.* **42**, 2379. 2. Marcus, Peters, Thomas, et al. (2005) *J. Biol. Chem.* **280**, 11569.

#### HS-173

This potent PI3K $\alpha$  inhibitor (FW = 422.26 g/mol; CAS 1276110-06-5; Solubility: 80  $\mu$ g/mL DMSO, with warming; <1  $\mu$ g/mL H<sub>2</sub>O), also named ethyl-6-(5-(phenylsulfonamido)pyridin-3-yl)imidazo[1,2-a]pyridine-3-carboxylate, targets phosphatidylinositol 3-kinase  $\alpha$  ( $IC_{50} = 0.8$  nM), a cell proliferation, growth, and survival signaling kinase is hyperactive in a wide variety of human cancers. HS-173 induces cell cycle arrest at the G<sub>2</sub>/M phase as well as apoptosis (1). It also decreases the expression HIF-1 $\alpha$  and VEGF, key factors in angiogenesis, evidenced by suppression of capillary tube formation and migration *in vitro* (1). Combined treatment of Panc-1 cells with HS-173 and Sorafenib synergistically inhibits viability, again with G<sub>2</sub>/M arrest and apoptosis (2). 1. Lee, Jung, Jeong, Hong & Hong (2013) *Cancer Lett.* **328**, 152. 2. Yun, et al. (2013) *Cancer Lett.* **331**, 250. 3. Son, et al. (2013) *Sci. Rep.* **3**, 3470.

#### HTH 01-015

This NUA K1 inhibitor (FW = 468.55 g/mol; CAS 1613724-42-7; Solubility: 100 mM in DMSO), systematically named 5,13-dihydro-4,5,13-trimethyl-2-[[1-(4-piperidinyl)-1H-pyrazol-4-yl]-amino]-6H-naphtho[2,3-e]pyrimido[5,4-b][1,4]diazepin-6-one, targets the NUA K family SNF1-like kinase-1, a serine/threonine-protein kinase regulating cell adhesion, ploidy, senescence, proliferation and Myc-driven tumor progression. HTH-01-015 inhibits only NUA K1 ( $IC_{50} = 100$  nM), displaying extreme selectivity and weak action against 139 other kinases that, including ten other AMP-activated protein kinase (AMPK) family members. In all cell lines tested, HTH-01-015 inhibits phosphorylation of the only well-characterized substrate, MYPT1 (myosin phosphate-targeting subunit 1), which is phosphorylated at Ser-445 by NUA K1. Attesting to its specificity, HTH-01-015 impairs the invasive potential of U2OS cells in a three-dimensional cell invasion assay to the same extent as NUA K1 knockdown. 1. Banerjee, Buhrlage, Huang, et al. (2004) *Biochem. J.* **457**, 215.

#### (±)-Huperzine A

This sesquiterpene alkaloid (FW = 242.32 g/mol; CAS 120786-18-7), also known as (±)-selagine, from the fir moss *Huperzia serrata*, inhibits acetylcholinesterase, with the (-)-stereoisomer more active ( $IC_{50} = 47$  nM). Huperzine A is also a NMDA receptor antagonist that readily crosses the blood-brain barrier. HupA also exerts effects on nicotinic acetylcholine receptors (mainly  $\alpha_7$  nAChRs and  $\alpha_4\beta_2$  nAChRs), evoking anti-inflammatory responses by decreasing IL-1 $\beta$ , TNF- $\alpha$  protein expression, and suppressing transcriptional activation of NF- $\kappa$ B signaling. HupA is classified as a dietary supplement in the U.S. **Target(s):** acetylcholinesterase, both enantiomers inhibit (1-6); aryl-acylamidase (3); cholinesterase, butyrylcholinesterase, very weakly inhibited (1,3-5). 1. Ashani, Peggins & Doctor (1992) *Biochem. Biophys. Res. Commun.* **184**, 719. 2. Dvir, Jiang, Wong, et al. (2002) *Biochemistry* **41**, 10810. 3. Costagli & Galli (1998) *Biochem. Chem.* **278**, 30905.

#### Huwentoxin XVI

This EF-hand protein and potential analgesic agent (FW = 4437.13 g/mol; CAS 1600543-88-1; Disulfide Bridges: 1-16,8-21,15-36; Solubility: 1 mg/mL H<sub>2</sub>O), one of many related polypeptide toxins from the poisonous venom of the Chinese bird spider, *or tarantula*, *Ornithoctonus huwena* (1), is a potent and reversible N-type Ca<sup>2+</sup> channel blocker that, in rat dorsal root ganglion cells, gives an IC<sub>50</sub> ~60 nM (2). N-type calcium ion channels play important CNS roles in neurotransmission and pain signaling. Huwentoxin XVI does not block T-type Ca<sup>2+</sup> channels, K<sup>+</sup> channels or Na<sup>+</sup> channels. 1. Jiang, Zhang, Zhang, *et al.* (2010) *Comp. Biochem. Physiol. (Part D: Genomics Proteomics)* **5**, 81. 2. Deng, Luo, Xiao, *et al.* (2014) *Neuropharmacol.* **79**, 657.

### Hyaluronic Acid

This unbranched, nonsulfated glycosaminoglycan (MW<sub>average</sub> ≈ 7 × 10<sup>6</sup> Da in synovial fluid of healthy subjects; MW<sub>average</sub> ≈ 4.8 × 10<sup>6</sup> in synovial fluid of rheumatoid arthritis patients; CAS 9004-61-9; *Symbol*: HA) is a viscous, extensively hydrated anionic polymer of disaccharide units. Each of the latter consists of an *N*-acetyl-D-glucosamine linked β1→4 to D-glucuronate, which is, in turn, linked β1→3 to the next disaccharide unit. Found chiefly in the vitreous humor, umbilical cord, synovial fluid, and loose connective tissue in all vertebrates, most hyaluronic acid preparations also contain 1-2% of tightly associated protein. HA's distinct physicochemical properties commend its application as a viscoelastic and biocompatible substance for use as a joint lubricant and anti-inflammatory agent. Hyaluronic acid can also be cross-linked with 1,4-butanediol diglycidyl ether to form a nonabsorbable supramolecular substance suitable for use as a subdermal filler in cosmetic surgery. The broadly distributed cell surface protein known as CD44 is a likely cell adhesion receptor that binds to hyaluronate with high affinity. **Target(s)**: *N*-acetylgalactosamine-6-sulfatase (1); acylphosphatase (2); cathepsin B (3); chondroitinase (4); β-fructofuranosidase (5,6); β-glucuronidase (7); γ-glutamyl hydrolase, weakly inhibited (8); histone acetyltransferase (9); lysozyme (5,10,11); phospholipase A<sub>2</sub> (12); ribonuclease (5,13); tissue kallikrein (14). 1. ### Hycanthone

This acid-sensitive thioxanthone (FW = 356.49 g/mol; CAS 3105-97-3; Abbreviation: HC) is a widely used drug for schistosomiasis. Hycanthone also intercalate into DNA, preferring AT sequences (predominantly composed of alternating A and T residues), and act as a mutagen. **Primary Mode of Action**: HC exerts its antischistosomal activity by undergoing metabolic activation to a reactive ester which then alkylates DNA. Resistant schistosomes are unaffected because they cannot convert HC to a reactive ester. **Target(s)**: Apurinic endonuclease-1 (APE1), IC<sub>50</sub> = 80 nM, by binding to the enzyme, *not* DNA (1); DNase (2); RNA, DNA, and protein biosynthesis (3). 1. Naidu, Agarwal, Pena, *et al.* (2011) *PLoS ONE* **6**, e23679. 2. Bailly & Waring (1993) *Biochemistry* **32**, 5985. 3. Pica-Mattocchia & Cioli (1985) *Amer. J. Trop. Med. Hyg.* **34**, 112.

### Hydantocidin

This potent, nonselective phytotoxin and pro-herbicide (FW = 218.16 g/mol; CAS 130607-26-0), systematically named (2*S*)-4,5-dihydro-3α,4α-dihydroxy-5β-(hydroxymethyl)spiro[furan-2(3*H*),4'-imidazolidine]-2',5'-dione and (4*S*)-3'α,4'α-dihydroxy-5'β-(hydroxymethyl)-4',5'-dihydrospiro [imidazolidine-4,2'(3'*H*)-furan]-2,5-dione, first isolated from a submerged culture of *Streptomyces hygroscopicus* SANK 63584 (1), causes immediate cessation of plant growth, meristematic necrosis, and plant death in annuals as well as perennials, including monocotyledonous and dicotyledonous weeds. In *Arabidopsis thaliana*, adenine supplementation alleviates hydantocidin-induced symptoms, but guanine does not (2). In *A. thaliana* plants growing on agar plates, herbicidal effects were also reversed when the agar medium is supplemented with AMP, but not IMP or GMP, suggesting that hydantocidin blocks one or both of the two enzymes that convert IMP to AMP in the *de novo* purine biosynthesis pathway. Hydantocidin itself does not inhibit adenylosuccinate synthetase or adenylosuccinate lyase from *Zea mays*; however, *N*-acetyl-5'-phosphohydantocidin, a phosphorylated derivative of hydantocidin, is a potent inhibitor of the synthetase, but not the lyase. Such findings identify the site of action of hydantocidin and establish adenylosuccinate synthetase as a pro-herbicide target. With *Zea mays* adenylosuccinate synthetase, 5'-phosphohydantocidin is a time-dependent competitive inhibitor with respect to IMP (*K*<sub>i</sub> = 22 nM), suggesting it bind to the IMP site as a tightly held dead-end complex (4). **See Hydantocidin 5'-Monophosphate** 1. Nakajima, Itoi, Takamatsu, *et al.* (1991) *J. Antibiot.* (Tokyo) **44**, 293. 2. Heim, Cseke, Gerwick, Murdoch & Green (1995) *Pesticide Biochem. Physiol.* **53**, 138. 3. ### Hydantocidin 5'-Monophosphate

This spironucleotide (FW<sub>free-acid</sub> = 298.15 g/mol), also known as 5'-phosphohydantocidin and HMP, is derived by metabolic phosphorylation of its pro-herbicide (**See Hydantocidin**). HMP inhibits adenylosuccinate synthetase, thereby blocking purine nucleotide biosynthesis (1-4). 1. Fonné-Pfister, Chemla, Ward, *et al.* (1996) *Proc. Natl. Acad. Sci. U.S.A.* **93**, 9431. 2. Poland, Lee, Subramanian, *et al.* (1996) *Biochemistry* **35**, 15753. 3. Walters, Lee, Niderman, *et al.* (1997) *Plant Physiol.* **114**, 549. 4. Siehl, Subramanian, Walters, *et al.* (1996) *Plant Physiol.* **110**, 753.

### 2-Hydrazino-3-(4-imidazolyl)propionic Acid

This histidine analogue competitively inhibits histidine ammonia-lyase and histidine decarboxylase. (**See also Histidine Hydrazide**) **Target(s):** histidine ammonia-lyase, inactivated by the D-stereomer; competitively inhibited by the L-isomer (1-3); histidine decarboxylase (4,5); histidyl-tRNA synthetase (6). 1. Brand & Harper (1976) *Biochemistry* **15**, 1814. 2. Allen, Clark & Phipps (1983) *Biochem. Soc. Trans.* **11**, 350. 3. Brand & Harper (1976) *Arch. Biochem. Biophys.* **177**, 123. 4. Biochem.* **56**, 369.

### Hydrochlorothiazide

This diuretic and most commonly prescribed antihypertensive (FW = 297.64 g/mol; CAS 58-93-5; *Abbreviations:* HCT, HCTZ, or HZT), also known as 6-chloro-1,1-dioxo-3,4-dihydro-2H-1,2,4-benzothiadiazine-7-sulfonamide is widely used in the treatment of congestive heart failure, diabetes insipidus, hypertension, renal tubular acidosis, and symptomatic edema (1,2). **Primary Mode of Action:** Hydrochlorothiazide reduces reabsorption of sodium and chloride ions at the beginning of the distal convoluted tubule, resulting in increased excretion of water and electrolytes (e.g., sodium, potassium, chloride, and magnesium). It also exerts a natriuretic effect, mainly by decreasing sodium and chloride reabsorption in the cortical segment of the ascending limb of the loop of Henle by inhibition of a specific Na<sup>+</sup>/Cl<sup>-</sup> co-transporter. The antihypertensive effects of hydrochlorothiazide are still poorly understood. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** Coenzyme Q<sub>10</sub>-NADH-oxidase (3); cyclic 3',5'-AMP-dependent protein kinase (4); bone resorption in men despite experimentally elevated serum 1,25-dihydroxyvitamin D concentrations (5). 1. Richterich (1959) *Klin Wochenschr.* **37**, 355. 2. Kennedy & Crawford (1959) *Lancet* **1**, 66. 3. Kishi, Kishi & Folkers (1975) *Res. Commun. Chem. Pathol. Pharmacol.* **12**, 533. 4. ### Hydrocinnamic Acid

This naturally occurring acid (FW<sub>free-acid</sub> = 150.18 g/mol; M.P. = 47-48°C), also known as 3-phenylpropionic acid and β-phenylpropionic acid, inhibits a surprising range of enzymes. **Target(s):** D-amino-acid oxidase (1,2); aromatic-amino-acid aminotransferase,  $K_i = 3.9$  mM (3,57); carboxypeptidase A (1,4-21); carboxypeptidase B (14,22); carboxypeptidase C, or carboxypeptidase Y (23-26); catechol oxidase (27); chymotrypsin (1,6,28-37); elastase, pancreatic (38); enoate reductase (39); esterase (40); hemoglobin S polymerization (41); kynurenine aminotransferase, weakly inhibited (42); melilotate 3-monooxygenase (43); nicotinamidase (44); nonenzymatic hydroxylaminolysis of amino acid esters at -18°C (45); peptidyl-dipeptidase A, angiotensin I converting enzyme (46); phenylalanine dehydrogenase (47,48); phenylalanine 2-monooxygenase (49); phenylalanine racemase, or ATP-hydrolyzing (50); phenylalanyl-tRNA synthetase, weakly inhibited,  $K_i = 9.7$  mM (51);

prephenate dehydratase, weakly inhibited (52); subtilisin (53); succinate dehydrogenase (54,55); tryptophan 2-monooxygenase (58); β-ureidopropionase, IC<sub>50</sub> = 5.6 μM (56). 1. **Hydrogen Cyanide (Prussic Acid), See Cyanide**

### Hydrogen Peroxide

This common laboratory reagent and redox-active signaling metabolite (FW = 34.015 g/mol; CAS 7722-84-1) is a strong oxidant that reacts with cysteinyl and methionyl residues in proteins. In the presence of certain organic acids, ethers, or metal ions, hydrogen peroxide also attacks cystinyl, tryptophanyl, and tyrosyl residues. At 6x10<sup>-4</sup> M, H<sub>2</sub>O<sub>2</sub> causes a 90% inhibition of CO<sub>2</sub>-fixation in isolated chloroplasts, but can be reversed by addition of catalase (2500 Units/mL) or DTT (10 mM). **Physical & Chemical Properties:** H<sub>2</sub>O<sub>2</sub> is a nonplanar molecule with (twisted) C<sub>2</sub> symmetry, having a dihedral angle of 90.2° (compare to 104.5° for water). It is miscible in water as well as ethanol and diethyl ether. Commonly sold as a 3-90% (weight/volume) solution, preferably in a dark glass bottle, aqueous hydrogen peroxide decomposes with time, its rate increased by metal ions, alkali, and even agitation. In dilute solutions, hydrogen peroxide is more acidic than water. H<sub>2</sub>O<sub>2</sub> is also an extremely powerful oxidizer (e.g., +1.8 V for the H<sub>2</sub>O<sub>2</sub>/H<sub>2</sub>O couple). Through catalysis, H<sub>2</sub>O<sub>2</sub> is converted into hydroxyl radical •OH, which is extremely reactive. **Enzymatic Reactions Involving Hydrogen Peroxide:** Catalase catalyzes the reaction: 2H<sub>2</sub>O<sub>2</sub> → 2H<sub>2</sub>O + O<sub>2</sub>. Peroxidases (EC number 1.11.1.x) comprise a large family of enzymes that typically catalyze a reaction of the form: ROOR' + Electron

donor ( $2e^-$ ) +  $2H^+ \rightarrow ROH + R'OH$ . D- and L-Amino oxidases also produce  $H_2O_2$ . **Target(s):** acetylacetone-cleaving enzyme (151,152); acetylcholinesterase (1-3); acetyl-CoA carboxylase (4); acetyl-CoA hydrolase (5); N-acetylneuraminate lyase (6); acid phosphatase (7-9); aconitase (aconitate hydratase) (10-14); adenosine nucleosidase (15); adenylate kinase (16,17); ADP ribosyl-[dinitrogen reductase] hydrolase (18); yeast alcohol dehydrogenase (19); aldehyde dehydrogenase (20); 1-alkylglycero-phosphocholine O-acetyltransferase (there are also reports of activation) (124); aminopeptidase I (21);  $\beta$ -amylase, weakly inhibited (22); arachidonyl-CoA synthetase, or arachidonate:CoA ligase (23); arylacetone nitrilase (24); arylamine N-acetyltransferase (126-128); asclepain (25); L-ascorbate oxidase (26,27,176); aureusidin synthase, hydrogen peroxide required for the oxidation of 2',4,4',6'-tetrahydroxychalcone, but inhibits the oxidation of 2',3,4,4',6' pentahydroxychalcone (28,29); bacterial leucyl aminopeptidase (30); betaine:homocysteine S-methyltransferase (129); biphenyl-2,3-diol 1,2-dioxygenase (155); bromelain (25);  $\gamma$ -butyrobetaine dioxygenase (146,147); calcineurin (31); calotropain, *Calotropis gigantea* latex protease (32); carbamoyl phosphate synthetase (33,34); 3-carboxyethylcatechol 2,3-dioxygenase (160); catechol 1,2 dioxygenase (174); catechol 2,3-dioxygenase (35,172,173); cathepsin B (36); chlorite  $O_2$ -lyase (153); choline O-acetyltransferase (125); chymopain (37,38); citrate (*re*)-synthase (123); clavaminatase synthase (144); clostripain (39-41); complement system, guinea pig (42); cyclohexyl-isocyanide hydratase, or isonitrile hydratase (43); CYP102 (138); cytochrome  $c_3$  hydrogenase (175); cytochrome *d* complex (44); cytosine deaminase ( $Fe^{2+}$ -enzyme inhibited (45); deoxyribo-dipyrimidine photolyase (46); 3,4 dihydroxyphenylacetate 2,3-dioxygenase (161-163); 2,5-dihydroxypyridine 5,6-dioxygenase (168,169); ficain, or ficin (47);  $\beta$ -fructofuranosidase, or invertase (38,48); fructose-1,6-bisphosphate aldolase (49); galactose oxidase (50); gallate decarboxylase (51); gentisate 1,2-dioxygenase (52,171); glucose oxidase (38,53); glucose-6-phosphate dehydrogenase (49); glutathione S-transferase (117); glyceraldehyde-3-phosphate dehydrogenase (38,54); glycerol-3-phosphate dehydrogenase (55); glycerol-3-phosphate oxidase (56); glycerophosphocholine cholinephosphodiesterase (57); glyceryl-ether monooxygenase (136); histidine ammonia-lyase (38,58); histidine kinase (59); HIV-2 retropepsin (60,61); hydrogen lyase (62); 3-(hydroxyamino)phenol mutase (63); hydroxylamine oxidoreductase (64); 3-hydroxy-4-oxoquinoline 2,4-dioxygenase (154); 4-hydroxyphenylpyruvate dioxygenase (156-158); 4-hydroxyquinoline 3-monooxygenase (139); indoleamine 2,3-dioxygenase (150,166,167); inositol oxygenase (148,149); isocitrate lyase (65);  $\beta$ -lactamase (penicillinase) (66); lipoygenase (164,165); lysozyme (67,68); maleate isomerase (69,70); 3-mercaptopyruvate sulfurtransferase (71); methionine S-adenosyltransferase (118,119); 2-methylcitrate synthase (122); methylisocitrate lyase (72); S-methyl-5'-thioadenosine phosphorylase (120); microbial collagenase (73); myosin ATPase (74-78); naphthalene 1,2 dioxygenase (143); nitric-oxide synthase (140); nitrile hydratase (79); pancreatic ribonuclease, or ribonuclease A (80); pantetheine hydrolase (81); papain (82-84); pectin lyase (85); peptide-methionine (*R*)-S-oxide reductase (177); peptide-methionine (*S*)-S-oxide reductase (177,178); phenol 2-monooxygenase (141,142); phenylalanine 4-monooxygenase (86); 1-phosphatidylinositol-4-phosphate 5-kinase (87); phosphofructo-kinase (88,89); 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase (90); 6-phosphogluconate dehydratase (91); phospholipase D (92); phosphoribulokinase (116); phyloquinone monooxygenase (2,3-epoxidizing) (133); procollagen-proline 4-dioxygenase (145); protein phosphatase, or phosphoprotein phosphatase (93-95); protein phosphatase 2A (93); protein phosphatase 7 (95); protein-tyrosine phosphatase (96,97); protocatechuate 4,5-dioxygenase (170); pyruvate kinase (49); reticuline oxidase (98); ribonucleoside-diphosphate reductase (130); ribulose-bisphosphate carboxylase/oxygenase (99); selenide,water dikinase (100); selenophosphate synthetase (101); soluble epoxide hydrolase (102); spleen acid deoxyribonuclease (103); squalene monooxygenase, or squalene epoxidase (134); subtilisin (104); succinate dehydrogenase (105); sulfur dioxygenase (159); thiol oxidase (179,180); thiosulfate sulfurtransferase, or rhodanese (106); thymidylate synthase (107); tryptophan 2,3-dioxygenase (108); tryptophan 5-monooxygenase (137); tyrosinase, or monophenol monooxygenase (135); tyrosine 3-monooxygenase (109); urease (110); uricase, or urate oxidase (111,112); very-long-chain fatty acid  $\alpha$ -hydroxylase (113); xanthine oxidase (114,115,131,132); xyloglucan:xyloglucosyl transferase (121). 1. ## Hydrogen Sulfide

This highly reactive metabolic signalling gas (FW = 34.08 g/mol; CAS 7783-06-4; M.P. = -85.5 °C; B.P. = -60.3 °C; pK<sub>1</sub> = 7.04, and pK<sub>2</sub> = 11.9) is formed endogenously and enzymatically (akin to the so-called gasotransmitters nitric oxide and carbon monoxide, reaching appreciable concentrations in brain, where it is thought to act as a neuromodulator and transmitter. H<sub>2</sub>S also relaxes vascular smooth muscle cells, primes angiogenesis, promotes wound healing, inhibits platelet aggregation, and regulates N-methyl D-aspartate (NMDA) receptors in brain. The mechanisms of H<sub>2</sub>S-mediated vasodilation include the activation of K<sub>ATP</sub> channels, a variety of other channels, inhibition of phosphodiesterases, and synergy with NO (1) By stimulating K<sub>ATP</sub> channels, H<sub>2</sub>S causes vasorelaxation within a physiological concentration range. H<sub>2</sub>S interacts with specific Cysteine-6 and Cysteine-26 on extracellular loop of SUR subunit of K<sub>ATP</sub> channel complex in a novel posttranslational modification mechanism, i.e., protein S-sulphydration (2). **H<sub>2</sub>S Formation in Cells:** Hydrogen sulfide is synthesized in two pyridoxal phosphate (or PLP) requiring, enzyme-catalyzed reactions: (a) Cystathionine β-Synthase (*Major Reaction*: L-Serine + L-Homocysteine ⇌ L-Cystathionine + H<sub>2</sub>O; *Minor H<sub>2</sub>S-Producing Reaction*: L-Cysteine + L-Homocysteine ⇌ L-Cystathionine + H<sub>2</sub>S), and (b) Cystathionine γ-Lyase (*Major Reaction*: L-Serine + L-Cystathionine ⇌ L-Cysteine + 2-Oxobutanoate + NH<sub>3</sub>; (a) *Minor H<sub>2</sub>S-Producing Elimination Reaction*: L-Cysteine ⇌ Pyruvate + NH<sub>3</sub> + H<sub>2</sub>S; (b) *Minor H<sub>2</sub>S-Producing Elimination Reaction*: L-Cystine ⇌ L-Cysteine + Pyruvate + H<sub>2</sub>S). (The first enzyme requires heme, which may serve a regulatory role by interacting with NO and/or CO.) H<sub>2</sub>S is involved in the regulation of vascular tone, myocardial contractility, neurotransmission, and insulin secretion. In vascular smooth muscle cells, neurons, cardiomyocytes and pancreatic β-cells, H<sub>2</sub>S stimulates ATP-sensitive potassium channels (K<sub>ATP</sub>). In addition, H<sub>2</sub>S may react with reactive oxygen species (ROS) and/or reactive nitrogen species to limiting their toxic effects. Note that propargylglycine inhibits cystathionine γ-lyase-catalyzed formation H<sub>2</sub>S from L-cysteine. **Generation of H<sub>2</sub>S for Metabolic Studies:** In the laboratory, H<sub>2</sub>S may be produced in a modified Kipp generator (3). Unless one uses a suitable chemical trap, it is advisable to avoid using such generators, which contain potentially toxic substances. Instead, one may directly administer 0.03–0.3 mM sodium hydrosulfide (Formula: NaHS; FW = 56.06 g/mol; CAS 16721-80-5), which is highly soluble in water. (**See also Sulfide Ions; Sulfur** Nucleoside phosphorothioates, such as adenosine 5'-thiomonophosphate (or AMPS) and guanosine 5'-thiomonophosphate (or GMPS), are also converted to H<sub>2</sub>S, allowing the latter to relax isolated kidney glomeruli *in vitro* and increasing glomerular filtration rate *in vivo* (4). AMPS and GMPS can be safely used as H<sub>2</sub>S donors in experimental studies and possibly as H<sub>2</sub>S-releasing drugs. **Slow-Releasing H<sub>2</sub>S Donor:** Another method for generating H<sub>2</sub>S relies on the use of GYY-4137 (FW = 377.48 g/mol; CAS 106740-09-4; IUPAC: 4-methoxyphenyl(morpholino)phosphinodithioate), a water-soluble H<sub>2</sub>S donor with vasodilatory and anti-inflammatory properties (5,6). GYY4137 slowly releases appreciable levels of H<sub>2</sub>S in the range of 10-250 μM, and the H<sub>2</sub>S that is released is long-lived. **Toxicity:** Despite its recently discovered physiologic roles, H<sub>2</sub>S gas is highly toxic, about 10-30x less so than hydrogen cyanide. Its distinctive odor of rotten eggs (perceptible over the 0.02-to-0.13 ppm range) provides some warning; however, at higher levels, olfactory fatigue occurs, making H<sub>2</sub>S both imperceptible and hazardous. **Target(s):** D-amino acid oxidase (7,8); ascorbate oxidase (9); carbonic anhydrase (10-15); catalase (16-19); catechol oxidase (20); galactose oxidase (21); lactoperoxidase (22); maleylacetoacetate isomerase (23); thyroxine deiodinase, iodothyronine

deiodinase (24); and tyrosinase (25). Sodium hydrosulfide (100  $\mu$ M) attenuates  $\beta$ -amyloid (residues 1-42) (A $\beta$ 2) production in SH-SY5Y cells stimulated by 10-200 nM of the selective A $_2A$  receptor agonist HENECA (25). NaHS also interferes with HENECA-stimulated production and post-translational modification of amyloid precursor protein (APP) by inhibiting its maturation. Measurement of the C-terminal APP fragments generated from its enzymatic cleavage by  $\beta$ -site amyloid precursor protein cleaving enzyme 1 (BACE1) showed that NaHS is without any significant effect on  $\beta$ -secretase activity (25). 1. **(6E,8Z,11Z,14Z)-(5S)-5-Hydroperoxyeicosa-6,8,11,14-tetraenoic Acid**

This unsaturated  $\delta$ -hydroperoxy acid (FW<sub>free-acid</sub> = 336.47 g/mol), often abbreviated 5-HPETE, is an intermediate in arachidonate metabolism and a precursor in leukotriene and hydroxy-eicosatetraenoate biosynthesis. It is a product of the reaction catalyzed by 5-lipoxygenase (Note that 5-HPETE is also a strong product inhibitor of the 5-lipoxygenase). Note that it is unstable and should be stored under an inert atmosphere. **Target(s):** 5-lipoxygenase, or arachidonate 5-lipoxygenase (1-3); lipoxygenase, potato (4). 1. Kim, Kim & Sok (1989) *Biochem. Biophys. Res. Commun.* **164**, 1384. 2. Wiseman, Skoog, Nichols & Harrison (1987) *Biochemistry* **26**, 5684. 3. **(9Z,11E)-(13S)-13-Hydroperoxyoctadeca-9,11-dienoic Acid**

This unsaturated  $\mu$ -hydroperoxy acid (FW<sub>free-acid</sub> = 312.45 g/mol), often abbreviated 13-HPODE, is produced by the action of lipoxygenase on linoleate. It induces moderate oxidative stress in cells and participates in the trapping of low-density lipoproteins in arterial subendothelial spaces. 13-HPODE also induces apoptosis and augments the epidermal growth factor receptor signaling pathway by attenuating receptor dephosphorylation. In addition, 13-HPODE inhibits prostacyclin biosynthesis. **Target(s):** glucosamine synthetase (1); 15-hydroxyprostaglandin dehydrogenase (2); 15-lipoxygenase, or arachidonate 15-lipoxygenase (3); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (4); prostacyclin synthase, or prostaglandin I synthase (5); prostaglandin-I synthase, prostacyclin synthase (6-8). 1. ### Hydroxocobalamin

This vitamin B<sub>12</sub> derivative (FW<sub>free-acid</sub> = 1346.4 g/mol; CAS 13422-51-0) is the conjugate base of aquacobalamin (pK<sub>a</sub> = 7.5) and a precursor in the biosynthesis of methylcobalamin. It binds tightly to the transcobalamins and is a nitric oxide scavenger. **Target(s):** ethanolamine ammonia-lyase (1-6); glycerol dehydratase (2,7); HIV-1 integrase (8); β-lysine 5,6-aminomutase (3); D-lysine-5,6-aminomutase (3); 2-methyleneglutarate mutase (9); propanediol dehydratase (2). 1. ### p-Hydroxyamphetamine

This adrenergic agent (FW<sub>free-base</sub> = 151.21 g/mol; CAS 103-86-6), also known as 4-(2-aminopropyl)phenol, inhibits dopamine β-monooxygenase (1) and is a competitive inhibitor of brain monoamine oxidase (2-4). The DL-mixture inhibits *Escherichia coli* tyrosyl-tRNA synthetase, *K<sub>i</sub>* = 10 μM (5). Both the free base and the hydrochloride salt are soluble in water and ethanol. 1. Goldstein & Contrera (1962) *J. Biol. Chem.* **327**, 1898. 2. Arai, Kim, Kinemuchi, *et al.* (1991) *Brain Res. Bull.* **27**, 81. 3. Arai, Kim, Kinemuchi, Tadano, *et al.* (1990) *J. ### 3-Hydroxyaspartic Acid

This hydroxy amino acid (FW = 149.10 g/mol; CAS 71653-06-0; Symbol = Hya), also known as β-hydroxyaspartate, exists as four possible stereoisomeric forms. It is a glutamate uptake inhibitor and a substrate for excitatory amino acid transporters. It has also been identified in a number of proteins (such as in the vitamin K dependent protein S and in bovine factor X) as well as a number of special peptides (for example, in antimycotics and pyoverdins). **Target(s):** argininosuccinate synthetase (the *erythro* form is the inhibitor) (1); asparagine synthetase, mildly inhibited (2,3); aspartate aminotransferase, also a weak substrate (4-9); aspartate 1-decarboxylase (10,11); aspartate 4-decarboxylase, by both the *erythro* and

*threo* forms (12-14); glutamate transporter (15-17); glycine:oxaloacetate aminotransferase (the *erythro*-L-form is the inhibitor) (5,18,19). 1. Ratner (1970) *Meth. Enzymol.* **17A**, 298. 2. #### 4-Hydroxybenzaldehyde

This aromatic aldehyde (FW = 122.12 g/mol; CAS 123-08-0; M.P. = 116°C), also referred to a *p*-hydroxybenzaldehyde and 4-formylphenol, inhibits a number of oxidoreductases. 4-Hydroxybenzaldehyde is widely distributed in plants and is released upon mild oxidation of certain lignins (e.g., monocotyledonous lignins) under alkaline conditions. **Target(s):** 4-aminobutyrate aminotransferase (1,2); *o*-aminophenol oxidase (3); chorismate lyase (4); cyanohydrin  $\beta$ -glucosyltransferase (5); dihydrodiol dehydrogenase (6); diphosphomevalonate decarboxylase (7); dopamine  $\beta$ -monoxygenase,  $K_i$  = 2.3 mM (8);  $\beta$ -glucosidase (9); 4-hydroxybenzoate 3-monoxygenase, weakly inhibited (10); 4-hydroxyphenylpyruvate dioxygenase (11); mandelonitrile lyase (12,13); phosphomevalonate kinase, weakly inhibited (7); succinate semialdehyde dehydrogenase (2,14,15); vomilenine glucosyltransferase (16). 1. #### *m*-Hydroxybenzoic Acid

This aromatic acid (FW<sub>free-acid</sub> = 138.12 g/mol; CAS 99-06-9), also known as 3-hydroxybenzoic acid, is a substrate for the reactions catalyzed by 3-hydroxybenzoate 4-monoxygenase, 3-hydroxybenzoate 6-monoxygenase, and 3-hydroxybenzoate 2-monoxygenase. It is an intermediate in the degradation of *m*-cresol. **Target(s):** D-amino-acid oxidase (1,2); anthranilate 3-monoxygenase (deaminating) (3); L-ascorbate peroxidase, weakly inhibited (28); benzoate 4-monoxygenase, weakly (4);  $\gamma$ -butyrobetaine hydroxylase, or  $\gamma$ -butyrobetaine:2-oxoglutarate dioxygenase,

$K_i$  = 0.02 mM (5); catechol 2,3-dioxygenase (27); catechol oxidase (29); cathepsin L, weakly inhibited (6); 4,5-dihydroxybenzoate decarboxylase (7); gentisate 1,2-dioxygenase (8); 3-hydroxy-anthranilate 3,4 dioxygenase (9); 4-hydroxybenzoate 4-*O*- $\beta$ -glucosyltransferase (10); 4-hydroxybenzoate 3-monoxygenase (11,12); 4-hydroxybenzoate 3-monoxygenase (NAD(P)H) (13); 15-lipoxygenase, or arachidonate 15-lipoxygenase (14); melilotate 3-monoxygenase (15); polyphenol oxidase (29); protocatechuate 3,4-dioxygenase (16-19); protocatechuate 4,5-dioxygenase (20,21); *o*-pyrocatechuate decarboxylase (22,23); salicylate monoxygenase (24); serine-sulfate ammonia-lyase (25); tannase (26). 1. #### *p*-Hydroxybenzoic Acid

This metabolite (FW<sub>free-acid</sub> = 138.12 g/mol; CAS 99-96-7; pK<sub>a</sub> values = 4.67 and 9.37 at 25°C) is an intermediate in the biosynthesis of ubiquinone in mammals. (See also *p*-Chloromercuribenzoate) **Target(s):**  $\gamma$ -butyrobetaine hydroxylase,  $\gamma$ -butyrobetaine:2-oxoglutarate dioxygenase,  $K_i$  = 0.51 mM (1); catechol oxidase (34-36); cathepsin L, weakly inhibited (2); chorismate lyase (3); dihydrofolate synthase (4); dihydropterolate synthase (4); 4,5-dihydroxyphthalate decarboxylase, also alternative substrate (5); diphosphomevalonate decarboxylase (6); estrone sulfotranferase7;  $\beta$ -glucosidase (8); 3-hydroxyanthranilate 3,4-dioxygenase (9); imidazoleacetate 4-monoxygenase (10); 15-lipoxygenase, arachidonate 15-lipoxygenase (11); mandelonitrile lyase (12); phenylalanine ammonia lyase (13,14); phosphomevalonate kinase (6); polyphenol oxidase (34-36); prephenate dehydrogenase (15); procollagen-proline 4-dioxygenase (16,17); protocatechuate 3,4-dioxygenase (18-23); protocatechuate 4,5-dioxygenase (24,25); salicylate monoxygenase (26); shikimate dehydrogenase (27,28); tannase (29); thiopurine *S*-methyltransferase, IC<sub>50</sub> = 1.7 mM (30); tyrosinase, or monophenol monoxygenase, or polyphenol oxidase (31-33). 1. ### 2-Hydroxybenzohydroxamoyl Adenylyl

This reaction product analogue (FW = 482.35 g/mol) inhibits (2,3-dihydroxybenzoyl)adenylate synthase,  $K_{i,app} = 37$  nM. The free energy of binding is nearly equivalent to the sum of the corresponding values for adenosine 5'-phosphate and 2,3-dihydroxybenzoate. **1.** Callahan, Lomino & Wolfenden (2006) *Bioorg. Med. Chem. Lett.* **16**, 3802.

### 4-Hydroxybenzoxonitrile

This toxic aromatic nitrile (FW = 119.12 g/mol; CAS 767-00-0; M.P. = 110-113°C), also known as *p*-hydroxybenzoxonitrile and *p*-cyanophenol, is a substrate for a number of nitrilases. 4-Hydroxybenzoxonitrile readily forms the anion ( $pK_a = 7.9$ ). **Target(s):** L-ascorbate oxidase (1);  $\beta$ -glucosidase (2); malate dehydrogenase, weakly inhibited (3); monoamine oxidase (4); toyocamycin nitrile hydratase (5). **1.** Gaspard, Monzani, Casella, *et al.* (1997) *Biochemistry* **36**, 4852. **2.** Dale, Ensley, Kern, Sastry & Byers (1985) *Biochemistry* **24**, 3530. **3.** Wedding, Hansch & Fukuto (1967) *Arch. ### (3-Hydroxybenzyl)hydrazine

This hydrazine (FW<sub>free-base</sub> = 138.17 g/mol; CAS 637-33-2), also known as NSD 1015, inhibits aromatic-L-amino-acid decarboxylase and is a slow-binding inhibitor of  $\gamma$ -aminobutyrate aminotransferase. **Target(s):** 4-aminobutyrate aminotransferase (1,2); aromatic-L-amino-acid decarboxylase, *or* dopa decarboxylase (3-7); 4-hydroxybenzoate decarboxylase (8); monoamine oxidase (6); tyrosine decarboxylase (7). **1.** Lightcap &

### D-2-Hydroxy-3-butynoic Acid

This acetylenic analogue (FW<sub>free-acid</sub> = 100.07 g/mol; CAS 38628-65-8) of lactate and  $\alpha$ -hydroxybutyrate acts as a suicide inhibitor for a number of enzymes. (See also 2-Keto-3-butynoate and 2-Keto-3-butynoic Acid) **Target(s):** D-amino-acid oxidase (1); cytochrome  $b_5$  (2); D- $\alpha$ -hydroxyacid oxidase (1-3); D-lactate dehydrogenase (2-6). **1.** Olson, Massey, Ghisla & Whitfield (1979) *Biochemistry* **18**, 4724. **2.** Walsh, Cromartie, Marcotte & Spencer (1978) *Meth. Enzymol.* **53**, 437. **3.** Maycock (1980) *Meth. Enzymol.* **66**, 294. **4.** Kaczorowski, Kohn & Kaback (1978) *Meth. Enzymol.* **53**, 519. **5.** Sigman & Mooser (1975) *Ann. Rev. ### 3-R-Hydroxybutyr-(CH<sub>2</sub>)-CoA

This hydroxybutyryl-S-coenzyme A analogue (FW = 837.53 g/mol; Symbol = HB-CH<sub>2</sub>-CoA), in which the sulfur atom in 3-R-hydroxybutyrate coenzyme A (HB-S-CoA) is replaced with a CH<sub>2</sub> group, is a competitive inhibitor ( $K_{is}$  values of 40 and 14  $\mu$ M, respectively) of a class I and a class III polyhydroxybutyrate (*or* PHB) synthases, enzymes that catalyze HB-S-CoA polymerization to produce polyoxoesters with molecular masses of 1–2 MDa. HB-CH<sub>2</sub>-CoA was synthesized in 13 steps by a chemo-enzymatic approach (overall yield = 7.5%). To probe the elongation steps of the polymerization, HBCH<sub>2</sub>CoA was incubated with a synthase already acylated with a [<sup>3</sup>H]-saturated trimer-CoA ([<sup>3</sup>H]-sTCoA). The reaction products were shown to be the methylene analogue of [<sup>3</sup>H]-sTCoA ([<sup>3</sup>H]-sT-CH<sub>2</sub>-CoA), saturated dimer-([<sup>3</sup>H]-sD-CO<sub>2</sub>H) and trimer-acid ([<sup>3</sup>H]-sT-CO<sub>2</sub>H), distinct from the expected methylene analogue of [<sup>3</sup>H]-saturated tetramer-CoA ([<sup>3</sup>H]-sTet-CH<sub>2</sub>-CoA). Detection of [<sup>3</sup>H]-sT-CH<sub>2</sub>-CoA and its slow rate of formation suggest that HB-CH<sub>2</sub>-CoA reports on the termination and re-priming process of the synthases, rather than elongation. **1.** Zhang, Shrestha, Buckley, *et al.* (2014) *ACS Chem. Biol.* **9**, 1773.

### D-2-Hydroxybutyrate (D-2-Hydroxybutyric Acid)

This  $\alpha$ -hydroxy acid (FW<sub>free-acid</sub> = 104.11 g/mol; CAS 20016-85-7), also known as (*R*)-2-hydroxybutanoic acid, inhibits D-3-hydroxybutyrate dehydrogenase (1-3), mandelate racemase,  $K_i = 17.3$  mM (4), and D-threonine dehydrogenase (5). **1.** Krebs, Gawehn, Williamson & Bergmeyer (1969) *Meth. Enzymol.* **14**, 222. **2.** Delafield & Doudoroff (1969) *Meth. Enzymol.* **14**, 227. **3.** Nakada, Fukui, Saito, *et al.* (1981) *J. Biochem.* **89**, 625. **4.** Siddiqi, Bourque, Jiang, *et al.* (2005) *Biochemistry* **44**, 9013. **5.** Misono, Kato, Packdibamrung, Nagata & Nagasaki (1993) *Appl. Environ. Microbiol.* **59**, 2963.

### D-3-Hydroxybutyrate (D-3-Hydroxybutyric Acid)

This  $\beta$ -hydroxyacid (FW<sub>free-acid</sub> = 104.11 g/mol; CAS 625-72-9; M.P. = 45.5-48°C; pK<sub>a</sub> = 4.41 at 22°C; Symbol: BHB), also known as D(-)- $\beta$ -hydroxybutyric acid and (R)-3-hydroxybutanoic acid, is one of three ketone bodies formed in ketogenesis (See also Acetoacetate and Acetone) (1-6). By providing an alternative substrate to fuel oxidative phosphorylation, ketone bodies support mammalian cell survival during periods of energy insufficiency. It is found in elevated concentrations in the urine of diabetics. The free acid is relatively unstable, forming esterification products; careless distillation will produce crotonic acid and water. Sodium and potassium salts are significantly more stable. The L-(+)-enantiomer, or (S)-3-hydroxybutyrate, is found as the CoA-thioester intermediate in fatty acid  $\beta$ -oxidation. The corresponding acyl-carrier protein intermediate in fatty acid biosynthesis is D-3-hydroxybutyryl-ACP. BHBA significantly increases levels of oxidation indicators (e.g., MDA, NO and iNOS), but decreases levels of anti-oxidation indicators (e.g., GSH-Px, CAT and SOD) in treated hepatocytes. IKK $\beta$  activity and phospho-I $\kappa$ B $\alpha$  (p-I $\kappa$ B $\alpha$ ) are also increased in treated hepatocytes, suggesting that BHBA can induce hepatocyte inflammatory injury through the NF- $\kappa$ B signaling pathway and may be activated by oxidative stress (9). **Anti-inflammatory Mechanism(s):** BHB suppresses the activation of the NLRP3 inflammasome in response to urate crystals, ATP, and lipotoxic fatty acids, whereas acetoacetate, butyrate and acetate cannot (10). Significantly, BHB does not inhibit caspase-1 activation in response to pathogens that activate the NLR family, CARD domain-containing 4 (or NLRP4) or Absent in Melanoma-2 (or AIM2) inflammasome and does not affect non-canonical caspase-11-mediated inflammasome activation. BHB reduces the NLRP3 inflammasome response by preventing K<sup>+</sup> efflux and reducing the oligomerization of Apoptosis-associated Speck-like protein containing a Caspase-recruitment domain (or ASC) and speck formation (10). BHB's inhibitory effects on NLRP3 are independent of chirality and starvation-regulated mechanisms (e.g., AMP-activated protein kinase (AMPK), reactive oxygen species (ROS), autophagy or glycolytic inhibition). BHB blocks the NLRP3 inflammasome without undergoing oxidation in the TCA cycle, and independently of Uncoupling Protein-2 (UCP2), Sirtuin-2 (SIRT2), the G-Protein-coupled Receptor GPR109A, or HydroCarboxylic Acid Receptor-2 (HCAR2). Instead, it reduces NLRP3 inflammasome-mediated interleukin (IL)-1 $\beta$  and IL-18 production in human monocytes (10). *In vivo*, BHB or a ketogenic diet attenuates caspase-1 activation and IL-1 $\beta$  secretion in mouse models of NLRP3-mediated diseases, suggesting the anti-inflammatory effects of caloric restriction or ketogenic diets may be linked to BHB-mediated inhibition of NLRP3 inflammasome (10). **Target(s):** aldehyde reductase, or aldose reductase (1); creatine kinase, weakly inhibited (2); 3-hydroxy-3-methylglutaryl-CoA reductase (3); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (4); pantothenate synthetase, or pantoate: $\beta$ -alanine ligase, slightly inhibited (5); procollagen-proline 4-dioxygenase, weakly inhibited (6); L-threonine dehydrogenase (7,8). 1. ### 10-Hydroxycamptothecin

This antitumor alkaloid (FW = 364.36 g/mol; CAS 67656-30-8) from the Chinese tree *Camptotheca acuminata* is a DNA intercalator that inhibits DNA topoisomerase (1-5). (S)-10-hydroxy-Camptothecin has strong anti-

tumor activity against a wide range of experimental tumors including L1210 leukemia cells (IC<sub>50</sub> = 1.15  $\mu$ M) (6). 1. Xu & Ling (1985) *Am. J. Chin. Med.* **13**, 23. 2. ### 25-Hydroxycholesterol

This endogenous cholesterol metabolite, LXR agonist, and ER partial agonist (FW = 402.66 g/mol; CAS 2140-46-7; Symbol: 27HC), also known as cholest-5-ene-3 $\beta$ ,25-diol, targets the Liver X Receptor (1) and Estrogen Receptor, respectively. The LXR is a member of the nuclear receptor family of transcription factors and is closely related to such nuclear receptors as the PPARs, FXR and RXR. LXRs are important regulators of cholesterol, fatty acid, and glucose homeostasis. While previously classified as orphan receptors, endogenous oxysterols were found to be their likely natural ligands. The most prevalent oxysterol in circulation, 27-hydroxycholesterol functions as a selective ER modulator (or SERM), the efficacy of which varies depends on the endpoints chosen (2). Importantly, 27HC positively regulates both gene transcription and cell proliferation in cellular models of breast cancer. Using combinatorial peptide phage display, we have determined that 27HC induces a unique conformational change in both ER $\alpha$  and ER $\beta$ , distinguishing it from 17 $\beta$ -estradiol and other SERMs (2). Hydroxycholesterol modulates hydroxymethylglutaryl-CoA reductase activity by rapidly increasing its degradation and decreasing its synthesis. Hydroxycholesterol suppresses  $\beta$ -estradiol-mediated breast cancer cell proliferation *in vitro*. It also increases  $\alpha$ -synuclein levels and induces apoptosis in human neuroblastoma cells *in vitro*. 25-Hydroxycholesterol also acts within the Golgi compartment to induce the degradation of tyrosinase. **Target(s):** cholesterol efflux (3); cholesterol 7 $\alpha$ -monooxygenase, or sterol 7 $\alpha$ -monooxygenase (4); dolichol synthesis (5,7); hydroxymethylglutaryl-CoA reductase turnover (6-8). 1. Fu, Menke, Chen, et al. (2001) *J. Biol. Chem.* **276**, 38378. 2. DuSell, Umetani, Shaul, Mangelsdorf & McDonnell (2008) *Mol. Endocrinol.* **22**, 65. 3. ### 2-Hydroxycitrate

This natural  $\alpha$ -hydroxycitrate derivative (FW<sub>free-acid</sub> = 208.12 g/mol) is a potent inhibitor of ATP:citrate lyase. It is the active ingredient in the herb *Garcinia cambogia*. Note that there are four stereoisomers of 2-hydroxycitrate. The strongest inhibitor of ATP:citrate lyase is (2S,3S)-2-hydroxycitrate. This isomer is also an alternative activator of acetyl-CoA

carboxylase and inhibits glucose-stimulated insulin secretion. **Target(s):** acetylcholine synthesis (1); acetyl-CoA hydrolase, inhibited by (-)-2-hydroxycitrate (2); ATP:citrate lyase, or ATP:citrate synthase,  $K_i = 0.15 \mu\text{M}$  (1,3-6); citrate (pro-S) lyase (7); citrate synthase, weakly inhibited (5); fatty acid biosynthesis (1); 6-phosphofructokinase (1,8); pyruvate dehydrogenase (1). 1. Lowenstein & Brunengraber (1981) *Meth. Enzymol.* **72**, 486. 2. Chabtree, Souter & Anderson (1989) *Biochem. J.* **257**, 673. 3. Watson, Fang & Lowenstein (1969) *Arch. Biochem. ### 16-Hydroxycleroda-3,13-dien-16,15-olide

This clerodane diterpene (FW = 318.46 g/mol; *Abbreviation:* HCD) is non-cytotoxic antileishmanial lead, as evidenced by its effects on long-term survival (exceeding 6 months) of treated animals. Visceral leishmaniasis (or *Kala-azar*), the most devastating form of leishmaniasis, begins with invasion of the reticuloendothelial system (e.g., spleen, liver and bone marrow) by the haemoflagellate protozoan parasite, *Leishmania donovani*. Since the 1940s, pentavalent antimony compounds have been a first-line treatment for all forms of leishmaniasis. Activity-guided fractionation of a crude ethanolic extract of the leaves of *Polyalthia longifolia* var. *pendula* led to the isolation of HCD (1), which arrests host cells in G<sub>0</sub>-G<sub>1</sub> phase and promotes apoptosis. HCD decreases anti-apoptotic proteins, while simultaneously increasing pro-apoptotic proteins. Treated cells also formed filopodia, with reduced levels of FAK, pFAK, Rac1 and Cdc42. HCD inhibited the activity of MMP-2 and MMP-9. 1. Koeneni, Sashidhara, Singh, *et al.* (2010) *Brit. J. Pharmacol.* **159**, 1143. 2. Thiyagarajan, Lin, Chia & Weng (2013) *Biochim. Biophys. Acta.* **1830**, 4091.

### 2-Hydroxydodecanoic Acid

This  $\alpha$ -hydroxy acid (FW<sub>free-acid</sub> = 216.32 g/mol), also known as 2-hydroxylauric acid, inhibits butyryl-CoA synthetase, or butyrate:CoA ligase, or medium-chain-fatty-acyl-CoA synthetase,  $K_i = 4.4 \mu\text{M}$ . 1. Kasuya, Yamaoka, Igarashi & Fukui (1998) *Biochem. Pharmacol.* **55**, 1769. 2. Kasuya, Igarashi & Fukui (1999) *Chem. Biol. Interact.* **118**, 233. 3. Kasuya, Hiasa, Kawai, Igarashi & Fukui (2001) *Biochem. Pharmacol.* **62**, 363. 4. Morszeck, Berger & Plum (2001) *Biochim. Biophys. Acta* **1521**, 59.

### 6-Hydroxy-DOPA

This allosteric RAD52 inhibitor (FW = 213.19 g/mol; CAS 21373-30-8; Soluble to 100 mM in 1 equivalent HCl), also named 2,5-dihydroxy-DL-tyrosine, targets Rad52, a ring-like oligomeric protein encoded by a gene sharing similarity with *Saccharomyces cerevisiae* Rad52 and a key protein in DNA double-strand break repair and homologous recombination. Rad52 binds to the ends of single-stranded DNA (ssDNA), mediating the requisite DNA-DNA interactions for annealing complementary DNA strands. 6-OH-dopa binds to and transforms RAD52 undecamer rings into dimers, abolishing ssDNA binding channel observed in crystal structures. 6-OH-Dopa also disrupts RAD52 heptamer and undecamer ring superstructures,

suppressing RAD52 recruitment and recombination activity in cells with negligible effects on other double-strand break repair pathways. 6-Hydroxy-DOPA selectively inhibits the proliferation of BRCA-deficient cancer cells, including those obtained from leukemia patients. 1. Chandramouly, McDevitt, Sullivan, *et al.* (2015) *Chem. Biol.* **22**, 1491.

### 6-Hydroxydopamine

This neurotoxic agent (FW<sub>free-base</sub> = 169.18 g/mol; CAS 1199-18-4; photosensitive), also known as 2,4,5-trihydroxyphenethylamine, oxydopamine, and ODHA, destroy dopaminergic and noradrenergic neurons in the brains of experimental animals. Selective destruction of adrenergic nerve terminals by 6-hydroxydopamine appears to result from the covalent binding of its oxidation/photooxidation products to nucleophilic groups of biological macromolecules. The reaction seems to be nonspecific, and the high selectivity of the destructive effect results from the efficient uptake of 6-hydroxydopamine into the adrenergic nerve terminals. **Target(s):** dihydropteridine reductase (1); glyceraldehyde-3-phosphate dehydrogenase (2); 5-lipoxygenase, or arachidonate 5-lipoxygenase, ID<sub>50</sub> = 26.7  $\mu\text{M}$  (3); 12-lipoxygenase, or arachidonate 12-lipoxygenase, ID<sub>50</sub> = 45.3  $\mu\text{M}$  (3); phenol sulfotransferase, or aryl sulfotransferase, also alternative substrate (4); prostaglandin synthase (ID<sub>50</sub> = 0.45 mM (3)). 1. S. Shen (1983) *Biochim. Biophys. Acta* **743**, 129. 2. Hayes & Tipton (2002) *Toxicol. Lett.* **128**, 197. 3. Hamasaki & Tai (1985) *Biochim. Biophys. Acta* **834**, 37. 4. Yasuda, Liu, Suiko, Sakakibara & Liu (2007) *J. Neurochem.* **103**, 2679.

### (5Z,8Z,11Z,13E)-(15S)-15-Hydroxyeicosa-5,8,11,13-tetraenoic Acid

This unsaturated  $\xi$ -hydroxyacid (FW = 320.47 g/mol), often abbreviated 15-HETE, is an arachidonate metabolite and lipoxygenase inhibitor. **Target(s):** 5-lipoxygenase, or arachidonate 5-lipoxygenase, I<sub>50</sub> values of 3 and 7.7  $\mu\text{M}$  are reported (1-4); 12-lipoxygenase, or arachidonate 12-lipoxygenase (5,6). 1. Coutts, Khandwala, Van Inwegen, *et al.* (1985) in *Prostaglandins, Leukotrienes, and Lipoxins* (Bailey, ed.), p. 627, Plenum Press, New York. 2. Vanderhoek, Bryant & Bailey (1980) *J. Biol. Enzymol.* **86**, 49. 6. Pace-Asciak & Smith (1983) *The Enzymes*, 3rd ed., **16**, 543.

### 9-Hydroxyellipticine

This antitumor agent (FW = 262.31 g/mol) binds to DNA and stabilizes the DNA topoisomerase II:DNA cleavable complex. It is oxidized to reactive quinone-imine intermediates, inhibits telomerase, suppresses phosphorylation of the mutant p53 protein, and is likewise cytotoxic. **Target(s):** cyclin-dependent kinases (1); cytochrome P-448 activity, or ethoxoresorufin O-deethylase and biphenyl 2-hydroxylase (2); cytochrome P450 proteins (e.g., benzo[a]pyrene hydroxylase activity) (3-5); DNA topoisomerase I (6); DNA topoisomerase II (7,8); p53 protein phosphorylation (9); telomerase (10). 1. Meijer & Kim (1997) *Meth.*

### Bis(2-Hydroxyethyl) disulfide

This symmetrical disulfide (FW = g/mol; CAS 1892-29-1), also known as 2-hydroxyethyl disulfide and 2,2-dithiodiethanol, is formed by the oxidation of the protein thiol reductant  $\beta$ -mercaptoethanol (See 2-mercaptoethanol). Bis(2-hydroxyethyl) disulfide inactivates horse liver aldehyde dehydrogenase (EC 1.2.1.3) with formation of mixed-disulfides between protein sulfhydryl groups and  $\beta$ -mercaptoethanol. Upon extended incubation, the enzyme retained 30% of its initial catalytic activity, suggesting that 2-hydroxyethyl disulfide-treated aldehyde dehydrogenase retains catalytic activity. 1. Brotherton & Rodwell (1980) *Physiol. Chem. Phys.* **12**, 483.

### 2-({[2-({3-[(2-Hydroxyethyl)amino]propyl)amino]phenyl)sulfonyl}amino)-5,6,7,8-tetrahydro-1-naphthalenecarboxylate

This substituted anthranilic acid sulfonamide (FW = 415.49 g/mol) inhibits methionyl aminopeptidase,  $IC_{50} = 0.015 \mu M$ . 1. Sheppard, Wang, Kawai, *et al.* (2006) *J. Med. Chem.* **49**, 3832.

### (2'-Hydroxyethyl)cobalamin

This vitamin B<sub>12</sub> derivative (FW = 1374.42 g/mol) inhibits ethanolamine ammonia-lyase (1-3), glycerol dehydratase (4), and propanediol dehydratase (1). 1. Abeles (1971) *The Enzymes*, 3rd ed., **5**, 481. 2. Stadtman (1972) *The Enzymes*, 3rd ed., **6**, 539. 3. Babior (1969) *J. Biol. Chem.* **244**, 2917. 4. Poppe, Hull, Nitsche, *et al.* (1999) *Helv. Chim. Acta* **82**, 1250.

### 2-Hydroxyethyl Disulfide

This toxic reagent (FW = 154.25 g/mol; M.P. = 25-27°C), also known as 2,2'-dithiodiethanol, oxidized 2-mercaptoethanol, 2 mercaptoethanol disulfide, thioethylene glycol disulfide, dithiodiglycol, and diethylene glycol disulfide, is the disulfide of 2-mercaptoethanol. Although this reagent accumulates upon atmospheric exposure of 2-mercaptoethanol solutions used as a protein disulfide reductant, the far higher concentration of thiol likely reverses the formation of any mixed disulfides. (See also 2-Mercaptoethanol) **Target(s)**: aldehyde dehydrogenase (1); ananin (2); bromelain (3); comosain (4); homocysteine desulfhydrase (5); 3-hydroxy-3-methylglutaryl-CoA reductase (6,7); iodothyronine 5'-deiodinase (8,9); L-methionone (*S*)-*S*-oxide reductase (10); ornithine carbamoyltransferase (11); pantetheine hydrolase, or pantetheinase (12); [phosphorylase] phosphatase (13); stem bromelain (3); thymidylate synthase (14). 1. Brotherton & Rodwell (1980) *Physiol. Chem. Phys.* **12**, 483. 2. Rowan (1998) in *Handb. Proteolytic Enzymes*, p. 569, Academic Press, San Diego. 3. Rowan (1998) in *Handb. ### 5'-(2-Hydroxyethylthio)immucillin-A

This nucleoside analogue (FW<sub>HCl-Salt</sub> = 373.87 g/mol), also known as (1*S*)-1-(9-deazaadenin-9-yl)-5-(2-hydroxyethylthio) 1,4-dideoxy-1,4-imino-D-ribose, inhibits 5'-methylthioadenosine/*S*-adenosylhomocysteine nucleosidase ( $K_i' = 0.41 \text{ nM}$ ). It is also a tight, slow-binding inhibitor of human *S*-methyl-5' thioadenosine phosphorylase ( $K_i = 14 \text{ nM}$ ). **Target(s)**: adenosylhomocysteine nucleosidase (1); 5'-methylthioadenosine/*S*-adenosylhomocysteine nucleosidase (1); *S*-methyl-5'-thioadenosine phosphorylase (2). 1. Singh, Evans, Lenz, *et al.* (2005) *J. Biol. Chem.* **280**, 18265. 2. Evans, Furneaux, Schramm, Singh & Tyler (2004) *J. Med. Chem.* **47**, 3275.

### $\alpha$ -Hydroxyfarnesylphosphonic Acid

This phosphonate (FW<sub>free-acid</sub> = 302.35 g/mol) is a strong competitive inhibitor of protein farnesyltransferase ( $IC_{50} = 30 \text{ nM}$ ) as well as geranylgeranyltransferase I and II, albeit at significantly higher concentrations ( $IC_{50} = 35.8$  and  $67 \mu M$ , respectively). Only 2*E*,6*E*- $\alpha$ -hydroxyfarnesyl-phosphonate induces alteration of Ras processing in intact human-derived leukemia cells and inhibits protein farnesyltransferase in enzyme assays. *Z,E*- $\alpha$ -farnesyl- and geranylphosphonates were inactive. **Target(s)**: lipid-phosphate phosphatase,  $IC_{50} = 73 \mu M$  (1); protein farnesyltransferase (2-7); rubber *cis*-polyprenylcistransferase (8); soluble epoxide hydrolase's phosphatase activity,  $IC_{50} = 73 \mu M$  (1). 1. Tran, Aronov, Tanaka, *et al.* (2005) *Biochemistry* **44**, 12179. 2. Terry, Long & Beese (2001) *The Enzymes*, 3rd ed., **21**, 19. 3. Gibbs (2001) *The Enzymes*, 3rd ed., **21**, 81. 4. **Hydroxyfasudil**

This potent protein kinase inhibitor and vasodilator (FW = 343.83 g/mol; CAS 155558-32-0), also known systematically as 1-(1-hydroxy-5-isoquinolinesulfonyl)homopiperazine, selectively targets RhoA/Rho kinase ( $IC_{50}$  = 10.7  $\mu$ M), an enzyme (abbreviated ROCK) that plays a role in mediating vasoconstriction and vascular remodeling. Extending earlier findings suggesting a role of RhoA/Rho kinase in hippocampal-mediated human memory, Huentelman, Stephan, Talboom, *et al.* (2009) demonstrated that peripheral administration of the ROCK inhibitor hydroxyfasudil improves spatial learning and working memory in a rodent learning model. See *Fasudil* 1. Huentelman, Stephan, Talboom, *et al.* (2009) *Behav. Neurosci.* **123**, 218.

**3-Hydroxyflavone**

This flavone (FW = 238.24 g/mol; M.P. = 169-171°C), also known as flavonol, inhibits certain cytochrome P450 systems, sulfotransferase, and arachidonate metabolism. Note that the synonym flavanol also refers to this class of hydroxylated flavones and their derivatives. **Target(s):** carboxylase (1,2); cyclic AMP-dependent protein kinase (3); cyclooxygenase (4); CYP1A1 (5); CYP1A2 (5,6); CYP3A4, with respect to testosterone (7); 17 $\beta$ -hydroxysteroid dehydrogenase (8); lactoylglutathione lyase, *or* glyoxalase I (9); 5-lipoxygenase, *or* arachidonate 5-lipoxygenase (4); 15-lipoxygenase, *or* arachidonate 15-lipoxygenase (10); phenol sulfotransferase, *or* 7-hydroxyflavone sulfotransferase, *or* SULT1A1 (11,12); quercetin 2,3-dioxygenase (13). 1. Karrer & Visconti (1947) *Helv. Chim. Acta* **30**, 268. 2. Massart (1950) *The Enzymes*, 1st ed. (Sumner & Myrback, eds.), **1** (part 1), 307. 3. Jinsart, Ternai & Polya (1992) *Biol. Chem. **5-Hydroxyflavone**

This flavone (FW = 238.24 g/mol; M.P. = 155-156°C), also known as primuletin, inhibits certain cytochrome P450 systems, certain matrix metalloproteinases, and a sulfotransferase. **Target(s):** CYP1A1 (1); CYP1A2 (1); gelatinase A, matrix metalloproteinase 2 (2); gelatinase B, *or* matrix metalloproteinase 9 (2); 17 $\beta$ -hydroxysteroid dehydrogenase (3); NADH oxidase (4); phenol sulfotransferase, *or* 7-hydroxyflavone sulfotransferase, *or* SULT1A1 (5,6); ribosylidihydrocinotamide dehydrogenase (quinone) (7). 1. **3-Hydroxyglutamate (3-Hydroxyglutamic Acid)**

This derivative of glutamic acid (FW<sub>neutral-species</sub> = 163.13 g/mol)  $pK_a$  values = 2.09, 4.18, and 9.20; Soluble in water and acetic acid; Insoluble in ethanol), also called  $\beta$ -hydroxyglutamate, has two chiral atoms and exists as four stereoisomers. The *threo* and *erythro* diastereoisomers of the L-compound are often used in neurochemical studies as well as in probes of a protein's specificity. **Target(s):** aspartate aminotransferase (Both the *erythro*- and *threo*-isomers are poor substrates, but are better inhibitors.) (1); glutamine synthetase (2);  $\gamma$ -glutamylcysteine synthetase, inhibited by the *threo*- $\beta$ -hydroxy-DL-glutamate (It is also a weak alternative substrate.) (3). 1. Braunstein (1973) *The Enzymes*, 3rd ed., **9**, 379. 2. Webb (1966)

*Enzyme and Metabolic Inhibitors*, vol. 2, p. 336, Academic Press, New York. 3. Sekura & Meister (1977) *J. Biol. Chem.* **252**, 2599.

### N-Hydroxy-DL-glutamate (N-Hydroxy-DL-glutamic Acid)

This modified amino acid (FW<sub>free-acid</sub> = 163.13 g/mol) irreversibly inhibits a number of pyridoxal-phosphate-dependent enzymes and reversibly inhibits glutamate dehydrogenase. **Target(s):** alanine aminotransferase (1); aspartate transaminase (1); glutamate decarboxylase (1); glutamate dehydrogenase (1); glutamate racemase (D-isomer also an alternative substrate) (2). 1. Cooper & Griffith (1979) *J. Biol. Chem.* **254**, 2748. 2. Glavas & Tanner (1997) *Bioorg. Med. Chem. Lett.* **7**, 2265.

### 2-Hydroxyglutarate (2-Hydroxyglutaric Acid)

This toxic and oncogenic  $\alpha$ -hydroxy dicarboxylic acid (FW<sub>free-acid</sub> = 148.12 g/mol) arises by way of the slow NADH-dependent conversion of  $\alpha$ -ketoglutarate, a side-reaction catalyzed by mitochondrial L-malate dehydrogenase (1) and by IDH1<sup>R132H</sup> and IDH1<sup>R132C</sup> mutants of isocitrate dehydrogenase isoform-1 (See AGI-5198). **L-2-Hydroxyglutaric Aciduria:** This disorder results from a defect in L-2-hydroxyglutarate dehydrogenase, a FAD-linked enzyme that catalyzes the irreversible conversion of L-2-hydroxyglutarate to  $\alpha$ -ketoglutarate. L-2-hydroxyglutarate is formed as a NADH-dependent side-reaction by mitochondrial L-malate dehydrogenase, which normally interconverts oxaloacetate and L-malate. L-2-hydroxyglutarate dehydrogenase (L2HDGH) catalyzes the formation of  $\alpha$ -ketoglutarate from L-2-hydroxyglutarate, and patients with this progressive neurodegenerative disease possess mutations in both alleles of the L2HDGH gene. **(R)-2HG's Oncometabolic Action:** A cardinal feature of several malignancies is the abundance of hydroxyglutarate. Isocitrate dehydrogenases IDH1 (cytosol) and IDH2 (mitochondrial matrix) catalyze the interconversion of isocitrate and  $\alpha$ -ketoglutarate, a TCA cycle intermediate and an essential cofactor for JmjC domain-containing histone demethylases, TET 5-methylcytosine hydroxylases, and EglN prolyl-4-hydroxylases. Cancer-associated mutations IDH alter the enzymes such that they reduce  $\alpha$ -ketoglutarate to the structurally similar metabolite (R)-2-hydroxyglutarate. These mutations are present in 5-20% of *de novo* NK-AML cases and in 10-20% of secondary AML cases resulting from "pre-malignant" myelodysplastic syndrome (MDS) and myeloproliferative neoplasm (MPN). IDH mutations are also present at a lower frequency (5-10%), in chronic-phase MDS and MP, but are rare in translocation-positive AML. (R)-2-Hydroxyglutarate levels in IDH mutant tumors are often greatly elevated, ranging from 1-30 mM. Because it is structurally and chemically very similar to  $\alpha$ -ketoglutarate, one idea is that (R)-2-hydroxyglutarate transforms cells by competitively inhibiting  $\alpha$ -ketoglutarate-dependent enzymes that function as tumor suppressors. Prolyl hydroxylation of Hypoxia-Inducible transcription Factor- $\alpha$  (HIF $\alpha$ ) increases its affinity for the von Hippel-Lindau protein (pVHL), so designating it for degradation by the ubiquitin-proteasome system. Diminished HIF levels have the effect of enhancing cell proliferation and motility. **Target(s):** 2-(acetamidomethylene)-succinate hydrolase (2); carbamoyl-phosphate synthetase, ammonia-dependent (3); creatine kinase, inhibited by D- and L-isomers (4-7); cytochrome c oxidase, inhibited by D-isomer (8); glutamate decarboxylase, inhibited by both the D- and L-isomers ( $K_i$  = 3.4 and 4.4 mM, respectively) (9); glutamate dehydrogenase, inhibited by L-isomer (10,11). 1. ### 12-Hydroxy-16-heptadecynoic Acid

This unsaturated  $\lambda$ -hydroxy acid (FW = 281.42 g/mol) irreversibly inhibits the cytochrome P450 system responsible for  $\omega$ -oxidation of prostaglandins. The 12S-enantiomer is more active ( $K_i$  = 1.8  $\mu$ M,  $t_{1/2}$  = 0.7 min) than the 12R-isomer ( $K_i$  = 3.6  $\mu$ M,  $t_{1/2}$  = 0.8 min). 1. Aitken, Roman, Loughran, de la Garza & Masters (2001) *Arch. Biochem. Biophys.* **393**, 329. 2. Burger, Clark, Nishimoto, et al. (1993) *J. Med. Chem.* **36**, 1418. 3. Muerhoff, Williams, Reich, et al. (1989) *J. Biol. Chem.* **264**, 749.

### 2-Hydroxyisonicotinate N-Oxide

This presumptive transition-state analogue (FW = 155.11 g/mol) inhibits protocatechuate 3,4-dioxygenase. Binding also results in a major change in the enzyme chromophore spectrum. **Target(s):** protocatechuate 2,3-dioxygenase (1); protocatechuate 3,4-dioxygenase (2-5); protocatechuate 4,5-dioxygenase (6). 1. Wolgel & Lipscomb (1990) *Meth. Enzymol.* **188**, 95. 2. May, Oldham, Mueller, Padgett & Sowell (1982) *J. Biol. Chem.* **257**, 12746. 3. Whittaker & Lipscomb (1984) *J. Biol. Arciero, Orville & Lipscomb (1985) *J. Biol. Chem.* **260**, 14035.

### 2-Hydroxy-4H-isoquinoline-1,3-dione

This isoquinoline derivative (FW = 177.16 g/mol) inhibits ribonucleases utilizing two divalent metal ions within their catalytic sites. **Target(s):** exoribonuclease H (1-3); HIV-1 reverse transcriptase (3,4); ribonuclease III (5); ribonuclease H (1-4); RNA-directed DNA polymerase (1,3,4). 1. Hang, Rajendran, Yang, et al. (2004) *Biochem. Biophys. Res. Commun.* **317**, 321. 2. Nakayama, Bingham, Tan & Maegley (2006) *Anal. Biochem.* **351**, 260. 3. Klumpp, Hang, Rajendran, et al. ### (S)-5-Hydroxy-4-ketonorvaline

This antifungal agent (FW = 147.13 g/mol), also known as (S)-2-amino-5-hydroxy-4-ketopentanoic acid and (S)-2-amino-5-hydroxy-4-oxopentanoic acid, inhibits homoserine dehydrogenase, forming a covalent adduct between C-5 of the agent and C-4 of the nicotinamide ring of NAD<sup>+</sup>. Note

that the (*S*)-stereoisomer is an L-aspartic acid analogue. **Target(s):** asparagine synthetase, weakly inhibited (1); homoserine dehydrogenase (2-4); porphobilinogen synthase, or  $\delta$ -aminolevulinic acid dehydratase (5). 1. Horowitz & Meister (1972) *J. Biol. Chem.* **247**, 6708. 2. Jacques, Mirza, Ejim, *et al.* (2003) *Chem. Biol.* **10**, 989. 3. Yamaki, Yamaguchi, Tsuruo & Yamaguchi (1992) *J. Antibiot. ### 3-Hydroxykynurenine

This amino acid (FW = 224.22 g/mol), also known as 3-(3-hydroxyanthraniloyl)alanine, is an intermediate in tryptophan catabolism. Note that it is highly autooxidizable in air and will generate hydrogen peroxide. Aqueous solutions are yellow at alkaline pH values. **Target(s):** arylformamidase, inhibited by DL-mixture (1); cysteine-S-conjugate  $\beta$ -lyase (2); kynurenine: oxoglutarate aminotransferase (3,4); pyridoxal kinase (5); tryptophan 2,3-dioxygenase (6-8). 1. Serrano & Nagayama (1991) *Comp. Biochem. Physiol. B Comp. Biochem.* **99**, 281. 2. Stevens (1985) *J. Biol. Chem.* **260**, 7945. 3. Guidetti, Okuno & Schwarcz (1997) *J. Neurosci. ### Hydroxylamine

This hygroscopic reagent (FW = 33.03 g/mol;  $pK_a = 7.97$  at 20°C; Very soluble in water) is a powerful nucleophile at neutral to slightly alkaline pH, reacting nonenzymatically with acyl-phosphates, acid anhydrides, thioesters, aldehydes, but not carboxyl groups. In its reaction with acetyl-P, hydroxylamine first forms the kinetically favored *O*-acetylhydroxamate (*i.e.*,  $CH_3(C=O)-O-NH_2$ ); however, in the presence of excess  $NH_2OH$ , the *O*-acetylhydroxamate forms the thermodynamically favored  $CH_3(C=O)-NH-OH$ . Hydroxylamine is an alternative substrate for most ammonia-dependent reactions, and suffices for ammonia in the glutamine synthetase reaction.  $NH_2OH$  also inhibits many enzymes, particularly those requiring pyridoxal 5'-phosphate. It is also a substrate of the reactions catalyzed by hydroxylamine reductase, hydroxylamine oxidase, hydroxylamine oxidoreductase, and aspartyltransferase. It is a product of hyponitrite reductase. It is also a chemical mutagen that deaminates cytosine residues within DNA, resulting in base pairing with an adenine residue instead of guanosine.

### 5-Hydroxylysine

This lysine derivative (FW<sub>monohydrochloride</sub> = 198.65 g/mol; Symbol = 5Hly or Hly), also called  $\delta$ -hydroxylysine, 2,6-diamino-5-hydroxycaproate, and *erythro*-5-hydroxy-L-lysine, has two chiral centers, giving rise to four stereoisomers. Commercial sources typically contain all four isomers: D- and L-5-hydroxylysine and D- and L-*allo*-5-hydroxylysine (which are the *threo* isomers). The *allo*-isomers can be removed by chromatographic methods. L-5-Hydroxylysine has  $pK_a$  values of 2.13, 8.85, and 9.83 ( $\epsilon$ -amino). L-5-Hydroxylysyl residues are also found in the collagens and is an enzyme-catalyzed post-translational modification. **Target(s):**  $\alpha$ -aminoacidase-semialdehyde dehydrogenase (1); glutamine synthetase (2,3); homocitrate synthase (4-6); homoserine kinase (7); D-lysine 5,6-aminomutase, inhibited by the DL mixture (8); L-lysine 6-aminotransferase, inhibited by the DL-5-hydroxylysine and DL-*allo*-5-hydroxylysine (9,10). 1. Schmidt, Bode & Birnbaum (1990) *FEMS Microbiol. Lett.* **58**, 41. 2. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 336, Academic Press, New York. 3. Orr & Haselkorn (1981) *J. Biol. Enzymol.* **17B**, 222. 10. Braunstein (1973) *The Enzymes*, 3rd ed., 9, 379.

### *p*-Hydroxymercuribenzoate

This sulfhydryl-reactive agent (FW<sub>free-acid</sub> = 338.71 g/mol; Abbreviation: PHMB) inhibits a large number of enzymes by modifying catalytically essential active-site thiols. The reactive species in aqueous solutions is the mercuric cation ( $O_3C-C_6H_4-Hg^+$ ). Inhibition is often reversed by the addition of sulfhydryl-containing reagents such as cysteine, dithiothreitol, and glutathione. PHMB is water-soluble and the solubility increases with certain buffers (*e.g.*, Tris, glycylglycine, and pyrophosphate). **Note:** PHMB precipitates when combined with phosphate buffer. A similar result should be anticipated with nucleotides and other phosphorylated metabolites. PHMB forms readily upon hydrolysis of *p*-chloromercuribenzoate (PCMB). The sodium salt is prepared (PCMB is frequently dissolved in 200 mM NaOH followed by an adjustment to a lower pH [*e.g.*, pH 8]). **Targets:** PubMed and related literature searches indicate that >900 enzymes lose catalytic activity upon reaction with PHMB.

### 3-Hydroxy-4-methoxybenzaldehyde

This aromatic aldehyde (FW = 152.15 g/mol; M.P. = 113–115°C), also known as isovanillin, inhibits hemoglobin S polymerization. It is also a precursor in the biosynthesis of *p*'-O-methylnorbeldidine and lycorine. **Target(s):** aldehyde oxidase (1-3); hemoglobin S polymerization, mildly inhibited (4). 1. Clarke, Harrell & Chenery (1995) *Drug Metab. Dispos.* **23**, 251. 2. Austin, Baldwin, Cutler, *et al.* (2001) *Xenobiotica* **31**, 677. 3. Panoutsopoulos & Beedham (2004) *Acta Biochim. Pol.* **51**, 649. 4. Zaugg, Walder & Klotz (1977) *J. Biol. Chem.* **252**, 8542.

### *N*'-Hydroxy-*N*'-methyl-L-arginine

This arginine derivative (FW = 205.24 g/mol) is both a reversible ( $K_i = 33.5 \mu M$ ) and irreversible inhibitor ( $k_{inact} = 0.16 \text{ min}^{-1}$  and  $K_i = 26.5 \mu M$ ) of nitric-oxide synthase. It also induces apoptosis in cell cultures and inhibited the growth of various transplantable mouse tumors. The demethylated *N*'-

hydroxy-L-arginine is an alternative substrate. 1. Pufahl, Nanjappan, Woodard & Marletta (1992) *Biochemistry* **31**, 6822.

### 6-(1S-Hydroxy-3-methylbutyl)-7-methoxy-2H-chromen-2-one

This recently discovered coumarin (FW = 262.31 g/mol) is a novel mechanism-based inhibitor of carbonic anhydrase. Human carbonic anhydrase I, II, and IV have  $K_i$  values of 0.08, 0.06, and 3.8  $\mu\text{M}$ , respectively. Unlike other anhydrase inhibitors, which coordinate directly to the active-site zinc ion, this agent undergoes slow conversion to its reaction product, *cis*-2-hydroxy-4-(1*S*-hydroxy 3-methylbutyl)-3-methoxycinnamic acid, which then remains firmly bound to the enzyme. The inhibition is time dependent, with maximum inhibition requiring 6 hours. The product adopts an extended conformation that plugs the entrance to the active site, while exhibiting no interaction with the zinc ion. 1. Maresca, Temperini, Vu, *et al.* (2009) *J. Amer. Chem. Soc.* **131**, 3057.

### 3-Hydroxy-3-methylglutaric Acid

This  $\beta$ -hydroxy acid and isoprenoids/steroid precursor (FW<sub>free-acid</sub> = 126.11 g/mol; often abbreviated HMG), also known as 3-hydroxy-3-methylpentanedioic acid and dicrotalic acid, is a component of a key intermediate in ketogenesis and steroid biosynthesis. Note that the free diacid is achiral; but becomes chiral upon formation of the CoA derivative. Only the (*S*)-isomer is biologically active. **Target(s)**: aerobactin synthase (1); 3-hydroxy-3-methylglutaryl-CoA reductase (2-6); [3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)]-phosphatase (7); kynurenine aminotransferase (8). 1. Appanna & Viswanatha (1986) *FEBS Lett.* **202**, 107. 2. Rodwell & Bensch (1981) *Meth. Enzymol.* **71**, 480. 3. Russell (1985) *Meth. Enzymol.* **110**, 26. 4. Sipat (1985) *Meth. Enzymol.* **110**, 40. 5. Fimognari & Rodwell (1965) *Biochemistry* **4**, 2086. 6. Kirtley & Rudney (1967) *Biochemistry* **6**, 230. 7. Hegardt, Gil & Calvet (1983) *J. Lipid Res.* **24**, 821. 8. Mason (1959) *J. Biol. Chem.* **234**, 2770.

### (S)-3-Hydroxy-3-methylglutaryl-CoA

This thiolester (FW = 899.66 g/mol) is a key intermediate in the formation of steroids, ketone bodies, and terpenes. It is a product of the reactions catalyzed by hydroxymethylglutaryl-CoA synthase, methylglutaconyl-CoA hydratase, and succinate: hydroxymethylglutarate CoA-transferase. It is a substrate for hydroxymethylglutaryl-CoA lyase, hydroxymethylglutaryl-CoA reductase, and hydroxymethylglutaryl-CoA hydrolase. **Target(s)**: [3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)] kinase (1); [3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)]-phosphatase (2); [3-methyl-2-

oxobutanoate dehydrogenase, or 2-methylpropanoyl-transferring]-phosphatase, or [branched-chain- $\alpha$ -keto-acid dehydrogenase] phosphatase (3,4); phosphoprotein phosphatase (2-4). 1. Omkumar, Darnay & Rodwell (1994) *J. Biol. Chem.* **269**, 6810. 2. Hegardt (1986) *Adv. Protein Phosphatases* **3**, 1. 3. Damuni, Merryfield, Humphreys & Reed (1984) *Proc. Natl. Acad. Sci. U.S.A.* **81**, 4335. 4. Reed & Damuni (1987) *Adv. Protein Phosphatases* **4**, 59.

### 9-(2-Hydroxymethylmorpholin-6-yl)adenine O<sup>2</sup>-Triphosphate

This nucleotide analogue (FW<sub>free-acid</sub> = 490.20 g/mol) acts as an alternative substrate for a number of DNA polymerases, resulting in chain termination. **Target(s)**: DNA-directed DNA polymerase; DNA polymerase  $\beta$ ; HIV-1 reverse transcriptase; Moloney murine leukemia virus reverse transcriptase (not a substrate); RNA directed DNA polymerase. 1. Lebedeva, Seredina, Silnikov, *et al.* (2005) *Biochemistry (Moscow)* **70**, 1.

### 2-Hydroxy-1-naphthoate and 2-Hydroxy-1-naphthoic Acid

This naphthoate derivative (FW<sub>free-acid</sub> = 188.18 g/mol) inhibits 6-methylsalicylate decarboxylase, medium-chain acyl-CoA synthetase, and plant cinnamate 4-monooxygenase. **Target(s)**: CYP73A family, or cinnamate 4-monooxygenase (1,2); medium-chain-fatty-acyl CoA synthetase, or butyryl-CoA synthetase, or butyrate:CoA ligase (3,4); 6-methylsalicylate decarboxylase (5). 1. Schalk, Batard, Seyer, *et al.* (1997) *Biochemistry* **36**, 15253. 2. Schoch, Nikov, Alworth & Werck-Reichhart (2002) *Plant Physiol.* **130**, 1022. 3. Kasuya, Igarashi & Fukui (1996) *Biochem. ### 1-Hydroxy-2-nitro-1,3-propanedicarboxylic Acid

This  $\alpha$ -hydroxy acid (FW<sub>free-acid</sub> = 193.11 g/mol), also known as nitroisocitrate, which is a mimic of an aconitase reaction-cycle intermediate mimic, displays slow-binding properties, with a  $K_i$  value of 0.7 nM (1). While the hydroxyl oxygen of both citrate and isocitrate are exchanged with solvent water via the action of aconitase, the hydroxyl oxygen of nitroisocitrate is not. 1. Schloss, Porter, Bright & Cleland (1980) *Biochemistry* **19**, 2358. 2. Ramsay, Dreyer, Schloss, *et al.* (1981) *Biochemistry* **20**, 7476. 3. Werst, Kennedy, Beinert & Hoffman (1990) *Biochemistry* **29**, 10526. 4. Telsler, Emptage, Merkle, *et al.* (1986) *J. Biol. Chem.* **261**, 4840. 5. Lauble, Kennedy, Beinert & Stout (1992) *Biochemistry* **31**, 2735.

**(3-Hydroxy-2-nitropropyl)phosphonate**

This transition-state inhibitor (FW<sub>free-acid</sub> = 185.07 g/mol) is an analogue of the intermediate in the reaction catalyzed by yeast enolase. The ionized (pK = 8.1) nitronate form, in the presence of 5 mM Mg<sup>2+</sup>, has a K<sub>i</sub> value of 6 nM. This finding supports a carbanion mechanism for enolase and suggests that the 3-hydroxyl of 2-phosphoglycerate is directly coordinated to Mg<sup>2+</sup> prior to its elimination to yield phosphoenolpyruvate. 1. Anderson, Weiss & Cleland (1984) *Biochemistry* **23**, 2779. 2. Poyner, Cleland & Reed (2001) *Biochemistry* **40**, 8009.

**4-Hydroxy-trans-2-nonenal**

This neurotoxic aldehyde (FW = 156.22 g/mol; Abbreviation: HNE) inhibits a wide variety of enzymes and induces apoptosis. It is a major product of lipid peroxidation and is elevated during oxidative stress. Levels are also elevated in Alzheimer and Parkinson diseases. HNE can modify amino, sulfhydryl, and imidazole groups in proteins as well as the sulfhydryl groups of dihydrolipoyl groups in the pyruvate dehydrogenase and  $\alpha$ -ketoglutarate dehydrogenase complexes. **Target(s):** adenylate cyclase (1); aldose reductase (2); bile-acid-CoA:amino acid *N*-acyltransferase (40); carbonic anhydrase (3); carnitine *O*-acetyltransferase (41,42); cathepsin B (4); Ca<sup>2+</sup>-transporting ATPase (5); creatine kinase (6); CYP1A1 (7,8); CYP1A2 (7,8); CYP3A6 (7); CYP2B1 (8); CYP2B4 (7,8); CYP2C3 (8); CYP2E1 (7,8); cytochrome-*c* oxidase (9,10,43); DNA-directed DNA polymerase (11); DNA polymerase  $\alpha$  (11); ecto-ATPase (12); glucose-6-phosphatase (13); glucose-6-phosphate dehydrogenase (14,15); glutamate transport (16); glutathione-disulfide reductase (17); glutathione peroxidase (18,19); glutathione *S*-transferase (20); glyceraldehyde-3-phosphate dehydrogenase (21,22); glycine decarboxylase H protein (23); hsp72 mediated protein refolding (24); I $\kappa$ B kinase (25); interleukin-1 $\beta$  converting enzyme (26); isocitrate dehydrogenase (NADP<sup>+</sup>) (27,28);  $\alpha$ -ketoglutarate dehydrogenase complex (23,29); lipoygenase-1, soybean (30); malic enzyme (23); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (31); 5'-nucleotidase (1); phospholipase D, sphingosine-stimulated (32); phospholipid-translocating ATPase ("flippase") (33); protein-disulfide isomerase (34); pyruvate dehydrogenase complex (23,28,35); succinate-semialdehyde dehydrogenase (36); thioredoxin reductase (37); ubiquitin thiolesterase (38); xanthine oxidase (39). 1. **erythro-9-(2-Hydroxy-3-nonyl)adenine**

This hygroscopic purine nucleoside analogue (FW<sub>free-base</sub> = 277.37 g/mol), also known as EHNA and erythro-3-(adenin-9-yl)-2-nonanol, is a strong (slow-binding) inhibitor of adenosine deaminase, K<sub>i</sub> = 4 nM (1-13), adenosine kinase (14), and cGMP-stimulated phosphodiesterase II, IC<sub>50</sub> = 0.8  $\mu$ M (15-19). EHNA also inhibits the enucleation of terminally differentiated erythroblasts, demonstrating a role for dynein in the formation of erythrocytes and suggesting that dynein helps to shift the nucleus to a position near the plasma membrane (20). EHNA dramatically inhibits 2D migration of the fibroblast, when cell contractility was blocked by Rho kinase or a myosin inhibitor, although EHNA itself did not affect cell migration (21). Cell migration in 3D soft collagen matrices, where the cell exerts a relatively low tractional force compared to that on a 2D stiff surface, is also profoundly inhibited by dynein intermediate chain (DIC) silencing regardless of the presence of myosin activity. **Target(s):** deoxycytidine kinase, K<sub>i</sub> = 0.45 mM (22); dynein ATPase (23-26); GMP synthetase, weakly inhibited (27); 5'-methylthioadenosine nucleosidase (28,29); phosphodiesterase-2 (14-18); phosphodiesterase 4 (18); protein-glutamate *O*-methyltransferase (24); purine-nucleoside phosphorylase (30). 1. ### N<sup>o</sup>-Hydroxy-nor-L-arginine

This arginine derivative (FW = 176.18 g/mol) is a slow-binding inhibitor of arginase II,  $K_i = 51$  nM at pH 7.5. Due to the reciprocal regulation between arginase and nitric oxide synthase, arginase inhibitors have therapeutic potential in treating nitric oxide-dependent smooth muscle disorders, such as erectile dysfunction. 1. Colleluori & Ash (2001) *Biochemistry* **40**, 9356.

### 3-endo-8-exo-8-Hydroxy-2-oxabicyclo[3.3.1]non-6-ene-3,5-dicarboxylate

This bicyclic inhibitor (FW<sub>free-acid</sub> = 228.20 g/mol), also known as (1*R*,3*R*,5*S*)-3-carboxy-1-hydroxy-2-oxabicyclo[3.3.1]non-6-ene-5-carboxylate is a putative transition-state analogue for the reaction catalyzed by chorismate mutase,  $K_i = 0.12$  μM for the *Escherichia coli* enzyme). 1. ### p-Hydroxyoxanilic Acid

This acid (FW<sub>free-acid</sub> = 181.14 g/mol) inhibits 4-hydroxyphenyl-pyruvate dioxygenase,  $K_i = 6$  μM (1) and phenylpyruvate tautomerase,  $K_i = 1.6$  mM (2), and exo- $\alpha$ -sialidase (or neuraminidase, or sialidase (3,4)). 1. ### 4-Hydroxyphenylacetate

This plant phenolic (FW<sub>free-acid</sub> = 152.15 g/mol; M.P. = 149-151°C), found in dandelions (*Taraxacum officinalis*), is a product of reactions catalyzed by 4-hydroxyphenylacetaldehyde dehydrogenase and 4-hydroxyphenylpyruvate oxidase. (Do not confuse this anion with the ester, 4-hydroxyphenyl acetate, i.e.,  $p$ -HO-C<sub>6</sub>H<sub>4</sub>-O(C=O)CH<sub>3</sub>.) **Target(s):** [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (1); dihydropteridine reductase (2); 3,4 dihydroxyphenylacetate 2,3-dioxygenase (3); diiodotyrosine aminotransferase (4); diphosphomevalonate decarboxylase (5);  $\beta$ -glucosidase (6); glutamate decarboxylase (7);

homogentisate 1,2-dioxygenase (8); 4-hydroxybenzoate 3-monooxygenase (9); imidazoleacetate 4-monooxygenase (10); laccase (11); protocatechuate 3,4-dioxygenase (12,13); tyrosine aminotransferase (14,15). 1. ### 4-Hydroxyphenylglyoxal

This  $\alpha$ -ketoaldehyde (FW = 150.13 g/mol) is a more hydrophilic derivative of phenylglyoxal that also chemically modifies arginyl residues in proteins. By comparing the rates of modification with these two reagents, one may assess the hydrophobic versus hydrophilic environment surrounding essential arginyl residues. **Target(s):** amadoriase II (1); 5-enolpyruvylshikimate-3-phosphate synthase (2);  $\beta$ -1,3 galactosyl-*O*-glycosyl-glycoprotein  $\beta$ -1,6-*N*-acetylglucosaminyltransferase (3); glutamine synthetase (4); homoserine kinase (5); peptidyl dipeptidase IV (6); phosphate transporter (7); protein-*S* isoprenylcysteine *O*-methyltransferase (8); tryptophan synthase (9). 1. Wu, Chen, Petrash & Monnier (2002) *Biochemistry* **41**, 4453. 2. Padgett, Smith, Huynh & Kishore (1988) *Arch. Biochem. Biophys.* **266**, 254. 3. Yang, Qin, Lehotay, et al. (2003) *Biochim. ### 4-Hydroxyphenyllactic Acid

This tyrosine metabolite (FW<sub>free-acid</sub> = 182.18 g/mol), also known as 3-(4-hydroxyphenyl)-2-hydroxypropanoic acid, is soluble in water and ethanol. If heated to 100°C, hydroxyphenyllactic acid is converted to 4-hydroxycinnamic acid. **Target(s):** [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or [3-methyl-2-oxobutanoate dehydrogenase acetyl-transferring] kinase, weakly inhibited (1,2); dihydropteridine reductase (3); diiodotyrosine aminotransferase, weakly inhibited (4); diphosphomevalonate decarboxylase (5); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (6); prephenate dehydrogenase (7,8); tyrosyl-tRNA synthetase,  $K_i = 8.1$  mM for the *Escherichia coli* enzyme (9). 1. Paxton (1988) *Meth. Enzymol.* **166**, 313. 2. Paxton & Harris (1984) *Arch. Biochem. Biophys.* **231**, 58. 3. Shen (1984) *Biochim. Biophys. Acta* **785**, 181. 4. Nakano (1967) *J. Biol. ### 3-(3-Hydroxyphenyl)-N-propylpiperidine

These dopamine receptor modulators (FW<sub>free-base</sub> = 219.33 g/mol) exert opposing CNS effects. The *R*(+)-stereoisomer, also known as *R*(+)-*N*-(*n*-propyl)-3-(3-hydroxyphenyl)piperidine (or, *R*(+)-3-PPP), is a dopamine D<sub>2</sub> receptor agonist and σ<sub>1</sub> receptor antagonist. The *S*(-)-enantiomer, or preclamol, is a dopamine receptor antagonist and a dopamine autoreceptor agonist. 1. Arnt, Bogeso, Christensen, *et al.* (1983) *Psychopharmacology* **81**, 199. 2. Hjorth, Carlsson, Clark, *et al.* (1983) *Psychopharmacology* **81**, 89. 3. Tokuyama, Hirata, Ide & Ueda (1997) *Neurosci. Lett.* **233**, 141. 4. Bergeron & Debonnel (1997) *Psychopharmacology* **129**, 215.

### 4-Hydroxyphenylpyruvate

This tyrosine metabolite (FW<sub>free-acid</sub> = 180.16 g/mol), also known as 3-(4-hydroxyphenyl)-2-oxopropanoic acid, is a product of the reaction catalyzed by tyrosine aminotransferase and prephenate dehydrogenase. 4-Hydroxyphenylpyruvate is rapidly oxidized in alkaline solutions, yielding 4-hydroxybenzaldehyde. **Target(s):** aromatic-amino-acid decarboxylase, or dopa decarboxylase (1); [branched-chain α keto-acid dehydrogenase] kinase, or [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase, weakly inhibited (2,3); carnitine:acylcarnitine translocase, weakly inhibited (4); cathepsin D (5); choline acetyltransferase (6); cyclohexadienyl dehydrogenase (7); dihydropteridine reductase (8); D-dopachrome decarboxylase (9); histidine ammonia-lyase (10,11); homogentisate 1,2-dioxygenase (12); horseradish peroxidase (13); kynureninase (14); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (15); peroxidase (13); phenylalanine 4-monooxygenase, activated at low concentrations (16); phenylpyruvate decarboxylase (17); prephenate dehydrogenase (18); pyruvate decarboxylase (1,19); rosmarinic synthase (20); transketolase (21,22); tyrosine 2,3-aminomutase (23); tyrosyl-tRNA synthetase, *K<sub>i</sub>* = 9.9 mM for the *Escherichia coli* enzyme (24). 1. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, Academic Press, New York. 2. Paxton (1988) *Meth. Enzymol.* **166**, 313. 3. Paxton & Harris (1984) *Arch. Biochem. Biophys.* **231**, 58. 4. ### (S)-9-(3-Hydroxy-2-phosphonylmethoxypropyl)adenine

This acyclic adenylyl analogue (FW<sub>free-acid</sub> = 303.21 g/mol), often abbreviated HPMPA, exhibits a broad-spectrum antiviral activity. The pseudonucleoside is phosphorylated *in vivo* to the diphosphate, which inhibits viral DNA phosphorylase. **Target(s):** herpes viruses (HSV-1 and HSV-2) replication (1,2); viral DNA polymerases (1,3,4). 1. Prisbe & Chen (1996) *Meth. Enzymol.* **275**, 425. 2. De Clercq, Holy, Rosenberg, *et al.* (1986) *Nature* **323**, 464. 3. ### 5-Hydroxypipercolate (5-Hydroxypipercolic Acid)

This cyclic amino acid and 4-hydroxyproline “homologue” (FW = 145.16 g/mol; CAS 13096-31-6 (free base) and 824943-40-0 (HCl salt)), also called 5-hydroxy-2-piperidinecarboxylic acid and 5-hydroxypipercolinic acid, is readily prepared from 5-hydroxylysine. The L-enantiomer is found in a number of plants. The *trans*-isomer has been identified in *Bocoa prouacensis*, *Candolleodendron brachystachyum*, *Xylia xylocarpa*, and *Swartzia macrosema*. Both the *cis*- and *trans*-isomers have been identified in *Gymnocladus dioica*. **Target(s):** hydroxylysine kinase (1); platelet aggregation (2). 1. Hiles & Henderson (1972) *J. Biol. Chem.* **247**, 646. 2. Mester, Szabados, Mester & Yadav (1979) *Planta Med.* **35**, 339.

### 17α-Hydroxyprogesterone

This steroid (FW = 330.47 g/mol), also known as 17α-hydroxypregn-4-ene-3,20-dione, is an intermediate in steroid hormone biosynthesis and a major metabolite of renal progesterone metabolism. It also exhibits antigluocorticoid activity (1) and is an estrus regulator. **Target(s):** arylamine *N*-acetyltransferase (2); glucose-6-phosphate dehydrogenase (3); 20α-hydroxysteroid dehydrogenase (4); steroid 17α-hydroxylase-C17,20 lyase, hydroxylase activity inhibited (5); steroid 5α-reductase (6,7); steroid sulfatase (8); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase (ACAT) (9); sterol demethylase (10); UDP-glucuronosyltransferase (11). 1. Scott & Tomkins (1975) *Meth. Enzymol.* **40**, 273. 2. Kawamura,

Westwood, Wakefield, *et al.* (2008) *Biochem. Pharmacol.* **75**, 1550. **3.** Criss & McKerns (1969) *Biochim. Biophys. Acta* **184**, 486. **4.** Robertson, Frost, Hoyer & Weinkove (1982) *J. #### 4-Hydroxy-L-proline

This hydroxylated imino acid (FW = 131.13 g/mol; pK<sub>a</sub> values of 1.82 and 9.66 at 25°C) has two stereoisomers, the most common being *trans*-4-hydroxy-L-proline (symbolized by 4Hyp). This nonproteogenic imino acid is abundant in collagen, arising by posttranslational modification catalyzed by prolyl hydroxylase. 4-Hydroxyproline can also be produced via the cyclization of  $\gamma$ -hydroxyglutamate. The *cis* form of L-proline (also called allo-4-hydroxy-L-proline) is found in free form in *Santalum album* and other plants. **Target(s):** alkaline phosphatase (1); arginase (1); hydroxyllysine kinase (2); pyrroline-5-carboxylate dehydrogenase (3,4); pyrroline-5-carboxylate reductase (5). **1.** Bodansky & Strachman (1949) *J. Biol. Chem.* **179**, 81. **2.** Hunter & Downs (1945) *J. Biol. Chem.* **157**, 427. **3.** Hiles & Henderson (1972) *J. Biol. Chem.* **247**, 646. **4.** Strecker (1971) *Meth. Enzymol.* **17B**, 262. **5.** Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 355, Academic Press, New York.

#### 3-Hydroxypyruvate

This  $\alpha$ -keto acid (FW<sub>free-acid</sub> = 104.06 g/mol), also known as 3-hydroxy-2-oxopropanoic acid, is soluble in diethyl ether, acetone, and water. Aqueous solutions spontaneously dimerize to form 2,3-dihydroxy-2-hydroxymethyl-4-ketoglutarate. 3-Hydroxypyruvate is a product of the reactions catalyzed by glycerate dehydrogenase, serine 2-dehydrogenase, serine:glyoxylate aminotransferase, and serine:pyruvate aminotransferase. It is also a substrate for hydroxypyruvate reductase, hydroxypyruvate decarboxylase, pyruvate decarboxylase, and hydroxypyruvate isomerase. It is a suicide inhibitor of acetolactate synthase. **Target(s):** acetolactate synthase (1); *N*-acetylneuraminidase (2); *N*-acetylneuraminidase lyase mutant with an increased dihydrodipicolinate synthase activity (3); acid phosphatase, weakly inhibited, K<sub>i</sub> = 111 mM (4); glycerate kinase (5); 4-hydroxy-2-oxoglutarate aldolase (6,7); lactate dehydrogenase, also alternative substrate (8); phosphoglycerate phosphatase (9); pyruvate carboxylase (10,11); pyruvate decarboxylase, also alternative substrate (12); pyruvate dehydrogenase complex (13,14); pyruvate:ferredoxin oxidoreductase (15). **1.** Duggleby (2005) *J. #### 8-Hydroxyquinoline

This laboratory reagent (FW = 145.16 g/mol; M.P. = 76°C), also known as 8-quinolinol, 8-oxyquinoline, and oxine, is a metal ion chelator that forms tight, water-insoluble complexes. Its solubility in diethyl ether, benzene, chloroform affords a way to deplete metal ion contaminants in aqueous solutions used in enzyme research. The copper complex has also been used as a fungicide. Chelators inhibit many metal ion-requiring enzymes as well as those enzymes, for which the active substrate must be complexed to a metal ion. **1.** Mellor & Maley (1947) *Nature* **159**, 370. **2.** Bjerrum (1941) *Metal Ammine Formation in Aqueous Solution*, P. #### 5-Hydroxytryptamine, See Serotonin

#### L-5-Hydroxytryptophan

This serotonin precursor (FW = 220.23 g/mol) is found in plants and animals. The L-enantiomer is a product of the reaction catalyzed by tryptophan 5-monoxygenase and substrate of L-aromatic amino-acid decarboxylase. 5-Hydroxytryptophan decomposes slowly when exposed to air and should be stored under nitrogen or argon. **Target(s):** alkaline phosphatase, by racemic mixture (1); anthranilate synthase (2); aromatic-L-amino-acid decarboxylase, or dopa decarboxylase, inhibited by the D-isomer (The L-enantiomer is an alternative substrate.) (3-6); catechol oxidase (7); chorismate mutase (8); 3-deoxy-7-phosphoheptulonate synthase, weakly inhibited (9); histidine decarboxylase (10); indoleamine 2,3-dioxygenase, also alternative substrate (11-13); nitronate monooxygenase (14); phenylalanine decarboxylase (15); thyroxine deiodinase, or iodothyronine deiodinase (16); tryptophan 2,3-dioxygenase (10,17-19); tryptophanyl-tRNA synthetase (20,21); tyrosinase, or monophenol monooxygenase (22); tyrosine aminotransferase (23); tyrosine 3-monoxygenase, moderately inhibited (24,25). **1.** Fishman & Sie (1971) *Enzymologia* **41**, 141. **2.** Widholm (1972) *Biochim. ### Hydroxyurea

This free radical-scavenging antineoplastic agent (FW = 76.06 g/mol), also called *N*-hydroxyurea and hydroxycarbamide, inhibits eukaryotic ribonucleoside diphosphate reductase, quenching a catalytic tyrosyl radical (1). The resulting inhibition of DNA biosynthesis stalls cells in S-phase, often attended by cell death. This property has been exploited in the cell-cycle synchronization of animal, plant and yeast cells. Hydroxyurea is also used to treat sickle cell patients by inducing synthesis of fetal hemoglobin and reducing HbS polymerization and blocking adhesion of sickle cells to capillary membranes. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** L-ascorbate peroxidase (2); carbonic anhydrase, human CAI,  $K_i = 0.1$  mM (3); propanediol dehydratase (4); ribonucleotide reductase (ribonucleoside-diphosphate reductase), by reacting with and trapping an essential free radical catalytic intermediate (1,5-19); ribonucleotide reductase (ribonucleoside-triphosphate reductase) (20,21); urease, weak alternative substrate (22-28). 1. ### Hydroxyzine

This diphenylmethane/piperazine-class antihistamine (FW = 374.90 g/mol; CAS 68-88-2), also known by the trade names Vistaril<sup>®</sup>, Atarax<sup>®</sup>, Equipose<sup>®</sup>, Masmoran<sup>®</sup>, and Paxistil<sup>®</sup> as well as the IUPAC name (±)-2-(2-

{4-[(4-chlorophenyl)-phenylmethyl]piperazin-1-yl}ethoxy)ethanol, exhibits anxiolytic, anti-obsessive, and antipsychotic properties. Hydroxyzine is a potent inverse histamine H<sub>1</sub> receptor agonist,  $K_i = 2$  nM (1-4). Hydroxyzine is also an antagonist for serotonin 5-HT<sub>2A</sub> receptor ( $K_i = \sim 50$  nM), dopamine D<sub>2</sub> receptor ( $K_i = 380$  nM), and  $\alpha_1$ -adrenergic ( $K_i = \sim 300$  nM) receptor (2,3,5). Hydroxyzine's antiserotonergic effects likely underlie its usefulness as an anxiolytic (6), as other antihistamines without such properties are not effective in the treatment of anxiety (7). Upon oral and intramuscular administration, hydroxyzine is rapidly absorbed, distributed, and metabolized to cetirizine by the action of alcohol dehydrogenase. Drug effects are observed within one hour of administration, with a mean half-life of  $\sim 3$  hours in adults. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) ### Hymenialdisine

This marine sponge alkaloid (FW = 324.14 g/mol) inhibits nuclear factor- $\kappa$ B and protein tyrosine kinases. [Mitogen-activated protein kinase] kinase 1 is also inhibited by both the 10E- and 10Z-isomers, with IC<sub>50</sub> values of 3 and 6 nM, respectively. **Target(s):** casein kinase 1 (1); cyclin-dependent kinase 2 (1); cyclin-dependent kinase 5/p35 (1); [glycogen synthase] kinase  $\beta$  (1); [mitogen-activated protein kinase] kinase 1 (2); nuclear factor- $\kappa$ B (3-5); protein-tyrosine kinase (5). 1. ### Hyperforin

This photosensitive constituent (FW = 536.80 g/mol; M.P. = 79-80°C) from St John's wort (*Hypericum perforatum*) inhibits the activity of a number of cytochrome P450 systems (1-3). Hyperforin also inhibits the synaptosomal uptake of serotonin, norepinephrine, and dopamine, actions that may be responsible for the antidepressant activity of St. John's wort. Hyperforin acts as a protonophore, inducing TRPC6-independent H<sup>+</sup> currents in HEK-

293 cells, cortical microglia, chromaffin cells and lipid bilayers (4). **Target(s):** cyclooxygenase I (1); CYP1A2 (2); CYP3A4 (2,3); CYP2C9 (2,3); CYP2C19 (2); CYP2D6 (2,3); dopamine reuptake (5,6); 5-lipoxygenase (1,7); norepinephrine reuptake (5,6); serotonin reuptake (5,6). 1. ### Hypoestoxide

This bicyclo[9.3.1]pentadecane (FW = 375.49 g/mol), a diterpene from *Hypoestes rosea* (a shrub found in the African rain forest and constituent in Nigerian folk medicine), inhibits IκB kinase, thereby suppressing the synthesis of such pro-inflammatory cytokines as tumor necrosis factor α, interleukin 1β, and interleukin-6. Hypoestoxide also inhibits vascular endothelial growth factor induced cell proliferation in vitro, with an IC<sub>50</sub> of 28.6 μM. 1. Ojo-Amaize, Kapahi, Kakkanaiah, *et al.* (2001) *Cell Immunol.* **209**, 149. 2. Ojo-Amaize, Nchekwube, Cottam, *et al.* (2002) *Cancer Res.* **62**, 4007.

### Hypoglycin A

This toxic amino acid (FW = 141.17 g/mol; CAS 156-56-9), also known as (α,1R)-α-amino-2-methylenecyclopropanepropionic acid, from unripe ackee fruit (*Blighia sapida*) gives rise to methylenecyclopropyl)acetyl-CoA, which inhibits several acyl-CoA dehydrogenases, including butyryl-CoA dehydrogenase and isovaleryl-CoA dehydrogenase. (**See also (Methylenecyclopropyl)acetyl-CoA**) As indicated by its name, hypoglycin A also induces severe hypoglycemia. 1. Billington & Sherratt (1981) *Meth. Enzymol.* **72**, 610.

### Hypophosphite Ion

This conjugate base of hypophosphorus acid H<sub>3</sub>PO<sub>2</sub> (FW<sub>free-acid</sub> = 64.99 g/mol; FW<sub>NaSalt</sub> = 87.98 g/mol; pK<sub>a</sub> = 1.1) is a formate analogue that inhibits a number of formate-dependent reactions. It is a specific *k*<sub>cat</sub> inhibitor of pyruvate formate-lyase, destroying the radical intermediate and forming enzyme-1-hydroxyethylphosphonate upon reaction with the acetyl-enzyme intermediate (1,2). **CAUTION:** Sodium hypophosphite (Formula: NaPO<sub>2</sub>H<sub>2</sub>·H<sub>2</sub>O; FW = 105.99 g/mol; CAS 10039-56-2; DEA Listed (See Section 1310.02)), also known as sodium phosphinate, will explode upon exposure to strong oxidants. It should be kept in a cool, dry place that is isolated from oxidizing materials. When heated, it decomposes to form phosphine gas, a respiratory irritant. **Target(s):** formate C-acetyltransferase, pyruvate formate-lyase (1-5); formate dehydrogenase (6-10); formate hydrogen-lyase (9). 1. Unkrig, Neugebauer & Knappe (1989)

*Eur. J. Biochem.* **184**, 723. 2. Plaga, Frank & Knappe (1988) *Eur. J. Biochem.* **178**, 445. 3. Brush, Lipsett & Kozarich (1988) *Biochemistry* **27**, 2217. 4. ### Hypotaaurine

This sulfonic acid (FW<sub>neutral</sub> = 109.15; pK<sub>a</sub> values of 2.16 and 9.56), also known as 2-aminoethanesulfinate, is an intermediate in taurine biosynthesis. Hypotaaurine also exhibits antioxidant properties. It is a product of the reactions catalyzed by cysteamine dioxygenase and sulfinolalanine decarboxylase. **Target(s):** acetyl-L-carnitine uptake (1); β-alanine uptake (2); cystathionase, or cystathionine γ-lyase (3); mercaptopyruvate sulfurtransferase (4); Na<sup>+</sup>-dependent γ-aminobutyrate uptake (5); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (6); taurine uptake (7,8). 1. Burlina, Seršen, Debler & Lajtha (1989) *Neurochem. Res.* **14**, 489. 2. Komura, Tamai, Senmaru, Terasaki, Sai & Tsuji (1996) *J. Neurochem.* **67**, 330. 3. Pharmacol.* **50**, 1783. 8. Tayarani, Cloez, Lefauconnier & Bourre (1989) *Biochim. Biophys. Acta* **985**, 168.

### Hypoxanthine

This purine (FW = 136.11 g/mol; CAS 68-94-0; Solubility: 0.07 g/100 mL H<sub>2</sub>O; more soluble in alkaline or acidic solutions; λ<sub>max</sub> (pH 6) at 249.5 nm; ε = 10700 M<sup>-1</sup>cm<sup>-1</sup>; λ<sub>max</sub> (pH 6) at 259 nm (ε = 11100 M<sup>-1</sup>cm<sup>-1</sup>; Abbreviated Hyp), also called 6-hydroxypurine and purin-6(1H)-one, is an intermediate in the degradation of adenine and its nucleoside and nucleotide forms. Hyp can also be chemically prepared from adenine by the action of nitrous acid. In addition to its role as a metabolic intermediate, hypoxanthine is also found in certain tRNA molecules, presumably as a consequence of deamination. Hypoxanthine exists as tautomers; with the equilibrium favoring the lactam. Hypoxanthine is a substrate or product (and product inhibitor) for a number of enzymes, including hypoxanthine phosphoribosyltransferase, inosine nucleosidase, inosinate nucleosidase, DNA deoxyinosine glycosylase, and adenine deaminase. It is an important alternative substrate for xanthine oxidase. **Target(s):** adenine phosphoribosyltransferase (1); adenosine deaminase (2,3); alcohol dehydrogenase, yeast (4); D-amino-acid oxidase (5); 3',5'-cyclic-nucleotide phosphodiesterase (6); DNA-(apurinic or apyrimidinic site) lyase (7); guanine deaminase, weakly inhibited (8,9); inosine nucleosidase, product inhibition (10,11); NAD<sup>+</sup> ADP ribosyltransferase (poly(ADP-ribose) polymerase; IC<sub>50</sub> = 1.7 mM (12); nicotinamide phosphoribosyltransferase (13); pteridine oxidase (14); purine nucleosidase (15,16); purine-nucleoside phosphorylase (or guanosine phosphorylase; product inhibition (17,18); tRNA-guanine transglycosylase, weakly inhibited (19); urate oxidase, or uricase (20); xanthine phosphoribosyltransferase, also alternative substrate (21,22). 1. ### IA<sub>3</sub>

This 68-residue vacuolar protease inhibitor (MW = 7707 Da), isolated from *Saccharomyces cerevisiae*, inhibits yeast proteinase A (saccharopepsin or YPrA):  $K_i = 1.7$  nM (1-7). The inhibitor appears to be completely selective in that only yeast aspartic proteinase A is inhibited to any significant extent. IA<sub>3</sub> thus represents the first example of a totally specific, naturally occurring, aspartic-proteinase inhibitor (1). The free inhibitor is intrinsically disordered in aqueous solution; however, upon binding to the protease, residues 2-34 form an  $\alpha$ -helix. Multi-scale computer simulations were used to explore the inhibitor's detailed binding trajectories, suggesting important roles of non-native interactions in the initial encounter and binding steps preceding IA<sub>3</sub> folding (8). 1. ### Ibandronate

This bone resorption inhibitor (FW<sub>free-acid</sub> = 308.23 g/mol; CAS 138926-19-9 (sodium salt)), also known by the trade names Boniva, Bondronat and Bonviva, and systematically as {1-hydroxy-3-[methyl(pentyl)-amino]propane-1,1-diyl}bis(phosphonic acid), inhibits farnesyl transferase and squalene synthase. The effects of nitrogen-containing bisphosphonates (N-BPs) on osteoclasts (Ocs) may differ with dose and regimen. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** farnesyltransferase, or geranylgeranyl-diphosphate synthase (1); geranyltransferase, or farnesyl-diphosphate synthase (2-6); protein farnesyltransferase (7); protein geranylgeranyltransferase (7,8); squalene synthase (9). 1. ### Iberitoxin

This 37-residue peptide (FW = 4221.90 g/mol; CAS 129203-60-7; Sequence: pEFTD<sup>pE</sup>VD<sup>pE</sup>DCSVSK<sup>pE</sup>CWSV<sup>pE</sup>CKDL<sup>pE</sup>FGVDRGK<sup>pE</sup>CMGKK<sup>pE</sup>CRCYQ, where pE is a pyroglutamate; internal disulfides: Cys7-to-Cys28, Cys13-to-Cys33, and Cys17-to-Cys35; Solubility = ~0.7 mg/mL H<sub>2</sub>O; Symbol: IbTx), from the venom of the Indian scorpion *Buthus tamulus*, is a selective and reversible high-affinity inhibitor of the high-conductance calcium ion-activated potassium channel, or PK<sub>2</sub>Ca (1). While charybotoxin, noxiustoxin and iberitoxin display a high degree of sequence homology, the first two are known to inhibit more than one class of channel (*i.e.*,

several Ca<sup>2+</sup>-activated and voltage-dependent K<sup>+</sup> channels). Iberitoxin (concentration range: 10-100 nM) is a selective inhibitor of PK<sub>2</sub>Ca, and tetraethylammonium ion that blocks PK<sub>2</sub>Ca at low (100-300 nM) concentrations, increasing the myogenic activity of bladder, but not portal vein (2). IbTx also causes a sustained contracture of aorta (2). 1. Galvez, Gimenez-Gallego, Reuben, *et al.* (1990) *J. Biol. Chem.* **265**, 11083. 2. Suarez-Kurtz, Garcia & Kaczorowski (1991) *J. Pharmacol. Exp. Ther.* **259**, 439.

### I-BET-762

This BET protein-directed inhibitor (FW = 423.90 g/mol; CAS 1260907-17-2; Solubility: 80 mg/mL DMSO or Ethanol, 11 mg/mL H<sub>2</sub>O), also known as GSK525762 and GSK525762A and systematically named 6-(4-chlorophenyl)-N-ethyl-8-methoxy-1-methyl-(4S)-4H-[1,2,4]triazolo[4,3-a][1,4]benzodiazepine-4-acetamide, targets Bromodomain and Extra-Terminal domain (BET) proteins (IC<sub>50</sub> ~35 nM), interfering with their recognition of acetylated histones, disrupting formation of chromatin complexes essential for expression of pro-inflammatory genes, and suppressing production of such proteins by macrophages. I-BET-762 blocks acute inflammation and is highly selective over other bromodomain-containing proteins. I-BET-762 confers protection against lipopolysaccharide-induced endotoxic shock and bacteria-induced sepsis. Treatment of naïve CD4<sup>+</sup> T cells with I-BET-762 during the first 2 days of differentiation has long-lasting effects on subsequent gene expression and cytokine production, with up-regulated expression of several anti-inflammatory gene products, including IL-10, Lag3, and Egr2, and down-regulated expression of several pro-inflammatory cytokines including GM-CSF and IL-17. The short 2-day treatment with I-BET-762 inhibits the ability of antigen-specific T cells (differentiated under Th1, but not Th17, conditions *in vitro*) to induce pathogenesis in an adoptive transfer model of experimental autoimmune encephalomyelitis. 1. Nicodeme, Jeffrey, Schaefer, *et al.* (2010) *Nature* **468**, 1119. 2. Bandukwala, Gagnon & Togher, *et al.* (2012) *Proc. Natl. Acad. Sci. USA* **109**, 14532.

**IBMX**, See *3-Isobutyl-1-methylxanthine*

### Ibodutant

This tachykinin/neurokinin, or NK<sub>2</sub>, receptor antagonist (FW = 644.37 g/mol), also known by the code name MEN15596 and its IUPAC name [1-(2-phenyl-1R-[[1-(tetrahydropyran-4-ylmethyl)piperidin-4-ylmethyl]carbamoyl]ethylcarbamoyl)cyclopentyl]amide is a candidate drug for the treatment of irritable bowel syndrome. In functional assays of phosphatidylinositol accumulation in human NK<sub>2</sub>R-expressing CHO cells, ibodutant gives a pK<sub>binding</sub> of 10.6. Its antagonism is competitive and is reversed by the natural ligand neurokinin A. The same assay indicated that ibodutant attains equilibrium quickly and is released slowly from NK<sub>2</sub>R (1). That ibodutant antagonizes NK<sub>2</sub>R internalization in the human colon suggests it may be useful in treating hypermotility gut diseases, especially because NK<sub>2</sub> receptors are the predominant mediator of spasmogenic activity of tachykinins on enteric smooth muscle (2). When examined over the 0.3 to 100 nM range, ibodutant produces a concentration-dependent inhibition (calculated pK<sub>binding</sub> = 8.31) for the nonadrenergic-noncholinergic (NANC) contractile response, as induced by electrical field stimulation (EFS) of intrinsic airway nerves in main bronchi isolated from guinea pig

(3). 1. Meini, Bellucci, Catalani, *et al.* (2009) *J. Pharmacol. Exp. Ther.* **329**, 486. 2. Cipriani, Santicioli, Evangelista, *et al.* (2011) *Neurogastroenterol. Motil.* **23**, 96. 3. Santicioli, Meini, Giuliani, Lecci & Maggi (2013) *Eur. J. Pharmacol.* **720**, 180.

### Ibogaine

This alkaloid (FW<sub>free-base</sub> = 310.44 g/mol; CAS 83-74-9) from the African shrub *Tabernanthe iboga* possesses hallucinogenic properties and is banned in many countries. Ibogaine is a noncompetitive NMDA (*N*-methyl-D-aspartate) receptor antagonist, a  $\sigma_2$  agonist, and also inhibits serotonin and dopamine transport. Ibogaine is an anti-addictive drug that decreases withdrawal symptoms and drug craving over an extended period of time after administration of a single dose. Extracts of the shrub are used by certain African natives when stalking game, enabling the hunter to remain motionless for long periods of time, while still remaining attentive and mentally alert. Ibogaine has a melting point of 152-153°C, is practically insoluble in water and soluble in ethanol and chloroform, and has  $\lambda_{\text{max}}$  values of 226 and 298 nm ( $\epsilon = 24,500$  and  $8,500 \text{ M}^{-1}\text{cm}^{-1}$ , respectively). Its  $\text{pK}_a$  is 8.1 in 80% methyl cellosolve. **Primary Mechanism of Inhibitory Action:** Although ibogaine's structural similarity to serotonin had spurred early suggestions that it binds to the substrate site of serotonin transporters, *or* SERT, ibogaine binds to a distinct site, one that is accessible only from the cell's exterior. Ibogaine thereby inhibits both serotonin transport and serotonin-induced ionic currents (1). When added to the extracellular medium, ibogaine inhibits SERT substrate-induced currents, but does not when introduced into the cytoplasm by means of a patch electrode. Ibogaine inhibition does not involve the formation of a long-lived complex with SERT; instead, it binds directly to the transporter, but only when the latter adopts an inward-open conformation. Ibogaine also noncompetitively inhibits the homologous dopamine transporter (DAT), blocking substrate-induced currents in DAT and increasing accessibility of the DAT cytoplasmic permeation pathway (1). **Target(s):** cholinesterase (2); dopamine transport (3); NMDA receptor (4,5); serotonin transport (1,3). 1. Bulling, Schicker, Zhang, *et al.* (2012) *J. Biol. Chem.* **287**, 18524. 2. Augustinsson (1950) *The Enzymes*, 1st ed., 1 (Part 1), 443. 3. Wells, Lopez & Tanaka (1999) *Brain Res. Bull.* **48**, 641. 4. Leal, de Souza & Elisabetsky (2000) *Neurochem. Res.* **25**, 1083. 5. Itzhak & Ali (1998) *Ann. N. Y. Acad. Sci.* **844**, 88.

### Ibotenic acid

This naturally occurring neurotoxic 3-isoxazolol amino acid (FW = 158.11 g/mol; CAS 2552-55-8; Symbol: IA) from the exquisitely poisonous mushrooms *Amanita muscaria*, *A. pantherina*, and *A. strobiliformis*, is a powerful brain-lesioning, excitotoxic amino acid, which (like kainic acid) produces profound neuropathological and neurochemical changes in the basal ganglia. Lesioned animals show a behavioral syndrome reminiscent of Huntington's chorea, accompanied by a substantial increase in local cerebral metabolic activity in several striatal target structures within the extrapyramidal motor system (1). Injection results in demyelination, disrupting axonal transport in areas containing diffuse fiber systems, presumably as a consequence of a non-specific inflammatory response (2). As a conformationally restricted glutamate analogue that is closely related to muscimol (**See Muscimol**), ibotenic acid activates **Inhibitory Glutamate Receptors** (IGluRs), a family of ion channel proteins closely related to ionotropic glycine and GABA receptors that are gated directly by glutamate; the open channel is permeable to chloride and sometimes potassium (3). **Note:** L-2-Amino-3-phosphonopropionate is a stereospecific inhibitor of ibotenic acid-stimulated phosphoinositide hydrolysis in rat brain slices, with little affinity for ionotropic receptors (4). L-2-Amino-3-phosphonopropionate's inhibitory effects are not readily reversed. 1.

### Ibrutinib

This highly potent, orally available protein kinase inhibitor (FW = 450.50 g/mol; CAS 936563-96-1; Solubility: 88 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known by the code name PCI-32765 and its systematic name 1-[(3*R*)-3-[4-amino-3-(4-phenoxyphenyl)pyrazole[3,4-*d*]pyrimidin-1-yl]piperidin-1-yl]prop-2-en-1-one, targets Bruton tyrosine kinase (BTK) autophosphorylation (IC<sub>50</sub> = 11 nM), phosphorylation of PLC $\gamma$ , BTK's physiological substrate (IC<sub>50</sub> = 29 nM), and phosphorylation of ERK (IC<sub>50</sub> = 13 nM) (1,2). That the Bruton tyrosine kinase (Btk) is specifically required for BCR signaling was demonstrated by human and mouse mutations disrupting Btk function and likewise preventing B-cell maturation at steps requiring a functional B-cell antigen receptor (BCR) pathway (1-4). In contrast to conventional chemo-immunotherapy, ibrutinib is not myelo-suppressive (3,4). In chronic lymphocytic leukemia (*or* CLL), ibrutinib characteristically causes an early redistribution of tissue-resident CLL cells into the blood, with rapid resolution of enlarged lymph nodes, along with a surge in lymphocytosis (3,4). After weeks to months of continuous ibrutinib therapy, the growth- and survival-inhibitory activities of ibrutinib result in the normalization of lymphocyte counts and remissions in a majority of patients (3,4). Ibrutinib is also under development for the treatment of other B-cell malignancies, mantle cell lymphoma (MCL) and diffuse large B-cell lymphoma (DLBCL), as well as multiple myeloma (MM), follicular lymphoma (FL) and Waldenström's macroglobulinemia (WM). Actin-based motility of *Shigella flexneri* is regulated by Bruton's tyrosine kinase, and treatment with ibrutinib effectively impairs cell-to-cell spread of this pathogen (5). 1. ### Ibuprofen

(S)-(+)-ibuprofen

This orally active, nonsteroidal anti-inflammatory drug (NSAID) and anti-pyretic agent (FW<sub>free-acid</sub> = 206.28 g/mol; CAS 15687-27-1; M.P. = 75-77°C), also known as 2-(4-isobutylphenyl)propionic acid, was introduced in the UK in 1966 and in the U.S. in 1974. Ibuprofen was the first non-steroidal anti-inflammatory drug licensed for over-the-counter use in the U.K. in 1983 and in the U.S. in 1984. **Primary Mode of Action:** In 1971, Nobelist J. R. Vane first reported that aspirin and indomethacin inhibit prostaglandin biosynthesis, an observation that led to the concept that nonsteroidal anti-inflammatory drugs inhibit cyclooxygenases, thereby blocking the formation of cyclooxygenase pathway products. Ibuprofen inhibits the cyclooxygenase activity of prostaglandin synthases 1 and 2, thereby reducing cytokine production, inhibiting associated signal transduction pathways, and modulating leucocyte activity. The (S)-(+)-stereoisomer is the more active, with IC<sub>50</sub> values of 8.9 and 7.2  $\mu\text{M}$  for

COX-1 and COX-2, respectively. Ibuprofen also selectively activates 15-lipoxygenase activity in human PMNs at concentrations that completely inhibit 5-lipoxygenase as well as the human platelet cyclooxygenase pathways. In human platelets, they found that ibuprofen inhibited thromboxane B<sub>2</sub> production (IC<sub>50</sub> = 65 μM), whereas the lipoxygenase product 12-HETE was not appreciably affected, even at 5 mM ibuprofen. **Pharmacokinetics:** Absorption of ibuprofen is rapid and complete when given orally. Ibuprofen binds to and is carried by serum albumin, mainly at its high-affinity binding site (K<sub>d</sub> for Site-II = 0.3 × 10<sup>-6</sup> M). When displaced by naproxen, ibuprofen binds to serum albumin's low-affinity binding site (K<sub>d</sub> for Site-I = 3 × 10<sup>-4</sup> M), where it competes with aspirin and other agents. At doses >600 mg, a greater fraction of drug remains unbound, resulting in an increased ibuprofen clearance and a reduced AUC of total drug. Substantial concentrations of ibuprofen are attained in synovial fluid, the proposed site of action for most nonsteroidal anti-inflammatory drugs. Ibuprofen has a short elimination half-life (t<sub>1/2</sub> ~2 hours) and exceptional gastrointestinal tolerability. Ibuprofen is eliminated following biotransformation to glucuronide conjugates that are excreted in urine, with little of the drug eliminated in its original form. *S*-Ibuprofen is also metabolized by cytochrome P450 (CYP2C9), as are many other agents, including naproxen, celecoxib, sildenafil, warfarin, and tamoxifen. Voriconazole and fluconazole inhibit CYP2C9, thereby affecting ibuprofen turnover. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** amidase (1,2); arylamine *N*-acetyltransferase (3); cyclooxygenase, or prostaglandin endoperoxide synthase (4-12); estrone sulfotransferase (13); fatty-acid amidohydrolase, or amidase (1,2); histidine decarboxylase (14); lysine decarboxylase (14); long-chain-fatty-acyl-CoA synthetase, or long chain-fatty-acid:CoA ligase, inhibited by the *R*-isomer (15); α-methylacyl-CoA epimerase (16,17); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (18); phenol sulfotransferase, or aryl sulfotransferase (13); phenyl-pyruvate tautomerase, weakly inhibited (19); phosphoribosylamino-imidazolecarboxamide formyltransferase (20); thiopurine *S* methyltransferase (21). Ibuprofen also enhances the anticancer activity of cisplatin in lung cancer cells by inhibiting the heat shock protein 70 (22). **1.** Fowler, Holt & Tiger (2003) *J. Enzyme Inhib. Med. ### IC261

This casein kinase inhibitor and microtubule-disrupting agent (FW = 311.30 g/mol; CAS 186611-52-9; Solubility: 10 mg/mL DMSO; Insoluble in water) selectively targets casein kinase 1δ (IC<sub>50</sub> = 0.7-1.3 μM), and casein

kinase 1ε (IC<sub>50</sub> = 0.6-1.4 μM), with weaker action against weakly inhibit casein kinase 1α<sub>1</sub> (IC<sub>50</sub> = 11-21 μM), PKA (IC<sub>50</sub> = >100 μM), p34/cdc2 (IC<sub>50</sub> = >100 μM), and Fyn, or p55 (IC<sub>50</sub> = >100 μM). X-ray structural analysis reveals that IC261 stabilizes casein kinase-1 in a conformation that is midway between nucleotide substrate-liganded and nonliganded conformations, with a delocalized network of side-chain interactions likely to account for the decreased dissociation rate for IC261 (1). Inhibition by is reversible and ATP-competitive. At low concentrations, IC261 causes centrosome amplification and multipolar mitosis, first suggesting a role for CK1δ and CK1ε isoforms in regulating centrosome or spindle function during mitosis (2). Later work, however, demonstrated that IC261 induces rapid and reversible microtubule depolymerization, an action that can be antagonized by pre-treatment of cells with taxol (3). (As shown above, IC261 has structural similarity to colchicine.) At lower IC261 concentrations, mitotic spindle microtubule dynamics are likewise affected, leading to cell-cycle arrest and, depending on the cellular background, to apoptosis in a dose-dependent manner. **1.** Mashhoon, DeMaggio, Tereshko, *et al.* (2000) *J. Biol. Chem.* **275**, 20052. **2.** Behrend, Milne, Stöter, *et al.* (2000) *Oncogene* **19**, 5303. **3.** Stöter, Krüger, Banting, Henne-Bruns & Knippschild (2014) *PLoS One* **9**, e100090.

### IC-87114

This ATP site-competitive (FW = 397.43; CAS 371242-69-2; Solubility (25°C): <1 mg/mL DMSO, <1 mg/mL Water), also known as 2-((6-aminophenyl)methyl)-5-methyl-3-o-tolylquinazolin-4(3H)-one, targets the phosphoinositide-3-kinase- (PI3K-) directed signal-transduction pathway by selectively inhibiting PI3Kδ, IC<sub>50</sub> = 0.5 μM. Although Class-I phosphoinositide 3-kinases (PI3Ks) had been previously implicated in inflammatory responses, the use of non-selective inhibitors (*e.g.*, LY294002 and wortmannin) did not permit an assessment of the contribution of the individual PI3K isoforms in neutrophil activation. IC-87114 is a novel PI3K inhibitor that is for PI3Kδ, an isoform expressed predominantly in hematopoietic cells. (Notably, IC87114 does not inhibit any other protein kinases tested.) At 5 μM, IC-87114 blocked both fMLP- and TNFα-induced neutrophil generation of superoxide as well as the exocytosis of elastase. IC87114 also blocked TNFα-stimulated elastase exocytosis from neutrophils in a mouse model for inflammation. IC-87114 also suppressed chemotaxis. When used in therapeutic mode, IC-87114 conferred prolonged protection from progression to overt diabetes in a number of animals, suggesting that PI3Kδ inhibitors could be useful for managing type 1 diabetes (3). **Targets:** PI3Kδ, IC<sub>50</sub> = 0.5 μM; PI3Kβ, IC<sub>50</sub> = 75 μM; and PI3Kγ, IC<sub>50</sub> = 29 μM. **1.** Sadhu, Masinovsky, Dick, Sowell & Staunton (2003) *J. Immunol.* **170**, 2647. **2.** Sadhu, Dick, Tino & Staunton (2003) *Biochem. Biophys. Res. Commun.* **308**, 764. **3.** Durant, Richer, Brenker, *et al.* (2013) *Autoimmunity* **46**, 62.

### ICA 069673

This orally available, potassium ion channel opener (FW = 269.63 g/mol; CAS 582323-16-8; Solubility: 100 mM in DMSO), also named *N*-(2-

chloro-5-pyrimidinyl)-3,4-difluorobenzamide, selectively targets the  $K_{v7.2}/K_{v7.3}$  (or KCNQ2/3) potassium channel opener ( $EC_{50} = 0.69 \mu\text{M}$ ), showing 20x greater selective for the  $K_{v7.2}/K_{v7.3}$  channel over  $K_{v7.3}/K_{v7.5}$  channels and showing little/no measurable activity over a panel of cardiac ion channels (*i.e.*,  $IC_{50} > 30 \mu\text{M}$  for  $K_{v11.1}$  (hERG) channels,  $Na_v1.5$  channels, L-type channels, and  $K_{v7.1}$  channels). 1. Amato, *et al.* (2011) *ACS Med. Chem. Lett.* 2, 481.

### Icatibant

This bradykinin peptidomimetic (FW = 1304.52 g/mol; CAS 130308-48-4), also known as Firazyr<sup>®</sup>, Hoe 140, and JE 049, is a bradykinin-competitive antagonist that binds to the kinin  $B_2$  receptor, a G-protein-coupled receptor coupled to  $G_q$  and  $G_i$ , with  $G_q$  stimulating phospholipase C to increase intracellular free calcium and  $G_i$  inhibits adenylate cyclase. Icatibant's five unnatural amino acid residues allows it to resist the metalloproteases normally involved in kinin catabolism. Icatibant is used clinically to limit inflammatory and angioedema (*i.e.*, vascular leakage) caused by an acute (uncontrolled) production of kinins and accumulation at the endothelium  $B_2$  receptor. Angioedema is characterized by edematous attacks of subcutaneous and submucosal tissues, often causing painful intestinal consequences and can be life-threatening, if the larynx is affected. Icatibant is FDA-approved for the treatment of acute attacks of the hereditary bradykinin-mediated angioedema, due to  $C_1$  inhibitor deficiency. 1. Charignon, Späth, Martin & Drouet (2012) *Expert Opin. Pharmacother.* 13, 2233.

### ICE Inhibitor I

This cell-permeable peptidomimetic (FW = 1920.39 g/mol; Sequence: Ac-AAVALLPAVLLALLPYVAD-CHO, where CHO indicates a C-terminal aldehyde), also called interleukin-1 $\beta$  converting enzyme (ICE) inhibitor I, targets Caspase-1 and Caspase-4. The C-terminal YVAD-CHO sequence of this peptide is a highly specific and potent inhibitor of caspase-1 ( $K_i = 1 \text{ nM}$ ), most likely by reversibly forming a thiohemiacetal adduct with an active-site cysteine sulfhydryl group. The N-terminal sequence (*i.e.*, residues 1–16) corresponds to the hydrophobic region (or H region) of the signal peptide of the Kaposi fibroblast growth factor (K-FGF), conferring cell permeability to the peptide. 1. Garcia-Calvo, Peterson, Leiting, *et al.* (1998) *J. Biol. Chem.* 273, 32608.

### Ice-IX

This fictive material (Molecular Formula =  $(\text{H}_2\text{O})_n$ ; FW = indefinite), first mentioned in Kurt Vonnegut's novel *Cat's Cradle*, is a polymorph of water invented by one Dr. Felix Hoenikker. Rather than melting at  $0^\circ\text{C}$ , Ice-IX melts at  $45.8^\circ\text{C}$ , such that once it contacts liquid water at temperatures below  $45.8^\circ\text{C}$ , Ice-IX seeds an immediate phase transition of liquid water, forming ever greater quantities of ice-nine. This unusual behavior anticipated the now well known behavior of prions in pathological amyloidogenesis.

### ICG-001

This cell-permeable pyrazino-pyrimidine carboxamide (FW = 548.63 g/mol; CAS 780757-88-2; 847591-62-2) competes with  $\beta$ -catenin for CBP (or CREB-binding protein) binding, down-regulates  $\beta$ -catenin/T cell factor signaling ( $EC_{50} = 3 \mu\text{M}$ ) by specifically binding to Cyclic AMP Response Element-Binding (or CREB) protein. ICG-001 selectively induces apoptosis in transformed cells but not in normal colon cells, reduces in vitro growth of colon carcinoma cells (2-5). Wnt signaling down-regulation by the inducible expression of Axin, ICAT, and dnTcf4E causes degeneration of hippocampal neurons, whereas Wnt signaling up-regulation by the inducible expression of Dvl and  $\beta$ -catenin has little effect. ICG-001 treatment results in hippocampal neuron degeneration, while the treatment with a JNK specific inhibitor is without effect. These data strongly support the idea that downregulation of Wnt/ $\beta$ -catenin signaling causes degeneration of hippocampal neurons *in vivo* and may be a cause of neurodegenerative diseases related to an anxiety related response. ICG-001 also selectively blocks CBP- (but not p300-) dependent TCF/ $\beta$ -catenin transcriptional regulation *in vitro* ( $IC_{50} = 5\text{--}25 \mu\text{M}$ ) and *in vivo* (Dose = 5 mg/kg/day, by osmotic pump in mice), without affecting CBP-dependent transcriptional activities mediated by the AP-1 or CRE complex. ICG-001 also reactivates p300-/TCF-/ $\beta$ -catenin-mediated neuronal differentiation upon NGF stimulation of PC-12 cells expressing PS-1 Leu-286-Val mutant cultures. 1. **Alternate Names:**  $\beta$ -Catenin/Tcf Inhibitor VI, Wnt Pathway Inhibitor XX, (6S,9aS)-hexahydro-6-((4-hydroxyphenyl)methyl)-8-(1-naphthalenylmethyl)-4,7-dioxo-N-(phenylmethyl)-2H-pyrazino[1,2-a]-pyrimidine-1(6H)-carboxamide, (6S)-N-benzyl-6-(p-hydroxyphenylmethyl)-8-(1-naphthylmethyl)-4,7-dioxo-hexahydro-2H-pyrazino[1,2-a]-pyrimidine-1-carboxamide. 2. Henderson, *et al.* (2010) *Proc. Natl. Acad. Sci. USA* 107, 14309.

### ICI-118551

This selective adrenoreceptor antagonist (FW<sub>free-base</sub> = 277.41 g/mol; CAS 72795-19-8 (free base); 72795-01-8(HCl salt)), also named ( $\pm$ )-erythro-( $S^*$ , $S^*$ )-1-[2,3-(dihydro-7-methyl-1H-inden-4-yl)oxy]-3-[(1-methylethyl)-amino]-2-butanol, targets the  $\beta_2$ -adrenergic receptor ( $K_i = 1.2 \text{ nM}$ ), with much greater affinity than the  $\beta_1$  ( $K_i = 120 \text{ nM}$ ) or  $\beta_3$  ( $K_i = 260 \text{ nM}$ ) subtypes. While specific antagonists of the beta 1-adrenoreceptor, such as atenolol and betaxolol, had been widely available, ICI-118551 was the first-in-class  $\beta_2$ -selective antagonist (1). ICI 118,551 has no partial agonist activity but has a membrane-stabilising action similar to that of propranolol (1). ICI-118551, reverses the inhibitory effect of  $\beta_2$ -agonists (PC, salbutamol, and tulobuterol B) on N-formyl-methionyl-leucyl-phenylalanine-induced superoxide production in granulocytes (2). 1. Bilski, Halliday, Fitzgerald & Wale (1983) *J. Cardiovasc. Pharmacol.* 5, 430. 2. Yasui, Kobayashi, Yamazaki, *et al.* (2006) *Int. Arch. Allergy Immunol.* 139, 1.

## ICI 230487

This *N*-methyl-quinolone (FW = 411.47 g/mol; IUPAC: 1-ethyl-6-[[3-fluoro-5-(4-methoxy-3,4,5,6-tetrahydro-2*H*-pyran-4-yl)phenoxy]methyl]-2-quinolone and ZM 230487, inhibits 5-lipoxygenase (IC<sub>50</sub> = 0.09 μM) and in turn leukotriene biosynthesis. **Target(s):** linoleate diol synthase (1); 5-lipoxygenase, or arachidonate 5-lipoxygenase (2-4). 1. Su, Brodowsky & Oliw (1995) *Lipids* **30**, 43. 2. Teixeira & Hellewell (1994) *Brit. J. Pharmacol.* **111**, 1205. 3. Araico, Terencio, Alcaraz, *et al.* (2006) *Life Sci.* **78**, 2911. 4. Young (1999) *Eur. J. Med. Chem.* **34**, 671.

## ICRF-159, See Razoxane

## Idarubicin

This anthracycline glycoside and antileukemic agent (FW<sub>free-base</sub> = 497.50 g/mol; CAS 58957-92-9), also known as Idamycin, is a structural analogue of daunorubicin. **Primary Mode of Inhibitory Action:** Like daunorubicin, idarubicin binds to and intercalates into DNA, inducing DNA strand breaks, delaying cell cycle progression, and inhibiting DNA topoisomerase II. Its higher lipophilicity than daunorubicin results in faster accumulation within nuclei, superior DNA-binding capacity, and greater cytotoxicity. Severe myelosuppression occurs when idarubicin is used at an effective therapeutic dose. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** *Ava*II restriction endonuclease (1); DNA ligase (ATP) (2); DNA topoisomerase II (3 5); *Eco*RI restriction endonuclease (1); *Hae*III restriction endonuclease (1); *Hha*I restriction endonuclease (1); *Hpa*II restriction endonuclease (1); *Sma*I restriction endonuclease (1). Idarubicin also inhibits phosphorylation of the main autophagy repressor mTOR and its downstream target p70S6 kinase (6). The treatment with the mTOR activator leucine prevented idarubicin-mediated induction of autophagy. Idarubicin-induced mTOR repression was associated with the activation of the mTOR inhibitor AMP-activated protein kinase and down-regulation of the mTOR activator Akt (6). 1. ## Idarucizumab, See Dabigatran

## Idelalisib

This orally active P110δ inhibitor (FW = 415.43 g/mol; CAS 1146702-54-6), code named GS-1101 or CAL-101 and systematically named 5-fluoro-3-phenyl-2-[(1*S*)-1-(7*H*-purin-6-ylamino)-propyl]-4(3*H*)-quinazolin-one, is an antineoplastic agent that targets the δ-isoform of the enzyme phosphoinositide 3-kinase (IC<sub>50</sub> = 2.5nM; EC<sub>50</sub> = 8 nM), thereby blocking constitutive phosphatidylinositol-3-kinase signaling and resulting in decreased phosphorylation of Akt (and other downstream effectors), increased poly(ADP-ribose) polymerase, as well as induction of caspase cleavage and apoptosis. (1). By inhibiting the production of phosphatidylinositol-3,4,5-trisphosphate (PIP<sub>3</sub>), idelalisib prevents activation of the PI3K signaling pathway, thus inhibiting tumor cell proliferation, motility, and survival. Idelalisib also induces apoptosis in B cell lines and primary B cells from patients with different B-cell malignancies, including chronic lymphoblastic leukemia, diffuse large B-cell lymphoma, multiple myeloma, and Hodgkin lymphoma. Idelalisib interferes with integrin-mediated CLL cell adhesion to EC and BMSC, providing a novel mechanism to explain idelalisib-induced redistribution of CLL cells from tissues into the blood (2). Idelalisib is metabolized by aldehyde oxidase to GS-563117, and to a lesser extent by cytochrome P450 (CYP) 3A and uridine 5'-diphospho (UDP)-glucuronosyltransferase (UGT) 1A4. *In vitro*, idelalisib inhibits P-glycoprotein (P-gp) and organic anion transporting polypeptides (OATP) 1B1 and 1B3, and GS-563117 is a time-dependent CYP3A inhibitor (3). **Target(s):** Idelalisib is 40-times to 300-times more selective for p110δ relative to other PI3K class I enzymes: p110α (IC<sub>50</sub> = 820 nM); p110β (IC<sub>50</sub> = 565 nM); and p110γ (IC<sub>50</sub> = 89 nM). Greater selectivity (400-times to 4000-times) is seen against related kinases C2β, hVPS34, DNA-PK, and mTOR, and no activity is observed against a panel of 402 diverse kinases, when assayed at 10μM (using Ambit KinomeScan). 1. Lannutti, Meadows, Herman, *et al.* (2011) *Blood* **117**, 591. 2. Fiorcari, Brown, McIntyre, *et al.* (2013) *PLoS One* **8**, e83830. 3. Jin, Robeson, Zhou, *et al.* (2015) *J. Clin. Pharmacol.* **326**, 90.

## IDX-899, See Fosdevirine

## Z-IETD-fmk

This irreversible, cell-permeable peptide (FW = 654.03 g/mol; *Sequence*: Z-Ile-Glu(OMe)-Thr-Asp(OMe)-fluoromethylketone, where Z designates a *N*-terminal carbobenzyoxy moiety; Solubility: 100 mM in DMSO; Use at 2-4 μM), also known as Caspase-8/FLICE inhibitor (fluoromethylketone), Granzyme B inhibitor (fluoromethyl-ketone), inhibits Caspase-8 and Granzyme B, with somewhat weaker action against caspase-10. The inhibitor possesses a Caspase-8 targeting IETD sequence and a methyl ester to facilitate cell permeability. Z-IETD-fmk inhibits Caspase-8 proteolysis, an essential step in TNF- and Fas-mediated apoptosis (1). To probe the underlying mechanism for phenylalanine-mediated neurotoxicity in phenylketonuria (PKU), Z-IETD-FMK (0.9 mM, 18 h) was found to strongly attenuate apoptosis in Phe-treated neurons, again suggesting involvement of the Fas receptor (FasR)-mediated cell death receptor pathway in Phe toxicity (2). **Targets:** Caspase-8 (Z-IETD-FMK), Caspase-9 (Z-LEHD-FMK), Pan-caspases (Z-VAD-FMK). 1. Hatano, *et al.* (2000) *J. Biol. Chem.* **275**, 11814. 2. Huang, Lu, Lv, *et al.* (2013) *PLoS One* **8**, e71553.

**Ifenprodil**

This subunit-selective NMDA antagonist (FW = 325.45 g/mol; CAS 23210-56-2), also named 4-[2-(4-benzylpiperidin-1-yl)-1-hydroxypropyl] phenol, targets those *N*-acetyl-D-glutamate receptors that contain NR2B. These glutamate-gated channels are the major excitatory neurotransmitters in the mammalian central nervous system (CNS) and are involved in numerous physiological and pathological processes including synaptic plasticity, chronic pain and psychosis. Ifenprodil shows efficacy in neuroprotection, anti-hyperalgesia, and anti-Parkinson models. Related NR2B-directed NMDA antagonists that are based on the ifenprodil pharmacophore include Eliprodil, CP-101,606, Ro25,6981 and PD0196860. 1. Mony, Kew, Gunthorpe & Paoletti (2009) *Brit. J. Pharmacol.* **157**, 1301.

**IKK-16**

This signal transduction inhibitor and antineoplastic agent (FW = 520.09 g/mol (HCl Salt); CAS 1186195-62-9), systematically named *N*-(4-Pyrrolidin-1-yl-piperidin-1-yl)-[4-(4-benzo[*b*]thiophen-2-yl-pyrimidin-2-ylamino)phenyl]carboxamide hydrochloride, targets IκB kinase (IKK), with IC<sub>50</sub> values of 40, 70 and 200 nM for IKK-2, IKK complex, and IKK-1. IKK-16 inhibits TNF-α-stimulated IκB degradation and expression of adhesion molecules E-selectin, ICAM and VCAM, with IC<sub>50</sub> values of 1.0, 0.5, 0.3 and 0.3 μM, respectively. IKK-16 inhibits LPS-induced TNF-α release in vivo and neutrophil extravasion in thioglycollate-induced peritonitis. 1. Waelchli, Bollbuck, Bruns, *et al.* (2006) *Bioorg. Med. Chem. Lett.* **16**, 108.

**IL-1RA, See Interleukin-1 Receptor Antagonist**

**Ilicicolin H**

This pyridinone (FW = 451.61 g/mol; CAS 12689-26-8), from *Cylindrocladium ilicicola* inhibits mitochondrial ubiquinol:cytochrome-*c* reductase (complex III), IC<sub>50</sub> = 3-5 nM for yeast cytochrome *c*. Ilicicolin H displays complex kinetic behavior indicative of slow-binding inhibitors. Ilicicolin H also binds stoichiometrically to the yeast cytochrome *bc*<sub>1</sub> complex, but binds approximately two orders of magnitude less tightly to the bovine enzyme and is essentially non-inhibitory to the *Paracoccus* enzyme. 1. Rotsaert, Ding & Trumpower (2008) *Biochim. Biophys. Acta* **1777**, 211. 2. Ding, di Rago & Trumpower (2006) *J. Biol. Chem.* **281**, 36036. 3. Gutierrez-Cirlos, Merbitz-Zahradnik & Trumpower (2004) *J. Biol. Chem.* **279**, 8708.

**Ilimaquinone**

This sesquiterpenoid quinone (FW = 358.48 g/mol), obtained from the marine sponge *Hippispongia metachromia*, induces reversible breakdown of Golgi membranes, inhibits protein processing and cellular secretions. Ilimaquinone also inhibiting gap-junction communication. **Targets:** *S*-adenosylhomo-cysteinase (1); gap junction communication (2,3); protein transport (4); pyruvate,orthophosphate dikinase (5,6). 1. Radeke & Snapper (1998) *Bioorg. Med. Chem.* **6**, 1227. 2. Feldman, Kim & Laird (1997) *J. Membr. Biol.* **155**, 275. 3. Cruciani, Leithe & Mikalsen (2003) *Exp. Cell Res.* **287**, 130. 4. Food Chem.* **53**, 3856.

**Ilomastat**

This substituted dipeptide (FW = 388.47 g/mol), also known as GM 6001, Galardin, and named systematically as *N*-[2*R*-(hydroxamidocarbonyl methyl)-4-methylpentanoyl]-*L*-tryptophanmethylamide, and *N*-[3-(*N*-hydroxycarbonyl)-2-isobutylpropionyl]-*L*-tryptophanmethylamide, is a broad-spectrum matrix metalloproteinase (MMP) inhibitor, with action against interstitial collagenase (*K*<sub>i</sub> = 0.4 nM; the value for the isobutyl diastereoisomer is 200 nM), gelatinase A (*K*<sub>i</sub> = 0.5 nM), stromelysin 1 (*K*<sub>i</sub> = 27 nM), neutrophil collagenase (*K*<sub>i</sub> = 0.1 nM), and gelatinase B (*K*<sub>i</sub> = 0.2 nM). It also inhibits *Pseudomonas aeruginosa* elastase (*K*<sub>i</sub> = 20 nM), thermolysin (*K*<sub>i</sub> = 20 nM), and peptide deformylase. **Targets:** gelatinase A, or matrix metalloproteinase 2 (1-6); gelatinase B, or matrix metalloproteinase 9 (1,2,4,5); interstitial collagenase, or matrix metalloproteinase 1 (2,4,7,8); membrane type matrix metalloproteinase 1 (matrix metalloproteinase 14 (9)); neutrophil collagenase, or matrix metalloproteinase 8 (1,2,4,5); peptide deformylase (10); *Pseudomonas aeruginosa* elastase (7); stromelysin 1, or matrix metalloproteinase 3 (1,2,4,5,11); thermolysin (7). 1. ### Imatinib

This first-in-class, rationally developed antineoplastic agent (FW<sub>free-base</sub> = 493.61 g/mol; CAS 152459-95-5; Symbol = IM; IUPAC Name: 4-[(4-methylpiperazin-1-yl)methyl]-N-(4-methyl-3-[[4-(pyridin-3-yl)pyrimidin-2-yl]amino]phenyl)benzamide), also known as CGP-57148 and STI-571 as well as by the proprietary names Gleevec® and Glivec®, potently inhibits protein-tyrosine kinases, showing high specificity for the Bcr-Abl (or Breakpoint Cluster Region/Abelson) oncoenzyme associated with chronic myelogenous leukemia (CML) and some forms of acute lymphoblastic leukemia (ALL) (1-7). CML is marked by myeloid proliferation, invariably terminating in acute leukemia. Prior to the advent of Gleevec, conventional therapeutic options included interferon-based regimens and stem-cell transplantation. **Rational Drug Discovery:** Chronic Myelogenous Leukemia is a clonal hematopoietic stem-cell disorder characterized by Chromosome 9:22 translocation. More than 90% of CML patients have hematopoietic cells showing evidence of a reciprocal translocation between Chromosomes-9 and 22. In this translocation, the *c-abl* gene, located on Chromosome-9q, is translocated to Chromosome-22, giving rise to a chimeric mRNA formed from exons at the 5'-end of the *bcr* gene and those from the 3'-end of the *c-abl* gene. The resulting Bcr-Abl oncoprotein exhibits elevated protein-tyrosine kinase activity, which is strongly implicated in the development of chronic myeloid leukemia. Imatinib inhibits Abl protein-tyrosine kinase *in vitro* and *in vivo* (1). Moreover, cellular proliferation and tumor formation by Bcr-Abl-expressing cells were specifically inhibited by this compound (2). Indeed, imatinib selectively inhibits the growth of BCR-ABL-positive cells (3,4). In the words of the Lasker Foundation, Druker, Lydon & Sawyers "seized upon the known molecular defect that underlies CML, formulated the idea of tackling this root cause of the disease, crafted a specific kinase inhibitor, and designed a second-generation inhibitor when drug resistance developed." In developing the first small molecule to target the activity of an oncoenzyme, they established a new paradigm for rational drug discovery. One can trace this historic development to work by Baltimore's lab on lymphocyte development, which used cells that has been immortalized by the Abelson mouse leukemia virus. While examining the virus's ability to cause cell transformation and cancer, they and Hunter's lab discovered that the oncoprotein was a growth-modulating protein tyrosine kinase. **Primary Mode of Inhibitory Action:** While many protein kinase inhibitors interact directly at the ATP-binding site, Gleevec is an example from a new class of allosteric inhibitors that alter protein kinase conformation to block productive ATP binding and/or transphosphorylation. The *c-Abl* protein kinase domain exists in active and inactive conformations, and, as shown by X-ray crystallography, imatinib binds only to the inactive enzyme. Imatinib is a competitive inhibitor relative to ATP, binding to a part of the ATP-binding site and extending into an adjacent hydrophobic region. Crystallographic analysis reveals that imatinib stabilizes the inactive, Aspartate-Phenylalanine-Glycine-out conformation of Abl, with the activation loop in a "closed" substrate-mimicking position and resultant distortion of the ATP binding loop. Imatinib prevents phosphoryl transfer to tyrosine and subsequent activation of phosphorylated targets, thereby blocking transmission of proliferative signals and inducing apoptosis in leukemic cells. **Off-Target Effects:** Beyond Bcr-Abl, imatinib is active against other tyrosine kinases, the inhibition of which has implications for treating other malignancies. For example, imatinib exhibits remarkable activity in gastrointestinal stromal tumors. Imatinib targets c-Kit receptor protein-tyrosine kinase (8-11), platelet-derived growth-factor receptor protein-tyrosine kinase (2,3), polo kinase (12), protein tyrosine kinase (1-7), receptor protein-tyrosine kinase (2,3,8-11,13,14), human quinone reductase 2, or NQO2 (15), ribosylidihydro-nicotinamide dehydrogenase (quinone) (16). It also stimulates low-density lipoprotein receptor-related protein 1-mediated ERK phosphorylation within insulin-producing  $\beta$ -cells (16).

**Resistance:** Imatinib resistance arises from mutations in residues of the Bcr-Abl kinase, mainly those making contact with the drug. Mutations at about 20 residues in the BCR-ABL kinase (particularly Bcr-Abl<sup>E255K</sup> and Bcr-Abl<sup>T315I</sup>) are associated with clinical resistance to imatinib in CML patients, most keeping the kinase from adopting a specific closed conformation stabilized by imatinib binding. A small number directly interfere with imatinib binding. The fusion gene *BCR/ABL* modulates cellular responses to DNA damage to promote genomic instability, a property that leads to resistance to imatinib, dasatinib and nilotinib, and likewise contributes to malignant disease progression. The former phenomenon is often caused by mutations in Bcr-Abl kinase, whereas the latter is associated with accumulation of additional genetic aberrations including chromosomal translocations, deletions, additional chromosomes, gene amplifications, and point mutations. **Treatment of Philadelphia-positive Acute Lymphoblastic Leukemia:** A thirteen-year follow-up study (17) on patients on hyper-CVAD (*i.e.*, cyclophosphamide, vincristine, adriamycin, plus dexamethasone) regimen, followed by imatinib-based consolidation/maintenance therapy, demonstrated: (a) that 42 of 45 patients treated for active disease achieved complete remission (one reaching full remission with incomplete recovery of platelets, 1 achieving partial remission, and one succumbing during induction); (b) the 5-year overall survival rate for all patients was 43%; (c) significant negative predictors of overall survival were: age >60 years, p190 molecular transcript, and active disease at enrollment; (d) while 16 patients underwent allogeneic stem cell transplantation, the median overall survival was no better; and (e) that patients with residual molecular disease at 3 months had improved complete remission duration with transplant. Hyper-CVAD and imatinib thus represents an effective regimen for treating Philadelphia-positive ALL. **Effect on Adriamycin/Doxorubicin-induced DNA Damage Checkpoint Arrest:** Src family kinases promote recovery from G<sub>2</sub> DNA damage checkpoint, and imatinib inhibits inactivation of ATM/ATR signaling pathway to suppress recovery from adriamycin/doxorubicin-induced DNA damage checkpoint arrest (18). Imatinib and pazopanib, two distinct inhibitors of PDGFR/c-Kit family kinases, delays recovery from checkpoint arrest and inhibited the subsequent S-G<sub>2</sub>-M transition after adriamycin exposure. By contrast, imatinib and pazopanib does not delay the recovery from checkpoint arrest in the presence of caffeine, an ATM/ATR inhibitor. Imatinib consistently induces a persistent activation of ATR-Chk1 signaling (18). Maintenance of G<sub>2</sub> checkpoint arrest largely depends on ATR-Chk1 signaling. However, unlike Src inhibition, imatinib does not delay the recovery from checkpoint arrest in the presence of KU-55933, an ATM inhibitor. Imatinib induces a persistent activation of ATM-KAP1 signaling, suggesting a possible involvement of imatinib in an ATM-dependent DNA damage response. These results raise the likelihood that imatinib may inhibit resumption of tumor proliferation after chemo- and radiotherapy (18). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) ### Imazapic

This imidazolinone herbicide (FW = 275.30 g/mol), also known as Cadre, Plateau, and systematically as  $(\pm)$ -2-[4,5-dihydro-4-methyl-4-(1-methylethyl)-5-oxo-1H-imidazol-2-yl]-5-methyl-3-pyridinecarboxylic acid, inhibits acetolactate synthase (tobacco  $K_i$  = 1.2  $\mu$ M). (See *Imazethapyr for mode of action*) Imazapac is a selective herbicide for both the pre- and post-emergent control of some annual and perennial grasses and some broadleaf weeds. Imazapac kills plants by inhibiting the production of branched chain amino acids essential for protein synthesis and cell growth. 1. Yoon, Chung, Chang, *et al.* (2002) *Biochem. Biophys. Res. Commun.* **293**, 433. 2. Oh, Park, Yoon, Han & Choi (2001) *Biochem. Biophys. Res. Commun.* **282**, 1237. 3. Le, Yoon, Kim & Choi (2005) *Biochim. Biophys. Acta* **1749**, 103. 4. Shin, Chong, Chang & Choi (2000) *Biochem. Biophys. Res. Commun.* **271**, 801. 5. Chong, Chang & Choi (1997) *J. Biochem. Mol. Biol.* **30**, 274. 6. Le, Yoon, Kim & Choi (2005) *J. Biochem.* **138**, 35.

### Imazapyr

This imidazolinone herbicide (FW<sub>free-acid</sub> = 261.28 g/mol; CAS 81334-34-1), also known as AC 243997, inhibits acetolactate synthase and the biosynthesis of branched-chain amino acids (*Zea mays*  $K_i$  = 12  $\mu$ M). Imazapyr is a non-selective herbicide used for the control of a broad range of weeds, including terrestrial annual and perennial grasses and broadleaved herbs, woody species, and riparian and emergent aquatic species. The isopropylamine salt is also known as Arsenal and Chopper. (See *Imazethapyr for mode of action*) 1. Zohar, Einav, Chipman & Barak (2003) *Biochim. Biophys. Acta* **1649**, 97. 2. Chang & Duggleby (1997) *Biochem. J.* **327**, 161. 3. Hill, Pang & Duggleby (1997) *Biochem. J.* **327**, 891. 4. Southan & Copeland (1996) *Physiol. Plant.* **98**, 824. 5. Muhitch, Shaner & Stidham (1987) *Plant Physiol.* **83**, 451. 8. Shaner, Anderson & Stidham (1984) *Plant Physiol.* **76**, 545.

### Imazaquin

This imidazolinone herbicide (FW<sub>free-acid</sub> = 311.34 g/mol; CAS 81335-37-7), also known as AC 252214 and named systematically as 2-[(*RS*)-4-isopropyl-4-methyl-5-oxo-2-imidazolin-2-yl]quinoline-3-carboxylic acid, is a slow-binding inhibitor of acetolactate synthase, or acetohydroxyacid synthase (*Zea mays*  $K_i$  = 3.4  $\mu$ M). (See *Imazethapyr for mode of action*) Imazaquin is often referred to by the proprietary name for the ammonium salt (Scepter). 1. Schloss & Van Dyk (1988) *Meth. Enzymol.* **166**, 445. 2. Shaner & Singh (1993) *Plant Physiol.* **103**, 1221. 3. Shaner, Anderson & Stidham (1984) *Plant Physiol.* **76**, 545. 4. Zohar, Einav, Chipman & Barak (2003) *Biochim. Biophys. Acta* **1649**, 97. 5. Southan & Copeland (1996) *Physiol. Plant.* **98**, 824. 6. Yang & Kim (1997) *J. Biochem. Mol. Biol.* **30**, 13.

### Imazethapyr

This imidazolinone herbicide (FW<sub>free-acid</sub> = 289.33 g/mol; CAS 81335-77-5), also named 5-ethyl-2-[(*RS*)-4-isopropyl-4-methyl-5-oxo-2-imidazolin-2-yl]nicotinic acid, inhibits acetolactate synthase, or acetohydroxyacid synthase, which catalyzes the first reaction in branched-chain amino acid biosynthesis. A virtue of imazethapyr is that it is not toxic to animals. By

starving grasses and dicotyledons of needed nutrients, acetohydroxyacid synthase inhibitors deprive cells of the ability to make key proteins and likewise inhibits DNA replication (1-4). Neither sulfonylurea- and imidazolinone-class herbicides are structural mimics of the substrates for the enzyme. They instead inhibit by blocking a channel through which substrates must pass to reach the active site. Sulfonylurea herbicides approach within 5 Å of the catalytic center, which is the C2 atom of the cofactor thiamin diphosphate, whereas imidazolinone herbicides are stationed at least 7 Å from this atom (5). The ammonium salt is known by the proprietary names Pivot and Pursuit. (See also *Imazapac, Imazapyr, and Imazaquin*) 1. Gaston, Zabalza, Gonzalez, *et al.* (2002) *Physiol. Plant.* **114**, 524. 2. Natl. Acad. Sci. U.S.A.* **103**, 569.

### IMC-1121B, See Ramucirumab

### IMD 0354

This signal transduction inhibitor and antineoplastic agent (FW = 383.67 g/mol; CAS 978-62-1, 634914-41-3 (sodium salt); Solubility: 10 mg/mL DMSO; <1 mg/mL Water; Formulation: Dissolve in 5% carboxymethylcellulose in PBS), systematically named *N*-[3,5-bis(trifluoromethyl)phenyl]-5-chloro-2-hydroxybenzamide, targets IκB-2 (IC<sub>50</sub> < 5  $\mu$ M), having the effect of selectively activating the NFκβ pathway and arresting the cell cycle at the G<sub>0</sub>/G<sub>1</sub> transition (1-4). Constitutive activation of NF-κB also up-regulates cell cycle progression and contributes to the proliferation of human breast cancer cells, and IMD-0354 treatment inhibits growth by promoting apoptosis as well as cell-cycle transition from the G<sub>1</sub> phase to the S phase through regulation of D-type cyclins (5). IMD 0354 is also highly effective against cancer stem cells, which, owing to their higher drug efflux capability and stem cell-like properties, are concentrated in a side population of cells thought to be responsible for multi-drug resistance and tumor repopulation, events that cause breast cancer patients to succumb (6). Although typically used to control inflammation, NF-κB signaling pathway has been linked to proliferation, anti-apoptosis, angiogenesis, and immune tolerance in the tumor microenvironment, making this pathway an attractive target in cancer treatment. Significantly, targeted delivery of IMD 0354 through the use of a legumain inhibitor also enhances drug delivery under hypoxia, a hallmark of the tumor microenvironment, but not under normoxia. 1. ### Imetelstat

This first-in-class telomerase inhibitor (FW = 4610 g/mol; CAS 868169-64-6; Sequence: d(3'-amino-3'-deoxy-5'-[O-][2-hydroxy-3-[(1-oxohexadecyl)amino]propyl]-P-thio-TAGGGTTAGACAA)), also known as GRN163L, is a palmitoylated 13-mer oligonucleotide *N*<sup>3'</sup>,*P*<sup>5'</sup>-thiophosphoramidate (or NPS oligonucleotide) that targets the template region of the human functional telomerase RNA (hTR) subunit (1,2). The essential role of telomerase in transformed cells makes telomere maintenance an attractive target for inhibition by GRN163L (3). Indeed, telomerase inhibition is observed with a wide range human tumor cells (including lung, breast,

prostate, liver, brain, bladder, and hematological malignancies including multiple myeloma and lymphoma), in both cell culture systems and mouse xenograft models. Imetelstat is additive or synergistic when used in combination with several cancer drugs and/or radiation. GRN163L shows off-target effects, with loss of adhesion in A549 lung cancer cells as a result of decreased E-cadherin expression. There is also consequential disruption of the cytoskeleton, loss of cell adherence, cell-cycle arrest in G<sub>1</sub> phase, and decreased matrix metalloproteinase-2 (MMP-2) expression (4). Continuous exposure of CAPAN1 (IC<sub>50</sub>=75 nM) and CD18 pancreatic cancer cells to GRN163L (IC<sub>50</sub>=204 nM) initially results in rapid telomere shortening, followed by the maintenance of extremely short but stable telomeres (5). Further continuous exposure eventually led to crisis, with complete loss of viability after 47 (CAPAN1) and 69 (CD18) doublings. In these cells, crisis was accompanied by activation of a DNA damage response ( $\gamma$ -H2AX), senescence and apoptosis. 1. Herbert, Gellert, Hochreiter, *et al* (2005) *Oncogene* **24**, 5262. 2. Burchett, Yan & Ouellette (2014) *PLoS One* **9**, e85155.

#### Imidacloprid

This insecticide (FW = 255.66 g/mol; CAS 138261-41-3), also known as *N*-{1-[(6-chloro-3-pyridyl)methyl]-4,5-dihydroimidazol-2-yl}nitramide, is a neonicotinoid that acts at pharmacologically distinct acetylcholine receptor (AChR) subtypes in the insect nervous system, but is ineffective on muscarinic receptors. By blocking nicotinic neuronal pathways, treatment with imidacloprid results in paralysis and eventual death of insects. Its much weaker action on human and domestic animals and pets commends its use by veterinarians to treat fleas and other insect pests (**See also Nitenpyram**). Monthly imidacloprid application of 7.5 to 10 mg/kg will rapidly kill existing and reinfesting flea infestations on dogs and break the flea life cycle by killing adult fleas before egg production begins (1). In single-channel patch clamp measurements on nicotinic acetylcholine receptors of rat pheochromocytoma (PC 12) cells, acetylcholine and imidacloprid induces single-channel currents of main conductance and subconductance states with conductances of 33.3 and 9.4 pS by acetylcholine and 30.4 and 9.8 pS by imidacloprid (2). However, the main conductance currents are generated predominantly by acetylcholine, whereas the subconductance currents are mainly generated by imidacloprid. 1. Arther, Cunningham, Dorn, *et al.* (1997) *Am. J. Vet. Res.* **58**, 848. 2. Nagata, Aistrup, Song & Narahashi (1996) *Neuroreport* **7**, 1025.

#### 4-Imidazoleacetate (4-Imidazoleacetic Acid)

This metabolite (FW<sub>free-base</sub> = 125.11 g/mol; FW<sub>hydrochloride</sub> = 162.57 g/mol; CAS 3251-69-2 (hydrochloride)), also known as imidazole-4-acetic acid and IMA, is a product of histamine degradation and an antagonist at GABA<sub>C</sub> receptors. IMA also activates GABA<sub>A</sub> receptors. 4-Imidazole acetate is a substrate of the reactions catalyzed by imidazoleacetate 4-monooxygenase and imidazoleacetate:phosphoribosylidiphosphate ligase, and it is produced by the action of aldehyde dehydrogenase on imidazole 4-acetaldehyde. **Target(s):** dopamine  $\beta$ -monooxygenase,  $K_i \approx 0.8$  mM (1); GABA<sub>C</sub> receptor (2,3); histidine ammonia-lyase (4); histidine decarboxylase (5-7). 1. Townes, Titone & Rosenberg (1990) *Biochim. Biophys. Acta* **1037**, 240. 2. Chebib, Mewett & Johnston (1998) *Eur. J. Pharmacol.* **357**, 227. 3. Tunnicliff (1998) *Gen. Pharmacol.* **31**, 503. 4. Press, New York. 5. Snell (1986) *Meth. Enzymol.* **122**, 128. 6. Snell & Guirard (1986) *Meth. Enzymol.* **122**, 139. 7. Rosenthaler, Guirard, Chang & Snell (1965) *Proc. Natl. Acad. Sci. U.S.A.* **54**, 152.

#### 4-Imidazolepropionate (4-Imidazolepropionic Acid)

This histidine derivative (FW = 140.14 g/mol; CAS 1074-59-5), also known as 3-(4-imidazolyl)propionic acid, is a competitive inhibitor of urocanase (*Reaction: L-Histidine*  $\rightleftharpoons$  *Urocanate* +  $\text{NH}_4^+$ ). **Target(s):** dimethyl-histidine *N*-methyltransferase, or histidine *N*-methyltransferase (1); histidine ammonia-lyase (2); histidine decarboxylase (3,4); histidyl-tRNA synthetase (5); urocanate hydratase, or urocanase (6-16). 1. Ishikawa & Melville (1970) *J. Biol. Chem.* **245**, 5967. 2. Brand & Harper (1976) *Biochemistry* **15**, 1814. 3. Snell (1986) *Meth. Enzymol.* **122**, 128. 4. #### *N*-(2-(1*H*-imidazol-4-yl)ethyl)-6-[4-(2-methoxy-phenoxy)-piperidin-1-yl]pyridazine-3-carboxamide

This potent, selective, orally bioavailable pyridazine (FW = 421.48 g/mol) inhibits stearoyl-CoA 9-desaturase (mouse, IC<sub>50</sub> = 6 nM), catalyzes the committed step in the biosynthesis of monounsaturated fatty acids from saturated, long-chain fatty acids. Studies with stearoyl-CoA 9-desaturase knockout mice have established that these animals are lean and protected from leptin deficiency-induced and diet-induced obesity, with greater whole body insulin sensitivity than wild-type animals. 1. Liu, Lynch, Freeman, *et al.* (2007) *J. Med. Chem.* **50**, 3086.

#### IMID-4F

This imidazole derivative (FW<sub>free-base</sub> = 338.21 g/mol), also known as 2-[*N*-(2,6-dichlorophenyl)-*N*-(4-fluorobenzyl)amino]imidazole, is a potent K<sub>ATP</sub> channel blocker. IMID-4F acts by interacting directly with the pore of the K<sub>IR</sub> channel, rather than through the sulphonylurea subunit of the K<sub>ATP</sub> channel complex. Note: IMID-4F is a *p*-fluorobenzyl derivative of clonidine. 1. McPherson, Bell, Favaloro, Kubo & Standen (1999) *Brit. J. Pharmacol.* **128**, 1636. 2. Bell, Favaloro, Khalil, Iskander & McPherson (2000) *Naunyn-Schmiedeberg's Arch. Pharmacol.* **362**, 145.

**Imidobisphosphate (Imidobisphosphoric Acid)**

This pyrophosphate analogue (FW<sub>free-acid</sub> = 175.98 g/mol), also known as imidodiphosphate, inhibits pyrophosphatase. It is also a valuable reagent for the synthesis of nucleotide analogues, such as p(NH)ppA and pp(NH)pA.

**Target(s):** DNA-directed RNA polymerase (1); geranyl-diphosphate cyclase, or bornyl diphosphate synthase (2); guanylate cyclase (3,4); *trans*-octaprenyltransferase (5); phospho-enol-pyruvate carboxykinase (6,7); pyrophosphatase (8-12); pyrophosphate-dependent phosphofructokinase, or diphosphate:fructose-6 phosphate 1-phospho-transferase (13); pyruvate,orthophosphate dikinase (14). 1. **2-Iminobiotin**

This guanidinium analogue of biotin (FW = 243.33 g/mol; CAS 13395-35-2), also known as guanidinobiotin, was first prepared in 1950 (1) and has been used in innumerable protein purification protocols and in binding investigations. 2-Iminobiotin is also a reversible inhibitor of murine inducible and rat neuronal nitric-oxide synthases, with  $K_i$  values of 21.8 and 37.5  $\mu$ M, respectively (2) 1. Hofmann & Axelrod (1950) *J. Biol. Chem.* **187**, 29. 2. Sup, Green & Grant (1994) *Biochem. Biophys. Res. Commun.* **204**, 962.

**Iminodiacetate (Iminodiacetic Acid)**

This dicarboxylic acid (FW<sub>free-acid</sub> = 133.10 g/mol), also known as *N*-(carboxymethyl)glycine and diglycine, is a structural analogue of glutamic acid. It is soluble in water (2.4 g/100 mL at 5°C) and will readily form complexes with divalent cations (e.g.,  $Mn^{2+}$ ). **Target(s):** acid phosphatase (1); glutamate dehydrogenase (2); phosphonoacetate hydrolase (3,4); pyrimidine-deoxynucleoside 2'-dioxxygenase, or thymidine:2-oxoglutarate dioxxygenase (5). 1. Kawabe, Sugiura, Terauchi & Tanaka (1984) *Biochim. Biophys. Acta* **784**, 81. 2. Smith, Austen, Blumenthal & Nyc (1975) *The Enzymes*, 3rd ed., **11**, 293. 3. McGrath, Kulakova & Quinn (1999) *J. ***N*<sup>ε</sup>-(1-Iminoethyl)-L-lysine**

This lysine derivative and arginine analogue (FW = 187.24 g/mol), often abbreviated L-NIL, is a highly selective inhibitor (IC<sub>50</sub> = 3.3  $\mu$ M) of inducible nitric-oxide synthase (iNOS). (The neuronal isoform has an IC<sub>50</sub> value of 92  $\mu$ M.) Studies using L-NIL suggest that total ablation of excess NO production does not improve cardiac graft survival, but partial inhibition does. This finding is consistent with the notion that NO may have both adverse and beneficial actions. **Target(s):** arginase (1); nitric-oxide synthase (2-6); transport system  $y^+$  (7). 1. Colleluori & Ash (2001) *Biochemistry* **40**, 9356. 2. Griffith & Kilbourn (1996) *Meth. Enzymol.* **268**, 375. 3. Pieper, Nilakantan, Hilton, et al. (2004) *Amer. J. Physiol. Heart Circ. ***N*<sup>ε</sup>-(1-Iminoethyl)-L-lysine**

This ornithine derivative and arginine isostere (FW = 174.12 g/mol) inhibits of nitric-oxide synthase, with respective IC<sub>50</sub> values of 20.2, 42.4, and 34.5  $\mu$ M for the neuronal, inducible, and endothelial enzymes. It is an alternative substrate for arginine decarboxylase (1). **Target(s):** amino-acid *N*-acetyltransferase (*Escherichia coli* enzyme is mildly inhibited) (2); arginase (3); nitric-oxide synthase (4-11); transport system  $y^+$  (12). 1. Balbo, Patel, Sell, et al. (2003) *Biochemistry* **42**, 15189. 2. Leisinger & Haas (1975) *J. Biol. Chem.* **250**, 1690. 3. Colleluori & Ash (2001) *Biochemistry* **40**, 9356. 4. **Imipenem**

This intravenously administered, semisynthetic  $\beta$ -lactam antibiotic (FW = 299.35; CAS 74431-23-5), also known as *N*-formimidoylthienamycin and Cilastatin, inhibits peptidoglycan biosynthesis and is a broad spectrum antibacterial agent. It is a stable derivative of thienamycin, produced by *Streptomyces cattleya*, and was the first of the carbapenems to be released for clinical use. Imipenem inhibits cell wall synthesis of various Gram-positive and Gram-negative bacteria and remains very stable, even in the presence of  $\beta$ -lactamase (e.g., penicillinase and cephalosporinase). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). (See *Carbapenem-Resistant Enterobacteriaceae; Ertapenem, Doripenem; Meropenem*) **Target(s):** D-alanine carboxypeptidase activities of penicillin-binding

proteins 4 and 5 (1);  $\beta$ -lactamase (2-5); transglycosylase activity of penicillin-binding protein-1A (1); transpeptidase activities of penicillin-binding proteins 1A, 1B, and 2 (1). 1. ### Imipramine

This tricyclic antidepressant (FW<sub>free-base</sub> = 280.41 g/mol; CAS 50-49-7; Photosensitive), also known as Melipramine, Tofranil, and 3-(10,11-dihydro-5H-dibenzo[*b,f*]azepin-5-yl)-*N,N*-dimethylpropan-1-amine, binds tightly to the serotonin transporter, inhibiting 5-HT re-uptake. Imipramine has other notable effects: strong inhibition of norepinephrine re-uptake; inhibitory action on  $\sigma$ -receptors (weak,  $K_i > 500$  nM); anticholinergic effects that limit its use in the elderly (especially suspected AD patients); action as a  $H_1$  histamine receptor antagonist; and inhibitory effects on re-uptake and release at  $D_1$  and  $D_2$  receptors. (See also Amitriptyline; Mianserin) **Target(s):**  $Ca^{2+}$ -transporting ATPase (1); flavin-containing monooxygenase (2); glucuronosyltransferase (reported to be a substrate for UGT1A3 and UGT1A4 (3,4));  $K^+$  channel, HERG (human ether-a-go-go related gene) (5);  $K^+$  channel, transient outward (6); norepinephrine uptake (7); protein kinase C (8,9); serotonin transport (10,11); thiamin-triphosphatase (12). 1. ### Immucillins

This novel class of rationally designed drugs maximizes binding affinity by replicating crucial stereoelectronic features of enzyme transition states, including, but not limited, to oxo-carbenium ion intermediates, attained during catalysis of various ribosyl transferase, nucleosidase, and nucleoside phosphorylase reactions. The systematic search for such high-affinity transition-state analogues by Schramm and associates is based on an approach termed Molecular Similarity (1-3). The overall goal is the rational design of extremely high-affinity inhibitors based on detailed reaction mechanism information that allows one to deduce an enzyme's transition-state configuration. One begins with the evaluation of multiple kinetic isotope effects arising from judiciously chosen heavy isotope substitutions at or near the scissile bond. These data provide a glimpse of the most likely catalytic mechanisms. The process then exploits molecular mechanical modeling of the electrostatic surface potential of that transition-state configuration as well as numerous candidate analogues to obtain the analogue structures that best match the inferred transition-state geometry. Subsequent testing of the inhibitory action of the most promising analogues provides an additional means for refining the investigator's structural model of the transition state. Vibrational modeling of a data set for experimentally determined kinetic isotope effects also allows one to obtain a geometric model of the ground state and transition state for the nucleoside hydrolase reaction. From these data, one creates an electrostatic potential surface for free inosine, the above-mentioned transition state, as well as the reaction products. In the Molecular Similarity Approach, a numerical index describes the similarity of geometric and electronic properties of an

analogue, a process intended to deduce the most likely transition-state configuration for an enzyme-catalyzed reaction. The strategy is in essence a tacit assertion of the Pauling postulate, namely that rate enhancement arises from the enzyme's ability to lower the energy input required to reach the transition state by selectively binding (and, hence, stabilizing) reactants in their transition-state configuration. That reaction transition states holds the secrets for the rational design of highly selective, if not specific, inhibitors for particular enzyme targets was first suggested by its principal proponent, Richard Wolfenden (5), who in turn credits Michael Polanyi's assertion in 1921 that to enhance the rate of any reaction, a catalyst must bind the altered substrate very tightly in the transition state. The approach for their design is best exemplified in studies of purine nucleoside phosphorylase, or PNP (*Reaction: Inosine + P<sub>i</sub> ⇌ Hypoxanthine + Ribose-1-P*), the inhibition of which has been exploited to treat leukemia, autoimmune disorders, and gout. Key features for tight binding are: (a) formation of ion-pair between bound phosphate (or its mimic) and inhibitor cation; (b) interaction of the leaving-group with  $N^1$ ,  $O^6$ , and  $N^7$  atoms of 9-deazahypoxanthine; (c) interaction between phosphate and inhibitor hydroxyl groups; and (d) interaction of His257 with the 5'-hydroxyl group (4). Four generations of ribocation transition-state mimics bind to PNP with roughly comparable affinity: (a) the first-generation drug known as Immucillin-H ( $K_i^* = 58$  pM) contains an iminoribitol cation with four asymmetric carbons; (b) the second-generation drug known as DADMe-Immucillin-H ( $K_i^* = 9$  pM) uses a methylene-bridged dihydroxypyrrrolidine cation with two asymmetric centers; (c) the third-generation drug known as DATMe-Immucillin-H ( $K_i^* = 9$  pM) contains an open-chain amino alcohol cation with two asymmetric carbons; and (d) the fourth-generation drug known as SerMe-ImmH ( $K_i^* = 5$  pM) uses achiral dihydroxyaminoalcohol seramide as the ribocation mimic. Because enzymes evolve to best meet the demands of individual cell types and the needs of organisms, Molecular Similarity allows for the likelihood that isozymes (different polypeptides catalyzing the very same chemical reaction) may have different transition states, despite the fact that they catalyze the same reaction. The target enzyme most likely binds the inhibitor rapidly to form a loose-filling complex ( $Enz \cdot I_{loose}$ ) that ratchets through a succession of reversible, albeit slow, conformational isomerizations (*e.g.*,  $Enz + I \rightleftharpoons Enz \cdot I_{loose} \rightleftharpoons Enz \cdot I_1 \rightleftharpoons Enz \cdot I_2 \rightleftharpoons Enz \cdot I_3 \rightleftharpoons \dots \rightleftharpoons Enz \cdot I_{final}$ ), ultimately resulting in extraordinarily tight binding that exploits multiple binding interactions and conformational adjustments. As pointed out by Ho *et al.* (4), despite the considerable chemical diversity in the structures of four generations of PNP transition-state analogues, the catalytic-site geometry is practically the same for all analogues, suggesting that, at least for human PNP, multiple solutions are available for converting the energy of transition-state stabilization into binding energy. 1. ### Immucillin-A

This adenosine nucleoside mimetic (FW = 264.27 g/mol) weakly inhibits 5'-methylthio-adenosine/*S*-adenosylhomo-cysteine nucleosidase. Immucillin-AP, which is the 5'-monophosphate derivative, is a potent inhibitor of adenine phosphoribosyl-transferase ( $K_i = 200$  nM). (For Mode of Action, See Immucillin) **Target(s):** adenine phosphoribosyl-transferase, inhibited by 5'-monophosphate (2); adenosyl-homocysteine nucleosidase, weakly inhibited (3); 5'-methylthioadenosine/*S*-adenosylhomocysteine nucleosidase, weakly inhibited (3); purine nucleosidase (4); purine-nucleoside phosphorylase (5). 1. Ho, Shi, Rinaldo-Matthis (2010) *Proc Natl Acad Sci U S A.* **107**, 4805. 2. Shi, Tanaka, Crother, *et al.* (2001) *Biochemistry* **40**, 10800. 3. Singh, Evans, Lenz, *et al.* (2005) *J. Biol. Chem.* **280**, 18265. 4. Versées, Barlow & Steyaert (2006) *J. Mol. Biol.* **359**, 331. 5. Rinaldo-Matthis, Wing, Ghanem, *et al.* (2007) *Biochemistry* **46**, 659.

**Immucillin-G**

This guanosine nucleoside mimetic (FW = 281.27 g/mol), also known as (1*S*)-1-(9-deazaguanin-9-yl)-1,4-dideoxy-1,4-imino-D-ribose, is an extremely high-affinity transition-state mimic for purine-nucleoside phosphorylase (*Toxoplasma gondii*  $K_i = 1.9$  nM (1-4)). (**For Mode of Action, See Immucillin**) 1. Miles, Tyler, Furneaux, Bagdassarian & Schramm (1998) *Biochemistry* **37**, 8615. 2. Bzowska, Kulikowska & Shugar (2000) *Pharmacol. Ther.* **88**, 349. 3. Rinaldo-Matthis, Wing, Ghanem, *et al.* (2007) *Biochemistry* **46**, 659. 4. Chaudhary, Ting, Kim & Roos (2006) *J. Biol. Chem.* **281**, 25652.

**Immucillin-H**

This purine nucleoside mimetic and novel T-cell selective immunosuppressive agent (FW = 265.25 g/mol; CAS 209799-67-7), also known as , also known by its code name BCX-1777, its systematic name (1*S*)-1-(9-deazahypoxanthin-9-yl)-1,4-dideoxy-1,4-imino-D-ribose, and its trade name Forodesine™, is an extremely high-affinity and orally effective transition-state mimic for purine nucleoside phosphorylase (PNP). The  $K_i$  values for human, bovine, and *Mycobacterium tuberculosis* PNP's are 73, 23, and 28 pM. (**For In Vitro Mode of Action, See Immucillin**) In the presence of 2'-deoxyguanosine (dGuo), Immucillin H inhibits human lymphocyte proliferation activated by various agents, including interleukin-2 (IL-2), mixed lymphocyte reaction and phytohemagglutinin. PNP catalyzes the phosphorolysis of dGuo to guanine (Gu) and 2'-deoxyribose-1-phosphate, whereas deoxycytidine kinase (dCK) converts dGuo to form dGMP, which undergoes metabolic phosphorylation to dGTP. The affinity of dGuo is higher for PNP than for dCK. However, if PNP is blocked by forodesine, plasma dGuo is not cleaved to Gu, and instead is converted to dGTP by dCK, leading to inhibition of ribonucleotide reductase (RR), an enzyme required for DNA synthesis and cell replication. Blockade of the latter then triggers apoptosis. **Target(s):** hypoxanthine(guanine) phosphoribosyltransferase (1); purine nucleosidase (2); purine-nucleoside phosphorylase (3-11). 1. Sauve, Cahill, Zech, *et al.* (2003) *Biochemistry* **42**, 5694. 2. Versées, Barlow & Steyaert (2006) *J. Mol. Biol.* **359**, 331. 3. **L-Immucillin-H**

This immucillin-H enantiomer (FW = 265.25 g/mol) inhibits purine-nucleoside phosphorylase ( $K_i = 12$  nM). (**See Immucillin for discussion of Primary Mode of Action**) 1. Rinaldo-Matthis, Murkin, Ramagopal, *et al.* (2008) *J. Amer. Chem. Soc.* **130**, 842.

**Immunophilins**

These clinically significant immunosuppressant-binding proteins include FK506-binding proteins (*or* FKBP), which also bind rapamycin, as well as the 16 human cyclophilins, which possess peptidyl-prolyl *cis-trans* isomerase activity and also bind cyclosporin A. Immunosuppression occurs when the resulting Drug-Immunophilin complex binds to and inhibits calcineurin, the calcium-calmodulin-activated serine/threonine-specific phosphoprotein phosphatase abundant in the brain. Rapamycin also binds to FKBP, and the Rapamycin-FKBP complex binds to RAFT (Rapamycin And FKBP-12 Target, which in turn modulates translation by phosphorylating p70-S6 kinase. Once activated, this kinase phosphorylates ribosomal S6 protein and 4E-BP1, thereby inhibiting the initiation of translation. Immunophilin ligands as well as those that fail to suppress immunity because they fail to inhibit calcineurin, stimulate regrowth of damaged peripheral and central neurons, including those that are dopaminergic, serotonergic, and cholinergic in intact animals. FKBP12 is physiologically associated with the ryanodine receptor and the inositol 1,4,5-trisphosphate (IP3) receptor, thereby regulating calcium ion flux. By influencing phosphorylation of neuronal nitric oxide synthase, FKBP12 also regulates formation of nitric oxide, which is reduced by FK506. In immune cells, formation of the Drug-Immunophilin-Calcineurin ternary complex blocks dephosphorylation-driven nuclear translocation of the nuclear factor of activated T cells (NFAT). This ultimately contributes to the failure of T cells to respond to antigenic stimuli. **See also Cyclosporin A; FK506; NIM811; Rapamycin**

**IMPDHII (or IMPDH2)**

This negative regulator of NF- $\kappa$ B activation (MW<sub>monomer</sub> = 55805 g/mol; Enzyme Commission Number = 1.1.1.205), also known as Inosine 5'-Monophosphate Dehydrogenase II, is a homodimer that decreases NF- $\kappa$ B activation by increasing SHP1 activity and subsequent dephosphorylation of the p85 $\alpha$  subunit of PI3K. It serves as a negative regulator of the PI3K/Akt-dependent pathway of NF- $\kappa$ B transactivation (1). By diverting IMP away into the GMP synthesis from AMP synthesis pathway, IMPDHII also fuels lymphocyte proliferation. The *IMPDHII* gene is up-regulated in cancer, suggesting a role in malignant transformation. Its broader biologic function within innate immune signal pathways has yet to be established. In contrast to the ubiquitously expressed IMPDH I isozyme, IMPDHII expression is restricted to hematopoietic stem cells and is essential for B- and T-cell proliferation. IMPDHII may also contribute to the production of TNF $\alpha$  and nitric oxide following macrophage stimulation with LPS and interferon- $\gamma$  through a guanosine-dependent mechanism (2). The rapid recruitment of IMPDH to lipid rafts was demonstrated by an unbiased proteomic analysis (1). Mounting evidence indicates that lipid rafts play a pivotal role in the fine regulation of the innate immune response through various mechanisms including the recruitment or exclusion of signaling molecules. 1. **Imperatorin**

This furanocoumarin (FW = 270.28 g/mol; M.P. = 102°C), isolated from *Imperatoria ostruthium*, *Angelica archangelica*, *A. dahurica*, and *Pastinaca sativa*, inhibits a number of cytochrome P450 systems. **Target(s):** acetylcholinesterase (1); 4-aminobutyrate aminotransferase (2); coumarin 7 monooxygenase (3); CYP1A1, moderately inhibited (4); CYP1B1 (5); CYP2B1, pentoxyresorufin *O*-dealkylase (6); electron transport (7,8). 1. Kim, Lim, Yang, *et al.* (2002) *Arch. Pharm. Res.* **25**, 856. 2. Choi, Ahn, Song, *et al.* (2005) *Phytother. Res.* **19**, 839. 3. Maenpaa, Sigus, Raunio, *et al.* (1993) *Biochem. ## Imperialine

This photosensitive alkaloid (FW = 429.64 g/mol; CAS 61825-98-7; photosensitive), also known as raddeamine and sipeimine, from the crown imperial (*Fritillaria imperialis*) as well as other species of *Fritillaria*, and *Petilium eduardi*. Imperialine resembles the alkaloid himbacine in terms of its pharmacological profile at muscarinic receptor subtypes in that it acts as an M<sub>2</sub>-selective antagonist with respect to M<sub>1</sub> or M<sub>3</sub> sites. *Note:* This alkaloid also exists as a β-D-glucopyranoside, which is known as edpetiline. **1.** Eglén, Harris, Cox, *et al.* (1992) *Naunyn Schmiedebergs Arch. Pharmacol.* **346**, 144.

**INCB-028050, See Baricitinib**

## INCB 024360-analogue

This potent, membrane-penetrating IDO inhibitor (FW = 271.64 g/mol; CAS 914471-09-3; Soluble to 100 mM in DMSO), also named 4-amino-*N*-(3-chloro-4-fluorophenyl)-*N*-hydroxy-1,2,5-oxadiazole-3-carboximidamide, targets indoleamine 2,3-dioxygenase, with a *K<sub>i</sub>* of 19 nM in *in vitro* enzyme assays and an IC<sub>50</sub> of 67 nM in HeLa cells, decreasing kynurenine levels in plasma and reducing tumor growth *in vivo* (1). The kynurenine pathway is responsible for the metabolism of >95% of dietary tryptophan and produces numerous bioactive metabolites. Indoleamine dioxygenase-1 (IDO1) inhibitors are currently in clinical trials for the treatment of cancer, and these agents may also have therapeutic utility in neurological disorders, including multiple sclerosis (2). **1.** Yue, Douty, Wayland, *et al.* (2009) *J. Med. Chem.* **52**, 7364. **2.** Dounay, Tuttle & Verhoest (2015) *J. Med. Chem.* **58**, 8762.

## Indatraline

This substituted indanamine (FW<sub>free-base</sub> = 292.21 g/mol), also known as Lu 19-005 and (±)-*trans*-3-(3,4-dichlorophenyl)-*N*-methyl-1-indanamine, is a strong inhibitor of dopamine, serotonin, and norepinephrine uptake, with *K<sub>i</sub>* values of 1.7 nM, 0.42 nM, and 5.8 nM, respectively. Because DA, 5-HT, and NA all seem to be involved in depression, Lu 19-005's profile makes it an interesting experimental tool and a candidate antidepressant. **Target(s):** dopamine uptake (1-3); norepinephrine uptake (1,2); serotonin uptake (1-3). **1.** Hyttel & Larsen (1985) *J. Neurochem.* **44**, 1615. **2.** Arnt, Christensen & Hyttel (1985) *Naunyn-Schmiedeberg's Arch. Pharmacol.* **329**, 101. **3.** Faraj, Olkowski & Jackson (1994) *Pharmacology* **48**, 320.

## Indican

plant indican  
indoxyl-β-D-glucoside

metabolic indican  
3-indoxyl sulfate

This glucoside (FW = 295.29 g/mol; CAS 487-60-5), also known as plant indican and indoxyl-β-D-glucoside, is isolated from species of *Indigofera*, *Polygonum*, and *Isatis*. Indican is the precursor of indigo and reportedly stimulates ecdysone 20-monoxygenase activity. Metabolic indicant (FW<sub>free-acid</sub> = 213.21 g/mol), also known as 3-indoxyl sulfate and indol-3-yl sulfate, is a uremic toxin found in the urine and blood plasma of mammals.

**Target(s):** *N*-acetylindoxyl oxidase, inhibited by 3-indoxyl sulfate (1); organic anion transporters, inhibited by 3-indoxyl sulfate (2); thyroxine transport, inhibited by 3-indoxyl sulfate (3). **1.** Beevers & French (1954) *Arch. Biochem. Biophys.* **50**, 427. **2.** Enomoto, Takeda, Taki, *et al.* (2003) *Eur. J. Pharmacol.* **466**, 13. **3.** Lim, Bernard, de Jong, *et al.* (1993) *J. Clin. Endocrinol. Metab.* **76**, 318.

## Indinavir

This antiretroviral (FW = 613.80 g/mol), also known as L-735524, Crixivan<sup>®</sup>, and (2*S*)-1-[(2*S*,4*R*)-4-benzyl-2-hydroxy-4-{{(1*S*,2*R*)-2-hydroxy-2,3-dihydro-1*H*-inden-1-yl}carbonyl}butyl]-*N*-*tert*-butyl-4-(pyridin-3-ylmethyl)piperazine-2-carboxamide, is an antiviral agent that inhibits Human Immunodeficiency Virus-1 protease (*K<sub>i</sub>* = 0.52 nM) and HIV-2 protease (*K<sub>i</sub>* = 3.3 nM) (1-11). Indinavir also inhibits the GLUT4 activity by binding reversibly to the glucose transporter's endofacial surface (12,13). Indinavir is effective against GLUT4 in its therapeutically relevant drug range (5-10 μM), but this range is without effect on the ubiquitously expressed erythrocyte transporter, GLUT1 (14). **Target(s):** candidapepsin, a secreted aspartic proteinase of *Candida albicans*, weakly inhibited (15,16); glucuronosyltransferase (UDP-glucuronosyl-transferases: UGT1A1, UGT1A3, and UGT1A4 (17); HIV-1 retropepsin, *or* human immunodeficiency virus 1 protease (1-10); HIV-2 retropepsin, *or* human immunodeficiency virus 2 protease (11). **1.** Vacca, Dorsey, Schleif, *et al.* (1994) *Proc. #### Indirubin-3'-oxime

This CDK inhibitor (FW = 277.28 g/mol; CAS 160807-49-8; Symbol = IO), also known as indirubin-3'-monoxime, is an indicant dye that inhibits a number of kinases, particularly cyclin-dependent kinases by competing at their ATP sites. Indirubin-3'-oxime is also a component of Danggui Longhui Wan, a traditional Chinese medicine widely used for treating gynecological ailments, fatigue, mild anemia and high blood pressure. Indirubin-3'-oxime inhibits vascular smooth muscle cell (VSMC) proliferation and neointima formation *in vivo*, operating by a novel dual inhibitory mode, first by interfering with pro-migratory signaling in VSMC, and second by suppressing leukotriene biosynthesis in monocytes via direct inhibition of 5-lipoxygenase. 1-Methyl-indirubin-3'-oxime (MeIO) is a kinase-inactive analogue of IO that may be used as a negative control.

**Target(s):** AMP-activated protein kinase,  $IC_{50}$  = 0.22  $\mu$ M (1); cAMP-dependent protein kinase, or protein kinase A, weakly inhibited (1); cyclin-dependent kinase, or cyclin-dependent kinase 2/cyclin A,  $IC_{50}$  = 0.59  $\mu$ M (1,2,6); cyclin-dependent kinase 1/cyclin B,  $IC_{50}$  = 0.18  $\mu$ M (3,4); cyclin-dependent kinase 5/p25 (3,5); [glycogen synthase] kinase 3, or [tau protein] kinase;  $IC_{50}$  = 0.19  $\mu$ M (1,3,5); Lck protein-tyrosine kinase (1); 5-lipoxygenase (7); lymphocyte kinase,  $IC_{50}$  = 0.3  $\mu$ M (1); mitogen-activated protein kinase (1); non-specific serine/threonine protein kinase (1); pro-migratory signaling in vascular smooth muscle cells (7); protein kinase C, weakly inhibited (1); protein-tyrosine kinase, non-specific protein-tyrosine kinase (1); serum- and glucocorticoid-induced kinase,  $IC_{50}$  = 0.38  $\mu$ M (1). **1.** Bain, McLauchlan, Elliott & Cohen (2003) *Biochem. #### Indole

This coal tar aromatic and tryptophan metabolite (FW = 117.15 g/mol; M.P. = 52°C), also known as 2,3-benzopyrrole and 1H-benzo[b]pyrrole, is produced in the degradation of tryptophan. Indole is soluble in hot water and ho. Concentrated solutions have a unpleasant odor, but highly dilute solutions are relatively pleasant. **Target(s):** N-acetylindoxyl oxidase (1); chymotrypsin (2-12); 3'-demethylstaurosporine O-methyltransferase (13); histidine decarboxylase (14); indoleamine 2,3-dioxygenase, weakly inhibited (15); lysozyme (16); metridin (17,18); monoamine oxidase (19); myeloperoxidase (20); peroxidase (20); subtilisin (21-23); tryptophanase (24); tryptophan 2,3-dioxygenase (14,25,26). **1.** Beever & French (1954) *Arch. #### Indole-3-acetate (Indole-3-acetic Acid)

This plant hormone (FW<sub>free-acid</sub> = 175.19 g/mol; CAS 6505-45-9; pK<sub>a</sub> = 4.75; Sparingly soluble in water), also known as 3-indoleacetic acid, indol-3-ylacetic acid, (3-indolyl)acetic acid (IAA), and heteroauxin, is the main auxin of higher plants. IAA plays a key role in both root and shoot development. The hormone moves from one part of the plant to another by a designated importer *AUX1* and the efflux pumps *PIN1-7*. In peas, wounding or application of IAA induces the expression of ACS2, an IAA-responsive gene, suggesting that IAA may also accumulate at wound sites. So significant is IAA to plant physiology that there are at least four pathways for its synthesis. **Target(s):** adenylate kinase (1-3); alcohol dehydrogenase (4); D-amino-acid oxidase,  $K_i$  = 2.3 mM (5,6); aromatic-amino-acid aminotransferase,  $K_d$  = 14 mM (30); aromatic-L-amino-acid decarboxylase (7); carboxypeptidase A (8-16); catalase (39); cysteine-type carboxypeptidase (17); glucan 1,3- $\beta$ -glucosidase, weakly inhibited (18);  $\beta$ -glucosidase (19); guanylate kinase (20); horseradish peroxidase (21,22); imidazoleacetate 4-monooxygenase, weakly inhibited (33,34); indoleamine 2,3-dioxygenase (38); mandelonitrile lyase, inactivation in light, not in dark (23); pectin lyase (24); peroxidase (21,22); tryptophanase (25,26); tryptophan 2,3-dioxygenase (25); tryptophan 2 monooxygenase (27,35-37); tryptophan synthase (28); tryptophanyl-tRNA synthetase (29); tyrosine aminotransferase (31); zeatin 9-aminocarboxy-ethyltransferase (32). **1.** Watanabe & Kubo (1982) *Eur. ### Indole-3-acrylate (Indole-3-acrylic Acid)

This tryptophan metabolite (FW<sub>free-acid</sub> = 187.20 g/mol; CAS 29953-71-7) inhibits tryptophan synthase, tryptophan 2,3-dioxygenase, L-dopachrome isomerase, and xanthine oxidase. Substrate channeling in *Salmonella typhimurium* tryptophan synthase is regulated by allosteric interactions that are triggered by binding of ligand to the  $\alpha$ -site and covalent reaction at the  $\beta$ -site. These interactions switch the enzyme between low-activity open conformations and high-activity closed conformations. This allosterism has been demonstrated between the  $\alpha$ -site and the external aldimine,  $\alpha$ -aminoacrylate, and quinonoid forms of the  $\beta$ -site. **Target(s):** L-dopachrome isomerase (1); indoleamine 2,3-dioxygenase (2); tryptophanase, or tryptophan indole-lyase (3); tryptophan 2,3-dioxygenase (4,5); tryptophan synthase (6-8); xanthine oxidase (9). 1. ### 3-Indolebutyrate (3-Indolebutyric Acid)

This synthetic plant hormone (FW<sub>free-acid</sub> = 203.24 g/mol), also known as 1*H*-indole-3-butyric acid and 4-(3 indolyl)butyric acid (IBA; is an auxin that is used to initiate root growth (2). It is an endogenous auxin in

*Arabidopsis*. (See also  $\beta$ -(3-Indolyl)butyrate and  $\beta$ -(3 Indolyl)butyric Acid) **Target(s):** D-amino-acid oxidase,  $K_i$  = 1.1 mM (2); aromatic-amino-acid aminotransferase,  $K_A$  = 0.78 mM (3); carboxypeptidase A (4); chymotrypsin (5,6); tryptophan synthase (7,8); tyrosine aminotransferase (9). 1. Hopkins (1999) *Introduction to Plant Physiology*, John Wiley & Sons. 2. Klein & Austin (1953) *J. Biol. Chem.* **205**, 725. 3. ### Indole-3-carbinol

This tryptophan metabolite (FW = 147.17 g/mol; CAS 700-06-1; Symbol: I3C), a dietary compound found in cruciferous vegetables of the *Brassica* genus, such as broccoli and brussels sprouts, induces a G<sub>1</sub> cell-cycle arrest in LNCaP human prostate cancer cells, a process requiring activated p53 tumor suppressor protein (1). Western blots using phospho-specific p53 antibodies revealed that I3C treatment increases phosphorylation at Ser-15, Ser-37, and Ser-392, sites known to increase p53 protein stability as well as its transactivation potential. Ablation of p53 production using short interfering RNA (siRNA) prevents I3C-induced G<sub>1</sub> arrest and up-regulation of p21 expression. In female Sprague-Dawley rats, I3C significantly increases the extent of estradiol 2-hydroxylation (from 29% to 45%), indicating it may be chemopreventive in estrogen-dependent diseases (2). Indole-3-carbinol also activates AMP-activated protein kinase  $\alpha$  (AMPK $\alpha$ ), inhibiting fatty acid synthesis and blocking adipogenesis in 3T3-L1 cells (3). 1. Hsu, Dev, Wing, et al. (2006) *Biochem. Pharmacol.* **72**, 1714. 2. Michnovicz & Bradlow (1990) *J. Natl. Cancer Inst.* **82**, 947. 3. Choi, Jeon, Lee & Lee (2014) *Biochimie* **104**, 127.

### Indole-3-pyruvate (Indole-3-pyruvic Acid)

This  $\alpha$ -keto acid (FW<sub>free-acid</sub> = 203.20 g/mol), also known as (indol-3-yl)pyruvic acid, is the product of the action of aromatic-amino-acid aminotransferase and L-amino-acid oxidase on L-tryptophan. It is also a product of the reactions catalyzed by indole-3-lactate dehydrogenase, tryptophan dehydrogenase, tryptophan aminotransferase, aromatic-amino-acid aminotransferase, and tryptophan:phenyl-pyruvate aminotransferase. It is a substrate of the reactions catalyzed by indole-3-pyruvate C-methyltransferase and indolepyruvate decarboxylase. It is also an intermediate in indolmycin, pigment, and auxin metabolism. **Target(s):** aromatic-amino-acid aminotransferase, product inhibition (1); cathepsin D (2); 3'-demethylstaurosporine O-methyltransferase (3); kynurenine:oxoglutarate aminotransferase (4); tryptophanase, or tryptophan indole-lyase (5); tryptophan 2-monooxygenase (6); tryptophan synthase (7); tryptophanyl-tRNA synthetase (8). 1. Soto-Urzua, Xochinua-Corona, Flores-Encarnacion & Baca (1996) *Can. J. Microbiol.* **42**, 294. 2. Woessner (1973) *J. Biol. Chem.* **248**, 1634. 3. Biol.* **42**, 287. 6. Sobrado & Fitzpatrick (2003) *Biochemistry* **42**, 13826 and 13833. 7. Wolf & Hoffmann (1974) *Eur. J. Biochem.* **45**, 269. 8. Kisselev, Favorova & Kolaleva (1979) *Meth. Enzymol.* **59**, 174.

**Indolicidin**

This tridecapeptide amide (FW = 1907.30 g/mol; *Sequence*: ILPWKWPWWPWR-NH<sub>2</sub>), from bovine neutrophils, exhibits bactericidal and fungicidal activity (1). Indolicidin binds to calmodulin and inhibits calmodulin-stimulated phosphodiesterase activity with IC<sub>50</sub> values in the nanomolar range (2). **Target(s)**: aminoglycoside acetyltransferase (6')-II (3); aminoglycoside kinase (2') (3); calmodulin-stimulated phosphodiesterase (2); kanamycin kinase, *or* aminoglycoside phosphotransferase (3')-IIIa (3). 1. Selsted, Novotny, Morris, *et al.* (1992) *J. Biol. Chem.* **267**, 4292. 2. Sitaram, Subbalakshmi & Nagaraj (2003) *Biochem. Biophys. Res. Commun.* **309**, 879. 3. Boehr, Draker, Koteva, *et al.* (2003) *Chem. Biol.* **10**, 189.

**Indolmycin**

This tryptophan metabolite and antibiotic (FW = 257.29 g/mol; CAS 21193-77-1), produced by *Streptomyces albus* (ATC12648) inhibits protein synthetase by targeting prokaryotic tryptophanyl-tRNA synthetase. Indolmycin is active against Gram-positive and negative microorganisms (1-3). Simultaneous binding of indolmycin and Mg<sup>2+</sup>•ATP results in movement of the Tyr-125 and Gln-107 side-chains, opening of the mobile loop containing Lys-111; displacement of the Mg<sup>2+</sup> ion by 0.4 Å, hexavalent metal coordination, stronger, nearly equivalent electrostatic interactions of Mg<sup>2+</sup> with an oxygen from each phosphate group of ATP, and weaker coordination of phosphate group oxygen atoms by active site lysine residues (4). **Target(s)**: tryptophan decarboxylase (1); tryptophan 2,3-dioxygenase, *or* tryptophan pyrrolase (1); tryptophanyl-tRNA synthetase (2,3). 1. Werner & Reuter (1979) *Arzneimittelforschung* **29**, 59. 2. Werner, Thorpe, Reuter & Nierhaus (1976) *Eur. J. Biochem.* **68**, 1. 3. Retailleau, Huang, Yin, *et al.* (2003) *J. Mol. **3-(Indol-3-yl)propionate (3-(Indol-3-yl)propionic Acid)**

This tryptophan analogue (FW<sub>free-acid</sub> = 189.21 g/mol), also known as 3-(3-indolyl)propionic acid, inhibits a number of enzymes, in some cases exploiting its hydroxyl radical-scavenging properties. **Target(s)**: D-amino acid oxidase, K<sub>i</sub> = 2.3 mM (1); aromatic-amino-acid aminotransferase, K<sub>d</sub> = 2.6 mM (2); carboxypeptidase A (3,4); chymotrypsin (4-7); cysteine-type carboxypeptidase (8); kynurenine aminotransferase, weakly inhibited (9); N-methyltryptophan oxidase (10); nicotinamidase (11); tryptophanase, *or* tryptophan indole-lyase (4,12-14); tryptophan 2,3-dioxygenase (4); tryptophan synthase (15,16); tryptophanyl-tRNA synthetase (17); tyrosine aminotransferase (18); zeatin 9-aminocarboxyethyltransferase (19). 1. Klein & Austin (1953) *J. Biol. Chem.* **205**, 725. 2. Okamoto, Ishii, Hirotsu & Kagamiyama (1999) *Biochemistry* **38**, 1176. 3. Neurath (1960) *The Enzymes*, 2nd ed., **4**, 11. 4. **Indomethacin**

This nonsteroidal anti-inflammatory drug (NSAID) and antipyretic (FW<sub>free-acid</sub> = 357.79 g/mol; CAS 53-86-1), also known as 1-(4-chlorobenzoyl)-5-methoxy-2-methyl-1H-indole-3-acetic acid, Indocin<sup>®</sup>, and Indo-Lemmon<sup>®</sup>, targets prostaglandin H synthase 1 and 2, with IC<sub>50</sub> values of 0.74 and 0.97 μM for COX-1 and COX-2 cyclooxygenases, respectively. Indomethacin is frequently used to relieve moderate/severe pain, tenderness, swelling, and stiffness caused by osteoarthritis, rheumatoid arthritis, and ankylosing spondylitis. It is also used to treat shoulder pain caused by bursitis and tendinitis. Indomethacin can also be used to treat acute gouty arthritis.

**Pharmacokinetics**: Indomethacin enjoys high bioavailability (~98 %) and plasma protein (mainly albumin) binding (~90 %). Metabolized primarily in the liver, it has a half-life between 3–10 hours, with maximal plasma levels after 2 hours. Compared to naproxen and ibuprofen, indomethacin shows higher penetration of the blood-brain barrier. **Key Pharmacokinetic Parameters**: See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s)**: alcohol dehydrogenase, NADP<sup>+</sup> (1); aldehyde reductase (1,2); 1-alkylglycerophosphocholine O-acetyl-transferase (38,39); 4-aminobutyrate aminotransferase, *or* GABA aminotransferase (3); ATPase, mitochondrial (4); carbonyl reductase (5,6); cathepsin B (7); cathepsin D (8); cathepsin L (9); cystinyl aminopeptidase, *or* oxytocinase (10,11); estrone sulfotransferase (36); glutamine:D-fructose-6-phosphate aminotransferase (12); glutathione S-transferase (13-16,37); hyaluronoglucosaminidase, *or* hyaluronidase (17,18); 15-hydroxyprostaglandin dehydrogenase (19,20); lactoperoxidase, weakly inhibited (54); leukotriene-C4 synthase (16); lipoprotein lipase (21); 5-lipoxygenase, *or* arachidonate 5-lipoxygenase (52); multidrug resistance associated protein (15); peroxidase, weakly inhibited (54); phenol sulfotransferase, *or* aryl sulfotransferase (36); phospholipase A<sub>2</sub> (22-25); phospholipase C (26); prostaglandin D<sub>2</sub> 11-ketoreductase (27); prostaglandin-D synthase, IC<sub>50</sub> = 0.3 mM (28); prostaglandin-endoperoxide synthase, *or* cyclooxygenase activity, (15,19,29-33,40-51,53); prostaglandin E<sub>2</sub> 9-reductase (19,34,35); succinate-semialdehyde dehydrogenase (3). **Inhibition of Viral Protein Translation by Vesicular Stomatitis Virus Infection**: Beyond its potent anti-inflammatory and analgesic properties, indomethacin also possesses antiviral activity (55). During VSV infection, indomethacin activates double-stranded RNA-activated protein kinase (PKR) in an interferon- and dsRNA-independent manner, causing rapid (< 5 min) phosphorylation of eukaryotic initiation factor-2 α-subunit (eIF2α), thereby shutting-off viral protein translation and blocking viral replication (IC<sub>50</sub> = 2 μM), while protecting host-cells from virus-induced damage. Indomethacin does not affect eIF2α kinases PERK and GCN2, and is unable to trigger eIF2α phosphorylation in the presence of 2-aminopurine, a PKR inhibitor. In addition, small-interfering RNA-mediated PKR-gene silencing dampened the antiviral effect in indomethacin-treated cells (55). Such results identify PKR as a critical target for the antiviral activity of indomethacin and indicate that eIF2α phosphorylation could be a key element in the broad-spectrum antiviral activity of the drug (55). 1. #### Indomethacin 4-Methoxyphenyl Ester

This anti-inflammatory agent (FW = 463.92 g/mol), also named 1-(*p*-chlorobenzoyl)-5-methoxy-2-methyl-1*H*-indole-3-acetic acid 4-methoxyphenyl ester, is a selective inhibitor of cyclooxygenase-2. The IC<sub>50</sub> value for COX-2 is 40 nM, whereas the value for COX-1 is > 66 μM. **1.** Kalgutkar, Marnett, Crews, Rimmel & Marnett (2000) *J. Med. Chem.* **43**, 2860. **2.** Kalgutkar, Crews, Rowlinson, *et al.* (2000) *Proc. Natl. Acad. Sci. U.S.A.* **97**, 925.

#### Indospicine

This hepatotoxic arginine analogue (FW = 173.22 g/mol; CAS 16377-01-8), also known as 6-amidino-2-aminohexanoic acid, is found in a tropical legume (*Indigofera spicata*) known to be toxic to sheep and cows. **Target(s):** amino-acid *N*-acetyltransferase (The *Escherichia coli* enzyme is inhibited by L-indospicine.) (1); arginase (2,3); arginyl-tRNA synthetase (4); nitric-oxide synthase (5). **1.** Leisinger & Haas (1975) *J. Biol. Chem.*

#### INDY & pro-INDY

This Dyrk1 inhibitor (FW = 235.30 g/mol; CAS 1169755-45-6; Solubility: 100 mM in DMSO; IUPAC: (1*Z*)-1-(3-ethyl-5-hydroxy-2(3*H*)-benzothiazolylidene)-2-propanone, targets the Dual-specificity tyrosine-phosphorylation regulated kinases Dyrk1A (IC<sub>50</sub> = 0.24 μM) and Dyrk1B (IC<sub>50</sub> = 0.23 μM) by binding within the ATP-binding cleft. INDY reverses aberrant tau-phosphorylation and rescues repressed calcineurin/Nuclear Factor of Activated T cell (*or* NFAT) signaling. INDY impairs the self-renewal capacity of subventricular zone neural stem cells. The cell-permeable form is pro-INDY (FW = 277.34 g/mol; CAS 719277-30-2; Solubility: 100 mM in DMSO), systematically named (1*Z*)-1-(5-acetyloxy-3-ethyl-2(3*H*)-benzothiazolylidene)-2-propanone. Note that the β-carboline alkaloid harmine is another highly selective and potent Dyrk1A inhibitor that has proven to be very useful in cellular assays. **1.** Ogawa, Nonaka, Goto, (2010) *Nature Commun.* **1**, 86. **2.** Pozo, Zahonero, Fernández, *et al.* (2013) *J. Clin. Invest.* **123**, 2475.

#### Inhibin

This heterodimeric gonadal hormone (MW<sub>α-subunit</sub> = 20 kDa; MW<sub>β-subunit</sub> = 12 kDa; CAS 57285-09-3) down-regulates Follicle-Stimulating Hormone (FSH) production by exerting specific negative feedback actions on the secretion of FSH from the gonadotropic cells of the pituitary gland. Inhibin thus acts as a paracrine factor in the regulation of ovarian folliculogenesis as well as steroidogenesis. Inhibin is a member of a much larger family of glycoprotein hormones and growth factors that includes Müllerian-inhibiting substance, transforming growth factor-β, erythroid differentiation factor, and activin, the latter consisting of a dimer of two inhibin β-subunits. Activin counteracts inhibin effects in pituitary cells. Inhibin α-subunit knock-down (both transcriptionally and translationally) in mice primary anterior pituitary cells promotes apoptosis by up-regulating Caspase-3, Bax and Bcl-2 genes, but without effect on p53, markedly impairing progression of G<sub>1</sub> cell-cycle phase and decreasing the fraction of cells in S phase (2). Inhibin-α silencing results in up-regulation of mRNA and protein expression of Gonadotropin releasing hormone receptors [GnRHRs] and down-regulates mRNA levels of β-glycans. Silencing of inhibin-α also significantly increases activin-β concentration, without affecting FSH and LH levels in anterior pituitary cells. Such findings suggest that up-regulation of GnRH receptors by inhibin α-subunit gene silencing might increase the concentration of activin-β in the culture medium (2). **1.** Makanji, Zhu, Mishra, *et al.* (2014) *Endocr. Rev.* **35**, 747. **2.** Han, Wu, Riaz, *et al.* (2013) *PLoS One* **8**, e74596.

#### Inhibitor & Antagonist Types

These organic or inorganic agents reduce the efficiency of an enzyme, receptor, transporter/carrier, mechanoenzyme, and/or metabolic pathway. When present at sufficient concentration, a **Total Inhibitor** reduces the reaction velocity to zero, whereas a **Partial Inhibitor** cannot completely block the action of a target enzyme, transporter, carrier, or metabolic process. By resembling a substrate or reversible bound co-substrate (e.g., NAD<sup>+</sup>), **Classical reversible inhibitors** are bound and released rapidly, attaining a thermodynamic equilibrium that is defined by a true equilibrium constant. **Tight-Binding Inhibitors** are high-affinity inhibitors that act without delay, whereas **Slow Inhibitors** and **Slow, Tight-Binding Inhibitors** require additional time to reach their fully inhibitory end-point, in most cases forming high-

affinity complexes. (Included under the latter are **Transition-State Inhibitors**, agents that mimic the configuration and/or charge of transitory intermediates formed during an enzyme reaction cycle. They initially form weak E·I complexes, but binding induces/triggers a subsequent series of conformational isomerizations (e.g.,  $E + I \rightleftharpoons (E \cdot I)_1 \rightleftharpoons (E \cdot I)_2 \rightleftharpoons (E \cdot I)_3 \rightleftharpoons \dots \rightleftharpoons (E \cdot I)_i \rightleftharpoons \dots \rightleftharpoons (E \cdot I)_{n-1} \rightleftharpoons (E \cdot I)_n$ ), ultimately resulting in tight binding and attended by total inhibition.) **Irreversible Inhibitors** form covalent bonds with enzymes, transporters/carriers, or mechanoenzymes, with attendant loss of catalytic activity. They first form weak E·I complexes, but binding induces/triggers formation of covalent bond with an active-site group (e.g.,  $E + I \rightleftharpoons (E \cdot I)_{\text{reversible}} \rightarrow (E \cdot I)_{\text{irreversible}}$ ), resulting total inhibition. **Mechanism-Based Inhibitors** (also called **Suicide Inhibitors**) are substrate-like molecules S' that undergo catalysis, most often forming reaction product P', but occasionally react with an active-site functional, resulting in total inhibition. The general scheme for their action is: *Catalysis*:  $E + S' \rightleftharpoons E \cdot S'_{\text{reversible}} \rightleftharpoons E \cdot X'_{\text{reactive}} \rightleftharpoons E \cdot P'_{\text{reversible}} \rightarrow E + P'$ ; *Enzyme Inactivation*:  $E \cdot X'_{\text{reactive}} \rightarrow E \cdot P'_{\text{irreversible}}$  **Antagonists** are inhibitors of receptor-triggered signaling processes, as are **Partial Agonists**, the latter impairing receptor-triggered processes to a lesser degree at full site occupancy, and **Inverse Agonists**, agents that bind to the same receptor as an agonist but induce a pharmacological response opposite to that agonist. Many antagonists are slow-binding, requiring time for full expression of their affinity for their target (e.g.,  $R + X \rightleftharpoons (R \cdot X)_1 \rightleftharpoons (R \cdot X)_2 \rightleftharpoons (R \cdot X)_3 \rightleftharpoons \dots \rightleftharpoons (R \cdot X)_i \rightleftharpoons \dots \rightleftharpoons (R \cdot X)_{n-1} \rightleftharpoons (R \cdot X)_n$ ). For a detailed discussion, consult Chapter 8 of Purich (2010) *Enzyme Kinetics: Catalysis & Control*, Academic Press (Elsevier).

### Inogatran

This unusual dipeptide (FW = 438.57 g/mol), systematically named 2-[[[(2R)-1-[(2S)-2-[(4-carbamimidamidobutyl)carbamoyl]piperidin-1-yl]-3-cyclohexyl-1-oxopropan-2-yl]amino]acetic acid, is a potent inhibitor of thrombin ( $K_i = 15$  nM). Stopped-flow data support the conclusion that kinetics are biphasic: the faster component accounted for the largest fraction of the change in the intrinsic fluorescence of thrombin induced by inhibitor binding and was dependent on the inhibitor concentration; the slower component was independent of inhibitor concentration. Inogatran was originally developed to treat arterial and venous thrombotic diseases. 1. Nilsson, Sjöling-Ericksson & Deinum (1998) *J. Enzyme Inhib.* **13**, 11. 2. ### Inosine

This ribonucleoside (FW = 268.23 g/mol; CAS 58-63-9), also known as 9-β-D-ribofuranosyl-hypoxanthine and hypoxanthine 9-β-D-ribofuranoside, is found in both free form and as a component of the anticodon of some forms of tRNA. It is formed in the degradation of adenosine and is also an intermediate in the purine salvage pathway. Inosine, often abbreviated by I or Ino, is soluble in water (1.6 g/100 mL at 20°C) and is hydrolyzed by mineral acids to hypoxanthine and D-ribose. The reaction of adenosine with nitrous acid will produce inosine. The UV spectra has a  $\lambda_{\text{max}}$  at pH 6 of 248.5 nm ( $\epsilon = 12300 \text{ M}^{-1}\text{cm}^{-1}$ ). **Target(s)**: adenosine deaminase (1,2); adenosine nucleosidase (3); adenosine-phosphate deaminase (4); adenosyl-homocysteinase (5-8); alcohol dehydrogenase, yeast (9); AMP nucleosidase (10); arginase (11); aspartate carbamoyltransferase, weakly inhibited (12); deoxycytidine kinase, weakly inhibited (13); dihydroorotase (14); GMP synthetase, weakly inhibited (15); guanine deaminase, weakly inhibited (16,17); hypoxanthine(guanine) phosphoribosyltransferase, weakly inhibited (18); IMP dehydrogenase, weakly inhibited (19); S-methyl-5'-deoxyadenosine phosphorylase, weakly inhibited (20); nucleoside-triphosphatase (21); 5'-nucleotidase (22-26); ribosylpyrimidine nucleosidase (27); urate-ribonucleotide phosphorylase, weakly inhibited (28); uridine nucleosidase (29). 1. ### Inosine 5'-Diphosphate

This nucleotide (FW<sub>free-acid</sub> = 428.19 g/mol; at pH 6.0,  $\lambda_{\text{max}} = 248.5$  nm and  $\epsilon = 12200 \text{ M}^{-1}\text{cm}^{-1}$ ), usually abbreviated IDP, is an analogue of both ADP and GDP, as evidenced by its ability to substitute for ADP and GDP in many nucleotide-requiring phosphotransfer reactions. IDP is generated by hydrolysis of the terminal phosphoryl group of inosine 5'-triphosphate (ITP), by phosphorylation of IMP, or by the nonenzymatic deamination of ADP, the latter achieved by the presence of nitrous acid. IDP is found in either the free form or, more commonly, associated with a divalent cation (1). **Target(s)**: adenine phosphoribosyltransferase (2); adenylosuccinate synthetase (3,4); amidophosphoribosyl-transferase (5,6); cytochrome  $b_5$  reductase (7); deoxyguanosine kinase (8); diacylglycerol kinase (9); glucokinase, weakly inhibited (10); glucose-6-phosphate dehydrogenase (11); glycoprotein 3-α-L-fucosyltransferase (12,13); hexokinase (14); hypoxanthine(guanine) phosphoribosyltransferase (15,16); isocitrate dehydrogenase (NAD<sup>+</sup>) (17,18); nicotinate phosphoribosyltransferase (19); nicotinate nucleotide diphosphorylase (carboxylating), weakly inhibited (20); nucleoside-triphosphatase (21); 5'-nucleotidase (22); phosphoenolpyruvate carboxykinase (ATP) (23); [protein-PII]

uridylyltransferase (24); ribose-5-phosphate adenylyltransferase, weakly inhibited (25); ribose phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (26,27). 1. ### Inosine 5'-Monophosphate

This nucleotide ( $FW_{\text{free-acid}} = 316.21 \text{ g/mol}$ ; at pH 6.0,  $\lambda_{\text{max}} = 248.5 \text{ nm}$  and  $\epsilon = 12200 \text{ M}^{-1}\text{cm}^{-1}$ ), often abbreviated IMP and called inosinic acid and hypoxanthine riboside 5'-monophosphate, is the first purine nucleotide formed in the *de novo* biosynthesis, and it is thus the precursor of all other purine nucleotides. IMP may also be generated by the nonenzymatic deamination of ADP, the latter achieved by the presence of nitrous acid. An important property of IMP is that the base readily undergoes amido/imido tautomerization, allowing the hydroxyl form to undergo phosphorylation to generate an essential 6-*O*-phosphoryl-IMP intermediate in the adenylosuccinate synthetase reaction. Note that its keto group (in the amido form) would be a proton-acceptor in hydrogen bond formation, whereas its hydroxy group (in the imido form) would be a proton-donor in hydrogen bond formation. Such ambiguous base-pairing is likely to be mutagenic in DNA and RNA. **Target(s):** adenine phosphoribosyltransferase (1); adenylosuccinate synthetase (2); alcohol dehydrogenase (3); amidophospho-ribosyltransferase (4-7); D-amino-acid oxidase, weakly inhibited (8); AMP nucleosidase (9-13); asparagine synthetase, weakly inhibited (14); carbamoyl-phosphate synthetase (glutamine-hydrolyzing) (15-17); FAD diphosphatase (18); fructose-1,6-bisphosphate aldolase (19,20); glucokinase (21); glucose-6-phosphate dehydrogenase, weakly inhibited (22); GMP reductase (23); GTP cyclohydrolase IIa (24); guanylate kinase (25); hexokinase (26); 5'-nucleotidase (27,28); orotate phosphoribosyltransferase (29); orotidylate decarboxylase (29); pancreatic ribonuclease (30); phosphoglycerate kinase (31); 5-phosphoribosylamine synthetase, or ribose-5-phosphate:ammonia ligase (32); phosphoribosylamino-imidazole-succinocarboxamide synthetase (33); phosphoribosyl-pyrophosphate synthetase, or ribose-5-phosphate pyrophosphokinase (34); phosphorylase phosphatase (35); polyphosphate kinase (36); [protein-PII] uridylyltransferase (37,38); ribonuclease (30); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (39); starch phosphorylase, weakly inhibited (40); thiamin kinase (41); threonine synthase, weakly inhibited (41). 1. ### myo-Inositol

This polyol (FW = 180.16 g/mol; CAS 87-89-8; light-sensitive; Solubility: 14 g/100 mL H<sub>2</sub>O at 25°C; *Abbreviation:* Ins) possesses an internal plane of symmetry and is accordingly optically inactive. When in the chair conformation, all but one hydroxyl group (designated the C2 position) are in the equatorial positions. *myo*-Inositol is a substrate in the following enzyme-catalyzed reactions: *myo*-inositol 2-dehydrogenase, inositol oxygenase, inositol 1-methyltransferase, inositol 3-methyltransferase, inositol 4-methyltransferase, indoleacetylglucose:inositol *O*-acyltransferase, inositol 3 $\alpha$ -galactosyltransferase, inositol 3-kinase, and CDP-diacylglycerol:inositol 3-phosphatidyltransferase. It can be produced by the action of certain phosphatases on *myo* inositol 3-phosphate as well as the

reactions catalyzed by galactinol:raffinose galactosyl-transferase, galactinol:sucrose galactosyl-transferase, and inositol-1(or 4) monophosphatase. **Target(s):** alkaline phosphatase (1); CDP-diacylglycerol:glycerol-3-phosphate 3-phosphatidyl-transferase (2); CDP-diacylglycerol:serine 0-phosphatidyl-transferase (3);  $\beta$ -fructofuranosidase, or invertase (4);  $\alpha$ -galactosidase (5-10); galactosyl-galactosylglucosyl-ceramidase, weakly inhibited (11); glucose dehydrogenase (NAD<sup>+</sup>) (12);  $\alpha$ -glucosidase (13);  $\beta$ -glucosidase (14); glycerophosphoinositol inositol-phosphodiesterase, or 1,2-cyclic-inositol-phosphate phosphodiesterase (15); inositol-phosphate phosphatase,  $K_i$  = 400 mM (16,17); inositol-3 phosphate synthase, or inositol-1-phosphate synthase (18,19); phosphatidylinositol diacylglycerol lyase (20-22); phospholipase D (23). 1. ### 1D-myo-Inositol 2,4-Bisphosphate

This phosphorylated inositol (FW<sub>free-acid</sub> = 340.12 g/mol; *Abbreviation:* Ins(2,4)P<sub>2</sub>) inhibits fructose-1,6-bisphosphate aldolase. 1. Koppitz, Vogel & Mayr (1986) *Eur. J. Biochem.* **161**, 421.

### 1D-myo-Inositol Hexasulfate

This sulfated inositol (FW<sub>free-acid</sub> = 660.53 g/mol), also known as 1D-*myo*-inositol hexakisulfate, inhibits phytase and certain protein kinases. **Target(s):** acid phosphatase (1); [ $\beta$ -adrenergic-receptor] kinase (2,3); casein kinase I (4); casein kinase II (5,6); L- and P-selectin (7); 3-phytase (10,14); 3- or 4-phytase (8,11-13); 4-phytase (9,10). 1. Biophys. Res. Commun.* **264**, 201.

#### 1D-*myo*-Inositol 1-Monophosphate

This optically active phosphoinositol ( $FW_{\text{free-acid}} = 260.14$  g/mol; *Abbreviation:* Ins(1)P) is a component of many phospholipids and inositides. Note that a mixture of 1- and 2-monophosphate derivatives are obtained upon treatment of 1D-*myo*-inositol 1-phosphate with hot dilute acid. 1D-*myo*-inositol 1 monophosphate is produced from enzyme-catalyzed hydrolysis of phosphatidylinositol. (D-*myo*-Inositol 1-phosphate is identical to L-*myo*-inositol 3-phosphate, *i.e.*, D-*myo*-inositol 1-phosphate is the enantiomer of D-*myo*-inositol 3-phosphate). **Target(s):** fructose-1,6-bisphosphate aldolase (1); glycerophosphoinositol inositol-phosphodiesterase, *or* 1,2-cyclic-inositol-phosphate phosphodiesterase (2). **1.** Koppitz, Vogel & Mayr (1986) *Eur. J. Biochem.* **161**, 421. **2.** Ross & Majerus (1986) *J. Biol. Chem.* **261**, 11119.

#### 1D-*myo*-Inositol 2-Monophosphate

This optically inactive phosphoinositol ( $FW_{\text{free-acid}} = 260.14$  g/mol; *Abbreviation:* Ins(2)P) is obtained upon treatment of 1D-*myo*-inositol 1-phosphate with hot dilute acid. It can also be generated by the action of phytase on phytic acid (*i.e.*, *myo*-inositol hexakisphosphate) and is stable in the presence of strong base. Migration of the phosphoryl moiety readily occurs, and 1-phosphate analogue is often formed. **Target(s):** glycerophosphoinositol inositolphospho-diesterase, *or* 1,2-cyclic-inositol phosphate phospho-diesterase (1); inositol-1-phosphatase (2). **1.** Ross & Majerus (1986) *J. Biol. Chem.* **261**, 11119. **2.** Hallcher & Sherman (1980) *J. Biol. Chem.* **255**, 10896.

#### 1D-*myo*-Inositol (4-Palmitoyloxybutane-1-yl)-phosphonate

This nonhydrolyzable phosphodiester analogue ( $FW_{\text{free-acid}} = \text{CHOP}$  g/mol) of 1-palmitoyl-lysophosphatidylinositol inhibits phosphatidylinositol-specific phospholipase C. **Target(s):** phosphatidylinositol-specific phospholipase C, *or* 1-phosphatidyl-inositol phosphodiesterase (1,2). **1.** Griffith, Volwerk & Kuppe (1991) *Meth. Enzymol.* **197**, 493. **2.** Shashidhar, Volwerk, Keana & Griffith (1990) *Biochim. Biophys. Acta* **1042**, 410.

#### 1D-*myo*-Inositol 1,3,4,5,6-Pentakisphosphate

This phosphorylated inositol ( $FW_{\text{free-acid}} = 580.06$  g/mol; *Abbreviation:* Ins(1,3,4,5,6)P<sub>5</sub>) modulates the binding of oxygen to avian and reptilian hemoglobins and also stimulates L-type Ca<sup>2+</sup> channels. **Target(s):** fructose-1,6-bisphosphate aldolase (1); inositol-hexakisphosphate kinase (13); inositol-phosphate phosphatase (2); inositol-polyphosphate 5-phosphatase, *or* inositol 1,4,5 trisphosphate/1,3,4,5-tetrakisphosphate 5-phosphatase (3); inositol-tetrakisphosphate 1-kinase (4); inositol trisphosphate receptors (5); L- and P-selectin (6); multiple inositol-polyphosphate phosphatase, *or* 1,3,4,5-tetrakisphosphate 3-phosphatase, also as an alternative substrate (5,7-13); phosphatidylinositide 3-kinase/Akt signalling pathway (14). **1.** Koppitz, Vogel & Mayr (1986) *Eur. J. Biochem.* **161**, 421. **2.** Roth, Harkness & Isaacs (1981) *Arch. Biochem. Biophys.* **210**, 465. **3.** Höer & Oberdisse (1991) *Biochem. #### 1DL-*myo*-Inositol 1-Phosphate 4,5-Bisphosphorothioate

This sulfur-containing 1D-*myo*-inositol 1,4,5-trisphosphate isomer ( $FW = 516.22$  g/mol) inhibits inositol-polyphosphate 5-phosphatase ( $K_i = 1.4$  μM) and inositol-trisphosphate 3-kinase ( $K_i = 46$  μM). **Target(s):** inositol-polyphosphate 5-phosphatase, *or* inositol-1,4,5-trisphosphate 5-phosphatase; inositol-trisphosphate 3-kinase. **1.** Safrany, Mills, Liu, *et al.* (1994) *Biochemistry* **33**, 10763.

#### *myo*-Inositol 1,2,3,5-Tetrakisphosphate

This phosphorylated inositol ( $FW_{\text{free-acid}} = 500.08$  g/mol; *Abbreviation:* Ins(1,2,3,5)P<sub>4</sub>) inhibits inositol-trisphosphate 3 kinase. **1.** Choi, Chang, Chung & Choi (1997) *Bioorg. Med. Chem. Lett.* **7**, 2709.

#### 1DL-*myo*-Inositol 1,2,4,5-Tetrakisphosphate

This 1D-*myo*-inositol tetrakisphosphate isomer ( $FW_{\text{free-acid}} = 500.08$  g/mol) inhibits inositol-polyphosphate 5-phosphatase, *or* inositol-1,4,5-

triphosphate 5 phosphatase ( $K_i = 2.9 \mu\text{M}$ ). 1. Safrany, Mills, Liu, *et al.* (1994) *Biochemistry* **33**, 10763.

#### 1D-myo-Inositol 1,2,5,6-Tetrakisphosphate

This phosphorylated inositol ( $\text{FW}_{\text{free-acid}} = 500.08 \text{ g/mol}$ ; *Abbreviation*: Ins(1,2,5,6)P<sub>2</sub>) is an intermediate in the inositol signaling pathway that inhibits inositol-tetrakisphosphate 1-kinase. 1. Phillippy (1998) *Plant Physiol.* **116**, 291.

#### 1D-myo-Inositol 1,3,4,5-Tetrakisphosphate

This polyphosphorylated inositol ( $\text{FW}_{\text{free-acid}} = 500.08 \text{ g/mol}$ ; *Abbreviation*: Ins(1,3,4,5)P<sub>4</sub>) regulates intracellular calcium ions by increasing Ca<sup>2+</sup> passage across the plasma membrane. It is also an immediate precursor to inositol 1,3,4-trisphosphate. Note that it is an enantiomer of D-myo-inositol-3,4,5,6-tetrakisphosphate (*i.e.*, L-myo-inositol-1,3,4,5-tetrakisphosphate). **Target(s)**: Ca<sup>2+</sup>-transporting ATPase (1); inositol-hexakisphosphate kinase (2); inositol tetrakisphosphate 1-kinase (3,4); inositol-trisphosphate 3-kinase, by product inhibition (5-7); inositol 1,3,4-trisphosphate 5/6-kinase (8-10); inositol-polyphosphate 5-phosphatase, *or* inositol 1,4,5 trisphosphate 5-phosphatase, as alternative substrate for some isozymes and sources (11-13). 1. Fraser & Sarnacki (1992) *Amer. J. Physiol.* **262**, F411. 2. Voglmaier, Bembenek, Kaplin, *et al.* (1996) *Proc. Natl. Acad. Sci. U.S.A.* **93**, 4305. 3. #### 1D-myo-Inositol 1,4,5-Trisphosphate

This phosphorylated inositol ( $\text{FW}_{\text{free-acid}} = 420.10 \text{ g/mol}$ ; *Abbreviation*: Ins(1,4,5)P<sub>3</sub>) mobilizes calcium ion concentrations. It is produced from phosphatidylinositol 4,5-bisphosphate via the action of phosphoinositase C. **Target(s)**: Ca<sup>2+</sup>-transporting ATPase (1,2); fructose-1,6-bisphosphate aldolase (3); guanylate cyclase (4); inositol-hexakisphosphate kinase (5); inositol-tetrakisphosphate 1-kinase (6,7); multiple inositol-polyphosphate phosphatase, *or* inositol-1,3,4,5-tetrakisphosphate 3-phosphatase (8-10); 3-phosphoglycerate kinase (11); sphingomyelin phosphodiesterase, mildly inhibited (12). 1. ### myo-Inosose-2

This optically inactive polyhydroxylated cyclohexanone (FW = 178.14 g/mol), also called *scyllo*-inosose and 2,4,6/3,5-pentahydroxycyclohexanone, is an intermediate in streptidine biosynthesis. *myo*-Inosose-2 is a substrate for glutamine:*scyllo*-inosose aminotransferase and *myo*-inosose-2 dehydratase. It decomposes slowly upon exposure to strong light and has a melting point of 199-202°C (with decomposition) (1). **Target(s)**: CDP-diacylglycerol: inositol 3-phosphatidyltransferase (2); inositol 4-methyltransferase (3); inositol oxygenase (4); D-xylose: NADP<sup>+</sup> 1-oxidoreductase, or D-xylose dehydrogenase, NADP<sup>+</sup>-requiring (5). 1. Posternak (1952) *Biochem. Prep.* **2**, 57. 2. Takenawa & Egawa (1977) *J. Biol. Chem.* **252**, 5419. 3. Wanek & Richter (1995) *Planta* **197**, 427. 4. ### Inostamycin

This polyether antibiotic (FW = 644.89 g/mol), first isolated from a species of *Streptomyces*, inhibits cytidine 5'-diphosphate 1,2-diacyl-sn-glycerol (CDP-DG): inositol transferase, caused a G<sub>1</sub>-phase accumulation in the cell cycle of small cell lung carcinomas (1-3). Inostamycin, a novel polyether compound, reverses multidrug resistance, thereby allowing a dose-dependent accumulation of [<sup>3</sup>H]-vinblastine in multidrug-resistant cell lines (2). **Target(s)**: CDP-diacylglycerol:inositol 3-phosphatidyltransferase (1); P-glycoprotein, or multidrug resistance transporter (2); phosphatidylinositol turnover (3). 1. Imoto, Taniguchi & Umezawa (1992) *J. Biochem.* **112**, 299. 2. Kawada & Umezawa (1995) *Jpn. J. Cancer Res.* **86**, 873. 3. Johtoh & Umezawa (1992) *Drugs Exp. Clin. Res.* **18**, 1.

### S-Inosyl-L-homocysteine

This S-substituted homocysteine (FW = 385.40 g/mol), formed by the enzymatic deamination of S-adenosyl-L-homocysteine, weakly inhibits mRNA (nucleoside-2'-O-) methyltransferase and DNA (cytosine-5-)-methyltransferase. **Target(s)**: DNA (cytosine-5-)-methyltransferase (1); *Hae*III DNA methyltransferase, *K<sub>i</sub>* = 450 μM (1); *Hha*I DNA methyltransferase, *K<sub>i</sub>* = 3.9 mM (1); mRNA (nucleoside-2'-O-) methyltransferase (2); tRNA (guanine-N<sup>7</sup>-)-methyltransferase (3). 1.

### Insensible

This novel nuclear inhibitor (MW = 19425.51 g; Accession Number = AE013599.5; Symbol = Insb) targets Notch signalling, which regulates a series of binary fate decisions in *Drosophila*, leading a single sensory organ precursor cell to form regularly spaced sensory organs through a series of asymmetric cell divisions. Insb over-expression leads to transcriptional repression of a Notch reporter and to phenotypes associated with Notch inhibition. While the complete loss of Insb activity showed no significant phenotype, it enhanced the bristle phenotype associated with reduced levels of Hairless, a nuclear protein acting as a co-repressor for Suppressor of Hairless. 1. Coumilleau & Schweisguth (2014) *PLoS One* **9**, e98213.

### Insulin degludec

This ultralong-acting insulin analogue (FW = 6103.97 g/mol; CAS 844439-96-9; Symbol: Ideg), also known as Tresiba<sup>®</sup>, provides a basal insulin level, reducing the need for frequent administration of fast-/short-acting bolus doses of insulin. The presence of the lysyl ε-amino-hexadecanediamide to Lysine-29 (B-chain) promotes self-assembly of insulin hexamers, which in turn form multi-hexamers, when deposited at appropriate levels within subcutaneous tissues. Insulin hexamerization and polymerization serve to retard insulin dissolution and mobilization, thus providing for the nearly zero-order release of this hormone into the bloodstream. There is a continuous and highly predictable slow dissociation of insulin monomers from this depot; insulin levels rise immediately reaching *t<sub>max</sub>* at 10-12 hours, followed by a slow decline, with a half-life of 17-21 hours, or roughly twice the duration of insulin glargine action. **Pharmacokinetics**: Onset of Action = 30-90 minutes (similar to insulin glargine and insulin detemir); Little or no

peak in activity (due to the slow release into systemic circulation); Duration of Action = >24 hours; Time to Attain Steady-State = 2-3 days. Once-daily dosing produces a steady-state profile characterized by a near-constant effect, which varies little from injection to injection in a given patient. 1. Rendell (2013) *Drugs Today (Barc)* **49**, 387. 2. Goldman-Levine, Patel & Schnee (2013) *Ann. Pharmacother.* **47**, 269.

### Inter- $\alpha$ -Trypsin Inhibitor (or Inter- $\alpha$ -Inhibitor)

This abundant plasma glycoprotein and trypsin inhibitor consists of three subunits (Heavy Chain 1, Heavy Chain 2, and Bikunin) joined covalently by a chondroitin sulfate chain originating at Ser-10 of bikunin. I $\alpha$ I interacts with the inflammation-associated Tumor Necrosis Factor-Inducible Gene 6 Protein (TNFAIP6 or TSG-6) within the extracellular matrix (ECM). This interaction leads to the transfer of the heavy chains from the chondroitin sulfate of inter- $\alpha$ -inhibitor to hyaluronan (HA), with consequential stabilization of the ECM. (Note: TNFAIP6 is itself secreted by various cells in response to stimulation by various inflammatory cytokines.) Hyaluronan and its binding proteins control inflammatory gene expression, inflammatory cell recruitment, and inflammatory cytokine release, thereby attenuating the course of inflammation and protecting against tissue damage. 1. Salier, Rouet, Raguenez, & Daveau (1996) *Biochem. J.* **315** (Pt 1), 1. 2. Zhuo, Hascall & Kimata (2004) *J. Biol. Chem.* **279**, 38079. 3. Kobayashi (2006) *Biol. Chem.* **387**, 1545.

### Interleukin-1 Receptor Antagonist

This protein (MW = 17,258 g/mol; CAS 143090-92-0; Symbol: IL-1RA), which in humans is encoded by the *IL1RN* gene, binds non-productively to the Interleukin-1 Receptor (IL-1R), preventing IL-1 signal propagation to downstream targets. A member of the interleukin 1 cytokine family, IL-1R $\alpha$  is secreted by immune cells, epithelial cells, and adipocytes. It is a natural inhibitor of the pro-inflammatory effect of IL-1 $\beta$ . This protein inhibits the activities of IL-1R $\alpha$  and IL-1 $\beta$ , and thereby modulates a variety of IL-1-related immune and inflammatory responses. It is commercially known as Anakinra (trade name Kineret<sup>®</sup>), is used to suppress inflammation and cartilage degradation associated with rheumatoid arthritis.

### Intoplicine

This anticancer agent (FW<sub>free-base</sub> = 348.45 g/mol; CAS 125974-72-3), also known as RP-60475, is a dual inhibitor of DNA topoisomerases I and II. Intoplicine induces both topoisomerase I- and II-mediated DNA strand breaks, and cleavage site patterns induced were different from those induced by camptothecin, *N*-[4-(9-acridinylamino)-3-methoxyphenyl]methanesulfonamide (m-AMSA), and other known topoisomerase inhibitors. Both topoisomerase I- and II-induced DNA breaks decreased at drug concentrations higher than 1  $\mu$ M, a feature that is consistent with intoplicine's DNA-intercalating activity. 1. Nabiev, Chourpa, Riou, *et al.* (1994) *Biochemistry* **33**, 9013. 2. Poddevin, Riou, Lavelle & Pommier (1993) *Mol. Pharmacol.* **44**, 767.

### Intrinsic Factor

This 417-residue glycoprotein (MW = 45,425 g; CAS 9008-12-2) is a vitamin B<sub>12</sub>-binding glycoprotein produced by the parietal cells of the stomach. **Role in Vitamin B<sub>12</sub> Absorption:** After dietary vitamin B<sub>12</sub> is released from ingested proteins through the action of pepsin and stomach acid, it is rapidly bound by one of two vitamin B<sub>12</sub>-binding proteins present in gastric juice. These binding proteins have a greater affinity for the vitamin than does intrinsic factor at acid pH. After transfer to the small intestine, pancreatic proteases digest the binding proteins, releasing vitamin B<sub>12</sub>, which then becomes bound to intrinsic factor. Finally, there are receptors for intrinsic factor on the ileal mucosa, which bind the complex, allowing vitamin B<sub>12</sub> to be enter portal circulation. **Physiology:** William Castle's

discovery of Intrinsic Factor in 1929 provided the first explanation for the pathogenesis and pathophysiology of pernicious anemia. He postulated that a factor was required to bind dietary vitamin B<sub>12</sub> in a manner that permitted facilitated entry of B<sub>12</sub> into circulation. The story is, of course, more complex. Cubilin (Mr = 215,000) is the intestinal receptor for the endocytosis of intrinsic factor-vitamin B<sub>12</sub> complex. When intrinsic factor was complexed with various analogs of cyanocobalamin, the dissociation constant ( $K_i$  = 0.25 nM) of these complexes for ileal microvillous membranes were similar to that of intrinsic factor-bound cyanocobalamin. Mutations in *CUBN*, the gene for cubilin, is one cause of hereditary megaloblastic anemia and associated neurological deficits. Overexpression of an unstable intrinsic factor-cobalamin receptor occurs in Imerslund-Gräsbeck syndrome, an autosomal recessive, familial form of vitamin B<sub>12</sub> deficiency caused by malfunction of the receptor located in the terminal ileum. **Mode of Inhibitory Action:** The dissociation constant for the intrinsic factor-cyanocobalamin complex was 0.066 nM. When added in excess, Intrinsic Factor tightly binds cobalamin derivatives, thereby depriving vitamin B<sub>12</sub>-dependent enzymes of their essential cofactor. This inhibition can often be overcome by the addition of excess cobalamin or cobalamin analogue. **Target(s):** ethanolamine ammonia-lyase (1); leucine 2,3-aminomutase (2-4);  $\beta$ -lysine 5,6-aminomutase (1,5); D-lysine 5,6-aminomutase (1,6,7);  $\beta$ -methylaspartate mutase, or glutamate mutase (8,9); 2-methyleneglutarate mutase (10); methylmalonyl-CoA mutase (11); D-ornithine 4,5-aminomutase (1). 1. ### Iodine & Iodide

This group 17 (or VIIB) element (Symbol = I; Atomic Number = 53; Atomic Weight = 126.90) is a halogen located directly below bromine in the Periodic Table. In its elemental state, I<sub>2</sub> is a powerful oxidizing agent that, when applied as a dilute solution, finds wide utility as a disinfectant. Common oxidation states are I<sup>-</sup>, I<sup>3+</sup>, and I<sup>7+</sup>, for which the ionic radii are 2.20, 0.62, and 0.50 Å, respectively. Iodine has only one stable isotope (<sup>127</sup>I), but several of its radioactive isotopes are used in biochemistry and biomedicine. Iodine-123 has a half-life of 13.2 hours and is used as a diagnostic imaging agent. Iodine-124 is a positron emitter with a half-life of 4.18 days and has been used in positron emission tomography. Iodine-125, which has a 59.4-day half-life for decay via electron capture (0.179 MeV), is frequently used to label macromolecules. Its emissions require the experimenter to employ thick lead shielding. The frequently used iodine-131 has a half-life of 8.04 days (0.971 MeV). The thyroid gland is the critical organ in terms of radiation exposure, and investigators are strongly encouraged to adhere to institutional regulations regarding thyroid monitoring for localized radioiodine uptake. The effective biological half-life in humans is about 140 days, kept mainly as iodide monoanion and combined with thyroglobulin. Iodide anion (I<sup>-</sup>) can react with one or more molecules of iodine (I<sub>2</sub>) to produce polyiodide anions, of which I<sub>3</sub><sup>-</sup> is found in aqueous systems. The triiodide ion is the most commonly used source for the iodination of proteins tyrosyl residues. Iodine is an important trace element required by a number of organisms. It is an essential element for vertebrates, Ascidians, corals, and possibly seed plants. It is accumulated in the mammalian thyroid gland (free iodide concentrations in the human thyroid are ~1 mM), in red and brown algae (and their marine predators), and a number of Porifera and Coelenterata. **See also Periodate**

### Iodoacetamide

This alkylating agent (FW = 184.96 g/mol; M.P. = 93–96°C) is a potent irreversible inhibitor of enzymes requiring reactive thiols,  $\epsilon$ -amino groups, and/or imidazole side chain groups. Nucleophilic displacement of the iodide by an enzyme sulfhydryl (*i.e.*, Enz-SH or Enz-S<sup>-</sup>) results in the formation of a stable thioether linkage (*i.e.*, Enz-S-CH<sub>2</sub>C(=O)NH). In certain instances,

methionyl residues also undergo alkylation. The reaction is typically a bimolecular process, rarely showing evidence of rate-saturation kinetics. Sulfhydryl groups are typically the most reactive protein functional moiety, with reactivity increasing with pH (optimal between pH 6 and 8.5). This toxic haloamide is soluble in water. Because iodoacetamide slowly decomposes in aqueous solutions, fresh stock solutions should be prepared. The reagent should also be stored away from light to minimize formation of iodine which often reacts with tyrosyl and histidyl residues. Iodoacetamide is usually slightly more reactive than iodoacetate.

**Iodoacetate**, *Similar in mode of action to iodoacetamide*

### 3-Iodoacetol Phosphate

This analogue of dihydroxyacetone phosphate ( $FW_{\text{free-acid}} = 279.95 \text{ g/mol}$ ), also known as 1-iodo-3-hydroxyacetone phosphate, inhibits a number of enzymes that utilize or produce dihydroxyacetone phosphate. Aqueous 3-iodoacetol phosphate is unstable (at pH 7,  $t_{1/2} = 6.8 \text{ hours}$ ; at pH 8,  $t_{1/2} = 3 \text{ hours}$ ). **Target(s):** fructose-1,6-bisphosphate aldolase (2,3); glycerol-phosphate dehydrogenase (2); methylglyoxal synthase (4); triose-phosphate isomerase (2,5-7). 1. Hartman (1970) *Biochemistry* **9**, 1776. 2. Hartman (1972) *Meth. Enzymol.* **25**, 661. 3. Hartman (1970) *Biochemistry* **9**, 1783. 4. Yuan, Gracy & Hartman (1977) *Biochem. Biophys. Res. Commun.* **74**, 1007. 5. Hartman & Norton (1975) *Meth. Enzymol.* **41**, 447. 6. Hartman (1977) *Meth. Enzymol.* **46**, 130. 7. Noltmann (1972) *The Enzymes*, 3rd ed., 6, 271.

### 5-Iodo-5'-amino-2',5'-dideoxyuridine-5'-N'-triphosphate

This phosphoramidate analogue ( $FW = 499.10 \text{ g/mol}$ ; *Abbreviation:* AIdUTP) of 5-iodo-2',5'-dideoxyuridine 5'-triphosphate reversibly inhibits thymidine kinase. Although AIdUTP is stable in alkaline solutions, below pH 8 it undergoes degradation by a novel phosphorylation reaction which exhibits first order kinetics. AIdUTP is, however, 60-fold more potent as an allosteric inhibitor than is TTP. 1. Chen & Prusoff (1978) *Meth. Enzymol.* **51**, 354. 2. Chen, Ward & Prusoff (1976) *J. Biol. Chem.* **251**, 4839. 3. Fischer, Fang, Lin, Hampton & Bruggink (1988) *Biochem. Pharmacol.* **37**, 1293.

### m-Iodobenzoate

This conjugate base of a substituted benzoic acid ( $FW_{\text{free-acid}} = 248.02 \text{ g/mol}$ ; M.P. = 186-188°C) inhibits D-amino-acid oxidase (1,2), glutamate dehydrogenase (2-4), porphobilinogen synthase (5), and serine-sulfate ammonia-lyase (6). 1. Bartlett (1948) *J. Amer. Chem. Soc.* **70**, 1010. 2. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, Academic Press, New York. 3. Caughey, Smiley & Helleman (1957) *J. Biol. Tudball & Thomas (1973) *Eur. J. Biochem.* **40**, 25.

### o-Iodobenzoate (o-Iodobenzoic Acid)

This substituted benzoic acid ( $FW_{\text{free-acid}} = 248.02 \text{ g/mol}$ ; M.P. = 162°C) inhibits aminopeptidase B (1); esterase (2); lysine 2-monooxygenase (3); macrocellulase complex (4); 6-phosphogluconate dehydrogenase (5); poly(A)-specific ribonuclease (6,7); propanediol dehydratase (8); and quinine oxidase (9). Note: Investigators should take care to not confuse o-iodobenzoate with o-iodosobenzoate. 1. Hopsu, Mäkinen & Glenner (1966) *Arch. Biochem. Biophys.* **114**, 567. 2. Weber & King (1935) *J. Biol. ### m-Iodobenzylguanidine

This norepinephrine analogue ( $FW_{\text{free-base}} = 275.09 \text{ g/mol}$ ; *Abbreviation:* MIBG), also known as iobenguane and often, interferes with cellular mono(ADP-ribosyl)transferases and acts as an alternative substrate for the ADP-ribosylating activity of cholera toxin and the mono(ADP-ribosyl)transferase of turkey erythrocyte membranes. MIBG is also used in the diagnosis and treatment of pheochromocytoma and inhibits mitochondrial respiration. **Target(s):** arginine-specific ADP-ribosyltransferase (1-4); monoamine oxidase (5); NADH dehydrogenase, *or* Complex I (6-8); ubiquinol:cytochrome *c* reductase, *or* Complex III (7,8). 1. Loesberg, van Rooij & Smets (1990) *Biochim. Biophys. Acta* **1037**, 92. 2. Kharadia, Huiatt, Huang, Peterson & Graves (1992) *Exp. Cell Res.* **201**, 33. 3. ### Iodocyanopindolol

This  $\beta_1$ -adrenoreceptor ligand ( $FW = 413.26 \text{ g/mol}$ ; CAS 85124-14-7; IUPAC: (*RS*)-4-[3-[(1,1-dimethylethyl)amino]-2-hydroxypropoxy]-3-iodo-1*H*-indole-2-carbonitrile) is a derivative of (*S*)-pindolol, a gold-standard  $\beta_1$ -adrenergic receptor antagonist (*See Pindolol*) and a partial-agonist/antagonist for 5-HT<sub>1A</sub> receptors. Its <sup>125</sup>I-labeled form has been widely exploited to map the distribution of  $\beta$ -adrenoreceptors, making it possible to directly determine the tissue concentration of  $\beta$ -adrenoreceptors and the responsiveness of tissues to  $\beta$ -adrenergic stimulation (1). A major insight to emerge from radioligand-binding studies is that the tissue

concentration of  $\beta$ -adrenoceptors is not a fixed number, but is instead dynamically regulated by a variety of drugs, hormones as well as physiological and pharmacological conditions. Moreover, because changes in  $\beta$ -adrenoceptors assessed in circulating lymphocytes mirror changes in density and functional responsiveness of the corresponding myocardial  $\beta$ -adrenoceptors, alterations in  $\beta$ -adrenoceptor function can be also examined in humans. Radioligand-binding studies also demonstrated the coexistence of  $\beta_1$ - and  $\beta_2$ -adrenoceptor subtypes in numerous tissues, including heart and lung. An example is the demonstration of the coexistence of  $\beta_1$ - and  $\beta_2$ -adrenoceptors in human right atrium by (+/-)-[ $^{125}$ I]iodocyanopindolol binding (2). 1. Brodde (1986) *J. Cardiovasc. Pharmacol.* **8** (Suppl. 4), S16. 2. Brodde, Karad, Zerkowski, Rohm & Reidemeister (1983) *Circulation. Res.* **53**, 752.

### 2-Iodo-6-isopropyl-3-methyl-2',4,4'-trinitrodiphenyl Ether

This ether (FW = 487.21 g/mol; Abbreviation: DNP-INT), also known as 2,4-dinitrophenyl 2-iodo-4-isopropyl-6-nitrotoluen-3-yl ether and *O*-(2,4-dinitrophenyl)-2-iodo-4-nitrothymol, is a competitive inhibitor of the plastoquinol oxidation at the Qo site of the cytochrome *b<sub>f</sub>* complex. **Target(s):** photosynthetic electron transport (1); plastoquinol:plastocyanin reductase (or cytochrome *b<sub>f</sub>* complex) (2-10); ubiquinol:cytochrome-*c* reductase, or Complex III of *Spinacia oleracea* (11). 1. Trebst (1980) *Meth. Enzymol.* **69**, 675. 2. Malkin (1988) *Meth. Enzymol.* **167**, 341. 3. Delosme, Joliot & Trebst (1987) *Biochim. Biophys. Acta* **893**, 1. 4. ### 5-Iodo-3-methoxy-tyrphostin AG538

This cell-permeable analogue of tyrphostin AG538 (FW = 437.19 g/mol) also known as  $\alpha$ -cyano(3-methoxy-4-hydroxy-5-iodo)cinnamoyl(3',4'-dihydroxyphenyl)ketone and tyrphostin I-OMe-AG538, inhibits insulin-like growth factor receptor protein-tyrosine kinase (IC<sub>50</sub> = 3.4  $\mu$ M). In computer modeling, the inhibitor docked in the kinase domain of the insulin receptor, sitting in place of tyrosines 1158 and 1162. The latter normally undergo autophosphorylation. Experimentally, it does not compete with ATP but instead competes with the IGF-1R substrate. 1. Blum, Gazit & Levitzki (2000) *Biochemistry* **39**, 15705.

### 1-(5-Iodonaphthalene-1-sulfonyl)-1H-hexahydro-1,4-diazepine

This diazepine (FW<sub>free-base</sub> = 416.28 g/mol), commonly referred to as ML-7, is a selective [myosin light-chain] kinase inhibitor, IC<sub>50</sub> = 0.3  $\mu$ M. Other kinases are inhibited much less effectively (e.g., protein kinase A, IC<sub>50</sub> = 21

$\mu$ M, and protein kinase C, IC<sub>50</sub> = 42  $\mu$ M). 1. Bain, McLauchlan, Elliott & Cohen (2003) *Biochem. J.* **371**, 199. 2. ### 6 $\beta$ -Iodopenicillanic Acid

This substituted penicillanate (FW<sub>free-acid</sub> = 327.14 g/mol) reacts selectively with the active site of D-Ala-D-Ala carboxypeptidase to form an adduct that is much more stable than that formed with benzylpenicillin. The  $\beta$ -lactamases of *Bacillus cereus* and *Streptomyces cacaoi* are also inactivated, whereas the corresponding enzymes from *Streptomyces albus* and *Actinomodura* R39 catalyze the hydrolysis of the inactivator for multiple turnovers prior to inactivation (515 for the *S. albus* enzyme and 80 for *Actinomodura* R39). 6 $\beta$ -Iodopenicillanate is a substrate for class-B Zn<sup>2+</sup>-containing  $\beta$ -lactamase II and inactivates lactamases from classes A, C, and D. **Target(s):**  $\beta$ -lactamase (1-7); zinc D-Ala-D-Ala carboxypeptidase (8-10). 1. Lenzini & Frere (1985) *J. Enzyme Inhib.* **1**, 25. 2. Amicosante, Oratore, Joris, et al. (1988) *Biochem. J.* **254**, 891. 3. Frere, Dormans, Duyckaerts & De Graeve (1982) *Biochem. ### p-Iodo-D-phenylalanine Hydroxamate

This hydroxamic acid (FW = 306.10 g/mol) inhibits *Vibrio* aminopeptidase. **Target(s):** bacterial leucyl aminopeptidase, *Vibrio* aminopeptidase, or *Aeromonas proteolytica* aminopeptidase. 1. Chevier & D'Orchymont (1998) in *Handb. Proteolytic Enzymes*, p. 1433, Academic Press, San Diego. 2. Chevier, D'Orchymont, Schalk, Tarnus & Moras (1996) *Eur. J. Biochem.* **237**, 393. 3. Schürer, Lanig & Clark (2004) *Biochemistry* **43**, 5414.

### (Z)-3-(4-Iodophenyl)-2-mercapto-2-propenoate

This selective calpain inhibitor, (FW = 306.12 g/mol; Photosensitive off-white solid), also known as PD150606, is cell-permeable. The *K<sub>i</sub>* value for calpain-I [ $\mu$ -calpain] is 0.21  $\mu$ M (noncompetitive) and 0.37  $\mu$ M for calpain-2 [ $\nu$ -calpain]. It is directed to calpain's calcium binding sites and does not protect calpain against inactivation by the active-site-directed inhibitor, *trans*-(epoxysuccinyl)-L-leucylamido-3-methylbutane. It also prevents

dexamethasone-induced apoptosis in thymocytes. Note that there is some confusion in the literature concerning PD 150606. For example, in one of the references below, PD150606 is referred to as 3-(4-iodobenzyl)-2-mercapto-2-propenoate (*i.e.*, a substituted 2-butenate) and not the inhibitor first reported in 1996. 1. Edelstein, Shi & Schrier (1999) *J. Amer. Soc. Nephrol.* **10**, 1940. 2. Lin, Chattopadhyay, Maki, *et al.* (1997) *Nat. Struct. Biol.* **4**, 539. 3. Squier & Cohen (1997) *J. Wang, Posner, Raser, *et al.* (1996) *Adv. Exp. Med. Biol.* **389**, 95.

### 5-Iodotubercidin

This adenosine analogue and genotoxic agent (FW = 392.15 g/mol; Symbol: Itu), also known as 7-iodo-7-deazaadenosine, NSC 113939, and 4-amino 5-iodo-7-(β-D-ribofuranosyl)pyrrolo[2,3-*d*]pyrimidine, inhibits adenosine kinase, reduces adenosine uptake, and stimulates glycogen synthesis (1-11). The  $K_i$  value for adenosine kinase is 30 nM. Because the use of adenosine receptor agonists is plagued by dose-limiting cardiovascular side effects, there is great interest in developing adenosine kinase inhibitors (AKIs) as a means for raising steady-state adenosine concentrations. However, 5-iodotubercidin also causes DNA damage, inducing DNA breaks and forming nuclear foci that are positive for γH2AX and TopBP1, activation of Atm and Chk2, and S15 phosphorylation and up-regulation of p53 (12). As such, 5-iodotubercidin induces G<sub>2</sub> cell-cycle arrest in a p53-dependent manner. It also induces cell death in p53-dependent and -independent modes. DNA breaks are likely generated by incorporation of a 5-iodotubercidin metabolite into DNA. Moreover, 5-iodotubercidin shows anti-tumor activity, reducing tumor size in carcinoma xenograft mouse models in p53-dependent and -independent ways (12). **See also Tubercidin**  
**Target(s):** adenosine kinase (1-11); adenosine transport (4,5); casein kinase I (13); [glycogen synthase] kinase (13,14); [3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)] kinase (14); mitogen-activated protein kinase ERK2,  $K_i$  = 530 nM (15); phosphorylase kinase (13); protein kinase A (13); protein-tyrosine kinase, insulin receptor (13). 1. ### 5-Iodouracil

This substituted pyrimidine (FW = 237.98 g/mol; CAS 696-07-1) inactivates dihydropyrimidine dehydrogenase by forming an adduct with a cysteinyl residue. 5-Iodouracil also inhibits L-3-aminoisobutyrate aminotransferase and 4-aminobutyrate aminotransferase. **Target(s):** 4-aminobutyrate aminotransferase (1); (*R*)-3-amino-2 methylpropionate: pyruvate aminotransferase, *or* D-3-aminoisobutyrate aminotransferase (2); (*S*)-3-amino-2-methylpropionate: pyruvate aminotransferase, *or* L-3-aminoisobutyrate aminotransferase (3); dihydropyrimidine dehydrogenase (4,5). 1. Tamaki, Kubo, Aoyama & Funatsuka (1983) *J. Biochem.* **93**, 955. 2. Kaneko, Kontani, Kikugawa & Tamaki (1992) *Biochim. Biophys. Acta* **1122**, 45. 3. ### Ionophorous Antibiotics

These lipid-soluble molecules form stoichiometric complexes with alkali metal cations and transport bound ions across a variety of membranes (1-6) or into a bulk organic phase (3,6,7). Neutral sequestering agents, such as valinomycin (2,4,6), or the macroretrolic homologues known as monactin, dinactin, tetranactin, and nonactin (2,4,7,8), form charged complexes with monovalent cations while the negatively charged carboxylic acid ionophores such as nigericin (3,4,9,10) or the monensins (11,12) form a neutral metal-antibiotic species. The carboxylic acid X537A binds barium (13), other divalent cations, and lanthanum (14) as well as alkali metal cations (4,5). While the neutral sequestering ionophores induce active, electrogenic accumulation of monovalent cations by respiring mitochondria of rat liver (2,4-6,8), the carboxylic acid antibiotics catalyze an electroneutral exchange of accumulated or endogenous alkali metal cations for extramitochondrial protons (3,6,10-12). A23187 is a carboxylic acid antibiotic that affects mitochondrial function by perturbing endogenous calcium and magnesium content. (**See also Valinomycin; Nactin; Monensin; Nigericin; X537A; A23187**) 1. Reed & Lardy (1972) *J. Biol. Chem.* **247**, 6970. 2. Pressman (1965) *Proc. Nat. Acad. Sci. USA.* **63**, 1076. 3. ### IP7e

This orally bioavailable, brain-penetrant Nurr1 activator (FW = 390.43 g/mol; CAS 500164-74-9; Solubility: 100 mM in DMSO; 20 mM in H<sub>2</sub>O, the latter with warming), also named 6-[4-[(2-methoxyethoxy)methyl]phenyl]-5-methyl-3-phenylisoxazolo[4,5-c]pyridin-4(5H)-one, targets the Nuclear receptor-related 1 (EC<sub>50</sub> = 3.9 nM), a protein that resembles steroid nuclear hormone receptor, but is not regulated by ligands and is instead locked in a constitutively active form. In Nurr1-knockout mice, complete midbrain dopamine cell agenesis is apparent at birth, and point mutations in Nurr1 gene are associated with a familiar form of Parkinson Disease. Reduced Nurr1 expression levels is observed in brains of aged individuals. Nurr1 also plays an anti-inflammatory role by inhibiting the expression of inflammatory genes in microglia and astrocytes, and Nurr1 helps to repress the activity of the pro-inflammatory transcription factor NF- $\kappa$ B. IP7e reduces the incidence and severity of experimental autoimmune encephalomyelitis (EAE) in mice, attenuating inflammation and neurodegeneration in spinal cords of EAE mice by an NF- $\kappa$ B pathway-dependent process. **1.** Montarolo, Raffaele, Perga, *et al.* (2014) *PLoS One* **9**, e108791. **2.** Hintermann, Chiesi, von Krosigk, *et al.* (2007) *Bioorg. Med. Chem. Lett.* **17**, 193.

### IPI-145

This novel small molecule protein kinase inhibitor (FW = 416.86 g/mol; CAS 1201438-56-3; Solubility = 84 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as Duvelisib, INK1197 and 8-chloro-2-phenyl-3-[(1S)-1-(9H-purin-6-ylamino)ethyl]-1(2H)-isoquinolinone, selectively targets PI3K- $\delta$  ( $K_i$  = 23 pM (calculated from  $k_{on}$  =  $15.2 \times 10^6$  M<sup>-1</sup>s<sup>-1</sup> and  $k_{off}$  = 0.9 hour<sup>-1</sup>); IC<sub>50</sub> = 1 nM), showing lesser affinity to PI3K- $\gamma$  ( $K_i$  = 243 pM (calculated from  $k_{on}$  =  $3.4 \times 10^6$  M<sup>-1</sup>s<sup>-1</sup> and  $k_{off}$  = 3 hour<sup>-1</sup>); IC<sub>50</sub> = 50 nM) and little inhibition of PI3K- $\beta$  ( $K_i$  = 15.5 pM (calculated from  $k_{on}$  =  $2.7 \times 10^6$  M<sup>-1</sup>s<sup>-1</sup> and  $k_{off}$  = 2.7 hour<sup>-1</sup>) and PI3K- $\alpha$  ( $K_i$  = 25.9  $\mu$ M (calculated from  $k_{on}$  =  $4.2 \times 10^6$  M<sup>-1</sup>s<sup>-1</sup> and  $k_{off}$  = >1800 hour<sup>-1</sup>). IPI-145 was a weaker inhibitor ( $K_i$  > 1  $\mu$ M) with 440 other protein kinases. This inhibitor inhibits human B and T cell proliferation, with EC<sub>50</sub> values of 0.5 and 9.5 nM. **1.** “Targeting PI3K- $\delta$  and PI3K- $\gamma$  in Inflammation”, by Palombella, Infinity Pharmaceuticals, Inc., *New York Acad. Sci. Conference*, June 27, 2012 (<http://www.infi.com/product-candidates-publications.asp>)

### Ipilimumab

This CTLA-4 function-blocking drug (MW = 148634.91 g/mol; CAS 477202-00-9), also known by the code names MDX-010 and MDX-101 and by its trade name Yervoy<sup>®</sup>, is a humanized IgG1 monoclonal antibody against the extracellular domain of the Cytotoxic T-Lymphocyte Antigen-4, a protein that activates the immune system by targeting the CTLA-4 receptor, inhibiting inappropriate or prolonged T-cell activation. Ipilimumab and like-acting anti-CTLA-4 antibodies bind to CTLA-4 on the cell surface, blocking its interaction with the costimulatory molecules B7.1 and B7.2 and interrupting the negative signalling mediated by CTLA-4 and blunting T-cell responses involved in immune tolerance against self antigens. Ipilimumab activates tumor-reactive T cells, while removing inhibitory activity with CTLA-4 blockade, a drug action that commends its use combination with other cancer immunotherapies to improve clinical outcomes, particularly in melanoma treatment. **Formulation:** Ipilimumab is diluted to 1–2 mg/mL in normal saline or 5% dextrose in water and administered intravenously over 90 minutes using an in-line filter. Among previously untreated patients with metastatic melanoma, nivolumab alone or combined with ipilimumab resulted in significantly longer progression-free survival than ipilimumab alone (3). **See Nivolumab** **1.** Maker, Phan, Attia, *et*

### Ipragliflozin

This orally active benzothiophene C-glucoside (FW = 404.45 g/mol; CAS 761423-87-4), also known by its code name ASP1941 and its systematic name (1S)-1,5-Anhydro-1-C-[3-[(1-benzothiophen-2-yl)methyl]-4-fluorophenyl]-D-glucitol, a potent and selective sodium glucose co-transporter 2 (SGLT2) inhibitor for the treatment of Type 2 Diabetes Mellitus (T2DM). **Rationale:** SGLT2 is a high-capacity, low-affinity transport system primarily expressed in the renal proximal tubules, where it plays an important role in the regulation of glucose levels. Ipragliflozin induces sustained increases in urinary glucose excretion by inhibiting renal glucose reabsorption, with subsequent antihyperglycemic effect and a low risk of hypoglycemia. Therefore, ipragliflozin has the therapeutic potential for treating hyperglycemia in diabetes by increasing glucose excretion into urine. **1.** Imamura, Nakanishi, Suzuki, *et al.* (2012) *Bioorg. Med. Chem.* **20**, 3263. **2.** Tahara, Kurosaki, Yokono, *et al.* (2012) *Naunyn. Schmiedeberg's. Arch. Pharmacol.* **385**, 423 **2.** Schwartz, Akinlade, Klasen, *et al.* (2011) *Diabetes Technol. Ther.* **13**, 1219.

### Iproniazid

This non-selective irreversible MAO inhibitor (FW<sub>free-base</sub> = 179.22 g/mol; CAS 54-92-2), also called isonicotinic acid 2-isopropylhydrazide, 1-isonicotinyl-2-isopropylhydrazine, and Marsilid<sup>®</sup> (iproniazid's phosphate salt; FW = 277.21 g/mol; CAS 305-33-9), is a first-generation isoniazid-based antidepressant. Initially developed to treat tuberculosis, iproniazid became the first antidepressant ever marketed, after its mood elevating properties were noted in the early 1950s. Hepatotoxicity eventually led to its withdrawal from the market. Once heralded as a “psychic energizer”, iproniazid's significance today is as the drug that awakened wider interest in monoamine oxidase as a gateway target in the development of numerous antidepressants for treating mood and anxiety spectrum disorders. **Target(s):** ethanalamine oxidase (1); 5-hydroxytryptophan decarboxylase, aromatic amino-acid decarboxylase (2); isopenicillin-N epimerase (3,4); monoamine oxidase (5-21); putrescine oxidase (22); taurine dehydrogenase (23). **1.** Narrod & Jakoby (1966) *Meth. ## IPSU

This selective OX<sub>2</sub>R antagonist (FW = 405.49 g/mol; CAS 1373765-19-5; Solubility: 100 mM in DMSO; 100 mM in H<sub>2</sub>O, as mono-HCl salt), also named 2-((1H-indol-3-yl)methyl)-9-(4-methoxypyrimidin-2-yl)-2,9-diazaspiro[5.5]undecan-1-one, targets orexin OX<sub>1</sub> receptors (IC<sub>50</sub> = 11 nM), exhibiting ~6-fold selectivity versus OX<sub>1</sub> receptors. Orexin receptor antagonists represent attractive targets for the development of drugs for the treatment of insomnia, inasmuch as the receptors are crucial for the stability of wake and sleep states. OX<sub>1</sub>R and OX<sub>2</sub>R are G protein-coupled receptors with 64% sequence identity in human. Both couple to G<sub>q</sub> and mobilize intracellular Ca<sup>2+</sup> via activation of phospholipase C, while OX<sub>2</sub>R also couples G<sub>i</sub>/G<sub>o</sub> and inhibit cAMP production via inhibition of adenylyl cyclase. In non-neuronal cells OX<sub>2</sub>R is capable of extracellular signal-regulated kinase activation via G<sub>s</sub>, G<sub>q</sub>, and G<sub>i</sub>. **See Orexins A & B; Almorexin** 1. Callander, Olorunda, Monna, *et al.* (2013) *Front. Neurosci.* 7, 230.

## IRAK1/4 Inhibitor I

This protein kinase inhibitor (FW = 395.41 g/mol; CAS 509093-47-4; Solubility: 20 mM in DMSO), also named N-[1-[2-(4-Morpholinyl)ethyl]-1H-benzimidazol-2-yl]-3-nitrobenzamide, targets interleukin-1 receptor-associated kinases IRAK-1 (IC<sub>50</sub> = 0.3 μM) and IRAK-4 (IC<sub>50</sub> = 0.2 μM), serine/threonine kinases that promote protein phosphorylation, ubiquitination, and degradation. Targeted inhibition of IRAK1 and IRAK4, either with shRNA or with a pharmacological IRAK1/4 inhibitor, dramatically impeded proliferation of T acute lymphoblastic leukemia (T-ALL) cells isolated from patients and T-ALL cells in a murine leukemia model; however, IRAK1/4 inhibition had little effect on cell death (2). 1. Powers, Li, Jaen, *et al.* (2006) *Bioorg. Med. Chem. Lett.* 16, 2842. 2. Li, Younger, *et al.* (2015) *J. Clin. Invest.* 125, 1081.

## Irbesartan

This oral antihypertensive (FW = 428.53 g/mol; CAS 138402-11-6; Soluble to 100 mM in DMSO), also named 2-butyl-3-({4-[2-(2H-1,2,3,4-tetrazol-5-yl)phenyl]phenyl}methyl)-1,3-diazaspiro[4.4]non-1-en-4-one and marketed under the trade names Aprovel<sup>®</sup>, Karvea<sup>®</sup>, and Avapro<sup>®</sup>, is a nonpeptide angiotensin II receptor antagonist (IC<sub>50</sub> = 1.2 nM), reportedly providing a blockade of the actions of angiotensin II other than inhibition of renin or angiotensin-converting enzyme (ACE). (**See also Candesartan; Eprosartan; Losartan; Olmesartan; Telmisartan; Valsartan**) **Key Pharmacological Parameters:** Bioavailability = 7 %; Food Effect? NO; Drug t<sub>1/2</sub> = 11–15 hours; Metabolite t<sub>1/2</sub> = not determined; Drug's Protein Binding = 90–95 %; Metabolite's Protein Binding = – %; Route of Elimination = 33 % Renal and 66 % Hepatic. 1. Massie, Carson, McMurray, *et al.* (2008) *New Engl. J. Med.* 359, 2456.

## Irinotecan

This antineoplastic pro-drug (FW<sub>free-base</sub> = 586.69 g/mol), also known as CPT-11 and 7-ethyl-10-[4-(1-piperidino)-1-piperidinocarbonyloxycamptothecin], is a water-soluble analogue of camptothecin and inhibits DNA topoisomerase I. Cancer cell deaths are reportedly due to DNA strand breaks caused by the formation of cleavable complexes. Irinotecan is deesterified *in vivo* to 7-ethyl-10-hydroxycamptothecin (SN-38). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Chabot (1997) *Clin. Pharmacokinet.* 33, 245. 2. Kawato, Aonuma, Hirota, Kuga & Sato (1991) *Cancer Res.* 51, 4187. 3. Iyer & Ratain (1998) *Cancer Chemother. Pharmacol.* 42 Suppl., S31.

## Isatin

This orange-colored indole derivative (FW = 147.13 g/mol; M.P. = 203.5°C), also known as indole-2,3-dione, is formed in the metabolism of many indole-containing compounds and has been used as a reagent in the detection of amino acids, mercaptans, cuprous ions, and thiophenes. It is also an intermediate in the chemical synthesis of indigo and other dyes. **Target(s):** acetylcholinesterase (1); N-acetylindoxyl oxidase, weakly inhibited (2); acid phosphatase (3); alkaline phosphatase (4–10); amine oxidase, *or* monoamine oxidase (1,11–13); arylalkylphosphatase, *or* paraoxonase (14); arylesterase (14); glucokinase (15); D-glucose transport, Na<sup>+</sup>-dependent (16–18); guanylate cyclase, *or* guanylyl cyclase (19); guanylate cyclase-coupled atrial natriuretic peptide receptors (20); hyaluronidase (21); lysine transport, Na<sup>+</sup>-dependent (22); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (1); sucrose (23,24); xanthine oxidase (25,26). 1. ## Isavuconazole &amp; Isavuconazonium sulfate

Isavuconazonium sulfate

Isavuconazole

This potent oral/intravenous triazole-class antifungal (FW = 814.83 g/mol; CAS 946075-13-4), also named BAL8557, Cresemba<sup>®</sup>, and [2-[1-[1-[(2*R*,3*R*)-3-[4-(4-cyanophenyl)-1,3-thiazol-2-yl]-2-(2,5-difluorophenyl)-2-hydroxybutyl]-1,2,4-triazol-4-ium-4-yl]ethoxycarbonylmethylamino]pyridin-3-yl]methyl 2-(methylamino)acetate, is a prodrug that is metabolized to the active drug isavuconazole (FW = 437.47 g/mol; CAS 241479-67-4; IUPAC: 4-{2-[(1*R*,2*R*)-(2,5-difluorophenyl)-2-hydroxy-1-methyl-3-(1*H*-1,2,4-triazol-1-yl)propyl]-1,3-thiazol-4-yl}benzonitrile), the latter inhibiting lanosterol 14  $\alpha$ -demethylase, which converts lanosterol into ergosterol. Depletion of ergosterol in the fungal cell membrane leads to a build-up of lanosterol, compromising fungal membrane integrity. Selectivity toward fungi is achieved, because mammalian cells are resistant to demethylation inhibition by azoles. BAL4815 shows broad-spectrum of activity against *Aspergillus spp.*, *Candida spp.*, *Cryptococcus spp.*, Mucorales (Order: Zygomycete), black yeasts and filamentous relatives. It is likewise cytotoxic against true pathogenic fungi, including *Histoplasma capsulatum* and *Blastomyces dermatitidis*. See (1) for a discussion of the pharmacodynamics of isavuconazole and its prodrug in an *Aspergillus fumigatus* mouse infection model. 1. Seyedmousavi, Brüggemann, Meis, *et al.* (2015) *Antimicrob. Agents Chemother.* **59**, 2855.

## 3-Isoadenosine 5'-Monophosphate

This AMP analogue (FW = 347.22 g/mol; CAS 2862-19-3; Symbol: piA) has the ribofuranosyl ring linked to the N<sup>3</sup>-atom of the pyridine ring (instead of the imidazole ring) of the purine. Iso-AMP is a strong inhibitor of AMP deaminase (1-3). It is also an activator of threonine dehydratase, acting in place of AMP. 1. Zielke & Suelter (1971) *The Enzymes*, 3rd ed., **4**, 47. 2. Setlow & Lowenstein (1968) *J. Biol. Chem.* **243**, 3409 and 6216. 3. Zielke & Suelter (1969) *Fed. Proc.* **28**, 728.

## Isoascorbate

This ascorbic acid epimer (FW = 176.13 g/mol), also known as D-isoascorbate, can substitute for ascorbate in a number of enzyme-catalyzed reactions (*e.g.*, procollagen-proline 4 monooxygenase) and is frequently used as an antioxidant. Isoascorbate exhibits about 5% of vitamin equivalence of L-ascorbate. **Target(s):** alkaline phosphatase (1); catechol oxidase (2,3); dihydrodiol dehydrogenase (4,5); hyaluronate lyase (6); hyaluronoglucosaminidase, hyaluronidase (6); laccase (7); lactoylglutathione lyase, *or* glyoxalase I (8); polyphenol oxidase (2,3); tyrosine monooxygenase (9). 1. Miggiano, Mordente, Martorana, Meucci & Castelli (1984) *Biochim. Biophys. Acta* **789**, 343. 2. Motoda (1979) *J. Ferment. Technol.* **57**, 79. 3. ## Isobongkreic Acid

This geometric isomer of bongkreic acid (FW<sub>free-acid</sub> = 486.61 g/mol; CAS 60132-21-0), from *Pseudomonas cocovenenans*, can be generated by exposing bongkreic acid to alkaline pH. It is an uncompetitive inhibitor of mitochondrial adenine nucleotide transporter, *or* ADP/ATP carrier. (**See also Bongkreikate and Bongkreic Acid**) **Target(s):** 1. Vignais, Block, Boulay, Brandolin & Lauquin (1982) in *Membranes and Transport*, (Martonosi, ed.) vol. **1**, 405, Plenum Press, New York. 2. Fiore, Trezeguet, Le Saux, *et al.* (1998) *Biochimie* **80**, 137. 3. Lauquin, Duplaa, Klein, Rousseau & Vignais (1976) *Biochemistry* **15**, 2323.

## isobutyl Alcohol

This polar organic solvent (FW = 74.12 g/mol; CAS 78-83-1), also known as 2-methyl-1-propanol and isobutanol, is a flammable liquid (M.P. = -108°C; B.P. = 108°C) with a dipole moment of 1.79 D at 25°C and a dielectric constant of 16.68 at 20°C. This solvent is often used in organic synthesis, extractions, chromatography, spectrophotometry, and in toxicology investigations. **Target(s):** arylalkyl-phosphatase, *or* paraoxonase, *or* arylesterase (2); carbonic anhydrase (3); glucan 1,3- $\alpha$ -glucosidase, *or* glucosidase II, *or* mannosyl oligosaccharide glucosidase II (4); hydroxynitrilase, *or* hydroxynitrile lyase (5); pepsin (6); pyroglutamyl peptidase I (7); pyrophosphatase (8); retinol isomerase (9); thermolysin (10). 1. Gopalan, Glew, Libell & DePetro (1989) *J. Biol. Chem.* **264**, 15418. 2. Debord, Dantoine, Bollinger, *et al.* (1998) *Chem. Biol. Interact.* **113**, 105. 3. Enzymol.* **316**, 330. 10. Muta & K. Inouye (2002) *J. Biochem.* **132**, 945.

**Isobutylamine**

This toxic primary amine (FW<sub>free-base</sub> = 73.14 g/mol; CAS 78-81-9), also known as 2-methyl-1-propylamine and 1-amino-2 methylpropane, will cause skin blistering and headaches when inhaled. The free base is a liquid (M.P. = -85°C; B.P. = 68-69°C) at room temperature and is miscible with water. **Target(s):**  $\delta$ -aminolevulinic synthase (1); glutamate:ethylamine ligase, or theanine synthetase (2); lysyl endopeptidase (3); spermidine synthase (4); valine decarboxylase, or leucine decarboxylase (5,6). 1. Jordan & Shemin (1972) *The Enzymes*, 3rd ed., 7, 339. 2. Sasaoka, Kito & Onishi (1965) *Agric. Biol. Chem.* **29**, 984. 3. Sakiyama & Masaki (1994) *Meth. Enzymol.* **244**, 126. 4. Sutton & King (1962) *Arch. Biochem. Biophys.* **96**, 360.

**N-[4-[N-(1-Isobutyl-1H-imidazol-5-yl)methylamino]-2-phenylbenzoyl]-L-methionine**

This imidazole-containing peptidomimetic agent (FW = 479.63 g/mol), also called FTI-2239, inhibits mouse protein farnesyltransferase (IC<sub>50</sub> = 36 nM). It is also highly selective for PFTase over PGGTase-I both *in vitro* and in intact cells. 1. Ohkanda, Strickland, Blaskovich, *et al.* (2006) *Org. Biomol. Chem.* **4**, 482.

**3-Isobutyl-8-methoxymethyl-1-methylxanthine**

This purine (FW = 266.30 g/mol; *Abbreviation*: MIMX), also named 8-methoxymethyl-1-methyl-3-(2-methylpropyl)xanthine, inhibits phosphodiesterase 1 (IC<sub>50</sub> = 4  $\mu$ M). **Target(s):** 3',5'-cyclic-GMP phosphodiesterase, or cGMP phosphodiesterase (1,2); 3',5' cyclic-nucleotide phosphodiesterase (2-8); phosphodiesterase 1 (2-5,7,8); phosphodiesterase 2 (2); phosphodiesterase 5 (1,2). 1. **3-Isobutyl-1-methylxanthine**

This purine derivative (FW = 222.25 g/mol; CAS 28822-58-4; M.P. = 200-201°C; Solubility = 75 mM in DMSO; *Abbreviations*: IBMX and MIX), also known as 1-methyl-3-isobutylxanthine and 3-isobutyl-1-methyl-2,6(1*H*,3*H*)-purinedione, is a nonselective cyclic-nucleotide phosphodiesterase inhibitor, with IC<sub>50</sub> values of 2-50  $\mu$ M. IBMX does not inhibit PDE-8 or PDE-9. IBMX also acts as a nonselective adenosine receptor antagonist. **Target(s):**  $\alpha_2$ -adrenoceptor-mediated 5-hydroxytryptamine release (1); Ca<sup>2+</sup>-channels, L type (2); 3',5'-cyclic-GMP phosphodiesterase, or cGMP phosphodiesterase (3-15); 3',5'-cyclic nucleotide phosphodiesterase (4-7,9,14,16-24); cytokinin 7 $\beta$ -glucosyltransferase (29); guanylate cyclase (25); NAD<sup>+</sup> ADP-ribosyltransferase (poly(ADP-ribose) polymerase; IC<sub>50</sub> = 3.1 mM (28); phosphodiesterase 1 (7); phosphodiesterase 2 (7); phosphodiesterase 3 (7); phosphodiesterase 4 (7,14); phosphodiesterase 5 (3,4,6-8,12,14,15); phosphodiesterase 6 (8); phosphodiesterase 7 (26); phosphodiesterase 9 (27); phosphodiesterase 10 (24); phosphodiesterase 11, slightly inhibited (17,18). 1. **Isobutyryl-CoA**

This thioester (FW = 855.65 g/mol; CAS 15621-60-0), also known as 2-methylpropanoyl-CoA, is an intermediate in the degradation of valine and a substrate of the reactions catalyzed by isobutyryl CoA mutase and dihydrolipoyllysine-residue (2-methylpropanoyl)transferase and an alternative substrate for phloroisovalero-phenone synthase. It is also a product of the reactions catalyzed by 2 oxoisovalerate dehydrogenase (acylating) and 3-methyl-2-oxobutanoate dehydrogenase (ferredoxin). **Target(s):** [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or [3-methyl-2 oxobutanoate dehydrogenase (acetyl-transferring)] kinase (1,2); glycine cleavage complex, or glucine synthase (3); 3-hydroxyisobutyryl-CoA hydrolase (4,5);  $\beta$ -ketoacyl-[acyl-carrier-protein] synthase III (6); 3-

methylcrotonoyl-CoA carboxylase (7); [3-methyl-2-oxobutanoate dehydrogenase, or 2-methylpropanoyl-transferring] phosphatase, or [branched-chain- $\alpha$ -keto-acid dehydrogenase] phosphatase (8-10); phosphoprotein phosphatase (10,11); pyruvate dehydrogenase (12). 1. #### Isocaproate (Isocaproic Acid)

This branched chain organic acid (FW<sub>free-acid</sub> = 116.16 g/mol; CAS 646-07-1; B.P. = 199-201°C), also known as 4-methylvaleric acid and 4-methylpentanoic acid, inhibits aminoacylase (1); branched-chain-amino-acid transaminase (2); leucyl aminopeptidase (3-5); ornithine aminotransferase (6). 1. Park & Fox (1960) *J. Biol. Chem.* **235**, 3193. 2. Koide, Honma & Shimomura (1977) *Agric. Biol. Chem.* **41**, 1171. 3. Smith & Hill (1960) *The Enzymes*, 2nd ed., 4, 37. 4. #### Isocitrate (Isocitric Acid)

This monohydroxy tricarboxylic acid (FW<sub>free-acid</sub> = 192.13 g/mol; CAS 320-77-4; pK<sub>a</sub> values of 3.29, 4.71, and 6.40 at 25°C), also known as (1R,2S)-1-hydroxypropane-1,2,3-tricarboxylic acid and formerly called *threo*-DS-isocitric acid, are key intermediates in the tricarboxylic acid and glyoxylate cycles. **Target(s):** aconitate decarboxylase (1); aspartate aminotransferase (30); ATP:citrate lyase, or ATP:citrate synthase (31); glucose-1,6-bisphosphate synthase (2); glucose-1-phosphate adenyltransferase (3); glutamate decarboxylase, inhibited by *dl*-isocitrate (4); [isocitrate dehydrogenase (NADP+)] kinase (5-7); L-lactate dehydrogenase (8); 2-methylcitrate dehydratase (9); 2 methylisocitrate dehydratase (10); oxaloacetate tautomerase, inhibited by *dl*-isocitrate (11); phosphoenolpyruvate carboxykinase (GTP), weakly inhibited by *dl*-isocitrate (12); phosphoenolpyruvate carboxylase (13,14); phosphoenolpyruvate mutase (15); 6-phosphofructokinase (16-20); phosphoglucosmutase, weakly inhibited (21); procollagen-proline 4-dioxygenase (33); pyruvate kinase (22-28); thiosulfate sulfurtransferase, rhodanese; inhibited by *dl*-isocitrate (29); trimethyllysine dioxygenase (32). 1. #### *threo*-Ls-Isocitrate (*threo*-Ls-Isocitric Acid)

This citrate stereoisomer (FW<sub>free-acid</sub> = 192.13 g/mol) inhibits aconitase (1), fumarase (2), isocitrate dehydrogenase, NADP<sup>+</sup>-requiring (3), 2-methylisocitrate dehydratase (4); phosphoenolpyruvate mutase (5). 1. Glusker (1971) *The Enzymes*, 3rd ed., 5, 413. 2. Hill & Teipel (1971) *The Enzymes*, 3rd ed., 5, 539. 3. Seelig & Colman (1978) *Arch. Biochem. Biophys.* **188**, 394. 4. #### Isocytosine

This structural isomer of cytosine (FW = 111.10 g/mol; CAS 108-53-2), also known as 2-amino-4-hydroxypyrimidine, inhibits cytosine deaminase (1), hypoxanthine(guanine) phosphoribosyltransferase (2,3), tRNA-guanine transglycosylase (4), and xanthine phosphoribosyltransferase (2). 1. Kream & Chargaff (1952) *J. Amer. Chem. Soc.* **74**, 5157. 2. Naguib, Iltzsch, el Kouni, Panzica & el Kouni (1995) *Biochem. Pharmacol.* **50**, 1685. 3. #### Isifagomine

This piperidine (FW<sub>free-base</sub> = 147.17 g/mol; CAS 161302-93-8), also known as (3R,4R,5R)-5-(hydroxymethyl)piperidine-3,4-diol, inhibits liver glycogen phosphorylase (IC<sub>50</sub> = 0.7 μM) and is a slow-binding inhibitor of almond β-glucosidase. **Target(s):** glucoamylase (1); α-glucosidase (1); β-glucosidase (1-4); glycogen phosphorylase (5,6); oligo-1,6-glucosidase, or isomaltase (1,2); α,α-trehalose phosphorylase, or configuration-retaining (7). 1. #### Isoferulate (Isoferulic Acid)

This  $\alpha,\beta$ -unsaturated acid (FW<sub>free-acid</sub> = 194.19 g/mol) inhibits diphosphomevalonate decarboxylase (1); phosphomevalonate kinase (1), tyrosinase, or monophenol monooxygenase, weakly inhibited (2), xanthine oxidase (3,4). 1. Shama Bhat & Ramasarma (1979) *Biochem. J.* **181**, 143. 2. Karioti, Protopappa, Magoulas & Skaltsa (2007) *Bioorg. Med. Chem.* **15**, 2708. 3. Chan, Wen & Chiang (1995) *Anticancer Res.* **15**, 703. 4. Chang, Lee, Chen, et al. (2007) *Free Rad. Biol. Med.* **43**, 1541.

### Isoflurane

This anesthetic (FW = 184.49 g/mol; CAS 26675-46-7; Nonflammable Liquid; B.P. = 48.5°C; Miscible with many organic solvents and usually co-administered by mask with O<sub>2</sub> or air), also known as 2-chloro-2-(difluoromethoxy)-1,1,1-trifluoroethane, appears to depress CA1 synapses at presynaptic sites downstream from sodium ion channels, as indicated by the increased facilitation that accompanies isoflurane depression of excitatory postsynaptic potential (1-3). The latter refers to the temporary depolarization of postsynaptic membrane potential caused by the flow of sodium ions into postsynaptic cells, after the opening of ligand-gated ion channels. **Targets:** Volatile anesthetics are known to depress glutamatergic synaptic transmission, although the molecular mechanisms are unclear. At clinically relevant concentrations, isoflurane inhibited the L-, N- and P/Q-types, but not toxin-resistant, Ca<sup>2+</sup> channel currents. The respective IC<sub>50</sub> values for the L-, N- and P/Q-type neuronal currents were 0.7%, 1.3% and 3.0%, corresponding to 0.35, 0.68 and 1.46 mM in the aqueous phase (3). In the nervous system, the precise physiological roles of these calcium currents remain to be elucidated, but N- and P/Q-types have important roles in synaptic transmission at the neuromuscular junction. Inhibition of such channels in the CNS may lead to loss of consciousness, loss of sensation, as well as circulatory and respiratory depression. Isoflurane also inhibits endothelium-dependent relaxation, apparently by inhibiting the nitric oxide-guanylyl cyclase signaling pathway. While isoflurane inhibits brain NO synthase *in vitro*, it has no effect at clinically relevant concentrations (4). Plasma membranes Ca<sup>2+</sup>-ATPase is significantly inhibited, in a dose-related manner, by clinically relevant partial pressures of halothane, isoflurane, xenon, and nitrous oxide (5). 1. Study (1994) *Anesthesiology* **81**, 104. 2. Puil, Hutcheon & Reiner (1994) *Neurosci. Lett.* **176**, 63. 3. Kameyama, Aono & Kitamura (1999) *Brit. J. Anaesth.* **82**, 402. 4. Tobin, Martin, Breslow & Traystman (1994) *Anesthesiology* **81**, 1264. 5. Franks, Horn, Janicki & Singh (1995) *Anesthesiology* **82**, 108.

### Iso glutamine

This  $\alpha$ -amide of glutamic acid (FW = 146.15 g/mol; pK<sub>a</sub> values of 3.81 and 7.88), also known as  $\gamma$ -aminoglutaric acid and 4-amino-4-carbamoylbutanoic acid. The L-stereoisomer has been observed in some proteins, whereas the D-isomer is a component of the peptidoglycan of a number of organisms (e.g., *Staphylococcus aureus*). **Target(s):** arginyltransferase (1); glutamate decarboxylase, inhibited by L-stereoisomer, K<sub>i</sub> = 95 mM (2). 1. Soffer (1973) *J. Biol. Chem.* **248**, 2918. 2. Fonda (1972) *Biochemistry* **11**, 1304.

### Isoguanine

This rare purine base (FW = 151.13 g/mol; CAS 3373-53-3) also known as isoguanine, 2-hydroxy-6-aminopurine, 2-oxoadenine, and 2-hydroxyadenine, was originally isolated from croton bean. It has also been reported in the nudibranch mollusk *Diaulula sandiegensis*. Isoguanine does not deaminate when treated with nitrous acid. Insertion of isoguanine into DNA increases the rate of mutagenesis. Both polar solvents and the DNA microenvironment dramatically change the intrinsic tautomeric properties of this purine (1). **Target(s):** hypoxanthine(guanine) phosphoribosyltransferase (2); xanthine phosphoribosyltransferase (2,3). 1. Blas, Luque & Orozco (2004) *J. Amer. Chem. Soc.* **126**, 154. 2. Naguib, Iltzsch, el Kouni, Panzica & el Kouni (1995) *Biochem. Pharmacol.* **50**, 1685. 3. Miller, Adamczyk, Fyfe & Elion (1974) *Arch. Biochem. Biophys.* **165**, 349.

### Isoguanosine

This rare nucleoside (FW = 283.24 g/mol), also known as crotonoside and 2-hydroxyadenosine, has been reported in croton bean and the nudibranch mollusk *Diaulula sandiegensis*. Isoguanosine incorporation into DNA increases the rate of mutagenesis. Both polar solvents and the DNA microenvironment dramatically change the intrinsic tautomeric properties of this nucleoside. **Target(s):** adenosine kinase (1); deoxycytidine kinase, weakly inhibited (2). 1. Long & Parker (2006) *Biochem. Pharmacol.* **71**, 1671. 2. Krenitsky, Tuttle, Koszalka, et al. (1976) *J. Biol. Chem.* **251**, 4055.

### L-Isoleucine

This nutritionally essential branched-chain amino acid (FW = 131.18 g/mol; pK<sub>a</sub> values of 2.32 (R-COOH) and 9.76 (R-NH<sub>2</sub>) at 25°C; Specific Rotation = + 39.5° at 25°C at the sodium D-line; Solubility: 4.12 g/100 mL H<sub>2</sub>O), also named (2S,3S)-2-amino-3-methylpentanoic acid, is one of two of proteogenic amino acids containing two chiral centers. There are three codons for isoleucine: AUU, AUC, and AUA. With its hydrophobic side-chain, isoleucine residues are usually located in the interior of proteins. They do not favor  $\alpha$ -helical structures, but instead appear in  $\beta$ -pleated sheets. Homologous proteins often have isoleucyl residues interchanged with valyl, leucyl, and threonyl residues. Because of the second chiral center, there are two diastereoisomers of D- and L-isoleucine: D- and L-alloisoleucine. L-isoleucine is a physiologic feedback inhibitor of *Escherichia coli* threonine deaminase and aspartokinase. Low isoleucine levels during amino acid starvation result in ppGpp ("Magic Spot") formation and interruption of ribosomal protein synthesis. **Target(s):** acetolactate synthase (1,50-61); aminopeptidase B (2); arginase, weakly inhibited (2-8); argininosuccinate synthetase (9); arylformamidase, weakly inhibited (10); aspartate kinase (11,12); bacterial leucyl aminopeptidase (13); (R)-citramalate synthase (48); creatine kinase (14); cytosol nonspecific Dipeptidase (15); dihydrodipicolinate synthase (16); 2-ethylmalate synthase, weakly inhibited (17); glutamine synthetase, weakly inhibited (17,18);  $\gamma$ -glutamyl transpeptidase, weakly inhibited (19,20); homoserine kinase (21-24); 2-isopropylmalate synthase (25); ornithine aminotransferase (44-46); ornithine N-benzoyltransferase, when arginine is the acceptor substrate (49); ornithine carbamoyltransferase (62,63); saccharopine dehydrogenase (26); threonine ammonia-lyase, or threonine dehydratase, or threonine deaminase (33-48); Xaa-Pro dipeptidase, or prolidase isozyme I (43). 1. ### L-Isoleucinol

This reduced isoleucine derivative (FW = 117.19 g/mol; Symbol = Ile-ol) competitively inhibits isoleucine interactions with isoleucyl-tRNA synthetase. Isoleucyl-tRNA synthetase from *Escherichia coli* catalyzes the activation of [<sup>18</sup>O<sub>2</sub>]isoleucine by adenosine 5'-[(R)-α-<sup>17</sup>O]triphosphate with inversion of configuration at phosphorus. Moreover, isoleucyl-tRNA synthetase does not catalyze positional isotope exchange in adenosine 5'-[β-<sup>18</sup>O]triphosphate in the absence of isoleucine or in the presence of the competitive inhibitor isoleucinol, which effectively eliminates the possibility of either adenyl-enzyme or adenosine metaphosphate intermediates being involved. These observations require that isoleucyl-tRNA synthetase catalyzes the activation of isoleucine by associative "in-

line" nucleotidyl transfer. 1. Lowe, Sproat, Tansley & Cullis (1983) *Biochemistry* **22**, 1229. 2. Freist & Cramer (1983) *Eur. J. Biochem.* **131**, 65. 3. Rainey, Hammer-Raber, Kula & Holler (1977) *Eur. J. Biochem.* **78**, 239.

### L-Isoleucinol Adenylate

This aminoalkyl adenylate (FW = 326.29 g/mol; Abbreviation: Ile-ol-AMP) is formed by the condensation of the amino alcohol analogue of isoleucine and AMP. Ile-ol-AMP is a structural analogue of the aminoacyl adenylate intermediate of the reaction catalyzed by isoleucyl-tRNA synthetase, and, as such, is a strong inhibitor of that enzyme (1-4). Ile-ol-AMP weakly inhibits valyl-tRNA synthetase and has been used to investigate kinetic proofreading mechanisms in the catalysis of aminoacyl-tRNA synthetases (1). 1. ### L-Isoleucyl-L-prolyl-L-isoleucine

This tripeptide (FW = 341.45 g/mol; CAS 90614-48-5), also known as diproton A and IPI, inhibits dipeptidyl-peptidase IV (or dipeptidyl-aminopeptidase IV),  $K_i = 4.6 \mu\text{M}$ . This tripeptide is actually a slowly hydrolyzed alternative substrate. **Target(s):** dipeptidyl-peptidase II (2); dipeptidyl-peptidase IV (1-15); prolyl oligopeptidase, *Pyrococcus furiosus* (6,17); tripeptidyl-peptidase I (18); tripeptidyl-peptidase II,  $K_i = 1 \mu\text{M}$  (19); Xaa-Pro dipeptidyl-peptidase,  $K_i = 2 \mu\text{M}$  (5). 1. ### 3-(L-Isoleucyl)thiazolidine

This dipeptide analogue (FW<sub>free-base</sub> = 202.32 g/mol), also known as isoleucyl-thiazolidide, inhibits cytosol nonspecific Dipeptidase, or prolyl dipeptidase (1), dipeptidyl-peptidase II (1-3), and dipeptidyl-peptidase IV (1-8). 1. Jiaang, Chen, Hsu, *et al.* (2005) *Bioorg. Med. Chem. Lett.* **15**, 687. 2. Leiting, Pryor, Wu, *et al.* (2003) *Biochem. J.* **371**, 525. 3. ### Isolinderalactone

This naturally occurring sesquiterpene (FW = 242.32 g/mol), obtained from the roots of *Lindera strychnifolia*, competitively inhibits prolyl oligopeptidase, (PEP, EC 3.4.21.26), an enzyme that plays a role in degradation of proline-containing neuropeptides (*e.g.*, vasopressin, substance P, and thyrotropin-releasing hormone, or TRH) involved in the processes of learning and memory. This oligopeptidase is also inhibited noncompetitively by two tannins (epicatechin and aesculitannin) and competitively by three other sesquiterpenes (linderene and linderene acetate, and linderalactone). Isolinderalactone readily isomerizes to lideralactone via a Cope rearrangement. 1. Kobayashi, Miyase, Sano, *et al.* (2002) *Biol. Pharm. Bull.* **25**, 1049.

### Isoliquiritigenin

This substituted chalcone (FW = 256.26 g/mol), also known as 4,2',4'-trihydroxychalcone and (*E*)-1-(2,4-dihydroxyphenyl)-3-(4-hydroxyphenyl)-

2-propen-1-one, which is found in licorice roots and other plants, is a guanylate cyclase activator that exhibits vasorelaxant effects. **Target(s):** aldose reductase (1,2); aryl hydrocarbon hydroxylase, cytochrome P450 (3); cAMP phosphodiesterase (4,5); catechol oxidase (6); fatty-acid synthase (7); glutathione *S*-transferase, *Triticum aestivum* (8); GLUT1 glucose transporter (9); monoamine oxidase (10); [myosin light-chain] kinase (11); naringenin-chalcone synthase (12); tyrosinase, or monophenol monooxygenase (6,13,14); xanthine oxidase (15). 1. Tawata, Aida, Noguchi, *et al.* (1992) *Eur. J. Pharmacol.* **212**, 87. 2. Aida, Tawata, Shindo, *et al.* (1990) *Planta Med.* **56**, 254. 3. ### Isomalathion

This malathion isomer (FW = 330.36 g/mol) inhibits acetylcholinesterases and butyrylcholinesterases. The (1*R*,3*R*)-isomer (shown above) displays greater potency than (1*S*,3*S*)-isomalathion. *Torpedo californica* acetylcholine esterase inhibited by either of the (1*R*)-isomers can be readily reactivated (1). The enzyme is significantly more difficult to reactivate following inhibition by either of the (1*S*)-isomers. The primary leaving group for the (1*R*)-isomers is diethyl thiosuccinyl, whereas it is thiomethyl for (1*S*)-isomalathions: the (1*R*)-isomalathion produces an *O,S*-dimethyl phosphate adduct whereas (1*S*)-isomalathions generated an *O*-methyl phosphate adduct (2). **Target(s):** acetylcholinesterase (1,2); butyrylcholine sterase (3); cholesterol esterase (3). 1. Berkman, Quinn & Thompson (1993) *Chem. Res. Toxicol.* **6**, 724. 2. Doorn, Thompson, Christner & Richardson (2003) *Chem. Res. Toxicol.* **16**, 958. 3. Doorn, Talley, Thompson & Richardson (2001) *Chem. Res. Toxicol.* **14**, 807.

### Isomaltose

This reducing disaccharide (FW = 342.30 g/mol), also known as brachyose, consists of two D-glucopyranosyl residues joined by  $\alpha$ 1,6 linkages. Isomaltose is a structural component of glycogen and amylopectin as well as certain dextrans. It is a substrate for sucrase-isomaltase. **Target(s):** concanavalin A (1);  $\alpha$ -dextrin endo-1,6- $\alpha$ -glucosidase (2,3); glucan 1,6- $\alpha$ -Oisomaltosidase (4);  $\alpha$ -glucosidase (2,5-7); isoamylase (8). 1. Goldstein, Hollerman & Smith (1965) *Biochemistry* **4**, 876. 2. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, pp. 416-423, Academic Press, New York. 3. ## Isomazole

This vasodilator (FW<sub>free-base</sub> = 287.34 g/mol; Hygroscopic; Photosensitive), also known as EMD 52750, LY 175326, and 2-[2-methoxy-4-(methylsulfinyl)phenyl]-1*H*-imidazo[4,5-*c*]pyridine, inhibits cGMP phosphodiesterase III, IC<sub>50</sub> = 42 μM for guinea pig enzyme (1-3) and cGMP phosphodiesterase V, IC<sub>50</sub> = 58 μM for pig enzyme (1). Isomazole is commercially available as the dihydrochloride. **1.** Coates, Connolly, Dhanak, Flynn & Worby (1993) *J. Med. Chem.* **36**, 1387. **2.** Bethke, Klimkiewicz, Kohl, *et al.* (1991) *J. Cardiovasc. Pharmacol.* **18**, 386. **3.** Hayes, Bowling, Pollock & Robertson (1986) *J. Pharmacol. Exp. Ther.* **237**, 18.

## Isoniazid

This antibiotic (FW = 137.14 g/mol; CAS 54-85-3), also known as and marketed under other names including Isonicotinylhydrazide (INH) and Hydra<sup>®</sup>, Sovit<sup>®</sup>, Laniazid<sup>®</sup>, and Nydravid<sup>®</sup>, is a first-line drug for preventing and treating both latent and active tuberculosis (See also *Ethionamide*). Isoniazid is effective against *Mycobacterium tuberculosis* as well as atypical strains like *M. kansasii* and *M. xenopi* (1). Itself a prodrug, isoniazid first must be activated by KatG, a mycobacterium catalase-peroxidase that oxidatively forms isonicotinic acyl-NADH (2). The latter binds to and inhibits InhA, an enoyl-acyl carrier protein reductase, thereby blocking the synthesis of mycolic acid, which is required for the mycobacterial cell membrane. The presence of a tyrosyl-like radical in KatG during catalase turnover has been demonstrated by RFQ-EPR spectroscopy. The persistence of this radical correlates with the amount of H<sub>2</sub>O<sub>2</sub> present during catalase turnover, and therefore it can be considered a catalytically competent species in the catalase cycle (2). Despite earlier evidence for a common site of action, Isoniazid and Ethionamide (ETA) are activated by different mechanisms as resistance to INH does not confer resistance to ETA. **1.** Berning SE, Peloquin (1998) "Antimycobacterial agents: Isoniazid," In: *Antimicrobial Therapy and Vaccines* (Yu, Merigan & Barriere, eds.), Williams and Wilkins, Baltimore 1998. **2.** Suarez, Rangelova, Jarzecki, *et al.* (2009) *J. Biol. Chem.* **284**, 7017.

## Isonicotinate (Isonicotinic Acid)

This nicotinic acid isomer (FW<sub>free-acid</sub> = 123.11 g/mol; CAS 16887-79-9; Solubility: 0.50 g/100 mL H<sub>2</sub>O), also known as 4-pyridinecarboxylic acid and 4-picolinic acid, is a secondary metabolite in plants and microorganisms. **Target(s):** acetoin dehydrogenase (1); alcohol dehydrogenase (NADP<sup>+</sup>) (1); 5-aminolevulinate aminotransferase (2); γ-butyrobetaine dioxygenase, or γ-butyrobetaine hydroxylase, K<sub>i</sub> = 0.08 mM (3); carbonyl reductase (NADPH) (1); *erythro*-3-hydroxyaspartate ammonia-lyase (4); NADase, weakly inhibited (5); nicotinamide-nucleotide amidase (6); nicotinate glucosyltransferase (7); nicotinate *N* methyltransferase (8); nicotinate phosphoribosyltransferase (9); procollagen-lysine 5-dioxygenase (10); procollagen-proline 3-dioxygenase (10); procollagen-proline 4-dioxygenase (10,11); tryptophan 2-*C* methyltransferase (12). **1.** Hara, Seiriki, Nakayama & Sawada (1985) *Prog. Clin. Biol. Res.* **174**, 291. **2.** Turner & Neuberger (1970) *Meth. Enzymol.* **17A**, 188. **3.** Ng, Hanauske-Abel & Englard (1991) *J. Biol. ## Isonicotinic Acid Hydrazide

This hepatotoxic hydrazide (FW = 137.14 g/mol), also called isoniazid and 1-isonicotinylhydrazine, is a tuberculostatic agent. This drug was first prepared in 1912, but was patented for its therapeutic effects by Hoffmann-La Roche in 1952. **Primary Mode of Action:** Oxidation of this hydrazide leads to the generation of reactive intermediates that inactivate an NADH-specific enoyl reductase of *Mycobacterium tuberculosis*, reacting with an active-site cysteinyl residue. The reductase undergoes slow-binding inhibition by an isoniazid-NAD<sup>+</sup> adduct (K<sub>i</sub> = 0.75 nM). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** Nicotinic acid hydrazide is a pyridoxine antagonist in some organisms, reacting with the pyridoxal 5-phosphate (PLP) cofactor of nearly every transaminase tested. One may anticipate similar inhibitory effects on PLP-dependent racemases, decarboxylase, dehydratases, *etc.* **1.** Johnsson, King & Schultz (1995) *J. Amer. Chem. Soc.* **117**, 5009. **2.** Gupta, Hollis, Patel, Patrick & Bell (2004) *J. Bone Miner. Res.* **19**, 680.

N<sup>6</sup>-(Δ<sup>2</sup>-Isopentenyl)adenine

This purine derivative (FW = 203.25 g/mol), also called N<sup>6</sup>-(γ,γ-dimethylallylamino)purine, 6-Δ<sup>2</sup>-isopentenylaminopurine (IPA), and bryokinin, inhibits cyclin-dependent kinases (IC<sub>50</sub> = 55 μM). It is also a rare base in certain tRNA and has been reported to act as a cytokinin (*e.g.*, in callus cells of moss sporophytes). IPA has a λ<sub>max</sub> of 269 nm at pH 7 (ε = 19400 M<sup>-1</sup>cm<sup>-1</sup>). **Target(s):** alcohol dehydrogenase (1); cyclin-dependent kinases (2); NADH dehydrogenase (3); xanthine oxidase (4); *cis*-zeatin O-β-D-glucosyltransferase (5). **1.** Zikmanis & Kruce (1990) *Biofactors* **2**, 237. **2.** Meijer & Kim (1997) *Meth. N<sup>6</sup>-(Δ<sup>2</sup>-Isopentenyl)adenosine

This rare, naturally occurring nucleoside (FW = 335.36 g/mol), also known as 6-( $\gamma,\gamma$  dimethylallylamino)purine-9-ribose, 6-(3-methyl-2-butenyl amino)-9- $\beta$ -D-ribofuranosylpurine, and 6-(3-methyl-2-butenylamino)purine-9-ribose, is a component of certain tRNA's and is produced by tRNA isopentenyltransferase. It also exhibits cytokinin activity and can induce apoptosis. This nucleoside has a  $\lambda_{\text{max}}$  at 269 nm at pH 7 ( $\epsilon = 20,000 \text{ M}^{-1} \text{ cm}^{-1}$ ). **Target(s):** adenosine kinase (1,2); adenosine nucleosidase (3); 3',5'-cyclic-nucleotide phosphodiesterase (4); cytidine transport (5); GMP synthetase (6); methionine *S*-adenosyltransferase (7); NADH dehydrogenase (8); tRNA methyltransferases (9); uridine transport (5). 1. ### Isopentenyl Diphosphate

This activated five-carbon building block (FW<sub>free-acid</sub> = 246.09 g/mol), also known as isopentenyl pyrophosphate (IPP), is a key intermediate in the biosynthesis of the sterols and other terpenes. Note that it is a geometric isomer of dimethylallyl diphosphate with which it is interconvertible via isopentenyl diphosphate  $\Delta$ -isomerase. **Target(s):** aspuvinone dimethylallyltransferase (1); dolichyl-diphosphatase (2); geranylgeranyl-diphosphatase (3); 4-hydroxy-benzoate nonaprenyltransferase (4); mevalonate kinase (5). 1. Takahashi, Ojima, Ogura & Seto (1978) *Biochemistry* **17**, 2696. 2. Scher & Waechter (1984) *J. Biol. Chem.* **259**, 14580. 3. Nah, Song & Back (2001) *Plant Cell Physiol.* **42**, 864. 4. ### N-Isopentyl-6-[4-(2-(trifluoromethyl)phenoxy)piperidin-1-yl]pyridazine-3-carboxamide

This pyridazine derivative (FW = 436.46 g/mol) inhibits stearoyl-CoA 9-desaturase (mouse, IC<sub>50</sub> = 34 nM). Studies with stearoyl-CoA 9-desaturase knockout mice have established that these animals are lean and protected from leptin deficiency-induced and diet-induced obesity, with greater whole body insulin sensitivity than wild-type animals. 1. Liu, Lynch, Freeman, et al. (2007) *J. Med. Chem.* **50**, 3086.

### Isophthalate (Isophthalic Acid)

This aromatic dicarboxylic acid (FW<sub>free-acid</sub> = 166.13 g/mol) is an unlikely glutamate analogue that inhibits many glutamate-dependent reactions, particularly the reactions catalyzed by glutamate dehydrogenase and glutamate decarboxylase. **Target(s):**  $\gamma$ -butyrobetaine dioxygenase, or  $\gamma$ -butyrobetaine hydroxylase;  $K_i = 3.8 \text{ mM}$  (1); dihydrodipicolinate reductase (2); glutamate decarboxylase (3,4); glutamate dehydrogenase (5-14);  $\alpha$ -ketoglutarate dehydrogenase (15); kynurenine aminotransferase (16); procollagen-lysine 5-dioxygenase (15); procollagen-proline 3-dioxygenase (15); procollagen-proline 4-dioxygenase (15,17-19); serine-sulfate ammonia-lyase (20). 1. ### Isophthalic Acid 2(S)-Acetylpyrrolidine N-(L-Prolyl)-2(S)-(hydroxyacetyl)pyrrolidine Diamide

This substrate analogue (FW = 469.54 g/mol) inhibits pig brain prolyl oligopeptidase (IC<sub>50</sub> = 1.2 nM). 1. Wallén, Christiaans, Jarho, et al. (2003) *J. Med. Chem.* **46**, 4543.

### 4-Isopropylcatechol

This substituted pyrocatechol (FW = 152.19 g/mol), also known as 1,2-dihydroxy-4-isopropylbenzene, inhibits steroid oxygenase and is a potent irreversible, cutaneous depigmenting agent. **Target(s):** 3,4-dihydroxy-9,10-secoandrosta-1,3,5(10)-triene-9,17-dione 4,5-dioxygenase, or steroid oxygenase (1,2). 1. Hayaishi, Nozaki & Abbott (1975) *The Enzymes*, 3rd ed., **12**, 119. 2. Nozaki (1974) in *Mol. Mech. Oxygen Activ.* (Hayaishi, ed.), p. 135, Academic Press, New York.

### Isopropylmalate (Isopropylmalic Acid)

This metabolite (FW<sub>free-acid</sub> = 176.17 g/mol) refers to either (2S)-2- or (2R,3S)-3-isopropylmalic acid (i.e., 3-carboxy-3-hydroxy-4-methylpentanoic acid and 3-carboxy-2-hydroxy-4-methylpentanoic acid). Both are intermediates in L-leucine biosynthesis, and they are interconverted in the reaction catalyzed by 3-isopropylmalate dehydratase. 2-Isopropylmalate is a product of 2-isopropylmalate synthase, and 3-isopropylmalate is a substrate of the reaction catalyzed by 3-isopropylmalate dehydrogenase. **Target(s):** isocitrate dehydrogenase, inhibited by 3-isopropylmalate, particularly the N99L enzyme (1); 3-isopropylmalate dehydratase, inhibited by racemic mixture (2). 1. Miyazaki, Yaoi & Oshima (1994) *Eur. J. Biochem.* **221**, 899. 2. Gross, Burns & Umbarger (1963) *Biochemistry* **2**, 1046.

### 2-Isopropyl-4-pentenamide

This mechanism-based inhibitor (FW = 141.21 g/mol; Abbreviation: AIA), also known as allylisopropylacetamide, inactivates cytochrome P450 systems. It also induces the synthesis of  $\delta$ -aminolevulinatase synthase. 1.

Ator & Ortiz de Montellano (1990) *The Enzymes*, 3rd ed., **19**, 213. **2.** Davies, Britt & Pohl (1986) *Chem. Biol. Interact.* **58**, 345. **3.** Davies, Britt & Pohl (1986) *Arch. Biochem. Biophys.* **244**, 387. **4.** Ortiz de Montellano, Yost, Mico, et al. (1979) *Arch. Biochem. Biophys.* **197**, 524.

### Isopropyl 1-thio- $\beta$ -D-galactopyranoside

This synthetic thioglycoside (FW = 238.30 g/mol; M.P. = 174-175°C; *Abbreviation*: IPTG) is a nonmetabolizable galactose analogue that is a convenient and widely used inducer of  $\beta$ -galactosidase and  $\beta$ -galactoside permease. The labeled galactopyranoside has also been used to isolate the Lac repressor. **Target(s)**:  $\beta$ -galactosidase (1-3); protein- $N\pi$ -phosphohistidine:sugar phosphotransferase (4). **1.** Shaikh, Khire & Khan (1999) *Biochim. Biophys. Acta* **1472**, 314. **2.** Huber, Roth & Bahl (1990) *J. Protein Chem.* **15**, 621. **3.** Nakao, Harada, Kodama, et al. (1994) *Appl. Microbiol. Biotechnol.* **40**, 657. **4.** Peters, Frank & Hengstenberg (1995) *Eur. J. Biochem.* **228**, 798.

### 2'-Isopropyl-4'-(trimethylammonium chloride)-5'-methylphenyl piperidine-1-carboxylate

This plant growth retardant (FW = 354.92 g/mol), also known as Amo 1618 and (5-hydroxycarvacryl)trimethylammonium chloride 1-piperidinecarboxylate, is a choline analogue that blocks gibberellin biosynthesis via inhibition of the copalyl diphosphate synthase activity. **Target(s)**: beyerene biosynthesis (1); cholinesterase, or butyrylcholinesterase (2,3); *ent*-copalyl diphosphate synthase (1,4-9); *ent*-kaurene synthase (1,4-9); 2,3-oxidosqualene-lanosterol cyclase, or lanosterol synthase (10); phospholipase D (11); sandaracopimaradiene biosynthesis (1); squalene:hopene cyclase (12,13); trachylobane biosynthesis (1). **1.** Robinson & West (1970) *Biochemistry* **9**, 80. **2.** Fluck & Jaffe (1975) *Biochim. Biophys. Acta* **410**, 130. **3.** Riov & Jaffe (1973) *Plant Physiol.* **51**, 520. **4.** West & Upper (1969) *Meth. Enzymol.* **15**, 481. **5.** Rademacher (2000) *Annu. Rev. Plant Physiol. Acta* **881**, 356. **13.** Ochs, Tappe, Gartner, Kellner & Poralla (1990) *Eur. J. Biochem.* **194**, 75.

### Isoquercitrin

This flavonoid glucoside (FW = 464.38 g/mol), also known as quercetin 3-O- $\beta$ -D-glucopyranoside, has been isolated from the flowers of *Gossypium herbaceum* (Levant cotton), *Eucommia ulmoides* (Hardy rubber tree), *Aesculus hippocastanum* (horse chestnut), *Tropaeolum majus* (garden

nasturtium), *Arnica montana* (Leopard's bane and Wolf's bane), and many other plants. It is a yellow solid with a low solubility in water. **Target(s)**: aldose reductase (1); fatty-acid synthase (2); 5-lipoxygenase, or arachidonate 5 lipoxygenase (3); monoamine oxidase B (4); Na<sup>+</sup>/glucose cotransporter, or SGLT-1 (5); neprilysin (6); peptidyl-dipeptidase A, or angiotensin I-converting enzyme (6,7); phosphatidylinositol 3-kinase (8); ribosyl-dihydronicotinamide dehydrogenase (quinone), IC<sub>50</sub> = 1.5  $\mu$ M (9); xanthine oxidase (10). **1.** Sakai, Izumi, Murano, et al. (2001) *Jpn. J. Pharmacol.* **85**, 322. **2.** Wang, Zhang, Ma & Tian (2006) *J. Enzyme Inhib. Med. Chem.* **21**, 87. **3.** Schneider & Bucar (2005) *Phytother. ### 1-(5-Isoquinolinesulfonyl)-2-methylpiperazine

This substituted isoquinoline (FW = 291.37 g/mol), commonly referred to as H-7, is a strong inhibitor of a number of protein kinases: e.g., cAMP-dependent protein kinase (protein kinase A; K<sub>i</sub> = 3  $\mu$ M), cGMP-dependent protein kinase (protein kinase G; K<sub>i</sub> = 5.3  $\mu$ M), [myosin light chain] kinase (K<sub>i</sub> = 97  $\mu$ M), protein kinase C (K<sub>i</sub> = 6  $\mu$ M), and casein kinase I (IC<sub>50</sub> = 0.1 mM). It also inhibits telomerase activity in quercetin-, H-89-, or herbimycin A-treated NPC-076 cells. **Target(s)**: [ $\beta$ -adrenergic-receptor] kinase, weakly inhibited (1,2); cAMP-dependent protein kinase, or protein kinase A (3-6); casein kinase I, mildly inhibited (4); cGMP-dependent protein kinase, or protein kinase G (3,4); microtubule-associated protein-2 kinase, weakly inhibited (7); [myosin light-chain] kinase (3,4); non-specific serine/threonine protein kinase (4,8); PknH protein kinase (8); protein kinase C (3,4,9-13); rhodopsin kinase (K<sub>i</sub> = 46  $\mu$ M (14); [RNA-polymerase]-subunit kinase, or CTD kinase (15,16); telomerase (17). **1.** Benovic (1991) *Meth. ### Isosteviol

This diterpene (FW<sub>free-acid</sub> = 318.46 g/mol; M.P. = 234°C), also known as *ent*-16-oxobeyeran-19-oic acid, is produced by acid hydrolysis of steviol via a Wagner-Meerwein rearrangement. **Target(s)**: ATPase (1); DNA-directed DNA polymerase (2); DNA polymerase  $\alpha$  (2); DNA topoisomerase II (2);

glucose-6-phosphatase (3); glutamate dehydrogenase (1); oxidative phosphorylation (1); succinate dehydrogenase (1). 1. Kelmer Bracht, Alvarez & Bracht (1985) *Biochem. Pharmacol.* **34**, 873. 2. Mizushima, Akihisa, Ukiya, *et al.* (2005) *Life Sci.* **77**, 2127. 3. Ishii & Bracht (1987) *Braz. J. Med. Biol. Res.* **20**, 837.

#### Isovalerate (Isovaleric Acid)

This branched-chain carboxylic acid (FW<sub>free-acid</sub> = 102.13 g/mol; M.P. = -37°C; B.P. = 175-177°C; pK<sub>a</sub> = 4.78 at 25°C), also known as 3-methylbutanoic acid and delphinic acid. Is found in urine at elevated levels in individuals with isovaleryl-CoA dehydrogenase deficiency. **Targets:** betaine:homocysteine *S*-methyltransferase (1-3); dimethylglycine *N*-methyltransferase, weakly inhibited (4); homoserine kinase (5); 2-isopropyl-malate synthase (6); 2 ketoisovalerate dehydrogenase (7); 3-methyl-2-ketobutanoate Hydroxymethyltransferase, *or* 3-methyl 2-oxobutanoate Hydroxymethyltransferase (8); ornithine aminotransferase (9); sarcosine/ dimethylglycine *N*-methyltransferase, weakly inhibited (4); valine decarboxylase, leucine decarboxylase (10,11). 1. Sutton & King (1962) *Arch. Biochem. Biophys.* **96**, 360.

#### Isovaleryl-CoA

This Coenzyme A thiolester (FW = 851.67 g/mol), itself an intermediate in leucine degradation, inhibits [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase and pyruvate dehydrogenase. It is also substrate of the reactions catalyzed by isovaleryl-CoA dehydrogenase and phloroisovalero-phenone synthase. **Target(s):** amino acid acetyltransferase (1); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, *or* [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (2,3); [3-methyl-2-oxobutanoate dehydrogenase, *or* 2-methylpropanoyl-transferring]-phosphatase, *or* [branched-chain- $\alpha$  keto-acid dehydrogenase] phosphatase (4-6); phosphoprotein phosphatase (6,7); pyruvate dehydrogenase (8,9). 1. Coude, Sweetman & Nyhan (1979) *J. Clin. Invest.* **64**, 1544. 2. Paxton (1988) *Meth. Enzymol.* **166**, 313. 3. Paxton & Harris (1984) *Arch. Biochem. Biophys.* **231**, 48. 4. #### N<sup>α</sup>-Isovaleryl-L-histidyl-L-prolyl-L-phenylalanyl-L-histidyl-statinyl-L-isoleucyl-L-phenylalaninamide

This peptidomimetic inhibitor (FW = 1037.28 g/mol), also known as ISCRIP and U-77455E, derives its high-affinity action on target aspartic proteases by virtue of its statine (*or* (3*S*,4*S*)-4-amino-3-hydroxy-6-methylheptanoyl) moiety., which resembles a tetrahedral reaction intermediate **Target(s):** cathepsin D (1,2); cathepsin E (1); endothiapepsin (1); gastricsin (1); pepsin, IC<sub>50</sub> = 0.87  $\mu$ M (1,2); renin, IC<sub>50</sub> = 2 nM (1-3). 1. Jupp, Dunn, Jacobs, *et al.* (1990) *Biochem. J.* **265**, 871. 2. Boger, Lohr, Ulm, *et al.* (1983) *Nature* **303**, 81. 3. Epps, Cheney, Schostarez, *et al.* (1990) *J. Med. Chem.* **33**, 2080.

#### Isovaline

This valine isomer (FW = 117.15 g/mol; CAS 465-58-7), also known as 2-amino-2-methylbutyric acid, which is present in a number of antibiotics (*e.g.*, suzukacillin-A and trichotoxins), inhibits D-amino-acid oxidase (1), 1-aminocyclopropanecarboxylate malonyltransferase, with the *R*-stereoisomer inhibiting more than the *S*-isomer (2). 1. Horowitz (1944) *J. Biol. Chem.* **154**, 141. 2. Liu, Su & Yang (1984) *Arch. Biochem. Biophys.* **235**, 319.

#### Isoxaflutole

Isoxaflutole

Active Form

This commercial isoxazole-based herbicide (FW = 359.32 g/mol; CAS 141112-29-0), also named 5-cyclopropyl-4-[2-(methylsulfonyl)-4-(trifluoromethyl)benzoyl]isoxazole, rearranges to diketone nitrile, a slow, tight-binding inhibitor of plant 4-hydroxyphenylpyruvate dioxygenase ( $K_i$  = 6 nM). Isoxaflutole prevents the biosynthesis of carotenoid pigments, which protect a chlorophyll from photodecomposition, such that carotenoid-depleted plants are damaged by the sun and eventually die. Isoxaflutole is the active ingredient in BALANCE<sup>®</sup>, a soil-applied pre-emergent herbicide that is spread before field corn begins growing in a field. Isoxaflutole's carcinogenic risk is estimated to be  $9.3 \times 10^{-8}$ . 1. Yang, Pflugrath, Camper, *et al.* (2004) *Biochemistry* **43**, 10414. 2. Garcia, Job & Matringe (2000) *Biochemistry* **39**, 7501.

#### ISP-1

This immunosuppressant (FW = 401.54 g/mol), also known as myriocin, thermozymocidin, and 2-amino-3,4-dihydroxy-2-hydroxymethyl-14-oxoeicos-6-enoate, is a potent inhibitor of fungal serine *C*-palmitoyltransferase. It is produced by *Myriococcum albomyces*, *Mycelia sterilia*, and *Isaria* (*or* *Cordyceps*) *sinclairii* (a parasite on moths). 1. Dickson, Lester & Nagiec (2000) *Meth. Enzymol.* **311**, 3. 2. ### Ispinesib

This potent, reversible allosteric inhibitor (FW = 517.06; CAS 336113-53-2, 514820-03-2 (methanesulfonate), 514820-04-3 (HCl); Solubility: 100 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as SB-715992, CK0238273, and (*R*)-*N*-(3-aminopropyl)-*N*-(1-(3-benzyl-7-chloro-4-oxo-3,4-dihydroquinazolin-2-yl)-2-methylpropyl)-4-methylbenzamide, specifically inhibits kinesin KSP ( $K_i = 1.7$  nM), also known as HsEg5, which is essential for the formation of a bipolar mitotic spindle and progression through mitosis (1). Ispinesib alters the ability of KSP to bind to microtubules (MTs) and inhibits its movement by preventing the release of ADP without preventing KSP·ADP dissociation from the MT·KSP·ADP complex. Ispinesib and monastrol share a common mode of inhibition. SB-715992 (6–10 mg/kg) also inhibits murine solid tumors, including Madison 109 lung carcinoma, M5076 sarcoma, as well as L1210 and P388 leukemias (2). 1. Lad, Luo, Carson, *et al.* (2008) *Biochemistry* **47**, 3576. 2. Davis, Sarkar, Hussain & Sarkar (2006) *BMC Cancer* **6**, 22.

### Isradipine

This L-class calcium channel blocker (FW = 371.39 g/mol; CAS 75695-93-1), also known by its trade names DynaCirc<sup>®</sup> and Prescal<sup>®</sup> as well as its systematic name 3-methyl 5-propan-2-yl 4-(2,1,3-benzoxadiazol-4-yl)-2,6-dimethyl-1,4-dihydropyridine-3,5-dicarboxylate, selectively inhibits the sinus node, but not atrioventricular, conduction, making it a potent vasodilator without deleterious effects on blood pressure either at rest or during exercise. Isradipine is usually prescribed for the treatment of high blood pressure in order to reduce the risk of stroke and heart attack. When administered at doses that are relevant for antihypertensive treatment, animal studies indicate that isradipine has powerful anti-atherosclerotic effects as well as a brain tissue-preserving effect after experimentally induced stroke. Recent rodent studies suggest that isradipine may be useful in treating Parkinson's disease, because isradipine appears to force dopaminergic neurons in to revert to a juvenile, Ca<sup>2+</sup>-independent mechanism to generate autonomous activity. 1. Surmeier (2007) *Lancet Neurol.* **6**, 933.

### Itaconate (Itaconic Acid)

This naturally occurring dicarboxylic acid (FW<sub>free-acid</sub> = 130.10 g/mol; pK<sub>a</sub> values of 3.63 and 5.00; Water-soluble in water (8.3 g/100 g at 20°C), also known as methylenebutanedioic acid and methylenesuccinic acid, is a product of the reaction catalyzed by aconitate decarboxylase and is an alternative substrate of succinate: citramalate CoA-transferase. **Target(s):** 2-(acetamidomethylene)-succinate hydrolase (1); carboxy-*cis,cis*-muconate cyclase (2); fumarase (3,4); glutamate decarboxylase (5); 2-(hydroxymethyl)-3 (acetamidomethylene)-succinate hydrolase (1); isocitrate lyase, slow-binding inhibition (6–22); kynurenine aminotransferase (23);

methylaspartate mutase, or glutamate mutase (24,25); 2-methyleneglutarate mutase (26–28); phosphofructokinase (29); succinate dehydrogenase, or succinate oxidase (30–34). 1. Huynh & Snell (1985) *J. ### Ivabradine

This first-in-class HCN channel blocker (FW = 468.59 g/mol; CAS 155974-00-8), also named 3-[3-({[(7S)-3,4-dimethoxy-bicyclo[4.2.0]octa-1,3,5-trien-7-yl]methyl}(methyl)amino)propyl]-7,8-dimethoxy-2,3,4,5-tetrahydro-1H-3-benzazepin-2-one, S-16257, and Corlanor<sup>®</sup>, is a bradycardic agent that acts on the I<sub>f</sub> (or I<sub>q</sub>) current, where subscripts f and q stand for "funny" or "queer" to connote the channel's unusual properties, as compared to already characterized ion currents. The Hyperpolarization-activated Cyclic Nucleotide-gated (or HCN) I<sub>h</sub> channel is highly expressed in the sinoatrial node (SAN), where its regulating pacemaker activity. HCN channels are of voltage-gated K<sup>+</sup> (K<sub>v</sub>) and cyclic nucleotide-gated (CNG) channels that consist of four identical or four non-identical subunits that become integrally embedded in the cell membrane, creating a potassium ion-conducting pore. HCN subunits have six membrane-spanning domains (numbered S1 to S6) that include: a putative voltage sensor (at S4) and a pore region (between S5 and S6) and a cyclic nucleotide-binding domain (CNBD) in the C-terminus. Within the SAN, the most prominently expressed I<sub>h</sub> channel is HCN4, with HCN2 and HCN1 present at moderate and low levels. When tested in rabbit isolated SAN tissue, S-16257 and UL-FS 49 (1, 3, and 10 μM) were equipotent in slowing spontaneous APs firing predominantly by decreasing the rate of diastolic depolarization (at 3 μM, -24% and -28 %, respectively) (1). Ivabradine selectively inhibits the pacemaker I<sub>h</sub> current in a dose-dependent manner, slowing heart rate and allowing more time for blood to flow to the myocardium. This anti-anginal and anti-ischemic agent selectively and specifically inhibits the I<sub>f</sub> current in

the sino-atrial node, provides pure heart rate reduction without altering other cardiac parameters, such as conduction, and without affecting other hemodynamic parameters. It is approved for the treatment of coronary artery disease and heart failure. Recent work (3) demonstrated that ivabradine can also interact with KCNH2-encoded human Ether-à-go-go-Related Gene (or hERG) potassium channels that strongly influence ventricular repolarization and susceptibility to torsades de pointes arrhythmia. Indeed, ivabradine does not discriminate between hERG and HCN channels: it inhibits Ih ERG with similar potency to that reported for native  $I_f$  and HCN channels, with S6 binding determinants resembling those observed for HCN4 (3). In 2015, the U.S. Food and Drug Administration (FDA) approved Corlanor to reduce the risk of hospitalization for worsening heart failure in patients with stable, symptomatic chronic heart failure with left ventricular ejection fraction (LVEF)  $\leq 35$  percent, who are in sinus rhythm with resting heart rate  $\geq 70$  beats per minute, and either are on maximally tolerated doses of  $\beta$ -blockers or have a contraindication to  $\beta$ -blocker use. 1. ### Ivermectin

This semi-synthetic anthelmintic and insecticide consists primarily of two components, 80% 22,23-dihydroabamectin B<sub>1a</sub> (FW = 875.11 g/mol; CAS 70288-86-7) and 20% 22,23-dihydroabamectin B<sub>1b</sub> (FW = 861.08 g/mol; CAS 71827-03-7). Both are slightly soluble in water (~4  $\mu$ g/mL) and are very soluble in methyl ethyl ketone and propylene glycol. The drug binds to glutamate-gated chloride channels (GluCl) in the membranes of invertebrate nerve and muscle cells, causing increased permeability to chloride ions, resulting in cellular hyper-polarization, followed by paralysis and death. Ivermectin has been used to treat heartworm in dogs and human filarial infections, particularly as a donated product for onchocerciasis and lymphatic filariasis. Ivermectin augments immune responses and impairs the neuromuscular function of the parasites, leading to paralysis. It is also an agonist of the glycine receptor chloride channel and is a substrate of CYP3A4. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** Ca<sup>2+</sup>-transporting ATPase (1); P-glycoprotein, multi-drug resistance factor (2). 1. Bilmen, Wootton & Michelangeli (2002) *Biochem. J.* **366**, 255. 2. Didier & Loor (1996) *Anticancer Drugs* **7**, 745.

### Ivosidenib

This first-in-class orally active IDH1 inhibitor (FW = 582.96 g/mol; CAS 1448347-49-6; Solubility: 100 mg/mL DMSO; < 1 mg/mL H<sub>2</sub>O), also known as AG-120 and (S)-N-((S)-1-(2-chlorophenyl)-2-((3,3-difluorocyclobutyl)-amino)-2-oxoethyl)-1-(4-cyano-pyridin-2-yl)-N-(5-fluoro-pyridin-3-yl)-5-oxopyrrolidine-2-carboxamide, targets a mutant form

of Isocitrate Dehydrogenase Type-1 located within the cytoplasm, which inhibits formation of the oncometabolite, 2-hydroxyglutarate (2HG), inducing cellular differentiation and inhibiting cellular proliferation in IDH1-expressing tumor cells. 1. Agresta, *et al.* (2015) PCT Int. Appl. (2015), WO 2015127172, A1 20150827.

### IVX-214, See HMN-214

### IWP-2

This novel Wnt pathway inhibitor (FW = 466.60 g/mol; CAS 686770-61-6; Solubility: < 1 mg/mL DMSO, Ethanol, or H<sub>2</sub>O), also named N-(6-methyl-2-benzothiazolyl)-2-[(3,4,6,7-tetrahydro-4-oxo-3-phenylthieno[3,2-d]pyrimidin-2-yl)thio]acetamide, targets Wnt processing and secretion (IC<sub>50</sub> = 27 nM), selectively blocking Porcupine-mediated Wnt palmitoylation, without affecting Wnt/ $\beta$ -catenin generally and without inhibiting Wnt-stimulated cellular responses (1). IWP-2 also reduces secretion of functionally active Wnt5a, suppressing both bacterial phagocytosis and the secretion of proinflammatory cytokines, and also accelerating the rate of bacterial killing (2). Suppression of Wnt secretion from Mesenchymal stem cells (MSCs) by IWP-2 (5  $\mu$ mol/L) reduces the efficacy of tyrode (or ConT) in inducing phospho-LRP6 and to increase cardiac conduction (3). Such findings support the hypothesis that MSC-mediated Cx43 upregulation is partly mediated through the canonical Wnt signaling pathway (3). IWP-2 decreases MKN28 gastric cancer cell proliferation, migration and invasion, as well as elevates caspase 3/7 activity (4). IWP-2 downregulates the transcriptional activity of the Wnt/ $\beta$ -catenin signaling pathway and downregulated the expression levels of downstream Wnt/ $\beta$ -catenin target genes in MKN28 cells (4). (See IWP-4; IWP-L6; IWR-1-endo) 1. Chen, Dodge, Tang, *et al.* (2009) *Nature Chem. Biol.* **5**, 100. 2. Maiti, Naskar & Sen (2012) *Proc. Natl. Acad. Sci. USA* **109**, 16600. 3. Mureli, Gans, Bare, *et al.* (2013) *Am. J. Physiol. Heart Circ. Physiol.* **304**, H600. 4. Mo, Li, Chen, *et al.* (2013) *Oncol. Lett.* **5**, 1719.

### IWP-4

This novel Wnt pathway inhibitor (FW = 496.62 g/mol; CAS 686772-17-8; IUPAC Name: N-(6-methyl-2-benzothiazolyl)-2-[(3,4,6,7-tetrahydro-3-(2-methoxyphenyl)-4-oxothieno[3,2-d]pyrimidin-2-yl)thio]acetamide) has a similar mode of action to IWP-2 and IWP-L6, inhibiting Wnt/ $\beta$ -catenin signaling (IC<sub>50</sub> = 25 nM), with minimal effect on Notch and Hedgehog signaling pathways. (See IWP-2; IWP-L6; IWR-1-endo) 1. Chen, *et al.* (2009) *Nature Chem. Biol.* **5**, 100. 2. Lian, *et al.* (2012) *Proc. Natl. Acad. Sci. U.S.A.* **109**, 1848. 3. Frith, *et al.* (2013) *PLoS One* **8**, e82931.

## IWP-L6

This potent Wnt signal transduction pathway inhibitor (FW = 472.58 g/mol; CAS 1427782-89-5; Solubility: 25 mg/mL DMSO; < 1 mg/mL H<sub>2</sub>O; *N*-(5-phenyl-2-pyridinyl)-2-[(3,4,6,7-tetrahydro-4-oxo-3-phenylthieno[3,2-*d*]pyrimidin-2-yl)thio]acetamido) targets Porcupine, or Porcn (EC<sub>50</sub> = 0.5 nM), a membrane-bound *O*-acyltransferase that catalyzes palmitoylation of Wnt proteins, which is required for their secretion and activity (1). Dysregulated Porcn commonly results in developmental disorders, such as focal dermal hypoplasia (Goltz syndrome), and Porcn hyperactivity is often associated with cancerous cell growth. (See *IWP-2*; *IWP-4*; *IWR-1-endo*) 1. Wang, Moon, Dodge, *et al.* (2013) *J. Med. Chem.* **56**, 2700.

## Ixabepilone

This novel epothilone B analogue (FW = 506.70 g/mol; CAS 219989-84-1), also known as azaepothilone B, its code name BMS-247550, its trade name Ixemptra®, and the IUPAC name (1*R*,5*S*,6*S*,7*R*,10*S*,14*S*,16*S*)-6,10-dihydroxy-1,5,7,9,9-pentamethyl-14-[(*E*)-1-(2-methyl-1,3-thiazol-4-yl)prop-1-en-2-yl]-17-oxa-13-azabicyclo[14.1.0]heptadecane-8,12-dione, inhibits microtubule disassembly and demonstrates antineoplastic properties that showed greater promise than paclitaxel (*e.g.*, requiring a less frequent treatment schedule than taxol and allowing for oral administration). *In vitro*, ixabepilone is twice as potent as paclitaxel in inducing tubulin polymerization (1). Like paclitaxel, BMS-247550 is a highly potent cytotoxic agent capable of killing cancer cells at low nanomolar concentrations; however, it retains its antineoplastic activity against human cancers that are naturally insensitive to paclitaxel or that have developed

resistance to paclitaxel, both *in vitro* and *in vivo* (1). This enhanced cytotoxic effect has been attributed to its poor substrate properties with  $\beta$ -glycoprotein drug multidrug resistance protein as well as its high affinity for various  $\beta$ -tubulin isoforms. **Background:** The epothilones constitute a novel class of non-taxane microtubule-stabilizing agents isolated from the cellulose degrading myxobacteria, *Sorangium cellulosum*. Their chemical structures are distinct from taxanes, stereochemically less complex, and therefore more amenable to synthetic modification (2). Other epothilones include patupilone (epothilone B), BMS 310705, sagopilone (ZK-EPO), KOS-862 (epothilone D), and KOS-1584. **Pharmacodynamics & Pharmacokinetics:** Ixabepilone induces cell cycle arrest at the G<sub>2</sub>-M phase transition, followed by apoptotic cell death of paclitaxel-resistant MDA-MB-468 cells (3). Treatment with EpoB triggers a conformational change in the Bax protein and its translocation from the cytosol to the mitochondria, which is accompanied by cytochrome *c* release from the inter-membrane space of mitochondria into the cytosol (3). In patients treated at 40 mg/m<sup>2</sup> (administered as a 1-hour intravenous infusion every 3 weeks), Plasma ixabepilone concentration and the severity of neutropenia correlate with the level of peak microtubule bundle formation (MBF) in peripheral blood mononuclear cells (PBMCs). When used in monotherapy or in combination with capecitabine, Ixemptra is indicated for the treatment of metastatic or locally advanced breast cancer in patients after failure of anthracycline and a paclitaxel. 1. Lee, Borzilleri, Fairchild, *et al.* (2001) *Clin Cancer Res.* **7**, 1429. 2. Kit, Cheng, Bradley, & Budman (2008) *Biologics* **2**, 789. 3. Yamaguchi, Paranawithana, Lee, *et al.* (2002) *Cancer Res.* **62**, 466.

## Ixazomib

This orally bioavailable, second-generation proteasome inhibitor (FW = 361.03 g/mol; CAS 1072833-77-2; Solubility: 72 mg/mL DMSO), codenamed MLN2238 and known as (*R*)-1-(2-(2,5-dichlorobenzamido)acetamido)-3-methylbutylboronic acid, is a boronate peptidomimetic that targets the chymotrypsin-like activity at the  $\beta$ 5 proteolytic site of the 20S proteasome (IC<sub>50</sub> = 3.4 nM; K<sub>i</sub> = 0.93 nM) as well as the caspase-like activity at the  $\beta$ 1 site (IC<sub>50</sub> = 31 nM) and trypsin-like activity at the  $\beta$ 2 site (IC<sub>50</sub> = 3.5  $\mu$ M). Ixazomib has greater pharmacodynamic effects in tissues than bortezomib, showing activity in both solid tumor and hematologic preclinical xenograft models. (See also *Bortezomib*; *Carfilzomib*; *Oprozomib*) 1. Kupperman, Lee, Cao, *et al.* (2010) *Cancer Res.* **70**, 1970. Erratum: *Cancer Res.* (2010) **70**, 3853. 2. Lee, Fitzgerald, Bannerman, *et al.* (2011) *Clin Cancer Res.* **17**, 7313.

# - J -

J 104129

This potent, orally bioavailable muscarinic acetylcholine receptor antagonist (FW = 500.63 g/mol; CAS 257603-40-0; Solubility: 100 mM in DMSO), also named (*αR*)-*α*-cyclopentyl-*α*-hydroxy-*N*-[1-(4-methyl-3-pentenyl)-4-piperidiny]benzeneacetamide, targets M<sub>3</sub> muscarinic acetylcholine receptors ( $K_i = 4.2$  nM), displaying 5x and ~110x selectivity over M<sub>1</sub> ( $K_i = 19$  nM) and M<sub>2</sub> ( $K_i = 490$  nM) receptors. J 104129 also exhibits >250x selectivity in its inhibition of acetylcholine-induced bronchoconstriction ( $K_B = 3.3$  nM) over acetylcholine-induced bradycardia. **1.** Mitsuya, Mase, Tsuchiya, *et al.* (1999) *Bioorg. Med. Chem.* **7**, 2555. **2.** Mitsuya, Ogino, Kawakami, *et al.* (2000) *Bioorg. Med. Chem.* **8**, 825. **3.** Mitsuya, Kawakami, Ogino, Miura & Mase (1999) *Bioorg. Med. Chem.* **9**, 2037.

J-104871

This potent inhibitor (FW<sub>free-acid</sub> = 708.68 g/mol) of rat brain protein farnesyltransferase (IC<sub>50</sub> = 3.9 nM) is without effect on squalene synthase. J-104871 weakly inhibits protein geranylgeranyltransferase I and Ras processing in activated *H-ras*-transformed NIH 3T3 cells. **Target(s):** protein farnesyltransferase (1,2). **1.** Gibbs (2001) *The Enzymes*, 3rd ed. (Tamanai & Sigman, eds), **21**, 81. **2.** Yonemoto, Satoh, Arakawa, *et al.* (1998) *Mol. Pharmacol.* **54**, 1.

J-107088, See *Edotecarin*

(±)-J 113397

This potent and selective non-peptidyl NOP receptor antagonist (FW = 399.58 g/mol; CAS 217461-40-0; Solubility: 50 mM in DMSO; 50 mM in Ethanol), a racemic mixture also named (±)-1-[(3*R*\*,4*R*\*)-1-(cyclooctylmethyl)-3-(hydroxymethyl)-4-piperidiny]-3-ethyl-1,3-dihydro-2*H*-benzimidazol-2-one, targets the nociceptin receptor (*or* NOP), also known as the orphanin FQ receptor *or* κ-type 3 opioid receptor, (IC<sub>50</sub> = 2.3 nM), κ-opioid receptor (IC<sub>50</sub> = 1400 nM), μ-opioid receptor (IC<sub>50</sub> 2200 nM) and δ-opioid receptor (IC<sub>50</sub> > 10000 nM). **1.** Kawamoto, Ozaki, Itoh, *et al.* (1999) *J. Med. Chem.* **42**, 5061.

J 113863

This potent chemokine receptor antagonist (FW<sub>iodide-salt</sub> = 655.44 g/mol; CAS 353791-85-2; Solubility: 100 mM in DMSO; 50 mM in Ethanol), also named 1,4-*cis*-1-(1-cycloocten-1-ylmethyl)-4-[[[2,7-dichloro-9*H*-xanthene-9-yl]carbonyl]amino]-1-ethylpiperidinium iodide, targets CCR<sub>1</sub> receptors (IC<sub>50</sub> = 0.9 nM for human; IC<sub>50</sub> = 5.8 nM for mouse), displaying high selectivity for human CCR<sub>3</sub> receptors (IC<sub>50</sub> = 0.58 nM), but not mouse CCR<sub>3</sub> receptors (IC<sub>50</sub> = 460 nM) (1). J-113863 improves paw inflammation, joint damage and dramatically reduces cell infiltration into joints in a mouse collagen-induced arthritis model (2). (*Note:* J-113863 is an isomer of the chemokine CCR<sub>1</sub> and CCR<sub>3</sub> receptor antagonist, UCB 35625.) **1.** Naya, Sagara, Ohwaki, *et al.* (2001) *J. Med. Chem.* **44**, 1429. **2.** Amat, Benjamin, Williams, *et al.* (2006) *Brit. J. Pharmacol.* **149**, 666.

JA-2, See *N*-(1-(*RS*)-Carboxy-3-phenylpropyl)-*L*-alanyl-*α*-aminoisobutyryl-*L*-tyrosine-*p*-aminobenzoate

Jaceosidin

This flavonoid (FW = 330.29 g/mol; CAS 18085-97-7), systematically named 5,7-dihydroxy-2-(4-hydroxy-3-methoxyphenyl)-6-methoxy-4*H*-1-benzopyran-4-one, from *Artemisia princeps* (Japanese mugwort), is more potent than cisplatin as an inhibitor of human endometrial cancer cells, increasing the phosphorylation of Cdc25C, ATM-Chk1/2, and ERK, leading to the inactivation of the Cdc2-cyclin B<sub>1</sub> complex, and resulting in G<sub>2</sub>/M cell cycle arrest. **1.** Lee, Kim, Ahn, *et al.* (2013) *Food Chem. Toxicol.* **55**, 214.

JAK3 Inhibitor I, See *WHI-P131*

JAK3 Inhibitor II, See *WHI-P154*

JAK3 Inhibitor III, See *WHI-P97*

JAK3 Inhibitor IV, See *ZM 39923*

JAK3 Inhibitor V, See *ZM 429829*

JAK3 Inhibitor VI

This cell-permeable, selective JAK3 inhibitor (FW<sub>Mesylate-Salt</sub> = 383.42 g/mol; CAS 856436-16-3; Solubility: 5 mg/mL in DMSO and 1 mg/mL in H<sub>2</sub>O), also named (3*Z*)-5-(3-pyridinyl)-3-(1*H*-pyrrol-2-ylmethylene)-1,3-dihydro-2*H*-indol-2-one(methanesulfonate salt), targets JAK3 tyrosine kinase, IC<sub>50</sub>

= 27 nM) *in vitro*, with action against IL-2-induced cell proliferation ( $IC_{50}$  = 760 nM in mouse CTLL) and IL-2-induced cell proliferation ( $IC_{50}$  = 250 nM in human T-cells) (1,2) It is also a mutant-specific inhibitor for gatekeeper mutant of Epidermal Growth Factor Receptor, selectively inhibiting EGFR T790M/L858R, with weaker action against wild-type EGFR *in vitro* (3). JAK3 inhibitor VI also specifically reduced autophosphorylation of EGFR T790M/L858R in NCI-H1975 cells upon EGF stimulation, but did not show the inhibitory effect on wild-type EGFR in A431 cells. Furthermore, JAK3 inhibitor VI suppressed the proliferation of NCI-H1975 cells, but showed limited inhibitory effects on the wild-type EGFR-expressing cell lines A431 and A549 (2). A docking simulation between JAK3 inhibitor VI and the ATP-binding pocket of EGFR T790M/L858R predicted a potential binding status with hydrogen bonds. Estimated binding energy of JAK3 inhibitor VI to EGFR T790M/L858R was more stable than its binding energy to the wild-type EGFR (2). 1. Adams, Aldous, Amendola, *et al.* (2003) *Bioorg. Med. Chem. Lett.* **13**, 3105. 2. Chen, Thakur, Clark, *et al.* (2006) *Bioorg. Med. Chem. Lett.* **16**, 5633. 3. Nishiya, Sakamoto, Oku, Nonaka & Uehara (2015) *World J. Biol. Chem.* **6**, 409.

**JANEX-1** See *WHI-P131*

### Janus Green B

This supravital mitochondria-staining dye (FW<sub>HCl-salt</sub> = 511.07 g/mol; CAS 2869-83-2), also named 3-(diethylamino)-7-[[4-(dimethylamino)phenyl]-azo]-5-phenylphenazinium chloride, interacts with double-stranded DNA and is also incorporated in mitochondria (1). The latter property is routinely exploited in histology. **Target(s)**:  $\beta$ -fructo-furanosidase, or invertase (2,3), fumarase (4), and urease (5). 1. Huang, Li, Huang & Li (2000) *Analyst* **125**, 1267. 2. Quastel & Yates (1936) *Enzymologia* **1**, 60. 3. Massart (1950) *The Enzymes*, 1st ed. (Sumner & Myrback, eds), **1** (part 1), 307. 4. Quastel (1931) *Biochem. J.* **25**, 898. 5. Quastel (1932) *Biochem. J.* **26**, 1685.

### Jasplakinolide

This cytotoxic, cell-permeant cyclodepsipeptide (FW = 695.66 g/mol; CAS 102396-24-7; Soluble to 2 mg/mL in DMSO), also named cyclo[(3R)-3-(4-hydroxyphenyl)- $\beta$ -alanyl-(2S,4E,6R,8S)-8-hydroxy-2,4,6-trimethyl-4-non-enoyl-L-alanyl-2-bromo-N-methyl-D-tryptophyl], from the marine sponge *Jaspis johnstoni* binds to monomeric actin ( $K_d$  = 15 nM; competitive with phalloidin) and promotes actin filament self-assembly by inhibiting actin depolymerization (1). Jasplakinolide exhibits both antifungal and antiproliferative activity. (Microtubules, intermediate filaments, and their associated proteins and processes are unaffected.) Cells allowed to recover from jasplakinolide treatment continue to grow, but show severe changes in the cell pattern and displacement of organelles, suggesting that even after removal of the drug, some basic morphogenetic features remain altered.

Jasplakinolide also blocks store-mediated  $Ca^{2+}$  entry into cells as well as enhances the induction of apoptosis by interleukin-2 deprivation. Jasplakinolide has a much greater effect on  $Mg^{2+}$ -actin than on  $Ca^{2+}$ -actin (2). Competitive binding studies using rhodamine-phalloidin suggest that jasplakinolide binds to F-actin competitively with phalloidin with a dissociation constant of ~15 nM. This compares favorably to the previously reported  $IC_{50}$  of 35 nM for the antiproliferative effect of jasplakinolide on PC3 prostate carcinoma cells. Somewhat paradoxically, jasplakinolide stabilizes actin filaments *in vitro*, but disrupts actin filaments *in vivo*, where it also induces amorphous aggregation of monomeric actin. The answer to this paradox lies in the ability of this agent to enhance the rate of nucleation markedly by switching the critical nucleus size from four to approximately three subunits, an action that is mechanistically consistent with the localization of the jasplakinolide-binding site at an interface of three actin subunits (3). Any or all of the above actions may account for jasplakinolide's potent antifungal and antitumor properties. 1. Holzinger (2001) *Methods Mol. Biol.* **161**, 109. 2. Bubb, Senderowicz, Sausville, Duncan & Korn (1994) *J. Biol. Chem.* **269**, 14869. 3. Bubb, Spector, Beyer & Fosen (2000) *J. Biol. Chem.* **275**, 5163.

### Jatrophone

This antibiotic (FW = 300.40 g/mol; CAS 29444-03-9;  $\lambda_{max}$  = 285 nm), diterpene of *Jatropha isabelli* (*Euphorbiaceae*), is active against *Leishmania amazonensis* and *Trypanosoma cruzi* and cancer of the nasopharynx (1,2). Jatrophone also binds tightly to RNA, greatly increasing its thermal stability. In the isolated longitudinal muscle from guinea-pig ileum, 1.6–12.8  $\mu$ M jatrophone produces a concentration-dependent inhibition of acetylcholine, bradykinin and histamine-induced contractions. In this tissue, jatrophone was about 5 to 8-fold more potent in inhibiting acetylcholine and bradykinin than in uterine muscle. 1. Akendengue, Ngou-Milama, Laurens & Hocquemiller (1999) *Parasite* **6**, 3. 2. Gutiérrez (2007) *Handbook of Compounds with Antiprotozoal Activity from Plants*, p. 86, Nova Science, Hauppauge, NY. 3. **JE 049**, See *Icatibant*

### Jervine

This signal transduction inhibitor (FW = 425.61 g/mol; CAS 469-59-0; Solubility: 50 mM in Ethanol; 20 mM in DMSO), also named 2'R,3S,3'R,3'aS,6'S,6aS,6bS,7'aR,11aS,11bR)-2,3,3'a,4,4',5',6,6',6a,6b,7,7',7'a,8,11a,11b-hexadecahydro-3-hydroxy-3',6',10,11b-tetramethyl-spiro[9H-benzo[a]fluorene-9,2'(3'H)-furo[3,2-b]pyridin]-11(1H)-one, from the white hellebore (*Veratrum album*) and green hellebore (*V. viride*), binds directly to Smoothed, or Smo ( $IC_{50}$  = 500-700 nM), targeting signal transduction via Sonic hedgehog (1) as well as the modification of proteins by cholesterol (2). 1. Cooper, Porter, Young & Beachy (1998) *Science* **280**, 1603. 2. Mann & Beachy (2000) *Biochim. Biophys. Acta* **1529**, 188.

**JFD01307SC**

This antimetabolite (FW = 193.22 g/mol; CAS 51070-56-5), also known as *N*-(tetrahydro-1,1-dioxido-3-thienyl)glycine, is a methionine sulfoximine analogue that targets *Mycobacterium tuberculosis* glutamine synthetase, presumably by mimicking the tetrahedral ammonia adduct formed upon attack of ammonia on the enzyme's catalytically essential  $\gamma$ -glutamyl-phosphate intermediate. JFD01307SC shows activity against *M. tuberculosis*, with a minimal inhibitory concentration (MIC) in the 8–16  $\mu$ g/mL range. 1. Lamichhane, Freundlich, Ekins, *et al.* (2011) *mBio*. 2, e00301.

**JH-II-127**

This highly potent and selective, brain-penetrating LRRK2 inhibitor (FW = 416.87 g/mol), also named 2-anilino-4-methylamino-5-chloropyrrolopyrimidine, targets Leucine-Rich Repeat Kinase-2, showing an  $IC_{50}$  value of 6.2 nM for the wild-type kinase and  $IC_{50}$  values of 2.2 nM and 47.7 nM, respectively, for the Gly-2019-Ser and Ala-2016-Thr mutants. JH-II-127 substantially inhibits Ser-910 and Ser-935 phosphorylation of both wild-type LRRK2 and G2019S mutant at a concentration of 0.1–0.3  $\mu$ M in a variety of cell types. It also inhibits phosphorylation at Ser-935 in mouse brain after oral delivery of doses as low as 30 mg/kg. The Gly-2019-Ser mutation, which enhances catalytic activity, is one of a small number of LRRK2 mutations likely to cause Parkinson's disease, especially the sporadic type. Notably, the Ala-2016-Thr catalytically is active, but resists inhibition by H-1152, Y-27632, and sunitinib (2). 1. Hatcher, Zhang, Choi, *et al.* (2015) *ACS Med. Chem. Lett.* 6, 584. 2. Nichols, Dzamko, Hutti, *et al.* (2009) *Biochem J.* 424, 47.

**JHW 007**

This potent dopamine uptake inhibitor (FW<sub>HCl-Salt</sub> = 421.95 g/mol; CAS = 202645-74-7; Solubility: 100 mM in DMSO), also named (3-endo)-3-bis(4-fluorophenyl)methoxy-8-butyl-8-azabicyclo[3.2.1]octane hydrochloride, displays high affinity for the dopamine transporter, *or* DAT ( $K_i$  = 25 nM). JHW-007 shows substantially weaker action against the serotonin transporter, *or* SERT ( $K_i$  = 1.73  $\mu$ M) as well as the norepinephrine transporter, *or* NET ( $K_i$  = 1.33  $\mu$ M), the latter also known as Solute Carrier family 6 member 2, *or* SLC6A2. JHW-007 suppresses cocaine's dopamine

effects in a dose-dependent manner. 1. Kopajtic, *et al.* (2010) *J. Pharmacol. Exp. Ther.* 335, 703. 2. Velaquez-Sanchez, *et al.* (2010) *Eur. Neuropsychopharmacol.* 20, 501. 3. Kristensen, *et al.* (2011) *Pharm. Rev.* 63, 585.

**JIB 04**

This pan Jumonji histone demethylase inhibitor (FW<sub>free-base</sub> = 308.77 g/mol; CAS 199596-05-9; Solubility: 100 mM DMSO; 50 mM in 1 equivalent of HCl), also named 5-chloro-2-[(*E*)-2-(phenyl(pyridin-2-yl)methylidene)hydrazin-1-yl]pyridine, targets JARID<sub>1A</sub> ( $K_i$  = 230 nM), JMJD<sub>2E</sub> ( $K_i$  = 340 nM), JMJD<sub>2B</sub> ( $K_i$  = 435 nM), JMJD<sub>2A</sub> ( $K_i$  = 445 nM), JMJD<sub>3</sub> ( $K_i$  = 855 nM) and JMJD<sub>2C</sub> ( $K_i$  = 1100 nM) demethylases (1,2). Grunicke & Hofmann (1997) *J. Med. Chem.* 40, 4420. 2. Wang, *et al.* (2013) *Nat. Commun.* 4, 2035.

**Jingzhaotoxin-I**

This venom-derived 33-residue polypeptide (MW = 3497 g/mol; Symbol: JZTX-I; Solubility: 1 mg/mL in H<sub>2</sub>O), from the Chinese tarantula *Chilobrachys jing-zhao*, interacts with sodium channels, showing high affinity ( $IC_{50}$  = 32 nM) for tetrodotoxin-resistant subtype found in mammalian cardiac myocytes. Because it neither modifies the current-voltage relationships nor shifts the steady-state inactivation of sodium channels, JZTX-I defines a new subclass of spider toxins. It binds to the Na<sub>v</sub>1.5 S3-S4 linker of domain II, thereby discriminating its action at cardiac sodium channels from inhibition of the presumably functionally similar, tetrodotoxin-resistant, neuronal isoforms. 1. Xiao, Tang, Hu, *et al.* (2005) *J. Biol. Chem.* 280, 12069.

**JIP-1 (153-163)**

This cJNK-selective peptide inhibitor (FW = 1341.6 g/mol; Sequence: RPKRPTTLNLF-NH<sub>2</sub>; CAS 438567-88-5; Solubility: 1 mg/mL in H<sub>2</sub>O), corresponding to the C-terminal eleven residues of I-JIP (Inhibitor of JNK-based on JIP-1), binds directly to and inhibits recombinant c-Jun N-terminal kinase, but not its substrates, based on surface plasmon resonance data. (JNK-interacting protein-1 (JIP1) is a scaffolding protein that enhances JNK signaling by creating a proximity effect between JNK and upstream kinases.) The JNK subfamily of the mitogen-activated protein kinases (MAPKs) transduce extracellular signals to inform cytoplasmic and nuclear targets. Four residues (*e.g.*, Arg-156, Pro-157, Leu-160, or Leu-162) are critical for inhibition (1), a finding that extends an earlier report that peptides corresponding to residues 143–163 inhibit cJNK (2). 1. Barr, Kendrick & Bogoyevitch (2002) *J. Biol. Chem.* 277, 10987. 2. Bonny, Oberson, Negri, Sauser & Schorderet (2001) *Diabetes* 50, 77.

**JJKK 048**

This potent and selective MAGL inhibitor (FW = 434.44 g/mol; CAS 1515855-97-6; Soluble to 100 mM in DMSO), also named 4-[bis(1,3-benzodioxol-5-yl)methyl]-1-piperidiny]-1*H*-1,2,4-triazol-1-yl-methanone, targets monoacylglycerol lipase ( $IC_{50}$  = 0.4 nM) and exhibits >13,000x and ~630x selectivity over FAAH and ABHD6, respectively (1,2). MAGL catalyzes the hydrolysis of 2-arachidonoylglycerol (*or* 2-AG), thereby terminating the signaling by this endocannabinoid. 2-AG hydrolysis liberates arachidonic acid, the principal substrate for the neuroinflammatory prostaglandins. MAGL also redirects lipid stores toward protumorigenic signaling lipids (1). Thus MAGL inhibitors may have great therapeutic potential. **1.** Aaltonen, *et al.* (2013) *Chem. Biol.* **20**, 379. **2.** Laitinen, *et al.* (2014) *Mol. Pharmacol.* **85**, 510.

#### JK 184

This signal transduction modulator (FW = 350.44 g/mol; CAS 315703-52-7; Solubility: 100 mM in DMSO; 25 mM in Ethanol), also named *N*-(4-ethoxyphenyl)-4-(2-methylimidazo[1,2-*a*]pyridin-3-yl)-2-thiazolamine, is an alcohol dehydrogenase-7 (Adh7) inhibitor ( $IC_{50}$  = 210 nM), a potent downstream hedgehog (Hh) signaling inhibitor that prevents Gli-dependent transcriptional activity ( $IC_{50}$  = 30 nM), and a microtubule depolymerizing agent *in vitro*. JK-184 also exhibits antiproliferative activity in a range of cancer cell lines ( $GI_{50}$  = 3-21 nM) and human cancer cell xenografts *in vivo*. **1.** Lee, *et al.* (2007) *Chembiochem.* **8**, 1916. **2.** Cupido, *et al.* (2009) *Angew. Chem. Int. Ed. Engl.* **48**, 2321.

#### JKC 301

This cyclic pentapeptide (FW<sub>free-acid</sub> = 624.74 g/mol; *Sequence*: cyclo[D-Asp-L-Pro-D-Ile-L-Leu-D-Trp]; CAS 136553-96-3) is a selective endothelin (ET-A) receptor antagonist (1,2). Selective ET-A antagonists (*e.g.*, BQ123, BMS-182,874 and JKC-301) all display low affinities at the endothelin receptors, whereas the selective ET-B antagonist BQ-788 showed moderate affinity, effective in the low nanomolar range (3) **1.** Fekete, Yang, Kimura & Aviv (1995) *J. Pharmacol. Exp. Ther.* **275**, 215. **2.** Nambi, Pullen, Kincaid, *et al.* 1997) *Mol. Pharmacol.* **52**, 582. **3.** Widdowson & Kirk (1996) *Br. J. Pharmacol.* **118**, 2126.

#### JKC 363

This potent and selective MC<sub>4</sub> receptor antagonist (FW = 1506.72 g/mol; CAS 436083-30-6; Sequence: XEHXRWGCPPKD, with a disulfide bridge between residues 1 - 8, where X-1 = Mpr, X-4 = D-2-Nal, Asp-12 = C-terminal amide); Solubility: 1 mg/mL in H<sub>2</sub>O) targets the melanocortin MC<sub>4</sub> receptor ( $IC_{50}$  = 0.5 nM), antagonizing the effects of  $\alpha$ -MSH, suppressing thyrotropin-releasing hormone (TRH) release, attenuating food intake, and reducing formalin-induced pain *in vivo* (1-3). JKC 363 shows weaker action against MC<sub>3</sub> ( $IC_{50}$  = 45 nM). **1.** Kim, Small, Russell, *et al.* (2002) *J. Neuroendocrinol.* **14**, 276. **2.** Verty, McFarlane, McGregor & Mallet (2004) *Endocrinol.* **145**, 3224.

#### JLK 6

This  $\gamma$ -secretase-mediated  $\beta$ -APP processing inhibitor (FW = 225.63 g/mol; CAS 62252-26-0; Solubility: 100 mM in DMSO; 25 mM in Ethanol), also named 7-amino-4-chloro-3-methoxy-1*H*-2-benzopyran, selectively targets  $\beta$ -Amyloid Precursor Protein cleavage without affecting other  $\gamma$ -secretase-mediated pathways (1). JLK-6 prevents recovery of A $\beta$ 40 and A $\beta$ 42 from HEK293 cell that overexpress wild-type or Swedish-mutated  $\beta$ APP ( $IC_{50}$  ~ 30  $\mu$ M), while displaying no effect on Notch cleavage and Notch-mediated intracellular signaling. JLK-6 displays no activity on BACE1, BACE2,  $\alpha$ -secretase, proteasome activity, or GSK3 $\beta$ . **1.** Petit, *et al.* (2001) *Nature Cell. Biol.* **3**, 507. **2.** Petit, *et al.* (2003) *J. Neurosci. Res.* **74**, 370. **3.** Hellstrom, *et al.* (2007) *Nature* **445**, 776.

**JLKG See 7-Amino-4-chloro-3-methoxyisocoumarin**

#### JMV 390-1

This neurotensin inhibitor and neuromedin N-degrading enzyme inhibitor (FW = 449.55 g/mol; CAS 148473-36-3; Solubility: 0.80 mg/mL in 0.01M sodium bicarbonate), also named *N*-[(2*R*)-4-hydroxyamino]-1,4-dioxo-2-(phenylmethyl)butyl]-L-isoleucyl-L-leucine, targets the major neurotensin and neuromedin N degrading enzymes, with respective  $IC_{50}$  values are 31, 40, 52, and 58 nM for endopeptidase 24.15, endopeptidase 24.11, leucine aminopeptidase and endopeptidase 24.16. Hydroxamate-based inhibitors are often highly effective against metalloproteinases. Cytotoxic activity of *Bacillus anthracis* lethal factor is inhibited by leukotriene A<sub>4</sub> hydrolase and this metalloproteinase inhibitor. JMV 390-1 exhibits analgesic effects in various nociception assays. **1.** Kitabgi, *et al.* (1992) *Neurosci. Lett.* **142**, 200. **2.** Doulut, *et al.* (1993) *J. Med. Chem.* **36**, 1369. **3.** Menard, *et al.* (1996) *Biochem. J.* **320**, 687.

#### JMV 449

This potent NTR agonist (FW = 746.96 g/mol; CAS 139026-66-7; Solubility: 2 mg/mL acetonitrile (20% vol/vol) in acetic acid (0.1% vol/vol)), is a pseudopeptide corresponding neurotensin (NT) residues 8-13 (KKPYIL), in which the Lys-Lys peptide bond is replaced by the nonhydrolyzable pseudopeptide moiety (*or*  $\Psi$ (CH<sub>2</sub>-NH)). JMV449 blocks

[<sup>125</sup>I]-neurotensin binding (IC<sub>50</sub> = 0.15 nM) to the neurotensin receptor (NTR) in neonatal mouse brain and inhibits the contraction of guinea pig ileum (EC<sub>50</sub> = 1.9 nM). JMV-449 also produces long-lasting hypothermic, neuroprotective, and analgesic effects in mice, when administered centrally. 1. Lugin, Vecchini, Doulut, *et al.* (1991) *Eur. J. Pharmacol.* **205**, 191. 2. Dubuc, Costentin, Doulut, *et al.* (1992) *Eur. J. Pharmacol.* **219**, 327. 3. Torup, Borsdall & Sager (2003) *Neurosci. Lett.* **351**, 173.

#### JMV 2959

This small-molecule ghrelin receptor antagonist (FW<sub>free-base</sub> = 508.63 g/mol; FW<sub>HCl-Salt</sub> = 545.08 g/mol; Solubility (hydrochloride): 100 mg/mL DMSO = 5 mg/mL H<sub>2</sub>O), known systematically as (*R*)-*N*-(2-(1*H*-indol-3-yl)-1-(4-(4-methoxybenzyl)-5-phenethyl-4*H*-1,2,4-triazol-3-yl)ethyl)-2-aminoacetamide, inhibits (IC<sub>50</sub> = 32 nM) [<sup>125</sup>I-His<sup>9</sup>]-ghrelin binding to the human ghrelin receptor-1a, or hGHS-1a, receptor (transiently expressed on LLC-PK1 cells), but does not induce any intracellular calcium mobilization (1,2). The dissociation constant of the receptor-JMV-2959 complex was determined by the Schild method. This experiment revealed a dissociation constant *K*<sub>d</sub> of 19 ± 6 nM. 1. Moulin, Demange, Bergé, *et al.* (2007) *J. Med. Chem.* **50**, 5790. 2. Moulin, Brunel, Boeglin, *et al.* (2012) *Forum Amino Acid, Peptide & Protein Research* **12**, 1355.

#### JNJ 303

This I<sub>Ks</sub> blocker (FW = 440.98 g/mol; CAS 878489-28-2; Solubility: 25 mM in DMSO), also named 2-(4-chlorophenoxy)-2-methyl-*N*-[5-[(methylsulfonyl)amino]tricyclo[3.3.1.1.3,7]dec-2-yl]propanamide, potently and selectively targets the cardiac I<sub>Ks</sub> channel (IC<sub>50</sub> = 64 nM), displaying no effects on other cardiac channels (*i.e.*, IC<sub>50</sub> values are 3.3, >10, 11.1 and 12.6 μM for I<sub>Na</sub>, I<sub>Ca</sub>, I<sub>to</sub> and I<sub>Kr</sub> currents, respectively). The I<sub>Ks</sub> channel is a major repolarization current in the heart and responds rapidly to sympathetic nervous system stimulation, ensuring an adequate diastolic filling time as the heart rate increases (2). In cardiac myocytes, the I<sub>Ks</sub> channel is a macromolecular complex composed of a pore-forming α (KCNQ1) subunit and modulatory β (KCNE1) subunit, as well as intercellular proteins critical for controlling the phosphorylation state of the complex (2). 1. Towart *et al.* (2009) *J. Pharm. Toxicol. Meth.* **60**, 1. 2. Osteen, Sampson & Kass (2010) *Proc. Natl. Acad. Sci. USA* **107**, 18751.

#### JNJ 5207787

This brain-penetrant and selective NPY antagonist (FW = 510.67 g/mol; CAS 683746-68-1; Solubility: 10 mM in DMSO (gentle warming); 10 mM in Ethanol (gentle warming)), also named (2*E*)-*N*-(1-acetyl-2,3-dihydro-1*H*-indol-6-yl)-3-(3-cyanophenyl)-*N*-[1-(2-cyclopentylethyl)-4-piperidinyl]-2-propanamide, displays 100x selectivity for the neuropeptide Y Y<sub>2</sub> receptor (IC<sub>50</sub> = 0.1 μM) over NPY Y<sub>1</sub>, NPY Y<sub>4</sub> and Y<sub>5</sub> receptors and much greater selectivity versus a panel of fifty other receptors, ion channels and

transporters. 1. Bonaventure, *et al.* (2004) *J. Pharmacol. Exp. Ther.* **308**, 1130. 2. Jablonowski, *et al.* (2004) *Bioorg. Med. Chem. Lett.* **14**, 1239.

#### JNJ-7706621

This cyclin kinase-directed inhibitor (FW = 394.36 g/mol; CAS 443797-96-4; Solubility: 80 mg/mL DMSO; <1 mg/mL Water; Formulation: Dissolve in 0.5% methylcellulose containing 0.1% polysorbate 80 in sterile water), systematically named 4-[5-amino-1-(2,6-difluorobenzoyl)-1*H*-[1,2,4]triazol-3-ylamino]benzenesulfonamide, targets CDK1/cyclin B, CDK2/cyclin A, CDK2/cyclin E, Aurora A kinase and Aurora B kinase with an IC<sub>50</sub> value of 9 nM, 4 nM, 3 nM, 11 nM and 15 nM, respectively. Flow cytometric analysis of DNA content showed that JNJ-7706621 delayed progression through G<sub>1</sub> and arrested the cell cycle at the G<sub>2</sub>-M phase. **Cyclin Target Selectivity:** Cdk1 (+++), Cdk2 (+++), Cdk3 (weak, if any), Cdk4 (weak, if any), Cdk5 (weak, if any), Cdk6 (weak, if any), Cdk7 (weak, if any), Cdk8 (weak, if any), Cdk9 (weak, if any), Cdk10 (weak, if any), Aurora A Kinase (++), Aurora B Kinase (++). 1. Emanuel, *et al.* (2005) *Cancer Res.* **65**, 9038. 2. Seamon, *et al.* (2006) *Mol. Cancer Ther.* **5**, 2459. 3. Lin, *et al.* (2005) *J. Med. Chem.* **48**, 4208.

#### JNJ 5207852

This high-affinity, brain-penetrant and orally active histamine receptor neutral antagonist (FW = 389.40 g/mol; CAS 398473-34-2; Solubility: 50 mM in water; 10 mM in DMSO), also named 1-[3-[4-(1-piperidinyl)methyl]phenoxy]propyl]piperidine, targets the H<sub>3</sub> receptor (human, p*K*<sub>i</sub> = 8.9; rat, p*K*<sub>i</sub> = 9.2), showing 100x and 3x greater affinity than thioperamide, respectively. JNJ 5207852 suppresses slow-wave sleep and exhibits wake-promoting effects in rodent arousal models. 1. Barbier *et al.* (2004) *Brit. J. Pharmacol.* **143**, 649. 2. Jia, *et al.* (2005) *Neuropharmacol.* **50**, 404. 3. Le, *et al.* (2008) *J. Pharmacol. Exp. Ther.* **325**, 902.

#### JNJ 7777120a

This anti-inflammatory (FW<sub>free-base</sub> = 277.75 g/mol; CAS 459168-41-3) was among the first potent, non-imidazole, human H<sub>4</sub> histamine receptor antagonists (1). JNJ7777120 also recruits β-arrestin to the H<sub>4</sub> receptor, independent of G protein activation (2). 1. Jablonowski, Grice, Chai, *et al.* (2003) *J. Med. Chem.* **46**, 3957. 2. Osethorne & Charlton (2011) *Mol. Pharmacol.* **79**, 749.

#### JNJ 10329670

## JNJ DGAT2-A

This potent and selective DGAT2 inhibitor (FW = 523.38 g/mol; Soluble to 100 mM in DMSO), also named 3-bromo-4-[2-fluoro-4-[[4-oxo-2-[[2-(pyridin-2-yl)ethyl]amino]-1,3-thiazol-5-(4H)-ylidene]methyl]phenoxy]benzonitrile, targets isoform-2 of diacylglycerol acyltransferase (DGAT), the enzyme catalyzing the final step in triglyceride (TG) synthesis. There are two enzyme isoforms, DGAT1 and DGAT2, each with different physiological functions, indicating the utility of differential inhibition of DGAT1 and DGAT2 to probe hepatic TG synthesis. Moreover, hyperglycemia and hypertriglyceridaemia are both characteristic of pre-diabetes conditions, and DGAT2 catalyzes the *de novo* synthesis of triacylglycerols from newly synthesized fatty acids and nascent diacylglycerols. This property identifies DGAT2 as a likely link between hyperglycemia and hypertriglyceridaemia. JNJ DGAT2-A inhibits DGAT2 (IC<sub>50</sub> = 140 nM), showing >70-fold selectivity for DGAT2 over DGAT1 and MGAT2. An intriguing finding is that DGAT1 inhibitors (JNJ-DGAT1-A and A-92250) block incorporation of exogenously added oleate, but do not disrupt incorporation of exogenously added glycerol into TG; the opposite is true for the selective DGAT2 inhibitor, JNJ DGAT2-A. In other words, DGAT2 preferentially esterifies exogenously added glycerol to endogenously synthesized FAs, and DGAT1 preferentially esterifies exogenously added oleic acid to already-existing diacylglycerol. 1. Qi, Lang, Geisler, *et al.* (2012) *J. Lipid Res.* **53**, 1106.

## JNK Inhibitor I

This cell-penetrating peptide (MW = 3920 g/mol; pI = 12.5; Sequence: GRKKRRRQRPRPKRPTTLNLFQVPRSQ-DT-NH<sub>2</sub>), also known as SAPK Inhibitor I, diminishes c-Jun amino-terminal kinase (JNK) signaling by blocking the activation of the transcription factor *c-jun*. JNK Inhibitor I is a fusion peptide consisting of the C-terminal sequence of the JNK binding protein attached to the HIV-TAT pentatrin domain (residues 48-57). The HIV-TAT sequence permits entry into the cytoplasm by means of micropinocytosis (2). 1. Barr, Kendrick & Bogoyevitch (2002) *J. Biol. Chem.* **277**, 10987. 2. Chauhan, Tikoo, Kapur & Singh (2007) *J. Control Release* **117**, 148.

## JNK Inhibitor II, See SP 600125

## JO146

This *Chlamydia* inhibitor (FW = 573.63 g/mol) induces complete or significant loss of viable elementary body formation when added during the replicative phase of *Chlamydia trachomatis*, an obligate intracellular bacterial pathogens with significant clinical importance inasmuch as it is now the most common sexually transmitted bacterial infection world wide and ocular-infecting serovars are the most common cause of preventable blindness worldwide. JO146 possesses a C-terminal phosphonate 'warhead' electrophile that reacts irreversibly with the protease active-site serine residue. When treated during the replicative phase of development, *Chlamydia* lose their distinctive morphology, with ultimate loss of inclusions from infected host cells. JO146 completely prevented the formation of viable *Chlamydia* elementary bodies. 1. Gloeckl, Ong, Patel, *et al.* (2013) *Mol. Microbiol.* **89**, 676.

## Joro Spider Toxin

This photosensitive polyamine toxin (shown above is the synthetic toxin JSTx-3, FW<sub>free-base</sub> = 565.71 g/mol) from the venom of the joro spider (*Nephila clavata*) irreversibly blocks excitatory postsynaptic potentials without affecting inhibitory postsynaptic potentials. JST not only inhibits L-glutamate binding to synaptic membrane receptors, but also L-glutamate uptake by synaptosomes. In fact, it joro spider toxins are one of the most potent antagonists of glutamatergic AMP<sub>A</sub>/K<sub>A</sub> (or  $\alpha$ -amino-3-hydroxy-5-methylisoxazole-4-propionate/kainate) receptor channels in invertebrates and vertebrates. (See also 1-Naphthylacetylspermine) **Target(s):** AMP<sub>A</sub> receptors (1); glutamate receptor (2) 1. Van Den Bosch, Vandenberghe, Klaassen, Van Houtte & Robberecht (2000) *J. Neurol. Sci.* **180**, 29. 2. Pan-Hou, Suda, Sumi, Yoshioka & Kawai (1989) *Brain Res.* **476**, 354.

## JP 1302

This  $\alpha_{2C}$  adrenoceptor antagonist (FW = 441.41 g/mol; CAS 1259314-65-2; Solubility: 100 mM in water (as dihydrochloride) and to 5 mM in DMSO), also named *N*-[4-(4-Methyl-1-piperazinyl)phenyl]-9-acridinamine, selectively targets the human  $\alpha_{2C}$  subtype ( $K_i$  = 28 nM), with much weaker action against  $\alpha_{2B}$  ( $K_i$  = 1470 nM),  $\alpha_{2D}$  ( $K_i$  = 1700 nM) and  $\alpha_{2A}$  ( $K_i$  = 3150 nM) receptor subtypes. JP-1302 also antagonizes epinephrine-stimulated GTP $\gamma$ S binding *in vitro* ( $K_B$  = 16 nM) and produces antidepressant and antipsychotic-like effects *in vivo*. 1. Sallinen, *et al.* (2007) *Brit. J. Pharmacol.* **150**, 391.

## (+)-JQ1

This potent, selective and cell-permeable BET bromodomain inhibitor (FW = 456.99 g/mol; CAS 1268524-70-4; Solubility: 100 mM in DMSO; 100 mM in Ethanol), also named (6S)-4-(4-chlorophenyl)-2,3,9-trimethyl-6H-thieno[3,2-f][1,2,4]triazolo[4,3-a][1,4]diazepine-6-acetic acid 1,1-dimethylethyl ester, targets BRD2 (N-terminal), IC<sub>50</sub> = 18 nM,  $K_d$  = 128 nM; BRD3 (N-terminal),  $K_d$  = 60 nM; BRD3 (C-terminal),  $K_d$  = 82 nM; BRD4 (C-terminal), IC<sub>50</sub> = 33 nM,  $K_d$  = 90 nM; BRD4 (N-terminal), IC<sub>50</sub> = 77 nM,  $K_d$  = 49 nM; and CREBBP, IC<sub>50</sub> = 12942 nM; and BRDT (N-terminal),  $K_d$  = 190 nM. Recurrent translocation of BRD4 is observed in a genetically-defined, incurable subtype of human squamous carcinoma. Competitive binding by JQ1 displaces the BRD4 fusion oncoprotein from chromatin, prompting squamous differentiation and specific antiproliferative effects in BRD4-dependent cell lines and patient-derived xenograft models (1). JQ1 also exerts major anti-leukemic effects in a broad range of human AML subtypes, including relapsed and refractory patients and all relevant stem- and progenitor cell compartments, including CD34<sup>+</sup>/CD38<sup>-</sup> and CD34<sup>+</sup>/CD38<sup>+</sup> AML cells (2). Treatment of mice with JQ1 reduces seminiferous tubule area, testis size, and spermatozoa number and motility, without affecting hormone levels (3). JQ1 exerts a complete

## JTT-130

This microsomal triglyceride transfer inhibitor (FW = 718.73 g/mol) inhibits enterocyte Microsomal Triglyceride-transfer Protein (MTP), a carrier playing a central role in intestinal lipid absorption and a druggable target for treating metabolic syndrome. JTT-130 potentially inhibited lipid transfer by MTP derived from human small intestine in a concentration-dependent manner for transfer of triglycerides ( $IC_{50}$  = 0.83 nM) and cholesteryl ester ( $IC_{50}$  = 0.74 nM). **Rationale fo Enterocyte-Directed Action:** Localized within the endoplasmic reticulum, MTP participates in the assembly of TG-rich lipoproteins, such as chylomicron particles in the small intestine, and very low-density lipoprotein (VLDL) particles in the liver. In view of reported undesirable *in vivo* effects of MTP inhibitors, it was evident that inhibition of hepatic MTP could result in the potent blockade of VLDL release, resulting in reduced plasma lipids and inducing fatty liver and hepatic dysfunction. In a strategy designed to minimize any tendency of enteric MTP inhibitors to interfere with hepatic MTP, JTT-130 was designed to undergo rapid metabolic hydrolysis after oral administration to its inactive metabolite M1 (shown above). 1. Mera, Odani, Kawai, *et al.* (2011) *J. Pharmacol. Exp. Ther.* **336**, 321.

## JTT-705, See Dalcetrapib

## JTV-803

This anticoagulant (FW = 409.49 g/mol; CAS 247131-79-9) potently inhibits coagulation factor Xa ( $K_i$  = 19 nM) but weakly inhibits trypsin ( $K_i$  = 13.6  $\mu$ M) and plasmin ( $K_i$  = 78  $\mu$ M). JTV-803 was dose-dependently effective against disseminated intravascular coagulation in both TF-induced and LPS-induced rat models 1. Hayashi, Matsuo, Nakamoto & Aisaka (2001) *Eur. J. Pharmacol.* **412**, 61. 2. Ieko, Tarumi, Takeda, *et al.* (2004) *J. Thromb. Haemost.* **2**, 612.

## Juglone

This pH-indicating, yellow-brown naphthoquinone (FW = 174.16 g/mol; CAS 481-39-0), also known as 5-hydroxy-1,4-naphthoquinone, from the walnut shells, leaves, and roots, potentially irreversibly inhibits sarcoplasmic reticulum  $Ca^{2+}$ -transporting ATPase activity (1). Another naphthoquinone, 5-OH-2-CH<sub>3</sub>-1,4-naphthoquinone (plumbagine) also inhibits irreversibly, whereas 2-CH<sub>3</sub>-1,4-naphthoquinone (menadione) and 2,3-(OCH<sub>3</sub>)<sub>2</sub>-1,4-naphthoquinone (2,3diOmeNQ) do not. Such findings suggest that the C5 hydroxyl is essential for juglone's direct interaction with a catalytic SH group. (See also Lawsone) **Target(s):**  $Ca^{2+}$ -transporting ATPase (1);  $\zeta$ -crystallin's lactate dehydrogenase activity (2,3); dihydroxy-acid dehydratase (4); ecdysone 20-monooxygenase (5); 3 $\alpha$ -hydroxysteroid transhydrogenase (6); peptidyl-prolyl isomerase, irreversibly modifying

sulfhydryl groups by a Michael-type addition (7,8); pyruvate decarboxylase (9); ribonuclease H activity associated with HIV-I reverse transcriptase (10); urease (11); acetyl-choline synthesis (12). 1. Floreani, Forlin, Bellin & Carpenedo (1995) *Biochem. Mol. Biol. Int.* **37**, 757. 2. Duhaime (1996) *Biochem. Biophys. Res. Commun.* **218**, 648. 3. Bazzi (2001) *Arch. Biochem. Biophys.* **395**, 185. 4. Babu & Brown (1995) *Microbios* **82**, 157. 5. Mitchell & Smith (1988) *Experientia* **44**, 990. 6. Koide (1962) *Biochim. Biophys. Acta* **59**, 708. 7. Chao, Greenleaf & Price (2001) *Nucl. Acids Res.* **29**, 767. 8. Hennig, Christner, Kipping, *et al.* (1998) *Biochemistry* **37**, 5953. 9. Kuhn & Beinert (1947) *Ber.* **80**, 101. 10. ## Justicidins

Justicidin A

Justicidin B

This class of lignans (FW<sub>Justicidin-A</sub> = 394.38 g/mol; CAS 25001-57-4; FW<sub>Justicidin-B</sub> = 364.35 g/mol; CAS 17951-19-8) from species of *Justicia*, *Sesbania*, and *Acanthaceae* is both cytotoxic and antiviral. They also inhibit platelet aggregation (1). Justicidin A inhibits the transport of TNF- $\alpha$  to cell surface in lipopolysaccharide-stimulated RAW 264.7 macrophages (2). 1. Chen, Hsin, Ko, *et al.* (1996) *J. Nat. Prod.* **59**, 1149. 2. Tsao, Lin & Wang (2004) *Mol. Pharmacol.* **65**, 1063.

## Juvenile Hormones

These insect hormones (JH) function to maintain the larval stage, thereby preventing maturation. As such, they have been exploited as insect-controlling agents (1,2). The best characterized examples are those of the silk moth: C-18 JH (JH I; *cis*-10,11-epoxy-7-ethyl-3,11 dimethyl-*trans,trans*-2,6-tridecadienoic acid methyl ester; FW = 294.43 g/mol) and C-17 JH (JH II; *cis*-10,11-epoxy-3,7,11-trimethyl-*trans,trans*-2,6-tridecadienoic acid methyl ester; FW = 280.41 g/mol). JH III is the smaller *cis*-10,11-epoxy-3,7,11-trimethyl-*trans,trans*-2,6 dodecadienoic acid methyl ester (FW = 266.38 g/mol). C-18 JH was stereochemically synthesized by Corey and coworkers in 1968 (3). **Target(s):** microsomal epoxide hydrolase (JH-I inhibition is competitive,  $K_i$  = 0.27 mM; JH-I is a very poor substrate for *Trypanosoma cruzi* epoxide hydrolase) (4). 1. Pratt & Brooks, eds (1981) *Juvenile Hormone Biochemistry*, Elsevier-North Holland, Amsterdam. 2. Davey (2000) *Insect Biochem. Mol. Biol.* **30**, 663. 3. Corey, Katzenellenbogen, Gilman, *et al.* (1968) *J. Amer. Chem. Soc.* **90**, 5618. 4. Yawetz & Agosin (1979) *Biochim. Biophys. Acta* **585**, 210.

## JW55

This tankyrase inhibitor (FW = 434.48 g/mol; CAS 664993-53-7; Solubility: 100 mM in DMSO), also named *N*-[4-[[[tetrahydro-4-(4-methoxyphenyl)-2*H*-pyran-4-yl]methyl]amino]carbonyl]phenyl]-2-furan carboxamide, binds selectively within the poly(ADP-ribose) polymerase (or PARP) domain of Tankyrases 1 and 2 (TNKS1/2), resulting in stabilization of Axin2 and increased degradation of  $\beta$ -catenin. JW55 inhibits the  $\beta$ -catenin signaling pathway, decreasing canonical Wnt signaling in SW480 and HCT-15 colon carcinoma cell lines and reducing cell cycle progression and proliferation in SW480 cells *in vitro*. 1. Waaler, Machon, Tumova, et al. (2012) *Cancer Res.* **72**, 2822.

## JW67

This canonical Wnt signaling pathway inhibitor (FW = 394.38 g/mol; CAS 442644-28-2; Solubility: 100 mM in DMSO), also named tri-spiro[3*H*-indole-3,2'-[1,3]dioxane-2'',3'''-[3*H*]indole]-2,2'''(1*H*,1'''*H*)-dione, targets ( $IC_{50}$  = 1.17  $\mu$ M) the  $\beta$ -catenin destruction complex (*i.e.*, GSK-3 $\beta$ /AXIN/APC) to induce  $\beta$ -catenin degradation, blocking cell cycle progression at G<sub>1</sub>/S in colorectal cancer cell lines ( $GI_{50}$  = 7.8  $\mu$ M). JW-67 is selective for the canonical Wnt pathway over the Sonic hedgehog (Shh) and NF- $\kappa$ B pathways. 1. Waaler, et al. (2011) *Cancer Res.* **71**, 197. 2. Shultz, et al. (2012) *J. Med. Chem.* **55**, 1127.

## JW74

This tankyrase inhibitor (FW = 456.52 g/mol; CAS 863405-60-1; Solubility: 20 mg/mL DMSO; IUPAC Name: 4-[4-(4-methoxyphenyl)-5-[[[3-(4-methylphenyl)-1,2,4-oxadiazol-5-yl]methyl]thio]-4*H*-1,2,4-triazol-3-yl]pyridine) is an efficient and specific inhibitor of the canonical Wnt signaling, both *in vitro* and *in vivo*. A major regulator of stem cell self-renewal and differentiation, the Wnt/ $\beta$ -catenin signaling pathway is aberrantly activated in a several cancers, including osteosarcoma. JW74 rapidly reduces active  $\beta$ -catenin, attended subsequently by downregulation of the Wnt target genes AXIN2, SP5, and NKD1. AXIN2 protein levels were strongly increased after compound exposure. Long-term treatment with JW74 inhibited the growth of osteosarcoma tumor cells in both a mouse xenograft model of CRC and in Apc(Min) mice. (Note: Min = Multiple intestinal neoplasias) See also G007-LK 1. Waaler, Machon, von Kries, et al. (2011) *Cancer Res.* **71**, 197. 2. Wessel, Daffinrud, Munthe, et al. (2013) *Cancer Med.* **3**, 36.

## JW480

This KIAA1363 inhibitor (FW = 333.43 g/mol; CAS 1354359-53-7; Solubility: 100 mM in DMSO or Ethanol), also named 2-Isopropylphenyl(2-(naphthalen-2-yl)ethyl)carbamate, potently and selectively targets ( $IC_{50}$  = 20 nM in mouse brain) Neutral Cholesterol Ester Hydrolase 1 (NCEH), also known as Arylacetamide deacetylase-like-1 (AADACL1) or KIAA1363, a so-called serine hydrolase. Impairs migration, invasion, survival and tumor growth of prostate cancer cell lines *in vivo*. Reduces monoalkylglycerol ether (MAGE) levels. NCEH hydrolyzes 2-acetyl monoalkylglycerol ether in the pathway regulating platelet activating factor (or =PAF) levels. 1. Chang, Nomura & Cravatt (2011) *Chem Biol.* **18**, 476.

## JW642

This MAGL inhibitor (FW = 462.39 g/mol; CAS 1416133-89-5; Solubility: 100 mM in DMSO) potently and selectively targets monoacylglycerol lipase, or MAGL, ( $IC_{50}$  = 3.7 nM), displaying a remarkable 6000x selectivity for MAGL over fatty acid amide hydrolase, or FAAH, ( $IC_{50}$  = 20.6  $\mu$ M). Because the endocannabinoids 2-arachidonoyl glycerol (2-AG) and *N*-arachidonoyl ethanolamine (or anandamide) are mainly degraded by monoacylglycerol lipase (MAGL) and fatty acid amide hydrolase (FAAH), respectively, JW642 selectively blocks a decrease in 2-AG without altering anandamide levels. 1. Chang, Niphakis, Lum, et al. (2012) *Chem. Biol.* **19**, 579.

## JWH-007

This naphthoylindole family analgesic (FW = 355.47 g/mol; CAS 155471-10-6; IUPAC Name: 1-pentyl-2-methyl-3-(1-naphthoyl)indole) acts as a cannabinoid CB<sub>1</sub> and CB<sub>2</sub> receptor agonist, with  $K_d$  values of 9.5 and 2.9 nM, respectively, or around 4-5x tighter than for  $\Delta^9$ -THC (1). JHW-007 exhibits high affinity binding to dopamine transporters (DAT), but lacks cocaine-like behavioral effects and antagonizes the effects of cocaine (2). JHW-007 shifts the cocaine dose-effect curve 3.07x to the right, a behavior that is suggestive of competitive antagonism (2). JHW-007 blocks cocaine-induced reward, locomotor stimulation, and sensitization (3). This atypical dopamine transport inhibitor also prevents amphetamine-induced sensitization and synaptic reorganization within the nucleus accumbens (4). Because DAT is considered the biological target responsible for the abuse liability of cocaine, DAT ligands like JWH-007 may be viewed as potential lead molecules in searches for suitable cocaine antagonists. 1. Huffman,

Dai, Martin, *et al.* (1994) *Bioorg. Med. Chem. Lett.* **4**, 563. 2. Desai, Kopajtic, Koffarnus, Newman & Katz (2005) *J. Neurosci.* **25**, 1889. 3. Velázquez-Sánchez, Ferragud, Murga, Cardá & Canales (2010) *Eur. Neuropsychopharmacol.* **20**, 501. 4. Velázquez-Sánchez, García-Verdugo, Murga & Canales (2013) *Prog. Neuropsychopharmacol. Biol. Psychiatry* **44**, 73.

**JX 401**

This potent p38 MAP kinase inhibitor (FW = 355.50 g/mol; CAS 349087-34-9; Solubility: 75 mM in DMSO), also named 1-[2-methoxy-4-(methylthio)benzoyl]-4-(phenylmethyl)piperidine, targets p38 $\alpha$  (IC<sub>50</sub> = 32 nM), a stress-activated protein kinase that negatively regulates malignant transformation induced by oncogenic H-Ras. p38 $\alpha$  is also hyperactive in inflammatory diseases, and various indications suggest that its inhibition would reverse inflammation. JX-401 inhibits the differentiation of myoblasts to myotubes in mammalian cells in culture. JX-401 also inhibits the p38 $\gamma$  isoform, but only weakly (IC<sub>50</sub> > 10  $\mu$ M). 1. Friedmann, Shriki, Bennett, *et al.* (2006) *Mol. Pharmacol.* **70**, 1395.

**JZL 184**

This potent and selective endocannabinoid hydrolysis inhibitor (FW = 520.50 g/mol; CAS 1101854-58-3;  $\lambda_{\text{max}}$  = 284 nm), also named 4-nitrophenyl-4-(dibenzo[*d*][1,3]dioxol-5-yl)(hydroxymethyl)piperidine-1-carboxylate, targets monoacylglycerol lipase (MAGL) and fatty acid amide hydrolase (FAAH) in mouse brain membranes, with respective IC<sub>50</sub> values of 8 nM and 4  $\mu$ M. MAGL catalyzes the hydrolysis of the endocannabinoid 2-arachidonoyl glycerol (2-AG) to arachidonic acid and glycerol, thus terminating its biological function (1). FAAH also catalyzes the hydrolysis of the endocannabinoid arachidonoyl ethanolamide (AEA). When administered to mice at 16 mg/kg, intraperitoneally, JZL184 reduces MAGL activity by 85%, elevates brain 2-AG levels by 8x, and elicits analgesic activity in a variety of pain assays that qualitatively mimics direct central cannabinoid (CB<sub>1</sub>) agonists. 1. Long, Li, Booker, *et al.* (2009) *Nature Chem. Biol.* **5**, 37.

## K-252a

This cell-permeable staurosporine analogue (FW = 467.48 g/mol; Pale yellow powder; Soluble in methylene chloride, *N,N*-dimethylformamide, and dimethyl sulfoxide) is a broad-spectrum protein kinase inhibitor, acting on CaM kinase II ( $K_i = 1.8$  nM), protein kinase A ( $K_i = 18$ -25 nM), protein kinase C ( $K_i = 25$  nM), protein kinase G ( $K_i = 20$  nM), phosphorylase kinase ( $IC_{50} = 1.7$  nM), and myosin-light-chain kinase ( $K_i = 17$  nM). K-252a also inhibits the protein-tyrosine kinase activity of the NGF receptor gp140trk ( $IC_{50} = 3$  nM) and induces apoptosis and cell cycle arrest by inhibiting Cdc2 and Cdc25c. (See also *KT5720; KT5823; KT5926; K-252b*) **Target(s):** AfsK serine/threonine protein kinase (1);  $Ca^{2+}$ /calmodulin-dependent kinase II, or calmodulin kinase II (2,3); cAMP-dependent protein kinase, or protein kinase A (4); cGMP dependent protein kinase, or protein kinase G (4); cyclin-dependent kinases (5); heat-shock protein (HSP25) kinase (6); mitogen-activated protein kinase activated protein kinase-27, or [myosin light chain] kinase (8); NGF receptor (9-13); non-specific serine/threonine protein kinase (1); phosphorylase kinase (14); protein kinase C (4,15-17); trk receptor-linked protein-tyrosine kinase (12). 1. ## K-252b

This cell-permeable general protein kinase inhibitor (FW = 453.45 g/mol; Photosensitive; Pale yellow powder) is a staurosporine analogue that inhibits protein kinase A ( $K_i = 90$  nM), protein kinase C ( $K_i = 20$  nM), protein kinase G ( $K_i = 100$  nM), and myosin-light-chain kinase ( $K_i = 147$  nM). K 252b (FW free acid = 453.45 g/mol) is soluble in soluble in *N,N*-dimethylformamide and dimethyl sulfoxide. The corresponding ester K-252a is a more potent and cytotoxic agent on intact cells than K-252b, and the former dissolves more effectively into the hydrophobic interior of cell membranes (1). **Target(s):** cAMP-dependent protein kinase (2); casein kinase II-like ectokinase (3); cGMP dependent protein kinase, or protein kinase G (2); myosin-light-chain kinase (2); protein kinase C (2,4). 1. Ross, McKinnon, Daou, Ratliff & Wolf (1995) *J. Neurochem.* **65**, 2748. 2. Kase, Iwahashi, Nakanishi, et al. (1987) *Biochem. Biophys. Res. Commun.* **142**, 436. 3. Teshima, Onose, Saito, et al. ## K-579

This long-lasting hypoglycemic agent (FW free-base = 328.41 g/mol; CAS 440100-64-1; Soluble to 50 mM as mono-HCl salt; 100 mM in DMSO as the free base), also named (2*S*)-1-[[[4-methyl-1-(2-pyrimidinyl)-4-piperidinyl]amino]acetyl]-2-pyrrolidinecarbonitrile, is a slow-binding inhibitor rat, canine, human and monkey dipeptidyl peptidase IV, with  $IC_{50}$  values of 3, 5, 8, and 8 nM, respectively. K-579 preserves the endogenously secreted active forms of glucagon-like peptide-1 (Glp-1), augments insulin responsiveness, and ameliorates the hyperglycemic excursions during oral glucose tolerance test in rats. It likewise attenuates hyperglycemic excursion following glucose loading in Zucker fatty rats (1). In glibenclamide-pretreated rats, K579 significantly suppresses blood glucose elevation without excessive hypoglycemia, and continues to inhibit plasma DPP-IV even 8 h after administration (2). K579's sustained inhibitory action is due to the presence of K579 metabolites that also inhibits dipeptidyl peptidase IV (3). 1. Takasaki, Iwase, Nakajima, et al. (2004) *Eur. J. Pharmacol.* **486**, 335. 2. Takasaki, Nakajima, Ueno, Nomoto & Higo (2004) *J. Pharmacol. Sci.* **95**, 291. 3. Takasaki, Takada, Nakajima, et al. (2004) *Eur. J. Pharmacol.* **505**, 237.

## K858

This mitotic drug (FW = 277.34 g/mol; CAS 910634-41-2), also known by the code names LY2523355 and KF 89617 as well as its systematic name, targets kinesin Eg5, a mitotic motor protein that plays a key role in the M-phase of the cell cycle. Long-term continuous treatment of cancer cells with K858 results in antiproliferative effects through the induction of mitotic cell death, polyploidy, and senescence. In contrast, treatment of nontransformed cells results in mitotic slippage without cell death, but leads to cell-cycle arrest in G<sub>1</sub> phase in a tetraploid state. (See also *Litnesib (structurally related), Monastrol, Terpendole E, S-Trityl-L-cysteine*) 1. Nakai, Iida, Takahashi, et al. (2009) *Cancer Res.* **69**, 3901.

## K03861

This type II CDK2 inhibitor (FW = 501.50 g/mol; CAS 853299-07-7; Solubility: 100 mg/mL DMSO), also named *N*-[4-[(2-amino-4-pyrimidinyl)

oxy]phenyl]-*N'*-[4-[(4-methyl-1-piperazinyl)methyl]-3-(trifluoro-methyl)phenyl]urea, targets Cyclin-Dependent Kinase-2 CDK2<sup>WT</sup> ( $K_d = 50$  nM), CDK2<sup>C118L</sup> ( $K_d = 18.6$  nM), CDK2<sup>A144C</sup> ( $K_d = 15.4$  nM), and CDK2<sup>C118L/A144C</sup> ( $K_d = 9.7$  nM). 1. Alexander, Möbitz, Drueckes, *et al.* (2015) *ACS Chem Biol.* **10**, 2116.

#### K-7174

This first-in-class, orally active proteasome inhibitor and novel cell adhesion inhibitor (FW = 568.76 g/mol), also known systematically as *N,N'*-bis-(*E*)-[5-(3,4,5-trimethoxyphenyl)-4-pentenyl]homopiperazine, targets all three proteasome catalytic subunits ( $\beta_1$ ,  $\beta_2$  and  $\beta_5$ ), whereas bortezomib and other proteasome inhibitors mainly act on the  $\beta_5$  subunit (1). Perhaps, more significantly, K-7174 inhibits the growth of bortezomib-resistant myeloma cells carrying a  $\beta_5$ -subunit mutation, and also acts additively, when used in combination with bortezomib, to inhibit proteasome action and induce apoptosis in myeloma cells (1). K-7174 induces transcriptional repression of Class I histone deacetylases HDAC1, 2 and 3 via caspase-8-dependent degradation of Sp1, the most potent transactivator of Class-I HDAC genes (2). HDAC1 overexpression ameliorates K-7174's cytotoxic effect and abrogates histone hyperacetylation without affecting the accumulation of ubiquitinated proteins in treated myeloma cells. K-7174 is also more effective when administered by oral, rather than an intravenous route. K-7174 is also novel cell adhesion inhibitor that blocks adhesion of monocytes to cytokine-stimulated endothelial cells by reducing endothelial VCAM-1 induction by binding to the GATA motifs in the VCAM-1 gene promoter region (3). Importantly, K-7174 did not influence the binding to any of the following binding motifs: octamer binding protein, AP-1, SP-1, ets, NF $\kappa$ B, or interferon regulatory factor, suggesting that the regulation of GATA binding may be a new druggable target for anti-inflammatory agents that act through a NF $\kappa$ B-independent mechanism (3). 1. Kikuchi, Shibayama, Yamada, *et al.* (2013) *PLoS One* **8**, e6064. 2. Kikuchi, Yamada, Koyama *et al.* (2013) *J. Biol. Chem.* **288**, 25593. 3. Umetani, Nakao, Doi, *et al.* (2000) *Biochem. Biophys. Res Commun.* **272**, 370.

#### K41448

This highly selective and peripherally acting CRF<sub>2</sub> antagonist (MW = 3632.26 g/mol; CAS 434938-41-7; Sequence: D-Phe-His-Leu-Leu-Arg-Lys-Nle-Ile-Glu-Ile-Glu-Lys-Gln-Gln-Ala-Ala-Asn-Asn-Arg-Leu-Leu-Leu-Asp-Thr-Ile-NH<sub>2</sub>; Solubility: 5 mg/mL H<sub>2</sub>O) targets human Corticotropin-Releasing hormone (CRH) Receptor-2 subtypes CRF<sub>2 $\alpha$</sub>  and CRF<sub>2 $\beta$</sub> , with  $K_i$  values of 0.66 and 0.62 nM, respectively, but with a much higher value of 425 nM for CRF<sub>1</sub>. (See also *Antisauvagine-30*; *Astressin*) Found in plasma membranes of hormone-sensitive cells, these Type-2 GPCRs bind Corticotropin-Releasing Hormone (CRH), a neurotransmitter peptide involved in stress responses. Produced by parvocellular neuroendocrine cells in the paraventricular nucleus of the hypothalamus, CRH is released into the primary capillary plexus of the hypothalamo-hypophyseal portal system. CRH is also synthesized by the placenta and appears to play a role in parturition. An analogue of antisauvagine-30, K41448 inhibits sauvagine-stimulated cAMP accumulation in hCRF<sub>2 $\alpha$</sub> - and hCRF<sub>2 $\beta$</sub> -expressing cells. In rats, K41448 blocks urocortin-induced hypotension after systemic administration. 1. Lawrence, *et al.* (2002) *Brit. J. Pharmacol.* **136**, 896. 2. Ruhmann, *et al.*, (2002) *Peptides* **23**, 453.

#### Kahweol

This anticarcinogenic agent (FW = 314.42 g/mol; CAS 6894-43-5; (3*b*S,5*a*S,7*R*,8*R*,10*a*R,10*b*S)-3*b*,4,5,6,7,8,9,10,10*a*,10*b*-decahydro-7-

hydroxy-10*b*-methyl-5*a*,8-methano-5*a*H-cyclohepta(5,6)naphtho(2,1-*b*)furan-7-methanol, is an antioxidant coffee diterpenoid that, among its many actions, inhibits cytochrome P450 enzymes (1-3). Kahweol prevents osteoclastogenesis by impairing NFATc1 expression and by blocking Erk phosphorylation (4). It also suppresses cell proliferation by inducing proteasomal degradation of cyclin D<sub>1</sub> via ERK1/2-, JNK- and GSK3 $\beta$ -dependent threonine-286 phosphorylation in human colorectal cancer cells (5). Indeed, epidemiologic evidence suggests a positive correlation between coffee consumption and a reduced risk of cancer and cirrhosis. Among the mechanisms likely to account for these chemoprotective effects are induction of conjugating enzymes (*e. g.*, glutathione *S*-transferases, glucuronosyl *S*-transferases), increased expression of cellular defense enzymes (*e. g.*,  $\gamma$ -glutamyl cysteine synthetase and heme oxygenase-1), and reduced CYP expression, perhaps decreasing carcinogen activation (6). **Targets:** 4-aminobiphenyl hydroxylation (2); CYP1A1 (1); CYP2B6 (1,3). 1. Cavin, Holzhaeuser, Scharf, *et al.* (2002) *Food Chem. Toxicol.* **40**, 1155. 2. Hammons, Fletcher, Stepps, *et al.* (1999) *Nutr. Cancer* **33**, 46. 3. Cavin, Mace, Offord & Schilter (2001) *Food Chem. Toxicol.* **39**, 549. 4. Fumimoto, Sakai, Yamaguchi, *et al.* (2012) *J. Pharmacol. Sci.* **118**, 479. 5. Park, Song & Jeong (2016) *Food Chem. Toxicol.* **95**, 142. 6. Cavin, Holzhaeuser, Scharf, *et al.* (2002) *Food Chem. Toxicol.* **40**, 1155.

#### Kainate (Kainic Acid)

This cyclic analogue of L-glutamate and marine natural product (FW<sub>free-acid</sub> = 213.23 g/mol; CAS 487-79-6), also known as (2*S*,3*S*,4*S*)-2-carboxy-4-(1-methylethenyl)-3-pyrrolidineacetic acid and digenic acid, is an agonist for the kainate class of glutamate receptors, inducing seizures and neurodegeneration. Kainate receptor agonists depress transmitter release at synapses in the hippocampus. Distinct mechanisms appear to underlie this phenomenon at different synapses. Pre-synaptic kainate receptors can also potentiate the release of both GABA and glutamate. **Target(s):** choline *O*-acetyltransferase. 1. Loureiro-Dos-Santos, Reis, Kubrusly, *et al.* (2001) *J. Neurochem.* **77**, 1136.

#### Kallistatin

This serpin (MW = 48.5 kDa), also known as protease inhibitor 4, is an acidic protein (Isoelectric Point = 4.6-5.2) that forms a 1:1 covalent complex with tissue kallikrein. Heparin blocks kallistatin: kallikrein complex formation. (For a discussion of the likely mechanism of inhibitory action, See *Serpins*; also  $\alpha_1$ -Antichymotrypsin) 1. Chao (1998) in *Handb. Proteolytic Enzymes*, p. 97, Academic Press, San Diego. 2. Zhou, Chao & Chao (1992) *J. Biol. Chem.* **267**, 25873. 3. Chao, Chai, Chen, *et al.* (1990) *J. Biol. Chem.* **265**, 16394. 4. #### Kanamycins

These aminoglycoside antibiotics produced by *Streptomyces kanamyceticus* include the major component Kanamycin A (FW<sub>free-base</sub> = 484.50 g/mol),

Kanamycins B (FW<sub>free-base</sub> = 483.52 g/mol), and Kanamycins C (FW<sub>free-base</sub> = 484.50 g/mol) varying only in the 6-glucosamine component. All are soluble in water (particularly as the sulfate salts) and each has antibacterial activity. (Numbers adjacent to the amino groups in kanamycin B correspond to the pK<sub>a</sub> values.) **Primary Mode of Action:** Kanamycins bind to both the 50S and 70S ribosomal subunits, inhibiting initiation and elongation and thus protein biosynthesis (1,2). The peptidyl-tRNA is fixed to the A-site of the ribosome. In addition, the kanamycins also inhibit the release of tRNA. Binding to the 16S component (near nucleotide 1400 of *Escherichia coli* 16S, with two adenine residues, 1408 and 1493 playing essential roles in binding) decreases the rate of dissociation of aminoacyl-tRNA, thus inhibiting processivity and resulting in miscoding. **Target(s):** cellulose 1,4-β-cellobiosidase (3); DNA-directed DNA polymerase (Klenow DNA polymerase) (4); gentamicin 3'-N-acetyltransferase, inhibited by kanamycins A and C (5); kanamycin 6'-acetyltransferase, by kanamycin C, but not kanamycin A (6); ornithine decarboxylase (7); phosphatidylinositol-specific phospholipase C (8); phospholipase D (9); protein biosynthesis (initiation and elongation) (1,2); poly(A)-specific ribonuclease (4); protein kinase C (10); ribonuclease P (11,12); ribozymes, group I (13); streptomycin 3'-adenyltransferase (14). 1. Pestka (1974) *Meth. Enzymol.* **30**, 261. 2. Jiménez (1976) *Trends Biochem. Sci.* **1**, 28. 3. Singh, Agrawal, Abidi & Darmwal (1990) *J. Gen. Appl. Microbiol.* **36**, 245. 4. ### Katanosins

These cyclic depsipeptide antibiotics (FW<sub>Katanosin-A</sub> = 1262.47 g/mol; CAS 116103-86-7; (FW<sub>Katanosin-B</sub> = 1276.49 g/mol; CAS 116340-02-4) from the culture broth of a strain related to the genus *Cytophaga* exhibit strong antimicrobial activity against methicillin-resistant *Staphylococcus aureus* and VanA-type vancomycin-resistant *enterococci*, with MICs ranging from 0.39 to 3.13 μg/mL, as well as against other Gram-positive bacteria (1). They inhibit incorporation of *N*-acetylglucosamine, a precursor of cell wall synthesis, into peptidoglycan of *S. aureus* whole cells at concentrations close to their MICs. *Note:* In katanosin B, the Val residue is replaced by Ile. 1. Maki, Miura & Yamano (2001) *Antimicrob. Agents Chemother.* **45**, 1823.

### Kasugamycin

This aminoglycoside antibiotic (FW = 379.37 g/mol) from a strain of *Streptomyces kasugaensis* inhibits prokaryotic protein biosynthesis (1,2) by binding to the 30S ribosomal subunit. It inhibits initiation-complex formation. In addition, kasugamycin will block translation in fungal systems at pH 4–5. Interestingly, translation of leaderless mRNA continues in the presence of kasugamycin (3). The amino sugar kasugamine (*i.e.*, 2,4-diamino-2,3,4,6-tetraoxo-D-arabino-hexose) is a component. Kasugamycin should be stored dry and at 4°C. 1. Pestka (1974) *Meth. Enzymol.* **30**, 261. 2. Jiménez (1976) *Trends Biochem. Sci.* **1**, 28. 3. Moll & Blasi (2002) *Biochem. Biophys. Res. Commun.* **297**, 1021. 4. Okuyama, Machiyama, Kinoshita & Tanaka (1971) *Biochem. Biophys. Res. Commun.* **43**, 196. 5. Masukawa, Tanaka & Umezawa (1968) *J. Antibiot. (Tokyo)* **21**, 73. 6. Tanaka, Yoshida, Sashikata, Yamaguchi & Umezawa (1966) *J. Antibiot. (Tokyo)* **19**, 65.

### KB-R7943

This potent and selective inhibitor (FW = 427.29 g/mol; CAS 182004-65-5; Solubility: 100 mM in DMSO; Stable at room temperature), also named 2-[2-[4-(4-nitrobenzyloxy)phenyl]ethyl]isothiourea mesylate, targets reverse mode of the Na<sup>+</sup>/Ca<sup>2+</sup> exchanger, or NCX, IC<sub>50</sub> = 0.7 μM (1). KB-R7943 significantly improves recovery of population spike amplitudes in rat hippocampal slices by inhibiting the Na<sup>+</sup>/Ca<sup>2+</sup> exchanger, operating in reverse mode, contributes to hypoxia/hypoglycemia-induced injury in CA1 neurons (2). KB-R7943 also suppresses ouabain-induced arrhythmias by inhibiting the reverse-mode NCX (3). KB-R7943 also potently inhibits the mitochondrial Ca<sup>2+</sup> uniporter (MCU). In permeabilized HeLa cells, KB-R7943 inhibits mitochondrial Ca<sup>2+</sup> uptake (K<sub>i</sub> = 5.5 μM). In intact cells, KB-R7943 (10 μM) reduces the histamine-induced mitochondrial [Ca<sup>2+</sup>] peak by 80%. KB-R7943 does not modify the mitochondrial membrane potential and is without effect on the mitochondrial Na<sup>+</sup>/Ca<sup>2+</sup> exchanger (4). KB-R7943 inhibits histamine-induced ER-Ca<sup>2+</sup> release in intact cells, but not in cells loaded with a Ca<sup>2+</sup>-chelator to dampen cytosolic [Ca<sup>2+</sup>] changes (4). Inhibition of ER-Ca<sup>2+</sup>-release by KB-R7943 was probably due to the increased feedback Ca<sup>2+</sup>-inhibition of inositol 1,4,5-trisphosphate receptors after MCU block. 1. Hoyt, Arden, Aizenman & Reynolds (1998) *Mol. Pharmacol.* **53**, 742. 2. Schröder et al (1999) *Neuropharmacology* **38**, 319. 3. Watano, Harada, Harada & Nishimura (1999) *Brit. J. Pharmacol.* **127**, 1846. 4. Santo-Domingo et al (2007) *Brit. J. Pharmacol.* **151**, 647.

### Kelatorphan

This potent neprilysin inhibitor (FW<sub>free-acid</sub> = 294.31 g/mol), also known as [(*R*)-3-(*N*-hydroxy)carboxamide-2-benzylpropanoyl]-L-alanine, is the first complete inhibitor of enkephalin metabolism and the only compound with analgesic activity exceeding the combined action of thiorphan and bestatin. **Target(s):** dactylisin (1); leukotriene-A<sub>4</sub> hydrolase (2,3); membrane alanyl aminopeptidase, also known as aminopeptidase N, K<sub>i</sub> = 380 nM (4,5); neprilysin, K<sub>i</sub> = 1.8 nM (4,5). 1. Carvalho, Joudiou, Boussetta, Leseny & Cohen (1992) *Proc. Natl. Acad. Sci. U.S.A.* **89**, 84. 2. Penning (2001) *Curr. Pharm. Des.* **7**, 163. 3. Haeggström, Kull, Rudberg, Tholander & Thunnissen (2002) *Prostaglandins* **68** **69**, 495. 4. Roques, Noble, Crine & Fournié-Zaluski (1995) *Meth. Enzymol.* **248**, 263. 5. Bauvois & Dauzonne (2006) *Med. Res. Rev.* **26**, 88.

**Kenpaullone**

This relatively nonselective paullone-derived protein kinase inhibitor (FW = 327.18 g/mol; CAS 142273-20-9; Solubility: 65 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as 9-bromo-7,12 dihydroindolo[3,2-*d*][1]benzazepin-6(5*H*)-one and NSC-664704, potently inhibits cyclin-dependent protein kinases, glycogen synthase kinase-3 $\beta$ , c-Src, casein kinase II, ERK1 (extracellular-regulated kinase-1), and ERK2. **Target(s):** casein kinase 2 (1); c-Src (1); cyclin-dependent kinase, or cyclin-dependent protein kinase 1/cyclin B, IC<sub>50</sub> = 0.4  $\mu$ M (1-3); cyclin-dependent protein kinase 2/cyclin A, IC<sub>50</sub> = 0.68  $\mu$ M (1,4); cyclin-dependent protein kinase 2/cyclin E, IC<sub>50</sub> = 7.5  $\mu$ M (1); cyclin-dependent protein kinase 5, IC<sub>50</sub> = 0.85  $\mu$ M (1); ERK1, or extracellular-regulated kinase 1 (1); ERK2, or extracellular-regulated kinase 2 (1); glycogen synthase kinase 3 $\beta$ , or [tau protein] kinase, IC<sub>50</sub> = 0.23  $\mu$ M (4,5); Lck protein-tyrosine kinase (4); lymphocyte kinase, IC<sub>50</sub> = 0.47  $\mu$ M (4); mitogen-activated protein kinase (4); non-specific serine/threonine protein kinase (1,4); protein-tyrosine kinase, or nonspecific protein-tyrosine kinase (4). **1.** Zaharevitz, Gussio, Leost, *et al.* (1999) *Cancer Res.* **59**, 2566. **2.** Schultz, Link, Leost, *et al.* (1999) *J. Med. Chem.* **42**, 2909. **3.** Woodard, Li, Kathcart, *et al.* (2003) *J. Med. Chem.* **46**, 3877. **4.** Bain, McLauchlan, Elliott & Cohen (2003) *Biochem. J.* **371**, 199. **5.** Cole, Frame & Cohen (2004) *Biochem. J.* **377**, 249.

**Ketamine**

This once commonly used dissociative anesthetic (FW<sub>ketamine</sub> = 237.73 g/mol; CAS 6740-88-1; IUPAC Name: (*RS*)-2-(2-chlorophenyl)-2-(methylamino)cyclohexanone; HCl salt is very soluble, 20 g/100 mL H<sub>2</sub>O) is a noncompetitive NMDA (*N*-methyl-D-aspartate) receptor antagonist. When administered at the higher doses required for anesthesia, ketamine is hallucinogenic, inducing schizophrenia-like symptoms, amnesia, loss of consciousness, and immobility. These properties explain why ketamine is not typically used as a primary anesthetic (although it becomes the anesthetic of choice when a reliable ventilator is unavailable) (1). **Mechanism of Ketamine Action:** Ketamine acts on the Central Nervous System, exerting both general and local anaesthetic properties that are mediated by noncompetitive antagonism of the NMDA receptor's Ca<sup>2+</sup> channel pore. Channel blockade appears to be the primary source of its anaesthetic and analgesic properties. Ketamine also reduces presynaptic glutamate release. The *S*(+) enantiomer has a three- to four-fold greater affinity for the NMDA receptor than the *R*(-) form. The *S*(+)-enantiomer inhibits more effectively than *R*(-)-isomer and shows fewer side effects. Ketamine also increases the phosphorylation of the transcription factor cAMP response element-binding protein (pCREB) and neurotrophic factor/tropomyosin related kinase B receptor (pTrkB) in the prefrontal cortex (PFC), and decreased pCREB in the hippocampus (2). The MEK inhibitor PD184161 abolishes ketamine's effects in the hippocampus (2). **(See also Phenacyclidine) Pharmacokinetics:** In humans, plasma ketamine concentration-time curves fit a two-compartment open model with a terminal *t*<sub>1/2</sub> of 186 min (3). Absorption after intramuscular injection was rapid and the bioavailability was 93%; however, only 17% of an oral dose was absorbed because of extensive first-pass metabolism (3). **Metabolism:** Ketamine's immediate metabolic products are norketamine (FW = 223.70 g/mol; CASs = 35211-10-0 (free base); 79499-59-5 (HCl salt); IUPAC = 2-amino-2-(2-chlorophenyl)cyclohexan-1-one); and *cis*-6-hydroxy-

norketamine (FW = 239.70 g/mol; CAS 81395-70-2; IUPAC: 2-amino-2-(2-chlorophenyl)-6-hydroxycyclohexan-1-one).

The former is a potent non-competitive NMDA receptor antagonist (*K*<sub>i</sub> = 3.6  $\mu$ M), whereas the latter increases AMPA receptor-mediated excitatory post-synaptic potentials in hippocampal slices. **Ketamine Abuse:** Ketamine is listed as a controlled substance under the United States Controlled Substance Act. Given the relative ease of its synthesis, ketamine is a widely abused recreational. Known by the street names "K", Special K, Vitamin K, or Lady K, ketamine displays potent PCP- and DXM-like qualities. Broadly classified as a dissociative anesthetic, ketamine distorts sight and sound perception, producing feelings of detachment and often inducing hallucinations. The onset of its effects depends on the mode of ingestion: 1-5 minutes, upon injection; 5-15 minutes, upon snorting the dry powder; 5-30 minutes, orally. A dose of 1-2 mg/kg body-weight produces an intense experience lasting ~1 hour. Side effects include flashbacks, amnesia, impaired motor functioning, hallucinations, disorientation, tachycardia, muscle rigidity, loss of coordination, sense of invulnerability, aggressive and/or violent behavior, and, in cases of overdose, death. Chronic use of ketamine alters apoptotic markers in the prefrontal cortex and causes abnormal walking, jumping, and climbing. **Target(s):** acetylcholinesterase (4); cholinesterase (5); K<sup>+</sup> channels, neuronal (6); Na<sup>+</sup> channels, voltage-gated (7); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (8); nicotinic acetylcholine receptors, neuronal (9); NMDA receptor (10). Ketamine also suppresses proinflammatory cytokine production in human whole blood *in vitro* (11). Curiously, a single dose of ketamine produces rapid (commencing within 2 hours) and sustained (lasting >7 days) antidepressant efficacy in treatment-resistant patients (12). **1.** Pai & Heining (2007) *Contin. **Ketene**

This powerful acetylating agent (FW = 42.04 g/mol; M.P. = -150°C; B.P. = -56°C), which is prepared by the thermal decomposition of acetone, diketene, or acetic anhydride, is an acylating agent that reacts with nucleophilic groups in proteins. Ketene is toxic, and all work with it should be conducted in a fume hood. **(See also Diketene) Target(s):** alkaline phosphatase (1,2); amylase, pancreatic (3); chymotrypsin (4); diphtheria toxin (5); papain (6); pepsin, with *O*-acetylation (not *N*-acetylation) of the latter leading to inactivation (7-10). **1.** Fernley (1971) *The Enzymes*, 3rd ed., **4**, 417. **2.**

### 2-Ketoadipate (2-Oxadipate)

This  $\alpha$ -keto acid (FW<sub>free-acid</sub> = 160.13 g/mol), also called  $\alpha$ -ketoadipic acid, 2-oxoadipic acid, and 2-oxohexanedioic acid, is an intermediate in the degradation of L-lysine and L-tryptophan. It is also an intermediate in the pathway for L-lysine biosynthesis in fungi. **Target(s):** 4-aminobutyrate aminotransferase (1); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or 3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring) kinase (2-4);  $\gamma$ -butyrobetaine dioxygenase, or  $\gamma$ -butyrobetaine hydroxylase,  $K_i$  = 0.17 mM (5); 4-hydroxy-4-methyl-2-oxoglutarate aldolase (6); kynurenine:oxoglutarate aminotransferase (7,8); lactate dehydrogenase (9); 3-oxoadipate CoA-transferase (10); phospho-enolpyruvate carboxylase, weakly inhibited (11); procollagen-lysine 5-dioxygenase (12); procollagen-proline 3-dioxygenase (12); procollagen-proline 4-dioxygenase (12-14); pyrimidine-deoxynucleoside 2'-dioxygenase, or thymidine,  $\alpha$ -ketoglutarate dioxygenase (15,16); pyruvate carboxylase (17); saccharopine dehydrogenase (18). **1.** Schousboe, Wu & Roberts (1974) *J. ### 3-Ketoadipate (3-Oxadipate)

This  $\beta$ -keto acid (FW<sub>free-acid</sub> = 160.13 g/mol), also called  $\beta$ -ketoadipic acid, 3-oxoadipic acid, and 3-oxohexanedioic acid, is an intermediate in the degradation of a number of aromatic compounds by bacteria. It has a melting point of 124-125°C and is slightly soluble in water. It generates a violet color with FeCl<sub>3</sub>. 3-Ketoadipate is a product of the reactions catalyzed by 3-oxoadipate enol-lactonase and maleylacetate reductase. It is also substrate for 3-oxoadipate CoA transferase. **Target(s):** deacetoxycephalosporin-C synthase (1); kynurenine aminotransferase (2); 3-oxoadipate enol-lactonase, or  $\beta$ -ketoadipate enol-lactonase (3); porphobilinogen synthase, or  $\delta$ -aminolevulinic acid dehydratase (4); pyridoxamine:oxaloacetate aminotransferase (5); pyrimidine deoxynucleoside 2'-dioxygenase, or thymidine,  $\alpha$ -ketoglutarate dioxygenase (6,7). **1.** Cortés, Martín, Castro, Láiz & Liras (1987) *J. ### 2-Keto-3-butyrate (2-Oxo-3-butyrate)

This acetylenic  $\alpha$ -keto acid (FW<sub>free-acid</sub> = 98.06 g/mol) is a mechanism-based inhibitor that irreversibly inactivates a number of flavoproteins. 2-Hydroxy-3-butyrate is both a substrate and an irreversible inactivator of the flavoenzyme L-lactate oxidase. The partitioning between catalysis and inactivation is determined by the concentration of the secoGnd substrate, dioxygen. The common intermediate that forms in these two pathways is a charge-transfer complex between enzyme-reduced flavin and 2-keto-3-butyrate. Inactivation occurs by covalent modification of the enzyme-bound cofactor and does not involve labeling of the apoprotein. The spectrum of the enzyme bound adduct suggests a 4a,5-adduct. **Target(s):** flavocytochrome *b*<sub>2</sub>, or L-lactate dehydrogenase (cytochrome) (1,2); L-hydroxyacid oxidase (3,4); lactate oxidase (5,6); 4-oxalocrotonate tautomerase (7); pyruvate decarboxylase (8); pyruvate dehydrogenase (8); pyruvate oxidase (8). **1.** Pompon & Lederer (1982) *Eur. ### 2-Ketobutyrate (2-Oxobutyrate)

This  $\alpha$ -keto acid (FW<sub>free-acid</sub> = 102.09 g/mol; Water-soluble; pK<sub>a</sub> = 2.5), also known as  $\alpha$ -ketobutyric acid, 2-oxobutyric acid, and 2-oxobutanoic acid, is formed from L-threonine by the action of threonine dehydratase. It is also produced in the degradation of L-methionine. 2-Ketobutyrate is the substrate of the reactions catalyzed by 2-ethylmalate synthase. It is an alternative substrate for  $\alpha$ -keto-acid dehydrogenase. **Target(s):** acetolactate synthase, or acetohydroxy acid synthase (1-3,25,26); aldehyde reductase, or aldose reductase (4); D-amino-acid oxidase (5); [branched-chain  $\alpha$ -keto acid dehydrogenase] kinase (6);  $\gamma$ -butyrobetaine dioxygenase, or  $\gamma$ -butyrobetaine hydroxylase,  $K_i$  = 1.3 mM (7); carbamoyl-phosphate synthetase I (8); deacetoxycephalosporin-C synthase (27); 2-dehydro-3-deoxy-L-arabinonate dehydratase (9); dihydrodipicolinate synthase (10); fumarylacetoacetase (11); 4-hydroxy-4-methyl-2-oxoglutarate aldolase (12); 4-hydroxy-2-oxoglutarate aldolase (13); malic enzyme (14); 3-mercaptopurinate sulfurtransferase (15); methylmalonyl-CoA carboxyltransferase, or transcarboxylase (16,17); ornithine  $\delta$ -aminotransferase (18); phosphoenolpyruvate carboxykinase (19); phosphoenolpyruvate carboxykinase (GTP) (19); phosphoenolpyruvate:glycose phosphotransferase transport system (20); procollagen-proline 3-dioxygenase (28); procollagen-proline 4-dioxygenase (28,29); pyruvate dehydrogenase, as alternative substrate (21,22); [pyruvate dehydrogenase (acetyl transferring)] kinase (23); saccharopine dehydrogenase (24). **1.** Shaw & Berg (1980) *J. ### 2-Ketocaproate (2-Oxocaproate)

This  $\alpha$ -keto acid (FW<sub>free-acid</sub> = 130.14 g/mol), also known as  $\alpha$ -ketocaproic acid, 2-oxocaproic acid, and 2-oxohexanoic acid, is an alternative substrate for a number of aminotransferases and inhibits [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase. **Target(s):** aldehyde reductase, *or* aldose reductase (1); branched-chain  $\alpha$ -keto-acid dehydrogenase (2); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, *or* [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (3); ornithine  $\delta$ -aminotransferase (4); saccharopine dehydrogenase (5). **1.** Hayman & Kinoshita (1965) *J. Biol. Chem.* **240**, 877. **2.** Paxton & Harris (1984) *Arch. Biochem. Biophys.* **231**, 48. **3.** Paxton (1988) *Meth. Enzymol.* **166**, 313. **4.** Strecker (1965) *J. Biol. Chem.* **240**, 1225. **5.** Fujioka & Nakatani (1972) *Eur. J. Biochem.* **25**, 301.

### Ketoconazole

This synthetic oral antifungal and anti-androgen (FW = 531.43 g/mol; CAS 65277-42-1; *Symbol*: KCZ), also known as Nizoral™, Sebizole™, and Ketomed™, and systematically as 1-[4-(4-[[[(2R,4S)-2-(2,4-dichlorophenyl)-2-(1H-imidazol-1-ylmethyl)-1,3-dioxolan-4-yl]methoxy]phenyl]piperazin-1-yl]ethan-1-one, is widely used clinically to treat fungal skin infections in immunocompromised patients, especially those with HIV-AIDS. **Primary Mode(s) of Action:** Ketoconazole interferes with the fungal ergosterol synthesis, thereby depriving fungal membranes of an essential constituent. Like fluconazole and itraconazole, ketoconazole inhibits the enzyme cytochrome P450 14 $\alpha$ -demethylase (*or* P45014DM) enzyme, which catalyzes the conversion of lanosterol into ergosterol (1). As an anti-androgen, ketoconazole blocks both testicular and adrenal androgen biosynthesis and is also a weaker androgen receptor antagonist (2). A third antifungal action is ketoconazole inhibition of mitochondrial NADH oxidase (3). Ketoconazole inhibition of triazolam  $\alpha$ - and 4-hydroxylation, midazolam  $\alpha$ -hydroxylation, testosterone 6 $\beta$ -hydroxylation, and nifedipine oxidation appeared to be a mixed competitive-noncompetitive process, with the noncompetitive component being dominant but not exclusive (4). Quantitative estimates of  $K_i$  were in the low-nanomolar range for all four substrates (4). **Target(s):** cortisol secretion of an adrenal adenoma *in vivo* and *in vitro* (5); adrenal steroidogenesis by inhibiting cytochrome P450-dependent enzymes (6); adrenocorticotropic hormone stimulated cyclicAMP production (6); leukotriene biosynthesis *in vitro* and *in vivo* (7); Cytochrome P450 CYP27-catalyzed oxidation of C27-steroid into C27-acid (8). A recent study found that KCZ inhibits the following P450 steroidogenic enzymes in a selective and dose-dependent manner: cholesterol side-chain cleavage cytochrome P450, *or* CYP11A1/P450scc (IC<sub>50</sub> = 0.56  $\mu$ M), 17 $\alpha$ -hydroxylase activity of CYP17A1/P450c17 (IC<sub>50</sub> = 3.36  $\mu$ M), and CYP19A1/P450arom (IC<sub>50</sub> = 0.56  $\mu$ M). At 10  $\mu$ g KCZ per mL, the following enzymes were unaffected: CYP17A1's 17,20 lyase

activity and five non-cytochrome steroidogenic enzymes (3 $\beta$ -hydroxysteroid dehydrogenase- $\Delta^{5,4}$  isomerase type 1, *or* 3 $\beta$ HSD1; 5 $\alpha$ -reductase; 20 $\alpha$ -hydroxysteroid dehydrogenase, *or* 20 $\alpha$ -HSD; 3 $\alpha$ -hydroxysteroid dehydrogenase, *or* 3 $\alpha$ -HSD; and 17 $\beta$ -hydroxysteroid dehydrogenase, type 1, *or* 17HSD1 (9)). **1.** Reinhardt & Horst (1989) *Arch. ### 2-Keto-D-gluconate (2-Oxo-D-gluconate)

This ketoadonic acid (FW<sub>free-acid</sub> = 194.14 g/mol), also called 2-dehydro-D-gluconic acid, 2-oxo-D-gluconic acid, D-glucosonic acid, fructuronic acid, and D-arabino-hexalulosonic acid, is a hygroscopic solid that is soluble in water. **Target(s):** cellobiose phosphorylase (1,2); 2-dehydro-3-deoxyglucuronate aldolase (3); tagaturonate reductase (4). **1.** Sasaki (1988) *Meth. Enzymol.* **160**, 468. **2.** Sasaki, Tanaka, Nakagawa & Kainuma (1983) *Biochem. J.* **209**, 803. **3.** Fish & Blumenthal (1966) *Meth. Enzymol.* **9**, 529. **4.** Portalier & Stoeber (1982) *Meth. Enzymol.* **89**, 210.

### $\alpha$ -Ketoglutarate ( $\alpha$ -Oxoglutarate)

This common  $\alpha$ -keto-dicarboxylic acid (FW<sub>free-acid</sub> = 146.10 g/mol; *Symbol*:  $\alpha$ -KG, 2-OG), also called 2-oxoglutaric acid and 2-oxopentanedicarboxylic acid, is a key intermediate in the tricarboxylic acid cycle and is a co substrate/product for many aminotransferases and other enzymes. It is also produced by oxidative deamination of glutamate.  $\alpha$ -Ketoglutaric acid is soluble in water and ethanol and slightly soluble in diethyl ether. It melts at 113.5°C and has pKa values of 2.47 and 4.68 (at 25°C). Note that this  $\alpha$ -keto acid is in equilibrium with the *gem*-diol and a cyclic lactol, *i.e.*, 5-hydroxy-2-oxo 5-tetrahydrofuran-2-carboxylic acid (1). <sup>13</sup>C-NMR indicates that the  $\alpha$ -keto acid is the predominant form at neutral pH with 7% *gem*-diol and a small amount of the lactol present (2). The relative amount of lactol increases with lower pH. With both carboxyl groups protonated there are relative amounts are 35%  $\alpha$ -keto acid, 30% lactol, and 35% *gem*-diol. Under slightly different conditions at pH 0.5 in D<sub>2</sub>O, the reported values are 31%, 16%, and 53% (1). **Target(s):** 2-(acetamidomethylene)-succinate hydrolase (3); acetoacetate decarboxylase (4); alanopine dehydrogenase (5); aldehyde reductase, *or* aldose reductase (6); aminocyclopropanecarboxylate oxidase (129); aminolevulinate aminotransferase (117-120); 5-aminolevulinate synthase (7); asparagine synthetase (8,9); D-aspartate oxidase (10); carbamoyl phosphate synthetase (11-13); choline acetyltransferase (14-16); citrate lyase, weakly inhibited (17); [citrate lyase] deacetylase, weakly inhibited (105); citrate (*re*)-synthase (123); citrate (*si*) synthase (18,19,124-128); cyanate hydratase (cyanase)20; cystathionine  $\gamma$ -lyase21; cysteine dioxygenase133; 3,4-dihydroxyphenylalanine oxidative deaminase (131); exo- $\alpha$ -sialidase, *or* neuraminidase, *or* sialidase (103); fumarase, *or* fumarate hydratase (22); fructose-1,6-bisphosphate aldolase (23); fumarylacetoacetase (24); glucose-6-phosphatase (104); glucose-6-phosphate dehydrogenase (25); glucose-6-phosphate isomerase, weakly inhibited (26); glutamate carboxypeptidase II (27); glutamate decarboxylase,  $K_i$  = 0.63 mM (28-32); glutamate racemase (33); glutaminase (34-36); glutamine synthetase (37-39); [glutamine-synthetase] adenyllyltransferase (37,40,41,110-112); D-2-hydroxyacid dehydrogenase (42,43); 4-hydroxy-4-methyl-2 ketoglutarate aldolase, *or* 4-hydroxy-4-

methyl-2-oxoglutarate aldolase (44-46); 4-hydroxy-2 oxoglutarate aldolase, or 2-keto-4-hydroxyglutarate aldolase (47,48); indolepyruvate decarboxylase (49); inositol oxygenase (130); isocitrate dehydrogenase (NAD<sup>+</sup>) (51); [isocitrate dehydrogenase (NADP<sup>+</sup>)] kinase (50,106); isocitrate lyase (52-56); kynurenine 3-monooxygenase (57); lactase-phlorizin hydrolase, or glycosylceramidase (102); D-lactate dehydrogenase (cytochrome) (58); L-lactate dehydrogenase (42,59); lysine 2-monooxygenase (132); malate dehydrogenase (60,61); 3-mercaptopyruvate sulfurtransferase (62); methylaspartate mutase, or glutamate mutase (63); N-methylglutamate dehydrogenase (64); nicotinate nucleotide diphosphorylase (carboxylating) (121,122); oxaloacetate decarboxylase, weakly inhibited (65); oxaloacetate tautomerase (66); phosphoenolpyruvate carboxykinase, or weakly inhibited (67); phosphoenolpyruvate carboxykinase (GTP) (67-71); phosphoenolpyruvate carboxylase (72-79); phosphoenolpyruvate mutase (80); 6-phosphofructokinase (81-83,115,116); pyridoxamine: oxaloacetate aminotransferase (84); pyridoxamine-5-phosphate oxidase (85); pyruvate carboxylase (86-92); pyruvate decarboxylase, weakly inhibited (42,93); pyruvate kinase (94,113,114); pyruvate,water dikinase (107-109); ribulose-bisphosphate carboxylase/oxygenase (97); succinyl-CoA synthetase (ADP-forming), or succinate:CoA ligase (ADP-forming) (98); thiosulfate sulfurtransferase, or rhodanase (95,96); threonine ammonia-lyase, or threonine dehydratase (99,100); tyrosine 2,3 aminomutase (101). 1. ### 3-Ketoglutarate (3-Oxoglutarate)

This  $\beta$ -keto dicarboxylic acid (FW free acid = 146.10 g/mol), also known as 3-oxoglutaric acid and acetonedicarboxylic acid, is an inhibitor of  $\gamma$ -butyrobetaine hydroxylase. Note that this water soluble acid decomposes in hot water, acids, and alkalis to acetone and carbon dioxide. **Target(s):** acetoacetate decarboxylase (1); aldehyde reductase, or aldose reductase (2);

$\gamma$ -butyrobetaine dioxygenase, or  $\gamma$ -butyrobetaine hydroxylase;  $K_i = 0.29$  mM (3); hyoscyamine (6S)-dioxygenase (4); procollagen-lysine 5-dioxygenase (5); procollagen-proline 3-dioxygenase (5); procollagen-proline 4-dioxygenase (5,6); pyrimidine-deoxynucleoside 2'-dioxygenase, or thymidine:2 oxoglutarate dioxygenase (7). 1. ### 2-Ketoisocaproate (2-Oxoisocaproate)

This  $\alpha$ -keto acid (FW<sub>free-acid</sub> = 130.14 g/mol; M.P. = -2 °C; B.P. = 84-85 °C at 15 mm Hg), also known as  $\alpha$ -ketoisocaproic acid, 2-oxoisocaproic acid, 4-methyl-2 oxovaleric acid, and 4-methyl-2-oxopentanoic acid, is an intermediate in both the biosynthetic and degradation pathways of L-leucine. This  $\alpha$ -keto acid analogue of leucine is prepared from leucine by the action of D- or L-amino acid oxidase (1). While relatively stable at room temperature, it decompose slowly, even at 0 °C (1). **Target(s):** aldehyde reductase, or aldose reductase (2); branched-chain  $\alpha$ -keto-acid dehydrogenase (3); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or 3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (4-10); glutamine:pyruvate aminotransferase (11); 2-isopropylmalate synthase (12-16);  $K^+$  channel, ATP-regulated (17);  $\alpha$ -ketoglutarate decarboxylation, presumably by pyruvate dehydrogenase in rat liver (18); kynurenine 3-monooxygenase (19); pyruvate carrier (20); pyruvate decarboxylation, presumably by pyruvate dehydrogenase in rat brain and liver (18,21). 1. ### 2-Ketoisovalerate (2-Oxoisovalerate)

This  $\alpha$ -keto acid (FW<sub>free-acid</sub> = 116.12 g/mol), also known as  $\alpha$ -ketoisovaleric acid, 2-oxoisovaleric acid, 3-methyl-2 oxobutanoic acid, and ketovaline, is an intermediate in both the biosynthetic and degradation pathways of L-valine. It is also an intermediate in the biosynthesis of L-leucine and pantothenate. 2-ketoisovalerate is  $\alpha$ -keto acid product of valine transamination. **Target(s):** aldehyde reductase, or aldose reductase (1); branched-chain  $\alpha$ -keto-acid dehydrogenase (2); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (3-9); 2-dehydropantholactone reductase (10); glutamine:pyruvate aminotransferase (11); ketol-acid reductoisomerase (12); kynurenine 3-monooxygenase (13); ornithine  $\delta$ -aminopeptidase (14); pyruvate dehydrogenase (15). 1. Hayman & Kinoshita (1965) *J. Biol. Chem.* **240**, 877. 2. Paxton & Harris (1984) *Arch. Biochem. Biophys.* **231**, 48. 3. Roach (1984) *Meth. Enzymol.* **107**, 81. 4. ### Ketomalonate (Oxomalonate)

This  $\alpha$ -keto dicarboxylic acid (FW<sub>free-acid</sub> = 118.05 g/mol), also known as oxomalonic acid, and oxopropanedioic acid, is a homologue of oxaloacetate and  $\alpha$ -ketoglutarate that is found in beet molasses. It is an alternative substrate for a number of enzymes: for example, serine:glyoxylate aminotransferase. Ketomalonate is typically supplied as the monohydrate, which is found mainly in the *gem*-diol form (*i.e.*, dihydroxymalonic acid; FW<sub>free-acid</sub> = 136.06 g/mol). Malic enzyme slowly reduces ketomalonate in the presence of NADPH, indicating formation of the ternary complex Enzyme·NADPH·Ketomalonate (1). The *gem*-diol binds to form the enzyme·NADP<sup>+</sup> binary complex. **Target(s):** acid phosphatase, weakly inhibited (2); D-aspartate oxidase ( $K_i = 10$  mM) (3,4); homocitrate synthase (5);  $\alpha$ -ketoglutarate dehydrogenase (6); L-lactate dehydrogenase (7); malic enzyme, or malate dehydrogenase (decarboxylating) (1,8,9); oxaloacetate decarboxylase (Na<sup>+</sup>-pumping) (10-13); procollagen-proline 4-dioxygenase (14); pyridoxamine: oxaloacetate aminotransferase (15); pyruvate decarboxylase (16-18). 1. Schimerlik & Cleland (1977) *Biochemistry* **16**, 565. 2. Kilsheimer & Axelrod (1957) *J. Biol. Chem.* **227**, 879. 3. de Marco & Crifò (1967) *Enzymologia* **33**, 325. 4. ### 2-Keto-3-methylvalerate (2-Oxo-3-methylvalerate)

This  $\alpha$ -keto acid (FW<sub>free-acid</sub> = 130.14 g/mol; M.P. = 38-40°C; B.P. = 73°C at 10 mm Hg; pK<sub>a</sub> = 2.3 at 25°C), also known as  $\alpha$ -keto- $\beta$ -methylvaleric acid, 2-oxo-3-methylvaleric acid, 3-methyl-2-oxopentanoic acid, and ketoisoleucine, is the  $\alpha$ -keto acid analogue of isoleucine and is an intermediate in both the biosynthetic and degradation pathways of L-isoleucine. *Note:* There are two possible stereoisomers: the natural isomer is the D-enantiomer (*i.e.*, the 3S-isomer). **Target(s):** branched-chain  $\alpha$ -keto-acid dehydrogenase (1); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (2-6); kynurenine 3-monooxygenase (7); pyruvate carrier (8). 1. Paxton & Harris (1984) *Arch. Biochem. Biophys.* **231**, 48. 2. Roach (1984) *Meth. Enzymol.* **107**, 81. 3. Harris, Kuntz & Simpson (1988) *Meth. Enzymol.* **166**, 114. 4. Paxton (1988) *Meth. Enzymol.* **166**, 313. 5. Randle, Patston & Espinal (1987) *The Enzymes*, 3rd ed., **18**, 97. 6. Paxton & Harris (1984) *Arch. Biochem. Biophys.* **231**, 48. 7. Shin, Sano & Umezawa (1982) *J. Nutr. Sci. Vitaminol. (Tokyo)* **28**, 191. 8. Paradies & Papa (1975) *Boll. Soc. Ital. Biol. Sper.* **51**, 1252.

**7-Keto-20-oxacholesterol (7-Oxo-20-oxacholesterol)**

This 20-oxa analogue of 7-ketocholesterol (FW = 388.59 g/mol), also known as 7-oxo-20-oxacholesterol and SC 31769, inhibits ACAT, or sterol acyltransferase (cholesterol acyltransferase). 1. Billheimer (1985) *Meth. Enzymol.* **111**, 286.

**(2S,4E)-3-Keto-N-palmitoylceramide ((2S,4E)-3-Oxo-N-palmitoylceramide)**

This ceramide analogue (FW = 535.90 g/mol) inhibits ceramidase. For inhibition, the enzyme requires the primary and secondary hydroxyl groups, the C<sup>4</sup>-C<sup>5</sup> double bond, the trans configuration of this double bond, and the NH-protons from either the amide of ceramide or the amine of sphingosine. 1. Usta, El Bawab, Roddy, *et al.* (2001) *Biochemistry* **40**, 9657.

**2-Ketopelargonate (2-Oxopelargonate)**

This  $\alpha$ -keto acid (FW<sub>free-acid</sub> = 172.22 g/mol), also known as 2-ketononanoic acid and 2-oxononanoic acid, inhibits lens aldose reductase, an enzyme that catalyzes the reduction of glucose to sorbitol, which cannot be exported from cells. These properties lead to the accumulation of this osmolyte (especially during hyperglycemic episodes), leading to osmotic damage to retinal neurons. 1. Hayman & Kinoshita (1965) *J. Biol. Chem.* **240**, 877.

**S-(2-Ketopentadecyl)-CoA (S-(2-Oxopentadecyl)-CoA)**

This acyl-CoA analogue (FW = 991.93 g/mol), also known as S-(2-oxopenta-decyl)-CoA, is a strong inhibitor of glycolipid N-tetradecanoyltransferase, or protein N-myristoyltransferase (1-5). 1. Glover, Tellez, Guziec & Felsted (1991) *Biochem. Pharmacol.* **41**, 1067. 2. Selvakumar, Lakshmikuttyamma, Shrivastav, *et al.* (2007) *Prog. Lipid Res.* **46**, 1. 3. Paige, Zheng, DeFrees, Cassidy & Geahlen (1990) *Biochemistry* **29**, 10566. 4. Rudnick, McWherter, Rocaque, *et al.* (1991) *J. Biol. Chem.* **266**, 9732. 5. Zhang, Jackson-Machelski & Gordon (1996) *J. Biol. Chem.* **271**, 33131.

**2-Keto-3-pentynoate (2-Oxo-3-pentynoate)**

This acetylenic  $\alpha$ -keto acid (FW<sub>free-acid</sub> = 112.08 g/mol) is an irreversible inhibitor of 4 oxalocrotonate tautomerase. The enzyme is covalently modified at Pro1 by the resulting 2-oxo-3-pentenoate adduct. The  $\epsilon$  and  $\eta$  nitrogens of the guanidinium side chain of Arg39" from a neighboring dimer interact with the C2 carbonyl oxygen and one C1 carboxylate oxygen of the adduct, respectively. The side-chain of Arg-61' from the same dimer as the modified Pro-1 interacts with the C1 carboxylate group in a bidentate fashion. Two ordered water molecules within the active site interact as well with the 2-carbonyl group of the adduct (1). **Target(s):** 4-oxalocrotonate tautomerase (1,2); pyruvate decarboxylase (3); pyruvate dehydrogenase (3); pyruvate oxidase (3); tryptophan 2-monooxygenase (4,5). 1. Taylor, Czerwinski, Johnson, Whitman & Hackert (1998) *Biochemistry* **37**, 14692. 2. Johnson, Czerwinski, Fitzgerald & Whitman (1997) *Biochemistry* **36**, 15724. 3. Gadda, Dangott, Johnson, Whitman & Fitzpatrick (1999) *Biochemistry* **38**, 5822.

**2-Ketopimelate (2-Oxopimelate)**

This  $\alpha$ -keto dicarboxylic acid (FW<sub>free-acid</sub> = 174.15 g/mol), also known as 2-oxopimelic acid and 2-oxoheptanedioic acid, inhibits dihydrodipicolinate synthase and is a weak inhibitor of pyrimidine-deoxynucleoside 2'-dioxxygenase. **Target(s):** dihydrodipicolinate synthase (1); 2,3,4,5-tetrahydropyridine-2,6-dicarboxylate N-succinyltransferase (2); pyrimidine-deoxynucleoside 2'-dioxxygenase, or thymidine:2-oxoglutarate dioxxygenase, weakly inhibited (3). 1. Blickling, Renner, Laber, *et al.* (1997) *Biochemistry* **36**, 24. 2. Berges, DeWolf, Dunn, *et al.* (1986) *J. Biol. Chem.* **261**, 6160. 3. Bankel, Lindstedt & Lindstedt (1972) *J. Biol. Chem.* **247**, 6128.

**(S)-Ketoprofen**

This nonsteroidal anti-inflammatory agent (FW<sub>free-acid</sub> = 254.29 g/mol; M.P. = 94°C) is a strong, nonselective inhibitor of prostaglandin-endoperoxide synthase (cyclooxygenase). The (S)-enantiomer is about 100-500-fold more potent than the (R)-stereoisomer. Ketoprofen is slightly soluble in water and soluble in dimethylformamide, ethanol, acetone, and ethyl acetate. **Target(s):** anandamide amidohydrolase (1); arylamine N-acetyltransferase (2); cyclooxygenase, or prostaglandin-endoperoxide synthase; COX-1 and COX-2 (3-18); CYP2C10 (19); glutathione S transferase- $\pi$  (20); neutrophil elastase (21); palmitoyl-CoA ligase, or long-chain-fatty-acyl-CoA synthetase, by R-isomer (22,23); phenol sulfotransferase (24); phospholipase A<sub>2</sub>, weakly inhibited (25); thiopurine S-methyltransferase (26). 1. ### Ketorolac

This anti-inflammatory agent (FW<sub>free-acid</sub> = 255.27 g/mol; pK<sub>a</sub> = 3.49; M.P. = 160-161 °C), also known as 5-benzoyl-2,3-dihydro-1*H*-pyrrolizine-1-carboxylic acid, inhibits the induction of nitric-oxide synthase by lipopolysaccharides. The (*S*)-stereoisomer is the more active enantiomer. **Target(s):** anandamide amidohydrolase (1); prostaglandin H synthase, *or* cyclooxygenase 1 and 2 (2-5). **1.** Fowler, Janson, Johnson, *et al.* (1999) *Arch. Biochem. Biophys.* **362**, 191. **2.** Dionne, Khan & Gordon (20 01) *Clin. Exp. Rheumatol.* **19** (6 Suppl. 25), S63. **3.** Jett, Ramesha, Brown, *et al.* (1999) *J. Pharmacol. Exp. **KF 89617**, See *Litronesib*

### KG 5

This allosteric inhibitor (FW = 459.45 g/mol; CAS 877874-85-6), also named 2-(methylthio)-6-[4-[5-[[3-(trifluoromethyl)phenyl]amino]-1*H*-1,2,4-triazol-3-yl]phenoxy]-4-pyrimidinamine, targets PDGFR $\beta$  and B-Raf, two important targets for pericyte recruitment and endothelial cell survival, respectively. KG-5 targets the allosteric site, binding to the inactive kinase conformation (type II inhibitors) and providing an alternative for selective inhibitors that are physiologically active. **1.** Murphy, Shields, Stoletov, *et al.* (2010) *Proc. Natl. Acad. Sci. USA* **107**, 4299.

### KGA-2727

This phlorizin-like pyrazole-*O*-glucoside (FW = 489.59 g/mol), also named 3-(3-{4-[3-( $\beta$ -D-glucopyranosyloxy)-5-isopropyl-1*H*-pyrazol-4-ylmethyl]-3-methylphenoxy}propylamino)propionamide, is a novel and selective inhibitor of high-affinity sodium glucose cotransporter-1, *or* SGLT1, exhibiting antidiabetic efficacy in rodent models. In the oral glucose tolerance test with streptozotocin-induced diabetic rats, KGA-2727 reduced plasma glucose after glucose loading, indicating that KGA-2727 improved postprandial hyperglycemia. In the Zucker diabetic fatty (ZDF) rat, chronic treatments with KGA-2727 reduced plasma glucose as well as glycated hemoglobin. **1.** Shibazaki, Tomae, Ishikawa-Takemura (2012) *J. Pharmacol. Exp. Ther.* **342**, 288.

### KGP94

This protease inhibitor (FW = 350.23 g/mol; dissolve in sterile DMSO to obtain 10-25 mM stock solutions and dilute 1000x in cell culture media), also named 3-bromophenyl-3-hydroxyphenyl-ketone thiosemicarbazone, targets Cathepsin L (1), a protease that plays a crucial role in remodeling the tumor microenvironment and freeing cells to disseminate, resulting in therapeutic failure, poor prognosis, and high mortality (2). Acute exposures to hypoxic or acidic conditions are known to significantly elevate secreted Cathepsin L concentration, either through an increase in intracellular Cathepsin L levels or through activation of lysosomal exocytosis, or both, depending on the tumor type. Increases in Cathepsin L secretion also closely parallel enhanced tumor cell migration and invasion suggesting that this protease could be an essential factor in tumor microenvironment triggered metastasis. KGP94 treatment markedly attenuates tumor cell invasion and migration under both normal and aberrant microenvironmental conditions, suggesting that Cathepsin L inhibitors may have significant utility as an anti-metastatic agent. **1.** Kishore-Kumar, Chavarría, Charlton-Sevcik, *et al.* (2010) *Bioorg. Med. Chem. Lett.* **20**, 1415. **2.** Sudhan & Siemann (2013) *Clin. Exp. Metastasis* **30**, 891. **3.** Sudhan & Siemann (2015) *Pharmacol. Ther.* **155**, 105.

### Khellin

This coronary vasodilator (FW = 260.25 g/mol; CAS 82-02-0; Solubility = 0.025 g/100 mL H<sub>2</sub>O at 25°C; M.P. = 154-155°C), systematically named 4,9-dimethoxy-7-methyl-5*H*-furo[3,2-*g*][1]benzopyran-5-one, is a furocoumarin that is abundant in the plant *Ammi visnaga*. It elicits an intracellular response by G<sub>ia</sub> protein, the inhibitory G-protein component that blocks adenylate cyclase (1). Khellin is structurally related to other furocoumarins and, with its photoreactive quinoidal structure, is a phototherapeutic agent that has been used to treat psoriasis and vitiligo. It forms furan and pyrone mono-photoadducts with thymine bases in DNA. Khellin is also a active principle in the traditional Egyptian medicine known as khella, which is prepared as an aqueous extract of the dried ripe fruit, and, owing to khellin's vasodilating properties, is used to treat respiratory conditions including asthma, bronchitis, persistent cough, as well as whooping cough. Its relatively low toxicity commends its use as an antilithogenic agent for treating calcium oxalate kidney stone formation. **Target(s):** adenylate cyclase system (1); cAMP phosphodiesterase, weakly inhibited (2). **1.** Di Stefano, La Gaetana, Bovalini, Lusini & Martelli (1996) *Biochim. Biophys. Acta* **1314**, 105. **2.** Bovalini, Lusini, Simoni, *et al.* (1987) *Z. Naturforsch. [C]* **42**, 1009.

### Kifunensine

This hygroscopic cyclic oxamide analogue (FW = 232.19 g/mol) of the alkaloid 1-aminomannojirimycin, produced by the actinomycetes

*Kitasatospora kifunense* strain 9482, is a potent inhibitor of the plant glycoprotein processing enzyme, mannosidase I ( $IC_{50} = 20\text{--}50$  nM), but is virtually inactive toward mannosidase II ( $K_i = 5.2$  mM). Kifunensine inhibits rat liver mannosidase I, but not the endoplasmic reticulum mannosidase. When tested *in vitro* for its ability to inhibit influenza virus glycoprotein processing in canine kidney cells, 4  $\mu\text{M}$  kifunensine completely shifted the structure *N*-linked oligosaccharide from complex chain to  $\text{Man}_9(\text{GlcNAc})_2$  structure, again in keeping its selected action on mannosidase I. **Target(s):** glycoprotein processing (1-3);  $\alpha$ -mannosidase (4,5); mannosyl-oligosaccharide (1,2);  $\alpha$ -mannosidase, or mannosidase I, or  $\alpha$ 1,2-mannosidase (1,2,6-14); mannosyl-oligosaccharide 1,3-1,6- $\alpha$  mannosidase, or mannosidase II, weakly (6). 1. ### Kinetensin

This nonapeptide (MW = 1172.40 g/mol; Sequence: IARRHPYFL; Isoelectric Point = 19.84), isolated from pepsin-treated human plasma, exhibits neurotensin-like immunoreactivity. Kinetensin also stimulates histamine release. It is an alternative substrate for tryptase, chymase, and mast cell carboxypeptidase. It is not a substrate of neurolysin. 1. Vincent, Dauch, Vincent & Checler (1997) *J. Neurochem.* **68**, 837. 2. Barelli, Vincent & Checler (1993) *Eur. J. Biochem.* **211**, 79.

### Kinetin

This adenine derivative (FW = 215.21 g/mol;  $\lambda_{\text{max}}$  in ethanol at 268 nm;  $\epsilon = 18650$   $\text{M}^{-1}\text{cm}^{-1}$ ), also known as 6-furfurylamino-purine and *N*<sup>6</sup>-furfuryladenine, is a synthetic cytokinin, exhibiting activity similar to that of *N*<sup>6</sup>-benzyladenine. Kinetin stimulates cell division in the presence of auxin. Kinetin was originally obtained in 1954 from the hydrolysis of herring sperm DNA and was soon found to stimulate cell division in tobacco pith cells (1) Note: A commercial form of hyaluronidase also goes by the name Kinetin. **Target(s):** Hill activity decay (2); 5-hydroxyfuranocoumarin 5-*O*-methyltransferase (3); 8-hydroxyfuranocoumarin 8-*O*-methyltransferase (3); indole-3-acetate  $\beta$ -glucosyltransferase, weakly inhibited (4); protein oxidation and glycooxidation (5); xanthine dehydrogenase (6); *cis*-zeatin *O*- $\beta$ -D-glucosyltransferase (7). 1. Miller, Skoog, Von Saltza & Strong (1955) *J. Amer. Chem. Soc.* **77**, 1392. 2. Banerji & Kumar (1975) *Biochem. Biophys. Res. Commun.* **65**, 940. 3. Thompson, Sharma & Brown (1978) *Arch. ### Kingianin A

This cytotoxic secondary metabolite and apoptosis-promoting agent (FW = 682.90 g/mol) from the bark of the Malaysian plant, *Endiandra kingiana* (Lauraceae), displays significant affinity for the protein Bcl-X<sub>L</sub>,  $K_i = 1\text{--}3$   $\mu\text{M}$ , thereby blocking its anti-apoptotic actions (1). Kingianin A was recently synthesized by a 12-step synthesis based on a radical cation Diels-Alder (RCDA) reaction that is believed to be biomimetic (2). 1. Leverrier, Awang, Guéritte & Litaudon (2011) *Phytochemistry* **72**, 1443. 2. Lim & Parker (2013) *Org. Lett.* **15**, 398.

### Kirromycin

This antibiotic (FW = 796.96 g/mol), also called mocimycin and delvomycin, prevents the release of elongation factor-Tu (EF-Tu) from the bacterial ribosome and thus inhibits protein biosynthesis. Translocation is inhibited by kirromycin stabilization of aminoacyl-tRNA bound to the ribosomal A-site. Kirromycin also inhibits the phosphorylation of EF-Tu. **Target(s):** elongation factor EF-Tu (1-4); RNA-directed RNA polymerase (Qb replicase), weakly inhibited (5). 1. Young & Neidhardt (1978) *J. Bacteriol.* **135**, 675. 2. Wolf, Chinali & Parmeggiani (1977) *Eur. J. Biochem.* **75**, 67. 3. Hogg, Mesters & Hilgenfeld (2002) *Curr. Protein Pept. Sci.* **3**, 121. 4. Parmeggiani & Swart (1985) *Annu. Rev. Microbiol.* **39**, 557. 5. Brown & Blumenthal (1976) *J. Biol. Chem.* **251**, 2749.

### KN-93

This cell-permeable, dual-action CaM kinase inhibitor and K<sub>v</sub> channel blocker (FW = 501.04 g/mol; CAS 139298-40-1; Solubility: 100 mM in DMSO with gentle warming), also named *N*-[2-[[[3-(4-chlorophenyl)-2-propenyl]methylamino]methyl]phenyl]-*N*-(2-hydroxyethyl)-4-methoxybenzenesulfonamide, has two modes of action. **Mechanism of Action as a CaM Kinase Inhibitor:** KN-73 selectively and potently targets the Ca<sup>2+</sup>/calmodulin-stimulated protein kinase CaM kinase II ( $IC_{50} = 0.37$   $\mu\text{M}$ ). KN-73 has no significant effect on cAMP-dependent protein kinase (PKA), Ca<sup>2+</sup>/phospholipid dependent protein kinase, myosin light chain kinase, and Ca<sup>2+</sup>-phosphodiesterase (1). A significant clinical finding is that persistently elevated CaMKII activity (by  $\beta$ -adrenergic stimulation or rapid heart rate, by reactive oxidative species (ROS), by angiotensin II signaling, or by GlcNAcylation during hyperglycemia) appears to be a key factor in heart failure, arrhythmia, and other forms of heart disease. KN-93 also inhibits autophosphorylation of both CaMKII  $\alpha$ - and  $\beta$ -subunits. KN-93 inhibits CaMKII competitively relative to calmodulin (1). In rabbit hearts pretreated for 10 min with 0.5  $\mu\text{M}$  KN-93 or a similar level of its inactive analogue KN-92 (FW = 554.98 g/mol; CAS 1135280-28-2; IUPAC Name: 2-[*N*-(4-methoxybenzenesulfonyl)]-amino-*N*-(4-chlorocinnamyl)-*N*-methylbenzyl

amine) before clofilium exposure, early after-depolarizations (EADs) are significantly suppressed by KN-93 (4 out of 10 hearts) compared to KN-92 (10 out of 11 hearts) (2). KN-93 was also instrumental in demonstrating calcium/calmodulin-dependent phosphorylation and activation of human Cdc25-C at the G<sub>2</sub>/M phase transition in HeLa cells (3). **Mechanism of Action as a K<sub>v</sub> Channel Blocker:** KN-93 is also a direct extracellular blocker of a wide range of cloned voltage-gated potassium (K<sub>v</sub>) channels from a number of different subfamilies (4). In all channels tested, this effect is CaMK II-independent, as indicated by the fact that KN-92 (1 μM) has a similar inhibitory action on these ion currents (4). Importantly, KN-93 is ineffective as a blocker, when applied intracellularly, suggesting that CaMK II-independent effects of KN-93 on K<sub>v</sub> channels can be circumvented by intracellular application of KN-93 (4). **Recommendation:** The dual action of KN-93 on CaMKII and ion channels requires that the effects of KN-93 and KN-92 must be separately evaluated before assigning the most likely mechanism of action. For example, one study showed that, with injection of 1, 3 and 6 μg KN93 into the nucleus accumbens, there is a dose-dependent increase in hindpaw withdrawal latency (HWL) upon exposure to noxious thermal and mechanical stimulation in mononeuropathic rats (5). Given the likely significance of both CaMKII and K<sub>v</sub> channels in the nucleus accumbens, however, one cannot unambiguously conclude, as the authors did, that the observed KN-93 effects are directed to CaMKII. **1.** Sumi, Kiuchi, Ishikawa, *et al.* (1991) *Biochem. Biophys. Res. Commun.* **181**, 968. **2.** Anderson, Braun, Wu, *et al.* (1998) *J. Pharmacol. Exp. Ther.* **287**, 996. **3.** Patel, Holt, Philipova, *et al.* (1999) *J. Biol. #### K-(D-1-Nal)-FWLL-NH<sub>2</sub>

This high affinity inverse agonist (FW = 902.13 g/mol; CAS 1394288-22-2; Soluble to 2 mg/mL in water), also named lysyl-D-naphthylamido-phenylalanyl-tryptophanyl-leucyl-leucylamide, targets the ghrelin receptor, a constitutive receptor activity that regulates appetite and food intake. Els, Schild, Petersen, *et al.* (1) showed that subtle changes in the core WFW binding motif of the ghrelin receptor ligand K<sup>1</sup>W<sup>2</sup>F<sup>3</sup>W<sup>4</sup>L<sup>5</sup>L<sup>6</sup>-NH<sub>2</sub> determine whether a resulting peptide analogue shows inverse agonism or agonism. Introduction of β-(3-benzothieryl)-D-alanine (D-Bth), 3,3-diphenyl-D-alanine (D-Dip) and 1-naphthyl-D-alanine (D-1-Nal) at Position-2 resulted in highly potent and efficient inverse agonists, whereas the substitution of D-tryptophan at Position-4 with 1-naphthyl-D-alanine (D-1-Nal) and 2-naphthyl-d-alanine (D-2-Nal) induces agonism in functional assays. **1.** Els, Schild, Petersen, *et al.* (2012) *J. Med. Chem.* **55**, 7437.

#### KNI 272

This peptide analogue (FW = 667.85 g/mol), also known as kynostatin-272, contains allophenylnorstatine and inhibits HIV-1 protease: K<sub>i</sub> = 9.8 pM. **1.** Clemente, Hemrajani, Blum, Goodenow & Dunn (2003) *Biochemistry* **42**,

15029. **2.** Huang, Xu, Luo, *et al.* (2002) *J. Med. Chem.* **45**, 333. **3.** Baldwin, Bhat, Gulnik, *et al.* (1995) *Structure* **3**, 581. **4.** Mimoto, Imai, Kisanuki, *et al.* (1992) *Chem. #### Ko 1173, See Mexiletine

#### Kobe0065

This orally active H-Ras-cRaf1 interaction inhibitor (FW = 449.79 g/mol; CAS 436133-68-5; Solubility: 5 mM in H<sub>2</sub>O, with gentle warming), also named N-(3-chloro-4-methylphenyl)-2-[2,6-dinitro-4-(trifluoromethyl)phenyl]hydrazinecarbothioamide, binds to the GTP-Ras complex, disrupting its interactions with c-Raf-1 (K<sub>i</sub> = 10<sup>-6</sup>-10<sup>-5</sup> M). Because mutational activation of H-Ras, K-Ras, and N-Ras is often observed in human cancers, protein interaction disruptors are promising anticancer drug targets. When added to the culture medium at 2 and 20 μM, respectively, Kobe0065 and its analogue Kobe2602 inhibit both anchorage-dependent and anchorage-independent growth and induce apoptosis of H-ras<sup>G12V</sup>-transformed NIH 3T3 cells, accompanied by down-regulation of downstream molecules such as MEK/ERK, Akt, and RafA as well as the upstream signaling molecule, Son of sevenless (SOS). Moreover, they exhibit antitumor activity on a xenograft of human colon carcinoma SW480 cells carrying the K-ras<sup>G12V</sup> gene by oral administration. The NMR structure of a complex of the compound with GTP-H-Ras<sup>T35S</sup> confirms its insertion into one of the surface pockets and provides a molecular basis for binding inhibition toward multiple Ras-GTP-interacting molecules. **1.** Shima, Yoshikawa, Ye, *et al.* (2013) *Proc. Natl. Acad. Sci. U.S.A.* **110**, 8182.

#### Kodaistatin A

This secondary fungal metabolite (FW = 628.63 g/mol), isolated from *Aspergillus terreus thom* DSM 11247, is a potent inhibitor of glucose-6-phosphate translocase (IC<sub>50</sub> = 80 nM). A hydroxylated kodaistatin A derivative, kodaistatin C is a slightly weaker inhibitor of the translocase (IC<sub>50</sub> = 130 nM). **1.** Van Schaftingen & Gerin (2002) *Biochem. J.* **362**, 513. **2.** Vértesy, Burger, Kenja, *et al.* (2000) *J. Antibiot.* **53**, 677.

#### Kojibiose

This α1,2-linked glucose disaccharide FW = 342.30 g/mol), named (2-O-α-D-glucopyranosyl-D-glucopyranose, is a substrate for a number of α-

glucosidases. Kojibiose is often found linked to teichoic acids in Gram-positive bacteria. **Target(s):** concanavalin A (1); mannosyl-oligosaccharide glucosidase, or glucosidase I (2-11). 1. ### Kojic Acid

This pyranone derivative (FW = 142.11 g/mol; M.P. = 153-154°C; Soluble in water, ethanol, methanol, and acetone), also known as 5-hydroxy-2-(hydroxymethyl)-4H-pyran-4-one, is an antibiotic that is produced by a number of microorganisms (e.g., *Aspergillus oryzae*, *A. terreus*, and *Penicillium* sp.). It is a slow-binding inhibitor of tyrosinase and inhibits melanin production. It has been used as a whitening agent and food additive. **Target(s):** alcohol dehydrogenase, yeast (1); D-amino-acid oxidase (2-5); L-amino-acid oxidase (3); catechol oxidase (6,23,35,36,38,39); laccase (7-11); phenol oxidases, insect (12); polyphenol oxidase (13,35,36); quercetin 2,3-dioxygenase (14,15); tyrosinase, or monophenol monooxygenase (6,12,13,16-35,37); xanthine oxidase (4). 1. ### K-Ras(G12C) inhibitor 6

This synthetic allosteric-type irreversible G-protein inhibitor (FW = 405.34 g/mol; Solubility: 80 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named N-(1-(2-(2,4-dichlorophenoxy)acetyl)piperidin-4-yl)-4-mercapto-butanamide, targets the frequently oncogenic Gly-to-Cys mutant form of K-Ras, blocking K-Ras(G12C) interactions with its proliferation-promoting binding partners. Oncogenic mutations result in functional activation of Ras family proteins by impairing GTP hydrolysis. With diminished regulation by GTPase activity, the nucleotide state of Ras becomes more dependent on relative nucleotide affinity and concentration, allowing GTP to outcompete GDP and increasing the proportion of active GTP-bound Ras. Binding of the inhibitor to K-Ras(G12C) disrupts both Switch-I and Switch-II, subverting the native nucleotide preference to favor GDP over GTP and impairing Ras binding to Raf. (See also K-Ras(G12C) Inhibitor 9) **Role in Modulating the Subcellular Localization of p21:** The nuclear exporter, known as exportin (XPO1; CRM1), controls the nucleo-cytoplasmic localization of more than two hundred Nuclear Export Signal (NES)-containing proteins, many of which are tumor suppressor proteins (TSPs), including p21. The latter was originally described as a cyclin-dependent-kinase inhibitor (CKI) of cyclin-CDK2, cyclin-CDK1, and cyclin-CDK4/6 complexes whose expression is classically regulated by p53. PO1 inhibition by KPT-330 attenuates renal cell carcinoma (RCC) viability through cell cycle arrest as well as induction of apoptosis, and that increased nuclear p21 by XPO1 inhibition plays a major role in the efficacy of KPT-330 in RCC (2). Although normally localized within the nucleus, p21 binds to cyclin-CDK complexes thereby inhibiting their function in cell cycle progression, resulting in cell cycle arrest. However, when p21 localizes to the cytosolic compartment, it inhibits apoptosis by complexing with pro-apoptotic proteins such as pro-caspase-3 or ASK. We show that KPT-330 potentiates the antitumor activity of sunitinib, resulting in complete inhibition of RCC tumor growth in vivo with this combination. KPT-330 resistant cells remains sensitive to sunitinib, sorafenib, everolimus, and temsirolimus, suggesting that patients who fail KPT-330 or for whom resistance develops, could still respond to these older drugs (2). Finally, given the aforementioned binding of KPT-330 to small G-proteins like K-Ras(G12C), it seems likely that KPT-330 binds directly to p21, thereby altering its capacity to be processed appropriately by XPO1. 1. Ostrem, Peters, Sos, Wells & Shokat (2013) *Nature* **503**, 548. 2. Wettersten, Landesman, Friedlander, et al. (2014) *PLoS One* **9**, e113867.

### K-Ras(G12C) Inhibitor 9

This synthetic allosteric-type irreversible G-protein inhibitor (FW = 513.78 g/mol; CAS 1469337-91-4; Solubility: 53 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O or Ethanol), also named N-[1-[2-[(4-chloro-5-iodo-2-methoxyphenyl)amino]acetyl]-4-piperidinyl]ethanesulfonamide, targets the frequently oncogenic Gly-to-Cys mutant form of K-Ras, blocking K-Ras(G12C) interactions with its proliferation-promoting binding partners. This compound relies on the mutant cysteine SH group for reactivity and does not affect the wild-type protein. Crystallographic studies reveal the formation of a new pocket that is not apparent in previous structures of Ras, beneath the effector binding switch-II region. Binding of this inhibitor to K-Ras(G12C) disrupts both switch-I and switch-II, favoring the binding of GDP over GTP and impairing K-Ras(G12C) binding to Raf. (See also K-Ras(G12C) Inhibitor 6) 1. Ostrem, Peters, Sos, Wells & Shokat (2013) *Nature* **503**, 548.

KT-5720

This potent and selective protein kinase inhibitor (FW = 537.61 g/mol; CAS 108068-98-0; Soluble to 50 mM in DMSO), also named (9*R*,10*S*,12*S*)-2,3,9,10,11,12-hexahydro-10-hydroxy-9-methyl-1-oxo-9,12-epoxy-1*H*-diindolo[1,2,3-*fg*:3',2',1'-*kl*]pyrrolo[3,4-*i*][1,6]benzodiazocine-10-carboxylate, hexyl ester, targets protein kinase A ( $K_i = 60$  nM), with no effect on PKG ( $K_i > 2$   $\mu$ M) or PKC ( $K_i > 2$   $\mu$ M). KT5720 reversibly arrests human skin fibroblasts, holding them in G<sub>1</sub> phase. PKA inhibition by KT-5720 results in altered astrocyte morphology, attended by a reduction in Profilin-2 levels (4). 1. Kase, *et al.* (1987) *Biochem. Biophys. Res. Commun.* **142**, 436. 2. Gadbois, *et al.* (1992) *Proc. Natl. Acad. Sci. U.S.A.* **89**, 8626. 3. Cabell, *et al.* (1993) *Int. J. Dev. Neurosci.* **11**, 357. 4. KT5823

This cell-permeable reagent (FW = 495.53 g/mol; Photosensitive), also known as (9*R*,10*S*,12*S*)-2,3,9,10,11,12 hexahydro-10-methoxy-9-methyl-1-oxo-9,12-epoxy-1*H*-diindolo[1,2,3-*fg*:3,2,1-*k*]-*N*-methylpyrrolo[3,4-*i*][1,6]benzodiazocine-10-carboxylic acid methyl ester, is a strong inhibitor of protein kinase G (cGMP-dependent protein kinase;  $K_i = 230$  nM). It will also inhibit protein kinase C ( $K_i = 4.0$   $\mu$ M) and weakly inhibit protein kinase A ( $K_i > 10$   $\mu$ M). It is a modified derivative of K-252a. Inhibition of p38-regulated/activated kinase by KT5823 varies from batch to batch, suggesting the actual inhibitory agent may vary from batch to batch (1). **Target(s):** cGMP-dependent protein kinase, *or* protein kinase G (1-7); [glycogen-synthase] kinase 3 $\beta$ , *or* [tau protein] kinase (1); p38-regulated/activated kinase (1); protein kinase A, weakly inhibited (1); protein kinase C, weakly inhibited (1). 1. KT5926

This potent and selective protein kinase inhibitor (FW = 525.56 g/mol), also known as ((8*R*\*,9*S*\*,11*S*\*)-(-)-9-hydroxy-9-methoxycarbonyl-8-methyl-14-*n*-propoxy-2,3,9,10-tetrahydro-8,11-epoxy,1*H*,8*H*,11*H*-2,7 $\beta$ ,11 $\alpha$ -triazadibenzo[*a,g*]cycloocta[*cde*]trinden-1-one, inhibits [myosin light-chain] kinase competitively relative to ATP ( $K_i = 18$  nM) and noncompetitively relative to the myosin light chain ( $K_i = 12$  nM). KT5926 exhibits lower affinity for protein kinase C ( $K_i = 723$  nM), cAMP dependent protein kinase ( $K_i = 1.2$   $\mu$ M), and cGMP-dependent protein kinase ( $K_i = 158$  nM). Notably, Ca<sup>2+</sup>-ATPase, Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase, hexokinase, and 5'-nucleotidase were not inhibited by KT5926 below 10  $\mu$ M. This agent inhibited serotonin secretion induced by platelet-activating factor, but its potency was significantly less than that of K-252a. The  $K_i$  value for Ca<sup>2+</sup>/calmodulin-dependent protein kinase II was 4.4 nM. (See also K-252a) **Target(s):** Ca<sup>2+</sup>/calmodulin-dependent protein kinase II (1); cAMP-dependent protein kinase (2); cGMP-dependent protein kinase, *or* protein kinase G (2,3,7,8); heat-shock protein (HSP25) kinase (5); [myosin light-chain] kinase (2,4,6); protein kinase C (2). 1. KU-55933

This potent, cell-permeable ATM inhibitor (FW = 395.49; CAS 587871-26-9; Solubility at 25°C = 50 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as 2-morpholino-6-(thianthren-1-yl)-4*H*-pyran-4-one, targets Ataxia Telangiectasia-Mutated (IC<sub>50</sub> = 13 nM;  $K_i = 2.2$  nM), a nonselective serine/threonine protein kinase that is recruited to and activated by DNA double-strand breaks, where it phosphorylates such downstream proteins as p53, CHK2, NBS1, and BRCA1 (1). **Background:** Ataxia-telangiectasia syndrome (also known as Louis-Bar syndrome) is a rare, neurodegenerative, autosomal recessive disability. ATM was first identified as a syndrome-associated protein that likely gave rise to the AT phenotype, the latter characterized by higher degrees of chromosome breakage, increased sensitivity to ionizing radiation and radiomimetic drugs, and defective cell-cycle checkpoints in response to genome damage. Cellular inhibition of ATM by KU-55933 is demonstrated by the ablation of ionizing radiation-dependent phosphorylation of a range of ATM targets, including p53,  $\gamma$ H2AX, NBS1, and SMC1. KU-55933 does not show

inhibition of UV light DNA damage induced cellular phosphorylation events (1). Indeed, exposure to KU-55933 significantly sensitizes cells to the cytotoxic effects of ionizing radiation as well as to DNA double-strand break-inducing chemotherapeutic agents (*e.g.*, etoposide, doxorubicin, and camptothecin). **Effects on Deoxynucleoside Homeostasis:** Inhibition of ATM by KU-55933 also causes loss of ionizing radiation-induced cell cycle arrest linked to changes in deoxynucleotide metabolism (1-4). Human cells use two different pathways to generate the 2'-deoxy-ribonucleoside triphosphates (dNTPs) needed for DNA replication and repair. While the main pathway involves *de novo* reduction of NDPs by ribonucleotide reductase (RNR) to their corresponding dNDPs, a second pathway salvages deoxynucleosides (dNs) through deoxynucleoside kinases. Cells coordinate *de novo* and salvage pathways to assure that the dNTP supply is sufficient for replication and repair, thereby avoiding deleterious genotoxic stress. In the salvage pathway, deoxynucleoside kinases are rate-limiting for dNTP supply, with thymidine kinase (TK1) and/or deoxycytidine kinase (dCK) in the cytosol and TK2 and deoxyguanosine kinase (dGK) in mitochondria. TK1 is S-phase specific through a mechanism similar to that of RNR. (The other three deoxynucleoside kinases are constitutively active across the cell cycle.) Deoxynucleoside kinases are variably expressed in human normal and cancer tissues, with TK1 being elevated in cervical cancers. The substrates of these salvage enzymes, deoxynucleosides, enter cells and mitochondria passively by plasma membrane-equilibrative nucleoside transporters. ATM integrates the DNA damage-response by catalyzing the phosphorylation of deoxy-cytidine kinase (dCK) at Ser<sup>74</sup> in response to cell exposure to ionizing radiation (IR). Deoxy-cytidine kinase catalyzes the phosphorylation pyrimidine (dC) as well as purine (dA, dG) deoxynucleosides, and a phosphomimetic Ser-74-Glu mutation increases catalysis of phosphorylation of dC, but not dA and dG (4). ATM-dependent phosphorylation of dCK at Ser<sup>74</sup> after ionizing radiation preferentially increases dCMP formation over dGMP and dAMP. dG and dA are not exclusively phosphorylated by dCK, and the rates of dA and dG phosphorylation remained unchanged. Moreover, Ser-74-Ala substitution decreased dCK activity for dC, but had little effect on dA and dG phosphorylation. dCK<sup>S74E</sup> tripled the rate of dC phosphorylation, but decreased dG and dA phosphorylation rates by 50%. Such findings suggest that IR-induced ATM-dependent phosphorylation of dCK at Ser-74 increases the flux of deoxy-cytidine through the salvage pathway (4). KU-55933 treatment increases intracellular dCTP pools post-IR and enhances the DNA repair rate. Mutation of Ser<sup>74</sup> profoundly affects murine T and B-lymphocyte development, suggesting posttranslational regulation of dCK is vitally for genomic stability during hematopoiesis (4). **Other Targets:** DNA-PK, IC<sub>50</sub> = 2.5 μM (1); mTOR PK, IC<sub>50</sub> = 9.3 μM (1); PI3K, IC<sub>50</sub> = 16.6 μM (1); ATM-mediated phosphorylation of AMP-activated protein kinase (AMPK) in HeLa and A29 cells (5); ATM signaling in primary A-T fibroblasts, resulting in global dysregulation of R<sub>1</sub>, R<sub>2</sub>, and p53R<sub>2</sub> subunits of RNR, abrogation of RNR-dependent up-regulation of *mt*-DNA in response to ionizing radiation, increase in mitochondrial transcription factor A to *mt*-DNA ratios, and increased resistance to inhibitors of mitochondrial respiration and translation (6); inhibition of phosphatidylinositol 3-kinase and autophagy at much higher KU-55933 concentrations (2 μM) (7); many other cellular processes, owing to ATM's notoriously promiscuous phosphorylation of numerous targets, including Abl gene, BRCA1, Bloom syndrome protein, DNA-PKcs, FANCD2, MRE11A, Nibrin, p53, RAD17, RAD51, RBBP8, RHEB, RRM2B, SMC1A, TERF1, and TP53BP1. **Other ATM Inhibitors:** KU-60019 (IC<sub>50</sub> = 6.3 nM), Wortmannin (IC<sub>50</sub> = 150 nM), CP-466722 (IC<sub>50</sub> = 450 nM), Torin 2 (IC<sub>50</sub> = 28 nM), and CGK733 (IC<sub>50</sub> = 200 nM). 1. #### KU-60019

This potent and specific ATM inhibitor (F.Wt. = 547.67; CAS 587871-26-9; Solubility (25°C): 40 mg/mL DMSO, <1 mg/mL Water), also known as 2-((2*S*,6*R*)-2,6-dimethylmorpholino)-*N*-(5-(6-morpholino-4-oxo-4*H*-pyran-2-yl)-9*H*-thioxanthen-2-yl)acetamide, targets Ataxia telangiectasia mutated, or ATM (IC<sub>50</sub> = 6.3 nM), the curiously named serine/threonine protein kinase recruited to and activated by DNA double-strand breaks (1). While similar in its action to KU-55933, KU-60019 has improved water-solubility. KU-60019 has little activity against DNA-PK's and ATR with IC<sub>50</sub> values of 1.7 μM and >10 μM, respectively, as well as 229 other protein kinases, including PI3K, mTOR and mTOR/FKBP12. 1. Golding, *et al.* (2009) *Mol. Cancer Ther.* 8, 2894.

#### KU-60648

This potent DNA-PK inhibitor (FW = 582.71 g/mol; CAS 881375-00-4), also known as 4-ethyl-*N*-[4-[2-(4-morpholinyl)-4-oxo-4*H*-1-benzopyran-8-yl]-1-dibenzothiényl]-1-piperazineacetamide, targets DNA-dependent protein kinase (IC<sub>50</sub> = 8.6 nM) as well as its autophosphorylation (IC<sub>50</sub> = 20-40 nM), depending on cell type. In SW620 cells, 1 μM KU-0060648 enhances etoposide cytotoxicity more than 100 times and doxorubicin cytotoxicity by more than 10 times (1). Although radiation and genotoxic drugs are used widely used in the clinic to treat cancer, DNA repair often limits their cytotoxic action. To increase the efficacy of such treatments, DNA-PK inhibitors promise to enhance cancer cell chemo- and/or radiosensitivity. 1. Furgason & Bahassi (2013) *Pharmacol. Ther.* 137, 298. 2. Munck, Batey, Zhao, *et al.* (2012) *Mol. Cancer Ther.* 11, 1789.

#### Kunitzins

These novel structurally related protease inhibitors, Kunitzin-RE (MW = 1894.37 g/mol; Sequence: AAKIIL-NPKFRCKAAFC; Isoelectric Point = 9.85) and Kunitzin-OS (MW = 1917.36 g/mol; Sequence: AVNIPFKVHLRCK-AAFC; Isoelectric Point = 9.51), from the lyophilized skin secretions of the European frog *Rana esculenta* and the Chinese frog *Odorrana schmackeri*, target serine proteases. Due to the presence of the canonical Kunitz-type protease inhibitor motif (CKAAFC), these peptides were named kunitzin-RE and kunitzin-OS. Both potently inhibit trypsin (*K<sub>i</sub>* = 5.56 μM and 7.56 μM), representing prototypes of a novel class of highly attenuated amphibian skin protease inhibitors. Substitution of Lys-13, the predicted residue occupying the P<sub>1</sub> position within the inhibitory loop, with Phe resulted in decrease in trypsin inhibitor effectiveness and antimicrobial activity against *Escherichia coli*, but exhibits a potential inhibition activity against chymotrypsin. 1. Chen, Wang, Shen, *et al.* (2016) *Biochem. Biophys. Res. Commun.* 477, 534.

#### Kurtoxin

This 63-residue oligopeptide (MW = 7394.48 g/mol) from the venom of the scorpion *Parabuthus transvaalicus*, blocks Ca<sup>2+</sup> channels, particularly low-threshold (T-type) channels. 1. Sidach & Mintz (2002) *J. Neurosci.* 22, 2023. 2. Nishio, Nishiuchi, Ishimaru & T. Kimura (2003) *Lett. Pept. Sci.* 10, 589. 3. Chuang, Jaffe, Cribbs, Perez-Reyes & Swartz (1998) *Nat. Neurosci.* 1, 668.

**KVX-478**, See *Amprenavir*

**KW-2478**

This nonansamycin Hsp90 inhibitor (FW<sub>free-base</sub> = 574.66 g/mol; CAS 819812-04-9; FW<sub>HCl-Salt</sub> = 610.13 g/mol; CAS 819812-18-5), also known as 2-(2-ethyl-3,5-dihydroxy-6-(3-methoxy-4-(2-morpholinoethoxy)benzoyl)phenyl)-*N,N*-bis(2-methoxyethyl)acetamide, targets Heat Shock Protein-90 (IC<sub>50</sub> = 3.8 nM), an ATP-dependent molecular chaperone that stabilizes various oncogenic kinases, including HER2, EGFR, BCR-ABL, B-Raf and EML4-ALK, all of which are essential for tumor growth. In a novel orthotopic multiple myeloma (MM) model of i.v. inoculated OPM-2-GFP protein, KW-2478 showed a significant reduction of both serum M protein and MM tumor burden in the bone marrow (1). (See also *Alvespimycin*; *Ansamycin*; *Dequelin*; *Derrubone*; *Ganetespib*; *Geldanamycin*; *Herbimycin*; *Macbecin*; *Radicalcol*; *Tanespimycin*) 1. Nakashima, Ishii, Tagaya, *et al.* (2010) *Clin. Cancer Res.* **16**, 2792.

**KW-3049**, See *Benidipine*

**KX2-391**

This orally bioavailable, non-ATP competitive inhibitor (FW<sub>free-base</sub> = 431.54 g/mol; CAS 897016-82-9 (dihydrochloride)); Solubility of free-base is 85 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O or Ethanol), known also by its alternate code name KX-01 and systematically as *N*-benzyl-2-(5-(4-(2-morpholinoethoxy)phenyl)pyridin-2-yl)acetamide, binds in the target protein substrate pocket of Src kinase, a proto-oncogene protein kinase that is up-regulated in many cancer cell lines and exerts control over multiple genetic and signaling pathways involved in the proliferation, survival, angiogenesis, invasion, and migration of various types of cancer cells. By targeting the peptide substrate rather than the ATP binding site, this inhibitor has a mode of action that is distinct from other Src kinase inhibitors. The KX2-391 binding site on tubulin (IC<sub>50</sub> = 0.5 μM) is distinct from sites for well-known tubulin inhibitors. KX2-391 nominally exhibits a GI<sub>50</sub> of 9-60 nM for the growth inhibition of various liver cancer cell lines (e.g., Huh7, PLC/PRF/5, Hep3B, and HepG2). 1. Fallah-Tafti, Forumadi, Tiwari, *et al.* (2011) *Eur. J. Med. Chem.* **46**, 4853.

**KY02111**

This (FW = 376.86 g/mol; CAS 1118807-13-8; Solubility: 15 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), systematically named *N*-(6-chloro-2-benzothiazolyl)-3,4-dimethoxybenzenepropanamide, promotes human pluripotent stem cell (hPSC) differentiation into cardiomyocytes by inhibiting Wnt signaling (renamed after *Drosophila* Wingless/int family of secreted lipid-modified signaling glycoproteins, with int1 becoming Wnt1). Although the direct target of KY02111 remains unknown, it is believed to

act downstream of APC and GSK3β. 1. Minami, Yamada, Otsuji, *et al.* (2012) *Cell Rep.* **2**, 1448.

**Kynurenate (Kynurenic Acid)**

This quinaldate biosynthesis intermediate (FW<sub>free-acid</sub> = 189.17 g/mol; M.P. = 282-283°C; Yellow solid; Slightly soluble in water (0.9% at 100°C); Insoluble in diethyl ether; λ<sub>max</sub> at 332 and 344 nm at pH 7; ε = 9800 and 7920 M<sup>-1</sup>cm<sup>-1</sup>, respectively), also known as 4-hydroxyquinaldate, 4-hydroxy-2-quinoline-carboxylate, and 4 oxo-4*H*-quinoline-2-carboxylate, is a nonselective NMDA and AMPA/kainate receptor antagonist. **Target(s):** acetyl-CoA carboxylase (1,2); aldehyde reductase, or aldose reductase (3); 2 aminoacidate aminotransferase (4); AMPA/kainate receptors (5,6); dihydrolipoamide dehydrogenase (7); glutamate dehydrogenase (8-10); glyceraldehyde-3-phosphate dehydrogenase (10); kynureninase (11); kynurenine 7,8-hydroxylase (12); kynurenine 3-monooxygenase, weakly inhibited (13); kynurenine: oxoglutarate aminotransferase (14); lactate dehydrogenase (8-10); malate dehydrogenase (10); NAD<sup>+</sup> ADP-ribosyltransferase, or poly(ADP-ribose) polymerase (15); NMDA receptor (5,6,16); tryptophan 2,3-dioxygenase (17). 1. **KYP-2047**

This brain-penetrating proline/cyanoproline-containing peptide derivative (FW = 339.43 g/mol; CAS 796874-99-2), also named (2S)-1-[[[(2S)-1-(1-oxo-4-phenylbutyl)-2-pyrrolidiny]carbonyl]-2-pyrrolidinecarbonitrile, modulates inflammation, angiogenesis and neurodegeneration by virtue of its extreme inhibition of prolyl oligopeptidase, or POP ( $K_i = 23$  pM), also known as prolyl endopeptidase (1). KYP-2047 rapidly penetrates mouse brain ( $t_{max} \leq 10$  min), achieving pharmacologically active concentrations after a single dose of 15 or 50  $\mu\text{mol/kg}$  (i.p.) (4). The brain/blood AUC ratio was 0.050 and 0.039 after 15 and 50  $\mu\text{mol/kg}$  (i.p.), respectively (2). KYP-2047 was equally distributed between the cortex, hippocampus and striatum. KYP-2047 clears the  $\alpha$ -synuclein aggregates induced by oxidative stress in cell lines overexpressing wild-type or A30P/A53T mutant

human  $\alpha$ -syn and in the brains of two A30P  $\alpha$ -synuclein transgenic mouse strains (3).  $\alpha$ -Synuclein is the main component of Lewy bodies in Parkinson Disease that cause neuronal cell death and dementia (3). KYP-2047 also inhibits AcSDKP formation from the actin monomer-sequestering protein thymosin  $\beta 4$  (Sequence: MSDKPDMAEIEKFDKSKLKKKTETQEKKNPLPSKETIEQEKQAGES). Ac-SDKP is a pro-angiogenic and antifibrogenic agent that is involved in hemopoietic stem cell differentiation (4). 1. Jalkanen, Puttonen, Venäläinen, *et al.* (2007) *Basic Clin. Pharmacol. L, See L-Leucine

#### L803-mts

This selective, cell-permeable peptide inhibitor (FW = 1464.64 g/mol; *Sequence*: Myr-GKEAPPAPPqSP-NH<sub>2</sub>, with modifications at: Gly-1 = *N*-Myristoyl-Gly, Ser-11 = pSer, and Pro-12 = C-terminal amide; CAS 1043881-55-5) targets glycogen synthase kinase-3, or GSK-3 (IC<sub>50</sub> = 40 μM), but is without effect on Cdc2, PKB, and PKC. This phosphorylated peptide inhibitor is protein substrate site-competitive, in sharp contrast to protein kinase inhibitors directed to ATP binding sites. L803-mts mimics insulin action, activating glycogen synthase activity (~2.5-fold) in HEK293 cells and improving glucose tolerance in diabetic mice. **1.** Plotkin, Kaidanovich, Talior & Eldar-Finkelman (2003) *J. Pharm. Exp. Ther.* **305**, 974.

#### L2-401

This thiazolidinone (FW = 304.34 g/mol), systematically named 4-[(4-fluorophenyl)methyl]-2-(4-methylphenyl)-1,2,4-thiazolidine-3,5-dione, is a slow binding inhibitor of the pyridoxal 5'-phosphate-dependent enzyme alanine racemase ( $K_i = 0.2 \mu\text{M}$ ), which catalyzes the racemization of L-alanine to D-alanine. The latter is an essential precursor for the synthesis of the pentapeptide cross-linkers in cell wall peptidoglycan of methicillin-resistant *Staphylococcus aureus*. When presented on a molar basis, L2-401 and D-cycloserine showed comparable inhibitory effects *in vitro* against methicillin-susceptible and methicillin-resistant *S. aureus* strains, as revealed by the MIC required to inhibit bacterial growth. L2-401 also inhibits HeLa cell proliferation. Thiazolidinediones are known to inhibit Glycogen Synthase Kinase-3 β, but it is not known whether GSK-3β inhibition is responsible for L2-401's growth-inhibiting effect on HeLa cells. **1.** Ciusteaa, Mootiena, Rosato (2012) *Biochem. Pharmacol.* **83**, 368.

L-163,191, See MK 0677

#### L 216140

This antibiotic (FW = 308.33 g/mol) competitively inhibits UDP-3-*O*-(*R*-3-hydroxymyristoyl)-GlcNAc deacetylase, or LpxC ( $K_i = 50 \text{ nM}$ ), an enzyme that catalyzes the committed reaction in the biosynthesis of Lipid A, an essential molecule for bacterial proliferation. LpxC is thus a prime target for the development of novel antibiotics (1). By using L-161,240-insensitive LpxC activity from *P. aeruginosa* expressed from a low copy plasmid, LpxC was shown to be the primary target of L-161,240 in *E. coli* (2). When challenged with a lethal dose of *E. coli*, L-161-240 protects mice against septicemia; however, it is ineffective against *Pseudomonas aeruginosa* or *Serratia marcescens*. **1.** Onishi, Pelak, Gerckens, *et al.* (1996) *Science* **274**, 980. **2.** Mdluli, Witte, Kline, *et al.* (2006) *Antimicrob. Agents Chemother.* **50**, 2178.

#### L-368899

This orally bioavailable, nonpeptide oxytocin receptor antagonist (FW<sub>free-base</sub> = 554.78 g/mol; CAS 148927-60-0; Soluble to 100 mM in water and to 100 mM in DMSO), also known as 1-((7,7-dimethyl-2(*S*)-(2(*S*)-amino-4-(methylsulfonyl)butylamido)bicyclo[2.2.1]-heptan-1(*S*)-yl)methyl)sulfonyl)-4-(2-methylphenyl)piperazine, exhibits good selectivity (IC<sub>50</sub> = 8.9 nM), with > 40-fold selectivity over vasopressin V<sub>1a</sub> (IC<sub>50</sub> = 370 nM) and V<sub>2</sub> (IC<sub>50</sub> = 570 nM) receptors. L-368899 antagonizes oxytocin-induced uterine contractions *in vitro* and *in vivo* (1). Unlike peripherally selective L-371257, brain penetration by L-368899 rapid and selectively accumulates in areas of the limbic system, making it a useful tool for investigating the centrally mediated roles of oxytocin, including social behaviour and pair bonding. L-368899 reduces sexual activity, food-sharing, and related mothering instincts. Treatment with L-368899 significantly reduced episodes luteolytic PGF<sub>2α</sub> release in ewes, suggesting it may have value in reducing early pregnancy failure (2). **1.** Williams, Anderson, Ball, *et al.* (1994) *J. Med. Chem.* **37**, 565. **2.** Mann, Lamming, Scholey, Hunter & Pettibone (2003) **25**, 255.

L-651,582, See Carboxyamidotriazole

#### L-655238

This substituted quinolone (FW = 335.45 g/mol; CAS 101910-24-1), also known as α-pentyl-4-(2-quinolinylmethoxy)benzenemethanol and REV 5901, is a potent inhibitor of the 5-lipoxygenase activating protein, or FLAP (IC<sub>50</sub> = 100 nM) and a competitive leukotriene D<sub>4</sub> antagonist. **Target(s):** leukotriene D<sub>4</sub> (1); 5-lipoxygenase-activating protein (2). **1.** Datta, Rathod, Manning, Turnbull & McNeil (1996) *J. Endocrinol.* **149**, 269. **2.** Evans, Leville, Mancini, *et al.* (1991) *Mol. Pharmacol.* **40**, 22.

#### L-658758

This cephalosporin derivative (FW<sub>free-acid</sub> = 414.41 g/mol), also known as 1-[[3-(acetoxymethyl)-7α-methoxy-8-oxo-5-thia-1-azabicyclo[4.2.0]oct-2-en-2-yl]carbonyl]proline *S,S*-dioxide, irreversibly inhibits leukocyte elastase, with acylation of an active-site serine hydroxyl. **Target(s):** leukocyte elastase, or neutrophil elastase (1-4); myeloblastin, or proteinase 3 (4). **1.** Davies, Ashe, Bonney, *et al.* (1991) *Ann. N. Y. Acad. Sci.* **624**, 219. **2.** Knight, Maycock, Green, *et al.* (1992) *Biochemistry* **31**, 4980. **3.** Pacholok,

Davies, Dorn, *et al.* (1995) *Biochem. Pharmacol.* **49**, 1513. 4. Rees, Brain, Wohl, Humes & Mumford (1997) *J. Pharmacol. Exp. Ther.* **283**, 1201.

**L-659,699**, See F-244

**L-660631**

This triyne carboxylate natural product (FW = 318.32 g/mol; CAS 115216-83-6), also known as 2-oxo-5-(1-hydroxy-2,4,6-heptatriynyl)-1,3-dioxolone-4-heptanoic acid, first isolated from a culture of *Actinomyces*, targets rat liver cytosolic acetyl-CoA C-acetyltransferase, thereby inhibiting sterol biosynthesis. L-660631 also regulates the growth of *Candida albicans*. The inhibitor had no effect on other sulfhydryl containing enzymes of lipid synthesis such as HMG-CoA synthase, HMG-CoA reductase, and fatty acid synthase. 1. Greenspan, Yudkovitz, Chen, *et al.* (1989) *Biochem. Biophys. Res. Commun.* **163**, 548.

**L-660711**, See MK-0571

**L-671,152**, See Dorzolamide

**L-687908**

This potent hydroxyethylene-containing peptidomimetic (FW = 681.88 g/mol) inhibits human immunodeficiency virus-1 protease (IC<sub>50</sub> = 30 pM). 1. Vacca (1994) *Meth. Enzymol.* **241**, 311. 2. Vacca, Guare, deSolms, *et al.* (1991) *J. Med. Chem.* **34**, 1225.

**L-700,462**, See Tirofiban

**L-739749**

This peptidomimetic (FW = 531.74 g/mol), also known as 2(S)-[2(S)-[2(R)-amino-3-mercapto]propylamino-3(S)-methyl]pentylloxy-3-phenylpropionyl-methioninesulfone methyl ester, is L-cysteinyl-L-isoleucyl-L-phenylalanyl-L-methionine methyl ester analogue and a prodrug for the early-stage inhibitor of protein farnesyltransferase L-739750 (1-3). L-739749 principally interferes with RhoB and suppresses Ras transformation. The half-life of RhoB was found to be ~2 h, and can be functionally depleted

during the 18-h period required by L-739749 to induce reversion. Cell treatment with L-739749 disrupted the vesicular localization of RhoB but did not effect the localization of the closely related RhoA protein. Ras-transformed Rat1 cells ectopically that express *N*-myristylated forms of RhoB (*e.g.*, Myr-RhoB, whose vesicular localization was unaffected by L-739749) were resistant to drug treatment (2). 1. Gibbs (2001) *The Enzymes*, 3rd ed., **21**, 81. 2. Prendergast, Davide, deSolms, *et al.* (1994) *Mol. Cell. Biol.* **14**, 4193. 3. Kohl, Wilson, Mosser, *et al.* (1994) *Proc. Natl. Acad. Sci. U.S.A.* **91**, 9141.

**L-739750**

This Cys-Ile-Phe-Met peptidomimetic (FW = 501.71 g/mol) is the metabolic product of the prodrug L-739749 and the similarly acting prodrug L-744832. It inhibits protein farnesyltransferase, which catalyzes posttranslational modification of signal-transduction G-proteins, including Ras (1-3). L-739750 suppresses the anchorage-independent growth of Rat1 cells transformed with viral H-ras. (See L-739749 above for additional details.) 1. Terry, Long & Beese (2001) *The Enzymes*, 3rd ed., **21**, 19. 2. Kohl, Wilson, Mosser, *et al.* (1994) *Proc. Natl. Acad. Sci. U.S.A.* **91**, 9141. 3. Guida, Hamilton, Crotty & Sebt (2006) *J. Comp.-Aided Mol. Des.* **19**, 871.

**L-743,726**, See Efavirenz

**L-745870**

This pyrrolopyridine (FW<sub>free-base</sub> = 326.83 g/mol), also known as 3-[(4-(4-chlorophenyl)piperazin-1-yl)methyl]-1*H*-pyrrolo[2,3-*b*]pyridine, is a selective D<sub>4</sub> dopamine receptor antagonist. It displaces the specific binding of 0.2 nM spiperone to cloned human dopamine D<sub>4</sub> receptors with a K<sub>i</sub> value of 0.43 nM. 1. Kulagowski, Broughton, Curtis, *et al.* (1996) *J. Med. Chem.* **39**, 1941. 2. Patel, Freedman, Chapman, *et al.* (1997) *J. Pharmacol. Exp. Ther.* **283**, 636.

**L-754030**, See Aprepitant

**L868275**, See Flavopiridol

**Laccaic Acid A**

This complex anthraquinone and widely used food colorant (FW = 537.43 g/mol; CAS 15979-35-8; *Abbreviation*: LCA) is a novel, first-in-class direct, DNA-competitive inhibitor (K<sub>i</sub> = 310 nM) of DNA methyltransferase 1 (*or* DNMT1), a key enzyme in the methylation of cytosines within CpG dinucleotide during epigenetic marking of vertebrate DNA, thereby repressing transcription. This enzyme binds to DNA replication sites in S-phase and acts to maintain the methylation pattern in the newly synthesized

strand, a condition that is essential for epigenetic inheritance. It also associates with chromatin during G<sub>2</sub> and M phases to maintain DNA methylation independently of replication. Significantly, LCA exhibited mixed inhibition with respect to *S*-adenosyl-methionine (1). Given its polycyclic aromatic structure, LCA is a likely DNA intercalator. Significantly, LCA and 5-aza-dC act synergistically in activating expression of silenced tumor suppressor genes, thus demonstrating the value of using agents having complementary mechanisms of action. Laccacia acid is a potent inhibitor of the autoactivation of the plasma hyaluronan-binding protein (PHBP) proenzyme, IC<sub>50</sub> ≈ 1 μM, as well as the PHB's catalytic activity of the active enzyme, IC<sub>50</sub> ≈ 1 μM (2). 1. Fagan, Cryderman, Kopelovich, Wallrath & Brenner (2013) *J. Biol. Chem.* **288**, 23858. 2. Sekido, Nishimura, Takai & Hasumi (2010) *Biosci. Biotechnol. Biochem.* **74**, 2320.

### Lacosamide

This functionalized amino acid (FW = 250.29 g/mol; CAS 175481-36-4; Abbreviation: LCM), also known as Vimpat<sup>®</sup> and systematically named *N*<sup>2</sup>-acetyl-*N*-benzyl-*D*-homoserinamide, is an orally available anticonvulsant that selectively enhances the slow inactivation of sodium channels and interacts with the neuroplasticity-relevant target, collapsin-response mediator protein-2 (CRMP-2), a cytosolic phosphoprotein involved in neuronal differentiation and axonal guidance. Pharmacokinetic studies show that it is renally excreted, minimally bound to plasma proteins, with no known drug-drug interactions. LCM inhibits CRMP2-mediated neurite outgrowth, an effect that is phenocopied by CRMP2 knockdown (1). At 10 μM, LCM does not bind to AMPA receptors; Kainate receptors; NMDA receptors; GABA<sub>A</sub> (muscimol/benzodiazepine) receptor; GABA<sub>B</sub> receptor, adenosine A<sub>1</sub> receptor, adenosine A<sub>2</sub> receptor, adenosine A<sub>3</sub> receptor; α<sub>1</sub>-receptor, α<sub>2</sub>-receptor; β<sub>1</sub>-receptor, β<sub>2</sub>-receptor; muscarinic M<sub>1</sub>, M<sub>2</sub>, M<sub>3</sub>, M<sub>4</sub>, and M<sub>5</sub> receptors, histamine H<sub>1</sub>, H<sub>2</sub>, and H<sub>3</sub> receptors, dopamine D<sub>1</sub>, D<sub>2</sub>, D<sub>3</sub>, D<sub>4</sub>, and D<sub>5</sub> receptors; serotonin HT<sub>1A</sub>, HT<sub>1B</sub>, HT<sub>2A</sub>, HT<sub>2C</sub>, HT<sub>3</sub>, HT<sub>5A</sub>, HT<sub>6</sub>, and HT<sub>7</sub> receptors, and K<sub>ATP</sub> receptor, indicating that LCM does not act by means of a high-affinity interaction with an acknowledged recognition site on a target for existing antiepileptic drugs (2). Instead, lacosamide affects voltage-gated sodium channels in a novel way by enhancing the slow-inactivating 'braking' state of these channels (3). 1. Wilson SM, Xiong W, Wang (2012) *Neuroscience* **210**, 451. 2. Errington, Coyne, Stöhr, Selve & Lees (2006) *Neuropharmacology* **50**, 1016. 3. Bee & Dickenson (2009) *Neuropharmacology* **57**, 472.

### Lactacystin

This cell-permeable, pro-inhibitor (FW<sub>free-acid</sub> = 376.43 g/mol), a *Streptomyces lactacystinaeus* metabolite that spontaneously converts to its *clasto*-lactacystin β-lactone (FW = 213.23 g/mol), also known as omuralide, which irreversibly inhibits mammalian proteasomes, blocking both chymotryptic- and tryptic-like activities (K<sub>i</sub> = 4 nM). It also inhibits NF-κB activation. Lactacystin is also an inducer of neurite outgrowth in mouse neuroblastoma cells. **Target(s):** carboxypeptidase C, or cathepsin A (1-3); HslVU protease (4); proteasome ATPase (5); proteasome endopeptidase complex (6-12). 1. Kozlowski, Stoklosa, Omura, *et al.* (2001) *Tumour Biol.* **22**, 211. 2. Ostrowska, Wojcik, Wilk, *et al.* (2000) *Int. J. Biochem. Cell Biol.* **32**, 747. 3. ### β-Lactam Antibiotics

These naturally occurring, fungus-derived antibiotics target the transpeptidases that catalyze a key step in the cross-linking of the peptidoglycan required in bacterial cell wall formation. These natural products are divided into five classes, the core structures of which are as follows.

The common structural element within these antibiotics is the central four-member β-lactam nucleus, a highly strained structure that intercepts the transpeptidase (TP) and activates covalent formation of *O*-acyl-TP. These antibiotics likewise exclude/diminish water attack on the *O*-acyl-TP, thereby preventing hydrolysis. The net effect is that β-lactam antibiotics successfully interrupt cell-wall formation. **See specific agent; For details on mode of action, See Penicillins**

### D-Lactate (D-Lactic Acid)

This α-hydroxyacid (FW = 90.08 g/mol; pK<sub>a</sub> = 3.86 at 25°C; Soluble in water, ethanol, and acetone; M.P. = 52.8°C), systematically named (*R*)-2-hydroxypropanoic acid, is produced by some microorganisms, fungi, plants, as well such microbes as *Escherichia coli* and *Lactobacillus leishmanii*. The solid is hygroscopic and concentrated solutions tend to oligomerize. (See also *DL*-Lactate; *L*-Lactate) **Target(s):** ε-crystallin L-lactate dehydrogenase (1); 3-hydroxybutyrate dehydrogenase (2-4); L-lactate dehydrogenase (1,5-7); L-lactate 2-monooxygenase (8-13); D-lactate-2-sulfatase (14); proline dehydrogenase (15); propionate CoA-transferase, also as an alternative substrate (16). 1. ### L-Lactate (L-Lactic Acid)

This  $\alpha$ -hydroxy acid (FW = 90.08 g/mol;  $pK_a$  = 3.86 at 25°C; Soluble in water, ethanol, and acetone; M.P. = 52.8°C), systematically named (*S*)-2-hydroxypropanoic acid, is the enantiomer that is most often encountered in Nature and is formed via anaerobic glycolysis. L-Lactate accumulates in muscle cells and blood following strenuous exercise. **Target(s):** aminoacylase (1); catalase (2); creatine kinase (3,4); cutinase (5); cystathionine  $\gamma$ -lyase, or cysteine desulfhydrase (6); D-2-hydroxy-acid dehydrogenase (7); D-lactate dehydrogenase (8); nicotinate-nucleotide diphosphorylase (carboxylating) (9); oxaloacetate tautomerase (10); phosphoenolpyruvate carboxylase (11); proline dehydrogenase (12); propionate CoA-transferase, also as an alternative substrate (13); pyrophosphatase (14); pyruvate kinase (15,16); taupine dehydrogenase (17); tyrosinase, or monophenol monooxygenase (18); tyrosine decarboxylase (19); UDP-*N*-acetylmuramate:L-alanine ligase (20). **1.** Tamura, Oki, Yoshida, *et al.* (2000) *Arch. ### Lactacin 481

This 1.7-kDa lanthionine-containing peptide antibiotic, produced by *Lactococcus lactis* CNRZ 481, is a bacteriocin that acts adversely on certain other microorganisms via pore formation (1-3). The sequence is shown above where single uppercase letters refer to standard aminoacyl residues and dhB, Abu-S-Ala, and Ala-S-Ala refer to didehydrobutyrine,  $\beta$ -methylanthionine, and lanthionine, respectively. Lactacin 481 is synthesized on ribosomes as a prepeptide (LctA) and posttranslationally modified to its mature form. These modifications include dehydration of serines and threonines, followed by intramolecular addition of cysteines to the unsaturated amino acids, which generates cyclic thioethers. This process breaks eight chemical bonds and forms six new bonds and is catalyzed by one enzyme, LctM (4). **1.** Piard, Delorme, Novel, Desmazeaud & Novel (1993) *FEMS Microbiol. Lett.* **112**, 313. **2.** Piard, Kuipers, Rollema, Desmazeaud & de Vos (1993) *J. Biol. Chem.* **268**, 16361. **3.** Piard, Muriana, Desmazeaud & Klaenhammer (1992) *Appl. Environ. Microbiol.* **58**, 279. **4.** Xie, Miller, Chatterjee, *et al.* (2004) *Science* **303**, 679.

### Lactitol

This hygroscopic reduced sugar (FW = 344.32 g/mol; CAS 585-86-4), also known as 4-*O*- $\beta$ -D-galactopyranosyl-D-glucitol and lacticol, is an artificial sweetener and as a laxative. **Target(s):** 3-galactosyl-*N*-acetylglucosaminide 4- $\alpha$ -L-fucosyltransferase, or galactoside 3(4)-L-fucosyltransferase,  $K_i$  = 17 mM (1,2); *trans*-sialidase (3). **1.** Sadler, Beyer, Oppenheimer, *et al.* (1982) *Meth. Enzymol.* **83**, 458. **2.** Priels, Monnom, Dolmans, Beyer & Hill (1981) *J. Biol. Chem.* **256**, 10456. **3.** Agusti, Paris, Ratier, Frasch & de Lederkremer (2004) *Glycobiology* **14**, 659.

### Lactocin S

This lanthionine-containing peptide antibiotic (CAS 125387-34-0), from *Lactobacillus sake*, is a bacteriocin that exhibits potent antimicrobial activity against a broad range of Gram-positive organisms. The sequence is shown above where single uppercase letters refer to standard aminoacyl residues, and dhB and Ala-S-Ala refer to didehydrobutyrine and lanthionine, respectively. Note that lactocin S also contains D-alanyl residues (DA). This bacteriocin is the first prokaryotic exception to the rule that only L-amino acids are included in ribosomally synthesized peptides. **1.** Skaugen, Nissen-Meyer, Jung, *et al.* (1994) *J. Biol. Chem.* **269**, 27183.

### Lactose

This disaccharide (FW = 342.30 g/mol; CAS 63-42-3), also known as 4-*O*- $\beta$ -D-galactopyranosyl-D-glucose, milk sugar, and lactobiose, is a yeast-fermentable reducing sugar. Both the  $\alpha$ - and  $\beta$ -anomers are commercially available, and  $\alpha$ -lactose is less soluble in water (1 g/2.6 mL boiling water vs. 1 g/1.1 mL for the  $\beta$ -anomer) and not as sweet as  $\beta$ -lactose. **Target(s):**  $\beta$ -*N*-acetylhexosaminidase (19,20); aldose 1-epimerase (1,2); arabinogalactan endo 1,4- $\beta$ -galactosidase (3); aralin (4); *Bauhinia purpurea* agglutinin (5); cellulase (25); cellulose 1,4- $\beta$  cellobiosidase (6-9); discoidins II (*Dictyostelium discoideum* agglutinins) (10); electrolectin (11);  $\beta$ -fructofuranosidase, or invertase, weakly inhibited (24);  $\beta$ -D-fucosidase (22,23); 1,2- $\alpha$ -L-fucosidase (12);  $\alpha$ -galactosidase (13); galactoside 2- $\alpha$ -L-fucosyltransferase (26); galactosylceramidase (21); glucuronosyltransferase (27); isomaltulose synthase (14); levansucrase (15); pallidin (*Polysphondylium pallidum* agglutinin) (16); phloretin hydrolase (17); rRNA *N*-glycosylase (4); *Sophora japonica* hemagglutinin (18). **1.** Bentley (1962) *Meth. ### Lactulose

This nonabsorbable disaccharide (FW = 342.30 g/mol; CAS 4618-18-2), also known by the brand names Constulose<sup>®</sup>, Enulose<sup>®</sup>, Generlac<sup>®</sup>, Cholac<sup>®</sup>, and Constilac<sup>®</sup>, as well as its IUPAC name 4-O-β-D-galactopyranosyl-β-D-fructofuranose, is an osmolyte that, when taken orally (typical dose = 10 g/15 mL), remains within the digestive tract, thereby increasing colon water content and relieving constipation within one day. Lactulose may also be taken orally or rectally to treat hepatic encephalopathy arising from hyperammonemia. In this case, lactulose is metabolized by gut flora, forming lactic acid and acetic acid and acidifying the colon. The latter converts otherwise freely diffusible NH<sub>3</sub> into NH<sub>4</sub><sup>+</sup> ion, which cannot diffuse back into the bloodstream and is instead eliminated. Lactulose also stimulates the growth of health-promoting bacteria (e.g., bifidobacteria and lactobacilli) in the GI tract, while inhibiting growth of pathogenic bacteria, including *Salmonella*. Pharmacological inhibition of galectin-1 by lactulose alleviates weight gain in diet-induced obese rats (1). Notably, lactulose reduces adipogenesis and fat accumulation *in vitro* by down-regulating such adipogenic transcription factors such as C/EBPα and PPARγ. *In vivo* treatment of lactulose in 5-week-old Sprague-Dawley male rats significantly alleviates High-Fat-Diet-induced body weight gain and food efficiency as well as improved plasma and other metabolic parameters. Lactulose treatment also down-regulates major adipogenic marker proteins (e.g., C/EBPα and PPARγ) in adipose tissue as well as stimulated expression of proteins involved in energy expenditure and lipolysis (e.g., ATP5B, COXIV, HSL, and CPT1). Lactulose was first identified in milk that was heat-treated, and it can now be prepared in highly efficient chemical and enzymatic syntheses. **1.** Mukherjee & Yun (2016) *Life Sci.* **148**, 112.

### Ladostigil

This orally bioavailable AChE inhibitor and novel multimodal neuroprotective drug (FW = 272.34 g/mol; CAS 209349-27-4), also codenamed TV-3,326 and known systematically as [(3R)-3-(prop-2-ynylamino)indan-5-yl]-N-propylcarbamate, reversibly targets both acetylcholinesterase (AChE) as well as butyrylcholinesterase (BuChE) in rats after oral doses of 10-100 mg/kg (1) and irreversibly inhibits monoamine oxidase B (2). Through the combination of the pharmacophore of rasagiline with the carbamate moiety of the cholinesterase inhibitor rivastigmine, ladostigil is a versatile inhibitor that shows promise for treating neurodegenerative disorders like Alzheimer's disease, Lewy body disease, and Parkinson's disease. (See also *Rasagiline*; *Rivastigmine*) After chronic but not acute treatment, it inhibits MAO-A and -B in the brain by more than 70% but has almost no effect on these enzymes in the small intestine in rats and rabbits (1). The brain selectivity results in minimal potentiation of the pressor response to oral tyramine. Ladostigil acts like other antidepressants in the forced swim test in rats, indicating a potential for antidepressant activity. Chronic treatment of mice with ladostigil (26 mg/kg) prevents the destruction of nigrostriatal neurons by the neurotoxin N-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (or MPTP) (2). An additional

and new neuroprotective effect, shared by propargylamine compounds, relates to their ability to regulate the processing of amyloid-β protein precursor (AβPP) by the non-amyloidogenic α-secretase pathway. Such effects are linked to the p42/44 mitogen-activated protein kinase (MAPK) and protein kinase C (PKC) signaling pathway (2). Moreover, by enhancing the expression of Glia-Derived Neurotrophic Factor (GDNF) and Brain-Derived Neurotrophic Factor (BDNF), ladostigil may reverse damaging effects of neurodegenerative diseases by inducing neurogenesis (3). Ladostigil has antidepressant effects, and may prove useful as a way to reduce comorbid depression and anxiety in such disorders (4,5). Recent work indicates that ladostigil prevents gliosis and oxidative-nitrate stress and reduced the deficits in episodic and spatial memory induced by intracerebroventricular injection of streptozotocin in rats (6). It also possesses potent anti-apoptotic and neuroprotective activities *in vitro* and in various neurodegenerative rat models, (e.g., hippocampal damage induced by global ischemia in gerbils and cerebral oedema induced in mice by closed head injury). These neuroprotective activities involve regulation of amyloid precursor protein processing; activation of protein kinase C and mitogen-activated protein kinase signaling pathways; inhibition of neuronal death markers; prevention of the fall in mitochondrial membrane potential and upregulation of neurotrophic factors and antioxidative activity. Recent findings demonstrated that the major metabolite of ladostigil, hydroxy-1-(R)-aminoindan has also a neuroprotective activity and thus, may contribute to the overt activity of its parent compound (6). **1.** Weinstock, Gorodetsky, Poltyrev, *et al.* (2003) *Prog. ### Lambrolizumab

This humanized monoclonal IgG<sub>4</sub>κ isotype antibody (MW = 146.3 kDa; CAS 1374853-91-4), also known as MK-3475, targets the programmed death-1 receptor (PD-1), a negative regulator of T-cell effector mechanisms that limits immune responses against cancer. The variable region sequences of a very-high-affinity mouse antihuman PD-1 antibody (K<sub>d</sub> = 28 pM) were grafted into a human IgG<sub>4</sub> immunoglobulin with a stabilizing S228P Fc alteration (1). The IgG<sub>4</sub> immunoglobulin subtype does not engage Fc receptors or activate complement, thus avoiding cytotoxic effects of the antibody when it binds to the T cells that it is intended to activate. In advanced stage melanoma patients, including those with disease progression while on ipilimumab, lambrolizumab treatment resulted in a high rate of durable tumor regression (1). Abrogating an immune-system checkpoint to limit the antitumor activity of preexisting tumor-specific cytotoxic T cells underscores the importance of focusing on immune regulatory events for cancer therapy (1). In April, 2013, Lambrolizumab was granted breakthrough therapy status to the experimental drug. **1.** Hamid, Robert, Daud, *et al.* (2013) *New Engl. J. Med.* **369**, 134.

### LamB Signal Peptide

This basic oligopeptide (MW = 2545.22 g/mol; Sequence: MMITLRKLLPLAVAVAAGVMSAQAMA; Isoelectric Point = 11.0), corresponds to the signal sequence of the *Escherichia coli* outer membrane protein, LamB, inhibits the signal-recognition-particle GTPase activity (K<sub>i</sub> = 5-8 μM), as does MMITLRKRRKLLPLAVAVAAGVMSAQAMA (MW = 2985.77; Isoelectric Point = 12.3; K<sub>i</sub> = 3 μM). With fully a third of the *E. coli* proteome comprised of proteins making up the cytoplasmic membrane, periplasm, or outer membrane, these peptides are useful probes of whether an *E. coli* protein is processed by the general secretion (Sec) pathway. **1.** Swain & Gierasch (2001) *J. Biol. Chem.* **276**, 12222.

### Lamivudine

This nucleoside RTI and antiviral (FW = 229.26 g/mol; CAS 134678-17-4; Symbol: 3TC; IUPAC Name: 4-amino-1-[(2R,5S)-2-(hydroxymethyl)-1,3-oxathiolan-5-yl]-1,2-dihydropyrimidin-2-one), also known as Epivir<sup>®</sup> and Epivir-HBV<sup>®</sup>, the (–)-enantiomer of 2'-deoxy-3'-thiacytidine,

inhibits HIV reverse transcriptase and prevents hepatitis B virus (HBV) infection by likewise targeting the HBV reverse transcriptase (1-7). Within the cell, lamivudine is converted to its triphosphate, or 3TC-TP (**See Lamivudine 5'-Triphosphate**), which can act (a) as a reverse transcriptase chain terminator, after incorporation into the growing HBV DNA chain and (b) as a competitive inhibitor of deoxycytidine triphosphate (dCTP) incorporation at the level of the DNA polymerase. 3TC-TP inhibits viral DNA synthesis, but without effect on mitochondrial DNA synthesis. Lamivudine also interrupts the recycling of virions to the nucleus and suppress formation of covalently closed circular DNA (or cccDNA). When receiving lamivudine for 3 years to treat chronic hepatitis B, 67-75% of patients develop drug-resistant B-domain (L528M), C-domain (M552I), or M552V mutations in HBV polymerase (8). *In vitro* studies show resistance in single-drug exposure of L528M-, M552I-, M552V-, L528M/M552I-, or L528M/M552V-containing hepatoma cells to lamivudine, adefovir, entecavir, racivir, emtricitabine, L-D4FC, clevudine, D-DAPD, or (-)-carbovir (8). Significantly, only adefovir and entecavir are effective against all five HBV mutants, and higher doses of these compounds were necessary to inhibit the double mutants compared with the single mutants. The B-domain mutation (L528M) of HBV polymerase not only restores the replication competence of C-domain mutants, but also increases resistance to nucleoside analogues. (**See also Adefovir & Adefovir Dipivoxil; Entecavir; Telbivudine; Tenofovir; Emtricitabine**) **Target(s):** deoxycytidine kinase (1); deoxynucleoside kinase (1); feline immunodeficiency virus reverse transcriptase, via the 5'-triphosphate (2); feline leukemia virus reverse transcriptase, via the 5'-triphosphate (2); HBV reverse transcriptase, via the 5'-triphosphate (3,4); HIV reverse transcriptase, via the 5'-triphosphate (5-7); RNA-directed DNA polymerase, via the 5' triphosphate (2-7). 1. #### Lamivudine 5'-Triphosphate

This nucleotide analogue (FW = 470.21 g/mol), the (-)-enantiomer of 2'-deoxy-3'-thiacytidine 5'-triphosphate, inhibits DNA polymerase (1), feline immunodeficiency virus reverse transcriptase (2), feline leukemia virus reverse transcriptase (2), HIV reverse transcriptase (1,3), and RNA-directed DNA polymerase (1-3). 3TC 5'-triphosphate is a competitive inhibitor with respect to dCTP in the RNA-dependent DNA polymerase activity ( $K_i = 10.6$  to  $1.24 \mu\text{M}$ , depending on the template and primer used). The DNA-dependent DNA polymerase activity is 50% inhibited at  $23 \mu\text{M}$  3TC 5'-triphosphate concentration (1). 1. Hart, Orr, Penn, *et al.* (1992) *Antimicrob. Agents Chemother.* **36**, 1688. 2. Operario, Reynolds & Kim (2005) *Virology* **335**, 106. 3. El Safadi, Vivet-Boudou & Marquet (2007) *Appl. Microbiol. Biotechnol.* **75**, 723.

#### Lamotrigine

This triazine (FW = 256.09 g/mol; CAS 84057-84-1), named systematically as 6-(2,3-dichlorophenyl)-1,2,4-triazine-3,5-diamine, is an anticonvulsant drug that has been used in the treatment of bipolar disorders. **Primary Mode of Action:** Lamotrigine acts presynaptically on voltage-gated sodium channels to decrease glutamate release. Its antiepileptic effects are, at least in part, due to use- and voltage-dependent modulation of fast voltage-

dependent sodium currents. **Key Pharmacokinetic Parameters:** *See* Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):**  $\text{Ca}^{2+}$  channels (1-3); glutamate release (4-6);  $\text{Na}^+$  channels (3,4,7,8). 1. #### Laninamivir Octanoate

This viral neuraminidase (NA) -directed prodrug (FW<sub>octanoyl-ester</sub> = 514.62 g/mol; FW<sub>alcohol</sub> = 472.53 g/mol CAS 203120-17-6), also known as CS-8958 and systematically named (4*S*,5*R*,6*R*)-5-acetamido-4-carbamimidamido-6-[(1*R*,2*R*)-3-(*O*)-octanoyl-2-methoxypropyl]-5,6-dihydro-4*H*-pyran-2-carboxylic acid, is the bioavailable ester that is metabolically hydrolyzed ( $\triangleright$  indicates the scissile bond) by *S*-formylglutathione hydrolase (esterase D) and acyl-protein thioesterase 1 (APT1) to generate the active drug used in treatment and prophylaxis of Influenza virus A and Influenza virus B infections. These inhibitors bind to the NA surface glycoprotein on newly formed virus particles, preventing their release from the host cell. The two widely used NA inhibitors are the inhaled drug zanamivir, or Relenza<sup>®</sup> (10 mg/dose, twice daily) and the oral drug oseltamivir phosphate, or Tamiflu<sup>®</sup> (75 mg/dose, twice daily). By contrast, single daily administration of CS-8958 is highly effective against Influenza viruses A and B. 1. Yamashita, Tomozawa, Kakuta, *et al.* (2009) *Antimicrob. Agents Chemother.* **53**, 186. 2. Kubo, Tomozawa, Kakuta, Tokumitsu & Yamashita (2010) *Antimicrob. Agents Chemother.* **54**, 1256.

#### Lankamycin

This macrolide antibiotic (FW = 920.53 g/mol; CAS 30042-37-6) from *Streptomyces violaceoniger* from the tropical forests of Sri Lanka, also known as kujimycin B, inhibits protein biosynthesis (1). Lankamycin binds to ribosomes in a similar manner to erythromycin; however, when in complex with lankacidin, lankamycin is posed so that it interacts with lankacidin in the adjacent ribosomal binding site. When paired, lankacidin and lankamycin inhibit the peptidyl transferase center and nascent peptide exit tunnel, respectively (2). 1. Pestka (1974) *Meth. Enzymol.* **30**, 261. 2. Belousoff, Shapira, Bashan, *et al.* (2011) *Proc. Natl. Acad. Sci. U.S.A.* **108**, 2717.

**Lanosterol**

This cholesterol precursor (FW = 426.73 g/mol; M.P. = 138-140°C), also known as kryptosterol and systematically named (3 $\beta$ )-lanosta-8,24-dien-3-ol, and 4,4,14 $\alpha$ -trimethylzymosterol, is also required for the synthesis of other steroids in animals. (In plants, lanosterol's role is fulfilled by cycloartenol.) Lanosterol is present at high concentrations in lanolin. **Target(s):** 3-hydroxy-3-methylglutaryl-CoA reductase (1); sterol acyltransferase, cholesterol acyltransferase (2). 1. Berg, Draber, von Hugo, Hummel & Mayer (1981) *Z. Naturforsch. [C]* **36**, 798. 2. Billheimer (1985) *Meth. Enzymol.* **111**, 286.

**Lanthanum & Lanthanum Ions**

Ions of this group 3 (or group IIIA) element (Symbol = La; Atomic Number = 57; Atomic Weight = 138.905), have valences of 1 or 3 (ionic radii for La<sup>+</sup> and La<sup>3+</sup> are 1.39 and 1.061 Å, respectively). There are two naturally occurring isotopes of lanthanum: <sup>138</sup>La (natural abundance = 0.0902%) and <sup>139</sup>La (99.9098%). Isotope-138 is radioactive, with a half-life of 1.06 x 10<sup>11</sup> years. Another radioisotope, <sup>137</sup>La, has a half-life of 8 x 10<sup>4</sup> years. With an ionic radius near that of Ca<sup>2+</sup>, trivalent lanthanum is often used as calcium channel blockers in the study of a number of calcium-dependent processes. Lanthanum ions also alter the stability of phospho-enzyme intermediates and compete with magnesium ions, inhibiting certain ATPases. When exposed to elevated levels of lanthanum ions, mammals tend to accumulate the metal in their bones. In addition, the tree *Carya* spp. has been reported to be a lanthanum accumulator. **Target(s):** acetylcholinesterase (1); acid phosphatase (2); arylalkyl-phosphatase, or paraoxonase (3,4); arylesterase (5); calcium channels (6-9); catechol O-methyltransferase (10); Ca<sup>2+</sup>-transporting ATPase (9,11-15); diphosphate:serine phosphotransferase (16); ferroxidase (35,36);  $\beta$ -fructofuranosidase (17);  $\beta$ -D-fucosidase (18); fumarylacetoacetase (22);  $\beta$ -glucosidase (19); glutamate formimidoyl-transferase (34); histamine release (20); 3-ketoalidoxylamine C-N-lyase (21); micrococcal nuclease (23); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (24); norepinephrine transport (25); phosphatidylinositol diacylglycerol-lyase, or phosphatidylinositol-specific phospholipase C (26); 1-phosphatidylinositol 4-kinase (27); phospholipase C (28); phospholipid-translocating ATPase, or flippase (29); 3-phosphoshikimate 1-carboxyvinyltransferase, or 3-enolpyruvylshikimate-5 phosphate synthase (30); protein-glutamine  $\gamma$ -glutamyltransferase, or transglutaminase (31); xyloglucan:xyloglucosyl transferase (32,33). 1. **Lansoprazole**

This proton-pump inhibitor prodrug, or PPI (FW = 369.36 g/mol; CAS 103577-45-3), also named AG-1749, Prevacid<sup>®</sup> and (RS)-2-([3-methyl-4-(2,2,2-trifluoroethoxy)pyridin-2-yl]methylsulfonyl)-1H-benzimidazole, reduces gastric acid production by targeting (H<sup>+</sup>,K<sup>+</sup>)-adenosine triphosphatase, or HK-ATPase (1). Lansoprazole inhibits acid formation after being transformed into its active forms within the acidic compartment of the parietal cells.

Inhibition of acid formation is reversible in parietal cells, and *de novo* synthesis of HK-ATPase does not participate in the recovery from the inhibition. Endogenous glutathione is involved in the recovery process and also affects the inhibitory action. Both the (+)- and the (-)-enantiomer of lansoprazole inhibit the acid formation stimulated by dibutylryl cyclic AMP (db-cAMP) in isolated canine parietal cells in a concentration-dependent manner with IC<sub>50</sub> values of 59 and 82 nM, respectively (3). The enantiomers showed concentration-dependent inhibition of HK-ATPase with IC<sub>50</sub> values of 4.2 and 5.2  $\mu$ M, respectively. On the other hand, the IC<sub>50</sub> values of lansoprazole for db-cAMP-stimulated acid formation and HK-ATPase were 59 nM and 2.1  $\mu$ M, respectively (3). Such results suggest that the two enantiomers of lansoprazole have antisecretory action due to inhibition of HK-ATPase. Lansoprazole's plasma elimination half-life (1.5 hours) is not proportional to the duration of its effects on gastric acid suppression. Indeed, when used for a day or more, its effects last for over 24 hours. 1. Nagaya, Satoh, Kubo & Maki (1989) *J. Pharmacol. Exp. Ther.* **248**, 799. 2. Nagaya, Satoh & Maki (1990) *J. Pharmacol. Exp. Ther.* **252**, 1289. 3. Nagaya, Inatomi, Nohara & Satoh (1991) *Biochem. Pharmacol.* **42**, 1875.

 **$\beta$ -Lapachone**

This cytotoxic agent (FW = 242.27 g/mol; CAS 4707-32-8; Solubility: >25 mg/mL DMSO at 5 °C), systematically named 3,4-dihydro-2,2-dimethyl-2H-naphtho[1,2-b]pyran-5,6-dione, is a DNA topoisomerase I inhibitor.

**Generation of Reactive Oxygen Species:**  $\beta$ -lapachone is redox-active, and its structural similarities to menadione suggest a common mechanism of action (1) that targets NQO1 NAD(P)H quinone dehydrogenase 1 and alters the NAD(P)H metabolism through the formation of hydroquinone and semiquinone species as well as reactive oxygen species (ROS):

Biochemical studies suggest that reduction of  $\beta$ -lapachone by NQO1 leads to a futile cycling between the quinone and hydroquinone forms, with a concomitant loss of reduced NAD(P)H. **DNA Damage:** Both quinones form adducts with mercaptoethanol, and  $\beta$ -lapachone is 10-times more reactive, and there is an apparent correlation between the rates of the adduct formation with thiols and of the topoisomerase II-poisoning activity of the aforementioned quinones (1).  $\beta$ -Lapachone induces protein-linked DNA breaks in the presence of purified human DNA topoisomerase II $\alpha$ , without intercalating into DNA or inhibiting topoisomerase II or ligation by mammalian or T4 DNA ligases. Its action is ATP-independent and involves the formation of reversible cleavable complexes. A 4-hour post-treatment with 4  $\mu$ M  $\beta$ -lapachone was previously shown to enhance the lethality of X-rays against human laryngeal epidermoid carcinoma (HEp-2) cells (2). It was subsequently demonstrated that  $\beta$ -lapachone (a) activates the DNA-unwinding activity of topoisomerase I, (b) inhibits the fast component of Potentially Lethal Damage Repair (PLDR) carried out by HEp-2 cells when present during or immediately following X-irradiation, (c) specifically and synergistically enhances the cytotoxic effects of DNA-damaging agents which induce DNA strand incisions, such as neocarzinostatin or X-rays, against a radioresistant human malignant melanoma (U1-Mel) cell line, (d) does not synergistically potentiate melphalan-induced lethality against U1-Mel cells but inhibits survival recovery and increases sister chromatid exchanges, and (e) does not further enhance the lethal effects of X-rays following prolonged drug exposures, indicating that  $\beta$ -lapachone modifies initially created DNA lesions or inhibits lesion repair, but does not create lethal lesions by itself (3). NQO1 enhances the cytotoxic effects of  $\beta$ -lapachone, and NQO1 gene expression levels directly correlate with sensitivity to a 4-hour pulse of  $\beta$ -lapachone in a panel of breast cancer cell lines (4).  $\beta$ -Lapachone accelerates the DNA-unwinding activity of topoisomerase I derived from avian erythrocytes, calf thymus, or HEp-2 cells.  $\beta$ -Lapachone activates apoptosis in a number of cell lines (4). **Dicoumarol Cytoprotection:** The NQO1 inhibitor, dicoumarol, significantly protects NQO1-expressing cells from all aspects of  $\beta$ -lapachone toxicity. Stable transfection of the NQO1-deficient cell line, MDA-MB-468, with an NQO1 expression plasmid increases apoptotic responses and lethality after  $\beta$ -lapachone exposure. Dicoumarol also blocks apoptotic responses and lethality. In addition, the activation of a cysteine protease, which has characteristics consistent with the neutral calcium-dependent protease, calpain, is observed after  $\beta$ -lapachone treatment (5). NQO1 expression directly correlated with sensitivity to a 4-hour pulse of  $\beta$ -lapachone in a panel of breast cancer cell lines, and the NQO1 inhibitor, dicoumarol, significantly protected NQO1-expressing cells from all aspects of  $\beta$ -lapachone toxicity. Stable transfection of the NQO1-deficient cell line, MDA-MB-468, with an NQO1 expression plasmid increases apoptotic responses and lethality after  $\beta$ -lapachone exposure. Dicoumarol blocks both the apoptotic responses and lethality. This finding is the first definitive elucidation of an intracellular target for  $\beta$ -lapachone in tumor cells. Such studies suggest that NQO1 may be exploited for gene therapy, radiotherapy, and/or chemopreventive interventions, since the enzyme is elevated in a

number of tumor types (*i.e.*, breast and lung) and during neoplastic transformation. **NAD(P) Depletion by  $\beta$ -Lapachone:** The aforementioned  $\beta$ -lapachone-induced DNA damage also hyperactivates poly(ADP-ribose)transferase-1 (PARP1), an enzyme that regulates molecular events involved in cell recovery. As a consequence, cellular stores of NAD<sup>+</sup> are greatly depleted by  $\beta$ -lapachone treatment. Finally,  $\beta$ -Lapachone is also a specific probe for ligand binding to the glucocorticoid receptor (6). Although structurally unlike any glucocorticoid,  $\beta$ -lapachone interacts rapidly and competitively with the ligand-binding site of unpurified and highly purified glucocorticoid receptor (6). 1. ### Lapatinib

This orally EGFR/HER2 tyrosine kinase inhibitor (F.Wt. = 925.46; CAS 388082-77-7, 231277-92-2 (free-base), 1187538-35-7 (4-methylbenzenesulfonate salt); Solubility: 185 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known as GW572016, GW2016, Tykerb<sup>®</sup>, Tyverb<sup>®</sup>, and *N*-(4-(3-fluorobenzoyloxy)-3-chlorophenyl)-6-(5-((2-(methylsulfonyl)ethylamino) methyl)furan-2-yl)quinazolin-4-amine, di-4-methylbenzene sulfonate, blocks phosphorylation of purified EGFR and ErbB-2 tyrosine kinase domains, with IC<sub>50</sub> of 10.2 and 9.8 nM, respectively (1). **Mode of Action:** GW2016 treatment inhibited tumor xenograft growth of the HN5 and BT474 cells in a dose-responsive manner at 30 and 100 mg/kg orally, twice daily, with complete inhibition of tumor growth at the higher dose. Lapatinib markedly reduces tyrosine phosphorylation of EGFR and erbB2, inhibiting the activation of Erk1/2 and AKT which are important downstream effectors of proliferation and cell survival, respectively. Complete inhibition of activated AKT in erbB2 overexpressing cells correlated with a 23-fold increase in apoptosis compared with vehicle controls. EGF, often elevated in cancer patients, did not reverse the inhibitory effects of GW572016 (2). Client protein kinases are recruited to the Hsp90 molecular chaperone by Cdc37, which simultaneously binds Hsp90 and kinases as well as regulates the Hsp90 chaperone cycle (3). Significantly, Cdc37 binding to protein kinases is itself antagonized by ATP-competitive kinase inhibitors, such as lapatinib, and in cancer cells, such inhibitors deprive access of oncogenic kinases, such as B-Raf and ErbB2, to Hsp90-Cdc37, resulting in degradation of these protein kinases (3). Lapatinib-induced cell growth inhibition and G<sub>1</sub> cell-cycle arrest in HER2-overexpressing human breast cancer cells depends on upregulated expression of p27 (Kip1), which is mediated through both transcriptional and post-translational mechanisms (4). **Metabolism & Distribution:** Lapatinib is metabolized by CYP3A4/5 to yield an *O*-debenzylated metabolite that undergoes further oxidation to a reactive quinone imine (5). The *O*-debenzylated metabolite is significantly more cytotoxic than lapatinib, and pre-treatment with L-buthionine sulfoximine (25  $\mu$ M) to deplete intracellular glutathione markedly enhances lapatinib cytotoxicity. In mice, lapatinib levels were 4x higher in tumor than blood, with a 4x longer half-life (6). Tumor concentrations exceeded the *in vitro* IC<sub>50</sub> (~900 nM or 500 ng/mL) for inhibition of HER2 phosphorylation throughout the 12-hour dosing interval. In patients, tumor levels were 6- and 10-fold higher with QD and BID dosing, respectively, compared to plasma trough levels. The relationship between tumor and plasma concentration was complex, indicating multiple determinants (6). 1. Rusnak, Lackey, Affleck, *et al.* (2001) *Mol. Cancer Ther.* **1**, 85. 2. **Largazole**

This novel cytotoxic cyclodepsipeptide (FW = 608.83 g/mol; CAS 1009815-87-5) from a marine cyanobacterium (*Symploca* sp., collected in the Florida Keys) exhibits potent antiproliferative activity. In studies with transformed and nontransformed epithelial cells, largazole gave respective growth-inhibition (GI<sub>50</sub>) values of 7.7 nM and 122 nM; similarly, with transformed and nontransformed fibroblast cells, it gave GI<sub>50</sub> values of 55 nM and 480 nM, respectively (1). Largazole possesses a densely assembled structure, with a rare 4-methylthiazoline linearly fused to a thiazole in its cyclic core and a hitherto undescribed 3-hydroxy-7-mercaptohept-4-enoic acid unit incorporated in an ester, thioester, and amide framework (1). Enantioselective total synthesis of (+)-largazole has been reported (2). Largazole is a potent inhibitor of class I histone deacetylases (HDACs) (1,3), a potent inducer of gene expression in latent Epstein-Bar Virus (EBV) (3), and a sensitizing agent that increases the susceptibility of lymphoma cells to nucleoside antiviral agents (3). 1. Taori, Paul & Luesch (2008) *J. Am. Chem. Soc.* **130**, 1806. 2. Ghosh & Kulkarni (2008) *Org. Lett.* **10**, 3907. 3. Ghosh, Perrine, Williams & Faller (2012) *Blood* **119**, 1008.

**Lasaloid A**

This ionophorus antibiotic (FW<sub>free-acid</sub> = 590.80 g/mol), also known as X-537A, from certain strains of *Streptomyces lasaliensis* facilitates the exchange of monovalent and divalent cations for protons. Nonvalent cations are transported about ten-times more effectively than divalent cations (1). Lasaloid A also will transport catecholamines across membranes. The Ca<sup>2+</sup>-dependent ATPase of the sarcoplasmic reticulum is strongly inhibited by lasaloid A. **Target(s):** ATPase (1,2); Ca<sup>2+</sup>-dependent ATPase (3-5); oxidative phosphorylation (2); protein tyrosine kinase (6). 1. Pressman (1976) *Ann. Rev. Biochem.* **45**, 501. 2. Reed (1979) *Meth. Enzymol.* **55**, 435. 3. Kawashima, Hara & Kanazawa (1990) *J. Biol. Chem.* **265**, 10993. 4. Petukhov, Chibalin, Kovalenko, Bulargina & Severin (1991) *Biokhimiya* **56**, 2077.

**Lasofloxifene**

This orally active selective estrogen receptor modulator, or SERM (FW = 413.55 g/mol; CAS 180916-16-9), also named (5*R*,6*S*)-6-phenyl-5-[4-(2-pyrrolidin-1-ylethoxy)phenyl]-5,6,7,8-tetrahydronaphthalen-2-ol, is a tamoxifen-related drug that competitively inhibits estradiol binding to both ERα and ERβ with high affinity. Its IC<sub>50</sub> for ERα is 1.5 nM, similar to that of estradiol (4.8 nM) and at least 10-fold tighter than tamoxifen and raloxifene. Lasofloxifene also shows remarkably improved oral bioavailability relative to tamoxifen and raloxifene, a property that may account for its greater potency. **See also** *Tamoxifen*; *Toremifene*

**LASSBio-1135**

This weak COX-2 inhibitor (FW = 286.34 g/mol) blocks capsaicin-elicited currents noncompetitively (IC<sub>50</sub> = 580 nM) as well as low pH-induced current at 50 μM. LASSBio-1135 also inhibits TNFα release in these cells stimulated by lipopolysaccharide with an IC<sub>50</sub> of 546 nM by reducing p38 MAPK phosphorylation. 1. Lima, Silva, Lacerda, *et al.* (2014) *PLoS One* **9**, e99510.

**Lassomycin**

This ribosomally encoded cyclic peptide antibiotic (FW = 1880.22 g/mol; Isoelectric Point = 12), which possesses an unusual structural fold partially resembling other lasso peptides, binds to a highly acidic region of the ClpC1 ATPase complex, thereby markedly stimulating its ATPase activity without stimulating ClpP1P2-catalyzed protein breakdown. The latter is essential for viability of *Mycobacterium tuberculosis*. Uncoupling of ATPase activity from proteolytic activity accounts for its bactericidal activity. 1. Gavrish, Sit, Cao, *et al.* (2014) *Chem. Biol.* **21**, 509.

**Latrunculin A**

This cell-permeant, marine natural product and actin polymerization inhibitor (FW = 421.56 g/mol; CAS 76343-93-6; Abbreviation: LAT-A) from the Red Sea sponge *Latrunculia magnifica* alters eukaryotic cell shape by disrupting microfilament organization and inhibiting the some microfilament-associated processes during fertilization and early development (1-4). **Primary Mode of Action:** Latrunculin-A inhibits the self-assembly of actin filaments (or microfilaments) by forming a one-to-one complex with monomeric actin, thereby hindering polymerization-requiring conformational rearrangements in Domains 1 and 2 (5). Latrunculin A has a K<sub>d</sub> of 180 nM–220 nM, as determined by binding to pyrene-labeled rabbit skeletal muscle actin. **Preparation:** Stock solutions of Latrunculin-A are prepared at 2-10 mM DMSO and then diluted to 100 μM in Actin Monomer-Stabilizing (or "G") Buffer (5 mM Tris (pH 7.8), 2 mM MgCl<sub>2</sub>, 0.1 mM CaCl<sub>2</sub>, 0.2 mM ATP, 0.2 mM DTT, and 0.01-0.1% sodium azide). **Cellular Effects:** Exposure of most cells to Latrunculin A or Latrunculin B (0.03 μg/mL for 1-3 hours) induces concentration-dependent changes in cell shape and actin organization, causing complete rounding-up of all cells. Latrunculins also inhibit cytokinesis in synchronized cells, with Latrunculin-A having longer-lasting effects (2,3). Latrunculin-A causes complete disruption of the yeast actin cytoskeleton within 2-5 min, suggesting that although yeast are nonmotile, their actin filaments undergo rapid cycles of assembly and disassembly *in vivo* (6). Latrunculin-A potently induces PMN leukocyte aggregation in a dose- and time-dependent manner over the 12 nM to 60 nM concentration range. At 120 nM, Latrunculin-A causes a 50% loss of actin filaments in PMN leukocyte after 5-min incubation (7). (The effects of Latrunculin-B were similar to

those of Latrunculin-A, albeit slightly less potent and effective for shorter periods. Some cells may possess the ability to deactivate Latrunculin-B, most likely by ATP-dependent export.) 1. ### Latrunculin B, Similar in action to Latrunculin A

#### Laulimalide

This marine macrolide and cytoskeleton-directed drug (FW = 514.66 g/mol), originally isolated from the marine sponges *Cacospongia mycofijiensis* from Fiji (1) and a *Hyattella* species in Indonesia (2), is a microtubule-stabilizing agent that inhibits cell-cycle progression (IC<sub>50</sub> ≈ 0.1 μM). Laulimalide promotes tubulin polymerization by preferentially stabilizing assembled microtubules and is quantitatively comparable to paclitaxel (taxol). Even so, laulimalide does not bind in the taxoid site (3). Significantly, laulimalide enhances assembly synergistically with paclitaxel, as would be expected if these drugs bound at different microtubule sites (4). Stoichiometric amounts of laulimalide and paclitaxel cause extensive tubulin polymerization, with maximum synergy observed at lower temperatures under conditions where paclitaxel is relatively inactive (5). Laulimalide-induced assembly, like paclitaxel-induced assembly, is inhibited by drugs that inhibit tubulin assembly by binding at either the colchicine- or vinblastine-binding site (4). When radiolabeled GTP is present in a reaction mixture with either laulimalide or paclitaxel, nucleotide hydrolysis occurs with incorporation of radiolabeled GDP into polymer (4). Laulimalide is also active in cells over-expressing multi-drug resistance (MDR) P-glycoprotein. Remarkably, eight different total syntheses of (–)-laulimalide reported in the span of less than two years (6). 1. Quinoa, Kakou & Crews (1988) *J. Org. Chem.* **53**, 3642. 2. #### Laurate (Lauric Acid)

This medium-chain fatty acid (FW<sub>free-acid</sub> = 200.32 g/mol; pK<sub>a</sub> = 4.8; M.P. = 44°C; B.P. = 298.9°C; Solubility: 0.0055 g/100 mL H<sub>2</sub>O), also called *n*-dodecanoic acid, is widely distributed in animals and plants. (Note: When heated to 60 °C in the presence of sufficient concentration (0.1% w/v) of Sodium Dodecyl Sulfate (*or* SDS), many proteins are denatured, with consequential loss of enzyme catalysis or biological function.) **Target(s):** acetyl-CoA carboxylase (1,2); alcohol dehydrogenase (3,4); D-amino-acid oxidase (5,6); ceramidase (at pH 5) (7); chondroitin AC lyase, weakly inhibited (8); chondroitin B lyase, weakly inhibited (8); cyclooxygenase (9); cytosol alanyl aminopeptidase (30); esterase (10); 7-ethoxycoumarin *O*-deethylase (cytochrome P450) (11); firefly luciferase, IC<sub>50</sub> = 1.2 μM (19,20,35,36); formaldehyde dehydrogenase (12); β-galactoside α-2,6 sialyltransferase (13,33); glucokinase (14); glutathione *S*-transferase (15); glycylopeptide *N* tetradecanoyltransferase (34); hexokinase (14,16,17,32); hyaluronate lyase (8); *S* (hydroxymethyl)glutathione dehydrogenase (12); lecithin:cholesterol acyltransferase, *or* phosphatidylcholine:cholesterol acyltransferase (18); lysozyme (21); monoamine oxidase (22);

pectinesterase, weakly inhibited (23); peptidyl-dipeptidase A, *or* angiotensin I-converting enzyme (24); phosphofructokinase (14,16,17); pyruvate kinase (17,25); sphingomyelin phosphodiesterase, *or* sphingomyelinase (31); steroid 5α-reductase (26-28); L-threonine dehydrogenase (29). 1. #### Lauroyl-CoA

This thioester (FW = + 767.54), also known as dodecanoyl-CoA, is a substrate for many acyltransferases. **Target(s):** acetyl-CoA carboxylase, K<sub>i</sub> = 74 μM for rat liver enzyme (1); 1-alkyl-*sn* glycerol-3-phosphate acetyltransferase (2); ATP:citrate lyase, *or* ATP-citrate synthase (3,4); carnitine *O*-octanoyl-transferase, also alternative substrate (5); citrate (*si*)-synthase (6); dodecanoyl-CoA Δ-isomerase (7); glucose-6-phosphatase (8,9); glucose-6-phosphate dehydrogenase (10); glycylopeptide *N*-tetradecanoyl-transferase, *or* protein *N*-myristoyltransferase (11); phosphoketolase (12); stearoyl-CoA 9-desaturase (13,14). 1. #### *N*-Lauroylsarcosine and *N*-Lauroylsarcosinate

This anionic surfactant (FW<sub>sodium-salt</sub> = 293.38 g/mol), also known as Sarcosyl, Sarkosyl, Gardol, and *N*-dodecanoylsarcosine, is a milder denaturing agent than sodium dodecyl sulfate and is frequently used to isolate DNA and RNA as well as to dissociate nucleosomes and ribosomes.

**Target(s):** ceramide kinase (1); 1,3- $\beta$ -glucan synthase (2);  $\alpha$ -glucosaminide *N*-acetyltransferase (3); guanylate cyclase (4); herpes simplex virus-1 (5); IgA-specific metalloendopeptidase (6); lipase, or triacylglycerol lipase (7); phenylacetone monooxygenase (8); phorbol diester hydrolase (9,10); protein xylosyltransferase (11); RNA polymerase II (12-15); trehalose phosphatase (16). 1. ### Lavendustin A

This salicylic acid derivative (FW<sub>free-acid</sub> = 381.39 g/mol), also called RG14355 and 5-amino[*N*-(2,5-dihydroxybenzyl)-*N*-(2-hydroxybenzyl)]salicylic acid, from *Streptomyces griseolavendus* and is a cell-permeable inhibitor of a number of protein-tyrosine kinases (1-5). Epidermal growth factor receptor protein-tyrosine kinase, IC<sub>50</sub> = 11 nM (2) and the p60c-src kinase, IC<sub>50</sub> = 500 nM, are inhibited with little effect on protein kinase A or protein kinase C (IC<sub>50</sub> > 200 nM). It also inhibits *N*-methyl-D-aspartate-stimulated cGMP production, IC<sub>50</sub> = 30 nM (6). Lavendustin A exhibits anti-proliferative properties and suppresses the angiogenic action of vascular endothelial growth factor in rats (7). **Target(s):** inositol-trisphosphate 3-kinase (8); protein-tyrosine kinase, non-specific protein-tyrosine kinase (1-5); receptor protein-tyrosine kinase (9). 1. Eriksson, Toivola, Sahlgren, Mikhailov & Härmälä-Braskén (1998) *Meth. Enzymol.* **298**, 542. 2. Hsu, Persons, Spada, *et al.* (1991) *J. Biol. Chem.* **266**, 21105. 3. ### Lazabemide

This pyridinecarboxamide (FW<sub>hydrochloride</sub> = 236.10 g/mol), also known as *N*-(2-aminoethyl)-5-chloro-2-pyridinecarboxamide and Ro 19-6327, is a potent and selective inhibitor of monoamine oxidase B. 1. Da Prada, Kettler, Keller, *et al.* (1990) *J. Neural Transm. Suppl.* **29**, 279. 2. Fernandes & Soares-da-Silva (1990) *J. Pharmacol. Exp. Ther.* **255**, 1309. 3. Pestana & P. Pharmacol.* **162**, 457.

### LB30870

This extremely potent anticoagulant (FW = 564.35 g/mol) is a direct benzamidine-based thrombin inhibitor ( $K_i$  = 15 pM), with oral bioavailabilities of 43%, 42%, and 15% in rats, dogs, and monkeys, respectively (1). On a gravimetric basis, LB30870 is more effective than enoxaparin, a low-molecular-weight heparin, in the venous thrombosis models in rats and rabbits. ED<sub>50</sub> values for LB30870, melagatran and enoxaparin are 50  $\mu$ g/kg/min, 35  $\mu$ g/kg/min and 200  $\mu$ g/kg/min, respectively, showing that LB30870 has promising properties for providing effective and safe prophylaxis for venous and arterial thrombosis (2). No significant bleeding was observed with LB30870 at the dose up to two times ED<sub>50</sub> in rats. LB30889, a double prodrug of LB30870, showed species difference in pharmacokinetics, and oral bioavailability in rats or dogs was no better than LB30870 (2). When studied in healthy men (at oral doses of 5–240 mg under fasting conditions), C<sub>max</sub> occurred at 1.3–3.0 hours post-dose, with a mean apparent terminal  $t_{1/2}$  of 2.8–4.1 hours (3). AUC after doses above 15 mg appeared greater than dose-proportional. In fed state, however, AUC data showed 80% reduction relative to fasting condition, suggesting that this food effect must be overcome for LB30870 to become a successful oral anti-coagulant (3). 1. Lee, Park, Jung, *et al.* (2003) *J. Med. Chem.* **46**, 3612. 2. Park, Lee, Kim, *et al.* (2013) *Biorg. & Med. Chem. Lett.* **23**, 4779. 3. Kim, Lee, Boyce, *et al.* (2015) *Xenobiotica* **45**, 663.

### LBH589, See Panobinostat

### LBQ657

This NEP inhibitor (FW = 383.44 g/mol; CAS 149709-44-4), also named (2*R*,4*S*)-5-(biphenyl-4-yl)-4-((3-carboxypropionyl)amino)-2-methyl-pentanoic acid, targets neprilysin (IC<sub>50</sub> = 5nM), the enzyme responsible for degrading atrial and brain natriuretic peptides, two blood pressure-lowering peptides that mainly work by reducing blood volume. LBQ-657 is formed from the prodrug AHU-377 by intracellular esterases (See AHU-377; LCZ696). 1. Ksander, Ghai, de Jesus, *et al.* (1995) *J. Med. Chem.* **38**, 1689. **LC-44, See Flupenthixol**

### LCB 03-0110

This protein kinase inhibitor (FW = 490.45 g/mol; Soluble to 100 mM in H<sub>2</sub>O; 100 mM in DMSO), also named 3-[[2-[3-(4-morpholinylmethyl)phenyl]thieno[3,2-*b*]pyridin-7-yl]amino]phenol, targets c-Src kinase

inhibitor ( $IC_{50} = 1.3$  nM) as well as discoidin domain receptor 2 (DDR2) family tyrosine kinases, BTK and Syk. LCB 03-0110 suppresses the proliferation and migration of primary dermal fibroblasts induced by transforming growth factor  $\beta 1$  and type I collagen, and this result correlates with the inhibition ability of the compound against enhanced expression of  $\alpha$ -smooth muscle actin and activation of Akt1 and focal adhesion kinase. In J774A.1 macrophage cells activated by lipopolysaccharide LCB 03-0110 inhibits cell migration and nitric oxide, inducible nitric-oxide synthase, cyclooxygenase 2, and tumor necrosis factor- $\alpha$  synthesis. When applied topically to full excisional wounds on rabbit ears, LCB 03-0110 suppresses the accumulation of myofibroblast and macrophage cells in the healing wound and reduces hypertrophic scar formation after wound closing, without delaying the wound closing process. 1. Sun, Phan, Jung, *et al.* (2012) *J. Pharmacol. Exp. Ther.* **340**, 510.

#### LCZ696

This novel binary drug consists of Valsartan, the angiotensin II receptor Type-1 ( $AT_1$ ) antagonist that causes vasodilation and increases renal excretion of sodium ion and water by reducing aldosterone production, and AHU-377, a prodrug that is converted to LBQ657, the latter inhibiting neprilysin. See Valsartan; AHU377 (and LBQ657) 1. McMurray, Packer, Desai, *et al.* (2014) *New Engl. J. Med.* **371**, 993.

**LDE225**, See Sonidegib (*Erismodegib*)

#### LDN 27219

This reversible transglutaminase inhibitor (FW = 408.50 g/mol; CAS 312946-37-5; Soluble in DMSO), named systematically as 2-[(3,4-dihydro-4-oxo-3,5-diphenylthieno[2,3-*d*]pyrimidin-2-yl)thio]acetylhydrazide, targets tissue transglutaminase (TGase), a  $Ca^{2+}$ -dependent enzyme that catalyzes the cross-linking of intracellular proteins through a mechanism involving isopeptide bond formation between Gln and Lys residues and that is allosterically regulated by GTP. The  $IC_{50}$  value is 0.25  $\mu$ M. LDN-27219 is a slow-binding inhibitor that appears to bind, not at the enzyme's active site, but instead its GTP regulatory site (or at a site that regulates GTP binding). The potency and kinetics of inhibitor are dependent on substrate, suggest a novel inhibitory mechanism involving differential binding of LDN-27219 to multiple conformational states of this enzyme. 1. Case & Stein (2007) *Biochemistry* **46**, 1106.

#### LDN-57444

This proteasome inhibitor (FW = 397.64 g/mol; CAS 668467-91-2; Solubility: 11 mg/mL DMSO; <1 mg/mL  $H_2O$  or Ethanol), also known as 5-chloro-1-[(2,5-dichlorophenyl)methyl]-1*H*-indole-2,3-dione 3-(*O*-acetyl-oxime), competitively and reversibly targets ubiquitin C-terminal hydrolase, or Uch-L1 ( $IC_{50} = 0.88$   $\mu$ M), showing 28x selectivity over isoform Uch-L3

(1-4). Abnormal accumulation and aggregation of  $\alpha$ -synuclein ( $\alpha$ -syn) within neurons, and mutations in the  $\alpha$ -syn and UCH-L1 genes have been shown to play a role in the pathogenesis of Parkinson Disease. In typical experiments, cultured neurons are treated with 10  $\mu$ M LDN-57444 for 24 hr, a dose assuring UCH-L1-specific action. For short-term *in vivo* experiments, mice are injected intraperitoneally (0.5 mg LDN-57444 per kg), at time zero and again with the same dosage four hours after the first injection. 1. Liu, Lashuel, Choi, *et al.* (2003) *Chem. Biol.* **10**, 837. 2. Cartier, Ubhi, Spencer, *et al.* (2012) *PLoS One* **7**, e34713. 3. Gong, Cao, Zheng, *et al.* (2006) *Cell* **126**, 775.

#### LDN 193188

This PC-TP inhibitor (FW = 494.35 g/mol; CAS 1267610-30-9; Soluble to 100 mM in DMSO), also named 2,4-dichloro-*N*-[[[4-[[[4,6-dimethyl-2-pyrimidinyl]amino]sulfonyl]phenyl]amino]carbonyl]benzamide, targets Phosphatidylcholine Transfer Protein (PC-TP, also referred to as StarD2) is a highly specific intracellular lipid-binding protein that catalyzes the transfer of phosphatidylcholines between membranes *in vitro*. Recent studies have suggested that PC-TP *in vivo* functions to regulate fatty acid and glucose metabolism, possibly via interactions with selected other proteins. LDN 193188 binds to PC-TP, displacing phosphatidylcholines from its lipid binding site and increasing the thermal stability of the protein. 1. Wagle, Xian, Shishova, *et al.* (2008) *Anal. Biochem.* **383**, 85. 2.

#### LDN-212854

This potent BMP receptor inhibitor (FW = 406.48 g/mol; CAS 1432597-26-6; Solubility: 80 mg/mL DMSO (with heating); <1 mg/mL  $H_2O$  or Ethanol), also named 5-[6-[4-(1-piperazinyl)phenyl]pyrazolo[1,5-*a*]pyrimidin-3-yl]quinoline, selectively targets Bone Morphogenetic Protein receptors, with  $IC_{50}$  of 1.3 nM for ALK2, about 2x, 66x, 1640x, and 7135x selectivity over ALK1, ALK3, ALK4, and ALK5, respectively. In contrast to previously described BMP receptor kinase inhibitors, LDN-212854 exhibits nearly four orders of selectivity versus closely related TGF- $\beta$  and Activin Type I receptors. LDN-212854 potently inhibits heterotopic ossification in an inducible transgenic mutant ALK2 mouse model of fibrodysplasia ossificans progressive, allowing selective targeting individual of the highly homologous members of the BMP type I receptor family. 1. Mohedas, Xing, Armstrong, *et al.* (2013) *ACS Chem. Biol.* **8**, 1291.

#### LDN-214117

This potent and selective BMP type I receptor kinase inhibitor (FW = 419.52 g/mol; CAS 1627503-67-6; Solubility: 83 mg/mL DMSO; < 1 mg/mol  $H_2O$ ), also named 1-(4-(6-methyl-5-(3,4,5-trimethoxyphenyl)

pyridin-3-yl)phenyl)piperazine, targets Bone Morphogenetic Protein receptor's Activin-Like Kinase 2, or ALK2 (IC<sub>50</sub> = 24 nM). Contrary to the notion that activating mutations of ALK2 might alter inhibitor efficacy due to potential conformational changes in the ATP-binding site, the action of LDN-214117 demonstrates consistent binding to a panel of mutant and wild-type ALK2 proteins. 1. Mohedas, Wang, Sanvitale, *et al.* (2014) *J. Med. Chem.* **57**, 7900.

## Lead

This Group 14 (or IVB) heavy metal element (Atomic Weight = 207.2; Symbol = Pb; Atomic Number = 82; Located beneath Tin in the Periodic Table) forms bioreactive ions and organic compounds that inhibit numerous proteins, enzymes and vital cellular processes. **Lead Ions:** Typical valences of lead are +2 and +4, having ionic radii of 1.20 and 0.84 Å, respectively. Although the exact solvation number *n* of the [Pb(H<sub>2</sub>O)<sub>*n*</sub>]<sup>2+</sup> ion is unknown for dilute Pb<sup>2+</sup> solutions, the hexaquo species is likely. Aqueated lead ions bind tightly to proteins, most often reacting with thiol groups (*Reaction:* Protein-SH + [Pb(H<sub>2</sub>O)<sub>*n*</sub>]<sup>2+</sup> ⇌ Protein-S-Pb(H<sub>2</sub>O)<sub>(*n*-1)</sub><sup>1+</sup> + H<sup>+</sup>), and less so with carboxyl groups (*Reaction:* Protein-C(=O)-O<sup>-</sup> + [Pb(H<sub>2</sub>O)<sub>*n*</sub>]<sup>2+</sup> ⇌ Protein-C(=O)-O-Pb(H<sub>2</sub>O)<sub>(*n*-1)</sub><sup>1+</sup> + H<sup>+</sup>), and neutral amino groups (*Reaction:* Protein-NH<sub>2</sub> + [Pb(H<sub>2</sub>O)<sub>*n*</sub>]<sup>2+</sup> ⇌ Protein-NH-Pb(H<sub>2</sub>O)<sub>(*n*-1)</sub><sup>1+</sup> + H<sup>+</sup>). Pb<sup>2+</sup> displaces Ca<sup>2+</sup> and Zn<sup>2+</sup> present in many proteins, binding oxygen atoms from amino acids or water as a major ligand, followed by sulfur and nitrogen. Around one-third of the lead binding sites are due to zinc or calcium ionic displacement, whereas two-thirds were opportunistic (1). As a heavy metal ion, Pb<sup>2+</sup> is an environmentally persistent toxin that impairs circulatory, hematological, gastrointestinal, neurological, reproductive, and immunological processes. It also catalyzes oxidation reactions, leading to the formation and accumulation of reactive oxygen species (ROS) that damage cells and tissues. With many divalent cation transporters in humans, there is still no clear view of which pump Pb<sup>2+</sup>. Given the similar radii of Ca<sup>2+</sup> and Pb<sup>2+</sup> ions, the ability of the latter to cross the blood-brain barrier is likely facilitated by calcium ion transporters, and, once within the brain, lead-induced damage can be observed in the prefrontal cerebral cortex, hippocampus, and cerebellum. CNS lead accumulation also affects the hypothalamic-pituitary axis, blunting responses to thyrotropin-releasing factor (TRF or TRH), growth-hormone-releasing factor (GRF or GHRH), and gonadotropin-releasing hormone (GnRH). Pb<sup>2+</sup> likewise binds to calmodulin, decreasing the efficiency of calmodulin in activating CAM-dependent protein kinases and reducing the phosphorylation of brain membrane proteins. Less appreciated, however, is that Pb<sup>2+</sup> also readily binds to the negatively charged phosphodiester of RNA and DNA, thereby interfering with nucleic acid regulatory interactions and worse still catalyzing nonenzymatic strand cleavage (2). The latter reactions are illustrated below, with bound lead ion acting as a Lewis acid that mediates general and specific acid catalysis, respectively, during DNA and RNA phosphodiester hydrolysis.

Lewis Acid Catalysis of DNA and RNA Cleavage by Bound Pb(II)

These inherently mutagenic reactions cause damage requiring prompt repair, but the exact enzymes responsible for removing bound lead ions and executing such strand breakage repair are still unclear. **Organolead:** The term organolead implies that a covalent bond joins a carbon atom to a lead atom within an organic molecule, a criterion that is different from O-Pb and N-Pb bonds found in chelate complexes with Pb<sup>2+</sup> or those compounds having S-Pb and Se-Pb bonds in sulfur- and selenium-containing molecules fixed to lead atoms. That said, the lead atoms in Pb-containing organic molecules often form strong coordinate covalent bonds with thiol-containing side-chain groups within enzymes, often resulting in loss of

catalytic activity. Moreover, whereas inorganic compounds tend to have Pb(II) centers, the dominant species is Pb(IV) in organolead compounds. Inorganic lead compounds form with elements, such as nitrogen, oxygen and the halides, which have higher electronegativity than lead, and the partial positive charge on lead leads to a stronger contraction of the 6s-orbital than the 6p-orbital, making the 6s-orbital inert (*i.e.*, the so-called “inert pair” effect). The biotransformation and metabolic impact of organolead is the subject of a monograph by Grandjean (3). Starting in 1920, tetraethyllead was added to gasoline (0.5 g per gallon) to suppress engine knocking (**See Tetraethyllead**). Much was oxidized, yielding CO<sub>2</sub>, H<sub>2</sub>O, and lead oxide, and, given the many billions of gallons used in automobiles over the ensuing fifty years, the amount of lead from auto exhaust is beyond reckoning. **Heme Biosynthesis:** Lead ions strongly inhibit heme biosynthesis in mammals, targeting δ-aminolevulinic synthetase (or ALA synthase), δ-aminolevulinic dehydrase (or porphobilinogen synthase), and the Fe(II)-inserting enzyme, ferrochelatase (4,5). As the only cytosolic enzyme, δ-aminolevulinic dehydrase is most affected, and the overall rate of heme synthesis remains unaffected until 80-90% of this enzyme is inhibited (occurring at 50 µg/dL plasma). Notably, lead inhibition of ferrochelatase results in the incorporation of divalent zinc into protoporphyrin IX, with consequential loss of the heme needed for oxygen transport and heme redox chemistry. **Transcription Factor Failure:** As assayed by DNase I protection, the interaction of Cys<sub>2</sub>His<sub>2</sub> zinc finger protein transcription factor IIIA (TFIIIA) with the 50-bp internal control region of the 5S ribosomal gene was completely inhibited at 10 µM Pb<sup>2+</sup> (or 300 µg/dL) an effect that cannot be reversed by addition of 2-mercaptoethanol (6). Moreover, prior incubation of free TFIIIA with lead resulted in DNA-binding inhibition, whereas prior incubation of a TFIIIA/5S RNA complex with lead did not. Inhibition of Cys<sub>2</sub>His<sub>2</sub> zinc finger transcription factors by lead ions at concentrations near those known to have deleterious physiological effects points to new molecular mechanisms for lead toxicity in promoting disease. **Lead Toxicity:** Lead exposure also induces certain stress-related proteins (7) as well as epoxide hydrolase (8) and the glutathione transferase P gene (9). Lead ions can replace Ca<sup>2+</sup> at their sites of calcium ion-binding proteins. For nearly two hundred years, manufacturers added high amounts of lead tetraoxide as a base pigment for white and lightly colored paints. Lead was also used to join cast iron pipes and to solder copper pipes and wires. Chronic lead exposure results in accumulation in mammalian bone as well as the roots of many plants. The Biological Exposure Index (BEI) for adult blood lead levels is 30 µg/dL. Lead poisoning is insidious, gradual at first, and then followed by its full-blown manifestations. Unfortunately, early evidence of lead poisoning can be elusive. Even seemingly healthy individuals can have high circulating lead levels. Signs and symptoms aren't apparent until dangerous amounts have accumulated. In children, they include irritability, loss of appetite, unaccountable weight loss, sluggishness and fatigue, unaccountable abdominal pain, vomiting, constipation, and learning difficulties. For children, a blood lead level (BLL) of 10 µg/dL is considered grounds for intervention (10,11). In fact, studies have repeatedly linked chronic exposure to BLLs < 10 µg/dL with impairments in cognitive function and behavior in young children despite the absence of overt signs of toxicity (10). The accumulation and efflux of lead depends in part on the ATP-dependent efflux pump, or Multidrug Resistance Protein-1, and requires glutathione, with the latter most likely forming a conjugate with lead ion, followed by export of that conjugate (12). **Abatement & Prophylaxis:** An imperative for lead abatement is the removal of flaking lead house paint from older homes (built prior to 1977 in the U.S.). Chelation therapy using EDTA has been an FDA-approved treatment for lead poisoning for more than forty years. *N*-Acetylcysteine, α-lipoic acid, vitamin E, quercetin and a few herbal extracts also show helpful prophylactic benefits against the majority of lead-mediated injuries, both *in vitro* and *in vivo*. **Enzyme Targets:** Over 1100 proteins and enzymes are inactivated upon even brief exposure to ionic and organic lead compounds – far too many to be conveniently listed in this monograph. Because metal ion exchange most often comports to the Eigen-Tamm mechanism, in which the ligation kinetics is dominated by ligand dissociation rates, the binding of lead ions can be complex. Typical targets have essential thiol groups in their active-sites or as functional groups in their substrates (*e.g.*, cysteine, glutathione, thiosulfate, *etc.*) and coenzymes (*e.g.*, CoA-SH, lipoic acid, and acyl carrier protein). Pb<sup>2+</sup> also replaces metal ions in enzyme active sites. Significantly, Pb<sup>2+</sup> also activates calmodulin and, in fact, has a higher affinity than Ca<sup>2+</sup> (13). One must not ignore that the heavy metal ion binds firmly to the cysteine-rich zinc finger proteins that bind to and modify DNA structure and function. 1. Kirberger & Yang (2008) *J. Inorg. ### LEDGIN-6

This HIV inhibitor (FW = 353.85 g/mol; off-white crystalline solid; M.P. = 215-217 °C), known systematically as 2-(6-chloro-2-methyl-4-phenylquinolin-3-yl)pentanoic acid, targets the multifunctional HIV-1 enzyme integrase, which interacts with viral DNA and its key cellular cofactor LEDGF to efficiently integrate the reverse transcript into a host cell chromosome (1,2). LEDGIN-6 and the structurally related 2-(quinolin-3-yl) acetate, BI-1001, selectively inhibit integrase-LEDGF interactions *in vitro*, with similar IC<sub>50</sub> values, defining each as an allosteric inhibitor of integrase function. In blocking the formation of the stable synaptic complex between integrase and viral DNA, they stabilize an inactive multimeric form of integrase (2). These compounds also inhibit LEDGF binding to the stable synaptic complex, resulting in cooperative inhibition of the concerted HIV integration and replication in cell culture. **1.** Christ, Voet, Marchand, *et al.* (2010) *Nat. Chem. Biol.* **6**, 442. **2.** Kessl, Jena, Koh, *et al.* (2012) *J. Biol. Chem.* **287**, 16801.

### Ledipasvir

This hepatitis C drug (FW = 889.00 g/mol; CAS 1256388-51-8), also named GS-5885 and methyl *N*-[(2*S*)-1-[(6*S*)-6-[5-[9,9-difluoro-7-[2-[(1*S*,2*S*,4*R*)-3-[(2*S*)-2-(methoxycarbonylamino)-3-methylbutanoyl]-3-azabicyclo[2.2.1]heptan-2-yl]-3*H*-benzimidazol-5-yl]fluorene-2-yl]-1*H*-imidazol-2-yl]-5-azaspiro[2.4]heptan-5-yl]-3-methyl-1-oxobutan-2-yl]carbamate, inhibits the viral non-structural protein 5A, or NS5A, a Zn(II)-binding and proline-rich hydrophilic viral phosphoprotein that is involved in viral replication, assembly, and secretion (1,2). NS5A also modulates the polymerase activity of NS5B, an RNA-dependent RNA polymerase (RdRp). Subject-derived Met-28-Thr, Gln-30-Arg, Leu-31-Met, and Tyr-93-Cys mutations all confer >30x reductions in GS-5885 and daclatasvir susceptibilities *in vitro* (3). Site-directed NS5A mutants also show reduced susceptibility. However, all NS5A mutants tested remained fully susceptible to other classes of direct-acting antivirals, interferon  $\alpha$ , and ribavirin. Moreover, the nonoverlapping resistance profiles and high potency of ledipasvir favor its use with other antivirals for treating chronic HCV (3). In 2014, the FDA approved Harvoni<sup>®</sup>, a combination drug consisting of ledipasvir (90 mg) and sofosbuvir (400 mg). **See also Sofosbuvir** **1.** Afdhal, Zeuzem, Kwo, *et al.* (2014). *New Engl. J. Med.* **370**, 1889. **2.** Mizokami,

### LEE011

This orally available and highly specific CDK4/6 inhibitor. (FW = 434.54 g/mol; CAS 1211441-98-3; Solubility: 7 mg/mL (16 mM) DMSO; <1 mg/mL H<sub>2</sub>O or Ethanol), also named 7-cyclopentyl-*N,N*-dimethyl-2-((5-(piperazin-1-yl)pyridin-2-yl)amino)-7*H*-pyrolo[2,3-*d*]pyrimidine-6-carboxamide, greatly reduces proliferation in 12 of 17 human neuroblastoma-derived cell lines by inducing cytostasis at (mean IC<sub>50</sub> = 307 ± 68 nM in sensitive lines). LEE011 causes cell-cycle arrest and cellular senescence attributable to dose-dependent decreases in phosphorylated RB and FOXM1, respectively. **1.** Rader, Russell, Hart, *et al.* (2013) *Clin. Cancer Res.* **19**, 6173.

### Leech-derived Tryptase Inhibitor

This 46-residue Kazal-type protein (MW = 4738 Daltons), often abbreviated LDTI and first isolated from the leech *Hirudo medicinalis*, is a potent inhibitor of human tryptase (*K<sub>d</sub>* = 1.4 nM). **Target(s):** chymotrypsin (1); trypsin (1-3); tryptase (1-4). **1.** Sommerhoff, Söllner, Mentle, *et al.* (1994) *Biol Chem Hoppe-Seyler.* **375**, 685. **2.** Erba, Fiorucci, Sommerhoff, Coletta & Ascoli (2000) *Biol. ### Leelamine

This chiral diterpene amine and investigational chemotherapeutic agent (FW = 285.48 g/mol; CAS 1446-61-3; from *leela* (Sanskrit for "play"), also named as 1*R*,2,3,4,4*a*,9,10,10*aR*-octahydro-1,4*a*-dimethyl-7-(1-methylethyl)-1-phenanthrenemethanamine, is a lysosomotropic, intracellular cholesterol transport inhibitor, resulting in the inhibition of autophagic flux and induction of cholesterol accumulation in lysosomal-endosomal cell compartments (1). Treatment of cells with leelamine results in the accumulation of cholesterol within acidic organelles such as lysosomes, disrupting autophagic flux and intracellular cholesterol trafficking as well as receptor-mediated endocytosis (1). Leelamine inhibited the growth of preexisting xenografted melanoma tumors by an average of 60% via targeting of the PI3K, MAPK and STAT3 pathways, without affecting animal body weight or blood markers of major organ function (2). Leelamine inhibits pyruvate dehydrogenase kinase, IC<sub>50</sub> = 9.5  $\mu$ M (3). Leelamine also shows weak cannabinoid receptor affinity, displacing 20% of [<sup>3</sup>H]-CP55940 from central CB<sub>1</sub> and the peripheral CB<sub>2</sub> receptors, when present at 10  $\mu$ M. **1.** Kuzu, Gowda, Sharma & Robertson (2014) *Mol. Cancer Ther.* **13**, 1690. **2.** Gowda, Madhanupantula, Kuzu, Sharma & Robertson (2014) *Mol. Cancer Ther.* **13**, 1679. **3.** Cadoudal, Distel, Durant, *et al.* (2008) *Diabetes* **57**, 2272.

### Leflunomide

Leflunomide

A771726

This antirheumatic (FW = 270.21 g/mol; CAS 75706-12-6), also known as *N*-[4-(trifluoromethyl)phenyl]-5-methylisoxazole-4-carboxamide, Arava, and SU 101, is metabolized to an open-ring derivative A771726 (**See Teriflunomide**) that is a potent, reversible inhibitor of mammalian dihydroorotate dehydrogenase, the rate-limiting step in *de novo* pyrimidine biosynthesis. (The bacterial enzyme is unaffected.) Because activated white blood cells have an elevated demand for purines and pyrimidines, they rely on both salvage and *de novo* synthesis pathways. In the presence of A771726, lymphocytes cannot accumulate sufficient stores of pyrimidine nucleotides to support DNA biosynthesis. Leflunomide prevents proliferative expansion of activated and autoimmune lymphocytes by interfering with their cell-cycle progression. By contrast, nonlymphoid cells rely on pyrimidine salvage pathway, making them less dependent on *de novo* synthesis. While the immunoregulatory effects of A771726 are observed at the lower concentrations, higher doses inhibit protein-tyrosine kinases responsible for early T-cell and B-cell signalling in the G<sub>0</sub>/G<sub>1</sub> phases are also inhibited (1). Leflunomide inhibits platelet-derived-growth factor-mediated signaling events, including receptor tyrosine phosphorylation, DNA synthesis, cell cycle progression, and cell proliferation (2). It also inhibits dihydroorotate dehydrogenase (DHODH), an enzyme that is involved in the biosynthesis of uridine (**See also 4SC-101**) (3). A77-1726, a pharmacologically active metabolite of leflunomide, attenuates lupus nephritis by promoting the development of regulatory T cells and inhibiting IL-17-producing double negative T cells (4). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) #### Leurotoxin I

This channel blocker (FW = 3429.18 g/mol; CAS 142948-19-4; *Sequence*: AFCNLRMCQLSCRSLLGKIGDKCECVKH; *Symbol*: LeTx1), also known as Scyllatoxin, is a peptide inhibitor of the small conductance, Ca<sup>2+</sup>-activated K<sup>+</sup> channels. Leurotoxin I comprises <0.02% of the protein in the venom of the scorpion (*Leiurus quinquestriatus hebraeus*). Leurotoxin shares some homology to other scorpion toxins such as charybdotoxin, noxiustoxin, and neurotoxin P<sub>2</sub>. Leurotoxin I completely inhibits <sup>125</sup>I-apamin binding to rat brain synaptosomal membranes (K<sub>i</sub> = 75 pM), but is some 10-20x less potent than apamin (**See Apamin**). Like apamin, leurotoxin I blocks the epinephrine-induced relaxation of guinea pig smooth muscle (ED<sub>50</sub> = 6.5 nM), but is without effect on the rate or force of contraction in guinea pig atria or rabbit portal vein preparations. The cysteine spacing and disulfides found in all scorpion toxins (and preserved in LeTx1) may play an active role in folding, with only two native disulfide bonds in LeTx1 sufficient to preserve its active conformation (3). 1. Chicchi, Gimenez-Gallego, Ber, *et al.* (1988) *J. Biol. Chem.* **263**, 10192. 2. Auguste, Hugues, Gravé, *et al.* (1990) *J. Biol. Chem.* **265**, 4753. 3. Zhu, Liang, Martin, *et al.* (2002) *Biochemistry* **41**, 11488.

#### Lenalidomide

This thalidomide derivative (FW = 259.26 g/mol; CAS 191732-72-6; Solubility: 50 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known by the trade name Revlimid<sup>®</sup> and its systematic name (*RS*)-3-(4-amino-1-oxo-1,3-dihydro-2*H*-isoindol-2-yl)piperidine-2,6-dione, is a TNF $\alpha$  secretion inhibitor (IC<sub>50</sub> = 13 nM) and is indicated for the treatment of patients with mantle cell lymphoma (MCL) whose disease has relapsed or progressed after two prior therapies, one of which included bortezomib. Although originally intended for treating multiple sclerosis, lenalidomide has proven to be an effective immunomodulatory agent that stimulates production of the cytokine IL-2 and induces the biosynthesis of interleukin-2 receptor (IL-2R), a heterotrimeric protein expressed on the outer surface of certain immune cells, including lymphocytes. 1. Muller, *et al.* *Bioorg. Med. Chem.*

*Lett.* (1999) **9**, 1625. 2. Zangari M, *et al.* (2005) *Expert Opin. Investig. Drugs* **14**, 1411. 3. Ramsay, *et al.* (2012) *Blood* **120**, 1412.

#### Lenvatinib

This TKI and angiogenesis inhibitor (FW = 426.86 g/mol; CAS 417716-92-8; Solubility: 40 mg/mL DMSO; <1mg/mL H<sub>2</sub>O), also named 1-(4-(6-carbamoyl-7-methoxyquinolin-4-yloxy)-2-chlorophenyl)-3-cyclopropyl-urea, E7080 and Lenvima<sup>®</sup>, shows potent action against Stem Cell Factor (SCF-) induced angiogenesis, both *in vitro* and in SCF-producing human small cell lung carcinoma H146 cells *in vivo* (1). It is specifically indicated for treating locally recurrent or progressive metastatic radioiodine-refractory thyroid cancer. Lenvatinib inhibits SCF-driven tube formation of HUVEC, which express SCF receptor, KIT (IC<sub>50</sub> = 5.2 nM) and is almost identical for VEGF (IC<sub>50</sub> = 5.1 nM). Imatinib, by contrast, do not show the potent antitumor activity against H146 cells *in vitro* (IC<sub>50</sub> = 2.2  $\mu$ M), because these cells do not express KIT. (**See Imatinib**) However, when administered orally at 160 mg/kg, imatinib slows tumor growth of H146 cells in nude mice, attended by decreased microvessel density. Oral administration of lenvatinib inhibits H146 cells at doses of 30 and 100 mg/kg in a dose-dependent manner, causing tumor regression at 100 mg/kg. While anti-VEGF antibody also slows tumor growth, it fails to cause tumor regression. Such results indicate that KIT signaling plays a role in tumor angiogenesis of SCF-producing H146 cells, and lenvatinib causes regression of H146 tumors as a result of antiangiogenic activity mediated by inhibition of both KIT and VEGF receptor signaling (1). VEGF-R3 kinase inhibition by E7080 also decreases lymphatic vessel density (LVD) within MDA-MB-231 tumors that express VEGF-C. Simultaneous inhibition of both VEGF-R2 and VEGF-R3 kinases by lenvatinib may be a promising new strategy to control regional lymph node and distant lung metastases (2). Lenvatinib inhibits VEGF- and FGF-driven angiogenesis and showed a broad spectrum of antitumor activity with a wide therapeutic window. MVD and pericyte-coverage of tumor vasculature might be biomarkers for lenvatinib-responsive therapies (3). 1. Matsui, Yamamoto, Funahashi, *et al.* (2008) *Int. J. Cancer* **122**, 664. 2. Matsui, Funahashi, Uenaka, *et al.* (2008) *Clin. Cancer Res.* **14**, 5459. 3. Yamamoto, Matsui, Matsushima, *et al.* (2014) *Vasc. Cell.* **6**, 18.

#### Leptomycin B

This unusual unsaturated fatty acid (FW<sub>free-acid</sub> = 540.74 g/mol) inhibits the nuclear export of proteins in eukaryotic cells. Leptomycin B binds covalently via its  $\alpha\beta$ -unsaturated  $\delta$ -lactone to the sulfhydryl group of a cysteinyl residues of CRM1 (*or* Exportin 1), a receptor for the nuclear export signal of proteins. 1. Nishi, Yoshida, Fujiwara, *et al.* (1994) *J. Biol. Chem.* **269**, 6320. 2. Fukuda, Asano, Nakamura *et al.* (1997) *Nature* **390**, 308. 3. Kudo, Matsumori, Taoka, *et al.* (1999) *Proc. Natl. Acad. Sci. U.S.A.* **96**, 9112. 4. Kudo, Wolff, Sekimoto, *et al.* (1998) *Exp. Cell Res.* **242**, 540.

## Lestaurtinib

This staurosporine-like multi-tyrosine kinase inhibitor, or TKI (FW = 439.47 g/mol; CAS 111358-88-4), also known as CEP-701 and KT-5555, potently targets the tyrosine kinase activity of the neurotrophin-specific Trk receptors ( $IC_{50} = 4$  nM), FMS-like tyrosine kinase-3 (FLT3), and JAK2, STAT5 and STAT3. Trk receptor ligands are neurotrophins, a family of neuronal growth factors, including NGR, that activate Trks, which in turn promote cell survival. With aberrant expression of the Trk receptors (Trk A, B, C) in pancreatic ductal adenocarcinoma (PDAC), lestaurtinib is active against xenograft models using the poorly differentiated PDAC cell line, Panc1, inhibiting both growth and invasion (1) and exerts similar effects on both primary and metastatic prostate cancer cells (2). Internal tandem duplication of FMS-like tyrosine kinase-3 (FLT3) is associated with poor outcomes in acute myelogenous leukemia and Hodgkin Lymphoma (HL), and lestaurtinib potently inhibits autophosphorylation of FLT3 and JAK2 *in vitro* (3-5). (See also Staurosporine) **IUPAC:** (9*S*,10*S*,12*R*)-2,3,9,10,11,12-hexahydro-10-hydroxy-10-(hydroxymethyl)-9-methyl-9,12-epoxy-1*H*-diindolo[1,2,3-*fg*:3',2',1'-*kl*]pyrrolo[3,4-*ij*][1,6]benzodiazocin-1-one. 1. ## Letrozole

This orally bioavailable, non-steroidal anti-estrogen agent (FW = 285.30 g/mol; CAS 112809-51-5; Symbol: LZ), known by the trade name Femara™ and systematically as 4,4'-((1*H*-1,2,4-triazol-1-yl)methylene)-dibenzonitrile, targets aromatase, or CYP19A1 ( $IC_{50} = 50$ -100 nM), a member of the cytochrome P450 superfamily (EC 1.14.14.1). This monooxygenase catalyzes numerous reactions in steroidogenesis and is responsible for the conversion of androgens into estrogens. Letrozole is widely used to treat post-surgical, hormonally-responsive breast cancer (1). Early studies showed that concurrent treatment of MCF-7 cells with 17- $\beta$ -estradiol in the presence of LZ significantly suppresses the estradiol-induced stimulation of matrix metalloproteinases (MMP) levels. These results indicate that letrozole is a potent inhibitor of *in vitro* cell proliferation and of type IV collagenase expression in ER-positive MCF-7 cells (2). Letrozole likewise suppresses breast tumor growth and invasiveness (2). LZ treatment of female germ cells brings about sex inversion in yellow catfish (*Pelteobagrus fulvidraco*), a species displaying sexual dimorphic growth. These results suggest that aromatase activity plays a vital role in sex differentiation. 1. Bhatnagar, Häusler, Schieweck, Lang & Bowman (1990) *J. Steroid Biochem. Mol. Biol.* 37, 1021. 2. ## L-Leucinal

This leucine derivative (FW<sub>free-base</sub> = 103.17 g/mol), also known as 2(*S*)-amino-4-methylpentanal, inhibits tripeptide aminopeptidase, leucyl aminopeptidase, and aminopeptidase N. **Target(s):** leucyl aminopeptidase (1-3); membrane alanyl aminopeptidase, or aminopeptidase N (1); tripeptide aminopeptidase (4). 1. Bauvois & Dauzonne (2006) *Med. Res. Rev.* 26, 88. 2. Sträter & Lipscomb (2004) in *Handbook of Metalloproteins*, 3, 199, Wiley, New York. 3. Andersson, MacNeela & Wolfenden (1985) *Biochemistry* 24, 330. 4. Frick & Wolfenden (1985) *Biochim. Biophys. Acta* 829, 311.

## D-Leucine

This branched chain amino acid (FW = 131.175 g/mol), (*R*)-2-amino-4-methylpentanoic acid, is the enantiomer of the proteogenic amino acid, L-leucine. D-Leucyl residues are present in a number of antibiotics: for example, gramicidin A, polymixin D<sub>1</sub>, and tolaasin. (See also L-Leucine) **Target(s):** alkaline phosphatase, weakly inhibited (1); carboxypeptidase A, weakly inhibited (2); 2-ethylmalate synthase, weakly inhibited (3); gramicidin S synthase (4); 2-isopropylmalate synthase, weakly inhibited (5); leucyl aminopeptidase (6); system L amino acid transport (7). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Hoylaerts, Manes & Millán (1992) *Biochem. J.* 286, 23. 2. Coleman & Vallee (1964) *Biochemistry* 3, 1874. 3. ## L-Leucine

This branched-chain amino acid (FW = 131.18 g/mol;  $pK_1 = 2.33$  ( $\alpha$ -COOH),  $pK_2 = 9.74$  ( $\alpha$ -NH<sub>2</sub>) at 25°C;  $dpK_{a2}/dT = -0.026$ ; Specific Rotation = +16.0° at 25°C; Symbol = Leu or L), named systematically (*S*)-2-amino-4-methylpentanoic acid, is a proteogenic amino acid that is nutritionally essential in mammals. Leucine was identified early on in biochemical investigations of protein components (1-5). The six codons for Leucine are UUA, CUU, UUG, CUA, CUC, and CUG. One of the most hydrophobic amino acids, leucine residues are usually buried in the apolar interior, where they are found in both  $\alpha$ -helices and  $\beta$ -pleated sheets. Leucine residues are also found in coiled-coil regions and most famously in so-called "leucine zipper" proteins. Homologous proteins often have leucine residues interchanged with valine, isoleucine, methionine, or phenylalanine residues. **Target(s):** acetolactate synthase (6,7,83-93); acetylcholinesterase8; alkaline phosphatase (9,10,52-55); D-amino-acid oxidase (11-14); 2-aminohexanoate transaminase, also weaker alternative substrate (59); 2-aminohexano-6-lactam racemase, weakly inhibited (15); arginase (16-19); asparagine:oxo-acid aminotransferase (61,62); aspartate kinase (20,57); ATP:citrate lyase, or ATP:citrate synthase, weakly inhibited (81); bacterial leucyl aminopeptidase, product inhibition (45); creatine kinase (56);

cystinyl aminopeptidase, or oxytocinase (46,48); cytosol alanyl aminopeptidase (43,44); cytosol nonspecific dipeptidase (21,40,41); dipeptidyl-peptidase IV (22); 2-ethylmalate synthase (82); 2-glucose-6-phosphatase (23); glutamine synthetase (24); homoserine kinase (58); (S)-2-hydroxy-acid oxidase (25); isoleucine incorporation into proteins (26); 2-isopropylmalate synthase (27-32,68-80); kynurenine: oxoglutarate aminotransferase (67); lactate 2-monooxygenase (97); leucyl aminopeptidase (51); membrane alanyl aminopeptidase, or aminopeptidase N (33,46,49,50); ornithine aminotransferase (63-66); ornithine carbamoyltransferase (34,94-96); saccharopine dehydrogenase (35); theanine hydrolase, or weakly inhibited (36); threonine ammonia-lyase, or threonine dehydratase (37,38); tripeptide aminopeptidase (39,47); valine:pyruvate transaminase (60); Xaa-Pro dipeptidase, or prolidase isozyme I (42). 1. ### 5-Leucine Enkephalin

This pentapeptide (FW = 553.62 g/mol; Sequence: YGGFL; Abbreviation: [Leu]Enkephalin) is an endogenous opioid neurotransmitter and neuromodulator that functions as an agonist at  $\mu$  and  $\delta$  opioid receptors. [Leu]Enkephalin is itself a substrate for dipeptidyl-peptidase III. **Target(s):** Ca<sup>2+</sup>-dependent ATPase (1); carboxypeptidase E,  $K_i$  = 6.5 mM (2,3); dactylolysin,  $K_i$  = 250  $\mu$ M (The amide also inhibits.) (4,5); protein-disulfide isomerase (6). 1. Yamasaki & Way (1985) *Neuropeptides* **5**, 359. 2. Hook (1990) *Life Sci.* **47**, 1135. 3. Hook & LaGamma (1987) *J. Biol. Chem.* **262**, 12583. 4. ### L-Leucine Hydroxamate

This hydroxamate (FW = 146.19 g/mol; CAS 31982-78-2) inhibits *Vibrio* aminopeptidase and thermolysin ( $K_i$  = 14  $\mu$ M). A substituted  $\beta$ -mercaptoketone is likely to inhibit in a similar manner ( $K_i$  = 1  $\mu$ M), suggesting a mechanism in which a zinc-bound hydroxide ion participates in concerted proton-transfer processes and where the coordination and charge field at the zinc atom remain unchanged. **Target(s):** atrolysin A (1); bacterial leucyl aminopeptidase, as alternative substrate (2,3); coccolysin (4); leucyl aminopeptidase, as alternative substrate (3,4); membrane alanyl aminopeptidase (3); thermolysin,  $K_i$  = 190  $\mu$ M (6-9); *Vibrio* aminopeptidase (10); vibriolysin (11). 1. ### Leucinostatins

This family of Class-II cystatins and antibiotic/phytotoxic nonapeptides (FW<sub>Leucostatins-A</sub> = 1218.66; CAS 76600-38-9) are produced by a number of different microorganisms, among them: *Paecilomyces marquandii*, *P. lilacinus*, and species of *Acremonium*. These agents also go by the synonyms Paecilotoxin, LS-87870, AC1051DJ, 39405-64-6, and Antibiotic A20668. By far the most abundant family member, Leucinostatin A inhibits mitochondrial (1-8) and chloroplast (9) ATP synthases as well as prostate cancer growth by reducing insulin-like growth factor-I expression in prostate stromal cells (10). 1. ### Leukemia Inhibitory Factor

This 202-residue interleukin-6 class cytokine (MW = 22007.74 g; NCBI Reference Sequence: NP 002300.1; Symbol: LIF) controls the induction of hematopoietic differentiation in normal myeloid and leukemia cells, the promotion of neuron and muscle cell differentiation, the regulation of mesenchymal-to-epithelial conversion, as well as trophoblast implantation (1-3). To activate signaling cascades in stromal cells, chondrocytes, osteoblasts, osteocytes, adipocytes, and synovial fibroblasts, LIF signals through cytokine-specific LIF receptor, or LIFR (also known as also known as Cluster of Differentiation-118, or CD118), which is complexed to the cytokine co-receptor Glycoprotein-130 (3). This same LIFR/Gp-130 receptor complex is also used by Ciliary Neurotrophic Growth Factor (CNTF), Oncostatin M, Cardiotrophin-1 (CT1) and Cardiotrophin-like Cytokine (CLC). **Role in Maintaining Embryonic Stem Cell Self-Renewal & Pluripotency:** Pluripotency is a transient *in vivo*, but cultured pluripotent cells can be indefinitely maintained in an artificially induced state of self-renewal by supplementing them with appropriate exogenous cues (2). An indispensable agent for the pluripotency of mouse embryonic stem cells (mESCs), LIF binds to the LIF receptor, thereby activating JAK/STAT3, PI3K/AKT and SHP2/MAPK signaling pathways to choreograph the gene expression pattern that is specific to mESCs (3). When LIF is withdrawn from culture medium, the activity of mTOR (mammalian Target of Rapamycin) increases rapidly, as indicated by the phosphorylation of its targets, ribosomal protein S6 and translation factor 4EBP1. Suppression of phosphorylation at Tyr-705 in STAT3 by WP1066 (IC<sub>50</sub> = 2.4 μM) also activates phosphorylation of the mTOR target S6 ribosomal protein (**See also WP1066**). LIF removal strongly activates ERK activity, either by direct phosphorylation of mTOR or by phosphorylation of upstream negative regulators of mTOR, such as TSC1 and TSC2 proteins (4). LIF withdrawal leads to phosphorylation of TSC2 protein, relieving its inhibition of mTOR activity and thereby decreasing pluripotent gene expression Oct-4, Nanog, Sox2, while augmenting expression of the *fgf5* gene, a marker of post-implantation epiblasts. Such findings indicate that LIF-depleted mouse ESCs undergo a transition from the LIF/STAT3-supported pluripotency to the FGFR/ERK-committed, primed-like state that attends expression of early differentiation markers, as mediated by mTOR signaling (5). Although LIF knockdown suppresses proliferation and invasion of osteosarcoma by

blocking the STAT3 signal pathway, treatment with recombinant LIF significantly promotes osteosarcoma growth and invasion by enhancing STAT3 phosphorylation, an effect that can be partially neutralized by the STAT3 inhibitor, HO-3867 (5). See Reference-6 for details on the molecular cloning and expression of murine myeloid LIF cDNA. 1. Granger, Moore, White, *et al.* (1970) *J. Immunol.* **104**, 1476. 2. ### Leukotriene A<sub>3</sub> & Leukotriene A<sub>3</sub> Methyl Ester

This 5-hydroperoxyeicosatrienoate metabolite (FW<sub>free-acid</sub> = 320.48 g/mol; IUPAC: 5*S*-*trans*-5,6-oxido-7*E*,9*E*,11*Z*-eicosatrienoic acid; *Abbreviation* = LTA<sub>3</sub>) and its cell-permeable methyl ester (FW<sub>ester</sub> = 334.49 g/mol; CAS 83851-38-1) are natural and synthetic precursors, respectively, of leukotriene C<sub>3</sub>. Leukotriene A<sub>3</sub> is an analogue of leukotriene A<sub>4</sub>, but lacks the C14-C15 double bond. As the free acid, LTA<sub>3</sub> is highly unstable, and the methyl ester is preferred in biochemical experiments that rely on endogenous esterases to generate the free acid. LTA<sub>3</sub> is a potent suicide inhibitor of leukotriene A<sub>4</sub> hydrolase, which catalyzes the conversion of the unstable epoxide LTA<sub>4</sub> into pro-inflammatory LTB<sub>4</sub>, by reacting covalently with an active-site residue (1-3). Mass spectroscopic analysis of proteolytic fragments are consistent with nucleophilic attack by the hydroxyl group of Tyrosine-383 at the conjugated triene epoxide of LTA<sub>3</sub>, thereby forming a triene ether carbinol covalent adduct (4). 1. ### Leukotriene A<sub>3</sub>

This 5-hydroperoxyeicosatrienoate metabolite (FW = 304.46 g/mol; CAS 83851-38-1 (cell-permeable methyl ester); *Abbreviation* = LTA<sub>3</sub>) is a precursor of leukotriene C<sub>3</sub>. Leukotriene A<sub>3</sub> is an analogue of leukotriene A<sub>4</sub>, lacking the C14 double bond. LTA<sub>3</sub> is a potent suicide inhibitor of leukotriene A<sub>4</sub> hydrolase, with an active-site tyrosine residue in the hydrolase acting as the nucleophile and forming a carbinol adduct. 1. Ohishi, Izumi, Seyama & Shimizu (1990) *Meth. Enzymol.* **187**, 286. 2. Mancini, Waugh, Thompson, *et al.* (1998) *Arch. Biochem. Biophys.* **354**, 117. 3. Evans, Nathaniel, Zamboni & Ford-Hutchinson (1985) *J. Biol. Chem.* **260**, 10966. 4. Evans, Nathaniel, Charleson, *et al.* (1986) *Prostaglandins Leukot. Med.* **23**, 167.

### Leukotriene A<sub>4</sub> & Leukotriene A<sub>4</sub> Methyl Ester

This unstable eicosatetraenoate (FW = 317.45 g/mol; IUPAC: 5(*S*)-*trans*-5,6-oxido-11,14-*cis*-eicosatetraenoate; *Abbreviation* = LTA<sub>4</sub>; FW<sub>ester</sub> = 332.48 g/mol; CAS 73466-12-3) is synthesized in mast cells, eosinophils, and neutrophils from arachidonic acid by 5-lipoxygenase (5-LO), which exhibits both lipoxygenase and LTA<sub>4</sub> synthase activities. It is a substrate of leukotriene A<sub>4</sub> hydrolase, which catalyzes the conversion of LTA<sub>4</sub> into pro-

inflammatory leukotriene B<sub>4</sub> (or LTB<sub>4</sub>). During catalysis, this hydrolase, which also exhibits peptidase activity, is inactivated through covalent binding to an active-site tyrosyl residue (1-17). This process blocks both enzyme activities and may be of importance for the overall regulation of LTB<sub>4</sub> biosynthesis. In addition, leukotriene A<sub>4</sub>, which is produced by 5-lipoxygenase, irreversibly inactivates the lipoxygenase, representing an unusual case of product inactivation (18,19). Note also that leukotriene A<sub>4</sub> is also a substrate of a glutathione S-transferase, producing leukotriene C<sub>4</sub>. 1. Haeggström (1998) in *Handb. #### 14,15-Leukotriene A<sub>4</sub>

This unstable fatty acid derivative (FW<sub>free-acid</sub> = 318.46 g/mol; *Abbreviation* = 14,15-LTA<sub>4</sub>), also known as 14,15-oxido-5,8-*cis*-10,12-*trans* eicosatetraenoic acid, is an analogue of leukotriene A<sub>4</sub> (1,2). 14,15-LTA<sub>4</sub> is not a substrate of leukotriene A<sub>4</sub> hydrolase. It is produced from 15 hydroperoxyeicosatetraenoate in anaerobic incubations. 1. Ohishi, Izumi, Seyama & Shimizu (1990) *Meth. Enzymol.* **187**, 286. 2. Ohishi, Izumi, Minami, *et al.* (1987) *J. Biol. Chem.* **262**, 10200.

#### Leukotriene A<sub>5</sub>

This leukotriene A<sub>4</sub> analogue (FW = 316.44 g/mol; CAS 90121-06-5 (membrane-penetrating methyl ester); *Abbreviation* = LTA<sub>5</sub>), also known as 5(*S*)-*trans*-5,6-oxido-7,9-*trans*-11,14,17-*cis* eicosapentaenoic acid, is also a substrate of leukotriene A<sub>4</sub> hydrolase, albeit weaker, and also acts as a suicide substrate inhibitor. 1. Ohishi, Izumi, Seyama & Shimizu (1990) *Meth. Enzymol.* **187**, 286. 2. Nathaniel, Evans, Leblanc, *et al.* (1985) *Biochem. Biophys. Res. Commun.* **131**, 827. 3. Evans, Nathaniel, Charleson, *et al.* (1986) *Prostaglandins Leukot. Med.* **23**, 167.

#### Leukotriene B<sub>4</sub>

This unstable leukotriene (FW<sub>free-acid</sub> = 336.47 g/mol; CAS71160-24-2; *Abbreviation* = LTB<sub>4</sub>), also known as 5*S*,12*R*-dihydroxy-6*Z*,8*E*,10*E*,14*Z*-eicosatetraenoic acid, is a potent chemotactic agent for polymorphonuclear leukocytes. It increases vascular permeability and functions an activator of inflammatory cells. LTB<sub>4</sub> also stimulated c-Fos and c-Jun proto-oncogene transcription in human monocytes. **Target(s):** leukotriene E<sub>4</sub> 20-

monooxygenase (1). 1. Huwyler, Jedlitschky, Keppler & Gut (1992) *Eur. J. Biochem.* **206**, 869.

#### Leukotriene C<sub>4</sub>

This leukotriene (FW = 625.77g/mol; CAS 72025-60-6; *Abbreviation* = LTC<sub>4</sub>) is formed by the conjugation of glutathione to leukotriene A<sub>4</sub>, via leukotriene C<sub>4</sub> synthase and glutathione S-transferases. It induces renal vasoconstriction and broncho-constriction. Leukotriene C<sub>4</sub> is an important mediator of vascular tone, permeability, and smooth muscle contractility. It is also a very good substrate ( $K_m = 6 \mu\text{M}$ ) in the  $\gamma$ -glutamyl transpeptidase reaction. **Target(s):** *N*-acetylgalactosamine-4-sulfatase, or arylsulfatase B (2); glutathione S transferase-1 (3); 15-hydroxyprostaglandin dehydrogenase (NADP+) (4); xenobiotic-transporting ATPase, multidrug-resistance protein (5,6). 1. Anderson, Allison & Meister (1982) *Proc. Natl. Acad. Sci. U.S.A.* **79**, 1088. 2. Weller, Corey, Austen & Lewis (1986) *J. Biol. Chem.* **261**, 1737. 3. Bannenberg, Dahlen, Luijckink, Lundqvist & Morgenstern (1999) *J. Biol. Chem.* **274**, 1994. 4. Chung, Harvey, Armstrong & Jarabak (1987) *J. Biol. Chem.* **262**, 12448. 5. Loe, Stewart, Massey, Deeley & Cole (1997) *Mol. Pharm.* **51**, 1034. 6. Paul, Breuninger, Tew, Shen & Kruh (1996) *Proc. Natl. Acad. Sci. U.S.A.* **93**, 6929.

#### Leukotriene D<sub>4</sub>

This leukotriene (FW = 496.66g/mol; CAS 73836-78-9; *Abbreviation* = LTD<sub>4</sub>), produced by  $\gamma$ -glutamyl transpeptidase on leukotriene C<sub>4</sub> (1), is a potent broncho-constrictor and participates in inflammatory processes. **Target(s):** *N*-acetylgalactosamine-4-sulfatase, or arylsulfatase B (2); leukotriene-C<sub>4</sub> synthase (3). 1. Anderson, Allison & Meister (1982) *Proc. Natl. Acad. Sci. U.S.A.* **79**, 1088. 2. Weller, Corey, Austen & Lewis (1986) *J. Biol. Chem.* **261**, 1737. 3. Nicholson, Klemba, Rasper, Metters & Zamboni (1992) *Eur. J. Biochem.* **209**, 725.

#### Leukotriene E<sub>4</sub>

This leukotriene (FW = 439.61g/mol; CAS 75715-89-8; *Abbreviation* = LTE<sub>4</sub>), produced from leukotriene D<sub>4</sub> via the action of a dipeptidase (1), mediates anaphalaxis and inflammatory processes. **Target(s):** *N*-acetylgalactosamine-4-sulfatase, or arylsulfatase B (2); leukotriene-C<sub>4</sub> synthase (3). 1. Anderson, Allison & Meister (1982) *Proc. Natl. Acad. Sci. U.S.A.* **79**, 1088. 2. Weller, Corey, Austen & Lewis (1986) *J. Biol. Chem.*

261, 1737. 3. Nicholson, Klemba, Rasper, Metters & Zamboni (1992) *Eur. J. Biochem.* **209**, 725.

### Leupeptin

This widely used, water-soluble tripeptide aldehyde (FW = 426.55 g/mol; CAS 55123-66-5; Sequence: *N*-Ac-LLR-CHO), originally isolated from an *Actinomyces* broth (1,2), is a transition-state mimic (as thye hydrated aldehyde) and potent competitive inhibitor of many proteinases, including trypsin, plasmin, cathepsin B, and papain. Leupeptin is an ineffective against chymotrypsin, pepsin, thrombin, elastase, cathepsin A, and cathepsin D. Leupeptin is itself an alternative substrate for some proteinases, such as thermolysin. Note that the terminal aldehyde group, which in aqueous solutions is either hydrated or rearranged into cyclic carbinolamine, is essential for inhibition. **Practical Considerations:** Due to its limited specificity, leupeptin is frequently used in conjunction with other protease inhibitors during the purification of protease-sensitive proteins. The effective inhibitory concentration range is 10-100  $\mu$ M. Stock solutions are prepared as a 5-10 mM aqueous solution. If needed, higher stock concentrations are achieved in *N,N*-dimethylformamide or ethanol. Aqueous stock solutions are stable for hours at room temperature, for days in an ice-bath, and for months at  $-20^{\circ}\text{C}$ . 1. Aoyagi, Takeuchi, Matsuzaki, *et al.* (1969) *J. Antibiotics (Tokyo)*, Series A **22**, 283. 2. Aoyagi, Miyata, Nanbo, *et al.* (1969) *J. Antibiotics (Tokyo)*, Series A **22**, 558.

### Leuprolide

This pituitary GnRH receptor desensitizer and luteinizing hormone-releasing hormone (LHRH) agonist (FW = 1209.40 g/mol; CAS 53714-56-0; Sequence: Pyro-Glu-His-Trp-Ser-Tyr-D-Leu-Leu-Arg-Pro-NHC<sub>2</sub>H<sub>5</sub>), also known as Leuprorelin and Lupron<sup>®</sup>, acts primarily on the anterior pituitary, inducing a transient early rise in gonadotrophin release. With continued use, leuprorelin treatment results in pituitary desensitization, indirectly down-regulating secretion of gonadotropins luteinizing hormone (LH) and follicle-stimulating hormone (FSH) and dramatically reducing estradiol and testosterone levels in both sexes. 1. Plosker & Brogden (1994) *Drugs* **48**, 930.

### Levamisole

This antihelminthic (FW<sub>free-base</sub> = 204.30 g/mol; M.P. = 60-61.5°C), also called (-)-2,3,5,6-tetrahydro-6-phenylimidazo[2,1-*b*]thiazole, is the 6*S* stereoisomer of tetramisole (*i.e.*, an equal mixture of levamisole, the (-)-stereoisomer, and dexamisole, the (+)-enantiomer). Some literature sources use the terms tetramisole and levamisole synonymously. Levamisole inhibits liver, bone, and kidney alkaline phosphatases; however, intestinal alkaline phosphatase is only weakly inhibited. (See also *Tetramisole*) **Target(s):** alkaline phosphatase (1-12); *Ascaridia galli* ATPase (13); *Ascaridia galli* acid phosphatase (13); Ca<sup>2+</sup>-dependent ATPase, *Setaria cervi* (14,15); ecto-alkaline phosphatase (3,4); membrane-specific ATPase (16); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (15,17); organic cation transporter rOCT1 (18); phosphotyrosine phosphatase (19); pyridoxal phosphatase (20). 1. ### Levetiracetam

This orally available nonanalaptic drug (FW = 170.21 g/mol; CAS 102767-28-2; the *S*-enantiomer of etiracetam), also known as UCB L059, Kepra<sup>®</sup> and (*S*)-2-(2-oxopyrrolidin-1-yl)butanamide, is a high-affinity synaptic vesicle protein 2A ligand that is indicated for the treatment of partial (focal), myoclonic, and tonic-clonic seizures. Absorption is rapid and essentially complete, putting levetiracetam's bioavailability at ~100%, with no effect of food on absorption. The volume of distribution of levetiracetam is similar to total body water. It is not extensively metabolized, and any metabolites that do form are pharmacologically inactive. The plasma half-life in adults is 6-8 hours. Levetiracetam is eliminated primarily by the kidneys, with ~66 percent of the drug unchanged. The drug is active, even when memory deficits are induced by electroconvulsive shock, undertraining, or by a long training-to-test interval (1). Levetiracetam induces alterations in GABA metabolism and turnover in discrete areas of rat brain and reduces neuronal activity in substantia nigra pars reticulata (2). It also prevents perforin-mediated neuronal injury induced by acute cerebral ischemia reperfusion (3). LEV inhibits voltage-gated presynaptic Cav channels, reducing neuronal excitability (4). Levetiracetam reverses the inhibition by negative allosteric modulators of neuronal GABA- and glycine-gated currents (5). 1. Sara (1980) *Psychopharmacol.* (Berl.) **68**, 235. 2. Löscher, Hönack & Bloms-Funke (1996) *Brain Res.* **735**, 208. 3. Zhang, Li, Zuo, *et al.* (2015) *Mol. Neurobiol.* Doi:10.1007/s12035-015-9467-9. 4. Vogl, Mochida, Wolff, Whalley & Stephens (2012) *Mol. Pharmacol.* **82**, 199. 5. Rigo, Hans, Nguyen, *et al.* (2002) *Brit. J. Pharmacol.* **136**, 659.

### Levofloxacin

This fluoroquinolone-class antibiotic (FW = 361.37 g/mol; CAS 100986-85-4; IUPAC Name: (*S*)-9-fluoro-2,3-dihydro-3-methyl-10-(4-methylpiperazin-1-yl)-7-oxo-7*H*-pyrido[1,2,3-*de*]-1,4-benzoxazine-6-carboxylate), also trade-named Levaquin<sup>®</sup>, Tavanic<sup>®</sup>, and Iquix<sup>®</sup>, is a broad-spectrum systemic antibacterial that targets Type II DNA topoisomerases (gyrases), enzymes that are required for bacterial replication and transcription. Levofloxacin shows greater action against the respiratory pathogen *Streptococcus pneumoniae* than ciprofloxacin. It is also used to treat urinary tract infections, prostatitis, anthrax, endocarditis, meningitis, pelvic inflammatory disease, traveler's diarrhea, tuberculosis, and bubonic plague. For the prototypical member of this antibiotic class, See *Ciprofloxacin*

### Levomilnacipran

This FDA-approved antidepressant (FW = 246.35 g/mol; CAS 96847-55-1; Symbol: LVM), also known by its code name F2695, its proprietary name Fetzima<sup>®</sup>, and (1*S*,2*R*)-2-(aminomethyl)-*N,N*-diethyl-1-phenylcyclopropanecarboxamide, is the more active enantiomer of milnacipran, displaying therefore similar pharmacological action as a serotonin-norepinephrine reuptake inhibitor (See *Milnacipran*). LVM exhibits high affinity for human norepinephrine transporter ( $K_i$  = 92.2 nM), 5-HT

transporter ( $K_i = 11.2$  nM), and potently inhibited norepinephrine ( $IC_{50} = 10.5$  nM) and 5-HT ( $IC_{50} = 19.0$  nM) reuptake (human transporter) *in vitro*. LVM had 2-fold greater potency for norepinephrine relative to serotonin reuptake inhibition (i.e. NE/5-HT potency ratio: 0.6) and 17 and 27 times higher selectivity for NE reuptake inhibition compared with venlafaxine and duloxetine, respectively. LVM exhibit inconsequential affinity for 23 off-target receptors. 1. Auclair, Martel, Assié, *et al.* (2013) *Neuropharmacol.* **70**, 338. 2. Citrome (2013) *Int. J. Clin. Pract.* **67**, 1089. 3. Saraceni, Venci & Gandhi (2013) *J. Pharm. Pract.* **27**, 389.

### Levonorgestrel

This orally available second-generation synthetic progestogen and emergency contraceptive, *or* ECP (FW = 312.45 g/mol; CAS 797-63-7; IUPAC: (-)-13-ethyl-17-ethynyl-17-hydroxy-1,2,6,7,8,9,10,11,12,13,14,15,16,17-tetradecahydrocyclopenta[*a*]phenanthren-3-one) is an active ingredient in several contraceptives (including combined oral contraceptive pills, progestogen-only pills, intrauterine devices and as contraceptive implants) as well as in hormone-replacement therapy. Levonorgestrel's action as an emergency contraceptive is mainly by preventing ovulation or fertilization by altering tubal transport of sperm and/or egg. It may also inhibit implantation by altering the endometrium. Efficacy is higher if taken as soon as possible after unprotected intercourse. Moreover, levonorgestrel can be used at any time during the menstrual cycle. Levonorgestrel is ineffective after implantation has commenced. **Pharmacokinetics:** *Absorption:* After administration of a single dose of Plan B (0.75 mg) under fasting conditions, maximum serum concentrations of levonorgestrel are  $14.1 \pm 7.7$  ng/mL for an average of  $1.6 \pm 0.7$  hours. *Distribution:* Serum levonorgestrel is primarily protein bound, with ~50% bound to albumin and 47.5% bound to Sex Hormone Binding Globulin (*or* SHBG). *Metabolism:* Following a single oral dosage, levonorgestrel does not appear to be extensively metabolized by the liver. The primary metabolites are 3 $\alpha$ ,5 $\beta$ - and 3 $\alpha$ ,5 $\alpha$ -tetrahydrolevonorgestrel, with 16 $\beta$ -hydroxynorgestrel also identified. Together, they account for less than 10% of parent plasma levels. Urinary metabolites are hydroxylated at the 2 $\alpha$ - and 16 $\beta$ -positions. Small amounts of these metabolites undergo sulfation and glucuronidation. *Excretion:* The elimination half-life of levonorgestrel following single dose administration as Plan B (0.75 mg) is  $24.4 \pm 5.3$  hours. **See also Mifepristone and Ulipristal acetate** 1. Brand Names of Levonorgestrel-Only ECPs: Escapelle<sup>®</sup>, Plan B<sup>®</sup>, Levonelle<sup>®</sup>, Glanique<sup>®</sup>, NorLevo<sup>®</sup>, Postinor-2<sup>®</sup>, i-Pill<sup>®</sup>, Next Choice<sup>®</sup>, and 72-HOURS<sup>®</sup>.

### Levulinate (Levulinic Acid)

This photosensitive  $\gamma$ -keto acid (FW = 116.12 g/mol; Soluble in water and ethanol; M.P. = 33-35°C), also known as 4-ketopentanoic acid and 4-oxopentanoic acid, which is produced by boiling starch or cellulose in aqueous HCl, inhibits porphobilinogen synthase by forming a Schiff base with the  $\epsilon$ -amino groups of an active-site lysyl residue. **Target(s):**  $\gamma$ -butyrobetaine dioxygenase, *or*  $\gamma$ -butyrobetaine hydroxylase,  $K_i = 13$  mM (1); porphobilinogen synthase, *or*  $\delta$ -aminolevulinatase synthase (2-10); procollagen-proline 3-dioxygenase (11). 1. Ng, Hanauske-Abel & England (1991) *J. Biol. Chem.* **266**, 1526. 2. Shemin (1970) *Meth. Enzymol.* **17A**, 205. 3. Erskine, Newbold, Brindley, *et al.* (2001) *J. Mol. Biol.* **312**, 133. 4. **LGD1069, See Bexarotene**

### LGK-974

This potent and specific PORCN inhibitor (FW = 396.44 g/mol; CAS 1243244-14-5; Solubility: <1 mg/mL DMSO, Ethanol, H<sub>2</sub>O), also known 2',3-dimethyl-N-[5-(2-pyrazinyl)-2-pyridinyl]-[2,4'-bipyridine]-5-acetamide, targets Wnt signaling with  $IC_{50}$  of 0.4 nM. LGK974 is potent and efficacious in multiple tumor models at well-tolerated doses *in vivo*, including murine and rat mechanistic breast cancer models driven by MMTV-Wnt1 and a human head and neck squamous cell carcinoma model (1,2). Mutational inactivation of RNF43 in pancreatic adenocarcinoma confers Wnt dependency. 1. Liu J, *et al.* (2013) *Proc. Natl. Acad. Sci. U.S.A.* **110**, 20224. 2. Jiang X, *et al.* (2013) *Proc. Natl. Acad. Sci. U.S.A.* **110**, 12649.

### Lidocaine

This rapid-acting local anesthetic (FW<sub>free-base</sub> = 234.34 g/mol; CAS 137-58-6; M.P. = 68-69°C; water-insoluble; Systematic Name: 2-(diethylamino)-N-(2,6-dimethylphenyl)acetamide; HCl monohydrate (FW<sub>HCl-H2O</sub> = 288.81 g/mol; CAS 6108-05-0), highly water-soluble;  $pK_a = 7.8$ ), also known by the trade names Xylocaine<sup>®</sup>, Recticare<sup>®</sup>, Lidoderm<sup>®</sup>, Solarcaine<sup>®</sup>, and Lmx4<sup>®</sup>, is a membrane-stabilizing agent and Na<sup>+</sup> channel blocker. Lidocaine finds broad utility in spinal anesthesia, intravenous regional anesthesia, surface anesthesia, emergency treatment of ventricular arrhythmias, and as a peripheral nerve block. In the heart, lidocaine reduces Phase-4 depolarization and automaticity. Lidocaine patches relieve the pain of post-herpetic neuralgia associated with shingles. **Primary Mode of Action:** Lidocaine stabilizes neuronal membranes by inhibiting the sodium ion fluxes needed to initiate nerve impulses, resulting in local anesthetic action. Most local anesthetics are hydrophobic and access the cytoplasmic-face of the sodium channel by diffusing through the peripheral membrane, thereby diminishing the excitability of all neurons, not just sensory neurons. The membrane-impermeant lidocaine derivative QX-314, however, relies on the TRPV1 (transient receptor potential vanilloid type-1) channel, to target primary sensory nociceptor neurons selectively, thereby eliciting its pain-specific local anesthetic effect on sodium channels (1) Moreover, capsaicin activates TRPV1, allowing more QX-314 (lidocaine) to enter primary sensory nociceptor neurons, thereby synergizing lidocaine anesthesia. Lidocaine also induces ROCK-dependent membrane blebbing and subsequent cell death in rabbit articular chondrocytes (2). **Target(s):** acetylcholinesterase (3); actomyosin motility (4); Ca<sup>2+</sup>-dependent cyclic-nucleotide phosphodiesterase (5); histamine *N*-methyltransferase (6); 15-hydroxyprostaglandin dehydrogenase (7); kinesin (8); M<sub>3</sub> muscarinic acetylcholine receptors (9); Na<sup>+</sup> channels (10-12); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase, weakly inhibited (13); protein-tyrosine kinase (14); sterol acyltransferase, *or* cholesterol acyltransferase, *or* ACAT (15-17). 1. ### LIMKi 3

This potent LIMK inhibitor (FW = 431.29 g/mol; CAS Registry Number = 1338247-35-0; Solubility: 100 mM in DMSO), also named BMS 5 and N-[5-[1-(2,6-dichlorophenyl)-3-(difluoromethyl)-1H-pyrazol-5-yl]-2-thiazolyl]-2-methylpropanamide, targets LIM kinases LIMK1 (IC<sub>50</sub> = 7 nM) and LIMK2 (IC<sub>50</sub> = 8 nM), inhibiting phosphorylation of ADF/cofilin in MDA-MB-231 breast cancer cells and reducing MDA-MB-231 tumor cell invasion in a 3D matrigel invasion assay (1-3). LIMK1 and LIMK2 regulate the actin cytoskeleton by phosphorylating (and thereby inactivating) the cofilin family of actin-depolymerizing factors. LIMK1 also acts to destabilize microtubules and regulates cell motility, including tumor metastasis. **1**. Ross-Macdonald, de Silva, Guo, *et al.* (2008) *Mol. Cancer Ther.* **7**, 3490. **2**. ### Linaclotide

This oral tetradecapeptide drug (FW = 1526.74 g/mol; CAS 851199-59-2), also known by the trade names Linzess<sup>®</sup> and Constella<sup>®</sup>, activates guanylate cyclase-C (GC-C) receptors on the luminal membrane surface to increase chloride and bicarbonate secretions into the intestine and to inhibit sodium ion absorption (1). By increasing the secretion of water into the lumen and improving defecation, linaclotide is an FDA-approved drug for the treatment of constipation-predominant irritable bowel syndrome (IBS-C) as well as chronic constipation. Linaclotide is minimally absorbed into systemic circulation. In mice, linaclotide inhibits colonic nociceptors with greater efficacy during chronic visceral hypersensitivity (2). Intra-colonic administration of linaclotide reduces signaling of noxious colorectal distention to the spinal cord. The colonic mucosa, but not neurons, expresses linaclotide's target, GC-C, and the latter's downstream effector cGMP is released after administration of linaclotide and also inhibited nociceptors. The linaclotide effects are lost in Gucy2c<sup>-/-</sup> knock-out mice and is likewise prevented by inhibiting cGMP transporters or removing the mucosa (2). **1**. Lee & Wald (2011) *Expert Opin. Drug Metab. Toxicol.* **7**, 651. **2**. Castro, Harrington, Hughes, *et al.* (2013) *Gastroenterology*. **145**, 1334.

### Linezolid

This orally available 1,3-oxazolidinone-containing antibiotic (FW = 337.35 g/mol; CAS 165800-03-3), also known by the trade names Zyvox<sup>®</sup> (U.S., UK, Australia), Zyvoxid<sup>®</sup> (Europe), and Zyvoxam<sup>®</sup> (Canada & Mexico), Linospan<sup>®</sup> (India) and Arlin<sup>®</sup> (Bangladesh) as well as by its systematic name (S)-N-({3-[3-fluoro-4-(morpholin-4-yl)phenyl]-2-oxo-1,3-oxazolidin-5-yl}methyl)acetamide, targets translation at its initiation stage, most likely by preventing the formation of the initiation complex (1-3). Linezolid is active against most disease-causing Gram-positive bacteria, including

vancomycin-resistant enterococci (VRE) and methicillin-resistant *Staphylococcus aureus* (MRSA). Due to its unique mechanism of action, cross-resistance between linezolid and other protein synthesis inhibitors is highly infrequent or nonexistent. **Mode of Antibiotic Action:** Initiation of protein synthesis requires the simultaneous presence of N-formylmethionyl-tRNA, 30S ribosome subunit, mRNA, GTP, and initiation factors IF1, IF2, and IF3. By binding at the 23S portion of the 50S subunit (near sites for chloramphenicol and lincomycin), linezolid distorts the local structure, preventing formation of the initiation complex from 30S and 50S units, tRNA, and mRNA. Linezolid does not inhibit the independent binding of either mRNA or N-formylmethionyl-tRNA to *E. coli* 30S ribosomal subunits, nor does it prevent the formation of the IF2-N-formylmethionyl-tRNA binary complex (3). Oxazolidinone antibiotics therefore inhibit the formation of the initiation complex in bacterial translation systems by preventing formation of N-formylmethionyl-tRNA-Ribosome-mRNA ternary complex (3). Linezolid is also a potent inhibitor of cell-free transcription-translation in *E. coli* (IC<sub>50</sub> = 1.8 μM). (See also *Tedizolid*) In view of structural similarities between bacterial and mitochondrial ribosomes, linezolid is apt to inhibit vital cellular processes that may account for neuropathies noted with long-term linezolid therapy. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1**. Spangler, Jacobs & Appelbaum (1996) *Antimicrob. Agents Chemother.* **40**, 481. **2**. Brickner, Hutchinson, Barbachyn, *et al.* (1996) *J. Med. Chem.* **39**, 673. **3**. Swaney, Aoki, Ganoza & Shinabarger (1998) *Antimicrob. Agents Chemother.* **42**, 3251.

### Lincomycin

This antibiotic (FW = 406.54 g/mol), produced by *Streptomyces lincolnensis*, inhibits protein biosynthesis in Gram-positive microorganisms, but is less effective against Gram-negative bacteria. Lincomycin belongs to a class of antibiotics that inhibits the binding of sRNA to the ribosome-messenger complex. In view of its adverse effects and toxicity, lincomycin is now rarely used in the clinic. **Target(s):** peptidyltransferase (1-6); peptidyl-tRNA hydrolase, or aminoacyl-tRNA hydrolase (7); protein biosynthesis, initiation and elongation (1-4,8-12). **1**. ### Lindane

This toxic pesticide and carcinogen (FW = 290.83 g/mol; M.P. = 112.5°C), also known as (1α,2α,3β,4α,5α,6β)-1,2,3,4,5,6-hexachlorocyclohexane, is an inhibitor of the γ-aminobutyrate receptor/chloride ionophore complex. Its resistance to hydrolysis accounts for its long biological half-life and the considerable concerns about ground water contamination. Another hazardous feature is the propensity of lindane to concentrate within

membranes and fat depots. **Target(s):**  $\gamma$ -aminobutyrate receptor/chloride ionophore complex (1,2);  $\alpha$ -amylase (3,4);  $\text{Ca}^{2+}$ -transporting ATPase (5); CDP-diacylglycerol:inositol 3-phosphatidyl-transferase, inhibited by several hexachlorocyclohexane stereoisomers (6-8); gap junction formation (9). 1. #### Linoleate (Linoleic Acid)

This all-*cis* unsaturated fatty acid ( $\text{FW}_{\text{free-acid}} = 280.45$  g/mol; M.P. =  $-12^\circ\text{C}$ ), also known as (Z,Z)-9,12-octadecadienoic acid, is a nutritionally essential fatty acid in mammals. It is commonly found esterified to glycerol and in many vegetable oils. **Target(s):** 2-acylglycerol *O*-acyltransferase, or monoacylglycerol *O*-acyltransferase (20); alcohol *O*-acyltransferase (18,19); chondroitin AC lyase (1); chondroitin B lyase (1); chymase (2,3); cyclooxygenase (4); DNA-directed DNA polymerase (5,6); DNA polymerases  $\alpha$ ,  $\gamma$ ,  $\delta$ , and  $\epsilon$  (5,6); DNA topoisomerase II (6); 1,3- $\beta$ -glucan synthase (7); hexokinase (8); hyaluronate lyase (1); leukocyte elastase (9); microbial collagenase (9);  $\text{NAD}^+$  ADP-ribosyltransferase, or poly(ADP-ribose) polymerase (10); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (11); peroxidase (23); phospholipid-hydroperoxide glutathione peroxidase (22); photophosphorylation, chloroplast (uncoupler) (12); photosystem II (13); platelet-derived growth factor receptor protein-tyrosine kinase (14); prostaglandin  $\text{D}_2$  dehydrogenase (15); prostaglandin D synthetase (15); prostaglandin-endoperoxide synthase, cyclooxygenase (21); protein-tyrosine kinase (14); sphingomyelin phosphodiesterase (16); steroid  $5\alpha$ -reductase (17). 1. #### Linolenate (Linolenic Acid)

This all-*cis* unsaturated fatty acid ( $\text{FW}_{\text{free-acid}} = 278.44$  g/mol; M.P. =  $-14.5^\circ\text{C}$ ), also known as (Z,Z,Z)-9,12,15-octadecadienoic acid and  $\alpha$  linolenic acid, is a nutritionally essential fatty acid in mammals. Linolenate is commonly found esterified to glycerol and in many vegetable oils.

**Target(s):** 2-acylglycerol *O*-acyltransferase, or monoacylglycerol *O*-acyltransferase (20); alcohol *O*-acyltransferase (18,19); chondroitin AC lyase (1); chondroitin B lyase (1); chymase (2,3); cyclooxygenase (4); DNA-directed DNA polymerase (5,6); DNA polymerases  $\alpha$ ,  $\gamma$ ,  $\delta$ , and  $\epsilon$  (5,6); DNA topoisomerase II (6); 1,3- $\beta$ -glucan synthase (7); hexokinase (8); hyaluronate lyase (1); leukocyte elastase (9); microbial collagenase (9);  $\text{NAD}^+$  ADP-ribosyltransferase, or poly(ADP-ribose) polymerase (10); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (11); peroxidase (23); phospholipid-hydroperoxide glutathione peroxidase (22); photophosphorylation, chloroplast (uncoupler) (12); photosystem II (13); platelet-derived growth factor receptor protein-tyrosine kinase (14); prostaglandin  $\text{D}_2$  dehydrogenase (15); prostaglandin D synthetase (15); prostaglandin-endoperoxide synthase, cyclooxygenase (21); protein-tyrosine kinase (14); sphingomyelin phosphodiesterase (16); steroid  $5\alpha$ -reductase (17). 1. #### (6,9,12)-Linolenate ((6,9,12)-Linolenic Acid)

This all-*cis* unsaturated fatty acid ( $\text{FW}_{\text{free-acid}} = 278.44$  g/mol), also known as (Z,Z,Z)-6,9,12-octadecadienoic acid and  $\gamma$ -linolenic acid, is a component of plants fatty esters, such as the evening primrose (*Oenothera* sp.), black current oil, and borage oil. It is a precursor in the biosynthesis of arachidonate. **Target(s):** carnitine *O*-palmitoyltransferase (1); DNA-directed DNA polymerase (2); DNA polymerase  $\alpha$  (2); leukocyte elastase (3);  $\text{NAD}^+$  ADP-ribosyltransferase, or poly(ADP-ribose) polymerase (4); steroid  $5\alpha$ -reductase (5). 1. ### Linuron

This urea derivative (FW = 249.10 g/mol; CAS 330-55-2), also known as Lorox<sup>®</sup> and *N*'-(3,4-dichlorophenyl)-*N*-methoxy-*N*-methylurea, is a selective pre- and post-emergence herbicide, targeting photosynthesis and photosynthetic electron transport. Linuron is used to control a wide variety of annual and perennial broadleaf and grassy weeds on both crop and noncrop sites. Linuron is also an anti-androgenic agent that produces reproductive malformations in male rats. 1. Hulsen, Minne, Lootens, Vandecasteele & Hofte (2002) *Environ. Microbiol.* **4**, 327. 2. Maier-Bode & Hartel (1981) *Residue Rev.* **77**, 1. 3. Dodge (1977) *Spec. Publ., Chem. Soc.* **29**, 7.

### Lipiamycins

Consisting of a complex mixture of lipiamycins A<sub>3</sub> and A<sub>4</sub> and two minor components, these antibiotics (FW<sub>Lipiamycin-A<sub>3</sub></sub> = 1060.06 g/mol (CAS 56645-60-4); FW<sub>Lipiamycin-A<sub>4</sub></sub> = 1046.04 g/mol; FW<sub>Lipiamycin-B<sub>3</sub></sub> = 1060.06 g/mol;

FW<sub>Lipiamycin-B<sub>4</sub></sub> = 1034.02 g/mol) amusingly draw their name from an *Actinoplanes* strain isolated on the leap year date, February 29, 1972. The B series of lipiamycins were isolated from *Actinoplanes deccanensis*. Note that clostomicins B<sub>1</sub> and B<sub>2</sub> of *Micromonospora echinospora* correspond to lipiamycins A<sub>3</sub> and B<sub>3</sub>, respectively. **Target(s):** DNA-directed RNA polymerase (1-8). 1. Chamberlin & Ryan (1982) *The Enzymes*, 3rd ed., **15**, 87. 2. Osburne & Sonenshein (1980) *J. Virol.* **33**, 945. 3. Sergio, Pirali, White & Parenti (1975) *J. Antibiot.* **28**, 543. 4. ### α-Lipoate (α-Lipoic Acid)

This acyl-transfer and redox coenzyme (FW<sub>free-acid</sub> = 206.33 g/mol; CAS 62-46-4), also known as 6-thioctic acid and (*R*)-1,2-dithiolane-3-pentanoic acid, has a melting point of 46-48°C and a pK<sub>a</sub> of 4.76 at 25°C. contains two sulfhydryl groups that form a dithiolane ring in the oxidized (disulfide) form. The redox potential at pH 7 is -0.29 volts. Lipoic acid is attached to the ε-amino group of lysyl residues of transacetylases (subunits of α-ketoacid dehydrogenase complexes; *i.e.*, the dihydrolipoyl acyltransferase subunit), thereby permitting acyl transfer as a swinging arm akin to that of carboxybiocytin. Note that free lipoate will not act as a substrate for the E<sub>1</sub> component (*i.e.*, α-keto acid decarboxylase) of the α-ketoacid dehydrogenase complexes. (See also Dihydrolipoate and Dihydrolipoic Acid) **Target(s):** acetyl-CoA hydrolase (1); choline *O*-acetyltransferase (2); dihydrolipoamide acetyltransferase (3); dihydrolipoamide dehydrogenase (3); glucose-6-phosphate dehydrogenase, moderately inhibited (4); glutamate dehydrogenase (5); glyceraldehyde-3-phosphate dehydrogenase, moderately inhibited (4); glycogen phosphorylase *b* (6); HIV-1 replication (7); (*S*)-2-hydroxy-acid oxidase (8); isocitrate dehydrogenase, moderately inhibited (4); lactate dehydrogenase, moderately inhibited (4); luciferase, firefly (*Photinus-luciferin* 4-monooxygenase (ATP-hydrolyzing), *K<sub>i</sub>* = 0.026 μM (17); malate dehydrogenase (4,9); NADPH:cytochrome P450 reductase (10); 6-phosphogluconate dehydrogenase, moderately inhibited (4); poly(ADP-ribose) synthetase (11); proline racemase (12,13); pyruvate dehydrogenase (acetyl-transferring) complex (3); [pyruvate dehydrogenase (acetyl-transferring)] kinase (14); thiosulfate sulfur transferase, *or* rhodanese (15-16).). 1. ### Lipstatin

This potent lipase irreversible pancreatic lipase inhibitor (FW = 505.74 g/mol; CAS 96829-59-3), also known as [(2*S*,4*E*,7*E*)-1-(3-hexyl-4-

oxooxetan-2-yl)trideca-4,7-dien-2-yl](2*S*)-2-formamido-3-methylpentanoate, a natural product from the actinobacterium, *Streptomyces toxytricin* (1). Lipstatin contains a reactive small-ring  $\beta$ -lactone structure that probably accounts for the irreversible inhibition of pancreatic lipase ( $IC_{50} = 0.14 \mu\text{M}$ ). In mice, triolein absorption is dose-dependently inhibited by lipstatin, whereas oleic acid is absorbed normally. Other pancreatic enzymes, such as phospholipase  $A_2$  and trypsin, are not inhibited, even at an inhibitor concentration of  $200 \mu\text{M}$  (1). Lipstatin is closely related structurally to the known esterase inhibitor, esterastin; the former contains a *N*-formyl-L-leucine side-chain and the latter an *N*-acetyl-L-asparagine side-chain (2). (See also *Orlistatin*) 1. Weibel, Hadvary, Hochuli, Kupfer & Lengsfeld (1987) *J. Antibiot.* (Tokyo). **40**, 1081. 2. Hochuli, Kupfer, Maurer, et al. (1987) *J. Antibiot.* (Tokyo). **40**, 1086.

### Liraglutide

This long-acting, intravenously administered GLP-1 Receptor agonist and Type-2 Diabetes drug (FW = 3751.20 g/mol; CAS 204656-20-2; Sequence: HAEGTFTSDVSSYLEGQAAK( $\gamma$ -E-palmitoyl)EPIAWLV-RGRG), which is marketed under the trade names Saxenda<sup>®</sup> and Victoza<sup>®</sup>, binds in place of the Glucagon-Like Peptide-1 (Sequence: HAEGTFTSDVSSYLEGQAAKEPIAWLVKGRG), the endogenous metabolic hormone that stimulates insulin secretion. By 12 hours, liraglutide begins to reduce fasting as well as meal-related glycemia by modifying insulin secretion, delaying gastric emptying, and suppressing prandial glucagon secretion. Liraglutide does so by activating the pancreatic  $\beta$ -cell GLP-1 receptor, the latter a G-protein-coupled receptor that increases intracellular 3',5'-cyclicAMP, thereby stimulating insulin release in the presence of elevated glucose (1,2). Experiments carried out both *in vitro* and in animals demonstrate that GLP-1 increases  $\beta$ -cell mass by stimulating islet cell neogenesis, while inhibiting islet apoptosis. Liraglutide has an 11-15 hour half-life upon subcutaneous injection, compared to 30 min for naturally occurring GLP-1. Liraglutide reduces body weight and food intake in obese candy-fed rats, whereas a dipeptidyl peptidase-IV inhibitor, vildagliptin, does not (2). In studies on primary neonatal rat islets, liraglutide inhibits both cytokine- and free fatty acid-induced apoptosis in a dose-dependent manner (3). This anti-apoptotic effect was mediated by the GLP-1 receptor, inasmuch as the specific GLP-1 receptor antagonist, exendin, blocks liraglutide's effect. The adenylate cyclase activator, forskolin, exerts a similar anti-apoptotic effect, indicating that liraglutide's effect is cAMP-mediated. Liraglutide's actions are inhibited by locking the PI3 kinase pathway with wortmannin, whereas inhibition of MAP kinase pathways by PD98059 is without effect. 1. ### Lisinopril

This antihypertensive agent (FW = 405.50 g/mol; CAS 83915-83-7), also known as Prinivil<sup>®</sup> and *N*<sup>ε</sup>-[(*S*)-1-carboxy-3-phenylpropyl]-L-lysyl-L-proline, is an orally active inhibitor of human angiotensin I-converting enzyme ( $IC_{50} = 4.7 \text{ nM}$ ) (1-17). Lisinopril treatment increases expression of eNOS, SK<sub>Ca</sub> and BK(Ca) proteins (18). In small mesenteric arteries, SK<sub>Ca</sub> and IK<sub>Ca</sub> channels play a predominant role in ACh mediated-relaxation compared to NO. Lisinopril treatment increased expression of eNOS, SK<sub>Ca</sub>, BK<sub>Ca</sub> channel protein and increased the contribution of NO to ACh-mediated relaxation (18). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** lysine carboxypeptidase, or lysine(arginine) carboxy-peptidase, or carboxypeptidase N (19); Xaa-Trp aminopeptidase, or aminopeptidase W (20). 1. ### Listeriolysin O

This thiol-activated, four-domain, pore-forming hemolysin (MW = 56-kDa; CAS 72270-41-8) is a toxic virulence factor produced by *Listeria monocytogenes*, the intracellular pathogen primarily responsible for listeriosis, a serious infection often caused by eating deli food contaminated with the *Listeria* bacterium. This disease primarily affects those with attenuated immunity, e.g., older adults, pregnant women, newborns, and adults with HIV-AIDS (1). Bacteremia, meningitis, and rhabdomyolysis are more serious manifestations of listeriosis. Listeriolysin O binds to cholesterol-rich membranes, assembling into pore-forming aggregates that create 10-20-nm interior holes (2-5). Similarly acting thiol-activated toxins include Streptolysin O, Alveolysin, and Theta toxin. **Role in Listeria Pathogenesis:** Upon phagocytosis of *Listeria* bacteria by a nonprofessional phagocyte, the latter's phagosome fuses with a lysosome to form a phagolysosome. Acidification of that compartment to pH ~5.5 initiates what will prove to be a futile attempt to initiate bacterial lysis. Paradoxically, that same pH change activates listeriolysin O (optimally active at pH 5.5-5.6), which undergoes a conformational change that potentiates its pore-forming and membrane-fragmenting power. The latter action destroys the phagolysosome, freeing the pathogen, which takes up residence within the cytoplasm, where it thrives and multiplies. *L. monocytogenes* eventually deploys its ActA surface protein to initiate actin-based *Listeria* motility, thereby promoting the pathogen's cell-to-cell spread before the host protein inevitably undergoes listeriolysin-induced autophagy, apoptosis and destruction (1). 1. ### Lithium Ion

This monovalent ion of the smallest Group 1 (or Group IA) element (Symbol = Li; Atomic Weight = 6.941) is itself so small (Ionic Radius = 0.68 Å, with refined estimates of 0.60 and 0.79 Å for four- and six-coordinate complexes) that its inner coordination sphere is very crowded, often containing as few as 3.6 water molecules in the first coordination sphere. Located directly above sodium in the Periodic Table, lithium is an alkali metal that readily oxidizes to Li<sup>+</sup>, which inhibits a range of biochemical processes, often by competing favorably with K<sup>+</sup> and Na<sup>+</sup> for monovalent cation sites within proteins, nucleic acids, and charged polysaccharides (1). **Clinical Aspects:** Marketed as Eskalith<sup>®</sup> and Lithobid<sup>®</sup>, lithium carbonate (FW = 73.89 g/mol; CAS 554-13-2) is widely used to treat bipolar disorder. This mood stabilizer influences behavior and Akt/GSK-3 signaling in mice and many antipsychotics have been shown to more potently antagonize the activity of the  $\beta$ -arrestin-2 pathway relative to the G protein-dependent pathway. It reduces the severity and frequency of mania and is often prescribed in combination with mildly anti-psychotic agents. In the context of mood disorders and neurodegenerative diseases, lithium ion is thought to target inositol monophosphatase in the phosphatidylinositol signalling pathway as well as the protein kinase glycogen synthase kinase-3 (2). Neuroprotection is the most likely outcome of lithium treatment in both preclinical and clinical models of bipolar disorder. Based on comprehensive reviews and meta-analysis of patient records and randomized clinical trials, McKnight et al. (3) report that patients taking lithium have a slightly reduced glomerular filtration rate, a slightly higher risk of renal failure, a tendency toward clinical

hypothyroidism, slightly increased blood calcium and parathyroid hormone, as well as greater weight gain. Other studies show a slight increase in suicide risk. Lithium ion is also a suspected teratogen (4). **Nonspecific Inhibition of Glycogen Synthase Kinase:** LiCl is an ATP noncompetitive inhibitor of GSK-3 $\beta$  activity ( $K_i \approx 2$  mM), and, although its has been commonly used to investigate the effects of GSK-3 $\beta$  inhibition, it is notoriously nonspecific and is unlikely to produce results strictly attributable to GSK inhibition. One should instead consider the use of SB415286, a far more potent inhibitor that is highly specific for GSK-3 $\beta$  (5). Other ways to inhibit cellular GSK-3 activity include antisense targeting of GSK-3 and overexpression of a dominant negative form of the kinase. **Removal from Commercial Nucleotides & Coenzymes:** By binding tightly to the phosphates of ATP, GTP and many other metabolites, lithium ions help to stabilize these molecules against hydrolysis, thus facilitating long-term storage. Nonetheless, 1 mM lithium salt of ATP contains 4 mM lithium ion, leading to the possibility that this monovalent ion will be a confounding variable in enzyme assays or metabolic experiments. To avoid such ambiguity, a good practice is to acidify commercial lithium salts by the addition of dilute acetic acid to pH 5 (thereby weakening lithium ion binding by protonating the phosphates), followed by passage over a small Dowex-50 column that has been previously equilibrated with sodium or potassium ion and thoroughly washed with deionized water. (*Best Source Recommendation:* AG<sup>®</sup> 50W and AG<sup>®</sup> MP-50 Cation Exchange Resins). Because ion exchange kinetics is rapid, this procedure can be conveniently accomplished by use of a Centricon Plus-20 PLGC centrifuge-tube filter. **Lithium Effect on Circadian Rhythm:** Lithium also appears to exert a novel amplitude-enhancing effect on the PER2 protein rhythms in the central and peripheral circadian clockwork, an action that may involve the glycogen synthase kinase-3-mediated signalling pathway (6). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** Lithium has many metabolic effects, inhibiting glucose synthesis in the liver, in part through effects on gene expression (7). Also inhibited are glycogen synthase kinase-3, or Tau kinase (8) and myo-inositol-1-phosphatase, the latter showing uncompetitive inhibition (9). When viewed in the context of the phosphatidylinositol cycle, lithium blocks conversion of inositol-1-phosphate (IP<sub>1</sub>) to myoinositol, resulting in the accumulation of inositol monophosphates and depletion of myoinositol, reducing PIP<sub>2</sub> as well as its cleavage products, IP<sub>3</sub> and DAG. Lithium is also a mixed-type noncompetitive inhibitor of sodium ion/dicarboxylate-1 (NaDC-1), an electrogenic anion transporter accepting either Na<sup>+</sup> or Li<sup>+</sup> as coupling cations (10). NaDC-1 possesses a single high-affinity binding site for Li<sup>+</sup> that, when occupied, inhibits dicarboxylate transport. In studies of fructose 1,6-bisphosphatase, Li<sup>+</sup> was found to be a linear noncompetitive inhibitor with respect to Mg<sup>2+</sup> (11). Li<sup>+</sup> is believed to inhibit FBPase, either by distorting the geometry of the active site or by retarding catalytic turnover or product release. 1. #### Lithocholate (Lithocholic Acid)

This steroid (FW<sub>free-acid</sub> = 376.58 g/mol; CAS 434-13-9; very low water-solubility and more soluble in diethyl ether), also known as (3 $\alpha$ ,5 $\beta$ )-3-hydroxycholan-24-oic acid, is one of the bile acids identified in human, bovine, rabbit, sheep, goat, and porcine bile. Lithocholate is typically found in the taurine or glycine conjugate. **Target(s):**  $\alpha$ -N-acetylglucosaminidase 2,3-sialyltransferase (1);  $\alpha$ -amylase (2); cAMP dependent protein kinase (3); carbonic anhydrase (4,5); choloyl-CoA synthetase, or cholate:CoA ligase (6,7); DNA polymerase  $\beta$  (8-10); DNA topoisomerase II (8); glutathione S-transferase (11-15); pepsin (16); steryl-sulfatase, or arylsulfatase C, mildly inhibited (17); threonine ammonia-lyase, or threonine dehydratase (18); UDP-glucuronosyltransferases (19). 1. #### Litronesib

This mitotic drug and cytostatic agent (FW = 511.70 g/mol; CAS 910634-41-2), also known as LY2523355, KF 89617 and its systematic name (*R*)-N-(5-((2-(ethylamino)ethylsulfonamido)methyl)-5-phenyl-4-pivaloyl-4,5-dihydro-1,3,4-thiadiazol-2-yl)pivalamide, targets kinesin Eg5, a mitotic motor protein that plays a key role in mitosis including chromosome positioning, separating the centrosome, and establishing a bipolar spindle in the M-phase of the cell cycle. Litronesib is an ATP-noncompetitive, allosteric, reversible inhibitor with no effect on microtubule formation. Litronesib has been investigated in clinical trials for the treatment of multiple cancers as well as collagen- and adjuvant-induced arthritis. Litronesib racemizes upon storage in aqueous solution, because its substituted 1,3,4-thiadiazoline ring forms a positively charged trigonal intermediate through a relay mechanism involving intramolecular deprotonation, attack of the resulting sulfonamide anion on C<sup>5</sup>, with cleavage of the C<sup>5</sup>-S bond to form an aziridine that suffers heterolytic dissociation to yield a reactive ylide (2). (*See also K858, Monastrol, Terpendole E, S-Trityl-L-cysteine*) 1. Wakui, Yamamoto, Kitazono, et al. (2014) *Cancer Chemother. Pharmacol.* 74, 15. 2. Baertschi, Jansen, Montgomery, et al. (2014) *J. Pharm. Sci.* 103, 2797.

#### Lividomycins

These 3'-deoxyaminoglycoside antibiotics (FW = 761.78 g/mol for lividomycin A (shown above)) are alternative substrate for a number of aminoglycoside-dependent enzyme (e.g., aminoglycoside 3' phosphotransferase III). **Target(s):** DNA-directed DNA polymerase, Klenow fragment (1); gentamicin 3'-N acetyltransferase, inhibited by lividomycin B,  $K_i = 2 \mu\text{M}$  (2); kanamycin 6'-acetyltransferase, inhibited by lividomycin A (3); poly(A)-specific ribonuclease (1). 1. Ren, Martinez, Kirsebom & Virtanen (2002) *RNA* **8**, 1393. 2. Williams & Northrop (1978) *J. Biol. Chem.* **253**, 5908. 3. Haas & Dowding (1975) *Meth. Enzymol.* **43**, 611.

**LJC10,627, See Biapenem**

#### LJH685

This potent pan-RSK inhibitor (FW = 381.43 g/mol; CAS 1627710-50-2; Solubility: 70 mg/mL DMSO; < 1 mg/mL H<sub>2</sub>O), also named 2,6-difluoro-4-[4-(4-methyl-1-piperazinyl)phenyl]-3-pyridinyl]phenol, targets p90 ribosomal S6 kinases RSK1 ( $IC_{50} = 6 \text{ nM}$ ), RSK2 ( $IC_{50} = 5 \text{ nM}$ ), and RSK3 ( $IC_{50} = 4 \text{ nM}$ ). Based on X-ray crystallography, the nonplanar shape of LJH685 and its conformational properties distinct from the currently available and commonly used inhibitor dihydropteridinone (BI-D1870) contribute to its significantly improved selectivity profile. LJH685 RSK inhibition correlates with antiproliferative effects in MAPK pathway-dependent cancer cell lines only in anchorage-independent growth setting. For further details on LJH685's inhibitory action and its morpholino analogue, **See LJ308**. 1. Aronchik, Appleton, Basham, *et al.* (2014) *Mol. Cancer Res.* **12**, 803.

#### LJI308

This potent pan-RSK inhibitor (FW = 368.38 g/mol; CAS 1627709-94-7; Solubility: 73 mg/mL DMSO; < 1 mg/mL H<sub>2</sub>O), also named 2,6-difluoro-4-[4-(4-morpholinyl)phenyl]-3-pyridinyl]phenol, targets p90 ribosomal S6 kinases RSK1 ( $IC_{50} = 6 \text{ nM}$ ), RSK2 ( $IC_{50} = 4 \text{ nM}$ ), and RSK3 ( $IC_{50} = 13 \text{ nM}$ ). The p90 ribosomal S6 kinase (RSK) comprises a family of four closely related proteins that are widely expressed in cancer cell lines and tissues and are activated in response to a number of growth factors and hormones. RSK kinases have a unique structure containing two nonidentical kinase domains, N-terminal and C-terminal, separated by a linker region. One physiologic RSK substrate is Y-box-binding protein 1 (YB1), which regulates transcription and translation by binding to its recognition motifs in both DNA and RNA to regulate key cell processes such as proliferation, motility, and stemness. Although phosphorylation of YB1 at Ser102 was well inhibited by LJH685 and LJI308, this did not closely correlate with widespread functional consequences. These results were surprising given that earlier work linked YB1 to important physiologic roles in cancer progression, including the expression of fibroblast growth factor receptor (FGFR), proliferating cell nuclear antigen (PCNA), MAP Kinase interacting serine/threonine kinase (MKNK1), and matrix metalloproteinase 2 (MMP2). Although earlier reports indicated that YB1 is critical for these widespread roles, results with LJH685 and LJI308 suggest that the importance of phosphorylation at Ser102 may be more nuanced. (**See also LJH685**) 1. Aronchik, Appleton, Basham, *et al.* (2014) *Mol. Cancer Res.* **12**, 803.

#### LLY-507

This potent methylation inhibitor (FW = 574.77 g/mol) targets the SMYD2, an enzyme that methylates histone H3 at Lysine-36,  $IC_{50} \sim 30 \text{ nM}$  (1). LLY-507 exhibits >100-fold selective for SMYD2 over a broad range of other methyltransferase and non-methyltransferase targets. The SMYD methylase family, consisting of SMYD1 through SMYD5, possess a distinctive SET domain that is split by a MYND domain. The SET domain is catalytic, and MYND domain is a zinc finger that facilitates binding to certain proline-rich sequences. SMYDs 1-5 also contain a C-terminal domain (CTD) that regulates histone methylation; and binding of Heat Shock Protein 90 (Hsp90) causes the CTD to swing out and fully expose the methylase active site. A 1.63 Å resolution crystal structure of a SMYD2·LLY-507 complex shows the inhibitor occupying the binding pocket for the substrate peptide (1). LLY-507 is active in cells, as measured by reduction of SMYD2-induced mono-methylation of p53 K370 at sub-micromolar doses (1). Mass spectrometry-based proteomics revealed that cellular global histone methylation levels are not significantly affected by SMYD2 inhibition with LLY-507, and subcellular fractionation studies indicate that SMYD2 is primarily cytoplasmic, suggesting SMYD2 targets a very small subset of histones at specific chromatin loci, and/or non-histone substrates (1). Unlike LLY-507, a previously disclosed SMYD2 inhibitor shows weak cellular activity (2). 1. Nguyen, Allali-Hassani, Antonysamy, *et al.* (2015) *J. Biol. Chem.* **290**, 13641. 2. Ferguson, Larsen, Howard, *et al.* (2011) *Structure* **19**, 1262.

#### LLY-2707

This novel non-steroidal glucocorticoid receptor antagonist (FW = 389.16 g/mol), named systematically as *N*-(5-(*tert*-butyl)-3-(2-fluoro-5-methylpyridin-4-yl)-2-methyl-1*H*-indol-7-yl)-methanesulfonamide, reduces weight gain in female rats treated with atypical antipsychotic drugs (or AAPDs), such as olanzapine (or Zyprexa®). In humans, clinically significant weight gain (~0.9 kg/month) results in a 6-10 kg body weight gain after one year on olanzapine (2), and LLY-2707 may represent a novel way for preventing weight gain and diabetes during AAPD treatment. (**See Olanzapine**) 1. Sindelar, Carson, Morin, *et al.* (2013) *J. Pharmacol. Exp. Ther.* **348**, 192. 2. Nemeroff (1997) *J. Clin. Psychiatry* **58** (Suppl 10) 45.

#### LM-10

This indole (FW = 229.22 g/mol; CAS 1316695-35-8), also named 6-fluoro-3-[(1*E*)-2-(2*H*-tetrazol-5-yl)ethenyl]-1*H*-indole, selectively inhibits tryptophan 2,3-dioxygenase (*Reaction*: L-tryptophan + O<sub>2</sub> ⇌ *N*-formyl-L-kynurenine), with respective IC<sub>50</sub> values of 0.62 and 2 μM for the human and mouse enzymes, and exhibiting lower action against IDO, MAO-A, MAO-B, and a panel of receptors and transporters. LM 10 educs growth of TDO-expressing P815 mastocytoma tumors in mice. **1.** Pilote, *et al.* (2012) *Proc. Natl. Acad. Sci. U.S.A.* **109**, 2497. **2.** Dolusić, *et al.* (2011) *J. Med. Chem.* **54**, 5320.

#### LN-1-255

This 6-alkylidene-2'-substituted penicillin sulfone (FW = 487.46 g/mol) targets Class C and Class A serine β-lactamases, thereby improving the antibiotic action of carbapenem antibiotics against otherwise resistant bacterial strains (1). By possessing a catecholic functionality resembling a natural bacterial siderophore, LN-1-255 is unique among β-lactamase inhibitors (2). In combination with LN-1-255, piperacillin is more potent against *Escherichia coli* DH10B strains bearing *bla*<sub>SHV</sub> extended-spectrum and inhibitor-resistant β-lactamases than an equivalent amount of tazobactam and piperacillin (2). LN-1-255 also significantly enhances the activity of ceftazidime and cefpirome against extended-spectrum cephalosporin- and Sme-1-containing carbapenem-resistant clinical strains (2). LN-1-255 inhibited SHV-1 and SHV-2 β-lactamases (K<sub>i</sub> = 110 nM and 100 nM, respectively). When LN-1-255 inactivates SHV β-lactamases, mass spectrometry reveals a single bicyclic aromatic intermediate that X-ray crystallography shows to have its carbonyl oxygen pointing out of the oxyanion hole and forming hydrogen bonds with Lys-234 and Ser-130 within the active site (2). (Covalent docking of LN-1-255 was applied between the catalytic Ser-81 (oxygen atom side chain) and the carboxylate group (oxygen atom) of the indolizine obtained after covalent modification of OXA-24/40 from *A. baumannii*.) LN-1-255 also inhibits OXA-48, the class D carbapenemase that presents unique challenges, inasmuch as it is resistant to most β-lactam inhibitors (3). Both OXA-48-producing clinical and transformant strains of *Klebsiella pneumoniae* and *Escherichia coli* display enhanced susceptibility to carbapenem antibiotics in the presence of 4 mg/L LN-1-255 (*i.e.*, 2-32x greater) and 16 mg/L LN-1-255 (*i.e.*, 4-64x greater). Kinetic measurements demonstrate that LN-1-255 inhibits OXA-48 with an acylation efficiency ( $k_2/K_m$ ) of  $10 \times 10^4 \text{ M}^{-1}\text{s}^{-1}$  and a slow deacylation rate  $k_{\text{off}}$  of  $7 \times 10^{-4} \text{ s}^{-1}$  (3). The IC<sub>50</sub> is 3 nM for LN-1-255, whereas an IC<sub>50</sub> of 1.5 μM is obtained for tazobactam, largely because  $k_{\text{cat}}/k_{\text{inact}}$  is 500x lower for LN-1-255 compared to tazobactam. Combined use of carbapenem antibiotics and LN-1-255 is highly effective against OXA-48, affording a promising route for circumventing antibiotic resistance (3). **See also** *Piperacillin; Tazobactam* **1.** Buynak, Rao, Doppalapudi, *et al.* (1999) *Bioorg. Med. Chem. Lett.* **9**, 1997. **2.** Pattanaik, Bethel, Hujer, *et al.* (2009) *J. Biol. Chem.* **284**, 945. **3.** Vallejo, Martínez-Gutián, Vázquez-Ucha, *et al.* (2016) **71**, 2171.

#### LOC14

This neuroprotective PDI modulator (FW = 316.41 g/mol; CAS 877963-94-5), also named 2-[[4-(cyclopropyl-carbonyl)-1-piperazinyl]methyl]-1,2-benzisothiazol-3(2*H*)-one, targets Protein Disulfide Isomerase (K<sub>d</sub> = 62 nM) by adopting an oxidized conformation and suppressing its activity. An endoplasmic reticulum enzyme in eukaryotes, PDI catalyzes the formation/breakage of disulfide bonds between cysteine residues within proteins as they fold. **1.** Kaplan, Gaschler, Dunn, *et al.* (2015) *Proc. Natl. Acad. Sci. USA* **112**, :E2245.

#### Lometrexol

This antifolate (FW = 443.65 g/mol; CAS 106400-81-1; Solubility: 5 mg/mL DMSO), also named *N*-[4-[2-[(6*R*)-2-amino-3,4,5,6,7,8-hexahydro-4-oxopyridin-2,3-d]pyrimidin-6-yl]ethyl]-benzoyl]-L-glutamate, 5,10-dideazatetrahydrofolate, and LY264618, targets glycylamide ribonucleotide formyltransferase (GARFTase *Reaction*: 10-Formyl-tetrahydrofolate + *N*<sup>1</sup>-(5-Phospho-D-ribosyl)glycinamide ⇌ Tetrahydrofolate + *N*<sup>2</sup>-Formyl-*N*<sup>1</sup>-(5-phospho-D-ribosyl)-glycinamide), a folate-requiring enzyme in *de novo* purine synthesis. Although a potent GARFTase inhibitor, lometrexol does not interfere with the enzymes involved in folate synthesis. Lometrexol has been evaluated clinically for the treatment of various cancers as an antifolate like agent, similar to methotrexate. Treatment of cells with lometrexol rapidly decreases ATP and GTP levels, resulting in cell cycle arrest and apoptosis. Although depletion of nucleotide pools induces p53 expression, lometrexol is cytotoxic in both wild type and mutant p53-expressing tumor cells. Lometrexol is cytotoxic in CCRF-Cem leukemia cells (IC<sub>50</sub> = 2.9 nM). **1.** Sessa, de Jong, D'Incalci, *et al.* (1996) *Clin. Cancer Res.* **2**, 1123.

#### Lomustine

This nitrosourea derivative (FW = 233.70 g/mol; CAS 13010-47-4), also known as 1-(2-chloroethyl)-3-cyclohexyl-1-nitrosourea (CCNU), is an alkylating reagent and exhibits antitumor activity in a manner resembling carmustine and nimustine. This nitrosourea undergoes hydrolysis *in vivo* to form reactive metabolites. With ability to cross the blood-brain barrier, lomustine is often used to treat brain tumors. (**For other mechanistic details, see Nitrosoureas**) CCNU is not detected in the plasma of patients, due to its complete conversion to monohydroxylated metabolites during the 'first pass' through liver and gut (1). Two monohydroxylated metabolites, *trans*-4-hydroxy CCNU and *cis*-4-hydroxy CCNU reach peak concentrations (0.8-0.9 μg/mL) within 2-4 hours. These metabolites are also detected in a tumor biopsy. Plasma clearance half-lives of the two metabolites are similar in each patient but showed a two-fold variation between patients, from 1.3-2.9 hours (1). **Target(s):** arylamine *N*-acetyltransferase (2); chymotrypsin, inhibited by metabolite of CCNU (3); CYP2D6, *or* dextromethorphan *O*-demethylase (4); DNA polymerase (5); esterase (6); glutathione-disulfide reductase (7); ribonucleotide reductase (7); thioredoxin reductase (7); transglutaminase, *or* protein-glutamine γ-glutamyltransferase (8); tyrosinase (9). **1.** Lee, Workman, Roberts & Bleeche (1985) *Cancer Chemother. **Lonafarnib**

This orally bioavailable farnesyltransferase inhibitor, or FTI (FW = 638.83 g/mol; CAS 193275-84-2; Solubility: 125 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named SCH66336 and 4-[2-[4-[(1*R*)-3,10-dibromo-8-chloro-6,11-dihydro-5*H*-benzo[5,6]cyclohepta[1,2-*b*]pyridin-11-yl]-1-piperidinyl]-2-oxoethyl]-1-piperidinecarboxamide, blocks farnesylation of H-ras (IC<sub>50</sub> = 1.9 nM), K-ras-4B (IC<sub>50</sub> = 5.2 nM) and N-ras (IC<sub>50</sub> = 2.8 nM), inhibiting anchorage-independent growth of many human tumor lines lacking an activated ras oncogene. In nude mouse xenograft models for human tumors of colon, lung, pancreas, prostate, and urinary bladder origin, SCH 66336 demonstrated potent oral activity (1). Enhanced *in vivo* efficacy is observed when combined with other cytotoxic agents, e.g., cyclophosphamide, 5-fluorouracil, and vincristine (1). Lonafarnib suppresses protein kinase B/Akt activity as well as the phosphorylation of the Akt substrates glycogen synthase kinase (GSK)-3β, forkhead transcription factor, and BAD (2). Infection of SqCC/Y1 cells with an adenovirus that contained a constitutively active form of Akt rescued cells from lonafarnib-induced apoptosis, suggesting it is a potent apoptosis inducer in HNSCC cells that acts by suppressing the Akt pathway. Lonafarnib treatment of tumor cells *in vitro* is proapoptotic under certain cell culture conditions, and induction of apoptosis generally requires a second death-promoting signal. At achievable clinical concentration ranges, lonafarnib effectively inhibits the growth of ten different non-small-cell lung cancer (NSCLC) cell lines, particularly after a prolonged treatment, regardless of Ras mutational status (3). Lonafarnib arrested cells growth at G<sub>1</sub> or G<sub>2</sub>M phase in the majority tested cell lines, but it also induced apoptosis when cells were cultured in a low serum (0.1%) medium. The majority of NSCLC cell lines expressed undetectable level of phosphorylated Akt (p-Akt). Lonafarnib at up to 10 μM did not decrease either total Akt or p-Akt levels in tested cell lines, even after a 48-hour treatment (3). It even increased p-Akt level in one cell line, although it was as sensitive as others to lonafarnib treatment and underwent lonafarnib arrest. Lonafarnib thus appears to be effective in inhibiting NSCLC cells via growth arrest at G<sub>2</sub>M or by induction of apoptosis, and, in some cases, does so without down-regulation of Akt. 1. Liu, Bryant, Chen, *et al.* (1998) *Cancer Res.* **58**, 4947. 2. Chun, Lee, Hassan, *et al.* (2003) *Cancer Res.* **63**, 4796. 3. Sun, Zhou, Wang, Fu & Khuri (2004) *Cancer Biol. Ther.* **3**, 1092.

**Lonidamine**

This antineoplastic agent (FW<sub>free-acid</sub> = 321.16 g/mol; M.P. = 207°C), also known as 1-(2,4-dichlorobenzyl)-1*H*-indazole-3-carboxylic acid, also functions as an antispermatogenic drug. Lonidamine is particularly effective in selectively sensitizing tumors to chemotherapy, hyperthermia and radiotherapy. LND potently inhibits mitochondrial pyruvate carrier (MPC) in isolated rat liver mitochondria (K<sub>i</sub> = 2.5 μM) and co-operatively inhibits L-lactate transport by MCT1, MCT2 and MCT4 expressed in *Xenopus laevis* oocytes (K<sub>0.5</sub> = 36-40 μM; Hill coefficient = 1.65-1.85) (1). In rat heart mitochondria LND inhibited the MPC with similar potency and uncoupled oxidation of pyruvate was inhibited more effectively (IC<sub>50</sub> = ~7 μM) than other substrates including glutamate (IC<sub>50</sub> = ~20 μM). In isolated DB-1 melanoma cells 1-10 μM, LND increases L-lactate output, consistent with MPC inhibition, but higher concentrations (150 μM) decreased L-lactate

output whereas increasing intracellular [L-lactate] > 5-fold, consistent with MCT inhibition (1). **Target(s):** cystic fibrosis transmembrane conductance regulator (CFTR) chloride channel (2); electron transport (3-6); hexokinase (3,7,8); lactate transport (9). 1. Nancolas, Guo, Zhou, *et al.* (2016) *Biochem. J.* **473**, 929. 2. Gong, Burbridge, Lewis, Wong & Linsdell (2002) *Brit. J. Pharmacol.* **137**, 928. 3. Biophys.* **226**, 73. 6. Turrens (1986) *Mol. Biochem. Parasitol.* **20**, 237. 7. Floridi, Paggi, Marcante, *et al.* (1981) *J. Natl. Cancer Inst.* **66**, 497. 8. Nista, De Martino, Malorni, *et al.* (1985) *Exp. Mol. Pathol.* **42**, 194. 9. Ben-Horin, Tassini, Vivi, Navon & Kaplan (1995) *Cancer Res.* **55**, 2814.

**Lonomycins**

These polyether antibiotics from *Streptomyces ribosidificus*, are ionophores that uncouple oxidative phosphorylation. The major component is lonomycin A (FW = 829.08 g/mol; CAS 58845-80-0), which was originally called simply lonomycin: lonomycins B and C are minor components. Lonomycin A more readily forms complexes with K<sup>+</sup> than with NH<sub>4</sub><sup>+</sup>, Rb<sup>+</sup>, or Na<sup>+</sup>. Complexes were not reported with Li<sup>+</sup>, Cs<sup>+</sup>, or Ca<sup>2+</sup>. 1. Reed (1979) *Meth. Enzymol.* **55**, 435.

**Loperamide**

This widely used antidiarrheal agent (FW<sub>free-base</sub> = 477.05 g/mol; CASs: 53179-11-6 (free base) and 34552-83-5 (HCl salt)), also known as Imodium® and 4-(4-chlorophenyl)-4-hydroxy-*N,N*-dimethyl- $\alpha,\alpha$ -diphenyl-1-piperidinebutanamide, is a nonselective Ca<sup>2+</sup> channel blocker and opioid agonist. While nanomolar concentrations of loperamide activate opioid receptors in the gastrointestinal tract, somewhat higher concentrations are required to block calmodulin activity, calcium channels, *N*-methyl-D-aspartate-receptor channels, and maitotoxin elicited calcium influx. P-glycoprotein-mediated efflux prevents loperamide from crossing the blood-brain barrier, thereby minimizing CNS effects. 1. Daly & Harper (2000) *Cell Mol. Life Sci.* **57**, 149. 2. Ooms, Degryse & Janssen (1984) *Scand. J. Gastroenterol. Suppl.* **96**, 145. 3. Church, Fletcher, Abdel-Hamid & MacDonald (1994) *Mol. Pharmacol.* **45**, 747.

**Lophotoxin**

This marine neurotoxin (FW = 416.43 g/mol; CAS 78697-56-0) from sea fans and whips (*e.g.*, species of *Lophogorgia*) irreversibly inactivates nicotinic acetylcholine receptors, targeting a tyrosyl residue within the  $\alpha$  subunit (1-4) (**See also** *Bipinnatins*). A total of 12 active lophotoxin analogues have been isolated from various species of the soft corals *Lophogorgia* and *Pseudopterogorgia* (Fenical *et al.*, 1981; Culver *et al.*, 1985; Abramson *et al.*, 1989; Wright *et al.*, 1989). A radiolabeled analog was used to show that the lophotoxins irreversibly inhibit nicotinic receptors by forming a covalent bond with Tyr<sup>190</sup> in the  $\alpha$ -subunits ( $\alpha$ Tyr<sup>190</sup>) of the receptor. Lophotoxins are unique among naturally occurring neurotoxins in their selective inhibition of a neurotransmitter receptor by irreversible, covalent modification. Structural comparison of lophotoxin and bipinnatins suggests that the greater stability of lophotoxin results from substituents at positions R<sub>1</sub> and R<sub>2</sub> (3). At position R<sub>2</sub>, lophotoxin lacks an acetate ester present in bipinnatins. Spontaneous hydrolysis of the acetate ester at position R<sub>2</sub> may be an initiating event in activation of the bipinnatins (3). Alternatively, the presence of an aldehyde at position R<sub>1</sub> in lophotoxin may account for the increased activity of lophotoxin as well as its greater stability. 1. Smythies (1983) *Med. Hypotheses* **10**, 465. 2. Hann, Pagan, Gregory, *et al.* (1998) *J. Pharmacol. Exp. Ther.* **287**, 253. 3. Groebe & Abramson (1995) *J. Biol. Chem.* **270**, 281. 4. Abramson, Culver, Kline, *et al.* (1988) *J. Biol. Chem.* **263**, 18568.

### Lopinavir

This antiviral agent (FW = 628.81 g/mol), also known as ABT-378, is a strong inhibitor of HIV-1 protease. Note that lopinavir is an effective inhibitor of ritonavir-resistant HIV strains, with a  $K_i$  of 1-4 pM for the Val-82-Phe viral proteinase (1-5). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** UGT1A1, UGT1A3, and UGT1A4 glucuronosyltransferase (6). 1. Carrillo, Stewart, Sham, *et al.* (1998) *J. Virol.* **72**, 7532. 2. Zhang, Chando, Everett, *et al.* (2005) *Drug Metab. Dispos.* **33**, 1729.

### Loratadine

This long-acting antihistamine pro-drug and antiallergic agent (FW = 382.89 g/mol; CAS 79794-75-5; IUPAC: ethyl 4-(8-chloro-5,6-dihydro-

11H-benzo[5,6]cyclohepta[1,2-b]pyridin-11-ylidene)-1-piperidinecarboxylate; Soluble to 20 mM in DMSO), also named SCH 29851, Claritin<sup>®</sup>, and Clarityn<sup>®</sup>, is metabolized to descarboxyethoxylopratadine, *or* desloratadine (FW = 310.82 g/mol; CAS 100643-71-8; IUPAC: 8-chloro-6,11-dihydro-11-(4-piperidinylidene)-5H-benzo[5,6]cyclohepta[1,2-b]pyridine; Soluble to 20 mM in DMSO), eventually forming the more active agent, 3-hydroxydesloratadine (FW = 326.82 g/mol; CAS 119410-08-1; IUPAC: 8-chloro-6,11-dihydro-11-(4-piperidinylidene)-5H-benzo[5,6]cyclohepta[1,2-b]pyridin-3-ol). UGT2B10 catalyzes glucuronidation of desloratadine, followed by CYP2C8-catalyzed oxidation and a de-conjugation to form 3-hydroxydesloratadine (6). Desloratadine is an inverse agonist ( $K_i$  = 0.87 nM) of histamine H<sub>1</sub> receptor, devoid of CNS effects (1-5). (Compare to a  $K_i$  value of 35 nM for loratadine.) Unlike most classical antihistamines, loratadine (ED<sub>50</sub> = 0.40 mg/kg, p.o.) is a peripheral H<sub>1</sub> antagonist that lacks central nervous system depressing effects, including drowsiness. In anti-immunoglobulin-triggered human basophils and 2,4-dinitrophenyl-triggered rat basophilic leukemia cells, dose-dependent inhibition of histamine release occurs at 2  $\mu$ M descarboxyethoxy-lopratadine or at 7  $\mu$ M loratadine (7). By using the whole-cell patch clamp technique, the effects of loratadine on the transient outward K current ( $I_{to}$ ), sustained current ( $I_{sus}$ ), and current measured at -100 mV ( $I_{K1}$  and  $I_{ns}$ ), the major inward and outward potassium currents present in human atrial myocytes, Crumb (8) assessed the possible molecular mechanisms for the observed atrial arrhythmias reported with loratadine use. Loratadine rate-dependently inhibited  $I_{to}$  at therapeutic concentrations with 10 nM loratadine reducing  $I_{to}$  amplitude at a pacing rate of 2 Hz by 35%. In contrast, loratadine had no effect on either  $I_{sus}$  or the current measured at -100 mV. Such results provide a possible explanation for the incidences of supraventricular arrhythmias reported with the use of loratadine. Inhibition of brain P-gP multi-drug resistance factor by verapamil can convert desloratadine to a sedating antihistamine in mice (9). BCR/ABL promotes histamine production in CML cells and desloratadine exerts antileukemic effects on CML cells (10). **See also** *Terfenadine*, the first FDA-approved non-sedating H<sub>1</sub>-directed antihistamine. **Note:** Loratadine is distantly related to quetiapine, an atypical antipsychotic. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** aldehyde oxidase (1); CYP3A4, as alternative substrate (2); CYP2C19 (2); CYP2D6 (2); glucuronidation reactions (2); histamine H<sub>1</sub> receptor (3,4); P-glycoprotein, *or* xenobiotic transporting ATPase, multidrug-resistance protein (5). When present at 10  $\mu$ M, H<sub>1</sub> antihistamines inhibit oxidative burst of human neutrophils (Rank Order of Potency: Dithiaden > Loratadine > Brompheniramine > Chlorpheniramine > Pheniramine) (11). 1. ### Lorazepam

This a high-potency, intermediate-duration, 3-hydroxybenzodiazepine anticonvulsant/antianxiety agent (FW = 321.16 g/mol; CAS 846-49-1) binds to GABA<sub>A</sub> receptors in the CNS, exhibiting anxiolytic effects, amnesic effects, sedative/hypnotic effects, anticonvulsant effects, antiemetic effects, and muscle relaxant effects. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.)

McGraw-Hill Medical, New York (2011). **Target(s):** glucuronosyl-transferase (1); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (2); adenosine deaminase (3). 1. Hara, Nakajima, Miyamoto & Yokoi (2007) *Drug Metab. Pharmacokin.* **22**, 103. 2. Saha, Sengupta, Dutta, Sirkar & Sengupta (1989) *Indian J. Exp. Biol.* **27**, 44. 3. Moosavi-Movahedi, Sepassi Tehrani, Amanlou, *et al.* (2010) *Protein Pept Lett.* **17**, 197.

### Lorcaserin

This centrally acting, selective serotonin receptor agonist and anti-obesity drug (FW = 195.68 g/mol; CAS 616202-92-7), also named Belviq<sup>®</sup> and (1*R*)-8-chloro-1-methyl-2,3,4,5-tetrahydro-1*H*-3-benzazepine, targets 5-HT<sub>2c</sub> receptors (EC<sub>50</sub> = 39 nM; K<sub>i</sub> = 13 nM), with weaker action against 5-HT<sub>2a</sub> receptors (EC<sub>50</sub> = 550 nM; K<sub>i</sub> = 90 nM) and 5-HT<sub>2b</sub> receptors (EC<sub>50</sub> = 2400 nM; K<sub>i</sub> = 150 nM). Lorcaserin does not compete for binding of ligands to serotonin, dopamine, and norepinephrine transporters. 5-HT<sub>2c</sub> receptors are located in the choroid plexus, cortex, hippocampus, cerebellum, amygdala, thalamus, and hypothalamus. Although lorcaserin's mechanism of appetite suppression is unclear, 5-HT<sub>2c</sub> receptor activation in the hypothalamus is thought to activate pro-opiomelanocortin (POMC), thereby promoting satiety and modest weight loss (3). 1. Smith, Smith, Tsai, *et al.* (2008) *J. Med. Chem.* **51**, 305. 2. Thomsen, Grottick, Menzaghi, *et al.* (2008) *J. Pharmacol. Exp. Ther.* **325**, 577. 3. Chan, He, Chui, *et al.* (2013) *Obesity Rev.* **14**, 383.

### Losmapimod

This orally bioavailable protein kinase inhibitor and anti-depression drug (FW = 383.46 g/mol; CAS 585543-15-3), also named GW856553X and 6-[5-(cyclopropylcarbamoyl)-3-fluoro-2-methylphenyl]-*N*-(2,2-dimethylpropyl)pyridine-3-carboxamide, selectively targets p38 mitogen-activated protein kinases that serve as mediators of inflammation (1). Inhibition of these enzymes produces antidepressant and antipsychotic effects in mechanism likely to involve release of bone-derived nerve factor (BDNF) release. It also reduces plasma fibrinogen in patients with chronic obstructive pulmonary disease (2). 1. Aston, Bamborough, Buckton, *et al.* (2009) *Journal of Medicinal Chemistry* **52**, 6257. 2. Lomas, Lipson, Miller, *et al.* (2012) *J. Clin. Pharmacol.* **52**, 416.

### Losartan

This oral antihypertensive drug (FW = 422.92 g/mol; CAS 114798-26-4), also named (2-butyl-4-chloro-1-[[2'-(1*H*-tetrazol-5-yl)biphenyl-4-yl]methyl]-1*H*-imidazol-5-yl)methanol and marketed under the trade name Cozaar, is a nonpeptide angiotensin II receptor antagonist (IC<sub>50</sub> = 19 nM) that reportedly provides a more specific and complete blockade of angiotensin II actions than inhibition of renin or angiotensin-converting enzyme (ACE). Indeed, All of the physiological effects of angiotensin II, including stimulation of release of aldosterone, are antagonized in the presence of losartan. Reduction in blood pressure occurs independently of

the status of the renin-angiotensin system. Losartan is the recommended first-line treatment in patients under age 55, who cannot tolerate an ACE inhibitor. (See also Candesartan; Eprosartan; Irbesartan; Olmesartan; Telmisartan; Valsartan) **Key Pharmacokinetic Parameters:** Bioavailability = 33 %; Food Effect? NO; Drug t<sub>1/2</sub> = 2 hours; Metabolite t<sub>1/2</sub> = 6–9 hours; Drug's Protein Binding = 98.7 %; Metabolite's Protein Binding = 99.8 %; Route of Elimination = 35 % Renal, 60 % Liver. See also Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Chiu, McCall, Price, *et al.* (1990) *J. Pharmacol. Exp. Ther.* **252**, 711. 2. Wong, Price, Chiu, *et al.* (1990) *J. Pharmacol. Exp. Ther.* **252**, 719 and 726.

### Lovastatin

This serum cholesterol-reducing drug (FW<sub>lactone</sub> = 404.55 g/mol), also known as MK-803, mevinolin, and monacolin K, is a fungal metabolite from *Aspergillus terreus* and *Monascus ruber* that inhibits 3-hydroxy-3-methylglutaryl-coenzyme A (or HMG-CoA) reductase. When taken at pharmacologic doses, this tight-binding competitive inhibitor blocks mevalonate biosynthesis and induces the expression of LDL receptors in the liver, which in turn increases the catabolism of plasma LDL and lowers the plasma concentration of cholesterol, an important determinant of atherosclerosis. When taken along with a low-fat diet, lovastatin reduces the risk of heart attack, stroke, certain types of heart surgeries, and chest pain in patients with heart disease or subjects having several common heart disease risk factors (*i.e.*, family history of heart disease, high blood pressure, age, low HDL cholesterol, and smoking). **Primary Mode of Action:** Lovastatin is a potent inhibitor of 3-hydroxy-3-methylglutaryl-CoA reductase (K<sub>i</sub> = 0.5 nM) and is highly effective in the treating hypercholesterolemia. Lovastatin received approval by the Food and Drug Administration in 1987. The lactone is very stable and is soluble in organic solvents, with lower solubility in water (0.4 x 10<sup>-3</sup> mg/mL at room temperature). The sodium salt is unstable at room temperature and should be prepared only immediately prior to use (1). Note that mevastatin is the 6-demethylated derivative of lovastatin. See *Mevastatin; Statin Side-Effects* **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). *Note:* Lovastatin is a CYP3A4-metabolized statin, and co-administration of a CYP3A4 inhibitors can result in adverse drug interactions. **Target(s):** acetylcholinesterase (2); cholinesterase, or butyrylcholinesterase (2); 3-hydroxy-3 methylglutaryl-CoA reductase (NADPH) (1,3-6). 1. ### Loxapine

This dibenzoxazepine-based antipsychotic agent (FW = 327.81 g/mol; CAS 27833-64-3; Solubility: 90 mg/mL DMSO), also named 2-chloro-11-(4-methyl-1-piperazinyl)dibenz[*b,f*][1,4]oxazepine, is a potent D<sub>2</sub>/D<sub>4</sub>-dopamine

receptor and 5-HT<sub>2A</sub>/5-HT<sub>2B</sub>/5-HT<sub>7</sub> serotonergic receptor antagonist that is frequently used in the treatment of schizophrenia (1-4). In studies with human receptors, its rank-order potency is: 5-HT<sub>2</sub> receptor  $\geq$  D<sub>4</sub> receptor  $\ggg$  D<sub>1</sub> receptor  $>$  D<sub>2</sub> receptor (5). 1. Roth, Tandra, Burgess, Sibley & Meltzer (1995) *Psychopharmacology* **120**, 365. 2. Shen, Monsma, Metcalf, et al. (1993) *J. Biol. Chem.* **268**, 18200. 3. ### Loxoprofen

This anti-inflammatory agent (FW<sub>free-acid</sub> = 246.31 g/mol), also named CS-600 and 2-[4-(2-oxocyclopentylmethyl)phenyl]propionic acid, is the prodrug of an inhibitor of prostaglandin synthesis (i.e., 2-[4-(trans-2-hydroxycyclopentylmethyl)phenyl]propionic acid). The (2*S*,1'*R*,2'*S*)-trans-alcohol isomer was found to be the most active metabolite. **Target(s):** carbonyl reductase (1); cyclooxygenase-1 and -2 (2,3). 1. Imamura, Koga, Higuchi, et al. (1997) *J. Enzyme Inhib.* **11**, 285. 2. Matsuda, Tanaka, Ushiyama, Ohnishi & Yamazaki (1984) *Biochem. Pharmacol.* **33**, 2473. 3. Riendeau, Salem, Styhler, et al. (2004) *Bioorg. Med. Chem. Lett.* **14**, 1201.

### Lq2

This oligopeptide (MW = 4250; *Sequence*: ZFTNESCTASNQCWSIC KRLHNTNRGKCMNKKCRCYS, where "Z" refers to a pyroglutamyl residue), also known as ChTX-Lq2, is a charybdotoxin homologue (**See Charybdotoxin**) from the venom of the Israeli scorpion *Leiurus quinquestriatus hebraeus*. Lq2 binds to the voltage-activated, the Ca<sup>2+</sup>-activated and the inward-rectifier potassium channels, with high affinity for the latter class, especially the Renal Outer Medullary Potassium channel ROMK1 that regulates the resting membrane potential. Note that Lq2 has disulfide bonds between Cys7–Cys28, Cys13–Cys33, and Cys17–Cys35. 1. Lucchesi, Ravindran, Young & Moczydlowski (1989) *J. Membr. Biol.* **109**, 269. 2. ### LspA Virulence Factor YL2 Domain

This protein domain (MW = 37 kDa) allows *Haemophilus ducreyi*, a microorganism that causes the sexually transmitted infection known as chancroid, to elude phagocytosis and eventual destruction. The YL2 domain of the 456-kDa LspA1 also inhibits phagocytosis of IgG-opsonized targets. When expressed in mammalian cells, YL2 decreases levels of active Src tyrosine kinases (SFKs). Tyrosine phosphorylation sites in two EPIYG motifs within YL2 are required, and purified Csk phosphorylates these motifs, in turn increasing Csk catalytic activity in a positive feedback loop. A dominant-negative Csk rescues phagocytosis in the presence of YL2, suggesting that Csk is the main host protein interacting with YL2. *Helicobacter pylori* CagA protein also inhibits phagocytosis in a Csk-dependent manner, suggesting a possibly general mechanism to subvert Fc $\gamma$  receptor (Fc $\gamma$ R)-mediated phagocytosis, the latter a crucial component of the innate immune response. 1. Dodd, Worth, Rosen, et al. (2014) *MBio.* **5**, e01178.

### Lu AA 47070

**Lu AA 47070 (prodrug)**

**Active Drug**

This orally bioavailable prodrug (FW = 463.39 g/mol; CAS 913842-25-8; Soluble to 100 mM in DMSO), also named 4-[(3,3-dimethyl-1-oxobutyl)amino]-3,5-difluoro-N-[3-[(phosphonoxy)methyl]-2(3*H*)-thiazolidine]benzamide, is metabolically converted into potent and selective adenosine A<sub>2A</sub> receptor antagonist ( $K_i$  = 5.9 nM), with much weaker action against the A<sub>2B</sub> ( $K_i$  = 260 nM), A<sub>1</sub> ( $K_i$  = 410 nM), and A<sub>3</sub> receptors ( $K_i$  < 10,000 nM) (1). The active drug had acceptable ADME properties; however, its low intrinsic solubility limited its development as a therapeutic agent, because oral bioavailability from dosing in suspension was significantly lower than the oral bioavailability from solution dosage. When administered intravenously, Lu AA47070 (dose: 3.75-30 mg/kg) reverses the effects of the D<sub>2</sub> receptor antagonist pimozide (1.0 mg/kg, administered intravenously) using several measures of motor impairment (e.g., catalepsy, locomotion, and tremulous jaw movements) in a rodent model of Parkinsonian tremor (2). 1. Sams, Mikkelsen, Larsen, et al. (2011) *J. Med. Chem.* **54**, 751. 2. Collins, Sager, Sams, et al. (2012) *Pharmacol. Biochem. Behav.* **100**, 498.

### Lu AF64280

This brain-penetrating PDE inhibitor (FW = 470.96 g/mol) targets phosphodiesterase PDE2a, both *in vitro* and *in vivo*, and is suitable for assessing roles played by PDE2A in synaptic plasticity under normal and perturbed conditions. Lu AF64280 attenuates spontaneous P20-N40 gating deficits in DBA/2 mice, an inbred mouse strain proposed to model P50 gating deficits observed in some schizophrenic patients. Lu AF64280 significantly increases cGMP levels in the hippocampus, attenuates sub-chronic phencyclidine-induced deficits in novel object exploration in rats, blocks early postnatal phencyclidine-induced deficits in the intradimensional/extradimensional shift task in rats and attenuates spontaneous P20-N40 auditory gating deficits in DBA/2 mice. At any dose tested, Lu AF64280 fails to attenuate phencyclidine-induced hyperactivity in mice, and is devoid of antipsychotic-like activity in the conditioned avoidance response paradigm in rats. **Target(s):** Lu AF64280 inhibits full-length human PDE2A ( $K_i$  = 20 nM) and moderately inhibits both human PDEs 9A ( $K_i$  = 1,000 nM) and 10A ( $K_i$  = 1,800 nM). Lu AF64280 displays a  $K_i$  above 5,000 nM against all other tested members of the PDE family,

revealing >250x selectivity window towards other PDEs. 1. Redrobe, Jørgensen, Christoffersen, *et al.* (2014) *Psychopharmacol.* **231**, 3151.

### Lubiprostone

This bowel movement-promoting medication (FW = 390.46 g/mol; CAS 136790-76-6; IUPAC: 7-[(1*R*,3*R*,6*R*,7*R*)-3-(1,1-difluoropentyl)-3-hydroxy-8-oxo-2-oxabicyclo[4.3.0]non-7-yl]heptanoic acid) is used to treat chronic idiopathic constipation, irritable bowel syndrome-associated constipation, as well as opioid-induced constipation. This bicyclic fatty acid, itself derived from prostaglandin E<sub>1</sub>, activates the ClC-2 voltage-gated Cl<sup>-</sup> channel on gastrointestinal epithelial cells, producing a chloride-rich fluid secretion that softens the stool, increases motility, and promotes spontaneous bowel movements. 1. Müller-Lissner (2013) *Expert Opin. Drug Metab. Toxicol.* **9**, 391. 2. Raschi & De Ponti (2014) *Expert Opin. Drug Metab. Toxicol.* **10**, 293.

### Lucanthone

This anthelmintic and bacterial antibiotic (FW<sub>free-base</sub> = 340.49 g/mol; FW<sub>hydrochloride</sub> = 376.49; CAS; IUPAC Name: 1-[[2-(diethylamino)ethyl]amino]-4-methyl-9*H*-thioxanthen-9-one hydrochloride), also known by the code names MS-752 and RP-3735 as well as the trade names Miracil D™, Nilodin™, Miracol™ and Tixantone™, is used to treat parasitic infections, particularly by *Schistosoma mansoni* (1). When administered at 30-60 μM, lucanthone is toxic to *Escherichia coli* and *Bacillus subtilis*. **Schistosomiasis:** Although these flatworms are not found in the United States, they infect more than 200 million people worldwide, making schistosomiasis a major health challenge. The causative organism is found throughout Africa, parts of South America (particularly Brazil, Venezuela, Surinam, and Guyana), and the Caribbean islands (mainly Peurto Rico, St. Lucia, and Martinique), where it flourishes in certain freshwater snails. **Primary Mode(s) of Action:** Lucanthone is a DNA intercalator that inhibits DNA and/or RNA biosynthesis inhibitor, DNA topoisomerase, and base-excision repair. Lucanthone inhibits the base-excision endonuclease activity of APE1, without affecting its redox activity, IC<sub>50</sub> = 5 μM (2). X-ray structures of APE1 reveal a hydrophobic pocket where hydrophobic small molecules like lucanthone can bind. Exposure of cells to lucanthone results in processing and recruitment of Microtubule-Associated Protein-1 light chain 3 (MAP1-LC3) to autophagosomes, but impairs autophagic degradation (3,4). **Target(s):** ribosomal RNA synthesis (5); butyrylcholinesterase (6). 1. Hirschberg (1975) in *Antibiotics* (Corcoran & Hahn, eds), Springer-Verlag, New York, p. 274. 2. Naidu, Agarwal, Pena, *et al.* (2011) *PLoS One* **6**, e23679. 3. Verdier & Wolfe (1986) *Biochem Pharmacol.* **35**, 1605.

### Lufaxin

This novel FXa inhibitor (MW = 32.4 kDa), from the salivary gland of the sand fly *Lutzomyia longipalpis*, blocks Protease-Activated Receptor 2 (PAR2) activation and inhibits inflammation and thrombosis *in vivo*. Also known as Coagulation Factor II (thrombin) Receptor-like 1 (F2RL1), PAR2

modulates inflammatory responses and acts as a sensor for proteolytic enzymes generated during infection. Lufaxin inhibits thrombin formation by prothrombinase, which consists of the serine proteins, Factor Xa, and the protein cofactor, Factor Va. It was identified as a slow, tight-binding noncompetitive (reversible) inhibitor of coagulation Factor Xa. Surface plasmon resonance revealed that FXa forms a high-affinity complex with Lufaxin (K<sub>d</sub> ~ 3 nM), and isothermal titration calorimetry demonstrated the binding stoichiometry was 1:1. Lufaxin also prevents PAR2 activation by FXa in the MDA-MB-231 cell line and abrogates edema formation triggered by injection of FXa in the paw of mice. Moreover, Lufaxin prevents FeCl<sub>3</sub>-induced carotid artery thrombus formation and prolongs aPTT *ex vivo*, implying that it works as an anticoagulant *in vivo*. 1. Collin, Assumpção, Mizurini, *et al.* (2012) *Arterioscler. Thromb. Vasc. Biol.* **32**, 2185.

### Luminespib

This highly potent HSP90 inhibitor (FW = 465.54 g/mol; CAS 747412-49-3; Solubility: 90 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as AUY922 and NVP-AUY922, targets Heat Shock Protein 90 (IC<sub>50</sub> = 13 nM and 21 nM for HSP90α and HSP90β) and human tumor cell proliferation with GI<sub>50</sub> values of 2–40 nM, inducing G<sub>1</sub>-G<sub>2</sub> arrest and apoptosis. Its action on is characterized by, respectively (1-2). NVP-AUY922 induces HSP70, the binding of which to client proteins (*e.g.*, HER-2, Akt and thymidylate synthase) results in their proteasomal degradation (3), with attendant cell growth inhibition. When used in combination with a PKC-9 inhibitor, AUY922 (15 nM) almost completely suppresses HIV-1 reactivation, with no apparent cytotoxicity (4). Indeed, Hsp90 is required downstream of PKCs but not for activation of mitogen-activated protein kinase. Inhibition of Hsp90 reduces degradation of IκBα and blocks nuclear translocation of transcription factor p65/p50, suppressing the NF-κB pathway. Coimmunoprecipitation experiments show that Hsp90 interacts with inhibitor of nuclear factor kappa-B kinase (IKK) together with cochaperone Cdc37, which is critical for the activity of several kinases. Targeting of Hsp90 by AUY922 dissociates Cdc37 from the complex. Hsp90 thus controls HIV-1 reactivation from latency by keeping the IKK complex functional and connects T-cell activation with HIV-1 replication (4). AUY922 treatment also interrupts HSP90 interactions with its protein clients Bcr-Abl or Bcr-Abl kinase domain mutants (T315I and E255K), leading to Bcr-Abl degradation, inhibiting cell proliferation and inducing apoptosis of both imatinib-sensitive 32Dp210 (IC<sub>50</sub> = 6 nM) and imatinib-resistant 32Dp210T315I cells (IC<sub>50</sub> ≈ 6 nM) and human KBM-5R/KBM-7R cell lines (IC<sub>50</sub> = 50 nM) (5). 1. Brough, Aherne, Barril, *et al.* (2008) *J. Med. Chem.* **51**, 196. 2. Eccles, Massey, Raynaud, *et al.* (2008) *Cancer Res.* **68**, 2850. 3. Lee, Lee, Han, *et al.* (2011) *Cancer Sci.* **102**, 1388. 4. Anderson, Low, Weston, *et al.* (2014) *Proc. Natl. Acad. Sci. U.S.A.* **111**, E1528. 5. Tao, Chakraborty, Leng, Ma & Arlinghaus (2015) *Genes Cancer* **6**, 19.

### Lurasidone

This orally active, atypical antipsychotic (FW = 491.69 g/mol; CAS 367514-87-2), also known by the trade Latuda<sup>®</sup>, the developmental code name SM-13496, and the systematic name (3*aR*,4*S*,7*R*,7*aS*)-2-[(1*R*,2*R*)-2-[4-(1,2-benzisothiazol-3-yl)piperazin-1-ylmethyl]cyclohexylmethyl]hexahydro-4,7-methano-2*H*-isoindole-1,3-dione, is an FDA-approved drug for the treatment of depressive episodes associated with bipolar type I disorder as well as bipolar type II disorder in adults, either alone or in combination with lithium or valproate (1,2). Lurasidone has negligible affinity for histamine H<sub>1</sub> and muscarinic M<sub>1</sub> receptors, which are thought to contribute to side effects such as weight gain, sedation, and worsening of cognitive deficits (3). Structural models of lurasidone-GPCR complexes were determined by homology modeling of receptors, exhaustive ligand docking, and molecular dynamics simulation-based refinement of these complexes. This modeling gave reliable structural models for D<sub>2</sub>, 5-HT<sub>2A</sub>, and 5-HT<sub>7</sub> receptors with overall structural complementarities with a salt bridge anchor at the center of the lurasidone molecule, but not for H<sub>1</sub> and M<sub>1</sub> receptors, owing to steric hindrance between the norbornane-2,3-dicarboximide and/or cyclohexane part of lurasidone and both receptors. By comparison with the structural models of olanzapine-GPCRs and ziprasidone-GPCRs using the same computational protocols, it was suggested that the bulkiness of the norbornane-2,3-dicarboximide part and the rigidity and the bulkiness of the cyclohexyl linker gave lurasidone high selectivity for the desired aminergic GPCRs (3). **Targets:**  $\alpha_1$ -adrenergic receptor, as antagonist ( $K_i = 48$  nM);  $\alpha_{2A}$ -adrenergic receptor, as antagonist ( $K_i = 1.6$  nM);  $\alpha_{2C}$ -adrenergic receptor, as antagonist ( $K_i = 10.8$  nM); dopamine D<sub>1</sub> receptor, as antagonist ( $K_i = 262$  nM); dopamine D<sub>2</sub> receptor, as antagonist ( $K_i = 1.7$  nM); serotonin 5-HT<sub>1A</sub> receptor, as partial agonist ( $K_i = 6.8$  nM); serotonin 5-HT<sub>2A</sub> receptor, as antagonist ( $K_i = 2.0$  nM); serotonin 5-HT<sub>2C</sub> receptor, as antagonist ( $K_i = 415$  nM); and serotonin 5-HT<sub>7</sub> receptor, as antagonist ( $K_i = 0.5$  nM). 1. Meyer, Loebel & Schweizer (2009) *Expert Opin. Investigatn. Drugs* **18**, 1715. 2. Ishibashi, Horisawa, Tokuda, (2010) *J. Pharmacol. Exper. Therapeut.* **334**, 171. 3. Ichikawa, Okazaki, Nakahira, *et al.* (2012) *Neurochem. Int.* **61**, 1133.

#### Luseogliflozin

This orally active and highly selective, second generation SGLT2 inhibitor (FW = 452.56 g/mol; CAS 898537-18-3), also known as (1*S*)-1,5-anhydro-1-[5-(4-ethoxybenzyl)-2-methoxy-4-methylphenyl]-1-thio-D-glucitol and TS-071, is a Type-2 diabetes drug that targets the sodium-glucose transporter, Subtype 2 (IC<sub>50</sub> = 2.26 nM), increasing urinary glucose excretion independently of insulin secretion/action. Chiefly expressed in the proximal tubules, the SGLT2 is a low-affinity, high-capacity glucose transporter that is responsible for >90% of kidney glucose reabsorbed in hyperglycemic patients. Because its inhibitory action is insulin-independent, luseogliflozin provides steady glucose control, without risk for hypoglycemia and with favorable reductions in both body weight and blood pressure. Other SGLT2 inhibitors include canagliflozin, dapagliflozin, empagliflozin, and tofogliflozin. 1. Kojima, Williams, Takahashi, Miyata & Roman (2013) *J. Pharmacol. Exp. Ther.* **345**, 464. 2. Kurosaki & Ogasawara (2013) *Pharmacol. Ther.* **139**, 51.

#### Luteolin 7-O-Glucoside

This yellow glycoside (FW = 448.38 g/mol), also known as cynaroside, from many plants (*e.g.*, *Achillea millefolium* and *Ixeris chinensis*) inhibits  $\alpha$ -glucosidase and  $\alpha$ -amylase. **Target(s):**  $\alpha$ -amylase (1,2); catechol oxidase (3); complement pathway (4); 3',5'-cyclic nucleotide phosphodiesterase (5);  $\alpha$ -glucosidase (1); phosphodiesterase 2 (5); phosphodiesterase 4 (5); thyroxine 5-deiodinase, *or* iodothyronine deiodinase (6,7); tyrosinase, *or* monophenol monooxygenase (3,8); xanthine oxidase (9). 1. Kim, Kwon & Son (2000) *Biosci. Biotechnol. Biochem.* **64**, 2458. 2. Funke & Melzig (2005) *Pharmazie* **60**, 796. 3. Kim & Uyama (2005) *Cell. Mol. Life Sci.* **62**, 1707. 4. Pieroni, Pachaly, Huang, Van Poel & Vlietinck (2000) *J. Ethnopharmacol.* **70**, 213. 5. Ko, Shih, Lai, Chen & Huang (2004) *Biochem. Pharmacol.* **68**, 2087. 6. Aufmkolk, Kohlr, Gumbinger, Winterhoff & Hesch (1984) *Horm. Metab. Res.* **16**, 188. 7. Aufmkolk, Koehle, Hesch & Cody (1986) *J. Biol. Chem.* **261**, 11623. 8. Karioti, Protopoulos, Magoulas & Skaltsa (2007) *Bioorg. Med. Chem.* **15**, 2708. 9. Nguyen, Awale, Tezuka, *et al.* (2006) *Planta Med.* **72**, 46.

#### LW8

This HIF-1 $\alpha$  modulator (FW = 435.51 g/mol; CAS 934593-90-5; Soluble in DMSO, but not H<sub>2</sub>O) inhibits the accumulation of Hypoxia-Induced Factor-1 $\alpha$ , promoting the degradation of wild-type HIF-1 $\alpha$ , but not of a DM-HIF-1 $\alpha$ , having P402A and P564A modifications, at hydroxylation sites within the O<sub>2</sub>-Dependent Degradation Domain (ODDD). In the presence of LW8, VHL knockdown does not abolish HIF-1 $\alpha$  protein accumulation, indicating that LW8 promotes HIF-1 $\alpha$  degradation by regulating expression of von Hippel-Lindau tumor suppressor (also known as pVHL). In mice carrying xenografts of human colon cancer HCT116 cells, LW8 shows strong anti-tumor efficacy *in vivo*, decreasing HIF-1 $\alpha$  expression in frozen-tissue immunohistochemical staining. 1. Lee, Kang, Park, *et al.* (2010) *Biochem. Pharmacol.* **80**, 982.

#### LY5

This non-peptide cell-permeable inhibitor (FW = 329.33 g/mol) targets STAT3 dimerization, blocking its activation with low IC<sub>50</sub> values in the 0.5–1.4  $\mu$ M range. Strong binding affinity to the STAT3 SH2 domain was confirmed by fluorescence polarization. The IC<sub>50</sub> values for the inhibition of viability are 0.364, 0.318, and 0.488  $\mu$ M, respectively, in UW288-1, UW426, and DAOY cells. Its ability to significantly inhibit STAT3 phosphorylation at the lower drug concentration in medulloblastoma expressing constitutive STAT3 indicates its high potency. Several known STAT3 downstream targets, such as cyclin-D1, survivin, and bcl-XL, were decreased by LY5 treatment, as demonstrated by RT-PCR analysis and angiogenesis array, again supporting the idea of LY5 as a potent STAT3 inhibitor. miR-21 gene expression was down-regulated by LY5, another indication of the inhibitory effect of LY5 on STAT3. The fact that LY5 inhibited STAT3 phosphorylation stimulated by cytokines and growth factors including IL-6, IGF-1, IGF-2, and LIF, but had no effect on STAT1 or STAT5 phosphorylation induced by IFN- $\gamma$  or EGF, suggests that it selectively suppresses STAT3 activation. LY5 shows anti-tumor action by inducing apoptosis in medulloblastoma cells, via STAT3 inhibition. That LY5 blocks tumor cell migration and angiogenesis *in vitro* through inhibition of STAT3 supports this suggestion. Treatment with LY5 and cisplatin or X-radiation produced a statistically greater inhibitory effect than single treatment. 1. Xiao, Bid, Jou, *et al.* (2015) *J. Biol. Chem.* **290**, 3418.

LY-146032, See Daptomycin

LY139603, See Atomoxetine

LY 210448, See Dapoxetine

LY 215840

This serotonin receptor antagonist (FW = 395.26 g/mol; CAS 137328-52-0; Solubility: 100 mM in DMSO), also named [8 $\beta$ (1*S*,2*R*)]-*N*-(2-hydroxycyclopentyl)-6-methyl-1-(1-methylethyl)ergoline-8-carboxamide, targets 5-HT<sub>2</sub> and 5-HT<sub>7</sub> receptors, reducing the stimulatory effects of serotonin on aldosterone secretion and reducing 5-HT-induced cAMP formation (p*K*<sub>B</sub> = 8.26). 1. Cushing, *et al.* (1996) *J. Pharmacol. Exp. Ther.* **277**, 1560. PMID: 8667223. 2. Lenglet, *et al.* (2002) *Endocrinology* **143**, 1748. 3. Louiset, *et al.* (2006) *J. Clin. Endocrinol. Metab.* **91**, 4578.

LY 225910

This potent CCK receptor antagonist (FW = 502.41 g/mol; CAS 133040-77-4; Solubility: 100 mM in DMSO), also named 2-[2-(5-bromo-1*H*-indol-3-yl)ethyl]-3-[3-(1-methylethoxy)phenyl]-4(3*H*)-quinazoline, targets the Cholecystokinin CCK<sub>2</sub> receptor, a G-protein coupled receptor that binds the peptide hormones cholecystokinin or gastrin. LY-225910 has an IC<sub>50</sub> value of 9.3 nM for the inhibition of binding of [<sup>125</sup>I]-CCK-8 sulfate at mouse brain receptors. 1. Yu, *et al.* (1991) *J. Med. Chem.* **34**, 1505. 2. Suman-Chauhan, *et al.* (1996) *Regul. Pept.* **65**, 37.

LY 223053

This NMDA receptor antagonist (FW = 211.22 g/mol; CAS 125546-04-5; Solubility: 100 mM in H<sub>2</sub>O or DMSO), also named (2*R*\*,4*S*\*)-4-(1*H*-tetrazol-5-ylmethyl)-2-piperidinecarboxylic acid, targets *N*-methyl-D-aspartate receptor (IC<sub>50</sub> = 7 nM), but displays no affinity for AMPA or kainate receptors, even at 10  $\mu$ M. LY-223052 inhibits NMDA-induced neuronal degeneration and also protects from NMDA-induced convulsions in neonatal rats. 1. Schoepp, *et al.* (1990) *J. Pharmacol. Exp. Ther.* **255**, 1301. 2. Madden, *et al.* (1992) *J. Neurosurg.* **76**, 106. 3. Madden, *et al.* (1993) *Stroke* **24**, 1068.

LY 264618, See Lometrexol

LY248686, See Duloxetine

LY 255283

This competitive BLT antagonist (FW = g/mol; CAS 117690-79-6; Solubility: 100 mM in DMSO), also named 1-[5-ethyl-2-hydroxy-4-[[6-methyl-6-(1*H*-tetrazol-5-yl)heptyl]oxy]-phenyl]-ethanone, selectively targets human recombinant Leukotriene B-2, or BLT<sub>2</sub> receptors (IC<sub>50</sub> ~ 1 nM), with an IC<sub>50</sub> value > 10  $\mu$ M against BLT<sub>1</sub> receptors. LY 255283 inhibits LTB<sub>4</sub>-induced contraction of lung parenchyma (pA<sub>2</sub> = 7.2), and reduces LTB<sub>4</sub>-mediated airway obstruction in guinea pigs following intravenous and oral administration. 1. Herron, *et al.* (1992) *J. Med. Chem.* **35**, 1818. 2. Silbaugh, *et al.* (1992) *Eur. J. Pharmacol.* **223**, 57. 3. Yokomizo, *et al.* (2001) *J. Biol. Chem.* **276**, 12454.

LY 266097

This serotonin receptor antagonist (FW = 370.88 g/mol; CAS 172895-39-5; Solubility: 100 mM in DMSO or Ethanol), also named 1-[(2-chloro-3,4-dimethoxyphenyl)methyl]-2,3,4,9-tetrahydro-6-methyl-1*H*-pyrido[3,4-*b*]indole, targets 5-HT<sub>2B</sub> receptor (p*K*<sub>i</sub> = 9.3), with >100x selectivity over 5-HT<sub>2A</sub> and 5-HT<sub>2C</sub> receptors. LY 266097 attenuates amphetamine-induced locomotion in the rat. (See LY 272015) 1. Audia, Evrard, Murdoch, *et al.* (1996) *J. Med. Chem.* **39**, 2773. 2. Auclair, Cathala, Sarrazin, *et al.* (2010) *J. Neurochem.* **114**, 1323.

LY 272015

This orally available serotonin receptor antagonist (FW = 336.74 g/mol; CAS 172895-15-7; Solubility: 100 mM in DMSO; 10 mM in Ethanol), also named 1-[(3,4-dimethoxyphenyl)methyl]-2,3,4,9-tetrahydro-6-methyl-1*H*-pyrido[3,4-*b*]indole, targets 5-HT<sub>2B</sub> receptors (*K*<sub>i</sub> = 0.75 nM), displays selectivity over 5-HT<sub>2C</sub> (*K*<sub>i</sub> = 22 nM) and 5-HT<sub>2A</sub> receptors (*K*<sub>i</sub> = 29 nM). (See LY 266097) 1. Cohen, *et al.* (1996) *Serotonin Res.* **3**, 131. 2. Sevoz-Couche, *et al.* (2000) *Br. J. Pharmacol.* **131**, 1445. 3. Niebert, *et al.* (2011) *PLoS One* **6**, e21395.

## LY 288513

This (FW = 436.31 g/mol; CAS 147523-65-7; Solubility = 100 mM in DMSO or Ethanol), also named (4*S*,5*R*)-*N*-(4-bromophenyl)-3-oxo-4,5-diphenyl-1-pyrazolidinocarboxamide, targets the Cholecystokinin CCK<sub>2</sub> receptor (IC<sub>50</sub> = 16 nM), a G-protein coupled receptor that binds the peptide hormones cholecystokinin or gastrin. It is a much weaker antagonist (IC<sub>50</sub> > 30,000 nM) for CCK<sub>1</sub> receptors). LY 288513 also displays anxiolytic and antipsychotic properties *in vivo*. **1** Rasmussen, *et al.* (1992) *J. Pharmacol. Exp. Ther.* **264**, 480. **2** Rasmussen, *et al.* (1994) *Ann. N.Y. Acad. Sci.* **713**, 300. **3** Helton, *et al.* (1996) *Pharmacol. Biochem. Behav.* **53**, 493.

## LY 294002

LY 294002

LY 303511

This chromone (FW = 307.34; CASs = 957054-30-7 and 957054-33-0 (hydrochloride); Solubility (25°C): 36 mg/mL DMSO, < 1 mg/mL Water), also known as 2-(4-morpholinyl)-8-phenyl-4*H*-1-benzopyran-4-one, completely inhibits phosphatidylinositol 3-kinase activity (IC<sub>50</sub> = 1.4 μM) and voltage-dependent K<sup>+</sup> channels, but does not inhibit phosphatidylinositol 4-kinase, protein kinase A, protein kinase C, diacylglycerol kinase, and EGF receptor protein-tyrosine kinase. Note that the structural analogue LY 303511 (*i.e.*, 2-(4-piperazinyl)-8-phenyl-4*H*-1-benzopyran-4-one; FW<sub>free-base</sub> = 306.36 g/mol) is inactive as an inhibitor of phosphatidylinositol 3-kinase but will inhibit voltage-dependent K<sup>+</sup> channels. **Target(s)**: casein kinase 2 (1); DNA-dependent protein kinase (2); phosphatidylinositol-4,5 bisphosphate 3-kinase (3-5); phosphatidylinositol 3-kinase (1,6-15); phosphatidylinositol-4-phosphate 3-kinase (16,17); polo kinase (18); voltage-dependent K<sup>+</sup> channel (19). **1** Davies, Reddy, Caivano & Cohen (2000) *Biochem. LY 300164, See *Talampanel*

## LY 311727

This selective phospholipase inhibitor (FW = 430.43 g/mol; CAS 164083-84-5; Solubility: 100 mM in DMSO; 100 mM in 1eq. NaOH), also named [3-[[[3-(2-amino-2-oxoethyl)-2-ethyl-1-(phenylmethyl)-1*H*-indol-5-yl]oxy]propyl]phosphonic acid, targets secreted phospholipase A<sub>2</sub> (sPLA<sub>2</sub>) inhibitor (IC<sub>50</sub> < 1 μM for group IIA PLA<sub>2</sub>; IC<sub>50</sub> < 50 μM for group V PLA<sub>2</sub>), attenuating synthesis of VEGF-mediated platelet-activating factor (*or* PAF) in both Bovine Aortic Endothelial Cells (BAEC) and Human Umbilical Vein Endothelial Cells (HUVEC) BAEC at 100 μM. **1** Schevitz, *et al.* (1995) *Nat. Struct. Biol.* **2**, 429. **2** Bernatchez *et al.* (2001) *Br. J. Pharmacol.* **134**, 197.

## LY 315920

This orally available selective sPLA<sub>2</sub> inhibitor (FW = 380.39 g/mol; CAS 172732-68-2; Solubility: 100 mM DMSO), also known as Varespladib and 2-[[[3-(2-amino-2-oxoacetyl)-2-ethyl-1-(phenylmethyl)-1*H*-indol-4-yl]oxy]acetate, targets secreted phospholipase A<sub>2</sub> (IC<sub>50</sub> = 50-750 nM for a range of sPLA<sub>2</sub> isoforms), but has no effect on cytosolic PLA<sub>2</sub>, COX-1, or COX-2. LY 315920 attenuates sPLA<sub>2</sub>-induced thromboxane formation in bronchoalveolar lavage (BAL) cells. It also suppresses sPLA<sub>2</sub>-induced contractions of lung pleural strips studied *ex vivo*. **1** Snyder, *et al.* (1999) *J. Pharmacol. Exp. Ther.* **288**, 1117. **2** Oslund, *et al.* (2008) *J. Med. Chem.* **51**, 4708.

## LY 320135

This potent cannabinoid receptor antagonist/inverse-agonist (FW = 383.40 g/mol; CAS 176977-56-3; Solubility: 30 mM in DMSO), also named 4-[[6-methoxy-2-(4-methoxyphenyl)-3-benzofuranyl]carbonyl]benzotrile, targets CB<sub>1</sub> receptors (K<sub>i</sub> = 141 nM), showing >70x selectivity over CB<sub>2</sub> receptors (K<sub>i</sub> > 10 μM). LY-320135 shows weak binding to both 5-HT<sub>2</sub> (K<sub>i</sub> = 6.4 μM) and muscarinic receptors (K<sub>i</sub> = 2.1 μM). **1** Felder, *et al.* (1998) *J. Pharmacol. Exp. Ther.* **284**, 291. **2** Holland, *et al.* (1999) *Brit. J. Pharmacol.* **128**, 597. **3** Pertwee (2005) *Life Sci.* **76**, 1307.

LY333328, See *Oritavancin*

## LY 333531

This isozyme-selective PKC inhibitor (FW = 466.58 g/mol; CAS 169939-93-9; Solubility: 20 mM in DMSO) competitively and reversibly inhibits protein kinase- $\beta$ I, or PKC $\beta$ I (IC<sub>50</sub> = 4.7 nM) and PKC $\beta$ II (IC<sub>50</sub> = 5.9 nM), with strong selectivity for PKC $\beta$  with respect to isozymes PKC- $\eta$  (IC<sub>50</sub> = 0.052  $\mu$ M), PKC- $\delta$  (IC<sub>50</sub> = 0.25  $\mu$ M), PKC- $\gamma$  (IC<sub>50</sub> = 0.30  $\mu$ M), PKC- $\alpha$  (IC<sub>50</sub> = 0.36  $\mu$ M), PKC- $\epsilon$  (IC<sub>50</sub> = 0.60  $\mu$ M), and PKC- $\zeta$  (IC<sub>50</sub> = >100  $\mu$ M). **1.** Jirousek, *et al.* (1996) *J. Med. Chem.* **39**, 2664. **2.** Samokhin, *et al.* (1999) *Eur. J. Pharmacol.* **386**, 297. **3.** Faul, *et al.* (2003) *Bioorg. Med. Chem. Lett.* **13**, 1857.

LY335979, See Zosuquidar

## LY 341495

This highly potent and selective group II metabotropic glutamate receptor antagonist (FW = 353.37 g/mol; CAS 201943-63-7; Solubility: 10 mM in DMSO with gentle warming; 100 mM in 1.2 equivalents NaOH), also named (2S)-2-amino-2-[(1S,2S)-2-carboxycycloprop-1-yl]-3-(xanth-9-yl)propanoic acid, targets human mGlu<sub>2</sub> receptors (IC<sub>50</sub> = 2.3 nM), mGlu<sub>3</sub> receptors (IC<sub>50</sub> = 1.3 nM), mGlu<sub>8</sub> receptors (IC<sub>50</sub> = 173 nM), mGlu<sub>7a</sub> receptors (IC<sub>50</sub> = 990 nM), mGlu<sub>1a</sub> receptors (IC<sub>50</sub> = 6800 nM), mGlu<sub>5a</sub> receptors (IC<sub>50</sub> = 8200 nM) and mGlu<sub>4a</sub> receptors (IC<sub>50</sub> = 22000 nM) (1-3). Although selective at low-nM concentrations, LY 341495 can be used in higher concentrations to block all hippocampal mGlu receptors (2). LY341495 competitively antagonizes DHPG-stimulated phosphatidylinositol (PI) hydrolysis in AV12-664 cells expressing either human mGlu<sub>1</sub> or mGlu<sub>5</sub> receptors with K<sub>i</sub>-values of 7.0 and 7.6  $\mu$ M, respectively (2). When tested against 10  $\mu$ M L-glutamate-stimulated Ca<sup>2+</sup> mobilisation in rat mGlu<sub>5</sub>-expressing CHO cells, it produces substantial or complete block at a concentration of 100  $\mu$ M. In rat hippocampal slices, LY341495 eliminates 30  $\mu$ M DHPG-stimulated PI hydrolysis and 100  $\mu$ M (1S,3R)-ACPD-inhibition of forskolin-stimulated cAMP formation at concentrations of 100 and 0.03  $\mu$ M, respectively (2). In area CA1 (*Cornu Ammon*, or Ammon's Horn) of the mammalian hippocampus in the medial temporal lobe, it antagonizes DHPG-mediated potentiation of NMDA-induced depolarisations and DHPG-induced long-lasting depression of AMPA receptor-mediated synaptic transmission (2). LY341495 also blocks NMDA receptor-independent depotentiation and setting of a molecular switch involved in the induction of Long-Term Potentiation (LTP), effects previously shown to be blocked by (S)-MCPG. **1.** Kingston, Ornstein, Wright, *et al.* (1998) *Neuropharmacol.* **37**, 1. **2.** Fitzjohn, Bortolotto, Palmer, *et al.* (1998) *Neuropharmacol.* **37**, 1445. **3.** Johnson, Wright, Arnold, *et al.* (1999) *Neuropharmacol.* **38**, 1519.

## LY 367265

This indole-based antidepressant (FW = 454.56 g/mol), also named (1-[2-[4-(6-fluoro-1H-indol-3-yl)-3,6-dihydro-1(2H)-pyridinyl]ethyl]-5,6-dihydro-1H,4H-[1,2,5]thiadiazolo[4,3,2-ij]quinoline-2,2-dioxide), has a high affinity for the 5-hydroxytryptamine transporter (K<sub>i</sub> = 2.3 nM) and is a 5-hydroxytryptamine (HT<sub>2A</sub>) receptor antagonist (K<sub>i</sub> = 0.81 nM). LY 367265 also presynaptically decreases nerve terminal excitability, which subsequently attenuates the Ca<sup>2+</sup> entry through voltage-dependent Ca<sup>2+</sup> channels to cause a decrease in evoked glutamate release (2). **1.** Pullar, Carney, Colvin, *et al.* (2000) *Eur. J. Pharmacol.* **407**, 39. **2.** Wang (2005) *Synapse* **55**, 156.

## LY 367385

This neuroprotective metabotropic glutamate receptor antagonist (FW = 209.2 g/mol; CAS 198419-91-9; Solubility: 100 mM in 1.1 equivalents of NaOH), also named (S)-(+)- $\alpha$ -amino-4-carboxy-2-methylbenzeneacetic acid, selectively targets mGlu<sub>1a</sub> receptors (IC<sub>50</sub> = 8.8  $\mu$ M for quisqualate-induced phosphoinositide hydrolysis), as contrasted with an IC<sub>50</sub> value >100  $\mu$ M for mGlu<sub>5a</sub>. LY 367385 shows negligible effects on group II and III metabotropic glutamate receptors (1). Activation of mGlu<sub>1</sub> receptors appears to contribute to a variety of epileptic syndromes, and antagonists of mGlu<sub>1</sub> receptors show promise as anticonvulsants (2). **1.** Bruno, *et al.* (1999) *Neuropharmacol.* **38**, 199. **2.** Chapman, *et al.* (1999) *Eur. J. Pharmacol.* **368**, 17.

## (±)-LY 395756

This sterically constrained aspartate/glutamate analogue (FW<sub>neutral</sub> = 199.21 g/mol; CAS 852679-66-4; Solubility: 100 mM in 1 equivalent of HCl and to 100 mM in 1 equivalent of NaOH), also named (1S,2S,4R,5R,6S)-rel-2-amino-4-methylbicyclo[3.1.0]-hexane-2,6-dicarboxylic acid, selectively targets mGlu<sub>2</sub> receptors (as agonist, K<sub>3</sub> = 0.165  $\mu$ M) and mGlu<sub>3</sub> receptors (as antagonist, K<sub>i</sub> = 0.302  $\mu$ M). **1.** Dominguez, Prieto, Valli, *et al.* (2005) *J. Med. Chem.* **48**, 3605.

LY-450139, See Semagacestat

## LY 456236

This metabotropic glutamate receptor antagonist (FW = 218.32 g/mol; CAS 338736-46-2; Solubility: 20 mM in DMSO), also named 6-methoxy-*N*-(4-methoxyphenyl)-4-quinazolinamine, selectively targets mGlu<sub>1</sub> receptors (IC<sub>50</sub> = 143 nM), with an IC<sub>50</sub> > 10 μM for mGlu<sub>5</sub> receptors. LY 456246 reduces hyperalgesic behavior induced by formalin in both mouse (ED<sub>50</sub> = 28 mg/kg) and rat (ED<sub>50</sub> = 16 mg/kg). In male and female DBA/2 mice, LY456236 produced a dose-related inhibition of sound-induced clonic-tonic seizures. In male CF1 mice, LY456236 produced a dose-related inhibition of tonic extensor seizures in the threshold electroshock model, and limbic seizures in the 6-Hz focal seizure model. 1. Shannon, Peters & Kingston (2005) *Neuropharmacol.* **49** (Suppl 1), 188.

#### LY2090314

This potent intravenous GSK-3 inhibitor (FW = 512.53 g/mol; CAS 603288-22-8), also named 3-(9-fluoro-2-(piperidine-1-carbonyl)-1,2,3,4-tetrahydro-[1,4]diazepino-[6,7,1-hi]indol-7-yl)-4-(imidazo[1,2-a]pyridin-3-yl)-1*H*-pyrrole-2,5-dione, targets both GSK-3α (IC<sub>50</sub> = 1.5 nM) and GSK-3β (IC<sub>50</sub> = 0.9 nM), with properties that promise to improve the efficacy of platinum-based chemotherapy regimens. In rats and humans, LY2090314 is rapidly cleared by extensive metabolism, with negligible circulating metabolite exposures due to biliary excretion of metabolites into feces and with no apparent intestinal reabsorption (1). While not a time-dependent CYP2B6 inhibitor, LY2090314 significantly reduces CYP2B6 mRNA levels, which significantly correlate with observed changes in catalytic activity (2). Cytotoxicity assays reveal that melanoma cell lines are very sensitive to LY2090314 *in vitro* (IC<sub>50</sub> ~10 nM after 72hr of treatment) in contrast to other solid tumor cell lines (IC<sub>50</sub> >10 μM), as evidenced by caspase activation and PARP cleavage (3). Cell lines harboring mutant B-RAF or N-RAS were equally sensitive to LY2090314 as were those with acquired resistance to the BRAF inhibitor vemurafenib (3). 1. Zamek-Gliszczynski, Abraham, Alberts, *et al.* (2013) *Drug Metab. Dispos.* **41**, 714. 2. Zamek-Gliszczyński, Mohutsky, Rehmel & Ke (2014) *Metab. Dispos.* **42**, 1008. 3. Atkinson, Rank, Zeng, *et al.* (2015) *PLoS One* **10**, :e0125028.

#### LY 2109761

This TGF-β receptor inhibitor (FW = 441.52 g/mol; CAS 700874-71-1; Solubility: <1 mg/mL DMSO, H<sub>2</sub>O, or Ethanol), also named 7-(2-morpholinoethoxy)-4-(2-(pyridin-2-yl)-5,6-dihydro-4*H*-pyrrolo[1,2-*b*]pyrazol-3-yl)quinoline, is a membrane-permeable synthetic compound that selectively targets TGF-β-I (K<sub>i</sub> = 38 nM) and TGF-β-II (K<sub>i</sub> = 300 nM) receptors, thereby reducing Smad2 phosphorylation (1-3). LY2109761 significantly inhibited the L3.6pl/GLT soft agar growth, suppressed both basal and TGF-β1-induced cell migration and invasion, and induced anoikis. When administered in combination with gemcitabine, LY2109761 significantly reduced the tumor burden, prolonged survival, and reduced spontaneous abdominal metastases (1). LY2109761 likewise blocks migration and invasion of hepatocellular carcinoma (HCC) cells by up-regulating E-cadherin (2). In an orthotopic intracranial model for glioblastoma multiforme, or GBM, LY2109761 significantly reduces tumor

growth, prolongs survival, and extends the prolongation of survival induced by radiation (3). Histologic analyses revealed that LY2109761 inhibited tumor invasion promoted by radiation, reduced tumor microvessel density, and attenuated mesenchymal transition (3). 1. Melisi, Ishiyama, Sclabas, *et al.* (2008) *Mol. Cancer Ther.* **7**, 829. 2. Fransvea, Angelotti, Antonaci & Giannelli (2008) *Hepatology* **47**, 1557. 3. Zhang, Kleber, Röhrich, *et al.* (2011) *Cancer Res.* **71**, 7155.

#### LY 2157299

This novel and orally available TGF-β signal transduction inhibitor (FW = 369.44 g/mol; CAS 700874-72-2; λ<sub>max</sub> at 238 and 282 nm), 4-[5,6-dihydro-2-(6-methyl-2-pyridinyl)-4*H*-pyrrolo[1,2-*b*]pyrazol-3-yl]-6-quinolinecarboxamide, targets TGF-β receptor type 1 kinase (IC<sub>50</sub> = 56 nM) (1) and chemotherapy-induced expansion of cancer stem-like cells in triple negative breast cancer cell lines and xenografts (2). By disrupting Smad-2 phosphorylation, LY2157299 inhibits migration and growth of hepatocellular carcinoma cells (3). TGF-β signaling helps to orchestrate a favorable microenvironment for tumor cell growth and to promote epithelial-mesenchymal transition (EMT) (4). TGF-β promotes hepatocellular carcinoma progression by an intrinsic activity as an autocrine/paracrine growth factor and also by an extrinsic activity by inducing microenvironment changes, including cancer-associated fibroblasts, T regulatory cells, and inflammatory mediators. Intriguingly, TGF-β signaling inhibitors can actually promote tumor progression under some conditions (4). Briefly, when Panc-1 pancreatic carcinoma cells and normal fibroblasts are placed atop a three-dimensional (3D) collagen gel, tumor cells scatter into the fibroblast layer, apparently undergoing epithelial-mesenchymal transition. However, when fibroblasts are first placed within collagen gel, Panc-1 cells actively invade the gel, extending long microtubule-based protrusions. Although TGF-β and HGF individually stimulate tumor cell invasion into collagen gel without fibroblasts, LY-2157299 significantly enhances Panc-1 cell invasion into fibroblast cocultures. 1. Bueno, de Alwis, Pitou, *et al.* (2008) *Eur. J. Cancer.* **44**, 142. 2. Bholá, Balko, Dugger, *et al.* (2013) *J. Clin. Invest.* **123**, 1348. 3. Cell Res.* **27**, 167.

#### LY2183240

This nonspecific endocannabinoid transport inhibitor (FW = 307.35 g/mol; CAS 874902-19-9; IUPAC Name: *N,N*-dimethyl-5-[(4-biphenyl)methyl]tetrazole-1-carboxamide) disrupts cellular uptake (IC<sub>50</sub> = 270 pM) of anandamide, an endogenous cannabinoid (EC) neurotransmitter, thereby giving rise to its analgesic and anxiolytic effects. LY2183240 covalently inactivates the EC-degrading enzyme fatty acid amide hydrolase (FAAH) by carbamylation of Serine-241, an active-site nucleophile (1). Activity-based proteomic screening of LY2183240 identified forty other serine hydrolase targets. Thus, while the blockade of anandamide uptake by LY2183240 may be due to FAAH inactivation, this inhibitor's promiscuity greatly limits its potential as a drug. 1. Alexander & Cravatt (2006) *J. Am. Chem. Soc.* **128**, 9699.

## LY 2365109

This potent GlyT<sub>1</sub> inhibitor (FW = g/mol; CAS 868265-28-5; Solubility: 100 mM in DMSO; 50 mM in Ethanol), also named *N*-[2-[4-(1,3-benzodioxol-5-yl)-2-(1,1-dimethylethyl)phenoxy]ethyl]-*N*-methylglycine, selectively targets the glycine transporter 1 (GlyT<sub>1</sub>) inhibitor (IC<sub>50</sub> = 15.8 nM), with far weaker action on GlyT<sub>2</sub> (IC<sub>50</sub> > 30,000 nM). LY 2365109 induces a dose-dependent elevation in CSF levels of glycine, and enhances acetylcholine and dopamine release in the striatum and prefrontal cortex, respectively, profoundly impairing locomotor and respiratory function at higher doses. 1. Perry, Falcone, Fell, *et al.* (2008) *Neuropharmacol.* **55**, 743.

## LY 2389575

This selective negative allosteric mGlu modulator (FW = 402.12 g/mol; CAS 885104-09-6; Solubility: 20 mM in DMSO), also named (3*S*)-*N*-(2,4-dichlorobenzyl)-1-(5-bromopyrimidin-2-yl)pyrrolidin-3-amine, targets the metabotropic glutamate receptor, *or* mGlu<sub>3</sub> (IC<sub>50</sub> = 190 nM), exhibiting > 65x weaker action against other mGlu receptors. LY 2389575 abolishes the neuroprotective action of LY 379268 against amyloid- $\beta$  toxicity in mixed cortical neuronal and astrocyte cell cultures. 1. Caraci, Molinaro, Battaglia, *et al.* (2011) *Mol. Pharmacol.* **79**, 618.

LY2523355, See *Litronesib*

## LY2584702

This potent and highly selective ATP-competitive protein kinase inhibitor (FW<sub>free-base</sub> = 445.43 g/mol; FW<sub>tosylate-salt</sub> = 617.62 g/mol; CAS 1082949-68-5), also named 4-{4-[4-(4-fluoro-3-trifluoromethylphenyl)-1-methyl-1H-imidazol-2-yl]piperidin-1-yl}-1H-pyrazolo[3,4-*d*]pyrimidine *p*-toluene sulfonate, targets p70S6K (IC<sub>50</sub> = 4 nM), a serine/threonine kinase that acts downstream of PIP<sub>3</sub> and phosphoinositide-dependent kinase-1 in the PI<sub>3</sub> kinase pathway. Its target substrate is the S6 ribosomal protein, the phosphorylation of which induces protein synthesis.

## LY2784544

This potent, selective and ATP-competitive tyrosine kinase inhibitor (FW = 469.95 g/mol; CAS 1229236-86-5; Solubility: 94 mg/mL in DMSO), also named 3-(4-chloro-2-fluorobenzyl)-2-methyl-*N*-(3-methyl-1*H*-pyrazol-5-yl)-8-(morpholinomethyl)imidazo-[1,2-*b*]pyridazin-6-amine, targets Janus Kinase-2, *or* JAK2, IC<sub>50</sub> = 3 nM, including its Val-617-Phe mutant, with 8x and 20x selectivity in its action against JAK1 and JAK3. 1. Ma, Clayton, Walgren, *et al.* (2013) *Blood Cancer J.* **3**, e109.

LY2835219, See *Abemaciclib*

## LY2940680

This synthetic inhibitor (FW = 512.50 g/mol; CAS 1258861-20-9), systematically named 4-fluoro-*N*-methyl-*N*-(1-(4-(1-methyl-1*H*-pyrazol-5-yl)phthalazin-1-yl)piperidin-4-yl)-2-(trifluoromethyl)benzamide, targets the smoothed (SMO) receptor, a key component in the hedgehog (Hh) signalling transduction pathway that helps maintain normal embryonic development and is also likely to play a role in carcinogenesis. LY2940680 potently inhibits Hh signaling in Daoy, a human medulloblastoma tumor cell line, and C3H10T1/2, a mouse mesenchymal cell line (1). It also inhibits the functional activity of resistant Smo mutant (Asp-473-His) produced by treatment with GDC-0449, another Smo receptor antagonist. LY2940680 induces Caspase-3 activity and reduces proliferation of medulloblastoma tumors. **Mode of Inhibitor Action:** LY2940680 binds to the transmembrane domain of the human SMO receptor, which shares the seven-transmembrane helical fold but lacks most of the conserved motifs for Class A GPCRs (2). Receptor-bound LY2940680 has a canonical GPCR 7TM bundle fold with a short helix VIII packed parallel to the membrane bilayer. The ligand binds at the extracellular end of the seven-transmembrane-helix bundle and forms extensive contacts with the loops. 1. Bender, Hipkind, Capen, *et al.* (2011) *Cancer Res.* **71**, (Supplement 1) Abstract 2819. 2. Wang, Wu, Katritch, *et al.* (2013) *Nature* **497**, 338.

## Lycorine

This photosensitive alkaloid (FW = 287.32 g/mol), isolated from *Lycoris radiata*, *Narcissus tazetta*, *Amaryllis belladonna*, and other members of the *Amaryllidaceae*, is biosynthesized from L-tyrosine and L-phenylalanine. Lycorine is an inhibitor of the peptidyltransferase center and also inhibits ascorbate biosynthesis *in vivo*. **Target(s):** acetylcholinesterase, weakly inhibited (1); L-galactono- $\gamma$ -lactone dehydrogenase (2,3); peptidyltransferase (4); protein biosynthesis, elongation, eukaryotic (4-7). Lycorine also inhibits lipopolysaccharide-induced up-regulation of iNOS and COX-2 by suppressing P38 and STATs activation, thereby increasing the survival rate of mice after LPS challenge (8). 1. ### Lyn Peptide Inhibitor

This stearylated signal transduction inhibitor (FW = 2370.91 g/mol; Sequence: N-Octadecanoyl-YGYRLRRK-WEEKIPNP; CAS 222018-18-0; Solubility: 10 mg/mL in H<sub>2</sub>O) is cell-permeable and blocks Lyn kinase-dependent effects of the IL-5 receptor (1,2). The IL-5, IL-3, and GM-CSF cytokines regulate hematopoietic cell growth, differentiation, and survival. While GM-CSF and IL-3 have broader overlapping hematopoietic activities, IL-5 is eosinophil-specific and plays a central role in eosinophilic inflammation in atopy and asthma (2). Receptors for all three cytokines are composed of a ligand-specific  $\alpha$  chain and a dimer of the common  $\beta$  subunit ( $\alpha$  or  $\beta$ ) that is shared by all three cytokines. Each specific  $\alpha$  chain forms a low-affinity receptor, when bound by its respective ligand, but association with  $\beta$  leads to high-affinity binding. Association of  $\alpha$  and  $\beta$  subunits, as mediated by ligand binding, initiates signaling through the JAK/STAT, Ras/MAPK, and PI3-K signaling pathways (2). Lyn peptide inhibitor blocks the association of Lyn, but not with the  $\beta$  receptor *in situ*, suggest that the N-terminal unique domain of Lyn kinase is important for binding to the  $\beta$  receptor (1). This novel Lyn-binding peptide inhibitor blocks eosinophil differentiation, survival, and airway eosinophilic inflammation (1). 1. Adachi, *et al.* (1999) *J. Immunol.* **163**, 939. 2. Martinez-Moczygemba & Huston (2001) *J. Clin. Invest.* **108**, 1797.

### Lysergic Acid Diethylamide (or LSD)

This potent hallucinogen and widely abused psychedelic agent (FW = 323.44 g/mol; CAS 50-37-3; M.P. = 80-85°C; Symbol: LSD or LSD-25), systematically named (6*aR*,9*R*)-*N,N*-diethyl-7-methyl-4,6,6*a*,7,8,9-hexahydroindolo[4,3-*fg*]quinoline-9-carboxamide, is a semisynthetic product of lysergic acid, the latter a secondary metabolite derived from tryptophan in the parasitic rye fungus *Claviceps purpurea*. First synthesized in 1938 by Albert Hofmann in his search for pharmacologically useful lysergic acid derivatives, its profound psychoactive properties were reported five years later (1). Marketed as Delysid by Sandoz in the 1950s, LSD's psychoactive properties were touted in the popular press as a "mind-expanding" synthetic drug, wherein stimulation of one sensory or cognitive pathway elicits automatic, involuntary experiences in other sensory and/or cognitive pathways. Already widely abused by the early 1960s, its actions soon became the topic of New Age poetry and song. **Pharmacology:** LSD's action is complex, with its mechanisms still incompletely understood (2,3). Although distributed throughout the body, where it alters phosphate

excretion, its main effects are central, altering dopamine excretion, but without effect on the metabolism or retention of other neurotransmitters (4). In humans, metabolism is rapid, and LSD undergoes hydroxylation, oxidation, and glucuronidation. LSD and its metabolites have been quantified in human biological fluids by HPLC and mass spectrometry (4). Numerous studies report nM-affinity for serotonin receptors, affecting nearly all, but showing strongest effects on 5-HT<sub>1A</sub> receptors ( $K_i$  = 1.1 nM) and 5-HT<sub>1B</sub> receptors ( $K_i$  = 4 nM) (3). **LSD-induced Euphoria:** At moderate doses (75–150  $\mu$ g p.o.), LSD alters one's perceptions, as indicated by euphoria, enhanced introspection, hypnagogic experiences, lost sense of time, and often wild and colorful dreams/hallucinations. First effects (dilated pupils, altered heart rate and blood pressure, and fluctuations in body temperature, including sweats or chills) typically occur within 30–90 minutes, soon impairing objectivity and judgement. Hallucinations often ensue, with visual perception of objects becoming distorted in size and shape, movements accentuated, colors more vivid, and sounds amplified. Some sensations are said to be strangely pleasurable (encouraging further use), but many individuals "have a bad trip", attended by mood swings, profound confusion, fright, extreme paranoia, and delirious flashbacks. Users quickly develop a high degree of tolerance and need higher doses to induce LSD's much-vaunted euphoria. **Target(s):** acetylcholinesterase (3,5); aryl-acylamidase (5,6); cholinesterase (7,8); serotonin receptors (9–11). 1. ### $\delta$ -Lysin

This 26-residue, N-formylated oligopeptide (MW = 3048.63 g; Sequence: N-formyl-MAQEIIISTIGELVKWIIETVNVKFK-TKK; Soluble in both aqueous and organic solvents such as chloroform/methanol) is a hemolytic peptide toxin secreted by *Staphylococcus aureus* that forms an amphipathic helix upon binding to lipid bilayers.  $\delta$ -Lysin aggregates in aqueous solution at concentrations  $\geq 1$   $\mu$ M, forming dimers, trimers and tetramers. Lysin insertion is strongly dependent on the peptide-to-lipid ratio, suggesting that association of a critical number of monomers on/within the membrane is required for activity. There is no evidence of a stable membrane-inserted pore; instead, the peptide appears to cross the membrane rapidly and reversibly, mediating the release of the lipid vesicle contents in the process. 1. Pokorny, Birkbeck & Almeida (2002) *Biochemistry* **41**, 11044.

### L-Lysine

This dibasic amino acid (FW<sub>free-base</sub> = 146.19 g/mol; Symbols: Lys and K; pK<sub>a</sub> values = 2.16 ( $\alpha$ -COOH), 9.06 ( $\alpha$ -NH<sub>2</sub>), and 10.54 ( $\epsilon$ -amino group) at 25°C; Specific Rotation = +25.9° at 25°C for the D-line), systematically named (S)-2,6-diaminohexanoic acid is one of the twenty proteogenic amino acids and is nutritionally essential for mammals. There are two codons: AAA and AAG. The side-chain of lysine consists of a hydrophobic chain of four methylene groups, ending with a charged amino group. Hence, most lysyl residues in proteins are on the protein surface, but the alkyl chain can make hydrophobic interactions. The  $\epsilon$ -amino group is protonated under most physiological conditions. A small fraction is always unprotonated and can act as a nucleophile. This amino group can thus become acylated, alkylated, arylated, and amidated. Lysines are found frequently in  $\alpha$ -helices. Those in collagens are often hydroxylated at the C5 position. In homologous proteins, lysyl residues are often interchanged with arginyl, asparaginyl, threonyl, seryl, and glutaminyl residues. **Target(s):** acetylcholinesterase (weakly inhibited) (1); alkaline phosphatase (2);  $\alpha$ -aminoadipate-semialdehyde dehydrogenase (3,4); 2-aminohexano-6-lactam

racemase (5); aminolevulinic aminotransferase, weakly inhibited (93); aminopeptidase B (6,70-72); 5 aminovalerate aminotransferase (93); D-arginase (7); arginase (8-20); arginine decarboxylase (21-24); arginine deaminase (25); arginine kinase, weakly inhibited (74); aspartate kinase (13,26,27,75-88); carboxypeptidase B (28); carboxypeptidase E (28); coagulation factor VIIa (30); L-cystine transport (31); 2-dehydro-3-deoxyglucuronate aldolase, or 2-keto-3-deoxyglucuronate aldolase (32); diamminopimelate decarboxylase (33); dihydrodipicolinate synthase (34-42); dipeptidyl-peptidase IV (43); GfMEP, or thermostable lysine-specific metalloendopeptidase (44,45); glutamate decarboxylase, mildly inhibited (56); glutamine synthetase (47);  $\gamma$ -glutamyl transpeptidase (48,49); histidine ammonia-lyase, weakly inhibited (13); homocitrate synthase (50,51,95-103); homoserine kinase (52,91); hydroxyllysine kinase (89,90); kynureninase (53-55); leucyl aminopeptidase (73); leucyltransferase (105); 15-lipoxygenase, or arachidonate 15-lipoxygenase (109); lipoxygenase, soybean, weakly inhibited (109); lysine carboxypeptidase, or lysine(arginine) carboxypeptidase, or carboxypeptidase N (56,57); D-ornithine 4,5 aminomutase, weakly inhibited (58); ornithine aminotransferase (94); ornithine carbamoyltransferase (59,106,107); ornithine decarboxylase (60-63); penicillopepsin (64); peptidyl-Lys metalloendopeptidase (*Armillaria mellea* protease) (44,45,65); procollagen C-endopeptidase (66-68); protein-glutamine  $\gamma$ -glutamyltransferase, or transglutaminase (104); [ribulose-bisphosphate carboxylase]-lysine N-methyltransferase (108); Xaa-Arg Dipeptidase, or aminoacyl-lysine dipeptidase (69). 1. #### L-Lysyl-D-amphetamine

This fatigue-reducing amphetamine prodrug (FW = 263.38 g/mol; CAS 608137-32-2), also named L-lysine-dextroamphetamine, (2*S*)-2,6-diamino-*N*-[(2*S*)-1-phenylpropan-2-yl]hexanamide, lisdexamfetamine, and Vyvanse, is metabolized to D-amphetamine (or dextroamphetamine), a CNS stimulant. L-lysine-dextroamphetamine is prescribed for the treatment of Attention Deficit Hyperactivity Disorder (ADHD) and narcolepsy. Amphetamine's augmentation of synaptic monoamine concentrations is mediated mainly by monoamine release, an effect that is complemented by reuptake inhibition as well as inhibition of monoamine oxidase (MAO). Given the need to set a narrow concentration range for circulating lisdexamfetamine, Vyvanse® is available 10-mg, 20-mg, 30-mg, 40-mg, 50-mg, 60-mg, and 70 mg doses. As an amphetamine precursor, lisdexamfetamine is a Class B/Schedule II substance in the United Kingdom and a Schedule II controlled substance in the United States (DEA Number: 1205). See also *Methamphetamine*

### Lysophosphatidate (Lysophosphatidic Acid)

1-Palmitoyl-*sn*-glycerol 3-phosphate

These fatty acetyl-glycerophosphate derivatives (FW = 409.48 g/mol for 1-palmitoyl-*sn*-glycerol 3-P), also called acylglycerophosphates, in which one of the hydroxyl groups is esterified to a fatty acid. Note that the term does not stipulate which hydroxyl group is acylated nor the location of the phosphoryl group. Nevertheless, unless otherwise stated below, lysophosphatidate is assumed to refer to 1-monoacyl-*sn*-glycerol 3-P. (**See also specific compound**) **Target(s):** adenylyl cyclase, inhibited by 1-oleoyl-*sn*-glycerol 3-phosphate (1); alkylglycerophospho-ethanolamine phosphodiesterase, lysophospholipase D (2); carboxylesterase (3); ceramidase (4); DNA-directed DNA polymerase (5); DNA polymerase  $\alpha$  (5); dolichyl-phosphatase (6,7); glycerol-3-phosphate *O*-acyltransferase (8); glycosylphosphatidylinositol-specific phospholipase D (9); Lysophospholipase (10,11); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (12); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (13); phosphatidylinositol 3-kinase (14,15); polar-amino-acid-transporting ATPase, or histidine permease (16); sphingomyelin phosphodiesterase (17). 1. ### Lysophosphatidylethanolamine

1-Palmitoyl-*sn*-glycerol 3-phosphoethanolamine

This naturally occurring lysophospholipid, or LPL (FW<sub>palmitoyl-ester</sub> = 453.56 g/mol), itself a product of the phospholipase A action on other membrane-associated phospholipids, functions as a mediator through G-protein-coupled receptors. It also retards the senescence of leaves, flowers, and postharvest fruits. **Target(s):**  $\alpha$ -N-acetylneuraminase  $\alpha$ -2,8-sialyltransferase (1); diacylglycerol *O* acyltransferase (2); 1,3- $\beta$ -glucan synthase (3); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase, weakly inhibited (4); phosphatidate phosphatase (5); phospholipase D (noncompetitive) (6); steryl- $\beta$ -glucosidase (7). 1. Eppler, Morr e & Keenan (1980) *Biochim. Biophys. Acta* **619**, 318. 2. Parthasarathy, Murari, Crilly & Baumann (1981) *Biochim. Biophys. Acta* **664**, 249. 3. ### *N*-[*N*-(*L*-Lysyl-*L*-prolyl-*L*-leucyl-*L*-glutamyl)-(2-amino-3-phenylpropyl)]-*L*-tyrosyl-*L*-arginyl-*L*-valine

This peptidomimetic inhibitor (FW = 1066.34 g/mol; *Sequence*: KPLEF ΨYRV, containing a nonhydrolyzable methyleneamino component, designated Ψ) inhibits cathepsin D,  $K_i$  = 8.5 nM, plasmepsin-2,  $K_i$  = 19.5  $\mu$ M, and plasmepsin-4 ( $K_i$  = 0.48 nM). 1. Beyer, Johnson, Chung, *et al.* (2005) *Biochemistry* **44**, 1768.

### D-Lyxose

This reducing aldopentose (FW = 150.13 g/mol; *Abbreviation* = Lyx), also known as D-lyxo-pentose, is a rare sugar and epimer of D-xylose, D-arabinose, and L-ribose. Note that it is a structural homologue of D-mannose. It is a substrate of the reaction catalyzed by D-lyxose ketol-isomerase and is an alternative substrate of mannose isomerase. Approximately 70% of D-lyxose is present as the  $\alpha$ -pyranose structure at 31°C in D<sub>2</sub>O, with 28% as the  $\beta$ -pyranose, 1.5% as the  $\alpha$ -furanose, and 0.5% as the  $\beta$ -furanose). **Target(s):**  $\beta$ -galactosidase (1-3); glucokinase (4,5);  $\alpha$ -glucosidase, weakly inhibited (6);  $\beta$ -glucosidase (7); hexokinase (8-10), where lyxose not only competes with hexose substrates, but also induces a conformational change in yeast hexokinase that greatly activates the enzyme's intrinsic ATPase activity (9); D-xylose dehydrogenase (11); xylose isomerase (12-15). 1. # - M -

**M**, See Methionine; Also used to represent a Methyl group, when indicating an epigenetic mark.

## M 25

This Smoothed receptor antagonist (FW = 379.50 g/mol; Solubility: 100 mM in DMSO; 100 mM in Ethanol), also named *N*-[[1-(2-methoxyphenyl)-1*H*-indazol-5-yl]methyl]-2-propylpentanamide, targets the Hedgehog signaling pathway, inhibiting Shh-induced Gli luciferase reporter activity in Shh-light 2 cells ( $IC_{50}$  = 5 nM) (1) and antagonizing GSA-10 ( $IC_{50}$  = 69 nM) and GSA-10 (or propyl 4-(1-hexyl-4-hydroxy-2-oxo-1,2-dihydroquinoline-3-carboxamido) benzoate) ( $IC_{50}$  = 115 nM) -mediated differentiation of the C3H10T1/2 cell line (2). 1. Dessole, Branca, Ferrigno, *et al.* (2009) *Bioorg. Med. Chem. Lett.* **19**, 4191. 2. Gorjankina, Hoch, Faure, *et al.* (2013) *Mol. Pharmacol.* **83**, 1020.

## M 084

This TRPC4/5 channel blocker (FW<sub>HCl-Salt</sub> = 225.72 g/mol; Solubility: 100 mM in water; 100 mM in DMSO), also named *N*-butyl-1*H*-benzimidazol-2-amine, targets Transient Receptor Potential Canonical (TRPC) channels TRPC4 ( $IC_{50}$  = 3.7-10.3  $\mu$ M) TRPC5 ( $IC_{50}$  = 8.2  $\mu$ M), while weakly blockong TRPC3 channels (1). These channels are non-selective cation channels that mediate Na<sup>+</sup> and Ca<sup>2+</sup> entry into cells, leading to membrane depolarization and an increase in intracellular Ca<sup>2+</sup> concentration ([Ca<sup>2+</sup>]<sub>i</sub>). A rise in Na<sup>+</sup> level at the cytoplasmic side may also be an important factor for Na<sup>+</sup>-dependent transport. Because PLC activation is commonly achieved by the stimulation of GPCRs or receptor tyrosine kinases, the TRPC channels are often referred to as receptor-operated channels. In mice subjected to chronic unpredictable stress, M084 treatment reverses the enhanced immobility time in forced swim test and decreases the latency to feed in novelty suppressed feeding test (2). M084 treatment increases BDNF expression in both mRNA and protein levels, as well as phosphorylation levels of AKT and ERK, in prefrontal cortex. Such findings suggest that M084 exerts rapid antidepressant and anxiolytic-like effects at least in part by acting on BDNF and its downstream signaling. 1. Shu, Lu, Qu, *et al.* (2015) *Br J Pharmacol.* **172**, 3495. 2. Yang, Jiang, Wu, *et al.* (2015) *PLoS One* **10**, e0136255.

## M344

This HDAC inhibitor and antiproliferative agent (FW = 307.19 g/mol; CAS 251456-60-7; Solubility: 100 mM in DMSO), also named 4-(diethylamino)-*N*-[7-(hydroxyamino)-7-oxoheptyl]benzamide, targets histone deacetylase ( $IC_{50}$  = 100 nM), inducing terminal cell differentiation. M344 up-regulates SMN2 protein expression in fibroblast cells derived from SMA patients up to 7x after 64 h of treatment (1). Moreover, M344 significantly raises the

total number of gems/nucleus as well as the number of nuclei that contain gems. Treatment with M-344 give rise to hyperacetylated histone H4. M-344 suppresses the growth of human endometrial and ovarian cancer cells by inducing cell cycle arrest and apoptosis (2). 1. Riessland, Brichta, Hahnen & Wirth (2006) *Hum. Genet.* **120**, 101. 2. Takai, Ueda, Nishida, Nasu & Narahara (2006) *Gynecol. Oncol.* **101**, 108.

## M617

This selective GAL<sub>1</sub> agonist (FW = 2361.68 g/mol; CAS 1172089-00-7; Sequence: GWTLNSAGYLLGPQPPGFSPFR-NH<sub>2</sub>; Soluble to 1 mg/mL in H<sub>2</sub>O), also named Galanin(1-13)-Gln<sup>14</sup>-bradykinin(2-9)amide, targets galanin GAL<sub>1</sub> receptor ( $K_i$  = 0.23 nM), with lowere activity against GAL<sub>2</sub> receptors ( $K_i$  = 5.71 nM). M617 enhances food consumption in rats, following intracerebroventricular administration, and reduces CAP-induced inflammatory pain. 1. Lundstrom, *et al.* (2005) *Int. J. Pept. Res. Ther.* **11**, 17. 2. Jimenez-Andrade, *et al.* (2006) *Pharmacol. Biochem. Behav.* **85**, 273. 3. Mazarati, *et al.* (2006) *J. Pharmacol. Exp. Ther.* **318**, 700.

## M871

This GAL<sub>2</sub> antagonist (FW = 2287.64 g/mol; CAS 908844-75-7; Sequence: WTLNSAGYLLGPPEHPPPALALA-NH<sub>2</sub>; Solubility: 1 mg/mL in acetonitrile:H<sub>2</sub>O (30% vol/vol)), also named Galanin-(2-13)-Glu-His-(Pro)<sub>3</sub>-(Ala-Leu)<sub>2</sub>-Ala-amide, selectively targets the galanin GAL<sub>2</sub> receptor antagonist ( $K_i$  = 13 nM) with much weaker action against GAL<sub>1</sub> receptors ( $K_i$  = 420 nM). M871 blocks the pro-nociceptive effect of GAL<sub>2</sub> receptor agonists. 1. Jimenez-Andrade, *et al.* (2006) *Pharmacol. Biochem. Behav.* **85**, 273. 2. Sollenburg, *et al.* (2006) *Int. J. Pept. Res. Ther.* **12**, 115.

## M1145

This GAL<sub>2</sub> agonist (FW = 2774.26 g/mol; CAS 860790-38-1; Sequence: RGRGNWTLNSAGYLLGPVLPALALA-NH<sub>2</sub>; Soluble to 5 mg/mL in H<sub>2</sub>O) potently and selectively targets the galanin receptor-2 ( $EC_{50}$  = 38 nM), with  $K_i$  values of 6.55, 497 and 587 nM for GAL<sub>2</sub>, GAL<sub>3</sub> and GAL<sub>1</sub> respectively. M 1145 yields an agonistic effect *in vitro*, observable as an increase in inositol phosphate (IP) accumulation in the absence or presence of galanin. 1. Runesson, Saar, Lundström, Järv & Langel (2009) *Neuropeptides* **43**, 187.

## MA 2029

This orally active, potent, and competitive motilin receptor antagonist (FW = 556.34 g/mol; CAS 287206-61-5; Solubility: 20 mM in 1eq. HCl; 100 mM in DMSO), also named 4-fluoro-*N*-methyl-L-phenylalanyl-*N*-methyl-L-valyl-3-(1,1-dimethylethyl)-*N*-ethyl-L-tyrosinamide, selectively targets the motilin receptor ( $IC_{50}$  = 4.9 nM) over a range of other receptors and ion channels. Inhibits motilin-induced duodenal muscle contractions *in vitro*. MA-2029 also inhibits motilin-induced colonic and abdominal contractions *in vivo*, but contractile responses to acetylcholine and substance P were unaffected even at 1  $\mu$ M MA-2029. 1. Sudo, Yoshida, Ozaki, *et al.* (2008) *Eur. J. Pharmacol.* **581**, 296.

## mAb100 & mAb114

These enzyme-inhibiting human monoclonal antibodies neutralize Ebola virus, preventing all signs of infection in nonhuman primates exposed to this notoriously contagious virus. Ebola virus glycoprotein (GP) is a Class-I fusion protein comprising disulfide-linked GP1 and GP2 subunits. GP1 binds to the Niemann-Pick C1 receptor, an event that allows GP2-mediated fusion of the viral and host-cell membranes. mAb100 binds to an ectodomain at the base of the chalice-shaped Ebola virus GP trimer, blocking access of cathepsin to its cleavage loop, thereby preventing GP proteolysis that is required for virus entry into host cells. By contrast, monoclonal mAb114 interacts with a different ectodomain on the glycan cap and inner chalice of the glycoprotein, remaining associated after proteolytic removal of the cap and inhibiting GP binding to its receptor. 1. Misasi, Gilman, Kanekiyo, *et al.* (2016) *Science* **351**, 1343.

### Macbecin I

This geldanamycin derivative (FW = 558.67 g/mol; CAS 73341-72-7; Soluble in DMSO), also named (15*R*)-6,17-didemethoxy-15-methoxy-6-methyl-11-*O*-methylgeldanamycin, is an ansamycin-related antibiotic compound that inhibits Hsp90 activity ( $IC_{50}$  = 2  $\mu$ M) by binding to the chaperonin ATP-binding site (1-3). Cytocidal changes induced by Macbecin I were also observed in cells which were temporarily prevented from entering mitosis by treatment with known antitumor agents such as 5-fluorouracil, cyclophosphamide, and neocarzinostatin, whereas such cytotoxicity was not observed in cells which were arrested in metaphase by treatment with ansamitocin P-3 (1). Cytotoxicity is observed at  $\geq$  0.1  $\mu$ g Macbecin I per mL. Macbecin I exhibits antitumor and cytotoxic activities ( $IC_{50}$  ~ 0.4  $\mu$ M) by blocking the folding of key oncogenic client proteins, including ErbB2 and cRaf1. Macbecin I displays higher affinity and potency than geldanamycin (2). (See also *Alvespimycin*; *Ansamycin*; *Deguelin*; *Derrubone*; *Ganetespib*; *Geldanamycin*; *Herbimycin*; *Radicicol*; *Tanespimycin*; and the nonansamycin Hsp90 inhibitor KW-2478) 1. Ono, Kozai & Ootsu (1982) *Gann.* **73**, 938. 2. Martin, Gaisser, Challis, *et al.* (2008) *J. Med. Chem.* **51**, 2853.

### Macitentan

Macitentan (R = CH<sub>2</sub>CH<sub>2</sub>CH<sub>2</sub>-) and ACT-132577 (R = H-)

This orally active, tissue-targeting, dual endothelin receptor antagonist (FW = 585.96 g/mol; CAS 441798-33-0; *n*-octanol/H<sub>2</sub>O distribution coefficient = 800), also called Actelion-1, ACT-064992, Opsumit<sup>®</sup>, *N*-[5-(4-bromophenyl)-6-(2-(5-bromopyrimidin-2-yloxy)ethoxy)pyrimidin-4-yl]-*N'*-propylaminosulfonamide, is metabolized into the pharmacologically active major metabolite, ACT-132577 (FW = 546.19 g/mol) (1,2). Macitentan and ACT-132577 antagonize the specific binding of ET-1 on membranes of cells overexpressing ET<sub>A</sub> and ET<sub>B</sub> receptors and blunt ET-1-induced calcium mobilization in various natural cell lines, with  $IC_{50}$  values of 0.2 nM for ET<sub>A</sub> and 381 nM for ET<sub>B</sub> (1,2). For ACT-132577,  $IC_{50}$  values were 3.4 nM for ET<sub>A</sub> and 987 nM for ET<sub>B</sub>. In functional assays, both macitentan and ACT-132577 inhibited ET-1-induced contractions in isolated endothelium-denuded rat aorta (ET<sub>A</sub> receptors) and sarafotoxin S6c-induced contractions in isolated rat trachea (ET<sub>B</sub> receptors) (3). In October 2013, Opsumit was approved by the U.S. FDA for the treatment of pulmonary arterial hypertension. 1. Iglarz, Binkert, Morrison, *et al.* (2008) *J. Pharmacol. Exptl. Ther.* **327**, 736. 2. Sidharta, van Giersbergen & Dingemans (2013) *J. Clin. Pharmacol.* **53**, 1131. 3. Bolli, Boss, Binkert, *et al.* (2012) *J. Med. Chem.* **55**, 7849.

### Macrophage Migration Inhibitory Factor

This pluripotent catalytic cytokine and upstream mediator of the inflammatory pathway (MW = 12,476 g; Sequence: MPMFIVNTNV PRASVPDGLSELTQQLAQATGKPPQYIAVHVVPDQLMAFGGSSEP CALCSLHSIGKIGGAQNRYSKLLCGLLAERLRISPDVYINYYDMN AANVGWNNSTFA), also known as MIF and Glycosylation-Inhibiting Factor (*or* GIF), plays a pivotal role in systemic as well as local inflammatory and immune responses. First identified as a T cell-derived lymphokine that inhibits the random migration of macrophages out of capillary tubes *in vitro* (1,2) MIF enhances adherence, phagocytosis, and tumoricidal activity (3-6). MIF is also expressed in a variety other cells, indicating its broader involvement within and beyond the immune system (7,8). MIF functions as an anterior pituitary-derived hormone and a glucocorticoid-induced immunomodulator (9). MIF inhibitory action is itself inhibited by p425 (See p425). While lacking any significant primary

sequence homology, MIF shares homologous three-dimensional features with several catabolic enzymes involved in the degradation of aromatic compounds. MIF also catalyzes tautomerization of 2-carboxy-2,3-dihydroindole-5,6-quinone to form dihydroxyindole carboxylic acid (10). A tautomerase-null MIF gene knock-in mouse model demonstrated that protein-protein interactions, and not enzymatic activity, are most likely required for MIF's role in cell growth regulation (11). **Role in Atherosclerosis:** MIF expression within atheromatous plaques has been closely associated with progression and instability in human disease, and MIF deficiency is known to significantly impair atheroma development in low-density lipoprotein receptor-deficient mice, and inhibition of MIF activity (using an anti-MIF antibody) prevents atherosclerosis in ApoE<sup>-/-</sup> mice (12). Proatherogenic stimuli that promote MIF expression by smooth muscle cells (SMCs) *in vivo* via a Tissue Factor-dependent mechanism. Inhibition of this process completely inhibits MIF secretion and subsequent development of atherosclerosis in mouse models (12). See also *Tissue Factor Pathway Inhibitor* 1. David (1966) *Proc. Natl. Acad. Sci. USA* **56**, 72. 2. Bloom & Bennett (1966) *Science* **153**, 80. 3. Nathan, Karnovsky & David (1971) *J. Exp. Med.* **133**, 1356. 4. Nathan, Remold & David (1973) *J. Exp. ### Macroautophagy Inhibitors

Macroautophagy is the main pathway that cells use to remove damaged cell organelles and/or unused proteins. It is characterized by the formation of a double membrane around the organelle, and this structure is termed an autophagosome. This universal cellular process is cytoprotective, allowing renewal by recycling degraded elements of organelles and proteins. In the canonical starvation-induced macroautophagic pathway, autophagosome formation is induced by class 3 phosphoinositide-3-kinases as well as GTP-regulatory proteins. Indeed, transfection of cells with specific class-specific PI3K antisense oligonucleotides greatly inhibits macroautophagy. Macroautophagy is also inhibited by small interfering RNA targeting key proteins (*e.g.*, Atg5, Atg6/Beclin 1-1, Atg10, or Atg12) and pharmacologically with 3-methyladenine, hydroxychloroquine, bafilomycin A<sub>1</sub>, Gö 6976, monensin, or the ATM kinase inhibitor KU-55933. Cell death occurs by apoptosis, but the extent of cell death can be reduced by stabilizing mitochondrial membranes with Bcl-2, vMIA (a cytomegalovirus-derived gene) or by caspase inhibition (1). Suppression of the ubiquitin-proteasome system by proteasome inhibitors induces macroautophagy through multiple pathways, including: (a) accumulation of ubiquitinated proteins; (b) activation of the IRE1-JNK pathway; (c) proteasomal stabilization of ATF4; (d) inhibition of mTOR signaling; and (e) reduced proteasomal degradation of LC3 (2). 1. Boya, González-Polo, Casares, *et al.* (2005) *Mol. Cell Biol.* **25**, 1025. 2. Wua, Sakamoto, Milanic *et al.* (2010) *Drug Resistance Updates* **13**, 87.

### MAFP

This FAAH inhibitor (FW = 370.24 g/mol; CAS 188404-10-6; Soluble in methyl acetate), also named methyl arachidonyl fluorophosphonate and (5*Z*,8*Z*,11*Z*,14*Z*)-5,8,11,14-eicosatetraenyl-methyl ester phosphonofluoric acid, targets fatty acid amide hydrolase, *or* FAAH, an anandamide amidase ( $IC_{50}$  = 1-3 nM), acting at about 1000x lower concentrations than required for phospholipase A<sub>2</sub> inhibition (1). As a phosphonofluoridate-based inhibitor, MAPF irreversibly modifies an active-site nucleophile in FAAH, with permanent loss of catalytic activity. As such, MAPF is among most potent anandamide amidohydrolase inhibitor described thus far. FAAH is responsible for anandamide hydrolysis ( $IC_{50}$  = 2.5 nM), making MAPF an important inhibitor in endocannabinoid metabolism. MAPF also binds irreversibly to CB<sub>1</sub> cannabinoid receptors ( $IC_{50}$  = 20 nM). In intact neuroblastoma cells, MAPF was also around 1000-fold more potent than arachidonyl trifluoromethyl ketone (*or* Arach-CF<sub>3</sub>), previously the best inhibitor (2). MAPF demonstrates selectivity towards anandamide amidase for which it was approximately 3000 and 30,000-fold more potent than

towards chymotrypsin and trypsin, respectively (1). MAFP displaced [ $^3$ H]CP-55940 binding to the CB1 cannabinoid receptor with an  $IC_{50}$  of 20 nM versus 40 nM for anandamide (1). It binds irreversibly and prevents subsequent binding of the cannabinoid radioligand [ $^3$ H]CP-55940. Subch findings suggest MAFP is a potent and specific inhibitor of anandamide amidase and can interact with the cannabinoid receptors at the cannabinoid binding site. 1. Deutsch, Omeir, Arreaza, *et al.* (1997) *Biochem. Pharmacol.* **53**, 255. 2. Koutek, Prestwich, Howlett, *et al.* (1997) *J. Biol. Chem.* **269**, 22937.

### Magnolol

This biphenyl derivative and free-radical scavenger (FW = 266.34 g/mol; CAS 528-43-8) is an anti-inflammatory agent found in the bark of *Magnolia officinalis*. **Target(s):** 1-alkylglycerophosphocholine *O*-acetyltransferase (1); Ca<sup>2+</sup> channels (2); cyclooxygenase (3,4); histamine release (5); 11 $\beta$ -hydroxysteroid dehydrogenase (6,7); leukotriene A<sub>4</sub> hydrolase (8); leukotriene C<sub>4</sub> synthase (8); 5-lipoxygenase (3,8); phospholipase A<sub>2</sub> (8); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, or ACAT (9); streptococcal glucosyltransferases (10,11). 1. Yamazaki, Sugatani, Fujii, *et al.* (1994) *Biochem. Pharmacol.* **47**, 995. 2. Teng, Yu, Chen, Huang & Huang (1990) *Life Sci.* **47**, 1153. 3. Hsu, Lu, Tsao, *et al.* (2004) *Biochem. ### Maitotoxin

This huge amphipathic polyether toxin (MW = 3425.91; CAS 59392-53-9; Abbreviation: MTX) from the marine, red-tide dinoflagellate (*Gambierdiscus toxicus*) is a pore-former that increases calcium ion uptake, thereby mobilizing internal calcium stores and enhancing Ca<sup>2+</sup>-dependent

phosphoinositide turnover and activating calpain (1,2). With 98 chiral centers, maitotoxin presents a daunting challenge for synthetic chemists. **Primary Mode of Action:** One of Nature's exquisitely potent toxins ( $LD_{50}$  = 25  $\mu$ g/g in mice), maitotoxin's toxicity remained unclear for decades. One clue to MTX action was that its toxic effects are blocked by SKF 96365, typically an inhibitor of receptor-mediated calcium entry (3). It now appears that MTX binds to the plasmalemmal Ca<sup>2+</sup>-ATPase (PMCA) pump, converting the latter into an open calcium ion channel (4). MTX-induced calcium ion currents were significantly reduced in PMCA1-knockdown cells and in fibroblasts from PMCA1(+/-) and PMCA4(-/-) transgenic mice. (See *Palytoxin*) **Targets:** actin cytoskeleton, significant reduction *in vivo* (5); cell cycle progression through the G<sub>1</sub>/S and G<sub>2</sub>/M transitions (6); G-protein  $\alpha$ -subunit guanine nucleotide exchange (7). 1. ### Malachite Green

This cytotoxic, triphenylmethane dye (FW<sub>chloride</sub> = 364.92 g/mol; CAS 569-64-2; Highly soluble in water, forming a blue-green solution), also known as aniline green, basic green 4 and China green, has green color reminiscent of the mineral malachite. Solutions are yellow below pH 2 and colorless at pH 14. Malachite green dissipates mitochondrial membrane potential and oxidative phosphorylation. The reduced metabolite is called leucomalachite green. Malachite green is used to treat and prevent fungal and parasitic infections in the aquaculture industry. **Target(s):** alcohol dehydrogenase, yeast (1); cholinesterase, or butyrylcholinesterase (2); cytochrome P450 monooxygenases (3); DNA-directed DNA polymerase (4); DNA polymerase I (4); F<sub>1</sub> ATPase (5,6); fumarase (7); glutathione *S*-transferase (8,9); oxidative phosphorylation (10,11); urease (12). 1. ### Malaoxon

This strong acetyl- and butyryl-cholinesterase inhibitor (FW = 314.30 g/mol; CAS 1634-78-2; IUPAC Name: diethyl 2-(dimethoxyphosphoryl sulfanyl)butanedioate) is the phosphorothioate that is formed upon hydrolysis of malathion, a once well known insecticide. **Target(s):** acetylcholinesterase (1-5,12-16); acylaminoacylpeptidase, moderately inhibited (6); cholinesterase, or butyrylcholinesterase (3,5,7-9,12); procollagen-lysine 5-dioxygenase, or lysyl hydrolase (10,11). 1. #### D-Malate (D-Malic Acid)

This dicarboxylic acid (FW<sub>free-acid</sub> = 134.09 g/mol; CAS 636-61-3), also known as D-(+)-monohydroxysuccinic acid and (R)-hydroxybutanedioic acid, is not the stereoisomer that participates in the tricarboxylic acid and glyoxylate cycles. The free acid is soluble in water and ethanol, has a melting point of 101°C, and pK<sub>a</sub> values of 3.5 and 5.1. (See also *DL-Malate and DL-Malic Acid*; *L-Malate and L-Malic Acid*) **Target(s)**: acid phosphatase, weakly inhibited (1-4); aspartate ammonia-lyase, K<sub>i</sub> = 0.66 mM (5,6); D-aspartate oxidase (7-9); cyanate hydratase, or cyanase (10); 2,3-diketogulonate reductase (11); fumarase (2,12,13); glutamate decarboxylase, K<sub>i</sub> = 15 mM (14); L-lactate dehydrogenase (cytochrome) (15); L-malate dehydrogenase (16); L-malate transport, as alternative substrate (17); maleate hydratase, as product inhibitor (18,19); malic enzyme (oxaloacetate decarboxylating activity) (20-22); (S)-2-methylmalate dehydratase (23,24); sinapoylglucose:malate O-sinapoyltransferase (25); tartrate decarboxylase (26); D(-)-tartrate dehydratase (27-29); L-(+)-tartrate dehydratase (30); meso-tartrate dehydratase (27). 1. #### L-Malate (L-Malic Acid)

This dicarboxylic acid (FW<sub>free-acid</sub> = 134.09 g/mol; CAS 97-67-6; free acid is soluble in water and ethanol; M.P. = 101°C; pK<sub>1</sub> = 3.40; pK<sub>2</sub> = 5.13), also known as L-(-)-monohydroxysuccinic acid and (S)-hydroxybutanedioic acid, is the stereoisomer that participates in the tricarboxylic acid and glyoxylate cycles. Surprisingly, L-malic acid is actually dextrorotatory at very high concentrations and 20°C. (See also *D-Malate and D-Malic Acid*; *DL-*

*Malate and DL-Malic Acid*) Malate is a substrate for reactions catalyzed by malate dehydrogenase, malate dehydrogenase (oxaloacetate decarboxylating) (known widely as the malic enzyme), malate dehydrogenase (decarboxylating), malate dehydrogenase (oxaloacetate decarboxylating) (NADP<sup>+</sup>), malate dehydrogenase (NADP<sup>+</sup>), malate oxidase, malate dehydrogenase (acceptor), sinapoylglucose:malate O-sinapoyltransferase, and malate:CoA ligase (malyl-CoA synthetase). It is a product of the reactions catalyzed by fumarate hydratase (fumarase), lactate:malate transhydrogenase, and malate synthase. **Target(s)**: acid phosphatase, weakly inhibited (1,67); aspartate aminotransferase (78-80); aspartate ammonia-lyase, very weakly inhibited (2); aspartate carbamoyltransferase (3,84); aspartate kinase (68); D-aspartate oxidase (4); carbamoyl-phosphate synthetase I (5); carboxy-*cis,cis* muconate cyclase (6); catalase (86); citrate (*si*)-synthase, weakly inhibited (83); cyanate hydratase, or cyanase (7); glucose-1,6-bisphosphate synthase, weakly inhibited (69); glutamate decarboxylase, K<sub>i</sub> = 13 mM (8-10); glutamate synthase (11); D-2-hydroxyacid dehydrogenase (12,13); isocitrate lyase (14,15); lactate dehydrogenase (12,16); D-lactate dehydrogenase (17,18); L-lactate dehydrogenase (cytochrome) (17); maleate hydratase (19); malic enzyme (oxaloacetate decarboxylating activity) (20,21); malic enzyme, NAD<sup>+</sup>-dependent (oxaloacetate decarboxylating activity) (22); N-methylglutamate dehydrogenase (23); 2-methyleneglutarate mutase (24,25); nicotinate-nucleotide diphosphorylase (carboxylating) (81,82); nucleotidases (26); oxaloacetate decarboxylase (27-31); pantothenase (32); phosphoenolpyruvate carboxykinase (ATP) (33,34); phosphoenolpyruvate carboxykinase (GTP) (35); phosphoenolpyruvate carboxykinase (36); phosphoenolpyruvate carboxylase (37-51); 6-phosphofructokinase (12,52,53,76,77); phosphoprotein phosphatase (66); phosphoribulokinase (75); procollagen-proline 4-dioxygenase (85); protein phosphatase 2A (66); pyrophosphatase, or inorganic diphosphatase (54,55); pyrophosphate-dependent phosphofructokinase, or diphosphate:fructose-6-phosphate 1-phosphotransferase (70); pyruvate carboxylase (56,57); pyruvate kinase (71-74); succinate dehydrogenase (12,59,60); tartrate decarboxylase, less inhibited than with D-malate (61); D(-)-tartrate dehydratase, weakly inhibited (62,63); L(+) tartrate dehydratase (64); tartronate-semialdehyde reductase, or 2-hydroxy-3-oxopropionate reductase, weakly inhibited (65); thiosulfate sulfurtransferase, or rhodanese (58). 1. #### Maleate (Maleic Acid)

This unsaturated dicarboxylic acid (FW<sub>free-acid</sub> = 116.07 g/mol; CAS 110-16-7; pK<sub>a</sub> values of 1.97 and 6.24), also known as (Z)-butenedioic acid and rarely as toxic acid, is the *cis*-isomer of fumaric acid. The free acid has a melting point of 130-131°C, significantly lower than that of fumaric acid (287°C). Maleic acid isomerizes to fumaric acid, when heated above its melting point. It is soluble in water (78.8 g/100 mL at 25°C), diethyl ether (7.6 g/100 g), and benzene (0.024 g/100 g). Sodium hydrogen maleate and potassium hydrogen maleate are common pH buffers. **Target(s):** 2-(acetamido-methylene)succinate hydrolase (1); acid phosphatase (2,3); aconitase, or aconitate hydratase (4); adenosine-phosphate deaminase (5,6); adenylosuccinate synthetase (7,8); alanine aminotransferase (10,11,113-115); alcohol dehydrogenase (12); aldose reductase (13); D-amino-acid aminotransferase, or D-alanine aminotransferase (9,109); 4-aminobutyrate aminotransferase (110); AMP deaminase (5);  $\alpha$ -amylase, weakly inhibited (14); arylsulfatase (15); asclepain (16,17); aspartate aminotransferase (2,18-25,116-119); aspartate carbamoyltransferase (26-28,127-130); aspartate 4-decarboxylase (29-31); -aspartate oxidase (32); bromelain, weakly inhibited (16); calotropain, or *Calotropis gigantea* latex protease (17); carbamoyl-phosphate synthetase (26); carboxy-*cis*,*cis* muconate cyclase (33); catalase (134); cellulose polysulfatase (34); ceruloplasmin (35); cholinesterase (36,37); citrate (*si*)-synthase, weakly inhibited (124); *p*-coumarate decarboxylase (38); cyanate hydratase, or cyanase (39); cysteine aminotransferase (112); cysteine desulfurase, or cystathionine  $\gamma$ -lyase (40); dehydro-L-gulonate decarboxylase (41); fatty-acid synthase (42,43); formate hydrogen-lyase (44); 5-formyltetrahydrofolate cyclo-ligase, or 5,10-methenyltetrahydrofolate synthetase (45);  $\beta$ -fructofuranosidase, or invertase (105); fumarase (2,46,47); glucose dehydrogenase, weakly inhibited (48); glucose-6-phosphate isomerase, moderately inhibited (49); glutamate decarboxylase, weakly inhibited, K<sub>i</sub> = 18 mM (50,51); glutamate formimidoyltransferase (131);  $\gamma$ -glutamyl transpeptidase, or  $\gamma$ -glutamyltransferase, hydrolase activity is stimulated and transpeptidase activity is inhibited (52 56,125,126); glutathione peroxidase (133);  $\beta$ -glycerophosphatase, or glycerol-2-phosphatase (3); glycine amino-

transferase (57); glycine:oxaloacetate aminotransferase (21,58); glycogen synthase (59); glyoxalase (60); *erythro*-3-hydroxyaspartate ammonia-lyase (58,61); 4-hydroxybenzoate 3-monooxygenase, weakly inhibited (132); 4-hydroxyglutamate aminotransferase (108); [3-hydroxy-3 methylglutaryl-CoA reductase (NADPH)]-phosphatase (106); isocitrate lyase (62-69);  $\alpha$ -ketoglutarate oxidase (70); lactase-phlorizin hydrolase, or glycosylceramidase (104); lactate dehydrogenase, weakly inhibited (71); leucine aminotransferase (111); malate dehydrogenase (70,72); malic enzyme (malate dehydrogenase (decarboxylating), weakly inhibited (73,74); 2-methyleneglutarate mutase (75); myrosulfatase (15); nicotinate-nucleotide diphosphorylase (carboxylating) (120,121); oxaloacetate keto enol tautomerase (76); oxaloacetate tautomerase (77,78); papain (16,60,79); pepsin (80); phenylpyruvate enol-keto tautomerase (81); phosphoenolpyruvate carboxykinase, pyrophosphate-requiring (82); phosphoenolpyruvate carboxylase (83,84); phosphofructokinase (85); phosphoribosylaminoimidazole-succinocarboxamide synthetase (86); polynucleotide 5'-hydroxyl kinase (107); progesterone 11 $\alpha$ -hydroxylase (87); progesterone 11 $\beta$ -hydroxylase (87); proline racemase (88,89); pyrophosphatase, or inorganic diphosphatase (90); pyruvate decarboxylase (91); pyruvate dehydrogenase (92); pyruvate oxidase (92); sterol  $\beta$ -glucosyltransferase (122); succinate dehydrogenase (2,60,93-100); succinate oxidase (92,101); sucrose-phosphate synthase (123); triose phosphate isomerase (102); urease (103). **1.** Huynh & Snell (1985) *J. #### Malformin A<sub>1</sub>

This cyclic peptide antibiotic (FW = 529.73 g/mol; CAS 3022-92-2) from the mycelium of *Aspergillus niger* promotes cell elongation in higher plants as well as malformations of stems and petioles. **Target(s):** interleukin-1 $\beta$  binding to human monocytes, IC<sub>50</sub> = 250 nM (1); protein biosynthesis (2).

#### Malonate (Malonic Acid)

This dicarboxylic acid (FW<sub>free-acid</sub> = 104.06 g/mol; CAS 141-82-2; decomposes ~135°C), is the first agent ever identified as a reversible competitive inhibitor (for succinate dehydrogenase). The free acid is very soluble in water (73.5 g/100 g at 20°C) and ethanol (57 g/100 g at 20°C). The pK<sub>a</sub> values are 2.58 and 5.17 at 37°C. Malonate is produced in the reactions catalyzed by malonate-semialdehyde dehydrogenase and barbiturase. It is also a substrate of the reactions catalyzed by malonate CoA-transferase and malonate decarboxylase. **Target(s):** 2-(acetamidomethylene)succinate hydrolase (1); acetoacetate decarboxylase (2); acid phosphatase (3,4); allophanate hydrolase (5); D-amino-acid oxidase (6); aspartate carbamoyltransferase (7,8); aspartate 4-decarboxylase (9); aspartate kinase (121); D-aspartate oxidase (10,11);  $\gamma$ -butyrobetaine dioxygenase, *or*  $\gamma$ -butyrobetaine hydroxylase, K<sub>i</sub> = 7.0 mM (12); carbamoyl-phosphate synthetase (13); carboxy-*cis,cis*-muconate cyclase (14); choline acetyltransferase (15); creatine kinase (16-18); cyanate hydratase, *or* cyanase (19,20); diamine oxidase (21); diisopropylfluorophosphate (22); dopamine  $\beta$ -monoxygenase (123); fructose-1,6 bisphosphatase (23); 1,3- $\alpha$ -L-fucosidase (118); fumarase, *or* fumarate hydratase (24,25); fumarylacetoacetase (26); glucose-6-phosphate isomerase, weakly inhibited (27);  $\beta$ -glucuronidase (28); glutamate decarboxylase, weakly inhibited, K<sub>i</sub> = 36 mM (29);  $\gamma$ -glutamyl transpeptidase (30); glycogen synthase (31); D-2-hydroxyacid dehydrogenase (3,32); (S)-2-hydroxy-acid oxidase (33,34); 3-hydroxybutyrate dehydrogenase (35); 2-(hydroxymethyl)-3-(acetamidomethylene)succinate hydrolase (1); [3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)]-phosphatase (119); IMP dehydrogenase (36); isocitrate lyase (37-52); kynurenine:2-oxoglutarate aminotransferase (53); lactase (127); D-lactate dehydrogenase (cytochrome) (54); L-lactate dehydrogenase (55-59); lactate 2 monoxygenase (60); lipase (61); malate dehydrogenase (59,62-65); malic enzyme, NAD<sup>+</sup>-dependent (decarboxylating), *or* malate dehydrogenase, NAD<sup>+</sup> (66); malic enzyme (oxaloacetate-decarboxylating activity) (67-70); malonyl-S-ACP:biotin-protein carboxyltransferase (122); N-methylglutamate dehydrogenase (71); NADH oxidase (72); nucleotidases, weakly inhibited (120); oxaloacetate decarboxylase (62,70,73-76); oxaloacetate tautomerase (77,78); 3-oxoacid CoA-transferase, *or* 3-ketoacid CoA-transferase, weakly inhibited (79,80); peptidyl-dipeptidase A, *or* angiotensin I-converting enzyme (117); phosphoenolpyruvate carboxykinase (GTP), weakly inhibited (81); phosphoenolpyruvate carboxylase (82-84); phosphonoacetate hydrolase, weakly inhibited (85); procollagen-lysine 5-dioxygenase (125); procollagen-proline 3-dioxygenase (125); procollagen-proline 4-dioxygenase (86,125,126); pyrophosphatase (87,88); pyruvate carboxylase (89,90); pyruvate kinase (91); ribose-5-phosphate isomerase (92); 3-serine dehydrogenase (93); succinate dehydrogenase (3,56,57,94-110); succinate:3-hydroxy-3-methylglutaryl CoA-transferase (Note: Malonate is an alternative product/substrate (111); succinyl-CoA synthetase (ADP-forming), *or* succinate:CoA ligase (ADP) (112); D-threonine dehydrogenase (113); L-threonine dehydrogenase (114); trimethyllysine dioxygenase (124); triose-phosphate isomerase (115); urease (116). **Malonate Neurotoxicity:** Malonate causes dose-dependent neurotoxicity, both *in vivo* and *in vitro*, via inhibition of succinate dehydrogenase and depletion of striatal ATP stores (128-131) resulting in neuronal depolarization and secondary excitotoxicity (132,133). Malonate also induces mitochondrial potential collapse, swelling, release of cytochrome *c* (Cyt *c*), depletion of glutathione (GSH), and reduction in nicotinamide adenine dinucleotide coenzyme (NAD(P)H) within brain-isolated mitochondria (134). Mitochondrial potential collapse occurs almost immediate after malonate addition, and mitochondrial swelling is evident after 15 min of drug addition (134). The latter effect is blocked by cyclosporin A (CsA), Ruthenium Red (RR), magnesium, catalase, GSH and vitamin E. When added to SH-SY5Y cell cultures, malonate produces a marked loss of cell viability together with the release of Cytochrome *c* and depletion of GSH and NAD(P)H concentrations. All these effects were not apparent in SH-SY5Y cells overexpressing Bcl-xL (134). Taken together, these data suggest that malonate causes a rapid collapse of mitochondrial potential and production

of reactive oxygen species, overwhelming mitochondrial antioxidant capacity and leads to mitochondrial swelling (134). 1. Huynh & Snell (1985) *J. Biol. Chem.* **260**, 2379. 2. #### Malonate Semialdehyde (Malonic Acid Semialdehyde)

This acid aldehyde (FW<sub>free-acid</sub> = 88.06 g/mol), an intermediate in the pyrimidine degradation, is also a product of the reactions catalyzed by β-alanine aminotransferase (or β-alanine:pyruvate transaminase), 3-hydroxypropionate dehydrogenase, 3-*aci*-nitropropanoate oxidase, acetylenecarboxylate hydratase, and *cis*- and *trans*-3-chloroacrylate dehalogenase. Malonate semialdehyde is also a substrate for malonate-semialdehyde dehydrogenase, malonate-semialdehyde dehydrogenase (acetylating), and malonate-semialdehyde dehydratase. **Target(s):** phosphonoacetaldehyde hydrolase (1); succinate-semialdehyde dehydrogenase (NAD(P)<sup>+</sup>) (2). 1. Olsen, Hepburn, Lee, et al. (1992) *Arch. Biochem. Biophys.* **296**, 144. 2. Jakoby (1962) *Meth. Enzymol.* **5**, 765.

#### Malondialdehyde

This mutagenic dialdehyde (FW = 72.06 g/mol; CAS 5578-67-6) is a quantifiable lipid peroxidation end-product of cellular oxidative stress. Lipid peroxidation is a process in which oxidants, such as free radicals, attack unsaturated lipids, especially polyunsaturated fatty acids. The main

primary products of lipid peroxidation are lipid hydroperoxides (LOOH). Among the different aldehydes that form as secondary products of lipid peroxidation are malondialdehyde (MDA), propanal, hexanal, and 4-hydroxynonenal (4-HNE). MDA has been widely used for many years as a convenient biomarker for lipid peroxidation of omega-3 and omega-6 fatty acids because of its facile reaction with 2-thiobarbituric acid (TBA). At low pH and elevated temperature, MDA reacts with TBA, generating the red-colored 1MDA:2TBA ternary adduct (shown below), the fluorescence of which may be used to measure malonaldehyde production.

That said, thiobarbituric acid is notoriously nonspecific, leading to controversy concerning its use in MDA quantification for *in vivo* samples. Better methods for determining free and total MDA include gas chromatography-mass spectrometry (GC-MS), liquid chromatography-mass spectrometry (LC-MS), and other derivitization techniques. Malondialdehyde also reacts with (a) guanidinium groups of arginyl residues in peptides and proteins under strongly acidic conditions and (b) amino groups of deoxyadenosine and guanosine within DNA. **Target(s):** aldehyde dehydrogenase (1); carnitine *O*-acetyltransferase (2); cytochrome P450 (3); glucose-6-phosphate dehydrogenase (4); pancreatic ribonuclease, or ribonuclease A (5,6); xanthine oxidase (7); xanthine oxidoreductase (7). Given the reactivity of this metabolite, this list is likely to under-represent the range of proteins and enzymes that react with malondialdehyde. 1. Hjelle, Grubbs & Petersen (1982) *Toxicol. #### Malonoben

This protonophore (FW = 282.38 g/mol; CAS 10537-47-0; Solubility: 75 mM DMSO), also named SF 6847 and 3,5-di-*tert*-butyl-4-hydroxybenzylidenemalononitrile, is the most powerful known uncoupler of oxidative phosphorylation. See reference (2) for pH-dependence of uncoupling activity, binding to mitochondria, as well as spectral properties in the presence of different types of liposomes, biopolymers and mitochondria, and model membranes. 1. Muraoka & Terada (1972) *Biochim. Biophys. Acta* **275**, 271. 2. Terada (1975) *Biochim. Biophys. Acta* **387**, 519. 3. Terada (1981) *Biochim. Biophys. Acta* **639**, 225.

#### Malonyl-CoA

This hygroscopic thioester (FW = 753.59 g/mol; CAS 524-14-1), itself a key intermediate in fatty-acid biosynthesis, is a product of the reactions catalyzed by acetyl-CoA carboxylase and malonate CoA-transferase. It inhibits the rate-limiting step in  $\beta$ -oxidation of fatty acids. It also regulates the enzyme carnitine acyltransferase, inhibiting fatty acids from combining with carnitine and thereby preventing their entry into mitochondria. Malonyl-CoA is also a substrate of the fatty acid chain-extending reactions catalyzed by fatty-acid synthase and fatty acyl-CoA synthase (*i.e.*, [acyl-carrier protein] *S*-malonyltransferase). Malonyl CoA:Acyl Carrier Protein

transacylase (MCAT) transfers malonate from malonyl-CoA to the terminal thiol of holo-acyl carrier protein (ACP). Malonyl-CoA is also a substrate for naringenin chalcone synthase, erythronolide synthase, trihydroxystilbene synthase, D-tryptophan *N*-malonyltransferase, anthranilate *N*-malonyltransferase, 3,4-dichloroaniline *N*-malonyltransferase, isoflavone-7-*O*- $\beta$ -glucoside 6''-*O*-malonyltransferase, flavonol-3-*O*- $\beta$ -glucoside *O*-malonyltransferase, icosanoyl-CoA synthase, pinosylvin synthase, benzophenone synthase, phloroisovalerophenone synthase, acridone synthase, lovastatin nonaketide synthase, 6-methylsalicylic acid synthase, and malonyl-CoA decarboxylase. **Target(s):** acetyl-CoA carboxylase (1,2); arylamine *N*-acetyltransferase (53); ATP:citrate lyase, or ATP:citrate synthase (3); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or [3-methyl-2 oxobutanoate dehydrogenase (acetyl-transferring)] kinase (4,5); carnitine *O*-acetyltransferase (6,7,52); carnitine *O*-octanoyltransferase (8-15); carnitine *O*-palmitoyltransferase (7,13,16,31-51); enoyl-[acyl carrier-protein] reductase (17); 3-hydroxyisobutyryl-CoA hydrolase (18,19); methylmalonyl-CoA decarboxylase (20); methylmalonyl-CoA epimerase (21); (*S*)-methylmalonyl-CoA hydrolase (22); pantothenate kinase (23-29); propionyl-CoA carboxylase (1); pyruvate carboxylase (30). 1. #### Maltitol

This reduced disaccharide and sweetening agent (FW = 344.31 g/mol; CAS 585-88-6), also known as 4-*O*- $\alpha$ -D-glucopyranosyl-D-sorbitol, inhibits glucoamylase and reportedly activates cyclomaltodextrin glucanotransferase. Maltitol is a high-sweetness, FDA-approved food additive that resists bacterial degradation, ideal for low-calorie hard candy and chewing gum. Many oral pharmaceuticals are likewise sweetened by maltitol. Excessive consumption may have a laxative effect. **Target(s):**  $\alpha$ -amylase (1);  $\beta$ -amylase (2); cyclomaltodextrin glucanotransferase (3); glucan 1,4- $\alpha$  glucosidase, or glucoamylase (1,4,5);  $\alpha$ -1,4-glucan lyase (6); glucoamylase/maltase complex, as a slow alternative substrate (7). **1.** De Mot & Verachtert (1987) *Eur. ### Maltose

This reducing disaccharide (FW = 342.30 g/mol; CAS 69-79-4), also known as 4-*O*- $\alpha$ -D-glucopyranosyl-D-glucose, maltobiose, and malt sugar, is very soluble in water (108 g/100 g at 20°C) and is typically supplied as the monohydrate. Maltose is a substrate of the reactions catalyzed by maltose *O*-acetyltransferase, maltose phosphorylase, sucrose  $\alpha$ -glucosidase, maltose-transporting ATPase, maltase ( $\alpha$ -glucosidase), maltose epimerase, maltose  $\alpha$ -D-glucosyltransferase, and exo-(1,4)- $\alpha$ -D-glucan lyase. It is product of the reactions catalyzed by maltose synthase,  $\beta$ -amylase, glucan 1,4- $\alpha$  maltohydrolase, pullulanase, and limit dextrinase. It is an alternative substrate of hexose oxidase and aldose 1-epimerase. **Target(s):** acetyl-CoA: $\alpha$ -glucosaminide *N*-acetyltransferase, or heparan- $\alpha$ -glucosaminide *N* acetyltransferase (1);  $\beta$ -*N*-acetylhexosaminidase (28); aldose 1-epimerase, or mutarotase (2-4);  $\alpha$ -amylase (5,6,43,44);  $\beta$ -amylase (7,8,39-42); amylo- $\alpha$ -1,6-glucosidase/4- $\alpha$ -glucanotransferase (glycogen debranching enzyme (30); concanavalin A (9); cyclomaltodextrin glucanotransferase (55,56); dextranase, also as a weak alternative substrate (57,58); dextrin Dextranase (59); exo-(1 $\rightarrow$ 4)- $\alpha$ -D-glucan lyase (10);  $\beta$ -fructofuranosidase, or invertase (11,31);  $\beta$ -D-fucosidase (29);  $\beta$ -galactosidase (32-36); GDP mannose 6-dehydrogenase (12); glucan 1,3- $\alpha$ -glucosidase, or glucosidase II, or mannosyl-oligosaccharide glucosidase II (13-16); glucan 1,6- $\alpha$ -isomaltosidase (17); glucokinase (53);  $\beta$ -glucosidase (18,19,37,38); D-glucosyltransferases, *Streptococcus* (20); glycogenin glucosyltransferase, weakly inhibited (54); isoamylase (21); limit dextrinase (22);  $\alpha$ -mannosidase (18,23); membrane-oligosaccharide glycerophosphotransferase (51); mycodextranase (24); phloretin hydrolase (25); riboflavin phosphotransferase (52); sucrose  $\alpha$ -glucosidase, or sucrose-isomaltase (29); sucrose-phosphatase (45-50); thioglucosidase, or myrosinase (26,27). **1.** Bame & Rome (1987) *Meth. ### Mambalgin 1

This analgesic (FW = 6554.51 g/mol; CAS 1609937-15-6; Disulfide bridges: Cys3-Cys19, Cys12-Cys37, Cys41-Cys49, Cys50-Cys55; Soluble to 1 mg/mL H<sub>2</sub>O) is a snake venom toxin from the Black Mamba (*Dendroaspis polylepis*), a deadly African snake from the *Elapidae* family. Mambalgin-1 selectively targets Acid-Sensing Ion Channel-1a, a neuronal voltage-insensitive cationic channel that activated by extracellular protons. Mambalgin-1 binds to closed (inactive) channel, with IC<sub>50</sub> values of 192 and 72 nM for human ASIC1a and ASIC1a/1b dimer, respectively. Mambalgin 1 is selective for ASIC1a versus ASIC2a, ASIC3, TRPV1, P2X<sub>2</sub>, 5-HT<sub>3</sub>, Na<sub>v</sub>1.8, Ca<sub>v</sub>3.2 and K<sub>v</sub>1.2 channels. It increases latency of tail and paw withdrawal in mouse tail-flick and paw-flick tests. **1.** Diochot, Baron, Salinas, et al. (2012) *Nature* **490**, 552.

### Mandelate (Mandelic Acid)

These naturally occurring stereoisomers (FW<sub>free-acid</sub> = 152.15 g/mol; CAS 611-71-2), also known as  $\alpha$ -hydroxybenzeneacetic acid and 2-hydroxy-2-phenylacetic acid, exists naturally. Mandelic acid is slightly photosensitive and has a pK<sub>a</sub> value of 3.37 at 25°C. The free acid is soluble in water (1 g/6.3 mL). Mandelate is a substrate of mandelate 4-monooxygenase and mandelate racemase. The (*R*)-enantiomer is also produced by mandelamide amidase. **Target(s):** L-amino-acid oxidase (1-3); benzoylformate decarboxylase, inhibited by (*R*)- and (*S*)-isomers (4,5); butyryl-CoA

synthetase, or butyrate:CoA ligase, or medium-chain-fatty-acyl-CoA synthetase (6); carboxypeptidase A (7,8); L-lactate dehydrogenase (9,10); L-lactate dehydrogenase (cytochrome) (11-13); D-mandelate dehydrogenase, inhibited by L-mandelate (14); mandelonitrile lyase (15); prunasin  $\beta$ -glucosidase, weakly inhibited (16); pyrophosphatase (17); succinate dehydrogenase, enantiomer not specified (18,19). 1. ### Mandelonitrile

This aromatic cyanohydrin (FW = 133.15 g/mol; CAS 532-28-5; almost insoluble in water), also known as  $\alpha$ -hydroxybenzeneacetonitrile, is a product of the reactions catalyzed by prunasin  $\beta$ -glucosidase and vicianin  $\beta$ -glucosidase as well as a substrate of mandelonitrile lyase, hydroxynitrilase, and cyanohydrin  $\beta$ -glucosyltransferase. The racemic mixture is an oily liquid (M.P. =  $-10^\circ\text{C}$ ), while the optically pure isomers melt at  $28-30^\circ\text{C}$ . Both enantiomers, their racemate, and their  $\beta$ -glycosides are naturally occurring (e.g., mandelonitrile is a component of amygdalin). **See also Prunasin Target(s):** cyanohydrin  $\beta$ -glucosyltransferase (1);  $\alpha,\alpha$ -trehalase (2,3). 1. ### Manganese Ion

Hexaquo-Mn(II) Cation

This divalent cation (Symbol =  $\text{Mn}^{2+}$ ) is the principal ionic form of the Group 7 (or Group VIIA) metal (Atomic Number = 25; Atomic Weight = 54.94), an element, located directly above technetium in the Periodic Table. The ground state electronic configuration of the neutral atom is  $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^5$ . The ionic radii for  $\text{Mn}^{2+}$ ,  $\text{Mn}^{3+}$ ,  $\text{Mn}^{4+}$ , and  $\text{Mn}^{7+}$  are 0.80, 0.66, 0.60, and 0.46 Å, respectively.  $\text{Mn}^{2+}$  is an essential trace element for living organisms and is an important agent in photosynthesis. In mammals,  $\text{Mn}^{2+}$  is transported by DCT1, a divalent cation transporter with unusually broad substrate range that also includes  $\text{Fe}^{2+}$ ,  $\text{Zn}^{2+}$ ,  $\text{Co}^{2+}$ ,  $\text{Cd}^{2+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Ni}^{2+}$  and  $\text{Pb}^{2+}$ . DCT1-mediated active transport is proton-coupled and depends on the cell membrane potential.  $\text{Mn}^{2+}$  substitutes for  $\text{Mg}^{2+}$  in numerous nucleotide-requiring enzyme-catalyzed reactions. It can also replace  $\text{Zn}^{2+}$  in certain zinc-dependent enzymes. The paramagnetic properties of  $\text{Mn}^{2+}$  have exploited it as an atomic-scale, distance-surveying probe of enzyme active sites. 1. ### $\alpha$ -Mangostin

This xanthone (FW = 410.47 g/mol; CAS 6147-11-1), also known as 1,3,6-trihydroxy-7-methoxy-2,8-bis(3-methyl-2-butenyl)-9H xanthone-9-one and NSC30552, is isolated from various parts, including the fruit, of the mangosteen tree (*Garcinia mangostana*). It is a yellow solid that is practically insoluble in water. **Target(s):**  $\text{Ca}^{2+}$ -transporting ATPase (1); cyclic AMP-dependent protein kinase (2); histamine  $\text{H}_1$  receptor (3); HIV-1 protease (4); 12-lipoxygenase, or arachidonate 12-lipoxygenase (5); 15-lipoxygenase, or arachidonate 15-lipoxygenase (5); myosin light-chain kinase (2); sphingomyelin phosphodiesterase, or acid sphingomyelinase (6,7). 1. ### D-Mannitol

This sugar alcohol (FW = 182.17 g/mol; CAS 69-65-8; M.P. =  $166-168^\circ\text{C}$ ), also known as mannite and manna sugar, is found in many microorganisms, algae, and plants, including the manna ash tree (*Fraxinus ornus*) and the edible Tamogi-take mushroom (*Pleurotus cornucopiae*). D-Mannitol has a sweet taste and is very soluble in water (15.6 g/100 mL at  $18^\circ\text{C}$ ) and glycerol (1 g/18 mL). D-Mannitol is a substrate of the reactions catalyzed by mannitol 2-dehydrogenase, mannitol 2-dehydrogenase ( $\text{NADP}^+$ ), mannitol 1-dehydrogenase, mannitol 2-dehydrogenase (cytochrome), and D-mannitol oxidase. It is a product of the reaction catalyzed by mannitol-1-phosphatase.

**Role in Enhancing Antibiotic Susceptibility in Persister-Containing Biofilms:** Antibiotic failure in clearing *Pseudomonas aeruginosa* lung infection, the key mortality factor for cystic fibrosis patients, is attributable, at least in part, to the high tolerance of *P. aeruginosa* biofilms. At 10-40 mM, mannitol restores aminoglycoside (tobramycin) biosensitivity of *P. aeruginosa* persister cells by generating a proton-motive force (PMF), thereby enhancing tobramycin sensitivity up to 1,000x (1). **Target(s):** aldose 1-epimerase, or mutarotase (2);  $\alpha$ -amylase (3); inositol-3-phosphate synthase (4); lipoxygenase, soybean (5); mannitol-1-phosphatase (6); mannonate dehydratase (7,8); mannose isomerase (9);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (10); peptidyl-dipeptidase A, or angiotensin I converting enzyme (11);  $\alpha,\alpha$ -phosphotrehalase, or trehalose-6-phosphate hydrolase (12); sulfite oxidase (13);  $\alpha,\alpha$ -trehalase, weakly inhibited (14); xylose isomerase (15,16). 1. **D-Mannitol 1-Phosphate**

This phosphorylated sugar alcohol (FW<sub>free-acid</sub> = 262.15 g/mol; CAS 15806-48-1), also called D-mannitol 6-phosphate, is a product of the reaction catalyzed by mannose-6-phosphate 6-reductase and is a substrate in the reactions catalyzed by mannitol 1-phosphate 5-dehydrogenase and mannitol 1-phosphatase. **Target(s):** glucose-6-phosphate isomerase (1,2); inositol-3-phosphate synthase (3); D-mannitol dehydrogenase (4,5), mannose-6-phosphate isomerase (1,2,6,7). 1. Noltmann (1972) *The Enzymes*, 3rd ed., 6, 271. 2. Lee & Matheson (1984) *Phytochemistry* 23, 983. 3. Barnett, Rasheed & Corina (1973) *Biochem. Soc. Trans.* 1, 1267. 4. **D-Mannonolactam**

This mannopyranosyl cation (FW = 176.17 g/mol; CAS 62362-63-4) mimic inhibits several mannosidases. **Target(s):**  $\alpha$ -mannosidase, IC<sub>50</sub> = 400 nM for the jack bean enzyme;  $\beta$ -mannosidase, moderately inhibited, IC<sub>50</sub> = 150  $\mu$ M; mannosyl-oligosaccharide 1,2- $\alpha$  mannosidase (mannosidase I; IC<sub>50</sub> = 4  $\mu$ M); mannosyl-oligosaccharide 1,3-1,6- $\alpha$ -mannosidase (mannosidase II; IC<sub>50</sub> = 90-100 nM). 1. Pan, Kaushal, Papandreou, Ganem & Elbein (1992) *J. Biol. Chem.* 267, 8313.

**D-Mannono-1,5-Lactone**

This putative transition-state analogue (FW = 178.14 g/mol; CAS 10366-75-3) adopts an *sp*<sup>2</sup> hybrid orbital that mimics the configuration of oxacarbenium ion intermediates. D-Mannono-1,5-lactone targets 2-deoxyglucosidase (1),  $\alpha$ -mannosidase, weakly inhibited (2-11),  $\beta$ -mannosidase (2,8), and mannosyl-oligosaccharide 1,2- $\alpha$ -mannosidase (11). 1. **D-Mannosamine**

This reducing amino sugar (FW<sub>hydrochloride</sub> = 215.63 g/mol; CAS 179-1711-2; Soluble in water and methanol; pK<sub>a</sub> = 7.28), also known as 2-amino-2-deoxy-D-mannose, is a constituent of many glycoproteins and mucolipids. The anomeric composition of D-mannosamine is 43%  $\alpha$ -anomer and 57%

$\beta$ -anomer in D<sub>2</sub>O at 40°C. **Target(s):**  $\beta$ -N-acetylglucosaminidase (1,2);  $\beta$ -N-acetylhexosaminidase (17,18); amine oxidase, semicarbazide-sensitive (or diamine oxidase; amine oxidase (copper-containing) (3); glucokinase (4); glycosylphosphatidylinositol anchor biosynthesis (5-9); mannosinase, as weak alternative substrate (22,23);  $\alpha$ -mannosidase (10,11);  $\beta$ -mannosidase (19-21); mannosyl-oligosaccharide 1,2- $\alpha$  mannosidase, or mannosidase I (12,16); 1,2- $\alpha$ -mannosyltransferase (9); protein and peptide glycosylation (12-14); protein-glucosylgalactosyl-hydroxylysine glucosidase (15). 1. **D-Mannose**

This reducing aldohexose (FW = 180.16 g/mol; CAS 3458-28-4) is a key component of many glycoproteins, hemicelluloses, and mannans. Mannose is very soluble in water (248 g/100 mL at 17°C) and sparingly soluble in ethanol and methanol. The  $\alpha$ -pyranose is the more abundant anomer (68%) at 21°C in D<sub>2</sub>O. The structure of mannose was determined by Nobelist Emil Fischer (1). **Target(s):**  $\beta$ -N-acetylhexosaminidase (22-24);  $\beta$ -amylase (42); concanavalin A<sub>4</sub>; cyclomaltodextrin glucanotransferase (50); fructokinase (44); 1,2- $\alpha$ -L-fucosidase (21);  $\alpha$ -galactosidase (37); glucan 1,3- $\alpha$ -glucosidase, or glucosidase II, or mannosyl-oligosaccharide glucosidase II (9); glucokinase (5,45); glucose oxidase (6);  $\alpha$ -glucosidase (7,8);  $\beta$ -glucosidase (38-41); glycogen phosphorylase, weakly inhibited (52); hexokinase, as an alternative substrate (10,45-48); laminaribiose phosphorylase (49); levansucrase (51);  $\alpha$ -mannosidase (11,12,18,29-36);  $\beta$ -mannosidase (13,26-28); mannosyl glycoprotein endo- $\beta$ -N-acetylglucosaminidase (2,3,14); mannosyl-oligosaccharide glucosidase, or glucosidase I (19,20); protein:N<sup>7</sup>-phosphohistidine:sugar phosphotransferase (43); thioglucosidase, or myrosinase (15,16);  $\alpha$ , $\alpha$ -trehalase (25); xylose isomerase, weakly inhibited (17). 1. ### L-Mannose

This reducing aldohexose (FW = 180.16 g/mol; CAS 10030-80-5; very soluble in water and sparingly soluble in ethanol and methanol) is the enantiomer of a key component of many glycoproteins, hemicelluloses, and mannans. L-Mannose was first synthesized in the laboratory by Nobelist Emil Fischer (1). **Target(s):**  $\beta$ -glucosidase,  $K_i = 550$  mM for the sweet almond enzyme (2);  $\alpha$ -L-rhamnosidase (3). **1.** Fischer (1890) *Ber.* **23**, 370 and (1891) *Ber.* **24**, 2683. **2.** Dale, Ensley, Kern, Sastry & Byers (1985) *Biochemistry* **24**, 3530. **3.** Jang & Kim (1996) *Biol. Pharm. Bull.* **19**, 1546.

### $\alpha$ -D-Mannose 1-Phosphate

This phosphorylated hexose (FW<sub>free-acid</sub> = 260.14; CAS 27251-84-9), a key intermediate in the formation of GDP-mannose, glycoproteins, and glucomannans, is more acid labile than D-mannose 6-phosphate. In 0.95 M acid at 30°C, the  $t_{1/2}$  for  $\alpha$ -D-mannose 1-phosphate hydrolysis is six hours. **Target(s):** galactose-1-phosphate uridylyltransferase (1); glucose-1-phosphate guanylyltransferase (2); glycolipid 3- $\alpha$ -mannosyl-transferase, *or*  $\alpha$ -1,3-mannosyltransferase (3); starch phosphorylase (4);  $\alpha$ , $\alpha$ -trehalose phosphorylase, configuration-retaining (5). **1.** Lang, Groebe, Hellkuhl & von Figura (1980) *Pediatr. Res.* **14**, 729. **2.** Danishefsky & Heritier-Watkins (1967) *Biochim. Biophys. Acta* **139**, 349. **3.** Doering (1999) *J. Bacteriol.* **181**, 5482. **4.** Hsu, Yang, Su & Lee (2004) *Bot. Bull. Acad. Sin.* **45**, 187. **5.** Eis & Nidetzky (2002) *Biochem. J.* **363**, 335.

### D-Mannose 6-Phosphate

This phosphorylated hexose (FW<sub>free-acid</sub> = 260.14; CAS 672-15-9), an important intermediate in mannose metabolism, is also a precursor in the formation of GDP-mannose, glycoproteins, and glucomannans. D-Mannose 6-phosphate is more stable in acid than D-mannose 1-phosphate: 50% is hydrolyzed in 16.6 hour in 1.0 M HCl at 100°C *versus* 6 hours in 0.95 M HCl at 30°C. D-Mannose 6-phosphate is a product of the reaction catalyzed by mannosinase and is a substrate of the reactions catalyzed by mannosinase-6-phosphatase, mannosinase-6-phosphate isomerase, and phosphomannomutase. It can also be synthesized by the action of hexokinase or acyl-phosphate:hexose phosphotransferase. Mannose 6-phosphate receptors are located in the Golgi apparatus, where they bind proteins containing phosphomannosyl residues and function in targeting proteins to lysosomes. **Target(s):** N-acetylglucosamine-1-phosphodiester  $\alpha$ -N-acetylglucosaminidase (1,2); glucosamine-6-phosphate isomerase (3); glucose-6-phosphate isomerase (4-6); inositol-3-phosphate synthase, *or* myo-inositol-1-phosphate synthase (7-9); mannosinase-6-phosphate isomerase, weakly inhibited by the  $\alpha$ -anomer, whereas the  $\beta$ -anomer is the substrate (10). **1.** Varki & Kornfeld (1981) *J. Biol. Chem.* **256**, 9937. **2.** Lee & Pierce (1995) *Arch. Biochem. Biophys.* **319**, 413. **3.** Friedman & Benson (1975) *Meth. ### Mannostatin A

This metabolite (FW<sub>free-base</sub> = 179.24 g/mol; CAS 102822-56-0) is produced by *Streptovorticillium verticillus* and is a potent inhibitor of  $\alpha$ -mannosidases and was the first nonalkaloidal glycoprotein processing inhibitor.

**Target(s):** arylmannosidase (1-3);  $\alpha$ -mannosidase (1,3-6); mannosyl-oligosaccharide 1,3-1,6- $\alpha$  mannosidase, *or* mannosidase II,  $K_i = 36$  nM (1,3,6-8). **1.** Kaushal & Elbein (1994) *Meth. ### Manoalide

This amphipathic marine sesterterpenoid (FW = 416.55 g/mol; CAS 75088-80-1) from the sponge *Luffariella variabilis* is an irreversible inhibitor of phospholipase A<sub>2</sub> by modifying several lysyl residues. At elevated pH, the ring opens to generate a molecular entity with  $\alpha$ , $\beta$  unsaturated aldehydes. Related inhibitors of *L. variabilis* PLA<sub>2</sub> include secmanoalide and luffariellins A, B, C, and D. Given the diverse isoforms and roles of PLA<sub>2</sub>, manoalide-like molecules hold considerable promise in pharmacology,

especially as immune modulators. **Target(s):** Ca<sup>2+</sup> channels (1); 5-lipoxygenase (2); phosphatidylinositol-specific phospholipase C, or 1-phosphatidylinositol phosphodiesterase (3,4); phospholipase A<sub>2</sub> (5-13). **1.** Wheeler, Sachs, De Vries, *et al.* (1987) *J. ### Manumycin A

This unusual antibiotic (FW = 550.65 g/mol; CAS 52665-74-4), also called UCF1-C, inhibits protein farnesyltransferases (IC<sub>50</sub> = 5 μM) and protein geranylgeranyltransferase type I (IC<sub>50</sub> = 180 μM). **Target(s):** protein farnesyltransferase (1-5); protein geranylgeranyltransferase type II, or sphingomyelin phosphodiesterase, or neutral sphingomyelinase (6,7). **1.** Mitsuzawa & Tamanoi (1995) *Meth. Enzymol.* **250**, 43. **2.** Gibbs (2001) *The Enzymes*, 3rd ed., **21**, 81. **3.** Hara, Akasaka, Akinaga, *et al.* (1993) *Proc. Natl. Acad. Sci. ### MAP-2 Fragment 1705-1722

This octadecapeptide fragment (FW = 1867.16; Sequence: VTSKCGSLKNIRHRPGGG; Isoelectric Point: 11.01) corresponding to residues 1705-1722 within the microtubule-binding domain of Microtubule-Associated Protein-2 (MAP2), stimulates polymerization of MAP-free tubulin and also inhibits the binding of microtubule-associated proteins (e.g., Tau proteins and MAP2) to microtubules. This peptide also greatly reduces microtubule dynamics. **1.** Joly & Purich (1990) *Biochemistry* **29**, 8916. **2.** Yamauchi, Flynn, Marsh & Purich (1993) *J. Neurochem.* **60**, 817.

**MAP4, See (S)-2-Amino-2-methyl-4-phosphonobutyrate**

### Maprotiline

This antidepressant (FW<sub>hydrochloride</sub> = 313.87 g/mol; CAS 10262-69-8; Solubility: 10 mM in H<sub>2</sub>O), also named 1-(3-methylaminopropyl)dibenz[*b,e*]bicyclo[2.2.2]octadiene hydrochloride, is a selective norepinephrine uptake inhibitor. Anxiolytic-like effects are also observed with a low-dose maprotiline (0.5 mg/kg), but are lost at higher doses. **Target(s):** aldehyde oxidase (1); diamine oxidase (2); monoamine oxidase (3,4); norepinephrine uptake (5,6). **1.** Obach, Huynh, Allen & Beedham (2004) *J. Clin. Pharmacol.* **44**, 7. **2.** Obata & Yamanaka (2000) *Neurosci. Lett.* **286**, 131. **3.** Egashira, Takayama & Yamanaka (1999) *Jpn.*

### Maraviroc

This synthetic antiretroviral drug (FW = 513.67 g/mol; CAS 376348-65-1), known also by its trade names, Selzentry<sup>®</sup> and Celsentri<sup>®</sup>, the code name UK-427,857, as well as 4,4-difluoro-N-{(1S)-3-[3-(3-isopropyl-5-methyl-4H-1,2,4-triazol-4-yl)-8-azabicyclo[3.2.1]oct-8-yl]-1-phenylpropyl}cyclohexanecarboxamide, is CCR5 receptor antagonist that binds to a hydrophobic pocket formed by the receptor's transmembrane helices, thus preventing HIV-1 from entering and infecting CD4<sup>+</sup> immune cells. CCR5 is a member of G-protein-coupled, seven transmembrane segment receptors, also known as C-C motif chemokine receptor-5. Because maraviroc binds at a site that is topologically distinct from the HIV-1 binding site, it is said to be an allosteric inhibitor. With its borderline physicochemical properties (i.e., moderate lipophilicity, slightly basic pK<sub>a</sub> of 7.3, and eight H-bonding groups, and MW > 500), maraviroc exhibits relatively poor membrane permeability, but its transcellular flux is enhanced in the presence of P-glycoprotein inhibitors (2). High-level resistance to maraviroc occurs when primary isolates are passaged in peripheral blood lymphocytes (3). Other similarly acting viral entry inhibitors include: aplaviroc, vivriviroc, TAK-779, SCH C (or SCH 351125). By contrast, the entry inhibitor PRO 140 is a human monoclonal antibody targeting the CCR5 receptor. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollman, eds.) McGraw-Hill Medical, New York (2011). **1.** Wood & Armour (2005) *Prog. Med. Chem.* **43**, 239. **2.** Walker, Abel, Comby, *et al.* (2005) *Drug Metab. Dispos.* **33**, 587.

### Marbofloxacin

This orally bioavailable third-generation fluoroquinolone-class antibiotic (FW = 362.36 g/mol; CAS 115550-35-1; IUPAC: 9-fluoro-2,3-dihydro-3-methyl-10-(4-methyl-1-piperazinyl)-7-oxo-7H-pyrido[3,2,1-*ij*][4,1,2]benzoxadiazine-6-carboxylate), is a broad-spectrum systemic antibacterial targeting Type II DNA topoisomerases (gyrases), thereby blocking bacterial replication and transcription in a wide range of Gram-positive and Gram-negative bacterial pathogens (e.g., *Aeromonas*, *Brucella*, *Campylobacter*, *Chlamydia trachomatis*, *Enterobacter*, *Escherichia coli*, *Haemophilus*, *Klebsiella* spp., *Mycobacterium*, *Mycoplasma*, *Proteus*, *Pseudomonas aeruginosa*, *Salmonella*, *Serratia*, *Shigella*, *Staphylococci* (including penicillinase-producing and methicillin-resistant strains), *Vibrio*, and *Yersinia*). Most often used as a monotherapy in veterinary medicine (where pathogen prevention and control are constant challenges, especially in densely populated stock) under the trade names Forcyl<sup>®</sup>, Marbocyl<sup>®</sup>, and Zeniquin<sup>®</sup>, marbofloxacin has also been combined with clotrimazole and dexamethasone under the trade name Aurizon<sup>®</sup>. For the prototypical member of this antibiotic class, See *Ciprofloxacin*

**Marimastat**

This peptidomimetic agent (FW = 331.41 g/mol; CAS 154039-60-8) is a strong inhibitor of several matrix metalloproteinases, among the interstitial collagenase ( $K_i = 0.7$  nM), gelatinase A ( $K_i = 0.6$  nM), stromelysin 1 ( $K_i = 8.9$  nM), matrilysin ( $IC_{50} = 20$  nM), neutrophil collagenase ( $IC_{50} = 2$  nM), gelatinase B ( $IC_{50} = 3$  nM), and ADAM 17 endopeptidase ( $K_i = 6.3$  nM).

**Target(s):** ADAM 17 endopeptidase, tumor necrosis factor- $\alpha$  converting enzyme, or TACE (1); gelatinase A, or MMP 2 (1,2); gelatinase B, or MMP 9 (2,3); interstitial collagenase MMP 1 (1,2); matrilysin, or MMP 7 (2); neutrophil collagenase, or MMP 8 (2); membrane-type MMP 1 autocatalytic processing (or MMP 14 autocatalytic processing) (4); stromelysin 1, or MMP 3 (1,2). 1. Kottirsch, Koch, Feifel & Neumann (2002) *J. Med. Chem.* **45**, 2289. 2. Whittaker & Brown (1998) *Curr. Opin. Drug Discov. Dev.* **1**, 157. 3. Underwood, Min, Lyons & Hambley (2003) *J. Inorg. **Maritoclax**

This axially dissymmetric marine-derived *Streptomyces* natural product (MW = 510.15 g/mol), also known as Marinopyrrole A, is active against methicillin-resistant *Staphylococcus aureus*, with an  $MIC_{90}$  of 2  $\mu$ M (1). Its structure was assigned by X-ray crystallography, and, although configurationally stable at room temperature, the naturally occurring *M*-(-)-enantiomer racemizes to the non-natural *P*-(+)-*atropo*-enantiomer at elevated temperatures (1). Maritoclax also binds to Mcl-1, but not Bcl-X<sub>L</sub>, a related anti-apoptotic factor in the Bcl-2 protein family (2). In doing so, Maritoclax disrupts the interaction between Bim and Mcl-1, inducing the latter's degradation by the proteasome system, an action associated with Maritoclax's pro-apoptotic activity. Importantly, Maritoclax selectively kills Mcl-1-dependent, but not Bcl-2- or Bcl-X<sub>L</sub>-dependent, leukemia cells and markedly enhances the efficacy of ABT-737 against hematologic malignancies, including K562, Raji, and multidrug-resistant HL60/VCR, by ~60- to 2000-fold at 1-2  $\mu$ M (2). 1. Hughes, Prieto-Davo, Jensen & Fenical (2008) *Org. Lett.* **10**, 629. 2. Doi, Li, Sung, et al. (2012) *J. Biol. Chem.* **287**, 10224.

**MARTA2 Dominant Negative Inhibitor**

Dendritic targeting of mRNAs encoding the microtubule-associated protein 2 (MAP2) in neurons involves high-affinity and high-specificity binding of its *cis*-acting dendritic targeting element to MARTA2 (or MAP2-RNA trans-acting) protein. MARTA2, bind to the *cis*-element with both high affinity and specificity. MARTA2 is an orthologue of human far-upstream element binding protein 3, which contains four centrally located KH domains that bind to single-stranded DNA and RNA. (KH domains were first identified in the human heterogeneous nuclear ribonucleoprotein (hnRNP K.) In neurons, MARTA2 resides in somatodendritic granules and dendritic spines, where it associates with MAP2 mRNAs. Expression of a dominant-negative MARTA2-KH-eGFP variant (containing only the KH domains and an enhanced-GFP reporter) disrupts dendritic targeting of endogenous MAP2 mRNAs, without noticeably disturbing the level and subcellular distribution of polyadenylated mRNAs. MAP2 transcripts also associate with the microtubule-based motor KIF5 and inhibition of KIF5, but not cytoplasmic dynein, disrupts extrasomatic trafficking of MAP2

mRNA granules. Such findings indicate that MARTA2 is a key *trans*-acting factor that factors in KIF5-mediated dendritic targeting of MAP2 mRNAs.

**Martentoxin**

This secreted high-affinity potassium channel antagonist (MW = 4056.3 g/mol; (Sequence: CSISICTEAFGLIDVKCFASSECWTA), also known as potassium channel toxin  $\alpha$ -KTx16.2, BmK 622, and BmTx3B, from the venom of the East-Asian scorpion *Buthus martensi*, inhibits the voltage-dependent, large-conductance  $Ca^{2+}$ -activated  $K^+$  channel, often referred to the BK channel ( $IC_{50} = 80$  nM). This toxin appears to block channel activity by a simple one-step binding reaction exhibiting a fast association to and slow dissociation from channels on rat brain synaptosomes. **Target(s):** BK<sup>+</sup> channel (1,2); delayed rectifying  $K^+$  channel ( $IC_{50} = 50$   $\mu$ M) (1,2). 1. Wang, Chen, Xhang, Wu & Wu (2005) *Proteins* **58**, 489. 2. Ji, Wang, Ye, et al. (2003) *Neurochem.* **84**, 325.

**Maslinat (Maslinic Acid)**

This triterpene acid (FW<sub>free-acid</sub> = 472.71 g/mol; CAS 4373-41-5) from a number of plants, including olive pomace (*Olea europaea*) is an antioxidant that also displays a broad spectrum of inhibitory actions. **Target(s):** DNA-directed DNA polymerase (1); DNA polymerase  $\alpha$  (1); DNA polymerase  $\beta$  (1); DNA topoisomerase II (1); glycogen phosphorylase (2-4); HIV-1 retropepsin (5); sterol *O*-acyltransferase, or acyl-CoA:cholesterol *O*-acyltransferase, or ACAT (6); tyrosinase, or monophenol monooxygenase,  $IC_{50} = 1.7$   $\mu$ M (7). 1. Mizushima, Ikuta, Endoh, et al. (2003) *Biochem. Biophys. Res. Commun.* **305**, 365. 2. Wen, Sun, Liu, et al. (2005) *Bioorg. Med. Chem. Lett.* **15**, 4944. 3. Wen, Zhang, Liu, et al. **Masitinib**

This novel, orally bioavailable, ATP-competitive tyrosine protein kinase inhibitor (FW = 498.65 g/mol; CAS 790299-79-5; Solubility: 100 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also named AB1010 and *N*-(4-methyl-3-(4-(pyridin-3-yl)thiazol-2-ylamino)phenyl)-4-((4-methylpiperazin-1-yl)methyl)benzamide, targets the stem cell factor receptor Kit ( $IC_{50} = 200$  nM) and platelet-derived growth factor receptors  $\alpha$  and  $\beta$ , or PDGFR $\alpha$  ( $IC_{50} = 540$  nM) and PDGFR $\beta$  ( $IC_{50} = 800$  nM), with weaker inhibition to ABL and c-Fms (1). When docked into the KIT binding site, masitinib's aminothiazole hydrogen bonds with the side-chain of the gatekeeper residue Thr-670. Its amide NH forms an H-bond to the Glu-640 side-chain, and the meta-nitrogen of the pyridine ring interacts with the backbone NH of Cys-673. For the methylpiperazine group, an additional H-bond occurs between the protonated CH<sub>3</sub>-NH and the backbone C=O of His-790. Its thiazole ring packs loosely between the aliphatic portions of the side-chains of Ala-621, Leu-799, Cys-809, and Phe-811 (1). Although c-Kit is required for early amplification of erythroid progenitors, it must disappear from cell surface

for the cell to enter the final steps of maturation in an erythropoietin-dependent manner. Both imatinib and masitinib block this internalization process (2) Importantly, masitinib was inactive against Flt3 (>10  $\mu\text{M}$ ), but moderately inhibited c-Fms in both cell proliferation and recombinant protein kinase assays,  $\text{IC}_{50}$  of 1.0  $\mu\text{M}$  and 1.5  $\mu\text{M}$ , respectively (1). Such selectivity is also consistent with the absence of masitinib-induced cardiotoxicity or genotoxicity in animal studies. Masitinib is an investigational drug for rheumatoid arthritis (3), progressive multiple sclerosis (4,5), Alzheimer disease (6), corticosteroid-dependent asthma (7), and gastrointestinal stromal tumors, or GIST (8). Masitinib mesylate (dose = 12.5mg/kg, once daily) is also the first anticancer therapy approved in veterinary medicine for the treatment of unresectable canine mast cell tumors (CMCTs), harboring activating c-KitR mutations (9). 1. ### 3-MATIDA

This sterically constrained glutamate analogue (FW = 215.22 g/mol; CAS 518357-51-2; Soluble to 100 mM in 1eq. NaOH and to 50 mM in DMSO) targets the metabotropic glutamate mGlu<sub>1</sub> receptor antagonist ( $\text{IC}_{50}$  = 6.3  $\mu\text{M}$ , rat mGlu<sub>1a</sub>) and displays  $\geq 40\times$  selectivity over mGlu<sub>5</sub>, mGlu<sub>2</sub>, mGlu<sub>4a</sub> (each with  $\text{IC}_{50}$  > 300  $\mu\text{M}$ ) as well as NMDA and AMPA receptors ( $\text{IC}_{50}$  = 250  $\mu\text{M}$ ). 3-Matida is neuroprotective in cultured murine cortical cells and rat hippocampal slice cultures *in vitro*. It also reduces the size of ischemia-induced brain infarcts in rats. 1. Cozzi, Meli, Carlà, *et al.* (2002) *Neuropharmacol.* **43**, 119. 2. Moroni, Attucci, Cozzi, *et al.* (2002) *Neuropharmacol.* **42**, 741.

### Maytansine

This microtubule-disrupting alkaloid (FW = 692.21 g/mol; CAS 35846-53-8) from the plant *Maytenus ovatus* is a potent antitumor agent that inhibits tubulin polymerization and is a potent inhibitor of mitosis. Although earlier work suggested that maytansine appears to compete with the *Catharanthus* alkaloids (vinblastine, vincristine, and vinleurosine) for a common or overlapping site on the tubulin dimer (1), new structural data shows that this macrocyclic drug binds to a site on  $\beta$ -tubulin that is distinct from the vinca domain and that blocks the formation of longitudinal tubulin interactions in microtubules (2). The total synthesis of (-)-maytansine was realized in 1980 by Corey and coworkers (3). **Target(s):** calmodulin (4); tubulin polymerization, or microtubule self-assembly (1,2,4,5); vinblastine and colchicine binding to tubulin (6). 1. Huang, Lin & Hamel (1985) *Biochem. Biophys. Res. Commun.* **128**, 1239. 2. Prota, Bargsten, Diaz, *et al.* (2014)

### MC 1742

This cell-permeable and potent Class I and IIb HDAC inhibitor (FW = 395.47 g/mol; CAS 1776116-74-5; Solubility: 100 mM in DMSO), also known as 5-[[[4-[1,1'-biphenyl]-4-yl]-1,6-dihydro-6-oxo-2-pyrimidinyl]thio]-N-hydroxypentanamide, targets histone deacetylases, with respective  $\text{IC}_{50}$  values of 7, 20, 40, 100, 110 and 610 nM for HDAC6, HDAC3, HDAC10, HDAC1, HDAC2 and HDAC8. MCC-1742 suppresses cell proliferation and induces apoptosis of sarcoma cancer stem cells (CSCs) when used at >500 nM. It also induces osteogenesis in sarcoma CSC cells in the 25–500 nM range. 1. Di Pompo, *et al.* (2015) *J. Med. Chem.* **58**, 4073. 2. Mai, *et al.* (2008) *Bioorg. Med. Chem. Lett.* **18**, 2530. 3. Mai, *et al.* (2006) *J. Med. Chem.* **49**, 6046.

### MDC-1016

This farnesyl analogue (FW<sub>free-acid</sub> = 510.63 g/mol; *Symbol*: PFTS), also known as phospho-farnesylthiosalicylate, inhibits the growth of human pancreatic cancer cells in culture and in a xenograft model in a concentration- and time-dependent manner. MDC-1016 prevents pancreatitis-accelerated acinar-to-ductal metaplasia in mice with activated K-ras. After oral administration, PFTS is rapidly absorbed, metabolized to FTS and FTS glucuronide, which are distributed through the blood to body organs. PFTS inhibits Ras-GTP, the active form of Ras, both *in vitro* and *in vivo*, leading to the inhibition of downstream effector pathways involving c-RAF/mitogen-activated protein-extracellular signal-regulated kinase (ERK) kinase, (MEK)/ERK1/2 kinase, and phosphatidylinositol 3-kinase/AKT. 1. Mackenzie, Bartels, Xie, *et al.* (2013) *Neoplasia* **15**, 1184.

### mdivi-1

This mitochondrial division inhibitor (FW = 353.22 g/mol; CAS 338967-87-6; Soluble to 100 mM in DMSO), systematically named 3-(2,4-dichloro-5-methoxyphenyl)-2,3-dihydro-2-thioxo-4(1*H*)-quinazolinone, attenuates mitochondrial division in yeast and mammalian cells by selectively inhibiting the mechano-protein Dynamin-1, or Dnm1/Drp1 GTPase ( $IC_{50}$  = 1-10  $\mu$ M). In cells, mdivi-1 retards apoptosis by inhibiting mitochondrial outer membrane permeabilization. *In vitro*, mdivi-1 potently blocks Bid-activated Bax/Bak-dependent cytochrome *c* release from mitochondria. These findings indicate that dynamin directly regulates mitochondrial outer membrane permeabilization independent of Drp1-mediated division. **1.** Cassidy-Stone, Chipuk, Ingeman, *et al.* (2008) *Dev. Cell* **14**, 193. **2.** Tanaka & Youle (2008) *Mol. Cell* **29**, 409. **3.** Lackner & Nunnari (2010) *Chem. Biol.* **17**, 578.

**MDL 11,939**

This orally active and centrally acting serotonin receptor antagonist (FW = 295.42 g/mol; CAS 107703-78-6; Solubility: 50 mM in DMSO), also named  $\alpha$ -phenyl-1-(2-phenylethyl)-4-piperidinemethanol, selectively targets rabbit 5-HT<sub>2A</sub> ( $K_i$  = 0.54 nM) and human 5-HT<sub>2A</sub> receptors ( $K_i$  = 2.5 nM), with much weaker action against rabbit 5-HT<sub>2C</sub> receptors ( $K_i$  = 82 nM) and human 5-HT<sub>2C</sub> receptors ( $K_i$  = ~10,000 nM). **1.** Dudley, *et al.* (1988) *Drug Dev. Res.* **13**, 29.

**MDL 12330A**

This reagent (FW<sub>free-base</sub> = 340.55 g/mol; FW<sub>HCl-Salt</sub> = 377.01 g/mol; CAS 40297-09-4; Solubility = 20 mg/mL DMSO), also known as *N*-(*cis*-2-phenylcyclopentyl)azacyclotridec-1-en-2-amine and RMI 12330A, inhibits adenylyl cyclase, or AC (1-3) and cAMP phosphodiesterase (4). MDL-12330A has a non-specific effect on glycine transport in Müller cells from the retina (5). Importantly, MDL-12,330A also enhances [Ca<sup>2+</sup>]<sub>i</sub> and insulin secretion via inhibition of KV-channels rather than AC antagonism in  $\beta$ -cells, suggesting that one must recognize the possibility of non-specific side effects when evaluating the action of this agent (5). MDL-12330A blocks slow extracellular and store-operated Ca<sup>2+</sup> entry into cells. **1.** Lippe & Ardizzone (1991) *Comp. Biochem. Physiol. **MDL100907**

This potent serotonin (5-hydroxytryptamine) receptor antagonist and antipsychotic agent *in vivo* (FW = 373.46 g/mol; CAS 139290-65-6), systematically named (*R*)-(+)- $\alpha$ -(2,3-dimethoxyphenyl)-1-[2-(4-fluorophenyl)ethyl]-4-piperinmethanol, selectively targets 5-HT<sub>2A</sub> ( $K_i$  = 0.36 nM), in behavioral, electrophysiological and neurochemical models of antipsychotic activity and extrapyramidal side-effect liability (1). Scatchard analysis shows high-affinity binding, single-site binding of [<sup>3</sup>H]-MDL100907 to 5-HT<sub>2A</sub> receptors in rabbit cortical membranes, with a mean B<sub>max</sub> was 8.5 fmol/mg tissue and a mean K<sub>d</sub> was 33 pM (2). MDL 100907 exhibits >80x selectivity over other 5-HT serotonergic receptor subtypes (1). In mice, MDL 100,907 blocked amphetamine-stimulated locomotion at doses that did not significantly affect apomorphine-stimulated climbing behavior (1). MDL 100,907 has a clozapine-like profile of potential antipsychotic activity with low extrapyramidal side-effect liability (1). Using inhibition of D-amphetamine-stimulated locomotion in mice as a measure of potential antipsychotic efficacy, MDL 100,907 shows a superior CNS safety index relative to reference compounds (*e.g.*, haloperidol, clozapine, risperidone, ritanserin, and amperozide) in each of five tests for side effect potential, including measures of ataxia, general depressant effects,  $\alpha_1$ -adrenergic antagonism, striatal D<sub>2</sub> receptor antagonism, and muscle relaxation (3). MDL 100,907 does not antagonize apomorphine-induced stereotypes in rats, suggesting that it may lack extrapyramidal side effect liability. MDL 100,907 shows selectivity as a potential antipsychotic in that it lacked consistent activity in selected rodent models of anticonvulsant, antidepressant, analgesic, or anxiolytic activity (3). **1.** Sorensen, Kehne, Fadayel, *et al.* (1993) *J. ### ME0328

This potent PARP inhibitor (FW = 321.37 g/mol; CAS 1445251-22-8; Solubility: <1 mg/mL DMSO, H<sub>2</sub>O, or Ethanol), also named 3,4-dihydro-4-oxo-*N*-[(1*S*)-1-phenylethyl]-2-quinazolinepropanamide, selectively targets ADP-ribosyltransferase-3/poly(ADP-ribose) polymerase-3 (ARTD3), a druggable regulator of DNA repair and mitotic progression. *In vitro* profiling against 12 PARP family members suggests that ME0328 is selective for ARTD3, and X-ray crystal structures provide a basis for such selectivity. ME0328 is active in cells, where it elicits ARTD3-specific effects at submicromolar concentration. **1.** Lindgren, Karlberg, Thorsell, *et al.* (2013) *ACS Chem Biol.* **8**, 1698.

**Mead Acid**, See 5*Z*,8*Z*,11*Z*-Eicosatrienoate and 5*Z*,8*Z*,11*Z*-Eicosatrienoic Acid

### Meayamycin

This FR901464 analogue (FW = 489.65) shows picomolar anti-proliferative activity of against various cancer cell lines and multidrug resistant cells. The observed time-dependence suggests that meayamycin may form a covalent bond with its protein target(s). Like FR901464 and spliceostatin A, meayamycin inhibits pre-mRNA splicing of the AdML pre-mRNA substrate in a concentration-dependent manner, with 50 nM sufficient for complete inhibition. Incubation of the same nuclear extract with up to 10  $\mu$ M of the non-epoxide analogue was without effect upon splicing. Unlike FR901464, meayamycin is very stable in phosphate buffer at pH 7.4 and is likewise relatively stable in cell culture medium. (See also E7107; FR901464; Pladienolide B; Spliceomycin A) **1.** Albert, McPherson, O'Brien, *et al.* (2009); *Mol. Cancer Ther.* **8**, 2308.

### Mebendazole

This benzimidazole-containing anthelmintic (FW = 295.30 g/mol; CAS 31431-39-7), also known as methyl-(5-benzoyl-1*H*-benzimidazol-2-yl)carbamate, is a widely used veterinary medicine for treating roundworm, whipworm, threadworm, and hookworm infestation. By binding to the colchicine-sensitive site of tubulin and inhibiting the assembly of microtubules, mebendazole brings about degenerative changes in the tegument and intestinal cells of the worm. **Target(s):** malate dehydrogenase (1,2); tubulin (3-5). **1.** Vessal & Tabei (1996) *Comp. Biochem. Physiol. B Biochem. Mol. Biol.* **113**, 757. **2.** Tejada, Sanchez-Moreno, Monteoliva & Gomez-Banqueri (1987) *Vet. Parasitol.* **24**, 269. **3.** Ochola, Prichard & Lubega (2002) *J. ### Mecamylamine

This noncompetitive nicotinic acetylcholine receptor antagonist (FW<sub>free-base</sub> = 167.29 g/mol; CAS 826-39-1), also known as Inversine<sup>TM</sup>, was the first orally available antihypertensive agent. While popular in the 1950s, it is now rarely used for hypertension owing to its widespread ganglionic side-effects. At lower doses, it blocks the physiological effects of nicotine, improving abstinence rates in those seeking to stop smoking. **1.** Damaj, Glassco, Dukat & Martin (1999) *J. Pharmacol. Exp. Ther.* **291**, 1284. **2.** Bissada, Welch & Finkbeiner (1978) *Urology* **11**, 425. **3.** Varanda, Aracava, Sherby, *et al.* (1985) *Mol. Pharmacol.* **28**, 128.

### Mechlorethamine

This nitrogen mustard (FW<sub>free-base</sub> = 156.05 g/mol; M.P. = -60°C; Slightly soluble in water; Soluble in many organic solvents; HCl Salt (M.P. = 109 111°C; CAS 55-86-7) is water-soluble), also known as HN-2 and *N*-bis(2-chloroethyl)methylamine, is a chemical warfare agent, acting as cholinesterase poison. It is also DNA and RNA alkylating agent, the latter actions inhibiting both transcription and translation (1) The hydrochloride is used to treat Hodgkin's disease. **CAUTION:** As the free base, HN-2 is a powerful vesicant, requiring use of a chemical hood or gas mask. Avoid contact with skin and wear protective gown and thick chemical rubber gloves. **History Note:** Although Germany and the United States produced nitrogen mustard agents in 1941 and 1943, respectively, there are no indications that they were ever used on the battlefield. Several nations currently maintain stockpiles of sulfur and nitrogen mustards. (See also 2,2'-Dichloro-*N*-triethylamine; *Tris*(2 chloroethyl)amine) **Target(s):** acetylcholinesterase (2-6); betaine-aldehyde dehydrogenase (7); choline acetyltransferase (8); choline dehydrogenase (9-12); choline oxidase (3); hemoglobin S polymerization (13-15); hexokinase (16,17); Na<sup>+</sup>/K<sup>+</sup>/Cl<sup>-</sup> cotransporter (18). **1.** Masta, Gray & Phillips (1995) *Nucl. **Meclofenamate (Meclofenamic Acid)**

This nonsteroidal anti-inflammatory, *or* NDAID, and “double” inhibitor ( $FW_{\text{free-acid}} = 296.15 \text{ g/mol}$ ; CAS 644-62-2), also known as Meclomen<sup>®</sup> and 2-[(2,6-dichloro-3-methylphenyl)amino]benzoic acid, targets the cyclooxygenase and lipoxygenase pathways of arachidonate metabolism. Meclomen also interferes with leukotriene receptors and post-receptor mechanisms. Meclomen inhibits leukotriene C<sub>4</sub> and leukotriene D<sub>4</sub> induced contractions, but had no effect on histamine induced contractions. Ibuprofen, naproxen and indomethacin had no effect on lipoxygenases or on leukotriene receptors but were powerful inhibitors of cyclooxygenases. It is FDA-approved for the treatment of joint, muscular pain, arthritis and dysmenorrhea. **Target(s):** cyclooxygenase, *or* prostaglandin-endoperoxide synthase (1-4); estrone sulfotransferase (5); hKv2.1, a major human neuronal voltage-gated K<sup>+</sup> channel (6); 5-lipoxygenase (1,2); 15-lipoxygenase (2); phenol sulfotransferase, *or* aryl sulfotransferase (5). **1.** Boctor, Eickholt & Pugsley (1986) *Prostaglandins Leukot. **MEDI-4736, See Durvalumab**

**MEDICA 16**

This nonmetabolizable long-chain fatty acid and FFA receptor agonist ( $FW = 342.51 \text{ g/mol}$ ; CAS 87272-20-6; Origin of Name: alpha, **o**MEga-DICarboxylic Acid; Solubility: 100 mM in DMSO or Ethanol), also named 3,3,14,14-tetramethylhexadecanedioate and  $\beta,\beta'$ -tetramethyl-hexadecanedioate, is a rotationally symmetric fatty acid analogue that targets Free Fatty Acid (*or* FFA) receptors, exhibiting selectivity for FFA<sub>1</sub> (GPR40) over GPR120. The latter are G-protein-coupled receptors (whose endogenous ligands are medium- and long-chain free fatty acids) thought to play an important physiological role in insulin release. MEDICA16 selectively activates [Ca<sup>2+</sup>]<sub>i</sub> response in GPR40-expressing cells, but not in GPR120-expressing cells (1). Medica-16 also inhibits ATP citrate lyase, limiting the supply of acetyl-CoA required by acetyl-CoA carboxylase (ACC), the rate-limiting liver enzyme in fatty acid biosynthesis and a key regulator of muscle fatty acid oxidation (2,3). Rat liver acetyl-CoA carboxylase activity was inhibited by the free as well as the CoA monothioester of  $\beta,\beta'$ -tetramethylhexadecanedioate (1). The CoA monothioester of MEDICA 16 is a dead-end inhibitor, with  $K_i$  values of 2  $\mu\text{M}$  and 58  $\mu\text{M}$  for carboxylated and noncarboxylated ACC (3). MEDICA 16-CoA binding is not mutually exclusive with that of citrate and does not affect the avidin-resistance of rat liver acetyl-CoA carboxylase. The free dioic acid of MEDICA 16 is competitive to citrate ( $K_i = 70 \mu\text{M}$ ), compared to a  $K_a$  of 2-8 mM for citrate as an activator. Inhibition of the carboxylase by the free dioic acid of MEDICA 16 is accompanied by an increase in its avidin resistance (3). The resultant inhibition of acetyl-CoA carboxylase by MEDICA 16 and its CoA thioester, together with the previously reported citrate-competitive inhibition of ATP-citrate lyase by MEDICA 16, may account for the drug's observed hypolipidemic effect under dietary conditions where liver lipogenesis constitutes a major flux of lipid synthesis (3). **1.** Hara, Hirasawa, Sun, *et al.* (2009) *Naunyn. **Mefloquine**

This antimalarial agent ( $FW_{\text{free base}} = 378.32 \text{ g/mol}$ ; CAS 53230-10-7) interacts with DNA, raises the intravascular pH in the acid vesicles of the parasite (*Plasmodium falciparum*), and blocks gap junction channels Cx36 and Cx50. Note that mefloquine is structurally related to quinine. It reportedly stimulates Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase, Ca<sup>2+</sup>/Mg<sup>2+</sup>-ATPase activity, and the choline/Mg<sup>2+</sup> antiport system. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** acetylcholinesterase (1,2); aromatase, *or* CYP19 (3); Ca<sup>2+</sup> currents; cholinesterase, *or* butyrylcholinesterase (1,2,5); Cl<sup>-</sup> channels, volume-regulated and Ca<sup>2+</sup>-activated (6); dolichol kinase (7); gap junction channels Cx36 and Cx50; halofantrine dealkylase (9); K<sup>+</sup> channels (10-12); ornithine decarboxylase, weakly inhibited (13); *Plasmodium falciparum* aminopeptidase (14); protein kinase C (15,16); ribosylidihydronicotinamide dehydrogenase (quinone) (17); tolbutamide hydroxylase (cytochrome P450) (18). **1.** Lim & Go (1985) *Clin. **MEK162, See Binimetinib**

**Melagatran**

This antithrombotic agent ( $FW = 429.52 \text{ g/mol}$ ; CAS 159776-70-2) inhibits thrombin,  $K_i = 2 \text{ nM}$  (1-5). The prodrug is known as ximelagatran. In early 2006, AstraZeneca withdrew the anticoagulant Exanta<sup>™</sup> (melagatran/ximelagatran) from the market; although effective for short-term prevention of venous thromboembolism following orthopedic surgery, Exanta showed a higher risk of liver injury. **1.** Nilsson, Sjöling-Ericksson & Deinum (1998) *J. **Melanostatin (or Melanotropin Release-inhibiting Hormone)**

This peptide amide (FW = 284.37 g/mol; CAS 2002-44-0; *Sequence*: PLG-NH<sub>2</sub>), which is derived by proteolysis of oxytocin (*Sequence*: CYIQNCPLG-NH<sub>2</sub>), inhibits anterior pituitary synthesis/secretion of melanotropin. This peptide blocks the effects of opioid receptor activation (1). Melanostatin is also an allosteric activator of the D<sub>2</sub> and D<sub>4</sub> dopamine receptor subtypes. (*Note*: Neuropeptide Y has also been called melanostatin.) I. Dickinson & Slater (1980) *Peptides* **1**, 293.

**Melarsen Oxide**

This organoarsenical (FW = 292.13 g/mol; CAS 21840-08-4), also named *p*-(4,6-diamino-1,3,5-triazin-2-yl)aminophenylarsine oxide, is the active form of the trypanocidal drugs melarsoprol and cymelarsan. Melarsen oxide forms tight complexes with DL-dihydrolipoamide and DL-dihydrolipoate with association constants of 5.47 x 10<sup>9</sup> and 4.51 x 10<sup>9</sup> M<sup>-1</sup>, respectively. It also forms a stable adduct with trypanothione (association constant = 1.05 x 10<sup>7</sup> M<sup>-1</sup>). (*Note*: In the older literature (e.g., in ref. 2 below), the oxide has also been referred to simply as melarsen.) (See also *Pentamidine*, *Suramin*, and *Eflornithine*) **Target(s)**: aldehyde dehydrogenase (1); calcineurin (2,3); dihydrolipoamide dehydrogenase (4); fructose-2,6-bisphosphatase (5); fumarase (6); glutamate dehydrogenase (7); glutathione-disulfide reductase (8,9); glycerol-3-phosphate dehydrogenase (10-12); malate dehydrogenase (7); malic enzyme (7); phosphoenolpyruvate carboxylase (13); 6-phosphofructo-2-kinase (5); pyruvate carboxylase (7); pyruvate kinase. weakly inhibited (5,7); succinate dehydrogenase (14); trypanothione reductase (9). 1. **Melatonin**

This photosensitive pineal hormone (FW = 232.28 g/mol; CAS 73-31-4; M.P. = 116-118°C; λ<sub>max</sub> at 223 nm (in 95% ethanol), with ε = 27550 M<sup>-1</sup>cm<sup>-1</sup>, and 278 nm, with ε = 6300 M<sup>-1</sup>cm<sup>-1</sup>), also known as *N*-acetyl-5-methoxytryptamine, mediates photoperiodicity and serves as a peroxynitrite scavenger. It also stimulates the aggregation of melanosomes in amphibians, affects locomotor activity in sparrows, and participates in thermoregulation of some ectotherms. Melatonin will lighten skin color by reversing the effect of melanocyte-stimulating hormone. **Target(s)**:

aralkylamine *N*-acetyltransferase (1,2); nitric-oxide synthase (3,4); ribosydihydrnicotinamide dehydrogenase (quinone) (5-8). 1. Ferry, Loynel, Kucharczyk, *et al.* (2000) *J. Biol. **Meldonium**

This carnitine analogue and anti-ischemic drug (FW = 147.19 g/mol; CAS 86426-17-7; Solubility: >40 mg/mL), also known as Mildronate, Mildronāts, MET-88, and Quaterine, as well as 2-(2-carboxyethyl)-1,1,1-trimethylhydrazinium, is listed (as of January, 2016) by the World Anti-Doping Agency (WADA) as a banned substance in athletic competition. Meldonium was originally developed as a performance-enhancing drug by selecting agents that increased the work capacity of previously trained animals (1). Treatment of guinea pigs with meldonium results in a 50% decline in myocardial carnitine content, from 11 to 5.6 μmol/g dry weight (2). Meldonium is a noncompetitive inhibitor of butyrobetaine hydroxylase and inhibits fatty acid oxidation (3). Meldonium inhibits carnitine acetyl transferase, thereby contributing to an increase in acetyl-CoA availability for intramitochondrial metabolic pathways. It also prevents L-carnitine-induced stimulation of [U-<sup>14</sup>C]-palmitic acid oxidation *in vitro*. During administration as well as after addition into incubation medium, meldonium shows no significant effects on the oxidation of [1-<sup>14</sup>C]-palmitoyl-L-carnitine, but decreased the exogenous L-carnitine induced oxidation of the substrate *in vitro*. It does not affect the activity of carnitine palmitoyl transferase I (3). Meldonium inhibits carnitine acetyltransferase competitively with respect to carnitine (K<sub>i</sub> = 1.6 mM), and NMR spectroscopy and molecular docking show that its bound conformation closely resembles that of carnitine, except for the orientation of the (CH<sub>3</sub>)<sub>3</sub>N<sup>+</sup> group of meldonium is exposed to the solvent (4). It now appears that, by reducing fatty acid oxidation, meldonium increases the amount of O<sub>2</sub> available for respiration and mitochondrial ATP synthesis, thereby giving an aerobic advantage to athletes using this agent. On March 7, 2016, tennis star Maria Sharapova admitted to having tested positive for meldonium and to having taken this drug for health reasons over the previous decade. During that interval, she had won four of her five Grand Slam tournament championships. 1. Seifulla, Trevisani, Morozov, *et al.* (1993) *Eksp. Klin. Farmakol.* **56**, 34. 2. **Melezitose**

This nonreducing tri-saccharide (FW = 504.44 g/mol; CAS 597-12-6), also known as *O*-α-D-glucopyranosyl-(1→3)-*O*-β-D-fructofuranosyl-(2→1)-α-D-glucopyranoside, is produced by many plants and is found in a manna produced by Douglas fir and certain pine trees. Bees that have collected manna from these trees during times of drought produce honey containing

elevated concentrations of melezitose, which is nutritionally unsuitable for maintenance of the hive. **Target(s):** concanavalin A (1);  $\beta$ -fructofuranosidase, *or* invertase, weakly inhibited (2);  $\alpha$ -glucosidase, weakly inhibited (3); inulinase (4); sucrose-phosphatase (5-8). 1. ### $\beta$ -D-Melibiose

This reducing disaccharide (FW = 342.30 g/mol; CAS 585-99-9), also known as 6-*O*- $\alpha$ -D-galactopyranosyl-D-glucose, is produced by a number of plants and is a component of the structure of raffinose. It is an epimer of isomaltose, is very soluble in water, and typically supplied as a mixture of the  $\alpha$ - and  $\beta$ -anomers. Dilute acids will hydrolyze melibiose to the constituent monosaccharides. It is also a substrate for many  $\alpha$ -galactosidases. **Target(s):** aldose 1-epimerase (1); aralin (2); *Bauhinia purpurea* agglutinin (3);  $\beta$ -Fructofuranosidase, *or* invertase, weakly inhibited (4); galactinol:raffinose galactosyltransferase, *or* stachyose synthase, weakly inhibited (5);  $\alpha$ -galactosidase (6-8);  $\beta$ -galactosidase (6,9,10);  $\beta$ -glucosidase (11); rRNA *N*-glycosylase (2). 1. Bailey, Fishman, Kusiak, Mulhern & Pentchev (1975) *Meth. Enzymol.* 41, 471. 2. Tomatsu, Kondo, Yoshikawa, *et al.* (2004) *Biol. Chem.* 385, 819. 3. Osawa, Irimura & Kawaguchi (1978) *Meth. ### Melittin

This oligopeptideamide apitoxin and membranolytic agent (MW = 2850 g; CAS 37231-28-0; *Sequence*: GIGAVLKVLTGLPALISWIKRKRQQ-NH<sub>2</sub>, with N-terminal glycolyl residue often formylated; *Solubility*: 1 mg/mL acetonitrile-H<sub>2</sub>O, 20% vol/vol) is the main hemolytic component in honey bee (*Apis mellifica*) venom, comprising ~40-50% of the dry venom by weight. Melittin forms transmembrane pores that alter permeability barriers. When adsorbed onto a membrane surface, melittin self-associates and perturbs bilayer structure. Melittin also activates many phospholipases and binds to calmodulin and calmodulin-dependent proteins. Its mouse LD<sub>50</sub> is about 4  $\mu$ g/g body weight. **Structural Features:** Like other pore-forming peptides, melittin is amphipathic. Its hydrophobic and positively charged groups arrange on opposite surfaces of an  $\alpha$ -helix, as indicated by helical wheel diagrams and its solubility (*i.e.*, >250 mg/mL H<sub>2</sub>O and ~20 mg/mL CH<sub>3</sub>OH). In the presence of a phospholipid-rich bilayer, melittin molecules bind within milliseconds and orient either parallel or perpendicular with respect to the plane of the membrane. Those molecules adopting the perpendicular orientation are believed to self-assemble into transmembrane pores, whereas those in the parallel arrangement are inactive (1). The kinetics of the overall pore-forming can be studied monitoring hemoglobin leakage from melittin-treated red blood cells. **Target(s):** acetylcholinesterase (2); calmodulin-lysine *N*-methyltransferase (3,4); Ca<sup>2+</sup>-transporting ATPase (5-10); epidermal growth factor-induced protein-tyrosine kinase (11); F<sub>1</sub>F<sub>0</sub> ATPase, *or* F<sub>1</sub>F<sub>0</sub> ATP synthase (12); G<sub>s</sub> activity of guanine nucleotide-dependent adenyl cyclase activity in synaptic membranes of the rat cerebral cortex by inhibition of GDP release in exchange for added guanine nucleotides or the association of guanine nucleotides (13); H<sup>+</sup>/K<sup>+</sup>-dependent ATPase (14-16); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (6,14,17-20); phosphorylase kinase (21); photophosphorylation (uncoupled) (22); protein kinase C (17,23-28); protein-tyrosine phosphatase

(29); Rho ADP-ribosyltransferase (30,31). 1. Guzmán, Mika & Poolman (2008) *J. Biol. Chem.* 283, 33854. 2. Mitchell, Lowy, Sarmiento & Dickson (1971) *Arch. Biochem. Biophys.* 145, 344. 3. ### Meloxicam

This non-steroidal anti-inflammatory drug (FW = 351.41 g/mol; CAS 71125-38-7) inhibits cyclooxygenase-2, the inducible isozyme associated with inflammatory responses (IC<sub>50</sub> = 4.7  $\mu$ M) with a selectivity for cyclooxygenase-1 (IC<sub>50</sub> = 37  $\mu$ M). In clinical studies, meloxicam has exhibited reliable efficacy against rheumatoid arthritis, osteoarthritis, lumbago, scapulohumeral peri-arthritis, and neck-shoulder-arm syndrome. **Target(s):** collagenase (1); cyclooxygenase, *or* prostaglandin-endoperoxide synthase (2-5); oxidative phosphorylation, as an uncoupler (6). Meloxicam also exerts antitumor effects by targeting the COX-2/MMP-2/E-cadherin, AKT, apoptotic and autophagic pathways in COX-2-dependent and COX-2-independent pathways, and by inhibiting cell autophagy (7). 1. Barracchini, Franceschini, Amicosante, *et al.* (1998) *J. Pharm. Pharmacol.* 50, 1417. 2. Noble & Balfour (1996) *Drugs* 51, 424. 3. Engelhardt (1996) *Brit. J. Rheumatol.* 35 (Suppl. 1), 4. 4. ### Melphalan

This antineoplastic agent (FW = 305.20 g/mol; CAS 148-82-3), also known as L-sarcosylsine, 4-[bis(2-chloroethyl)amino]-L-phenylalanine, and L-phenylalanine mustard, forms inter-strand cross-links in duplex DNA. The mutation-induced alkylations result primarily in transversions and occur preferentially at GGC sequences. The agent selectively forms a two base-staggered inter-strand cross-link between the 5'-G and the G-opposite-C in the 5'-GGC sequence (1). (*Note:* The term melphalan refers specifically to the L-enantiomer. The D-isomer is known as medphalan, and the racemic mixture is merphalan.) **Target(s):** p34-cdc2 kinase (1,2); RNA polymerase

(2,3); thioresodoxin reductase (4). 1. Bauer & Povirk (1997) *Nucl. Acids Res.* **25**, 1211. 2. Orlandi, Zaffaroni, Bearzatto & Silvestrini (1996) *Brit. J. Cancer* **74**, 1924. 3. Hill (1977) *Cancer Biochem. Biophys.* **2**, 43. 4. Witte, Anestel, Jerremalm, Ehrsson & Arner (2005) *Free Radic. Biol. Med.* **39**, 696.

### Memantine

This voltage-dependent, low-affinity noncompetitive NMDA receptor antagonist (FW = 215.76 g/mol; CAS 41100-52-0, for the HCl salt; Solubility: 100 mM in H<sub>2</sub>O for HCl salt), also known by the code name D145, trade names Axura™, Akatinol™, Namenda™, Ebixa™, Abixa™ and Memox™, and its systematic name 1,3-dimethyl-5-aminoadamantan or 3,5-dimethyl-tricyclo-[3.3.1.1<sup>3,7</sup>]decan-1-amine, is a neuroprotective drug used in the symptomatic treatment of Alzheimer's Disease and mild to moderate vascular dementia. By binding with more tightly to the NMDA receptor than Mg<sup>2+</sup>, memantine inhibits prolonged Ca<sup>2+</sup> influx, thereby forming the basis for its action in ameliorating neuronal excitotoxicity (1-3). This FDA-approved AD drug, which has been shown to modestly benefit cognition, function, and global outcome in patients with moderate to severe AD, is also a noncompetitive serotonin 5HT<sub>3</sub> receptor antagonist (4). A sensitive and rapid HPLC method for the determination of memantine in human plasma has been reported (5). It should also be noted that memantine is a non-competitive antagonist of the type-3 5-hydroxytryptamine (serotonin) receptor, or 5-HT<sub>3</sub> receptor and a non-competitive antagonist of different neuronal nicotinic acetylcholine receptors (nAChRs), with potencies comparable to NMDA and 5-HT<sub>3</sub> receptors. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Wesemann, Sontag & Maj (1983) *Arzneimittelforschung.* **33**, 1122. 2. Rogawski & Wenk (2003) *CNS Drug Rev.* **9**, 275. 3. ### MEN 10376

This potent and selective NK receptor antagonist (FW = 1081.24 g/mol; CAS 135306-85-3; Peptide Sequence: L-Asp-L-Tyr-D-Trp-L-Val-D-Trp-D-Trp-L-Lys-NH<sub>2</sub>) targets Tachykinin NK<sub>2</sub> receptors ( $K_d$  = 9 nM, rabbit pulmonary artery). MEN 10376 shows >250x selectivity over NK<sub>1</sub> ( $K_d$  = 0.4 μM, guinea pig ileum) and NK<sub>3</sub> ( $K_d$  = 1 mM, guinea pig brain) (1-3). Tachykinin receptors regulate both excitatory and inhibitory intestinal motor functions as well as secretions, inflammation and visceral sensitivity. In particular, the NK<sub>2</sub> receptor stimulation inhibits intestinal motility by activating sympathetic extrinsic pathways or NANC intramural inhibitory components (4). MEN 10,376 is devoid of significant agonist activity (intravenous dose: 1-3 μmol/kg), selectively antagonizing the effects of an NK-2 agonist [β-Ala<sup>8</sup>]-Neurokinin A(4-10) in bladder contraction in rats and bronchoconstriction in guinea pigs, without affecting the response to the NK-1 agonist, [Sar<sup>9</sup>]-substance P sulfone on hypotension, salivation and bladder contraction in rats, bronchoconstriction in guinea pigs (1). 1. Maggi, Giuliani, Ballati, *et al.* (1991) *J. Pharmacol. Exp. Ther.* **257**, 1172. 2. Bartho, Santicioli, Patacchini & Maggi (1992) *Brit. J. Pharmacol.* **105**, 805. 3. ### MEN 11270

This conformationally constrained bradykinin receptor antagonist (FW = 1299.56 g/mol; CAS 235082-52-7; Structure: RRPX<sub>1</sub>GX<sub>2</sub>X<sub>3</sub>X<sub>4</sub>X<sub>5</sub>R, with modifications: first Arg = D-Arg, X<sub>1</sub> = Hyp, X<sub>2</sub> = Thi, X<sub>3</sub> = Dab, X<sub>4</sub> = D-Tic, X<sub>5</sub> = Oic, cyclized 7γ-10α; Solubility: 1 mg/mL in acetonitrile/water (30% vol/vol)) targets the B<sub>2</sub> bradykinin receptor ( $K_i$  = 0.2 nM). *Note:* MEN 11270 is the cyclized analogue of HOE 140 (See HOE 140), and blocks hypotension and bronchoconstriction *in vivo*. MEN 11270 displays selectivity for B<sub>2</sub> over twenty-nine other receptors and ion channels (pIC<sub>50</sub> < 5.5). 1. Meini, *et al.* (1999) *J. Pharmacol. Exp. Ther.* **289**, 1250. 2. Tramontana, *et al.* (2001) *J. Pharmacol. Exp. Ther.* **296**, 1051. 3. Cucchi, *et al.* (2002) *Peptides* **23**, 1457.

### MEN15596, See Ibodutant

### Menadione

This photosensitive dione (FW = 172.18 g/mol; CAS 58-27-5; M.P. = 105-107°C), also known as 2-methyl-1,4-naphthalenedione and vitamin K<sub>3</sub>, is a synthetic quinone that exhibits the physiological properties and characteristics of vitamin K. Menadione functions as an electron carrier and participates in a number of oxidation-reduction reactions. Menadione is also a thiol reactive reagent. (See also Menadiol; Menadione Bisulfite) **Target(s):** aldehyde oxidase (1,2); aldose reductase, or aldehyde reductase (3,4); alkane 1-monooxygenase (37); aminopyrine N-demethylase (cytochrome P450) (5); aniline-p-hydroxylase (cytochrome P450) (5); (S)-canadine synthase (34); Ca<sup>2+</sup>-transporting ATPase (6); choline acetyltransferase (7,8); cholinesterase (7,9); trans-cinnamate 4-monooxygenase (39,40); glutathione disulfide reductase (10); α-glycerophosphatase (11); histidine kinase (12); horseradish peroxidase (13); β-hydroxybutyrate dehydrogenase, weakly inhibited (14); 3α-hydroxysteroid transhydrogenase (15); indoleamine 2,3-dioxygenase (41,42); myo-inositol oxygenase (16,17); iodide peroxidase, or thyroid peroxidase (44); lactate dehydrogenase (18); 5-lipoxygenase, or arachidonate 5-lipoxygenase (43); 3-mercaptopyruvate sulfurtransferase (19); [mitogen-activated protein kinase kinase] kinase (20); NAD<sup>+</sup> ADP-ribosyltransferase, or poly(ADP-ribose) polymerase (32); NADH dehydrogenase (21); nitrate reductase (22); peroxidase (13); protein-glutamine γ-glutamyltransferase, or transglutaminase (33); pyruvate decarboxylase (23); quinone oxidase (24); ribonuclease H activity associated with HIV-1 reverse transcriptase (25); stearoyl-CoA Δ<sup>9</sup>-desaturase (35,36); steroid 9α-monooxygenase (26); sterol 14-demethylase, or CYP51 (38); succinate dehydrogenase (27); thiosulfate sulfurtransferase, rhodanese (19); ubiquinone thiolesterase (28); urease (29,30); vitamin K-dependent carboxylase, or protein-glutamate carboxylase (31). 1. #### O-Menthyl Hexylphosphonochloridate

This phosphonochloridate (FW = 322.86 g/mol) is an irreversible inhibitor of *Candida rugosa* lipase (or triacylglycerol lipase, reacting covalently with an active-site serine residue. While both *S*- and *R*-stereoisomers inhibit, the *R*-isomer is more efficient. **1.** Ransac, Gargouri, Marguet, *et al.* (1997) *Meth. Enzymol.* **286**, 190. **2.** Cygler, Grochulski, Kazlauskas, *et al.* (1994) *J. Amer. Chem. Soc.* **116**, 3180.

#### Mepacrine, See Quinacrine

#### Mepanipirim

This substituted pyrimidine (FW = 223.28 g/mol; CAS 110235-47-7; Solubility: 5.58 mg/L H<sub>2</sub>O at 20°C and soluble in most organic solvents), also known as *N*-(4-methyl-6-prop-1-ynylpyrimidin-2-yl)aniline, is a fungicide that inhibits the secretion of host cell wall-degrading enzymes. Mepanipirim does not inhibit the cell wall-degrading enzymes (*e.g.*, cutinase, pectinase, and cellulases). Mepanipirim also inhibits secretion of lipases, proteases, and invertase. **Target(s):** intracellular transport of very-low-density lipoprotein, or VLDL (1); retrograde Golgi-to-ER trafficking (2); secretion of host-cell wall degrading enzymes (3). **1.** Terada, Mizuhashi, Murata & Tomita (1999) *Toxicol. Appl. Pharmacol.* **154**, 1. **2.** Nakamura, Kono & Takatsuki (2003) *Biosci. Biotechnol. Biochem.* **67**, 139. **3.** Miura, Kamakura, Maeno, *et al.* (1994) *Pest. Biochem. Physiol.* **48**, 222.

#### Meperidine

This analgesic and  $\mu$ -opioid receptor agonist (FW<sub>free-base</sub> = 247.34 g/mol; CAS 57-42-1), is known in the U.S. by the trade name Demerol™ (as the hydrochloride) and elsewhere as pethidine, Isonipecaine™, Lidol™, Pethanol™, Piridosal™, Algil™, Alodan™, Centralgin™, Dispadol™, Dolantin™, and Mialgin™. When compared with morphine, demerol is safer, less addictive, and, due to its anticholinergic effects, is also superior in the treatment of pain associated with biliary spasm or renal colic. **Pharmacokinetic Parameters:** Meperidine is rapidly hydrolysed in the liver

to pethidinic acid and is also demethylated (by CYP2B6, CYP3A4, and CYP2C19) to norpethidine, the latter having half its analgesic activity but a longer elimination half-life (8–12 hours). Meperidine is also de-esterified by hepatic carboxylesterase to form Pethidinic acid (inactive), which is then demethylated (by CYP2B6, CYP3A4, and CYP2C19) to Norpethidinic acid (inactive). Meperidine, Norpethidine, Pethidinate and Norpethidinate all undergo glucuronidation and subsequent renal excretion. *See also* Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** K<sup>+</sup> channel (1); Na<sup>+</sup> channel (1,2); NADH dehydrogenase (or complex I or NADH:ubiquinone reductase) (3-5); NMDA (*N*-methyl-D-aspartate) receptor (6). **1.** Brau, Koch, Vogel & Hempelmann (2000) *Anesthesiology* **92**, 147. **2.** Wagner, Eaton, Sabnis & Gingrich (1999) *Anesthesiology* **91**, 1481. **3.** Hatefi & Stiggall (1978) *Meth. Enzymol.* **53**, 5. **4.** Hatefi (1978) *Meth. Enzymol.* **53**, 11. **5.** Hatefi & Stiggall (1976) *The Enzymes*, 3rd ed., **13**, 175. **6.** Yamakura, Sakimura & Shimoji (2000) *Anesth. Analg.* **90**, 928.

#### Mephedrone

This CNS-penetrant, serotonin reuptake inhibitor and “designer” stimulant (FW<sub>HCl-Salt</sub> = 213.69 g/mol; CAS 1189726-22-4; Soluble to 100 mM in H<sub>2</sub>O; 100 mM in DMSO), also named (±)-2-methylamino-1-(4-methylphenyl)propan-1-one hydrochloride and 4-methylmethcathinone, targets striatal dopamine uptake (IC<sub>50</sub> = 467 nM) and hippocampal 5-HT uptake into synaptosomes (IC<sub>50</sub> = 558 nM). Administration of Mephedrone depletes dopamine and reduces 5-HT transporter function. Mephedrone has a unique pharmacological profile with both abuse liability and neurotoxic potential. **1.** Hadlock, Webb, McFadden, *et al.* (2011) *J. Pharmacol. Exp. Ther.* **339**, 530.

#### Mepivacaine

This local anesthetic (FW = 246.35 g/mol; CAS 22801-44-1) reversibly blocks the transient inward sodium ion current (IC<sub>50</sub> = 0.3 mM for rat dorsal horn neurons of the spinal cord) and the steady-state potassium ion outward current (IC<sub>50</sub> = 0.2 mM for rat dorsal horn neurons of the spinal cord). **Target(s):** cholinesterase (1); hKv1.5 potassium channel (2); K<sup>+</sup> channel (3,4); Na<sup>+</sup> channel (3,4); TASK tandem pore baseline K<sup>+</sup> channel (5). **1.** Perez-Guillermo, Delgado & Vidal (1987) *Biochem. Pharmacol.* **36**, 3593. **2.** Longobardo, Delpont, Caballero, Tamargo & Valenzuela (1998) *Mol. Pharmacol.* **54**, 162. **3.** Brau, Vogel & Hempelmann (1998) *Anesth. Analg.* **87**, 885. **4.** Olschewski, Hempelmann, Vogel & Safronov (1998) *Anesthesiology* **88**, 172. **5.** Kindler, Yost & Gray (1999) *Anesthesiology* **90**, 1092.

#### Meprobamate

This anxiolytic agent and muscle relaxant (FW = 218.25 g/mol; CAS 57-53-4; M.P = 104–106°C), also known as 2-methyl-2-propyl-1,3-propanediol dicarbamate, Miltown™, and Equanil™, is not as effective as benzodiazepines and is often used for short-term relief of anxiety or

nervousness (1). The drug can also be delivered as a pro-drug (Tybamate). **Target(s):** carbonic anhydrase (2); ecto-ATPase (3); protein-binding of histamine and serotonin (4). 1. Ludwig & Piech (1951) *J. Amer. Chem. Soc.* **73**, 5779. 2. Parr & Khalifah (1992) *J. Biol. Chem.* **267**, 25044. 3. Melzig, Michalski & Teuscher (1989) *Biomed. Biochim. Acta* **48**, 431. 4. Di Maggio, Cannavà & Ciaceri (1968) *Boll. Soc. Ital. Biol. Sper.* **44**, 2096.

### Mepyramine

This selective histamine receptor inverse agonist (FW = 401.46 g/mol; CAS 59-33-6; Solubility: 10 mM in H<sub>2</sub>O), also named Ppyrilamine and 2-((2-(dimethylamino)ethyl)(p-methoxybenzyl)amino)pyridine maleate, targets H<sub>1</sub> receptors, inhibiting (log EC<sub>50</sub> = -7.94) histamine-induced inositol phosphate production and intracellular calcium mobilization. [<sup>3</sup>H]-Mepyramine labels the H<sub>1</sub> receptor as well as a liver [<sup>3</sup>H]-Mepyramine-binding protein (MBP) related to debrisoquine 4-hydroxylase, or cytochrome P450IID (1). Binding of [<sup>3</sup>H]-Mepyramine to cloned H<sub>1</sub> receptor is unaffected by 1 μM quinine, an inhibitor of debrisoquine 4-hydroxylase (1). H<sub>1</sub> receptors represent the majority of [<sup>3</sup>H]-Mepyramine binding sites in the cerebral cortex, thalamus and hypothalamus, hippocampus, heart, aorta, lung and spleen (2). Mepyramine sequesters G<sub>q/11</sub>, reducing its availability to other unrelated receptors within the same signaling pathway (2). 1. Liu, Horio, Fujimoto & Fukui (1994) *J. Pharmacol. Exp. Ther.* **268**, 959. 2. Fitzsimons, Monczor, Fernández, Shayo & Davio (2004) *J. Biol. Chem.* **279**, 34431.

### Merbarone

This antitumor agent (FW = 263.28 g/mol; CAS 97534-21-9), also known as 5-(N-phenylcarboxamido)-2-thiobarbituric acid and NSC 336628, inhibits DNA topoisomerase II and blocks DNA cleavage (1-4). 1. Andersen, Bendixen & Westergaard (1996) *DNA Replication in Eucaryotic Cells*, Cold Spring Harbor Laboratory Press, p. 587. 2. Drake, Hofmann, Mong, et al. (1989) *Cancer Res.* **49**, 2578. 3. ### 2-Mercaptobenzothiazole

This thiol (FW = 167.26 g/mol; CAS 149-30-4; *Abbreviation:* MBT), also called Mercap, Captax, and 2(3*H*)-benzothiazolethione, is a pale yellow solid that binds copper ions and inhibits some copper-dependent enzymes. Note that 2-mercaptobenzothiazole has a very low solubility in water, but is soluble in ethanol (2 g/100 mL at 25°C). 2-Mercaptobenzothiazole can also be used as a reducing reagent. Its primary commercial use is as a vulcanization accelerator in rubber production and as an inhibitor the corrosion of copper immersed in water. **Target(s):** catechol oxidase (1); dopamine β-monooxygenase (2); laccase (3); polyphenol oxidase (1,4); tyrosinase (5). 1. Motoda (1979) *J. Ferment. Technol.* **57**, 79. 2. Johnson, Boukma & Platz (1970) *J. Pharm. Pharmacol.* **22**, 710. 3. Ishigami, Hirose & Yamada (1988) *J. Gen. Appl. Microbiol.* **34**, 401. 4. Palmer & Roberts (1967) *Science* **157**, 200. 5. Zhang, van Leeuwen, Wichers & Flurkey (1999) *J. Agric. Food Chem.* **47**, 374.

### 2-Mercaptoethanol

This reducing reagent (FW = 78.14 g/mol; CAS 60-24-2; Density = 1.114 g/mL; Concentration = 14.3 M), commonly known as β-mercaptoethanol (*or*, βME), reduces disulfide groups, thereby restoring the activity of many enzymes with catalytically essential thiol groups. When present in large molar excess relative to a disulfide-containing peptide or protein, 2-mercaptoethanol reduces accessible disulfide bonds with stoichiometric formation of the disulfide HOCH<sub>2</sub>CH<sub>2</sub>-S-S-CH<sub>2</sub>CH<sub>2</sub>OH (See *Bis(2-hydroxyethyl) disulfide*). Mercaptoethanol is also used to maintain reduced thiols in coenzyme A and lipoic acid. The equilibrium constant for the thiol-disulfide exchange with glutathione disulfide (thus, 2 βME + GS-SG ⇌ βME-S-S-βME + 2 GSH) is approximately one, whereas the corresponding value for disulfide bonds in intact proteins is often considerably less than one. For this reason, a large excess of 2-mercaptoethanol is required in order to reduce recalcitrant disulfides. Note that 2-mercaptoethanol is easily air oxidized, requiring βME solutions to be freshly prepared. Those enzymes and cofactors requiring disulfides to maintain their active conformation may be inhibited by 2-mercaptoethanol. βME complexation of metal ions can also result in inhibition.

### 2-Mercaptoethanol Disulfide, See 2-Hydroxyethyl Disulfide

### Mercaptoethylguanidine

This peroxyxynitrite scavenger (FW = 119.19 g/mol) inhibits the inducible isoform of nitric-oxide synthase. **Target(s):** cysteamine dioxygenase (1); dopamine β-hydroxylase (2); nitric-oxide synthase (3-5). 1. Richerson & Ziegler (1987) *Meth. Enzymol.* **143**, 410. 2. Diliberto, DiStefano & Smith (1973) *Biochem. Pharmacol.* **22**, 2961. 3. Szabo, Ferrer-Sueta, Zingarelli, et al. (1997) *J. Biol. Chem.* **272**, 9030. 4. Zingarelli, Cuzzocrea, Szabo & Salzman (1998) *J. Pharmacol. Exp. Ther.* **287**, 1048. 5. Southan, Zingarelli, O'Connor, Salzman & Szabo (1996) *Brit. J. Pharmacol.* **117**, 619.

### 8-Mercaptoguanine

This antineoplastic guanine derivative (FW = 362.35 g/mol; CAS 6324-72-7) inhibits hypoxanthine(guanine) phosphoribosyltransferase (1). The essential folate biosynthetic enzyme, 6-hydroxymethyl-7,8-dihydropterin pyrophosphokinase, which catalyzes the Mg<sup>2+</sup>-dependant transfer of pyrophosphate from ATP to 6-hydroxymethyl-7,8-dihydropterin binds 8-mercaptoguanine at the substrate site (K<sub>d</sub> ~13 μM) and inhibits *Staphylococcus aureus* enzyme HPPK (IC<sub>50</sub> ~ 41 μM) (2). 8-Mercaptoguanine is also a useful starting reagent for the synthesis of various C-8 derivatives of purines. 1. Miller, Ramsey, Krenitsky & Elion (1972) *Biochemistry* **11**, 4723. 2. Chhabra, Barlow, Dolezal, et al. (2013) *PLoS One* **8**, e59535.

### N-(2(R,S)-Mercaptoheptanoyl)-L-phenylalanyl-L-alanine

This  $\alpha$ -mercaptoacyldipeptide (FW<sub>free-acid</sub> = 380.51 g/mol), also known as *N*-(2(*R,S*)-sulfanylheptanoyl)-*L*-phenylalanyl-*L*-alanine, inhibits neprilysin and thermolysin:  $K_i$  = 2.9 and 48 nM, respectively. Crystal structure analysis suggests that the mercaptoacyl moieties act as bidentates, with Zn-S and Zn-O distances of 2.3 and 2.4 Å, respectively. The side chains fit within the  $S_1$ ,  $S_1'$ , and  $S_2'$  pockets. Moreover, a distance of 3.1 Å between the sulfur atom and the OE1 of Glu<sup>143</sup> suggests that they are H-bonded and that one of these atoms is protonated. This H-bond network involving Glu<sup>143</sup>, the mercaptoacyl group of the inhibitor, and the Zn ion could be considered a "modified" transition state mimic of the peptide bond hydrolysis. **1.** Gaucher, Selkti, Tiraboschi, *et al.* (1999) *Biochemistry* **38**, 12569.

### 3-Mercapto-2-ketoglutarate

This  $\alpha$ -ketoglutarate derivative (FW<sub>free-acid</sub> = 178.17 g/mol), also known as 3-mercapto-2-oxoglutarate and  $\beta$ -mercapto- $\alpha$ -ketoglutarate, potently inhibits isocitrate dehydrogenase and is an alternative substrate of  $\alpha$ -ketoglutarate dehydrogenase. For porcine mitochondrial NADP<sup>+</sup>-specific isocitrate dehydrogenase, inhibition is competitive with respect to isocitrate,  $K_i$  = 5 nM (**1**). **Target(s):** isocitrate dehydrogenase, NAD<sup>+</sup>-specific (**1**); isocitrate dehydrogenase NADP<sup>+</sup>-specific (**1**);  $\gamma$ -butyrobetaine dioxygenase, thereby blocking *L*-carnitine synthesis (**2**). **1.** Plaut, Aogaichi & Gabriel (1986) *Arch. Biochem. Biophys.* **245**, 114. **2.** Wehbie, Puneekar & Lardy (1988) *Biochemistry* **27**, 2222.

### Mercaptomerin

This diuretic (FW<sub>disodium-salt</sub> = 606.01 g/mol), also known as thiomerin, reportedly inhibits ATPase, ouabain-sensitive (**1**), glutamine synthesis (**2**), histamine *N*-methyltransferase, weakly inhibited (**3**), and Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (**4**). **1.** Nechay, Nelson, Contreras, *et al.* (1975) *J. Pharmacol. Exp. Ther.* **192**, 303. **2.** Richterich-Van Baerle, Goldstein & Dearborn (1957) *Enzymologia* **18**, 327. **3.** Thithapandha & Cohn (1978) *Biochem. ### DL-2-Mercaptomethyl-3-guanidinoethylthiopropionic Acid

This thiol-containing arginine analogue (FW = 237.35 g/mol), also known as MGTA, MERGETPA, and Plummer's inhibitor, is a potent inhibitor of carboxypeptidase N, which catalyzes the hydrolysis of bradykinin. **Target(s):** carboxypeptidase B (**1,12**); carboxypeptidase D (**2**); carboxypeptidase E, or carboxypeptidase H (**2,3,12**); carboxypeptidase M (**4-9,12**); carboxypeptidase U (**10-12**); lysine carboxypeptidase, or lysine(arginine) carboxypeptidase, or carboxypeptidase N, or arginine carboxypeptidase,  $K_i$  = 2 nM (**12-19**); metallo-carboxypeptidase D (**20**); Xaa-Pro aminopeptidase, or aminopeptidase P (**21-23**). **1.** Muto, Suzuki, Sato & Ishii (2003) *Eur. ### 2-Mercaptomethyl-5-guanidinopentanoic Acid

This thiol-containing arginine analogue (FW = 205.28 g/mol), also known as SQ 24798, is a carboxypeptidase B inhibitor ( $K_i$  = 0.42 nM). The inhibitor potency is attributed to the combined action of substrate specificity-conferring features and thiol-mediated chelation of an active-site zinc ion. It is a weaker inhibitor of carboxypeptidase A ( $K_i$  = 11.6  $\mu$ M) and angiotensin-converting enzyme ( $K_i$  = 288  $\mu$ M). **Target(s):** carboxypeptidase A (**1**); carboxypeptidase B (**1,2**); lysine carboxypeptidase or carboxypeptidase N, or lysine(arginine) carboxypeptidase (**3**); peptidyl-dipeptidase A, or angiotensin converting enzyme (**1**). **1.** Ondetti, Condon, Reid, *et al.* (1979) *Biochemistry* **18**, 1427. **2.** Avilés & Vendrell (1998) in *Handb. Proteolytic Enzymes*, p. 1333, Academic Press, San Diego. **3.** Plummer & Ryan (1981) *Biochem. Biophys. Res. Commun.* **98**, 448.

### 3-[(*R*)-1-(Mercaptomethyl)-2-phenylethyl]amino-3-oxopropanoate

This thiorphan analogue (FW = 253.32 g/mol), also known as *retro*-thiorphan, inhibits neprilysin; the *R*-stereoisomer has a  $K_i$  value of 2.3 nM, whereas the value for the *S*-isomer is 210 nM (**1-3**). The  $K_i$  value for thrombolysin is 0.8  $\mu$ M (**3-5**). (**See also Thiorphan**) **1.** Roques, Noble, Crine & Fournié-Zaluski (1995) *Meth. Enzymol.* **248**, 263. **2.** Fournie-Zaluski, Lucas-Sorooca, Devin & Roques (1986) *J. Med. ### 3-Mercaptopicolinate (3-Mercaptopicolinic Acid)

This hypoglycemic agent (FW<sub>free-acid</sub> = 155.18 g/mol; CAS 14623-54-2 (HCl salt)) inhibits gluconeogenesis, binds metal ions (particularly iron), and inhibits phosphoenolpyruvate carboxykinase. **Target(s):** glucose-6-phosphatase (**1,2**); glucose-6-phosphate translocase (**3**); phosphoenolpyruvate carboxykinase (ATP) (**4,5**); phosphoenolpyruvate carboxykinase (GTP) (**6-14**). **1.** Bode, Foster & Nordlie (1993) *Biochem. ### 3-Mercaptopropionate (3-Mercaptopropionic Acid)

This toxic  $\beta$ -thiol acid and coenzyme M analogue (FW<sub>free-acid</sub> = 106.15 g/mol; CAS 107-96-0; M.P. = 17-19°C), also known as 3-mercaptopropionic acid, is a convulsion-inducing agent. **Target(s):** 4-aminobutyrate aminotransferase (1,2); aspartate aminotransferase (3); aspartate carbamoyltransferase, weakly inhibited (4); butyrate uptake (5); cathepsin B (6); cystathionine  $\gamma$  synthase, also alternative substrate (7,8); cysteine dioxygenase, weakly inhibited (9-11); cysteinesulfonic acid decarboxylase (12); dihydroorotase (13); glutamate decarboxylase (14-23); guanidinobutyrase (24); long-chain acyl-CoA dehydrogenase (25); 3-mercaptopropionate sulfurtransferase (26); phosphoenol-pyruvate carboxylase (27); *O*-succinylhomoserine (thiol)-lyase (28); urocanate hydratase, *or* urocanase (29); Zn<sup>2+</sup>-type D-alanyl-D-alanine-cleaving carboxypeptidase (30,31). **1.** Gale (1984) *Life Sci.* **34**, 701. **2.** Schousboe, Wu & Roberts (1974) *J. **N-(2-Mercaptopropionyl)glycine, See Tiopronin**

### 2-(3-Mercaptopropyl)pentanedioic acid

This orally bioavailable substituted dicarboxylic acid (FW = 206.26 g/mol; CAS 254737-29-6; Solubility: 100 mM in H<sub>2</sub>O or DMSO), also known as 2-MPPA, is a selective inhibitor (IC<sub>50</sub> = 90 nM) of glutamate carboxypeptidase II (GCP II), also variously known as *N*-acetyl-L-aspartyl-L-glutamate peptidase I (*or* NAALADase I), NAAG peptidase, or Prostate specific membrane antigen (*or* PSMA) (1-3). This zinc metalloenzyme catalyzes the formation of glutamate and *N*-acetyl-aspartate from *N*-acetyl-aspartyl-L-glutamate (*or* NAAG), the latter one of the three most abundant neurotransmitters in the central nervous system. By reducing the amount of glutamate formed, selective GCP II inhibitors protect motor neurons (MN) against glutamate excitotoxicity, a process believed to be a factor in both sporadic (ALS) and familial (FALS) forms of amyotrophic lateral sclerosis. 2-MPPA prevents MN cell death in both of these systems because of the resultant decrease in glutamate levels (1,2). When administered at 60 mg/kg (but not 10 or 30 mg/kg), 2-MPPA prevented morphine tolerance without

affecting acute morphine antinociception (3). **1.** Ghadge, Slusher, Bodner, *et al.* (2003) *Proc. Natl. Acad. Sci. U.S.A.* **100**, 9554. **2.** Majer, Jackson, Delahanty, *et al.* (2003) *J. Med. Chem.* **46**, 1989. **3.** Kozela, Wrobel, Kos, *et al.* (2005) *Psychopharmacology* (Berlin) **183**, 275.

### 2-Mercaptopurine

This substituted purine (FW = 152.18 g/mol; CAS 28128-19-0), also known as 2-purinethiol and 2-thiopurine, inhibits 6-phosphofructo-2-kinase (1), transaminidase (2), and xanthine phosphoribosyltransferase (3). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** Mojena, Bosca, Rider, Rousseau & Hue (1992) *Biochem. Pharmacol.* **43**, 671. **2.** Karelin (1974) *Vopr. Med. Khim.* **20**, 406. **3.** Miller, Adamczyk, Fyfe & Elion (1974) *Arch. Biochem. Biophys.* **165**, 349.

### 6-Mercaptopurine

This toxic hypoxanthine analogue (FW = 152.18 g/mol; CAS 50-44-2; yellow, with  $\lambda_{\text{max}}$  at 222 (9240 M<sup>-1</sup>cm<sup>-1</sup>) and 327 nm (21300 M<sup>-1</sup>cm<sup>-1</sup>) in 0.1 N HCl, and  $\lambda_{\text{max}}$  values of 230 (14000 M<sup>-1</sup>cm<sup>-1</sup>) and 312 nm (19600 M<sup>-1</sup>cm<sup>-1</sup>) in 0.1 N NaOH), also called 6-thiopurine and thiohypoxanthine, was first synthesized in the 1950s by Gertrude Elion and George Hitchings, the 1988 Nobel Laureates in Medicine/Physiology. (**See also prodrug Azathioprine**) In humans, 6-MP transport involves sodium-dependent, purine-selective transporters SLC28A2, SLC28A3, SLC29A1 and SLC29A2. As an alternative substrate for the salvage enzyme, hypoxanthine:guanine phosphoribosyltransferase (*Physiologic Reaction:* Guanine (or Hypoxanthine) + PRPP  $\rightleftharpoons$  GMP (or IMP) + PP<sub>i</sub>), 6-mercaptopurine is converted to 6-mercaptopurine- $\beta$ -D-ribose 5'-monophosphate, *or* 6-thio-IMP (*Drug Reaction:* 6-Thiopurine + PRPP  $\rightleftharpoons$  6-thio-IMP + PP<sub>i</sub>). (**See also 6-Thioinosine 5'-Triphosphate; 6-Thioinosine 5'-Triphosphate**) 6-Thio-IMP is a potent inhibitor (slow alternative substrate) for IMP dehydrogenase (*Physiologic Reaction:* IMP + NAD<sup>+</sup> + H<sub>2</sub>O  $\rightleftharpoons$  XMP + NADH + H<sup>+</sup>; *Thio-IMP Reaction:* 6-Thio-IMP + NAD<sup>+</sup> + H<sub>2</sub>O  $\rightleftharpoons$  6-Thio-XMP + NADH + H<sup>+</sup>), and 6-Thio-XMP is then converted to 6-Thio-GMP by GMP synthase. 6-Thio-IMP is also a competitive inhibitor for adenylosuccinate synthetase (*Reaction:* IMP + Aspartate + GTP  $\rightleftharpoons$  Adenylosuccinate + GDP + P<sub>i</sub>). 6-Thio-IMP is likewise an feedback inhibitor for glutamine:phosphoribosylamine synthetase (*Reaction:* Glutamine + PRPP  $\rightleftharpoons$  Glutamate + Phosphoribosylamine + PP<sub>i</sub>), the first committed step and pacemaker in *de novo* purine nucleotide biosynthesis. These properties commend 6-mercaptopurine as a powerful immunosuppressant and antileukemic agent that throttles purine biosynthesis as well as cell proliferation. In humans, 6-thio-IMP is converted to thio-guanosine nucleotides, the cytotoxicity of which occurs through 6-mercaptopurine-dGTP incorporation into DNA, thereby impairing enzymes involved in DNA replication and repair and inducing DNA damage (*e.g.*, single strand-breaks, DNA-protein cross-links, and chromatid exchanges). Incorporation of 6-mercaptopurine triphosphate into RNA also impairs mRNA structure and subsequent translation. (**See also 6-Thioguanine; 6-Thioguanosine 5'-Monophosphate**) Note also that 6-mercaptopurine is a substrate for thio-purine methyltransferase (*Reaction:* 6-Mercaptopurine + *S*-Adenosyl-Methionine  $\rightleftharpoons$  *S*-CH<sub>3</sub>-Mercaptopurine + *S*-Adenosyl-homocysteine), with *S*-methylthiopurine preventing the formation of thio-guanosine nucleotides. Moreover, because xanthine oxidase metabolizes 6-mercaptopurine, patients taking xanthine oxidase inhibitors (*e.g.*, allopurinol, oxypurinol, tiopurine, febuxostat, topiroxostat, and phytic acid) to prevent gout are therefore at elevated risk for mercaptopurine toxicity. **See other IMPDH inhibitors: Merimepodib; Mycophenolate; Mycophenolate mofetil** **Target(s):** adenylosuccinate synthetase (1); cyclooxygenase (2); DNA methylation

(3,4); hypoxanthine(guanine) phosphoribosyltransferase, also as an alternative substrate (5-8); methionine *S*-adenosyltransferase (9); 6-phosphofructo-2-kinase (10); purine-nucleoside phosphorylase, or guanosine phosphorylase, as product inhibitor (11,12); succinate dehydrogenase (13); urate oxidase, or uricase (14); xanthine dehydrogenase (15); xanthine oxidase (16); xanthine phosphoribosyltransferase (6,17). 1. ### 3-Mercaptopyruvate (3-Mercaptopyruvic Acid)

This naturally occurring pyruvate derivative (FW<sub>free-acid</sub> = 120.13 g/mol; CAS 2464-23-5) is an intermediate in the catabolism of cysteine in a number of organisms. It is formed in the cysteine aminotransferase reaction and a substrate for 3-mercaptopyruvate sulfurtransferase. In some organisms, 3-mercaptopyruvate is an alternative substrate of tRNA sulfurtransferase. It is also an alternative substrate of lactate dehydrogenase and a mechanism-based inactivator of pyruvate formate-lyase. Note that aqueous solutions of 3-mercaptopyruvic acid readily dimerize to form 2,5-dihydroxy-1,4-dithiane-2,5-dicarboxylic acid (1). The equilibrium constant favors the cyclic form at pH 5-7. In neutral or alkaline solutions, 3-mercaptopyruvate irreversibly forms the acyclic aldol dimer (OOCCH(SH)C(OH)(CH<sub>2</sub>SH)COO<sup>-</sup>), which then undergoes further oligomerization. **Target(s):** glutamine:pyruvate aminotransferase (2,3); 4-hydroxy-2-oxoglutarate aldolase (4); pyruvate formate-lyase (5); tRNA sulfurtransferase (6). 1. ### Mercuric Ion

This heavy metal cation (Symbol: Hg<sup>2+</sup>; Atomic Number: 80; Atomic Weight: 200.59), a Group 12 element (or group IIB), reacts rapidly with sulfhydryl groups, accounting for its frequent use as an enzyme inhibitor as well as an analytical reagent for detecting and quantifying cysteinyl residues and other thiol-containing substances. Because mercuric ion is divalent, it reacts with up to two sulfhydryl groups. At low concentrations, a simple mercaptide is generated (*Reaction:* R-SH + Hg<sup>2+</sup> → R-S-Hg<sup>+</sup> + H<sup>+</sup>). This mercaptide reacts with a second thiol to produce a bridged structure (*Reaction:* R-SHg<sup>+</sup> + R'-SH → R-S-Hg-S-R' + H<sup>+</sup>). Excess mercuric ion favors reformation of the mercaptide from this bridged structure (*Reaction:* R-S-Hg-S-R' + Hg<sup>2+</sup> → R-S-Hg<sup>+</sup> + R'-S-Hg<sup>+</sup>). Compounds containing Hg(II) are also common. The majority of organomercurials have either the general structure R-HgX or R<sub>2</sub>-Hg. The CH<sub>3</sub>-Hg<sup>+</sup> ion, for example, which is formed by methylation of metallic mercury by methylcobalamin, binds firmly to sulfur in biomolecules. In addition, mercuric ion can denature DNA and damage chromosomes. **Toxicity:** In humans and mammals, mercury ions have toxic effects on number organs, and the proximal kidney tubule is especially vulnerable. Because cysteines in most cell-surface proteins/receptors are mainly disulfides, mercuric ions rarely inhibit them. Even so, circulating mercury ions combine with albumin, metallothionein,

glutathione, and cysteine, and these mercurated substances have been implicated in mechanisms involved in the proximal tubular uptake, accumulation, transport, and toxicity of mercuric ions. Ionic mercury and certain organomercurials also react with aquaporins, inhibiting water transport (3). 1. Zalups (2000) *Pharmacol. Rev.* **52**, 113. 2. ### Merimepodib

This orally bioavailable IMPDH inhibitor (FW = 452.17 g/mol; CAS 198821-22-6), also known as VX-497, VX497, VI21497, and (S)-tetrahydrofuran-3-yl 3-(3-(3-methoxy-4-(oxazol-5-yl)phenyl)ureido)benzyl carbamate, targets IMP dehydrogenase and inhibits the proliferation of primary human, mouse, rat, and dog lymphocytes at concentrations of ~100 nM (1). Its inhibitory effect on lymphocytes is reversed in the presence of exogenous guanosine, but not in the presence of adenosine or uridine, confirming that the antilymphocytic activity of VX-497 is specifically due to inhibition of IMPDH. In mice, oral administration of merimepodib inhibits the primary IgM antibody response in a dose-dependent manner (ED<sub>50</sub> = 30-35 mg/kg) (1). Merimepodib is an uncompetitive inhibitor, K<sub>i</sub> = 6 nM for IMPDH-II (2). It inhibits proliferation of mitogen-stimulated primary human lymphocytes (IC<sub>50</sub> = ~80 nM). Merimepodib does not inhibit proliferation of nonlymphoid cell types, such as fibroblasts, indicating selectivity for IMPDH inhibition (2). It also prolongs skin graft survival and improves graft *versus* host disease in mice (3). 1. Jain, Almquist, Shlyakhter & Harding (2001) *J. Pharm. Sci.* **90**, 625. 2. Jain, Almquist, Heiser, *et al.* (2002) *J. Pharmacol. Exp. Ther.* **302**, 1272. 3. Decker, Heiser, Chaturvedi, *et al.* (2001) *Drugs Exp. Clin. Res.* **27**, 89.

### Meropenem

This ultra-broad-spectrum, injectable, carbapenem-class antibiotic (FW = 383.46 g/mol; CAS 119478-56-7), also named SM-7338, Merofit<sup>®</sup> (India), Meronem<sup>®</sup> (Germany), 3-[5-(dimethyl-carbamoyl)pyrrolidin-2-yl]sulfanyl-6-(1-hydroxyethyl)-4-methyl-7-oxo-1-azabicyclo[3.2.0]hept-2-ene-2-carboxylate, inhibits bacterial wall synthesis like other β-lactam antibiotics, but enjoys high resistance to enzymatic degradation by β-lactamases or cephalosporinases. Meropenem shows potent antibacterial activity against a broad spectrum of aerobes, including *Staphylococcus aureus*, β-hemolytic streptococci, *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Neisseria* spp., as well as members of the family *Enterobacteriaceae*, *Pseudomonas* spp., as well as Gram-positive and Gram-negative anaerobes in a collection of 1,102 unselected clinical isolates (1). Clinical meropenem response *in vitro* is defined as: susceptible (MICs ≤ 4 μg/mL); intermediate susceptibility (MICs = 8 μg/mL); and resistance (MICs ≥ 16 μg/mL) (2). In six volunteers given a single 1-g intravenous dose, the mean elimination t<sub>1/2</sub> in plasma was 1.1 hours, with a mean plasma concentration of 24 μg/mL at 1 hour to 0.7 μg/mL at 6 hours (3). Inflammatory fluid penetration is rapid (reaching maximum concentration of drug in serum in 45 minutes) with a penetration of 111% (3). ## Mersalyl

This sulfhydryl-reactive agent ( $FW_{\text{sodium-salt}} = 505.85$  g/mol; CASs = 492-18-2, 486-67-9 (mersalyl acid); photosensitive), also known as Salyrgan and [3-[[2-(carboxylatomethoxy)benzoyl]amino]-2-methoxypropyl]hydroxymercurate, was originally adapted for use as a diuretic from calomel (HgCl<sub>2</sub>), itself a diuretic first discovered by the German-Swiss Renaissance physician Paracelsus. In mice, mersalyl exhibits LD<sub>50</sub> values of 400, 500, and 1400 mg/Kg for intravenous, subcutaneous, and oral routes. Because the cysteine sulfur atoms of cell-surface proteins and receptors are present as disulfides, mersalyl rarely inhibits these processes. Moreover, although many thiol-requiring enzymes are inhibited *in vitro*, mersalyl does not cross biomembranes and rarely inhibits enzymes *in vivo*. In addition to the enzymes listed below, mersalyl inhibits transporters for orthophosphate, sulfate, glutamine, and carnitine/acetylcarnitine. **Target(s)**: 4-acetamidobutyrate deacetylase (1);  $\alpha$ -N-acetylneuraminyl-2,3- $\beta$ -galactosyl 1,3-N-acetyl-galactosamide 6- $\alpha$ -sialyltransferase (79); aconitase (aconitate hydratase) (2); actin polymerization (3,4); adenine nucleotide carrier (5); adenylate cyclase (6); alcohol dehydrogenase, yeast (7); amine oxidase (8); aquacobalamin reductase (10); aquacobalamin reductase (NADPH) (9,10,83,84); arginine deaminase (11); L-ascorbate peroxidase (89); aspartate aminotransferase (76); aspartate carbamoyltransferase (12); benzylamine oxidase (8); benzylamine/putrescine oxidase (8); branched-chain amino-acid aminotransferase (74,75); Ca<sup>2+</sup>-dependent ATPase (13,14); carbamoyl-phosphate synthetase (15); carbon monoxide dehydrogenase (16); catechol 1,2-dioxygenase (17); cathepsin L (18); chloride/bicarbonate-dependent ATPase (19); CoB-CoM heterodisulfide reductase (90); 3-cyanoalanine hydratase (20); cyanoalanine nitrilase (20); cytidine deaminase (21-23); cytochrome b<sub>5</sub> reductase (24); cytosine deaminase (25); dynein ATPase (26); ecto-ATPase (27); endopeptidase La (68); 2-enoate reductase (28); ferredoxin hydrogenase (88); ferredoxin:nitrite reductase (29); formyltetrahydrofolate synthetase (30); glutaminase (31,32); glutathione dehydrogenase (ascorbate) (91); glutathione S-transferase (77); glycerol kinase (73); glycoprotein 6- $\alpha$ -L-fucosyltransferase (81); 9-hydroxyprostaglandin dehydrogenase (33); imidazoleacetate 4-monooxygenase (86); levansucrase (82); lysine 2-monooxygenase (34,87); lysyl aminopeptidase, bacterial (35); macropain (proteasome endopeptidase complex) (36-38); methylamine oxidase (8); methylglutaconyl-CoA hydratase (39); microsomal epoxide hydrolase, weakly inhibited (70); NADH dehydrogenase (40-45); NADH: ferricyanide reductase (46); NADH:hexacyanoferrate(III) reductase (47); NADPH:cytochrome c reductase (46,48); NADPH:cytochrome P450 reductase, *or* NADPH: ferrihemoprotein reductase (24,46); NAD(P)H dehydrogenase (49,50); NADPH oxidase (51); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (52,53); peroxidase, gastric (54,55); 1-phosphatidylinositol 4-kinase (72); polygalacturonidase, *or* pectinase (71); proline dehydrogenase, *or* proline oxidase (56); prollyl aminopeptidase (69); prostaglandin E<sub>2</sub> 9-reductase (57,58); proteasome endopeptidase complex (36-38); pyrophosphatase, *or* inorganic diphosphatase (59); ribose-5-phosphate isomerase (60,61); rubredoxin:NAD<sup>+</sup> reductase (62); steroid 21-monooxygenase, *or* CYP21A1 (63,64,85); steroid 5 $\alpha$ -reductase, rat (65); steroid 3 $\beta$ -glucosyltransferase (80); succinate dehydrogenase (66); thiamin pyridinylase, *or* thiaminase I (78); threonine dehydratase (67). **1.** Haywood & Large (1986) *J. **Merthiolate, See Thimerosal**

**Mesaconate (Mesaconic Acid)**

This dicarboxylic acid (FW<sub>free-acid</sub> = 130.10 g/mol; CAS 498-24-8), also referred to as methylfumaric acid and (*E*)-2-methyl-2-butenedioic acid, is an intermediate in the catabolism of glutamate in a number of organisms (e.g., *Clostridium tetanomorphum*). The free acid is soluble in water (2.7 g/100 g at 18°C) and has p*K*<sub>a</sub> values of 3.07 and 4.82 at 25°C. Mesaconate is an activator of dopamine β-monooxygenase. **Target(s):** carboxy-*cis,cis*-muconate cyclase (1); fumarase (2-4); fumarate reductase activity of *Shewanella putrefaciens* flavocytochrome *c* (5); glutamate decarboxylase, *K*<sub>i</sub> = 4.1 mM (6); 2-methyleneglutarate mutase (7,8). 1. **Mesalamine**

This anti-inflammatory aminosalicylate (FW = 153.14 g/mol; CAS 89-57-6), also known 5-aminosalicylic acid (or 5-ASA) and 5-amino-2-hydroxybenzoate, is a mainstay drug in the treatment of inflammatory bowel disease, such as ulcerative colitis. Mesalamine is bowel-specific, acting locally in the gut and showing few systemic side effects. Mesalamine is the active moiety in sulfasalazine (FW = 398.41 g/mol; CAS 599-79-1; formed by linking 5-ASA with sulfapyridine; IUPAC: 2-hydroxy-5-[(*E*)-2-{4-[(pyridin-2-yl)sulfamoyl]phenyl}diazen-1-yl]benzoic acid), which was initially developed for the treatment of rheumatoid arthritis more than 60 years ago. Mesalamine dose-dependently inhibits IL-1-stimulated NF-κB-dependent transcription without preventing IκB degradation or nuclear translocation and DNA binding of the transcriptionally active NF-κB proteins, RelA, c-Rel, or RelB. It also inhibits IL-1-stimulated RelA phosphorylation, suggesting that pharmacologic modulation of the phosphorylation status of RelA regulates the transcriptional activity of NF-κB in a manner that is independent of nuclear translocation and DNA binding (1). NCX-456, the nitric oxide-releasing derivative of mesalamine is significantly more effective than mesalamine in reducing the severity of colitis (i.e., damage and granulocyte infiltration) (2). Unlike mesalamine, NO-mesalamine significantly suppresses leukocyte adherence to the vascular endothelium in vivo. NO-mesalamine inhibited IL-1β and IFN-γ release and caspase 1 activity in splenocytes; such effects were not found in the inflamed colon (2). 1. Egan, Mays, Huntoon, et al. (1999) *J. Biol. Chem.* **274**, 26448. 2. Wallace, Vergnolle, Muscará, et al. (1999) *Gastroenterol.* **117**, 557.

**Mescaline**

This alkaloid and hallucinogenic tyrosine derivative (FW = 211.26 g/mol; CAS 832-92-8 (hydrochloride)), from the flowering buds of the mescal peyote cactus *Lophophora williamsii*, is a partial agonist at 5-HT<sub>2A</sub> and 5-HT<sub>2</sub> receptors, subtypes of the serotonin G protein-coupled receptor family. Its free base (M.P. = 35-36°C) is moderately water-soluble, but the hydrochloride is far more so. Psychedelic effects often include altered

thinking, distorted sense of time and self-awareness, and vivid visual hallucinations. **Target(s):** diamine *N*-acetyltransferase (1); weakly inhibits microtubule self-assembly, or tubulin polymerization (2). Note also mescaline's structural similarity with the trimethoxyphenyl ring and amino group location in colchicine. Native North Americans used peyote for spiritual purposes for nearly six millennia. 1. Seiler & al-Therib (1974) *Biochim. Biophys. Acta* **354**, 206. 2. Andreu & Timasheff (1982) *Biochemistry* **21**, 534.

**Mesopram**

This orally active PDE inhibitor (FW = 265.31 g/mol; CAS 189940-24-7; Solubility: 100 mM in DMSO) targets type IV phosphodiesterase (PDE IV), inhibiting type 1 helper T (Th1) cell proliferation and markedly decreasing production of IFN-γ, TNF-α, IL-10 and iNOS *in vitro* (1,2). Pharmacological inhibition of PDE IV by mesopram triggers ovulation in follicle-stimulating hormone-primed rats (3). It also exhibits efficacy against experimental autoimmune encephalomyelitis and murine colitis *in vivo*. 1. Dinter, Tse, Halks-Miller, et al. (2000) *J. Neuroimmunol.* **108**, 136. 2. Loher, Schmall, Freytag (2003) *J. Pharmacol. Exp. Ther.* **305**, 549. 3. McKenna et al (2005) *Endocrinology* **146**, 208.

**Mesoxalonnitrile 3-Chlorophenylhydrazone**

This protonophore (FW = 204.62 g/mol; CAS 555-60-2; *Abbreviation*: CCCP), also named carbonyl cyanide *m*-chlorophenylhydrazone, uncouples oxidative phosphorylation and photophosphorylation. (See also *p*-Nitrophenol, FCCP, Protonophore) **Target(s):** ATP synthase (1); chloride/proton symporter (2); H<sup>+</sup>-transporting ATPase, lysosomal (3); L-lysine 6-monooxygenase (NADPH) (4); nickel-transporting ATPase (5); oxidative and photophosphorylation (uncoupler) (1,6-13). 1. Stiggall, Galante & Hatefi (1979) *Meth. Enzymol.* **55**, 308. 2. Alvarado & Vasseur (1998) *Amer. J. Physiol.* **274**, C481. 3. Jonas, Smith, Allison, et al. (1983) *J. Biol. Chem.* **258**, 11727. 4. Thariath, Fatum, Valvano & Viswanatha (1993) *Biochim. Biophys. Acta* **1203**, 27. 5. Yang, Daniel, Hsu & Drake (1989) *Appl. Environ. Microbiol.* **55**, 1078. 6. Acta* **234**, 92. 13. Heytler & Prichard (1962) *Biochem. Biophys. Res. Commun.* **7**, 272.

**Mesulergine hydrochloride**

This receptor antagonist (FW = 398.95 g/mol; CAS 72786-12-0; Solubility: 100 mM in DMSO and to 5 mM in H<sub>2</sub>O with gentle warming), also named *N'*-(8- $\alpha$ ,6-dimethylergolin-8-yl)-*N,N*-dimethylsulfamide hydrochloride, targets 5-HT<sub>2A</sub> (pA<sub>2</sub> = 9.1) and HT<sub>2C</sub> receptor antagonist (pA<sub>2</sub> = 9.1) (1-3). Mersulergine is also D<sub>2</sub>-like dopamine receptor partial agonist (K<sub>i</sub> = 8 nM). Mersulergine displays antiprolactin and antiparkinsonian effects *in vivo*. Like mesulergine, its 1,20-*N,N*-bidemethylated metabolite interact directly with D<sub>1</sub>- and D<sub>2</sub>-receptors. 1. Markstei (1983) Mesulergine and its 1,20-*N,N*-bidemethylated metabolite interacts directly with D<sub>1</sub>- and D<sub>2</sub>-receptors. *Eur.J.Pharmacol.* **95**, 101. 2. Marko (1984) *Eur. J. Pharmacol.* **101**, 263. 3. Hoyer, *et al.* (1994) *Pharmacol. Rev.* **46**, 157.

### Metformin

This oral, biguanide-class antidiabetic drug (FW = 129.17 g/mol; CAS 657-24-9), also named *N,N'*-dimethyl-biguanide, is the longstanding first-line treatment for Type 2 diabetes, decreasing hepatic glucose production, increasing insulin sensitivity (without stimulating endogenous insulin secretion), and enhancing peripheral glucose uptake (1,2). Metformin also transiently inhibits the mitochondrial respiratory chain Complex-1, decreasing hepatic energy state and thereby activating the AMP protein kinase (AMPK); however, this idea has been challenged on the basis of loss-of-function experiments. Other evidence suggests metformin inhibits hepatic glucose output, reducing cellular energy status of adenine nucleotides instead of directly affecting gluconeogenic gene expression.

**Role in Cancer Therapy:** Metformin significantly inhibits cell proliferation and apoptosis in all pancreatic cell lines. In these and other human cancer cells, metformin inhibits mitochondrial Complex I (NADH dehydrogenase) as well as respiration (3). It likewise inhibits cellular proliferation in the presence of glucose, but induces cell death upon glucose deprivation. These findings suggest that cancer cells rely exclusively on glycolysis for survival in the presence of metformin. Metformin also reduces hypoxic activation of hypoxia-inducible factor 1 (HIF-1). All effects of metformin were reversed when the metformin-resistant *Saccharomyces cerevisiae* NADH dehydrogenase (NDI1) is overexpressed. When tested in mice, metformin inhibits the growth of control human cancer cells, but not those expressing NDI1. [Note: The related biguanides phenformin (*or*, 2-(*N*-phenethyl-carbamimidoyl)guanidine) and buformin (*or*, *N*-butylimidocarbonimidic diamide) were withdrawn from the market in most countries as a consequence of toxicity, mainly severe lactic acidosis.] Metformin-treated cells exhibited significantly lower viability and proliferation and significantly more cell cycle arrest in G<sub>1</sub> and G<sub>2</sub>/M than control cells (4). These cells also exhibited significantly more apoptosis via both intrinsic and extrinsic pathways. In addition, metformin treatment induced autophagy. Inhibition of autophagy, either by Beclin1 knockdown or by 3-methyladenine-mediated inhibition of Caspase-3/7, suppressed the anti-proliferative effects of metformin on endometrial cancer cells.

**Pharmacokinetics:** Intestinal metformin absorption is most likely mediated by the plasma membrane monoamine transporter (PMAT), whereas uptake into epithelial cells from circulation is primarily facilitated by OCT2. Metformin is not metabolized and is excreted unmodified in urine (*t*<sub>1/2</sub> ~5 hours), with a renal clearance (CL<sub>r</sub>) of 510 mL/min. The Organic Cation Transporter 1 (OCT1) plays a key role in cellular uptake of metformin, and OCT1 is strongly inhibited by verapamil (5). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** spermidine uptake, competitively (6); basal glycogenesis, but restores insulin-stimulated glycogenesis in cholesterol hemisuccinate-treated cells (6); leptin secretion in cultured rat adipose tissue (7); non-enzymatic glycation in diabetes (8); also binds  $\alpha$ -dicarbonyls, such as methylglyoxal and 3-deoxyglucosone, thereby lowering nonenzymatic protein modification (8); tyrosine phosphatase activity, thereby stimulating insulin receptor tyrosine kinase (9); hepatic gluconeogenesis via AMP-activated protein kinase-dependent regulation of the orphan nuclear receptor SHP (10); Stat3 activation by phosphorylation at Tyr-705 and Ser-727 residues and Stat3-downstream signaling, thereby inhibiting cell growth and inducing apoptosis in triple-negative breast cancers (11); AMP deaminase, thereby activating AMP-stimulated protein kinase, *or* AMPK (12); mTOR, with cell-cycle arrest mediated through REDD1 (13). 1. Edelman (1998)

### Metavanadate

This vandate ion (FW<sub>sodium-salt</sub> = 121.93 g/mol; CAS 16389-35-8; Oxidation State = 5) is a metaphosphate ion analogue that forms indefinite chains as well as cyclic structures. Investigators should be certain that the correct form of vanadate is used in investigations. (See *Orthovanadate; Vanadium and Vanadium Ions*) **Target(s):** acid phosphatase (1); alkaline phosphatase (2); bisphosphoglycerate phosphatase (3); carbonic anhydrase (4); dynein ATPase (5); fructose-1,6-bisphosphatase (3); hexokinase (3); phosphoglucomutase (3); phosphoglycerate kinase (3); phosphoglycerate mutase (3,6,7); sabinene-hydrate synthase (8); succinyl-CoA synthetase (ADP-forming) (9,10); succinyl-CoA synthetase (GDP-forming) (9); UDP-*N*-acetylglucosamine 2-epimerase (11). 1. ### Metergoline

This serotonin (HT) antagonist (FW<sub>free-base</sub> = 403.52 g/mol; CAS 17692-51-2; Soluble to 100 mM in DMSO), also named [(8 $\beta$ )-1,6-dimethylergolin-8-yl]methyl]carbamic acid phenylmethyl ester, targets 5-HT<sub>1</sub>/5-HT<sub>2</sub> with activity at 5-HT<sub>1D</sub>. Specific binding site for [<sup>3</sup>H]-metergoline characterized by a K<sub>d</sub> of 0.5-1.0 nM was detected in microsomal and synaptic plasma membranes from various areas of the adult rat brain. Metergoline has moderate affinity for 5-HT<sub>6</sub> and high affinity for 5-HT<sub>7</sub>. It is also a full agonist at 5-HT<sub>1D $\beta$</sub>  receptors (2). 1. Hamon, Mallat, Herbet, *et al.* (1981) *J. Neurochem.* **36**, 613. 2. Miller, King, Demchyshyn, Niznik & Teitler M (1992) *Eur. J. Pharmacol.* **227**, 99.

**Methadone**

This orally available narcotic analgesic and full opioid agonist (FW = 309.45 g/mol; CAS 76-99-3), also known as 6-dimethylamino-4,4-diphenyl-3-heptanone and amidon, is widely used to treat individuals with moderate to severe opioid dependency. It is a  $\mu$ -opioid receptor agonist that, upon chronic exposure, desensitizes both the  $\mu$ - and  $\delta$ -receptors. Both (*R*)- and (*S*)-methadone are *N*-methyl-D-aspartate (NMDA) receptor antagonists, but the latter is strongest. **Methadone Maintenance Therapy:** MMT is prescribed to individuals who wish to abstain from illicit drug use but have failed to maintain abstinence from opiates for significant periods. Therapeutic goals mainly focus on reducing withdrawal symptoms and managing psychosocial problems and psychiatric co-morbidity. The duration of methadone maintenance can be for months or even years. Side-effects include cardiac dysrhythmia, hypotension, diaphoresis, constipation, nausea, vomiting, dizziness, and sedation. Methadone is hardly innocuous: ~5,000 U.S. drug users die annually as a consequence of methadone overdose. **Pharmacokinetics:** Pharmacologically active (*R*)-methadone (shown above) is metabolized slowly and has very high fat solubility, lasting longer than morphine-based drugs. Its mean bioavailability is around 75%, and its elimination half-life of 15-60 hours, with mean of ~22 hours. Blood concentrations fluctuate greatly between dosing. Cytochrome P450 3A4 and 2D6 are involved in its hepatic metabolism. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** aldehyde oxidase, mixed non-competitive type inhibition,  $K_{is} = 0.03 \mu\text{M}$ ,  $K_{ii} = 0.57 \mu\text{M}$  (1); calcium channels, L-type (2); cholinesterase (3,4); CYP2D6, or cytochrome P450 2D6 (5); glycogen phosphorylase (6); glycogen synthase (6); hexokinase (7); *N*-methyl D-aspartate (NMDA) receptor (8); rhodamine123 transport (9). 1. **Methamphetamine, See *N*-Methyl- $\alpha$ -methylphenethylamine**

**Methaqualone**

This synthetic, barbiturate-like, central nervous system depressant and anticonvulsant (FW = 250.30 g/mol; CAS 72-44-6), also known as 2-methyl-3-*o*-tolyl-4(3*H*)-quinazolinone and Quaalude<sup>TM</sup>, is a controlled (often abused) substance with hypnotic and sedative properties. Its principal mode of action centers on GABA receptor blockade, rather than effects on glycine receptors. In the 1980's, it gained popularity as a euphoriant among casual recreational drug users. Methaqualone also induces the activities of cytochrome P450-dependent systems and UDPglucuronosyltransferases. Methaqualone significantly stimulates the activity of hepatic  $\delta$ -aminolevulinic acid (ALA) synthetase, the first committed step and pacemaking enzyme in heme biosynthesis in mammals. Methaqualone is a noncompetitive antagonist for the  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionate, or AMPA, receptor (1). 1. Chenard, Menniti, Pagnozzi, et al. (2000) *Bioorg. Med. Chem. Lett.* **10**, 1203.

**Methicillin**

This  $\beta$ -lactam antibiotic (FW<sub>free-acid</sub> = 380.42 g/mol; CAS 61-32-5), also known as 6-(2,6-dimethoxybenzamido)penicillanic acid and methicillin, is a semisynthetic, narrow-spectrum penicillin that is bacteriostatic by virtue of its inhibition of peptidoglycan biosynthesis by binding to and competitively inhibiting the transpeptidase enzyme used by bacteria to cross-link the peptide (D-alanyl-D-alanine) required in peptidoglycan synthesis. A defining quality of methicillin is its resistance to the action of many  $\beta$ -lactamases. In the clinic, methicillin has been largely replaced by flucloxacillin and dicloxacillin. The term MRSA refers any *Staphylococcus aureus* strain that resists  $\beta$ -lactam antibiotics, including the penicillins (e.g., methicillin, dicloxacillin, nafcillin, oxacillin, etc.) as well as the cephalosporins. **Target(s):** alanyl aminopeptidase, or aminopeptidase N (1,2); aminopeptidase D (3); cytosol alanyl aminopeptidase (1,2); glycopeptide transpeptidase (4);  $\beta$ -lactamase, or penicillinase (5-11); lecithin:cholesterol acyltransferase, or LCAT (12); lipase (13); membrane alanyl aminopeptidase, aminopeptidase N (2); muramoylpentapeptide carboxypeptidase (4,14,15); serine-type D-Ala-D-Ala carboxypeptidase (16). 1. **Methimazole**

This widely used antihyperthyroid agent (FW = 114.17 g/mol; CAS 60-56-0), also known as 1-methyl-2-mercaptoimidazole and 1-methylimidazole-2-thiol, binds to thyroid peroxidase and blocks the conversion of iodide to iodine, thereby limiting thyroglobulin iodination. **Target(s):** albenzazole monooxygenase (1); catechol oxidase (31); chlorophenol 4-monooxygenase (2); CYP3A4 (3); CYP2B6 (3); CYP2C9 (3); CYP2C19 (3); cysteine conjugate *S*-oxidase (4); cytochrome P450 (3,5); dopamine  $\beta$ -monooxygenase (6-9); flavin-containing monooxygenase, also as an alternative substrate (10-14); iodide peroxidase, or thyroid peroxidase (18,26-29,33,34); aactoperoxidase (15-18,35); myeloperoxidase (19-21); peroxidase (15-22,35); prostaglandin H synthase (23-25); tyrosinase, or monophenol monooxygenase (30-32). 1. ### D-Methionine

This naturally occurring, sulfide-containing amino acid (FW = 149.21 g/mol; CAS 348-67-4; pK<sub>a</sub> values of 2.13 and 9.28 at 25°C), the enantiomer of the proteogenic amino acid L-methionine, is a component in the cyanobacterial cyclic peptide, nostocyclamide M (1). **Target(s):** D-alanine aminotransferase (2); homoserine O-succinyltransferase (3); methionine S-adenosyltransferase (4); methionine decarboxylase (5,6); methionine S-methyltransferase, weakly inhibited (7); methionyl-tRNA synthetase (8); murein tetrapeptide LD-carboxypeptidases (9); tryptophan 2-monooxygenase, weakly inhibited (10). **1.** Juttner, Todorova, Walch & von Philipsborn (2001) *Phytochemistry* **57**, 613. **2.** Martinez-Carrion & Jenkins (1965) *J. ### L-Methionine

This nutritionally essential, sulfide-containing amino acid (FW = 149.21 g/mol; CAS 63-68-3; pK<sub>a</sub> values of 2.13 and 9.28 at 25°C; Codon = AUG (AUA in certain mitochondria; Symbol = Met and M), also known as (S)-2-amino-4-(methylthio)butanoic acid, is one of the twenty proteogenic amino acids and is the initiating, N-terminal aminoacyl residue in translation. In prokaryotes, the methionyl residue is N-formylated, and the formyl group is usually removed post-translationally via an enzyme-catalyzed reaction. For other proteins, the methionyl residue is removed by a specific aminopeptidase. Methionine is regarded as a nonpolar amino acid in protein and peptide structures. Methionyl residues are frequently found in α-helices as well as β-pleated sheets in proteins. In homologous proteins, methionyl residues are often interchanged with leucyl and isoleucyl residues. The sulfur atom of the side-chain can act as a nucleophile, even under acidic conditions, and reacts famously with cyanogen bromide. The resulting acid-catalyzed cleavage of the polypeptide chain converts the methionyl residue to L-homoserine lactone. Mueller (1,2) first its presence in meat infusion was essential for the growth of hemolytic streptococcus. After he announced the discovery of a new amino acid in the hydrolysate of casein (3,4). Barger and Coyne (5) synthesized γ-methylthiol-α-aminobutyric acid, naming it methionine. **Target(s):** O-acetylhomoserine aminocarboxy-

propyltransferase or O-acetylhomoserine sulfhydrylase (6,7,54-63); O-acetylserine/O-acetylhomoserine sulfhydrylase, or cysteine synthase (8,9,63); S-adenosylmethionine cyclotransferase, weakly inhibited (68); alkaline phosphatase, mildly inhibited by the racemic mixture (10); D-amino-acid oxidase (11); 2-amino-hexano-6-lactam racemase (12); arginase (13,14); aromatic-amino-acid aminotransferase (51); arylformamidase, weakly inhibited (15); asparagine:oxo-acid aminotransferase (52,53); aspartate kinase (43-46); choline kinase (16,49); L-3-cyanoalanine synthase (17); cystathionine β-lyase (18); cysteine synthase (8,9,63-67); cystinyl aminopeptidase, or oxytocinase (36-38); cytosol alanyl aminopeptidase (19,20); diaminopimelate decarboxylase (21); dimethylglycine N-methyltransferase, weakly inhibited (81); dipeptidyl-peptidase IV (22); glutamine synthetase (23); [glutamine-synthetase] adenylyltransferase (41); γ-glutamyl transpeptidase, or γ-glutamyltransferase, weakly inhibited (24,25,70,71); homoserine O-acetyltransferase (26,27,75); homoserine kinase (47,48); homoserine O-succinyltransferase (72-74); iodide peroxidase, thyroid peroxidase (84); kynureninase, weakly inhibited by racemic mixture (28); membrane alanyl aminopeptidase, or aminopeptidase N (36,39,40); methionyl aminopeptidase, as product inhibitor (29,30); S-methyl-5'-thioadenoside phosphorylase, weakly inhibited (69); ornithine carbamoyltransferase (78,79); phenylalanine(histidine) aminotransferase (50); phenylalanine 4-monooxygenase (83); phosphoprotein phosphatase, mildly inhibited (31); sarcosine/dimethylglycine N-methyltransferase, weakly inhibited (81); serine O acetyltransferase (76,77); serine hydroxymethyltransferase, or glycine hydroxymethyltransferase (80); sulfate adenylyltransferase, weakly inhibited (42); sulfinoalanine decarboxylase, or cysteinesulfinate decarboxylase (32); tRNA (uracil-5-)-methyltransferase, weakly inhibited (82); tryptophanase, or tryptophan indole-lyase (33-35). **1.** Mueller (1921) *Proc. #### L-Methionine S,S-Dioxide

This L-methionine sulfone (FW = 181.21 g/mol; CAS 7314-32-1), also known as L-2-amino-4 (methylsulfonyl)butanoic acid, inhibits glutamine synthetase. It has also been identified as a residue in a number of proteins, including actin. It is more soluble in water than methionine but not as soluble as the sulfoxide. **Target(s):** asparagine synthetase, weakly inhibited (1); glutamate synthase (2,3); glutamine synthetase (2,4-10); [glutamine synthetase] adenylyltransferase (11); methionine S-adenosyltransferase, weakly inhibited (12); methionyl-tRNA synthetase (13). **1.** Pike & Beevers (1982) *Biochim. #### Methionine S-Oxide

This methionine sulfoxide (FW = 165.21 g/mol; CAS 3226-65-1), also known as 2-amino-4(methylsulfinyl)butanoic acid, inhibits glutamine synthetase. It can undergo further oxidation to form methionine sulfone. It is a substrate in the reaction catalyzed by methionine-S-oxide reductase and, when incorporated as a residue in a protein, it is a substrate for protein-methionine-S-oxide reductase. **Target(s):** asparagine synthetase (1); creatine kinase (2); glutamate synthase (3); glutamine synthetase (2,4-10); methionine S-adenosyltransferase, weakly inhibited (11); methionyl aminopeptidase (12). **1.** Pike & Beevers (1982) *Biochim. #### L-Methionine Sulfoximine

This potent convulsant (FW = 180.23 g/mol; CAS 15985-39-4) binds at the active site of glutamine synthetase where it is phosphorylated to produce a tight-binding geometric analogue of the  $\gamma$ -glutamyl phosphate intermediate. Methionine sulfoximine was first isolated from nitrogen trichloride-treated protein and was later identified as the toxic factor causing convulsions in dogs fed  $\text{NCl}_3$ -treated flour (1). Nitrogen trichloride (Agene™) has been used to artificially bleach and age freshly milled wheat flour, which has a pale yellow color. **Origin of MSOX Convulsant Action:** Methionine sulfoximine inhibits brain glutamine synthetase so well that its action is essentially irreversible, with the inhibitor becoming firmly bound to the active site of the enzyme as methionine sulfoximine-phosphate. L-methionine-S-sulfoximine is the only one of the four methionine sulfoximine isomers to inhibit glutamine synthetase. When these isomeric forms were tested in mice for convulsant activity, only L-methionine-S-sulfoximine produced convulsions. The findings that only one of the four optical isomers of methionine sulfoximine induces convulsions and that same isomer inhibits brain glutamine synthetase lends strong support to the conclusion that these two effects of methionine sulfoximine are mechanistically connected (1). Recent studies suggest MSOX also increases the concentration of glutamate, which activates NMDA receptors, leading to excitotoxic cell death (2).

**Target(s):** asparagine:oxo-acid aminotransferase (3); asparagine synthetase (weakly inhibited) (4); glutamate synthase (5,6); glutamin-(asparagin)-ase (7); glutamine synthetase (5,8-29);  $\gamma$ -glutamylcysteine synthetase (12,22,30-37);  $\gamma$ -glutamyl kinase (glutamate S-kinase) (38); methionine S-adenosyltransferase (weakly inhibited) (39); L-methionine (S)-S-oxide reductase (methionine sulfoxide reductase) (41,42); 4-methyleneglutamine synthetase (4-methyleneglutamate:ammonia ligase; partial inhibition) (42). **1.** Rowe & Meister (1970) *Proc. ### Methiothepin

This piperazine derivative (FW<sub>free-base</sub> = 356.56 g/mol; M.P. = 88-89°C; CASs = 20229-30-5 (mesylate), 19728-88-2 (maleate)), also named Ro-8-6837, metitepine, and 1-[10,11-dihydro-8 (methylthio)dibenzo[*b,f*]thiepin-10-yl]-4-methylpiperazine, is a 5-HT<sub>1</sub>, 5-HT<sub>6</sub>, and 5-HT<sub>7</sub> serotonin receptor antagonist. It also blocks serotonin autoreceptors. Methiothepin is typically supplied commercially as either the maleate or mesylate salt. **Target(s):** aryl-acylamidase (1); 5-HT<sub>1</sub> serotonin receptor (2-4); 5-HT<sub>6</sub> serotonin receptor (5); 5-HT<sub>7</sub> serotonin receptor (6). **1.** Hsu, Halaris & Freedman (1982) *Int. J. Biochem.* **14**, 581. **2.** Nilsson, Longmore, Shaw, *et al.* (1999) *Eur. J. Pharmacol.* **372**, 49. **3.** Granas & Larhammar (1999) *Eur. J. Pharmacol.* **54**, 577. **6.** Schoeffter, Ullmer, Bobirnac, Gabbiani & Lubbert (1996) *Brit. J. Pharmacol.* **117**, 993.

### Metoprolol

This  $\beta$ -blocker (FW<sub>free-base</sub> = 267.37 g/mol; CAS 51384-51-1; IUPAC: (*RS*)-1-(isopropylamino)-3-[4-(2-methoxyethyl)phenoxy]propan-2-ol), also named Lopressor<sup>®</sup>, selectively targets  $\beta_1$ -adrenoceptors and shows no reversal of  $\beta_2$ -mediated vasodilating effects of epinephrine. Likely modes of loproressor action include: competitive antagonism of catecholamines at peripheral (especially cardiac) adrenergic sites, attended by decreased cardiac output; CNS effects, leading to reduced sympathetic outflow to the periphery; as well as suppression of renin activity. **Pharmacokinetics:** Bioavailability 50%; Protein binding = 12%; Hepatic metabolism by CYP2D6 and CYP3A4; Biological  $t_{1/2}$  = 6-7 hours; Renal excretion.

### Methotrexate

This anti-rheumatic/anti-neoplastic agent (FW<sub>free-acid</sub> = 454.45 g/mol; CAS 59-05-2; photo- and alkali-sensitive; *Abbreviation:* MTX), also known as 4-amino-10-methylfolic acid and (+)-amethopterin as well as the trade names Rheumatrex<sup>®</sup>, Trexall<sup>®</sup>, Otrexup<sup>®</sup>, and Rasuvo<sup>®</sup>, is a potent, slow-binding inhibitor of dihydrofolate reductase ( $K_i$  = ~1 nM). Upon entry via the folate transporter, MTX becomes polyglutamylated, thereby increasing its binding

affinity for and inhibitory action on dihydrofolate reductase. (**See 4-Amino-10-methylpteroyl- $\gamma$ -glutamyl- $\gamma$ -glutamyl- $\gamma$ -glutamate; Methotrexate Polyglutamate; Pemetrexed**) A plasma methotrexate level of approximately 7–10  $\mu$ M is cytotoxic to leukemic cells. MTX is taken up by cancer cells by means of the reduced folate carrier SLC19A1, with efflux mediated by various drug-resistance-conferring ABC transporters. Once within cells, MTX is rapidly converted to active methotrexate polyglutamates (MTXPGs) by folylpolyglutamate synthetase (FPGS), the latter adding as many as six glutamate residues to MTX as isopeptides. (Red blood cell uptake of MTX occurs only during the erythroblast stage of development, using the same mechanisms as folate.) The primary target of MTX and MTXPGs is dihydrofolate reductase (DHFR), which converts dihydrofolate (DHF) to tetrahydrofolate (THF), the latter required for *de novo* purine nucleotide synthesis. Inhibition also results in decreased protein and DNA methylation and impaired DNA regulation and repair. **Primary Mode of MTX Action:** Detailed analysis of the slow-binding kinetics of MTX indicates that dihydrofolate reductase rapidly binds the drug to form an Enz-NADPH-MTX ternary complex that subsequently undergoes one or more relatively slow, reversible isomerizations (1). From the apparent  $K_i$  value of 23 nM for the dissociation of methotrexate from the Enz-NADPH-MTX complex and values of 5.1 and 0.013  $\text{min}^{-1}$  for the forward and reverse rate constants of the isomerization reaction, the overall inhibition constant for methotrexate was calculated to be 58  $\mu$ M. Under conditions where reassociation of free enzyme and inhibitor is prevented by the presence of excess folate, the DHFR-bound MTX dissociated with a half-life of ~1 hour. Formation of an initial Enz-MTX complex was demonstrated by means of fluorescence quenching, and a value of 0.36  $\mu$ M was determined for its dissociation constant. The same technique was used to determine dissociation constants for the reaction of MTX with the E-NADP and E-NADPH complexes. The results indicate that in the presence of either NADPH or NADP there is enhancement of the binding of methotrexate to the enzyme. In this respect, that methotrexate behaves as a pseudosubstrate for dihydrofolate reductase. **Use of MTX in Cancer Chemotherapy:** By preventing cells from utilizing folate-based cofactors to make nucleotide precursors for DNA and RNA, methotrexate is especially toxic to rapidly proliferating cells. By blocking the dihydrofolate reductase reaction and depleting the one-carbon pool, methotrexate inhibits DNA biosynthesis, often leading to programmed cell death. This property and reversal by the more weak inhibitor leucovorin (**See N<sup>5</sup>-Formyltetrahydrofolate**) forms the basis for the well-known “Methotrexate-Leucovorin Rescue” protocol for treating certain cancers (*e.g.*, gestational trophoblastic neoplasias). High-dose MTX (high doses 3–7.5  $\text{g}/\text{m}^2$ ) are delivered, followed by infusion of leucovorin (folinic acid). Myelotoxicity occurs in 28% of the patients, usually as a result of delayed MTX excretion. HDMTX-LCV is not recommended as conventional treatment of metastatic cancer, simply because response rates cited are not superior to those achievable by conventional MTX dosing. Given the wide spectrum of available treatment options, methotrexate is primarily used to treat choriocarcinoma, leukemia in the spinal fluid, osteosarcoma, breast cancer, lung cancer, non-Hodgkin lymphoma, and head and neck cancers. When tested at various MTX concentrations (0.5, 1, 3, and 10  $\mu$ M) for 24 hours in human MCF-7 breast cancer cells, followed by rescue with labeled leucovorin (0.5 to 50  $\mu$ M), total labeled intracellular folate pools increase in a log-linear fashion with respect to leucovorin exposure concentrations up to 100  $\mu$ M (2). Tetrahydrofolate, 10-formyl tetrahydrofolate, 5-formyl tetrahydrofolate, 5-methyl tetrahydrofolate, and 5,10-methylene tetrahydrofolate pools reach levels present in cells not exposed to MTX at concentrations of leucovorin that are inadequate in rescuing MTX-treated cells. At rescue-concentrations of leucovorin, individual folate pool levels are up to twelve times greater than those in untreated cells, consistent with competition for catalytic activity at folate-dependent enzymes in addition to dihydrofolate reductase (2). The dihydrofolate pool also increases with increasing leucovorin concentration; however, unlike the reduced folates, this oxidized folate reaches a maximal level that is dependent on the MTX concentration to which the cells are exposed. Such findings suggest that competition between MTX and leucovorin occurs at the level of dihydrofolate reductase via a competitive interaction with dihydrofolate in this intact cell system (2). The ability of leucovorin and its metabolites to compete with direct inhibitors of dihydrofolate reductase and other metabolically important folate-dependent enzymes forms the basis of leucovorin rescue. **MTX Treatment of Rheumatoid Arthritis:** Methotrexate is generally administered to RA patients as a single dose administered either intramuscularly or orally (15 to 17.5 mg/week). Beyond its role in cancer chemotherapy, methotrexate is also the most frequently used first-line anti-

rheumatic drug, inhibiting proliferation of the lymphocytes and other cells responsible for inflammation in joints. Mounting evidence favors the view that the endogenous anti-inflammatory autocoid adenosine mediates the anti-inflammatory effects of methotrexate. It also inhibits the formation of potentially toxic compounds (e.g., the transmethylation products spermine and spermidine found in chronically inflamed tissues). Other ideas are that methotrexate inhibits proliferation of the cells responsible for synovial inflammation in RA and that methotrexate reduces intracellular glutathione levels by an oxidant-associated mechanism that reduces macrophage recruitment and function. **Use of MTX to Synchronize Cells:** Reference (3) provides detailed procedures for inducing synchrony in human cancer cell lines (Jurkat, K562, U937, SW626) and murine L1210 cells by using very low non-toxic methotrexate concentrations (0.04–0.08  $\mu\text{M}$  for 13–24 hours) under standard culture conditions. This protocol offers a method for synchronization of cells at the G<sub>1</sub>/S boundary and through the S-G<sub>2</sub>-M phases of the cell cycle (**See also Thymidine for "Double-Thymidine Block Method for G<sub>1</sub>/S Cell Synchronization"**). **Mechanisms of MTX Resistance:** Resistance to can arise from decreased methotrexate uptake, induction of xenobiotic transporters, defects in folate oligoglutamylating enzyme, and increased dihydrofolate reductase (DHFR) activity. An association between lack of the retinoblastoma protein and intrinsic MTX resistance has also been reported. Methotrexate is also known to increase homocysteine, the latter associated with an elevated risk of heart disease, Alzheimer's disease, and neural tube defects. Homocysteine is formed by hydrolysis of S-adenosylhomocysteine, an inhibitor of SAM-dependent methyltransferases, including isoprenylcysteine carboxyl methyltransferase (ICMT), the enzyme that methylates Ras in a reaction needed for the latter's eventual plasma membrane localization and function. Upon methotrexate treatment of DKOB8 cells, Ras methylation is decreased by ~90%, resulting in mislocalization of Ras to the cytosol and a 4x decrease in the activation of p44 mitogen-activated protein kinase and Akt (4). Importantly, cells lacking ICMT are highly MTX-resistant. While cells expressing wild-type levels of ICMT are inhibited by MTX, stable expression of myristoylated H-Ras, which does not require carboxylmethylation for membrane attachment, confers resistance to methotrexate. Such findings suggest isoprenylcysteine carboxyl methyltransferase inhibition may be a critical factor influencing methotrexate effectiveness (3). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** arylamine N-acetyltransferase (5-7); deoxycytidylate 5-hydroxymethyl-transferase (7); dihydrofolate reductase (8-25,54-56,58,62); dihydropterin reductase (26,27); dihydropterin reductase (NADPH) (28); formimidoyl-tetrahydrofolate cyclodeaminase, or formiminotetrahydrofolate cyclodeaminase (29,30); glucose-6-phosphate dehydrogenase (30); glutamate dehydrogenase (31,32); glutamate formimidoyltransferase (33); glutathione synthetase (34); glycine N-methyltransferase (64); glycogen phosphorylase b (34); lactate dehydrogenase (31); malate dehydrogenase (31); mandelate 4-monooxygenase (36); methenyltetrahydrofolate cyclohydrolase, weakly inhibited (37); methionyl-tRNA formyltransferase (38); phenylalanine 4-monooxygenase (26,39); phenylpyruvate tautomerase (40); phosphoribosyl-aminoimidazole-carboxamide formyltransferase, or 5-aminoimidazole-4-carboxamide ribonucleotide transformylase, weakly inhibited by the monoglutamate, but strongly inhibited by the pentaglutamate derivative (41-48); phosphoribosylglycinamide formyltransferase, or glycinamide ribonucleotide transformylase (41); sepiapterin deaminase (49); serine Hydroxymethyl-transferase, or glycine hydroxymethyltransferase, partial inhibitor (50,51); *Thermotoga maritima* dihydrofolate reductase (12); thymidylate synthase (52,56-62); xanthine oxidase (53). 1. ### Methotrexate Polyglutamate

These oligo( $\gamma$ -glutamylated) derivatives of methotrexate (FW<sub>di-glutamyl</sub> = 729.69 g/mol; FW<sub>tri-glutamyl</sub> = 858.80 g/mol; FW<sub>tetra-glutamyl</sub> = 987.92 g/mol; FW<sub>penta-glutamyl</sub> = 1117.03 g/mol; FW<sub>hexa-glutamyl</sub> = 1246.15 g/mol; CAS 82334-40-5) are potent inhibitors of dihydrofolate reductase. (**See also 4-Amino-10-methylpteroyl- $\gamma$ -glutamyl- $\gamma$ -glutamyl- $\gamma$ -glutamate; Methotrexate**) **Target(s):** amidophosphoribosyltransferase, inhibited by methotrexate pentaglutamate (1); dihydrofolate reductase (2,3); 5-formyl-tetrahydrofolate synthetase, or N<sup>5</sup>,N<sup>10</sup>-methenyltetrahydrofolate synthetase, inhibited by the pentaglutamate (4,5); phosphoribosylaminoimidazole carboxamide formyltransferase, or 5-aminoimidazole-4-carboxamide ribonucleotide transformylase, weakly inhibited by the monoglutamate but strongly inhibited by the tri- and pentaglutamate derivative (6,7); serine hydroxymethyltransferase, or glycine hydroxymethyl-transferase, inhibited by the triglutamate (8); thymidylate synthase, inhibited by the pentaglutamate (9). 1. ### Methoxetamine

This ketamine derivative and designer drug (FW = 247.33 g/mol; CAS 1239943-76-0), also named (*R/S*)-2-(3-methoxyphenyl)-2-(ethylamino)-cyclohexanone, is a dissociative anesthetic that exerts NMDA receptor antagonist, with appreciable affinity for serotonin transporters (1,2). Its misuse in humans has resulted in serious or even fatal outcomes. In evidence of its abuse potential, methoxetamine evokes conditioned place preference and is self-administered by rats (3). (See *Ketamine*) 1. Ward, Rhyee, Plansky & Boyer (2011) *Clin. Toxicol.* (Philadelphia) **49**, 874. 2. Methoxetamine Policy Paper (18 October 2012) *Advisory Council on the Misuse of Drugs*. 3. ### Methoxyamine

This highly toxic hydroxylamine derivative (FW = 47.06 g/mol; CAS 67-62-9), also called methoxylamine, is nucleophilic amine that is frequently used to derivatize aldehydes and ketones. The free base is a water-soluble liquid that boils at 49-50°C. Methoxyamine is frequently supplied commercially as the hydrochloride (FW = 85.54 g/mol). **Primary Mode of Action:** Methoxyamine reacts with aldehydes at abasic sites in DNA, making them refractory to  $\beta$ -elimination in deoxyribosephosphate lyase catalysis, thereby blocking single-nucleotide base-excision repair. *O*<sup>6</sup>-methylguanine, 7-methylguanine, and 3-methyladenine DNA adducts are repaired by at least two mechanisms. The *O*<sup>6</sup>-CH<sub>3</sub>G DNA adduct, a cytotoxic and genotoxic lesion, is repaired by *O*<sup>6</sup>-CH<sub>3</sub>G DNA-methyltransferase (*or* MGMT), which confers resistance to anticancer methylating agents. Meanwhile, cell death caused by *O*<sup>6</sup>-CH<sub>3</sub>G adducts is promoted by mismatch repair system, such that deficiency in the latter is associated with pronounced resistance to methylating agents. *N*<sup>7</sup>-CH<sub>3</sub>G, another lesion formed by methylating agents, and *N*<sup>3</sup>-CH<sub>3</sub>A DNA adducts are removed by the base excision repair pathway. Efficient base excision repair minimizes the impact of these lesions in normal and tumor cells. Only when BER is disrupted, do these abundant *N*-methylated DNA adducts become highly cytotoxic. **Target(s):** carbamoyl-phosphate synthetase (1); DNA-directed DNA polymerase (2); DNA polymerase  $\beta$  (2); endodeoxyribonuclease (pyrimidine dimer), *or* apurinic/aprimidinic endonuclease activity (3); hydroxymethylbilane synthase (4); serine hydroxymethyltransferase, *or* glycine hydroxymethyltransferase (5); threonine ammonia-lyase, *or* threonine dehydratase (6); thrombin (7); tyrosine decarboxylase (8); urocanate hydratase, *or* urocanase (9). 1. Kaseman (1985) Ph.D. thesis, Dept. Biochemistry, Cornell University Medical College, New York, New York. 2. Horton, Prasad, Hou & Wilson (2000) *J. Biol. Chem.* **275**, 2211. 3. ### *p*-Methoxyamphetamine

This amphetamine and CNS stimulant (FW<sub>free-base</sub> = 165.24 g/mol; CAS 64-13-1; *Abbreviation:* PMA) is a potent hallucinogen that largely replaced LSD in the 1970s. When used recreationally, overdoses often prove fatal.

PMA acts as a potent selective serotonin releasing agent (SSRA) with only very weak effects on dopamine and norepinephrine. *p*-Methoxyamphetamine is also an alternative substrate of CYP2D6. **Target(s):** 5-hydroxytryptamine (serotonin) re-uptake (1); monoamine oxidase (2). 1. Hegadoren, Greenshaw, Baker, *et al.* (1994) *J. Psychiatry Neurosci.* **19**, 57. 2. Green & El Hait (1980) *J. Pharm. Pharmacol.* **32**, 262

### 2-Methoxyestradiol

This endogenous estrogen metabolite (FW = 302.41 g/mol; CAS 362-07-2) inhibits angiogenesis and mitosis, the latter accounting for its antiproliferative and antitumor effects. **Primary Mode of Action:** 2-Methoxyestradiol binds to tubulin and *in vitro* assembled tubulin sheet structures with higher affinity than to microtubules (MTs). This metabolite is readily displaced by colchicine and colchicine-like ligands. Recent studies suggest that this mammalian estradiol metabolite inhibits MT assembly and appears to be incorporated into a polymer with altered stability properties. **Target(s):** catechol *O*-methyltransferase, product inhibition (1); estrogen 2-monoxygenase (2,3); HIF-1 $\alpha$  (hypoxia-inducible factor 1 $\alpha$ ), a key angiogenic transcription factor (4); tubulin polymerization, microtubule self-assembly, IC<sub>50</sub> = 5.3  $\mu$ M (5-7). 1. ### *N*<sup>3</sup>-(4-Methoxyfumaryl)-(*S*)-2,3-diaminopropanoate

This amino acid (FW = 216.19 g/mol) is a specific and potent inactivator of glucosamine-6 phosphate synthase, *or* glutamine:fructose-6-phosphate aminotransferase (isomerizing). **Target(s):** glucosamine-6-phosphate deaminase (1); glutamine:fructose-6-phosphate aminotransferase (isomerizing) (2-7). 1. ### 2-Methoxy-5-nitrotropone

This reagent (FW = 181.15 g/mol) reacts with amino groups under relatively mild conditions (pH 7.0 to 8.5). (No other functional group appears to be modified under these same conditions.) The resulting covalent adduct ( $\lambda_{\max}$  = 420 nm,  $\epsilon$  = 20700 M<sup>-1</sup>cm<sup>-1</sup> for the adduct) can be removed by incubation of the modified protein with 1-2 M hydrazine at pH 8.5-9.0.1 *Note:* Solutions of 2-methoxy-5-nitrotropone should always be freshly prepared. It slowly decomposes at neutral pH and decomposes rapidly above pH 8.5. **Target(s):**  $\alpha$ -amylase (1,2); CYP2B6 (*or* cytochrome P450

LM2) (3); 3-phosphoglycerate kinase4; porphobilinogen deaminase (5); ribosomal subunits (6-10); taka-amylase A (1,2); thioglucosidase, *or* myrosinase, *or* sinigrinase (11,12); uroporphyrinogen decarboxylase (13). 1. ### 3-(4-(2-Methoxyphenoxy)piperidin-1-yl)-6-(3-methyl-1,2,4-oxadiazol-5-yl)pyridazine

This potent, selective, orally bioavailable pyridazine (FW = 367.41 g/mol) derivative inhibits stearoyl-CoA 9-desaturase (mouse,  $IC_{50}$  = 85 nM), which catalyzes the committed step in the biosynthesis of monounsaturated fatty acids from saturated, long-chain fatty acids. The rationale for targeting this enzyme is based on studies with SCD1 knockout mice that established that such animals are lean and protected from leptin deficiency-induced and diet-induced obesity, with greater whole body insulin sensitivity than wild-type animals. 1. Liu, Lynch, Freeman, *et al.* (2007) *J. Med. Chem.* **50**, 3086.

### 4-N-(2-Methoxyphenyl)amino-5-(4-ethoxyphenyl)-7-(β-D-erythro-furanosyl)pyrrolo[2,3-d]pyrimidine

This tubercidin analogue (FW = 462.51 g/mol) inhibits human adenosine kinase ( $IC_{50}$  = 5.3 nM). Because the use of adenosine receptor agonists is plagued by dose-limiting cardiovascular side effects, there is great interest in developing adenosine kinase inhibitors (AKIs) as a means for raising steady-state adenosine concentrations. 1. Boyer, Ugarkar, Solbach, *et al.* (2005) *J. Med. Chem.* **48**, 6430.

### N-(4-(4'-Methoxyphenyl)benzoyl)-syn-(2-(3-aminobenzyl)-3-trans-styryl)-β-alanine Methyl Ester

This 2,3-disubstituted β-alanine (FW<sub>free-base</sub> = 547.65 g/mol) is a first-in-class inhibitor that targets coagulation factor Xa ( $IC_{50}$  = 0.08 μM). It is a much weaker inhibitor of the related proteases, thrombin ( $IC_{50}$  = 2.7 μM) and trypsin ( $IC_{50}$  = 2.9 μM). 1. Klein, Czekaj, Gardner, *et al.* (1998) *J. Med. Chem.* **41**, 437.

### 2'-Methoxyphenyl 4-Guanidinobenzoate

This ester (FW<sub>free-base</sub> = 285.30 g/mol) is a strong inhibitor of human acrosin ( $IC_{50}$  = 27 nM) and trypsin ( $IC_{50}$  = 88 nM), suggesting its potential as a contraceptive alternative to nonoxynol-9, the most commonly used active ingredient in today's vaginal contraceptive preparations. 1. Kaminski, Bauer, Mack, *et al.* (1986) *J. Med. Chem.* **29**, 514.

### 4-Methoxyphenyl-[4-(4-methoxyphenyl)-4,5,6,7-tetrahydrothieno[3,2-c]pyridin-5-yl]methanone

This tetrahydrothienopyridine (FW = 363.48 g/mol) inhibits pig glucose-6-phosphatase activity ( $K_i$  = 0.61 μM) and pyrophosphatase activity ( $IC_{50}$  = 0.43-0.55 μM) of the hepatic ER-associated glucose-6-P transporter required for terminal glucose formation in the glycogenolysis and gluconeogenesis pathways. In experiments with cultured rat hepatocytes using glycerol as the substrate, this inhibitor prevented glucose production, with a concomitant 2.3-fold increase in the glucose-6-P content. 1. Westergaard, Madsen, Lundbeck, *et al.* (2002) *Diabetes Obes. Metab.* **4**, 96.

### [α-Methoxy Poly(ethylene glycol)]-1-(N-Benzylloxycarbonyl-L-leucyl)-5-(L-phenylalanyl-L-leucyl)carbohydrazide

This lysosomotropic macromolecular inhibitor (FW = indefinite), consisting of a polyethylene glycol and an a high-affinity inhibitor, targets cathepsin K ( $K_{i,app}$  = 6.6 nM). It also inhibits cathepsin B and papain ( $K_{i,app}$  = 1.6 and 2.4 μM, respectively). The polymer-bound inhibitor was internalized by endocytosis and was ultimately trafficked to the lysosomal compartment. 1. Wang, Pechar, Li, *et al.* (2002) *Biochemistry* **41**, 8849.

### 5-Methoxypsoralen

This phototoxic phytoalexin (FW = 216.19 g/mol; CAS 484-20-8; Abbreviation: 5-MOP), found in many plants, is part of a defense scheme against fungi and insects. Upon activation by ultraviolet light, 5-

methoxypsoralen, also called bergapten, induces interstrand cross-links in DNA (1) 5-MOP intercalates between DNA base pairs and, upon uv absorption, it forms an adduct with a pyrimidine. If at an appropriate site, a second photoaddition can occur, with formation of an interstrand cross-link. 5-MOP is frequently used to investigate DNA repair and recombination. The combination of psoralens and UVA radiation (PUVA photochemotherapy) is also an established treatment for many skin disorders. Note that unsaturated fatty acids and proteins undergo a photoaddition reaction with psoralen and psoralen derivatives. (See also other psoralen derivatives) **Target(s):** arylamine *N*-acetyltransferase, activated at low concentrations (2); cAMP dependent protein kinase (weakly inhibited) (3); CYP1A1 (3); CYP1A2 (3); CYP2A6 (4); CYP3A (4-5); CYP6D1 (6); melatonin 6-monooxygenase (7) 1. Wang, Ternai & Polya (1997) *Phytochemistry* **44**, 787. 2. Lee & Wu (2005) *In Vivo* **19**, 1061. 3. Tassaneeyakul, Birkett, Veronese, et al. (1993) *J. Pharmacol. Exp. Ther.* **265**, 401. 4. Koenigs & Trager (1998) *Biochemistry* **37**, 10047. 5. Saville & Wanwimolruk (2001) *J. Pharm. Pharm. Sci.* **4**, 217. 6. Scott (1996) *Insect Biochem. Mol. Biol.* **26**, 645. 7. Mauviard, Raynaud, Geoffriau, Claustrat & Pevet (1995) *Biol. Signals* **4**, 32.

### 8-Methoxypsoralen

This phototoxic phytoalexin and minor isoprenoid product (FW = 216.19 g/mol; CAS 298-81-7; *Abbreviation:* 8-MOP), found in many plants, including false Queen Anne's Lace (*Ammi majus* in the family Apiaceae), is part of a plant defense scheme to protect against fungi and insects. Its alternative name is methoxsalen, and its IUPAC name is 9-methoxy-7H-furo[3,2-g]chromen-7-one. **Principal Mode of Inhibitory Action:** 8-Methoxypsoralen intercalates between DNA base pairs and, upon activation with UV light (A-Band:  $\lambda = 315$  to 400 nm; energy = 3.94 to 3.10 eV), forms a photoadduct with a pyrimidine base. If located at a appropriate site, a second photoaddition occurs, with interstrand cross-linking. 8-MOP is frequently used to investigate DNA repair and recombination events. The combination of psoralens and UV-A radiation (PUVA) is also an established photochemotherapy for many skin disorders. **Mode of Cytochrome P450 Inhibition:** CYP2A6 is inhibited by 8-methoxypsoralen, bergapten (5-methoxypsoralen) or psoralen as a result of mechanism-based inhibition. The enzyme system initially oxidizes the psoralen to form a furanoepoxide followed by hydrolytic attack, or attack of exogenous nucleophiles, to form dihydrofuranocoumarin products. (See also other psoralen derivatives) **Other Actions:** Unsaturated fatty acids and proteins can also undergo a photoaddition reaction with psoralen and certain psoralen derivatives. These photobiological processes may impact cellular functions, protein immunogenicity, as well the accumulation of potentially toxic substances. **Target(s):** chemotactic activity of polymorphonuclear neutrophils (2); *trans*-cinnamate 4-monooxygenase (3,4); CYP1A1 (5); CYP1A2 (5); CYP2A6 or coumarin 7-hydroxylase (6-12); DNA-directed RNA polymerase (13); DNA polymerase (1,14); DNA replication (15); glutamate dehydrogenase (1); lysozyme (1); ribonuclease (1). 1. ### *N*-(Methoxysuccinyl)-L-alanyl-L-alanyl-L-prolyl-L-valine Chloromethyl Ketone

This halomethyl ketone (FW = 503.00 g/mol) is an analogue of an acylated tetrapeptide and inhibits leukocyte elastase, chicken oviduct signal peptidase, and myeloblastin. **Target(s):** cathepsin G (1); leukocyte elastase (1-9); myeloblastin (9,10); pancreatic elastase (1); signal peptidase, chicken oviduct (11). 1. Powers, Gupton, Harley, Nishino & Whitley (1977) *Biochim. Biophys. Acta* **485**, 156. 2. Bieth (1998) in *Handb. Proteolytic Enzymes*, p. 54, Academic Press, San Diego. 3. Barrett (1981) *Meth. Enzymol.* **80**, 581. 4. Fletcher, Osinga, Hand, et al. (1990) *Amer. Rev. Respir. Dis.* **141**, 672. 5. Stein & Trainor (1986) *Biochemistry* **25**, 5414. 6. Proteolytic Enzymes*, p. 455, Academic Press, San Diego.

### 9-Methoxythieno[2,3-c]isoquinolin-5(4H)-one

This substituted isoquinoline (FW = 231.28 g/mol), also known as 9-CH<sub>3</sub>O-TIQ-A, inhibits poly(ADP-ribose) polymerase-1 (PARP-1), IC<sub>50</sub> = 0.21  $\mu$ M. **Primary Mode of Action:** The rationale for this approach is based on the observation that excessive activation of poly(ADP-ribose) polymerase-1 (PARP-1), a nuclear enzyme catalyzing the transfer of ADP-ribose units from NAD<sup>+</sup> to acceptor proteins, induces cellular energy failure by depleting NAD<sup>+</sup> and ATP and thereby serving a causative role in ischemia/reperfusion injury. 1. Chiarugi, Meli, Calvani, et al. (2003) *J. Pharmacol. Exp. Ther.* **305**, 943.

### L-Methoxyvinylglycine

This amino acid (FW = 131.13 g/mol; *Abbreviation:* MVG), also known as L-2-amino-4-methoxy-3-butenic acid and, inhibits the biosynthesis of ethylene in plants. It is produced by *Pseudomonas aeruginosa*. **Target(s):** 1-aminocyclopropane-1-carboxylate synthase (1,2); aspartate aminotransferase (3); methionine *S*-adenosyltransferase, inhibited by the *cis* isomer (4,5); tryptophan synthase (3,6). 1. Yu, Adams & Yang (1979) *Arch. Biochem. Biophys.* **198**, 280. 2. Jakubowicz (2002) *Acta Biochim. Pol.* **49**, 757. 3. Rando (1977) *Meth. Enzymol.* **46**, 28. 4. Enzymol.* **142**, 398.

### Methyl Acetimidate

This imido ester (FW<sub>hydrochloride</sub> = 109.56 g/mol; CAS 14777-29-8) acetimidates amino groups in proteins, while allowing the protein to retain positive charges at the modified residue. **Primary Mode of Action:** All of the amino groups in pancreatic ribonuclease are modified and, although the

protein is catalytically inactive, RNase A retains its physical and chemical properties (1). All fourteen  $\epsilon$  amino groups of trypsin are modified with this reagent and the modified trypsin retains catalytic activity (2). Methyl acetimidate, which decomposes at 105°C, is an irritant and is moisture sensitive. It should be stored in a desiccator. It is slowly hydrolyzed in aqueous solutions; however, between pH values of 6.8 and 8.8, the rate of hydrolysis of methyl acetimidate decreases and the rate of amidination increases (3). **Target(s):** aspartate aminotransferase (4); chymotrypsin (5); EcoRI restriction endonuclease (type II site-specific deoxyribonuclease) (6,7); glyceraldehyde-3-phosphate dehydrogenase (8); inositol 1,3,4-trisphosphate 5/6-kinase (9); K<sup>+</sup> channel, ATP-sensitive (KATP) (10); penicillinase (11); ribonuclease A, or pancreatic ribonuclease (1,12); RNA polymerase (13). 1. Reynolds (1968) *Biochemistry* **7**, 3131. 2. Nureddin & Inagami (1975) *Biochem. J.* **147**, 71. 3. Makoff & Malcolm (1981) *Biochem. J.* **193**, 245. 4. ### 1-Methyladenine

This modified purine (FW<sub>free-base</sub> = 149.16 g/mol; CAS 1670-69-5) has been identified as a component in certain RNA. For example, it is produced by the action of tRNA (adenine-*N*<sup>1</sup>-) methyltransferase. It is also a product of the reaction catalyzed by 1-methyladenosine nucleosidase. In addition, 1-methyladenine is the oocyte maturation-inducing substance of starfish. 1-Methyladenine has a  $\lambda_{\text{max}}$  at 270 nm at pH 9 and 13 ( $\epsilon = 11900 \text{ M}^{-1}\text{cm}^{-1}$  at pH 9 which rises to 14400  $\text{M}^{-1}\text{cm}^{-1}$  at pH 13). **Target(s):** deoxycytidine kinase,  $K_i = 9.4 \text{ mM}$  (1); hypoxanthine(guanine) phosphoribosyltransferase (2); xanthine phosphoribosyltransferase (2). 1. Krenitsky, Tuttle, Koszalka, et al. (1976) *J. Biol. Chem.* **251**, 4055. 2. Naguib, Iltzsch, el Kouni, Panzica & el Kouni (1995) *Biochem. Pharmacol.* **50**, 1685.

### 2-Methyladenine

This modified purine (FW = 149.16 g/mol; CAS 1445-08-5;  $\lambda_{\text{max}}$  at pH 7 of 263 nm ( $\epsilon = 12700 \text{ M}^{-1}\text{cm}^{-1}$ )) can be formed as a component of RNA via reaction with methyl radicals (1). It also protects against methotrexate inhibition (2). **Target(s):** adenine deaminase (3,4); hypoxanthine(guanine) phosphoribosyltransferase (5); inosine phosphorylase, or purine-nucleoside phosphorylase (3,4); xanthine phosphoribosyltransferase (5). 1. Kang, Gallagher & Cohen (1993) *Arch. Biochem. Biophys.* **306**, 178. 2. Loebeck (1960) *J. Bacteriol.* **79**, 384. 3. Pharmacol.* **50**, 1685.

### 3-Methyladenine

This naturally occurring purine metabolite (FW = 149.16 g/mol; CAS 5142-23-4; *Symbol*: 3-MA) is released from alkylated DNA by the action of DNA-3 methyladenine glycosylases I and II. (Note bonding change in the ring relative to unmodified adenine.) 3-MA is often used as a standard in detecting methylation of nucleic acid. At 5 mM, 3-methyladenine inhibits endogenous protein degradation in isolated rat hepatocytes by ~60%, with no adverse effects on exogenous protein degradation, protein synthesis, or intracellular ATP (1). Its ability to suppress the formation of electron microscopically visible autophagosomes first suggested that 3-MA may inhibit autophagy (1). 3-MA and wortmannin are widely used as autophagy inhibitors, based on their inhibitory effect on class III phosphoinositide 3-kinase (PI3K), which is known to be essential factor in inducing autophagy (2). (See *Wortmannin*) **Target(s):** autophagosome formation (1); class III phosphoinositide 3-kinase (2); deoxycytidine kinase,  $K_i = 0.42 \text{ mM}$  (3); DNA-3 methyladenine glycosylase I (4-9). 1. Seglen & Gordon (1982) *Proc. Natl. Acad. Sci. U.S.A.* **79**, 1889. 2. Blommaert, Krause, Schellens, Vreeling-Sindelárová & Meijer (1997) *Eur. J. Biochem.* **243**, 240. 3. Thomas, Yang & Goldthwait (1982) *Biochemistry* **21**, 1162. 9. Riazuddin & Lindahl (1978) *Biochemistry* **17**, 2110.

### *N*<sup>6</sup>-Methyladenine

This modified purine (FW = 149.16 g/mol; CAS 443-72-1;  $\lambda_{\text{max}} = 266 \text{ nm}$ ,  $\epsilon = 16200 \text{ M}^{-1}\text{cm}^{-1}$  at pH 7), also known as 6-(methylamino)purine, is a modified base that is often found in nucleic acids (e.g., it is produced by the actions of rRNA (adenine *N*<sup>6</sup>-)methyltransferase, tRNA (adenine-*N*<sup>6</sup>-)methyltransferase, and site-specific DNA methyltransferase (adenine-specific)). *N*<sup>6</sup>-methylated adenine also functions as a plant growth regulator. **Target(s):** adenine deaminase (1,2); adenosine nucleosidase (1);  $\beta$ -glucosidase, *Dictyostelium discoideum* (3); guanine deaminase (1); hypoxanthine(guanine) phosphoribosyltransferase (4); xanthine phosphoribosyl-transferase (4). 1. Nolan & Kidder (1980) *Antimicrob. Agents Chemother.* **17**, 567. 2. Jun & Sakai (1979) *J. Ferment. Technol.* **57**, 294. 3. Parish (1977) *J. Bacteriol.* **129**, 1642. 4. Naguib, Iltzsch, el Kouni, Panzica & el Kouni (1995) *Biochem. Pharmacol.* **50**, 1685.

### 7-Methyladenine

This modified purine (FW = 149.16 g/mol; CAS 935-69-3) is a minor base occasionally found in nucleic acids. (Note bonding change in the ring relative to unmodified adenine.) It is also produced nonenzymatically upon reaction of DNA with dimethyl sulfate. The methyl group is removed spontaneously from DNA *in vitro* by hydrolysis at neutral pH. Pulse-chase studies demonstrated that the half-life of 7-methyladenine *in vivo* is short (2-3 hours). At pH 1, methyladenine has a  $\lambda_{\text{max}}$  of 273 nm ( $\epsilon = 14000 \text{ M}^{-1}\text{cm}^{-1}$ ); at pH 12,  $\lambda_{\text{max}} = 270 \text{ nm}$  ( $\epsilon = 10600 \text{ M}^{-1}\text{cm}^{-1}$ ). Adenosine levels increase at seizure foci as part of a negative feedback mechanism that controls seizure activity through adenosine receptor signaling. Agents that inhibit adenosine kinases increase/sustain site/event-specific adenosine surges, thereby providing anti-seizure activity akin to that of adenosine receptor agonists, but with fewer dose-limiting cardiac side effects. **Target(s):** adenosine kinase (1); deoxycytidine kinase, weakly inhibited,  $K_i = 4.3 \text{ mM}$  (2). 1. Miller, Adamczyk, Miller, et al. (1979) *J. Biol. Chem.* **254**, 2346. 2. Krenitsky, Tuttle, Koszalka, et al. (1976) *J. Biol. Chem.* **251**, 4055.

**1-Methyladenosine**

This methylated purine nucleoside (FW<sub>free-base</sub> = 281.27 g/mol; CAS 15763-06-1) has been identified as a component in tRNA, produced by the action of tRNA (adenine-N<sup>1</sup>-) methyltransferase. It is also a substrate of the reaction catalyzed by 1-methyladenosine nucleosidase. The  $\lambda_{\text{max}}$  value is 258 nm ( $\epsilon = 13900 \text{ M}^{-1}\text{cm}^{-1}$ ) at pH 7 and 259 nm ( $\epsilon = 14600 \text{ M}^{-1}\text{cm}^{-1}$ ) at pH 10.5. Because the use of adenosine receptor agonists is plagued by dose-limiting cardiovascular side effects, there is great interest in developing adenosine kinase inhibitors (AKIs) as a means for raising steady-state adenosine concentrations. **Target(s):** adenosine deaminase (1,2); adenosine kinase (3,4); adenosylhomocysteinase (5); cytidine deaminase (6); GMP synthetase (7). 1. Agarwal & Parks (1978) *Meth. Enzymol.* **51**, 502. 2. Challa, Johnson, Robertson & Gunasekaran (1999) *J. Basic Microbiol.* **39**, 97. 3. Long & Parker (2006) *Biochem. **N<sup>6</sup>-Methyladenosine**

This analogue of adenosine (FW = 281.27 g/mol; at pH 7 and 13,  $\lambda_{\text{max}} = 266 \text{ nm}$ ,  $\epsilon = 15900 \text{ M}^{-1}\text{cm}^{-1}$ ; at pH 7,  $\lambda_{\text{max}} = 262 \text{ nm}$ ,  $\epsilon = 16600 \text{ M}^{-1}\text{cm}^{-1}$ ), also known as 6-methylaminopurine 9 ribofuranoside, inhibits calf muscle adenosine deaminase ( $K_i = 5.3 \mu\text{M}$ ) and is also a weak alternative substrate. It has been observed as a component of certain nucleic acids (*e.g.*, it is produced via the actions of rRNA (adenine-N<sup>6</sup>-) methyltransferase, tRNA (adenine-N<sup>6</sup>-) methyltransferase, and site-specific DNA methyltransferase (adenine-specific)). **Target(s):** adenosine deaminase (1-5); adenosine kinase, also as an alternative substrate (6); adenosylhomocysteinase (7,8); AMP nucleosidase (9); deoxycytidine kinase, weakly inhibited (10); GMP synthetase (11); and hypoxanthine transport (12). 1. **2'-C-Methyladenosine 5'-Diphosphate**

This synthetic nucleotide (FW = 440.20 g/mol) is a mechanism-based inhibitor of ribonucleoside-diphosphate reductase (RNR). **Primary Mode of**

**Action:** Reaction of 2'-C-methylADP with the reduced enzyme yielded a 318-nm chromophore (2), similar that obtained upon modification of RNR by furanone (3). Incubation of radiolabeled 2'-C-methylADP with reduced RNR resulted in the covalent incorporation of radiolabel into the protein and aquacobalamin, indicating it is a mechanism-based inhibitor of *C. nephridii* RNR, undergoing enzyme-catalyzed conversion to a 2'-deoxy-2'-C-methyl-3'-ketonucleotide that then collapses to a reactive furanone. 2'-C-methylADP is neither a substrate nor an inhibitor for *Escherichia coli* RNR (2). 1. Ong, McFarlan & Hogenkamp (1993) *Biochemistry* **32**, 11397. 2. McFarlan, Ong & Hogenkamp (1996) *Biochemistry* **35**, 4485. 3. Harris, Ator & Stubbe (1984) *Biochemistry* **23**, 5214.

**N<sup>6</sup>-Methyladenosine 5'-Triphosphate**

This ATP analogue (FW<sub>free-acid</sub> = 521.21 g/mol), also known as 6-methylaminopurine riboside 5'-triphosphate, inhibits *Escherichia coli* leucyl-tRNA synthetase (1) and yeast tyrosyl-tRNA synthetase (2). 1. Marutzky, Flossdorf & Kula (1976) *Nucl. Acids Res.* **3**, 2067. 2. Freist, von der Haar, Faulhammer & Cramer (1976) *Eur. J. Biochem.* **66**, 493.

**Methylamine**

This simple alkylamine CH<sub>3</sub>NH<sub>2</sub> (FW<sub>free-base</sub> = 31.06 g/mol; CAS 74-89-5; FW<sub>hydrochloride</sub> = 67.52 g/mol; pK<sub>a</sub> = 10.62, dpK<sub>a</sub>/dT = -0.032) is actually a stronger base than ammonia. The free base is a flammable gas at room temperature and very soluble in water. The hydrochloride is a deliquescent solid and should be stored in tightly closed containers in a desiccator. Methylamine is a substrate for the reactions catalyzed by methylamine dehydrogenase (amine dehydrogenase), methylamine: glutamate N-methyltransferase (N-methylglutamate synthase), and glutamate: methylamine ligase ( $\gamma$ -glutamylmethylamide synthetase). It is also an alternative substrate for many additional enzymes. It is a product of the reactions catalyzed by N methylalanine dehydrogenase, glycine oxidase (when sarcosine is the substrate), dimethylamine dehydrogenase, sarcosine reductase, N-methyl-2-oxoglutarate hydrolase, alkylamidase, methylguanidinase, and synephrine dehydratase. **Target(s):** acetylcholinesterase, weakly inhibited by the hydrochloride (1-3); N-acetylneuraminate 7-O(or 9-O)-acetyltransferase, weakly inhibited (4);  $\omega$ -amidase (5,6); anthranilate synthase (7); clostripain (8); diaminopropionate ammonia-lyase (9); dimethylargininase (10); dipeptidyl peptidase I, weakly inhibited (11); electron transport, chloroplast (12);  $\beta$ -glucosidase, weakly inhibited (13); glycyl-tRNA synthetase (14); hydroxymethylbilane synthase (15); lysyl endopeptidase, *or* *Achromobacter* proteinase I (16,17); methane monooxygenase, weakly inhibited (18); methanethiol oxidase (19); peptidyl-Lys metalloendo-peptidase (20); photophosphorylation (uncoupler) (12,21); transglutaminase, *or* protein-glutamine  $\gamma$ -glutamyl-transferase (22,23); trypsin, weakly inhibited,  $K_i = 260 \text{ mM}$  (8,24-26); UDP-N-acetylmuramoyl-L-alanyl-D-glutamate:2,6-diaminopimelate ligase (27); UDP-N-acetylmuramoyl-tripeptide-D-alanyl-D-alanine ligase (27). 1. #### Methyl 3-Amino-3-deoxy- $\beta$ -D-galactopyranosyl-(1 $\rightarrow$ 4)-2-acetamido-2-deoxy- $\beta$ -D-glucopyranoside

This glycoside, also known as methyl 3'-amino-3'-deoxy-N-acetyllactosaminide, has an amino group at the position that undergoes galactosylation by UDP-D-galactose: $\beta$ -D-galactopyranosyl (1 $\rightarrow$ 4)-2-acetamido-2-deoxy-D-glucose(1 $\rightarrow$ 3)- $\alpha$ -D-galactopyranosyltransferase, strongly inhibiting that enzyme ( $K_i$  = 104  $\mu$ M). **Target(s)**: UDP-D-galactose: $\beta$ -D-galactopyranosyl-(1 $\rightarrow$ 4)-2-acetamido-2-deoxy-D-glucose (1 $\rightarrow$ 3)- $\alpha$ -D-galactopyranosyltransferase. 1. Helland, Hindsgaul, Palcic, Stults & Macher (1995) *Carbohydr. Res.* **276**, 91.

#### N-[2-(Methylamino)ethyl]-5-isoquinoline sulfonamide

This sulfonamide (FW = 265.34 g/mol), also known as H-8, inhibits a number of protein kinases: IC<sub>50</sub> values for protein kinase G, protein kinase A, protein kinase C, and myosin light chain kinase are 0.48, 1.2, 15, and 68  $\mu$ M, respectively. **Target(s)**: cAMP-dependent protein kinase, or protein kinase A (1,2); casein kinase I, weakly inhibited (1); cGMP-dependent protein kinase, or protein kinase G (1,2); cyclin-dependent protein kinase 9 (3); G-protein coupled receptor kinase 2, mildly inhibited (4); myosin-light-chain kinase (1); protein kinase C (1); rhodopsin kinase,  $K_i$  = 58  $\mu$ M (5); [RNA-polymerase]-subunit kinase, or CTD kinase (6). 1. #### O-Methyl Arachidonyl Fluorophosphonate

This arachidonate derivative (FW = 370.49 g/mol), often abbreviated MAFP and called O-methyl arachidonylphosphonofluoridate, is a selective irreversible inhibitor of the Group IV cytosolic phospholipase A<sub>2</sub> and the Ca<sup>2+</sup>-independent cytosolic phospholipase A<sub>2</sub>. O-methyl arachidonylphosphonofluoridate is also a cannabinoid receptor antagonist. **Target(s)**: acylglycerol lipase, or monoacylglycerol lipase (1-6); 1-alkyl-2-acetylglucero-phosphocholine esterase, or platelet-activating-factor acetylhydrolase (7,8); cannabinoid receptor (9); fatty-acid amide hydrolase, or anandamide amidase (10-12); Lysophospholipase (13-15); phospholipase A<sub>1</sub>, phosphatidate-specific (16,17); phospholipase A<sub>2</sub> (18-22). 1. #### N<sup>o</sup>-Methyl-L-Arginine

This modified amino acid (FW = 196.26 g/mol), often referred to as N<sup>o</sup>-monomethyl-L-arginine (or L-NMMA) inhibits nitric oxide synthase, with the IC<sub>50</sub> values of 0.7, 0.65, and 3.9  $\mu$ M for the endothelial, neuronal, and inducible enzymes, respectively. The D-enantiomer is not inhibitory. Methylated arginyl residues have also been identified in a number of proteins (e.g., histones, cytochrome c, and myelin basic protein). N<sup>o</sup>-Methyl-L-arginine is an alternative substrate of arginine decarboxylase. (Do not confuse this derivative, also known as N<sup>o</sup>-methyl-L-arginine, with  $\gamma$ -methyl-L-arginine.) **Target(s)**: arginine kinase, weakly inhibited (1); nitric-oxide synthase (2-23). 1. #### 3-Methyl-L-aspartate (3-Methyl-L-aspartic Acid)

This methylated aspartic acid derivative (FW = 147.13 g/mol), also known as 2-amino-3-methyl-succinic acid, is an intermediate in the conversion of glutamate to citramalate in certain organisms (e.g., *Chlostridium tetanomorphum*). Both the (2S,3S)- and (2S,3R)-isomers inhibit *Escherichia coli* asparagine synthetase B ( $K_{is}$  = 0.25 mM for the (2S,3R)-isomer).

**Target(s):** asparagine synthetase, inhibited by both *erythro*- and *threo*-isomers (1-3); aspartate 4-decarboxylase, inhibited by the *erythro*-DL-stereoisomer, also a weak alternative substrate (4,5); aspartyl-tRNA synthetase (6); tyrosine aminotransferase (7). 1. Lea & Fowden (1975) *Proc. R. Soc. Lond. B Biol. Sci.* **192**, 13. 2. Parr, Boehlein, Dribben, Schuster & Richards (1996) *J. Med. Chem.* **39**, 2367. 3. Boehlein, Stewart, Walworth, et al. ### N-Methyl-D-Aspartate (N-Methyl-D-Aspartic Acid)

This synthetic neuroactive amino acid derivative (FW = 147.13 g/mol; CAS 6384-92-5; IUPAC Name: (2*R*)-2-(methylamino)butanedioate; water-soluble) is a specific partial agonist at the so-called NMDA receptor (NMDAR), mimicking the natural action of glutamate, its physiologic neurotransmitter agonist. **Mechanism of Action:** The NMDA receptor forms a heterotetramer between two GluN1 and two GluN2 subunits (the subunits were previously denoted as NR1 and NR2), two obligatory NR1 subunits and two regionally localized NR2 subunits. Upon specific agonist-binding to its NR2 subunits, a non-specific cation channel opens, allowing Ca<sup>2+</sup> and Na<sup>+</sup> to pass into the cell and K<sup>+</sup> to pass out of the cell. The excitatory postsynaptic potential (EPSP) produced by activation of an NMDA receptor also increases the concentration of Ca<sup>2+</sup> in the cell. The Ca<sup>2+</sup> can in turn function as a second messenger in various signaling pathways. Activation of the *N*-methyl-D-aspartate receptor plays a role in activity-dependent synaptic plasticity, such as long-term potentiation (1), and the patterning of connections during development of the visual system (2,3). **Effect of Tau Protein Phosphorylation:** The extent of the microtubule-associated protein Tau phosphorylation at Serine 199-202 residues (but not Serine 262 and Serine 404) is decreased in NMDA-treated hippocampal slices (4). NMDA-induced reduction of Tau phosphorylation at Serine 199-202 was blocked completely by the NR2A receptor antagonist NVP-AAM077. Compared with untreated slices, NMDA receptor activation is reflected in high Serine 9 and low Tyrosine 216 phosphorylation of GSK3β, suggesting NMDA receptor activation might diminish Tau phosphorylation via a pathway involving inhibition of GSK3β. In support of this idea is the finding that PKC-mediated GSK3β is involved in the NMDA-induced reduction of Tau phosphorylation at Ser199-202. These data suggest NR2A receptor activation may be an important factor in limiting Tau phosphorylation by a PKC/GSK3β pathway. **NMDA Receptor Isoforms:** Eight NR1 subunit variants are generated by alternative splicing of GRIN1, namely NR1-1a (most abundant form) and NR1-1b; NR1-2a and NR1-2b; NR1-3a and NR1-3b; and NR1-4a and NR1-4b. In vertebrates, there are four distinct NR2 subunit isoforms: GRIN2A, GRIN2B, GRIN2C, GRIN2D. **NMDA Receptor Antagonists:** *ACBC*, acts at glycine site ligand; *D-AP5*, potent, selective NMDA antagonist; *DL-AP7*, highly selective; *Arcaïne*, competitive; (*R*)-4-*Carboxyphenylglycine*, moderately potent; *Cerestat*, potent and noncompetitive; *CGP-37849*, potent and selective; *CGP-39551*, potent, selective and competitive; *CGP-78608*, potent, selective, glycine-site ligand; *CGS-19755*, potent and competitive; 7-*Chlorokynurenate*, glycine site ligand; (2*R*,3*S*)-*Chlorphleg*, weak antagonist; *CNQX*, glycine site ligand; *Co 101244*, NR2B-selective; *Conantokin G*, NR2B-selective; *Conantokin-R*, potent noncompetitive; *Conantokin-T*, noncompetitive; (*R*)-*CPP*, more active enantiomer of (*RS*)-*CPP*; (*RS*)-*CPP*, potent; *D-CPP-ene*, potent and competitive; *Dextromethorphan*; 5,7-*Dichlorokynurenate*, potent, glycine site ligand; (±)-1-(1,2-*Diphenylethyl*)piperidine, acts ion channel site; *DQP-1105*, selective for NR2C/NR2D; *Eliprodil*, noncompetitive NR2B-selective; *Felbamate*, acts glycine site; *Flupirtine*, indirect antagonist, potent and selective glycine site antagonist, orally available and active *in vivo*; (*S*)-(-)-*HA-966*, partial agonist; *HU 211*, NMDAR antagonist and NF-κB inhibitor; *N*-(4-*Hydroxyphenylacetyl*)spermine, wasp toxin analogue; *Ifenprodil*, noncompetitive NMDAR antagonist, also σ ligand; *threo-Ifenprodil*, NR2B-selective NMDA antagonist; also σ agonist; *Ketamine*, noncompetitive; L-689,560, very potent; *L-701,252*, acts glycine site; *L-701,324*, acts at glycine site; *Loperamide*, reduces Ca<sup>2+</sup> flux; *LY 233053*, competitive; *LY 235959*, competitive; *Memantine*, acts at ion channel site; (-)-*MK 801*, less active

enantiomer; (+)-*MK 801*, noncompetitive, acts at ion channel site; *Norketamine*, potent and noncompetitive; *Pentamidine*, antimicrobial agent that also antagonizes NMDARs; *Phencyclidine*, noncompetitive; *PPPA*, competitive; *PPDA*, subtype-selective NR2C/NR2D antagonist; *PPPA*, competitive; *QNZ 46*, NR2C/NR2D-selective noncompetitive antagonist; *Remacemide*, blocks ion channel and allosteric modulatory site; *Ro 04-5595*, NR2B-selective; *Ro 25-6981*, NR2B-selective; *Ro 61-8048*, increases kynurenic acid levels; *Ro 8-4304*, NR2B-selective; *SDZ 220-040*, potent and competitive; *SDZ 220-581*, competitive; *Synthalin*, noncompetitive; TCN 201, selective for NR1/NR2A; *TCN 213*, selective for NR2A over NR2B; *TCN 237*, highly potent and selective for NR2B; *TCS-46b*, orally active, NR1A/NR2B-subtype selective; *ZD 9379*, brain-penetrating, glycine site ligand. 1. ### (24*R*)-24-Methyl-25-azacycloartanol

This positively charged aza-analogue (FW = 433.77 g/mol), which mimics the putative high-energy C-25 carbocation intermediate, potentially inhibits maize *S*-adenosyl-L-methionine-sterol-24-*C*-methyltransferase (*K<sub>i</sub>* = 20 nM). Its 24*S* counterpart is a slightly weaker inhibitor (*K<sub>i</sub>* = 30 nM). 1. Rahier, Génot, Schuber, Benveniste & Narula (1984) *J. Biol. Chem.* **259**, 15215. 2. ### 3-Methylcatechol

This substituted catechol (FW = 124.14 g/mol; M.P. = 65-68°C) inhibits 1,2-dihydroxynaphthalene dioxygenase and protocatechuate 4,5-dioxygenase. It is also an alternative substrate of 2,3-dihydroxybiphenyl 1,2-dioxygenase and catechol 1,2-dioxygenase. **Target(s):** biphenyl-2,3-diol 1,2-dioxygenase, also as a weak alternative substrate (1); catechol 1,2-dioxygenase, also as an alternative substrate (2-4); catechol 2,3-dioxygenase, also as an alternative substrate and suicide inhibitor (5); 1,2-dihydroxynaphthalene dioxygenase (6); 4,5-dihydroxyphthalate decarboxylase, weakly inhibited (7); protocatechuate 4,5-dioxygenase (8).

#### 4-Methylcatechol

This substituted catechol (FW = 124.14 g/mol; M.P. = 67-69°C) inhibits a number of dioxygenases as well as some metalloproteinases. It is an alternative substrate of tyrosinase, 2,3 dihydroxybiphenyl 1,2-dioxygenase, and catechol 1,2-dioxygenase. Catechol 2,3-dioxygenase is inactivated at an appreciable rate during the ring cleavage of 4-methylcatechol, a consequence of oxidation of the Fe(II) cofactor to Fe(III). **Target(s):** aminopeptidase N, *or* membrane alanyl aminopeptidase (1); biphenyl-2,3-diol 1,2 dioxygenase (2); catechol 1,2-dioxygenase, also as an alternative substrate (3,4); catechol 2,3-dioxygenase, as alternative substrate and suicide inhibitor (5-7); 1,2-dihydroxynaphthalene dioxygenase (8); 3,4 dihydroxyphenylacetate 2,3-dioxygenase (9); peptidyl-dipeptidase A, *or* angiotensin I-converting enzyme (1); protocatechuate 3,4-dioxygenase (10,11); protocatechuate 4,5-dioxygenase (12); tyrosine 3 monooxygenase (13). 1. #### Methylcobalamin

This form of vitamin B<sub>12</sub> (FW<sub>free-acid</sub> = 1344.4 g/mol), which participates in the formation of methionine from homocysteine, is rapidly oxidized in aqueous solution in the presence of dioxygen, producing aquacobalamin. This rate is significantly slower under anaerobic conditions and increased

by the presence of thiols and ethanol. **Target(s):** ethanolamine ammonia-lyase (1-6); glutamate mutase (7); propanediol dehydratase (2); HIV-1 integrase (8). 1. Kaplan & Stadtman (1971) *Meth. Enzymol.* **17B**, 818. 2. Abeles (1971) *The Enzymes*, 3rd ed., **5**, 481. 3. Stadtman (1972) *The Enzymes*, 3rd ed., **6**, 539. 4. Mauck, Hull & Babior (1975) *J. Biol. Chem.* **250**, 8997. 5. #### S-Methyl-L-cysteine

This cysteine derivative (FW = 135.19 g/mol) is found in many proteins, presumably as a consequence of nonspecific alkylation (*e.g.*, reaction with methyl mercury cation) or by methyltransfer (*e.g.*, formation via methylated-DNA:[protein]-cysteine S-methyltransferase in the repair of alkylated DNA). **Target(s):** alkaline phosphatase, mildly inhibited (1); alliin lyase (2); asparagine:oxo-acid aminotransferase (3); cysteine dioxygenase (4,5); cysteine synthase, weakly inhibited (6); cysteinyl tRNA synthetase (7); glyoxalase, weakly inhibited (8); phenylalanine 4-monooxygenase (9,10); serine O-acetyltransferase (11,12); tryptophanase (13). 1. #### Methyl 2,5-Dihydroxycinnamate

This cell-permeable erbstatin analogue (FW = 194.19 g/mol; Photosensitive) inhibits protein-tyrosine kinases (IC<sub>50</sub> = 0.78 μM) for the epidermal growth factor-receptor (EGFR) protein-tyrosine kinase. DNA topoisomerase II is inhibited by alkylation of catalytically essential amino acyl residues. **Target(s):** *bcr-abl* protein-tyrosine kinase (1); DNA topoisomerase II (2,3); EGF-receptor protein-tyrosine kinase (4,5); Lyn protein-tyrosine kinase (6); PDGF-receptor protein-tyrosine kinase (7); protein-tyrosine kinase (1,4-6,8,9); receptor protein-tyrosine kinase (4,5,7,8); Syk protein tyrosine kinase (6). 1. #### α-Methyl-3,4-dihydroxyphenylalanine

This photosensitive dopa derivative (FW = 211.22 g/mol), also known as  $\alpha$ -methyl-dopa and 3-(3,4-dihydroxyphenyl)-2-methylalanine, is an antihypertensive agent that is metabolized to  $\alpha$ -methyl-norepinephrine which stimulates  $\alpha_2$  receptors. The L-enantiomer of  $\alpha$ -methyl-dopa is also a potent competitive inhibitor of aromatic-L-amino-acid decarboxylase. **Target(s):** alkaline phosphatase (1); aromatic-L-amino-acid decarboxylase, *or* dopa decarboxylase (2-11); carnosine synthetase (12); tyrosine aminotransferase (13); tyrosine decarboxylase (11); tyrosine 3-monooxygenase (14). 1. ### 2-(4-Methyl-2,6-dinitroanilino)-N-methylpropionamide

This herbicide (FW = 282.26 g/mol), often abbreviated MDMP, is a specific inhibitor of ribosomal peptide-chain initiation, blocking the binding of the 60S subunit to the initiation complex, the latter consisting of the 40S subunit, mRNA, and initiator RNA. MDMP also causes the diaggregation of yeast polysomes. 1. Fresno & Vázquez (1979) *Meth. Enzymol.* **60**, 566. 2. Jiménez (1976) *Trends Biochem. Sci.* **1**, 28. 3. Weeks & Baxter (1972) *Biochemistry* **11**, 3060.

### $\alpha,\beta$ -Methyleneadenosine 5'-Diphosphate

This nonhydrolyzable ADP analogue and potent vasoconstrictor (FW<sub>sodium-salt</sub> = 469.19 g/mol; CAS 104835-70-3; Abbreviations: AMPCP, APCP, or p(CH<sub>2</sub>)pA) inhibits many ADP-dependent systems. With its *sp*<sup>3</sup> or tetrahedral methylene bridge, the methylene analogue is not a true ADP isostere. Its pK<sub>a</sub> values are also 1-2 units higher than ADP, and its divalent metal ion binding is substantially weaker. Even so, many ATP-dependent enzymes bind this analogue, and its resistance to hydrolysis commends its use in many experiments. It is also a substrate for mitochondrial uptake by the ADP-ATP translocase, when assayed with isolated mitochondria. Importantly, adenosine receptor activation by adenine nucleotides requires conversion of the nucleotides to adenosine, making APCP inhibition of 5'-nucleotidase a useful way to modulate adenosine receptor activation and vascular tone. (In view of its high ionic charge, p(CH<sub>2</sub>)pA requires intravenous administration and is unlikely to be taken up by most cells.) **Target(s):** carbamoyl-phosphate synthetase (1); 5'-nucleotidase (2-13) [Note: In certain MDR cell lines, ecto-5'NT serves as a required accessory molecule in resistance mediated by ATP-dependent mechanisms, and growth-sustaining nucleosides are provided by this salvage pathway (14). MDR cells with increased ecto-5'NT expression also have a lower intracellular ATP level than their parental cells.]; polynucleotide phosphorylase, *or* polyribonucleotide nucleotidyltransferase (15); thiamin-triphosphatase (16); triphosphate:protein phosphotransferase (17). 1. ### $\alpha,\beta$ -Methylene- Methyleneadenosine 5'- $\gamma$ -S

This nonhydrolyzable  $\gamma$ -thio-ATP analogue (FW = 518.25 g/mol) protects against oxidative stress and Amyloid- $\beta$  oligomers toxicity, conditions that are hallmarks in Alzheimer's Disease (1,2).. Unlike ATP- $\gamma$ -S, its nonhydrolyzable analogue  $\alpha,\beta$ -CH<sub>2</sub>-ATP- $\gamma$ -S resists hydrolysis. Both inhibit ROS formation in PC12 cells previously subjected to Fe(II)-oxidation, with IC<sub>50</sub> values of 0.18  $\mu$ M for  $\alpha,\beta$ -CH<sub>2</sub>-ATP- $\gamma$ -S and 0.20  $\mu$ M for ATP- $\gamma$ -S. ATP- $\gamma$ -S-( $\alpha,\beta$ -CH<sub>2</sub>) also rescues primary neurons from A $\beta$ <sub>42</sub> toxicity, with four times the potency if ATP- $\gamma$ -S, (IC<sub>50</sub> = 0.2 and 0.8  $\mu$ M, respectively). ATP- $\gamma$ -S-( $\alpha,\beta$ -CH<sub>2</sub>) also resists hydrolysis by ecto-nucleotidases such as NPPs and TNAP, and is seven times more potent than ATP as a P2Y11 receptor agonist. Note: Although ATP- $\gamma$ -S-( $\alpha,\beta$ -CH<sub>2</sub>) is a promising agent for rescuing neurons from debilitating insults typical of Alzheimer's disease, its structural similarity to ATP suggests that it may likewise affect many other ATP. 1. Danino, Giladi, Grossman & Fischer (2014) *Biochem. Pharmacol.* **88**, 384. 2. Danino, Grossman & Fischer (2015) *Biochem. Biophys. Res. Commun.* **460**, 466.

### $\alpha,\beta$ -Methyleneadenosine 5'-Triphosphate

This nonhydrolyzable ATP analogue (FW<sub>lithium-salt</sub> = 511.14 g/mol; CAS 104809-20-3; Symbol: AMPCPP and pp(CH<sub>2</sub>)pA) inhibits many ATP-dependent reactions and processes requiring scission of the P-O bond lying between the  $\alpha$  and  $\beta$  phosphoryls. With its tetrahedral methylene bridge, this analogue is also not a true ATP isostere, inasmuch as the bridge oxygen is trigonal. The pK<sub>a</sub> values of pp(CH<sub>2</sub>)pA are also 1-2 units higher and its divalent metal ion binding substantially weaker. pp(CH<sub>2</sub>)pA is also a P<sub>2</sub> purinoceptor agonist. Many ATP-hydrolyzing mechanoenzymes that employ a  $\gamma$ -phosphoryl sensor or molecular switch are parsimonious and will not bind pp(CH<sub>2</sub>)pA. **Target(s):** (N-acetylneuraminy)-galactosyl-glucosylceramide N-acetylgalactosaminyl-transferase (43); adenylyl cyclase, *or* adenylyl cyclase (1,2); aminoacyl-tRNA synthetases (3); 2-amino-4-hydroxy-6-hydroxymethyl-7,8-dihydropteridine diphosphokinase (13,14,40); arginyl-tRNA synthetase (4); asparagine synthetase (5); carbamoyl phosphate synthetase (6,7); cysteinyl-tRNA synthetase (8); dTMP kinase, *or* thymidylate kinase (41); ecto-ATPase (9); endopeptidase La (31); formyltetrahydrofolate synthetase (10); glycyl-tRNA synthetase (11); GTP diphosphokinase (39); 3-hydroxymethylcephem carbamoyltransferase (12); leucyl-tRNA synthetase (15); methionine S-adenosyltransferase (16,42); mitochondrial ATP dependent protease (17); nucleoside-triphosphatase (18); 5'-nucleotidase (19); nucleotide diphosphatase (20-23); pantothenate synthetase (24); phosphodiesterase I,

or 5'-exonuclease (32); polynucleotide adenylyltransferase, or poly(A) polymerase (36,37); pyruvate, orthophosphate dikinase (25); pyruvate, water dikinase (34); ribose-phosphate diphosphokinase, or phosphoribosyl pyrophosphate synthase (26); RNA ligase, ATP-requiring (27); selenide, water dikinase (33); streptomycin 3'' adenylyltransferase (35); sulfate adenylyltransferase (38); tRNA adenylyltransferase (28); tryptophanyl tRNA synthetase (29); tyrosyl-tRNA synthetase (30). 1. ### β,γ-Methyleneadenosine 5'-Triphosphate

This nonhydrolyzable ATP analogue (FW<sub>free-acid</sub> = 505.21 g/mol; Abbreviation: AMP-PCP and p(CH<sub>2</sub>)ppA) also called adenosine β,γ-methylene triphosphate and adenylyl (β,γ-methylene)-diphosphonate, is an inhibitor of many ATP-dependent enzymes that produce ADP and orthophosphate. Its P-C-P linkage has a bond angle closer to sp<sup>3</sup>-hybridized C-C-C bonds than the P-O-P bond in ATP. p(CH<sub>2</sub>)ppA can also serve as an alternative substrate for enzymes that hydrolyze ATP between the β and γ phosphorus atoms. With its tetrahedral methylene bridge, the methylene analogue is not a true ATP isostere, wherein the bridge oxygen is trigonal. Its pK<sub>a</sub> values are also 1-2 units higher and its divalent metal ion binding substantially weaker. pp(CH<sub>2</sub>)pA is also a P<sub>2</sub> purinoceptor agonist. In addition, p(CH<sub>2</sub>)ppA is a selective P<sub>2x</sub> purinoceptor agonist that is more potent than ATP, although less potent than p(CH<sub>2</sub>)ppA (i.e., α,β-methyleneadenosine 5' triphosphate). *Escherichia coli* alkaline phosphatase hydrolyzes this nucleotide analogue to orthophosphate and the corresponding nucleoside diphosphate derivative. p(CH<sub>2</sub>)ppA is

hygroscopic and is very soluble in water. It also binds metal ions with a great affinity. It is more stable in acidic solutions than AMP-PNP (adenosine β,γ-imidotriphosphate). Note: Many ATP-hydrolyzing mechanoenzymes that employ a γ-phosphoryl sensor or molecular switch are especially parsimonious and do not bind p(CH<sub>2</sub>)ppA. **Target(s):** adenylyl cyclase (1); apyrase (2); asparagine synthetase (3); ATP phosphoribosyltransferase (53); Ca<sup>2+</sup>/Mg<sup>2+</sup>-dependent ATPase (4); cobaltochelate (5); diphosphomevalonate decarboxylase (6); DNA helicase (7); DNA ligase (8); DNA topoisomerase II (9); ecto-ATPase (10); endopeptidase La (46,47); endothelial growth factor receptor-2 tyrosine kinase (11); folic polyglutamate synthetase (12); formyltetrahydrofolate synthetase (13); fructokinase (14); glucokinase (15); glutamyl-tRNA synthetase, or glutamine-hydrolyzing (16); glycyl-tRNA synthetase (17); hexokinase (18); 3-hydroxymethylcephem carbamoyltransferase (19); insulin (20); leucyl-tRNA synthetase (21); methionine S-adenosyltransferase (52); mitochondrial ATP-dependent protease (22); mitogen-activated protein kinase, or p38 mitogen-activate protein (MAP) kinase (31,50); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (23); nucleoside-triphosphatase (7,24); 5'-nucleotidase (25,26,48); nucleotide diphosphatase (27); 2',5'-oligoadenylate synthetase (28); phosphofructokinase (29); 3-phosphoglycerate kinase (30,51); polar-amino-acid-transporting ATPase, or histidine permease (32,33); polynucleotide phosphorylase, or polyribonucleotide nucleotidyltransferase (4,35); pyruvate, orthophosphate dikinase (36); RNA ligase, ATP-requiring (37); SecA ATPase (38); tetrahydrofolate synthetase (39-42); thiamin triphosphatase (43); triphosphate:protein phosphotransferase (49); UDP-N-acetylmuramate:L-alanine ligase (44,45). 1. **2,2'-Methylenebis(4-chlorophenol)**

This chlorinated bisphenol (FW = 269.13 g/mol; M.P. = 177-178°C; *Abbreviation*: MBC) also known as dichlorophen(e) and often abbreviated DCP and, is an antibacterial, antifungal, and anthelmintic agent that is used in agriculture as well as in soaps and shampoos. **Target(s)**: chitin synthase (1); cystathionine  $\beta$ -synthase, *or* serine sulfhydrase (2-4); glucose-6 phosphate dehydrogenase (5); homocysteine desulfhydrase (2); hydroquinone glucosyltransferase (6); lactoylglutathione lyase, *or* glyoxalase I (7). 1. **Methylene bisphosphonate**

This nonhydrolyzable pyrophosphate analogue (FW<sub>free-acid</sub> = 176.00; CAS 194931-67-4), also named Medronate, methylenediphosphonate, and methanebisphosphonate, inhibits several pyrophosphate-dependent reactions. Methylene bisphosphonate is frequently condensed with nucleosides (N) and nucleoside 5'-monophosphates (NMP) to form the nonhydrolyzable nucleotide analogues p(CH<sub>2</sub>)pN, pp(CH<sub>2</sub>)pN, p(CH<sub>2</sub>)ppN, *etc.* **Treating Osteoporosis**: There are many bone-stabilizing drugs that have a methylene bisphosphonate nucleus, a polydentate structure that binds metal ions and maintains bone mineralization. Bisphosphonates "home" to bone, where they concentrate. Upon acidification by bone-resorbing osteoclasts, these phosphonates are released and inhibit isopentenyl-pyrophosphate-dependent reactions, thereby reducing osteoclasts podosome. The latter are essential for bone remodeling by means of local acidification by podosomal V-APTase. Based on isothermal titration calorimetry (ITC) on the binding of a variety of bisphosphonates to human bone, there appear to be two binding sites: (a) a weak, highly populated site, with average  $\Delta G$  of binding of -5.2 kcal/mol; and (b) stronger binding site, with a  $\Delta G$  of binding of -8.5 kcal (1). Binding to both sites is entropy-driven. **Target(s)**: geranyl-diphosphate cyclase, *or* bornyl-diphosphate synthase (2); GTP cyclohydrolase IIa (3); *trans*-octaprenyltransferase (21); phosphate carrier (4); phosphoenolpyruvate carboxykinase (diphosphate) (5,6); pyrophosphatase (8-14); pyrophosphate-dependent phosphofructokinase, *or* diphosphate:fructose-6 phosphate 1-phosphotransferase (7,20); pyruvate,orthophosphate dikinase (15,16); succinate dehydrogenase (17,18); vacuolar H<sup>+</sup>-translocating inorganic diphosphatase (19). 1. **Methylene Blue**

This widely used redox dye (FW<sub>anhydrous</sub> = 319.86 g/mol; CAS 61-73-4; Symbol: MB<sup>+</sup>; Soluble in water and ethanol;  $\lambda_{max}$  = 663-667 nm (undergoes concentration-dependent changes above 1 mM, with loss of 663-667 nm peak). Methylene blue ( $E^{\circ}$  = 0.011 V at 30°C) is reduced to a colorless (or slightly yellow) compound in the absence, and becomes blue again, when exposed to O<sub>2</sub>. This property is exploited in verifying that anaerobic bacterial culture medium is O<sub>2</sub>-free. MB<sup>+</sup> has also inhibits oxidative phosphorylation and photophosphorylation. It has also inhibits tau polymerization in Alzheimer's Disease. Methylene Blue hydrate (FW = 337.87 g/mol; CAS 122965-43-9) is a frequently used nucleic acid stain in both agarose and polyacrylamide gel electrophoresis, because it is less hazardous than ethidium bromide. Moreover, DNA bands are viewable in visible light. Significantly, MB<sup>+</sup> photosensitizes DNA (occurring in both aerated or de-aerated solutions), causing guanine-specific phosphodiester-bond cleavage and making additional bonds alkali labile. **Target(s)**: acetylcholinesterase (1); acetyl-CoA synthetase, *or* acetate:CoA ligase (2); adenylate kinase (3); adrenodoxin reductase, NADPH-dependent (4); alkaline mesentericopeptidase (5); alkaline phosphatase (6); amine oxidase and/or diamine oxidase (7-9); aminopeptidase B (10); arginine aminopeptidase (11,12); bromelain (13,14); carboxylesterase, *or* procaine esterase (15); cholinesterase (1,16); chymotrypsin (17); collagenase (18,19); dextranucrase (20,21); diol dehydratase (22); dipeptidyl-peptidase IV (70); enolase (23);  $\beta$ -fructofuranosidase, *or* invertase, weakly inhibited (24);  $\beta$ -fructosidase (25);  $\beta$ -galactosidase (26,27); glucose-6-phosphatase (28); glucosyltransferases (*e.g.*, levansucrase and dextranucrase) (20,21); glutaminase (29); glutamine synthetase (30);  $\gamma$ -glutamyl transpeptidase (31); guanylate cyclase (32); hexokinase (33); S-2-hydroxyacylglutathione hydrolase, *or* glyoxalase II (34,75,76); 3-hydroxydecanoyl-[acyl-carrier-protein] dehydratase (35,36); isocitrate dehydrogenase, NADP<sup>+</sup>-dependent (37); leucyl aminopeptidase (71); levansucrase (20,21); lysozyme (17,38-41); magnesium protoporphyrin IX monomethyl ester (oxidative) cyclase (80-82); malic enzyme, NAD<sup>+</sup>-dependent (42); NAD<sup>+</sup> kinase (43); NADPH peroxidase (83); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (44); nitric-oxide synthase (45,46); oligo 1,6-glucosidase (47); palmitoyl-CoA hydrolase, *or* acyl-CoA hydrolase (48,74); pancreatic ribonuclease, *or* ribonuclease A (49-53); phosphoenolpyruvate phosphatase (73); phosphofructokinase (54); phosphoglucomutase (55); 6-phosphogluconate dehydrogenase (56); phosphoglycerate mutase (57,58); phosphopantothenoyl-cysteine decarboxylase (59); progesterone monooxygenase (78); purine nucleoside phosphorylase (60,61); pyruvate kinase (62); ribonuclease T<sub>1</sub> (63,64); ribonuclease T<sub>2</sub> (72); stearoyl-CoA 9-desaturase (79); stem bromelain (13,14); steroid  $\Delta$  isomerase (65); sulfate adenylyltransferase (77); sulfite oxidase (84); taurine dehydrogenase (66); transketolase (67); trypsin (17,68); urease (69). 1. #### (Methylenecyclopropyl)acetyl-CoA

This toxic acyl-CoA is produced from hypoglycin A, isolated from unripe ackee fruit (*Blighia sapida*), and is the causative agent of Jamaican vomiting sickness. It is an irreversible inhibitor of several acyl-CoA dehydrogenases, including butyryl-CoA dehydrogenase and isovaleryl-CoA dehydrogenase, and causes severe hypoglycemia. **Target(s):** acyl-CoA dehydrogenase (1,2); butyryl-CoA dehydrogenase (2-5); glutaryl-CoA dehydrogenase (6); isovaleryl-CoA dehydrogenase (3,4); medium-chain acyl-CoA dehydrogenase (2,4); methylmalonyl-CoA mutase (7). **1.** Wenz, Thorpe & Ghisla (1981) *J. Biol. Chem.* **256**, 9809. **2.** Ator & Ortiz de

#### 3,4-Methylenedioxyamphetamine

This amphetamine derivative (FW = 193.25 g/mol), also known as MDMA and ecstasy, is a hallucinogen and potent CNS stimulator. It is a neurotoxin that promotes the release of serotonin and blocks its reuptake. MDMA induces short- and long-term neuropsychiatric behaviors and is a widely abused recreational drug. In addition to being toxic to serotonergic neurons, it induces programmed cell death in cultured human serotonergic cells and rat neocortical neurons. It also alters the release of several neurotransmitters in the brain, induces re-compartmentation of intracellular serotonin and c-fos, and modifies the expression of a number of genes. **Target(s):** monoamine oxidase (1); serotonin transport (2); tryptophan 5-monoxygenase, inhibited mainly by MDMA metabolites (3,4). **1.** Leonardi & Azmitia (1994) *Neuropsychopharmacol.* **10**, 231. **2.** Rudnick & Wall (1992) *Proc. Natl. Acad. Sci. U.S.A.* **89**, 1817. **3.** Schmidt & Taylor (1987) *Biochem. Pharmacol.* **36**, 4095.

#### $\alpha,\beta$ -Methyleneguanosine 5'-Triphosphate

This nonhydrolyzable GTP analogue (FW<sub>free-acid</sub> = 521.21 g/mol; *Abbreviation:* GMPCPP and pp(CH<sub>2</sub>)pG) also called guanosine  $\alpha,\beta$ -methylene triphosphate and guanylyl ( $\beta,\gamma$ -methylene)-diphosphonate, is an inhibitor of many GTP-dependent enzymes that produce GMP and pyrophosphate. Its P-C-P linkage has a bond angle closer to  $sp^3$ -hybridized C-C-C bonds than the P-O-P bond in GTP. p(CH<sub>2</sub>)ppA can also serve as an alternative substrate for enzymes that hydrolyze GTP between the  $\alpha$  and  $\beta$  phosphorus atoms. With its tetrahedral methylene bridge, the methylene analogue is not a true GTP isostere, wherein the bridge oxygen is trigonal. Its  $pK_a$  values are also 1-2 units higher and its divalent metal ion binding substantially weaker. pp(CH<sub>2</sub>)pG is also a P<sub>2</sub> purinoceptor agonist. GMPCPP inhibits GTP cyclohydrolase IIa (1). **1.** Graham, Xu & White (2002) *Biochemistry* **41**, 15074.

#### $\beta,\gamma$ -Methyleneguanosine 5'-Triphosphate

This nonhydrolyzable GTP analogue (FW<sub>free-acid</sub> = 521.21 g/mol; *Abbreviation:* GMP-PCP and p(CH<sub>2</sub>)ppA) also called guanosine  $\beta,\gamma$ -methylene triphosphate and guanylyl ( $\beta,\gamma$ -methylene)-diphosphonate, is an inhibitor of many ATP-dependent enzymes that produce GDP and orthophosphate. Its P-C-P linkage has a bond angle closer to  $sp^3$ -hybridized C-C single-bonds than the P-O-P bond in GTP. p(CH<sub>2</sub>)ppG can also serve as an alternative substrate for enzymes that hydrolyze GTP between the  $\alpha$

and  $\beta$  phosphorus atoms. With its tetrahedral methylene bridge, the methylene analogue is not a true GTP isostere, wherein the bridge oxygen is trigonal. Its  $pK_a$  values are also 1-2 units higher and its divalent metal ion binding substantially weaker.  $\text{pp}(\text{CH}_2)\text{pG}$  is also a  $\text{P}_2$  purinoceptor agonist. Guanylyl ( $\beta,\gamma$ -methylene)-diphosphonate inhibits numerous GTP-dependent enzymes that typically produce GDP and orthophosphate from GTP hydrolysis. It can also serve as a slow, alternative substrate for enzymes hydrolyzing GTP between the  $\alpha$  and  $\beta$  phosphorus atoms. GMP-PCP is very soluble in water and binds metal ions with a great affinity. It is more stable in acidic solutions than GMP-PNP (guanosine  $\beta,\gamma$ -imidotriphosphate). **Target(s):** adenylosuccinate synthetase (1); dynamin GTPase (2); GTP cyclohydrolase IIa (3); phosphatidylinositol-4,5-bisphosphate phospholipase C (4); protein biosynthesis (translocation) (5,6); protein-glutamine  $\gamma$ -glutamyltransferase (transglutaminase) (7); releasing factor (8); microtubule depolymerization and dynamicity (9). 1. ### 3,4-Methylene- $\beta$ -nitrostyrene

This Spleen tyrosine kinase (Syk) inhibitor (FW = 193.16 g/mol; *Symbol* = MNS) represents a new class of Src and Syk tyrosine kinase inhibitors, potentially preventing GPIIb/IIIa activation and platelet aggregation without directly affecting other signaling pathways required for platelet activation (1). MNS exhibits potent and broad-spectrum inhibitory effects on human platelet aggregation observed by various stimulators. Addition of MNS to already ADP-aggregated human platelets also brings about rapid disaggregation by inhibiting GPIIb/IIIa activation. MNS potently inhibits tyrosine kinases (Src and Syk) and prevented protein tyrosine phosphorylation and cytoskeletal association of GPIIb/IIIa and talin, but it has no direct effects on protein kinase C,  $\text{Ca}^{2+}$  mobilization,  $\text{Ca}^{2+}$ -dependent enzymes (myosin light chain kinase and calpain), and arachidonic acid metabolism, and it does not affect the cellular levels of cyclic nucleotides. MNS also targets ATP-induced activation of the NOD-like Receptor Protein-3 (or NLRP3) inflammasome, the dysregulation of which is implicated in several inflammation-associated disorders (e.g., gouty arthritis, silicosis, Type 2 diabetes, Alzheimer's disease, and Cryopyrin-associated periodic syndrome (CAPS) fever) (2). MNS does not affect the activation of the NLR4 and AIM2 inflammasomes at concentrations that abrogated NLRP3 inflammasome activation. Moreover, deletion of Syk kinase in macrophages does not affect NLRP3 inflammasome activation-induced by ATP, nigericin and silica, a surprising finding indicating that Syk is dispensable for NLRP3-mediated inflammasome activation. MNS also inhibits NLRP3 ATPase activity *in vitro*, suggesting that MNS blocks the NLRP3 inflammasome by directly targeting NLRP3 or NLRP3-associated complexes. The site of unsaturation in 3,4-methylene- $\beta$ -nitrostyrene is required for these potent pharmacologic effects. 1. Wang, Wu & Wu (2006) *Mol. Pharmacol.* **70**, 1380. 2. ### Methyl Gallate

This gallate ester (FW = 184.15 g/mol), also known as gallic acid methyl ester and methyl 3,4,5-trihydroxybenzoate, inhibits chitin synthase. Methyl gallate is an effective antioxidant in a variety of acellular experiments. **Target(s):** catechol *O*-methyltransferase (1); chitin synthase (2);  $\alpha$ -glucosidase, or sucrase (3); 3-galactosyl-*N*-acetylglucosaminide 4- $\alpha$ -L-

fucosyltransferase (4); glycoprotein 3- $\alpha$ -L-fucosyltransferase (4); 15-lipoxygenase, or arachidonate 15-lipoxygenase (5); ribonucleoside diphosphate reductase (6); xanthine oxidase (7). 1.  **$\gamma$ -Methylglutamate ( $\gamma$ -Methylglutamic Acid)**

This methylated amino acid (FW = 161.16 g/mol) inhibits  $\gamma$ -glutamylcysteine synthetase. It is an alternative substrate of glutamate dehydrogenase. The (2*S*,4*R*)-stereoisomer is a selective and potent kainate receptor antagonist. **Target(s):** [glutamine-synthetase] adenyltransferase (1);  $\gamma$ -glutamylcysteine synthetase (2-4); glutamyl-tRNA synthetase, inhibited by the D-*threo*-isomer (5); kainate receptor (6); UDP-N acetylmuramoylalanine:D-glutamate ligase, inhibited by the D-*erythro*-isomer, also an alternative substrate (7). **1.** Ebner, Wolf, Gancedo, Elsässer & Holzer (1970) *Eur. **( $\pm$ )-*threo*-3-Methylglutamic acid****1:1 racemic mixture**

This potent neurotransmitter EAAT blocker (FW = 161.16 g/mol; CAS 63088-04-0; Soluble to 100 mM, when converted to the sodium salt by addition of 1 eq. NaOH) targets the **Excitatory Amino-Acid Transporters** EAAT<sub>2</sub> (IC<sub>50</sub> = 90  $\mu$ M) and EAAT<sub>4</sub> (IC<sub>50</sub> = 109  $\mu$ M), with much weaker action against EAAT<sub>1</sub> (IC<sub>50</sub> = 1600  $\mu$ M) and EAAT<sub>3</sub> (IC<sub>50</sub> = 1080  $\mu$ M). As the principal excitatory neurotransmitter in the vertebrate brain, glutamate is released by a change in the action potential, whereupon EAAT transporters quickly remove glutamate from the extracellular space (synaptic groove) to terminate synaptic transmission. **1.** Vandenberg, et al. **Methylglyoxal**

This simple  $\alpha$ -keto aldehyde (FW = 72.06 g/mol), also known as 2-oxopropanal, pyruvaldehyde, and acetylformaldehyde, is a hygroscopic yellow liquid (boiling point = 72°C) that readily polymerizes to a glassy mass. This polymeric substance is easily dissolved into water and regenerates the monomer. Note that methylglyoxal will react with guanidinium groups and amines. Elevated levels of methylglyoxal can initiate protein cross linkage, exacerbate advanced glycation of proteins, and cause endothelial injury. It will also cross link DNA polymerase with the substrate DNA. Methylglyoxal is a product of the reactions catalyzed by D-lactaldehyde dehydrogenase, methylglyoxal synthase, and lactoylglutathione lyase (glyoxalase I) and is a substrate of aldose reductase. It is an intermediate in the metabolism of glyceraldehyde 3-phosphate in species of *Pseudomonas*. **Target(s):** aldehyde dehydrogenase, human E<sub>3</sub> isozyme (5); aminolevulinic aminotransferase (1-4,27-30); bacterial leucyl aminopeptidase (25); cathepsin (6); DNA polymerase (7); electron transport (8); formaldehyde dehydrogenase (glutathione) (9); fructose-1,6-bisphosphate aldolase (10,11); glutamine:fructose-6 phosphate aminotransferase (isomerizing) (12,31); glutamine synthetase (13); glutathione-disulfide reductase (14,15); glutathione peroxidase (16); glyceraldehyde-3-phosphate dehydrogenase (10,14,17,18); histidine ammonia-lyase (19); hydroxyacylglutathione hydrolase, or glyoxalase II (26); S-(hydroxymethyl)glutathione dehydrogenase (9); lactate dehydrogenase (14); malate synthase (32); malic enzyme, or malate dehydrogenase, or oxaloacetate decarboxylating (20); NADH dehydrogenase, or Complex I (8); papain (6); phosphofructokinase (10); 3-phosphoglycerate mutase (10); *Streptomyces* R61 DD-carboxypeptidase (21); succinate dehydrogenase (22); superoxide dismutase, Cu,Zn (23); L-threonine dehydrogenase (24). **1.** Sagar, Salotra, Bhatnagar & Datta (1995) *Microbiol. ### 1-Methylguanine

This methylated purine (FW = 165.15 g/mol) is a component in a number of transferRNAs and ribosomalRNAs and is formed in reactions catalyzed by tRNA (guanine-*N*<sup>1</sup>-)-methyltransferase and rRNA (guanine-*N*<sup>1</sup>-)-methyltransferase (1). Methylguanine has  $\lambda_{\text{max}}$  values at 248 and 272 nm at pH 7, with respective  $\epsilon$  values of 10000 and 7900  $\text{M}^{-1}\text{cm}^{-1}$ . **Target(s)**: guanosine phosphorylase, *or* purine-nucleoside phosphorylase (1); hypoxanthine(guanine) phosphoribosyltransferase (2,3); purine-nucleoside phosphorylase (4); xanthine phosphoribosyltransferase (2). **1.** Baker & Schaeffer (1971) *J. Med. Chem.* **14**, 809. **2.** Naguib, Iltzsch, el Kouni, Panzica & el Kouni (1995) *Biochem. ### O<sup>6</sup>-Methylguanine

This modified guanine (FW = 165.15 g/mol), also known as 2-amino-6-methoxyuracil, base pairs in DNA with thymine and is highly mutagenic. This residue in DNA is a substrate of the reaction catalyzed by methylated-DNA:[protein]-cysteine *S*-methyltransferase. **Target(s)**: methionine *S*-adenosyltransferase (1); methylated-DNA:[protein]-cysteine *S* methyltransferase (*O*<sup>6</sup>-alkylguanine-DNA alkyltransferase (2-5)). **1.** Berger & Knodel (2003) *BMC Microbiol.* **3**, 12. **2.** Dexter, Yamashita, Donovan & Gerson (1989) *Cancer Res.* **49**, 3520. **3.** McMurry (2007) *DNA Repair* **6**, 1161. **4.** Terashima, Kawata, Sakumi, Sekiguchi & Kohda (1997) *Chem. Res. Toxicol.* **10**, 1234. **5.** Shibata, Glynn, McMurry, *et al.* (2006) *Nucl. Acids Res.* **34**, 1884.

### 7-Methylguanine

This methylated guanine (FW = 165.15 g/mol) is a component in eukaryotic mRNA and some tRNA molecules. It is produced in tRNA by the action of tRNA (guanine-*N*<sup>7</sup>-)-methyltransferase and in mRNA by mRNA(guanine-*N*<sup>7</sup>-)-methyltransferase. 7-Methylguanine has  $\lambda_{\text{max}}$  values at 248 and 283 nm at pH 7, with respective  $\epsilon$  values of 5700 and 7400  $\text{M}^{-1}\text{cm}^{-1}$ . **Target(s)**: hypoxanthine(guanine) phosphoribosyltransferase, weakly (1); purine-nucleoside phosphorylase (2); tRNA-guanine transglycosylase (3-5); xanthine phosphoribosyltransferase, weakly (1). **1.** Naguib, Iltzsch, el Kouni, Panzica & el Kouni (1995) *Biochem. Pharmacol.* **50**, 1685. **2.** Wielgus-Kutrowska & Bzowska (2006) *Biochim. Biophys. Acta* **1764**, 887. **3.** Goodenough-Lashua & Garcia (2003) *Bioorg. ### 7-Methylguanosine

This modified nucleoside (FW = 298.28 g/mol) is a component of the cap on the 5'-terminus of eukaryotic mRNA. It is also an inhibitor of pteridine biosynthesis and is a component in some tRNA molecules. It is produced in tRNA by the action of tRNA (guanine-*N*<sup>7</sup>-)-methyltransferase and in mRNA by mRNA (guanine-*N*<sup>7</sup>-)-methyltransferase. 7-Methylguanosine has  $\lambda_{\text{max}}$  values at 258 and 281 nm at pH 7 ( $\epsilon = 8500$  and 7400  $\text{M}^{-1}\text{cm}^{-1}$ , respectively). **Target(s)**: m<sup>7</sup>G(5')pppN diphosphatase, *or* 7-methylguanosine-5'-triphospho-5' polynucleotide 7-methylguanosine-5'-phosphohydrolase; decapase (1-3). **1.** Nuss & Furuichi (1977) *J. Biol. Chem.* **252**, 2815. **2.** Kumagi, R. Kon, T. Hoshino, T. Aramaki, Nishikawa, Hirose & Igarashi (1992) *Biochim. Biophys. Acta* **1119**, 45. **3.** Nuss, Altschuler & Peterson (1982) *J. Biol. Chem.* **257**, 6224.

## 7-Methylguanosine 5'-Monophosphate

This analogue (FW = 377.25 g/mol; CAS 10162-58-0) of the nucleotide cap on eukaryotic mRNAs and is an inhibitor of mRNA translation. 7-Methylguanosine 5'-monophosphate has  $\lambda_{\text{max}}$  values at 258 and 280 nm at pH 7.4 ( $\epsilon = 10300$  and  $8600 \text{ M}^{-1}\text{cm}^{-1}$ , respectively) and is a product of the reaction catalyzed by m<sup>7</sup>G(5')pppN diphosphatase. **Target(s):** m<sup>7</sup>G(5')pppN diphosphatase (7-methylguanosine-5'-triphospho-5' polynucleotide 7-methylguanosine-5'-phosphohydrolase; decapase; product inhibition (1,2); mRNA translation (3-12); protein biosynthesis (3-12). 1. ## 7-Methylguanosine 5'-Triphosphate

This analogue (FW = 526.21 g/mol; CAS 57718-00-0) of the nucleotide cap on eukaryotic mRNAs and is produced by the action of mRNA (guanine-N<sup>7</sup>-)-methyltransferase. 7-Methylguanosine 5'-triphosphate has  $\lambda_{\text{max}}$  values at 258 and 280 nm at pH 7.4 ( $\epsilon = 10300$  and  $8600 \text{ M}^{-1}\text{cm}^{-1}$ , respectively). **Target(s):** m<sup>7</sup>G(5')pppN diphosphatase (7-methylguanosine-5'-triphospho-5'-polynucleotide 7-methylguanosine-5'-phosphohydrolase; decapase) (1,2); NMN nucleosidase (3); polypeptide biosynthesis (4-6). 1. Biol.* **109**, 173.

## N-Methylhistamine

This methylated histamine (FW<sub>free-base</sub> = 125.17 g/mol) inhibits tryptase non-linearly. Note that the name N-methylhistamine has also been used to refer to N<sup>ε</sup>-methylhistamine, produced by histamine N-methyltransferase, and N<sup>α</sup>-methylhistamine. **Target(s):** histamine N-methyltransferase, weakly inhibited (1); histamine uptake (2); tryptase (3). 1. Barth, Lorenz & Niemeyer (1973) *Hoppe-Seyler's Z. Physiol. Chem.* **354**, 1021. 2. Schayer & Reilly (1975) *Agents Actions* **5**, 231. 3. Alter & Schwartz (1989) *Biochim. Biophys. Acta* **991**, 426.

## Methylhydrazine

This versatile nucleophilic reagent and chemical building block (FW = 46.072 g/mol; CAS 60-34-4; M.P. = -52.4°C; B.P. = 87.5°C; clear, colorless, hygroscopic; miscible with water and ethanol), reacts with aldehydes and ketones in sugars, ketoacids, and numerous metabolites. It also reacts with the pyridoxal cofactor in vitamin B<sub>6</sub>-dependent enzymes as well as with the pyrroloquinoline quinone (PQQ) cofactor in glucose oxidase. Methylhydrazine is also a DNA-methylating agent as a consequence of peroxidase-catalyzed oxidation, the latter generating methyl radicals. Inhalation of N-methylhydrazine induces both benign and malignant tumors in mice and hamsters. Methylhydrazine is also a skin and nasal irritant. **Target(s):** amine oxidase (1-3); 4-aminobutyrate aminotransferase (4); carbamoyl-phosphate synthetase (5); diamine oxidase (6); dopamine β-monooxygenase (7); formate dehydrogenase (8); glucose dehydrogenase (9); hydroxylamine oxidoreductase, *or* hydroxylamine oxidase (10); manganese peroxidase (11); methanol dehydrogenase (12); methylamine dehydrogenase (13); methylamine oxidase (14,15); methylaspartate ammonia-lyase (16); nitrite reductase, *or* cytochrome *cd*<sub>1</sub> (17); ornithine decarboxylase (18); peroxidase, horseradish (19); pyridoxal kinase (20). 1. ## (18E)- and (18Z)-29-Methylidene-2,3-oxidoheptacosane

This epoxysqualene analogue (FW = 356.59 g/mol), also known as (6E,10E,14E,18E)-2,3-epoxy-2,6,10,15-tetramethyl-6,10,14,18,20-heneicosapentaene, is a irreversible inhibitor of squalene:hopene cyclase, IC<sub>50</sub> = 0.2 μM (1) and lanosterol synthase, IC<sub>50</sub> = 1.5 μM for *Saccharomyces cerevisiae* enzyme and 3.5 μM for the pig liver protein (1-4). The 18Z-isomer inhibits *S. cerevisiae* lanosterol synthase with IC<sub>50</sub> = 15 μM. 1. Rocco, Bosso, Viola, *et al.* (2003) *Lipids* **38**, 201. 2. Soc. Perkin Trans. 1*, 1477.

## 1-Methylimidazole

This hygroscopic imidazole (FW<sub>free-base</sub> = 82.11 g/mol), also known as N-methylimidazole, forms complexes with a number of metal ions, especially Co<sup>2+</sup> and Zn<sup>2+</sup>. At room temperature, the free base is a liquid (M.P. = -6°C; B.P. = 198°C). **Target(s):** CYP2E1, weakly inhibited (1); estrogen 2-monooxygenase (2); glutaminyl-peptide cyclotransferase, *or* glutaminyl

cyclase,  $K_i = 30 \mu\text{M}$  (3-8); histidine decarboxylase (9); thromboxane-A synthase (10). 1. Hargreaves, Jones, Smith & Gescher (1994) *Drug Metab. Dispos.* **22**, 806. 2. #### 5'-O-Methylimmucillin-A

This nucleoside analogue (FW = 277.28 g/mol), also known as (1S)-1-(9-deazaadenin-9-yl)-5-(methoxy)-1,4-dideoxy-1,4-imino-D-ribose, inhibits 5'-methylthioadenosine/S-adenosylhomocysteine nucleosidase,  $K_i^* = 10 \text{ nM}$  (1). The immucillins are transition-state mimics that are rationally designed to maximize binding affinity through their ability to closely replicate key stereoelectronic features of oxa-carbenium ion intermediates formed in ribosyltransfer reactions. (See *Immucillin* for discussion of *Primary Mode of Action*) 5'-O-Methyl-immucillin-A is also a slow, tight-binding inhibitor of human S-methyl-5' thioadenosine phosphorylase,  $K_i = 134 \text{ nM}$  (2). 1. Singh, Evans, Lenz, *et al.* (2005) *J. Biol. Chem.* **280**, 18265. 2. Evans, Furneaux, Schramm, Singh & Tyler (2004) *J. Med. Chem.* **47**, 3275.

#### N-Methyl-4-isoleucine Cyclosporin

This substituted Cyclosporin A analogue (FW = 1315.88 g/mol), also known as NIM811, has the ability to bind to cyclophilin; however, the resulting Cyclophilin-NIM811 binary complex cannot bind calcineurin, and therefore lacks immunosuppressive activity of Cyclosporin A (CsA). NIM811 also blocks the mitochondrial permeability transition (MPT) that is induced by  $\text{Ca}^{2+}$  and  $\text{P}_i$ , alone or in combination with 1-methyl-4-phenyl-1,2,3,6-tetrahydro-pyridine (a dopaminergic neurotoxin), rotenone (a ETS Complex I inhibitor), and *t*-butylhydroperoxide (a pro-oxidant) (1). NIM811 was equipotent to CsA. NIM811 also blocks cell killing and prevents in situ mitochondrial inner membrane permeabilization and depolarization during tumor necrosis factor- $\alpha$ -induced apoptosis to cultured rat hepatocytes (1). NIM811 inhibition of apoptosis was equipotent with CsA except at higher concentrations: CsA lost efficacy but NIM 811 did not. We conclude that NIM811 is a useful alternative to PKF220-384 to investigate the role of the mitochondrial permeability transition in apoptotic and necrotic cell death (1). (See *Malonate*) Liquid chromatographic tandem mass spectrometric detection (LC-MS/MS) permits determination of NIM811 over the concentration range 1-2500 ng/mL in human whole blood, using a sample volume of 0.05 mL (2). 1. Waldmeier, Feldtrauer, Qian & Lemasters (2002) *Mol. Pharmacol.* **62**, 22. 2. Li, Luo, Hayes, He & Tse (2007) *Biomed. Chromatogr.* **21**, 249.

#### S-Methyl-L-isothiocitrulline

This citrulline derivative (FW = 205.28 g/mol), also known as S-methyl-L-thiocitrulline, is a potent inhibitor of nitric oxide synthase:  $K_i = 1.2 \text{ nM}$  for human neuronal NOS;  $K_i = 11 \text{ nM}$  for human endothelium NOS, and  $K_i = 40 \text{ nM}$  for human inducible NOS. **Target(s):** arginase (1); nitric-oxide synthase (2-9). 1. Colleluori & Ash (2001) *Biochemistry* **40**, 9356. 2. Garvey, Furfine & Sherman (1996) *Meth. Enzymol.* **268**, 339. 3. Ichimori, Stuehr, Atkinson & King (1999) *J. Med. Chem.* **42**, 1842. 4. Griffith & Stuehr (1995) *Ann. Rev. Physiol.* **57**, 707. 8. Komers, Oyama, Chapman, Allison & Anderson (2000) *Hypertension* **35**, 655. 9. Narayanan, Spack, McMillan, *et al.* (1995) *J. Biol. Chem.* **270**, 11103.

#### Methyllycaconitine

This stereochemically complex diterpenoid and insecticide (FW = 682.81 g/mol; CAS 21019-30-7; Soluble in  $\text{CHCl}_3$ , but not  $\text{H}_2\text{O}$ ; often supplied commercially as the citrate salt; Symbol: MLA) is the principal toxin of the larkspur (*Delphinium brownie*). MLA exhibits tubocurarine-like action by blocking neuromuscular transmission in skeletal muscle, but not smooth muscle (1-4). MLA inhibits ( $K_i \sim 2.5 \times 10^{-10} \text{ M}$ ) the binding of propionyl- $\alpha$ -bungarotoxin to a house-fly receptor preparation (1), competes with  $\alpha$ -bungarotoxin ( $K_i \sim 1 \times 10^{-9} \text{ M}$ ) and (-)-nicotine ( $K_i \sim 4 \times 10^{-6} \text{ M}$ ) in a rat brain receptor preparation (2), and displaces  $\alpha$ -bungarotoxin ( $K_i \sim 1 \times 10^{-6} \text{ M}$ ) from purified Torpedo nicotinic acetylcholine receptors (2). Methyllycaconitine also attenuates methamphetamine-induced neurotoxicity in the striatum of mouse brain. **Cattle Poisoning:** This alkaloid is one of the main causes of livestock poisoning, killing some 5-15% of the cattle on North American mountain range lands. When treated with sublethal doses, test animals were reluctant to move, trembled, and developed dyspnea, muscular twitches, and convulsions (5). Within several minutes, the clinical signs abated, slowly returning to normal over ~20 min. Methyllycaconitine elimination follows a normal biphasic redistribution, with  $t_{1/2} = 17.5 \text{ min}$  (5). 1. Jennings, Brown & Wright (1986). *Experientia* **42**, 611. 2. Macallan, Lunt, Wonnacott, *et al.* (1988) *FEBS Lett.* **226**, 357. 3. Alkondon, Pereira, Wonnacott & Albuquerque (1992) *Mol. Pharmacol.* **41**, 802. 4. #### N-Methylmaleimide

This alkylating agent (FW = 111.10 g/mol; M.P. = 95-97°C; *Abbreviation:* NMM), also known as 1-methyl-1H-pyrrole-2,5-dione, reacts readily and

irreversibly with sulfhydryl groups in proteins. Under alkaline conditions NMM also reacts with amino groups. Reaction with of R-SH or R-NH<sub>2</sub> occurs by addition across the double bond of NMM, yielding the corresponding thioether or secondary amine. If the modified aminoacyl residue is catalytically essential and/or is at the active site, the protein will undergo inactivation. Some enzymes are inactivated at faster rates with NMM analogues having longer alkyl chains (e.g., the inactivation rate of yeast alcohol dehydrogenase with *N*-octylmaleimide is significantly faster than with *N*-ethylmaleimide (1)). (See also *N*-Ethylmaleimide) **Target(s):** acetyl-CoA *C*-acyltransferase (2); caffeine synthase (3); desulfo-glucosinolate sulfotransferase (4); loganate *O*-methyltransferase (5); long-chain-enoil-CoA hydratase (6); *N*-methyl-2 oxoglutarate hydrolase (7); mitochondrial m-AAA protease (8); 4-nitrophenol 2-monooxygenase (9); progesterone 11 $\alpha$ -monooxygenase (10); theobromine synthase (3). 1. ### Methyl malonate (Methyl Malonic Acid)

This cell-permeable pro-inhibitor (FW = 118.09 g/mol), also named propanedioic acid methyl ester and hydrogen methyl malonate, is metabolized to malonic acid, a well-known inhibitor of succinate dehydrogenase (See *Malonate*). Upon entry into cells, methyl malonate is hydrolyzed to malonate. Exposure of rat embryonic brain striatal and cortical neurons for 24 hours to 10 mM methylmalonate causes DNA fragmentation and reduced [ATP]/[ADP] within 3 hours, culminating in necrotic and apoptotic cell death. Cell death is attenuated in a medium containing antioxidants. (Note: The term methyl malonate is occasionally used for dimethylmalonate, or H<sub>3</sub>CO-C(=O)-CH<sub>2</sub>-C(=O)-OCH<sub>3</sub>, whereas the single-word term methylmalonate, or <sup>-</sup>OOC-HC(CH<sub>3</sub>)-COO<sup>-</sup> (See below) is used to designate 2-methylpropanedioic acid.) 1. McLaughlin, Nelson, Silver, Erecinska & Chesselet (1998) *Neuroscience* **86**, 279.

### Methylmalonate (Methylmalonic Acid)

This toxic dicarboxylic acid (FW<sub>free-acid</sub> = 118.09 g/mol), also known as 2-methylpropanedioic acid, is very soluble in water (66 g/100 g at 20°C) and has pK<sub>a</sub> values of 3.05 and 5.76. Methylmalonyl-CoA is converted into succinyl-CoA by the action of methylmalonyl-CoA mutase, a vitamin B<sub>12</sub>-requiring enzyme. (Note: One must not confuse this compound with methyl malonate, i.e., the mono-ester (H<sub>3</sub>CO-C(=O)-CH<sub>2</sub>-COOH). **Target(s):** cyanate hydratase, or cyanase (1); glycine transport (2);  $\beta$ -hydroxybutyrate dehydrogenase (3-5); isocitrate lyase (6); malic enzyme, or malate dehydrogenase (oxaloacetate decarboxylating) (7); NADH dehydrogenase, or Complex I (8); pantothenate synthetase (9); serine 3-dehydrogenase (10); succinate dehydrogenase, Complex II (3,8,11,12); L-threonine dehydrogenase (13). 1. ### Methylmalonyl-CoA

This pair of thiolester diastereoisomers (FW = 867.61 g/mol; CAS 1264-45-5) are intermediates in the conversion of propionyl-CoA to succinyl-CoA. (Note: These two metabolites are often incorrectly referred to as enantiomers. There are five chiral centers in the coenzyme A moiety of the molecule, and these centers remain unchanged. The thioesters thus differ only in the stereochemistry of one carbon, making them epimers, and the enzyme catalyzing their interconversion is methylmalonyl-CoA epimerase, not racemase.) The (*S*)-diastereoisomer is a product of the reaction catalyzed by propionyl-CoA carboxylase. It is a substrate for methylmalonyl-CoA carboxytransferase, (*S*)-methylmalonyl-CoA hydrolase, methylmalonyl-CoA decarboxylase, and methylmalonyl-CoA epimerase. The (*R*) diastereoisomer, produced by methylmalonyl-CoA epimerase, is a substrate in the reaction catalyzed by methylmalonyl-CoA mutase (with the (*S*)-epimer acting as an inhibitor). **Target(s):** acetoacetyl-CoA reductase (1); acetyl-CoA carboxylase (2); *N*-acetylglutamate synthase, or glutamate acetyltransferase (3); [acyl-carrier-protein] *S*-malonyltransferase (29); amino-acid acetyltransferase (3); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or 3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring) kinase (4-6,28); carnitine *O*-palmitoyltransferase (7,8,30); fatty acid synthase complex (1,2,9-12); glycine cleavage complex, or glycine synthase (13); 3-hydroxyisobutyryl-CoA hydrolase, inhibited by the DL-mixture (14,15);  $\alpha$ -ketoglutarate dehydrogenase (lipoamide) (16); malonyl-CoA decarboxylase (17-24); methylmalonyl-CoA mutase, inhibited by (*S*)-methylmalonyl-CoA (25); pyruvate carboxylase (26); pyruvate dehydrogenase (lipoamide) (27). 1. ### 6-Methylmercaptapurine 9-β-D-Ribonucleoside

This cytotoxic nucleoside with antineoplastic and anti-angiogenic properties (FW = 298.32 g/mol) is an alternative substrate of adenosine kinase, forming 6-methylmercaptapurine-9-β-D-ribose 5'-P, which then inhibits amidophosphoribosyltransferase, the first committed step in *de novo* purine nucleotide synthesis. It also inhibits fibroblast growth factor-2 (FGF2)-induced cell proliferation. **Target(s):** adenosine deaminase (1,2); adenosine kinase, also as a weak alternative substrate (3-6); amidophosphoribosyltransferase (7); GMP synthetase (8); phosphoribosyl-pyrophosphate synthetase (7,9). 1. Van Heukelom, Boom, Bartstra & Staal (1976) *Clin. Chim. Acta* **72**, 109. 2. Daddona, Wiesmann, Lambros, Kelley & Webster (1984) *J. Biol. Chem.* **259**, 1472. 3. Long & Parker (2006) *Biochem. ### S-Methylmethionine Sulfonium Bromide

This methionine derivative (FW<sub>bromide</sub> = 244.15 g/mol), also known as (3-amino-3-carboxypropyl)dimethylsulfonium bromide, has been isolated from a large number of flowering plants and has been used in the treatment of ulcers. This photosensitive amino acid is soluble in water and slightly soluble in methanol (0.439 g/100 g at 25°C) and ethanol (0.012 g/100 g at 25°C). Note that S-methyl-methionine slowly decomposes at room temperature; this rate increases when exposed to light. S-Methylmethionine is a product of the reaction catalyzed by S-adenosyl-L-methionine:L-methionine S-methyltransferase and is both an alternative substrate and an inactivator of 1-aminocyclopropane-1-carboxylate synthase. **Target(s):** S-adenosylmethionine cyclotransferase, weakly inhibited (1); 1-aminocyclopropane-1-carboxylate synthase (2). 1. Mudd (1959) *J. Biol. Chem.* **234**, 87. 2. Ko, Eliot & Kirsch (2004) *Arch. Biochem. Biophys.* **421**, 85.

### N-Methyl-α-methylphenethylamine

This potent neurotoxin and CNS stimulant (FW = 149.23 g/mol; CAS 33817-09-3), widely known by the street names methamphetamine, "METH" and "Crystal Meth", "Crank", as well as N-methyl-1-phenylpropan-2-amine, has been used to treat attention deficit hyperactivity disorder (ADHD), to promote weight loss, and as a drug of abuse. There are two enantiomers: (R(-)-methamphetamine (the more potent) and S(+)-methamphetamine. Like dopamine and amphetamine, methamphetamine is

a dopamine transporter (*or* DAT) substrate. It interacts with and is subsequently transported into the DAT<sup>+</sup> neurons in a Na<sup>+</sup>/Cl<sup>-</sup>-dependent mechanism, thereby increasing the excitability of dopaminergic neurons. **Likely Mechanisms of Action:** A stimulant that induces a cocaine-like euphoria, methamphetamine appears to operate by two mechanisms: (a) drug-induced catecholamine redistribution from synaptic vesicles to the cytosol, and (b) drug-induced induced reverse neurotransmitter transport. These processes affect extracellular catecholamine levels, uptake inhibition, exocytosis, neurotransmitter synthesis, and drug metabolism. Methamphetamine affects excitatory synaptic transmission by activating dopamine and serotonin receptor systems in the hippocampus, a modulatory effect that may contribute to synaptic maladaptation during METH addiction and/or METH-mediated cognitive dysfunction (1,2). Intracellular application of methamphetamine, but not amphetamine, prevents the dopamine-induced increase in the spontaneous firing of dopaminergic neurons and the corresponding DAT-mediated inward current. **Drug Abuse:** Methamphetamine is highly addictive, and its use in humans is often associated with neurocognitive impairment (2). Ready synthesis from simple precursors also contributes to methamphetamine's illicit use. Users typically cite availability, low cost, and a longer duration of action (than cocaine) as the basis for its preferential use. METH abusers are at high risk of neurodegenerative disorders, including Parkinson disease, and there are still no effective treatments to METH-induced neurodegeneration. Phasic dopamine (DA) signaling, characterized by burst firing by DA neurons, generates short-lived elevations in extracellular DA in terminal field. These DA transients are implicated in reinforcement learning. Disrupted phasic DA signaling is thought to link DA depletions and cognitive-behavioral impairment in METH-induced neurotoxicity (3). 1. Swant, Chirwa, Stanwood & Khoshbouei (2010) *PLoS One* **5**, e11382. 2. North, Swant, Salvatore, *et al.* (2013) *Synapse* **67**, 245. 3. Robinson, Howard, Pastuzyn, *et al.* (2014) *Neurotox. Res.* **26**, 152.

### Methylnaltrexone

This peripheral μ-opioid receptor antagonist (FW = 356.44 g/mol; CAS 83387-25-1; *Symbol:* MNTX), also known as Relistor®, N-methylnaltrexone, and (5α)-17-(cyclopropylmethyl)-3,14-dihydroxy-17-methyl-4,5-epoxymorphinan-17-ium-6-one, possesses a quaternized ammonium site that prevents penetration of the blood-brain barrier. This property endows methylnaltrexone with μ-opioid receptor antagonist action throughout the body (thus counteracting such effects, as itching and constipation observed with oxycodone and naltrexone), but without affecting opioid analgesia in the brain. Notably, quaternary derivatives were ineffective as antagonists of heroin self-administration, indicating that acute reinforcing properties of intravenous opiates associated with the sensation of a "rush" involve opiate receptors located within the central nervous system and not peripheral opiate receptors (1). Intracerebroventricular administration and peripheral administration of N-methylnaltrexone allows one to distinguish centrally acting versus peripherally acting effects of μ-opioid receptors. **Metabolism:** Intravenous administration of [<sup>14</sup>C-N]-methylnaltrexone, 40% to 60% of the radioactivity is excreted in urine within 24 hours, with biphasic plasma decay curves indicating a short distribution phase over 6-9 minutes, with a far longer elimination phase from 4 and 22 hours (2). MNTX undergoes sulfation of the phenolic group to MNTX-3-sulfate as well as reduction of the carbonyl group to form the epimeric alcohols, methyl-6α-naltrexol and methyl-6β-naltrexol (3). Neither naltrexone nor its metabolite 6β-naltrexol are detected in human plasma after administration of MNTX, confirming earlier observations that N-demethylation is not a metabolic pathway of MNTX in humans (3). 1. Koob, Pettit, Ettenberg & Bloom (1984) *J. Pharmacol. Exp. Ther.* **229**, 481. 2. Kotake, Kuwahara, Burton, McCoy & Goldberg (1989) *Xenobiotica* **19**, 1247. 3. Chandrasekaran, Tong, Li, *et al.* (2010) *Drug Metab. Dispos.* **38**, 606.

**1-Methylnicotinamide**

This naturally occurring pyridine (FW = 137.16 g/mol), formed in the reaction catalyzed by nicotinamide *N*-methyltransferase, is an end-product of niacin metabolism. MNA also inhibited platelet-dependent thrombosis by a mechanism involving cyclooxygenase-2 and prostacyclin (1). Endogenous MNA, produced in the liver by nicotinamide *N*-methyltransferase, may well be an endogenous activator of prostacyclin production, regulating thrombotic as well as inflammatory processes in the cardiovascular system (1). **Target(s):** acetylcholinesterase (2); alcohol dehydrogenase (3-5); NAD<sup>+</sup> ADP ribosyltransferase, or poly(ADP-ribose) polymerase, IC<sub>50</sub> = 1.7 mM (6,7); NAD<sup>+</sup> nucleosidase, or NADase (8); nicotinate glucosyltransferase (9). 1. Chlopicki, Swies, Mogielniki, *et al.* (2007) *Br. J. Pharmacol.* **152**, 230. 2. Bergmann, Wilson & Nachmansohn (1950) *J. Biol. Chem.* **186**, 693. 3. Anderson & Reynolds (1966) *Arch. Biochem. Biophys.* **114**, 299. 4. Atkinson, Eckermann & Lilley (1967) *Biochem. J.* **104**, 872. 5. Anderson & Anderson (1964) *Biochem. Biophys. Res. Commun.* **16**, 258. 6. Chem.* **247**, 515. 9. Taguchi, Sasatani, Nishitani & Okumura (1997) *Biosci. Biotechnol. Biochem.* **61**, 720.

**5-Methylnicotinamide**

This substrate analogue (FW<sub>free-base</sub> = 136.15 g/mol; CAS 70-57-5; *Abbreviation:* 5MN) inhibits *Micrococcus luteus* nicotinamidase (1,2). While it cannot support NAD<sup>+</sup> synthesis, 5-methylnicotinamide is an equipotent inhibitor of NAD<sup>+</sup>-hydrolyzing enzymes. **Target(s):** NAD<sup>+</sup> ADP-ribosyltransferase, or poly(ADP-ribose) polymerase (3-5); dose-dependent increase in NAD<sup>+</sup> content in the renal cortex and specific inhibition of sodium gradient-dependent phosphate transport across the renal brush-border membrane (BBM) (6). 1. Johnson & Gadd (1974) *Int. J. Biochem.* **5**, 633. 2. Gadd & Johnson (1974) *Int. J. Biochem.* **5**, 397. 3. Banasik, Komura, Shimoyama & Ueda (1992) *J. Biol. Chem.* **267**, 1569. 4. Physiol.* **251**, F520.

**Methyl *p*-Nitrobenzenesulfonate**

This methylating reagent (FW = 217.20 g/mol; M.P. = 93-95°C) covalently modifies a number of proteins. Note that, while methyl *p*-nitrobenzenesulfonate methylates a histidyl residue in chymotrypsin, it does not inhibit trypsin or subtilisin. **Target(s):** D-amino-acid oxidase (1); bacterial luciferase, or alkanal monooxygenase (2); bromelain (3); chloramphenicol acetyltransferase (4); chymotrypsin (5-9); 3-hydroxy-3-methylglutaryl CoA lyase (10); inositol 1,3,4-trisphosphate 5/6-kinase (11); poly(β-D-mannuronate) lyase (12); stem bromelain (3); system A amino acid transport (13); system ASC amino acid transport (13); L-threonine dehydrogenase (14). 1. Swenson, Williams & Massey (1984) *J. Biol. Chem.* **259**, 5585. 2. Paquette & Tu (1989) *Photochem. Photobiol.* **50**, 817. 3. Silverstein & Kezdy (1975) *Arch. Biochem. **1-Methyl-3-nitro-1-nitrosoguanidine**

This water-soluble carcinogen (FW = 147.09 g/mol; decomposes at 118°C; *Abbreviation:* MNNG), also known as *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine, is an extremely potent mutagen that methylates DNA. **CAUTION:** Extreme care should be exercised to avoid skin irritation and to minimize cancer-risk. MNNG also methylates cysteinyl residues in proteins. (See also *N*-Methyl-*N*-nitroso-*p*-toluenesulfonamide) **Target(s):** CMP-*N*-acetylneuraminase phosphodiesterase (1); DNA methyltransferases (2-5); DNA polymerases (6). 1. Corfield, Stewart, Houghton, *et al.* (1987) *Biochem. Soc. Trans.* **15**, 1052. 2. Drahovsky & Wacker (1975) *Eur. J. Cancer* **11**, 517. 3. Cox (1986) *Toxicol. Pathol.* **14**, 477. 4. **O<sup>6</sup>-(1-Methyl-4-nitropyrrol-2-ylmethyl)guanine**

This modified guanine (FW = 289.26 g/mol) inactivates methylated-DNA:[protein]-cysteine *S*-methyltransferase, or O<sup>6</sup>-alkylguanine-DNA alkyltransferase (IC<sub>50</sub> = 0.55 μM). The enzyme reverses specific types of alkylation damage by removing the offending alkyl group, while itself becoming covalently modified and inactivated. 1. McMurry (2007) *DNA Repair* **6**, 1161.

**N<sup>1</sup>-Methyl-N<sup>1</sup>-nitrosourea**

This carcinogenic/mutagenic alkylating reagent (FW = 103.08 g/mol; CAS 684-93-5), also known as nitrosomethylurea (NMU) modifies DNA and inhibits O<sup>6</sup>-alkylguanine-DNA alkyltransferase (1) and DNA polymerase (2). NMU-induced rat mammary carcinogenesis is a frequently used experimental model for breast cancer. **CAUTION:** Likely carcinogen. Exercise care when handling this reagent. Acute exposure can result in eye and/or skin irritation, headache, nausea, and vomiting. Use heavy chemical rubber gloves (*not* latex hospital gloves). Sigma-Aldrich packages NMU in a 100 mL serum bottle with butyl rubber stopper and aluminum tear seal. Injecting 100 mL of any compatible solvent directly into the vial allows one to prepare a 1% (wt/vol) solution with minimal risk of exposure. 1. Link & Tempel (1991) *J. Cancer Res. Clin. Oncol.* **117**, 549. 2. Chan & Becker (1981) *Biochem. J.* **193**, 985.

**N-Methylnorsalsolinol**

This dopaminergic neurotoxin ( $FW_{\text{free-base}} = 179.22$  g/mol), also known as *N*-methyl-6,7-dihydroxy-1,2,3,4-tetrahydroisoquinoline, inhibits monoamine oxidase. It has been identified in patients with Parkinson's disease and found to be able to cross the blood-brain barrier. **Target(s):** monoamine oxidase (1,2); tyrosine 3-monooxygenase (3,4). 1. Minami, Maruyama, Dostert, Nagatsu & Naoi (1993) *J. Neural. Transm. Gen. Sect.* **92**, 125. 2. Moser, Scholz, Bamberg & Bohme (1996) *Neurochem. Int.* **28**, 109. 3. **2-Methylornithine**

This amino acid ( $FW = 146.19$  g/mol) is a potent inhibitor of ornithine decarboxylase, but activity is restored by treatment with excess pyridoxal phosphate. **Target(s):** glutamate *N*-acetyltransferase (1); ornithine decarboxylase (2-7); tyrosine:arginine ligase, or kyotorphin synthetase, inhibited by L-isomer (8,9). 1. Jain & Shargool (1984) *Anal. Biochem.* **138**, 25. 2. Tyagi, Tabor & Tabor (1983) *Meth. Enzymol.* **94**, 135. 3. Arteaga-Nieto, Villagomez-Castro, Calvo-Mendez & Lopez-Romero (1996) *Int. J. Kawabata, Muguruma, Tanaka & Takagi (1996) *Peptides* **17**, 407.

**5-Methylorotate (5-Methylorotic Acid)**

This orotic acid derivative ( $FW_{\text{free-acid}} = 170.12$  g/mol) inhibits dihydroorotate dehydrogenase (1-4), orotate phosphoribosyltransferase (5), and dihydroorotate (6,7). 1. Friedmann (1963) *Meth. Enzymol.* **6**, 197. 2. Friedmann & Vennesland (1960) *J. Biol. Chem.* **235**, 1526. 3. Krungkrai, Krungkrai & Phakanont (1992) *Biochem. Pharmacol.* **43**, 1295.

**3-(3-Methyl-1,2,4-oxadiazol-5-yl)-6-(4-(2-methylphenoxy)piperidin-1-yl)pyridazine**

This potent, selective, and orally available pyridazine derivative ( $FW = 351.41$  g/mol) inhibits stearyl-CoA 9-desaturase (mouse,  $IC_{50} = 5.3$  nM). This DCD1 inhibitor exhibits excellent cellular activity in blocking the conversion of saturated long-chain fatty acid-CoAs (LCFA-CoAs) to mono-

unsaturated LCFA-CoAs in HepG2 cells. 1. Liu, Lynch, Freeman, *et al.* (2007) *J. Med. Chem.* **50**, 3086.

**4-Methyl-5-oxoproline**

This substrate analogue ( $FW = 143.14$  g/mol) is a weak alternative substrate (~ 4% of rate with 5-oxoproline) potentially inhibits 5-oxoprolinase. 1. Griffith & Meister (1977) *Proc. Natl. Acad. Sci. U.S.A.* **74**, 3330.

**Methyl Parathion**

This insecticide ( $FW = 263.21$  g/mol), which targets acetylcholinesterase (1-4),  $Ca^{2+}$ -dependent ATPase (5,6), cholinesterase, or butyrylcholinesterase (3,7,8), and succinate dehydrogenase (9), must first undergo metabolic transformation to the corresponding paraoxon to inhibit AChE. Paraoxon is subsequently detoxified enzymatically by A-esterase, glutathione-S-aryl transferase, and glutathione-S-alkyl-transferase. **CAUTION:** Methyl parathion is very toxic and should be handled with care. Signs of toxicity include sweating, dizziness, vomiting, convulsions, cardiac arrest, respiratory arrest, and, in extreme cases, death. The U.S. Environmental Protection Agency now restricts the use of this insecticide. Methyl parathion is no longer to be used on food crops commonly consumed by children. 1. **Methylphenidate**

This piperidine-class dopamine-norepinephrine reuptake inhibitor, or NDRI ( $FW_{\text{free-base}} = 233.31$  g/mol; CAS 113-45-1; asterisks indicate stereocenters), also known as methyl phenidylacetate, Ritalin<sup>®</sup>, Concerta<sup>®</sup>, Methylin<sup>®</sup>, Medikinet<sup>®</sup>, Equasym XL<sup>®</sup>, Quillivant XR<sup>®</sup>, and Metadate<sup>®</sup>, targets dopamine ( $K_i = 40$  nM) and norepinephrine ( $K_i = 350$  nM) transporters (1,2). The (2*R*,2'*R*)-(+)-*threo*-stereoisomer is more effective, with levorotary enantiomers displaying affinity toward the serotonergic 5HT<sub>1A</sub> and 5HT<sub>2B</sub> receptor subtypes, and no direct binding to the serotonin transporter ( $K_i > 10,000$  nM). Methylphenidate is widely used in the treatment of attention-deficit hyperactivity disorder (or ADHD). Note that, as a dopamine reuptake inhibitor, methylphenidate differs from amphetamine, which is both a dopamine and norepinephrine releasing agent and a reuptake inhibitor. Methylphenidate has a well-know addiction liability, and ΔFosB overexpression in D1-type medium spiny neurons within the nucleus accumbens is implicated in methylphenidate addiction. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1.

### $\alpha$ -Methyl-DL-phenylalanine

This phenylalanine derivative (FW = 179.22 g/mol) is a strong inhibitor of phenylalanine monooxygenase that is used to induce experimental hyperphenylalaninemia. It is also an inhibitor of chorismate mutase.

**Target(s):** chorismate mutase (1); 3-deoxy-7-phosphoheptulonate synthase, or 3-deoxy-D-arabinoheptulosonate-7-phosphate synthetase (2); phenylalanine monooxygenase (3-5); phenylalanyl-tRNA synthetase,  $K_i = 2$  mM (6); tyrosine 3-monoxygenase (7). 1. ### 1-Methyl-4-phenyl-2,3-dihydropyridinium Ion

This photosensitive cation (FW<sub>ion</sub> = 172.25 g/mol; *Abbreviation:* MPDP<sup>+</sup>) is a neurotoxicant and an inhibitor of monoamine oxidase B. It is an intermediate metabolite of the dopaminergic neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine. (See also 1-Methyl-4-phenyl-1,2,3,6-tetrahydropyridine) **Target(s):** acetylcholinesterase (1); cytochrome P450 (2); glutathione S-transferase (3); monoamine oxidase A, slowly inactivated (4-6); monoamine oxidase B (4-7). 1. Zang & Misra (1996) *Arch. Biochem. Biophys.* **336**, 147. 2. Das, Shahi, Mochhala, Sato & Sunamoto (1992) *Chem. Phys. Lipids* **62**, 303. 3. Awasthi, Singh, Shen, et al. (1987) *Neurosci. ### $\beta$ -Methylphenethylamine

This amphetamine isomer (FW<sub>free-base</sub> = 135.21 g/mol; CAS 582-22-9; FW<sub>HCl-Salt</sub> = 171.67 g/mol), also known as BMPEA,  $\beta$ -Me-PEA, and 1-amino-2-phenylpropane, is a partial agonist for human Trace Amine-Associated Receptor-1 (TAAR1), a G<sub>s</sub>- and G<sub>q</sub>-coupled G protein-coupled receptor (GPCR) that is activated by endogenous monoamines (e.g., m-tyramine, p-tyramine, m-tryptamine, tryptamine, phenylethylamine (PEA), and both m-octopamine and p-octopamine) and is located within neural presynaptic membrane and on some lymphocytes. Upon association with this receptor, BMPEA, amphetamine, methamphetamine, 3,4-methylenedioxymethamphetamine (MDMA), and 2,5-dimethoxy-4-iodoamphetamine (DOI), increase 3',5'-cyclicAMP concentration in target cells.  $\beta$ -methylphenethylamine has approximately 0.0013 the pressor activity of epinephrine, or about one-third that of amphetamine (1).  $\beta$ -methylphenethylamine also has about twice the bronchodilating power of amphetamine, when tested in rabbit lung, and an LD<sub>50</sub> of 50 mg/kg (rat, i.v.) (1).  $\beta$ -methylphenethylamine can be analyzed in urine by a two-step liquid-liquid extraction, followed by UPLC/MS/MS (2). Some over-the-counter diet supplements containing *Acacia rigidula* have  $\beta$ -methylphenethylamine, raising concerns over their safety (3,4). 1. Graham, Cartland & Woodruff (1945) *Ind. Eng. ### 1-Methyl-4-phenylpyridinium Cation

This photosensitive dopaminergic neurotoxin (FW<sub>iodide-salt</sub> = 297.14 g/mol; CAS 36913-39-0; Symbol: MPP<sup>+</sup>) causes irreversible symptoms of Parkinson disorder in humans and other primates. MPP<sup>+</sup> is produced from 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (FW = 173.26 g/mol; CAS 28289-54-5; Symbol: MPTP), the latter a byproduct in the preparation of the synthetic opioid known as desmethylprodine (FW = 247.33 g/mol; CAS 13147-09-6; Symbol: MPPP; IUPAC Name: 1-(methyl-4-phenylpiperidin-4-yl) propanoate). (See also 1-Methyl-4-phenyl-1,2,3,6-tetrahydropyridine) Effects are often observed in heroin users inasmuch as they also tend to abuse opioid. Like rotenone, MPP<sup>+</sup> is a potent inhibitor of Complex I in the mitochondrial electron transport system (See *Rotenone*). **Mechanism of Neurotoxicity:** Conversion of MPTP to MPP<sup>+</sup> is catalyzed by monoamine oxidase-B, an enzyme that is primarily located in serotonergic neurons and astrocytes. Neuronal transmembrane polarization is likely to contribute to MPP<sup>+</sup> transport as well as its accumulation within nerve terminals. Following concentration within dopamine neurons, MPP<sup>+</sup> is further concentrated by the electrical gradient of the mitochondrial inner membrane, attended by slow binding to NADH dehydrogenase. Both events are facilitated by tetraphenylboron anion, which forms membrane-penetrating ion-pairs with MPP<sup>+</sup> and its analogues. **Target(s):** aromatic-amino-acid decarboxylase, or dopa decarboxylase (1,2); dihydropteridine reductase, weakly inhibited (3);  $\alpha$ -ketoglutarate dehydrogenase (4); monoamine oxidase (5-7); NADH dehydrogenase, or Complex I (8-10); tyrosine monooxygenase (11,12). 1. ### N'-[(3-Methylphenyl)sulfonyl]dibenzofuran-2-carbohydrazide

This hydrazide (FW = 380.42 g/mol) inhibits human cytosolic branched-chain-amino-acid aminotransferase (IC<sub>50</sub> = 2.8  $\mu$ M), the BCAT isoenzyme expressed specifically in neuronal tissue and which is a likely treatment target for neurodegenerative/neurological disorders in which glutamatergic mechanisms are implicated. The 2-methylphenylsulfonyl and 4-methylphenylsulfonyl analogues are weaker inhibitors (IC<sub>50</sub> = 3.2 and 51.0  $\mu$ M, respectively). 1. Hu, Boxer, Kesten, et al. (2006) *Bioorg. Med. Chem. Lett.* **16**, 2337.

**1-Methyl-4-phenyl-1,2,3,6-tetrahydropyridine**

This highly neurotoxic piperidine (FW<sub>free-base</sub> = 173.26 g/mol), often abbreviated MPTP, targets dopaminergic neurons, devastatingly bringing about irreversible onset of the hallmarks of Parkinson's disease in humans and other primates. MPTP is a byproduct in the preparation of a synthetic opioid, and its effects as a toxic opioid impurity were first noted in drug abusers (See also *1-Methyl-4-phenylpyridinium Cation*). MPTP preferentially destroys the *substantia nigra pars compacta*, but appears to spare the adjacent pigmented ventral tegmental areas, as well as other neuronal systems. This apparent selectivity obviously decreases with age inasmuch as more widespread damage is observed in older animals. MPTP provides an animal model for its effects in humans. In addition, it is one of the first environmental neurotoxins known to cause parkinsonism in humans. As an alternative substrate of monoamine oxidase, MPTP is metabolized in primates to the 1-methyl-4-phenylpyridinium cation (MPP<sup>+</sup>), a potent Complex I inhibitor in mitochondrial electron transport. (See also *1-Methyl-4-phenylpyridinium Cation*) **Target(s):** benzylamine oxidase, weakly inhibited (1); dopamine uptake (2); monoamine oxidase-3; tyrosine 3-monooxygenase (6,7). 1. Devlin, Bhatti, Williams & Ramsden (1990) *Toxicol. Lett.* **54**, 135. 2. Denton & Howard (1984) *Biochem. Biophys. Res. Commun.* **119**, 1186. 3. **5'-(4-Methylphenylthio)immucillin-A**

This nucleoside analogue (FW = 359.45 g/mol), also known as (1S)-1-(9-deazaadenin-9-yl)-1,4-dideoxy-1,4-imino-5-(4-methylphenylthio)-D-ribose, inhibits 5'-methylthio-adenosine/S-adenosylhomocysteine nucleosidase ( $K_i$  = 8 pM). The *meta*-methyl analogue is a weaker inhibitor ( $K_i$  = 9 pM). The 4-methylphenyl analogue is also a tight, slow-binding inhibitor of human S-methyl-5' thioadenosine phosphorylase ( $K_i$  = 0.64 nM). The 3-methylphenyl analogue also inhibits ( $K_i$  = 0.63 nM). (**For mode of action, See Immucillin**) **Target(s):** adenosylhomocysteine nucleosidase (1); 5'-methylthioadenosine/S-adenosylhomocysteine nucleosidase (1); S-methyl-5'-thioadenosine phosphorylase (2). 1. Singh, Evans, Lenz, et al. (2005) *J. Biol. Chem.* **280**, 18265. 2. Evans, Furneaux, Schramm, Singh & Tyler (2004) *J. Med. Chem.* **47**, 3275.

**4-Methylphenyl-2,4,6-trimethylphenylsulfone**

This membrane-permeant EPAC-2 selective inhibitor (FW = 274.38 g/mol; CAS 5148-64-5; Symbol: ESI-05; Spectra:  $\lambda_{max}$  = 244 nm;  $\epsilon$  = 19000 M<sup>-1</sup>cm<sup>-1</sup>) targets the exchange protein directly activated by cAMP (low- $\mu$ M IC<sub>50</sub>). The major physiological effects of cAMP in mammalian cells are transduced by two ubiquitously expressed intracellular cAMP receptors: protein kinase A (PKA) and exchange protein directly activated by cAMP (EPAC), as well as cyclic nucleotide-gated ion channels in certain tissues. EPAC2-specific inhibitors exert their isoform selectivity through a unique mechanism by binding to a previously undescribed allosteric site positioned at the interface of the two cAMP binding domains, but absent in the EPAC1 isoform. 1. Tsalkova, Mei, Li, et al., *Proc. Natl. Acad. USA*, **109**, 18613 (2012).

**2-Methyl-3-phytyl-1,4-naphthoquinone**

This photosensitive quinone (FW = 450.71 g/mol), also known as vitamin K<sub>1</sub> and phylloquinone, is a photosynthetic electron carrier and a factor in the posttranslational modification of prothrombin and other coagulation factors. It is required for the formation of  $\gamma$ -carboxyglutamyl (*or* GLA) residues needed to bind calcium ion. Vitamin K was first identified by Henrik Dam (1,2) and the structure of K<sub>1</sub> was determined by Doisy et al. (3) and was first chemically synthesized by Fieser (1). This vitamin is a viscous yellow oil (M.P. = -20°C) that is moderately stable to air, but rapidly decomposed when exposed to UV light and alkali. The absorption spectra, in petroleum ether, has  $\lambda_{max}$  values (with corresponding molar extinction coefficients) of 242 nm ( $\epsilon$  = 17850 M<sup>-1</sup>cm<sup>-1</sup>), 248 nm (18880 M<sup>-1</sup>cm<sup>-1</sup>), 260 nm (17260 M<sup>-1</sup>cm<sup>-1</sup>), 269 nm (17440 M<sup>-1</sup>cm<sup>-1</sup>), and 325 nm (3065 M<sup>-1</sup>cm<sup>-1</sup>). Treatment with dithionite or sodium borohydride produces the corresponding quinol. **Target(s):** arachidonate release in vascular cells (5); CYP1A1 (6); mono(ADP-ribose)transferase (7); NAD<sup>+</sup> ADP-ribosyltransferase, *or* poly(ADP-ribose) polymerase (8); protein glutamine  $\gamma$ -glutamyltransferase, *or* transglutaminase (9); retinyl-palmitate esterase, *or* retinyl ester hydrolase (10,11); testosterone 5 $\alpha$ -reductase (12). 1. **N-Methyl-N-propargyl-3-(2,4-dichlorophenoxy)propylamine**

This tertiary amine, also known as clorgyline (FW = 272.17 g/mol), is an antidepressant agent and a selective, mechanism-based inhibitor of monoamine oxidase A. 1. Figueiredo, Caramona, Paiva & Guimaraes (1998) *J. Auton. Pharmacol.* **18**, 123. 2. Coulson (1971) *Biochem. J.* **121**, 38P. 3. Hall & Logan (1969) *Biochem. Pharmacol.* **18**, 1955. 4. **N-Methylprotoporphyrin IX**

two of four possible isomeric species

These *N*-methyl regioisomers of protoporphyrin IX (FW = 576.69 g/mol; CAS 79236-56-9; *Abbreviation*: NMPP) are potent ferrochelatase inhibitors ( $K_i \sim 10$  nM), resulting in accumulation of metal-free protoporphyrin IX in liver cells (1-6). **Primary Mode of Inhibitory Action:** *N*-alkylation of a pyrrole nitrogen atom introduces non-planarity into the porphyrin macrocycle, and the inhibitory potency of NMPP is thought to arise from its structural similarity to the distorted porphyrin intermediate in the ferrochelatase-catalyzed reaction. The high affinity of the enzyme towards the inhibitor is attributed to a slow, second kinetic step corresponding to the rearrangement of the initial weak enzyme-inhibitor complex into a more stable enzyme-inhibitor complex. Commercial sources typically consist of all four isomers. The *N*-ethyl derivative is also a potent inhibitor (2). ***N*-Methylprotoporphyrin IX Synthesis:** When administered griseofulvin or 3,5-dicarboxy-1,4-dihydrocollidine, porphyric patients often worsen, occasionally with fatal outcomes. While such drugs result in ferrochelatase inhibition *in vivo*, they are completely without effect when added *in vitro*. That some heme metabolite is the ferrochelatase inhibitor was indicated by the observation that, when incubated with microsomal cytochrome proteins (CYP's), these drugs give rise green pigments among them *N*-methylprotoporphyrin. **Related Aspects of Ferrochelatase Inhibition:** Manganese ion  $Mn^{2+}$  inhibits ferrochelatase competitively with respect to  $Fe^{2+}$  ( $K_i = 15$  microM) and noncompetitively with respect to the porphyrin substrate. Heme, one of the reaction products, is a noncompetitive inhibitor with respect to iron. These findings lead to a sequential Bi Bi kinetic model for ferrochelatase with iron binding occurring prior to porphyrin binding and heme being released prior to the release of two protons (4). **Target(s):** ferrochelatase (1-6); heme oxygenase, zinc complex (6). 1. Dailey, Fleming & Harbin (1986) *Meth. Enzymol.* **123**, 401. 2. Ortiz de Montellano, Kunze, Cole & Marks (1980) *Biochem. Biophys. Res. Commun.* **97**, 1436. 3. #### 6-Methylpurine Ribonucleoside

This nucleoside analogue (FW = 266.26 g/mol) is converted metabolically to its nucleoside 5'-monophosphate which then inhibits *Escherichia coli* GMP synthetase. **Target(s):** adenosine kinase, *Mycobacterium tuberculosis*, also as alternative substrate (1); GMP synthetase (2). 1. Long & Parker (2006) *Biochem. Pharmacol.* **71**, 1671. 2. Spector & Beecham III (1975) *J. Biol. Chem.* **250**, 3101.

#### 4-Methylpyrazole

This antidote (FW = 82.11 g/mol; CAS 7554-65-6; Soluble in  $H_2O$  and ethanol; M.P. = 15.5-18.5° C), also known as 4-methyl-1*H*-pyrazole and Fomepizole™, potently inhibits alcohol dehydrogenase and is indicated in cases of methanol or ethylene glycol poisoning. **Primary Mode of Action:** With rat liver alcohol dehydrogenase (ADH), 4-methylpyrazole is a potent competitive inhibitor relative to ethanol ( $K_{is} = 0.11$   $\mu$ M at pH 7.3, 37° C) and is likewise competitive *in vivo* ( $K_{is} = 1.4$   $\mu$ mol/kg) (1). Methanol is readily oxidized by ADH to formaldehyde, which is further oxidized to formic acid by formaldehyde dehydrogenase. It is formic acid that is primarily responsible for the metabolic acidosis and visual disturbances associated with methanol poisoning. Likewise, oxidation of ethylene glycol to glycolaldehyde in the first step toward forming oxalate (the toxin). By inhibiting ADH with 4-methylpyrazole, there is greater opportunity for methanol and ethylene glycol to be excreted harmlessly. Importantly, ADH

binds 4-methylpyrazole some 400-500x more tightly than glycolaldehyde. **Target(s):** alcohol dehydrogenase (1-6); CYP2E1 (7); cinnamyl-alcohol dehydrogenase (8); retinol dehydrogenase, cytosolic (9). 1. Plapp, Leidal, Smith & Murch (1984) *Arch. Biochem. Biophys.* **230**, 30. 2. Raia, Giordano & Rossi (2001) *Meth. Enzymol.* **331**, 176. 3. Leo, Kim & Lieber (1987) *Arch. Biochem. Biophys.* **259**, 241.

#### [[[4-Methylpyridin-2-yl)amino]methylene]-bis(phosphonate)

This bisphosphonate (FW = 268.12 g/mol) inhibits *Trypanosoma brucei* geranyltransferase, or farnesyl-diphosphate synthase ( $K_i = 7$  nM). The 3-methyl analogue is a slightly weaker inhibitor ( $K_i = 10$  nM). 1. Montalvetti, Fernandez, Sanders, et al. (2003) *J. Biol. Chem.* **278**, 17075. 2. Dunford, Kwaasi, Rogers, et al. (2008) *J. Med. Chem.* **51**, 2187.

#### 2-[[[2-((1-Methyl-2-pyrrolidinyl)ethyl)amino]phenyl]sulfonyl]amino-5,6,7,8-tetrahydro-1-naphthalenecarboxylate

This substituted anthranilic acid sulfonamide (FW = 457.58 g/mol) inhibits methionyl aminopeptidase ( $IC_{50} = 0.017$   $\mu$ M), as identified with Affinity Selection by Mass Spectrometry (ASMS) screening. 1. Sheppard, Wang, Kawai, et al. (2006) *J. Med. Chem.* **49**, 3832.

#### 3-Methylquercetin

This redox-active *O*-methylated flavonol (FW = 316.26 g/mol; CAS 480-19-3; Symbol: 3-MQ; IUPAC Name: 3,5,7-trihydroxy-2-(4-hydroxy-3-methoxyphenyl)chromen-4-one), variously known as isorhamnetol, isorhamnetin, isorhamnetine, iso-rhamnetin, 3'-methoxyquercetin, protect the host cells from a viral induced shutdown of the cellular protein synthesis. When administered intraperitoneally at a daily dose of 20 mg/kg for nine days, 3-MQ protected mice from viremia and lethal infections from coxsackie B4 virus and polio virus ( $IC_{50} = 6.3 \times 10^{-6}$  M) (1). In poliovirus-infected cells, the viral protein and RNA synthesis were severely reduced, when 3-methylquercetin is present 1-2 hours post-infection (2). On the other hand, in uninfected HeLa cells, protein and RNA synthesis was inhibited only slightly by 3-methylquercetin. planar flavones and flavonols with a 7-hydroxyl group, such as 3-MQ, chrysin, luteolin, kaempferol, quercetin, and myricetin inhibited xanthine oxidase activity at low concentrations ( $IC_{50}$  range: 0.40 to 5.02  $\mu$ M) in a mixed-type mode, while the nonplanar flavonoids, isoflavones and anthocyanidins were less

inhibitory (3). Isorhamnetin also inhibits *Prevotella intermedia* lipopolysaccharide-induced production of interleukin-6 in murine macrophages via anti-inflammatory heme oxygenase-1 induction and inhibition of nuclear factor- $\kappa$ B and signal transducer and activator of transcription 1 activation (4). *P. intermedia* is a Gram-negative, obligate anaerobic pathogen involved in periodontal infections. 3-MQ also activates AMP-stimulated protein kinase (AMPK) to protect hepatocytes against oxidative stress and mitochondrial dysfunction (5). 1. ### $N^5$ -Methyltetrahydrofolate & Polyglutamylated Derivatives

This tetrahydrofolate derivative (FW = 454.42 g/mol; CAS 134-35-0;  $\lambda_{\text{max}}$  at pH 7.0 is 290 nm ( $\epsilon = 31700 \text{ M}^{-1}\text{cm}^{-1}$ ), also known as  $N^5$ -methyltetrahydropteroylglutamate, is an intermediate in the formation of methylcobalamin, which is used to convert L-homocysteine to L-methionine as well as S-adenosyl-L-homocysteine to S-adenosyl-L-methionine.  $N^5$ -CH<sub>3</sub>-THF is slowly oxidized in air at room temperature, forming  $N^5$ -methyl-dihydrofolate, a process that is accelerated by heavy metal ions. **Target(s):** folypolyglutamate synthetase (1,2); 5-formyltetrahydro-folate cyclo-ligase, or  $N^5,N^{10}$ -methenyltetrahydrofolate synthetase (3,4); 5-formyltetrahydrofolate transport (5,6); glycine N-methyltransferase, inhibited by the mono-, tri-, penta-, and hexaglutamyl forms (7-14); glycogen phosphorylase *b* (15); methionyl-tRNA formyltransferase (16,17); 5-methyltetrahydropteroyltriglutamate: homocysteine S-methyltransferase, inhibited by the monoglutamate coenzyme derivative (*i.e.*,  $N^5$ -methyltetrahydrofolate) (18); serine hydroxymethyl-transferase, or glycine hydroxymethyltransferase, also inhibited by the polyglutamate (19-23). 1. ### 5'-(Methylthio)immucillin-A

This nucleoside analogue (FW = 294.36 g/mol), also known as (1S)-1-(9-deazaadenin-9-yl)-1,4-dideoxy-1,4-imino-5-(methylthio)-D-ribose, inhibits 5'-methylthioadenosine/S-adenosylhomocysteine nucleosidase ( $K_i = 77 \text{ pM}$ ) and S-methyl-5'-thioadenosine phosphorylase ( $K_i = 1 \text{ nM}$ ). (See *Immucillin* for details on mode of action) **Target(s):** adenosylhomocysteine nucleosidase (1,2); 5'-methylthioadenosine/S-adenosylhomocysteine nucleosidase (1,2); S-methyl-5'-thioadenosine phosphorylase (3-5). 1. Singh, Evans, Lenz, *et al.* (2005) *J. Biol. Chem.* **280**, 18265. 2. Singh, Lee, Nuñez, Howell & Schramm (2005) *Biochemistry* **44**, 11647. 3. Evans, Furneaux, Schramm, Singh & Tyler (2004) *J. Med. Chem.* **47**, 3275. 4. Singh, Shi, Evans, *et al.* (2004) *Biochemistry* **43**, 9. 5. Evans, Furneaux, Lenz, *et al.* (2005) *J. Med. Chem.* **48**, 4679.

### 5'-(Methylthio)immucillin-H

This nucleoside analogue (FW = 296.35 g/mol), also known as (1S)-1-(9-deazahypoxanthin-9-yl)-1,4-dideoxy-1,4-imino-5-(methylthio)-D-ribose, inhibits purine-nucleoside phosphorylase. Note that this immucillin favors inhibition of the *Plasmodium falciparum* enzyme over the human enzyme ( $K_d = 2.7$  versus 303 nM). (See *Immucillin* for details on mode of action) 1. Shi, Ting, Kicska, *et al.* (2004) *J. Biol. Chem.* **279**, 18103. 2. Chaudhary, Ting, Kim & Roos (2006) *J. Biol. Chem.* **281**, 25652.

### S-Methyl-thioinosine 5'-Monophosphate

This modified thiopurine nucleotide (FW = 377.29 g/mol) is formed by the S-methylation of 6-mercaptopurine (6-MP) to 6-methylmercaptopurine (6-MMP) through the action of thiopurine methyl transferase (TPMT). The latter catalyzes the main inactivation pathway of thiopurines in hematopoietic cells, and patients deficient in TPMT accumulate excessive concentrations of the active thioguanine nucleotides in blood cells when treated with conventional doses of these drugs (1-3). Delayed cytotoxicity of S-Methyl-thioinosine 5'-monophosphate is the consequence of mitotic death arising from DNA damage due to incorporation of 6-thioguanine into DN. (See *6-Mercaptopurine*) 1. Tay, Lilley, Murray & Atkinson (1969) *Biochem. Pharmacol.* **18**, 936. 3. Elion (1989) *Science* **244**, 41. 3. Sahasranaman, Howard & Roy (2008) *Eur. J. Clin. Pharmacol.* **64**, 753.

### O-Methyl-DL-thyroxine

This thyroxine derivative (FW = 790.90 g/mol) inhibits thyroxine deiodinase. These data, together with the observations that 3,3',5'-triiodo-DL-thyronine blocks the metabolic effect of thyroxine *in vivo*, provided the first strong support for the concept (a) that thyroxine is converted to another compound before becoming active at the cellular level, and (b) that one step in this conversion is the removal of one iodine atom from the terminal ring of the thyronine. 1. Larson & Albright (1961) *J. Clin. Invest.* **40**, 1132.

**Methyltrienolone**

This anabolic steroid (FW = 284.40 g/mol; CAS 965-93-5; M.P. = 170°C), also known as 17 $\beta$ -hydroxy-17 $\alpha$ -methyl-estra-4,9,11-trien-3-one and R 1881, is a non-metabolizable androgen that binds to androgen receptors. Methyltrienolone can also be used as a photoaffinity ligand for steroid binding proteins. **Target(s):** 3 $\beta$ -hydroxysteroid dehydrogenase (1); steroid  $\Delta$ -isomerase (2); steroid 17,20 lyase (1); steroid 11 $\beta$ -monooxygenase, or CYP11B1 (3); steroid 17 $\alpha$ -monooxygenase (1). 1. Fanjul, Estevez, Deniz, *et al.* (1989) *Biochem. Int.* **19**, 301. 2. Weintraub, Vincent, Baulieu & Alfsen (1977) *Biochemistry* **16**, 5045. 3. Ohnishi, Miura & Ichikawa (1993) *Biochim. Biophys. Acta* **1161**, 257.

 **$\beta$ -Methyltryptophan**

This tryptophan derivative (FW = 218.26 g/mol), also occasionally called 3-methyltryptophan, is an alternative substrate for tryptophan aminotransferase, acting competitively relative to tryptophan. **Target(s):** 3-deoxy-7-phosphoheptulonate synthase, inhibited by the DL-erythro isomer (1); tryptophan aminotransferase, also alternative substrate (2); tryptophan 2,3-dioxygenase (3); tryptophanyl-tRNA synthetase (4-6). 1. Görisch & Lingens (1971) *Biochim. Biophys. Acta* **242**, 630. 2. Speedie, Hornemann & Floss (1975) *J. Biol. Chem.* **250**, 7819. 3. **1-Methyltryptophan**

This tryptophan derivative (FW = 218.26 g/mol; CAS 21339-55-9) inhibits indoleamine 2,3-dioxygenase. Inhibition of this enzyme results in suppression of NK (natural killer) cell activity and acceleration of tumor growth. **Target(s):** indoleamine 2,3-dioxygenase (each stereoisomer selectively inhibits an isoform) (1-10); tryptophan 2,3-dioxygenase (11); tryptophan 2-C-methyltransferase (12). 1. Cady & Sono (1991) *Arch. Biochem. Biophys.* **291**, 326. 2. Kai, Goto, Tahara, *et al.* (2003) *J. Exp. Ther. Oncol.* **3**, 336. 3. Southan, Truscott, Jamie, *et al.* (1996) *Med. Chem. Biophys.* **278**, 35.

**1-Methyl-D-tryptophan**

This D-tryptophan derivative (FW = 218.26 g/mol; CAS 110117-83-4; Soluble to 5 mM in water with gentle warming) inhibits indoleamine 2,3-dioxygenase (IC<sub>50</sub> = 7  $\mu$ M), catalyzes the rate-limiting step in the metabolism of tryptophan along the kynurenine pathway. In tumors, increased IDO activity inhibits proliferation and induces apoptosis of T cells and natural killer cells. IDO is known to suppress antitumor CD8<sup>+</sup> T-cells (TCD8). 1-Methyl-D-tryptophan enhances the antitumor and antiviral immunoresponses of CD8<sup>+</sup> T-cells *in vitro*. It also reduces tumor volume in mice with xenografts overexpressing IDO, especially when used in combination with cyclophosphamide is an effective treatment for lymphoma in a mouse model (1,2). 1. Rytelewski, Meilleur, Yekta, *et al.* (2014) *PLoS One* **9**, e90439. 2. Nakamura, Hara, Shimizu, *et al.* (2015). *Int. J. Hematol.* **102**, 327.

**2-Methyltryptophan**

This rare tryptophan analogue (FW = 218.26 g/mol; CAS 33468-32-5) inhibits: 3-deoxy-7-phosphoheptulonate synthase, inhibited by the DL-mixture (1); phenylalanine decarboxylase, inhibited by the L-isomer (2); and tyrosine 3-monooxygenase, inhibited by the L-isomer (3). (**See also  $\alpha$ -Methyl L-tryptophan**) 1. Görisch & Lingens (1971) *Biochim. Biophys. Acta* **242**, 630. 2. Lovenberg, Weissbach & Udenfriend (1962) *J. Biol. Chem.* **237**, 89. 3. Moore & Dominic (1971) *Fed. Proc.* **30**, 859.

**4-Methyltryptophan**

This tryptophan derivative (FW = 218.26 g/mol; CAS 1139-73-7) inhibits tryptophan synthase and is an activator of chorismate mutase. **Target(s):** alkaline phosphatase, mildly inhibited by the racemic mixture (1); anthranilate synthase (2); chorismate mutase (3); 3-deoxy-7-phosphoheptulonate synthase (4); indoleamine 2,3 dioxygenase, also weak alternative substrate (5); prephenate dehydratase; tryptophan 2,3 dioxygenase (7); tryptophan synthase (8,9); tyrosine 3-monooxygenase, moderately inhibited (10). 1. Fishman & Sie (1971) *Enzymologia* **41**, 141. 2. Widholm (1972) *Biochim. Biophys. Acta* **279**, 48. 3. Hertel, Hieke & Gröger (1991) *Acta Biotechnol.* **11**, 39. 4. ### 5-Methyltryptophan

This methylated tryptophan (FW = 218.26 g/mol; CAS 2283-43-4) is a competitive inhibitor of tryptophanyl-tRNA synthetase and a false feedback inhibitor of anthranilate synthesis. **Target(s):** alkaline phosphatase, inhibited by the racemic mixture (1); anthranilate phosphoribosyltransferase (2); anthranilate synthase (3-7); indoleamine 2,3-dioxygenase, also alternative substrate (8); prephenate dehydratase (9); tryptophan 2,3-dioxygenase, inhibited by the DL-mixture, also weak alternative substrate (3,10,11); tryptophanyl-tRNA synthetase (12,13); tyrosine 3-monooxygenase (14,15). 1. Fishman & Sie (1971) *Enzymologia* **41**, 141. 2. O'Gara & Dunican (1995) *Appl. Environ. Microbiol.* **61**, 4477. 3. ### 6-Methyltryptophan

This tryptophan derivative (FW = 218.26 g/mol; CAS 1991-93-1) inhibits tryptophanyl-tRNA synthetase and tryptophan 2,3-dioxygenase. **Target(s):** chorismate mutase (1); 3-deoxy-7-phosphoheptulonate synthase (2); indoleamine 2,3-dioxygenase, also alternative substrate (3); prephenate dehydratase (4); tryptophan 2,3 dioxygenase (5); tryptophanyl-tRNA synthetase (6,7); tyrosine 3-monooxygenase, moderately inhibited (8). 1. Hertel, Hieke & Gröger (1991) *Acta Biotechnol.* **11**, 39. 2. Görisch & Lingens (1971) *Biochim. Biophys. Acta* **242**, 630. 3. Southan, Truscott, Jamie, *et al.* (1996) *Med. Chem. ### $\alpha$ -L-Methyltyrosine

This modified aromatic amino acid (FW = 195.22 g/mol; CAS 658-48-0), also known as metyrosine, inhibits tyrosine 3-monooxygenase and is an orally active inhibitor of catecholamine synthesis. **Target(s):** aromatic-L-amino-acid decarboxylase, *or* dopa decarboxylase (1); chorismate mutase (2); dihydropteridine reductase (3); prephenate dehydratase (4); tyrosine aminotransferase (5); tyrosine decarboxylase (1); tyrosine 3-monooxygenase (6-11). 1. Nagy & Hiripi (2002) *Neurochem. Int.* **41**, 9. 2.

### $\alpha$ -Methyl-*m*-tyrosine

This L-phenylalanine derivative (FW = 195.22 g/mol; CAS 305-96-4), also known as  $\alpha$ -methyl-3-hydroxy-L-phenylalanine, inhibits aromatic-L-amino-acid decarboxylase, *or* dopa decarboxylase (1-6), dopamine  $\beta$ -monooxygenase (1,7), phenylalanine decarboxylase (4), and tyrosine decarboxylase (5). 1. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, Academic Press, New York. 2. Daly, Mauger, Yonemitsu, *et al.* (1967) *Biochemistry* **6**, 648. 3. O'Leary & Baughn (1977) *J. Biol. Chem.* **252**, 7168. 4. Lovenberg, Weissbach & Udenfriend (1962) *J. Biol. Chem.* **237**, 89. 5. Nagy & Hiripi (2002) *Neurochem. Int.* **41**, 9. 6. Bender & Coulson (1977) *Biochem. Soc. Trans.* **5**, 1353. 7. Hess, Connamacher, Ozaki & Udenfriend (1961) *J. Pharmacol. Exptl. Therap.* **134**, 129.

### 4-Methylumbelliferone

This fluorescent coumarin (FW = 176.17 g/mol; CAS 90-33-5), also known as hymecromone, is released by the action of specific glycosidases on synthetic glycosides containing the 4-methylumbelliferyl group. 4-Methylumbelliferyl-sulfate is also an alternative substrate for aryl sulfatases and 4-methylumbelliferyl oleate is hydrolyzed by lipases. Enzyme activity can be easily measured via fluorescence ( $\lambda_{\text{max}} = 448 \text{ nm}$ ,  $\lambda_{\text{excitation}} = 364 \text{ nm}$ ). 4-Methylumbelliferone is also a substrate for UDP-glucuronosyltransferases and phenol sulfotransferases. **Target(s):** 17 $\beta$ -hydroxysteroid dehydrogenase (1); xanthine oxidase (2). 1. Le Lain, Barrell, Saeed, *et al.* (2002) *J. Enzyme Inhib. Med. Chem.* **17**, 93. 2. Beiler & Martin (1951) *J. Biol. Chem.* **192**, 831.

### O-Methyluniconazole

This synthetic plant growth retardant (FW = 305.81 g/mol) strongly inhibits (+)-abscisate 8'-hydroxylase ( $K_i = 8.6 \mu\text{M}$ ), a key enzyme in the catabolism of abscisic acid. The latter is a plant hormone involved in stress tolerance, stomatal closure, flowering, seed dormancy, and other physiological events. Conformational analysis and *in vitro* assays of enzyme inhibition underscore the importance of substituting a triazole in place of imidazole, the need of polar group at the 3-position to increase affinity for the active site via electrostatic or hydrogen-bonding interactions, and the conformer preference for a polar environment partially contributes to affinity for the active site. 1. Todoroki, Kobayashi, Yoneyama, *et al.* (2008) *Bioorg. Med. Chem.* **16**, 3141.

**6-Methyluracil**

This pyrimidine (FW = 126.11 g/mol; CAS 626-48-2), also known as 2,4-dihydroxy-6-methylpyrimidine, inhibits dihydroorotate dehydrogenase (1,2), thymidine phosphorylase (3), thymine dioxygenase (4), and uridine phosphorylase (3). **1.** Friedmann & Vennesland (1958) *J. Biol. Chem.* **233**, 1398. **2.** Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 470, Academic Press, New York. **3.** Avraham, Yashphe & Grossowicz (1988) *FEMS Microbiol. Lett.* **56**, 29. **4.** Bankel, Lindstedt & Lindstedt (1977) *Biochim. Biophys. Acta* **481**, 431.

**1-Methylxanthine**

This substituted purine (FW = 166.14 g/mol; CAS 6136-37-4) inhibits hypoxanthine (guanine) phosphoribosyltransferase (1,2), methionine S-adenosyltransferase (3), xanthine phosphoribosyltransferase (1,4). **1.** Naguib, Iltzsch, el Kouni, Panzica & el Kouni (1995) *Biochem. Pharmacol.* **50**, 1685. **2.** Miller, Ramsey, Krenitsky & Elion (1972) *Biochemistry* **11**, 4723. **3.** Berger & Knodel (2003) *BMC Microbiol.* **3**, 12. **4.** Miller, Adamczyk, Fyfe & Elion (1974) *Arch. Biochem. Biophys.* **165**, 349.

**Methyl β-D-Xylopyranoside**

This glycoside (FW = 164.16 g/mol) inhibits acetylxyylan esterase (1); aldose 1-epimerase (2), aryl-β-hexosidase (3,4), xylan 1,4-β xylosidase (5), and β-xylosidase/β-glucosidase (6). **1.** Biely, Mastihubová, Côté & Greene (2003) *Biochim. Biophys. Acta* **1622**, 82. **2.** Bailey, Fishman, Kusiak, Mulhern & Pentchev (1975) *Meth. Enzymol.* **41**, 471. **3.** Distler & Jourdian (1978) *Meth. Enzymol.* **50**, 524. **4.** Distler & Jourdian (1977) *Arch. Biochem. Biophys.* **178**, 631. **5.** John & Schmidt (1988) *Meth. Enzymol.* **160**, 662. **6.** Yasui & Matsuo (1988) *Meth. Enzymol.* **160**, 696.

**Methysergide**

This semisynthetic ergot alkaloid ergometrine derivative and serotonin antagonist (FW = 469.54 g/mol; CAS 129-49-7; Soluble to 10 mM in water with gentle warming), also named [8β(S)-9,10-didehydro-N-[1-(hydroxymethyl)propyl]-1,6-dimethylergoline-8-carboxamide maleate, targets 5-HT<sub>1</sub> and 5-HT<sub>2</sub> receptors. Methysergide was synthesized from lysergic acid diethylamide (LSD) by adding a methyl group and a butanolamide group and resulting in a compound with selectivity and high potency as a serotonin (5-HT) inhibitor (1). Methysergide use in treating migraine declined considerably, when it was found to cause retroperitoneal fibrosis after chronic intake. The mechanism for its preventive effect in migraine remains elusive. **1.** Koehler & Tfelt-Hansen (2008) *Cephalalgia* **28**, 1126.

**Metoclopramide**

This antiemetic and antipsychotic agent (FW = 299.80 g/mol; CAS 364-62-5) is a dopamine D<sub>2</sub> receptor antagonist (1) as well as a 5-HT<sub>2</sub> serotonin receptor antagonist (2). It is also a reversible inhibitor of cholinesterases from human central nervous system and blood (3-5). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** Keabian & Calne (1979) *Nature* **277**, 93. **2.** De Winter, Boeckxstaens, De Man, *et al.* (1999) *Gut* **45**, 713. **3.** Kao, Tellez & Turner (1990) *Brit. **Metolachlor**

This selective, pre-emergence herbicide (FW = 283.80 g/mol; CAS 51218-45-2), also known as Dual and 2-chloro-N-(2-ethyl-6-methylphenyl)-N-(2-methoxy-1-methylethyl)acetamide, is used to control certain broadleaf and annual grassy weeds. It also inhibits protein biosynthesis; thus, high-protein crops (*e.g.*, soy) can be adversely affected by excessive metolachlor applications. Additives may be included to help protect sensitive crops. It is detoxified by the formation of a glutathione adduct. **Target(s):** fatty-acid elongase; chalcone synthase; stilbene synthase. **1.** Eckermann, Matthes, Nimt, *et al.* (2003) *Phytochemistry* **64**, 1045.

**Metoprine**

This lipid-soluble antifolate agent (FW = 269.13 g/mol; CAS 7761-45-7), also known as 2,4-diamino-5-(3,4-dichlorophenyl)-6-methylpyrimidine, reversibly inhibits dihydrofolate reductase, mouse leukemia cell line L1210, IC<sub>50</sub> ≈ 0.01 μM (1-3) and histamine N-methyltransferase (4-7). **1.** Nichol, Cavillito, Woolley & Sigel (1977) *Cancer Treat Rep.* **61**, 559. **2.** Baker & Vermeulen (1970) *J. Med. Chem.* **13**, 82. **3.** Baker, Vermeulen, Ashton & Ryan (1970) *J. Med. Chem.* **13**, 1130. **4.** Nishibori, Oishi, Itoh & Saeki (1991) *Neurochem. **Metoprolol**

This orally active, selective β<sub>1</sub> receptor blocker (FW = 267.36 g/mol; CAS 51384-51-1), also known by its trade names Lopressor<sup>TM</sup>, Toprol-XL<sup>TM</sup> and by its IUPAC name (*RS*)-1-(isopropylamino)-3-[4-(2-methoxyethyl)phenoxy]propan-2-ol, is an FDA-approved drug for treating hypertension, angina pectoris and, more generally, heart failure (1-3). While its precise

antihypertensive mechanism of this  $\beta$ -blocker remains unknown, likely actions include: (a) competitive antagonism of catecholamines at peripheral (*i.e.*, cardiac) adrenergic neuron sites, thereby decreasing cardiac output; (b) central effects resulting in reduced sympathetic outflow to the periphery; and/or (c) suppression of renin-mediated effects. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** insulin release in response to glucose, suggesting a partial dependence on intact  $\beta$ -adrenoceptors (4); mitochondrial coenzyme Q<sub>10</sub>-enzymes of heart tissue, *i.e.*, succinoxidase and NADH-oxidase (5); hepatic 3,5,3'-triiodothyronine production (6); synaptosomal noradrenaline uptake (7); lysosomal phospholipase A<sub>1</sub> (8). 1. ### Metoxuron

This herbicide (FW = 228.68 g/mol; CAS 19937-59-8; MP = 124-127 °C), also known as Deftor<sup>®</sup>, Pestanal<sup>®</sup>, Sulerex<sup>®</sup>, and 3-(3-chloro-4-methoxyphenyl)-1,1-dimethylurea, exerts selective pre- and post-emergence actions as a plant growth regulator and defoliant. Its primary mechanism of action is as a photosynthetic electron transport inhibitor, interrupting the flow of electrons in photosystem II and thereby blocking the chemiosmotic proton flow driving ATP synthesis. Metoxuron is effective against black grass, silky bent grass, wild oats, ryegrass, and most annual broad leaf weeds. UV irradiation of metoxuron in aerated aqueous solutions results in photohydrolysis of the C-Cl bond to form 3-(3-hydroxy-4-methoxyphenyl)-1,1-dimethylurea. 1. Dodge (1977) *Spec. Publ., Chem. Soc.* **29**, 7.

### Metronidazole

This oral antibiotic/antiprotozoal pro-drug (FW = 171.16 g/mol; CAS 443-48-1), also known by the brand name Flagyl<sup>®</sup> and as 2-methyl-5-nitroimidazole-1-ethanol and 1-(2-hydroxyethyl)-2-methyl-5-nitroimidazole, is active against anaerobic and some microaerophilic bacteria, including infections caused by *Bacteroides*, *Clostridium*, *Fusobacterium*, *Peptostreptococcus*, and *Prevotella* species. Metronidazole is an FDA-approved drug for the treatment of bacterial vaginosis in non-pregnant women (1). Metronidazole is also useful in treating parasitic infections, especially trichomoniasis. The U.S. Center for Disease Control and Prevention notes that trichomoniasis can be cured with a single oral dose of metronidazole or tinidazole. Given its mutagenic and potential carcinogenic properties, however, metronidazole is banned in the European Union and United States in the feed of animals and is likewise banned for use in food animals. **Mechanism of Action:** Metronidazole and related 5-nitroimidazole pro-drugs (tinidazole and ornidazole) exert their antimicrobial actions via inhibition of DNA synthesis, an action that first requires intracellular reduction of the nitro group to form a reactive radical species (likely pathway shown below).

(Beyond microbial reduction, pro-drug activation can be mediated by rat liver microsomes, as demonstrated by using a mutant of *S. typhimurium* unable to activate metronidazole (2).) Once reduced, metronidazole binds to and lowers the melting temperature ( $T_m$ ) of DNA, increasing the melting range, without affecting the cooling profile. The reduced drug also causes single- and double-strand breaks in DNA, but does not break single-stranded DNA. No such effects are observed with the unreduced drug. Upon reduction by sodium dithionite in the presence of DNA, metronidazole becomes covalently bound to DNA. Such properties are likely to explain the biological basis of Flagyl's action, not only as an antimicrobial agent, but also as a radiosensitizer (especially in hypoxic cells), and may underlie its mutagenic/carcinogenic properties. Likely radiosensitization mechanisms include enzyme-catalyzed depletion of nucleophiles, such as glutathione, fixation of organic radicals, interference with recombination reactions, and formation of toxic products (3). **Pharmacokinetics:** Oral metronidazole has a bioavailability approaching 100%. It shows limited plasma protein binding, yet attains favorable tissue distribution, even penetrating the Central Nervous System. It is oxidatively metabolized in the liver, forming two primary metabolites: the hydroxy- and acetate-containing derivatives. See also Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** alcohol dehydrogenase (4-6); nitrogenase (7,8); and xanthine oxidase (9). 1. Carey, Klebanoff, Hauth, *et al.* (2000) *New Engl. J. Med.* **342**, 534. 2. Rosenkranz & Speck (1975) *Biochem. Biophys. Res. Comm.* **66**, 520. 3. Wilson, Cramp & Ings (1974) *Internat. J. Rad. Biol.* **26**, 557. 4. ### Metronomic Chemotherapy

This term describes a strategy for treating advanced stage cancer relies on the chronic administration of chemotherapeutic agents at relatively low, minimally toxic doses on a frequent and regular schedule of administration (hence the term "metronomic") and without prolonged drug-free breaks. Metronomic chemotherapy is believed to exert its beneficial effects by disrupting tumor-supportive angiogenesis mechanisms, thereby limiting tumor growth while significantly reducing a drug's undesirable toxic side effects. Rapidly eliminated vascular disrupting agents (VDAs), such as Combretastatin, appear to be especially well-suited for metronomic chemotherapy.

### Metsulfuron-methyl

This pre- and post-emergence herbicide (FW = 381.37 g/mol; CAS 74223-64-6), also known as Ally and Allie, inhibits acetolactate synthase and branched-chain amino acid biosynthesis. **Target(s):** acetolactate synthase

(1-7); firefly luciferase, or *Photinus*-luciferin 4-monooxygenase (8). 1. Zohar, Einav, Chipman & Barak (2003) *Biochim. Biophys. Acta* **1649**, 97. 2. ### Metrapone

This Cytochrome P450 inhibitor and drug (FW = 226.28 g/mol; CAS 54-36-4; Soluble to 100 mM in H<sub>2</sub>O and to 100 mM in DMSO), also known as 2-methyl-1,2-di-(3-pyridyl)-1-propanone, metopirone, 1,2-bis(3-pyridyl)-2-methyl-1-propanone, and SU 4885, is used to diagnose adrenal insufficiency and to treat Cushing's syndrome (hypercortisolism). Metrapone is a nonspecific cytochrome P450 inhibitor, targeting CYP11B1 (steroid 11- $\beta$  hydroxylase, IC<sub>50</sub> = 7.8  $\mu$ M), CYP2B, CYP 3A, and cytochrome P450-mediated prostaglandin  $\omega/\omega$ -1 hydroxylase. Metrapone also induces glucocorticoid depletion, thereby modulating tyrosine hydroxylase and phenylethanolamine *N*-methyltransferase gene expression in the rat adrenal gland via noncholinergic transsynaptic activation. **Target(s):** abietadiene hydroxylase (85); abietadienol hydroxylase (85); aldehyde dehydrogenase (1); aldehyde oxygenase (2); alkane-1 monooxygenase (3-6); aromatase, or CYP19 (7); aryl hydrocarbon monooxygenase (8); biphenyl hydroxylase (9); bufuralol 1'-hydroxylase, or cytochrome P450 (10,11); calcidiol 1-monooxygenase, or 25-hydroxyvitamin D 1 $\alpha$ -hydroxylase (38-40,98-102); camphor 5-monooxygenase, or CYP101 (1); *S*-canadine synthase (77); cholestanetriol 26-monooxygenase, weakly inhibited (97); corticosterone 6 $\beta$ -hydroxylase (13); corticosterone 18-monooxygenase, steroid 18-monooxygenase (65); coumarin 7-hydroxylase, or CYP2A6 (14-19); CYP2A3 (15); CYP2A5 (16-20); CYP3A (21); CYP3A1 (21,22); CYP3A4 (21-23); CYP2B122,24-26; CYP2B224,25; CYP2B622; debrisoquine 4-monooxygenase (11); 7-deoxyloganin 7-hydroxylase (90); deoxysarpagine hydroxylase (27); dihydrochelirubine 12-monooxygenase (92); 8-dimethylallylnaringenin 2'-hydroxylase (86); ecdysone 20-monooxygenase (28,29,71-73); entisopimara 8(14),15-dien-3 $\beta$ -ol monooxygenase (30); estradiol 2-monooxygenase (31); estradiol 6 $\alpha$  monooxygenase (31); estrogen-2/4-hydroxylase (32); 13-ethyl-gon-4-ene-3,17-dione 15 $\alpha$  monooxygenase (33); glyceollin synthase (88);  $\omega$ -hydroxylase, or alkane-1 monooxygenase (3-6); 11 $\beta$  hydroxysteroid dehydrogenase (34,35); 17 $\beta$ -hydroxysteroid dehydrogenase (36,37); 25-hydroxyvitamin D<sub>3</sub> 24-hydroxylase (41,42); leukotriene B<sub>4</sub> 20-monooxygenase, or leukotriene B<sub>4</sub>  $\omega$  and  $\omega$ -1 monooxygenase (44,96); licodione synthase (87); (*R*)-limonene 6-monooxygenase (89); (*S*)-limonene 3 monooxygenase (94); (*S*)-limonene 6-monooxygenase (94); (*S*)-limonene 7-monooxygenase (94); lipoxygenase, soybean (45); methyltetrahydroprotoberberine 14-monooxygenase (95); 11-oxo- $\Delta^8$  tetrahydrocannabinol monooxygenase (46); progesterone 11 $\alpha$ -monooxygenase (74-76); progesterone 14 $\alpha$ -monooxygenase (47); prostaglandin  $\omega$  and  $\omega$ -1 hydroxylase (5,48,49); protopine 6 monooxygenase (93); steroid 7 $\alpha$ -monooxygenase (50,51); steroid 9 $\alpha$ -monooxygenase (70); steroid 11 $\beta$  monooxygenase, or CYP11B1, K<sub>i</sub> = 0.1  $\mu$ M (52-63,78-84); steroid 17 $\alpha$ -monooxygenase (64); sterol 14-demethylase, or CYP51, or lanosterol 14 $\alpha$ -demethylase (43,91); styrene monooxygenase (66,67); tangeretin *O*-demethylase (68); thromboxane synthase (54); vitamin D<sub>25</sub>-hydroxylase, weakly inhibited (69). 1. ### Mevalonate (Mevalonic Acid)

This  $\beta,\delta$ -dihydroxy acid (FW<sub>free-acid</sub> = 148.16 g/mol; CAS 150-97-0; pK<sub>a</sub> = 4.3; Very soluble in H<sub>2</sub>O and many organic solvents) is a key metabolite in isoprenoid biosynthesis. The naturally occurring stereoisomer is (*R*)-mevalonate, and the (*S*)-isomer is biologically inactive. Its  $\delta$ -lactone (shown above) is mevalonolactone (FW = 130.14 g/mol; CAS 674-26-0; Hygroscopic; M.P. = 28°C; rapidly hydrolyzed under alkaline conditions). It is enzymatically hydrolyzed, both in plasma and within liver cells. Mevalonolactone has no direct inhibitory effect on HMG-CoA reductase. Mevalonolactone administration to rats *in vivo* is associated with an inhibition of HMG-CoA reductase activity: (a) by increasing in the degree of phosphorylation of both HMG-CoA reductase and reductase kinase due to increased activity of reductase kinase; and (b) by decreasing the dephosphorylation of both HMG-CoA reductase and reductase kinase, secondary to inhibition of phosphoprotein phosphatase activity (1). These combined effects favor an increase in the steady-state level of the phosphorylated forms of both HMG-CoA reductase and reductase kinase, resulting in a net reduction in the enzymic activity of HMG-CoA reductase and mevalonate formation. **Mevalonate's Role in Cellular Metabolism:** Mevalonate is a direct precursor of isopentenyl-pyrophosphate, which lies at a metabolic crossroad, with one path leading to isopentenyl-tRNA, and the other proceeding to farnesyl-pyrophosphate. The latter lies at a second crossroad, with paths ultimately leading to ubiquinone, cholesterol (via squalene formation), and dolichol. **Target(s):** diphosphomevalonate decarboxylase (2); phospho-mevalonate kinase (3). **1.** Beg, Stonik & Brewer (1984) *Proc. Natl. Acad. Sci. U.S.A.* **81**, 7293. **2.** Jabalquinto & Cardemil (1989) *Biochim. Biophys. Acta* **996**, 257. **3.** Pilloff, Dabovic, Romanowski, *et al.* (2003) *J. Biol. Chem.* **278**, 4510.

### Mevalonic Acid 5-Diphosphate

This metabolite (FW = 308.12 g/mol), also known as 5-pyrophosphomevalonate, diphosphomevalonate, and mevalonate 5-pyrophosphate, is an intermediate in the biosynthesis of sterols and isoprenoids. Note that aqueous solutions are relatively unstable: *t*<sub>1/2</sub> at 0°C and pH 6 is about three months, decomposing to mevalonate 5-phosphate and orthophosphate (the rate of decomposition is slower at alkaline pH). It is a product of the reaction catalyzed by phospho-mevalonate kinase and a substrate for diphosphomevalonate decarboxylase. **Target(s):** mevalonate kinase, IC<sub>50</sub> = 180  $\mu$ M for the rat enzyme (1,2). **1.** Qiu & Li (2006) *Org. Lett.* **8**, 1013. **2.** Andreassi, Bilder, Vetting, Roderick & Leyh (2007) *Protein Sci.* **16**, 983.

### Mevalonic Acid 5-Phosphate

This metabolite (FW<sub>lithium-salt</sub> = 245.94 g/mol (anhydrous); CAS 868553-49-5), also known as 5-phosphomevalonate, is an intermediate in isoprenoids and sterols biosynthesis. The (*R*)-enantiomer is a product of the reaction catalyzed by mevalonate kinase and is a substrate for phosphomevalonate kinase. Mevalonate 5-phosphate has pK<sub>a</sub> values of 1.7, 4.6, and 6.9. Approximately 9% is hydrolyzed in one hour in 1 M HCl at 100°C. **Target(s):** diphosphomevalonate decarboxylase (1). **1.** Jabalquinto & Cardemil (1989) *Biochim. Biophys. Acta* **996**, 257.

### Mevastatin

This fungal metabolite and hypolipemic agent (FW<sub>lactone</sub> = 390.52 g/mol; CAS 73573-88-3), also named ML-236B, compactin and (1*S*,7*R*,8*S*,8*aR*)-8-{2-[(2*R*,4*R*)-4-hydroxy-6-oxotetrahydro-2*H*-pyran-2-yl]ethyl}-7-methyl-1,2,3,7,8,8*a*-hexahydronaphthalen-1-yl(2*S*)-2-methylbutanoate, first found in *Penicillium citrinum*, is a highly effective prodrug that is metabolically hydrolyzed to the potent inhibitor (*K*<sub>i</sub> = 1 nM, See structure above) of 3-hydroxy-3-methylglutaryl-CoA (or HMG-CoA) reductase (1-8). Although one of the first inhibitors used in the treatment of hypercholesterolemia, mevastatin was never commercialized. Mevastatin is unstable at room temperature and should be prepared immediately prior to use (1). Given mevastatin's powerful effects on the synthesis and action of other downstream isoprenoids, its not surprising that mevastatin should affect cell cycle kinetics, often resulting in arrest in the late G<sub>1</sub> phase. Like other statins, mevastatin induces antiproliferative effects and apoptotic responses in various cancer cell types. It also sensitizes tumor cell lines of different origins to many agents. CR200 cells show > 100x higher mevastatin resistance than the parental FM3A cell line, when grown in the presence of low-density lipoprotein, or LDL (9). CR200 cells also have decreased levels of LDL receptor and defective mevalonate end-product regulation of HMG-CoA reductase, two properties that may underlie the over-accumulation of HMG-CoA reductase in CR200 cells and the basis of mevastatin resistance. **Prenylation Block & Release Assay:** This protocol relies upon mevastatin's ability to inhibit production of geranylgeranyl (GGPP) and farnesyl (FPP) pyrophosphates, key precursors in protein prenylation (10). Mevastatin blocks prenylation of newly synthesized substrates of GGT, RGGT and FT (e.g. Rho, Rab and Ras GTPases). Removal of the inhibitor releases this block, allowing GGPP and FPP biosynthesis, immediate protein prenylation, and subsequent membrane targeting of prenylated proteins. The process of membrane targeting from the cytosolic pool of modulator proteins like Rho, Rab and Ras to the membrane may then be observed directly using fluorescence microscopy. **1.** Endo (1981) *Meth. Enzymol.* **72**, 684. **2.** Qureshi, Nimmannit & Porter (1981) *Meth. Enzymol.* **71**, 455. **3.** Monger (1985) *Meth. Enzymol.* **110**, 51. **4.** Elbein (1987) *Meth. Sci.* **6**, 10. **6.** Chang (1983) *The Enzymes*, 3rd ed., **16**, 491. **7.** Gibson & Parker (1987) *The Enzymes*, 3rd ed., **18**, 179. **8.** Istvan & Deisenhofer (2001) *Science* **292**, 1160. **9.** Hasumi, Yamada, Shimizu & Endo (1987) *Eur. J. Biochem.* **164**, 547. **10.** Ali, Nouvel, Leung, Hume & Seabra (2010) *Biochem. Biophys. Res. Commun.* **397**, 34.

**Mevinphos**

This organophosphate cholinesterase-type insecticide (FW = 224.15 g/mol; CAS 26718-65-0), readily produced by reacting trimethyl phosphite with chloroacetate, is usually a mixture of the (*E*)- and (*Z*)-isomers. The (*E*)-isomer (shown above) is a hundred-times more potent. One experimental model for brain stem death employs mevinphos (10 nmol) injected bilaterally into Rostral Ventrolateral Medulla (RVLM) of Sprague-Dawley rats. **Target(s):** carboxylesterase (1); cholinesterase (2,3); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (4). 1. Siddalinga Murthy & Veerabhadrapa (1996) *Insect Biochem. Mol. Biol.* **26**, 287. 2. Watanabe & Sharma (1972) *Toxicol. Appl. Pharmacol.* **23**, 692. 3. Sharma, Shupe & Potter (1973) *Toxicol. Appl. Pharmacol.* **24**, 645. 4. Brown & Sharma (1976) *Experientia* **32**, 1540.

**Mexiletine**

This class 1B antiarrhythmic drug (FW<sub>free-base</sub> = 179.26 g/mol; CAS 5370-01-4; Soluble to 100 mM in water and to 100 mM in DMSO; pK<sub>a</sub> = 9.0; Symbol: Mex), also known by the code name Ko 1173 and the systematic name 1-(2,6-dimethylphenoxy)-2-propanamine hydrochloride, blocks the rapid inward sodium current responsible for Phase 0 of the action potential (1-4). It is primarily a use-dependent sodium channel blocker, showing IC<sub>50</sub> values of 75.3 and 23.6 μM for tonic and use-dependent block respectively. Mexiletine is used to treat ventricular arrhythmias. It is a neuroprotective and antimyotonic agent that has also been found to be effective for myotonia and neuropathic pain. Mexiletine, *p*-hydroxy-mexiletine (PHM), hydroxy-methyl-mexiletine (HMM), *N*-hydroxy-mexiletine (NHM) (phase I reaction products) and *N*-carboxyloxy-β-D-glucuronide (NMG) (phase II reaction product) gave sodium currents with depolarizing pulses from different holding potentials (HP=-140, -100, -70 mV) and stimulation frequencies (0.25, 0.5, 1, 2, 5, 10 Hz) using voltage-clamp methods. Although less potent than Mex, its phase I metabolites tested demonstrated similar pharmacological behaviour and may well contribute to its clinical profile (4). **Target(s):** Na<sup>+</sup> channel (1-4); monoamine oxidase (1-3). 1. Clarke, Lyles & Callingham (1982) *Biochem. Pharmacol.* **31**, 27. 2. Sicouri, Antzelevitch, Heilmann & Antzelevitch (1997) *J. Cardiovasc. Electrophysiol.* **8**, 1280. 3. Labbe & Turgeon (1999) *Clin. Pharmacokinet.* **37**, 361. 4. Monk & Brogden (1990) *Drugs* **40**, 374. 5. De Bellis, De Luca, Rana, et al. (2006) *Brit. J. Pharmacol.* **149**, 300. 6. Eriksson & Fowler (1984) *Naunyn Schmiedeberg's Arch. Pharmacol.* **327**, 273. 7. Callingham (1977) *Brit. J. Pharmacol.* **61**, 118P.

**MFZ 10-7**

This metabotropic glutamate receptor allosteric inhibitor (FW<sub>HCl-salt</sub> = 272.70 g/mol; CAS 1224431-15-5; Solubility: 100 mM in DMSO or Ethanol), also named 3-fluoro-5-[2-(6-methyl-2-pyridinyl)ethynyl]benzonitrile hydrochloride, targets the mGlu<sub>5</sub> receptor, K<sub>i</sub> = 0.67 nM, potently inhibiting mGlu<sub>5</sub> glutamate-mediated calcium mobilization, IC<sub>50</sub> = 1.22 nM (1,2). MFZ 10-7 also suppresses cocaine-taking and cocaine-seeking behavior in rats (3). 1. Alagille, et al. (2011) *Bioorg. Med. Chem. Lett.* **21**, 3243. 2. Keck, et al. (2012) *ACS Med. Chem. Lett.* **3**, 544. 3. Keck, et al. (2014) *Addict. Biol.* **19**, 195.

**MG-132**

This peptidomimetic proteasome inhibitor (FW = 475.62 g/mol; CAS 133407-82-6; Solubility: 90 mg/mL DMSO; <1 mg/mL Water), also known as carbobenzoxy-leucyl-leucyl-leucinal (or zLLLal) and systematically as benzyl (S)-4-methyl-1-((S)-4-methyl-1-((S)-4-methyl-1-oxopentan-2-ylamino)-1-oxopentan-2-ylcarbamate, targets the 20S proteasome, with IC<sub>50</sub> value of 100 nM. MG-132 inhibits calpain with IC<sub>50</sub> value of 1.2 μM and induces neurite outgrowth in PC12 cells, optimally at 20 nM, with 500x greater potency than ZLLal (1). MG-132 (10 μM) inhibits TNF-α-induced NF-κB activation, interleukin-8 (IL-8) gene transcription, and IL-8 protein release in A549 cells by inhibition of proteasome-mediated IκBα degradation (2) MG-132 treatment potently induces p53-dependent apoptosis in KIM-2 cells by 26S proteasome inhibition (3). (See also Syringolin A) 1. Tsubuki, et al. (1996) *J. Biochem.* **119**, 572. 2. Fiedler, et al. (1998) *Am. J. Respir. Cell Mol. Biol.* **19**, 259. 3. MacLaren AP, et al. (2001) *Cell Death Differ.* **8**, 210.

**MHPT**

This novel synthetic tubulin polymerization inhibitor (FW = 326.37 g/mol), also named 2-((4-hydroxyphenyl)imino)-5-(3-methoxybenzylidene)thiazolidin-4-one, targets microtubule self-assembly (IC<sub>50</sub> = 6.3 μM), exhibiting selective cytotoxic action against rhabdomyosarcoma, both *in vitro* and *in vivo*. MHPT inhibited 50% of the growth of the rhabdomyosarcoma cell lines RD and SJ-RH30 at 0.44 μM and 1.35 μM, respectively, while displaying no obvious toxicity against normal human fibroblast cells at 100 μM. MHPT treatment leads to rhabdomyosarcoma cell cycle arrest at the G<sub>2</sub>/M phase, followed by apoptosis. 1. Mu, Liu, Li, et al. (2015) *PLoS One* **10**, e0121806.

**MHY1485**

This potent, cell-permeable mTOR activator (FW = 387.39 g/mol; CAS 326914-06-1), also known as 4,6-dimorpholino-*N*-(4-nitrophenyl)-1,3,5-triazin-2-amine, potently inhibits autophagy. MHY1485 suppresses the basal autophagic flux in cells experiencing starvation, a strong physiological inducer of autophagy. The levels of p62 and beclin-1 do not change significantly after treatment with MHY1485. Decreased colocalization of autophagosomes and lysosomes in confocal microscopic images revealed MHY1485's inhibitory effect on lysosomal fusion during starvation-induced autophagy. These effects of MHY1485 led to the accumulation of LC3II and enlargement of the autophagosomes in a dose- and time-dependent manner. MHY1485 induces mTOR activation and show

a higher docking score than PP242, a well-known ATP-competitive mTOR inhibitor. 1. Choi, Park, Park, *et al.* (2012) *PLoS One* 7, e43418.

### MI-3

This protein-protein interaction inhibitor (FW = 375.55 g/mol; CAS 1271738-59-0), also named Menin-MLL Inhibitor and 4-[4-(4,5-dihydro-5,5-dimethyl-2-thiazolyl)-1-piperazinyl]-6-(1-methylethyl)thieno[2,3-*d*]pyrimidine, targets the binding of menin to Mixed Lineage Leukemia, or MLL (IC<sub>50</sub> = 56 nM), an interaction that plays a critical role in the viability of acute leukemias (1). This disruptor was identified by high-throughput screening, using 288,000 small molecule probes. Two aminoglycoside antibiotics (neomycin and tobramycin) are also inhibitors of menin-MLL interactions, albeit with much higher K<sub>i</sub> values of 18.8 and 59.9 μM, respectively (2). Inhibition of this interaction therefore represents promising therapeutic strategy for combatting MLL leukemias. 1. He, Senter, Pollock, *et al.* (2014) *J. Med. Chem.* 57, 1543. 2. Li, Zhou, Geng, *et al.* (2014) *Bioorg. Med. Chem. Lett.* 24, 2090.

### MI 192

This potent and selective HDAC inhibitor (FW = 383.44 g/mol; CAS 1415340-63-4; Soluble to 100 mM in DMSO), also named *N*-(2-aminophenyl)-4-[(3,4-dihydro-4-methylene-1-oxo-2(1H)-isoquinolinyl)-methyl]benzamide, targets histone deacetylases HDAC2 (IC<sub>50</sub> = 16 nM) and HDAC1 (IC<sub>50</sub> = 30 nM), exhibiting >250-fold selectivity over other HDAC isoforms. First-generation HDAC inhibitors (*e.g.*, butyrate and valproate) are simple short chain aliphatic compounds with a broad spectrum of activity against HDACs. MI-192 induces differentiation and was cytotoxic through promotion of apoptosis of leukemia cell lines *in vitro* (1). MI192 also inhibits TNF production at high concentrations and dose-dependently inhibited IL-6 in peripheral blood mononuclear cells (PBMCs) from RA patients, but not healthy PBMCs, when tested across a dose range of 5 nM to 10 μM (2). 1. Boissinot, Inman, Hempshall, *et al.* (2012) *Leuk. Res.* 36, 1304. 2. Gillespie, Savic, Wong, *et al.* (2012) 64, 418.

### (S)-Mianserin

This tetracyclic antidepressant (FW = 264.37 g/mol; CAS 24219-97-4), also known as Depnon<sup>®</sup>, Lantanon<sup>®</sup>, Lerivon<sup>®</sup>, Lumin<sup>®</sup>, Norval<sup>®</sup>, Tolvon<sup>®</sup>, Tolmin<sup>®</sup>, and (±)-2-methyl-1,2,3,4,10,14b-hexahydrodibenzo[*c,f*]pyrazino[1,2-*a*]azepine, is an antagonist/inverse agonist of the H<sub>1</sub> receptors (K<sub>i</sub> = 1 nM), 5-HT<sub>1A</sub> receptors (K<sub>i</sub> ≈ 1500 nM), 5-HT<sub>1F</sub> receptors (K<sub>i</sub> = 13 nM), 5-HT<sub>2A</sub> receptors (K<sub>i</sub> = 3 nM), 5-HT<sub>2B</sub> receptors (K<sub>i</sub> = 10 nM), 5-HT<sub>2C</sub> receptors (K<sub>i</sub> = 3 nM), 5-HT<sub>6</sub> receptors (K<sub>i</sub> = 70 nM), 5-HT<sub>7</sub> receptors (K<sub>i</sub> = 60 nM), α<sub>1</sub>-adrenoceptors (K<sub>i</sub> = 70 nM), α<sub>2A</sub>-adrenoceptors (K<sub>i</sub> ≈ 5 nM), and α<sub>2A</sub>-adrenoceptors (K<sub>i</sub> ≈ 30 nM). Such broad action may also accounts for

why mianserin also exhibits a range of anxiolytic, hypnotic, antiemetic, orexigenic, and antihistamine effects. That serotonin also plays a role in migraine, nociception, dumping syndrome, vascular disease, and hypertension, also suggests why mianserin has broad action. Used in the treatment of depressive illness and depression associated with anxiety, mianserin combines antidepressant activity with a sedative effect and has an EEG and clinical activity profile similar to that of amitriptyline (1). Its overall efficacy is comparable to amitriptyline and imipramine in depressive illness, but causes significantly fewer anticholinergic side effects and appears less likely than these drugs to cause serious cardiotoxicity on overdosage (1). Abrupt discontinuation often provokes withdrawal effects that can include depression, anxiety, panic attacks, decreased appetite, insomnia, diarrhea, nausea and vomiting. (**See also Amitriptyline; Fibanserin; Imipramin**) (Although the racemic mixture is most often used as a drug, *S*-(+)-mianserin is some 200 to 300 times more active than (*R*)-(-)-mianserin.) 1. Brogden, Heel, Speight & Avery (1978) *Drugs* 16, 273.

### Mibefradil

This antihypertensive agent (FW<sub>free-base</sub> = 495.64 g/mol; CAS 116666-63-8), also known as Ro 40-5967, is a nonselective T-type calcium channel blocker that was withdrawn from commerce amid evidence of dangerous and even fatal interactions with at least 25 other drugs, including common antibiotics, antihistamines, and cancer drugs. **Target(s):** Ca<sup>2+</sup> channel (1-5); CYP3A (6,7); Na<sup>+</sup> channels (8). 1. Mehrke, Zong, Flockner & Hofmann (1994) *J. Pharmacol. Exp. Ther.* 271, 1483. 2. Fang & Osterrieder (1991) *Eur. J. Pharmacol.* 196, 205. 3. Osterrieder & Holck (1989) *J. Cardiovasc. Pharmacol.* 13, 232. 7. Wandel, Kim, Guengerich & Wood (2000) *Drug Metab. Dispos.* 28, 895. 8. McNulty & Hanck (2004) *Mol. Pharmacol.* 66, 1652.

### Micafungin

This semisynthetic echinocandin antifungal (FW<sub>free-acid</sub> = 1270.29 g/mol; CAS 235114-32-6; water-soluble lipopeptide), also known as Mycamine<sup>™</sup> and FK463, is an intravenously administered drug that is effective against *Candida* and *Aspergillus* species. **Primary Mode of Action:** Micafungin inhibits β-1,3-glucan, an essential component in the formation of fungal cell walls. It also enhances the polymorphonuclear leukocytes oxidative burst in a dose-dependent manner, especially when PMN are pretreated with granulocyte-macrophage colony-stimulating factor. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** CYP3A4, mildly inhibited (1,2); 1,3-β-glucan synthase (3,4). 1. Hebert, Blough, Townsend, *et al.* (2005) *J. Clin. Pharmacol.* 45, 1018. 2. Sakaeda, Iwaki, Kakumoto, *et al.* (2005) *J. Pharm. Pharmacol.* 57, 759. 3. Maesaki,

Hossain, Miyazaki, *et al.* (2000) *Antimicrob. Agents Chemother.* **44**, 1728.  
4. Georgopapadakou (2001) *Expert Opin. Investig. Drugs* **10**, 269.

#### Michellamine B

This antioxidant and radical scavenger (FW<sub>free-base</sub> = 756.90 g/mol; Code Name: NSC 661755) from *Ancistrocladus korupensis* found in the Korup rain forest of Cameroon, inhibits HIV-1- and -2 induced cell killing. **Target(s):** bontoxilysin (1); DNA-directed DNA polymerase (2); DNA polymerases  $\alpha$  and  $\beta$  (2); HIV reverse transcriptase (2); 12-lipoxygenase, or arachidonate 12-lipoxygenase (3); protein kinase C (4); RNA-directed DNA polymerase (2). 1. Burnett, Schmidt, Stafford, *et al.* (2003) *Biochem. Biophys. Res. Commun.* **310**, 84. 2. McMahon, Currens, Gulakowski, *et al.* (1995) *Antimicrob. Agents Chemother.* **39**, 484. 3. Deschamps, Gautschi, Whitman, *et al.* (2007) *Bioorg. Med. Chem.* **15**, 6900. 4. White, Chao, Ross, *et al.* (1999) *Arch. Biochem. Biophys.* **365**, 25.

#### Miconazole

This antifungal agent (FW = 416.13 g/mol; CAS 22916-47-8; Soluble to 100 mM in DMSO and to 10 mM in Ethanol), also known as Desenex™ and (*RS*)-1-(2-(2,4-dichlorobenzoyloxy)-2-(2,4-dichlorophenyl)ethyl)-1*H*-imidazole, exerts its action against *Candida* and those causing athlete's foot, ringworm, jock itch, oral or vaginal thrush, by inhibiting synthesis of ergosterol, a fungal membrane component critical for growth and proliferation. Miconazole and warfarin are CYP2C9 substrates and thus retard each other's hydroxylation. The net effect is that warfarin exerts a greater hypothermic effect in miconazole's presence. In Ca<sup>2+</sup> signaling research, miconazole has also been employed as a partial blocker for store-operated Ca<sup>2+</sup> entry. **Mode of Action:** Although lanosterol 14 $\alpha$ -demethylase (*or* CYP51) is widely distributed, it plays an essential role in mediating membrane permeability in fungi, with CYP51 catalyzing demethylation of lanosterol to create an essential precursor for ergosterol. The latter alters the permeability and rigidity of plasma membranes in a manner akin to that of cholesterol in animals. Many antifungal medications therefore target 14 $\alpha$ -demethylase to limit fungal infections. **Target(s):** abietadiene hydroxylase (1); abietadienol hydroxylase (1); aromatase, *or* CYP19 (2,3); CYP1A1 (4); CYP3A4 (5); ATPase, plasma membrane (6); 7-deoxyloganin 7-hydroxylase (7); 1,25-dihydroxycholecalciferol metabolism (8); 8-dimethylallylnaringenin 2'-hydroxylase (9); F<sub>1</sub> ATPase, mitochondrial, *or* ATP synthase (10); H<sup>+</sup>-exporting ATPase (11-13); (*R*)-limonene 6-monooxygenase (14); (*S*)-limonene 3-monooxygenase, weakly inhibited (15); (*S*)-limonene 6-monooxygenase (15,16); (*S*)-limonene 7-monooxygenase, weakly inhibited (15); nitric oxide dioxygenase (17-19); steroid 11 $\beta$ -monooxygenase (20); sterol *O*-acyltransferase, *or* cholesterol *O*-acyltransferase, ACAT (21); sterol 14-demethylase, *or* CYP51 (22,23); tabersonine 16-hydroxylase (24); taxadiene 5 $\alpha$ -hydroxylase (25); partial blocker for store-operated Ca<sup>2+</sup> entry, such as in HL-60 cells (26), astrocytes (27), megakaryoblastic cells (28), and *Xenopus* oocytes (29). 1. Funk & Croteau (1994) *Arch. Biochem. Biophys.* **308**, 258. 2. Doody, Murry & Mason (1990) *J. Enzyme Inhib.* **4**, 153. 3. Moslemi & Serailini (1997) *J. Enzyme Inhib.* **12**, 241. 4. #### Microcin C<sub>7</sub>

This toxin is a linear heptapeptide antibiotic (MW = 1171 Da; CAS 1403-96-9) is bacteriocidal by virtue of its inhibition of aspartyl-tRNA synthetase, thereby stalling the ribosomal protein translation machinery *in vivo* and *in vitro* (1-3). Microcin C<sub>7</sub> is effective against *Klebsiella*, *Escherichia coli*, *Shigella*, *Salmonella*, and *Yersinia*. The required aminopropylation uses *S*-adenosyl methionine to transfer 3-amino-3-carboxypropyl group onto a phosphate of an intermediate consisting of adenylated heptapeptide (4). 1. Gonzalez-Pastor, San Millan, Castilla & Moreno (1995) *J. Bacteriol.* **177**, 7131. 2. Guijarro, Gonzalez-Pastor, Baleux, *et al.* (1995) *J. Biol. Chem.* **270**, 23520. 3. #### Micrococcin P<sub>1</sub>

This protein biosynthesis inhibitor and antibiotic (FW<sub>Micrococcin-P1</sub> = 1151.29 g/mol; CAS 1392-45-6; Symbol: MC-LR) from *Staphylococcus equorum* Strain WS 2733 (*Micrococcus*) from French Raclette cheese species consists of two components, P<sub>1</sub> and P<sub>2</sub>, with the former the major component. The antibiotic binds to the ribosomal protein L11 binding domain of 23S ribosomal RNA, preventing the binding of elongation factor G to the ribosome. **Target(s):** GTP diphosphokinase (1); protein biosynthesis (2-8). 1. Knutsson Jenvert & Holmberg Schiavone (2005) *FEBS J.* **272**, 685. 2. Pestka (1974) *Meth. Enzymol.* **30**, 261. 3. Jiménez (1976) *Trends Biochem. Sci.* **1**, 28. 4. Otaka & Kaji (1974) *Eur. J. ### Microcystin LR

This cyclo-heptapeptide antibiotic (FW = 995.17 g/mol; CAS 101043-37-2), isolated from *Microcystis aeruginosa*, is a potent inhibitor of protein phosphatases types 1 and 2A (IC<sub>50</sub> = 0.04 nM for phosphatase 2A and 1.7 nM for phosphatase 1). It is also a weak inhibitor of protein phosphatase 2B (IC<sub>50</sub> = 200 nM). The microcystins, also known as cyanoginosins, are among the most important natural toxins of cyanobacterial origin. In cultured hepatocytes, Microcystin-LR significantly increases the expression of p53 and Bax, and decreases the expression of Bcl-2, which are involved in the regulation of Microcystin-LR-induced apoptosis (25). **Other Targets:** phosphoprotein phosphatase (1-23); [phosphorylase] phosphatase (1-7); protein phosphatase type 1 (1-7,11,14,15,19); protein phosphatase type 2A (1,3-6,12,13,15,20,22); protein phosphatase type 3 (23); protein phosphatase type 4 (8,9,15,17); protein phosphatase type 5 (10,15). MC-LR also increases Tau phosphorylation, with the dissociation of phosphorylated Tau from the cytoskeleton (24). MC-LR-induced Tau phosphorylation is suppressed by an activator of PP2A and by an inhibitor of p38 MAPK. VASP was also hyperphosphorylated upon MC-LR exposure, altering its cellular localization; its phosphorylation was unaffected by PP2A activators. Such data suggest that phosphorylated Tau is regulated by p38 MAPK, possibly as a consequence of PP2A inhibition (24). **IUPAC:** cyclo[2,3-didehydro-N-methylalanyl-D-alanyl-L-leucyl-(3S)-3-methyl-D-β-aspartyl-L-arginyl-(2S,3S,4E,6E,8S,9S)-3-amino-9-methoxy-2,6,8-trimethyl-10-phenyl-4,6-decadienyl-D-γ-glutamyl]. 1. ### MicroRNAs

These small non-coding RNAs (MW = 6-8 kDa; Length: ~22 bases), also called small interfering RNA (or siRNA), bind to 3'-untranslated region (3'-UTR) of a complementary mRNA sequence, regulating post-transcriptional mRNA expression and resulting in translational repression and gene silencing. Animal genomes contain numerous small genes coding for micro RNAs that are diverse, both in their sequence and expression patterns. MicroRNAs are thus widespread negative regulators of gene expression and playing pivotal roles in regulating cell proliferation, cancer, and apoptosis. See *PubMed listing of known microRNAs* (<http://www.ncbi.nlm.nih.gov/gene/?term=microRNA>).

### Micrurotoxins

These first-in-class toxins, designated MmTX1 (MW = 7.2 kDa) and MmTX2 (MW = 7.2 kDa), from Costa Rican coral snake venom, bind to GABA<sub>A</sub> receptors at sub-nM concentrations, allosterically increasing GABA<sub>A</sub> receptor susceptibility to agonist, thereby potentiating receptor opening as well as desensitization, possibly by interacting at the α/β interface. Hippocampal neuron excitability measurements reveal toxin-induced transitory network inhibition, followed by an increase in spontaneous activity. MmTX1 and MmTX2 injections into mouse brain reduce basal activity between intense seizures. 1. Rosso, Schwarz, Diaz-Bustamante, et al. (2015) *Proc. Natl. Acad. Sci. U.S.A.* **112**, E891.

### Midazolam

This benzodiazepine-class drug (FW = 325.77 g/mol; CAS 59467-70-8) is used to treat acute seizures, moderate to severe insomnia, and to induce sedation and amnesia prior to medical procedures. Midazolam has a similar pharmacologic potency and broad therapeutic range as diazepam, exerting profound anxiolytic, amnesic, hypnotic, anticonvulsant, skeletal muscle relaxant, and sedative properties (1-3). With its fast recovery time, midazolam is often used as a premedication for sedation, and less commonly for inducing/maintaining anesthesia. Its anterograde amnesia property also commends its use as a premedication to inhibit unpleasant memories of surgery. Like classic benzodiazepines, midazolam enhances the inhibitory action of γ-aminobutyric acid by increasing the flow of chloride ions. When given intravenously, midazolam is rapidly distributed throughout the body (t<sub>1/2</sub> = 6-15 minutes, drowsiness commencing in 3 minutes (compared to ~15 minutes upon oral administration)). Relative to other benzodiazepines, midazolam exhibits the shortest recovery time and a high metabolic clearance. When used in the U.S. as part of a three-drug cocktail: midazolam renders the condemned unconscious, at which time vecuronium bromide and potassium chloride are administered to arrest breathing and heart beat. (In the U.S., midazolam is classified as a non-narcotic agent, with low potential for abuse.) **Target(s):** Midazolam dose-dependently inhibits K<sub>v</sub>1.5 current in an HEK cell line (IC<sub>50</sub> = 17 μM) and in *Xenopus* oocytes (IC<sub>50</sub> = 104 μM) (4). The inhibitory effects of midazolam on cloned hERG (human Ether-à-go-go-Related Gene) potassium channels have been examined using double-electrode voltage clamp on *Xenopus* oocytes heterologously expressing hERG channels, and, at 200 μM, midazolam significantly reduces the hERG activation current by 43 % and the hERG tail current amplitude by 52 % (5). Midazolam also has protective effects on the proliferation and apoptosis of astrocytes via JAK2/STAT3 signal pathway *in vitro* (6). 1. Pieri, Schaffner, Scherschlicht, et al. (1981) *Arzneimittelforschung.* **31**, 2180. 2. Carlen, Gurevich, Davies, Blaxter & O'Beirne (1985) *Can. J. Physiol. Pharmacol.* **63**, 831. 3. Kanto & Allonen (1983) *Int. J. Clin. Pharmacol. Liu, You, Tu, et al. (2015) *Cell Physiol. Biochem.* **35**, 126.

**Midodrine****Midodrine****Desglymidodrine**

This vasopressor/antihypertensive agent (FW = 254.28 g/mol; CAS 133163-28-7), also known as Amatine<sup>®</sup>, ProAmatine<sup>®</sup>, Gutron<sup>®</sup>, and (*R,S*)- *N*-[2-(2,5-dimethoxyphenyl)-2-hydroxyethyl]glycinamide, is used to treat dysautonomia and orthostatic hypotension. Midodrine is actually a prodrug of the active metabolite, desglymidodrine (FW = 197.23 g/mol; CAS 3600-87-1; IUPAC: 1-(2',5'-dimethoxyphenyl)-2-aminoethanol), which is an  $\alpha_1$ -receptor agonist and exerts its actions via activation of the  $\alpha$ -adrenergic receptors of the arteriolar and venous vasculature. Accordingly, midodrine increases vascular tone and elevates blood pressure. 1. Pittner & Turnheim (1974) *Arch. Int. Pharmacodyn. Ther.* **207**, 180. 2. McTavish & Goa (1989) *Drugs* **38**, 757.

**Mifepristone**

This selective progesterone receptor modulator, or SPRM (FW = 429.60 g/mol; CAS 84371-65-3; IUPAC: 11β-[*p*-(dimethylamino)phenyl]-17β-hydroxy-17-(1-propynyl)estra-4,9-dien-3-one), also known by the proprietary name Mifeprex<sup>®</sup> and more famously as RU-486 (previously, RU 38486), is a steroid analogue that exhibits great affinity for the progesterone receptor, but lacks progesterone activity (1). As a strong antagonist of both progesterone and glucocorticoid receptors in the ovary, RU-486 blocks progesterone effects. Indeed, oral administration interrupts the luteal phase of the menstrual cycle and early pregnancy (1-3). At all concentrations tested in castrated adult female cynomolgus monkeys, menstruation follows RU 486 injection within 48 hours and persists through 72 hours (4). A combination of the antiprogesterone mifepristone and an exogenous prostaglandin (See *Misoprostol*) given by intramuscular injection or intravaginal pessary is a highly effective means of inducing abortion in early pregnancy (5). Such properties commended their combined action as an oral emergency contraceptive and abortifacient, and in an FDA-approved protocol, mifeprex ends most early pregnancies within seven weeks after the start of the last menstrual period. The stereochemical antipode of RU-486 lacks antiprogesterone nor antigluco-corticoid activity (6), making it a valuable control in ligand binding experiments. RU 486 also elevates plasma ACTH, cortisol, and Plasma arginine vasopressin (AVP) concentrations in a manner that is both dose and time dependent (7) After RU 486 treatment, ACTH release occurs at an order of magnitude lower dose than did AVP release, and plasma AVP changes are glucocorticoid dependent (7). 1. Herrmann, Wyss, Riondel, *et al.* (1982) *C. R. Seances Acad. Sci. III.* **294**, 933. 2. Herrmann, Wyss, Riondel, *et al.* (1982) *C. R. Seances Acad. Sci. III.* **296**, 591. 3. Schreiber, Hsueh & Baulieu (1983) *Contraception* **28**, 77. 4. Healy, Baulieu & Hodgen (1983) *Fertil. Steril.* **40**, 253. 5. Norman, Thong & Baird (1991) *Lancet* **338**, 1233. 6. **Milacemide**

This glycinamide derivative and anti-epileptic (FW<sub>free-base</sub> = 144.22 g/mol; CAS 76990-56-2), also known as 2-*n*-pentylaminoacetamide, is converted to the inhibitory amino acid neurotransmitter, glycine, by monoamine oxidase B ( $K_m$  = 49  $\mu$ M for the rat liver mitochondrial enzyme). A reversible inhibition of monoamine oxidase A is also observed at higher concentrations. **Target(s):** amine oxidase (flavin-containing) (1-4). 1. Silverman (1995) *Meth. Enzymol.* **249**, 240. 2. O'Brien, Tipton, McCrodden & Youdim (1994) *Biochem. Pharmacol.* **47**, 617. 3. Truong, Diamond, Pezzoli, Mena & Fahn (1989) *Life Sci.* **44**, 1059. 4. Janssens de Varebeke, Pauwels, Buyse, *et al.* (1989) *J. Neurochem.* **53**, 1109.

**Millipede Toxins**

These cytotoxic substances are produced by one or more of 8,000 different species of multi-legged, worm-like arthropods (Class: *Diplopoda*) and include hydrochloric acid, hydrogen cyanide, various organic acids, phenol, cresols, benzoquinones, and hydroquinones. Some large species actually eject secretions over distances of up to 80 cm. One such substance, Ubiquinone-O (FW = 182.17 g/mol; CAS 605-94-7; IUPAC Name: 2,3-dimethoxy-5-methyl-1,4-benzoquinone) forms an unstable hydroquinone intermediate in the nonenzymatic oxidation of ascorbate and epinephrine and damages neuroblastoma cells (1,2). 1. Sugihara, Watanabe, Kawamatsu & Morimoto (1972) *Justus Liebigs Ann. Chem.* **763**, 109. 2. Roginsky, Bruchelt & Bartuli (1998) *Biochem. Pharmacol.* **55**, 85.

**Milnacipran**

This antidepressant (FW = 246.35 g/mol; CAS 92623-85-3), also known as Ixel<sup>®</sup>, Savella<sup>®</sup>, Dalcipran<sup>®</sup>, Toledomin<sup>®</sup>, midalcipran, and (1*R*\*,2*S*\*)-2-(aminomethyl)-*N,N*-diethyl-1-phenylcyclopropane carboxamide, is a serotonin-norepinephrine reuptake inhibitor (or SNRI), with IC<sub>50</sub> values of 203 and 100 nM, respectively, for serotonin and norepinephrine, but without effect on dopamine reuptake (1). Milnacipran is used to treat fibromyalgia and major depressive disorder. This drug is a racemate, with one enantiomer more active (See *Levomilnacipran*). Midalcipran is largely eliminated in the urine as parent drug or as a glucuronide (2). **Target(s):** Midalcipran does not inhibit monoamine oxidase, either *in vitro* or *in vivo*, and, in contrast to imipramine and desipramine, it showed no affinity for  $\alpha$ - or  $\beta$ -adrenoceptors, muscarinic, histaminergic H<sub>1</sub>, dopaminergic D<sub>2</sub> or serotonergic 5-HT<sub>2</sub> receptors, suggesting a general absence of anticholinergic, sedative and other side-effects (1). 1. Moret, Charveron, Finberg, Couzinier & Briley (1985) *Neuropharmacol.* **24**, 1211. 2. Puzozzo & Leonard (1996) *Int. Clin. Psychopharmacol.* **4**, 15.

**Milrinone**

This vasodilator and cardiotoxic (FW = 211.22 g/mol; CAS 78415-72-2), also known as 1,6-dihydro-2-methyl-6-oxo-(3,4'-bipyridine)-5-carbonitrile, is a competitive inhibitor phosphodiesterase III ( $IC_{50}$  = 0.15  $\mu$ M) and is employed to treat heart failure and reduce pulmonary hypertension. At doses to 100  $\mu$ M, milrinone is without effect on human cardiac cAMP-dependent protein kinase and adenylate cyclase. Moreover, cyclicAMP PDEs from human kidney, liver and lung are not readily inhibited, as  $IC_{50}$  values for cAMP-PDEs from these tissues are about 7-30x higher than for the heart isozyme. Intravenous administration of milrinone produces improves hemodynamics, reducing systemic vascular resistance as well as left and right heart filling pressures (1). There is also a downward displacement of the left ventricular pressure-volume curve and acceleration of isovolumic relaxation. **Target(s):** 3',5'-cyclic-GMP phosphodiesterase (2); 3',5'-cyclic-nucleotide phosphodiesterase (2-9); phosphodiesterase 1 (2); phosphodiesterase 3A (2); phosphodiesterase 3B (2); phosphodiesterase 4 (2); phosphodiesterase 5 (2); phosphodiesterase 7 (2). 1. ### Miltefosine

This lysophosphatidylcholine derivative and broad-spectrum antibiotic (FW<sub>inner-salt</sub> = 407.57 g/mol; CAS 58066-85-6), also known as hexadecylphosphocholine and choline hexadecyl phosphate, is a phospholipid analogue and antitumor agent that acts on cell membranes. Miltefosine also inhibits inositol phosphate formation and phosphatidylcholine biosynthesis. **Antibiotic Spectrum:** Miltefosine is primarily used in the treatment of visceral and New World cutaneous leishmaniasis, but is also available under an expanded-access IND protocol to treat infections arising from free-living amoeba, including primary amoebic meningoencephalitis caused by *Naegleria fowleri* and granulomatous amoebic encephalitis caused by *Balamuthia mandrillaris*, as well as infections by various *Acanthamoeba* species. **Target(s):** CTP:choline-phosphate cytidyltransferase translocation (1); cytochrome-c oxidase (2); glyceryl-ether monoxygenase (3,4); phosphatidylcholine biosynthesis (5); phosphatidylinositol 3-kinase (6); phosphoethanolamine N-methyltransferase (7); phosphoinositide phospholipase C (8-10); phospholipase A<sub>2</sub> (11); phospholipase C (9,12); phosphoserine phosphatase (13); protein kinase C (8,14). 1. ### Mimosine

This amino acid (FW = 198.18 g/mol; CAS 500-44-7), also known as leucenol and 3-[3-hydroxy-4-oxo-1-(4H)-pyridinyl]alanine, is an iron chelator that inhibits DNA replication in mammalian cells. Mimosine is also a folate antagonist and its effects are cell-specific. Large quantities of mimosine are found in species of the legume genera *Leucena* and *Mimosas*.

**Target(s):** aromatic-L-amino-acid decarboxylase, or dopa decarboxylase, weakly inhibited (1); aspartate aminotransferase, pig heart (2); catechol oxidase (14,17,20,22); deoxyhypusine monoxygenase (3-6); L-dopachrome isomerase (7); dopamine  $\beta$ -hydroxylase (8); peptidylglycine  $\alpha$ -amidating enzyme (9); polyphenol oxidase (20); procollagen-proline 4-dioxygenase (4); ribonucleotide reductase (10); serine hydroxymethyltransferase, or glycine hydroxymethyl-transferase (11); tyrosinase, or monophenol monoxygenase, by L-isomer (8,12-17,21); tyrosine decarboxylase (18); tyrosine 3-monoxygenase (19). 1. ### Minodronate

This bisphosphonate-based anti-osteoporosis drug (FW<sub>free-acid</sub> = 322.15 g/mol; CAS 180064-38-4), also named (1-hydroxy-2-imidazo[1,2-a]pyridin-3-yl-1-phosphonoethyl)phosphonate and YM-529, blocks osteoclast-mediated bone resorption by inhibiting *trans*-hexaprenyltransferase and geranyltransferase. The most likely direct target is podosome assembly, a processes that assembles an actin filament-rich ring structure that localizes the proton-extruding V-ATPase for acidification and demineralization. Protein prenylation is required for prenylation of Rac and Rho, two small G-proteins that regulate actin systems. Minodronate is also a potent inducer of apoptosis in human myeloma cells. **Target(s):** dimethylallyltransferase, or geranyl-diphosphate synthase (1); geranyltransferase, or farnesyl-diphosphate synthase (2-4); *trans*-hexaprenyl-transferase, or geranylgeranyl-diphosphate synthase (5). 1. ### Minoxidil

This antihypertensive agent (FW = 209.25 g/mol; CAS 38304-91-5), also known as 2,4-diamino-6-piperidinopyrimidine-3-oxide, is vasodilator that activates ATP-activated potassium channels, bring about hyperpolarization. Minoxidil stops hair loss, by stimulating regrowth. Its mode of action is unclear. **Target(s):** prostaglandin-I synthase, or prostacyclin synthase (1); procollagen-lysine 5 dioxygenase, or lysyl hydroxylase (2,3); uridine kinase (4) **1.** Haurand & Ullrich (1992) *Front. Biotransform.* **6**, 183. **2.** Saika, Ooshima, Hashizume, *et al.* (1995) *Graefes Arch. Clin. Exp. Ophthalmol.* **233**, 347. **3.** Murad, Walker, Tajima & Pinnell (1994) *Arch. Biochem. Biophys.* **308**, 42. **4.** Macdonald, Walker, Assef & Duggan (1990) *Clin. Exp. Pharmacol. Physiol.* **17**, 287.

### Mipomersen
