This second-generation anti-sense oligonucleotide inhibitor (FW = 7595 g/mol; CAS 629167-92-6 (sodium salt); Tradename = Kynamro® Code Name = ISIS 301012) is as an adjunct to lipid-lowering medications and diet to reduce low-density lipoprotein-cholesterol (LDL-C), apolipoprotein B (apo B), total cholesterol (TC), and non-high density lipoprotein-cholesterol (non-HDL-C) in homozygous familial hypercholesterolemia (HoFH) patients. **Complete Sequence:** G\*-C\*-C\*-U\*-C\*-dA-dG-dT-dC-dT-dG-dmC-dT-dmC-G\*-C\*-A\*-C\*-C\*, where stabilizing modifications are: d = 2'-deoxy-; m = methyl-; and \* = 2'-O-(2-methoxyethyl)-groups, with all nucleotides joined by 3'→5' phosphorothioate linkages. The indicated chemical modifications render the drug resistant to nuclease degradation, allowing it to be administered on a once-weekly schedule. In January 2013, the FDA approved Kynamro as a once-weekly subcutaneous injection for use as an adjunct to maximally tolerated lipid-lowering medications for the treatment of patients with homozygous familial hypercholesterolemia (HoFH). **Mode of Action:** Hybridization of mipomersen by Watson-Crick base-pairing to the apolipoprotein B mRNA results in RNase H-mediated degradation of the mRNA, thereby inhibiting the biosynthesis of the apo B-100 protein (1-3). Mipomersen is a first-in-class mRNA-silencing agent that inhibits synthesis of apoB-100, the core protein for all atherogenic lipids, including low-density lipoprotein cholesterol, or LDL-C (1-3). The agent has been shown to produce significant reductions in LDL-C from baseline values compared with placebo. Inhibition of apolipoprotein B synthesis by antisense methodology represents a novel, effective therapy for reducing LDL cholesterol in HoFH patients who are already receiving lipid-lowering drugs, including high-dose statins. **Delivery & Lack of Pharmacokinetic Side-Effects:** The drug is administered as a single oral dose of 40 mg simvastatin or 10 mg ezetimibe, followed by four 2-hour intravenous doses of 200 mg mipomersen over an 8-day period, with ezetimibe and simvastatin again administered with the last dose of mipomersen sodium. Mipomersen exhibits no clinically relevant pharmacokinetic interactions with the disposition and clearance of simvastatin or ezetimibe, and *vice versa*. Moreover, mipomersen sodium does not inhibit CYP1A2, CYP2C9, CYP2C19, CYP2D6 or CYP3A4. The results support the use of mipomersen sodium in combination with oral lipid-lowering agents. **Note:** ApoB-100 is the principal carrier of 3-iodothyronamine, a naturally occurring derivative of thyroid hormone with biological actions that are distinct from those of T<sub>4</sub> and T<sub>3</sub> (4). **1.** Kastelein, Wedel, Baker, *et al.* (2006) *Circulation* **114**, 1729. **2.** Merki, Graham, Mullick, *et al.* (2008) *Circulation* **118**, 743. **3.** Yu, Geary, Flaim *et al.* (2009) *Clin. Pharmacokinet.* **48**, 39. **4.** Roy, Placzek & Scanlan (2012) *J. Biol. Chem.* **286**, 1790.

### Mirtazapine

This  $\alpha_2$ -adrenoceptor antagonist and specific serotonergic antidepressant, or NaSSA (FW = 265.35 g/mol; CAS 61337-67-5; Soluble to 50 mM in ethanol and to 20 mM in DMSO; IUPAC Name: (±)-2-methyl-1,2,3,4,10,14b-hexahydropyrazino[2,1-a]pyrido[2,3-c][2]benzazepine), known also by the trade name Remeron®, Avanza®, Axit®, Mirtazon®, an Zispin®, is used primarily to treat depression, but is also an antiemetic, anxiolytic, hypnotic, and appetite stimulant. Although mirtazapine has low affinity for 5-HT<sub>1A</sub> receptors, it nonetheless shows 5-HT<sub>1A</sub>-agonistic-like

effects in a conditioned taste aversion test (1). Other studies show that both 5-HT<sub>2</sub> and 5-HT<sub>3</sub> receptors are blocked. The enhancement of both noradrenergic and serotonergic transmission is likely to underlie the therapeutic activity of mirtazapine (1). Mirtazapine also potentiates neurite outgrowth in PC12 pheochromocytoma cells, indicating that this process may mediate part of its beneficial pharmacological effects (2). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** de Boer (1996) *J. Clin. Psychiatry.* **57** (Supplement 4), 19. **2.** Ishima, Fujita & Hashimoto (2004) *Eur. J. Pharmacol.* **727**, 167.

### Misakinolide A

This actin filament-disrupting marine toxin (FW = 1369.80 g/mol; CAS 105304-96-9), also called bistheonellide A, was first isolated from a sponge (*Theonella* sp.) is a 40-membered dimeric lactone macrolide that differs from swinholid A with respect to the size of the macrolide ring. Misakinolide-treated cells tend to accumulate in the G<sub>1</sub> phase. **Primary Mode of Action:** Analytical ultracentrifugation and steady-state fluorescence experiments show that misakinolide A binds simultaneously to two actin subunits with virtually the same affinity ( $K_d \sim 50$  nM) as swinholid A, suggesting that its ring size does not affect actin binding. Unlike swinholid A, misakinolide A does not sever actin filaments; rather, it caps actin filament barbed-ends, or (+)-ends. Misakinolide A has essentially no effect on the off-rate of actin subunits from the (+)-end. Energy-minimized models of misakinolide A and swinholid A are consistent with conservation of identical binding sites in both molecules, but a difference in orientation of one binding site relative to the other is likely to explain why swinholid A has severing activity, whereas misakinolide A only exhibits capping activity. **1.** Terry, Spector, Higa & Bubb (1997) *J. Biol. Chem.* **272**, 7841. **2.** Bubb & Spector (1998) *Meth. Enzymol.* **298**, 26.

### Misoprostol

This synthetic prostaglandin E<sub>1</sub> (PGE<sub>1</sub>) analogue (FW = 382.53; CAS 59122-46-2), also known as SC-29333, Cytotec® and its IUPAC name methyl 7-((1R,2R,3R)-3-hydroxy-2-((S,E)-4-hydroxy-4-methyl-1-enyl)-5-oxocyclopentyl)heptanoate, is widely used to prevent gastric ulcers, to treat missed miscarriage, to induce abortion, especially when combined with RU-486 (See *Mifepristone*), and to induce labor. It inhibits secretion gastric acid secretion by G-protein coupled receptor-mediated inhibition of adenylate cyclase, leading to decreased intracellular cyclic AMP levels and decreased proton pump activity at the apical surface of the parietal cell. Other classes of drugs (especially H<sub>2</sub>-receptor antagonists and proton pump

inhibitors) are, however, more effective in the treatment of acute peptic ulcers, and misoprostol is only indicated for those who are taking NSAIDs and are at high risk for NSAID-induced ulcers, such as the elderly and people with ulcer complications. 1. Akdamar, Agrawal & Ertan (1982) *Am. J. Gastroenterol.* **77**, 902. 2. Ramage, Denton & Williams (1985) *Brit. J. Clin. Pharmacol.* **19**, 9.

### Mithramycin

This chromomycin-like antibiotic (FW = 1085.16 g/mol; CAS 18378-89-7), also known as plicamycin and aureolic acid, is isolated from *Streptomyces argillaceus* and *S. tanashiensis*. Mithramycin binds reversibly to DNA with G:C base specificity and blocks protein biosynthesis via transcription inhibition. The Mg<sup>2+</sup>-antibiotic complex interacts with chromatin and the complex stabilizes the DNA duplex and the histone-DNA contacts within chromatin fiber. The sugar moieties of mithramycin are thought to play a key role in the binding process. **Target(s):** DNA-directed RNA polymerase (1-4); DNA topoisomerase II (5). 1. Kersten, Kersten, Szybalski & Fiandt (1966) *Biochemistry* **5**, 236. 2. Mir, Majee, Das & Dasgupta (2003) *Bioorg. Med. Chem.* **11**, 2791. 3. Chowdhury, Chowdhury & Neogy (1981) *Indian J. Med. ### Mitochondrial ATPase Inhibitor

Mitochondrial ATP synthase (i.e., F<sub>1</sub>F<sub>0</sub>-ATPase) is regulated by an intrinsic ATPase inhibitor protein. The bovine inhibitor protein, IF<sub>1</sub>, contains 84 aminoacyl residues and is an α helical dimer. The proton-motive force across the inner mitochondrial membrane collapses when a cell is deprived of oxygen. If this occurs, the F<sub>1</sub>F<sub>0</sub> ATP synthase switches from synthesis to hydrolysis. This hydrolytic activity is prevented by a natural inhibitor protein, IF<sub>1</sub>, and the action of this protein depends on the presence of ATP: the ATP molecule is trapped in the enzyme in the presence of IF<sub>1</sub>. **Target(s):** F<sub>1</sub> ATP synthase (1-8). 1. Monroy & Pullman (1967) *Meth. Enzymol.* **10**, 510. 2. Ernster, Carlsson, Hundal & Nordenbrand (1979) *Meth. Enzymol.* **55**, 399. 3. Cintrón & Pedersen (1979) *Meth. Enzymol.* **55**, 408. 4. ### Mitomycin C

This interstrand cross-linker, or ICL (FW = 334.33 g/mol; CAS 50-07-7; Symbol: MMC; decomposed upon exposure to light; hence, solutions should be stored in the dark; stable in solution at pH 6–9 at 5°C for at least a week) from *Streptomyces caespitosus* chemically alters DNA, physically blocking replication, recombination, and transcription (1). In mice, the i.v. LD<sub>50</sub> is 5–9 mg/kg, but there is a delayed response, with death occurring in 2–14 days following injection. **Chemistry:** Once within cells, mitomycin C undergoes rearrangement and reduction to generate a bifunctional alkylating

reagent, which then binds preferentially to the N-position of guanine in the minor groove of duplex DNA, forming monoadducts. The latter reach out to form intrastrand crosslinks with an adjacent guanine residue as well as interstrand crosslinks at opposite guanines of adjacent base-pairs, specifically in the sequence orientation of CpG, but not GpC.

Mitomycin also binds to both RNA. *Note:* This dark blue solid is readily soluble in water and is Mitomycin C, the least toxic of the mitomycins, is a potent antitumor agent. **Target(s):** DNA biosynthesis (1–4); DNase (5); DT diaphorase, or NAD(P)H dehydrogenase (6); indoleamide 2,3-dioxygenase (7). 1. ### Mitoxantrone

This DNA-intercalating drug (FW<sub>free-base</sub> = 444.49 g/mol; CAS 65271-80-9), also known by its trade name Novantrone™ and by its IUPAC name, 1,4-dihydroxy-5,8-bis[2-(2-hydroxyethylamino)ethylamino]anthracene-9,10-dione, is an immunosuppressive and cytostatic agent that exhibits antitumor activity. Mitoxantrone is a type II topoisomerase inhibitor that disrupts DNA synthesis and repair in healthy and cancer cells. Novantrone is also an FDA-approved MS drug that delays the time to first treated relapse as well as disability progression. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** DNA helicase (1); DNA topoisomerase II (2-8); [myosin light-chain] kinase (9); nucleoside-triphosphatase (1). 1. Borowski, Niebuhr, Schmitz, et al. (2002) *Acta Biochim. Pol.* **49**, 597. 2. Epstein & Smith (1988) *Cancer Res.* **48**, 297. 3. Crespi, Ivanier, Genovese & Baldi (1986) *Biochem. Biophys. Res. ### Mitragynine & Mitragynine Pseudoindoxyl

This alkaloid (FW = 398.49 g/mol; CAS 6202-22-8), from the Thai medicinal plant *Mitragyna speciosa* (kratom), is oxidized metabolically oxidized to form the  $\mu$ -opioid receptor agonist, mitragynine pseudoindoxyl (FW = 414.50 g/mol), with the latter showing lower affinity for  $\delta$  or  $\kappa$  receptors (1). Mitragynine pseudoindoxyl inhibits the electrically stimulated ileum and mouse vas deferens contractions in a concentration-dependent manner (2). In the ileum, its nM-range  $EC_{50}$  is in an nM order, being nearly equivalent to reported concentrations of the micro-opioid receptor agonist [D-Ala<sup>2</sup>,N-MePhe<sup>4</sup>,Gly-ol]-enkephalin (or DAMGO), and is 100- and 20x smaller than those of mitragynine and morphine, respectively. In the vas deferens, it is 35x smaller than that of morphine (2). The inhibitory action of mitragynine pseudoindoxyl in the ileum was antagonized by the non-selective opioid receptor antagonist naloxone and the micro-receptor antagonist naloxonazine (2). 1. Takayama, Ishikawa, Kurihara, *et al.* (2002) *J. Med. Chem.* **45**, 1949. 2. Yamamoto, Horie, Takayama, *et al.* (1999) *Gen. Pharmacol.* **33**, 73.

**MIX, See 3-Isobutyl-1-methylxanthine**

### Mizoribine

This inosine/guanosine analogue (FW = 259.22 g/mol; CAS 50924-49-7), also known as *N'*-( $\beta$ -D-ribofuranosyl)-5-hydroxyimidazole-4-carboxamide, is an imidazole-based nucleoside that is metabolically phosphorylated to mizoribine 5'-monophosphate (MZP). The latter inhibits *de novo* purine nucleotide biosynthesis by targeting IMP dehydrogenase (1). X-ray crystal structure of the Enz-MZP complex reveals that IMP dehydrogenase undergoes a conformational change, wherein a flap folds into the NAD site, such that MZP, Cys319, and a water molecule are arranged in a geometry resembling the enzyme's likely transition-state intermediate (2). Depletion of GTP and dGTP stores disrupts G-protein system and DNA replication. Indeed, measurements of purine ribonucleotide pools by HPLC show that mizoribine reduces intracellular GTP levels; repletion of GTP reverses its

antiproliferative effects (3). Mizoribine also exerts strong immunosuppressive properties, selectively blocking T-cell proliferation in response to mitogenic and allo-antigenic stimulation. Mizoribine likewise blocks T-cell progression from G-phase to S-phase. Because the structure of MZP closely resembles the purine nucleotide biosynthetic intermediate, aminoimidazole-carboxamide ribonucleotide (AICAR), it is likely to inhibit the synthesis of *N*-formyl-aminoimidazole-carboxamide ribonucleotide. 1. Hedstrom (1999) *Curr. Med. Chem.* **6**, 545. 2. Gan, Seyedsayamdest, Shuto, *et al.* (2003) *Biochemistry* **42**, 857. 3. Turka, Dayton, Sinclair, Thompson & Mitchell (1991) *J. Clin. Invest.* **87**, 940.

### Mizoribine & Mizoribine 5'-Monophosphate

This nucleoside (FW = 259.22 g/mol), also known as bredinin, is produced by *Eupenicillium brefedianum* and is readily converted to the monophosphate, the latter a transition-state inhibitor of IMP dehydrogenase (IMPDH) with a nanomolar  $K_i$  value. The imidazole-containing molecule is a strong immunosuppressive agent that blocks T-cell proliferation. It also blocks the movement of T cells from the G<sub>1</sub> to the S phase. **Target(s):** DNA-directed DNA polymerase (1); DNA polymerase  $\beta$  (1); GMP synthetase, inhibited by the monophosphate (2); IMP dehydrogenase, inhibited by the monophosphate (2-8). 1. Mizushima, Matsukage & Sakaguchi (1998) *Biochim. Biophys. Acta* **1403**, 5. 2. Kusumi, Tsuda, Katsunuma & Yamamura (1989) *Cell Biochem. Funct.* **7**, 201. 3. Koyama & Tsuji (1983) *Biochem. Colby (1999) *Curr. Med. Chem.* **6**, 519. 7. Kerr & Hedstrom (1997) *Biochemistry* **36**, 13365. 8. Hager, Collart, Huberman & Mitchell (1995) *Biochem. Pharmacol.* **49**, 1323.

### MJ 15

This potent cannabinoid receptor antagonist (FW = 471.77 g/mol; CAS 944154-76-1; Soluble to 100 mM in DMSO), also named 5-(4-chlorophenyl)-1-(2,4-dichlorophenyl)-4-methyl-*N*-(3-pyridinylmethyl)-1*H*-pyrazole-3-carboxamide, selectively targets CB<sub>1</sub> receptors ( $K_i$  = 27.2 pM, IC<sub>50</sub> = 118.9 pM for rat CB<sub>1</sub> receptors). MJ15 dose-dependently blocks Win55212-2 mediated increase of intracellular calcium ion levels in hippocampal cells and reversed the inhibitory effects of cannabinoid CB<sub>1</sub> receptor agonist on forskolin-stimulated adenylyl cyclase activity in CHO cells expressing the human cannabinoid CB<sub>1</sub> receptor. MJ-15 also exhibits potency in obesity and hyperlipidemia models, inhibiting food intake and increasing body weight in diet-induced obese rats and mice. 1. Chen, Tang, Liu, *et al.* (2010) *Eur. J. Pharmacol.* **637**, 178.

**MK 990**, See *Rafoxanide*

#### MK-1064

This orally bioavailable 2,5-disubstituted nicotinamide and receptor antagonist (FW = 461.91 g/mol), also known as 5''-chloro-N-[(5,6-dimethoxypyridin-2-yl)methyl]-2,2':5',3''-terpyridine-3'-carboxamide, selectively targets the Orexin-2 Receptor (or OX<sub>2</sub>R or Hypocretin Receptor), a G-protein coupled receptor exclusively in the brain. MK-1064 is an investigational drug intended for the treatment of insomnia. OX<sub>2</sub> also plays a part in a CNS feedback loop that regulates feeding behavior. 1. Roecker, Mercer, Schreier, *et al.* (2013) *Chem. Med. Chem.* **9**, 311.

**MK-1439**, See *Doravirine*

#### MK-1775

This orally bioavailable non-receptor, ATP-competitive TKI (FW = 500.60; CASs = 955365-80-7, 1075739-30-8 (H<sub>2</sub>O), 1075739-32-0 (xHCl); Solubility: 100 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O; **Formulation**: Dissolve in PBS at 0.5% methylcellulose), named systematically as 2-allyl-1-(6-(2-hydroxypropan-2-yl)pyridin-2-yl)-6-(4-(4-methylpiperazin-1-yl)phenylamino)-1,2-dihydropyrazolo[3,4-d]pyrimidin-3-one, targets Wee1 (IC<sub>50</sub> = 5 nM), a tyrosine kinase that phosphorylates and inactivates CDC2 at tyrosine-15, thereby abrogating the G<sub>2</sub> DNA damage checkpoint and resulting in apoptosis, when administered in combination with DNA-damaging agents, such as gemcitabine, carboplatin, and cisplatin in p53-deficient cells. 1. Hirai, Iwasawa, Okada, *et al.* (2009) *Mol. Cancer Ther.* **8**, 2992. 2. Davies, *et al.* (2011) *Cancer Biol. Ther.* **12**, 788.

#### MK-2206 Dihydrochloride

This highly selective pan-Akt inhibitor (FW = 480.39 (as dihydrochloride); CAS 1032350-13-2, 1032349-93-1 (free base), 1032349-77-1 (HCl salt); Solubility: 14 mg/mL DMSO, 1 mg/mL H<sub>2</sub>O; IUPAC: 8-(4-(1-aminocyclobutyl)phenyl)-9-phenyl[1,2,4]triazolo[3,4-f][1,6]naphthyridin-3(2H)-one, is an allosteric signal-transduction pathway inhibitor targets Akt1 (IC<sub>50</sub> = 8 nM), Akt2 (IC<sub>50</sub> = 12 nM), and Akt3 (IC<sub>50</sub> = 65 nM), also known as the Protein Kinases B isoforms PKB-1, PKB-2, and PKB-3. MK-2206 is a tight binding, uncompetitive inhibitor of MEK1/2, binding to an allosteric binding pocket adjacent to the MgATP site. Akt's pleckstrin homology (PH) domain folds over, interacting with the bound MK-2206 and forming an auto-inhibited complex, blocking ATP binding. MK2206 also blocks influenza pH1N1 virus infection *in vitro* by inhibiting endocytic uptake of the virus (3). MK2206 does not inhibit H3N2, H7N9 and H5N1 influenza, indicating that pH1N1 apparently evolved specific requirements for efficient infection. MK2206 blocks Akt phosphorylation at Ser-473, reducing proliferation of cholangiocarcinoma (CCA) cells, an aggressive disease with limited effective treatment options (4). 1. Hirai, Sootome, Nakatsuru, *et al.* (2010) *Mol. Cancer Ther.* **9**, 1956. 2. Lindsley (2010) *Curr. Top. Med. Chem.* **10**, 458. 3. Denisova, Söderholm, Virtanen, *et al.* (2014) *Antimicrob. Agents Chemother.* **58**, 3689. 4. Wilson, Kunnimalaiyaan, Kunnimalaiyaan & Gamblin (2015) *Cancer Cell Int.* **15**, 13.

#### MK-2048

This second-generation integrase (or IN) inhibitor (FW = 435.28 g/mol; CAS 269055-15-4; Solubility: 9 mg/mL DMSO), also known as 2-[(3-chloro-4-fluorophenyl)methyl]-8-ethyl-1,2,6,7,8,9-hexahydro-10-hydroxy-N,6-dimethyl-1,9-dioxo-(6S)-pyrazino[1',2':1,5]pyrrolo[2,3-d]pyridazine-4-carboxamide, targets IN<sup>wild-type</sup> (IC<sub>50</sub> = 2.6 nM) and IN<sup>R263K</sup> (IC<sub>50</sub> = 1.5 nM). IC<sub>50</sub> values for MK-2048 against subtype B and C enzymes were 0.075  $\mu$ M and 0.08  $\mu$ M, respectively, and disintegration was inhibited by high concentrations of MK-2048 to a comparable extent with both subtype B and C enzymes (1). MK-2048 was specifically developed with the goal of retaining activity against viruses containing mutations associated with raltegravir- and elvitegravir-resistant HIV (2). That said, IN<sup>G118R</sup> and IN<sup>E138K</sup> confer resistance to MK-2048, but not to raltegravir or elvitegravir (2,3). 1. Bar-Magen, Sloan, Faltenbacher, *et al.* (2009) *Retrovirology* **6**, 103. 2. Bar-Magen, Sloan, Donahue, *et al.* (2010) *J. Virol.* **84**, 9210. 3. Quashie, Mesplède, Han, *et al.* (2012) *J. Virol.* **86**, 2696.

**MK-3102**, See *Omarigliptin*

**MK-3118**

This orally bioavailable synthetic derivative (FW = 727.07 g/mol) of the novel triterpene glycoside natural product enfumafungin has improved fungal  $\beta$ -1,3-glucan synthase inhibitor properties. While echinocandins are also potent, naturally occurring GS inhibitors, their clinical utility is limited, because they can only be administered intravenously. MK-3118 exhibits better whole-cell antifungal activity and displays an improved spectrum of antifungal action and efficacy in animal models of invasive aspergillosis (*i.e.*, DBA/2N and neutropenic CD-1 mice after infection with *Aspergillus fumigatus*, strain MF5668; ED<sub>90</sub> 1-8 mg/kg). MK-3118 is also highly effective against 71 *Aspergillus* spp., including itraconazole-resistant strains (MIC  $\geq$  4  $\mu$ g/ml). With 29 strains of *Candida albicans*, 29 strains of *Candida glabrata*, 21 strains of *Candida tropicalis*, 15 strains of *Candida parapsilosis* and 19 strains of *Candida krusei*, including azole- and echinocandin-resistant isolates, MK-3118 gave MIC values ranging from 0.06 to 16 mg/L depending on duration of treatment and endpoint criteria. (Although carrying an “MK” in a code name typical of Merck’s investigational drugs, all rights were returned to Scynexis, Inc., in 2013, following Merck’s review and prioritization of its infectious disease portfolio.) 1. **MK-8745**

This novel potent inhibitor (FW = 431.91 g/mol; CAS 885325-71-3; Solubility: 86 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named (3-chloro-2-fluorophenyl)[4-[[6-(2-thiazolylamino)-2-pyridinyl]methyl]-1-piperazinyl]methanone, selectively targets Aurora A kinase (IC<sub>50</sub> = 0.6 nM), with more than 450x selectivity for Aurora A over Aurora B. Treatment of non-Hodgkin lymphoma (NHL) cell lines with MK-8745 results in cell cycle arrest at the G<sub>2</sub>/M phase, with accumulation of tetraploid nuclei and subsequent death. Sensitivity to MK-8745 correlates with the expression level of Aurora-A activator. Indeed, siRNA knockdown of Aurora-A activator TPX2 (Targeting Protein for *Xenopus* kinase-like protein 2) increases MK-8745 sensitivity in NHL cell lines that are otherwise less sensitive to this drug; by contrast, TPX2 overexpression in NHL cell lines with high MK-8745-sensitivity increases drug resistance (1). MK8745 induces apoptotic cell death in a p53-dependent manner, when tested *in*

*vitro* in cell lines of multiple lineages. Cells expressing wild-type p53 showed a short delay in mitosis, followed by cytokinesis and resulting in tetraploid cells, along with apoptosis. However, cells lacking or with mutant p53 resulted in a prolonged arrest in mitosis, followed by endoreduplication and polyploidy. Cytokinesis was completely inhibited in p53-deficient cells, as observed by the absence of 2N cell population. The induction of apoptosis in p53-proficient cells was associated with activation of caspase 3 and release of cytochrome c but was independent of p21 (2). 1. Chowdhury, Chowdhury & Tsai (2012) *Leuk. Lymphoma* **53**, 462. 2. Nair, Ho & Schwartz (2012) *Cell Cycle* **11**, 807.

**MKT-077**

This rhodacyanine dye and mitochondrial Hsp70 inhibitor (FW = 432.00 g/mol; CAS 147366-41-4; orange-red powder; Solubility = 200 mg/mL), also known as FJ-776 and 1-ethyl-2-[[3-ethyl-5-(3-methyl-2(3H)-benzothiazolylidene)-4-oxo-2-thiazolidinylidene]methyl]pyridinium chloride, is a lipophilic cation that targets mortalin, a mitochondrial Hsp70-family chaperone that plays roles in protein import and quality control, Fe-S cluster protein biogenesis, mitochondrial homeostasis, and regulation of p53 (1). Mortalin is implicated in the regulation of apoptosis, cell stress response, neurodegeneration, and cancer. Subcellular localization indicates that MKT-077 is taken up and retained by mitochondria, making it suitable for flow cytometric analysis (2). X-ray crystallography suggests how mortalin’s nucleotide binding domain is likely to interact with the nucleotide exchange factor GrpEL<sub>1</sub>, p53, as well as MKT-077 (3). In nude mice, MKT-077 inhibits the growth of subcutaneously implanted human renal carcinoma A498 and human prostate carcinoma DU145 and prolongs survival of mice bearing intraperitoneal implanted human melanoma (2). MKT-077 treatment induces changes in mitochondrial ultrastructure in carcinoma cells, but not in similarly treated normal epithelial cells (4) MKT-077 also inhibits respiratory activity in isolated intact mitochondria and electron transport activity in freeze-thawed mitochondrial membrane fragments in a dose-dependent manner. The MKT-077 concentration needed to reach half-maximal inhibition of ADP-stimulated respiration was approximately 4-fold greater in mitochondria isolated from cells of the normal epithelial cell line, CV-1 (15  $\mu$ g MKT-077/mg protein), as compared to the human colon carcinoma cell line, CX-1 (4  $\mu$ g/mg protein). Treatment is attended by selective loss of mitochondrial DNA in CX-1 and CRL1420 carcinoma cells, but not CV-1 (normal epithelial) cells treated with MKT-077 at 3  $\mu$ g/mL for up to 3 days. Nuclear DNA was unaffected in all three similarly treated cell lines. MKT-077 sensitivity of the cell lines to mitochondrial damage correlates well with their sensitivity to MKT-077 cytotoxicity. Such results provide a basis for the selective malignant cell killing exhibited by MKT-077 (4). Significantly, the concentration of MKT-077 required to achieve half-maximal inhibition of ADP-stimulated respiration is 6x lower in the presence versus absence of high-intensity light, *i.e.*, 2.5 versus 15  $\mu$ g MKT-077/mg (5). Photoirradiation also produced a 25x increase in inhibition of succinate-cytochrome c reductase activity by MKT-077 (5). **Other Target(s):** MKT-077 inhibits telomerase *in vitro* assay has no detectable effect on telomerase activity *in vivo* (6). MKT-077 is also an F-actin cross-linker (7). 1. Wadhwa, Sugihara, Yoshida *et al.* (2000) *Cancer Res.* **60**, 6818. 2. Koya, Li, Wang, *et al.* (1996) *Cancer Res.* **56**, 538. 3. **ML 00253764**, See *ML 253764*

## ML-7

This selective, ATP-competitive protein kinase inhibitor (FW = 452.74 g/mol; CAS 110448-33-4; Solubility = 50  $\mu\text{M}$  in DMSO), named systematically as 1-(5-iodonaphthalen-1-yl)sulfonyl-1H-hexahydro-1,4-diazepine hydrochloride, targets  $\text{Ca}^{2+}$ -calmodulin-dependent smooth muscle myosin light chain kinase ( $K_i = 0.3 \mu\text{M}$ ), exhibiting greater potency than the parent compound ML-9. ML7 blocks or slows chromosome movement when added to anaphase crane-fly spermatocytes (2). For all chromosomes whose movements were affected by a drug, the corresponding spindle fibres of the affected chromosomes had reduced levels of 1P- and 2P-myosin. The more general phosphorylation inhibitor, staurosporine, also reduced MRLC phosphorylation, causing anaphase chromosomes to stop or slow. 1. Dhawan & Helfman (2004) *J. Cell Sci.* **117**, 3735. 2. Sheykhan, Shirodkar & Forer (2013) *Eur. J. Cell Biol.* **92**, 175.

## ML 18

This BRS-3 antagonist (FW = 569.66 g/mol; CAS 1422269-30-4; S-enantiomer of PD176252, itself a nonpeptide antagonist for the neuromedin B receptor), also named ( $\alpha$ S)-N-[[1-(4-methoxyphenyl)cyclohexyl]methyl]- $\alpha$ -[[[(4-nitrophenyl)amino]carbonyl]amino]-1H-indole-3-propanamide, targets Bombesin Receptor, Subtype 3 ( $\text{IC}_{50} = 4.8 \mu\text{M}$ ), a G protein coupled receptor (GPCR) for the bombesin (BB)-family of peptides. ML-18 binds with lower affinity to the GRPR ( $\text{IC}_{50} = 16 \mu\text{M}$ ) and NMBR (with  $\text{IC}_{50} > 100 \mu\text{M}$ ). ML-18, but not its enantiomer EMY-98, inhibited the ability of BA1 to elevate cytosolic  $\text{Ca}^{2+}$  in a reversible manner using lung cancer cells loaded with FURA2-AM. ML18, but not EMY-98, inhibited the ability of BA1 to cause tyrosine phosphorylation of the EGFR and ERK in lung cancer cells. 1. Moody, Mantey, Moreno, *et al.* (2015) *Peptides* **64**, 55.

## ML130

This potent inhibitor (FW = 287.34 g/mol; CAS 799264-47-4; Solubility: 57 mg/mL DMSO, <1 mg/mL Water), also known systematically as 1-(4-methylphenyl)sulfonyl-1H-benzimidazol-2-amine, selectively targets NOD1, a Nucleotide-binding Oligomerization Domain protein that operates via NF- $\kappa\text{B}$  activation and functions as an innate-immunity sensor of microbial components derived from bacterial peptidoglycan. NOD1 participates in host defense against *Helicobacter pylori*. **Selectivity:** NOD1

( $\text{IC}_{50} = 0.56 \mu\text{M}$ ); NOD2 ( $\text{IC}_{50} > 20 \mu\text{M}$ ); and TNF- $\alpha$  ( $\text{IC}_{50} > 20 \mu\text{M}$ ). 1. Khan, *et al.* (2011) *ACS Med. Chem. Lett.* **2**, 780. 2. Correa, *et al.* (2011) *Chem. Biol.* **18**, 825.

## ML133

This potent and selective potassium channel blocker (FW<sub>HCl-salt</sub> = 313.82 g/mol; CAS 1222781-70-5; Solubility: 100 mM in DMSO; 20 mM in H<sub>2</sub>O, with warming), systematically named N-[(4-methoxyphenyl)methyl]-1-naphthalenemethanamine·HCL, targets inwardly rectifying K<sub>ir</sub>2 potassium channels: mK<sub>ir</sub>2.1 ( $\text{IC}_{50} = 1.8 \mu\text{M}$ ), hK<sub>ir</sub>2.6 ( $\text{IC}_{50} = 2.8 \mu\text{M}$ ), hK<sub>ir</sub>2.2 ( $\text{IC}_{50} = 2.9 \mu\text{M}$ ) and hK<sub>ir</sub>2.3 ( $\text{IC}_{50} = 4.0 \mu\text{M}$ ). ML-1333 exhibits no effect on rK<sub>ir</sub>1.1 ( $\text{IC}_{50} > 300 \mu\text{M}$ ) and weak activity at hK<sub>ir</sub>7.1 ( $\text{IC}_{50} = 33 \mu\text{M}$ ) and rK<sub>ir</sub>4.1 ( $\text{IC}_{50} = 76 \mu\text{M}$ ). 1. Wu, *et al.* (2010) *Probe Reports* from the NIH Molecular Libraries Pro. **PMID:** 21433384. 2. Wang, *et al.* (2011) *ACS Chem.Biol.* **6**, 845.

## ML 141

This allosteric (noncompetitive) Cdc inhibitor (FW = 407.49 g/mol; CAS 71203-35-5; Soluble to 100 mM in DMSO), also named CID 2950007 and 4-[4,5-dihydro-5-(4-methoxyphenyl)-3-phenyl-1H-pyrazol-1-yl]benzenesulfonamide, selectively targets Cdc42 GTPase ( $\text{IC}_{50} \sim 200 \text{ nM}$ ;  $\text{EC}_{50} = 2.1 \mu\text{M}$ ), with weaker action against Rho GTPase family, including Rac1, Rab2 and Rab7 (all with  $\text{IC}_{50} > 100 \mu\text{M}$ ). CID2950007 decreased the  $B_{\text{max}}$  of GTP-binding, while BODIPY-FL-GTP affinity to wild type Cdc42 ( $K_d \sim 4 \text{ nM}$ ) was essentially unchanged by CID2950007 ( $K_d \sim 50 \text{ nM}$ ). ML-141 also inhibits ovarian cancer cell migration *in vitro* as well as actin-based filopodia formation in 3T3 fibroblasts. 1. Surviladze, Waller, Strouse, *et al.* (2010) *Probe Reports from the Molecular Libraries Program NBK5196*. **PMID:** 21433396. 2. Hong, Kenney, Phillips, *et al.* (2011) *J. Biol. Chem.* **288**, 8531.

## ML154

This brain-penetrant NPSR antagonist (FW<sub>HBr-salt</sub> = 545.46 g/mol; CAS 1345964-89-7; Solubility: 100 mM in DMSO; 50 mM in Ethanol), also named 3-(diphenylphosphinothioyl)-2-methyl-1-[(2E)-3-phenyl-2-propen-1-yl]imidazo[1,2-a]pyridinium bromide, targets the neuropeptide S receptor ( $\text{pA}_2 = 9.98$ ), decreasing operant alcohol self-administration in rats. ML 154 selectively inhibits neuropeptide S-induced ERK phosphorylation ( $\text{IC}_{50} = 9.3 \text{ nM}$ ) over cAMP responses ( $\text{IC}_{50} = 22 \text{ nM}$ ) and calcium responses ( $\text{IC}_{50} = 36 \text{ nM}$ ). ML-154 also appears to modulate addictive behavior *in vivo*. This antagonist displays no activity against vasopressin V<sub>1B</sub> receptors. 1. Patnaik, *et al.* (2013) *J. Med. Chem.* **56**, 9045. 2. Thorsell, *et al.* (2013) *J. Neurosci.* **33**, 10132.

## ML188

This nonpeptidyl antiviral lead (FW = 432.56 g/mol; IUPAC Name: *(R)*-*N*-(4-(tert-butyl)phenyl)-*N*-(2-(tert-butylamino)-2-oxo-1-(pyridin-3-yl)ethyl)-furan-2-carboxamide) is a noncovalent inhibitor of the 3CL protease from Severe Acute Respiratory Syndrome Coronavirus (SARS-CoV), displaying good enzyme inhibition and antiviral activity. ML188 is unlike the majority of reported coronavirus 3CLpro inhibitors, which act via covalent modification of the enzyme. **1.** Jacobs, Grum-Tokars, Zhou, *et al.* (2013) *J. Med. Chem.* **56**, 534.

## ML204

This novel antagonist (FW = 226.32 g/mol; CAS 5465-86-1; IUPAC Name: 4-methyl-2-(1-piperidinyl)quinoline) selectively modulates Transient Receptor Potential Canonical (TRPC4/C5) channels, which are nonselective Ca<sup>2+</sup>-permeable channels implicated in diverse physiological functions, including smooth muscle contractility and synaptic transmission. IC<sub>50</sub> values were 0.96 and 2.6 μM, respectively, based on fluorescent and electrophysiological assays. **Selectivity:** ML204 exhibits 19-fold selectivity against TRPC6, and 9-fold selectivity against TRPC5, with no significant inhibition of TRPV1, TRPV3, TRPA1 and TRPM8 channels, even when tested at concentrations up to 22 μM. **1.** Miller, Shi, Zhu, *et al.* (2011) *J. Biol. Chem.* **286**, 33436.

## ML216

This first-in-class non-nucleoside inhibitor (FW = 383.32 g/mol; CAS 1430213-30-1), also known as 1-(4-fluoro-3-(trifluoromethyl)phenyl)-3-(5-(pyridin-4-yl)-1,3,4-thiadiazol-2-yl)urea, targets BLM helicase, a DNA unwinding enzyme that is critical in DNA repair via homologous recombination. Mutations in BLM give rise to Bloom's Syndrome and a predisposition to cancers. ML216 also sensitizes tumor cells to conventional cancer therapies, such as camptothecin. ML216 selectively inhibits cell proliferation of BLM-proficient PSNF5 fibroblasts over BLM-deficient PSNG13 cells. ML216 caused a significant increase in the frequency of sister chromatid exchanges in PSNF5 cells, a cytogenetic marker for BLM-deficient cells. ML216 also exhibits excellent liver microsomal stability and plasma stability, indicating that it may retain its BLM helicase inhibitor action *in vivo*. ML216 shows limited oral bioavailability, additional improvement in the aqueous solubility needs to be made. **Target(s):** BLM helicase, IC<sub>50</sub> = 1.2 μM; RecQ1 helicase, IC<sub>50</sub> ~ 50 μM; RecQ5 helicase, IC<sub>50</sub> > 50 μM; *E. coli* UvrD helicase, IC<sub>50</sub> > 50 μM. **1.** Rosenthal, Dexheimer, Nguyen, *et al.* (2013, updated from 2011) *Probe Reports, NIH*

*Molecular Libraries Program, Program, Bethesda: National Center for Biotechnology Information (US), PMID: 24027802.*

ML-236B, See *Mevastatin*

## ML267

This novel antibiotic (FW = 431.86 g/mol) targets phosphopantetheinyl transferase, or PPTase (IC<sub>50</sub> = 0.3 μM) is effective against Gram-positive bacteria, including community-acquired methicillin-resistant *Staphylococcus aureus* (CA MRSA). ML267 shows no cytotoxicity against HepG2 cells. ML267 has promising *in vitro* absorption, distribution, metabolism, and excretion (ADME) profile, commending for further testing in animal models of bacterial infection and virulence. **1.** Foley, Rai, Yasgar, *et al.* (2013) *Probe Reports from the NIH Molecular Libraries Program PMID: 24260781.*

## ML295, ML296, and Analogue-12

ML 295 (CID 53364533, SID125269138)

ML 296 (CID 53364510, SID125269096)

Analogue 12 or KT182  
(CID 53364491, SID125269091)

These triazole urea-based endocannabinoid inhibitors (FW<sub>ML-295</sub> = 412.49 g/mol; FW<sub>ML-296</sub> = 466.54 g/mol; FW<sub>Analogue-12</sub> = 438.53 g/mol; Solubility: ML295 (<1 μM), ML296 (12 μM) and Analogue-12 (27 μM), but higher in DMEM-FBS medium) target Abhydrolase Domain-containing protein-6 (*or* ABHD6), a serine hydrolase that controls the accumulation and efficacy of 2-arachidonoyl-glycerol (2-AG) at cannabinoid receptors. **Mode of Inhibitory Action:** Three enzymes (monoacylglycerol lipase (MAGL), ABHD6, and ABHD12) catalyze hydrolysis and inactivation of 2-AG, which regulates neurotransmission and neuroinflammation by activating CB<sub>1</sub> cannabinoid receptors on neurons and CB<sub>2</sub> cannabinoid receptors on microglia. Enzymes that hydrolyze 2-AG therefore regulate the accumulation and efficacy of 2-AG at these cannabinoid receptors. ML295, ML296, and Analogue-12 were examined both by means of in-gel activity assays as well as *in vitro* in effort to develop more potent, *in vivo*-active ABHD6 inhibitors to serve as either control probes for the recently developed dual DAGL-β/ABHD6 inhibitor (ML294) or for biological investigation of ABHD6 only. ML295, ML296, and Analogue-12 show IC<sub>50</sub> values of 38 nM, 0.8 nM, and nM, respectively, for the target enzyme. **1.** Hsu, Tsuboi, Speers, *et al.* (2013) *Probe Reports from the NIH Molecular Libraries Program, National Center for Biotechnology Information, PMID: 23762934.*

## ML309

This potent, first-in-class inhibitor (FW = 484.58 g/mol; IUPAC: 2-(N-[2-(benzimidazol-1-yl)acetyl]-3-fluoroanilino)-N-cyclopentyl-2-(2-methylphenyl)acetamide) targets the R132H mutant of Isocitrate Dehydrogenase 1 (IDH1), a common mutation in secondary gliomas and acute myeloid leukemia, generating a mutant enzyme that, while failing to catalyze its normal TCA cycle reaction, instead catalyzes the formation of the oncometabolite, 2-hydroxyglutarate. ML-309 has IC<sub>50</sub> values of 96 nM and >35 μM versus mutant and wild-type IDH1, respectively, as well as a 500 nM EC<sub>50</sub> in assays of cell-based 2-hydroxyglutarate formation. 1. Davis, Pragani, Popovici-Muller. *Et al.* (2012) *Probe Reports from the NIH Molecular Libraries Program*, Bethesda: National Center for Biotechnology Information (US). Updated: 2013 May 8. PMID: 23905201.

## ML324

This histone demethylation inhibitor (FW = 349.43 g/mol; CAS 1432500-66-7; Soluble to 100 mM in DMSO), also named *N*-(3-(dimethylamino)propyl)-4-(8-hydroxyquinolin-6-yl)benzamide, is cell-permeable and targets LSD1/2 and Jumonji domain (JMJD)-containing demethylase, two histone demethylases involved in the dynamic epigenetic post-translational *N*-methylation/demethylation of histone lysine residues (1). ML324 possesses excellent *in vitro* absorption, distribution, metabolism, and excretion properties commending its use in cell-based studies of these enzymes. ML324 also exhibits potent anti-viral activity (IC<sub>50</sub> = 10 μM) against both herpes simplex virus (HSV) and human cytomegalovirus (hCMV) infection via inhibition viral IE gene expression. It likewise suppresses the formation of HSV plaques, even at high MOI, blocking HSV-1 reactivation in a mouse ganglia explant model of latently infected mice. 1. Rai, Kawamura, Tumber, *et al.* (2013) *Probe Reports from the NIH Molecular Libraries Program* PMID: 24260783.

## ML345

This high-affinity inhibitor (FW = 479.5 g/mol) targets insulin-degrading enzyme, *or* IDE, with an IC<sub>50</sub> of 1.1 μM, promising new leads in the development of drugs that enhance/sustain insulin's role in promoting euglycemia (1). A thiol-sensitive zinc-metalloproteinase, IDE is the principal insulin-degrading enzyme *in vivo*, terminating insulin's action by modulating the hormone's off rate from its receptor (2). ML145 is superior to IDE inhibitor-1 (*or* Ii1), a peptide-derived hydroxamic acid that, while both highly potent (K<sub>i</sub> = 1.7 nM) and selective (10,000x relative to other

zinc-metalloproteinases) is a peptide that is too rapidly degraded (t<sub>1/2</sub> ~9 min in mice) to become a useful drug. ML145 reacts with Cys819 and, to a lesser extent, Cys812, in IDE. 1. Bannister, Wang, Abdul-Hay, *et al.* (2013) *Probe Reports from the NIH Molecular Libraries Program* PMID: 23833801 [PubMed]. 2. Leissring, Malito, Hedouin, *et al.* (2010) *PLoS One* 5, e10504.

## ML352

This selective CHT inhibitor (FW = 387.48 g/mol) targets the high-affinity Choline Transporter (K<sub>t</sub> = 92 nM), the rate-limiting step in acetylcholine biosynthesis. At ML352 concentrations that fully antagonized CHT in transfected cells and nerve terminal preparations, there is no inhibition of acetylcholinesterase (AChE) or cholineacetyltransferase (ChAT). ML352 also lacks activity against many receptors and channels, including dopamine transporters, serotonin transporters, and norepinephrine transporters. ML352 noncompetitively inhibits choline uptake in intact cells and synaptosomes and reduces the apparent density of hemicholinium-3 binding sites in membrane assays. Pharmacokinetic studies reveal limited *in vitro* metabolism of ML352 as well as significant CNS penetration, with features predicting rapid clearance. 1. Ennis, Wright, Retzlaff, *et al.* (2015) *ACS Chem. Neurosci.* 6, 417.

## ML 253764

This orally available nonpeptide melanocortin receptor antagonist (FW<sub>HCl-salt</sub> = 413.71 g/mol; Solubility: 10 mM in H<sub>2</sub>O, 100 mM in DMSO), also named 2-[2-[2-(5-bromo-2-methoxyphenyl)ethyl]-3-fluorophenyl]-4,5-dihydro-2-1H-imidazole·HCl, targets MC<sub>4</sub> receptors (IC<sub>50</sub> = 0.32 μM), MC<sub>3</sub> receptors (IC<sub>50</sub> = 0.81 μM), and MC<sub>5</sub> receptors (IC<sub>50</sub> = 2.12 μM) (1-3). The MC<sub>4</sub> receptors plays an important role in body weight regulation and energy homeostasis, and intracerebroventricular injection of peptidic antagonists (usually) helps to increase body weight and/or food intake in mouse models of tumor-induced weight loss (*i.e.*, cancer cachexia). ML 00253764 is a novel nonpeptidic antagonist that, upon peripheral administration in mice, reduces tumor-induced weight loss (1). 1. Vos, Caracoti, Che, *et al.* (2004) *J. Med. Chem.* 47, 1602. 2. Tucci, White, Markison, *et al.* (2005) *Bioorg. Med. Chem. Lett.* 15, 438.

MLN8237, See Alisertib

MLN9708, Undergoes hydrolysis to form MLN2238

## MM-102

This peptidomimetic MLL1 inhibitor (FW = 669.82 g/mol; CAS 1417329-24-8; Solubility: 100 mg/mL DMSO, H<sub>2</sub>O, or Ethanol; IUPAC Name: *See below*), targets the Mixed Lineage Leukemia 1 enzyme, or MLL1 (IC<sub>50</sub> = 1 nM), a histone H3 lysine 4 (H3K4) methyltransferase. MLL1-WDR5 protein-protein interactions are essential for MLL1's enzymatic activity, and MM-102 binding to WDR5 potentially inhibits Histone3 lysine 4 (H3K4) methylation. MM-102 inhibits expression of HoxA9 and Meis-1, two critical MLL1 target genes, in bone marrow cells transduced with an MLL1-AF9 fusion gene. Significantly, MM-102 selectively inhibits cell growth in leukemias carrying MLL1 fusion proteins. **1.** Karatas, Townsend, Cao, *et al.* (2013) *J. Am. Chem. Soc.* **135**, 669. **IUPAC Name:** 1-[[[(2*S*)-5-[(aminoiminomethyl)amino]-2-[[2-ethyl-2-[(2-methyl-1-oxopropyl)amino]-1-oxobutyl]amino]-1-oxopentyl]amino]-*N*-[bis(4-fluorophenyl)methyl]cyclopentanecarboxamide.

#### MMI270

This orally bioavailable hydroxamate (FW = 392.48 g/mol), also named CGS 27023A and IUPAC name *N*-hydroxy-2(*R*)-[(4-methoxysulfonyl)(3-picolyl)amino]-3-methylbutaneamide, targets the active-site Zn<sup>2+</sup> atom in many matrix metalloproteinases, inhibiting interstitial collagenase (*K<sub>i</sub>* = 33 nM), gelatinase A (*K<sub>i</sub>* = 20 nM), stromelysin 1 (*K<sub>i</sub>* = 43 nM), gelatinase B (*K<sub>i</sub>* = 8 nM), and neutrophil collagenase (*K<sub>i</sub>* = 10 nM). MMI270 also exhibits antimetastatic effects *in vivo* as well as antiangiogenic effects *in vitro*. **Target(s):** collagenase 3 (matrix metalloproteinase 13) (1); gelatinase A (matrix metalloproteinase 2) (2,3); gelatinase B (matrix metalloproteinase 9) (2,3); interstitial collagenase (matrix metalloproteinase 1) (1-3); macrophage elastase (matrix metalloproteinase 12) (4); microbial collagenase (3); neutrophil collagenase (matrix metalloproteinase 8) (3); stromelysin 1 (matrix metalloproteinase 3) (1,2,5,6). **1.** Zhang, Gonnella, Koehn, *et al.* (2000) *J. Mol. Biol.* **301**, 513. **2.** Leung, Abbenante & Fairlie (2000) *J. Med. Chem.* **43**, 305. **3.** Ilies, Banciu, Scozzafava, *et al.* (2003) *Bioorg. Med. #### Modafinil

This orally available, wakefulness-promoting drug and weak, atypical dopamine reuptake inhibitor (FW = 273.36 g/mol; CAS 68693-11-8 (for racemate) and 112111-43-0 (for (-)-*R* enantiomer); off-white, crystalline powder; practically insoluble in water and cyclohexane; slightly soluble in methanol and acetone), also known as Provigil<sup>®</sup> (racemate) as well as Armodafinil<sup>®</sup> (*R*-enantiomer) and named systematically as 2-[[diphenylmethyl]sulfinyl]acetamide, exhibits robust effects on catecholamines, serotonin, glutamate,  $\gamma$ -amino-butyric acid, orexin, and histamine systems in the brain. Many may be secondary to catecholamine

effects, with some selectivity for cortical over subcortical sites of action (1-3). At well-tolerated doses, modafinil improves cognitive function, including working memory and episodic memory. Modafinil does not bind to known sleep/wake-regulating receptors (*e.g.*, those for norepinephrine, serotonin, dopamine, GABA, adenosine, histamine-3, melatonin, or benzodiazepines), and it does not inhibit the activities of MAO-B or phosphodiesterases II-V. Given its abuse by athletes in training, the World Anti-Doping Agency (WADA) banned modafinil and its pro-drug adrafinil in sports in 2004. **Action as Weak, Atypical Dopamine Reuptake Inhibitor:** Ferraro *et al.* (2) suggested modafinil's dopamine-releasing action in the rat nucleus accumbens is secondary to its ability to reduce local GABAergic transmission, leading to reduction of GABA<sub>A</sub> receptor signaling on dopamine terminals. However, of the receptors and transporters assayed, modafinil only displays measurable potency at DA transporters (DAT), inhibiting [<sup>3</sup>H]-DA uptake, with an IC<sub>50</sub> of 4.0  $\mu$ M (4). Moreover, modafinil pretreatment (10  $\mu$ M) antagonizes methamphetamine-induced release of the DAT substrate [<sup>3</sup>H]-1-methyl-4-phenylpyridinium. Intravenous modafinil (20 and 60 mg/kg) produces dose-dependent increases in motor activity and extracellular DA, without affecting serotonin (4). **Pharmacokinetics:** Modafinil is absorbed readily, reaching maximum plasma concentrations at 2-4 hours and pharmacokinetic steady-state within 2-4 days. Its elimination half-life is 12-15 hours (dominated by the longer-lived L-enantiomer). It is primarily eliminated via hepatic metabolism, with subsequent urinary excretion (<10% of the excreted unchanged). Metabolism is largely via amide hydrolysis, with lesser contributions from cytochrome P450 (CYP)-mediated oxidative pathways. Modafinil induces CYP1A2, CYP3A4, and CYP2B6, but inhibits CYP2C9 and CYP2C19 *in vitro*. *See also* Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Targets:** dopamine reuptake *in vitro*, causing an increase in extracellular dopamine, but no increase in dopamine release (2); firing of dopaminergic, but not GABAergic neurons (3). **1.** Saper & Scammell (2004) *Sleep* **27**, 11. **2.** Ferraro, Tanganelli, O'Connor, *et al.* (1996) *Eur. Ther.* **329**, 738.

#### Modeccin

This protein toxin from the root of *Adenia digitata* (*Passifloraceae*), an indigenous South African plant easily mistaken for the edible root of *Coccinia* Species (*Cucurbitaceae*), is a ricin/abrin-like ribosome-inactivating agent. (**For mechanism, see Ricin**) Death follows vomiting and bloody diarrhea, with the most common postmortem findings of necrosis, vascular thrombosis within the rectum and large intestine, acute nephritis, and hemorrhages within the liver. **1.** Green & Kamerman (1924) *J. South Africa Chem. Inst.* **7**, 3. **2.** Watt & Breyer-Brandwijk (1962) *The Medicinal and Poisonous Plants of Southern and Eastern Africa*, pp. 826-828, Livingstone, London.

#### Moenomycins

This antibiotic (FW<sub>Moenomycin-A</sub> = 1583.87 g/mol; CAS 11015-37-5; soluble in H<sub>2</sub>O and DMF), also known as bambermycin and flavomycin, is the major component of at least four liposaccharidic compounds produced by *Streptomyces bambergiensis*, *S. ghanaensis*, *S. ederenensis*, and *S. geysiriensis*. **Target(s):** penicillin-binding protein 1b (1-4); penicillin-binding protein 3 (5); peptidoglycan cell wall biosynthesis (1-9); peptidoglycan glycosyltransferase (3,4,10-15); peptidoglycan polymerases (9); transglycosylase (16,17); trehalose-phosphatase (18,19);  $\alpha$ , $\alpha$ -trehalose-

phosphate synthase, UDP-forming (20); undecaprenol kinase, or C<sub>55</sub>-isoprenoid-alcohol kinase (21); MurG transferase (22). 1. Kurz, Guba & Vertesy (1998) *Eur. J. Biochem.* **252**, 500. 2. ### Moexipril

This potent, orally active ACE inhibitor and antihypertensive prodrug (FW<sub>free-monoacid</sub> = 498.58 g/mol; CAS 103775-10-6), also named (3S)-2-[(2S)-2-[[[(2S)-1-ethoxy-1-oxo-4-phenylbutan-2-yl]amino]propanoyl]-6,7-dimethoxy-1,2,3,4-tetrahydroisoquinoline-3-carboxylic acid, is rapidly metabolized to the diacid, moexiprilat (See Moexiprilat). **Mechanism of Action:** As a long-acting, non-sulphydryl angiotensin-converting enzyme inhibitor, moexipril is useful in treating arterial hypertension. It is a prodrug that yields moexiprilat by hydrolysis of an ethyl ester group, and moexiprilat is the pharmacologically active metabolite. The cardioprotective effects of this ACE inhibitor are mediated through decreased angiotensin II and increased bradykinin, the latter stimulating the production of prostaglandin E<sub>2</sub> and nitric oxide and consequentially exerting vasodilatory and anti-proliferative effects. Moexiprilat has an extended duration of action, owing to its long terminal half-life and persistent ACE inhibition. **Other Target(s):** Moexipril inhibits 3',5'-cyclicAMP phosphodiesterase Type 4 (PDE4), with a micromolar range IC<sub>50</sub> (2). 1. Chrysant & Chrysant (2004) *J. Clin. Pharmacol.* **44**, 827. 2. Brogden & Wiseman (1998) *Drugs* **55**, 845. 3. Cameron, Coleman, Day, et al. (2013) *Biochem. Pharmacol.* **85**, 1297.

### Moexiprilat

This diacid (FW<sub>hydrochloride</sub> = 506.98 g/mol) is a potent inhibitor of peptidyl-dipeptidase A, or angiotensin I-converting enzyme, IC<sub>50</sub> = 2.6 nM (1,2). Both, moexipril and moexiprilat inhibited the angiotensin I (ANG I)-induced contractions of rabbit aorta concentration-dependently, whereas contractions by other agents were not affected, indicating a high selectivity of both compounds for ACE. Moexiprilat is also the 6,7-dimethoxy analogue of quinaprilat. 1. Klutcho, Blankley, Fleming, et al. (1986) *J. Med. Chem.* **29**, 1953. 2. Friche & Ney (1997) *Arzneimittelforschung.* **47**, 132.

### Mofegiline

This orally active MAO-B inhibitor (FW<sub>free-base</sub> = 197.23 g/mol; CAS 119386-96-8; Soluble as the monohydrochloride salt), also named MDL-72,974 and (2E)-2-(fluoromethylidene)-4-(4-fluorophenyl)butan-1-amine, selectively and irreversibly targets monoamine oxidase B (MAO-B) and vascular adhesion protein 1 (VAP-1), the latter known also as semicarbazide-sensitive amine oxidase (SSAO). Although extensively researched as a potential treatment of Parkinson's disease and Alzheimer's disease, mofegiline was never marketed. **Human Studies:** A Phase-I study showed rapid absorption and elimination (time to maximum concentration = 1 hour; half-life = 1–3 hours; maximal plasma concentration and area under the plasma concentration-time curve increased) (3). Mofegiline also rapidly and markedly inhibited platelet monoamine oxidase B (MAOB) activity, which returned to baseline within 14 days. No changes in urinary elimination of catecholamines, blood pressure, heart rate, or ECG were observed. The 48-mg single dose and the 24 mg multiple daily dose far exceeded the dose (1-mg) need to observe >90% platelet MAOB inhibition (3). **Mode of Action:** Mofegiline competitively inhibits MAO-B (K<sub>i,apparent</sub> = 28 nM), with irreversible formation of a 1:1 molar stoichiometry attended by loss of catalytic turnover (4). The absorption spectral properties of mofegiline inhibited MAO-B show features (λ<sub>max</sub> ≈ 450 nm) and Visible/Near-UV CD spectra resembling N<sup>5</sup>-flavocyanine adducts. X-ray crystallography of the mofegiline-MAO-B adduct shows a covalent bond between the flavin cofactor at N<sup>5</sup> with the distal allylamine carbon atom as well as the absence of the fluorine atom (4). 1. Yu & Zuo (1992) *Biochem. Pharmacol.* **43**, 307. 2. Zreika, Fozard, Dudley, et al. (1989) *J. Neural Transm. Park. Dis. Dement. Sect. 1*, 243. 3. ### Molidustat

This HIF-PH inhibitor (FW = 314.00 g/mol; CAS 1154028-82-6; λ<sub>max</sub> = 250 nm), also known as BAY 85-3934 and 1,2-dihydro-2-[6-(4-morpholinyl)-4-pyrimidinyl]-4-(1H-1,2,3-triazol-1-yl)-3H-pyrazol-3-one, targets Hypoxia Inducible Factor Prolyl Hydroxylase (IC<sub>50</sub> = 0.49 μM). Because oxygen-dependent degradation of the α subunit of HIF heterodimer suppresses erythropoietin expression, erythropoiesis is stimulated by agents preventing HIF. BAY 85-3934 stabilizes HIF from degradation in the proteasome by inhibiting HIF-1α PH. Molidustat increase endogenous production of erythropoietin. HIF-PH inhibitors promise to provide a novel approach for treating anemia that is based on mimicking the hypoxia-driven expression of endogenous EPO in the kidney. 1. Flamme, Oehme, Ellinghaus, et al. (2014) *PLoS One* **9**, e111838.

### Molybdate

This Mo(VI) oxo dianion (FW<sub>ion</sub> = 159.94 g/mol; CAS 7782-91-4) is an isosteric analogue of sulfate and phosphate ions, and, as such, it inhibits many phosphatases. Molybdate dianion is also an activator of adenylate cyclase. Note that when solutions of MoO<sub>4</sub><sup>2-</sup> are weakly acidified, oligomeric and polymeric anions form. Ammonium molybdate (NH<sub>4</sub>)<sub>6</sub>Mo<sub>7</sub>O<sub>24</sub> is a redox active reagent used in spot tests and in sprays for detecting inorganic and organic phosphates in thin-layer and paper chromatography. Molybdate can also be used to test for reducing sugars. Froehde's reagent (formed by dissolving sodium molybdate (Na<sub>2</sub>MoO<sub>4</sub>) in

- concentrated sulfuric acid) is used in spot tests for alkaloids, particularly opium alkaloids. Given its promiscuity, molybdate is best used in single-enzyme experiments, where the goal is to exploit its higher affinity to conduct mechanistic studies. **Target(s):** *N*-acetylgalactosamine-4-sulfatase, or arylsulfatase (1); acid phosphatase (2-16,96-124); adenosine-tetraphosphatase (17); alkaline phosphatase (4,18,125-129); Arylsulfatase (1,4,55); asparagine synthetase, ADP-forming (19); cAMP phosphodiesterase (20); carbonic anhydrase, weakly inhibited (21); 2-carboxy-D-arabinitol-1-phosphatase (59); catechol *O*-methyltransferase (22); cyclomalto-dextrin glucanotransferase (138); cysteine synthase (133,134); exopolyphosphatase (17); FAD diphosphatase, weakly inhibited (23);  $\beta$ -fructofuranosidase, or invertase, inhibited by  $\text{Mo}_7\text{O}_{24}^{6-}$  (52-54); fructose-1,6-bisphosphate aldolase (24); glucan 1,3- $\beta$  glucosidase (50,51); glucocorticoid receptor (25); glucose-1-phosphatase, inhibited by ammonium and sodium molybdate (92-94); glucose-6-phosphatase,  $K_i = 3.7 \mu\text{M}$  for rabbit intestinal enzyme (26-29,45); glutathione: cystine transhydrogenase (145); glyceryl-ether monooxygenase (142,143); glycogen phosphorylase (141); inositol-phosphate phosphatase (86); isoamylase, inhibited by ammonium molybdate (49); isocitrate dehydrogenase,  $\text{NAD}^+$ -dependent (30,31); isocitrate dehydrogenase,  $\text{NADP}^+$ -dependent, weakly inhibited (31); lipid-phosphate phosphatase, weakly inhibited (56); monoterpenyl diphosphatase (32); nucleotidase (79); 5'-nucleotidase (95); phloretin hydrolase (33); phosphoamidase34; *N*-phosphoarginine hydrolase35; phosphoenolpyruvate phosphatase (60,61); 6-phosphofructo-2 kinase, when fructose-2,6-bisphosphatase activity is activated (36); 3-phosphoglycerate phosphatase (78); phosphoprotein phosphatase (13,37-40,90,91); phosphoprotein phosphatase, CD45 (40); 3-phosphoshikimate 1-carboxyvinyltransferase, or 3-enolpyruvylshikimate-5-phosphate synthase (135,136); 3-phytase (81,85); 4-phytase (80-84); phytoglycogen synthase (41); polynucleotide-5' hydroxyl-kinase (42); protein-tyrosine-phosphatase (40,63-77); purple acid phosphatase (12,114); pyridoxal phosphatase (43,57,58); pyrophosphatase (44,45); riboflavin phosphotransferase (132); ribonuclease, pea leaf (46); salicylate 1-monooxygenase, weakly inhibited (144); sorbitol-6-phosphatase (62); starch synthase (137); sucrose-phosphatase (87-89); sucrose phosphate synthase (139,140); sulfate adenyllyltransferase (130,131); sulfate transport (47); tripeptide aminopeptidase (48). 1. ### Molybdenum & Molybdenum Ions

This Group 6 (or Group VIA) element (Symbol = Mo; Atomic Number = 42; Atomic Weight = 95.94), located directly beneath chromium in the Periodic Table, has the following ground state electronic configuration for the neutral atom is  $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^1 4d^5$ . Molybdenum has valencies of 2, 3, 6, and possibly 4 and 5, with ionic radii 0.93, 0.70, and 0.62 Å of  $Mo^{1+}$ ,  $Mo^{4+}$ , and  $Mo^{6+}$ , respectively. The plant *Grindelia fastigiata* may be a molybdenum accumulator. (See also *Molybdate*; *Permolybdate*) **Target(s):** acid phosphatase (4); alkaline phosphatase (5,6); benzoate 4-monooxygenase (7); carnosine synthetase (8); chitinase (9); chitosanase (10); cholinesterase (5); cyclomaltodextrin glucanotransferase (11,12);  $\beta$ -fructofuranosidase, or invertase, inhibited by  $MoCl_2$  (13); glucose 6 phosphatase (5); indoleacetaldoxime dehydratase (14); laccase (15); phenylacetyl-CoA synthetase, or phenylacetate:CoA ligase (16);  $\beta$ -(pyradoxyl-*N*)-L-alanine (17); ribonuclease, plant (18); stizolobate synthase (19); stizolobinate synthase (19). **1.** Yenigün & Güvenilir (2003) *Appl. ### Mometasone furoate

This synthetic glucocorticoid (FW = 421.43 g/mol; CASs = 105102-22-5 and 83919-23-7), also known by the trade names Elocon<sup>®</sup>, Elocorm<sup>®</sup>, Elomet<sup>®</sup>, Elosalic<sup>®</sup>, Novasonex<sup>®</sup>, Nasonex<sup>®</sup>, Asmanex<sup>®</sup>, Twisthaler<sup>®</sup>, Essex<sup>®</sup> and its systematic name (11 $\beta$ ,16 $\alpha$ )-9,21-dichloro-11-hydroxy-16-methyl-3,20-dioxopregna-1,4-dien-17-yl 2-furoate, blocks cytokine-induced surface

expression of vascular cell adhesion molecule-1 (VCAM-1) and intercellular adhesion molecule-1 (ICAM-1) on BEAS-2B bronchial epithelial cells *in vitro* ( $IC_{50}$  = 10 pM). Although both PDE-4 inhibitors and glucocorticoids suppress secretion of TNF $\alpha$  and IL-10, PDE-4 inhibitors are more potent in suppressing cytokine secretion by PBMCs from atopic individuals (2). Although less potent in inhibiting production of IL-10, PDE-4 inhibitors now have greater therapeutic potential than glucocorticoids in allergic diseases. **Formulation:** Mometasone Furoate Cream USP, 0.1%, contains mometasone furoate, USP for dermatologic use. Each gram of mometasone furoate cream (0.1% weight/weight) contains mometasone furoate (1 mg) dissolved in a cream base of hexylene glycol, phosphoric acid, propylene glycol monostearate, stearyl alcohol/ceteareth-20, aluminum starch octenylsuccinate, white wax, white petrolatum, and purified water. **1.** Atsuta, Plitt, Bochner & Schleimer (1999) *Am. J. Respir. Cell Mol. Biol.* **20**, 643. **2.** Crocker, Ohia, Church & Townley (1998) *J. Allergy Clin. Immunol.* **102**, 797.

### MON-097, See Acetochlor

### Monastrol

This cell-permeable kinesin Eg5 inhibitor (F.Wt. = 292.35; CAS 254753-54-3; Solubility = 5 mg/mL DMSO; Photosensitive), known systematically as ethyl-4-(3-hydroxyphenyl)-6-methyl-2-sulfanylidene-3,4-dihydro-1H-pyrimidine-5-carboxylate, arrests mammalian cells in mitosis, as characterized by monopolar spindles. Inhibition appears to be allosteric mechanisms, inasmuch as monastrol does not competitively inhibit ATP binding. [Motors actually catalyze translocation:  $ATP + MT_{\text{Position-1}} \rightleftharpoons ADP + P_i + MT_{\text{Position-2}}$ , where the microtubule (MT) scaffold, indicating two successive translocation states), suggesting that the rate equation has the form  $v = V_m / (1 + [ATP]/K_{ATP} + [MT_{\text{SITES}}]/K_{MT} + [ATP][MT_{\text{SITES}}]/K_{ATP}K_{MT})$ , such that monastrol may compete for MT sites for kinesin docking on the microtubule.] Unlike other mitotic spindle poisons (*e.g.*, colchicine, vinblastine, and nocodazole) that target tubulin polymerization or affect microtubule stability, monastrol ( $IC_{50}$  = 14  $\mu$ M) inhibits a motor protein. **1.** Mayer, Kapoor, Haggarty, King, Schreiber & Mitchison (1999) *Science* **286**, 971. **2.** Kapoor, Mayer, Coughlin & Mitchison (2000) *J. Cell Biol.* **150**, 975. **3.** Maliga, Kapoor & Mitchison (2002) *Chem. Biol.* **9**, 989.

### Monensin

This monovalent ionophore (FW<sub>free-acid</sub> = 670.88 g/mol; CAS 17090-79-8), produced by *Streptomyces cinnamomensis*, is a powerful antibiotic that disrupts a number of cellular functions, including oxidative phosphorylation and photophosphorylation (1,2). Monensin forms a stable complex with  $Na^+$  and exhibits high  $Na^+/K^+$  selectivity. Monensin itself and Monensin- $Na^+$  complexes are very soluble in organic solvents. Monensin facilitates the transmembrane exchange of principally  $Na^+$  ions for protons. Monensin impairs post-translational protein processing of in the Golgi complex (3), and treatment with monensin results in an accumulation of non-secreted proteins. **1.** Izawa & Good (1972) *Meth. Enzymol.* **24**, 355. **2.** Reed (1979) *Meth. Enzymol.* **55**, 435. **3.** Ledger & Tanzer (1984) *Trends Biochem. Sci.* **9**, 313.

**Moniliformin**

This fungal toxin (FW<sub>anion</sub> = 73.03 g/mol), produced by *Fusarium moniliforme* a pathogen common to stored grains, inhibits a number of thiamin-dependent enzymes by forming an adduct between the cofactor and a reactive carbonyl in moniliformin. **Target(s):** acetoxyacid synthase (1,2); glutathione-disulfide reductase (3); glutathione peroxidase (3);  $\alpha$ -ketoglutarate dehydrogenase complex (1,4); pyruvate decarboxylase (1,5); pyruvate dehydrogenase complex (1,6-8); transketolase (8). 1. Pirrung, Nauhaus & Singh (1996) *J. Org. Chem.* **61**, 2592. 2. Singh, Stidham & Shaner (1988) *Anal. Biochem.* **171**, 173. 3. Chen, Tian & Yang (1990) *Mycopathologia* **110**, 119. 4. **Monobenzene**

This substituted hydroquinone (FW = 200.24 g/mol; M.P. = 122.5°C), also known as 4-(phenylmethoxy)phenol, *p*-(benzyloxy)phenol, and benzyloxyhydroquinone, is a redox-active substance that inhibits tyrosinase, *or* monophenol monooxygenase, and, as such, has been used as a depigmenting agent. 1. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 304, Academic Press, New York. 2. Hogeboom & Adams (1942) *J. Biol. Chem.* **145**, 273. 3. **N<sup>6</sup>-Monobutyryladenose 3',5'-Cyclic Monophosphate**

This membrane-permeable cyclic-AMP derivative (FW<sub>free-acid</sub> = 399.30 g/mol), often abbreviated monobutyryl-cAMP, retains the ability to activate cAMP-dependent protein kinases and the glycogen phosphorylase system. N<sup>6</sup>-monobutyryl-cAMP is lipophilic, whereas cAMP is not. It is less susceptible to hydrolysis by phosphodiesterases. N<sup>6</sup>-monobutyryl-cAMP is also the active form of the more popularly used cell-penetrating substance, N<sup>6</sup>,O<sup>2</sup>-dibutyryladenose 3',5'-cAMP (1). **Target(s):** poly(ADP-ribose) glycohydrolase (2). 1. Kaukel, Mundhenk & Hilz (1972) *Eur. J. Biochem.* **27**, 197. 2. Miwa, Tanaka, Matsushima & Sugimura (1974) *J. Biol. Chem.* **249**, 3475.

**Monocrotophos**

This toxic organophosphate (FW = 223.17 g/mol), itself a direct metabolite of dicrotophos, is an pesticide and cholinesterase inhibitor. **Target(s):** acetylcholinesterase (1-5); arylformamidase (6); carboxylesterase (esterase) (1); cholinesterase (7); glutaminase (8); glutathione *S*-transferase (9); monoamine oxidase (10). 1. Siddiqui, Rahman, Mahboob, Anjum & Mustafa (1988) *J. Environ. Sci. Health B* **23**, 291. 2. Siddiqui, Rahman, Mustafa, Rahman & Bhalerao (1991) *Ecotoxicol. Environ. Saf.* **21**, 283. 3. Biol.* **30**, 543. 9. Siddiqui, Mahboob & Mustafa (1990) *Toxicology* **64**, 27. 10. Nag & Nandy (2001) *Indian J. Exp. Biol.* **39**, 802.

**Monomethyl Auristatin E**

This highly toxic synthetic tubulin polymerization inhibitor and antineoplastic agent (FW = 717.99 g/mol; CAS 474645-27-7; *Symbol*: MMAE), is not employed directly as a drug, but rather as a conjugate, joined by a suitable linker (indicated as R in the above structure) to a monoclonal antibody and relying on the latter to target a specific cancer cell type (1,2). When employed as an antibody-drug conjugate (ADC), MMAE is referred to as vedotin (**See for example Brentuximab vedotin**). The antibody-drug linker (consisting of the amino acids valine and citrulline) is readily cleaved by cathepsin, once within the targeted cancer cell. The peptide-linked mAb-Valine-Citrulline-MMAE and mAb-phenylalanine-lysine-MMAE conjugates are much more stable in buffers and plasma than the conjugates of mAb and the hydrazone of 5-benzoylvaleric acid-AE ester (AEVB) (3). As a result, the mAb-Val-Cit-MMAE conjugates exhibited greater specificity *in vitro* and lower toxicity *in vivo* than corresponding hydrazone conjugates. *In vivo* studies demonstrated the peptide-linked conjugates induced regressions and cures of established tumor xenografts with therapeutic indices as high as 60-fold. These conjugates illustrate the importance of linker technology, drug potency and conjugation methodology in developing safe and efficacious mAb-drug conjugates for cancer therapy (3). **See also Dolastatin 10** 1. Francisco, Cerveny, Meyer, *et al.* (2003) *Blood* **102**, 1458. 2. Ma, Hopf, Malewicz, *et al.* (2006) *Clin. Cancer Res.* **12**, 2591. 3. Dronina, Toki, Torgov *et al.* (2003) *Nature Biotechnol.* **21**, 778.

**Montelukast**

This potent, orally administered CysLT<sub>1</sub> antagonist (FW = 586.18 g/mol; CAS 158966-92-8; Code name MK-0476; Trade names: Singulair<sup>®</sup>, Montelo-10<sup>®</sup> and Monteflo<sup>®</sup>; IUPAC name (*R,E*)-2-((1-(1-(3-(2-(7-chloroquinolin-2-yl)vinyl)phenyl)-3-(2-(2-hydroxypropan-2-yl)phenyl)propylthio)methyl)cyclopropyl)acetic acid), is a selective inhibitor of

cyteinyll leukotriene D<sub>4</sub> receptor binding in guinea pig lung ( $K_i = 0.18$  nM), sheep lung ( $K_i = 4$  nM), and dimethylsulfoxide-differentiated U937 cells ( $K_i = 0.52$  nM), but it is essentially inactive against leukotriene C<sub>4</sub>-specific binding in dimethylsulfoxide-differentiated U937 cell membranes ( $IC_{50} > 10$   $\mu$ M) and [<sup>3</sup>H]leukotriene B<sub>4</sub>-specific binding in THP-1 cell membranes ( $IC_{50} \approx 40$   $\mu$ M). Importantly, LTD<sub>4</sub> receptor blockade and LTD<sub>4</sub> synthesis inhibition also suppress pentylene-tetrazol (PTZ)-induced kindling and pilocarpine-induced recurrent seizures (2). Montelukast (0.03 and 0.3  $\mu$ M) prevented PTZ-induced BBB disruption, an effect that was reversed by LTD<sub>4</sub> at the dose of 6 pmol, but not at the doses 0.2 and 2 pM (2). Moreover, the doses of LTD<sub>4</sub> (0.2 and 2 pM) that reverted the effect of montelukast on seizures did not alter montelukast-induced protection of BBB, dissociating BBB protection and anticonvulsant activity (2). See (3) for pharmacokinetics, bioavailability, and safety data. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Jones, Labelle, Belley, et al. (1995) *Can. J. Physiol. Pharmacol.* **73**, 191. 2. Lenz, Arroyo, Temp, et al. (2014) *Neuroscience*. **277**, 859. 3. Cheng, Leff, Amin, et al. (1996) *Pharm. Res.* **13**, 445.

### Moronone

This bis-geranylacetylphloroglucinol protonophore (FW = 502.70 g/mol), isolated from an active *Moronobea coccinea* extract, exhibits enhanced cytotoxic and antiproliferative activity against tumor cells already subjected to rotenone-imposed metabolic stress. Surprisingly, moronone does not inhibit glycolysis, but functions instead as a protonophore, dissipating the mitochondrial proton gradient. That moronone fails to inhibit glycolysis, even in the face of likely depletion of ATP stores, suggests that glycolysis (*Overall Reaction:* Glucose + 2ATP + 4ADP + 2P<sub>i</sub> + 2NAD<sup>+</sup> → 2pyruvic acid + 2ADP + 4ATP + 2NADH + 2H<sup>+</sup> + 2H<sub>2</sub>O) supplies sufficient ATP to sustain glucose phosphorylation. 1. Datta, Li, Mahdi, et al. (2012) *J. Nat. Prod.* **75**, 2216.

### Morphine

This strongly habit-forming opium alkaloid (FW<sub>free-base</sub> = 285.34 g/mol) is the prototypic  $\mu$ -opioid receptor ( $\mu$ OR) agonist (as well as a  $\kappa$ -receptor ( $\kappa$ OR) agonist), resulting in deranged receptor-mediated physiology that is manifested as long-lasting pain relief. (**For other alkaloids in opium poppy, see Opium**) **Primary Mode of Action:** Morphine profoundly alters receptor-mediated signal transduction throughout the nervous system. Indeed,  $\mu$ -opioid receptors are prominent within the brain (concentrated mainly in the cortex, thalamus, striosomes, periaqueductal gray matter, and rostral ventromedial medulla), spinal cord, peripheral sensory neurons, and intestinal tract neurons.  $\kappa$ -Opioid receptors are found within the brain (mainly in the hypothalamus, periaqueductal gray matter, and claustrum), spinal cord, and peripheral sensory neurons. The robust diversity of opioid receptor pharmacology is best explained by the interplay of various receptor subtypes, thereby expanding the repertoire of responses beyond those predicted on the basis of the known opioid receptors. A likely mechanism involves the assembly of novel signaling complexes through hetero-

oligomerization of receptor subunits as well as some degree of promiscuity in opioid receptor interactions with other G-protein-coupled receptors. The  $\alpha_{2A}$ -adrenoceptor/ $\mu$ -opioid receptor heterodimer complex, for example, relies on ligand binding to propagate allosteric conformational changes among its constituent subunits (*or* protomers). Upon binding to  $\mu$ OR, morphine triggers a conformational change in the associated norepinephrine-occupied  $\alpha_{2A}$ -adrenoceptor, which, within milliseconds, results in reduced GTP regulatory protein activation by the  $\alpha_{2A}$ -adrenoceptor protomer. **Uptake & Metabolism:** Morphine can be administered by many routes (*e.g.*, oral, sublingual, rectal, subcutaneous, intravenous, epidural), including inhalation of finely dispersed drug. If delivered orally, morphine's first-pass kinetics assure that less than half reaches the central nervous system. Morphine is converted to morphine-3-glucuronide and morphine-6-glucuronide by UDP-glucuronosyl transferase. Morphine's long-lasting diacetyl ester (heroin) and the even more potent semisynthetic opioids (Bentley compounds) are more active, at least in part, because they resist glucuronidation. Morphine addiction is confounded by psychological dependence, physical dependence, as well as drug tolerance. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** acetylcholinesterase (1,2); cholinesterase, *or* butyrylcholinesterase (1,3,4); Ca<sup>2+</sup>-dependent ATPase (5); glucuronosyltransferase, as alternative substrate for UGT2B7 (6); phosphofructokinase (7); oxidative phosphorylation (8); oxytocin secretion (9). 1. ### Mosquito Oostatic Factor

This naturally occurring decapeptide (FW = 1047.18 g/mol; *Sequence:* YDPAPPPPPP; *Abbreviation:* MOOF), also known as trypsin modulating oostatic factor, inhibits egg development in mosquitos as well as trypsin- and chymotrypsin like enzyme biosynthesis (1). When microinjected into *Listeria*-infected cells, mosquito oostatic factor also blocks *Listeria*-induced actin rocket tail assembly as well as the intracellular locomotion of this pathogen (2). Co-administration of the actin regulatory protein profilin neutralize the inhibitory action of mosquito oostatic factor. Actin-based motility relies on two types of proline-rich sequences to assemble actin locomotory units. *Listeria monocytogenes* ActA surface protein contains a series of nearly identical EFPPPTDE-type oligoproline sequences for binding vasodilator-stimulated phospho-protein (VASP). The latter is a tetrameric protein with numerous GPPPPP docking sites for profilin, a 15-kDa regulatory protein that promotes actin filament assembly. Analysis of known actin regulatory proteins led to the identification of the following Actin-Based Motility homology sequences: ABM-1, *Sequence* = (D/E)FPPPPX(D/E); and ABM-2, *Sequence* = XPPPPP, where X denotes G, A, L, P and S). MOOF appears to be an ABM-2 binding antagonist (3). 1. Borovsky, Carlson, Griffin, Shabanowitz & Hunt (1990) *FASEB J.* **4**, 3015. 2. Southwick & Purich (1995) *Infect. Immun.* **63**, 182. 3. Purich & Southwick (1997) *Biochem. Biophys. Res. Commun.* **231**, 686.

**Motesanib**

This orally bioavailable VEGF receptor kinase inhibitor (FW<sub>free-base</sub> = 373.46 g/mol; FW<sub>di-phosphate-salt</sub> = 569.44 g/mol; CAS 857876-30-3; Solubility: 100 mg/mL DMSO; 100 mg/mL H<sub>2</sub>O), also known as AMG-706 and *N*-(2,3-dihydro-3,3-dimethyl-1*H*-indol-6-yl)-2-[[4-pyridinylmethyl]amino]-3-pyridinecarboxamide, VEGFR1/Flt1 (IC<sub>50</sub> = 2 nM); VEGFR2/Flt2 (IC<sub>50</sub> = 3 nM); VEGFR3/Flt4 (IC<sub>50</sub> = 6 nM); PDGFR (IC<sub>50</sub> = 84 nM); c-Kit (IC<sub>50</sub> = 8 nM); and Ret (IC<sub>50</sub> = 59 nM). AMG 706 inhibits human endothelial cell proliferation induced by VEGF, but not by basic fibroblast growth factor in vitro, as well as vascular permeability induced by VEGF in mice (1). It is also effective in combination with radiation to treat head and neck squamous cell carcinoma (HNSCC) in mouse xenograft models (2). It is also highly effective against breast cancer xenografts (3). 1. Polverino, Coxon, Starnes, *et al.* (2006) *Cancer Res.* **66**, 8715. 2. Kruser, Wheeler, Armstrong, *et al.* (2010) *Clin. Cancer Res.* **16**, 3639. 3. Coxon, Bush, Saffran, *et al.* (2009) *Clin. Cancer Res.* **15**, 110.

**Motilin**

This gastrointestinal peptide (FW = 2699.08 g/mol; *Human Sequence*: FVPIFTYQELQRMQEKERNKGQ) is produced by motilin-immunopositive cells (Mo cells) present in the upper small intestine. Motilin's main action is to stimulate stomach contractions, resulting in release from parietal cells in the stomach lining. Motilin also inhibits luteinizing hormone release (1). 1. Tsukamura, Tsukahara, Maekawa, *et al.* (2000) *J. Neuroendocrinol.* **12**, 403.

**Moxalactam**

This cephalosporin antibiotic (FW<sub>free-acid</sub> = 520.48 g/mol; CAS 75007-71-5), also known as latamoxef, is a pseudosubstrate that inactivates  $\beta$ -lactamases via the formation of a stable covalent bond. The methylthiotetrazole side chain of moxalactam inhibits  $\gamma$ -carboxylation of glutamic acid residues on blood clotting factors, thereby interfering with the clot-promoting actions of vitamin K (1). Vitamin K deficiency is amplified by an administration of LMOX even in the absence of intestinal flora. **Target(s)**: alcohol dehydrogenase (2); aldehyde dehydrogenase (3);  $\beta$ -lactamase (4-11); penicillin binding proteins (12). 1. **Moxifloxacin**

This fourth-generation fluoroquinolone-class antibiotic (FW = 401.44 g/mol; CAS 354812-41-2), also named BAY 12-8039, Avelox<sup>®</sup>, Vigamox<sup>®</sup>, Moxeza<sup>®</sup>, and 1-cyclopropyl-7-[(1*S*,6*S*)-2,8-diazabicyclo[4.3.0]non-8-yl]-6-fluoro-8-methoxy-4-oxoquinoline-3-carboxylic acid, exhibits broad action against enteric Gram-negative rods (*Escherichia coli*, *Proteus* species, *Klebsiella* species), *Haemophilus influenzae*, as well as atypical bacteria (*e.g.*, *Mycoplasma*, *Chlamydia*, *Legionella*), and *Streptococcus pneumoniae*, as well as many anaerobic bacteria. Moxifloxacin differs from earlier fluoroquinolone-class agents (*e.g.*, levofloxacin and ciprofloxacin) in having greater activity against Gram-positive bacteria and anaerobes (1). MIC<sub>90</sub> values for moxifloxacin action against ciprofloxacin-resistant, methicillin-susceptible and methicillin-resistant *Staphylococcus aureus* are 8  $\mu$ g/mL (1). Following oral administration, moxifloxacin absorption is fast, with low to medium variability, and an absolute bioavailability of 86% (2). The excretion of moxifloxacin and its metabolites was quantified in a subset of eight subjects (2). **Key Pharmacokinetic Parameters**: See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) **MP-470, See Amuvatinib****MP A08**

This first-in-class, cell-permeable SphK2/1 inhibitor (FW = 519.64 g/mol; CAS 219832-49-2; Solubility: 100 mM in DMSO), also known as MP-A08 and 4-methyl-*N*-[2-[[[2-[[[4-methyl-phenyl]sulfonyl]amino]phenyl]imino]methyl]phenyl]benzenesulfonamide, targets sphingosine kinase-2,  $K_i$  = 6.9  $\mu$ M, and sphingosine kinase-1,  $K_i$  = 27  $\mu$ M (1). MP-A08 blocks proliferative signalling pathways, inducing mitochondria-associated apoptosis in a SK-dependent manner and reducing the growth of human lung adenocarcinoma tumours in a mouse xenograft model by both inducing tumor cell apoptosis and inhibiting tumour angiogenesis (1). 1. Pitman, Powell, Coolen, *et al.* (2015) *Oncotarget* **6**, 7065.

**MPC-1303, See Aranidipine****MPC-4326, See Bevirimat**

## MPP

This substituted pyrazole (FW<sub>free-base</sub> = 469.58 g/mol), also known as methyl-piperidino-pyrazole, is an estrogen receptor  $\alpha$  antagonist. The gene-regulating actions of estrogens are mediated through ER $\alpha$  and ER $\beta$ , two estrogen receptor subtypes receptors that function as ligand-modulated transcription factors with distinctive tissue distributions. *Note*: Do not confuse this pyrazole with the 1-methyl-4-phenylpyridinium cation, also abbreviated MPP<sup>+</sup>. 1. Sun, Huang, Harrington, *et al.* (2002) *Endocrinology* **143**, 941.

## Mps1-IN-1

This ATP-competitive protein kinase inhibitor (FW = 535.66 g/mol) targets Mps1 (IC<sub>50</sub> = 367 nM), a dual-specificity kinase required for the proper spindle assembly checkpoint control and maintenance of chromosomal stability. Although spindle assembly checkpoint (SAC) is a well-conserved pathway in eukaryotes, there is good reason to believe that small-molecule inhibitors can hobble the pathway in a manner that is anti-proliferative. With the major exceptions of Alk and Ltk, this compounds demonstrated greater than 1000x selectivity relative to the 352-member kinase panel. Notably, Mps1-IN-1 treatment leads to defects in Mad1 and Mad2 establishment at unattached kinetochores, decreased Aurora B kinase activity, premature mitotic exit, and gross aneuploidy, without any evidence of centrosome duplication defects. Upon inhibitor binding, Mps1 adopts an inactive conformation as indicated by incorrect positioning of the regulatory helix  $\alpha$ C, the lack of a salt bridge between the conserved  $\alpha$ C glutamate (E571) and the active site lysine (K553), and an unstructured activation loop (M671-V684). (See also *MPS1-IN-2*, *Mps BAY 2a*, and *NMS-P715*) 1. Kwiatkowski, Jelluma, Filippakopoulos, *et al.* (2010) *Nature Chem. Biol.* **6**, 359.

## MPS1-IN-2

This ATP-competitive protein kinase inhibitor (FW = 480.61 g/mol) targets Mps1 (IC<sub>50</sub> = 145 nM), a dual-specificity kinase required for the proper

spindle assembly checkpoint control and maintenance of chromosomal stability. With the major exceptions of Gak and Plk1, this compounds demonstrated greater than 1000x selectivity relative to the 352-member kinase panel. (For other details on its mode of of inhibitor action. (See also *MPS1-IN-1*, *Mps BAY 2a*, and *NMS-P715*) 1. Kwiatkowski, Jelluma, Filippakopoulos, *et al.* (2010) *Nature Chem. Biol.* **6**, 359.

## Mps BAY 2a

This mitosis inhibitor (FW = 476.57 g/mol; CAS 1382477-96-4; Solubility: 100 mM in DMSO; IUPAC: *N*-Cyclopropyl-4-[8-[(2-methylpropyl)amino]-6-(5-quinolinyl)imidazo[1,2-*a*]pyrazin-3-yl]benzamide, targets monopolar spindle-1 (Mps1 or TTK protein kinase), an essential serine/threonine kinase in the mitotic spindle assembly checkpoint (SAC) pathway. By selectively inactivating Mps1, this inhibitor arrests cancer cell proliferation, causing polyploidy and/or cell death. Direct videomicroscopic cell-fate profiling of histone 2B-green fluorescent protein-expressing cells revealed the capacity of Mps BAY 2a to subvert the correct timing of mitosis as they induce a premature anaphase entry in the context of misaligned metaphase plates. In the presence of the inhibitor, cells either divided in a bipolar (often asymmetric) manner or entered one or more rounds of abortive mitoses, generating gross aneuploidy and polyploidy, respectively, ultimately dying as a result of mitotic catastrophe-induced activation of the mitochondrial apoptosis pathway. (See also *MPS1-IN-1*, *MPS1-IN-2*, and *NMS-P715*) 1. Jemaà, Galluzzi, Kepp, *et al.* (2013) *Cell Death Differ.* **20**, 1532.

## MPT0B098

This novel vascular-disrupting agent (FW = 399.44 g/mol), also known as 7-aryl-indoline-1-benzene-sulfonamide, is a potent microtubule inhibitor that binds to the colchicine-binding site on tubulin. MPT0B098 is active against the growth of various human cancer cells, including several chemoresistant cell lines, with IC<sub>50</sub> values of 70-150 nM. MPT0B098 arrests cells in the G<sub>2</sub>-M phase and induces subsequent apoptosis. MPT0B098 effectively suppresses VEGF-induced cell migration and disrupts capillary tube formation from human umbilical vein endothelial cells, or HUVECs. Vascular disrupting agents (VDAs) are compounds that block the formation of or cause the disorganization of blood vessels needed to nourish tumors, thereby starving the central tumor. The ideal VDA will bind to its target binding partner, bringing about the disruption of the capillary vasculature. It will then be released from its target binding partner, followed by timely metabolic deactivation and/or elimination. (See *Combretastatin*) 1. Cheng, Liou, Kuo, *et al.* (2013) *Mol. Cancer Ther.* **12**, 1202.

MPTP, See *1-Methyl-4-phenyl-1,2,3,6-tetrahydropyridine*

## MRK 560

This oral  $\gamma$ -secretase inhibitor (FW = 517.92 g/mol; CAS 67772-84-8; Solubility: 100 mM in DMSO), also named *N*-[*cis*-4-[(4-chlorophenyl)sulfonyl]-4-(2,5-difluorophenyl)cyclohexyl]-1,1,1-trifluoro-methanesulfonamide, preferentially inhibits proteolytic cleavage of amyloid precursor protein (APP). MRK-560 reduces A $\beta$  accumulation in the brain and cerebrospinal fluid, inhibiting formation of A $\beta$ 40 and A $\beta$ 42 peptides in SH-SY5Y neuroblastoma cells (IC<sub>50</sub> = 0.65 nM), thereby attenuating AD plaque deposition. MRK560 also reduces amyloid plaque deposition, while showing no evidence of Notch-related pathology in the Tg2576 mouse **1**. Best, *et al.* (2006) *J. Pharm. Exp. Ther.* **317**, 786. **2**. Best, *et al.* (2007) *J. Pharm. Exp. Ther.* **320**, 552.

**MRS 1220**

This potent and highly selective adenosine receptor antagonist (FW = 403.83 g/mol; CAS 183721-15-5; Soluble to 100 mM in DMSO with gentle warming), also named *N*-[9-chloro-2-(2-furanyl)[1,2,4]triazolo[1,5-*c*]quinazolin-5-yl]benzenacetamide, targets the human A<sub>3</sub> adenosine receptor ( $K_i$  = 0.65 nM), rat A<sub>1</sub> ( $K_i$  = 305 nM), and rat A<sub>3</sub> ( $K_i$  = 52 nM; IC<sub>50</sub> > 1  $\mu$ M). **1**. Kim, *et al.* (1996) *J. Med. Chem.* **39**, 4142. **2**. Jacobson, *et al.* (1997) *Neuropharmacol.* **36**, 1157. **3**. Kim, *et al.* (1998) *J. Med. Chem.* **41**, 2835.

**MRS 1334**

This potent and highly selective adenosine receptor antagonist (FW = 522.56 g/mol; CAS 192053-05-7; Soluble to 100 mM in DMSO), also named 1,4-dihydro-2-methyl-6-phenyl-4-(phenylethynyl)-3,5-pyridinedicarboxylic acid 3-ethyl-5-[(3-nitrophenyl)methyl] ester, targets the human A<sub>3</sub> adenosine receptor ( $K_i$  = 2.7 nM), with  $K_i$  values in excess of 100  $\mu$ M for rat A<sub>1</sub> and A<sub>3</sub> receptors. **1**. Li, *et al.* (1998) *J. Med. Chem.* **41**, 3186. **2**. Baraldi & Borea (2000) *Trends Pharmacol. Sci.* **21**, 456.

**MRS 1706**

This potent and highly selective adenosine receptor inverse agonist (FW = 503.56 g/mol; CAS 264622-53-9; Soluble to 5 mM in DMSO), also named *N*-(4-cetylphenyl)-2-[4-(2,3,6,7-tetrahydro-2,6-dioxo-1,3-dipropyl-1*H*-

purin-8-yl)phenoxy]acetamide, targets the human A<sub>2B</sub> adenosine receptor ( $K_i$  = 1.4 nM), with much higher  $K_i$  values of 157, 112 and 230 nM for human A<sub>1</sub>, A<sub>2A</sub> and A<sub>3</sub> receptors, respectively. **1**. Kim, *et al.* (2000) *J. Med. Chem.* **43**, 1165. **2**. Kiec-Kononowicz, *et al.* (2001) *Pure Appl. Chem.* **73**, 1411. **3**. Li, *et al.* (2007) *J. Pharmacol. Exp. Ther.* **320**, 637.

**MRS 2159**

This pyridoxal phosphate derivative (FW = CHNO g/mol; CAS 83654-06-2) is a P<sub>2X1</sub> purinoceptor antagonist. Extracellular adenine nucleosides and nucleotides act as neuromodulators and neurotransmitters by binding to P<sub>1</sub> and P<sub>2</sub> purine receptors in the central and peripheral nervous systems. Two families of P<sub>2</sub> receptors (*e.g.*, ligand-gated ion channels (the P<sub>2X</sub> subtype) and G protein-coupled receptors (the P<sub>2Y</sub> subtype) are widely studied, and it is now clear that uracil nucleotides are also active, perhaps even preferred ligands for some P<sub>2Y</sub> subtypes. **1**. Kim, Camaioni, Ziganshin, *et al.* (1998) *Drug Develop. Res.* **45**, 52.

**MRS 2179**

This nucleotide (FW = 459.29 g/mol; IUPAC: 2'-deoxy-N<sup>6</sup>-methyladenosine 3',5'-bisphosphate, is a competitive antagonist of P<sub>2Y1</sub> purinoceptor, which upon agonist binding activates phospholipase C (PLC), which generates inositol phosphates and diacylglycerol from phosphatidylinositol-4,5-bisphosphate, leading to a rise in intracellular calcium ion. The P<sub>2Y1</sub> receptor in platelets is involved in ADP-promoted aggregation, making P<sub>2Y1</sub>-selective antagonists highly promising as antithrombotic agents. Selective P<sub>2Y1</sub> receptor agonist may also have potential as anti-hypertensive or anti-diabetic agents. **1**. Nandan, Jang, Moro, *et al.* (2000) *J. Med. Chem.* **43**, 829. **2**. Boyer, Mohanram, Camaioni, Jacobson & Harden (1998) *Brit. J. Pharmacol.* **124**, 1.

**MRS 2395**

This chlorpurine diester (FW = 439.94 g/mol) is a P<sub>2Y12</sub> purinoceptor antagonist. Extracellular adenine nucleosides and nucleotides act as neuromodulators and neurotransmitters by binding to P<sub>1</sub> and P<sub>2</sub> purine receptors in the central and peripheral nervous systems. Two families of P<sub>2</sub> receptors (*e.g.*, ligand-gated ion channels (the P<sub>2X</sub> subtype) and G protein-coupled receptors (the P<sub>2Y</sub> subtype) are widely studied, and it is now clear that uracil nucleotides are also active, perhaps even preferred ligands for some P<sub>2Y</sub> subtypes. **1**. Xu, Stephens, Kirschenheuter, *et al.* (2002) *J. Med. Chem.* **45**, 5694.

**MRS 2578**

This potent, insurmountable P2Y purinoceptor-6 receptor antagonist (FW = 472.67 g/mol; CAS 711019-86-2; Solubility: 50 mg/mL DMSO; <1 mg/mL Water), named systematically as *N,N''*-1,4-butanediylbis[*N'*-(3-isothiocyanatophenyl)thiourea], targets the P2Y6 receptor ( $IC_{50}$  = 37 nM), a G-protein-coupled receptor that is activated by extracellular nucleotides. **1.** Mamedova, *et al.* (2004) *Biochem. Pharmacol.* **67**, 1763. **2.** Riegel, *et al.* (2011) *Blood* **117**, 2548. **3.** Talasila, *et al.* (2009) *Br. J. Pharmacol.* **158**, 339. **4.** Vieira, *et al.* (2011) *Am. J. Respir. Crit. Care Med.* **184**, 215.

**MRT00033659**

This pyrazolo-pyridine analogue (FW = 266.30 g/mol) exhibits novel multi-target inhibitory action against Checkpoint Kinase 1, *or* CHK1 ( $IC_{50}$  = 0.9  $\mu$ M, *in vitro*) and Casein Kinase 1, *or* CK1 $\delta$  ( $IC_{50}$  = 0.23  $\mu$ M, *in vitro*). MRT00033659 shows sub-micromolar bioactivity in cells with respect to p53 protein stabilization and E2F-1 destabilization, with pharmacological similarities to the CK1-inhibitor D4476 and the MDM2-inhibitor Nutlin-3. While single-target activity has been pursued traditionally in search of selective, low-toxicity drugs, multi-target leads offer the advantage of simultaneously disrupting several signal transduction pathways, thereby placing certain cancer cell types at much higher jeopardy. **Other Target(s):** ERK8 ( $IC_{50}$  = 0.4  $\mu$ M); FGF-R1 ( $IC_{50}$  = 6  $\mu$ M); Nek2 $\alpha$  ( $IC_{50}$  = 2  $\mu$ M). **1.** Huart, Saxty, Merritt, *et al.* (2013) *Bioorg. Med. Chem. Lett.* **23**, 5578.

**MRT67307**

This potent and dual IKK $\epsilon$ /TBK1 inhibitor (FW<sub>free-base</sub> = 434.58 g/mol; CAS 1190379-70-4 (free base)), also named *N*-[3-[[5-cyclopropyl-2-[(1,2,3,4-tetrahydro-2-methyl-6-isoquinolinyl)amino]-4-pyrimidinyl]amino]propyl]cyclobutanecarboxamide hydrochloride, targets Inhibitor- $\kappa$ B kinase  $\epsilon$  (IKK $\epsilon$ ), recently identified as a protein kinase with a high degree of homology to the classical I- $\kappa$ B kinase subunits, IKK $\alpha$  and IKK $\beta$ , and TANK-binding kinase-1 (TBK1), a serine/threonine kinase that plays an essential role in regulating inflammatory responses to foreign agents. Following activation of toll-like receptors by viral or bacterial components, TBK1 associates with TRAF3 and TANK and phosphorylates Interferon Regulatory Factors IRF3 and IRF7 as well as DDX3X. MRT67307 increases TLR-stimulated production of anti-inflammatory cytokines while suppressing proinflammatory cytokine secretion. MRT67307 has little effect on TLR-stimulated phosphorylation of CREB at Ser133 or the closely related ATF1 at Ser-63. Inhibition of SIKs by MRT67307, MRT199665, and HG-9-91-01 increases IL-10 production, while suppressing the secretion of IL-6, IL-12, and TNF. **1.** Clark, MacKenzie, Petkevicius, *et al.* (2012) *Proc. Natl. Acad. Sci. U.S.A.* **109**, 16986.

**MS 023**

This potent and selective type I PRMT inhibitor (FW = 360.32 g/mol; Soluble to 100 mM in H<sub>2</sub>O and to 100 mM in DMSO), also named *N*<sup>1</sup>-methyl-*N*<sup>1</sup>-[[4-[4-(1-methylethoxy)-phenyl]-1*H*-pyrrol-3-yl]methyl]-1,2-ethanediamine di-HCl, targets Protein Arginine Methyltransferase (PRMT), with respective  $IC_{50}$  values of 4, 5, 30, 83 and 119 nM for PRMT6, PRMT8, PRMT1, PRMT4 and PRMT3, while showing no significant activity against PRMT2, protein lysine methyltransferases (PKMTs), DNA methyltransferases (DNMTs), histone lysine demethylases (or KDMs) and methyllysine reader proteins. A crystal structure of PRMT6 in complex with MS023 revealed that MS023 binds the substrate binding site. MS-023 potently decreased cellular levels of histone arginine asymmetric dimethylation. It also reduced global levels of arginine asymmetric dimethylation and concurrently increased levels of arginine monomethylation and symmetric dimethylation in cells. **1.** Eram, Shen, Szewczyk, *et al.* (2016) *ACS Chem Biol.* **11**, 772.

**MS-275, See Entinostat**

**MS-752, See Lucanthone**

**MSC1992371A1**

This oral, adenosine triphosphate-competitive inhibitor (FW = 451.54 g/mol; CAS 871357-89-0), also known by the code name AS703569 and systematically as (1*S*,2*S*,3*R*,4*R*)-3-((5-fluoro-2-((3-methyl-4-(4-methylpiperazin-1-yl)phenyl)amino)pyrimidin-4-yl)amino)bicyclo-[2.2.1]hept-5-ene-2-carboxamide, targets mammalian aurora-kinase isoforms A, B, and C. MSC1992371A blocks cell separation by disrupting the mitotic spindle, leading to polyploidy and, ultimately, cell death. *In vitro*, MSC1992371A is a potent inhibitor of tumor cell growth, with  $IC_{50}$  values <100 nM [5]. *In vivo*, the compound has demonstrated significant antitumor activity in several xenograft models including those of the pancreas, breast, colon, kidney, lung, and ovary. With MiaPaca-2 pancreatic and Colo-205 colorectal xenografts, weekly dosing offered the best therapeutic window. **1.** Martinelli, Iacobucci, Papayannidis, *et al.* (2009) *Clin. Haematol.* **22**, 445. **2.** McLaughlin, Markovtsov, Li, Sacha, *et al.* (2010) *J. Cancer Res. Clin. Oncol.* **136**, 99.

**MSC2032964A**

This potent and selective ASK1 inhibitor (FW = 362.31 g/mol; CAS 1124381-43-6; Solubility: 20 mM in DMSO), also named *N*-[5-

(cyclopropylamino)-7-(trifluoromethyl)[1,2,4]triazolo[1,5-*a*]pyridin-2-yl]-3-pyridinecarboxamide, is an orally bioavailable and brain-penetrant agent that targets Apoptosis Signal-regulating Kinase-1 ( $IC_{50} = 93$  nM), also known as mitogen-activated protein kinase kinase 5 (MAP3K5), with much weaker action on 210 other kinases. (Apoptosis signal-regulating kinase 1 (ASK1) is an evolutionarily conserved mitogen-activated protein kinase (MAPK) kinase kinase which plays important roles in stress and immune responses.) MSC-2032964A blocks LPS-induced ASK1 and p38 phosphorylation in cultured mouse astrocytes. It also suppresses neuroinflammation in a mouse EAE model. 1. Guo, Harada, Namekata, *et al.* (2010) *EMBO Mol. Med.* 2, 504.

#### MTEP

This orally active anxiolytic agent (FW = 236.72 g/mol; CAS 1186195-60-7; Soluble to 100 mM in water and to 100 mM in DMSO), also named 3-((2-methyl-1,3-thiazol-4-yl)ethynyl)pyridine hydrochloride, is a potent, selective and non-competitive antagonist of the mGlu<sub>5</sub> metabolomics glutamate receptor,  $IC_{50} = 5$  nM in  $Ca^{2+}$ -flux assay,  $K_i = 16$  nM (1-4). Metabotropic glutamate receptor mGlu<sub>5</sub> is a mediator of appetite and energy balance in rats and mice (5). 1. Brodtkin, *et al.* (2002) *Eur. J. Neurosci.* 16, 2241. 2. Cosford, *et al.* (2003) *J. Med. Chem.* 46, 204. 3. Klodzinska, *et al.* (2004) *Neuropharmacol.* 47, 342. 4. Roppe, *et al.* (2004) *Bioorg. Med.*

#### mTOR Inhibitors

These agents, which include temsirolimus (CCI-779), everolimus (RAD001) and deforolimus (AP23573), inhibit mammalian Target of Rapamycin (or mTOR), a protein kinase within the phosphatidylinositol 3-kinase (PI3K)/Akt signalling cascade. The latter plays a central role in controlling cell proliferation, survival, mobility and angiogenesis. Dysregulation of mTOR pathway has been found in many human tumors, making the mTOR pathway an important target for developing a promising new class of anticancer drugs. In tumor cells, mTOR is activated by various mechanisms, including growth factor surface receptor tyrosine kinases, oncogenes, and loss of tumor suppressor genes. Such activating factors are important in malignant transformation and progression. See *Deforolimus, Everolimus, Temsirolimus, and Zotarolimus*

#### MTPG

This metabotropic glutamate receptor antagonist (FW = 233.23 g/mol; CAS 169209-66-9; Soluble to 100 mM as sodium salt), also named (*RS*)- $\alpha$ -methyl-4-tetrazolylphenylglycine, targets mGlu<sub>2</sub> (Group II) and mGlu<sub>3</sub> (Group III) metabotropic glutamate receptor antagonist, showing selectivity for mGlu<sub>2</sub> in electrophysiological studies. 1. Jane, *et al.* (1995) *Neuropharmacol.* 34, 851. 2. Bedingfield, *et al.* (1996) *Eur. J. Pharmacol.* 309, 71. 3. Bushell, *et al.* (1996) *Brit. J. Pharmacol.* 117, 1457.

#### Mucus Proteinase Inhibitor

This 107-residue, mucus-derived, acid-stable protein (MW = 11.7 kDa), also called secretory leukocyte protease inhibitor (SLPI) and antileukoprotease, is a potent serine-protease inhibitor thought to increase in inflammation and infection and to primarily target human leukocyte elastase. **Target(s):** cathepsin G (1-3); chymase (1,3,4); chymotrypsin (1-3); elastase (1,2,5-7); leukocyte elastase (3,6,7); pancreatic elastase (5); stratum corneum chymotryptic enzyme, or kallikrein-7 (8); trypsin (1-3); trypsin (3,9). 1. **$\mu$ -SLPTX-Ssm6a**, See *SLPTX-Ssm6a*

#### Mupirocin

This isoleucyl t-RNA synthetase inhibitor (FW = 500.62 g/mol; CAS 12650-69-0; Solubility: 200 mM in DMSO, with heating), also known as pseudomonic acid A and (*2E*)-5,9-anhydro-2,3,4,8-tetradecoxy-8-[[[(2S,3S)-3-[(1S,2S)-2-hydroxy-1-methylpropyl]oxiranyl]methyl]-3-methyl-L-talono-2-enonic acid 8-carboxyooctyl ester, is an antibiotic produced by *Pseudomonas fluorescens*, with a high level of activity against staphylococci and streptococci and against certain Gram-negative bacteria, including *Haemophilus influenzae* and *Neisseria gonorrhoeae*, but was much less active against most gram-negative bacilli and anaerobes (1,2). Nearly all clinical isolates of *Staphylococcus aureus* and *Staphylococcus epidermidis*, including multiply resistant strains, are susceptible to mupirocin (MIC  $\leq 0.5$   $\mu$ M). **Mechanism of Inhibitory Action:** Mupirocin is a powerful inhibitor of *Escherichia coli* B isoleucyl-tRNA synthetase (or Ile-tRNA synthetase), acting competitively ( $K_i = 6$  nM) with respect to isoleucine (3). [<sup>3</sup>H]-Mupirocin forms a stable complex with Ile-tRNA synthetase, and gel-filtration and gel-electrophoresis showed that the antibiotic is fully released only upon treatment with 5 M urea treatment or upon boiling in 0.1% sodium dodecyl sulfate. The binding stoichiometry is 0.85 mol mupirocin per mol enzyme, as determined by equilibrium dialysis. Aminoacylation of yeast tRNA<sup>Ile</sup> by rat liver Ile-tRNA synthetase was also competitively inhibited with respect to isoleucine ( $K_i = 20$   $\mu$ M), some 8000 times higher than for binding to the *E. coli* enzyme and providing a basis for the low toxicity of the antibiotic in mammals (3). 1. Reilly & Spencer (1984) *J. Antimicrob. Chemother.* 13, 295. 2. Sutherland, Boon, Griffin, *et al.* (1985) *Antimicrob. Agents Chemother.* 27, 495. 3. Hughes & Mellows (1980) *Biochem. J.* 191, 209.

#### Mureidomycin A

This antibiotic (FW = 840.91 g/mol; CAS 114797-04-5) and related metabolites from *Streptomyces flavidovirens* WD31235, are slow-binding inhibitors of phospho-*N*-acetylmuramoyl-pentapeptide-transferase ( $K_i = 36$  nM and  $K_i^* = 2$  nM). 1. Brandish, Burnham, Lonsdale, *et al.* (1996) *J. Biol. Chem.* 271, 7609. 2. Brandish, Kimura, Inukai, *et al.* (1996) *Antimicrob. Agents Chemother.* 40, 1640. 3. Stachyra, Dini, Ferrari, *et al.* (2004) *Antimicrob. Agents Chemother.* 48, 897.

#### (+)-Muscarine

This toxic quaternary ammonium-containing alkaloid and acetylcholine receptor agonist (FW = 209.72 g/mol; CAS 2936-25-6; muscarine hydrochloride is freely soluble in water and ethanol) is the prototypical muscarinic agonist of cholinergic receptors. Isolated from the mushroom *Amanita muscaria* and related gill fungi, muscarine is also a potent cholinesterase inhibitor (1). Gaskell (2) first applied galvanometry to describe the action of muscarine and pilocarpine on the dissected heart and on the electrical changes in the non-beating cardiac muscle brought about by stimulation of inhibitory and augmentor nerves. The toxic actions of muscarine include Parkinson-like CNS effects (e.g., tremor, ataxia, and spasticity). The intravenous LD<sub>50</sub> in mice is 0.23 mg/kg, similar to pilocarpine. Treatment of muscarine poisoning involves parenteral administration of atropine, supported clinically by efforts to minimize pulmonary edema. Bebbington & Brimblecombe (3) and Kosterlitz (4) have reviewed the chemistry and pharmacology of various natural and synthetic muscarinic agents. Muscarine's pharmacologic action on mAChR's can be scored as follows: Cardiovascular, ++; Gastrointestinal, +++; Bladder, +++; Eye, ++ (applied topically). **Target(s):** acetyl-cholinesterase (1,2); calcium channels, ω-conotoxin-sensitive (5). 1. Augustinsson (1950) *The Enzymes*, 1st. ed., 1 (part 1), 443. 2. Gaskell (1887) *J. Physiol.* 8, 404. (This must-read classic is available in *PubMed Central*. PMID: PMC1485142) 3. Bebbington & Brimblecombe (1965) *Adv. Drug Res.* 22, 143. 4. Kosterlitz (1967) in *Physiological Pharmacology* (Root & Hofmann, eds.) vol. 3, p. 97, Academic Press, New York. 5. Toselli, Perin & Taglietti (1995) *J. Neurophysiol.* 74, 1730.

### Muscarinic Acetylcholine Receptor Agonists

These agents bind to and activate muscarinic acetylcholine receptors (or mAChRs), which are receptors that form G protein-receptor complexes in the cell membranes of certain neurons and other cells. mAChRs act as the main end-receptors that are stimulated by acetylcholine, after the latter is released presynaptically from postganglionic fibers in the parasympathetic nervous system. The name "mAChR" derives from the fact that these receptors are more sensitive to muscarine than to nicotine (See (+)-Muscarine; Nicotine). Muscarinic AChRs are found both in post-synaptic and pre-synaptic sites. Although this reference book focuses on enzyme inhibitors and receptor antagonists, muscarinic receptor agonists are of such widespread utility that they should be briefly described here.

**mAChR Agonist: Acetylcholine** (FW = 146.21 g/mol; CAS 51-84-3), which acts on both peripheral and central neurons, is the only neurotransmitter used in the motor division of the somatic nervous system and is also the principal neurotransmitter in all autonomic ganglia. Acetylcholine's pharmacologic action on mAChR's can be scored as follows: Cardiovascular, ++; Gastrointestinal, ++; Bladder, ++; Eye, + (applied topically).

**mAChR Agonist: Bethanechol** (FW = 161.22 g/mol; CAS 674-38-4), also named Duvoid<sup>®</sup>, Myotonachol<sup>®</sup>, Urecholine<sup>®</sup>, Urocarb<sup>®</sup>, and 2-(carbamoyloxy)-N,N,N-trimethylpropan-1-aminium, is a parasympathomimetic choline carbamate that selectively stimulates muscarinic receptors without any effect on nicotinic receptors. Unlike acetylcholine, however, bethanechol is not hydrolyzed by cholinesterase and has a long duration of action. Bethanechol's pharmacologic action on mAChR's can be scored as follows: Cardiovascular, ±; Gastrointestinal, +++; Bladder, +++; Eye, ++ (applied topically).

**mAChR Agonist: Carbachol** (FW = 146.21 g/mol; CAS 51-84-3), also named Miostat<sup>®</sup> and 2-[(aminocarbonyloxy)-N,N,N-trimethylethanamine,

is a cholinomimetic drug that binds and activates acetylcholine receptors. It is used mainly for ophthalmic purposes, including glaucoma and during ophthalmic surgery. Carbachol's pharmacologic action on mAChR's can be scored as follows: Cardiovascular, +; Gastrointestinal, +++; Bladder, +++; Eye, ++ (applied topically).

**mAChR Agonist: Methacholine** (FW = 160.23 g/mol; CASs = 55-92-5 (free base) and 62-51-1 (chloride)) is highly active at all muscarinic receptors, but exerts little effect on the nicotinic receptors. With its quaternary amine structure, methacholine has poor absorption from the gastrointestinal tract and does not cross the blood-brain barrier and. The additional methyl group renders methacholine highly resistant to acetylcholinesterases. Methacholine's pharmacologic action on mAChR's can be scored as follows: Cardiovascular, +++; Gastrointestinal, ++; Bladder, ++; Eye, + (applied topically).

**mAChR Agonist: Pilocarpine** (FW = 155.19 g/mol; CAS 63-75-2) is a parasympathomimetic alkaloid from the leaves of tropical American shrubs (genus *Pilocarpus*) that acts as a nonselective muscarinic receptor agonist in the parasympathetic nervous system, acts therapeutically at the M<sub>3</sub> muscarinic receptors and is applied topically to treat glaucoma and xerostomia. Pilocarpine's pharmacologic action on mAChR's can be scored as follows: Cardiovascular, +; Gastrointestinal, +++; Bladder, +++; Eye, ++ (applied topically). See also Pilocarpine. Other mAChR agonists include: Muscarine (See (+)-Muscarine); Aceclidine; Alvimeline; Arecoline; Cevimeline; Cl-1017; Milameline; Muscarine; Sabcomeline; Talsacidine; Tazomeline; Vedaclidine; Xanomeline.

### Muscarinic Acetylcholine Receptor Antagonists

These mAChR blockers include: Abediterol; Acridinium bromide; AFDX-384; Atropine; Benztropine; Benzilylcholine mustard; Bevonium; Bornaprine; Cyanothiepin; Darifenacin; Dexetimide; Dicycloverine; Dimenhydrinate; Diphepanil metilsulfate; Diphen-hydramine; Emepronium bromide; Etybenzotropine; Fenpiverinium; Fesoterodine; Flavoxate; Glycopyrronium bromide; Hexocyclium; Homatropine; Hydroxyzine; Hyoscyamine; Imidafenacin; Ipratropium bromide; Medrylamine; Mepenzolate; Methantheline; Methoctramine; Methylatropine; Methylhomatropine; Octatropine methylbromide; Orphenadrine; Otilonium bromide; Oxybutynin; Oxyphenonium bromide; PD-0298029; PD-102,807; Penthienate; Pipenzolate; Piperidolate; Pirenzepin; Poldine; Prifinium bromide; Procyclidine; Propantheline bromide; Propiomazine; Scopolamine; Solifenacin; Tiemonium iodide; Tiotropium bromide; Tolterodine; Trihexyphenidyl; Vedaclidine.

### Muscimol

This γ-aminobutyrate analogue and CNS depressant (FW<sub>free-base</sub> = 114.10 g/mol) from the mushroom *Amanita muscaria* crosses the blood-brain barrier and acts as a GABA<sub>A</sub> receptor agonist (1). Muscimol injections induce an increase in serotonin in the hypothalamus and midbrain of mice and rats. (See Ibotenic Acid) **Target(s):** 4-aminobutyrate aminotransferase (2); 4-aminobutyrate uptake (3). 1. DeFeudis (1982) *Rev. Pure Appl. Pharmacol. Sci.* 3, 319. 2. Jeffery, Rutherford, Witzman & Lunt (1988) *Biochem. J.* 249, 795. 3. Johnston (1971) *Psychopharm.* 22, 230.

### Mustard Gas

This membrane-penetrating chemical warfare agent (FW = 159.08 g/mol; CAS 505-60-2), also called sulfur mustard, 1,1'-thiobis(2-chloroethane), and Yperite, is a deadly vesicant. An oily liquid at room temperature (M.P.

= 13–14°C; B.P. = 215–217°C, although U.S. military reports puts that value at 227.8°C), mustard gas is readily volatilized by steam, producing a sweet, agreeable garlic-like odor. Contact with skin causes severe irritation and subepidermal blistering (1,2), with fluid accumulating in cavities created by separation of the moribund basal cell layer from the basement membrane (3). **Use in Warfare:** During World War I, Germany became the first nation to use mustard gas on July 12, 1917 as a CW agent, first delivered by artillery shells near Ypres, Belgium. Indeed, it was none other than Fritz Haber (Nobel Laureate, 1919 for chemical fixation), who put his mind to weaponizing toxic compounds (mainly chlorine, phosgene, and mustard gas) during WWI, where he personally witnessed the first large-scale CW deployment. Italy reportedly used mustard gas in Ethiopia in the 1930s, as did the Japanese against the Chinese from 1937 to 1944. **Reaction with DNA:** Mustard gas is a bifunctional alkylating agent that reacts with guanine bases, introducing intrastrand cross-links. Cells treated with mustard gas (prior to DNA synthesis in the G<sub>1</sub>-phase) are not delayed in their progression to S-phase, but show a dose-dependent decrease in the rate and extent of DNA synthesis. Treatment during the S-phase also resulted in a dose-dependent depression in the rate of DNA synthesis, with a corresponding mitotic delay. Treatment in G<sub>2</sub> does not delay mitosis, but inhibits DNA synthesis in the next cell cycle. Specific endonucleases act at sites of modification to produce strand breaks. Poly(ADP-ribose) polymerase is also activated by mustard gas, resulting in a depletion of NAD<sup>+</sup> and inhibition of glycolysis. **Other Targets:** hexokinase (4-7); oxidative phosphorylation, as an uncoupler (8,9); pepsin (5,6,10,11); phosphoprotein phosphatase, as the mustard gas hydrolysis product, 2,2'-thiobis-ethanol, or thiodiglycol (1); pyrophosphatase (6); urease (12). **1.** Brimfield, Zweig, Novak & Maxwell (1998) *J. Biochem. Mol. Toxicol.* **12**, 361. **2.** Brimfield (1995) *Toxicol. Lett.* **78**, 43. **3.** Papirmeister, Gross, Meier, Petrali & Johnson (1985) *Fund. Appl. ### Muzolimine

This diuretic (FW<sub>free-base</sub> = 272.13 g/mol), also known as Bay g 2821, inhibits human pyridoxal kinase, reportedly by forming a covalent complex with pyridoxal. The enzyme is inactivated when pyridoxal is the substrate, but not with pyridoxamine. **Target(s):** Ca<sup>2+</sup> reabsorption (1); chloride transport (2,3); Na<sup>+</sup>/K<sup>+</sup> cotransport, weakly inhibited (3,4); Na<sup>+</sup> reabsorption (1); pyridoxal kinase (5). **1.** Hanson, White & Gomoll (1982) *Miner. ### Mycophenolate mofetil

This orally bioavailable, cell-permeant mycophenolate-based pro-drug (FW = 433.49 g/mol; CAS 128794-94-5 and 116680-01-4 (HCl); Solubility: 85 mg/mL DMSO, <1 mg/mL Water; Formulation: 65.8 mg/mL in 5% Dextrose Injection), also known as RS 61443, MMF, Myfortic, CellCept<sup>®</sup>, and named systematically as (E)-2-morpholinoethyl 6-(4-hydroxy-6-methoxy-7-methyl-3-oxo-1,3-dihydroisobenzofuran-5-yl)-4-methylhex-4-

enoate, undergoes hydrolysis to the active drug mycophenolate, which targets inosine monophosphate dehydrogenase, IMPDH-1 (IC<sub>50</sub> = 39 nM) and IMPDH-2 (IC<sub>50</sub> = 10-12 nM). The IMPDH reaction is the rate-limiting reaction step of *de novo* synthesis of guanosine nucleotides. Although liver is the primary organ of purine nucleotide biosynthesis, T- and B-lymphocytes are highly proliferative and depend on this pathway. With IMPDH-II highly expressed in activated lymphocytes and more susceptible to MPA inhibition, this drug exerts a stronger cytostatic effect on lymphocytes than other cell types. While this is the principal mechanism by which MPA exerts its immunosuppressive effects, other mechanisms may contribute to MPA's efficacy in preventing allograft rejection: (a) induced apoptosis of activated T-lymphocytes, thereby eliminating clones that respond to antigenic stimulation; (b) induced depletion of guanosine nucleotides, suppressing expression of some adhesion molecules, thereby decreasing lymphocyte and monocyte recruitment into sites of inflammation and graft rejection; and (c) induced depletion of guanosine nucleotides, attended by diminished tetrahydrobiopterin biosynthesis and consequentially lower iNOS activity. TM-MMF suppresses T-lymphocytic responses to allogeneic cells and other antigens. **Bioactivation:** Both intestinal and hepatic microsomal carboxylesterases, and in particular microsomal carboxylesterase-1, are likely to be involved in MMF hydrolysis and play important roles in MMF bioactivation. **Inhibitory Mechanism:** The bicyclic ring system of MPA binds beneath the hypoxanthine ring of Enz-S-XMP\* adduct, trapping this enzyme-bound reactant intermediate in a nonproductive Enz-S-XMP\*-Mycophenolate complex. **1.** Allison & Eugui (1996) *Clin. Transplant.* **10**, 77. **2.** Sintchak & Nimmegern (2000) *Immunopharmacology* **47**, 163. **3.** Ji, Gu, Makhov, et al. (2006) *J. Biol. Chem.* **281**, 206.

### Mycophenolate (Mycophenolic Acid)

This antibiotic, immunosuppressant, and antitumor agent (FW = 320.34 g/mol; CAS 24280-93-1; **Abbreviation:** MPA; Soluble to 100 mM in DMSO), systematically known as (4E)-6-(1,3-dihydro-4-hydroxy 6-methoxy-7-methyl-3-oxo-5-isobenzofuranyl)-4-methyl-4-hexanoic acid, from *Penicillium brevicompactum* and *P. stoloniferum* inhibits IMP dehydrogenase, thereby suppressing lymphocyte proliferation. MPA is a strong inhibitor of the mammalian enzyme but a much weaker inhibitor of microbial IMP dehydrogenases. It depletes guanosine nucleotides preferentially in T and B lymphocytes, thereby inhibiting their proliferation. Cell-mediated immune responses are thus suppressed, as is antibody formation. Mycophenolic acid also inhibits the glycosylation and expression of adhesion molecules, and the recruitment of lymphocytes and monocytes into sites of inflammation. In addition, it depletes tetrahydrobiopterin concentrations and decreases the production of nitric oxide by inducible nitric-oxide synthase (1). Nobelist H. W. Florey first reported mycophenolate's antimicrobial activity (2). It was the first antibiotic ever to be crystallized (3). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** glucuronosyltransferase (4); glycosylation of adhesion molecules (5); GMP synthetase (6); IMP dehydrogenase (1,7-12); lymphocyte proliferation (1,13,14). **1.** Allison (2005) *Lupus* **14** Suppl. 1, s2. **2.** Florey, Gilliver, Jennings & Sanders (1946) *Lancet* **1**, 46. **3.** Gosio (1896) *Riv. ### Myeloid Translocation Gene-16

The 559-residue transcriptional co-repressor (MW = 61,528 Da, *Mus musculus*) inhibits glycolysis and stimulates mitochondrial respiration. Expression of certain genes involved in tumor cell metabolism (including 6-phosphofructo-2-kinase/fructose-2,6-biphosphatase 3 and 4 (PFKFB3 and PFKFB4), and pyruvate dehydrogenase kinase isoenzyme 1 (PDK1)) was rapidly diminished upon MTG16 expression. Moreover, hypoxia-stimulated production of PFKFB3, PFKFB4 and PDK1 was inhibited by MTG16 expression. Expression of MTG16 reduced glycolytic metabolism, while increasing mitochondrial respiration and formation of reactive oxygen species (ROS). These metabolic changes were paralleled by increased phosphorylation of mitogen-activated protein kinases, reduced levels of amino acids, reduced proliferation, and a decreased fraction of cells in S-phase. MTG16 may serve as a brake on glycolysis, exerting an anti-tumor effect. **1.** Kumar, Sharoyko, Spégl, *et al.* (2013) *PLoS One* **8**, e68502.

### Myostatin

This secreted growth differentiation factor and myogenesis inhibitor (MW<sub>Human</sub> = 25.0 kDa; Accession Number = ABI48514), also known as Growth Differentiation Factor-8 (*or* GDF-8), is a TGF $\beta$  family member that binds to the activin type II receptor, triggering the recruitment of the Alk-3 or Alk-4 coreceptor. In muscle, the latter initiates a signal transduction cascade that activates SMAD2 and SMAD3, thereby inhibiting differentiation into mature muscle fibers (1). Myostatin also inhibits preadipocyte differentiation in 3T3-L1 cells, an effect that is partly mediated by altered regulation of C/EBP $\alpha$  and Peroxisome Proliferator-Activated Receptor- $\gamma$ , or PPAR $\gamma$  (2). Myostatin is also an inhibitor of myoblast differentiation by Smad3-mediated down-regulation of MyoD expression via increased Smad3-MyoD complex formation (3). Myostatin induces muscle atrophy by inhibiting myoblast proliferation, with an attendant rise in ubiquitin-proteasomal activity and downregulation of the IGF-Akt pathway (4). Such effects occur in multiple atrophy-causing events, including injury, diseases such as cachexia, disuse and space flight. Significantly, myostatin knockout drives the browning of white adipose tissue by activating the AMPK-PGC1 $\alpha$ -Fndc5 pathway in muscle (5). While myostatin deletion or loss of function induces muscle hypertrophy, its overexpression or systemic administration causes muscle atrophy. Since myostatin blockade would be effective in increasing skeletal muscle mass, myostatin inhibitors are of interest in finding treatments for muscle disorders. Indeed, myostatin blockade with a humanized monoclonal antibody induces muscle hypertrophy and reverses muscle atrophy in young and aged mice (6). By utilizing recombinant adeno-associated virus to overexpress a secretable dominant-negative myostatin exclusively in the liver of mice, systemic myostatin inhibition was found to increase skeletal muscle mass and strength in control C57 Bl/6 mice and in the dystrophin-deficient MDX model of Duchenne muscular dystrophy (7). **1.** Han, Zhou, Mitch & Goldberg (2013) *Int. ### Myricetin

This DNA-intercalating bioflavonoid (FW = 318.24 g/mol; CAS 529-44-2;  $\lambda_{\max}$  = 255 and 376 nm; Solubility: 10 mg/mL DMSO), also named Cannabiscetin, NSC 407290, 3,5,7-trihydroxy-2-(3,4,5-trihydroxyphenyl)-4-chromenone and 3,5,7-trihydroxy-2-(3,4,5-trihydroxyphenyl)-4H-1-benzopyran-4-one, is a nutraceutical and antioxidant found in vegetables, fruits, nuts, berries, tea, and red wine. It is often marketed in doses of 100 mg, and, in some published reports, subjects consumed as much as gram-level quantities daily. Myricetin also crosses the blood-brain barrier. In rats, myricetin is metabolized to both 3-hydroxyphenylacetate and 3,5-dihydroxyphenylacetate. Myricetin is often present as glycoconjugates: myricetin 3-O-galactoside, myricetin 3-O-glucoside, myricetin 3-O-

rhamnoside (also known as myricitrin). **Inhibitory Targets:** Myricetin protects against some forms of cancer and cardiovascular disease, inhibiting Advanced Glycation End-product- (*or* AGE-) induced migration of retinal pericytes through enhanced phosphorylation of ERK1/2, FAK-1, and paxillin, both *in vitro* and *in vivo* (1). Myricetin also inhibits signaling by Hepatocyte Growth Factor (HGF) as well as its receptor-associated tyrosine kinase Met (*or* HGF/Met) in the medulloblastoma cell line DAOY, thereby preventing formation of actin-rich membrane ruffles and resulting in the inhibition of Met-induced cell migration in Boyden chambers (2). Myricetin is also a mixed-type noncompetitive inhibitor of both isoforms of human IMP dehydrogenase, with respective IC<sub>50</sub> values of 7 and 4  $\mu$ M for IMPDH-I and IMPDH-II, that exerts potent anti-proliferative and pro-apoptotic effects on K562 human leukemia cells in a dose-dependent manner (3). This cytotoxicity is markedly attenuated by exogenous addition of guanosine *in vitro*, a finding that is fully consistent with myricetin's action as an IMPDH inhibitor. Myricetin causes toxic DNA damage by stabilizing covalent DNA-topoisomerase cleavage complexes (4). It inhibits: aldehyde oxidase (5), xanthine oxidase (5), human pancreatic  $\alpha$ -amylase competitively (6), porcine aldose reductase, IC<sub>50</sub> = 40  $\mu$ M (7), and glutathione-S-transferase (8). It also inhibits cytokine-induced cell death in RIN-m5f  $\beta$ -cells (9). Myricetin binds to JAK1/STAT3, inhibiting the neoplastic transformation of murine JB6 P<sup>+</sup> cells and inhibiting MEK1 kinase activity (10,11). **1.** Kim, Kim, Kim, *et al.* (2015) *Biochem. ### Myriocin

This sphingosine-like immunosuppressant and antibiotic (FW = 401.54 g/mol; CAS 35891-70-4; known also as ISP-1, thermozymocidin, and 2-amino-3,4-dihydroxy-2-(hydroxymethyl)-14-oxoicos-6-enoic acid; Soluble: 25mg/mL (dissolves best when heat briefly in boiling water bath); 5mg/mL in 50mM NaOH), from the thermophilic fungi *Mycelia sterilia* and Chinese herb *Isaria sinclairii*, potently inhibits serine palmitoyltransferase (SPT), thereby reducing plasma sphingolipids, cholesterol and triglycerides in hyperlipidemic, apolipoprotein E knockout mice (1). Myriocin also significantly reduces the synthesis of inositol phosphorylceramide, the major sphingolipid expressed in cultured *Leishmania (Viannia) braziliensis* promastigotes (2). Log-phase promastigotes treated with 1  $\mu$ M myriocin showed a 52% reduction in growth rate and morphological alterations such as more rounded shape and shorter flagellum. (See also *Fingolimod*) **1.** Miyake, Kozutsumi, Nakamura, Fujita & Kawasaki (1995) *Biochem. Biophys. Res. Commun.* **211**, 396. **2.** Castro, Yoneyama, Haapalainen, *et al.* (2013) *J. Eukaryot. ### Myristate (Myristic Acid)

This medium chain-length saturated fatty acid (FW<sub>free-acid</sub> = 228.38 g/mol; CAS 208-875-2; pK<sub>a</sub>  $\approx$  4.8; M.P. = 58.5°C; B.P. = 326.2°C; Solubility: 0.002 g/100 mL H<sub>2</sub>O; IUPAC Name: tetradecanoic acid) is widely distributed as trimyristin (trimyristoylglycerol) in plants, particularly in nutmeg (in which it comprises 20-25% of the dry weight of the nut and 80% of nutmeg oil) as well as coconut oil. After conversion to myristoyl-CoA, myristoylation plays a co-/post-translational role in anchoring signal transduction enzymes and proteins to cellular membranes. (See *Myristoyl-CoA*) **Inhibitory Target(s):** acetyl-CoA carboxylase (1,2); alcohol dehydrogenase (3); carbonyl reductase (4); chondroitin AC lyase (5);

chondroitin B lyase, weakly inhibited (5); cytosol alanine aminopeptidase (22); esterase (6); estrone sulfotransferase (23); ethanolamine-phosphotransferase (24); 7-ethoxycoumarin *O*-deethylase (P450) (7);  $\beta$ -galactosidase  $\alpha$ -2,6-sialyltransferase (8); glucokinase (9); glucose-6-phosphate dehydrogenase (10); glycylopeptide *N*-tetradecanoyltransferase (26); hexokinase (9,11,25); hyaluronate lyase, weakly inhibited (5); leukocyte elastase (12); luciferase, firefly (*Photinus*-luciferin 4-monooxygenase;  $IC_{50}$  = 0.68  $\mu$ M (13,27,28); microbial collagenase (12);  $Na^+/K^+$ -exchanging ATPase (14); pectinesterase (15); peptidyl dipeptidase, or angiotensin I-converting enzyme (16); prostaglandin  $D_2$  dehydrogenase (17); prostaglandin dehydrogenase (17,18); prostaglandin dehydrogenase ( $NAD^+$ ) (type I) (17); prostaglandin D synthetase (17); prostaglandin E isomerase (17); pyruvate kinase (19); steroid 5 $\alpha$ -reductase (20); L-threonine dehydrogenase (21); thromboxane synthetase (17). 1. ### Myristoyl-CoA

This fatty acyl-coenzyme A derivative (FW = 991.02 g/mol), also called tetradecanoyl-CoA, is an intermediate in the  $\beta$ -oxidation of fatty acids and the substrate for glycylopeptide *N*-tetradecanoyltransferase I (also known as myristoyl-CoA:protein *N*-myristoyltransferase 1, or NMT-1). This enzyme catalyzes co-/post-translational modification of N-terminal glycine-containing proteins and enzymes destined to become bound to biomembranes. In co-translational myristoylation, which accounts for approximately 80% of known myristoylated proteins, the N-terminal glycine is modified after removal of the N-terminal methionine residue in the newly forming polypeptide. In post-translational myristoylation, caspase cleavage exposes an internal glycine residue, which then undergoes myristoylation. Myristoylated proteins tend to interact relatively weakly with biomembranes, a property suggesting that additional factors may be needed

to stabilize their docking with membrane lipids. (See also *Myristic Acid*)  
**Inhibitory Target(s):** acetyl-CoA carboxylase,  $K_i$  = 11  $\mu$ M for rat liver enzyme (1-3); aralkylamine *N*-acetyltransferase (4); ATP: citrate lyase, or ATP: citrate synthase (5,6); dynein ATPase (7); fatty-acid synthase (8); glucose-6-phosphatase (9); protein kinase C (10); [pyruvate dehydrogenase, acetyl-transferring] kinase (11); RNA polymerase (12). 1. ### Myxothiazol

This bacterially derived antibiotic (FW = 487.68 g/mol; CAS 76706-55-3; IUPAC: 7-{2'-[(1*S*,2*E*,4*E*)-1,6-dimethyl-2,4-heptadienyl][2,4'-bithiazol]-4-yl}-3,5-dimethoxy-4-methyl-(2*E*,4*R*,5*S*,6*E*)-2,6-heptadienamide), isolated from *Myxobacterium fulvus*, is a strong inhibitor of Complex III of the mitochondrial electron transport chain and suppressing growth of many yeasts and fungi. Myxothiazol binds to the ubiquinol oxidation site Qo of CIII (1-13). Myxothiazol is a competitive inhibitor of ubiquinol and binds at the quinol oxidation (Qo) site of the cytochrome *bc*<sub>1</sub> complex, blocking electron transfer to the Rieske iron-sulfur protein. Binding of myxothiazol induces a red-shift to the visible absorption spectrum of reduced haem *b*<sub>L</sub>. Unlike stigmatellin, myxothiazol does not form a hydrogen bond to the Rieske iron-sulfur protein, binding instead in the 'b-proximal' region of the cytochrome *b* Quinone<sub>outside</sub> (or Qo) site. Movement of the cytoplasmic domain of the Rieske protein is therefore unaffected by the binding of this inhibitor. Myxothiazol has been utilized as a tool in studies of respiratory chain function, both in *in vitro* and with cell culture models. Davoudi *et al.* (14) recently developed a mouse model of biochemically induced and reversible CIII inhibition using myxothiazol. **Target(s):** methane monooxygenase (15); mitochondrial processing peptidase (16); ubiquinol: cytochrome-*c* reductase, or Complex III. 1. **N**, See Asparagine; Nitrogen

### N20C

This selective, non-competitive NMDA receptor antagonist (FW = 304.82 g/mol; CAS 1177583-87-7; Soluble to 100 mM in H<sub>2</sub>O), also named 2-[(3,3-diphenylpropyl)amino]acetamide, penetrates the blood-brain barrier and binds to the receptor-associated ion channel (IC<sub>50</sub> = 5 μM), thereby preventing glutamate-induced Ca<sup>2+</sup> influx. Saturation of the blocker binding-site with N20C prevents dizolcipine (MK-801) blockade of the NMDA receptor, implying that both ligands bind at the same receptor site. N20C displays neuroprotective activity *in vivo*. **1.** Planells-Cases, Montoliu, Humet, *et al.* (2002) *J. Pharmacol. Exp. Ther.* **302**, 163.

### N6022

This potent, selective, and reversible GSNOR inhibitor (FW = 414.46 g/mol; CAS 1208315-24-5; Solubility = 82 mg/mL), also named 3-(5-(4-(1*H*-imidazol-1-yl)phenyl)-1-(4-carbamoyl-2-methylphenyl)-1*H*-pyrrol-2-yl) propanoate, targets human *S*-nitrosogluthathione reductase, (IC<sub>50</sub> = 8 nM; K<sub>i</sub> = 2.5 nM), a class III alcohol dehydrogenase. *S*-nitrosogluthathione (GSNO) serves as a reservoir of nitric oxide (NO), a key regulator of airway smooth muscle tone and inflammation (1). Decreased levels of GSNO in the lungs of asthmatics have been attributed to increased GSNO catabolism via GSNO reductase (GSNOR) leading to loss of GSNO- and NO- mediated bronchodilatory and anti-inflammatory actions (1). N6022 is well tolerated in animals. N6022 binds in the GSNO substrate binding pocket like a competitive inhibitor, although it behaves as a mixed uncompetitive inhibitor relative to GSNO substrate and a mixed competitive inhibitor relative to the formaldehyde adduct, *S*-hydroxymethylglutathione. N6022 is uncompetitive with cofactors NAD<sup>+</sup> and NADH (1). The significant bronchodilatory and anti-inflammatory actions of N6022 in the airways are consistent with restoration of GSNO levels through GSNOR inhibition (2). GSNOR inhibition may offer a therapeutic approach for the treatment of asthma and other inflammatory lung diseases. N6022 is currently being evaluated in clinical trials for the treatment of inflammatory lung disease (2). **1.** Green, Chun, Patton, *et al.* (2012) *Biochemistry* **51**, 2157. **2.** Blonder, Mutka, Sun, *et al.* (2014) *BMC Pulm. Med.* 10.1186/1471-2466-14-3.

### NAB 2

This *N*-aryl-benzimidazole (FW = 389.88 g/mol; CAS 1504588-00-4; Solubility: 100 mM in DMSO; *N*-[(2-chlorophenyl)methyl]-1-(2,5-dimethylphenyl)-1*H*-benzimidazole-5-carboxamide) promotes endosomal transport events that depend on the E3 ubiquitin ligase Rsp5/Nedd4, strongly and selectively protecting diverse cell types from  $\alpha$ -synuclein toxicity (1). Rsp5 is the single yeast member of the highly conserved mammalian family of HECT domain-containing Nedd4 E3 ligases, which catalyze formation of K63 linkages between ubiquitin and diverse membrane proteins, thereby regulating endosomal trafficking, *not* proteasomal degradation. NEDD4 family E3 ubiquitin ligase is involved in regulating many cellular processes including Multi-Vesicular-Body (MVB) sorting, heat shock response, transcription, endocytosis, and ribosome stability. NAB 2 reverses pathologic phenotypes in cortical neurons generated from induced pluripotent stem (iPS) cell from patients harboring critical  $\alpha$ -synuclein mutations, placing them are at high risk of developing PD dementia (2).  $\alpha$ -Synuclein is a small lipid-binding protein that has been implicated in several neurodegenerative diseases, including Parkinson's disease. **1.** Tardiff, Jui, Khurana, *et al.* (2013) *Science* **342**, 979. **2.** Chung, Khurana, Auluck *et al.* (2013) *Science* **342**, 983.

### NAD<sup>+</sup>

This centrally important redox coenzyme (FW = 663.43 g/mol; CAS 53-84-9), also known as nicotinamide adenine dinucleotide and  $\beta$ -NAD<sup>+</sup> (previously DPN<sup>+</sup> and diphosphopyridine nucleotide) is an essential cofactor and hydride acceptor for many oxidoreductases. Its reduced form NADH is a reducing reagent as well as the substrate for Complex I in electron transport or respiratory chain. NAD<sup>+</sup> also serves as ADPR donor in ADP-ribosylation reactions. It is likewise a required cofactor in Class III NAD<sup>+</sup>-dependent histone deacetylases, *or* sirtuins, which deacetylate Lysine-9 and Lysine-14 of histone H3 and specifically Lysine-16 of histone H4. **Chemical Properties:** NAD<sup>+</sup> is a hygroscopic solid that is very soluble in water. NAD<sup>+</sup> is relatively stable in slightly acidic pH conditions (*i.e.*, pH 3–7) but will decompose in alkaline pH (the rate of decomposition increases in the presence of orthophosphate, carbonate, or malate). The solid should be stored in a desiccator at 0°C in the dark. This photosensitive coenzyme absorbs light significantly in the ultraviolet:  $\lambda_{\text{max}}$  at pH 7.0 is 260 nm ( $\epsilon = 18000 \text{ M}^{-1}\text{cm}^{-1}$ ). The reduced form, NADH, exhibits another peak at higher wavelength:  $\lambda_{\text{max}}$  at pH 7.0 is 339 nm ( $\epsilon = 6200 \text{ M}^{-1}\text{cm}^{-1}$ ). **Target(s):** acetyl-CoA *C*-acyltransferase (72); *N*-acetylneuraminatase 4-*O* acetyltransferase (71); acid phosphatase (1); adenylate cyclase (2); adenylate kinase (63); L-aspartate oxidase (3); CDP-diaclyglycerol diphosphatase (4); choline oxidase (5); citrate (*si*)-synthase, weakly inhibited (69); creatine kinase (6,7); 3',5'-cyclic-nucleotide phosphodiesterase (47); DNA-(apurinic or apyrimidinic site) lyase (8); FAD diphosphatase (9); FAD synthetase (61); fructose-1,6 biphosphatase (53,54); fucosterol-epoxide lyase (10); glucose-1-phosphate adenyltransferase (58); glutamine synthetase, *Neurospora crassa* (11);  $\gamma$ -glutamylcysteine synthetase (12); glutathione peroxidase (13); malate oxidase (14); malic enzyme, oxaloacetate decarboxylating activity, weakly inhibited (15); methylenetetrahydrofolate dehydrogenase (NADP<sup>+</sup>) (16); 6-methylsalicylic acid synthase (70); m7G(5')pppN diphosphatase, slightly inhibited (17); nicotinamidase (18-20); nicotinamide phosphoribosyltransferase (21,22,65-67); nicotinate-nucleotide adenyltransferase (59); nicotinate-nucleotide pyrophosphorylase (carboxylating) (23); nicotinate phosphoribosyltransferase, weakly inhibited (68); nitrate reductase (NADPH) (24); NMN nucleosidase (44); nucleotide diphosphatase, alternative substrate (25-29); nucleotidases (52); 5'-nucleotidase (30,31); oligosaccharide-diphosphodolichol diphosphatase (32); oxaloacetate decarboxylase (33); palmitoyl-CoA hydrolase, *or* acyl-CoA hydrolase (55);

pectin lyase (34); phosphodiesterase I, or 5'-exonuclease (49-51); poly(ADP-ribose) glycohydrolase (45,46); [protein ADP-ribosylarginine] hydrolase (43); [protein-P<sub>II</sub>] uridylyltransferase (57); [pyruvate dehydrogenase (acetyl-transferring)] kinase (56); ribose-phosphate diphosphokinase, or phosphoribosyl pyrophosphate synthetase (62); ribose-5-phosphate isomerase (35,36); ribosylnicotinamide kinase (64); serine hydroxymethyltransferase, or glycine hydroxymethyl-transferase (73); sphingomyelin phosphodiesterase, or sphingomyelinase (48); sterol 24-C-methyltransferase (74); sulfate adenylyltransferase (60); UDP-glucose 4-epimerase (37,38); UDP-glucuronate 4-epimerase (39,40); UDP sugar diphosphatase (41); xylose isomerase (42). 1. ### NAD 299

This selective, high-affinity serotonin antagonist (FW = 354.85 g/mol; CAS 184674-99-5; Soluble to 100 mM in H<sub>2</sub>O and to 100 mM in DMSO), also named (3R)-3-(dicyclobutylamino)-8-fluoro-3,4-dihydro-2H-1-benzopyran-5-carboxamide hydrochloride, targets the 5-HT<sub>1A</sub> receptor antagonist (K<sub>i</sub> = 0.6 nM, *in vitro*), with >400x selectivity over α-1 and β adrenoceptors (1-3). NAD-299 also differs in selectivity from the structurally related 5-HT<sub>1A</sub> receptor antagonist (S)-UH-301, which has considerable affinity for D<sub>2</sub> receptors (1). NAD-299 enhances the action of selective 5-HT reuptake inhibitors and reverses citalopram-induced inhibition of serotonergic cell firing. 1. Johansson, Sohn, Thorberg, et al. (1997) *J. Pharmacol. ### NADH 2',3'-Dialdehyde

This periodate-modified NADH affinity-labeling reagent (FW<sub>free-acid</sub> = 662.85 g/mol; Abbreviation: oNAD<sup>+</sup>) contains two aldehyde groups that facilitate imine formation with ε-amino groups of active-site lysine residues in NAD<sup>+</sup>-dependent oxidoreductases. Dialdehyde-containing nucleotides are formed by periodate oxidation, usually requiring the addition of 20-40% molar excess of sodium metaperiodate (reaction period = 30 min); unreacted periodate is deactivated by the addition of 2-3x molar excess of ethylene glycol. **Target(s):** isocitrate dehydrogenase, NAD<sup>+</sup>-requiring (1,2). 1. Colman (1990) *The Enzymes*, 3rd ed., **19**, 283. 2. Saha & Colman (1988) *Arch. Biochem. Biophys.* **264**, 665.

### NADH

This vital redox coenzyme (FW<sub>free-acid</sub> = 664.86 g/mol), also known as reduced nicotinamide adenine dinucleotide and βNADH is a major redox energy store that is also utilized by many oxidoreductases, serving as a hydride donor and reducing agent. NADH is the substrate for the first complex in electron transport. Only the β-anomer is physiologically relevant, the α-anomer is commercially available and frequently used in specificity and inhibitor investigations. **Chemical Properties:** NADH is a photosensitive and hygroscopic solid that is very soluble in water. The solid should be stored in a desiccator at 0-4°C in the dark. It is destroyed at pH < 4 at room temperature, but is relatively stable at alkaline pH. Note that the presence of orthophosphate buffer also decreases the stability of NADH. This coenzyme absorbs UV light: λ<sub>max</sub> at pH 7.5 is 259 nm (ε = 16900 M<sup>-1</sup>cm<sup>-1</sup>) and 339 nm (ε = 6200 M<sup>-1</sup>cm<sup>-1</sup>). NADH is also fluorescent at 460 nm

when excited at 340 nm. **Target(s):** acetyl-CoA C-acetyltransferase (106,107); acetyl-CoA hydrolase (70); adenylate cyclase, or adenylate cyclase (1-3); adenylate kinase (73); ADP-dependent medium-chain-acyl-CoA hydrolase (68,69); ADP-dependent short-chain-acyl-CoA hydrolase (68,69); ADP-glyceromanno heptose 6-epimerase (4); ADP-ribose diphosphatase (5); alkaline phosphatase (66); arginine kinase (74); arsenate reductase, or glutaredoxin (110); bile-acid 7 $\alpha$ -dehydroxylase (111); CDP-paratose 2-epimerase (6); citrate (*si*)-synthase (7-11,89-104); decylcitrate synthase, weakly inhibited (88); 3-dehydroquinate synthase (12-14); deoxyhypusine synthase (81); 3,4-dihydroxyphenylalanine oxidative deaminase (114); ferredoxin:NADP<sup>+</sup> reductase (15); fructose-1,6-bisphosphatase (64,65); GDP-mannose 3,5 epimerase (16);  $\gamma$ -glutamylcysteine synthetase (17,18); glyceraldehyde-3-phosphate dehydrogenase (NADP<sup>+</sup>) (19); glycogen phosphorylase *b* (20); homospermidine synthase (82,83); inositol-3-phosphate synthase, or inositol-1-phosphate synthase (21); kynurenine 3-monoxygenase (113); 2-methylcitrate synthase (87); methylisocitrate lyase (22); 6-methylsalicylic acid synthase (105); NAD<sup>+</sup> ADP ribosyltransferase, or poly(ADP-ribose) synthetase (23); NAD<sup>+</sup>:[dinitrogen-reductase] ADP-D-ribosyltransferase (84); NAD<sup>+</sup> kinase (25-29,76-80); NAD<sup>+</sup> nucleosidase, or NADase (24,58); NADPH:cytochrome *c*<sub>2</sub> reductase (30); nicotinamide phosphoribosyltransferase, weakly inhibited (85); nicotinate phosphoribosyltransferase, weakly inhibited (86); NMN nucleosidase (57); 5'-nucleotidase (31); octadecanal decarboxylase (32,33); oxaloacetate decarboxylase (34); 3-oxoadipyl CoA thiolase, or 3-oxoadipate CoA-transferase (35); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (67); pectin lyase (36); phosphate acetyltransferase (108,109); phosphodiesterase I, or 5'-exonuclease (60); phosphoenolpyruvate carboxykinase (37); phosphoenolpyruvate carboxykinase (ATP) (38); 6-phospho- $\beta$ -glucosidase (59); phosphoketolase (39); [protein-P<sub>II</sub>] uridylyltransferase (71); pyridoxal kinase, weakly inhibited (75); pyruvate carboxylase, *Saccharomyces cerevisiae* (40); [pyruvate dehydrogenase (acetyl-transferring)]-phosphatase (41-43,61-63); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (72); rifamycin-B oxidase (116); stearoyl-CoA 9 $\alpha$ -desaturase (112); succinyl-CoA synthetase (ADP-forming), or succinate-CoA ligase (ADP-forming) (44); thyroxine deiodinase, or iodothyronine deiodinase (45); tryptophan 2,3 dioxxygenase (115); UDP-N-acetyl-D-glucosamine 4-epimerase (46); UDP-glucosamine 4-epimerase (47); UDP-glucose 4-epimerase (48-51); UDP-glucuronate decarboxylase (52-54); UDP-glucuronate 5' epimerase (55,56). 1. #### Nadifloxacin

This topical fluoroquinolone-class antibiotic (FW = 360.38 g/mol; CAS 124858-35-1), also named (*RS*)-9-Fluoro-8-(4-hydroxy-piperidin-1-yl)-5-

methyl-1-oxo-6,7-dihydro-1*H*,5*H*-pyrido[3,2,1-*ij*]quinoline-2-carboxylate, is a broad-spectrum systemic antibacterial targeting Type II DNA topoisomerases (gyrases) and thereby blocking bacterial replication and transcription. Nadifloxacin is broadly active against aerobic Gram-positive, Gram-negative and anaerobic bacteria, including *Propionibacterium acnes* and *Staphylococcus epidermidis*. For further information on mechanism of action, See *Ciprofloxacin*

### Nadolol

This orally bioavailable tetrahydronaphthalene derivative and propranolol-like drug (FW = 309.41 g/mol), also known as SQ-11725 and Corgard, is a  $\beta$ -adrenergic blocker used in the once daily treatment of angina and hypertension. It is a preferred  $\beta$ -blockers for managing cardiac patients with Long QT Syndrome (LQTS) and both shortens the QT interval and prevents ventricular arrhythmia. Nadolol is more efficacious than metoprolol in the prevention of breakthrough cardiac events, while on therapy. **Target(s):**  $\beta$ -adrenergic receptor (1,2); ATPase, mitochondrial,  $IC_{50} = 5.3$  mM (3); calmodulin-activated  $Ca^{2+}$ -dependent ATPase (4); lipoprotein lipase, weakly inhibited (5);  $Na^+/K^+$ -exchanging ATPase (6). 1. ### NADP<sup>+</sup>

This important redox coenzyme (FW<sub>free-acid</sub> = 744.41 g/mol), also known as nicotinamide-adenine dinucleotide phosphate and  $\beta$  NADP<sup>+</sup>, is utilized by many enzymes catalyzing oxidation/reduction reactions, acting as a hydride acceptor. Only the  $\beta$ -anomer is physiologically relevant; however, the  $\alpha$ -anomer is commercially available and is frequently used in specificity and inhibitor investigations. NADP<sup>+</sup> is a hygroscopic solid that is very soluble in water: it is relatively stable in slightly acidic pH (*i.e.*, pH 3–7) but will decompose in alkaline or strongly acidic conditions. The solid should be stored in a desiccator at 0°C in the dark. This coenzyme absorbs light significantly in the ultraviolet:  $\lambda_{max}$  at pH 7.0 is 260 nm ( $\epsilon = 18000$  M<sup>-1</sup>cm<sup>-1</sup>). The reduced form, NADPH, exhibits another peak at higher wavelength:  $\lambda_{max}$  at pH 7.0 is 339 nm ( $\epsilon = 6200$  M<sup>-1</sup>cm<sup>-1</sup>). **Target(s):** acetylactate synthase (56); acetyl-CoA C-acetyltransferase (55); adenylate cyclase (1); alcohol dehydrogenase (2,3); barley nuclease (4); [branched-chain  $\alpha$ -ketoacid dehydrogenase] kinase, or [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (5,6,40); citrate (*si*) synthase (52,53); 3',5'-cyclic-nucleotide phosphodiesterase (33); ecdysone 20-monooxygenase (58); FAD diphosphatase (7,8); fructose-1,6-bisphosphatase (38); glucose-1-phosphate adenyllyltransferase (42,43); glucose-6-phosphate 1-epimerase (9,10);  $\gamma$ -glutamylcysteine synthetase (11); glutathione peroxidase (12); glycogen phosphorylase (51); *myo*-inositol oxygenase (13,59); [isocitrate dehydrogenase (NADP<sup>+</sup>)] kinase (39); laminaribiose phosphorylase (14,50); malic enzyme, oxaloacetate decarboxylating activity (15); D-mannitol dehydrogenase, *Lactobacillus brevis* (16); methenyltetrahydrofolate cyclohydrolase (17,18); NAD<sup>+</sup>:[dinitrogen-reductase] ADP-D-ribosyltransferase (47); NAD<sup>+</sup> nucleosidase, or NADase (19,20); NADH

peroxidase (21); nicotinamidase (22,23); nicotinamide-nucleotide adenyllyltransferase (44); nicotinamide phosphoribosyltransferase (48); nicotinate phosphoribosyltransferase, weakly inhibited (49); NMN nucleosidase (24); nucleotidase (37); 5'-nucleotidase (25,26); phosphate butyryltransferase (54); phosphodiesterase I, or 5'-exonuclease (35,36); phytoene synthase (45); prenyltransferase (27); [protein P<sub>11</sub>] uridylyltransferase (41); ribose-5-phosphate isomerase, weakly inhibited (28); ribozyme, group I (29); sphingomyelin phosphodiesterase, or sphingomyelinase (34); squalene synthase (46); sterol 24-C methyltransferase (57); UDP-glucuronate decarboxylase (30); UDP-glucuronate 4-epimerase (31,32). 1. ### NADP<sup>+</sup> 2',3'-Dialdehyde

This modified NADP<sup>+</sup> affinity-labeling reagent (FW<sub>free-acid</sub> = 744.40 g/mol; *Abbreviation*: oNADP<sup>+</sup>) contains two aldehyde groups that facilitate imine formation with ε-amino groups of active-site lysine residues in NADP<sup>+</sup>-dependent oxidoreductases. Dialdehyde-containing nucleotides are formed by periodate oxidation, usually requiring the addition of 20-40% molar excess of sodium metaperiodate (reaction period = 30 min); unreacted periodate is deactivated by the addition of 2-3x molar excess of ethylene glycol. **Target(s)**: ferredoxin:NADP<sup>+</sup> reductase (1-3); glucose-6-phosphate dehydrogenase (1,4,5); isocitrate dehydrogenase (6,7); malic enzyme (1); NADPH:cytochrome P450 reductase (8); 6-phosphogluconate dehydrogenase (1,9,10); ribozyme, group I (11). 1. ### NADPH

This important coenzyme (FW<sub>free-acid</sub> = 744.42 g/mol; Photosensitive; Hygroscopic and very soluble in water), also known as reduced nicotinamide-adenine dinucleotide phosphate and β-NADPH, is a hydride-donating agent in many oxidation/reduction reactions. Store in a desiccator at 0-4°C in the dark. NADPH is destroyed at pH < 4 at room temperature but is relatively stable at alkaline pH. Note that the presence of orthophosphate buffer decreases the stability of NADPH and that NADPH is slightly less stable than NADH. This coenzyme absorbs UV light, with λ<sub>max</sub> at pH 7.5 is 259 nm (ε = 16900 M<sup>-1</sup>cm<sup>-1</sup>) and 339 nm (ε = 6200 M<sup>-1</sup>cm<sup>-1</sup>). The 339-nm peak is absent in the spectra of NADP<sup>+</sup>. NADPH is also fluorescent at 460 nm when excited at 340 nm. **Target(s)**: flavanone 7-O-β-glucosyltransferase, weakly inhibited (1); fructose-1,6-bisphosphatase (2); GDP-mannose 3,5-epimerase (3); γ-glutamylcysteine synthetase (4); glutathione peroxidase (5); glutathione synthetase, weakly inhibited (6); glycogen phosphorylase (7); [3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)]-phosphatase (8); isocitrate dehydrogenase (NAD<sup>+</sup>) (9); [isocitrate dehydrogenase (NADP<sup>+</sup>)] kinase (10,11); [isocitrate dehydrogenase] phosphatase (10-12); 15-ketoprostaglandin 13-reductase (13); methylisocitrate lyase (14); NAD<sup>+</sup> kinase (15-23); nicotinamide phosphoribosyltransferase, weakly inhibited (24); nicotinate phosphoribosyltransferase, weakly inhibited (25); 5'-nucleotidase (26); octadecanal decarboxylase (27); phosphodiesterase I, or 5'-exonuclease (28); phosphoketolase (29); phosphoprotein phosphatase (7); phytoene synthase (30,31); [protein-P<sub>II</sub>] uridylyltransferase (32); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (33); ribozyme, group I (34); rubredoxin:NAD<sup>+</sup> reductase (35); thyroxine deiodinase, or iodothyronine deiodinase (36); 2-methylcitrate synthase (37); citrate (si)-synthase (38-41); acetylneuraminase 4-O-acetyltransferase (42); phosphate butyryltransferase (43); acetyl-CoA C-acetyltransferase (44); acetolactate synthase (45); thymidylate synthase (FAD) (46,47); N-bile-acid 7α-dehydroxylase (48); deoxyhypusine monooxygenase (49); NADH peroxidase (50); rifamycin-B oxidase (51). 1. ### Nafadotride

This dopamine receptor antagonist (FW = 365.47 g/mol; CAS 149649-22-9; Soluble to 100 mM in 1 eq. HCl), also named *N*-[(1-butyl-2-pyrrolidinyl)methyl]-4-cyano-1-methoxy-2-naphthalenecarboxamide, is a centrally active agent that preferentially targets D<sub>3</sub> receptors ( $K_i = 0.52$  nM), with lower affinity for D<sub>2</sub> ( $K_i = 5$  nM) and D<sub>4</sub> ( $K_i = 269$  nM) receptors (1-3). (The dextroisomer displays 20x lower affinity at the dopamine D<sub>3</sub> receptor and reduced selectivity.) Nafadotride displaces *N*-[<sup>3</sup>H]propylnorapomorphine accumulation *in vivo* at lower dosage and for longer periods in limbic structures, containing both dopamine D<sub>2</sub> and D<sub>3</sub> receptors than in the stratum, containing dopamine D<sub>2</sub> receptor only (1). Nafadotride also inhibits augmentation of the locomotion response to repetitive amphetamine, a finding that is consistent with the proposed model of adaptive down-regulation of D<sub>3</sub> dopamine receptor function contributing to the development of behavioral sensitization (3). **1.** Sautel, Griffon, Sokoloff, *et al.* (1995) *J. ### Nafcillin

This semi-synthetic penicillin (FW<sub>free-acid</sub> = 414.48 g/mol), also known as 6-(2-ethoxy-1-naphthamido)penicillin, is a suicide inhibitor of β-lactamase, combining with its active-site seryl residue. **Target(s):** cytosol alanine aminopeptidase (1); β-lactamase (2-4); neprilysin, or enkephalinase (5). **1.** Starnes, Szechinski & Behal (1982) *Eur. J. Biochem.* **124**, 363. **2.** Tan & Fink (1992) *Biochem. J.* **281**, 191. **3.** Fink, Behner & Tan (1987) *Biochemistry* **26**, 4248. **4.** O'Callaghan & Morris (1972) *Antimicrob.*

*Agents Chemother.* **2**, 442. **5.** Livingston, Smith, Sewell & Ahmed (1992) *J. Enzyme Inhib.* **6**, 165.

### Nafenopin

This hypolipidemic agent (FW<sub>free-acid</sub> = 310.39 g/mol; CAS 3771-19-5), also known as 2-methyl-2-[*p*-(1,2,3,4-tetrahydro-1 naphthyl)phenoxy]propionate and SU-13,437, inhibits acetyl-CoA carboxylase. Note also that administration of nafenopin can lead to hepatocellular carcinomas in mice and rats. A low incidence of pancreatic tumors was also observed in rats. **Target(s):** acetyl-CoA carboxylase (1-4); palmitate:CoA ligase (5). **1.** Tanabe, Nakanishi, Hashimoto, *et al.* (1981) *Meth. Enzymol.* **71**, 5. **2.** Scott, Reich & Goodman (1979) *J. Biol. Chem.* **254**, 4957. **3.** Lien, Goodman & Rasmussen (1975) *Biochemistry* **14**, 2749. **4.** Rainwater & Kolattukudy (1982) *Arch. Biochem. Biophys.* **213**, 372. **5.** Roberts & Knights (1992) *Biochem. Pharmacol.* **44**, 261.

### Naftifine

This antifungal agent (FW<sub>free-base</sub> = 287.40 g/mol) inhibits cholesterol Δ-isomerase, or sterol Δ<sup>7,8</sup>-isomerase (1) and squalene monooxygenase, or squalene epoxidase (*Candida albicans*  $K_i = 1.1$  μM, rat liver  $K_i = 144$  μM (2-7)). **1.** Moebius, Reiter, Bermoser, *et al.* (1998) *Mol. Pharmacol.* **54**, 591. **2.** Ryder, Seidl & Troke (1984) *Antimicrob. Agents Chemother.* **25**, 483. **3.** Paltauf, Daum, Zuder, *et al.* (1982) *Biochim. Biophys. ### Naftopidil

This antihypertensive agent (FW = 392.50 g/mol; CAS Registry = 1164469-60-6; Soluble to 100 mM in DMSO), also known as KT-611 and 4-(2-methoxyphenyl)-α-[(1 naphthalenyloxy)methyl]-1-piperazineethanol, is an α<sub>1</sub>-adrenergic blocker,  $K_i = 58$  nM (1-3) and a 5-HT<sub>1A</sub> receptor agonist (1-4). Naftopidil also inhibits the sympathetic adrenergic contraction evoked by electrical transmural stimulation in the dog mesenteric artery, and the inhibition is not relieved upon repetitive washing for 1 hour with the drug-free solution (4). **1.** Takei, Ikegaki, Shibata, Tsujimoto & Asano (1999) *Jpn. J. Pharmacol.* **79**, 447. **2.** Yamada, Suzuki, Kato, *et al.* (1992) *Life Sci.* **50**, 127. **3.** Sponer, Borbe, Muller-Beckmann, Freud & Jakob (1992) *J. Cardiovasc. Pharmacol.* **20**, 1006. **4.** Muramatsu, Yamanaka & Kigoshi (1991) *Jpn. J. Pharmacol.* **55**, 391.

### Nalidixate (Nalidixic Acid)

This antibacterial agent (FW<sub>free-acid</sub> = 232.24 g/mol; CAS 389-08-2), systemically referred to as 1-ethyl-1,4-dihydro-7-methyl-4-oxo-1,8-naphthyridine-3-carboxylate and often abbreviated NAL, inhibits bacterial DNA biosynthesis via DNA gyrase, binding to subunit A. **Target(s):** AKR

virus reverse transcriptase (1); avian myeloblastosis virus reverse transcriptase (1,2); butyryl-CoA synthetase, or butyrate:CoA ligase, or medium-chain-fatty-acyl-CoA synthetase (3,4); DNA gyrase, or DNA topoisomerase II (5-15); DNA topoisomerase I, *Vaccinia* (16); glycyl-tRNA synthetase (17,18); leucyl-tRNA synthetase (18); RNA-directed DNA polymerase (1,2). 1. ### Nalbuphine

This naltrexone analogue (FW<sub>HCl-salt</sub> = 357.44 g/mol; CAS 20594-83-), also known as EN-2234A Nubain<sup>®</sup>, and (–)-17-(cyclobutylmethyl)-4,5α-epoxy-morphinan-3,6α,14-triol, is a semi-synthetic opioid used commercially as an analgesic (1). It is approximately equipotent in analgesic activity to morphine on a weight basis, with an ability to induce respiratory depression that is comparable to that of morphine. Nalbuphine binds tightly to the μ-opioid receptor ( $K_i = 0.89$  nM) and κ-opioid receptor ( $K_i = 2.2$  nM), but displays relatively low affinity ( $K_i = 240$  nM) for the δ-opioid receptor (2). It is a moderate-efficacy partial agonist (or mixed agonist/antagonist) of the μ-opioid receptor (IA = 47%; EC<sub>50</sub> = 14 nM) and as a high-efficacy partial agonist of the κ-opioid receptor (IA = 81%; EC<sub>50</sub> = 27 nM) (2). 1. Elliott, Navarro & Nomof (1970) *J. Med.* **1**, 74. 2. Peng, Knapp, Bidlack & Neumeyer (2007) *J. Med. Chem.* **50**, 2254.

### Naloxegol

This pegylated μ-opioid antagonist (FW = 651.78 g/mol; CAS 854601-70-0), also named (5α,6α)-4,5-epoxy-6-(3,6,9,12,15,18,21-heptaooxadocos-1-yloxy)-17-(2-propen-1-yl)morphinan-3,14-diol, Movantik<sup>®</sup>, and Moventig<sup>®</sup>, is a peripherally-selective opioid antagonist indicated for the treatment of opioid-induced constipation. When administered along with opioid analgesics, naloxegol reduces constipation-related side effects, while maintaining comparable levels of analgesia. Significantly, pegylation reduces naloxegol's ability to cross the blood-brain barrier. 1. Corsetti & Tack (2015) *Expert Opin. Pharmacother.* **16**, 399.

### Naloxol

These naloxone-like opioid antagonists (FW = 329.39 g/mol; CAS 20410-95-1 (α); 53154-12-4 (β); 58691-01-3 (α/β)) exist in two isomeric forms, α-naloxol and β-naloxol, the former a human metabolite of naloxone (1) and the β-naloxol prepared α-naloxol by a Mitsunobu reaction. α-Naloxol is a neutral μ-opioid receptor antagonist, regardless of morphine pretreatment (3). 1. Weinstein, Pfeffer, Schor, Indindoli & Mintz (1971) *J. Pharm. Sci.* **60**, 1567. 2. Simon (1994) *Tetrahedron* **50**, 9757. 3. Wang, Raehal, Bilsky & Sadée (2001) *J. Neurochem.* **77**, 1590.

### Naloxone

This synthetic congener of oxycodone (FW<sub>free-base</sub> = 327.38 g/mol; CAS 465-65-6; photosensitive), also known by the trade name Narcan<sup>™</sup>, is a tight-binding competitive antagonist for μ, κ, δ, and σ opioid receptors (1-3). It is used as an emergency medicine to counteract narcotic (most often heroin, morphine, oxycodone) overdose. Geary & Wooten (4) reported that sixty-one saturation experiments conducted in 13 regions of naive rat brains yielded monophasic Eadie-Hofstee plots for [<sup>3</sup>H]-naloxone binding, with a  $K_d$  of 1.87 nM and a  $B_{max}$  of 0.1 pmol/mg protein. The sixty-one  $K_d$  values in naive rats described a normal distribution of regional binding affinities that may reflect the biological variation of a single high-affinity binding site. Similar studies in the morphine-dependent and precipitated withdrawal states showed no apparent changes in either the  $K_d$  or  $B_{max}$  of regional [<sup>3</sup>H]-naloxone binding. Preincubation had no effect on the ability of either opiate agonist or antagonist to compete for [<sup>3</sup>H]-naloxone binding in the naive, morphine dependent or precipitated withdrawal states (4). *Note:* In 2014, the U.S. Food & Drug Administration approved a prescription treatment that can be used by family members or caregivers to treat a person known or suspected to have had an opioid overdose. Evzio<sup>™</sup> (naloxone hydrochloride, injectable) rapidly delivers a single dose of naloxone via a hand-held auto-injector that can be carried in a pocket or stored in a medicine cabinet. Evzio is injected into the muscle (intramuscular) or under the skin (subcutaneous). Once actuated, the device provides verbal instructions on how to deliver the medication. Prior to the advent of this device, the CDC estimated that U.S. programs providing drug-users and their caregivers with take-home naloxone had already prevented ~10,000 deaths from opioid overdose. **Target(s):** μ $\mathcal{R}$ , κ $\mathcal{R}$ , δ $\mathcal{R}$ , and σ $\mathcal{R}$  opioid receptors (2-4); glucuronosyltransferase (1); 1. Goodrich (1990) *AANA J.* **58**, 14. 2. Sawynok, Pinsky & LaBella (1979) *Life Sci.* **25**, 1621. 3. Fischer & Udem (1999) *Brit. J. Pharmacol.* **127**, 605. 4. Geary & Wooten (1985) *Brain Res.* **360**, 214. 5. Hara, Nakajima, Miyamoto & Yokoi (2007) *Drug Metab. Pharmacokin.* **22**, 103.

### Naloxone Benzoylhydrazone

This hydrazone (FW<sub>free-base</sub> = 445.52 g/mol), also known as 6-deoxy-6-benzoylhydrazido-N-allyl-14-hydroxydihydronormorphinone, is an antagonist at the ORL1 nociceptin receptor, i.e., opioid receptor-like orphan receptor (1) as well as the μ opioid receptor (2). (*See Nociceptin*) Naloxone benzoylhydrazone is also a κ<sub>3</sub> agonist. 1. Chiou (2000) *J. Biomed. Sci.* **7**, 232. 2. Gistrak, Paul, Hahn & Pasternak (1989) *J. Pharmacol. Exp. Ther.* **251**, 469.

**Naloxone Methiodide**

This quaternary ammonium naloxone derivative (FW = 469.32 g/mol) is a nonselective antagonist at opioid receptors. It does not cross the blood-brain barrier and is used in the treatment of opioid overdoses. **1.** Milne, Coddington & Gamble (1990) *Neurosci. Lett.* **114**, 259.

**Naltrexone**

This naloxone analogue (FW<sub>free-base</sub> = 341.41 g/mol; CAS 16590-41-3) is a nonselective opioid receptor antagonist that acts at  $\mu$ ,  $\kappa$ ,  $\delta$ , and  $\sigma$  receptors (1-3). Like naloxone, it is used in cases of narcotic overdoses; however, it is longer acting. Naltrexone has also been used in the treatment of alcoholism. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** Powell & Holtzman (1999) *Eur. J. Pharmacol.* **377**, 21. **2.** Bienkowski, Kostowski & Koros (1999) *Eur. J. Pharmacol.* **374**, 321. **3.** Gonzalez & Brogden (1988) *Drugs* **35**, 192.

**Naltriben**

This naltrexone derivative (FW<sub>free-base</sub> = 415.49 g/mol; CAS 103429-31-8) is a selective  $\delta_2$  opioid receptor antagonist (1-3). Naltriben is also a noncompetitive antagonist for  $\mu$  receptors and is an agonist for  $\kappa_2$  receptors in rat cerebral cortex. Naltriben is often supplied commercially as the methanesulfonate salt. **1.** Takemori, Sultana, Nagase & Portoghese (1992) *Life Sci.* **50**, 1491. **2.** Miyamoto, Portoghese & Takemori (1993) *J. Pharmacol. Exp. Ther.* **264**, 1141. **3.** Kim, Son, Shin & Cho (2001) *Life Sci.* **68**, 1305.

**L-NAME, See N<sup>o</sup>-Nitro-L-arginine Methyl Ester**

**Napabucasin**

This orally bioavailable Stat3 inhibitor (FW = 240.21 g/mol; CAS 83280-65-3; Solubility: 10 mg/mL in DMSO; < 1 mg/mL in H<sub>2</sub>O), also named BBI608 and 2-acetylnaphtho[2,3-*b*]furan-4,9-dione, targets cancer stemness by targeting gene transcription driven by Stat3 (IC<sub>50</sub> = 142 nM) and suppressing cancer relapse/metastasis. Other agents have much higher IC<sub>50</sub> values: Sunitinib, 9  $\mu$ M; Gefitinib, 22  $\mu$ M; Regorafenib, 16  $\mu$ M; and Erlotinib, 12  $\mu$ M). **1.** Li, Rogoff, Keates, *et al.* (2015) *Proc. Natl. Acad. Sci. USA* **112**, 1839.

**Naphalecin**

This novel antibiotic and likely protonophore (FW = 274.27 g/mol), also known as 1,6,8-trihydroxynaphthalen-2-yl)propan-1-one, isolated from a strictly Gram-positive anaerobe (Genus: *Sporotalea*; Strain SYB), is broadly active: *Rhodococcus rhodochrous* (Minimal Inhibitory Concentration  $\approx$  25  $\mu$ g/mL), *Bacillus subtilis* (MIC  $\approx$  25  $\mu$ g/mL), *Staphylococcus epidermidis* (MIC  $\approx$  25  $\mu$ g/mL), *Micrococcus luteus* (MIC  $\approx$  3  $\mu$ g/mL), *Pseudomonas fluorescens* (MIC > 100  $\mu$ g/mL), *Pseudomonas putida* (MIC > 100  $\mu$ g/mL), *Escherichia coli* (MIC > 100  $\mu$ g/mL), *Saccharomyces cerevisiae* (MIC > 100  $\mu$ g/mL), *Aspergillus niger* (MIC > 100  $\mu$ g/mL). Toxicity to human cells was observed at concentrations exceeding 160  $\mu$ g/mL. **1.** Ezaki, Muramatsu, Takase, Hashimoto & Nagai (2008) *J. Antibiot.* (Tokyo) **61**, 207.

**Naphazoline**

This vasoconstrictor (FW<sub>free-base</sub> = 210.28 g/mol; CAS 835-31-4), also called Privine and systematically named 2-(naphthalen-1-ylmethyl)-4,5-dihydro-1H-imidazole, is an imidazoline receptor agonist as well as an  $\alpha$ -adrenergic receptor agonist. Naphazoline acts on  $\alpha$ -receptors in the arterioles of the conjunctiva to produce constriction, resulting in decreased congestion. Its rapid action in reducing swelling, when applied to mucous membrane, commends its use in eye drop formulations, such as Clear Eyes<sup>®</sup> and Naphcon<sup>®</sup>. **Target(s):** cholinesterase (1); monoamine oxidase (2). **1.** Augustinsson (1950) *The Enzymes*, 1st. ed., **1** (Part 1), 443. **2.** Carpine, Collon, Remaury, *et al.* (1995) *J. Pharmacol. Exp. Ther.* **272**, 681.

**1-Naphthaleneacetate**

This aromatic acid (FW<sub>free-acid</sub> = 186.21 g/mol), also known as NAA and 1-naphthylacetic acid, is a synthetic plant growth regulator (auxin). It has been used to promote flowering in certain plants and induce root growth. The free acid has low water solubility (0.038 g/100g at 17°C) but is more soluble in ethanol and acetone. *Note:* Do not confuse naphthylacetate with the ester, naphthyl acetate (**See 1-Naphthyl Acetate; 2-Naphthyl Acetate**) **Target(s):** aryl sulfotransferase (1);  $\beta$ -glucosidase, maize (2); isochorismate synthase (3); tyrosine-ester sulfotransferase (4). **1.** Rao & Duffel (1991) *Drug Metab. Dispos.* **19**, 543. **2.** Feldwisch, Vente, Zettl, *et al.* (1994) *Biochem. J.* **302**, 15. **3.** Stalman, Koskamp, Luderer, *et al.* (2003) *J. Plant Physiol.* **160**, 607. **4.** Duffel (1994) *Chem. Biol. Interact.* **92**, 3.

**$\alpha$ -Naphthol**

This photosensitive naphthalene derivative (FW = 144.17 g/mol; M.P. = 96°C;  $pK_a$  = 9.34 at 25°C), also known as 1-naphthol, 1-naphthalenol, and 1-hydroxynaphthalene, is a precursor in the chemical synthesis of dyes, intermediates, inhibitors, and reagents. It is an alternative substrate for a number of UDP-glucuronosyltransferases and aryl sulfotransferases (phenol sulfotransferases). **Target(s):** amine oxidase (1); catechol oxidase (2,3); chymotrypsin (4); cyclooxygenase (5); glutathione *S*-transferase (6); *N*-hydroxyarylamine *O*-acetyltransferase (7); lipoxygenase (8-10); nitronate monooxygenase (11); polyphenol oxidase (2,3). 1.  **$\beta$ -Naphthol**

This photosensitive naphthalene derivative (FW = 144.17 g/mol; CAS 90-15-3; M.P. = 121-123°C;  $pK_a$  = 9.51 at 25°C), also known as 2-naphthol, 2-naphthalenol, and 2-hydroxynaphthalene, is a precursor in the chemical synthesis of dyes, intermediates, inhibitors, and reagents. It is an alternative substrate for a number of UDP-glucuronosyltransferases and aryl sulfotransferases. **Target(s):** *N*-hydroxyarylamine *O*-acetyltransferase (1); D-3-hydroxybutyrate dehydrogenase (2); monoamine oxidase (3,4); nitronate monooxygenase (5); tyrosine-ester sulfotransferase (6). 1. Yamamura, Sayama, Kakikawa, *et al.* (2000) *Biochim. Biophys. Acta* **1475**, 10. 2. Gotterer (1969) *Biochemistry* **8**, 641. 3. Yamada, Kumagai & Uwajima (1971) *Meth. Enzymol.* **17B**, 722. 4. **1,2-Naphthoquinone**

This quinone, also known as  $\beta$ -naphthoquinone (FW = 158.16 g/mol; CAS 524-42-5; M.P. = 145-147°C), is a yellow solid that is practically insoluble in water, but dissolves upon addition of NaOH or concentrated sulfuric acid. **Target(s):**  $\alpha$ -amylase (1);  $\beta$ -amylase (1); catalase (2); catechol 1,2-dioxygenase (3);  $\zeta$ -crystallin, *or* NADPH:quinone oxidoreductase (4); glutathione *S*-transferase (5-7);  $\alpha$ -glycerophosphatase (8); 15-hydroxyprostaglandin dehydrogenase (NAD<sup>+</sup>) (9); 3 $\alpha$ -hydroxysteroid transhydrogenase (10); indoleamine 2,3-dioxygenase (11); NAD<sup>+</sup>:protein-arginine ADP-ribosyltransferase, *or* arginine-specific mono(ADP-ribosyl)transferase (12); nicotinate oxidase (13); papain (14); pyruvate decarboxylase (15). 1. Owens (1953) *Contrib. Boyce Thompson Inst.* **17**, 273. 2. Hoffmann-Ostenhof & E. Biach (1947) *Monatsh. Chem.* **76**, 319. 3. Itoh (1981) *Agric. Biol. Chem.* **45**, 2787. 4. Bazzi (2001) *Arch. **1,4-Naphthoquinone**

This quinone (FW = 158.16 g/mol; CAS 130-15-4; M.P. = 126°C), also called  $\alpha$ -naphthoquinone, is a yellow solid that is sparingly soluble in water. When dissolved in aqueous NaOH, a reddish brown solution is obtained. Among the many naturally occurring 1,4-naphthoquinone derivatives are juglone, lapachol, alkannin, *etc.* (See specific compound).

**Target(s):** alkaline phosphatase (1);  $\alpha$ -amylase (2);  $\beta$ -amylase (2); carbonic anhydrase (4); catalase (5); catechol 2,3-dioxygenase (6); *trans*-cinnamate 4-monooxygenase (7);  $\zeta$ -crystallin, *or* NADPH:quinone oxidoreductase (8); deoxyribonuclease (9); glutamate dehydrogenase (10); 3 $\alpha$ -hydroxysteroid transhydrogenase (11); indoleamine 2,3-dioxygenase (12); NAD<sup>+</sup> ADP-ribosyltransferase, *or* poly(ADP-ribose) polymerase (13); NADH:tetrazolium oxidoreductase, *or* NADH dehydrogenase (14); NAD<sup>+</sup>:protein-arginine ADP-ribosyltransferase, *or* arginine-specific mono(ADP-ribosyl)transferase (3); nicotinate oxidase (15); nitrite reductase (16); papain, weakly inhibited (17); polyphenol oxidase (18); pyruvate decarboxylase (19,20); ribonuclease H activity associated with HIV-1 reverse transcriptase (21); succinate dehydrogenase (22,23); succinate oxidase (22); urease (24); vitamin K-dependent carboxylase, *or* protein-glutamate carboxylase (25). 1. Anderson (1961) *Biochim. Biophys. Acta* **54**, 110. 2. Owens (1953) *Contrib. Boyce Thompson Inst.* **17**, 273. 3. Davis, Sabir, Tavassoli & Shall (1997) *Adv. Exp. Med. Biol.* **419**, 145. 4. **1-Naphthylacetyl spermine**

This synthetic spermine derivative and selective AMPAR antagonist (FW<sub>free-base</sub> = 370.54 g/mol; FW<sub>triHCl-salt</sub> = 479.91 g/mol; CAS 1049731-36-3; Tri-HCl salt is soluble to 100 mM in H<sub>2</sub>O), also named Naspm and *N*-[3-[[4-[(3-aminopropyl)amino]butyl]amino]propyl]-1-naphthaleneacetamide, is a Joro spider toxin, JSTX (See *Joro Spider Toxin*) analogue that targets Ca<sup>2+</sup>-permeable  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (*or* AMPA) receptors that lack the GluR2 subunit. (AMPA<sub>R</sub>'s are glutamate-gated ion channels that play central roles in the mammalian brain, mediating fast excitatory synaptic transmission and facilitating several

forms of synaptic plasticity.) Naspmp depresses the excitatory postsynaptic currents (EPSCs) mediated by non-NMDA receptor channels (1). EPSCs in CA1 neurons after ischemia are mediated by  $\text{Ca}^{2+}$ -permeable, non-NMDA receptor-mediated conductances, and Naspmp and JSTX are effective at blocking abnormal EPSCs that induce  $\text{Ca}^{2+}$  accumulation leading to delayed neuronal death after transient ischemic insult (1). In cultured rat hippocampal neurons probed by whole-cell patch clamp techniques, NASPM selectively suppressed the inwardly rectifying and  $\text{Ca}^{2+}$ -permeable AMP<sub>A</sub> receptors expressed in type II neurons (2). When the effect of NASPM reaches a steady state, current responses induced by ionophoretic applications of kainate, a non-desensitizing agonist of AMP<sub>A</sub> receptors, in type II neurons are suppressed by NASPM in a dose-dependent manner at -60 mV, with  $\text{IC}_{50} = 0.33 \mu\text{M}$  and a Hill coefficient of 0.94 (2). Naspmp was also used to implicate GluR2-lacking AMPA receptors in the ischemia-induced rise in free  $\text{Zn}^{2+}$  and death of CA1 neurons, although a direct action at the time of the rise in  $\text{Zn}^{2+}$  remains unproven (3). 1. ### ***N*<sup>α</sup>-(2-Naphthylsulfonylglycyl)-4-amidino-DL-phenylalanine piperidine**

This naphthyl sulfonamide (FW<sub>acetate-salt</sub> = 581.69 g/mol; *Abbreviation*: NAPAP), also known as 4-amidino-*N*<sup>α</sup>-(naphthalene-2-sulfonylglycyl)-DL-phenylalanine piperidide, *N*<sup>α</sup>-(2-naphthalenesulfonylglycyl)-4-amidino-DL-phenylalanine piperidide, and by its proprietary name Pefabloc TH, is a potent inhibitor of thrombin ( $K_i = 6.5 \text{ nM}$ ). It is a slightly weaker inhibitor of trypsin ( $K_i = 330 \text{ nM}$ ). **Target(s)**: coagulation factor Xa, weakly inhibited (1); plasmin, weakly inhibited (1,2); complement factor I (3); platelet-aggregating endopeptidase of *Bothrops jararaca* venom (4); thrombin (1,2,4-13); trypsin (1,2). 1. ### **5'-(1-Naphthylthio)-immucillin-A**

This nucleoside analogue (FW<sub>free-base</sub> = 408.50 g/mol), also known as (1*S*)-1-(9-deazaadenin-9-yl)-5-(1-naphthylthio)-1,4-dideoxy-1,4-imino-D-ribose,

inhibits 5'-methylthioadenosine/*S*-adenosylhomocysteine nucleosidase ( $K_i = 750 \text{ pM}$ ). It is also a tight, slow-binding inhibitor of human *S*-methyl-5' thioadenosine phosphorylase ( $K_i = 90 \text{ nM}$ ). **Target(s)**: adenosylhomocysteine nucleosidase (1); 5'-methylthioadenosine/*S*-adenosylhomocysteine nucleosidase (1); *S*-methyl-5'-thioadenosine phosphorylase (2). 1. Singh, Evans, Lenz, et al. (2005) *J. Biol. Chem.* **280**, 18265. 2. Evans, Furneaux, Schramm, Singh & Tyler (2004) *J. Med. Chem.* **47**, 3275.

### **α-Naphthylthiourea**

This substituted thiourea (FW = 202.28 g/mol; *Abbreviation*: ANTU) inhibits flavin-containing monooxygenases and is frequently used as a rodenticide. Although highly toxic for the adult Norway rat, this thiourea is less toxic to most other rat strains. **Target(s)**: flavin-containing monooxygenase (1-3); succinate dehydrogenase (4); tyrosinase, or monophenol monooxygenase, weakly inhibited (4); unspecific monooxygenase (1,2,5). 1. Itoh, Kimura, Yokoi, Itoh & Kamataki (1993) *Biochim. Biophys. Acta* **1173**, 165. 2. Ziegler & Mitchell (1972) *Arch. Biochem. Biophys.* **160**, 116. 3. Chiba, Kobayashi, Itoh, et al. (1995) *Eur. J. Pharmacol.* **293**, 97. 4. DuBois & Erway (1946) *J. Biol. Chem.* **165**, 711. 5. Diaz Gomez & Castro (1986) *Arch. Toxicol.* **59**, 64.

### **Naproxen**

This anti-inflammatory agent (FW<sub>free-acid</sub> = 230.26 g/mol; CAS 22204-53-1), also known as (α*S*)-6-methoxy-α-methyl-2-naphthaleneacetic acid, inhibits the cyclooxygenase activity of prostaglandin endoperoxide synthases 1 and 2. Naproxen photolysis generates radicals that result in single-strand DNA cleavage. **Primary Mode of Inhibitory Action**: Based on their kinetic behavior, nonsteroidal anti-inflammatory drugs (NSAIDs) exhibit four modes of COX inhibition: Type-1, simple competitive inhibition (*example*: ibuprofen); Type-2, weak, time-dependent binding (*example*: oxycam); Type-3, tight binding, time-dependent (*example*: indomethacin); Type-4, site-directed covalent modification (*example*: aspirin) (1). Naproxen's action resembles that of oxycam, but with mixed inhibition ( $K_i \approx 10\text{-}15 \mu\text{M}$ ), with time-dependence toward COX-2. **Pharmacokinetic Properties**: When administered orally, naproxen is absorbed rapidly and virtually completely, remaining protein-bound (mainly to serum albumin) during its distribution. Its metabolism relatively simple, as is its renal excretion. The mean half-life in humans is 13 hours, nearly ideal for twice-daily administration. In man, naproxen and its only detected metabolite (demethylated at position-6) are excreted in the urine, mainly as conjugates. **Key Pharmacokinetic Parameters**: See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). (See also ATB-346, an *H*<sub>2</sub>*S*-producing naproxen derivative) **Target(s)**: cyclooxygenase, or prostaglandin-endoperoxide synthase 1 and 2 (2,3); estrone sulfotransferase (4); long-chain-fatty-acyl-CoA synthetase, (5); phenol sulfotransferase (4); phosphoribosyl-aminoimidazolecarboxamide formyltransferase (6); thiopurine *S*-methyltransferase (7); tyrosine-ester sulfotransferase (8). 1. Gierse, Koboldt, Walker, Seibert & Isakson (1999) *Biochem. J.* **339** (Part 3), 607. 2. Barnett, Chow, Ives, et al. (1994) *Biochim. Biophys. Acta* **1209**, 130. 3. ### Napsagatran

This antithrombotic agent (FW = 558.66 g/mol; CAS 159668-20-9), also known as Ro 46-6240, is a potent inhibitor of thrombin,  $K_i = 0.27$  nM (1-3) and a weaker inhibitor of trypsin,  $K_i = 1.9$   $\mu$ M (1,2). The ethyl ester is a weaker inhibitor. 1. Hilpert, Ackermann, Banner, *et al.* (1994) *J. Med. Chem.* **37**, 3889. 2. Dullweber, Stubbs, Musil, Stürzebecher & Klebe (2001) *J. Mol. Biol.* **313**, 593. 3. Russo, Gast, Schlaeger, Angiolillo & Pietropaolo (1997) *Protein Expr. Purif.* **10**, 214.

### Naptalam

This aromatic amide (FW = 291.31 g/mol; CAS 132-66-1), also known as *N*<sup>1</sup>-naphthylphthalamic acid (NPA) and Alanap™, is a selective pre-emergence herbicide and anti-auxin. The application of this phytohormone to various plant tissues results in inhibition of auxin efflux carrier activity and, as a consequence, increases auxin accumulation in cells. Although the mechanism of its inhibitory action on polar auxin transport remains unclear, it appears to be mediated by a specific, naptalam binding protein. Naptalam has a low solubility in water and is hydrolyzed by strong acids and bases.

**Target(s):** auxin transport (1-4); indole-3-acetate  $\beta$ -glucosyltransferase (5). 1. Morris (2000) *Plant Growth Regul.* **32**, 161. 2. Katekar & Geissler (1980) *Plant Physiol.* **66**, 1190. 3. Rubery (1990) *Symp. Soc. Exp. Biol.* **44**, 119. 4. Petráek, Cerná, Schwarzerová, *et al.* (2003) *Plant Physiol.* **131**, 254. 5. Leznicki & Bandurski (1988) *Plant Physiol.* **88**, 1481.

### Naringin

This flavanone glycoside (FW = 580.54 g/mol; CAS 10236-47-2), also known as naringenin 7-rhamnoglucoside, is found in a number of plants, and is the primary bitter component of the grapefruit. (See also Naringenin)

**Target(s):** CYP3A4, weakly inhibited (1); flavanone 7-*O*-glucoside 2''-*O*- $\beta$ -L-rhamnosyltransferase, weakly inhibited (2);  $\beta$ -glucuronidase, weakly inhibited (3); [3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)] kinase (4); iodide peroxidase, or thyroid peroxidase (5); phenol sulfotransferase, or aryl sulfotransferase (6,7); tyrosinase, weakly inhibited

(3); xanthine oxidase (8). 1. Ho, Saville & Wanwimolruk (2001) *J. Pharm. Pharm. Sci.* **4**, 217. 2. Bar-Peled, Lewinsohn, Fluhr & Gressel (1991) *J. Biol. Chem.* **266**, 20953. 3. Dew, Day & Morgan (2005) *J. Agric. Food Chem.* **53**, 6510.

### Navitoclax

This apoptosis-promoting antineoplastic agent (FW = 974.61 g/mol; CAS 923564-51-6; Solubility: 190 mg/mL DMSO, < 1 mg/mL H<sub>2</sub>O), also known by the developmental code name ABT-263 and structurally related to ABT-737, is a potent, orally bioavailable disruptor of Bcl-2/Bcl-X<sub>L</sub> interactions with anti-apoptotic proteins. IC<sub>50</sub> values for Bcl-X<sub>L</sub>, Bcl-2, and Bcl-w interactions are < 0.5 nM, < 1 nM, and < 1 nM, respectively (1). Oral administration of ABT-263 alone induces complete tumor regression in xenograft models of small-cell lung cancer and acute lymphoblastic leukemia (1). Evasion of apoptosis can be achieved by overexpression of anti-apoptotic BCL2 family members. Navitoclax is a first-in-class BCL2 family inhibitor that restores the ability of cancer cells to undergo apoptosis by inhibiting protein-protein interactions. Cells that successfully resist ABT-263 possess high levels of MCL1, a BCL2 family member that is not targeted by the drug. MCL1 expression is regulated transcriptionally, translationally, and through proteasome-mediated degradation. Significantly, several recently screened micro-RNA mimics were also found to induce apoptosis, but only in the presence of ABT-263 (2). Whereas all 12 of these micro-RNAs reduced MCL1 protein expression, only 10 of them targeted MCL1 through direct binding to the 3'-untranslated region of the gene, raising the possibility that other resistance regulators of MCL1 expression may be identified using this approach (2). The pro-apoptotic action of Navitoclax is also potentiated by 2-deoxyglucose, which is transported into normal and cancer cells and subsequently undergoes phosphorylation by hexokinase (3). With malignant (*i.e.*, rapidly growing tumor cells) typically displaying glycolytic rates up to 200x faster than their normal tissues of origin, inhibition of glycolysis by 2-deoxyglucose-6-P apparently stresses cancer cells, making them more susceptible to Navitoclax. Another important finding is that Navitoclax has little effect on cell death during interphase, but strongly accelerates apoptosis during mitotic arrest (4). With reduced glycolysis in the presence of 2-deoxyglucose likely to reduce ATP stores needed for cell division and with cancer cell aneuploidy delaying mitosis by checkpoint control, Navitoclax is likely to act on an increased fraction of poorly dividing cells. Such findings also suggest Navitoclax will prove to be more effective as an antineoplastic agent when administered along with cytostatic agent(s). 1. Tse, Shoemaker, Adickes, *et al.* (2008) *Cancer Res.* **68**, 3421. 2. Lam, Lu, Zhang, *et al.* (2010) *Mol. Cancer Ther.* **9**, 2943. 3. ### NBD 556

This small-molecule CD4 mimetic (FW = 337.84 g/mol; CAS 333353-44-9; Soluble to 100 mg/mL in DMSO), also named *N*'-(4-chlorophenyl)-*N*'-(2,2,6,6-tetramethyl-4-piperidinyl)ethanedi- amide, induces structural changes in the HIV-1 envelope protein gp120 in a manner analogous to CD4, thereby blocking virus-cell and cell-cell fusion as well as inhibiting HIV-1 entry ( $IC_{50} \approx 2-5$  mM, depending on cell type and HIV strain) in CXCR4- and CCR5-expressing cell lines (1). To initiate HIV entry into host cells, the HIV envelope protein gp120 must engage its primary receptor CD4 as well as a coreceptor (*i.e.*, CCR5 or CXCR4). Systematic studies showed this compound targets viral entry by inhibiting the binding of HIV-1 envelope glycoprotein gp120 to the cellular receptor CD4 but did not inhibit reverse transcriptase, integrase, or protease, indicating that they do not target the later stages of the HIV-1 life cycle to inhibit HIV-1 infection. This compound was equally effective as inhibitors of both X4 and R5 viruses tested in CXCR4- and CCR5-expressing cell lines, respectively, indicating that their anti-HIV-1 activity is not dependent on the coreceptor tropism of the virus. Surface plasmon resonance demonstrates that NBD 556 bind to unliganded HIV-1 gp120, but not to the cellular receptor CD4. 1. Zhao, Ma, *et al.* (2005) *Virology* **339**, 213.

#### NB-598

This benzylamine derivative (FW<sub>free-base</sub> = 449.68 g/mol) is a strong competitive inhibitor of cholesterol biosynthesis and squalene monoxygenase, *or* squalene epoxidase:  $K_i = 0.68$  nM for the HepG2 epoxidase. NB-598 also suppresses triacylglycerol biosynthesis. 1. Horie, Tsuchiya, Hayashi, *et al.* (1990) *J. Biol. Chem.* **265**, 18075. 2. Nagumo, Kamei, Sakakibara & Ono (1995) *J. Lipid Res.* **36**, 1489. 3. Satoh, Horie, Watanabe, Tsuchiya & Kamei (1993) *Biol. Pharm. Bull.* **16**, 349.

#### NC-1400, See Bevantolol

#### NCI 47729-M

This non-folate dye (FW = 563.00 g/mol) inhibits ( $IC_{50} = 3.3$   $\mu$ M) phosphoribosylaminoimidazolecarboxamide formyltransferase, one of the two folate-dependent enzymes in the *de novo* purine biosynthesis pathway. This formyltransferase is a promising target for anti-neoplastic chemotherapy. 1. Xu, Li, Olson & Wilson (2004) *J. Biol. Chem.* **279**, 50555.

#### NCX 429

This nitric oxide- and naproxen-releasing drug (FW = 361.45 g/mol), also named (*S*)-6-(nitrooxy)hexyl-2-(6-methoxynaphthalen-2-yl)propanoate, is a new class of cyclooxygenase (COX)-inhibiting nitric oxide donors (CINODs) that combine a COX inhibitor with a nitric oxide- (NO-) donating moiety, reducing the toxicity of the non-steroidal anti-inflammatory drugs (NSAIDs), while exerting their analgesic and anti-

inflammatory effects. NSAID-induced gastroenteropathy is a significant limitation to the use of this class of drugs, and nitric oxide is an important mediator of gastric mucosal defense. (See also Naproxen; NCX 429) 1. Amoroso, Fresu, Dalli, *et al.* (2015) *Life Sci.* **126**, 28.

#### NE-10064, See Azimilide

#### Nebivolol

This presumptive third-generation  $\beta_1$ -adrenoceptor blocker and anti-hypertensive drug (FW = 405.43 g/mol (free base) = 441.9 g/mol (as hydrochloride); CAS 99200-09-6; Solubility: 88 mg/mL DMSO; <1 mg/mL Water), also known as R-67145, Bystolic, and named systematically as 1-(6-fluorochroman-2-yl)-[2-(6-fluorochroman-2-yl)-2-hydroxyethyl]-amino ethanol, is a selective antagonist ( $IC_{50} = 0.8$  nM), displaying nitric oxide-potentiating vasodilatory effects (1-3). Significantly, nebivolol treatment (intravenously within 10 min of reperfusion and continued orally) reduces the myocardial apoptosis after myocardial infarction (4). **Primary Mode of Action:** Although the mechanism of nebivolol-induced NO production remains controversial, there are parallels with carvedilol, another  $\beta$ -blocker that displays biased agonism that is independent of  $G_{\alpha s}$  and involves G-protein-coupled receptor kinase (GRK)/ $\beta$ -arrestin signaling, with downstream activation of EGFR and ERK (5). In experiments with mouse embryonic fibroblasts (MEFs), a cell line solely expressing  $\beta_2$ -ARs, and HL-1 cardiac myocytes, a cell line expressing both  $\beta_1$ - and  $\beta_2$ -ARs (but no detectable  $\beta_3$ -ARs), nebivolol did not significantly alter cAMP levels, demonstrating that it cannot be a classical agonist. In both cell types, nebivolol induced rapid internalization of  $\beta$ -ARs, indicating that it is also not a classical  $\beta$ -blocker (5). Furthermore, nebivolol treatment resulted in a time-dependent phosphorylation of ERK that was indistinguishable from the action of carvedilol and similar in duration, but not amplitude, to isoproterenol. Nebivolol-mediated ERK phosphorylation was sensitive to propranolol (a non-selective  $\beta$ -AR-blocker) and AG1478 (an EGFR inhibitor), indicating that the signaling emanates from  $\beta$ -ARs and involves the EGFR. Moreover, nebivolol-mediated phosphorylation of ERK in MEFs was sensitive to pharmacological inhibition of GRK2 as well as siRNA knockdown of  $\beta$ -arrestin 1/2. Such findings indicate that nebivolol is a  $\beta_2$ -AR, and likely a  $\beta_1$ -AR, GRK/ $\beta$ -arrestin-biased agonist (5). 1. Pauwels, *et al.* (1988) *Mol. Pharmacol.* **34**, 843. 2. #### Nebularine

This toxic and water-soluble nucleoside (FW = 252.23 g/mol; CAS 118457-14-0), also called 9-( $\beta$ -D-ribofuranosyl)purine, 9-( $\beta$ -D-ribofuranosyl)purine, 9-purine ribonucleoside, and purine riboside, is a structural analogue of adenosine and inhibitor of adenosine deaminase ( $K_i = 8.8$   $\mu$ M). It has been isolated from the mushroom *Clitocybe nebularis* as well as species of *Streptomyces*. **Target(s):** adenosine deaminase (1-11); adenosine kinase, also weak alternative substrate (12); adenosine-phosphate deaminase (13); adenosylhomocysteinase, *or* *S*-adenosylhomocysteine hydrolase, weakly inhibited (14-17). 1. ### Nebularine 5'-Triphosphate

This nucleotide (FW<sub>free-acid</sub> = 492.17 g/mol), also known as 9-purine riboside 5'-triphosphate, inhibits several aminoacyl-tRNA synthetases. **Target(s):** arginyl-tRNA synthetase (1); isoleucyl-tRNA synthetase (2); leucyl-tRNA synthetase (3); lysyl-tRNA synthetase (1); threonyl-tRNA synthetase (1). **1.** Freist, Sternbach, von der Haar & Cramer (1978) *Eur. J. Biochem.* **84**, 499. **2.** Freist, von der Haar & Cramer (1981) *Eur. J. Biochem.* **119**, 151. **3.** Marutzyk, Flossdorf & Kula (1976) *Nucl. Acids Res.* **3**, 2067.

### Nefazodone

This antidepressant (FW<sub>free-base</sub> = 470.01 g/mol; CAS 83366-66-9), also known as 2-[3-[4-(3-chlorophenyl)-1-piperazinyl]propyl]-5-ethyl-2,4-dihydro-4-(2-phenoxyethyl)-3H-1,2,4-triazol-3-one, is a mixed serotonin 5-HT<sub>2A</sub> receptor antagonist and serotonin uptake inhibitor. **Target(s):** CYP1A2, moderately inhibited (1,2); CYP3A3/4, strongly inhibited (2,3); CYP2B6 (4); CYP2D6 (2,3); serotonin 5-HT<sub>2A</sub> receptor (5,6); serotonin uptake (5,7,8). **1.** von Moltke, Greenblatt, Duan, *et al.* (1996) *Psychopharmacology (Berlin)* **128**, 398. **2.** Owen & Nemeroff (1998) *Depress. Anxiety* **7** Suppl. 1, 24. **3.** Schmider, Greenblatt, von Moltke, Harmatz & Shader (1996) *Brit. J. Clin. ### Nefopam

This benzoxazocine-class analgesic and muscle relaxant (FW = 253.34 g/mol; CAS 13669-70-0), also known as Acupan<sup>®</sup>, Ajan<sup>®</sup>, Nefadol<sup>®</sup>, and Silentan<sup>®</sup>, is a centrally acting, non-opioid drug for managing moderate to severe pain, with analgesic potency similar to that of codeine phosphate (1). Nefopam is a "triple reuptake inhibitor" (or TRI), exhibiting the capacity to inhibit transporters responsible for the reuptake for serotonin, norepinephrine, and dopamine. Nefopam also inhibits calcium influx, cGMP formation, and NMDA receptor-dependent neurotoxicity following activation of voltage sensitive calcium channels (2). (+)-Nefopam is

substantially more potent than (-)-nefopam. **1.** Tobin & Gold (1972) *J. Clin. Pharmacol. New Drugs* **12**, 230. **2.** Novelli, Diaz-Trelles, Groppetti & Fernández-Sánchez (2005) *Amino Acids* **28**, 183.

### Negamycin

This antibiotic (FW<sub>free-base</sub> = 248.28 g/mol; CAS 83366-66-9; Insoluble in ethanol; Soluble in water; pK<sub>a</sub> values of 3.55, 8.10, and 9.75), isolated from strains of *Streptomyces purpeofuscus*, inhibits bacterial protein biosynthesis. **1.** Uehara, Hori & Umezawa (1976) *Biochim. Biophys. Acta* **442**, 251. **2.** Uehara, Hori & Umezawa (1974) *Biochim. Biophys. Acta* **374**, 82. **3.** Mizuno, Nitta & Umezawa (1970) *J. Antibiot.* **23**, 581. **4.** Uehara, Hori & Umezawa (1976) *Biochim. Biophys. Acta* **447**, 406.

### Nelfinavir

This peptide analogue, also known as AG-1346 (FW<sub>free-base</sub> = 567.79 g/mol; CAS 159989-64-7), is an oral antiviral agent that inhibits human immunodeficiency virus-1 protease (K<sub>i</sub> = 1.5 nM). The methane sulfonate salt (AG-1343) is known commercially as Viracept or Agouron. It was approved for human use in 1997. **Target(s):** candidapepsin (1); glucuronosyltransferase, or UDP-glucuronosyltransferase, UGT1A (1), UGT1A (3), and UGT1A4 (2); HIV-1 retropepsin (1,3-8). **1.** Tossi, Benedetti, Norbedo, *et al.* (2003) *Bioorg. Med. Chem.* **11**, 4719. **2.** Zhang, Chando, Everett, *et al.* (2005) *Drug Metab. Dispos.* **33**, 1729. **3.** Patlick, Mo, Markowitz, *et al.* (1996) *Antimicrob. Agents Chemother.* **40**, 292. **4.** Clemente, Moose, Hemrajani, *et al.* (2004) *Biochemistry* **43**, 12141. **5.** Wilson, Phylip, Mills, *et al.* (1997) *Biochim. Biophys. Acta* **1339**, 113. **6.** Clemente, Hemrajani, Blum, Goodenow & Dunn (2003) *Biochemistry* **42**, 15029. **7.** Clemente, Coman, Thiaville, *et al.* (2006) *Biochemistry* **45**, 5468. **8.** Surleraux, de Kock, Verschuere, *et al.* (2005) *J. Med. Chem.* **48**, 1965.

### Nematode Anticoagulant Protein c<sub>2</sub>

This 85-residue polypeptide, originally isolated from the hematophagous hookworm *Ancylostoma caninum*, is a tight binding, competitive inhibitor of coagulation factor Xa (K<sub>d</sub> ≈ 1 nM) and coagulation factor VIIa (K<sub>i</sub> ≈ 10 pM). **1.** Stassens, Bergum, Gansemans, *et al.* (1996) *Proc. Natl. Acad. Sci. U.S.A.* **93**, 2149. **2.** Buddai, Touloukhonova, Bergum, Vlasuk & Krishnaswamy (2002) *J. Biol. Chem.* **277**, 26689.

### Nemonapride

This benzamide (FW<sub>free-base</sub> = 387.91 g/mol; CAS 75272-39-8), also known as YM-09151-2 and *rel*-5-chloro-2-methoxy-4-(methylamino)-*N*-[(2*R*,3*R*)-2-methyl-2-(phenylmethyl)-3-pyrrolidiny]benzamide, is a selective D<sub>2</sub> dopamine receptor antagonist (K<sub>i</sub> = 0.1 nM), with much less affinity for D<sub>1</sub> receptors (K<sub>i</sub> = 740 nM). Nemonapride is also a potent SR-1A agonist with an IC<sub>50</sub> value of 34 nM (1,2). With potassium phosphate buffer with 25 nM spiperone, [<sup>3</sup>H]-nemonapride bound with high affinity to σ-receptors,

showing no affinity for D<sub>2</sub> dopamine or 5-HT<sub>1A</sub> receptors in rat brain (3). The order of pK<sub>i</sub> values of various  $\sigma$ -compounds at [<sup>3</sup>H]-nemonapride binding sites and stereoisomer selectivity were consistent with previous studies using other  $\sigma$ -ligands. Although Scatchard analysis fitted a one-site model, competition between [<sup>3</sup>H]-nemonapride and (+)-pentazocine revealed two sites,  $\sigma$ -1 and  $\sigma$ -2 receptors, at which the K<sub>i</sub> values of nemonapride were 8.4 nM and 9.6nM, respectively (3). Unlike clozapine and bromerguride, nemonapride exhibited marked 5-HT<sub>1A</sub> receptor agonist properties both *in vitro* and *in vivo* (4). 1. Grewe, Frey, Cote & Keabian (1982) *Eur. J. Pharmacol.* **81**, 149. 2. Terai, Usuda, Kuroiwa, Noshiro & Maeno (1983) *Jpn. J. Pharmacol.* **33**, 749. 3. Ujike, Akiyama & Kuroda (1996) *Neuroreport* **7**, 1057. 4. Assié, Cosi & Koek (1997) *Eur. J. Pharmacol.* **334**, 141.

#### Neocitreamicin I & II

These citreamicin-class antibiotics (FW<sub>I</sub> = 825.82 g/mol; FW<sub>II</sub> = 653.54 g/mol), from a novel *Nocardia* strain G0655 found in a sandy soil sample collected in Falmouth, Massachusetts (USA), show good antibacterial activity against Gram-positive bacteria, including methicillin-resistant *Staphylococcus aureus* and vancomycin-resistant *Enterococcus faecalis*. Both show little or no activity against Gram-negative bacteria. All previously reported citreamicins bear a methoxy group at Position-17, where the neocitreamicins lack any substitution at the 17-position. While Position-18 is occupied by a free hydroxyl group in Neocitreamicin I, it was glycosylated in Neocitreamicin II. The fact that both show similar antibacterial activity suggests that the ring end of the structure can be modified without loss of activity. The free hydroxyl group at Position-18 makes Neocitreamicin I more amenable to medicinal chemistry efforts for the improvement of drug properties. 1. Peoples, Zhang, Millett, Rothfeder, et al. (2008) *J. Antibiot.* (Tokyo) **61**, 457.

#### Neocuproine

This metal ion chelator (FW = 208.26 g/mol; CAS 484-11-7), also known as 2,9-dimethyl-1,10-phenanthroline, is frequently used in the determination of copper(I). **Target(s)**: alcohol dehydrogenase, yeast (1,2); amine oxidase (copper-containing) (3-6); catechol oxidase (7); cysteamine dioxygenase (8); cysteine dioxygenase (9); cytosol alanyl aminopeptidase (10); 2,3-dihydroxybenzoate 2,3-dioxygenase (11,12); fructose-2,6-bisphosphate 6-phosphatase (13); histone deacetylase (14); human immunodeficiency virus type 1 (HIV-1) integrase, inhibited by the cuprous-neocuproine complex (15); indole 2,3-dioxygenase (16); laccase (22); porphobilinogen synthase, or  $\delta$ -aminolevulinic dehydratase (17); RNA polymerase and transcription, inhibited by the cuprous-neocuproine complex (18); stizolobate synthase (19); stizolobinate synthase (19); taurine dehydrogenase (20); vellosimine reductase (21). 1. #### Neo-Kyotorphin

This basic pentapeptide (FW = 653.74 g/mol; *Sequence*: TSKYR), corresponding to residues 137-141 in the  $\alpha$ -chain of hemoglobin, was first isolated as an analgesic peptide from bovine brain. Hibernating ground squirrels (*Citellus undulatus*) produce this bioactive peptide. ITSKYR also stimulates proliferation of normal cells and tumor cells in the absence of fetal bovine serum. **Target(s)**: aminopeptidase, IC<sub>50</sub> = 131  $\mu$ M; angiotensin-converting enzyme, or peptidyl dipeptidase A, IC<sub>50</sub> = 200  $\mu$ M; dipeptidyl aminopeptidase, IC<sub>50</sub> = 306  $\mu$ M. 1. Hazato, Kase, Ueda, Takagi & Katayama (1986) *Biochem. Int.* **12**, 379.

#### Neomycins

These aminoglycoside antibiotics (FW<sub>free-base</sub> = 908.88 g/mol; CAS 1404-04-2), first isolated from *Streptomyces fradiae* by Salman Waksman in 1949, was later shown 16S and 23S ribosomal RNA. Neomycin decreases translational fidelity, altering the error rate from its normal value of ~1:1000 to ~1:100. This effect arises because neomycin binds to the decoding region (interacting with Helix-45) of 16S rRNA, changing the conformation near nucleotide residues A1492 and A1493, thereby reducing the ability to discriminate between cognate and noncognate anticodons. Neomycin also binds to Helix-69 of the 23S rRNA in the 50S ribosome subunit. It is typically used as a topical preparation, such as Neosporin. Neomycin can also be given orally, where it is usually combined with other antibiotics. It is not absorbed from the gastrointestinal tract and has been used as a preventive measure for hepatic encephalopathy and hypercholesterolemia. By killing bacteria in the intestinal tract, it keeps ammonia levels low to prevent hepatic encephalopathy prior to GI surgery. Neomycin is not administered via injection, because it is extremely nephrotoxic (causes kidney damage). In experimental molecular biology, the cDNA for a neomycin-resistance is commonly incorporated into plasmids used to establish stable mammalian cell lines expressing a desired recombinant protein (the cDNA for which is likewise in the plasmid). Non-transfected

cells die off when the culture is treated with neomycin. Many commercially available protein expression plasmids use the neomycin resistance-conferring gene as a selectable marker. **Target(s):** catalase (1); cellulose 1,4- $\beta$ -cellobiosidase (2); DNA-directed DNA polymerase (Klenow polymerase) (3); DNA-directed RNA polymerase (4); DNA topoisomerase I (5,6); exoribonuclease H (7); gentamicin 3'-N-acetyltransferase,  $K_i = 0.4 \mu\text{M}$  (8); hammerhead ribozyme (9); ornithine decarboxylase,  $K_i = 1.3 \text{ mM}$  (10); phosphoinositide 5-phosphatase (11); phosphoinositide phospholipase C, or phosphatidylinositol-specific phospholipase C, or 1-phosphatidylinositol-4,5 bisphosphate phosphodiesterase (12-16); phospholipase D (17-20); poly(A)-specific ribonuclease (3); protein biosynthesis (4,21-23); protein kinase C (24); protein-synthesizing GTPase (elongation factor) (23); ribonuclease H (7); ribonuclease P (25,26); ribozymes, group I (27); streptomycin 3''-adenylyltransferase (28). 1. ### Neopterin

This fluorescent pteridinone (FW = 253.22 g/mol; CAS 670-65-5), also known as 2-amino-6-(1,2,3-trihydroxypropyl)-4(3H)-pteridinone, can exist as four possible stereoisomers, of which two have been identified in nature. The *D-erythro* isomer is a precursor to biopterin while the *L-threo* form is a growth factor for the protozoan *Crithidia fasciculata* and has also been identified in *Serratia indica*. **Target(s):** GTP cyclohydrolase I (1); NADPH-dependent superoxide-generating oxidase, or NADPH oxidase (2); ricin (3); xanthine oxidase (4,5). 1. Shen, Alam & Zhang (1988) *Biochim. Biophys. Acta* **965**, 9. 2. Kojima, Nomura, Icho, et al. (1993) *FEBS Lett.* **329**, 125. 3. Yan, Hollis, Svinth, et al. (1997) *J. Mol. ### Neostigmine

This *N,N,N*-trimethylaniline derivative (FW<sub>bromide</sub> = 303.20 g/mol; CAS 114-80-7; photosensitive), also known as prostigmine and proserine, is a strong reversible acetyl-/butyryl- cholinesterase inhibitor that has been used as an antidote for curare and to treat myasthenia gravis. **Target(s):** acetylcholinesterase,  $IC_{50} = 11.3 \text{ nM}$  for electric eel enzyme (1-12,31-35); acid phosphatase (24); aryl-acylamidase (12-16); carboxylesterase, esterase (17-19,36,37); carnitine acetyltransferase (39); cholinesterase, or butyrylcholinesterase (1,7,12,20,21,26-30); choline sulfotransferase (38); 1,4-lactonase (25); nicotinic acetylcholine receptors (22); sodium pump, electrogenic (23). 1. ### Nepicastat

This potent and selective dopamine  $\beta$ -hydroxylase inhibitor (FW = 295.35 g/mol; CAS 173997-05-2), also known by the code names SYN117 and RS-25560-197 and by its systematic name, 5-(aminomethyl)-1-[(2*S*)-5,7-difluoro-1,2,3,4-tetrahydronaphthalen-2-yl]-1,3-dihydro-2*H*-imidazole-2-thione, inhibits the bovine and human enzymes, both with  $K_i$  values  $\sim 9 \text{ nM}$  (1). The *R*-enantiomer (RS-25560-198) was approximately 2-3 times less potent than nepicastat. When tested in the artery, left ventricle and cerebral cortex of spontaneously hypertensive rats, nepicastat reduces noradrenaline content, increases dopamine content, and increases the Dopamine-to-Noradrenaline concentration ratio in a dose-dependent manner (1). Nepicastat modulates sympathetic drive to cardiovascular tissues, indicating its potential value in treating cardiovascular disorders associated with overactivation of the sympathetic nervous system, including hypertension and congestive heart failure (2). 1. Stanley, Li, Bonhaus, et al. (1997) *Br. J. Pharmacol.* **121**, 1803. 2. Stanley, Lee, Johnson, et al. (1998) *J. Cardiovasc. Pharmacol.* **31**, 963.

## Neplanocin A

This cyclopentenyl adenosine analogue (FW = 263.26 g/mol; CAS 72877-50-0) is a mechanism-based inhibitor of *S*-adenosylhomocysteine hydrolase (1-10) and also inhibits tRNA-guanine transglycosylase (11) and vaccinia virus multiplication (10,12). 1. Chiang (1987) *Meth. Enzymol.* **143**, 377. 2. Ator & Ortiz de Montellano (1990) *The Enzymes*, 3rd ed., **19**, 213. 3. Gordon, Ginalski, Rudnicki, *et al.* (2003) *Eur. J. ## Neral

This monoterpene aldehyde (FW = 152.24 g/mol; CAS 5392-40-5), also known as *cis*-citral (it is one of the two components of citral, is a geometric isomer of geranial and is found in many natural oils, including lemon and orange oils. Neral has also been observed in a number of insect pheromone mixtures. Upon heating, neral converts to isocitral. (See also Geranial) **Target(s)**: aldehyde dehydrogenase (1-3); CYP1A1, inhibited by citral (4); CYP1A2, inhibited by citral (5); CYP2B4, inhibited by citral (5); retinal dehydrogenase, inhibited by citral (6,7); retinol dehydrogenase, inhibited by citral (8,9). 1. ## Neratinib

This potent irreversible inhibitor (FW = 557.04 g/mol; CAS 698387-09-6 and 915942-22-2 (Maleate Salt); Solubility (25°C): 2 mg/mL DMSO, <1 mg/mL Water), also known as HKI-272 and by its IUPAC name (2*E*)-*N*-[4-[[3-chloro-4-[(pyridin-2-yl)methoxy]phenyl]amino]-3-cyano-7-ethoxyquinolin-6-yl]-4-(dimethylamino)but-2-enamide, targets HER-2 (IC<sub>50</sub> = 59 nM)

*in vitro*, while showing weaker inhibition (IC<sub>50</sub> = 92 nM) of epidermal growth factor receptor autophosphorylation (1). Unlike structurally related EKB-569, which potently inhibits EGFR autophosphorylation (IC<sub>50</sub> = 39 nM), HKI-272 possesses an anilino group that fits into a long lipophilic pocket on Her-2. A lipophilic 2-pyridinylmethyl moiety, itself placed at the para-position of the aniline, and a lipophilic chlorine atom at the meta-position allow HKI-272 to interact directly with its target, with which its form a covalent adduct between its Michael acceptor (located at the 6-position) and a nearby sulfhydryl group. This mode of inhibition, which accounts for the sustained inhibition of phosphorylation after withdrawal of drug from the medium, was confirmed by direct labeling of HER-2 by [<sup>14</sup>C]HKI-272 (1). Neratinib is in development for treating early- and late-stage HER2-positive breast cancers. 1. Rabindran, Discifani, Rosfjord (2004) *Cancer Res.* **64**, 3958. Burstein, Sun, Dirix, *et al.* (2010) *J. Clin. Oncol.* **28**, 1301.

## Neridronate

This alkyl-bisphosphonate (FW = 277.15 g/mol; CAS 79778-41-9) is a slow, tight-binding inhibitor of geranyltransferase, or farnesyl-diphosphate synthase, suppressing bone turnover in postmenopausal women. Nitrogen-containing bisphosphonates (N-BPs) inhibit by a mechanism involving time-dependent isomerization of the enzyme. 1. Dunford, Kwaasi, Rogers, *et al.* (2008) *J. Med. Chem.* **51**, 2187.

## Nervonate (Nervonic Acid)

This very-long-chain monounsaturated acid (FW<sub>free-acid</sub> = 366.63 g/mol; CAS 506-37-6), also called *cis*-15-tetracosenoic acid and *cis*-15-tetraeicosenoic acid, is present in marine oils and brain lipids (*e.g.*, the cerebroside known as nervon). Nervonate is also present in milk phosphatidylcholines as well as in sphingolipids. The naturally occurring *cis*-isomer is soluble in ethanol and chloroform and has a melting point of 39-43°C. The *trans*-isomer has a melting point of 61°C. **Target(s)**: chondroitin AC lyase (1); DNA polymerase β (2,3); DNA topoisomerase II (4); HIV 1 reverse transcriptase (2); hyaluronate lyase (1). 1. Suzuki, Terasaki & Uyeda (2002) *J. Enzyme Inhib. Med. Chem.* **17**, 183. 2. Mizushina, Yoshida, Matsukage & Sakaguchi (1997) *Biochim. Biophys. Acta* **1336**, 509. 3. Mizushina, Ohkubo, Date, *et al.* (1999) *J. Biol. Chem.* **274**, 25599. 4. Mizushina, Sugawara, Iida & Sakaguchi (2000) *J. Mol. Biol.* **304**, 385.

## Neryl Diphosphate

This monoterpene phosphoester and *cis* isomer of geranyl diphosphate (FW<sub>free-acid</sub> = 314.21 g/mol), also known as neryl pyrophosphate, is a precursor for the biosynthesis of a number of cyclic monoterpenes. Neryl

diphosphate is also an alternative substrate for Z-farnesyl diphosphate synthase and geranyl pyrophosphate:sabinene hydrate cyclase. Carbocyclase can utilize either geranyl or neryl pyrophosphate as a substrate; however, the ability to utilize neryl pyrophosphate is reportedly almost completely lost with aging (1). **Target(s):** isopentenyl-diphosphate  $\Delta$ -isomerase (2). 1. Rojas, Chayet, Portilla & Cori (1983) *Arch. Biochem. Biophys.* **222**, 389. 2. Banthorpe, Doonan & Gutowski (1977) *Arch. Biochem. Biophys.* **184**, 381.

#### Netilmicin

This semi-synthetic aminoglycoside antibiotic (FW<sub>free-base</sub> = 475.59 g/mol; CAS 56391-56-1) binds to the 30S ribosomal subunit and causes mRNA misreading. Except for an ethyl group on the 2-deoxystreptamine residue, netilmicin is identical to sisomicin. **Target(s):** glucose-6-phosphate dehydrogenase (1); ornithine decarboxylase,  $K_i = 1.7$  mM (2); 6-phosphogluconate dehydrogenase (3); phospholipase A<sub>1</sub> (4); phospholipase A<sub>2</sub> (4); protein biosynthesis (5,6). 1. Ciftci, Kufrevioglu, Gundogdu & Ozmen (2000) *Pharmacol. Res.* **41**, 109. 2. Henley, Mahran & Schacht (1988) *Biochem. Pharmacol.* **37**, 1679. 3. Ciftci, Beydemir, Yilmaz & Bakan (2002) *Pol. J. Loveless, Kohlhepp & Gilbert (1984) *J. Lab. Clin. Med.* **103**, 294.

#### Netropsin

This non-intercalating, photosensitive peptide antibiotic (FW<sub>dihydrochloride</sub> = 503.39 g/mol; CAS 1438-30-8), produced by *Streptomyces netropsis*, selectively binds to Adenine:Thymine base pairs within the minor groove of double-stranded B-DNA, thereby inhibiting deoxyribonuclease I. By binding in the minor groove, netropsin causes under-condensation of heterochromatic regions of metaphase chromosomes, disrupting the cell cycle, prolonging G<sub>1</sub>, and arresting G<sub>2</sub>. Netropsin is typically supplied as either the disulfate or dihydrochloride salt. **Target(s):** deoxyribonuclease I (1); DNA-adenine methyltransferase (2); DNA-dependent RNA polymerase (3); DNA helicase (4); DNA polymerase (5-7); DNA topoisomerase II (8,9); *BalI* restriction endonuclease (10); *EcoRI* restriction endonuclease (10-12); *EcoRV* restriction endonuclease (10); *HincII* restriction endonuclease (13); *HpaI* restriction endonuclease (13); phage T7 RNA polymerase (14); *SgrAI* restriction endonuclease (15); reverse transcriptase, or RNA-directed DNA polymerase (16). 1. Zimmer, Luck & Nuske (1980) *Nucl. Acids Res.* **8**, 2999. 2. Schmidt, Reinert, Venner & Bieber (1979) *Z. Allg. Mikrobiol.* **19**, 489. 3. #### Neuramate (Neuraminic Acid)

This nine-carbon amino sugar acid (FW = 295.29 g/mol; CAS 497-43-8) is the parent compound of a family of closely related sugar acids. Note that, although free neuramate is not typically observed in nature, many *N*- and *O*-substituted derivatives have been isolated. *N*-acetylneuramate is the most notable example. Indeed, the influenza C virus uses 9-*O*-acetyl-*N*-acetylneuraminic acid as a high-affinity receptor determinant for attachment to cells. *N*-Acetylation increases the stability of the metabolite (2). **Target(s):** exo- $\alpha$ -sialidase, or neuraminidase, or sialidase. 1. Martinez-Zorzano, Feijoo, de la Cadena, et al. (1996) *Enzyme Protein* **48**, 282. 2. Rogers, Herrler, Paulson & Klenck (1986) *J. Biol. Chem.* **261**, 5947.

#### Neuropeptide S

This endogenous NPSR agonist (FW<sub>human</sub> = 2187.50 g/mol; Sequence: SFR NGVGTGMKKTTSFQRAKS; CAS 412938-67-1; Solubility: 1 mg/mL H<sub>2</sub>O; FW<sub>mouse</sub> = 2182.47 g/mol; Sequence: SFRNGVGSAGAKKTSFRRA KQ; CAS 412938-74-0; Solubility: 2 mg/mL H<sub>2</sub>O), binds to the Neuropeptide S Receptor (EC<sub>50,hNSP</sub> = 9.4 nM; EC<sub>50,mNSP</sub> = 3 nM), mobilizing intracellular Ca<sup>2+</sup>, increasing locomotor activity and wakefulness in mice, and reducing anxiety-like behavior in mice. 1. Xu et al (2004) *Neuron* **43**, 487.

#### Neuropeptide Y

This vasoconstricting brain peptide amide (FW = 4272 g/mol; Sequence: YPSKPDNPGEDAPAEDMARYYSALR-HYINLITRQRY-NH<sub>2</sub>), formerly known as melanostatin, inhibits Ca<sup>2+</sup>-activated K<sup>+</sup> channels (1,2) and is a potent stimulator of feeding (3). Neuropeptide Y also inhibits cholecystokinin- and secretin-stimulated pancreatic secretions (1-3). The porcine sequence is identical, except for Leu-17, and the ovine peptide is identical, albeit for Asp-10 and Leu17. 1. Beech (1997) *Pharmacol. Ther.* **73**, 91. 2. Sun, Philipson & Miller (1998) *J. Pharmacol. Exp. Ther.* **284**, 625. 3. Clark, Kalra, Crowley & Kalra (1984) *Endocrinology* **115**, 427.

#### Neuroserpin

This 410-residue human serpin (MW = 46427 g; GenBank: CAB03626.1) inhibits tissue-type plasminogen activator and is located primarily in neurons within the central nervous system. Neuroserpin plays a role in neuronal survival following strokes by regulating the morphology of neuroendocrine cells in culture by modulating the proteolytic degradation of the extracellular matrix. Although neuroserpin binds to and inhibits tPA, uPA, and plasmin, its CNS target remains uncertain. Familial encephalopathy, a neurodegenerative disease caused by point mutations within the neuroserpin gene, is characterized by the intracellular accumulation and polymerization of mutated neuroserpin, eventually leading to neuronal death and dementia. (For a discussion of the likely mechanism of inhibitory action, See Serpins; also  $\alpha_1$ -Antichymotrypsin) **Target(s):** nerve growth factor- $\gamma$  (1); plasmin, weakly inhibited (1,2); thrombin, weakly inhibited (1,2); t-plasminogen activator, or tissue-type plasminogen activator (1-5); trypsin (1); u-plasminogen activator, or urokinase (1,2). 1. Hastings, Coleman, Haudenschild, et al. (1997) *J. Biol. Chem.* **272**, 33062. 2. Osterwalder, Cinelli, Baici, et al. (1998) *J. Biol. Chem.* **273**, 2312. 3. Yepes, Sandkvist, Wong, et al. ## Nevirapine

This dipyrindiazepinone-based, non-nucleoside reverse transcriptase inhibitor (or NNRTI) and first-line drug for HIV infection (FW = 266.30 g/mol; CAS 129618-40-2; *Symbol*: NVP), also known as BI-RG-587, inhibits human immunodeficiency virus type 1 (HIV-1) reverse transcriptase,  $IC_{50} = 80\text{--}90$  nM (1-10). Nevirapine rapidly selects for mutant human immunodeficiency virus (HIV) *in vivo*, with the most common mutation occurring at residue-181 in patients on NVP monotherapy. The X-ray structure of HIV-1 RT heterodimer with bound nevirapine reveals that NVP is almost completely buried in a pocket near, but not overlapping with, the polymerase active site (11). NVP and MgATP show strong negative cooperativity, such that binding of MgATP reduces the fraction of reverse transcriptase (RT) bound to NVP and enhances the dissociation rate constant of the NVP, resulting in an increase of the open/closed conformation of the RT fingers/thumb subdomains (12). Comparisons of the NMR spectra of three conservative mutations, Ile-63-Met, Leu-74-Met, and Leu-289-Met, indicated that Met-63 showed the greatest shift sensitivity to the addition of NVP. Protein-mediated interactions thus appear to explain most of the affinity variation of NVP for RT. Sex-dependent conversion to 12-hydroxy-nevirapine and 3-hydroxy-nevirapine may contribute to the sexual dimorphism in nevirapine toxicity (13). **1.** Merluzzi, Hargrave, Labadia, *et al.* (1990) *Science* **250**, 1411. **2.** Mui, Jacober, Hargrave & Adams (1992) *J. NF- $\kappa$ B Activation Inhibitor VIII

This cell-permeable peptide (FW = 2781.5 g/mol; CAS CAS 213546-43-3; Sequence: AAVALLPAVLLALLAPVQRKRQKLMP), also known as NF- $\kappa$ B SN50, contains the nuclear localization sequence (NLS) of the transcription factor NF- $\kappa$ B p50 linked to the hydrophobic region (h-region) of the signal peptide of Kaposi fibroblast growth factor (K-FGF). SN50 inhibits NF- $\kappa$ B translocation ( $IC_{90} = 18$   $\mu$ M) into the nucleus in cultured endothelial and monocytic cells stimulated with lipopolysaccharide or Tumor Necrosis Factor- $\alpha$ , or TNF $\alpha$ ). SN50 attenuates inflammation and acute respiratory distress syndrome, but the mechanisms associated with the effects of SN50 in VILI have not been fully elucidated (2). **1.** Lin, Yao, Veach, Torgerson & Hawiger (1995) *J. Biol. Chem.* **270**, 14255. **2.** Chiang, Chiang, Chuang, Liu & Tsai (2016) *Shock* **46**, 194.

## NG2 Proteoglycan

This 2300-residue major chondroitin sulfate proteoglycan (MW = ~280 kDa) is produced upon spinal cord injury and expressed by macrophages and oligodendrocyte progenitors (1). It inhibits axon regeneration within the injured central nervous system, presumably by binding to growth cone receptors (Rc), via inhibition of Rho family GTP-regulatory proteins, and disruption of the actin cytoskeleton. NG proteoglycan plays a role in regulating endothelial cell proliferation and migration during motility during microvascular morphogenesis. It may also inhibit neurite outgrowth and growth cone collapse during axon regeneration. The net effect of NG2 proteoglycan is growth cone collapse/repulsion (2). **1.** Dou & Levine (1994) *J. Neurosci.* **14**, 7616. **2.** Sandvig, Berry, Barrett, *et al.* (2004) *Glia* **46**, 225.

## NH125

This imidazolium salt (FW<sub>iodide-salt</sub> = 524.57 g/mol), also known as 1-benzyl-3-cetyl-2-methylimidazolium cation, inhibits bacterial protein-histidine kinase and eukaryotic [elongation factor 2] kinase. **Target(s)**: [elongation factor-2] kinase, eukaryotic, or eEF-2 kinase,  $IC_{50} = 60$  nM (1); protein-histidine kinase,  $IC_{50} = 6.6$   $\mu$ M for the *Bacillus subtilis* system (2,3); protein kinase A, or PKA,  $IC_{50} = 80$   $\mu$ M (1); protein kinase C, or PKC,  $IC_{50} = 7.5$   $\mu$ M (1). **1.** Arora, Yang, Kinzy, *et al.* (2003) *Cancer Res.* **63**, 6894. **2.** Yamamoto, Kitayama, Ishida, *et al.* (2000) *Biosci. Biotechnol. Biochem.* **64**, 919. **3.** Yamamoto, Kitayama, Minagawa, *et al.* (2001) *Biosci. Biotechnol. Biochem.* **65**, 2306.

## NI 42

This orally bioavailable, high-affinity BRPF inhibitor (FW = 353.39 g/mol; CAS 1884640-99-6), also named 4-cyano-N-(1,2-dihydro-1,3-dimethyl-2-oxo-6-quinolinyl)benzenesulfonamide, targets bromodomain-containing proteins BRPF1B ( $K_d = 40$  nM), BRPF2 ( $K_d = 0.21$   $\mu$ M), BRPF1B ( $K_d = 0.94$   $\mu$ M), and BRD9 ( $K_d = 1.13$   $\mu$ M), with much weaker action against forty-four other bromodomain-containing proteins. Bromodomains (the 110-residue domains that recognize acetylated lysine residues, such as those on the N-terminal tails of histones.) are epigenetic readers of histone acetylation, which factors into chromatin remodeling and transcriptional regulation. The human proteome comprises forty-six bromodomain-containing proteins with a total of sixty-one bromodomains, which, despite highly conserved structural features, recognize a wide array of natural peptide ligands. **See NI 57** Some enzymes (e.g., histone acetyltransferases, HATs, etc.) “write” transcription markers, other enzymes (e.g., histone deacetylases, HDACs, etc.) “erase” these signals. Still other enzymes and regulatory factors (e.g., bromodomain-containing protein) “read” the state of histone acetylation.

## NI 57

This potent and selective BRPF inhibitor (FW = 383.42 g/mol;  $\lambda_{max}$  at 210, 236, 279, 310, and 334 nm; Soluble to 100 mM in DMSO; 4-cyano-N-(1,3-dimethyl-2-oxo-1,2-dihydroquinolin-6-yl)-2-methoxybenzene-1-sulfonamide, targets Bromodomain/PHD finger-containing proteins (BRPFs), binding to BRPF1B ( $K_d = 31$  nM), BRPF2 ( $K_d = 108$  nM), and BRPF3 ( $K_d = 408$  nM), as determined by isothermal calorimetry. NI-57 is very selective against other non-Class IV bromodomains, including the BETs, as measured by both biophysical and biochemical methods. The bromodomain and PHD finger-containing (BRPF) proteins are scaffolding components of chromatin-binding MOZ/MORF histone acetyltransferase complexes, which are transcriptional regulators. Closest off-target effects are against BRD9 (32-fold less effective). **See:** <http://www.thesgc.org/chemical-probes/NI-57/>

**Niacin**, See *Nicotinate (Nicotinic Acid)*

**Niacinamide**, See *Nicotinamide*

### NIBR 189

This potent and selective EB12 receptor antagonist (FW = 429.31 g/mol; CAS 1599432-08-2; Solubility: 100 mM in DMSO), also named (2E)-3-(4-bromophenyl)-1-[4-(4-methoxybenzoyl)-1-piperazinyl]-2-propene-1-one, targets (Binding  $IC_{50}$  = 16 nM; Functional  $IC_{50}$  = 11 nM) the G protein-coupled receptor known as EB12 (or Epstein-Barr Virus-Induced Gene 2, also known as GPR183). Activation of this receptor has been shown to be critical for the adaptive immune response and has been genetically linked to autoimmune diseases, including type I diabetes. NIBR-189 also blocks the migration of the monocyte cell line U937, suggesting a functional role of the oxysterol/EB12 pathway in these immune cells. 1. Gessier, Preuss, Yin, et al. (2014) *J. Med. Chem.* **57**, 3358.

### Nicardipine

This antihypertensive agent (FW<sub>free-base</sub> = 479.53 g/mol; CAS 55985-32-5), originally referred to as YC-93, is the first intravenously administered dihydropyridine calcium channel blocker and has been used in the treatment of angina, hypertension, and cardiovascular disorders. **Target(s)**:  $Ca^{2+}$  channels, L-type voltage-dependent (1-3);  $3',5'$ -cyclic-nucleotide phosphodiesterase, cAMP phosphodiesterase (3-5); fatty acid  $\Delta^5$ -desaturase (6); phosphodiesterase 7, weakly inhibited (5). 1. Zangar, Okita, Kim, et al. (1999) *J. Pharmacol. Exp. Ther.* **290**, 1436. 2. Thellung, Florio, Villa, et al. (2000) *Neurobiol. Dis.* **7**, 299. 3. Satoh, Yanagisawa & Taira (1980) *Clin. Exp. ### Nickel Ions

These Group 10 (or Group VIIIA) cations (Atomic Symbol = Ni; Atomic Number = 28; Atomic Weight = 58.6934) have valencies of 0, 1, 2, or 3. The ionic radius of  $Ni^{2+}$  is 0.69 Å (compare to 0.86 Å for  $Mg^{2+}$  and 1.14 Å for  $Ca^{2+}$ ). There are five stable isotopes:  $^{58}Ni$  (natural abundance = 68.077%),  $^{60}Ni$  (28.223%),  $^{61}Ni$  (1.140%),  $^{62}Ni$  (3.634%), and  $^{64}Ni$  (0.926%). The radioisotope with the longest half-life is  $7.6 \times 10^4$  years for  $^{59}Ni$ . Nickel is an essential trace element for a number of plants and microorganisms as well as birds and mammals. Nickel is an important component for a number of macromolecules. Enzymes requiring nickel ions include carbon-monoxide dehydrogenase (EC 1.2.99.2), hydrogen dehydrogenase (EC 1.1.2.1.2), coenzyme F420 hydrogenase (EC 1.1.2.99.1), hydrogenase (EC 1.18.99.1), and Jack bean urease (EC 3.5.1.5). Perhaps the best known of these is urease, an enzyme that contains two atoms of Ni(II) and catalyzes the hydrolysis of urea to ammonium ion and carbamate, the latter spontaneously undergoing nonenzymatic hydrolysis to produce bicarbonate and a second molecule of ammonia. Nickel ions have also been demonstrated to stabilize ribosomes. Nickel ions inhibit numerous enzymes, but, given the low concentration of uncomplexed nickel ion in most living organisms, these effects are unlikely to be physiologically relevant.  $Ni^{2+}$  is also a contact allergen, giving rise to allergic dermatitis. In humans, nickel's toxic range begins at ~40 ppm. In the 1990s, American astrophysicist Thomas Wdowiak suggested that the dinosaurs became extinct after a nickel-laden asteroid impacted Earth, briefly raising environmental nickel to around 150 ppm.

### Niclosamide

This classical anthelmintic (FW = 327.12 g/mol; CAS 50-65-7), also named 5-chloro-N-(2-chloro-4-nitrophenyl)-2-hydroxybenzamide and Niclocide<sup>®</sup>, inhibits glucose uptake, oxidative phosphorylation, and anaerobic metabolism in tapeworms, but is not cytotoxic other worms, such as pinworms or roundworms (1). Niclosamide undergoes metabolic hydroxylation (forming 3-hydroxyniclosamide) and glucuronidation (forming niclosamide-2-O-glucuronide), with CYP1A2 and UGT1A1 mainly responsible (2). Adult T-cell leukemia and lymphoma is caused by chronic infection by HTLV-1 (Human T cell Leukemia Virus Type 1), and the oncogenic viral protein, known as Tax, plays a role in trans-activating viral gene transcription and deregulating oncogenic signaling, thereby promoting survival, proliferation and transformation of virally infected T cells (4). Niclosamide induces apoptosis of HTLV-1-transformed T cells by facilitating Tax degradation in proteasomes, a process linked to MAPK/ERK1/2 and I $\kappa$ B inhibition, and down-regulation of Stat3 and Mcl-1, the latter a pro-survival Bcl-2 family member (3). Niclosamide also suppresses cell migration and invasion in enzalutamide-resistant prostate cancer cells via Stat3-AR axis inhibition (4). 1. Katz (1977) *Drugs* **13**, 124. 2. ### Nicotianamine

This naturally occurring azetidinium, found in many plants, is a metal ion chelator and it inhibits peptidyl-dipeptidase A ( $IC_{50}$  = 0.085  $\mu$ M). **Target(s)**: peptidyl-dipeptidase A, or angiotensin I-converting enzyme (1-3); gelatinase (4). 1. Aoyagi (2006) *Phytochemistry* **67**, 618. 2. Kinoshita,

### Nicotinamide

This essential redox-active constituent of pyridine dinucleotide coenzymes (FW = 122.13 g/mol; CAS 98-92-0), also known as niacinamide and 3-pyridinecarboxamide, functions as a vitamin (*i.e.*, as vitamin B<sub>3</sub>). Nicotinamide is nutritionally equivalent to nicotinate; however, elevated nicotinamide concentrations have a different effect upon lipoprotein concentrations compared to nicotinate. The pyridinium nitrogen has a pK<sub>a</sub> of 3.3 at 20°C. Nicotinamide is water-soluble (~1 g/mL) and stable at neutral pH, but is hydrolyzed slowly to nicotinic acid under acidic or alkaline conditions. Nicotinamide has a λ<sub>max</sub> at 261.5 nm, and the molar extinction coefficient varies with pH. **Inhibition of Histone Deacetylation:** Silent information regulator 2 (Sir2) enzymes catalyze NAD<sup>+</sup>-dependent protein/histone deacetylation, where the acetyl group from the lysine epsilon-amino group is transferred to the ADP-ribose moiety of NAD<sup>+</sup>, producing nicotinamide and the novel metabolite *O*-acetyl-ADP-ribose (1). Nicotinamide inhibition is the result of nicotinamide intercepting an ADP-ribosyl-Sir2-acetyl peptide intermediate, with regeneration of NAD<sup>+</sup> via transglycosylation. Nicotinamide inhibits both Sir2 and SIRT1 noncompetitively *in vitro*. Its IC<sub>50</sub> value of <50 μM is equivalent to, or better, than the most effective known synthetic inhibitors of Sir2 and SIRT1. **Target(s):** acetylcholinesterase (2); alcohol dehydrogenase (3); alkane 1-monooxygenase, *or* ω-hydroxylase (4); cAMP phosphodiesterase (5); choline acetyltransferase (6); choline oxidase (7); cytochrome P450 (8,9); ecdysone 20-monooxygenase (47); glucose dehydrogenase (10-12); glucose-6 phosphate dehydrogenase (12); L-lactate dehydrogenase (12); malate dehydrogenase (13); NAD<sup>+</sup> ADP ribosyltransferase, *or* poly(ADP-ribose) polymerase, product inhibition (14-17,40-46); NAD<sup>+</sup> nucleosidase, *or* NADase, product inhibition (9,18-32); NAD<sup>+</sup>:protein-arginine ADP ribosyltransferase, product inhibition (33,34); nicotinate phosphoribosyltransferase (35); nucleotide diphosphatase, *or* nucleotide pyrophosphatase (36); 6-phosphogluconate dehydrogenase (17,37); tRNA methyltransferases (38); xanthine oxidase (39). acetate incorporation into free fatty acids and lipids of rat tissues (48); DNA methylation in bacteriophage ΦX174 (49); Aryl hydrocarbon hydroxylase, both constitutive and induced forms (50); *in vitro* production of interleukin-12 and TNF-α in peripheral whole blood of people at high risk of developing type-1 diabetes and those with newly diagnosed type 1 diabetes (51); β-NAD<sup>+</sup>-induced, but not cADPR-elicited, elevation of cytoplasmic Ca<sup>2+</sup><sub>free</sub> concentration and calcium ion influx through voltage-activated Ca<sup>2+</sup> channels, *or* VACCs (52); sodium-dependent phosphate co-transport activity in rat small intestine (53); macrophage NO synthase, noncompetitive relative to L-arginine (K<sub>i</sub> = 13 mM) and uncompetitive versus NADPH and tetrahydrobiopterin (54); alternative vascularization pathway observed in highly aggressive melanoma (55). **1.** Jackson, Schmidt, Oppenheimer & Denu (2003) *J. ### Nicotinamide 2'-Deoxy-2'-fluoroarabinoside Adenine Dinucleotide

This NAD<sup>+</sup> analogue (FW = 681.42 g/mol), also known as araF-NAD<sup>+</sup>, is a slow-binding inhibitor of NAD<sup>+</sup> nucleosidase (*or* NAD<sup>+</sup> glycohydrolase). K<sub>i</sub> = 32 nM (See *Nicotinamide Arabinoside Adenine Dinucleotide*). The kinetic data are consistent with both slow *k*<sub>on</sub> and slow *k*<sub>off</sub> in the formation of an enzyme-inhibitor complex (*i.e.*, the association rate constants are about 10<sup>4</sup> and 10<sup>6</sup> times slower than diffusion rates, respectively, for araF-NAD<sup>+</sup> and ara-NAD<sup>+</sup>, and the half-life of the complex is about 3-10 min for both analogues. The kinetic model does not account for a slow turnover of an ADP-ribosyl-enzyme intermediary complex. **1.** Muller-Steffner, Malver, Hosie, Oppenheimer & Schuber (1992) *J. Biol. Chem.* **267**, 9606.

### Nicotinamide Mononucleotide

This naturally occurring redox nucleotide (FW = 334.22 g/mol; CAS 1094-61-7; *Abbreviation:* NMN<sup>+</sup> (or NMN)), is a product of the reaction catalyzed by NAD<sup>+</sup> diphosphatase, ribosylnicotinamide kinase, nicotinamide phosphoribosyltransferase, and the NAD<sup>+</sup>-dependent DNA ligases. NMN is a substrate for nicotinamine-nucleotide adenyllyltransferase (NMN adenyllyltransferase), NMN nucleosidase, and nicotinamide-nucleotide amidase. It is typically stored frozen in a solution rather than as a solid. The λ<sub>max</sub> value at pH 7.0 is 266 nm (ε = 4600 M<sup>-1</sup>cm<sup>-1</sup>). **Target(s):** ADP-ribose diphosphatase (1); DNA ligase (NAD<sup>+</sup>) (2); DNA polymerase I

with RecBC, or exodeoxyribonuclease V (3); isocitrate dehydrogenase (NADP<sup>+</sup>) (4,5); glutamate dehydrogenase (6,7); 3 $\alpha$ ,20 $\beta$ -hydroxysteroid dehydrogenase, in the presence of AMP (8); L-lactate dehydrogenase, in the presence of AMP (9); NADase (10-12); NAD<sup>+</sup> kinase, weakly inhibited (13); NAD<sup>+</sup>:protein-arginine ADP-ribosyltransferase (14); nicotinamide phosphoribosyl-transferase (15); nicotinate-nucleotide adenyltransferase (16,17); 5'-nucleotidase (18); nucleotide diphosphatase, nucleotide pyrophosphatase, weakly inhibited (19). 1. ### Nicotinamide-Mononucleotide Adenyltransferase

This enzyme, also known as NAD<sup>+</sup> pyrophosphorylase, catalyzes the reaction of ATP with nicotinamide ribonucleotide (NMN) to produce NAD<sup>+</sup> and pyrophosphate. When pure enzyme is incubated in the presence of the poly(ADP-ribose) polymerase, the polymerase activity is inhibited, both in the presence and in the absence of histones. Elevated concentrations of DNA, NAD<sup>+</sup>, or Mg<sup>2+</sup> did not affect the inhibition. 1. Ruggieri, Gregori, Natalini, et al. (1990) *Biochemistry* **29**, 2501.

### Nicotinate (Nicotinic Acid)

This vitamin (FW<sub>free-acid</sub> = 123.11 g/mol; CAS 59-67-6;  $\lambda_{max}$  at 261.5 nm), also commonly known as niacin, but also named 3-picolinic acid, vitamin B<sub>3</sub>, and 3-pyridinecarboxylic acid, is a precursor of the pyridine coenzymes (1). Niacin is soluble in water (1 g/60 mL at 20°C) and is stable in both acidic and alkaline conditions. This vitamin is anionic under most physiological conditions. **Pellagra**: Niacin deficiency occurs only rarely in developed countries, and is associated with poverty, malnutrition, and chronic alcohol use. Corn is low in digestible niacin, giving rise to niacin insufficiency in places where corn is the main starch-containing food. Severe niacin deficiency in causes pellagra, a disorder characterized by diarrhea, dermatitis, and dementia. **Anti-atherogenic Properties**: Elevated niacin levels are known to increase plasma HDL concentrations, but the mechanism is uncertain. Recent work (2) suggests that, through ROS-mediated signaling, niacin decreases neutrophil myeloperoxidase (MPO) release as well as its catalytic activity, protecting apolipoprotein-AI (apo-AI) modification and improving HDL function. Beyond its potent bacteriocidal action against invading pathogens by generating HOCl from H<sub>2</sub>O<sub>2</sub> and Cl<sup>-</sup>, MPO-derived oxidants also play critical roles in tissue injury and such chronic diseases/conditions as cancer, renal disease, lung injury, atherosclerosis, multiple sclerosis, Alzheimer's Disease and Parkinson's Disease. Specifically, 0.25-0.5 mM niacin decreases phorbol myristic acid- (or PMA-) induced MPO activity in cells as well as that released into the medium. Niacin also reduces MPO protein mass in the medium without affecting its mRNA expression. Increased NADPH oxidase and ROS production by phorbol myristic acid (PMA) are significantly inhibited by niacin. Studies with specific inhibitors suggest that ROS-dependent Src and p38MAP kinase mediate decreased MPO activity by niacin. Niacin blocked apo-AI degradation, and apo-AI from niacin treated cells decreased monocyte adhesion to aortic endothelial cells (2). **Target(s)**: acetylcholinesterase (3); acetyl-CoA carboxylase (4,5); adenylate cyclase (6); D-amino-acid oxidase, K<sub>i</sub> = 0.11 mM (7,8);  $\gamma$ -butyrobetaine dioxygenase, or  $\gamma$ -butyrobetaine hydroxylase, K<sub>i</sub> = 0.41 mM (9); choline acetyltransferase (10); diacylglycerol O-acyltransferase (11,12); glucose dehydrogenase (7,13,14); histidine kinase (15); imidazoleacetate 4-

monooxygenase (16); kynurenine:oxoglutarate aminotransferase, weakly inhibited (17); lactate dehydrogenase, weakly inhibited (7,13); monophenol monooxygenase (7); NAD<sup>+</sup> nucleosidase, or NADase (7,18-22); nicotinamide nucleotide amidase (23); nitrilase (24); orotate phosphoribosyltransferase, weakly inhibited (25); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (26); procollagen-lysine 5-dioxygenase (27); procollagen-proline 3-dioxygenase (28); procollagen-proline 4-dioxygenase (27,28). 1. ### Nicotine

This toxic alkaloid (FW<sub>free-base</sub> = 162.23 g/mol; CAS 54-11-5), abundantly present in the leaves of the tobacco plant (*Nicotiana tabacum* and *N. rustica*), is the prototypic nicotinic acetylcholine receptor agonist. While known as early as 1571, the earliest report on nicotine was included in *Esperienze inforno a diverse Cose Naturli* (1686) by Francesco Redi (the very same Redi who convincingly demonstrated that insects (and hence all life forms) are not the product of spontaneous generation). **Chemical Properties**: In tobacco, nicotine is largely (>99%) the (S)-isomer. It is weak base with a pK<sub>a</sub> of 8.0. The free base is a hygroscopic liquid that turns brown upon exposure to air or light. It is miscible with water below 60°C. The free base is itself well absorbed through the skin, a property that explains occupational risks of nicotine poisoning (or Green Tobacco Sickness) in those harvesting wet tobacco leaves with bare hands. **Pharmacokinetics**: The disposition of nicotine in humans is complex, showing multi-compartment kinetics for its metabolic and physiologic effects (1). Briefly, much of nicotine is protonated in physiologic fluids and does not cross membranes rapidly. That said, the huge surface area of the alveoli and small airways favors efficient nicotine absorption from cigarette smoke in the lungs. Indeed, the lag-time between inhaling cigarette smoke and nicotine arrival at the brain is only 10–20 seconds. Once in circulation, nicotine shows highest affinity for liver, kidney, spleen, and lung. It likewise concentrates in the brain, where high-affinity binding sites are plentiful. Nicotine is metabolized primarily by the liver enzymes UDPglucuronosyltransferase (or UGT), CYP2A6, and flavin-containing monooxygenase (FMO). **Primary Mode of Action**: Nicotine binds to nicotinic cholinergic receptors, facilitating the release of neurotransmitters (particularly dopamine, glutamate, and  $\gamma$ -aminobutyric acid) that mediate a manifold of psychophysiological actions, leading to and maintaining tobacco (nicotine) dependence. With regular use, one develops nicotine dependence, a condition that is manifestly an addiction that is characterized by nicotinic receptor activation, desensitization, up-regulation, and subsequent modulation of the mesocorticolimbic dopaminergic system. The complexity of nicotine dependence is indicated in functional magnetic resonance

images (fMRI) demonstrating involvement of the anterior and posterior cingulate cortex, medial and lateral orbitofrontal cortex, ventral striatum, amygdala, thalamus and insula in the maintenance of smoking and nicotine withdrawal. **Effect on Chromatin:** Nicotine enhances the extent of histone acetylation by inhibiting histone deacetylases (HDACs), the action of the latter favoring gene silencing. This nicotine-induced epigenetic modification is likely give rise to an open chromatin structure that primes FosB for enhanced transcriptional activation after chronic cocaine use, thus facilitating or promoting cocaine-use behaviors (2). (**See also the naturally occurring structural analogues Anabasine & Anabaseine**) **Target(s):** antheraxanthin  $\kappa$ -cyclase (3); aromatase, or CYP19 (3,5); azaheterocycle *N*-methyltransferase, inhibited by *S*-(-)-nicotine (6); choline acetylase, or choline acetyltransferase (7); CYP2E1 (8);  $\beta$ -fructofuranosidase, or invertase (9);  $3\alpha$ -hydroxysteroid dehydrogenase (10); lycopene  $\beta$  cyclase (3); NADH dehydrogenase, or Complex I (11); sea urchin cortical granule protease (12); sodium channels, voltage-dependent (13); steroid 17,20-lyase (14); steroid 11- $\beta$ -monooxygenase (15,16); steroid 17 $\alpha$ -monooxygenase (14); steroid 21-monooxygenase (15,16); thromboxane synthase (17). 1. #### Nicotinic Acid Adenine Dinucleotide

This NAD<sup>+</sup> analogue (FW = 686.39 g/mol; CAS 6450-77-7), also known as deamido-NAD<sup>+</sup>, is the product of the reaction catalyzed by nicotinate-nucleotide adenylyltransferase and is the naturally occurring substrate of NAD<sup>+</sup> synthetase and NAD<sup>+</sup> synthetase (glutamine-hydrolyzing). **Target(s):** alcohol dehydrogenase, yeast (1); lactate dehydrogenase (2); NADase (3,4); NAD<sup>+</sup> kinase (5); nicotinamide-nucleotide amidase (6); nicotinamide phosphoribosyltransferase (7); nicotinate phosphoribosyltransferase (8); NMN nucleosidase (9). 1. Sund & Theorell (1963) *The Enzymes*, 2nd ed., 7, 25. 2. Chang, Huang & Chiou (1991) *Arch. Biochem. Biophys.* 284, 285. 3. Okayama, Ueda & Hayaishi (1980) *Meth. Enzymol.* 66, 151. 4. #### Nicotinic Acid Hydrazide

This toxic hydrazide (FW<sub>free-base</sub> = 137.14 g/mol; CAS 553-53-7), also known as 3-pyridine carboxylic acid hydrazide, inhibits diamine oxidase. Note that this hydrazide is the *meta*-isomer of isonicotinic acid hydrazide (*i.e.*, isoniazid), a well-known tuberculostatic agent. **Target(s):** diamine oxidase, or amine oxidase, copper-containing (1); NADase, weakly inhibited (2); nicotinamidase (3,4). 1. Pec, Haviger, Kopecna & Frebort (1992) *J. Enzyme Inhib.* 6, 243. 2. Hofmann & Rapaport (1957) *Biochem. Z.* 329, 437. 3. Tanigawa, Shimiyama, Dohi & Ueda (1972) *J. Biol. Chem.* 247, 8036. 4. #### Nifedipine

This photosensitive pyridine derivative (FW = 346.34 g/mol; CAS 21829-25-4), also known as Procardia™ and 2,6-dimethyl-3,5-dicarboxymethoxy-4-(2-nitrophenyl)-1,4-dihydropyridine, is a dihydropyridine-based calcium channel blocker that acts as a vasodilator, reduces blood pressure. Procardia has been used to treat angina. It also induces apoptosis in human glioblastoma cells. **Primary Mode of Inhibitory Action:** By virtue of its ability to inhibit calcium ion influx via L-type calcium channels, nifedipine decreases arterial smooth muscle contractility and subsequent vasoconstriction. Calcium ions normally enter these cells and bind to calmodulin, thereby activating myosin light chain kinase (MLCK). The latter catalyzes myosin light chain phosphorylation. Signal amplification is achieved by calcium-induced calcium release from the sarcoplasmic reticulum through ryanodine receptors. By inhibiting the contractile processes of smooth muscle cells, nifedipine administration causes of coronary and systemic artery dilation, increasing oxygen delivery to the myocardial tissue, decreasing peripheral resistance, lowering systemic blood pressure, and decreasing afterload. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** acetylcholinesterase (1); Ca<sup>2+</sup> channel (2-4); cAMP-dependent protein kinase, or Protein Kinase A (5); cholinesterase, or butyrylcholinesterase (1); fatty acid  $\Delta^6$ -desaturase (6); orotidine 5'-phosphate decarboxylase (7); uridine kinase (7). 1. #### Niflumate (Niflumic Acid)

This anti-inflammatory drug and chelating agent (FW<sub>free-acid</sub> = 282.22 g/mol; CAS 4394-00-7) inhibits prostaglandin H synthase 2 (IC<sub>50</sub> = 20 nM) and blocks calcium-activated chloride channels. **Primary Mode of Action:** By promoting a depolarizing influence on the resting membrane potential of vascular smooth muscle cells, calcium-activated chloride channels are crucially important in regulating vascular tone. A potent blocker of calcium-activated chloride channels in vascular myocytes, NFA's action results from sustained calcium-activated chloride currents. Niflumic acid also forms complexes copper ion, significantly inhibiting polymorphonuclear leukocyte oxidative metabolism. In addition to these actions, it appears to

affect brain GABA<sub>A</sub> receptors (1). **Target(s):** Al<sup>3+</sup>-activated malate channel (2); anion channel (3,4); catechol sulfotransferase (5); channel-conductance-controlling ATPase, or cystic-fibrosis membrane-conductance-regulating protein, or CFTR (6); chloride channels, Ca<sup>2+</sup>-activated (7-11); cyclooxygenase 2, or prostaglandin-endoperoxide synthase (12,13); fatty acid amide hydrolase (14,15); gap junction intercellular communication (16); glucuronosyltransferase, substrate for certain transferases (17,18); nonselective cation channels (19); 15-oxoprostaglandin 13-reductase/leukotriene B<sub>4</sub> 12-hydroxydehydrogenase/eicosanoid oxidoreductase (20); phenol sulfotransferase (5); phosphate transport (21); sulfate transport (22). 1. #### Nifurtimox

This orally available 5-nitrofurans and anti-trypanosomal agent (FW = 287.30 g/mol; CAS 23256-30-6), also known by its code name Bayer-2502, trade name Lampit<sup>TM</sup>, and systematic name (*RS*)-3-methyl-*N*-[(*E*)-(5-nitro-2-furyl)methylene]thiomorpholin-4-amine 1,1-dioxide, inhibits is used to treat of Chagas' disease and African Sleeping Sickness (1-5). **Likely Mechanisms of Trypanocidal Action:** Although the precise biochemical basis for nifurtimox poisoning of trypanosomes has yet to be established, several ideas have gained traction. The first relates to nifurtimox's ability to generate a nitro-anion radical metabolite that reacts with parasite's DNA, inducing strand breakage and ensuing apoptosis. The second relates to the production of superoxide anion, which also generates hydrogen peroxide through the action of superoxide dismutase. Both oxidants might then inhibit trypanothione reductase (a parasite-specific antioxidant defense enzyme) and ascorbate-linked peroxidase (another likely nifurtimox target). A third model (5) views nifurtimox as a prodrug that is activated by trypanosomal type I nitroreductases, which catalyze its reduction to an unsaturated open-chain nitrile derivative that has growth inhibitory properties against parasite and mammalian cells. In principle, nitrofurans activation would occur by either of two routes: (a) by a two-electron reduction mediated by type I nitroreductases, or (b) by a one-electron pathway catalyzed by type II enzymes. **Target(s):** DNA topoisomerase I (1); DNA topoisomerase II (1); glutathione-disulfide reductase, IC<sub>50</sub> = 40 μM (2,3); oxidative phosphorylation (4); trypanothione reductase, IC<sub>50</sub> = 200 μM (3). 1. #### Nigericin

This polyether K<sup>+</sup>/H<sup>+</sup> ionophore and antibiotic (FW<sub>free-acid</sub> = 724.97 g/mol; CAS 28380-24-7) from *Streptomyces hygroscopicus*, inhibits both oxidative phosphorylation and photophosphorylation. Its metal ion specificity is: K<sup>+</sup> > Rb<sup>+</sup> ≥ Cs<sup>+</sup> >> Na<sup>+</sup> (1). **Primary Mechanism of Inhibitory Action:** As a potassium ionophore, nigericin induces caspase-1-mediated pro-protein processing and release of IL-1β, an important 17.5-kDa protein mediator of the inflammatory response, and one that is involved in regulating cell proliferation, differentiation, and apoptosis. **Target(s):** cadmium-exporting ATPase (2); F<sub>1</sub>F<sub>0</sub> ATP synthase (3,4); insulin-stimulated glucose transport (5); oxidative and photophosphorylation (1,3,4,6,7). 1. Reed (1979) *Meth. Enzymol.* **55**, 435. 2. Tsai, Yoon & Lynn (1992) *J. Bacteriol.* **174**, 116. 3. Stiggall, Galante & Hatefi (1979) *Meth. Enzymol.* **55**, 308. 4. #### Nigerose

This α<sub>1,3</sub>-linked glucosyl disaccharide (FW = 342.30 g/mol; CAS 497-48-3) inhibits glucosidase II. **Target(s):** concanavalin A (1); glucan 1,3-α-glucosidase, or glucosidase II, or mannosyl oligosaccharide glucosidase II (2-6); mycodextranase (7); *Streptococcus sobrinus* GTF-I glucosyltransferase (8). 1. Res.* **187**, 131.

#### Nikkomycin Wx

This nucleoside peptide antibiotic (FW = 450.41 g/mol; CAS 59456-70-1), from *Streptomyces tendae* is a conjugate of L-tyrosine, 5-amino-5-deoxy-D-allo-furanuronic acid, and 4-formyl-4-imidazolin-2-one. Although nikkomycin Wx is an effective *in vitro* inhibitor (K<sub>i</sub> = 12 μM) of chitin

synthase from *Coprinus cinereus*, it is rapidly hydrolyzed *in vivo*, thereby negating any inhibitory effect on the growth of this multicellular basidiomycete. 1. Decker, Walz, Bormann, *et al.* (1990) *J. Antibiot.* **43**, 43.

### Nikkomycin Z

This nucleoside peptide antibiotic (FW = 495.45 g/mol; CAS 59456-70-1), first isolated from *Streptomyces tendae*, is an UDP-*N*-acetylglucosamine analogue that inhibits chitin synthase, showing potent antifungal, insecticidal, and acaricidal properties. 1. Cabib, Kang & Au-Young (1987) *Meth. Enzymol.* **138**, 643. 2. Dahn, Hagenmaier, Hohne, *et al.* (1976) *Arch. Microbiol.* **107**, 143. 3. Yadan, Gonneau, Sarthou & Le Goffic (1984) *J. ### Nilotinib

This TKI (FW = 529.52 g/mol; CAS 641571-10-0), also known as AMN107 and Tasigna™, specifically targets Bcr-Abl protein-tyrosine kinase (1-4). In 2007, nilotinib was approved by the U.S. Food and Drug Administration for the treatment of adult patients with chronic-phase and accelerated-phase Philadelphia chromosome-positive (Ph<sup>+</sup>) chronic myelogenous leukemia resistant to or intolerant of prior treatment that included imatinib. Parkinson Disease (PD)-associated dyskinesia is striatal dysfunction, arising from an imbalance of dopamine and glutamate transmissions that are integrated by the 32-kDa Dopamine- and cAMP-Regulated Phosphoprotein (DARPP-32), the phosphorylation of which requires c-Abl activation of Cdk5 by phosphorylation in the striatum. Systemic administration of nilotinib, which inhibits both Cdk5 and DARPP-32 phosphorylation, normalizes striatal motor behaviors in a MPTP mouse model for PD (5). c-Abl is activated in the brains of PD patients and in 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine- (MPTP-) poisoned mice, where it inhibits parkin through tyrosine phosphorylation, leading to the accumulation of parkin substrates and neuronal cell death. Administration of nilotinib reduces c-Abl activation and the levels of the parkin substrate, PARIS, resulting in prevention of dopamine (DA) neuron loss and behavioral deficits following MPTP intoxication (6). **Target(s):** Bcr-Abl protein-tyrosine kinase (1-4); protein-tyrosine kinase (1-4); ribosylidihydronicotinamide dehydrogenase (quinone) (7). 1. Tauchi & Ohyashiki (2006) *Int. J. Hematol.* **83**, 294. 2. O'Hare, Walters, Deininger & Druker (2005) *Cancer Cell* **7**, 11. 3. (2014) *Sci. Rep.* **4**, 4874. 7. Winger, Hantschel, Superti-Furga & Kuriyan (2009) *BMC Struct. Biol.* **9**, 7.

### Nilutamide

This antiandrogen (FW = 317.22 g/mol; CAS 63612-50-0), also known as RU23908 and Anandron™, is used for the combined antihormonal treatment of prostatic cancer. **Target(s):** benzo[*a*]pyrene hydroxylase, cytochrome P450 (1); benzphetamine *N*-demethylase, cytochrome P450 (1); 7-ethoxycoumarin *O*-deethylase, cytochrome P450 (1); hexobarbital hydroxylase, cytochrome P450 (1); mephenytoin 4-hydroxylase (2); NADH dehydrogenase, mitochondrial Complex I (3); steroid 17,20-lyase (4); steroid 17 $\alpha$ -monooxygenase (4). 1. Babany, Tinel, Letteron, *et al.* (1989) *Biochem. Pharmacol.* **38**, 941. 2. Horsmans, Lannes, Larrey, *et al.* (1991) *Xenobiotica* **21**, 1559. 3. Berson, Schmets, Fisch, *et al.* (1994) *J. Pharmacol. Exp. Ther.* **270**, 167. 4. Ayub & Levell (1987) *J. Steroid Biochem.* **28**, 43.

### (+)-Nilvadipine

This L-type calcium channel antagonist, antihypertensive agent and Syk inhibitor (FW = 385.37 g/mol; CAS 75530-68-6), also named 2-cyano-1,4-dihydro-6-methyl-4-(3-nitrophenyl)-3,5-pyridinedicarboxylic acid 3-methyl 5-(1-methylethyl) ester, exerts anti-hypertensive activity, showing good antiatherogenic properties, high vascular selectivity, an elimination half-life of 15-20 hours that commends once daily dosing, and good tolerance (1,2). The (-)-enantiomer is around 1000x less potent than its antipode in opposing vasoconstriction induced by FPL64176, a selective L-type calcium channel agonist (3). **Alzheimer Disease Treatment:** Syk regulates NF $\kappa$ B activity, which beyond its role in neuroinflammatory processes also regulates BACE-1 expression, the rate-limiting enzyme in A $\beta$  production. A $\beta$  has been shown to stimulate Syk activity resulting in microglial activation and neurotoxicity. Both nilvadipine enantiomers are equipotent in reducing A $\beta$  production in a cell line that overexpresses A $\beta$ , showing that its A $\beta$ -lowering properties are not related to L-type calcium channel inhibition (3). Notably, both (+)- and (-)-nilvadipine target Spleen tyrosine kinase, a non-receptor cytoplasmic enzyme that encoded by the *SYK* gene in humans (3). Both enantiomers also inhibit Syk in a cell-free assay, and binding kinetics using biolayer interferometry show that both nilvadipine enantiomers bind to full-length human Syk with relatively high affinity ( $K_d$  = 2.1  $\mu$ m). Such findings identify Syk as the likely nilvadipine target responsible for its A $\beta$ -lowering properties. This property was demonstrated by showing that pharmacological inhibition of Syk *in vitro* and *in vivo* as well as down-regulation of *syk* expression result in a reduction of A $\beta$  production (3). Syk inhibition also reduces sAPP $\beta$  production and BACE-1 transcription, mimicking the observed effect of (-)-nilvadipine. Syk inhibition also increases the clearance of A $\beta$  across the BBB recapitulating to the full extent the A $\beta$ -lowering properties of (-)-nilvadipine. *Note:* The related dihydropyridine- (DHP-) class antitensive Nimodipine (Nimotop) passes through the blood-brain barrier and is currently used to prevent cerebral vasospasm. 1. Cho, Ueda, Shima, *et al.* (1989) *J. Med. Chem.* **32**, 2399. 2. Rosenthal (1994) *J Cardiovasc Pharmacol.* **24** (Suppl 2), S92-107 (a review). 3. Paris, Ait-Ghezala, Bachmeier *et al.* (2014) *J. Biol. Chem.* **289**, 33927.

## NIM811

This orally available cyclophilin inhibitor (MW = 1183.67 g/mol), also known as *N*-methyl-4-isoleucine cyclosporine, has a higher affinity than cyclosporine, but is non-immunosuppressive that exhibits potent anti-human immunodeficiency virus type 1 (HIV-1) activity, selectively inhibiting HIV-1 replication in T4 lymphocyte cell lines, in a monocytic cell line, and in HeLa T4 cells (1). NIM811 also induces a concentration-dependent reduction of hepatitis C virus (HCV) RNA in the replicon cells (IC<sub>50</sub> of 0.66 μM at 48 hours), with >1000x reduction after treating the cells with as little as 1 μM of NIM811 for 9 days (2). In addition, the combination of NIM811 with α-interferon significantly enhances anti-HCV activities without causing any increase of cytotoxicity. **Mechanism of Action:** NIM811 differs from other anti-HIV agents that inhibit reverse transcriptases, proteases, and integrases or interfere with Rev or Tat function. Instead, NIM 811 inhibits (IC<sub>50</sub> = 0.17 μg/mL) formation of two-long terminal repeat (2-LTR) circles in a concentration-dependent manner that is indicative of nuclear localization of preintegration complexes, with IC<sub>50</sub> of 0.01-0.2 μg/mL for viral growth inhibition. Integration of proviral DNA into cellular DNA was likewise inhibited by NIM811. Treatment of chronically infected cells reveals the presence capsid proteins, reverse transcriptase activity, and viral RNA comparable to those of the untreated control. However, these particles showed a dose-dependent reduction in infectivity (50% inhibitory concentration of 0.03 μg/mL), indicating that viral assembly is also impaired. Given the central involvement of Gag proteins are in virus assembly and also in nuclear localization of the preintegration complex, Gag-cyclophilin interactions are clearly responsible for the antiviral action of NIM811. Indeed, Cyclophilin A binds to HIV-1 p24<sup>gag</sup>, and this cyclophilin-Gag interaction leads to the incorporation of cyclophilin A into HIV-1 virions. NIM811 inhibits this protein interaction is likely to be the molecular basis for its antiviral activity (3). In activated primary T cells, NIM811 interferes with two stages of the virus replication cycle: (a) translocation of pre-integration complexes into the nucleus and (b) production of infectious virus particles. NIM811 not only inhibits translocation of HIV-1 pre-integration complexes in primary T cells, but also in a growth-arrested T cell line. 1. Rosenwirth, Billich, Datema, *et al.* (1994) *Antimicrob. ## Nimesulide

This anti-inflammatory agent (FW = 308.31 g/mol; CAS 51803-78-2), also known as *N*-(4-nitro-2-phenoxyphenyl)methanesulfonamide, and nimesulide, inhibits prostaglandin biosynthesis and platelet aggregation. **Target(s):** collagenase (1); cyclic-nucleotide phosphodiesterase type IV (2); cyclooxygenase-2, or prostaglandin-endoperoxide synthase-2 (3-12); estrone sulfotransferase (13); oxidative phosphorylation, mitochondrial (uncoupling) (14); phenol sulfotransferase, or aryl sulfotransferase (13,15). 1. Barracchini, Franceschini, Amicosante, *et al.* (1998) *J. Pharm. Pharmacol.* **50**, 1417. 2. Bevilacqua, Vago, Baldi, *et al.* (1994) *Eur.*

## Nimodipine

This dihydropyridine calcium channel blocker (FW = 418.44 g/mol; CAS 66085-59-4), also known as BAY e 9736, Nimotop™, Nymalize™ and 3-(2-methoxyethyl) 5-propan-2-yl 2,6-dimethyl-4-(3-nitrophenyl)-1,4-dihydropyridine-3,5-dicarboxylate, is an FDA-approved treatment for reducing the incidence and severity of ischemic deficits in adult patients with subarachnoid hemorrhage (SAH) from ruptured intracranial berry aneurysms, mainly acting to reduce blood pressure (1-3). **Primary Mechanism of Inhibitory Action:** Nimodipine inhibits calcium ion transfer into vascular smooth muscle cells, thereby inhibiting contractions and reducing the incidence and severity of ischemic deficits in adult patients with subarachnoid hemorrhage from ruptured intracranial berry aneurysms is unknown. Significantly, nimodipine has no effect on cerebral metabolism but increases CBF, particularly after disruption of the blood-brain barrier. The apparent K<sub>d</sub> is 0.3-0.4 nM for binding sites in brain membranes, with maximum number of binding sites (B<sub>max</sub>) of 300-350 fmol/mg protein, roughly in the range commonly observed for neurotransmitters, hormones or channel toxins (4). **Target(s):** Ca<sup>2+</sup> channel, L-type (5,6); calmodulin-dependent cAMP phosphodiesterase (7); nitric-oxide synthase (8); orotidine-5'-phosphate decarboxylase (9); uridine kinase (9). 1. ## Nimustine

This nitrosourea (FW = 272.69 g/mol; CAS 42471-28-3), also known as *N'*-[(4-amino-2-methyl-5-pyrimidinyl)methyl]-*N*-(2-chloroethyl)-*N*-nitrosourea, exhibits antitumor activity by alkylating DNA, which alters DNA replication and repair and triggering apoptosis. (See *Nitrosoureas*) **Target(s):** acetylcholinesterase (1); butyrylcholinesterase (1); glutathione-disulfide reductase (2); ribonucleotide reductase (2); thioredoxin reductase (2). 1. Fujii, Ohnoshi, Namba & Kimura (1982) *Gan To Kagaku Ryoho* **9**, 831. 2. Schallreuter, Gleason & Wood (1990) *Biochim. Biophys. Acta* **1054**, 14.

**Nintedanib**

This oral angiokinase inhibitor and antineoplastic agent (FW = 539.64 g/mol; CAS 656247-17-5), also known by its code name BIBF 1120, its trade name Vargatef<sup>®</sup>, and its systematic name methyl (3Z)-3-[[[4-(methyl[(4-methylpiperazin-1-yl)acetyl]amino}phenyl)amino](phenyl)-methylidene]-2-oxo-2,3-dihydro-1H-indole-6-carboxylate, inhibits vascular endothelial growth factor receptor (VEGFR1, IC<sub>50</sub> = 34 nM; VEGFR2, IC<sub>50</sub> = 13 nM; VEGFR3, IC<sub>50</sub> = 13 nM), fibroblast growth factor receptor (FGFR1, IC<sub>50</sub> = 69 nM; FGFR2, IC<sub>50</sub> = 37 nM; FGFR3, IC<sub>50</sub> = 108 nM), and platelet-derived growth factor receptor (PDGFR $\alpha$ , IC<sub>50</sub> = 59 nM; PDGFR $\beta$ , IC<sub>50</sub> = 65 nM), thus providing sustained receptor blockade and good antitumor efficacy. In tested tumor models that included human tumor xenografts growing in nude mice and a syngeneic rat tumor model, BIBF 1120 is highly active at well-tolerated doses (25-100 mg/kg daily p.o.), as evaluated by (a) MRI of tumor perfusion after three days, (b) reduction in vessel density and vessel integrity after five days, and (c) profound tumor growth inhibition (1). So designated as a triple angiokinase inhibitor, Nintedanib binds to the ATP-binding site in the cleft between the N- and C-terminal lobes of the kinase domain. Significantly, Nintedanib induces hypoxia, but not epithelial-to-mesenchymal transition (EMT), and blocks progression of preclinical models of lung and pancreatic cancer (3). 1. Hilberg, Roth, Krssak, *et al.* (2008) *Cancer Res.* **68**, 4774. 2. Roth, Heckel, Colbatzky, *et al.* (2009) *J. Med. Chem.* **52**, 4466. 3. Kutluk Cenik, Ostapoff, Gerber & Brekken (2013) *Mol. Cancer Ther.* **12**, 992.

**Nipecotate (Nipecotic Acid)**

This water-soluble piperidine derivative (FW = 129.16 g/mol; CAS 498-95-3), also known as 3-piperidinecarboxylic acid, is a structural analogue of  $\gamma$ -aminobutyric acid (GABA) and a strong inhibitor of GABA uptake. **Target(s):**  $\gamma$ -aminobutyrate (GABA) transport (1-3); L-carnitine uptake (4); carnosine synthetase (5). 1. Balcar, Mark, Borg & Mandel (1979) *Neurochem. Res.* **4**, 339. 2. Johnston, Krogsgaard-Larsen, Stephanson & Twitchin (1976) *J. Neurochem.* **26**, 1029. 3. Krogsgaard-Larsen & Johnston (1975) *J. Neurochem.* **25**, 797. 4. Hannuniemi & Kontro (1988) *Neurochem. Res.* **13**, 317. 5. Seely & Marshall (1982) *Life Sci.* **30**, 1763.

**Niraparib**

This selective PARP inhibitor (FW = 320.39 g/mol; CAS 1038915-60-4), also named (S)-2-(4-(piperidin-3-yl)phenyl)-2H-indazole-7-carboxamide and MK-4827, targets the poly(D-phosphoribosyl)polymerases PARP1 (IC<sub>50</sub> = 3.8 nM) and PARP2 (IC<sub>50</sub> = 2.1 nM), with >330x selectivity against PARP3, V-PARP and Tank1 (1). Poly(ADP-ribose) polymerases are involved in DNA repair following damage by endogenous or exogenous processes, and it has become clear that, in the context of defects in other DNA repair mechanisms, PARP inhibition can provide for tumor specific chemotherapy. Niraparib is highly active against cancer cells with BRCA-1 and BRCA-2 mutations. MK-4827 shows a high potential for improving radiotherapy efficacy, based on results of a study of fractionated radiotherapy (*e.g.*, 2 Gy per fraction, given once or twice a day for 1-2 weeks) combined with MK-4827 (*e.g.*, 50 mg/kg once daily or 25 mg/kg twice daily), using a variety of human tumor xenografts of differing p53

status (*e.g.*, Calu-6 (p53<sup>null</sup>), A549 (p53<sup>wild-type</sup>) and H-460 (p53<sup>wild-type</sup>) lung cancers as well as triple-negative MDA-MB-231 human breast carcinoma (2). Combined use of MK-4827 and radiation may also provide effective therapy for children with high-risk neuroblastoma (3). Significantly, niraparib radiosensitizes human lung and breast cancer cells (4). 1. Jones, Altamura, Boueres, *et al.* (2009) *J. Med. Chem.* **52**, 7170. 2. Wang, Mason, Ang, *et al.* (2012) *Invest. New Drugs* **30**, 2113. 3. Mueller, Bhargava, Molinaro, *et al.* (2013) *Anticancer Res.* **33**, 755. 4. Bridges, Toniatti, Buser, *et al.* (2014) *Oncotarget* **5**, 5076.

**Nisin A**

This polypeptide antibiotic (FW = 3354.07 g/mol; CAS 1414-45-5; where Abu =  $\alpha$ -aminobutyric acid, Dha = dehydroalanine, and Dhb = dehydrbutyrine) from *Streptococcus lactis* (*Lactococcus lactis*) binds specifically to the peptidoglycan precursor Lipid II, thereby combining the formation of bacteriocidal membrane pores with inhibition of cell wall biosynthesis. The presence of dehydrated residues and thioether bonds constrain the peptide's conformation. It is bacteriocidal at nM concentrations. Note that Nisin Z is identical to Nisin A, except for an asparaginyl residue at position 27 in place of a histidyl. **Pore Formation:** Nisin first associates tightly with the anionic membrane surface leading to a high local concentration, disturbing the lipid dynamics near the interface of the solvent and phospholipid polar head groups, thereby immobilizing nearby lipids. Then, in the presence of a transmembrane electrical potential, the molecules reorient, giving rise to a wedge-like, nonspecific, water-filled pore (1). **Target(s):** peptidoglycan biosynthesis (1-4); peptidoglycan glycosyltransferase (5); undecaprenyl-diphospho-muramoylpentapeptide  $\beta$ -N-acetylglucosaminyl-transferase, or MurG transferase (6). 1. Moll, Roberts, Konings & Driessen (1996) *Antonie Van Leeuwenhoek* **69**, 185. 2. Reisinger, Seidel, Tschesche & Hammes (1980) *Arch. Microbiol.* **127**, 187. 3. **NITD008**

This nucleoside analogue and pro-drug (FW = 290.28 g/mol; CAS 1044589-82-3), also named 7-deaza-2'-C-acetylene-adenosine, potently inhibits the four serotypes of the mosquito-borne Dengue virus (DENV), both *in vitro* and *in vivo* (1). Its triphosphate form directly inhibits the RNA-dependent RNA polymerase activity of DENV, indicating that NITD008 must first be phosphorylated to the triphosphate, which then functions as a polymerase chain terminator during viral RNA synthesis. NITD008 also inhibits other flaviviruses, including West Nile virus, yellow fever virus, and Powassan virus. While this agent also suppresses hepatitis C virus, it does not inhibit nonflaviviruses, such as Western equine encephalitis virus and vesicular stomatitis virus (1). Treatment of DENV-infected mice with NITD008 suppressed peak viremia, reduced cytokine elevation, and completely prevented the infected mice from death (1). It is also effective against Enterovirus 71 (EV71), a major viral pathogen in China and Southeast Asia (2). Combined treatment with NITD008 and the histone deacetylase inhibitor vorinostat is a useful immunotherapy for ameliorating West Nile virus infection (3). 1. Yin, Chen, Schul, *et al.* (2009) *Proc. Natl. Acad. Sci. U.S.A.* **106**, 20435. 2. Deng, Yeo, Ye, *et al.* (2014) *J. Virol.* **88**, 11915. 3. Nelson, Roe, Orillo, Shi & Verma (2015) *Antiviral Res.* **122**, 39.

## Nitecapone

This antiulcer drug (FW = 265.22 g/mol; CAS 116313-94-1), also known as 3-(3,4-dihydroxy-5-nitrobenzylidene)-2,4-pentanedione and OR-462, targets catechol *O*-methyltransferase (COMT) and was originally intended to be a treatment for Parkinson Disease. Later work, however, showed that low COMT is associated with increased sensitivity to acute pre-/post-operative pain. In fact, a single nucleotide polymorphism (Val-158-Met) results in the low-activity variant of COMT that is associated with migraine and/or increased risk for fibromyalgia. Nitecapone is a water-soluble compound with antioxidative properties and inhibits oxidation of low-density lipoproteins promoted by copper ions. **Target(s):** catechol *O*-methyltransferase (1-6); glycosulfatase (7,8); NF- $\kappa$ B activation induced by tumor necrosis factor- $\alpha$  (9); xanthine oxidase (1,2). 1. Marcocci, Suzuki, Tsuchiya & Packer (1994) *Meth. Enzymol.* **234**, 526. 2. Suzuki, Tsuchiya, Safadi, Kagan & Packer (1992) *Free Radic. Biol. Med.* **13**, 517. 3. ## Nitenpyram

This neonicotinoid (FW = 270.72 g/mol; CAS 150824-47-8), also known as Capstar<sup>®</sup> and (*E*)-*N*-(6-chloro-3-pyridylmethyl)-*N*-ethyl-*N'*-methyl-2-nitrovinylidenediamine, is an insecticide/pesticide used to exterminate external parasites of livestock and pets. Nitenpyram is a short-acting agent that is without effect on insect eggs and pupa. Capstar is therefore especially useful in treating flea infestations in household pets. (See also *Imidacloprid*) Nitenpyram exhibits much lower toxicity to nicotinic acetylcholine receptors in mammals.

## Nitidine

This DNA-intercalating benzo[*c*]phenanthridinium alkaloid (FW<sub>chloride</sub> = 383.83 g/mol; CAS 13063-04-2), isolated from trees belonging to the genus *Zanthoxylum*, inhibits a number of enzymes with nucleotide or DNA substrates or cofactors. **Target(s):** catechol *O*-methyltransferase (1); DNA-directed DNA polymerase (2,3); DNA ligase (ATP, human, IC<sub>50</sub> = 69  $\mu$ M (4); DNA topoisomerase I (5-7); DNA topoisomerase II (5,7); polyadenylic acid polymerase (3); RNA-directed DNA polymerase, *or* reverse transcriptase (2,3,8-10); RNA polymerase (2,3); tRNA methyltransferase (1). 1. Lee, MacFarlane, Zee-Cheng & Cheng (1977) *J. Pharm. Sci.* **66**, 986. 2. Sethi (1977) *Ann. N. Y. Acad. Sci.* **284**, 508. 3. Sethi (1976) *Cancer Res.* **36**, 2390. 4. ## Nitisinone

This herbicidal triketone (FW = 329.23 g/mol), also known as 2-[2-nitro-4-(trifluoromethyl)benzoyl]-1,3 cyclohexane-dione and NTBC, inhibits 4-hydroxyphenylpyruvate dioxygenase in plants and animals. It has been used in the treatment of type I tyrosinemia. **Target(s):** 4-hydroxymandelate synthase (1); 4-hydroxyphenylpyruvate dioxygenase (2-7). 1. Conrad & Moran (2008) *Inorganica Chim. Acta* **361**, 1197. 2. Kavana & Moran (2003) *Biochemistry* **42**, 10238. 3. Mitchell (1996) *Hum. Exp. Toxicol.* **15**, 179. 4. Ellis, Whitfield, Gowans, *et al.* (1995) *Toxicol. Appl. ## Nitrazepam

This depressant and hypnosis-inducing agent (FW = 281.27 g/mol; CAS 146-22-5), also known as 1,3-dihydro-7-nitro-5-phenyl-2H-1,4-benzodiazepin-2-one, is practically insoluble in water, but very soluble in ethanol and *n*-octanol. Note: Nitrazepam is a controlled substance. **Target(s):** alcohol dehydrogenase (1); glycine receptors (2); 3(20) $\alpha$ -hydroxysteroid dehydrogenase (3). 1. Roig, Bello, Burguillo, Cachaza & Kennedy (1991) *J. Pharm. Sci.* **80**, 267. 2. Thio, Shanmugam, Isenberg & Yamada (2003) *J. Neurophysiol.* **90**, 89. 3. Usami, Yamamoto, Shintani, *et al.* (2002) *Biol. Pharm. Bull.* **25**, 441.

## Nitric Oxide

This key signaling gas (FW = 30.01 g/mol; CAS 10102-43-9) has an unpaired electron in an antibonding orbital (configuration =  $\sigma_1^2 \sigma_2^2 \sigma_3^2 \pi^4 \pi^*$ ; bond-length = 115.06 pm), making it paramagnetic and highly reactive. Nitric oxide can be generated nonenzymatically. Peroxynitrite (ONOO<sup>-</sup>) reacts with reduced glutathione (GSH) to form GS-NO<sub>2</sub>, which decomposes to NO. (See *Nitroprusside*; *S-Nitroso-N-acetylpenicillamine*; *3,3-Bis(aminoethyl)-1-hydroxy-2-oxo-1-triazine*; *S-Nitrosoglutathione*) In physiological solutions,  $\cdot\text{NO}$  has a short half-life (~5 seconds), reacting rapidly with dissolved dioxygen to form the nitrogen dioxide radical (*Reaction*:  $2 \cdot\text{NO} + \text{O}_2 \rightleftharpoons 2 \cdot\text{NO}_2$ ). In cellular processes, nitric oxide is formed by various constitutive and inducible nitric oxide synthases (*Reaction*: L-arginine + 3/2 NADPH + H<sup>+</sup> + 2 O<sub>2</sub>  $\rightleftharpoons$  Citrulline +  $\cdot\text{NO}$  + 3/2 NADP<sup>+</sup>). Previously called endothelium-derived relaxation factor (EDRF), nitric oxide has many diverse biochemical and physiological roles as a neurotransmitter, vasodilator, nitrogen fixation, and cytostatic agent. Binding of nitric oxide to the heme iron of soluble guanylyl cyclase results in activation of the enzyme. Nitric oxide also activates cyclooxygenase and p21ras. Note that many reported cases of enzyme inhibition by nitric oxide results from the presence of peroxynitrite (See *Peroxynitrite*). Although ethylene is a long-known signaling gas in plants, NO, CO, and H<sub>2</sub>S are the three gasotransmitters known to be active humans. Nitrate, the main nitric oxide metabolite, is excreted in the urine. **Target(s):** acetylcholinesterase (1-5); adenain, *or* adenovirus proteinase (6); ADP-ribose diphosphatase (7); [ $\beta$ -adrenergic-receptor] kinase (76); alcohol dehydrogenase (8); aldehyde dehydrogenase (9); O<sup>2</sup>-

alkylguanine-DNA alkyltransferase (10,11); L-ascorbate peroxidase (12); caspase-3 (13,73,74); catalase (12,93); catechol 2,3-dioxygenase (89); Ca<sup>2+</sup>-transporting ATPase (72); CF<sub>1</sub> ATP synthase, or chloroplast H<sup>+</sup>-transporting two-sector ATPase (14); coagulation factor XIII (15); creatine kinase (16,17); cruzipain (18,19); cystathionine β-synthase (20); cytochrome *c* oxidase, or Complex IV (21-25,96-105); cytochrome *c* peroxidase (94,95); cytochrome P450 (1); dimethylargininase (26,27); DNA ligase (28); dopamine β-monooxygenase (29); epidermal growth factor receptor protein-tyrosine kinase (30); falcipain (19,31); flavin-containing monooxygenase (83); formamidopyrimidine-DNA glycolyase (32); glutamate decarboxylase (33); γ-glutamylcysteine synthetase (43); glutathione peroxidase (92); glyceraldehyde-3-phosphate dehydrogenase (34-36); heme oxygenase (82); HIV-1 protease (37); HIV-1 reverse transcriptase (38); hydrogenase (39,40); hydrogenase (acceptor) (90); hydrogen dehydrogenase (91); indoleamine 2,3-dioxygenase (41,84-88); insulin receptor kinase (42); K<sup>+</sup> current, glutamate-induced (44); α-ketoglutarate dehydrogenase (4); lactoylglutathione lyase, or glyoxalase I (45,46); *Leishmania infantum* cysteine proteinase (19,47); 12-lipoxygenase, or arachidonate 12-lipoxygenase (48); methionine S-adenosyltransferase (77-80); methionine synthase, or homocysteine methyltransferase (49); methylmalonyl-CoA mutase (50); Na<sup>+</sup>/K<sup>+</sup>-exchanging sATPase (51,52); nitrile hydratase (53); nitrogenase (54-56); ornithine decarboxylase (57,58); papain (59,60); phospholipase D (61); poly(ADPribose) polymerase (62); prolyl monooxygenase (63); prostaglandin-I synthase, inhibited at elevated concentrations (64); protein-glutamine γ-glutamyltransferase, or transglutaminase (81); protein-tyrosine-phosphatase (75); protocathechuate 4,5-dioxygenase (89); ribonucleotide reductase (66); sulfinoalanine decarboxylase, or cysteinesulfinate decarboxylase (33); thiosulfate sulfurtransferase, or rhodanese (65); thromboxane-A synthase (64); tryptophan monooxygenase (67,68); xanthine dehydrogenase (69,70); xanthine oxidase (69-71). 1. #### 4-Nitro-5-aminoimidazole Ribonucleoside 5'-Monophosphate

This synthetic nucleotide (FW<sub>free-acid</sub> = 340.19 g/mol; Symbol: NAIR), also known as 5-amino-1-(5'-phospho-β-D-ribofuranosyl)-4-nitroimidazole, is a tight-binding inhibitor of *Gallus gallus* phosphoribosylaminoimidazole carboxylase ( $K_i = 0.34$  nM), but a weaker inhibitor ( $K_i = 0.5$  μM) of the *Escherichia coli* enzyme. While the inhibition kinetics suggested this compound as a transition state or reactive intermediate mimic, it is unclear what molecular features of NAIR contribute to the mimetic properties for either of the two proposed mechanisms of AIR carboxylase (3). Significantly, a variety of AIR, CAIR and NAIR analogues were found to exhibit less binding affinity than NAIR, despite only modest structural modifications. Such investigations are significant inasmuch as vertebrates synthesize purines in ten steps (as originally proposed by Buchanan), whereas bacteria, yeast and fungi make an additional pathway intermediate (*i.e.*, 4-carboxy-5-aminoimidazole ribonucleotide). 1. Firestone, Poon, Mueller, Stubbe & Davisson (1994) *Biochemistry* **33**, 11927. 2. Firestone & Davisson (1993) *J. Med. Chem.* **36**, 3484. 3. Firestone, Wu, Youn & Davisson (2009) *Bioorg. Med. #### Nitroarachidonate (Nitroarachidonic Acid)

12-Nitroarachidonate

This isomeric mixture of mono-nitrated arachidonic acids (FW = 351.48 g/mol) includes 9-nitroicososa-5,8,11,14-tetraenoic acid (9-AANO<sub>2</sub>), 12-nitroicososa-5,8,11,14-tetraenoic acid (12-AANO<sub>2</sub>), 14-nitroicososa-5,8,11,14-tetraenoic acid (14-AANO<sub>2</sub>), and 15-nitroicososa-5,8,11,14-tetraenoic acid (15-AANO<sub>2</sub>) (1). They inhibit both the COX activity (*i.e.*, conversion of AA to prostaglandin G<sub>2</sub>, or PGG<sub>2</sub>) and POX activity (*i.e.*, reduction of PGG<sub>2</sub> to PGH<sub>2</sub>) of Prostaglandin Endoperoxide H Synthase-1, but *only* the POX activity of PGHS-2. Kinetic analysis suggests that inactivation of PGHS by AANO<sub>2</sub> is a two-step process: first, reversible binding ( $E + I \rightleftharpoons E \cdot I$ ), described by  $K_i$ , followed by a practically irreversible event ( $E \cdot I \rightleftharpoons E^* \cdot I$ ), described by  $K_i^{*app}$  and leading to an inactivated enzyme  $E^* \cdot I$  (2). The plot of  $k_{obs}$  versus [AANO<sub>2</sub>] showed a hyperbolic function with  $k_{inact} = 0.045$  s<sup>-1</sup> and  $K_i^{*app} = 0.019$  μM for PGHS-1 and  $k_{inact} = 0.057$  s<sup>-1</sup> and  $K_i^{*app} = 0.020$  μM for PGHS-2. Nitroarachidonic acids are likely immunomodulators. 1. Trostchansky, Souza, Ferreira, *et al.* (2007) *Biochemistry* **46**, 4645. 2. Trostchansky, Bonilla, Thomas, *et al.* (2011) *J. Biol. Chem.* **286**, 12891.

#### N<sup>ω</sup>-Nitro-L-arginine

This arginine derivative (FW<sub>zwitterion</sub> = 219.20 g/mol; FW<sub>HCl-Salt</sub> = 269.70 g/mol) is an irreversible inhibitor of constitutive nitric oxide synthase (nNOS) and a reversible inhibitor of inducible nitric oxide synthase (iNOS). N<sup>ω</sup>-Nitro-L-arginine inhibits brain nitric-oxide synthase and endothelial nitric-oxide synthase with  $K_i$  values of 25 nM and 90 nM, respectively, while the inducible enzyme has a  $K_i$  value of 8.1 μM. N<sup>ω</sup>-Nitro-L-arginine reduces cardiac output and causes significant vasoconstriction. A good control is the use of N<sup>ω</sup>-nitro-D-arginine, an agent that is likewise commercially available. **Target(s):** arginase (1,2); arginine kinase (3,4); catalase (5); nitric-oxide synthase (6-21). 1. #### N<sup>ω</sup>-Nitro-L-arginine Methyl Ester

This arginine derivative (FW = 233.23 g/mol; CAS 51298-62-5; Soluble to 100 mM in water and to 100 mM in DMSO), often abbreviated L-NAME, is much more water soluble than N<sup>ω</sup>-nitro-L-arginine and is also an inhibitor of nitric-oxide synthase, albeit not as potent as N<sup>ω</sup>-nitro-L-arginine. Note that L-NAME elicits a variety of physiological effects (*e.g.*, induces leukocyte adhesion, inhibits relaxation induced by acetylcholine, impairs reference memory formation, and modulates microvascular permeability). L-NAME inhibits cGMP formation in endothelial cells with an IC<sub>50</sub> of 3.1 μM (in the presence of 30 μM arginine) and reverses the vasodilatory effects of acetylcholine in rat aorta rings (EC<sub>50</sub> = 0.54 μM). **Target(s):** arginase (1); nitric-oxide synthase (2-11); protein-arginine deaminase (12); tyrosine:arginine ligase, or kyotorphin synthetase (13,14). A good control is the use of the same concentration N<sup>ω</sup>-nitro-D-arginine methyl ester, an agent that is likewise commercially available. 1. Reisser, Onier-Cherix & Jeannin (2002) *J. Enzyme Inhib. Med. Chem.* **17**, 267. 2. Griffith & Kilbourn (1996) *Meth. Enzymol.* **268**, 375. 3. Rees, Palmer, Schulz, Hodson & Moncada (1990) *Brit. J. Pharmacol.* **101**, 746. 4. #### 2-Nitrobenzenesulfonyl Chloride

This moisture-sensitive reagent (FW = 189.6 g/mol; CAS 7669-54-7; M.P. = 74–76°C), also called 2-nitrophenylsulfonylchloride, reacts with tryptophanyl and cysteinyl residues in peptides and proteins, in the presence of 20–60% acetic acid (producing a 2-thioether tryptophanyl derivative and a mixed disulfide, respectively). Reaction conditions for 2-nitrobenzenesulfonyl chloride are often too harsh to observe any effects on enzyme activity. Many investigators argue for the importance of an active-site tryptophanyl residue, when a substrate or active-site metal ion inhibits the labeling of an enzyme. **Target(s):** Brazilian scorpion (*Tityus serrulatus*) toxin VII (Ts γ) (1); cholera toxin (toxicity and ADP-ribosylating activity are lost) (2); king cobra (*Ophiophagus hannah*) venom α-neurotoxin Oh-4 (3); king cobra (*Ophiophagus hannah*) venom α-neurotoxin Oh-7 (3); lactose synthase (4); lysophospholipase, Australian elapid snake (*Pseudechis australis*) (5); lysozyme (6,7); phospholipase A<sub>2</sub> (8,9); *Rhizopus* ribonuclease (10). 1. Hassani, Mansuelle, Cestele, *et al.* (1999) *Eur. J. Biochem.* **260**, 76. 2. De Wolf, Fridkin, Epstein & Kohn

### **p**-Nitrobenzoate (**p**-Nitrobenzoic Acid)

This aromatic acid (FW<sub>free-acid</sub> = 167.12 g/mol; CAS 62-23-7; pK<sub>a</sub> value of 3.41 at 25°C), also known as 4-nitrobenzoic acid, inhibits propionyl-CoA synthetase, monoamine oxidase, and D-amino-acid oxidase. The free acid (M.P. = 242.4°C) is very slightly soluble (1 g/2380 mL H<sub>2</sub>O), and the sodium salt is much more soluble). **Target(s)**: D-amino-acid oxidase (1-3); benzoate 4-monooxygenase (4); monoamine oxidase (5); propionyl-CoA synthetase (6); thiopurine S-methyltransferase, IC<sub>50</sub> = 0.5 mM (7). 1. ### **3**-(*m*-Nitrobenzoyl)alanine

This unusual aromatic amino acid (FW = 238.20 g/mol) inhibits kynureninase, IC<sub>50</sub> = 100 μM (1-3) and kynurenine 3-monooxygenase, IC<sub>50</sub> = 077 μM (1,2,4,5). 1. ### **N**-(2-Nitrobenzyl)-**N**-(4-nitrophenylsulfenyl)-**β**-alanine Hydroxamate

This hydroxamate (FW = 420.41 g/mol) inhibits interstitial collagenase, or MMP-1 (K<sub>i</sub> = 28 nM), gelatinase A, or MMP-2 (K<sub>i</sub> = 15 nM), neutrophil collagenase, or MMP-8 (K<sub>i</sub> = 14 nM), gelatinase B, or MMP-9 (K<sub>i</sub> = 19 nM), and microbial collagenase (K<sub>i</sub> = 30 nM). 1. Scozzafava, Ilies, Manole & Supuran (2000) *Eur. J. Pharm. Sci.* **11**, 69.

### **S**-(**p**-Nitrobenzyloxycarbonyl)glutathione

This glutathione derivative (FW = 486.46 g/mol) inhibits hydroxyacyl-glutathione hydrolase, or glyoxalase II (1-4) and glyoxalase I (5-7). The *o*- and *m*-nitro analogues also inhibit glyoxalase II. 1. Uotila (1989) in *Coenzymes and Cofactors, Glutathione, Chem. Biochem. Med. Aspects Pt. ### **3**-[**N**<sup>c</sup>-(4-Nitrobenzyloxycarbonyl)-**L**-lysyl]thiazolidine

This dipeptide analogue (FW = 396.47 g/mol), also known as 3-[<sup>N</sup>c-(4-nitrobenzyloxycarbonyl)-L-lysyl]thiazolidine, is a strong inhibitor of dipeptidyl-peptidase IV. 1. ### **S**-(**p**-Nitrobenzyl)-**6**-thioinosine

This potent nucleoside transport inhibitor (FW = 419.41 g/mol; CAS 38048-32-7; *Abbreviation*: NBMPR) binds tightly and reversibly to HeLa cell membrane sites associated with the nucleoside transport. Site-specific binding was assayed with [<sup>35</sup>S]NBMPR and a competing, unlabeled congener. HeLa cells possess ~10<sup>3</sup> binding sites of a single class that bound NBMPR tightly (K<sub>i</sub> ≈ 0.1 nM). Occupancy of these binding sites by NBMPR inhibits uridine and thymidine uptake, but the relationship between these parameters is complex; as binding saturation is approached (at ~5 nM NBMPR), a substantial fraction (25-30%) of the transport capability remained active. By blocking adenosine re-uptake, NBMPR increases the extracellular adenosine concentration, thereby increasing adenosinergic neurotransmission. Indeed, the adenosine transporter (mENT1) is a target for adenosine receptor signaling (2). **Target(s)**: adenosine kinase, also alternative substrate (The *meta*-analogue also inhibits.) (3,4); adenosine transport (5-8); thymidine transport (9); uridine transport (10,11). 1. Lauzon & Paterson (1977) *Mol. Pharmacol.* **13**, 88. 2. Chaudary, Naydenova, Shuralyova & Coe (2004) *J. ### 2-Nitro-4-carboxyphenyl-*N,N*-Diphenylcarbamate

This carbamate (FW = 378.34 g/mol; *Abbreviation*: NCDC) is an inactivator of chymotrypsin and has been used to quantify that enzyme. This reagent produces a modified protein (*i.e.*, diphenylcarbamoyl-chymotrypsin) and releases an equimolar amount of 3-nitro-4-hydroxybenzoate. The latter has a molar extinction coefficient at 410 nm of 3910 M<sup>-1</sup>cm<sup>-1</sup>, where as NCDC has negligible absorbance at this wavelength. **Target(s)**: chymotrypsin (1); envelysin, or sea urchin hatching enzyme (2); phospholipase C (3,4); pancreatic elastase II (5). 1. Erlanger & Edel (1964) *Biochemistry* **3**, 346. 2. Post, Schuel & Schuel (1988) *Biochem. Cell. Biol.* **66**, 1200. 3. Saetrum Opgaard, Nothacker, Ehlert & Krause (2000) *Eur. J. ### 4-Nitrocatechol

This aromatic diol (FW = 155.11 g/mol; CAS 3316-09-4; M.P. = 174-176°C), also known as 1,2-dihydroxy-4-nitrobenzene, is an alternative substrate for catechol *O*-methyltransferase and CYP2E1 and inhibits a number of non-heme iron dioxygenases. Interestingly, Fe(III)-soybean lipoxigenase-1 binds 4-nitrocatechol and produces a green-colored complex, which exhibits  $\lambda_{\max}$  values at 385 and 650 nm at pH 7.0. **Target(s)**: catechol 1,2-dioxygenase, or pyrocatechase (1-3); catechol *O*-methyltransferase, weak alternative substrate (4); catechol oxidase (5,6); 3,4-dihydroxyphenylacetate 2,3-dioxygenase (7,8); 15-lipoxygenase, or arachidonate 15-lipoxygenase, IC<sub>50</sub> = 4.6  $\mu$ M (9,10); lipoxygenase, soybean (11-14); protocatechuate 2,3-dioxygenase and homoprotocatechuate 2,3-dioxygenase, or 3,4-dihydroxyphenylacetate 2,3-dioxygenase (15,16); protocatechuate 3,4 dioxygenase (1,17-22); protocatechuate 4,5-dioxygenase (23); tyrosinase, or monophenol monooxygenase (6,24). 1. ### Nitroethane & Nitroethane Anion

This nitroalkane (FW = 75.067 g/mol; CAS 79-24-3), which generates a carbanion at the  $\alpha$ -carbon in the presence of excess base ( $pK_a = 8.6$ ), is an alternative substrate for D-amino-acid oxidase, yielding acetaldehyde and nitrite stoichiometrically. When present simultaneously, nitroethane anion and cyanide inhibit this oxidase irreversibly, and spectral properties of the enzyme-bound FAD cofactor indicate that the *N*<sup>5</sup>-adduct is formed. Nitroethane is also a substrate for the nitroalkane-oxidizing enzyme 2-nitropropane dioxygenase. **Target(s)**: D-amino acid oxidase, in the presence of cyanide (1,2); flavocytochrome *b*<sub>5</sub>, or L-lactate dehydrogenase (cytochrome) (3). 1. Walsh, Cromartie, Marcotte & Spencer (1978) *Meth. Enzymol.* **53**, 437. 2. Porter, Voet & Bright (1973) *J. Biol. Chem.* **248**, 4400. 3. Genet & Lederer (1990) *Biochem. J.* **266**, 301.

### Nitroglycerin

This oral vasodilator (FW = 227.09 g/mol; CAS 55-63-0; *Abbreviation*: GTN; sweet tasting, clear viscous liquid; odorless), also called glycerine trinitrate, glycerol trinitrate, 1,3-dinitrooxypropan-2-yl nitrate, and propane-1,2,3-triyl trinitrate, has been employed as a fast-acting antianginal agent for well over a century. **Mechanism of Nitric Oxide Formation**: When taken sublingually, nitroglycerin relieves angina (acute chest pain) by forming nitric oxide (*See Nitric Oxide*) upon reaction with active-site cysteine thiol groups in aldehyde dehydrogenase-2 (ALDH2). The precise mechanism by which this mitochondrial matrix enzyme catalyzes NO formation remains unknown. **Mechanism of Vasodilatory Action**: Nitroglycerin is a direct precursor of nitric oxide and consequently a guanylate cyclase activator that promotes vasodilation therapeutically relevant concentrations ( $\leq 1 \mu$ M) of nitroglycerin. Nitroglycerin relaxes blood vessels mainly by way of activating soluble guanylyl cyclase (sGC) and the cGMP-dependent protein kinase (cGK-I) signal transduction pathway (1-3). Vasodilation strongly correlates with cGK-I-dependent phosphorylation of the vasodilator-stimulated phosphoprotein (VASP), a key actin-filament (+)-end-tracking motor (actoclampin) protein. Consistent with ALDH2's role in nitroglycerin bioactivation was suggested in earlier studies showing that the East Asian variant of ALDH2 exhibits significantly reduced dehydrogenase, esterase, and nitroglycerin denitrating activities (4). **Dynamite**: Nitroglycerin is the famously shock-sensitive explosive that was first prepared by dissolving glycerol in concentrated nitric acid in the presence of sulfuric acid (5). Seeking to increase its safety and reliability, Alfred Nobel invented Dynamite by combining nitroglycerin, sorbents (*e.g.*, powdered shells or clay), and stabilizers. His formulation proved so stable that a blasting cap is required for detonation. **Key Pharmacokinetic Parameters**: *See Appendix II in Goodman & Gilman's THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Opelt, Eroglu, Waldeck-Weiermair, *et al.* (2016) *J. Biol. Chem.* **261**, 24076. 2. Kleschyov, Oelze, Daiber, *et al.* (2003) *Circ. Res.* **93**, e104. 3. ### 7-Nitroindazole

This NOS inhibitor (FW = 163.13 g/mol; CAS 2942-42-9; Symbol = 7-NI), also named 7-nitro-1*H*-indazole, selectively targets neuronal nitric oxide synthase, IC<sub>50</sub> = 0.5  $\mu$ M (1,2). 7-NI also attenuates cocaine kindling and partially blocked the effects produced by activation of the NMDA receptor, but not the effects induced by acute cocaine administration (3). 7-NI treatment provides full protection against dopamine depletion and loss of dopamine transporter binding sites (4), indicating a role for NO in

methamphetamine-induced neurotoxicity and suggesting that NOS blockade may be used to manage Parkinson's disease. When delivered at 40 or 80 mg/kg (i.p.), 7-NI inhibits the development of tolerance to the antinociceptive action of morphine ( $\mu$ -opioid agonist) and U-50,488H ( $\kappa$ -opioid agonist), but lower doses are ineffective (5). 1. ### Nitromethane

This powerful methylating agent (FW = 61.040 g/mol; M.P. =  $-29^{\circ}\text{C}$ ; B.P. =  $101.2^{\circ}\text{C}$ ). It is slightly soluble in water (9.5% by volume at  $20^{\circ}\text{C}$ ) and will react with dehydroalanyl residues in proteins. Nitromethane's acidity allows it to undergo deprotonation, enabling condensation reactions analogous to those of carbonyl compounds. Under conditions of base catalysis, nitromethane adds to aldehydes in 1,2-addition in the nitroaldol reaction. Care should be exercised when handling sodium salts of nitromethane, which are explosive and will burst into flame upon contact with water.

**Target(s):** D-amino-acid oxidase (1); glyceraldehyde-3-phosphate dehydrogenase (sulfenic acid form), acyl phosphatase activity (2); histidine ammonia-lyase (3-5); horseradish peroxidase (6); nitronate monooxygenase (7); peroxidase (6); phenylalanine ammonia-lyase (3). 1. Walsh, Cromartie, Marcotte & Spencer (1978) *Meth. Enzymol.* **53**, 437. 2. Benitez & Allison (1974) *J. Biol. Chem.* **249**, 6234. 3. Hanson & Havir (1972) *The Enzymes*, 3rd ed., **7**, 75. 4. ### N-(5-(5-Nitro-2-oxo-1,2-dihydro-3H-indol-3-ylidene)4-oxo-2-thioxo-1,3-thiazolidin-3-yl)nicotinamide

This bacterial MurD ligase inhibitor (FW = 427.41 g/mol) targets UDP-N-acetylmuramyl-L-alanine:D-glutamate ligase (MurD) belongs to a family of Mur ligases that are essential for the synthesis of bacterial peptidoglycan. Indeed, it is a competitive inhibitor ( $K_i = 115 \mu\text{M}$ ) with respect to the substrate UDP-MurNAc-l-Ala (UMA). NMR and molecular dynamics data of this new MurD inhibitor reveal a different binding mode compared to the naphthalene-*N*-sulfonyl-D-glutamic acid derivatives. The pattern of the CSP of MurD methyl groups upon binding of this compound clearly indicates that it is located within the UMA binding site and interacts only with the *N*-terminal and central MurD domains. The 2-oxoindolinyldiene ring is located within the uracil binding site, while the 4-oxo-2-thioxo-1,3-thiazolidine ring and the pyridine ring are close to the part of the binding site occupied by the UMA phosphate groups and *N*-acetylmuramic acid ring respectively. 1. Simčić, Pureber, Kristan, *et al.* (2014) *Eur. J. Med. Chem.* **83**, 92.

### *m*-Nitrophenol

This protonophore (FW = 139.11 g/mol; CAS 554-84-7) is soluble in water (3.02 g/100 g at  $40^{\circ}\text{C}$ ) and ethanol (116.9 g/100 g at  $1^{\circ}\text{C}$ ) and has a melting point of  $97^{\circ}\text{C}$ . With a  $\text{p}K_a$  value of 8.34 at  $18^{\circ}\text{C}$ , *m*-nitrophenol has been used as a pH indicator: a 0.3% solution in 50% ethanol is colorless below

pH 6.8 and yellow above pH 8.6. **Target(s):** catechol 2,3-dioxygenase (1);  $\text{Ca}^{2+}$ -transporting ATPase (2);  $\beta$ -fructofuranosidase, *or* invertase (3); glycogen phosphorylase (4); haloalkane dehalogenases (5); (*R*)-2-hydroxyglutaryl-CoA dehydratase (6); protocatechuate 3,4-dioxygenase (7). 1. ### *o*-Nitrophenol

This phenol (FW = 139.11 g/mol; CAS 88-75-5), also known as 2-nitrophenol, is slightly soluble in cold water, soluble in ethanol and hot water, and has a melting point of  $44-45^{\circ}\text{C}$ . Its  $\text{p}K_a$  value of 7.17 at  $25^{\circ}\text{C}$  and has been used as a pH indicator (a 2% aqueous solution is colorless below pH 5 and yellow above pH 7). **Target(s):** amidase, *or* acetanilide hydrolase (1); *o*-aminophenol oxidase (2); carbonic anhydrase, carbonate dehydratase (3,4); catechol 2,3-dioxygenase (5-7); catechol oxidase (8,9); (*R*)-2 hydroxyglutaryl-CoA dehydratase (10); malate dehydrogenase, weakly inhibited (11); monophenol monooxygenase (9); NADH oxidase (12); NAD(P)H dehydrogenase (quinone) (13-15); quinone reductase (14,15). 1. Alt, Heymann & Krisch (1975) *Eur. J. Biochem.* **53**, 357. 2. Suzuki, Furusho, Higashi, Ohnishi & Horinouchi (2006) *J. Biol. Chem.* **281**, 824. 3. Wosilait & Nason (1955) *Meth. Enzymol.* **2**, 725. 14. Wosilait, Nason & Terrell (1954) *J. Biol. Chem.* **206**, 271. 15. Wosilait & Nason (1954) *J. Biol. Chem.* **208**, 785.

### *p*-Nitrophenol

This highly effective oxidative phosphorylation uncoupler (FW = 139.11 g/mol; CAS 100-02-7; Moderately soluble in cold water; Soluble in ethanol; M.P. =  $113-114^{\circ}\text{C}$ ;  $\lambda_{\text{max}} = 400 \text{ nm}$ ,  $\epsilon = 18300 \text{ M}^{-1}\text{cm}^{-1}$  at pH 10.2), also known as 4-nitrophenol, is a protonophore that dissipates transmembrane proton gradients generated by the electron transport chain. It is also a substrate for a number of UDP-glucuronosyltransferases, phenol sulfotransferases, and cytochrome P450 systems (particularly CYP2E1). *p*-Nitrophenol ( $\text{p}K_a = 7.15$  at  $25^{\circ}\text{C}$ ) is also a pH indicator (*e.g.*, a 0.1% solution in ethanol is colorless below pH 5.6 and yellow above pH 7.6). 4-Nitrophenol absorbs only weakly at 405 nm ( $\epsilon = 0.2 \text{ mM}^{-1}\text{cm}^{-1}$ ), whereas its nitrophenolate anion absorbs more intensely at 405 nm ( $\epsilon = 18.1 \text{ mM}^{-1}\text{cm}^{-1}$ ). The isosbestic point occurs at 348 nm for 4-nitrophenol/4-nitrophenoxide ( $\epsilon = 5.4 \text{ mM}^{-1}\text{cm}^{-1}$ ). **Action in Dissipating pH-Gradients and Uncoupling Oxidative Phosphorylation:** Facilitated transport of protons across the biological membrane by protonophore is achieved in a multi-step process: (a) an electron-rich, anionic protonophore species ( $\text{P}^-$ ) is adsorbed onto the net-positively charged face of a biological membrane; (b) protons ( $\text{H}^+$ ) leave the aqueous solution phase and combine with the anionic protonophore to produce the neutral form ( $\text{H}\cdot\text{P}$ ); (c) the latter enters and diffuses across the biological membrane, whereupon  $\text{H}\cdot\text{P}$  dissociates into  $\text{H}^+$  and  $\text{P}^-$  on the opposite face; (d) protons are released from the biological membrane into the other aqueous phase; and (e) the reformed  $\text{P}^-$  diffuses through the membrane, returning to the initial face by electrostatic attraction. Because ATP synthase catalysis is driven by proton gradients, and *p*-nitrophenol prevents proton gradient-driven ATP formation from

ADP and  $P_i$ . **Target(s):**  $\beta$ -N-acetylhexosaminidase (1); D-amino-acid oxidase (2);  $\beta$ -apiosyl- $\beta$ -glucosidase (3); L-ascorbate oxidase (5); carbonic anhydrase (6); carboxylesterase (7); catalase (41); catechol 2,3-dioxygenase (40); catechol oxidase (8,9,44);  $Ca^{2+}$ -transporting ATPase (10); choline sulfotransferase (11); galactosylgalactosylglucosylceramidase (12);  $\beta$ -glucosidase (13,14);  $\beta$ -glucuronidase (15); glucuronosyltransferase, substrate for UGT1A6 and UGT1A9 (30,34,35); glycogen phosphorylase (36); 4-hydroxybenzoate 3-monooxygenase, weakly inhibited (39); hydroxyglutaryl-CoA dehydratase (16); laccase (42,43); malate dehydrogenase (17); monophenol monooxygenase (18); NADH oxidase (19); NAD(P)H dehydrogenase (quinone) (20-22); neuraminidase (23); nicotinamidase (24); oligo-1,6-glucosidase (25,26); phenol sulfotransferase, or aryl sulfotransferase, also alternative substrate (4,32,33); 4-phytase (27); polyphenol oxidase (44); quinine 3-monooxygenase (38); quinone reductase (22); tyrosinase, or monophenol monooxygenase (18,28,29,37); (R)-2-UDP glucuronosyltransferase (30); xylan 1,4- $\beta$ -xylosidase (31). 1. #### **p-Nitrophenylacetate (p-Nitrophenylacetic Acid)**

This substituted acetic acid ( $FW_{\text{free-acid}} = 181.15$  g/mol; CAS 830-03-5), also known as 4-nitrobenzeneacetic acid, is a pale yellow solid with a melting point of 153°C and a  $pK_a$  of 3.98 at 25°C. The free acid is sparingly soluble in water, but the sodium salt is water-soluble. **Target(s):** carboxypeptidase A (1-4); chymotrypsin (5-7); creatine kinase (8-10); glyceraldehyde 3-phosphate dehydrogenase (11-13); lipase, or triacylglycerol lipase (14). 1. Pétra (1970) *Meth. Enzymol.* **19**, 460. 2. Smith (1951) *The Enzymes*, 1st ed., 1 (part 2), 793. 3. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol.

#### **p-Nitrophenyl Phosphate**

This organophosphate ( $FW_{\text{free-acid}} = 219.09$  g/mol;  $\lambda_{\text{max}} = 290$  nm at pH 2.3 and 310 nm at pH 9.2, where  $\epsilon = 9500$   $M^{-1}cm^{-1}$  at both pH values) is a chromogenic substrate for many phosphatases, including alkaline phosphatase. The second  $pK_a$  value is about 5.7. Note that the  $\lambda_{\text{max}}$  value for *p*-nitrophenol product is 400 nm ( $\epsilon = 18300$   $M^{-1}cm^{-1}$  in alkaline pH); however, the product is typically measured at 405-420 nm, because *p*-nitrophenyl phosphate has a slight absorbance at 400 nm. Solutions of *p*-nitrophenyl phosphate decompose slowly and must be stored in the dark at about 4°C. The solid should also be stored in the dark. **Target(s):** arylsulfatase (1); bis(2-ethylhexyl)phthalate esterase (2); glycerol-1,2-cyclic phosphate phosphodiesterase (3); glycerophosphocholine cholinephosphodiesterase (4); nonspecific lipase5; 5'-nucleotidase (6); phosphatidate phosphatase, alternative substrate (7); phosphoprotein phosphatase (8); protein-tyrosine-phosphatase (9,10); pyridoxal phosphatase (11); [pyruvate dehydrogenase (acetyl-transferring)]-phosphatase (12); *Xenopus* ribosomal protein S6 kinase II (13). 1. #### **5-Nitro-2-(3-phenylpropylamino)benzoic acid**

This chloride current blocker and putative GPR35 agonist ( $FW = 300.31$  g/mol; CAS 107254-86-4; Symbol: NPPB; Solubility: 100 mM in DMSO) inhibits  $Ca^{2+}$ -sensitive chloride currents ( $ICl_{Ca}$ ) evoked by caffeine (10 mM) and by noradrenaline (10  $\mu$ M) by 58% and 96%, respectively, at a holding potential of -60 mV in  $K^+$ -free, caesium-containing solutions, NPPB (10  $\mu$ M) (1). At a holding potential of -2 mV in  $K^+$ -containing solutions, NPPB (10  $\mu$ M) inhibited charybdotoxin-sensitive  $K^+$ -currents ( $IBK_{Ca}$ ) induced by noradrenaline (10  $\mu$ M) and acetylcholine (10  $\mu$ M) by ~90% (1). In contrast,  $IBK_{Ca}$  induced by caffeine (10 mM) was unaffected in the presence of NPPB (10  $\mu$ M). Conversely,  $IBK_{Ca}$  elicited by caffeine (2 mM) was reduced by ~50% whereas  $IBK_{Ca}$  evoked by noradrenaline (50  $\mu$ M) was not significantly inhibited by NPPB (1) In  $K^+$ -containing solutions, NPPB (10  $\mu$ M) abolished spontaneous transient outward currents (STOCs) and induced a slowly-developing outward  $K^+$ -current (1). NPPB is also a GPR35 agonist. In human embryonic kidney 293 (HEK293) cells, NPPB activates the GPR35- $G_{i\alpha}$  and GPR35-G16 pathways (2). It also mobilizes

intracellular calcium in a concentration-dependent manner in HEK293 cells coexpressing human, rat or mouse GPR35 and the chimeric G protein  $G_{q5}$ . Kynurenate, an ionotropic glutamate receptor antagonist, and zaprinast, a phosphodiesterase inhibitor, are also GPR35 agonists. **1.** Kirkup, Edwards & Weston (1996) *Br. J. Pharmacol.* **117**, 175. **2.** Taniguchi, Tonai-Kachi & Shinjo (2008) *Pharmacology* **82**, 245.

### *p*-Nitrophenyl riboside 5'-phosphate

This synthetic substrate analogue (FW = g/mol) targets orotate phosphoribosyltransferase (OPRT), an indispensable enzyme for the malaria-causative parasite, *Plasmodium falciparum*. Human and parasite OPRTs are characterized by highly dissociative transition states, showing ribocation character. *p*-Nitrophenyl riboside binds surprisingly well to OPRTs with  $K_d$  values near 40 nM. Nitrophenyl  $\beta$ -D-ribose 5'-phosphate is a mechanistic tool used to distinguish relative forces for leaving group activation and for ribocation formation (2). Presence of the 5'-phosphate causes only 3-4x increased binding affinity, indicating a relatively weak role of the phosphate region for inhibitor binding. Notably, iminoribitol mimics of the ribocation transition state give  $K_d$  values as low as 80 nM. Inhibitors with pyrrolidine groups as ribocation mimics display slightly weaker binding affinities to OPRTs. Analogues with a C<sup>5</sup> pyrimidine carbon-carbon bond as ribocation mimics give  $K_d$  values in the range of 80-500 nM. Acyclic inhibitors with achiral serinol groups as the ribocation mimics also display nanomolar inhibition against OPRTs. Despite their tight-binding to the targets, none of these inhibitors is effective in killing *P. falciparum* in culture. **1.** Zhang, Evans, Clinch (2013) *J. Biol. Chem.* **288**, 34746. **2.** Mazzella, Parkin, Tyler, Furneaux & Schramm (1996) *J. Am. Chem. Soc.* **118**, 211.

### 3-Nitropropionate (3-Nitropropionic Acid)

This naturally occurring excitotoxin (FW = 119.08 g/mol; *Symbol*: 3-NP) is a succinate analogue and the intermediate in the reaction catalyzed by isocitrate lyase,  $K_i = 1.5$  nM (1-4). Inhibition of isocitrate lyase by 3-NP proceeds through a "double slow-onset" process, in which an initial complex ( $K_i = 3.3$   $\mu$ M) forms during the first minute, followed by formation of a final complex ( $K_i^* = 44$  nM) over the next minutes to hours (5). 3-NP inhibition involves an unfavorable isomerization of active-site Cys191 and His193 to its thiolate-imidazolium pair prior to inhibitor binding, followed by proton transfer from 3-NP to Cys191. Propionate-3-nitronate, the conjugate base of 3-NP, is thus the "true inhibitor", one that does not bind directly, but instead must be generated enzymatically. 3-NP is also a suicide inactivator of succinate dehydrogenase, producing 3-nitroacrylate ( $O_2N-CH=CH-COO^-$ ), which inactivates the enzyme rapidly and irreversibly (6,7). **Other Target(s):** aspartate ammonia-lyase, or aspartase (8-11); aspartate carbamoyltransferase (12); cyanate hydratase, or cyanase (13); fumarase, by the C3 carbanion (7); nitronate monooxygenase (14). **1.** Schloss & Cleland (1982) *Biochemistry* **21**, 4420. **2.** Sharma, Sharma, Höner zu Bentrup, et al. ### 3-Nitrosobenzamide

This light-yellow *C*-nitroso compound (FW = 150.14 g/mol; CAS 144189-66-2; *Abbreviation*: NOBA) inactivates caspase 3 by *S*-nitrosylation of cysteinyl residues. It will also induce DNA fragmentation and has been shown to remove zinc from the retroviral-type zinc finger of HIV-1 nucleocapsid proteins. **Target(s):** caspase-3 (1); HIV-1 infectivity (2); poly(ADP-ribose) polymerase, or NAD<sup>+</sup>:poly(adenosine diphosphate-D-ribose) ADP-ribosyltransferase (3). **1.** Mihalik, Bauer, Petak, et al. ### S-Nitrosoglutathione

This vasodilator and smooth muscle relaxant (FW = 336.32 g/mol; CAS 57564-91-7) is a nitric oxide donor and inhibitor of platelet activation. Ornithine decarboxylase is inhibited by via *S*-transnitrosation. (**See also Nitric Oxide**) **Target(s):** alcohol dehydrogenase-2, *Entamoeba histolytica* (1); aldose reductase (2); annexin II (3); arylamine *N*-acetyltransferase (34); Ca<sup>2+</sup> channels, L-type (4); caspase-3 (5); catalase (35); cathepsin K (6); coagulation factor XIII (7); creatine kinase (8,9); *Entamoeba histolytica* cysteine proteinases (1); falcipain (10); glutathione-disulfide reductase (11-13); glutathione *S*-transferase (14); glyceraldehyde-3 phosphate dehydrogenase (15,16); hexokinase (17); lactoylglutathione lyase, or glyoxalase I (15,18-20); methionine *S*-adenosyltransferase (21-24); ornithine decarboxylase (25,26); papain (27); platelet aggregation (28); prolyl monooxygenase (29); thiosulfate sulfurtransferase, or rhodanese (30,31); vacuolar H<sup>+</sup>-ATPase (32); xanthine dehydrogenase (33); xanthine oxidase (33). **1.** Siman-Tov & Anri (2003) *Parasitol. ### 2-Nitro-5-thiocyanatobenzoate

This moisture-sensitive reagent (FW<sub>free-acid</sub> = 224.20 g/mol; M.P. = 156–157°C) selectively cyanylates cysteinyl thiols in peptides and proteins, inhibiting enzymes with catalytically essential thiols. Note that these modified cysteinyl residues can be cleaved on the N-terminal side after incubation for a few hours at pH 9. Interestingly, although pig heart 3-oxoacid CoA-transferase is inactivated with this reagent, the thiol group is not catalytically essential. **Target(s):** acetolactate synthase (1); aspartate racemase (2); bifunctional regulatory protein of maize leaf pyruvate, orthophosphate dikinase (3); deoxyribonuclease I (4–6); glucosamine-1-phosphate *N*-acetyltransferase (7,8); glucose-6-phosphatase (9); glutamate racemase (10–12); glutathione synthetase (13); glyceraldehyde-3-phosphate dehydrogenase (14); NADPH:ferrihemoprotein reductase, or NADPH:cytochrome P450 reductase (15); nitrile hydratase (16); 2,3-oxidosqualene cyclase (17); 3-oxoacid CoA-transferase, or 3-ketoacid CoA-transferase, or succinyl-CoA:3-ketoacid CoA-transferase (18); pantetheine hydrolase (19); phosphoribulokinase (20); tryptophanase (21); UDP-*N* acetylmuramoylalanine:D-glutamate ligase (22). **1.** Shin, Chong, Chang & Choi (2000) *Biochem. ### Nitrosoureas

These agents (See *Nimustine*, *Carmustine* (BCNU), *Lomustine*, *Semustine*, *Ethyl nitrosourea*) are among the more active, if not the most active, anticancer drugs – both quantitatively (*e.g.*, the *in vivo* log[Kill] of sensitive tumor cells) and qualitatively (*e.g.*, spectrum of tumors responding to treatment), whether administered orally or parenterally. **Primary Mode of Inhibitory Action:** These agents are highly active against experimental meningeal leukemias and intracerebrally implanted transplantable primary tumors of CNS origin, including astrocytomas, ependymoblastomas, and gliomas. By their action on DNA, nitrosoureas often impart additive lethal toxicity when combined with other classes of anticancer agents, such as folate antagonists, purine antagonists, pyrimidine antagonists, DNA polymerase inhibitors, ribonucleotide reductase inhibitors, mitotic inhibitors, DNA intercalators, topoisomerase inhibitors, as well as other types of alkylating agents. The demonstrated lack of cross-resistance of several cancer types for resistance to nitrosoureas and other alkylating suggests these agents need not share a similar mode of inhibitory action, such that resistance to one alkylating is not predictive for cross-resistance to all alkylating agents (1). **DNA Alkylation Mechanism:** Alkyl-nitrosoureas are prodrugs that first must be hydroxylated by cytochrome P450 hydroxylases, followed by chemical rearrangement to generate the active methylating agent.

Only then may a base undergo *N*-alkylation or *O*-alkylation, as outlined in the following reaction scheme.

**Specificity/Selectivity of Nitrosourea Toxicity:** Although DNA modification appears to be the primary mode of nitrosourea cellular toxicity, the tissue- and cancer-type selectivity of drugs like Nimustine, Carmustine, Lomustine, Semustine, and Ethyl nitrosourea, appear to be determined by other factors. Thioredoxin reductase and glutathione reductase, for example, function as alternative electron donors for ribonucleotide reductase, and inhibition of these thiol-containing electron transfer proteins by nitrosoureas determines the availability of deoxynucleotide precursors needed for DNA synthesis. Calcium ion is also known to shield thioredoxin reductase from nitrosourea-mediated deactivation, and reduced thioredoxin is known to reactivate thioredoxin reductase and glutathione reductase by reducing and displacing nitrosoureas from their active sites. Cellular levels of glutathione are likewise a factor. Differences in the availability of calcium ion and reduced thioredoxin are likely to explain why certain cell types are more or less susceptible to nitrosoureas. The lipophilicity of some nitrosoureas also accounts for their ability to penetrate the blood-brain barrier, rendering them especially effective against the devastating cancers such as

glioblastoma multiforme. Moreover, the unique killing action of streptozotocin (another nitrosourea) on pancreatic  $\beta$ -cells is related to its structural resemblance to glucose, allowing it to gain access to these cells via the GLUT2 transporter. **Nitrosourea Resistance:** As is also true for the action of other alkylating agents (including busulfan, procarbazine, temozolomide, mercaptopurine, 6-thioguanine, Cisplatin, and carboplatin), mounting evidence indicates that tumors acquire resistance to nitrosoureas by loss of DNA-mismatch repair (MMR) activity and MMR-associated signal-transduction pathways causing programmed cell death (3). Other mutations in MMR-deficient tumors provide additional secondary phenotypes for drug resistance to other antineoplastic agents. The antitumor activity of bifunctional nitrosoureas, like BCNU, is based on their ability to form cytosine-guanine crosslinks, and resistance occurs when the enzyme, O<sup>6</sup>-alkylguanine-DNA alkyltransferase, repairs an intermediate in crosslink formation (4). Inhibition of this alkyltransferase often restores BCNU sensitivity, although other repair mechanisms may contribute to resistance. 1. Schabel (1976) *Cancer Treat Rep.* **60**, 665. 2. ### 5-Nitouracil

This uracil derivative (FW = 157.09 g/mol; CAS 611-08-5) is a strong inhibitor of ribonuclease and thymidine phosphorylase. **Target(s):** 4-aminobutyrate aminotransferase, weakly inhibited (1); (R)-3-amino-2-methylpropionate:pyruvate aminotransferase (2); isoorotate decarboxylase (3); NAD<sup>+</sup> ADP ribosyltransferase, or poly(ADP-ribose) polymerase, IC<sub>50</sub> = 0.43 mM (4); orotate phosphoribosyltransferase (5); pancreatic ribonuclease, or ribonuclease A (6); thymidine phosphorylase (7-10); thymine dioxygenase (11); UDP-glucuronosyltransferase (12); uracil phosphoribosyltransferase (13); uridine phosphorylase, K<sub>i</sub> = 56  $\mu$ M (14,15). 1. ### Nitrous Acid

This weak acid (FW = 47.01 g/mol; CAS 7782-77-6; pK<sub>a</sub> = 3.35 at 25°C) is known only in solution and gas phases, where it is produced by the action of strong acids on inorganic nitrites. (For example, nitrous acid can be formed by the reaction of sulfuric acid on barium nitrite, with the insoluble barium sulfate coproduct removed by precipitation.) Freshly prepared solutions of nitrous acid are pale blue in color. Nitrous acid solutions are unstable, disproportionating into nitric acid and nitric oxide. **Role in Diazotization:** Reaction of primary aromatic amines (Ar-NH<sub>2</sub>) with nitrous acid (the latter generated *in situ* by combining sodium nitrite with a strong acid, such as HCl, H<sub>2</sub>SO<sub>4</sub>, or HBF<sub>4</sub>) leads to the formation of diazonium salts (Ar-N<sup>+</sup>=N). Although diazonium salt formation occurs reasonably rapidly (on the 5–15 minute time-scale), the likely stepwise chemical scheme is surprisingly

elaborated, detailing all of the rearrangements, with protonation/deprotonation playing central roles.

The latter is a versatile synthetic intermediate for preparation of halides, azo compounds, and phenols. A classic example is the nitrous acid-mediated conversion of adenine to hypoxanthine. Note that intermediates resulting from the diazotization of primary, aliphatic amines are unstable, converting rapidly to carbocations, attended by loss of dinitrogen (N<sub>2</sub>). Nitrous acid also reacts with  $\alpha$ -amino groups in free amino acids, peptides, and proteins, resulting in deamination with release of dinitrogen (1). Note that  $\alpha$ -amino groups are more reactive than  $\epsilon$  amino groups. Other modifications include reaction with tryptophanyl and tyrosyl residues as well as reacting with sulfhydryl groups. Note that modification by nitrous acid does not necessarily result in enzyme inhibition. For example, asparaginase undergoes deamination yet retains its activity (2). (See also *Nitrite*; *Nitrate*; *Nitric Oxide*) **Target(s):** alkaline phosphatase (3,4);  $\beta$ -amylase (5-7); chymotrypsin (8); elastase (9);  $\beta$ -fructofuranosidase, or invertase (10,11); hurain, or cucumisin (12); papain (13); pepsin (14); thrombin (15-17); trypsin (18). 1. ### Nitrous Oxide

This colorless gas (FW = 44.013 g/mol; CAS 10024-97-2; M.P. = -90.91°C; B.P. = -88.46°C; Soluble in water, ethanol, and diethyl ether), also known as dinitrogen monoxide and laughing gas, is a linear molecule with two major resonance hybrids (see above). The dipole moment is 0.161 D. Cobalamin-dependent methionine synthases from both *Escherichia coli* and pig liver are irreversibly inactivated by N<sub>2</sub>O, with the latter generating hydroxyl radical. **Target(s):** Ca<sup>2+</sup>-transporting ATPase (1); CO-methylating acetyl-CoA synthase, or carbon monoxide dehydrogenase (2); homocysteine methyltransferase, or methionine synthase (3); 5-

methyltetrahydrofolate: homocysteine methyltransferase (3); nitrogenase (4); tetrachloroethene reductive dehalogenase (5,6). 1. Franks, Horn, Janicki & Singh (1995) *Anesthesiology* **82**, 108. 2. ### Nitroxyl

This triatomic molecule (FW = 31.014 g/mol; CAS 14332-28-6), also known as nitrosyl hydride, is a degradation product of a number of metabolites and synthetic donors (e.g., *N*-hydroxycyanamide, HONHCN). It can also be generated nonenzymatically from Angeli's salt ( $\text{Na}_2\text{N}_2\text{O}_3$ ) at physiological pH. **Chemical Reactivity:** Deprotonation of HNO is a slow spin-forbidden process that controls the observed chemistry in alkaline solutions. The simplest molecule with nitrogen in the +1 oxidation state, nitroxyl readily dimerizes and then disproportionates to form nitrous oxide and water. A frequently used source for aqueous HNO is sodium trioxodinitrate, also known as Angeli's salt, which is an HNO-releasing reagent (1). It is widely accepted that slow decomposition of the monoprotanated anion occurs through heterolytic N-N bond cleavage (Reaction:  $\text{HN}_2\text{O}_3^- \rightleftharpoons \text{HNO} + \text{NO}_2^-$ ). Nitroxyl is also oxidized by  $\text{O}_2$  to form peroxyxynitrite. Superoxide dismutase also produces nitric oxide from HNO, with the latter more cytotoxic than NO. (See also *Nitrosobenzene*)

**Aldehyde Dehydrogenase Inhibition:** Nitroxyl is a potent inhibitor of aldehyde dehydrogenase, or AIDH in a time- and concentration-dependent manner (2-4).  $\text{IC}_{50}$  values are 1.3 and 1.8  $\mu\text{M}$  under anaerobic conditions, with and without  $\text{NAD}^+$ , respectively (4). Benzaldehyde, a well-known AIDH substrate, competitively blocks nitroxyl inhibition in the presence of  $\text{NAD}^+$ , but not in its absence, a finding that fits with the ordered kinetic mechanism employed by this enzyme (4). Dithiothreitol (5 mM) and reduced glutathione (10 mM) also block inhibition of AIDH by Angeli's salt (1). They can also restore activity partially, with the extent of reactivation depending on the pH at which the inactivation occurs. The reversible form of the inhibited enzyme is thought to be an intra-subunit disulfide, and the irreversible form a sulfonamide. Both forms of the inhibited enzyme are derived via a common *N*-hydroxysulfenamide intermediate produced by the addition of nitroxyl to active site thiol(s) (4). **Target(s):** aldehyde dehydrogenase, irreversibly (2-4); aldehyde succinate dehydrogenase (5); nitric oxide synthase (6); papain (7); poly(ADPribose) polymerase (8). 1. ### Nivalenol

This mycotoxin and protein biosynthesis inhibitor (FW = 312.32 g/mol; CAS 23282-20-4), the toxic principle isolated from *Fusarium nivale*, is structurally related to T-2 toxin and should be handled with extreme care. 1. Ueno & Fukushima (1968) *Experientia* **24**, 1032. 2. Ueno, Hosoya, Morita, Ueno & Tatsuno (1968) *J. Biochem.* **64**, 479. 3. Ohtsubo, Yamada & Saito (1968) *Jpn. J. Med. Sci. Biol.* **21**, 185.

### Nivolumab

This fully humanized IgG4 antibody and PD-1 checkpoint inhibitor (MW = 143.6 kDa; CAS 946414-94-4), also known as BMS-936558, MDX1106 and Opdivo<sup>®</sup>, blocks ligand binding to Programmed Death-1 (PD-1), an immunologic checkpoint receptor on the surface of activated T-cells. When bound by Programmed Death Ligand-1 (PD-L1), T cells quiesce/die, limiting bystander tissue damage and preventing development of autoimmunity during an inflammatory response. Many cancer cell types make PD-L1, preventing T-cells from mounting an immune attack on tumors. Nivolumab binds to PD-1 with high affinity and specificity, and *in vitro* assays demonstrate its ability to enhance T-cell responses and cytokine production in mixed lymphocyte reaction and superantigen or cytomegalovirus-stimulation assays. No antibody-dependent cell-mediated or complement-dependent cytotoxicity is observed *in vitro*, when nivolumab and activated T cells are used as targets. Moreover, nivolumab treatment does not induce adverse events when given to cynomolgus macaques, even at high concentrations. Among previously untreated patients with metastatic melanoma, nivolumab alone or combined with ipilimumab resulted in significantly longer progression-free survival than ipilimumab alone (2). See *Ipilimumab* 1. Wang, Thudium, Han, et al. (2014) *Cancer Immunol. Res.* **2**, 846. 2. Larkin, Chiarion-Sileni, Gonzalez, et al. (2015) *New Engl. J. Med.* **373**, 23.

### Nizatidine

This anti-ulcerative agent (FW = 331.46 g/mol; CAS 76963-41-2) is a histamine  $\text{H}_2$  receptor antagonist that has been used to treat gastroesophageal reflux disease. **Target(s):** acetylcholinesterase, weakly inhibited (1,2); CYP3A (3); histamine  $\text{H}_2$  receptor (4). 1. ### NLG919

This potent, orally active IDO inhibitor (FW = 282.39 g/mol; CAS 1402836-58-1; Solubility: 56 mg/mL DMSO or Ethanol; <1 mg/mL  $\text{H}_2\text{O}$ ), also named  $\alpha$ -cyclohexyl-5*H*-imidazo[5,1-*a*]isoindole-5-ethanol, targets indoleamine-(2,3)-dioxygenase, with a  $K_i$  of 7 nM and  $\text{EC}_{50}$  of 75 nM (). The IDO pathway mediates immunosuppressive effects through the metabolic conversion of tryptophan (Trp) to kynurenine (Kyn), triggering downstream signaling through GCN2, mTOR and AHR and affecting T cell differentiation and proliferation. A single oral dose of NLG919 reduces the concentration of plasma and tissue Kyn by ~50%. Similarly, using IDO-expressing mouse DCs from tumor-draining lymph nodes, NLG919 abrogated IDO-induced suppression of antigen-specific T cells (OT-I) *in vitro*, with  $\text{ED}_{50}$  = 120 nM. 1. Mautino, Jaipuri, Waldo, et al. (2013) *Cancer Res.* **73**, Suppl. 1: Abstract 491.

**NLX104, See Avibactam**

**NMS-873**

This is an allosteric and specific ERAD inhibitor (FW = 520.67 g/mol; CAS 1418013-75-8), also known as 3-[3-(cyclopentylthio)-5-[[[2-methyl-4'-(methylsulfonyl)[1,1'-biphenyl]-4-yl]oxy]methyl]-4*H*-1,2,4-triazol-4-yl]pyridine, targets p97 (IC<sub>50</sub> = 30 nM), reducing its sensitivity to trypsin digestion. p97 (also known as VCP, or Cdc48p in yeast) is an AAA<sup>+</sup> ATPase that regulates endoplasmic reticulum-associated degradation (or ERAD). NMS-873 modulates ERAD, resulting in the formation of mislocalized polypeptides that are ubiquitinated and subsequently degraded as part of the Unfolded Protein Response (UPR). NMS-873 is an allosteric inhibitor that binds to a region spanning the D<sub>1</sub> and D<sub>2</sub> domains of adjacent p97 protomers, encompassing elements important for nucleotide-state sensing and ATP hydrolysis. **1.** Magnaghi, D'Alessio, Valsasina, *et al.* (2013) *Nature Chem. Biol.* **9**, 548.

**NMS-P715**

This oral ATP-competitive inhibitor (FW = 675.76 g/mol; CAS 1202055-34-2; IUPAC = *N*-(2,6-diethylphenyl)-1-methyl-8-({4-[(1-methylpiperidin-4-yl)carbamoyl]-2-(trifluoromethoxy)phenyl}amino)-4,5-dihydro-1*H*-pyrazolo[4,3-*h*]quinazoline-3-carboxamide) targets the mitosis-regulating protein kinase MPS1 (IC<sub>50</sub> = 180 nM, K<sub>i</sub> = 1 nM; reversible/time-dependent), causing cell death associated with impaired spindle assembly checkpoint (SAC) function and increasing chromosome mis-segregation (1). MPS1 kinases target chromosome attachment and spindle checkpoint, and, beyond mitosis, they have been implicated in development and cytokinesis (2). *In vitro* kinase assays of 60 kinases revealed that NMS-P715 is selective for MPS1, displaying activity against only three kinases (CK2, MELK, and NEK6), with IC<sub>50</sub> < 10 μM, but not against other mitotic kinases (e.g., PLK1, CDK1, Aurora A, and Aurora B) or the SAC kinase BUB1. NMS-P715 promotes massive SAC override, with an EC<sub>50</sub> of 65 nM, in nocodazole-arrested U20S cells, reducing the G<sub>1</sub> and G<sub>2</sub>/M phase of the cell cycle in A2780 ovarian cancer cells. NMS-P715 also inhibits the proliferation of select cancer cell lines (IC<sub>50</sub> ~ 1 μM), without noticeable effects on 127 normal cell lines. NMS-P715 (90 mg/kg/day) also inhibits growth of A2780 tumor xenograft in mice by 53% without marked loss of body weight. *In vitro* growth of human and murine pancreatic ductal adenocarcinoma (PDAC) cells is also inhibited by NMS-P715, whereas adipose-derived human mesenchymal stem cells are relatively resistant and maintain chromosome stability upon exposure to NMS-P715 (3). (See also *MPS1-IN-1* and *MPS1-IN-2*) **1.** Colombo, Caldarelli, Mennecozzi, *et al.* (2010) *Cancer Res.* **70**, 10255. **2.** Liu & Winey (2012) *Annu. Rev. **Nobiletin**

This citrus-derived hexamethoxyflavone (FW = 402.39 g/mol; CAS 478-01-3), also known as 2-(3,4-dimethoxyphenyl)-5,6,7,8-tetramethoxy-chromen-4-one, suppresses phorbol ester-induced expression of multiple scavenger receptor genes in THP-1 human monocytic cells. Nobiletin also induces G<sub>1</sub> cell cycle arrest, but not apoptosis, in human breast and colon cancer cells.

**Target(s):** cAMP phosphodiesterase (1); 15-lipoxygenase (2); mitogen-activated protein/extracellular signal-regulated kinase (or MEK) (3); P-glycoprotein (4,5); phenol sulfotransferase, or aryl sulfotransferase (6); tyrosinase, or monophenol monooxygenase (7,8). **1.** Nikaido, Ohmoto, Sankawa, Hamanaka & Totsuka (1982) *Planta Med.* **46**, 162. **2.** Malterud & Rydland (2000) *J. **Nociceptin**

This 17-residue opioid-related neuropeptide and potent anti-analgesic (FW = 1809.04 g/mol; CAS 170713-75-4; Sequence: FGGFTGARKSARKLA NQ), also known as Orphanin FQ, is the endogenous ligand for the nociceptin receptor NOP, or ORL-1. Nociceptin is derived from the pre-pro-nociceptin, the human gene for which is located on Ch8p21. While displaying some opioid-related peptide properties, nociceptin does not act at μ<sub>1</sub>, κ, and δ opioid receptors; moreover, its actions are not antagonized by the opioid antagonist naloxone. (See *Naloxone*) Nociceptin is widely distributed in the hypothalamus, brainstem, and forebrain, and both ventral and dorsal horns of the spinal cord.

**Nocodazole**

This cytotoxic carbamate (FW = 300.33 g/mol; CAS 31430-18-9), also known as methyl *N*-(5-[2-thienylcarbonyl]-1*H*-benzimidazol-2-yl) carbamate, reversibly inhibits tubulin polymerization and microtubule assembly. Nocodazole binds to the β-subunit of the αβ-heterodimer, promoting rapid microtubule disassembly, while also preventing self-assembly of nascent microtubules. Microtubules in interphase as well as early mitosis are especially susceptible to nocodazole. Cells treated with 30-40 μM nocodazole undergo cell-cycle arrest, accumulating in G<sub>2</sub>- and/or M-phase. Depending on the cell type, Golgi complexes are also dispersed when cells are similarly treated for several hours. Unlike high-affinity tubulin ligands (such as colchicine, vinblastine, or taxol), the action of nocodazole is reversible, and cells washed several times with nocodazole-free buffer will soon recover, displaying apparently normal microtubule arrays and Golgi location. When used in conjunction with thymidine, colcemid can be used to synchronize cells in a single division cycle. *N*-(7-

Nitrobenz-2-oxa-1,3-diazol-4-yl)-colcemid is a useful fluorescent probe for colcemid binding to tubulin (1). **Target(s):** glucose transport by GLUT4 (2); tubulin polymerization (3-6). 1. Hiratsuka & Kato (1987) *J. Biol. Chem.* **262**, 6318. 2. Molero, Whitehead, Meerloo & James (2001) *J. Biol. Chem.* **276**, 43829. 3. Rosenshine, Ruschkowski & Finlay (1994) *Meth. ### Nodularin

This toxic protein phosphatase 2A inhibitor (FW = 824.96 g/mol; CAS 118399-22-7) from the cyanobacterium *Nodularia spumigena* is a cyclic heptapeptide that contains D-glutamic acid (linked via an isopeptide bond), D-erythro- $\beta$ -methylaspartic acid, L-arginine, N-methyldehydrobutyryne (*i.e.*, 2-(methylamino)-2(Z) dehydrobutyric acid), and (2S,3S,8S,9S)-3-amino-9-methoxy-2,6,8-trimethyl-10-phenyldeca 4,6,-dienoic acid. This last amino acid (often referred to as Adda) is unique to nodularin, motuporin, and microcystins. Different forms of nodularin have been identified, differing in what is known as the variable residue (*i.e.*, the L-arginyl residue in nodularin R) as well as the degree of methylation and the stereochemistry. Motuporin, also known as nodularin-V, has L-valyl residue instead of an arginyl residue. There is a non-toxic nodularin isomer, usually occurring as a minor contaminant in nodularin samples, in which the double bond C6-C7 of Adda is in the *cis* configuration. Nodularin is a water-soluble hepatotoxin, which can persist in seawater well after the decay of the cyanobacteria. The process of nodularin degradation takes days or weeks, depending on conditions. On acute exposure, nodularin causes vomiting, nausea, sensation of cold-warm extremities, and anorexia. Liver damage follows if exposure to nodularin continues; in extreme cases, liver necrosis, coma, and death can occur. **Target(s):** phosphoprotein phosphatase (1-8); protein phosphatase 1 (1,2,5); protein phosphatase 2A (1-4,6,7); protein phosphatase 4 (7); protein phosphatase 5 (7). 1. Honkanen, Dukelow, Zwiller, *et al.* (1991) *Mol. Pharmacol.* **40**, 577. 2. Gullledgea, Aggena, Huangb, Nairnc & Chamberlin (2002) *Curr. Med. Chem.* **9**, 1991. 3. ### Nogalamycin

This intercalating anthracycline-based antibiotic (FW<sub>free-base</sub> = 787.82 g/mol; CAS 1404-15-5), produced by *Streptomyces nogalater*, inhibits DNA-directed RNA polymerase. **Target(s):** deoxyribonuclease (1); DNA-directed RNA polymerase (2-5); DNA helicase/ATPase (6-12); DNA topoisomerase I (13,14); nucleoside-triphosphatase (12); ribonuclease (1). 1. ### Nojirimycin

This sugar derivative (FW<sub>free-base</sub> = 179.17 g/mol; pK<sub>a</sub> = 5.3; CAS 15218-38-9), also called 5-amino-5-deoxy-D-glucopyranose, was isolated in 1966 from the culture broth of *Streptomyces roseochromogenes* R-468 and *S. lavendulae* SF-425, becoming the first 5-aminosugar found in nature. It was soon found to be a potent inhibitor of a number of  $\alpha$ - and  $\beta$ -glucosidases, presumably by mimicking the oxacarbenium ion intermediate formed during catalysis. This inhibitor is relatively unstable, owing to the presence of the hydroxyl group at the C<sub>1</sub> position, and should be stored as the bisulfite adduct. The reduced form, 1-deoxynojirimycin, is more stable and can be prepared from nojirimycin by reaction with sodium borohydride or by catalytic hydrogenation with platinum. 1-Deoxynojirimycin has also been found naturally. (See also 1-Deoxynojirimycin; N-Methyl-1-deoxynojirimycin; N-Nonyl-1-deoxynojirimycin) **Target(s):**  $\alpha$ -amylase (1); amylo- $\alpha$ -1,6-glucosidase/4- $\alpha$ -glucanotransferase, or glycogen debranching enzyme (2,3); cellobiose phosphorylase (4,5); dextranucrase (19); glucan 1,3- $\beta$  glucosidase (6);  $\alpha$ -glucosidase (1,7,8,18);  $\beta$ -glucosidase (2,8-14); glycoprotein processing (1,7,15); mannosyl oligosaccharide glucosidase, or glucosidase I (15,16); sucrose  $\alpha$ -glucosidase, or sucrase (17);  $\beta$  xylosidase/ $\beta$ -glucosidase (4). 1. ### Nojirimycin 6-Phosphate

This nojirimycin derivative (FW = 179.17 g/mol; CAS 116026-31-4) is a mechanism-based inactivator of rabbit muscle phosphoglucosyltransferase. The phosphorylated form of the enzyme catalyzes the phosphorylation of nojirimycin 6-phosphate at the C<sub>1</sub> hydroxyl, and this intermediate rapidly eliminates orthophosphate to form an imine and the dephosphorylated enzyme. The dephosphorylated enzyme is then rephosphorylated by the D-glucose 1,6-bisphosphate cofactor, concomitantly forming D-glucose 6-phosphate. The imine is nonenzymatically hydrated back to nojirimycin 6-phosphate. Occasionally (*i.e.*, ~5% of the times), the imine isomerizes to a compound that is not processed by PGM. 1. Kim & Raushel (1988) *Biochemistry* 27, 7328.

### Nolatrexed

This novel lipophilic and orally active antineoplastic antifolate (FW = 284.34 g/mol; CAS 147149-76-6), also known as AG-337, Thymitaq™, and 2-amino-6-methyl-5-(4-pyridylthio)-1*H*-quinazolin-4-one, inhibits thymidylate synthase (1,2), inducing by S-phase arrest, biphasic mitochondrial alterations, and caspase-dependent apoptosis in leukemia cells (3). Lipophilic inhibitors should gain entry in ways that are independent of the reduced folate carrier transporter (RFC) for uptake, allowing them to avoid resistance arising from impaired RFC. 1. Tong, Liu-Chen, Ercikan-Abali, *et al.* (1998) *J. Biol. Chem.* 273, 11611. 2. Webber, Bleckman, Attard, *et al.* (1993) *J. Med. Chem.* 36, 733. 3. Sakoff & Ackland (2000) *Cancer Chemother. Pharmacol.* 46, 477.

### Nomifensine

This antidepressant (FW<sub>free-base</sub> = 238.33 g/mol; CAS 89664-20-0 (free base) and 32795-47-4 (maleate salt)), also known as 1,2,3,4-tetrahydro-2-methyl-4-phenyl-8-isoquinolinamine, binds to the dopamine transporter at a site that is topologically distinct from that for cocaine. Nomifensine has an intravenous LD<sub>50</sub> of 72 mg/kg in rats. **Target(s):** amine oxidase (1-3); dihydropteridine reductase (4); dopamine transporter (5-7). 1. Obata & Yamanaka (2000) *Neurosci. Lett.* 286, 131. 2. Egashira, Takayama & Yamanaka (1999) *Jpn. J. Pharmacol.* 81, 115. 3. Izumi, Togashi, Hayakari, Hayashi & Ozawa (1976) *Tohoku J. Exp. Med.* 118, 223. 4. Shen, Sheng & Abell (1984) *J. Pharm. Pharmacol.* 36, 411. 5. Dembiec-Cohen (1998) *J. Neural. Transm.* 105, 735. 6. Meiergerd & Schenk (1994) *J. Neurochem.* 63, 1683. 7. Ehsanullah & Turner (1977) *Brit. J. Clin. Pharmacol.* 4 Suppl. 2, 159S.

### Nonactin

This ionophoric antibiotic (FW = 736.94 g/mol; CAS 6833-84-7), produced by certain strains of *Streptomyces*, is a neutral ionophoric homologue of monactin. When present at or above 10<sup>-7</sup> M, nonactin binds to membranes and transports monovalent cations, particularly potassium and ammonium ions. Nonactin's selectivity is: NH<sub>4</sub><sup>+</sup> > K<sup>+</sup> ≈ Rb<sup>+</sup> > Cs<sup>+</sup> > Na<sup>+</sup> (1-3).

**Target(s):** adenylate cyclase (4); oxidative phosphorylation, as an ionophoric uncoupler (1,3,5); photophosphorylation, as an ionophoric uncoupler (3). 1. Pressman (1976) *Ann. Rev. Biochem.* 45, 501. 2. Haynes & Pressman (1974) *J. Membr. Biol.* 18, 1. 3. Izawa & Good (1972) *Meth. Enzymol.* 24, 355. 4. Kuo & Dill (1968) *Biochem. Biophys. Res. Commun.* 32, 333. 5. Graven, Lardy, Johnson & Rutter (1966) *Biochemistry* 5, 1729.

### Nonoxynols

These nonionic detergents (CAS 26027-38-3), which differ only in their degree of polymerization, are frequently employed to solubilize membrane-bound or membrane-associated enzymes. Nonoxynol-9 (CAS 20427-84-3), which has an average of nine repeating ethoxy groups, is an especially effective spermicide solubilizes acrosin, a protease released from the sperm acrosome to cleave egg surface glycoproteins, thereby facilitating fertilization. (See also *Nonadet P-40*) 1. Muller-Esterl & Schill (1982) *Andrologia* 14, 309.

### N-Nonyl-1-deoxynojirimycin

This sugar analogue (FW = 289.42 g/mol; CAS 81117-35-3) inhibits processing α-glucosidases and is also highly effective in inhibiting hepatitis B virus and bovine viral diarrhea virus in cell-based assays. Viral DNA replication is also inhibited. It is believed that N-nonyl-1-deoxynojirimycin prevents the proper encapsidation of the viral pregenomic RNA. In addition, N-nonyl-1-deoxynojirimycin can act as a chemical chaperone. Gaucher disease is a lysosomal storage disorder caused by deficient lysosomal β-glucosidase. The presence of this inhibitor in fibroblast culture medium leads to a two-fold increase in the activity of N370S β-glucosidase, the most common mutation causing Gaucher disease. It has been proposed that this inhibitor chaperones β-glucosidase folding, stabilizes the enzyme in transit from the endoplasmic reticulum to the Golgi, and enables proper trafficking to the lysosome. **Target(s):** α-glucosidase (1,2); α-glucosidase I, or mannosyl-oligosaccharide α-glucosidase I (2); α-glucosidase II, mannosyl-oligosaccharide α-glucosidase II (2); α-1,6-glucosidase (1); β-glucosidase (3); glucosylceramidase, or ceramide glucosyltransferase (4,5). 1. Andersson, Reinkensmeier, Butters, Dwek & Platt (2004) *Biochem. Pharmacol.* 67, 697. 2. Mellor, Neville, Harvey, *et al.* (2004) *Biochem. J.* 381, 867. 3. Mellor, Neville, Harvey, *et al.* (2004) *Biochem. J.* 381, 861.

### 2-n-Nonyl-4-hydroxyquinoline-N-oxide

This quinoline derivative (FW = 287.40 g/mol; *Abbreviations:* NOQNO or NQNO) inhibits mitochondrial and chloroplast electron transport. It is more effective than 2-n-heptyl-4-hydroxyquinoline-N-oxide, albeit ten-times less soluble. **Target(s):** cytochrome *bo*<sub>3</sub> ubiquinol oxidase complex, *Escherichia coli* (1); electron transport, chloroplast (2); electron transport,

mitochondrial (3-8); sulfide:quinone reductase (9-11); ubiquinol: cytochrome-*c* reductase, or Complex III (3-6,12,13). 1. Musser, Stowell, Lee, Rumbley & Chan (1997) *Biochemistry* **36**, 894. 2. ### S-(3-Nonynoyl)-*N*-acetylcysteamine

This acylated acyl-carrier protein analogue (FW = 255.38 g/mol), also known as *N*-acetylcysteamine 3 nonynoate thioester, inhibits 3-hydroxydecanoyl-[acyl-carrier-protein] dehydratase within the fatty acid synthase complex. 1. Bloch (1971) *The Enzymes*, 3rd ed., **5**, 441. 2. Helmkamp, Rando, Brock & Bloch (1968) *J. Biol. Chem.* **243**, 3229.

### Norartocarpetin

This flavone (FW = 286.24 g/mol; CAS 520-30-9), isolated from the wood of *Artocarpus heterophyllus*, inhibits tyrosinase, or monophenol monooxygenase (IC<sub>50</sub> = 0.46 μM). 1. Zheng, Cheng, To, Li & Wang (2008) *Mol. Nutr. Food Res.* **52**, 1530. 2. Likhitwitayawuld, Sritularak & De-Eknamkul (2000) *Planta Med.* **66**, 275. 3. Ryu, Ha, Curtis-Long, *et al.* (2008) *J. Enzyme Inhib. Med. Chem.* **23**, 922.

### Norbuprenorphine, See Buprenorphine

### Norcantaridin

This orally bioavailable cantharidin analogue (FW = 168.15 g/mol; CAS 29745-04-8; Symbol: NCTD) also known as 7-oxabicyclo[2.2.1]heptane-2,3-dicarboxylic anhydride, is the demethylated derivative of cantharidin. (As a cyclic carboxylic anhydride, one would anticipate NCTD would indiscriminantly modify many enzymes and proteins via nucleophilic displacement.) NCTD inhibits phosphoprotein phosphatase-2A, or PP2A, an enzyme that regulates the restriction point and G<sub>2</sub> and M stages of the cell cycle (1). Daily intraperitoneal injection induces dose- and circadian time-dependent transient leukocytosis in normal mice, without accelerating bone marrow (BM) regeneration. NCTD stimulates the cell cycle progression of granulocyte-macrophage colony-forming cells (GM-CFC), increasing DNA synthesis and the frequency of mitosis in short-term human BM cultures. NCTD also stimulates the production of interleukin IL-1β, colony-stimulating activity (CSA) and tumor necrosis factor TNFα (1). Norcantaridin inhibits HeLa cell growth in a time- and dose-dependent manner, showing characteristic apoptotic morphological changes and DNA

fragmentation (2). Caspase family inhibitor (z-VAD-fmk), caspase-8 inhibitor (z-IETD-fmk), caspase-9 inhibitor (Ac-LEHD-CHO), and caspase-3 inhibitor (z-DEVD-fmk) partially prevent norcantharidin-induced apoptosis, but initiator caspase-1 inhibitor (Ac-YVAD-fmk) will not (2). In the DU145 prostate cancer cell line, NCTD induces the degradation of Cdc6, an essential initiation protein for DNA replication, impairing pre-replication complex assembly and inhibiting DNA replication (3). **Target(s):** arylamine *N*-acetyltransferase (4); protein-serine/threonine phosphatases 1, 2A, and 2B (5-7). 1. Liu, Blazsek, Comisso, *et al.* (1995) *Eur. J. Cancer* **31A**, 953. 2. An, Gong, Wang, *et al.* (2004) *Acta Pharmacol. Sin.* **25**, 1502. 3. Chen, Wan, Ding, *et al.* (2013) *Int. J. Mol. ### Nordihydroguaiaretic Acid

This bis(benzenediol) (FW = 302.37 g/mol; CAS 500-38-9) is a strong lipoxygenase inhibitor that is often used as an antioxidant in foods. The *meso*-form occurs naturally in the creosote bush (*Larrea divaricata*). Nordihydroguaiaretic acid is soluble in ethanol and diethyl ether and slightly soluble in hot water. (See also *Heminordihydroguaiaretic Acid*) **Target(s):** 1-alkylglycerophosphocholine *O*-acetyltransferase (26,27); aryl hydrocarbon monooxygenase, or cytochrome P450 (1); ascorbate oxidase (2); carboxylesterase (3); β-carotene (15,16); monooxygenase (29); carotene oxidase (4); catechol *O*-methyltransferase (28); electron transport (5); 9-*cis*-epoxycarotenoid dioxygenase (30,31); 7-ethoxyresorufin *O*-deethylase activity, or cytochrome P450 (1); fatty-acid synthase (25); formyltetrahydrofolate synthetase (3); glucuronosyltransferase (6); hyaluronoglucosaminidase, or hyaluronidase (7); hydroperoxide dehydratase (8,9); K<sup>+</sup> and Ca<sup>2+</sup> channels, voltage-sensitive (10,11); linoleate diol synthase (32); lipoxygenase (12-14,48-54); 5-lipoxygenase, or arachidonate 5-lipoxygenase (15,34-37); 8-lipoxygenase, arachidonate 8-lipoxygenase (33); 12-lipoxygenase, arachidonate 12-lipoxygenase (36,39,40,45-47); 15-lipoxygenase, arachidonate 15-lipoxygenase (38-44); myosin ATPase (16); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (17); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (18); phospholipase A<sub>2</sub> (19,20); respiratory burst (21); steroid 5α-reductase (22); taurine channel, swelling-activated, ATP-sensitive (23); vesicle-mediated protein transport (24). 1. ### Norepinephrine

This photosensitive adrenergic neurotransmitter and vasodilator (FW<sub>free-base</sub> = 169.18 g/mol; CAS 51-41-2), also known as noradrenaline, L-(–)-norepinephrine, and 4 [(1R)-2-amino-1-hydroxyethyl]-1,2-benzenediol, is an agonist for adrenoceptors and the immediate precursor to epinephrine. Norepinephrine is a product of the dopamine β monoxygenase reaction. Note that the amino group has a pK<sub>a</sub> value of 8.64, while one of the phenolic groups has a pK<sub>a</sub> value of 9.70. **Target(s):** alanine aminotransferase, weakly inhibited (1); aldehyde oxidase (2); aromatic-L amino-acid decarboxylase, *or* dopa decarboxylase (3,4); carnosine synthetase (5); catechol O-methyltransferase, product inhibition (6); diacylglycerol cholinephosphotransferase (7); dihydropteridine reductase (8,9); ethanolamine phosphotransferase (7); glutamate decarboxylase, weakly inhibited (1); glutamate dehydrogenase (10); γ-glutamylhistamine synthetase (11); 5-lipoxygenase, *or* arachidonate 5-lipoxygenase (30); phenol sulfotransferase, *or* aryl sulfotransferase (12); phenylalanine 4-monooxygenase (13-15); phenylethanolamine N-methyltransferase (16); procollagen lysine 5-dioxygenase (17); pyridoxal kinase (18); L-serine dehydratase (1); sulfinoalanine decarboxylase, *or* cysteinesulfinate decarboxylase (19); tyrosine aminotransferase (1,20,21); tyrosine 3-monooxygenase (22-29); xanthine oxidase (2). **1.** Pestaña, Sandoval & Sols (1971) *Arch. ### Norfloxacin

This fluoroquinolone (FW<sub>free-acid</sub> = 319.34 g/mol; CAS 70458-96-7) is an orally absorbed antibacterial agent that is structurally related to nalidixic acid, but with fluorine at position-6 and a piperazine ring at position-7. These two changes markedly enhance the *in vitro* antibacterial activity. The antibacterial spectrum includes *Pseudomonas aeruginosa* as well as enteric pathogens. Norfloxacin is also active against both penicillin-susceptible and penicillin resistant strains of *Neisseria gonorrhoeae*. **Primary Mode of Action:** The mechanism of action of norfloxacin involves inhibition of the A subunit of DNA gyrase, which is essential for bacterial DNA replication. The inhibition of DNA gyrase reportedly occurs as a result of binding to a site, which appears after the formation of a gyrase-DNA complex. **Target(s):** CYP1A2 (1); DNA gyrase, *or* DNA topoisomerase II (2-7). **1.** Kinzig-Schippers, Fuhr, Zaigler, *et al.* (1999) *Clin. Pharmacol. Ther.* **65**, 262. **2.** Landini, Pagani, Debiaggi, Cereda & Romero (1989) *Microbiologica* **12**, 247. **3.** Shen, Kohlbrenner, Weigl & Baranowski (1989) *J. Biol. ### Norharmaline

This indole derivative (FW = 168.20 g/mol; CAS 244-63-3), also known as 9H-pyrido[3,4-b]indole and β-carboline, is an alkaloid that modulates the activity of a number of oxidases. **Target(s):** S-adenosylmethionine decarboxylase (1); aldehyde oxidase (2,3); benzodiazepine receptor (4); cholesterol-5,6-oxide hydrolase (5); CYP1A (6); CYP2E1 (7); DNA topoisomerase I (6,8); IκB kinase (9); indoleamine 2,3-dioxygenase (10-14); monoamine oxidase A15; monoamine oxidase B16; NAD<sup>+</sup> ADP-ribosyltransferase, *or* poly(ADP-ribose) polymerase, weakly inhibited (17); steroid 11β-monooxygenase (18); steroid 17α-monooxygenase (18). **1.** Lapinjoki & Gynther (1986) *Biochem. ## Norisoboldine

This alkaloid (FW = 313.35 g/mol; CAS 23599-69-1; *Symbol*: NOR) from *Radix linderiae* significantly suppresses synovial angiogenesis by selectively inhibiting endothelial cell migration via a cAMP-PKA-NF- $\kappa$ B/Notch1 signaling pathway (1). NOR markedly suppresses VEGF-induced intracytoplasmic cAMP production and PKA activation and thereby down-regulating the activation of downstream components of the PKA pathway, including src tyrosine kinase, the actin filament motor component VASP, and eNOS, as well as the transcription factor NF- $\kappa$ B. The transcription activation potential of NF- $\kappa$ B is reduced by NOR. NOR selectively inhibits expression of p-p65 (ser276), but not p-p65 (ser536) or PKAc, indicating that PKAc participates in the regulation of NF- $\kappa$ B by NOR. Simulation of ligand docking suggests that NOR affinity for PKA is likely to be higher than that of the original PKA ligand (1). Norisoboldine also suppresses osteoclast differentiation, most likely by preventing the accumulation of TRAF6-TAK1 complexes and the activation of MAPKs/NF- $\kappa$ B/c-Fos/NFATc1 pathways (2). 1. Lu, Tong, Luo, *et al.* (2013) *PLoS One* 8, e81220. 2. Wei, Tong, Xia, *et al.* (2013) *PLoS One* 8, e59171.

## Norleucine

This leucine/isoleucine/methionine analogue (FW = 131.17 g/mol; CAS 327-56-0;  $pK_a$  values of 2.34 and 9.81; Solubility: 1.5 g/100 mL H<sub>2</sub>O at 25°C; insoluble in ethanol; *Abbreviation*: Ahx or Nle), also known as 2-aminohexanoic acid and  $\alpha$ -aminocaproic acid, is a lysine deamination product and, as such, is found in collagen. Norvaline substitutes for methionine in protein biosynthesis. **Target(s)**: alanine aminotransferase, by L-enantiomer (1); arginase, weakly inhibited (2); homocitrate synthase, by L-enantiomer (3); insulin release (4); lipid methylation (5); membrane alanyl aminopeptidase, microsomal aminopeptidase (6); methionine  $\gamma$ -lyase, by L-enantiomer (7,8); methionyl aminopeptidase, by L-enantiomer (9); methionyl-tRNA synthetase, also alternative substrate (10); ornithine carbamoyltransferase (11,12); saccharopine dehydrogenase (13); tRNA (uracil-5-)-methyltransferase, weakly inhibited (14). 1. ## 19-Nortestosterone

This controlled substance (FW = 274.40 g/mol; CAS 434-22-0;  $\lambda_{max}$  at 241 nm;  $\epsilon = 1700 \text{ M}^{-1} \text{ cm}^{-1}$ ), also called nandrolone and 17 $\beta$ -hydroxyestr-4-en-3-one, has a higher anabolic activity than testosterone. **Target(s)**:

[pyruvate dehydrogenase (acetyl-transferring)] kinase,  $IC_{50} = 120 \mu\text{M}$  (1); steroid  $\Delta$ -isomerase ( $K_i = 13 \mu\text{M}$  (2-7); steroid 5 $\alpha$ -reductase (8). 1. 11-Nor- $\Delta^9$ -tetrahydrocannabinol-9-carboxylate

This nonpsychoactive plant isoprenoid (FW<sub>free-acid</sub> = 344.45 g/mol), also called  $\Delta^9$ -tetrahydrocannabinol-7-oic acid, is a major  $\Delta^9$ -tetrahydrocannabinol (THC) metabolite in most species, including humans and is likely responsible for the well-known analgesic properties of THC. It also exhibits antinociceptive properties. **Target(s)**: cyclooxygenase; 5-lipoxygenase; platelet activating factor. 1. Burstein, Audette, Doyle, *et al.* (1989) *J. Pharmacol. Exp. Ther.* 251, 531.

## Nortriptyline

This antidepressant (FW<sub>free-base</sub> = 263.38 g/mol; CAS 72-69-5) is a serotonin receptor antagonist that preferentially inhibits norepinephrine uptake. **Key Pharmacokinetic Parameters**: See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s)**: acetylcholinesterase, *Electrophorus electricus* (1);  $\gamma$ -aminobutyrate transport (2); bufuralol L'-hydroxylase (3); CYP2C11 (4,5); CYP2D6 (6); norepinephrine uptake (7-10); serotonin, or 5-hydroxytryptamine, receptor (11). 1. ### Noscapine

This opium alkaloid (FW<sub>free-base</sub> = 413.43 g/mol; CAS 128-62-1; triboluminescent solid that forms unstable salts with acids and strong bases), known also as narcosine, narcotine and gnoscopine (*dl*-noscapine) from the plant *Papaver somniferum* is reduces microtubule assembly/disassembly dynamics, thereby arresting mitosis, inducing apoptosis, and exerting potent antitumor activity. 1. Landen, Lang, McMahon, *et al.* (2002) *Cancer Res.* **62**, 4109.

### Nosiheptide

This branched polypeptide antibiotic (FW = 1222.38 g/mol; CAS 56377-79-8), also known as multithiomycin, from *Streptomyces actuosus* binds to bacterial ribosome-associated elongation factors Tu and G<sub>1</sub>, thereby inhibiting protein biosynthesis. 1. Cundliffe & Thompson (1981) *J. Gen. Microbiol.* **126**, 185. 2. Lentzen, Klinck, Matassova, Aboul-ela & Murchie (2003) *Chem. Biol.* **10**, 769.

### Novobiocin

This photosensitive aminocoumarin antibiotic (FW = 612.63 g/mol; CAS 303-81-1;  $\lambda_{\text{max}}$  = 307 nm (0.1N NaOH),  $\lambda_{\text{max}}$  = 324 nm (0.1N CH<sub>3</sub>OH/HCl; E<sub>1%,1-cm</sub> = 390);  $\lambda_{\text{max}}$  = 390 nm (pH 7); E<sub>1%,1-cm</sub> = 350), from *Streptomyces spheroides* and *S. niveus*, also named 4-hydroxy-3-[4-hydroxy-3-(3-methylbut-2-enyl)benzamido]-8-methylcoumarin-7-yl 3-*O*-carbamoyl-5,5-di-*C*-methyl- $\alpha$ -L-lyxofuranoside, is a competitive inhibitor of ATP binding to topoisomerase II, thereby blocking DNA synthesis. Aminocoumarins are potent inhibitors of bacterial DNA gyrase, targeting the GyrB subunit.

**Target(s):** CDP-glycerol glycerophosphotransferase (3,35); CDP-ribitol ribitolphosphotransferase, *or* teichoic acid synthase (4); CYP3A (5); DNA ligase (ATP), *Vaccinia* virus (6); DNA-directed DNA polymerase (7); DNA polymerase  $\alpha$  (7); DNA topoisomerase I (8-11); DNA topoisomerase II, *or* DNA gyrase (9,12-23); F<sub>1</sub> ATP synthase, yeast (24); glycyl-tRNA synthetase (25); leucyl-tRNA synthetase (25); NAD<sup>+</sup> ADP-ribosyltransferase, *or* poly(ADP-ribose) polymerase (37); NAD<sup>+</sup>:protein-arginine ADP-ribosyltransferase, *or* arginine-specific mono-ADP ribosyltransferase (1,2,36); nucleolar ATPase (26); oxidative phosphorylation, uncoupling (27); RNA directed DNA polymerase, *or* reverse transcriptase (7,28,29); RNA polymerase (30-32); self-splicing of transcripts of the T<sub>4</sub> phage thymidylate synthase gene (39);  $\alpha,\alpha$ -trehalose-phosphate synthase, UDP-forming (38); UDP-glucuronosyltransferase (5,33); undecaprenyldiphospho muramoyl-pentapeptide  $\beta$ -*N*-acetylglucosaminyltransferase, weakly inhibited (34). 1. **Noxiustoxin**

This arachnid toxin (MW = 4201.95 g/mol; *Sequence*: TIINVKCTSPK QCSKPCKELYGSSAGAKCMNGKCKCYNN-NH<sub>2</sub>) from the predatory Mexican scorpion *Centruroides noxius* is a powerful blocker of lymphocyte voltage-dependent K<sup>+</sup> channels (K<sub>i</sub> ≈ 2 nM), but is without effect on Ca<sup>2+</sup>-activated K<sup>+</sup> channels. Synthetic peptide NTX10-20 (corresponding to residues 10-20 of noxiustox) showed remarkable preference for the IA K<sup>+</sup> current of cerebellum granular cells, using the patch-clamp technique in whole-cell assay (3). 1. **NS 1619**

This benzimidazolone (FW = 362.23 g/mol), also named 1,3-dihydro-1-[2-hydroxy-5-(trifluoromethyl)phenyl]-5-(trifluoromethyl)-2*H*-benzimidazol-2-one, is a selective large conductance Ca<sup>2+</sup>-activated K<sup>+</sup>-channel activator and an inhibitor of mitochondrial electron transport. 1. Debska, Kicinska, Dobrucki, *et al.* (2003) *Biochem. Pharmacol.* **65**, 1827.

**NSC 23766**

This Rac GTPase inhibitor (FW<sub>free-base</sub> = 427.62 g/mol; FW<sub>tri-HCl</sub> = 530.96 g/mol; CAS 1177865-17-6; Solubility: 100 mg/mL DMSO, 100 mg/mL H<sub>2</sub>O), also known as *N*<sup>6</sup>-[2-[[4-(diethylamino)-1-methylbutyl]amino]-6-methyl-4-pyrimidinyl]-2-methyl-4,6-quinolinediamine, targets activation of Rac by guanine nucleotide exchange factors (*or* GEFs), displaying an IC<sub>50</sub> of ~50 μM, with no inhibition of such structurally related targets as Cdc42 or RhoA (See also *EHop-016*). NSC23766 was identified by a structure-based virtual screening of compounds that fit into a surface groove of Rac1 known to be critical for GEF specification (1,2). *In vitro*, it effectively inhibits Rac1 binding and activation by the Rac-specific GEF Trio or Tiam1 in a dose-dependent manner, without interfering with the closely related Cdc42 or RhoA binding or activation by their respective GEFs or with Rac1 interaction with BcrGAP or effector PAK1 (1). In cells, NSC23766 potently blocked serum or platelet-derived growth factor-induced Rac1 activation and lamellipodia formation without affecting the activity of endogenous Cdc42 or RhoA (1). Blockade of Rac1 activity by NSC23766 induces G<sub>1</sub> cell-cycle arrest or apoptosis in breast cancer cells through downregulation of cyclin D<sub>1</sub>, survivin, and X-linked inhibitor of apoptosis protein (3). Although LPS challenge leads to increases of both Rac1 and Rac2, (but not

CDC42 or RhoA) activities in lungs, intraperitoneal administration with NSC23766 inhibited both Rac1 and Rac2, but not CDC42 or RhoA activities (4). Treatment with NSC23766 at 1 or 3mg/kg not only reduced the inflammatory cells infiltration and MPO activities, but also inhibited pro-inflammatory mediators, tumor necrosis factor- $\alpha$  and interleukin-1 $\beta$ , mRNA expression. Moreover, *in vitro* neutrophil migration assay and *in vivo* microvascular permeability assay indicates that NSC23766 not only inhibits neutrophil transwell migration toward the chemoattractant fMLP, but also reduces Evans Blue and albumin accumulation in LPS-challenged lungs (4). NSC23766 inhibition of Rac1 also impairs replication of a wide variety of influenza viruses, including a human virus strain of the pandemic from 2009 as well as highly pathogenic avian virus strains (5). These and other findings identified a crucial role of Rac1 for the activity of the viral polymerase complex, and the antiviral potential of NSC23766 was confirmed in mouse experiments, identifying Rac1 as a new cellular target for therapeutic treatment of influenza virus infections (5). 1. Gao, Dickerson, Gao, Zheng & Zheng (2004) *Proc. Natl. Acad. Sci. U.S.A.* **101**, 7618. 2. Akbar, Cancelas, Williams, Zheng & Zheng (2006) *Meth. Enzymol.* **406**, 554. 3. Yoshida, et al. **NSC 66811**

This p53/MDM2 antagonist/inhibitor (FW = 340.42 g/mol; CAS 6964-62-1; Solubility: 25 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 2-methyl-7-[phenyl(phenylamino)methyl]-8-quinolinol, targets Mouse Double Minute-2 (MDM2), also known as E<sub>3</sub> ubiquitin-protein ligase that recognizes the N-terminal trans-activation domain of the p53 tumor suppressor, inhibiting p53 transcriptional activation (IC<sub>50</sub> = 120  $\mu$ M). NSC 66811 binds MDM2 in the p53-binding pocket, leading to cell cycle arrest, apoptosis, and growth inhibition of human tumor xenografts in nude mice (1,2). NSC 66811 mimics three p53 residues critical in the binding to MDM2. 1. Lu, Nikolovska-Coleska, Fang, et al. (2006) *Med. Chem.* **49**, 3759. 2. Shangary & Wang (2009) *Annu. Rev. Pharmacol. Toxicol.* **49**, 223.

**NSC 405020**

This cell-permeable MT1-MMP inhibitor (FW = 260.16 g/mol; CAS 7497-07-6; Solubility: 52 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 3,4-dichloro-N-(1-methylbutyl)benzamide, does not directly bind to the active site to alter catalysis, but instead binds to a subunit-subunit interaction site within the PEX domain of MT1-MMP, thereby blocking PEX homo-

dimerization. **Mode of Action:** Most matrix metalloproteinases (MMPs inhibitors) target the conserved active site and consequently inhibit multiple MMPs instead. The MT1-MMP, however, contains a hemopexin domain (PEX) that is distinct from and additional to the catalytic domain, making it an ideal druggable target. NSC 405020 only weakly inhibits MT1-MMP (IC<sub>50</sub> = 100  $\mu$ M), suggesting it is best suited for *in vitro* experiments or as a lead molecule for developing higher affinity agents. 1. Remacle, Golubkov, Shiryaev, et al. (2012) *Cancer Res.* **72**, 2339.

**NSC 407290**, See *Myricetin*

**NSC 609699**, See *Topotecan*

**NSC624206**

This disulfide-containing ubiquitin pathway inhibitor (FW = 389.08 g/mol) specifically blocks (IC<sub>50</sub> = 9  $\mu$ M) ubiquitin-thioester formation in the E<sub>1</sub> activation reaction, without any effect on ubiquitin adenylation, thus defining a promising new way for limiting excessive ubiquitin-mediated proteolysis *in vivo*. NSC524206 is believed to react with ubiquitin ligase E<sub>1</sub>-SH to form E<sub>1</sub>-S-S-(CH<sub>2</sub>)<sub>9</sub>-NH-(CH<sub>2</sub>)<sub>9</sub>-CH<sub>3</sub> with the release of *p*-chlorobenzyl thiol. Treatment of Kip16 cells with 3  $\mu$ M of NSC524206 for 24 h results in a uniform stabilization of the tumor suppressor protein p27. (See also *PYR-41*) 1. Ungermannova, Parker, Nasveschuk, et al. (2012) *J. Biomol. Screen.* **17**, 421.

**NSC 630176**, See *Romidepsin*

**NSC 632839**

This deubiquitylase (DUB) and deSUMOylase inhibitor (FW = 339.86 g/mol; CAS 157654-67-6), also named 3,5-bis[(4-methylphenyl)methylene]-4-piperidinone, targets USP2 (IC<sub>50</sub> = 45  $\mu$ M), USP7 (IC<sub>50</sub> = 37  $\mu$ M), and SENP2 (IC<sub>50</sub> = 10  $\mu$ M). Deconjugation of ubiquitin (Ub) or ubiquitin-like proteins (UBL) from proteins is performed by a specific class of isopeptidases. Small ubiquitin-like modifier (SUMO) are removed by sentrin/SUMO-specific proteases (SENPs), the first known class of deSUMOylase. NSC 632839 was identified on the basis of its ability to initiate a Bcl-2-dependent but apoptosome-independent pathway of caspase activation. DUBs have been divided into five distinct subfamilies based on structural similarities and mechanisms of action and include a large group of enzymes that are mainly cysteine proteases. The pharmacophore NSC 632839 should inhibit cysteine proteases, but all of the targets are still unknown (2). Interestingly, prostaglandin  $\Delta^{12}$ -PGJ2 holds the same pharmacophore and similarly induces apoptosis *via* accumulation of polyubiquitinated proteins (3, 4), and  $\Delta^{12}$ -PGJ2 has been suggested to inhibit UCH-L1 and UCH-L3 at micromolar concentrations (5). 1. Nicholson, Leach, Goldenberg, et al. (2008) *Protein Sci.* **17**, 1035. 2. Aleo, Henderson, Fontanini, Solazzo & Brancolini (2006) *Cancer Res.* **66**, 9235. 3. Mullally & Fitzpatrick (2002) *Mol. ## NT219

This novel, long-lasting and highly efficient inhibitor (FW = 412.25 g/mol) targets the insulin/IGF signaling pathway and protects against age-onset, neurodegeneration-linked proteotoxicity of the sort observed in Alzheimer's and Huntington's Diseases. Prior studies suggested that reducing the activity of the insulin/IGF signaling cascade (IIS), a highly conserved aging-regulating pathway, elevates stress resistance, thereby extending the lifespans of worms, flies, and mice. NT219 efficiently blocks IGF1R to AKT signaling in mammalian cells by (a) reducing IGF1-induced phosphorylation and by activating AKT, directing IRS1/2 for inhibitory serine-phosphorylation and degradation and (b) by increasing expression of FOXO target genes in mammals. **1.** El-Ami, Moll, Carvalho Marques, *et al.* (2013) *Aging Cell* **13**, 165.

## NU6027

This potent ATR/CDK inhibitor (FW = 251.29 g/mol; CAS 220036-08-8; Solubility: 50 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as 6-(cyclohexylmethoxy)-5-nitroso-2,4-pyrimidinediamine, targets Cyclin-Dependent Kinases CDK1 ( $K_i = 2.5 \mu\text{M}$ ) and CDK2 ( $K_i = 1.3 \mu\text{M}$ ) as well as ATR ( $K_i = 0.4 \mu\text{M}$ ) and DNA-PK ( $K_i = 2.2 \mu\text{M}$ ), entering cells more readily than well-known 6-aminopurine-based inhibitors (1,2). NU6027 exerts its cytotoxicity by interfering with the DNA damage response (DDR), for which ATR is a major regulator. This inhibitor shows >600-fold selectivity over related kinases ATM or DNA-PK, and markedly enhances death induced by DNA-damaging agents in certain cancers, but not in normal cells. This differential response highlights the great potential for ATR inhibition as a druggable target to increase dramatically the efficacy of many established DNA-damaging drugs and ionizing radiation (2). NU6027 inhibits ATR, resulting in G<sub>2</sub>/M arrest, inhibition of homologous recombination, and increasing sensitivity to DNA-damaging agents and PARP inhibitors (3). **1.** Arris, Boyle, Calvert, *et al.* (2000) *J. Med. Chem.* **43**, 2797. **2.** Charrier, Durrant, Golec, *et al.* (2011) *J. Med. Chem.* **54**, 2320. **3.** Peasland, Wang, Rowling, *et al.* (201) *Br. J. Cancer.* **105**, 372.

## NU7441

This selective, ATP-competitive, DNA-PK inhibitor (F.Wt. = 413.49; CAS 503468-95-9; Solubility (25°C): 3 mg/mL DMSO, <1 mg/mL Water), also known as KU-57788 and 8-(4-dibenzothienyl)-2-(4-morpholinyl)-4H-1-benzopyran-4-one, inhibits DNA-dependent protein kinase, a trimeric nuclear serine/threonine kinase composed of a large catalytic subunit and

two DNA-targeting proteins (1, 2). NU7441 potentiates the apoptotic and/or toxic effects of radiation, doxorubicin, and etoposide in human tumor cell lines *in vitro* and etoposide in a human tumor xenograft model *in vivo* (3). **Targets:** DNA-PK (IC<sub>50</sub> = 14 nM); mTOR (IC<sub>50</sub> = 1.7 μM); PI<sub>3</sub>-K (IC<sub>50</sub> = 5 μM); ATM (IC<sub>50</sub> = 100 μM); and ATR (IC<sub>50</sub> = 100 μM). **1.** Leahy, *et al.* (2004) *Bioorg. Med. Chem. Lett.* **14**, 6083. **2.** Zhao, *et al.* (2006) *Cancer Res.* **66**, 5354. **3.** Willmore, *et al.* (2008) *Clin. Cancer Res.* **14**, 3984.

## Nucleocidin

This purine antibiotic (FW = 364.31 g/mol; CAS 24751-69-7), produced by *Streptomyces calvus*, has been used as an antitrypanosomal agent. The first naturally occurring fluoro-sugar identified, nucleocidin has a potency that exceeds puromycin, making it one of the most potent inhibitors of translation. **Target(s):** adenosylhomocysteinase (1); protein biosynthesis (2). **1.** Chiang (1987) *Meth. Enzymol.* **143**, 377. **2.** Florini, Bird & Bell (1966) *J. Biol. Chem.* **241**, 1091.

## Nucleoside diphosphate kinase

This ubiquitous transphosphorylase (EC 2.7.4.6) is a hexameric enzyme that catalyzes the interconversion nucleoside 5'-di- and tri-phosphates (*Reaction:* NDP + YTP  $\rightleftharpoons$  NTP + YDP), possesses a single nucleotide binding site and employs an active-site histidyl residue to preserve group transfer potential as a phosphoryl-enzyme intermediate. Beyond its role in the balanced synthesis of nucleotide triphosphates as well as nucleic acids, proteins and nucleotidylated sugars and lipids, NDPK isoforms play regulatory functions in diverse cellular processes, including proliferation and endocytosis. Although it plays a positive regulatory role in clathrin- and dynamin-mediated micropinocytosis, NDPK also alters growth, endocytosis and exocytosis. In *Dictyostelium*, NDPK negatively regulates endocytosis, contrasting with its positive regulatory role in higher eukaryotes. micropinocytosis in mammalian cells. **1.** Annesley, Bago, Bosnar *et al.* (2011) *PLoS One* **6**, e26024.

## Nutlin-3b

This p53/MDM2 antagonist/inhibitor (FW = 581.49 g/mol; CAS 675576-97-3) targets Mouse Double Minute-2 (MDM2), also known as E<sub>3</sub> ubiquitin-protein ligase that recognizes the N-terminal trans-activation domain of the p53 tumor suppressor, inhibiting p53 transcriptional activation (IC<sub>50</sub> = 13.6 μM). Nutlin-3b binds MDM2 in the p53-binding pocket and activates the p53 pathway in cancer cells, leading to cell cycle arrest, apoptosis, and growth inhibition of human tumor xenografts in nude mice. **1.** Vassilev, Vu, Graves, *et al.* (2004) *Science* **303**, 844.

**NVP 231**

This CerK inhibitor (FW = 431.55 g/mol; CAS 362003-83-6; Soluble: 100 mM in DMSO and to 5 mM in ethanol), also named *N*-[2-(benzoylamino)-6-benzothiazolyl]tricyclo[3.3.1.1<sup>3,7</sup>]-decane-1-carboxamide, selectively and reversibly targets ceramide kinase (IC<sub>50</sub> = 12 nM, *in vitro*), displaying 8000x selectivity versus sphingosine kinases (IC<sub>50</sub> ≥ 100 μM) and other lipid kinases. 1. Graf, *et al.* (2009) *Mol. Pharmacol.* **74**, 925. 2. Niwa, *et al.* (2009) *Microvasc. Res.* **77**, 389.

**NVP CXCR2 20**

This orally bioavailable and potent CXCR2 antagonist (FW = 319.33 g/mol; CAS 1029521-30-9; Soluble to 50 mM in DMSO), systematically named 4-cyclopropyl-2-[[[2,3-difluorophenyl)methyl]thio]-1,6-dihydro-6-oxo-5-pyrimidinocarbonitrile, selectively targets the chemokine CXCR2 receptors (IC<sub>50</sub> = 40 nM), which are G-protein-coupled seven-transmembrane domain receptors that are found on the surface of leukocytes. NVP CXCR2 20 exhibits selectivity over a panel of 49 other GPCRs. 1. Porter, Bradley, Brown, *et al.* (2014) *Bioorg. Med. Chem. Lett.* **24**, 3285.

**N-WASP Inhibitor**

This cyclic tetradecapeptide inhibitor (MW = 1784.13; Sequence: *cyclo*-(L-Lys-D-Phe-D-Pro-D-Phe-L-Phe-D-Pro-L-Gln)<sub>2</sub>; CAS 380488-27-7; Store desiccated at -20°C) binds to Neural Wiskott-Aldrich Syndrome Protein (N-WASP), thereby stabilizing its autoinhibited and blocking (IC<sub>50</sub> ~ 2 μM) phosphatidylinositol 4,5-bisphosphate- (PIP<sub>2</sub>-) stimulated actin cytoskeletal assembly. Notably, N-WASP inhibitor is without any direct inhibitory effect on the polymerization of pure G-actin. 1. Peterson *et al.* (2001) *Proc. Natl. Acad. Sci. USA* **98**, 10624. 2. This *Streptomyces*-derived antifungal antibiotic (FW<sub>free-base</sub> = 926.11 g/mol for nystatin A<sub>3</sub>; CAS 1400-61-9), most often composed of three active components (designated A<sub>1</sub>, A<sub>2</sub>, and A<sub>3</sub>) are polyene derivatives that bind to ergosterol, an essential fungal cell component. By forming transmembrane ion pores, treatment results in fungal death, making nystatin an effective fungicide. Nystatin is used prophylactically in patients at risk for fungal infections, especially those with HIV AIDS who have a low CD4<sup>+</sup>. Patients undergoing chemotherapy similarly require nystatin. For nystatin-sensitive fungi, the minimal inhibitory concentration is typically 1.5-7 μg/mL, often attended by resultant loss of cations (*e.g.* K<sup>+</sup>, Na<sup>+</sup>, and H<sup>+</sup>) as well as other low-molecular-weight substances, including sugars, amino acids and nucleotides. **Applications in Neurophysiologic Experiments:** Nystatin increases membrane conductance of *Aplysia* neurons in a dose-dependent manner, with little or no effect <10 μM, but with effects too large to measure at concentrations >20 μM (1). Upon return to antibiotic-free solution, membrane conductance returned to pre-treatment levels within 30 minutes. When ion-specific microelectrodes are used, it is possible to record changes of intracellular univalent ion activities that attend nystatin-induced permeability. Changes in permeability mainly involve univalent cations, but chloride ion permeability also increases. Nystatin may therefore be used to selectively rearrange the cell's internal ionic milieu to study the effect of such changes on membrane transport, electrical properties, or metabolic processes. For example, while conventional recording methods, using either KCl or CsCl in the patch pipet, reveal *N*-methyl-D-aspartate (NMDA) currents of neocortical neurons to be biphasic (consisting of peak and steady-state currents with similar reversal potentials), recordings with the nystatin-perforated patch method and KCl as the principal intracellular cation disclosed an NMDA-evoked outward current (2). **Target(s):** alkaline phosphatase, weakly inhibited (3); chitin synthase (4); dimethylpropiothetin dethiomethylase (5); sterol 24-C-methyltransferase, slightly inhibited, activates at high concentrations (6). 1. ### O-1918

This endocannabinoid antagonist (FW = 286.42 g/mol; CAS 536697-79-7), systematically named 1,3-dimethoxy-5-methyl-2-[(1*R*,6*R*)-3-methyl-6-(1-methylethenyl)-2-cyclohexen-1-yl]benzene, is a cannabidiol analogue that selectively targets a putative G-coupled endothelial anandamide receptor that is distinct from CB<sub>1</sub> or CB<sub>2</sub> endocannabinoid receptors. O-1918 does not bind to CB<sub>1</sub> or CB<sub>2</sub> receptors and does not cause vasorelaxation at concentrations up to 30 μM, but inhibits the vasorelaxant effects of abn-cbd and anandamide in a concentration-dependent manner (1–30 μM). (See *abn-cbd; Anandamide; Oleamide*). While the atypical cannabinoids O-1602 and abn-cbd (*or* abnormal cannabidiol) stimulate GPR55-dependent GTPγS activity (EC<sub>50</sub> ~ 2 nM), O-1918 antagonizes such effects (1). O-1918 is involved in the delayed hypotension induced by anandamide in anesthetized rats (2). 1. Johns, Behm, Walker, *et al.* (2007) *Brit. J. Pharmacol.* **152**, 825. 2. Zakrzewska, Schlicker, Baranowska, *et al.* (2010) *Brit. J. Pharmacol.* **160**, 574.

### O-2093

This anandamide uptake inhibitor (FW = 584.62 g/mol; CAS 439080-01-0), also named *N*-(bis-3-chloro-4-hydroxybenzyl)-5*Z*,8*Z*,11*Z*,14*Z*-eicosatetraenamide, exhibits an IC<sub>50</sub> of 17.3 μM, with little or no activity detected at cannabinoid receptors CB<sub>1</sub> and CB<sub>2</sub>, Transient receptor potential subfamily V member-1 cation channel (TrpV1), and Fatty Acid Amide Hydrolase, *or* FAAH (also known as oleamide hydrolase and anandamide amidohydrolase). It shows anti-spastic activity in a mouse model of multiple sclerosis. 1. Di Marzo, *et al.* (2002) *J. Pharmacol. Exp. Ther.* **300**, 984. 2. Ligresti, *et al.* (2006) *Brit. J. Pharmacol.* **147**, 83.

OAA, See *Oxaloacetate (Oxaloacetic Acid)*

### OBAA

This potent PLA inhibitor (FW = 428.65 g/mol; CAS 221632-26-4; Soluble to 10 mM in DMSO with gentle warming), also named 4-(4-octadecylphenyl)-4-oxobutenoic acid, targets phospholipase A<sub>2</sub> (IC<sub>50</sub> = 70 nM). OBAA is a mechanism-based inhibitor, showing a typical time-dependence as well as a molar inactivation ratio of twenty OBAA hydrolyzed per molecule of irreversibly inactivated enzyme (1). Double-reciprocal replots of the apparent inactivation constants versus OBAA concentration gave a (pseudo) first-order rate constant of inactivation of 2.3 min<sup>-1</sup> and a dissociation constant of 6 × 10<sup>-6</sup> M<sup>-1</sup> for the enzyme-inhibitor intermediate (1). OBAA reduces bronchospasm in guinea pigs *in vivo* (2). 1. Köhler, Heinisch, Kirchner, *et al.* (1992) *Biochem. Pharmacol.* **44**, 805. 2.

Madi, Giessler, Hirschelmann, Friedrich, Braquet (1991) *Agents Actions* **32**, 144.

### Obatoclax

This cell-permeable antiapoptotic agent (FW<sub>free-base</sub> = 317.39 g/mol; FW<sub>mesylate-salt</sub> = 413.49 g/mol; CAS 803712-79-0; Solubility: 83 mg/mL DMSO, also known as GX15-070 and (Z)-2-(5-((3,5-dimethyl-1*H*-pyrrol-2-yl)methylene)-4-methoxy-5*H*-pyrrol-2-yl)-1*H*-indole mesylate, is a pan-Bcl-2 antagonist (K<sub>i</sub> = 0.22 μM), binding to the BH3-binding groove of the B-cell lymphoma-2 (*i.e.*, Bcl) family of proteins (1). Bcl-2 proteins confer a protective effect on malignant cells against death signals of apoptosis, and cancer cells that are resistant to various anti-cancer drugs and treatment regimen are often found to overexpress these Bcl-2, Bcl-X<sub>L</sub>, Mcl-1, Bcl-w, and A1/Bfl1. Obatoclax inhibits the binding of Bak to Mcl-1, up-regulating Bim, inducing cytochrome *c* release, and activating capase-3 in human myeloma cell lines (1). Acting as a single agent, it also induces potent cytotoxic responses against diverse patient-derived neoplasias, including multiple myeloma (1). Obatoclax retains its efficacy in cells overexpressing the P-glycoprotein multidrug-resistance transporter (P-gp), multidrug resistance-associated protein 2 (MRP2), or breast cancer resistance protein (BCRP) and might also act as a perpetrator drug in interactions with drugs, for example being substrates of CYP1A2 or BCRP (2). In human pharmacokinetic experiments, Obatoclax has C<sub>max</sub> of 10 to 80 ng/mL, below the level needed for effective *in vitro* activity against most tumor targets, a finding that is consistent with its failure to reach levels in a mouse xenograft tumor model sufficient to disrupt Mcl-1/Bax protein-protein interaction (3). 1. Trudel, Li, Rauw, *et al.* (2007) *Blood* **109**, 5430. 2. Theile, Allendorf, Köhler, Jassowicz & Weiss (2015) *J. Pharm. Pharmacol.* **67**, 1575. 3. Azmi & Mohammad (2009) *J. ### Obeticholate (Obeticholic Acid)

This semisynthetic bile acid analogue (FW = 420.63 g/mol; CAS 459789-99-2), also named INT-747, 6α-ethyl-chenodeoxycholate, and (3α,5β,6α,7α)-6-ethyl-3,7-dihydroxycholan-24-oic acid, is an analogue (1) of the naturally occurring bile acid (FW = 392.57 g/mol; CAS 474-25-9). The latter is synthesized in the liver, where it conjugated to form taurochenodeoxycholate and glycol-chenodeoxycholate, reducing its pK<sub>a</sub> and increasing retention in the gastrointestinal tract, until reabsorption by the ileum. Chenodeoxycholate is the most active physiological ligand known for the farnesoid X receptor, *or* FXR (encoded by the *NR1H4* gene in humans) that translocates to the nucleus, dimerizes, and binds to hormone response elements (2). Obeticholic acid reduces bacterial translocation and invasion in cirrhotic rats by restoring intestinal barrier integrity (through increased expression of tight junction proteins) and by inhibiting inflammation (3). Obeticholate likewise up-regulated expression of the FXR-associated gene small heterodimer partner (SHP). 1. Gioiello, Macchiarulo, Carotti, *et al.* (2011) *Bioorg. Med. Chem.* **19**, 2650. 2. Forman, Goode, Chen, *et al.* (1995) *Cell* **81**, 687. 3. Ubeda, Lario, Muñoz, *et al.* (2015) *J. Hepatol.* **64**, 1049.

### Obiltoximab

This anti-anthrax therapeutic (MW = 145.5 kDa; CAS 1351337-07-9; Trade Name = Anthim<sup>®</sup>) is an FDA-approved mouse/human chimeric monoclonal antibody that binds to protective antigen (K<sub>d</sub> = 0.3 nM), blocking the latter's

interaction with host cell anthrax receptor, which mediates the translocation of lethal factor [LF] and edema factor into the host cell cytoplasm (**See Anthrax Lethal Toxin**). Anthim is recommended for the treatment (when combined with antibacterial drugs, such as levofloxacin, ciprofloxacin and doxycycline) and prophylactically (when used alone) treat inhalational anthrax (*i.e.*, exposure to *Bacillus anthracis* spores. Obiltoximab was been designed to neutralize the free protective antigen of *B. anthracis*, thereby inhibiting the lethal effects of anthrax toxins. Inasmuch as it would be unethical to conduct clinical trials in humans with clinically induced inhalational anthrax, Anthim's efficacy was evaluated in NZW rabbits and cynomolgus macaques. **See also** *JMV 390-1* 1. Greig (2016) *Drugs* 76, 823.

### Obtustatin

This 41-residue disintegrin (FW = 4401 g/mol; *Sequence* CTTGPCCRQCKLKPAAGTTCTCWKTSLSLTSHTSYCTGKSCDCLPYPG, with disulfide bonds at Cys1-Cys10, Cys6-Cys29, Cys7-Cys34, and Cys19-Cys36) from the venom of the blunt-nosed viper *Vipera lebetina obtusa* exhibits tight binding to integrins (1), inhibiting platelet aggregation, IC<sub>50</sub> = 2 nM (2). It is the shortest polypeptide to contain an integrin-recognition loop. **Target(s)**: Obtustatin is a highly potent integrin α<sub>v</sub>β<sub>3</sub> inhibitor (IC<sub>50</sub> = 0.8 nM for α<sub>v</sub>β<sub>3</sub> binding to type IV collagen), displaying specificity for α<sub>v</sub>β<sub>3</sub> over α<sub>2</sub>β<sub>1</sub>, α<sub>11b</sub>β<sub>3</sub>, α<sub>4</sub>β<sub>3</sub>, α<sub>4</sub>β<sub>1</sub>, α<sub>5</sub>β<sub>6</sub>, α<sub>9</sub>β<sub>1</sub> and α<sub>4</sub>β<sub>7</sub>. 1. Marcinkiewicz, Weinreb, Calvete, *et al.* (2003) *Cancer Res.* 63, 2020. 2. Moreno-Murciano, Monleon, Calvete, Celda & Marcinkiewicz (2003) *Protein Sci.* 12, 366.

### OC252-324

This highly constrained pseudo-tetrapeptide (FW<sub>inner-salt</sub> = 541.65 g/mol) defines a new allosteric binding site (*n*<sub>Hill</sub> = 2) that is located near the center of *Escherichia coli* fructose-1,6-bisphosphatase, showing uncompetitive inhibition. Binding is synergistic with both AMP and fructose 2,6-bisphosphate. OC252-324 contact with three of four subunits of the tetramer, hydrogen bonding with the side chain of Asp-187 and the backbone carbonyl of Residue-71, and electrostatically interacting with the backbone carbonyl of Residue-51. 1. Choe, Nelson, Arienti, *et al.* (2003) *J. Biol. Chem.* 278, 51176.

### Ochratoxins

These mycotoxins, produced by *Aspergillus ochraceus* and certain other fungi, are calcium ion modulators frequently found in decaying vegetables and grain. The major component is ochratoxin A (FW<sub>free-acid</sub> = 403.82 g/mol;

CAS 303-47-9), also known as (*R*)-*N*-[(5-chloro-3,4-dihydro-8-hydroxy-3-methyl-1-oxo-1*H*-2-benzopyran-7-yl)carbonyl]-L-phenylalanine. It has a green fluorescence and induces differentiation in cloned renal cell lines. It also promotes free radical formation, lipid peroxidation, and stimulates Ca<sup>2+</sup>-exporting ATPase activity in the endoplasmic reticulum. Ochratoxin B is less toxic than Ochratoxin A and has a blue fluorescence. Ochratoxin C is the ethyl ester of A. **Target(s)**: electron transport, mitochondrial (1-3); mitochondrial respiration (1-3); phenylalanine monooxygenase (4); phenylalanyl-tRNA synthetase (1,5-9); protein biosynthesis (10-12); succinate: cytochrome *c* reductase (2); succinate dehydrogenase (2); succinate oxidase (2). 1. ### Oclacitinib

This JAK family inhibitor (FW = 453.51 g/mol; CAS 1640292-55-2; Solubility: 90 mg/mL DMSO; 18 mg/mL H<sub>2</sub>O), also named Apoquel and *N*-methyl-4-(methyl-7*H*-pyrrolo[2,3-*d*]pyrimidin-4-ylamino)cyclohexane-methane sulfonamide and, targets Janus Kinases (JAK1, 10 nM; JAK2, 18 nM; JAK3, 99 nM; TYK2, 84 nM), inhibiting the function of JAK1-dependent cytokines involved in allergy and inflammation (IL-2, IL-4, IL-6, and IL-13) as well as pruritus (IL-31). Oclacitinib had minimal effects on cytokines that did not activate the JAK1 enzyme in cells (erythropoietin, granulocyte/macrophage colony-stimulating factor, IL-12, IL-23; IC<sub>50</sub> values greater than 1000 nM). These results demonstrate that oclacitinib is a targeted therapy that selectively inhibits JAK1-dependent cytokines involved in allergy, inflammation, and pruritus and suggests these are the mechanisms by which oclacitinib effectively controls clinical signs associated with allergic skin disease in dogs. Apoquel is FDA-approved for canine allergic dermatitis, including flea allergy dermatitis, food allergy, atopic dermatitis, and contact dermatitis. **Other Targets**: (% Inhibition at 1 μM): ABL tyrosine kinase, 13%; RAC-α serine/threonine kinase (Protein kinase B), 3%; ZAP-70 tyrosine kinase, 10%; Angiotensin 1 receptor (TIE-2) (TEK), 3%; Aurora-related kinase 1 (ARK1), 40%; Ste20-like kinase MST2, 18%; SRC kinase, 17%; Serum glucocorticoid-regulated kinase (SGK1), 14%; p160ROCK protein kinase, 33%; Protein kinase C β II Isoform, 7%; Protein kinase A α, 17%; Serine/threonine protein kinase PIM-2, 9%; PAK-4 (p21 activated kinase 4), 13%; High-affinity nerve growth factor receptor (TRK-A), 31%; Serine/threonine protein kinase NEK2, 3%; Myosin light chain kinase (skeletal), 6%; Serine/threonine protein kinase MASK, 4%; Hepatocyte growth factor receptor (MET Proto-oncogene tyrosine kinase), 15%; Serine/threonine protein kinase MARK, 42%; MAP kinase activated protein kinase 2 (MAPKAPK-2), 3%; Mitogen-activated protein kinase 1 (MAPK1/ERK2), 8%; Mitogen-activated protein kinase kinase 4 (MAP4K4/HGK), 38%; Proto-oncogene LCK tyrosine kinase, 22%; Vascular Endothelial Growth Factor Receptor 2 (VEGFR-2/FLK1), 39%; Tyrosine-protein kinase JAK3 (JANUS KINASE 3), 95%; Insulin receptor, 5%; Glycogen Synthase Kinase-3 β (GSK-3β), 8%; FGF Receptor-1 (FGFR1), 10%; Ephrin type-A Receptor 2 (ECK), 5%; Epidermal growth factor receptor, 8%; Casein Kinase II α prime chain (CK II), 5%; Casein Kinase-1, α, 1%; Checkpoint kinase (CHK2), 7%; Checkpoint kinase CHK1, 14%; CDK2/Cyclin-A, 10%; Calcium/calmodulin-dependent protein kinase II α-B subunit, 18%; Bruton's tyrosine kinase (BTK), 7%; TAO Kinase-2, 10%; Mitogen-Activated Protein Kinase-14 (MAPK14/P38-α), 8%. 1. Gonzales, Bowman, Fici, *et al.* (2014) *J. Vet. Pharmacol. Ther.* 37, 317.

**Ocrelizumab**

This second-generation humanized anti-CD20 monoclonal antibody and CD20 antagonist (MW = 148 kDa; CAS 637334-45-3), also named Ocrevus<sup>®</sup>, targets mature B lymphocytes, making it a highly effective, FDA-approved immunosuppressive drug for the treatment of Primary Progressive Multiple Sclerosis (PPMS). **Mode of Action:** B cells are known to play central roles in MS pathogenesis (*e.g.*, activation of proinflammatory T cells, secretion of proinflammatory cytokines, as well as production of anti-myelin autoantibodies). CD20 (also called B-lymphocyte antigen CD20) is an activated-glycosylated phosphoprotein of unknown function that is expressed on the surface of all B-cells, beginning at the pro-B phase (CD45R<sup>+</sup>, CD117<sup>+</sup>), with its concentration increasing progressively until maturity. Compared with placebo, two doses of Ocrevus (600 and 2000 mg on days 1 and 15) show a pronounced effect on disease activity seen in MRI as gadolinium-enhanced lesions and also has a significant effect on relapses. Other CD20-targeting drugs include ofatumumab, hA20, and TRU-015, again mainly acting to deplete B cells. 1. Sorensen & Blinksberg (2016) *Ther. Adv. Neurol. Disord.* **9**, 44.

**9Z,11E-Octadecadienoate**

This unsaturated fatty acid (FW<sub>free-acid</sub> = 280.45 g/mol), also known as *cis*<sup>9</sup>,*trans*<sup>11</sup>-conjugated linoleic acid, inhibits linoleoyl-CoA Desaturase (*Reaction:* Linoleoyl-CoA + AH<sub>2</sub> + O<sub>2</sub> ⇌  $\gamma$ -Linolenoyl-CoA + A + 2 H<sub>2</sub>O, where AH<sub>2</sub> is the electron acceptor) (1,2) and stearyl-CoA 9-desaturase (*Reaction:* Stearyl-CoA + 2 Ferrocyclochrome *b*<sub>5</sub> + O<sub>2</sub> + 2 H<sup>+</sup> ⇌ Oleoyl-CoA + 2 Ferricyclochrome *b*<sub>5</sub> + 2 H<sub>2</sub>O) (3). 1. Chuang, Leonard, Liu, *et al.* (2001) *Lipids* **36**, 1099. 2. Chuang, Thurmond, Liu, *et al.* (2001) *Lipids* **36**, 139. 3. Choi, Park, Storkson, Pariza & Ntambi (2002) *Biochem. Biophys. Res. Commun.* **294**, 785.

**9-Octadecanyl Sulfate**

This lipid sulfate (FW<sub>free-acid</sub> = 350.56 g/mol) is allosteric competitive inhibitor of the intrinsic phosphatase activity of soluble epoxide hydrolase (IC<sub>50</sub> = 4.7  $\mu$ M). Intriguingly, soluble epoxide hydrolase (sEH) is a homodimeric enzyme. Each monomer contains a C-terminal domain with epoxide hydrolase activity that is involved in the metabolism of arachidonic acid epoxides, endogenous chemical mediators that play important roles in blood pressure regulation, cell growth, and inflammation. The N-terminal domain, however, contains a Mg<sup>2+</sup>-dependent lipid phosphate phosphatase activity. 1. Tran, Aronov, Tanaka, *et al.* (2005) *Biochemistry* **44**, 12179.

**9Z-Octadecen-12-ynoate**

This linoleic acid analogue (FW<sub>free-acid</sub> = 278.44 g/mol), also known as 9Z-octadecen-12-ynoic acid, inhibits linoleate isomerase (1) and inactivates soybean lipoxygenase (2). 1. Kepler, Tucker & Tove (1970) *J. Biol. Chem.* **245**, 3612. 2. Nieuwenhuizen, Van der Kerk-Van Hoof, van Lenthe, *et al.* (1997) *Biochemistry* **36**, 4480.

**Octadecylamine**

This long-chain aliphatic amine (FW<sub>free-base</sub> = 269.51 g/mol; CAS 124-30-1), also known as stearylamine and 1-aminooctadecane, is a cationic detergent

that inhibits numerous enzymes at relatively low concentrations. Stearylamine can be considered a structural analogue of sphingosine. **Target(s):** 2-acylglycerol O-acyltransferase, *or* monoacyl-glycerol O-acyltransferase (1); glucosylceramidase (2); [myosin light-chain] kinase (3); NADPH oxidase (4); phosphatidyl-glycerophosphatase (5); phosphatidylinositol diacylglycerol-lyase, *or* phosphatidylinositol-specific phospholipase C (6); phospholipase A<sub>2</sub> (7); phospholipase D (8); protein kinase C (8); protein-tyrosine sulfotransferase (9). 1. **1-O-Octadecyl-2-O-methyl-sn-glycero-3-phosphocholine**

This phosphatidylcholine/lysophosphatidylcholine analogue (FW = 523.73 g/mol), also known as edelfosine and ET-18-OCH<sub>3</sub>, is an antiproliferative agent that is cytotoxic to transformed cells both *in vitro* and *in vivo*. It induces apoptosis in HeLa and HL-60 cells and is a noncompetitive inhibitor of phosphatidylinositol 3-kinase (IC<sub>50</sub> = 35  $\mu$ M). **Target(s):** arachidonoyl-CoA:1-acyl-*sn*-glycero-3-phosphocholine acyltransferase (1); asialomucin-sialyltransferase (2); choline-phosphate cytidylyltransferase, *or* CTP: phosphocholine cytidylyltransferase; inhibited by the racemic compound)3-5; glycerophospholipid arachidonoyltransferase (CoA-independent), IC<sub>50</sub> = 0.5  $\mu$ M (6); phosphoinositide phospholipase C, *or* phosphatidylinositol-dependent phospholipase C (7,8); phosphatidylinositol 3-kinase (9); phospholipase C (7,10); protein kinase C (11). 1. **R-3,4-Octadienoyl-CoA**

This unusual thiolester (FW<sub>free-acid</sub> = 889.71 g/mol) inhibits medium-chain acyl-Coenzyme A dehydrogenase, rapidly undergoing inhibition, with a stoichiometry of two mol racemate per mol enzyme-bound flavin. Synthesis of *R*- and *S*-3,4-decadienoyl-CoA shows that the *R*-enantiomer is the inhibitor.  $\alpha$ -Proton abstraction yields an enolate to oxidized flavin charge-transfer intermediate prior to adduct formation. Crystal structure data on the reduced, inactive enzyme shows a single covalent bond linking the C-4 carbon of the 2,4-dienoyl-CoA moiety and the N5 locus of reduced flavin. The kinetics of reversible adduct formation, with release of the conjugated 2,4-diene, were evaluated as a function of both acyl chain length and truncation of the CoA moiety. The adduct is most stable with medium chain length allenic inhibitors. However, the adducts with *R*-3,4-decadienoyl-pantetheine and *N*-acetylcysteamine are some 9- and >100-fold more kinetically stable than the full-length CoA thioester. Crystal structures of these reduced enzyme species, determined to 2.4 Å, suggesting the placement of H-bonds to the inhibitor carbonyl oxygen and the positioning of the catalytic base are important determinants of adduct stability. While not an inhibitor, the *S*-isomer is rapidly isomerized to the *trans-trans*-2,4-conjugated diene. Protein modeling suggests the *S*-enantiomer cannot approach close enough to the isoalloxazine ring to form a flavin adduct, but

can be easily reprotonated by the catalytic base. 1. Wang, Fu, Zhou, Kim & Thorpe (2001) *Biochemistry* **40**, 12266.

### Octahydropericidin A

Octahydropericidin A<sub>1</sub>

This reduced antibiotic (FW = 423.64 g/mol; CAS 2738-64-9; Soluble in ethanol, methanol, DMF or DMSO) is a structural analogue of ubiquinone and a partially competitive inhibitor of bacterial and mitochondrial Type-I NADH-ubiquinone oxidoreductases (or Complex I). Octahydropericidin A also inhibits glucose dehydrogenase (3). 1. Jeng, Hall, Crane, *et al.* (1968) *Biochemistry* **7**, 1311. 2. Ramsay, Krueger, Youngster & Singer (1991) *Biochem. J.* **273**, 481. 3. Friedrich, van Heek, Leif, *et al.* (1994) *Eur. J. Biochem.* **219**, 691.

### 1-Octanethiol

This foul-smelling thiol (FW = 146.30 g/mol; B.P. = 197-200°C) is an irreversible inhibitor of soybean lipoxygenase-1, which catalyzes an oxygenation reaction, converting 1-octanethiol to 1-octanesulfonic acid, with 1 in 48 turnovers resulting in enzyme inactivation. No inactivation was observed with several more polar thiols, such as mercaptoethanol, dithiothreitol, L-cysteine, glutathione, *N*-acetylcysteamine, or captopril, suggesting that a hydrophobic thiol is required to irreversibly inactivate soybean lipoxygenase. 1. Clapp, Grandizio, Yang, *et al.* (2002) *Biochemistry* **41**, 11504.

### Octanoate (Octanoic Acid)

This medium-chain fatty acid (FW<sub>free-acid</sub> = 144.21 g/mol), also called *n*-octanoic acid and caprylic acid, has a pK<sub>a</sub> value of 4.85 at 25°C. It is an oily liquid (M.P. = 16.7°C; B.P. = 239.7°C) with a slightly rancid taste. Octanoic acid is slightly soluble in water (0.068 g/100 g H<sub>2</sub>O at 20°C) and soluble in ethanol, diethyl ether, benzene, and glacial acetic acid. **Target(s):** alanyl aminopeptidase (1,30); alcohol dehydrogenase (2); aldehyde reductase, aldose reductase (3); D-amino-acid oxidase, weakly inhibited; K<sub>i</sub> = 6.3 mM (4,5); [branched-chain α-keto-acid dehydrogenase] kinase, or 3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring) kinase (6-8,32,33); carbonyl reductase (9); choline acetyltransferase (10); cutinase (11); cytosol alanyl aminopeptidase (1,30); esterase (12,13); firefly luciferase, IC<sub>50</sub> = 2.9 mM (35); β-galactoside α-2,6 sialyltransferase, weakly inhibited (34); glucokinase (14,15); glucose-6-phosphate dehydrogenase (15); glutathione *S*-transferase (16); hexokinase (14,15,17); kynurenine aminotransferase, weakly inhibited (18); L-lactate dehydrogenase (19-21); lipoxygenase (22); monoamine oxidase (23); NAD<sup>+</sup> nucleosidase, NADase, K<sub>i</sub> = 56 mM (31); penicillin acylase (24); penicillocarboxypeptidases (25); phenylacetyl-CoA synthetase, or phenylacetate:CoA ligase (26); phosphofructokinase (14,15,17); propionyl-CoA synthetase, K<sub>i</sub> = 58 μM (27,28); pyruvate kinase (15,29). 1. ### Octanoyl-CoA

This coenzyme thiolester (FW<sub>free-acid</sub> = 893.72 g/mol), also known as caproyl-CoA and capryl-CoA (note that this term has also been used for decanoyl-CoA), is an inhibitor of enoyl-CoA hydratase in β-oxidation.

**Target(s):** acetyl-CoA carboxylase (1); 1-alkyl-*sn*-glycero-3-phosphate acetyltransferase (2); aralkylamine *N*-acetyltransferase (3); arylamine *N*-acetyltransferase (4); citrate synthase (5); enoyl-CoA hydratase (6,7); fatty-acid synthase (8); glutamate dehydrogenase (5); 3-hydroxy-3-methylglutaryl-CoA synthase (9); isocitrate dehydrogenase (NADP<sup>+</sup>) (10); α-ketoglutarate dehydrogenase (10); lipoyl(octanoyl) transferase (11); methylmalonyl-CoA epimerase (12); (*S*)-methylmalonyl-CoA hydrolase (13); pantothenate kinase (14); [pyruvate dehydrogenase] kinase (15). 1. ### 2-Octenoyl-CoA

This unsaturated fatty-acyl-CoA metabolite (FW<sub>free acid</sub> = 891.72 g/mol) is a product of the reaction catalyzed by medium-chain fatty-acyl-CoA dehydrogenase and will act as a product inhibitor (the *trans*-isomer is an intermediate in the β-oxidation of saturated fatty acids). **Target(s):** acyl-CoA dehydrogenases (1,2); fatty-acid synthase (3). 1. Beinert (1963) *The Enzymes*, 2nd ed., **7**, 447. 2. Peterson, Sergienko, Wu, *et al.* (1995) *Biochemistry* **34**, 14942. 3. Podack, Saathoff & Seubert (1974) *Eur. J. Biochem.* **50**, 237.

### Octopamine

This substituted tyramine (FW = 153.18 g/mol; CAS 104-14-3), also called  $\beta$ -hydroxytyramine, is an  $\alpha$ -adrenergic receptor agonist. The D-enantiomer was first isolated from the salivary glands of a species of *Octopus* in 1951, hence the name, and has now been found in many invertebrates, in which it acts as neurohormone, a neuromodulator, and a neurotransmitter. It will inhibit adenylate cyclase via the  $\alpha_{2A}$ -adrenoreceptor. **Target(s):** arylsulfatase (1,2); CYPc1 (13); dihydropteridine reductase (4);  $\gamma$ -glutamylhistamine synthetase (5). 1. Okamura, Yamada, Murooka & Harada (1976) *Agric. Biol. Chem.* **40**, 2071. 2. Murooka, Yim & Harada (1980) *Appl. Environ. Microbiol.* **39**, 81. 3. Louw, Allie, Swart & Swart (2000) *Endocr. Res.* **26**, 729. 4. Shen (1983) *Biochim. Biophys. Acta* **743**, 129. 5. Stein & Weinreich (1982) *J. Neurochem.* **38**, 204.

### D-Octopin

This arginine derivative (FW<sub>hydrochloride</sub> = 282.73 g/mol; CAS 34522-32-2), also known as *N*<sup>2</sup>-([*R*]-1-carboxyethyl)-L-arginine (note that it can also be regarded as an *N*-substituted derivative of D-alanine), is found in the muscles of various invertebrates (first isolated from octopus). In addition, it is found in plant tumors of crown gall disease. Note that the term has also been used to describe similar *N*-substituted alanines. Octopine is a substrate for D-octopine dehydrogenase. **Target(s):** histidine ammonia-lyase. 1. Leuthardt (1951) *The Enzymes*, 1st ed., 1 (part 2), 1156.

### Octreotide

This orally bioavailable octapeptide somatostatin analogue (FW = 1019.24 g/mol; CAS 83150-76-9; 79517-01-4 (acetate salt); 135467-16-2 (pamoate salt); D-Phe-Cys-Phe-D-Trp-Lys-Thr-Cys-NH-CH(CH<sub>2</sub>OH)CHOHCH<sub>3</sub>), also known as SMS 201-995 and Sandostat<sup>®</sup>, is a long-lasting and more potent inhibitor of growth hormone, glucagon, and insulin than is somatostatin. Its synthesis was enabled by stepwise modification of a conformationally stabilized analogue of the fragment of somatostatin that had been thought to be a biologically active moiety (1). Indeed, octreotide displaces [<sup>3</sup>H]naloxone from its binding sites (IC<sub>50</sub> = 38 nM), or >200x more potent than somatostatin (2). As measured by the difference between the binding of [<sup>3</sup>H]-dihydromorphine, [<sup>3</sup>H]-[D-Ala<sub>2</sub>,D-Leu<sub>5</sub>]enkephalin, and (-)-[<sup>3</sup>H]-bremazocine, SMS 201-995 appears to be highly specific for the

opioid  $\mu$  binding site (2). Octreotide immediate-release injection is used to decrease the amount of growth hormone produced in acromegaly. 1. Bauer, Briner, Doepfner, *et al.* (1982) *Life Sci.* **31**, 1133. 2. Maurer, Gaehwiler, Buescher, Hill & Roemer (1982) *Proc. Natl. Acad. Sci. U.S.A.* **79**, 4815. 3.

### Octylamine

This toxic alkylamine (FW<sub>free-base</sub> = 129.25 g/mol; M.P. = -5 to -1°C; B.P. = 175-176°C; 111-86-4), also known as 1-aminooctane and caprylamine, inhibits many enzyme activities. **Target(s):** alanyl aminopeptidase (1,2); benzo(*a*)pyrene hydroxylase (3); carnosine synthetase (4); cysteine-conjugate *S*-oxidase activity (5); cytosol alanyl aminopeptidase (1,2); deoxyhypusine synthase (6); flavin-containing monooxygenase (7);  $\beta$ -glucosidase (8); glucosylceramidase (9); guanidinoacetase (10); guanylate cyclase (11); NAD<sup>+</sup> nucleosidase, or NADase, K<sub>i</sub> = 21 mM (12); NADPH oxidase (13); phospho-*N*-acetylmuramoyl pentapeptide-transferase (14). 1. Garner & Behal (1975) *Biochemistry* **14**, 5084. 2. Garner & Behal (1977) *Arch. Biochem. Biophys.* **182**, 667. 3. Ahokas, Pelkonen & Karki (1977) *Cancer Res.* **37**, 3737. 4. ### Octyl-CoA Disulfide

This synthetic disulfide (FW<sub>free-acid</sub> = 943.89 g/mol) inhibits *Mycobacterium tuberculosis*  $\beta$ -ketoacyl [acyl-carrier-protein] synthase III, IC<sub>50</sub> = 30  $\mu$ M. The kinetics of MeSSCoA indicate rapid inhibition of one monomer of ecFabH by forming a methyl disulfide conjugate with this cysteine. Reaction of the second subunit with either MeSSCoA or acetyl-CoA is much slower. In the presence of malonyl-ACP, the acylation rate of the second subunit is restored to that of the native ecFabH. Such findings suggest a catalytic model, in which a structurally disordered apo-ecFabH dimer orders on binding either the first substrate, acetyl-CoA, or the inhibitor MeSSCoA, and is restored to a disordered state on binding of malonyl-ACP. 1. Alhamadsheh, Musayev, Komissarov, *et al.* (2007) *Chem. Biol.* **14**, 513.

### S-Octylglutathione

This *S*-alkylated glutathione (FW<sub>hydrochloride</sub> = 456.00 g/mol) inhibits glutathione *S*-transferase (1,2); hydroxyacyl-glutathione hydrolase, or glyoxalase II (7); lactoylglutathione lyase, or glyoxalase I (3-8); xenobiotic-transporting ATPase (multidrug resistance protein) (9). 1. Pace-Asciak & Smith (1983) *The Enzymes*, 3rd ed. (Boyer, ed.), **16**, 543. 2. Ortiz-Salmeron, Yassin, Clemente-Jimenez, *et al.* (2001) *Biochim. Biophys. Acta* **1548**, 106. 3. ### Octylguanidine

This hygroscopic guanidine derivative (FW<sub>hydrochloride</sub> = 217.82 g/mol; CAS 3038-42-4) will inactivate the mitochondrial permeability transition pore. It is also an inhibitor of oxidative and photophosphorylation. **Target(s):** ATPase, plasma membrane (1); cation translocation (2); chloroplast uncoupler (3); F<sub>1</sub> ATPase, or H<sup>+</sup>-transporting two-sector ATPase (1,4-6); oxidative phosphorylation (6). 1. Bowman, Mainzer, Allen & Slayman (1978) *Biochim. Biophys. Acta* **512**, 13. 2. Beatty, Gutierrez, Lopez-Vancell & Estrada (1986) *Acta Physiol. Pharmacol. Latinoam.* **36**, 217. 3. Acta* **461**, 101. 6. Papa, Tuena de Gomez-Puyou & Gomez-Puyou (1975) *Eur. J. Biochem.* **55**, 1.

### N-Octylindomethacin Amide

This anti-inflammatory (FW = 469.02 g/mol), also known as 1-(*p*-chlorobenzoyl)-5-methoxy-2-methyl-1*H* indole-3-octylacetamide, is a selective inhibitor of cyclooxygenase-2. The IC<sub>50</sub> value for COX-2 is 40 nM, whereas the value for COX-1 is 66 μM. 1. Kalgutkar, Marnett, Crews, Remmel & Marnett (2000) *J. Med. Chem.* **43**, 2860. 2. Kalgutkar, Crews, Rowlinson, *et al.* (2000) *Proc. Natl Acad. Sci. U.S.A.* **97**, 925.

### 3-Octylthio-1,1,1-trifluoropropan-2-one

This halomethyl ketone (FW = 256.33 g/mol), also known as 1,1,1-trifluoro-(3-octylsulfanyl)-2-propanone, inhibits *Tenebrio molitor* juvenile-hormone esterase (IC<sub>50</sub> = 4.6 nM). **Target(s):** acetylcholinesterase (1); carboxylesterase (1); cutinase, IC<sub>50</sub> = 1.6 μM (2); juvenile hormone epoxide hydrolase (3); juvenile-hormone esterase (1,4-13); microsomal epoxide hydrolase (3). 1. ### Odanacatib

This investigational osteoporosis/bone-metastasis drug (FW = 525.56 g/mol; CAS 603139-19-1), also known by the code name MK-0822 and its systematic name *N*-(1-cyanocyclopropyl)-4-fluoro-*N*'-{(1*S*)-2,2,2-trifluoro-1-[4'-(methylsulfonyl)biphenyl-4-yl]ethyl}-*L*-leucinamide, targets the cathepsin K, a unique collagenolytic lysosomal cysteine protease that is secreted, thereby facilitating bone resorption by cleaving type-1 collagen under acidic pH (1,2). Cathepsin K exhibits a unique cleavage pattern of type I collagen molecules that is fundamentally different from that of other endogenous collagenases. Women receiving ODN (10-50 mg) for 5 years had gains in spine and hip bone mineral density (BMD), showing larger reductions in bone resorption than bone formation markers (4). Significantly, discontinuation of ODN resulted in reversal of treatment effects. An odanacatib synthesis, which describes a novel stereospecific S<sub>N</sub>2 triflate displacement of a chiral α-trifluoromethylbenzyl triflate with (*S*)-γ-fluoroleucine ethyl ester, achieves a 61% overall yield in 6 steps (4). 1. Gauthier, Chauret, Cromlish, *et al.* (2008) *Bioorg. Med. Chem. Lett.* **18**, 923. 2. Le Gall, Bonnelye & Clézardin (2008) *Curr. Opin. Support Palliat. Care.* **2**, 218. 3. Langdahl, Binkley, Bone, *et al.* (2012) *J. Bone Miner. Res.* **27**, 2251. 4. O'Shea, Chen, Gauvreau, *et al.* (2009) *J. Org. Chem.* **74**, 1605.

### OD1

This scorpion toxin (FW = 7206.10 g/mol; Disulfide bridge: Cys13-Cys64, Cys17-Cys37, Cys23-Cys47, Cys27-Cys49), from the venom of the scorpion *Odonthobuthus doriae*, modulates Na<sub>v</sub>1.7 (1), dramatically impairing fast inactivation (EC<sub>50</sub> = 4.5 nM), substantially increasing the peak current at all voltages, and inducing a substantial persistent current (2). Na<sub>v</sub>1.8 is unaffected up to 2 μM OD1, whereas Na<sub>v</sub>1.3 is sensitive only to concentrations >100 nM. OD1 impairs the inactivation process of Na<sub>v</sub>1.3 (EC<sub>50</sub> = 1.3 μM). The effects of OD1 were compared with a classic α-toxin, AahII from *Androctonus australis* Hector and a classic α-like toxin, BmK M1 from *Buthus martensii* Karsch. At a concentration of 50 nM, both toxins affected Na<sub>v</sub>1.7. Na<sub>v</sub>1.3 was sensitive to AahII but not to BmK M1, whereas Na<sub>v</sub>1.8 was affected by neither toxin. The scorpion toxin OD1 is therefore a potent Na<sub>v</sub>1.7 modulator, with a unique selectivity pattern. A high-resolution X-ray structure (1.8 Å) of synthetic OD1 showed the typical βαββ α-toxin fold and revealed important conformational differences in the pharmacophore region when compared with other α-toxin structures (3). Investigation of nine OD1 mutants revealed that three residues in the reverse turn contributed significantly to selectivity, with the triple OD1 mutant (D9K, D10P, K11H) being 40-fold more selective for Na<sub>v</sub>1.7 over Na<sub>v</sub>1.6, while OD1 K11V was 5-fold more selective for Na<sub>v</sub>1.6 than Na<sub>v</sub>1.7 (3). 1. Jalali, Bosmans, Amininasab, *et al.* (2005) *FEBS Lett.* **579**, 4181. 2. Maertens, Cuyper, Amininasab, *et al.* (2006) *Mol. Pharmacol.* **70**, 405. 3. Durek, Vetter, Wang, *et al.* (2013) *ACS Chem. Biol.* **8**, 1215.

### Oenothien B

This macrocyclic ellagitannin (FW = 1569.09 g/mol; CAS 104987-36-2) inhibits neprilysin, peptidyl-dipeptidase A, and poly(ADP-ribose) glycohydrolase. It also suppresses glucocorticoid-sensitive mouse mammary

tumor virus transcription. **Target(s):** aromatase, or CYP 19 (1); DNA polymerase, Epstein-Barr virus (2); neprilysin (3); peptidyl-dipeptidase A, or angiotensin I-converting enzyme (3); poly(ADP-ribose) glycohydrolase (4); steroid 5 $\alpha$ -reductase (1,5). 1. Ducrey, Marston, Göhring, Hartmann & Hostettmann (1997) *Planta Med.* **63**, 111. 2. Lee, Chiou, Yen & Yang (2000) *Cancer Lett.* **154**, 131. 3. ### Ofloxacin

This potent fluoroquinolone antibacterial (FW<sub>free-acid</sub> = 361.37 g/mol; CAS 82419-36-1) inhibits DNA gyrase and is active against both Gram-positive and Gram-negative bacteria (1-7). (For the prototypical member of this antibiotic class, See *Ciprofloxacin*) **Mode of Inhibitory Action:** The drug's bactericidal effect is mediated through the stabilization of a cleavable complex via a cooperative drug binding to a partially denatured DNA pocket created by DNA gyrase. The drug binds to supercoiled DNA in a manner similar to that to which it binds to the enzyme-DNA complex. The bacteria chromosome is composed mainly of double-stranded DNA, with 60-70 domains of supercoiling, each attached to an RNA core and organized by its own second echelon of supercoiling. DNA supercoiling is determined by DNA gyrase, an enzyme that introduces transient breaks into both DNA strands of each domain, removing ~400 helical turns before resealing the DNA and locking in the supercoiling. Ofloxacin blocks gyrase action by preferential binding to supercoiled DNA. The (*S*)-isomer, levofloxacin, has twice the antimicrobial activity of the (*R*)-isomer. Uptake of ofloxacin in moderately resistant strains is almost the same in the presence or absence of carbonyl cyanide *m*-chlorophenylhydrazone (CCCP), whereas in highly resistant strains, uptake increased when CCCP is added (8). Such findings suggest that resistance may depend, at least in part, to an energy-requiring drug export system. **Target(s):** DNA gyrase, or DNA topoisomerase II (1-7); glutathione-disulfide reductase, inhibited by levofloxacin (9); medium-chain-fatty-acyl-CoA synthetase, or butyryl-CoA synthetase, or butyrate:CoA ligase (10). 1. ### OG-L002

This histone H3K9 demethylase inhibitor (FW = 669.82 g/mol; CAS 1357302-64-7; Solubility: 45 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O) potently and specifically inhibits the histone demethylase LSD1 (IC<sub>50</sub> = 20 nM), resulting in increased repressive chromatin assembly and suppression of gene expression during the lytic phase of herpes simplex virus and varicella-zoster virus infection. This LSD1 inhibitor also blocks initial gene expression of the human cytomegalovirus and adenovirus type 5, attesting to the critical role of LSD1 in regulating DNA virus infection. Because this small-molecule inhibitor was originally designed to inhibit monoamine oxidases, it is noteworthy that its affinity for LSD1 is 36x and 69x higher than MAO-B and MAO-A, respectively. 1. Liang, Quenelle, Vogel, et al. (2013) *mBio* **4**, e00558.

### Ogerin

This GPR68 activator (FW = 307.35 g/mol; CAS 1309198-71-7), also named 2-[4-amino-6-[(phenylmethyl)amino]-1,3,5-triazin-2-yl]benzenemethanol, selectively and allosterically targets G-Protein-coupled Receptor 68, one of at least 120 non-olfactory G-protein-coupled receptors in the human genome that remain 'orphans' (i.e., they are pharmacologically dark, with no known endogenous ligands). Ogerin suppresses recall in fear conditioning in wild-type, but not in GPR68-knockout mice. GPR68 is also a newly recognized metastasis suppressor gene in certain cancers. 1. Huang, Karpiak, Kroeze, (2015) *Nature* **527**, 477.

### Okadaic Acid

This marine sponge toxin and potent cell-permeable ionophoric polyether (FW = 824.42 g/mol; CAS 78111-17-8; *Symbol*: OA), also known as 9,10-deepithio-9,10-didehydroacanthifolicin, is a widely distributed marine toxin that accumulates by filtering shellfish (mainly bivalve mollusks) as well as fish, and is then consumed by humans, giving rise to intestinal poisoning. **Primary Mode of Action:** Kinetic studies showed that okadaic acid acts as a noncompetitive (mixed-type) inhibitor of phosphoprotein phosphatase types PP-1 and PP-2A. (1). The Type-2A protein phosphatases in mammalian tissue extracts are inhibited completely and specifically by 1–2 nM okadaic acid (1). In contrast, Type-1 protein phosphatases are hardly affected at these concentrations, complete inhibition requiring 1  $\mu$ M okadaic acid (IC<sub>50</sub>  $\approx$  100 nM). These observations provide a means for identifying and quantifying type 1, type 2A, and type 2C protein phosphatases in tissue extracts. Bialojan & Takai (2) also investigated the inhibitory action of this dinoflagellate natural product. Of the protein phosphatases examined, the catalytic subunit of rabbit skeletal muscle 2A phosphatase was most potently inhibited. For the phosphorylated myosin light-chain (PMLC) phosphatase activity of the enzyme, the okadaic acid concentration required to obtain 50% inhibition was about 1 nM. The PMLC phosphatase activities of type 1 and PCM phosphatase were also strongly inhibited (IC<sub>50</sub>  $\approx$  0.1–0.5  $\mu$ M). The PMCL phosphatase activity of type 2B phosphatase (calcineurin) was inhibited to a lesser extent (IC<sub>50</sub>  $\approx$  4–5  $\mu$ M). These investigators obtained similar results for the phosphorylase *a* phosphatase activity of type 1 and PCM phosphatases and for calcineurin's *p* nitrophenyl phosphate phosphatase activity. The following phosphatases were not affected by up to 10  $\mu$ M okadaic acid: type 2C phosphatase, phosphotyrosyl phosphatase, inositol-1,4,5 trisphosphate phosphatase, acid phosphatases, and alkaline phosphatases. These results suggest that okadaic acid is relatively specific for type 2A, type 1, and PCM phosphatases. **Other Actions:** This light-sensitive substance also disrupts Golgi, arrests transport on the rough endoplasmic reticulum, alters nitric oxide metabolism, and markedly influences calcium ion signalling. **CAUTION:** In view of its documented capacity to promote tumorigenesis, investigators should carefully read precautions and recommended procedures in commercial product insert data pertaining to okadaic acid. Avoid direct contact with or inhalation of the dry powder. **Target(s):** [acetyl-CoA carboxylase]-phosphatase (3); [myosin-light-chain] phosphatase (4-8); phosphoprotein phosphatase (1,2,9-18,21-40); [phosphorylase] phosphatase (9-11,15); protein phosphatase 1 (9-11,15,16,22,23,32,37,38); protein phosphatase 2A (1-3,9-14,17,18,21,23,28,30,31,34,35); protein phosphatase 3 (36); protein phosphatase 4 (23,26); protein phosphatase 5 (23); protein-tyrosine phosphatase (19); rod outer segment protein phosphatase 2A (opsin phosphatase) (13,14); soluble epoxide hydrolase, weakly inhibited (20). 1.

### Olanzapine

This widely used atypical antipsychotic drug, or AAPD (FW<sub>free-base</sub> = 312.44 g/mol; CAS 132539-06-1), also known as Zyprexa<sup>®</sup> and 2-methyl-4-(4-methyl-1-piperazinyl)-10H-thieno[2,3-b][1,5]benzo-diazepine, is a dual serotonin (5-HT<sub>2</sub>) and dopamine (D<sub>1</sub>/D<sub>2</sub>) receptor antagonist used to treat bipolar disorders (1). Olanzapine is metabolized by the CYP1A2 and to a lesser extent by CYP2D6, resulting in removal of more than 40% of the oral dose by the liver on first pass. Olanzapine pharmacokinetics display large inter-individual variation, with multiple-fold differences in drug exposure between patients given the same dose. Formation of the various olanzapine metabolites is influenced by polymorphisms in the genes coding for CYP1A2, CYP1A expression regulator AHR, UGT1A4 and UGT2B10, as well as FMO3 (2). **Note:** Olanzapine is FDA-approved for treating symptoms of schizophrenia and bipolar disorder in adults and teenagers age thirteen and older, but is not approved for treating behavior disorders in older adults with dementia. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** Dopamine D<sub>1</sub> receptor, K<sub>i</sub> = 70 nM; dopamine D<sub>2</sub> receptor, K<sub>i</sub> = 31 nM; dopamine D<sub>3</sub> receptor, K<sub>i</sub> = 11 nM; dopamine D<sub>4</sub> receptor, K<sub>i</sub> = 18 nM; serotonin 5-HT<sub>1A</sub> receptor, K<sub>i</sub> = 2300 nM; serotonin 5-HT<sub>2A</sub> receptor, K<sub>i</sub> = 3.7 nM; serotonin 5-HT<sub>2B</sub> receptor, K<sub>i</sub> = 8.2 nM; serotonin 5-HT<sub>2C</sub> receptor, K<sub>i</sub> = 10 nM; serotonin 5-HT<sub>3</sub> receptor, K<sub>i</sub> = 57 nM; serotonin 5-HT<sub>6</sub> receptor, K<sub>i</sub> = 5 nM;

serotonin 5-HT<sub>7</sub> receptor, K<sub>i</sub> = 7.1 nM; muscarinic M<sub>1</sub> receptor, K<sub>i</sub> = 2.5 nM; muscarinic M<sub>2</sub> receptor, K<sub>i</sub> = 18-96 nM; muscarinic M<sub>3</sub> receptor, K<sub>i</sub> = 25-132 nM; muscarinic M<sub>4</sub> receptor, K<sub>i</sub> = 13-32 nM; muscarinic M<sub>5</sub> receptor, K<sub>i</sub> = 48 nM; adrenergic α<sub>1A</sub> receptor, K<sub>i</sub> = 110 nM; adrenergic α<sub>2A</sub> receptor, K<sub>i</sub> = 310 nM; and histamine H<sub>1</sub> receptor, K<sub>i</sub> = 2.2 nM; CYP3A (2); CYP2C9 (3) CYP2C19 (3); CYP2D6 (3); dopamine receptor (1,4); glucuronosyltransferase (5). ### Olaparib

This orally active poly-ADP ribose polymerase inhibitor (FW = 435.08 g/mol; CAS 763113-22-0; Solubility: 80 mg/mL; << 1 mg/mL H<sub>2</sub>O), also known as AZD-2281, Lynparza<sup>®</sup>, and 4-[(3-[(4-cyclopropyl-carbonyl) piperazin-4-yl]carbonyl)4-fluorophenyl]methyl-(2H)-phthalazin-1-one, targets PARP1 (IC<sub>50</sub> = 5 nM) and PARP 2 (IC<sub>50</sub> = 1 nM). Clinical evaluation of olaparib action against cancers lacking the BRCA1 or BRCA2 genes exemplifies the promise of targeted therapies exploiting specific molecular defects in cancer cells. Since <5% of patients are BRCA1 or BRCA2 mutation carriers, small molecules that functionally mimic BRCA1 or BRCA2 mutations promise to extend the synthetic lethal therapeutic option for non-mutation carriers (2). A deficiency of RAD51C, a key participant in recombinational repair of damaged DNA, is also a biomarker for predicting the patients most likely to respond to olaparib (2). In patients with prostate cancers that no longer responded to standard treatments and who had defects in DNA-repair genes, olaparib treatment led to a high response rate (3). 1. Fong, Boss, Yap, *et al.* (2009) *New Engl. J. Med.* **361**, 123. 2. Pessetto, Yan, Bessho & Natarajan A. (2012) *Breast Cancer Res Treat.* **134**, 511. 3. Min, Im, Yoon *et al.* (2013) *Molec. Cancer Ther.* **12**, 865. 3. Mateo, Carreira, Sandhu, *et al.* (2015) *New Engl. J. Med.* **373**, 1697.

### Oleamide

This fatty acid amide (FW = 281.48 g/mol; CAS 301-02-0), also known as *cis*-9-octadecenamide and oleic acid amide, accumulates in the cerebral spinal fluid on sleep deprivation. It also induces sleep in animals, reversibly enhances GABA<sub>A</sub> currents, and depresses the frequency of spontaneous excitatory and inhibitory synaptic activity in cultured networks. The *trans* form (known as elaidamide) is inactive. Oleamide is a substrate of fatty acid amide hydrolase. Originally referred to as cerebrotene, oleamide was originally isolated from the brain of sleep-deprived cats (1,2). **Target(s):** chymase (3); 5-HT<sub>7</sub> serotonin receptors modulation (4); microsomal epoxide hydrolase (5); Na<sup>+</sup> channel-dependent rises in intrasynaptosomal calcium ions (6). 1. Lerner, Siuzdak, Prospero-Garcia, *et al.* (1994) *Proc. Natl. Acad. Sci. U.S.A.* **91**, 9505. 2. Cravatt, Prospero-Garcia, Siuzdak, *et al.* (1995) *Science* **268**, 1506. 3. ## Oleanolate

This triterpene alcohol (FW<sub>free-acid</sub> = 456.71 g/mol; CAS 508-02-1), also known as oleanolic acid, is present in certain plants (e.g., *Olea europaea*, *Viscum album*, mistletoe, cloves, cacti, sugar beets, etc.), where it is found in free form, esterified with acetic acid, and as a glycoside. It has a pK<sub>a</sub> value of 2.52 and is practically insoluble in water. Barton and Holness (1) were able to use conformational analysis to assign a conformational structure to oleanolic acid in the early 1950s. X-ray crystallographic studies demonstrated that one of their two possible conformations was correct (2).

**Target(s):** α-amylase (3); cAMP-dependent protein kinase (4); chitin synthase II (5); complement C3 convertase (6); cyclooxygenase-2 (COX-2) (7,8); CYP1A2 (9); CYP3A4 (9); diacylglycerol *O*-acyltransferase (10); DNA-directed DNA polymerase (12,13); DNA ligase (ATP), human, IC<sub>50</sub> = 216 μM (11); DNA polymerase α (12); DNA polymerase β (12,13); DNA topoisomerase I (14); DNA topoisomerase II (12,14); α-glucosidase (15,16); glucosyltransferase (17); glycogen phosphorylase, IC<sub>50</sub> = 14 μM (16,18,19,22); 11β-hydroxysteroid dehydrogenase (20); leukocyte elastase (21); 5-lipoxygenase, or arachidonate 5-lipoxygenase (24); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, ACAT (23). 1. ## Oleate (Oleic Acid)

This unsaturated fatty acid (FW<sub>free-acid</sub> = 282.47 g/mol; CAS 112-80-1), also known as oleic acid and (*Z*)-octadec-9-enoic acid, is found in most organisms, often as a constituent of phospholipids and triacylglycerols. It is insoluble in water and the sodium salt, sodium oleate, has a low solubility. The free acid is a colorless liquid at room temperature and readily oxidizes in air, acquiring rancid odor. Oleic acid should be stored in a tight container and protected from light. Note that the *trans*-isomer is elaidic acid (See also *Elaidate & Elaidic Acid*). Elevated concentrations of oleate are toxic and will uncouple oxidative phosphorylation. **Target(s):** 2-acylglycerol *O*-acyltransferase, or monoacylglycerol *O*-acyltransferase (57-59); 1-acylglycerophosphocholine *O*-acyltransferase, or lysophosphatidylcholine *O*-acyltransferase (56); adenine nucleotide translocase (1); adenylate kinase (2); 1-alkylglycerophosphocholine *O* acetyltransferase (55); arachidonyl-CoA synthetase, or arachidonate:CoA ligase (3); ATPase (4); choloyl CoA

synthetase, or cholate:CoA ligase (6,7); chondroitin AC lyase (8); chondroitin B lyase (8); chymase (9,36); diacylglycerol *O*-acyltransferase (60); DNA (adenine-*N*<sup>6</sup>-)-methyltransferase (10); DNA directed DNA polymerase (11,12); DNA polymerases α, β, γ, δ, and ε (11,12); DNA topoisomerase I (12); DNA topoisomerase II (12); electron transport and uncoupling, mitochondrial (13,14); ethanolamine-phosphate cytidyltransferase (49); 7-ethoxycoumarin *O*-deethylase (15); β-galactoside α-2,6-sialyltransferase (50); gelatinase A (16); 1,3-β-glucan synthase (53,54); β-glucuronidase (17); glycerol 3-phosphate *O*-acyltransferase (61-63); hexokinase (18); hormone-sensitive lipase (19,20); hyaluronate lyase (8); leukocyte elastase, or neutrophil elastase (25,35); linoleate isomerase (21,22); lipase, or triacylglycerol lipase (46); lipoxygenase (23); 5-lipoxygenase, or arachidonate 5-lipoxygenase (66); *N*-(long-chain-acyl)ethanolamine deacylase (24); lysophospholipase (45); microbial collagenase (35); monogalactosyldiacylglycerol synthase (52); [myosin light-chain] kinase (47); NAD<sup>+</sup> ADP ribosyltransferase, or poly(ADP-ribose) polymerase (51); NADH dehydrogenase (13); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (41,42); peroxidase (68); peroxidase activity of metmyoglobin (26); phosphatidate cytidyltransferase (48); phosphatidate phosphatase (27,28); phosphatidylglycerophosphatase, inhibited at elevated concentrations (i.e., >1.5 mM) (40); phospholipase A<sub>1</sub> (43); phospholipase D (38,39); phospholipid-hydroperoxide glutathione peroxidase (67); plasmalethanolamine desaturase, weakly inhibited (64); prostaglandin D<sub>2</sub> dehydrogenase (29); prostaglandin D synthetase (29); prostaglandin-endoperoxide synthase, or cyclooxygenase (65); pyruvate kinase (30); sphingomyelin phosphodiesterase (37); steroid 5α-reductase (31,32); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, ACAT (5); sterol esterase, or cholesterol esterase (44); tyrosine kinase (33); uroporphyrinogen decarboxylase (34). 1. ### 1-Oleoyl-2-acetyl-sn-glycerol

This 1,2-diacylglycerol (FW = 398.58 g/mol), often abbreviated OAG, is an activator of protein kinase C and a cell-permeable analogue of larger 1,2-diacylglycerols. Commercial preparations often contain 1-elaidoyl-2-acetyl-*sn*-glycerol (*i.e.*, the *trans* isomer), which accumulates upon storage. **Target(s):** 1-alkyl-2-acetyl-glycerol *O*-acyltransferase (1); nonspecific serine/threonine protein kinase (2); phospholipase C (3); protein kinase D (2). **1.** Kawasaki & Snyder (1988) *J. Biol. Chem.* **263**, 2593. **2.** Valverde, Sinnott-Smith, Van Lint & Rozengurt (1994) *Proc. Natl. Acad. Sci. U.S.A.* **91**, 8572. **3.** Haeflner & Wittmann (1992) *J. Lipid Mediat.* **5**, 237.

### Oleoylcarnitine

This acylated carnitine (FW = 425.65 g/mol; CAS 13962-05-5) is transported across the mitochondrial membrane prior to  $\beta$ -oxidation of the unsaturated fatty acid. **Target(s):** adenine nucleotide translocase (1); phosphatidylcholine: cholesterol acyltransferase, LCAT of rat and rabbit (2); Na<sup>+</sup>/Cl<sup>-</sup>-dependent glycine transporter GlyT<sub>2</sub> (IC<sub>50</sub> = 340 nM, ~15x lower than *N*-arachidonyl-glycine). **1.** Bell (1980) *Atherosclerosis* **37**, 21. **2.** Bell (1983) *Int. J. Biochem.* **15**, 133. **3.** Carland, Mansfield, Ryan & Vandenberg (2013) *Br. J. Pharmacol.* **168**, 891.

### Oleoyl-CoA

This fatty acyl-CoA thioester (FW<sub>free-acid</sub> = 1031.99 g/mol; CAS 1716-06-9; Critical Micelle Concentration  $\approx$  4.7  $\mu$ M) is a common intermediate in fatty acid metabolism and is a substrate of many acyltransferases. *Note:* When oleoyl-CoA is present at concentrations exceeding its critical micelle concentration, micelles will form, giving rise to the likelihood that the observed inhibition is merely the nonphysiologic consequence of clustered surface charge. Experiments with mixed micelles may be required to reach

an unambiguous conclusion. **Target(s):** acetyl-CoA carboxylase,  $K_i = 1.3 \mu$ M for the rat liver enzyme (1-5); acetyl CoA synthetase, or acetate:CoA ligase (6,7); adenine nucleotide translocase (8,9); alcohol *O*-acetyltransferase (41); 1-alkyl-*sn*-glycero-3-phosphate *O*-acetyltransferase (10,12); 1-alkylglycerophosphocholine *O*-acetyltransferase (11,12,42); ATP:citrate lyase, or ATP:citrate synthase (13,39,40); citrate synthase (14); cyclooxygenase (15); fatty-acid synthase (16); glucose-6-phosphatase (35,36); glucose-6-phosphate dehydrogenase (17,18); glucose-6-phosphate translocase (19); glycerol-3-phosphate dehydrogenase (20); hexokinase (21); hormone-sensitive lipase (22,23); 3-hydroxydecanoyl-[acyl-carrier-protein] dehydratase (24); lipoxigenase (15); lyso-[platelet-activating factor] acetyltransferase (12); nicotinamide nucleotide transhydrogenase (25); *p*-nitroanisole *O*-demethylase (25); nuclear thyroid hormone receptor (26); pantothenate kinase (38); phosphatidate phosphatase (27,28); phosphoglyceride:lysophosphatidylglycerol *O*-acyltransferase (29); phospholipase A<sub>2</sub> (30); protein kinase C (31); [pyruvate dehydrogenase (acetyl-transferring)] kinase (37); RNA polymerase (32); stearoyl-CoA 9-desaturase, as product inhibitor (43); UDPglucuronosyl-transferase (33,34).

### *N*-Oleylethanolamide

This endocannabinoid-related metabolite (FW = 325.54 g/mol; CAS 111-58-0; *Symbol:* NOE and OEA; Soluble in Ethanol, Chloroform, or Methanol) is widely employed to inhibit acid and neutral ceramidases (IC<sub>50</sub> ~ 500  $\mu$ M) that cleave fatty acids from ceramide, producing sphingosine (SPH), which is then enzymatically phosphorylated to form the receptor-sensitized metabolite, sphingosine-1-phosphate, or SIP (1-4). NOE also

inhibits the glucosylation of naturally occurring ceramides (5). In CHP-100 neuroepithelioma cells treated with *N*-hexanoylsphingosine ( $C_6$ -Cer; 30  $\mu$ M), NOE affected only marginally short-chain glucocerebroside accumulation, but markedly decreased accumulation of glucocerebrosides originating from glucosylation of a long-chain ceramide (Lc-Cer) produced upon  $C_6$ -Cer treatment (5). NOE also inhibits fatty acid hydrolase (*or* FAAH), an integral membrane hydrolase possessing an unusual catalytic triad Ser-Ser-Lys (6). FAAH catalysis is based on the formation of a tetrahedral intermediate, which is a product of the nucleophilic attack of Ser241 on the carbonyl group of the substrate. In the presence of NOE, TNF $\alpha$  leads to a sustained accumulation of ceramide and induces DNA fragmentation in renal mesangial cells (7). **Membrane & Receptor Interactions:** NOE forms stable complexes with phospholipid vesicles, lowering diphenylhexatriene polarization ratios in dimyristoylphosphatidylcholine and dipalmitoylphosphatidylcholine uni- and multilamellar bilayer vesicles (8). Once incorporated into the lipid bilayer of phospholipid vesicles, *N*-oleoylethanolamine partitions preferentially into more fluid areas, producing a concentration-dependent decrease in their phase transitions (9). *N*-Oleoylethanolamine is also an effective inhibitor of mitochondrial swelling, but does not inhibit phospholipase  $A_2$  or ruthenium red-induced  $Ca^{2+}$  release (10). Moreover, among naturally occurring *N*-acylethanolamines, only NOE (at 10  $\mu$ M) inhibits the accumulation of *N*-arachidonylethanolamine (*or* Anandamide, AEA), a putative endogenous ligand of the cannabinoid receptor, into cerebellar granule cells occurs by means of facilitated diffusion (10). Ethanolamides of palmitic acid and linolenic acid are inactive at 10  $\mu$ M. **Role as an Anorexic Lipid Mediator:** *N*-Oleoylethanolamine is a structural analogue of the endogenous cannabinoid anandamide, but does not activate cannabinoid receptors. NOE biosynthesis in rat small intestine is increased by feeding and reduced by fasting. NOE decreases food intake in food-deprived rats via a mechanism that requires intact sensory fibers. Such results suggest that OEA may contribute to the peripheral regulation of feeding. NOE may contribute to regulation of satiety, providing a chemical scaffold for the design of novel appetite-suppressing medications (11). Despite its designation as endocannabinoid-like compound, NOE is unable to bind with significant affinity to either CB $_1$  or CB $_2$  cannabinoid receptors (12). **SIRT6 Activation:** *N*-Oleoylethanolamine binds to and activates Sirtuin 6 ( $EC_{50} = 3.1 \mu$ M), an NAD $^+$ -dependent histone deacetylase that selectively deacetylates H3K9Ac and H3K56Ac, but acts preferentially on long-chain fatty acyl groups over acetyl groups *in vitro* (13). ### 1-Oleoyleglycerol

This monoacylglycerol (FW = 356.55 g/mol; M.P. = 35°C; CAS 111-03-5), also known as glycerol 1-oleate, 1-monoolein, and 1 monooleoylglycerol, inhibits electron transport and diacylglycerol kinase. Note that commercial sources are often the racemic mixture (1-oleoyl *rac*-glycerol), consisting of a mixture of 1-oleoyl-*sn*-glycerol and 3-oleoyl-*sn*-glycerol. In addition, acyl migration readily occurs. **Target(s):** alcohol *O*-acetyltransferase (1); diacylglycerol kinase,  $K_i = 91 \mu$ M (2,3); electron transport, mitochondrial (4); 7-ethoxycoumarin *O*-deethylase (cytochrome P450) (5); 1,3- $\beta$ -glucan

synthase (6); glycerol-3-phosphate *O*-acyltransferase (7); NADH dihydrogenase (4); sphingomyelin phosphodiesterase, inhibited by the racemic mixture (8); triacylglycerol lipase, also a substrate (9). **1.** Yoshioka & Hashimoto (1981) *Agric. Biol. Chem.* **45**, 2183. **2.** Zawalich & Zawalich (1990) *Mol. Cell. Endocrinol.* **68**, 129. **3.** Bishop, Ganong & Bell (1986) *J. Biol. ### 2-Oleoyleglycerol

This 2-monoacylglycerol (FW = 356.55 g/mol; CAS 3443-84-3) is not optically active and inhibits fatty acid amide hydrolase. Acyl migration readily occurs. **Target(s):** fatty acid amide hydrolase, *or* anandamide amidohydrolase (1); glycerol-3 phosphate *O*-acyltransferase (2). **1.** Ghafouri, Tiger, Razdan, *et al.* (2004) *Brit. J. Pharmacol.* **143**, 774. **2.** Coleman (1988) *Biochim. Biophys. Acta* **963**, 367.

### 1-Oleoyle-*sn*-glycerol 3-Phosphate

This lysophosphatidate (FW<sub>free-acid</sub> = 436.53 g/mol; CAS 22556-62-3; Hygroscopic, Photosensitive), also called monooleoylphosphatidate, is prepared from 1,2-dioleoyl-*sn*-glycerol 3-phosphate by the action of phospholipase  $A_2$ . It is the endogenous agonist for the LPA receptor. (See also *Lysophosphatidate and Lysophosphatidic Acid*) **Target(s):** adenylyl cyclase, mediated by the inhibitory coupling protein, Ni (1); alkylglycerophosphoethanolamine phosphodiesterase, *or* lysophospholipase D (2); chymase (3). **1.** Proll, Clark & Butcher (1985) *Mol. ### 1-Oleoyle-*sn*-glycero-3-phosphocholine

This lysophospholipid (FW = 521.68 g/mol; CAS 19420-56-5), also known as oleoyl lysolecithin and 1-oleoyllysophosphatidylcholine, inhibits cholinephosphate cytidyltransferase (1), 1,3- $\beta$ -glucan synthase (2), and Na $^+$ /K $^+$  exchanging ATPase (3-5). **1.** Vance, Pelech & Choy (1981) *Meth. ## Oligomycin

These macrolide antibiotics from *Streptomyces diastatochromogenes* have three major members: Oligomycin A (FW = 791.08 g/mol; CAS 14104-19-9), Oligomycin B (FW = 805.06 g/mol; CAS 11050-94-5), and Oligomycin C (FW = 775.08 g/mol; CAS 11052-72-5). Others include Oligomycin D (also known as rutamycin; FW = 777.05 g/mol; CAS 1404-59-7), Rutamycin B (isolated from *Streptomyces aureofaciens* (See also *Rutamycin*)), and Oligomycin E (FW = 822.07 g/mol; CAS 110231-34-0; isolated from *Streptomyces* sp. MCI-2225). **Primary Mode of Inhibitory Action:** The oligomycins inhibit the ATP synthesis activity of the mitochondrial  $F_0F_1$  ATP synthase, defining the “o” (not 0) in the first subscript. The ATPase activity of the isolated  $F_1$  complex is unaffected by oligomycins, unlike the  $F_0$  portion. Oligomycin-sensitivity conferring protein (OSCP) interacts with other components in the ATP synthase complex and facilitates oligomycin's binding to the  $F_0$  unit. The  $F_0$  complex is, in fact, an integral membrane protein that functions as a proton channel.

**Other Actions:** Oligomycins also inhibit  $Na^+/K^+$ -exchanging ATPases that transport sodium ions from the inside to the outside of animal cells while translocating potassium ions in the reverse direction with the concomitant hydrolysis of ATP. Oligomycin inhibits  $Na^+$  translocation *in vivo* (i.e., the enzyme activity is inhibited by stabilizing the  $Na^+$  occlusion but not the  $K^+$  occlusion). **Other Properties:** The oligomycins are slightly soluble in water (e.g., oligomycin A has a solubility of 2  $\mu$ g per 100 mL at 25°C) and are considerable more soluble in water-miscible solvents such as ethanol, acetone, and glacial acetic acid. **Target(s):** aldehyde oxidase (1); ammonia kinase (2); apyrase, membrane-bound (3); ATP synthase, or  $F_0F_1$  ATP synthase (4-19); calcidiol 1-monooxygenase (20); copper-exporting ATPase, partially inhibited (21); endopeptidase La, weakly inhibited (22);  $H^+$ -transporting ATPase, lysosomal (23);  $Na^+/K^+$ -exchanging ATPase (24-32); nucleoside triphosphatase (33); photophosphorylation in *Rhodospirillum rubrum* (34); xenobiotic-transporting ATPases (35,36). 1. ## Olivanates

These  $\Delta^2$ -penem-type antibiotics (FW<sub>free-acid</sub> = 394.40 g/mol for MM4550; CAS 64761-66-6) from *Streptomyces olivaceus* are  $\beta$ -lactamase inhibitors, consisting of seven structurally related members (of which three are sulfated). Certain ampicillin-resistant bacteria are rendered sensitive to ampicillin in the presence of olivanic acid at concentrations that did not inhibit growth when administered separately. Note that these antibiotics are also unstable in the presence of hydroxylamine and cysteine. 1. Brown, Corbett, Eglinton & Howarth (1977) *J. Chem. Soc., Chem. Commun.* (15), 523. 2. Butterworth, Cole, Hanscomb & Rolinson (1979) *J. Antibiot. (Tokyo)* **32**, 287.

## Olivomycins

These chromomycin-like antibiotics (FW<sub>Olivomycin-A</sub> = 1197.3 g/mol; CAS 6988-58-5) produced by *Streptomyces olivoreticuli* anthat bind to DNA in a base pair-specific manner, preferring Guanine:Cytosine pairs. The major component, olivomycin A, is a yellow solid that is insoluble in water and soluble in ethanol and chloroform. **Target(s):** DNA-directed DNA polymerase (1-3); DNA-directed RNA polymerase (4-7); *EcoRI* restriction endonuclease, or Type II site-specific deoxyribonuclease (8). 1. Skripal', Bezuglyi & Babichev (1993) *Mikrobiol. Zh.* **55**, 24. 2. Müller, Zahn & Seidel (1971) *Nature New Biol.* **232**, 143. 3. Müller, Yamazaki & Zahn (1972) *Enzymologia* **43**, 1. 4. ## Olmesartan

This antihypertensive agent and ARB (FW = 445.50 g/mol; Code Name CS-866) is the pharmacologically active angiotensin receptor target formed by enzymatic hydrolysis of its prodrug olmesartan medoxomil (FW =

458.60 g/mol; CAS 144689-63-4; Code Name: CS-866; IUPAC: (5-methyl-2-oxo-2H-1,3-dioxolen-4-yl)methyl-4-(2-hydroxypropan-2-yl)-2-propyl-1-({4-[2-(2H-1,2,3,4-tetrazol-5-yl)phenyl]phenyl)methyl)-1H-imidazole-5-carboxylate). Olmesartan blocks [<sup>125</sup>I]angiotensin II binding to bovine adrenal cortical membranes (containing angiotensin AT<sub>1</sub> receptors) with an IC<sub>50</sub> of 7.7 nM, but not [<sup>125</sup>I]angiotensin II binding to bovine cerebellar membranes (containing angiotensin AT<sub>2</sub> receptors), thereby indicating its selectivity for AT<sub>1</sub> receptors (1). Unlike other ACE inhibitors, however, its actions are therefore independent of angiotensin II synthesis pathways. (**See also** Candesartan; Eprosartan; Irbesartan; Losartan; Telmisartan; Valsartan) Although SKF-525A, a potent P-450 inhibitor, suppresses the angiotensin II inhibitory effect of losartan, the same was not true for olmesartan medoxomil (1). Plasma levels of angiotensin II, renin, angiotensin converting enzyme and chymase are unchanged by the high-cholesterol diet, whereas vascular angiotensin converting enzyme, but not chymase, is significantly increased (2). Serum levels of macrophage-colony stimulating factor, transforming growth factor-β<sub>1</sub> and intracellular adhesion molecule-1 are significantly increased in monkeys fed a high-cholesterol diet but they were suppressed by olmesartan medoxomil (2). The relaxation response of isolated carotid arteries to acetylcholine is suppressed in the high-cholesterol group, whereas it was improved by CS-866 (2). Olmesartan-associated sprue-like enteropathy was first described in 2012, and the syndrome is characterized by severe diarrhea and sprue-like histopathologic findings in the intestine, often leading to increased sub-epithelial collagen.

**Key Pharmacological Parameters:** Bioavailability = 26 %; Food Effect? None; Drug *t*<sub>1/2</sub> = 3.5–4 hours; Metabolite *t*<sub>1/2</sub> = 3–11; Drug's Protein Binding = 99 %; Metabolite's Protein Binding = not determined; Route of Elimination = 35–50 % Renal, 50–65 % Hepatic. 1. Mizuno, Sada, Ikeda, *et al.* (1995) *Eur. J. Pharmacol.* **285**, 181. 2. Takai, Kim, Sakonjo & Miyazaki (2003) *J. Hypertens.* **21**, 361.

#### Olodaterol

This long-acting β-adrenoceptor agonist (FW = 386.44 g/mol; CAS 868049-49-4), also known as Striverdi<sup>®</sup> and 6-hydroxy-8-({1*R*)-1-hydroxy-2-{{[1-(4-methoxyphenyl)-2-methylpropan-2-yl]amino}ethyl}-4*H*-1,4-benzoxazin-3-one, is used to treat patients with chronic obstructive pulmonary disease (COPD) by causing the bronchi to relax and reducing resistance to airflow. Olodaterol is nearly full agonist (EC<sub>50</sub> = 0.1 nM), displaying 88% intrinsic activity of isoprenaline. Once olodaterol is bound to a β<sub>2</sub>-receptor, the dissociation half-life is 17.8 hours, permitting once-a-day application. Olodaterol has a higher *in vitro* selectivity for β<sub>2</sub>-receptors, as compared, with 241-fold *versus* β<sub>1</sub>-receptors and 2300-fold *versus* β<sub>3</sub>-receptors. Stiolto Respimat<sup>®</sup> is a once-daily fixed-dose drug consisting of olodaterol and tiotropium. 1. Bouyssou, Hoenke, Rudolf, *et al.* (2010). *Bioorg. Med. Chem. Lett.* **20**, 1410. 2. #### Olomoucine

This ATP site-competitive purine derivative (FW = 298.35 g/mol; CAS 101622-51-9), systematically named 6-benzylamino-2-[2-hydroxyethylamino]-9-methylpurine, is a potent inhibitor of cyclin-dependent kinases, with an IC<sub>50</sub> value of 7 μM for both cdk1 and cdk2 and an IC<sub>50</sub> value of 3 μM for cdk5, arresting cells in G<sub>1</sub> (1-6). Olomoucine also inhibits cytokinin 7β-glucosyltransferase (7). 1. Meijer & Kim (1997) *Meth. Enzymol.* **283**, 113. 2. Vesely, Havlicek, Strnad, *et al.* (1994) *Eur. J. Biochem.* **224**, 771. 3. #### Olsalazine

This anti-inflammatory agent (FW<sub>free-acid</sub> = 302.24 g/mol; CAS 15722-48-2) inhibits myeloperoxidase myeloperoxidase (1), Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (2), and thiopurine *S* methyltransferase (3,4). 1. Kettle & C. C. Winterbourn (1991) *Biochem. Pharmacol.* **41**, 1485. 2. Scheurlen, Allgayer, Kruijs, Erdmann & Sauerbruch (1993) *Clin. Investig.* **71**, 286. 3. Zhou & Chowbay (2007) *Curr. Pharmacogenomics* **5**, 103. 4. Oselin & Anier (2007) *Drug Metab. Dispos.* **35**, 1452.

#### Oltipraz

This schistosomicide (FW = 226.35 g/mol; CAS 64224-21-1), also known as 5-(2-pyrazinyl)-4-methyl-1,2-dithiole-3-thione, is used to treat disease caused by parasitic flatworms and is also a potent cancer chemopreventive agent. Oltipraz was found to protect against chemically induced carcinogens within the lung, stomach, colon, and urinary bladder. The anti-HIV activity of the pharmaceutical is believed to be due to its ability to irreversibly inhibit HIV reverse transcriptase. **Target(s):** CYP1A2 (1-3); CYP3A4 (3); HIV I reverse transcriptase (4); RNA-directed DNA polymerase (4). 1. Sofowora, Choo, Mayo, Shyr & Wilkinson (2001) *Cancer Chemother. Pharmacol.* **47**, 505. 2. Langouet, Furge, Kerriguy, *et al.* (2000) *Chem. Res. Toxicol.* **13**, 245. 3. Langouet, Coles, Morel, *et al.* (1995) *Cancer Res.* **55**, 5574. 4. Chavan, Bornmann, Flexner & Prochaska (1995) *Arch. Biochem. Biophys.* **324**, 143.

#### Omacetaxine

This alkaloid and protein synthesis inhibitor (FW = 545.63 g/mol; CAS 26833-87-4), also known as homoharringtonine and Synribo<sup>®</sup>, from *Cephalotaxus harringtonia* is indicated for treatment of Chronic Myelogenous Leukemia (CML). Omacetaxine binds to the ribosomal A-site, thereby preventing proper positioning of amino acid side-chains of incoming aminoacyl-tRNAs. With mounting evidence of resistance to imatinib and other tyrosine kinase inhibitors (TKIs), particularly as a consequence of an ABL mutation at position-315, omacetaxine offers hope for CML patients failing to respond to TKIs (1). Indeed, Synribo is a FDA-approved treatment for Philadelphia-positive CML either in chronic or accelerated phase whose disease failed two prior TKIs. 1. Wetzler & Segal (2011) *Curr. Pharm. Des.* **17**, 59.

#### Omarigliptin

This oral DPP-4 inhibitor (MW = 398.43 g/mol; CAS 1226781-44-7), also known MK-3102 and systemically as (2*R*,3*S*,5*R*)-2-(2,5-difluorophenyl)-5-[2-(methylsulfonyl)-2,6-dihydropyrrolo[3,4-*c*]pyrazol-5(4*H*)-yl]tetrahydro-2*H*-pyran-3-amine, is a potent and selective reversible competitive inhibitor of Dipeptidyl Peptidase-4 ( $IC_{50} = 1.6$  nM,  $K_i = 0.8$  nM). It is highly selective over all proteases tested ( $IC_{50} > 67$   $\mu$ M), including QPP (or quiescent cell proline dipeptidase), FAP (or fibroblast activation protein, or seprase), DPP8 and DPP9 (or dipeptidyl peptidase 8 and 9). Omarigliptin has weak ion channel activity ( $IC_{50} > 30$  nM at IKr, Ca<sub>v</sub>1.2, and Na<sub>v</sub>1.5). **Mode of Inhibitory Action:** Glucagon-like peptide 1 (GLP-1), which is released by the gut in response to food intake, stimulates insulin secretion in a glucose-dependent manner. Inhibition of DPP-4 prolongs the circulating half-life of glucagon-like peptide 1 and glucose-dependent insulinotropic polypeptide. By increasing the circulating concentration of GLP-1 and GIP, omarigliptin improves glucose control in Type-2 diabetes. Omarigliptin has a long half-life (rat,  $t_{1/2} = 11$  hours; dog,  $t_{1/2} = 22$  hours) and lower clearance (rat, 1.1 mL/min/kg; dog, 0.9 mL/min/kg). Based on the human pharmacokinetics prediction, omarigliptin is projected to be amenable for once-weekly dosing. This conclusion is recapitulated in the clinical studies, where omarigliptin is shown to have a biphasic PK profile with a terminal  $t_{1/2}$  of 120 hours. Indeed, the average renal clearance of omarigliptin was ~2 Liters/hour (2). Over the dose range studied, DPP-4 inhibition ranged from ~77–89% at one week following the last of three once-weekly doses Omarigliptin resulted in ~ 2-fold increases in weighted average postprandial active GLP-1 (2). 1. Biftu, Sinha-Roy, Chen, *et al.* (2014) *J. Med. Chem.* **57**, 3205. 2. Krishna, Addy, Tatosia, *et al.* (2016) *J. Clin. Pharmacol.* **56**, 1528.

### Omareloxolone

This antioxidant inflammation modulator, or AIM (FW = 554.71 g/mol; CAS 1474034-05-3; Solubility: 100 mg/mL DMSO; < 1 mg/mL H<sub>2</sub>O; topical formulation vehicle: Sesame oil), also known as RTA-408 and *N*-((4*aS*,6*aR*,6*bS*,8*aR*,12*aS*)-11-cyano-2,2,6*a*,6*b*,9,9,12*a*-heptamethyl-10,14-dioxo-1,2,3,4,4*a*,5,6,6*a*,6*b*,7,8,8*a*,9,10,12*a*,14,14*a*,14*b*-octadecahydricen-4*a*-yl)-2,2-difluoropropanamide, is a synthetic triterpenoid that activates nuclear factor erythroid 2-related factor 2, or Nrf2 (1). A powerfully cytoprotective transcription factor, Nrf2 elicits the coordinated induction of cytoprotective genes in response to oxidative and electrophilic stress. It rapidly translocates to the nucleus, recognizes and binds to antioxidant response elements in the upstream promoter regions of its target genes, thereby facilitating coordinated responses that serve to alleviate oxidative trauma (2,3). It also inhibits signaling by the proinflammatory transcription factor NF- $\kappa$ B. Topical application of RTA-408 protects mice from radiation-induced dermatitis, with significant increases in Nrf2 target genes and significant decreases in NF- $\kappa$ B target genes in mouse skin tissue. 1. Probst, Trevino, McCauley, *et al.* (2015) *PLoS One* **10**, e0122942. 2. Klaassen & Reisman (2010) *Toxicol. Appl. Pharmacol.* **244**, 57. 3. Taguchi, Motohashi & Yamamoto (2011) *Genes Cells* **16**, 123. 3.

### Ombitasvir

This *N*-phenylpyrrolidine-based, pan-genotypic HCV NS5A protease inhibitor (FW = 893.14 g/mol), also named ABT-267, targets Nonstructural protein 5A (NS5A), a zinc-binding and proline-rich hydrophilic phosphoprotein that plays a key role in Hepatitis C virus RNA replication.

Ombitasvir exhibits low-picomolar EC<sub>50</sub> values against Hepatitis C virus, with superior pharmacokinetics (1). Although ombitasvir shows a low barrier to resistance, when given as monotherapy, co-administration with other antivirals enhances its barrier to resistance. Indeed, a 12-week, Phase-3 study demonstrated that a multi-targeted regimen consisting of ombitasvir, dasabuvir and ribavirin is highly effective and showed a low rate of treatment discontinuation (2). 1. DeGoey, Randolph, Liu, *et al.* (2014) *J. Med. Chem.* **57**, 2047. 2. Feld, Kowdley, Coakley, *et al.* (2014) *New Engl. J. Med.* **370**, 1594.

### Omeprazole

This proton pump inhibitor and antacid drug (FW = 345.42 g/mol; CASs = 73590-58-6 and 119141-88-7; Soluble in ethanol and methanol and only very slightly soluble in H<sub>2</sub>O), also known as Nexium<sup>®</sup>, Essocam<sup>®</sup>, Esomeprazole<sup>®</sup>, and Esomezol<sup>®</sup>, and (S)-5-methoxy-2-[(4-methoxy-3,5-dimethylpyridin-2-yl)methylsulfinyl]-3*H*-benzimidazole, is used to treat dyspepsia, peptic ulcer disease, gastroesophageal reflux disease, and Zollinger-Ellison syndrome. **Primary Mode of Inhibitory Action:** Omeprazole is a prodrug which is converted to its active form only at the site of action, namely the parietal cell. It then binds and reacts irreversibly with an active-site thiol on H<sup>+</sup>/K<sup>+</sup>-ATPase, causing effective and long-lasting inhibition ( $IC_{50} = 3.9$   $\mu$ M) of gastric acid secretion.

Inhibition is selective and irreversible, suppressing gastric acid secretion by targeting the H<sup>+</sup>/K<sup>+</sup>-ATPase. Gastro-esophageal reflux disease arises from the interaction of several anatomical and physiological factors, with a striking correlation between symptoms of heartburn with acid regurgitation and reflux esophagitis first noted in 1934. Allison (1,2) first described hiatus hernia as a factor in the development of the reflux disease. Episodes of reflux were related to transient relaxations of lower oesophageal sphincter. Omeprazole was introduced in 1989 as the first proton pump inhibitor for treating gastro-esophageal reflux disease. **Target(s):** F<sub>1</sub> ATPase, or H<sup>+</sup>-transporting two-sector ATPase (3); H<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (4-11); pyruvate decarboxylase (12); Na<sup>+</sup>/K<sup>+</sup>-ATPase activity,  $IC_{50} = 186$   $\mu$ M (13). **Inhibition of Melanogenesis:** There is great interest in topical products capable of reducing undesired hyperpigmentation, such as irregular hyperpigmentation of the skin, leading to melasma, solar lentigenes, age spots, and uneven skin color. Omeprazole and closely related congeners inhibit melanogenesis at  $\mu$ M concentrations in B16 mouse melanoma cells,

normal human epidermal melanocytes, and in a reconstructed human skin model (14). When omeprazole is applied topically to the skin of UV-irradiated human subjects, pigment levels after 3 weeks are significantly reduced, when compared with untreated controls. Omeprazole has no significant inhibitory effect on purified human tyrosinase, a copper-containing glycoprotein that catalyzes the hydroxylation of tyrosine to dihydroxyphenylalanine (DOPA); nor does omeprazole affect levels of mRNAs for tyrosinase, dopachrome tautomerase, Pmel17, or MITF. Although melanocytes do not express ATP<sub>4</sub>A, they do express ATP7A, a copper transporting P-type ATPase in the *trans*-Golgi network required for copper acquisition by tyrosinase. Omeprazole inhibits ATP7A relocation from the *trans*-Golgi network to the plasma membrane in response to elevated copper concentrations in melanocytes. Omeprazole treatment increased the proportion of EndoH-sensitive tyrosinase, indicating that tyrosinase maturation was impaired. In addition, omeprazole reduced tyrosinase protein abundance in the presence of cycloheximide, a finding that suggests increased degradation (14). 1. Allison (1946) *J. Thorac. Surg.* **15**, 308. 2. #### Ondansetron

This serotonin 5-HT<sub>3</sub> receptor antagonist and anti-emetic (FW = 293.40 g/mol; CAS 99614-02-5), also known by its code name GR38032F, its trade names Zofran® and Emetron®, as well as by its systematic name (*RS*)-9-methyl-3-[(2-methyl-1*H*-imidazol-1-yl)methyl]-2,3-dihydro-1*H*-carbazol-4(9*H*)-one, is used to treat episodes of nausea and vomiting following chemotherapy. Ondansetron affects both peripheral and central nervous systems, reducing vagus nerve activity and thereby deactivating the 5-HT<sub>3</sub> receptor-dense vomiting center located in the medulla oblongata. Ondansetron is without effect on dopamine receptors or muscarinic receptors. **Primary Mode of Inhibitor Action:** On the isolated vagus nerve and superior cervical ganglion of the rat, racemic GR38032F behaved as a reversible competitive antagonist of 5-HT-induced depolarization with p*K*<sub>B</sub> values of 8.61 and 8.13, respectively (1). The resolved *R*- and *S*-isomers were equipotent 5-HT antagonists on the rat vagus nerve, with p*K*<sub>B</sub> values were 8.95 and 8.63, respectively. (Similar 5-HT<sub>3</sub> antagonists include: tropisetron, granisetron, dolasetron, and palonosetron. The effectiveness of each depends on particular variants of 5-HT<sub>3</sub> receptors expressed by the patient, including changes in promoters for the receptor genes.) Ondansetron had a terminal plasma half-life of 3.0-3.5 h and plasma clearance of 600 mL/min, with no evidence of accumulation at steady state (2). Its absolute oral bioavailability was 59%, and its metabolism involves CYP3A4, CYP1A2, and CYP2D6. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Butler, Hill, Ireland, Jordan & Tyers (1988) *Br. J. Pharmacol.* **94**, 397. 2. Blackwell & Harding (1989) *Eur. J. Cancer Clin. Oncol. Suppl* **1**, S21.

#### ONX-0801

This antifolate (FW = 647.63 g/mol; CAS 501332-69-0), also known as BGC 945, CB 300945 as well as *N*-[4-[2-propyn-1-yl][(6*S*)-4,6,7,8-tetrahydro-2-(hydroxymethyl)-4-oxo-3*H*-cyclopenta[*g*]quinazolin-6-yl]amino]benzoyl-L- $\gamma$ -glutamyl-D-glutamic acid, is an anticancer drug that combines the virtues of thymidylate synthase transition-state inhibition with lower toxicity due to selective intracellular accumulation through  $\alpha$ -folate receptor ( $\alpha$ -FR) transport in tumor cells. Indeed,  $\alpha$ -FR is overexpressed in many carcinomas, particularly those of the ovary and uterus, and this property has been exploited for folate-mediated targeting of macromolecules, anticancer drugs, imaging agents, and nucleic acids to cancer cells. ONX 0801 forms a high-affinity complex, when incubated with thymidylate synthase in the presence of 2'-dUMP. The *K*<sub>i</sub> for ONX 0801 with isolated thymidylate synthase is 1.2 nM, whereas the IC<sub>50</sub> for growth inhibition of  $\alpha$ -FR-negative mouse L1210 or human A431 cells is approximately 7  $\mu$ M. In contrast, BGC 945 is highly potent (IC<sub>50</sub>  $\approx$  1-300 nM) in  $\alpha$ -FR-overexpressing human tumor cell lines (1). 1. Gibbs, Theti, Wood, *et al.* (2005) *Cancer Res.* **65**, 11721.

**ONX 0912**, See *Oprozomib*

#### ONX-0914

This potent protease inhibitor (FW = 580.67 g/mol; CAS 960374-59-8; Solubility: 100 mg/mL DMSO or H<sub>2</sub>O), also known as PR-957 and *N*-[2-(4-morpholinyl)acetyl]-L-alanyl-*O*-methyl-*N*-[(1*S*)-2-[(2*R*)-2-methyl-2-oxiranyl]-2-oxo-1-(phenylmethyl)ethyl]-L-tyrosinamide, targets (IC<sub>50</sub> = 10 nM) the chymotrypsin-like protease activity of immunoproteasomes, a distinct class of proteasomes found mainly in monocytes and lymphocytes. These specialized proteasomes shape the antigenic repertoire presented on class I major histocompatibility complexes (MHC-I). ONX-0914 shows minimal cross-reactivity for the constitutive proteasome. Selective inhibition blocks production of Interleukin-23 (IL-23) by activated monocytes and interferon- $\gamma$  and IL-2 by T cells. 1. #### Opium

While not a drug *per se*, opium refers to the latex-like substance exuded by the seedpod of the opium poppy *Papaver somniferum*. Because it contains mainly morphine (~12% by dry weight), the extract is a powerful analgesic. Even so, opium is so bitter that the only convenient route for consuming this plant extract is through smoking it, and that process undoubtedly alters the composition, if not the chemical nature, of opium ingredients. The following excerpt from the *Pharmaceutical Journal & Transactions* of the Pharmaceutical Society of Great Britain (Third Series, Volume XIV, p. 28,

July 14, 1883) is illuminating: "It has not as yet been found practicable to take, with any approximation to accuracy, the temperature at which the prepared opium is smoked, but it would appear to be a higher temperature than that at which the opium alkaloids are decomposed. Should this prove to be the case, it will be of itself sufficient to show that none of the active constituents exist in the smoke in the same condition as they do in opium. It appears perfectly clear from the general composition of opium and the method of manufacturing the extract, that morphine, codeine, and narceine are the only bodies of importance. Codiene and narceine give no sublimate. Moreover, opium smoke does not possess the well-marked bitterness of morphine. The variety of opium most affected by smokers is characterized by the small percentage of morphine which it contains." We now know that temperature, moisture, and even construction of the opium pipe itself can influence the composition of opium smoke, and, even though the resulting smoke is rich in only the most volatile (free-base) form of morphine, other agents are present in lesser abundance. Collectively, these substances are apt to exert a manifold of pharmacologic actions within the lungs and beyond. Although the composition of opium smoke is highly variable, the raw opium extract is the repository of many constituents, and among them:  **$\alpha$ -Allocryptopine** (CAS 24240-04-8, an anti-arrhythmia drug); **Berberine** (CAS 2086-83-1, an anti-pyretic); **Canadine** (CAS 522-97-4, a mild sedative); **Coptisine** (CAS 3486-66-6, an antibacterial and anti-inflammatory agent); **Corytuberine** (CAS 517-56-6, a toxin causing asphyxia and convulsive seizures); **Cryptopine** (CAS 482-74-6, anti-arrhythmia drug); **Dihydrosanguinarine** (CAS 3606-45-9, a sanguinarine mimic); **Isoboldine** (CAS 3019-51-0, an antimicrobial agent); **Isocorypalmine** (CAS 483-34-1; a platelet aggregation inhibitor); **Laudanine** (CAS 85-64-3, an accelerator of respiration); **Laudanosine** (CAS 1699-51-0, a hypotensive agent); **Magnofluorine** (CAS 2141-09-5, an anti-inflammatory agent); **Narceine** (CAS 131-28-2, a mild codeine mimic); **Narcotoline** (CAS 521-40-4, a cough suppressant); **Neopine** (CAS 32404-16-3, a mild codeine mimic); **Oripavine** (CAS 467-04-9, an analgesic); **Protopine** (CAS 130-86-9, an anti-arrhythmia drug); **Pseudomorphine** (CAS 57-27-2, an antihypertensive agent); **Reticuline** (CAS 485-19-8, a mild DOPA antagonist); **Rhoeadine** (CAS 2718-25-4, a mild sedative); **Salutaridine** (CAS 1936-18-1, a mild GABA receptor agonist); **Sanguinarine** (CAS 2447-54-3, a hypertensive agent); **Scoulerine** (CAS 6451-73-6, a mild sedative); and **Stepholidine** (CAS 16562-13-3, an antihypertensive agent), and **Thebaine**, or **Paramorphine** (CAS 115-37-7, exerts stimulatory rather than depressant effects).

#### Ophthalmate (Ophthalmic Acid)

This tripeptide (FW<sub>hydrochloride</sub> = 325.75 g/mol; CAS 495-27-2), also known as L- $\gamma$ -glutamyl-L- $\alpha$ -aminobutyrylglycine, is a glutathione analogue first found in lens of the eye. **Target(s):** formaldehyde dehydrogenase, glutathione-dependent (1);  $\gamma$ -glutamylcysteine synthetase (2-6); lactoylglutathione lyase, or glyoxalase I (7). 1. Valiakina, Reznikova, Novikova, Gorbunov & Zhuze (1972) *Biokhimiia* **37**, 757. 2. Seelig & Meister (1985) *Meth. Enzymol.* **113**, 379. 3. Meister (1995) *Meth. Enzymol.* **252**, 26. 4. Chem.* **268**, 19675. 7. Cliffe & Waley (1961) *Biochem. J.* **79**, 475.

#### Oprozomib

This orally active inhibitor (FW = 532.61 g/mol; CAS 935888-69-0; Solubility: 105 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known as ONX 0912 and *O*-methyl-*N*-[(2-methyl-5-thiazolyl)carbonyl]-L-seryl-*O*-methyl-*N*-

[(1*S*)-2-[(2*R*)-2-methyl-2-oxiranyl]-2-oxo-1-(phenylmethyl)-ethyl]-L-serinamide, selectively targets the chymotrypsin-like (CT-L) activity of 20S proteasome  $\beta 5$  (IC<sub>50</sub> = 36 nM) and 20S proteasome LMP7 (IC<sub>50</sub> = 82 nM). In animal tumor model studies, ONX 0912 significantly reduced tumor progression and prolonged survival. Immunostaining of multiple myeloma tumors from ONX 0912-treated mice showed growth inhibition, apoptosis, and a decrease in associated angiogenesis (2). Oprozomib is distinct from carfilzomib, even though the same chemistry was employed to selectively target the proteasome. Oprozomib is under development as an oral therapy for hematologic malignancies, including multiple myeloma, and for patients with recurrent or refractory solid tumors (**See also Carfilzomib**). 1. Zhou, Aujay, Bennett, *et al.* (2009) *J. Med. Chem.* **52**, 3028. 2. Chauhan, Singh, Aujay, *et al.* (2010) *Blood* **116**, 4906.

#### Opsopyrroledicarboxylic Acid

This porphobilinogen analogue (FW<sub>free-acid</sub> = 197.19 g/mol), also known as pyrrole-3-(acetic acid)-4-(propionic acid) and 4-(carboxymethyl)-1*H*-pyrrole-3-propionic acid, competitively inhibits hydroxymethylbilane synthase, or porphobilinogen deaminase. 1. Bogorad (1962) *Meth. Enzymol.* **5**, 885. 2. Carpenter & Scott (1961) *Biochim. Biophys. Acta* **52**, 195. 3. Bogorad & Pluscec (1970) *Biochemistry* **9**, 4736. 4. **OPT-80**, *See Fidaxomicin*

**OR-462**, *See Nitecapone*

**OR-611**, *See Entacapone*

#### Orbifloxacin

This fluoroquinolone-class antibiotic (FW = 395.37 g/mol; CAS 113617-63-3), also named 1-cyclopropyl-7-[(3*S*,5*R*)-3,5-dimethylpiperazin-1-yl]-5,6,8-trifluoro-4-oxo-1,4-dihydroquinoline-3-carboxylate, is a broad-spectrum systemic antibacterial that targets Type II DNA topoisomerases (gyrases), thereby blocking bacterial replication and transcription. For the prototypical member of this antibiotic class, **See Ciprofloxacin**

#### Orexin A & B

These 33- and 28-residue appetite- and sleep-regulating neuropeptide hormones (FW<sub>Orexin-A</sub> = 3561.12 g/mol; CAS 205640-90-0; *Sequence*: XPLPDCCRQKTCSCRLYELLHGAGNHAAGILTL-NH<sub>2</sub>, where X = Glp, Disulfides join residues 6 to 12 and 7 to 14; FW<sub>Orexin-B</sub> = 2899.36 g/mol; CAS 205640-91-1; *Sequence*: RSGPPGLQGRLLQASGNHAAGIL TM-NH<sub>2</sub>), also called hypocretins, are produced from a common 131-residue precursor named prepro-orexin. The latter is exclusively expressed by orexin-producing neurons in the perifornical nucleus, the dorsomedial hypothalamic nucleus, and the dorsal and lateral hypothalamic areas. Although rodents have only a few thousand orexin-producing neurons, humans have more (~30–70,000). Intracerebroventricular injections of orexins A and B stimulate feeding in a dose-related manner, with orexin A significantly more effective than orexin B. Orexins are strongly linked to the regulation of sleep-activity cycles, the dysfunction of which results in some forms of narcolepsy. Both receptors can couple to G<sub>q</sub> and mobilize intracellular Ca<sup>2+</sup> via activation of phospholipase C, whereas OX<sub>2</sub>R can also

couple  $G_i/G_o$  and inhibit cAMP production via inhibition of adenylate cyclase. In non-neuronal cells  $OX_2R$  mediates extracellular signal-regulated kinase activation via  $G_s$ ,  $G_q$ , and  $G_i$ . In competition radioligand binding  $OX_1R$  has a 10–100x higher affinity for orexin A (20 nM) than for orexin B (250 nM), whereas  $OX_2R$  binds both orexin peptides with similar affinity. 1. de Lecea, Kilduff, Peyron, *et al.* (1998) *Proc. Natl. Acad. Sci. U.S.A.* **95**, 322. 2. Sakurai, Amemiya, Ishii, *et al.* (1998) *Cell* **92**, 573.

**Org 5222, See Asenapine**

**Org 25935**

This synthetic drug (FW = 339.43 g/mol; CAS 949588-40-3), known systematically as 2-([(1*R*,2*S*)-6-methoxy-1-phenyl-1,2,3,4-tetrahydronaphthalen-2-yl]methylmethylamino)acetate, is a selective inhibitor of the sodium/chloride-dependent glycine transporter GlyT<sub>1</sub>, counteracting the effects of the dissociative drug ketamine (1). **Rationale:** Elevation of extracellular synaptic concentration of glycine by blockade of GlyT<sub>1</sub> is believed to potentiate NMDA receptor function *in vivo*, thereby suggesting a rational approach for the treatment of schizophrenia and cognitive disorders. Moreover, accumbal glycine receptors (GlyRs) are involved in mediating the dopamine activating effects of ethanol, and that administration of glycine locally into the nucleus accumbens (nAc) reduces ethanol consumption in ethanol high-preferring rats (1). Org-25935 decreased ethanol intake and ethanol preference, as compared with vehicle, whereas water intake was unaffected. This effect was dose-dependent, developed gradually and was sustained for up to 40 days (1) *Note:* Other GlyT<sub>1</sub> inhibitors include GSK931145, Lu AA21279, NFPS, Org 25935, SB-710622, SSR 504734, whereas D-serine is an agonist. All GlyT<sub>1</sub> inhibitors increased seizure thresholds dose-dependently, indicative of anticonvulsant activity (2). 1. Molander, Lidö, Löf, Ericson & Söderpalm (2007) *Alcohol Alcohol.* **42**, 11. 2. Kalinichev, Starr, Teague, *et al.* (2010) *Brain Res.* **1331**, 105.

**Oritavancin**

This novel, semi-synthetic glycopeptide antibiotic (FW = 1793.10 g/mol; CAS 171099-57-3), also known as LY333328, Orbactiv<sup>®</sup>, and (4*R*)-22-*O*-(3-amino-2,3,6-trideoxy-3-*C*-methyl- $\alpha$ -L-arabinohexopyranosyl)-*N*<sup>3</sup>-(*p*-chlorophenyl)benzyl)vancomycin, disrupts the cell membrane of Gram-positive bacteria (1-3) and inhibits both transglycosylation and transpeptidation (2). Oritavancin differs from vancomycin by the presence of a hydrophobic *N*-4-(4-chlorophenyl)benzyl substituent on the disaccharide, the addition of a 4-epi-vancosamine monosaccharide to the amino acid residue in Ring-6, and replacement of the vancosamine moiety by 4-epi-vancosamine (3). When compared vancomycin, teicoplanin, and quinupristin-dalfopristin (Synercid) against 219 strains of enterococci and staphylococci, including vancomycin-resistant enterococci and methicillin-

resistant *Staphylococcus aureus*, LY333328 demonstrated superior activity against vancomycin-resistant enterococci and was the only antibiotic which was bactericidal. Indeed, a single infusion of this antibiotic (1200 mg) can clear serious bacterial skin infections, including methicillin-resistant *Staphylococcus aureus*, or MRSA, as effectively as the usual 7-10 day, twice-daily regimen of vancomycin now needed to treat patients (5). 1. Cooper, Snyder, Zweifel, *et al.* (1996) *J. Antibiot.* (Tokyo) **49**, 575. 2. Schwalbe, McIntosh, Qaiyumi, *et al.* (1996) *Antimicrob. Agents Chemother.* **40**, 2416. 3. Belley, McKay, Arhin, *et al.* (2010) *Antimicrob. Agents & Chemother.* **54**, 5369. 4. Zhanel, Schweizer & Karlowsky (2012) *Clin. Infect. Dis.* **54** (Suppl 3), S214. 5. Corey, Kabler, Mehra, *et al.* (2014) *New Engl. J. Med.* **370**, 2180.

**Orlistat**

This potent pancreatic lipase inhibitor (FW = 509.77 g/mol; CAS 96829-58-2), also known as tetrahydrolipstatin and Ro 18-0647 as well as by its proprietary name Xenical<sup>™</sup> and Alli<sup>™</sup>, is the saturated derivative of lipstatin and reacts irreversibly with an essential serine (1,2). An amphiphile, orlistat efficiently inactivates enzymes catalyzing lipolytic reactions at the lipid/water interface. One lipase molecule among 10<sup>5</sup> substrate molecules in a membrane is sufficient to reduce lipase activity to half its initial velocity (1). Lipase inactivation is surface pressure-independent. (**See also Lipstatin**) **Use in Weight Control:** Orlistat acts locally within the gastrointestinal tract, and systemic absorption is not required for efficacy (3). Serum total cholesterol and low-density lipoprotein-cholesterol levels are reduced in obese, but not in healthy, patients. Obese patients who maintained a hypocaloric diet and received orlistat (360 mg/day for 12 weeks) lost 5% of bodyweight, significantly greater than placebo recipients (3.5%) (3). In 2-year studies, weight loss was significantly greater in orlistat than in placebo recipients. Ro 18-0647 also reliably increases fecal fat excretion, commending its use in treating obesity and hyperlipidemia by limiting the hydrolysis of triglycerides. **Other Target(s):** Orlistat also inhibits human gastric lipase, pancreatic carboxyl ester lipase (*or* cholesterol esterase), and the closely related bile-salt-stimulated lipase from human milk (1). It does not inhibit the exocellular lipase from *Rhizopus arrhizus* or a lipase recently isolated from *Staphylococcus aureus* (1). 1. Borgström (1988) *Biochim. Biophys. Acta* **962**, 308. 2. Ransac, Gargouri, Moreau & Verger (1991) *Eur. J. Biochem.* **202**, 395. 3. McNeely & Benfield (1998) *Drugs* **56**, 241.

**ORM-10103**

This novel and specific sodium/calcium exchanger inhibitor (FW = 348.36 g/mol), also known as 5-nitro-2-(2-phenylchroman-6-yloxy)pyridine, significantly reduces both the inward ( $EC_{50} = 780$  nM) and outward ( $EC_{50} = 960$  nM) currents of the electrogenic sodium-calcium exchanger (*or* NCX), without significantly change in the L-type  $Ca^{2+}$  current (*or*  $I_{CaL}$ ) and the maximum rate of depolarization (*or*  $dV/dt_{max}$ ), indicative of the fast inward  $Na^+$  current. The NCX is widely expressed in different tissues. In heart, NCX plays an important role in calcium ion homeostasis, in excitation-contraction coupling, and in the electrophysiological properties of cardiac myocytes. ORM-10103 does not influence  $Na^+/K^+$  pump or the main  $K^+$  currents of canine ventricular myocytes, but at 3  $\mu$ M slightly diminishes the rapid delayed rectifier  $K^+$  current. Amplitudes of early and delayed after-depolarizations were significantly decreased by ORM-10103 in a concentration-dependent manner. Such findings suggest that ORM-10103

can abolish triggered arrhythmias and may have antiarrhythmic electrophysiological properties. Other NCX inhibitors include: KB-R7943, SEA0400, SN-6, and YM-244769, but KB-R7943 (2) and SEA-0400 (3) also inhibit the  $I_{CaL}$ , leaving the interpretation of their antiarrhythmic effects less certain. 1. #### D-Ornithine

This dibasic amino acid (FW<sub>dihydrochloride</sub> = 205.08 g/mol; CAS 410523-47-6) is the unnatural enantiomer of the common intermediate of the urea cycle and can be found in a number of antibiotics, including bacitracin A. D-Ornithine is a product of the reaction catalyzed by D-arginase and ornithine racemase and is a substrate for D-ornithine 4,5-aminomutase. (See also L-Ornithine) **Target(s):** 2-aminoheptano-6-lactam racemase (1); L-arginine deaminase, weakly inhibited (2); arginine racemase (3); hydroxylysine kinase (4,5); L-ornithine decarboxylase (6-10); pyrroline 5-carboxylate synthase, or glutamate-5-semialdehyde dehydrogenase (11). 1. Ahmed, Esaki, Tanaka & Soda (1985) *Agric. Biol. Chem.* **49**, 2991. 2. Eichler (1989) *Biol. Chem. Hoppe Seyler* **370**, 1127. 3. Yorifuji (1971) *J. Biol. Chem.* **246**, 5093. 4. #### L-Ornithine

This dibasic amino acid (FW<sub>dihydrochloride</sub> = 205.08 g/mol; CAS 70-26-8; Symbol: Orn; pK<sub>a</sub> values of 1.94, 8.65, and 10.76), also known as 2,5-diaminovaleric acid and 5 aminonorvaline, is a key intermediate in the urea cycle (and arginine biosynthesis). It is also a precursor for the tropane alkaloids and is found in a number of antibiotics and naturally occurring peptides. The monohydrochloride is readily soluble in water and practically insoluble in methanol, ethanol, and diethyl ether (See also D-Ornithine). L-Ornithine is a substrate of reactions catalyzed by N<sup>5</sup>-(carboxyethyl)ornithine synthase, ornithine carbamoyl-transferase, ornithine N-benzoyltransferase, ornithine:oxo-acid aminotransferase, ornithine(lysine) aminotransferase, ornithine decarboxylase, ornithine cyclodeaminase, and ornithine racemase. It is a product in reactions catalyzed by glycine amidinotransferase, scyllo-inosamine-4-phosphate amidinotransferase, glutamate N-acetyltransferase, acetyloronithine deacetylase, citrullinase, and arginase. **Target(s):** acetyloronithine aminotransferase, also alternative substrate (47); agmatinase (2); aminoacyl-lysine dipeptidase, or Xaa-Arg dipeptidase (3); 2-aminoheptano-6-lactam racemase (4,5); aminolevulinatase aminotransferase, weakly inhibited (46); aminopeptidase B, weakly inhibited (40); 5-aminovaleate transaminase (45); arginase (6); D-arginase (33); arginine decarboxylase (7-12); arginine deaminase (13,34-37); arginine racemase (14,15); arginyl-tRNA synthetase (16); carboxypeptidase B (18); diaminopimelate decarboxylase (19);  $\gamma$ -glutamyl kinase, or glutamate 5-kinase, weakly inhibited (41); glycine amidinotransferase (49); histidyl-tRNA synthetase, weakly inhibited (20); homoserine kinase (44); hydroxylysine kinase (42,43); kynureninase (21-23); D-lysine 5,6-aminomutase (24,25); lysine 2-monooxygenase (50); lysyl endopeptidase, or *Achromobacter* proteinase I (26); lysyl-tRNA synthetase (27); methionine S-adenosyltransferase (48); D-ornithine 4,5-aminomutase (28); ornithine carbamoyltransferase, inhibited by the zwitterionic neutral species (the monocationic form is the true substrate) (29); peptidyl-Lys metalloendopeptidase (17,38,39);  $\Delta^1$ -pyrroline 5-carboxylate synthase, or glutamate-5-semialdehyde dehydrogenase (30-32); Xaa-Arg dipeptidase (3). 1. #### Ornithodorin

This toxic protein (MW = 12.6 kDa) from the blood-sucking tick *Ornithodoros moubata*, is a potent inhibitor ( $K_i = 1-3$  pM) of thrombin, binding near the catalytic site (1,2). The N-terminal portion and the C-terminal helix of each domain are structurally very similar to BPTI, whereas the regions corresponding to the binding loop of BPTI adopt different conformations (3). Neither of the two 'reactive site loops' of ornithodorin contacts the protease in the ornithodorin-thrombin complex. Instead, the N-terminal residues of ornithodorin bind to the active site of thrombin, reminiscent of the thrombin-hirudin interaction. The C-terminal domain binds to the fibrinogen recognition exosite (3). 1. Van de Loch, Stubbs, Bode, *et al.* (1996) *EMBO J.* **15**, 6011. 2. Klinger & Friedrich (1997) *Biophys. J.* **73**, 2195. 3. van de Loch, Stubbs, Bode, *et al.* (1996) *EMBO J.* **15**, 6011.

#### Orotate (Orotic Acid)

This pyrimidine biosynthesis intermediate (FW<sub>free-acid</sub> = 156.10 g/mol; Solubility = 0.2 g/100 mL H<sub>2</sub>O at 18°C;  $\lambda_{max}$  at 279 nm at pH 7 ( $\epsilon = 7700$  M<sup>-1</sup>cm<sup>-1</sup>); pK<sub>a</sub> values of 2.4, 9.5, and >13.0), also known as uracil-4-carboxylic acid and uracil-6-carboxylic acid, is the product of dihydroorotate oxidase and dihydroorotate dehydrogenase reactions. It is also a substrate in the reactions catalyzed by the orotate reductases and orotate phosphoribosyltransferase. **Target(s):** acetyl-CoA synthetase (1); acylphosphatase (2); dihydroorotate (3-9); ornithine carbamoyltransferase (with D-ornithine concentrations above 5 mM) (10); orotidine-5'-phosphate decarboxylase (11); urate-ribonucleotide phosphorylase, weakly inhibited

### Orotidine

This water-soluble ribonucleoside (FW<sub>free-acid</sub> = 288.21 g/mol; CAS 314-50-1;  $\lambda_{\text{max}}$  of 267 nm in 0.1 N HCl ( $\epsilon = 9570 \text{ cm}^{-1}\text{M}^{-1}$ ; another report lists 9800) and 265 nm in 0.1 N methanolic NaOH ( $\epsilon = 8960 \text{ cm}^{-1}\text{M}^{-1}$ ; another report lists 7800)), first observed in *Neurospora crassa*, is also found in the urine of cancer patients treated with 6-azauridine, Orotidine is most likely formed from OMP, its 5'-monophosphate ester and the direct precursor of UMP. Orotidine is readily hydrolyzed in dilute mineral acids.

**Target(s):** orotate phosphoribosyltransferase (1); orotidine-5'-phosphate decarboxylase (2,3). 1. Javaid, el Kouni & Iltzsch (1999) *Biochem. Pharmacol.* **58**, 1457. 2. Miller, Butterfoss, Short & Wolfenden (2001) *Biochemistry* **40**, 6227. 3. Sievers & Wolfenden (2005) *Bioorg. Chem.* **33**, 45.

### Orotidine 5'-Monophosphate

This pyrimidine nucleotide (FW<sub>free-acid</sub> = 368.19 g/mol; CAS 2149-82-8; *Abbreviation:* OMP;  $\lambda_{\text{max}}$  at 266 nm at pH 7), also called orotidylic acid, is an intermediate in the biosynthesis of the uridine monophosphate. OMP is a product of the reaction catalyzed by orotate phosphoribosyltransferase and is a substrate of orotidine-5'-phosphate decarboxylase. **Target(s):** adenylosuccinate synthetase (1); amidophospho-ribosyltransferase, weakly inhibited (2); cytosine deaminase (3,4). 1. Van der Weyden & Kelly (1974) *J. Biol. Chem.* **249**, 7282. 2. Holmes, McDonald, McCord, Wyngaarden & Kelley (1973) *J. Biol. Chem.* **248**, 144. 3. West, Shanley & O'Donovan (1982) *Biochim. Biophys. Acta* **719**, 251. 4. West (1988) *Experientia* **41**, 1563.

### Orphenadrine

This muscle relaxant and antihistaminic agent (FW<sub>free-base</sub> = 269.39 g/mol; CAS 83-98-7) is both a muscarinic and histamine H<sub>1</sub> receptor antagonist that also inhibits some cytochrome P450 systems. Classified as an anticholinergic drug (with 58% as potent as atropine) and an ethanolamine-class antihistamine, it also inhibits the noradrenergic transporter and NMDA receptor ion channel ( $K_i \approx 6 \mu\text{M}$ ). Commercially available as either the hydrochloride or citrate salt, orphenadrines used to relieve pain of muscle injuries, such as strains and sprains. **Target(s):** aldehyde oxidase (1); CYP1A2 (2); CYP2A6 (2); CYP3A4 (2); CYP2B (3,4); CYP2B6

(2,5,6); CYP2C9 (2); CYP2C19 (2); CYP2D6 (2); histamine H<sub>1</sub> receptor (7); N-methyl-D-aspartate (NMDA) receptor (8); muscarinic receptor (9,10); noradrenaline reuptake (11). 1. ### Orthophosphate (or Inorganic Phosphate)

These conjugate bases (Symbol: P<sub>i</sub>) of phosphoric acid H<sub>3</sub>PO<sub>4</sub> (pK<sub>a</sub> values of 2.15, 7.20, and 12.33 at 25°C, with corresponding dpK<sub>a</sub>/dT values are 0.0044, -0.0028, and -0.026) are commonly used as buffers in biochemical experiments. Monobasic orthophosphate is a major intracellular buffer, second only to bicarbonate for pH control in humans. Monobasic phosphate (NaH<sub>2</sub>PO<sub>4</sub>; FW = 119.98 g/mol; CAS 7558-79-4; KH<sub>2</sub>PO<sub>4</sub>; FW = 136.09 g/mol; CAS 7778-77-0) is typically found as the mono- or dehydrate, and both are freely soluble in water. **Use as Buffers:** Dibasic phosphate (Na<sub>2</sub>HPO<sub>4</sub>; FW = 141.96 g/mol; CAS 7782-85-6; K<sub>2</sub>HPO<sub>4</sub>; FW = 174.20 g/mol; CAS 7758-11-4) is found as the anhydrous powder as well as the di-, hepta-, and dodecahydrate; all are soluble in water. The anhydrous material will readily absorb atmospheric water. Tribasic phosphate (Na<sub>3</sub>PO<sub>4</sub>; FW = 163.94 g/mol; CAS 7601-54-9; K<sub>3</sub>PO<sub>4</sub>; FW = 212.27 g/mol; CAS 7778-53-2) is typically supplied as the dodecahydrate, which is soluble in about 3.5 parts water. NaH<sub>2</sub>PO<sub>4</sub> and Na<sub>2</sub>HPO<sub>4</sub> salts are solids, and buffer solutions are easily and reproducibly prepared. (Even so, care must be exercised because these salts are hygroscopic). Orthophosphate is also transparent to ultraviolet light. On the other hand, orthophosphate ions bind metal ions (e.g., calcium phosphate has a low solubility in water and precipitates out of solution, depending on the conditions). Phosphate-containing solutions also tend to support fungal and algal growth. Most importantly, orthophosphate is a substrate, product, and/or effector of a wide number of enzymes, and, when present at elevated concentrations in buffer, phosphate can mask a kinetic or regulatory event that would be evident had a different buffer had been used. **Phosphate-Buffered Saline (PBS):** A 1.0-liter stock of 10x stock solution may be prepared by combining 80.00 g NaCl, 2.00 g KCl, 14.40 g Na<sub>2</sub>HPO<sub>4</sub> · 2H<sub>2</sub>O, 2.40 g KH<sub>2</sub>PO<sub>4</sub> in 800 mL distilled water. Bring the final solution to 1.00 L. The pH of the 10X stock is will be approximately 6.8, but changes to 7.4, when diluted to 10x to obtain PBS. It is wise to measure the pH with a pH meter, adjusting it to 7.4 by the addition of either 1 M hydrochloric acid or 1 M sodium hydroxide (The latter should be freshly prepared to prevent introduction of atmospheric carbon dioxide.) **Targets:** Orthophosphate is a substrate/product in over 2000 enzyme-catalyzed reactions, and its inhibitory effects, while too numerous to list here, are generally mild, with K<sub>i</sub> values typically in the 0.1–2 mM range.

### Orthovanadate Ion

This vanadium(V) anion VO<sub>4</sub><sup>3-</sup> (FW<sub>trisodium-orthovanadate</sub> = 183.91 g/mol) inhibits many phosphotransferases and phosphohydrolases, often adopting a structure that mimics the geometry of intermediates in associative (in-line) S<sub>N</sub>2 nucleophilic displacement reactions. Because tungstate and molybdate ions are isoelectronic with orthovanadate and exert similar effects, they are likely to interact with enzyme targets in a similar manner, albeit with different affinities. (See also *Decavanadate*; *Pervanadate*; *Metavanadate*) **Solution Behavior:** At physiological pH values, orthovanadate tends to form larger aggregations (e.g., V<sub>3</sub>O<sub>9</sub><sup>3-</sup> and V<sub>4</sub>O<sub>10</sub><sup>4-</sup>). At lower pH, the predominant species is decavanadate (V<sub>10</sub>O<sub>28</sub>H<sub>5</sub><sup>-</sup>). After making a vanadate solution, the latter should stand for several days to ensure that equilibrium has been reached among its various forms. Solutions of orthovanadate may be prepared as follows: dissolve Vanadium(V) oxide in 2.1 molar

equivalents of 1 N NaOH, stir 2-3 days until the yellow color becomes faint, and dilute with water to a final concentration of 100 mM. Vanadate-inhibited enzymes often reactivate on addition of EDTA, which forms high-affinity Vanadate:EDTA complexes. When divalent cations must be chelated, one may use EGTA. Vanadate also interacts with many other organic compounds and buffer salts; HEPES is a useful exception. Some commercial preparations of nucleoside triphosphates and carbamoyl phosphate also contain trace amounts of vanadate, and one should ascertain that reagents are vanadate-free before using them in kinetic and mechanistic studies. Orthovanadate also complexes with peroxide anion to produce pervanadate, a reagent that can oxidatively inactivate enzymes with active-site thiols. **Does Vanadate Form True Transition State-like Complexes?** Vanadate often binds to phosphotransferases to form a trigonal-bipyramidal structure at the active site, with the enzyme-vanadate  $K_d$  values that are much lower than those for phosphate. Although enzyme-bound vanadate moieties are often touted as transition state analogues, one must learn whether the bond orders of the VO bonds in the complex approach those of the PO bonds in an authentic transition state (1). In steady-state kinetic measurements and difference Raman experiments on vanadate binding to *Yersinia* protein tyrosine phosphatase (PTPase) and its T410A, D356N, W354A, R409K, and D356A mutants, there is clear no correlation between  $K_i$  and  $k_{cat}$  or  $k_{cat}/K_m$ . The bond order change of the nonbridging V-O bonds in the vanadate complexes does not correlate with the kinetic parameters in a number of PTPase variants, as required by the transition state binding assumption. Moreover, the ionization state of bound vanadate is not invariant across the PTPase variants studied, and the average bond order of the nonbridging VO bonds decreased by 0.06–0.07 valence unit in wild type and all the mutant PTPases, either in dianionic or in monoanionic form. In this respect, the complex would resemble an associative transition state, contrary to the previously determined dissociative structure of the transition state, suggesting that vanadate cannot be a true transition-state analogue for the PTPase reactions (1). Such findings also point to the overly simplistic view that vanadate combines with target enzymes to form a true transition-state analogue. **Other Effects:** Vanadate also exerts insulin-like effects on glucose metabolism by activating glucose transport and oxidation. It also raises fructose 2,6-bisphosphate (or Fru(2,6)P<sub>2</sub>) levels, activating glycolysis in hepatocytes from normal or diabetic rats. In other reports, oral administration of vanadate to diabetic rats normalizes hepatic glucose metabolism and glucose blood levels and restores insulin-responsiveness of target tissues. **Target(s):** N-acetylgalactosamine-4-sulfatase, or arylsulfatase B (141); acid phosphatase (2-3,216-224); adenosine-tetraphosphatase (4); Ag<sup>+</sup>-exporting ATPase (5); alkaline phosphatase (2,3,6,225-228); 1-alkyl-2-acetylgllycerophosphatase (148); alkylglycerol-phosphate 2-O-acetyltransferase (239); apyrase (other apyrases report no inhibition by orthovanadate or different degrees of inhibition of ADP vs. ATP hydrolysis) (7-10); arylsulfatase (2,142); ATPase, slow-binding inhibition (3,11); cadmium-transporting ATPase, glutathione-conjugate-transporting ATPase (12-14); Ca<sup>2+</sup> transporting ATPase (3,15-23); CD45 protein phosphatase (24); centromere binding protein E (25); channel-conductance-controlling ATPase, or cystic-fibrosis membrane-conductance-regulating protein (26); chloroplast protein-transporting ATPase (27); Cl<sup>-</sup>-transporting ATPase (28-33); copper-exporting ATPase (34-37); DNA topoisomerase II (38,39); dolichyl-phosphatase (149); dual-specificity protein phosphatase (208,210); dynein ATPase (3,40-54); endopeptidase La, inhibition attributed to decavanadate (55,134-140); exopolyphosphatase (4,56); Fe<sup>3+</sup>-transporting ATPase (57); fructose-1,6 bisphosphate aldolase (58); fructose-2,6-bisphosphate 2-phosphatase (185,186); FtsH protease (59); glucose-1-phosphatase (211); glucose-6-phosphatase (212,213); glyceraldehyde-3-phosphate dehydrogenase (3); glycerol-1-phosphatase (202); glycogen phosphorylase (238); glycosylphosphatidylinositol diacylglycerol-lyase (60); H<sup>+</sup>-exporting ATPase (61-64); H<sup>+</sup>/K<sup>+</sup> exchanging ATPase (3,65-69,188); inositol-trisphosphate 3-kinase (233); kinesin (25,70-72); K<sup>+</sup> transporting ATPase (73-81); β-lactamase, in the presence of hydroxamates (82); lipid-phosphate phosphatase (144); maltose-transporting ATPase (83); minus-end-directed kinesin ATPase (25,48,70); mitochondrial ATP-dependent protease (84); monoterpenyl-diphosphatase (85); MutS ABC ATPase (86); myosin ATPase (3,87-90); NADH:cytochrome *c* reductase, or NADH dehydrogenase (91); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (3,92-97,187); 4-nitrophenylphosphatase activity of H<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (188); 4-nitrophenylphosphatase activity of Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (187); nucleotidases (189); 5'-nucleotidase (214); P-glycoprotein98-103; phosphatidylinositol diacylglycerol lyase, or phosphatidylinositol-specific phospholipase C (104); phosphatidylinositol-3 phosphatase (147); phosphoenolpyruvate mutase (105); 6-phosphofructo-2-kinase (106); phosphoglucomutase (107); phospholipase A<sub>1</sub>, phosphatidate-

specific (229); phospholipase C (108); phospholipid-translocating ATPase, or flippase (103,109-113); phosphomannomutase (114); phosphoprotein phosphatase (24,115-118,203-210); phosphoserine phosphatase (215); 2-phosphosulfolactate phosphatase (146); 3-phytase (119,191,197,198); 3- or 4-phytase (194); 4-phytase (190-193,195,196); 5-phytase (145); plus-end-directed kinesin ATPase (71,72); polar-amino-acid-transporting ATPase, or histidine permease (120,121); polynucleotide adenyllyltransferase, or poly(A) polymerase (231); protein-synthesizing GTPase (elongation factor) (122); protein-tyrosine kinase (230); protein-tyrosine-phosphatase (117,118,123,151-184); ribonuclease (3); soluble epoxide hydrolase, weakly inhibited (143); sorbitol-6-phosphatase (150); sucrose-phosphatase (199-201); sucrose phosphate synthase (237); sulfate adenyllyltransferase (ADP) (232); thiamin-triphosphatase (124); thymidine-triphosphatase (125); α,α-trehalose phosphorylase (configuration-retaining) (234-236); xenobiotic-transporting ATPase, multidrug-resistance protein (98-103,126-131); zinc-exporting ATPase (132,133). 1. ### Orvepitant

This selective NK<sub>1</sub> receptor antagonist (FW = 628.62 g/mol; CAS 579475-18-6; Soluble in DMSO, but not H<sub>2</sub>O), also named (2*R*,4*S*)-*N*-((*R*)-1-(3,5-bis(trifluoromethyl)phenyl)-ethyl)-2-(4-fluoro-2-methylphenyl)-*N*-methyl-4-((*S*)-6-oxohexahydropyrrolo[1,2-*a*]pyrazin-2(1*H*)-yl)piperidine-1-carboxamide and GW823296, provides full and long-lasting blockade of central Neurokinin-1 receptors and may represent an efficacious mechanism for treating Major Depressive Disorder (MDD), anxiety, and insomnia. (**See also the NK<sub>1</sub> antagonist, Aprepitant**) I. Ratti, Bettica, Alexander, *et al.* (2013) *J. Psychopharmacol.* **27**, 424.

### Oseltamivir (Oseltamivir Carboxylate)

This zanamivir analogue (FW = 284.36 g/mol), also known by its code name GS 4071, and systematic name (3*R*,4*R*,5*S*)-5-amino-4-acetamido-3-(pentan-3-yloxy)cyclohex-1-ene-1-carboxylate, is a potent inhibitor of influenza A and B neuraminidase (IC<sub>50</sub> = 1 nM). The pro-drug ester (FW = 312.40 g/mol; CAS 196618-13-0; Generic Name: Oseltamivir; Systematic Name: ethyl (3*R*,4*R*,5*S*)-5-amino-4-acetamido-3-(pentan-3-yloxy)cyclohex-1-ene-1-carboxylate; tradename: Tamiflu<sup>®</sup>) is known as oseltamivir. **Pharmacokinetics:** Oseltamivir is readily absorbed from the gastrointestinal tract and is subsequently converted by hepatic esterases to its pharmacologically active form (oseltamivir carboxylate). It is widely distributed in the body, showing a half-life is 6 to 10 hours. The drug is excreted primarily through the kidneys, and dosing must be adjusted for patients with renal insufficiency. Oseltamivir achieves high plasma levels and thus can be effective beyond the respiratory tract. (**See Zanamivir**) **Potential Use as an Antipandemic Agent:** Analysis data for patients (all ages) admitted to hospital worldwide with laboratory-confirmed or clinically diagnosed infection with the pandemic influenza A H1N1pdm09 virus indicates that early treatment in adults admitted to hospital with suspected/proven influenza infection can be effective in reducing mortality

(3). In the United States, tamiflu has been stockpiled as the front line of its national pandemic defense strategy. Indeed oseltamivir's producer, Roche, in coordination with external partners now possesses the capacity to produce more than 400 million courses of Tamiflu yearly. 1. **Osimertinib, See AZD9291**

### OSU-03012

This PDK1 inhibitor (FW = 460.45 g/mol; CAS 742112-33-0; Soluble to 100 mM in DMSO), systematically named 2-Amino-N-[4-[5-(2-phenanthrenyl)-3-(trifluoromethyl)-1*H*-pyrazol-1-yl]phenyl]acetamide, blocks Akt signaling by targeting 3-Phosphoinositide-Dependent Protein Kinase-1 (IC<sub>50</sub> = 2-3 μM) (1). Exposure of PC-3 cells to this agent leads to Akt dephosphorylation and inhibition of p70 S6 kinase activity. OSU-03012 promotes glioma cell killing that is dependent on endoplasmic reticulum stress, lysosomal dysfunction, and BID-dependent release of AIF from mitochondria, and whose lethality is enhanced by irradiation or by inhibition of protective signaling pathways (2). OSU03012 induced mitochondrial-dependent apoptosis of medulloblastoma cells and enhanced the cytotoxic effects of chemotherapeutic drugs in a synergistic or additive manner (3) When tested *in vivo*, OSU03012 inhibits the growth of established medulloblastoma xenograft tumors in a dose-dependent manner and augmented the antitumor effects of mammalian target of rapamycin inhibitor CCI-779 (3). 1. Zhu, Huang, Tseng, *et al.* (2004) *Cancer Res.* **64**, 4309. 2. Yacoub, Park, Hanna, *et al.* (2006) *Mol. Pharmacol.* **70**, 589. 3. ### Otlertuzumab

This intravenously administered anti-CD37 IgG fusion protein (MW = 107.5 kDa; CAS 1372645-37-8), also known by its code name TRU-016, is intended for the treatment of B-cell malignancies, including chronic lymphocytic leukemia (CLL) and non-Hodgkin's lymphoma (NHL), as well as for autoimmune and inflammatory diseases. Otlertuzumab was created by humanizing SMIP-016, a mouse/human chimeric protein that demonstrates antitumor activity against lymphoid malignancies in preclinical studies, including in human B-cell tumor mouse xenograft models. TRU-016 demonstrates synergistic or additive activity in NHL cells in combination with rituximab, rapamycin, doxorubicin and bendamustine. In a phase I/II clinical trial in refractory or relapsed patients with CLL or small lymphocytic lymphoma, Otlertuzumab is well tolerated, with clinical benefit and a reduced absolute lymphocyte count observed in all cohorts dosed at > 0.1 mg/kg. TRU-016 is a promising therapeutic agent for patients with B-cell lymphoid malignancies, especially patients refractory to standard treatment.

### OTX015

This bromodomain inhibitor (FW = 491.99 g/mol; CAS 202590-98-5; Solubility: 98 mg/mL DMSO; <1mg/mL H<sub>2</sub>O), also named (6*S*)-4-(4-

chlorophenyl)-*N*-(4-hydroxyphenyl)-2,3,9-trimethyl-6*H*-thieno[3,2-*f*][1,2,4]triazolo[4,3-*a*][1,4]diazepine-6-acetamide, targets the Bromodomain and Extra Terminal (BET) domain proteins BRD2, BRD3, and BRD4, with EC<sub>50</sub> values in the 10-19 nM range, exhibiting cytostatic anti-proliferative activity in several anaplastic large cell lymphoma (ALCL) cell lines. Treatment leads to rapid down-regulation of c-MYC expression followed by the cell cycle G<sub>1</sub> arrest. The synergistic effects of OTX-015 with anti-ALK inhibitors provide the rationale for lower-toxicity protocols for the treatment of ALKpos ALCL patients. **1.** Noel, *et al.* (2013) *Mol. Cancer Ther.* **12**, C244. **2.** Boi, *et al.* (2013) *Mol Cancer Ther.* **12**, A219.

### Ouabain

This cardiac glycoside (FW = 584.66 g/mol) from *Strophanthus gratus* and *Acokanthera ouabaio*, also called  $\gamma$ -strophanthin and *gratus* strophanthin, selectively inhibits Na<sup>+</sup>/K<sup>+</sup> exchanging ATPases by binding to the  $\alpha$ -subunit near its amino terminal and to the H<sub>5</sub>-H<sub>6</sub> hairpin region, blocking the active efflux of sodium ion as well as the reuptake of potassium ion by blocking movement of the H<sub>5</sub> and H<sub>6</sub> transmembrane domains (1,2). Ouabain increases natriuresis (3), slows heart rate with its positive inotropic effect (4), increases intracellular Ca<sup>2+</sup> (4,5), and induces hypertension (6). Recently, endogenous inhibitors of the Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase have been identified in adrenal cortex and brain that are stereoisomers of ouabain and possess inotropic and vasopressor activities (7-9). Hydrolysis of ouabain will yield ouabagenin and L-rhamnose. Ouabain octahydrate (FW = 728.78 g/mol) is soluble in boiling water (200 mg/mL), cold water (10 mg/mL), and ethanol (10 mg/mL at room temperature). Ouabain should be stored in the dark. **Target(s):** adenylate cyclase, *Phycomyces blakesleeanus* (10); H<sup>+</sup>/K<sup>+</sup>-exchanging ATPase, moderately sensitive (11); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (12-32); 4-nitrophenylphosphatase activity of Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (31,32). **1.** Lingrel, Croyle, Woo & Arguello (1998) *Acta Physiol. ### Ovomucoid

This egg white glycoprotein (MW  $\approx$  28 kDa) is a multidomain Kazal-type protease inhibitor. The chicken (*Gallus gallus*) protein contains 210 aminoacyl residues, and its carbohydrate chains are N-linked at asparaginy residues. (See also *Ovoinhibitors*). **Target(s):** acrosin (1,21-23); archaebacterial serine proteinase of *Halobacterium mediterranei* (2); brachyuran (3); chymotrypsin (4-6,26); envelysin, *Xenopus* (7); glutamyl endopeptidase II, inhibited notably by [Leu18 $\rightarrow$ Glu]-modified ovomucoid (8,9); leukocyte elastase (10-12); pancreatic elastase, inhibited by third domain (6,12,13); peptidase K, or proteinase K, inhibited by third domain (6); peptidyl-glycinamidase, or carboxamidopeptidase (14); spermosin (1); streptogrisin A, inhibited by third domain (6); streptogrisin B, inhibited by third domain (6,15); *Streptomyces erythraeus* trypsin (16); subtilisin (6,17); subtilisin BPN<sup>+</sup> (6); subtilisin Carlsberg (6); trypsin (4,5,18-20,24-26). **1.** Sawada, Yokosawa & Ishii (1984) *J. ### Ovostatin

This tetrameric protein, also called ovomacroglobulin, inhibits proteinases of all four mechanistic classes. Ovostatin inhibits proteinases in a manner similar to  $\alpha_2$ -macroglobulin. Protease-catalyzed hydrolysis of a peptide bond in the susceptible region of the ovostatin polypeptide chain triggers a conformational change that hinders binding of macromolecular substrates, while remaining accessible to small synthetic substrates. **Target(s):** chymotrypsin (1,2); cortical granule protease (1); interstitial collagenase, matrix metalloproteinase 1 (3-5); leukocyte elastase (6-8); matrilysin, matrix metalloproteinase 7 (9-11); papain (2,12); procollagen C-endopeptidase (13); *Pseudomonas aeruginosa* alkaline protease (7); serralyisin (14); stromelysin 1, matrix metalloproteinase 3 (3,15,16); thermolysin (2,4,5,12,17,18); trypsin (1,2,12). **1.** Yamada & Aketa (1988) *Gamete Res.* **19**, 265. **2.** Osada, Sasaki & Ikai (1988) *J. ## 1H-[1,2,4]Oxadiazolo[4,3-a]quinoxalin-1-one

This hygroscopic quinoxaline ( $FW = 187.16$  g/mol; *Abbreviation:* ODQ), is an irreversible inhibitor of soluble guanylate cyclase, whereas particulate guanylate cyclase is unaffected. It is insoluble in water and soluble in dimethyl sulfoxide (5 mg/mL) and acetonitrile (20 mg/mL). 1. Schrammel, Behrends, Schmidt, Koesling & Mayer (1996) *Mol. Pharmacol.* **50**, 1. 2. ## Oxalate (Oxalic Acid)

This dicarboxylic acid ( $FW_{\text{free-acid}} = 90.04$  g/mol; CAS 144-62-7), is the simplest dicarboxylic acid (the  $pK_a$  values are 1.27 and 4.29 at 25°C). Oxalate is produced by a number of plants (*e.g.*, species of *Oxalis* and *Rumex*) and is toxic to mammals. Small amounts are formed in humans, particularly in individuals with primary hyperoxaluria. Life-threatening oxalate poisoning occurs whenever humans mistakenly consume ethylene glycol. Oxalate is also a natural product of ascorbate and proline degradation. The most common renal calculi are composed of calcium oxalate monohydrate, which is virtually insoluble in water and forms opportunistically when oxalate and calcium ions combine within renal tubules, eventually filling and occluding the renal pelvis and ureters, thereby obstructing urine flow. The physicochemical basis oxalate biomineralization and stone formation is best understood as a condensation-equilibrium process (1). Oxalate also inhibits many enzymes, mainly as a consequence of its metal-ion chelating properties. **Target(s):** acetylpyruvate hydrolase (2); acid phosphatase (3-9,158,159);  $\epsilon$ -acyl-lysine deacylase (10); acylphosphatase (11); alanine aminotransferase (178); alcohol dehydrogenase (12); alkaline phosphatase (9,13); allantoinase (14); arylsulfatase A, *or* cerebroside-sulfatase, mildly inhibited (15); arylsulfatase B, *or* N-acetylgalactosamine-4-sulfatase (15); aspartate ammonia lyase (16); D-aspartate oxidase (17); atrazine chlorohydrolase (18); benzoate 4-monooxygenase, weakly inhibited (187); bothropasin (146); carbamoyl-phosphate synthetase (19); carboxy-*cis,cis*-muconate cyclase (20); carboxypeptidase A (21-23); catalase (192); catechol oxidase, *or* polyphenol oxidase, *or* tyrosinase (5,24); cholinesterase (25); cyanate

hydratase, cyanase (26-28); cytosol alanyl aminopeptidase (148); dehydrogluconate dehydrogenase (29); esterase, *or* lipase (30); 5-formyltetrahydrofolate cyclo-ligase, *or* 5,10-methenyltetrahydrofolate synthetase (31); fumarylacetoacetase (32); gluconate 2-dehydrogenase (33); glucose-6-phosphatase (34); glutamate decarboxylase, (35); glycogen synthase (36); homocitrate synthase (179); D-2 hydroxy-acid dehydrogenase (5,37-41); (S)-2-hydroxy-acid oxidase (42); hydroxyacylglutathione hydrolase (glyoxalase II)160; [3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)] phosphatase (154); inositol oxygenase (188); isocitrate lyase (43-57); L-kynurenine aminotransferase (58,59); laccase (193); lactase-phlorizin hydrolase, *or* glycosylceramidase (152); D-lactate dehydrogenase (5,38,60-64); L-lactate dehydrogenase (5,60,62,63,65-79); D-lactate dehydrogenase (cytochrome) (5,38,63); L-lactate dehydrogenase (cytochrome) (63); lactate 2-monooxygenase, slow-binding inhibition (80,81,189-191); levanase (150,151); malate dehydrogenase (82); malate synthase (83-86,180-185); malic enzyme, *or* malate dehydrogenase (decarboxylating) (87); malyl-CoA lyase (88); D-mandelate dehydrogenase (64); L-mandelate dehydrogenase (89); membrane alanyl aminopeptidase, *or* aminopeptidase N, inhibited by ammonium salt (149); N-methylglutamate dehydrogenase, mildly inhibited (/90); methylmalonyl-CoA carboxyltransferase, *or* transcarboxylase (68,91-93); nucleotidases (94,155); oxaloacetate decarboxylase (68,95-103); oxaloacetate tautomerase (104,105); 3-oxoacid CoA-transferase (106); 2 oxopent-4-enoate hydratase (107); pantothenase (108,143-145); peptidyl-dipeptidase A, *or* angiotensin I converting enzyme (147); peroxidase (109); phosphoenolpyruvate carboxykinase (ATP) (110); phosphoenolpyruvate carboxykinase (GTP) (111-114); phosphoenolpyruvate carboxylase (115); phosphoenolpyruvate mutase ( $K_i = 32$   $\mu$ M (116-118); phosphoenolpyruvate phosphatase (153); phosphoenolpyruvate:protein phosphotransferase (164,165); phosphoglycerate mutase (119); phosphonopyruvate hydrolase (120); phytase (121); 4-phytase (156,157); procollagen-proline 4-dioxygenase (122); pyrophosphatase (123,124); pyruvate carboxylase (125-129); pyruvate kinase (68,130-132,166-176); pyruvate,orthophosphate dikinase (133,161-163); pyruvate,water dikinase (134); serine:glyoxylate aminotransferase (177); succinate dehydrogenase (135-138); tartronate semialdehyde reductase, *or* 2-hydroxy-3-oxopropionate reductase (139); thermolysin (140); triose phosphate isomerase (141); tyrosinase, *or* monophenol monooxygenase, *or* polyphenol oxidase (186); urease (142). 1. #### Oxaliplatin

This potent anti-cancer drug (FW = 397.29 g/mol; CAS 63121-00-6; IUPAC Name: [(1*R*,2*R*)-cyclohexane-1,2-diamine](ethanedioato-*O*,*O'*)platinum(II)), also known as Eloxatin<sup>®</sup>, is a intravenously administered DNA crosslinker and mutagen. The combination of amine group- and carboxyl group-donating bidentate ligands results in significantly lower pharmacologic inactivation as a consequence of nonenzymatic hydrolysis. (See also *Cisplatin* (for mechanism of action) and *Carboplatin*) Unlike cisplatin, oxaliplatin forms both interstrand and

intrastrand DNA cross links that prevent DNA replication and transcription, thereby promoting programmed cell death (2). Oxaliplatin also crosses the blood-brain barrier. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) ### Oxaloacetate (Oxaloacetic Acid)

This tricarboxylic acid cycle intermediate (FW<sub>free-acid</sub> = 132.07 g/mol; CAS 328-42-7; *Abbreviation*: OAA), also known as 2-oxosuccinic acid, 2-oxobutanedioic acid, and oxalacetic acid, is the α-keto acid transamination product of aspartate. **Solution Chemistry:** OAA has pK<sub>a</sub> values of 2.22 and 3.67, and the OH group in enol form has a pK<sub>a</sub> value of 13.03. Note that it is relatively unstable in aqueous solutions and undergoes β-decarboxylation. The half-life of oxaloacetate at pH 7 and 25°C is between 30 and 60 minutes. Equilibrium exchange studies of malate dehydrogenase were made at 1°C to minimize the decarboxylation rate of oxaloacetate. While the solid dicarboxylic acid exists primarily as the enol, aqueous oxaloacetate, at pH 6 to 10, is roughly 82-88% keto, 7-10% enol, and 5-8% gem-diol. At pH 1.3, most of the oxaloacetic acid is present as the gem-diol (~81% vs. 13% keto and 6% enol). In diethyl ether, more than 90% is found as the enol. The rate of decarboxylation is maximum at pH 3-4; this rate is accelerated in the presence of metal ions, with the pH optimum shifting to 5-6.5. **Metabolism:** Oxaloacetate is a product of the reactions catalyzed by the malate dehydrogenases, malate oxidase, D- and L-aspartate oxidases, methylmalonyl-CoA carboxyltransferase, aspartate aminotransferase, aspartate:phenylalanine aminotransferase, 4-methylglutamate esterase, citrate lyase, oxalomalate lyase, citryl-CoA lyase, L(+)- and D(-)-tartrate dehydratases, *threo-* and *erythro-*3-hydroxyaspartate ammonia-lyases, and pyruvate carboxylase. It is a substrate for lactate:malate transhydrogenase, citrate (*si-*) and (*re-*)-synthases, decylcitrate synthase, 2-methylcitrate synthase, ATP citrate synthase pyridoxamine:oxaloacetate aminotransferase, glycine:oxaloacetate aminotransferase, oxaloacetase, oxaloacetate decarboxylase, phosphoenol-pyruvate carboxylase, phosphoenolpyruvate carboxy-kinases, and oxaloacetate tautomerase. It is also an alternative substrate/product for many other aminotransferases, homocitrate synthase, and opine dehydrogenase. **Target(s):** 2-(acetamidomethylene)-succinate hydrolase (78); acetoacetate decarboxylase (1); acetylpyruvate hydrolase (2); aconitase (3); adenylate cyclase (4-6); adenylosuccinate synthetase (7); aldehyde reductase, aldose reductase (8); allophanate hydrolase (76); amino-acid N acetyltransferase (100); 4-aminobutyrate aminotransferase (93); aminolevulinatase aminotransferase (91,92); asparagine synthetase (9); aspartate 1-decarboxylase (10,11); γ-butyrobetaine dioxygenase, γ-butyrobetaine hydroxylase, K<sub>i</sub> = 0.12 mM (12); citrate lyase (13-15); cyanate hydratase, *or* cyanase (16,17); decylhomocitrate synthase (18); fructose-1,6-bisphosphate aldolase (19); fumarylacetoacetase (20); glucose-6-phosphatase (84); glucose-6-phosphate isomerase, weakly inhibited (21); glutamate decarboxylase, K<sub>i</sub> = 2.9 mM (22-24); glutamate synthase (25); glycogen synthase (26); guanylate cyclase (27-29); histidine decarboxylase, weakly inhibited (30); homocitrate synthase (97); 3-hydroxybutyrate dehydrogenase (31); 4-hydroxy-4-methyl-2-oxoglutarate aldolase (32); 4-hydroxy-2-oxoglutarate aldolase (33,34); inositol oxygenase (105); isocitrate dehydrogenase (NADP<sup>+</sup>), particularly in the presence of glyoxylate (36-40); [isocitrate dehydrogenase (NADP<sup>+</sup>) kinase (35,85,86); isocitrate lyase (41-45); α-ketoglutarate dehydrogenase (46,47); lactase-phlorizin hydrolase, *or* glycosylceramidase (83); D-lactate dehydrogenase, cytochrome (48,49); lysine 2-monooxygenase (106); malate synthase, weakly inhibited (98,99); maleate hydratase (50); malic enzyme (51); N-methylglutamate dehydrogenase (52); N-methyl-2-oxoglutarate hydrolase (77); nicotinate-nucleotide diphosphorylase, carboxylating (95,96); ornithine aminotransferase (94); pantothenase (53,79-82); phosphogluconate dehydrogenase, decarboxylating (54); procollagen-lysine 5-dioxygenase (101); procollagen-proline 3-dioxygenase (101); procollagen-proline 4-dioxygenase (101-104); pyridoxamine-5-phosphate oxidase (55); pyruvate kinase, weakly inhibited (89,90); pyruvate, water dikinase (87,88); saccharopine dehydrogenase (57); succinate dehydrogenase (49,58-73); succinyl-CoA synthetase (74); theanine hydrolase (75); thiosulfate

sulfurtransferase, *or* rhodanese (56). 1. Davies (1943) *Biochem. J.* **37**, 230. 2. Davey & Ribbons (1975) *J. Biol. Chem.* **250**, 3826. 3. Glusker (1971) *The Enzymes*, 3rd ed., **5**, 413. 4. ### N-Oxaloglycine

This iron-binding  $\alpha$ -ketoglutarate (2-oxoglutarate) analogue (FW = 147.09 g/mol; also named *N*-oxaloglycine) competitively inhibits prolyl-4-hydroxylase (*Reaction*: Procollagen(L-proline) +  $\alpha$ -ketoglutarate + O<sub>2</sub> → Procollagen(2*S*,4*R*)-4-hydroxyproline) + succinate + CO<sub>2</sub>) (1). During catalysis, prolyl-4-hydroxylase forms Fe(III), and the latter most likely makes an extremely stable metal ion complex with *N*-oxaloglycine. Substitution on the glycine moiety alters inhibitor activity stereoselectively and that, if the  $\omega$ -carboxylate is homologated or replaced, either by acylsulfonamides or anilide, activity is likewise sharply reduced (1). **Prolyl-4-Hydroxylase Catalysis:** Each catalytic round of this posttranslational modifying enzyme reaction occurs in two stages. O<sub>2</sub> is bound end-on in an axial position, producing a dioxygen unit. Nucleophilic attack at C-2 generates a tetrahedral intermediate, with loss of the double bond in dioxygen and bonds to iron and the  $\alpha$ -carbon of  $\alpha$ -ketoglutarate. Elimination of CO<sub>2</sub> coincides with formation of the Fe(IV)=O species. The second stage involves the abstraction of the pro-*R* hydrogen atom from C-4 of proline, followed by radical combination, yielding hydroxyproline (2). In the presence of  $\alpha$ -ketoglutarate, enzyme-bound Fe<sup>2+</sup> is rapidly converted to Fe<sup>3+</sup>, resulting in inactivation of the enzyme (3). Ascorbate is utilized as a cofactor to reduce Fe(III) back to Fe(II) (4). **Cell-Permeable Analogue:** Dimethyloxalylglycine (FW = 175.14 g/mol; CAS 89464-63-1; Symbol: DMOG, also named *N*-(methoxyoxoacetyl)-glycine methyl ester) is metabolically demethylated to form *N*-oxaloglycine upon entry to many cells. **1.** Cunliffe, Franklin, Hales & Hill (1992) *J. ### Oxalomalate (Oxalomalic Acid)

This  $\alpha$ -hydroxy- $\beta$ -oxalosuccinate (FW<sub>free-acid</sub> = 206.11 g/mol), which is formed by the combination of glyoxylate and oxaloacetate, spontaneously loses carbon dioxide to form  $\gamma$ -hydroxy- $\alpha$ -ketoglutarate (OOC-CH(OH)-CH<sub>2</sub>-COCOO<sup>-</sup>). Oxalomalate is a competitive inhibitor of aconitase (1,3) and NADP<sup>+</sup>-dependent isocitrate dehydrogenase (3-7). It also modulates the RNA-binding activity of iron-regulatory proteins. **1.** Glusker (1971) *The Enzymes*, 3rd ed., **5**, 413. **2.** Adinolfi, Guarriera-Bobyleva, Olezza & Ruffo (1971) *Biochem. ### $\beta$ -N-Oxalyl-L- $\alpha$ , $\beta$ -diaminopropionate

This excitatory neurotoxin (FW<sub>hydrochloride</sub> = 212.59 g/mol; water-soluble; pK<sub>a</sub> values of 1.95, 2.95, and 9.25), also known as  $\beta$ -N-oxalyl-amino-L-alanine, was first isolated from the seeds of *Lathyrus sativus* (1) results in the progressive neurodegenerative condition known as neurolathyrism. Ingestion of this amino acid results in a paralytic condition characterized by lack of strength in or inability to move the lower limbs. Neurolathyrism is a motor neuron disease affecting upper motor neurons and anterior horn cells of the lumbar spinal cord. Note that  $\beta$ -N-oxalyl-L- $\alpha$ , $\beta$ -diaminopropionate is a glutamate analogue and acts as an agonist at the AMPA receptor. **Mechanism of Action:** Although the receptor antagonist 2-amino-5-phosphonovaleric acid and divalent cadmium ion did not alter the conductance increase evoked by  $\beta$ -ODAP, they markedly depressed responses to L-aspartate. Such differences suggest that  $\beta$ -ODAP's mechanism of excitatory action is similar to that of kainic and quisqualic acids (3). The membrane conductance effects of  $\alpha$ -ODAP, the 2-oxalylamino isomer, are about 10x weaker (1). With voltage-clamp recordings of an AMPA receptor,  $\beta$ -ODAP was a strong agonist, the potency being almost the same as L-glutamate. On the other hand,  $\beta$ -ODAP had little effect on the glutamate-evoked currents through the expressed NMDA receptor, showing only a weak inhibitory effect on the glycine-modulatory site (4). **Target(s):** NADH dehydrogenase, or Complex I (2); tyrosine aminotransferase (3). **1.** Rao, Adiga & Sarma (1964) *Biochemistry* **3**, 432. **2.** Ravindranath (2002) *Neurochem. ### Oxamate (Oxamic Acid)

This dicarboxylic monoamide (FW<sub>free-acid</sub> = 89.05 g/mol), also known as aminooxoacetic acid and oxalic acid monoamide, is an isoelectronic and isosteric analogue of pyruvic acid. The free acid is sparingly soluble in water whereas the ammonium and sodium salts are very soluble.

**Target(s):** acetolactate synthase (1); alanopine dehydrogenase (2); aspartate aminotransferase (3); carbonic anhydrase (4);  $\epsilon$ -crystallin L-lactate dehydrogenase (5); dehydrogluconate dehydrogenase (6); gluconate 2-dehydrogenase (7); glutamate dehydrogenase, weakly inhibited (8); glyoxylate reductase (9,10); D-lactate dehydrogenase (11,12); L-lactate dehydrogenase (5,8,9,13-24); lactate 2-monooxygenase (25); lactate racemase (26); malate synthase (27); pyruvate carboxylase (26,28-30). 1. #### Oxamflatin

This anti-tumor agent (FW = 342.38 g/mol; CAS 151720-43-3; Solubility: 13 mg/mL DMSO, methanol, acetonitrile, 10 mg/mL), also known as (2E)-5-[3-[(phenylsulfonyl)amino]phenyl]-pent-2-en-4-ynohydroxamate, inhibits histone deacetylase. Oxamflatin shows antiproliferative activity *in vitro* against various mouse and human tumor cell lines, attended by drastic changes in the cell morphology and *in vivo* antitumor activity against B16 melanoma. Oxamflatin causes an elongated cell shape with filamentous protrusions as well as arrest of the cell cycle at the G<sub>1</sub> phase in HeLa cells. These phenotypic changes in HeLa cells were similar to those induced by trichostatin A (TSA), a specific inhibitor of histone deacetylase (HDAC). 1. Kim, Lee, Sugita, Yoshida & Horinouchi (1999) *Oncogene* **18**, 2461. 2. Monneret (2005) *Eur. J. Med. Chem.* **40**, 1.

#### Oxanilate (Oxanilic Acid)

This acid (FW<sub>free acid</sub> = 165.15 g/mol), also known as N-phenyloxamate and oxanilic acid, is a structural analogue of phenylpyruvate. **Target(s):** glutamate dehydrogenase, weakly inhibited (1); lactate dehydrogenase (1,2); neuraminidase, or sialidase (3); pyruvate decarboxylase, weakly inhibited (4). 1. Baker, Lee, Tong, Ross & Martinez (1962) *J. Theoret. Biol.* **3**, 446. 2. Yu, Deck, Hunsaker, Deck, Royer, Goldberg & Vander Jagt (2001) *Biochem. Pharmacol.* **62**, 81. 3. Gottschalk & Bhargava (1971) *The Enzymes*, 3rd ed., **5**, 321. 4. Gale (1961) *Arch. Biochem. Biophys.* **94**, 236.

#### 4-(2-Oxapentadeca-4-yne)phenylpropanoate

This isoform-specific inhibitor (FW<sub>free-acid</sub> = 358.52 g/mol) binds to both the ferrous- and ferric-forms of 12-lipoxygenase (arachidonate 12-lipoxygenase), binding to the Fe<sup>2+</sup> form with K<sub>i</sub> of 70 nM. 1. Moody & Marnett (2002) *Biochemistry* **41**, 10297. 2. Richards, Moody & Marnett (1999) *Biochemistry* **38**, 16529.

#### Oxatamide

This anti-allergic agent (FW = 426.56 g/mol), initially characterized as an H<sub>1</sub> antagonist, inhibits the secretion of a number of inflammation mediators in human basophils and mast cells. *In vitro*, oxatimide inhibits the release of both preformed (e.g., histamine and tryptase) and *de novo* synthesized mediators (e.g., leukotriene C<sub>4</sub> and prostaglandin D<sub>2</sub>). **Target(s):** dopamine uptake (1); inflammation mediator release (2,3); NADPH oxidase, human neutrophil (4). 1. Matsunaga, Sato, Shuto, *et al.* (1998) *Eur. J. Pharmacol.* **350**, 165. 2. Marone, Granata, Spadaro, Onorati & Triggiani (1999) *J. Invest. Allergol. Clin. Immunol.* **9**, 207. 3. Awouters, Niemegeers, Van den Berk, *et al.* (1977) *Experientia* **33**, 165. 4. Umeki (1992) *Biochem. Pharmacol.* **43**, 1109.

#### Oxazepam

This benzodiazepinone (FW = 286.72 g/mol) is an anxiolytic agent that inhibits a number of UDP-glucuronosyltransferases (1-8) and nitric-oxide synthase (9). 1. Kirkwood, Nation & Somogyi (1998) *Clin. Exp. Pharmacol. Physiol.* **25**, 266. 2. Sim, Back & Breckenridge (1991) *Brit. J. Clin. Pharmacol.* **32**, 17. 3. #### Oxindolyl-L-alanine

This tryptophan analogue (FW = 220.23 g/mol) is a tight-binding competitive inhibitor of both and tryptophanase (or tryptophan indole-lyase) (1,2) and tryptophan synthase (3,4), with K<sub>i</sub> values in the 10 μM range, corresponding to an affinity that is 10-100-fold higher than the corresponding K<sub>m</sub> or K<sub>i</sub> values for the substrate L-tryptophan. Its mode of

inhibition suggests that substrate analogues with tetrahedral geometry at C-3 induce new enzyme-substrate contacts, resulting in the accumulation of a putative a *gem*-diamine intermediate (4). 1. Kiick & Phillips (1988) *Biochemistry* **27**, 7339. 2. Faleev, Dementieva, Zakomirdina, Gogoleva & Belikov (1994) *Biochem. Mol. Biol. Int.* **34**, 209. 3. Roy & Miles (1999) *J. Biol. Chem.* **274**, 31189. 4. Roy, Miles, Phillips & Dunn (1988) *Biochemistry* **27**, 8661.

### Oxipurinol

This xanthine analogue and potent xanthine oxidase inhibitor (FW = 152.11 g/mol; CAAS Registry Number = 2465-59-0), also known as alloxanthine, oxoallopurinol, and 1*H*-pyrazolo[3,4-*d*]pyrimidine-4,6-diol; is formed metabolically from allopurinol, thereby accounting for allopurinol hypouricemic efficacy. (See *Allopurinol for oxypurinol pharmacokinetics*.)

**Target(s):** hypoxanthine (guanine) phosphoribosyltransferase (1); orotate phosphoribosyltransferase (2); purine-nucleoside phosphorylase (3); salicylhydroxamic acid reductase (4); xanthine dehydrogenase (5-8); xanthine oxidase (9-14); xanthine phosphoribosyltransferase, also an alternative substrate (15). 1. Miller, Ramsey, Krenitsky & Elion (1972) *Biochemistry* **11**, 4723. 2. Jones, Kavipurapu & Traut (1978) *Meth. Enzymol.* **51**, 155. 3. Parks & Agarwal (1972) *The Enzymes*, 3rd ed., 7, 483. 4. Bray (1975) *The Enzymes*, 3rd ed., 12, 299. 11. Spector, Hall & Krenitsky (1986) *Biochem. Pharmacol.* **35**, 3109. 12. Hawkes, George & Bray (1984) *Biochem. J.* **218**, 961. 13. Chalmers, Kromer, Scott & Watts (1968) *Clin. Sci.* **35**, 353. 14. Terada, Leff & Repine (1990) *Meth. Enzymol.* **186**, 651. 15. Miller, Adamczyk, Fyfe & Elion (1974) *Arch. Biochem. Biophys.* **165**, 349.

### 1-Oxipurinol Ribonucleoside 5'-Monophosphate

This ribonucleotide (FW<sub>free-acid</sub> = 364.21 g/mol), also known as 1-riboseoxipurinol 5'-phosphate, inhibits orotidylate decarboxylase. Three separate numbering schemes have been used with respect to allopurinol and oxipurinol; hence, the term could be applied to each of the three nucleotides shown above. Orotidine-5'-phosphate decarboxylase is inhibited by the first and third nucleotides depicted above, and the third is the one originally called the 1-oxipurinol nucleotide. 1. Silva & Hatfield (1978) *Meth. Enzymol.* **51**, 143. 2. Brown & O'Sullivan (1977) *Biochem. Pharmacol.* **26**, 1947. 3. Porter & Short (2000) *Biochemistry* **39**, 11788. 4. Acheson, Bell, Jones & Wolfenden (1990) *Biochemistry* **29**, 3198. 5. Fyfe, Miller & Krenitsky (1973) *J. Biol. Chem.* **248**, 3801.

### 7-Oxipurinol Ribonucleoside 5'-Monophosphate

This ribonucleotide (FW<sub>free-acid</sub> = 364.21 g/mol) inhibits orotidylate decarboxylase. Care should be exercised when this name appears in the literature. Three separate numbering schemes have been used with respect to allopurinol and oxipurinol; hence, this name can apply to each of the three depicted nucleotides depicted. Orotidine-5'-phosphate decarboxylase

is inhibited by the left and right structures shown above. (The rightmost derivative was originally called the 7-oxipurinol nucleotide.) 1. Silva & Hatfield (1978) *Meth. Enzymol.* **51**, 143. 2. Brown & O'Sullivan (1977) *Biochem. Pharmacol.* **26**, 1947. 3. Porter & Short (2000) *Biochemistry* **39**, 11788. 4. Fyfe, Miller & Krenitsky (1973) *J. Biol. Chem.* **248**, 3801.

**Oxo acid, See the corresponding keto acid**

### *cis*-3-Oxo-8-*trans*-(*N*<sup>1</sup>-acrylamidospermidyl)-9*b*-*trans*-ethylacrylyl-1,2,3,4,4*a*,9*b*-hexahydrodibenzofuran

This lunarine analogue (FW<sub>free-base</sub> = 497.63 g/mol) is a time-dependent inhibitor of trypanothione-disulfide reductase. Kinetic data are consistent with an inactivation mechanism involving a conjugate addition of an active site cysteine residue onto the C<sup>24</sup>-C<sup>25</sup> double bond of its tricyclic nucleus, confirming the importance of the unique structure of the tricyclic core as a motif for inhibitor design. 1. Hamilton, Saravanamuthu, Poupat, Fairlamb & Eggleston (2005) *Bioorg. Med. Chem.* **14**, 2266.

### 24-Oxo-25-azacycloartanol

This sterol analogue (FW = 443.71 g/mol) inhibits sterol 24-C-methyltransferase (maize, *K<sub>i</sub>* = 170 nM). Microsomes from maize seedlings catalyze C-24 alkylation of 4,4,14  $\alpha$ -trimethyl-9- $\beta$ ,19-cyclo-5- $\alpha$ -cholest-24-en-3- $\beta$ -ol (*i.e.*, cycloartenol) by (*S*)-adenosyl-L-methionine leading to 24-methylene cycloartenol. Derivatives of cycloartenol bearing a nitrogen atom at C-25 have been previously shown to be potent inhibitors of the AdoMet-cycloartenol-C-24-methyltransferase (2). The presence of a positive charge at Position-25 is the major cause of inhibition, because electrostatically neutral isosteric compounds (with a carbon in place of the nitrogen atom) do not inhibit (1). The positive charge leading to inhibition may be conferred by a protonated amine, a quaternary ammonium group, as well as by a sulfonium or an arsonium group (1). A steroid-like structure of the inhibitor is also important. Finally, the presence of a free  $\beta$ -hydroxy group and the bent conformation of cycloartenol, which are essential molecular features of the substrate for the methylation reaction, are no longer required for inhibition (1). 1. Rahier, Génot, Schuber, Benveniste & Narula (1984) *J. Biol. Chem.* **259**, 15215. 2. Narula, Rahier, Benveniste & Schuber (1981) *J. Am. Chem. Soc.* **103**, 2408.

### Oxodipine

This dihydropyridine-class calcium ion blocker (FW = 359.37 g/mol; CAS 90729-41-2), also known as 4-(1,3-benzodioxol-4-yl)-2,6-dimethyl-1,4-dihydropyridine-3,5-dicarboxylic acid *O*<sup>2</sup>-ethyl,*O*<sup>5</sup>-methyl ester, greatly depresses KCl-induced contraction of rabbit aorta and also decreases the

contractile force of rat ventricular strips, the latter with lower potency. Oxodipine markedly shortens cardiac action potentials, and, in rat cultured neonatal ventricular myocytes, oxodipine decreases the L-type  $\text{Ca}^{2+}$  current ( $I_{\text{CaL}}$ ) with  $\text{IC}_{50}$  of 0.24  $\mu\text{M}$  and is also an effective blocker of T-type  $\text{Ca}^{2+}$  current ( $I_{\text{CaT}}$ ) than elgodipine ( $\text{IC}_{50} = 0.41 \mu\text{M}$ ). 1. Galán, Talavera, Vassort & Alvarez (1998) *Eur. J. Pharmacol.* **357**, 93.

### 2-Oxoglutaconic Acid & Dimethyl Esters

A *cis/trans*-mixture of these  $\alpha$ -ketoglutarate analogues ( $\text{FW}_{\text{acid}} = 142.07$  g/mol;  $\text{FW}_{\text{ester}} = 155.13$  g/mol), also known as  $\alpha$ -ketoglutaconic acid, irreversibly inhibits aspartate aminotransferase. It is an alternative substrate for glutamate dehydrogenase. Note that the dimethyl ester also inactivates. 1. Kato, Asano, Makar & Cooper (1996) *J. Biochem.* **120**, 531.

### Oxolinate (Oxolinic Acid)

This quinolone-type antibiotic ( $\text{FW}_{\text{free-acid}} = 261.23$  g/mol), also known as 5-ethyl-5,8-dihydro-8-oxo-1,3-dioxolo[4,5-g]quinoline-7-carboxylate, inhibits bacterial DNA gyrase, binding to subunit A and arresting DNA replication (1-7). Certain mutant DNA gyrases fail to bind oxolinic acid, accounting for oxolinate-resistant bacteria. In male rats, oxolinate raises the serum levels of luteinizing hormone (LH), increasing the incidence of testicular Leydig cell tumors (8). It also inhibits ( $\text{IC}_{50} = 4.3 \mu\text{M}$ ) neuronal dopamine uptake (9). **Target(s):** DNA topoisomerase IV (2,10); glycyl tRNA synthetase (11,12); and leucyl-tRNA synthetase (11). 1. Gellert (1981) *The Enzymes*, 3rd ed., **14**, 345. 2. Chen, Malik, Snyder & Drlica (1996) *J. Mol. Biol.* **258**, 627. 3. Thielmann, Popanda & Edler (1991) *J. Cancer Res. Clin. Oncol.* **117**, 19. 4. Huff & Kreuzer (1990) *J. Biol. Chem.* **265**, 20496. 5. Sugino, Peebles, Kreuzer & Cozzarelli (1977) *Proc. Natl. Acad. Sci. U.S.A.* **74**, 4767. 6. Gellert (1981) *Ann. Rev. Biochem.* **50**, 879. 7. Vosberg (1985) *Curr. Top. Microbiol. Immunol.* **114**, 19. 8. Yamada, Nakamura, Okuno, et al. (1995) *Toxicol. Appl. Pharmacol.* **134**, 35. 9. Agents Chemother.* **43**, 1574. 11. Wright, Nurse & Goldstein (1981) *Science* **213**, 455. 12. Freist, Logan & Gauss (1996) *Biol. Chem. Hoppe-Seyler* **377**, 343.

### Oxonate (Oxonic Acid)

This orotic acid analogue ( $\text{FW}_{\text{free-acid}} = 157.09$  g/mol), also known as 5-azaorotic acid and allantoxanic acid, is often used in cancer chemotherapy, because it suppresses the gastrointestinal toxicity of 5-fluorouracil and its derivatives without altering their antitumor activity. Note that the free acid is very unstable ( $\text{pK}_a = 6.85\text{-}6.90$ ), and it is frequently prepared as the monopotassium salt. **Target(s):** dihydroorotate dehydrogenase (1); orotate

phosphoribosyl-transferase (1-4); orotidylate decarboxylase (1,3); urate oxidase, uricase;  $K_i = 0.1 \mu\text{M}$  (5-9); urate transport (9-11). 1. Gero, O'Sullivan & Brown (1985) *Biochem. Med.* **34**, 60. 2. Iltzsch, Niedzwicki, Senft, Cha & el Kouni (1984) *Mol. Biochem. Parasitol.* **12**, 153. 3. O'Sullivan & Ketley (1980) *Ann. Trop. Med. Parasitol.* **74**, 109. 4. Javaid, el Kouni & Iltzsch (1999) *Biochem. Pharmacol.* **58**, 1457. 5. Fridovich (1965) *J. Biol. Chem.* **240**, 2491. 6. Cartier & Thuillier (1974) *Anal. Biochem.* **61**, 416. 7. Truscoe (1968) *Enzymologia* **34**, 337. 8. Bongaerts, Uitzetter, Brouns & Vogels (1978) *Biochim. Biophys. Acta* **527**, 348. 9. Leal-Pinto, London, Knorr & Abramson (1995) *J. Membr. ### Oxophenarsine

This sulfhydryl-reactive arsenical ( $\text{FW} = 199.04$  g/mol; CAS 306-12-7), variously named Mapharsen, Ehrlich-5, oxyphenarsine, oxarsan, arsinoxide, 3-amino-4-hydroxybenzenearsenoxide, and 2-amino-4-arsenosphenol, was originally developed by Nobelist Paul Ehrlich as an anti-syphilis drug. (Note: do not confuse this compound with oxophenylarsine, also known phenylarsine oxide). It is now used as an antiprotozoal agent, particularly against *Trypanosoma*. Oxophenarsine is typically supplied as the hydrochloride ( $\text{FW} = 235.50$  g/mol) and is readily soluble in water. (See also *Dichlorophenarsine*) **Target(s):** acetyl-CoA acyltransferase (1); actomyosin ATPase (2); aldehyde dehydrogenase (3-5); alkaline phosphatase (6); asparagine synthetase (7); ATPase, rat brain (8); ATPase, trypanosomal (9); cathepsin (10); cholinesterase (11,12); deoxyribonuclease (13); diisopropylfluorophosphatase (14);  $\gamma$ -glutamyl hydrolase, or pteroylglutamate conjugase (15); glyceraldehyde-3-phosphate dehydrogenase (9);  $\alpha$ -glycerophosphate oxidase (16); hexokinase (9); myosin ATPase (2,17,18); pyrophosphatase (19); pyruvate decarboxylase (20,21); pyruvate oxidase (22); ribose-5-phosphate isomerase (23); succinate dehydrogenase (12,24,25); succinate oxidase (26); urease (12,27). 1. ### N-[2-(4-oxo-1-phenyl-1,3,8-triazaspiro[4,5]dec-8-yl)ethyl]-2-naphthalene-carboxamide

This phospholipase D inhibitor ( $\text{FW} = 428.54$  g/mol; CAS 1130067-34-3) targets phospholipase D isoforms  $\text{PLD}_1$  and  $\text{PLD}_2$ , which catalyze

phospholipid hydrolysis and release phosphatidic acid. The latter is a second messenger that promotes Ras activation, cell spreading, stress fiber formation, chemotaxis, and membrane vesicle trafficking. Indeed, the machinery of PLD-induced cell invasion is mediated by PA and involves Wiscott-Aldrich Syndrome protein, Growth Receptor-bound Protein-2 and Rac2 signaling events that ultimately affect actin polymerization and cell invasion. The use of this inhibitor helped to demonstrate that PLD2 has a central role in the development, metastasis, and level of aggressiveness of breast cancer, suggesting that PLD<sub>2</sub> could become a useful therapeutic target. (See also 5-Fluoro-2-Indolyl des-Chlorohalopemide) 1. Henkels, Boivin, Dudley, Berberich & Gomez-Cambronero (2013) *Oncogene* **32**, 5551.

### 5-Oxoprolinal

This 5-oxoprolidine derivative (FW = 113.12 g/mol) is a transition-state aldehyde inhibitor of pyroglutamyl-peptidase. It is a competitive inhibitor with a  $K_i$  value of 26 nM. 1. Friedman, Kline & Wilk (1985) *Biochemistry* **24**, 3907. 2. Robert-Baudouy, Clauziat & Thierry (1998) in *Handb. Proteolytic Enzymes*, p. 791, Academic Press, San Diego. 3. McKeon & O'Connor (1998) in *Handb. Proteolytic Enzymes*, p. 796, Academic Press, San Diego.

### L-5-Oxoproline

This pyrrolidone-carboxylic acid (FW = 129.12 g/mol;  $pK_a = 3.32$ ; Specific rotation at the D-line =  $-11.3^\circ$  at  $20^\circ\text{C}$  for 2 g/100 mL), also known as pyroglutamic acid, is an amino acid that is found in many peptides and proteins (often at the N-terminus) as well as in physiological fluids. Although oxoproline can form nonenzymatically from L-glutamine, L-glutamate, and  $\gamma$ -glutamylated peptides, it is commonly the product of the reaction catalyzed by  $\gamma$ -glutamylcyclotransferase. 5-Oxoproline is converted to glutamic acid upon boiling for 1-2 hours in 2.0 M HCl or 0.5 M NaOH. **Target(s):** CTP synthetase, moderately inhibited (1); glutamate carboxypeptidase II (2);  $\gamma$ -glutamyl kinase, or glutamate 5-kinase (3,4);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (5); prolactin release (6); pyroglutamyl-peptidase II (7); 1-pyrroline-5-carboxylate reductase (8). 1. ### 4-Oxo-4-[(pyrazolo[4,3-b]olean-12-en-28-yl)oxy]butanoic Acid

This oleanolic acid derivative (FW = 564.81 g/mol) inhibits rabbit muscle glycogen phosphorylase ( $IC_{50} = 24.7 \mu\text{M}$ ). 1. Chen, Gong, Liu, et al. (2008) *Chem. Biodivers.* **5**, 1304.

### (E,E)-2-[2-Oxo-2-[[[(3,7,11-trimethyl-2,6,10-dodecatrienyl)oxy]amino]ethyl]phosphonate

This long-chain phosphonate (FW<sub>free-acid</sub> = 359.40 g/mol; *Abbreviation:* FPT inhibitor II) is an unreactive farnesyl pyrophosphate analogue that inhibits Ras protein farnesyltransferase,  $IC_{50} = 75 \text{ nM}$  (1). It also inhibits protein geranylgeranyltransferases I and II at elevated concentrations,  $IC_{50} = 24 \mu\text{M}$  (2). 1. Terry, Long & Beese (2001) *The Enzymes*, 3rd ed., **21**, 19. 2. Manne, Ricca, Brown, et al. (1995) *Drug Development Res.* **34**, 121.

### Oxycodone

This thebaine derivative (FW = 315.36 g/mol; CAS 76-42-6), also known as Roxicodone<sup>®</sup>, OxyContin<sup>®</sup>, Oxecta<sup>®</sup>, OxyIR<sup>®</sup>, and systematically as (5R,9R,13S,14S)-4,5 $\alpha$ -epoxy-14-hydroxy-3-methoxy-17-methylmorphinan-6-one, is a widely used (and abused) narcotic analgesic that is indicated for the relief of moderate-to-severe pain. In use since its successful semi-synthesis in 1917, oxycodone carries with it a significant risk for dependence, especially when administered for chronic pain. Although the precise receptor that binds oxycodone has been disputed, it now appears that oxycodone binds to  $\mu$ ,  $\kappa$  and  $\delta$  receptors, inhibiting adenylyl cyclase, and resulting in neuron hyperpolarization and decreased excitability. **Pharmacokinetics:** Oxycodone's analgesic effects commence ~1 hour after administration and last for ~12 hours, when administered in the controlled-release form (1). These properties distinguish oxycodone from its rapid-onset and longer-lasting opioids, morphine and heroin. Electrophysiological measurements reveal low-affinity oxycodone inhibition ( $IC_{50} = 170 \mu\text{M}$ ) of the potassium current through hERG channels expressed in HEK293 cells (2). Oxycodone plasma half-life is 3-5 hours (roughly half that of morphine), with stable plasma levels reached within 24 hours (compare to 2-7 days for morphine) (1). Oral bioavailability ranges from 60 to 87%, and plasma protein binding is 45%. Most of the drug is metabolized in the liver, with the remainder excreted by the kidney (1). Its major metabolites are oxymorphone (a highly potent analgesic) and noroxycodone (weaker analgesic). (See *Tapentadol*) **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Ordóñez Gallego, González Barón & Espinosa Arranz (2007) *Clin. Transl. Oncol.* **9**, 298. 2. Fanoë, Jensen, Sjøgren, Korsgaard & Grunnet (2009) *Br. J. Clin. Pharmacol.* **67**, 172.

### Oxy-coenzyme A

This biochemically inert coenzyme A analogue (FW<sub>free-acid</sub> = 751.46 g/mol), which contains a hydroxyl group in place of its thiol group, binds to and inhibits most Coenzyme A-dependent enzymes. **Target(s):** 3-ketoacid

CoA-transferase (1); phosphate acetyltransferase (2,3). 1. Jencks (1973) *The Enzymes*, 3rd ed., 9, 483. 2. Shimizu (1970) *Meth. Enzymol.* **18A**, 322. 3. Stewart & Miller (1965) *Biochem. Biophys. Res. Commun.* **20**, 433.

### Oxygen

This diatomic gas (FW = 31.99 g/mol) of the Group 16 (or Group VIB) element oxygen (Symbol: O; Atomic Number: 8; Atomic Weight: 15.9994; Valence: 2; with ionic radii for  $O^{2-}$ ,  $O^-$ ,  $O^+$ , and  $O^{2+}$  are 1.32, 1.76, 0.22, 0.09 Å, respectively), also known as dioxygen, is a colorless and odorless gas that constitutes 20.946% of Earth's dry atmosphere. At saturation, aqueous  $O_2$  is about 1.4 mM. Its structure and reactivity are predicted by valence bond theory to be  $O=O$ , having one  $\sigma$  and one  $\pi$  bond, with each oxygen having two pairs of unshared electrons. Such a structure does not account for the observation that  $O_2$  is paramagnetic in all phases, but molecular orbital theory correctly predicts the two unpaired electrons in dioxygen both in  $\pi^*$  orbitals (the bond length is 0.1208 nm). The singlet state of oxygen (the  $^1\Delta_g$  state), in which the two  $\pi$  electrons are paired, is actually an excited state and is about 92 kJ·mol<sup>-1</sup> above the triplet ground state (the  $^3\Sigma_g^-$  state). Singlet dioxygen can react with many unsaturated compounds and can be readily generated by numerous photochemical reactions. Singlet oxygen is generated and/or utilized in many biochemical processes, particularly in the presence of light. Many enzymes are inhibited by dioxygen, among them a significant contain active-site sulfhydryl groups that participate in substrate binding and/or catalysis. Enzymes requiring pantothenate and Coenzyme A are also inhibited by oxygen, which most often converts the thiol-containing metabolites to their inactive disulfide forms. Dioxygen also inhibits photophosphorylation and is a competitive inhibitor of the carboxylase activity of ribulose biphosphate carboxylase/oxygenase. **See also** Ozone

### Oxymatrine

This quinolizidine alkaloid (FW = 264.37 g/mol), also known as matrine oxide, matrine *N*-oxide, matrine 1-oxide, and (7*aS*,13*aR*,13*bR*,3*cS*) dodecahydro-1*H*,5*H*,10*H*-dipyrido[2,1-*f*:3',2',1'-*i'*][1,6]naphthyridin-10-one 4-oxide, from the root of the traditional Chinese herb *Sophora flavescens* inhibits/suppresses ulceration (e.g., experimental gastric ulcer, pylorus ligation ulcer and indomethacin), most likely by decreasing acid secretion and inhibiting gastric motility. Oxymatrine induces mitochondria dependent apoptosis in human osteosarcoma MNNG and HOS cells through the inhibition of PI3K/Akt pathway (2). Oxymatrine also prevents NF- $\kappa$ B nuclear translocation, thereby ameliorating acute intestinal inflammation (3). 1. Yamazaki (2000) *Yakugaku Zasshi.* **120**, 1025. 2. Zhang, Sun, Chen, *et al.* (2013) *Tumor Biol.* (2014) *Tumor Biol.* **35**, 1619. 3. Guzman, Koo, Goldsmith, *et al.* (2013) *Sci. Rep.* **3**, 1629.

### Oxymetazoline

This vasoconstrictor and nasal decongestant (FW = 260.38 g/mol; CAS 1491-59-4), systematically named as 6-*t*-butyl-3-(4,5-dihydro-1*H*-imidazol-2-ylmethyl)-2,4-dimethylphenol, is a partial  $\alpha_{2A}$ -adrenergic agonist as well as a 5-HT<sub>1A</sub>, 5-HT<sub>1B</sub>, and 5-HT<sub>1D</sub> serotonin receptor agonist. It is an over-the-counter drug that is most often used topically to treat rhinitis and sinusitis. Oxymetazoline exerts a dose-dependent inhibitory effect on total iNOS activity, as indicated by nitrite/nitrate formation, and this effect is

attributable to inhibition of enzyme induction rather than direct inhibition of the enzyme itself. 1. Westerveld, Voss, van der Hee, *et al.* (2000) *Eur. Respir. J.* **16**, 437.

### Oxymorphone

This semi-synthetic opioid analgesic and oxycodone metabolite (FW = 301.34 g/mol; CAS 76-41-5), also named 4,5*a*-epoxy-3,14-dihydroxy-17-methylmorphinan-6-one and marketed under the trade names Numorphan® (suppository and injectable solution), Opana ER® (extended-release tablet), and Opana IR® (immediate-release tablet), is used to relieve moderate to severe pain and preoperatively to alleviate apprehension and to maintain anaesthesia, especially as an obstetric analgesic. Opana IR is an oral drug that is indicated for the management of chronic pain; however, when injected recreationally, Opana can be deadly. Overdose is attended by respiratory depression, somnolence (progressing to stupor and/or coma), skeletal muscle flaccidity, bradycardia, and hypotension. In severe cases, cardiac arrest and death can occur. 1. Vadivelu, Maria, Jolly, *et al.* (2013) *J. Opioid Manag.* **9**, 439.

### Oxytetracycline

This tetracycline analogue (FW = 460.44 g/mol; CAS 79-57-2), also called terramycin, inhibits protein biosynthesis by blocking aminoacyl-tRNA binding to the acceptor site (A-site) on ribosomes. The half-life of oxytetracycline at 37°C and pH 7.0 is 26 hours. Oxytetracycline also binds metal ions tightly. **Target(s):** anhydrotetracycline monooxygenase (1); catalase (2); cytochrome *c* oxidase (3); cystathionine  $\gamma$ -lyase, or cysteine desulfhydrase (4); fructose-1,6-bisphosphate aldolase (5); glyoxalase I, or lactoylglutathione lyase (6); lactate dehydrogenase (7); malate dehydrogenase (7); phosphatase (8); protein biosynthesis (6-11); urease (12). 1. Laskin & Chan (1964) *Biochem. Biophys. Res. Commun.* **14**, 137. 12. Reithel (1971) *The Enzymes*, 3rd ed., **4**, 1.

### Oxytocin

This peptide hormone (MW = 1007.19 g/mol; CAS: 50-56-6; *Sequence*: CYIQNCPLG-NH<sub>2</sub>, with an intramolecular disulfide bond) induces uterine contraction and lactation, increases sodium ion secretion, and stimulates myometrial GTPase and phospholipase C. Oxytocin is produced via proteolysis of a precursor protein and released by the posterior pituitary gland. (**See also** *Isotocin; Glumitocin; Mesotocin; Vasopressin*) Oxytocin was one of the first naturally occurring polypeptides to be synthesized in the laboratory. **Target(s):** carboxypeptidase E (1); hydroxyindole O-

methyltransferase, or acetylserotonin *O*-methyltransferase (2); protein-disulfide reductase (glutathione),  $K_i = 20 \mu\text{M}$ , also possible alternative substrate (3); serotonin *N*-acetyltransferase (4). 1. Hook & LaGamma (1987) *J. Biol. Chem.* **262**, 12583. 2. Sugden & Klein (1987) *J. Biol. Chem.* **262**, 6489. 3. Varandani, Nafz & Chandler (1975) *Biochemistry* **14**, 2115. 4. Klein & Namboodiri (1982) *Trends Biochem. Sci.* **7**, 98.

#### Ozanimod

This orally available  $\text{S1P}_{\text{R1}}$  modulator (FW = 404.46 g/mol; CAS 1306760-87-1; Solubility: 81 mg/mL DMSO; < 1 mg/mL  $\text{H}_2\text{O}$ ), also named RPC1063 and 5-[3-[(1*S*)-2,3-dihydro-1-[(2-hydroxyethyl)amino]-1*H*-inden-4-yl]-1,2,4-oxadiazol-5-yl]-2-(1-methylethoxy)benzoyl nitrile, selectively targets sphingosine 1-Phosphate ( $\text{S1P}$ ) receptors, which mediate multiple processes, including lymphocyte trafficking, cardiac function, and endothelial barrier integrity (1). Ozanimod is specific for  $\text{S1P}_{\text{R1}}$  ( $\text{IC}_{50} = 0.4 \text{ nM}$ ) and  $\text{S1P}_{5\text{R}}$ , inducing  $\text{S1P}_{\text{R1}}$  internalization and reversibly reducing the number of circulating B and  $\text{CCR7}^+$  T lymphocytes *in vivo*. It shows high oral bioavailability and volume of distribution, and a circulatory half-life that supports once daily dosing (1). Oral ozanimod reduced inflammation and disease parameters in three autoimmune disease models, commending

its use in the treatment of relapsing multiple sclerosis (RMS) and inflammatory bowel disease (IBD). Indeed, the safety and efficacy of this modulator ozanimod in relapsing multiple sclerosis is indicated on the basis of a randomized, placebo-controlled, Phase 2 trial (2). Other  $\text{S1P}_{\text{R1}}$ -directed immunomodulators include laquinimod, poniesimod, and siponimod. 1. Scott, Clemons, Brooks, *et al.* (2016) *Br. J. Pharmacol.* **173**, 1778. 2. Cohen, Arnold, Comi, *et al.* (2016) *Lancet Neurol.* **15**, 373.

#### Ozone

This molecular oxygen allotrope and powerful oxidant (FW = 48.00 g/mol; M.P. =  $-192.7^\circ\text{C}$  and B.P. =  $-111.9^\circ\text{C}$ ) is a colorless gas with a distinctive odor. Whereas  $\text{O}_2$  is paramagnetic,  $\text{O}_3$  is diamagnetic. Ozone is formed by electrical discharge or UV irradiation in an  $\text{O}_2$ -rich atmosphere. Even the Greek Poet Homer (800 BC) noted the odor often associated with thunderstorms. The molecule is symmetrical and bent, having a bond angle of  $117^\circ$  and an oxygen-oxygen bond length of 0.127 nm, showing considerable double-bond character. Ozone is highly toxic, and inhalation is lethal to the ciliated cells of the upper airways and centriacinar region. Ozone exposure leads to free-radical-mediated or lipid peroxide-mediated toxicity.

**Target(s):** catalase (1);  $\beta$ -glucosidase (2-4); glyceraldehyde-3-phosphate dehydrogenase (5); lysozyme (6,7);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (8); ribonuclease  $\text{T}_1$  (9); superoxide dismutase (1). 1. Whiteside & Hassan (1987) *Arch. Biochem. Biophys.* **257**, 464. 2. Hestrin, Feingold & Scramm (1955) *Meth. Enzymol.* **1**, 231. 3. Helferich & Petersen (1935) *Hoppe Seyler's Z. Physiol. # - P -

**P** Symbol for Phosphorus in its elemental or combined form; Proline, especially to denote prolyl residues within a peptide or protein.

## P1

This cell-permeable PDI inhibitor (FW = 583.70 g/mol; CAS 1461648-55-4; Soluble to 100 mM in DMSO; *N*-[(1,1-dimethylethoxy)carbonyl]-*L*-phenylalanyl-*O*-(ethenyl-sulfonyl)-*N*-4-penten-1-yl-*L*-tyrosinamide) targets protein disulfide isomerase (IC<sub>50</sub> = 1.7 μM), an enzyme that assists in the folding of cellular proteins within the endoplasmic reticulum of mammalian cells. P1 reduces the proliferation of numerous cancer cell lines, with nominal GI<sub>50</sub> values of ~4 μM. PDI binds to the axonal microtubule-associated protein known as Tau, mainly through its thioredoxin-like catalytic domain, by forming a one-to-one complex that prevents Tau misfolding. 1. Ge, Zhang, Li, *et al.* (2013) *ACS Chem. Biol.* **8**, 2577. 2. Xu, Liu, Chen & Liang (2013) *PLoS One* **8**, e76657.

## P<sub>II</sub> (or P<sub>2</sub>)

This 44-kDa homotetrameric regulatory protein operates both as an inhibitor and activator in the glutamine synthetase (GS) adenylylation/deadenylation cascade in *Escherichia coli* and related Gram-negative bacteria (1-3). Glutamine synthetase plays the crucial role of providing sufficient glutamine to satisfy biosynthetic needs as a source of nascent ammonia in those enzymes possessing an ammonia-transfer tunnel connecting glutaminase and biosynthetic active sites. At low ammonia concentration, dodecameric GS is enzymatically deadenylylated (*Reaction*: GS-(*O*-pA)<sub>*m*</sub> + *m*P<sub>i</sub> ⇌ GS<sub>0</sub> + *m*ADP, where the *O*-pA represents the adenylyl group attached by a phosphodiester linkage to Tyrosine-397, and *m* indicates the degree of dodecamer adenylylation (*i.e.*, 0 < *m* < 12)). At high intracellular concentrations, ammonia replaces glutamine as a nitrogen donor in various biosynthetic reactions, thereby limiting cellular glutamine needs to that mainly required for protein synthesis. Under such conditions, GS is enzymatically adenylylated (*Reaction*: GS<sub>0</sub> + *m*ATP ⇌ GS-(*O*-pA)<sub>*m*</sub> + PP<sub>i</sub>), with commensurate loss of catalytic activity. Unmodified protein P<sub>IIA</sub> promotes adenylylation and GS inhibition, whereas P<sub>IID</sub> (containing an enzymatically introduced Tyr-*O*-pU linkage) promotes deadenylylation and GS activation (1-3). P<sub>II</sub> is also an important effector in the broader context of microbial nitrogen metabolism. 1. Brown, Segal & Stadtman (1971) *Proc. Natl. Acad. Sci. U.S.A.* **68**, 2949. 2. Mangum, Magni & Stadtman (1973) *Arch. Biochem. Biophys.* **158**, 514. 3. Adler, Purich & Stadtman (1975) *J. Biol. Chem.* **250**, 6264.

## P11

This potent PDZ motif-containing anti-angiogenic agent (FW = 720.78 g/mol; CAS 848644-86-0; Sequence: HSDVHK-NH<sub>2</sub>) targets the integrin α<sub>v</sub>β<sub>3</sub>-vitronectin interaction, blocking proliferation and inducing apoptosis in human vascular endothelial cells (HUVECs) (1,2). Arg-Gly-Asp (or RGD) binding-site recognition by P11 is site-specific, showing a strong antagonism against α<sub>v</sub>β<sub>3</sub>-vitronectin interaction, IC<sub>50</sub> = 26 nM (2). The binding orientation of docked P11 in α<sub>v</sub>β<sub>3</sub> is similar to that for RGD, suggesting a divalent metal-ion coordination is a common driving force for the formation of both SDV-α<sub>v</sub>β<sub>3</sub> and RGD-α<sub>v</sub>β<sub>3</sub> complexes. P11 appears to inhibit β-Fibroblast Growth Factor (or βFGF) -induced HUVEC proliferation via mitogen-activated protein kinase kinase and extracellular-regulated kinase inhibition as well as p53-mediated apoptosis related with activation of caspases (3). (*Note*: Consisting of 80-90 amino-acids in far-flung signaling proteins and binding to short C-terminal regions in protein interaction partners, "PDZ" is an acronym that includes the first letters of Post-synaptic density protein (PSD95), *Drosophila* Dlg1 tumor suppressor, and Zonula occludens-1 protein (zo-1), the first proteins

discovered to share this domain.) 1. Lee, Kang, Chang, Han & Kang (2004) *J. Biomol. Screen.* **9**, 687. 2. Choi, Kim, Lee, Han & Kang (2010) *Proteomics* **10**, 72. 3. Bang, Kim, Kang, *et al.* (2011) *Molec. Cell. Proteom.* **10**, M110.005264.

## p35

This single-chain baculovirus protein (MW = 35 kDa) inhibits apoptosis in virally infected host insect cells and also potently inhibits (K<sub>i</sub> < 9 nM) human caspase-1 (1,2), caspase-1, *Spodoptera frugiperda* (1,3), caspase-2 (1), caspase-3 (1,2), caspase-4 (1), caspase-6 (1,2), caspase-7 (1,2), caspase-8 (1,3,4), caspase-10 (1,2), and Ced-3 (1,5). This protein belongs to MEROPS proteinase inhibitor family 150, clan IQ. Purified recombinant p35 does not significantly inhibit unrelated serine or cysteine proteases, a property implying p35 is a potent caspase-specific inhibitor. The interaction of p35 with caspase-3, as a model of the inhibitory mechanism, revealed classic slow-binding inhibition, with both active-sites of the caspase-3 dimer acting equally and independently. 1. Zhou & Salvesen (2000) *Meth. Enzymol.* **322**, 143. 2. Zhou, Krebs, Snipas, *et al.* (1998) *Biochemistry* **37**, 10757. 3. Ahmad, Srinivasula, Wang, *et al.* (1997) *J. Biol. Chem.* **272**, 1421. 4. Xu, Cirilli, Huang, *et al.* (2001) *Nature* **410**, 494. 5. Bertin, Mendrysa, LaCount, *et al.* (1996) *J. Virol.* **70**, 6251.

**p38 Mitogen-Activated Protein Kinase Inhibitor (p39 MAP Kinase Inhibitor)**, See *specific inhibitor*; e.g., PD 169316; 2-(4-Chlorophenyl)-4-(4-fluorophenyl)-5-pyridin-4-yl-1,2-dihydropyrazol-3-one

## p425

This C<sub>2</sub>-rotationally symmetric, synthetic allosteric inhibitor (FW = 876.83 g/mol), identified by high throughput screening, targets the cytokine known as Macrophage Migration Inhibitory Factor (MIF), strongly inhibiting MIF-mediated catalysis of 4-hydroxyphenyl pyruvate tautomerization. p425 also blocks the interaction of MIF with its receptor, CD74, and likewise interfere with the pro-inflammatory activities of the cytokine. Structural studies revealed a unique mode of allosteric binding, wherein a single p425 molecule occupies the interface of two MIF trimers. The inhibitor binds mainly on MIF's surface by means of hydrophobic interactions that are stabilized by hydrogen bonding with four highly specific residues contributed by three different monomers. The mode of p425 binding reveals a unique way to block the activity of the cytokine for potential therapeutic benefit in MIF-associated diseases. (See *Macrophage Migration Inhibitory Factor*) 1. Bai, Asojo, Cirillo, *et al.* (2012) *J. Biol. Chem.* **287**, 30653.

## p276-00

This cell cycle-inhibiting flavone and anticancer agent (FW = 438.30 g/mol; CAS 920113-03-7), also named 2-(2-chlorophenyl)-5,7-dihydroxy-8-[(2*R*,3*S*)-2-(hydroxymethyl)-1-methyl-3-pyrrolidiny]-4*H*-1-benzopyran-4-one, targets the Cyclin-Dependent Kinases CDK1 (IC<sub>50</sub> = 79 nM), CDK4 (IC<sub>50</sub> = 63 nM) and CDK9 (IC<sub>50</sub> = 20 nM). p276-00 showed potent antiproliferative effects against various human cancer cell lines (IC<sub>50</sub> values ranging from 300 to 800 nmol/L), but has little effect on cultured fibroblasts (1). A significant down-regulation of cyclin D1 and Cdk4 and a decrease in Cdk4-specific pRb Ser(780) phosphorylation is observed. P276-00 produces potent inhibition of Cdk4-D1 activity that is competitive with ATP, and not with retinoblastoma protein. The compound also induced apoptosis in

human promyelocytic leukemia (HL-60) cells, as evidenced by the induction of caspase-3 and DNA ladder studies (1). In 22 human cancer xenografts, P276-00 is approximately 26x more potent than cisplatin, and is also active against cisplatin-resistant tumors of central nervous system, melanoma, prostate, and renal cancers (2). Synchronized human non-small cell lung carcinoma (H-460) and human normal lung fibroblast (WI-38) cells are arrested in G<sub>1</sub> (2). 1. Joshi, Rathos, Joshi, *et al.* (2007) *Mol. Cancer Ther.* **6**, 918. 2. Joshi, Rathos, Mahajan, *et al.* (2007) *Mol. Cancer Ther.* **6**, 926.

**P107**

This potent potassium ion channel opener, *or* KCO (FW = 231.30 g/mol; CAS 60559-98-0; Solubility: 50 mM in Ethanol; 100 mM in DMSO), also known as *N*-cyano-*N'*-(1,1-dimethylpropyl)-*N''*-3-pyridyl-guanidine, targets K<sub>ir</sub>6 (*or* K<sub>ATP</sub>) channels (EC<sub>50</sub> = 7.5 nM; for relaxation of rat aorta). In studies on rats, rabbit and dogs, P1075 effects only correlate with the presence of specific receptor binding sites in rat vascular preparations, showing there are significant species-specific and raising questions about the pharmacological significance of this K<sub>ATP</sub> opener binding site (1). These channels are heteromultimers composed with a 4:4 stoichiometry of an inwardly rectifying K<sup>+</sup> channel subunit plus a regulatory subunit comprising the receptor sites for hypoglycemic sulfonylureas and KCOs (a sulfonylurea receptor) (2). P1075-induced channel activation IS mediated by drug interaction with a single binding site per tetradimeric complex (2). P-1075 also binds to sulfonylurea receptors SUR2A (K<sub>d</sub> = 17 nM) and SUR2B (K<sub>d</sub> = 3 nM) (3). 1. Higdon, Khan, Buchanan & Meisheri (1997) *J. Pharmacol. Exp. Ther.* **280**, 255. 2. Gross, Toman, Uhde, Schwanstecher & Schwanstecher (1999) *Mol. Pharmacol.* **56**, 1370. 3. Buckner, Milicic, Daza, *et al.* (2000) *Eur. J. Pharmacol.* **400**, 287.

**P22077**

This ubiquitin cycle inhibitor (FW = 315.33 g/mol; CAS 1247819-59-5; Solubility: 60 mg/mL DMSO), also known as 1-[5-[(2,4-difluorophenyl)thio]-4-nitro-2-thienyl]ethanone, targets Ubiquitin-Specific Peptidase-7 (*or* USP-7) with an EC<sub>50</sub> value of 8.6 μM. P22077 also inhibits the structurally related peptidase USP-47. 1. Altun, Kramer, Willems, *et al.* (2011) *Chem. Biol.* **18**, 1401. 2. Tian, Isamiddinova, Peroutka, *et al.* (2011) *Assay Drug Dev. Technol.* **9**, 165.

**17-PA**, See 17-Phenyl-(3α,5α)-androst-16-en-3-ol

**PA-452**

This RXR antagonist (FW = 439.59 g/mol; CAS 457657-34-0; Solubility: 100 mM in DMSO; 10 mM in Ethanol), also named 2-[[3-(hexyloxy)-5,6,7,8-tetrahydro-5,5,8,8-tetramethyl-2-naphthalenyl]methylamino]-5-pyrimidinecarboxylic acid, blocks RXR-RAR heterodimer interactions (IC<sub>50</sub> = 90 nM). By inducing dissociation of nuclear RXR tetramers into dimers,

RXR antagonists can display potent anticarcinogenic activities that alter gene expression by modulating the chromatin architecture. 1. Takahashi, *et al.* (2002) *J. Med. Chem.* **45**, 3327. 2. Yasmin, *et al.* (2010) *J. Mol. Biol.* **397**, 1121. 3. Nakayama, *et al.* (2011) *J. Med. Chem. Lett.* **2**, 896.

**PA-457**, See *Bevirimat*

**PA 824**

This first-in-class tuberculosis pro-drug (FW = 359.26 g/mol; CAS 187235-37-6), also named (6*S*)-2-nitro-6-[[4-(trifluoromethoxy)-benzyl]oxy]-6,7-dihydro-5*H*-imidazo[2,1-*b*][1,3]oxazine, is active against both replicating and hypoxic, non-replicating forms of *Mycobacterium tuberculosis*. After activation by a process that depends on *M. tuberculosis* F420 cofactor, PA-824 exerts its bacteriocidal action by inhibiting protein biosynthesis and cell wall lipid synthesis (1). Its reduction potential does not appear to be the main driver for inhibitor efficacy (2). Significantly, PA-824 generates a des-nitro metabolite, along with a reactive nitrogen species (including nitric oxide), that may be effectors of the anaerobic activity of these compounds (3). Furthermore, nitric oxide scavengers protected *M. tuberculosis* from the lethal effects of the drug. This finding suggests PA-824 releases a lethal nitrogen oxide-like metabolite that factors into its bacteriocidal action. That PA-824 is without effect on *M. leprae* is consistent with the absence of a required activating enzyme, namely nitroimidazo-oxazine-specific nitroreductase (encoded by Rv3547), in the *M. leprae* genome (4). 1. Stover, Warrenner, VanDevanter, *et al.* (2000) *Nature* **405**, 962. 2. Thompson, Blaser, Anderson, *et al.* (2009) *J. Med. Chem.* **52**, 637. 3. Singh, Manjunatha, Boshoff, *et al.* (2008) *Science* **322**, 1392. 4. Manjunatha, Lahiri, Randhawa, *et al.* (2006) *Antimicrob. Agents Chemother.* **50**, 3350.

**PACAP<sub>6-38</sub>**

This potent and competitive PAC antagonist (FW = 4024.78 g/mol; CAS 143748-18-9; Sequence: FTDSYSRYRKQMAVKKYLAAVLGKRYKQR VKNK-NH<sub>2</sub>; Solubility: 2 mg/mL in H<sub>2</sub>O) targets Pituitary Adenylate Cyclase-Activating Polypeptide receptor *or* PAC<sub>1</sub> (IC<sub>50</sub> = 2 nM), blocking PACAP<sub>1-27</sub>-induced stimulation of adenylate cyclase (K<sub>i</sub> = 1.5 nM) (1). PACAP<sub>6-38</sub> also inhibits growth of prostate cancer cells (2). PACAP<sub>6-38</sub> inhibition aided in demonstrating that the neuropeptide PACAP promotes α-secretase pathway for processing Alzheimer amyloid precursor protein (3). Note that the longer peptide, PACAP<sub>1-38</sub> (FW = 4535 g/mol; CAS 137061-48-4), Sequence: HSDGIFTDSYSRYRKQMAVKKYLAAVLGK RYKQRVKNK-NH<sub>2</sub>) is an endogenous neuropeptide agonist, showing considerable homology with vasoactive intestinal peptide (VIP), but with more potent stimulation of adenylyl cyclase (4). 1. Robberecht, *et al.* (1992) *Eur. J. Biochem.* **207**, 239. 2. Leyton, *et al.* (1998) *Cancer Lett.* **125**, 131. 3. Kojro, *et al.* (2006) *FASEB J.* **20**, 512. 4. Rawlings, *et al.* (1994) *J. Biol. Chem.* **269**, 5680.

**Paclitaxel**

This potent anticancer agent (FW = 853.92 g/mol; CAS 33069-62-4; Solubility = 170 mg/mL DMSO, <<1 mg/mL H<sub>2</sub>O), more widely known as Taxol<sup>®</sup> and systematically as (2α,4α,5β,7β,10β,13α)-4,10-bis(acetyloxy)-13-[[[(2*R*,3*S*)-3-(benzoylamino)-2-hydroxy-3-phenylpropanoyl]oxy]-1,7-

dihydroxy-9-oxo-5,20-epoxytax-11-en-2-yl benzoate, from the bark of the Pacific yew *Taxus brevifolia* inhibits microtubule disassembly and induces microtubule bundling (1-4). Taxol greatly reduces the normal turnover of cellular microtubules, perturbs kinetochore-to-microtubule attachments, and disrupts chromosome segregation, thereby activating checkpoint pathway(s) that delay cell cycle progression and induce programmed cell death. Paclitaxel thus potently inhibits replication and proliferation, arresting cells at the G<sub>2</sub>-M stage, with an IC<sub>50</sub> value of 0.1 pM in human endothelial cells.

**Paclitaxel-Induced Tubulin Polymerization:** With purified tubulin (*i.e.*, containing no microtubule-associated proteins, *or* MAPs), taxol induces polymerization only if GTP is present when the reaction warmed to 30-37° C (5). Under such conditions, GTP is stoichiometrically hydrolyzed relative to tubulin in tandem with polymerization, whereas GDP inhibits both polymerization and hydrolysis. The polymerized protein shows only a few microtubules and instead consists mainly of sheets of protofilaments that undergo cold-induced disassembly. To prevent gross morphologic changes in microtubules in *in vitro* experiments, one should limit the amount of taxol added to 10-20% of the total tubulin. **Mode of Action:** Taxol alters the steady-state tubulin flux and the apparent molecular rate constants for tubulin addition and loss at the two ends of bovine brain microtubules *in vitro* (4-6). Reassembled bovine brain microtubules (consisting of 70% tubulin and 30% microtubule-associated proteins, *or* MAPs), undergo subunit exchange reactions at both ends with a net steady state flux. Once treated with taxol, these microtubules lose their dynamicity, showing little evidence of dynamic instability. Taxol (5-7 μM) slows the flux by 50% inhibition. To a first approximation, taxol decreases the magnitudes of the dissociation rate constants at the two ends to similar extents, while exerting little effect on the tubulin association rate constants. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Paclitaxel Resistance:** Although paclitaxel has improved both duration and quality of life for some cancer patients, the majority eventually develop progressive disease, representing a major obstacle to improving overall response and survival. Resistance arises mainly from tubulin mutations, tubulin isotype selection and post-translational modifications (7). Overexpression of Class III β-tubulin (TUBB3), for example, has emerged as a biomarker in a number of cancers, a prognostic indicator of more aggressive disease, and a predictor of resistance to taxanes and vinca alkaloids (8). The semisynthetic taxane Yg-3-46a effectively evades P-glycoprotein-mediated drug efflux and β-III tubulin-mediated drug resistance *in vitro* (9). **Formulations:** Paclitaxel is highly insoluble in water, necessitating initial dissolution in DMSO for biochemical and cell experiments. The resulting solution may then be diluted 20x with aqueous solutions of tubulin or cell suspensions. In the clinic, Taxol is principally used to combat ovarian and breast carcinomas. Taxol Injection<sup>®</sup> is a clear, colorless to slightly yellow viscous nonaqueous solution. (Each mL of this sterile nonpyrogenic solution contains 6 mg paclitaxel, 527 mg purified Cremophor<sup>®</sup> (*i.e.*, polyoxyethylated castor oil) and 49.7% (vol/vol) dehydrated alcohol) that is diluted with a suitable parenteral fluid prior to intravenous infusion.) Abraxane<sup>®</sup> is a nanoparticle-based formulation that exploits the ability of human albumin to bind paclitaxel, thereby avoiding disadvantages of cremaphor. **Effect of Microtubule End-Binding Proteins:** Analysis of microtubule (MT) growth times supports the view that catastrophic MT disassembly depends on the age of MTs (10). Colchicine and Vinblastine accelerate aging in a manner that depends on the presence of end-binding proteins. On the other hand, while Paclitaxel and Peloruside A induce catastrophes, they compensate by promoting MT rescues and reversing the MT aging. **Low-Temperature Tubulin Polymerization in the Presence of Paclitaxel:** Depolymerized bovine brain microtubule protein reassembles at 0° C in the presence of paclitaxel (11). Initial polymerization does not form microtubules, resulting instead in the formation of protofilamentous ribbons. Microtubules are first noted after 1 hour of incubation with the drug. After 20 hours with taxol at 0° C, the bulk of the polymerized tubulin is present as microtubules. 1. Schiff & Horwitz (1980) *Proc. Natl. Acad. Sci. U. S. A.* **77**, 1561. 2. ### Paclitaxel

This synthetic plant growth regulator (FW = 293.80 g/mol; CAS 76738-62-0; white solid; solubility = 35 mg/L water; (2*RS*,3*RS*)-1-(4-chlorophenyl)-4,4-dimethyl-2-([1*H*]-1,2,4-triazol-1-yl)pentan-3-ol) inhibits three steps in the conversion of *ent*-kaurene to *ent*-kaurenoate, exerting the overall effect of blocking gibberellin biosynthesis. **Target(s):** cytochrome P450 (1-3); *ent*-kaurene oxidase, inhibited by both 2*R*,3*R*- and 2*S*,3*S*-isomers (2,3); and phytosterol biosynthesis (4). 1. Coulson, King & Wiseman (1984) *Trends Biochem. Sci.* **9**, 446. 2. Ashman, Mackenzie & Bramley (1990) *Biochim. Biophys. Acta* **1036**, 151. 3. ### Pacritinib

This pyrimidine-based macrocycle and potent protein kinase inhibitor (FW = 472.59 g/mol; CAS 937272-79-2; Solubility: 11 mg/mL DMSO), also known as SB1518, selectively targets Janus Kinase 2 (*or* JAK2; IC<sub>50</sub> = 23 nM) and Fms-Like Tyrosine Kinase-3 (*or* FLT3; IC<sub>50</sub> = 22 nM), with values of 1280 and 522 nM for JAK1 and JAK3. FLT3 is genetically altered in up to 35% of acute myeloblastic leukemias, making it an attractive target for AML patients. Pacritinib has potent anti-proliferative effects on myeloid and lymphoid cell lines driven by mutant or wild-type JAK2 or FLT3, resulting from cell cycle arrest and induction of apoptosis (1). SB1518 has favorable pharmacokinetic properties after oral dosing in mice, is well tolerated and significantly reduces splenomegaly and hepatomegaly in a JAK2(Val-617-Phe)-driven disease model (1). **Primary Mode of Inhibitory Action:** Upregulation of JAK2 in FLT3-TKI-resistant AML cells was identified as a potential mechanism of resistance to selective FLT3 inhibition (2). This resistance could be overcome by pacritinib's combined inhibition of FLT3 and JAK2 in this cellular model. Pacritinib potently inhibits FLT3 auto-phosphorylation and downstream STAT5, MAPK and PI3K signaling pathways in AML cell lines with highest potency against cells harboring FLT3-ITD mutations (2). Blockade of FLT3 signaling was also demonstrated in primary AML blasts treated *ex vivo* with pacritinib. In both cell lines and primary blasts, pacritinib treatment led to the induction of G<sub>1</sub> arrest, inhibition of cell proliferation, as well as caspase-dependent apoptosis. The anti-proliferative effects of pacritinib on the FLT3-ITD harboring cell lines MV4-11 (IC<sub>50</sub> = 47 nM) and MOLM-13 (IC<sub>50</sub> = 67 nM), which have been reported previously, 16 are in the same range as the inhibition of intracellular FLT3 signalling (3). 1. Hart, Goh, Novotny-Diermayr, *et al.* (2011) *Leukemia* **25**, 1751. 2. Hart, Goh, Novotny-Diermayr, *et al.* (2011) *Blood Cancer J.* **1**, e44.

### Pactamycin

This universal translation inhibitor (FW = 558.63 g/mol; CAS 23668-11-3; soluble in ethanol and benzene; *Abbreviation:* Pct) from *Streptomyces pactum*, previously known as NSC 52947 and named systematically as benzoic acid, 2-hydroxy-6-methyl-[(1*S*,2*R*,3*R*,4*S*,5*S*)-5-[(3-acetylphenyl)amino]-4-amino-3-[[dimethylamino]carbonyl]amino]-1,2-dihydroxy-3-[(1*S*)-1-hydroxyethyl]-2-methylcyclopentylmethyl ester, inhibits protein synthesis and exhibits antitumor activity (1-10). Because the optical rotation of dissolved pactamycin changes upon standing, some as-yet undefined chemical rearrangement must take place. Solutions should be freshly prepared. **Primary Mode of Inhibitory Action:** Pct restricts structural transitions in ribosomal RNA, preventing the ribosome blocks the binding of initiator tRNA to the initiator complex, preventing formation of the 80S ribosomal complex and arresting protein biosynthesis immediately after the initial dipeptide is formed. **Binding Interactions:** Pct binds in a single site on the 30S ribosome subunit in the upper part of the platform, very close to the cleft in the subunit that is responsible for binding of the three tRNA molecules (1). It interacts primarily with residues at the tips of the stem loops H23b and H24a in the central domain of 16S RNA, where it folds up to mimic an RNA dinucleotide. The interaction between N6 of A694 and Pct is crucial for binding of the drug since this is the only interaction with that particular base. *N*-methylation of this residue causes resistance, most likely from distortions of the local structure. 1. #### Pactimibe

This indoline (FW = 416.61 g/mol; CAS 189198-30-9; liquid; Density = 1.071), also known as CS-505 and systematically as 7-[(2,2-dimethyl-1-oxopropyl)amino]-2,3-dihydro-4,6-dimethyl-1-octyl-1*H*-indole-5-acetic acid, inhibits cholesterol *O*-acyltransferase, or cholesterol *O*-acyltransferase (ACAT),  $K_i = 5.6 \mu\text{M}$ , and reduces plasma cholesterol concentrations (1-3). Although this ACAT-inhibiting drug appears to be of limited value in the management of atherosclerosis (4), CS-505 is being investigated with respect to Alzheimer's disease. 1. Terasaka, Miyazaki, Kasanuki, *et al.* (2007) *Atherosclerosis* **190**, 239. 2. Kitayama, Tanimoto, Koga, *et al.* (2006) *Eur. J. Pharmacol.* **540**, 121. 3. **PAF, See Platelet-Activating Factor**

**PAH, See 4-Aminohippurate**

**PAI-1 and PAI-2, See Plasminogen Activator Inhibitor Types 1 and 2**

#### PAI-749

This potent and selective synthetic antagonist of plasminogen activator inhibitor 1, or PAI-1 (FW = 501.63 g/mol; CAS 481631-45-2), systematically named as 3-pentyl-1-(phenylmethyl)-2-[6-(2*H*-tetrazol-5-ylmethoxy)naphthalen-2-yl]indole, maintains the activity of tissue-type plasminogen activator (tPA) and urokinase-type plasminogen activator (uPA) activities in the presence of PAI-1, with  $\text{IC}_{50}$  values of 157 and 87 nM, respectively (1). PAI-749 preserved tPA and uPA activity in the face of neutralizing amounts of PAI-1. That PAI-1 is the target is strongly suggested by observation of the same rank order for PAI inhibition and its binding to PAI, the latter deduced from fluorescence binding experiments. Even so, one unresolved point is the observation that the apparent  $\text{IC}_{50}$  values of PAI-749 with tPA and uPA are not identical. That PAI-749 induces PAI-1 polymerization may explain this discrepancy. PAI-749 does not affect thrombus formation or fibrinolysis in a range of established human plasma and whole blood-based systems (2). **See also Plasminogen Activator Inhibitor 1.** Gardell, Krueger, Antrilli, *et al.* (2007) *Mol. Pharmacol.* **72**, 897. 2. Lucking, Visvanathan, Philippou, *et al.* (2010) *J. Thromb. Haemost.* **8**, 1333.

#### PAK-104P

This MDR inhibitor (FW = 698.76 g/mol; CAS 131356-86-0), also known as 2-[4-(diphenylmethyl)-1-piperazinyl]ethyl 5-(*trans*-4,6-dimethyl-1,3,2-dioxaphosphorinan-2-yl)-2,6-dimethyl-4-(3-nitrophenyl)-3-pyridine-carboxylate *P*-oxide, reverses multidrug resistance and lowers calcium channel blocking activity (1). PAK-104P also inhibits cadmium-transporting ATPase (2). 1. Shudo, Mizoguchi, Kiyosue, *et al.* (1990) *Cancer Res.* **50**, 3055. 2. Ren, Furukawa, Chen, *et al.* (2000) *Biochem. Biophys. Res. Commun.* **270**, 608.

**PALA, See N-(Phosphonoacetyl)-L-aspartate**

**Palatinose, See Isomaltulose**

#### Palbociclib

This orally active, non-ATP-competitive cyclin kinase-directed inhibitor (FW = 483.99 g/mol (mono-HCl); CASs = 827022-32-2 (mono-hydrochloride, 571190-30-2 (free base); Solubility: 10 mg/mL DMSO; 30 mg/mL Water; Formulation: Dissolved in sodium lactate buffer (50 mM, pH 4.0)), also known as PD-0332991, Ibrance<sup>®</sup>, and 6-acetyl-8-cyclopentyl-5-methyl-2-(5-(piperazin-1-yl)pyridin-2-ylamino)pyrido[2,3-*d*]pyrimidin-7(8*H*)-one hydrochloride, targets Cdk-4 (Cyclin D<sub>1</sub>) and Cdk-6 (Cyclin D<sub>2</sub>), enzymes that participate in the so-called CDK4/6-retinoblastoma signaling pathway governing the cell-cycle restriction point. Palbociclib induces rapid G<sub>1</sub> cell-cycle arrest in primary human myeloma cells (1-4). This agent also shows significant efficacy in a broad spectrum of human tumor xenografts *in vivo*, resulting in complete regression in some tumors with no evidence of acquired resistance or ability to circumvent the growth inhibitory properties of this agent (1). Ibrance received FDA approval in 2015 for combined use with letrozole to treat postmenopausal women with estrogen receptor-positive, (HER2)-negative advanced breast cancer as an initial endocrine-based therapy for metastatic disease. **Cyclin Target Selectivity:** Cdk1 (weak, if any), Cdk2 (weak, if any), Cdk3 (weak, if any), Cdk4 ( $\text{IC}_{50} = 11 \text{ nM}$ ), Cdk5 (weak, if any), Cdk6 ( $\text{IC}_{50} = 16 \text{ nM}$ ), Cdk7 (weak, if any), Cdk8 (weak, if any), Cdk9 (weak, if any), Cdk10 (weak, if any). 1. Fry, *et al.* (2004) *Mol. Cancer Ther.* **3**, 1427. 2. Menu, *et al.* (2008) *Cancer Res.* **68**,

### Palinavir

This peptide analogue (FW<sub>free-base</sub> = 708.90 g/mol; CAS 154612-39-2) is a potent inhibitor of HIV-1,  $K_i = 30$  nM, and HIV-2 proteases,  $K_i = 130$  pM. 1. Lamarre, Creteau, Wardrop, *et al.* (1997) *Antimicrob. Agents Chemother.* **41**, 965.

### Paliperidone

This long-acting atypical antipsychotic drug (FW = 426.48 g/mol; CAS 144598-75-4), also named (*RS*)-3-[2-[4-(6-fluorobenzo[*d*]isoxazol-3-yl)-1-piperidyl]-ethyl]-7-hydroxy-4-methyl-1,5-diazabicyclo[4.4.0]deca-3,5-dien-2-one, is an  $\alpha_1$  and  $\alpha_2$  adrenergic receptor antagonist and  $H_1$  histamine receptor antagonist. Routes of delivery include long-acting oral form (Chemical Form: Paliperidone; Trade Name: Invega™) and an even longer-acting intramuscular form (Chemical Form: Paliperidone palmityl ester; Trade Name(s): Invega Sustenna or Xeplion). Paliperidone is also the primary metabolite of another antipsychotic drug, Risperidone. The half-life of risperidone conversion to paliperidone is about 3 hours for typical metabolizing individuals, compared with about 19 hours in slow-metabolizing subjects. **Primary Mode of Action:** Risperidone and 9-hydroxyrisperidone had similar *in vitro* binding profiles, with highest affinity was for 5-HT<sub>2A</sub> receptors ( $K_i = 0.4$  nM);  $K_i$  values for other 5-HT-receptor subtypes were at least 100-times higher. The binding affinity of risperidone and 9-hydroxyrisperidone for the D<sub>2</sub> family of receptors (D<sub>2L</sub>, D<sub>2S</sub>, D<sub>3</sub>, D<sub>4</sub>) was one order of magnitude lower than their affinity for 5-HT<sub>2A</sub> receptors. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Leysen, Janssen, Megens & Schotte (1994) *J. Clin. Psychiatry* **55**, Supplement 5-12.

**Paliperidone palmityl ester, See Paliperidone**

### Palmitate

This saturated fatty acid (FW<sub>free-acid</sub> = 256.43 g/mol; CAS 57-10-3;  $pK_a \approx 4.8$ ; M.P. = 63-64°C; B.P. = 351.5°C), also called palmitic acid, hexadecanoic acid and cetylic acid, is found throughout nature. Palmitic acid is insoluble in water but is soluble in ethanol (7.21 g per 100 mL), chloroform (15.1 g per 100 mL), as well as benzene, acetone, and ethyl acetate. **Micelle Formation:** Dissolve 1 mg into 1 mL of a chloroform:methanol solution (1:4, vol/vol), add to aqueous buffer, and disperse with the aid of a sonicator (5-6 30-sec bursts) while maintained at 24°C in a water bath. Resulting lipid solutions/dispersions can be stored

temporarily at 4°C. Before use, solutions are warmed to RT and vortexed three times for a few seconds with a Vortex Genie (at maximum setting) to obtain a homogenous preparation. *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **Target(s):** acetyl-CoA carboxylase (1,2); 1-acylglycerophosphocholine *O*-acyltransferase, or lysophosphatidylcholine *O*-acyltransferase (39); alcohol dehydrogenase (3); alkylidihydroxyacetone-phosphate synthase (4); arachidonyl-CoA synthetase, or arachidonate:CoA ligase (23); aspartate aminotransferase (35); branched-chain  $\alpha$ -keto-acid dehydrogenase (5); ceramidase (26); choloyl-CoA synthetase, or cholate:CoA ligase (24); chondroitin AC lyase (25); chondroitin B lyase, weakly inhibited (25); DNA-directed DNA polymerase (6); DNA polymerase  $\alpha$  (6); 7-ethoxycoumarin *O*-deethylase (7); fatty-acid synthase (1,8); firefly luciferase, or *Photinus*-luciferin 4-monooxygenase,  $IC_{50} = 0.67$   $\mu$ M (9,40);  $\beta$ -galactoside  $\alpha$ -2,6-sialyltransferase (10,36); 1,3- $\beta$ -glucan synthase (37); glucokinase (11); glucose-6-phosphate dehydrogenase (12); glutathione *S*-transferase (13); glycolipid *N*-tetradecanoyltransferase (38); hexokinase (14,34); hyaluronate lyase, weakly inhibited (25); leukocyte elastase, or neutrophil elastase (27); Lysophospholipase (30,31); microbial collagenases (27); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (15); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (29); phosphatidate cytidyltransferase (32); phosphatidate phosphatase (16); phosphatidylinositol 3-kinase (33); phospholipase D (28); photophosphorylation (17); prostaglandin dehydrogenase (18); protein kinase B (19); pyrophosphatase, or inorganic diphosphatase (20); pyruvate kinase (21); and L-threonine dehydrogenase (22). 1. **1-Palmitin, See Palmitoylglycerol**

### Palmitoleate

This common unsaturated fatty acid (FW<sub>free-acid</sub> = 254.41 g/mol; CAS 373-49-9; pK<sub>a</sub> ≈ 4.8; M.P. = -0.5-0.5°C) is known commonly as palmitoleic acid, less frequently as zoomaric acid, and systematically as (*Z*)-Δ<sup>9</sup>-hexadecenoic acid. Palmitoleic acid is the *cis*-isomer of palmitelaidic acid. At elevated concentrations, palmitoleate is a protein denaturant. *Note*: Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **Target(s)**: ammonia-dependent O<sub>2</sub> uptake activity and ammonia monooxygenase (1); Ca<sup>2+</sup> uptake, mitochondrial (2); cGMP-stimulated cAMP phosphodiesterase (3,4); choloyl-CoA synthetase, cholate:CoA ligase (5); chondroitin AC lyase (17); chondroitin B lyase (17); DNA polymerase (6); epidermal-growth-factor-induced increases in cytosolic [Ca<sup>2+</sup>], membrane potential, and inositol-1,4,5-trisphosphate generation (7); 1,3-β-glucan synthase (21,22); glucose-6-phosphate dehydrogenase (8); glycerol-3-phosphate *O*-acyltransferase (23); hexokinase (9); hyaluronate lyase (17); isocitrate dehydrogenase (8); KinA signal-transducing protein kinase (10); lactate dehydrogenase (8); leukocyte elastase, *or* neutrophil elastase (18); malate dehydrogenase (8); microbial collagenases (18); NAD<sup>+</sup> ADP-ribosyltransferase, *or* poly(ADP-ribose) polymerase (20); NAD<sup>+</sup> kinase (11); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (12); palmitoyl-CoA hydrolase, *or* acyl-CoA hydrolase (19); phospholipase A<sub>2</sub> (13); renin (14); steroid Δ<sup>5</sup>-reductase (15); and valyl-tRNA synthetase (16). **1.** Juliette, Hyman & Arp (1995) *J. ### Palmitoleoyl-Coenzyme A

This fatty acyl-CoA metabolite (FW = 1003.94 g/mol), also known as *cis*-9-hexadecenoyl-CoA, which is an alternative substrate for several acyltransferases as well as in β-oxidation, inhibits acetyl-CoA carboxylase (1). *Note*: Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **1.** Tanabe, Nakanishi, Hashimoto, *et al.* (1981) *Meth. Enzymol.* **71**, 5.

### Palmitoyl-D-carnitine

This acylated carnitine derivative (FW = 399.62 g/mol) is not the naturally occurring ester; it is the enantiomer of the natural intermediate of the mitochondrial degradation of palmitate. *Note*: Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **Target(s)**: carnitine:acylcarnitine translocase (1); and carnitine palmitoyltransferase (2,3), however, see also (1). **1.** Baillet, Mullur, Esser & McGarry (2000) *J. Biol. Chem.* **275**, 36766. **2.** Bieber & Farrell (1983) *The Enzymes*, 3rd ed. (Boyer, ed.), **16**, 627. **3.** Arduini, Mancinelli, Radatti, *et al.* (1992) *J. Biol. Chem.* **267**, 12673.

### Palmitoyl-DL-carnitine

This acylcarnitine racemate (FW = 436.07 g/mol) is significantly cheaper source than the pure naturally occurring L-enantiomer and is frequently used instead in investigations into lipid metabolism and regulation. *Note*: Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **See also Palmitoyl-L-carnitine; Palmitoyl-D-carnitine** **Target(s)**: 1,3-β-glucan synthase (1); NADH oxidation, mitochondrial (2); and protein kinase C (3-7). **1.** Kauss & Jeblick (1986) *Plant Physiol.* **80**, 7. **2.** Dargel & Strack (1966) *Acta Biol. Med. Ger.* **16**, 271. **3.** Katoh, Wrenn, Wise, Shoji & Kuo (1981) *Proc. Natl. Acad. Sci. U.S.A.* **78**, 4813. **4.** Kikkawa & Nishizuka (1986) *The Enzymes*, 3rd ed. Biophys.* **257**, 328. **7.** Takahashi, Kamimura, Shirai & Yokoo (2000) *Skin Pharmacol. Appl. Skin Physiol.* **13**, 133.

### Palmitoyl-L-carnitine

This naturally occurring acylated derivative (FW = 436.07 g/mol; CAS 18877-64-0) is an intermediate in the mitochondrial palmitic acid oxidation. Palmitoyl-L-carnitine reduces negative charge of membrane surfaces, when incorporated into the plasma membrane in erythrocytes and myocytes (1). *Note*: Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **Target(s)**: 7-ethoxycoumarin *O*-deethylase, cytochrome P450 (2); lysophospholipase (3-9); [myosin light-chain] kinase (10); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (11-13); palmitoyl-CoA hydrolase, *or* acyl-CoA hydrolase (14-16); phosphatidylcholine:cholesterol acyltransferase, LCAT (17); and protein kinase C (18). **1.** Gruver & Pappano (1993) *J. ### Palmitoylcholine

This acylated choline (FW<sub>bromide</sub> = 422.47 g/mol; CAS 2932-74-3 for the chloride salt) inhibits carnitine *O*-palmitoyltransferase (1), [myosin light-chain] kinase (2), and phosphatidylinositol diacylglycerol-lyase, or phosphatidylinositol-specific phospholipase C (3). *Nte*: Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). 1. Gandour, Colucci, Stelly, Brady & Brady (1988) *Arch. Biochem. Biophys.* **267**, 515. 2. Jinsart, Ternai & Polya (1991) *Plant Sci.* **78**, 165. 3. Hirasawa, Irvine & Dawson (1981) *Biochem. J.* **193**, 607.

### Palmitoyl-Coenzyme A

This thioester (FW = 1005.95 g/mol), consisting of palmitic acid and Coenzyme A, often abbreviated as Palmitoyl-S-CoA and Palmitoyl-CoA, is a key metabolite in the degradation of longer chain fatty acids and in the posttranslational palmitoylation of membrane-targeted proteins. Palmitoyl-CoA readily forms micelles, with critical micelle concentration (*cmc*) of 30-60 μM (1); one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when palmitoyl-CoA is present at concentrations above the *cmc*. **Target(s)**: acetoacetyl-CoA synthetase (2); acetyl-CoA carboxylase,  $K_i = 7.2 \mu\text{M}$  for the rat liver enzyme (3-16); acetyl-CoA hydrolase (119,120); acetyl-CoA synthetase, or acetate:CoA ligase (108-111); acylglycerol lipase (monoacylglycerol lipase; inhibited by micellar concentrations of propionyl-CoA (121); acylglycerone-phosphate reductase, or acyl/alkyl dihydroxyacetone-phosphate reductase (17,18); adenine-nucleotide translocase (19-23); 1-alkyl-*n*-glycerol-3-phosphate *O*-acetyltransferase (25); 1-alkylglycero-phosphocholine *O*-acetyltransferase (24,144); amine acetyltransferase (26); AMP deaminase (27); anion-conducting channel (28); arylalkylamine *N*-acetyltransferase (143); arylamine *N*-acetyltransferase (29,148); ATP:citrate lyase, or ATP:citrate synthase (30,31,136,137); carbamoyl-phosphate synthetase I, ammonia-requiring (107); carnitine *O*-acetyltransferase (32-34,147); carnitine *O*-octanoyltransferase, also alternative substrate (139,140); citrate synthase (35-43); cyclooxygenase (44); decylcitrate synthase (138); decylhomocitrate synthase (45); diacylglycerol cholinephosphotransferase (122); dicarboxylic acid carrier (46); dihydrofolate reductase (47); dihydrolipoyllysine-residue acetyltransferase (145); dihydroxyacetone phosphate *O*-acetyltransferase, or glycerone-3-phosphate *O*-acetyltransferase (48); DNA polymerases  $\alpha$  and  $\gamma$  (49); dopamine sulfotransferase (50); dynein ATPase (51); enoyl-[acyl-carrier protein] reductase (52); *trans*-2-enoyl-CoA reductase, NADPH-dependent or crotonyl-CoA reductase (53); ethanolamine phosphotransferase (122,123); fatty-acid synthase (15,54-61); glucokinase (62-65,133); glucose-6-phosphatase (66,67,117); glucose-6-phosphate dehydrogenase (68-76); glutamate dehydrogenase (40,77); glutaminase, phosphate-activated (78); glycerol-3-phosphate dehydrogenase (79-82); glycogen synthase (83); hexokinase (62-65,84,133); hormone-sensitive lipase (85); 4-hydroxybenzoate nonaprenyltransferase (134); 3-hydroxydecanoyl-[acyl-carrier-protein] dehydratase (113); 3-hydroxy-3-methylglutaryl-CoA synthase (135); isocitrate dehydrogenase, NADP<sup>+</sup>-dependent (86,87);  $K_{ATP}$  channel, mitochondrial (88);  $\alpha$ -ketoglutarate dehydrogenase complex (87); lipase (triacylglycerol lipase (85,89,90); lipoxigenase (42); long-chain-acyl-CoA synthetase (91); malate dehydrogenase (77); malonyl-CoA decarboxylase (114,115); meromyosin ATPase (92);  $\alpha$ -methylacyl-CoA epimerase, inhibition due to micelle formation (112); 2-methyl branched-chain acyl-CoA dehydrogenase (93); 3-methylcrotonyl-CoA carboxylase (94,95); (S)-methylmalonyl-CoA hydrolase (118); NADH dehydrogenase transhydrogenase activity (96); NAD(P)<sup>+</sup> transhydrogenase (97-99); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (100); palmitoyl-CoA hydrolase, by micellar form (101); pantothenate kinase (126-132); phenol sulfotransferase (50); phosphate acetyltransferase (146);

phosphatidate cytidyltransferase (124,125); phosphatidate phosphatase (102); phosphatidylcholine:retinol *O*-acyltransferase (141); 6-phosphogluconate dehydrogenase (74); phytanoyl-CoA dioxygenase (150); propionyl-CoA carboxylase (103); protein kinase C (104,105); RNA polymerase (106); stearoyl-CoA 9-desaturase (149); and 3 $\alpha$ ,7 $\alpha$ ,12 $\alpha$ -trihydroxy-5 $\beta$ -cholestanoyl-CoA 24-hydroxylase (116). 1. ## 2-Palmitoylglycerol

This monoacylglyceride (FW = 330.51 g/mol; CAS 23470-00-0; M.P. = 68.5°C), also known as 2-monopalmitoylglycerol and 2-monopalmitin, inhibits hormone-sensitive lipase and cytochrome P450-dependent 7-ethoxycoumarin *O*-deethylase. Acyl group migration can readily occur. *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **Target(s):** 7-ethoxycoumarin *O*-deethylase, or cytochrome P450 (1); 1,3- $\beta$ -glucan synthase (2); and hormone-sensitive lipase (3). **1.** Muller-Enoch, Fintelmann, Nicolaev & Gruler (2001) *Z. Naturforsch. [C]* **56**, 1082. **2.** Ko, Frost, Ho, Ludescher & Wasserman (1994) *Biochim. Biophys. Acta* **1193**, 31. **3.** Jepson & Yeaman (1992) *FEBS Lett.* **310**, 197.

## 1-Palmitoyl-*sn*-glycero-3-phosphate

This monoacylglycerol phosphate (FW = 407.46 g/mol), also known as 1-palmitoyllysofosphatidate, inhibits 1-alkyl-2-acetylgllycerophosphatase (1), alkylglycerophospho-ethanolamine phosphodiesterase, or lysophospholipase D (2), and chymase (3). *Note:* Because palmitoylglycero-P readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when palmitoylglycero-P is present at concentrations above the critical micelle concentration (*cmc*). **1.** Tellis & Lekka (2000) *J. Eukaryot. Microbiol.* **47**, 122. **2.** van Meeteren, Ruurs, Christodoulou, et al. (2005) *J. Biol. Chem.* **280**, 21155. **3.** Kido, Fukusen & Katunuma (1985) *Arch. Biochem. Biophys.* **239**, 436.

## 1-Palmitoyl-*sn*-glycero-3-phosphocholine

This lysolecithin (FW = 495.64 g/mol; CAS 17364-16-8), also known as 1-palmitoylglycerophosphocholine or lysophosphatidylcholine (palmitate-containing), is the hydrolysis reaction product formed by phospholipase A<sub>2</sub> and is a substrate for 1-acylglycerophosphocholine *O*-acyltransferase, lysophospholipase, and lysolecithin acylmutase. *Note:* Because palmitoylglycero-phosphocholine readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when palmitoylglycero-phosphoryl choline is present above the critical micelle concentration (*cmc*). **See also 1-Acylglycero-phosphocholine** **Target(s):** 1-alkyl-2-acetylgllycerophosphocholine esterase, or platelet-activating-factor acetylhydrolase (1,2); 1-alkylglycero-phosphocholine *O*-acyltransferase (3,4); 1,3- $\beta$ -glucan synthase (5); glycerophosphatidylinositol phospholipase D (6); glyceryl-ether monoxygenase (7); lipase, or triacylglycerol lipase (8); and Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (9,10). **1.** Tsoukatos, Liapikos, Tselepis, Chapman & Ninio (2001) *Biochem. J.* **357**, 457. **2.** Chroni & Mavri-Vavayanni (2000) *Life Sci.* **67**, 2807. **3.** Lee, Vallari & Snyder (1992) *Meth. Enzymol.* **209**, 396. **4.** Lee (1985) *J. Biol. ## 3-Palmitoyl-5-hydroxymethyltetronic Acid, See RK-682

## Palmitoyl-inosino-Coenzyme A

This inosine-containing acyl-CoA analogue (FW = 1005.93 g/mol) inhibits acetyl-CoA carboxylase (1,2). *Note:* Because palmitoyl-inosino-CoA

readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when palmitoyl-inosino-CoA is present at concentrations above the critical micelle concentration (*cmc*). 1. Tanabe, Nakanishi, Hashimoto, *et al.* (1981) *Meth. Enzymol.* **71**, 5. 2. Nikawa, Tanabe, Ogiwara, Shiba & Numa (1979) *FEBS Lett.* **102**, 223.

### Palmitoyl-keto-Coenzyme A

This thiol ester (FW = 1021.85 g/mol), consisting of a hexadecanoyl moiety linked to an oxidized form of natural coenzyme A, inhibits acetyl-CoA carboxylase (1,2). *Note:* Because palmitoyl-keto-CoA readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). 1. Tanabe, Nakanishi, Hashimoto, *et al.* (1981) *Meth. Enzymol.* **71**, 5. 2. Nikawa, Tanabe, Ogiwara, Shiba & Numa (1979) *FEBS Lett.* **102**, 223.

### 1-Palmitoyl-2-palmitoylamino-2-deoxy-*sn*-glycero-3-phosphorylcholine

This amide-containing phosphatidylcholine analogue (FW = 733.07 g/mol) inhibits cobra venom (*Naja naja naja*) phospholipase A<sub>2</sub>, IC<sub>50</sub> = 156 μM (1). *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). 1. Yu, Deems, Hajdu & Dennis (1990) *J. Biol. Chem.* **265**, 2657.

### *N*-Palmitoyl-D-sphingomyelin, See *N*-Palmitoyl-D-sphingosine-1-phosphocholine

### *N*-Palmitoyl-D-sphingosine-1-phosphocholine

This sphingomyelin, frequently misnamed *N*-palmitoyl-D-sphingomyelin (FW = 703.04 g/mol), inhibits phospholipase C δ (1). *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). 1. Pawelczyk & Lowenstein (1997) *Biochimie* **79**, 741.

### Palmityl Alcohol, See *Cetyl Alcohol*

### Palmityl-CoA, See *Palmitoyl-CoA*; *S*-*Cetyl-CoA*

### Palmityl Gallate, See *Cetyl Gallate*

### *O*-(Palmitoxyethyl)phosphocholine

This alkylated phosphocholine (FW = 451.63 g/mol) inhibits phospholipase A<sub>2</sub> (1). *Note:* Because this substance readily forms micelles, one must take care to discriminate whether monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). 1. Magolda, Ripka, Galbraith, Johnson & Rudnick

(1985) in *Prostaglandins, Leukotrienes, and Lipoxins* (Bailey, ed.), p. 669, Plenum Press, New York.

### 1-Palmityl-2-palmitoylamino-2-deoxy-*sn*-glycero-3-phosphorylcholine

This ether amide-phosphocholine (FW = 719.08 g/mol) is an analogue of phosphatidylcholine and inhibits cobra venom (*Naja naja naja*) phospholipase A<sub>2</sub>, IC<sub>50</sub> = 38 μM (1). A six-step synthesis of this compound is presented. *Note:* Because this substance readily forms micelles, one must take care to discriminate whether monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). 1. Yu, Deems, Hajdu & Dennis (1990) *J. Biol. Chem.* **265**, 2657.

### Palmitylsulfonate, See *Cetyl Sulfonate, Sodium*

### 1-Palmitylthio-2-palmitoylamino-1,2-dideoxy-*sn*-glycero-3-phosphorylcholine

This thioether amide-containing phosphatidylcholine analogue (FW = 735.15 g/mol) strongly inhibits cobra venom (*Naja naja naja*) phospholipase A<sub>2</sub>, IC<sub>50</sub> = 2 μM (1). *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). 1. Yu, Deems, Hajdu & Dennis (1990) *J. Biol. Chem.* **265**, 2657.

### 1-Palmitylthio-2-palmitoylamino-1,2-dideoxy-*sn*-glycero-3-phosphoryl-ethanolamine

This thioether amide-containing phosphatidylethanolamine analogue (FW = 693.07 g/mol) potently inhibits cobra venom (*Naja naja naja*) phospholipase A<sub>2</sub>, IC<sub>50</sub> = 0.45 μM (1). *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). 1. Yu, Deems, Hajdu & Dennis (1990) *J. Biol. Chem.* **265**, 2657.

### *O*-(Palmitylthiopropyl)phosphocholine

This alkylated phosphocholine (FW = 481.72 g/mol) inhibits phospholipase A<sub>2</sub> (1). *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). 1. Magolda, Ripka, Galbraith, Johnson & Rudnick (1985) in *Prostaglandins, Leukotrienes, and Lipoxins* (Bailey, ed.), p. 669, Plenum Press, New York.

### Palmityl Trifluoromethyl Ketone

Palmityl Trifluoromethyl Ketone

Palmityl Trifluoromethyl Ketone Hydrate

This palmityl trifluoromethyl ketone (FW = 308.43 g/mol), also named 1,1,1-trifluoro-2-heptadecanone, is a potent reversible inhibitor of acylglycerol lipase, or monoacylglycerol lipase (1), 1-acylglycerophosphocholine *O*-acyltransferase, or lysophosphatidylcholine *O*-acyltransferase (2), fatty acid amide hydrolase, or anandamide amidohydrolase (1), and phospholipase A<sub>2</sub> (3,4). Inhibition is doubtlessly the consequence of hydration of the ketone (strongly favored by the presence of its trifluoromethyl group.) and attack of an active-site nucleophile. The hydrate then forms a tight-binding analogue of presumed tetrahedral and/or acyl-enzyme intermediates in the hydrolase-type reaction. 1. Ghafouri, Tiger, Razdan, *et al.* (2004) *Brit. J. Pharmacol.* **143**, 774. 2. Kerkhoff, Habben, Gehring, Resch & Kaever (1998) *Arch. Biochem. Biophys.* **351**, 220. 3. Ackermann, Conde-Frieboes & Dennis (1995) *J. Biol. Chem.* **270**, 445. 4. Holk, Rietz, Zahn, Quader & Scherer (2002) *Plant Physiol.* **130**, 90.

**PALO**, See *N*-(Phosphonacetyl)-*L*-ornithine

#### Palomid 529

This novel Akt inhibitor (FW = 406.43 g/mol; CAS 914913-88-5; Solubility: 80 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O or Ethanol; Abbreviation: P529), also named 8-(1-hydroxyethyl)-2-methoxy-3-(4-methoxybenzyloxy) benzo[*c*]chromen-6-one, inhibits tumor angiogenesis, vascular permeability, and tumour growth (1). P529 has the additional benefit of blocking pAktS473 signaling consistent with blocking TORC2 in all cells and thus bypassing feedback loops that lead to increased Akt signaling in some tumor cells (1). P529 significantly enhance the antiproliferative effect of radiation in prostate cancer PC-3 cells (2). Analysis of signal transduction pathways targeted by P529 exhibited a decrease in p-Akt, VEGF, MMP-2, MMP-9, and Id-1 levels after radiation treatment. Palomid 529 is an effective suppressor of Müller cell proliferation, glial scar formation, and photoreceptor cell death in a rabbit model of retinal detachment, or RD (3). Palomid 529 significantly suppresses breast cancer susceptibility gene (Brca1) -deficient tumor growth in mice through inhibition of both Akt and mTOR signaling (4). 1. Xue, Hopkins, Perruzz, *et al.* (2008) *Cancer Res.* **68**, 9551. 2. Diaz, Nguewa, Diaz-Gonzalez, *et al.* (2009) *Brit. J. Cancer* **100**, 932. 3. Lewis, Chapin, Byun, *et al.* (2009) *Invest. Ophthalmol. Vis. Sci.* **50**, 4429. 4. Xiang, Jia, Sherris, *et al.* (2011) *Oncogene* **30**, 2443.

#### Palonosetron

This serotonin 5-HT<sub>3</sub> receptor antagonist and longacting anti-emetic (FW = 296.41 g/mol; CAS 135729-61-2), known by code name RS 25259, RS 25259-197, trade name Aloxi<sup>®</sup>, and systematic name (3*a*S)-2-[(3*S*)-1-azabicyclo[2.2.2]oct-3-yl]-2,3,3*a*,4,5,6-hexahydro-1*H*-benz[*de*]isoquinolin-1-one, is used to treat chemotherapy-induced nausea/vomiting (1-3). Palonosetron affects both peripheral and central nervous systems, reducing vagus nerve activity, thereby deactivating the 5-HT<sub>3</sub> receptor-dense vomiting center located in the medulla oblongata. It is without effect on dopamine receptors or muscarinic receptors. **Primary Mode of Inhibitor Action:** Intravenously administered palonosetron has a linear pharmacokinetic profile, with a long terminal elimination half-life of ~40 hours and moderate (62%) plasma protein binding (4). Its high affinity and long half-life most likely explains its persistent antiemetic effect. Similar 5-HT<sub>3</sub> antagonists include tropisetron, ondansetron, dolasetron, and granisetron. The effectiveness of each depends on particular variants of 5-HT<sub>3</sub> receptors expressed by the patient, including changes in promoters for the receptor genes. 1. #### Palytoxin

This structurally complex neurotoxin (FW = 2680.17 g/mol; CAS 11077-03-5; Abbreviation: PLTX), from the Pacific soft coral *Palythoa toxica*, binds slowly, but with extreme affinity, to Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase, converting the latter into an open channel, allowing unhindered passage of potassium and sodium ions. Less than 1 pM palytoxin is required for rapid potassium ion outflow from erythrocytes, thereby dissipating its transmembrane electric potential (1-7). Palytoxin is lethal in mice, exhibiting an impressive LD<sub>50</sub> of 15 ng/kg. The pore-forming action of palytoxin is not restricted to Na<sup>+</sup>/K<sup>+</sup>-ATPase, but is also observed with the colonic H<sup>+</sup>/K<sup>+</sup>-ATPase (8). This observation raises the likelihood that the toxin reacts at functionally and/or structurally similar manner with these pumps. PLTX brings about depolarization of the cellular membrane, disrupting intracellular calcium concentration ([Ca<sup>2+</sup>]<sub>i</sub>) and leading to smooth and cardiac muscle contraction, cytoskeletal dysregulation, and neurotransmitter release (9). Second only to maitotoxin as the most toxic natural product known, palytoxin evokes prompt onset of severe agonia and asthma-like airway effects, followed quickly by tachycardia and death, often within minutes. SKF-96365 and Gd<sup>3+</sup> are widely used to block store-operated and stretch-activated Ca<sup>2+</sup> channels, respectively. SKF-96365 fails to affect the long-lasting phase elicited by PLTX, excluding the activation of the store-operated channels during this phase (9). In contrast, Gd<sup>3+</sup> abolishes the long-lasting phase of the [Ca<sup>2+</sup>]<sub>i</sub> increase, suggesting a possible role for stretch-activated channels in PLTX action. While Gd<sup>3+</sup> is also known to inhibit voltage-dependent Ca<sup>2+</sup> conductance in neural cells, voltage-dependent Ca<sup>2+</sup> blockade seems unlikely in muscle cells. Even at a level (100 μM) commonly used to investigate stretch-activated channels activity, Gd<sup>3+</sup> does not affect the transient phase as Verapamil and La<sup>3+</sup>/Cd<sup>2+</sup> does. In addition to the selective inhibitory action of Gd<sup>3+</sup> on the long-lasting phase, Gd<sup>3+</sup> also significantly reduces, albeit incompletely, the toxic effects of PLTX on skeletal muscle cells, suggesting a role for the stretch-activated channels in the chain of events culminating in death of cultured muscle cells (9). Palytoxin also binds to erythrocyte Band-3 protein (B3 or AE1), altering the anionic flux and seriously compromising not only CO<sub>2</sub> (bicarbonate) transport, thereby also affecting hemoglobin oxygenation/deoxygenation (10). The stereocontrolled synthesis of palytoxin (11) was heralded as one of the most complicated syntheses ever undertaken. (See *Maitotoxin*) 1. Habermann (1989) *Toxicon* **27**, 1171. 2. ### Pancreastatin

This polypeptide (MW = 5103 g/mol; CAS 106477-83-2; Porcine Sequence: GWPQAPAMDGAGKTGAEEAQPPEGKGGAREHSRQEEEE TAGAPQGLFRG-NH<sub>2</sub>; pI = 4.6), formed by processing of the glycoprotein Chromogranin A in neuroendocrine cells, inhibits glucose-induced insulin release from the pancreas. Human, porcine, and bovine pancreastatins have 52, 49, and 47 residues, respectively. Pancreastatin reportedly inhibits glucose uptake in rat adipocytes by signaling through the Gα<sub>q</sub>-subunit of heterotrimeric G proteins in the insulin signaling pathway, thus preventing GLUT4 translocation to the plasma membrane. Pancreastatin also inhibits glycogen synthesis in rat adipocytes by activating [glycogen synthase] kinase-3 activity through the activation of protein kinase C (1). **Note:** Porcine pancreastatin is commercially available (Gene-Script). **Storage:** Store in dry form in a desiccator at 0–5°C. For most reliable results, rehydrate the peptide immediately prior to use, and do not re-freeze any unused portion of the dissolved peptide. **Target(s):** glucose-induced insulin release (2-4); and GLUT-4-mediated glucose transport (5). 1. ### Pancreatic Secretory Trypsin Inhibitor

This polypeptide (FW = 6247 g/mol; Abbreviation: PSTI) also known as pancreatic trypsin inhibitor and Kunitz & Northrop inhibitor, forms a high-affinity complex with trypsin. Synthesized in the gut mucosa and secreted from pancreatic acinar cells into pancreatic juice, PSTI prevents premature trypsin-catalyzed zymogen activation within the pancreas and/or pancreatic duct. Mutations in its gene are associated with hereditary pancreatitis and tropical calcific pancreatitis. **See Trypsin Inhibitors** 1. Kunitz & Northrop (1936) *J. Gen. Physiol.* **19**, 991. 2. ### Pancreozymin, See Cholecystokinin

### Pancuronium Bromide

This cationic aminosteroid (FW = 732.68 g/mol; CAS 15500-66-0; Soluble to 1 g/mL H<sub>2</sub>O at 20°C), is a long-acting, nondepolarizing relaxant used to induce skeletal muscle relaxation during anesthesia. It binds to post-synaptic nicotinic acetylcholine receptors, displacing acetylcholine competitively (1-4). Infusion of the reversible competitive inhibitor pancuronium for up to 12 hrs does not reduce acetylcholine receptor number, an action that contrasts with that of the irreversible acetylcholine receptor blocker α-bungarotoxin. Because equilibrium conditions of neurotransmitter concentration and receptor binding are rarely, if ever, achieved during synaptic transmission at the neuromuscular junction, one must consider the binding kinetics of drugs acting at this synapse. Based on a single high-affinity site model of competitive inhibition, rate constants for pancuronium ( $k_{on}$  is  $2.7 \times 10^8 \text{ M}^{-1} \text{ s}^{-1}$ ;  $k_{off}$  is  $2.1 \text{ s}^{-1}$ ) are in reasonably good agreement with an IC<sub>50</sub> value of 5.5 nM (4). Pancuronium bromide has been used in lethal injection protocols for capital punishment. Sodium pentathol is administered first, followed by pancuronium bromide, with potassium chloride given last. **Target(s):** acetylcholine receptors (1-3); acetylcholine esterase, weakly inhibited (5); choline acetyltransferase (6); cholinesterase (5); diamine oxidase (6); histamine N-methyltransferase (8,9); and Na<sup>+</sup> currents (10). 1. ### Pantherine, See Muscimol

### Panobinostat

This pan-HDAC inhibitor (FW = 349.43 g/mol; CASs = 404950-80-7, 960055-57-6 (Maleic acid), 960055-60-1 (methanesulfonate); Solubility: 70 mg/mL DMSO; <1 mg/mL Water), also known as LBH589 and named systematically as (E)-N-hydroxy-3-(4-((2-methyl-1H-indol-3-yl)ethyl)amino)methylphenyl)acrylamide, exhibits a broad spectrum of action, targeting histone acetylases with IC<sub>50</sub> values of 5-20 nM and resulting in histone hyperacetylation (1,2). Low nanomolar concentrations of LBH589 inhibit the growth of all melanoma cell lines tested, but not normal melanocytes. Inhibition is characterized by increased apoptosis as well as a G<sub>1</sub> cell-cycle arrest (3). Panobinostat induces E-cadherin expression on cell membranes of MDA-MB-231 cells (as a model for triple-negative breast cancer, *or* TNBC), reducing cell invasion and migration (4). When LBH589 is combined with the mTORC1 inhibitor RAD001, there is strong synergy in inducing cytotoxicity in multiple myeloma cells (5). 1. Scuto A, *et al.* (2008) *Blood* **111**, 5093. 2. ### Pantoprazole

This racemic benzimidazole (FW = 383.38 g/mol; CAS 102625-70-7), also known as BY-1023, SKF 96022 and marketed under the names Protium™ and Protonix™, inhibits the gastric proton pump, *or* H<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (1,2). **Primary Mode of Action:** Like other proton pump inhibitors, *or* PPIs (such as omeprazole, lansoprazole and rabeprazole), pantoprazole is a prodrug that undergoes acid-catalyzed conversion to its sulfhydryl-reactive form. The activated PPI then binds to and covalently modifies gastric H<sup>+</sup>/K<sup>+</sup>-ATPase, forming a disulfide bond with Cys813 and inhibiting the pump. Pantoprazole also inhibits the exchange between <sup>18</sup>O-labeled orthophosphate and HOH, a well-known feature of H<sup>+</sup>/K<sup>+</sup>-ATPase catalysis. **Metabolism:** Pantoprazole degradation proceeds mainly by CYP2C19-catalyzed demethylation, followed by sulfation. Another pathway involves CYP3A4-catalyzed oxidation. In either case, pantoprazole metabolites are not believed to be pharmacologically significant. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner

& Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Shin & Sachs (2004) *Biochem. Pharmacol.* **68**, 2117. 2. Simon, Keeling, Laing, Fallowfield & Taylor (1990) *Biochem. Pharmacol.* **39**, 1799.

### Papaverine

This opium metabolite (FW<sub>free-base</sub> = 339.39 g/mol; CAS 61-25-6; triboluminescent solid; pK<sub>a</sub> = 8.07 at 25°C), also known as 1-[(3,4-dimethoxy-phenyl)methyl]-6,7-dimethoxyisoquinoline, is a smooth muscle relaxant and cerebral vasodilator. It is most stable when stored as the hydrochloride or in aqueous solutions at pH 2.0-2.8. **Target(s):** acetylcholinesterase (1,2); Ca<sup>2+</sup> current, voltage-dependent (3); 3',5'-cyclic-GMP phosphodiesterase, or cGMP phosphodiesterase (5,7,9, 12,24,26); 3',5'-cyclic-nucleotide phosphodiesterase, or cAMP phosphodiesterase (4-11,24-27); guanylate cyclase (13); HIV replication (14,15); HVJ (Sendai virus) replication (16); 15-hydroxyprostaglandin dehydrogenase (17); K<sup>+</sup> current, Ca<sup>2+</sup>-activated oscillatory (3); K<sup>+</sup> current, voltage-dependent transient outward (3); lactate dehydrogenase (18); malate dehydrogenase (18); monoamine oxidase (19); NADH dehydrogenase, or complex I (20); NAD(P)H dehydrogenase, or DT diaphorase (21); oxidative phosphorylation (22); purine transport (23); and rhodopsin kinase, weakly inhibited (28). 1. ### Paradoxin

This presynaptic neurotoxin (MW = 17.5 kDa; CAS 70699-67-1; Symbol: PDX) from the venom of the inland taipan snake (*Oxyuranus microlepidotus*) is a heterotrimeric phospholipase A<sub>2</sub> that catalyzes the hydrolysis of 2-acyl groups within 3-*sn*-phosphoglycerides (1). Paradoxin abolishes indirect twitches of the chick biventer cervicis and mouse phrenic nerve diaphragm preparations, when present at 65 nM (2). The time to 90% inhibition by PDX was significantly increased by replacing 2.5 mM Ca<sup>2+</sup> in the physiological solution with 10 mM Sr<sup>2+</sup> (2). In the mouse diaphragm (at low Ca<sup>2+</sup> and at room temperature), the inhibitory effect of PDX (6.5 nM) is delayed, attended by a transient increase of contractions. In intracellular recording experiments using the mouse hemidiaphragm, PDX (6.5-65 nM) significantly increases quantal content and miniature endplate potential frequency prior to blocking evoked release of acetylcholine. In extracellular recording experiments using the mouse triangularis sterni, PDX (2.2-65 nM) significantly inhibits the voltage-dependent potassium ion, but not sodium ion, waveform (2). In patch clamp experiments on B82 mouse fibroblasts that had been stably transfected with rKv 1.2, PDX (22 nM) is without significant effect on currents evoked by 10mV step depolarizations from -60 to +20mV. PDX exhibits the pharmacological properties of a β-neurotoxin, and is likely to be one of the most potent, if not the most potent β-neurotoxin yet discovered (2). The toxic effects of paradoxin are blocked upon incubation with 4-bromophenacyl bromide (1.8 mM). 1. Bell, Sutherland & Hodgson (1998) *Toxicon* **36**, 63. 2. ### Parathion

This insecticide (FW = 291.26 g/mol; CAS 56-38-2), also known as E605, phosphostigmine, and phosphorothioic acid *O,O*-diethyl *O*-(4-nitrophenyl) ester, is a cholinesterase inhibitor. **Primary Mode of Action:** Like other phosphorothioate organophosphorus pesticides, parathion is metabolized by cytochrome P450s, either through a dearylation reaction to form an inactive metabolite, or through a desulfuration to form the active oxon metabolite, paraoxon-ethyl (e.g., (CH<sub>3</sub>CH<sub>2</sub>-O)<sub>2</sub>P(=O)-O-C<sub>6</sub>H<sub>4</sub>-NO<sub>2</sub>). The latter is a highly effective mechanism-based acetylcholinesterase inhibitor. The primary enzymes involved in parathion bioactivation are CYP2B6, CYP2C19, and CYP1A2. **CAUTION:** Parathion is highly toxic by all routes of exposure. Its use and that of related organophosphorus compounds annually accounts for 200,000 deaths worldwide, mainly farmworkers. The lowest dosage with detectable toxic effects in humans is 240 μg/kg (< 0.1 ounce). The most common cause of death is failure to maintain adequate oxygenation. Clinical signs of organophosphate poisoning include excess salivation, lacrimation, abdominal pain, vomiting, intestinal hypermotility, and diarrhea. The consensus treatment is early resuscitation with atropine and use of a mechanical respirator, supplemented with oxygen, to provide adequate oxygenation of vital tissues. **Target(s):** acetylcholinesterase (1-5); (Ca<sup>2+</sup>/Mg<sup>2+</sup>)-ATPase (6); carboxylesterase (7-9); cholinesterase, or butyrylcholinesterase (1-3,10,11); CYP1A1 (12); CYP3A2 (13); CYP3A4 (14); CYP3A27 (12); CYP2B1 (15); CYP2C6 (13); CYP2C11 (13); cytochrome P450 (12-17); nicotinic acetylcholine receptor (18); and photosynthetic system (19). 1. ### Paricalcitol

This vitamin D receptor agonist (FW = 416.64 g/mol; CAS 131918-61-1), also named (1*R*,3*R*,5*Z*)-5-[(2*E*)-2-[(1*R*,3*aS*,7*aR*)-octahydro-1-[(1*R*,2*E*,4*S*)-5-hydroxy-1,4,5-trimethyl-2-hexen-1-yl]-7*a*-methyl-4*H*-inden-4-ylidene]ethylidene]-1,3-cyclohexanediol, is a vitamin D analogue that suppresses elevated parathyroid hormone (PTH) concentrations in patients with hyperparathyroidism, especially those maintained on chronic hemodialysis (1). The vitamin D receptor is a ligand-induced transcription factor that regulates the expression of the genes involved in controlling calcium homeostasis, bone remodeling, hormone secretion, as well as the growth and differentiation of target cells (1). Paricalcitol also inhibits tumor formation in a murine model of uterine fibroids, suggesting its use as a noninvasive medical treatment option for uterine fibroids (2). **1.** Goldenberg (1999) *Clin. Ther.* **21**, 432. **2.** Halder, Sharan, Al-Hendy & Al-Hendy (2014) *Reprod. Sci.* **21**, 1108.

### Parinaric Acids

This term refers to any of octadeca-9,11,13,15-tetraenoic acid's sixteen different *cis/trans*-isomers (FW<sub>free-acid</sub> = 276.42 g/mol), all possessing a conjugated double-bond network first found in the seeds of *Parinarium laurinum*. The (9*Z*,11*E*,13*E*,15*Z*)-isomer is frequently referred to as  $\alpha$ - or *cis*-parinaric acid, while the (9*E*,11*E*,13*E*,15*Z*)-isomer is usually referred to as  $\beta$ - or *trans*-parinaric acid (however, note that the all-*E*-isomer has also been called  $\beta$ -parinaric acid). **Note:** The common terms *cis*- or *trans*-parinaric acid do not refer to either the all-*cis*- or all-*trans*-isomers. **Target(s):** DNA-directed DNA polymerase (1); DNA polymerases  $\alpha$ ,  $\beta$ , and  $\delta$ , inhibited by  $\alpha$ -parinarate (1); DNA topoisomerase I, inhibited by  $\alpha$ -parinarate (1); DNA topoisomerase II, inhibited by  $\alpha$ -parinarate (1); gelatinase A, inhibited by  $\alpha$ - and  $\beta$ -parinarate (2); gelatinase B, inhibited by  $\alpha$ - and  $\beta$ -parinarate (2); hexokinase, inhibited by  $\alpha$ -parinarate (3); neutrophil elastase, inhibited by  $\alpha$ - and  $\beta$ -parinarate (4). **1.** Mizushima, Tsuzuki, Eitsuka, *et al.* (2004) *Lipids* **39**, 977. **2.** Berton, Rigot, Huet, *et al.* (2001) *J. Biol. Chem.* **276**, 20458. **3.** Stewart & Blakely (2000) *Biochim. Biophys. Acta* **1484**, 278. **4.** Tyagi & Simon (1991) *J. Biol. Chem.* **266**, 15185.

### *trans*-Parinaroyl Ganglioside G<sub>M3</sub>

This fluorescent ganglioside G<sub>M3</sub> analogue (FW = 1173.44 g/mol), with the fatty acyl component is replaced with *trans*-9,11,13,15-octadecatetraenoic acid, inhibits the EGF receptor protein-tyrosine kinase of the epidermal growth factor receptor. The deacetylated analogue is not inhibitory. **Note:** Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **1.** Song, Welti, Hafner-Strauss & Rintoul (1993) *Biochemistry* **32**, 8602.

### Paritaprevir

This potent macrocyclic HCV NS3 protease inhibitor (FW = 729.87 g/mol; CAS 1216941-48-8), also known as ABT-450, causes a mean maximum viral decline of about 4 logs, when given in monotherapy to Hepatitis C

Virus-infected patients for 3 days at different doses (1). ABT-450 has been combined with ritonavir (designated ABT-450/r) to increase the ABT-450 plasma concentration and half-life, permitting once-daily dosing for interferon-free treatment of chronic HCV infection (2). The macrocycle-based structure gives ABT-450 higher efficacy and better safety than Telaprevir or Boceprevir, first-generation HCV drugs that possess so-called linear structures. Several second-generation HCV NS3 protease inhibitors (e.g., ABT-450 from AbbVie, RG-7227 from Roche, and MK-7009 from Merck) have emerged from clinical trials, and the U.S. Food and Drug Administration approved Viekira Pak<sup>®</sup> (tablets consisting of ombitasvir, paritaprevir and ritonavir that co-packaged with dasabuvir tablets) to treat patients with chronic hepatitis C virus (HCV) genotype 1 infection, including those with a type of advanced liver disease called cirrhosis. 1. Gentile, Borgia, Buonomo, *et al.* (2014) *Curr. Med. Chem.* **21**, 3261. 2. Poordad, Lawitz, Kowdley, *et al.* (2013) *New Engl. J. Med.* **368**, 45.

**Park Nucleotide**, See *UDP-N-acetylmuramyl-L-alanyl-γ-(D-glutamyl)-(meso-2,6-diaminopimeloyl)-D-alanyl-D-alanine*; *UDP-N-acetylmuramyl-L-alanyl-γ-(D-glutamyl)-L-lysyl-D-alanyl-D-alanine*

### Paromomycin

This water-soluble aminoglycoside antibiotic (FW<sub>free-base</sub> = 615.64 g/mol; CAS 7542-37-2) from a number of *Streptomyces* species inhibits protein biosynthesis in a streptomycin-like manner (1,2) by binding to 16S ribosomal RNA at the aminoacyl-tRNA site, resulting in misreading and inhibition of translocation. Note the structural similarity to neomycin B. The numbers adjacent to the amino groups correspond to the pK<sub>a</sub> values. **Target(s)**: aminoglycoside N<sup>6</sup>-acetyltransferase, or kanamycin 6'-acetyltransferase (1-5); DNA-directed DNA polymerase, Klenow polymerase (6); exoribonuclease H (7,8); gentamicin 3'-N-acetyltransferase, K<sub>i</sub> = 8.3 μM (9); poly(A)-specific ribonuclease (6); protein biosynthesis, initiation and translocation (8,10-13); ribonuclease A (7); ribonuclease H (7,8); and ribonuclease P (14-16). 1. ### Paroxetine

This SSRI antidepressant (FW = 260.25 g/mol; CAS 22994-85-0; *Abbreviation*: PXT), known by its trade name Aropax<sup>®</sup>, Paxil<sup>®</sup>, Pexeva<sup>®</sup>, Seroxat<sup>®</sup>, Sereupin<sup>®</sup> and Brisdelle<sup>®</sup> as well as its systematic name (3S,4R)-3-[(2H-1,3-benzodioxol-5-yloxy)methyl]-4-(4-fluorophenyl)piperidine, is a selective serotonin reuptake inhibitor (IC<sub>50</sub> = 33 μM) that is indicated for the treatment of major depression, obsessive-compulsive disorder, panic disorder, posttraumatic stress disorder, generalized anxiety disorder and vasomotor symptoms, such as hot flashes and night sweats, that are associated with menopause (1-4). Significantly, Antidepressant responses to selective serotonin reuptake inhibitors (citalopram or paroxetine) are abolished in mice unable to synthesize histamine due to either targeted disruption of histidine decarboxylase gene (*or* HDC<sup>-/-</sup>) or injection of α-fluoromethylhistidine, a suicide inhibitor of this enzyme (5). Such findings demonstrate that SSRIs selectively require the integrity of the brain histamine system to exert their preclinical responses (5). (See also *Citalopram; α-Fluoromethyl histidine*) **Pharmacokinetic Properties**: Plasma concentration and time-curves fit a two-compartment open model (6), with the oral route giving a longer t<sub>1/2</sub> (30 hours) than by the intravenous route (12 hours). Deviations probably reflect saturated elimination kinetics during first-pass metabolism (6). Co-administration of lipoic acid and PXT may improve anxiolytic and antidepressant responses (7), suggesting that PXT may deplete lipoic acid stores or that PXT interferes with some lipoic acid-requiring metabolic pathway. Somewhat surprisingly, Paroxetine (20-40 μM) induces growth inhibition and apoptosis in prostate cancer cells *in vitro* (8). Paroxetine is metabolized by CYP2D6 *via* demethylenation of the methylenedioxy group, yielding a catechol metabolite and formic acid. Paroxetine is also a potent inhibitor of cytochrome P450 2D6 (CYP2D6). Time-dependent inhibition was demonstrated with an apparent K<sub>i</sub> of 4.8 μM and an apparent k<sub>inact</sub> value of 0.17 min<sup>-1</sup> (9). Paroxetine has critical but differential effects on IL-6 and TNFα production in macrophages and likely regulates their formation by different mechanisms (10). **Key Pharmacokinetic Parameters**: See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Heydorn (1999) *Expert Opin. Investig. Drugs* **8**, 417. 2. Habert, Graham, Tahraoui, Claustre & Langer (1985) *Eur. J. Pharmacol.* **118**, 107. 3. ### Parthenolide

This sesquiterpene lactone (FW = 248.32 g/mol; CAS 70-70-2), also named [1aR-(1aR\*,4E,7aS\*,10aS\*,10bR\*)]-2,3,6,7,7a,8,10a,10b-octahydro-1a,5-dimethyl-8-methylene-oxireno[9,10]cyclodeca[1,2-b]furan-9(1aH)-one, is an active component of the herb feverfew (*Tanacetum parthenium*) and a number of Mexican-Indian medicinal plants. Parthenolide is a potent anti-inflammatory agent that suppresses expression of certain interleukins and inhibits the activation of p42/44 mitogen-activated protein kinase. It also inhibits the release of 5-HT from blood platelets. Also inhibits generation of leukotriene B<sub>4</sub> and thromboxane B<sub>2</sub>. **Target(s)**: IκB kinase (1-3); NF-κB (1,3-5); phenylpyruvate tautomerase, weakly inhibited (6); prostaglandin synthase (7); and eicosanoid generation (appears to be irreversible but not time-dependent) (8). 1. Zingarelli, Hake, Denenberg & Wong (2002) *Shock* **17**, 127. 2. Kwok, Koh, Ndubuisi, Eloffsson & Crews (2001) *Chem. Biol.* **8**, 759. 3. Hehner, Hofmann, Droge & Schmitz (1999) *J. **Parvaquone**

This hydroxynaphthylquinone antiprotozoal agent (FW = 256.30 g/mol; CAS 4042-30-2), first synthesized by Fieser in 1948 (U.S. Patent Number 2553648), is a yellow solid that resembles ubiquinone and acts as an electron transport inhibitor and uncoupler, with some 20 times greater toxicity to *Toxoplasma* than to humans (1,2). 1. Tappel (1960) *Biochem. Pharmacol.* **3**, 289. 2. Howland (1967) *Biochim. Biophys. Acta* **131**, 247.

**PAS**, See 4-Aminosalicylate and 4-Aminosalicylic Acid

**Pathocidin**, See 8-Azaguanine

**Patulin**

This antibiotic (FW = 154.12 g/mol; CAS 149-29-1), known also as clavacin and systematically as 4-hydroxy-4H-furo[3,2-c]pyran-2(6H)-one, from *Aspergillus*, *Gymnoascus*, and *Penicillium* inhibits K<sup>+</sup> uptake. Patulin also causes breaks single-stranded DNA and even double-stranded DNA at higher concentrations. *Note*: This water-soluble mycotoxin is unstable in alkaline solutions, with consequential loss of biological activity.

**Target(s)**: alcohol dehydrogenase (1); aldolase (2); aminoacyl-tRNA synthetases (3); carboxylase (4,5); DNA-directed RNA polymerase (6); K<sup>+</sup> uptake (7); lactate dehydrogenase (1); 6-methylsalicylate synthetase (8); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (9); protein farnesyltransferase (10); protein prenylation (10); ribonuclease H (6); and urease (11). 1. **Paxilline**

This BK<sub>Ca</sub>/K<sub>Ca</sub>1.1 channel blocker (FW = 435.56 g/mol; CAS 57186-25-1; Solubility: 100 mM in DMSO), also named (2*R*,4*b**S*,6*a**S*,12*b**S*,12*c**R*,14*a**S*)-5,6,6*a*,7,12,12*b*,12*c*,13,14,14*a*-decahydro-4*b*-hydroxy-2-(1-hydroxy-1-methylethyl)-12*b*,12*c*-dimethyl-2*H*-pyrano[2',3'': 5',6']benz[1',2':6,7]indeno[1,2-*b*]indol-3(4*b**H*)-one, binds to the  $\alpha$ -subunit of BK<sub>Ca</sub>, exhibiting a K<sub>i</sub> value of 1.9 nM in blocking currents in  $\alpha$ -subunit-expressing oocytes and enhancing binding of to BK<sub>Ca</sub> channels in vascular smooth muscle (1,2). (See *Charybdotoxin*) Paxilline also inhibits sarco/endoplasmic reticulum Ca<sup>2+</sup>-ATPase, IC<sub>50</sub> = 5 - 50  $\mu$ M (3). 1. Knaus, *et al.* (1994) *Biochemistry* **33**, 5819. 2. Sanchez & McManus (1996) *Neuropharmacol.* **35**, 963. 3. Bilmen, *et al.* (2002) *Arch. Biochem. Biophys.* **406**, 55.

**Pazopanib**

This novel multi-kinase inhibitor (FW = 437.52 g/mol; CAS 444731-52-6; Solubility: 17 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known by its trade name Votrient<sup>®</sup>, and its systematic name 5-[4-[(2,3-dimethyl-2*H*-indazol-6-yl)methylamino]-2-pyrimidinyl]amino]-2-methyl-benzosulfonamide, targets VEGFR1 (IC<sub>50</sub> = 10 nM), VEGFR2 (IC<sub>50</sub> = 30 nM), VEGFR3 (IC<sub>50</sub> = 47 nM), PDGFR (IC<sub>50</sub> = 84 nM), FGFR (IC<sub>50</sub> = 74 nM), c-Kit (IC<sub>50</sub> = 140 nM), and c-Fms (IC<sub>50</sub> = 146 nM). *In vitro*, pazopanib inhibits the growth of synovial sarcoma cells, inducing G<sub>1</sub> arrest, with high suppression of the PI3K-AKT pathway (2). Moreover, pazopanib administration suppresses the tumor growth in a xenograft model. Pazopanib also reduces light-induced overexpression and secretion of VEGF and platelet-derived growth factor in human retinal pigment epithelial cells (3). 1. Harris, Bolour, Cheun, *et al.* (2008) *J. Med. Chem.* **51**, 4632. 2. Hosaka, Horiuchi, Yoda, *et al.* (2012) *J. Orthop. Res.* **30**, 1493. 3. Kernt, *et al.* (2012) *Retina* **32**, 1652.

**Pazufloxacin**

This fluoroquinolone-class antibiotic (FW = 318.29 g/mol; CAS 127046-18-8; IUPAC Name: (3*R*)-10-(1-aminocyclopropyl)-9-fluoro-3-methyl-7-oxo-1*H*,7*H*-[1,3]oxazino[5,4,3-*ij*]quinoline-carboxylate) is a broad-spectrum systemic antibacterial agent that targets Type II DNA topoisomerases (gyrases), which are required for bacterial replication and transcription. For the prototypical member of this antibiotic class, See *Ciprofloxacin*

**PBA**, See *N*<sup>6</sup>-Benzyl-*N*<sup>9</sup>-(2-tetrahydropyranyl)adenine

**PBD**, See 5-(4-Biphenyl)-2-phenyl-1,3,4-oxadiazole

**PBDA**, See 4,4'-Phosphonicobis(butane-1,3-dicarboxylate); Phenylbutyl dopamine

**PBG**, See Porphobilinogen

**PBIT**

This JARID1 Histone Demethylase inhibitor (FW = 241.31 g/mol; CAS 2514-30-9; Soluble to 100 mM in DMSO), also named 2-(4-methylphenyl)-1,2-benzisothiazol-3(2*H*)-one, targets the Jumonji AT-Rich Interactive Domain 1, with respective IC<sub>50</sub> values of 3, 4.9 and 6  $\mu$ M for JARID1B, JARID1A or JARID1C. The enzymes responsible for the demethylation of trimethylated lysine 4 in histone H3 (H3K4me3) are the Jumonji AT-rich interactive domain 1 (JARID1) or lysine demethylase-5 (KDM5) family of lysine demethylases. This family consists of JARID1A (also known as KDM5A or RBP2), JARID1B (also known as KDM5B or PLU1), JARID1C (also known as KDM5C or SMCX), and JARID1D (also known as KDM5D or SMCY) in mammals. Like other JmjC domain-containing demethylases, JARID1 enzymes catalyze histone demethylation in a Fe(II) and  $\alpha$ -ketoglutarate ( $\alpha$ -KG)-dependent reaction. Oxidative decarboxylation

of  $\alpha$ -KG results in an unstable hydroxylated methyl-lysine intermediate. Release of the hydroxyl and methyl groups as formaldehyde from this intermediate results in demethylation. JARID1 demethylases have been linked to human diseases such as cancer and X-linked mental retardation. Both JARID1A and JARID1B are potential oncoproteins, and both are overexpressed in a variety of cancers. Increased expression of JARID1A promotes a more stem-like phenotype and enhanced resistance to anticancer agents. PBIT was identified by high-throughput screening (using biotinylated H3K4me3 peptide substrate) of agents that are selective for JARID1 over UTX and JMJD3. PBIT increases levels of methylated H3K4 in JARID1B-transfected HeLa cells and MCF7 cells. (JARID1A and JARID1B knock-out mice are viable, suggesting that inhibition of JARID1A or JARID1B has minimal effects on normal cells *in vivo*.) PBIT also inhibits proliferation of breast cancer cell lines expressing high levels of JARID1B. **1.** Sayegh, Cao, Zou, *et al.* (2013) *J. Biol. Chem.* **288**, 9408.

### 1,3-PBIT

This symmetrical arginine analogue (FW<sub>free-base</sub> = 282.43 g/mol), systematically known as phenylene-1,3-bis(ethane-2-isothiourethane), exhibits a  $K_i$  value of 47 nM for the inducible nitric-oxide synthase, whereas the values for the neuronal and endothelial enzymes are 0.25 and 9  $\mu$ M, respectively (1,2). As a selective iNOS blocker, cells may be incubated with 1,3-PBIT (50-70 nM) in modified Krebs solution. **1.** Garvey, Oplinger, Tanoury, *et al.* (1994) *J. Biol. Chem.* **269**, 26669. **2.** Raman, Li, Martásek, Babu, Griffith, *et al.* (2001) *J. Biol. Chem.* **276**, 26486.

### 1,4-PBIT

This bisisothiourethane nitric oxide synthase inhibitor (FW<sub>free-base</sub> = 282.43 g/mol), also known as 1,4-phenylene-bis(1,2-ethanediy)bisisothiourethane, targets inducible NO synthase ( $K_i$  = 7.4 nM) and endothelial NO synthase ( $K_i$  = 0.36 nM) (1,2). Crystal structures of the heme domain of the three NOS isoforms show a very high degree of similarity in the immediate vicinity of the heme active site illustrating the challenge of isoform-selective inhibitor design. Isothiourethane are potent NOS inhibitors, and the structures of the endothelial NOS heme domain complexed with isothiourethane bearing small *S*-alkyl substituents have been determined (3). **1.** Garvey, Oplinger, Tanoury, *et al.* (1994) *J. Biol. Chem.* **269**, 26669. **2.** Raman, Li, Martásek, Babu, Griffith, *et al.* (2001) *J. Biol. Chem.* **276**, 26486. **3.** Li, Raman, Martásek, *et al.* (2000) *J. Inorg. Biochem.* **81**, 133

### PBN, See *N*-(*t*-Butyl)-*a*-phenylnitron

### PC, See Phosphatidylcholine; Phosphocreatine

### PC 15

This thiol (FW = 152.31 g/mol), also known as 2-amino-4-methylthiobutane-1-thiol and methionine thiol, inhibits aminopeptidase N, or APN/CD13 (IC<sub>50</sub> = 11 nM), a transmembrane protease that is present in endothelial, epithelial, fibroblast, leukocyte cell types (1,2). APN/CD13 expression is dysregulated in inflammatory diseases and in both solid and hematologic tumors. APN/CD13 is also a receptor for coronaviruses. The corresponding sulfoxide also inhibits (IC<sub>50</sub> = 20 nM). **1.** Fournié-Zaluski, Coric, Turcaud, *et al.* (1992) *J. Med. Chem.* **35**, 1259. **2.** Bauvois & Dazonne (2006) *Med. Res. Rev.* **26**, 88.

### PC 57

This tripeptide analogue (FW = 409.53 g/mol) exerts its anti-hypertensive effects by inhibiting neprilysin,  $K_i$  = 1.4 nM, and dipeptidyl-peptidase A, or angiotensin I-converting enzyme, with a  $K_i$  value of 0.2 nM. **1.** Roques, Noble, Crine & Fournié-Zaluski (1995) *Meth. Enzymol.* **248**, 263.

### PC190723

This bacterial cytoskeletal inhibitor (FW = 355.74 g/mol) inhibits the assembly of the tubulin-like protein FtsZ, arresting its polymerization in *Staphylococcus aureus* and blocking cell division, showing strong bacteriocidal action (1,2). The likely interaction site is analogous to the paclitaxel (taxol) binding site on tubulin. In keeping with the microtubule-stabilizing effects of paclitaxel, the crystal structure of the *S. aureus* FtsZ-PC190723 complex suggests that a domain movement is likely to stabilize the FtsZ protofilament rather than the monomer, with the conformational change transmitted from the GTP binding site to the C-terminal domain via FtsZ Helix-7 (2). ### PCI-24781

This broad-spectrum histone deacetylase inhibitor (FW = 394.48 g/mol; CASs = 783355-60-2, 783356-67-2 (HCl)); Solubility: 80 mg/mL DMSO; <1 mg/mL Water; Formulated in 30% HP-cyclodextrin (in water), also known as CRA-024781 and systematically as 3-((dimethylamino)methyl)-*N*-(2-(4-(hydroxycarbonyl)phenoxy)ethyl)benzofuran-2-carboxamide, is a novel broad-spectrum HDAC inhibitor targeting HDAC1, HDAC2, HDAC3, HDAC6, HDAC8 and HDAC10 with  $K_i$  of 7 nM, 19 nM, 8.2 nM, 17 nM, 280 nM, 24 nM, respectively. PCI-24781 treatment causes dose-dependent accumulation of both acetylated histones and acetylated tubulin in HCT116 or DLD-1 cells (1). It also induces expression of p21 and leads to PARP cleavage and accumulation of the  $\gamma$ H2AX. **1.** Buggy, *et al.* (2006) *Mol. **PCS1055**

This novel M<sub>4</sub> subtype-preferring acetylcholine receptor antagonist (FW = 384.53 g/mol) inhibits [<sup>3</sup>H]-N-methylscopolamine binding to the muscarinic M<sub>4</sub> receptor ( $K_i$  = 6.5 nM). Although of lower potency than the pan-muscarinic antagonist atropine, PCS1055 exhibits better subtype selectivity over previously reported M<sub>4</sub>-selective reagents, such as the muscarinic-peptide toxins and PD102807. In GTP- $\gamma$ -[<sup>35</sup>S] binding studies, PCS1055 exhibits 255-, 69-, 342- and >1000-fold greater inhibition of Oxo-M activity at the M<sub>4</sub> versus the M<sub>1</sub>-, M<sub>2</sub>-, M<sub>3</sub>- or M<sub>5</sub>-receptor subtypes, respectively. Schild analysis indicates PCS1055 is a competitive antagonist to muscarinic M<sub>4</sub> receptor ( $K_b$  = 5.7 nM). Identification of receptor subtype-selective ligands is challenging in view of the high sequence identity and structural homology of muscarinic acetylcholine receptors. **1.** Croy, Chan, Castetter, *et al.* (2016) *Eur. J. Pharmacol.* **782**, 70.

**PD 083176**

This peptide (FW<sub>free-base</sub> = 976.10 g/mol), also known as N<sup>α</sup>-Cbz-L-His-L-Tyr(O-Bn)-L-Ser(O-Bn)-L-Trp-D-Ala-NH<sub>2</sub>, is an early inhibitor of protein farnesyltransferase, IC<sub>50</sub> = 76 nM (1,2) and protein geranylgeranyl-transferase type I (3). **1.** Gibbs (2001) *The Enzymes*, 3rd ed., **21**, 81. **2.** Leonard, Shuler, Poulter, *et al.* (1997) *J. **PD 123319**

This potent non-peptide receptor antagonist (FW = 508.61 g/mol; CAS 130663-39-7), also named 1-[[[4-(dimethylamino)-3-methylphenyl]methyl]-5-(2,2-diphenylacetyl)-4,5,6,7-tetrahydro-(6S)-1H-imidazo[4,5-c]pyridine-6-carboxylate, selectively targets AT<sub>2</sub> angiotensin II receptor (IC<sub>50</sub> = 34 nM). This class of 4,5,6,7-tetrahydro-1H-imidazo[4,5-c]pyridine-6-carboxylic acid derivatives displace <sup>125</sup>I-labeled angiotensin II from a specific subset of angiotensin II (Ang II) binding sites (that are different from those mediating vascular contraction or aldosterone release) that are likely to have novel properties (1). PD-123319 and another nonpeptide antagonist (DuP-753) discriminate between two subclasses of All receptors in many different tissues (2). PD 123319 does not influence baseline cerebral blood flow, with minor drop in blood pressure (3). 1. Blankley, Hodges, Klutchnko, et al. (1991) *J. Med. Chem.* **34**, 3248. 2. **PD 150606**, See (Z)-3-(4-Iodophenyl)-2-mercapto-2-propenoate

**PD 151746**

This cell-permeable thiol-reactive agent (FW = 237.25 g/mol; CAS 179461-52-0), also named (Z)-3-(5-fluoroindol-3-yl)-2-mercapto-2-propenoate, inhibits  $\mu$ -calpain ( $K_i$  = 0.21  $\mu$ M) decreases oxLDL-induced cytotoxicity, whereas the general caspase inhibitor BAF (*t*-butoxycarbonyl-Asp-methoxyfluoromethylketone) is without effect. Note that the structurally related inhibitor (Z)-3-(4-iodophenyl)-2-mercapto-2-propenoate does not appear to react at the active site, instead targeting the calcium ion binding site. (See also (Z)-3-(4-iodophenyl)-2-mercapto-2-propenoate) 1. Pörn-Ares, Saido, Andersson & Ares (2003) *Biochem. J.* **374**, 403.

**PD 152247**, See PNQX

**PD153035**

This extraordinarily potent EGFR inhibitor (F.Wt. = 396.67 (as hydrochloride); CAS 183322-45-4 (hydrochloride), 153436-54-5 (free base); Solubility (25°C): <1 mg/mL DMSO, <1 mg/mL Water), also known systematically as *N*-(3-bromophenyl)-6,7-dimethoxyquinazolin-4-amine, rapidly suppresses *in vitro* EGFR autophosphorylation ( $K_i$  = 5.2 pM; IC<sub>50</sub> = 29 pM) and selectively blocks EGF-mediated cellular processes including mitogenesis, early gene expression, and oncogenic transformation (1). PD153035 exposure does not affect the expression of either EGF receptors or HER2/neu (2). PD153035 causes dose-dependent growth inhibition of EGF receptor-overexpressing cell lines at low micromolar concentrations, and the IC<sub>50</sub> values in monolayer cultures at less than 1  $\mu$ M in most cell lines tested (2). 1. Fry, Kraker, McMichael, et al. (1994) *Science* **265**, 1093. 2. Bos, Mendelsohn, Kim, et al. (1997) *Clin. Cancer Res.* **3**, 2099.

**PD 156273**

This photosensitive EPGFR inhibitor (FW = 344.21 g/mol), also named 6-amino-4-[(3-bromophenyl)amino]-7-(methylamino)quinazolin-2-one, targets epidermal growth factor receptor protein-tyrosine kinase, IC<sub>50</sub> = 0.69 nM

(1,2). 1. Baguley, Marshall, Holdaway, Rewcastle & Denny (1998) *Eur. J. Cancer* **34**, 1086. 2. Bridges, Zhou, Cody, et al. (1996) *J. Med. Chem.* **39**, 267.

**PD 157432**, See 2'-Thioadenoside

**PD 158780**

This photosensitive pyridopyrimidine (FW = 330.19 g/mol), known systematically as 4-[(3-bromophenyl)amino]-6-(methylamino)pyrido[3,4-d]pyrimidine, inhibits EPGFR (epidermal growth factor receptor) protein-tyrosine kinase (IC<sub>50</sub> = 8 pM). In addition, PD 158780 inhibits heregulin-stimulated autophosphorylation in SK-BR-3 (IC<sub>50</sub> = 49 nM) and MDA-MB-453 (IC<sub>50</sub> = 52 nM) breast carcinomas. 1. Rewcastle, Murray, Elliott, et al. (1998) *J. Med. Chem.* **41**, 742.

**PD0166285**

This potent G<sub>2</sub> checkpoint abrogator (FW = 512.43 g/mol; CAS 185039-89-8; Solubility = 100 mg/mL DMSO), also named 6-(2,6-dichlorophenyl)-2-[[4-[2-(diethylamino)ethoxy]phenyl]amino]-8-methylpyrido[2,3-d]pyrimidin-7(8H)-one, targets Wee1 kinase (IC<sub>50</sub> = 24 nM), an enzyme that is crucial for maintaining G<sub>2</sub> cell-cycle arrest through its inhibitory phosphorylation of Cdc2 (1). PD-166285 was identified in a screening campaign that was premised on the idea that cells that lack p53 would lack the capacity to engage effective G<sub>1</sub> checkpoint regulation, such that they would depend on the G<sub>2</sub> checkpoint to permit DNA repair prior to mitosis. This logic led to the hypothesis that a G<sub>2</sub> checkpoint abrogator would preferentially kill p53-inactive cancer cells by removing the only checkpoint protecting such cells from premature mitosis in response to DNA damage (1). At an intracellular concentration of 0.5  $\mu$ M, PD0166285 potentially inhibits irradiation-induced Cdc2 phosphorylation at Tyr-15 and Thr-14 in seven of seven cancer cell lines tested, showing that this G<sub>2</sub> checkpoint abrogator can kill cancer cells (1). Notably, PD0166285 is a radiosensitizer, enhancing cell sensitivity to radiation-induced cell death, showing a sensitivity enhancement ratio of 1.23 in a standard clonogenic assay (1). Its radiosensitizing activity is p53-dependent, showing a higher efficacy in p53-inactive cells (1). Treatment of B16 mouse melanoma cells with the inhibitor B16 cells also dramatically abrogates the G<sub>2</sub> checkpoint, with arrest in the early G<sub>1</sub> phase at 0.5  $\mu$ M for 4 hours observed by flow cytometry. Cyclin D mRNA decreased within 4 hours observed by Real-time PCR. Rb was dephosphorylated for 24 hours. However, B16 cells did not undergo cell death after treatment with 0.5  $\mu$ M PD0166285 for 24 hours. Immunofluorescence microscopy also showed that the cells become round and small in the morphogenesis, suggesting that microtubule stabilization is blocked and that Wee1 distribution was restricted after treatment for 4 hours (2). PD0166285 also abrogates the G<sub>2</sub> checkpoint in osteosarcoma (OS) cells, pushing them into mitotic catastrophe and sensitizing them to irradiation-induced cell death (3). Other agents, like caffeine (4) and UCN-01 (5), can also abrogate the G<sub>2</sub> checkpoint, thereby sensitizing p53 inactive cells to apoptosis. **Other Targets:** Myelin transcription factor-1, or Myt1 (IC<sub>50</sub> = 72 nM); checkpoint kinase Chk1 IC<sub>50</sub> = 3.4  $\mu$ M). 1. ## PD 168393

This photosensitive quinazoline (FW = 369.22 g/mol), also known as 4-[(3-bromophenyl)amino]-6-acrylamido-quinazoline, irreversibly inhibits epidermal growth factor receptor (EGFR) protein-tyrosine kinase, IC<sub>50</sub> = 0.7 nM (1,2). **See also PD 174265** 1. Fry, Bridges, Denny, *et al.* (1998) *Proc. Natl. Acad. Sci. U.S.A.* **95**, 12022. 2. Hubbard & Miller (2007) *Curr. Opin. Cell Biol.* **19**, 117.

## PD 173074

This pyrido[2,3-d]pyrimidine (FW<sub>free-base</sub> = 523.68 g/mol; CAS 219580-11-7; Solubility: 100 mM in DMSO, 100 mM in ethanol), also known as *N*-[[4-(diethylamino)butyl]amino]-6-(3,5-dimethoxyphenyl)pyrido[2,3-d]pyrimidin-7-yl]-*N'*-(1,1-dimethylethyl)urea, inhibits the fibroblast growth factor receptor protein-tyrosine kinase and vascular endothelial growth factor receptor protein-tyrosine kinase (1). PD173074 inhibits FGF-2-mediated effects on proliferation, differentiation, as well as MAPK activation in oligodendrocyte-lineage cells (2). It likewise inhibits fibroblast growth factor receptor-3, inducing differentiation and apoptosis in t(4;14) myeloma (3). PD173074 also selectively inhibits fibroblast growth factor receptor-3 (FGFR3) tyrosine kinase. It inhibits proliferation of bladder cancer cell carrying the FGFR3 gene mutation along with up-regulation of p27/Kip1 and G<sub>1</sub>/G<sub>0</sub> arrest (4). PD173074 blocks small cell lung cancer growth *in vitro* and *in vivo* (5). 1. Mohammadi, Froum, Hamby, *et al.* (1998) *EMBO J.* **17**, 5896. 2. Bansal, *et al.* (2003) *J. Neurosci. Res.* **74**, 486. 3. Trudel, *et al.* (2004) *Neoplasia* **103**, 3521. 4. Miyake, *et al.* (2010) *J. Pharmacol. Exp. Ther.* **332**, 795. 5. Pardo, *et al.* (2010) *Cancer Res.* **69**, 8645.

## PD173955

This tyrosine kinase inhibitor (FW = 443.35 g/mol; CAS 260415-63-2; Solubility: <1 mg/mL DMSO, Ethanol, H<sub>2</sub>O), 6-(2,6-dichlorophenyl)-8-methyl-2-((3-(methylthio)phenyl)amino)pyrido[2,3-d]pyrimidin-7(8H)-one targets Bcr-Abl (IC<sub>50</sub> = 1-2 nM, *in vitro*), the constitutively active tyrosine kinase that results from inadvertent fusion of bcr and abl genes and that causes oncogenic transformation in chronic myelogenous leukemia, *or* CML, inhibiting Bcr-Abl-dependent cell growth with an IC<sub>50</sub> of 2-35 nM in different cell lines (1,2). PD173955 also inhibits kit ligand-dependent c-kit autophosphorylation (IC<sub>50</sub> = ~25 nM) and kit ligand-dependent proliferation of M07e cells (IC<sub>50</sub> = 40 nM), but had a lesser effect on interleukin 3-dependent (IC<sub>50</sub> = 250 nM) or granulocyte macrophage colony-stimulating factor (IC<sub>50</sub> = 1 μM)-dependent cell growth. PD173955 also increases the susceptibility of HT29 cells to detachment-induced apoptosis (anoikis) in a dose- and time-dependent manner (3). **Structural Features Distinguishing Imatinib & PD173955 Binding:** Crystal structures of Abl kinase domain complexes with imatinib (Gleevec) and PD173955 show that both bind to the canonical ATP-binding site, but in distinctive ways. Imatinib captures a specific inactive conformation of Abl's activation loop, mimicking the bound peptide substrate. In contrast, PD173955 binds to the Abl activation loop in a way that resembles the active kinase conformation. The 10x greater potency of PD173955 over imatinib is attributed to its ability to target multiple active and inactive forms of Abl, whereas imatinib binds only to a specific catalytically inactive conformation (4). 1. Moasser, Srethapakdi, Sachar, Kraker & Rosen (1999) *Cancer Res.* **59**, 6145. 2. Wisniewski, Lambek, Liu, *et al.* (1999) *Cancer Res.* **59**, 4244. 3. Windham, Parikh, Siwak, *et al.* (2002) *Oncogene* **21**, 7797. 4. Nagar, Bornmann, Pellicena, *et al.* (2002) *Cancer Res.* **62**, 4236.

## PD 174265

This substituted quinazoline (FW<sub>free-base</sub> = 371.24 g/mol), also known as 4-[(3-bromophenyl)amino]-6-propionylamidoquinazoline, inhibits epidermal growth factor receptor (EGFR) protein-tyrosine kinase, IC<sub>50</sub> = 0.45 nM (1). PD 174265 selectively targets and irreversibly inactivates the epidermal growth factor receptor tyrosine kinase through specific, covalent modification of a Cys-773. **See also PD 168393** 1. Fry, Bridges, Denny, *et al.* (1998) *Proc. Natl. Acad. Sci. U.S.A.* **95**, 12022.

## PD 180557

This diphenylsulfonamide (FW<sub>free-base</sub> = 551.46 g/mol) inhibits various matrix metalloproteinases, *or* MMPs (1,2), including collagenase 3, *or* MMP 13 (IC<sub>50</sub> = 12 nM), gelatinase A, *or* MMP 2 (IC<sub>50</sub> = 2 nM), gelatinase B, *or* MMP 9 (IC<sub>50</sub> = 2.3 μM), interstitial collagenase, *or* MMP 1 (IC<sub>50</sub> = 27 μM), matrilysin, *or* MMP 7 (IC<sub>50</sub> = 15 μM), and stromelysin 1, *or* MMP 3 (IC<sub>50</sub> = 7 nM). Systematic use of isothermal calorimetry provided estimates of the solvation, translational, and conformational components of the entropy term, and this analysis suggests: (a) that a polar group at the P<sub>1</sub> position contributes the observed, large and favorable enthalpy, (b) that a hydrophobic group at P<sub>2</sub> contributes favorably to the entropy of desolvation, and (3) that P<sub>1</sub> substituents may trigger an entropically unfavorable conformational change in the enzyme upon inhibitor binding. 1. O'Brien, Ortwine, Pavlovsky, *et al.* (2000) *J. Med. Chem.* **43**, 156. 2. Parker, Lunney, Ortwine, *et al.* (1999) *Biochemistry* **38**, 13592.

## PD 180970

This pyridopyrimidine (FW<sub>free-base</sub> = 429.28 g/mol) inhibits Bcr-Abl protein-tyrosine kinase and induces apoptosis of K562 leukemic cells (1-3). *In vitro*, PD180970 potently inhibited p210Bcr-Abl autophosphorylation (IC<sub>50</sub> = 5 nM) as well as the kinase activity of purified Abl tyrosine kinase (IC<sub>50</sub> = 2.2 nM). Incubation of K562 cells with PD180970 resulted in cell death, with results of nuclear staining, apoptotic-specific poly(ADP-ribose) polymerase cleavage, and annexin V binding assays confirming as much. Significantly, PD180970 is without effect on the growth and viability of p210Bcr-Abl-negative HL60 human leukemic cells. Such findings demonstrate that PD180970 is among the most potent known inhibitors of the p210Bcr-Abl tyrosine kinase and that it is a promising candidate as a novel therapeutic agent for Bcr-Abl-positive leukemia. **1.** Tauchi & Ohyashiki (2006) *Int. J. Hematol.* **83**, 294. **2.** Dorsey, Jove, Kraker & Wu (2000) *Cancer Res.* **60**, 3127. **3.** Wisniewski, Lambek, Liu, *et al.* (2002) *Cancer Res.* **62**, 4244.

Med.* **5**, 810. **6.** Spicer, Rewcastle, Kaufman, *et al.* (2007) *J. Med. Chem.* **50**, 5090.

**PD 0313052**

This substituted benzimidazole (FW<sub>free-base</sub> = 448.59 g/mol) is a slow, tight-binding inhibitor of coagulation factor Xa. Analysis of the association and dissociation kinetics of PD0313052 with human factor Xa demonstrated a reversible, slow-onset mechanism of inhibition, with a simple, single-step bimolecular association between factor Xa and inhibitor. This interaction was governed by association  $k_{on}$  and dissociation  $k_{off}$  rate constants of  $10^7$  M<sup>-1</sup>s<sup>-1</sup> and  $1.9 \times 10^{-3}$  s<sup>-1</sup>. The inhibition of human factor Xa by PD0313052 displayed tight-binding behavior, as indicated by a  $K_i^*$  value of 0.3 nM. **1.** Gould, Cladera, Harris, *et al.* (2005) *Biochemistry* **44**, 9280.

**PD 404182**

This KDO-8-P synthase inhibitor and potential antibiotic (FW = 217.29 g/mol), also named 6*H*-6-imino(2,3,4,5-tetrahydropyrimido)[1,2-*c*][1,3]benzothiazine, is a slow, tight-binding agent that targets 3-deoxy-*D*-mannooctulosonate-8-phosphate synthase, an enzyme participating in the synthesis of 3-deoxy-*D*-manno-2-octulosonic acid (KDO). The latter is an essential component of LPS (lipopolysaccharide) in the outer membrane of Gram-negative bacteria. PD 404182 is an antiretroviral agent with submicromolar

inhibitory activity against human immunodeficiency virus-1 (HIV-1) and HIV-2 infection (2). PD-404182 also potently inhibits dimethylarginine dimethylaminohydrolase isoform-1 (DDAH1), the human enzyme that degrades Asymmetric Dimethylarginine, or ADMA (See *Asymmetric Dimethylarginine*) (3). Because ADMA inhibits nitric oxide synthesis and because ADMA levels are predictive for future cardiovascular disease, chronic use of PD-404182 is apt to have side-effects. **1.** Birck, Holler & Woodard (2000) *J. Am. Chem. Soc.* **122**, 9334. **2.** Mizuhara, Oishi, Ohno, *et al.* (2012) *Bioorg. Med. Chem.* **20**, 6434. **3.** Ghebremariam, Erlanson & Cooke (2013) *J. Pharmacol. Exp. Ther.* **348**, 69.

**PE859**

This orally bioavailable tau aggregation inhibitor (FW = 448.53 g/mol; IUPAC: 3-[(1*E*)-2-(1*H*-indol-6-yl)ethenyl]-5-[(1*E*)-2-[2-methoxy-4-(2-pyridylmethoxy)phenyl]ethenyl]-1*H*-pyrazole) significantly reduces formation of sarkosyl-insoluble aggregates of Tau, the principal axonal microtubule-associated protein, and prevents onset and progression of the motor dysfunction in JNPL3 Pro-301-Leu-mutated human tau transgenic mice. PE859 also inhibits aggregation of three-repeat Tau, or 3RMBD-Tau (IC<sub>50</sub> = 0.81 μM), and four-repeat Tau, or 2N4R-Tau (IC<sub>50</sub> = 2.23 μM). **1.** Okuda, Hijikuro, Fujita, *et al.* (2015) *PLoS One* **10**, e0117511.

**PEAQX**

This potent NMDA receptor antagonist and experimental anticonvulsant (FW = 542.14 g/mol), also known as NVP-AAM077 and tetrasodium [[(1*S*)-1-(4-bromophenyl)ethyl]amino](1,2,3,4-tetrahydro-2,3-dioxo-5-quinoxaliny)methyl] phosphonate, is a competitive antagonist for ionotropic glutamate [*N*-methyl-*D*-aspartate] receptors (or GluN receptors). Although originally described as being 100x more active against GluN1/GluN2A receptors versus GluN1/GluN2B receptors (1), later studies revealed only a 5x difference in affinity (2). There is no difference in the steady-state levels of inhibition produced by NVP-AAM077 when it was either preapplied or coapplied with glutamate. **1.** Auberson, Allgeier, Bischoff, *et al.* (2002) *Bioorg. Med. Chem. Letts.* **12**, 1099. **2.** Frizelle, Chen, Wyllie, *et al.* (2006) *Molec. Pharmacol.* **70**, 1022.

**PEC-60**

This 60-residue intestine and brain polypeptide (MW = 6835 g/mol) inhibits glucose-induced insulin secretion from perfused pancreas, activates Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase and reduces cAMP production. **Target(s):** adenylate cyclase (1); and insulin secretion, glucose-induced (2-4). **1.** Laasik & Sillard (1993) *Biochem. Biophys. Res. Commun.* **197**, 849. **2.** Norberg, Gruber, Angelucci, *et al.* (2003) *Cell Mol. Life Sci.* **60**, 378. **3.** Ahren,

### Pectin Methyltransferase Inhibitors (PMEI's)

These proteins assist in regulating the methylation of pectin, a plant cell wall component that is secreted in highly methyl-esterified form and is subsequently dimethylated *in vivo* by pectin methyltransferase (PME). Pectin is a structurally complex polysaccharide that, by weight, comprises slightly more than one-third of the primary cell wall of dicots and nongraminaceous monocots. Demethylated pectin is susceptible to hydrolysis and fragmentation by host- and pathogen-derived endopolygalacturonases (1,2). In *Arabidopsis thaliana*, the only two PMEIs are the 151-residue AtPMEI-1 (MW = 16,266 Da; pI = 7.7) and the 148-residue AtPMEI-2 (MW = 15,615 Da; pI = 9.0), consisting of an  $\alpha$ -helix up-and-down four-helical bundle fold and five strictly conserved Cys residues, with four forming two structure-maintaining disulfide bridges. These proteins inhibit PMEs of plant origin by forming a noncovalent stoichiometric 1:1 complex with the latter. That they do not typically inhibit PMEs produced by plant pathogenic microorganisms suggests roles in modulating endogenous PME activity during development and growth. Overexpression of a pectin methyltransferase inhibitor in *Arabidopsis* also alters growth morphology of the stem and defective organ separation. 1. ### Peficitinib

This orally bioavailable JAK inhibitor and anti-rheumatoid arthritis drug (FW = 326.39 g/mol; CAS 944118-01-8; Solubility: 200 mM in DMSO), also named ASP015K, JNJ-54781532, and *trans*-4-[[5-hydroxy-2-adamantyl]amino]-1*H*-pyrrolo[2,3-*b*]pyridine-5-carboxamide, targets Janus Kinase JAK1, JAK2, JAK3 and the nonreceptor tyrosine kinase Tyk2 enzyme with IC<sub>50</sub> values of 3.9, 5.0, 0.71 and 4.8 nM, respectively (1). Its

milder inhibition of JAK2, compared tofacitinib and baricitinib, which selectively suppress JAK3 or JAK1/2, respectively, may explain the weaker effects on red blood cells and platelets reported to be caused by JAK2 inhibition (2). Moreover, peficitinib improves symptoms in RA animal models after once-daily oral administration (3) and demonstrates dose-dependent improvement in psoriatic disease activities in a 6-week phase IIa study (4). The terminal mean half-life of peficitinib is 7–13 hours in pharmacological studies with healthy subjects (5). 1. Takeuchi, Tanaka, Iwasaki, *et al.* (2015) *Ann. Rheum. Dis.* E-document 208279. 2. ### Pelargonate (Pelargonic Acid)

This medium-chain fatty acid (FW = 158.24 g/mol; CAS 112-05-0; pK<sub>a</sub> ≈ 4.8 at 25°C) also called nonanoic acid, is an oily liquid (M.P. = 12.5°C; B.P. = 252-253°C). Pelargonic acid has a low solubility in water (0.026 g/100 mL at 20°C), but is soluble in ethanol, diethyl ether, benzene, and chloroform. **Target(s):** alcohol dehydrogenase (1); *p*-aminohippurate transport (2); kynurenine aminotransferase, weakly inhibited (3); and phenylacetyl-CoA synthetase, or phenylacetate:CoA ligase (4). 1. Winer & Theorell (1960) *Acta Chem. Scand.* 14, 1729. 2. Ullrich, Rumrich & Kloss (1987) *Pflugers Arch.* 409, 547. 3. Mason (1959) *J. Biol. Chem.* 234, 2770. 4. ### Pelargonidin

This flavylum cation (FW<sub>chloride</sub> = 306.79 g/mol; CAS 134-04-3), also spelled pelargonidine chloride and named systematically as 3,5,7,4'-tetrahydroxyflavylium cation, is the aglycon of many plant anthocyanins (e.g., pelargonin, callistephin, and fragarin). The chloride salt is a reddish-

brown solid that has a  $\lambda_{\text{max}}$  of 530 nm ( $\epsilon = 32000 \text{ M}^{-1}\text{cm}^{-1}$ ) in ethanol and 0.01% HCl. **Target(s):** aflatoxin B<sub>1</sub> biosynthesis (1); K<sup>+</sup> channel, ATP-dependent (2,3); DNA topoisomerase II decatenation activity (4); glycogen phosphorylase (5); inositol-trisphosphate 3-kinase (6); leucoanthocyanidin reductase (7); and nitric oxide production (8). 1. ### Peloruside A

This novel marine metabolite and microtubule-stabilizing agent (FW = 548.67 g/mol; IUPAC: (1S,3S,4R,7R,9R,11R,13S,14S,15S)-4,11,13,14-tetrahydroxy-7-[(2Z,4S)-4-(hydroxymethyl)hex-2-en-2-yl]-3,9,15-trimethoxy-12,12-dimethyl-6,17-dioxabicyclo[11.3.1]heptadecan-5-one) from the New Zealand sponge *Mycale hentscheli* has potent paclitaxel-like activity and is cytotoxic at low-nM concentrations. Its 16-membered macrolide ring resembles that found in the anticancer agent epothilone (1,2). Peloruside A arrests cells in the G<sub>2</sub>-M phase of the cell cycle and induces apoptosis (2). The peloruside A site on the  $\alpha$ , $\beta$ -tubulin heterodimer is topologically distinct from the taxoid site (which is used by paclitaxel, docetaxel, epothilone A, and discodermolide) and synergizes with these agents, enhancing their antimetabolic action (3). Based on an earlier model for peloruside A binding to  $\beta$ -tubulin (4), a later and more persuasive model (5) shows more extensive desolvation and a greater array of favorable hydrophobic and electrostatic interactions for peloruside A binding. The latter model is also suitable for laulimalide binding. Peloruside A-resistant lines contain single-base mutations in  $\beta$ -tubulin that result in the following substitutions: Arg-306-His, Tyr-340-Ser, Asn-337-Asp, and Ala-296-Ser in various combinations (6). These mutations are localized to peptides previously identified by Hydrogen-Deuterium exchange mapping, and center on a cleft in which the drug side chain appears to dock (6). Significantly,  $\beta_{II}$ -tubulin and  $\beta_{III}$ -tubulin mediate sensitivity to peloruside A and laulimalide, but not paclitaxel or vinblastine, in human ovarian

carcinoma cells (7). Analysis of microtubule (MT) growth times supports the view that catastrophic MT disassembly depends on the age of MTs (8). Colchicine and vinblastine accelerate aging in a manner that depends on the presence of end-binding proteins. On the other hand, while Paclitaxel and Peloruside A induce catastrophes, they compensate by promoting MT rescues and reversing the MT aging. 1. West, Northcote, Battershill, et al. (2000) *J. Org. Chem.* **65**, 445. 2. Hood, West, Rouwé, et al. (2002) *Cancer Res.* **62**, 3356. 3. Wilmes, Bargh, Kelly, Northcote & Miller (2007) *Mol. Pharm.* **4**, 269. 4. Huzil et al. (2008) *J. Mol. ### Pembrolizumab

This humanized receptor-directed monoclonal antibody and anticancer agent (MW = 146.3 kDa; CAS 1374853-91-4), also known by its code name MK-3475, its former name lambrolizumab, and its trade name Keytruda<sup>®</sup>, targets the Programmed Death-1 (PD-1 or Pdc1) receptor, a well-known negative regulator of T-cell effector mechanisms that limits immune responses against cancer. Having received "Breakthrough Therapy" designation in April, 2013 to expedite its development as a melanoma therapy, pembrolizumab won final FDA approval in September, 2014. **Mechanism of Inhibitor Action:** An immunoreceptor belonging to the CD28/CTLA-4 family, PD-1 negatively regulates antigen receptor signaling by recruiting the protein tyrosine phosphatase SHP-2, after interacting with either of two ligands, PD-L1 or PD-L2. With its wide range of ligand distribution in the body, PD-1 is significant in nearly every aspect of immune responses (e.g. autoimmunity, tumor immunity, infectious immunity, transplantation immunity, allergy and immunological privilege). Pembrolizumab blocks the interaction between PD-1 and its ligands, PD-L1 and PD-L2. PD-1 and related target PD-ligand 1 (PD-L1) are normally expressed on the surface of activated T cells, and formation of the PD-L1·PD-1 complex inhibits immune activation and reduces T-cell cytotoxic activity when bound. This negative feedback loop maintains normal immune responses by limiting T-cell activity and thereby protecting normal cells during chronic inflammation. Tumor cells can circumvent T-cell-mediated cytotoxicity by expressing PD-L1 on their outer surface or on tumor-infiltrating immune cells to inhibit immune-mediated tumor cell killing. Use of pembrolizumab is indicated in the treatment of patients with unresectable or metastatic melanoma and disease progression following ipilimumab, especially if positive for the BRAF<sup>V600</sup> mutation. MK3475 is also highly selective, humanized monoclonal IgG4- $\kappa$  isotype antibody against PD-1 that is designed to block the negative immune regulatory signaling of the PD-1 receptor on T cells. **Inhibitor Design:** To prepare pembrolizumab, the variable region sequences of a very high affinity ( $K_d = 28 \text{ pM}$ ) mouse anti-human PD-1 antibody were grafted into a human IgG4 immunoglobulin with a stabilizing Ser-228-Pro alteration in Fc receptors. The IgG4 subtype does not engage Fc receptors and does not activate complement, thereby avoiding cytotoxic effects of the antibody when it binds to the T cells that it is intended to activate. **Pharmacokinetics:** The recommended dose (2 mg/kg) is administered as an intravenous infusion over 30 minutes every 3 weeks, or until disease progression resumes or toxicity becomes unacceptable. Its steady-state concentration is reached by 18 weeks. (Half-life: 26 days; Clearance: 0.22 L/day) 1. Hamid, Robert, Daud, et al. (2013) *New Engl. J. Med.* **369**, 134. 2. ### Pemetrexed

This antifolate prodrug (FW<sub>free-base</sub> = 425.40 g/mol; CAS 357166-30-4), known by the code name LY 231514, the trade name Alimta<sup>™</sup> and systematically as *N*-[4-[2-(2-amino-3,4-dihydro-4-oxo-7H-pyrrolo[2,3-d]pyrimidin-5-yl)ethyl]benzoyl]-L-glutamic acid, undergoes enzyme-catalyzed polyglutamylation after cellular uptake, whereupon it inhibits dihydrofolate reductase (1-4), 10-formyltetrahydrofolate synthase (2); 5,10-

methylene-tetrahydrofolate dehydrogenase (2); phosphoribosyl-aminoimidazolecarboxamide formyltransferase (1,2); phosphoribosylglycinamide formyltransferase (1,2,5); and thymidylate synthase (1-4,6,7). By inhibiting the formation of purine and pyrimidine nucleotides, pemetrexed blocks DNA and RNA synthesis needed for the growth and survival of proliferating cells. Pemetrexed is recommended for the treatment of malignant pleural mesothelioma. When used in combination with carboplatin or cisplatin, it is also effective in the treatment of non-small cell lung cancer. (See *Methotrexate*) 1. ### Penbutolol

This non-selective antihypertensive  $\beta$ -blocker (FW = 291.43 g/mol; CAS 36507-48-9; IUPAC: (*S*)-1-(*tert*-butylamino)-3-(2-cyclopentylphenoxy)propan-2-ol), known variously as Levatol<sup>®</sup>, Levatolol<sup>®</sup>, Lobeta<sup>®</sup>, Paginol<sup>®</sup>, Hostabloc<sup>®</sup>, and Betapressin, binds to both  $\beta_1$ - and  $\beta_2$ -adrenergic receptors, thus exhibiting the sympathomimetic effects of a partial  $\beta$ -adrenergic agonist, while also acting as a serotonin (5-HT<sub>1A</sub>) receptor antagonist (1,2). By blocking  $\beta$ -adrenergic receptors and the sympathetic nervous system, penbutolol decreases heart rate and cardiac output, thereby lowering arterial blood pressure. 1. Katzung, Bertram G. (1998). *Basic & Clinical Pharmacology* (7<sup>th</sup> ed.). London: Appleton & Lange. 2. Frishman & Covey (1990). *J. Clin. Pharmacol.* **30**, 412.

### Penciclovir

This ganciclovir analogue (FW = 253.26 g/mol; CAS 39809-25-1), also known as 9-[4-hydroxy-3-(hydroxymethyl)but-1-yl]guanine, is (upon phosphorylation to its triphosphate form) a potent inhibitor of viral DNA polymerases and is also an analogue of. The (*S*)-enantiomer of penciclovir triphosphate is preferentially formed in herpes virus-infected cells and is a more active agent against the herpes simplex virus. However, the (*R*)-enantiomer of penciclovir triphosphate is the more potent inhibitor of hepatitis B virus DNA polymerase-reverse transcriptase. Penciclovir is soluble in water (1.7 mg/mL at 20°C; the sodium salt has a solubility of > 200 mg/mL) and has  $\lambda_{\text{max}}$  values (in 0.01 N NaOH) of 215 and 268 nm ( $\epsilon = 18140$  and  $10710 \text{ M}^{-1}\text{cm}^{-1}$ , respectively). The prodrug is called famciclovir. (See also prodrug *Famciclovir*) **Target(s)**: DNA polymerases  $\alpha$ ,  $\delta$ , and  $\epsilon$  (1); DNA polymerases, viral (2); DNA primase (1); Epstein-Barr virus replication (2,3); hepatitis B virus DNA polymerase (4-10); herpes simplex virus replication (2,11-13); and varicella zoster virus replication (2). 1. ### Penciclovir Triphosphate, See *Penciclovir*

### D-Penicillamine

This water-soluble amino acid (FW = 149.21 g/mol; CAS 52-67-5), also known as D-2-amino-3-mercapto-3-methylbutyrate, 3-mercapto-D-valine, and 3,3-dimethyl-D-cysteine, is a penicillin degradation. Penicillamine is a strong chelator of metal ions as well as a radical and H<sub>2</sub>O<sub>2</sub> scavenger. The reported pK<sub>a</sub> values for DL-penicillamine are 1.8, 7.9, and 10.5. **Target(s)**: alanine racemase, *Acidiphilium organovorum* (1); alkaline phosphatase (2-4); D-amino-acid aminotransferase (36); amino-acid racemase (23); 4-aminobutyrate transaminase (37,38); 8-amino-7-oxononanoate synthase (5,39); aminopeptidase B (6); arginine racemase, inhibited by DL-penicillamine (24); aspartate racemase (7); carboxy-peptidase A (8); 3-chloro-D-alanine dehydrochlorinase (25); collagenases (9); complement component C4 (10); cystathionine  $\gamma$ -lyase (11,27-29); D-cysteine desulfhydrase (26); cysteinylglycine dipeptidase (12,13); diaminopimelate decarboxylase (14); diaminopropionate ammonia-lyase (30); gelatinase B (15); glucose-6-phosphate dehydrogenase (16); glutamate decarboxylase, weakly inhibited (17,32); glutamate-1-semialdehyde 2,1-aminomutase, *or* glutamate-1-semialdehyde aminotransferase (18); glutathione peroxidase (19); glyceraldehyde-3-phosphate dehydrogenase (3); kynureninase (33,34);  $\beta$ -lactamase, *or* penicillinase (20); leukotriene D<sub>4</sub> dipeptidase (13); matrilysin (8); nitrile hydratase (21); phosphatidylserine decarboxylase (31); pyridoxal kinase (35); L-serine dehydratase (17); serine hydroxymethyltransferase, *or* glycine hydroxymethyltransferase (22); thermolysin (8); tyrosinase, *or* monophenol monooxygenase (40); and tyrosine aminotransferase (17). 1. ## L-Penicillamine

This water-soluble amino acid (FW = 149.21 g/mol; ), also known as L-2-amino-3-mercapto-3-methylbutyrate, 3-mercapto-L-valine, and 3,3-dimethyl-L-cysteine, is a strong chelator of metal ions as well as a radical and H<sub>2</sub>O<sub>2</sub> scavenger. L-Penicillamine also inhibits several pyridoxal-phosphate-dependent enzymes. The reported pK<sub>a</sub> values for DL-penicillamine are 1.8, 7.9, and 10.5. *Note:* Both D- and L-forms are readily oxidized to the corresponding disulfides. **Target(s):** O-acetylhomoserine aminocarboxy-propyltransferase (48,49); adenosyl-methionine: 8-amino-7-oxononanoate transaminase, or diaminopelargonate aminotransferase, inhibited by DL-penicillamine (42); alanine aminotransferase (2); alanine:glyoxylate aminotransferase (44); alanine racemase, mildly inhibited (3); alkaline phosphatase (4); D-amino-acid aminotransferase (46); 5-aminolevulinatase aminotransferase (5,6,45); 5-aminolevulinatase synthase (7); 8-amino-7-oxononanoate synthase (8); aminopeptidase B (9); arginine racemase, inhibited by DL-penicillamine (24); aspartate racemase (10); carboxypeptidase A (41); 3-chloro-D-alanine dehydrochlorinase (25); cystathionine β-lyase, inhibited by DL-penicillamine (29); cystathionine γ-lyase (11,31-33); D-cysteine desulfhydrase (26); cysteinylglycine dipeptidase (12); diaminopimelate decarboxylase (13); diaminopropionate ammonia-lyase (34); D-glucosaminatase dehydratase (14); glutamate decarboxylase, inhibited by DL-mixture (38); homocysteine desulfhydrase, inhibited by DL-penicillamine (30); homoserine O-acetyltransferase, inhibited by DL-penicillamine (51); isocitrate lyase, inhibited by DL-penicillamine (36); kynureninase (40); kynurenine:oxoglutarate aminotransferase (47); β-lactamase, or penicillinase (15,16); leukotriene D<sub>4</sub> dipeptidase (17); matrilysin (41); methionine S-adenosyltransferase, weakly inhibited (50); methionine γ-lyase, inhibited by DL- and L-penicillamine (18,19,27,28); nitrile hydratase (20,35); ornithine:α-keto-acid aminotransferase (21); phosphatidylserine decarboxylase (37); serine:glyoxylate aminotransferase, weakly inhibited (43); serine Hydroxymethyltransferase, or glycine hydroxymethyltransferase (22); superoxide dismutase (52); thermolysin (41); valine decarboxylase, stereochemistry not reported (39); and valyl-tRNA synthetase (23). 1. **Penicillanate**

This penicillin building block (FW<sub>free-acid</sub> = 201.25 g/mol), also known as penicillanic acid and (2*S*,5*R*)-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo [3.2.0]heptane-2-carboxylic acid, weakly inhibits serine-type D-Ala-D-Ala carboxypeptidase but is devoid of significant antibacterial activity. 1. Frère, Kelly, Klein & Ghuyssen (1982) *Biochem. J.* **203**, 223.

**Penicillanic Acid Sulfone, See Sulbactam**

**Penicillate (Penicillic Acid) & Lactone**

This water-soluble toxic metabolite (FW = 170.17 g/mol), also known 3-methoxy-5-methyl-4-oxo-2,5-hexadienoic acid and produced by a number of fungi (e.g., certain species of *Penicillium* and *Aspergillus*) exists as an equilibrium mixture of uncyclized and lactone forms. Note that this mycotoxin is not related to the penicillins nor to penicillanic acid. **Target(s):** alcohol dehydrogenase (1); Ca<sup>2+</sup> channels (2); carboxypeptidase A (3); caspase-8 self-processing (4); fructose-1,6-bisphosphate aldolase (5); glutathione S-transferase (6); K<sup>+</sup> channels (2); lactate dehydrogenase (1); and Na<sup>+</sup> channels (2). 1. **Penicillins**

penicillin core structure

These structurally related bacterial cell wall biosynthesis inhibitors, which possess a distinctive β-lactam/ thiazolidine nucleus (or drug warhead), are used to treat a wide range of infections caused by susceptible bacteria, including *Streptococci*, *Staphylococci*, *Clostridium*, and *Listeria* genera. Others include *Listeria monocytogenes* (MIC = 0.06–0.25 μg/mL), *Neisseria meningitidis* (MIC = 0.03–0.5 μg/mL), and *Staphylococcus aureus* (MIC = 0.015–0.3 μg/mL). Although superseded by the action of later-generation derivatives, penicillin G (see entry below) is still highly effective in controlling *Treponema pallidum*, the causative agent for syphilis. Naturally occurring penicillins are produced by species of *Penicillium*, *Aspergillus*, *Cephalosporium*, *Trichophyton*, *Epidermophyton*;

others are produced by semisynthesis. **Core Structure:** The term *penam* refers to the common core skeleton of the penicillins, consisting of a  $\beta$ -lactam ring fused to a five-membered thiazolidine ring. The  $\beta$ -lactam ring is highly strained, with its four atoms joined at nearly  $90^\circ$  angles. Adding to the ring's instability is the geometrically imposed lack of amide-bond resonance.

**Classification:** The R-group in the structure above is the variable component. *Naturally Occurring* – Penicillin G and Penicillin V;  *$\beta$ -Lactamase-Resistant* – Methicillin, Nafcillin, Oxacillin, Cloxacillin, and Dicloxacillin; *Aminopenicillins* – Ampicillin, Amoxicillin, Bacampicillin, Hetacillin, Metampicillin, Pivampicillin, Talampicillin, and Epicillin; *Carboxypenicillins* – Carbenicillin, Ticarcillin; *Ureidopenicillins* – Mezlocillin and Piperacillin.

**Mode of Inhibitor Action:** That penicillin is a highly specific inhibitor of bacterial cell wall biosynthesis was first indicated by the formation of penicillin-induced *Escherichia coli* spheroplasts, the latter membrane-bounded cells lacking an intact peptidoglycan cell walls. In penicillin-treated bacteria, the enzymes that hydrolyze the peptidoglycan cross-links continue to function, while those that form such cross-links cannot. This weakens the cell wall of the bacterium, and uncompensated osmotic pressure eventually causes cytolysis and death. Penicillin also leads to the accumulation of a uridine nucleotide in penicillin-treated *Staphylococcus aureus*, which, in view of its structural similarity to the cell wall, appeared to be a biosynthetic precursor of the cell wall. This idea was amply documented by direct isotopic measurements of cell wall synthesis carried out in the presence of several penicillins and in both Gram-negative and Gram-positive bacteria. A linear cell wall glycopeptide is synthesized from UDP-acetylmuramyl-L-Ala-D-Glu-L-Lys-D-Ala-D-Ala (or UDP-MurNAc-pentapeptide) and is cross-linked by peptide bridges. From studies of the structure of the cell wall glycopeptide in normal cells and in penicillin-induced L-forms of *Proteus mirabilis*, it was evident that penicillin blocks formation of essential peptide crosslinks (See *Amoxicillin*). Penicillin thus kills susceptible bacteria by specifically inhibiting the transpeptidase that catalyzes the cross-linking of peptidoglycan, the final step in cell wall biosynthesis. As originally hypothesized (1), penicillin is a structural analogue of the acyl-D-alanyl-D-alanine terminus of the pentapeptide side chains of nascent cell wall peptidoglycan, such that, by virtue of its highly reactive  $\beta$ -lactam ring, penicillin irreversibly acylates the active site of the transpeptidase. Indeed, when the cell wall transpeptidase was first purified from membranes of *Bacillus stearothermophilus* using a penicillin affinity chromatography, this enzyme was shown to be covalently labeled with either [ $^{14}\text{C}$ ]penicillin G or the substrate, [ $^{14}\text{C}$ ]diacetyl-L-lysyl-D-alanyl-D-lactate, with both bound as esters to Serine-36 (2). The remarkable effectiveness of penicillins in inactivating the cell wall transpeptidase has been attributed to their ability to mimic a catalytic transition-state in the naturally occurring transpeptidase reaction, a property allowing them to bind tightly and afford a more efficient path to acylation. A more likely explanation is that they are slow alternative substrates, the bactericidal action of which arises from their ability to form long-lived acyl-enzyme intermediates, thereby blocking the peptidoglycan-forming transpeptidase reaction. In some cases, the penicillanoyl-ester requires hours to days to undergo hydrolysis (3), whereas penicillin-inactivating  $\beta$ -lactamases transiently form acyl-enzyme intermediates, which are hydrolyzed in only a few microseconds.

As noted by Walsh & Wenczewicz (3), the penicillanoyl scaffold imposes an orientation on the transpeptidase that prevents displacement by the normal cosubstrate (*i.e.*, a nearby  $\epsilon\text{-NH}_2$  on an adjacent pentapeptidyl arm of another Lipid II molecule). Water access to the transpeptidase active site

must likewise be greatly reduced to prevent hydrolysis. **Penicillin Resistance:** Organism-to-organism transmission, or horizontal gene transfer, plays the predominant role in the acquisition and evolution of antibiotic resistance, both in community- and hospital-based infections (4). The catchy term “superbugs” refers to microbes exhibiting enhanced morbidity and mortality due to multiple mutations endowing microorganisms with a high-level of antibiotic resistance. Gram-negative pathogens, such as *Escherichia coli*, *Salmonella enterica*, and *Klebsiella pneumoniae*, show a strong correlation between antibiotic use in the treatment and development of  $\beta$ -lactam antibiotic resistance attributable to the emergence of numerous antibiotic-inactivating  $\beta$ -lactamases that bind and hydrolyze penicillin and many of its derivatives. Super-resistant strains also often acquire increased virulence and transmissibility. The emergence of widespread acquired resistance underscores the potential for antibiotic failure. 1. ### Penicillin G

This naturally-occurring antibiotic (FW<sub>free-acid</sub> = 334.39 g/mol), also known as benzylpenicillin and penicillin II, from *Penicillium* species was the first penicillin, discovered by Alexander Fleming in 1928. Penicillin G's bacteriostatic action stems from its inhibition of peptidoglycan biosynthesis, a key requirement for bacterial proliferation. While the free acid is sparingly soluble in water, the sodium and potassium salts are very soluble.

**As Treatment for Syphilis:** A chronic multi-stage infectious disease, syphilis is transmitted sexually by contact with an active lesion of a partner or congenitally from an infected woman to her fetus. Although endemic in developing countries, syphilis remains a problem in even developed countries. Its resurgence is a global public health issue, because the lesions of early syphilis increase the risk of acquiring and transmitting infection, along with HIV-AIDS. Absent a vaccine, syphilis control requires treatment of infected individuals and their sexual partners with penicillin G (less so with azithromycin). Penicillin G is thus the first-line drug for syphilis in all its stages. **For details on mode of action, See Penicillins Target(s):** acylaminoacyl-peptidase (1); aminopeptidase D, or D-stereospecific aminopeptidase (2,3); fructose-1,6-bisphosphatase (4); glucose-6-phosphate dehydrogenase (5);  $\gamma$ -glutamyl transpeptidase (6,7); glycopeptide transpeptidase (8);  $\beta$ -lactamase, penicillinase, also substrate (9); lecithin:cholesterol acyltransferase, or LCAT (10); muramoylpentapeptide carboxypeptidase (8,11-13); muramoyltetrapeptide carboxypeptidase (14); neprilysin, or enkephalinase (15); penicillin amidase, also alternative substrate (16-18); penicillin-binding proteins (19); penicillin-binding protein 1b transpeptidase (20); penicillin-binding protein 2a (21); penicillin-binding protein 4 (22); phospholipase (23); serine-type D-Ala-D-Ala carboxypeptidase (24-30); D-stereospecific aminopeptidase (2,3); u-plasminogen activator, or urokinase (31). 1. ### Penicillin N

This antibiotic (FW<sub>free-acid</sub> = 359.40 g/mol; CAS 525-94-0; Water-soluble), also known as (2*S*,5*R*,6*R*)-6-[[*(5R)*-5-amino-5-carboxy-1-oxopentyl]amino]-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylic acid, (D-4-amino-4-carboxybutyl)-penicillanic acid, Adicillin<sup>®</sup>, Synnematin B<sup>®</sup>, as well as cephalosporin N, is produced by species of *Cephalosporium* as well as by *Paecilomyces pericimus* and *Penicillium chrysogenum*. (**For details on mode of action, See Penicillins**) **Spectrum of Antibiotic Action:** Penicillin N bacteriocida against *Diplococcus pneumoniae*, *Proteus vulgaris*, *Salmonella typhimurium*, *Sarcina lutea*, but shows little no activity against *Bacillus subtilis* and *Staphylococcus aureus*. **Target(s):** deacetoxycephalosporin-C hydroxylase (1); and deacetylcephalosporin-C acetyltransferase (2). **1.** Baker, Dotzlaef & Yeh (1991) *J. Biol. Chem.* **266**, 5087. **2.** Scheidegger, Gutzwiller, Kuenzi, Fiechter & Nuesch (1985) *J. Biotechnol.* **3**, 109.

### Penicillin V

This peptidoglycan biosynthesis inhibitor and antibiotic (FW<sub>free-acid</sub> = 350.40 g/mol), also known as phenoxymethylpenicillin, is produced by species of *Penicillium* grown on yeast broth supplemented with 2-phenoxyethanol. While the free acid is sparingly soluble in water, the sodium and potassium salts are very soluble. Penicillin V is relatively stable is not hydrolyzed in the stomach. (**For details on mode of action, See Penicillins**) **Target(s):** aminopeptidase D (1); cytosol alanyl aminopeptidase (2); deacetoxycephalosporin-C synthase (3); penicillin-binding protein 4 (4); serine-type D-Ala-D-Ala carboxypeptidase, or penicillin-binding protein 5 (5-9). **1.** Starnes, Desmond & Behal (1980) *Biochim. Biophys. Acta* **616**, 290. **2.** Starnes, Szechinski & Behal (1982) *Eur. J. Biochem.* **124**, 363. **3.** Dotzlaef & Yeh (1989) *J. Biol. Chem.* **264**, 10219. **4.** Wilkin (1998) in *Handb. ### Penitrem A

This neurotoxin (FW = 634.21 g/mol; CAS 12627-35-9), also called tremortin A, from a common fungus (*Penicillium palitans*) associated with rye grass, inhibits Ca<sup>2+</sup>-activated K<sup>+</sup> channels (EC<sub>50</sub> = 10 nM), which are found at highest density within cerebellar Purkinje cells. **1.** Knaus, McManus, Lee, et al. (1994) *Biochemistry* **33**, 5819.

**PENTA, See Fondaparinux**

**Penta(L-arginine), See L-Arginyl-L-arginyl-L-arginyl-L-arginyl-L-arginine**

### 2,4,5,3',4'-Pentabromobiphenyl

This persistent environmental pollutant (FW = 548.69 g/mol; CAS 67888-97-5), often abbreviated 2,4,5,3',4'-PBB and 2,4,5,3',4'-PBBP, inhibits uroporphyrinogen decarboxylase. **1.** Sinclair, Bement, Bonkovsky & Sinclair (1984) *Biochem. J.* **222**, 737.

### Pentachlorophenol

This electron transport uncoupler (FW = 266.34 g/mol; abbreviated PCP; pK<sub>a</sub> = 4.89) is often employed as an insecticide, fungicide, herbicide, and a pre-emergence defoliant that acts by inhibiting both mitochondrial oxidative phosphorylation and photophosphorylation. Pentachlorophenol is slightly soluble in water (8 mg/100 mL), but the commercially available sodium salt is much more soluble). **Target(s):** acetylcholinesterase (1,2); adenosine deaminase (3); arylamine *N*-acetyltransferase (4); arylhydroxamic acid *N,O*-acetyltransferase (4); ATP phosphoribosyltransferase (5); ATP synthase (6); bioluminescence, bacterial (7); chitin synthase (26); electron transport (8); estrone sulfotransferase (9); fumarate reductase, or menaquinol:fumarate oxidoreductase, *Escherichia coli* (10); *N*-hydroxyarylamine *O*-acetyltransferase (4,27); iodothyronine sulfotransferase, or thyroid hormone sulfotransferase (11); lipase, or triacylglycerol lipase (12); luciferase, bacterial (7); NAD(P)H dehydrogenase, or diaphorase (13); oxidative phosphorylation, uncoupler (6,14-16); phenol sulfotransferase, or aryl sulfotransferase (11,17-23); photophosphorylation, uncoupler (8); porphyrinogen carboxy-lyase (24); steroid 5α-reductase, NADH-dependent (25); succinate dehydrogenase, or succinate:ubiquinone oxidoreductase, *Escherichia coli* (10). **1.** Matsumura, Matsuoka, Igisu & Ikeda (1997) *Arch. ### Pentadecane-2-one

This long-chain ketone (FW = 226.40 g/mol), also called 2-pentadecanone, from the essential oils of the leaves and stems of *Pilocarpus microphyllus* inhibits lanosterol demethylase and lathosterol isomerase. Cholesterol biosynthesis, which is stimulated by cell culture in lipid-depleted medium, is inhibited by pentadecane-2-one, the latter acting mainly at two post-HMG-CoA steps: lanosterol demethylation and lathosterol isomerisation to cholesterol. A parallel pentadecane-2-one inhibition of cell growth is also observed, even when cells were cultured in the presence of whole serum, a finding suggesting a causal relationship between endogenous cholesterol synthesis and cell growth. **1.** Tabacik, Aliau & Sultan (1985) *Biochim. Biophys. Acta* **837**, 152.

### 1-N-Pentadecanoyl-3'-N-trifluoroacetyl-kanamycin A

This antiviral agent (FW<sub>free-base</sub> = 804.90 g/mol), often abbreviated PTKA, inhibits herpes simplex virus type 2 replication *in vitro* (1). *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric or micelle is inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **1.** Rahman, Yamamoto, Morishima, Maeno & Nishiyama (1988) *Antiviral Res.* **9**, 11.

**Pentadecylate, See Pentadecanoate**

### 2,3-Pentadienoyl-S-pantetheine 11-Pivalate

This Michael-type mechanism-based inhibitor (FW = 442.58 g/mol) irreversibly inhibits acetyl-CoA C-acetyltransferase ( $K_i = 1.25$  mM;  $k_{inact} = 0.26$  min<sup>-1</sup>), trapping Cys-378, the active site cysteine residue. **1.** Palmer, Differding, Gamboni, et al. (1991) *J. Biol. Chem.* **266**, 8369.

**Pentaeicosanoate, See Pentacosanoate**

### 2-Pentafluoropropionamidobenzenesulfonyl Fluoride

This aryl sulfonyl fluoride (FW = 321.20 g/mol) is an irreversible inhibitor of pancreatic and leukocyte elastases, but a weak inhibitor of cathepsin G and chymotrypsin. A model for the elastase inhibition reaction is proposed which involves interaction of the fluoroacyl group of the inhibitor with the primary substrate recognition site S<sub>1</sub> of the enzyme. Hydrogen bonding also occurs between the inhibitor NH and a backbone peptide carbonyl group, probably from residue-214. The 2-fluoroacyl group plays the dual role of binding in the hydrophobic S<sub>1</sub> pocket and through electronic effects, increasing the strength of the hydrogen bond. **1.** Yoshimura, Barker & Powers (1982) *J. Biol. Chem.* **257**, 5077.

### Pentagastrin

This synthetic peptide (FW<sub>free-acid</sub> = 767.90 g/mol), also named *N*-[(1,1-dimethylethoxy)carbonyl]-β-alanyl-L-tryptophanyl-L-methionyl-L-aspartyl-L-phenylalaninamide, is an analogue of gastrin I (the so-called 'big gastrin'), except that the C-terminal tetrapeptidamide Trp-Met-Asp-Phe-NH<sub>2</sub> of gastrin I has an additional N-terminal *N*-(*t*-butyloxycarbonyl)-β-alanyl residue. Pentagastrin is a cholecystokinin B receptor agonist and stimulates gastric acid secretion. **Target(s):** Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (1). **1.** Mozsik, Kutas, Nagy & Tarnok (1979) *Acta Med. Acad. Sci. Hung.* **36**, 459.

**Pentamethylenediamine, See Cadaverine**

### 1,1'-Pentamethylenepyridinium Iodide, 3-Hydroxypyridinium Iodide Methanesulfonate

This pyridinium salt (FW = 576.24 g/mol) irreversibly inhibits acetylcholinesterase with a  $K_i$  value of 20 μM and  $k_{inact} = 5.5 \times 10^{-4}$  sec<sup>-1</sup>. *Note:* The authors also developed a graphical method (now called the Kitz-Wilson Plot) for analyzing irreversible enzyme inhibition kinetics (2). **1.** Kitz & Wilson (1962) *J. Biol. Chem.* **237**, 3245. **2.** Purich & Allison (1995) *Handbook of Biochemical Kinetics*, Academic Press, New York.

**Pentamethylenetetrazole, See Pentylene tetrazole**

### Pentamidine & Pentamidine Methylene Analogues

This aromatic diamidine-class antiprotozoal (FW = 340.42 g/mol; CAS 100-33-4; FW<sub>isethionate</sub> = 592.68 g/mol; CAS 140-64-7 (isethionate salt)), known systematically as 4,4'-[pentane-1,5-diylbis(oxy)]dibenzencarboximidamide, targets an as-yet unspecified vital process in parasite mitochondria. Although readily metabolized by human P450 systems, pentamidine is not processed likewise in trypanosomes, suggesting an explanation for its differential action (1). Pentamidine typically requires intracellular concentrations of 1 mM, or greater. Its uptake by *T. brucei* in the bloodstream involves the *T. brucei* P<sub>2</sub> aminopurine permease (or TbAT<sub>1</sub>), a transporter that likewise mediates the uptake of melarsoprol. Because this parasite cannot synthesize adenine, purine uptake is a druggable target (1). (See also Suramin, Melarsoprol, and Eflornithine) Pentamidine and related homologues also bind the CTG\*CAG repeat in DNA to inhibit transcription, and analysis of methylene linker analogues, *n,n'*-[(CH<sub>2</sub>)<sub>*n*</sub>-1,5-diylbis(oxy)]dibenzene-carboximidamide, where the integer *n* varies from 3 to 9, reveals that heptamidine (*n* = 7) is exceptionally effective at reversing splicing defects and rescues myotonic dystonia in a mouse model (2). *Note:* Amidines are reasonably good bases, mainly because the protonation *sp*<sup>2</sup>-hybridized nitrogen can be stabilized by delocalization of the resulting positive charge on both nitrogen atoms. 1. Wilkinson & Kelly (2009) *Expert Rev. Molec. Med.* **1**, e31. 2. Coonrod, Nakamori, Wang, *et al.* (2013) *ACS Chem Biol.* **8**, 2528.

**1,5-Pentandiol 1,5-Bisphosphate**

This fructose 1,6-bisphosphate analogue (FW = 260.08 g/mol) inhibits fructose-1,6-bisphosphatase,  $K_{0.5} = 5$  mM (1), fructose-1,6-bisphosphate aldolase,  $K_i = 29$   $\mu$ M (2), and pyrophosphate-dependent phosphofructokinase, or diphosphate:fructose-6-phosphate 1-phosphotransferase (3). 1. Marcus (1976) *J. Biol. Chem.* **251**, 2963. 2. Hartman & Barker (1965) *Biochemistry* **4**, 1068. 3. Bertagnolli, Younathan, Voll, Pittman & Cook (1986) *Biochemistry* **25**, 4674.

**2,4-Pentanedione, See Acetylacetone**

**Pentanoate, See Valerate**

**Pentanochlor**

This photosynthetic electron transport inhibitor (FW = 239.74 g/mol; CAS 2307-68-8), also known as Solan<sup>®</sup>, (*RS*)-3'-chloro-2-methylvaler-p-toluidide, and *N*-(3-chloro-4-methylphenyl)-2-methylpentanamide, is a selective pre- and post-emergence herbicide used to control annual weeds in fields producing carrots, celery, fennel, and parsley. Pentanochlor is also used in contact sprays with flowers and ornamental plants. 1. Dodge (1977) *Spec. Publ., Chem. Soc.* **29**, 7.

**Pentanoyl-CoA, See Valeryl-CoA**

**4-Pentenoate (4-Pentenoic Acid)**

This unsaturated carboxylic acid (FW<sub>free-acid</sub> = 100.12 g/mol; CAS 591-80-0; M.P. = -22.5°C), also known as 4-pentenoic acid, reversibly inhibits carbamoyl-phosphate synthetase (1) and is also metabolized to form an irreversible inhibitor of 3-ketoacyl-CoA thiolase, or acetyl-CoA

acyltransferase, and acetoacetyl-CoA thiolase, or acetyl-CoA acetyltransferase (2,3), and palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (4). 1. Pausch, Rasenack, Haussinger & Gerok (1985) *Eur. J. Biochem.* **150**, 189. 2. Schulz & Fong (1981) *Meth. Enzymol.* **72**, 604. 3. Schulz (1987) *Life Sci.* **40**, 1443. 4. Dixon, Osterloh & Becker (1990) *J. Pharm. Sci.* **79**, 103.

**Pentylguanidine Sulfate, See Galegine Sulfate**

**Pentetate (Pentetic Acid)**

This EDTA-like chelator, antimicrobial, and food stabilizer (FW = 393.35 g/mol; CAS 67-43-6; Symbol: DTPA), systematically named 2-[bis[2-(bis(carboxymethyl)amino)ethyl]amino]acetic acid, inhibits many biochemical processes by binding divalent and trivalent metal ions, especially Fe<sup>3+</sup>. DTPA inhibits bacterial growth by sequestering Fe(III), a nutrient metal ion required by aconitase (also known as iron-responsive element-binding protein), cytochromes, other redox enzymes, and ribonucleotide reductase (needed for DNA synthesis). The US Food and Drug Administration has also determined that Zn<sup>2+</sup>-DTPA and Ca<sup>2+</sup>-DTPA are safe and effective oral treatments for individuals who inhaled or ingested Plutonium, Americium, or Curium.

**Pentifylline**

This xanthine-based vasodilator (FW = 264.33 g/mol; CAS 6493-05-6; M.P. = 82-83°C), also named Cosaldon<sup>®</sup>, 1-hexyl-3,7-dimethylxanthine, and 1-hexyl-theobromine, exhibits many of the biological effects of theobromine, but is more lipid-soluble. **Target(s):** cAMP phosphodiesterase (1,2); and Mg<sup>2+</sup>-ATPase (3). 1. Stefanovich (1975) *Arzneimittelforschung* **25**, 740. 2. Stefanovich, von Polnitz & Reiser (1974) *Arzneimittelforschung* **24**, 1747. 3. Porsche & Stefanovich (1979) *Arzneimittelforschung* **29**, 1089.

**Pentobarbital**

This barbiturate (FW = 226.28 g/mol; CAS 76-74-4), known systematically as 5-ethyl-(1-methylbutyl)-2,4,6-(1*H*,3*H*,5*H*)-pyrimidinetrione, is an anesthetic and sedative. The sodium salt, also called pentobarbitone sodium and Nembutal, is freely water soluble, but unstable, in water. The (+)-isomer is predominantly excitatory, while the (-)-enantiomer is predominantly inhibitory. The latter is considerably more effective in potentiating inhibitory responses to the transmitter  $\gamma$ -aminobutyrate, or GABA (1). **Target(s):** acetylcholine release (2); adenylate cyclase (3,4); alcohol dehydrogenase, NADP<sup>-</sup>-dependent, or aldehyde reductase (5);  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptor (6,7); Ca<sup>2+</sup> current, voltage-dependent (8); GABA receptor, both stimulation and inhibition (9); GABA uptake (10); glucose-6-phosphatase (11); D-glucose transport (12); inositol phospholipid hydrolysis (13); K<sup>+</sup> currents (14); monoamine oxidase (15); norepinephrin release (16); phospholipase C (17); and substance P receptor (18). 1. #### D-glycero-2,3-Pentodiulose 1,5-Bisphosphate

This bisphospho-diketo sugar (FW<sub>free-acid</sub> = 308.08 g/mol) is a potent slow, tight-binding inhibitor of ribulose-bisphosphate carboxylase/ oxygenase (1,2). H<sub>2</sub>O<sub>2</sub> and D-glycero-2,3-pentodiulose-1,5-bisphosphate are predicted products arising from elimination of H<sub>2</sub>O<sub>2</sub> from a peroxyketone intermediate, a reaction that is specific to Rubisco-catalyzed oxidation of D-ribulose-1,5-bisphosphate during synthesis and/or storage. 1. Kane, Wilkin, Portis, Jr., & Andrews (1998) *Plant Physiol.* **117**, 1059. 2. Kim & Portis (2004) *FEBS Lett.* **571**, 124.

#### Pentopril (and Pentoprilat)

This indole derivative (FW<sub>pentopril</sub> = 318.37 g/mol; CAS 82924-03-6), also known as CGS 13945, is an angiotensin I-converting enzyme inhibitor. The pharmacologically active metabolite is the diacid, known as pentoprilat and CGS 13934. **Target(s):** peptidyl-dipeptidase A, or angiotensin I-converting enzyme (1,2); and Xaa-Trp aminopeptidase, or aminopeptidase W (3). 1. Jacot des Combes, Turini, Brunner, *et al.* (1983) *J. Cardiovasc. Pharmacol.* **5**, 511. 2. Rakhit, Hurley, Tipnis, *et al.* (1986) *J. Clin. Pharmacol.* **26**, 156. 3. Tiekku & Hooper (1982) *Biochem. Pharmacol.* **44**, 1725.

#### Pentosan Polysulfate

This heparin-like polysulfated polysaccharide anticoagulant (MW = indefinite; CAS 37300-21-3), also called xylan polysulfate, xylan hydrogen sulfate, and Elmiron™, is a semi-synthetic inhibitor of the cell surface protease, often referred to as guanidinobenzoate, associated with colonic carcinoma tissues (1). The polymer does not, however, bind to the guanidinobenzoate isoenzyme of normal colon epithelial cell surfaces. Pentosan polysulfates electrostatically block the action of antithrombin III and heparin cofactor II inhibition (2). Xylan polysulfate also binds to cationic proteins, such as ribonuclease H, inhibiting the latter (3). The sodium salt of this polymer is a slightly hygroscopic white solid that is freely soluble in water. Note that the name is ambiguous, also referring to the sulfated polymer of any pentose. **See also Xylans Target(s):** alcohol dehydrogenase (4); calcium oxalate crystal growth (5,6); cAMP-dependent protein kinase (7); cathepsin B1, or cathepsin B (8); cathepsin G9; coagulation factor VIIIa (10); guanidinobenzoate (1); hyaluronidase (11);

protein kinase C (7,12,13); protein-serine/threonine kinases (7); protein-tyrosine kinase (7); and ribonuclease H (3). 1. Anees (1996) *J. Enzyme Inhib.* **10**, 203. 2. #### Pentoxifylline

This methylxanthine (FW = 278.31 g/mol; CAS 6493-05-6; Solubility = 77 mg/mL H<sub>2</sub>O at 25°C), known also as Trental™ and systematically as 1-(5-oxohexyl)-3,7-dimethylxanthine, is a theobromine derivative that improves blood flow by decreasing blood viscosity. Pentoxifylline also inhibits the synthesis of tumor necrosis factor α. Major metabolites are 1-[5-hydroxyhexyl]-3,7-dimethylxanthine and 1-[3-carboxypropyl]-3,7-dimethylxanthine, accumulating to plasma levels that are 5 and 8 times higher, respectively, than pentoxifylline. (**See Torbafylline Target(s):** alkaline phosphatase (1); and cAMP phosphodiesterase (2-4). 1. Glogowski, Danforth & Ciereszko (2002) *J. Androl.* **23**, 783. 2. Reuter & Wallace (1999) *Amer. J. #### 9-(n-Pentyl)adenine

This alkylated adenine analogue (FW = 205.26 g/mol), known also as 9-amyldenine, is a moderately potent inhibitor of calf muscle adenosine deaminase, K<sub>i</sub> = 50 μM (1) Its inhibitory behavior is consistent with Baker's concept of "exo"-inhibition, whereby incorporation of a bulky side-chain favors tight binding of a reversible enzyme inhibitor by means of interactions at sites immediately adjacent to the substrate binding pocket (2). 1. Cory & Suhadolnik (1965) *Biochemistry* **4**, 1729 and 1733. 2. Baker (1967) *Design of Active-Site-Directed Irreversible Enzyme Inhibitors*, Wiley, New York.

#### tert-Pentyl Alcohol, See 2-Methyl-2-butanol

#### 1-Pentyl-3-(4'-aminophenyl)pyrrolidine-2,5-dione, See 3-(4'-Aminophenyl)-1-pentylpyrrolidine-2,5-dione

#### Pentylentetrazole

This stable tetrazole (FW = 138.17 g/mol; CAS 54-95-5; M.P. = 57-60°C; soluble in water and many polar organic solvents), also known as 6,7,8,9-tetrahydro-5H-tetrazolo[1,5-a]azepine and metrazol and 1,5-

pentamethylenetetrazole, is a non-specific central-nervous-system stimulant and a convulsant. It is used experimentally to induce epileptic activity.

**Target(s):** acetylcholinesterase (1); cholesterol biosynthesis (2); dihydropyrimidinase, or hydantoinase, or dihydroorotase (3,4); and  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (5). 1. Mahon & Brink (1970) *J. Neurochem.* **17**, 949. 2. Alexander & Alexander (1962) *Biochemistry* **1**, 783. 3. Bernheim (1952) *The Enzymes*, 1st ed. ### S-Pentylglutathione

This S-alkylated glutathione derivative (FW = 378.46 g/mol), also known as S-amylglutathione, inhibits glutathione S-transferase (1) and lactoylglutathione lyase, or glyoxalase I (2-4). 1. Board & Mannervik (1991) *Biochem. J.* **275**, 171. 2. Vince & Wadd (1969) *Biochem. Biophys. Res. Commun.* **35**, 593. 3. Allen, Lo & Thornalley (1993) *Biochem. Soc. Trans.* **21**, 535. 4. Regoli, Saccucci & Principato (1996) *Comp. Biochem. Physiol. C, Pharmacol. Toxicol. Endocrin.* **113**, 313.

### (3-Pentynoyl)panthetheine

This mechanism-based agent (FW = 358.46 g/mol) inactivates acetyl-CoA C-acetyltransferase (1) and butyryl-CoA dehydrogenase from *Megasphaera elsdenii* (2,3). For the latter, the inactivator becomes covalently attached, with a stoichiometry of 0.61 mol  $^{14}\text{C}$ -inactivator/mol per enzyme-bound flavin, but with no modification of the flavin itself. The covalent adduct is labile toward base and neutral  $\text{NH}_2\text{OH}$ , releasing 85% of incorporated  $^{14}\text{C}$ -label from the protein. Base-catalyzed hydrolysis of the adduct releases 3-oxopentanoic acid (0.6 mol/mol of incorporated inactivator). Moreover,  $\text{NH}_2\text{OH}$  treatment forms an enzyme-bound hydroxamate (0.64 mol/mol of incorporated inactivator). The covalent adduct is reduced with  $\text{NaBH}_4$ , liberating 1,3-pentandiol. Hydrolysis of the protein with 6 N HCl after  $\text{NaBH}_4$  reduction yields 2-amino-5-hydroxyvaleric acid and proline, indicating that the inactivator reacts with the  $\gamma$ -carboxyl group of a glutamyl residue in the active site. Inactivation most likely proceeds through enzyme-catalyzed rearrangement of the acetylene to an allene, followed by nucleophilic addition of the carboxyl group to the allene. Similarly, (3-chloro-3-butenyl)panthetheine inactivates the enzyme and modifies a glutamyl residue. Butyryl-CoA dehydrogenase also catalyzes the isomerization of (3-butenyl)panthetheine to (2-butenyl)panthetheine. The enzyme catalyzes the elimination of HF from 3-fluoropropionyl-CoA and (3,3-difluorobutyl)panthetheine, again supporting an oxidative mechanism that is initiated by  $\alpha$ -proton abstraction. 1. Holland, Clark & Bloxham (1973) *Biochemistry* **12**, 3309. 2. Ator & Ortiz de Montellano (1990) *The Enzymes*, 3rd ed. (Sigman & Boyer, eds.), **19**, 213. 3. ### Peonidin

This inhibitor of nitric oxide formation (FW<sub>chloride</sub> = 336.73 g/mol; reddish-brown anthocyanidin flavylum cation), also spelled peonidin, is the aglucon of peonin, a major pigment in peonies. Glycosides of peonidin are also found in red wine and exhibits antioxidant activity. **Target(s):** 3',5'-cyclic-GMP phosphodiesterase, or cGMP phosphodiesterase, isozyme-5 (1); DNA topoisomerase II decatenation activity (2); glycogen phosphorylase (3); and nitric oxide production (4). 1. Dell'Agli, Galli, Vrhovsek, Mattivi & Bosio (2005) *J. Agric. Food Chem.* **53**, 1960. 2. Habermeyer, Fritz, Barthelmes, et al. (2005) *Chem. Res. Toxicol.* **18**, 1395. 3. Jakobs, Fridrich, Hofem, Pahlke & Eisenbrand (2006) *Mol. Nutr. Food Res.* **50**, 52. 4. Wang & Mazza (2002) *J. Agric. Food Chem.* **50**, 850.

### Peonidin 3-[6'-Caffeoyl-6''-feruloylsophoroside] 5-Glucoside

This natural acylated anthocyanin (FW<sub>chloride</sub> = 1149.46 g/mol), known systematically as 3-O-[2-O-(6-O-E-feruloyl- $\beta$ -D-glucopyranosyl)-6-O-E-caffeoyl- $\beta$ -D-glucopyranoside]-5-O- $\beta$ -D-glucopyranoside, from the red flowers of the morning glory (*Pharbitis nil*) and the storage roots of purple sweet potato (*Ipomoea batatas*) strongly inhibits  $\alpha$ -glucosidase (1,2). 1. Matsui, Ueda, Oki, et al. (2001) *J. Agric. Food Chem.* **49**, 1952. 2. Matsui, Ebuchi, Kobayashi, et al. (2002) *J. Agric. Food Chem.* **50**, 7244.

### Pepsinostreptin

This statin-containing peptidomimetic (FW = 670.87 g/mol) Structure: Isobutyryl-L-Val-L-Val-Sta-L-Ala-Sta, where Sta is statine, or (3S,4S)-4-amino-3-hydroxy-6-methylheptanoic acid, from a strain of *Streptomyces* forms a high-affinity complex with pepsin, inhibiting its activity. Pepsinostreptin, which is identical to pepstatin A, except for the N-terminal isobutyryl group in place of pepstatin's isovaleryl group, probably inhibits other aspartate proteinases. 1. Kakinuma & Kanamaru (1976) *J. Takeda Res. Lab.* **35**, 123, 128, and 136.

### Pepstatin

This naturally occurring statine-containing peptidomimetic (FW<sub>free-acid</sub> = 685.90 g/mol; CAS 26305-03-3), also called pepstatin A and isovaleryl-pepstatin and named systematically as N-(isovaleryl)-L-valyl-L-valyl-statyl-L-alanyl-statine (where the statyl residue is a (3S,4S)-4-amino-3-hydroxy-6-methylheptanoyl residue and the C-terminal statine is the corresponding acid), is a presumptive transition-state analogue for prototypical aspartate proteinase pepsin ( $K_i = 46$  pM). Pepstatin will also inhibit other carboxy proteinases. The inhibitory effectiveness of statine-containing peptides has been widely exploited by incorporating the statine residue into peptides that otherwise match sequence preferences of the target enzyme's sub-sites. Because pepstatin has a low solubility in water, it is often dissolved in

dimethyl sulfoxide, methanol, or ethanol. Note that many derivatives of pepstatin are available, each displaying a different spectrum of inhibitory effects. Pepstatin B and C are the *N*-(*n*-caproyl)- and *N*-(*iso*-caproyl)-derivatives, respectively. *Note:* Above a critical concentration of 0.1 mM in low ionic-strength and neutral buffers, pepstatin often polymerizes into filaments that be several micrometers in length and have characteristic diameters ranging between 6 and 12 nm. **1.** Umezawa, Aoyagi, Morishima, Matsuzaki & Hamada (1970) *J. Antibiot.* **23**, 259. **2.** Umezawa, Aoyagi, Morishima, *et al.* (1970) *J. Antibiot.* **23**, 259. **3.** Seglen (1983) *Meth. Enzymol.* **96**, 737. **4.** Knight (1995) *Meth. ### Peptide 6

This twenty-residue peptide (*Sequence:* DAAREGFLDTLVVLRAGAR; MW = 2167.46 g/mol), derived from the third ankyrin-like repeat (residues 84-103) of human p16CDKN2/INK4a (p16) tumor suppressor protein, binds to cyclin-dependent kinases cdk4 and cdk6 and inhibits cdk4-cyclin D1 kinase activity *in vitro* and also blocks cell cycle progression through G1 (1). [Ala92]-Peptide 6 (*Sequence:* DAAREGFLATLVVLRAGAR; MW = 2123.45 g/mol) binds to these targets with hig82.74her affinity (1). **1.** Fahraeus, Paramio, Ball, Lain & Lane (1996) *Curr. Biol.* **6**, 84.

### Peptide A

This 21-residue peptide (*Sequence:* VAPSDSIQAEWYFGKITRRE; MW = 2482.74 g/mol), corresponding to a part of the noncatalytic domain of p60v-src, inhibit the protein-tyrosine kinase activity of p60v-src. It is a noncompetitive inhibitor of Src/EGF (epidermal growth factor) receptor. Peptide A is not a substrate for tyrosyl residue phosphorylation. **1.** Sato, Miki, Tachibana, *et al.* (1990) *Biochem. Biophys. Res. Commun.* **171**, 1152.

### Peramivir

This substituted cyclopentane (FW = 345.42 g/mol; CAS 330600-85-6), also known as BCX 1812 and RWJ 270201, inhibits influenza A and B neuraminidase (sialidase), IC<sub>50</sub> values of < 1 and 10 nM, respectively (1,2). **1.** Chand, Kotian, Dehghani, *et al.* (2001) *J. Med. Chem.* **44**, 4379. **2.** Sidwell & Smee (2002) *Expert Opin. Investig. Drugs* **11**, 859.

### Perampanel

This highly potent, first-in-class antiepileptic drug (FW = 349.39 g/mol; CAS 380917-97-5), also known by its trade name Fycampa® and its systematic name 2-(2-oxo-1-phenyl-5-pyridin-2-yl-1,2-dihydropyridin-3-yl)benzimidazole, is a selective noncompetitive antagonist (IC<sub>50</sub> = 180 nM) of  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (or AMPA) receptors, the major subtype of ionotropic glutamate receptors. (*Note:* AMPA receptors are designated GluR1 (*or* GRIA1), GluR2 (*or* GRIA2),

GluR3 (*or* GRIA3), and GluR4 (*or* GRIA4), the latter also called GluRA-D2.) Perampanel increases intracellular Ca<sup>2+</sup> and selectively blocks AMPA receptor-mediated synaptic transmission, thereby reducing neuronal excitation. In hippocampal slices, perampanel reduces AMPA receptor-mediated excitatory postsynaptic field potentials (f-EPSPs) with an IC<sub>50</sub> of 0.23  $\mu$ M, with full block at 3  $\mu$ M. This behavior compares with an IC<sub>50</sub> of 7.8  $\mu$ M for GYKI52466. Perampanel (10  $\mu$ M) was without effect on NMDA or kainate receptors (1). As an AMPA-receptor antagonist, perampanel may possess antiepileptogenic properties in addition to its demonstrated antiseizure properties (2,3). **1.** Ceolin, Bortolotto, Bannister, *et al.* (2012) *Neurochem Int.* **61**, 517. **2.** Shih, Tatum & Rudzinski (2013) *Ther. Clin. Risk Manag.* **9**, 285. **3.** Krauss (2013) *Epilepsy Curr.* **13**, 269.

**Percaine, See Dibucaine Hydrochloride**

### Perchloric Acid

This strongly oxidizing inorganic acid HClO<sub>4</sub> (FW = 100.46 g/mol; CAS 7601-90-3; hygroscopic liquid; M.P. = -112°C; B.P. = 39°C at 56 mm Hg) readily dissociates. (This anion has tetrahedral geometry with a Cl-O bond distance of 1.42 Å. Shown above are the chlorate monocation's four resonance species, all obeying the Octet Rule.) **Caution:** This agent often explodes upon distilled at atmospheric pressure (typically at about 90°C) and will also deflagrate upon contact with oxidizable substances. Commercial perchloric acid is often supplied as a 60-72% solution in water (note that water and perchloric acid form a binary azeotrope: 72.4% perchloric acid which boils at 203°C). The pK<sub>a</sub> value is 1.77 at 20°C. The perchlorate anion (ClO<sub>4</sub><sup>-</sup>), also known as chlorate(VII), inhibits many enzymes. Perchlorate anion is a strong chaotropic reagent that is capable of acting as a protein denaturant (it is a destabilizing anion in the Hofmeister series). **Target(s):** acetoacetate decarboxylase (1,36); acylase (2); acylphosphatase (37); alcohol dehydrogenase (3,4); alkaline phosphatase (5);  $\beta$ -amylase (2); ATPase, bicarbonate-stimulated (6,7); carbonic anhydrase (8-14); catalase (15); chymotrypsin (2); cytidylate kinase (16); dihydroorotate dehydrogenase, at elevated concentrations (17); enolase, *or* phosphopyruvate hydratase (18,19); estradiol-17 $\beta$  dehydrogenase (2); fumarylacetoacetase (20); 3- $\beta$ -galactosidase2; glutaminase (41); glycogen phosphorylase *b* (21); guanine deaminase (40); iodide uptake (22,23); 3-ketoacid CoA-transferase, *or* 3-oxoacid CoA-transferase (24,39); lactate dehydrogenase (25-27); lipase (2); luciferase, firefly (28); NADH:cytochrome *c* reductase, *or* NADH dehydrogenase (29); NAD(P)<sup>+</sup> nucleosidase (42); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (30); peptide  $\alpha$ -N-acetyltransferase (48); phosphoglucomutase (31,32); succinate dehydrogenase (33); succinate:3-hydroxy-3-methylglutarate CoA-transferase (38); sulfate adenyltransferase (43-47); superoxide dismutase (49); tRNA methyltransferases (34); and vacuolar ATPase (35). **1.** Westheimer (1969) *Meth. ### Permethrin

This synthetic pyrethroid and insect neurotoxin (FW = 391.21 g/mol; CAS 52645-53-1), also known as 3-phenoxybenzyl (1*RS*)-*cis,trans*-3-(2,2-dichloro-vinyl)-2,2-dimethylcyclopropanecarboxylate, is a widely used insecticide, acaricide, and repellent that causes prolonged activation of voltage-gated sodium channel (See *Pyrethrins*). Although permethrin finds wide use in agriculture to rid cotton, wheat, maize, and alfalfa crops of insect infestations, its broad spectrum action also kills many beneficial insects. **Treatment of Scabies:** Scabies is a skin disorder caused by the mite *Sarcoptes scabiei var hominis*. About 300 million cases of scabies occur annually worldwide, aided by several predisposing factors (*e.g.*, overcrowding, immigration, poor hygiene, poor nutritional status, homelessness, dementia, and sexual contact). Direct skin-to-skin contact for 15-20 minutes is needed to transfer the mites from one person to another. The first-line treatment permethrin (5% weight/weight), marketed as Lyclear® and Nix®. The degree of permethrin absorption is assessed by determining conjugated and unconjugated *cis/trans* 3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropane-carboxylic acid, a permethrin metabolite that is excreted in the urine. The major pyrethroid-hydrolyzing esterase is located in mammalian liver microsomes. **Pyrethroid Resistance in *Aedes aegypti*:** Mutations in hydrophobic segment-6 of Domain II of para in *Ae. Aegypti* (the most prevalent vector of Dengue and Yellow Fever viruses.) reduce nerve sensitivity to permethrin inhibition (3). Two occur at codons Iso1011 and Val1016 in Exons 20 and 21, respectively. A transition in the third position of Iso1011 encoded a Met1011 replacement and a transversion in the second position of Val1016 encoded a Gly1016 replacement. **Health Effects of Permethrin-Impregnated Army Battle-Dress Uniforms:** Because the U.S. Environmental Protection Agency classifies permethrin as a potential carcinogen, concerns arose about health risks to soldiers wearing permethrin-impregnated battle dress uniforms. A full account of the current status was prepared by a National Research Council Subcommittee (4). **1.** Miyamoto (1976) *Environ Health Perspect.* **14**, 15. **2.** Taplin & Meinking (1996) *Curr. Probl. Dermatol.* **24**, 255. **3.** Saavedra-Rodriguez, Urdaneta-Marquez, Rajatileka, *et al.* (2007) *Insect Mol Biol.* **16**, 785. **4.** *National Research Council (US) Subcommittee to Review Permethrin Toxicity from Military Uniforms* (1994) National Academies Press, Washington, DC. **PMID:** 25101418

### Performate (Performic Acid)

This strong oxidizing agent (FW = 62.03 g/mol; CAS 107-32-4), also called peroxyformic acid, will oxidize cysteinyl and cystinyl residues in proteins to cysteic acid residues. Indeed, judicious use of performic acid enabled

Sanger to separate the two chains of insulin, an essential simplifying step in his successful Nobel Prize-winning determination of the primary structure of insulin A and B chains. Methionine is also converted to methionine sulfone. Degradation of tryptophanyl residues is typically minimized by reacting the protein at low temperature ( $-10^{\circ}\text{C}$ ) in the presence of a cryoagent, such as methanol. Harsher conditions result in the oxidation of tyrosyl, seryl, and threonyl residues. A 90% solution of performic acid is produced by reacting formic acid with hydrogen peroxide in the presence of  $\text{H}_2\text{SO}_4$ . **Caution:** Concentrated performic acid solutions often explode upon contact with readily oxidized metals, metal oxides, reducing agents, or even during distillation. **Note:** This reagent is likely to be nonselective in its oxidative action, and the fact that only two targets are listed below is probably misleading. **Target(s):** pancreatic ribonuclease, or ribonuclease A (1,2); and papain (3). **1.** Scheraga & Rupley (1962) *Adv. Enzymol.* **24**, 161. **2.** Richards & Wyckoff (1971) *The Enzymes*, 3rd ed., **4**, 647. **3.** Smith & Kimmel (1960) *The Enzymes*, 2nd ed. (Boyer, Lardy & Myrback, eds.), **4**, 133.

### Perhexiline

This calcium-blocking vasodilator (FW = 277.49 g/mol; CAS 6621-47-2; typically supplied as the maleate or HCl salt), also known as Pexid™ and 2-(2,2-dicyclohexylethyl)piperidine, is used to treat angina. It does so by targeting carnitine palmitoyltransferase-1 (CPT-1), an enzyme that controls the access of long chain fatty acids to the mitochondrial site of  $\beta$ -oxidation, showing concentration-dependent inhibition *in vitro*, using rat cardiac mitochondria,  $\text{IC}_{50} = 77 \mu\text{M}$ , and hepatic mitochondria,  $\text{IC}_{50} = 148 \mu\text{M}$  (1). Amiodarone, another drug with anti-anginal properties, likewise inhibits cardiac CPT-1 ( $\text{IC}_{50} = 228 \mu\text{M}$ ). The rank order of potency for inhibition was malonyl-CoA > 4-hydroxyphenylglyoxylate = perhexiline > amiodarone = monohydroxy-perhexiline. Inhibition was competitive with respect to palmitoyl-CoA but non-competitive inhibition with respect to carnitine. This shifts myocardial metabolism from fatty acid to glucose utilisation which results in increased ATP production for the same  $\text{O}_2$  consumption and consequently increases myocardial efficiency (1). (See also *Meldonium*) **Other Target(s):** CYP2D6 (3); glutathione *S*-transferase (4);  $\text{Mg}^{2+}$ -ATPase (5); NADH dehydrogenase (6);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (5);  $\beta$ -oxidation (6,7); oxidative phosphorylation (6,7); and succinate dehydrogenase (6). **1.** Kennedy, Unger & Horowitz (1996) *Biochem. ### Perifosine

This novel Akt signal-transduction pathway inhibitor (F.Wt. = 461.66; CAS 157716-52-4; Solubility (25°C): <1 mg/mL DMSO, 8 mg/mL Water), also known as KRX-0401 and 1,1-dimethylpiperidinium-4-yl octadecyl phosphate (zwitterion), inhibits Akt protein kinases,  $\text{IC}_{50} = 5 \mu\text{M}$ . Perifosine strongly inhibits Akt and extracellular signal-regulated kinase (Erk) 1/2, inducing cell cycle arrest in  $\text{G}_1$  and  $\text{G}_2$ , as well as dose-dependent growth inhibition of mouse glial progenitors (2). Perifosine (10  $\mu\text{M}$ ) completely inhibits Akt in MM.1S cells (3) and induces cell cycle arrest and apoptosis in human hepatocellular carcinoma cell lines, again by inhibiting Akt phosphorylation (4). **Note:** Perifosine is related structurally to miltefosine. **1.** Vyomesh Patel, *et al.* (2002) *Cancer Res.* **62**, 1401. **2.** Momota, *et al.* (2005) *Cancer Res.* **65**, 7429. **3.** Hideshima, *et al.* (2006) *Blood* **107**, 4053. **4.** Fei, *et al.* (2010) *Cytotechnology* **62**, 449.

### Perillyl Alcohol

This limonene metabolite (FW = 152.24 g/mol; CAS 536-59-4), which has been used to treat breast cancer, inhibits post-translational isoprenylation of cysteinyl residues of susceptible proteins. **Target(s):** protein farnesyltransferase (1,2); and protein geranylgeranyltransferase (1-4). **1.** Gelb, Tamanoi, Yokoyama, *et al.* (1995) *Cancer Lett.* **91**, 169. **2.** Hardcastle, Rowlands, Barber, *et al.* (1999) *Biochem. ### Periodate Ions

These strongly oxidizing inorganic ions (Sodium Hydrogen Orthoperiodate: Na<sub>2</sub>H<sub>3</sub>IO<sub>6</sub>; FW<sub>anhydrous</sub> = 273.91; CAS 15599-97-0; Sodium Metaperiodate: NaIO<sub>4</sub>; FW = 213.89 g/mol; CAS 7790-28-5) is a hygroscopic solid that is freely soluble in water and has pK<sub>a</sub> values of 1.6 and 5.7 at 20°C. H<sub>3</sub>IO<sub>6</sub> is the "ortho" form of periodic acid (*i.e.*, *ortho*-periodic acid or *o*-periodic acid). When orthoperiodate is heated at 100°C and 12 mm Hg, the *meta*-periodic acid is produced. Both forms are strong oxidizing agents. *meta*-Periodic acid will bind to and oxidatively cleave the carbon-carbon bond of susceptible organic compounds, namely those containing (a) two hydroxyl groups, each attached to adjacent carbon atoms (*i.e.*, 1,2-glycols), (b) an alcohol and an aldehyde/ketone, or (c) one hydroxyl group and one primary or secondary amino group, each again attached to adjacent carbon atoms (*i.e.*, β-amino alcohols). If neither carbon atom is a terminal carbon, then the resulting product will contain aldehyde or ketone moieties, depending on what other groups are attached to those carbon atoms (*e.g.*, RCH(OH)CH(OH)R' + HIO<sub>4</sub> → RCHO + R'CHO + H<sub>2</sub>O + HIO<sub>3</sub> and RCH(OH)CH(NH<sub>2</sub>)R' + HIO<sub>4</sub> → RCHO + R'CHO + NH<sub>3</sub> + HIO<sub>3</sub>). If there are three or more hydroxyl groups on three or more adjacent carbon atoms, the middle carbon atoms are converted to formic acid. Periodic acid oxidation will also work on α-hydroxy aldehydes and ketones, α-diketones, α-keto aldehydes, and glyoxal. If the two neighboring hydroxyl groups are on an aromatic ring, the carbon-carbon bond is not cleaved but the reactant is still oxidized. Thus, catechol is oxidized to the corresponding quinone. Periodic acid is a highly effective oxidizing agent in aqueous solution. If the reaction must be carried out in organic solvents, lead tetraacetate is often included. *Note:* Periodic acid will not act on α-keto acids or α-hydroxy acids whereas lead tetraacetate does. The corresponding reactions are actually oxidative decarboxylations. **Preparation of Enzyme Inhibitors:** Periodic acid oxidation has also proved to be a very useful tool in enzymology, simply because a wide variety of biochemicals contain hydroxyl groups on adjacent carbon atoms. For example, periodate-oxidized ATP (also called adenosine 5'-triphosphate 2',3'-dialdehyde) has often been used as an alternative substrate or irreversible inhibitor for a wide variety of ATP-utilizing enzymes. This and similar compounds are now commercially available, even though they are readily synthesized: *e.g.*, periodic acid-oxidized ADP, AMP, adenosine, P<sup>1</sup>,P<sup>5</sup>-di(adenosine-5')pentaphosphate, P<sup>1</sup>,P<sup>4</sup>-di(adenosine-5')tetraphosphate, GTP, GDP, GMP, guanosine, CTP, CDP, CMP, *etc.* In the case of nucleosides, commercial sources also can supply the dialcohol form of the nucleoside: *i.e.*, the nucleoside has first been oxidized with periodic acid and then reduced to the dialcohol with borohydride. **Target(s):** *N*-acetylglucosamine kinase (1); acid phosphatase (2); *N*-acetylmannosamine kinase (1); alkaline phosphatase (3); carbonic anhydrase, or carbonate dehydratase (4-6); chymotrypsin, partial inhibition (7); dextranase (8); β-fructofuranosidase (9); γ-glutamyl transpeptidase (10); lysozyme (11); maleate isomerase (12,13); pancreatic ribonuclease (14,15); 6-phosphofructo-2-kinase (16); and thymidylate synthase (17,18). **1.** Hinderlich, Nöhring, Weise, *et al.* (1998) *Eur. ### PERK Inhibitor I

This first-in-class, orally bioavailable pyrolopyrimidamine and small-molecule protein kinase inhibitor (FW = 449.42 g/mol; CAS 1337531-89-1; Soluble in DMSO; Cell Permeable), also known by its code name GSK-2606414 (or GSK2606414), its systematic name 7-methyl-5-(1-(3-(trifluoromethyl)phenyl)acetyl)-2,3-dihydro-1H-indol-5-yl)-7H-pyrrolo[2,3-d]pyrimidin-4-amine, and by many aliases (1), targets the protein kinase R (PKR)-like endoplasmic reticulum kinase, or PERK, IC<sub>50</sub> = 0.4 nM (2), a key transducer of the unfolded protein response, or UPR. **Primary Mode of Inhibition:** Accumulation of unfolded proteins within the ER elicits release of ER chaperones from the stress-sensing domain of PERK. Once activated by oligomerization and autophosphorylation, PERK phosphorylates Ser-51 of eukaryotic initiation factor 2α (eIF2α), thereby inhibiting overall protein synthesis and providing time for the ER to clear itself of accumulated unfolded proteins. PERK Inhibitor I blocks ER stress-induced PERK autophosphorylation (nearly 100% inhibition at ≤30 nM after 30 min) after thapsigargin treatment (*See Thapsigargin*) of A549 cultures *in vitro* and effectively retards PxBc-3 tumor growth in mice *in vivo* (2). **Other Target(s):** c-Kit (IC<sub>50</sub> = 150 nM), Aurora B (IC<sub>50</sub> = 410 nM), BRK (IC<sub>50</sub> = 410 nM), HRI/EIF2AK1 (IC<sub>50</sub> = 420 nM), MLK2/MAP3K10 (IC<sub>50</sub> = 450 nM), c-MER (IC<sub>50</sub> = 470 nM), DDR2 (IC<sub>50</sub> = 520 nM), PKR/EIF2AK2 (IC<sub>50</sub> = 700 nM), and MLCK2/MYLK2 (IC<sub>50</sub> = 700 nM), with little activity against more than 280 other kinases (IC<sub>50</sub> >1 μM). **1. Aliases:** 1-(5-(4-Amino-7-methyl-7H-pyrrolo[2,3-d]pyrimidin-5-yl)indolin-1-yl)-2-(3-(trifluoromethyl)phenyl)ethanone; DDR2 Inhibitor I, EIF2AK1 Inhibitor I, EIF2AK2 Inhibitor II, HRI Inhibitor I, MLCK Inhibitor VI, MLK2/MAP3K10 Inhibitor I, PKR-like ER Kinase Inhibitor I, Aurora Kinase Inhibitor IX, BRK Inhibitor I, c-Kit Inhibitor III, Mer RTK Inhibitor II, EIF2AK3 Inhibitor I, PKR Inhibitor I, MERTK Inhibitor II, RP38 Inhibitor II, TAM Family RTK Inhibitor II, Double-stranded RNA-activated Protein Kinase Inhibitor II, Double-stranded RNA-dependent Protein Kinase Inhibitor II. **2.** Axten, Medina, Feng, *et al.* (2012) *J. Med. Chem.* **55**, 7193.

### Permanganate

This extremely reactive oxidizing Mn(VII) oxide ion inhibits many enzymes, often nonspecifically, by modifying susceptible functional groups (*e.g.*, cysteine (-SH), methionine (-CH<sub>2</sub>-S-CH<sub>3</sub>), tryptophan (indole), and tyrosine (phenol)). Potassium permanganate (FW = 158.03 g/mol; CAS 7722-64-7) is a purple solid that is soluble in water (14.2 parts cold water) and will decompose in ethanol. It readily reacts with oxidizable compounds: *e.g.*, alcohols, sulfites, organohalides, arsenites, *etc.* **Target(s):** acid phosphatase (1); adenosine deaminase, weakly inhibited (35); alkaline

phosphatase (1-4);  $\alpha$ -amylase (5);  $\beta$ -amylase (6); arginine decarboxylase (7); aspartate carbamoyltransferase (8,9); bromelain (10);  $\text{Ca}^{2+}$ -dependent ATPase (11); calotropain, *or Calotropis gigantea* latex protease (12); carbonic anhydrase, *or* carbonate dehydratase (13-16); cathepsin D (41); cellulase (60);  $\text{CF}_1$  ATP synthase, *or* chloroplast  $\text{H}^+$ -transporting two-sector ATPase (33); chymotrypsin (17); dextranase (56); dextrin dextranase (63,64); endo-1,3(4)- $\beta$ -glucanase (59); endo-1,4- $\beta$ -xylanase (57,58); filamentous actin (18);  $\beta$ -fructofuranosidase (19); glucan endo-1,3- $\beta$ -D-glucosidase (52-54); glucan endo-1,6- $\beta$ -glucosidase (45); glucan 1,3- $\beta$ -glucosidase (49); glucan 1,4- $\alpha$ -glucosidase, *or* glucoamylase (61); glucan 1,6- $\alpha$ -glucosidase (46,47); glucan 1,6- $\alpha$ -isomaltosidase (43,44);  $\beta$ -glucosidase (55); glutamate decarboxylase (7,20);  $\beta$ -glycerophosphatase (21); histidine decarboxylase (7,34); hydrogenlyase (22); isopullulanase (50); levanase (23,48); levan fructotransferase, DFA-IV forming (31); lipoxygenase (24); lysine decarboxylase (7); mucorpepsin (39); nucleotide diphosphokinase (62); ornithine decarboxylase (7); oryzin (42); pectin lyase (32); penicillopepsin (40); pullulanase (51); riboflavin kinase (25,26); scytallopepsin A, weakly inhibited (38); serralyisin (36,37); succinyl-CoA synthetase, ADP-forming (27); thrombin (28); thymidylate synthase (29); tyrosine decarboxylase (7); and urocanase, *or* urocanate hydratase (30). 1. ### Permethrin

This synthetic insecticide and acaricide (FW = 391.29 g/mol; CAS 52645-53-1; M.P.  $\approx$  35°C) is insoluble in water but readily soluble in many organic solvents. *Note:* There are four possible stereoisomers, and commercial sources typically supply their own proprietary mixtures of these isomers. As a consequence, the reproducibility of inhibitory effects may depend on its source. **Target(s):** acetylcholinesterase (1,2); adenylate cyclase (3);  $\text{Ca}^{2+}$ -stimulated ATPase (4); glutamate uptake (5); glutathione *S*-transferase (6-8); monoamine oxidase A (9); NADH dehydrogenase, *or* complex I (10); and tryptophan 2,3-dioxygenase (11). 1. ### Peroxynitrite

This highly reactive, naturally occurring inorganic anion (FW<sub>anion</sub> = 62 g/mol; CAS 19059-14-4) is responsible for lipid peroxidation, protein modification, as well as DNA damage, the latter forming 8-nitroguanine and 8-oxoguanine and also inducing single-strand breaks. **Chemical Properties:** Peroxynitrite is a relatively long-lived oxidant that is produced *in vivo* from the diffusion-controlled ( $k = 10^{10} \text{ M}^{-1}\text{sec}^{-1}$ ) reaction of superoxide anion radical and nitric oxide (itself a radical). This reaction occurs in neutrophils, activated macrophages, and endothelial cells, where mitochondria are a primary site of formation. Because peroxynitrite crosses cell membranes, immediately neighboring cells are also targets during its 10-millisecond lifetime. Because NO is constitutively produced *in vivo* and is uncharged and freely diffusible, production of peroxynitrite is more likely governed by local production of superoxide. Under physiological conditions the major reactive form of peroxynitrite ( $\text{pK}_a = 6.8$ ) is peroxynitrous acid (HOONO), a reactive species that itself decomposes on the one-second timescale. **Preparation:** Sodium peroxynitrite (FW = 85.02 g/mol; CAS 14042-01-4;  $\lambda_{\text{max}} = 302 \text{ nm}$ ; Formulated as a solution in 0.3 M sodium hydroxide); is commercially available (Cayman Chemicals, Inc.; Purity  $\geq$  90%, with balance as nitrite and nitrate), but is expensive. Peroxynitrite is prepared by treating acidified hydrogen peroxide with a solution of sodium nitrite, followed by rapid addition of NaOH. 3-Morpholino-sydnominine hydrochloride (also called SIN-1-HCl), may also be used to generate both the superoxide anion and nitric oxide, which spontaneously react to produce peroxynitrite. **Detection:** Peroxynitrite concentration is determined by its absorbance at 302 nm (pH 12,  $\epsilon = 1670 \text{ M}^{-1}\text{cm}^{-1}$ ). **Lipid Peroxidation:** Addition of peroxynitrite to liposomes results in the formation of malondialdehyde and conjugated dienes, consuming  $\text{O}_2$  in the process. Lipid peroxidation is greater at acidic and neutral pH, with little lipid peroxidation occurring above pH 9.5. **Protein Modification:** Peroxynitrite promotes the nitration of protein hydroxyls, thiols, and tyrosines. It also activates src protein-tyrosine kinase, while inhibiting protein tyrosine phosphatases (*e.g.*, PTP 1B) by reacting rapidly ( $k = 2.2 \times 10^8 \text{ M}^{-1}\text{sec}^{-1}$ ) with the active-site cysteine thiolate. Such reactivity is most likely due to the fact that the active-site thiol is ionized at pH 7.4, with peroxynitrite resembling the natural phosphate in terms of molecular radii and charge. Glutathione also undergoes *S*-nitrosation in the presence of this anion. **Metalloporphyrin-mediated Decomposition of Peroxynitrite:** In the presence of Fe(III)-porphyrins, peroxynitrite rapidly isomerizes to nitrate; however, the same cannot be said for Mn(III)-porphyrins. Unlike Fe(III)-porphyrins,

Mn(III)-porphyrins are readily reduced by mitochondrial complexes I and II, yielding Mn(II). Once in this reduced state, Mn-porphyrins promote the two-electron reduction of peroxynitrite to nitrite and Mn(IV) complex, a reaction that can be readily reversed to Mn(III) by endogenous reductants, thereby completing a cycle for peroxynitrite decomposition. Mn- and Fe-porphyrins may also promote the one-electron oxidation of peroxynitrite to NO<sub>2</sub> and Mn/Fe(IV) state, which is then reduced back to the (III) redox state.

**Target(s):** aconitase, *or* aconitate hydratase (1-4); actin polymerization (5); arylamine *N*-acetyltransferase (50-52); Ca<sup>2+</sup>-dependent ATPase (6-8); caspase-3 (9); catalase (10); choline acetyltransferase (11,12); creatine kinase (13-15); cyclooxygenase, *or* prostaglandin-endoperoxide synthase (16,55,56); cytochrome *c* oxidase (17,18); electron transport (19); glutaredoxin (20); glyceraldehyde-3-phosphate dehydrogenase (21,22); glycerophosphocholine cholinephosphodiesterase (48); glycogen phosphorylase (49); K<sup>+</sup> channels, Ca<sup>2+</sup>-activated (23); NADH dehydrogenase, *or* complex I (24,25); NADH oxidase (26); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (27,28); neutral sphingomyelinase 1 (29); nitric-oxide synthase (30,31); ornithine decarboxylase (32); prostaglandin-I synthase, *or* prostacyclin synthase (33-36); protein kinase C (37); protein-tyrosine phosphatase (38); ribonucleotide reductase (39); superoxide dismutase (40-43,53,54); tryptophan monooxygenase (44); tubulin polymerization, *or* microtubule self-assembly (45); tyrosine monooxygenase (46); and xanthine oxidase (47).

### Perphenazine

This photosensitive phenothiazine (FW<sub>free-base</sub> = 403.98 g/mol; CAS 58-39-9) is a D<sub>2</sub> dopamine receptor antagonist and a σ receptor agonist. Perphenazine is insoluble in water and soluble in ethanol (153 mg/mL). **Target(s):** acetylcholinesterase (1); Ca<sup>2+</sup>-dependent ATPase (2); CYP2D6 (3,4); D<sub>2</sub> dopamine receptor (5); glutamate dehydrogenase (6-8); monoamine oxidase (9); trypanothione reductase, inhibited by cationic free radicals (10,11). 1. ### Perseitol

This seven-carbon sugar polyol (FW = 212.20 g/mol; CAS 527-06-0), also known as D-glycero-D-galacto-heptitol and α-mannoheptitol, from the avocado (*Persea americana*) and leaves of *Scurrula fusca*. Perseitol inhibits EIIMtl, the membrane-bound mannitol-specific enzyme II (EIIMtl) of the phosphoenolpyruvate-dependent phosphotransferase of *Escherichia coli*. 1. Lolkema, Wartna & Robillard (1993) *Biochemistry* **32**, 5848.

### Persulfate

This free-radical initiator (Ammonium Persulfate: (NH<sub>4</sub>)<sub>2</sub>S<sub>2</sub>O<sub>8</sub>, FW = 228.20, CAS 7727-54-0; Potassium Persulfate: K<sub>2</sub>S<sub>2</sub>O<sub>8</sub>, FW = 270.32, CAS 7727-21-1; Sodium Persulfate: Na<sub>2</sub>S<sub>2</sub>O<sub>8</sub>, FW = 238.11 g/mol, CAS 7775-27-1; Redox Potential = 2.1 V), perhaps more rationally described as peroxydisulfate, is strongly oxidizing and generates free radicals in the presence of a catalyst. For example, in the presence of tetramethylethylenediamine (TEMED), persulfate forms sulfate radicals (SO<sub>4</sub><sup>•-</sup>) that initiate the free radical polymerization of alkenes, including the famously important polyacrylamide gels formed from acrylamide and bisacrylamide. Indeed, ammonium persulfate is the reagent of choice for making polyacrylamide gels, but potassium persulfate is recommended when one must work with weakly buffered basic systems (pH ≈ 9). Because some persulfate inevitably persists after polyacrylamide gel formation, pre-electrophoresis is advised, when analyzing persulfate-sensitive enzymes in active-enzyme electrophoresis experiments. Persulfate salts, particularly ammonium persulfate, should be stored in air-tight containers in a cool

environment. In aqueous solution, ammonium persulfate slowly decomposes with liberation of O<sub>2</sub> to form NH<sub>4</sub>H<sub>2</sub>SO<sub>4</sub>. *Note:* Beyond those specifically listed below, many other enzymes, especially those employing thiol groups in catalysis, are likely to be inhibited by persulfate. **Target(s):** acid phosphatase (1); carbonic anhydrase, weakly inhibited (2,3); deoxyribose pyrimidine photo-lyase (4); fumarase, or fumarate hydratase, inhibited by ammonium persulfate (5); gallate decarboxylase, inhibited by ammonium persulfate (6); glycogen phosphorylase (7); levanase, inhibited by ammonium persulfate (8); lipase, or triacylglycerol lipase, inhibited by ammonium persulfate (9); procollagen N-endopeptidase, inhibited by ammonium persulfate (10); and tannase (11). 1. ### Pertussis Toxin

This enterotoxin (EC 2.4.2.31; Symbol: PT) produced by the Gram-negative pathogenic aerobic *Bordetella pertussis* is an oligomeric enzyme catalyzing the NAD<sup>+</sup>-dependent ADP-ribosylation of  $\alpha$ -subunits of the GTP-regulatory protein G<sub>i</sub>, other trimeric cytosolic G-proteins, as well as transducin (1,2). Modification prevents the G proteins from binding to their respective receptors, and the associated adenylate cyclase remains inactive. A cysteinyl residue within the  $\alpha$ -subunit of G<sub>i</sub>, G<sub>o</sub>, and G<sub>ust</sub> undergoes ADP-ribosylation, but G<sub>s</sub> is not a substrate. PT is known to dissociate into two components: the enzymatically active A subunit (S<sub>1</sub>) and the cell-binding B subunit. S<sub>1</sub> is thus a major virulence factor of *Bordetella pertussis*, with ADP-ribosylation of host-cell G-proteins a way to inhibit GPCR signaling. The intracellular pathway of PT action includes endocytosis and retrograde transport to the trans-Golgi network (TGN) and endoplasmic reticulum (ER). Subsequent translocation of S<sub>1</sub> to the cytosol is presumably preceded by dissociation from the holotoxin. PT dissociation is stimulated by ATP *in vitro*. 1. Sprang (1997) *Ann. Rev. Biochem.* **66**, 639. 2. Wise, Watson-Koken, Rees, Lee & Milligan (1997) *Biochem. J.* **321**, 721.

### Pertuzumab

This breast cancer drug (MW = 148 kDa; CAS 380610-27-5), also known by the trade name Perjeta<sup>®</sup>, is a humanized, first-in-class recombinant IgG1 monoclonal antibody that inhibits dimerization of HER/erbB tyrosine kinases. **Mechanism of Inhibitory Action:** The EGF receptor family consists of four transmembrane receptors: EGFR (HER1/erbB-1), HER2 (erbB-2/neu), HER3 (erbB-3), and HER4 (erbB-4) (1-3). HER1, HER3, and HER4 each contain three major functional domains: an extracellular ligand-binding domain, a hydrophobic transmembrane domain, and a cytoplasmic tyrosine kinase domain. No ligand has been clearly identified for HER2; however, HER2 can be activated as a result of ligand binding to other HER receptors with the formation of receptor homodimers and/or heterodimers. Pertuzumab prevents ERBB2 receptor protein from binding (dimerizing) to other HER family receptors. Recent work also suggests that the HER-2-targeting antibodies Pertuzumab and Trastuzumab synergistically inhibit the survival of breast cancer cells growing *in vitro* (4). Because HER1 and HER2 are overexpressed on many solid tumors (*e.g.*, breast, non-small cell lung, head and neck, and colon), pertuzumab prevents tumor cell growth by blocking the pairing of the most potent signaling heterodimer: HER2/HER3. **Use in Combination with Trastuzumab:** Because pertuzumab and trastuzumab (*See also Trastuzumab*) bind to unique antigenic regions on HER2, use of both provides a more complete blockade of HER2-mediated signal transduction than either agent alone. Clinical studies on their combined action suggest their likely utility as a first-line treatment for HER2-positive metastatic breast cancer treatment (5). The initial dose of 840 mg pertuzumab (60-minute I.V. infusion) is followed every 3 weeks thereafter by a 420-mg I.V. dose administered over 30-60 minutes (6). When administered with pertuzumab, the recommended initial dose of trastuzumab is 8 mg/kg administered as a 90-minute I.V. infusion, followed every 3 weeks thereafter by a dose of 6 mg/kg administered as an I.V. infusion over 30 to 90 minutes (6). 1. Adams, Allison, Flagella, *et al.* (2006) *Cancer Immunol. Immunother.* **55**, 717. 2. Agus, Gordon, Taylor, *et al.* (2005) *J. Clin. Oncol.* **23**, 2534. 3. Ng, Lum, Gimenez, Kelsey &

Allison (2006) *Pharm. Res.* **23**, 1275. 4. Nahta, Hung & Esteva (2004) *Cancer Res.* **64**, 2343. 5. Harbeck, Beckmann, Rody, *et al.* (2013) *Breast Care* (Basel). **8**, 49. 6. Genentech Inc., Reference ID: 3143182.

### Peruvoside

This cardiotoxic glycoside or cardenolide (FW = 548.67 g/mol; CAS 1182-87-2), named systematically as (3 $\beta$ ,5 $\beta$ )-3-(6-deoxy-3-O-methyl- $\alpha$ -L-glucopyranosyl)oxyl-14-hydroxy-19-oxocardi-20(22)-enolide, a component of neriperside from *Thevetia nerifolia* (yellow oleander) resembles ouabain in its inotropic (force of contraction) and chronotropic (rate of contraction) effects on heart function. Orally administered peruvoside is effective in treating congestive heart failure. Note the structural similarities of the aglycon to digitoxigenin. **Target(s):** Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (1). 1. Ye & Yang (1990) *Zhongguo Yao Li Xue Bao* **11**, 491.

### 5-(Perylen-3-yl)ethynyl-arabino-uridine

This bulky aryl-alkyne-substituted arabinonucleoside (FW = 516.55 g/mol), also known as aUY11, is a rigid amphipathic fusion inhibitor that targets virion envelope lipids, blocking fusion of influenza virus, hepatitis C virus (HCV), vesicular stomatitis virus (VSV), and even protein-free liposomes to cells (1). Infection by viruses having lipid-bilayer envelopes proceeds through fusion of the viral membrane with a target cell membrane, a process facilitated by viral fusion proteins that vary greatly in structure, but have a common mechanism of action, *i.e.*, ligand-triggered, large-scale conformational change in the fusion protein, coupled to merger of suitably apposed viral and host bilayers (2). Significantly, aUY11 inhibits formation of negative curvature in model lipid bilayers, such that its effect results from a purely biophysical phenomenon relating to its shape and amphipathicity, and not by direct binding to an enzyme active site or a receptor binding site (1). 1. Colpitts, Ustinov, Epan, *et al.* (2013) *J. Virol.* **87**, 3640. 2. Harrison (2008) *Nature Struct. Mol. Biol.* **15**, 690.

### Petroselaidate

This unsaturated fatty acid (FW<sub>free-acid</sub> = 282.47 g/mol; M.P. = 53°C), also known as petroselaidic acid and named systematically as (*E*)-octadec-6-enoic acid, inhibits DNA-directed DNA polymerase and DNA polymerase  $\alpha$  non-competitively with respect to the DNA template and substrate (dTTP), while DNA polymerase  $\beta$  inhibited competitively with both DNA and substrate. 1. Mizushima, Tanaka, Yagi, *et al.* (1996) *Biochim. Biophys. Acta* **1308**, 256.

### Petroselenate, See Petroselinate

### Petroselinate

This unsaturated fatty acid (FW<sub>free-acid</sub> = 282.47 g/mol; M.P. = 29.5–30.1°C; CAS 4712-34-9; (*Z*)-isomer, CAS 593-39-5; (*E*)-isomer, CAS 593-40-8), also known as petroselinic acid and named systematically (*Z*)-octadec-6-

(2010) *Cancer Res.* **70**, 9413. **3.** Sun, Pisle, Gardner & Figg (2010) *Cancer Biol. Ther.* **10**, 38. **4.** Bagi, Roberts & Andresen (2008) *Cancer* **112**, 2313.

**PF-868554**, See *Filbuvir*

**PF-915275**

This orally bioavailable 11 $\beta$ HSD1 inhibitor (FW = 350.39 g/mol; CAS 857290-04-1; Soluble to 100 mM in DMSO), also named *N*-(6-amino-2-pyridinyl)-4'-cyano-[1,1'-biphenyl]-4-sulfonamide, potent and selective targets 11 $\beta$ -hydroxysteroid dehydrogenase type 1 (11 $\beta$ HSD1) inhibitor ( $K_i$  = 2.3 nM) that displays little activity at 11 $\beta$ HSD2 (1.5% inhibition at 10  $\mu$ M). PF-915275 inhibits the conversion of prednisone to prednisolone in human hepatocytes *in vitro* ( $EC_{50}$  = 15 nM) and has antidiabetic activity *in vivo*. **1.** Bhat, *et al.* (2008) *J. Pharmacol. Exp. Ther.* **324**, 299. **2.** Courtney, *et al.* (2008) *J. Clin. Endocrinol. Metab.* **93**, 550. **3.** Fotsch & Wang (2008) *J. Med. Chem.* **51**, 4851.

**PF-1247324**

This novel oral Na $_v$ 1.8 blocker (FW = 330.59 g/mol) attenuates nociception and neuronal excitability by selectively targeting voltage-gated sodium transporter Na $_v$ 1.8, with much weaker action against Na $_v$ 1.1, Na $_v$ 1.2, Na $_v$ 1.4, Na $_v$ 1.5, Na $_v$ 1.6, and Na $_v$ 1.7 transporters. PF-01247324 inhibited native tetrodotoxin-resistant (TTX-R) currents in human dorsal root ganglion (DRG) neurons ( $IC_{50}$  = 331 nM) and in recombinantly expressed hNa $_v$ 1.8 ( $IC_{50}$  = 196 nM), with 50-fold selectivity over recombinantly expressed TTX-R hNa $_v$ 1.5 channels ( $IC_{50}$  ~ 10  $\mu$ M) and 65-100 greater selectivity over TTX-sensitive (TTX-S) channels ( $IC_{50}$  ~ 10-18  $\mu$ M). Native TTX-R currents in small diameter rodent DRG neurons were inhibited with an  $IC_{50}$  of 448 nM, and the block of both human recombinant Na $_v$ 1.8 and TTX-R from rat DRG neurons was both frequency and state-dependent. Unlike previously published Na $_v$ 1.8 blockers, PF-01247324 demonstrates frequency-dependence, and off-target frequency-dependence at other sodium channel subtypes may reduce its selectivity window. The majority of small molecule sodium channel blockers interact at the local anesthetic binding site, which due to a high level of sequence homology across voltage-gated sodium channel subtypes seems an unlikely site for interaction of selective agents such as PF-01247324. The majority of small molecule sodium channel blockers interact at the local anesthetic binding site, which due to a high level of sequence homology across voltage-gated sodium channel subtypes seems an unlikely site for interaction of selective agents such as PF-01247324. **1.** Payne, Brown, Theile, *et al.* (2015) *Brit. J. Pharmacol.* **172**, 1258.

**PF-1367338**, See *Rucaparib*

**PF-2341066**

This antitumor agent (FW = 449.34 g/mol), also known as [(*R*)-3-[1-(2,6-dichloro-3-fluorophenyl)ethoxy]-5-(1-piperidin-4-yl)-1H-pyrazol-4-yl]pyridin-2-ylamine, inhibits c-Met and RON receptor protein-tyrosine kinases, thereby exhibiting antiproliferative and antiangiogenic mechanisms (1).

Aberrant expression of RON (*Recepteur d'Origine Nantais*) receptor tyrosine kinase and the generation of multiple-splicing/truncation variants contributes to pathogenesis of epithelial cancers. The six variants include RON- $\Delta^{55}$ , RON- $\Delta^{110}$ , RON- $\Delta^{155}$ , RON- $\Delta^{160}$ , RON- $\Delta^{165}$ , and RON- $\Delta^{170}$ , and deletions/truncations in the extracellular or intracellular regions have been identified. The extracellular sequences contain functional structures such as a SEMA domain, PSI motif, and IPT units. Deletion or truncation results in constitutive phosphorylation and increased kinase activities, attended by or associated with epithelial cell cancer. **1.** Lu, Yao & Wang (2007) *Cancer Lett.* **257**, 157. **2.** Zou, Li, Lee, *et al.* (2007) *Cancer Res.* **67**, 4408.

**PF-299804**, See *Dacomitib*

**PF-3084014**

This novel  $\gamma$ -secretase inhibitor (FW = 489.66 g/mol; CAS 1290543-63-3; soluble in DMSO), also code-named HY-15185 and systematically named [(*S*)-2-((*S*)-5,7-difluoro-1,2,3,4-tetrahydronaphthalen-3-ylamino)-*N*-(1-(2-methyl-1-(neopentylamino)propan-2-yl)-1H-imidazol-4-yl)pentanamide], inhibits  $\gamma$ -secretase reversibly, noncompetitively, and selectively, thereby reducing amyloid- $\beta$  (A $\beta$ ) production, with an *in vitro*  $IC_{50}$  of 1.2 nM in a whole-cell assay and 6.2 nM in cell-free assay (1). PF-03084014 inhibits Notch-related T- and B-cell maturation in an *in vitro* thymocyte assay with an  $EC_{50}$  of 2.1  $\mu$ M. PF-3084014 had an  $IC_{50}$  on B- and T-cell reductions of 1.3 to 3  $\mu$ M with a mean  $EC_{50}$  of 2.1  $\mu$ M. This represents >300-fold separation from the broken-cell A $\beta$   $IC_{50}$  and >1500x separation from the whole-cell  $IC_{50}$ . A single acute dose showed dose-dependent reduction in brain, cerebrospinal fluid (CSF), and plasma A $\beta$ . When dosed with PF-3084014 for 5 days using an osmotic minipump (0.03 to 3 mg/kg/day), Guinea pigs exhibited dose-dependent A $\beta$  reduction in brain, CSF, and plasma. While other  $\gamma$ -secretase inhibitors show high potency at elevating A $\beta$  in the conditioned media of whole cells and the plasma of multiple animal models and humans, such potentiation is not observed with PF-3084014 (1). By evoking antitumor and antimetastatic properties via pleiotropic mechanisms, experiments with PF-03084014 offer hope that Notch pathway downstream genes may be used to predict the antitumor activity of PF-03084014 in breast cancer patients (2). **1.** Lanz, Wood, Richter, *et al.* (2010) *J. Pharmacol. Exp. Ther.* **334**, 269. **2.** Zhang, Pavlicek, Zhang, *et al.* (2012) *Clin. Cancer Res.* **18**, 5008.

**PF 3491390**, See *Emricasan*

**PF-4691502**

This ATP-competitive PI3K/mTOR dual inhibitor (FW = 325.49 g/mol; CAS 1013101-36-4; Solubility = 14 mg/mL DMSO, < 1 mg/mL H $_2$ O), also systematically named 2-amino-8-((1*R*,4*R*)-4-(2-hydroxyethoxy)cyclohexyl)-6-(6-methoxy-pyridin-3-yl)-4-methylpyrido[2,3-*d*]pyrimidin-7(8*H*)-one, potently inhibits recombinant Class-I PI3K $\alpha$  ( $K_i$  = 1.8 nM), PI3K $\beta$  ( $K_i$  = 2.1 nM), PI3K $\delta$  ( $K_i$  = 1.6 nM), PI3K $\gamma$  ( $K_i$  = 1.9 nM), and mTOR ( $K_i$  = 16 nM) in biochemical assays, with little activity against either Vps34, AKT, PDK1, p70S6K, MEK, ERK, p38, or JNK. PF-04691502 also suppresses avian fibroblast transformation mediated by wild-type PI3K  $\gamma$ ,  $\delta$ , or mutant PI3K $\alpha$  (1). In PIK3CA-mutant and PTEN-deleted cancer cell lines, PF-04691502 reduces phosphorylation of AKT T308 ( $IC_{50}$  = 7.5–47 nM) and AKT S473 ( $IC_{50}$  = 3.8–20 nM) and inhibits cell proliferation ( $IC_{50}$  = 180–310 nM). PF-04691502 also inhibite mTORC1 activity within cells, as

measured by PI3K-independent, nutrient-stimulated assay ( $IC_{50} = 32$  nM) and inhibited the activation of PI3K and mTOR downstream effectors, including AKT, FKHL1, PRAS40, p70S6K, 4EBP1, and S6RP. Short-term exposure to PF-04691502 predominantly inhibits PI3K, whereas mTOR inhibition persists for 24 to 48 hours. PF-04691502 also induces cell cycle  $G_1$  arrest, concomitant with upregulation of p27 Kip1 and reduction of retinoblastoma protein, or Rb (1). At doses below the maximal tolerable dose, PD-0325901 potently inhibits tumor growth, when Kras and/or PI3K are drivers of tumor growth and progression (2). 1. Yuan, Mehta, Yin, *et al.* (2011) *Mol. Cancer Ther.* **10**, 2189. 2. Simmons, Lee, Lalwani, *et al.* (2012) *Cancer Chemother. Pharmacol.* **70**, 213.

#### PF-4708671

This cell-permeable protein kinase inhibitor (FW = 390.41 g/mol; CAS 1255517-76-0; Solubility = 30 mg/mL DMSO, <1 mg/mL  $H_2O$ ) targets p70 ribosomal S6 kinase (S6K1, isoform) with  $K_i$  of 20 nM and  $IC_{50}$  of 160 nM, without significant inhibition of S6K2 isoform or Akt1, Akt2, PKA, PKC $\alpha$ , PKC $\epsilon$ , PRK2, ROCK2, RSK1, RSK2, or SGK1. PF-4708671 prevents the S6K1-mediated phosphorylation of S6 protein in response to IGF-1 (insulin-like growth factor 1), while having no effect upon the PMA-induced phosphorylation of substrates of the highly related RSK (p90 ribosomal S6 kinase) and MSK (mitogen- and stress-activated kinase) kinases. 1. Pearce, Alton, Richter, *et al.* (2010) *Biochem. J.* **431**, 245.

#### PF-4859989

This systemically available KAT II inhibitor (FW = 178.19 g/mol; CAS 34783-48-7; IUPAC: (3S)-3-amino-1-hydroxy-3,4-dihydroquinolin-2(1H)-one) irreversibly inhibits kynurenine amino transferase II, or KAT II, with  $K_i = 23$  nM,  $k_{inact}/K_i = 112,000$   $M^{-1}s^{-1}$ ,  $IC_{50} = 263$  nM, and Partition-Coefficient $_{n-octanol/H_2O} = 3 \times 10^8$  (1). This inhibitor most likely makes an enamine adduct with enzyme-bound pyridoxal-P. **Rationale:** Kynurenate is a tryptophan-derived endogenous antagonist for glutamate and  $\alpha_7$ -nicotinic acetylcholine receptors in the brain. Increased levels are observed postmortem in the brains of patients with a range of neurocognitive disorders, including schizophrenia. Kynurenate may well contribute to the cognitive symptoms of these conditions. **Pharmacology:** PF-04859989 restores glutamate release "transients" evoked by ejections of nicotine into the prefrontal cortex of rats exhibiting elevated kynurenate levels. Systemic administration of PF-04859989 30 min prior to administration of L-kynurenine (but not when administered 30 min after L-kynurenine) restores glutamatergic transients recorded up to 120 min after the administration of the KAT II inhibitor. Furthermore, the KAT-II inhibitor significantly reverses L-kynurenine-induced elevations of brain KYNA levels. The KAT-II inhibitor does not affect nicotine-evoked glutamatergic transients in rats not pre-treated with L-kynurenine. 1. Dounay, Anderson, Bechle, *et al.* (2013) *Bioorg. Med. Chem. Lett.* **23**, 1961. 2. Cherian, Gritton, Johnson, *et al.* (2014) *Neuropharmacol.* **82**, 41.

#### PF-4929113

This potent and selective HSP90 inhibitor (FW = 521.54 g/mol; CAS 908115-27-5; Solubility: 100 mg/mL DMSO, <1mg/mL  $H_2O$ ), also known

as SNX-5422 and (1*R*,4*R*)-4-(2-carbamoyl-5-(6,6-dimethyl-4-oxo-3-(trifluoromethyl)-4,5,6,7-tetrahydroindazol-1-yl)phenylamino)cyclohexyl 2-aminoacetate, targets heat shock protein-90 ( $K_d = 41$  nM) and also inhibits Her-2 degradation ( $IC_{50} = 37$  nM). PF-04929113 also shows potent anti-proliferative activity against a broad range of cancer cell types, e.g. MCF-7 ( $IC_{50} = 16$  nM), SW620 ( $IC_{50} = 19$  nM), K562 ( $IC_{50} = 23$  nM), SK-MEL-5 ( $IC_{50} = 25$  nM), and A375 ( $IC_{50} = 51$  nM) (1). SNX2112 inhibits *in vitro* proliferation, inducing  $G_2/M$  arrest, and enhanced cytotoxicity, chemosensitivity, and radiosensitivity between 25 and 250 nM (2), decreasing expression and/or phosphorylation of EGFR, c-MET, AKT, ERK-1 and -2, I $\kappa$ B kinase, and STAT3, corresponding downstream NF $\kappa$ B, AP-1, and STAT3 reporter genes, and target oncogenes and angiogenic cytokines (2). 1. Huang, Veal, Fadden, *et al.* (2009) *J. Med. Chem.* **52**, 4288. 2. Friedman, Wise, Hu, *et al.* (2013) *Transl. Oncol.* **6**, 429.

#### PF-05089771

This potent voltage-gated sodium ion channel blocker (FW = 500.38 g/mol; CAS 1430806-04-4; Solubility: 100 mM in DMSO), also known as 4-[2-(3-Amino-1*H*-pyrazol-4-yl)-4-chlorophenoxy]-5-chloro-2-fluoro-*N*-4-thiazol-ylbenzenesulfonamide tosylate, targets the  $Na_v1.7$  channel, with  $IC_{50}$  values of 8, 11 and 171 nM for mouse, human and rat.  $Na_v1.7$  is the predominant functional tetrodotoxin-sensitive  $Na_v$  in mouse and human nociceptors and contributes to the initiation and the upstroke phase of the nociceptor action potential.  $Na_v1.7$  also influences synaptic transmission in the dorsal horn of the spinal cord as well as peripheral neuropeptide release in the skin. PF-05089771 also exhibits selectivity for  $Na_v1.7$  over  $Na_v1.2$  ( $IC_{50} = 0.11$   $\mu$ M),  $Na_v1.6$  ( $IC_{50} = 0.16$   $\mu$ M),  $Na_v1.1$  ( $IC_{50} = 0.85$   $\mu$ M),  $Na_v1.4$  ( $IC_{50} = 10$   $\mu$ M),  $Na_v1.3$  ( $IC_{50} = 11$   $\mu$ M) and  $Na_v1.5$  ( $IC_{50} = 25$   $\mu$ M). It likewise exhibits selectivity over a panel of 81 other ion channels, receptors, enzymes, and transporters. PF-05089771 blocks spontaneous firing of inherited erythromelalgia (IEM)-derived iPSC sensory neurons *in vitro*. 1. Alexandrou, Brown, Chapman, *et al.* (2016) *PLoS One* **11**, e0152405. 2. Cao, McDonnell, Nitzsche, *et al.* (2016) *Sci. Transl. Med.* **8**, 335ra56.

#### PF-5175157

This orally bioavailable ACC inhibitor (FW = 405.49 g/mol; CAS 1301214-47-0; Solubility: 50 mM in DMSO), also named 1,4-dihydro-1'-[2-methyl-1*H*-benzimidazol-6-yl]carbonyl]-1-(1-methylethyl)-spiro[5*H*-indazole-5,4'-piperidin]-7(6*H*)-one, targets Acetyl-CoA Carboxylase-1 ( $IC_{50} = 98$  nM) and ACC-2 ( $IC_{50} = 45$  nM). Reduces hepatic and skeletal muscle malonyl-CoA levels in rats. PF-05175157 also inhibits hepatic *de novo* lipogenesis and reduces whole body respiratory exchange ratio in rats. 1. Griffith, Kung, Esler, *et al.* (2014) *J. Med. Chem.* **57**, 10512.

#### PF-5274857

This brain-penetrating Smoothed (Smo) antagonist (FW = 436.96 g/mol; CAS 1373615-35-0), also known as 1-(4-(5-chloro-4-(3,5-dimethylpyridin-2-yl)pyridin-2-yl)piperazin-1-yl)-3-(methylsulfonyl)propan-1-one, potently

and selectively inhibits Hedgehog (Hh) signaling ( $IC_{50} = 5.8$  nM;  $K_i = 4.6$  nM). PF-5274857 elicits robust antitumor activity in a mouse model of medulloblastoma ( $IC_{50} = 8.9$  nmol/L), with down-regulation of Gli1, a marker closely linked to the tumor growth inhibition in patched (+/-) medulloblastoma mice. PF-5274857 also inhibits Smo activity within the brain of primary medulloblastoma mice, improving survival. PF-5274857 is orally available and metabolically stable *in vivo*. **Other Hedgehog inhibitors include:** GANT61, BMS-833923, Purmorphamine, SANT-1, LY2940680, Cyclopamine, LDE225 (or NVP-LDE225, Erismodegib), Vismodegib (GDC-0449) **1.** Rohner, Spilker, Lam, *et al.* (2012) *Mol. Cancer Ther.* **11**, 57.

**PF-6274484**

This EGFR kinase inactivator (FW = 372.78 g/mol; CAS 1035638-91-5; Soluble to 100 mM in DMSO), also named *N*-[4-[(3-chloro-4-fluorophenyl)amino]-7-methoxy-6-quinazoliny]-2-propenamide, targets Epidermal Growth Factor Receptor ( $K_i = 0.14$  nM), inhibiting autophosphorylation of wild-type EGFR ( $IC_{50} = 5.8$  nM;  $k_{inact} = 11$  ms<sup>-1</sup>;  $k_{inact}/K_i = 100$  μM<sup>-1</sup>s<sup>-1</sup>) and mutant EGFR<sup>L858R/T790M</sup> ( $IC_{50} = 6.6$  nM). Although this covalent inhibitor targets a cysteinyl residue in a Michael-type addition reaction, oxidation of the EGFR cysteine nucleophile does not alter catalysis, but has widely varied effects on inhibitor potency, depending on the EGFR context (*e.g.*, oncogenic mutations), type of oxidation (sulfenylation or glutathiolation), and inhibitor architecture. **1.** Schwartz, Kuzmic, Solowiej, *et al.* (2014) *Proc. Natl. Acad. Sci. U.S.A.* **111**, 173.

**PF-6447475**

This potent, brain penetrant and selective LRRK2 inhibitor (FW = 305.44 g/mol; CAS 1527473-33-1), also named 3-[4-(4-morpholinyl)-7H-pyrrolo[2,3-d]pyrimidin-5-yl]benzonitrile, targets Leucine-Rich Repeat Kinase 2,  $IC_{50} = 3$  nM, (encoded by the *PARK8* gene), which phosphorylates Akt1 (Ser-473), suggesting that Akt1 is a convincing candidate for the physiological substrate of LRRK2 (1,2). Disease-associated mutations forms of LRRK2 (including Arg-1441-Cys, Gly-2019-Ser, and Ile-2020-Thr) exhibit reduced interaction with, and phosphorylation of, Akt1, a finding that suggests a possible mechanism for the neurodegeneration caused by LRRK2 mutations. Therapeutic approaches to slow or block the progression of Parkinson disease (PD) do not exist. Given that genetic and biochemical studies implicate α-synuclein and leucine-rich repeat kinase 2 (LRRK2) in late-onset PD. In wild-type rats as well as transgenic [Gly-2019-Ser]-LRRK2 rats that were injected intracranially with adeno-associated viral vectors expressing human α-synuclein in the substantia nigra, those expressing [Gly-2019-Ser]-LRRK2 show exacerbated dopaminergic neurodegeneration and inflammation in response to the overexpression of α-synuclein (2). Both neurodegeneration and neuroinflammation associated with [Gly-2019-Ser]-LRRK2 expression were mitigated by PF-06447475, which provided neuroprotection in wild-

type rats. There are no adverse pathological indications in the lung, kidney, or liver of rats treated with PF-06447475. Pharmacological inhibition of LRRK2 is well tolerated for a 4-week period of time in rats and can counteract dopaminergic neurodegeneration caused by acute α-synuclein overexpression. **1.** Henderson, Kormos, Hayward, *et al.* (2015) *J. Med. Chem.* **58**, 419. **2.** Daher, Abdelmotilib, Hu, *et al.* (2015) *J. Biol. Chem.* **290**, 19433.

**PF-6463922**

This potent, dual ALK/ROS1 inhibitor (FW = 406.41 g/mol; CAS 1454846-35-5), also named (10*R*)-7-amino-12-fluoro-10,15,16,17-tetrahydro-2,10,16-trimethyl-15-oxo-2*H*-4,8-methenopyrazolo[4,3-*h*][2,5,11]benzoxadiazacyclotetradecine-3-carbonitrile, targets the proto-oncogene tyrosine-protein kinase ROS1 ( $K_i < 0.02$  nM) as well as wild-type anaplastic lymphoma kinase ALK<sup>WT</sup> ( $K_i < 0.07$  nM) and its Leu-to-Met mutant ALK<sup>L1196M</sup> ( $K_i$  of = 0.7 nM) (1). PF-06463922 significantly inhibits cell proliferation and induces cell apoptosis in the HCC78 human NSCLC cells harboring SLC34A2-ROS1 fusions and the BaF3-CD74-ROS1 cells expressing human CD74-ROS1 (2). **1.** Johnson, Richardson, Bailey, *et al.* (2014) *J. Med. Chem.* **57**, 4720. **2.** Zou, Engstrom, Li, *et al.* (2013) "PF-06463922, a novel ROS1/ALK inhibitor, demonstrates sub-nanomolar potency against oncogenic ROS1 fusions and capable of blocking the resistant ROS1<sup>G2032R</sup> mutant in preclinical tumor models" *Mol. Cancer Ther.* **12**, Abstract 277.

**(R)-PFI**

This SETD7 inhibitor (FW = 499.52 g/mol; CAS 1627676-59-8; IUPAC: 8-fluoro-1,2,3,4-tetrahydro-*N*-[(1*R*)-2-oxo-2-(1-pyrrolidinyl)-1-[[3-(trifluoromethyl)phenyl]methyl]ethyl]-6-isoquinolinesulfonamide, targets the SET domain containing lysine methyltransferase, or SETD7 ( $K_i = 0.33$  nM;  $IC_{50} = 2$  nM), showing 1000-times selectivity versus other methyltransferases and other non-epigenetic targets. (*R*)-PFI-2 exhibits an unusual cofactor-dependent and substrate-competitive inhibitory mechanism by occupying the substrate peptide binding groove of SETD7, including the catalytic lysine-binding channel, and by making direct contact with the donor methyl group of the cofactor, S-adenosylmethionine. In murine embryonic fibroblasts, (*R*)-PFI-2 treatment phenocopies the effects of Setd7 deficiency on Hippo pathway signaling, via modulation of the transcriptional coactivator Yes-associated protein (YAP) and regulation of YAP target genes. In confluent MCF7 cells, (*R*)-PFI-2 rapidly alters YAP localization, suggesting continuous and dynamic regulation of YAP by the methyltransferase activity of SETD7. **1.** Barsyte-Lovejoy, Li, Oudhoff, *et al.* (2014) *Proc. Natl. Acad. Sci. U.S.A.* **111**, 12853.

**PGE<sub>2</sub>, PGF<sub>2α</sub>, etc., See specific prostaglandin****[D-pGlu<sup>1</sup>,D-Phe<sup>2</sup>,D-Trp<sup>3,6</sup>]-Luteinizing Hormone-Releasing Hormone**

This decapeptide amide (Sequence: D-pGlu-D-Phe-L-Trp-L-Ser-L-Tyr-D-Ala-L-Leu-L-Arg-L-Pro-Gly-NH<sub>2</sub>, where pG is the cyclic pyroglutamate; MW = 1207.35 g/mol), an analogue of the luteinizing hormone-releasing hormone (*i.e.*, gonadotropin releasing hormone), is a substance P antagonist and inhibits sympathetic vasomotor outflow. **1.** Takano, Sawyer, Sanders & Loewy (1985) *Brain Res.* **337**, 357.

## PH 797804

This orally active, potent, and selective p38 $\alpha$ / $\beta$  inhibitor (FW = 477.31 g/mol; CAS 1358027-80-1; Solubility: 50 mM in DMSO), also named (-)-3-[3-bromo-4-[(2,4-difluorophenyl)methoxy]-6-methyl-2-oxo-1(2H)-pyridin-yl]-N,4-dimethylbenzamide, targets p38 mitogen-activated protein kinases, with IC<sub>50</sub> values of 26 and 102 nM for p38 $\alpha$  ( $K_i$  = 5.8 nM; ATP-competitive and readily reversible) and p38 $\beta$ , respectively (1). The latter are signal-transducing enzymes that respond to stress stimuli (e.g., cytokines, ultraviolet irradiation, heat shock, and osmotic shock) and are involved in regulating cell differentiation, apoptosis and autophagy. PH-797804 blocks inflammation-induced production of cytokines and proinflammatory mediators, such as prostaglandin E<sub>2</sub>, at concentrations that parallel inhibition of cell-associated p38 MAP kinase (2). When administered orally, PH-797804 inhibits acute inflammatory responses induced by systemically administered endotoxin in both rat and cynomolgus monkeys (2). It also demonstrates robust anti-inflammatory activity in chronic disease models, significantly reducing both joint inflammation and associated bone loss in streptococcal cell wall-induced arthritis in rats and mouse collagen-induced arthritis. PH-797804 reduces Tumor Necrosis Factor- $\alpha$  (TNF $\alpha$ ) and interleukin-6 production in clinical studies after endotoxin administration in a dose-dependent manner, paralleling inhibition of the target enzyme (2). Low-nanomolar biochemical enzyme inhibition potency correlated with p38 MAP kinase inhibition in human cells and in vivo studies. 1. Selness, Devraj, Devadas, *et al.* (2011) *Bioorg. Med. Chem. Lett.* **21**, 4066. 2. Hope, Anderson, Burnette, *et al.* (2009) *J. Pharmacol. Exp. Ther.* **331**, 882.

## PHA 408

This potent and highly selective, ATP-competitive IKK-2 inhibitor (FW = 560.02 g/mol; CAS 503555-55-3; Soluble in DMSO), also named 8-(5-chloro-2-(4-methylpiperazin-1-yl)isonicotinamido)-1-(4-fluorophenyl)-4,5-dihydro-1H-benzol[g]indazole-3-carboxamide, targets I $\kappa$ B kinase-2 (IC<sub>50</sub> = 40 nM). PHA-408 binds tightly to IKK-2, showing a relatively slow off rate (1). In arthritis-relevant cells and animal models, PHA-408 suppresses inflammation-induced cellular events, including I $\kappa$ B $\alpha$  phosphorylation and degradation, p65 phosphorylation and DNA binding activity, the expression of inflammatory mediators, and joint pathology (1). It selectively inhibits IL-1 $\beta$ - and LPS-induced expression of various inflammatory mediators. PHA-408 inhibits LPS-induced TNF- $\alpha$  production *in vivo* in a rat acute model of inflammation. Significantly, PHA-408 is efficacious in a chronic model of arthritis with no adverse effects at maximally efficacious doses. 1. Mbalaviele, Sommers, Bonar, *et al.* (2009) *J. Pharmacol. Exp. Ther.* **329**, 14.

## PHA-767491

This cyclin kinase-directed inhibitor (FW = 213.24 g/mol; CAS 845714-00-3, 942425-68-5 (HCl)); Solubility: 24 mg/mL DMSO; <1 mg/mL Water;

Formulation: Dissolve in DMSO, and then dilute in saline), named systematically as 2-(pyridin-4-yl)-6,7-dihydro-1H-pyrrolo[3,2-c]pyridin-4(5H)-one, targets Cdc7 and CDK9, with IC<sub>50</sub> values of 10 nM and 34 nM, respectively. PHA-767491 displays approximately 20-times lower inhibition of Cdk1, Cdk2 and GSK3- $\beta$ , 50-times lower for MK2 and Cdk5 and 100-times lower for PLK1 and Chk2. **Cyclin Target Selectivity:** Cdk1 (weak, if any), Cdk2 (weak, if any), Cdk3 (weak, if any), Cdk4 (weak, if any), Cdk5 (weak, if any), Cdk6 (weak, if any), Cdk7 (+++), Cdk8 (weak, if any), Cdk9 (++), Cdk10 (weak, if any). 1. Montagnoli, *et al.* (2008) *Nat. Chem. Biol.* **4**, 357. 2. Yecies, *et al.* (2010) *Blood* **115**, 3304. 3. Natoni, *et al.* (2011) *Mol. Cancer Ther.* **10**, 1624.

## PHA-793887

This cyclin kinase-directed inhibitor (FW = 361.48 g/mol; CAS 718630-59-2, 718630-60-5 (HCl); Solubility: 70 mg/mL DMSO; <1 mg/mL Water; Formulation: Dissolve in 5% dextrose solution), also known as N-(6,6-dimethyl-5-(1-methylpiperidine-4-carbonyl)-1,4,5,6-tetrahydropyrrolo[3,4-c]pyrazol-3-yl)-3-methylbutanamide, targets CDK2, CDK5 and CDK7 with IC<sub>50</sub> values of 8 nM, 5 nM and 10 nM, respectively. **Alternative target:** glycogen synthase-3 kinase- $\beta$  (GSK-3 $\beta$ ). **Cyclin Target Selectivity:** Cdk1 (weak, if any), Cdk2 (+++), Cdk3 (weak, if any), Cdk4 (weak, if any), Cdk5 (+++), Cdk6 (weak, if any), Cdk7 (+++), Cdk8 (weak, if any), Cdk9 (weak, if any), Cdk10 (weak, if any). 1. Brasca, *et al.* (2010) *Bioorg. Med. Chem.* **18**, 1844. 2. Alzani, *et al.* (2010) *Exp. Hematol.* **38**, 259. 3. Pevarello, *et al.* (2004) *J. Med. Chem.* **47**, 3367.

## PHA-848125

This cyclin kinase-directed inhibitor (FW = 460.57 g/mol; CAS 802539-81-7, 802540-32-5 (3HCl), 1253645-38-3 (Maleic acid); Solubility: 90 mg/mL DMSO; <1 mg/mL Water), systematically named N,1,4,4-tetramethyl-8-(4-(4-methylpiperazin-1-yl)phenylamino)-4,5-dihydro-1H-pyrazolo[4,3-h]quinazolin-3-carboxamide, targets cyclin A/CDK2 inhibitor with IC<sub>50</sub> of 45 nM. PHA-848125-treated cells show cell cycle arrest in G<sub>1</sub> and reduced DNA synthesis, accompanied by inhibition of pRb phosphorylation and modulation of other CDK-dependent markers. **Cyclin Target Selectivity:** Cdk1 (weak, if any), Cdk2 (++), Cdk3 (weak, if any), Cdk4 (weak, if any), Cdk5 (weak, if any), Cdk6 (weak, if any), Cdk7 (weak, if any), Cdk8 (weak, if any), Cdk9 (weak, if any), Cdk10 (weak, if any). 1. Brasca, *et al.* (2009) *J. Med. Chem.* **52**, 5152. 2. Albanese, *et al.* (2010) *Mol. Cancer Ther.* **9**, 2243.

## Phaclofen

This (-)-(*R*)-phosphonic acid (FW = 249.63 g/mol; CAS 108351-35-5), systematically named as 3-amino-2-(4-chlorophenyl)propanephosphonic acid, is a GABA<sub>B</sub>  $\gamma$ -aminobutyric acid receptor antagonist (1-3). Although synaptic action of GABA is mediated by bicuculline-sensitive GABA<sub>A</sub> receptors that selectively increase chloride conductance, GABA has a presynaptic inhibitory action that is bicuculline-insensitive and is mimicked by baclofen. This distinctive behavior defines the GABA<sub>B</sub> receptor, allowing one to distinguish them from classic bicuculline-sensitive GABA<sub>A</sub>

receptors. In hippocampal slices, phaclofen (baclofen's phosphonate derivative) is a remarkably selective antagonist of both the postsynaptic action of baclofen and GABA's bicuculline-resistant action (1). Phaclofen selectively abolishes the slow inhibitory postsynaptic potential in pyramidal cells (1). It is ineffective in antagonizing competitively the synaptically-mediated Late Hyperpolarizing Response (LHP) recorded from the same or similar Dorsolateral Septal Nucleus (DLSN) neurons, from which baclofen responses were recorded (3). Such findings support the usefulness of phaclofen as a competitive antagonist of baclofen, and suggest that when larger stimulus intensities are applied, the LHP in the rat DLS may be mediated by a transmitter in addition to GABA (3). Moreover, (-)-(*R*)-phaclofen inhibits the binding of [<sup>3</sup>H]-(*R*)-baclofen to GABA<sub>B</sub> receptor sites on rat cerebellar membranes (IC<sub>50</sub> = 76 μM), whereas (+)-(*S*)-phaclofen is inactive (IC<sub>50</sub> > 1000 μM) (4). 1. ### Phallacidin

This cyclic heptapeptide toxin (FW<sub>free-acid</sub> = 846.92 g/mol; CAS 26645-35-2) from the poisonous green fungus *Amanita phalloides* stabilizes actin filaments and inhibits actin filament depolymerization. NBD phallacidin is a high-affinity, filamentous actin probe consisting of rabbit actin that is conjugated by reacting its thiol group with 4-chloro-7-nitrobenzofurazan, a yellow-green fluorescent dye. NBD phallacidin (Excitation at 465 nm; Emission at 536 nm) selectively stains F-actin in a manner that is superior to antibody staining, preferably in fixed and permeabilized samples. See *Phalloidin* 1. Fechtmeier & Zigmond (1983) *Cell Motil.* **3**, 349.

### Phalloidin

This bicyclic heptapeptide toxin (FW = 788.88 g/mol; CAS 17466-45-4) was first isolated from the poisonous green fungus *Amanita phalloides*. **Primary Mode of Action:** Phalloidin binds preferentially to filamentous actin; little or no binding to globular actin has been detected. such preferential action stimulates actin polymerization, and phalloidin lowers the actin monomer critical concentration by 30x, from 50-100 nM down to 2-3 nM. When present at 1 to 10 concentration ratio of phalloidin to total actin subunits, actin filaments are also greatly stabilized toward depolymerization. **Effects on Actin Filaments:** Cellular processes requiring filament disassembly are likewise inhibited. Depolymerization of F-actin by cytochalasins, potassium iodide, and elevated temperatures are inhibited by phalloidin binding. Because the toxin and its fluorescent derivatives are relatively small, a wide variety of actin-binding proteins can still bind to phalloidin-labeled filaments. Perhaps more significantly, phalloidin-labeled actin filaments retain many of their functional properties, such that phalloidin-labeled, glycerinated muscle fibers can still contract, and labeled actin filaments still move on myosin that has been tethered to solid-phase substrates. Phalloidin can be also be used to assess the relative

concentrations of these two forms of actin as well as a means to label actin filaments in a cell (See *Phallacidin*). 1. Cooper (1987) *J. Cell Biol.* **105**, 1473. 2. ### PhcrTx1 Toxin

This marine peptide toxin (MW = 3476.03 g/mol; *Sequence*: CASQGQ KCKTKSDCCNGMWCAGTRGHTCYKPK) from the sea anemone *Phymanthus crucifer* is a novel Acid-Sensing Ion Channel (ASIC) inhibitor that partially blocks ASIC currents (IC<sub>50</sub> ~100 nM), as well as voltage-gated K<sup>+</sup> currents (or K<sub>v</sub> channels), the latter with much lower potency. PhcrTx1's effects on the peak and steady-state currents were lower than 20% in dorsal root ganglion (DRG) neurons at micromolar concentrations. No significant effect was observed on Na<sup>+</sup> voltage-gated currents in these neurons. Analysis of the cysteine pattern and predicted secondary structure suggest this peptide is likely to have an Inhibitor Cystine Knot scaffold already observed in other spider, scorpions and *Conus* toxins. 1. Rodríguez, Salceda, Garateix, et al. (2013) *Peptides* **53**, 3.

### Phebestin

This bestatin analogue (FW = 441.53 g/mol), known systematically as (2*S*,3*R*)-3-amino-2-hydroxy-4-phenylbutanoyl-L-valyl-L-phenylalanine, isolated from *Streptomyces* inhibits a number of aminopeptidases. **Target(s):** aminopeptidase I1; Jc-peptidase, or Japanese cedar pollen aminopeptidase (1); and membrane alanyl aminopeptidase, or aminopeptidase N (2-4). 1. Noguchi, Nagata, Koganei, et al. (2002) *J. Agric. Food Chem.* **50**, 3540. 2. Nagai, Kojima, Naganawa, et al. (1997) *J. Antibiot.* **50**, 82. 3. Xu & Li (2005) *Curr. Med. Chem. ### Phenacetin

This first-in-class, synthetic antipyretic (FW = 179.22 g/mol; CAS 62-44-2), also known as *N*-(4-ethoxyphenyl)acetamido, was synthesized by American chemist Harmon Northrop Morse in 1897. Phenacetin was used as an analgesic/antipyretic, but was withdrawn from the market in view of adverse effects, including methemoglobinemia and renal failure (1,2). Phenacetin is metabolized to acetaminophen (See *Acetaminophen*). Hydrolysis by arylacetamide deacetylase (or AADAC) and subsequent metabolism by CYP1A2 and CYP2E1 play predominant roles in phenacetin-induced methemoglobinemia (3). Indeed, treatment with eserin, a potent AADAC inhibitor, greatly reduces metabolic hydrolysis of phenacetin as well as the severity of methemoglobinemia (3). 1. Boyd (1970) *Appl. Ther.* **12**, 9. 2. Hinson (1983) *Environ. Health Perspect.* **49**, 71. 3. Kobayashi, Fukami, Higuchi, Nakajima & Yokoi (2012) *Biochem. Pharmacol.* **84**, 1196.

### 1-Phenacyl-2-methylpyridinium Chloride

This cationic pyridinium salt (FW = 247.72 g/mol) inhibits human blood acetylcholinesterase, binding to both the catalytic and the allosteric sites of the enzyme, with K<sub>i</sub> and K<sub>d</sub> values of 6.9 μM and 27 μM, respectively. 1. Skrinjaric-Spoljar, Burger & Lovric (1999) *J. Enzyme Inhib.* **14**, 331.

**Phenamil**

This amiloride derivative (FW = 306.73 g/mol; CAS 2038-35-9), also known as 3,5-diamino-6-chloro-*N*-[imino(phenylamino)methyl]pyrazine carboxamide, irreversibly inhibits amiloride-sensitive Na<sup>+</sup> channels. It is often supplied commercially as the methanesulfonate salt. Na<sup>+</sup> channel blockers, such as phenamil and benzamil, are also explored as a way to counteract the hyperabsorption of NaCl in cystic fibrosis airways. **Target(s):** diamine oxidase (1); Na<sup>+</sup> channels (2,3); and Na<sup>+</sup>-driven flagellar motility (4-9). 1. **9,10-Phenanthrenequinone**

This orange-red diketone (FW = 208.22 g/mol; M.P. = 206–207°C; CAS 84-11-7), also called 9,10-phenanthrenequinone and phenanthraquinone, reacts with the guanidinium group of arginyl residues in peptides and proteins (1). 9,10-Phenanthrenequinone is also an alternative substrate for a number of oxidoreductases (e.g., 20 $\alpha$ -hydroxysteroid dehydrogenase,  $\zeta$ -crystallin, and prostaglandin D<sub>2</sub> 11-ketoreductase). **Target(s):** cAMP-dependent protein kinase (2); Deoxyribonuclease, weakly inhibited (3); and nitric-oxide synthase (4); protein-tyrosine phosphatase (5). 1. Yamada & Itano (1966) *Biochim. Biophys. Acta* **130**, 538. 2. Wang, Ternai & Polya (1994) *Biol. Chem. Hoppe Seyler* **375**, 527. 3. Hoffmann-Ostenhof & Frisch-Niggemeyer (1952) *Monatsh. **Phenanthriplatin**

This potent Pt(II) complex (FW = 505.82 g/mol; CAS 1416900-51-0), also known as *cis*-diamminephenanthridinechloroplatinum(II), penetrates cell membranes either by passive diffusion or carrier-mediated active transport, with the hydrophobic ligand maximizing cellular uptake and making it cytotoxic compared with cisplatin and carboplatin (1). Its molecular structure was designed with based the X-ray structure of RNA polymerase II (Pol II), when stalled at a monofunctional pyriplatin-DNA adduct (1). Phenanthriplatin interacts with guanine residues, forming highly potent, monofunctional DNA adducts. While many Pol II elongation complexes stall after successful addition of CTP opposite the phenanthriplatin-dG adduct in an error-free manner, a few slowly undergo error-prone bypass of the phenanthriplatin-dG lesion, a behavior that resembles DNA polymerases that similarly switch from high-fidelity replicative DNA processing (error-free) to low-fidelity translesion DNA synthesis (error-prone) at DNA damage sites (2). 1. Park, Wilson, Song & Lippard (2012) *Proc. Natl. Acad. Sci. U.S.A.* **109**, 11987. 2. Kellinger, Park, Chong, Lippard & Wang (2013) *J. Am. Chem. Soc.* **135**, 13054.

**1,10-Phenanthroline**

This metal ion chelator (FW<sub>free-base</sub> = 180.21 g/mol; CAS 66-71-7), also called *o*-phenanthroline, is especially effective as a zinc ion chelator. It is a relatively low-affinity reversible inhibitor that acts by chelating active-site metal ions in certain metal-activated and metalloenzymes. Given the fact that active-site metal ions are most often bound by multiple amino acid side-chains, one must consider the likelihood that 1,10-phenanthroline will act slowly in a manner akin to most slow-binding enzyme inhibitors. Another consideration is that the observed inhibitory effect of 1,10-phenanthroline has nothing to do with chelation but is simply a consequence of its hydrophobicity. (See comment under 4,7-Phenanthroline) The inhibitory range is typically 1–5 mM; however, some iron-dependent proteins are reportedly inhibited at 10<sup>-8</sup> M. The reported K<sub>i</sub> values for angiotensin I-converting-enzyme (peptidyl-dipeptidase A), thermolysin, and astacin are 6, 50, and 50 mM for, respectively. In addition to iron and zinc, it will also bind Mn, Co, Ni, Ag, Ru, and Cu. This chelator will also inhibit dioxygen production in photosynthesis and has been reported to exhibit nuclease activity when complexed with copper. The ferrous complex, frequently referred to as Ferroin and available commercially, is used as an indicator in oxidation/reduction systems. 1,10-Phenanthroline is hygroscopic and is usually supplied as the monohydrate (FW = 198.22 g/mol). It has a melting point of 93-94°C (anhydrous melting point = 117°C) and is soluble in about 300 parts water. It is typically prepared as 100-200 mM stock solution using dimethyl sulfoxide (preferred), methanol, or ethanol. *Note:* When testing for the inhibitory effects of 1,10-phenanthroline, a good practice is to also test 1,7-phenanthroline or 4,7-phenanthroline as controls for nonchelating binding effects. Another distinguishing feature is that metal ion resolution by 1,10-phenanthroline is typically time-dependent, whereas binding of non-chelating isomers is rarely time-dependent.

**4,7-Phenanthroline**

This hygroscopic reagent (FW<sub>free-base</sub> = 180.21 g/mol; M.P. = 172-174°C; CAS 230-07-9), is a non-chelating isomer of 1,10-phenanthroline. Before inferring that the action of 1,10-phenanthroline is metal ion chelation, one should also assess the inhibitory effect of this non-chelating isomer. If a similar degree of inhibition is observed with both, one may assume that the effect has nothing to do with chelation an essential metal ion activator. **See also 1,10-Phenanthroline; 1,7-Phenanthroline** **Target(s):** aldehyde dehydrogenase (1); leucyl aminopeptidase, weakly inhibited (2); nitrilase (3); pyroglutamyl-peptidase II, or thyrotropin-releasing-hormone-degrading ectoenzyme (4-6). 1. Hoe & Crabbe (1987) *Exp. Eye Res.* **44**, 663. 2. Cahan, Axelrad, Safrin, Ohmann & Kessler (2001) *J. Biol. Chem.* **276**, 43645. 3. Almatawah, Cramp & Cowan (1999) *Extremophiles* **3**, 283. 4. **Phenazine Methosulfate**

This redox-active reagent (FW = 306.34 g/mol; CAS 299-11-6; E<sub>o</sub>' = +0.080 V, pH = 7 and T = 30°C), also known as *N*-methylphenazonium

methosulfat, is frequently used as an artificial electron acceptor and carrier in studies of redox reactions. The reduced semiquinone, which may be prepared nonenzymatically from NADH or NADPH, is a colorless product (occasionally, a green color is reported) and can be used as an electron donor. This reduced compound is rapidly oxidized by dioxygen and will reduce cytochrome *c*, indophenol dyes, and many other electron acceptors. It is often used with ascorbic acid to determine nitric oxide reductase activity. **Action as a Redox Substrate:** Phenazine methosulfate (MTT) is a synthetic electron acceptor substrate for many enzymes (*e.g.*, succinate dehydrogenase, holine dehydrogenase, glycolate dehydrogenase, polyvinyl-alcohol dehydrogenase, (*R*)-pantolactone dehydrogenase, formate dihydrogenase, isoquinoline 1-oxidoreductase, quinaldate 4-oxidoreductase, aralkylamine dehydrogenase, glycine dehydrogenase (cyanide-forming), trimethylamine dehydrogenase, cytokinin dehydrogenase, and 4-cresol dehydrogenase (hydroxylating). When used in enzyme assays, MTT is converted to formazan, an intensely purple-colored product. To achieve high-sensitivity and a linear dependence, one must use a solubilization solution (usually either dimethyl sulfoxide, an acidified ethanol solution, or a solution of the detergent sodium dodecyl sulfate in diluted hydrochloric acid) to disperse/dissolve the otherwise insoluble formazan to obtain colored suspension/solution. The absorbance of this solution may then be quantified by measuring the wavelength between 500 and 600 nm in a spectrophotometer. The degree of light absorption depends on the solvent. **Cell Viability Assays:** MTT has been widely employed in colorimetric assays for assessing the viability of cells. When tested under defined conditions, NAD(P)H-dependent cellular oxidoreductase enzymes catalyze the conversion of MTT to formazan, the intensity of which indicates cell viability. Other related tetrazolium dyes (including XTT, MTS and the WSTs) are used in conjunction with the intermediate electron acceptor, 1-methoxy phenazine methosulfate (PMS). **Target(s):** ferredoxin:NADP<sup>+</sup> reductase (1); magnesium-protoporphyrin IX monomethyl ester (oxidative) cyclase (2); photophosphorylation (3); progesterone monooxygenase (4); protein-*N*<sup>γ</sup>-phosphohistidine:sugar phosphotransferase (5); stearyl-CoA 9-desaturase (6,7); steroid 9 $\alpha$ -monooxygenase (8); steroid 11 $\beta$ -monooxygenase (9); and testosterone 5 $\alpha$ -reductase (10). 1. ### Phenazone

This antipyretic agent (FW = 188.23 g/mol; CAS 60-80-0;  $pK_a = 1.4$ ; IUPAC Name: 1,2-dihydro-1,5-dimethyl-2-phenyl-3H-pyrazol-3-one), also known as antipyrine, nonselectively inhibits COX-1 and COX-2, showing little anti-inflammatory activity. It was first synthesized in 1884, more than a decade before the much-heralded synthesis of acetylsalicylic acid. **See Antipyretic Agents**

### Phenbenicillin, See Fenbenicillin

### Phencyclidine

This piperidine (FW<sub>free-base</sub> = 243.39 g/mol; CAS 77-10-1; *Symbol*: PCP), commonly known as Angel Dust (1) and systematically as 1-(1-phenylcyclohexyl)piperidine, is a NMDA (*N*-methyl-D-aspartate) antagonist, psychostimulant,  $\sigma$  receptor agonist, and frequent drug of abuse (2-5). Formerly used as a veterinary anesthetic and briefly as a general

anesthetic in humans, phencyclidine is also a powerful hallucinogen. **Mode of Action:** NMDA receptors play important roles in mediating excitatory neurotransmission and are preferentially inhibited by some general anesthetics. Phencyclidine is similar to ketamine in structure and in many of its effects; both produce a dissociative state (**See Ketamine**). Phencyclidine inhibits activation of NMDA receptors (3-5), inducing schizophrenia-like symptoms in healthy individuals and exacerbating pre-existing symptoms in patients with schizophrenia (6). PCP behavioral effects are strongly dose-dependent: low doses (3-5 mg) produce intoxication (characteristics: numbness in the extremities, staggering or unsteady gait, slurred speech, and bloodshot eyes); moderate doses (*e.g.*, 5-10 mg intranasal or 0.01-0.02 mg/kg IM or IV) produce analgesia and anesthesia; and high doses often lead to convulsions. **Pharmacokinetics & Metabolism:** PCP is well absorbed by all routes of administration, but, in cigarette smoke, about half is converted to an inactive thermal degradation product. PCP is highly lipid-soluble, accounting for its tendency to concentrate in fat and brain tissue. The plasma binding of PCP is 65%, and its  $t_{1/2}$  ranges from 7-46 hours, with a 21-hour average. PCP is extensively metabolized to inactive metabolites by a variety of metabolic routes. Benzodiazepines decrease PCP's hypertensive effects and reverse seizure activity. PCP is also an inhibitor of a number of cytochrome P450 systems and a suicide inhibitor of nitric-oxide synthase (7). However, the inhibition of nitric-oxide synthase is not related to the psychotomimetic action of phencyclidine. **Target(s):** Ca<sup>2+</sup>-dependent ATPase (8,9); CYP2B1 (10); K<sup>+</sup> channels, ATP-sensitive (11); nitric-oxide synthase (7); and NMDA-receptor channel (4-6,12). Phencyclidine is a powerful, noncompetitive inhibitor of the nicotinic acetylcholine receptor in a sympathetic nerve cell line, PC-12. In the presence of 1 mM carbamoylcholine, the rate of the receptor-controlled influx of <sup>22</sup>Na<sup>+</sup> is reduced by a factor of 2 by 0.7  $\mu$ M phencyclidine (13,14). **1. ### Phenelzine

This hydrazine (FW = 136.20 g/mol; CAS 51-71-8 and 156-51-4), also known as (2-phenethyl)hydrazine and (2-phenylethyl)hydrazine, is an antidepressant and nonselective monoamine oxidase inhibitor. Phenelzine is often supplied commercially as the sulfate or hydrochloride salt. **Target(s):** alanine aminotransferase (1); 4-aminobutyrate aminotransferase (1); aromatic-L-amino acid decarboxylase (2); cytochrome P450 (3-5); dopamine  $\beta$ -monooxygenase (6); histidine ammonia-lyase (7); monoamine oxidase (2,8-12); taurine dehydrogenase (13); and tyrosine aminotransferase (2,14). **1.** Tanay, Parent, Wong, *et al.* (2001) *Cell. **Phenformin**

This oral, biguanide-class antidiabetic (FW<sub>hydrochloride</sub> = 241.72 g/mol; M.P. = 175-178°C; typically supplied as the water-soluble hydrochloride salt), also known as phenethylbiguanide and phenylethylbiguanide, and named systematically as *N<sup>1</sup>-β-phenethylformamidinyliminourea*, was withdrawn from the U.S. market in 1977 due to high risk of inducing often fatal lactic acidosis. **Target(s)**: cholesterol biosynthesis (1,2); 7-dehydrocholesterol reductase (3); diamine oxidase (4,5); glucose transport (6); insulin (7); pyruvate kinase (8-10); and ubiquinol:cytochrome *c* reductase (11). Phenformin is an activator of AMP-stimulated protein kinase, and like the AMPK activators also induce nucleoli re-organization, with attendant changes in cell proliferation. Among the compounds tested, phenformin and resveratrol had the most pronounced impact on nucleolar organization (12). 1. McDonald & Dalidowicz (1962) *Biochemistry* **1**, 1187. 2. **Phenidone**, See *1-Phenyl-3-pyrazolidone*

**Pheniprazine**, See *β-Phenylisopropylhydrazine*

**Pheniramine**

This antihistamine (FW<sub>free-base</sub> = 240.35 g/mol; CAS 86-21-5; insoluble in water; maleate and *p*-aminosalicylate salts are water-soluble), also known as *N,N*-dimethyl-γ-phenyl-2-pyridinepropanamide, is more frequently abused than other antihistamines relative to its market share. One of the histamine H<sub>1</sub> antagonists with little sedative action, pheniramine is often used in treatment of hay fever, rhinitis, allergic dermatoses, and pruritus. **Target(s)**: H<sub>1</sub> histamine receptor (1,2); and histamine *N*-methyltransferase, mildly inhibited (3). 1. Karadag, Ulugol, Dokmeci & Dokmeci (1996) *Jpn. J. Pharmacol.* **71**, 109. 2. Paton & Webster (1985) *Clin. Pharmacokin.* **10**, 477. 3. Thithapandha & Cohn (1978) *Biochem. Pharmacol.* **27**, 263.

**Phenobarbital**

This barbiturate (FW = 232.24 g/mol; CAS 50-06-6;  $pK_1$  = 7.3 and  $pK_2$  = 11.8; water-soluble), known also as phenobarbitone, luminal, and 5-ethyl-5-phenyl-2,4,6-(1*H*,3*H*,5*H*)-pyrimidinetrione, is a sedative and anticonvulsant that induces the biosynthesis of several proteins. **Key Pharmacokinetic Parameters**: See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s)**: alcohol dehydrogenase, NADP<sup>+</sup>-dependent, or aldehyde reductase (1-5); alkaline phosphatase (6); 1,6-anhydro-D-fructose reductase (7); γ-aminobutyrate aminotransferase (8); cholesterol-5,6-oxide hydrolase (9); glucose-6-phosphatase (10); glucuronate reductase (11); γ-glutamyl transpeptidase, or γ-glutamyltransferase (12,13); glycerol dehydrogenase (14); inositol oxygenase (15); pyrophosphatase, or inorganic diphosphatase (16); and succinate-semialdehyde dehydrogenase (8). 1. **Phenolphthalein**

This common pH-indicating dye and laxative (FW = 318.33 g/mol; CAS 77-09-8;  $pK_a$  = 9.7 at 25°C), named systematically as 3,3-bis(4-hydroxyphenyl)-1(3*H*)-isobenzofuranone, is soluble in ethanol (~1 g/12 mL) and nearly insoluble in water. Phenolphthalein is colorless at pH ≤ 8.2, but turns red at pH ≥ 10.

A typical stock indicator solution is 0.05 g phenolphthalein in 100 mL of 50% v/v ethanol/water. A drop added per 50 mL is sufficient for use as a visual indicator in acid/base titrimetry. **Use as a Laxative**: Phenolphthalein was for many years a key component of several commercial laxatives. Perfusion of phenolphthalein results in significantly reduced water absorption in both ileum and colon. In humans, 30 mg phenolphthalein is the optimum laxative dose. Even so, the typical single oral dose was 30-200

mg for adults and children 12 years of age and older. (It was often also present as an undeclared additive in weight-loss products sold as food supplements.) Although laxatives are infrequently used, some 3-4% of the U.S. population had a lifetime use of a laxative product that exceeded 350 times. Concerns about its potential as a cancer-causing agent and other questions about its effectiveness eventually resulted in its removal from many over-the-counter laxative formulations. **Carcinogenic Potential:** Phenolphthalein is *reasonably anticipated to be a human carcinogen*, based on sufficient evidence of carcinogenicity in experimental animals (1). In humans, it is absorbed from the gastrointestinal tract and undergoes extensive first-pass metabolism in the intestinal epithelium and liver, resulting in almost complete conversion to its glucuronide and consequential elimination in the bile. Aneuploidy is a major cause of human reproductive failure and plays a large role in cancer. Phenolphthalein induces tumors in rodents, but its primary mechanism does not seem to be DNA damage. In heterozygous TSG-p53 mice, PHT induces lymphomas and also micronuclei, many containing kinetochores indicative of chromosome loss (2). The induction of aneuploidy would be compatible with the loss of the normal p53 gene seen in the lymphomas. Phenolphthalein also induces abnormalities in tubulin polymerization and deregulates the centrosome duplication cycle, causing centrosome amplification, often attended by apoptosis (2). **Target(s):** aldo-keto reductases 1C1, 1C2, and 1C4, or dihydrodiol dehydrogenases DD1, DD2, and DD4 (3,4); cytochrome P450 (5); glucose transport (6,7); glucuronosyltransferase (8,9); glutathione S-transferase (10); iodothyronine deiodinase (11); and thymidylate synthase (11-14). 1. *National Toxicology Program Report on Carcinogens Background Document for Phenolphthalein* (1999) Research Triangle Park, 92 pp. 2. #### Phenolphthalein Bisphosphate

This water-soluble reagent (FW = 491.26 g/mol), also known as phenolphthalein diphosphate and phenolphthalein phosphate, is an alternative substrate for phosphomonoesterases (e.g., alkaline phosphatase), as is the monophosphate. Hydrolysis of the phosphate group generates free phenolphthalein which is red in alkaline conditions (1). **Target(s):** inositol 1,4,5-trisphosphate receptors, weakly inhibited (2); phosphoprotein phosphatase (3). 1. Manning, Steinetz, Babson & Butler (1966) *Enzymologia* 31, 309. 2. Richard, Bernier, Boulay & Guillemette (1994) *Can. J. Physiol. Pharmacol.* 72, 174. 3. Polya & Haritou (1988) *Biochem. J.* 251, 357.

#### Phenolphthalein Bissulfate

This water-soluble reagent (FW = 493.45 g/mol), also known as phenolphthalein disulfate, inhibits iduronate 2-sulfatase. It is a weak

alternative substrate for steryl-sulfatase. **Target(s):** arylsulfatase (1); iduronate-2-sulfatase (2); and inositol 1,4,5-trisphosphate receptors, weakly inhibited (3). 1. Sampson, Vergara, Fedor, Funk & Benkovic (1975) *Arch. Biochem. Biophys.* 169, 372. 2. Yutaka, Fluharty, Stevens & Kihara (1982) *J. Biochem.* 91, 433. 3. #### Phenol Red

This pH-indicating dye (FW = 354.38 g/mol; CAS 143-74-8; pK<sub>a</sub> = 7.9; yellow < pH 6.8; red > pH 8.4), also known as phenolsulfonphthalein and sulfophthalein, is a diagnostic aid for evaluating renal function. A typical stock indicator solution is 0.1 g phenol red in 28.2 mL 10 mM NaOH and 221.8 mL water. **Target(s):** aldehyde reductase (1); glutaminase (2,3);  $\gamma$ -glutamyl transpeptidase (4); glutathione S-transferase (5-7); 4-methyleneglutaminase (8); phosphate uptake (9); thromboxane A<sub>2</sub>/prostaglandin H<sub>2</sub> receptor (10); and thyroglobulin iodination (11). 1. #### Phenol N-(5-Salicylato)carbamate, See 5-(Carbophenoxyamino)salicylate

#### Phenolsulfonphthalein, See Phenol Red

#### Phenothiazine

This antiprotozoal agent (FW = 199.28 g/mol; CAS 92-84-2), also known as dibenzothiazine, is a yellow solid that is used as an insecticide and in the chemical synthesis of many pharmaceuticals (e.g., chlorpromazine and thioridazine). Phenothiazine is soluble in benzene and insoluble in chloroform and water. It is also readily oxidized in air. **Target(s):** cGMP phosphodiesterase (1); cholinesterase, or butyrylcholinesterase, K<sub>i</sub> = 31  $\mu$ M (2); 3',5'-cyclic-nucleotide phosphodiesterase (3); pyruvate dehydrogenase complex (4). 1. Filburn, Colpo & Sacktor (1979) *Mol. Pharmacol.* 15, 257. 2. Darvesh, McDonald, Penwell, et al. (2005) *Bioorg. Med. Chem.* 13, 211. 3. #### Phenothiazone

This phenothiazine metabolite (FW = 213.26 g/mol), found in urine and feces, inhibits creatine kinase (1,2) and succinate dehydrogenase (3). 1. Kuby & Noltmann (1962) *The Enzymes*, 2nd ed. (Boyer, Lardy & Myrback,

eds.), 6, 515. 2. Solvonuk, McRae & Collier (1956) *Can. J. Biochem. Physiol.* **34**, 481. 3. Collier & Allen (1941) *J. Biol. Chem.* **140**, 675.

### Phenoxyacetamide

This amide (FW = 151.17 g/mol; CAS 129689-30-1; M.P. = 101-103°C) inhibits soluble epoxide hydrolase,  $K_i = 0.6$  mM (1) and weakly inhibits chymotrypsin,  $IC_{50} \approx 25$  mM (2). Notably, phenoxyacetamide has been used as a pharmacophore to produce small, drug-like molecules that are low- $\mu$ M inhibitors of Type III Secretion System (T3SS) in *Pseudomonas aeruginosa* in assays of T3SS-mediated secretion and translocation (3). 1. Rink, Kingma, Lutje Spelberg & Janssen (2000) *Biochemistry* **39**, 5600. 2. Baker & Hurlbut (1967) *J. Med. Chem.* **10**, 1129. 3. Williams, Torhan, Neelagiri, et al. (2015) *Bioorg. Med. Chem.* **23**, 1027.

### Phenoxyacetic Acid

This acid (FW = 152.15 g/mol), also known as *O*-phenylglycolic acid and phenyloxyacetic acid (FW<sub>free-acid</sub> = 152.15 g/mol; melting point = 98°C) has a  $pK_a$  value of 3.12 at 25°C and exhibits a fungicide activity. **Target(s):** benzoylformate decarboxylase (1); lactate dehydrogenase (2,3); mandelate racemase (4); penicillin amidase, or penicillin V acylase, product inhibition (5). 1. Weiss, Garcia, Kenyon, Cleland & Cook (1988) *Biochemistry* **27**, 2197. 2. Baker (1967) *Design of Active-Site-Directed Irreversible Enzyme Inhibitors*, Wiley, New York. 3. ### Phenoxybenzamine

This tertiary amine (FW<sub>free-base</sub> = 303.83 g/mol; CAS 59-96-1; M.P. = 38-40°C), known systematically as *N*-(2-chloroethyl)-*N*-(1-methyl-2-phenoxyethyl)benzenemethanamine, is a calmodulin antagonist and a nonselective  $\alpha$ -adrenergic antagonist. The free base is soluble in benzene

and the hydrochloride salt is soluble in ethanol and chloroform and sparingly soluble in water. **Target(s):** adenylate cyclase (1);  $\alpha$ -adrenergic receptor (2,3);  $Ca^{2+}$ -dependent cyclic-nucleotide phosphodiesterase (4); calmodulin (5-8); prostaglandin synthase, weakly inhibited (9); and retinyl ester hydrolase (10). 1. ### 2-(3-Phenoxybenzoylamino)benzoic Acid

This benzoic acid derivative (FW = 333.34 g/mol) inhibits *Enterococcus faecalis*  $\beta$ -ketoacyl-[acyl-carrier-protein] synthase III,  $IC_{50} = 2.7$   $\mu$ M (1,2). 1. Nie, Perretta, Lu, et al. (2005) *J. Med. Chem.* **48**, 1596. 2. Ashek, San Juan & Cho (2007) *J. Enzyme Inhib. Med. Chem.* **22**, 7.

### 3-(3-Phenoxybenzoylamino)thiophene-2-carboxylic Acid

This benzoic acid derivative (FW = 338.36 g/mol) inhibits *Enterococcus faecalis*  $\beta$ -ketoacyl-[acyl-carrier-protein] synthase III,  $IC_{50} = 10$   $\mu$ M (1,2). Note that the 2-(3-phenoxybenzoylamino)thiophene-3-carboxylic acid analogue is an even weaker inhibitor,  $IC_{50} = 43$   $\mu$ M. 1. Nie, Perretta, Lu, et al. (2005) *J. Med. Chem.* **48**, 1596. 2. Ashek, San Juan & Cho (2007) *J. Enzyme Inhib. Med. Chem.* **22**, 7.

### 3-(4-Phenoxybenzyl)thiazolidin-2-one

This thiazolidin-2-thione (FW = 285.37 g/mol) inhibits *Escherichia coli*  $\beta$ -ketoacyl-[acyl-carrier-protein] synthase III. The 1,1-dioxide also inhibits. 1. Alhamadsheh, Waters, Huddler, et al. (2007) *Bioorg. Med. Chem. Lett.* **17**, 879.

### 2-[(2-Phenoxybiphenyl-4-ylcarbonyl)amino]benzoic Acid

This aminobenzoic acid derivative (FW = 408.43 g/mol) inhibits *Enterococcus faecalis*  $\beta$ -ketoacyl-[acyl-carrier-protein] synthase III,  $IC_{50} = 56$  nM (1,2). 1. Nie, Perretta, Lu, et al. (2005) *J. Med. Chem.* **48**, 1596. 2. Ashek, San Juan & Cho (2007) *J. Enzyme Inhib. Med. Chem.* **22**, 7.

**Phoxymethylpenicillin, See Penicillin V**

**2(R)-[2-[4-Phenoxyphenyl]ethyl]-4(S)-butylpentanedioic Acid 1-((S)-tert-Butylglycine Methylamide) Amide**

This peptidomimetic (FW = 509.67 g/mol), also known as *N*-[4(*S*)-carboxy-2(*R*)-[2-[4-phenoxyphenyl]ethyl]octanoyl]- $\alpha$ (*S*)-(tert-butyl)glycine methylamide, inhibits gelatinase A, or matrix metalloproteinase 2 and stromelysin 1 or matrix metalloproteinase 3, with  $K_i$  values of 3000 and 200 nM, respectively. 1. Esser, Bugianesi, Caldwell, *et al.* (1997) *J. Med. Chem.* **40**, 1026.

**4-(4-Phenoxyphenylsulfonyl)butane-1,2-dithiol**

This dithiol (FW = 354.50 g/mol) is a slow-binding inhibitor of gelatinase A, or matrix metalloproteinase 2,  $K_i = 0.046 \mu\text{M}$  (1,2), gelatinase B, or matrix metalloproteinase 9,  $K_i = 0.1 \mu\text{M}$  (2), membrane-type matrix metalloproteinase 1, matrix metalloproteinase 14 (2), and stromelysin, or matrix metalloproteinase 3 (2). 1. Rosenblum, Meroueh, Kleinfeld, *et al.* (2003) *J. Biol. Chem.* **278**, 27009. 2. Bernardo, Brown, Li, Fridman & Mobashery (2002) *J. Biol. Chem.* **277**, 11201.

**(4-Phenoxyphenylsulfonyl)methylthiirane**

This thiirane (FW = 306.41 g/mol), also known as matrix metalloproteinase-2/matrix metalloproteinase-9 inhibitor IV (MMP-2/MMP-9 inhibitor IV) and SB-3CT, is a mechanism-based inhibitor of gelatinase A, or matrix metalloproteinase 2,  $K_i = 0.014 \mu\text{M}$  (1,2), gelatinase B, or matrix metalloproteinase 9,  $K_i = 0.6 \mu\text{M}$  (2), membrane-type matrix metalloproteinase 1, matrix metalloproteinase 14 (2), matrilysin,  $K_i = 96 \mu\text{M}$ , stromelysin 1, or matrix metalloproteinase 3,  $K_i = 15 \mu\text{M}$  (2). 1. Rosenblum, Meroueh, Kleinfeld, *et al.* (2003) *J. Biol. Chem.* **278**, 27009. 2. Bernardo, Brown, Li, Fridman & Mobashery (2002) *J. Biol. Chem.* **277**, 11201.

**2-(3-Phenoxy-4-piperidin-1-ylbenzoylamino)benzoic Acid**

This ACPS inhibitor (FW = 415.47 g/mol) targets *Enterococcus faecalis*  $\beta$ -ketoacyl-[acyl-carrier-protein] synthase III,  $\text{IC}_{50} = 0.29 \mu\text{M}$  (1-3). A related analogue with piperazine in place of piperidine is a weaker inhibitor,  $\text{IC}_{50} = 185 \mu\text{M}$ . 1. Castillo & Perez (2008) *Mini Rev. Med. Chem.* **8**, 36. 2. Nie, Perretta, Lu, *et al.* (2005) *J. Med. Chem.* **48**, 1596. 3. Ashek, San Juan & Cho (2007) *J. Enzyme Inhib. Med. Chem.* **22**, 7.

**6-[4-(Phenoxy)piperidin-1-yl]-*N*-(3-methylbutyl)pyridazine-3-carboxamide**

This pyridazine derivative (FW = 365.19 g/mol) inhibits stearyl-CoA 9-desaturase (mouse  $\text{IC}_{50} = 63 \text{ nM}$ ), which catalyzes the rate-limiting step in the cellular synthesis of monounsaturated fatty acids from saturated fatty acids (1). A proper ratio of saturated to monounsaturated fatty acids contributes to membrane fluidity. Alterations in this ratio have been implicated in various disease states including cardiovascular disease, obesity, non-insulin-dependent diabetes mellitus, hypertension, neurological diseases, immune disorders, and cancer. Studies with SCD-1 knockout mice established that these animals are lean and protected from leptin deficiency-induced and diet-induced obesity, with greater whole body insulin sensitivity than wild-type animals. 1. Liu, Lynch, Freeman, *et al.* (2007) *J. Med. Chem.* **50**, 3086.

**Phenoxy-2-propanone, See Phenoxyacetone**

**(-)-Phenserine**

This long-acting AChE inhibitor and  $\text{A}\beta_{25-35}$ -lowering agent (FW = 337.42 g/mol; CAS 101246-66-6), also known as (-)-*N*-phenylcarbamoyl eseroline, is a carbamate analogue of eserine (or physostigmine) that inhibits acetylcholinesterase and is under active investigation for its potential in cholinomimetic therapy to reduce cognitive impairments associated with aging and Alzheimer's Disease. Phenserine is a potent and highly selective AChE inhibitor ( $\text{IC}_{50} = 22 \text{ nM}$ ), displaying 70x greater inhibitory action than observed with butyrylcholinesterase, or BChE ( $\text{IC}_{50} = 1560 \text{ nM}$ ), both *in vitro* and in clinical trials for treatment of Alzheimer's disease (1-5). Compared to physostigmine and tacrine, phenserine appears to be less toxic and robustly enhances cognition in animal models. In rats, phenserine achieves maximum acetylcholinesterase inhibition of 73.5% at 5 min, maintaining high and relatively constant inhibition for >8 hours (6). Phenserine decreased the levels of secreted  $\beta$ -amyloid precursor protein ( $\beta$ -APP) in the cerebrospinal fluid (CSF) of forebrain cholinergic system-lesioned rats, whereas DFP, a relatively non-specific cholinesterase inhibitor, failed to affect CSF levels of secreted  $\beta$ -APP. Such findings suggest that phenserine alters the induction of cortical  $\beta$ -APP mRNAs and increased levels of secreted  $\beta$ -APP in the CSF (7). Phenserine reduces  $\text{A}\beta$  levels by regulating  $\beta$ -APP translation via a recently described iron regulatory element in the 5'-untranslated region of  $\beta$ -APP mRNA that was previously shown to be up-regulated in the presence of interleukin-1 (8). Other dual AChE/ $\text{A}\beta_{25-35}$  inhibitors include: rivastigmine, ladostigil, asenapine, phenserine, amitriptyline, clomipramine, doxepin and desipramine. Posiphen, the better-tolerated (+)-enantiomer of phenserine, is devoid of anticholinesterase action, but represses translation of neural  $\alpha$ -synuclein, a druggable target in the treatment of Parkinson Disease (9). 1. **Phentermine**

This central nervous system stimulant and sympathomimetic agent (FW<sub>free-base</sub> = 149.24 g/mol; CAS 122-09-8 (free-base) and 1197-21-3 (HCl salt); B.P. = 205°C at 750 mmHg), also known as  $\alpha,\alpha$ -dimethylbenzene ethanamine, is a tertiary butylamine that exhibits pharmacologic actions and uses similar to those of dextroamphetamine, has been used most frequently in the treatment of obesity and as an anorexic agent. One example is Qsymia<sup>®</sup>, an extended release formulation of phentermine and topiramate used in weight control. *Note:* Phentermine is classified as a controlled substance. **Target(s):** K<sup>+</sup> channel, voltage-gated, hK<sub>v</sub>1.5 (1); monoamine oxidase, weakly inhibited (2-4). **1.** Perchenet, Hilfiger, Mizrahi & Clement-Chomienne (2001) *J. Pharmacol. Exp. Ther.* **298**, 1108. **2.** Nandigama, Newton-Vinson & Edmondson (2002) *Biochem. Pharmacol.* **63**, 865. **3.** Kilpatrick, Traut & Heal (2001) *Int. J. Obes. Relat. Metab. Disord.* **25**, 1454. **4.** Ulus, Maher & Wurtman (2000) *Biochem. Pharmacol.* **59**, 1611.

**Phentolamine**

This versatile nonselective  $\alpha$ -adrenergic receptor antagonist (FW<sub>free-base</sub> = 281.36 g/mol; CAS 50-60-2 (free base), 65-28-1 (mesylate salt), and 73-05-2 (mono-HCl salt, which is slightly soluble in water (1 g/50 mL water)), known systematically as 3-[4,5-dihydro-1H-imidazol-2-ylmethyl-(4-methylphenyl)amino]phenol, has been used to treat hypertension, hypertensive emergencies, pheochromocytoma, vasospasm associated with Reynaud's Disorder and frostbite. The methanesulfonate salt is also known as Regitine<sup>™</sup>. *Note:* Aqueous solutions are unstable and must be freshly prepared and cannot be stored. **Target(s):**  $\alpha$ -adrenergic receptor (1); K<sup>+</sup> channels, ATP-sensitive, or K<sub>ATP</sub> channels (2-4); and protein kinase C (5,6). **1.** Langer (1998) *Eur. Urol.* **33** Suppl. 2, 2. **2.** Proks & Ashcroft (1997) *Proc. Natl. Acad. Sci. U.S.A.* **94**, 11716. **3.** Dunne (1991) *Brit. J. Pharmacol.* **103**, 1847. **4.** Plant & Henquin (1990) *Brit. (Boyer & Krebs, eds.), **17**, 167.

**Phenylacetaldehyde**

This aldehyde (FW = 120.15 g/mol; CAS 122-78-1; M.P. = 33-34°C; B.P. = 195°C), also known as  $\alpha$ -tolualdehyde and Hyacinthin, is an oily liquid with an odor that is reminiscent of hyacinth. Phenylacetaldehyde is produced in the degradation of L-phenylalanine and is a mechanism-based inhibitor of dopamine  $\beta$ -monoxygenase (1,2). *Note:* Phenylacetaldehyde polymerizes upon standing. **1.** Ator & Ortiz de Montellano (1990) *The Enzymes*, 3rd ed., **19**, 213. **2.** Bossard & Klinman (1986) *J. Biol. Chem.* **261**, 16421.

**2-Phenylacetamidine**

This amidine (FW<sub>free-base</sub> = 134.18 g/mol) inhibits trypsin ( $K_i$  = 15.1 mM) and phenylalanyl-tRNA synthetase ( $K_i$  = 0.23 mM). 2-Phenylacetamidine should not be confused with N-phenylacetamidine (CH<sub>3</sub>C(NH<sub>2</sub>)<sup>+</sup>NHC<sub>6</sub>H<sub>5</sub>). **Target(s):** complement system, guinea pig, weakly inhibited (1); phenylalanyl-tRNA synthetase (2); tryptophan 2-monoxygenase (3); trypsin, weakly inhibited (4). **1.** Baker & Erickson (1969) *J. Med. Chem.* **12**, 408. **2.** Danenberg & Santi (1975) *J. Med. Chem.* **18**, 528. **3.** Emanuele, Heasley & Fitzpatrick (1995) *Arch. Biochem. Biophys.* **316**, 241. **4.** Mares-Guia & Shaw (1965) *J. Biol. Chem.* **240**, 1579.

**1-Phenyl-2-acetamido-3-butanone, See 2-Acetamido-1-phenyl-3-butanone****Phenylacetic Acid**

This phenylalanine-derived metabolite (FW<sub>free-acid</sub> = 136.15 g/mol; CAS 103-82-2 (acid) and 114-70-5 (Na salt); pK<sub>a</sub> = 4.25 at 25°C) has a melting point of 76.5°C, a boiling point of 265.5°C, and is slightly soluble in water (1.6 g per 100 mL at 20°C). It is more soluble in ethanol, chloroform, and diethyl ether. *Note:* Because phenylacetic acid is a precursor of phenylacetone, which in turn is used in the illicit production of methamphetamine, its purchase is regulated in the U.S. **Target(s):** D-amino-acid oxidase (1); decarboxylase (2); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (3,4); carboxypeptidase A (5-11); catechol oxidase (12); Ca<sup>2+</sup>-transporting ATPase (13); choline O-acetyltransferase (14,15); chymotrypsin, weakly inhibited (16,17); glutamate decarboxylase (9); haloacetate dehalogenase (18); (S)-2-hydroxy-acid oxidase (19); hydroxylaminolysis (nonenzymatic) of amino acid esters (20); imidazoleacetate 4-monoxygenase (21,22); (S)-mandelate dehydrogenase (23); mandelate racemase,  $K_i$  = 0.2 mM (24,25); monophenol monoxygenase (9); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (26); penicillin amidase (27-32); phenylalanine 2-monoxygenase (33); pyruvate carboxylase (34,35); stearoyl-CoA 9-desaturase (36); succinate dehydrogenase (37,38); tyrosine aminotransferase (39); tyrosine-ester sulfotransferase (40); and zeatin 9-aminocarboxyethyltransferase (41). **1.** Klein & Austin (1953) *J. **Phenylacetone**

This plant auxin (FW = 134.18 g/mol; oily liquid. M.P. = -16 to -15°C; B.P. = 214°C), also known as 1-phenyl-2-propanone, It is a competitive inhibitor of acetylcholinesterase (1) and a weak inhibitor of chymotrypsin,

$IC_{50} \approx 19$  mM (2). *Note:* Phenylacetone is photosensitive and liberates highly reactive benzyl radicals upon photolysis. Moreover, because phenylacetone is used in the illicit production of methamphetamine, its purchase is regulated in the U.S. 1. Dafforn, Anderson, Ash, *et al.* (1977) *Biochim. Biophys. Acta* **484**, 375. 2. Baker & Hurlbut (1967) *J. Med. Chem.* **10**, 1129.

**Phenylacetonitrile**, *See Benzyl Cyanide*

### Phenylacetyl-CoA

This arylacyl coenzyme A derivative (FW = 785.67 g/mol) is a product of phenylacetyl-CoA synthetase and a substrate for glutamine *N*-phenylacetyltransferase and isopenicillin *N*-acyltransferase. **Target(s):** choline *O*-acetyltransferase (1); glycine acyltransferase (2); and glycine *N*-benzoyltransferase (3). 1. Potempska, Loo & Wisniewski (1984) *J. Neurochem.* **42**, 1499. 2. Webster, Jr. (1981) *Meth. Enzymol.* **77**, 301. 3. Nandi, Lucas & Webster, Jr. (1979) *J. Biol. Chem.* **254**, 7230.

### Phenylacetylene

This alkyne (FW = 102.14 g/mol; CAS 536-74-3; M.P. = -44.8°C; B.P. = 142.4°C), known systematically as ethynylbenzene, inhibits ammonia monooxygenase (1), CYP2B1, *or* cytochrome P450 2B1 (2), methane monooxygenase, soluble (1), phenol 2-monooxygenase (3), and toluene 4-monooxygenase (4). 1. ### D-Phenylalanine

This aromatic amino acid (FW = 165.19 g/mol; CAS 673-06-3) is the enantiomer of the proteogenic amino acid, L-phenylalanine. D-Phenylalanine occurs in a number of antibiotics, including gramicidin S, tyrocidin A, and bacitracin A. **See L-Phenylalanine** **Target(s):** alkaline phosphatase, weakly inhibited (1); aminoacylase (2); aminopeptidase B, weakly inhibited (3); carboxypeptidase A (4-10); carboxypeptidase C, *or* carboxypeptidase Y (11); neprilysin, *or* enkephalinase (12-14); phenylalanine ammonia-lyase (15-20); phenylalanine dehydrogenase (21); phenylalanine 2-monooxygenase (22); phenylalanyl-tRNA synthetase (23); pyruvate kinase, Co(II)-substituted (24); tryptophan 2-monooxygenase (25); tyrosine phenol-lyase (26); and urease (27,28). 1. ### L-Phenylalanine

This aromatic amino acid (FW = 165.19 g/mol; CAS 63-91-2;  $pK_1 = 2.20$  and  $pK_2 = 9.31$  at 25°C; decomposes at 283-284°C), named systematically as (*S*)-2-amino-3-phenylpropanoic acid and symbolized by Phe and F) is one of the twenty proteogenic amino acids. Phenylalanine is nutritionally essential in the diets of mammals. The L-stereoisomer has a specific rotation of  $-4.47^\circ$  at 25°C of the D line for 1.0-2.0 g/100 mL in 5 M HCl ( $-34.5^\circ$  in distilled water). It is soluble in water (2.96 g/100 mL at 25°C; 4.46 g/100 mL at 50°C; and 6.62 g/100 mL at 75°C). L-Phenylalanine is very slightly soluble in ethanol and methanol and insoluble in diethyl ether. The solubility of the racemic mixture in water is 1.411 g/100 mL at 25°C (3.708 g/100 mL at 75°C). This aromatic amino acid has both useful absorbance and fluorescent properties. It absorbs light in the ultraviolet region of the spectrum ( $\lambda_{max} = 257.5$  nm with  $\epsilon = 195$  M $^{-1}$ cm $^{-1}$  in 0.1 M HCl). DL-Phenylalanine, which has a sweetish taste, is unstable in alkaline solutions. Approximately three-fourths of the amino acid will decompose in five hours at 110-115°C in a sealed ampule in 5 M NaOH. **Role in Phenylketonuria:** The autosomal recessive disorder Phenylketonuria (PKU) is caused by mutations in the phenylalanine hydroxylase (*PAH*) gene, leading to childhood mental retardation by exposing neurons to cytotoxic phenylalanine (Phe) levels. Although many of the effects of PKU-associated Phe accumulation are indirect (*e.g.*, decreased creatine kinase activity, deficient myelin production, and reduced dopamine synthesis), high Phe concentrations also trigger apoptosis by activating the mitochondria-initiated intrinsic pathway through the RhoA/Rho-associated kinase pathway (140) and through the Fas receptor (FasR)-mediated cell death receptor pathway (141). **Target(s):** acetylcholinesterase, inhibited by DL- and L-phenylalanine (1,100); agaritine  $\gamma$ -glutamyltransferase (132); alkaline phosphatase, also inhibited by DL-phenylalanine (3-7,86-91); D-amino-acid oxidase (8); 2-aminohexano-6-lactam racemase, weakly inhibited (48); aminopeptidase B, weakly inhibited (77,78); apyrase (9,10); arginase, weakly inhibited (11); argonate dehydrogenase, *or* cyclohexadienyl dehydrogenase (12); arylformamidase, weakly inhibited (69); asparagine:oxo-acid aminotransferase (103,104); aspartokinase III, weakly inhibited (13); benzoate 4-monooxygenase (136); carboxypeptidase A (72,73); carboxypeptidase C, *or* carboxypeptidase Y (74); catechol oxidase (14,15); chorismate mutase (16-22); cystathionine  $\gamma$ -lyase, *or* cysteine desulfhydrase, mildly inhibited by racemic mixture (23); cystinyl aminopeptidase, *or* oxytocinase (79); cytosol alanyl aminopeptidase (2,75,76); 3-deoxy-7-phosphoheptulonate synthase, *or* 3-deoxy-D-arabino-heptulosonate-7-phosphate synthetase (24,25,108-121); dimethylglycine *N*-methyltransferase, weakly inhibited (125);  $\beta$ -glucosidase (83); hemoglobin S polymerization (26,27); (*S*)-2-hydroxy-acid oxidase (28); 2-isopropylmalate synthase (29); kynurenine:oxoglutarate aminotransferase (105-108); lactate 2-monooxygenase (138); membrane alanyl aminopeptidase, *or* aminopeptidase N (80-82); Na $^+$ /K $^+$ -exchanging ATPase (68); ornithine (lysine) transaminase, weakly inhibited (102); pepsin, weakly inhibited (30); 4-phytase (85); polyphenol oxidase (127,128); prephenate dehydratase (16,17,22,31-33,49-57); prephenate dehydrogenase (34); procollagen-lysine 5-dioxygenase, weakly inhibited (137); propionyl-CoA carboxylase (35); pyruvate kinase (36-39,93-101); sarcosine/dimethylglycine *N*-methyltransferase, weakly inhibited (125); shikimate kinase (40); starch phosphorylase (122,123); thermolysin,  $K_i = 15.6$  mM

- (70,71); tryptophanase, or tryptophan indole-lyase (41,42,63-67); tryptophan 5-monooxygenase (43,44,130-133); tyrosinase, or monophenol monooxygenase (45,126-129); tyrosine 3-monooxygenase (46,47,132,134, 135); tyrosine phenol-lyase (58-62); and tyrosine-phosphatase (84); 3-deoxy-D-arabino-heptulosonate 7-phosphate synthase (DAH7PS), *Neisseria meningitidis*, allosteric (139). 1. ### β-Phenyl-β-alanine

This β-amino acid (FW = 165.19 g/mol), also known as 3-amino-3-phenylpropionic acid, inhibits alkaline phosphatase (1,2), GABA<sub>B</sub> receptor (3,4), and gramicidin S biosynthesis (5-7). 1. Fernley (1971) *The Enzymes*,

#### L-Phenylalanine Chloromethyl Ketone

This halomethyl ketone, also known as (*S*)-3-amino-1-chloro-4-phenyl-2-butanone (FW<sub>free-base</sub> = 197.66 g/mol), inhibits leucyl aminopeptidase. (See also *N*-(*p*-Tosyl-L-phenylalanine Chloromethyl Ketone) **Target(s)**: leucyl aminopeptidase (1,2); phenylalanine racemase, ATP-hydrolyzing (3); tripeptidyl-peptidase I (4); and Tyr/Phe transport protein (5). 1. Hanson & Frohne (1976) *Meth. Enzymol.* **45**, 504. 2. Fittkau (1972) *Acta Biol. Med. Ger.* **28**, 259. 3. Nguyen Huu, von Dungen & Kleinkauf (1976) *FEBS Lett.* **67**, 75. 4. Vines & Warburton (1998) *Biochim. Biophys. Acta* **1384**, 233. 5. Hartman (1977) *Meth. Enzymol.* **46**, 130.

#### Phenylalanine Hydroxamate

This amino acid hydroxamate (FW<sub>free-base</sub> = 180.21 g/mol) inhibits atrolysin A (1), bacterial leucyl aminopeptidase, inhibited by both L- and DL-phenylalanine hydroxamate (2,3), chorismate mutase (4), and vibriolysin (5). 1. Fox, Campbell, Beggerly & Bjarnason (1986) *Eur. J. Biochem.* **156**, 65. 2. Baker, Wilkes, Bayliss & Prescott (1983) *Biochemistry* **22**, 2098. 3. Wilkes & Prescott (1983) *J. Biol. Chem.* **258**, 13517. 4. Sugimoto & Shiio (1980) *J. Biochem.* **88**, 167. 5. Wilkes, Bayliss & Prescott (1988) *J. Biol. Chem.* **263**, 1821.

#### L-Phenylalanine β-Naphthylamide

This amino acid amide (FW<sub>free-base</sub> = 290.36 g/mol) inhibits *Escherichia coli* phenylalanyl-tRNA synthetase:  $K_i = 0.41$  mM (1) and tyramine *N*-feruloyltransferase (2). 1. Santi & Danenberg (1971) *Biochemistry* **10**, 4813. 2. Negrel & Javelle (2001) *Phytochemistry* **56**, 523.

#### L-Phenylalaninol Adenylate

This aminoacyl adenylate analogue (FW = 480.42 g/mol), also known as adenosine 5'-*O*-(2(*S*)-amino-3-phenylpropyl)phosphate, has a methylene group substituted for the carbonyl group and is a competitive inhibitor of phenylalanyl-tRNA synthetase (1-3). 1. Moor, Lavrik, Favre & Safo (2003) *Biochemistry* **42**, 10697. 2. Lavrik, Moor & Nevinsky (1978) *Bioorg. Khim.* **4**, 1480. 3. Hertz & Zachau (1973) *Eur. J. Biochem.* **37**, 203.

#### L-Phenylalanyl-L-alanine

This dipeptide (FW = 236.27 g/mol; Sequence: FA), inhibits alanine carboxypeptidase, also alternative substrate (1) and dipeptidyl-peptidase IV2; neprilysin,  $K_i = 5.5$  μM (3,4), and vibriolysin (5). 1. Levy & Goldman (1969) *J. Biol. Chem.* **244**, 4467. 2. Bella, Jr., Erickson & Kim (1982) *Arch. Biochem. Biophys.* **218**, 156. 3. Marie-Claire, Ruffet, Antonczak, et al. (1997) *Biochemistry* **36**, 13938. 4. Dion, Cohen, Crine & Boileau (1997) *FEBS Lett.* **411**, 140. 5. Wilkes, Bayliss & Prescott (1988) *J. Biol. Chem.* **263**, 1821.

#### L-Phenylalanyl-L-alanine Methyl Ester

This dipeptide ester (FW<sub>free-base</sub> = 250.30 g/mol), abbreviated by FA-OME, inhibits rabbit muscle pyruvate kinase (ATP:pyruvate 2-*O*-phosphotransferase, EC 2.7.1.40), as analyzed with the Yagi-Ozawa equation. Straight-line plots obtained for L-phenylalanine + L-alanine and L-phenylalanine + L-phenylalanyl methyl ester (PheAlaOMe), indicative of competition for common sites. Parabolic plots for 2-phosphoglycerate and L-phenylalanine or PheAlaOMe suggest a lack of competition between these compounds. Biphasic concave plots were obtained for 2-phosphoglycerate and L-1-amino-2-phenylethyl phosphonic acid (PnPhe), and mixtures of inhibitory (L-phenylalanine, PheAlaOMe) and activatory (PnPhe, L-alanine and L-1-aminoethyl phosphonic acid (PnAla)) amino acid derivatives. Such non-classical Yagi-Ozawa plots suggest the existence of distinct regulatory sites for inhibitory and activatory ligands. 1. Izbicka-Dimitrijevic, Dimitrijevic & Kochman (1982) *Biochim. Biophys. Acta* **703**, 101.

#### L-Phenylalanyl-L-alanyl-L-alanine Chloromethyl Ketone

This halomethyl ketone (FW = 340.83 g/mol), abbreviated by FAA-cmk, inhibits tripeptidyl-peptidase I, which cleaves tripeptides from synthetic substrates provided that the N-terminus is unsubstituted and the amino acid in the P<sub>1</sub> position is not charged. The enzyme also cleaves small peptides (angiotensin II and glucagon) releasing tripeptides but does not appear to demonstrate any preference for amino acids on either side of the cleavage site. The peptidase was potently inhibited by a series of substrate-based tripeptidyl chloromethyl ketones ( $K_i$  values ranging from 10-100 nM). Inhibition was rapid and reversible, a mode of inhibition that differs from chloromethyl ketones interactions with cysteine or serine peptidases. These tripeptidyl chloromethyl ketones were also inhibitors of bone resorption using an in vitro assay suggesting that a tripeptidyl peptidase is involved in the degradation of bone matrix proteins. 1. Vines & Warburton (1998) *Biochim. Biophys. Acta* **1384**, 233.

#### D-Phenylalanyl-3,4-dehydro-L-prolyl-L-arginine Chloromethyl Ketone

This halomethyl ketone (FW = 417.53 g/mol) inhibits activated protein C, or blood coagulation factor XIV, a serine protease that plays a pivotal role in regulating anticoagulation, inflammation, and cell death, as well as maintaining the permeability of blood vessel walls in humans. Activated protein C (APC) proteolytically inactivates Factor Va and Factor VIIIa. Unlike thrombin, APC accommodates large hydrophobic residues such as phenylalanine and leucine in the P<sup>2</sup> position. In the P<sup>3</sup> position, the enzyme prefers an apolar D-amino acid residue. 1. Stone & Hofsteenge (1985) *Biochem. J.* **230**, 497.

#### L-Phenylalanylglycine

This dipeptide (FW = 206.24 g/mol; Sequence: FG) inhibits cytochrome c aggregation (1),  $\gamma$ -glutamyl transpeptidase (2,3), neprilysin, IC<sub>50</sub> = 30.2  $\mu$ M (4), and peptidyl-dipeptidase A (5). 1. La Rosa, Milardi, Amato, Pappalardo & Grasso (2005) *Arch. Biochem. Biophys.* **435**, 182. 2. Allison (1985) *Meth. Enzymol.* **113**, 419. 3. Thompson & Meister (1977) *J. Biol. Chem.* **252**, 6792. 4. Dion, Cohen, Crine & Boileau (1997) *FEBS Lett.* **411**, 140. 5. Kawamura, Kikuno, Oda & Muramatsu (2000) *Biosci. Biotechnol. Biochem.* **64**, 2193.

#### L-Phenylalanyl-L-norleucyl-statiny-L-alanyl-statine Methyl Ester

This pepstatin-like peptidomimetic (FW<sub>free-base</sub> = 677.88 g/mol; Sequence: Phe-Nor-(Sta)-Ala-(Sta)-CH<sub>3</sub>, where Sta = (S,S)-statine), also known as (3S,4S)-4-amino-3-hydroxy-6-methylheptanoate, inhibits renin, IC<sub>50</sub> = 7.7  $\mu$ M. 1. Guégan, Diaz, Cazaubon, et al. (1986) *J. Med. Chem.* **29**, 1152.

#### D-Phenylalanyl-L-phenylalanyl-L-arginine Chloromethyl Ketone

This tripeptide halomethyl ketone (FW<sub>free-base</sub> = 501.03 g/mol; Sequence: FFR-cmk) inhibits a number of proteinases, including coagulation factor VIIa (1,2), coagulation factor XIIa (3), gingipain R (4,5), mouse  $\gamma$ -nerve growth factor (6), plasma kallikrein (3,6), plasmin (3), activated protein C (7), thrombin (3,6), tissue kallikrein (6), u-plasminogen activator, or urokinase (8). 1. Persson, Bak & Olsen (2001) *J. Biol. Chem.* **276**, 29195. 2. Pike, Brzozowski, Roberts, Olsen & Persson (1999) *Proc. Natl. Acad. Sci. U.S.A.* **96**, 8925. 3. Hayashi, Salomon & Hugli (2002) *Int. Immunopharmacol.* **2**, 1667. 4. Eichinger, Beisel, Jacob, et al. (1999) *EMBO J.* **18**, 5453. 5. Chao (1983) *J. Biol. Chem.* **258**, 4434.

#### L-Phenylalanyl-L-phenylalanyl-L-arginine Chloromethyl Ketone

This tripeptide halomethyl ketone FFR-cmk (FW<sub>free-base</sub> = 501.03 g/mol), irreversibly inhibits a number of proteinases, including coagulation factor VIIa (1), coagulation factor XIIa (2), mouse  $\gamma$ -nerve growth factor (3), plasma kallikrein (3,4), activated protein C (5), and tissue kallikrein (6). 1. Morrissey (1998) in *Handb. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.), p. 161, Academic Press, San Diego. 2. Silverberg & Kaplan (1988) *Meth. Enzymol.* **163**, 68. 3. Enzymol.* **163**, 128.

#### D-Phenylalanyl-L-prolyl-L-arginal

This tripeptide aldehyde (FW<sub>free-base</sub> = 402.50 g/mol; unstable in neutral aqueous solutions) inhibits a number of proteinases, including plasmin (1), protein-glutamate methyltransferase (2), thrombin (1,3), and urokinase, or u-plasminogen activator (1). 1. Bajusz, Széll, Barabás & Bagdy (1982) *Folia Haematol. Int. Mag. Klin. Morphol. Blutforsch.* **109**, 16. 2. Veeraragavan & Gagnon (1987) *Biochem. Biophys. Res. Commun.* **142**, 603. 3. Bajusz, Szell, Bagdy, et al. (1990) *J. Med. Chem.* **33**, 1729.

#### D-Phenylalanyl-L-prolyl-L-arginine Chloromethyl Ketone

This halomethyl ketone containing tripeptide (FW<sub>free-base</sub> = 450.97 g/mol) inhibits a number of proteinases, including batroxobin (1,2), cancer procoagulant (3), clostripain (4), coagulation factor IXa (5), coagulation factor XIIa (6), limulus clotting factor C (7,8) plasmin (9), activated protein C (10), snake venom factor V activator, or thrombocytin (11), thrombin (12-15), and t-plasminogen activator (7,16). 1. #### L-Phenylalanyl-L-prolyl-L-arginine Chloromethyl Ketone

This tripeptide halomethyl ketone FPR-cmk (FW<sub>free-base</sub> = 450.97 g/mol), inhibits gingipains K and R. The arginine-specific enzyme was found to be a high-molecular-mass gingipain, formed by 50-kDa gingipain complexed to a 44-kDa hemagglutinin. This complex is believed to play a role in the uptake of hemin, a vital metabolite for *Pseudomonas gingivalis*. **1**. Pike, McGraw, Potempa & Travis (1994) *J. Biol. Chem.* **269**, 406.

#### D-Phenylalanyl-L-prolyl-L-boroarginine

This boroarginine-containing tripeptide (FW<sub>dihydrochloride</sub> = 491.23 g/mol) is a potent inhibitor of thrombin,  $K_i < 1$  pM, and a weaker inhibitor of plasma kallikrein,  $K_i = 0.6$  nM, coagulation factor Xa,  $K_i = 8.2$  nM, and t-plasminogen activator,  $K_i = 2.3$  nM. **1**. Kettner, Mersinger & Knabb (1990) *J. Biol. Chem.* **265**, 18289.

#### L-Phenylalanyl-L-seryl-L-arginyl-L-phenylalanyl-L-leucyl-L-asparaginyl-L-lysyl-L-glutamyl-L-proline

This nonapeptide (Sequence: FSRFLNKQP; MW = 1136.32 g/mol), corresponding to a sequence in the phosphotransferase recognition site in cathepsin A, inhibits UDP-N-acetylglucosamine:lysosomal-enzyme N-acetylglucosaminophosphotransferase,  $K_i = 0.45$  mM. **1**. Lukong, Elsliger, Mort, Potier & Pshezhetsky (1999) *Biochemistry* **38**, 73.

#### 4-N-Phenylamino-5-phenyl-7-(5'-deoxy-4'-C-methyl-β-D-ribofuranosyl)pyrrolo[2,3-d]pyrimidine

This tubercidin analogue (FW = 416.48 g/mol) inhibits human adenosine kinase,  $IC_{50} = 4$  μM. Because the use of adenosine receptor agonists is plagued by dose-limiting cardiovascular side effects, there is great interest in developing adenosine kinase inhibitors (AKIs) as a means for raising

steady-state adenosine concentrations. **1**. Boyer, Ugarkar, Solbach, *et al.* (2005) *J. Med. Chem.* **48**, 6430.

#### 4-N-Phenylamino-5-phenyl-7-(β-D-erythro-furanosyl)pyrrolo[2,3-d]pyrimidine

This tubercidin analogue (FW = 388.43 g/mol) inhibits human adenosine kinase,  $IC_{50} = 4$  nM. An endogenous neuromodulator when produced in the central and peripheral nervous systems, adenosine has anticonvulsant, anti-inflammatory, and analgesic properties. Even so, efforts to use adenosine receptor agonists have been limited by dose-limiting cardiovascular side effects. The use of adenosine kinase inhibitors (AKIs) is yet another potential route to prevent seizures in the absence of adenosine's overt cardiovascular side effects. **1**. Boyer, Ugarkar, Solbach, *et al.* (2005) *J. Med. Chem.* **48**, 6430.

#### 17-Phenyl-(3α,5α)-androst-16-en-3-ol

This selective neurosteroid antagonist (FW = 350.54 g/mol; CAS 694438-95-4; Soluble to 25 mM in DMSO and to 50 mM in ethanol), also known as 17-PA, targets neurosteroid potentiation (1) and directly gates GABA<sub>A</sub> receptors (2). 17-PA inhibition was also useful in demonstrating that ethanol modulates the interaction of the endogenous neurosteroid allopregnanolone with the  $\alpha_1\beta_2\gamma_2$ L GABA<sub>A</sub> receptor. 17-PA selectively reduces the effects of 5α-reduced steroids compared to 5β-reduced steroids and displays no effect on potentiation evoked by barbiturates and benzodiazepines (2). It also attenuates 3α,5α-THP-induced loss of righting reflex and total sleep time, following intracerebroventricular administration in rats (3). **1**. Mennerick, *et al.* (2004) *Mol. Pharmacol.* **65**, 1191. PMID: 15102947. **2**. Akk, *et al.* (2007) *Mol. Pharmacol.* **71**, 461. **3**. Kelley, *et al.* (2007) *Eur. J. Pharmacol.* 572 94.

#### N-Phenylanthranilate (Phenylanthranilic Acid)

This acid (FW<sub>free-acid</sub> = 213.24 g/mol), also known as diphenylamine-2-carboxylic acid, targets the channel-conductance-controlling ATPase, or cystic-fibrosis membrane-conductance-regulating protein (1,2). **1**. Kogan, Ramjeesingh, Huan, Wang & Bear (2001) *J. Biol. Chem.* **276**, 11575. **2**. McDonough, Davidson, Lester & McCarty (1994) *Neuron* **13**, 623.

#### Phenylarsine Oxide

This arsenical (FW = 168.03 g/mol; CAS 8052-79-7; M.P. = 144-146°C), also known as phenylarsenoxide and oxophenylarsine, reacts with neighboring cysteinyl residues within peptides and proteins. Although enzyme inhibition by phenylarsinoxides is taken to indicate the presence of functionally important neighboring thiols, such is not always the case. For example, arginyl-tRNA:protein transferase (or arginyltransferase) is inhibited by phenylarsine oxide by a thiol-independent mechanism (1). Phenylarsine oxide is a cell-permeant protein-tyrosine phosphatase inhibitor. Phenylarsine oxide stimulates 2-deoxyglucose transport in insulin-resistant human skeletal muscle and activates p56<sup>lck</sup> protein-tyrosine kinase. In addition, it blocks TNF- $\alpha$ -dependent activation of NF- $\kappa$ B in human myeloid ML-1a cells. **Target(s):** acetate kinase (2,3); alcohol dehydrogenase, yeast (4,5); arginyltransferase, or arginyl-tRNA:protein transferase (1); aspartate ammonia-lyase (6,7); Ca<sup>2+</sup>-dependent ATPase (8); calcineurin (9,10); carboxylesterase (68); caspases (11); choline oxidase (12); dipeptide/proton cotransport system (13); diphospho-mevalonate decarboxylase (63); glucose transporter trafficking (14); glucose transport, insulin-stimulated (15-17); glyceraldehyde-3-phosphate dehydrogenase, or acetylphosphatase activity (18); D- $\beta$ -hydroxybutyrate dehydrogenase (19); 3-hydroxy-3-methylglutaryl-CoA synthase, weakly inhibited (74); inositol 1,2,3,5,6-pentakisphosphate 5-phosphatase (20); insulin activation of phosphatidylinositol 3'-kinase (21);  $\alpha$ -ketoglutarate oxidase (22); lactose carrier (23); malate dehydrogenase, or malate oxidase (22); morphine 6-dehydrogenase (24); NADH oxidase (25,26); NADPH oxidase (27-31); Na<sup>+</sup>/H<sup>+</sup> exchanger (32); NF- $\kappa$ B activation (33-35); nicotinamide-nucleotide transhydrogenase (36,37); nucleoside-triphosphatase (64); oxidative phosphorylation (38,39); pantetheine hydrolase (65); phosphate uptake (40); phosphatidylcholine:sterol O-acyltransferase, or LCAT (75); 1-phosphatidylinositol 4-kinase (41-44,70-73); phospholipase C $\gamma$  (45); protein-tyrosine-phosphatase (46,47,66,67); pyruvate dehydrogenase (48); pyruvate oxidase (49,50); retinol dehydrogenase (51-53); RhoA GTPase (54); rhodanese, or thiosulfate sulfurtransferase (55); squalene monooxygenase, or squalene epoxidase (56); succinate oxidase, or succinate dehydrogenase (22,57); system A amino acid transporter (58); tubulin polymerization, or microtubule assembly (59); tyrosine-ester sulfotransferase, or aryl sulfotransferase IV (89); ubiquitin-conjugating enzyme E2-230K (60); and urease (61,62). 1. #### N<sup>-</sup>(4-Phenylbenzoyl)-syn-(2-(3-aminobenzyl)-3-trans-styryl)- $\beta$ -alanine

This substituted  $\beta$ -alanine (FW = 503.60 g/mol) inhibits coagulation factor Xa, IC<sub>50</sub> = 2.7  $\mu$ M, thrombin, IC<sub>50</sub> = 7.7  $\mu$ M, and trypsin, IC<sub>50</sub> = 22  $\mu$ M, and its methyl ester also inhibits these three enzymes, with IC<sub>50</sub> values of 0.11, 18, and 5.3  $\mu$ M, respectively. 1. Klein, Czekaj, Gardner, et al. (1998) *J. Med. Chem.* **41**, 437.

#### N<sup>+</sup>-(3-Phenylbenzoyl)-L-boroarginine O,O-(+)-pinanediol Ester

This boronate ester (FW<sub>hydrochloride</sub> = 524.90 g/mol) inhibits thrombin and trypsin, with K<sub>i</sub> values of 110 and 7.4 nM, respectively. The corresponding 4-phenylbenzoyl analogue inhibits thrombin and trypsin, with K<sub>i</sub> values of 0.94 and 33 nM, respectively. 1. Quan, Wityak, Dominguez, et al. (1997) *Bioorg. Med. Chem. Lett.* **7**, 1595.

**2(R)-[2-(4'-Phenylbiphenyl-4-yl)ethyl]-4(S)-(n-butyl)-1,5-pentanedioic Acid 1-( $\alpha$ (S)-tert-Butylglycine Methylamide) Amide**

This protease inhibitor (FW = 570.77 g/mol), known systematically as 2(R)-[2-[4-(4-phenylphenyl)phenyl]ethyl]-4(S)-butylpentanedioic acid 1-((S)-tert-butylglycine methylamide) amide, inhibits gelatinase A, or matrix metalloproteinase 2, and stromelysin 1, or matrix metalloproteinase 3, with  $K_i$  values of 84 and 39 nM, respectively. 1. Esser, Bugianesi, Caldwell, et al. (1997) *J. Med. Chem.* **40**, 1026.

**2-Phenyl-5-(4-biphenyl)-1,3,4-oxadiazole, See 5-(4-Biphenyl)-2-phenyl-1,3,4-oxadiazole**

**Phenylboronic Acid**

This arylboronic acid (FW = 121.93 g/mol; CAS 98-80-6), also known as benzenboronic acid, phenylboric acid, and phenylboron dihydroxide, inhibits a number of serine-dependent enzymes. *Note:* Commercial sources typically contain varying amounts of phenylboronic anhydride, and prolonged storage results in the formation of significant amounts of phenylboroxide. **Target(s):** aminoacylase (1); *Aspergillus melleus* semi-alkaline protease, identical or closely related to oryzin (2); bacterial leucyl aminopeptidase (21); cholesterol esterase, or sterol esterase,  $K_i$  = 36  $\mu$ M (3-5,23); chymotrypsin (19); cutinase (6,22); diacylglycerol lipase (7);  $\beta$ -lactamase (8); lecithin:cholesterol acyltransferase, or LCAT (9); lipase, or triacylglycerol lipase (10-13); lipoprotein lipase (5,14); oryzin (2); pancreatic elastase (19); peptidyltransferase (24); serine-type D-Ala-D-Ala carboxypeptidase (20); subtilisin (15,16); *Treponema denticola* protease (17); and urease, weakly inhibited (18). 1. **Phenylbutazone**

This anti-inflammatory agent (FW = 308.38 g/mol), also known as 4-butyl-1,2-diphenyl-3,5-pyrazolidinedione, butazolidine, and 1,2-diphenyl-3,5-dioxo-4-*n*-butylpyrazolidine, is an alternative substrate for prostaglandin peroxidase and glucuronosyltransferase. Phenylbutazone also forms carbon-centered radicals in a reaction catalyzed by horseradish peroxidase and hydrogen peroxide. **Target(s):** alcohol dehydrogenase (1,2); ATPase, mitochondrial (3); carbonyl reductase (4); cathepsin L (5); creatine kinase, in the presence of hydrogen peroxide and horseradish peroxidase (2); cyclooxygenase (6-8); CYP2C, probable alternative substrate (9); glutamate dehydrogenase (10); L-glutamine:D-fructose-6-phosphate aminotransferase (11,12); glyceraldehyde-3-phosphate dehydrogenase, in the presence of hydrogen peroxide and horseradish peroxidase (2); hyaluronidase (13);  $K^+$ -ATPase (14); phenylpyruvate tautomerase, weakly inhibited (15); urate-ribonucleotide phosphorylase (16); and xanthine dehydrogenase (17). 1. **4-Phenyl-3-butenolate**

This acid (FW<sub>free-acid</sub> = 162.19 g/mol) is a mechanism-based inhibitor of peptidylglycine monooxygenase (1-4). The methyl ester also inhibits. 1. Katopodis & May (1990) *Biochemistry* **29**, 4541. 2. Sunman, Foster, Folse, May & Matesic (2004) *Mol. Carcinog.* **41**, 231. 3. Bauer, Sunman, Foster, et al. (2007) *J. Pharmacol. Exp. Ther.* **320**, 1171. 4. Labrador, Brun, König, Roatti & Baertschi (2004) *Circ. Res.* **95**, e98.

**Phenyl-*n*-butylborinic Acid**

This putative transition-state analogue (FW = 162.04 g/mol) has a  $K_i$  value for cholesterol esterase, or sterol esterase, of 2.9 nM (1-3) and lipoprotein lipase,  $K_i = 1.7 \mu\text{M}$  (2). 1. Feaster & Quinn (1997) *Meth. Enzymol.* **286**, 231. 2. Sutton, Stout, Hosie, Spencer & Quinn (1986) *Biochem. Biophys. Res. Commun.* **134**, 386. 3. Sutton, Froelich, Hendrickson & Quinn (1991) *Biochemistry* **30**, 5888.

**4-Phenyl-1-butyne**

This arylalkyne (FW = 130.19 g/mol) is a mechanism-based (or suicide) inhibitor of the mouse cytochrome P450 CYP2b (*i.e.*, dealkylation of benzyloxycorufin) and rat CYP2B1. 1. Beebe, Roberts, Fornwald, Hollenberg & Alworth (1996) *Biochem. Pharmacol.* **52**, 1507.

**2-Phenylbutyrate (2-Phenylbutyric Acid)**

This carboxylic acid (FW<sub>free-acid</sub> = 164.20 g/mol; CAS 1009-67-2; M.P. = 42-44°C) inhibits acetyl-CoA synthetase (1,2), histone deacetylase (3), and kynurenine aminotransferase, weakly inhibited (4). The (*R*)-(-) and (*S*)-(+)-enantiomers are frequently used as chiral building blocks in organic syntheses and as resolving agents. *Note:* 2-Phenylbutyric acid should not be confused with the ester phenyl butyrate (*i.e.*, CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>COOC<sub>6</sub>H<sub>5</sub>). 1. Webster, Jr., (1969) *Meth. Enzymol.* **13**, 375. 2. Jencks (1962) *The Enzymes*, 2nd ed., 6, 373. 3. Lea, Randolph & Hodge (1999) *Anticancer Res.* **19**, 1971. 4. Mason (1959) *J. Biol. Chem.* **234**, 2770.

**3-Phenylbutyrate (3-Phenylbutyric Acid)**

This carboxylic acid (FW<sub>free-acid</sub> = 164.20 g/mol; CAS 4593-90-2; M.P. = 37-39°C) inhibits carboxypeptidase A (1) and histone deacetylase (2). The (*R*)- and (*S*)-enantiomers are frequently used as chiral building blocks in organic syntheses. *Note:* 2-Phenylbutyric acid should not be confused with the ester phenyl butyrate (*i.e.*, CH<sub>3</sub>CH<sub>2</sub>CH<sub>2</sub>COOC<sub>6</sub>H<sub>5</sub>). 1. Elkins-Kaufman, Neurath & De Maria (1949) *J. Biol. Chem.* **178**, 645. 2. Lea, Randolph & Hodge (1999) *Anticancer Res.* **19**, 1971.

**4-Phenylbutyrate (4-Phenylbutyric Acid)**

This short-chain fatty acid and ammonia-scavenging pro-drug (FW<sub>free-acid</sub> = 164.20 g/mol; CAS 1821-12-1; *Abbreviation:* PBA), which is administered orally as sodium phenylbutyrate (FW<sub>sodium-salt</sub> = 186.18 g/mol; CAS 1716-12-7; Trade Name = Buphenyl<sup>®</sup>; *Abbreviation:* NaPBA), is an FDA-approved treatment for hyperammonia as a result of urea cycle disorders. **Primary Mode of Action:** PBA undergoes two-carbon loss to form the active drug, phenylacetate, which is then enzymatically conjugated to glutamine to

form phenylacetylglutamine, with the latter excreted in urine (1). Because glutamine contains two equivalents of ammonia, PBA is especially effective in its action. Twenty-four-hour urinary phenylacetylglutamine levels correlate strongly with dose, making it a clinically useful non-invasive biomarker for compliance and therapeutic monitoring (2). Glycerol phenylbutyrate (FW = 530.67 g/mol; CAS; 611168-24-2; IUPAC Name: propane-1,2,3-triyl-*tris*(4-phenylbutanoate; Other Names: HPN-100 and Ravicti<sup>®</sup>) is a non-sodium-releasing FDA-approved pro-pro-drug that releases PBA and glycerol upon metabolic hydrolysis (3). **Other PBA Actions:** Sodium PBA also acts as a chaperone, reducing the load of mutant or unfolded proteins retained in the ER during cellular stress. For example, PBA protects against liver ischemia re-perfusion injury by inhibiting endoplasmic reticulum stress-mediated apoptosis (4). By stimulating fetal hemoglobin synthesis, PBA is useful in treating sickle cell disease (5). PBA also induces Arginase I in many tissues (by as much as 4x in brain) (6), a finding that suggests reduced arginine may be manifested as reduced nitric oxide synthesis. **Historical Note:** In his classic studies elucidating the  $\beta$ -oxidation pathway, Knoop (7) used phenylbutyrate to demonstrate that, after oral administration, phenylacetylglutamine (phenaceturic acid) appears in the urine. This observation suggested phenylbutyrate underwent one cycle of two-carbon chain shortening, forming phenylacetate, which was then coupled to glycine. 1. **1-Phenylcyclopropylamine**

This amine (FW<sub>free-base</sub> = 133.19 g/mol) is a mechanism-based (or suicide) inactivator of both monoamine oxidases A and B, with preference for the latter (1-7). Monoamine oxidase B is inactivated via attachment to both a cysteinyl residue and the flavin, while monoamine oxidase A is inhibited only via a covalent adduct formed with the flavin cofactor. Another target is trimethylamine dehydrogenase (8). 1. Silverman (1995) *Meth. Enzymol.* **249**, 240. 2. Brush & Kozarich (1992) *The Enzymes*, 3rd ed. (Sigman, ed.), **20**, 317. 3. **(+)-(E)-7-[4-[4-[[[2-(trans)-Phenylcyclopropyl]amino]carbonyl]-2-oxazolyl]phenyl]-7-(3-pyridyl)hept-6-enoate**

This substituted oxazolecarboxamide ( $FW_{\text{free-acid}} = 508.60$  g/mol) inhibits human thromboxane-A synthase ( $IC_{50} = 8.5$  nM) and is a thromboxane receptor antagonist ( $K_d = 62.6$  nM). With the (-)-isomer,  $IC_{50} = 5.9$  nM and  $K_d = 104.7$  nM, respectively. 1. Takeuchi, Kohn, True, *et al.* (1998) *J. Med. Chem.* **41**, 5362.

**D-threo-1-Phenyl-2-decanoylamino-3-morpholino-1-propanol**

This structural analogue ( $FW_{\text{free-base}} = 390.57$  g/mol) of the natural sphingolipid substrate of ceramide glucosyltransferase inhibits that enzyme (the actual active agent is the D-threo-isomer [*i.e.*, the (*R,R*)-isomer]) and reversibly depletes cellular glycosphingolipids. Note that intracellular ceramide concentrations also increase cytotoxic levels. **Target(s):** 1-O-acylceramide synthase (1); ceramide glucosyltransferase, or glucosylceramide synthase (2-13); ceramide glycanase (2); glucosylceramide galactosyl-transferase, or lactosylceramide synthase (14). 1. **Phenyldichloroarsine**

This sulfhydryl group-directed organoarsenic ( $FW = 222.93$  g/mol) reacts with many proteins, inactivating those enzymes with essential thiols. **Caution:** A strong vesicant that is readily hydrolyzed in the lung to form hydrogen chloride and phenylarsenious oxide, phenyldichloroarsine should be handled only in chemical fume hoods and with protective equipment. It also has an immediate effect on eyes and will cause blisters on skin and can induce vomiting. First synthesized by Fritz Haber, and briefly used as chemical warfare agent by Germany in World War I in 1917-18, phenyldichloroarsine has been given the chemical warfare designation PD. When administered in a timely manner, 2,3-Dimercapto-1-propanol (British Anti-Lewisite, or BAL) and 2,3-dithioerythritol (DTE) can be effective antidotes (1). Phenyldichloroarsine readily enters cells and forms adducts with glutathione (2). **Target(s):** SH-dependent enzymes. 1. Boyd, Harbell, O'Connor & McGown (1989) *Chem. Res. Toxicol.* **2**, 301. 2. Dill,

Adams, O'Connor, Chong & McGown (1987) *Arch. Biochem. Biophys.* **257**, 293.

**1-Phenylethanol**

This alcohol ( $FW = 122.17$  g/mol; M.P. = 19-20°C) inhibits  $\beta$ -alanine:pyruvate aminotransferase, weakly inhibited by the *R*-enantiomer (1) and  $\beta$ -glucosidase (2). 1. Yun, Yang, Cho, Hwang & Kim (2003) *Biotechnol. Lett.* **25**, 809. 2. Dale, Ensley, Kern, Sastry & Byers (1985) *Biochemistry* **24**, 3530.

**2-Phenylethanol**

This alcohol ( $FW = 122.17$  g/mol; M.P. = -27°C; B.P. = 219-221°C at 750 mm Hg; slightly soluble in water (1.6 g/100 mL at 20°C); miscible in ethanol), also known as phenethyl alcohol,  $\beta$ -phenylethyl alcohol, and benzyl carbinol, is found in a number of essential oils. 2-Phenylethanol has a distinct floral odor, reminiscent of roses, and is often used in formulating perfumes and flavors. At a concentration of 0.25%, 2-phenylethanol will inhibit DNA biosynthesis without affecting RNA or protein biosynthesis. At higher concentrations, RNA and protein biosynthesis are also inhibited. **Target(s):** choline linase (1); chymotrypsin (2); DNA biosynthesis (3,4);

DNA-dependent DNA polymerase (5); excision repair of DNA (5);  $\beta$ -glucosidase (6); *sn*-glycerol 3-phosphate acyltransferase (7); signal peptidase II (8); and uridine kinase (1). 1. ## 2-Phenylethylamine

This phenylalanine-derived monoamine (FW<sub>free-base</sub> = 121.18 g/mol; M.P. < -20°C; B.P. = 194.5°C), also known as  $\beta$ -phenethylamine, which is structurally related to amphetamine, is normally present in human urine at ~30  $\mu$ g/L. 2-Phenylethylamine is also used as an organic solvent in chromatography, spectrophotometry, and in liquid scintillation counting. It will absorb carbon dioxide from air and has a low solubility in water (3.4% at 20°C). **Target(s):** aldehyde oxidase, weakly inhibited (1); aromatic-L-amino-acid decarboxylase (2); chymotrypsin (3); dopamine  $\beta$ -monoxygenase (4-6);  $\beta$ -glucosidase (7); glutamate:ethylamine ligase, or theanine synthetase (8); hemoglobin S polymerization (9); histamine *N*-methyltransferase (10); monoamine oxidase (11); phenylalanine ammonia-lyase (12); phenylalanine racemase, ATP-hydrolyzing (13); phenylalanyl-tRNA synthetase,  $K_i$  = 93  $\mu$ M (14); renin (15); trypsin, weakly inhibited (16,17); tryptophan 2-monoxygenase (18); and tyrosine aminotransferase (19,20). 1. ## 2-Phenylethanesulfonamide

This synthetic Hsp70 protein substrate-binding inhibitor (FW = 181.21 g/mol; CAS 64984-31-2; *Abbreviation*: PES) selectively interacts with the multifunctional, stress-inducible molecular chaperone HSP70, disrupting its association with several of co-chaperones and client proteins (1). Treatment of cultured tumor cells with PES promotes cell death as a consequence of protein aggregation, impaired autophagy, and inhibition of lysosomal function. (Typical doses are 1–10  $\mu$ g/g injected intraperitoneally in mice, and 1–10  $\mu$ M *in vitro*.) PES also exerts profound effects both *in vivo* and *in vitro* by: (a) preventing LPS-induced increase in serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activity, reducing infiltration of inflammatory cells, and promoting liver cell apoptosis; (b) reducing inducible nitric oxide synthase (iNOS) protein expression as well as that of serum nitric oxide (NO), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), and interleukin-6 (IL-6) content in LPS-stimulated mice; (c) decreasing the mRNA levels of iNOS, TNF- $\alpha$ , and IL-6 in LPS-stimulated liver; (d) attenuating the degradation of inhibitor of  $\kappa$ B- $\alpha$  ( $\kappa$ B- $\alpha$ ) as well as the phosphorylation and nuclear translocation of nuclear factor- $\kappa$ B (NF- $\kappa$ B) in LPS-stimulated liver (1). PES also remarkably reduces typically observed increases in intracellular  $[Ca^{2+}]$  and intracellular pH value in LPS-stimulated RAW 264.7 cells. Moreover, PES significantly reduces the increase in Na<sup>+</sup>/H<sup>+</sup> exchanger 1 (NHE1) association to Hsp70 in LPS-stimulated macrophages and liver, suggesting that NHE1-Hsp70 interaction is required for the involvement of NHE1 in the inflammation response. By disrupting HSP70 actions of in multiple cell signaling pathways, PES offers a way to probe the diverse functions of this molecular. 1. Leu, Pimkina, Frank, Murphy & George (2009) *Mol. Cell.* **36**, 15. 2. Huang, Wang, Chen, Wang & Zhang (2013) *PLoS One* **8**, e67582.

## DL- $\alpha$ -Phenylglycidate (DL- $\alpha$ -Phenylglycidic Acid)

This oxirane-containing agent (FW<sub>free-acid</sub> = 164.16 g/mol), also known as phenylloxiranecarboxylate, is an active-site-directed, irreversible inhibitor of mandelate racemase, with inhibition only expressed by the (*R*)-enantiomer. The enzyme is inactivated following nucleophilic attack of the  $\epsilon$ -amino group of a lysyl residue on the distal carbon on the epoxide ring of (*R*)-isomer (1-6). The (*S*)-isomer also binds to the active site, albeit with a weaker affinity. 1. Mitra, Kallarakal, Kozarich, et al. (1995) *Biochemistry* **34**, 2777. 2. Kenyon & Hegeman (1977) *Meth. (1994) *Plant J.* **6**, 251.

### Phenylglyoxal

This commercially available peptide/protein-modifying reagent (FW = 134.13 g/mol; CAS 1074-12-0), occasionally called benzoylformaldehyde, is a mild oxidant that reacts covalently with guanidinium groups at pH ~ 7, consuming two moles of reagent per mole of reactive arginyl residue. Modified guanidinium groups are relatively stable below pH 4; however, the original guanidinium group is slowly regenerated at neutral or alkaline pH. Upon prolonged incubation with phenylglyoxal,  $\alpha$ -amino groups may also be modified. **See also** *Glyoxal*; *4-Hydroxyphenylglyoxal*; *etc.* **Target(s):** To date, over 240 enzymes are inhibited by phenylglyoxal.

### Phenylguanidine

This guanidine salt (FW = 136.18 g/mol; CAS 2002-16-6) inhibits trypsin,  $K_i = 72.5 \mu\text{M}$  (1-7) and urokinase, or u-plasminogen activator (8). **1.** Walsh (1970) *Meth. Enzymol.* **19**, 41. **2.** Shaw (1970) *The Enzymes*, 3rd ed. ### DL-threo-1-Phenyl-2-hexadecanoylamino-3-morpholino-1-propanol

This inhibitor (FW = 474.73 g/mol), also known as DL-threo-1-phenyl-2-palmitoylamino-3-morpholino-1-propanol and often abbreviated DL-threo-PHMP or PPMP, is a structural analogue of the natural sphingolipid substrate of ceramide glucosyltransferase. **See also** *DL-threo-1-Phenyl-2-decanoylamino-3-morpholino-1-propanol* **Target(s):** ceramide glucosyltransferase (1-5); and ceramide glycanase (6,7). **1.** Nakamura, Kuroiwa, Kono & Takatsuki (2001) *Biosci. Biotechnol. Biochem.* **65**, 1369. **2.** di Bartolomeo & Spinedi (2001) *Biochem. Biophys. Res. Commun.* **288**, 269. **3.** Chujor,

### Phenylhydrazine

This toxic hydrazine (FW<sub>free-base</sub> = 108.14 g/mol; CAS 100-63-0; M.P. = 19.5°C) inhibits many pyridoxal 5'-phosphate-dependent enzymes and also reacts with aldehyde- and ketone-containing substances, especially reducing sugars. **Caution:** This substance is highly toxic, giving rise to oxidative hemolysis, the latter accounting for its use in stimulating reticulocyte formation in experimental animals. In the 1870s, phenylhydrazine proved invaluable in the structural characterization of monosaccharides, for which Fischer was awarded the Nobel Prize in Chemistry (1902). However, Fischer's overexposure to phenylhydrazine was responsible in part for his failing health and contributed to his decision to end his own life with cyanide in 1919. **Target(s):** Literature survey indicates >120 enzyme targets, too many to list here.

### Phenylhydrazone Malononitrile, See Mesoxalonitrile Phenylhydrazone

### 2-Phenyl-1,3-indandione, See Phenindione

### Phenylisocyanate

This toxic liquid, also known as isocyanatobenzene and phenyl isocyanate (FW = 119.12 g/mol; melting point = -30 °C boiling point = 158-168°C), can react with the free amino group at the N-terminus of a peptide or protein, transiently producing the hydantoic acid derivative. This product subsequently generates the phenyl hydantoin derivative upon cleavage of the N-terminal aminoacyl residue. **Target(s):** alkaline phosphatase (1,2); amylase, pancreatic (3); ribonuclease, pancreatic (4); and urease (5). **1.** Fernley (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), **4**, 417. **2.** Gould (1944) *J. Biol. Chem.* **156**, 365. **3.** Little & Caldwell (1942) *J. Biol. Chem.* **142**, 585. **4.** McDonald (1955) *Meth. ### 3-Phenyllactic Acid

This  $\alpha$ -hydroxy acid ( $F_{W, \text{free-acid}} = 166.18$  g/mol; CAS 156-05-8), also known as  $\alpha$ -hydroxyhydrocinnamic acid and  $\beta$ -phenyllactic acid, is found naturally as the L-enantiomer and is a degradation product of L-phenylalanine *via* phenylpyruvate. The free acid of the L-enantiomer is a solid (melting point = 124°C) that is soluble in hot water. **Target(s):** aminoacylase I, by the L-enantiomer (1); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, *or* [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (2,3); carboxypeptidase A, by the L-enantiomer (4-8); carboxypeptidase C, *or* carboxypeptidase Y (9,10); crayfish carboxypeptidase (11,12); diphosphomevalonate decarboxylase (27); fumarase, *or* fumarate hydratase, inhibited by DL-mixture (13); histidine decarboxylase, weakly inhibited (14); hydroxylaminolysis of amino acid esters at  $-18^\circ\text{C}$ , nonenzymatic (15); mandelate racemase (16);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (17); phenylalanine ammonia-lyase, by the L-enantiomer (18,19); phenylalanine dehydrogenase, by the L-enantiomer (20); phenylalanyl-tRNA synthetase, weakly inhibited,  $K_i = 2.2$  mM (21); stearoyl-CoA desaturase (22); thyroid-hormone aminotransferase (23); tryptophanase, tryptophan indole-lyase (24); tryptophan 2-monooxygenase (25); and tryptophan 5-monooxygenase (26). 1. ### Phenylmercuric Acetate

This reagent ( $F_{W} = 336.74$  g/mol), which is often used as a fungicide and herbicide, inhibits enzymes with a catalytically essential sulfhydryl group or when a thiol is critical for maintaining a state of oligomerization required for enzymatic activity. The reactive species in aqueous solutions is the phenylmercuric cation,  $\text{C}_6\text{H}_5\text{-Hg}^+$ . Phenylmercuric acetate is soluble in about 600 parts water. **See also p-Hydroxymercuribenzoate Target(s):** adenosine deaminase (1-3); adenyl-lyl-sulfate kinase (37); alliin lyase (4); D-amino-acid oxidase (5,6);  $\alpha$ -amylase (31); asclepain (7); bromelain (8,9); bromoxynil nitrilase (10); carboxypeptidase C, carboxypeptidase Y (28); desulfoglucosinolate sulfotransferase (11); dextranucrase (45-47); electron transport, bacterial photosynthetic (12); flavonol 3-O-glucosyltransferase (42,43); flavonol 7-O- $\beta$ -glucosyltransferase (38,39); formate dehydrogenase (13); fruit bromelain (8);  $\beta$ -glucosidase (30); glutamate racemase (14); glutathione-disulfide reductase (15); glycerol dehydratase (16); glycogen synthase (44); haloalkane dehalogenase (17); [heparan sulfate]-glucosamine

### Phenylmethanesulfonyl Fluoride

This toxic sulfonylating agent, abbreviated as PMSF ( $F_{W} = 174.20$  g/mol; CAS 329-98-6), also known as phenylmethylsulfonyl fluoride and  $\alpha$ -tolylsulfonyl fluoride, irreversibly inhibits many enzymes by reacting with an active-site hydroxyl group. Our literature survey indicates that more than 260 enzymes are inactivated by PMSF. Reactivity is enhanced by proton transfer from the nucleophilic serine hydroxyl group to a nearby imidazole nitrogen, such as that within the so-called Ser/His/Asp catalytic triad of many serine proteinases and serine esterases (1,2). Inactivation requires 1-3 mM concentrations (higher concentrations precipitate spontaneously). Typically, a 20-50 mM solution is freshly prepared in 2-propanol or dioxane, followed by dilution with water or directly into the enzyme-containing solution, with the aid of a vortex mixer. The half-life of an aqueous 0.1-1.0 mM PMSF solution is about one hour at pH 7.5. *Note:*

PMSF is the recommended alternative to the neurotoxic fluorophosphates and fluoro-phosphonates. (Even so, PMSF should still be handled with care to avoid inhalation of the powdered reagent.) PMSF also inactivates papain, and reactivation occurs upon treating the modified protein with a thiol reagent (3-5). 1. Gold (1967) *Meth. Enzymol.* **11**, 706. 2. Halfon & Craik (1998) in *Handb. Toxicol.* **72**, 637.

### Phenyl Phosphate

This phosphorylated phenol (FW<sub>disodium salt</sub> = 218.06 g/mol; soluble in water and methanol) is an chromogenic alternative substrate for phosphomonoesterases (*i.e.*, activity can be spectrophotometrically assayed by the release of phenolate ion). Phenol phosphate should be stored a refrigerated, light-tight desiccator. Once prepared, aqueous solutions hydrolyze slowly. **Target(s):** Arylsulfatase (1); glycerol-1,2-cyclic-phosphate phosphodiesterase (2); pancreatic ribonuclease, *or* ribonuclease A (3); and pyridoxal phosphatase (4). 1. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 443, Academic Press, New York. 2. Clarke & Dawson (1978) *Biochem. J.* **173**, 579. 3. Richards & Wyckoff (1971) *The Enzymes*, 3rd ed., **4**, 647. 4. Fonda (1992) *J. Biol. Chem.* **267**, 15978.

### Phenylphosphonate (Phenylphosphonic Acid)

This corrosive aryl phosphonic acid (FW<sub>free-acid</sub> = 158.09 g/mol; CAS 1571-33-1; M.P. = 163-166 °C) inhibits alkaline phosphatase (1-4). 1. Reid & Wilson (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), **4**, 373. 2. Farley, Puzas

### Phenylphosphorodiamidate

This diphosphoramidate (FW = 172.12 g/mol; M.P. = 185-190°C) is a slow-binding competitive inhibitor of *Klebsiella aerogenes* urease,  $K_i = 94 \mu\text{M}$  (1-3) and urethase (4). 1. Todd & Hausinger (1989) *J. Biol. Chem.* **264**, 15835. 2. Clemens, Lee & Horwitz (1995) *J. Bacteriol.* **177**, 5644. 3. Benini, Ciurli, Nolting & Mangani (1996) *Eur. J. Biochem.* **239**, 61. 4. Kobashi, Takebe & Sakai (1990) *Chem. Pharm. Bull.* **38**, 1326.

### N-Phenylphosphoryl-L-phenylalanyl-L-alanine

This phosphoramidate (FW<sub>free-acid</sub> = 392.35 g/mol) inhibits a number of metalloproteinases, including bacillolysins, peptidyl-dipeptidase A, *or* angiotensin-I-converting enzyme, and thermolysin. 1. Holmquist & Vallee (1979) *Proc. Natl. Acad. Sci. U.S.A.* **76**, 6216.

### (20R)-20-Phenyl-5-pregnene-3β,20-diol

This sterol derivative (FW = 394.60 g/mol) is a potent competitive inhibitor of CYP11A, *or* cholesterol side-chain-cleaving enzyme,  $K_{i,app} = 30 \text{ nM}$ ; it is not an alternative substrate (1-4). 1. Vickery (1991) *Meth. Enzymol.* **206**, 548. 2. Jacobs, Singh & Vickery (1987) *Biochemistry* **26**, 4541. 3. Vickery & Kellis (1983) *J. Biol. Chem.* **258**, 3832. 4. ### Phenylpropionic Acid

This mechanism-based (suicide) inhibitor (FW<sub>free-acid</sub> = 146.15 g/mol; CAS 637-44-5) inactivates Fe(II)- and  $\alpha$ -ketoglutarate-dependent dioxygenase (the latter catalyzing the hydroxylation of the herbicide 2,4-dichlorophenoxyacetic acid), with  $K_i = 38.1 \mu\text{M}$  and  $k_{inact} = 2.3 \text{ min}^{-1}$ , covalently modifying a side-chain functional group in the proteolytic fragment (166-AEHYALNSR-174) forming one side of the substrate-binding pocket. Phenylpropionic acid also inhibits esterase (2) and phenylalanine ammonia-lyase (3). 1. Hotopp & Hausinger (2002) *Biochemistry* **41**, 9787. 2. Weber & King (1935) *J. Biol. Chem.* **108**, 131. 3. #### 4-Phenylpyridine

This substituted pyridine (FW = 155.20 g/mol; CAS 939-23-1; M.P. = 69-73°C; B.P. = 274-275°C), which occurs naturally and is likewise a manmade pollutant, inhibits human placental aromatase,  $K_i = 0.36 \mu\text{M}$  (1), monoamine oxidase (2), and NADH dehydrogenase (3,4). 4-Phenylpyridine is also an effective inhibitor of mitochondrial complex I. Note that it both occurs naturally and is an environmental pollutant. **1.** Vaz, Coon, H. Peegel & Menon (1992) *Drug Metab. Dispos.* **20**, 108. **2.** Arai, Kinemuchi, Hamamichi, *et al.* (1986) *Neurosci. Lett.* **66**, 43. **3.** Ramsay, McKeown, Johnson, Booth & Singer (1987) *Biochem. Biophys. Res. Commun.* **146**, 53. **4.** Ramsay, Salach, Dadgar & Singer (1986) *Biochem. Biophys. Res. Commun.* **135**, 269.

#### Phenylpyruvate (Phenylpyruvic Acid)

This aromatic  $\alpha$ -keto acid and PKU biomarker (FW<sub>free-acid</sub> = 164.16 g/mol; CAS 156-06-9 for acid; CAS 114-76-1 for sodium salt; CAS 51828-93-4 for calcium salt);  $\lambda_{\text{max}} = 320 \text{ nm}$ ,  $\epsilon = 17500 \text{ M}^{-1}\text{cm}^{-1}$  in 0.7 M NaOH, also known as 2-oxo-3-phenylpropanoic acid and  $\alpha$ -oxohydrocinnamic acid, is readily formed by the action of a number of aminotransferases on phenylalanine. Phenylpyruvate is only slightly soluble in boiling water but is soluble in ethanol and diethyl ether. The solid oxidizes in air and decomposes on storage, if not dry. Sodium phenylpyruvate is a water-soluble monohydrate salt. **Phenylketonuria:** Phenylpyruvate is present at high urinary concentrations in phenylalanine monooxygenase deficiency, better known as Phenylketonuria. Indeed, individuals suffering PKU tend to excrete urine containing large quantities of phenyl-pyruvate, phenyl-acetate and phenyl-lactate, along with phenylalanine. If untreated, mental retardation and microcephaly are evident by the first year, along with irritability, epileptic seizures, and skin lesions. **Target(s):** acetolactate synthase (1); aldehyde reductase (2); apyrase (3); branched-chain  $\alpha$ -keto acid dehydrogenase (4); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (5-8); carnitine-acylcarnitine translocase (9); cathepsin D (10); choline acetyltransferase (11); 3-deoxy-7-phosphoheptulonate synthase, or 3-deoxy-D-arabino-heptulosonate 7-phosphate synthetase (12-14); dihydropteridine reductase (15); diphosphomevalonate decarboxylase (43); glutamate decarboxylase (16); glutamine:pyruvate aminotransferase (17); glycerate dehydrogenase, weakly inhibited (16,18); hexokinase (human brain),  $K_i = 2 \text{ mM}$  (19); histidine decarboxylase (20); 4-hydroxyphenylpyruvate dioxygenase (16);  $3\alpha$ -hydroxysteroid dihydrogenase (2);  $3\beta$ -hydroxysteroid dehydrogenase (2); hypothalamus acid proteinase (21); indolepyruvate decarboxylase,  $K_i = 50 \mu\text{M}$  (22); kynureninase (23); L-lactate dehydrogenase (16,24); L-lactate dehydrogenase (cytochrome) (24,25); mercaptopyruvate sulfurtransferase (26); mevalonate-5-pyrophosphate decarboxylase (27); oxaloacetate tautomerase (28); phenylalanine ammonia-lyase (29-31); phenylalanyl-tRNA synthetase, weakly inhibited,  $K_i = 7.6 \text{ mM}$  (32); pyruvate carboxylase (33,34); pyruvate decarboxylase (16,35,36); pyruvate dehydrogenase (37); pyruvate kinase (human),  $K_i = 8.5 \text{ mM}$  (19,38); pyruvate oxidase (16); pyruvate transport (39); stearyl-CoA 9-desaturase (40); tryptophan 2-monooxygenase (44); tryptophan 5-monooxygenase (41); tyrosinase (16); and tyrosine 2,3-aminomutase (42). **1.** Stormer (1975) *Meth. **Phenyl-p-quinone, See Phenyl-p-benzoquinone**

#### 5-(Phenylselenenyl)acyclouridine

This nucleoside analogue (FW = 341.23 g/mol) inhibits uridine phosphorylase (1,2). **1.** Ashour, Naguib, Goudgaon, Schinazi & el Kouni (2000) *Cancer Chemother. Pharmacol.* **46**, 235. **2.** Ashour, Al Safarjalani, Naguib, *et al.* (2000) *Cancer Chemother. Pharmacol.* **45**, 351.

#### Phenyl Selenoacetylene

This selenide (FW = 257.19 g/mol) inhibits rat porphobilinogen synthase, or ( $\delta$ -aminolevulinic acid dehydratase,  $\text{IC}_{50} = 0.25 \text{ mM}$ , with inhibition requiring formation diphenyl diselenide which mediates oxidation of a catalytically essential sulfhydryl group (1,2). **1.** Bolzan, Folmer, Farina, *et al.* (2002) *Pharmacol. Toxicol.* **90**, 214. **2.** Folmer, Bolzan, Farina, *et al.* (2005) *Toxicology* **206**, 403.

#### Se-Phenyl-L-selenocysteine

This S-phenyl-L-cysteine and homophenylalanine analogue (FW = 244.15 g/mol) inhibits a number of cytochrome P450 systems, including CYP1A1,

CYP1A2, CYP3A4, CYP2C9, CYP2D6, and CYP2E1 (1,2). 1. Rooseboom, Vermeulen, Durgut & Commandeur (2002) *Chem. Res. Toxicol.* **15**, 1610. 2. Venhorst, Rooseboom, Vermeulen & Commandeur (2003) *Xenobiotica* **33**, 57.

### $\beta$ -Phenylserine

This serine derivative (FW = 169.18 g/mol), which is an alternative substrate for serine hydroxymethyltransferase, phenylserine aldolase (L-threo-isomer), and threonine dehydratase, inhibits alkaline phosphatase (1), 3-deoxy-7-phosphoheptulonate synthase (2), nonenzymatic hydroxyl-aminolysis of amino acid esters at  $-18^{\circ}\text{C}$  (3), phenylalanine ammonia-lyase (4,5) and tryptophanase, or tryptophan indole-lyase (6). 1. Fishman & Sie (1971) *Enzymologia* **41**, 141. 2. Simpson & Davidson (1976) *Eur. J. Biochem.* **70**, 509. 3. Grant & Alburn (1965) *Biochemistry* **4**, 1913. 4. Koukol & Conn (1961) *J. Biol. Chem.* **236**, 2692. 5. Jorin, Lopez-Valbuena & Tena (1988) *Biochim. Biophys. Acta* **964**, 73. 6. Snell (1975) *Adv. Enzymol. Relat. Areas Mol. Biol.* **42**, 287.

### Phenylsuccinic Acid

This dicarboxylic acid (FW<sub>free-acid</sub> = 194.19 g/mol; M.P. = 167-169°C) inhibits the  $\alpha$ -ketoglutarate transporter. *Note:* Phenylsuccinic acid should not be confused with phenyl succinate monoester ( $\text{OOCCH}_2\text{CH}_2\text{COOC}_6\text{H}_5$ ). **Target(s):** dicarboxylic acid transporter (1); glutamate decarboxylase,  $K_i = 55$  mM (2); hydroxyproline transport (3);  $\alpha$ -ketoglutarate transporter (4); and oxalate uptake (5). 1. Quagliariello, Passarella & Palmieri (1974) in *Dynamics of Energy-Transducing Membranes* (Ernster, Estabrook & Slater, eds.), p. 483, Elsevier, Amsterdam. 2. Fonda (1972) *Biochemistry* **11**, 1304. 3. Atlante, Passarella & Quagliariello (1994) *Biochem. Biophys. Res. Commun.* **202**, 58. 4. ### 7-Phenylsulfonyl-1,2,3,4-tetrahydroisoquinoline

This substrate analogue (FW = 272.35 g/mol) inhibits phenylethanolamine N-methyltransferase,  $K_i = 14$   $\mu\text{M}$  (1,2). 1. Grunewald, Dahanukar, Jalluri & Criscione (1999) *J. Med. Chem.* **42**, 118. 2. Grunewald, Seim, Regier, et al. (2006) *J. Med. Chem.* **49**, 5424.

### 4-Phenyl-1,2,3,4-tetrahydroisoquinoline

This dopamine release inhibitor (FW = 245.75 g/mol; CAS 6109-35-9; Soluble in DMSO and to 25 mM in  $\text{H}_2\text{O}$ ; Symbol: 4-PTIQ)  $10^{-6}$  M inhibited the dopamine-releasing effect of methamphetamine when present

at  $10^{-6}$  M. 4-PTIQ did not affect the elevation of the extracellular dopamine level induced by high concentrations of nomifensine ( $10^{-5}$  M) and cocaine ( $3 \times 10^{-5}$  M). 4-PTIQ was the weakest inhibitor of dopamine uptake by rat striatal synaptosomes. Such results suggest that 4-PTIQ is a selective antagonist against the dopamine-releasing effect of methamphetamine in the nucleus accumbens. 1. Tateyama, Nagao, Ohta, Hirobe & Ono (1993) *Eur. J. Pharmacol.* **240**, 51.

### 2-Phenyl-4,4,5,5-tetramethylimidazole-1-oxyl 3-oxide, See PTIO

### O<sup>6</sup>-(4-Phenylthienyl)guanine

This modified guanine inactivates methylated-DNA:[protein]-cysteine S-methyltransferase, or O<sup>6</sup>-alkylguanine-DNA alkyltransferase,  $I_{50} = 15$  nM. The 5-phenyl analogue is a weaker inhibitor,  $I_{50} = 0.75$   $\mu\text{M}$ . 1. McMurry (2007) *DNA Repair* **6**, 1161.

### Phenylthiocarbamate, See Phenylthiourea

### 2-Phenylthiochromen-4-one 1-Oxide

This substituted 2-phenyl-4-quinolone (FW = 254.31 g/mol) targets DNA topoisomerase I, displaying significant growth inhibitory action against a panel of tumor cell lines, including human ileocecal carcinoma (HCT-8), murine leukemia (P-388), human melanoma (RPM1), and human central nervous system tumor (TE671) cells. 1. Wang, Bastow, Cosentino & Lee (1996) *J. Med. Chem.* **39**, 1975.

### 5'-(Phenylthio)-immucillin-A

This nucleoside-based transition-state analogue (FW = 355.42 g/mol), also known as (1S)-1-(9-deazaadenin-9-yl)-1,4-dideoxy-1,4-imino-5-(phenylthio)-D-ribose, inhibits 5'-methylthioadenosine/S-adenosylhomocysteine nucleosidase,  $K_i' = 32$  pM (1) and S-methyl-5'-thioadenosine phosphorylase,  $K_i = 1$  nM (1), and S-methyl-5'-thioadenosine phosphorylase (2,3). 1. Singh, Evans, Lenz, et al. (2005) *J. Biol. Chem.* **280**, 18265. 2. Evans, Furneaux, Schramm, Singh & Tyler (2004) *J. Med. Chem.* **47**, 3275. 3. Singh, Shi, Evans, et al. (2004) *Biochemistry* **43**, 9.

### 3-(Phenylthio)-1,1,1-trifluoropropan-2-one

This halomethyl ketone (FW = 220.21 g/mol), also known as 3-phenylsulfanyl-1,1,1-trifluoro-2-propanone, inhibits juvenile-hormone esterase,  $IC_{50} = 8.2$   $\mu\text{M}$ , and acetylcholinesterase,  $IC_{50} = 3.7$   $\mu\text{M}$ . 1. Hammock, Abdel-Aal, Mullin, Hanzlik & Roe (1984) *Pest. Biochem. Physiol.* **22**, 209.

### Phenylthiourea

This thiourea (FW = 152.22 g/mol; M.P. = 154°C; = 0.25 g/100 g cold H<sub>2</sub>O) either tastes bitter or is tasteless, depending on the heredity of the taster.

**Target(s):** *N*-acetyl-6-hydroxytryptophan oxidase (1); aromatic-L-amino-acid decarboxylase, or dopa decarboxylase (2); aureusidin synthase (3); bacterial leucyl aminopeptidase (4); catechol oxidase (5); cytochrome *c* oxidase (6); dynein ATPase (7); succinate dehydrogenase (6); tyrosinase, or monophenol monooxygenase, or pluperphenol oxidase (1,6,8-17); and xanthine oxidase (18). 1. ### Pheophorbide a

This chlorophyll *a* degradation intermediate (MW = 579.68 g/mol; CAS 15664-29-6), which is identical to chlorophyll *a*, except for the absence of the latter's magnesium ion and ester at the 17-position, is obtained by acid hydrolysis of chlorophyll *a*. Pheophorbide *a* inhibits acyl-CoA:cholesterol acyltransferase (1) and magnesium protoporphyrin IX methyltransferase (2), acts as an endothelin receptor antagonist (3), and also induces apoptosis. Pheophorbide *a* is also as an anti-tumor promoter. 1. Song, Rho, Lee, *et al.* (2002) *Planta Med.* **68**, 845. 2. Ellsworth & St. Pierre (1976) *Photosynthetic* **10**, 291. 3. Ohshima, Hirata, Oda, Sasaki & Shiratsuchi (1994) *Chem. Pharm. Bull.* **42**, 2174.

### Phethiol

This thiol (FW<sub>free-base</sub> = 167.27 g/mol), also known as 2-amino-3-phenylpropane-1-thiol, inhibits membrane alanyl aminopeptidase, or aminopeptidase N, *K<sub>i</sub>* = 39 nM (1-4) and *Clostridium botulinum* bontoxilysin, *K<sub>i</sub>* = 100 μM (5). 1. ### Philanthotoxin 343

This hygroscopic polyamine derivative (FW<sub>free-base</sub> = 435.61 g/mol; CAS 115976-93-7), often abbreviated PhTX-343, is a synthetic analogue of the wasp toxin philanthotoxin 433 that blocks NMDA-gated ion channels (1-3) and nicotinic acetylcholine receptors (4). The designation 343 refers to the number of methylene groups between the nitrogen atoms in the polyamine portion of the molecule (*i.e.*, 3, 4, and 3). With whole-cell ion transport recordings and outside-out patch clamp recordings, Brier *et al.* (4) investigated antagonism of human muscle nicotinic acetylcholine receptors (nAChR) by PhTX-343. When co-applied with AChR, PhTX-343 caused activation-dependent, noncompetitive inhibition (IC<sub>50</sub> = 17 μM at -100 mV) of whole-cell currents that was strongly voltage-dependent. Preapplication of PhTX-343 unveiled a voltage-independent antagonism that also required receptor activation, which is suggestive of desensitization enhancement. In single-channel studies, 10 μM PhTX-343 significantly reduced the mean open time of channel openings evoked by 1 μM acetylcholine, indicating that PhTX-343 predominantly blocks the opening of channels by acetylcholine. **Target(s):** acetylcholine receptor (4,5); GluR6(Q) glutamate receptor channel (6); IRK1 K<sup>+</sup> channel (7); NMDA-gated (*N*-methyl-D-aspartate-gated) channels (1-3). 1. Jones & Lodge (1991) *Eur. J. Pharmacol.* **204**, 203. 2. Fedorov, Screbitsky & Reymann (1992) *Eur. J. Pharmacol.* **228**, 201. 3. ### Philanthotoxin 433

This hygroscopic polyamine toxin (FW<sub>free-base</sub> = 435.61 g/mol; CAS 77108-00-0), abbreviated PhTX-443, from the Digger wasp *Philanthus triangulum* blocks NMDA-gated ion channels (1) and nicotinic acetylcholine receptors (2). The designation 433 refers to the number of methylene groups between the nitrogen atoms in the polyamine portion of the molecule (*i.e.*, 4, 3, and 3). **Target(s):** acetylcholine receptor (2); NMDA-gated (*N*-methyl-D-aspartate-gated) channels (1,3); and porin OmpF-mediated current, *Escherichia coli* (4). 1. Jones & Lodge (1991) *Eur. J. Pharmacol.* **204**, 203. 2. Rozental, Scoble, Albuquerque, *et al.* (1989) *J. Pharmacol. Exp. Ther.* **249**, 123. 3. Ragsdale, Gant, Anis, *et al.* (1989) *J. Pharmacol. Exp. Ther.* **251**, 156. 4. Basle & Delcour (2001) *Biochem. Biophys. Res. Commun.* **285**, 550.

### Phleomycins

Phleomycin D1

These glycopeptide antibiotics (FW<sub>Phleomycin-D1</sub> = 1427.60 g/mol; CAS 11031-11-1), like the closely related bleomycins, inhibit DNA biosynthesis, and are active *in vivo* against most bacteria (including *Escherichia coli*), filamentous fungi, yeasts, plant, and animal cells. Phleomycins are bleomycin analogues in which the penultimate thiazolium ring of the bithiazole tail is reduced. Phleomycins partially intercalate into DNA and

participate in the iron- and oxygen-dependent cleavage of the DNA duplex.

1. Tanaka, Yamaguchi & Umezawa (1963) *Biochem. Biophys. Res. Commun.* **10**, 171.

### Phloretin

This naturally occurring aglucon (FW = 274.27 g/mol; CAS 60-82-2) of phlorizin (or phloridzin) is generated from the latter by the action of  $\beta$ -glucosidases, the phlorizin hydrolase activity of lactase, and by dilute mineral acids. Phloretin is soluble in ethanol and acetone. It is almost insoluble in water; however, the solubility is increased upon addition of ethanol. It adsorbs to lipid surfaces and alters the dipole potential of lipid monolayers and bilayers. Adsorption to biological and artificial membranes results in a change of the membrane permeability for a variety of charged and neutral compounds. **Target(s):** aldose 1-epimerase, or mutarotase (1,27,28); ATPases, chloroplast (29);  $\text{Ca}^{2+}$  channels, L-type (2);  $\text{Ca}^{2+}$ -dependent ATPase (29); cAMP phosphodiesterase (3);  $\beta$ -carotene 15,15'-monooxygenase (4); chalcone isomerase (5); electron transport, chloroplast (29); fatty-acid synthase (32); glucose transport (6-10); glycogen phosphorylase (11,12); inositol-trisphosphate 3-kinase (31); iodothyronine deiodinase (13); lactate transport (14); L-leucine transport (15);  $\text{Na}^+$  and  $\text{K}^+$  uptake (16); oxidative phosphorylation (mitochondrial), uncoupler (17); phenylpyruvate tautomerase (18); photophosphorylation (29); prostaglandin  $\text{F}_{2\alpha}$  receptor (19); protein kinase C (20,21); pyruvate transport (14); starch phosphorylase (22);  $\alpha,\alpha$ -trehalase (23,30); tyrosinase, or monophenol monooxygenase (33); urea transport (24,25); and water permeability (25,26). 1. ### Phlorizin

This glucosuria-inducing agent (FW = 436.42 g/mol; CAS 60-81-1), also known as phlorrhizin, phloridzin, phlorrhizin, and 4,4',6'-trihydroxy-2'-glucosidodihydrochalcone, is found in all parts of the apple tree except for the mature fruit. Phlorizin blocks glucose reabsorption in the kidney and

intestine by inhibiting glucose/ $\text{Na}^+$  cotransporters as well as glucose transport into red blood cells and hepatocytes. Commercial phlorizin, typically supplied as the dihydrate, should be treated with activated charcoal before use and recrystallized from hot water. Note that muscle phosphorylase is much more inhibited than potato phosphorylase.

**Target(s):** aldose 1-epimerase, or mutarotase (1,2,40,41); ATPase, chloroplast, and photophosphorylation (3-7); ATPase, mitochondrial (8); bicarbonate-chloride exchange (9); complement component C'3, guinea pig (10); galactosyltransferase (11); glucose-6-phosphatase (12-15); glucose transport (16-23); glucoside 3-dehydrogenase (24); glycogen phosphorylase (25-29); glycogen synthase (30); lactase, or lactase/phlorizin hydrolase, or glycosylceramidase (42-46); laminaribiose phosphorylase (31,57);  $\text{Na}^+/\text{myo-inositol}$  cotransporter (32,33);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (34); phloretin hydrolase (42); 3-phytase (55,56); starch phosphorylase, weakly inhibited (25,35); sucrose phosphorylase (36);  $\alpha,\alpha$ -trehalase (37-39,50-54); tyrosinase, monophenol monooxygenase, weakly inhibited (58). 1. ### Phloroglucinol

This reagent (FW = 126.11 g/mol; CAS 108-73-6), also known as 1,3,5-trihydroxybenzene and phloroglucin, is a white solid, soluble in ten parts ethanol and in 100 parts water at 25°C. Resorcinol is a component of many naturally-occurring compounds (e.g., phloretin) and is often used in the qualitative detection of carbohydrates, aldehydes, and lignin. A solution of phloroglucinol acidified with HCl turns red, when boiled in the presence of pentoses. Phloroglucinol is a product of the reaction catalyzed by phloretin hydrolase and is a substrate of phloroglucinol reductase. **Target(s):** carboxylase (1,2); catechol oxidase (3,4);  $\beta$ -glucosidase (5); lipoxygenase (6); nitronate monooxygenase (7); phloretin hydrolase, product inhibition (8); 3-phytase (9); 4-phytase (9); aand tyrosinase (10). 1. ### Phomopsin A

This mycotoxin and antibiotic (FW = 789.24 g/mol; CAS 64925-80-0) is obtained from *Diaporthe toxica* (formerly *Phomopsis leptostromiformis*), a fungus that grows mainly within lupin stems, the consumption of which leads to lupinosis in sheep grazing on lupin stubble. Intoxication results in liver damage, disorientation, blindness, lethargy and death in severe cases. Phomopsin A is a 13-membered ether oxygen-containing macrolide that blocks tubulin polymerization ( $K_i < 1 \mu\text{M}$ ). It also inhibits vinblastine binding to tubulin and, in common with vinblastine and maytansine, enhances colchicine binding (1). Phomopsin A and the depsipeptide, Dolastatin 10, bind to a site adjacent to the vinca alkaloid and nucleotide sites. This mycotoxin induces tubulin oligomerization into ring structures that cannot form microtubules (2). Scatchard analysis suggests two classes of binding sites: a high-affinity site ( $K_1 = 1 \times 10^{-8} \text{ M}$ ) and a low-affinity site ( $K_2 = 3 \times 10^{-7} \text{ M}$ ) (3). Phomopsin A also inhibits rhizoxin binding, with a  $K_i$  of  $0.8 \times 10^{-8} \text{ M}$ , suggesting that the high-affinity site of phomopsin A is identical to the rhizoxin binding site (3). The development and validation of an LC-MS/MS method for detecting Phomopsin A in lupin and lupin-containing retail food has been reported (4). 1. Lacey, Edgar & Culvenor (1987) *Biochem. ### Phorbol 12-Myristate 13-Acetate

This photosensitive diester (FW = 616.84 g/mol; Symbol: PMA), also known as 12-*O*-tetradecanoylphorbol 13-acetate, found naturally in oil expressed from *Croton tiglium* seeds, is an activator of protein kinase C, a ligand for histone H<sub>1</sub>, and a potent tumor promoter. It also induces nitric oxide production. Phorbol 12-myristate 13-acetate will inhibit apoptosis induced by the Fas antigen but will induce apoptosis in HL-60 leukemia cells. *Note:* The 4 $\alpha$ -epimer (4 $\alpha$ -phorbol 12-myristate 13-acetate) is not biologically active and can be used as a negative control. **Target(s):** [elongation factor 2] kinase (1); and protein-disulfide isomerase (2). 1. Sans, Xie & Williams (2004) *Biochem. Biophys. Res. Commun.* **319**, 144. 2. Mayumi, Azuma, Kobayashi, et al. (2000) *Biol. Pharm. Bull.* **23**, 1111.

### Phosphamidon

This insecticide (FW = 299.69 g/mol; CAS 13171-21-6; 297-99-4 for (*E*)-isomer; 23783-98-4 for (*Z*)-isomer; Density = 1.2132 g/cm<sup>3</sup>; M.P. = 120-123 °C; B.P. = 162 °C at 1.5 mm Hg; miscible in water; LD<sub>50</sub> = 13 mg/kg (mouse, oral) = 6 mg/kg (mouse, IV); LD<sub>50</sub> = 20 mg/kg (rat, oral) = 26 mg/kg (rat, subcutaneous), known systematically as (*E/Z*)-[3-chloro-4-(diethylamino)-4-oxobut-2-en-2-yl] dimethyl phosphate and phosphoric acid, 2-chloro-3-(diethylamino)-1-methyl-3-oxo-1-propenyl dimethyl ester, inhibits cholinesterases. Commercial sources typically are a mixture of *cis* and *trans* isomers. Phosphamidon is membrane-permeant, and contact with the skin should be avoided. Prolonged treatment with vitamin C partially corrects the oxidative stress observed in phosphamidon-treated animals. **Target(s):** acetylcholinesterase (1-5); carboxylesterase (5,6); cholinesterase (7,8); monoamine oxidase (9); and neuropathy target esterase (5). 1. ### Phosphapyrimidine Nucleoside 1

This tetrahedral transition-state analogue (FW = g/mol) resembles the putative tetrahedral intermediate in the associative ( $S_N2$ ) reaction catalyzed by cytidine deaminase. As such, it is a slow-binding inhibitor at pH 6, with the following parameters:  $K_i = 0.9 \text{ nM}$ ;  $k_{on} = 8300 \text{ M}^{-1}\text{s}^{-1}$ ,  $k_{off} = 7.8 \times 10^{-6} \text{ s}^{-1}$  (1,2). With as tetrahyouridine as an inhibitor of this enzyme, the initial interaction is a loose complex ( $K_D = 1.2 \mu\text{M}$ ), attended by slower isomerization to give a more tightly bound complex ( $K_i = 0.24 \mu\text{M}$ , with forward and reverse rate constants of  $3.81 \text{ min}^{-1}$  and  $0.95 \text{ min}^{-1}$ , respectively). 1. Ashley & Bartlett (1984) *J. Biol. Chem.* **259**, 13621. 2. Ashley & Bartlett (1982) *Biochem. Biophys. Res. Commun.* **108**, 1467.

## Phosphatidate (Phosphatidic Acid)

These fatty acyl glycerophosphate derivatives are intermediates in the biosynthesis of phosphoglyceridase and complex phospholipids. Although the term does not stipulate the hydroxyl group(s) that is(are) acylated, nor the location of the phosphoryl group, phosphatidate refers to 1,2-diacyl-*sn*-glycerol 3-phosphate. *Note:* Acid-catalyzed hydrolysis yields both  $\alpha$ - and  $\beta$ -glycerophosphate, whereas base-catalyzed hydrolysis is unattended by phosphoryl group migration. (See also specific phosphatidate) **Target(s):**  $\beta$ -*N*-acetylglucosaminyl-glycopeptide  $\beta$ -1,4-galactosyl-transferase (47,48); *N*-acetyllactosamine synthase (47,48); adenyl cyclase (1); AMP deaminase, inhibited by 1,2-dioleoyl-*sn*-glycerol 3-phosphate (2); Ca<sup>2+</sup>/calmodulin-dependent protein kinase, activated at low concentrations (40); cardiolipin synthase (3); Ca<sup>2+</sup>-transporting ATPase, inhibited by 1,2-dioleoyl-*sn*-glycerol 3-phosphate (4); ceramidase (5); chymase (6,24); CMP-*N*-acetylneuraminate monooxygenase (53); cytidylate cyclase (7); diacylglycerol kinase, product inhibition (44); dolichylidiphosphatase (8); dolichyl-phosphatase (8,9,31-33); dopamine  $\beta$ -monooxygenase (10); ethanolaminophosphotransferase (42); glycerol-1,2-cyclic-phosphate phosphodiesterase (27); glycerol-3-phosphate *O*-acyltransferase (11,51,52); glycerone-phosphate *O*-acyltransferase, dihydroxyacetone-phosphate *O*-acyltransferase (50); glycosylphosphatidylinositol phospholipase D (12,25,26); G-protein signaling regulator (13); hydroxyacylglutathione hydrolase, glyoxalase II (36); indole-3-acetate  $\beta$ -glucosyltransferase (46); insulin receptor protein-tyrosine kinase (14); Lysophospholipase (15,38,39); lysophospholipase/transacyclase (15,38); [myosin-light-chain] phosphatase (30); nitric-oxide synthase, neuronal (16); phosphatidylglycerophosphatase (34); 1-phosphatidylinositol 3-kinase (17,18,43); 1-phosphatidylinositol 4-kinase, weakly inhibited (45); phospholipase C (also weak substrate (29); phospholipase D (28); phosphoprotein phosphatase (20,21,35); polar-amino-acid-transporting ATPase, or histidine permease (19); protein phosphatase-1 (20,21,35); tubulin polymerization, or microtubule assembly, as stimulated by microtubule-associated proteins (22,23); UDP-*N*-acetylglucosamine: lysosomal-enzyme *N*-acetylglucosamine phosphotransferase (41). 1. ## Phosphatidylcholine

This phospholipid, also called lecithin and 1,2-diacyl-*sn*-glycerol-3-phosphocholine, is an important constituent of biomembranes and lipoproteins. The physical properties depend on the nature of the acyl groups and on the nature of other lipids. Freshly prepared phosphatidylcholines are white solids that turn yellow and brown on exposure to air. They typically sinter between 75 and 120°C and melt in the neighborhood of 230°C. **See also specific compound Target(s):**  $\beta$ -*N*-acetylhexosaminidase (1); alcohol *O*-acetyltransferase (47); 1-alkyl-2-acetyl-glycerophospho-choline esterase, weakly inhibited (33); acylglycerol kinase, or monoacylglycerol kinase (43); arylalkylphosphatase, or paraoxonase (37); arylesterase (37); carnitine *O*-palmitoyltransferase (48); ceramidase (2,3); cerebrosidase-sulfatase, or arylsulfatase A (4); cholesterol monooxygenase, side-chain-cleaving, or CYP11A1 (50,51); choline-phosphate cytidylyltransferase (5); cyclopropane-fatty-acyl-phospholipid synthase (6); diacylglycerol kinase (42); dolichylidiphosphatase (7); dolichyl-phosphatase (7-9,31);  $\alpha$ -glucosidase (10);  $\beta$ -glucosidase (11,12); glucuronosyltransferase (46); glutamate dehydrogenase (16); glycosylphosphatidylinositol diacylglycerol-lyase, weakly inhibited (13); hormone-sensitive lipase (35); indole-3-acetate  $\beta$ -glucosyltransferase, weakly inhibited (45); lecithin:cholesterol acyltransferase, or LCAT, inhibited by the diphtanoyl derivative (14); linoleate diol synthase (52); lipoxygenase (15); lysophospholipase36; microsomal epoxide hydrolase, inhibited when lipid is above the critical micelle concentration (17); phosphatidate phosphatase, weakly inhibited (32); phosphatidyl-ethanolamine methyltransferase (18); phosphatidylinositol diacylglycerol-lyase, phosphatidylinositol-specific phospho-lipase C (19-22); 1-phosphatidylinositol 3-kinase (40,41); 1-phosphatidylinositol 4-kinase (44); phosphatidyl-*N*-methylethanolamine *N*-methyltransferase (49); phosphoinositide phospholipase C (23); protein-tyrosine sulfotransferase, weakly inhibited (38); sphingomyelin phosphodiesterase, or sphingomyelinase (24-29); sterol esterase, or cholesterol esterase (34,35); steryl- $\beta$ -glucosidase (30); and UDP-*N*-acetylglucosamine:dolichylphosphate *N*-acetylglucosaminephosphotransferase (39). 1. ### Phosphatidylethanolamine

1-Palmitoyl-2-stearoyl-*sn*-glycerol 3-phosphoethanolamine

This hygroscopic phospholipid, also called cephalin and 1,2-diacyl-*sn*-glycerol-3-phosphoethanolamine, is an important constituent of biomembranes and lipoproteins. It is the major structural phospholipid in brain tissue. The physical properties depend on the nature of the acyl groups and on the presence of other lipids. Freshly prepared phosphatidylethanolamines are white solids that turn yellow and brown on exposure to air. They typically sinter between 80 and 90°C and melt in the neighborhood of 175°C. Solutions of phosphatidylethanolamine slowly decompose at room temperature (roughly 0.3-0.5% per day); hence, solutions should always be freshly prepared and kept cold prior to use. It is labile in alkaline conditions. **See also specific compound Target(s):**  $\beta$ -*N*-acetylglucosaminyl-glycopeptide  $\beta$ -1,4-galactosyltransferase (23); *N*-acetylglucosamine synthase (23); acylglycerol kinase, or monoacylglycerol kinase (1); cholesterol monooxygenase, side-chain-cleaving, or CYP11A1 (26,27); chymase (2); cytidylate cyclase (3); dolichyldiphosphatase (4); dolichyl-phosphatase (4,5,16); dopamine  $\beta$ -monooxygenase (6); ethanolaminephosphotransferase (18); glutamate dehydrogenase (7);  $\gamma$ -glutamyl transpeptidase, mildly inhibited (8); glycerol-3-phosphate *O*-acyltransferase (25); glycerone-phosphate *O*-acyltransferase, or dihydroxyacetone-phosphate *O*-acyltransferase (24); hormone-sensitive lipase (9); 3-hydroxybutyrate dehydrogenase (10); indole-3-acetate  $\beta$ -

glucosyltransferase (22); phosphatidate cytidyltransferase (19); 1-phosphatidylinositol 4-kinase (20,21); phosphoinositide phospholipase C (11,12); phospholipase D, phosphatidylcholine-specific enzyme (13); sphingomyelin phosphodiesterase (14); steryl- $\beta$ -glucosidase (15); UDP-*N*-acetylglucosamine:dolichyl-phosphate *N*-acetylglucosaminephosphotransferase (17). **1.** Shim, Lin & Strickland (1989) *Biochem. ### Phosphatidylglycerol

1-Palmitoyl-2-stearoyl-*sn*-glycerol 3-phospho-(1-glycerol)

These phospholipids, also called 1,2-diacyl-*sn*-glycerol-3-phospho-(1-glycerol), is an important constituent of some biomembranes and a structural component of more complex phospholipids and is found more frequently in plants. The physical properties depend on the nature of the acyl groups and on the presence of other lipids. **See specific compound Target(s):**  $\beta$ -*N*-acetylglucosaminylglycopeptide  $\beta$ -1,4-galactosyltransferase (1); *N*-acetylglucosamine synthase (1); *N*-acetylmuramoyl-L-alanine amidase, at concentrations above the 0.3 mM critical micelle concentration (2,3); alcohol *O*-acetyltransferase (20); carbamoyl-phosphate synthetase I, ammonia-utilizing (4); ceramidase (5); chlorophyllase (6); diacylglycerol kinase (7); glycerol-3-phosphate *O*-acyltransferase, activated at low concentrations (21);  $\alpha$ -glucosidase (8); glycosylphosphatidylinositol diacylglycerol-lyase (9); glycosylphosphatidylinositol phospholipase D (10);  $\alpha$ -mannosidase (11); peptidase Do (HtrA heat shock protease) (12); phosphatidate phosphatase (13); 1-phosphatidylinositol 4-kinase (14); polar-amino-acid-transporting ATPase, or histidine permease (15); tubulin polymerization, or microtubule assembly, as stimulated by microtubule-associated proteins, weakly inhibited (16,17); UDP-*N*-acetylglucosamine:lysosomal-enzyme *N*-acetylglucosamine phosphotransferase (18); and undecaprenyl-phosphate mannosyltransferase (19). **1.** Clark & Moscarello (1986) *Biochim. ### Phosphatidylinositol

These phospholipid, often abbreviated PI or PtdIns, containing *sn*-glycerol 3-phosphate, two fatty acyl residues, and *myo*-inositol, is a common constituent of the membranes of eukaryotes and eubacteria and a key precursor in an intracellular signaling pathway. In addition, a derivative of phosphatidylinositol, namely glycosylphosphatidylinositol, assists in anchoring a number of proteins to membranes. **See specific compound**  
**Target(s):** actin filament bundling in the presence of microtubule-associate protein (21); alcohol *O*-acetyltransferase (30,31); Ca<sup>2+</sup>/calmodulin-dependent protein kinase (24); carbamoyl-phosphate synthetase I, ammonia-requiring (2); chymase (3,4); CMP-*N*-acetylneuraminase monooxygenase (35); diacylglycerol kinase (26); dolichyl-phosphatase (20); dolichyl-phosphate-mannose:protein mannosyltransferase (29); glucose-6-phosphatase (21); β-glucosidase (5); glycerol-3-phosphate *O*-acyltransferase (6,7,34); glycerone-phosphate *O*-acyltransferase, or dihydroxyacetone-phosphate *O*-acyltransferase (32); glycosylphosphatidylinositol diacylglycerol-lyase (8); glycosylphosphatidylinositol phospholipase D (9); hexokinase (27); 3-hydroxybutyrate dehydrogenase (10); indole-3-acetate β-glucosyltransferase (28); α-mannosidase (11); mannosyl-oligosaccharide 1,2-α-mannosidase, or mannosidase I (11,12); [myosin-light-chain] phosphatase (13); phosphatidate cytidyltransferase (25); phosphatidate phosphatase (22); phospholipase D (14); sphingomyelin phosphodiesterase (15-17); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, or ACAT (33); sterol esterase, or cholesterol esterase (23); tubulin polymerization, or microtubule assembly, as stimulated by microtubule-associated proteins (18,19). **1.** Yamauchi & Purich (1993) *Biochem. ### Phosphatidylinositol 3,4-Bisphosphate

These low-abundance membrane phospholipids (FW = 1011.07 g/mol for 1'-stearoyl-2'-arachidonoyl-*sn*-glycerol-3-phospho-1D-*myo*-inositol 3,4-bisphosphate (shown above)), also called triphosphoinositides and abbreviated PIP<sub>2</sub> or PI-3,4-P<sub>2</sub>, are important intermediates in signal transduction pathways that generate regulatory effectors of a number of metabolic processes. Each member of this class differs only in the fatty acyl components linked to C<sup>1</sup> and C<sup>2</sup> on the glycerol moiety. **Target(s):** glucose-6-phosphatase. **1.** Mithieux, Daniele, Payrastré & Zitoun (1998) *J. Biol. Chem.* **273**, 17.

### Phosphatidylinositol 4,5-Bisphosphate

These membrane phospholipids, differing only in the fatty acyl components linked to C1 and C2 of the glycerol moiety, also called triphosphoinositides and abbreviated PIP<sub>2</sub> or PI-4,5-P<sub>2</sub>, are important intermediates in a metabolic scheme that generates effectors for a number of metabolic processes. Phosphatidylinositol 4,5-bisphosphate is a precursor to the intracellular messengers inositol 1,4,5-trisphosphate and *sn*-1,2-diacylglycerol. Phosphatidylinositol 4,5-bisphosphate is an essential cofactor and stimulator of phospholipase D and is a substrate for specific isoforms of phospholipase C. **See specific compound** **Note:** The free acid slowly decomposes whereas the sodium salt can be stored cold in chloroform for extended periods. The stearoyl arachidonoyl form (*i.e.*, 1'-stearoyl-2'-arachidonoyl-*sn*-glycerol-3-phospho-1D-*myo*-inositol 4,5-bisphosphate, shown above) is a form commonly found in mammals. **Target(s):** [β-adrenergic-receptor] kinase (1); AMP deaminase (2); arachidonoyl-diacylglycerol kinase, a specific diacylglycerol kinase (3); casein kinase I (4-7); caspase 8 (8); caspase 9 (8); ER-60 protease (9); glucose-6-phosphatase (10,11); nitric-oxide synthase (12); phosphatidate cytidyltransferase (13); 1-phosphatidylinositol 4-kinase (20,25,26); 1-phosphatidylinositol-4-phosphate 5-kinase, product inhibition (14-19); protein kinase C (20); protein-tyrosine kinase (21); and sphingomyelin phosphodiesterase, or sphingomyelinase (22-24). **1.** Onorato, Gillis, Liu, Benovic & Ruoho (1995) *J. ### Phosphatidylinositol 3-Phosphate

These membrane phospholipids, also called phosphoinositides and abbreviated PIP or PI-3-P, are important intermediates in a metabolic scheme that generates effectors of a number of metabolic processes (each member of this class differ only in the fatty acyl components linked to C1 and C2 of the glycerol moiety: 1'-stearoyl-2'-arachidonoyl-*sn*-glycerol-3-phospho-1D-*myo*-inositol 3-phosphate is shown above). **Target(s):** glucose-6-phosphatase (1). **1.** Mithieux, Daniele, Payrastra & Zitoun (1998) *J. Biol. Chem.* **273**, 17.

### Phosphatidylinositol 4-Phosphate

These membrane phospholipids, also called phosphoinositides and abbreviated PIP or PI-4-P, are important intermediates in a metabolic scheme that generates effectors of a number of metabolic processes (each member of this class differ only in the fatty acyl components linked to C1 and C2 of the glycerol moiety: 1'-stearoyl-2'-arachidonoyl-*sn*-glycerol-3-phospho-1D-*myo*-inositol 4-phosphate is shown above). It is a component of the lipid signaling pathway and promotes  $\beta$ -adrenergic receptor kinase phosphorylation. **Target(s):** glucose-6-phosphatase (1); and phosphatidate cytidyltransferase, weakly inhibited (2). **1.** Mithieux, Daniele, Payrastra & Zitoun (1998) *J. Biol. Chem.* **273**, 17. **2.** Saito, Goto, Tonosaki & Kondo (1997) *J. Biol. Chem.* **272**, 9503.

### Phosphatidylinositol 3,4,5-Trisphosphate

These membrane phospholipids, differing only in the fatty acyl components linked to C1 and C2 of the glycerol moiety, are important intermediates in a signal transduction cascades that generate a number of key metabolic effectors. **Target(s):** glucose-6-phosphatase (1); and sphingomyelin phosphodiesterase (2). **1.** Mithieux, Daniele, Payrastra & Zitoun (1998) *J. Biol. Chem.* **273**, 17. **2.** Testai, Landek, Goswami, Ahmed & Dawson (2004) *J. Neurochem.* **89**, 636.

### Phosphatidyl-L-serine

### 1-Palmitoyl-2-stearoyl-*sn*-glycerol 3-phospho-L-Serine

These phospholipids, also called cephalin and 1,2-diacyl-*sn*-glycerol-3-phospho-L-serine, is an important constituent of biomembranes and lipoproteins and the major structural phospholipid in brain tissue. The physical properties depend on the nature of the acyl groups and on the presence of other lipids. Freshly prepared phosphatidylserines are white solids that turn yellow and brown on exposure to air. They typically sinter about 120°C and melt in the neighborhood of 159°C. Solutions will typically undergo decomposition at room temperature at a rate of 0.5% per day. (**See specific compound**) **Target(s):** acetylcholinesterase (37);  $\beta$ -*N*-acetylglucosaminylglycopeptide  $\beta$ -1,4-galactosyltransferase (44); *N*-acetylglucosamine synthase (44); alcohol *O*-acetyltransferase (45); ATP diphosphatase1;  $\text{Ca}^{2+}$ -exporting ATPase (2,3); carbamoyl-phosphate synthetase I, ammonia-requiring (4); ceramidase (5); chymase (6,7); cytidylate cyclase (8); dopamine  $\beta$ -monoxygenase (9); elastase (6); fructose-1,6-bisphosphate aldolase, inhibited by phosphatidylserine liposomes (10);  $\beta$ -glucosidase (11); glutamate dehydrogenase (12);  $\gamma$ -glutamyl transpeptidase (13); glycerol-3-phosphate *O*-acyltransferase (14,15,48); glycerone-phosphate *O*-acyltransferase, or dihydroxyacetone-phosphate *O*-acyltransferase, weakly inhibited (46); glycosylphosphatidylinositol diacylglycerol-lyase (16); glycosylphosphatidylinositol phospholipase D (17); hexokinase (43); hormone-sensitive lipase (36); hydroxyacyl-glutathione hydrolase, or glyoxalase II (34); 3-hydroxybutyrate dehydrogenase (18); lactate dehydrogenase (19); monoamine oxidase (20,21); [myosin-light-chain] phosphatase (22); phosphatidate cytidyltransferase (40); phosphatidate phosphatase (23); 1-phosphatidylinositol 4-kinase (41,42); phosphatidylinositol-3,4,5-trisphosphate 3-phosphatase (24); phosphoinositide phospholipase C (25-27); polar-amino-acid-transporting ATPase, histidine permease (28); sphingomyelin phosphodiesterase, or sphingomyelinase (29,30); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, or ACAT (47); sterol esterase, or cholesterol esterase (35,36); tubulin polymerization, or microtubule assembly, as stimulated by microtubule-associated proteins, weakly inhibited (31,32); tumor necrosis factor (33); UDP-*N*-acetylglucosamine: dolichyl-phosphate *N*-acetylglucosamine-phosphotransferase (38); and UDP-*N*-acetylglucosamine:lysosomal-enzyme *N*-acetylglucosaminephosphotransferase (39). **1.** Capito, Hansen, Hedeskov & Thams (1986) *Diabetes* **35**, 1096. **2.** Dalton, East, Mall, *et al.* (1998) *Biochem. #### 4,4'-Phosphinocobis(butane-1,3-dicarboxylic Acid)

This tetracarboxylic acid (FW<sub>free-acid</sub> = 354.25 g/mol) inhibits glutamate carboxypeptidase II ( $K_i$  = 21.7 nM) and is a mGluR3 receptor agonist (1,2). **1.** Kozikowski, Zhang, Nan, *et al.* (2004) *J. Med. Chem.* **47**, 1729. **2.** Kozikowski, Nan, Conti, *et al.* (2001) *J. Med. Chem.* **44**, 298.

#### Phosphinothricin

This dephospho transition-state analogue (FW = 177.10 g/mol; CAS 51276-47-2) is naturally occurring glutamate analogue, first isolated from *Streptomyces viridochromogenes*. Phosphinothricin is a slow, tight-binding inhibitor of glutamine synthetase (1-9) that binds at the glutamate binding site and stabilizes the flap of a glutamyl residue in a position blocking glutamate entry into the active site, thereby trapping the inhibitor on the enzyme. Phosphinothricin undergoes an ATP-dependent phosphorylation. *Note:* Phosphinothricin is a component of the antibiotics bialaphos and phosalacine. The monoammonium salt of the racemic compound, also called glufosinate-ammonium, is a post-emergent herbicide. **1.** Logusch, Walker, McDonald & Franz (1989) *Biochemistry* **28**, 3043. **2.** Gill & Eisenberg (2001) *Biochemistry* **40**, 1903. **3.** Abell & Villafranca (1991) *Biochemistry* **30**, 6135. **4.** Robertson & Alberte (1996) *Plant Physiol.* **111**, 1169. **5.** Garcia-Dominguez, Reyes & Florencio (1997) *Eur. #### 2'-Phospho-ADP-ribose

This inhibitor (FW = 667.25 g/mol; CAS 13552-81-3; 16562-85-9 for the  $\beta$ -D-ribofuranose-isomer), also known as 2'-monophosphoadenosine 5'-diphosphoribose and adenosine-2'-monophospho-5'-diphosphoribose, is structurally equivalent to pyridine-less NADP<sup>+</sup> or NADPH. **Target(s):**

glucose-6-phosphate dehydrogenase (1); glutamate dehydrogenase (2); glutathione-disulfide reductase, NADPH-dependent (3); 3-hydroxy-3-methylglutaryl-CoA reductase (4-7); isocitrate dehydrogenase, NADP<sup>+</sup>-dependent (1,8); and 6-phosphogluconate dehydrogenase (1). **1.** Grafe, Bormann & Truckenbrodt (1980) *Z. Allg. Mikrobiol.* **20**, 607. **2.** Smith, Austen, Blumenthal & Nyc (1975) *The Enzymes*, 3rd ed., **11**, 293. **3.** Llobell, Fernandez & Lopez-Barea (1986) *Arch. Biochem. #### 5-Phospho-D-arabinonamide

This glucosamine 6-phosphate analogue (FW = 258.12 g/mol) inhibits glutamine:fructose-6-phosphate aminotransferase (isomerizing) and glucose-6-phosphate isomerase, with respective  $K_i$  values of 6.2 mM and 4.6  $\mu$ M. **1.** Milewski, Janiak & Wojciechowski (2006) *Arch. Biochem. Biophys.* **450**, 39.

#### 5-Phospho-D-arabinonate, See D-Arabinonic Acid 5-Phosphate

#### 5-Phosphoarabonate, See D-Arabinonic Acid 5-Phosphate

#### N<sup>6</sup>-Phospho-L-arginine

This metabolite (FW = 254.18 g/mol; CAS 1189-11-3;  $pK_1$  = 2.0,  $pK_2$  = 4.5,  $pK_3$  = 9.4, and  $pK_4$  = 11.2), formerly called arginine phosphate, is the most common phosphagen in invertebrates. It is produced by the action of arginine kinase and is a substrate of phosphoamidase and alkaline phosphatase. Complete hydrolysis occurs after one minute at 100°C in 0.1 M HCl. **Target(s):** adenylate kinase, weakly inhibited (1); creatine kinase (2); 6-phosphofructokinase (3); and pyruvate kinase (4-7). **1.** Storey (1976) *J. Biol. Chem.* **251**, 7810. **2.** Watts (1973) *The Enzymes*, 3rd ed. (Boyer, ed.), **8**, 383. **3.** Storey (1982) *Meth. Enzymol.* **90**, 39. **4.** Giles, Poat & Munday (1980) *Biochem. Soc. #### Phosphoaspartate, See $\beta$ -Aspartyl Phosphate

#### Phosphocholine

This choline phosphomonoester (FW<sub>zwitterion</sub> = 183.14 g/mol; CAS 107-73-3), also known as choline phosphate and phosphorylcholine, is a key intermediate in the biosynthesis of many phospholipids. Both the free acid and the calcium salt are very soluble in water. The free acid is relatively stable in acidic conditions: only 15% is hydrolyzed in five hours in 1 M HCl at 100°C. Under alkaline conditions, there is complete hydrolysis after four hours by refluxing with barium hydroxide. The phosphocholine chloride calcium salt is stable for months at room temperature. **Target(s):** 1-alkyl-2-acetyl-glycerophosphocholine esterase, or platelet-activating-factor acetylhydrolase (1); choline-sulfatase (2,3); choline sulfotransferase (4); ethanolamine kinase (5-7); ethanolamine-phosphate cytidylyltransferase (8); glutamate decarboxylase (9); glycerophosphocholine cholinephosphodiesterase (10); ornithine decarboxylase (9); phosphoethanolamine *N*-methyltransferase (11-14); phosphoserine phosphatase (15); and

sphingomyelin phosphodiesterase, or sphingomyelinase (16-18). 1. Chroni & Mavri-Vavayanni (2000) *Life Sci.* **67**, 2807. 2. Lucas, Burchiel & Segel (1972) *Arch. Biochem. Biophys.* **153**, 664. 3. **Phospho-CPI-17, See CPI-17**

### Phosphocreatine

This phosphagen (FW = 211.11 g/mol; CAS 67-07-2; 922-32-7 for disodium salt), known almost as commonly as creatine phosphate, is the primary cytosolic phosphoryl donor for the resynthesis of MgATP from MgADP through the action of creatine kinase in vertebrates and some invertebrates. While abundant in skeletal and cardiac muscle (40-60 mM), nonmuscle cells contain 3-5 mM, and some fungi (e.g., *Candida*) have intermediate levels of this metabolite. *Note:* The reported inhibitory action by creatine kinase is often due to impurities (e.g., the inhibition of 5'-nucleotidase is due to an impurity in the commercial phosphocreatine). The reported inhibition of AMP deaminase is due mainly to the presence of pyrophosphate (1). Phosphocreatine is a hygroscopic solid and very soluble in water. Unstable in acid, all is hydrolyzed after one minute at 100°C in 1.0 M HCl, and half is hydrolyzed in 4 min at 25°C in 0.5 M HCl. Molybdate and certain buffers reportedly accelerate hydrolysis. Hydrolysis is slow under slightly alkaline conditions (e.g., pH 7.8). Nevertheless, solutions should always be freshly prepared and stored frozen. **Target(s):** adenylate cyclase (1); AMP deaminase (2-4); glutamine synthetase (5); H<sup>+</sup>-extrusion by plasma membrane ATPase (6); NADH peroxidase (7); phosphofructokinase (8,9); and thiamin-phosphate diphosphorylase (10-12). 1. **Phosphoenol-3-fluoropyruvic Acid, See 3-Fluoro-phosphoenolpyruvic Acid**

### Phosphoenol- $\alpha$ -ketobutyric Acid

Both the (Z)- and (E)-isomers of this phosphoenolpyruvate homologue (FW<sub>free-acid</sub> = 182.07 g/mol) are alternative substrates for pyruvate kinase. There is less than a three-fold difference between the two  $V_{max}/K_m$  ratios for

the two isomers (note that the  $V_{max}$  values are substantially smaller than that of phosphoenolpyruvate (PEP), but the  $K_m$  value of (Z)-phosphoenol- $\alpha$ -ketobutyrate is close to that of PEP (1). Both isomers inhibit phosphoenolpyruvate carboxykinase, with the (E)-isomer being the more potent inhibitor, and neither isomer is a substrate for this enzyme (2,3). The (Z)-isomer is the more effective inhibitor of enolase, with the (E)-isomer becoming a better inhibitor in the presence of Mg<sup>2+</sup> (3). Both isomers also inhibited plant phosphoenolpyruvate carboxylase in the presence of 5 mM Mg<sup>2+</sup>, with the (Z)-isomer having the smaller  $K_i$  value. In the presence of 0.5 mM Mn<sup>2+</sup>, the (Z)-isomer is still effective as inhibitor while the (E)-isomer produced activation by binding at an allosteric site. Both compounds were alternative substrates of the enzyme with similar  $V_{max}/K_m$  values. **Target(s):** 3-deoxy-7-phosphoheptulonate synthase (4,5); enolase (3); phosphoenolpyruvate carboxykinase (2,3); phosphoenolpyruvate carboxylase (6); pyruvate kinase,  $K_i$  = 65  $\mu$ M (3,7-9). 1. ### Phosphoenolpyruvate

This key intermediate in glycolysis and gluconeogenesis (FW<sub>free-acid</sub> = 168.04 g/mol; CAS 73-89-2), frequently abbreviated as PEP, is the phosphate ester formed from the hydroxyl group of the enol tautomer of pyruvate. The  $\Delta G^\circ$  value for hydrolysis is -62 kJ/mol at pH 7. The half-life of PEP is 8.3 min in 1.0 N HCl at 100°C. PEP is also readily hydrolyzed by base. Solutions should be immediately neutralized after dissolution of the vacuum-dessicated powder and never stored beyond a few days. **Target(s):** acetolactate synthase (131); acylphosphatase (57,58); adenylate kinase (78,79); adenylosuccinate synthetase (1); cAMP-dependent protein kinase phosphorylation of pyruvate kinase (2); diglucosyl diacylglycerol synthase (124); farnesyl-diphosphate kinase, weakly inhibited (77); fructose-1,6-bisphosphatase (Note: PEP is an activator of many FBPsases.) (66-68); fructose-1,6-bisphosphate aldolase (51,52); 1,3- $\beta$ -glucan synthase (125); glucose-1,6-bisphosphate synthase (80-82); glucose-1-phosphate adenyllyltransferase (3,74-76); glucose-6-phosphate isomerase (4); glycerol-3-phosphate dehydrogenase (5); glycogen synthase (6); guanylate cyclase (7-9); hexokinase (122); [isocitrate dehydrogenase (NADP<sup>+</sup>)] kinase (10,69); isocitrate lyase (11,12,42-50); L-lactate dehydrogenase (13); malate synthase (128-130); methylglyoxal synthase (14,36-41); NADH kinase (106,107); NADH peroxidase (15); NAD<sup>+</sup> kinase, weakly inhibited (109); oxaloacetate decarboxylase (54,55); oxaloacetate tautomerase (16); 6-phosphofructokinase (17-24,115-121); 6-phosphofructo-2-kinase (83-100); 6-phospho- $\beta$ -galactosidase (62,63); phosphoglucomutase (25); 6-phospho- $\beta$ -glucosidase (61); phosphoketolase (53); phosphopyruvate hydrolase (56); phosphoprotein phosphatase (64,65); phosphoribulokinase (110-114); protein phosphatase 2A (65); [protein-PII] uridylyltransferase (73); pyrophosphate-dependent phosphofructokinase, or diphosphate: fructose-6-phosphate 1-phosphotransferase (101-105); pyruvate carboxylase (26); pyruvate kinase (2,27,108); pyruvate, orthophosphate dikinase (71,72); pyruvate, water dikinase (70); ribulose-5-phosphate kinase (28); starch phosphorylase (127); sucrose-phosphate synthase, weakly inhibited (126); thiamin-phosphate diphosphorylase (29,30,123); threonine ammonia-lyase, or threonine dehydratase (31); triose-phosphate isomerase (4,32-35); and Xaa-Pro Dipeptidase, or prolidase,  $K_i$  = 8.5 nM (59,60). 1. ### 6-Phospho-D-gluconate

This water-soluble metabolite ( $\text{FW}_{\text{free-acid}} = 276.14$  g/mol), also called D-gluconic acid 6-phosphate, is a key intermediate in the pentose phosphate and Entner-Doudoroff pathways. It lactonizes upon heating to 70°C.

**Target(s):** cellobiose phosphorylase (1); fructose-1,6-bisphosphate aldolase (46); fructose-2,6-bisphosphate 2-phosphatase (51,52); glucose-6-phosphate dehydrogenase (2); glucose-6-phosphate isomerase (3-20,37-41,60); glyceraldehyde-3-phosphate dehydrogenase (21); 1L-*myo*-inositol-1-phosphatase (22); inositol-3-phosphate synthase, *or myo*-inositol-1-phosphate synthase (22-25); isocitrate lyase (26); L-lactate dehydrogenase (27); levansucrase (61); mannose-6-phosphate isomerase (6,19,20); phosphoenolpyruvate carboxykinase (28); phosphofructokinase (29); phosphoglucomutase (30); phosphoglycolate phosphatase (53); phosphoribulokinase (55-59); pyruvate kinase (54); ribose-5-phosphate isomerase (31,42-44); ribulose-1,5-bisphosphate carboxylase/oxygenase (32-36,47-50); and triose-phosphate isomerase, weakly inhibited (45). **1.** Sasaki (1988) *Meth. ### D-2-Phosphoglycerate (D-2-Phosphoglyceric Acid)

This metabolite ( $\text{FW}_{\text{free-acid}} = 186.06$  g/mol; CAS 2553-59-5; 23295-92-3 for (S)-isomer; 3443-57-0 for (R)-isomer), also called 2-phospho-D-glycerate, D-glycerate 2-phosphate, and (R)-2,3-dihydroxypropionate 2-(dihydrogen phosphate), is an important intermediate in carbohydrate metabolism. D-2-Phosphoglycerate is slowly hydrolyzed by acids and salts and is readily soluble in water and. It is a substrate or product in the reactions catalyzed by phosphoglycerate phosphatase, enolase, and phosphoglycerate mutase. D-2-Phosphoglycerate is an ADPglucose synthetase activator (1). **Target(s):** bisphosphoglycerate mutase (2); bisphosphoglycerate phosphatase (2-4); 3-deoxy-7-phosphoheptulonate synthase, *or* 3-deoxy-D-arabinoheptulonate-7-phosphate synthetase (5); glycerol-3-phosphate dehydrogenase (6); hexokinase (7,8); methylglyoxal synthase (9); NADH peroxidase (10); phosphoenolpyruvate carboxylase (11); phosphoenolpyruvate:protein phosphotransferase (12); 6-phosphofructokinase (13-18); 6-phosphofructo-2-kinase (19-21); 6-phospho-β-galactosidase (22); phosphoglycerate kinase (23); pyrophosphatase, *or* inorganic diphosphatase (24); pyruvate kinase (25-27); and triose-phosphate isomerase (28). **1.** Gardiol & Preiss (1990) *Arch. ### D-3-Phosphoglycerate (D-3-Phosphoglyceric Acid)

This metabolite ( $\text{FW}_{\text{free-acid}} = 186.06$  g/mol; CAS 820-11-1; 3443-58-1 for (R)-isomer; 61546-67-6 for tri-Na salt; 927-10-6 for mono-Na salt), also called 3-phospho-D-glycerate, D-glycerate 3-phosphate, and (R)-2,3-dihydroxypropionate 3-(dihydrogen phosphate), is an important intermediate in carbohydrate metabolism. It is also a precursor in the biosynthesis of L-serine and L-cysteine. In addition, D-3-phosphoglycerate

was the first intermediate identified in the photosynthetic carbon reduction cycle by Melvin Calvin and coworkers. D-3-Phosphoglycerate was the first example of a feedback inhibitor (2,3). The alkaline metal salts of this metabolite are readily soluble in water; however, the barium salt is sparingly soluble (albeit, soluble in dilute mineral acids). D-3-Phosphoglycerate is very slowly hydrolyzed by acids. Half is hydrolyzed by 1.0 M HCl at 100°C in 35.7 hours (and about 3 hours at 125°C). Note that solutions of D-3-phosphoglycerate can quickly become contaminated with microorganisms: hence, solutions should be stored frozen. **Target(s):** acetolactate synthase (80); acylphosphatase (50); ADP-sugar diphosphatase (49); bisphosphoglycerate mutase (4); bisphosphoglycerate phosphatase (4-6,57-60); 1-deoxy-D-xylulose-5-phosphate synthase (79); enolase (7-10); fructose-1,6-bisphosphate aldolase (46); glucose-1,6-bisphosphate synthase (64,65); glucose-6-phosphate dehydrogenase (11); glucose-6-phosphate isomerase (12,13); [glutamine-synthetase] adenyllyltransferase (62); glyceraldehyde-3-phosphate dehydrogenase (8); glycerol-3-phosphate dehydrogenase (14,15); hexokinase (16,77,78); inositol-phosphate phosphatase, weakly inhibited (54); [isocitrate dehydrogenase] kinase/phosphatase (17,18); isocitrate dehydrogenase, NADP<sup>-</sup>-dependent (19); isocitrate lyase (20,44,45); methylglyoxal synthase (21,40-43); NADH peroxidase (22); phosphoenolpyruvate carboxykinase, ATP-dependent (47); phosphoenolpyruvate carboxylase (48); phosphoenolpyruvate phosphatase (51-53); phosphoenolpyruvate:protein phosphotransferase (63); 6-phosphofructokinase (23-26,71-76); 6-phosphofructo-2-kinase (27,28); phosphoglucomutase (29,30); phosphoglycerate phosphatase 55; phosphoprotein phosphatase (weakly inhibited) 56; phosphoribulokinase (70); [protein-P<sub>II</sub>] uridylyltransferase (61); pyrophosphate-dependent phosphofructokinase, or diphosphate:fructose-6-phosphate 1-phosphotransferase (66,67); pyruvate kinase (31,32,68,69); ribulose-bisphosphate carboxylase (33-35); ribose-5-phosphate isomerase (36,37); triose-phosphate isomerase (38,39). 1. ### 3-Phospho-D-glyceroyl Phosphate

This key glycolytic pathway intermediate (FW<sub>free-acid</sub> = 266.04 g/mol), more commonly known as 1,3-bisphospho-D-glycerate (albeit incorrectly), is quite unstable: 50% is hydrolyzed in 27 minutes at pH 7.2 and 38°C, producing D-glycerate 3-phosphate. **Target(s):** ATPase (1); methylglyoxal synthase (2); 6-phosphofructokinase (3); and phosphoglucomutase (4,5). 1. Ellis & Faulkner (1961) *Biochem. Biophys. Res. Commun.* **5**, 255. 2. Murata, Fukuda, Watanabe, et al. (1985) *Biochem. Biophys. Res. Commun.* **131**, 190. 3. ### 2-Phosphoglycolate (2-Phosphoglycolic Acid)

This metabolite (FW<sub>free-acid</sub> = 156.03 g/mol), also known as phosphoglycolate and glycollic acid phosphate, is a putative transition-state analogue of the reaction catalyzed by triose-phosphate isomerase. **Target(s):** bisphosphoglycerate mutase (1); enolase (2-4); glycerol-3-phosphate dehydrogenase (5); methylglyoxal synthase (6-8); phosphoenolpyruvate carboxylase (9); phosphoenolpyruvate mutase (10); 6-phosphofructokinase (11-15); 6-phosphofructo-2-kinase (16); 3-phosphoglycerate kinase (17); phosphoprotein phosphatase (18); pyrophosphate-dependent phosphofructokinase, or diphosphate:fructose-6-phosphate 1-phosphotransferase (19); pyruvate kinase (20-22); pyruvate, orthophosphate dikinase (23); and triose-phosphate isomerase (24-36). 1. ### Phosphoglycolohydrazide

This hydrazide (FW<sub>free-acid</sub> = 169.05 g/mol) is a strong reversible inhibitor of class II fructose-1,6-bisphosphate aldolase,  $K_i = 0.34 \mu\text{M}$  (1,2) and rabbit muscle triose-phosphate isomerase,  $K_i = 111 \mu\text{M}$  (1). **1.** Fonvielle, Mariano & Therisod (2005) *Bioorg. Med. Chem. Lett.* **15**, 2906. **2.** Fonvielle, Weber, Dabkowska & Therisod (2004) *Bioorg. Med. Chem. Lett.* **14**, 2923.

### Phosphoglycolohydroxamate

This hydroxamate (FW<sub>free-acid</sub> = 171.05 g/mol) is a mimic of dihydroxyacetone phosphate and an enediolate transition-state analogue for triose-phosphate isomerase, fructose-1,6-bisphosphate aldolase, and other aldolases. **Target(s):** fructose 1,6-bisphosphate aldolase (1-7); L-fuculose-phosphate aldolase (8-10); methylglyoxal synthase,  $K_i = 39 \text{ nM}$  (11); L-rhamnulose-1-phosphate aldolase (8); tagatose-1,6-bisphosphate aldolase (12); and triose-phosphate isomerase (1,5,7,13-21). **1.** Wolfenden (1969) *Nature* **223**, 704. **2.** Wolfenden (1977) *Meth. ### Phospholipase C-γ1 D-domain Hexadecapeptide

This hexadecapeptide (Sequence: RRRKIALELSELVVYC; FW = 1920.34 g/mol) inhibits mitogen-activated protein kinase. **1.** Buckley, Sekiya, Kim, Rhee & Caldwell (2004) *J. Biol. Chem.* **279**, 41807.

### Phosphonoacetate (Phosphonoacetic Acid)

This pyrophosphate and carbamoyl phosphate analogue (FW<sub>free-acid</sub> = 140.03 g/mol; CAS 4408-78-0) exhibits antihyperthermic activity. **See also Phosphonoformate** **Target(s):** adenosine kinase (25,26); African swine fever virus-induced DNA polymerase (1,23); aspartate carbamoyltransferase (2); bacteriophage T<sub>4</sub> DNA polymerase (3,22); bacteriophage λ protein phosphatase (4); biotin carboxylase,  $K_{is} = 1.8 \text{ mM}$  for the *Escherichia coli* enzyme (5); carbamate kinase (24); DNA-directed DNA polymerase (1,3,6-8,22,23); DNA polymerases α, β, and γ (6-8); DNA polymerase, cytomegalovirus (8); DNA polymerase, viral (e.g., Herpes simplex-induced DNA polymerase and Vaccinia-induced DNA polymerase) (1,8-16); Epstein-Barr virus induced DNA polymerase (12,16); formyltetrahydrofolate synthetase (17); phosphate transport (18,19); phosphoenolpyruvate mutase (20); phosphonoacetaldehyde hydrolase (21); ribokinase (27); and RNA-directed DNA polymerase (6). **1.** Marques & Costa (1992) *Virology* **191**, 498. **2.** Burns, Mendz & Hazell (1997) *Arch. ### Phosphonoacetohydroxamate

This hydroxamate (FW<sub>free-acid</sub> = 155.05 g/mol) inhibits 1-deoxy-D-xylulose-5-phosphate synthase (1) and enolase, or phosphopyruvate hydratase, the latter with a  $K_i$  value of 15 pM in the presence of optimal Mg<sup>2+</sup> concentration (1,2). 1. Eubanks & Poulter (2003) *Biochemistry* **42**, 1140. 2. Brewer, Glover, Holland & Lebioda (1998) *Biochim. Biophys. Acta* **1383**, 351. 3. Anderson, Weiss & Cleland (1984) *Biochemistry* **23**, 2779.

### 3-(Phosphonoacetylamido)-L-alanine

This unreactive structural analogue (FW<sub>ion</sub> = 224.11 g/mol) of the  $\gamma$ -glutamyl phosphate intermediate formed during glutamine synthetase catalysis is initially a low-affinity competitive inhibitor of the synthetase, which upon binding of PA<sub>2</sub>LA, undergoes subsequent conformational changes. It remains to be determined whether its weak binding relative to the  $\gamma$ -glutamyl-phosphate intermediate results from restricted rotation of the internal amide group, differences in its acid/base properties, or some obligatory conformational changes during ATP-dependent phosphorylation of the  $\gamma$ -carboxyl group. **Target(s):** glutamate-semialdehyde dehydrogenase, or  $\gamma$ -glutamylphosphate reductase (1,2); and glutamine synthetase, slow-binding inhibition (3-5). 1. Hayzer & Leisinger (1983) *Biochim. Biophys. Acta* **742**, 391. 2. Krishna, Beilstein & Leisinger (1979) *Biochem. J.* **181**, 223. 3. Morrison (1982) *Trends Biochem. Sci.* **7**, 102. 4. Wedler & Horn (1976) *J. Biol. Chem.* **251**, 7530. 5. Purich (1982) *Meth. Enzymol.* **87**, 3.

### N<sup>α</sup>-(Phosphonoacetyl)-L-asparagine

This substrate analogue (FW<sub>ion</sub> = 251.11 g/mol) inhibits *Escherichia coli* aspartate carbamoyltransferase, IC<sub>50</sub> = 225 nM, albeit not as potently as N-(phosphonoacetyl)-L-aspartate. 1. Eldo, Heng & Kantrowitz (2007) *Bioorg.*

*Med. Chem. Lett.* **17**, 2086. 2. Cardia, Eldo, Xia, et al. (2008) *Proteins Struct. Funct. Bioinform.* **71**, 1088.

### N<sup>α</sup>-(Phosphonoacetyl)-α-aspartamide

This substrate analogue (FW<sub>ion</sub> = 251.11 g/mol) inhibits aspartate carbamoyltransferase (*Escherichia coli* IC<sub>50</sub> = 87 nM), albeit not as potently as N-(phosphonoacetyl)-L-aspartate (1). 1. Eldo, Heng & Kantrowitz (2007) *Bioorg. Med. Chem. Lett.* **17**, 2086.

### N-(Phosphonoacetyl)-L-aspartate

This tight-binding inhibitor (FW<sub>free-acid</sub> = 255.12 g/mol), often abbreviated as PALA, is a geometric analogue that collectively incorporates key features of the two natural substrates of aspartate carbamoyltransferase to achieve nanomolar-level dissociation constants. While PALA potently inhibits the enzyme, some cells compensate for loss of enzymatic activity by synthesizing elevated levels of the enzyme. 1. Collins & Stark (1971) *J. Biol. Chem.* **246**, 6599. 2. Wolfenden (1977) *Meth. Enzymol.* **46**, 15. 3. Sigman & Mooser (1975) *Ann. Rev. Biochem.* **44**, 889. 4. Purcarea (2001) *Meth. Enzymol.* **331**, 248. 5. ### N<sup>ε</sup>-(Phosphonoacetyl)-L-ornithine

This ornithine derivative (FW = 252.16 g/mol), often abbreviated PALO, is a bisubstrate or geometric analogue of the two natural substrates of ornithine carbamoyltransferase (1-11). 1. **(Z)-3-(2-Phosphonoethen-1-yl)pyridine-2-carboxylic Acid**

This homoserine phosphate analogue (FW<sub>ion</sub> = 226.10 g/mol) inhibits wheat cystathionine  $\gamma$ -synthase,  $K_i = 40 \mu\text{M}$ . The same enzyme is irreversibly inhibited by DL-propargylglycine ( $K_i = 45 \mu\text{M}$ ,  $k_{\text{inact}} = 0.16 \text{ min}^{-1}$ ). Other homoserine phosphate analogues, such as 4-(phosphonomethyl)-pyridine-2-carboxylic acid and DL-E-2-amino-5-phosphono-3-pentenoic acid, are also reversible competitive inhibitors of wheat cystathionine  $\gamma$ -synthase, with respective  $K_i$  values of 40 and 1.1  $\mu\text{M}$ . 1. Krefl, Townsend, Pohlenz & Laber (1994) *Plant Physiol.* **104**, 1215.

**Phosphonoformate (Phosphonoformic Acid)**

This pyrophosphate analogue (FW<sub>trisodium salt</sub> = 191.95 g/mol; CAS 4428-95-9), also called foscarnet, exhibits antihherpetic activity. It is a strong inhibitor of viral reverse transcriptases and viral replication as well as Na<sup>+</sup>/phosphate cotransporters. **Target(s)**: adenylyl cyclase (1); avian myeloblastosis virus reverse transcriptase (2,3); cytomegalovirus DNA polymerase (4-6); DNA-directed DNA polymerase (7,46); DNA polymerase  $\beta$  (7); DNA polymerases, viral (2-6,8-29); duck hepatitis B virus reverse transcriptase (13,17); Epstein-Barr virus DNA polymerase (16,21); equine infectious anemia virus reverse transcriptase (12); exoribonuclease H (44); feline immunodeficiency virus reverse transcriptase (11,29); geranyl-diphosphate cyclase, or bornyl-diphosphate synthase (30); guanylyl cyclase (1); HIV-1 reverse transcriptase (4,8,10,11,14, 18,31,44,45); human T-lymphotropic virus type III reverse transcriptase (19); herpes virus reverse transcriptase (6,20,21,25,28); human hepatitis B virus reverse transcriptase (22,26); Moloney murine leukemia virus reverse transcriptase (3); Na<sup>+</sup>-dependent phosphate transport (32-38); phosphoenolpyruvate carboxylase (39); phosphoenolpyruvate mutase (40); phosphonoacetate hydrolase (41,43); phosphonopyruvate hydrolase (42); ribonuclease H (44); RNA-directed DNA polymerase (2-6,8-29,31,44,45); simian immunodeficiency virus reverse transcriptase (15); and woodchuck hepatitis virus reverse transcriptase (22,24). 1. **9-[2-(Phosphonomethoxy)ethyl]adenine**

This acyclic AMP analogue (FW<sub>free-acid</sub> = 273.19 g/mol), also known as adefovir and 9-(2-phosphonylmethoxyethyl)adenine (abbreviated PMEa), exhibits a broad spectrum of antiviral activity. The diphosphate (i.e., an analogue of ATP) inhibits avian myeloblastosis virus reverse transcriptase and herpes simplex virus DNA polymerase via chain termination after its incorporation into the growing chain. Interestingly, the diphosphate, PMEApp, is produced by the action of 5-phosphoribosyl-1-pyrophosphate synthetase, in which the pyrophosphate group of PRPP is directly transferred to PMEa (1). PMEa has pK<sub>a</sub> values of 2.0 and 6.8. **Target(s)**: adenylyl cyclase, inhibited by the diphosphate (2); avian myeloblastosis virus reverse transcriptase, inhibited by the diphosphate (3); DNA-directed DNA polymerase (4,5); DNA polymerase  $\alpha$ , inhibited by the diphosphate, IC<sub>50</sub> = 3.7  $\mu\text{M}$  (4); DNA polymerase  $\delta$ , moderately inhibited by the diphosphate (5); DNA polymerases, viral (6-11); feline immunodeficiency virus reverse transcriptase, inhibited by the diphosphate (9); herpes simplex virus DNA polymerase, inhibited by the diphosphate (8,10); herpes viruses replication (6); HIV-1 and HIV-2 (4,6,7,11); human immunodeficiency virus reverse transcriptase, inhibited by the diphosphate (4,11); purine-nucleoside phosphorylase, inhibited by the monophosphate (12); Rauscher murine leukemia virus reverse transcriptase (11); ribose-phosphate diphosphokinase (13); and RNA-directed DNA polymerase (3,4,6-11). 1. #### 9-[2-(Phosphonomethoxy)ethyl]guanine

This acyclic GMP analogue (FW<sub>free-acid</sub> = 289.19 g/mol), often abbreviated PMEG, exhibits a broad spectrum of antiviral activity. The diphosphate (*i.e.*, an analogue of GTP) inhibits avian myeloblastosis virus reverse transcriptase and herpes simplex virus DNA polymerase. **Target(s):** avian myeloblastosis virus reverse transcriptase, inhibited by the diphosphate (1); DNA-directed DNA polymerase (2); DNA polymerases  $\alpha$  and  $\epsilon$ , inhibited by the diphosphate (2); GMP kinase, also alternative substrate (3); herpes simplex virus DNA polymerase, inhibited by the diphosphate (4). 1. Votruba, Travnicek, Rosenberg, *et al.* (1990) *Antiviral Res.* **13**, 287. 2. Kramata, Votruba, Otova & Holy (1996) *Mol. Pharmacol.* **49**, 1005. 3. #### 9-[2-(Phosphonomethoxy)ethyl]guanine Diphosphate, See 9-[2-(Phosphonomethoxy)-ethyl]guanine

#### 9-[2-(Phosphonomethoxy)ethyl]-6-thioguanine

This acyclic GMP analogue (FW<sub>free-acid</sub> = 304.24 g/mol), also known as 2-amino-9-[2-(phosphonomethoxy)ethyl]-6-sulfanylpurine, inhibits purine-nucleoside phosphorylase (1-3). 1. Wielgus-Kutrowska & Bzowska (2006) *Biochim. Biophys. Acta* **1764**, 887. 2. Wielgus-Kutrowska, Antosiewicz, Dłogosz, Holy & Bzowska (2007) *Biophys. Chem.* **125**, 260. 3. Antosiewicz, Wielgus-Kutrowska, Dłogosz, Holy & Bzowska (2007) *Nucleosides Nucleotides Nucleic Acids* **26**, 969.

#### 1-[2-(Phosphonomethoxy)ethyl]thymine

This thymine derivative (FW<sub>ion</sub> = 262.16 g/mol) inhibits rat T-cell lymphoma thymidine phosphorylase,  $K_i = 1.5 \mu\text{M}$  (1,2). 1. Votruba, Pomeisl, Tloust'ová, Holy & Otová (2005) *Biochem. Pharmacol.* **69**, 1517. 2. Pomeisl, Holy, Votruba & Pohl (2008) *Bioorg. Med. Chem. Lett.* **18**, 1364.

#### (R)-9-[2-(Phosphonomethoxy)propyl]adenine

This acyclic AMP analogue (FW<sub>free-acid</sub> = 287.22 g/mol), also known as (R)-9-(2-phosphonylmethoxypropyl)adenine and tenofovir and abbreviated PMPA, exhibits a broad spectrum of antiviral activity. The diphosphate (*i.e.*, an analogue of ATP) inhibits reverse transcriptases. **Target(s):** HIV-1 reverse transcriptase, inhibited by the diphosphate (1-4); purine-nucleoside phosphorylase (5); and RNA-directed DNA polymerase (1-4). 1. Balzarini & De Clercq (1996) *Meth. Enzymol.* **275**, 472. 2. Suo & Johnson (1998) *J. Biol. Chem.* **273**, 27250. 3. Cihlar, Birkus, Greenwalt & Hitchcock (2002) *Antiviral Res.* **54**, 37. 4. El Safadi, Vivet-Boudou & Marquet (2007) *Appl. Microbiol. Biotechnol.* **75**, 723. 5. Bzowska, Kulikowska & Shugar (2000) *Pharmacol. Ther.* **88**, 349.

#### (S)-1-[2-(Phosphonomethoxy)propyl]thymine

This thymine derivative (FW<sub>ion</sub> = 263.17 g/mol) inhibits rat T-cell lymphoma thymidine phosphorylase,  $K_i = 0.68 \mu\text{M}$  (1). The (R)-enantiomer is a slightly weaker inhibitor ( $K_i = 1.90 \mu\text{M}$ ). 1. Votruba, Pomeisl, Tloust'ová, Holy & Otová (2005) *Biochem. Pharmacol.* **69**, 1517.

#### N-(Phosphonomethyl)iminodiacetic Acid

This modified triacid (FW = 224.08 g/mol) inhibits adenosine kinase (1,2) and ribokinase (3). Because the use of adenosine receptor agonists is plagued by dose-limiting cardiovascular side effects, there is great interest in developing adenosine kinase inhibitors (AKIs) as a means for raising steady-state adenosine concentrations. 1. Park, Singh, Maj & Gupta (2004) *Protein J.* **23**, 167. 2. Park, Singh & Gupta (2006) *Mol. Cell. Biochem.* **283**, 11. 3. Park, van Koeverden, Singh & Gupta (2007) *FEBS Lett.* **581**, 3211.

#### 2-(Phosphonomethyl)pentanedioate

This hygroscopic phosphono-dicarboxylic acid (FW<sub>free-acid</sub> = 226.12 g/mol), often abbreviated 2-PMPA, is a competitive inhibitor of glutamate carboxypeptidase II, or N-acetylated- $\alpha$ -linked-acidic Dipeptidase,  $K_i = 0.275 \text{ nM}$  (1-9). 1. Jackson, Cole, Slusher, *et al.* (1996) *J. Med. Chem.* **39**, 619. 2. Luthi-Carter, Barczak, Speno & Coyle (1998) *Brain Res.* **795**, 341. 3. Rojas, Frazier, Flanary & Slusher (2002) *Anal. #### 4-(Phosphonomethyl)pyridine-2-carboxylic Acid

This homoserine phosphate analogue (FW<sub>ion</sub> = 214.09 g/mol) inhibits cystathionine  $\gamma$ -synthase, with  $K_i$  values of 45 and 300  $\mu\text{M}$  for the wheat and tobacco enzymes, respectively (1). 1. Kreft, Townsend, Pohlenz &

Laber (1994) *Plant Physiol.* **104**, 1215. 2. Clausen, Wahl, Messerschmidt, *et al.* (1999) *Biol. Chem.* **380**, 1237.

### 3-Phosphonopropionate (3-Phosphonopropionic Acid)

This succinate analogue ( $FW_{\text{free-acid}} = 154.06$  g/mol), also known as 2-carboxyethylphosphonic acid, inhibits adenosine kinase, thereby raising steady-state adenosine concentrations and consequentially stimulating adenosine receptors. **Target(s):** adenosine kinase (1,2); aspartate carbamoyltransferase (3); carboxypeptidase A (4); dicarboxylate transporter (5); herpes simplex virus type-1 DNA polymerase (6); phosphonoacetate hydrolase (7,8); phosphonopyruvate hydrolase (9); 2-phosphosulfolactate phosphatase, weakly inhibited (10); ribokinase (11); succinate dehydrogenase (12,13); and triose-phosphate isomerase (14,15). 1. Park, Singh, Maj & Gupta (2004) *Protein J.* **23**, 167. 2. Park, Singh & Gupta (2006) *Mol. Cell. Biochem.* **283**, 11. 3. Laing, Chan, Hutchinson & Åberg (1990) *FEBS Lett.* **260**, 206. 4. D* **54**, 1419.

### 9-[3-(3-Phosphonoprop-1-yl)benzyl]guanine

This nucleoside analogue ( $FW_{\text{ion}} = 344.25$  g/mol) inhibits purine-nucleoside phosphorylase ( $K_i = 1.3$  nM), a ubiquitous enzyme that plays a key role in the purine salvage pathway. In humans PNP deficiency impairs T-cell function, usually with no effect on B-cell function. This property has been exploited in the synthesis of much higher affinity transition-state analogues (See *Immuclilins*) to treat T-cell lymphomas. 1. Bzowska, Kulikowska & Shugar (2000) *Pharmacol. Ther.* **88**, 349.

**Phosphon S**, See *Tributyl-2,4-dichlorobenzyl-ammonium Chloride*

### Phosphoramidon

This glycosyl phosphoramidopeptide ( $FW_{\text{free-acid}} = 543.51$  g/mol; CAS 36357-77-4), also systematically named as *N*-( $\alpha$ -rhamnopyranosyl-oxyhydroxyphosphinyl)-L-leucyl-L-tryptophan, is a slow-binding thermolysin inhibitor ( $K_i = 30$  nM). *Note:* Phosphoramidon is an epimer of

talopeptin. Stock 1 mg/mL aqueous solutions of phosphoramidon are stable for one month at  $-20^{\circ}\text{C}$ . **Target(s):** atrolysin A (56); atrolysin C (1-3); bacillolysin (4); carboxypeptidase C, weakly inhibited (59); coccolysin (5); cytosol alanyl aminopeptidase, weakly inhibited (62); dactylisin (6); endothelin-converting enzyme (17-13); endothelin-converting enzyme 2 (14,15); fungalsin (16); gametolysin (17-19); granzyme B (57); *Legionella* metalloendopeptidase (20,21); leucyl aminopeptidase, weakly inhibited (64); *Listeria* metalloprotease Mpl (22); lysine carboxypeptidase, *or* lysine(arginine) carboxypeptidase; carboxypeptidase N (58); mycolysin (23); neprilysin, *or* enkephalinase,  $K_i = 0.8$  nM (14,24-34); oligopeptidase O (35); peptidyl-dipeptidase A, *or* angiotensin I-converting enzyme (60,61); pitrilysin, *or* protease Pi (36); pseudolysin, *or* *Pseudomonas aeruginosa* elastase (37-41); pyruvate decarboxylase (42); thermolysin (27,28,41,43-53); urethanase (54); vibriolysin (55); and Xaa-Pro aminopeptidase, *or* aminopeptidase P (63). 1. Fox & Bjarnason (1998) in *Handb. Proteolytic Enzymes*, p. 1266, Academic Press, San Diego. 2. Fox, Campbell, Beggerly & Bjarnason (1986) *Eur. J. Biochem.* **156**, 65. 3. #### *N*-(5'-Phosphoribityl)anthranilate

This inhibitory deoxyphosphoribityl-anthranilate (FW<sub>free-acid</sub> = 351.25 g/mol) targets *N*-(5-phosphoribosyl)anthranilate isomerase/indoleglycerol-P synthase (1-6). 1. Kirschner, Szadkowski, Jardetzky & Hager (1987) *Meth. Enzymol.* **142**, 386. 2. Bisswanger, Kirschner, Cohn, Hager & Hansson (1979) *Biochemistry* **18**, 5946. 3. #### Phosphoribosylaminoimidazole-succinocarboxamide

This purine nucleotide intermediate (FW<sub>free-acid</sub> = 451.26 g/mol), abbreviated SAICAR and also known as 4-(*N*-succinocarboxamide)-5-aminoimidazole ribotide, inhibits adenylosuccinate synthetase. 1. Ryzhova, Andreichuk & Domkin (1998) *Biochemistry (Moscow)* **63**, 650.

#### 1-(5'-Phospho-D-ribose)barbituric Acid

This UMP and OMP analogue (FW<sub>free-acid</sub> = 340.17 g/mol), also known as 6-hydroxyuridine 5'-phosphate and barbiturate ribofuranoside 5'-monophosphate, inhibits orotidine 5'-phosphate decarboxylase (1-10). 1.

#### 5-Phospho- $\alpha$ -D-ribose 1-Pyrophosphate

This key metabolite (FW<sub>free-acid</sub> = 390.07 g/mol), abbreviated PRPP and also known as 5-phospho- $\alpha$ -D-ribose diphosphate and 5-phosphoribose 1-diphosphate, is an intermediate in the biosynthesis of the purines, pyrimidines, and histidine. It is also an essential co-substrate in purine salvage (e.g., Hypoxanthine:Guanine Phosphoribosyltransferase). PRPP is completely hydrolyzed to ribose 5-phosphate and pyrophosphate in 20 min at pH 3.0 and 65°C, whereas half is hydrolyzed at pH 6.7. Aqueous solutions are stable, if kept frozen at pH 8.0. The solid should be stored in a desiccator and protected from light. **Target(s)**: NMN nucleosidase (1); purine-nucleoside phosphorylase (2); ribose-phosphate diphosphokinase, or phosphorinosyl-pyrophosphate synthetase (3-8); and transketolase (9). 1. Imai (1987) *J. Biochem.* **101**, 163. 2. Ropp & Traut (1991) *Arch. Biochem. Biophys.* **288**, 614. 3. Becker, Kostel & Meyer (1975) *J. Biol. Chem.* **250**, 6822. 4. Fox & Kelley (1972) *J. Biol.* **42**, 52.

#### *N* <sup>$\alpha$</sup> -Phosphoryl-L-alanyl-L-proline

This phosphorylated dipeptide (FW<sub>free-acid</sub> = 266.19 g/mol) is a strong inhibitor of angiotensin I-converting enzyme, or peptidyl-dipeptidase A,  $K_i$  = 9 nM (pH 8.3) and 1.4 nM (pH 7.5) (1-3). 1. Galaray (1980) *Biochem. Biophys. Res. Commun.* **97**, 94. 2. Galaray (1982) *Biochemistry* **21**, 5777. 3. Ondetti & Cushman (1982) *Ann. Rev. Biochem.* **51**, 283.

#### *N*-Phosphoryl-L-leucinamide

This phosphorylated amino acid amide (FW<sub>free-acid</sub> = 210.17 g/mol) inhibits thermolysin,  $K_i$  = 1.3  $\mu$ M (1). Upon binding to the enzyme, two of the phosphoramidate oxygens of the inhibitor interact with the protein's zinc ion to form a complex that approximates a pentacoordinate system and mimics the transition-state. The *O*-methyl phosphoester is a weaker thermolysin inhibitor ( $K_i$  = 150  $\mu$ M). **Target(s)**: carboxypeptidase A,  $K_i$  = 160  $\mu$ M (1); and thermolysin,  $K_i$  = 1.3  $\mu$ M (1-4). 1. Kam, Nishino & Powers (1979) *Biochemistry* **18**, 3032. 2. Beynon & Beaumont (1998) in *Handb. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.), p. 1037,

Academic Press, San Diego. 3. Tronrud, Monzingo & Matthews (1986) *Eur. J. Biochem.* **157**, 261. 4. Gettins (1988) *J. Biol. Chem.* **263**, 10208.

### *N*<sup>α</sup>-Phosphoryl-L-leucyl-L-phenylalanine

This phosphorylated dipeptide ( $FW_{\text{free-acid}} = 358.33$  g/mol) inhibits neprilysin, or enkephalinase (1), pseudolysin,  $K_i = 0.2$   $\mu\text{M}$  (2-4), and thermolysin,  $K_i = 19$  nM (2,5). 1. Altstein, Blumberg & Vogel (1981) *Eur. J. Pharmacol.* **76**, 299. 2. Kessler & Ohman (1998) in *Handb. Proteolytic Enzymes*, p. 1058, Academic Press, San Diego. 3. Kessler, Spierer & Blumberg (1983) *Invest. Ophthalmol. Vis. Sci.* **24**, 1093. 4. Kessler, Israel, Landshman, Chechick & Blumberg (1982) *Infect. Immun.* **38**, 716. 5. Kam, Nishino & Powers (1979) *Biochemistry* **18**, 3032.

### *N*<sup>α</sup>-Phosphoryl-L-leucyl-L-tryptophan

This phosphorylated dipeptide ( $FW_{\text{free-acid}} = 397.37$  g/mol) inhibits carboxypeptidase A,  $K_i = 54$   $\mu\text{M}$  (1), pseudolysin (2,3), and thermolysin,  $K_i = 15$  nM (1,2,4). 1. Kam, Nishino & Powers (1979) *Biochemistry* **18**, 3032. 2. Kessler & Ohman (1998) in *Handb. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.), p. 1058, Academic Press, San Diego. 3. Poncz, Gerken, Dearborn, Grobelny & Galardy (1984) *Biochemistry* **23**, 2766. 4. Kitagishi & Hiromi (1986) *J. Biochem.* **99**, 191.

### *O*-Phospho-L-serine

This phosphomonoester of L-serine ( $FW = 183.06$  g/mol), also called serine phosphate, is an intermediate in L-serine biosynthesis and an agonist at metabotropic the AP4 receptors GluR<sub>4</sub>, GluR<sub>8</sub>, and GluR<sub>7</sub>. *O*-Phospho-L-serine concentrations are elevated in Alzheimer's Disease brains. In addition, *O*-phospho-L-seryl residues are generated as intermediates in enzyme-catalyzed reactions and specific proteins are phosphorylated at seryl residues by the action of a number of protein kinases. *O*-Phospho-L-serine is soluble in water (2.8 g/100 mL at 20°C for the free acid and 25 g/100 mL for the sodium salt) and is hydrolyzed in acidic or basic conditions (61% hydrolysis in 24 h in 1 M HCl and 51% hydrolysis in 24 h in 0.5 M NaOH). **Target(s):** *O*-acetylhomoserine aminocarboxytransferase, or *O*-acetylhomoserine sulfhydrylase (1,2); arylsulfatase B (3); aspartate ammonia-lyase (4); choline acetyltransferase (5);  $\gamma$ -glutamylcysteine synthetase (6);  $\gamma$ -glutamyl transpeptidase (7); glycine transport (8); homoserine kinase (9); kynurenine:oxoglutarate aminotransferase (10); ornithine decarboxylase (11); phosphoglycerate phosphatase (12); phosphoprotein phosphatase (13); serine hydroxymethyltransferase, or glycine hydroxymethyltransferase (14); serine C-

palmitoyltransferase (15); serine-sulfate ammonia-lyase (16-19); and threonine synthase (20). 1. Yamagata (1987) *Meth. Enzymol.* **143**, 465. 2. Yamagata (1984) *J. Biochem.* **96**, 1511. 3. ### Phosphostim

This isopentenyl pyrophosphate bromohydrin ( $FW = 340.99$  g/mol) inhibits geranyltransferase, or farnesyl-diphosphate synthase (1) and isopentenyl-diphosphate  $\Delta$ -isomerase, or isopentenyl pyrophosphate/dimethylallyl pyrophosphate isomerase (2). 1. Montalvetti, Fernandez, Sanders, et al. (2003) *J. Biol. Chem.* **278**, 17075. 2. Wouters, Yin, Song, et al. (2005) *J. Amer. Chem. Soc.* **127**, 536.

**Phosphosulfate, See Thiophosphate, Sodium**

### *O*-Phospho-L-threonine

This phosphorylated amino acid ( $FW_{\text{ion}} = 198.09$  g/mol), also called threonine phosphate, is found as a residue in the amino acid sequence of a number of proteins. These residues are generated as intermediates in enzyme-catalyzed reactions and specific proteins are phosphorylated at threonyl residues by the action of a number of protein kinases. **Target(s):** phosphoprotein phosphatase (1); phosphoserine aminotransferase (2); and threonine synthase (3-5). 1. Polya & Haritou (1988) *Biochem. J.* **251**, 357. 2. Ali & Nozak (2006) *Mol. Biochem. Parasitol.* **145**, 71. 3. **5'-Phosphothymidine 3'-Phosphate, See Thymidine 3',5'-Bisphosphate**

**Phosphotrienin, See Fostriecin**

### *O*-Phospho-L-tyrosine

This phosphorylated amino acid ( $FW = 260.16$  g/mol), also called tyrosine phosphate, is found as a residue in the amino acid sequence of a number of proteins. Specific proteins are phosphorylated at tyrosyl residues by the action of a number of protein kinases. **Target(s):** ornithine decarboxylase (1); phosphoprotein phosphatase (2); and protein-tyrosine phosphatase (3,4). 1. Tsirka, Sklaviadis & Kyriakidis (1986) *Biochim. Biophys. Acta*

884, 482. 2. Polya & Haritou (1988) *Biochem. J.* **251**, 357. 3. Ballou & Fischer (1986) *The Enzymes*, 3rd ed. (Boyer & Krebs, eds.), **17**, 311. 4. Hörlein, Gallis, Brautigan & Bornstein (1982) *Biochemistry* **21**, 5577.

#### Phrixotoxin-1 and -2

These spider venom oligopeptides (Phrixotoxin-1 Sequence: TCQKWMK TCDSARKCCEGLVCRLWCKKII; MW = 3435 g/mol; Phrixotoxin-2 Sequence: YCQKWMWTCEERDKCCEGLVCRLWCKRIINM; MW = 3929 g/mol) from the tarantula *Phrixotrichus auratus*, are high-affinity, reversible voltage-gated  $K_v4.2$  and  $K_v4.3$  channel blockers (1,2). Phrixotoxin-1 and -2 each have three intrachain disulfide bonds. 1. Diochot, Drici, Moinier, Fink & Lazdunski (1999) *Brit. J. Pharmacol.* **126**, 251. 2. Chagot, Escoubas, Villegas, et al. (2004) *Protein Sci.* **13**, 1197.

#### PHT-427

This orally bioavailable, dual Akt/PDPK1 inhibitor (F.Wt. = 409.61; CAS 1191951-57-1 and 1178893-77-0; Solubility (25°C): 80 mg/mL DMSO, <1 mg/mL Water), known systematically as 4-dodecyl-N-(1,3,4-thiadiazol-2-yl)benzenesulfonamide, targets Akt (also known as Protein Kinase B, or PKB) and 3-phosphoinositide-dependent protein kinase-1, with  $K_i$  of 2.7  $\mu$ M and 5.2  $\mu$ M, respectively (1). PHT-427 was designed to bind to the pleckstrin homology (PH) auto-inhibitory domains of the signal cascade protein kinase Akt (2). 1. Meuillet, et al. (2010) *Mol. Cancer Ther.* **9**, 706. 2. Moses, et al. (2009) *Cancer Res.* **69**, 5073. 2. Mahadevan, Powis, Mash, et al. (2008) *Mol. Cancer Ther.* **7**, 2621.

#### o-Phthalaldehyde

This dialdehyde (FW = 134.13 g/mol; M.P. = 55-58°C), also known as o-phthalaldehyde and benzene-1,2-dicarboxaldehyde reacts readily with primary amines (e.g., of amino acids) to produce a fluorescent derivative. Hence, this derivatization reagent is frequently used in chromatography and amino acid analysis. It has also been used as a bifunctional cross-linking reagent. In octopine dehydrogenase, o-phthalaldehyde binds to proximal cysteinyl and lysyl residues leading to the formation of an isoindole derivative (1). **Target(s):** alcohol dehydrogenase (2); aminolevulinate aminotransferase (31);  $\alpha$ -amylase (3); *Aspergillus* nuclease S (14); biliverdin reductase (5);  $Ca^{2+}$ -dependent ATPase (6); creatine kinase (7,8);  $\zeta$ -crystallin9; cytochrome *b<sub>6</sub>f* complex (10); dextranucrase (11-13); electron transport (14); fatty-acid synthase (15-17); glucan 1,4- $\beta$ -glucosidase (18); glutamate dehydrogenase (19); glutathione-disulfide reductase (20); glycerol dehydrogenase (21); glyoxylate synthetase (22); 3-ketoacyl-[acyl-carrier protein] synthase (16,17); malate dehydrogenase (23); nitrogenase (24); octopine dehydrogenase (1,25); oxidative phosphorylation (14); 6-phosphofructo-2-kinase (26); porphobilinogen synthase, or 5-aminolevulinate dehydratase (27); pyruvate kinase (28); pyruvate carboxylase (29); and succinate-semialdehyde dehydrogenase (30). 1. #### m-Phthalamide

This amide (FW = 140.14 g/mol) inhibits bovine poly(ADP-ribose) polymerase,  $IC_{50}$  = 0.05 mM (1). The o-analogue is a weaker inhibitor ( $IC_{50}$  = 1 mM). 1. Banasik, Komura, Shimoyama & Ueda (1992) *J. Biol. Chem.* **267**, 1569.

#### Phthalascidin

This semisynthetic antitumor agent (FW<sub>free-base</sub> = 650.69 g/mol), also known as Pt 650, binds to the minor groove of DNA and inhibits DNA topoisomerase I (1,2). Phthalascidin is prepared from ecteinascidin 743. 1. Meng, Liao & Pommier (2003) *Curr. Top. Med. Chem.* **3**, 305. 2. Martinez, Owa, Schreiber & Corey (1999) *Proc. Natl. Acad. Sci. U.S.A.* **96**, 3496.

#### Phthalate (Phthalic Acid)

This aromatic acid (FW<sub>free-acid</sub> = 166.13 g/mol; M.P. = ~230°C), also known as 1,2-benzenedicarboxylic acid, is readily converted to the anhydride when heated. The free acid is soluble in water (1 g/160 mL) and has  $pK_a$  values (at 25°C) of 2.95 ( $dpK_a/dT = 0.0020$ ) and 5.41 ( $dpK_a/dT = -0.001$  at  $T < 25^\circ C$  and  $+0.001$  at  $T > 25^\circ C$ ). **Target(s):** aconitase (1); aspartate aminotransferase (2); aspartate 4-decarboxylase (3); benzoylformate decarboxylase (4);  $\gamma$ -butyrobetaine dioxygenase, or  $\gamma$ -butyrobetaine hydroxylase,  $K_i = 17$  mM (5); dehydro-L-gulonate decarboxylase (6); 4,5-dihydroxyphthalate decarboxylase (7); diphospho-mevalonate decarboxylase (8,9); glucose oxidase (10); glutamate decarboxylase (11); kynurenine aminotransferase (12); nicotinate-nucleotide diphosphorylase, carboxylating, or quinolinate phosphoribosyltransferase (13-18); peptidyl-dipeptidase A, or angiotensin I-converting enzyme (19); procollagen-proline 3-dioxygenase (20); succinate dehydrogenase (21); and tyrosine decarboxylase (22). 1. ### Phthalide

This lactone on the above left (FW = 134.13 g/mol; CAS 87-41-2; M.P. = 72-74°C) reportedly inhibits chymotrypsin. Phthalide is a fungicide that inhibits melanin biosynthesis and has been used in the treatment of rice blast disease. *Note:* The term phthalide has also been used to refer to the tetrachloro derivative (*i.e.*, 4,5,6,7-tetrachlorophthalide (on the right above); FW = 271.91 g/mol; CAS: 27355-22-2; also known as BAYER 96610, KF-32, Rabcide, and TCP). **Target(s):** chymotrypsin (1); scytalone dehydratase, inhibited by the tetrachloride derivative (2); and trihydroxynaphthalene reductase, inhibited by the tetrachloride derivative (3,4). 1. Wallace, Kurtz & Niemann (1963) *Biochemistry* **2**, 824. 2. Wheeler & Greenblatt (1988) *Exp. Mycol.* **12**, 151. 3. ### Phthiocol

This quinone pigment (FW = 188.18 g/mol; yellow solid; slightly soluble in water; freely soluble in most organic solvents), also called 3-hydroxymenadione, from *Mycobacterium tuberculosis* possesses some vitamin K activity. **Target(s):** lactoylglutathione lyase, or glyoxalase I (1); pyruvate decarboxylase (2); succinate dehydrogenase, or succinate oxidase (3,4). 1. Allen, Lo & Thornalley (1993) *Biochem. Soc. Trans.* **21**, 535. 2. Kuhn & Beinert (1947) *Ber.* **80**, 101. 3. Herz (1954) *Biochem. Z.* **325**, 83. 4. Ball, Anfinsen & Cooper (1947) *J. Biol. Chem.* **168**, 257.

### Phycocyanin, See Phycocyanobilin

### Phycocyanobilin

This linear tetrapyrrole (FW = 559.64 g/mol) is a prosthetic group of blue, highly fluorescent photoreceptor pigments (phycocyanins) found in certain algae. It is soluble in water and polar organic solvents. Phycocyanins, found in Cyanophyta, are proteins, which typically contain three molecules of covalently bound phycocyanobilin per subunit. One molecule of phycocyanobilin is bound per molecule of allophycocyanin, found in Cyanophyta and Rhodophyta. Phycocyanins and their chromophore

phycocyanobilin are peroxy radical scavengers and inhibits ONOO<sup>-</sup>-mediated biological effects (1,2). **Target(s):** cyclooxygenase-2, inhibited by C-phycocyanin and poorly by phycocyanobilin (3). 1. Bhat & Madyastha (2001) *Biochem. Biophys. Res. Commun.* **285**, 262. 2. Bhat & Madyastha (2000) *Biochem. Biophys. Res. Commun.* **275**, 20. 3. Reddy, Bhat, Kiranmai, *et al.* (2000) *Biochem. Biophys. Res. Commun.* **277**, 599.

### Physostigmine, See Eserine

### Physostigmine N-Oxide, See Eseridine

### Physovenine

This physostigmine analogue (FW = 250.30 g/mol; CAS 6091-05-0) is a Calabar bean alkaloid that inhibits acetylcholinesterase and butyrylcholinesterase, with IC<sub>50</sub> values of 27 and 4 nM, respectively (1,2). 1. Luo, Yu, Zhan, *et al.* (2005) *J. Med. Chem.* **48**, 986. 2. Dale & Robinson (1970) *J. Pharm. Pharmacol.* **22**, 889.

### Phytanate (Phytanic Acid)

This branched-chain fatty acid (FW = 312.54 g/mol; CAS 14721-66-5; M.P. = -65°C), also called 3,7,11,15-tetramethylhexadecanoic acid, is produced from the degradation of phytol, a constituent of chlorophyll. **Target(s):** cholesterol biosynthesis (1); and long-chain fatty acid activation (2). 1. Kuroda & Endo (1976) *Biochim. Biophys. Acta* **486**, 70. 2. Pande, Siddiqui & Gattereau (1971) *Biochim. Biophys. Acta* **248**, 156.

### Phytate (Phytic Acid)

This water-soluble poly-anion (FW<sub>free-acid</sub> = 660.04 g/mol; CAS 83-86-3), also known as *myo*-inositol hexakisphosphate, is an important phosphate storage molecule in plants. It is found in elevated concentrations in seeds, legumes, and grains. Phytic acid binds di- and trivalent cations tightly and is known to inhibit a number of metalloenzymes. It has also been identified in insulin-secreting pancreatic  $\beta$ -cells. It has been reported to modulate the binding of oxygen to avian and reptilian hemoglobins. **Target(s):** acid phosphatase (31); [ $\beta$ -adrenergic-receptor] kinase (1,32); alkaline phosphatase (2,3); AMP deaminase (4); arrestin binding to rhodopsin kinase (5); bisphosphoglycerate mutase (6); bisphospho-glycerate phosphatase (6); carboxypeptidase A (7,8); cytochrome *c* oxidase (8); diphosphoinositol-

polyphosphate diphosphatase (9); diphtheria toxin binding (10); fructose-1,6-bisphosphate aldolase (11); guanylate cyclase (12); inositol-polyphosphate 5-phosphatase, *or* inositol-1,4,5-trisphosphate/1,3,4,5-tetrakisphosphate 5-phosphatase (13); inositol-tetrakisphosphate 1-kinase (33); iron uptake (14); multiple inositol-polyphosphate phosphatase, *or* inositol 1,3,4,5-tetrakisphosphate 3-phosphatase (13,15-18); phosphatidylinositol-3,4-bisphosphate 4-phosphatase (19); phosphatidylinositol 3'-kinase (20); phosphatidylinositol-specific phospholipase C (21); phosphoglycerate mutase (22); phospholipase A<sub>2</sub> (23); phosphoprotein phosphatase (30); polyphenol oxidase (8); pteroylpolyglutamate hydrolase (24); L- and P-selectin (25); serine/threonine protein phosphatases type 1, type 2A, and type 3 (26); ultraviolet B-induced signal transduction (27); and zinc absorption (28,29). 1. ### Phytohemagglutinins

This class of toxic plant lectins (MW depends on species; CAS 9008-97-3) is a carbohydrate-binding protein, consisting mainly of the leucoagglutinins PHA-L and PHA-E, indicating their ability to agglutinate leukocytes and erythrocytes. Phytohemagglutinins occur at the highest concentrations in uncooked red and white kidney beans, green beans, broad beans, and fava beans. *Phaseolus vulgaris* phytohemagglutinin consists of seven different glycosylated polypeptides. Phytohemagglutinins induce mitosis, alter membrane transport, and increase membrane permeability to proteins. In humans, poisoning can be induced from as few as five raw beans, with symptoms occurring within three hours, beginning with nausea, then vomiting, followed by diarrhea. Medical intervention is rarely required.

### Phytol

This long-chain alcohol (FW = 296.54 g/mol; CAS 150-86-7), also known as (2E,7R,11R)-3,7,11,15-tetramethyl-2-hexadecen-1-ol, is a component of chlorophyll and vitamin K<sub>1</sub>. It is an oily liquid with a very low solubility in water that is always released in the degradation of chlorophyll (it is a product in the reaction catalyzed by chlorophyllase). **Target(s):** Ca<sup>2+</sup>-induced cytosolic enzyme efflux from skeletal muscle (1); and chlorophyllase (2-4). 1. Phoenix, Edwards & Jackson (1989) *Biochem. J.* **257**, 207. 2. Khalyfa, Kermasha, Marsot & Goetghebeur (1995) *Appl. Biochem. Biotechnol.* **53**, 11. 3. Samaha & Kermasha (1997) *J. **Phytol Pyrophosphate, See Phytol Pyrophosphate**

### Phytosphingosine

This triol (FW<sub>free-base</sub> = 317.51 g/mol; CAS 554-62-1), also known as 2S,3S,4R-2-amino-1,3,4-octadecanetriol and D-ribo-1,3,4-trihydroxy-2-amino-octadecane, is a component of plant and fungal sphingolipids. **Target(s):** 2-acylglycerol O-acyltransferase, *or* monoacylglycerol O-acyltransferase (1); Ca<sup>2+</sup> release channel, *or* ryanodine receptor (2); CDP-diacylglycerol:serine O-phosphatidyltransferase, *or* phosphatidylserine synthase (3); ceramidase (4,5); DNA primase (6); 1,3-β-glucan synthase (7); histidine uptake (8); leucine uptake (8); phosphatidate phosphatase (9,10); phospholipase C-δ1, weakly inhibited (11); sphingomyelin phosphodiesterase, *or* sphingomyelinase (12); tryptophan uptake (8); uracil uptake (8). 1. Bhat, Wang & Coleman (1995) *Biochemistry* **34**, 11237. 2. Sharma, Smith, Li & Schroepfer, Jr., & Needleman (2000) *Chem. Phys. Lipids* **104**, 1. 3. Yamashita & Nikawa (1997) *Biochim. Biophys. ### Phytol Pyrophosphate

This phytol derivative (FW<sub>free-acid</sub> = 456.50 g/mol), also called phytol diphosphate, is a precursor in the biosynthesis of the tocopherols and related molecules. A synthetic preparation of a mixture of the 2E and 2Z isomers was found to inhibit squalene synthase. **Target(s):** mevalonate kinase (1,2); and squalene synthase (3). 1. Gray & Kekwick (1973) *Biochem. J.* **133**, 335. 2. Gray & Kekwick (1972) *Biochim. Biophys. Acta* **279**, 290. 3. de Montellano, Wei, Castillo, Hsu & Boparai (1977) *J. Med. Chem.* **20**, 243.

### PI-103

This potent, ATP-competitive, phosphoinositide-3-kinase (PI3K) inhibitor (FW = 348.4; CAS = 371935-74-9; Solubility: 0.25 mg/mL in 1 part PBS and 2 parts DMSO), named systematically as 3-[4-(4-morpholinyl)pyrido[3',2':4,5]furo[3,2-d]pyrimidin-2-yl]phenol and also known as S1038, exhibits selectivity toward: DNA-PK, IC<sub>50</sub> = 2 nM; p110α, IC<sub>50</sub> = 8 nM; mTORC1, IC<sub>50</sub> = 20 nM; PI3KC2β, IC<sub>50</sub> = 26 nM; p110δ, IC<sub>50</sub> = 48 nM; mTORC2, IC<sub>50</sub> = 83 nM; p110β, IC<sub>50</sub> = 88 nM; and p110γ, IC<sub>50</sub> = 150 nM (1). 1. Knight, Gonzalez, Feldman, *et al.* (2006) *Cell* **125**, 733. 2. Rückel, Schwartz & Rommel (2006) *Drug Discovery* **5**, 903. 3. Fan, Knight, Goldenberg, *et al.* (2006) *Cancer Cell* **9**, 341.

## PI-1840

This potent proteasome inhibitor (FW = 394.38 g/mol) selectively targets its chymotrypsin-like activity, *or* CT-L ( $IC_{50}$  = 27 nM), while showing much weaker action ( $IC_{50}$  values >100  $\mu$ M) against its Trypsin-Like (T-L) and peptidylglutamyl peptide hydrolyzing, *or* PGPH activities. Mass spectrometry and equilibrium dialysis show no evidence of covalent linkage of PI-1840 with any proteasomal protein component. In intact cancer cells, PI-1840 inhibits CT-L activity, inducing the accumulation of proteasome substrates p27, Bax and I $\kappa$ B- $\alpha$ , thereby inhibiting survival pathways and viability, and inducing apoptosis. PI=1840 is also >100x more active against the constitutive proteasome, compared to immunoproteasome. 1. Kazi, Ozcan, Tecleab, *et al.* (2014) *J. Biol. Chem.* **289**, 11906.

PI3K $\alpha$  inhibitor-2

This PI3K $\alpha$ -/KDR-selective inhibitor (F.Wt. = 313.4 g/mol; CAS = 371943-05-4;  $\lambda_{max}$  = 255, 299 nm), also known as 3-[4-(4-morpholinyl)thieno[3,2-*d*]pyrimidin-2-yl]phenol, inhibits phosphatidylinositol 3-kinase (PI3K), which catalyzes the phosphorylation of the 3'-hydroxyl position of phosphatidylinositols to produce the second messengers PtdIns-(3,4)-P<sub>2</sub> and PtdIns-(3,4,5)-P<sub>3</sub> (1-4). **Targets:** PI3K $\alpha$ ,  $IC_{50}$  = 2 nM; KDR (Kinase-insert Domain-containing Receptor, alternatively referred to as VEGFR-2),  $IC_{50}$  = 3.4 nM; PI3K $\beta$ ,  $IC_{50}$  = 16 nM; cyclin E/CDK2,  $IC_{50}$  = 28 nM; PKA,  $IC_{50}$  = 91 nM; PI3K2C $\beta$ ,  $IC_{50}$  = 220 nM; PKC $\alpha$ ,  $IC_{50}$  = 466 nM; and PI3K $\gamma$ ,  $IC_{50}$  = 660 nM. 1. ## Piceatannol

This photosensitive *trans*-stilbene phytopolyphenol and F<sub>1</sub> ATPase inhibitor (FW = 244.25 g/mol; CAS 10083-24-6), also named 4-[(*E*)-2-(3,5-Dihydroxyphenyl)ethenyl]benzene-1,2-diol *or* 3,4,3',5'-tetrahydroxy-*trans*-stilbene, from the mycorrhizal and non-mycorrhizal roots of Norway spruces (*Picea abies*), binds to a pocket on ATP synthase that is formed by contributions from  $\alpha$  and  $\beta$  stator subunits and the carboxyl-terminal region of the rotor  $\gamma$  subunit (1-3). Piceatannol also exerts anti-leukemic and immunomodulatory actions by interfering with the cytokine signaling pathway by inhibiting certain protein-tyrosine kinases. It inhibits myosin light-chain kinase ( $IC_{50}$  = 12  $\mu$ M), protein kinase A ( $IC_{50}$  = 3  $\mu$ M), and protein kinase C ( $IC_{50}$  = 8  $\mu$ M). **Mode of F<sub>1</sub> ATPase Inhibition:** Single-molecule observations, made under  $V_{max}$  conditions and minimal load, show that the uninhibited F<sub>1</sub> sector of the ATP synthase rotates through cycles, with catalytic dwells of ~0.2 msec and 120° rotational steps in ~0.6 msec time-frame (3). The rate-limiting transition step occurs during the catalytic dwell at the initiation of the 120° rotation. Piceatannol does not interfere with the movement through the 120° rotation step, but causes both an

increase in the duration of the catalytic dwell as well as a significantly longer duration time for the intrinsic inhibited state of F<sub>1</sub> (3) All of the beads rotated at a lower rate in the presence of saturating piceatannol, indicating that the inhibitor stays bound throughout the rotational catalytic cycle. An Arrhenius plot for the reciprocal of catalytic dwell duration (*i.e.*, the catalytic rate) shows a significantly higher activation energy for the rate-limiting step to trigger the 120° rotation (3). Because the activation energy is further increased by combination of piceatannol and a M23K substitution in the  $\gamma$  subunit, it appears that the inhibitor and the  $\beta/\gamma$  interface mutation affect the same transition step, even though they perturb topologically distinct rotor-stator interactions (3). **Target(s):** F<sub>1</sub>F<sub>0</sub>-ATPase, *or* ATP synthase; H<sup>-</sup>-transporting two-sector ATPase (1-3); I $\kappa$ B $\alpha$  kinase (4); protein-tyrosine kinase, *or* non-specific protein-tyrosine kinase (5-10); serine/threonine-specific protein kinases, *or* protein kinase A, protein kinase C, and Ca<sup>2+</sup>-dependent protein kinase (11); and Syk protein-tyrosine kinase,  $IC_{50}$  = 10  $\mu$ M (7,10). 1. ## Piclamilast

This benzamide (FW = 381.25 g/mol; CAS 144035-83-6), also known as RP-73401 and named systemically as 3-(cyclopentyloxy)-*N*-(3,5-dichloro-4-pyridyl)-4-methoxybenzamide, is a selective cyclic-nucleotide phosphodiesterase 4 inhibitor,  $IC_{50}$  = 1 nM (1,2). 1. O'Grady, Jiang, Maniak, *et al.* (2002) *J. Membr. Biol.* **185**, 137. 2. Ashton, Cook, Fenton, *et al.* (1994) *J. Med. Chem.* **37**, 1696.

## 2-Picolinate (2-Picolinic Acid)

This acid (FW<sub>free-acid</sub> = 123.11 g/mol; CAS 98-98-6; pK<sub>1</sub> = 1.07 and pK<sub>2</sub> = 5.25), also known as 2-pyridinecarboxylic acid, is soluble in water and very soluble in glacial acetic acid. **Target(s):** acetylcholinesterase (1); aconitase, *or* aconitate hydratase (2); altronate dehydratase (3); D-amino-acid oxidase (4);  $\gamma$ -butyrobetaine dioxygenase, *or*  $\gamma$ -butyrobetaine hydroxylase,  $K_i$  = 39  $\mu$ M (5); deoxyhypusine monooxygenase (6-9); homocitrate synthase (10); 3-hydroxyanthranilate 3,4-dioxygenase (11); mannonate dehydratase (3); nicotinamide-nucleotide amidase (12); nicotinate *N*-methyltransferase (13); nicotinate-nucleotide diphosphorylase, carboxylating (14); nicotinate phosphoenolpyruvate carboxylase (15); nicotinate phosphoribosyltransferase (16); phosphoribosyltransferase (17); phenol oxidase (18); procollagen-lysine 5-dioxygenase (19); procollagen-proline 3-dioxygenase (19); procollagen-proline 4-dioxygenase, *or* prolyl 4-hydroxylase (19-24); pyridoxal kinase (25); and the zinc transporter (26). 1. ### Picolinohydroxamate (Picolinohydroxamic Acid)

This iron-binding hydroxamic acid (FW = 138.13 g/mol; CAS 31888-72-9), also named *N*-hydroxy-2-pyridinecarboxamide, 2-pyridinecarboxamide, and *N*-hydroxy-2-pyridinehydroxamic acid, inhibits ribonucleoside diphosphate reductase, most likely by chelating one or both of the active-site iron ions. **1.** Elford, Van't Riet, Wampler, Lin & Elford (1981) *Adv. Enzyme Regul.* **19**, 151.

### Picotamide

This antithrombotic agent (FW = 376.41 g/mol; CAS 32828-81-2), also known as 4-methoxy-*N,N'*-bis(3-pyridinylmethyl)-1,3-benzenedicarboxamide, is a dual eicosanoid receptor antagonist (1-4) and a thromboxane A<sub>2</sub> synthase inhibitor (2,5). **1.** Modesti, Colella, Abbate, Gensini & Neri Serneri (1989) *Eur. J. Pharmacol.* **169**, 85. **2.** Berrettini, De Cunto, Parise, Grasselli & Nenci (1990) *Eur. J. Clin. Pharmacol.* **39**, 495. **3.** Pulcinelli, Pignatelli, Pesciotti, et al. (1997) *Thromb. ### Picrate (Picric Acid)

This nitrated phenol (FW = 229.11 g/mol; CAS 88-89-1; M.P. = 122-123°C; pK<sub>a</sub> = 0.38 at 25°C), also called 2,4,6-trinitrophenol and nitroanthanic acid, is a pale yellow solid that explodes when heated above 300°C. Caution: Picric acid also explodes by percussion, and serious laboratory injuries and death have occurred with this common laboratory reagent. **Target(s):** D-amino-acid oxidase (1); ATP synthase (2);  $\beta$ -fructofuranosidase, or invertase (3); malate dehydrogenase (4); NAD(P)H dehydrogenase, quinone (5-8); oxidative phosphorylation, protonophoric uncoupler in suitably prepared mitochondria (9); photosystem II, inhibited by picrate and 18-crown-6 potassium picrate (10,11); and quinone reductase

(7,8). **1.** Yagi, Osawa & Okada (1959) *Biochim. Biophys. Acta* **35**, 102. **2.** Stiggall, Galante & Hatefi (1979) *Meth. ### Picromycin

This polyketide (FW = 525.68 g/mol; CAS 19721-56-3; bitter-tasting solid; low water solubility; soluble in benzene and acetone) from *Actinomyces* spp., and originally spelled pikromycin, was the first identified macrolide antibiotic (1-3). Picromycin is most likely produced as the inactive diglucoside and liberated extracellularly as the active antibiotic through the action of a  $\beta$ -glucosidase. **1.** Maezawa, Hori, Kinumaki & Suzuki (1973) *J. Antibiot.* **26**, 771. **2.** Brockmann & Henkel (1951) *Chem. Ber.* **84**, 284. **3.** Brockmann & Henkel (1950) *Naturwissenschaften* **37**, 138.

### Picrotoxin

These neurotoxic GABA<sub>A</sub> receptor antagonists, consisting of a nearly 1:1 mixture of picrotoxinin, (FW = 292.29 g/mol; CAS 17617-45-7) and picrotin (FW = 310.30 g/mol; CAS 124-87-8), is a bitter-tasting (hence the Greek prefix *picros*) principle, also known as cocculin, from fishberry seeds (*Anamirta cocculus*) and the Philippine bayating (*Tinomisium philippinense*). Picrotoxin binds to the chloride channel of the receptor without displacing  $\gamma$ -aminobutyric acid (1-3). Picrotoxin is highly toxic, exerting both stimulant and convulsant effects, and care must be exercised when handling this agent. **1.** Chapouthier & Venault (2002) *Curr. Top. Med. Chem.* **2**, 841. **2.** Yoon, Covey & Rothman (1993) *J. Physiol.* **464**, 423. **3.** Gottesfeld & Elliott (1971) *J. Neurochem.* **18**, 683.

### Picrylsulfonate (Picrylsulfonic Acid)

This yellow-colored protein-modifying reagent (FW<sub>free-acid</sub> = 293.17 g/mol; CAS 2508-19-2; 5400-70-4 for sodium salt), abbreviated TNBS and also known as 2,4,6-trinitrobenzenesulfonic acid, reacts with amino groups in peptides and proteins under mildly alkaline conditions (pH ~ 9), with the

release of a sulfite ion. The absorption spectrum of the product has a  $\lambda_{\max}$  of about 345 nm. (Note: Sulfite ion affects the absorption spectra by forming an aromatic ring adduct with the modified amino acid). Picrylsulfonic acid also reacts with sulfhydryl groups to form an unstable product that decomposes to regenerate the sulfhydryl group. **Target(s):** acetate kinase (72); acetolactate decarboxylase, weakly inhibited (46); acetylcholinesterase (54); *N*-acyl-D-amino-acid deacylase (52); 2-acylglycerol *O*-acyltransferase, or monoacylglycerol *O*-acyltransferase (23,82,83); adenylyl-sulfate kinase (73,74); alcohol *O*-acetyltransferase (80,81); alkaline phosphatase (62); alliin lyase (37); AMP deaminase (51); aryl-acylamidase (53,54); *Aspergillus* nuclease S1 (59); bisphosphoglycerate mutase (3-5); bisphosphoglycerate phosphatase (4,61); butyrylcholinesterase (53); cellulase (58); chorismate mutase (6); collagenase, neutrophil (7); 3-deoxy-7-phosphoheptulonate synthase (75); dextranucrase (79); 4,5-dihydrophthalate decarboxylase (45); elastase (8); exo-(1 $\rightarrow$ 4)- $\alpha$ -D-glucan lyase (41);  $F_1$  ATPase, or  $H^+$ -transporting two-sector ATPase (9); fatty-acid synthase (10); *S*-formylglutathione hydrolase (11,64); fumarylacetoacetase (47); 3-galactosyl-*N*-acetylglucosaminide 4- $\alpha$ -L-fucosyltransferase (77); glutamate dehydrogenase (12);  $\gamma$ -glutamylcysteine synthetase (13,14); glutathione-disulfide reductase (15,16); glutathione *S*-transferase (17,76); glyceraldehyde-3-phosphate dehydrogenase (18); glycerophosphocholine cholinephosphodiesterase (60); hydroxyacylglutathione hydrolase, glyoxalase II (65-69); inositol-3-phosphate synthase, or inositol-1-phosphate synthase (19); 3-ketovalidoxyamine C-N-lyase (38); lactose synthase (78); lactoylglutathione lyase, or glyoxalase I (20,21); leukotriene- $A_4$  hydrolase (55); lima bean trypsin inhibitor (22); lipase, or triacylglycerol lipase (71); myosin ATPase (48);  $Na^+/K^+$ -exchanging ATPase (24-26); neutrophil collagenases (7); ornithine carbamoyltransferase (84); ovomucoids (22); pectate lyase (44); pepsin (27); phenylalanine ammonia-lyase (39,40); phosphoglycerate mutase (3-5,28); poly( $\alpha$ -L-gulonate) lyase (42); poly( $\beta$ -D-mannuronate) lyase (43); protein-glutamate methyltransferase (70); pyrophosphatase, or inorganic diphosphatase (29,49,50); pyruvate carboxylase (30,31); pyruvate kinase (32,33); rhodanese, or thiosulfate sulfurtransferase (34,35); salicylate 1-monooxygenase (86); *S*-succinylglutathione hydrolase (63); superoxide dismutase (85); thioglucosidase, or myrosinase, or sinigrinase (56,57); and UDP-*N*-acetylmuramoylalanine-D-glutamate ligase (36). 1. ### Pictilisib

This potent PI3K inhibitor (FW = 513.64 g/mol; CAS 957054-30-7; Solubility: 44 mg/mL DMSO), also known as GDC-0941 and 2-(1*H*-indazol-4-yl)-6-((4-(methylsulfonyl)piperazin-1-yl)methyl)-4-morpholino-thieno[3,2-*d*]pyrimidine, targets phosphatidylinositol-4,5-bisphosphate 3-kinase, catalytic subunit  $\alpha$ , or PIK3CA and p110 $\alpha$  (IC<sub>50</sub> = 3 nM); PI3K $\delta$ , or p110 $\delta$  (IC<sub>50</sub> = 3 nM); PI3K $\beta$ , or p110 $\beta$  (IC<sub>50</sub> = 33 nM); and PI3K $\gamma$ , or p110 $\gamma$  (IC<sub>50</sub> = 75 nM), important targets in cancers exploiting the dysregulation of PI3K/Akt signaling (1). Ellagic acid enhances the efficacy GDC-0941 in breast cancer cells (2). **Binding Mode:** An X-ray crystal structure of GDC-0941 bound to human p110 $\gamma$  shows that it is very efficiently anchored in the ATP-binding site (1). Similar to LY294002, GDC-0941 uses an essential morpholino group to form the key hydrogen bond with the hinge. Its indazole moiety also fits snugly deep in the affinity

pocket with the two indazole nitrogen atoms forming hydrogen bonds with the hydroxyl group of Tyr 867 and the carboxylate group of Asp 841, further strengthening the interactions in this pocket (1). 1. Folkes, Ahmadi, Alderton, *et al.* (2008) *J. Med. Chem.* **51**, 5522. 2. Shi, Gao, Li, *et al.* (2015) *Curr. Mol. Med.* **15**, 478.

#### Piericidin A<sub>1</sub>

This antibiotic (FW = 415.57 g/mol; CAS 2738-64-9; IUPAC: 2-(10-hydroxy-3,7,9,11-tetramethyl-2,4,7,11-tridecatetraenyl)-5,6-dimethoxy-3-methyl-4-pyridinol, from species of *Streptomyces*, is a structural analogue of ubiquinone and inhibits NADH dehydrogenase and electron transport by binding to the ubiquinone binding site. **Target(s):** cytochrome *d* complex (1); cytochrome *o* complex (1); electron transport (2-8); glucose dehydrogenase, ubiquinone (9); NADH dehydrogenase, complex I (2-7,9-21); photosystem II (22); succinate dehydrogenase, inhibited at high concentrations (7); ubiquinol:cytochrome *c* reductase activity of complex III (23); and ubiquinol oxidase, *Escherichia coli* (1,24). 1. **Piericidin A, Reduced, See Octahydropiericidin A**

**Piericidin B, Reduced, See Octahydropiericidin B**

#### Pifithrin- $\alpha$

This p53 inhibitor (FW<sub>hydrobromide</sub> = 367.31 g/mol), also known as 2-(2-imino-4,5,6,7-tetrahydrobenzothiazol-3-yl)-1-*p*-tolylethanone, protects wild type mice against lethal doses of radiation, but is without effect on p53-deficient animals. **Target(s):** caspase-2 activation (1); luciferase, firefly, or *Photinus*-luciferin 4-monooxygenase, ATP-hydrolyzing (2-4); p53 (5,6); p53-mediated apoptosis (5,6); and p53-dependent gene transcription (5,6). 1. Tyagi, Singh, Agarwal & Agarwal (2006) *Carcinogenesis* **27**, 2269. 2. Rocha, Campbell, Roche & Perkins (2003) *BMC Mol. Biol.* **4**, 9. 3. Auld, Southall, Jadhav, *et al.* (2008) *J. Med. Chem.* **51**, 2372. 4. Inouye (2010) *Cell. Mol. Life Sci.* **67**, 387. 5. Komarov & Gudkov (2000) *Biochemistry (Moscow)* **65**, 41. 6. Komarov, Komarova, Kondratov, *et al.* (1999) *Science* **285**, 1733.

#### Pifithrin- $\mu$

This cell-permeable sulfonamide-based inhibitor and anti-apoptotic factor (FW = 181.20 g/mol; CAS 64984-31-2; Solubility: >10 mg/mL DMSO, <2 mg/mL H<sub>2</sub>O; pK<sub>a</sub> = 8; *Symbol* = PFT $\mu$  and PAS), also known as 2-phenylethynylsulfonamide, targets p53 and Heat Shock Protein-70, or HSP 70 (1). Because it only targets the mitochondrial branch of the p53 pathway without affecting the important transcriptional functions of p53, Pifithrin- $\mu$  is recommended over Pifithrin- $\alpha$  for *in vivo* studies. PFT $\mu$  exhibits high specificity for p53 and does not protect cells from apoptosis induced by overexpression of the proapoptotic protein Bax or by treatment with dexamethasone. With B-chronic lymphocytic leukemia (CLL) cells, Pifithrin- $\mu$  (5–20  $\mu$ M) initiated apoptosis within 24 hours, with maximal death at 48 hours, as assessed by cell morphology, cleavage of poly(ADP-ribose) polymerase (PARP), caspase-3 activation, and annexin V staining (2). 1. Strom, Sathe, Komarov, *et al.* (2006) *Nature Chem Biol.* **2**, 474. 2. Steele, Prentice, Hoffbrand, *et al.* (2009) *Blood* **114**, 1217.

#### Pilaralisib

This selective, reversible, and ATP-competitive Class I PI3K inhibitor (FW = 541.02 g/mol; CAS 934526-89-3; Solubility: 100 mg/mL DMSO, when warmed; < 1 mg/mL H<sub>2</sub>O), also known as XL147, SAR245408, and *N*-(3-[(3-[[2-chloro-5-(methoxyphenyl)amino]quinoxalin-2-yl]amino]sulfonyl]phenyl)-2-methylalaninamide, targets PI3K $\alpha$  (IC<sub>50</sub> = 39 nM, PI3K $\delta$  (IC<sub>50</sub> = 36 nM), and PI3K $\gamma$  (IC<sub>50</sub> = 23 nM), but only weakly for PI3K $\beta$ . Pilaralisib is active against human breast cancer cell lines with constitutive PI3K activation (1). PI3K inhibitors reduce AKT activity and relieves suppression of receptor tyrosine kinase expression and activity. XL147 shows dose-dependent inhibition of cell growth and levels of pAKT and pS6, signal transducers in the PI3K/AKT/TOR pathway (1). In HER2-overexpressing cells, pilaralisib inhibition of PI3K is attended by up-regulation of expression and phosphorylation of multiple receptor tyrosine kinases, including HER3. Knockdown of FoxO1 and FoxO3a transcription factors suppressed the induction of HER3, InsR, IGF1R, and FGFR2 mRNAs upon inhibition of PI3K. In HER2(+) cells, knockdown of HER3 with siRNA or cotreatment with the HER2 inhibitors trastuzumab or lapatinib enhance XL147-induced cell death and inhibition of pAKT and pS6 (1). When tested separately, trastuzumab and lapatinib synergized with XL147 for inhibition of pAKT and growth of established BT474 xenografts. Compared with XL147 alone, the combination exhibited a superior antitumor effect against trastuzumab-resistant tumor xenografts. 1. Chakrabarty, Sánchez, Kuba, Rinehart & Arteaga (2012) *Proc. Natl. Acad. Sci. U.S.A.* **109**, 2718.

#### PIK-75

This novel phosphoinositide-3 kinase p110 $\alpha$  inhibitor (F.Wt. = 488.74; CAS 372196-67-3; Solubility (25°C): 98 mg/mL DMSO, <1 mg/mL Water), also known as (*E*)-*N*'-((6-bromoH-imidazo[1,2-*a*]pyridin-3-yl)methylene)-*N*,2-dimethyl-5-nitrobenzenesulfonohydrazide-HCl, competes with respect to a substrate (phosphatidylinositol, PI), unlike most other PI3K inhibitors, which bind at or near the ATP site. PIK-75 exhibits impressive isoform selectivity, with an IC<sub>50</sub> value of 5.8 nM for p110 $\alpha$ , while the corresponding IC<sub>50</sub> values are 1300 nM, 76 nM and 510 nM for p110 $\beta$ , p110 $\gamma$ , and p110 $\delta$ , respectively. 1. Zheng, Amran, Zhu, *et al.* (2012) *Biochem. J.* **444**, 529.

## PIK-90

This potent, cell-permeable p110 inhibitor (F.Wt. = 351.36; CAS 1349796-36-6 and 1123889-87-1; Solubility (25°C): <1 mg/mL DMSO, <1 mg/mL Water), is also known as *N*-(2,3-dihydro-7,8-dimethoxyimidazo[1,2-*c*]quinazolin-5-yl)-3-pyridinecarboxamide, has the following targets: p110 $\alpha$ ,  $IC_{50}$  = 11 nM; p110 $\beta$ ,  $IC_{50}$  = 350 nM; p110 $\gamma$ ,  $IC_{50}$  = 18 nM; and p110 $\delta$ ,  $IC_{50}$  = 58 nM (1). PIK-90 also exhibits significant antiproliferative activity by blocking Akt phosphorylation. 1. [1] Van Keymeulen, *et al.* (2006) *J. Cell Biol.* 174, 437.

## PIK-93

This potent and selective PI3K $\gamma$ /PI4KIII $\beta$  inhibitor (FW = 389.88; CAS 593960-11-3; Solubility (25°C): 78 mg/mL DMSO, <1 mg/mL Water), also known as *N*-[5-[4-chloro-3-[(2-hydroxyethyl)sulfamoyl]phenyl]-4-methylthiazol-2-yl]acetamide, impairs actin filament consolidation and stability at the leading edge in cells treated with *N*-formyl-Met-Leu-Phe (2) as well as ceramide transport between ER and Golgi compartments (3). The inhibition of PI3K by PIK-93, LY294002, or wortmannin decreased carbachol-induced translocation of TRPC6 to the plasma membrane and carbachol-induced net Ca<sup>2+</sup> entry into T6.11 cells (4). PIK-93 inhibits both poliovirus (PV) and hepatitis C virus (HCV) replication, with  $EC_{50}$  values of 0.14  $\mu$ M and 1.9  $\mu$ M, respectively (5). Targets: PI3K $\gamma$ ,  $IC_{50}$  = 16 nM; PI4KIII $\beta$ ,  $IC_{50}$  = 19 nM; PI3K $\alpha$ ,  $IC_{50}$  = 39 nM; PI3K $\delta$ ,  $IC_{50}$  = 0.12  $\mu$ M; and PI3K $\beta$ ,  $IC_{50}$  = 0.59  $\mu$ M (1). 1. Knight (2006) *Cell* 125, 733. 2. Van Keymeulen, *et al.* (2006) *Cell Biol.* 174, 437. 3. Tóth B, *et al.* (2006) *J. Biol. Chem.* 281, 36369. 4. Monet, Francoeur & Boulay (2012) *J. Biol. Chem.* 287, 17672. 5. Arita, *et al.* (2011) *J. Virol.* 85, 2364.

## PIK-294

This pseudopurine-containing phosphatidylinositol kinase inhibitor (FW = 489.53 g/mol; CAS = 900185-02-6; Solubility: 98 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 2-((4-amino-3-(3-hydroxyphenyl)-1*H*-pyrazolo[3,4-*d*]pyrimidin-1-yl)methyl)-5-methyl-3-ortho-tolylquinazolin-4(3*H*)-one, selectively targets p110 $\delta$  ( $IC_{50}$  = 10 nM), with much weaker inhibition of PI3K $\alpha$  ( $IC_{50}$  = 10,000 nM), PI3K $\beta$  ( $IC_{50}$  = 490 nM), and PI3K $\gamma$  ( $IC_{50}$  = 160 nM), respectively. 1. Knight, Gonzalez, Feldman, *et al.* (2006) *Cell* 125, 733. 2. Bobrovnikova-Marjon, Pytel, Riese, *et al.* (2012) *Mol. Cell Biol.* 32, 2268.

## Pilocarpine

This photosensitive alkaloid (FW<sub>free-base</sub> = 208.26 g/mol; CAS 92-13-7; 148-72-1 for the (3*S*-*cis*)-isomer, mononitrate salt; 54-71-7 for the (3*S*-*cis*)-

isomer, mono-HCl salt; M.P. = 34°C; water-soluble; imidazole  $pK_a$  = 7.15 at 20°C) from the leaves of *Pilocarpus jaborandi* and other *P.* species is a nonselective muscarinic acetylcholine receptor agonist used in the treatment of glaucoma, as a diaphoretic, and as an agent to produce experimental epilepsy. **Target(s):** CYP2A5 (1,2); CYP2A6 (1-4); CYP3A, moderately inhibited (2); CYP2B (1,2,5);  $\beta$ -fructofuranosidase, or invertase (6); and urease, inhibited by free base (7). 1. Kinonen, Pasanen, Gynther, *et al.* (1995) *Brit. J. Pharmacol.* 116, 2625. 2. Kimonen, Juvonen, Alhava & Pasanen (1995) *Brit. J. Pharmacol.* 114, 832. 3. Xia, Peng, Yu, Wang & Wang (2002) *Acta Pharmacol. Sin.* 23, 471. 4. Li, Li & Sellers (1997) *Eur. J. Drug Metab. Pharmacokin.* 22, 295. 5. Skaanild & Friis (2002) *Pharmacol. Toxicol.* 91, 198. 6. Neuberg & Mandl (1950) *The Enzymes*, 1st ed. (Sumner & Myrback, eds.), 1 (part 1), 527. 7. Onodera (1915) *Biochem. J.* 9, 544.

## Pimasertib

This selective, orally bioavailable MEK inhibitor (FW = 431.20 g/mol; CAS 1236699-92-5; Solubility: 86 mg/mL DMSO), also known as AS-703026 and (*S*)-*N*-(2,3-dihydroxypropyl)-3-(2-fluoro-4-iodophenylamino)-isonicotinamide, targets MEK1 ( $IC_{50}$  = 5 nM) and MEK2 ( $IC_{50}$  = 2  $\mu$ M) in multiple myeloma (MM) cell lines. MEK is an alternate name for Mitogen-Activated Protein Kinase Kinase (MAP2K or MAPKK), a signal transduction kinase that phosphorylates Mitogen-Activated Protein Kinase (MAPK). AS703026 is an ATP-noncompetitive (allosteric) inhibitor that exhibits exquisite kinase selectivity. AS703026 sensitizes MM cells to a broad spectrum of conventional (*e.g.*, dexamethasone, melphalan) and novel/emerging (*e.g.*, lenalidomide, perifosine, bortezomib, rapamycin) anti-MM therapies (1). Significant tumor growth reduction is observed in AS703026-treated *versus* vehicle-treated mice bearing H929 MM xenograft tumors, which correlated with downregulation of pERK1/2, induction of PARP cleavage, and decreased microvessel formation *in vivo* (1). AS703026 circumvents resistance to the BRAF inhibitor PLX4032 in human malignant melanoma cells (*e.g.*, RPMI-7951 and SK-MEL5) harboring BRAF<sup>V600E</sup> (2). Combination of a PI3K/mTOR inhibitor (SAR245409) with a MEK inhibitor (AS703026) induces a synergistic antitumor effect in certain endometrial cancer cells, underscores the utility of optimized doses of antitumor agents in treating endometrial cancer (3). A kinome siRNA library assay targeting 790 kinases, plus or minus AS703026, indicated that SAR245409 and AS703026 acting in combination is likely to be an effective treatment of Triple-Negative Breast Cancer, or TNBC (4). 1. Kim, Kong, Fulciniti, *et al.* (2010) *Brit. J. Haematol.* 149, 537. 2. Park, Hong, Moon, *et al.* (2013) *Am. J. Med. Sci.* 346, 494. 3. Inaba, Oda, Ikeda, *et al.* (2015) *Gynecol. Oncol.* 138, 323. 4. Lee, Galloway, Grandjean, *et al.* (2015) *J. Cancer.* 6, 1306.

## Pimavanserin

This orally active atypical non-dopaminergic antipsychotic (FW<sub>free-base</sub> = 427.56 g/mol; CAS 706779-91-1 (free base) and 706782-28-7 (tartrate salt)), also known as ACP-103, Nuplazid<sup>®</sup> and *N*-(4-fluorophenylmethyl)-*N*-(1-methyl-piperidin-4-yl)-*N'*-(4-(2-methylpropoxy)phenyl-methyl)carbamide, is a potent inverse agonist and antagonist at serotonin 5-HT<sub>2A</sub> receptors ( $K_i$  = 0.087 nM) and less so at serotonin 5-HT<sub>2C</sub> receptors ( $K_i$  = 0.44 nM) (1-3). Pimavanserin shows low binding to  $\sigma_1$  receptors ( $K_i$  = 120 nM), with no appreciable affinity ( $K_i$  > 300 nM) to serotonin 5-HT<sub>2B</sub>, dopaminergic (including D<sub>2</sub>), muscarinic, histaminergic, or adrenergic

receptors, or to calcium channels. 5-HT<sub>2A</sub> receptor dysregulation is implicated in both the etiology and treatment of schizophrenia, and the same receptor plays an active role in the regulation of sleep architecture. Nuplazid is specifically indicated in its FDA approval (April, 2016) for the treatment of hallucinations and delusions associated with Parkinson disease. Significantly, 5-HT<sub>2A</sub> serotonin receptor antagonists differentially regulate 5-HT<sub>2A</sub> receptor protein level in vivo (4). **See also** *Ketanserin*; *RH-34*; *Risperidone*; *Ritanserlin*; *Setoperone*; *Volinanserlin*. **1.** Vanover, Weiner, Makhay, *et al.* (2006) *J. ### Pimecrolimus

This immunophilin ligand (FW = 810.46 g/mol; CAS 137071-32-0; Solubility = 100 mg/mL DMSO), also known as ASM 981 and SDZ ASM 981, is a ascocyclic macrolactam that binds to macrophilin-12 (also known as FKBP-12) and inhibits phosphoprotein phosphatase calcineurin, thereby blocking T-cell activation by inhibiting cytokine synthesis and release from T-cells. Pimecrolimus downregulates production of Th1 [interleukin (IL)-2, interferon-gamma] and Th2 (IL-4, IL-10) type cytokines after antigen-specific stimulation of a human T-helper cell clone isolated from the skin of an atopic dermatitis patient (1). SDZ ASM 981 inhibits phorbol myristate/phytohemagglutinin-stimulated transcription of a reporter gene coupled to the human IL-2 promoter in the human T-cell line Jurkat and the IgE/antigen-mediated transcription of a reporter gene coupled to the human tumour necrosis factor (TNF)-alpha promoter in the murine mast-cell line CPII (1). Pharmacokinetic studies demonstrated very low blood levels of pimecrolimus following topical application, with no accumulation after repeated applications. Pimecrolimus is thus a versatile treatment for inflammatory skin diseases. **1.** Grassberger, Baumruker, Enz, *et al.* (1999) *Brit. J. Dermatol.* **141**, 264.

### Pimelate (Pimelic Acid)

This dicarboxylic acid (FW<sub>free-acid</sub> = 160.17 g/mol; CAS 111-16-0; pK<sub>1</sub> = 4.46 and pK<sub>2</sub> = 5.58), also known as heptanedioic acid, is soluble in water (5 g/100 mL at 20°C). Pimelate is excreted in elevated amounts in urine in individuals with disorders in mitochondrial and peroxisomal β-oxidation, for which it is of significant diagnostic value. **Target(s):** 2-aminoadipate aminotransferase (1); 4-aminobutyrate aminotransferase (2); carbamoyl-phosphate synthetase (3); carboxy-*cis,cis*-muconate cyclase (4); glutamate decarboxylase, K<sub>i</sub> = 0.81 mM (5,6); kynurenine:oxoglutarate aminotransferase (7-11); and 2,3,4,5-tetrahydropyridine-2,6-dicarboxylate *N*-succinyltransferase (12). **1.** Deshmukh & Mungre (1989) *Biochem. J.* **261**, 761. **2.** Schousboe, Wu & Roberts (1974) *J. Neurochem.* **23**, 1189. **3.** Jones (1962) *Meth. Enzymol.* **5**, 903. **4.** Thatcher & Cain (1975) *Eur. J. ### Pimozide

This oral antipsychotic drug (FW<sub>free-base</sub> = 461.55 g/mol; CAS 2062-78-4) is a D<sub>2</sub> receptor antagonist, Ca<sup>2+</sup> channel antagonist, and high-affinity antagonist for the 5-hydroxytryptamine-7 receptor. Pimozide is used to control motor or verbal tics (*i.e.*, an uncontrollable need to repeat certain movements or sounds) caused by Tourette's disorder. Pimozide likewise inhibits the dopamine transporter (DAT), a property that accounts for its stimulant properties. Inhibition of dopamine-reuptake may explain the synergistic effects of pimozide in the treatment of ADHD, when administered with a stimulant. **Caution:** Pimozide can have severe, even potentially fatal side-effects. **Target(s):** adenylate cyclase, dopamine-stimulated (1,2); and CYP2D6 (3). **1.** Iversen (1975) *Science* **188**, 1084. **2.** Iversen (1976) *Trends Biochem. Sci.* **1**, 121. **3.** Desta, Kerbusch, Soukhova, *et al.* (1998) *J. Pharmacol. Exp. Ther.* **285**, 428.

### Pinacoyl Methylphosphofluorodate, See Soman

### Pinane Thromboxane A<sub>2</sub>

This stable thromboxane A<sub>2</sub> analogue (FW<sub>free-acid</sub> = 376.58 g/mol) is a partial thromboxane A<sub>2</sub> receptor agonist. **Target(s):** GABA-gated chloride channels (1); 15-hydroxyprostaglandin dehydrogenase (2); thromboxane receptor (3); and thromboxane synthase (4). **1.** Schwartz-Bloom, Cook & Yu (1996) *Neuropharmacology* **35**, 1347. **2.** Robinson & Houlst (1983) *Biochim. Biophys. Acta* **754**, 190. **3.** Armstrong, Jones, Peesapati, Will & Wilson (1985) *Brit. J. Pharmacol.* **84**, 595. **4.** Nicolaou, Magolda, Smith, *et al.* (1979) *Proc. Natl. Acad. Sci. U.S.A.* **76**, 2566.

### Pinan-3-ol

This bicyclic terpenol (FW = 154.25 g/mol; CAS 25465-65-0) inhibits α-pinene-oxide decyclase by 88% when present at 2.8 mM. **1.** Griffiths, Harries, Jeffcoat & Trudgill (1987) *J. Bacteriol.* **169**, 4980.

### Pindobind

This  $\alpha$ -haloacetamido pindolol analogue (FW = 480.45 g/mol; hygroscopic), also known as  $N^6$ -(bromoacetyl)- $N^1$ -[3-(4-indolyloxy)-2'-hydroxypropyl]-(*Z*)-1,8-diamino-*p*-menthane, is an affinity label for  $\beta$ -adrenoceptors (1). Pindobind does not stimulate adenylate cyclase activity, but does inhibit (-)-isoproterenol-stimulated adenylate cyclase activity. 1. Pitha, Buchowiecki, Milecki & Kusiak (1987) *J. Med. Chem.* **30**, 612.

### Pindolol

This antihypertensive agent (FW = 248.33 g/mol; CAS 13523-86-9), also known as 1-(1*H*-indol-4-yloxy)-3-[(1-methylethyl)amino]-2-propanol and Visken, is a moderately lipophilic  $\beta_1$ -adrenergic receptor antagonist and a 5-HT<sub>1A</sub> serotonin receptor partial agonist,  $K_i = 30$  nM (1-3). *Note:* The pharmacologically active stereoisomer is the (-)-*S*-enantiomer. **See also lodocyanopindolol** **Target(s):** glycogenolysis in rat liver (4); endogenous prostaglandin synthesis (5); hepatic 3,5,3'-triiodothyronine production (6); inhibition of thromboxane and prostacyclin production in whole blood (7); rat brain serotonin (5-HT) synthesis (8). 1. Watkins, Lawrence, Lewis & Jarrott (1996) *J. Auton. Nerv. Syst.* **60**, 12. 2. Salimi (1975) *Pharmacology* **13**, 441. 3. Frishman (1983) *N. Engl. J. Med.* **308**, 940. 4. Greer, Walker, McLaren, Calder & Forbes (1985) *Prostaglandins Leukot. Med.* **19**, 209. 8. Hjorth & Carlsson (1985) *Neuropharmacology* **24**, 1143.

### $\alpha$ -Pinene

This cyclic monoterpene antifungal agent (FW = 136.24 g/mol; CAS 80-56-8; 7785-70-8 for (+)- $\alpha$ -pinene; 7785-26-4 for (-)- $\alpha$ -pinene), named systematically as (1*S*,5*S*)-2,6,6-trimethyl bicyclo[3.1.1]hept-2-ene, is found in turpentine oil. (*Note:*  $\alpha$ -Pinene from North American turpentine is primarily dextrorotatory, whereas European turpentine  $\alpha$ -pinene is levorotatory.) The *d*-form is found in Port Oxford cedar wood oil (*Chamaecyparis lawsoniana*) and the *l*-stereoisomer is in mandarin peel oil. The boiling point of each enantiomer is 155-156°C. **Target(s):** acetylcholinesterase, both (+)- and (-)-isomers inhibit, with respective  $K_i$  values of 0.15 and 0.17 mM for the bovine enzyme (1,2); CYP3A (3); CYP2B1 (4); and methane monooxygenase (5). 1. Perry, Houghton, Theobald, Jenner & Perry (2000) *J. Pharm. Pharmacol.* **52**, 895. 2. Miyazawa & Yamafuji (2005) *J. Agric. Food Chem.* **53**, 1765. 3. Pass & McLean (2002) *Xenobiotica* **32**, 1109. 4. De-Oliveira, Ribeiro-Pinto & Paumgarten (1997) *Toxicol. Lett.* **92**, 39. 5. Amaral, Ekins, Richards & Knowles (1998) *Appl. Environ. Microbiol.* **64**, 520.

### Pinosylvin

This *trans*-stilbene derivative (FW = 212.25 g/mol; CAS 102-61-4; M.P. = 155.5-156°C; low solubility in water), also known as (*E*)-3,5-stilbenediol and *trans*-3,5-dihydroxystilbene and named systematically as 5-[(*E*)-2-phenylethenyl]benzene-1,3-diol, occurs naturally in the hardwood of pine

and other woody plants. Pinosylvin exhibits micromolar  $K_i$  values for specific isozymes of stilbene synthase and chalcone synthase (1). **Target(s):** chalcone synthase (1); stilbene synthase (1); tyrosinase, *or* monophenol monooxygenase (2). 1. Kodan, Kuroda & Sakai (2002) *Proc. Natl. Acad. Sci. U.S.A.* **99**, 3335. 2. Lin, Hsu, Chen, Chern & Lee (2007) *Phytochemistry* **68**, 1189.

### Pioglitazone

This thiazolidinedione (FW = 356.45 g/mol; CAS 11025-46-8), also known by the trade names Actos<sup>®</sup>, Glustin<sup>®</sup>, Glizone<sup>®</sup>, and Pioz<sup>®</sup> as well as (*RS*)-5-(4-[2-(5-ethylpyridin-2-yl)ethoxy]benzyl)thiazolidine-2,4-dione, is an insulin sensitizer and a specific Peroxisome Proliferator-Activated Receptor- $\gamma$ , *or* PPAR- $\gamma$  agonist. **Mode of Action:** Pioglitazone selectively stimulates the nuclear receptor PPAR- $\gamma$  (and PPAR- $\alpha$  to a lesser degree), thereby modulating insulin-sensitive gene transcription, reducing insulin resistance in the liver and peripheral tissues, increasing the expense of insulin-dependent glucose, decreasing circulating levels of glucose, insulin and glycated hemoglobin. Pioglitazone likewise decreases the level of triglycerides and increases that of high-density lipoproteins (HDL) without altering low-density lipoproteins and total cholesterol in patients with lipid metabolism disorders. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** CYP2C8, weakly inhibited (1); CYP2C9, weakly inhibited (1); CYPc17 (2); 3 $\beta$ -hydroxysteroid dehydrogenase type II (2); long-chain-fatty-acyl-CoA synthetase 5, *or* long-chain-fatty-acid:CoA ligase 5 (3). 1. Yamazaki, Suzuki, Tane, *et al.* (2000) *Xenobiotica* **30**, 61. 2. Arlt, Auchus & Miller (2001) *J. Biol. Chem.* **276**, 16767. 3. Kim, Lewin & Coleman (2001) *J. Biol. Chem.* **276**, 24667.

**PIP**, See *Phosphatidylinositol 4-Phosphate*

**PIP<sub>2</sub>**, See *Phosphatidylinositol 4,5-Bisphosphate*

### Pipamperone

This orally bioavailable antipsychotic agent (FW<sub>free-base</sub> = 375.49 g/mol; CAS 1892-33-0), marketed as Dipiperone<sup>®</sup> and known systematically as 1'-[4-(4-fluorophenyl)-4-oxobutyl]-1,4'-bipiperidine-4'-carboxamide, is a D<sub>2</sub> dopamine receptor and 5-HT<sub>2</sub> serotonin receptor antagonist (1-4). 1. Vanhauwe, Ercken, van de Wiel, Jurzak & Leysen (2000) *Psychopharmacology (Berlin)* **150**, 383. 2. Van Oekelen, Megens, Meert, Luyten & Leysen (2002) *Behav. Pharmacol.* **13**, 313. 3. Nisijima, Yoshino, Yui & Katoh (2001) *Brain Res.* **890**, 23. 4. Ilien, Gorissen & Laduron (1982) *Mol. Pharmacol.* **22**, 243.

### Pipecolic Acid

This amino acid (FW = 129.16 g/mol; CAS 3105-95-1), also called 2-piperidinecarboxylic acid and pipecolic acid, is readily prepared from lysine and can be regarded as a proline homologue. The *L*-enantiomer has been identified in mushrooms, fruits, malt, and seeds. Elevated levels of pipecolate (*i.e.*, hyperpipecolic acidemia) have been observed in certain inborn errors in metabolism. Note that the  $pK_a$  values of pipecolic acid are 2.28 and 10.72; hence, under most aqueous conditions, this molecule exists

as a zwitterion. The L-isomer is a product of the reaction catalyzed by  $\Delta^1$ -piperidine-2-carboxylate reductase and is a substrate for L-pipecolate oxidase and L-pipecolate dehydrogenase. **Target(s):** bovine leukemia virus retropepsin (1); and proline racemase, weakly inhibited (2). 1. Ménard & Guillemain (1998) in *Handb. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.), p. 940, Academic Press, San Diego. 2. Cardinale & Abeles (1968) *Biochemistry* 7, 3970.

**Pipecolinic Acid, See Pipecolic Acid**

### Piperacillin

This semisynthetic broad-spectrum antibiotic (FW<sub>free-acid</sub> = 517.56 g/mol; CAS 61477-96-1; 59703-84-3 for monosodium salt), known systematically as (2*S*,5*R*,6*R*)-6-[[[(2*R*)-2-[(4-ethyl-2,3-dioxo-piperazine-1-carbonyl)-amino]-2-phenylacetyl]amino]-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylic acid, inhibits proteoglycan biosynthesis. Piperacillin is often used in combination with tazobactam and marketed as Tazocin<sup>®</sup>, Zosyn<sup>®</sup>, Brodactam<sup>®</sup> and Trezora<sup>®</sup>. **Target(s):** penicillin-binding protein-3 (1); serine-type D-Ala-D-Ala carboxypeptidase, or D-alanine carboxypeptidase (2). 1. Botta & Park (1981) *J. Bacteriol.* 145, 333. 2. Suginaka, Shimatani, Ogawa & Kotani (1979) *J. Gen. Microbiol.* 112, 181.

### Piperine

This traditional medicine and insecticide (FW = 285.34 g/mol; CAS 94-62-2; Solubility; IUPAC Name: 1-[5-(1,3-benzodioxol-5-yl)-1-oxo-2,4-pentadienyl]piperidine), which gives black pepper (*Piper nigrum*) and long peppers their pungency, enhances the potency of various drugs by inhibiting enzymes catalyzing arylhydrocarbon hydroxylation, ethylmorphine-*N*-demethylation, 7-ethoxycoumarin-*O*-deethylation and 3-hydroxybenzo(*a*)pyrene glucuronidation (1). Piperine also inhibits the drug transporter P-glycoprotein and CYP3A4, the latter a major drug-metabolizing enzyme (2). Because both enzymes are expressed in enterocytes and hepatocytes, where they play major roles in first-pass elimination of many orally administered drugs, dietary piperine is likely to affect plasma concentrations of drugs in humans. In Ca<sup>2+</sup>-free medium, piperine (1-30  $\mu$ M) exhibits vasoconstrictor effects. In rat aorta, piperine demonstrates endothelium-independent vasodilator effect and is more potent against high K<sup>+</sup> pre-contractions than phenylephrine (3). In bovine coronary artery preparations, piperine likewise inhibits high K<sup>+</sup>-stimulated pre-contractions completely. Piperine also suppresses phorbol-12-myristate-13-acetate-induced tumor cell invasion by inhibiting PKC $\alpha$ /ERK1/2-dependent matrix metalloproteinase-9 expression (4). At 75-150  $\mu$ M, piperine inhibits the growth of several colon cancer cell lines, with little effect on the growth of normal fibroblasts and epithelial cells (5). Notably, piperine inhibits HT-29 colon carcinoma cell proliferation by causing G<sub>1</sub> phase cell cycle arrest that was associated with decreased expression of cyclins D1 and D3 and their activating partner CDK-4 and -6, as well as reduced phosphorylation of the retinoblastoma protein and up-regulation of p21/WAF1 and p27/KIP1 expression. In addition, piperine causes hydroxyl radical production and apoptosis. Piperine-treated HT-29 cells show loss of mitochondrial membrane integrity and cleavage of poly(ADP-ribose) polymerase-1, as well as caspase activation and reduced apoptosis in the presence of the pan-caspase inhibitor zVAD-FMK. Increased expression of the endoplasmic reticulum stress-associated proteins inositol-requiring 1 $\alpha$  protein, C/EBP homologous protein, and binding immunoglobulin protein, and activation of c-Jun N-terminal kinase and p38 mitogen-activated protein kinase, as well as decreased phosphorylation of Akt and reduced survivin expression are also observed in piperine-treated HT-29 cells (5). 1. Atal, Dubey & Singh (1985) *J. Pharmacol. Exp. Ther.* 232, 258. 2. Bhardwaj,

Glaeser, Becquemont, *et al.* (2002) *J. Pharmacol. Exp. Ther.* 302, 645. 3. Taqvi, Shah & Gilani (2008) *J. Cardiovasc. Pharmacol.* 52, 452. 4. Hwang, Yun, Kim, *et al.* (2011) *Toxicol. Lett.* 203, 9. 5. Yaffe, Power Coombs, Doucette, Walsh & Hoskin (2014) *Mol. Carcinog.* 54, 1070.

### PI3K/HDAC Inhibitor I

This orally available, dual-PI3K/HDAC inhibitor (FW = 508.55 g/mol; CAS 1339928-25-4); Solubility: 100 mg/mL DMSO; <1 mg/mL Water), known as *N*-hydroxy-2-(((2-(6-methoxy-pyridin-3-yl)-4-morpholino-thieno[3,2-*d*]pyrimidin-6-yl)methyl)(methyl)amino)-pyrimidine-5-carboxamide, targets the phosphatidylinositol 3-kinase PI3K $\alpha$ , and histone deacetylases HDAC1, HDAC2, HDAC3 and HDAC10 with IC<sub>50</sub> values of 19 nM, 1.7 nM, 5 nM, 1.8 nM and 2.8 nM, respectively. PI3K/HDAC Inhibitor I inhibits other PI3K isoforms such as PI3K $\beta$ , PI3K $\gamma$ , PI3K $\delta$ , PI3K $\alpha$ H1047R and PI3K $\alpha$ E545K with IC<sub>50</sub> of 54 nM, 311 nM, 39 nM, 73 nM and 62 nM, respectively. [1] Bao, Wang, Qu, *et al.* (2012), *American Association for Cancer Research Meeting*, Chicago, Illinois, Poster # 3744.

### Piperastatin A

This piperazate-containing peptidomimetic (FW = 809.1 g/mol; NLM Unique Identifier C103102), corresponding to *N*-formyl-*allo*-Ile-Thr-Leu-Val-Pip-Leu-Pip, where Pip is piperazate (or hexahydropyridadine-3-carboxylate), is obtained from *Streptomyces lavendofoliae* MJ908-WF13. *Note:* This inhibitor is chemically unstable, and its inhibitory activity diminishes in a time-dependent manner. **Target(s):** carboxypeptidase C, or carboxypeptidase Y (1-5). 1. Murakami, Harada, Yamazaki, *et al.* (1996) *J. Enzyme Inhib.* 10, 93. 2. Murakami, Takahashi, Naganawa, Takeuchi & Aoyagi (1996) *J. Enzyme Inhib.* 10, 105. 3. Satoh, Kadota, Oheda, *et al.* (2004) *J. Antibiot.* 57, 316.

### 2-(2-Piperidinyl)ethylidene-1,1-bisphosphonate

This bisphosphonate (FW<sub>ion</sub> = 271.15 g/mol), also known as NE58034, inhibits geranyltransferase, or farnesyl-diphosphate synthase. The main drugs currently used to treat diseases characterized by excessive bone resorption, nitrogen-containing bisphosphonates (N-BPs) The major molecular target of N-BPs inhibit farnesylpyrophosphate synthase, by a mechanism that involves time-dependent isomerization of the enzyme. 1. Dunford, Kwaasi, Rogers, *et al.* (2008) *J. Med. Chem.* 51, 2187.

**20-Piperidin-2-yl-pregnan-20(R),3 $\beta$ -diol, See 22,26- Azasterol**

### 3-[5-(2-(Piperidin-1-ylsulfonylamino)ethyl)-5-(pyrid-3-ylmethyl)-1-benzene-propionate

This sulfonamide (FW<sub>free-acid</sub> = 431.56 g/mol) inhibits human thromboxane-A synthase (IC<sub>50</sub> = 43 nM) and also is a thromboxane receptor antagonist. Introduction of a 5-(1*H*-imidazol-1-ylmethyl), a 5-(3-pyridinyl-methyl), or a 5-(3-pyridinyloxy) substituent leads to dual agents with thromboxane

synthase inhibitory activity comparable with that of dazmegrel (7). In addition, 3-pyridinylalkyl substituents also make a significant contribution to thromboxane receptor binding. 1. Dickinson, Dack, Long & Steele (1997) *J. Med. Chem.* **40**, 3442.

## 2-Piperidone, See $\delta$ -Valerolactam

### Piperine

This peppery-tasting alkaloid (FW = 285.34 g/mol; CAS 7780-20-3; 30511-76-3 for (*Z,E*)-isomer; 30511-77-4 for (*E,Z*)-isomer; 495-91-0 (*Z,Z*)-isomer; 94-62-2 (*E,E*)-isomer), also known as piperic acid piperidide and (*E,E*)-1-piperoylpiperidine, from black pepper (*Piper nigrum*) inhibits arylhydrocarbon hydroxylase (1), CYP1A1 (2), CYP3A4 (3), electron transport (4), malate dehydrogenase (5), P-glycoprotein (3), UDP-glucose dehydrogenase (6), and UDP-glucuronosyltransferase (6). 1. Reen & Singh (1991) *Indian J. Exp. Biol.* **29**, 568. 2. Reen, Roesch, Kiefer, Wiebel & Singh (1996) *Biochem. Biophys. Res. Commun.* **218**, 562. 3. ### Piperonyl Butoxide

This insecticide synergist (FW = 338.44 g/mol), which is frequently used in mixtures with rotenone or pyrethroids, is a substrate for cytochrome P450 systems and competes with other xenobiotics for available enzymes. In addition, an intermediate produced during its metabolism binds cytochrome P450, forming a catalytically inactive complex. **Target(s):** arylesterase (1); cytochrome P450 (2,3); and ecdysone 20-monooxygenase (4). 1. Young, Gunning & Moores (2005) *Pest Manag. Sci.* **61**, 397. 2. Friedman & Woods (1977) *Res. Commun. Chem. Pathol. Pharmacol.* **17**, 623. 3. Franklin (1976) *Environ. Health Perspect.* **14**, 29. 4. Feyereisen & Durst (1978) *Eur. J. Biochem.* **88**, 37.

## Pipsyl Fluoride, See *p*-Iodobenzenesulfonyl Fluoride

### Pirarubicin

This doxorubicin-derived antineoplastic agent (FW<sub>free-base</sub> = 627.65 g/mol; CAS 72496-41-4, 95343-20-7 (HCl); Solubility: 125 mg/mL DMSO; <1 mg/mL Water), also known as THP-adraimycin and systematically as (7*S*,9*S*)-7-((2*R*,4*S*,5*S*,6*S*)-4-amino-6-methyl-5-((*R*)-tetrahydro-2*H*-pyran-2-ylloxy)tetrahydro-2*H*-pyran-2-ylloxy)-6,9,11-trihydroxy-9-(2-hydroxyacetyl)-4-methoxy-7,8,9,10-tetrahydrotetracene-5,12-dione, inhibits DNA polymerases and DNA topoisomerase II. Pirarubicin intercalates into DNA, while also interacting with topoisomerase II, thereby inhibiting DNA replication repair, and transcription. This agent is less cardiotoxic than doxorubicin and exhibits activity against some doxorubicin-resistant cell lines. **Target(s):** cytochrome *c* oxidase (1); DNA-directed DNA

polymerase (2); DNA polymerase I, *Escherichia coli* (2); DNA polymerase  $\alpha$ , calf thymus (2); DNA polymerase  $\beta$ , calf thymus (2); DNA topoisomerase II (3); and oxidative phosphorylation (4). 1. Del Tacca, Danesi, Solaini, Bernardini & Bertelli (1987) *Anticancer Res.* **7**, 803. 2. Tanaka, Yoshida & Kimura (1983) *Gann* **74**, 829. 3. Insaif, Danks & Witiak (1996) *Curr. Med. Chem.* **3**, 437. 4. Solaini, Ronca & Bertelli (1985) *Drugs Exp. Clin. Res.* **11**, 115 and 533.

### Pirenperone

This agent (FW<sub>free-base</sub> = 393.46 g/mol; CAS 75444-65-4), also known as 3-[2-[4-(4-fluorobenzoyl)-1-piperidinyl]ethyl-2-methyl-4*H*-pyrido[1,2-*a*]pyrimidin-4-one, is a 5-HT<sub>2</sub> serotonin receptor antagonist (1-4) and an LSD (lysergic acid diethylamine) antagonist. 1. Walker, Poulos & Le (1994) *Psychopharmacology (Berlin)* **113**, 527. 2. Fiorella, Rabin & Winter (1995) *Psychopharmacology (Berlin)* **119**, 222. 3. ### Pirfenidone

This anti-fibrotic/anti-inflammatory drug (FW = 185.23 g/mol; CAS 53179-13-8), also known as 5-methyl-1-phenylpyridin-2-one, reduces fibroblast proliferation (1-4), inhibits TGF- $\beta$  stimulated collagen production (1,2,5-7), and reduces the production of fibrogenic mediators such as TGF- $\beta$ 1 (3,6). The latter is secreted by aberrantly activated alveolar epithelial cells (AEC), and, along with other pro-fibrotic factors, promotes fibroblast and AEC differentiation into myofibroblasts, resulting in overproduction of ECM within the lung. Pirfenidone also reduces the production of TNF- $\alpha$  and IL-1 $\beta$  in both cultured cells and isolated human peripheral mononuclear cells (7,8). Pirfenidone attenuates the IL-1 $\beta$ -induced hyaluronic acid production in orbital fibroblasts from patients with thyroid-associated ophthalmopathy (TAO), at least in part, through suppression of the MAPK-mediated hyaluronic acid synthase (HAS) expression (9). Pirfenidone is indicated for the treatment of idiopathic pulmonary fibrosis (IPF), the most common form of the interstitial lung diseases, marked by chronic, progressive

fibrosing interstitial pneumonia, primarily affecting older adults. is approved for use in Europe and U.S. (trade name: Esbriet®), Japan (trade name: Pirespa®), and India (trade name: Pirfenex®). With IPF remaining a ill-defined collection of disorders, it seems unlikely that any single drug will be an effective treatment for all forms of IPF. 1. ### Pirimicarb

This pyrimidine carbamate-based insecticide (FW = 238.29 g/mol; CAS 23103-98-2), systematically named 2-Dimethylamino-5,6-dimethylpyrimidin-4-yl dimethylcarbamate, is a frequently used miticide and aphicide, inhibits acetylcholinesterase (1-3). **Toxicity:** LD<sub>50</sub> (Dermal) > 500 mg/kg in rats; LD<sub>50</sub> (Oral) = 147 mg/kg in rats. 1. Li & Han (2002) *Arch. Insect Biochem. Physiol.* **51**, 37. 2. Belzunces & Colin (1991) *Neuroreport* **2**, 265. 3. Baranyovits & Ghosh (1969) *Chem Ind.* **30**, 1018.

### Piriprost

This lipoxygenase-inhibiting pyrrole analogue of prostacyclin (FW<sub>potassium salt</sub> = 463.66 g/mol; CAS 79672-88-1), also known as U60257B and 6,9-deepoxy-6,9-(phenylimino)-Δ<sup>6,8</sup>-prostaglandin II, [4*R*-[4α(1*E*,3*S*\*)],5β]-1,4,5,6-tetrahydro-5-hydroxy-4-(3-hydroxy-1-octenyl)-1-phenylcyclopenta[*b*]pyrrole-2-pentanoate, inhibits leukotriene C and D formation. 1-5 Piriprost also inhibits the release of histamine and leukotrienes from isolated porcine lung cells. 6 Note that both priprost and its methyl ester (U-56467) inhibit leukotriene biosynthesis: ID<sub>50</sub> = 4.6 and 0.31 μM, respectively. **Target(s):** glutathione *S*-transferase (4,5); and 5-lipoxygenase, or arachidonate 5-lipoxygenase (1-3). 1. Cejic & Kennedy (1991) *Prostaglandins* **42**, 179. 2. Lawson, Smith & Fitzpatrick (1986) *Wien Klin. Wochenschr.* **98**, 110. 3. Sun & McGuire (1983) *Prostaglandins* **26**, 211. 4. McCormack & Peterson (1989) *Amer. Rev. Respir. Dis.* **139**, 100.

### Piritrexim

This antifolate (FW = 325.37 g/mol; CAS 72732-56-0; 72676-60-9 for the mono-HCl), also known as 2,4-diamino-6-(2,5-dimethoxybenzyl)-5-methylpyrido[2,3-*d*]pyrimidine and BW301U, is an antineoplastic agent and potent inhibitor of dihydrofolate reductase. **Target(s):** amidophosphoribosyl-transferase (1,2); dihydrofolate reductase (3-6); and histamine *N*-methyltransferase (7). 1. Schoettle, Crisp, Szabados & Christopherson (1997) *Biochemistry* **36**, 6377. 2. Sant, Lyons, Phillips & Christopherson (1992) *J. Biol. Chem.* **267**, 11038. 3. ### Piroxicam

This long-lasting anti-inflammatory agent (FW = 331.35 g/mol; CAS 36322-90-4), also known as 4-hydroxy-2-methyl-*N*-(2-pyridyl)-2*H*-1,2-benzothiazine-3-carboxamide 1,1-dioxide, is a potent inhibitor of prostaglandin production (1). **Target(s):** chloride/ bicarbonate antiports (2); collagenase (3); cyclooxygenase, or prostaglandin-endoperoxide synthase, selective for COX-1 (4-7); dihydrofolate reductase (8); elastase, granulocyte (9); estrone sulfotransferase (10); leukocyte thioltransferase (11); myeloperoxidase (12); ornithine decarboxylase (13); oxidative phosphorylation, as an uncoupler (14); phenol sulfotransferase, or aryl sulfotransferase (10); phenylpyruvate tautomerase (15); phosphoribosylamino-imidazolecarboxamide formyltransferase, or AICAR transformylase (8); and thiopurine *S*-methyltransferase (16). 1. ### Pitavastatin

This HMG-CoA reductase inhibitor (FW = 421.46 g/mol; CAS 147511-69-1; IUPAC Name: (3*R*,5*S*,6*E*)-7-[2-cyclopropyl-4-(4-fluorophenyl)quinolin-3-yl]-3,5-dihydroxyhept-6-enoic acid), also known as itavastatin, itabavastin, nisvastatin, NK-104, NKS-104, and the trade name Livalo®, is indicated for ameliorating hypercholesterolemia and preventing cardiovascular disease (1,2). NK-104 potency is dose-dependent and is roughly equivalent to that of atorvastatin. It is well-tolerated in the treatment of patients with hypercholesterolemia. Pitavastatin uptake is carrier-mediated (3). **Target(s):** Reduces inflammatory cytokine production from human bronchial epithelial cells (4); Decreases microtubule tau protein levels via the inactivation of Rho/ROCK (5); Inhibits hepatic steatosis and fibrosis in non-alcoholic steatohepatitis model (6); Suppresses atherosclerosis induced by chronic inhibition of the synthesis

of nitric oxide in moderately hypercholesterolemic rabbits (7); Decreases the expression of endothelial lipase both *in vitro* and *in vivo* (8); Inhibits NF $\kappa$ B pathway in brain (9); Inactivates NF $\kappa$ B and decreases IL-6 production through Rho kinase pathway in MCF-7 human breast cancer cells (10); Reduces C-reactive-protein-induced interleukin-8 production in human aortic endothelial cells (11); Inhibits lysophosphatidic acid-induced proliferation and monocyte chemoattractant protein-1 expression in aortic smooth muscle cells by suppressing Rac-1-mediated reactive oxygen species generation (12); Inhibits upregulation of intermediate conductance calcium-activated potassium channels and coronary arteriolar remodeling induced by long-term blockade of nitric oxide synthesis (13); Inhibits migration and proliferation of rat vascular smooth muscle cells (14). 1. **Pixantrone**

This DNA-intercalator and mitoxantrone analogue (FW = 325.37 g/mol; CAS 144510-96-3), also known as Pixuvri<sup>®</sup> and 6,9-bis[(2-aminoethyl)amino]benzo[*g*]isoquinoline-5,10-dione, is a second-generation anthracenedione that selectively targets topoisomerase II and is an experimental anti-cancer agent (1). (Note: The code name BBR-2778 is assigned to pixantrone dimaleate, the salt most often used in clinical trials.) *In vitro* pixantrone showed a median relative IC<sub>50</sub> value of 54 nM (range <3 nM to 1.03 μM) against Wilms tumor and other cancers (2). 1. **2-Pivaloyl-1,3-indandione**, See *Pindone*

**PJ-34**

This PARP inhibitor (FW<sub>free-base</sub> = 295.34 g/mol; FW<sub>hydrochloride</sub> = 331.80 g/mol), systematically named *N*-(6-oxo-5,6-dihydro-phenanthridin-2-yl)-*N,N*-dimethylacetamide and known for its activity in neuroprotection under stress conditions, exclusively eradicates multi-centrosomal human mammary, colon, lung, pancreas, ovarian cancer cells, by acting as an extra-

centrosome(s) de-clustering agent in mitosis (1). When applied at 20-30 μM, PJ-34 caused G<sub>2</sub>/M-arrest and a massive cell death. Normal human proliferating endothelial, epithelial and mesenchymal cells were unaffected. PJ-34's cytotoxicity on cancer cells is not attributable to PARP inhibition alone. PJ-34 was originally designed to protect neuronal cells in the central nervous system from cell death evoked by high activity of PARP-1 in response to DNA damage caused by brain injury, stroke or inflammation (2,3). **Targets:** extra-centrosome de-clustering (1); polyADP-ribose polymerase-1, EC<sub>50</sub> = 20 nM (2-6). 1. **PKI-587**

This dual PI3K/mTOR (phosphoinositide-3-kinase and mammalian target of rapamycin) signal-transduction pathway inhibitor and antineoplastic agent (F.Wt. = 615.73; CAS 1197160-78-3; Solubility (25°C): 2 mg/mL DMSO, <1 mg/mL Water), also known as PF-05212384 and systematically as 1-(4-(4-(dimethylamino)piperidine-1-carbonyl)phenyl)-3-(4-(4,6-dimorpholino-1,3,5-triazin-2-yl)phenyl)urea, inhibits PI3K-α, PI3K-γ and mTOR with IC<sub>50</sub> of 0.4 nM, 5.4 nM and 1.6 nM, respectively. PKI-587 also inhibits mutant forms of PI3Kα, including the PI3Kα-H1047R and PI3Kα-E545K with IC<sub>50</sub> of 0.6 nM and 0.6 nM, respectively. 1. Venkatesan, Dehnhardt, Delos Santos (2010) *J. Med. Chem.* **53**, 2636.

### Plasminogen Activator Inhibitor Type 1

This single-chain glycoprotein (MW = 42.5 kDa), often abbreviated PAI-1, consisting of 379 residues and produced by the vascular endothelium and various other cells, is a serpin family member that controls fibrinolysis. PAI-1 also interacts with vitronectin and with the urokinase receptor and its co-receptors. Defects in the PAI-1 gene are the cause of plasminogen activator inhibitor-1 deficiency, whereas high concentrations of the gene product are associated with thrombophilia. Alternatively spliced transcript variants encoding different isoforms have been found for this gene. Plasma levels of PAI-1 also increase in several chronic inflammatory states that are associated with chronic kidney disease. (For a discussion of the likely mechanism of inhibitory action, See *Serpins*; also  $\alpha_1$ -Antichymotrypsin) PAI-1 has many targets (1-24). The novel and specific small-molecule PAI-1 inhibitor IMD-4690 reduces allergic airway remodeling in a mouse model of chronic asthma via regulating angiogenesis and remodeling-related mediators (25).

**Target(s):** acrosin (1); bat salivary plasminogen activator (2); matriptase (3); pancreatic elastase (24); plasminogen activator Pl4, protein C activated (5); t-plasminogen activator (2,4-15,24); u-plasminogen activator, or urokinase (2,4,5,7,16-24). 1. ### Plasminogen Activator Inhibitor Type 2

This protein inhibitor (MW = 44.5 kDa), often abbreviated PAI-2, inhibits plasminogen activators and is a member of the serpin family. It has been isolated from placental extracts and it controls fibrinolysis. **Target(s):** acrosin (1); t-plasminogen activator (2-5); u-plasminogen activator, or urokinase (4-8). (For a discussion of the likely mechanism of inhibitory action, See *Serpins*; also  $\alpha_1$ -Antichymotrypsin) 1. Zheng, Geiger, Ecke, *et al.* (1994) *Fibrinolysis* **8**, 364. 2. Schmitt, Jänicke, Moniwa, *et al.* (1992) *Biol. Chem. Hoppe-Seyler* **373**, 611.

### Plasminogen Activator Inhibitor Type 3, See Protein C Inhibitor

#### Plasminostreptin

This 109-residue protease inhibitor (MW = 11402 g/mol; CAS 50864-63-6) from *Streptomyces antifibrinolyticus*, inhibits selected serine proteases, but not chymotrypsin, thrombin, kallikrein, or elastase (1). Plasminostreptin reportedly also inhibits certain metalloendopeptinases, such as mycolysin.

**Target(s):** mycolysin (1,2); plasmin (3,4); *Streptomyces griseus* metalloendopeptidases (12); *Streptomyces griseus* metalloendopeptidases II (2,5); subtilisin (3,4); and trypsin (3,4,6). 1. ### Plasmochin, See Pamaquine Pamoate

#### Plastoquinones

Plastoquinone 9

This family of polyisoprenoid quinones participates in photosynthetic electron transport and vary only in the length of the isoprenoid side chain. The most common member is plastoquinone 9 (FW = 749.22 g/mol, M.P. = 48-49°C; PQ-10 at 50-51°C) consisting of nine isoprene units. PQ-9 is a yellow solid with  $\lambda_{max}$  values (in isoctane) of 254 and 262 nm. Plastoquinones are unstable in oxygen and light, dictating storage in a well-sealed and light-tight container. **Target(s):** 5-lipoxygenase, or arachidomate 5-lipoxygenase, inhibited by PQ-7 (1); vitamin K-dependent carboxylase, inhibited by PQ-9 (2); and vitamin K-epoxide reductase, inhibited by PQ-9 (2). 1. Odukoya, Houghton & Raman (1999) *Phytomedicine* **6**, 251. 2. Ronden, Soute, Thijssen, Saupé & Vermeer (1996) *Biochim. Biophys. Acta* **1298**, 87.

#### Platelet Activating Factor

1-O-hexadecyl-2-acetyl-sn-glycerol-3-phosphocholine

This phospholipid (abbreviated PAF), typically consisting of either 1-O-hexadecyl-2-acetyl-sn-glycerol 3-phosphocholine or 1-O-octadecyl-2-acetyl-sn-glycerol 3-phosphocholine, is a key mediator of platelet aggregation, inflammation, and anaphylaxis. PAF also stimulates uterine contractions, decrease cardiac output, and mediate hypertension. **Target(s):** 1,3- $\beta$ -glucan synthase (1,2); sphingomyelin phosphodiesterase, or sphingomyelinase, also an alternative substrate for the rat alkaline enzyme (3). 1. Kauss & Jeblick (1986) *Plant Physiol.* **80**, 7. 2. Ko, Frost, Ho, Ludescher & Wasserman (1994) *Biochim. Biophys. Acta* **1193**, 31. 3. Wu, Nilsson, Jönsson, *et al.* (2006) *Biochem. J.* **394**, 299.

#### Platelet Aggregation Inhibitors

These agents antagonize or impair mechanisms leading to blood platelet aggregation during the phases of platelet activation and shape change, or after the dense-granule release reaction and stimulation of the prostaglandin-thromboxane system. Platelet aggregation inhibitor types include: *cyclooxygenase inhibitors*, such as acetylsalicylic acid (aspirin); *adenosine 5'-diphosphate receptor inhibitors*, such as clopidogrel (Plavix<sup>TM</sup>), prasugrel (Effient<sup>TM</sup>), ticlopidine (Ticlid<sup>TM</sup>); *phosphodiesterase inhibitors*, such as cilostazol (Pletal<sup>TM</sup>); *glycoprotein IIb/IIIa inhibitors*, including abciximab (ReoPro<sup>TM</sup>), eptifibatid (Integrilin<sup>TM</sup>), tirofiban (Aggrastat<sup>TM</sup>); and *adenosine reuptake inhibitors*, such as dipyridamole (Persantine<sup>TM</sup>) and picotamide. See also *Abciximab*; *Acetylsalicylic Acid*; *Cilostazol*; *Clopidogrel*; *Dipyridamole*; *Eptifibatid*; *Picotamide*; *Prasugrel*; *Ticlopidine*; *Tirofiban*; *Vorapaxar*

#### Platelet-Derived Growth Factor Receptor $\beta$ Fragment 751-755, Phosphorylated

This phosphorylated pentapeptide (MW = 700.76 g/mol; Sequence: Y(PO<sub>3</sub><sup>2-</sup>)VPML), which contains a phosphorylated tyrosyl residue, inhibits binding of the 85-kDa subunit of phosphatidylinositol 3-kinase to the PDGF  $\beta$ -receptor. It was observed (a) that neutralization of the amine and carboxy terminus led to analogues with enhanced activity and (b) that only minimal modifications were allowed for pTyr and Met, while the other positions were quite tolerant of modification. 1. Ramalingam, Eaton, Cody, *et al.* (1995) *Bioorg. Med. Chem.* **3**, 126.

**Placotylene A**

This novel bone resorption inhibitor (FW = 328.24 g/mol), an iodinated polyacetylene class of natural products from a Korean marine sponge (*Placospongia* sp.), targets the Receptor Activator of NF- $\kappa$ B Ligand (RANKL)-induced osteoclast differentiation. The chemical structure was elucidated on the basis of 1D and 2D NMR, supplemented by MS data. Placotylene A (10  $\mu$ M) effectively inhibits RANKL-induced osteoclast differentiation, but the structurally placotylene B does not show significant activity up to 100  $\mu$ M. 1. Kim, Kim, Yeon, *et al.* (2014) *Marine Drugs* **12**, 2054.

**Pladienolide B**

This *Streptomyces platensis* macrocyclic lactone (FW = 636.71 g/mol; CAS 445493-23-2; Soluble in DMSO) exhibits strong antitumor activities, both *in vitro* and in xenograft models (1,2). Pladienolide binds to the SF3b complex and inhibits mRNA splicing and changes splicing patterns (1). Pladienolide-resistant clones from several colorectal cancer cells are insensitive to pladienolide's inhibitory action on cell proliferation and splicing (3). Moreover, an mRNA-Seq differential analysis revealed that these cell lines have an identical mutation at Arg1074 in the gene for SF3B1, which encodes a subunit of the SF3b complex. Reverse expression of the mutant protein transferred pladienolide resistance to WiDr cells. Furthermore, immunoprecipitation analysis using a radiolabeled probe showed that the mutation impaired the binding affinity of pladienolide to its target (3). Significantly, pladienolide-B induce an early pattern of mRNA intron retention, or spliceosome modulation. This process was associated with apoptosis preferentially in cancer cells as compared to normal lymphocytes. Its pro-apoptotic activity is observed regardless of poor prognostic factors such as  $\Delta^{17p}$ , TP53 or SF3B1 mutations and can overcome the protective effect of culture conditions that resemble the tumor microenvironment (4). 1. **Plasminogen Activator Inhibitor-1**

This 402-residue serine protease inhibitor, or serpin (MW = 45074 g/mol; Abbreviation: PAI-1) binds to and inhibits plasminogen activators-tissue-type plasminogen activator (tPA) and urokinase-type plasminogen activator (uPA). This inhibition reduces plasmin production and suppresses dissolution of fibrin clots. Elevated PAI-1 levels correlate with an increased cardiovascular disease risk, a behavior that has also been linked to obesity and metabolic syndrome. Pharmacological suppression of PAI-1 is a likely way to prevent or treat vascular disease. Reduced PAI-1 levels may result in increased fibrinolysis and an associated bleeding diathesis. PAI-1 was initially identified in the 1980s, and the first reported case of PAI-1 deficiency appeared in 1989. Unambiguous proof that PAI-1 deficiency as a cause of a bleeding disorder has been rare, but use of selective PAI inhibitors (See PAI-749) may clarify this point. Because of lack of standardized commercially available PAI-1 activity assay sensitive in the lowest range, the true prevalence of this rare condition has yet to be established. 1. Vaughan (2005) *J. Thromb. Haemost.* **3**, 1879. 2. Fortenberry (2013) *Expert Opin. Ther. Pat.* **23**, 801.

**Platencin**

This antibiotic (FW = 425.2 g/mol; CAS 869898-86-2; Soluble in ethanol, methanol, DMF or DMSO) inhibits both *Staphylococcus aureus*  $\beta$ -ketoacyl-[acyl-carrier-protein] synthases II and III, with IC<sub>50</sub> values of 1.95 and 3.91  $\mu$ g/mL, respectively (1). Platencin exhibits strong, broad-spectrum, Gram-positive antibacterial activity to key antibiotic resistant strains, including methicillin-resistant *Staphylococcus aureus*, vancomycin-intermediate *S. aureus*, and vancomycin-resistant *Enterococcus faecium*, without evidence of toxicity in humans. 1. Wang, Kodali, Lee, *et al.* (2007) *Proc. Natl. Acad. Sci. U.S.A.* **104**, 7612.

**Platensimycin**

This thiol-reactive *Streptomyces platensis*-derived antibiotic (FW = 438.50 g/mol; CAS 835876-32-9), also named 3-[[3-[(1R,3R,4R,5aR,9R,9aS)-1,4,5,8,9,9a-hexahydro-3,9-dimethyl-8-oxo-3H-1,4:3,5a-dimethano-2-benzoxepin-9-yl]-1-oxopropyl]amino]-2,4-dihydroxybenzoic acid, inhibits *Staphylococcus aureus*  $\beta$ -ketoacyl-[acyl-carrier-protein] synthase II, or FabF (IC<sub>50</sub> = 290 nM) (1-3). This enzyme, which allows bacteria to produce the fatty acids needed for making cell membranes, is thus a uniquely druggable prokaryotic target. Platensimycin has potent, broad-spectrum Gram-positive activity *in vitro* and exhibits no cross-resistance to other key antibiotic-resistant bacteria including Methicillin-resistant *Staphylococcus aureus* (MRSA), vancomycin-intermediate *S. aureus*, vancomycin-resistant *Enterococci*, as well as linezolid-resistant and macrolide-resistant pathogens. Platencin is a more potent analogue of Platensimycin. While effective *in vivo* when continuously administered, its efficacy is reduced when administered by more conventional means. **Mechanism of Action:** The Cys163 within the FabF active site is activated through the dipole moment of helix N- $\alpha$ -3, lowering its pK<sub>a</sub>, also increasing its nucleophilicity by the stabilizing effects of FabF's catalytically required oxyanion hole. Interestingly, the crystal structure complex with platensimycin employed a C163Q mutant which gave a 50-fold increase in apparent binding. **See Platencin** 1. Wang, Kodali, Lee, *et al.* (2007) *Proc. Natl. Acad. Sci. U.S.A.* **104**, 7612. 2. Wang, Soisson, Young, *et al.* (2006) *Nature* **441**, 358. 3. Häbich, F. Von Nussbaum (2006) *ChemMedChem* **1**, 951.

**Platinic Chloride, See Chloroplatinic Acid****Platinum**

Platinum (Pt; atomic number 78; atomic weight 195.084) is a group 10 (or group VIIIa) element, located directly beneath palladium in the Periodic Table. The ground state electronic configuration of the neutral atom is  $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^{10} 5p^6 6s^1 4f^{14} 5d^9$ . The principal oxidation states are II and IV, with respective ionic radii of 0.80 and 0.65 Å, respectively; however, compounds of oxidation states III, IV, V, and VI have also been identified. In addition to its numerous uses in laboratory equipment and instruments, platinum derivatives have been found to have important pharmacological properties. Perhaps the best known is cisplatin (or, *cis*-diamminedichloroplatinum), noted for its antitumor properties. Glutathione reportedly contributes to tumor cell resistance toward cisplatin. There are also numerous reports on the interaction of platinum derivatives with DNA to form platinum-adducts. When the chlorides of these complexes are replaced with adenine, cytosine, or other purine/pyrimidine, the resulting complexes have been used as models in the investigation of DNA interactions. **See specific platinum complex**

***cis*-Platinum(II) Diammine Dichloride, See Cisplatin*****trans*-Platinum(II) Diammine Dichloride, See Transplatin****Plecanatide**

This uroguanylin analogue (FW = 1681.90 g/mol; CAS 467426-54-6), also known by the codename SP-304, binds to and activates guanylate cyclase-C (GC-C) receptors (EC<sub>50</sub>  $\approx$  0.3  $\mu$ M) expressed on the epithelial cells lining

the gastrointestinal mucosa, stimulating cyclic GMP production, which in turn sequentially activates protein kinase G-II and the chloride channel known as the Cystic Fibrosis Transmembrane-conductance Regulator (CFTR) to regulate ion and fluid transport, to promote epithelial cell homeostasis, and to maintain barrier function in the GI mucosa. Plecanatide is a hexadecapeptide that is structurally identical to uroguanylin, except for an glutamate substitution at position-3. Oral treatment with plecanatide at a dose range between 0.05-2.5 mg/kg per day is as effective as once-daily treatment with 5-amino salicylic acid (100 mg/kg) or sulfasalazine (80 mg/kg). Amelioration of colitis by the treatment with plecanatide or dolcanatide was not dose-dependent, most likely due to saturation of available GC-C receptors. **1.** Shailubhai, Palejwala, Arjunan, *et al.* (2015) *World J. Gastrointest. Pharmacol. Therapeut.* **6**, 213

#### Plerixafor

This metal ion-chelating immunostimulant (FW = 502.80 g/mol; CAS 155148-31-5), also known by its code names AMD3100 and JM3100, its trade name Mozobil™ as well as its systematic name 1,1'-[1,4-phenylenebis(methylene)]bis-[1,4,8,11-tetraazacyclotetradecane], is an  $\alpha$ -C-X-C chemokine receptor CXCR<sub>4</sub> antagonist (or partial agonist) and an allosteric CXCR7 agonist (1-4). The active chemical form is likely to contain divalent zinc ion. (See also TC 14012) **Likely Mode of Action:** The CXCR4  $\alpha$ -chemokine is stimulated by Stromal cell-Derived Factor-1 (or SDF-1) that plays roles in hematopoietic stem cell homing to the bone marrow and in hematopoietic stem cell (HSC) quiescence. CXCR7 is a G-protein-coupled receptor (GPCR) that binds the chemokines CXCL12/SDF-1 and CXCL11 and serves as a coreceptor for human immunodeficiency viruses. Plerixafor inhibits the replication of various HIV-1 and HIV-2 strains in various cell lines ( $EC_{50}$  = 1-10 ng/mL, or >100,000x lower than its cytotoxic concentration of 500  $\mu$ g/mL) (1). When combined with either 3'-azido-2',3'-dideoxythymidine or 2',3'-dideoxyinosine, JM3100 achieved an additive inhibition of HIV replication, and when repeatedly subcultured in the presence of JM3100, with the virus remaining sensitive to the compound for at least 30 passages in culture (1). AMD3100 blocks HIV-1 entry and membrane fusion via the CXCR4 co-receptor, blocking the latter's role as both a HIV-1 co-receptor and a CXCR4-chemokine receptor (2). **Use as an Investigational Drug:** Plerixafor's discovery provided a new way to mobilize HSC for autologous transplantation (4). In 2008, plerixafor was approved by the FDA for the mobilization of hematopoietic stem cells. Plerixafor is also an investigational drug for the treatment of WHIM Syndrome (standing for Warts, Hypogammaglobulinemia, Infection & Myelokathexis Syndrome), a rare congenital immunodeficiency disorder characterized by chronic noncyclic neutropenia and arising from gain-of-function deletion mutations in CXCR4. In a Phase-I study, circulating leukocytes were durably increased throughout the trial in all patients, and this was associated with fewer infections and improvement in warts in combination with imiquimod; however immunoglobulin levels and specific vaccine responses were not fully restored (5). **Metal Ion Binding:** Plerixafor binds zinc, copper nickel, cobalt and rhodium ions, and the biologically active form is the 1:2 Plerixafor-Zn<sup>2+</sup> ternary complex (FW = 627.53 g/mol). Other CXCR4 antagonists include: AMD070, T140, FC131, FC122, with several being evident metal ion-binding chelators. The diversity of their structures suggests the possibility that they may act as divalent metallophores, a unique class of organic molecules that facilitate metal ion transfer across membrane bilayers in a manner akin to the valinomycin-facilitated transport of potassium ion or by means of a vesicle pathway, such as receptor-mediated endocytosis. **1.** De Clercq, Yamamoto, Pauwels, *et al.* (1994) *Antimicrob. #### Plinabulin

This vascular disrupting agent and antineoplastic drug (FW = 336.39 g/mol; CAS 714272-27-2 and 1367709-16-7 (TFA); Solubility = 67 g/mol DMSO; <1 g/mol Water; <1 g/mol Ethanol), also known as NPI-2358 and systematically as (3Z,6Z)-3-benzylidene-6-((5-tert-butyl-1H-imidazol-4-yl)methylene)piperazine-2,5-dione, binds reversibly with tubulin ( $IC_{50}$  = 9-18 nM) to prevent microtubule assembly (1-3), selectively disrupting the abnormal vasculature associated with disease processes such as cancer and macular degeneration. Such action has been attributed to the ability of these agents to selectively destroy the central regions of tumors, areas widely believed to contain cell populations resistant to cytotoxic therapies (4). **1.** Nicholson, *et al.* (2006) *Anticancer Drugs* **17**, 25. **2.** Singh, *et al.* (2011) *Blood* **117**, 5692. **3.** Bertelsen, *et al.* (2011) *Int. #### Plumbagin

This yellow-colored naphthoquinone (FW = 188.18 g/mol; CAS 481-42-5; M.P. = 78-79°C; Soluble to 100 mM in DMSO and to 50 mM in Ethanol), also known as 5-hydroxymenadione and 5-hydroxy-2-methyl-1,4-naphthoquinone, from the roots of *Plumbago* species is a membrane-permeant, sulfhydryl-modifying reagent. At 50  $\mu$ M, plumbagin induces oxidative stress in treated cells by depleting intracellular stores of reduced glutathione and inducing reactive oxygen species (ROS). It is also an anticancer agent that induces cell-cycle arrest at G<sub>2</sub>/M and apoptosis in A549 cells via JNK-dependent p53 Ser-15 phosphorylation. Inhibits A549 and MDA-MD-231 tumour xenograft growth in nude mice (1). Plumbagin promotes autophagic cell death in MDA-MB-231 and MCF-7 cells and inhibits Akt/mTOR signaling (2). Plumbagin inhibits bacterial proliferation by inhibiting FtsZ assembly (3). **Target(s):** (S)-canadine synthase (4); chitin synthase (5); cytochrome P450-linked monooxygenase (6); dihydroxy-acid dehydratase, or  $\alpha,\beta$ -dihydroxyisovalerate dehydratase (7,8); ecdysone 20-monooxygenase (2); lactose transporter (9); NAD<sup>+</sup> ADP-ribosyltransferase, or poly(ADP-ribose) polymerase (10); NADH dehydrogenase (11); prostaglandin-endoperoxide synthase (12); protein-N<sup>F</sup>-phosphohistidine:sugar phosphotransferase, or glucose enzyme II and mannose enzyme II of bacterial phosphotransferase system (13); ribonuclease H (14); succinate dehydrogenase (15); vitamin K-dependent

carboxylase, or protein-glutamate carboxylase (16). 1. Hsu, *et al.* (2006) *J. Pharmacol. Exp. Ther.* **318**, 484. 2. Kuo, *et al.* (2006) *Mol. Cancer Ther.* **5**, 3209. 3. #### PluriSIn #1

This stearoyl-CoA desaturase 1 inhibitor, or SCD1 (FW = 213.24 g/mol; CAS 91396-88-2; Solubility: 43 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as NSC 14613 an 4-pyridinecarboxylic acid, 2-phenylhydrazide, selectively eliminates human Pluripotent Stem Cells (hPSCs), while sparing a large array of progenitor and differentiated cells, thus providing a promising approach for minimizing the tumorigenic risk from residual undifferentiated cells. Closer examination identified PluriSIn #1 as an SCD1, thereby indicating a role for lipid metabolism in hPSC survival. PluriSIn #1 is likewise cytotoxic to mouse blastocysts, again suggesting a dependence on oleate in cells in a pluripotent state. SCD is key and highly regulated enzyme which catalyzes the  $\Delta^9$ -*cis* desaturation of a range of palmitoyl- and stearoyl-CoA to palmitoleoyl- and oleoyl-CoA respectively. 1. #### PMP-C

This insect peptide (*Sequence*: EISCEPGKTFKDKCNTCRGADGKSA ACTLKACPNO; FW = 3779.32 g/mol), also known as *pars intercerebralis* major peptide C, from *Locusta migratoria* is a potent inhibitor of chymotrypsin ( $K_i$  = 0.13 nM) and a weaker inhibitor of leukocyte elastase ( $K_i$  = 180 nM). PMP-C contains three intrachain disulfide bonds: Cys4-Cys19, Cys17-Cys28, and Cys14-Cys33 (1). 1. Roussel, Mathieu, Dobbs, *et al.* (2001) *J. Biol. Chem.* **276**, 38893.

#### PMP-D2

This insect peptide (*Sequence*: EEKCTPGQVKQQDCNTCTCTPYGVW GCTRKGCQPA; MW = 3821.32 g/mol), also known as *pars intercerebralis* major peptide D2, is isolated from *Locusta migratoria* and inhibits trypsin and chymotrypsin ( $K_i$  = 100 and 1500 nM for the bovine enzymes, and is a much stronger inhibitor of *Locusta* trypsin. PMP-D2 consists of thirty-five aminoacyl residues with three disulfide bonds: Cys4-Cys19, Cys17-Cys27, and Cys14-Cys32 (1). 1. Roussel, Mathieu, Dobbs, *et al.* (2001) *J. Biol. Chem.* **276**, 38893.

#### PMX 205

This potent C5aR antagonist (FW = 839.05 g/mol; CAS 514814-49-4; Soluble to 1 mg/mL in 20% Ethanol/H<sub>2</sub>O) is a cyclic peptide analogue (*Sequence*: X<sub>1</sub>PX<sub>3</sub>WR, where X<sub>1</sub> = N<sup>2</sup>-(1-*exo*-3-phenylpropyl)-ornithine, X<sub>3</sub>

= D-Cha (or  $\beta$ -cyclohexylalanine), with a lactam bridge between Orn-1 and Arg-5) that targets human Complement 5a (IC<sub>50</sub> = 31 nM), a plasma protein with both potent chemoattractant and pro-inflammatory properties (1). C5a binds to its G protein-coupled receptor (C5aR) on polymorphonuclear leukocytes (PMNLs) through a high-affinity helical bundle and a low-affinity C-terminus, the latter solely responsible for receptor activation (1). C5aR overexpression correlates with severity of inflammatory diseases, suggesting a rationale for it serving as a druggable target. Computer modeling suggests that potent antagonists have a cyclic backbone shape, with affinity-determining side-chains of defined volume projecting from the cyclic scaffold (1). PMX-205 was helpful in adducing first evidence that C5aR inhibition can interfere with neuroinflammation and neurodegeneration in AD rodent models, making C5aR a novel therapeutic target for reducing pathology and improving cognitive function in human AD patients (2). 1. ### Poly(L-glutamate)

This L-glutamate homopolymer (MW = indefinite, depending on the degree of polymerization; CAS 25513-46-6 (free acid) and 26247-79-0 (sodium salt)) possesses little  $\alpha$ -helical content at neutral pH, but its helicity increases dramatically with decreasing pH. Titration of the  $\gamma$ -carboxyl group yields a  $pK_a$  value of 4.94 (1). **Target(s):**  $\beta$ -*N*-acetylglucosaminylglycopeptide  $\beta$ -1,4-galactosyltransferase (2); *N*-acetylglucosamine synthase (2); [ $\beta$ -adrenergic-receptor] kinase (3,4); cartilage metalloproteinases (5); casein kinase type 2 (6,7); DNA polymerase- $\alpha$ -primase (8); elongation factor-3 ATPase (9); histone acetyltransferase (10); lysozyme, weakly inhibited (11-13); microtubule assembly, or MAP-stimulated tubulin polymerization (14); polygalacturonidase (15); procollagen N-endopeptidase (16,17); rhodopsin kinase (18,19); stromelysin (5); trypsin (12); tubulin-tyrosine carboxypeptidase (20); UDPgalactose:glycoprotein galactosyltransferase (2); vaccinia RNA polymerase (21); vesicular stomatitis virus-associated RNA-directed RNA polymerase (22). 1. ### Poly(L-lysine)

This water-soluble L-lysine homopolymer (MW = 30–50 kDa; indefinite polymer, depending on the degree of polymerization) is an inhibitor of several enzymes as well as a stabilizer/activator of other proteins. High-molecular-weight poly(L-lysine) (MW = 100–300 kDa) promotes the adhesion of cell to solid substrates, most often without blocking their proliferation. This property commending its use as a coating on plastic cell culture dishes, serving in place of more costly collagen and fibronectin. **Target(s):** adenylate cyclase (1); [ $\beta$ -adrenergic-receptor] kinase (2,3); alkaline phosphatase (47); Ca<sup>2+</sup>-dependent calmodulin-like domain protein kinase, *Arabidopsis* (4); carboxylester lipase (5); carboxypeptidase C, or carboxypeptidase Y (6); casein kinase I, *Trypanosoma cruzi* (7); chloroplast electron transport, as an uncoupler (8); cholinesterase (9); cytochrome *c* oxidase, complex IV (10-12); cytochrome *c* peroxidase (13); elongation factor-3 ATPase (14); [glycogen-synthase] kinase 3, or [tau protein] kinase (15); GroEL16; guanylate cyclase (17); histone acetyltransferase (18); inositol-1,3,4-trisphosphate 5/6-kinase (19); iodide uptake (20); lipase, or pancreatic lipase, or triacylglycerol lipase (5); lipoprotein lipase (21); lipoxigenase, soybean, inhibited by the octamer (53); [low-density-lipoprotein receptor] kinase (48); lysozyme (22); [myosin heavy-chain] kinase (51); ornithine decarboxylase (23); papain (24); pepsin A (21,25-30); peroxidase (31); phospholipase A<sub>2</sub> (32); phosphoprotein phosphatase (33-35); phosphorylase kinase (49); [phosphorylase] phosphatase (33,36); photosystem I (37-39); poly(ADP-ribose) glycohydrolase (40-42); protein kinase C (43); protein phosphatase 1 (33); protein phosphatase 7 (35); rhodopsin kinase (50); ribonuclease U2, or *Ustilago sphaerogena* ribonuclease (44); RNA-directed RNA polymerase (45,52); trypsin, immobilized trypsin inhibited by polylysine of MW < 13000 (46). 1. ### Polymethacrylate (Poly(methacrylic acid))

This homopolymeric polyelectrolyte (MW = Indefinite Polymer) inhibits and/or inactivates many enzymes. Polymethacrylate should not be confused with the following polyesters: poly(methyl methacrylate) (i.e.,  $\cdots\text{CH}_2\text{C}(\text{CH}_3)(\text{CO}_2\text{CH}_3)\cdots$ ) or poly(methyl acrylate) (i.e.,  $\cdots\text{CH}_2\text{CH}(\text{CO}_2\text{CH}_3)\cdots$ ). **Target(s):** complement component C1q (1); hyaluronidase (2); glutamate dehydrogenase (3); and lactate dehydrogenase (3). **1.** Burdelev, Kaplun, Kozlov, et al. (2003) *Bioorg. Khim.* **29**, 159. **2.** Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. **2**, p. 459, Academic Press, New York. **3.** Saburova, Bobreshova, Elphimova & Sukhorukov (2000) *Biochemistry (Moscow)* **65**, 976.

### Polymin P, See Poly(ethyleneimine)

### Polymyxins

These decapeptide antibiotics (MW  $\approx$  1300 g/mol; NLM Unique Identifier D011113), containing a heterodetic ring, are produced by *Bacillus polymyxa*, and contain five or six residues of L-2,4-diaminobutyrate (L-DAB). The N-terminal residue is typically acylated with a 6-methyloctanoyl or 6-methylheptanoyl group (e.g., polymyxin B<sub>1</sub> and B<sub>2</sub>, respectively; note that the term polymyxin B refers to a mixture of both B<sub>1</sub> and B<sub>2</sub>). Polymyxins are effective against Gram-negative bacteria and typically bind to and interfere with the permeability of the cytoplasmic membrane, resulting in loss of cytosolic components. The membranes of eukaryotic cells can also undergo attack. Circulins are structurally related polypeptide antibiotics isolated from *Bacillus circulans*. Circulin A is identical to polymyxin B<sub>1</sub>, albeit with a D-leucyl residue instead of D-phenylalanine and an L-isoleucyl residue instead of L-leucine in the cycloheptapeptide component of the antibiotic. (See also *Colistins*) **Target(s):** Ca<sup>2+</sup>/calmodulin-dependent protein kinase II, weakly inhibited (1); calmodulin (2); glucose transporter, insulin-induced, inhibited by polymyxin B (3,4); glycerol-3-phosphate O-acyltransferase, microsomal, inhibited by polymyxin B; however, the mitochondrial enzyme is stimulated (5-8); IGF II receptor translocation, inhibited by polymyxin B (3); K<sup>+</sup> channel, ATP-sensitive, inhibited by polymyxin B (9); K<sup>+</sup> channel, Ca<sup>2+</sup>-activated (10); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase, weakly inhibited (1); protein kinase C, inhibited by polymyxin B (1,11); ribonuclease I (12); and  $\alpha,\alpha$ -trehalose-phosphate synthase (UDP-forming), inhibited by circulins (13). **1.** Raynor, Zheng & Kuo (1991) *J. ### Poly(L-ornithine)

This positively charged homopolymer (MW = Indefinite Polymer; CAS 25104-12-5) of indefinite length is commercially available in many molecular weight ranges. Large polymers have been used to transfect DNA into mammalian cells. **Target(s):** angiogenin binding to ribonuclease inhibitor (1); foot-and-mouth disease virus RNA-directed RNA polymerase (2); iodide uptake (3); pepsin (4); poly(ADP-ribose) glycohydrolase (5); protein biosynthesis (6);  $\alpha,\alpha$ -trehalose-phosphate synthase, UDP-forming (7). **1.** Moenner, Chauviere, Chevaillier & Badet (1999) *FEBS Lett.* **443**, 303. **2.** Lazarus & Itin (1973) *Arch. ### Polyoxin A

This antifungal agent (FW<sub>free-acid</sub> = 616.54 g/mol; CAS 19396-03-3; IUPAC: (S-(E))-1-(5-(2-amino-5-O-(aminocarbonyl)-2-deoxy-L-xyloonyl)amino)-1,5-dideoxy-1-(3,4-dihydro-5-(hydroxymethyl)-2,4-dioxo-1(2H)-pyrimidinyl)- $\beta$ -D-allofuranuronoyl)-3-ethylidene-2-azetidinecarboxylic acid and produced by *Streptomyces cacaoi* and *S. piomogenus*, inhibits chitin biosynthesis (1-4). **1.** Cabib (1972) *Meth. Enzymol.* **28**, 572. **2.** Cabib, Kang & Au-Young (1987) *Meth. Enzymol.* **138**, 643. **3.** Elbein (1987) *Meth. Enzymol.* **138**, 661. **4.** Ruiz-Herrera & San-Blas (2003) *Curr. Drug Targets Infect. Disord.* **3**, 77.

### Polyoxin B

This antifungal antibiotic (FW<sub>free-acid</sub> = 507.14 g/mol), produced by *Streptomyces cacaoi* and *S. piomogenus*, inhibits chitin synthase (1-3) and is frequently used to control many plant fungal pathogens. **1.** Cann, Kobayashi, Onoda, Wakita & Hoshino (1993) *J. Appl. Bacteriol.* **74**, 127. **2.** Cohen & Casida (1982) *Pestic. Biochem. Physiol.* **17**, 301. **3.** Gow & Selitrennikoff (1984) *Curr. Microbiol.* **11**, 211.

### Polyoxin D

This pyrimidin nucleoside analogue and antifungal antibiotic (FW<sub>free-acid</sub> = 521.39 g/mol; CAS 22976-86-9; 33401-46-6 for the zinc salt), produced by soil organisms *Streptomyces cacaoi* and *S. piomogenus*, inhibits chitin biosynthesis,  $K_i = 6 \mu\text{M}$ , thereby blocking septum formation. The zinc salt of polyoxin is used to control Rice Sheath Blight, caused by the fungus *Rhizoctonia solani*, as well as the turfgrass disease Brown Patch, caused by other *Rhizoctonia* species. Polyoxin D also inhibits *Neurospora crassa*, but is nontoxic to land mammals, insects, or birds, when applied to plants as the wettable powder form known as Endorse™. **Target(s):** chitin synthase (1-24); chitin synthase B (5); chitin synthase, canChs1A (6); WdChs4p, a chitin synthase 3 homologue (25). 1. Cann, Kobayashi, Onoda, Wakita & Hoshino (1993) *J. Appl. Bacteriol.* **74**, 127. 2. Cabib, Kang & Au-Young (1987) *Meth. Enzymol.* **138**, 643. 3. Elbein (1987) *Meth. Enzymol.* **138**, 661. 4. ### Polyphloretin Phosphate

This water-soluble polyanion (MW = Indefinite Polymer; *Abbreviation:* PPP) is a mixture of polyesters of phosphoric acid and phloretin. PPP is a light-green or brown powder that inhibits alkaline phosphatase and is a prostaglandin antagonist. PPP is a non-specific and reversible antagonist of the response of non-gravid rat uterine smooth muscle to oxytocins *in vitro*, and its specificity of action as a prostaglandin antagonist is likely to be species/tissue-dependent. **Target(s):** acid phosphatase (1); adenylate cyclase (2); alkaline phosphatase (3,4); cystinyl aminopeptidase, or oxytocinase (5,6); hyaluronidase (4); 15-hydroxyprostaglandin dehydrogenase (7); phospholipase A (8); and ribonuclease (9). 1. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 464, Academic Press, New York. 2. Hynie & Klenerova (1979) *Prostaglandins Med.* **2**, 11. 3. Stadtman (1961) *The Enzymes*, 2nd ed. ### Polyphosphate

This homopolymeric anhydride, also called polymeta-phosphate and hexametaphosphate (with sodium hexametaphosphate known also as Calgon®), is a linear sequence of phosphoric acid (or, polyphosphoric acid) in any of its many ionization states. Polyphosphate is produced in a number of microorganisms and accumulates in highly refractile subcellular regions

known as metachromatic granules. Oligo- and poly-phosphates are thought to be phosphate reserves. Cyclic metaphosphates are known to have 3–10 metaphosphate subunits, and ultraphosphate, containing variously branched units, are also known to exist. Polyphosphate dissolves slowly in water and slowly hydrolyzes to produce trimetaphosphate and orthophosphate. **See also Tripolyphosphate; Tetrapolyphosphate** **Target(s):** acid phosphatase (1); adenylate kinase (2); AMP deaminase (3);  $\alpha$ -amylase (4); cAMP phosphodiesterase (5); DNA ligase6; DNA polymerase (6); fructose-1,6-bisphosphate aldolase (7); glutamate dehydrogenase (8); lactate dehydrogenase (8); NMN nucleosidase (9); phosphofructokinase (10); 3-phosphoglycerate kinase (16); phosphorylase kinase (11); 3- or 4-phytase (12); polynucleotide adenyllyltransferase, or poly(A) polymerase (15); pyrophosphatase, or inorganic diphosphatase (13); restriction endonucleases (6); RNA polymerase (14); *TaqI* DNA polymerase (6); and T4 DNA ligase (6). 1. ### 3-Polyprenyl-4-hydroxybenzoate and 3-Polyprenyl-4-hydroxybenzoic Acid, See specific compound; e.g., 3-Nonaprenyl-4-hydroxybenzoate

### Poly(L-proline)

This indefinite L-proline homopolymer (CAS 25191-13-3) of indefinite length, is frequently used in structural and conformational investigations, adopting one of two major conformations: Poly(L-Pro) I helix (with  $\phi$  and  $\psi$  angles of  $-83^\circ$  and  $158^\circ$ , respectively, with peptide bonds that are all *cis*) and poly(L-Pro) II helix (with  $\phi$  and  $\psi$  angles of  $-78^\circ$  and  $149^\circ$ , and containing peptide bonds that are all *trans*). Collagen strands adopt a conformation similar to that of poly(L-Pro) II helix. Proline-rich regions in other proteins also have secondary structures similar to poly(L-Pro) II. Poly(L-proline) also binds tightly ( $K_i = 10 \mu\text{M}$ ) to the actin regulatory protein profilin, which within all eukaryotic cells interacts with corresponding Actin-Based Motility-2 sequences (e.g., Xaa-Pro-Pro-Pro sequences) found as multiple registers within the actin-filament end-tracking Ena/VASP proteins, WASP, N-WASP, and formins. Poly(L-proline) and analogous GPPPPPGPPPPGPPPP sequences in VASP immediately disperse profilin·Actin·ATP from active polymerization sites in lamellipodia and filopodia, thereby arresting all actin-based motility (2). **See also GPPPPPGPPPPGPPPP** **Target(s):** actin-based motility (1,2); procollagen-proline 3-dioxygenase (3); and procollagen-proline 4-dioxygenase, or prolyl hydroxylase (4-11). 1. **Pomalidomide**

This orally active, immunomodulatory antineoplastic agent (FW = 273.24 g/mol; CAS 19171-19-8; Solubility =  $\geq 14$  mg/mL DMSO), also known as Pomalyst™, CC-4047, 4-amino-thalidomide, and systematically as 4-amino-2-(2,6-dioxopiperidin-3-yl)isoindole-1,3-dione, inhibits proliferation of hematopoietic tumor cells (attended by induced apoptosis) as well as monocyte production of pro-inflammatory cytokines, while potentiating T cell- and natural killer cell-mediated immunity. Receiving FDA approval in 2013 for the treatment for relapsed/refractory multiple myeloma, pomalidomide is indicated for patients, who were unsuccessfully treated with bortezomib and lenalidomide (1). When tested in fifteen patients with relapsed/refractory myeloma, pomalidomide gave clear evidence of activation of endothelium, coagulation, and fibrinolysis, in the absence of either platelet activation or endothelial cell damage (2). Although pomalidomide treatment frequently results in deep vein thrombosis, alternate-day pomalidomide administration was associated with a marked reduction in the incidence of DVT, while retaining excellent anti-myeloma properties (3). Co-administration of pomalidomide plus low-dose dexamethasone is therapeutically active and well tolerated in lenalidomide-refractory multiple myeloma (4). Repression of TNF- $\alpha$  expression is the crucial factor of many of pomalidomide's anti-inflammatory properties. Pomalidomide also regulates the activity of Rho GTPases, altering the formation of actin filaments in primary human T cells and monocytes, showing that RhoA activation was essential for pomalidomide-induced interleukin-2 expression in T cells (5). 1.  **$\alpha$ -Pompilidotoxin &  $\beta$ -Pompilidotoxin**

$\alpha$ -PMTX: RIKIGLFDQLSKL-NH<sub>2</sub>  
 $\beta$ -PMTX: RIKIGLFDQLSRL-NH<sub>2</sub>

These structurally related 13-residue neurotoxins (FW <sub>$\alpha$ -PMTX</sub> = 1530.87 g/mol; Isoelectric Point = 9.99; FW <sub>$\beta$ -PMTX</sub> = 1558.89 g/mol; Isoelectric Point = 10.84) are novel neurotoxins from the venom of a solitary wasp *Anoplus saffariensis* (1). With neuromuscular synapses in lobster walking leg and the rat trigeminal ganglion (TG) neurons, paired intracellular recordings from the presynaptic axon terminals and the innervating lobster leg muscles revealed that  $\alpha$ -PMTX (at 10-100  $\mu$ M) induces long bursts of action potentials in the presynaptic axon, resulting in both facilitated excitatory and inhibitory synaptic transmission (2).  $\alpha$ -PMTX's action is distinct from that of other known facilitatory presynaptic toxins, including sea anemone toxins (See AETX) and  $\alpha$ -scorpion toxins, which modify the fast inactivation of Na<sup>+</sup> current. Using whole-cell recordings from rat trigeminal neurons,  $\alpha$ -PMTX slowed the Na<sup>+</sup> channels inactivation process without changing the peak current-voltage relationship or the activation time course of tetrodotoxin-sensitive Na<sup>+</sup> currents (See Tetrodotoxin) and that  $\alpha$ -PMTX had voltage-dependent effects on the rate of recovery from Na<sup>+</sup> current inactivation and deactivating tail currents (2). Such results suggest that  $\alpha$ -PMTX slows or blocks conformational changes required for fast inactivation of the Na<sup>+</sup> channels on the extracellular surface (2). Voltage-gated tetrodotoxin-sensitive sodium channels of Purkinje neurons produce "resurgent" current with repolarization, resulting from relief of an open-channel block that terminates current flow at positive potentials (3). The associated recovery of sodium channels from inactivation is thought to facilitate the rapid firing patterns characteristic of Purkinje neurons. Resurgent current appears to depend primarily on Nav1.6  $\alpha$ -subunits, because it is greatly reduced in "med" mutant mice that lack Nav1.6.  $\beta$ -PMTX increases resurgent current in wild-type neurons and induces resurgent current in med neurons (3). In med cells, the resurgent component of  $\beta$ -PMTX-modified sodium currents cannot be selectively abolished by application of intracellular alkaline phosphatase, suggesting that, like in Nav1.6-expressing cells, the open-channel block of Nav1.1 and Nav1.2 subunits is regulated by constitutive phosphorylation (3). Such results

indicate the endogenous blocker exists independently of Nav1.6 expression, and conventional inactivation regulates resurgent current by controlling the extent of open-channel block. In Purkinje cells, therefore, the relatively slow conventional inactivation kinetics of Nav1.6 appears to be well adapted to carry resurgent current (3). 1. Konno, Miwa, Takayama, *et al.* (1997) *Neurosci. Lett.* **238**, 99. 2. Sahara, Gotoh, Konno, *et al.* (2000) *Eur. J. Neurosci.* **12**, 1961. 3. Grieco & Raman (2004) *J. Neurosci.* **24**, 35.

**Ponatinib**

This orally bioavailable tyrosine kinase inhibitor (FW = 532.56 g/mol; CAS 943319-70-8), also known as AP24534, Iclusig®, and systematically named as 3-2-(imidazo[1,2-b]pyridazin-3-yl)ethynyl-4-methyl-N-4-(4-methylpiperazin-1-yl)methyl-3-trifluoromethylphenylbenzamide, targets the Breakpoint Cluster Region-Abelson (BCR-ABL) kinase. Ponatinib was developed by a structure-guided design for use against chronic myeloid leukemia (CML) and Philadelphia chromosome positive (Ph<sup>+</sup>) acute lymphoblastic leukemia (ALL), including the so-called Bcr-Abi<sup>T315I</sup> gatekeeper mutant that is resistant to Gleevec (Imatinib), Tasigna and Sprycel. On October 31, 2013, the U.S. Food and Drug Administration announced that it had asked the manufacturer, Ariad Pharmaceuticals, to suspend marketing and sales of Iclusig in view of the risk of life-threatening blood clots and severe narrowing of blood vessels. 1. Huang, Metcalf, Sundaramoorthi, *et al.* (2010) *J. Med. Chem.* **53**, 4701. 2. O'Hare, Shakespeare, Zhu, *et al.* (2009) *Cancer Cell* **16**, 401.

**POPSO**

This widely used Good's Buffer (FW<sub>free-acid</sub> = 362.43 g/mol; pK<sub>a</sub> = 7.8 (25°C);  $\Delta pK_a/\Delta C = -0.013$ ), also known as piperazine-*N,N'*-bis(2-hydroxypropanesulfonic acid), inhibits the anion uniport, a member of the solute carrier (SLC) family (1). *Note:* Chloroethane sulfonate, which is an essential ingredient in the synthesis of Good's Buffers that contain ethane sulfonic acid, gives rise to variable amounts of oligovinylsulfonate (OVS). The latter strongly inhibits ribonuclease (2) and is likely to inhibit other enzymes that bind polyanions. 1. Ng, Selwyn & Choo (1993) *Biochim. Biophys. Acta* **1143**, 29. 2. Smith, Soellner & Raines (203) *J. Biol. Chem.* **278**, 20934.

**Porfiromycin**

This bioreductive antibiotic (FW = 349.36 g/mol; CAS 801-52-5; E<sup>0</sup> = -0.4 V) from *Streptomyces ardens* alkylates DNA and RNA, producing inter-strand cross-links and single-strand breaks, with selective toxicity to cells operating at low oxygen, making it an effective agent in solid tumor radiotherapy. Target(s): DNA biosynthesis (2); NAD(P)H dehydrogenase, or DT diaphorase (3). 1. Keyes, Rockwell & Sartorelli (1984) *Cancer Research* **45**, 3642. 2. Weissbach & Lisio (1965) *Biochemistry* **4**, 196. 3. Siegel, Beall, Kasai, *et al.* (1993) *Mol. Pharmacol.* **44**, 1128.

## Porphycenes

These synthetic photosensitizers (FW = 310.36 g/mol; CAS 100572-96-1) are Fe(II)- and Fe(III)-binding structural isomers of porphyrin that promote singlet oxygen-mediated photodamage and are used in photodynamic therapy, or PDT (1-3). Their unique solubility and photochemical properties depend on the nature of ring substituents and bound metal ion. Photosensitizers with specific targets (e.g., mitochondria, lysosomes, and plasma membrane) may be used to delineate the mechanism of PDT-induced apoptosis in cancer cells (3). One example is 9-acetoxy-2,7,12,17-tetrakis-( $\beta$ -methoxyethyl)-porphycene (ATMPn), which enters cells and concentrates within mitochondria (4). 1. Aramendia, Redmond, Nonell, *et al.* (1986) *Photochem. Photobiol.* **44**, 555. 2. Richert, Wessels, Müller, *et al.* (1994) *J. Med. Chem.* **37**, 2797. 3. Kessel & Luo (1998) *J. Photochem. Photobiol. B.* **42**, 89. 4. Szeimies, Karrer, Abels, *et al.* (1996) *J. Photochem. Photobiol. B.* **34**, 67.

## Porphyrexide

This paramagnetic sulfhydryl-modifying reagent (FW = 129.14 g/mol; CAS 15622-62-5;  $\lambda_{\max}$  = 460 nm), also known systematically as 4-amino-2,5-dihydro-2-imino-5,5-dimethyl-1H-imidazol-1-yloxy, reacts with many sulfhydryl-containing substances, with loss of its characteristic red color (1). Porphyrexide is also used as an oxidant substrate by a number of enzymes, including galactose oxidase (2). The *Escherichia coli* sulfite reductase heme protein subunit reacts at nearly unit stoichiometry with porphyrexide to produce a ferrisiroheme  $\pi$ -cation radical (3). **Target(s):** alcohol dehydrogenase (4); glyceraldehyde-3-phosphate dehydrogenase (4);  $\alpha$ -glycerophosphate dehydrogenase (4); lactate dehydrogenase (4); and pyruvate decarboxylase (5). 1. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, pp. 664-670, Academic Press, New York. 2. Kwiatkowski, Adelman, Pennelly & Kosman (1981) *J. Inorg. Biochem.* **14**, 209. 3. ## Potato Protease Inhibitors

These proteolysis inhibitors are abundant in tubers and plant seeds, where they are frequently regarded as storage and/or defense proteins. They accumulate in potato leaves in response to wounding or ultraviolet irradiation. Potato inhibitors have been classified into seven different families: potato inhibitor I, potato inhibitor II, potato cysteine protease inhibitor, potato aspartate protease inhibitor, potato Kunitz-type protease inhibitor, potato carboxypeptidase inhibitor, and other serine protease inhibitors (1). **See also Trypsin Inhibitors** The potato carboxypeptidase inhibitor (MW ~4 kDa), often abbreviated CPI, inhibits carboxypeptidases from numerous sources. Three isoforms CPI-I, -II, and -III have been reported with pI values of 4.6, 5.6, and 6.5. Carboxypeptidase A is inhibited with  $K_i$  = 1.5–3.5 nM and carboxypeptidase B is inhibited with  $K_i$  = 1–6 nM. **Target(s):** actinidain, inhibited by potato cysteine proteinase inhibitor (2); ananain, inhibited by potato cysteine proteinase inhibitor (2); carboxypeptidase A (21-30); carboxypeptidase B (16,20,21,28,30,34); carboxypeptidase U (15-18,31); caricain, or papaya proteinase III, inhibited by potato cysteine proteinase inhibitor (2); cathepsin B, inhibited by potato cysteine proteinase inhibitor (2,3); cathepsin D (4-6); cathepsin H, inhibited by potato cysteine proteinase inhibitor (3); cathepsin L, inhibited by potato cysteine proteinase inhibitor (2,3); cerevisin (7); chymopapain, inhibited by potato cysteine proteinase inhibitor (2,8); chymotrypsin (9); ficain, or ficin,

inhibited by potato cysteine proteinase inhibitor (2,8); fruit bromelain, inhibited by potato cysteine proteinase inhibitor (2); lysine carboxypeptidase, or lysine(arginine) carboxypeptidase, or carboxypeptidase N (19); mast cell carboxypeptidase (29,32,33); oryzin (1,11-13); papain, inhibited by potato cysteine proteinase inhibitor (2,3,8); pinguinain, inhibited by potato cysteine proteinase inhibitor (2); saccharopepsin (4); stem bromelain, inhibited by potato cysteine proteinase inhibitor (2); streptogrisin B (10); and trypsin (9,14). 1. ## Poziotinib

This orally administered, irreversible pan-Human Epidermal growth factor Receptor (HER) inhibitor (FW<sub>free-base</sub> = 441.28 g/mol), also known by the code name HM781-36B and systematically as 1-[4-[4-(3,4-dichloro-2-fluorophenylamino)-7-methoxyquinazolin-6-yloxy]-piperidin-1-yl]prop-2-en-1-one hydrochloride, is a new anticancer drug intended to treat advanced solid tumors in clinical trial. HER2-amplified cells were sensitive to HM781-36B (IC<sub>50</sub>=1-10 nM), arresting in G<sub>1</sub> arrest and undergoing subsequent apoptosis. HM781-36B shows promise in the treatment for HER2-amplified breast cancer, especially as a chemosensitizer when used in combination with other cytotoxic agents (e.g., 5-fluorouracil, cisplatin, paclitaxel, or gemcitabine). 1. Cha, Lee, Kim, *et al.* (2012) *Int. J. Cancer* **130**, 2445. 2. Kim, Kim, Yoon, *et al.* (2012) *Anticancer Drugs* **23**, 288.

## PP1

This cell-permeable ATP site-directed pyrazolopyrimidine (FW = 281.36 g/mol), also known as 4-amino-5-(4-methylphenyl)-7-(*t*-butyl)pyrazolo[3,4-*d*]pyrimidine, inhibits a number of protein kinases, including the non-receptor, proto-oncogenic Src protein-tyrosine kinase (1-4). **Target(s):** Bcr-Abl protein-tyrosine kinase (5); casein kinase 1 $\delta$ , IC<sub>50</sub> = 1.06  $\mu$ M (1); Csk protein-tyrosine kinase, IC<sub>50</sub> = 0.52  $\mu$ M (2); lymphocyte kinase, IC<sub>50</sub> = 0.05  $\mu$ M (1,2); polo kinase (7); protein-tyrosine kinase (1-6); Src protein-tyrosine kinase (1-4,6); and stress-activated protein kinase 2a/p38, IC<sub>50</sub> = 0.64  $\mu$ M (1). 1. **PPI-0903, See Ceftaroline Fosamil**

## PP1 Analogue

This cell-permeable ATP site-directed pyrazolopyrimidine, also known as 4-amino-5-(1-naphthyl)-7-(*t*-butyl)pyrazolo[3,4-*d*]pyrimidine (FW = 317.39 g/mol), inhibits Src-family protein-tyrosine kinases, including Ile-338-Gly  $\nu$ -Src, IC<sub>50</sub> = 1.5 nM, wild-type  $\nu$ -Src, IC<sub>50</sub> = 1.0  $\mu$ M, and Fyn, IC<sub>50</sub> = 0.6  $\mu$ M (1-3). 1. Bishop, Ubersax, Petsch, *et al.* (2000) *Nature* **407**, 395. 2. Bishop, Kung, Shah, *et al.* (1999) *J. Amer. Chem. Soc.* **121**, 627. 3. Merciris, Claussen, Joiner & Giraud (2003) *Pflugers Arch.* **446**, 232.

## PP2

This cell-permeable and photosensitive ATP site-directed pyrazolopyrimidine (FW = 301.78 g/mol), also known as 4-amino-5-(4-chlorophenyl)-7-(*t*-butyl)pyrazolo[3,4-*d*]pyrimidine and tyrphostin AG 1879, potently inhibits Lck and Fyn protein kinases, with IC<sub>50</sub> values of 4 nM and 5 nM. PP2 is ~100x less potent toward EGFR and is inactive for ZAP-70, JAK2 and PKA (1-3). PP2 prevented serum-independent growth of RET/PTC1-transformed NIH3T3 fibroblasts and of TPC1 and FB2, two human papillary thyroid carcinoma cell lines that carry spontaneous RET/PTC1 rearrangements (1). PP2 activates the E-cadherin-mediated cell adhesion system, suppressing metastasis in cancer cells (2). In cervical

cancer cells (HeLa and SiHa), 10  $\mu$ M PP2 down-regulates pSrc-Y416, pEGFR-Y845, and pEGFR-Y1173 expression levels, while down-regulating pSrc-Y416 and pEGFR-Y845, but not pEGFR-Y1173 (3). PP2 is also a potential neuroprotective agent in cerebral ischemia-reperfusion (4). **Target(s):** casein kinase 1 $\delta$ , IC<sub>50</sub> = 1.3  $\mu$ M (5); Csk protein-tyrosine kinase (6); focal adhesion kinase (7); lymphocyte kinase, IC<sub>50</sub> = 0.06  $\mu$ M (5,8); p56lck, IC<sub>50</sub> = 4 nM (8,9); p59fynT, IC<sub>50</sub> = 5 nM (8); receptor protein-tyrosine kinase (10); src protein-tyrosine kinase, IC<sub>50</sub> = 0.7  $\mu$ M (5,11,12-23); stress-activated protein kinase 2a/p38, IC<sub>50</sub> = 1.4  $\mu$ M (5); and Yes kinase (13). 1. ## PP 242

This ATP-competitive mTORC1/mTORC2 inhibitor (FW = 308.34 g/mol; CAS 1092351-67-1; Solubility: 25 mM in DMSO), also named 2-[4-amino-1-(1-methylethyl)-1H-pyrazolo[3,4-*d*]pyrimidin-3-yl]-1H-indol-5-ol, has a IC<sub>50</sub> = 8 nM for both isoforms of mammalian target of rapamycin (mTOR), also known as FK506-binding protein 12-rapamycin-associated protein 1, or FRAP1, a serine/threonine protein kinase that regulates cell growth, cell proliferation, cell motility, cell survival, protein synthesis, autophagy, and transcription. PP-242 shows considerable selectivity for mTOR versus

PI3K family kinases (1,2). In models of acute leukemia harboring the Philadelphia chromosome (Ph) translocation, PP242, but not rapamycin, causes death of mouse and human leukemia cells (3). Indeed, PP242 completely inhibits TORC1 and TORC2 signaling in BCR-ABL<sup>+</sup> cells, whereas rapamycin partially suppresses TORC1 and drives a PI3K/AKT surge. Moreover, PP242 augments TNF-related apoptosis-inducing ligand-(TRAIL-) induced apoptosis in NSCLC cells, indicating that mTORC2 regulates Cbl-dependent FLIP<sub>s</sub> degradation and TRAIL-induced apoptosis (4) **Other Targets:** p110 $\gamma$  (IC<sub>50</sub> = 0.102  $\mu$ M); DNA-PK (IC<sub>50</sub> = 0.408  $\mu$ M); p110 $\delta$  (IC<sub>50</sub> = 1.27  $\mu$ M); p110 $\alpha$  (IC<sub>50</sub> = 1.96  $\mu$ M), and p110 $\beta$  (IC<sub>50</sub> = 2.2  $\mu$ M), with much weaker inhibition of 215 other kinases. 1. Apse *et al.* (2008) *Nature Chem. Biol.* **4**, 691. 3. Feldman, *et al.* (2009) *PLoS Biol.* **7**, 371. 3. Janes, Limon, So, *et al.* (2010) *Nature Med.* **16**, 205. 4. Zhao, Yue, Khuri & Sun (2013) *Cancer Res.* **73**, 1946.

#### PPI-2458

This orally bioavailable, selectively cytotoxic agent (FW<sub>free-acid</sub> = 424.54 g/mol; Photosensitive; Store in dark: IUPAC: [(3*R*,4*S*,5*S*,6*R*)-5-methoxy-4-[(2*R*,3*R*)-2-methyl-3-(3-methylbut-2-enyl)oxiran-2-yl]-1-oxaspiro[2.5]octan-6-yl] *N*-[(2*R*)-1-amino-3-methyl-1-oxobutan-2-yl]carbamate), a synthetic analogue of an *Aspergillus fumigatus* secondary metabolite (See *Fumagillin*), suppresses the formation of new blood vessels and inhibits endothelial cell proliferation and angiogenesis. Its epoxide group reacts with an active-site histidyl residue in methionyl aminopeptidase type II. Because removal of the *N*-terminal methionine from many proteins is required for their biologic activity, subcellular localization, and stability, methionyl-aminopeptidase plays a pivotal co-regulatory role in translation. PPI-2458 potently inhibits the proliferation of human fibroblast-like synoviocytes, or HFLS-RA (GI<sub>50</sub> = 0.04 nM) derived from RA patients, showing >95% inhibition at 1 nM. Proliferation of human umbilical vein endothelial cells (HUVEC) is similarly inhibited (GI<sub>50</sub> = 0.2 nM) by PPI-2458. Moreover, PPI-2458 inhibition of MetAP-2 catalysis (IC<sub>50</sub> = 0.2 nM) in HFLS-RA is directly correlated with cell growth inhibition and a decrease in the DNA polymerase processivity factor PCNA. PPI-2458 also protects the  $\alpha$ -subunit of eukaryotic initiation factor 2 from inhibitory phosphorylation. Based on the structure of TNP-470, a fumagillin analogue that exhibits dose-limiting CNS toxicity, PPI-2458 was designed to retain antiproliferative activity while improving its CNS toxicity profile. PPI-2458 also inhibits proliferation of B16F10 melanoma cells *in vitro*, (GI<sub>50</sub> = 0.2 nM). This property, coupled with the absence of detectable resistance to PPI-2458 and the induction of morphological features of differentiated melanocytes, commends this agent for melanoma chemotherapy (2). PPI-2458 also inhibits non-Hodgkin's lymphoma cell proliferation *in vitro* and *in vivo* (3). Metabolic data demonstrate the participation of active metabolites in the *in vivo* efficacy of PPI-2458 (4). 1. Bernier, Lazarus, Clark, *et al.* (2004) *Proc. Natl. Acad. Sci. U.S.A.* **101**, 10768. 2. Hannig, Lazarus, Bernier, *et al.* (2006) *Int. J. Oncol.* **28**, 955. 3. Cooper, Karp, Clark, *et al.* (2006) *Clin. Cancer Res.* **12**, 2583. 4. Arico-Muendel, Belanger, Benjamin, *et al.* (2013) *Drug Metab Dispos.* **41**, 814.

#### PPTN

This highly potent and receptor type-selective P2Y<sub>14</sub> antagonist (FW = 511.96 g/mol; Solubility: 100 mM in DMSO), also named 4-[4-(4-piperidinyl)phenyl]-7-[4-(trifluoromethyl)phenyl]-2-naphthalenecarboxylic acid hydrochloride, targets the UDP-glucose-specific G<sub>i</sub> protein-coupled P2Y purinoceptor-14, or named previously as UDP-glucose receptor (K<sub>s</sub> =

0.43 nM), which binds uridine nucleotides and UDP-glucose that are released into the extracellular environment upon cell lysis (1). Two UDP analogues selectively activate the P2Y<sub>14</sub> receptor over the UDP-activated P2Y<sub>6</sub> receptor, and these molecules stimulate phosphorylation of ERK1/2 in differentiated human HL-60 promyeloleukemia cells (2). PPTN exhibits >10,000x selectivity toward P2Y<sub>14</sub> relative other P2Y receptors and inhibits UDP-glucose and MRS 2690 (or 2-thiouridine-5'-diphosphoglucose)-induced porcine pancreatic artery contraction *ex vivo*. Indeed, PPTN also shows no agonist or antagonist affinity at P2Y<sub>1</sub>, P2Y<sub>2</sub>, P2Y<sub>4</sub>, P2Y<sub>6</sub>, P2Y<sub>11</sub>, P2Y<sub>12</sub> or P2Y<sub>13</sub> receptors. It also blocks UDP-glucose-induced chemotaxis of HL-60 leukemia cells *in vitro* (3). The P2Y<sub>14</sub> receptor (P2Y<sub>14-R</sub>) is highly expressed in hematopoietic cells, and, while its physiologic functions remain undefined, it has been linked to immune and inflammatory responses. 1. Barrett, Sesma, Ball, *et al.* (2013) *Mol. Pharmacol.* **84**, 41. 2. Carter, Fricks, Barrett, *et al.* (2009) *Mol. Pharmacol.* **76**, 1341. 3. Alsaqati, Latif, Chan & Ralevic (2014) *Brit. J. Pharmacol.* **171**, 701.

#### PQ 69

This potent and selective hA<sub>1</sub> receptor antagonist (FW = 359.39 g/mol; CAS 910045-32-8; Soluble to 100 mM in DMSO), also named 4-(butylamino)-2-(3-fluorophenyl)-1,2-dihydro-3*H*-pyrazolo[4,3-*c*]quinolin-3-one, targets adenosine A<sub>1</sub> receptors, with an *in vitro* K<sub>i</sub> of 0.96 nM for the cloned receptor, with 217-fold lower activity against hA<sub>2A</sub> receptors and >1,000-fold lower action against hA<sub>3</sub> receptors. [<sup>35</sup>S]-GTP $\gamma$ S binding and cAMP assays indicates that PQ-69 is an A1AR inverse agonist activity. PQ-69 displays highly inhibitory activities on isolated guinea pig contraction (pA<sub>2</sub> = 9), as induced by an A1AR agonist, 2-chloro-*N*<sup>6</sup>-cyclopentyl adenosine. Systemic administration of PQ-69 increases urine flow and sodium excretion in normal rats. It has better metabolic stability than 1,3-dipropyl-8-cyclopentylxanthine, in terms of *in vitro* properties and longer terminal elimination *t*<sub>1/2</sub> *in vivo*. 1. Lu, Wang, Zhang, *et al.* (2014) *Purinergic Signal.* **10**, 619.

#### PR-619

This non-selective, cell-permeable pyridinamine (FW = 223.28 g/mol; CAS 2645-32-1) reversibly inhibits deubiquitylating enzymes, or DUBs, with EC<sub>50</sub> values typically in the 1 to 20  $\mu$ M range. **Targets:** ATXN3, BRCA1 Associated Protein-1 (or BAP1), Josephin domain containing-2 (or JOSD2), Ovarian Tumor Domain-containing-5 (or OTUD5), Ubiquitin Carboxyl-Terminal Hydrolase Isozyme-1 (or UCH-L1, UCH-L3, UCH-L5, UCH37, Ubiquitin-Specific Peptidase-1 (or USP-1), USP-2, USP-4, USP-5, USP-7, USP-8, USP-9X, USP-10, USP-14, USP15, USP-16, USP-19, USP-20, USP-22, USP-24, USP-28, USP-47, USP-48, Valosin-containing protein (or VCI135), YOD1, as well as deISGylase PLpro, deNEDDylase DEN1, and deSUMOlyase SENP6. 1. Altun, Kramer, Willems, *et al.* (2011) *Chem. Biol.* **18**, 1401.

#### PRA, See Phosphoribosylamine

#### Pralidoxime

This water-soluble, oxime-containing 2-formyl-1-methylpyridinium ion analogue (FW = 172.61 g/mol; CAS 6735-59-7; 1200-55-1 for the methyl sulfate salt; 154-97-2 for mesylate salt; 21239-05-4 for the monolactate; 3687-33-0 for trichloroacetate salt; 51-15-0 for the chloride salt), also called pyridine-2-aldoxime methochloride and 2-PAM, effectively reverses the inhibition of acetylcholinesterase and cholinesterase (1-3) by organophosphate-containing insecticide, thereby serving as an antidote. 2-PAM has even been observed to reactivate blood and diaphragm

cholinesterase inhibited by the biowarfare agent VX. 1. Kovarik, Cibán, Radic, Simeon-Rudolf & Taylor (2006) *Biochem. Biophys. Res. Commun.* **342**, 973. 2. Reiner, Simeon-Rudolf & Skrinjaric-Spoljar (1995) *Toxicol. Lett.* **82/83**, 447. 3. Petroianu, Nurulain, Arafat, Rajan & Hasan (2006) *Arch. Toxicol.* **80**, 777.

### Pramipexole

This non-ergoline receptor agonist (FW<sub>free-base</sub> = 211.33 g/mol; CAS 104632-26-0; FW<sub>dihCl-monohydrate</sub> = 302.26 g/mol; CAS = 191217-81-9; Solubility = 42 mg/mL DMSO), also known as (*S*)-*N*<sup>6</sup>-propyl-4,5,6,7-tetrahydrobenzo[*d*]thiazole-2,6-diamine, Mirapexin, Sifrol, and SND-919, exerts partial/full antagonist action on dopamine D<sub>2S</sub> (*K*<sub>i</sub> = 3.9 nM), D<sub>2L</sub> (*K*<sub>i</sub> = 2.2 nM), D<sub>3</sub> (*K*<sub>i</sub> = 0.5 nM), and D<sub>4</sub> (*K*<sub>i</sub> = 5.1 nM) receptors (1). D<sub>2S</sub> and D<sub>2L</sub> are G protein-coupled receptors that respectively participate in presynaptic and postsynaptic dopaminergic transmission; D<sub>3</sub> subtype receptors inhibit adenylyl cyclase through inhibitory G-proteins; as does the D<sub>4</sub> subtype. Although L-DOPA is the gold-standard for treating Parkinson Disease, its effectiveness fades rapidly and its continued use can result in serious motor fluctuations. Pramipexole selectively acts at dopamine receptors in the D<sub>2</sub> subfamily and possesses full activity that is comparable to dopamine (2). Its preferential affinity for the D<sub>3</sub> receptor subtype may well account for its efficacy in the treatment of both the motor and psychiatric symptoms of Parkinson disease (2). Unlike the long-term use of the ergot-derived dopamine agonists, pramipexole does not carry the risk to induce valvular heart disease or pulmonary and retroperitoneal fibrosis. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Mierau & Schingnitz (1992) *Eur. J. Pharmacol.* **215**, 161. 2. Bennett & Piercey (1999) *J. Neurol. Sci.* **163**, 25.

### Pramiracetam

This memory-enhancing (*or* nootropic) drug (FW = 269.39 g/mol; CAS 68497-62-1) also known by the trade names Remen<sup>®</sup>, Neupramir<sup>®</sup>, and Pramistar<sup>®</sup>, as well as by its systematic name *N*-[2-(diisopropylamino)ethyl]-2-(2-oxopyrrolidin-1-yl)acetamide, reverses electroconvulsive shock (ECS)-induced amnesia in mice, when administered after ECS treatment, but is inactive in a general observational test for CNS activity (1). The anti-amnesic effect of pramiracetam and related nootropic drugs parallel their *in vitro* inhibitory activities on prolyl endopeptidase, suggesting that the inhibitors exhibit their anti-amnesic effects by reducing this enzyme's activity in the brain. For pharmacokinetics of oral pramiracetam in normal volunteers, see (3). Prolyl oligopeptidase a cytosolic serine peptidase that hydrolyzes proline-containing peptides at the carboxy terminus of proline residues. It has been associated with schizophrenia, bipolar affective disorder, and related neuropsychiatric disorders. (See *Baicalin*) 1. Butler, Nordin, L'Italien, *et al.* (1984) *J. Med. Chem.* **27**, 684. 2. Yoshimoto T, Kado K, Matsubara, *et al.* (1987) *J. Pharmacobiodyn.* **10**, 730. 3. Chang, Young, Goulet & Yakatan (1985) *J. Clin. Pharmacol.* **25**, 291.

### Prasugrel

This oral thienopyridine-containing antithrombotic prodrug (FW = 373.44 g/mol; CAS 150322-43-3), known also by its codename KS-747, its trade names Effient<sup>™</sup> (U.S.), Efient<sup>™</sup> (E.U.), and Prasita<sup>™</sup> (India), and its systematic name 5-[2-cyclopropyl-1-(2-fluorophenyl)-2-oxoethyl]-4,5,6,7-

tetrahydrothieno[3,2-*c*]pyridin-2-yl acetate, is metabolized to the thiol-containing active metabolite R-138727. In the following scheme, esterase-catalyzed hydrolysis of the acetate function results in a thiolactone species that then undergoes cytochrome P450-dependent oxidative opening of the thiolactone ring to form a reactive sulfenic acid metabolite that is eventually reduced to the active thiol-containing active drug (2).

R-138727 binds to and irreversibly inhibits the P2Y<sub>12</sub>-subtype of the adenosine 5'-diphosphate (ADP) receptor, blocking platelet aggregation in the presence of fibrin (1). R-138727 is actually a mixture of (*R*, *S*), (*R*, *R*), (*S*, *S*), and (*S*, *R*) stereoisomers, where the first letter indicates the configuration of the sulfur-bearing carbon and the second indicates the configuration of the benzylic carbon. As compared with clopidogrel, lower levels of prasugrel consistently resulted in a higher degree of inhibition of platelet aggregation (3). There was no relevant effect of genetic variation in CYP2B6, CYP2C9, CYP2C19, or CYP3A5 on the pharmacokinetics of prasugrel's active metabolite or its inhibition of platelet aggregation. 1. Hasegawa, Sugidachi, Ogawa *et al.* (2007) *Thromb. Hemost.* **94**, 593. 2. Dansette, Rosi, Debernardi, Bertho & Mansuy (2012) *Chem. Res. Toxicol.* **25**, 1058. 3. Jakubowski, Matsushima, Asai *et al.* (2007) *Brit. J. Clin. Pharmacol.* **63**, 421.

### Pravastatin

This therapeutic anticholesterogenic HMG-CoA inhibitor (FW<sub>free-acid</sub> = 424.53 g/mol; CAS 81093-37-0), also known as CS-514 and Pravachol<sup>®</sup>, inhibits 3-hydroxy-3-methylglutaryl-CoA reductase, *K*<sub>i</sub> ≈ 1 nM (1-3). Orally administered pravastatin exhibits one-pass absorption by the liver. Moreover, because there is no uptake of pravastatin by most extrahepatic cells, this statin will be unable to mitigate the increase in mevalonate synthesis in extrahepatic tissues accompanying the decrease in circulating cholesterol caused by its inhibition of hepatic HMG-CoA reductase. This inhibitor produced dose-related reduction in total cholesterol and low-density lipoprotein cholesterol. Pravastatin reportedly modifies cholesterol exchange between plasma and the erythrocyte membrane. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Nakaya, Homma, Tamachi & Goto (1986) *Atherosclerosis* **61**, 125. 2. Yoshino, Kazumi, Kasama, *et al.* (1986) *Diabetes Res. Clin. Pract.* **2**, 179. 3. Rabini, Polenta, Staffolani, *et al.* (1993) *Exp. Mol. Pathol.* **59**, 51.

### Praziquantel

This antihelmintic agent (FW = 312.41 g/mol; CAS 55268-74-1; 57452-97-8 for the (*S*)-isomer; 57452-98-9 for the (*R*)-isomer), also known as 2-(cyclohexylcarbonyl)-1,2,3,6,7,11b-hexahydro-4*H*-pyrazino[2,1-*a*]isoquin-

olin-4-one, is a *Schistosoma japonicum* glutathione S-transferase inhibitor used in the treatment of schistosomiasis. It reportedly has a selective effect on the tegument of trematodes and increases permeability of calcium. Praziquantel is soluble in ethanol (9.7 g/100 g) and has a low solubility in water (0.04 g/100 g). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** N-acetylgalactosamine-4-sulfatase, or arylsulfatase B (1);  $\gamma$ -glutamyl transpeptidase, or  $\gamma$ -glutamyltransferase (2); glutathione S-transferase (3,4); and lactate dehydrogenase (5). 1. Balbaa & Bassiouny (2006) *J. Enzyme Inhib. Med. Chem.* **21**, 81. 2. Wang, Cheng, Huang & Zheng (1987) *Zhongguo Ji Sheng Chong Xue Yu Ji Sheng Chong Bing Za Zhi* **5**, 32. 3. Parasitol.* **91**, 129.

### Prazobind

This alkylating agent and antihypertensive (FW = 422.49 g/mol; CAS 107021-36-3; Soluble in Chloroform, DMSO, Ethanol and Methanol), also known as SZL-49, irreversibly antagonizes  $\alpha_1$  adrenoreceptors (1-4). 1. Helman, Kusiak, Pitha & Baum (1987) *Biochem. Biophys. Res. Commun.* **142**, 403. 2. Mante & Minneman (1991) *Eur. J. Pharmacol.* **208**, 113. 3. Pitha, Szabo, Szurmai, Buchowiecki & Kusiak (1989) *J. Med. Chem.* **32**, 96. 4. Piascik, Butler, Kusiak, Pitha & Holtman (1989) *J. Pharmacol. Exp. Ther.* **251**, 878.

### Prednisolone

This semisynthetic corticosteroid (FW = 360.45 g/mol; CAS 50-24-8), also known as (11 $\beta$ )-11,17,21-trihydroxypregna-1,14-diene-3,20-dione, is a potent antiinflammatory and antiallergic agent. Note that prednisolone has a short biological half-life and is interconverted to prednisone (via the action of 11 $\beta$ -hydroxysteroid dehydrogenase). Prednisolone binds irreversibly to the glucocorticoid receptors  $\alpha$ GR and  $\beta$ GR, of which 3-10,000 are found in virtually all cell types, depending on the tissue involved. The steroid/receptor complexes dimerize, whereupon they interact with DNA in the nucleus, binding to steroid-response elements and modifying the transcription of target genes. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** catalase (1); fumarase, or fumarate hydratase (1); interleukin-1 $\beta$  release (2); and peptidyl-dipeptidase A, or angiotensin-converting enzyme (3). 1. Shyadehi & Harding (2002) *Biochim. Biophys. Acta* **1587**, 31. 2. Uehara, Kohda, Sekiya, Takasugi & Namiki (1989) *Experientia* **45**, 166. 3. Roulston & Galloway (1986) *Clin. Chem.* **32**, 697.

### Pregabalin

This novel Ca<sup>2+</sup> channel  $\alpha_2\delta$ -subunit antagonist and anticonvulsant drug (FW = 159.23 g/mol; CAS 148553-50-8), known by its trade name, Lyrica™, and its IUPAC name, (S)-3-(aminomethyl)-5-methylhexanoic

acid, targets  $\gamma$ -aminobutyric acid (GABA) aminotransferase (*Reaction:* GABA +  $\alpha$ -Ketoglutarate  $\rightleftharpoons$  Succinate Semialdehyde + L-Glutamate). This pyridoxal 5'-dependent enzyme is responsible for the degradation of the inhibitory neurotransmitter GABA and stoichiometric formation of the excitatory neurotransmitter L-glutamate (1,2). Notably, compounds inhibiting this enzyme often exert anticonvulsant actions and may also affect other disorders, such as Alzheimer's Disease, Huntington's disease, Parkinson Disease, as well as drug addiction. With its low potential for abuse and limited dependence liability, pregabalin is classified by the FDA as a Schedule V drug. **Primary Mode of Action:** Discovery of this alternative substrate inhibitor was premised on the need to explore how the introduction of a lipophilic side-chain might allow a GABA analogue to cross the blood-brain barrier as a prelude to designing mechanism-based irreversible inhibitors. Ironically, the need for developing a suicide inhibitor was deemed unnecessary, inasmuch as this substituted GABA analogue proved to be a poor alternative substrate that effectively ties up GABA-AT, reducing the enzyme's ability to form L-Glutamate. Beyond blocking L-Glutamate formation, pregabalin has the added benefit of activating glutamate decarboxylase (*Reaction:* L-Glutamate  $\rightleftharpoons$  GABA + CO<sub>2</sub>), the latter raising the concentration of the inhibitory neurotransmitter. The mechanism by which pregabalin inhibits pain is by suppressing Ca<sup>2+</sup> influx through  $\alpha_2\delta$  subunit-containing voltage-gated calcium channel (3,4). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Andruszkiewicz & Silverman (1990) *J. Biol. Chem.* **265**, 22288. 2. Silverman (2008) *Angew. Chem. Int. Ed.* **47**, 3500. 3. Bian, Li, Offord *et al.* (2006) *Brain Res.* **1075**, 68. 4. Taylor, Angelotti & Fauman (2007) *Epilepsy Res.* **73**, 137.

### 4,9-Pregadiene-3,20-dione

This steroid (FW = 298.43 g/mol) competitively inhibits *Pseudomonas testosteroni* 3-oxosteroid  $\Delta^5$ - $\Delta^4$ -isomerase ( $K_i = 5.3 \mu\text{M}$ ), helping to define the structural features of sterols acting as competitive or noncompetitive inhibitors of the interconversion of 3-oxo- $\Delta^5$ -steroids and 3-oxo- $\Delta^4$ -steroids. 1. Weintraub, Vincent, Baulieu & Alfsen (1977) *Biochemistry* **16**, 5045.

### 5 $\alpha$ -Pregnane-3 $\beta$ ,20 $\alpha$ -diol

This isomer of pregnanediol (FW = 318.50 g/mol) a mixed-type noncompetitive inhibitor ( $K_{i,app} = 0.7 \mu\text{M}$ ) of 3 $\beta$ -hydroxysteroid dehydrogenase. 1. Chavatte, Rossdale & Tait (1995) *Equine Vet. J.* **27**, 342.

### 5 $\alpha$ -Pregnane-3 $\beta$ ,17 $\alpha$ -diol-20-one

This steroid (FW = 334.50 g/mol) is one of 14 steroids that inhibit rat mammary glucose-6-phosphate dehydrogenase *in vitro*. Inhibition requires

the presence of a keto group at position C-17 for androstanes and estanes or at position C-20 for pregnanes. Binding occurs through hydrophobic interactions, and all modifications that diminish ligand planarity likewise reduce binding affinity. Note also that other hydrophobic compounds also inhibit G6PDH, including various antimalarials. 1. Raineri & Levy (1970) *Biochemistry* **9**, 2233.

**Pregnenolone**

This steroid (FW = 316.48 g/mol; CAS 145-13-1), also known as (3 $\beta$ )-3-hydroxypregnen-5-en-20-one and  $\Delta^5$ -pregnen-3 $\beta$ -ol-20-one, is a key intermediate in the biosynthesis of progesterone and has glucocorticoid activity. Pregnenolone has a low solubility in water and is used in the treatment of rheumatoid arthritis. **Target(s)**: arylamine *N*-acetyltransferase (1); cholesterol 7 $\alpha$ -monooxygenase (2); glucose-6-phosphate dehydrogenase (3-7); ketosteroid monooxygenase, or androst-4-ene-3,17-dione monooxygenase, inhibits lactonization of androstenedione (8); malic

enzyme (9); steroid 11 $\beta$ -monooxygenase (10); steroid 16 $\alpha$ -monooxygenase (11); steroid 20-monooxygenase (12); steroid sulfatase (13); steroid sulfotransferase, also alternative substrate (14); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, or ACAT (15,16); sterol demethylase (17); steryl-sulfatase, weakly inhibited (18). 1. **Prenylamine**

This vasodilator and a Ca<sup>2+</sup> channel blocker (FW<sub>free-base</sub> = 329.49 g/mol; CAS 390-64-7), also named *N*-(1-methyl-2-phenylethyl)- $\gamma$ -phenylbenzene propanamine, is often supplied as the lactate salt (FW = 419.56 g/mol), which is slightly soluble in water (approximately 0.5%) and melts at 140-142°C. **Target(s)**: Ca<sup>2+</sup>-dependent cyclic-nucleotide phosphodiesterase (1); Ca<sup>2+</sup>-transporting ATPase (2-5); and glibenclamide-sensitive K<sup>+</sup> channels (6,7). 1. Hidaka, Inagaki, Nishikawa & Tanaka (1988) *Meth. Enzymol.* **159**, 652. 2. Hasselbach (1974) *The Enzymes*, 3rd ed. (Boyer, ed.), **10**, 431. 3. **8-Prenylnaringenin**

This prenylated phytoestrogenic flavonoid (FW = 340.38 g/mol), isolated from hops (*Humulus lupulus*), inhibits cytochrome P450 systems CYP1A2 (1,2) and CYP19, or aromatase (3). 8-Prenylnaringenin also inhibits angiogenesis *in vitro* and *in vivo*. 1. Henderson, Miranda, Stevens, Deinzer & Buhler (2000) *Xenobiotica* **30**, 235. 2. Miranda, Yang, Henderson, *et al.* (2000) *Drug Metab. Dispos.* **28**, 1297. 3. Monteiro, Hecker, Azevedo & Calhau (2006) *J. Agric. Food Chem.* **54**, 2938.

**Prenyl Pyrophosphate, See specific metabolite**

**Prephenic Acid**

This dicarboxylic acid (FW<sub>free-acid</sub> = 226.19 g/mol; CAS 126-49-8; IUPAC: 1-carboxy-4-hydroxy-2,5-cyclohexadiene-1-pyruvate), an intermediate in the biosynthesis of L-phenylalanine and L-tyrosine, inhibits arogenate dehydratase (1,2), arogenate dehydrogenase, or cyclohexadienyl dehydrogenase (3), 3-deoxy-7-phosphoheptulonate synthase (4-7), and shikimate kinase (8). Under strongly acidic conditions (0.5 M HCl), this metabolite is unstable, converting to phenylpyruvic acid and liberating carbon dioxide and reaching 100% completion at 37° C in 10 min. The half-life at pH 4 and 0° C is seven hours. It is more stable at neutral or alkaline pH, but still decomposes upon heating to form *p*-hydroxyphenyllactate. 1. Xia, Ahmad, Zhao & Jensen (1991) *Arch. Biochem. Biophys.* **286**, 461. 2. Zhao, Xia, Fischer & Jensen (1992) *J. Biol. Chem.* **267**, 2487. 3. Lingens, Keller & Keller (1987) *Meth. **Pressinoic Acid**

This cyclic hexapeptide (FW = 774.86 g/mol; CAS 35748-51-7) corresponds to the N-terminal six amino acyl residues of vasopressin. If Phe-3 is replaced with Ile, the resulting cyclic hexapeptide, known as tocinoic acid, is identical to the N-terminal six amino acid residues of oxytocin. Pressinoic acid has no known pressor activity, perhaps as result of the loss of the carboxy-terminal tripeptide and/or the incorrect orientation of the Asn-5 side-chain (1) This hexapeptide also activates pineal acetyl-CoA hydrolase (2) and has a potent corticotrophin-releasing activity (3). Target(s): serotonin *N*-acetyltransferase (4). 1. Langs, Smith, Stezowski & Hughes (1986) *Science* **232**, 1240. 2. Namboodiri, Favilla & Klein (1982) *J. Biol. Chem.* **257**, 10030. 3. **P-RibPP, See 5-Phospho- $\alpha$ -D-riboseyl 1-Pyrophosphate**

**Prilocaine**

This powerful Na<sup>+</sup> channel-blocking anesthetic (FW<sub>free-base</sub> = 220.31 g/mol; CAS 721-50-6; HCl salt freely soluble in water) with properties resembling

those of lidocaine, is an antagonist of  $\beta_2$ -adrenergic receptors (1) as well as an inhibitor of monoamine oxidase (2), Na<sup>+</sup> channels (3), and Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (4). 1. Butterworth, James & Grimes (1997) *Anesth. Analg.* **85**, 336. 2. Yasuhara, Wada, Sakamoto & Kamijo (1982) *Jpn. J. Pharmacol.* **32**, 213. 3. Tella & Goldberg (1998) *Pharmacol. Biochem. **Primaquine**

This antimalarial (FW<sub>free-base</sub> = 259.35 g/mol; CAS 90-34-6), also known systematically as *N*<sup>6</sup>-(6-methoxy-8-quinolinyl)-1,4-pentanediamine, was used widely during World War II, until it was discovered that individuals with glucose-6-phosphate dehydrogenase deficiency are especially sensitive to this and related antimalarial drugs. Primaquine retards nonenzymatic formation of hemozoin, the malaria parasite pigment that is a paracrystalline aggregate of ferriprotoporphyrin IX (FP-Fe(III)) produced during hemoglobin digestion by the *Plasmodium* enzyme plasmepsin. Because hemozoin formation is essential for FP-Fe(III) detoxification within the parasite, quinolines are highly effective antimalarials. Target(s): acetylcholinesterase (1); alcohol dehydrogenase (2,3); aminopyrine *N*-demethylase (4); calcium-release-activated current (5); CYP3A4 (6,7,19); estrogen 2-hydroxylase (8); glutathione *S*-transferase (9); histamine *N*-methyltransferase, weakly inhibited (10); HIV integrase (11); monoamine oxidases A and B (12); myeloperoxidase (13); Na<sup>+</sup> channels (14); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (15); peroxidase (13); phospholipase A<sub>1</sub> (16); phospholipase A<sub>2</sub> (16); protein biosynthesis (17); protein kinase A (18); quinine 3-monoxygenase (19); tolbutamide hydroxylase (20); and vesicular transport (5). 1. **Primsulfuron-methyl**

This post-emergence herbicide (FW = 468.34 g/mol) inhibits acetolactate synthase and branched-chain amino acid biosynthesis (1-4). 1. Zohar, Einav, Chipman & Barak (2003) *Biochim. Biophys. Acta* **1649**, 97. 2. Choi, Noh, Choi, *et al.* (2006) *Bull. Korean Chem. Soc.* **27**, 1697. 3. Yang & Kim (1997) *J. Biochem. Mol. Biol.* **30**, 13. 4. Choi, Yu, Hahn, Choi & Yoon (2005) *FEBS Lett.* **579**, 4903.

**Prinomastat**

This antineoplastic agent (FW = 423.51 g/mol; NLM Unique Identifier C113282), also known as AG3340, inhibits a number of matrix metalloproteinases, including collagenase-3 ( $K_i = 38$  pM), gelatinase A ( $K_i = 83$  pM), stromelysin 1 ( $K_i = 0.27$  nM), and interstitial collagenase ( $K_i = 8.2$  nM). Note that both the 3- and 4-pyridyl structures have been reported for prinomastat; however, the 4-analogue is the original structure reported for this inhibitor. **Target(s):** ADAM 17 endopeptidase, or tumor necrosis factor- $\alpha$  converting enzyme, or TACE (1,2); ADAMTS-4 endopeptidase, or aggrecanase (3); collagenase-3 (2,4,5); gelatinase A (1,2,4,5); gelatinase B (4,5); interstitial collagenase (1,2,4,5); matrilysin (4,5); membrane-type matrix metalloproteinase-1, or matrix metalloproteinase 14 (4-6); and stromelysin 1 (2,4,5). 1. Leung, Abbenante & Fairlie (2000) *J. Med. Chem.* **43**, 305. 2. Holms, Mast, Marcotte, et al. (2001) *Bioorg. Med. Chem. Lett.* **11**, 2907. 3. **Pristinamycin IA**

This antibacterial agent (FW = 866.97 g/mol; CAS 3131-03-1), also known as streptogramin B, mikamycin IA, ostreogrycin B, synergistin B, and vernamycin B $\alpha$ , is one of two components produced by *Streptomyces pristinaespiralis*, the other component being pristinamycin IIA, or virginiamycin M (1). This white powder inhibits protein biosynthesis by binding to the 50S ribosomal subunit. Greater inhibition is observed with ribosomes from Gram-positive microorganisms compared to those from Gram-negative bacteria. **Target(s):** peptidyltransferase (2); and protein biosynthesis (1-3). 1. Jiménez (1976) *Trends Biochem. Sci.* **1**, 28. 2. Porse & Garrett (1999) *J. Mol. Biol.* **286**, 375. 3. Pestka (1974) *Meth. Enzymol.* **30**, 261.

**Pritelivir**

This antiviral (FW = 402.49 g/mol; CAS 348086-71-5), also named BAY 57-1293 and *N*-methyl-*N*-(4-methyl-5-sulfamoyl-1,3-thiazol-2-yl)-2-[4-(pyridin-2-yl)phenyl]acetamide, inhibits replication of herpes simplex virus (HSV) types 1 and 2 by blocking the enzymatic activity of the viral primase-helicase complex ( $IC_{50} \approx 20$  nM). Although pritelivir is highly active against HSV-1 and superior to acyclovir in Vero cells, drug resistance has been detected in two different strains of HSV at  $10^{-4}$  to  $10^{-5}$ , and resistant variants are present, even before the selection was applied (2). Resistant variants did not readily revert to a drug-sensitive phenotype in the absence of the inhibitor, and representative pritelivir-resistant variants were cross-resistant to BILS-22-BS, another helicase-primase inhibitor (HPI). Notably, variants resistant to BAY 57-1293 retained sensitivity to the nucleoside analogue, ACV (2). Two HSV-1 mutants, that are 100x and >3000x resistant to pritelivir, have substitutions in the UL5 helicase protein (e.g., one with A4V and K356Q mutations, and the other with a single

G352R mutation) (3). Marker transfer experiments confirmed that K356Q and G352R (near the predicted functional domain of HSV-1 helicase) are the drug-resistance mutations that are directly associated with differences in virus growth in tissue culture (3). Moreover, to achieve maximum potency, pritelivir interacts with both components (UL5 and UL52) of the helicase-primase complex, but BILS-22-BS does not (4). Herpes simplex type 1 (HSV1) infected cells form  $\beta$ -amyloid ( $A\beta$ ) and abnormally phosphorylated Tau (P-Tau) *in vitro*, and pritelivir is more effective than acyclovir in preventing these Alzheimer-associated proteins (5). 1. **Privine Hydrochloride, See Naphazoline****[Pro<sup>3</sup>]-GIP (Mouse)**

This GIPR antagonist (FW = 4971.62 g/mol; Sequence: YAPGTFISDY SIAMDKIRQQDFVNWLLAQRGKKSDWKHNITQ, noting Prolyl for Glutamyl substitution at Position-3; Solubility: 2 mg/mL in H<sub>2</sub>O) inhibits Glucose-dependent Insulinotropic Polypeptide Receptor-mediated release of insulin from pancreatic  $\beta$ -cells *in vitro* (1). Although native GIP (also previously termed Gastric Inhibitory Polypeptide) is rapidly degraded by human plasma (~40 % remains after 8 hours), (Pro<sup>3</sup>)GIP is completely stable, even after 24 h. In CHL cells expressing the human GIP receptor, (Pro<sup>3</sup>)GIP antagonizes the 3',5'-cyclicAMP stimulatory effects of  $10^{-7}$  M native GIP ( $IC_{50} = 2.6$   $\mu$ M). In the clonal pancreatic  $\beta$ -cell line (BRIN-BD11), (Pro<sup>3</sup>)GIP dose dependently inhibits GIP-stimulated insulin release by 1.2x to 1.7x over the  $10^{-13}$ - $10^{-8}$  M concentration range (1). In *ob/ob* mice, it blocks the effects of GIP on insulin release and plasma glucose levels. Also improves intraperitoneal glucose tolerance, insulin sensitivity, and glucose response to feeding in *ob/ob* mice (1). Early administration of GIP<sup>P3E</sup> prevents development of diabetes and related metabolic abnormalities associated with genetically inherited obesity in *ob/ob* mice (2). 1. Gault, O'Harte, Harriott & Flatt (2002) *Biochem. Biophys. Res. Commun.* **290**, 1420. 2. Irwin, McClean, O'Harte, et al. (2007) *Diabetologia* **50**, 1532.

**PRO 140**

This first-in-class, humanized anti-CCR5 monoclonal antibody (MW  $\approx$  150,000) potently inhibits HIV-1 entry and replication in both primary peripheral blood mononuclear cells and primary macrophages at concentrations that do not affect CCR5's chemokine receptor activity (1). CCR5 is a member of G-protein-coupled, seven transmembrane segment receptors, also known as C-C motif chemokine receptor-5. Acute HIV infection almost always involves virus binding to the CCR5 co-receptor, and, during advanced HIV disease, the virus may shift to the alternate CXCR4 receptor, but half of the virus still binds to the CCR5 co-receptor (2). When tested as single intravenous doses (ranging up to 5 mg/kg of body weight or three subcutaneous doses of up to 324 mg), viral loads reached their nadir by post-treatment day-12 and remained significantly reduced through day-29, with no dose-limiting toxicity (3). Although intravenously administered HIV drugs are unlikely to rival their orally available, small-molecule counterparts (e.g., aplaviroc, viviviroc, maraviroc, and SCH-C, or SCH 351125), PRO 140 nonetheless promises to be of great prophylactic value in lowering the risk of HIV infection in rape victims as well in other clinical settings. PRO 140 will also have enduring value as a tool for investigating the cellular mechanisms underlying HIV infection. 1. Trkola, Ketas, Nagashima, et al. (2001) *J. Virol.* **75**, 579. 2. **Proadifen**

This nonselective P450 inhibitor (FW<sub>free-base</sub> = 353.50 g/mol; CAS 302-33-0; 62-68-0 for the HCl salt), also known as SKF-525A,  $\beta$ -diethylaminoethyl 2,2-diphenylpropylacetate, and *N,N*-diethylaminoethyl 2,2-diphenylvalerate, blocks glibenclamide-sensitive K<sup>+</sup> channels, including ATP-sensitive inward rectifier potassium channel 8 (KIR6.1). As a nonselective inhibitor of cytochrome P450 systems, proadifen also inhibits

drug metabolism, thereby potentiating the action of many pharmaceuticals. For example, proadifen inhibits the demethylation of 2-methoxyestrogens (1). **Target(s):** aldehyde oxidase (2,3); alkanal monooxygenase, FMN-linked (4,5); aromatase, or CYP19 (6); bacterial luciferase, or alkanal monooxygenase, FMN-linked (4,5); benzoate 4-monooxygenase (45); bromomethane monooxygenase; calcium influx; *ent*-copalyl-diphosphate synthase (9); CYP2C11 (10); cytochrome P450 (1,6,10-23); diamine *N*-acetyltransferase (34); *N,N*-dimethylaniline demethylase (24); ecdysone 20-monooxygenase (37); ethoxyresorufin *O*-deethylase (14); flavin-containing monooxygenase, or dimethylaniline-*N*-oxide aldolase (17,18); glyceollin synthase (42); 2-hydroxyisoflavanone synthase (41); 25-hydroxyvitamin D<sub>3</sub> 24-monooxygenase (24); isopentenyl-diphosphate  $\Delta$ -isomerase, or isopentenyl-pyrophosphate  $\Delta$ -isomerase (25,26); *ent*-kaurene synthase (9); leukotriene B<sub>4</sub> 20-hydroxylase (12); (*S*)-limonene 3-monooxygenase (44); (*S*)-limonene 6-monooxygenase (44); (*S*)-limonene 7-monooxygenase (44); methane monooxygenase (27); monoamine oxidase (28,29); NADPH:cytochrome P450 reductase (16); nitric-oxide synthase, neuronal (30); pentoxyresorufin *O*-deethylase (16); phenol *O*-methyltransferase (35); progesterone 11 $\alpha$ -monooxygenase (38); steroid 11 $\beta$ -monooxygenase (40); steroid 21-monooxygenase, or CYP21A1, weakly inhibited (39); sterol 14-demethylase, or CYP51 (43); styrene monooxygenase (31); thiol *S*-methyltransferase (36,37); thromboxane production (32); and trimethylamine-oxide aldolase (33). 1. ### Probenecid

This prototypical uricosuric agent (FW<sub>free-acid</sub> = 285.36 g/mol; CAS 57-66-9; pK<sub>a</sub> = 5.8), also known as 4-[[dipropylamino]sulfonyl]benzoic acid, inhibits

the renal excretion of organic anions and reduces tubular reabsorption of urate. Probenecid has also been used to treat patients with renal impairment, and, because it reduces the renal tubular excretion of other drugs, has been used as an adjunct to antibacterial therapy. **Target(s):** cadmium-transporting ATPase (1), cysteine-*S*-conjugate *N*-acetyltransferase, weakly inhibited (2), glucuronosyltransferase, or UDP-glucuronosyltransferase (3-7), glutathione *S*-transferase (8,9), glutathione-transporting ATPase (1), leukotriene-C<sub>4</sub> synthase (9), and organic anion transporter (10,11). 1. ### Probestin

This aminopeptidase inhibitor (FW = 502.61 g/mol; CAS 123652-87-9), also known as *N*-[(2*S*,3*R*)-3-amino-2-hydroxy-4-phenylbutanoyl]-*L*-leucyl-*L*-prolyl-*L*-proline, from a strain of *Streptomyces azureus* inhibits dipeptidyl-peptidase III (1), glutamyl aminopeptidase, or aminopeptidase A (2), membrane alanyl aminopeptidase, aminopeptidase M, or aminopeptidase N, K<sub>i</sub> = 19 nM (2-9); Xaa-Trp aminopeptidase, or aminopeptidase W (2,10,11). 1. ### Probuco

This is an orally active cholesterol-reducing agent (FW = 516.85 g/mol; CAS 23288-49-5), also known as Lorelco, reduces total cholesterol and low-density-lipoprotein cholesterol levels and also serves as a free radical-scavenging antioxidant. **Target(s):** Ca<sup>2+</sup>-sensitive K<sup>+</sup> channel (1); lipid efflux (2); low density lipoprotein oxidation (3,4); and retinyl ester hydrolase (5). 1. Howland, Daughtey, Donatelli & Theofrastous (1984) *Pharmacol. Res. Commun.* **16**, 1057. 2. Tsujita & Yokoyama (1996) *Biochemistry* **35**, 13011. 3. ### Procainamide

This local anesthetic and cardioactive drug (FW<sub>free-base</sub> = 235.33 g/mol; CAS 51-06-9; 614-39-1 for HCl salt), also known as 4-amino-N-[2-(diethylamino)ethyl]benzamide and pronestyl, is a Na<sup>+</sup> channel blocker that is a widely used antiarrhythmic agent. Along with hydralazine, RG108, procaine, IM25, and disulfiram, it is also a potent nonnucleoside DNA methylase inhibitor. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** acetylcholinesterase (1); ATPase, mitochondrial (2); cocaine degradation (3); DNA methyltransferase (4,5); F<sub>1</sub> ATPase, H<sup>+</sup>-transporting two-sector ATPase (6); K<sup>+</sup> channel (7,8); lactate dehydrogenase, weakly inhibited (9); Na<sup>+</sup> channel (7,8); and Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (10-13). **1.** Talesa, Romani, Rosi & Giovanni (1996) *Eur. ### Procaine

This local anesthetic and vasodilator (FW<sub>free-base</sub> = 236.31 g/mol; CAS 59-46-1; 51-05-8 for the HCl salt), also known as 4-aminobenzoic acid 2-(diethylamino)ethyl ester, is a Na<sup>+</sup> channel blocker and calmodulin antagonist. It also constricts blood vessels, reducing bleeding. The hydrochloride is Novocain, which is highly water-soluble (~1 g/mL). Procaine is hydrolyzed by esterases to *p*-aminobenzoate and diethylaminoethanol, and is somewhat unstable in solution and is slowly oxidized in the presence of heavy metal ions and alkali. Procaine was first synthesized in 1905 by German chemist Alfred Einhorn, who named it Novocain (novel + cocaine). Prior to its discovery, cocaine was the most commonly used local anesthetic. Procaine became the first injectable man-made local anesthetic; epinephrine was often co-administered to counteract its vasodilator effects. Along with hydralazine, RG108, procainamide, IM25, and disulfiram, procaine is also a potent nonnucleoside DNA methylase inhibitor. **Target(s):** acetylcholine receptor (1-3); acetylcholinesterase (4,5,28); acid phosphatase (26); 1-acylglycerophosphocholine *O*-acyltransferase, or lysophosphatidylcholine *O*-acyltransferase, or alkanal monooxygenase (7); bacterial luciferase, or alkanal monooxygenase (7); calmodulin (8); calmodulin stimulation of Ca<sup>2+</sup>-dependent ATPase (8); calmodulin stimulation of cyclic nucleotide phosphodiesterase (8); cholesterol esterase, weakly inhibited (9); cholinesterase, or butyrylcholinesterase (10,27); electron transport, mitochondrial, or cytochrome *c* oxidase, or durohydroquinone oxidase, or succinate oxidase, or NADH oxidase, or succinate dehydrogenase, or succinate: cytochrome *c* oxidoreductase, or NADH:cytochrome *c* oxidoreductase (11); F<sub>1</sub> ATPase, or H<sup>+</sup>-transporting two-sector ATPase (12); histamine *N*-methyltransferase, mildly inhibited (30); lecithin:cholesterol acyltransferase, or LCAT, weakly inhibited (13); *N*-methyl-D-aspartate (NMDA) receptor (14,15); monoamine oxidase, weakly inhibited (16-18); Na<sup>+</sup> channel (19,20); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase, weakly inhibited (21-23); phospholipase A<sub>2</sub>, weakly inhibited (24,25); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, or ACAT, weakly inhibited (6). **1.** Yost & Dodson (1993) *Cell. Mol. Neurobiol.* **13**, 159. **2.** Forman & Miller (1989) *Biochemistry* **28**, 1678. **3.** Shiono, Takeyasu, Udgaonkar, *et al.* (1984) *Biochemistry* **23**, 6889. **4.** al-Jafari, Kamal,

### Prochloraz

This imidazole fungicide (FW = 376.67 g/mol; CAS 67747-09-5; M.P. = 38.5-41°C) is widely applied to packaging used for cereals, fruits, and vegetables. Prochloraz exerts multiple mechanisms of action *in vitro*, acting to antagonize androgen and oestrogen receptors, to agonize aryl hydrocarbon receptors, and to inhibit aromatase activity. **Target(s):** aldrin epoxidase (1); aromatase, or CYP19 (2,3); (*S*)-canadine synthase (4); cytochrome P450 (2,3,5-8); 7-ethoxyresorufin-*O*-deethylase (1,7); methyltetrahydro-protoberberine 14-monooxygenase (9); protopine 6-monooxygenase (10); salutaridin synthase (11); steroid 16 $\alpha$ -monooxygenase (2); steroid 17 $\alpha$ -monooxygenase (2); steroid 21-monooxygenase (2); steroid 5 $\alpha$ -reductase (8); sterol 14-demethylase, or CYP51 (12,13). **1.** Snegaroff & Bach (1989) *Xenobiotica* **19**, 255. **2.** Mason, Carr & Murry (1987) *Steroids* **50**, 179. **3.** Vinggaard, Hnida, Breinholt & Larsen (2000) *Toxicol. ### Prochlorperazine

This antipsychotic drug (FW<sub>free-base</sub> = 373.95 g/mol; CAS 58-38-8), systematically named as 2-chloro-10-(3-(4-methyl-1-piperazinyl)propyl)-10H-phenothiazine, is a D<sub>2</sub> antagonist that is used in the treatment of dizziness and vertigo. Prochlorperazine inhibits adenylate cyclase (1-3). Prochlorperazine also exhibits antiemetic properties. **1.** Iversen (1975) *Science* **188**, 1084. **2.** Iversen (1976) *Trends Biochem. Sci.* **1**, 121. **3.** Wolff & Jones (1970) *Proc. Natl. Acad. Sci. U.S.A.* **65**, 454.

**Proscillaridin A**

This cardiac glycoside (FW = 530.65 g/mol; CAS 466-06-8) was identified as an inhibitor of HIF-1 $\alpha$  protein translation and HIF-2 $\alpha$  mRNA expression in a cell-based screen of a library of drugs (at 50 nM in the case of Proscillaridin A) currently in clinical trials (See also Digoxin; Oabain). 1. Zhang, Qian, Tan, *et al.* (2008) *Proc. Natl. Acad. Sci. USA* **105**, 19579.

**Procion Blue H-B**

This reactive dye (FW<sub>trisodium-salt</sub> = 840.11 g/mol;  $\lambda_{\max}$  = 607 nm), also known as Reactive Blue 2 and Cibacron Blue F3G-A, is a sulfonated triazine often used to probe nucleotide binding sites. Procion Blue H-B is also a P2Y purinoceptor antagonist and is one of the most potent antagonists for ATP-activated channels (See also Cibacron Blue). When immobilized on a support matrix, this triazine can be used to purify proteins that bind nucleotides or nucleotide-containing coenzymes. Note: Given its tendency to bind in place of nucleotides, this agent is apt to have inhibitory effects beyond those listed below. Target(s): aldehyde reductase (1); alkaline phosphatase (2); ATP-activated channels (3); carbonyl reductase (4); choline O-acetyltransferase (5); choline-phosphate cytidyltransferase (6); coenzyme F<sub>420</sub> hydrogenase (7); ferredoxin:NADP<sup>+</sup> oxidoreductase (8); glucose-6-phosphate dehydrogenase (9); glutathione S-transferase (10); hexokinase (11); NAD<sup>+</sup> nucleosidase, or NADase, or NAD<sup>+</sup> glycohydrolase (12); nucleotide diphosphatase (13); phosphoglycerate kinase (14); P2Y purinoceptor (15,16); thymidylate synthase (17); and UDP-glucose 4-epimerase (18). 1. **Procion Red HE-3B**

This triazine dye (FW<sub>free-acid</sub> = 1338.11 g/mol), which inhibits several enzymes, is frequently immobilized on a polymeric matrix and used in dye-affinity chromatography in protein purification. Note: Given its tendency to bind in place of nucleotides, this agent is apt to have inhibitory effects beyond those listed below. Target(s): aldehyde reductase, or alcohol dehydrogenase, NADP<sup>+</sup>-dependent (1); alkaline phosphatase (2); ferredoxin hydrogenase (3); ferredoxin:NADP<sup>+</sup> reductase (4,5); glucose-6-phosphate dehydrogenase (6); hexokinase (7); and 6-phosphogluconate dehydrogenase (8). 1. **Procion Red MX-2B**

This dye (FW<sub>free-acid</sub> = 648.39 g/mol), also known as Reactive Red 1 and Procion Brilliant Red 2B, inhibits several enzymes. Note: Given its tendency to bind in place of nucleotides, this agent is apt to have inhibitory effects beyond those listed below. Target(s): 2,4-dichlorophenol hydroxylase (1); ferredoxin:NADP<sup>+</sup> oxidoreductase (2); glutamate carboxypeptidase, or carboxypeptidase G-2 (3); and ribulose-5-phosphate kinase (4). 1. Radjendirane, Bhat & Vaidyanathan (1991) *Arch. Biochem. Biophys.* **288**, 169. 2. Levy & Bets (1988) *Biochim. Biophys. Acta* **955**, 236. 3. Hughes, Sherwood & Lowe (1984) *Eur. J. **Proctolin**

This insect neuromodulator/neurotransmitter/ neurohormone (FW = 648.76 g/mol; CAS : 100930-02-7; Sequence: L-Arg-L-Tyr-L-Leu-L-Pro-L-Thr) exerts its proctolinergic action by changing the way impulses are transmitted across a synapse, often assisting a more common neurotransmitter, such as glutamate. Mode of Action: Proctolin potently stimulates visceral and skeletal muscles contraction of a number of insects. The *Drosophila melanogaster* proctolin receptor (CG6986) is an orphan G-protein coupled receptor and is strongly expressed in the head, the larval hindgut, the aorta and on neuronal endings in adult hearts. Unlike classical neurotransmitters, proctolin does not change the postsynaptic conductance. It also modulates reproductive tissue, stimulating contractions of the oviducts in the American cockroach *Periplaneta americana*, as well as *Leucophaea maderae*, *L. migratoria*, and spermathecae in *L. migratoria* and *Rhodnius prolixus*. Proctolin also speeds up heart rate in some insects. Target(s); dipeptidyl-peptidase III, or aminoenkaphalinase (1,2). 1. Hui, Hui, Ling & Lajtha (1985) *Life Sci.* **36**, 2309. 2. Abramic, Schleuder, Dolovcak, *et al.* (2000) *Biol. Chem.* **381**, 1233.

### Procyanidins

These redox-active catechin oligomers (procyanidin B-2; FW = 575.50 g/mol; procyanidin B-3; FW = 575.50 g/mol) exhibit potent antioxidant activity. After lignin, they are among the most abundant natural phenolics. Fourteen dimeric, eleven trimeric, and one tetrameric procyanidins already identified within grape seeds. **Target(s):** 1-alkylglycerophosphocholine *O*-acetyltransferase, inhibited by procyanidin B-2 3,3'-di-*O*-gallate and procyanidin B-5 3,3'-di-*O*-gallate (1); 5-lipoxygenase, *or* arachidonate 5-lipoxygenase, inhibited by di- and trimeric procyanidins (2); 12-lipoxygenase, *or* arachidonate 12-lipoxygenase, inhibited most by decameric procyanidins (3); 15-lipoxygenase, *or* arachidonate 15-lipoxygenase, inhibited most by decameric procyanidins (3); myosin-light-chain kinase (4); peptidyl-dipeptidase A, *or* angiotensin I-converting enzyme (5,6); protein kinase A (4); protein kinase C, inhibited by procyanidin B-2 and procyanidin C-1 (4,7); squalene monooxygenase, *or* squalene epoxidase, inhibited by procyanidin B-2 3,3'-di-*O*-gallate and procyanidin B-5 3,3'-di-*O*-gallate (8); tyrosinase, *or* monophenol monooxygenase, weakly inhibited (9). 1. ### Prodigiosin

This red bacterial pigment (FW<sub>free-base</sub> = 323.44 g/mol; melting point = 151-152°C) is an antibiotic produced by *Serratia marcescens* (formerly *Chromobacterium prodigiosum*). Prodigiosin is the parent member of a class of pyrrole-containing natural products that exhibit immunosuppressive, cytotoxic, and apoptotic activity and can facilitate copper-promoted oxidative double-strand DNA cleavage through reductive activation of Cu<sup>2+</sup>. They also uncouple lysosomal vacuolar-type ATPases by promoting H<sup>+</sup>/Cl<sup>-</sup> symport activity. The solid pigment is dark red and displays a green reflex. Acidic aqueous solutions are also red, but neutral or alkaline solutions are orange-yellow. **Target(s):** DNA topoisomerase I (1); DNA topoisomerase II (1); F<sub>0</sub>F<sub>1</sub> ATPase, *or* H<sup>+</sup>-transporting two-sector ATPase, as an uncoupler (2); H<sup>+</sup>/K<sup>+</sup>-ATPase, as an uncoupler (3); proton translocation, as an uncoupler (4); and *Serratia marcescens* nuclease (5). 1. Montaner, Castillo-Avila, Martinell, *et al.* (2005) *Toxicol. Sci.* **85**, 870. 2.

### Prodiptine

This name refers to two distinctly different molecular entities: the phosphonate (above left; FW<sub>free-base</sub> = 400.41 g/mol), also known as diphenyl 1-(*S*)-prolylpyrrolidine-2-(*R,S*)-phosphonate and Pro-Pro-diphenylphosphonate, that inhibits CYP2D6 (1) and dipeptidyl peptidase IV (2); and the antiparkinson drug (above right, FW<sub>free-base</sub> = 279.43 g/mol), also known as 1-(1-methylethyl)-4,4-diphenylpiperidine, that inhibits CYP2D6 and monoamine oxidase (3). 1. de Groot, Bijloo, van Acker, *et al.* (1997) *Xenobiotica* **27**, 357. 2. De Meester, Belyaev, Lambeir, *et al.* (1997) *Biochem. Pharmacol.* **54**, 173. 3. Planz, Palm & Quiring (1973) *Arzneimittelforschung* **23**, 281.

### Profenofos

This broad-spectrum thiophosphorotriester insecticide (FW = 373.64 g/mol; CAS 41198-08-7), also known as Curacron™ and Selecron™™ and named systematically as *O*-(4-bromo-2-chlorophenyl) *O*-ethyl *S*-propyl phosphorothioate, inhibits cholinesterase's and other hydrolases. After feeding on a treated plant or crawling over a treated leaf, the pest is first paralyzed and then quickly succumbs. *In vitro*, the (–)-isomer is 34x more active as a cholinesterase inhibitor. Chromosome aberrations in spermatogonia and sperm abnormalities have been reported in Curacron-treated mice. **Target(s):** acetylcholinesterase (1-4); acylglycerol lipase, *or* monoacylglycerol lipase (4); 1-alkyl-2-acetyl-glycerophosphocholine esterase, *or* platelet-activating-factor acetylhydrolase (5); butyrylcholinesterase (1); carboxylesterase (1,4); fatty acid amide hydrolase, *or* anandamide amidohydrolase (4); lysophospholipase (4); and neuropathy target esterase (4). 1. Leader & Casida (1982) *J. Agric. Food Chem.* **30**, 546. 2. El-Sebae, Enan, Soliman, El-Fiki & Khamees (1981) *J. Environ. Sci. Health B* **16**, 475. 3. Quistad, Fisher, Owen, Klintonberg & Casida (2005) *Toxicol. Appl. Pharmacol.* **205**, 149.

### Proflavine

This dye (FW<sub>free-base</sub> = 209.25 g/mol; CAS 92-62-6; orange-red solid; M.P. = 281 or 288°C; soluble in water; pK<sub>a</sub> = 9.65; solutions are light sensitive; insoluble in organic solvents such as benzene, diethyl ether, and chloroform), also known as proflavin and 3,6-acridinediamine, is a mutagen that intercalates in double-stranded DNA, inhibiting both DNA and RNA biosynthesis. Proflavine can also participate in the photooxidation of proteins (*e.g.*, dopa decarboxylase (1)). In addition, proflavine can inhibit a number of enzymes directly. For example scriflavine, a mixture of proflavine with 3,6-diamino-10-methylacridinium chloride, inhibits protein kinase C. **Target(s):** L-amino-acid oxidase (2); carbonic anhydrase, *or* carbonate dehydratase, K<sub>i</sub> ≈ 10 mM (3); chymotrypsin (4-7,25); DNA (cytosine-5)-

methyltransferase (8); DNA-directed RNA polymerase (9,29); dopa decarboxylase (1);  $F_1F_0$  ATPase, or  $F_1F_0$  ATP synthase, or  $H^+$ -transporting two-sector ATPase (10); ficain, or ficin (11); glutamate decarboxylase (12); lysozyme (13); monoamine oxidase (14); NADH:cytochrome  $b_5$  reductase (15); nucleoside-triphosphatase, nuclear-envelope (16,26); papain (11); poly(ADP-ribose) glycohydrolase (17); polynucleotide adenyltransferase, or poly(A) polymerase (27,28); pyruvate kinase (18); RNA-directed DNA polymerase (19); thrombin (20); tRNA adenylyltransferase (22); tRNA (guanine- $N^2$ -)-methyltransferase (30); tRNA cytidylyltransferase (22); tRNA methyltransferases (8,21); tRNA nucleotidyltransferase (22); and trypsin (4,7,23,24). 1. ### Profluralin

This pre-planting herbicide and anti-mitotic agent (FW = 347.29 g/mol; CAS 26399-36-0; M.P. = 33-36°C), also known as Tolban® and named systematically as *N*-(cyclopropylmethyl)-2,6-dinitro-*N*-propyl-4-(trifluoromethyl)benzamide aids in controlling such weeds as barnyard grass, panicums, foxtails, goosegrass, crabgrass, witchgrass, pigweed, Florida pursley, kochia, pigweed, purslane, stinkgrass, and sprangletop. **Target(s):** tubulin polymerization (microtubule self-assembly) (1). 1. Schibler & Huang (1991) *J. Cell Biol.* **113**, 605.

### Progabide

This anticonvulsant, antidepressant, and anti-parkinson disease drug (FW = 334.78 g/mol; CAS 62666-20-0), which displaces  $\gamma$ -aminobutyrate from its binding sites in membranes and behaves as a GABA agonist, inhibits  $\gamma$ -aminobutyrate receptor (1,2), microsomal epoxide hydrolase (3), and pyridoxal kinase (4). 1. Kaplan, Raizon, Desarmenien, et al. (1980) *J. Med. Chem.* **23**, 702. 2. Lloyd, Arbilla, Beaumont, et al. (1982) *J. Pharmacol. Exp. Ther.* **220**, 672. 3. ### Progesterone

This steroid hormone (FW = 314.47 g/mol; CAS 57-83-0), also known as progestin (although the term progestin historically refers to a mixture of steroids, with progesterone is the major component), pregn-4-ene-3,20-dione, and 4-pregnene-3,20-dione, is synthesized in the corpus luteum and is secreted during the latter half of the menstrual cycle. Progesterone induces the biosynthesis of uterus-specific proteins. Progesterone is also present in the testis and the adrenal cortex. It modulates the acrosome reaction in human sperm cells and also exhibits antigluco-corticoid and antiminerocorticoid activity (1). This hormone has also been identified in certain plants (e.g., *Holarrhena floribunda*). **Target(s):** aldehyde dehydrogenase (2); aldehyde oxidase (3); aldose 1-epimerase, or mutarotase, weakly inhibited (4); cortisol sulfotransferase (29-31);  $F_1F_0$  ATPase, or  $H^+$ -transporting two-sector ATPase (5); glucose-6-phosphate dehydrogenase (however, note that (6) reports no inhibition (2,7,8); glutamate dehydrogenase (2,9,11); hydroxyindole *O*-methyltransferase (11); 15-hydroxyprostaglandin dehydrogenase (12);  $3\beta$ -hydroxysteroid dehydrogenase (13,14);  $3\beta$ -hydroxy-5 $\alpha$ -steroid dehydrogenase (15); 21-hydroxysteroid dehydrogenase,  $NAD^+$ -dependent (16); isocitrate dehydrogenase, weakly inhibited (6); ketosteroid monooxygenase, or androst-4-ene-3,17-dione monooxygenase, inhibits lactonization of 17-ketosteroids (37);  $Na^+/K^+$ -exchanging ATPase (5); 6-phosphogluconate dehydrogenase; retinol *O*-fatty-acyltransferase (19,34,35); steroid  $\Delta$ -isomerase (20,21); steroid 21-monooxygenase (20,38); steroid sulfatase (21); steroid sulfotransferase (30); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, or ACAT (22,23,34-36); sterol demethylase (24); sterol esterase, or cholesterol esterase (27,28); tryptophan 2,3-dioxygenase (29); and xanthine oxidase (30). 1. **Progestin, See Progesterone**

### Proglumide

This anticholinergic agent (FW<sub>free-acid</sub> = 334.42 g/mol; CAS 6620-60-6), also known as DL-4-benzamido-N,N-dipropylglutamic acid and 4-(benzoylamino)-5-(dipropylamino)-5-oxopentanoic acid, is a cholecystokinin receptor antagonist. Proglumide A also exerts an inhibitory effect on gastric secretion and reduces gastrointestinal motility. It finds use clinically as a therapy for gastrointestinal ulcers. **Target(s):** cholecystokinin receptor (1); gastrin receptor (2). 1. Hahne, Jensen, Lemp & Gardner (1981) *Proc. Natl. Acad. Sci. U.S.A.* **78**, 6304. 2. Johnson & Guthrie (1984) *Amer. J. Physiol.* **246**, G62.

### Progranulin

This 93-residue, cysteine-rich granulin precursor (MW = 88 kDa; Symbol: PGRN), also called proepithelin and PC cell-derived growth factor, is a pleiotrophic growth factor with important roles in maintaining and regulating the homeostatic dynamics of normal tissue development, proliferation, regeneration, and host-defense. PGRN also has potent anti-inflammatory properties, and its deregulation is associated with rheumatoid arthritis and inflammatory bowel disease. Progranulin plays crucial roles in preserving bone mass by inhibiting TNF- $\alpha$ -induced osteoclastogenesis and promoting osteoblastic differentiation in mice (1). Recombinant PGRN protein strongly inhibits TNF and the expression of interferon- $\gamma$ -induced chemokines CXCL9 and CXCL10 (2). Moreover, in PGRN<sup>null</sup> mice, many chemokines, including CXCL9 and CXCL10, are significantly induced (2). 1. Noguchi, Ebina, Hirao, *et al.* (2015) *Biochem. Biophys. Res. Commun.* **465**, 638. 2. Mundra, Jian, Bhagat & Liu (2016) *Sci. Rep.* **6**, 21115.

### Proguanil, See Chlorguanide

### Prohexadione

This plant growth regulator (FW<sub>free-acid</sub> = 178.19 g/mol), also named 3-hydroxy-5-oxo-4-propionylcyclohex-3-ene-1-carboxylic acid, inhibits the biosynthesis of growth active gibberellins (GAs), thereby reducing longitudinal shoot growth. Prohexadione resembles 2-oxoglutaric acid, the co-substrate the dioxygenases that catalyze hydroxylation steps in late stages of GA biosynthesis. Its primary target of is 3 $\beta$  hydroxylation, thereby reducing levels of GA<sub>1</sub> (the highly active form) and bringing about the accumulation of its immediate precursor (inactive). **Targets:** flavanone 3-dioxygenase (1) flavonol synthase (1); and gibberellin biosynthesis (1). 1. Halbwirth, Fischer, Schlangen, *et al.* (2006) *Plant Sci.* **171**, 194.

### L-Prolinal

This proline derivative (FW = 100.14 g/mol), with an aldehyde that undoubtedly hydrates to a tetrahedral species, inhibits tripeptide aminopeptidase. Aldehyde hydrates and bestatin resemble intermediates formed during direct attack by water on peptide substrates. Alternatively, inhibitors of both kinds might form derivatives of an active site nucleophile, resembling intermediates in a double-displacement mechanism. Exchange experiments with H<sub>2</sub><sup>18</sup>O suggest that bestatin is bound intact by leucine aminopeptidase, lending support to the first mechanism. 1. Frick & Wolfenden (1985) *Biochim. Biophys. Acta* **829**, 311.

### L-Proline

This pyrrolidine (FW = 115.13 g/mol; pK<sub>1</sub> = 1.95; pK<sub>2</sub> = 10.64), symbolized as either Pro or P, is one of the twenty proteogenic amino acids. Its five-

membered ring is usually puckered, with the  $\gamma$  carbon (position C4 of the ring) out of the plane by about 0.5 Å. There are six codons that code for L-proline: CCC, CCU, CCA, and CCG. This amino acid is unique among the twenty proteogenic amino acids in that the "side chain" is covalently linked to the nitrogen. Proline is regarded as a nonpolar amino acid; interestingly, however, most prolyl residue in proteins are located on the surface of proteins, since the steric constraints of the pyrrolidine ring results in reverse turns. Such constraints make prolyl residues incompatible with  $\alpha$ -helical structures and  $\beta$ -pleated sheets. Even so, prolyl residues can be found at N-termini of  $\alpha$ -helices. In addition, prolyl residues can be found in long helices; the residue cause a small distortion of the helical structure. Prolyl residues are also abundant and structural important in the collagen triple helix. In homologous proteins, if a prolyl residue is interchanged, it is usually with either an alanyl or a seryl residue. The L-stereoisomer has a specific rotation of  $-60.4^\circ$  at 25°C of the D line for a 1.0–2.0 g/100 mL solution in 5 M HCl ( $-86.2^\circ$  in distilled water). It is soluble in water (162.3 g/100 mL at 25°C; 206.7 g/100 mL at 50°C; and 239 g/100 mL at 65 °C) and is one of the few common amino acids that is soluble in ethanol (67 g/100 mL at 19°C). It is insoluble in diethyl ether, butanol, and isopropanol. While the proline "side chain" is relatively inert, prolyl residues in certain proteins, including collagen, undergo enzyme-catalyzed hydroxylation reactions at the C3 or C4 positions. Free proline also react with periodate to produce 2-pyrrolidone. A number of enzymes use D- or L-proline as an alternative substrate (and competitive inhibitor). These include the amino-acid dehydrogenase, the amino acid oxidases, alanine:oxo-acid aminotransferase, ornithine:oxo-acid aminotransferase, asparagine:oxo-acid aminotransferase, and amino-acid racemase. **Target(s):** acetylcholinesterase, weakly inhibited (1); 2-aminohexano-6-lactam racemase, weakly inhibited (2); arginase, weakly inhibited (3-5); arginine deiminase (6); aspartate aminotransferase (7); [citrate lyase] deacetylase, weakly inhibited (8); CTP synthetase, weakly inhibited (9); cysteinyl-tRNA synthetase activity of *Methanococcus jannaschii* prolyl-cysteinyl-tRNA synthetase (10); glutamine synthetase, weakly inhibited (11);  $\gamma$ -glutamyl kinase, or glutamate 5-kinase (12-19); glycine/sarcosine N-methyltransferase (30); hydroxy-L-proline oxidase (20); membrane alanyl aminopeptidase, or aminopeptidase N (21); phosphorylase kinase (22); polar-amino-acid-transporting ATPase, histidine permease, also alternative substrate (23); pyrroline-5-carboxylate dehydrogenase (24,25); 1-pyrroline-5-carboxylate reductase (14); pyruvate kinase (26);  $\alpha,\alpha$ -trehalose-phosphate synthase, or UDP-forming (27); and Xaa-Pro dipeptidase, or prolidase, or imidodipeptidase (28,29). 1. ### Prolixin-S

This 20-kDa hemoprotein from the blood-sucking insect *Rhodnius prolixus* (a vector for American trypanosomiasis) binds and transports nitric oxide. Prolixin-S also binds directly to coagulation factors IX and IXa (1). *Note:*

This term is also a proprietary name for fluphenazine dihydrochloride. 1. Isawa, Yuda, Yoneda & Chinzei (2000) *J. Biol. Chem.* **275**, 6636.

**Proluton**, See *Progesterone*

#### L-Prolyl-L-alanine

This dipeptide (FW = 186.21 g/mol) inhibits dipeptidyl-peptidase IV (1) and Xaa-Pro dipeptidyl-peptidase (2). 1. Yoshimoto, Fischl, Orlowski & Walter (1978) *J. Biol. Chem.* **253**, 3708. 2. Yan, Ho & Hou (1992) *Biosci. Biotechnol. Biochem.* **56**, 704.

**N-[L-Prolyl-L-histidyl-L-prolyl-L-phenylalanyl-L-histidyl]-2(S)-amino-1-hydroxy-4-methylpentyl-L-valyl-L-isoleucyl-L-histidyl-L-lysine**, See *Renin Inhibitor H142*

**L-Prolyl-L-leucylglycinamide**, See *Melanostatin*

#### L-Prolyl-L-leucylglycine Hydroxamate

This tripeptide hydroxamate (Sequence: PLG-(NHOH); FW<sub>free-base</sub> = 300.36 g/mol), which bears notable structural similarity to actinonin, inhibits a number of metalloendoproteases, including: astacin (1-3); collagenase (4); meprin A (3); and meprin B (3). 1. Stöcker (1998) in *Handb. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.), p. 1219, Academic Press, San Diego. 2. Reyda, Jacob, Zwilling & Stöcker (1999) *Biochem. J.* **344**, 851. 3. #### L-Prolyl-L-leucyl-L-phosphonotryptophan

This phosphonate (FW = 437.46 g/mol) inhibits gelatinase B, or matrix metalloproteinase 9 (1) and neutrophil collagenase, or matrix metalloproteinase 8 (1,2). 1. Gallina, Gavuzzo, Giordano, et al. (1999) *Ann. N. Y. Acad. Sci.* **878**, 700. 2. Gavuzzo, Pochetti, Mazza, et al. (2000) *J. Med. Chem.* **43**, 3377.

#### L-Prolyl-L-lysyl-L-methionyl-L-cysteinylglycyl-L-valinamide

This hexapeptide amide (Sequence: PKMCGV-NH<sub>2</sub>; FW<sub>free-base</sub> = 632.85 g/mol) inhibits *Crotalus adamanteus* adamalysin (IC<sub>50</sub> = 3.2 μM, the corresponding D-cysteiny residue-containing hexapeptide amide has a IC<sub>50</sub> of 74 μM (1,2). 1. Kress & Catanese (1998) in *Handb. Proteolytic Enzymes*

(Barrett, Rawlings & Woessner, eds.), p. 1262, Academic Press, San Diego. 2. Grams, Huber, Kress, Moroder & Bode (1993) *FEBS Lett.* **335**, 76.

#### D-Prolyl-L-phenylalanyl-L-arginal

This tripeptide aldehyde (FW = 302.48 g/mol) inhibits plasma kallikrein, and its sequence is based on cleavage sites in the natural Kex2 substrate pro-alpha-factor. This inhibitor exhibited a K<sub>i</sub> of 3.7 nM and a second-order inactivation rate constant (k<sub>2</sub>/K<sub>i</sub>) of 1.3 x 10<sup>7</sup> M<sup>-1</sup>s<sup>-1</sup> and is comparable with the value of k<sub>cat</sub> and the K<sub>m</sub> obtained with Kex2 for the corresponding peptidyl methylcoumarinyl-amide substrate. The enzyme is also sensitive to the other peptidyl chloromethanes over a range of concentrations, depending on peptide sequence and α-amino decanoylation, but was completely resistant to peptidyl sulphonium salts. 1. Evans, Jones, Pitt, et al. (1996) *Immunopharmacology* **32**, 117.

#### L-Prolyl-L-phenylalanyl-L-arginine Chloromethyl Ketone

This halomethyl ketone (FW<sub>free-base</sub> = 450.97 g/mol) typically inhibits amidohydrolase targets irreversibly by virtue of its susceptibility to attack by an active-site nucleophile (see exception below). **Target(s):** coagulation factor XIIIa (1,2); crotalase, or fibrinogen-clotting snake venom enzyme (3,4); histolysain, or *Entamoeba histolytica* cysteine endopeptidase, or histolysin, inhibited reversibly (5,6); mouse γ-nerve growth factor (7); plasma kallikrein (8,9); tissue kallikrein (7,8); and venombin A (3,4). 1. #### L-Prolyl-L-prolylglycyl-L-phenylalanyl-L-seryl-L-proline

This hexapeptide PPGFSP (FW = 600.67 g/mol), corresponding to residues 2-7 within bradykinin and hence known as bradykinin<sub>2-7</sub>, is a strong inhibitor of Xaa-Pro aminopeptidase, or aminopeptidase P (1-3). 1. Matos & Monnet (1998) in *Handb. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.), p. 1410, Academic Press, San Diego. 2. Orawski & Simmons (1995) *Biochemistry* **34**, 11227. 3. Simmons & Orawski (1992) *J. Biol. Chem.* **267**, 4897.

**Promazine**

This pheniazine antipsychotic (FW<sub>free-base</sub> = 284.43 g/mol; CAS 58-40-2; free base is oily liquid; hydrochloride is very soluble in water) is a dopamine receptor antagonist and tranquilizer. Although similar in action to chlorpromazine, promazine exhibits less antipsychotic activity, and is used primarily for short-term treatment of disturbed behavior and as an antiemetic. **Target(s):** CYP2B1 (1); D<sub>2</sub> dopamine receptor (2,3); monoamine oxidase (4); and Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (5,6). 1. Murray (1992) *Biochem. Pharmacol.* **44**, 121. 2. Daniel, Syrek & Wojcikowski (1999) *Eur. Neuropsychopharmacol.* **9**, 337. 3. Horn, Post & Kennard (1975) *J. Pharm. Pharmacol.* **27**, 553. 4. Pharmacol.* **15**, 703.

**Promegestone**

This synthetic progestin (FW = 326.48 g/mol; CAS 34184-77-5), also known as (17β)-17-methyl-17-(1-oxopropyl)estra-4,9-dien-3-one, is a tight-binding ligand of the progesterone/progesterin receptor. It is not bound by transcortin and binds to progesterone receptors with higher affinity than progesterone. Promegestone is also a noncompetitive acetylcholine receptor antagonist that may alter the receptor's function by interacting at the lipid-protein interface (1). **Target(s):** acetylcholine receptor, Torpedo nicotinic (1); CYP17 (2); estrone sulfatase (3-5); estrone sulfotransferase, but activated at low concentrations (6); gonadotropin secretion (7); 17α-hydroxyprogesterone aldolase (8); steroid Δ-isomerase, or 3β-hydroxysteroid dehydrogenase/Δ<sup>3</sup>,Δ<sup>4</sup>-isomerase (9). 1. Blanton, Xie, Dangott & Cohen (1999) *Mol. Pharmacol.* **55**, 269. 2. Kuhn-Velten, Bunse & Forster (1991) *J. Biol. Chem.* **266**, 6291. 3. Biol.* **37**, 231.

**Promethazine**

This antihistaminic drug (FW<sub>free-base</sub> = 284.43 g/mol; CAS 60-87-7), also known as 10-[(2-dimethylamino)propyl]phenothiazine, is a histamine H<sub>1</sub> receptor antagonist and CNS depressant. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** *Bacillus subtilis*

sporulation (1); Ca<sup>2+</sup>-dependent ATPase (2,3); cAMP phosphodiesterase (4,5); CYP2D6 (6,7); H<sub>1</sub> histamine receptor (8-11); hydroxysteroid sulfotransferase (12); monoamine oxidase (13); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (3,14); nucleoside-diphosphatase (15); osteoclastic bone resorption (16); phospholipase A<sub>2</sub> (17); UDP-glucuronosyltransferase (18). 1. Burke, Jr., & Spizzen (1977) *J. Bacteriol.* **129**, 1215. 2. Agarwal, Shukla & Tekwani (1992) *Int. J. Biochem.* **24**, 1447. 3. Agarwal, Tekwani, Shukla & Ghatak (1990) *Indian J. Exp. **Prometryn**

This selective post-emergence triazine herbicide (FW = 241.36 g/mol; CAS 7287-19-6; M.P. = 118-120°C), also known as Gesagard, Caparol, and systematically as *N,N'*-bis(1-methylethyl)-6-methylthio-1,3,5-triazine-2,4-diamine, is used to control annual grasses and broadleaf weeds in the cultivation of a variety of crops, including cotton and celery. *Note:* Prometryn is toxic to a number of organisms, including humans and fish, but is not toxic to birds, bees, and earthworms. **Target(s):** electron transport, photosynthetic 1. Dodge (1977) *Spec. Publ., Chem. Soc.* **29**, 7.

**Prontosil, See Sulfamidochrysoidine**

**Propachlor**

This herbicide (FW = 211.69 g/mol; CAS 1918-16-7; M.P. = 67-76°C), also known as Bexton, Ramrod, and systematically as α-chloro-*N*-isopropylacetanilide, is widely used to protect corn, maize, onion, cotton, sugarcane, sorghum, cabbage, rose bushes, and ornamental plants. Propachlor is effective against annual grasses and certain broad-leaved weeds. More than one degradative pathway for propachlor has been identified. **Target(s):** protein biosynthesis (1,2). 1. Jaworski (1969) *J. Agric. Food Chem.* **17**, 165. 2. Duke, Slife, Hanson & Butler (1975) *Weed Sci.* **29**, 142.

**Propafenone**

This class 1C antiarrhythmic agent (FW<sub>free-base</sub> = 341.45 g/mol; CAS 54063-53-5), also known as 1-[2-[2-hydroxy-3-(propylamino)propoxy]-phenyl]-3-phenyl-1-propanone, is a β-adrenergic receptor antagonist that also blocks a number of K<sup>+</sup> channels. The (*S*)-(-)-enantiomer is the more potent blocker

of cardiac  $\beta$ -adrenoceptors. **Target(s):**  $\beta$ -adrenoceptor (1); aldehyde oxidase (2); calcium ion current (3); CYP1A2 (4); CYP2D1 (5); HERG  $K^+$  channel (6,7);  $hK_{v1.5}$  channels (8);  $IK_r$  potassium current (9);  $K^+$  channels, ATP-sensitive (10); and the TWIK-related spinal cord  $K^+$  channel, or TRESK (11). 1. ### Propamidine

This trypanocidal agent (FW<sub>free-base</sub> = 312.37 g/mol; CAS 104-32-5) is a DNA intercalator that binds within the minor groove. **Target(s):** S-adenosylmethionine decarboxylase (1); aldehyde oxidase (2); complement component C5 binding to C3b (3); deoxyribonuclease I (4); and diamine oxidase (5). 1. Hugo & Byers (1993) *Biochem. J.* **295**, 203. 2. Knox (1946) *J. Biol. Chem.* **163**, 699. 3. Vogt, Schmidt & Hinsch (1979) *Immunology* **36**, 139. 4. Sutton, Conn, Brown & Lane (1997) *Biochem. **Propane-1,3-bisphosphonate, See 1,3-Bis(phosphono)propane**

**Propanedioic Acid, See Malonic Acid**

### 1,2-Propanediol

This vicinal diol (FW = 76.095 g/mol; CAS 57-55-6; 4254-14-2 for the (*R*)-isomer; 4254-15-3 for the (*S*)-isomer; 4254-16-4 for the (+/-)-isomer), also known as propylene glycol and propane-1,2-diol, is a product of the reaction catalyzed by lactaldehyde reductase. 1,2-Propanediol is a substrate of propanediol dehydratase and an alternative substrate for (*R,R*)-butanediol dehydrogenase and glycerol dehydrogenase. Both enantiomers are hygroscopic and miscible with water. The racemic mixture melts at  $-59^\circ\text{C}$  and boils at  $188.2^\circ\text{C}$ . Note that the (+)-enantiomer corresponds to 3-deoxy-*sn*-glycerol. **Target(s):** actin polymerization (1); bacterial leucyl aminopeptidase (2); CYP2E1 (3); glucan 1,4- $\alpha$ -glucosidase, or glucoamylase (4); glycerol kinase (5-7); oxidative phosphorylation (8); and propanediol dehydratase, as substrate and inactivator (9). 1. Vincent, Pruliere, Pajot-Augy, *et al.* (1990) *Cryobiology* **27**, 9. 2. Dick, Matheson & Wang (1970) *Can. J. Biochem.* **48**, 1181. 3. Thomsen, Loft, Roberts & Poulsen (1995) *Pharmacol. Biophys. Acta* **397**, 110. 7. Eisenthal, Harrison & Lloyd (1974) *Biochem. J.* **141**, 305. 8. Lovett & Sweetman (1983) *Methods Find. Exp. Clin. Pharmacol.* **5**, 695. 9. Bachovchin, Eagar, Jr., Moore & Richards (1977) *Biochemistry* **16**, 1082.

### 1,3-Propanediol

This diol (FW = 76.095 g/mol; CAS 504-63-2; B.P. =  $214.22^\circ\text{C}$ ; miscible with water), also known as trimethylene glycol, is a viscous liquid with a sweet taste. It is a glycerol fermentation product and substrate for 1,3-propanediol dehydrogenase. **Target(s):** diol dehydratase (1); glycerol dehydratase (1); and *N*-methyl-D-aspartate receptor, or NMDA receptor (2). 1. Knietsch, Bowien, Whited, Gottschalk & Daniel (2003) *Appl. Environ. Microbiol.* **69**, 3048. 2. Peoples & Ren (2002) *Mol. Pharmacol.* **61**, 169.

### *n*-Propanethiol

This foul-smelling thiol  $\text{CH}_3\text{CH}_2\text{CH}_2\text{SH}$  (FW = 76.163 g/mol; CAS 107-03-9 as well as 6898-84-6 for sodium salt; M.P. =  $-113^\circ\text{C}$ ; B.P. =  $67-68^\circ\text{C}$ ), also known as propyl mercaptan, inhibits

**Propane-1,2,3-tricarboxylic Acid, See Tricarballic Acid**

**1,2,3-Propanetriol, See Glycerol**

### Propanil

This contact herbicide and nematocide (FW = 218.08 g/mol; CAS 709-98-8), also known as Stam, Stampede, and Rogue, is effective against numerous grasses and broad-leaved weeds in crops of rice, which possesses an aryl acylamidase that inactivates propanil. Weeds that do not have this activity are killed by propanil. Propanil also inhibits tumor necrosis factor- $\alpha$  production by reducing nuclear levels of the transcription factor nuclear factor- $\kappa\text{B}$ . **Target(s):** electron transport, photosynthetic (1). 1. Dodge (1977) *Spec. Publ., Chem. Soc.* **29**, 7.

**Propanoic Acid, See Propionic Acid**

**3-Propanolamine, See 3-Aminopropanol**

### (+)-8'-Propargylabscisic Acid

This substrate analogue (FW = 272.34 g/mol) is a competitive inhibitor of (+)-abscisate 8'-hydroxylase,  $K_i = 1.1 \mu\text{M}$ . The (-)-stereoisomer is a significantly weaker inhibitor,  $K_i = 56 \mu\text{M}$ . 1. Cutler, Rose, Squires, *et al.* (2000) *Biochemistry* **39**, 13614.

### (+)-9'-Propargylabscisic Acid

This seed germination inhibitor (FW<sub>free-acid</sub> = 288.34 g/mol) is mechanism-based inactivator of (+)-abscisate 8'-hydroxylase,  $K_i = 0.27 \mu\text{M}$ ,  $k_{\text{inact}} = 0.11 \text{ min}^{-1}$  (1). The (-)-stereoisomer is a weaker inhibitor. 1. Cutler, Rose, Squires, *et al.* (2000) *Biochemistry* **39**, 13614.

### Propargyl Amine

This alkynyl amine  $\text{HC}\equiv\text{C}-\text{CH}_2-\text{NH}_2$  (FW<sub>free-base</sub> = 55.08 g/mol), also known as propargylamine and 3-amino-1-propyne, is a toxic liquid that boils at  $83^\circ\text{C}$ . The water-soluble hydrochloride melts at  $179-182^\circ\text{C}$ . **Target(s):** aldehyde dehydrogenase (1); diamine oxidase, or amine oxidase [copper-containing] (2,3); glycine cleavage complex, or glycine synthase (4); and monoamine oxidase, or amine oxidase [flavin-containing] (2,5-9). 1. DeMaster, Shirota & Nagasawa (1986) *Biochem. Pharmacol.* **35**, 1481. 2. Rando (1977) *Meth. Enzymol.* **46**, 158. 3. Jeon & Sayre (2003) *Biochem. Biophys. Res. Commun.* **304**, 788. 4. **Propargylate**

This alkynyl carboxylic acid (FW = 70.05 g/mol; M.P. = 9°C; B.P. = 144°C), also known as propiolic acid and 2-propynoic acid, inhibits acyl-CoA dehydrogenase (1) and pyruvate formate-lyase, or formate acetyltransferase (2). 1. Freund, Mizzer, Dick & Thorpe (1985) *Biochemistry* **24**, 5996. 2. Brush & Kozarich (1992) *The Enzymes*, 3rd ed. (Sigman, ed.), **20**, 317.

**10-Propargyl-5,8-dideazafolic Acid**

This folate analogue (FW<sub>free-acid</sub> = 477.47 g/mol), often abbreviated PDDF and also known as CB3717, is a potent inhibitor of thymidylate synthase, human IC<sub>50</sub> = 85 nM (1-5). It is a weaker inhibitor of dihydrofolate reductase (human IC<sub>50</sub> = 1.9 μM (4,5)). 1. Spencer, Villafranca & Appleman (1997) *Biochemistry* **36**, 4212. 2. Anderson, O'Neil, DeLano & Stroud (1999) *Biochemistry* **38**, 13829. 3. Arvizu-Flores, Sugich-Miranda, Arreola, et al. (2008) *Int. J. Biochem Cell Biol.* **40**, 2206. 4. **10-Propargylestr-4-ene-3,17-dione**

This 10β-propynyl-substituted steroid (FW = 310.44 g/mol), often abbreviated PED, is a Michael addition-type suicide inhibitor of aromatase, K<sub>i</sub> = 23 nM and k<sub>inact</sub> = 1.1 × 10<sup>-3</sup> s<sup>-1</sup> (1-3). 1. Doody, Murry & Mason (1990) *J. Enzyme Inhib.* **4**, 153. 2. Brandt, Covey & Zimniski (1990) *J. Enzyme Inhib.* **4**, 143. 3. Covey, Hood & Parikh (1981) *J. Biol. Chem.* **256**, 1076.

**D-Propargylglycine**

This acetylenic amino acid (FW = 113.12 g/mol; CAS 23235-03-2), also known as D-2-amino-4-pentynoate and D-2-amino-4-pentynoic acid, is a Michael addition-type suicide inhibitor of D-amino-acid oxidase (1-5). (See also *DL-Propargylglycine*; *L-Propargylglycine*) 1. Marcotte & Walsh (1978) *Biochemistry* **17**, 2864. 2. Walsh, Cromartie, Marcotte & Spencer (1978) *Meth. Enzymol.* **53**, 437. 3. **DL-Propargylglycine**

This naturally occurring δ-acetylenic α-amino acid (FW = 113.12 g/mol; CAS 64165-64-6; 16900-57-5 for HCl salt; 23235-03-2 for the (R)-isomer), also known as DL-2-amino-4-pentynoate, C-propargylglycine, and systematically as DL-2-amino-4-pentynoic acid, is a racemic mixture of a

potent inhibitor of cystathionine γ-lyase, cystathionine γ-synthase, and methionine γ-lyase. See also *D-Propargylglycine*; *L-Propargylglycine* **Target(s)**: O-acetylhomoserine aminocarboxypropyl-transferase (1-3); alanine aminotransferase (4,5); cystathionine β-lyase (6); cystathionine γ-lyase (7-13); cystathionine γ-synthase, or O-succinylhomoserine (thiol)-lyase (5,13-17); cysteine dioxygenase (18); homocysteine desulfhydrase (19,20); and methionine γ-lyase (21-23). 1. **L-Propargylglycine**

This alkynyl amino acid and mechanism-based inhibitor (FW = 113.11 g/mol; CAS 23235-01-0), also known as (S)-2-amino-4-pentynoic acid, irreversibly inactivates γ-cystathionase (an enzyme that also catalyzes the synthesis of the metabolic signaling gas, H<sub>2</sub>S, See also *Hydrogen Sulfide*), acting as a Michael addition type suicide inhibitor of cystathionine γ-lyase, cystathionine γ-synthase, alanine aminotransferase, and methionine γ-lyase. Propargylglycine inactivates γ-cystathionase with pseudo-first-order kinetics and incorporation of 1 mol inhibitor per 80 kDa enzyme (1,2). When studied *in vivo*, inactivation of cystathionine γ-lyase in rat kidney was less than that in the liver, owing to the presence of a higher cysteine concentration in kidney (3). L-Propargylglycine was found to inactivate pig heart L-alanine transaminase (EC 2.6.1.2) at 37° C with a K<sub>i</sub> = 3.9 mM, an observed maximal first order rate constant, k<sub>inact</sub> = 0.26 min<sup>-1</sup>, a minimal stoichiometric ratio necessary for inactivation of 2.7 L-propargylglycine molecules/enzyme subunit, with 2.2 molecules/subunit undergoing transamination before inactivation ensues (4). Experimental cystathioninuria, induced in rats by administration of D,L-propargylglycine, results in the formation of the cystathionine metabolites, cystathionine ketimine and perhydro-1,4-thiazepine-3,5-dicarboxylic acid, in various regions of the brain (5). L-Propargylglycine irreversibly inactivates proline dehydrogenase, which catalyzes the first step of proline catabolism, oxidizing proline to pyrroline-5-carboxylate (6). The 1.9-Å resolution structure of the inactivated *Thermus thermophilus* enzyme shows that N<sup>5</sup> of the flavin cofactor is covalently connected to the ε-amino group of Lys-99 via a three-carbon linkage, consistent with the mass spectral analysis of the inactivated enzyme. The isoalloxazine ring has a butterfly angle of 25°, suggesting the cofactor is reduced. Two mechanisms, both involving oxidation to N-propargyliminoglycine, can account for these properties (6). L-Propargylglycine irreversibly inhibits L-amino acid oxidase from the venom of *Crotalus adamanteus* (Eastern diamondback rattlesnake) and *Crotalus atrox* (Western diamondback rattlesnake) in a dose- and time-dependent manner that was blocked by the substrate L-phenylalanine (7). Other targets include methionine γ-lyase (8,9) and UDP-N-acetylmuramate:L-alanine ligase, or L-alanine-adding enzyme, or UDP-N-acetylmuramoyl-L-alanine synthetase (7,8). 1. Abeles & Walsh (1973) *J. ### Propentofylline

This peripheral xanthine-based vasodilator and neuroprotector (FW = 306.36 g/mol; CAS 55242-55-2), known systematically as 3,7-dihydro-3-methyl-1-(5-oxohexyl)-7-propyl-1H-purine-2,6-dione, is a nerve growth factor stimulator that is also a non-selective adenosine receptor antagonist. Propentofylline used to treat or ameliorate peptic ulcer or irritation of the gastrointestinal tract. **Target(s)**: adenosine receptor (1); adenosine transport (1,2); cAMP phosphodiesterase (1,3-5); and cGMP-stimulated phosphodiesterase (5). 1. Borgland, Castanon, Spevak & Parkinson (1998) *Can. J. Physiol. Pharmacol.* **76**, 1132. 2. Peralta, Hotter, Closa, et al. (1999) *Hepatology* **29**, 126. 3. Biochem. Biophys.* **251**, 276. 4. Trösken, Adamska, Arand, et al. (2006) *Toxicology* **228**, 24.

### Propidium Diiodide

This fluorescent DNA- and RNA-intercalating dye (FW = 668.40 g/mol; CAS 36015-30-2 and 25535-16-4) is often used as a stain for nucleic acids and as a probe of chromatin structure and exhibits a ten-fold enhancement

of fluorescence upon binding to acetylcholinesterase (1). **Target(s)**: acetylcholinesterase (1-6); cholinesterase, or butyrylcholinesterase (7); protein kinase C, IC<sub>50</sub> = 16 μM (8); and restriction endonuclease (9). 1. Taylor & Lappi (1975) *Biochemistry* **14**, 1989. 2. Costagli & Galli (1998) *Biochem. Pharmacol.* **55**, 1733. 3. Cohen, Kronman, Chitlaru, et al. (2001) *Biochem. J.* **357**, 795. 4. ### Propiolaldehyde

This aldehyde (FW = 54.048 g/mol; CAS 624-67-9), also known as propynal, synthesized from propargyl alcohol, is an irreversible inhibitor of aldehyde dehydrogenases (1-6). 1. DeMaster, Shirota & Nagasawa (1986) *Biochem. Pharmacol.* **35**, 1481. 2. Shirota, DeMaster & Nagasawa (1979) *J. Med. Chem.* **22**, 463. 3. Pietruszko, MacKerell, Jr., & Ferencz-Biro (1985) *Prog. Clin. Biol. Res.* **183**, 67. 4. Ferencz-Biro & Pietruszko (1984) *Alcohol Clin. Exp. Res.* **8**, 302. 5. Shirota, DeMaster, Elberling & Nagasawa (1980) *J. Med. Chem.* **23**, 669. 6. DeMaster, Shirota & Nagasawa (1980) *Adv. Exp. Med. Biol.* **132**, 219.

### Propiolyl-CoA

This fatty-acyl-CoA analogue (FW = 820.58 g/mol), also known as 2-propynoyl-CoA, inactivates general acyl-CoA dehydrogenase. 1. Freund, Mizzer, Dick & Thorpe (1985) *Biochemistry* **24**, 5996.

### Propiomazine

This substituted phenothiazine (FW<sub>free-base</sub> = 340.49 g/mol; CAS 362-29-8), known systematically as 1-(10-(2-(dimethylamino)propyl)-10H-phenothiazin-2-yl)-1-propanone and often used clinically as a sedative, inhibits oxidative phosphorylation. The maleate salt is frequently referred to as Propavane or Propavan. 1. Rasmussen (1964) *Biochem. Biophys. Res. Commun.* **16**, 19.

**Propionaldehyde**, See *Propanal*

### Propionamide

This simple alkylamide CH<sub>3</sub>CH<sub>2</sub>CONH<sub>2</sub> (FW = 73.095 g/mol; CAS 79-05-0; M.P. = 79°C; B.P. = 222.2°C) is freely soluble in water, ethanol, and chloroform. Propionaldehyde is an alternative substrate for a many amidases. **Target(s)**: alcohol dehydrogenase (1,2); dihydropyrimidinase, or hydantoinase (3); and nitrile hydratase, weakly inhibited (4). 1. Woronick (1961) *Acta Chem. Scand.* **15**, 2062. 2. Winer & Theorell (1960) *Acta Chem. Scand.* **14**, 1729. 3. Jahnke, Podschun, Schnackerz, Kautz & Cook (1993) *Biochemistry* **32**, 5160. 4. Hjort, Godtfredsen & Emborg (1990) *J. Chem. Technol. Biotechnol.* **48**, 217.

**Propionic Acid N-Hydroxysuccinimide Ester**, See *N-Succinimidyl Propionate*

**Propionitrile**

This toxic nitrile  $\text{CH}_3\text{CH}_2\text{CN}$  (FW = 55.079 g/mol; CAS 107-12-0; M.P. =  $-91.8^\circ\text{C}$ ; B.P. =  $97.2^\circ\text{C}$ ), itself a substrate for nitrile hydratase, inhibits amidase (1) and succinate dehydrogenase, or succinate oxidase (2,3). 1. Maestracci, Bui, Thiery, Arnaud & Galzy (1984) *Biotechnol. Lett.* **6**, 149. 2. Stoppani (1948) *Enzymologia* **13**, 165. 3. Sen (1931) *Biochem. J.* **25**, 849.

**Propionohydroxamic Acid**

This metal ion-chelating hydroxamic acid (FW = 89.094 g/mol) inhibits ribonucleoside-diphosphate reductase (1) and urease (2,3), most likely by forming coordination complexes with their respective active-site iron and nickel ions. 1. Larsen, Sjöberg & Thelander (1982) *Eur. J. Biochem.* **125**, 75. 2. Fishbein & Daly (1970) *Proc. Soc. Exp. Biol. Med.* **134**, 1083. 3. Martelli, Buli, Cortecchia, et al. (1987) *Contrib. Nephrol.* **58**, 196.

**Propionylcholine Chloride**

This hygroscopic acetylcholine analogue (FW = 195.69 g/mol) is a substrate of cholinesterase (or butyrylcholinesterase) and a weak substrate for acetylcholinesterase. Solutions should always be freshly prepared as propionylcholine chloride hydrolyzes nonenzymatically. **See also Acetylcholine Target(s):** aryl-acylamidase (1); choline kinase (2); ethanolamine kinase (3); and  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (4). 1. Oommen & Balasubramanian (1979) *Eur. J. Biochem.* **94**, 135. 2. Ishidate & Nakazawa (1992) *Meth. Enzymol.* **209**, 121. 3. Sung & Johnstone (1967) *Biochem. J.* **105**, 497. 4. Takachuk, Lopina & Boldyrev (1975) *Biokhimiia* **40**, 1032.

**Propionyl-CoA**

This thio ester (FW<sub>free-acid</sub> = 823.61 g/mol), also known as propanoyl-CoA, is a key intermediate in the degradation of odd-chain fatty acids, L-methionine, L-valine, L-threonine, and L-isoleucine. **Target(s):** acetyl-CoA synthetase, or acetate:CoA ligase (1); *N*-acetylglutamate synthase, or glutamate *N*-acetyltransferase, or amino-acid *N*-acetyltransferase (2); [acyl-carrier-protein] *S*-malonyltransferase (32); 1-alkyl-*sn*-glycero-3-phosphate acetyltransferase, weakly inhibited (3); amino-acid acetyltransferase, or glutamate acetyltransferase, or *N*-acetylglutamate synthase (2); arylamine *N*-acetyltransferase, as alternative substrate for the enzyme from certain sources (34); carbamoyl-phosphate synthetase, ammonia-requiring (4); carnitine *O*-palmitoyltransferase (5); citrate (*si*)-synthase, as alternative substrate for the enzyme from several sources (6); glycine cleavage complex, or glycine synthase (7); 3-hydroxyisobutyryl-CoA hydrolase (8,9); 3-hydroxy-3-methylglutaryl-CoA reductase, weakly inhibited (10); 3-hydroxy-3-methylglutaryl-CoA synthase (11,12);  $\alpha$ -ketoglutarate dehydrogenase (13); malonyl-CoA decarboxylase (14-20); malyl-CoA lyase (21); 3-methylcrotonoyl-CoA carboxylase,  $K_i = 1.78$  mM (22); 3-methylcrotonoyl-CoA hydratase, or enoyl-CoA hydratase (23); methylmalonyl-CoA epimerase (24); (*S*)-methylmalonyl-CoA hydrolase (25); [3-methyl-2-oxobutanoate dehydrogenase, or 2-methylpropanoyl-transferring] phosphatase, or [branched-chain- $\alpha$ -keto-acid dehydrogenase] phosphatase (26,27); oxaloacetate decarboxylase (28); pantothenate kinase (29); phosphoprotein phosphatase (27); pyruvate dehydrogenase complex (25); and succinyl-CoA synthetase (31). 1. **Propionyl Pantetheine**

This acylated pantetheine (FW = 334.44 g/mol) inhibits methylmalonyl-CoA carboxyltransferase, or transcarboxylase,  $K_i = 4$  mM (1,2). 1. Wood, Jacobson, Gerwin & Northrop (1969) *Meth. Enzymol.* **13**, 215. 2. Wood (1972) *The Enzymes*, 3rd ed. (PBoyer, ed.), **6**, 83.

**Propioxatin A and B**

These hydroxamic acids (MW = 360.43g/mol for proploxatin A (R = H); CAS 102962-94-7; MW = 374.46 g/mol for proploxatin B (R =  $\text{CH}_3$ ); CAS 102962-95-8) from *Kitasatosporia setae*, inhibit dipeptidyl-peptidase III with respective  $K_i$  values of 13 and 110 nM (1-3) as well as *Serratia* metalloproteinase (4). 1. Inaoka & Tamaoki (1987) *Biochim. Biophys. Acta* **925**, 27. 2. Inaoka, Tamaoki, Takahashi, Enokita & Okazaki (1986) *J. Antibiot.* **39**, 1368. 3. Inaoka & Naruto (1988) *J. Biochem.* **104**, 706. 4. Murao, Imafuku & Oyama (1997) *Biosci. Biotechnol. Biochem.* **61**, 561.

**Propofol**

This intravenously administered, nonanalgesic anesthetic (FW = 178.27 g/mol; CAS 2078-54-8;  $\text{p}K_a = 11$ ; *n*-Octanol:H<sub>2</sub>O Partition Coefficient = 6761:1, over pH 6–8.5 range), known also by its brand name Diprivan® and systematically as 2,6-diisopropylphenol, induces and maintains general anesthesia, as required for surgery. Propofol has a predictable duration of action, arising from its rapid penetration of the blood-brain barrier, followed by redistribution to inactive tissue depots, such as muscle and fat. **Likely Mode(s) of Action:** Anesthetics typically exert wide-ranging effects, targeting ligand-gated ion channels or receptors for GABA, glycine, and NMDA as well as channels for  $\text{K}^+$ ,  $\text{Na}^+$ , and  $\text{Ca}^{2+}$ . Propofol enhances two

types of GABAergic inhibition: (a) a synaptic form (referred to as phasic inhibition) that regulates neural excitability by means of activating postsynaptic GABA<sub>A</sub> receptors through intermittent GABA release from presynaptic terminals, and (b) a persistent form (known as tonic inhibition) that is generated through continuous activation of extrasynaptic GABA<sub>A</sub> receptors by low concentrations of ambient GABA (1). **Pharmacokinetics:** In humans, a two-compartment analysis (2) yields the central volume of distribution ( $V_c = 24.7$  liters), the peripheral volume of distribution ( $V_T = 112$  liters), the metabolic clearance ( $Cl = 2.64$  l/min), and the inter-compartmental clearance ( $Q = 0.989$  l/min). The delay of the anesthetic effect (expressed with respect to plasma concentrations) is described by the effect compartment with the rate constant for the distribution to the effector compartment equal to  $0.24 \text{ min}^{-1}$  (2). Despite its 2–24 hour biological half-life, propofol's sedative effect is much shorter, allowing for rapid recovery of consciousness. In a three-compartment model (3), the first exponential ( $t_{1/2} = 2\text{--}3$  minutes) describes its rapid onset of action, the second exponential ( $t_{1/2} = 0.5\text{--}1$  hour) defines its high metabolic clearance, and the long third exponential phase ( $t_{1/2} = 3\text{--}6$  hours) describes the slow elimination of a small proportion of the drug remaining in poorly perfused tissues. Importantly, propofol sedation should only occur while patients are under mechanical ventilation, a precaution relying on its fast metabolism and clearance to assure full regain of consciousness. (The notorious death of Singer Superstar Michael Jackson is believed to have occurred as the result of the tragic failure to heed such precautions.) Reference-(4) provides information on inter-racial variability, defined the difference between races in the median dose of propofol required for loss of consciousness within a race. Propofol is cleared reasonably quickly after metabolic glucuronidation, forming propofol-glucuronide, as well as sulfo- and glucuro-conjugation of its hydroxylated metabolite (6-diisopropyl-1,4-quinol) mainly by CYP2C9, but also CYP2A6, CYP2C8, CYP2C18, CYP2C19 and CYP1A2 (5). **See also:** Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Other Effects:** Rho-kinase is essential for propofol-induced neurite retraction in cortical neurons, and activation of PKC inhibits neurite retraction caused by propofol (5). Orexin A blocks propofol-induced neurite retraction by a PLD/PKC $\epsilon$ -mediated pathway, and PKC $\epsilon$  maybe the key enzyme, where wakefulness and anaesthesia signal pathways converge (6). **Target(s):** Cytochrome P450, as an alternative hydroxylation substrate (7); glucuronosyltransferase, as an alternative bioconjugation substrate (8); glutamate-dependent Ca<sup>2+</sup> entry (8); glutamate transport, ATP-dependent (9); and ouabain-insensitive synaptosomal ATPase (9). **Formulation:** A typical neutral-pH formulation contains: the active ingredient propofol at 1% wt/vol (10 mg/mL); emulsifiers like soybean oil at 10% wt/vol (100 mg/mL) and egg phospholipid at 1.2% wt/vol (12 mg/mL); glycerol at 2% wt/vol (20 mg/mL); as well as EDTA to suppress microbial growth during storage. 1. ### D-Propoxyphene

This widely used analgesic (FW<sub>free-base</sub> = 325.45 g/mol; CAS 469-62-5), also known as (αS)-α-[(1R)-2-(dimethylamino)-1-methylethyl]-α-phenylbenzeneethanol propionate and Darvon® for its hydrochloride salt), is sufficiently habit-forming that its use is controlled. First marketed as an alternative to codeine by Eli Lilly and Co. in 1957, propoxyphene is an opioid receptor agonist. In addition, it is an NMDA (*N*-methyl-D-aspartate) receptor antagonist. Only the dextro-isomer has an analgesic effect, and the levo-isomer appears to exert an antitussive effect. **Target(s):** aldehyde oxidase (1); Ca<sup>2+</sup> channels (2); carboxylesterase (3); CYP2C9 (4); and NMDA receptor (5,6). 1. Robertson & Gamage (1994) *Biochem. Pharmacol.* **47**, 584. 2. Seyler, Borowitz & Maickel (1983) *Fundam. Appl. Toxicol.* **3**, 536. 3. Zhang, Burnell, Dumaul & Bosron (1999) *J. Pharmacol. Exp. Ebert, Andersen, Hjedts & Dickenson (1998) *J. Pain Symptom Manage.* **15**, 269.

### Propranolol

This β-blocking antihypertensive (FW<sub>free-base</sub> = 259.35 g/mol; CAS 525-66-6; stable at acidic/neutral pH, but not at alkaline pH), widely known as Inderal® and systematically named as 1-[(1-methylethylamino)-3-(1-naphthalenylloxy)-2-propanol], is widely used to treat hypertension, cardiac arrhythmia, and migraines. Propranolol is both a β-adrenergic receptor antagonist and a 5-HT<sub>1</sub>/5-HT<sub>2</sub> serotonin receptor antagonist. While the (*S*)-enantiomer is the active β-antagonist, racemic propranolol is most often dispensed. Propranolol is also effective for controlling intentional tremor, but with a requirement for escalating drug levels, when used chronically. For his germinal work on β-antagonists, including propranolol, the Scottish pharmacologist James Whyte Black was awarded the Nobel Prize in Physiology or Medicine in 1988. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** acetylcholine esterase (1); β-adrenergic receptor (2-4); [β-adrenergic-receptor] kinase (5); alcohol dehydrogenase (6,7); aldehyde dehydrogenase (7); 1-alkylglycerophosphocholine *O*-acetyltransferase (38); 5-aminolevulinic synthase (39); Ca<sup>2+</sup>-dependent ATPase (8-10); cellobiohydrolase (11); choline-phosphate cytidyltransferase (37); cholinesterase (1,12); CYP2D (6) and a few other cytochrome P450, or CYP, family members (13); glycosylphosphatidylinositol diacylglycerol-lyase (14); hexokinase (15); K<sup>+</sup> channels, ATP-sensitive (16); lecithin:cholesterol acyltransferase, or LCAT (17); lipoprotein lipase (18); Mg<sup>2+</sup>-dependent ATPase (1,8,19); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (1,8); phosphatidate phosphatase (20-29); phospholipase A (30); prolyl hydroxylase, or procollagen-proline monooxygenase (31); prostaglandin-endoperoxide synthase, or cyclooxygenase (40); protein kinase C (22); serotonin 5-HT<sub>1</sub>/5-HT<sub>2</sub> receptor (32-34); thyroxine 5'-deiodinase (35); and xanthine oxidase (36). 1. #### **N<sup>o</sup>-Propyl-L-arginine**

This alkylated arginine/mol derivative (FW = 216.28 g/mol; CAS 137361-05-8) inhibits neuronal nitric-oxide synthase (IC<sub>50</sub> = 57 nM). It is a weaker inhibitor of the endothelial and inducible forms of the enzyme, which have IC<sub>50</sub> values of 8.5 and 180 μM, respectively (1-4). 1. Griffith & Kilbourn (1996) *Meth. Enzymol.* **268**, 375. 2. Cooper, Mialkowski & Wolff (2000) *Arch. Biochem. Biophys.* **375**, 183. 3. Zhang, Fast, Marletta, Martasek & Silverman (1997) *J. Med. Chem.* **40**, 3869. 4. **N-(α(R)-Propylbenzylaminocarbonyl) 4(S)-(4-carboxymethyl-phenoxy)-3,3-diethylazetidin-2-one**

This nonpeptidic alkylazetidinone (FW<sub>free-acid</sub> = 452.55 g/mol), also known as L-680414, is stable, potent, highly specific, and time-dependent monocyclic β-lactam inhibitor of human leucocyte elastase (HLE). The specificity of this compound toward HLE *versus* porcine pancreatic elastase (PPE) is consistent with the differences in substrate specificity reported for

these enzymes. 1. Knight, Green, Chabin, et al. (1992) *Biochemistry* **31**, 8160.

**N-L-3-*trans*-(Propylcarbamoyl)oxirane-2-carbonyl-L-isoleucyl-L-proline**

This oxirane-containing peptide (FW<sub>free-acid</sub> = 383.44 g/mol), known also as cathepsin B inhibitor III and CA-074 and named systematically as *N*-propylamido-epoxysuccinyl-*L*-isoleucyl-*L*-proline, is a potent, irreversible, and specific inhibitor of cathepsin B, with a IC<sub>50</sub> value of 2.2 nM for the rat liver enzyme (1-8), but weakly inhibits cathepsin K (9,10) cathepsin X (11), and miltpain (12). CA-074 also reduces ischemia-induced neural death. 1. Buttle, Murata, Knight & Barrett (1992) *Arch. Biochem. Biophys.* **299**, 377. 2. Mort (1998) in *Handb. **N-L-3-*trans*-(Propylcarbamoyl)oxirane-2-carbonyl-L-isoleucyl-L-proline Methyl Ester**

This methyl ester (FW = 397.47 g/mol), also known as CA-074 methyl ester, is a prodrug for *N*-*L*-3-*trans*-(propylcarbamoyl)oxirane-2-carbonyl-*L*-isoleucyl-*L*-proline, or CA-074, a potent inhibitor of cathepsin B (1), with weaker action on miltpain (2). 1. Buttle, Murata, Knight & Barrett (1992) *Arch. Biochem. Biophys.* **299**, 377. 2. Kawabata & Ichishima (1997) *Comp. Biochem. Physiol. B Biochem. Mol. Biol.* **117**, 445.

**α-Propyl-3,4-dihydroxyphenylacetamine**, See *2*-(3,4-Dihydroxyphenyl)-2-propylacetamide

**Propyl-2,2-diphenyl Diselenide**

This poorly named organoselenium compound (FW = 354.21 g/mol) inhibits 5-aminolevulinic acid dehydratase, or porphobilinogen synthase (1). The effect may be mediated by diphenyl diselenide, because propyl-2,2-diphenyl diselenide is known to decompose rapidly, forming diphenyl diselenide in aqueous media. 1. Barbosa, Rocha, Zeni, et al. (1998) *Toxicol. Appl. Pharmacol.* **149**, 243.

**Propylene Dichloride**, See *1,2-Dichloropropane*

**Propylene Glycol**, See *1,2-Propanediol*

**Propylene Oxide**

This oxirane (FW = 58.080 g/mol; CAS 75-56-9; M.P. = -112.13°C; B.P. = 34.23°C; very soluble in water), also known as 1,2-epoxypropane, is produced enzymatically from propene by methane monooxygenase. *Note*: There are two stereoisomers of propylene oxide. **Target(s)**: alkene

monooxygenase (1); glutathione S-transferase (2); and methane monooxygenase, as alternative product inhibition (3). 1. Habets-Cruetzgen & de Bont (1985) *Appl. Microbiol. Biotechnol.* **22**, 428. 2. ### *n*-Propyl Gallate

This antioxidant (FW = 212.20 g/mol; CAS 121-79-9; B.P. = 150°C, Solubility: 0.35 g/100 mL water at 25°C; Decomposes in the presence of iron ions), also known as Tenox PG and 3,4,5-trihydroxybenzoic acid propyl ester, exhibits antimicrobial activity and is frequently used as an additive in food products. *n*-Propyl gallate also inhibits the production of ethylene (1,2). In the presence of copper ions, elevated concentrations of *n*-propyl gallate, induce single-strand DNA breaks. *n*-Propyl gallate also inhibits the superoxide-generating activity of xanthine oxidase. Note that this reagent is also reported to prevent neuronal apoptosis. In addition, this reagent has proved useful in fluorescence microscopy, reducing photobleaching. **Target(s):** alkylglycerophosphoethanolamine phosphodiesterase, or lysophospholipase D (17,27); alternative oxidase (3-6); aminocyclopropane-carboxylate oxidase (36); 1-aminocyclopropane-1-carboxylate synthase (7); ascorbate oxidase (8);  $\beta$ -carotene 15,15'-monooxygenase (30); carotene oxidase (9); cyclooxygenase (10); CYP1A2 (11); ethylene production (1,2,7); fatty-acid  $\Delta^5$ -desaturase (21); fatty-acid  $\Delta^6$ -desaturase (21); fatty-acid synthase (29); 3-galactosyl-*N*-acetylglucosaminide 4- $\alpha$ -L-fucosyltransferase (28); glucan 1,3- $\alpha$ -glucosidase, or glucosidase II, or mannosyl-oligosaccharide glucosidase II (25); glucose-6-phosphatase (12); glycoprotein 3- $\alpha$ -L-fucosyltransferase (28); horseradish peroxidase (13); hyaluronoglucosaminidase, or hyaluronidase (26); iodide peroxidase, or thyroid peroxidase (13); lipoxygenase (10,14-16,34,35,38-40); 15-lipoxygenase, or arachidonate 15-lipoxygenase (33,34); NADPH:cytochrome *c* reductase (18); peroxidase (13,41); phytanoyl-CoA dioxygenase (31); procollagen-proline 4-dioxygenase (32); retinal oxidase (19); staphylococcal thermonuclease (20); tyrosine 3-monooxygenase (22,23); and xanthine oxidase (24,37). 1. ### *S*-Propylglutathione

This *S*-alkylated glutathione (FW = 337.40 g/mol) inhibits glutathione S-transferase (1), hydroxyacylglutathione hydrolase, or glyoxalase II (2,3), and lactoylglutathione lyase, or glyoxalase I (4-6). 1. ### 1-Propylguanidinium Ion

This substituted guanidine (FW<sub>free-base</sub> = 101.15 g/mol) is a simple structural analogue of arginine and, as expected, inhibits trypsin. **Target(s):** arginine decarboxylase (1), clostripain (2,3), guanidinoacetase (4), Na<sup>+</sup> channels (5), and trypsin,  $K_i = 0.9$  mM at pH 6 and 0.53 mM at pH 8 (3,6-8). 1. ***N*-(*n*-Propyl)-3-(3-hydroxyphenyl)piperidine, See 3-(3-Hydroxyphenyl)-*N*-propylpiperidine**

***n*-Propyl Iodide, See 1-Iodopropane**

### Propyl Isocyanate

This alkyl isocyanate (FW = 85.106 g/mol; CAS 110-78-1; B.P. = 83-84°C) is a lachrymator that inhibits aldehyde dehydrogenase (1) and protein-glutamine  $\gamma$ -glutamyltransferase, or transglutaminase (2). 1. Nagasawa, Elberling, Goon & Shirota (1994) *J. Med. Chem.* **37**, 4222. 2. Gross, Whetzel & Folk (1975) *J. Biol. Chem.* **250**, 7693.

### *N*-Propylmaleimide

This thiol-reactive reagent (FW = 139.15 g/mol; CAS 21746-40-7), also known as NPM and 1-propyl-1*H*-pyrrole-2,5-dione, readily alkylates protein sulfhydryl groups. Under alkaline conditions it can also react with amino groups. Some enzymes are inactivated at faster rates with analogues having longer alkyl chains (e.g., the inactivation rate of yeast alcohol dehydrogenase with *N*-octylmaleimide is significantly faster than with *N*-

ethylmaleimide1). **See also *N*-Ethylmaleimide Target(s):** acylglycerol lipase, or monoacylglycerol lipase (2). 1. Heitz, Anderson & Anderson (1968) *Arch. Biochem. Biophys.* **127**, 627. 2. Saario, Salo, Nevalainen, *et al.* (2005) *Chem. Biol.* **12**, 649.

#### *N,N*-Propyl-D-mannoamidine

This mannose (FW = 217.26 g/mol) analogue inhibits several glycosidases:  $\alpha$ -mannosidase ( $K_i = 0.11 \mu\text{M}$ ),  $\beta$ -mannosidase ( $K_i = 0.19 \mu\text{M}$ ),  $\alpha$ -glucosidase ( $K_i = 125 \mu\text{M}$ ),  $\beta$ -glucosidase ( $K_i = 111 \mu\text{M}$ ),  $\alpha$ -galactosidase ( $K_i = 4700 \mu\text{M}$ ),  $\beta$ -galactosidase ( $K_i = 2200 \mu\text{M}$ ),  $\alpha$ -fucosidase ( $K_i = 34 \mu\text{M}$ ), and  $\beta$ -*N*-acetylhexosaminidase ( $K_i = 900 \mu\text{M}$ ). 1. Heck, Vincent, Murray, *et al.* (2004) *J. Amer. Chem. Soc.* **126**, 1971.

#### Propyl-2-methoxy-2-phenyl Selenide

This selenide (FW = 229.18 g/mol) inhibits 5-aminolevulinatase, or porphobilinogen synthase (1). This inhibitory effect may be mediated by diphenyl diselenide, because propyl-2-methoxy-2-phenyl selenide is known to decompose rapidly, forming diphenyl diselenide in aqueous media. 1. Barbosa, Rocha, Zeni, *et al.* (1998) *Toxicol. Appl. Pharmacol.* **149**, 243.

**1-Propyl-3-methylimidazolium Tetrafluoroborate**, *See 1-Methyl-3-propylimidazolium Tetrafluoroborate*

#### 2-Propyl Methylphosphonochloridate

This phosphonate ester (FW = 156.55 g/mol; CAS 1445-76-7) inhibits chymotrypsin, forming diastereomeric phosphonate ester adducts with chymotrypsin's active-site serine hydroxyl(1). **Caution:** Because this agent is an obvious analogue of di-isopropylfluorophosphate and other skin-penetrating cholinesterase-directed chemical warfare agents, caution should be exercised. Use of heavy rubber (not latex!) gloves and a fume hood is strongly advised. 1. Kovach, McKay & Vander Velde (1993) *Chirality* **5**, 143.

#### *N-n*-Propylnorapomorphine

This apomorphine analogue (FW = 295.38 g/mol; CAS 58479-52-0 (for racemate); 18426-20-5 (for *R*-isomer); 20382-71-2 (*R*-isomer hydrochloride)) interacts with dopamine receptor, with the *R*(-)-enantiomer acting as a strong agonist and the *S*(+)-isomer acting as a weak antagonist (1), as well as an inhibitor of dihydropteridine reductase (2). 1. Neumeyer, Reischig, Arana, *et al.* (1983) *J. Med. Chem.* **26**, 516. 2. Shen, Smith, Davis & Abell (1984) *J. Biol. Chem.* **259**, 8994.

#### 2(*R*)-[2-[4-(*n*-Propyl)phenyl]ethyl]-4(*S*)-butylpentanedioic Acid 1-((*S*)-*tert*-Butylglycine Methylamide) Amide

This peptidomimetic (FW<sub>free-acid</sub> = 447.64 g/mol), also known as *N*-[4(*S*)-carboxy-2(*R*)-[2-[4-(*n*-propyl)phenyl]ethyl]-octanoyl]- $\alpha$ (*S*)-(*tert*-butyl)glycine methylamide, inhibits stromelysin 2 (matrix metalloproteinase 3) and gelatinase A (matrix metalloproteinase 2), with  $K_i$  values of 140 and 47 nM, respectively). 1. Esser, Bugianesi, Caldwell, *et al.* (1997) *J. Med. Chem.* **40**, 1026.

#### 2(*R*)-[2-[4-(*n*-Propyl)phenyl]ethyl]-4(*S*)-butylpentanedioic Acid 1-((*S*)-*tert*-Butylglycine 4-Pyridylamide) Amide

This peptidomimetic (FW<sub>free-acid</sub> = 512.72 g/mol) inhibits stromelysin 2 (matrix metalloproteinase 3) and gelatinase A (matrix metalloproteinase 2), with  $K_i$  values of 11 and 22 nM, respectively). 1. Esser, Bugianesi, Caldwell, *et al.* (1997) *J. Med. Chem.* **40**, 1026.

#### 3-[5-(2-(*n*-Propylsulfonylamino)ethyl)-5-(pyrid-3-ylmethyl)-1-benzenepropionate

This sulfonamide (FW<sub>free-acid</sub> = 390.50 g/mol) inhibits human thromboxane-A synthase (IC<sub>50</sub> = 29 nM) and is a thromboxane receptor antagonist (1). 1. Dickinson, Dack, Long & Steele (1997) *J. Med. Chem.* **40**, 3442.

#### *S*-Propyl-L-thiocitrulline

This thiocitrulline derivative (FW = 234.34 g/mol) inhibits neuronal and inducible nitric-oxide synthases, with IC<sub>50</sub> values of 3.75 and 2.55  $\mu\text{M}$ , respectively (1,2). 1. Griffith & Kilbourn (1996) *Meth. Enzymol.* **268**, 375. 2. Narayanan, Spack, McMillan, *et al.* (1995) *J. Biol. Chem.* **270**, 11103.

#### 6-(*n*-Propyl)-2-thiouracil

This uracil derivative (FW = 170.24 g/mol), also known as 2,3-dihydro-6-propyl-2-thioxo-4(1*H*)-pyrimidinone, inhibits the production of thyroxine and triiodothyronine and is used in the treatment of hyperthyroidism. It is slightly soluble in water (approximately 1 g/900 g H<sub>2</sub>O) and more soluble in ethanol (1 g/60 g). 6-(*n*-Propyl)-2-thiouracil is also a mechanism-based inactivator of an isoform of nitric-oxide synthase (1). **Target(s):** dopamine  $\beta$ -hydroxylase (2); glutathione *S*-transferase (3); glyceraldehyde-3-phosphate dehydrogenase, acetylphosphatase activity thereof (4); iodide peroxidase, thyroid peroxidase (8,12,13,27,28); iodothyronine secretion (7); lactoperoxidase (8,29); myeloperoxidase (9,10); NADH:cytochrome *b*<sub>5</sub> reductase (11); nitric-oxide synthase (1); peroxidase (5,6,8-10,12,13,29); peroxidase, horseradish (5,6); thyroxine 5-deiodinase (14,15); thyroxine 5'-deiodinase, or iodothyronine deiodinase (14,16-26). 1. Wolff & Marks (2002) *Arch. Biochem. Biophys.* **407**, 83. 2. Hidaka & Nagasaka (1977)

### Propyl Xanthate

This xanthic acid salt (FW = 146.21 g/mol) inhibits mushroom tyrosinase, or monophenol monooxygenase, with a  $K_i$  value of 5  $\mu$ M for the catecholase activity. The length of the hydrophobic tail of the xanthates has a stronger effect on the  $K_i$  values for catecholase inhibition than for cresolase inhibition. Increasing the length of the hydrophobic tail leads to a decrease of the  $K_i$  values for cresolase inhibition and an increase of the  $K_i$  values for catecholase inhibition. **1.** Saboury, Alijanianzadeh & Mansoori-Torshizi (2007) *Acta Biochim. Pol.* **54**, 183.

### Propyne

This simple alkyne (FW = 40.065 g/mol; CAS 74-99-7; M.P. =  $-102.7^\circ\text{C}$ ; B.P. =  $-23.2^\circ\text{C}$ ) inhibits the growth of *Burkholderia cepacia* G4 on toluene. Propyne is a suicide inhibitor of alkene monooxygenase. **Target(s):** alkene monooxygenase (1-3); and toluene 2-monooxygenase (4). **1.** Fosdike, Smith & Dalton (2005) *FEBS J.* **272**, 2661. **2.** Small & Ensign (1997) *J. Biol. Chem.* **272**, 24913. **3.** Gallagher, Cammack & Dalton (1997) *Eur. J. Biochem.* **247**, 635. **4.** Yeager, Bottomley, Arp & Hyman (1999) *Appl. Environ. Microbiol.* **65**, 632.

### 1-Propynyl Diethyl Phosphate

This phosphate ester (FW = 192.15 g/mol) is an irreversible inhibitor of a number of enzymes, with the enzyme-activated reagent converting to a highly reactive ketene intermediate that reacts with an active-site nucleophile. **Target(s):** acetylcholinesterase (1); arylalkyl-phosphatase, or phosphotriesterase (2); butyryl-cholinesterase (1); cholesterol esterase (1); chymotrypsin (1); elastase (1); esterase (1); kallikrein (1); lipase (1); proteinase K (1); subtilisin BPN (1); subtilisin Carlsberg (1); and thrombin (1). **1.** Segal, Shalitin, Shalitin, Fischer & Stang (1996) *FEBS Lett.* **392**, 117. **2.** Banzon, Kuo, Miles, *et al.* (1995) *Biochemistry* **34**, 743.

**4S-(Prop-2-ynyl)-D-glutamate**, See (2R,4S)-2-Amino-4-(prop-2-ynyl)pentanedioic Acid

### 2-Propynyl-17 $\alpha$ -methyleneestradiol

This estradiol derivative (FW = 324.46 g/mol) inhibits tubulin polymerization, or microtubule self-assembly ( $IC_{50}$  = 11  $\mu$ M) and possesses moieties that are expected to inhibit/resist deactivating enzymes. **1.** Edsall, Mohanakrishnan, Yang, *et al.* (2004) *J. Med. Chem.* **47**, 5126.

### Propyzamide

This herbicide (FW = 256.13 g/mol; CAS 23950-58-5; M.P. =  $155-156^\circ\text{C}$ ), also known as Pronamide and Kerb, is a preemergence agent (1) that also inhibits microtubule formation (2,3). Propyzamide is often used in fields of alfalfa, bird's-foot trefoil, woody nursery stock, lettuce, apples, pears, and lowbush blueberries. Perennial grasses including quack grass, annual grasses, volunteer cereals, and common chickweed are sensitive to propyzamide. **1.** Swithenbank, McNulty & Viste (1971) *J. Agric. Food Chem.* **19**, 417. **2.** Hirai, Sonobe & Hayashi (1998) *Proc. Natl. Acad. Sci. U.S.A.* **95**, 15102. **3.** Schibler & Huang (1991) *J. Cell Biol.* **113**, 605.

### Prorenin Fragment 10P-20P, Human

This undecapeptide (*Sequence*: RIFLKRMPISIR; FW = 1416.79 g/mol), corresponding to residues 10P to 20P of the prorenin region of human prorenin, is a mild competitive inhibitor of endothiapepsin and calf chymosin, with respective  $K_i$  values of 11 and 37  $\mu$ M (1). **1.** Richards, Kay, Dunn, Bessant & Charlton (1992) *Int. J. Biochem.* **24**, 297.

### Prorenin Fragment 32P-43P, Human

This dodecapeptide (*Sequence*: RLGPEWSQPMKR; FW = 1484.74 g/mol), corresponding to residues 32P to 43P of the prorenin region of human prorenin, is a competitive inhibitor of several proteases: the apparent  $K_i$  values for endothiapepsin, human pepsin, human gastricsin, and human renin are 7, 15, and 18 and 115  $\mu$ M, respectively (1). **1.** Richards, Kay, Dunn, Bessant & Charlton (1992) *Int. J. Biochem.* **24**, 297.

### pro-SAAS Fragment 235-246

This dodecapeptide (*Sequence*: VLGALLRVKRLRE; FW = 1366.71 g/mol) corresponds to residues 235-246 of the neuroendocrine secretory protein pro-SAAS, inhibits proprotein convertase 1,  $K_i$  = 51 nM (1), and is a significantly weaker inhibitor of furin, proprotein convertase 5, and proprotein convertase 7 ( $K_i$  = 39.4, 100, and 4.75  $\mu$ M, respectively). Twelve variants of this peptide containing an alanyl residue substitution at each position were reported to be weaker inhibitors (1). **1.** Basak, Koch, Dupelle, *et al.* (2001) *J. Biol. Chem.* **276**, 32720.

### Proscillaridin

This cardiac glycoside (FW = 530.66 g/mol), also known as desglucoprosillaridin A and scillarinenin  $\beta$ -rhamnoside, is almost insoluble in water and soluble in ethanol and dioxane. Proscillaridin is obtained from scillarinenin A by partial enzymatic degradation. **Target(s):** acetylcholinesterase (1); ATPase (2);  $H^+/K^+$ -exchanging ATPase (3); and  $Na^+/K^+$ -

exchanging ATPase (4,5). 1. Hanke, Nelson & Baskin (1991) *J. Appl. Toxicol.* **11**, 119. 2. Kleeberg & Belz (1974) *Naunyn Schmiedebergs Arch. Pharmacol.* **282**, 433. 3. **Proserine, See Neostigmine**

**[D-Pro<sup>9</sup>-(spiro-g-lactam)<sup>9,10</sup>,Trp<sup>11</sup>]-Substance P**

This substance P analogue (FW<sub>free-acid</sub> 1444.38 g/mol; *Sequence*: L-Arg-L-Pro-L-Lys-L-Pro-L-Gln-L-Gln-L-Phe-L-Phe-D-Pro-L-Leu-L-Trp-NH<sub>2</sub>, with an ethylene moiety bridging the  $\alpha$ -position of Pro<sup>9</sup> and the nitrogen of Leu<sup>10</sup>) is a strong NK-1 receptor antagonist. 1. Ward, Ewan, Jordan, *et al.* (1990) *J. Med. Chem.* **33**, 1848.

**Prostaglandin A<sub>1</sub>**

This eicosanoid (FW<sub>free-acid</sub> = 336.47 g/mol; CAS 14152-28-4; Symbol: PGA<sub>1</sub>) induces apoptosis and stimulates the expression of stress genes. The structure and role of the prostaglandin A<sub>1</sub> was investigated by Bergström and Samuelsson, who shared the 1982 Nobel Prize in Physiology or Medicine for their pioneering work on the eicosanoids. **Target(s)**: CYP4F2 (1); DNA topoisomerase II (2); HIV-1 transcription (3); 3 $\alpha$ -hydroxysteroid dehydrogenase, NADP<sup>+</sup>-dependent (4); I $\kappa$ B kinase (5,6); Mayaro virus replication (7); stress-induced NF- $\kappa$ B activation (8); and virus protein biosynthesis, or translation (9). 1. **Prostaglandin B<sub>1</sub> and Prostaglandin B<sub>x</sub>**

This eicosanoid (FW<sub>B1(free-acid)</sub> = 336.47 g/mol; CAS 13345-51-2, for PGB<sub>1</sub>, and 39306-29-1, for B<sub>x</sub>) is a metabolite of prostaglandin E<sub>1</sub>: prostaglandin B<sub>x</sub> is an oligomer of prostaglandin B<sub>1</sub>. The X-ray crystal structure of prostaglandin B<sub>1</sub> suggests this prostaglandin has an unusual L-shaped configuration, with the  $\alpha$  and  $\omega$  side chains roughly perpendicular to one another (1). The 15-hydroxyl group, which is normally directed away from the centroid of the prostaglandin in the standard hairpin model, is turned inward in prostaglandin B<sub>1</sub>. **Target(s)**: F<sub>0</sub>F<sub>1</sub> ATPase, or H<sup>+</sup>-transporting two-sector ATPase, inhibited by prostaglandin B<sub>x</sub> (2,3); 15-hydroxyprostaglandin dehydrogenase (4); phospholipase A<sub>2</sub>, inhibited by prostaglandin B<sub>x</sub> (5,6). 1. DeTitta (1976) *Science* **191**, 1271. 2. Devlin, Krupinski-Olsen, Uribe & Nelson (1986) *Biochem. Biophys. Res. Commun.* **137**, 215. 3. Kreutter & Devlin (1983) *Arch. Biochem. Biophys.* **221**, 216. 4. Jarabak (1982) *Meth. Enzymol.* **86**, 126. 5. Franson, Raghupathi, Fry, *et al.* (1990) *Adv. Exp. Med. Biol.* **279**, 219. 6. Franson & Rosenthal (1989) *Biochim. Biophys. Acta* **1006**, 272.

**Prostaglandin B<sub>2</sub>**

This eicosanoid (FW<sub>free-acid</sub> = 334.46 g/mol; CAS 13367-85-6; Symbol: PGB<sub>2</sub>), the major prostaglandin of osteoblasts, induces pulmonary hypertension. **Target(s)**: 15-hydroxyprostaglandin dihydrogenase (1); and prostaglandin E<sub>2</sub> 9-reductase (2,3). 1. Lee & Levine (1975) *J. Biol. Chem.* **250**, 548. 2. Tai & Yuan (1982) *Meth. Enzymol.* **86**, 113. 3. Pace-Asciak & Smith (1983) *The Enzymes*, 3rd ed. (Boyer, ed.), **16**, 543.

**Prostaglandin B<sub>x</sub>, See Prostaglandin B<sub>1</sub> and Prostaglandin B<sub>x</sub>**

**Prostaglandin D<sub>2</sub>**

This eicosanoid (FW<sub>free-acid</sub> = 352.47 g/mol; CAS 41598-07-6; Symbol: PGD<sub>2</sub>) is the principal cyclooxygenase metabolite of arachidonic acid. The primary prostaglandin in brain is a stimulator of adenylate cyclase and can induce inflammation. Prostaglandin D<sub>2</sub> is released upon activation of mast cells and is also synthesized by alveolar macrophages. Among its many

biological actions, the most important are its role as a bronchoconstrictor, acting as a platelet-activating-factor inhibitory. **Target(s):** platelet aggregation (1); and prostaglandin E<sub>2</sub> 9-reductase (2,3). 1. Nishizawa, Miller, Gorman, *et al.* (1975) *Prostaglandins* 9, 109. 2. Tai & Yuan (1982) *Meth. Enzymol.* 86, 113. 3. Pace-Asciak & Smith (1983) *The Enzymes*, 3rd ed. (Boyer, ed.), 16, 543.

#### Prostaglandin E<sub>1</sub>

This bioactive prostaglandin (FW<sub>free-acid</sub> = 354.49 g/mol; CAS 745-65-3; Symbol: PGE<sub>1</sub>) is a vasodilator that activates adenylyl cyclase through a G-protein-coupled receptor. **Target(s):** adenylyl cyclase (1); cystinyl aminopeptidase, *or* oxytocinase (2-6); and IκB kinase (7). 1. Reddy, Oliver, Festoff & Engel (1978) *Biochim. Biophys. Acta* 540, 371. 2. Roy, Yeang & Karim (1982) *Prostaglandins Leukot. Med.* 8, 173. 3. #### Prostaglandin E<sub>2</sub>

This bioactive prostaglandin (FW<sub>free-acid</sub> = 352.47 g/mol; CAS 363-24-6; Symbol: PGE<sub>2</sub>) is a vasodilator. It can be used to induce cervical ripening and parturition as well as regulate the sleep/wake cycle. In addition, it modulates adenylyl cyclase via G protein receptors. **Target(s):** cystinyl aminopeptidase, *or* oxytocinase (1-5); IκB kinase (6); MAP kinase (7); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (8); sterol acyltransferase, *or* cholesterol acyltransferase, *or* ACAT (9). 1. Roy, Yeang & Karim (1982) *Prostaglandins Leukot. Med.* 8, 173. 2. Roy, Yeang, Tan, Kottegoda & Ratnam (1985) *Prostaglandins* 30, 255. 3. Roy, Yeang, Kottegoda & Ratnam (1984) *Prostaglandins Leukot. Med.* 14, 105. 4. Roy, Yeang & Karim (1981) *Prostaglandins Med.* 6, 577. 5. Roy, Sen & Ratnam (1989) *J. Reprod. Fertil.* 87, 163. 6. Rubinger, Wald, Scherzer & Popovtzer (1990) *Prostaglandins* 39, 179. 9. Billheimer (1985) *Meth. Enzymol.* 111, 286.

#### Prostaglandin F<sub>2α</sub>

This bioactive prostaglandin (FW<sub>free-acid</sub> = 354.49 g/mol; Symbol: PGF<sub>2α</sub>) is a vasoconstrictor and can induce parturition. **Target(s):** cystinyl aminopeptidase, *or* oxytocinase (1-5); and sterol acyltransferase, *or* cholesterol acyltransferase, *or* ACAT (6). 1. Roy, Yeang & Karim (1982) *Prostaglandins Leukot. Med.* 8, 173. 2. Roy, Yeang, Tan, Kottegoda & Ratnam (1985) *Prostaglandins* 30, 255. 3. Roy, Yeang, Kottegoda &

Ratnam (1984) *Prostaglandins Leukot. Med.* 14, 105. 4. Roy, Yeang & Karim (1981) *Prostaglandins Med.* 6, 577. 5. Roy, Sen & Ratnam (1989) *J. Reprod. Fertil.* 87, 163. 6. Billheimer (1985) *Meth. Enzymol.* 111, 286.

#### Prostaglandin G<sub>1</sub>

This 9,11-endoperoxide 15-hydroperoxide (FW<sub>free-acid</sub> = 370.49 g/mol; Symbol: PGG<sub>1</sub>), itself an intermediate in the biosynthesis of biologically active series-1 prostaglandins, inhibits prostacyclin synthase. 1. Ham, Egan, Soderman, Gale & Kuehl, Jr. (1979) *J. Biol. Chem.* 254, 2191.

#### Prostaglandin I<sub>2</sub>

This (FW = 374.45 g/mol; CAS 61849-14-7; Symbol: PGI<sub>1</sub>), also called prostacyclin and epoprostenol, is produced in endothelial cells from prostaglandin H<sub>2</sub> by the action of the enzyme prostacyclin synthase. Prostacyclin chiefly prevents formation of the platelet plug involved in primary hemostasis (a part of blood clot formation). It does this by inhibiting platelet activation.[5] It is also an effective vasodilator.

#### Prostigmine, See Neostigmine

#### Prostratin

This orally active, nontumorigenic phorbol ester (FW = 390.47 g/mol; CAS 60857-08-1; Soluble to 75 mM in DMSO; Code Name: P-4462), isolated from the groundcover plant *Pimelea prostrata* as well as the bark of the Samoan mamala tree, *Homalanthus nutans* (*Euphorbiaceae*) (1), is a selective Protein Kinase C activator (**See Phorbol Myristate Acetate**), but exhibits profound growth-suppressing action against certain tumors. Prostratin inhibits the growth of myeloid leukemia cells by a predominant G<sub>i</sub> arrest and variable induction of apoptosis (2). It also induces significant differentiation of AML cell lines and primary AML blasts by reprogramming transcriptional factor expression. Ectopic expression of c-Myc in HL-60 cells eliminates prostratin-mediated cellular differentiation and cell cycle arrest, indicating an essential role for c-Myc suppression in the differentiation-inducing effects of prostratin (1). Prostratin also potentiates induction of cellular differentiation by Ara-C (2). Prostratin also represses tumorigenesis in K-Ras mutant pancreatic cancer cells (3). Prostratin also shows promise for eradicating the latent HIV-1 provirus by inducing HIV-1 transcriptional activation, most likely through effects on protein kinase D<sub>3</sub> (3). Silencing PKD3, but not the other PKD family members, blocked prostratin-induced transcription of HIV-1. Overexpression of the constitutively active form of PKD3, but not the wild-type

or kinase-dead form of PKD3, augments the expression of HIV-1. Moreover, prostratin triggers PKD3 activation by inducing the phosphorylation of its activation loop by PKC $\epsilon$ . The activating effect of PKD3 on HIV-1 transcription depends on the presence of  $\kappa$ B element and the prostratin-induced activation of NF- $\kappa$ B, and PKD3 silencing blocks prostratin-induced NF- $\kappa$ B activation and NF- $\kappa$ B-dependent HIV-1 transcription (4). **Use in HIV Therapy:** Prostratin is of interest because of its ability to activate otherwise latent viral reservoirs. Prostratin also inhibits *de novo* infection by Human Immunodeficiency Virus type-1 (HIV-1) (5), while up-regulating viral expression from latent proviruses, commending it for use as an inductive adjuvant therapy for patients treated with highly active antiretroviral therapy (HAART) (4). Prostratin blocks HIV-1 infection by inducing the down-regulation of CD4 receptor expression, with similar down-regulation of the HIV-1 co-receptors, CXCR4 and CCR5, actions that may also reduce viral infectivity of treated host cells. Prostratin also up-regulates HIV-1 expression from CD8<sup>+</sup> T lymphocyte-depleted peripheral blood mononuclear cells of patients undergoing HAART (5). Such observations suggest Prostratin is a candidate for augmenting HAART by inducing expression of latent HIV-1, and when combined with other agents, helping to eliminate persistent viral reservoirs in certain individuals infected with HIV-1 (5). 1. Cashmore, *et al.* (1976) *Tetrahedron Lett.* **20**, 1737. 2. Shen, Xiong, Jing, *et al.* (2015) *Cancer Lett.* **356**, 686. 2. Wang, Holderfield, Galeas, *et al.* (2015) *Cell* **163**, 1237. 3. #### pro-TAME

This cell-permeable TAME analogue (FW<sub>hydrochloride</sub> = 670.23 g/mol) hydrolyzes upon entering cells, yielding a synthetic substrate that is useful for quantifying the esterase activity of many neutral proteinases, including trypsin, plasmin, and papain (1-10). Depending on the target enzyme, TAME may act as a slow alternative substrate that competitively inhibits the peptide-hydrolyzing activities of proteases (**See TAME**). 1. Zeng, Sigollot, Gaur, *et al.* (2010) *Cancer Cell* **18**, 382.

#### Protamine & Protamine Sulfate

Protamines are small basic proteins and oligopeptides, typically rich in arginyl residues, that are found in the sperm of all animals. They are often associated with polynucleic acids such as double-stranded DNA (they compact DNA into a more condensed structure). Protamine sulfate is sulfated salt of a protamine. It binds to and inactivates heparin; hence, it is often used in cases of heparin overdose. As mentioned above, it also binds to and precipitates DNA and can be used to remove DNA from a protein sample or in the purification of DNA-binding proteins. It has also been used in retroviral-mediated gene transfers as a substitute for polybrene. Note that salmine is the protamine sulfate salt from salmon and clupeine is the salt from herring. **See also specific protamine; e.g., Salmine; Clupeine Target(s):** acetylcholinesterase (1); acylglycerol lipase, *or* monoacylglycerol lipase (34); adenylate cyclase (2); alkaline phosphatase (28); AMP deaminase (3); carbamoyl-phosphate synthetase (4); cholinesterase (1); cytochrome *c* oxidase (6,7); diacylglycerol lipase (38); electron transport (6,7); glycoprotein Ib-von Willebrand factor activity (8); histone acetyltransferase (42); IgA-specific serine endopeptidase (9); lipase, *or* triacylglycerol lipase (8,10,37-39); lipoprotein lipase (11-13,29-33); lysine carboxypeptidase, *or*

carboxypeptidase N, *or* lysine(arginine)carboxypeptidase (5,24,25); oxidative phosphorylation (7); pantothenoylcysteine decarboxylase (14); phospholipase A<sub>2</sub> (15); phospholipase D (16); phosphoprotein phosphatase-1, *or* [phosphorylase] phosphatase (17,18); phosphorylase kinase (19,40); poly(ADP-ribose) glycohydrolase (26,27); protein xylosyltransferase (41); sterol esterase, *or* cholesterol esterase (35,36); thrombin (20); trypsin (21); and tryptophan synthase (22,23). 1. #### Protease Inhibitor 4, *See Kallistatin*

#### Protease Inhibitor "Cocktails"

Enzymatic proteolysis can be arrested or minimized through the use of so-called cocktails containing combinations of serine protease, cysteine protease, aspartic protease, and metalloprotease inhibitors. The following combinations (or cocktails) have proved to be highly effective in the isolation of intact proteins, and some have are so popular that they are commercially available. **General Protease Cocktails** typically contain AEBSF, E-64, bestatin, leupeptin, aprotinin, and sodium EDTA. The latter is included only if the protein or enzyme being purified does not require a divalent metal cofactor for structural integrity. **Fungal and Yeast Protease Cocktails** typically contain AEBSF, pepstatin A, E-64, and 1,10-phenanthroline. **Mammalian Cell Protease Inhibitor Cocktails** typically contain AEBSF, pepstatin A, E-64, bestatin, leupeptin, and aprotinin. (Other metal ion chelators, such as 0.5 mM EGTA, may be added to suppress the activity of calcium ion-dependent proteases such as calpain. Again, one must determine whether the protein or enzyme being purified does not require a divalent metal cofactor for structural integrity or biological activity. **Bacterial Extract Protease Cocktails** typically contain AEBSF, pepstatin A, E-64, bestatin, and sodium EDTA. For convenience, the inhibitory properties of these reagents are summarized as follows. **AEBSF:** This broad-spectrum serine protease inhibitor, which is stable in water for one month when stored at -20 °C, has an inhibitory range 0.1-1.0 mM. AEBSF also inhibits cysteine proteases, such as papain. **Antipain:** This inhibitor is effective against serine proteases (*e.g.*, plasmin, thrombin and trypsin, but not chymotrypsin, as well as some cysteine proteases, such as calpain and papain. Its inhibitory range is 1-100  $\mu$ M, with IC<sub>50</sub> = 0.15 mg/mL for

papain, 0.25 mg/mL for trypsin, 1.2 mg/mL for cathepsin A). Prepare at 10 mM in water. **Aprotinin:** This water-soluble inhibitor, which is stable for months, when stored at 4 °C, blocks and many serine proteases at 0.3 μM (or equimolar with proteinase), but is without effect on thrombin or blood-clotting factor Xa. **Bestatin:** This aminopeptidase inhibitor, which has an inhibitory range of 1-10 μM, is prepared as a 1 mM stock solution in methanol and stable for 1 month, when stored at -20 °C. **Chymostatin:** This chymotrypsin-like serine protease inhibitor blocks chymase and cathepsins A,B,D and G, as well as some cysteine proteases (including papain). Its inhibitory range is 10-100 μM; IC<sub>50</sub> = 0.1 mg/mL for chymotrypsin). Stock solutions are prepared at 10 mM in DMSO. **DFP:** This highly effective broad-spectrum serine-protease inhibitor is also a highly toxic nerve poison, and a well-ventilated fume hood and heavy rubber gloves should be used to avoid inhalation or contact with skin. For safety, DFP should be prepared as a 200 mM solution in anhydrous isopropanol or propylene glycol and then diluted 60-100x into cell extract. In aqueous solution, DFP rapidly decomposes (*t*<sub>1/2</sub> = 20 min in water). **E-64:** This thiol protease inhibitor, which is effective in the 1-10 μM concentration range, is prepared as a 1 mM stock solution in water and is stable 1-2 weeks at -20 °C. **EDTA:** This broad-spectrum metalloproteinase inhibitor (effective range = 1-10 mM) nonspecifically inhibits many metalloenzymes, especially those with metal ion *K*<sub>4</sub> values above 1 mM. **N-Ethylmaleimide:** This chemical modifying agent inhibits most thiol-proteases by reacting irreversibly with essential active-site thiol groups. NEM is water-soluble at >10mg/ml, and must be prepared freshly. **Leupeptin:** This inhibitor blocks trypsin-like serine proteases, such as trypsin, chymotrypsin, chymase, pepsin and thrombin. Leupeptin inhibits selected cysteine proteases (calpain, cathepsin B, H & L and papain). The inhibitory range is 10-100 μM, with the following IC<sub>50</sub> values: 2 mg/mL for trypsin; 8 mg/mL for plasmin; and 0.5 mg/mL for cathepsin B. When prepared at 10 mM in water, leupeptin is stable 6 months when stored at -20 °C. **Pepstatin A:** This inhibitor blocks aspartic proteases, such as renin, chymosin and pepsin (inhibits at 1 μM). Prepare as 1mM stock solution in methanol or DMSO. **1,10-Phenanthroline:** This broad-spectrum metallo-proteinase inhibitor (with an inhibitory range of 1-10 mM) is prepared at 200mM in methanol or DMSO. This reagent nonspecifically inhibits many metalloenzymes, especially zinc- and manganese-dependent enzymes and those with metal ion *K*<sub>4</sub> values above 1 mM. **PMSF:** This broad-spectrum serine protease inhibitor, which is soluble in DMSO and stable for 1 month at -20 °C, has an inhibitory range of 0.1-1.0 mM. PMSF also inhibits cysteine proteases (including papain), which are reactivated by 1 mM 2-mercaptoethanol or dithiothreitol. **Phosphoramidon:** This agent potently inhibits metalloendoproteinases, including thermolysin and elastases at 1-10 μM, but only weakly inhibits collagenase. When prepared at 1 mM in water, phosphoramidon solutions are stable for 1 month at -20 °C. **TLCK:** This haloketone-containing reagent inhibits trypsin-like serine proteases at 10-100 μM. TLCK solutions must be freshly prepared at 10 mM in 1 mM HCl and then diluted 100x into cell extracts. **TPCK:** This haloketone-containing reagent inhibits chymotrypsin-like serine proteases at 10-100 μM. TPCK solutions must be freshly prepared at 10 mM in 1 mM HCl and then diluted 100x into cell extracts. **See also** AEBSF; Antipain; Aprotinin; Bestatin; Chymostatin; E-64; N-Ethylmaleimide; Leupeptin; Pepstatin A; 1,10-Phenanthroline; PMSF; Phosphoramidon; TPCK

#### Protease Inhibitor Nexin I

This 43.9-kDa glycoprotein serpin, also called protease nexin-1, inhibits thrombin-like proteases. It is found in several tissues throughout the body including a platelet-bound form. Protease nexin-1 forms tight complexes with the target proteases, acting as a suicide inhibitor, and is presumably cleaved during the inhibitory reaction. It also promotes neurite extension. (For a discussion of the likely mechanism of inhibitory action, **See Serpins; also** α<sub>1</sub>-Antichymotrypsin) **Target(s):** acrosin (1,2); coagulation factor Xa (3); coagulation factor Xia (4); granzyme A (5,6); plasmin (3,7); protein C, activated (8); thrombin (3,7,9,10); trypsin (3); and u-plasminogen activator, or urokinase (3,7,11-16). 1. #### Protease Inhibitor Nexin II

This term, also called protease nexin-2 (PN-2), refers to the subset of the several differentially spliced forms (including the 751-aminoacyl residue isoform) of the amyloid precursor protein that contains a Kunitz-type inhibitor domain. PN-2 reversibly inhibits a number of coagulation factors. **Target(s):** chymotrypsin (1); coagulation factor VIIa (2); coagulation factor IXa (3); coagulation factor Xa (4); coagulation factor Xia, *K*<sub>i</sub> = ~400 pM, heparin improves the inhibition (5-14). 1. #### Protein C Inhibitor (Activated Protein C Inhibitor)

This secreted heparin-binding glycoprotein (MW = 57000 g; *Symbol:* PCI), commonly abbreviated PCI and also called plasminogen activator inhibitor 3 (PAI-3), is a member of the plasma serine protease inhibitor (serpin) family. It was initially identified as an inhibitor of activated Protein C, the main proteolytic enzyme in the protein C anticoagulant pathway (*K*<sub>i</sub> = 58 nM). This inhibitor forms an acyl-bond complex with activated protein C, a reaction that is enhanced by heparin and dextran sulfate. (For a discussion of the likely mechanism of inhibitory action, **See Serpins; also** α<sub>1</sub>-Antichymotrypsin) Govern its cationic nature, PCI likewise binds negatively charged phospholipids (e.g., unsaturated phosphatidylserine (PS), oxidised

phosphatidyl-ethanolamine, phosphatidic acid (PA), cardiolipin (CL), and phosphoinositides (PIPs)), thereby stimulating PCI's inhibitory action on different proteases (1). The interaction of phospholipids with PCI might also alter the lipid distribution pattern of blood cells and influence the remodeling of cellular membranes. **Modulation of the Phagocytosis of PS-Presenting Cells:** PCI binds to PS exposed on apoptotic cells, thereby regulating their removal by phagocytosis (2). With Jurkat T-lymphocytes and U937 myeloid cells, PCI binds to apoptotic cells to a similar extent at the same sites as Annexin V, but in a different manner compared to live cells (defined as spots of concentration on ~10-30% of cells). PCI dose dependently decreases phagocytosis of apoptotic Jurkat cells by U937 macrophages. Phagocytosis of PS exposing, activated platelets by human blood derived monocytes likewise declines in the presence of PCI. In U937 cells, PCI expression and cell surface binding increase with time after phorbol ester treatment/macrophage differentiation. Such results suggest a role of PCI as a negative regulator of apoptotic cell and activated platelets removal (2). **Target(s):** acrosin (3-6); chymotrypsin (7); coagulation factor Xa (6-8); coagulation factor Xia (6,8,9); matriptase (10); plasmin, with the bovine inhibitor transiently inhibiting bovine plasmin, but not human plasmin (11); protein C (activated) (6-8,12,13,23-26); semenogelase (14); thrombin (6-8,15,25); thrombin-thrombomodulin complex (15); tissue kallikrein (6,8,9,16-19); tissue kallikrein hK (4), human (9,17-19); t-plasminogen activator (6,20); trypsin (7); u-plasminogen activator, or urokinase (6,20-22,25). 1. ### Protein Kinase A Inhibitors

These small, heat-stable proteins, also known as adenosine-3',5'-cyclic-monophosphate-dependent protein kinase inhibitor proteins and abbreviated PKIs or PKAIs, bind to the catalytic subunit of protein kinase A and inhibit the activity (1-10). The  $K_i$  value for the  $\alpha$  isoform is 98 pM, and many fragments have 1-3 nM  $K_i$  values. This inhibitor was first identified in the laboratories of Edmund H. Fischer and Edwin G. Krebs, who shared the 1992 Nobel Prize in Physiology or Medicine for their discovery on protein kinases. **Note:** The TTTADFIASGRTGRRNAIHD corresponds to the active site of the rabbit skeletal muscle inhibitor protein and also inhibits the catalytic subunit of protein kinase A. 1. ### Protein Kinase A Inhibitor Fragment 5-24

This eicosapeptide fragment from the rabbit skeletal muscle protein kinase A inhibitor, consisting of residues TTYADFIASGRTGRRNAIHD (also known as IP20) has a  $K_i$  value of 2.3 nM for the catalytic subunit of protein kinase A (1). Kinases other than the catalytic subunit of protein kinase A are also inhibited; hence, this peptide is also simply called protein kinase inhibitor. Note also that the *N*-myristoylated peptide is also commercially available. **Target(s):** Ca<sup>2+</sup>/calmodulin-dependent protein kinase (2); cAMP-dependent protein kinase, or protein kinase A (1-13); cGMP-dependent protein kinase, or protein kinase G (2); and [myosin light-chain] (2). 1. ### Protein Kinase A Inhibitor Fragment 6-22 Amide

This octadecapeptide amide (*Sequence:* TYADFIASGR-TGRRNAI-NH<sub>2</sub>) corresponds to residues 6-22 of the rabbit skeletal muscle protein kinase inhibitor (1,2). The peptide amide inhibits the catalytic subunit of the kinase with a  $K_i$  value of 1.7-1.9 nM. Note that the phenylalanyl residue is a major factor in the inhibitory activity of this peptide. 1. Glass, Lundquist, Katz & Walsh (1989) *J. Biol. Chem.* **264**, 14579. 2. Walsh & Glass (1991) *Meth. Enzymol.* **201**, 304.

### Protein Kinase A Inhibitor Fragment 14-24 Amide

This undecapeptide amide (*Sequence:* GRTGRRNAIHD-NH<sub>2</sub>) inhibits protein kinase A. 1. Norenberg, Wirkner, Assmann, Richter & Illes (1998) *Amino Acids* **14**, 33.

### Protein Kinase A Regulatory Subunit

Type I protein kinase A (*i.e.*, cAMP-dependent protein kinase) consists of two catalytic and two regulatory subunits. The regulatory subunits inhibit the activity of the catalytic subunits. Upon binding of cyclic AMP to the regulatory subunits, the catalytic subunits dissociate from the complex and become catalytically active. **Target(s):** cAMP-dependent protein kinase, or protein kinase A (1-5); and phosphorylase phosphatase (6). 1. Traugh, Ashby & Walsh (1974) *Meth. Enzymol.* **38**, 290. 2. Beavo, Bechtel & Krebs (1974) *Meth. Enzymol.* **38**, 299. 3. Lohmann, De Camilli & Walter (1988) *Meth. Enzymol.* **159**, 183. 4. Enzymol.* **159**, 377.

### Protein Kinase C Inhibitor Fragment 19-31

This tridecapeptide (FW = 1543.84 g/mol; *Sequence:* RFARKGALRQ KNV), corresponding to a sequence of residues in the regulatory domain of protein kinase C, inhibits protein kinase C with a IC<sub>50</sub> value of about 0.1  $\mu$ M. 1. House & Kemp (1987) *Science* **238**, 1726.

### Protein Kinase C Inhibitor Fragment 19-36

This fragment (FW = 2151.51 g/mol; *Sequence:* RFARKGALRQKN VHEVKN) of the regulatory domain of protein kinase C resembles a substrate phosphorylation site and acts as a potent inhibitor of protein kinase C autophosphorylation and protein substrate phosphorylation,  $K_i$  = of 147 nM (1,2). 1. House & Kemp (1987) *Science* **238**, 1726. 2. Kemp, Pearson & House (1991) *Meth. Enzymol.* **201**, 287.

### Protein Kinase C Inhibitor Fragment 20-28, Myristoylated, See *N*-(Myristoyl)-Protein Kinase C Inhibitor Fragment 20-28

**Protein Kinase C- $\zeta$  Pseudosubstrate Inhibitor, 113-125**

This tridecapeptide (FW = 1718.04 g/mol; *Sequence*: SIYRRGARRWRKL, matching residues 113-125 of the autoinhibitory domain) is a selective inhibitor of protein kinase C- $\zeta$ . 1. Laudanna, Mochly-Rosen, Liron, Constantin & Butcher (1998) *J. Biol. Chem.* **273**, 30306.

**Protein Kinase C- $\zeta$  Pseudosubstrate Inhibitor, 113-125, Myristoylated, See N-(Myristoyl)-Protein Kinase C- $\zeta$  Pseudosubstrate Inhibitor, 113-125****Protein Kinase C- $\eta$  Pseudosubstrate Inhibitor, Myristoylated, See N-(Myristoyl)-Protein Kinase C- $\eta$  Pseudosubstrate Inhibitor****Protein Kinase C- $\theta$  Pseudosubstrate Inhibitor, Myristoylated, See N-(Myristoyl)-Protein Kinase C- $\theta$  Pseudosubstrate Inhibitor****Protein Kinase G Inhibitor, See L-Arginyl-L-lysyl-L-arginyl-L-alanyl-L-arginyl-L-lysyl-L-glutamate****Protein Kinase Inhibitor, See Protein Kinase A Inhibitor Fragment 5-24; Protein Kinase A Inhibitors; Protein Kinase C Inhibitor Peptide 19-31; Protein Kinase C Inhibitor Peptide 19-36; Protein Kinase G Inhibitor****Protein Phosphatase Inhibitor-1**

This endogenous regulatory protein (MW<sub>human</sub> = 28 kDa; 171 residues) is a specific inhibitor of type 1 serine/threonine protein phosphatases. Its phosphorylation at Threonine-35 (T35) by PKA greatly enhances its ability to bind and inhibit protein phosphatase-1 (PP1), a serine/threonine phosphatase that plays a critical role in glycogen metabolism, muscle contraction, cell progression, neurotransmission, RNA splicing, mitosis, cell division, apoptosis, protein synthesis, and regulation of membrane receptors and channels. A hallmark of heart failure, for example, is deficient sarcoplasmic reticulum (SR) Ca<sup>2+</sup> uptake, which impairs contractility. This disorder results, at least partially, from dephosphorylation of phospholamban by a disease-associated increase in protein phosphatase 1 (PP1) activity. Decreased expression and phosphorylation of inhibitor-1 at Thr35 contribute to observed increases in PP1 activity and dysregulated Ca<sup>2+</sup> homeostasis. **Target(s):** phosphoprotein phosphatase (1-13); [phosphorylase] phosphatase (1-10); and protein phosphatase-1 (1-11,13). 1. McNall, Ballou, Villa-Moruzzi & Fischer (1988) *Meth. Enzymol.* **159**, 377. 2. Ballou & Fischer (1986) *The Enzymes*, 3rd ed. (Boyer & Krebs, eds.), **17**, 311. 3. Cohen, Alemany, Hemmings, et al. **Protein Phosphatase 2A Inhibitor I<sub>1</sub><sup>PP2A</sup>**

This heat-stable protein (MW = 39 kDa) acts as a potent, non-competitive inhibitor of protein phosphatase 2A, K<sub>i</sub> = 30 nM with myelin basic protein, histone H<sub>1</sub>, or phosphorylase as substrate (1,2). Protein Phosphatase 2A Inhibitor I<sub>1</sub><sup>PP2A</sup> is highly expressed in some cancers and may trigger apoptosis. 1. Li, Guo & Damuni (1995) *Biochemistry* **34**, 1988. 2. Li, Makkinje & Damuni (1996) *Biochemistry* **35**, 6998.

**Protein Phosphatase 2A Inhibitor I<sub>2</sub><sup>PP2A</sup>**

This heat-stable protein (MW = 39 kDa) inhibits protein phosphatase 2A, K<sub>i</sub> ≈ 0.1 nM with myelin basic protein, histone H<sub>1</sub>, and other protein substrates (1,2). Protein Phosphatase 2A Inhibitor I<sub>2</sub><sup>PP2A</sup> also stimulates protein phosphatase 1 and regulates histone binding to DNA. I<sub>2</sub><sup>PP2A</sup> is a truncated form of SET, a largely nuclear protein that is fused to nucleoporin Nup214 in acute non-lymphocytic myeloid leukemia. 1. Li, Guo & Damuni (1995) *Biochemistry* **34**, 1988. 2. Li, Makkinje & Damuni (1996) *Biochemistry* **35**, 6998.

**14-3-3 Protein-Protein Interaction Inhibitors 9 & 10**

These small-molecule PPIs (FW<sub>Compound-9</sub> = 395.37g/mol; FW<sub>Compound-10</sub> = 438.44 g/mol) target are 14-3-3 Protein-Protein Interaction Inhibitors that sensitize multidrug-resistant (MDR) cancer cells to doxorubicin and the Akt inhibitor GSK690693 (1). The 14-3-3 family of highly conserved adapter proteins adapter proteins play roles in eukaryotic cellular signaling, cell cycle regulation, protein trafficking, metabolism, and control of apoptosis. Based on bioinformatic and proteomic studies, 14-3-3 isoforms carry out their functions by interacting with >500 protein partners, including c-Abl and Raf kinases, p53, MLF1, FOXO transcription factors, Cdc25, Bad, and Tau. This fact has motivated the search for small-molecule protein-protein interaction inhibitors (PPIs) that can disrupt interactions of 14-3-3 isoforms with their partners. The most active of these PPIs, designated Compounds, 9 and 10 promote translocation of c-Abl into the nucleus, suggesting that they interact with 14-3-3 $\sigma$ . Notably, Compound 9 undergoes spontaneous dehydration to form a phthalimide form, a property that was eliminated through the synthesis of Compound 10. These 14-3-3 PPIs provide anticancer effects in cells by significantly enhancing the activity of the doxorubicin and the pan-Akt inhibitor GSK690693 in MDR cancer cells by decreasing P-glycoprotein expression and inducing apoptosis. 1. Mori, Vignaroli, Cau, et al. (2014) *Chem. Med. Chem.* **9**, 973.

**Protein Synthesis Inhibitors**

These agents retard or arrest protein synthesis by interacting with essential reaction components in multistep ribosome-catalyzed processes. Cycloheximide effectively inhibits eukaryotic protein synthesis on cytoplasmic ribosomes, at 1 mg/mL resulting in 70-75% inhibition for cell-free translation, whereas 30 mg/mL almost totally blocks intracellular protein synthesis. Chloramphenicol blocks the peptidyltransferase reaction, but DNA synthesis can also be reduced by this inhibitor. Other protein synthesis inhibitors include:  $\alpha$ -amino- $\beta$ -butyric acid (an analogue of valine); aurintricarboxylic acid (an inhibitor of initiation at 50 mM); 7-azatryptophan (a tryptophan analogue that blocks bacteriophage synthesis); azetidine-2-carboxylic acid (a four-membered ring analogue of proline that can be incorporated into bacterial proteins); canavanine (an arginine analogue that inhibits bacterial protein synthesis); emetine (binds to the 40S eukaryotic ribosome and inhibits translocation); erythromycin (bacterial protein synthetase inhibitor); ethionine (a methionine analogue that inhibits bacterial protein synthesis); 5-fluorotryptophan; 6-fluorotryptophan; methyltryptophan; fusidic acid; kasugamycin; 7-methylguanosine 5'-

phosphate;  $\omega$ -methyllysine; *O*-methylthreonine; norleucine; pactamycin; puromycin (a potent inhibitor of prokaryotic and eukaryotic protein synthesis); selenomethionine; sparsomycin; streptomycin; tetracycline antibiotics; and tryptazan. **See specific inhibitor;  $\alpha$ -Amino- $\beta$ -Butyric Acid; 7-Azatryptophan; Azetidine-2-Carboxylic Acid; Canavanine; Chloramphenicol; Cycloheximide; Emetine; Erythromycin; Ethionine; 5-Fluorotryptophan; 6-Fluorotryptophan; Fusidic acid; Kasugamycin; 7-Methylguanosine 5'-phosphate; *w*-Methyllysine; *O*-Methylthreonine; Methyltryptophan Norleucine; Pactamycin; Puromycin; Selenomethionine; Sparsomycin; Streptomycin; Tetracycline; and Tryptazan.**

**Prothionine & Prothionine Sulfoximine Phosphate**

These tetrahedral transition-state analogues PSOX (FW<sub>ion</sub> = 207.27 g/mol) and PSOX-P (FW<sub>ion</sub> = 285.24 g/mol) potentially inhibit  $\gamma$ -glutamylcysteine synthetase in a manner similar to the inhibition of glutamine synthetase by methionine sulfoximine. The phosphorylated analogue mimics the acyl-P reaction intermediate. The propyl group presumably binds at the enzyme site pocket normally occupied by L-cysteine. **Target(s):** glutamine synthetase, mildly inhibited (1); and  $\gamma$ -glutamylcysteine synthetase (1-4). 1. Griffith, Anderson & Meister (1979) *J. Biol. Chem.* 254, 1205. 2. Seelig & Meister (1985) *Meth. Enzymol.* 113, 379. 3. Griffith (1987) *Meth. Enzymol.* 143, 286. 4. Griffith & Meister (1979) *J. Biol. Chem.* 254, 7558.

**Protoanemonin**

This antibacterial and antifungal lactone (FW = 96.09 g/mol), also called 5-methylene-2(5*H*)-furanone, 4-methylenebut-2-en-4-olide, and  $\gamma$ -hydroxyvinylacrylic acid lactone, is produced as a glucoside by *Anemone pulsatilla*. Protoanemonin is also formed in the degradation of some chloroaromatic compounds, such as polychlorinated biphenyls, by natural microbial action. It not only inhibits the growth of bacteria, it will also inhibit elongation of oat coleoptile segments and growth of roots. Protoanemonin reportedly reacts with sulfhydryl groups in proteins. **Note:** Protoanemonin can also be produced from 2-chloro-*cis,cis*-muconate by the combined action of muconate cycloisomerase and muconolactone isomerase (1). **Target(s):** carboxymethylenebutenolidase, or dienelactone hydrolase, also weak alternative substrate (2); and pyruvate oxidase (3). 1. Skiba, Hecht & Pieper (2002) *J. Bacteriol.* 184, 5402. 2. Brückmann, Blasco, Timmis & Pieper (1998) *J. Bacteriol.* 180, 400. 3. Baer (1948) *J. Biol. Chem.* 173, 211.

**Protocatechualdehyde**

This aldehyde (FW = 138.12 g/mol), also known as 3,4-dihydroxybenzaldehyde and 4-formylcatechol, is soluble in water (5 g/100 mL at 20°C) and has a p*K*<sub>a</sub> value of 7.55 at 25°C. Protocatechualdehyde induces apoptosis in cytotoxic T cells. **Target(s):** aldehyde oxidase (1); aldose reductase (2);  $\beta$ -carotene 15,15'-monooxygenase (3); mandelonitrile lyase (4); protocatechuate 3,4-dioxygenase (5-11); protocatechuate 4,5-dioxygenase (12,13); tyrosinase, weakly inhibited, IC<sub>50</sub> = 620  $\mu$ M (14); and xanthine oxidase (15,16). 1. **Protocatechuate (Protocatechuic Acid)**

This aromatic acid (FW<sub>free-acid</sub> = 154.12 g/mol), also known as 3,4-dihydroxybenzoic acid, is a white-to-brownish solid that discolors in air. The free acid is slightly soluble in water (1.8 g/100 g H<sub>2</sub>O at 14°C) and has p*K*<sub>a</sub> values of 4.49, 8.83, and 12.6. Store in a well sealed container. Protocatechuate is produced in reactions catalyzed by 4-hydroxybenzoate 3-monooxygenase, 4-dihydroxybenzoate 3-monooxygenase (NAD(P)H); vanillate demethylase, (3*S*,4*R*)-3,4-dihydroxy-cyclohexa-1,5-diene-1,4-dicarboxylate dehydrogenase, terephthalate 1,2-*cis*-dihydrodiol dehydrogenase, 4-sulfobenzate 3,4-dioxygenase, 3-hydroxybenzoate 4-monooxygenase, 4,5-dihydroxyphthalate decarboxylase, and 3,4-dihydroxyphthalate decarboxylase. It is a substrate for protocatechuate 4,5-dioxygenase, protocatechuate 3,4-dioxygenase, and protocatechuate decarboxylase. **Target(s):**  $\gamma$ -butyrobetaine dioxygenase, or  $\gamma$ -butyrobetaine hydroxylase, K<sub>i</sub> = 0.6  $\mu$ M (1); CYP1A2 (2); CYP2B (2); dehydroquinone synthase (3); 5-demethylubiquinone-9 3-*O*-methyltransferase (4); deoxyhypusine monooxygenase (26); dihydroorotate dehydrogenase (5); 1,2-dihydroxynaphthalene dioxygenase (40); 3,4-dihydroxyphenylacetate 2,3-dioxygenase (43,44); 4,5-dihydroxyphthalate decarboxylase (6); diphosphomevalonate decarboxylase (7,8); DNA topoisomerase I (9); fatty acid synthase, weakly inhibited (10); 3-galactosyl-*N*-acetylglucosaminide 4- $\alpha$ -L-fucosyltransferase (11); glutamate decarboxylase (12,13); glycoprotein 3- $\alpha$ -L-fucosyltransferase (11); 4-hydroxybenzoate 3-monooxygenase, product inhibition (30-32); 4-hydroxyphenylpyruvate dioxygenase (42); hyoscyamine (6*S*)-dioxygenase (14); lipase, or triacylglycerol lipase (15); 15-lipoxygenase, or arachidonate 15-lipoxygenase (41); pancreatic lipase (15); peptide-aspartate  $\beta$ -dioxygenase (33); phenol sulfotransferase, or aryl sulfotransferase (16); phenylalanine ammonia-lyase (17); procollagen-proline 4-dioxygenase, or prolyl 4-hydroxylase (18,33-35,37-39); proline 4-dioxygenase (36); prolyl hydroxylase, Skp1 (19); *o*-pyrocatechuate decarboxylase, weakly inhibited (20,21); shikimate dehydrogenase (22,23); tannase (24); tyrosinase, or monophenol monooxygenase (27,28); tyrosine 3-monooxygenase (29); and urease (25). 1. #### Protocatechuic Acid Methyl Ester

This aromatic ester (FW = 168.15 g/mol), also known as methyl 3,4-dihydroxybenzoate, inhibits protocatechiate 3,4-dioxygenase. 1. Que, Lipscomb, Münck & Wood (1977) *Biochim. Biophys. Acta* **485**, 60.

#### Protohemin IX, See Hemin

#### Protolichesterinic Acid

This aliphatic  $\alpha$ -methylene- $\gamma$ -lactone (FW = 324.46 g/mol; CAS 493-46-9) from the lichen *Cetraria islandica* inhibits human DNA ligase (ATP-dependent),  $IC_{50} = 20 \mu M$  (1). Protolichesterinate is a strong inhibitor of the DNA polymerase activity associated with the HIV-1 reverse transcriptase (2) and 5-lipoxygenase, or arachidonate 5-lipoxygenase (3,4). It also exhibits both antibiotic and antitumor properties. 1. Tan, Lee, Lee, et al. (1996) *Biochem. J.* **314**, 993. 2. Pengsuparp, Cai, Constant, et al. (1995) *J. Nat. #### Protoporphyrin IX

This iron-free, immediate precursor of heme (FW<sub>free-acid</sub> = 562.67 g/mol; CAS 553-12-8; brownish-yellow solid; soluble in a number of organic solvents; disodium and dipotassium salts solubilized in the presence of Tween 80) has  $\lambda_{max}$  values in 25% HCl are 602.4, 582.2, and 557.2 nm. Protoporphyrin IX is also an activator of guanylate cyclase. **See also Iron Protoporphyrin IX; Heme; Hemin Target(s):** aminolevulinatase aminotransferase (1); 5-aminolevulinatase synthase (2-5); glutamate: glyoxylate aminotransferase (6); glutathione S-transferase (7-10); glyoxalase I, or lactoylglutathione lyase (11); guanylate cyclase (12); heme oxygenase (13); hydroxymethylbilane synthase, or porphobilinogen deaminase (14,15); nitric-oxide synthase (16); porphobilinogen synthase, or 5-aminolevulinatase dehydratase (17,18); succinyl-CoA synthetase (19,20); tryptophan pyrrolase, or tryptophan 2,3-dioxygenase (21); and uroporphyrinogen decarboxylase (18,22). 1. #### PRT062607

This novel orally available Syk inhibitor (FW<sub>free-base</sub> = 393.46 g/mol; FW<sub>HCl</sub> = 429.91 g/mol; CAS 1370261-97-4), also known as P505-15 and BIIB057 and systematically named 2-[[[(1*R*,2*S*)-2-aminocyclohexyl]amino]-4-[[3-(2*H*-1,2,3-triazol-2-yl)phenyl]amino]-5-pyrimidinecarboxamide, exhibits greater than 80x selectivity for Spleen Tyrosine Kinase Syk (IC<sub>50</sub> = 1 nM) over Fgr, Lyn, FAK, Pyk2 and Zap70. Syk is a B-cell signal-transduction kinase, suggesting that its inhibition should have implications in immune processes. Mice lacking Syk die during embryonic development around midgestation. Abnormal Syk activity is observed in several hematopoietic malignancies, including those having translocations in Itk and Tel. In human whole blood, PRT062607 potently inhibits B cell antigen receptor-mediated B cell signaling and activation (IC<sub>50</sub> = 0.27 and 0.28  $\mu$ M, respectively) and Fc $\epsilon$  receptor 1-mediated basophil degranulation (IC<sub>50</sub> = 0.15  $\mu$ M) (1). Similar levels of *ex vivo* inhibition are measured after dosing in mice (Syk signaling IC<sub>50</sub> = 0.32  $\mu$ M). Syk-independent signaling and activation are unaffected at much higher PRT062607 concentrations, demonstrating the specificity of kinase inhibition in cellular systems (1). In assays that model chronic lymphocytic leukemia (CLL) interactions with the microenvironment, PRT062607 effectively antagonizes CLL cell survival after BCR triggering and in nurse-like cell-co-cultures (2). Moreover, it inhibits BCR-dependent secretion of the chemokines CCL3 and CCL4 by CLL cells, and leukemia cell migration toward the tissue homing chemokines CXCL12, CXCL13, and beneath stromal cells. PRT062607 also inhibits Syk and extracellular signal-regulated kinase phosphorylation after BCR triggering (2). Such findings demonstrate that selective Syk inhibitors inhibition CLL survival and tissue homing circuits, supporting therapeutic development of such agents in patients with CLL, other B cell malignancies, and autoimmune disorders (2). **Target(s):** Syk (IC<sub>50</sub> = 1 nM); Fgr (IC<sub>50</sub> = 81 nM); Mlk1 (IC<sub>50</sub> = 88 nM). 1. Coffey, DeGuzman, Inagaki, *et al.* (2012) *J. Pharmacol. Exp. Ther.* **340**, 350. 2. Hoellenriegel, Coffey, Sinha, *et al.* (2012) *Leukemia* **26**, 1576.

#### PRX-08066

This selective 5-hydroxytryptamine (serotonin) receptor antagonist (FW = 517.96 g/mol; CAS = 866206-55-5), also named 5-((4-(6-chlorothieno[2,3-*d*]pyrimidin-4-ylamino)piperidin-1-yl)methyl)-2-fluorobenzonitrile, targets 5-HT<sub>2B</sub> (IC<sub>50</sub> of 3.4 nM), showing high selectivity over the closely related 5-

HT<sub>2A</sub>, 5-HT<sub>2C</sub> and other receptors and preventing the severity of pulmonary arterial hypertension in the monocrotaline (MCT)-induced rat pulmonary artery hypertension model. PRX-08066 significantly attenuates the elevation in pulmonary artery pressure and right ventricular hypertrophy, thereby improving cardiac function (1). Targeting the 5-HT<sub>2B</sub> receptor also appears to be an effective antiproliferative and antifibrotic strategy for small intestinal neuroendocrine tumors (SI-NETs), because it inhibits tumor microenvironment fibroblasts as well as NET cells (2). 1. Porvasnik, Germain, Embury, *et al.* (2010) *J. Pharmacol. Exp. Ther.* **334**, 364. 2. Svejda, Kidd, Giovinazzo, *et al.* (2010) *Cancer* **116**, 2902.

#### Prucalopride

This novel enterokinetic drug (FW = 367.87 g/mol; CAS 179474-81-8), also known by the tradename Resolor<sup>®</sup> and its systematic name, 4-amino-5-chloro-*N*-[1-(3-methoxypropyl)piperidin-4-yl]-2,3-dihydro-1-benzofuran-7-carboxamide, is a selective, high affinity serotonin 5-HT<sub>4</sub> receptor agonist with that stimulates colonic mass movements, which provide the main propulsive force for defecation. It exhibits high affinity to both 5-HT<sub>4</sub> receptor isoforms, with respective pK<sub>i</sub> values of 8.60 and 8.10 for the human 5-HT<sub>4A</sub> and 5-HT<sub>4B</sub> receptors. Based on 50 other binding assays, only the human D<sub>4</sub> receptor (pK<sub>i</sub> = 5.63), the mouse 5-HT<sub>3</sub> receptor (pK<sub>i</sub> = 5.41) and the human  $\sigma_1$  (pK<sub>i</sub> = 5.43) shown measurable affinity, resulting in >290x selectivity for 5-HT<sub>4</sub> receptors. Prucalopride also differs from other 5-HT<sub>4</sub> agonists, such as tegaserod and cisapride, that interact with other receptors (5-HT<sub>1B/D</sub>) and cardiac human ether-a-go-go K<sup>+</sup> or hERG channel, respectively). 1. Briejer, Bosmans, Van Daele, *et al.* (2001) *Eur. J. Pharmacol.* **423**, 71.

#### Prulifloxacin

This fluoroquinolone-class antibiotic (FW = 461.46 g/mol; CAS 123447-62-1; IUPAC: (*RS*)-6-fluoro-1-methyl-7-[4-(5-methyl-2-oxo-1,3-dioxolene-4-yl)methyl-1-piperazinyl]-4-oxo-4*H*-[1,3]thiazeto[3,2-*a*]quinoline-3-carboxylate), marketed in Japan, Italy and Austria under the tradenames Quisnon<sup>®</sup>, Unidrox<sup>®</sup>, Prixina<sup>®</sup>, and Glimbax<sup>®</sup>, is metabolically de-esterified to ulifloxacin, a broad-spectrum systemic antibacterial agent that targets Type IV DNA topoisomerases (gyrases), thereby impairing replication and transcription. Prulifloxacin is used orally to treat urinary tract infections, community-acquired respiratory tract infections, gastroenteritis, and infectious diarrheas. For the prototypical member of this antibiotic class, **See Ciprofloxacin**

#### Prunasin

This cyanogenic glucoside (FW = 295.29 g/mol; CAS 99-18-3), also known as D(*R*)-mandelonitrile- $\beta$ -D-glucoside, is readily obtained from amygdalin and is found in the pits of *Prunus serotina*. Prunasin is soluble in water and will give rise to prulaurasin (*i.e.*, the diastereoisomeric mixture of DL(*RS*)-mandelonitrile- $\beta$ -D-glucoside [*i.e.*, prunasin and sambunigrin]). **Target(s):** DNA-directed DNA polymerase (1); DNA polymerase  $\beta$  (1); and  $\alpha$ -

trehalase (2,3). 1. Mizushima, Takahashi, Ogawa, *et al.* (1999) *J. Biochem.* **126**, 430. 2. Silva, Terra & Ferreira (2006) *Comp. Biochem. Physiol. B Biochem. Mol. Biol.* **143**, 367. 3. Silva, Terra & Ferreira (2004) *Insect Biochem. Mol. Biol.* **34**, 1089.

#### Prunetin

This *Prunus* species isoflavone (FW = 284.27 g/mol; CAS 552-59-0; melting point = 240°C), also known as 4',5-dihydroxy-7-methoxyisoflavone and 5-hydroxy-3-(4-hydroxyphenyl)-7-methoxy-4H-1-benzopyran-4-one, inhibits alcohol dehydrogenase (1), aldehyde dehydrogenase (2-4), 3',5'-cyclic-nucleotide phosphodiesterase (5), phosphodiesterase 4 (5), and protein-tyrosine kinase (6). Its 4'-glucoside is prunitrin. Methylated isoflavones, such as prunetin, are rapidly converted by CYP1A2 to more active genistein and daidzein, which inhibit formation of acetaminophen from phenacetin with an IC<sub>50</sub> value of 16 μM. 1. Keung (1993) *Alcohol Clin. Exp. Res.* **17**, 1254. 2. Shen, Benson, Johnson, Lipsky & Naylor (2001) *J. Amer. Soc. Mass Spectrom.* **12**, 97. 3. Sheikh & Weiner (1997) *Biochem. #### PS10

This novel ATP binding pocket-directed inhibitor (FW = 323.32 g/mol), systematically named 2-[(2,4-dihydroxyphenyl)sulfonyl]isoindoline-4,6-diol, targets all four PDK isoforms, with an IC<sub>50</sub> = 0.8 μM and K<sub>i</sub> = 0.24 μM for PDK2. Its design is based on structure-guided design, converting a known Hsp90 inhibitor into a series of highly specific PDK inhibitors, substituting a sulfonyl group in place of a carbonyl in the parent compound. This modification results in weak binding to Hsp90 (K<sub>i</sub> = 47 μM). PS10 administration (70 mg/kg) to diet-induced obese mice significantly augments PDC activity with reduced phosphorylation in different tissues. Prolonged treatment improves glucose tolerance, with notably lessened hepatic steatosis in a mouse model. Such findings suggest pharmacological targeting of PDK may be useful in controlling glucose and fat levels in obesity and type 2 diabetes. 1. Tso, Qi, Gui, *et al.* (2014) *J. Biol. Chem.* **289**, 4432.

**PS-341, See Bortezomib**

**PS 1145, See 6-Chloro-8-nicotinamido-β-carboline**

#### Psalmotoxin-1

This 40-residue spider toxin (MW = 4695 Da; Smbol = PcTx1) from the venom of the Trinidad tarantula *Psalmopoeus cambridgei* binds to cysteine-rich domains (IC<sub>50</sub> = 0.9 nM) within the extracellular loop of the pain-sensing Acid-Sensing Ion Channel (*or* ASIC), rapidly desensitizing these proton-gated sodium channels. 1. Escoubas, De Weille, Lecoq, *et al.* (2000) *J. Biol. Chem.* **275**, 25116.

#### Psammaplin A

This marine natural product (FW = 640.37 g/mol), first isolated from the sponges *Poecillastra* sp. and *Jaspis* sp., is cytotoxic against several cancer cell lines. **Target(s):** chitinase (1,2); DNA methyltransferase (3); DNA

topoisomerase II (4); histone deacetylase (3,5); membrane alanyl aminopeptidase, *or* aminopeptidase N (6-8); and mycothiol-S-conjugate amidase (9). 1. **PSC-833, See Valspodar**

#### Pseudocarpa-NAD<sup>+</sup>

This NAD<sup>+</sup> analogue (FW = 925.39 g/mol), also known as carbanicotinamide adenine dinucleotide, has an L-2,3-dihydroxycyclopentyl moiety in place of the D-ribose residue of the nicotinamide nucleotide. It is a potent inhibitor of *Bungarus fasciatus* venom NAD<sup>+</sup> nucleosidase as well as the bovine and ovine brain enzymes. It is not a substrate of alcohol dehydrogenase. **Target(s):** NAD<sup>+</sup> nucleosidase, *or* NADase, *or* NAD<sup>+</sup> glycohydrolase (1-4). 1. Oppenheimer & Handlon (1992) *The Enzymes*, 3rd ed. (Sigman, ed.), **20**, 453. 2. Slama & Simmons (1989) *Biochemistry* **28**, 7688. 3. **Pseudocarbancotinamide Adenine Dinucleotide, See Pseudocarpa-NAD<sup>+</sup>**

#### Pseudoephedrine

This common decongestant and monoamine oxidase inhibitor (FW = 165.24 g/mol) is a nonselective adrenergic agonist and is the (+)-*threo*-isomer of ephedrine. Pseudoephedrine is the sympathomimetic amine found in species of *Ephedra*. Its hydrochloride salt, also known by the proprietary names Novafed and Sudafed, is soluble in water (2 g/mL at 20°C). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Ulus, Maher & Wurtman (2000) *Biochem. Pharmacol.* **59**, 1611.

#### Pseudohypericin

This anti-retroviral agent (FW = 520.45 g/mol) inhibits protein kinase C with an IC<sub>50</sub> value of 28.7 μM and dopamine β-hydroxylase with IC<sub>50</sub> = 3 μM. Pseudohypericin is a component of St. John's Wort (*Hypericum perforatum*). **Target(s):** dopamine β-hydroxylase (1); inositol-trisphosphate 3-kinase (2); and protein kinase C (3). 1. Denke, Schempp, Weiser & Elstner (2000) *Arzneimittelforschung* **50**, 415. 2. Mayr, Windhorst & Hillemeier (2005) *J. Biol. Chem.* **280**, 13229. 3. Takahashi, Nakanishi, Kobayashi, *et al.* (1989) *Biochem. Biophys. Res. Commun.* **165**, 1207.

**Pseudo-iodotyrostatin**

This tyrostatin analogue (FW = 522.38 g/mol) inhibits the pepstatin-insensitive carboxyl protease from *Pseudomonas* sp.:  $K_i = 14$  nM (1). **Target(s):** pseudomonalisin, or pseudomonapepsin (1-3); and sedolisin (3). 1. Wlodawer, Li, Dauter, *et al.* (2001) *Nature Struct. Biol.* **8**, 442. 2. Wlodawer, Li, Gustchina, *et al.* (2001) *Biochemistry* **40**, 15602. 3. Wlodawer, Li, Gustchina, *et al.* (2004) *Biochem. Biophys. Res. Commun.* **314**, 638.

**Pseudomauveine, See Mauve*****Pseudomonas* Exotoxin A**

This 613-residue toxin (Molecular Mass = 71.5 kDa) excreted by *Pseudomonas aeruginosa* catalyzes the NAD<sup>+</sup>-dependent ADPribosylation of elongation factor 2 (EF-2), inhibiting protein biosynthesis (1-4). 1. Iglewski & Sadoff (1979) *Meth. Enzymol.* **60**, 780. 2. Saelinger (1988) *Meth. Enzymol.* **165**, 226. 3. Passador & Iglewski (1994) *Meth. Enzymol.* **235**, 617. 4. Lai (1986) *Adv. Enzymol.* **58**, 99.

**Pseudomonic Acids**

These carboxylic acids (FW<sub>Pseudomonate-A</sub> = 499.62 g/mol; FW<sub>Pseudomonate-B</sub> = 483.62 g/mol; FW<sub>Pseudomonate-C</sub> = 497.61 g/mol) are antibiotics produced by a strain of *Pseudomonas fluorescens*. Pseudomonic acid A, also known as mupirocin, is the major component of the isolated mixture of pseudomonic acids. Pseudomonic acid A inhibits isoleucyl-tRNA synthetase via a slow-tight binding competitive mechanism. 1. Jenal, Rechsteiner, Tan, *et al.* (1991) *J. Biol. Chem.* **266**, 10570. 2. Brown, Mensah, Doyle, *et al.* (2000) *Biochemistry* **39**, 6003. 3. Pope, Moore, McVey, *et al.* (1998) *J. Biol. Chem.* **273**, 31691. 4. Pope, McVey, Fantom & Moore (1998) *J. Biol. Agents Chemother.* **48**, 525. 8. Nakama, Nureki & Yokoyama (2001) *J. Biol. Chem.* **276**, 47387. 9. Yanagisawa & Kawakami (2003) *J. Biol. Chem.* **278**, 25887. 10. Silvan, Wang & Steitz (1999) *Science* **285**, 1074.

**Pseudo-tyrostatin**

This tyrostatin analogue (FW = 412.49 g/mol) inhibits the pepstatin-insensitive carboxyl protease from *Pseudomonas* sp.,  $K_i = 56$  nM (1) and kumamolysin ( $K_i = 17$  μM at 22.4°C (2)). 1. Wlodawer, Li, Gustchina, *et al.* (2001) *Biochemistry* **40**, 15602. 2. Oyama, Hamada, Ogasawara, *et al.* (2002) *J. Biochem.* **131**, 757.

**Pseudouridine**

This pseudonucleoside (FW = 244.20 g/mol), also known as 5-D-β-ribofuranosyluracil and 5-D-β-riboseuracil and symbolized by ψ, is a nonglycosidic constituent of tRNA and snRNA. The λ<sub>max</sub> value at pH 7 is 263 nm (ε = 8100 M<sup>-1</sup>cm<sup>-1</sup>); the value at pH 12 is 286 nm (ε = 7700 M<sup>-1</sup>cm<sup>-1</sup>). It has pK<sub>a</sub> values of 9.0 and > 13. **Target(s):** cytidine deaminase (1); and UDP-*N*-acetylglucosamine diphosphorylase, or *N*-acetylglucosamine-1-phosphate uridylyltransferase (2). 1. Cacciamani, Vita, Cristalli, *et al.* (1991) *Arch. Biochem. Biophys.* **290**, 285. 2. Yamamoto, Moriguchi, Kawai & Tochikura (1980) *Biochim. Biophys. Acta* **614**, 367.

**PSI, See *N*-(Benzyloxycarbonyl)-*L*-isoleucyl-*L*-(glutamyl-*O*<sup>β</sup>-*t*-butyl ester)-*L*-alanyl-*L*-leucinal**

**PSI-7977**

This prodrug of 2'-deoxy-2'-α-F-2'-β-C-methyluridine 5'-monophosphate (FW = 541.47 g/mol; CAS 1190307-88-0), known systematically as isopropyl (2*S*)-2-[[[(2*R*,3*R*,4*R*,5*R*)-5-(2,4-dioxypyrimidin-1-yl)-4-fluoro-3-hydroxy-4-methyl-tetrahydrofuran-2-yl]methoxyphenoxy-phosphoryl]-amino]propanoate, potentially inhibits chronic hepatitis C virus. Once within liver cells, PSI-7977 is converted to 2'-deoxy-2'-α-F-2'-β-C-methyluridine 5'-triphosphate in a multi-step process: (a) stereospecific hydrolysis of the carboxyl ester by human cathepsin A and/or carboxylesterase; (b) nucleophilic attack on the phosphorus by the carboxyl group, resulting in the spontaneous elimination of phenol and the production of an alaninyl phosphate metabolite, PSI-352707; (c) removal of the amino acid moiety by histidine triad nucleotide-binding protein 1; and (d) phosphorylation of the 5'-monophosphate to the active triphosphate by sequential action by

UMP/CMP kinase and nucleoside diphosphate kinase, respectively (1). 1. Murakami, Tolstykh, Bao, *et al.* (2011) *J. Biol. Chem.* **285**, 34337.

### Psicofuranine

This adenosine analogue (FW = 297.27 g/mol; CAS 1874-54-0), also known as 6-amino-9-D-psicofuranosylpurine, 9 $\beta$ -D-(psicofuranosyl)-adenine, and angustmycin C, is a nucleoside antibiotic isolated from *Streptomyces hygroscopicus* that also exhibits antitumor activity. Psicofuranine is soluble in water (8 mg/mL at 25°C) and has a  $\lambda_{\text{max}}$  value of 261 nm in 10 mM base or 259 nm in 10 mM acid. Psicofuranine is an irreversible inhibitor of GMP synthetase that acts by preventing the release (or further reaction) of adenylyl-XMP with water or ammonia; however, it does not suppress exchange reactions (1). **Target(s):** deoxycytidine kinase, weakly inhibited,  $K_i = 12$  mM (1); GMP synthetase, or XMP aminase (2-11); and NAD<sup>+</sup> synthetase (12,13). 1. Krenitsky, Tuttle, Koszalka, *et al.* (1976) *J. Biol. Chem.* **251**, 4055. 2. Fukuyama (1966) *J. Biol. Chem.* **241**, 4745. 3. Sakamoto (1978) *Meth. Enzymol.* **51**, 213. 4. Enzymol.* **113**, 297. 13. Spencer & Preiss (1967) *J. Biol. Chem.* **242**, 385.

### D-Psicose

This ketohexose (FW = 180.16 g/mol), also known as D-ribo-2-hexulose and reportedly found in cane molasses, has epimers of D-psicose are D-fructose, D-sorbose, and L-tagatose. D-Psicose is an alternative substrate for fructokinase. The structural composition of D-psicose at 27°C in D<sub>2</sub>O is 22%  $\alpha$ -pyranose, 24%  $\beta$ -pyranose, 39%  $\alpha$ -furanose, and 15%  $\beta$ -furanose. **Target(s):** ketohexokinase, or hepatic fructokinase; also alternative substrate (1). 1. Raushel & Cleland (1977) *Biochemistry* **16**, 2169.

### D-Psicose 1,6-Bisphosphate

This phosphorylated ketohexose (FW<sub>free-acid</sub> = 340.12 g/mol) is an epimer of D-fructose 1,6-bisphosphate. It inhibits bacterial and plant pyrophosphate-dependent phospho-fructokinase ( $K_i = 0.88$  mM for the bacterial enzyme), or diphosphate:fructose-6-phosphate 1-phosphotransferase. 1. Bertagnolli, Younathan, Voll, Pittman & Cook (1986) *Biochemistry* **25**, 4674.

### D-Psicose 6-Phosphate

This phosphorylated ketose (FW<sub>free-acid</sub> = 260.14 g/mol), an alternative substrate for 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase, inhibits fructose-2,6-bisphosphate 2-phosphatase, weakly inhibited (1,2) and pyrophosphate-dependent phosphofructokinase, or diphosphate:fructose-6-phosphate 1-phosphotransferase,  $K_i = 3.78$  mM (3). 1. Pilkis, Pilkis, El-Maghrabi & Claus (1985) *J. Biol. Chem.* **260**, 7551. 2. Pilkis, Claus, Kountz & El-Maghrabi (1987) *The Enzymes*, 3rd ed. (Boyer & Krebs, eds.), **18**, 3. 3. Bertagnolli, Younathan, Voll, Pittman & Cook (1986) *Biochemistry* **25**, 4674.

### Psilocybin

This serotonergic psychedelic (mind-altering) agent (FW = 284.25 g/mol; CAS 520-52-5); IUPAC Name: 4-hydroxy-N,N-dimethyltryptamine, also known as 3-[2-(dimethyl-amino)ethyl]-4-indolol, is found in psilocybin mushrooms (e.g., *Psilocybe azurescens*, *P. semilanceata*, and *P. cyanescens*), but is rapidly dephosphorylated in humans to form psilocin (FW = 204.27 g/mol; CAS 520-53-6; IUPAC: 3-[2-(dimethylamino)ethyl]-4-indolol), which is a serotonin 5-HT<sub>2A</sub>, 5-HT<sub>2C</sub>, and 5-HT<sub>1A</sub> receptor agonist (or partial agonist). Psilocin is a phospholipase A<sub>2</sub> activator, unlike the endogenous ligand serotonin, which activates phospholipase C. Psilocin is structurally similar to serotonin, differing only by the position of its hydroxyl group and the dimethylated nitrogen. Psilocin is thought to be a partial agonist activity at 5-HT<sub>2A</sub> serotonin receptors in the prefrontal cortex. Ingestion of psilocybin or psilocybin mushrooms leads dilated pupils, restlessness, euphoria, open- and closed-eye visualizations, synesthesia, tachycardia, elevated temperature, headache, sweating, chills, and nausea. 1. Passie, Seifert, Schneider & Emrich (2002) *Addict. Biol.* **7**, 357.

### Psoralen

This phototoxic phytoalexin (FW = 186.17 g/mol), found in many plants, is part of a plant defense scheme to protect against fungi and insects. Upon activation by ultraviolet light, psoralen induces interstrand cross-links in DNA. Psoralen intercalates between DNA base pairs and, upon UV irradiation, forms covalent bonds with a pyrimidine. If posed at a susceptible site, a second photoaddition can occur, forming interstrand cross-links. The combination of psoralens and UVA radiation (PUVA photochemotherapy) is an established treatment for many skin disorders. Note that unsaturated fatty acids and proteins can also undergo a photoaddition reaction with psoralen and psoralen derivatives. **See also psoralen derivatives** (e.g., 8-Methoxy-psoralen) **Target(s):** trans-cinnamate 4-monooxygenase (2,3); CYP2A6 (4); Cyp2a-5 (5); CYP6D1 (6); DNA replication (7); lysozyme (1); and monoamine oxidase (8). 1. Schmitt, Chimenti & Gasparro (1995) *J. Photochem. Photobiol. B: Biol.* **27**, 101. 2. Hübner, Hehmann, Schreiner, *et al.* (2003) *Phytochemistry* **64**, 445. 3. ### Psychosine

This cationic brain lysosphingolipid (FW<sub>free-base</sub> = 461.64 g/mol; CAS 2238-90-6), also known as 1-*O*-β-D-galactosylsphingosine, inhibits metabotropic α<sub>1</sub>-adrenergic receptor signaling-induced phospholipase C activation in rat brain astrocytes. Psychosine also exerts protective effects against quisqualate, suggesting it may be useful in prophylaxis of neurodegenerative disorders arising from over-stimulation of hippocampal Group 1 metabotropic glutamate receptor, *or* mGluR (1). Psychosine is the product of the reaction catalyzed by sphingosine β-galactosyltransferase and is the substrate for psychosine sulfotransferase and galactosylceramidase. **Target(s):** cerebrosidase-sulfatase, *or* arylsulfatase A (2); cytochrome *c* oxidase (3-5); cytokinesis (6); electron transport (7); galactosylgalactosylglucosylceramidase (8); glucocerebrosidase, lysosome (9); β-glucosidase (10); phosphorylase kinase (10); protein kinase C (11-14); protein-tyrosine sulfotransferase (15); and sphingomyelinase (16). 1. ### PT1

This AMPK activator (FW = 497.91 g/mol; CAS 331002-70-1), systematically named 2-chloro-5-[[5-[[4,5-dimethyl-2-nitrophenyl]-2-furanyl]methylene]-4,5-dihydro-4-oxo-2-thiazolyl]amino]benzoic acid, targets AMP-activated protein kinase (EC<sub>50</sub> = 0.3 μM) by antagonizing its built-in autoinhibition mechanism (1). PT1 dose-dependently activates AMPK α<sub>1394</sub>, α<sub>1335</sub>, α<sub>2398</sub>, and even the heterotrimer α<sub>1</sub>β<sub>1</sub>γ<sub>1</sub> form. Based on the structure of PT1 docked to AMPK α<sub>1</sub> subunit, it appears that PT1 interacts with Glu-96 and Lys-156 near the autoinhibitory domain, directly relieving autoinhibition. In studies using L6 myotubes, the phosphorylation of AMPK and its downstream substrate, acetyl-CoA carboxylase, were dose-dependently and time-dependently increased by PT1 without any change in cellular AMP:ATP concentration ratio. 1. Pang, Zhang, Gu, *et al.* (2008) *J. Biol. Chem.* **283**, 16051.

### PT70

This slow, tight-binding enzyme inhibitor (FW = 284.40 g/mol; IUPAC: 2-(*o*-tolylloxy)-5-hexylphenol) targets InhA, the enoyl-ACP reductase ( $K_i = 22$  pM) in *Mycobacterium tuberculosis*, a pathogen that kills more than two

million people annually (1). PT70 binds preferentially to the InhA·NAD<sup>+</sup> complex, after which it has a residence time of 24 min, or ~14,000 times longer than that of the rapidly reversible inhibitor from which it is derived. The off-rate constant for PT70 is 0.043 min<sup>-1</sup>. Parameters for related inhibitors are: PT10 ( $K_i = 129$  pM,  $k_{off} = 0.037$  min<sup>-1</sup>); PT91 ( $K_i = 0.96$  pM,  $k_{off} = 0.048$  min<sup>-1</sup>); PT92 ( $K_i = 0.2$  pM,  $k_{off} = 0.033$  min<sup>-1</sup>); PT155 ( $K_i = 12$  pM,  $k_{off} = \text{rapid}$ ). A large-scale conformational change accounts for the slow conversion of EI to EI\* in a two-step, induced-fit scheme: *Step-1*, E·NAD<sup>+</sup> + I  $\rightleftharpoons$  E·NAD<sup>+</sup>·I; *Step-2*, E·NAD<sup>+</sup>·I  $\rightleftharpoons$  E·NAD<sup>+</sup>·I\* (2). Analogues of the slow-onset inhibitor PT70 permitted identification of the structure of the initial reversible E·I complex, which resembled the E·S complex. Energy profiles were then calculated, using the structures of E·I and E·I\* complexes as the respective initial and final points on the reaction coordinate, leading from the “open” to the “closed” state (2). Crystal structures of the slow-onset and rapidly-reversible ternary complexes suggest that there exist two major enzyme conformations from which the diphenyl ether may select, thus influencing the binding kinetics. Since slow inhibition lags about 4 orders of magnitude behind the rate of catalysis, structural conversions between these two major enzyme conformers when bound to inhibitor must be separated by a much larger energy barrier than that between any conformers on the catalytic reaction coordinate (2). The energy profiles rationalize the observed inhibition kinetics by rapid reversible and slow-onset inhibitors, providing a framework for rationally modulating residence time for InhA inhibitors (2). 1. ### PTC124, See Ataluren

### PTEN

This tumor-suppressing, Mg<sup>2+</sup>-dependent dual-specificity protein phosphatase (MW = 47166 g/mol; GenBank: AAD13528.1), which catalyzes the dephosphorylation of phosphotyrosine-, phosphoserine- and phosphothreonine-containing proteins, is also a lipid phosphatase (*Reaction*: Phosphatidylinositol 3,4,5-trisphosphate + H<sub>2</sub>O  $\rightleftharpoons$  Phosphatidylinositol 4,5-bisphosphate + P<sub>i</sub>), with the following *in vitro* substrate preference: PtdIns(3,4,5)P<sub>3</sub> > PtdIns(3,4)P<sub>2</sub> > PtdIns3P > Ins(1,3,4,5)P<sub>4</sub>. PTEN antagonizes PI3K-AKT/PKB signaling by dephosphorylating phosphoinositides and reduces cell cycle progression and survival. The unphosphorylated form cooperates with AIP1 to suppress AKT1 activation. PTEN catalyzes the dephosphorylation of tyrosine-phosphorylated focal adhesion kinase, inhibiting cell migration and integrin-mediated cell spreading. PTEN also modulates AKT-mTOR signaling. PTEN plays an essential role in the maintenance of genome stability (1,2). PTEN also dephosphorylates MCM2 and inhibits replication fork progression under replication stress, suggesting that PTEN is involved in an S-phase checkpoint (3). DNA molecular combing analysis revealed that replication forks in PTEN-proficient cells are subject to more efficient braking in response to fork stalling than the forks in PTEN-deficient cells. 1. ### Pterin

This aromatic reagent (FW = 163.14 g/mol), also known as 2-amino-4-hydroxypteridine and 2-amino-4-oxopteridine, is the structural unit for folic acid, folic acid antagonists, plant and animal pigments, enzyme cofactors, *etc.* **Target(s):** adenosine deaminase (1); γ-glutamyl hydrolase, *or* pteroylpolyglutamate hydrolase (2); hypoxanthine(guanine) phosphoribosyltransferase (3); NAD(P)H dehydrogenase, quinone-dependent (4); sepiapterin deaminase (5-7); and tRNA-guanine transglycosylase (8). 1. ### Pterin-6-aldehyde, See 2-Amino-4-hydroxypteridine-6-aldehyde

**Pterico Acid**

This metabolite (FW<sub>free-acid</sub> = 312.29 g/mol; CAS 119-24-4), also known as 4-[[[(2-amino-1,4-dihydro-4-oxo-6-pteridiny)methyl]amino]benzoic acid, is a structural component of folates. Pterico acid is a growth factor for a number of *Enterococci*. Pterico acid is a yellow powder that is slightly soluble in aqueous NaOH. The  $\lambda_{\text{max}}$  values in 0.1 M NaOH are 255, 275, and 365 nm ( $\epsilon$  = 26300, 23400, and 8900 M<sup>-1</sup>cm<sup>-1</sup>, respectively).

**Target(s):** arylamine *N*-acetyltransferase (1); dihydrofolate reductase (2,3); dihydrofolate synthetase, weakly inhibited (4); dihydropteroate synthase (5); glutamate carboxypeptidase (6); and xanthine oxidase (7-9). 1. **Pteropterin**, See *Pteroyltriglutamate*

**Pteroyldiglutamate**, See *Pteroyl-( $\gamma$ -glutamyl)-glutamate; Diopterin*

**Pteroylglutamate**, See *Folic Acid*

**Pteroyl-( $\gamma$ -glutamyl)glutamate**

This form of folic acid, also called pteroyldiglutamate (FW<sub>free-acid</sub> = 569.51 g/mol), a precursor in the formation of longer polyglutamate forms, is reportedly the only folate form in the *Halobacterium* strain GN-1. Note: This precursor should not be confused with diapterin, also known as pteroyl- $\alpha$ -glutamylglutamate. **Target(s):** N<sup>5</sup>-methyltetrahydrofolate: homocysteine *S*-methyltransferase (1); and thymidylate synthase (2,3). 1. Whitfield, Steers & Weissbach (1970) *J. Biol. Chem.* **245**, 390. 2. Danenberg (1977) *Biochim. Biophys. Acta* **473**, 73. 3. Radparvar, Houghton & Houghton (1988) *Arch. Biochem. Biophys.* **260**, 342.

**Pteroyl- $\gamma$ -glutamyl- $\gamma$ -glutamylglutamate**, See *Pteroyltriglutamate*

**Pteroylhexaglutamate**

This folic acid polyglutamate (FW = 1091.1 g/mol) inhibits thymidylate synthase (1-3). 1. Kisiuk, Gaumont & Baugh (1974) *J. Biol. Chem.* **249**, 4100. 2. Radparvar, Houghton & Houghton (1988) *Arch. Biochem. Biophys.* **260**, 342. 3. Danenberg (1977) *Biochim. Biophys. Acta* **473**, 73.

**Pteroylpentaglutamate**

This folic acid polyglutamate (FW<sub>free-acid</sub> = 957.87 g/mol), the major form in liver and murine erythroleukemia cells, inhibits amidophosphoribosyltransferase (1), N<sup>5</sup>,N<sup>10</sup>-methylenetetrahydrofolate synthetase (2),

phosphoribosyl-aminoimidazolecarboxamide formyltransferase, or 5-aminoimidazole-4-carboxamide ribotide transformylase (3), and thymidylate synthase (4,5). 1. Santi, Lyons, Phillips & Christopherson (1992) *J. Biol. Chem.* **267**, 11038. 2. Jolivet (1997) *Meth. Enzymol.* **281**, 162. 3. Baggott, Vaughn & Hudson (1986) *Biochem. J.* **236**, 193. 4. Dolnick & Cheng (1978) *J. Biol. Chem.* **253**, 3563. 5. Radparvar, Houghton & Houghton (1988) *Arch. Biochem. Biophys.* **260**, 342.

**Pteroyltriglutamic Acid**

This folate (FW<sub>free-acid</sub> = 699.63 g/mol), also known as pteropterin and pteroyl- $\gamma$ -glutamyl- $\gamma$ -glutamylglutamate, is a precursor to polyglutamated forms of folic acid. It is the major form of folate in certain microorganisms. **Target(s):** 5-methyl-tetrahydro-pteroyl-triglutamate:homocysteine *S*-methyltransferase (1); and thymidylate synthase (2-5). 1. Whitfield, Steers & Weisbach (1970) *J. Biol. Chem.* **245**, 390. 2. Lockshin & Danenberg (1979) *J. Biol. Chem.* **254**, 12285. 3. Kisiuk, Gaumont & Baugh (1974) *J. Biol. Chem.* **249**, 4100. 4. Dolnick & Cheng (1978) *J. Biol. Chem.* **253**, 3563. 5. Radparvar, Houghton & Houghton (1988) *Arch. Biochem. Biophys.* **260**, 342.

**Pterulnic Acid**

This novel acid (FW<sub>free-acid</sub> = 290.70 g/mol), produced by species of *Pterula*, inhibits complex I of mitochondrial electron transport, also known as NADH dehydrogenase and NADH:ubiquinone oxidoreductase (1,2). 1. Engler, Anke, Sterner & Brandt (1997) *J. Antibiot.* **50**, 325. 2. Engler, Anke & Sterner (1997) *J. Antibiot.* **50**, 330.

**PTP Inhibitor**

This cell-permeable SHP2 catalytic domain inhibitor (FW = 557.61 g/mol; Solubility: 100 mg/mL DMSO; Protect from light: IUPAC: 3-(1-(3-(biphenyl-4-ylamino)-3-oxopropyl)-1*H*-1,2,3-triazol-4-yl)-6-hydroxy-1-methyl-2-phenyl-1*H*-indole-5-carboxylate), also variously known as SHP2 Inhibitor VI, CD45 Inhibitor V, FAP1 Inhibitor, LMWPTP Inhibitor, Lyp Inhibitor III, PTP1B Inhibitor IX, SHP1 Inhibitor IX, and code-named II-B08, targets SHP2-catalyzed pNPP hydrolysis (IC<sub>50</sub> = 5.5  $\mu$ M; reversible and noncompetitive manner,  $K_i$  = 5.2  $\mu$ M), exhibiting selectivity over PTP1B (IC<sub>50</sub> = 14  $\mu$ M), SHP1 (IC<sub>50</sub> = 16  $\mu$ M), FAP1 (IC<sub>50</sub> = 20  $\mu$ M), Lyp (IC<sub>50</sub> = 25  $\mu$ M), CD45 (IC<sub>50</sub> = 30  $\mu$ M), and LMWPTP (IC<sub>50</sub> = 31  $\mu$ M, respectively), with >9-fold selectivity over Cdc14A, HePTP, LAR, PTP $\alpha$ , and VHR, all having IC<sub>50</sub> values in excess of 50  $\mu$ M. Gain-of-function KIT receptor mutation (e.g., KIT<sup>D814V</sup> in mice and KIT<sup>D816V</sup> in humans) results in altered substrate recognition and constitutive tyrosine autophosphorylation leading to promiscuous signaling that is associated with gastrointestinal stromal tumors (GIST), systemic mastocytosis (SM), and acute myelogenous leukemia (AML). Likewise, the Src Homology-2 domain containing protein tyrosine Phosphatase-2 (SHP2) plays a pivotal role in

growth factor and cytokine signaling, and gain-of-function SHP2 mutations are associated with various leukemias and solid tumors. Screening of a salicylate-based combinatorial library led to the discover of this inhibitor's highly efficacious cellular activity, blocking growth factor stimulated ERK1/2 activation and hematopoietic progenitor proliferation, thereby showing SHP2 inhibition may be exploited to combat cancer (1). X-ray crystallographic analysis of the structure of SHP2 in complex with this inhibitor reveals molecular determinants that can be exploited for the acquisition of other SHP2 inhibitors (1). Indeed, pharmacologic inhibition of SHP2 phosphatase by II-B08 results in reduced SHP2 constitutive phosphorylation in KIT<sup>D814V</sup>-bearing cells (2). Inhibition of SHP2 phosphorylation by II-B08 also results in significant repression in ligand-independent growth and survival of cells bearing KIT<sup>D814V</sup> and primary human KIT<sup>D816V</sup>-bearing CD34<sup>+</sup> cells (2). Consistent with such findings, deficiency of SHP2 in HSC/Ps expressing KIT<sup>D814V</sup> likewise inhibits ligand-independent growth and survival (2). Inhibition of protein tyrosine phosphatase 1B (PTP1B) by II-B08 also promotes endothelial cell migration and angiogenesis by enhancing VEGFR2 signaling and increases p130Cas phosphorylation as well as the interactions among p130Cas, Crk and DOCK180 (3). (Phosphorylation levels of focal adhesion kinase, Src, paxillin, or Vav2 remain unchanged.) Gene silencing of DOCK180, but not Vav2, was found to abrogate the effects of PTP1B inhibitor on EC motility (3). The effects of PTP1B inhibitor on EC motility and p130Cas/DOCK180 activation persisted in the presence of the VEGFR2 antagonist, suggesting stimulation of the DOCK180 pathway represents an alternative mechanism of PTP1B inhibitor-stimulated EC motility, one that does not require concomitant VEGFR2 activation as a prerequisite (3). 1. #### PTX042695

This peptide analogue (FW = 561.63 g/mol) is a strong inhibitor of *Escherichia coli* pantetheine-phosphate adenylyltransferase (IC<sub>50</sub> = 6 nM) but does not inhibit the porcine enzyme (1). Replacing the D-histidyl residue with D-serine weakens the inhibition (IC<sub>50</sub> = 0.12 μM). Replacing the L-glutamyl residue with S-carboxymethyl-D-cysteine or the corresponding sulfone slightly weakens the inhibition (IC<sub>50</sub> = 20 and 10 nM, respectively). 1. Zhao, Allanson, Thomson, *et al.* (2003) *Eur. J. Med. Chem.* **38**, 345.

#### Puerarin

This C-glycoside isoflavone (FW = 416.38 g/mol; M.P. = 190°C), isolated from the root of a wild leguminous creeper, *Pueraria lobata*, is a major component of ge-gen, which is used in traditional Asian medicine. **Target(s):** aldose reductase (1); Ca<sup>2+</sup> channel, L-type (2); K<sup>+</sup> currents, transient outward and delayed rectifier currents (3); and Na<sup>+</sup> current, tetrodotoxin-resistant (4). 1. Zhang & Zhou (1989) *Zhongguo Zhong Yao Za Zhi* **14**, 557. 2. Qian, Li, Huang, *et al.* (1999) *Chin. Med. J. (Engl.)* **112**, 787. 3. Zhang, Hao, Zhou, Wu & Dai (2001) *Acta Pharmacol. Sin.* **22**, 253. 4. Ji & Wang (1996) *Zhongguo Yao Li Xue Bao* **17**, 115.

#### Pullulan

This glucan is a branched polymer (M.W. ranging between 10<sup>5</sup> and 10<sup>6</sup> Da) of D-glucose linked α(1→4) and α(1→6), first isolated from the fungi *Aureobasidium pullulans* and later observed in other fungi. Pullulan is much more highly branched than either amylopectin or glycogen and can be regarded as a polymer of α-maltotriosyl units joined by α(1→6) linkages with a few α-maltotetraosyl units also present. **Target(s):** cyclomaltodextrin glucanotransferase, alkaliphilic bacteria, slight inhibition (1); and leukocyte elastase, inhibited by sulfated pullulans (2). 1. Zhang, Yan & Zhang (1998) *Wei Sheng Wu Xue Bao* **38**, 98. 2. Becker, Franz & Alban (2003) *Thromb. Haemost.* **89**, 915.

#### Pulvomycin

This antibiotic (FW = 839.03 g/mol), also known as antibiotic 1063-Z, inhibits protein biosynthesis by blocking ternary complex formation between elongation factor Tu, GTP, and aminoacyl-tRNA (1-6). 1. Mesters, Potapov, de Graaf & Kraal (1994) *J. Mol. Biol.* **242**, 644. 2. Wolf, Assmann & Fischer (1978) *Proc. Natl. Acad. Sci. U.S.A.* **75**, 5324. 3. Pingoud, Block, Urbanke & Wolf (1982) *Eur. Parmeggiani, Krab, Okamura, *et al.* (2006) *Biochemistry* **45**, 6846.

#### Pumiliotoxins

These neurotoxins are found in the skin secretions of neotropical poison arrow frogs, occurring in all species groups of *Dendrobates* and *Phylllobates*. There are more than one hundred toxins designated as pumiliotoxins, and they are currently divided into major groups referred to as Pumiliotoxins A, B, and C. Pumiliotoxins A and B, also known as pumiliotoxin 307A and pumiliotoxin 323A (with the number refers to the nominal mass: *i.e.*, 307.48 and 323.48 g/mol) are far more toxic than the pumiliotoxins C, which is virtually nontoxic. Subcutaneous injection of pumiliotoxin A or B in mice causes locomotor difficulties, partial paralysis

of hind limbs, salivation, extensor movements, and finally, clonic convulsions and death, all in less than ten minutes. Even at lower doses, one member of the B group can cause death in less than twenty minutes. Pumiliotoxin C, now referred to as decahydroquinoline *cis*-195A, interacts with acetylcholine receptor-regulated ion channels (2,3), whereas pumiliotoxins A and B stimulate Na<sup>+</sup> channels. **Target(s):** Ca<sup>2+</sup>-transporting ATPase, inhibited by pumiliotoxins A, B, and 251D (4); nicotinic acetylcholine receptor-channels, by pumiliotoxin C (2,3). **1.** Daly & Myers (1967) *Science* **156**, 970. **2.** Conn (1983) *Meth. Enzymol.* **103**, 401. **3.** Daly, Nishizawa, Padgett, *et al.* (1991) *Neurochem. Res.* **16**, 1207. **4.** Tamburini, Albuquerque, Daly & Kauffman (1981) *J. Neurochem.* **37**, 775.

### Punicic Acid
