## PREFACE

The roots of this reference book first took hold in 1967, when the purchase of a small notebook permitted me – then a first-year graduate student at Iowa State University – to record the names and properties of every enzyme and metabolic inhibitor then in use in the Department of Biochemistry & Biophysics. That practice was sparked by my graduate work in the laboratory of Professor Herbert J. Fromm, the enzyme kineticist who pioneered the use of dead-end competitive inhibitors, alternative substrate inhibitors, and multisubstrate geometrical analogues to define the steady-state behavior of multisubstrate enzyme-catalyzed reactions. Although a famously demanding taskmaster, Herb never discouraged his students from visiting the Physical Sciences Reading Room, and I spent many an hour reading research journals in quiet comfort, learning more and more about the primary modes of action of countless inhibitors. During a visit to Ames several years later, the celebrated enzymologist Ephraim Racker presented a seminar, in which he restated his oft-quoted and playful adage: “An inhibitor is most specific on the day of its discovery.” Little did Racker know how he had inspired me to pay more attention to the off-target and toxic effects of inhibitors.

This systematic effort continued, when, as a NIH Staff Fellow, I joined Earl Stadtman in the NIH Laboratory of Biochemistry to study the adenylylation/deadenylylation cascade that controls the *Escherichia coli* glutamine synthetase, an enzyme that is unrivaled in the complexity of its feedback inhibition, posttranslational modification, and transcriptional regulation. As a mecca for biomedical research, Earl and Terry Stadtman’s lab attracted many famous researchers, who were always eager to share their latest findings. The Library in nearby Building 10 was also an ideal setting for me to add new compounds and to gather details about the actions of inhibitors acting on all manner of biochemical and physiological processes.

This practice continued with heightened interest, when I moved to the Department of Chemistry at the University of California Santa Barbara, where I filled the position and occupied the office previously occupied by the late Professor B. R. Baker, a pioneer in the synthesis of puromycin and anti-folates. Baker was the author of *THE DESIGN OF ACTIVE SITE-DESIGNED IRREVERSIBLE ENZYME INHIBITORS*. That seminal monograph described the logic of his determined efforts to synthesize and screen many hundreds of potential anticancer agents.

In the early 1970s, the field of enzyme chemistry was also abuzz with new ideas about the nature of enzyme intermediates, the action of mechanism-based inhibitors, the theory and design of first-generation transition-state inhibitors, as well as first recognition of slow, tight-binding inhibitors. The nature of allosteric feedback inhibition was yet another focus of enzyme science in that era.

Upon becoming the Chair of Biochemistry & Molecular Biology at the University of Florida College of Medicine in 1984, I had the opportunity to attend numerous pharmacology, physiology, and neuroscience seminars, a practice that fostered greater awareness of the clinical significance of receptor antagonists. A few years later, the department was fortunate to hire Dr. R. Donald Allison as an instructor. Previously my doctoral student at UC Santa Barbara, Don was keenly aware of the “Inhibitor Project”, and, in 2004, offered to consolidate my inhibitor database and to collect additional information. Tragically, that effort was cut short in 2010, when Don perished from injuries from an auto accident. I dedicate this monograph to Don Allison in honor of our 37-year friendship. A better friend no one can have!

Now, fifty years after this project began, the first edition of *THE INHIBITOR INDEX* will provide readers with a single-source reference citing over 50,000 original research publications on the actions of nearly 8000 enzyme inhibitors, receptor antagonists, drugs, toxins, poisons, and/or therapeutic leads. Many are widely used in research and medicine; others should stimulate novel approaches and further research; still others are offered to acknowledge their historical significance. Future editions will include additional entries from an already compiled master source list of over 12,000 compounds. Readers are advised that suggestions for new entries and corrections will always be welcomed.

Lastly, I thank Fiona Macdonald at CRC Press for making the publication of this book so pleasant, even as she deftly applied her considerable chemical prowess to detect and correct my errors.

March, 2017

# INTRODUCTION

In the molecular life sciences, metabolic inhibitors and receptor antagonists are indispensable tools of the trade. Because enzymes carry out their tasks with fidelity, catalysis underlies most cellular processes, from facilitating central pathway metabolism to driving signal transduction (*e.g.*, 3',5'-cyclic-AMP, 3',5'-cyclic-GMP, and nitric oxide stimulation of protein kinases). Receptors are no less remarkable, and such considerations explain why cellular processes are exquisitely sensitive to inhibitors and antagonists. By blocking specific enzymes and/or receptor-mediated signaling, inhibitors and antagonists simplify the analysis of complex cellular processes. They are also incredibly useful in demonstrating that a process is functionally linked to an inhibitor-sensitive enzyme or an antagonist-sensitive receptor. Indeed, such target-specific agents provide a straightforward way to minimize the influence of competing pathways that might otherwise obscure mechanistic features of a reaction or process of experimental interest.

Inhibitors are incredibly versatile in the analysis of metabolite and signal transduction pathways. Although mutations can be used to block specific enzymes and receptors, an inhibitor's potency (a) can be conveniently ramped from low to high, based on the chosen value of  $[I]/K_i$ , where  $[I]$  is the inhibitor concentration and  $K_i$  is the inhibition constant; (b) can be modulated by changes in substrate concentration, which can often displace or compete with the inhibitor; and (c) can be attenuated or completely reversed by dilution or dialysis. Enzyme inhibitors and receptor antagonists also allow one to retard processes that might otherwise occur on a timescale too rapid for convenient observation.

Through the use of microbe-killing antibiotics, cholesterol-reducing statins, mood-controlling agents, etc., modern medicine has benefitted from enzyme inhibitors and receptor antagonists. Chief limitations on their use concern bioavailability, potency, specificity, and above all – safety. Although improved mainly by trial and error, bioavailability is often predicted by *Lipinski's Rule of Fives*, which suggests that druglike properties of small molecules can be achieved if the molecular mass is less than *five* hundred daltons, if the  $\log_{10}$  value of the *n*-octanol/H<sub>2</sub>O partition coefficient *P* exceeds *five*, if there are fewer than *five* hydrogen-bond donors, and if there are fewer than twice *five* (*i.e.*, 10) hydrogen-bond acceptor groups. That said, more and more drugs are administered intravenously or orally as membrane-penetrating prodrugs. Improvements in potency are driven by greater awareness of the atomic-level structure of enzymes and receptors and by the successful characterization of the underlying mechanisms of catalysis and signal transduction. Specificity is always a challenge, because off-target effects are not always evident, especially when agents are used persistently to treat chronic ailments. And, consistent with *Rackner's Rule*, asserting that an inhibitor is most specific on the day of its discovery, one must await further investigation to uncover off-target effects of inhibitors and antagonists. The advent of metabolomics, pharmacogenomics, and toxicogenomics offer hope that off-target effects can be detected or predicted, thus providing a wider margin of safety.

Beyond human medicine, enzyme inhibitors and receptor antagonists improve the lives of pets and show animals as well as the health and productivity of livestock. And no one can dispute the impact, albeit controversial, of glyphosate, the broad-spectrum systemic herbicide that provides farmers a way to control weeds, and, when coupled with GM glyphosate-resistant seeds, a way to improve per-acre crop yields.

***HOW COMPOUNDS WERE SELECTED FOR THE INHIBITOR INDEX*** – This reference describes the inhibitory action of nearly 8000 biologically significant agents, ranging from natural products to those now synthesized on the basis of structural biology and fragment-based approaches. Included are natural antibiotics, ultrahigh-affinity transition-state analogues, toxins, and receptor-neutralizing antibodies, ranging from molecules consisting of only a few atoms to those with 30,000 atoms. The goal of *THE INHIBITOR INDEX* is to describe both their primary mode of action as well as their off-target effects, simply because lack of specificity most often compromises the unambiguous use of inhibitors and antagonists.

The challenge of selecting compounds is illustrated with inhibitors of angiotensinogen-converting enzyme (ACE). Well over one-million candidate compounds have been tested for their antihypertensive effects, making it abundantly clear that no book or database can include all of the known ACE inhibitors. The same can be said for the myriad of receptor ligands that have been tested for action as agonists, partial agonists, inverse agonists, and antagonists or as direct and indirect inhibitors of receptor-mediated autophosphorylation and/or G-protein-coupled processes. Such considerations drive the logic for focusing mainly on: (a) enzyme inhibitors that molecular life scientists reliably use to impede/block cellular processes (*e.g.*, transporters, ion channels, metabolic pathways, chromosome remodeling, replication, transcription, translation, protein folding, cytoskeletal processes, or distinct organelle functions, etc.); (b) those receptor antagonists that are well-characterized in terms of their ability to reduce signal transduction processes vital to cell and/or organ function; and (c) inhibitors that have already become drugs or are valuable as “lead molecules” for the development of novel drug-based therapies.

Of the 12,000 molecules currently in *THE INHIBITOR INDEX* master file, it seemed prudent to begin with approximately 7800 molecules, a number large enough to represent the inhibitors frequently used by practicing molecular life scientists, while including other drugs, antibiotics, and poisons used less often. The goal was to provide a one-volume compendium with adequate documentation of each entry's class, structure, formula weight, solubility, mode of action, off-target effects, and pertinent literature citations. Target selectivity and frequency of citation have and will always commend a molecule for inclusion in the first and sub-

sequent editions. Even so, other notable compounds, having been historically significant by serving as prototypes for developing later-generation agents. Their mechanisms of action are milestones in the molecular life sciences. Other less frequently used toxins and poisons are also included, as are many drug leads, to foster broader awareness and encourage future development.

**HOW INHIBITOR INDEX ENTRIES ARE CURATED** – Every effort has been made to confirm the accuracy of the structures, stereochemistry, physical and chemical properties as well as other details for listed compounds. In most cases, the original research paper was examined, and, when conflicts arose, they were often resolved by contacting by one or more authors or by consulting other experts. Given the ongoing need to rename certain enzymes, alternate names were also used to search for inhibitor information. It has proved infeasible, however, to specify the organism or tissue of origin for every enzyme/receptor target; however, the literature citations should permit interested readers with ready access to these and other details. Because this book is intended for practicing molecular life scientists, no information concerning chemical syntheses and/or patents is provided. And, given the rapid pace of biomedical research, the latest findings on currently listed compounds will be incorporated into future editions, and every effort will be made to add promising inhibitors and antagonists in a timely manner.

**MAKING BEST USE OF THE INHIBITOR INDEX** – Experiments with enzyme inhibitors and receptor antagonists are least ambiguous when researchers maximize target specificity/selectivity. This can be best achieved by employing the electronic version to identify all agents having a particular enzyme or receptor as the primary target. When affinity data are available, one should favor agents having the lowest  $K_i$  or  $IC_{50}$  values, thereby minimizing the occurrence of spurious off-target effects, as the concentration of inhibitor or antagonist reaches the oversaturation range (*e.g.*, when [Inhibitor] or [Antagonist]  $\gg K_i$  or  $IC_{50}$ ). When multiple agents are available, experiments should be conducted in parallel using each inhibitor. Greatest confidence arises when the target enzyme or receptor is inhibited by two or more structurally unrelated, target-specific inhibitors/antagonists, each exhibiting a unique set of off-target effects.

**DISCLAIMERS** – The information in this book is solely intended for laboratory use and *NOT* for clinical purposes. Physicians or veterinarians should instead consult *THE PHYSICIANS DESK REFERENCE* or *THE VETERINARIANS DESK REFERENCE*, as well as the manufacturer's FDA-approved package insert describing a drug's pharmacologic action, approved indications and dosages. The author also makes no direct, or implied, warranty as to the safety of any listed practices; nor should the reader infer that information provided here is completely current. Because *ALL* listed substances inhibit one or more vitally important enzymes or receptors, they should be treated as dangerous or potentially so. Nor should the absence of a specific cautionary be taken to imply that a listed substance is harmless. Recommendations provided here are based on information contained in source publications; however, best-practice standards evolve, when previously unknown hazards are discovered. Readers seeking specific advice concerning the safe handling of agents listed in *THE INHIBITOR INDEX* should consult additional sources, including *CHEM SOURCES* or specific-use data sheets supplied by manufacturers and distributors. In the absence of such information, it would be wise to treat all listed agents as potentially hazardous. Good laboratory practice demands that experimenters avoid contacting, swallowing, or inhaling chemical fluids, fumes and particulates. One must likewise minimize exposure to skin, eyes, and nasal passages by appropriate use of gloves, glasses, masks, laboratory garb, closed-toe shoes, as well as a chemical fume hood. Note also that static electricity frequently disperses finely divided powders during weighing, with consequential risk of inhalation. Protein and peptide inhibitors may also be allergenic. Above all, one must proceed with an abundance of caution. The reader accepts full responsibility for the safe use of agents mentioned in this book. The author and publisher bear no responsibility for any loss or damage, arising from use of information provided in *THE INHIBITOR INDEX*, whether such loss is direct, indirect, special, or incidental.

## ABOUT THE AUTHOR

Dan Purich earned his Ph.D. for ground-breaking work on brain hexokinase, adenine nucleotide control, and multisubstrate inhibitors under Herbert Fromm at Iowa State University. After investigating the glutamine synthetase adenylylation cascade as an NIH Staff Fellow under Earl Stadtman, he joined the Chemistry Department at UC Santa Barbara. Awarded a Sloan Fellowship in Chemistry and NIH Research Career Development Award, Purich rose to full professor before moving to the University of Florida College of Medicine to become Chair of Biochemistry & Molecular Biology. He served on the *Journal of Biological Chemistry*, *Archives of Biochemistry & Biophysics*, and *Biophysical Chemistry* editorial boards. He also edited the six-volume *Enzyme Kinetics & Mechanism* sub-series of *METHODS IN ENZYMOLOGY* and wrote *THE HANDBOOK OF BIOCHEMICAL KINETICS* (2000), *THE ENZYME REFERENCE* (2002), and *ENZYME KINETICS: CATALYSIS & CONTROL* (2010). Author of over 170 peer-reviewed papers, chapters and reviews on enzyme action and cytoskeleton self-assembly, Purich discovered the actoclampins, the (+)-end-tracking motors that power actin-based motility by harnessing the Gibbs energy of on-filament ATP hydrolysis, while catalyzing monomer insertion. For fun, he travels and writes mystery novels.

A, See Adenine; Alanine

A3, See *N*-(2-Aminoethyl)-5-chloronaphthalene-1-Sulfonamide

## A20 Protein

This novel zinc finger protein (MW = 89614 g; Isoelectric Point = 8.62) is a key player in the negative feedback regulation of the NF- $\kappa$ B pathway in response to multiple stimuli. Tumor necrosis factor alpha (TNF $\alpha$ ) dramatically increases A20 expression in all tissues. A20 drives the adipogenic capacity of human mesenchymal stromal cells (MSCs), even in the presence of TNF $\alpha$ . 1. Dorronsoro, Lang, Jakobsson, *et al.* (2013) *Cell Death Dis.* 4, e972.

## A46 Protein

This receptor signal-interference protein (MW = 27622 g; GenBank: CAM58344.1) targets the Toll-like receptor/ interleukin-1R (TIR) domain of Toll-like receptors (TLRs) and intracellular adaptor proteins, such as MAL, TRAM, TRIF and MyD88, promoting vaccinia virus replication in host cells. Full-length A46 behaves as a tetramer, whereas variants lacking the N-terminal 80 residues are dimeric. Both forms bind to the TLR domains of MAL and MyD88 with  $K_d$  values in the low  $\mu$ M range. A46 also shows a Bcl-2 like fold, but differences from that of A52, another Vaccinia signaling interference protein. A46 employs helices  $\alpha$ -4 and  $\alpha$ -6 to dimerize, whereas to the  $\alpha_1$ - $\alpha_6$  face is used by A52 and other Bcl-2 like Vaccinia proteins. Comparisons of A46 and A52 exemplify how subtle changes in viral proteins with the same fold can lead to crucial differences in biological activity. 1. Fedosyuk, Grishkovskaya, De Almeida Ribeiro & Skern (2013) *J. Biol. Chem.* 289, 3749.

## A66

This potent and highly selective p110 $\alpha$  inhibitor (FW = 393.53; CAS 1166227-08-2; Solubility: 79 mg/mL DMSO, 1 mg/mL H<sub>2</sub>O), also known as (2*S*)-*N*<sup>1</sup>-(5-(2-*tert*-butylthiazol-4-yl)-4-methylthiazol-2-yl)pyrrolidine-1,2-dicarboxamide, has a IC<sub>50</sub> value of 32 nM for the wild-type phosphoinositide-3 kinase p110  $\alpha$  as well as oncogenic forms of p110 $\alpha$  such as p110 $\alpha$  E545K (IC<sub>50</sub> = 43 nM) and p110 $\alpha$  H1047R (IC<sub>50</sub> = 43 nM) (1). A66 inhibition also demonstrated that cancer-specific mutations in the iSH<sub>2</sub> (inter-SH<sub>2</sub>) and nSH<sub>2</sub> (N-terminal SH<sub>2</sub>) domains of p85 $\alpha$ , the regulatory subunit of phosphatidylinositol 3-kinase (PI3K), show gain of function, inducing oncogenic cellular transformation, stimulating cellular proliferation, and enhancing PI3K signaling (2). 1. Jamieson, *et al.* (2011) *Biochem. J.* 438, 53. 2. Sun, Hillmann, Hofmann, Hart & Vogt (2010) *Proc. Natl. Acad. Sci. USA* 107, 15547.

## A 83-01

This TGF $\beta$  inhibitor (FW = 421.52 g/mol; CAS 909910-43-6; Solubility: 50 mM in DMSO), named 3-(6-methyl-2-pyridinyl)-*N*-phenyl-4-(4-

quinolinyl)-1*H*-pyrazole-1-carbothioamide, selectively targets TGF- $\beta$  type I receptor ALK5 kinase (IC<sub>50</sub> = 12 nM), Type I Activin/Nodal receptor ALK4 (IC<sub>50</sub> = 45 nM), and type I nodal receptor ALK7 (IC<sub>50</sub> = 7.5 nM), blocking the phosphorylation of Smad2 and inhibiting TGF- $\beta$ -induced epithelial-to-mesenchymal transitions. TGF- $\beta$  signaling inhibitors represent a useful strategy for treating patients with tumor growth and metastasis in advanced cancer. A-83-01 only weakly inhibits ALK-1, ALK-2, ALK-3, ALK-6 and MAPK. It also has little or no effect on bone morphogenetic protein type I receptors, p38 mitogen-activated protein kinase, or extracellular regulated kinase (1). A-83-01 inhibits Smad signaling and epithelial-to-mesenchymal transition by transforming growth factor- $\beta$  (1). Its use also instrumental in demonstrating that attachment to Laminin-111 facilitates TGF- $\beta$ -induced expression of matrix metalloproteinase-2 in synovial fibroblasts (2). 1. Tojo, *et al.* (2005) *Cancer. Sci.* 96, 791. 2. Hoberg, *et al.* (2008) *Ann. Rheum. Dis.* 66, 446.

## A-100

This novel exosite-directed inhibitor (*Sequence*: EEWELCWTWET CEREGE-NH<sub>2</sub>; MW = 2242.42 g/mol), first identified and affinity-matured using naive and partially randomized peptide phage libraries against the immobilized tissue factor x Factor VIIa (TF x FVIIa) complex, is an exosite inhibitor of human coagulation factor VIIa (IC<sub>50</sub> = 1.5 nM). This so-called A-series peptide represents a new class of peptide exosite inhibitors that are capable of attenuating, rather than completely inhibiting, the activity of TF x FVIIa, commending the development anticoagulants with an increased therapeutic window. 1. Dennis, Roberge, Quan & Lazarus (2001) *Biochemistry* 40, 9513.

## A-132

This antibiotic (FW = 728.71 g/mol) is a chartreusin derivative that has been used in the treatment of breast cancer (1). A pharmacokinetic and pharmacodynamic (PK/PD) study of 6-*O*-(3-ethoxypropionyl)-3',4'-*O*-exobenzylidene-chartreusin (IST-622) demonstrated that the latter is converted to A-132 and 3"-demethyl-3',4'-*O*-exo-benzylidene-chartreusin (A-132M) (2), **Target(s)**: DNA topoisomerase II (1). 1. Christmann-Franck, Bertrand, Goupil-Lamy, *et al.* (2004) *J. Med. Chem.* 47, 6840. 2. Asai, Yamamoto, Toi, *et al.* (2002) *Cancer Chemother. Pharmacol.* 49, 468.

## A-183

This pentadecapeptide (MW = 1999.2 g/mol; *Sequence*: EEWELCWT WETCER, with disulfide linkage between Cys-7 and Cys-13) is an exosite inhibitor of human coagulation factor VIIa, IC<sub>50</sub> = 1.6 nM (1-4). A-183 was a partial (hyperbolic) mixed-type inhibitor of FX activation having a  $K_i$  of 200  $\mu$ M as well as acting as a partial competitive inhibitor of amidolytic activity. The location of the exosite was refined by a series of FVIIa alanine mutants, which showed that proximal residues Trp-61 and Leu-251 were critical for binding. 1. Eigenbrot, Kirchhofer, *et al.* (2001) *Structure* 9, 627. 2. Dennis, Roberge, Quan & Lazarus (2001) *Biochemistry* 40, 9513. 3. Roberge, Santell, Dennis, *et al.* (2001) *Biochemistry* 40, 9522. 4. Maun, Eigenbrot & Lazarus (2003) *J. Biol. Chem.* 278, 21823.

## A238L Protein

This 226-residue immunomodulatory protein (MW = 26205) from African Swine Fever Virus inhibits calcineurin phosphatase activity and down-regulates the activation of the NF- $\kappa$ B and NF-AT transcription factors. A238L competitively inhibits calcineurin by occupying a substrate recognition site, while at the same time leaving the catalytic center fully accessible (1). The 1.7 Å structure of the A238L-calcineurin complex reveals how calcineurin recognizes residues in A238L that are analogous to the substrate motif, "LxVP." The high-resolution structure enabled modeling of a peptide substrate bound to calcineurin, even predicting substrate interactions beyond the catalytic center. Importantly, "LxVP"

This phenidone homologue (FW = 176.22 g/mol), also known as 1-phenyl[2H]tetrahydropyridazin-3-one, inhibits erythrocyte 5-lipoxygenase, or arachidonate 5-lipoxygenase (human),  $IC_{50} = 0.7 \mu M$  (1,2). 1. Brooks, Albert, Dyer, *et al.* (1992) *Bioorg. Med. Chem. Lett.* **2**, 1353. 2. Young (1999) *Eur. J. Med. Chem.* **34**, 671.

#### A54145

These 13-residue branched peptidolactone antibiotics from *Streptomyces fradiae*, possessing a medium-chain-acylated amino terminus and a 10 amino-acid residue lactone ring, are closely related to daptomycin and A21978C. A54145 forms (substituents) are Form A ( $R = 8$ -methylnonanoyl-;  $AA_1 = L$ -Glu); Form B ( $R = \text{decanoyl-}$ ); Form B<sub>1</sub> ( $R = 8$ -methylnonanoyl-); Form C ( $R = 8$ -methyldecanoyl-;  $AA_2 = L$ -Val); Form D ( $R = 8$ -methyldecanoyl-;  $AA_1 = L$ -Glu); Form E ( $R = 8$ -methyldecanoyl-); Form F ( $R = 8$ -methyldecanoyl-;  $AA_1 = L$ -Glu;  $AA_1 = L$ -Glu;  $AA_2 = L$ -Val).  $MIC_{0.25}$  is approximately 32  $\mu g/mL$  against Gram-positive aerobic organisms. **Target(s):** peptidoglycan synthesis (1-6). 1. Wessels, von Dohren & Kleinkauf (1996) *Eur. J. Biochem.* **242**, 665. 2. Counter, Allen, Fukuda, Hobbs, Ott, Ensminger, Mynderse, Preston & Wu (1990) *J. Antibiot.* **43**, 616. 3. #### A-63124

This hydroxyamide (FW = 271.32 g/mol) inhibits 5-lipoxygenase, or arachidonate 5-lipoxygenase, the enzyme that catalyzes two steps in biosynthesis of leukotrienes (LTs). Because leukotrienes are lipid mediators of inflammation, LT antagonism is used in treatment of asthma and atherosclerosis. **See Zileuton** 1. Young (1999) *Eur. J. Med. Chem.* **34**, 671.

#### A-64077, See Zileuton

#### A-70450

This peptidomimetic (FW = 739.06 g/mol; CAS 142928-23-2) is a strong inhibitor of the secreted aspartic proteinase of *Candida albicans*:  $IC_{50} = 1.4$  nM as well as renin,  $IC_{50} = 7.1$  nM, and cathepsin D,  $IC_{50} = 770$  nM. **Target(s):** candidapepsin, or secreted aspartic proteinase of *Candida albicans* (1-4,6); renin (4,6); cathepsin D (4,6); candidapepsin, or secreted aspartic proteinase 2X of *Candida tropicalis* (5). 1. #### A-77003

This rotationally symmetric peptidomimetic (FW = 794.99 g/mol) inhibits HIV-1 protease,  $K_i = 1.4$  nM (1-3). When tested in asymptomatic HIV patients, plasma A77003 concentrations reached the *in vitro*  $IC_{50}$  (0.16  $\mu g/mL$ ) in the 0.28-mg/kg/h dosage group, but never attained the  $IC_{90}$  (0.48  $\mu g/mL$ ). No statistically significant effect on CD4 cell numbers occurred in any of the groups, and there was no evidence of antiviral activity, as determined by HIV-1 p24 antigen level, quantitative plasma and cell culture, and quantitation of viral RNA in plasma (2). The lack of antiviral activity observed in the study may be a consequence of the low concentrations in plasma in all groups. 1. Wilson, Phylip, Mills, *et al.* (1997) *Biochim. Biophys. Acta* **1339**, 113. 2. Reedijk, Boucher, van Bommel, *et al.* (1995) *Antimicrob. Agents Chemother.* **39**, 1559. 3. Kageyama, Weinstein, Shirasaka, *et al.* (1992) *Antimicrob. Agents Chemother.* **36**, 926

**A-79175, See A-78733**

#### A-79285

This pseudo-C<sub>2</sub> symmetric difluoroketone (FW = 812.96 g/mol) inhibits HIV-1 protease, or HIV-1 retropepsin (1-2). In the water, the ketone quickly converted to a *gem*-diol. Refinement of the 1.7-Å structure of the EI complex revealed a unique, and almost symmetric, set of interactions between the geminal hydroxyl groups, the geminal fluorine atoms, and the active-site aspartate residues, with only one active-site aspartate protonated. 1. Silva, Cachau, Sham & Erickson (1996) *J. Mol. Biol.* **255**, 321. 2. Silva, Cachau, Baldwin, Gulnik, Sham & Erickson (1995) *Adv. Exp. Med. Biol.* **362**, 451.

**A-85380, See 3-(2(S)-Azetidinylmethoxy)pyridine**

reduced body fat and normalized an insulin tolerance test, showing that this histamine receptor antagonist has potential as an antiobesity agent. **1.** Faghiih, Esbenshade, Krueger, *et al.* (2004) *Inflamm. Res.* **53** Suppl. 1, S79. **2.** Hancock, Bennani, Bush, *et al.* (2004) *Eur. J. Pharmacol.* **487**, 183.

#### A-425619

This TRPV1 antagonist (FW = 345.32 g/mol; CAS 581809-67-8; Soluble to 100 mM in DMSO), also named *N*-5-isoquinolinyl-*N'*-[[4-(trifluoromethyl)phenyl]methyl]urea, targets (IC<sub>50</sub> = 3-9 nM) Transient Receptor Potential cation channel subfamily V member 1 (also known as the capsaicin receptor and the vanilloid receptor 1), a nonselective cation channel that integrates responses to multiple stimuli, such as capsaicin, acid, heat, endovanilloids, and allyl isothiocyanate (the pungent compound present in mustard and wasabi). TRPV1 plays a key role in the transmission of inflammatory pain. A-425619 potently blocks capsaicin-evoked increases in intracellular calcium concentrations in HEK293 cells expressing recombinant human TRPV1 receptors, IC<sub>50</sub> = 5 nM (1). It shows similar potency (IC<sub>50</sub> = 3-4 nM) in blocking TRPV1 receptor activation by anandamide and *N*-arachidonoyl-dopamine (1). Electrophysiological experiments show that A-425619 also potently blocks the activation of native TRPV1 channels in rat dorsal root ganglion neurons (IC<sub>50</sub> = 9 nM). Compared with other known TRPV1 antagonists, A-425619 exhibits superior potency in blocking both naive and phorbol ester-sensitized TRPV1 receptors. Like capsazepine, A-425619 demonstrates competitive antagonism (pA<sub>2</sub> = 2.5 nM) of capsaicin-evoked calcium flux (1). Systemic injection of A-425619 (3-30 micromol/kg, iv) reduces neuronal wide dynamic range (*or* WDR) responses to thermal stimulation in both complete Freund's adjuvant- (*or* CFA-) inflamed (47 °C) and uninjured (52 degrees C) rats. However, the efficacy of A-425619 to attenuate thermally-evoked WDR activity is significantly greater (P < 0.01) in CFA-treated rats. Both intradorsal root ganglion (DRG; L5; 20 nmol) and intraplantar (30-300 nmol) injection of A-425619 reduces WDR responses to thermal stimulation. While the effectiveness of A-425619 is similar between CFA-inflamed and uninjured rats after intraplantar injection, the effects of A-425619 after intra-DRG injection are enhanced in the inflamed rats (compared with the uninjured rats). Spontaneous WDR discharges are unaltered by systemic or site-specific injections of A-425619. **1.** El Kouhen, Surow, Bianchi *et al.* (2005) *J. Pharmacol. Exp. Ther.* **314**, 400. **2.** McGaraughty, Chu, Faltynek & Jarvis (2006) *J. Neurophysiol.* **95**, 18.

#### A-674563

This ATP-competitive protein kinase inhibitor (FW = 358.44; CAS 552325-73-2; Solubility (25°C): 70 mg/mL DMSO; 70 mg/mL H<sub>2</sub>O), systematically named (2*S*)-1-(5-(3-methyl-1*H*-indazol-5-yl)pyridin-3-yloxy)-3-phenylpropan-2-amine, shows slightly greater inhibition of Akt1, as compared to protein kinase A (PKA) and cyclin-dependent kinase-2 (CDK2), as indicated by *K*<sub>i</sub> values of 11 nM, 16 nM, and 46 nM. A-674563 does not inhibit Akt phosphorylation itself, but blocks the phosphorylation of Akt's downstream targets in a dose-dependent manner. **Cyclin Target Selectivity:** Cdk1 (weak, if any), Cdk2 (++) , Cdk3 (weak, if any), Cdk4 (weak, if any), Cdk5 (weak, if any), Cdk6 (weak, if any), Cdk7 (weak, if any), Cdk8 (weak, if any), Cdk9 (weak, if any), Cdk10 (weak, if any), Akt1 (++) , PKA (++) . **1.** Luo, *et al.* (2005) *Mol. Cancer Ther.* **4**, 977.

**2.** Zhu, *et al.* (2008) *Cancer Res.* **68**, 2895. **3.** Okuzumi, *et al.* (2010) *Mol. Biosyst.* **6**, 1389.

#### A-769662

This potent, reversible AMPK activator (FW = 360.39 g/mol; CAS 844499-71-4) targets AMP-stimulated protein kinase (EC<sub>50</sub> = 0.8 μM), a key sensor and regulator of intracellular and whole-body energy metabolism. (**See also *Acadesine***) AMPK activation has been shown to alleviate symptoms of type 2 diabetes, making it a druggable target. Short-term treatment of normal Sprague Dawley rats with A-769662 decreases liver malonyl CoA levels and the respiratory exchange ratio, V<sub>CO2</sub>/V<sub>O2</sub>, indicating increased whole-body fatty acid oxidation (1). Treatment (30 mg/kg b.i.d.) of ob/ob mice decreases hepatic expression of PEPCK, G6Pase, and FAS, lowered plasma glucose (by 40%), reduces body weight gain, and significantly decreases both plasma and liver triglycerides (1). A-769662 activates AMPK, both allosterically and by inhibiting AMPK dephosphorylation (at Thr-172), similar to the effects of the natural effector, 5'-AMP (2). It also activates AMPK harboring a γ-subunit mutation that abolishes AMP activation. An AMPK complex that lacks the glycogen binding domain of the β-subunit abolishes the allosteric effect of A-769662, but not allosteric activation by AMP (2). AMPK activation by A-769662 results in the inhibition of endothelial cell proliferation, by elevating p21 and p27 expression, show that AMPK regulates endothelial cell migration and differentiation (3). **Off-Target Effect(s):** Contrary to the mechanism of action of most proteasome inhibitors, A769662 inhibits the 26S proteasome by an AMPK-independent mechanism that does not affect the proteolytic activities of the 20S core subunit (4). This novel mechanism of inhibition of 26S proteasome activity is reversible and results in of cell-cycle arrest. Such side effects of this new activator of AMPK should be considered when this compound is used as an alternative activator of the kinase (4). Other AMPK activators also induce nucleoli reorganization, with attendant changes in cell proliferation. Among the compounds tested, phenformin and resveratrol had the most pronounced impact on nucleolar organization (5). **1.** Cool, *et al.* (2006) *Cell Metab.* **3**, 403. **2.** Sanders (2007) *J. Biol. Chem.* **282**, 32539. **3.** Peyton, Liu, Yu, Yates & Durante (2012) *J. Pharmacol. Exp. Ther.* **342**, 827. **4.** Moreno, *et al.* (2008) *FEBS Lett.* **583**, 2650. **5.** Kodiha, Salimi, Wang & Stochaj (2014) *PLoS One.* **9**, e88087.

#### A771726, See Leflunomide

#### A-803467

This potent sodium channel blocker (FW = 357.79 g/mol; CAS 944261-79-4; Solubility: 72 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 5-(4-chlorophenyl)-*N*-(3,5-dimethoxyphenyl)furan-2-carboxamide, selectively targets Nav1.8 channels (IC<sub>50</sub> = 8 nM), blocking tetrodotoxin-resistant currents and exhibiting >100x selectivity against human Nav1.2, Nav1.3, Nav1.5, and Nav1.7. A-803467 potently blocks tetrodotoxin-resistant currents (IC<sub>50</sub> = 140 nM), generating spontaneous and electrically evoked action potentials *in vitro* in rat dorsal root ganglion neurons (1). Later studies reported the additive antinociceptive effects of the selective Nav1.8 blocker A-803467 and selective TRPV1 antagonists in rat inflammatory and neuropathic pain models (2). **Inhibition of Drug Efflux:** ATP-binding cassette (ABC) multidrug transporters (such as ABCB1, *or* MDR1/P-glycoprotein); ABCC1 (MRP1) and ABCG2 (BCRP/MXR)) mediate drug

efflux in human cancers (3). ABCG2 is a 72-kDa half transporter that is specifically localized at the apical surface of enterocytes, the luminal surface of liver canaliculi, the luminal surface of the proximal convoluted tubule of the kidneys, the blood-brain barrier (BBB), blood-testis barrier (BTB), blood-placental and blood-retinal barriers. Because of its localization on the secretory surface of the major organs involved in drug transport, ABCG2 alters absorption, distribution, metabolism and elimination of its substrate drugs. A-803467 significantly increases the cellular sensitivity to ABCG2 substrates in drug-resistant cells overexpressing either wild-type or mutant ABCG2. At 7.5  $\mu\text{M}$ , A-803467 significantly increases the intracellular accumulation of [ $^3\text{H}$ ]-mitoxantrone by inhibiting the transport activity of ABCG2, without altering its expression levels. In addition, A-803467 stimulates the ATPase activity in membranes overexpressed with ABCG2. In a murine model system, combination treatment of A-803467 (35 mg/kg) and topotecan (3 mg/kg) significantly inhibits the tumor growth in mice xenografted with ABCG2-overexpressing cancer cells. Such findings indicate that a combination of A-803467 and ABCG2 substrates may potentially be a novel therapeutic treatment in ABCG2-positive drug resistant cancers. **1.** Jarvis, Honore, Shieh, *et al.* (2007) *Proc. Natl. Acad. Sci. U.S.A.* **104**, 8520. **2.** Joshi, Honore, Hernandez, *et al.* (2009) *J. Pain* **10**, 306. **3.** Anreddy, Patel, Zhang, *et al.* (2015) *Oncotarget* **6**, 39276.

#### A 939572

This potent oleate synthesis inhibitor (FW = 387.86 g/mol; CAS 1032229-3-6; Soluble to 100 mM in DMSO), also named 4-(2-chlorophenoxy)-*N*-[3-[(methylamino)carbonyl]phenyl]-1-piperidine carboxamide, selectively targets stearoyl-CoA desaturase 1 (SCD1) inhibitor ( $\text{IC}_{50}$  = 0.4 nM), showing selectivity over a range of kinases and hERG channels. The utility of human pluripotent stem cells (hPSCs) in cell therapy is hindered by the tumorigenic risk from residual undifferentiated cells. A-939572 was identified among 15 pluripotent cell-specific inhibitors (PluriSins), of which nine share a common structural moiety. It selectively eliminates hPSCs, while sparing a large array of progenitor and differentiated cells, doing so by inducing ER stress, protein synthesis attenuation, and apoptosis (1). Further examination identified A-939572 as an inhibitor of stearoyl-CoA desaturase (SCD1), revealing a unique role for lipid metabolism in hPSCs. A-939572 is also cytotoxic to mouse blastocysts, indicating that the dependence on oleate is inherent to the pluripotent state. Application of A-939572 also prevents teratoma formation from tumorigenic undifferentiated cells. **1.** Xin, Zhao, Serby, *et al.* (2008) *Bioorg. Med. Chem. Lett.* **18**, 4298. **2.** Ben-David, Gan, Golan-Lev, *et al.* (2013) *Cell Stem Cell.* **12**, 167.

#### A- 971432

This orally active potent and selective S1P<sub>5</sub> agonist (FW = 366.24 g/mol; CAS 1240308-45-5; Soluble to 100 mM in 1 eq. NaOH and to 100 mM in 1eq. HCl), also named 1-[[4-[(3,4-dichlorophenyl)-methoxy]phenyl]methyl]-3-azetidinecarboxylic acid, selectively targets Sphingosine-1-phosphate receptor-5, a receptor that is highly expressed on endothelial cells within the blood-brain barrier, where it helps to maintain barrier integrity in *in vitro* models. S1P acts as an extracellular ligand for a family of G-protein coupled receptors that are crucial in cell migration. S1P5 is exclusively expressed in oligodendrocytes and oligodendrocyte precursor cells (OPCs), which migrate considerable distances during brain development. [For reference, S1P binding to the S1P5 receptor blocks OPC migration ( $\text{IC}_{50}$  = 30 nM).]  $\text{EC}_{50}$  values for A-971432 activation of S1P5 receptor are 4.1 and 5.7 nM in cAMP and GTP $\gamma\text{S}$  assays, respectively. A-971432 is highly efficacious in reversing lipid accumulation and age-related cognitive decline in rats. It also improves blood-brain barrier integrity *in vitro* and reverses age-related cognitive decline in mice. Such

results suggest S1P5 agonism may prove beneficial in treating neurodegenerative disorders involving lipid imbalance and/or compromised blood-brain barrier. **1.** Hobson, Harris, van der Kam, *et al.* (2015) *J. Med. Chem.* **58**, 9154.

#### A-1070722

This potent, brain-penetrating GSK inhibitor (FW = 362.31 g/mol; CAS 1384424-80-9), also named 1-(7-methoxyquinolin-4-yl)-3-[6-(trifluoromethyl)pyridin-2-yl]urea, targets glycogen synthase kinase-3, with  $K_i$  = 0.6 nM for both GSK-3 $\alpha$  and GSK-3 $\beta$ , with >50x weaker action on other kinases tested, including CDK family members. Its high degree of selectivity was confirmed using a biochemical affinity approach employing ATP-binding in rat brain lysates. In cells, A-1070722 decreases phosphorylation of the microtubule-associated protein Tau, as well as accumulation of cellular  $\beta$ -catenin. In addition, A-1070722 protected rat primary cortical neurons against a  $\beta$ -amyloid or glutamate challenge. **1.** Bakker, van Gaalen, Bitner, *et al.* (2011) Society for Neuroscience National Meeting, Washington, DC, November 12-16, *Abstract* 568.04/Z7.

**ABA**, See *Abscisic Acid*

**pABA**, See *4-Aminobenzoic Acid*

#### Abacavir

This carbocyclic diaminopurine nucleoside analogue and antiviral prodrug (FW = 286.34 g/mol; CAS 136470-78-5), named systematically as (1*S*,4*R*)-4-(2-amino-6-(cyclopropylamino)-9*H*-purin-9-yl)-2-cyclopentene-

1-methanol, is metabolized to carbovir triphosphate (**See Carbovir**), latter inhibiting viral reverse transcriptase (1,2). When incorporated into the growing viral DNA strand, abacavir blocks strand elongation, leading to a premature halt in viral DNA synthesis and chain termination. It is typically used in combination with other antiretroviral agents in the treatment of HIV infection. **Systemic Abacavir Hypersensitivity:** Abacavir induces powerful immunosensitivity, which is driven by activation of HLA-B\*5701 in CD8<sup>+</sup> T cells, resulting in secretion of inflammatory mediators (*e.g.*, TNF- $\alpha$  and IFN- $\gamma$ ). Delayed hypersensitivity reactions, including systemic syndromes and organ-specific toxicities, can be triggered by abacavir (3,4), and there is a strong genetic association with the human leukocyte antigen (HLA)-B\*57:01 allele. Abacavir is a prodrug, and one its metabolites binds to an antigen-presenting cleft unique to HLA-B\*5701, explaining why the drug *per se* does not cause a hypersensitivity syndrome in carriers of other HLA-B alleles and why compounds similar to abacavir fail to react with HLA-B\*5701. Patients should be tested for hypersensitivity prior to using abacavir. **Target(s):** HIV-1 reverse transcriptase (1,2); RNA-directed DNA polymerase (1,2). 1. Tisdale, Alnadaf & Cousins (1997) *Antimicrob. Agents Chemother.* **41**, 1094. 2. El Safadi, Vivet-Boudou & Marquet (2007) *Appl. Microbiol. Biotechnol.* **75**, 723. 3. Mallal, Nolan, Witt, *et al.* (2002) *Lancet* **359**, 727. 4. Chessman, Kostenko, Lethborg, Purcell, *et al.* (2008) *Immunity* **28**, 822.

### Abamectin

These macrocyclic metabolites (FW<sub>Abamectin-B1a</sub> = 873.09 g/mol, R = -CH<sub>2</sub>CH<sub>3</sub>; FW<sub>Abamectin-B1b</sub> = 859.06, R = -CH<sub>3</sub>; CAS 71751-41-2; Trade Names: Agri-Mek<sup>®</sup>, Avid<sup>®</sup>, Avert<sup>®</sup>), obtained from *Streptomyces avermitilis*, are natural insecticides, acaricides, and antihelmintics that stimulate  $\gamma$ -aminobutyrate release. Abamectin is more effective when consumed orally, and irreversible paralysis is the main effect. By the 1985 convention, commercial sources contain 80% B<sub>1a</sub> and 20 % B<sub>1b</sub>. **Note:** Abamectin is toxic (in rats, LD<sub>50</sub>(oral) = 10 mg/kg; LD<sub>50</sub>(dermal) = >20000 mg/kg). Abamectin is safest when applied to mature plants, because harder leaves are more resistant to abamectin penetration. 1. Wislocki, *et al.* "Environmental Aspects of Abamectin Use in Crop Protection" in Campbell (ed.). 1989. *Ivermectin and Abamectin*. Springer-Verlag, NY.

### Abamine

This tertiary amine (FW = 373.42 g/mol) inhibits 9-*cis*-epoxycarotenoid dioxygenase, with respective K<sub>i</sub> values of 132  $\mu$ M and 39  $\mu$ M for the *Arabidopsis thaliana* and spinach enzymes (1-3). Abscisic acid (ABA) is a major regulator in the adaptation of plants to environmental stresses, plant growth, and development. In higher plants, the ABA biosynthesis pathway involves the oxidative cleavage of 9-*cis*-epoxycarotenoids, the key regulatory step in the pathway catalyzed by 9-*cis*-epoxycarotenoid dioxygenase. 1. Boyd, Gai, Nelson, *et al.* (2009) *Bioorg. Med. Chem.* **17**, 2902. 2. Han, Kitahata, Saito, *et al.* (2004) *Bioorg. Med. Chem. Lett.* **14**, 3033. 3. Han, Kitahata, Sekimata, *et al.* (2004) *Plant Physiol.* **135**, 1574.

### Abatacept

This recombinant anti-inflammatory protein (MW = 92 kDa; CAS 213252-14-3), marketed under the trade name Orencia<sup>®</sup>, inhibits T-cell activation in

rheumatoid arthritis and reduces the B-cell production of rheumatoid factor. **Primary Mode of Inhibitory Action:** Abatacept is a CTLA4-Ig fusion protein, consisting of the extracellular domain of the cytotoxic T lymphocyte-associated antigen 4-immunoglobulin CTLA-4, along with the hinge, CH2, and CH3 domains of IgG1. It selectively modulates co-stimulation by interrupting the CD28:CD80/86 pathway, resulting in downregulation of T-cell activation (1-3). Presentation of antigen to the T-cell receptor without co-stimulation results in antigen-specific unresponsiveness upon re-challenge, a phenomenon known as anergy *in vitro* and tolerance *in vivo*. **Use in Therapy:** Abatacept is used to treat arthritic inflammation (*e.g.*, pain, swelling and prolonged joint stiffness). Abatacept is a second-line drug that is mainly used, when other anti-rheumatic drugs, such as methotrexate, fail to control inflammation. When used in combination with methotrexate, abatacept prevents the progression of joint damage and improves physical function in rheumatoid arthritis patients. 1. Allison (2005) *Issues Emerg. Health Technol.* (73), 1. 2. Kremer (2005) *J. Clin. Rheumatol.* **11** (3 Suppl.), S55. 3. Teng, Turkiewicz & Moreland (2005) *Expert Opin. Biol. Ther.* **5**, 1245.

### Abciximab

This antithrombotic (MW = 47455 g/mol; CAS 143653-53-6; also known as Reopro<sup>®</sup>) consists of an immunoglobulin G<sub>1</sub> Fab fragment from a chimeric human-murine monoclonal antibody directed against the human platelet glycoprotein IIb/IIIa receptor (1,2). Abciximab also facilitates the dispersal of newly formed platelet aggregates *in vitro*, by partially displacing fibrinogen from activated GPIIb/IIIa receptors. *In vivo*, abciximab may destabilize coronary thrombi by preventing aggregate formation and dispersing mural thrombi (3). **Target(s):** coagulation factor Xa, in presence of heparin (1); glycoprotein IIb/IIIa receptor (1,2). 1. Li, Spencer, Ball & Becker (2000) *J. Thromb. Thrombolysis* **10**, 69. 2. Knight, Wagner, Jordan, *et al.* (1995) *Mol. Immunol.* **32**, 1271. 3. Marciniak, Mascelli, Furman, *et al.* (2002) *Thrombosis & Haemostasis* **87**, 928.

### Abemaciclib

This oral cell cycle inhibitor (FW<sub>free-base</sub> = 506.61 g/mol; FW<sub>mesylate-salt</sub> = 602.70 g/mol; CAS 1231930-82-7 (mesylate salt)), also known as LY2835219 and *N*-[5-[(4-ethyl-1-piperazinyl)methyl]-2-pyridinyl]-5-fluoro-4-[4-fluoro-2-methyl-1-(1-methylethyl)-1*H*-benzimidazol-6-yl]-2-pyrimidinamine, targets the cyclin-dependent kinase CDK4, or cyclin D<sub>1</sub> (IC<sub>50</sub> = 2 nM) and CDK6, or cyclin D<sub>3</sub> (IC<sub>50</sub> = 6 nM), inhibiting retinoblastoma (Rb) protein phosphorylation in early G<sub>1</sub>, thereby arresting the cell cycle in the G<sub>1</sub>, suppressing DNA synthesis, and inhibiting cancer cell growth (1). LY2835219 inhibits activation of AKT and ERK, but not mTOR (2). 1. Sanchez-Martinez, Gelbert & Shannon (2011) *Molec. Cancer Therapeut.* **10**, (Supplement 1) Abstract Number B234. 2. Ku, Yi, Koh, *et al.* (2016) *Oncotarget* **12**, 14803.

### Abietamide

This diterpenoid amide (FW = 301.47 g/mol; CAS 40713-30-2) inhibits [pyruvate dehydrogenase (acetyl-transferring)] kinase, IC<sub>50</sub> = 6.7  $\mu$ M. Abietamide, its oxime, and dehydroabietyl amine-2 exhibit a blood glucose lowering effect in the diabetic *ob/ob* mouse after a single oral dose of 100

micromol/kg, but the mechanism of this effect is unlikely to be related to PDK inhibition. 1. Aicher, Damon, Koletar, *et al.* (1999) *Bioorgan. Med. Chem. Lett.* **9**, 2223.

### Abietic Acid

This diterpenoid resin acid (FW<sub>free-acid</sub> = 302.46 g/mol; CAS 514-10-3; M.P. = 172-175°C), a major component of rosin, is also present in many plants and amber. Abietic acid has a low solubility in water and is soluble in organic solvents. Note: Abietic acid readily isomerizes to neoabietic acid. **Target(s):** 5-lipoxygenase (1); myeloperoxidase (2); [pyruvate dehydrogenase (acetyl transferring)] kinase, IC<sub>50</sub> = 20 μM (3). 1. Ulusu, Ercil, Sakar & Tezcan (2002) *Phytother. Res.* **16**, 88. 2. Fernandez, Tornos, Garcia, *et al.* (2001) *J. Pharm. Pharmacol.* **53**, 867. 3. Aicher, Damon, Koletar, *et al.* (1999) *Bioorgan. Med. Chem. Lett.* **9**, 2223.

### Abiraterone Acetate

This steroid-based antineoplastic pro-drug (FW = 391.55 g/mol; CAS 154229-18-2), also known as Zytiga™, CB-7630, and systematically as (3β)-17-(pyridin-3-yl)androst-5,16-dien-3-ol, is converted *in vivo* to abiraterone (FW = 349.51 g/mol; CAS 154229-19-3), an androgen biosynthesis inhibitor that targets 17-α-hydroxylase/C17,20-lyase, or CYP17 (K<sub>i</sub> = 2 nM), an enzyme expressed in testicular, adrenal, and prostatic tumor tissues and required for androgen biosynthesis (1-3). CYP17A1 catalyzes the conversion of pregnenolone (and progesterone) to 17-α-hydroxy derivatives via its 17 α-hydroxylase activity, as well as the subsequent formation of dehydroepiandrosterone, or DHEA, (and androstenedione) via its C17,20 lyase activity. Zytiga is effective for the treatment of castration-resistant prostate cancer (previously known as hormone-resistant prostate cancer). A sensitive and selective LC-MS/MS method is available for the quantification of abiraterone acetate and abiraterone (4). The major circulating metabolites of abiraterone in humans are abiraterone sulfate and the N-oxide of abiraterone sulfate. Each of these metabolites occur at >100 times the respective concentration of abiraterone. The sulfate metabolite is approximately 7x more potent than abiraterone against rat testicular microsomal CYP17 (5). 1. Barrie, Potter, Goddard, *et al.* (1994) *J. Steroid Biochem. Mol. Biol.* **50**, 267. 2. Haidar, Ehmer, Barassin, Batzl-Hartmann, and Hartmann (2003) *J. Steroid Biochem. Mol. Biol.* **84**, 555. 3. O'Donnell, Judson, Dowsett, *et al.* (2004) *Br. J. ### ABM-1/2 Inhibitors of Actin-Based Motors

**ABM-1 Inhibitor:** FEFPPPTDEC

**ABM-2 Inhibitor:** GPPPPPGPPPPGPPPPP

These actin-based motility inhibitors (**See also ActA FEFPPPTDE Fragment; VASP GPPPPP Trimer**) are based respectively on (a) the consensus

oligoproline docking sites within *Listeria monocytogenes* ActA surface protein, which binds to human platelet vasodilator-stimulated phosphoprotein (VASP) and related proteins containing an EVH1 pleckstrin homology-like domain (1,2) and (b) profilin-binding domains in Ena/VASP proteins. Analysis of known actin regulatory proteins led to the identification of distinct Actin-Based Motility homology sequences:

**Consensus ABM-1 Sequence:** (D/E)FPPPPX(D/E) [where X = P or T]

**Consensus ABM-2 Sequence:** XPPPPP [where X = G, A, L, P, or S]

Actin-based motility involves a cascade of binding interactions designed to assemble actin regulatory proteins into functional locomotory units. *Listeria* ActA surface protein contains a series of nearly identical EFPPPTDE-type oligoproline sequences for binding vasodilator-stimulated phosphoprotein (VASP). The latter, a tetrameric protein with 20-24 GPPPPP docking sites, binds numerous molecules of profilin, a 15-kDa regulatory protein known to promote actin filament assembly. Laine *et al.* (4) demonstrated that proteolysis of the focal contact component vinculin unmasks an ActA homologue for actin-based *Shigella* motility. The ABM-1 sequence (PDFPPPPDL) is located at or near the C-terminus of the p90 proteolytic fragment of vinculin. Unmasking of this site serves as a molecular switch that initiates assembly of an actin based motility complex containing VASP and profilin. Another focal adhesion protein zyxin (4) contains several ABM-1 homology sequences that are also functionally active in reorganizing the actin cytoskeletal network (1-6). **FPPPP-mito:** Actin-based motility of lamellipodia and filopodia may be suppressed by transfecting target cells with a vector containing a cDNA coding for a chimeric protein possessing a EVH1 ligand as well as a mitochondria-targeting sequence (7). In this case Ena/VASP proteins are misdirected from their sites at the leading edge to motility-idling sites on the outer surface of mitochondria. **FPPPP-CAAX:** Actin-based motility of lamellipodia and filopodia may also be suppressed by transfecting target cells with a vector containing a cDNA coding for a chimeric protein possessing an EVH1 ligand as well as the CAAX peripheral membrane-targeting sequence (7). The latter is modified by farnesyltransferase (*Reaction:* Farnesyl-PP + Protein-CAAX ⇌ Protein-C(S-Farnesyl)AAX + PP<sub>i</sub>). In this way, Ena/VASP proteins are misdirected from their sites at the leading edge to motility-idling sites on the inner surface of the peripheral membrane. 1. Purich (2016) *Biophys. ### abn-cbd

This synthetic cannabidiol regioisomer (FW = 314.47 g/mol; CAS 22972-55-0), also called Abnormal Cannabidiol and 4-[(1R,6R)-3-methyl-6-(1-methylethenyl)-2-cyclohexen-1-yl]-5-pentyl-1,3-benzenediol, produces vasodilator effects, lowering blood pressure and inducing cell migration and proliferation, as well as mitogen-activated protein kinase activation in microglia, without psychoactive effects (1-4). Abnormal Cannabidiol binds to a site (possibly the "orphan" receptor GPR18) that is distinct from the CB<sub>1</sub> and CB<sub>2</sub> receptors. Abnormal Cannabidiol relaxes human pulmonary arteries in an endothelium-independent and endothelium-dependent manner. The latter component is probably mediated via the putative endothelial cannabinoid receptor, activation of which may release endothelium-derived hyperpolarizing factor, which in turn acts via calcium-activated potassium channels. Abnormal cannabidiol is behaviorally inactive; it may have a therapeutic implication in vascular diseases, especially in the treatment of pulmonary hypertension (5). 1. Jarai, *et al.*

(1999) *Proc. Natl. Acad. Sci. U.S.A.* **96**, 14136. **2.** Ho & Hiley (2003) *Brit. J. Pharmacol.* **138**, 1320. **3.** Mo, *et al.* (2004) *Eur. J. #### ABP 688

This high-affinity mGluR antagonist (FW = 240.31 g/mol; CAS 924298-51-1; Soluble to 100 mM in DMSO; 50 mM in 1 eq. HCl), also named 3-[2-(6-methyl-2-pyridinyl)ethynyl]-2-cyclohexene-1-one *O*-methyloxime, targets the human metabotropic glutamate receptor-5 (mGluR<sub>5</sub>) ( $K_i = 1.7$  nM) and inhibits glutamate-induced calcium release from Ltk-cells expressing human mGlu<sub>5</sub> receptors ( $IC_{50} = 2.3$  nM) (1). Indeed, [<sup>11</sup>C]-ABP688 is a useful PET tracer for *in vivo* imaging of the mGluR5 in rodents (2). **1.** Hintermann, Vranesic, Allgeier, *et al.* (2007) *Bioorg. Med. Chem.* **15**, 903. **2.** Ametamey, Kessler, Honer, *et al.* (2006) *J. Nucl. Med.* **47**, 698.

#### Abrin

This type-II ribosome-inactivating glycoprotein toxin (MW = 65 kDa; CAS 1393-62-0) from the seeds of *Abrus precatorius* (common names: rosary pea and jequirity) is composed of an acidic A chain and a neutral B chain joined by disulfide bonds. The A chain exhibits the toxic rRNA *N*-glycosidase activity, catalyzing the endohydrolysis of a specific *N*-glycosidic bond at an adenosine on rRNA, thereby irreversibly inactivating protein synthesis (See Ricin). The B chain has lectin-like properties that assist A chain entry into cells. Chewing jequirity seeds has proved fatal, because each molecule of abrin can inactivate as many as 1,500 ribosomes per second (~75x more active than ricin). *Note:* Abrin should not be confused with abrine, or *N*<sup>7</sup>-methyl-L-tryptophan. **Mode of Apoptotic Action:** The abrin A chain also promotes apoptosis, which is preceded by mitochondrial cytochrome *c* release, followed by caspase-3 and -9 activation (4). The broad-spectrum caspase inhibitor, benzyloxycarbonyl-Val-Ala-Asp-fluoromethyl ketone (zVADfmk), prevents abrin-triggered caspase activation and reduces apoptotic cell death, but is without effect on cytochrome *c* release. Such results suggest that the sequential caspase activation is crucial for abrin-induced apoptosis (4). Abrin also inhibits the mitochondrial antioxidant protein AOP-1 (5). Recent studies suggest that abrin-induced apoptosis depends on p38 MAPK (but not JNK), attended by activation of caspase-2 and caspase-8, triggering Bid cleavage and and to subsequent mitochondrial membrane potential loss (6). Such a pathway connects the signaling events from ER stress to mitochondrial death machinery. **Target(s):** protein biosynthesis (1-3); ribosome (1-3); antioxidant protein AOP-1 (4). **1.** Jiménez (1976) *Trends Biochem. Sci.* **1**, 28. **2.** Benson, Olnes, Phil, Skorve & Abraham (1975) *Eur. J. Biochem.* **59**, 573. **3.** Olsnes, Fernandez-Puentes, Carrasco & Vazquez (1975) *Eur. J. Chem.* **276**, 21870. **6.** Mishra & Karande (2014) **9**, e92586.

#### *cis,trans*-Abscisate (Abscisic Acid)

This plant metabolite (FW<sub>free-acid</sub> = 264.32 g/mol; CAS 14375-45-2; M.P. 183-185 °C; Soluble in DMSO; *Abbreviation:* ABA), known also as (+/-)-abscisic acid and named systematically as (2-*cis,4-trans*)-5-(1-hydroxy-2,6,6-trimethyl-4-oxo-2-cyclohexen-1-yl)-3-methyl-2,4-pentadienoic acid, is a component of a abscisoyl-β-D-glucopyranoside, which plays an profound role in plant growth and development, promotes abscission, and regulates seed maturation, germination, and adaptation to environmental stresses (*e.g.*, dehydration, high salt concentrations, and low temperature) (1-5). ABA is found in most vascular plants, green algae, certain fungi, and mosses. Note that *trans,trans* abscisic acid, which is also commercially available, has been reported in low concentrations in a few organisms. ABA also inhibits DNA replication in the rice shoot apical meristem and

inhibits shoot growth in rice by inducing expression of OsKRP4, OsKRP5, and OsKRP6, which collectively inhibit the G<sub>1</sub>/S transition (6). Salicylate blocks these effects, overcoming ABA-induced cell-cycle arrest by blocking expression of OsKRP genes. **Target(s):** coleoptile growth (1); seed germination (1,4,5); inward K<sup>+</sup> currents (2); indole-3 acetate β-glucosyltransferase, weakly inhibited (3). **1.** Grill & Himmelbach (1998) *Curr. Opin. Plant Biol.* **1**, 412. **2.** Schwartz, Wu, Tucker & Assmann (1994) *Proc. Natl. Acad. Sci. U.S.A.* **91**, 4019. **3.** Leznicki & R. S. Bandurski (1988) *Plant Physiol.* **88**, 1481. **4.** Cutler, Rose, Squires, *et al.* (2000) *Biochemistry* **39**, 13614. **5.** Ueno, Araki, Hirai, *et al.* (2005) *Bioorg. Med. Chem.* **13**, 3359. **6.** Meguro & Sato (2014) *Sci. Rep.* **4**, 4555.

#### Abscisic Aldehyde

This aldehyde (FW = 248.32 g/mol; CAS 41944-86-9) is the immediate biosynthetic precursor of abscisic acid. The short-chain alcohol dehydrogenase ABA2 catalyzes the conversion of xanthoxin to abscisic aldehyde, with the latter undergoing selective oxidation (*Abscisic Aldehyde Oxygenase Reaction:* Abscisic aldehyde + O<sub>2</sub> + H<sub>2</sub>O ⇌ Abscisic Acid + H<sub>2</sub>O<sub>2</sub>). **Target(s):** (+)-abscisate 8'-hydroxylase, mildly inhibitory. **1.** Ueno, Araki, Hirai, *et al.* (2005) *Bioorg. Med. Chem.* **13**, 3359.

#### ABT

This cytochrome P450 suicide inhibitor (FW = 134.14 g/mol; CAS 1614-12-6; Soluble to 100 mM in water and to 100 mM in DMSO), also named 1*H*-benzotriazol-1-amine, inhibits the synthesis of eicosanoid 20-hydroxyeicosa-tetraenoate (*or* 20-HETE). ABT reduces intimal hyperplasia and vascular remodeling following endothelial injury in rat carotid arteries (1,2). Microsomal benzphetamine *N*-demethylase (BND) and 7-ethoxyresorufin *O*-deethylation (ERF) activities (catalyzed by P-450 isozymes 2 and 6, respectively) and specific P-450 content were determined after incubation with ABT (1). In vitro destruction of P-450 was dependent on ABT concentration and required NADPH. Significant losses in both activities are observed only at ABT concentrations >10 μM (1). **1.** Mathews, Dostal & Bend (1985). *J. Pharmacol. Exp. Ther.* **235**, 186. **2.** Orozco, Liu, Perkins, *et al.* (2013) *J Pharmacol. Exp. Ther.* **346**, 67.

**ABT-299, See A-85783**

**ABT-378, See Lopinavir**

**ABT-450, See Paritaprevir**

**ABT-491**

This substituted indole (FW<sub>free-base</sub> = 479.52 g/mol; IUPAC: 4-ethynyl-*N,N*-dimethyl-3-[3-fluoro-4-[(2-methyl-1*H*-imidazo[4,5-*c*]pyridin-1-yl)methyl]benzoyl]-1*H*-indole-1-carboxamide), is a strong human platelet-activating factor receptor antagonist,  $K_i = 0.6$  nM (1-3). Its binding kinetics to the

PAF receptor is consistent with a slower off-rate for the antagonist compared to PAF. Inhibition of PAF binding is selective and correlates with functional antagonism of PAF-mediated cellular responses (e.g.,  $\text{Ca}^{2+}$  mobilization, priming, and degranulation). Administration of ABT-491 *in vivo* results in potent inhibition of PAF-induced inflammatory responses (e.g., increased vascular permeability, hypotension, and edema) and PAF-induced lethality. Oral potency ( $\text{ED}_{50}$ ) was between 0.03 and 0.4 mg/kg in rat, mouse, and guinea pig. When administered intravenously in these species, ABT-491 exhibited  $\text{ED}_{50}$  values between 0.005 and 0.016 mg/kg. In the rat, an oral dose of 0.5 mg/kg provides > 50% protection for 8 hours against a cutaneous PAF challenge. When administered orally, ABT-491 is also effective in inhibiting lipopolysaccharide-induced hypotension ( $\text{ED}_{50}$  = 0.04 mg/kg), gastrointestinal damage (0.05 mg/kg, 79% inhibition), and lethality (1 mg/kg, 85% vs. 57% survival). 1. ### ABT-702

This potent and orally effective adenosine-like non-nucleoside inhibitor ( $\text{FW}_{\text{free-base}}$  = 463.34 g/mol; CAS 214697-26-4), also known as 4-amino-5-(3-bromophenyl)-7-(6-morpholinopyridin-3-yl)pyrido[2,3-*d*]pyrimidine, targets cytosolic adenosine kinase ( $\text{IC}_{50}$  = 1.7 nM), thereby increasing adenosine and providing anti-seizure activity akin to that of adenosine receptor agonists, but with fewer dose-limiting cardiac side effects (1-5). ABT-702 shows analgesic effect in animal models of pain via nociceptive and motor reflex pathways in the isolated spinal cord of neonatal rats (6). It inhibits slow Ventral Root Potentials (sVRPs) in the nociceptive pathway more potently than monosynaptic reflex potentials (MSRs) in the motor reflex pathway. ABT-702's inhibitory effects are mimicked by exogenously applied adenosine, blocked by the adenosine  $\text{A}_1$  receptor antagonist 8-cyclopentyl-1,3-dipropylxanthine, and augmented by the adenosine deaminase (ADA) inhibitor EHNA (*erythro*-9-(2-hydroxy-3-nonyl)adenine). Equilibrative nucleoside transporter (ENT) inhibitors reverse the effects of ABT-702, but not those of adenosine. ABT-702 stimulates adenosine release from the spinal cord, an effect that is also reversed by ENT inhibitors. ABT-702-facilitates release of adenosine by way of ENTs inhibits nociceptive pathways more potently than motor reflex pathways in the spinal cord via activation of  $\text{A}_1$  receptors (6). 1. Jarvis, Yu, Kohlhaas, *et al.* (2000) *J. Pharmacol. Exp. Ther.* **295**, 1156. 2. Lee, Jiang, Cowart, *et al.* (2001) *J. Med. Chem.* **44**, 2133. 3. ### ABT-719

This first-in-class 2-pyridone-containing bacterial antibiotic ( $\text{FW}$  = 345.37 g/mol), also named 8-(3-(*S*)-aminopyrrolidin-1-yl)-1-cyclopropyl-7-fluoro-

9-methyl-4*H*-4-oxoquinolizine-3-carboxylic acid, inhibits DNA topoisomerase II. ABT-719 was more effective than ciprofloxacin, sparfloxacin, and clinafloxacin against Gram-positive bacteria. It was particularly active against *Staphylococcus aureus* ( $\text{MIC}_{90}$  = 0.015  $\mu\text{g/mL}$ ) and *Streptococcus pneumoniae* ( $\text{MIC}_{90}$  = 0.03  $\mu\text{g/mL}$ ). ABT-719 was also highly active of the compounds tested against ciprofloxacin-resistant *S. aureus* isolates ( $\text{MIC}_{90}$  = 0.25  $\mu\text{g/mL}$ ), compared with 64  $\mu\text{g/mL}$  for ciprofloxacin. Against Gram-negative organisms, ABT-719 was as active as, or slightly more active, than ciprofloxacin and was the most active compound against ciprofloxacin-resistant *Pseudomonas aeruginosa* ( $\text{MIC}_{90}$  = 2  $\mu\text{g/mL}$ ). ABT-719 was also the most active compound against both Gram-positive and Gram-negative anaerobes, with  $\text{MIC}_{90}$  values ranging from 0.12 to 0.25  $\mu\text{g/mL}$ . 1. Flamm, Vojtko, Chu, *et al.* (1995) *Antimicrob. Agents Chemother.* **39**, 964.

### ABT-737

This small-molecule inhibitor ( $\text{F.W.}$  = 813.43; CAS 852808-04-9; Solubility: 160 mg/mL DMSO, <1 mg/mL  $\text{H}_2\text{O}$ ), also known as 4-[4-(4'-chloro[1,1'-biphenyl]-2-yl)methyl]-1-piperazinyl]-*N*-[[4-[[[(1*R*)-3-(dimethylamino)-1-[(phenylthio)methyl]propyl]amino]-3-nitrophenyl]sulfonyl]benzamide, is a BH3 (Bcl-2 homology domain) mimetic that targets the apoptosis regulatory protein Bcl-xL (B-cell lymphoma-extra large), Bcl-2 (B-cell lymphoma 2) and pro-survival protein Bcl-w with  $\text{EC}_{50}$  values of 79 nM, 30 nM and 198 nM, respectively (1-7). Significantly, ABT-737 induces autophagy through a BAX- and BAK1-independent mechanism that is likely disrupt BECN1 binding to antiapoptotic BCL2 family members (8). When administered along with Sorafenib (an inhibitor of VEGFR and PDGFR tyrosine protein kinases), ABT-737 induces apoptosis of targeted tumor cells. ABT-737 sensitizes androgen-dependent castration-resistant prostate cancer PC3 cells to ENMD-1198-mediated, caspase-dependent apoptosis (9). While showing demonstrated efficacy in several forms of hematological and non-hematological cancers, ABT-737's efficacy is diminished in cancer cells producing high levels of Mcl-1, another anti-apoptotic member of the Bcl-2 family (10). When used in combination with the Mcl-1-selective inhibitor maritoclax (See *Maritoclax*), however, ABT-737 greatly decreases the survival of human melanoma cells (10). 1. Konopleva, *et al.* (2006) *Cancer Cell* **10**, 375. 2. van Delft, *et al.* (2006) *Cancer Cell* **10**, 389. 3. Del Gaizo Moore, *et al.* (2007) *J. Clin. Invest.* **117**, 112. 4. ### Ac2-12

This annexin/lipocortin-1 peptidomimetic ( $\text{FW}$  = 1351.58 g/mol; Sequence: Acetyl-AMVSEFLKQAW; CAS 256447-08-2; Soluble to 1 mg/mL in 20% (vol/vol) acetonitrile- $\text{H}_2\text{O}$ ) markedly reduces the degree of neutrophil adhesion and emigration across mouse mesenteric postcapillary venules, when administered at 13 mg/kg (s.c.), but does not modify cell rolling, when assessed directly by intravital microscopy (1). Ac2-12 also promotes neutrophil detachment from mesenteric endothelium after activation by intraperitoneal injection of 1 mg zymosan in mice (*i.e.*, zymosan peritonitis). Ac2-12 phenocopies the effects observed in Formylated

Peptide Receptor (FPR) knock-out mice (2). 1. Lim, Solito, Russo-Marie, Flower & Perretti (1998) *Proc. Natl. Acad. Sci. U.S.A.* **95**, 14535. 2. Perretti, Getting, Solito, Murphy & Gao (2001) *Am. J. Pathol.* **158**, 1969.

#### AC220, See Quizartinib

#### Ac2-26

This anti-inflammatory agent (FW = 3089.46 g/mol; Acetyl-AMVSEFLKQAWFIENEEQEYVQTVK), corresponding to N-terminal residues 2-26 of steroid-inducible lipocortin-1; CAS 151988-33-9; Soluble to 1 mg/mL in PBS Buffer) inhibits leukocyte extravasation, reducing neutrophil adhesion and emigration and promoting neutrophil detachment from activated mesenteric endothelium in mice *in vivo* (1). Such observations show that peptides derived from LC1 mimic the activity of the full-length molecule, pointing the way for development of new anti-inflammatory inhibitors of leukocyte trafficking. 1. Perretti, Ahluwalia, Harris, Goulding & Flower (1993) *J. Immunol.* **151**, 4306. 2. Lim, Solito, Russo-Marie, Flower & Perretti (1998) *Proc. Natl. Acad. Sci. U.S.A.* **95**, 14535.

#### AC-4

This photoswitchable TRPV1 channel blocker (FW = 514.56 g/mol; CAS 1459809-09-6; Solubility: 100 mM in DMSO; 20 mM in H<sub>2</sub>O, with gentle warming), also known as 1,3,4,5-tetrahydro-7,8-dihydro-*N*-[2-[4-[2-[4-(trifluoromethyl)phenyl]diazanyl]phenyl]ethyl]-2*H*-2-benzazepine-2-carboxamide, acts as an antagonist of Transient Receptor Potential cation channel, subfamily V member 1, when in its *trans*-conformation during voltage-gated activation, but as an antagonist when in the *cis*-formation on capsaicin-induced TRPV1 currents. (AC4 switches conformation from *cis* to *trans* at 440 nm and *trans* to *cis* at 360 nm.) TRPV1 (also known as the Vanilloid Receptor 1) is a nonselective cation channel that is permeable to Ca<sup>2+</sup> ions, but shows little discrimination between mono- and divalent cations. It is abundantly expressed in nociceptive neurons (e.g., dorsal root ganglion (DRG), trigeminal ganglion (TG), as well as spinal and peripheral nerve terminals and cornea. This channel is located in the plasma membrane but occasionally is found on sarco-/endo-plasmic reticulum membranes, where it may function in intracellular Ca<sup>2+</sup> release. TRPV1 activation gives rise to burning and pain sensations, making it a target for developing analgesics. TRPV1 is activated by several chemical and physical stimuli (e.g., voltage, heat, capsaicin, spider toxins, low pH, and the endocannabinoid anandamide). AC4 acts as a *cis*-antagonist of CAP-induced TRPV1 currents but becomes a *trans*-antagonist upon voltage activation, in good agreement with the observation that agonists interact with TRPV1 channels in a state-dependent fashion and that specific antagonists differ in their ability to block distinct agonists. 1. Stein, Breit, Fehrentz, Gudermann & Trauner (2013) *Angew. Chem. Int. Ed. Engl.* **52**, 9845.

#### AC 187

This orally active receptor antagonist (FW = 2890.25 g/mol; Sequence: Acetyl-VLGKLSQELHKLQTYPRNTGNSNTY-NH<sub>2</sub>; CAS 151804-77-2) targets (IC<sub>50</sub> = 0.5 nM) receptors for amylin, the 37-residue hormone (Sequence: KCNTATCATQRLANFLVHSSNFGAILSSTNVGSNTY, with a single disulfide bridge) co-secreted from the pancreatic β-cells with insulin (1-3). Amylin slows gastric emptying, thereby promoting satiety and preventing post-prandial spikes in blood glucose levels. Amylin is postulated to act as a hormonal signal from pancreas to brain, inhibiting food intake and regulating energy reserves by reducing food intake, body weight, and adiposity, when administered systemically or into the brain (2). AC-187 displays 38x and 400x selectivity over calcitonin and CGRP receptors, respectively. By attenuating the activation of initiator and

effector caspases, AC-187 also blocks amyloid β-induced neurotoxicity *in vitro*. Other effects include increasing glucagon secretion, accelerating gastric emptying, altering plasma glucose levels, and increasing food intake *in vivo*. 1. Jhamandas & MacTavish (2004) *J. Neurosci.* **24**, 5579. 2. Reidelberger, Haver, Arnelo, *et al.* (2004) *Am. J. Physiol. Inter. Comp. Physiol.* **287**, R568. 3. Gedulin, Jodka, Herrmann & Young. (2006) *Regul. Pept.* **137**, 121.

#### AC 222164

This herbicide (FW = 260.29 g/mol) uncompetitively inhibits acetolactate synthase,  $K_i = 1.7 \mu\text{M}$  (1) as well as branched-chain amino acids (2). Often used as an herbicide in the cultivation of soybeans, Scepter® has been known to inhibit the growth of corn, and this herbicide is surprisingly long-lived in event of drought. 1. Shaner, Anderson & Stidham (1984) *Plant Physiol.* **76**, 545. 2. Hawkes, Howard & Pontin (1990) in *Herbicides and Plant Metabolism* (Dodge, ed.), p. 313, Soc. Exp. Biol. Sem. Ser., Cambridge University Press, UK.

#### Acacetin

This naturally occurring flavone (FW = 286.27 g/mol; CAS 480-44-4), also known as 5,7-dihydroxy-4'-methoxyflavone and 7-*O*-methylapigenin, and systematically named as 5,7-dihydroxy-2-(4-methoxyphenyl)-chromen-4-one, from the black locust *Robinia pseudoacacia* is the aglycon of linarin and acaciin and is biosynthesized by apigenin 4'-*O*-methyltransferase from *S*-adenosyl-methionine and 5,7,4'-trihydroxyflavone (apigenin), yielding *S*-adenosylhomocysteine and acacetin. The chemical synthesis of acacetin was accomplished by Robert Robinson, who was awarded the 1947 Nobel Prize in Chemistry for his work on alkaloids and organic synthesis. **Target(s):** glutathione *S*-transferase (1); xanthine oxidase,  $K_i = 0.11 \mu\text{M}$  (2); CYP1A (3); CYP1B1 (3); glutathione-disulfide reductase (4); DNA topoisomerase I (5); [myosin light-chain] kinase (6); and protein-tyrosine kinase, or non-specific protein-tyrosine kinase (7). 1. #### Acadesine

This dephosphorylated form of a key purine nucleotide biosynthetic intermediate (FW = 258.23 g/mol; CAS 2627-69-2), also known as 5-aminoimidazole-4-carboxamide 1- $\beta$ -D-ribofuranoside and 5-amino-1-((2R,3R,4S,5R)-3,4-dihydroxy-5-(hydroxymethyl)tetrahydro-furan-2-yl)-1H-imidazole-4-carboxamide, is phosphorylated to aminoimidazole carboxamide ribonucleotide (or AICAR, or ZMP), which mimics AMP's activating effect on AMP-dependent protein kinase, or AMPK (See also A-769662). **Tool for Exploring AMPK Signal Transduction Pathways:** The latter is believed to protect cells against environmental stress (e.g. heat shock) by switching off biosynthetic pathways, the key signal being elevation of AMP. Identification of novel targets for the kinase cascade are thus facilitated by development of acadesine as a specific agent for activating the kinase in intact cells (1). ZMP mimics both activating effects of AMP on AMPK (i.e., by direct allosteric activation and by promotion of phosphorylation by AMPK kinase). Unlike existing methods for activating AMPK in intact cells (e.g. fructose, heat shock), AICAR does not perturb the cellular contents of ATP, ADP or AMP. Acadesine (500  $\mu$ M) causes a transient 12x activation of AMPK within 15 minutes in rat hepatocytes and 2-3x activation of AMPK in adipocytes, again without affecting levels of ATP, ADP or AMP. Acadesine activates AMPK and induces apoptosis in B-cell chronic lymphocytic leukemia cells but not in T lymphocytes (2). **Target(s):** At 500  $\mu$ M, acadesine dramatically inhibits both fatty acid and sterol synthesis. It likewise phosphorylates and inactivates HMG-CoA reductase (1). Although acadesine kills chronic myelogenous leukemia (CML) cells, AMPK knock-down by Sh-RNA fail to prevent the effect of acadesine, indicating an AMPK-independent mechanism (3). Surprisingly, acadesine triggers relocation and activation of several PKC isoforms (3). Acadesine inhibits neutrophil CD11b up-regulation *in vitro* and during *in vivo* cardiopulmonary bypass (4). Other AMPK activators also induce nucleoli re-organization, with attendant changes in cell proliferation. Among the compounds tested, phenformin and resveratrol had the most pronounced impact on nucleolar organization (5). Notably, AICA riboside uptake into cells, as mediated by the adenosine transport system, is blocked by a number of protein kinase inhibitors, such that ZMP does not accumulate to sufficient levels to stimulate AMPK (6). Such findings demonstrate that careful interpretation is required when using AICA riboside in conjunction with protein kinase inhibitors to investigate the physiological role of AMPK. 1. ### Acamprosate

This antimetabolite (FW = 181.21 g/mol; CAS 77337-76-9; Symbol = AC), also known as *N*-acetylhomotaurate, decreases voluntary ethanol drinking in laboratory animals and relapse behavior in human alcoholics. Although glutamatergic mechanisms have been implicated in several recent studies on the action of acamprosate, its underlying mechanism of action remains unknown. While AC appears to bind to *N*-methyl-D-aspartic acid (NMDA) targets (1), acamprosate strongly inhibits the binding of taurine to taurine receptors. It has little effect on the binding of glutamate to glutamate receptors or muscimol to GABA<sub>A</sub> receptors (2). AC is neurotoxic, at least in culture, triggering neuronal damage at 1 mM. The underlying mechanism of AC-induced neuronal injury appears to be due to its action in increasing intracellular calcium ion levels (2). 1. Tomek, Lacrosse, Nemirovsky & Olive (2013) *Pharmaceuticals* (Basel) **6**, 251. 2. Wu, Jin, Schloss, *et al.* (2001) *J. Biomed. Sci.* **8**, 96.

### Acanthoate (Acanthoic Acid)

This diterpenoid (FW = 302.46 g/mol), also named 1R,4aR,7S, 8aS,10aS)-1,4a,7-trimethyl-7-vinyl-1,2,3,4,4a,6,7,8,8a,9,10,10a-dodecahydrophenanthrene-1-carboxylic acid, from the roots of *Acanthopanax koreanum*, inhibits human protein tyrosine-phosphatase 1B (IC<sub>50</sub> = 24  $\mu$ M) and cyclooxygenases-1 and -2, with IC<sub>50</sub> values of 116 and 790  $\mu$ M, respectively. **Target(s):** cyclooxygenases-1 and -2 (1,2); protein-tyrosine-phosphatase (3). 1. Jung, Shim, Suh, *et al.* (2007) *Cancer Sci.* **98**, 1943. 2. Suh, Kim, Park, *et al.* (2001) *Bioorg. Med. Chem. Lett.* **11**, 559. 3. Na, Oh, Kim, *et al.* (2006) *Bioorg. Med. Chem. Lett.* **16**, 3061.

### Acarbose

This pseudotetrasaccharide (FW = 645.61 g/mol; CAS 56180-94-0), also named *O*-[4,6-dideoxy-4-[1S-(1 $\alpha$ ,4 $\alpha$ ,5 $\beta$ ,6 $\alpha$ )-4,5,6-trihydroxy-3-hydroxymethyl-2-cyclohexen-1-yl]amino- $\alpha$ -D-glucopyranosyl]-(1 $\rightarrow$ 4)-*O*- $\alpha$ -D-glucopyranosyl-(1 $\rightarrow$ 4)-D-glucopyranose, inhibits many  $\alpha$ -glucosidases, including pig intestinal sucrase (IC<sub>50</sub> = 0.5  $\mu$ M). Acarbose also reduces sugar absorption in the gastrointestinal tract as well as the level of circulating glycosylated hemoglobin (i.e., HbA<sub>1c</sub>). First marketed in Germany in 1990 as Glucobay<sup>TM</sup> and in the United States in 1996 as Precose<sup>TM</sup> for the treatment of Type 2 diabetes, acarbose enables patients to achieve better control of blood sugar levels, while on starch-containing diets. **Target(s):** cyclomaltodextrin glucono-transferase (1,15-18,45-47); *O*-glycosyl glycosidase (2);  $\alpha$ -glucosidase, or maltase (3,4,8,9,18,29-31,48);  $\alpha$ -amylase (3,6,7,10,11, 18,20,36-40); sucrose  $\alpha$ -glucosidase, or sucrase (2,3,12, 28); glycogen phosphorylase *a* (3,14); glucan 1,4- $\alpha$ -glucosidase, or glucoamylase (3,19,20,32-35); 4- $\alpha$ -glucanotransferase (5,42-44); maltodextrin phosphorylase (13,20); exo(1 $\rightarrow$ 4)- $\alpha$ -D-glucan lyase, *K<sub>i</sub>* = 20 nM (21-23); maltose-transporting ATPase (24); glucan 1,4- $\alpha$  maltohydrolase (25); cyclomaltodextrinase (26,27); oligosaccharide 4- $\alpha$ -glucosyltransferase (41); amyloamylase (42,44); and maltodextrin phosphorylase, poorly inhibited (49). 1. #### Acarviosine-glucose

This pseudo-trisaccharide (FW = 475.49 g/mol) is a truncated acarbose analogue that inhibits  $\alpha$ -amylase (1,2) and cyclomaltodextrin glucanotransferase (1). IsoAca and AcvGlc are competitive inhibitors that allow one to classify  $\alpha$ -glucosidases into two groups (3). Enzymes of the first group were strongly inhibited by AcvGlc and weakly by IsoAca, in which the  $K_i$  values of AcvGlc (0.35-3.0  $\mu$ M) were 21- to 440-fold smaller than those of IsoAca. However, the second group of enzymes showed similar  $K_i$  values, ranging from 1.6 to 8.0  $\mu$ M for both compounds. This classification for  $\alpha$ -glucosidases is in total agreement with that based on the similarity of their amino acid sequences (family I and family II). This indicated that the  $\alpha$ -glucosidase families I and II could be clearly distinguished based on their inhibition kinetic data for IsoAca and AcvGlc. **1.** Kim, Lee, Lee, *et al.* (1999) *Arch. Biochem. Biophys.* **371**, 277. **2.** Li, Begum, Numao, *et al.* (2005) *Biochemistry* **44**, 3347. **3.** Kimura, Lee, Lee, *et al.* (2004) *Carbohydr. Res.* **339**, 1035.

#### ACEA

This synthetic CB<sub>1</sub> receptor agonist (FW = 365.99 g/mol; CAS 220556-69-4), also known as arachidonyl-2'-chloroethylamide and *N*-(2-chloroethyl)-5Z,8Z,11Z,14Z-eicosatetraenamide, selectively targets the CB<sub>1</sub> cannabinoid receptor ( $K_i$  = 1.4 nM) with >1400-fold selectivity over CB<sub>2</sub> receptors. Two subtypes of the cannabinoid receptor (CB<sub>1</sub> and CB<sub>2</sub>) are expressed in mammalian tissues. Although selective antagonists are available for each of the subtypes, most of the available cannabinoid agonists bind to both CB<sub>1</sub> and CB<sub>2</sub> with similar affinities (1). ACEA possesses the characteristics of CB<sub>1</sub> receptor agonists, inhibiting forskolin-induced cAMP accumulation in Chinese hamster ovary cells expressing the human CB<sub>1</sub> receptor. It also increases the binding of [<sup>35</sup>S]GTP $\gamma$ S to cerebellar membranes and inhibits electrically evoked contractions of the mouse *vas deferens* (1). ACEA produces hypothermia in mice, an effect that is inhibited by co-administration of the CB<sub>1</sub> receptor antagonist SR141716A (1). Like other CB<sub>1</sub> receptor agonists (*e.g.*, CP55940, Win 55212-2,  $\Delta^9$ -tetrahydrocannabinol, arachidonylethanolamide (AEA)), arachidonyl-2-chloroethylamide produces increases in gait width, a measure of truncal ataxia (2). All of these CB<sub>1</sub> agonists significantly increased the number of slips on the bar cross test, which is consistent with loss of motor coordination. Pretreatment with the CB<sub>1</sub> receptor antagonist SR141716 attenuated both the change in gait width and number of slips induced by

CP55940 and AEA (2). **See also** ACPA **1.** Hillard, Manna, Greenberg, *et al.* (1999) *J. Pharmacol. Exp. Ther.* **289**, 1427. **2.** Patel & Hillard (2001) *J. Pharmacol. Exp. Ther.* **297**, 629.

#### ACEA-1011

This quinoxaline-2,3-dione (FW = 264.59 g/mol), also known as 5-chloro-7-trifluoromethyl-2,3-quinoxalinedione, is an AMPA (*i.e.*,  $\alpha$ -amino-3-hydroxy-5-methylisoxazole-4-propionic acid) receptor antagonist. ACEA-1011 also blocks the currents in DRG cells with a  $K_b$  of approximately 1  $\mu$ M, but in cortical neurons the  $K_b$  for this drug was 10-12  $\mu$ M. **1.** Wilding & Huettner (1996) *Mol. Pharmacol.* **49**, 540.

#### Acebutolol

This lipophilic, cardioselective  $\beta$ -adrenergic blocker (FW<sub>free-base</sub> = 336.43 g/mol; CAS Reg. Nos 37517-30-9 and 34381-68-5 (HCl)), also known as Sectral™ and named systematically as (*RS*)-*N*-[3-acetyl-4-[2-hydroxy-3-(propan-2-ylamino)propoxy]phenyl]butanamide, displays intrinsic sympathomimetic activity (ISA) and is used to treat hypertension and angina. Acebutolol is metabolized to diacetolol, which is as active as acebutolol and shows a same pharmacologic profile. **Target(s):**  $\beta$ -adrenergic receptor (1,2). **1.** Cuthbert & Owusu-Ankomah (1971) *Brit. J. Pharmacol.* **43**, 639. **2.** Basil, Jordan, Loveless & Maxwell (1973) *Brit. J. Pharmacol.* **48**, 198.

**Acein-1, See** *L-Tyrosyl-L-leucyl-L-tyrosyl-L-glutamyl-L-isoleucyl-L-alanyl-L-arginine*

**Acein-2, See** *L-Leucyl-L-isoleucyl-L-tyrosine*

#### Acenocoumarol

This warfarin analogue (FW = 353.33 g/mol; CAS 152-72-7), also known as acenocoumarin and (*RS*)-4-hydroxy-3-[1-(4-nitrophenyl)-3-oxobutyl]-2*H*-chromen-2-one, is a short-lived oral anti-coagulant that functions by inhibiting vitamin K epoxide reductase, with higher intrinsic anticoagulant potency *in vitro* than warfarin. Acenocoumarol also inhibits rat liver NAD(P)H dehydrogenase competitively with respect to NADH,  $K_i$  = 1.7  $\mu$ M (2) and galactose transport (3). **1.** Ufer (2005) *Clin. Pharmacokin.* **44**, 1227. **2.** Almeda, Bing, Laura & Friedman (1981) *Biochemistry* **20**, 3731. **3.** Larralde, Ruano, Bolufer & Jordana (1975) *Arch. Int. Physiol. Biochim.* **83**, 271.

#### ACES

This alkyl-sulfonic acid (FW = 182.20 g/mol; CAS 7365-82-4;  $pK_2$  = 6.88 at 20°C, with  $dpK_2/dT$  = -0.020 pH unit/°C), named systematically as *N*-(2-acetamido)-2-aminoethanesulfonic acid, is frequently used as a neutral pH buffer. **Note:** Chloroethane sulfonate is an essential ingredient in the chemical synthesis of ethane sulfonic acid-containing Good's Buffers,

giving rise to variable contaminating levels of oligovinylsulfonate (OVS) that inhibit ribonuclease (1) and are likely to act similarly with other enzymes that bind polyanions. **Target(s):** GABA ( $\gamma$ -aminobutyrate) receptor (2). 1. Smith, Soellner & Raines (203) *J. Biol. Chem.* **278**, 20934. 2. Tunnickliff & Smith (1981) *J. Neurochem.* **36**, 1122.

### Acetaldehyde

This simple aldehyde (FW = 44.053 g/mol; CAS 75-07-0; Miscible with water and ethanol), is a metabolite produced during carbohydrate degradation. The pure aldehyde is a flammable (M.P. = -123.5°C; B.P. = 21°C) and is best stored in a sealed glass ampoule which should be cooled on ice prior to opening. Storage in a glass ampoule also suppresses spontaneous polymerization at room temperature. As illustrated above, the carbonyl of acetaldehyde readily undergoes hydration to form  $\text{CH}_3\text{CH}(\text{OH})_2$  in aqueous solution, especially in the presence of imidazole or phosphate. Indeed, reversible hydration of acetaldehyde is a general acid- and general base-catalyzed reaction, wherein acidic and basic components in the reaction medium independently contribute to the overall reaction rate. Acetaldehyde reacts with protein amino and sulfhydryl groups to form a variety of adducts, of which are most are Schiff bases and hemiacetals that are readily reversible. The  $\epsilon$ -amino groups of certain lysine residues and free N-terminal residues bind acetaldehyde and can be reduced by sodium cyanoborohydride to produce ethylated amino groups formed. **Target(s):** trimethylamine dehydrogenase (1); pyruvate carboxylase (2-5); pyruvate decarboxylase (6,7,13,14,42,43,47); sarcosine oxidase (8); 2-aminoadipate-6-semialdehyde dehydrogenase (9); lipase (10); xanthine oxidase (11,21,52); pyrophosphatase, or inorganic diphosphatase (12); monoamine oxidase (15); proteasome (16); pyruvate dehydrogenase (17,37,41); chymotrypsin (18,27);  $\text{Ca}^{2+}$  channels, voltage-dependent (19); glutamyl aminopeptidase, or aminopeptidase A (20); membrane alanyl aminopeptidase, or aminopeptidase M (20); lysozyme (22); peptidyl-dipeptidase A, or angiotensin-converting enzyme (23); tubulin polymerization, or microtubule self-assembly (24,29,30); porphobilinogen synthase, or  $\delta$ -aminolevulinic acid dehydratase (25); carboxypeptidase C, or cathepsin A (26); trypsin (27); methylated-DNA[protein]-cysteine S methyltransferase, or *O*<sup>6</sup>-methylguanine transferase (28); dihydroxyacetone-phosphate acyltransferase (31); ribonuclease A (32,33); glucose-6-phosphate dehydrogenase (33); nitrogenase (34); hydrogenase (34);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (35,36,39,40);  $\text{Mg}^{2+}$ -ATPase (35,40); 5'-nucleotidase (35); succinate dehydrogenase (36); cytochrome *c* oxidase (36); phosphoenolpyruvate carboxykinase (38); 4-hydroxy-2-oxoglutarate aldolase (44); hydroxynitrilase, or hydroxynitrile lyase (45); acetoacetate decarboxylase (46); amidase (48,49); malate synthase, weakly inhibited (50); glycerone-phosphate *O*-acyltransferase, or dihydroxyacetone-phosphate *O*-acyltransferase (51); and xanthine dehydrogenase (53). 1. ### Acetamide

This simple amide (FW = 59.07 g/mol; CAS 142-26-7; M.P. = 81°C; B.P. = 222°C), Deliquescent solid; Solubility: 97 g/100 mL  $\text{H}_2\text{O}$ ). **Target(s):** thermopsin (1,2);  $\beta$ -*N*-acetylglucosaminidase (3); urease, weakly inhibited (4); alcohol dehydrogenase, weakly inhibited (5); carbonic anhydrase (6,10); acetylcholinesterase, weakly inhibited (7,8);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase, weakly inhibited (9); urea carboxylase (11); amidase, also alternative substrate (12); pyroglutamyl-peptidase I (13); soluble epoxide hydrolase,  $K_i = 37$  mM (14); glucan 1,3- $\beta$ -glucosidase (15); and  $\beta$ -*N*-acetylhexosaminidase (16,17). 1. **N-(2-Acetamido)-2-aminoethanesulfonate, See ACES**

### 3-[(6-Acetamido-2-amino-3-pyridinyl)methyl-5-(2-hydroxyethyl)-4-methylthiazolium] Pyrophosphate

This pyridine analogue (FW<sub>hydrochloride</sub> = 502.81 g/mol) of thiamin pyrophosphate inhibits transketolase,  $K_i = 23$  nM. A key enzyme in the synthesis of ribose, and hence nucleotide biosynthesis, transketolase is a druggable target for treatment of cancer. In nude mice with xenografted HCT-116 tumors, this inhibitor almost completely suppressed transketolase activity in blood, spleen, and tumor cells, but there was little effect on other thiamine-utilizing enzymes  $\alpha$ -ketoglutarate dehydrogenase or glucose-6-phosphate dehydrogenase. 1. Thomas, Le Huerou, De Meese, *et al.* (2008) *Bioorg. Med. Chem. Lett.* **18**, 2206.

**3-[(2-Acetamido-4-amino-5-pyrimidinyl)methyl]-5-(2-hydroxyethyl)-4-methylthiophene Pyrophosphate**

This desamino thiamin pyrophosphate analogue (FW = 462.05 g/mol) inhibits transketolase (TK),  $K_i = 3.0$  nM (1). The depyrophosphorylated derivative is a weaker inhibitor ( $K_i = 1.1$   $\mu$ M). Most thiamine antagonists have a permanent +1 charge on the B-ring, but the affinity of this inhibitor shows that this charge is not required for binding. 1. Thomas, De Meese, Le Huerou, *et al.* (2008) *Bioorg. Med. Chem. Lett.* **18**, 509.

**rel-(3a*S*,6*S*,6a*R*)-4-(4-Acetamidobenzenesulfonyl)-6-methyl-5-oxohexahydro-pyrrolo[3,2-*b*]pyrrole-1-carboxylic Acid Benzyl Ester**

This mechanism-based HCMV protease inhibitor (FW = 459.52 g/mol) targets human cytomegalovirus assemblin. ESI/MS studies have shown that this and related inhibitors can bind covalently and reversibly to the viral enzyme in a time-dependent manner by a mechanism which is consistent with acylation of HCMV  $\delta$ Ala protease at the active site nucleophile Ser-132. 1. Borthwick, Angier, Crame, *et al.* (2000) *J. Med. Chem.* **43**, 4452.

**2-Acetamido-2-deoxy-D-galactonolactone**

This lactone (FW = 219.19 g/mol) inhibits  $\beta$ -*N*-acetylgalactosaminidase (1,2),  $\beta$ -*N*-acetylglucosaminidase (1,2), and  $\beta$ -*N*-acetylhexosaminidase (3-8). Note that the 1,4-lactone is shown above; however, in some cases, the 1,5-lactone may be the true inhibitor. 1. Walker & Nicholas (1961) *Biochem. J.* **78**, 10p. 2. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 419-420, Academic Press, New York. 3. Pócsi, Kiss, Zsoldos-Mádi & Pintér (1990) *Biochim. Biophys. Acta* **1039**, 119. 4. **6-Acetamido-1,6-dideoxy-D-mannojirimycin**

This mannosamine analogue (FW = 204.23 g/mol) potently inhibits  $\alpha$ -L-fucosidase (1). When the ring nitrogen is protonated, this analogue mimics the charge of oxo-carbenium ion intermediate thought to form transiently in many glycosidase reactions. 1. Berteau, McCort, Goasdoué, Tissot & Daniel (2002) *Glycobiology* **12**, 273.

***N*-(2-Acetamido)iminodiacetic Acid, See ADA**

**2-Acetamido-1,5-imino-1,2,5-trideoxy-D-glucitol**

This *N*-acetylglucosamine analogue (FW = 204.23 g/mol), also known as 2-acetamido-1,2-dideoxyjirimycin, inhibits  $\beta$ -*N*-acetylhexosaminidase (1,2) and  $\beta$ -*N*-acetylglucosaminidase (2). When the ring nitrogen is protonated, this analogue mimics the charge of oxo-carbenium ion intermediate that forms transiently in many glycosidase reactions. This property results in tight binding. 1. Nagahashi, Tu, Fleet & Namgoong (1990) *Plant Physiol.* **92**, 413. 2. Woynarowska, Wikel, Sharma, *et al.* (1992) *Anticancer Res.* **12**, 161.

**4-Acetamido-4'-isothiocyanatostilbene-2,2'-disulfonate**

This reagent (FW<sub>disodium salt</sub> = 498.47 g/mol), also known by the abbreviation SITS, inhibits anion permeability of membranes (1). It exists primarily in the *trans* geometric isomer. SITS also can function as a fluorescent marker for membranes. **Target(s):** anion transport (1); Cl<sup>-</sup> channel (2); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (3); F<sub>1</sub> ATPase (4); and thiamin-triphosphatase (5). 1. Zoccoli & Karnovsky (1980) *J. Biol. Chem.* **255**, 1113. 2. Tauskela, Mealing, Comas, *et al.* (2003) *Eur. J. Pharmacol.* **464**, 17. 3. ***N*-(4-Acetamidophenylsulfonyl)-*N*-(4-nitrobenzyl)- $\beta$ -alanine Hydroxamate**

This hydroxamate (FW = 435.44 g/mol) inhibits interstitial collagenase ( $K_i$  = 13 nM), gelatinase A ( $K_i$  = 9 nM), neutrophil collagenase ( $K_i$  = 8 nM), gelatinase B ( $K_i$  = 11 nM), and microbial collagenase ( $K_i$  = 13 nM). **Target(s):** gelatinase A (matrix metalloproteinase-2); gelatinase B (matrix metalloproteinase-9); interstitial collagenase (matrix metalloproteinase-1); microbial collagenase; neutrophil collagenase (matrix metalloproteinase-8). 1. Scozzafava, Iliés, Manole & Supuran (2000) *Eur. J. Pharm. Sci.* **11**, 69.

### 5-Acetamidofluoranthene-3-(3,4-dichlorobenzyl)-isatin 3-(*O*-acetyl)oxime

This acylated isatin oxime (FW = 484.32 g/mol) inhibits ubiquitin thiolesterase,  $IC_{50}$  = 15  $\mu$ M. Neuronal ubiquitin C-terminal hydrolase (UCH-L1) has been linked to Parkinson's disease (PD) as well as the progression of certain nonneuronal tumors, and neuropathic pain. 1. Liu, Lashuel, Choi, *et al.* (2003) *Chem. Biol.* **10**, 837.

### 2-Acetamido-1,2,5-trideoxy-1,5-imino-D-glucitol, See 2-Acetamido-1,5-imino-1,2,5-trideoxy-D-glucitol

### 5-Acetamidouracil

This xanthine/urate analogue (FW = 169.14 g/mol) inhibits *Streptococcus faecalis* xanthine phosphoribosyltransferase. Inhibition studies with 42 purine and purine analogues indicated that oxo groups at positions-2 and-6 of the purine ring were required for optimal binding. The substitution of thio for oxo reduced binding to the enzyme ca. 20-fold. In contrast to its rigid specificity with respect to the 2,6-dioxo substituents, the enzyme bound a variety of 4,5-condensed pyrimidine systems containing a nitrogen at the position corresponding to the N-7 of xanthine. At concentrations of 1 mM, hypoxanthine, adenine, and 4,6-dihydropyrazolo[3,4-*d*]pyrimidine were converted to their corresponding ribonucleotides at rates approximately 0.1% of the rate for xanthine. 1. Miller, Adamczyk, Fyfe & Elion (1974) *Arch. Biochem. Biophys.* **165**, 349.

### Acetaminophen

This centrally acting analgesic and antipyretic agent (FW = 151.17 g/mol; CAS 103-90-2; Solubility: 100 mM in DMSO), also known as *N*-acetyl-*p*-aminophenol, paracetamol, Tylenol, and Panadol, inhibits prostaglandin biosynthesis through its action against prostaglandin-endoperoxide synthase (EC 1.14.99.1). (See also *Phenacetin*) **Cyclooxygenase Inhibition:** Acetaminophen is somewhat more active against COX-3 ( $IC_{50}$  = 460  $\mu$ M) versus COX-1 ( $IC_{50}$  > 1000  $\mu$ M) and COX-2 ( $IC_{50}$  > 1000  $\mu$ M), but its true selectivity and mechanism of therapeutic action remains to be fully determined. Under most circumstances, acetaminophen is a relatively weak cyclooxygenase inhibitor; however, its potency against both purified ovine cyclooxygenase-1 (oCOX-1) and human cyclooxygenase-2 (hCOX-2) increases approximately 30x in the presence of glutathione peroxidase and glutathione, yielding  $IC_{50}$  values of 33  $\mu$ M and 980  $\mu$ M, respectively (1). Acetaminophen is a good reducing agent of both oCOX-1 and hCOX-2, suggesting an inhibitory mechanism in which it acts to reduce the active oxidized form of COX to the resting form (1). This results in inhibition of phenoxyl radical formation from a critical tyrosine residue essential for the

cyclooxygenase activity of COX-1 and COX-2 and prostaglandin (PG) synthesis (2). Acetaminophen shows selectivity for inhibition of the synthesis of PGs and related factors, when low levels of arachidonic acid and peroxides are available (2). Conversely, it has little activity at substantial levels of arachidonic acid and peroxides. Furthermore, inhibition would therefore be expected to be more effective under conditions of low peroxide concentration, a prediction that is consistent with the known tissue selectivity of acetaminophen (2). Although the exact site and mechanism of acetaminophen analgesia remains to be established, it appears to elevate the pain threshold by inhibiting the nitric oxide pathway, as mediated by a variety of neurotransmitter receptors, including *N*-methyl-D-aspartate and substance P. **Antipyretic Effects:** Acetaminophen is thought to inhibit the action of endogenous pyrogens on the heat-regulating centers in the brain by blocking the formation and release of prostaglandins in the central nervous system. **Pharmacokinetics:** Oral acetaminophen is rapidly and almost completely absorbed from the GI tract, primarily in the small intestine by passive transport. Relative bioavailability is 85-98%. Acetaminophen appears to be widely distributed throughout most body fluids, except fat. The apparent volume of distribution of acetaminophen is 0.95 L/kg. A small fraction (10-25%) of acetaminophen is bound to plasma proteins. The biologic half-life of acetaminophen in normal adults is approximately 2-3 hours in the usual dosage range, and the half-life for CSF clearance is 3 hours. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Toxicity:** After FDA approval in 1961, acetaminophen quickly became one of the most widely used analgesics. Often taken in excess by those ignoring clearly stated warnings, acute overdoses can result in potentially fatal liver damage. Harmful effects of acetaminophen have been attributed to the production of its toxic metabolite, *N*-acetyl-*p*-benzoquinone imine (or NAPQI), a topoisomerase II poison. (See *N-Acetyl-p-benzoquinone imine*) Acetylcysteine is often effective in the treatment of acetaminophen overdose, acting, in part, by inhibiting cytochrome P-448. **Target(s):** cyclooxygenase, or prostaglandin synthase (1-3,6); peroxynitrite-mediated chemiluminescence (4); glucosamine synthase (5); phenylpyruvate tautomerase (7); adenosine deaminase,  $K_i$  = 0.13 mM (8);  $\beta$ -glucosidase (9); arylamine *N*-acetyltransferase (10); phosphoribosylamino-imidazole carboxamide formyltransferase (11); thiopurine *S* methyltransferase (12); linoleate diol synthase (13); tryptophan 2,3-dioxygenase (14); 3-hydroxyanthranilate 3,4-dioxygenase (15); myeloperoxidase [where inhibition involves acetaminophen oxidation and concomitant decreased formation of halogenating oxidants (e.g. hypochlorous acid, hypobromous acid) that may be associated with multiple inflammatory pathologies including atherosclerosis and rheumatic diseases (2).] 1. ### Acetanilide

This acetylated aniline (FW = 135.17 g/mol; CAS 103-84-4 M.P. = 113-115°C) is a component in the synthesis of numerous pharmaceuticals, inhibitors, and dyes. Acetanilide is toxic *in vivo*, owing in part to its hydrolysis to aniline, with consequential methemoglobinemia. **Target(s):** chymotrypsin (1,2); D-3-hydroxybutyrate dehydrogenase (3); and amidase, also as an alternative substrate (4). 1. Baker (1967) *Design of Active-Site-Directed Irreversible Enzyme Inhibitors*, Wiley, New York. 2. Wallace,

Kurtz & Niemann (1963) *Biochemistry* **2**, 824. 3. Gotterer (1969) *Biochemistry* **8**, 641. 4. Alt, Heymann & Krisch (1975) *Eur. J. Biochem.* **53**, 357.

### Acetarsone

This organoarsenical (FW<sub>free-acid</sub> = 275.09 g/mol; CAS 97-44-4), also known as Stovarsol, Spirozid, Ehrlich 594, and [3-(acetylamino)-4-hydroxyphenyl]arsenate, is an antiprotozoal agent that was first prepared by Paul Ehrlich in 1909 during his classic campaign to identify a “silver bullet” for treating syphilis (1). **Target(s):**  $\gamma$ -butyrobetaine dioxygenase, mildly inhibited (2). 1. Mitchell (1935) *Can. Med. Assoc. J.* **33**, 377. 2. Lindstedt & Lindstedt (1970) *J. Biol. Chem.* **245**, 4178.

### Acetate (Acetic Acid)

This two-carbon alkyl acid (FW = 60.05 g/mol; CAS 64-19-7) is the most common carboxylic acid in biological systems. Acetate is the anion form or conjugate base of acetic acid, which has a  $pK_a$  value of 4.76 at 25°C (the  $dpK_a/dT$  value is +0.0002). The acid is a colorless liquid (M.P. = 16.7°C; B.P. = 118°C) with a distinctively strong and pungent odor. Acetic acid is miscible with water, ethanol, diethyl ether, glycerol, and carbon tetrachloride. The pure acid is often referred to as glacial acetic acid because, when poured on a surface, it resembles ice in appearance. Note that, just as water has an autoprotolysis constant of  $10^{-14} M^2$  at 24°C, the autoprotolysis constant for glacial acetic acid is  $10^{-13} M^2$  at 25°C. Salts of acetic acid (e.g., sodium acetate, ammonium acetate, etc.) are very hygroscopic and are very soluble in water; for example, 119 g of sodium acetate dissolve in 100 mL water at 0°C and 253 g potassium acetate dissolve in 100 mL water at 20°C. **Target(s):** sarcosine dehydrogenase (1);  $\beta$ -*N*-acetylhexosaminidase (2,7,25,26,43,89-101); membrane dipeptidase (3); (*S*)-2-hydroxy-acid oxidase (4); 4-aminobutyrate aminotransferase (5,46,120); penicillo-carboxypeptidase (6); hexose oxidase (8); diacetyl reductase, or acetoin dehydrogenase (9); 3-dehydroquinate dehydratase (10,62); methylamine oxidase (11); glutamyl endopeptidase (12); endopeptidase Clp (13); glutathione *S*-transferase (14); catalase (15); alanine aminotransferase (16); L-lactate dehydrogenase (17,23); carbonic anhydrase (18,28,50,63-66); triose-phosphate isomerase (19); phosphoglucosyltransferase (20); aspartate aminotransferase (21); rat liver mitochondrial ATPase (22); galactose oxidase (24); glutamate decarboxylase (25,33);  $\beta$ -*N*-acetyl-glucosaminidase (25,26,43,94); pantothenate synthetase (27); aspartate 4-decarboxylase (29,30); myosin ATPase (31); estradiol-17 $\beta$  dehydrogenase (31);  $\beta$ -galactosidase (31); angiotensin-converting enzyme, or peptidyl-dipeptidase A (34); aldose reductase, or aldehyde reductase (35); alcohol dehydrogenase, or weakly inhibited (36); *N*-methylglutamate dehydrogenase (37); creatine kinase (38); sarcosine oxidase (39); sepiapterin reductase (40); rhodanese, or thiosulfate sulfurtransferase (41); hyaluronoglucosaminidase, or hyaluronidase (42); cystathionine  $\gamma$ -lyase, or cysteine desulfhydrase (44); pyrophosphatase, or inorganic diphosphatase (45); cutinase (47); laccase (48); urease (49); pyridoxamine:pyruvate aminotransferase (51); pepsin (52); xanthine oxidase (53); UDP-*N*-acetylmuramoyl-tripeptide-D-alanyl-D-alanine ligase (54); asparaginyl-tRNA synthetase (55); aspartyl-tRNA synthetase (55); bisphosphoglycerate mutase (56); isopentenyl-diphosphate  $\Delta$ -isomerase (57); alanine racemase (58); pectin lyase (59); cyanate hydratase, or cyanase (60); nitrile hydratase (61); mandelonitrile lyase (67); glutamate decarboxylase (68); oxaloacetate decarboxylase (69,70); haloacetate dehalogenase (71); 1,5-anhydro-D-fructose reductase, or 1,5-anhydro-D-mannitol forming (72); succinate:3-hydroxy-3-methylglutarate CoA-transferase (73); theanine hydrolase (74);  $N^H$ -( $\beta$ -*N*-acetylglucosaminyl)-L-asparaginase (75); pantothenase (76);  $\beta$ -ureidopropionase (77); amidase (78-80); carboxypeptidase A, inhibited by concentrated

acetic acid (81); carboxypeptidase B, inhibited by concentrated acetic acid (81); carboxypeptidase A (82,83); peptidyl-dipeptidase A, or angiotensin I converting enzyme (84); aminopeptidase B (85); chitosanase (86,87); mannosyl-glycoprotein endo- $\beta$ -*N* acetylglucosaminidase (88);  $\alpha$ -L-rhamnosidase, weakly inhibited (102);  $\alpha$ , $\alpha$ -trehalase (103,104); poly(A) specific ribonuclease (105); 2',3'-cyclic-nucleotide 3'-phosphodiesterase (106,107); cephalosporin-C deacetylase (108-111); lipase, or triacylglycerol lipase (112); [ $\beta$ -adrenergic-receptor] kinase (113); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (114); thymidine kinase (115); glucokinase (116); hexokinase IV (116); serine:glyoxylate aminotransferase (117); 2-aminoethylphosphonate:pyruvate aminotransferase (118); L-lysine 6-aminotransferase (119); protein geranylgeranyltransferase type II (121); methionine *S*-adenosyltransferase, weakly inhibited (122); nicotinate-nucleotide diphosphorylase (carboxylating) (123); starch phosphorylase, weakly inhibited (124); peptide  $\alpha$ -*N* acetyltransferase (125); amino-acid *N*-acetyltransferase (126); acetolactate synthase (127); aspartate carbamoyl-transferase (128); glutamate formimidoyltransferase (129,130); glycine/sarcosine *N*-methyltransferase (131); tRNA (cytosine-5-)-methyltransferase (132); glycine *N*-methyltransferase (133); superoxide reductase (134); phenol 2-monoxygenase, weakly inhibited (135); 4-hydroxybenzoate 2-monoxygenase, weakly inhibited (136); lactate 2-monoxygenase, product inhibition (137,138); lysine 2-monoxygenase (139); protocatechuate 3,4-dioxygenase (140); manganese peroxidase (141,142); and laccase (143). 1. #### Acetazolamide

This universally used diuretic (FW = 222.25 g/mol; CAS 59-66-5), also known as Diamox™, *N*-(5-sulfamoyl-1,3,4-thiadiazol-2-yl)acetamide, and 2-acetamido-1,3,4-thiadiazole-5-sulfonamide, is a potent and reversible noncompetitive carbonic anhydrase inhibitor. Although aqueous solutions are stable for up to week, the recommended practice is to freshly prepare acetazolamide solutions and use them within 24 hours. **Primary Mode of Action:** Carbonic anhydrase catalysis may be depicted as the following multi-step reaction sequence: *Step-1*,  $E-Zn^{2+}(H_2O) \rightleftharpoons E-Zn^{2+}(OH) + H^+$ ; *Step-2*,  $E-Zn^{2+}(OH) + O=C=O \rightleftharpoons E-Zn^{2+}(OC(=O)OH)$ ; *Step-3*,  $E-Zn^{2+}(OC(=O)OH) + H_2O \rightleftharpoons HCO_3^- + E-Zn^{2+}(H_2O)$ , where the latter is the transient  $E-H^+$  species. Acetazolamide binds to  $E-H^+$ , and, because  $E-H^+$  must be deprotonated to regenerate the active catalyst, acetazolamide effectively blocks catalysis. Note that the sulfonamide moiety is believed to resemble enzyme-bound carbon dioxide, thus accounting for its high affinity ( $K_i \approx 10^{-8}$  M). **Medical Uses:** Because hemoglobin's  $O_2$  affinity is reduced at lower blood pH and because carbonic anhydrase inhibition tends to lower blood pH, acetazolamide is frequently used to reduce the severity and duration of symptoms of "mountain sickness" (e.g., upset stomach, headache (and, in severe cases, cerebral edema), shortness of breath (often attending pulmonary edema), dizziness, drowsiness, and fatigue). Acetazolamide also reduces hydrogen ion secretion in the renal tubule, increasing renal excretion of sodium, potassium, bicarbonate, and resulting in net water loss. Acetazolamide is also used to treat glaucoma (See also *Dorzolamide*), to reduce edema, and to control seizures in certain types of epilepsy. Acetazolamide also decreases renal ammonia production. Because there are multiple isozyme forms of carbonic anhydrase, including some ectoplasmic isozymes, acetazolamide is likely to have metabolic consequences beyond its effects on diuresis. **Target(s):** carbonic anhydrase (1-36); chloride-transporting ATPase (37); 3,5'-cyclic-nucleotide phosphodiesterase (38); dihydroorotase ( $K_i = 4.2$  mM (39)); glutaminase (40);  $\gamma$ -glutamyl transpeptidase, or  $\gamma$ -glutamyltransferase (41-44). 1. ### Acetic Anhydride

This carboxylic anhydride (FW = 102.09 g/mol; CAS 108-24-7; M.P. = -73°C; B.P. = 139°C) reacts with amino groups in peptides/proteins under slightly alkaline conditions. If the amino group is essential for biological or catalytic activity, its acetylation will often inhibit the modified peptide/protein. Tyrosyl residues are also acetylated; however, under alkaline condition, *O*-acetyltyrosyl residues hydrolyze readily. The latter can occasionally be trapped as the *N*-acetylhydroxamate after reaction with neutral hydroxylamine. Acetic anhydride hydrolyzes slowly ( $t_{1/2}$  at 0°C = 50 min;  $t_{1/2}$  at 25°C = 4.5 min) to yield two molecules of acetic acid, the presence of which imparts a distinct odor. **CAUTION:** This liquid is a skin and eye irritant. Avoid breathing acetic anhydride vapor. In view of its relatively low flash point of 54°C, acetic anhydride is a combustible liquid requiring appropriate caution. **Target(s):** glucose dehydrogenase (1); citrate (*si*)-synthase (2); thrombin (3,5); carboxypeptidase A (4,6,22); chymotrypsin (7); acetoacetate decarboxylase (8); trypsin (9); crotonin B (10); dendrotoxin I (11); cAMP-dependent protein kinase (12); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (13,14); collagenase (15); alkaline phosphatase (16,24); fructose-1,6-bisphosphatase (17); arylsulfatase (18); lysozyme (19); glutamine synthetase (20,25); glutamate dehydrogenase (21); hexokinase (23); phenylalanine ammonia-lyase (26,27); 3-oxoacid CoA-transferase, or 3-ketoacid CoA-transferase (28); aryl-acylamidase, but stimulated at low concentrations (29,30); butyrylcholinesterase, but stimulated at low concentrations (29); acetylcholinesterase (30); leukotriene-A4 hydrolase (31); endo-1,4-β-xylanase (32); ribonuclease T<sub>1</sub> (33); poly(3-hydroxyoctanoate) depolymerase (34,35); phospholipase A<sub>2</sub> (36); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, or ACAT (37,38); and glycerol-3-phosphate *O*-acyltransferase (39). 1. ### Acetoacetate (Acetoacetic Acid)

This β-keto acid (FW<sub>free-acid</sub> = 102.09 g/mol; CAS 541-50-4; M.P. = 36-37°C; pK<sub>a</sub> = 3.58 at 18°C), also known as 3-oxobutanoic acid, is one of the three ketone bodies (*i.e.*, fatty acid-derived metabolites) formed during ketogenesis (**See also Acetone and D-3-Hydroxybutyrate**). **Formation:** When carbohydrates are scarce, metabolic energy is obtained from fatty acid degradation, and ketone bodies are produced in hepatocytes from acetyl-CoA within the mitochondrial matrix. High acetyl CoA concentrations (from β-oxidation of fatty acids) inhibit pyruvate dehydrogenase and also activate pyruvate carboxylase allosterically. High ATP and NADH inhibit isocitrate dehydrogenase, decreasing TCA cycle flux, resulting in an increase malate concentration (derived from oxaloacetate). Malate leaves the mitochondrion to undergo gluconeogenesis. Those on low-carbohydrate diets also develop ketosis (called nutritional ketosis), where ketone body concentrations typically range between 0.5 to 5 mM. Ketone bodies are taken up by various cells, whereupon they reconverted to acetyl-CoA, which enters the tricarboxylic acid cycle and oxidized in the mitochondria for energy. By providing an alternative substrate to fuel oxidative phosphorylation, ketone bodies support mammalian cell survival during periods of energy insufficiency. The free acid is unstable to heat, decomposing to acetone and CO<sub>2</sub>, and is miscible with water and ethanol. Neutral solutions are stable for two-to-three weeks at -15°C. In the pathological ketoacidosis, however, they can rise to 15-25 mM, lowering blood pH considerably. Ketoacidosis is a complication of untreated Type I diabetes and is occasionally in end-stage Type II diabetes (known as diabetic ketoacidosis). **Acetoacetate-Requiring & -Utilizing Enzymes:** Acetoacetate is the direct product of reactions catalyzed by 3-hydroxybutyrate dehydrogenase, hydroxyacid:oxoacid transhydrogenase, 2-oxopropyl-CoM reductase, butyrate:acetoacetate CoA-transferase, acetoacetyl-CoA hydrolase, fumarylacetoacetase, hydroxymethylglutaryl-CoA lyase, acetylene-carboxylate hydratase, and acetone carboxylase. It is a substrate for acetoacetate decarboxylase, 3-oxoacid CoA-transferase, and acetoacetate:CoA ligase. **Target(s):** succinate dehydrogenase (1-3); aldehyde reductase, or aldose reductase (4); succinate:3-hydroxy-3-methylglutarate CoA-transferase (5,11); papain (6); monoamine oxidase (6); urease (6); F<sub>1</sub> ATPase (7); 3-methylcrotonyl-CoA carboxylase (8); malate dehydrogenase (9); oxaloacetate tautomerase (10); allophanate hydrolase (12); prostaglandin-endoperoxide synthase, or cyclooxygenase, weakly inhibited (13). 1. ### Acetoacetate Ethyl Ester, See Ethyl Acetoacetate

### Acetoacetyl-CoA

This β-ketoacyl-CoA (FW = 851.61 g/mol; CAS 1420-36-6), also known as acetoacetyl-S-CoA and 3-oxobutyryl-CoA, is an intermediate in fatty acid β-oxidation and ketogenesis. Note that acetoacetyl-CoA is rapidly hydrolyzed in alkaline solutions. Acetoacetyl-CoA is a product of the reactions catalyzed by 3-hydroxyacyl-CoA dehydrogenase, 3-hydroxybutyryl-CoA dihydrogenase, acetyl-CoA C-acetyltransferase, butyrate: acetoacetate CoA-transferase, and acetoacetate:CoA ligase. It is a substrate for β-ketoacyl-CoA thiolase, hydroxy-methylglutaryl-CoA synthase, and acetoacetyl-CoA hydrolase. Note that it is also a strong substrate inhibitor of 3-hydroxy-3-methylglutaryl-CoA synthase. **Target(s):**

pyruvate carboxylase (1,9), 3-methylcrotonoyl-CoA carboxylase (2,7,15,18,27); enoyl-CoA hydratase, or crotonase, the enol tautomer is the inhibitory species (3-5,8,19,20,26,29); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or 3-methyl-2-oxobutanoate dehydrogenase (acetyl transferring) kinase (6,11,22,32); 3-ketoacid CoA-transferase (10); 3-methylcrotonyl-CoA carboxylase (12); 3-hydroxy-3-methylglutaryl-CoA reductase (13,28); citrate synthase (14); short-chain acyl-CoA dehydrogenase (16); L-3-hydroxyacyl-CoA dehydrogenase (17); acyl-CoA dehydrogenase (21); 2-methyl branched-chain acyl-CoA dehydrogenase (23); succinate:3-hydroxy-3 methylglutarate CoA-transferase (24); glutaryl-CoA dehydrogenase (25); 3-hydroxyisobutyryl-CoA hydrolase (30,31); pantothenate kinase (33); [acyl-carrier-protein] S-malonyltransferase (34); acetyl-CoA C-acyltransferase (35,36); and arylamine N-acetyltransferase (37). 1. #### Acetobixan

This cellulose biosynthesis inhibitor, or CBI (FW = 287.38 g/mol) reduces incorporation [ $^{14}\text{C}$ ]-labeled glucose into crystalline cellulose. Cellulose is biosynthesized at the plasma membrane by the multi-enzyme/multi-component cellulose synthase A (CesA) complex. In living *Arabidopsis* cells, acetobixan treatment caused CesA particles localized at the plasma membrane (PM) to rapidly re-localize to cytoplasmic vesicles. Moreover, cortical microtubule dynamics were not disrupted by acetobixan, suggesting specific activity towards cellulose synthesis. 1. Xia, Lei, Brabham, et al. (2014) *PLoS One* **9**, e95245.

#### Acetochlor

This toluidine derivative (FW = 269.77 g/mol; CAS 34256-82-1; low water solubility (200 ppm)), also known as MON-097, Harness<sup>TM</sup>, Surpass<sup>TM</sup>, and Trophy<sup>TM</sup>, and named systematically as 2-chloro-N-(ethoxymethyl)-N-(2-ethyl-6-methylphenyl)acetamide, is a pre-emergent herbicide that acts on most annual grasses and certain broadleaf weeds. Acetochlor inhibits human multidrug resistance transporters MDR1, as measured by ATPase activity, inhibition of fluorescent dye efflux and vesicular transport. This herbicide also inhibits synthesis of very-long-chain fatty acids in plants. **Caution:** Acetochlor is classified as a probable human carcinogen.

#### Acetone

This common organic solvent (FW = 58.08 g/mol; CAS 67-64-1; M.P. = -94.7 °C; B.P. = 56.3 °C; flammable liquid; freely soluble in water, ethanol, chloroform, and other polar organic solvents; dipole moment of 2.69 D at 20°C; dielectric constant of 20.7 at 25°C), inhibits many enzymes by forming reversible adducts with active-site amino and thiol groups. Acetone is also a nonspecific protein denaturant at high concentrations. A highly effective lipid-extracting solvent, ice-cold acetone is frequently used to prepare tissue powders that are both long-lived and well suited for the extraction and purification of both water-soluble and membrane-associated proteins (1). **Target(s):** catechol 2,3-dioxygenase (2,17,71-73); subtilisin (3); lipase, or triacylglycerol lipase (4,28,54-56); acetyl-CoA carboxylase (5); L-glycol dehydrogenase (6,21); sterol O acyltransferase, or cholesterol O-acyltransferase, or ACAT (7,63,64); microsomal glycerol-3-phosphate O-acyltransferase (8,15);  $\beta$ -fructofuranosidase, or invertase (9);  $\alpha$ -glucosidase, or maltase (10);  $\beta$ -lactamase (11); carbonic anhydrase, weakly inhibited (12,25,34); DNA polymerase (13); camphor 5-monooxygenase, or CYP101 (14); chymotrypsin (16);  $\text{Ca}^{2+}$ -dependent ATPase (18); epoxide hydrolase (19); acetoacetate decarboxylase (20); enolase, in presence of ammonium sulfate and EDTA (22); diacetyl reductase, or  $\alpha$ -diketone reductase, NAD<sup>+</sup>-dependent (23); adenylate cyclase, or adenylyl cyclase (24); esterase or lipase (26); asparaginase (27); cystathionine  $\gamma$ -lyase, or cysteine desulfurase (29); dihydropyrimidinase, or hydantoinase (30); pyrophosphatase, or inorganic diphosphatase (31); aminoacylase (32); ribonuclease A, in the presence of sodium borohydride (33); 3-hydroxybutyrate dehydrogenase (35); hydroxynitrilase, or hydroxynitrile lyase (36,37); uroporphyrinogen decarboxylase (38); myosin ATPase, strongly inhibited under alkaline conditions (39); thiamin-triphosphatase (40); cytidine deaminase (41); pantothenase (42); arylformamidase (43); coagulation factor IXa (44); pyroglutamyl-peptidase I (45); cholesterol-5,6-oxide hydrolase (46); soluble epoxide hydrolase (47-49); poly(ADP-ribose) glycohydrolase (50);  $\beta$ -D-fucosidase (51); chitinase (52); retinyl-palmitate esterase (53); carboxylesterase, weakly inhibited (57,58); diacylglycerol cholinephosphotransferase (59); ethanolaminophosphotransferase (59); N acetyllactosamine synthase (60); lactose synthase (60); glucuronosyltransferase (61); 2,3 diaminopropionate N-oxalyltransferase (62); 2-acylglycerol O-acyltransferase, or monoacylglycerol O-acyltransferase, weakly inhibited (65); steroid 11 $\beta$ -monooxygenase (66); bacterial luciferase, or alkanal monooxygenase (FMN-linked), weakly inhibited (67); phenylacetone monooxygenase (68); nitronate monooxygenase (69); biphenyl-2,3-diol 1,2-dioxygenase (70); peroxidase (74); and laccase (75). 1. ### S-Acetyl-CoA

This coenzyme A derivative (FW = 821.59 g/mol), also known as 1-[(S-(coenzyme A)]propan-2-one, is a nonreactive acetyl-CoA analogue and is a potent competitive inhibitor of citrate synthase, phosphotransacetylase, and carnitine acetyltransferase. **Target(s):** citrate (*si*)-synthase (1,3,5); protein acetyltransferase (2,4); phosphate acetyltransferase, or phosphotransacetylase (1); carnitine acetyltransferase (1); malate synthase (6); and histone acetyltransferase (7). **1.** Rubenstein & Dryer (1980) *J. Biol. Chem.* **255**, 7858. **2.** Redman & Rubenstein (1984) *Meth. Enzymol.* **106**, 179. **3.** Wiegand, Remington, Deisenhofer & Huber (1984) *J. Mol. Biol.* **174**, 205. **4.** Rubenstein, Smith, Deuchler & Redman (1981) *J. Biol. Chem.* **256**, 8149. **5.** Kurz, Shah, Crane, et al. ### Acetophenone

This aromatic ketone (FW = 120.15 g/mol; CAS 98-86-2; M.P. = 20.5°C; B.P. = 202°C; slightly soluble in water) inhibits carboxylase (1,2), aldehyde dehydrogenase (NAD<sup>+</sup>),  $K_i = 48 \mu\text{M}$  (3,4), chymotrypsin (5), esterase (6), lipase (7), NAD<sup>+</sup> ADP-ribosyltransferase, poly(ADP-ribose) polymerase,  $IC_{50} = 2.3 \text{ mM}$  (8), tyrosinase, or monophenol monooxygenase,  $IC_{50} = 0.85 \text{ mM}$  (9), catechol 2,3-dioxygenase (10). **1.** Karrer & Visconti (1947) *Helv. Chim. Acta* **30**, 268. **2.** Massart (1950) *The Enzymes*, 1st ed., **1** (part 1), 307. **3.** Weiner, Freytag, Fox & Hu (1982) *Prog. Clin. Biol. ### Acetosyringone

This acetophenone-based, plant-pathogen recognition substance (FW = 196.20 g/mol; CAS 2478-38-8) is a volatile antioxidant produced within the wounds of certain plants. Acetosyringone triggers the *VirA* gene in *Agrobacterium tumefaciens* to promote more efficient transformation. Acetosyringone is also produced by the male leafhopper bug *Leptoglossus phyllopus* for use as a pheromone. **Target(s):**  $\alpha$ -glucosidase (1). **1.** Berthelot & Delmotte (1999) *Appl. Environ. Microbiol.* **65**, 2907.

### (3aS,6S,6aR)-4-Acetoxyacetyl-6-methyl-5-oxohexahydro-pyrrolo[3,2-b]pyrrole-1-carboxylic Acid Benzyl Ester

This pyrrolidine-5,5-*trans*-lactam (FW = 374.39 g/mol) inhibits human cytomegalovirus assemblin,  $IC_{50} = 6 \mu\text{M}$ , and the *rel*-(3a*S*,6*R*,6a*R*)-stereoisomer is a weaker inhibitor ( $IC_{50} = 805 \mu\text{M}$ ). **Target(s):** assemblin (1,2); elastase (2); and thrombin (2). **1.** Borthwick, Crame, Ertl, et al. (2002) *J. Med. Chem.* **45**, 1. **2.** Borthwick, Angier, Crame, et al. (2000) *J. Med. Chem.* **43**, 4452.

### 3 $\beta$ -Acetoxy-17-(4'-imidazolyl)androsta-5,16-diene

This synthetic steroid (FW = 380.25 g/mol) inhibits human steroid 17 $\alpha$ -monooxygenase, or CYP17, ( $IC_{50} = 75 \text{ nM}$ ), a key enzyme in androgen biosynthesis. The partially reduced 3 $\beta$ -acetoxy-17 $\beta$ -(4'-imidazolyl)andro-

5-ene is a slightly weaker inhibitor (human  $IC_{50}$  = 200 nM). 1. Ling, Li, Liu, *et al.* (1997) *J. Med. Chem.* **40**, 3297.

#### o-(Acetoxyphenyl)hept-2-ynyl Sulfide

This aspirin analogue (FW = 262.37 g/mol; Abbreviated APHS) preferentially acetylates and irreversibly inactivates cyclooxygenase. Relative to aspirin, APHS was 60 times as reactive against COX-2 and 100 times as selective for its inhibition; it also inhibited COX-2 in cultured macrophages and colon cancer cells and in the rat air pouch *in vivo*.

**Target(s):** cyclooxygenase-1,  $IC_{50}$  = 10  $\mu$ M (1); and cyclooxygenase-2,  $IC_{50}$  = 0.8  $\mu$ M (2). 1. Hochgesang, Nemeth-Cawley, Rowlinson, Caprioli & Marnett (2003) *Arch. Biochem. Biophys.* **409**, 127. 2. Kalgutkar, Crews, Rowlinson, *et al.* (1998) *Science* **280**, 1268.

#### Acetylacetone

This  $\beta$ -diketone (FW = 100.12 g/mol; flammable liquid; M.P. =  $-23^{\circ}\text{C}$ ; B.P. =  $140.5^{\circ}\text{C}$ ; moderately soluble in water, 0.1 g/mL), also known as 2,4-pentanedione and acetoacetone, reacts with amino groups and also chelates metal ions. **Target(s):** acetoacetate decarboxylase, slow-binding inhibition (1-3,8,14,15);  $\text{NAD}^{+}$  glycohydrolase, *or*  $\text{NADase}$  (4,13); aspartate aminotransferase (5); peroxidase (6); lipase, *or* triacylglycerol lipase (7,17); actin interaction with tropomyosin (9); malic enzyme, *or* malate dehydrogenase (10); pyridoxamine-5'-phosphate oxidase (11); estradiol 17 $\beta$ -dehydrogenase (12); acid phosphatase (16); aminolevulinatase aminotransferase (18); tryptophan dimethylallyltransferase (19); and tyrosinase, *or* monophenol monooxygenase (20). 1. #### N-Acetyl-Adhesin Amide Fragment 1025-1044

This acetylated eicosapeptide amide (MW = 2161.44 g/mol; Sequence: N-Acetyl-QLKTADLPAGRDETTSFVLV-NH<sub>2</sub>) inhibits *Streptococcus mutans* adhesion to salivary receptors. *S. mutans* is the main etiological agent of dental caries. The earliest step in microbial infection is adherence by specific microbial adhesins to the mucosa of the oro-intestinal, nasorespiratory, or genito-urinary tract. The binding of a cell surface adhesin of *Streptococcus mutans* to salivary receptors can be inhibited *in vitro*, as measured by surface plasmon resonance, using a synthetic peptide (p1025) corresponding to residues 1025-1044 of the adhesin. 1. Kelly, Younson, Hikmat, *et al.* (1999) *Nat. Biotechnol.* **17**, 42.

#### N-Acetyl-L-alanine

This acetylated amino acid (FW<sub>free-acid</sub> = 131.13 g/mol) is frequently used in peptide synthesis. N-Acetyl-L-alanine, together with N-acetyl-L-leucine, was the first amino acid mixture to be separated with partition chromatography. **Target(s):** acylaminoacyl-peptidase (1-3). 1. Kobayashi & Smith (1987) *J. Biol. Chem.* **262**, 11435. 2. Sharma & Orthwerth (1993) *Eur. J. Biochem.* **216**, 631. 3. Raphel, Giardina, Guevel, *et al.* (1999) *Biochim. Biophys. Acta* **1432**, 371.

#### N-Acetyl-L-alanine Chloromethyl Ketone

This halomethyl ketone (FW = 163.60 g/mol), also known as N-acetyl-3-amino-1-chloro-2-butanone and 3 acetamido-1-chloro-2-butanone, irreversibly inactivates elastase (1) and acylaminoacyl-peptidase (2). 1. Powers (1977) *Meth. Enzymol.* **46**, 197. 2. Kobayashi & Smith (1987) *J. Biol. Chem.* **262**, 11435.

#### N-Acetyl-L-alanine 2-(N-(p-nitrophenoxy)carbonylsarcosyl)-2-methylhydrazide

This azapeptide (FW = 395.37 g/mol) inhibits human leukocyte elastase, which, in addition to catalyzing elastin proteolysis, also disrupts tight junctions, damages certain tissues, breaks down cytokines and alpha proteinase inhibitor, cleaves IgA and IgG, cleave complement component C3bi, a component and the CR1, receptor that triggers phagocytosis in neutrophils. 1. Powers, Boone, Carroll, *et al.* (1984) *J. Biol. Chem.* **259**, 4288.

#### N-Acetyl-L-alanyl-L-alanyl-L-alanine Chloromethyl Ketone

This halomethyl ketone (FW = 305.76 g/mol) irreversibly inactivates elastase, which, in addition to catalyzing elastin proteolysis, also disrupts tight junctions, damages certain tissues, breaks down cytokines and alpha proteinase inhibitor, cleaves IgA and IgG, cleave complement component C3bi, a component and the CR1, receptor that triggers phagocytosis in neutrophils. **Target(s):** elastase (1,2); leukocyte elastase (3); myeloblastin, weakly inhibited (3); on pancreatic endopeptidase E (4). 1. Powers (1977) *Meth. Enzymol.* **46**, 197. 2. Galdston & Carter (1975) *Amer. Rev. Respir. Dis.* **111**, 873. 3. Kam, Kerrigan, Dolman, *et al.* (1992) *FEBS Lett.* **297**, 119. 4. Mallory & Travis (1975) *Biochemistry* **14**, 722.

#### N-Acetyl-L-alanyl-L-alanyl-azanolleucine 2,2,2-Trifluoroethyl Ester

This azapeptide ester (FW = 398.38 g/mol) inhibits a number of serine proteinases, including cathepsin G (1) and human leukocyte elastase (2). 1. Gupton, Carroll, Tuhy, Kam & Powers (1984) *J. Biol. Chem.* **259**, 4279. 2. Powers, Boone, Carroll, *et al.* (1984) *J. Biol. Chem.* **259**, 4288.

#### N-Acetyl-L-alanyl-L-alanyl-L-prolyl-L-alanine Chloromethyl Ketone

This halomethyl ketone (FW = 402.88 g/mol) irreversibly inactivates several serine proteinases, including cathepsin B (1), cathepsin H (2), pancreatic elastase (3,6,7), leukocyte elastase (4,6,7), myeloblastin, weakly inhibited (4), pancreatic endopeptidase E (5), cathepsin G (7), and chymotrypsin (7). 1. Olstein & Liener (1983) *J. Biol. Chem.* **258**, 11049. 2. Raghav, Kamboj, Parnami & Singh (1995) *Indian J. Biochem. Biophys.* **32**, 279. 3. Powers (1977) *Meth. Enzymol.* **46**, 197. 4. Kam, Kerrigan, Dolman, *et al.* (1992) *FEBS Lett.* **297**, 119. 5. Mallory & Travis (1975) *Biochemistry* **14**, 722. 6. Starkey & Barrett (1976) *Biochem. J.* **155**, 265. 7. Powers, Gupton, Harley, Nishino & Whitley (1977) *Biochim. Biophys. Acta* **485**, 156.

**N<sup>α</sup>-Acetyl-L-alanyl-L-cysteinyl-L-arginyl-L-alanyl-L-threonyl-L-lysyl-L-methionyl-L-leucinamide**

This acetylated octapeptide amide (FW = 936.18 g/mol; Sequence: Ac-ACRATKML-NH<sub>2</sub>) inhibits *Clostridium botulinum* bontoxilysin,  $K_i = 0.15$  nM (1). The D-cysteinyl analogue is slightly stronger ( $K_i = 0.026$  nM). 1. Schmidt, Stafford & Bostian (1998) *FEBS Lett.* **435**, 61.

**N<sup>α</sup>-Acetyl-D-alanyl-D-glutamic Acid**

This acetylated dipeptide (FW = 261.26 g/mol; Sequence: Acetyl-AE) is a competitive inhibitor of muramoylpentapeptide carboxypeptidase (1,2) and zinc D-Ala-D-Ala carboxypeptidases (3). 1. Nieto, Perkins, Leyh-Bouille, Frère & Ghuysen (1973) *Biochem. J.* **131**, 163. 2. DeCoen, Lamotte-Brasseur, Ghuysen, Frère & Perkins (1981) *Eur. J. Biochem.* **121**, 221. 3. Joris, Van Beeumen, Casagrande, *et al.* (1983) *Eur. J. Biochem.* **130**, 53.

**N<sup>α</sup>-Acetyl-Acetyl-L-alanyl-L-glutamyl-L-valyl-L-aspartal, See N<sup>α</sup>-(t-Butoxycarbonyl)-L-alanyl-L-glutamyl-L-valyl-L-aspartate  $\alpha$ -Semialdehyde****N-Acetyl-L-alanylglycyl-L-phenylalanine Chloromethyl Ketone**

This halomethyl ketone (FW = 367.83 g/mol) irreversibly inactivates chymotrypsin (1), chymase (2) trypsin (2,3), and cathepsin G (4). 1. Segal, Powers, Cohen, Davies & Wilcox (1971) *Biochemistry* **10**, 3728. 2. Powers, Tanaka, Harper, *et al.* (1985) *Biochemistry* **24**, 2048. 3. Yoshida, Everitt, Neurath, Woodbury & Powers (1980) *Biochemistry* **19**, 5799. 4. Powers, Gupton, Harley, Nishino & Whitley (1977) *Biochim. Biophys. Acta* **485**, 156.

**N-Acetyl-L-alanyl-L-leucyl-L-cysteinyl-L-aspartyl-L-aspartyl-L-prolyl-L-arginyl-L-valyl-L-aspartyl-L-arginyl-L-tryptophanyl-L-tyrosyl-L-cysteinyl-L-glutamyl-L-phenylalanyl-L-valyl-L-glutamylglycinamide (3-13 Disulfide Bridge)**

This octadecapeptide amide (Sequence: Acetyl-ALCDDPRDRWYQCQF VEG-NH<sub>2</sub>; MW = 2215.47 g/mol), with an intrapeptide disulfide bond between Cys3 and Cys13, inhibits tissue-factor-dependent clotting by blocking the activation of coagulation factors VIIIa and X, the latter with an IC<sub>50</sub> of 1 nM). 1. Dennis, Eigenbrot, Skelton, *et al.* (2000) *Nature* **404**, 465.

**N-Acetyl-L-alanyl-L-phenylalanine Chloromethyl Ketone**

This halomethyl ketone (FW = 310.78 g/mol) irreversibly inactivates protease IV (1), chymotrypsin (2,3), trypsin (4), and cathepsin G (5). 1. Miller (1998) in *Handbook of Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds), p. 1589, Academic Press, San Diego. 2. Shaw (1972) *Meth. Enzymol.* **25**, 655. 3. Segal, Powers, Cohen, Davies & Wilcox (1971) *Biochemistry* **10**, 3728. 4. Yoshida, Everitt, Neurath, Woodbury & Powers (1980) *Biochemistry* **19**, 5799. 5. Powers, Gupton, Harley, Nishino & Whitley (1977) *Biochim. Biophys. Acta* **485**, 156.

**N-Acetyl- $\beta$ -aletheine**

This pantothenate analogue (FW = 190.27 g/mol) inhibits 3-oxoacid CoA-transferase, or 3-ketoacid CoA-transferase, which catalyzes the reversible conversion of succinyl-CoA and acetoacetate into acetoacetyl-CoA and succinate through a covalent enzyme thiol ester intermediate, E-CoA. Substrate analogue binding studies with N-Acetyl- $\beta$ -aletheine helped to clarify how this enzyme exploits binding energy from noncovalent interactions with CoA to bring about an increase in  $k_{cat}/K_m$  of  $\sim 10^{10}$  M<sup>-1</sup>s<sup>-1</sup>. 1. Whitty, Fierke & Jencks (1995) *Biochemistry* **34**, 11678.

**2-(Acetylamino)-N-[4-[(aminoiminomethyl)amino]-1-(2-benzothiazolyl-carbonyl)butyl]acetamido**

This benzothiazole derivative of glycylarginine (FW = 391.47 g/mol) is a transition-state analogue that potently and reversibly inhibits trypsin ( $K_i = 260$  nM) and trypsinase ( $K_i = 470$  nM), the latter a human mast cell enzyme (EC 3.4.21.59) with therapeutic potential for the treatment of allergic or inflammatory disorders. The 1.9-Å resolution X-ray structure of the enzyme-inhibitor complex depicts a hemiketal adduct involving Ser-189, and hydrogen bonds with His-57 and Gln-192. 1. Costanzo, Yabut, Almond, *et al.* (2003) *J. Med. Chem.* **46**, 3865.

**8-(N-Acetyl-4-aminobenzyl)-1-benzyl-3-butylxanthine**

This 3-alkyl-1,8-dibenzylxanthine (FW = 445.52 g/mol) inhibits human GTP-dependent phosphoenol-pyruvate carboxykinase, or PEPCK (IC<sub>50</sub> = 19  $\mu$ M), a druggable target for improving glucose homeostasis in Type 2 diabetes. This agent is the first nonsubstrate-like inhibitor of human cytosolic PEPCK that is competitive with GTP. 1. Foley, Wang, Dunten, *et al.* (2003) *Bioorg. Med. Chem. Lett.* **13**, 3607.

**8-(N-Acetyl-4-aminobenzyl)-3-butyl-1-(2-fluorobenzyl)xanthine**

This GTP-competitive synthetic purine (FW = 463.51 g/mol) inhibits human phosphoenolpyruvate carboxykinase (GTP-requiring), IC<sub>50</sub> = 2.1  $\mu$ M. Increased hepatic gluconeogenesis is thought to lead to fasting hyperglycemia in patients with Type 2 diabetes. Because cytosolic phosphoenolpyruvate carboxykinase (PEPCK) catalyzes the rate-limiting step in gluconeogenesis, it is deemed a druggable target for controlling Type 2 diabetes. 1. Foley, Wang, Dunten, *et al.* (2003) *Bioorg. Med. Chem. Lett.* **13**, 3607.

**S-Acetyl-2(S)-amino-3-[4-(benzyloxy)phenyl]-1-propanethiol**

This thioamine (FW<sub>free-base</sub> = 315.43 g/mol), S-acetyl-3-[4-(benzyloxy)phenyl]-2-amino-1-propanethiol, inhibits leukotriene A<sub>4</sub> hydrolase, IC<sub>50</sub> = 1  $\mu$ M. The R-enantiomer is a weaker inhibitor (IC<sub>50</sub> = 8  $\mu$ M). A free thiol is needed for sub- $\mu$ M binding, with the enzyme preferring the R-enantiomer over the S-enantiomer, in contrast to the stereoselectivity displayed towards bestatin, an inhibitor of somewhat similar structure. Substitution of acid moieties around the periphery of the benzyloxyphenyl portion results in substantially weaker binding, suggesting this group resides within a large hydrophobic pocket when bound to the enzyme. 1. Ollmann, Hogg, Muñoz, *et al.* (1995) *Bioorg. Med. Chem.* **3**, 969.

**[3-(*N*-Acetylamino)-3-(carboxymethyl)propanoyl]-7-glutamate**

This acetylated dipeptide (FW = 306.27 g/mol) inhibits glutamate carboxypeptidase II, or *N*-acetylated  $\alpha$ -linked acidic dipeptidase,  $K_i = 3.2 \mu\text{M}$ . These results suggest that the relative spacing between the side chain carboxyl and the alpha-carboxyl group of the C-terminal residue may be important for binding to the active site of the enzyme. They also indicate that the  $\chi_1$  torsional angle for the aspartyl residue is  $\sim 0^\circ$ . 1. Subasinghe, Schulte, Chan, *et al.* (1990) *J. Med. Chem.* **33**, 2734.

***N*-Acetyl-DL-aminocarnitine**

This carnitine analogue (FW<sub>inner-salt</sub> = 202.25 g/mol), also known as 3-acetamino-4-(trimethylammonio)butyric acid, is a strong inhibitor of carnitine *O*-palmitoyltransferase (IC<sub>50</sub> for carnitine *O*-palmitoyltransferase-2 is 0.8  $\mu\text{M}$ ) and carnitine *O*-acetyltransferase ( $K_i = 24 \mu\text{M}$ ) (1.2). Moreover, this compound readily undergoes metabolic hydrolysis to form aminocarnitine, a good inhibitor of fatty acid oxidation. Aminocarnitine also acts as a hypoglycemic and antiketogenic compound and alters lipidic metabolism by inhibiting carnitine acetyltransferase (CAT) and carnitine palmitoyltransferase (CPT). 1. Jenkins & Griffith (1985) *J. Biol. Chem.* **260**, 14748. 2. Brass, Gandour & Griffith (1991) *Biochim. Biophys. Acta* **1095**, 17.

**2-Acetylaminoethyltrimethylammonium iodide**

This nonhydrolyzable acetylcholine analogue (FW = 272.13 g/mol), also known as acetylaminocholine, inhibits choline *O*-acetyltransferase competitively with respect to choline and noncompetitive with respect to acetyl-CoA, while product inhibition by choline is competitive with respect to acetylcholine and noncompetitive with respect to coenzyme A. These and related kinetic data are not consistent with the previously proposed ordered Theorell-Chance reaction mechanism, and have been interpreted in terms of a random binding mechanism. 1. Hersh & Peet (1977) *J. Biol. Chem.* **252**, 4796.

**4-(Acetylamino)-3-guanidinobenzoic Acid**

This benzoic acid derivative (FW = 236.23 g/mol), also known as BCX 140, inhibits influenza virus neuraminidase, or sialidase, with an IC<sub>50</sub> value of 2.5-10  $\mu\text{M}$ , but did not exhibit *in vivo* activity in a mouse model of influenza (1,2). 1. Singh, Jedrzejewski, Air, *et al.* (1995) *J. Med. Chem.* **38**, 3217. 2. Chand, Babu, Bantia, *et al.* (1997) *J. Med. Chem.* **40**, 4030.

**(2*S*,4*R*)-1-Acetyl-*N*-[(1*S*)-4-[(aminoiminomethyl)-amino]-1-(2-benzothiazolylcarbonyl)-butyl]-4-hydroxy-2-pyrrolidine carboxamide**

This arginine derivative (FW = 430.53 g/mol), also known as RWJ-56423, inhibits several serine proteinases (1), including trypsin and trypsinase, for which  $K_i = 8.1$  and 10 nM, respectively). The (2*R*)-stereoisomer is a weaker inhibitor. **Target(s):** coagulation factor Xa, weakly inhibited; kallikrein; plasmin; thrombin (weakly inhibited); trypsin; trypsinase; and u-plasminogen activator, or urokinase. 1. Costanzo, Yabut, Almond, *et al.* (2003) *J. Med. Chem.* **46**, 3865.

**5-(Acetylamino)-4-oxo-6-phenyl-2-hexenoate and Methyl Ester**

This acid (FW = 261.28 g/mol; CAS 477769-02-1; Abbreviation: AOPHA) and its methyl ester (FW = 275.30 g/mol; Abbreviation: AOPHA-Me) are both mechanism-based inactivators of peptidylglycine monooxygenase (PAM). Significantly, AOPHA-Me also inhibits carrageenan-induced edema in rats in a dose-dependent manner. Neither 4-phenyl-3-butenic acid nor AOPHA-Me exhibits significant cyclooxygenase (COX) inhibition *in vitro*, indicating that the anti-inflammatory activities of PBA and AOPHA-Me are unlikely to be the consequence of COX inhibition. 1. Bauer, Sunman, Foster, *et al.* (2007) *J. Pharmacol. Exp. Ther.* **320**, 1171.

***N*<sup>ε</sup>-Acetyl-L-arginine**

This acetylated amino acid (FW<sub>inner-salt</sub> = 216.24 g/mol; CAS 155-84-0; IUPAC Name: (2*S*)-2-acetamido-5-(diaminomethylideneamino)pentanoate) inhibits carboxypeptidase B (1). **Target(s):** carboxypeptidase B (1,2); actinidain (3); lysine carboxypeptidase, or lysine(arginine) carboxypeptidase; carboxypeptidase N (4). 1. Folk (1971) *The Enzymes*, 3rd ed., **3**, 57. 2. Zisapel, Navon & Sokolovsky (1975) *Eur. J. Biochem.* **52**, 487. 3. J. Boland & Hardman (1972) *FEBS Lett.* **27**, 282. 4. Juillerat-Jeanneret, Roth & Bargetzi (1982) *Hoppe-Seyler's Z. Physiol. Chem.* **363**, 51.

***N*-Acetyl-L-arginyl-L-arginyl-L-lysyl-L-arginyl-L-arginyl-L-arginamide**

This acetylated hexapeptide amide (MW = 970.18 g/mol; *Sequence*: Ac-RRKRRR-NH<sub>2</sub>; Isoelectric Point = 12.6) inhibits furin and proprotein convertase-2 (1). Significantly, proteolytic activation of the spike protein at a novel RRRR/S motif is implicated in furin-dependent entry, syncytium formation, and infectivity of coronavirus infectious bronchitis virus in

cultured cells (2). 1. Cameron, Appel, Houghten & Lindberg (2000) *J. Biol. Chem.* **275**, 36741. 2. Yamada & Liu (2009) *J. Virol.* **83**, 8744.

#### **N-Acetyl-L-arginyl-L-arginyl-L-prolyl-L-tyrosyl-L-isoleucyl-L-leucine and N-Acetyl-L-arginyl-L-arginyl-L-prolyl-L-tyrosyl-L-isoleucyl-L-leucineamide**

This acetylated hexapeptide (FW = 860.05 g/mol; Sequence: Ac-RRPYIL) and its corresponding amide (FW = 859.97 g/mol; Sequence: Ac-RRPYIL-NH<sub>2</sub>), where the sequence corresponds to the C-terminus of neurotensin, inhibit neurolysin, or endopeptidase-24.16 (1,2). Both are poor alternative substrates, suggesting that slow catalysis account for their inhibitory effects on natural neurolysin substrates (1,2). 1. Barelli, Vincent & Checler (1988) *Eur. J. Biochem.* **175**, 481. 2. Vincent, Dauch, Vincent & Checler (1997) *J. Neurochem.* **68**, 837.

#### **N<sup>ε</sup>-Acetyl-L-arginyl-L-cysteinylglycyl-L-valyl-L-prolyl-L-aspartate α-Amide**

This pentapeptide amide (FW<sub>free-base</sub> = 686.79 g/mol; Sequence: N<sup>ε</sup>-Acetyl-RCGVPD-NH<sub>2</sub>) inhibits matrix metalloproteinase-3, or stromelysin I, IC<sub>50</sub> = 5 μM (1,2). 1. Hanglow, Lugo, Walsky, et al. (1993) *Agents Actions* **39**, C148. 2. Fotouhi, Lugo, Visnick, et al. (1994) *J. Biol. Chem.* **269**, 30227.

#### **{N-[N-Acetyl-L-asparaginyl]-(5S-amino-4S-hydroxy-2-isopropyl-7-methyloctanoyl)}-L-isoleucinamide**

This pseudopeptide amide (FW = 613.78 g/mol; Sequence: Acetyl-Asn-Leuψ[CH(OH)CH<sub>2</sub>]Val-Ile-NH<sub>2</sub>), also known as U92516E, inhibits rhizopuspepsin, K<sub>i</sub> = 510 nM (1) and HIV-1 protease, K<sub>i</sub> = 90 nM (2). 1. Lowther, Sawyer, Staples, et al. (1992) in *Peptides: Chemistry and Biology Proc. of the 12th Amer. Peptide Symp.* (June 16-21, 1991) (Smith & Rivier, eds), pp. 413-414. 2. Sawyer, Staples, Liu, et al. (1992) *Int. J. Pept. Protein Res.* **40**, 274.

#### **N<sup>ε</sup>-Acetyl-L-asparaginyl-L-cysteinyl-L-arginyl-L-alanyl-L-threonyl-L-lysyl-L-methionyl-L-leucinamide**

This acetylated octapeptide (FW = 993.23 g/mol; Sequence: Acetyl-QCRATKML-NH<sub>2</sub>) amide inhibits *Clostridium botulinum* bontoxilysin, K<sub>i</sub> = 0.50 nM (1). The D-cysteinyl analogue is a slightly better inhibitor (K<sub>i</sub> = 0.15 nM). 1. Schmidt, Stafford & Bostian (1998) *FEBS Lett.* **435**, 61.

#### **N-Acetyl-L-aspartic Acid**

This acetylated amino acid (FW<sub>free-acid</sub> = 175.14 g/mol; M.P. = 137-140°C), which reportedly makes up slightly less than 1% of the dry weight of human brain (1), plays roles in myelin biosynthesis and osmotic regulation. It is also an alternative activator of carbamoyl-phosphate synthetase I. **Target(s):** *Escherichia coli* aspartate ammonia-lyase, K<sub>i</sub> = 6.7 mM (2); 2-(acetamidomethylene)succinate hydrolase, inhibited by N-acetyl-DL-aspartate (3); glutamate carboxypeptidase II, or N-acetylated-γ-linked acidic dipeptidase (4); amino-acid N-acetyltransferase (5). 1. Birken & Oldendorf (1989) *Neurosci. Biobehav. Rev.* **13**, 23. 2. Falzone, Karsten, Conley & Viola (1988) *Biochemistry* **27**, 9089. 3. Huynh & Snell (1985) *J. Biol. Chem.* **260**, 2379. 4. #### **N-Acetyl-L-aspartyl-L-aspartyl-L-aspartyl-L-tryptophanyl-L-aspartyl-L-phenylalanine**

This acetylated hexapeptide (Sequence: Ac-DDDWDF; FW = 854.22 g/mol), corresponding the C-terminus of the small subunit of *Mycobacterium tuberculosis* ribonucleoside diphosphate reductase, inhibits

ribonucleoside-diphosphate reductase, IC<sub>50</sub> = 100 μM (1,2). 1. Nurbo, Roos, Muthas, et al. (2007) *J. Pept. Sci.* **13**, 822. 2. Yang, Curran, Li, et al. (1997) *J. Bacteriol.* **179**, 6408.

#### **N-Acetyl-L-aspartyl-D-aspartyl-L-isoleucyl-L-valyl-L-prolyl-L-cysteine, See N-Acetyl-L-aspartyl-L-aspartyl-L-isoleucyl-L-valyl-L-prolyl-L-cysteine**

#### **N-Acetyl-L-aspartyl-L-aspartyl-L-isoleucyl-L-valyl-L-prolyl-L-cysteine**

This acetylated hexapeptide (Sequence: Ac-DDIVPC; FW<sub>free-acid</sub> = 686.78 g/mol), whose sequence corresponds to the N-terminal cleavage product of an HCV dodecapeptide substrate derived from the NS5A/5B cleavage site, inhibits hepacivirin, or hepacivirin (hepatitis C virus NS3 serine proteinase, IC<sub>50</sub> = 28 μM (1). 1. Llinàs-Brunet, Bailey, Fazal, et al. (1998) *Bioorg. Med. Chem. Lett.* **8**, 1713.

#### **N-Acetyl-L-aspartyl-D-aspartyl-L-isoleucyl-L-valyl-L-prolyl-DL-norvaline Benzylamide**

This acetylated hexapeptide (FW<sub>free-acid</sub> = 844.96 g/mol; Sequence: Ac-DDIVP-norV-benzylamide), whose sequence corresponds to the N-terminal cleavage product of an HCV dodecapeptide substrate derived from the NS5A/5B cleavage site, inhibits hepacivirin, or hepacivirin (hepatitis C virus NS3 serine proteinase, IC<sub>50</sub> = 0.7 μM (1). 1. Llinàs-Brunet, Bailey, Fazal, et al. (1998) *Bioorg. Med. Chem. Lett.* **8**, 1713.

#### **N-Acetyl-L-aspartyl-D-(γ-carboxy)glutamyl-L-leucyl-L-isoleucyl-3-cyclohexyl-L-alanyl-L-cysteine**

This acetylated hexapeptide (FW = 788.96 g/mol; Sequence: Ac-Asp-(γ)D-Glu-Leu-Ile-cyclohex-Ala-Cys) inhibits hepacivirin, or hepatitis C virus NS3 serine proteinase, IC<sub>50</sub> = 1.5 nM (1,2). The strategy began by optimizing S'-binding in the context of noncleavable decapeptides spanning the P<sub>6</sub>-P<sub>4</sub>' region. Binding was sequentially increased by starting the previously optimized P-region (1), by changing the P<sub>4</sub>' residue, and by combinatorially optimizing positions P<sub>2</sub>'-P<sub>3</sub>' (2) That effort led to an increase in binding of more than three orders of magnitude, with the best decapeptides showing IC<sub>50</sub> values below 200 pM. The binding mode of the decapeptide inhibitors shares features with the binding mode of the natural substrates, but incorporates novel interactions in the S' subsite (2). Similar inhibitor potency was observed with full-length Hepatitis C NS3 protein, expressed by viral mRNA extracted from the serum of a patient infected with HCV Strain-1a. Sequencing of that protease gene identified the virus to be a new variant closely related to Strain H77. The NS3 protein from Strain-1a differs in 15 out of 631 amino acid residues, of which none are predicted to be directly involved in catalysis or binding of substrate or cofactor (3). 1. Ingallinella, et al. (1998) *Biochemistry* **37**, 8906. 2. Ingallinella, Bianchi, Ingenito, et al. (2000) *Biochemistry* **39**, 12898. 3. #### **N-Acetyl-p-benzoquinone imine**

This toxic acetaminophen metabolite (FW = 149.15g/mol; CAS 50700-49-7; Symbol: NAPQI), also systematically named N-(4-oxo-1-cyclohexa-2,5-dienylidene)acetamide, causes severe liver damage, usually within 3-4 days after acetaminophen (paracetamol) overdose (typically 4-6 g) (See *Acetaminophen*). Severe NAPQI toxicity is known to lead to death from fulminant liver failure. NAPQI induces the depletion of reduced glutathione (GSH), the peroxidation of lipids, as well as cytotoxicity in hepatocytes to the same extent as excess acetaminophen (1). The preferred antidote for NAPQI poisoning is acetylcysteine, which can be given in large amounts without side effects (See *Acetylcysteine*). Notably, NAPQI is

a strong topoisomerase II poison, increasing levels of enzyme-mediated DNA cleavage >5-fold at 100  $\mu\text{M}$  (2). It induces scission at a number of DNA sites similar to those observed in the presence of etoposide. NAPQI strongly impairs the ability of topoisomerase II $\alpha$  to reseal cleaved DNA molecules, suggesting inhibition of DNA religation is the primary mechanism for enhancing cleavage. NAPQI also increases levels of DNA scission mediated by human topoisomerase II $\alpha$  in CEM leukemia cells (2). In mice, knockout of Cu,Zn-SOD superoxide dismutase (SOD1) alone, or in combination with selenium-dependent glutathione peroxidase-1 (GPX1) blocks acetaminophen-induced liver toxicity (3). 1. van de Straat, de Vries, Debets & Vermeulen (1987) *Biochem. Pharmacol.* **36**, 2065. 2. Bender, Lindsey, Burden & Osherooff (2004) *Biochemistry* **43**, 3731. 3. Lei, Zhu, McClung, Aregullin & Roneker (2006) *Biochem J.* **399**, 455.

**Acetyl Ceramide**, See *D-erythro-N-Acetyl sphingosine*

### 10-Acetyl-2-chloroacetylphenothiazine

This phenothiazine (FW = 317.80 g/mol) inhibits trypanothione-disulfide reductase (IC<sub>50</sub> = 440  $\mu\text{M}$ ) and glutathione-disulfide reductase (1,2). The corresponding *O*-benzylloxime derivative also inhibits. 1. Iribarne, Paulino, Aguilera & Tapia (2009) *J. Mol. Graph. Model.* **28**, 371. 2. Chan, Yin, Garforth, et al. (1998) *J. Med. Chem.* **41**, 148.

### Acetylcholine

This prototypical neurotransmitter (FW<sub>chloride</sub> = 181.66 g/mol; CAS 51-84-3; aqueous solutions, relatively stable at pH 4, but decompose under alkaline conditions; IUPAC: 2-Acetoxy-*N,N,N*-trimethylethanaminium), acts (a) *peripherally* as a neurotransmitter at the neuromuscular junction (*i.e.*, its release by motor neurons activates muscle contraction; (b) *autonomically* (*i.e.*, functionally independent; not under voluntary control), both as an internal transmitter for the sympathetic nervous system and as the final product released by the parasympathetic nervous system; and (c) *centrally*, as a neuromodulator that allows the brain to process information rather than to transmit information from point to point, also affecting arousal, attention, and motivation. Acetylcholine-containing synaptic vesicles (30-nm diameter; containing ~5000 acetylcholine molecules, the net positive charge of which is neutralized by the high molar content of GTP) are formed presynaptically. Upon fusion with the axon terminus, each vesicle spills its contents, causing a miniature end-plate potential (*or* MEPPs) that is <1 mV in amplitude and insufficient to reach threshold. However, once an action potential is strong enough to bring about the release of many acetylcholine-containing vesicles, acetylcholine diffuses across the neuromuscular junction, binds to ligand-gated nicotinic receptors on the muscle fiber, increasing sodium and potassium conductance and depolarizing of the muscle cell membrane (sarcolemma).

Nicotinic Receptors	N1 or Nm (neuromuscular junction)
	N2 or Nn (autonomic ganglia, CNS)
Muscarinic Receptors	M1 (striatum, cortex, hippocampus)
	M2 (forebrain, thalamus, heart, pupil, spinal cord, exocrine)
	M3 (brain, hypothalamus, exocrine, pupil, peripheral arteries)
	M4 (striatum, cortex, hippocampus, spinal cord)
	M5 (dopaminergic neurons, basal ganglia, brain vasculature)

Acetylcholine binds at (a) *Nicotinic Acetylcholine Receptors*, which muscle-type (located on muscle end-plates and blocked by curare) and neuronal-type (located in autonomic ganglia (both sympathetic and

parasympathetic) and in central nervous system and blocked by hexamethonium) ligand-gated ion channels that, when activated, become permeable to sodium, potassium, and calcium ions; (b) *Muscarinic Acetylcholine Receptors*, which have a more complex mechanism that affects target cells over a longer timescale. In mammals, there are five muscarinic receptor subtypes (*e.g.*, M<sub>1</sub>, M<sub>2</sub>, M<sub>3</sub>, M<sub>4</sub> and M<sub>5</sub>) that function as G-protein-coupled receptors (GPCRs), exerting their effects via a second messenger system. M<sub>1</sub>, M<sub>3</sub>, and M<sub>5</sub> are G<sub>q</sub>-coupled subtypes that increase intracellular levels of Inositol trisphosphate, *or* InsP<sub>3</sub> (*or* Inositol 1,4,5-trisphosphate (Ins3P) and triphosphoinositol (IP<sub>3</sub>)) and Ca<sup>2+</sup> through its activation of phospholipase C. Their effect on target cells is usually excitatory. M<sub>2</sub> and M<sub>4</sub> subtypes are G<sub>i</sub>/G<sub>o</sub>-coupled and decrease intracellular levels of cAMP by inhibiting adenylate cyclase. Muscarinic acetylcholine receptors are found in both CNS and peripheral neurons in the heart, lungs, upper gastrointestinal tract, and sweat glands. **Target(s):** Acetylcholine inhibits several enzymes *in vitro*, but its rapid hydrolysis *in vivo* probably limits its effectiveness as an inhibitor. Aqueous solutions are relatively stable at pH 4, but acetylcholine decomposes in alkaline pH conditions. Its targets include: aryl-acylamidase (1,2); choline kinase (3,11); glutamate dehydrogenase (4); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (5); diisopropylfluorophosphatase (6); glycerophosphocholine phosphodiesterase (7); choline sulfotransferase (8); diacylglycerol cholinephosphotransferase (9); ethanolamine phosphotransferase (9); ethanolamine kinase (10); and carnitine *O*-acetyltransferase (12). 1. ### Acetyl-Coenzyme A (or Acetyl-CoA)

This key thiolester (FW = 809.57 g/mol; CAS 72-89-9) is the main C<sub>2</sub> acyl donor in biosynthetic reactions in all living organisms. Acetyl-CoA is also an immediate product of fatty acid  $\beta$ -oxidation. The standard Gibbs free energy of hydrolysis ( $\Delta G^{\circ}$ ) of its thioester linkage is about -32.2 kJ/mol. Acetyl-CoA is water-soluble and stable in acid conditions (*e.g.*, resisting hydrolysis for 15 minutes at pH 3.5-5 at 100°C), but readily hydrolyzed in alkaline solutions. Acetyl-S-CoA should be stored in a desiccator at +4°C. Its  $\lambda_{\text{max}}$  at 260 nm ( $\epsilon = 16,400 \text{ M}^{-1}\text{cm}^{-1}$ ) at pH 7 is chiefly attributable to its adenine moiety. As is true for other thiolesters, the  $\alpha$ -carbon of the acetyl moiety is a weak carbon acid, forming reactive carbanion species <sup>-</sup>CH<sub>2</sub>C(=O)-S-CoA. **Target(s):** glucose-6-P dehydrogenase (1,2); pyruvate kinase (3); NAD(P)<sup>+</sup> transhydrogenase, AB-specific (4); enoyl-[acyl-carrier protein] reductase (5); pantothenate kinase (6,31-40); 3-hydroxy-3-methylglutaryl-CoA reductase (7,13); malonyl-CoA decarboxylase (8);

oxaloacetate decarboxylase (9); methylmalonyl-CoA epimerase (11); pyruvate dehydrogenase complex (12); succinyl-CoA synthetase (14); malyl-CoA lyase (15); phosphoketolase (16); aspartate 4 decarboxylase (17); succinate:3-hydroxy-3-methylglutarate CoA-transferase (18); [3-methyl-2 oxobutanoate dehydrogenase (2-methylpropanoyl-transferring)] phosphatase, or [branched-chain  $\alpha$ -keto-acid dehydrogenase] phosphatase (19-21); phosphoprotein phosphatase (19-22); palmitoyl CoA hydrolase, or acyl-CoA hydrolase (23,24); (S)-methylmalonyl-CoA hydrolase (25); 3-hydroxyisobutyryl-CoA hydrolase (26,27); [protein-PII] uridylyltransferase (28); adenylate kinase (29); glucose-1,6-bisphosphate synthase (30); cysteine synthase (41); 4-hydroxybenzoate nonaprenyltransferase, weakly inhibited (42); 2-methylcitrate synthase (43); decylcitrate synthase (44); anthocyanin 5-O-glucoside 6"-O-malonyltransferase (45); anthocyanin 6"-O-malonyl-transferase (46); propionyl-CoA C<sub>2</sub>-trimethyltridecanoyl-transferase (47);  $\beta$ -ketoacyl-[acyl-carrier-protein] synthase I (48); [acyl-carrier-protein] S-malonyltransferase (49); and carnitine O-palmitoyltransferase (50-52). 1. ### 1-Acetyl-7-cyano-2,3-diphenylindolizine

This cyano-indolizine (FW = 336.13 g/mol) inhibits (IC<sub>50</sub> = 23  $\mu$ M) arachidonate 15-lipoxygenase, or 15-lipoxygenase, an enzyme that has been implicated in oxidation of low-density lipoproteins (LDL) and may be involved in the development of atherosclerosis. I. Gundersen, Malterud, Negussie, et al. (2003) *Bioorg. Med. Chem.* **11**, 5409.

### cyclic-[N-Acetyl-Cys<sup>3</sup>,Nle<sup>4</sup>,Arg<sup>5,3</sup>-(2'-Naphthyl)-D-Ala<sup>7</sup>,Cys<sup>11</sup>]- $\alpha$ -Melanocyte-Stimulating Hormone Fragment 3-11 Amide

This cyclic nonapeptide amide (FW = 1266.50 g/mol; Sequence: CH<sub>3</sub>CO-Cys-Nle-Arg-His-D-2-Nal-Arg-Trp-Gly-Cys-NH<sub>2</sub>, where Nle refers to L-norleucine, and D-2-Nal refers to 3-(2 naphthyl)-D-alanine), is a modified fragment of  $\alpha$ -melanocyte-stimulating hormone ( $\alpha$ -MSH) that acts as a melanocortin-4 receptor antagonist, K<sub>d</sub> = 0.29 nM. This agent antagonizes an  $\alpha$ -MSH-induced cAMP response in cells expressing the human MC1, MC3, MC4, or MC5 receptor and also causes a dose-dependent increase in food intake, with a maximum response when a 1-nmol dose injected intracerebroventricularly in freely feeding rats. It does not show evidence of affecting emotionality or locomotor activity, suggesting that the MC4 receptor does not mediate anxiogenic-like and locomotor effects related to the melanocortin peptides. I. Kask, Mutulis, Muceniec, et al. (1998) *Endocrinology* **139**, 5006.

### N-Acetyl-L-cysteine & N-Acetyl-L-cysteine amide

These neuroprotective antioxidants and copper chelators (N-Acetyl-L-cysteine: FW<sub>free-acid</sub> = 163.20 g/mol; CAS 616-91-1; Abbreviation: NAC; (N-Acetyl-L-cysteine amide: FW<sub>free-acid</sub> = 162.21 g/mol; CAS 38520-57-9; Abbreviation: NACA) are metabolizable cysteine derivatives that are frequently used as an antidote in acetaminophen (Tylenol) and carbon monoxide (CO) poisoning. After oral administration of a 200–400 mg dose, NAC enters circulation, where it is rapidly oxidized to its homo-disulfide, reaching peak plasma concentrations of 0.35–40 mg/L in 1–2 hours. Its volume of distribution is 0.33–0.47 L/kg, with significant protein binding of 50%. Upon transporter-independent cellular uptake, N-acetyl-L-cysteine is deacetylated, giving rise to elevated intracellular cysteine concentrations and thereby enhancing glutathione production. While NAC inhibits neuronal cell apoptosis, it induces apoptosis in smooth muscle cells. NAC inhibits homocysteine-enhanced expression of an ox-LDL receptor. N-acetylcysteine amide crosses the blood-brain barrier, chelating Cu<sup>2+</sup> (which is known to catalyze free radical formation) and preventing ROS-induced activation of JNK, p38 and MMP-9. Note: Mercapturic acids are S-substituted derivatives of NAC (1). Target(s): N<sup>4</sup>-( $\beta$ -N-acetylglucosaminyl)-L-asparaginase, K<sub>i</sub> = 3.2 mM (2,3); cysteine dioxygenase (4,5); alkaline phosphatase (6); HIV replication (7);

prolyl/cysteinyI-tRNA synthetase, *Methanocaldococcus jannaschii* (8); alliin lyase (9); and 5'-nucleotidase (10); serine *O*-acetyltransferase (11,12). 1. Offen, Gilgun-Sherki, Barhum, et al. (2004) *J. Neurochem.* **89**, 1241. 2. Dugal & Stromme (1977) *Biochem. J.* **165**, 497. 3. Dugal (1978) *Biochem. J.* **171**, 799. 4. Yamaguchi & Hosokawa (1987) *Meth. Enzymol.* **143**, 395. 5. Liu & Sok (2000) *Neurochem. Res.* **25**, 1475. 11. Nozaki, Shigeta, Saito-Nakano, Imada & Kruger (2001) *J. Biol. Chem.* **276**, 6516. 12. Kredich & Tomkins (1966) *J. Biol. Chem.* **241**, 4955.

#### **N<sup>α</sup>-Acetyl-L-cysteinyl-L-arginyl-L-alanyl-L-threonyl-L-lysyl-L-methionyl-L-leucinamide**

This acetylated heptapeptide amide (*Sequence*: Ac-CRATKML-NH<sub>2</sub>; FW = 865.10 g/mol) inhibits *Clostridium botulinum* bontoxilysin;  $K_i = 1.9$  pM. The D-cysteinyl analogue has a  $K_i$  value of 1.8 pM (1,2). The D-arginine-containing analogue is considerably weaker ( $K_i = 0.41$  nM). 1. Schmidt, Stafford & Bostian (1998) *FEBS Lett.* **435**, 61. 2. Ahmed, Byrne, Jensen, et al. (2001) *J. Protein Chem.* **20**, 221.

#### **N<sup>α</sup>-Acetyl-L-cysteinyl-D-cysteinyl-L-arginyl-L-alanyl-L-threonyl-L-lysyl-L-methionyl-L-leucinamide**

This acetylated octapeptide amide (*Sequence*: Ac-C-DC-RATKML-NH<sub>2</sub>; FW = 968.24 g/mol) inhibits *Clostridium botulinum* bontoxilysin ( $K_i = 0.11$  nM), taking advantage of the fact that Botox A's requirement for arginine as the P<sub>1</sub>' inhibitor residue is dissimilar to other zinc metalloproteases. Substrate analog peptides with P<sub>4</sub>, P<sub>3</sub>, P<sub>2</sub>' or P<sub>3</sub>' cysteine are readily hydrolyzed by the toxin, but those with P<sub>1</sub> or P<sub>2</sub> cysteine were not cleaved and were inhibitors. Peptides with either D- or L-cysteine as the N-terminus, followed by the last six residues of the substrate, are the most effective inhibitors, each with a  $K_i$  value of 2 microM. Elimination of the cysteine sulfhydryl group results in much less effective inhibitors, suggesting that inhibition is due primarily to binding of the active-site zinc by the sulfhydryl group. 1. Schmidt, Stafford & Bostian (1998) *FEBS Lett.* **435**, 61.

#### **N-Acetyl-L-cysteinyl-L-glutaminyI-L-arginyl-L-alanyl-L-threonyl-L-lysyl-L-methionyl-L-leucinamide**

This acetylated octapeptide amide (FW = 994.22 g/mol; *sequence*: Ac-CERATKML-NH<sub>2</sub>) inhibits ( $K_i = 0.19$  nM) *Clostridium botulinum* bontoxilysin, the zinc metalloprotease/neurotoxin (or botox A) that cleaves only one peptide bond in the synaptosomal protein, SNAP-25. The D-cysteinyl analogue is a slightly better inhibitor,  $K_i = 0.14$  nM. Botox A displays an unusual requirement for arginine as the P<sub>1</sub>' inhibitor residue, demonstrating that botox A differs from most other zinc metalloproteases and offering a strategy for achieving inhibitor selectivity. 1. Schmidt, Stafford & Bostian (1998) *FEBS Lett.* **435**, 61.

#### **N<sup>2</sup>-Acetyl-2'-deoxyguanosine 5'-Monophosphate**

This acetylated dGMP (FW<sub>free-acid</sub> = 389.26 g/mol) competitively inhibits a bifunctional enzyme exhibiting IMP cyclohydrolase (and 5-aminimidazole-4-carboxamide ribotide (AICAR) transformylase) activity in human CCRF-CEM leukemia cells. Other competitive inhibitors of IMP cyclohydrolase include: 2-mercaptoinosine 5'-monophosphate ( $K_i = 0.09$  μM), xanthosine 5'-monophosphate ( $K_i = 0.12$  μM), 2-fluoroadenine arabinoside 5'-monophosphate ( $K_i = 0.16$  μM), 6-mercaptopurine riboside 5'-monophosphate ( $K_i = 0.20$  μM), adenosine N<sup>1</sup>-oxide 5'-monophosphate ( $K_i = 0.28$  μM), and N<sup>6</sup>-(carboxymethyl)adenosine 5'-monophosphate ( $K_i = 1.7$  μM). 1. Szabados, Hindmarsh, Phillips, Duggleby & Christopherson (1994) *Biochemistry* **33**, 14237.

#### **6-S-Acetyldihydroliipoamide**

This acetylated dihydroliipoamide (FW = 381.02 g/mol) is thought to mimic an intermediate in the reaction catalyzed by the dihydroliopolylysine-residue acetyltransferase component within the pyruvate dehydrogenase complex. 1. Butterworth, Tsai, Eley, Roche & Reed (1975) *J. Biol. Chem.* **250**, 1921.

#### **DL-erythro-N-Acetyldihydrosphingosine**

This ceramide analogue (FW = 343.55 g/mol), also known as DL-erythro-C<sup>2</sup>-dihydroceramide and DL-erythro-N-acetylsphinganine, is an inactive form of C<sup>2</sup> ceramide that inhibits acyl-CoA:cholesterol acyltransferase, or ACAT, as does DL-erythro-N-acetylsphingosine. 1. Ridgway (1995) *Biochim. Biophys. Acta* **1256**, 39.

#### **7-Acetyl-2,3-diphenyl-1-(p-tosyloxy)indolizine**

This indolizine (FW = 481.57 g/mol) inhibits 15-lipoxygenase, or arachidonate 15-lipoxygenase, IC<sub>50</sub> = 23 μM. The enzyme inhibition was not affected by preincubation or the presence of a detergent and no significant particle formation was observed. Hence, inhibition from aggregates of indolizines, promiscuous inhibition, is highly unlikely. 1. Teklu, Gundersen, Larsen, Malterud & Rise (2005) *Bioorg. Med. Chem.* **13**, 3127.

#### **Acetyldithio-CoA**

This readily enolizable acetyl-CoA analogue (FW = 814.64 g/mol), a product analogue of the reaction catalyzed by 3-hydroxy-3-methylglutaryl-CoA, supports enzyme-catalyzed exchange of the methyl protons of the acetyl group with the solvent. Citrate synthase catalyzes the slow condensation of acetyldithio-CoA with oxaloacetate to form thiocitrate. **Target(s)**: 3-hydroxy-3-methylglutaryl-CoA lyase (1); 3-hydroxy-3-methylglutaryl-CoA synthase (2). 1. Tuinstra, Wang, Mitchell & Mizziorko (2004) *Biochemistry* **43**, 5287. 2. Wang, Misra & Mizziorko (2004) *J. Biol. Chem.* **279**, 40283.

#### **N-Acetyldopamine**

This metabolite (FW = 195.22 g/mol) is a relatively nontoxic analogue and precursor of dopamine that has shown significant antitumor activity.

**Target(s):** aromatic L-amino-acid decarboxylase, or L-dopa decarboxylase (1,2) and sepiapterin reductase (3,4). 1. Fragoulis & Sekeris (1975) *Arch. Biochem. Biophys.* **168**, 15. 2. Clark, Pass, Venkataraman & Hodgetts (1978) *Mol. Gen. Genet.* **162**, 287. 3. Ruiz-Vazquez, Silva & Ferre (1996) *Comp. Biochem. Physiol. B Biochem. Mol. Biol.* **113**, 131. 4. Smith, Duch, Edelstein & Bigam (1992) *J. Biol. Chem.* **267**, 5599.

**N-Acetyl-[D-Trp16]-Endothelin 1 Fragment 16-21**, See *N-Acetyl-D-tryptophanyl-L-leucyl-L-aspartyl-L-isoleucyl-L-isoleucyl-L-tryptophan*

#### N-Acetyl-Eglin c

This acetylated polypeptide contains 70-residue (MW = 8.1 kDa; *Sequence*: Ac-TEFGSELKSFPEVVGKTVDCAREYFTLHYPQYDVVYFLPEGSPVT LDLRYNRVRVFNYPGTNVVNHVPHVG) from the medicinal leech (*Hirudo medicinalis*) inhibits cathepsin G and elastase (1). See also *Eglin* 1. Seemuller, Eulitz, Fritz & Strobl (1980) *Hoppe-Seyler's Z. Physiol. Chem.* **361**, 1841.

#### Acetylene

This industrial gas H-C≡C-H (FW = 26.038 g/mol; CAS 74-86-2; IUPAC Name: Ethyne) sublimes at -31°C serves as an alternative substrate for nitrogenase. It also alkylates the prosthetic heme group of many cytochrome P450 enzymes, especially those acting on olefinic π-bond systems to form epoxides. Acetylene is also formed from 1,1,1-trichloroethane (TCE), a widely used industrial solvent that exhibits low acute toxicity. **Target(s):** methane monooxygenase (1,2,18-22); cytochrome P450 (3,6); hydrogenase (4,7,11); nitrous oxide reductase (5,9); ammonia monooxygenase (8); alkene monooxygenase (10,17); nitrogenase, as alternative substrate (12-16); and L-ascorbate peroxidase (23,24). 1. #### (+)-8'-Acetyleneabscisic Acid

This seed germination retardant (FW = 276.33 g/mol; CAS 191610-47-6; IUPAC Name: (2Z,4E)-rel-5-[(1R,6R)-6-ethynyl-1-hydroxy-2,6-dimethyl-4-oxo-2-cyclohexen-1-yl]-3-methyl-2,4-pentadienoic Acid Methyl Ester, is a mechanism-based inhibitor of (+)-abscisate 8'-hydroxylase ( $K_i = 19 \mu\text{M}$ ;  $k_{\text{inact}} = 0.053 \text{ min}^{-1}$  (1,2). 1. Cutler, Rose, Squires, et al. (2000) *Biochemistry* **39**, 13614. 2. Rose, Cutler, Irvine, et al. (1997) *Bioorg. Med. Chem. Lett.* **7**, 2543.

#### Acetylene Dicarboxylic Acid

This toxic dicarboxylic acid (FW<sub>free-acid</sub> = 114.06 g/mol), also known as butynedioic acid, inhibits fumarase (1,2), succinate dehydrogenase (3,4,7), glutamate decarboxylase (5), succinate oxidase (6), argininosuccinate lyase (8), maleate hydratase (9), and 3-oxoacid CoA-transferase, the latter weakly (10). 1. Hill & Bradshaw (1969) *Meth. Enzymol.* **13**, 91. 2. Massey (1953) *Biochem. J.* **55**, 172. 3. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, pp. 36 & 239, Academic Press, New York. 4. #### 8-Acetylenyl-6-indolin-N-yl-9-(β-D-ribofuranosyl)-purine

This modified nucleoside (FW = 381.39 g/mol) inhibits human adenosine kinase, IC<sub>50</sub> = 1 μM (1). Because the use of adenosine receptor agonists is plagued by dose-limiting cardiovascular side effects, there is great interest in developing adenosine kinase inhibitors (AKIs) as a means for raising steady-state adenosine concentrations. 1. Bookser, Matelich, Ollis & Ugarkar (2005) *J. Med. Chem.* **48**, 3389.

#### Acetyl-1,N<sup>6</sup>-EthenoCoA, See 1,N<sup>6</sup>-Etheno-acetyl-CoA

#### N-Acetyl-S-trans,trans-farnesyl-L-cysteine

This N- and S-acylated L-cysteine (FW<sub>free-acid</sub> = 367.55 g/mol) is an alternative substrate ( $K_m = 20 \mu\text{M}$ ) of S-farnesylcysteine methyltransferase (i.e., protein-S-isoprenylcysteine O-methyltransferase) and thus inhibits posttranslational modification of proteins (1-5) as well as chemotaxis (3). 1. #### N-[N-Acetyl-L-(N-indole-formyl)tryptophanyl-L-prolyl-L-phenylalanyl-L-histidyl-(2S-amino-3-phenylpropyl)]-L-phenylalaninamide

This pseudopeptide amide (FW<sub>free-base</sub> = 935.10 g/mol; *Sequence*: Ac-Ftr-Pro-Phe-His-Pheψ[CH<sub>2</sub>-NH]Phe-NH<sub>2</sub>, where Ftr refers to an N-indole-formyltryptophanyl residue and a reduced peptide bond between two phenylalanyl residues), also known as U-71908E, inhibits renin, IC<sub>50</sub> = 0.56

nM. I. Sawyer, Maggiora, Liu, *et al.* (1990) in *Peptides: Chemistry, Structure, and Biology* (Rivier & Marshall, eds), p. 46, Escom Sci. Publ.

**N-[N-Acetyl-L-(N-indole-formyl)tryptophanyl-L-prolyl-L-phenylalanyl-L-histidyl-(2S-amino-3-phenylpropyl)]-L-phenylalanyl-L-valyl-L-tyrosinamide**

This renin-inhibiting pseudopeptide amide (FW<sub>free-base</sub> = 1197.40 g/mol; Sequence: Ac-Ftr-Pro-Phe-His-Pheψ[CH<sub>2</sub>-NH]Phe-Val-Tyr-NH<sub>2</sub>, where Ftr refers to an N-indole-formyltryptophanyl residue and a reduced peptide bond between two phenylalanyl residues) inhibits renin, IC<sub>50</sub> = 3.0 nM (1). I. Sawyer, Maggiora, Liu, *et al.* (1990) in *Peptides: Chemistry, Structure, and Biology* (Rivier & Marshall, eds), p. 46, Escom Sci. Publ.

**N-Acetyl-D-galactosamine**

This acetylated aminosugar (FW = 221.21 g/mol), also known as 2-acetamido-2-deoxy-D-galactopyranose and abbreviated D-GalpNAc and NAGA, is a component of many glycoproteins, chondroitin, and blood-group substances. N-Acetyl-D-galactosamine will also inhibit the binding of ligands to many lectins. **Target(s):** β-N-acetylhexosaminidase (1,2,13-15,17,26-43); α-N-acetylgalactosaminidase (3,12,19,44-46); discoidins I and II, or *Dictyostelium discoideum* agglutinins (4); *Bauhinia purpurea* agglutinin (5); lima bean (*Phaseolus luteolus*) lectin (6); *Wistarina floribunda* phytomitinogen (7); horse gram (*Dolichos biflorus*) lectin (8); *Sophora japonica* hemagglutinin (9); soybean (*Glycine max*) agglutinin (10,16); snail (*Helix pomatia*) hemagglutinin (11); α-galactosidase B (12); β-N-acetylglucosaminidase (13-15,35); β-N-acetylglucosaminidase (13-15,17,24,25); galactose oxidase, also alternative substrate (18); keratan sulfotransferase, weakly inhibited (20); aralin (21); rRNA N-glycosylase (21); peptidoglycan β-N-acetylmuramidase (22,23); polypeptide N-acetylglucosaminyltransferase (47,48). 1. **N-Acetyl-D-glucosamine**

This acetylated aminosugar (FW = 221.21 g/mol; CAS 7512-17-6), also known as β-acetamido-2-deoxy-D-glucopyranose and abbreviated D-GlcNAc and NAG, is a component of many glycoproteins. NAG also inhibits the binding of ligands to many lectins. **Target(s):** glucokinase (1,5,12,19,66-69,71); β-N-acetylhexosaminidase (2,3,8,12,14-16,21,27-48); α-N-acetylglucosaminidase (4,18); hexokinase (6,19,20,69-72); acetyl-CoA:α-glucosaminide N-acetyltransferase, or heparan-α-glucosaminide N-acetyltransferase (7); chitinase (9,58-60); concanavalin A (10); lysozyme, both anomers (11,22,50-57); fructokinase (12,13); α-galactosidase (12,14); β-N-acetylgalactosaminidase (12,14,16,21); β-N-acetylglucosaminidase (12,14-16,34,37,48); glucosamine kinase (17); keratan sulfotransferase (23); N-acetylmuramoyl-L-alanine amidase (24); peptidoglycan β-N-acetylmuramidase (25,26); α-N-acetylglucosaminidase (49); N-acetylglucosamine-1-phosphodiester α-N-acetylglucosaminidase (61-64); acyl-phosphate:hexose phosphotransferase, also weak alternative substrate (65); α-1,6-mannosyl-glycoprotein 4-β-N-acetylglucosaminyl transferase, weakly inhibited (73); β-1,4-mannosyl-glycoprotein 4-β-N-acetylglucosaminyltransferase (74); and β-N-acetylglucosaminyl-glycopeptide β-1,4-galactosyl-transferase (75,76). 1. #### N-Acetyl-D-glucosamine-1,5-lactone

This *N*-acetylglucosamine derivative (FW = 219.19 g/mol; deliquescent), inhibits  $\alpha$ -*N*-acetylglucosaminidase (1,5), mannosyl-glycoprotein endo- $\beta$ -*N*-acetylglucosaminidase (2,4,6,7,9-11), lysozyme (3),  $\beta$ -*N*-acetylglucosaminidase (4,7), chitinase (8), and  $\beta$ -*N*-acetylhexosaminidase (12-22). *Note*: Several literature citations do not distinguish between the 1,5- or the 1,4-lactone. **1.** Weissmann (1972) *Meth. #### N-Acetyl-D-glucosamine 1-Phosphate

This phosphorylated metabolite (FW<sub>free-acid</sub> = 301.19 g/mol; hygroscopic; pK<sub>a</sub> values of < 1.4 and 6.0), also named 2-acetamido-2-deoxy-D-glucose 1-phosphate, is a product of the reaction catalyzed by glucosamine-1-phosphate *N*-acetyltransferase and is a substrate for *N*-acetylglucosamine-1-phosphate uridylyltransferase (*or* UDP-*N*-acetylglucosamine diphosphorylase) and phosphoacetylglucosamine mutase. The  $\alpha$ -anomer is more stable in acids than the  $\beta$ -epimer; however, both are completely hydrolyzed in ten minutes in 0.1 M HCl at 100°C. The  $\beta$ -anomer is completely hydrolyzed in 0.67 M H<sub>2</sub>SO<sub>4</sub> and 26°C in 45 min, whereas only 5-6% of the  $\alpha$ -anomer has undergone hydrolysis. **Target(s)**: *N*-acetylglucosamine-1-phosphodiester  $\alpha$ -*N*-acetylglucosaminidase, inhibited by the  $\alpha$ -anomer (1-4);  $\beta$ -1,4-mannosyl-glycoprotein 4- $\beta$ -*N*-acetylglucosaminyl-transferase, inhibited by the  $\alpha$ -anomer (5). **1.** Page, Zhao, Tao & Miller (1996) *Glycobiology* **6**, 619. **2.** Mullis, Huynh & Kornfeld (1994) *J. Biol. Chem.* **269**, 1718. **3.** Varki & Kornfeld (1981) *J. Biol. Chem.* **256**, 9937. **4.** Lee & Pierce (1995) *Arch. Biochem. Biophys.* **319**, 413. **5.** Ikeda, Koyota, Ihara, *et al.* (2000) *J. Biochem.* **128**, 609.

#### N-Acetyl-D-glucosamine 6-Phosphate

This phosphorylated metabolite (FW<sub>free-acid</sub> = 301.19 g/mol), also known as 2-acetamido-2-deoxy-D-glucose 6-phosphate, is hygroscopic. About 60% will be hydrolyzed in three minutes in 0.2 M alkali at 100°C. A product of the reaction catalyzed by glucosamine 6-phosphate *N*-acetyltransferase and *N*-acetylglucosamine kinase, *N*-acetylglucosamine 6-P inhibits glucosamine-6-phosphate deaminase. **1.** Weidanz, Campbell, DeLucas, *et al.* (1995) *Brit. J. Haematol.* **91**, 72.

#### O-[N-Acetyl-D-glucosaminyl-1,2-( $\alpha$ -6-deoxy-D-mannosyl)-1,6-( $\beta$ -D-glucosyl)]-8-octanol

This substrate analogue (FW = 624.70 g/mol) inhibits  $\alpha$ -1,6-mannosyl-glycoprotein 6- $\beta$ -*N*-acetylglucosaminyl-transferase,  $K_i$  = 30  $\mu$ M (1-3). **1.** Khan, Crawley, Kanie & Hindsgaul (1993) *J. Biol. Chem.* **268**, 2468. **2.** Palcic, Ripka, Kaur, *et al.* (1990) *J. Biol. Chem.* **265**, 6759. **3.** Hindsgaul, Kaur, Srivastava, *et al.* (1991) *J. Biol. Chem.* **266**, 17858.

#### O-[N-Acetyl-D-glucosaminyl-1,2-( $\alpha$ -4-O-methyl-D-mannosyl)-1,6-( $\beta$ -D-glucosyl)]-8-octanol

This substrate analogue (FW = 641.58 g/mol) inhibits  $\alpha$ -1,6-mannosyl-glycoprotein 6- $\beta$ -*N*-acetylglucosaminyl-transferase,  $K_i = 14 \mu\text{M}$ . NMR data show no evidence of important conformational differences between the trisaccharide analogs, and kinetic experiments detected no differences for the binding of UDP-GlcNAc in their presence. These findings suggest that the large methyl group introduced on *O*-4' sterically prevented the formation of product even though both potential substrates were bound by the enzyme. This "steric exclusion" strategy offers potential for designing inhibitors for that class of glycosyltransferases in which the reactive hydroxyl group is also an essential recognition element. 1. Khan, Crawley, Kanie & Hindsgaul (1993) *J. Biol. Chem.* **268**, 2468.

### *N*-Acetyl-L-glutamic Acid

This acetylated amino acid (FW<sub>free-acid</sub> = 189.17 g/mol), itself an essential activator for the mammalian urea cycle enzyme carbamoyl-phosphate synthetase I, or carbamoyl-phosphate synthetase (ammonia), is an intermediate in the biosynthesis of arginine in microorganisms, including *Escherichia coli*, *Neurospora crassa*, *Pisum sativum*, *Mycobacterium smegmatis*, *Pseudomonas aeruginosa*, and *P. putida*. *N*-Acetyl-L-glutamic acid is the product of the reactions catalyzed by amino-acid *N*-acetyltransferase and glutamate *N*-acetyltransferase (Reaction: L-Glutamate + Acetyl-CoA  $\rightleftharpoons$  *N*-Acetyl-L-glutamate + CoA-SH), the latter activated by arginine. **Target(s):** *N*-formylglutamate deformylase (1); 4-methyleneglutaminase (2); glutamate carboxypeptidase II (3); glutamate carboxypeptidase (4); and glutamate formimidoyltransferase (5). 1. Hu, Mulfinger & Phillips (1987) *J. Bacteriol.* **169**, 4696. 2. Ibrahim, Lea & Fowden (1984) *Phytochemistry* **23**, 1545. 3. Robinson, Blakely, Couto & Coyle (1987) *J. Biol. Chem.* **262**, 14498. 4. Goldman & Levy (1967) *Proc. Natl. Acad. Sci. U.S.A.* **58**, 1299. 5. Miller & Waelsch (1957) *J. Biol. Chem.* **228**, 397.

### *N*<sup>ε</sup>-Acetyl-L-glutamine

This acetylated amino acid (FW<sub>free-acid</sub> = 188.18 g/mol) inhibits asparagine synthetase (1), *N*-formylglutamate deformylase, weakly (2), 4-methyleneglutaminase (3), and amino-acid *N*-acetyltransferase (4). 1. Lea & Fowden (1975) *Proc. R. Soc. Lond. B Biol. Sci.* **192**, 13. 2. Hu, Mulfinger & Phillips (1987) *J. Bacteriol.* **169**, 4696. 3. Ibrahim, Lea & Fowden (1984) *Phytochemistry* **23**, 1545. 4. Shigesada & Tatibana (1978) *Eur. J. Biochem.* **84**, 285.

### {*N*-[*N*-Acetyl-L-glutaminy]-L-asparaginy]-(*5S*-amino-4*S*-hydroxy-2-isopropyl-7-methyloctanoyl)]-L-isoleucinamide

This pseudopeptide amide (Sequence: Ac-Gln-Asn-Leuψ[CH(OH)CH<sub>2</sub>]Val-Ile-NH<sub>2</sub>; FW = 627.77 g/mol), also known as U92517E, inhibits rhizopuspepsin,  $K_i = 1.36 \text{ nM}$  (1) and HIV-1 protease,  $K_i = 28 \text{ nM}$  (2). 1. Lowther, Sawyer, Staples, *et al.* (1992) in *Peptides: Chemistry and Biology Proc. of the 12th Amer. Peptide Symp.* (June 16-21, 1991) (Smith & Rivier, eds), p. 413. 2. Sawyer, Staples, Liu, *et al.* (1992) *Int. J. Pept. Protein Res.* **40**, 274.

### *N*-Acetyl-L-glutamyl-L-aspartyl-L-aspartyl-L-aspartyl-L-tryptophanyl-L-aspartyl-L-phenylalanine

This acetylated heptapeptide (Sequence: Ac-QDDDWDF; FW = 982.94 g/mol) inhibits ribonucleoside-diphosphate reductase. The sequence is derived from the C-terminus of the small subunit of *Mycobacterium tuberculosis* ribonucleoside diphosphate reductase, IC<sub>50</sub> = 20 or 135  $\mu\text{M}$  (1,2). Substitution of an alanyl residue at each position weakens the inhibitory effect. 1. Nurbo, Roos, Muthas, *et al.* (2007) *J. Pept. Sci.* **13**, 822. 2. Yang, Curran, Li, *et al.* (1997) *J. Bacteriol.* **179**, 6408.

### *N*<sup>α</sup>-Acetylhistamine

This acetylated histamine (FW<sub>free-base</sub> = 153.18 g/mol) inhibits  $\beta$ -glucosidase (1), cytochrome P450 (2), and glutaminy-peptide cyclotransferase (3-6). 1. Field, Haines, Chrystal & Luszniak (1991) *Biochem. J.* **274**, 885. 2. Morris, Tucker, Crewe, *et al.* (1989) *Biochem. Pharmacol.* **38**, 2639. 3. Schilling, Niestroj, Rahfeld, *et al.* (2003) *J. Biol. Chem.* **278**, 49773. 4. Schilling, Lindner, Koch, *et al.* (2007) *Biochemistry* **46**, 10921. 5. Huang, Liu, Cheng, Ko & Wang (2005) *Proc. Natl. Acad. Sci. U.S.A.* **102**, 13117. 6. Huang, Liu & Wang (2005) *Protein Expr. Purif.* **43**, 65.

### *N*-Acetylhomocysteine Thiolactone

This reagent (FW = 159.21 g/mol), also called citiolone, has been used to covalently modify proteins, thereby introducing a sulfhydryl group into the protein. It has also been used to treat a number of liver disorders. **Target(s):** ribonuclease (1,2); phenylalanine monooxygenase (3); and insulin (4). 1. Shall & Barnard (1969) *J. Mol. Biol.* **41**, 237. 2. Richards & Wyckoff (1971) *The Enzymes*, 3rd ed., **4**, 647. 3. Weiss, Hui & Lajtha (1979) *Res. Commun. Chem. Pathol. Pharmacol.* **25**, 153. 4. Virupaksha & Tarver (1964) *Biochemistry* **3**, 1507.

### *N*-Acetylhydantocidin 5'-Monophosphate

This nucleoside derivative (FW<sub>free-acid</sub> = 340.18 g/mol), also known as *N*-acetyl-5'-phosphohydantocidin, is the metabolically phosphorylated form of *N*-acetyl-5'-phosphohydantocidin, and, when tested in *Arabidopsis thaliana*, potently inhibits adenylosuccinate synthetase, but not adenylosuccinate lyase. Such findings explain the observation that its herbicidal effects of *N*-acetyl-5'-phosphohydantocidin are reversed, when the agar growth medium is supplemented with AMP, but not IMP or GMP, suggesting that hydantocidin blocked the two-step conversion of IMP to AMP in *de novo* purine biosynthesis pathway. 1. Siehl, Subramanian, Walters, *et al.* (1996) *Plant Physiol.* **110**, 753.

### 3-(*N*-Acetyl-*N*-hydroxyamino)-2-benzylpropanoic Acid

This hydroxamate (FW = 189.26 g/mol) inhibits bovine carboxypeptidase A,  $K_i = 8.06 \mu\text{M}$ . Its hydroxamate anion displaces a relatively acidic  $\text{H}_2\text{O}$  ligand ( $\text{p}K_a = 6$ ) from the active-site zinc ion of carboxypeptidase A. In solution, metal ion-coordinating, *N*-substituted hydroxamic acid groups often exist as a mixture of *syn* and *anti* rotamers, with relative abundances depending on their  $\text{p}K_a$ . Pyrrolidinone analogues that are conformationally in the *syn* form are not especially potent inhibitors. Structure-activity relationships thus define criteria for designing hydroxamic acid inhibitors of metalloenzymes. 1. Mock & Cheng (2000) *Biochemistry* **39**, 13945.

***N*-Acetyl-5-hydroxytryptamine, See *N*-Acetylserotonin**

#### ***N*-Acetylimidazole**

This relatively indiscriminant acetylating reagent (FW = 110.12 g/mol; Most stable at pH 7.5) modifies both amino groups and tyrosyl hydroxyl groups within proteins, but the latter are preferred under normal reaction conditions. When utilizing *N*-acetylimidazole, fresh solutions must always be used, because the reagent is relatively unstable in water. Above pH 8.0, the *O*-acetyltyrosyl products are readily deacetylated. When residues essential for catalysis are modified, treatment with *N*-acetylimidazole can lead to loss of enzyme activity. **Target(s):** mouse submandibular renin (1); aspergillopepsin I (2); carboxypeptidase A, peptidase activity is inhibited, while esterase activity is enhanced (3-5,37-39,58); thrombin (6); phosphofructokinase (7); fructose-1,6-bisphosphate aldolase (8,32,41); nitric-oxide synthase (9); prostaglandin endoperoxide synthase (10);  $\text{H}^+$ -importing ATPase (11);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (12,18); transketolase (13); ribulose-1,5-bisphosphate carboxylase (14); neutrophil collagenase (15); succinate dehydrogenase (16); cytochrome P450LM2 (17); diamine oxidase (19); angiotensin I-converting enzyme, or peptidyl-dipeptidase A (20); trypsin (21); 3-hydroxyisobutyrate dehydrogenase (22); D- $\beta$  hydroxybutyrate dehydrogenase (23);  $\alpha$ -amylase (24,25); microbial collagenase (26); fructose-1,6 bisphosphatase (27,29); lysozyme (28,33); arylsulfatase (30); D-lysine 5,6-aminomutase (31,45); arginine kinase (34); glutamine synthetase (35,51); filamentous phage gene-5 DNA binding protein (36); ribonuclease A (40); protein-L-isoaspartate(D-aspartate) *O*-methyltransferase (42); galactolipase (43); ornithine carbamoyltransferase (44); aldose 1-epimerase, or mutarotase (46); lactoylglutathione lyase, or glyoxalase I (47); alliin lyase, slightly inhibited (48); phenylalanine ammonia-lyase (49); heparin lyase (50); aminocarboxymuconate-semialdehyde decarboxylase (52); thiamin-triphosphatase (53); 3-oxoacid CoA-transferase, or 3-ketoacid CoA-transferase (54); allantoicase (55); *N*-acyl-D-amino-acid deacylase (56); aryl-acylamidase, but stimulated at low concentrations (57); butyrylcholinesterase, but stimulated at low concentrations (57); membrane dipeptidase, or renal dipeptidase, or dehydropeptidase I (59); soluble epoxide hydrolase, weakly inhibited (60); leukotriene-A4 hydrolase (61); glucan endo-1,6- $\beta$ -glucosidase (62);  $\beta$ -*N*-acetylhexosaminidase (63);  $\alpha$ -*N* acetylgalactosaminidase (64); glucan endo-1,3- $\beta$ -D-glucosidase (65);  $\beta$ -D-fucosidase66;  $\beta$ -glucosidase (67); chitinase (68); endo-1,4- $\beta$ -xylanase (69);  $\alpha$ -amylase (70); fructose-1,6-bisphosphatase (71); protein glutamate methyltransferase (72); galactolipase (73); gluconolactonase (74); serine-phosphoethanolamine synthase (75); sulfate adenyltransferase (76); aspartate kinase (77); *N*-acetylglucosamine synthase (78);  $\beta$ -*N*-acetylglucosaminylglycopeptide  $\beta$ -1,4-galactosyltransferase (78); lactose synthase (79); starch phosphorylase (80); glutaminyl-peptide cyclotransferase (81); *N*-acetylneuraminate 7-*O*- (or 9-*O*-) acetyltransferase (82); dihydrolipoyllysine-residue acetyltransferase (83); ornithine carbamoyltransferase (84) 1. #### ***N*-Acetyl-L-isoleucyl-L-alanyl-L-phenylalaninal**

This peptide aldehyde (Sequence: Ac-IAF-CHO; FW = 375.47 g/mol), which as a hydrate adopts a structure resembling the tetrahedral intermediate-like oxyanion in protease catalysis, inhibits the pepstatin-

insensitive carboxyl protease from *Pseudomonas* sp.,  $K_i = 0.6 \mu\text{M}$ , and kumamolysin,  $K_i = 0.9 \mu\text{M}$  at 22.4°C. **Target(s):** kumamolysin (1,2); pseudomonalysin, or pseudomonapepsin (3), and tripeptidyl peptidase I (4). 1. Oyama, Hamada, Ogasawara, *et al.* (2002) *J. Biochem.* **131**, 757. 2. Comellas-Bigler, Fuentes-Prior, Maskos, *et al.* (2002) *Structure* **10**, 865. 3. #### **N<sup>ε</sup>-Acetyl-L-isoleucyl-L-glutamyl-L-threonyl-L-aspartate Semialdehyde**

This tetrapeptide aldehyde (*Sequence*: Ac-IETD-CHO;  $\text{FW}_{\text{free-acid}} = 502.52 \text{ g/mol}$ ), is a strong inhibitor of caspase-8 and granzyme B. Ac-IETD-CHO also blocks the cleavage of the pro-form of caspase 3 and prevents the formation of active caspase-3. *Note*: A cell-permeable derivative (*Sequence*: Ac-AAVALLPAVLLALLAPIETD-CHO;  $\text{FW}_{\text{free-acid}} = 2000.45 \text{ g/mol}$ ) is also commercially available. This eicosapeptide consists of the N-terminal sequence (residues 1-16) of the signal peptide of Kaposi fibroblast growth factor linked to IETD-CHO. **Target(s):** caspase-8 (1-4); caspase-6 (1); caspase-9 (1); caspase-10 (1); granzyme B (1); caspase-3 activation (2). 1. #### **N-Acetylglucosamine**

This modified disaccharide ( $\text{FW} = 383.35 \text{ g/mol}$ ), often abbreviated Gal-(β1,4)-GlcNAc, is a common component of glycoproteins and an

alternative acceptor substrate for many sialyltransferases. N-Acetylglucosamine is also a substrate for β-galactosidases. **Target(s):** electrolectin (1); *Bauhinia purpurea* agglutinin (2); calf heart lectin (3); *Rana catesbiana* lectin (4); *Datura stramonium* lectin (5); *Achatina fulica* agglutinin (6); galaptin, human spleen (7); *Arum maculatum* lectin (8); *Phalera flavescens* agglutinin (9); rabbit serum lectin (10); *Octopus vulgaris* lectin (11); β-galactoside α-2,6-sialyltransferase, also an alternative substrate (12); and glucuronosyltransferase (13). 1. #### **N-Acetyl-L-leucine Chloromethyl Ketone**

This halomethyl ketone ( $\text{FW} = 205.68 \text{ g/mol}$ ) inhibits acylaminoacyl-peptidase, or acylpeptide hydrolase, and induces apoptosis of U937 cells (1,2). 1. Yamaguchi, Kambayashi, Toda, *et al.* (1999) *Biochem. Biophys. Res. Commun.* **263**, 139. 2. Scaloni, Jones, Barra, *et al.* (1992) *J. Biol. Chem.* **267**, 3811.

#### **N-Acetyl-L-leucyl-L-alanyl-L-alanyl-L-(N,N-dimethylglutaminyl)**

This peptide aldehyde ( $\text{FW} = 200.24 \text{ g/mol}$ ) irreversibly inhibits picornain 3C proteases (1), enzymes that adopt a chymotrypsin-like fold and display an active-site configuration like those of the serine proteinases (2,3). Peptide-aldehydes based on the preferred peptide substrates for hepatitis A virus (HAV) 3C proteinase were synthesized by reduction of a thioester precursor. Acetyl-Leu-Ala-Ala-(N,N'-dimethylglutaminyl) is a reversible, slow-binding inhibitor for HAV 3C with a  $K_i^*$  of  $(4.2 \times 10^{-8} \text{ M})$ . This inhibitor shows 50x less activity against the highly homologous human Rhinovirus (Strain 14) 3C proteinase, whose peptide substrate specificity is slightly different, suggesting a high degree of selectivity. NMR spectrometry of the adduct of the  $^{13}\text{C}$ -labeled inhibitor with the HAV-3C proteinase indicate that a thiohemiacetal is formed between the enzyme and the aldehyde carbon, as previously noted for peptide-aldehyde inhibitors of papain (4,5). 1. #### **3-[N<sup>1</sup>-(N-Acetyl-L-leucyl-L-alanyl-L-alanyl)-N<sup>2</sup>-(o-nitrophenyl-sulfonyl)hydrazino]-N,N-(dimethyl)propanamide**

This azaglutamine derivative (FW = 568.68 g/mol) inactivates picornain 3C, a cysteine proteinase essential for cleavage of the initially synthesized viral polyprotein precursor into mature fragments. Because picornain 3C is essential for viral replication *in vivo*, it is an obvious druggable target for developing antivirals. 1. Huang, Malcolm & Vederas (1999) *Bioorg. Med. Chem.* **7**, 607.

#### **N-Acetyl-L-leucyl-L-arginal**

This dipeptide aldehyde (FW<sub>free-base</sub> = 313.40 g/mol) inhibits dipeptidyl-peptidase III, most likely by forming a tetrahedral transition-state mimic. (1,2). Note that this is a shorter analogue of leupeptin, a broad-specificity serine/cysteine protease inhibitor. **See also Leupeptin** 1. McDonald (1998) in *Handbook of Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds), p. 536, Academic Press, San Diego. 2. Nishikiori, Kawahara, Naganawa, *et al.* (1984) *J. Antibiot.* **37**, 680.

#### **N-[N-[N-Acetyl-L-leucyl-L-asparaginy]]-(3S-amino-2S-hydroxy-4-phenylbutyl)]-L-prolyl-L-isoleucyl-L-valine Methyl Ester and Amide**

This peptide analogue (Sequence: Ac-Leu-Asn-[Phe-HEA-Pro]-Ile-Val-Ome; FW = 773.97 g/mol), inhibits HIV-1 protease, or HIV-1 retropepsin,  $K_i = 21$  nM (1-3). The corresponding amide has a  $K_i$  value of 3 nM. 1. Rich, Green, Toth, *et al.* (1990) *J. Med. Chem.* **33**, 1285. 2. March, Abbenante, Bergman, *et al.* (1996) *J. Amer. Chem. Soc.* **118**, 3375. 3. Abbenante, March, Bergman, *et al.* (1995) *J. Amer. Chem. Soc.* **117**, 10220.

#### **N<sup>α</sup>-Acetyl-L-leucyl-L-glutamyl-L-histidyl-L-aspartate-α-semialdehyde**

This tetrapeptide aldehyde (FW = 636.57 g/mol; Sequence: Ac-LEHD-CHO) inhibits caspase-9 (1,2). Acetyl-AAVALLPAVLLALLAPLEHD-CHO is the commercially available cell-permeable derivative of this tetrapeptide, and this eicosapeptide aldehyde consists of the N-terminal sequence (residues 1-16) of the cell-penetrating signal peptide of Kaposi fibroblast growth factor covalently linked to LEHD-CHO. 1. Thornberry & Lazebnik (1998) *Science* **281**, 1312. 2. Thornberry, Rano, Peterson, *et al.* (1997) *J. Biol. Chem.* **272**, 17907.

#### **N<sup>α</sup>-Acetyl-L-leucyl-L-glutamyl-L-valyl-L-aspartate-α-semialdehyde**

This tetrapeptide aldehyde (Sequence: Ac-LEVD-CHO; FW<sub>free-acid</sub> = 500.55 g/mol), inhibits caspase-4 (1). The commercially available cell-penetrating derivative (N<sup>α</sup>-Acetyl-AAVALLPAVLLALLAPLEVD-CHO) is an eicosapeptide, consisting of the N-terminal sequence (residues 1-16) of the signal peptide of Kaposi fibroblast growth factor covalently linked to LEVD-CHO. 1. Talanian, Quinlan, Trautz, *et al.* (1997) *J. Biol. Chem.* **272**, 9677.

**N-Acetyl-L-leucyl-L-leucyl-L-arginal**, See *Leupeptin*

#### **N-Acetyl-L-leucyl-L-leucyl-L-arginyl-L-valyl-L-lysyl-L-arginine**

This acetylated hexapeptide (FW = 827.07 g/mol; Sequence: Ac-LLRVKR) and its amide Ac-LLRVKR-NH<sub>2</sub> (FW = 826.06 g/mol) inhibit furin and proprotein convertase 2, respectively (1,2). 1. Apletalina, Muller & Lindberg (2000) *J. Biol. Chem.* **275**, 14667. 2. Cameron, Appel, Houghten & Lindberg (2000) *J. Biol. Chem.* **275**, 36741.

#### **N-Acetyl-L-leucyl-L-leucyl-L-methioninal**

This membrane-permeable, transition state-mimicking endopeptidase inhibitor (FW = 401.57 g/mol; Sequence: Ac-LLM-CHO) targets calpain I,  $K_i = 120$  nM, calpain II,  $K_i = 230$  nM, cathepsin B,  $K_i = 100$  nM, and cathepsin L,  $K_i = 600$  pM. **Target(s)**: calpain-1 (1,3); calpain-2, or  $\mu$ -calpain (1,3,6,7); cathepsin L (1); cathepsin B (1); proteasome (chymotrypsin and trypsin-like activity,  $K_i = 33$  (2); HIV retropepsin, or HIV protease, IC<sub>50</sub> = 5  $\mu$ M (4); peptide deformylase (5); and cathepsin K (8). 1. Sasaki, Kishi, Saito, *et al.* (1990) *J. Enzyme Inhib.* **3**, 195. 2. Vinitsky, Michaud, Powers & Orłowski (1992) *Biochemistry* **31**, 9421. 3. Saito & Nixon (1993) *Neurochem. Pharm. Bull.* **19**, 1026.

#### **N-Acetyl-L-leucyl-L-leucyl-L-norleucinal**

This acetylated tripeptide aldehyde (FW = 383.53 g/mol), also known as Calpain Inhibitor I and ALLN, inhibits many proteinases by forming a tightly bound, reversible tetrahedral hemiacetal adduct that resembles a key intermediate (shown in the inset above) in the catalytic reaction cycles of the above enzymes. ALLN also inhibits cyclin B degradation and alters the rate of processing and secretion of the  $\beta$ -amyloid precursor protein. ALLN also reportedly inhibits nitric oxide production by interfering with transcription of the inducible nitric oxide synthase gene. **Target(s)**: calpain-1,  $K_i = 0.19$   $\mu$ M; (1,6,7,10); *Thermoplasma* proteasome (Archaeon proteasome) (2); HsLVU protease (3); proteasome endopeptidase complex,  $K_i = 5.7$   $\mu$ M (4,5,13,14); calpain-2, or  $\mu$ -calpain,  $K_i = 0.22$   $\mu$ M (1,10,15,16); cathepsin L,  $K_i = 0.5$  nM (1); cathepsin B,  $K_i = 0.15$   $\mu$ M (1);  $\gamma$ -secretase (8,9); HIV retropepsin, IC<sub>50</sub> = 5.2  $\mu$ M (11); pepsin, IC<sub>50</sub> = 24  $\mu$ M (11); cathepsin D, IC<sub>50</sub> = 35  $\mu$ M (11); and peptide deformylase (12). Like its substrate counterparts, this inhibitor enters through a narrow side entrance to the active site of the PRE2 subunit of the 20S proteasome from *Saccharomyces cerevisiae*, whereupon it binds and forms the hemiacetal (17). 1. #### **N<sup>ε</sup>-Acetyl-L-lysine**

This posttranslationally derived amino acid (FW = 188.23 g/mol), first isolated from calf thymus histone IV in the late 1960s (1-3) and formed by histone acetyltransferase or synthetically by acetylation of the copper complex of L-lysine (4), inhibits D-lysine 5,6-aminomutase, by the racemic mixture (5,6), histone acetyltransferase (7), and lysyl-tRNA synthetase (8). 1. J. DeLange, Smith, Fambrough & Bonner (1968) *Proc. Natl. Acad. Sci. U.S.A.* **61**, 1145. 2. DeLange, Fambrough, Smith & Bonner (1969) *J. Biol. Chem.* **244**, 319. 3. Stadtman (1972) *The Enzymes*, 3rd ed., **6**, 539. 7. Wiktorowicz, Campos & Bonner (1981) *Biochemistry* **20**, 1464. 8. Takita, Ohkubo, Shima, *et al.* (1996) *J. Biochem.* **119**, 680.

### **N<sup>α</sup>-Acetyllysyltyrosylcysteine Amide**

This novel inhibitor (FW = 453.55 g/mol; Sequence: Ac-KYC-NH<sub>2</sub>) targets myeloperoxidase, a heme peroxidase that is formed in and released by activated neutrophils, macrophages and monocytes, playing important roles in host defense. Ferric MPO reacts with hydrogen peroxide to form compound I, an oxy-ferryl-cation (P<sup>+</sup>Fe<sup>4+</sup>=O) radical intermediate that oxidizes a wide variety of substrates to form an equally wide variety of toxic oxidants and free radicals that kill invading bacteria. Ac-KYC-NH<sub>2</sub> reduces production of hypochlorous acid, lowers the peroxidation of LDL lipids, suppresses protein nitration, and inhibits tryptophan oxidation. Ac-KYC-NH<sub>2</sub> specifically inhibits the myeloperoxidase activity released from PMA-activated HL-60 cells, but not the NOX activity essential for HL-60 cells to generate O<sub>2</sub><sup>-</sup> that can dismutate to hydrogen peroxide to activate MPO. While Ac-KYC-NH<sub>2</sub> is cytotoxic to bovine aortic endothelial cell cultures, even when incubated at 4 mM, it protects these cells from MPO-induced injury and death at 100x lower concentrations. Support for intramolecular electron transfer playing a role in the mechanisms by which Ac-KYC-NH<sub>2</sub> detoxifies MPO activity comes from data showing that MPO-dependent Ac-KYC-NH<sub>2</sub> oxidation forms exclusively a disulfide, not dityrosine, since the latter is formed only when one Tyr<sup>•</sup> free radical condenses with another Tyr<sup>•</sup> free radical. Notably, Ac-KYC-NH<sub>2</sub> enjoys great advantage over azides, hydrazides and hydroxamic acids, which are MPO suicide inhibitors that irreversibly modify the iron heme site of MPO, but lack specificity and are inherently toxic. 1. Zhang, Jing, Shi, *et al.* (2013) *J. Lipid Res.* **54**, 3016.

### **N-Acetyl-L-lysyl-(N-methyl)-L-leucyl-L-valyl-(N-methyl)-L-phenylalanyl-L-phenylalaninamide**

This acetylated heptapeptide amide (FW<sub>free-base</sub> = 721.93 g/mol; water-soluble), itself containing N-methylated amino acids is homologous to the central core domain of the Alzheimer's β-amyloid peptide and adopts the structure of an extended β-strand. **Target(s):** amyloid β-40 fibrillogenesis. 1. Gordon, Tappe & Meredith (2002) *J. Pept. Res.* **60**, 37.

### **N<sup>1</sup>-[N-Acetyl-D-lysyl-L-phenylalanyl-L-phenylalanyl-L-prolyl-L-leucyl-L-glutamic Acid α-Amide**

This substituted hexapeptide amide (FW = 822.98 g/mol; Sequence: Ac-KFFPLE-NH<sub>2</sub>) inhibits human tissue kallikrein, thrombin, coagulation factor Xa, plasmin, cathepsin G, and plasma kallikrein, with K<sub>i</sub> values of 29, 700, 130, 170, 170, and 8 nM, respectively. If inhibition of kinin release is the main goal, acetyl-Lys-Phe-Phe-Pro-Leu-Glu-NH<sub>2</sub> may be a useful lead molecule for designing specific inhibitors for human tissue kallikrein (hK1), plasma kallikrein, or for both at same time. 1. Pimenta, S. Fogaça, Melo, Juliano & Juliano (2003) *Biochem. J.* **371**, 1021.

### **N-Acetyl-D-mannosamine**

This acylamino sugar (FW = 221.21 g/mol), also known as 2-acetamido-2-deoxy-D-mannose, inhibits α-N-acetylglucosaminidase (1,2), β-N-acetylhexosaminidase (3,4), peptidoglycan β-N-acetylmuramidase (5,6), N-acetylglucosamine kinase (7), mannokinase (8), and hexokinase (9). 1. Weissmann (1972) *Meth. Enzymol.* **28**, 796. 2. Weissmann, Rowan, Marshall & Friederici (1967) *Biochemistry* **6**, 207. 3. Mommsen (1980) *Biochim. Biophys. Acta* **612**, 361. 4. Geimba, Riffel & Brandelli (1998) *J. Appl. Microbiol.* **85**, 708. 5. del Rio & Berkeley (1976) *Eur. J. Biochem.* **65**, 3. 6. del Rio, Berkeley, Brewer & Roberts (1973) *FEBS Lett.* **37**, 7. 7. Allen & Walker (1980) *Biochem. J.* **185**, 577. 8. Sabater, Sebastián & Asensio (1972) *Biochim. Biophys. Acta* **284**, 406. 9. E. Machado de Domenech & Sols (1980) *FEBS Lett.* **119**, 174.

### **S-Acetylmercaptosuccinic Anhydride**

This reagent (FW = 174.18 g/mol), also known as 2-(acetylthio)succinic anhydride, has been used to acylate proteins and introduce sulfhydryl groups (1). **Note:** Care must be exercised when working with this moisture-sensitive agent, which is also skin irritant. **Target(s):** phenylalanine monooxygenase (2). 1. Klotz & Heiney (1962) *Arch. Biochem. Biophys.* **96**, 605. 2. Weiss, Hui & Lajtha (1979) *Res. Commun. Chem. Pathol. Pharmacol.* **25**, 153.

### **3-(N-Acetyl-L-methionyl)pyruvic Acid**

This methionine derivative (FW<sub>free-acid</sub> = 261.30 g/mol) inhibits peptidylamidoglycolate lyase, a bifunctional enzyme catalyzing C-terminal amidation, as seen in the essential post-translational modification of many neuropeptides. C-terminal amidation entails sequential action by peptidylglycine mono-oxygenase (EC 1.14.17.3) and peptidylamidoglycolate lyase (EC 4.3.2.5), with the mono-oxygenase catalyzing conversion of a glycine-extended pro-peptide into the corresponding α-hydroxyglycine derivative, which is then converted by the lyase into amidated peptide plus glyoxylate. Since the mono-oxygenase and lyase reactions exhibit tandem reaction stereospecificities, the possibility of channelling of the α-hydroxy intermediate was investigated. Selective inhibition of the mono-oxygenase by competitive ester inhibitors, as well as mechanism-based mono-oxygenase inactivation by the novel olefinic inhibitor 5-acetamido-4-oxo-6-phenylhex-2-enoate (N-acetylphenylalanyl acrylate), was found to exert little to no effect on the kinetic parameters of the lyase domain of the AE from *Xenopus laevis*. Similarly, inhibition of the lyase domain by the potent dioxo inhibitor 2,4-dioxo-5-acetamido-6-phenylhexanoate had little effect on the activity of the monooxygenase domain in the bifunctional enzyme. A assessment of intermediate accumulation and conversion, bolstered by kinetic investigations of the reactivities of the monofunctional and bifunctional enzyme forms towards substrates and inhibitors, provide strong evidence for the kinetic independence of the mono-oxygenase and lyase, absent any evidence for substrate channelling. 1. Moore & May (1999) *Biochem. J.* **341**, 33.

**N-Acetyl-5-methoxytryptamine**, See *Melatonin*

### Acetyl- $\beta$ -methylcholine Chloride

This acetylcholine analogue (FW = 195.69 g/mol), also known as methacholine chloride, is photosensitive, very deliquescent, and hygroscopic (the bromide and iodide salts are less hygroscopic). Acetyl- $\beta$ -methylcholine chloride is a muscarinic receptor agonist and parasympathomimetic bronchoconstrictor (the (+)-enantiomer is the more active stereoisomer). Note that it is a weaker acetylcholinesterase substrate than acetylcholine; hence, its physiological effects are longer lasting.

**Target(s):** aryl-acylamidase (1); carnitine acetyltransferase (2); ethanolamine kinase (3). 1. Oommen & Balasubramanian (1979) *Eur. J. Biochem.* **94**, 135. 2. Fritz & Schultz (1965) *J. Biol. Chem.* **240**, 2188. 3. Sung & Johnstone (1967) *Biochem. J.* **105**, 497.

### N-Acetyl- $\alpha$ -methyl-L-phenylalanine Methyl Ester

While this ester (FW = 235.28 g/mol) is a weak alternative substrate for chymotrypsin, both stereoisomers are effective competitive inhibitors when chymotrypsin operates on better substrates (1-3). 1. Almond, Manning & Niemann (1962) *Biochemistry* **1**, 243. 2. Baker (1967) *Design of Active-Site-Directed Irreversible Enzyme Inhibitors*, Wiley, New York. 3. Hein & Niemann (1962) *J. Amer. Chem. Soc.* **84**, 4495.

### N-Acetylmuramic Acid

This modified *N*-acetyl-D-glucosamine (FW<sub>free-acid</sub> = 293.27 g/mol; CAS 10597-89-4), also known as 2-acetamido-3-*O*-(D-1-carboxyethyl)-2 deoxy-D-glucose, is a component of many peptidoglycans and inhibits lysozyme and peptidoglycan  $\beta$ -*N*-acetylmuramidase. In bacterial cell wall peptidoglycan, alternating units of *N*-acetylglucosamine (GlcNAc) and *N*-acetylmuramic acid (MurNAc) form a polymer that is cross-linked with oligopeptides at the lactic acid residue of MurNAc. **Target(s):** lysozyme (1,6); peptidoglycan  $\beta$ -*N*-acetylmuramidase (2,5); alkaline phosphatase (3); *N*-acetylmuramoyl-L-alanine amidase (4). 1. Imoto, Johnson, North, Phillips & Rupley (1972) *The Enzymes*, 3rd ed., 7, 665. 2. del Rio & Berkeley (1976) *Eur. J. Biochem.* **65**, 3. 3. Komoda & Sakagishi (1977) *Biochim. Biophys. Acta* **482**, 79. 4. Van Heijenoort, Parquet, Flouret & Van Heijenoort (1975) *Eur. J. Biochem.* **58**, 611. 5. del Rio, Berkeley, Brewer & Roberts (1973) *FEBS Lett.* **37**, 7. 6. Pahud & Widmer (1982) *Biochem. J.* **201**, 661.

### N-Acetylmuramoyl-L-alanyl-D-isoglutamine

This peptidoglycan derivative (FW<sub>free-acid</sub> = 492.48 g/mol), also known as muramyl-dipeptide and MDP, is a water-soluble, synthetic immunoadjuvant (1) that enhances the antigenicity of weak antigens.

**Target(s):** HIV replication (2). 1. Lefrancier, Choay, Derrien & Lederman (1977) *Int. J. Pept. Protein Res.* **9**, 249. 2. Masihi, Lange, Rohde-Schulz & Chedid (1990) *AIDS Res. Hum. Retroviruses* **6**, 393.

### N<sup>1</sup>-Acetyl-N<sup>4</sup>-(N<sup>2</sup>-2-naphthalenesulfonyl-L-3-amidinophenylalanyl)piperazine

This substituted phenylalanine (FW = 506.61 g/mol) inhibits thrombin and trypsin, the latter with a  $K_i$  value of 44 nM. Isothermal calorimetry and protein crystallographic analysis demonstrated changes of protonation states attend inhibitor binding, resulting from induced  $pK_a$  shifts that depend on interactions with protein functional groups. A strong negative heat capacity change  $\Delta C_p$  is detected suggests binding becomes more exothermic and entropically less favorable with increasing temperature. Due to a mutual compensation, the Gibbs free energy of inhibitor binding remains virtually unchanged. The strongly negative  $\Delta C_p$  value cannot solely be explained on the basis of the removal of hydrophobic surface portions of the protein or ligand from water exposure, suggesting additional contributions from modulations of the local water structure, changes in vibrational modes, or other ordering parameters. 1. Dullweber, Stubbs, Musil, Stürzebecher & Klebe (2001) *J. Mol. Biol.* **313**, 593.

### N-Acetyl- $\beta$ -(2-naphthyl)-D-alanyl-4-chloro-D-phenylalanyl- $\beta$ -(3-pyridyl)-D-alanylglycyl-L-arginyl-L-prolyl-D-alaninamide

This modified heptapeptide amide is a luteinizing hormone-releasing agent (*i.e.*, a gonadotropin releasing hormone) and has a high receptor binding affinity (IC<sub>50</sub> = 7 nM), as compared to that of gonadotropin itself (IC<sub>50</sub> = 2 nM). 1. Yahalom, Rahimipour, Koch, Ben-Aroya & Fridkin (2000) *J. Med. Chem.* **43**, 2831.

### N-Acetyl- $\beta$ -(1-naphthyl)-L-alanyl-L-valylstatinyl-L-glutamyl- $\beta$ -(1-naphthyl)-L-alaninamide

This peptidomimetic (FW<sub>free-acid</sub> = 839.00 g/mol), also known as LP-149, is a strong inhibitor of feline immunodeficiency virus retropepsin and HIV retropepsin ( $K_i$  = 260 and 1.7 nM, respectively). **Target(s):** feline immunodeficiency virus retropepsin (1,2); HIV retropepsin, or HIV protease (1-3). 1. Dunn (1998) in *Handbook of Proteolytic Enzymes*, p.

949, Academic Press, San Diego. 2. Wlodawer, Gustchina, Reshetnikova, *et al* (1995) *Nature Struct. Biol.* **2**, 480. 3. Dunn, Pennington, Frase & Nash (1999) *Biopolymers* **51**, 69.

### N-Acetylneuraminic Acid

This acetylated sugar acid (FW<sub>free-acid</sub> = 309.27 g/mol; frequently abbreviated NANA), also known as 5-(acetylamino)-3,5-dideoxy-D-glycero-D-galacto-2-nonulosonic acid, is a building block for many complex carbohydrates, glycoproteins, and proteoglycans. Although often regarded to be synonymous with sialate, this term actually refers to a class of acylated neuraminates and esters. Other sialates include N-glycolylneuraminate and N,O<sup>6</sup>-diacetylneuraminate. Soluble in water and methanol, NANA is more stable than neuraminate, its deacetylated analogue. Greatest stability is observed at pH 4.5, but N-acetylneuraminic acid is moderately stable in alkaline solutions. NANA decomposes at 185-187°C and has a pK<sub>a</sub> value of 2.60 at 25°C. **Target(s):** alkaline phosphatase (1); exo- $\alpha$ -sialidase, *or* neuraminidase; sialidase (2-7); limulin, *or* *Limulus polyphemus* agglutinin (8); phospholipase A<sub>2</sub> (9); neolactotetrasylceramide  $\alpha$ -2,3 sialyltransferase (10); and ganglioside galactosyltransferase (11). 1. Komoda & Sakagishi (1977) *Biochim. Biophys. Acta* **482**, 79. 2. Gottschalk & Bhargava (1971) *The Enzymes*, 3rd ed., **5**, 321. 3. Sastre, Cobaleda, Cabezas & Villar (1991) *Biol. Chem. Yang, Farooqui & Horrocks (1996) *Adv. Exp. Med. Biol.* **416**, 309. 10. Dasgupta, Chien & Hogan (1986) *Biochim. Biophys. Acta* **876**, 363. 11. Yip & Dain (1970) *Biochem. J.* **118**, 247.

### N-Acetyl-[Nle<sup>4</sup>,Asp<sup>5</sup>,D-2-Nal<sup>7</sup>,Lys<sup>10</sup>]-Cyclo- $\alpha$ -Melanocyte Stimulating Hormone Amide Fragment 4-10

This peptide lactam (*Sequence*: CH<sub>3</sub>CO-Nle-cyclo( $\beta$ -Asp-His-D-2-Nal-Arg-Trp- $\epsilon$ -Lys-NH<sub>2</sub>), where Nle refers to L-norleucine and D-2-Nal refers to D-2'-naphthylalanine) is an analogue of  $\alpha$ -melanocyte stimulating hormone ( $\alpha$ -MSH) and a potent antagonist of the melanocortin-4 receptor. It is also a weaker antagonist at the melanocortin-3 receptor. 1. Hruby, Lu, Sharma, *et al.* (1995) *J. Med. Chem.* **38**, 3454.

### O-Acetyloctahydropiperidin B<sub>1</sub>

This reduced antibiotic (FW = 479.70 g/mol) and its deacetylated derivative are structural analogues of ubiquinone and moderately inhibit NADH dehydrogenase and electron transport. 1. Jeng, Hall, Crane, *et al.* (1968) *Biochemistry* **7**, 1311.

### 3-(Acetyl)oxanilic Acid

This arylated oxamic acid (FW<sub>free acid</sub> = 207.19 g/mol), also called N-(3-acetylphenyl)oxamic acid, inhibits lactate and glutamate dehydrogenase

(1,2). 1. Baker (1967) *Design of Active-Site-Directed Irreversible Enzyme Inhibitors*, Wiley, New York. 2. Baker, Lee, Tong, Ross & Martinez (1962) *J. Theoret. Biol.* **3**, 446.

### 3-Acetyl-4-oxo-1,7-heptanedioic Acid

This porphobilinogen analogue (FW = 216.19 g/mol) inhibits porphobilinogen synthase, *or*  $\delta$ -aminolevulinate dehydratase, with the formation of a Schiff base complex between the inhibitor and an active-site lysine. Comparative studies of pea ALAD with *E. coli* ALAD using the inhibitors 3-acetyl-4-oxoheptane-1,7-dioic acid (AOHD) and succinylacetone (SA) indicated similar modes of inhibition. Studies with the ALA homologue, 4-amino-3-oxobutanoic acid (AOB), revealed that it is specific for the A-site of both the pea and *E. coli* ALADs. An interesting difference exists between the enzymes, however, with pea ALAD far more susceptible to inhibition with AOB than the bacterial enzyme. 1. Cheung, Spencer, Timko & Shoolingin-Jordan (1997) *Biochemistry* **36**, 1148.

### N-Acetyl-4-oxo-D-neuraminic Acid

This neuraminic acid derivative (FW<sub>free acid</sub> = 307.26 g/mol) inhibits N-acetylneuraminic acid lyase ( $K_i = 25 \mu\text{M}$  and  $150 \mu\text{M}$  for the *Clostridium perfringens* and *Escherichia coli* enzymes, respectively) (1,2). 1. Groß & Brossmer (1988) *FEBS Lett.* **232**, 145. 2. Schauer, Wember, Wirtz-Peitz & Ferreira do Amaral (1971) *Hoppe-Seyler's Z. Physiol. Chem.* **352**, 1073.

### [(S)-1-((3R,S)-1-Acetyl-4-oxopiperidin-3-ylcarbamoyl)-3-methylbutyl]carbamic Acid Benzyl Ester

This leucine derivative (FW = 415.49 g/mol) inhibits cathepsin K, ( $K_{i,app} = 230 \text{ nM}$ ), a cysteine protease in the papain superfamily that is predominantly expressed in osteoclasts and a drug target in the treatment of osteoporosis. 1. Marquis, Ru, Zeng, *et al.* (2001) *J. Med. Chem.* **44**, 725.

### 2-Acetyloxybenzoic Acid, See Acetylsalicylic Acid

### 4-Acetyloxybenzoyl Chloride Phenylhydrazone

This hydrazone (FW = 288.73 g/mol) inhibits soybean lipoxygenase and human platelet 12-lipoxygenase ( $K_i = 11$  and  $29 \text{ nM}$ , respectively, using measurements of oxygen consumption). 1. Wallach & Brown (1981) *Biochim. Biophys. Acta* **663**, 361.

**Acetyl Pepstatin**

This peptide (FW<sub>free acid</sub> = 643.82 g/mol; CAS 11076-29-2; Soluble to 2 mg/mL in phosphate-buffered saline), also known as *N*-acetyl-L-valyl-L-valyl-L-sta-L-alanyl-Sta, where Sta refers to (3*S*,4*S*)-4-amino-3-hydroxy-6-methylheptanoic acid, inhibits a number of proteases. **Target(s):** cathepsin E (1); HIV-1 retropepsin, or human immunodeficiency virus 1 protease,  $K_i = 20$  nM (2,3,5,6,10,12); HIV-2 retropepsin, or human immunodeficiency virus 2 protease,  $K_i = 5$  nM (3,9,14); pepsin (4,7,8); gastricsin (4,8); cathepsin D (4,8); chymosin (4,7,8); penicillopepsin (4); mucorpepsin, or *Mucor pusillus* pepsin (4); endothiapepsin, or *Endothia parasitica* proteinase (4); saccharopepsin, or yeast proteinase A (4); rhizopuspepsin,  $K_i = 10.3$  nM (11,15); and plasmepsin II (13). 1. ***N*-Acetylphenethylamine**, See *N*- $\beta$ -Phenethylacetamide

***N*-Acetylphenothiazine**

This acylated phenothiazine (FW = 241.31 g/mol), also known as 10-acetyl-10*H*-phenothiazine, inhibits acetylcholinesterase and butyrylcholinesterase, with  $K_i$  values of 39 and 36  $\mu$ M, respectively, for the human enzymes. 1. Darvesh, McDonald, Penwell, et al. (2005) *Bioorg. Med. Chem.* **13**, 211.

***N*<sup>1</sup>-Acetyl-*N*<sup>4</sup>-[*N*-(phenoxy-carbonyl)-L-valyl-L-prolyl]-1,4(*S*)-diamino-2,2-difluoro-5-methyl-3-oxohexane**

This peptide analogue (FW = 526.58 g/mol) inhibits leukocyte elastase ( $K_i = 2.3$  nM), which, in addition to catalyzing elastin proteolysis, also disrupts tight junctions, damages certain tissues, breaks down cytokines and alpha proteinase inhibitor, cleaves IgA and IgG, cleave complement component C3bi, a component and the CR1 receptor that triggers phagocytosis in neutrophils. 1. Veale, Bernstein, Bohnert, et al. (1997) *J. Med. Chem.* **40**, 3173.

***N*-Acetyl-DL-phenylalanine Trifluoromethyl Ketone**

This halomethyl ketone (FW = 259.23 g/mol), also known as *N*-(1-benzyl-2-oxo-3,3,3-trifluoropropyl)acetamide, inhibits chymase and chymotrypsin ( $K_i = 22$  and 24  $\mu$ M, respectively). **Target(s):** chymase (1); chymotrypsin (1,2). 1. Akahoshi, Ashimori, Yoshimura, et al. (2001) *Bioorg. Med. Chem.* **9**, 301. 2. Lin, Cassidy & Frey (1998) *Biochemistry* **37**, 11940.

***N*-(*N*-Acetyl-L-phenylalanyl)aminoacetonitrile**

This peptidonitrile (FW = 245.28 g/mol) is a reversible inhibitor of papain. <sup>13</sup>C NMR spectroscopy demonstrated covalent adduct formation, the reversibility of which was shown by displacement with an aldehyde inhibitor, regenerating the nitrile. No hydrolysis of the nitrile was observed. The covalent adduct is most likely a thioimidate formed between the catalytically essential thiol and nitrile. Based on kinetic studies with several *p*-nitroanilide substrates and their corresponding nitrile inhibitors, correlation was found between  $K_i$  and  $k_{cat}/K_m$  was observed. The finding that the pH-dependence of  $K_i$  parallels that of  $k_{cat}/K_m$  suggests that the interaction of nitriles and papain has considerable transition-state character. 1. Liang & Abeles (1987) *Arch. Biochem. Biophys.* **252**, 626.

**(2*S*,6*RS*)-2-(*N*-(*N*-Acetyl-L-phenylalanyl)amino)-6-hydrazinoheptane-1,7-dioate**

This slow, tight-binding inhibitor (FW = 392.42 g/mol) targets *Escherichia coli* succinyldiaminopimelate aminotransferase ( $K_i = 0.9$   $\mu$ M). These dipeptide substrates were converted to hydrazines by treatment with hydrazine, followed by reduction with sodium cyanoborohydride. 1. Cox, Schouten, Stentiford & Wareing (1998) *Bioorg. Med. Chem. Lett.* **8**, 945.

***N*-Acetyl-L-phenylalanyl-azalanine Phenyl Ester**

This azapeptide ester (FW = 355.39 g/mol) inactivates papain and cathepsin B. The ester derivatives inactivated papain and cathepsin B at rates which increased dramatically with leaving group hydrophobicity and electronegativity. The authors stress that the ease of synthesis coupled with good solution stability suggests that azapeptide esters may be useful as active site titrants of cysteine proteinases and probes of their biological function *in vivo*. 1. Xing & Hanzlik (1998) *J. Med. Chem.* **41**, 1344.

***N*-Acetyl-L-phenylalanylglycyl-L-alanyl-L-leucine Chloromethyl Ketone**

This halomethyl ketone (FW = 480.99 g/mol) inhibits subtilisin, protein-tyrosine kinase, cathepsin G4, and rat mast cell proteinase II. 1. Powers (1977) *Meth. Enzymol.* **46**, 197. 2. Navarro, Abdel-Ghany & Racker

(1982) *Biochemistry* **21**, 6138. **3.** Yoshida, Everitt, Neurath, Woodbury & Powers (1980) *Biochemistry* **19**, 5799. **4.** Powers, Gupton, Harley, Nishino & Whitley (1977) *Biochim. Biophys. Acta* **485**, 156.

**N-Acetyl-L-phenylalanyl-L-histidyl-(4-amino-5-cyclohexyl-3-hydroxypentanoic acid) N-(2(S)-Methylbutyl)amide**

This peptide amide analogue (FW<sub>free base</sub> = 610.80 g/mol) inhibits a number of aspartic proteinases. The IC<sub>50</sub> value for renin was 42 nM whereas gastricsin and pepsin had weak affinities (IC<sub>50</sub> = 15 and 16 μM, respectively). **Target(s):** cathepsin D; cathepsin E; endothiapsin; gastricsin; pepsin; renin. **1.** Jupp, Dunn, Jacobs, *et al.* (1990) *Biochem J.* **265**, 871.

**N-Acetyl-L-phenylalanyl-L-histidyl-(4-amino-5-cyclohexyl-3-hydroxypentanoyl)-L-leucyl-L-phenylalaninamide**

This peptide amide analogue (FW<sub>free base</sub> = 801.00 g/mol) inhibits a number of aspartic proteinases, including cathepsin D, cathepsin E, endothiapsin, gastricsin, pepsin, and renin. The IC<sub>50</sub> value for renin was 3 nM, whereas endothiapsin and pepsin had weak affinities (IC<sub>50</sub> = 2.7 and 1.5 μM, respectively). **1.** Jupp, Dunn, Jacobs, *et al.* (1990) *Biochem J.* **265**, 871.

**N-[N-Acetyl-L-phenylalanyl-L-histidyl]-N-(2S-amino-3-phenylpropyl)-L-phenylalaninamide**

This pseudopeptide amide (FW<sub>free base</sub> = 623.76 g/mol; Ac-Phe-His-Pheψ[CH<sub>2</sub>-NH]Phe-NH<sub>2</sub>, where ψ indicates a pseudopeptide linkage, with a reduced peptide bond) inhibits renin with IC<sub>50</sub> = 450 nM. **1.** Sawyer, Maggiora, *et al.* (1990) in *Peptides: Chemistry, Structure, and Biology* (Rivier & Marshall, eds), pp. 46-48, Escom Sci. Publ.

**N-Acetyl-D-phenylalanyl-L-prolyl-L-boroarginine**

This boroarginine-containing tripeptide (FW<sub>HCl</sub> = 496.80 g/mol), also known as DuP714, is a potent inhibitor of thrombin (K<sub>i</sub> = 41 pM). It also inhibits, albeit with a weaker affinity, other proteinases, including plasma kallikrein (K<sub>i</sub> = 1.9 nM) and coagulation factor Xa. **1.** Weber, Lee, Lewandowski, *et al.* (1995) *Biochemistry* **34**, 3750.

**N-Acetyl-D-phenylalanyl-L-prolyl-L-boroarginine-pinanediol**

This peptide analogue (FW<sub>free base</sub> = 594.56 g/mol) inhibits thrombin (K<sub>i</sub> = 0.07 nM). It is a slightly weaker inhibitor of trypsin and plasmin (K<sub>i</sub> = 0.14 and 9.9 nM, respectively). **1.** Tapparelli, Metternich, Ehrhardt, *et al.* (1993) *J. Biol. Chem.* **268**, 4734. **2.** Kettner & Shenvi (1988) European Patent Application 0293-881 (1/6/1988).

**N-Acetyl-L-phenylalanyl-L-threonyl-L-leucyl-L-aspartyl-L-alanyl-L-aspartyl-L-phenylalanine**

This acetylated heptapeptide (FW<sub>free acid</sub> = 869.93 g/mol) inhibits mammalian ribonucleotide reductase. The sequence Ac-FTLDADF corresponds to the C-terminus of mR<sub>2</sub> subunit of the reductase and disrupts the enzyme's quaternary structure. **1.** Tan, Gao, Kaur & Cooperman (2004) *Bioorg. Med. Chem. Lett.* **14**, 5301. **2.** Cooperman, Gao, Tan, Kashlan & Kaur (2005) *Adv. Enzym. Regul.* **45**, 112. **3.** Yang, Spanevello, Celiker, Hirschmann, Rubin & Cooperman (1990) *FEBS Lett.* **272**, 61. **4.** Xu, Fairman, Wijerathna, *et al.* (2008) *J. Med. Chem.* **51**, 4653.

**Acetyl Phosphate**

This acyl phosphate (FW<sub>free acid</sub> = 140.03 g/mol; CAS 590-54-5; pK<sub>a</sub> values: 1.2 and 4.8; Most stable as dilithium salt), first identified by Nobelist Fritz Lipmann, led to the development of his concept of group transfer potential. Depending upon the nature of the enzyme-catalyzed reaction, acetyl-P can serve as a substrate for either acetyl or phosphoryl transfer. Acetyl phosphate is a labile metabolite that is rapidly hydrolyzed in acidic or alkaline conditions: approximately one-fifth is hydrolyzed after thirty minutes at pH 7 and room temperature (45% is hydrolyzed in ten minutes in 0.5 M HCl). Solutions should always be freshly prepared (aqueous neutral solutions are relatively stable when stored at -30°C). Acetyl phosphate is a product of the reactions catalyzed by acetate kinase, acetate kinase (diphosphate), pyruvate oxidase, glycine reductase, sarcosine reductase, betaine reductase, phosphate acetyltransferase, phosphoketolase, and fructose-6-phosphate phosphoketolase. It is an alternative product for propionate kinase. It is a substrate for sulfoacetaldehyde acetyltransferase and is an alternative substrate for several phosphotransferases and ATPases (*e.g.*, a substrate for the Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase). **Target(s):** triose-phosphate isomerase (1,2); thiamin-phosphate diphosphorylase (3,4,12); glyceraldehyde-3-phosphate dehydrogenase (5); pyruvate dehydrogenase (8); formyltetrahydrofolate synthetase (9); acetyl-CoA synthetase, *or* acetate:CoA ligase (10); acetoacetate decarboxylase, inhibited by the monoanion (11); aspartate carbamoyltransferase (13,14). **1.** Krietsch (1975) *Meth. Enzymol.* **41**, 434. **2.** Krietsch (1975) *Meth. Enzymol.* **41**, 438. **3.** Penttinen (1979) *Meth. Enzymol.* **62**, 68. **4.** Kawasaki & Esaki (1970) *Biochem. Biophys. Res. #### Acetylphosphinate (Acetylphosphinic Acid)

This phosphinic acid ( $\text{FW}_{\text{free-acid}} = 108.03$  g/mol; CAS 50654-76-7) is a strong inhibitor of the pyruvate dehydrogenase complex (requiring the presence of thiamin pyrophosphate) and inactivates formate C-acetyltransferase. Acetylphosphinate is the transamination product of L-aminoethylphosphinate. **Target(s):** formate C-acetyltransferase, or pyruvate formate-lyase (1-3); pyruvate dehydrogenase (4,5). **1.** Brush & Kozarich (1992) *The Enzymes*, 3rd ed., **20**, 317. **2.** Parast, Wong, Lewisch, Kozarich, Peisach & Magliozzo (1995) *Biochemistry* **34**, 2393. **3.** Ulissi-DeMario, Brush & Kozarich (1991) *J. #### Acetylphosphonate (Acetylphosphonic Acid)

This pyruvate analogue ( $\text{FW}_{\text{free-acid}} = 124.03$  g/mol; CAS 6881-54-5) inhibits pyruvate (1), pyruvate dehydrogenase (2,3), pyruvate oxidase (3), and phosphoenolpyruvate:protein phosphotransferase (4). **1.** Kluger (1977) *J. Amer. Chem. Soc.* **99**, 4504. **2.** Dixon, Giddens, Harrison, *et al.* (1991) *J. Enzyme Inhib.* **5**, 111. **3.** O'Brien, Kluger, Pike & Gennis (1980) *Biochim. Biophys. Acta* **613**, 10. **4.** Saier, Schmidt & Lin (1980) *J. Biol. Chem.* **255**, 8579.

#### *N*-[*N*-Acetyl-L-prolyl-L-phenylalanyl-L-histidyl]-*N*-(2*S*-amino-3-cyclohexylpropyl)-L-phenylalaninamide

This pseudopeptide amide ( $\text{FW} = 726.92$  g/mol), also known as U-79465E and Ac-Pro-Phe-His-Cha $\psi$ [CH<sub>2</sub>NH]Phe-NH<sub>2</sub> (where  $\psi$  indicates a reduced peptide bond between a cyclohexylalanyl and a phenylalanyl residue), potently inhibits renin,  $\text{IC}_{50} = 1.7$  nM, and weakly inhibits rhizopuspepsin,  $K_i = 218$   $\mu\text{M}$  (2). **1.** Sawyer, Maggiora, Liu, *et al.* (1990) in *Peptides: Chemistry, Structure, and Biology* (Rivier & Marshall, eds), pp. 46-48, Escom Sci. Publ. **2.** Lowther, Sawyer, Staples, *et al.* (1992) in *Peptides: Chemistry and Biology Proc. of the 12th Amer. Peptide Symp.* (June 16-21, 1991) (Smith & Rivier, eds), pp. 413.

#### *N*-[*N*-Acetyl-L-prolyl-L-phenylalanyl-L-histidyl]-(*5S*-amino-4*S*-hydroxy-2-isopropyl-7-methyloctanoyl)-L-isoleucinamide

This pseudopeptide amide ( $\text{FW}_{\text{free-base}} = 674.93$  g/mol), also known as U77647E and Ac-Pro-Phe-His Leu $\psi$ [CH(OH)CH<sub>2</sub>]Val-Ile-NH<sub>2</sub> (where  $\psi$  indicates a reduced peptide bond), inhibits rhizopuspepsin:  $K_i = 54$  nM. **1.** Lowther, Sawyer, Staples, *et al.* (1992) in *Peptides: Chemistry and Biology Proc. of the 12th Amer. Peptide Symp.* (June 16-21, 1991) (Smith & Rivier, eds), pp. 413.

#### *N*-[*N*-Acetyl-L-prolyl-L-phenylalanyl-L-histidyl]-*N*-(2*S*-amino-3-phenylpropyl)-L-(4-chlorophenyl)alaninamide

This pseudopeptide amide ( $\text{FW}_{\text{free-base}} = 755.32$  g/mol), also known as U-80011E and Ac-Pro-Phe-His-Phe $\psi$ [CH<sub>2</sub>NH]Phe(*p*-Cl)-NH<sub>2</sub> (where  $\psi$  indicates a reduced peptide bond between a phenylalanyl and a *p*-chlorophenylalanyl residue), inhibits renin,  $\text{IC}_{50} = 38$  nM (1) and rhizopuspepsin,  $K_i = 13.3$   $\mu\text{M}$  (2). **1.** Sawyer, Maggiora, Liu, *et al.* (1990) in *Peptides: Chemistry, Structure, and Biology* (Rivier & Marshall, eds), pp. 46-48, Escom Sci. Publ. **2.** Lowther, Sawyer, Staples, *et al.* (1992) in *Peptides: Chemistry and Biology Proc. of the 12th Amer. Peptide Symp.* (June 16-21, 1991) (Smith & Rivier, eds), pp. 413.

#### *N*-[*N*-Acetyl-L-prolyl-L-phenylalanyl-L-histidyl]-*N*-(2*S*-amino-3-phenylpropyl)-L-tyrosinamide

This pseudopeptide amide ( $\text{FW}_{\text{free-base}} = 736.87$  g/mol), also known as Ac-Pro-Phe-His-Phe $\psi$ [CH<sub>2</sub>NH]Tyr-NH<sub>2</sub>, containing a reduced pseudopeptide bond between a phenylalanyl and a tyrosyl residue, inhibits renin with  $\text{IC}_{50} = 25$  nM. **1.** Sawyer, Maggiora, Liu, *et al.* (1990) in *Peptides: Chemistry, Structure, and Biology* (Rivier & Marshall, eds), pp. 46-48, Escom Sci. Publ.

#### *N*-Acetyl-purinomycin

This puromycin analogue ( $\text{FW} = 513.55$  g/mol; CAS 22852-13-7; Solubility: 100 mM in DMSO; 100 mM HCl salt in H<sub>2</sub>O) downregulates SnoN and Ski protein expression and promotes TGF- $\beta$  signaling, the latter independent of MAPK activation. Unlike puromycin, *N*-acetyl-purinomycin does not bind to ribosomes or block protein synthesis (1). (See Puromycin) SnoN and Ski proteins function as Smad transcriptional co-repressors and are implicated in the regulation of diverse cellular processes such as proliferation, differentiation and transformation (1). Transforming growth factor- $\beta$  (TGF- $\beta$ ) signaling causes SnoN and Ski protein degradation via proteasome with the participation of phosphorylated R-Smad proteins. Intriguingly, the antibiotics anisomycin (ANS) and puromycin (PURO) are also able to downregulate Ski and SnoN proteins via proteasome. By controlling Ski and SnoN protein levels, antibiotic analogues that lack ribotoxic effects are promising tools for studying TGF-

$\beta$  signaling. 1. Hernández-Damián, Tecalco-Cruz, Ríos-López, *et al.* (2013) *Biochim. Biophys. Acta* **1830**, 5049.

### 3-Acetylpyridine

This substituted nicotinamide analogue (FW = 121.14 g/mol; Boiling Point = 220°C), also known as methyl 3-pyridyl ketone, inhibits many NAD<sup>+</sup>-dependent reactions. 3-Acetylpyridine is often an alternative substrate for nicotinamide-utilizing enzymes. **Target(s):** nicotinamidase (1,8,10,11); NAD<sup>+</sup> ADP-ribosyltransferase (2); NAD<sup>+</sup> nucleosidase, *or* NADase (3-5,13); cAMP phosphodiesterase (6); acetylcholinesterase (7); NAD<sup>+</sup> diphosphatase (9); nicotinamide phosphoribosyltransferase, weakly inhibited (13); nicotinate phosphoribosyltransferase (14). 1. Joshi, Calbreath & Handler (1971) *Meth. Enzymol.* **18B**, 180. 2. Nishizuka, Ueda & Hayaishi (1971) *Meth. Enzymol.* **18B**, 230. 3. Anderson & Yuan (1980) *Meth. Enzymol.* **66**, 144. 4. ### 3-Acetylpyridine Adenine Dinucleotide Phosphate

This NADP<sup>+</sup> analogue (FW<sub>free-acid</sub> = 742.42; CAS 150729-98-9 (free acid)), also known as 3-acetyl-NADP<sup>+</sup>, is a poor substrate for many NADP<sup>+</sup>-dependent enzymes, including glucose-6-phosphate dehydrogenase (1); 4-hydroxyacetophenone monooxygenase (2); phenylacetone monooxygenase (3). 1. Noltmann & Kuby (1963) *The Enzymes*, 2nd ed., 7, 223. 2. Kamerbeek, Fraaije & Janssen (2004) *Eur. J. Biochem.* **271**, 2107. 3. Fraaije, Kamerbeek, Heidekamp, Fortin & Janssen (2004) *J. Biol. ### Acetylsalicylate (Acetylsalicylic Acid & Aspirin)

This first-in-class pain-relieving and fever-lowering anti-inflammatory agent (FW<sub>free-acid</sub> = 180.16 g/mol; CAS 50-78-2; pK<sub>a</sub> = 3.49 at 25°C; Solubility = 3.3 mg/mL at 25°C; Symbol: ASA) is the original synthetic nonsteroidal anti-inflammatory drug, *or* NSAID. Aspirin exerts its effects by inactivating cyclooxygenase (*or* prostaglandin G/H synthase, *or* PGHS). It shows somewhat greater selectivity toward COX-1, the type-1 isozyme, with attendant inhibition of prostaglandin formation. Acetylsalicylic acid also inhibits platelet thromboxane synthesis as well as the ADP- and collagen-induced platelet release reaction. Low-dose aspirin is effective in preventing ~20% of atherothrombotic complications (including non-fatal myocardial infarction, non-fatal stroke, or vascular death) in patients with prior evidence of myocardial infarction, stroke, or transient cerebral ischemia. **Mechanism of Action:** That aspirin targets prostaglandin formation was first demonstrated by Piper & Vane (1), a finding that earned Vane the Nobel Prize in Physiology and Medicine in 1982. Aspirin selectively acetylates the hydroxyl group of Ser-530 in COX-1, irreversibly inhibiting the enzyme (2). This outcome requires *de novo* enzyme synthesis before prostanoid synthesis can resume. When purified PGHS is acetylated, its COX activity is inhibited, but *not* its hydroperoxidase activity. One acetyl group is incorporated per monomer of the dimeric enzyme. At low concentrations, aspirin acetylates PGHS rapidly (usually within minutes) in a highly selective reaction that prevents arachidonate binding. At higher concentrations, aspirin non-specifically acetylates a variety of proteins and even nucleic acids. Upon modification of COX-2, the latter produces lipoxins, of which most are anti-inflammatory. **Pharmacokinetics & Metabolism:** Aspirin is both a drug and prodrug, depending on its target. It is rapidly absorbed from the stomach and intestine by passive diffusion. Pertinent PK parameters for acetylsalicylate are: Oral Bioavailability = 68%; Clearance = 39 L/hour; Volume of Distribution = 10.5 L; and *t*<sub>1/2</sub> = 0.25 hours. Acetylsalicylate is transformed into salicylate in stomach, intestinal mucosa, blood, and liver, the latter being the main site. Salicylate distributes rapidly into the body fluid compartments, binding to albumin within plasma. With increasing total plasma salicylate concentrations, the unbound fraction increases. Pertinent PK parameters for salicylate are: Clearance = 0.6-3.6 L/hour, depending on dose; Volume of Distribution = 11.5 L; and *t*<sub>1/2</sub> = 2-30 hours, depending on aspirin dose. Salicylate also activates AMP-stimulated protein kinase (AMPK), a property likely to account for some of aspirin's anti-cancer and anti-inflammatory effects (3). ASA can also be used during a heart attack to reduce the risk of dying from the heart attack. **Chemical Synthesis:** Acetylsalicylate was first synthesized from salicylate and acetyl chloride by Felix Hofmann at Friedrich Bayer & Co. in 1897, and its name universally known name, "aspirin", was coined by then supervising pharmacologist, Heinrich Dreser, to avoid confusion with salicylic acid. The famously high purity and stability of the Bayer product is evident by the absence of a vinegary odor, long after the packaged product is first opened. Prolonged exposure to moisture, however, generates both acetate and salicylate, with the latter inhibiting some 20-30 enzymes (*See Salicylate*). **Nonenzymatic Aspirin Hydrolysis:** Hydrolysis of acetylsalicylic acid presents the interesting case where the reaction rate is pH-independent over range from 4 to 8. As shown nearly a half century ago (4), aspirin undergoes general base catalysis. Later work suggests that aspirin anion exists only fleetingly, rearranging by acetyl transfer to the *ortho*-carboxylate group, as indicated by IR, UV and NMR (5). The mixed anhydride then cyclizes to the more stable bicyclic orthoacetate isomer, a process facilitated by time and increasing pH. **Target(s):** prostaglandin-endoperoxide synthase, *or* cyclooxygenase (6,7,10,11,16,28-31);  $\zeta$ -crystallin (8); creatine kinase (9), 15-

hydroxyprostaglandin dehydrogenase (10); cyclooxygenase-16 (16); cyclooxygenase-26 (16); hemoglobin S polymerization (12), however, See Reference 13; glutamine:D-fructose-6-phosphate aminotransferase (14); ATPase, mitochondrial (15); aryl-acylamidase (17); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (18); phospholipase A<sub>2</sub> (19); estrone sulfotransferase (20); phenol sulfotransferase, or aryl sulfotransferase (20); IκB kinase (21,22); procollagen glucosyltransferase (23); N-hydroxyarylamine O-acetyltransferase (24); 1-alkylglycerophosphocholine O-acetyltransferase (25,26); thiopurine S-methyltransferase (32); 3-hydroxyanthranilate 3,4 dioxxygenase (32). 1. #### N-Acetyl-seryl-aspartyl-lysyl-proline

This human plasma hemoregulatory peptide (FW = 487.51 g/mol; Sequence: AcSDKP), also known by the trade name Seraspenside<sup>®</sup>, is a bone marrow-derived negative regulator that inhibits pluripotent hematopoietic stem cell entry into the S-phase of the cell cycle (1-4). It increases the survival of mice treated with chemotherapeutic agents, such that the agents are selectively cytotoxic to cancer, but not untransformed, cells. Ac-SDKP inhibits endothelin-1-induced activation of p44/42 mitogen-activated protein kinase and collagen production in cultured rat cardiac fibroblasts by preserving SHP-2 activity and thereby preventing p44/42 MAPK activation (5). Incubation of normal human mononuclear cells with AcSDKP (10<sup>-10</sup> to 10<sup>-9</sup> M) significantly inhibits GMCF- and erythroid burst-forming growth, but no effect is seen at higher AcSDKP concentrations (6). **Metabolism:** AcSDKP is most likely derived from thymosin-β4 (7), the human actin monomer-sequestering protein (Sequence: MSDKPDMAEIEKFDKSKLKKTTETQEKNPPLSKETIEQEK QAGES), suggesting the likely involvement of proteases and an acetylase. AcSDKP is completely degraded (t<sub>1/2</sub> = 80 min) in human plasma (8). After 128 nmol/kg was given as a 12-hr intravenous infusion, NAc-SDKP was quickly eliminated, with a mean t<sub>1/2</sub> of 4.5 min (9). While insensitive to leupeptin. AcSDKP cleavage is sensitive to metalloprotease inhibitors (8). The finding that cleavage is blocked by specific angiotensin I-converting enzyme (or ACE) inhibitors, demonstrated that the first step is catalyzed by this hydrolase. Hydrolysis of AcSDKP by commercial rabbit lung ACE generated the C-terminal dipeptide Lys-Pro. Depending on the kinetics, an alternative substrate like AcSDKP may well be an endogenous ACE modulator (8). 1. Frindel & Guigon (1977) *Exp. Hematol.* **5**, 74. 2. #### D-erythro-N-Acetyl sphingosine

This short-chain ceramide (FW = 341.53 g/mol), also known as D-erythro-C2-ceramide, is a cell-permeable, biologically active ceramide that induces differentiation and apoptosis. It also stimulates certain protein phosphatases as well as phosphatidylglycerol phosphate synthase. **Target(s):** acyl-CoA:cholesterol acyltransferase, or ACAT (1); Ca<sup>2+</sup> channels, L-type (2,3); choline-phosphate cytidyltransferase, or CTP:phosphocholine cytidyltransferase (4,9,10); Na<sup>+</sup>/Ca<sup>2+</sup> exchange (5); phospholipase D (6,7); ubiquinol:cytochrome c reductase, complex III (8); ceramide kinase, as weak alternative substrate (11,12). 1. #### N-Acetyltryptamine

This partial receptor agonist (FW = 202.26 g/mol; CAS 1016-47-3; Soluble to 100 mM in DMSO) is a melatonin (or 5-methoxy-N-acetyltryptamine) mimic and is more potent than melatonin in inhibiting dopamine release from presynaptic melatonin receptor site of rabbit retina labeled *in vitro* with [<sup>3</sup>H]dopamine. 1. Dubocovich (1988) *J. Pharmacol. Exp. Ther.* **246**, 902.

#### N-Acetyl-L-tryptophan 3,5-bis(trifluoromethyl)-benzyl Ester

This ester (FW = 472.39 g/mol) is a potent substance P receptor antagonist of the human substance P receptor, or neurokinin-1 (NK-1) receptor, with 230- and 10-fold reduced affinity for mutant NK-1 receptors in which histidine 265 or histidine 197, respectively, are replaced by alanine. These residues play key roles in the binding of quinuclidine antagonists to the NK-1 receptor. 1. MacLeod, Merchant, Cascieri, et al. (1993) *J. Med. Chem.* **36**, 2044. 2. Cascieri, Macleod, Underwood, et al. (1994) *J. Biol. Chem.* **269**, 6587.

**N<sup>ε</sup>-Acetyl-L-tryptophanyl-L-glutamyl-L-histidyl-L-aspartate α-Semialdehyde**

This tetrapeptide aldehyde (MW = 585.57), abbreviated Ac-WEHD-CHO, strongly inhibits caspase-1,  $K_i = 56$  pM (1,4), caspase-3 (4); caspase-4 (1,4); caspase-5 (1,4); caspase-6 (4); caspase-8,  $K_i = 21.1$  nM (4); caspase-9 (4); caspase-10 (4). 1. **N-Acetyl-D-tryptophanyl-L-leucyl-L-aspartyl-L-isoleucyl-L-isoleucyl-L-tryptophan**

This acetylated hexapeptide (FW<sub>free-acid</sub> = 887.05 g/mol), corresponding to residues 16-21 of human, pig, and dog endothelin-1 (except that D-Trp16 is in place of L-His16), inhibits endothelin ETA receptor. Endothelins are 21-amino acid vasoconstricting peptides mainly produced in the endothelium and exerting a key role in vascular homeostasis. 1. Cody, Doherty, He, *et al.* (1992) *J. Med. Chem.* **35**, 3301.

**N-Acetyl-L-tyrosine Ethyl Ester**

This ester (FW = 251.28 g/mol; Abbreviation ATEE) is a substrate for chymotrypsin that is frequently used in assays of that enzyme. The reaction can be followed by observing the production of free carboxyl groups or by the decrease in absorbance at 237 nm and pH 7. Supersaturated stock solutions (*i.e.*, 10-20 mM) can be prepared by dissolving ATEE in water at 85°C, followed by rapidly cooling to room temperature. These solutions are typically stable for six to twelve hours. N-Acetyl-L-tyrosine ethyl ester inhibits protein-disulfide reductase, glutathione-requiring (1); thiolsubtilisin (2); complement component C<sup>3</sup> (3). 1. Tomizawa (1971)

**N<sup>ε</sup>-Acetyl-L-tyrosyl-L-valyl-L-alanyl-L-aspartate Chloromethyl Ketone**

This halomethyl ketone (FW<sub>free-acid</sub> = 541.00 g/mol), often abbreviated Ac-YVAD-CMK and referred to as interleukin-1β converting enzyme inhibitor II, inhibits caspase-1 ( $K_i = 760$  pM) and caspase-4. It also protects against neurodegeneration by inhibition of cathepsin B. **Target(s):** caspase-1 (1-4); caspase-4 (3); cathepsin B (4). **See also** L-Tyrosyl-L-valyl-L-alanyl-L-aspartic Chloromethyl Ketone 1. **N<sup>ε</sup>-Acetyl-L-tyrosyl-L-valyl-L-alanyl-L-aspartate α-Semialdehyde**

This tetrapeptide aldehyde (FW<sub>free-acid</sub> = 492.53 g/mol), often abbreviated Ac-YVAD-CHO, inhibits caspase-1 ( $K_i = 0.2$  nM) and caspase-4. A cell-permeable derivative of this inhibitor is Ac-AAVALLPAVLLALLA PYVAD-CHO, in which the N-terminus of YVAD-CHO has been linked to the N-terminal sequence (residues 1-16) of the membrane-penetrating signal peptide of the Kaposi fibroblast growth factor. **Target(s):** caspase-1 (1-7,10); caspase-4 (3,6,9,10); caspase-3 (5); caspase-5 (3,6,9); caspase-8 (3); caspase-9 (3); caspase-10 (3,8). 1. **N<sup>ε</sup>-Acetyl-L-valyl-L-aspartyl-L-valyl-L-alanyl-L-aspartate α-Semialdehyde**

This pentapeptide aldehyde (FW<sub>free-acid</sub> = 543.57 g/mol), often abbreviated Ac-VDVAD-CHO, inhibits caspase-2,  $K_i = 3.5$  nM (1), caspase-3,  $K_i = 1.0$

nM (1), caspase-7,  $K_i = 7.5$  nM (1), and an ecdysone-inducible *Drosophila* caspase, DRONC (2). 1. Talanian, Quinlan, Trautz, *et al.* (1997) *J. Biol. Chem.* **272**, 9677. 2. Dorstyn, Colussi, Quinn, Richardson & Kumar (1999) *Proc. Natl. Acad. Sci. U.S.A.* **96**, 4307.

**{N-[N-Acetyl-L-valyl-L-valyl]-(5S-amino-4S-hydroxy-2-isopropyl-7-methyloctanoyl)]-L-isoleucine 2-Pyridylmethylamide**

This pseudopeptide amide (FW = 674.93 g/mol), also named U85964E and Ac-Val-Val-Leuψ[CH(OH)CH<sub>2</sub>]Val-Ile-Amp (where ψ indicates a reduced peptide linkage), inhibits rhizopuspepsin,  $K_i = 0.12$  nM (1,2), HIV-1 protease,  $K_i = 19$  nM (1), HIV-2 protease,  $K_i = 12$  nM), and human pepsin,  $K_i = 0.1$  nM (1). 1. Lowther, Sawyer, Staples, *et al.* (1992) in *Peptides: Chemistry and Biology Proc. of the 12th Amer. Peptide Symp.* (June 16-21, 1991) (Smith & Rivier, eds), p. 413. 2. Sawyer, Staples, Liu, *et al.* (1992) *Int. J. Pept. Protein Res.* **40**, 274.

**ACHP**

This novel IKK inhibitor (FW = 364.44 g/mol; CAS 406208-42-2; Soluble to 20 mM in DMSO), also named 2-amino-6-[2-(cyclopropylmethoxy)-6-hydroxyphenyl]-4-(4-piperidinyl)-3-pyridinecarbonitrile, targets IκB kinases, with respective IC<sub>50</sub> values of 8.5 and 250 nM for IKKβ and IKKα. ACHP's selectivity is indicated by its > 20-μM IC<sub>50</sub> values toward IKK3, Syk, and MAPKKK4. Inhibition of the TNFα-mediated gene expression could occur at low ACHP concentration (<1 μmol/L), with higher concentrations (>10 μmol/L) required to inhibit the constitutive phosphorylation of p65, expression of NF-κB-mediated genes (e.g., *CYCLIN D1*, *BCL-xL*, *XIAP*, *c-IAP1*, and *IL-6*), ultimately achieving myeloma cytostasis. Such findings indicate that ACHP's growth inhibitory effects may be mediated through inhibition of both IKKα and IKKβ. By inhibiting NF-κB's DNA binding activity, ACHP blocks the NF-κB pathway in multiple myeloma cell lines, inducing growth arrest and apoptosis. 1. Sanda, Iida, Ogura, *et al.* (2005) *Clin. Cancer Res.* **11**, 1974.

**Acitretin**

This orally active, synthetic retinoid (FW = 326.43 g/mol; CAS 55079-83-9), systematically named as (2E,4E,6E,8E)-9-(4-methoxy-2,3,6-trimethylphenyl)-3,7-dimethylnona-2,4,6,8-tetraenoic acid, inhibits calcineurin, weakly (1), retinol dehydrogenase (2), retinyl-palmitate esterase (3), and ribonuclease P (4,5). Acitretin is used to treat psoriasis by binding to nuclear receptors regulating gene transcription and inducing keratinocyte

differentiation, thereby reducing epidermal hyperplasia. 1. Spannaus-Martin & Martin (2000) *Biochem. Pharmacol.* **60**, 803. 2. Karlsson, Vahlquist, Kedishvili & Törmä (2003) *Biochem. Biophys. Res. Commun.* **303**, 273. 3. Ritter & Smith (1996) *Biochim. Biophys. Acta* **1291**, 228. 4. Papadimou, Georgiou, Tsambaos & Drinas (1998) *J. Biol. Chem.* **273**, 24375. 5. Papadimou, Pavlidou, Séraphin, Tsambaos & Drinas (2003) *Biol. Chem.* **384**, 457.

**Acivicin**

This cytotoxic isoxazole and copper chelator (FW = 178.57 g/mol; CAS 42228-92-2; Source: *Streptomyces sviveus*), also known as L-(αS,5S)-α-amino-3-chloro-4,5-dihydro-5-isoxazoleacetic acid, AT-125, and NSC-165301, strongly inhibits γ-glutamyl transpeptidase (1-5,9,10,18,19,26-30). Its clinical application in cancer treatment failed as a consequence of unacceptable toxicity, and the cause(s) of the desired and undesired biological effects have never been elucidated and only limited information about acivicin-specific targets is available (32). Target deconvolution by quantitative mass spectrometry (MS) has now revealed acivicin's preference for the specific aldehyde dehydrogenase known as ALDH4A1 by binding to the catalytic site (32). Moreover, siRNA-mediated downregulation of ALDH4A1 results in a severe inhibition of cell growth, a finding that may explain acivicin's cytotoxicity (32). **Targets:** Acivicin is thought to be a glutamine analogue, an assumption that is amply supported by its ability to inhibit the following enzymes that possess essential amidohydrolase activities that generate nascent ammonia: asparagine synthetase (6,24); carbamoyl-phosphate synthetase (7,8,12,13,23); anthranilate synthase (11); glutamate synthase (11); CTP synthetase (13,15,25); amidophospho-ribosyltransferase (13); glutaminase (asparaginase), or glutaminase-asparaginase (14); GMP synthase, glutamine-dependent (15,20,22); phosphoribosyl-formylglycinamide synthetase (formylglycinamide ribonucleotide synthetase (16); thiol oxidase (17,31); γ-glutamyl hydrolase (21); imidazole-glycerol phosphate synthetase (22). 1. ## Aclacinomycin A

This non-peptidic aclacinomycin antibiotic (FW = 811.88 g/mol; CAS 57576-44-0; Source: strain of *Streptomyces galilaeus*), also known as aclarubicin, induces DNA strand scission. **Target(s):** nitric oxide synthase (1); RNA biosynthesis (2); DNA polymerase I (3,5); RNA polymerase, *Escherichia coli* (3); reverse transcriptase, avian myeloblastosis virus (3); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (4); Ca<sup>2+</sup>-transporting ATPase (4); cyclic-nucleotide phosphodiesterase (6); electron transport and oxidative phosphorylation, mitochondrial (7); DNA helicase (8); DNA topoisomerase II (9,13-15); 20S proteasome, chymotrypsin-like activity (10); DNA topoisomerase I (11); 3'-5' DNA helicase, *Plasmodium falciparum* (12). 1. **cis-Aconitate (cis-Aconitic Acid)**

This tricarboxylic acid (FW<sub>free-acid</sub> = 174.11 g/mol; CAS 585-84-2), systematically referred to as (Z)-prop-1-ene-1,2,3-tricarboxylic acid, is an intermediate in the reversible conversion of citrate to isocitrate: the enzyme aconitate hydratase catalyzes the interconversion of citrate and *cis*-aconitate as well as *cis*-aconitate with isocitrate. *cis*-Aconitate is also a product of the reactions catalyzed by citrate dehydratase and aconitate Δ-isomerase. It is a substrate for aconitate decarboxylase and an alternative substrate for *trans*-aconitate 2-methyltransferase and *trans*-aconitate 3-methyltransferase. **Target(s):** phosphofructokinase (1,2,4); glutamate decarboxylase (2,5,7); isocitrate dehydrogenase, NADP<sup>+</sup>-dependent (3,11); 3-carboxy-*cis,cis*-muconate cyclase (6); chorismate mutase/prephenate dehydratase (8,10); α-ketoglutarate dehydrogenase (9); isocitrate lyase (12); phosphoglucumutase, weakly inhibited (13); prephenate dehydratase (8); fumarase, or fumarate hydratase (15); glucose-1,6-bisphosphate synthase (16). **Note:** Aqueous solutions are relatively stable between pH 7 and 10 at temperatures up to 90°C; however, isomerization to *trans*-aconitate occurs at pH values outside of that range (69% *cis* aconitate is recovered after 96 hours at pH 3 and 25°C [43.7% after 72 hours at pH 3 and 65°C] and 73.6% is recovered after 96 hours at pH 13 and 25°C [48.5% after 72 hours at pH 13 and 65°C] (14). 1. **trans-Aconitate (trans-Aconitic Acid)**

This tricarboxylic acid (FW<sub>free-acid</sub> = 174.11 g/mol; CAS 585-84-2), named systematically as (E)-prop-1-ene-1,2,3-tricarboxylic acid, is the geometric isomer of the intermediate in the reversible conversion of citrate to isocitrate. *trans*-Aconitate occurs naturally and is a substrate for aconitate Δ-isomerase, *trans*-aconitate 2-methyltransferase, and *trans*-aconitate 3-methyltransferase. **Target(s):** aconitate, or *cis*-aconitate hydratase (1,4-8,10,13,14,18,19); fumarase, or fumarate hydratase (2,3,9,10,15,20); glutamate decarboxylase (10,11); chorismate mutase/prephenate dehydratase (12); carboxy-*cis,cis*-muconate cyclase (16); phosphoenolpyruvate mutase (17); prephenate dehydratase (12); aconitate decarboxylase (21); β-fructofuranosidase, or invertase (22); glucose-1,6-bisphosphate synthase (23). 1. **Aconitine**

This violently poisonous alkaloid (FW<sub>free-base</sub> = 645.75 g/mol; CAS 302-27-2), obtained from *Aconitum napellus* (wolf's bane or monk's hood) is a neurotoxin that activates tetrodotoxin-sensitive sodium channels (1), inducing presynaptic depolarization and blocking nerve action potential. In addition, aconitine blocks norepinephrine reuptake (K<sub>i</sub> = 230 nM) and inhibits pig heart aconitase (K<sub>i</sub> = 0.11 mM). In humans, the lethal dose can be <2 mg. In ancient times, aconitine preparations were used as arrow poisons. **Target(s):** aconitase (2); neurotransmitter release (3); norepinephrine reuptake (4). 1. Conn (1983) *Meth. Enzymol.* **103**, 401. 2.

### ACPA

This highly selective, synthetic CB<sub>1</sub> receptor agonist (FW = 343.55 g/mol; CAS 229021-64-1), also known as arachidonylcyclopropylamide and *N*-(cyclopropyl)-5*Z*,8*Z*,11*Z*,14*Z*-eicosatetraenamide, targets CB<sub>1</sub> cannabinoid receptor agonist ( $K_i = 2.2$  nM) with >325-fold selectivity over CB<sub>2</sub> receptors. Two subtypes of the cannabinoid receptor (CB<sub>1</sub> and CB<sub>2</sub>) are expressed in mammalian tissues. Although selective antagonists are available for each of the subtypes, most of the available cannabinoid agonists bind to both CB<sub>1</sub> and CB<sub>2</sub> with similar affinities (1). ACPA possesses the characteristics of CB<sub>1</sub> receptor agonists, inhibiting forskolin-induced cAMP accumulation in Chinese hamster ovary cells expressing the human CB<sub>1</sub> receptor. It also increases the binding of [<sup>35</sup>S]GTPγS to cerebellar membranes and inhibits electrically evoked contractions of the mouse *vas deferens* (1). **See also ACEA 1.** Hillard, Manna, Greenberg, *et al.* (1999) *J. Pharmacol. Exp. Ther.* **289**, 1427. **2.** Patel & Hillard (2001) *J. Pharmacol. Exp. Ther.* **297**, 629.

### Acridine Orange

This cell-permeable dye (FW<sub>free-base</sub> = 265.36 g/mol; CAS 65-61-2), also known as *N,N,N',N'*-tetramethylacridine-3,6-diamine, is an intercalator that binds tightly to nucleic acids. Binding to DNA is characterized by excitation maximum at 502 nm (cyan) and an emission maximum at 525 nm, producing a green fluorescence. (A 120 μM solution of acridine orange will detect 25-50 ng DNA per band in an agarose or polyacrylamide gel.) Binding to RNA is characterized by an excitation maximum at 460 nm and the emission maximum is located at 650 nm, yielding a reddish-orange fluorescence. Acridine orange also penetrates acidic compartments (*e.g.*, lysosomes and phagolysosomes); upon protonation, the dye emits orange light when excited by blue light. **1.** Ranadive & Korgaonkar (1960) *Biochim. Biophys. Acta.* **39**, 547. **2.** Boyle, Nelson, Dollish & Olsen (1962) *Arch. Biochem. Biophys.* **96**, 47.

### Acrivastine

This oral, non-sedating antihistamine (FW<sub>free-acid</sub> = 348.44 g/mol; CAS 87848-99-5), also named Semprex and (*E*)-3-{6-[(*E*)-1-(4-methylphenyl)-3-pyrrolidin-1-yl-prop-1-enyl]-pyridin-2-yl}prop-2-enoic acid, is a histamine H<sub>1</sub> receptor antagonist,  $K_i = 0.63$  nM. **1.** Hill, Ganellin, Timmerman, *et al.* (1997) *Pharmacol. Rev.* **49**, 253.

### Acrolein

This α,β-unsaturated aldehyde and thiol-reactive reagent (FW = 56.06 g/mol; CAS 107-02-8; M.P. = -88°C; B.P. = 52.5°C), also known as propenal, is an unstable liquid that polymerizes readily in the presence of light, alkali, or strong acid. Acrolein is soluble in water and ethanol. It is highly toxic, reactive, and irritating aldehyde that is often a product of organic pyrolysis (it has been identified in automobile exhaust, cigarette smoke, and burnt eggs). Acrolein has also been used as a herbicide. In addition, acrolein concentrations are reportedly elevated in the brains of individuals with Alzheimer's disease. Note also that acrolein is a reactive metabolite of both cyclophosphamide and allylamine. Acrolein is an irreversible active-site inhibitor of deoxyribose 5-phosphate aldolase. Treatment of carbonic anhydrase with acrolein results predominantly in the alkylation of a single histidyl residue, which is implicated in the transfer of a proton from zinc-bound water to buffer in solution. **Target(s):** 21-hydroxysteroid dehydrogenase, NAD<sup>+</sup>-dependent (1,9); carboxylase (2,3); aspartate aminotransferase (4); lecithin:cholesterol acyltransferase, *or* LCAT (5,25); succinate-semialdehyde dehydrogenase (6); glutathione *S*-transferase (7,18,21,27); deoxyribose-5-phosphate aldolase (8); carbonic anhydrase, *or* carbonate dehydratase (10,11,28); asparaginase12; NADPH:cytochrome *c* reductase (13,17); aldehyde dehydrogenase (14,19); *O*6-methylguanine-DNA methyl-transferase (15); 15 hydroxyprostaglandin dehydrogenase, NAD<sup>+</sup>-dependent (16); DNA methyltransferase (20); electron transport (22); glucose-6-phosphate dehydrogenase (23); DNA polymerase α (24); DNA-directed DNA polymerase (24); glutathione-disulfide reductase (26); alcohol dehydrogenase (29); protein phosphatase type 1 (30); pyruvate dehydrogenase complex (31); α-ketoglutarate dehydrogenase complex (31); protein-disulfide isomerase (32); phospholipid-translocating ATPase, *or* flippase (33); glycerol-2-phosphatase (34). **1.** Monder & Furfine (1969) *Meth. ### Acrylamide

This common laboratory reagent and neurotoxin (FW = 71.079 g/mol; CAS 79-06-1) reacts with sulfhydryl and amino groups. Acrylamide readily polymerizes in the presence of UV light or free radicals (such as those generated by ammonium persulfate) or when heated at the melting point (84.5°C). When copolymerized with a bifunctional cross-linker, acrylamide polymerization forms a well-hydrated gel suitable for many forms of

protein and nucleic acid electrophoresis. It is conveniently recrystallized by dissolving in hot chloroform and cooling overnight. **Caution:** Acrylamide is absorbed through unbroken skin, and the powdery solid is easily inhaled. Extreme care must be exercised when working with this reagent. **Target(s):** creatine kinase (1,2,12); cytochrome P450 C-2 (13); mitochondrial respiration (4); protein-glutamine  $\gamma$ -glutamyltransferase, or transglutaminase (5); enolase (6,9); glyceraldehyde-3 phosphate dehydrogenase (6-8); alcohol dehydrogenase (10); cytochrome  $b_2$  (11). 1. #### ACT 335827

This brain-penetrant and orally available orexin receptor antagonist (FW = 518.64 g/mol; CAS 1354039-86-3; Soluble to 100 mM in DMSO, also known as (aR,1S)-1-[(3,4-Dimethoxyphenyl)methyl]-3,4-dihydro-6,7-dimethoxy-N-(1-methylethyl)-a-phenyl-2(1H)-isoquinoline acetamide, elicits its anxiolytic effects *in vivo* by targeting OX<sub>1</sub> (K<sub>i</sub> = 41 nM) and OX<sub>2</sub> (K<sub>i</sub> = 560 nM) receptors. ACT-335827 decreases fear, compulsive behaviors, and autonomic stress reactions in rats. 1. Steiner, Gatfield, Brisbane-Roch, *et al.* (2013) *Chem. Med. Chem.* **8**, 898.

#### ACT-129968, See Setipiprant

#### ActA Fragment 269-278 or 304-313

This decapeptide FEFPPPTDE (MW = 1175.26 g/mol), corresponding the second oligoproline repeat in *Listeria monocytogenes* ActA surface protein, blocks actin-based locomotion *in vitro* or when micro-injected into *Listeria*-infected or *Shigella*-infected host cells, typically at submicromolar concentrations. FEFPPPTDE inhibits actin-based motility by disrupting the binding of vasodilator stimulated phosphoprotein (VASP) and other members of the Ena/VASP superfamily from binding to ActA on the surface of motile *Listeria* or proteolytically cleaved vinculin in the case of *Shigella flexnerii*. **See also ABM-1 & ABM-2 Sequences in Actin-Based Motors Target(s):** *Listeria* locomotion (1); vasodilator-stimulated phosphoprotein (VASP) binding to *Listeria* ActA, vinculin p90, and zyxin (1,2); *Shigella* locomotion (1). 1. Zeile, Purich & Southwick (1996) *J. Cell Biol.* **133**, 49. 2. Purich & F. Southwick (1997) *Biochem. Biophys. Res. Commun.* **231**, 686.

#### Acteoside

This plant glycoside and antioxidant (FW = 624.60 g/mol; CAS 61276-17-3), also known as verbascoside, inhibits TNF $\alpha$ -mediated apoptosis in LPS-stimulated macrophages (1) as well as 1-methyl-4-phenylpyridinium-induced apoptosis in cerebellar granule neurons (2). It also inhibits proliferation of human promyelocytic HL-60 leukemia cells by inducing cell cycle arrest at the G<sub>0</sub>/G<sub>1</sub> phase, followed by differentiation into

monocytes (3). Acteoside inhibits PMA-induced invasion and migration of human fibrosarcoma cells by Ca<sup>2+</sup>-dependent CaMK/ERK and JNK/NF- $\kappa$ B-signaling pathways. Acteoside thus shows the potential as antimetastatic agent (4). Another intriguing finding is that acteoside inhibits amyloid- $\beta$  aggregation (5). **Target(s):** aldose reductase (6); protein kinase C (7); integrase, HIV-1 (8); peptidyl-dipeptidase A, or angiotensin-converting enzyme (9,10); tyrosinase, or monophenol monooxygenase (11); 5-lipoxygenase, or arachidonate 5-lipoxygenase (12,13). 1. #### Actinomycin D

This widely used member (FW = 1255.44 g/mol; CAS 50-76-0; where Sar = sarcosine; mV = N-methyl-valine) of the actinomycin family of structurally related antibiotics was isolated from *Streptomyces* strains by Selman Waksman, who was awarded the 1952 Nobel Prize in Physiology or Medicine for his codiscovery of streptomycin. All actinomycins share a substituted phenoxazine ring and contain two cyclic heterodetic peptides differing only with respect to side-chain groups. Also known as actinomycin C1, cosmegen, and dactinomycin, actinomycin D is a potent transcription inhibitor in eukaryotes, prokaryotes, and chloroplasts, acting by intercalating into duplex DNA (reportedly at GpC sequences), blocking the latter's ability to serve as a template for DNA-directed RNA polymerases. Use of actinomycin D actually assisted in the discovery of messenger RNA. Actinomycin D does not greatly alter DNA replication and does not bind to RNA or single-stranded DNA and will inhibit the replication of DNA viruses. DNA polymerase can be inhibited at elevated concentrations. Despite its low therapeutic index, actinomycin D is used as an antineoplastic agent (under the generic name Dactomycin) to treat various sarcomas, carcinomas, and adenocarcinomas. In 1943, it became the first antibiotic discovered to have antitumor activity. **Properties:** Unstable in dilute base or bright light, actinomycins form bright red-colored crystals that are highly soluble in benzene and chloroform but only slightly soluble in water and methanol. The UV/visible spectrum of actinomycin D exhibits  $\lambda_{max}$  values (in methanol) at 244 and 441 nm. **Target(s):** DNA-directed RNA polymerase (1-4,12,15,16,27,28); viral RNA polymerase (5,14); deoxyribonuclease I (6); DNA-directed DNA polymerase (7,18); RNA-directed DNA polymerase (8); deoxyribonuclease II (spleen acid deoxyribonuclease)10; DNA methyltransferases (11); *EcoRI* (13); *EcoRII* restriction endonuclease (13); *HinDII* restriction endonuclease (13); *HinDIII* restriction endonuclease (13); *HpaI* restriction endonuclease (13); *HpaII* restriction endonuclease (13); exodeoxyribonuclease I (17); DNA ligase (ATP), Vaccinia virus (19); DNA topoisomerase I (20-22); DNA topoisomerase II (23,24); P-glycoprotein (25); xenobiotin-transporting ATPase, or multidrug-resistance protein (25); thermite, inhibited by actinomycins D and SG3 (26); subtilisin (26); peptidase K, or proteinase K (26); tryptophan 2,3-dioxygenase, inhibited by actinomycin D (29). 1. ### Actinonin

This antibiotic (FW = 385.50 g/mol; CAS 13434-13-4), also named (2*R*)-*N*<sup>4</sup>-hydroxy-*N*<sup>1</sup>-[(2*S*)-1-[(2*S*)-2-(hydroxymethyl)pyrrolidin-1-yl]-3-methyl-1-oxobutan-2-yl]-2-pentylbutanediamide, is an actinomycete metabolite that potentially inhibits peptide deformylase as well as other peptidases. **Target(s):** leucyl aminopeptidase, *Leishmania* sp. (8); membrane alanyl aminopeptidase, or aminopeptidase N (1,2,27-32); meprin A, *K<sub>i</sub>* = 0.135 μM (3,4,11); astacin, weakly inhibited (4,11,24); acyl amidase-like leucyl aminopeptidase (5); neprilysin (6); neutrophil leucyl aminopeptidase, weakly inhibited (7); collagenase (9,10); interstitial collagenase, or fibroblast collagenase (12); stromelysin 1 (12); peptide deformylase (13,15-22); gelatinase A (14); ADAMTS-4 endopeptidase, or aggrecanase (23); meprin B (24); meprin A (11,24); cytosol alanyl aminopeptidase (25); aminopeptidase B (26). **1.** Umezawa, Aoyagi, Tanaka, et al. ### Aculeacin A

This antifungal antibiotic (FW = 1036.23 g/mol; CAS 58814-86-1) is a cyclopeptide-containing long-chain fatty acid that inhibits cell wall biosynthesis by targeting 1,3-β-D-glucan synthase. **1.** Taft, Zugel & Selitrennikoff (1991) *J. Enzyme Inhib.* **5**, 41. **2.** Beaulieu, Tang, Zeckner & Parr, Jr. (1993) *FEMS Microbiol. Lett.* **108**, 133.

### ACV 1

This neuronal nicotinic acetylcholine receptor antagonist (FW = 1806.98 g/mol; CAS 740980-24-9), also known as Conotoxin Vc1.1, is produced from mRNA in venom duct of *Conus victoriae* (1). ACV 1 selectively targets the α<sub>9</sub>α<sub>10</sub> nAChR subtype (IC<sub>50</sub> = 19 nM), with weaker action against α<sub>6</sub>/α<sub>3</sub>β<sub>2</sub>β<sub>3</sub> (IC<sub>50</sub> = 140 nM), α<sub>6</sub>/α<sub>3</sub>β<sub>4</sub> (IC<sub>50</sub> = 980 nM), α<sub>3</sub>β<sub>4</sub> (IC<sub>50</sub> = 4200 nM), and α<sub>3</sub>β<sub>2</sub> (IC<sub>50</sub> = 7300 nM) nAChR subtypes (2). ACV-1 suppresses vascular responses to unmyelinated sensory nerve C-fiber activation in rats, as related to pain transmission (1). ACV-1 and its posttranslationally modified analogues vc1a, [P6O]Vc1.1, and [E14γ]Vc1.1 are equally potent at inhibiting ACh-evoked currents mediated by α<sub>9</sub>α<sub>10</sub> nAChRs (3). **1.** Sandall, Satkunanathan, Keays, et al. (2003) *Biochemistry* **42**, 6904. **2.** Vincler, Wittenauer, Parker, et al. (2006) *Proc. Natl. Acad. Sci. USA.* **103**, 17880. **3.** Nevin, Clark, Klimis, et al. (2007) *Mol. Pharmacol.* **72**, 1406.

### Acyclovir

This guanosine analogue (FW = 225.21 g/mol; CAS 59277-89-3), also known as acycloguanosine and 9-(2-hydroxyethoxymethyl)guanine, is a widely used and highly effective pro-drug for the treatment of herpes infections (1-5). Once transported in cells, where it is metabolically phosphorylated by viral thymidine kinases to the monophosphate and then to the di- and triphosphate by host cell guanylate kinase and nucleoside 5'-diphosphokinase, acyclovir becomes a potent inhibitor of viral DNA polymerases, with minimal host toxicity. The triphosphate halts viral replication via inhibition of viral DNA polymerases, attended by incorporation and termination of growing viral DNA chains. The selectivity of acyclovir action was investigated by Gertrude Elion and coworkers (Elion shared the 1988 Nobel Prize in Physiology or Medicine). **Target(s):** viral DNA polymerases, via the 5'-triphosphate (1-4); HSV-1 replication (2); varicella zoster virus replication (2); murine cytomegalovirus DNA polymerase (5); purine-nucleoside phosphorylase (6,8-11); thymidine kinase (7); glycine *N*-methyltransferase, weakly inhibited (12); tryptophan 2,3-dioxygenase (13). **Key Pharmacokinetic Parameters:** After intravenous dosing of patients with normal renal function, 8-14% of the dose is recovered in the urine as the metabolite 9-carboxymethylguanine (14). Adequate distribution of acyclovir occurs in the cerebrospinal fluid, vesicular fluid, vaginal secretions and tissues. The low plasma protein binding of acyclovir precludes drug interactions involving binding displacement. When IV doses in the range of 2.5-15 mg/kg are given every 8 h to adult patients, dose-independent

kinetics is observed. Continuous infusions of acyclovir over an equivalent daily dose range have achieved predictable plasma levels. Acyclovir half-life and total body clearance are influenced significantly by renal function, and dosage adjustments should be made for patients with impaired renal function (14). **See also** Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). For additional information on acyclovir's PK properties. **1.** Wilson, Porter & Reardon (1996) *Meth. Enzymol.* **275**, 398. **2.** Prisbe & Chen (1996) *Meth. ### Acyclovir Triphosphate

This nucleotide analogue, also known as acycloguanosine triphosphate and 9-([2'-hydroxyethoxy]methyl)guanine 2'-triphosphate (FW free acid = 465.15 g/mol), halts viral replication via inhibition of viral DNA polymerases and incorporation and termination of growing viral DNA chains. The selectivity of its action was investigated by Nobelist Gertrude Elion and coworkers. **Target(s):** DNA polymerases, viral (1-4); mRNA (nucleoside-2'-O-)-methyltransferase (5). **1.** Ator & Ortiz de Montellano (1990) *The Enzymes*, 3<sup>rd</sup> ed., **19**, 213. **2.** Elion, Furman, Fyfe, de Miranda, Beauchamp & Schaeffer (1977) *Proc. Enzymol.* **275**, 398. **5.** Benarroch, Egloff, Mulard, Guerreiro, Romette & Canard (2004) *J. Biol. Chem.* **279**, 35638.

### ACZ885, See Canakinumab

### Adalimumab

This widely used human monoclonal antibody (Mol. Wt. = 144,190.3 kDa; CAS 331731-18-1; bioavailability = 64% Subcutaneous; Half-life = 10-20 days), known commercially as Humira, is used in the treatment of autoimmune diseases by blocking the action of the soluble pro-inflammatory cytokine, tumor necrosis factor, or TNF (1). Adalimumab and four other anti-TNF agents (infliximab, etanercept, golimumab and certolizumab pegol) are approved worldwide for the treatment of rheumatoid arthritis. These anti-TNF agents bind to and neutralize soluble TNF-alpha, exerting different effects on transmembrane TNF-alpha-expressing cells. Differences in affinity and avidity for soluble and transmembrane TNF-alpha have been demonstrated (2). **1.** Kempeni (1999) *Ann. Rheum. Dis.* **58**, 170. **2.** Benucci, Saviola, Manfredi, Sarzi-Puttini & Atzeni (2012) *Acta Biomed.* **83**, 72.

### 2-((3R,5R,7R)-Adamantan-1-yl)-N-(2-(4-benzylpiperazin-1-yl)-2-oxoethyl)acetamide

This novel Ebola virus entry inhibitor (FW = 409.57 g/mol) targets Niemann-Pick C<sub>1</sub> (NPC<sub>1</sub>), an endosomal membrane protein that plays an essential role in Ebola infection by binding to the virus glycoprotein (GP). When combined with earlier findings, an emerging model of EboV infection involves cleavage of the GP<sub>1</sub> subunit by endosomal cathepsin

proteases, removing heavily glycosylated domains and exposing an N-terminal ligand for binding to NPC<sub>1</sub>. **1.** Côté, Misasi, Ren, *et al.* (2011) *Nature* **477**, 344.

### N-[N-(3-Adamant-1-yl)carbamoyl]-3-amidino-D-phenylalanine N-Phenethylamide

This phenylalanine derivative (FW = 457.58 g/mol), also known as (R)-2-(3-adamant-1-ylureido)-3-(3-carbimido[phenyl]-N-benzylpropionamide, inhibits serine proteases with moderately high affinity. Other amides also inhibit (*e.g.*, N-(4-aminophenyl)ethylamide, N-(2-chlorophenyl)ethylamide, N-(3-chlorophenyl)ethylamide, and N-(4-tert-butylphenyl)ethylamide). **Target(s):** coagulation factor Xa ( $K_i = 0.025 \mu\text{M}$ ); thrombin ( $K_i = 0.9 \mu\text{M}$ ); trypsin ( $K_i = 7.0 \mu\text{M}$ ). **1.** Mueller, Sperl, Stürzebecher, Bode & Moroder (2002) *Biol. Chem.* **383**, 1185.

### Adapalene

This synthetic retinoid (FW = 412.52 g/mol; CAS 106685-40-9), also known by the trade name Differin<sup>®</sup> Gel – 0.1% and systematically as 6-[3-(1-adamantyl)-4-methoxyphenyl] naphthalene-2-carboxylic acid, received FDA approval in 1996 for the treatment of acne. **Primary Mode of Action:** Adapalene does not bind to cytosolic retinoic acid binding proteins, binding instead to nuclear retinoic acid receptor (RAR) subtypes RAR $\beta$  and RAR $\gamma$ , thereby inhibiting keratinocyte differentiation. This inhibitory action on keratinocyte differentiation/ proliferation underlies adapalene's ability to resolve blemishes that form when oil becomes trapped in pore of the dermis. **Target(s):** triacylglycerol biosynthesis (1); inflammation (2); cell proliferation (3); induction of apoptosis in colorectal cancer cells *in vitro* (3). **1.** Sato, Akimoto, Kitamura, *et al.* (2013) *J. Dermatol. Sci.* **70**, 204. **2.** Akdeniz, Calka, Ozbek & Metin (2005) *Clin. Exp. Dermatol.* **30**, 570. **3.** Ocker, Herold, Ganslmayer, Hahn & Schuppan (2003) *Int. J. Cancer* **107**, 453.

### Adaptaquin

This brain-penetrant PHD2 inhibitor and antioxidant (FW = 377.82 g/mol; CAS 385786-48-1; Soluble to 100 mM in DMSO), also named 7-[(4-chlorophenyl)[(3-hydroxy-2-pyridinyl)amino]methyl]-8-quinolinol, targets Hypoxia-Inducible Factor (*or* HIF) prolyl hydroxylase-2 (1), a critical regulator of hematopoietic stem cell (HSC) maintenance during steady-state and stress (2). Indeed, this branched oxyquinoline molecule was named adaptaquin (AQ) to signify its ability to inhibit the HIF-PHDs and activate *adaptive* responses to hypoxia (1). Hypoxia is a prominent feature in the maintenance of HSC quiescence and multipotency. Adaptaquin also exhibits neuroprotective effects, enhancing functional recovery in rodent intracerebral hemorrhage models, via inhibition of ATF4 dependent genes (3). **1.** Neitemeier, *et al.* (2016) *Cell Death Dis.* **7**, e2214. **2.** Singh, Franke, Kalucka, *et al.* (2013) *Blood* **121**, 5158. **3.** Karuppagounder, *et al.* (2016) *Sci. Transl. Med.* **8**, 328.

**Adderall**

This proprietary mixture of amphetamine and dextroamphetamine salts (CAS Reg. Nos = 300-62-9 and 51-64-9; NLM Unique ID = C090411) is a CNS stimulant that is widely used to treat Attention Deficit Hyperactivity Disorder (ADHD) and narcolepsy. These agents act by blocking the reuptake of dopamine and norepinephrine into presynaptic neurons and by stimulating the release of these monoamines into the synaptic cleft (**See Amphetamine**). Adderall is also used as a performance and cognitive enhancer, and recreationally as an aphrodisiac and euphoriant.

**Adecyphenol**

This compound (FW = 280.28 g/mol; CAS Number = 104493-13-2) from *Streptomyces* sp. OM-3223 potently inhibits adenosine deaminase. The  $K_i$  value for the calf intestinal enzyme is 4.7 nM, showing slow, tight-binding characteristics. 1. Omura, Ishikawa, Kuga, *et al.* (1986) *J. Antibiot. (Tokyo)* **39**, 1219. 2. Omura, Tanaka, Kuga & Imamura (1986) *J. Antibiot. (Tokyo)* **39**, 309.

**Adefovir & Adefovir Dipivoxil**

This nucleotide analogue (FW = 273.19 g/mol; CAS 106941-25-7; IUPAC: {[2-(6-(6-amino-9H-purin-9-yl)ethoxy)methyl]phosphonic acid}) and its membrane-permeant prodrug (FW = 501.48 g/mol; CAS 142340-99-6; IUPAC: [2-(6-aminopurin-9-yl)ethoxymethyl-(2,2-dimethylpropanoyloxy methoxy)phosphoryl]oxymethyl 2,2-dimethylpropanoate; Trade Names: Hepsara<sup>®</sup> and Preveon<sup>®</sup>) are technically both prodrugs, inasmuch as they are metabolically transformed to adefovir triphosphate, which is the active reverse transcriptase inhibitor. It is approved for treating chronic hepatitis B in adults with evidently active viral replication as well as either evidence of persistent elevations in serum aminotransferases (primarily ALT) or histologically active disease. Adefovir also offers the advantage that resistance develops more slowly than Lamivudine. (**See also Entecavir; Lamivudine; Telbivudine; Tenofovir; Emtricitabine**) 1. De Clercq, Holý & Rosenberg (1989) *Antimicrob. Agents Chemother.* **33**, 185. 2. Barditch-Crovo, Toole, Hendrix *et al.* (1997) *J. Infect. Dis.* **176**, 406.

**Adenanthin**

This diterpenoid (FW = 484.63 g/mol; CAS 111917-59-0) from the leaves of *Rabdosia adenantha*, induces differentiation of acute promyelocytic leukemia (APL) cells. Adenanthin targets the conserved cysteine thiols of peroxiredoxins I and II (*or* Prx I and Prx II), inhibiting their peroxidase activities and consequently increasing cellular hydrogen peroxide. The latter leads to the activation of Extracellular signal-Regulated Kinases (ERKs) and increased transcription of CCAAT/enhancer-binding protein  $\beta$  (*or* C/EBPs), further contributing to differentiation. Adenanthin induces APL-like cell differentiation, represses tumor growth *in vivo* and prolongs the survival of mouse APL models that are sensitive and resistant to retinoic acid. 1. Liu, Yin, Zhou, *et al.* (2012) *Nature Chem. Biol.* **8**, 486.

**Adenine 9- $\beta$ -D-Arabinofuranoside**

This ribo- and 2'-deoxyriboadenosine analogue and anti-viral (FW = 267.24 g/mol; CAS 58-61-7;  $\lambda_{\text{max}}$  = 259 nm;  $\epsilon_{\text{M}}$  = 15400 M<sup>-1</sup>cm<sup>-1</sup>; Source: *Streptomyces antibioticus* strain), also known as Ara-A, arabinofuranosyladenine, vidarabine, spongoadenosine and (2R,3S,4S,5R)-2-(6-amino-9H-purin-9-yl)-5-(hydroxymethyl)oxolane -3,4-diol, undergoes metabolic phosphorylation to form Ara-ATP. The latter inhibits viral DNA replication by sequence-specific inhibition of strand elongation, attended by incorporation of this purine nucleoside (2). Vidarabine, the very first synthetic purine nucleoside anti-viral, was synthesized by B. R. Baker and his associates in 1960 (1). **Target(s)**: adenosylhomo-cysteinase, *or* S-adenosylhomocysteine hydrolase (3-10,16,19-22); adenylate cyclase (11,18); DNA polymerase, via the 5'-triphosphate (12-14); double-strand DNA breaks (15); herpes virus replication (14); GMP synthetase (17); [3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)] kinase (23); deoxyguanosine kinase (24); deoxyadenosine kinase (25); deoxycytidine kinase (26); adenosine kinase (27); S-methyl-5'-deoxyadenosine phosphorylase, weakly (28). 1. **Adenine 9-β-D-Arabinofuranoside 5'-Monophosphate**

This AMP and dAMP analogue (FW<sub>free acid</sub> = 347.22 g/mol), also known as Ara-AMP, is metabolically transformed into Ara-ATP, which can be incorporated into viral DNA. Ara-AMP is also an alternative substrate of adenylate kinase. **Target(s):** adenine phosphoribosyl-transferase (1); fructose-1,6-bisphosphatase (2); 5' phosphoribosyl-1-pyrophosphate synthetase (1); replication, viral (3); sphingomyelin phosphodiesterase, or sphingomyelinase (4,5,9); adenylosuccinate lyase (7,8); ADP:thymidine kinase (6); AMP:thymidine kinase (6). 1. **Adenine 9-β-D-Arabinofuranoside 5'-Triphosphate**

This ATP and dATP analogue (FW<sub>free acid</sub> = 507.18 g/mol; CAS 3714-60-1), also known as 9-(5-(5-(hydroxy(hydroxy(phosphonooxy) phosphinyl)-phosphinyl)-β-D-arabinofuranosyl)-9H-purin-6-amine, Ara-ATP, adenine arabinoside 5'-triphosphate, and vidarabine 5'-triphosphate, is incorporated into viral DNA, thus inhibiting viral polymerase-mediated DNA synthesis via chain termination. *Note:* Some DNA polymerases are known to extend chains ending in the ara-nucleotide. Ara-ATP is available commercially for *in vitro* experimentation. **Target(s):** DNA primase (1,2,28); mRNA translocation (3); DNA-directed DNA polymerase (4,5,7,10-12,14-16,18-20,28); DNA polymerase α (4,5,11,12,14,28); DNA polymerase β (4,5,11,12,14); DNA polymerase γ (11,14); ribonucleotide reductase (4,9); S-adenosylhomocysteine hydrolase (4,6); RNA polymerase (8); polynucleotide adenyltransferase (13,17); GMP synthetase (21); lysyl-tRNA synthetase (22); leucyl-tRNA synthetase (23); adenylate cyclase (24); [hydroxymethylglutaryl-CoA reductase (NADPH)] kinase, possible alternative substrate (25); duck hepatitis B virus reverse transcriptase (26); RNA-directed DNA polymerase (26); DNA nucleotidyl exotransferase, or terminal deoxyribonucleotidyl transferase (27). 1. **Adenylpentylcobalamin**

This vitamin B<sub>12</sub> analogue (FW = 1534.69 g/mol) inhibits Class-II ribonucleoside-triphosphate reductase ( $K_i = 1.3 \mu\text{M}$ ), thereby generating a radical intermediate by mechanisms involving 5'-deoxyadenosylcobalamin. In 5'-deoxyadenosylcobalamin-dependent eliminases, the  $\gamma$ -band of bound cob(II)alamin is shifted from the 473 nm for free cob(II)alamin to longer wavelengths, 475–480 nm. However, in mutases, the  $\gamma$ -band of bound cob(II)alamin is shifted to shorter wavelengths, 465–470 nm. Such results provide strong evidence that two subclasses of AdoCbl-dependent enzymes exist, and they give insight into the probable post-homolysis state in RTPR and other eliminases. They likewise identify the C<sub>5</sub>-analog as the tightest-binding analogue for crystallization and other biophysical studies. 1. Suto, Poppe, Rétey & Finke (1999) *Bioorg. Chem.* **27**, 451.

**Adenosine 2',5'-Bisphosphate**

This rare ribonucleotide (FW<sub>free acid</sub> = 427.20 g/mol;  $\lambda_{\text{max}} = 259 \text{ nm}$ ;  $\epsilon_M = 15400 \text{ M}^{-1}\text{cm}^{-1}$ ), a structural element of NADP<sup>+</sup> and NADPH, inhibits erythrose reductase (1); isocitrate dehydrogenase, NADP<sup>+</sup>-requiring (2); RNA ligase (ATP) (3); NAD<sup>+</sup> diphosphatase (4); ferredoxin:NADP<sup>+</sup> reductase (5,6,11); methenyl-tetrahydrofolate cyclohydrolase (7); barley nuclease (8); thiol sulfotransferase (9); estrone sulfotransferase (10); and [methionine synthase] reductase (12). 1. **Adenosine 3',5'-Bisphosphate**

This ribonucleotide (FW<sub>free acid</sub> = 427.20 g/mol; *Symbol:* pAp), also known as 3'-phosphoadenosine 5'-phosphate and adenosine 3' phosphate 5'-phosphate, is produced in mammalian cells, primarily by the transfer of the

sulfate group of PAPS (phosphoadenosine 5' phosphosulfate) to various acceptor molecules. pAp is recycled into AMP and P<sub>i</sub> by pAp-phosphatases, hydrolases that are competitively inhibited by sub-mM concentrations of lithium (1,2). **Target(s):** bile-salt sulfotransferase (3,23-26); ribonuclease A, or pancreatic ribonuclease (4); Rat1p nuclease (5); sulfate adenylyltransferase, or ATP sulfurylase (6,41-43); phenol sulfotransferase, or aryl sulfotransferase; as product inhibitor (7,29,36,37); adenylosuccinate synthetase (6); 4-chlorobenzoyl-CoA dehalogenase, weakly inhibited (9); nucleotide diphosphatase (10,11); sphingomyelin phosphodiesterase (12); glycochenodeoxycholate sulfotransferase (13); scymnol sulfotransferase (14,15); flavonol 3-sulfotransferase (16); deoxysulfoglucosinolate sulfotransferase (17-19); cortisol sulfotransferase (20); thiol sulfotransferase (21); steroid sulfotransferase (22); galactosylceramide sulfotransferase (27); tyrosine-ester sulfotransferase, or aryl sulfotransferase IV (28,29); [heparan sulfate]-glucosamine N-sulfotransferase (30); choline sulfotransferase (31); estrone sulfotransferase (32,33); alcohol sulfotransferase (34,35); holo-[acyl-carrier-protein] synthase, as product inhibitor (36-40); N-acetylneuraminidase 4-O-acetyltransferase (44); arylamine N-acetyltransferase (45); and adenylyl-sulfate reductase (46). 1. #### Adenosine-5'-(β-bromoethyl Phosphonate)

This nucleotide analogue (FW<sub>free-acid</sub> = 438.17 g/mol; λ<sub>max</sub> = 259 nm; ε<sub>M</sub> = 15400 M<sup>-1</sup>cm<sup>-1</sup>), also known as AMP-CH<sub>2</sub>-CH<sub>2</sub>-Br and adenosine 5'-(2-

bromoethyl)phosphate, inhibits tryptophanyl-tRNA synthetase (1,2), isocitrate dehydrogenase (3), and phosphorylase kinase (4). 1. Kisselev, Favorova & Kolaleva (1979) *Meth. Enzymol.* **59**, 174. 2. Kovaleva, Ivanov, Madoian, et al. (1978) *Biokhimiia* **43**, 525. 3. Colman (1990) *The Enzymes*, 3rd ed., **19**, 283. 4. Guliaeva, Vulfson & Severin (1978) *Biokhimiia* **43**, 373.

#### Adenosine 5'-Carboxamide

This nucleoside analogue and coronary dilator (FW = 280.24 g/mol; λ<sub>max</sub> = 259 nm; ε<sub>M</sub> = 15400 M<sup>-1</sup>cm<sup>-1</sup>) inhibits adenylylhomocysteine (1) and 5'-methylthioadenosine nucleosidase (2-4). 1. Wnuk, Liu, Yuan, Borchardt & Robins (1996) *J. Med. Chem.* **39**, 4162. 2. Guranowski, Chiang & Cantoni (1983) *Meth. Enzymol.* **94**, 365. 3. Guranowski, Chiang & Cantoni (1981) *Eur. J. Biochem.* **114**, 293. 4. Yamakawa & Schweiger (1979) *Dev. Cell Biol.* **3**, 241.

#### Adenosine-5'-(β-chloroethyl Phosphate)

This nucleotide analogue (FW<sub>free-acid</sub> = 409.72 g/mol), often abbreviated as AMP-O-CH<sub>2</sub>-CH<sub>2</sub>-Cl inhibits tryptophanyl-tRNA synthetase (1,2), phosphorylase kinase (3), and leucyl-tRNA synthetase (4). 1. Kisselev, Favorova & Kolaleva (1979) *Meth. Enzymol.* **59**, 174. 2. Kovaleva, Ivanov, Madoian, et al. (1978) *Biokhimiia* **43**, 525. 3. Guliaeva, Vulfson & Severin (1978) *Biokhimiia* **43**, 373. 4. Krauspe, Kovaleva, Guliaeva, Baranova & Agalarova (1978) *Biokhimiia* **43**, 656.

#### Adenosine 2',3'-Cyclic Monophosphate

This adenosine phosphoric diester (FW<sub>free-acid</sub> = 329.21 g/mol; λ<sub>max</sub> = 259 nm; ε<sub>M</sub> = 15400 M<sup>-1</sup>cm<sup>-1</sup>), also known as 2',3'-cyclic AMP and 2',3'-cAMP, is produced nonenzymatically as an intermediate in the alkaline hydrolysis of RNA as well as an enzymatically as an intermediate by several ribonucleases (e.g., pancreatic ribonuclease, ribonuclease T<sub>1</sub>, ribonuclease T<sub>2</sub>, ribonuclease U<sub>2</sub>, *Bacillus subtilis* ribonuclease, etc.). 2',3'-cyclic AMP is also a substrate for 2',3'-cyclic-nucleotide 2'-phosphodiesterase (EC 3.1.4.16) and 2',3'-cyclic nucleotide 3'-phosphodiesterase (EC 3.1.4.37). A 2',3'-cyclic phosphate termini is produced in the endonucleolytic cleavage of pre-tRNA by tRNA-intron endonuclease (EC 3.1.27.9). This cyclic nucleotide can also be used in the synthesis of oligonucleotides of the form ApX using the reversible reaction catalyzed by *Ustilago sphaerogena* ribonuclease U2: 2',3'-cAMP is reacted with an acceptor substrate containing a free 5'-hydroxyl group (this reactant can be a single nucleotide or nucleoside or an oligonucleotide). **Note:** Hydrolysis by dilute acid or base produces a mixture of 2'-AMP and 3'-AMP (often referred to as 2'(3')-AMP). Do not confuse this mixture with 2',3'-cAMP; both are commercially available. **Target(s):** choline kinase (1); 3'-exonuclease, salmon testes (2); nucleotide diphosphatase, weakly inhibited (3); and poly(ADP-ribose) glycohydrolase (4,5). 1. ### Adenosine 3',5'-Cyclic Monophosphate

This prototypical second messenger (FW<sub>free-acid</sub> = 329.21 g/mol;  $\lambda_{\max}$  = 259 nm;  $\epsilon_M$  = 15400 M<sup>-1</sup>cm<sup>-1</sup>; Abbreviation: 3',5'-cyclic AMP, 3',5'-cAMP, or cAMP), the isolation of which in the late 1950s earned Earl Sutherland his share of the 1971 Nobel Prize in Medicine & Physiology, activates susceptible protein kinases in signal transduction cascades. Elevated cAMP concentrations also activate cyclicAMP-gated ion channels; Exchange Proteins Activated by cAMP (or EPAC), such as RAPGEF3; and popeye domain-containing proteins (or Popdc). While many enzymes are weakly inhibited by cAMP (with inhibition constants typically in the 0.1 mM range or above), the peak physiologic concentration of cAMP rarely exceeds 10-20  $\mu$ M. **Target(s):** phosphate-activated glutaminase (1); glyceraldehyde-3-phosphate dehydrogenase,  $K_i$  = 0.11 mM for the yeast enzyme (2,16,17); choline kinase (3); *Bacillus subtilis* ribonuclease (7); NAD(P)<sup>+</sup> transhydrogenase, AB-specific (8); phosphofructokinase, weakly inhibited (9,10); hexokinase (12); adenosine deaminase (13); NAD<sup>+</sup> nucleosidase, or NADase (14,29,30); poly(ADP-ribose) glycohydrolase (15,31-37); GMP synthetase (18); 5-phosphoribosylamine synthetase, or ribose-5-phosphate:ammonia ligase (19); tyrosyl-tRNA synthetase, weakly inhibited (20); adenylylsulfatase (21); CDP-diacylglycerol diphosphatase (22); nucleotide diphosphatase, weakly inhibited (23); ATP diphosphatase, slight inhibition (24); keratan sulfotransferase, weakly inhibited (25); adenosylhomocysteinase (26-28); 6-phospho- $\beta$ -glucosidase (38); prenyl-diphosphatase (39); CMP-N-acylneuraminate phosphodiesterase (40,41); 2',3'-cyclic-nucleotide 3'-phosphodiesterase, or cCMP phosphodiesterase (42,43); 3',5'-cyclic-GMP phosphodiesterase, or cGMP phosphodiesterase (44-47); sphingomyelin phosphodiesterase (48); phosphoprotein phosphatase (49); 5'-nucleotidase (50); acid phosphatase (51); diacylglycerol cholinephosphotransferase (52); ethanolamine-phosphotransferase (52); glucose-1-phosphate adenylyltransferase (53); nucleoside diphosphate kinase (54,55); AMP:thymidine kinase (56); diacylglycerol kinase (57); nucleoside phosphotransferase (58); 1-phosphatidylinositol 4-kinase (59-62); NAD<sup>+</sup> kinase (63); procollagen glucosyltransferase (64); chitin synthase, weakly inhibited (65); glycogen phosphorylase, weakly inhibited (66); luciferase, firefly (*Photinus-luciferin* 4-monooxygenase, ATP-hydrolyzing (67,68). **1.** Kvamme, Torgner & Svenneby (1985) *Meth. ### Adenosine 2',3'-Dialdehyde

This nucleoside derivative (FW = 265.23 g/mol) alkylates susceptible enzymes, most often by combining with an  $\epsilon$ -amino group of an active-site lysine residue. Because the dialdehyde is of limited stability, it is usually prepared by treating adenosine with a slight molar excess of sodium periodate, followed by a larger molar excess of ethylene glycol to reduce ant unreacted periodate. **Target(s):** adenosine kinase (1); histamine N-methyltransferase (2); S-adenosylhomocysteinase, or S-AdoHcy hydrolase, IC<sub>50</sub> = 2-3  $\mu$ M (3,4); ribonucleotide reductase (5); histone-arginine N-methyltransferase (6). **1.** Pak, Haas, Decking & Schrader (1994) *Neuropharmacology* **33**, 1049. **2.** Borchardt, Wu & Wu (1978) *Biochemistry* **17**, 4145. **3.** Bartel & Borchardt (1984) *Mol. ### Adenosine 5'-Diphosphate

Adenosine 5'-Diphosphate Dianion

Me<sup>2+</sup> Complex with Adenosine 5'-Diphosphate

This adenine nucleotide (FW<sub>free-acid</sub> = 504.16 g/mol; CAS 58-64-0; Molar Absorptivity = 15,400 M<sup>-1</sup>cm<sup>-1</sup>, λ = 259 nm) is a product in ATP-dependent transphosphorylases, phosphohydrolases, and molecular motors; as such, ADP often inhibits these enzymes. **Enzymatic Phosphorylation:** ADP is a substrate for adenylate kinase (*Reaction:* ADP<sup>2-</sup> + MeADP ⇌ MeATP<sup>2-</sup> + AMP) and other enzymes that stabilize ATP concentrations in prokaryotes [e.g., acetate kinase (*Reaction:* MgADP + Acetyl-phosphate ⇌ MeATP<sup>2-</sup> + Acetate)] and eukaryotes [e.g., pyruvate kinase (*Reaction:* MgADP + Phosphoenolpyruvate ⇌ MgATP<sup>2-</sup> + Pyruvate), creatine kinase (*Reaction:* MgADP + Creatine-phosphate ⇌ MgATP<sup>2-</sup> + Creatine), arginine kinase (*Reaction:* MgADP + Arginine-phosphate ⇌ MgATP<sup>2-</sup> + Arginine), and nucleotide diphosphate kinase (*Reaction:* ADP<sup>2-</sup> + MgGTP<sup>2-</sup> ⇌ MgATP<sup>2-</sup> + GDP<sup>2-</sup>)]. **ATP Synthase:** ADP is a primary substrate for the F<sub>0</sub>F<sub>1</sub> ATP synthase (*Reaction:* MgADP + P<sub>i</sub> + High Chemiosmotic Gradient Energization State ⇌ MgATP<sup>2-</sup> + Low Chemiosmotic Gradient Energization State). ADP can also become entrapped within a catalytic site of the rotary motor, when proton motive is low, absent, or uncoupled, and its inhibitory action under such conditions is believed to prevent wasteful hydrolysis of ATP (*Reaction:* MgATP<sup>2-</sup> + H<sub>2</sub>O → MgADP + P<sub>i</sub>). **Metal Ion Binding Properties:** As a polyanion, ADP not only binds physiologic divalent cations Mg<sup>2+</sup> and Ca<sup>2+</sup>, but also forms reversible complexes with Mn<sup>2+</sup> and Co<sup>2+</sup>. For reversible complexation of ADP<sup>2-</sup> with a metal ion Me<sup>2+</sup>, (*Reaction:* ADP<sup>2-</sup> + Me<sup>2+</sup> ⇌ MeADP),  $K_{\text{formation}} = [\text{MeADP}]/[\text{ADP}^{2-}]_{\text{free}}[\text{Me}^{2+}]_{\text{free}}$ , indicating that  $[\text{MeADP}]/[\text{ADP}^{2-}]_{\text{free}} = K_{\text{formation}} \times [\text{Me}^{2+}]_{\text{free}}$ . In many cases, metal-free ADP is not a substrate and instead acts as a reversible inhibitor. Good experimental design therefore demands rigorous control of free metal ion concentration to control the ratio of metal-bound and metal-free forms (1,2). When exposed to Cr(III) at elevated temperature, ADP also forms ligand exchange-inert complexes with Cr<sup>3+</sup> (2). **Platelet Aggregation:** ADP is also a well-known activator of platelet aggregation, as mediated by the ADP receptors P2Y<sub>1</sub>, P2Y<sub>12</sub> and P2X<sub>1</sub>. Upon conversion to adenosine by ecto-ADPases, platelet activation is inhibited by means of adenosine receptors. **Target(s):** *Hydrogenomonas facilis* ribulosediphosphate (RuDP) carboxylase and NADH-, ATP-dependent CO<sub>2</sub> fixation (3); platelet (Na<sup>+</sup>/K<sup>+</sup>)-ATPase (4); hydrogen-ion transport in chloroplasts (5); pyruvate dehydrogenase kinase (6); 5-oxo-L-proline, or L-pyroglyutamate hydrolase (7); α-NADH-dependent reductase, rat liver microsomes (8); nitrogenase (9); *Trypanosoma cruzi* hexokinase (10); maize leaf acetyl-coenzyme A carboxylase (11); rat brain mitochondrial calcium-efflux (12); sarcoplasmic reticulum Ca<sup>2+</sup> ATPase (13); Na<sup>+</sup>-Na<sup>+</sup> exchange mediated by (Na<sup>+</sup>/K<sup>+</sup>)-ATPase reconstituted into liposomes (14); nitrate and nitrite assimilation in *Zea mays* under dark conditions (15); PGE<sub>1</sub>-activated platelet adenylate cyclase in rats and rabbits (16); mitochondrial F<sub>1</sub>-ATPase, inactive complex formed upon binding ADP at a catalytic site (1,17,18); ATP-sensitive K<sup>+</sup> channels, frog skeletal muscle (19); human 5-phosphoribosyl-1-pyrophosphate synthetase (20); *Critidia fasciculata* glutathionyl-spermidine synthetase (21); myosin V ATPase (22); cystic fibrosis transmembrane conductance regulator (ABC transporter) via its adenylate kinase activity (23); V type ATPase/synthase (24). 1. ### Adenosine 5'-(β,γ-Imido)triphosphate

This ATP analogue (FW<sub>free-acid</sub> = 506.20 g/mol), also called AMP-PNP and β,γ-imidoadenosine 5'-triphosphate, is an inhibitor of many ATP-dependent enzymes. It can also serve as an alternative substrate for enzymes that hydrolyze ATP between the α and β phosphorus atoms. Snake venom phosphodiesterase hydrolyzes AMP-PNP to produce AMP and imidodiphosphate (PNP). *Escherichia coli* alkaline phosphatase will hydrolyze the nucleotide to orthophosphate and the corresponding nucleoside diphosphate derivative. AMP-PNP is very soluble in water and tends to bind metal ions with a greater affinity than ATP. It is unstable in acidic solutions, producing the corresponding phosphoramidate and orthophosphate. **Target(s):** choline kinase (1); formyltetrahydrofolate synthetase (2); methionine S adenosyltransferase, also as alternative substrate (3,91); chaperonin ATPase, or chaperonin 60 (4,56); 5'→3' exoribonuclease (5); mitogen-activated protein kinase activated protein kinase (26); pantothenate kinase (7); adenosine-5'-phosphosulfate kinase (8); ecto-ATPase (9); ATP synthase, or F<sub>1</sub> ATPase, or H<sup>+</sup>-transporting two-sector ATPase (10,17,19,20,24,25,63); DNA helicase (11,29,34,64); DNA gyrase (12,33); protein kinase C (13); kinesin (14,57,59); glycerol kinase (15); myosin ATPase (16,30); cAMP dependent protein kinase (18); K<sup>+</sup>/H<sup>+</sup>-ATPase (21); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (22); T<sub>4</sub> polynucleotide kinase (23); glutamine synthetase (26); [myosin light-chain] kinase (27); DNA topoisomerase II (28,36,51,52); type I site-specific deoxyribonucleases (32); phosphoprotein phosphatase types 1 and 2A (35); dynein ATPase (37,38); GTP diphosphokinase, or GTP pyrophosphokinase (39); cobaltochelate (40); RNA ligase (ATP) (41); DNA ligase (ATP), bacteriophage T<sub>7</sub> (42); asparagine synthetase (43); CTP synthetase (44,45); dethiobiotin synthetase (46); tetrahydrofolate synthetase (47); phosphoribosylamino-imidazole-succinocarboxamide synthetase (48); glycyl-tRNA synthetase (49); leucyl-tRNA synthetase (50); guanylate cyclase (53); adenylate cyclase (54); protein-synthesizing GTPase, elongation factor (55); minus-end-directed kinesin ATPase (57,58); centromere binding protein E58; plus-end-directed kinesin ATPase (14,59); channel-conductance-controlling ATPase, cystic-fibrosis membrane-conductance-regulating protein (60); polar-amino-acid-transporting ATPase, histidine permease (61,62); nucleoside-triphosphatase (64); nucleotide diphosphatase (65); apyrase (66); endopeptidase La (67); nucleotidases (68); 5'-nucleotidase (69); estrone sulfotransferase (70); alcohol sulfotransferase (70); triphosphate:protein phosphotransferase (71); histidine kinase (72); [tau protein] kinase, or glycogen synthase kinase 3β (73); phosphorylase kinase (74); cAMP-dependent protein kinase, or protein kinase A (75); [pyruvate dehydrogenase (acetyl-transferring)] kinase (76,77); non-specific serine/threonine protein kinase (78); PknB serine/threonine protein kinase (78); pyruvate, orthophosphate dikinase (79); GTP diphosphokinase (80); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (81); phosphomevalonate kinase (82); 3-phosphoglycerate kinase (83); polo kinase (84); polynucleotide 5'-hydroxyl-kinase (85,86); homoserine kinase (87); xylulokinase (88); ribulokinase (89); glucokinase (90); hexokinase IV (90). 1. **Adenosine 5'-( $\alpha,\beta$ -Methylene)diphosphate, See  $\alpha,\beta$ -Methyleneadenosine 5'-Diphosphate**

**Adenosine 5'-( $\alpha,\beta$ -Methylene)- $\gamma$ -thio-triphosphate, See  $\alpha,\beta$ -Methyleneadenosine 5'-Triphosphate**

**Adenosine 5'-( $\alpha,\beta$ -Methylene)triphosphate, See  $\alpha,\beta$ -Methyleneadenosine 5'-Triphosphate**

**Adenosine 5'-Monophosphate**

This adenine nucleotide ( $FW_{\text{free-acid}} = 346.06$  g/mol; CAS 61-19-8; Molar Absorptivity =  $15,400 \text{ M}^{-1}\text{cm}^{-1}$ ,  $\lambda = 259$  nm) is formed by the action of adenylosuccinate lyase in the *de novo* purine nucleotide biosynthetic pathway. AMP is a feedback inhibitor of adenylosuccinate synthase. AMP is also a substrate for adenylate kinase (*Reaction*:  $\text{MeATP}^{2-} + \text{AMP} \rightleftharpoons \text{ADP}^{2-} + \text{MeADP}$ ). **Target(s)**: skeletal muscle fructose 1,6-bisphosphatase by adenosine monophosphate (1-4); pea seed phosphofructokinase by phosphoenolpyruvate (5); *Escherichia coli* ATP phosphoribosyltransferase (6); glutamine 5-phosphoribosyl-1-pyrophosphate amidotransferase (7); ADP-glucose synthetase (8); brown adipocyte nonselective cation channel (9). **1.** Opie & Newsholme (1967) *Biochem. **Adenosine 5'-Monophosphate 2',3'-Dialdehyde**

This nucleotide analogue ( $FW_{\text{free-acid}} = 345.21$  g/mol), also known as dial AMP and oAMP, alkylates susceptible enzymes, most often combining with an  $\epsilon$ -amino group of an active-site lysine residue. Because the dialdehyde is of limited stability, it is usually prepared by treating adenosine with a slight molar excess of sodium periodate, followed by a larger molar excess of ethylene glycol to reduce any unreacted periodate. **Target(s)**:  $F_1$  ATPase (1,2); pyruvate,orthophosphate dikinase (3-5); ribonucleotide reductase (6); fructose-1,6-bisphosphatase (7); sphingomyelin phosphodiesterase (8). **1.** Satre, Lunardi, Dianoux, et al. **P<sup>1</sup>-(Adenosine-5')-P<sup>3</sup>-(nicotinamide riboside-5')triphosphate**, **Similar in action to P<sup>1</sup>-(Adenosine-5')-P<sup>4</sup>-(nicotinamide riboside-5')tetraphosphate**

**P<sup>1</sup>-(Adenosine-5')-P<sup>4</sup>-(nicotinamide riboside-5')tetraphosphate**

This multisubstrate geometric analogue (FW<sub>free-acid</sub> = 816.4 g/mol) targets nicotinamide-nucleotide adenyltransferase, most likely occupying both the NMN and ATP substrate subsites (1,2). (See *Adenylate Kinase Inhibitors for discussion of the related agents*, P<sup>1</sup>,P<sup>4</sup>-di-(adenosine-5')tetraphosphate; P<sup>1</sup>,P<sup>5</sup>-di-(adenosine-5')pentaphosphate) **1.** Franchetti, Cappellacci, Pasqualini, *et al.* (2003) *Nucleosides Nucleotides Nucleic Acids* **22**, 865. **2.** Sorci, Cimadamore, Scotti, *et al.* (2007) *Biochemistry* **46**, 4912.

#### Adenosine N<sup>1</sup>-Oxide

This oxidized purine-containing nucleoside (FW = 283.24 g/mol), also called adenosine 1-N-oxide, inhibits adenosylhomocysteinase (1,2), dihydroorotase (3), GMP synthetase (4), and adenosine kinase (also alternative substrate) (5). **1.** Guranowski, Montgomery, Cantoni & P. K. Chiang (1981) *Biochemistry* **20**, 110. **2.** Shimizu, Shiozaki, Ohshiro & Yamada (1984) *Eur. J. Biochem.* **141**, 385. **3.** Bresnick & Blatchford (1964) *Biochim. Biophys. #### Adenosine 5'-(β,γ-Peroxytriphosphate)

This ATP analogue (FW = 523.18 g/mol), abbreviated AMP-PO<sub>2</sub>P, is a competitive inhibitor of a number of kinases. It is also an alternative substrate for NAD pyrophosphorylase. **Target(s):** glycerokinase (K<sub>i</sub> = 140 μM); hexokinase (K<sub>i</sub> = 90 μM); nucleoside diphosphate kinase (K<sub>i</sub> = 3.1 mM); phosphofructokinase (K<sub>i</sub> = 200 μM); phosphoglycerate kinase (K<sub>i</sub> = 400 μM); phosphoribosyl-pyrophosphate synthetase (K<sub>i</sub> = 33 μM). NAD<sup>+</sup> pyrophosphorylase is the only enzyme, among 13 tested, that uses adenosine 5'-(β,γ-peroxytriphosphate) as a substrate. The peroxy compounds tested inactive with *Escherichia coli* RNA polymerase and DNA polymerase I, as well as with wheat germ RNA polymerase II. **1.** Gibson & Leonard (1984) *Biochemistry* **23**, 78.

#### Adenosine 3'-Phosphate 5'-Phosphosulfate

This nucleotidyl-sulfate (FW<sub>free-acid</sub> = 507.27 g/mol; *Symbol*: PAPS), also known as 3'-phosphoadenosine-5'-phosphosulfate and 3' phospho-adenylsulfate, is an important metabolite in sulfate reduction and in the formation of sulfate esters. Note that PAPS is an unstable derivative; the solid decomposes at 15-20% per day at 37°C. Commercial preparations can often contain substantial amounts of adenosine 3',5'-bisphosphate and sulfate as impurities. AMPS is even more unstable under acidic conditions; the half-life at 37°C in 0.1 M HCl is 6 minutes. Aqueous solutions are more stable in alkaline conditions. Solutions requiring storage should be kept frozen at pH 8.0. In addition, solutions should be kept free of ammonia-free, because NH<sub>3</sub> readily reacts with PAPS to produce the 5' phosphoramidate. PAPS is readily prepared in the laboratory via the action of ribonuclease T<sub>2</sub> on adenosine 2',3'-cyclic phosphate 5'-phosphosulfate (1). **Target(s):** sulfate adenyltransferase, or ATP Sulfurylase (2,3); threonine synthase, weakly inhibited (4). **1.** Horwitz, Neenan, Misra, *et al.* (1977) *Biochim. Biophys. Acta* **480**, 376. **2.** Peck (1974) *The Enzymes*, 3<sup>rd</sup> ed., **10**, 651. **3.** Hanna, Ng, MacRae, *et al.* (2004) *J. Biol. Chem.* **279**, 4415. **4.** Giovaneli, Mudd, Datko & Thompson (1986) *Plant Physiol.* **81**, 577.

#### Adenosine 5'-O-(γ-Thio)triphosphate

This ATP analogue (FW<sub>free-acid</sub> = 523.25 g/mol), also known as adenosine 5'-(3-thiotriphosphate) and ATPγ-S, is an inhibitor and/or alternative substrate of a number of ATP-dependent systems. ATPγ-S is a P2 purinergic agonist and will increase the activity of Ca<sup>2+</sup>-activated K<sup>+</sup> channels. (P1 and P2 purinergic receptor refers to classes of membrane receptors that mediate relaxation of gut smooth muscle as a response to the release of adenosine and ATP, respectively. **Target(s):** diphosphomevalonate decarboxylase (1,12); folylpolyglutamate synthetase (2,7); protein-tyrosine phosphatase (3); recA ATPase (4); pyruvate dehydrogenase complex (5); succinyl CoA synthetase (6); RNA ligase, ATP-dependent (8); glutamyl-tRNA synthetase, glutamine-hydrolyzing (9); CTP synthetase (10); tetrahydrofolate synthetase (11); chaperonin ATPase (13); microtubule-severing ATPase, or katanin (14,15); polar-amino-acid-transporting ATPase, or histidine permease (16,17); Na<sup>+</sup>-transporting two-sector ATPase (18); Na<sup>+</sup>-exporting ATPase (18); DNA helicase (19); nucleoside-triphosphatase (19); insulysin (20); endopeptidase La (21); protein-tyrosine kinase (22); Src protein tyrosine kinase (22); selenide,water dikinase (23); acetate kinase (24); diacylglycerol kinase (25,26); 1-phosphatidylinositol 4-kinase (27,28); galactokinase (29). **1.** Cardemil & Jabalquinto (1985) *Meth. ### Adenosine 5'-Triphosphate

Adenosine 5'-Triphosphate Tri-anion

Me<sup>2+</sup> Complex with Adenosine 5'-Triphosphate

This adenine nucleotide (FW<sub>free-acid</sub> = 507.18 g/mol; CAS 56-65-5; Molar Absorptivity = 15,400 M<sup>-1</sup>cm<sup>-1</sup>, λ = 259 nm) is the phosphoryl-donor substrate for numerous transphosphorylases, phosphohydrolases, and molecular motors; as such, ADP often inhibits these enzymes. **Enzymatic Phosphorylation:** ATP is a substrate for adenylate kinase reaction: MeATP<sup>2-</sup> + AMP ⇌ ADP<sup>2-</sup> + MeADP. It is also the product of other reactions that stabilize ATP concentrations in prokaryotes [e.g., acetate kinase (*Reaction:* MgADP + Acetyl-phosphate ⇌ MeATP<sup>2-</sup> + Acetate)] and eukaryotes [e.g., pyruvate kinase (*Reaction:* MgADP + Phosphoenolpyruvate ⇌ MgATP<sup>2-</sup> + Pyruvate), creatine kinase (*Reaction:* MgADP + Creatine-phosphate ⇌ MgATP<sup>2-</sup> + Creatine), arginine kinase (*Reaction:* MgADP + Arginine-phosphate ⇌ MgATP<sup>2-</sup> + Arginine), and nucleotide diphosphate kinase (*Reaction:* ADP<sup>2-</sup> + MgGTP<sup>2-</sup> ⇌ MgATP<sup>2-</sup> + GDP<sup>2-</sup>)]. **ATP Synthase:** ADP is a primary product of the F<sub>0</sub>F<sub>1</sub> and CF<sub>0</sub>CF<sub>1</sub> ATP synthases (*Reaction:* MgADP + P<sub>i</sub> + High Chemiosmotic Gradient Energization State ⇌ MgATP<sup>2-</sup> + Low Chemiosmotic Gradient Energization State). When the proton motive is low, absent, or uncoupled, the synthase catalyzes hydrolysis of ATP (*Reaction:* MgATP<sup>2-</sup> + H<sub>2</sub>O → MgADP + P<sub>i</sub>). **Metal Ion Binding Properties:** As a polyanion, ATP not only binds physiologic divalent cations Mg<sup>2+</sup> and Ca<sup>2+</sup>, but also forms reversible complexes with Mn<sup>2+</sup> and Co<sup>2+</sup>. For reversible complexation of ATP<sup>4-</sup> with a metal ion Me<sup>2+</sup>, (*Reaction:* ATP<sup>4-</sup> + Me<sup>2+</sup> ⇌ MeATP<sup>2-</sup>),  $K_{\text{formation}} = \frac{[\text{MeATP}^{2-}]}{[\text{ATP}^{4-}][\text{Me}^{2+}]_{\text{free}}}$ , indicating that  $\frac{[\text{MeATP}^{2-}]}{[\text{ATP}^{4-}]_{\text{free}}} = K_{\text{formation}} \times [\text{Me}^{2+}]_{\text{free}}$ . Formation constants typically range from 10<sup>4</sup>–10<sup>5</sup> M<sup>-1</sup>. In many cases, metal-free ATP is not a substrate and instead acts as a reversible inhibitor. In the case of bovine brain hexokinase, metal-free ATP<sup>4-</sup> is a linear competitive inhibitor relative to MgATP<sup>2-</sup> complex (1). HATP<sup>3-</sup> also inhibits this enzyme. Good experimental design therefore requires rigorous control of free metal ion concentration to control the ratio of metal-bound and metal-free forms (2,3). When exposed to Cr(III) at elevated temperature, ATP also forms ligand exchange-inert complexes with Cr<sup>3+</sup> (3). **False Inhibition by Metal Ion Chelation:** Many enzymes require divalent or trivalent metal ions for activity, and the addition of metal ion-free ATP inhibits such enzymes by sequestering metal ions. When ATP is found to inhibit an enzyme of interest, it is advisable to determine whether the observed effect remains after ATP is augmented by sufficient Mg<sup>2+</sup> to form MgATP<sup>2-</sup>, thereby minimizing nonphysiologic effects of ATP<sup>4-</sup>. The simplest way to test for this possibility is to add equimolar amounts of ATP and MgCl<sub>2</sub> to a buffer already supplemented with 1-3 mM additional

MgCl<sub>2</sub>. Under such conditions, >95% of the ATP will be MgATP<sup>2-</sup> complex (1-3). **Target(s):** Phosphofructokinase, liver – low ATP concentrations inhibit PFK by decreasing its affinity for fructose 6-phosphate (citrate and other tricarboxylic acid cycle intermediates also inhibit, and this inhibition was relieved by either AMP or fructose 1,6-diphosphate; however, higher concentrations of ATP decrease and finally remove the effect of these activators (4,5); brain hexokinase (by metal-free ATP<sup>4-</sup>) – the apparently sigmoidal saturation curves for MgATP<sup>2-</sup> observed by Bachelard (6) studies can be corrected to hyperbolic curves by use of a stability constant for MgATP<sup>2-</sup> complex formation, especially when corrected for the presence of the inhibitory free uncomplexed ATP<sup>4-</sup> concentration (1), which presents a simple model demonstrating how enzymes obeying Michaelis-Menten kinetics can falsely demonstrate sigmoidal velocity responses, if the true substrate is the metal-substrate complex (1); phosphorylase *b* (7); locust pyruvate kinase (8); skeletal muscle pyruvate kinase reaction, dependence on the total magnesium ion concentration (9); glucose-6-phosphate dehydrogenase, variability in ATP inhibition (10); *Rhodospseudomonas spheroides* aminolevulinatase (ALA) synthetase activity (11); phosphorylase *b*, effect on AMP activation (12); leaf adenosine diphosphate sulphurylase (13); *Escherichia coli* phosphofructokinase, ATP-sensitive and ATP-insensitive forms (14); cardiac mitochondrial pyruvate dehydrogenase (15); phosphofructokinase, skeletal muscle – citrate, 3-P-glycerate and P-enolpyruvate each act synergistically in the presence of ATP to inhibit the PFK reaction, and the sensitivity to these inhibitors is more pronounced at elevated ATP concentrations; moreover, these metabolites do not inhibit, when ITP is used as the phosphoryl donor (16); *Escherichia coli* glutaminase, metal ion effects on (17); terminal deoxynucleotidyltransferase, mechanism of ATP (18); *Kluyveromyces lactis* phosphofructokinase, ATP inhibition and Pasteur Effect (19); human phosphofructokinase isozymes, ATP inhibition (20); NAD-linked glutamate dehydrogenase (21); liver phosphofructokinase, lessened ATP inhibition after hormonally stimulated phosphorylation (22); muscle AMP deaminase, lowered ATP inhibition at higher (physiologic) ATP concentration (23); mammalian brain Na<sup>+</sup>/K<sup>+</sup>-ATPase (24); ATP synthase, catalytic and regulatory features of ATP inhibition (25); maize leaf acetyl-coenzyme A carboxylase, inhibition by ATP<sup>4-</sup> but not MgATP<sup>2-</sup> (26); bovine heart NAD-specific isocitrate dehydrogenase, activation and inhibition by ATP (27); ATP-inhibited K<sup>+</sup> channels, paradoxical role of ATP in maintain its channel-open state (28); human red cell sugar transporter (29); adult and fetal myocardial phosphofructokinase, relief of cooperativity and competition between fructose 2,6-bisphosphate, ATP, and citrate (30); muscle phosphofructokinase, desensitization to ATP inhibition by removal of a carboxyl-terminal heptadecapeptide (31); soluble 5'-nucleotidase of rat kidney (32); DNA topoisomerase, type I (33); modulation of nucleotide-sensitive K<sup>+</sup> channel gating in insulin-secreting cells by changes in the ratio ATP<sup>4-</sup>/ADP<sup>3-</sup> and by nonhydrolyzable derivatives of both ATP and ADP (34); mitochondrial NAD(P)-malic enzyme, from herring skeletal muscle (35); 6-Phosphofructo-2-kinase and fructose-2,6-bisphosphatase, *Saccharomyces cerevisiae* (36); 5-nucleotidase, rat heart (37); CTP:cholinephosphate cytidyltransferase, castor bean endosperm (38); *Phycomyces* pyruvate kinase (39); NAD(P)<sup>+</sup>-malic enzyme, ATP inhibition competes with activating cations in modulating the activity in the mitochondrial matrix of *Xenopus laevis* oocytes (40); neutrophil migration (41); *Escherichia coli* phosphofructo-1-kinase (42); ventricular myocyte calcium current, neuromodulation by extracellular ATP (43); Ca<sup>2+</sup>-dependent K<sup>+</sup> channels, in soma membrane of cultured leech *Retzius neurons* (44); ADP-ribosylation of membrane-bound actin and actin-binding to membranes (45); agonist-induced mobilization of internal calcium in human platelets by extracellular ATP (46); *Saccharomyces cerevisiae* glycine amide ribonucleotide synthetase (47); *Saccharomyces cerevisiae* aminoimidazole ribonucleotide synthetase (47); adrenergic agonist-induced hypertrophy of neonatal cardiac myocytes, inhibition by extracellular ATP (48); hepatic fatty acid metabolism, inhibition by extracellular ATP (49); Cytochrome *c* oxidase, allosteric ATP inhibition in eukaryotes but not prokaryotes (50); ATP-inhibitable K<sup>+</sup> channels in insulin secreting cells (51); ATP inhibition of K<sub>ATP</sub> channels, PIP<sub>2</sub> and PIP as determinants of (52); kidney phosphofructokinase, relief from ATP inhibition by ribose 1,5-bisphosphate (53,54); glycolytic flux in *Saccharomyces cerevisiae*, targeting PFK and PK (55); inositol 1,4,5-trisphosphate receptor type-1 and type-3, differential modulation by ATP (56); 2-oxoglutarate dehydrogenase complex (57); Mg<sup>2+</sup> uptake in MDCT cells via P2X purinoceptors (58); NMDA receptors in cultured hippocampal neurons (59); endothelin-1 production by rat inner medullary collecting duct cells (60); UDP-glucuronosyltransferase, or UGT (61);

### [5-(Adenosin-5'-O-yl)pentyl]cobalamin

This vitamin B<sub>12</sub> analogue (FW = 1665.74 g/mol) inhibits ribonucleoside-triphosphate reductase ( $K_i = 7.7 \mu\text{M}$ ). Note that the propyl, butyl, hexyl, and heptyl homologues also inhibit ( $K_i = 55.8, 18.9, 24.6,$  and  $12.8 \mu\text{M}$ , respectively). In addition, all five (adenosin-5'-O-ylalkyl)cobalamins also inhibit glycerol dehydratase ( $K_i = 10.5, 9.7, 5.9, 15.1,$  and  $11.7 \text{ nM}$  for the C3, C4, C5, C6, and C7 analogues, respectively), diol dehydratase ( $K_i = 0.77, 0.86, 0.50, 0.83,$  and  $0.63 \mu\text{M}$ , respectively), and methylmalonyl-CoA mutase ( $K_i = 2.48, 1.45, 1.13, 0.77,$  and  $2.10 \mu\text{M}$ , respectively). **Target(s):** diol dehydratase (1,2); glycerol dehydratase (1,2); methylmalonyl-CoA mutase (1,3); ribonucleoside-triphosphate reductase (1). 1. ### S-(5'-Adenosyl)-L-cysteine

This substituted cysteine (FW = 370.39 g/mol; CAS 35899-53-7) is an alternative substrate for S-adenosylhomocysteinases, often acting as a potent competitive inhibitor that protracts each catalytic round. **Target(s):** acyl-homoserine-lactone synthase (1); spermidine synthase (2); mRNA (guanine-N<sup>7</sup>-)-methyltransferase (3); mRNA (nucleoside-2'-O-)-methyltransferase (3); histone-lysine N methyltransferase (4); tRNA (adenine-N<sup>7</sup>-)-methyltransferase (5); tRNA (guanine-N<sup>7</sup>-)-methyltransferase (6). 1. ### S-Adenosyl-D-homocysteine

This epimer (FW = 384.41 g/mol; CAS 979-92-0) of S-adenosyl-L-homocysteine inhibits acyl-homoserine-lactone synthase. **Target(s):** acyl-homoserine-lactone synthase (1,2); [cytochrome c]-methionine S-methyltransferase (3); [cytochrome c]-methionine S-methyltransferase (3); histone-arginine N-methyltransferase (4); [cytochrome c]-lysine N-methyltransferase (5); mRNA (guanine-N<sup>7</sup>-)-methyltransferase (6,7); mRNA (nucleoside-2'-O-)-methyltransferase (6); tRNA (adenine-N<sup>7</sup>-)-methyltransferase (8); tRNA (uracil-5-)-methyltransferase (9); tRNA (guanine-N<sup>7</sup>-)-methyltransferase (10); tRNA (guanine-N<sup>2</sup>-)-methyltransferase (11). 1. Parsek, Val, Hanzelka, Cronan, & Greenberg (1999) *Proc. Natl. Acad. Sci. U.S.A.* **96**, 4360. 2. Hanzelka, Parsek, Val, et al. (1999) *J. Bacteriol.* **181**, 5766. 3. **S-Adenosyl-L-homocysteine**

This S-substituted homocysteine (FW = 384.42 g/mol; CAS 979-92-0; Abbreviation: SAH) is an L-cysteine synthesis intermediate and potent product inhibitor of numerous SAM-dependent methyltransferases. SAH is also a substrate for adenosylhomocysteine nucleosidase, adenosylhomocysteinease, and S-adenosylhomocysteine deaminase. S-adenosyl-L-homocysteine is relatively stable in neutral or alkaline solutions; however, oxidation is more rapid in alkaline conditions. Because solid SAH slowly oxidizes to its sulfoxide, it should be stored under nitrogen and at a low temperature. 2,2'-Thioethanol (thiodiglycol) is often added to protect against oxidation. Treatment of SAH in 0.1 M HCl at 100°C results in the formation of S-ribosyl-L-homocysteine in ninety minutes. **Target(s):** L-lysine 2,3-aminomutase (1,15); S-adenosylmethionine hydrolase (2,18); formate C-acetyltransferase, or pyruvate formate lyase (3,37); spermidine synthase, or putrescine aminopropyltransferase (4); 5'-methylthioadenosine nucleosidase (5,19); 1-aminocyclopropane-1 carboxylate synthase (6,16,17); O-acetylhomoserine aminocarboxy-propyltransferase, or O-acetyl-homoserine sulfhydrylase (7,26,27); type I site-specific Deoxyribonuclease (8,21); valyl-tRNA synthetase (9); cyclopropane-fattyacyl-phospholipid synthase (10,93,94); homoserine O-acetyltransferase (11); guanidinoacetate methyltransferase (12); leucine transport (13); S-adenosylmethionine cyclotransferase (14); ribonuclease H (20); S-methyl-5-thioribose kinase (22); adenosine kinase (23); adenosyl-methionine:8-amino-7-oxonanoate transaminase or diaminopelarginate aminotransferase (24); adenosyl-fluoride synthase (25); cystathionine  $\gamma$  synthase (28); spermine synthase, weakly inhibited (29); methionine S-adenosyltransferase (30,31); S-adenosylmethionine cyclotransferase (32,33); S-methyl-5'-thioadenosine phosphorylase, weakly inhibited (34); acyl-homoserine-lactone synthase (35,36); homoserine O-acetyltransferase, (38); glycine/sarcosine/ dimethylglycine N-methyl-transferase (39); dimethylglycine N-methyl-transferase (40); sarcosine/ dimethylglycine N-methyltransferase (40,41); glycine/sarcosine N-methyltransferase (40,41); kaempferol 4'-O-methyltransferase (42); isoliquiritigenin 2'-O methyltransferase (43); vitexin 2''-O-rhamnoside 7-O-methyltransferase (44); corydaline synthase (45); 3'-demethylstaurosporine O-methyltransferase (47); chlorophenol O-methyltransferase (48); inositol 4-methyltransferase (49); (RS)-norococlaurine 6-O-methyltransferase (50,51); [myelin basic protein] arginine N-methyltransferase (52,53); histone-arginine N-methyltransferase (54-56); [cytochrome c] arginine N-methyltransferase (57); [cytochrome c]-methionine S-methyltransferase (57); (S)-tetrahydroprotoberberine N-methyltransferase (58,59); 6-O-methylnorlaudanosoline 5'-O methyltransferase (60); coilumbamine O-methyltransferase (61); site-specific DNA-methyltransferase, cytosine-N4-specific, M.BamHI (62); site-specific DNA-methyltransferase adenine-specific (62,99-103); strigimacrocystin 8-O-methyltransferase (63); 6-hydroxymellein O-methyltransferase (64,65); uroporphyrinogen-III C-methyltransferase (66); tryptophan 2-C methyltransferase, weakly inhibited (67); caffeoyl-CoA O-methyltransferase (68); phosphoethanolamine N-methyltransferase (69-71); demethylmacrocin O-methyltransferase (72); macrocin O-methyltransferase (73); protein-S-isoprenylcysteine O-methyltransferase (74-82); thioether S-methyltransferase (83); tocopherol methyltransferase (84); tabersonine 16-O-methyltransferase (85); isobutyraldoxime O-methyltransferase (86); 8-hydroxyquercetin 8-O methyltransferase (87); pyridine N-methyltransferase (88); methylquercetagenin 6-O-methyltransferase (89); 3,7-dimethyl-quercetin 4'-O-methyltransferase (89); protein-glutamate O-methyltransferase (90-92); protein-L-isoaspartate (D-aspartate) O-methyltransferase (95-97); quercetin 3-O-methyltransferase (89); apigenin 4'-O-methyltransferase (98); phosphatidyl-N methylethanolamine N-methyltransferase (104); caffeate O-methyltransferase (105-108); thiopurine S methyltransferase (109,110); rRNA (adenosine-2'-O)-methyltransferase (111); calmodulin-lysine N-methyltransferase (112,113); [cytochrome c]-lysine N-methyltransferase (114-118); mRNA (guanine N<sup>7</sup>-)-methyltransferase (119,123-126); mRNA (nucleoside-2'-O)-methyltransferase (119-122); putrescine N-methyltransferase (127,128); rRNA (adenine-N<sup>6</sup>-)-methyltransferase (129); isoflavone 4' O-methyltransferase (130);

dimethylhistidine N-methyltransferase (131); histone-lysine N methyltransferase (132-134); luteolin O-methyltransferase (135); sterol 24-C-methyltransferase, or cycloartenol 24-C-methyltransferase (46,136); DNA (cytosine-5-)-methyltransferase (137-140); HaeIII DNA methyltransferase (137); HhaI DNA methyltransferase (137); tRNA (adenine-N<sup>7</sup>-) methyltransferase (141-146); tRNA (uracil-5-)-methyltransferase (147-152); tRNA guanosine-2'-O methyltransferase (153); tRNA (guanine-N<sup>7</sup>-)-methyltransferase (150,154); tRNA (guanine-N<sup>2</sup>-) methyltransferase (144,155-158); tRNA (guanine-N<sup>1</sup>-)-methyltransferase (150,158-161); tRNA (cytosine 5-)-methyltransferase (150,162,163); phenylethanolamine N-methyltransferase (164-166); glycine N methyltransferase (167-169); phosphatidylethanolamine N-methyltransferase (170-173); fatty-acid O-methyltransferase (174,175); magnesium protoporphyrin IX methyltransferase (176-181); homocysteine S-methyltransferase (182); thiol S-methyltransferase (183-185); histamine N-methyltransferase (186-190); nicotinate N-methyltransferase (191); catechol O-methyltransferase (192-196); betaine:homocysteine S-methyltransferase (197); acetylserotonin O-methyltransferase, or hydroxyindole O-methyltransferase (198-200); guanidinoacetate N-methyltransferase (201-203); nicotinamide N methyltransferase (204). 1. ### Adenylate Kinase Inhibitors

Most cells contain adenylate kinase (*Reaction*:  $\text{ADP} + \text{MgADP} \rightleftharpoons \text{MgATP} + \text{AMP}$ ) in abundance, maintaining adenine nucleotide concentrations at, or very near, equilibrium. Even after extensive purification, many proteins and enzymes are contaminated by trace amounts of adenylate kinase, often frustrating experiments requiring the presence of one or more adenine nucleotide. The presence of this kinase can confound efforts to quantify processes requiring ADP or any process requiring the presence of both ATP and AMP. To minimize the effects by contaminating levels of adenylate kinase, one can utilize the bisubstrate geometrical analogues  $\text{Ap}_3\text{A}$  and  $\text{Ap}_4\text{A}$  that simultaneously occupy both nucleotide-binding pockets within the active site of this kinase (1,2). Effective inhibition by  $\text{Ap}_3\text{A}$  and  $\text{Ap}_4\text{A}$  occurs at 0.3 and 1 mM, respectively. Powers *et al.* (3) also demonstrated the inhibitory effects of a series of di(adenosine-5')-polyphosphates (*e.g.*,  $\text{Ap}_n\text{A}$ , where  $n = 2, 3, 4, 5$  and 6) on carbamyl phosphate synthetase. Only  $\text{Ap}_3\text{A}$  was found to be an effective inhibitor of the overall reaction. See  $\text{P}^i, \text{P}^d$ -Di(adenosine 5') tetraphosphate;  $\text{P}^i, \text{P}^d$ -Di(adenosine 5') pentaphosphate 1. Purich & Fromm (1972) *Biochim. Biophys. Acta* **276**, 563. 2. Leinhard & Secemski (1973) *J. Biol. Chem.* **248**, 1121. 3. Powers, Griffith & Meister (1977) *J. Biol. Chem.* **252**, 3558.

## Adenyomalic Acid

This adenylosuccinate analogue (FW<sub>free-acid</sub> = 479.30 g/mol), also known as *N*<sup>6</sup>-(DL-1,2-dicarboxy-*threo*-2-hydroxyethyl)adenosine 5'-monophosphate, inhibits ( $K_i = 1.2 \mu\text{M}$ ) chicken liver adenylosuccinate lyase (*Reaction*: Adenylosuccinate  $\rightleftharpoons$  AMP + Fumarate). Adenyomalixacid therefore represents a lead molecule for the development of novel inhibitors of AMP synthesis. 1. Brand & Lowenstein (1978) *Biochemistry* 17, 1365.

## Adenylosuccinate

This purine nucleotide biosynthesis intermediate (FW<sub>free-acid</sub> = 463.30 g/mol; CAS 19240-42-7; Symbols: AMP-Succ, Succ-AMP or S-AMP), also named succinyl-AMP and *N*<sup>6</sup>-(1,2-dicarboxyethyl)AMP, is the immediate product of the adenylosuccinate synthetase (*Reaction*: IMP + Aspartate + GTP  $\rightleftharpoons$  Adenylosuccinate + GDP + P<sub>i</sub>) and the substrate for adenylosuccinate lyase, or ADSL (*Reaction*: Adenylosuccinate  $\rightleftharpoons$  AMP + Fumarate). In ADSL deficiency, biologic fluids accumulate succinyladenosine (S-Ado), which is formed by enzymatic hydrolysis of AMP-Succ (1). Adenylosuccinate also appears to be an insulin secretagogue that is formed during glucose-induced purine metabolism and may play a role in loss of glucose-stimulated insulin secretion (GSIS) from islet  $\beta$ -cells, a transition that heralds the onset of type 2 diabetes, or T2D (2). Indeed, exposure of the robustly glucose responsive INS-1-derived insulinoma cell line 832/13 to stimulatory glucose concentrations results in a striking increase in adenylosuccinate levels, and molecular or pharmacological manipulation of S-AMP levels results in alterations in insulin secretion that are consistent with a regulatory role for this metabolite (2). Addition of S-AMP to the interior of patch-clamped human  $\beta$ -cells amplifies exocytosis, an effect that depends upon expression of Sentrin/SUMO-specific protease-1 (SEN1). S-AMP also overcomes a defect in glucose-induced exocytosis in  $\beta$ -cells from a human donor with T2D. S-AMP is therefore an insulin secretagogue capable of reversing  $\beta$  cell dysfunction in T2D (2). The *N*<sup>6</sup>-(D-1,2-dicarboxyethyl)adenosine 5'-monophosphate epimer inhibits adenylosuccinate lyase ( $K_i = 100 \mu\text{M}$ ). Adenylosuccinate also inhibits IMP cyclohydrolase, which in humans is actually a bifunctional enzyme consisting of 5-aminoimidazole-4-carboxamide ribotide (AICAR) transformylase and IMP cyclohydrolase activities (3). **See also Hydantocidin** 1. Brand & Lowenstein (1978) *Biochemistry* 17, 1365. 2. Gooding, Jensen, Dai, *et al.* (2015) *Cell Rep.* 13, 157. 3. Szabados, Hindmarsh, Phillips, Duggleby & Christopherson (1994) *Biochemistry* 33, 14237.

## 9-O-(Adenylyl)spectinomycin

This alternative product (FW<sub>free-acid</sub> = 642.54 g/mol), which is formed by the *Escherichia coli* streptomycin/spectinomycin resistance factor, inhibits streptomycin 3'-adenylyltransferase, the newly discovered bifunctional enzyme and aminoglycoside antibiotic resistance factor in *Serratia marcescens*. 1. Kim, Heseck, Zajicek, Vakulenko & Mobashery (2006) *Biochemistry* 45, 8368.

## Adipic Acid

This six-carbon dicarboxylic acid (FW<sub>free-acid</sub> = 146.14 g/mol; CAS 124-04-9; M.P. = 152°C;  $pK_1 = 4.43$  and  $pK_2 = 5.41$ ) derives its name from *adipis* (Greek for "fat"), because it was first prepared by oxidation of various lipids. It is often employed in controlled-release formulations that facilitate pH-independent release for weakly basic and weakly acidic drugs. **Target(s)**: glutamate decarboxylase (1,10); kynurenine:oxoglutarate aminotransferase (2,5,11,18,27,30,31); carbamoyl-phosphate synthetase (3); fumarase (4,6); aspartate aminotransferase (7-10,17,33); succinate dehydrogenase (10,12);  $\gamma$ -butyrobetaine dioxygenase, or  $\gamma$ -butyrobetaine hydroxylase,  $K_i = 0.15 \text{ mM}$  (13); D-aspartate oxidase, weakly inhibited (14); pyrophosphatase, or inorganic diphosphatase (15); 4-aminobutyrate aminotransferase (16,29); glutamate dehydrogenase (19); carboxy-*cis,cis*-muconate cyclase (20); nitrile hydratase (21); aconitase, or aconitate hydratase (22); diaminopimelate decarboxylase (23); cytosol alanyl aminopeptidase (24); 3-oxoadipate CoA-transferase, activated at 2 mM, but inhibited at higher concentrations (25); 2-aminoadipate aminotransferase (26,27); pyridoxamine:oxaloacetate aminotransferase, weakly inhibited at pH 8 (28); leucine aminotransferase (32); procollagen-lysine 5-dioxygenase (34); procollagen-proline 3 dioxygenase (34). 1. ### Adiphenine

This anticholinergic agent (FW<sub>free-base</sub> = 311.42 g/mol; CAS 50-42-0), also named Diphacil and 2-(diethylamino)ethyl 2,2-diphenylacetate, targets both muscarinic (1,2) and nicotinic (3) acetylcholine receptors (3). Adiphenine is a fat-soluble compound that freely crosses the blood brain barrier. In rats, adiphenine was extensively metabolized by hydrolysis of the ester bond into diethylaminoethanol, diphenylacetic acid, diphenylacetic acid glucuronide and, in small quantities, the corresponding glycine and glutamine conjugates (4). **1.** Eglén & Whiting (1987) *Brit. ### Adiponectin

This 244-residue anti-diabetic hormone (MW<sub>monomer</sub> = 30 kDa; Symbol: Ad) is a adipocyte-derived polypeptide that regulates energy homeostasis and glucose and lipid metabolism, mainly by increasing the insulin responsiveness of susceptible cells and by stimulating the phosphorylation/activation of the 5'-AMP-activated protein kinase, or AMPK (1-3). Adiponectin circulates in human plasma mainly as a 180-kDa middle molecular weight (MMW) hexamer and a high molecular weight (HMW) multimer of approximately 360 kDa. It has four topologically distinct regions: a short signal sequence targeting the hormone for secretion; a short species-variant region; a 65-residue region resembling collagens; and a globular domain. This adipokine, which bears similarities in domain structure to the complement protein C1q, is processed into at least three homomeric complexes, trimer, hexamer, and a high-molecular-weight (HMW) octadecamer. In skeletal muscle, AMPK is stimulated with globular and full-length Ad, whereas AMPK is only stimulated by full-length Ad in liver. Ad stimulates phosphorylation of acetyl coenzyme A carboxylase (ACC), fatty-acid oxidation, glucose uptake and lactate production in myocytes, phosphorylation of ACC and reduction of molecules involved in gluconeogenesis in the liver, and reduction of glucose levels *in vivo*. Inhibition of AMPK activation (**See Dominant Negative Mutants**) blocks each of these effects, indicating that stimulation of glucose utilization and fatty-acid oxidation by Ad occurs through activation of AMPK (4). **1.** Nawrocki, Rajala, Tomas, *et al.* (2006) *J. ### AdipoRon

This orally bioavailable adiponectin receptor agonist (FW = 428.52 g/mol; CAS 924416-43-3; Solubility: 100 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as 2-(4-benzoylphenoxy)-N-(1-benzylpiperidin-4-yl)acetamide,

stimulates AMPK-mediated phosphorylation and activation of AdipoR1 ( $K_d = 1.8 \mu\text{M}$ ) and AdipoR2 ( $K_d = 3.1 \mu\text{M}$ ), which are orientated oppositely to most GPCRs within the membrane (*i.e.*, cytoplasmic N-terminus, extracellular C-terminus), such that they cannot associate with G-proteins. In wild type mice, AdipoRon (orally administered at 50 mg/kg) improves insulin resistance, glucose intolerance, and dyslipidemia by activating AdipoR1-AMPK-PGC-1 $\alpha$  pathways in skeletal muscle, while by activating AdipoR2-PPAR- $\alpha$  (Peroxisome Proliferator-Activated Receptor) pathways in the liver. **1.** Okada-Iwabu, Yamauchi, Iwabu, *et al.* (2013) *Nature* **503**, 493.

### Adociasulfate-2

This marine natural product (FW<sub>disodium-salt</sub> = 738.92 g/mol; CAS 208181-29-7; Abbreviated: AS-2) from the sponge *Haliclona* sp. (also known as *Adocia* sp.) specifically inhibits kinesin activity by interfering with microtubule binding. This mechanism is unlike that of any known kinesin (or other motor) inhibitor, and AS-2 is thought to mimic tubulin binding to a region within kinesin's microtubule-binding site.<sup>1</sup> This potent inhibitor (IC<sub>50</sub> = 2.7  $\mu\text{M}$ ) may generally arrest transport by other members of the kinesin superfamily. **1.** Sakowicz, Berdelis, Ray, *et al.* (1998) *Science* **280**, 292.

### Ado-Trastuzumab Emtansine

This antibody-drug conjugate or ADC (FW = 146.3 kDa; CAS 400010-39-1; Abbreviation: T-DM1, marketed under the name Kadcyla<sup>TM</sup>) is a novel cancer therapeutic that attaches to surface determinants on targeted cancer cells and, upon internalization, releases the powerful anti-microtubule drug mertansine, thereby killing them. T-DM1 is a humanized epidermal growth factor receptor (HER2)-targeted antibody-drug conjugate consisting of trastuzumab (MW = 145,500; CAS 180288-69-1; also known as Herclon<sup>TM</sup> and Herceptin<sup>TM</sup>) joined by means of a stable, 4-mercaptovalerate thioether linker to the potent cytotoxic agent DM1 or Derivative of Maytansine-1 (*or* Mertansine, FW = 739.29 g/mol). Kadcyla is the first FDA-approved ADC for treating HER2-positive mBC, an aggressive form of the disease. To generate thioTMAb-mpeo-DM1, mertansine was conjugated to an engineered cysteine residue at Ala114 (Kabat numbering) on each trastuzumab-heavy chain, resulting in two DM1 molecules per antibody (1). ThioTMAb-mpeo-DM1 retained similar *in vitro* anti-cell proliferation activity and human epidermal growth factor receptor 2 (HER2) binding properties to that of the conventional ADC. Furthermore, it showed improved efficacy over the conventional ADC at DM1-equivalent doses ( $\mu\text{g}/\text{m}^2$ ) and retained efficacy at equivalent antibody doses (mg/kg). Moreover, its pharmacokinetic profile is unaffected by circulating levels of HER2 extracellular domain or residual trastuzumab (2). **1.** Junutula, Flagella, Graham, *et al.* (2010) *Clin. Cancer Res.* **16**, 4769. **2.** Girish, Gupta, Wang, *et al.* (2012) *Cancer Chemother Pharmacol.* **69**, 1229.

## ADP-D-glucose

This starch biosynthesis intermediate (FW<sub>free-acid</sub> = 589.35 g/mol; CAS 2140-58-1), also known as adenosine (5')diphospho(1)- $\alpha$ -D-glucose, has the following inhibitory targets: UDP-glucuronate 4-epimerase (1,7); starch phosphorylase (2,15,16,19-26,28,29,32); UDP-glucose pyrophosphorylase, or glucose-1-phosphate uridylyltransferase (3); alcohol dehydrogenase,  $K_i$  = 0.48 mM (4); ADP-glyceromanno-heptose 6-epimerase (5,6); UDP-sugar diphosphatase (8); pyruvate, water dikinase, weakly inhibited (9); glucose-1-phosphate cytidylyltransferase, weakly inhibited (10);  $\beta$ -1,4-mannosyl-glycoprotein 4- $\beta$ -N acetylglucosaminyltransferase (11); maltose synthase (12);  $\alpha$ , $\alpha$ -trehalose-phosphate synthase, or UDP forming (13); glycogen synthase, alternative substrate (14); glycogen phosphorylase (17,18,27,30,31,33). 1. ## ADP-D-ribose

This sugar nucleotide (FW<sub>free-acid</sub> = 559.32 g/mol; CAS 68414-18-6), often referred to as ADPR and adenosine 5'-diphosphoribose, is a primary 5'-phosphoribosylation substrate in both purine and pyrimidine nucleotide biosynthesis. It is also component of NAD<sup>+</sup> and inhibits a number of NAD<sup>+</sup>-dependent enzymes. ADPR binds to and activates the Transient Receptor Potential cation, subfamily M, member 2 (or TRPM2) channel, a non-selective calcium-permeable cation channel. **Target(s)**: formaldehyde dehydrogenase (glutathione) (1,18); S-(hydroxymethyl)-glutathione dehydrogenase (1,18); nicotinamide-nucleotide adenyltransferase (2,11,33,34); alcohol dehydrogenase,  $K_d$  = 9  $\mu$ M at pH 6 (3,4,12-14,19); NAD<sup>+</sup> kinase (5,9,35); isocitrate dehydrogenase, NAD<sup>+</sup> (6,8); malate dehydrogenase (7); poly(ADP-ribose) glycohydrolase (10); DNA-(apurinic or apyrimidinic site) lyase (15); ADP-ribosyl-[dinitrogen reductase]

hydrolase (16); nucleotide diphosphatase (17); [protein ADP-ribosylarginine] hydrolase (20-24); NMN nucleosidase (25); NAD(P)<sup>+</sup> nucleosidase, product inhibition (26); NAD<sup>+</sup> nucleosidase, NADase, product inhibition (27-30); phosphodiesterase I, or 5' exonuclease (31); ribose-5-phosphate adenyltransferase (32); NAD<sup>+</sup>:protein-arginine ADP ribosyltransferase (36); glycogen phosphorylase (37); procollagen-proline 4-dioxygenase, weakly inhibited (38); lactate dehydrogenase (39). 1. ADP[S] or ADP $\beta$ S, See Adenosine 5'-(2-Thiodiphosphate)

## Adrafinil

This hydroxamate-containing pro-drug (FW = 289.35 g/mol; CAS 63547-13-7), also known by its code name CRL-40028 and trade name Olmifon<sup>®</sup>, is a mild CNS stimulant used to relieve excessive sleepiness and inattention in elderly patients. Adrafinil is mainly metabolized to modafinil (See Modafinil), with which it shares many pharmacologic properties. Given its abuse by athletes in training, the World Anti-Doping Agency (WADA) banned adrafinil and modafinil in sports since 2004.

## Adrenate

This long-chain, unsaturated fatty acid (FW<sub>free-acid</sub> = 332.53 g/mol; CAS 28874-58-0), also known as adrenic acid and (7Z,10Z,13Z,16Z)-docosatetraenoic acid, inhibits arachidonyl-CoA synthetase, or

arachidonate:CoA ligase (1) and prostaglandin biosynthesis (2). 1. Taylor, Sprecher & Russel (1985) *Biochim. Biophys. Acta* **833**, 229. 2. Cagen & Baer (1980) *Life Sci.* **26**, 765.

### Aducanumab

This high-affinity, fully human IgG1 monoclonal antibody (MW = 149.5 kDa; CAS 1384260-65-4), also known by the developmental code name BIIB037, selectively targets aggregated forms of  $\beta$ -amyloid protein (EC<sub>50</sub> = 0.1 nM), while showing weak binding to  $\beta$  monomer. In the brains of transgenic mice, aducanumab preferentially binds to parenchymal  $\beta$  over vascular  $\beta$  deposits, consistent with the lack of effect on vascular  $\beta$  following chronic dosing. Aducanumab dose-dependently reduces amyloid deposition in six cortical regions of the brain. <sup>ch</sup>Aducanumab, a murine IgG2a/ $\kappa$  chimeric analogue, dose-dependently reduces  $\beta$  measured in brain homogenates by up to 50% relative to the vehicle control in the diethylamine fraction that extracted soluble monomeric and oligomeric forms of  $\beta$ <sub>40</sub> and  $\beta$ <sub>42</sub>, and in the guanidine hydrochloride fraction that extracted insoluble  $\beta$  fibrils. The clearance of  $\beta$  deposits was accompanied by enhanced recruitment of microglia. Together with the reduced potency of the aglycosylated form of <sup>ch</sup>aducanumab and the *ex vivo* phagocytosis data, such findings suggest that Fc $\gamma$ R-mediated microglial recruitment and phagocytosis played an important role in  $\beta$  clearance in these models. Activated microglia appeared to encapsulate the remaining central dense core of plaques in treated animals, possibly isolating them from the surrounding neuropil. 1. Sevigny, Chiao, Bussière, *et al.* (2016) *Nature* **537**, 50.

### ADX 71743

This brain-penetrant mGlu<sub>7</sub> allosteric negative modulator (FW = 269.34 g/mol; CAS 1431641-29-0; Solubility: 100 mM in DMSO), also named 6-(2,4-dimethylphenyl)-2-ethyl-6,7-dihydro-4(5H)-benzoxazolone, potently and selectively targets the metabotropic glutamate receptor-7, itself a promising novel target for treatment of anxiety, post-traumatic stress disorder, depression, drug abuse, and schizophrenia. When tested *in vitro*, Schild plot analysis and reversibility tests at the target confirmed the NAM properties of the compound and attenuation of L-(+)-2-amino-4-phosphonobutyric acid (*or* L-AP4)-induced synaptic depression confirmed activity at the native receptor. When tested *in vitro*, ADX-71743 gives a IC<sub>50</sub> value versus EC<sub>80</sub> of glutamate = 22 nM at human mGlu<sub>7</sub> in a 3',5'-cyclic-AMP assay, with IC<sub>50</sub> values versus EC<sub>80</sub> of L-AP4 are 63 and 125 nM at human mGlu<sub>7</sub> in Ca<sup>2+</sup> and cAMP assays respectively; IC<sub>50</sub> value versus EC<sub>80</sub> of L-AP4 = 88 nM at rmGlu<sub>7</sub> in a Ca<sup>2+</sup> assay. Selective for mGlu<sub>7</sub> over all other mGlu receptor subtypes and a panel of relevant GPCRs. Exhibits an anxiolytic-like profile *in vivo*. The Schild plot experiments clearly indicate the noncompetitive nature of ADX71743 inhibition, whereas simple wash experiments seem to indicate that its binding to the receptor is readily reversible. **Other Targets:** When tested for its action at other mGlu-expressing cells in series of FLIPR experiments, ADX71743 showed no detectable activity (either agonist or allosteric effects) in cell lines expressing hmGlu<sub>3</sub>, hmGlu<sub>4</sub>, rmGlu<sub>5</sub>, hmGlu<sub>6</sub>, and hmGlu<sub>8</sub>. A negligible inhibition of rmGlu<sub>1</sub> (32% at 30  $\mu$ M) and a weak positive allosteric modulator effect on hmGlu<sub>2</sub> (EC<sub>50</sub> = 11  $\mu$ M) was measured. When further tested in a functional GPCR screen against 27 targets in agonist and antagonist modes, ADX71743 exhibited no stimulation or inhibition above 27% was observed. 1. Kalinichev, Rouillier, Girard, *et al.* (2013) *J. Pharmacol. Exp. Ther.* **344**, 624.

**AESBF, See 4-(2-Aminoethyl)benzenesulfonyl Fluoride**

### Aedesin

This cecropin-like antimicrobial (FW = 3676.54 g/mol; Sequence: GGLKLLGKLEAGKRVFKASEKALPVVVGKAIK, matching residues 26-61 in the longer polypeptide AEEL000598, *or* Q17NR1), is a pore-forming, helix-bend-helix peptide that kill drug-resistant Gram-negative bacterial strains displaying resistance to carbapenems, aminoglycosides, cephalosporins, antifolates, fourth generation fluoroquinolones, and monobactams (**See also Cecropins**). Aedesin is isolated from infected salivary glands from the mosquito *Aedes aegypti*, the well-known dengue virus (*or* DV) vector. Its anti-bacterial activity is salt-

resistant, indicating it remains active in physiological fluids. Aedesin has two amphipathic  $\alpha$ -helices within the Lys<sup>30</sup>-Lys<sup>48</sup> and Val<sup>52</sup>-Ile<sup>59</sup> regions at the N- and C-terminal part of the peptide. While the N-terminal region contains a large stretch of positively charged residues including six Lys residues, the C-terminal helix is clearly hydrophobic, with two Ile and three Val residues, separated by a Lys residue. Gram-positive strains are insensitive to Aedesin's lytic effects. Significantly, Aedesin plays a role in protecting mosquitoes from infection by dengue virus, which is not simply passively transported to humans by its vector *A. aegypti*. Viral replication in the mosquito salivary gland is essential for the later injection of infectious saliva into the human host and continuation of the dengue virus transmission cycle. Aedesin may offer a measure of protection against overgrowth of virus in the salivary gland. In this respect, the mosquito vector is likely to have various ways to assure its own survival while harboring a variety of pathogens. 1. Godreuil, Leban, Padilla, *et al.* (2014) *PLoS One.* **9**, e105441.

### Aerothricin 3

This cyclic lipopeptide lactone (FW = 1474.72 g/mol), produced by *Deuteromycotina* spp. NR7379, inhibits *Saccharomyces cerevisiae* 1,3- $\beta$ -glucan synthase, which contains two catalytic subunits (Fks1p and Fks2p) and makes a main component of the cell wall. Although highly homologous (88.1% identity), Fks2p is more sensitive than Fks1p to inhibition by aerothricin-3. By constructing a series of chimeric FKS genes and examining their sensitivity to aerothricin-3, it was shown that a region around the fourth extracellular domain of Fks2p, containing 10 different amino acid residues from those of Fks1p, conferred Fks1p aerothricin-3 sensitivity, when the region was replaced with a corresponding region of Fks1p. To identify essential amino acid residue(s) responsible for the sensitivity, each of the 10 non-conserved amino acids of Fks1p was substituted into the corresponding amino acid of Fks2p by site-directed mutagenesis. Only one amino acid substitution of Fks1p (Lys-1336-Ile) was needed to confer Fks1p hypersensitivity to aerothricin-3. On the other hand, reverse substitution of the corresponding amino acid of Fks2p (Ile-1355-Lys) resulted in loss of hypersensitivity to aerothricin-3. Such findings results suggest this isoleucine of Fks2p plays a key role in aerothricin-3 sensitivity. 1. Kondoh, Takasuka, Arisawa, Aoki & Watanabe (2002) *J. Biol. Chem.* **277**, 41744.

**AF 802, See Alectinib**

### Afatinib

This oral quinazoline derivative and EGFR/HER2-directed protein kinase inhibitor (FW = 485.94; CASs = 439081-18-2 (free base), 936631-70-8 (maleic acid salt), 1254955-21-9 (HCl salt); Solubility (at 25°C): 197 mg/mL DMSO, 1 mg/mL Water), also known by its code name BIBW2992, its trade names Gilotrif<sup>®</sup> Tomtovok<sup>®</sup>, Tovok<sup>®</sup>, and its systematic name (*S,E*)-*N*-(4-(3-chloro-4-fluorophenyl-amino)-7-(tetrahydrofuran-3-yloxy)quinazolin-6-yl)-4-(dimethylamino)but-2-enamide, irreversibly inactivates EGFR<sup>wt</sup>, EGFR<sup>L858R</sup>, EGFR<sup>L858R/T790M</sup> and HER2

with IC<sub>50</sub> values of 0.5 nM, 0.4 nM, 10 nM and 14 nM, respectively (1). **Mode of Action:** The irreversible binding of afatinib to HER2 inactivates its interactions with a preferred partner of EGFR, and blocking the HER2-EGFR heterodimerization reduces their intrinsic tyrosine kinase activities. Irreversible inhibitors (such as afatinib and dacomitinib) that target all ErbB family receptor tyrosine kinases are intended to confer sustained disease control in ErbB-dependent cancers. Because nearly all EGFR-mutated patients eventually develop resistance to reversible EGFR-TKIs after a median of 14 months, afatinib's irreversible action is thought to be a promising feature of its mode of action. **Pharmacokinetics:** Afatinib's PK profile is best described by a two-compartment disposition model, with first-order absorption and linear elimination. There was a slightly more than proportional increase in exposure with increasing dose, most likely due to dose-dependent relative bioavailability. For the therapeutic dose of 40 mg, the estimated apparent total clearance rate at steady state was 734 mL/min (2). 1. Li, Ambrogio, Shimamura *et al.* (2008) *Oncogene* **27**, 4702. 2. Freiwald, Schmid, Fleury, *et al.* (2014) *Cancer Chemother. Pharmacol.* **73**, 759.

### Aflatoxins

These mycotoxins (FW<sub>B1</sub> = 312.30 g/mol; CAS 1162-65-8; FW<sub>B2</sub> = 314.29 g/mol; CAS 7220-81-7; FW<sub>G1</sub> = 328.27 g/mol; CAS 1165-39-5; FW<sub>G2</sub> = 330.29 g/mol; CAS 7241-98-77; FW<sub>M1</sub> = 328.27 g/mol; CAS 6795-23-9; FW<sub>M2</sub> = 330.29 g/mol; CAS 6885-57-0), produced by the fungus *Aspergillus flavus*, *A. parasiticus*, *A. oryzae*, and some *Penicillium* strains, are a set of closely related metabolites that are known carcinogens. The B and G designations in the name refer to the blue or green fluorescence, respectively, that are exhibited by the mycotoxins (aflatoxins B<sub>2</sub> and G<sub>2</sub> are dihydro derivatives of B<sub>1</sub> and G<sub>1</sub> that are less toxic). The M series of aflatoxins are hydroxylated derivatives of the B series toxins isolated from the milk of cows that ingested aflatoxin-contaminated feed. Initially innocuous forms are bioactivated by members of the cytochrome p450 family into mutagenic and carcinogenic intermediates. Aflatoxin-B<sub>1</sub>, for example, is converted into aflatoxin B<sub>1</sub>-8,9 *exo*-epoxide, which is in turn converted into the 8,9-dihydroxy-8-*N*'-guanyl-9-hydroxy aflatoxin B<sub>1</sub> adduct. This adduct is metabolized into aflatoxin B<sub>1</sub> formaminopyrimidine adduct. It is these adducts that prove to be strongly mutagenic and often carcinogenic. Chronic hepatitis B virus (HBV) infection and persistent AFB<sub>1</sub> exposure are major risk factors for developing hepatocellular carcinogenesis, suggesting synergy in the action of these agents. **Nucleic Acid Interactions:** Aflatoxins have dimensions and so-called bay region aromatic characteristics that allow them to intercalate between base-pairs in DNA and double-stranded segments of RNA. Major groove recognition of DNA by proteins also relies on the variation in hydrogen-bond donor/acceptor content to makes DNA base-pairs distinguishable from one another, and aflatoxins may mimic major groove-binding proteins. Aflatoxins also inhibit RNA biosynthesis, transcription, and protein biosynthesis. **CAUTION:** Aflatoxin B<sub>1</sub> is a highly potent mutagen and carcinogen. Avoid

direct exposure to the skin or eyes as well as inhalation. **Target(s):** RNA polymerase (1-4,6,8,9); DNase-I (deoxyribonuclease I), by Aflatoxin B<sub>2a</sub> > Aflatoxin G<sub>2a</sub>; (5); electron transport (7,11); nucleoside transport (10); oxidative phosphorylation, uncoupled (11); β-galactoside α-2,6-sialyltransferase, inhibited by Aflatoxins B<sub>1</sub>, B<sub>2a</sub>, and G<sub>1</sub> (12); glycoprotein sialyltransferase (12); acetylcholinesterase, inhibited by Aflatoxin B<sub>1</sub> (13); aminopeptidase B (14). 1. ### AFN-1252

This selective, orally available, first-in-class antibiotic (FW = 375.43 g/mol; CAS 620175-39-5; Formulated in 1% Poloxamer 407) is a potent inhibitor of *Staphylococcus aureus* enoyl-acyl carrier protein reductase (FabI), thereby preventing fatty acyl chain elongation and disrupting biosynthesis of both saturated and unsaturated fatty acids needed for bacterial growth. It demonstrates exceptional potency and specificity against staphylococcal isolates, with typical *S. aureus* MIC ranges of 0.002–0.12 μg/mL and MIC<sub>90s</sub> of ≤ 0.015 μg/mL (1). **Mode of Action:** FabI is the only enoyl-ACP reductase in *S. aureus*, *S. epidermidis*, and related staphylococci, with no alternative enzyme or rescue pathway, including processing of exogenously supplied fatty acids (1,2). Such metabolic features suggest FabI may be essential to cell viability in *Staphylococcus* spp. The inhibitor's target was convincingly confirmed (a) by using direct enzyme assays (IC<sub>50</sub> = 14 nM, with no inhibition of the human enzyme, even at 67 μM); (b) by employing radiolabeled acetate to demonstrate that AFN-1252 greatly reduced incorporation into lipids; (c) by co-crystallizing AFN-1252 and FabI in the presence of the unnatural substrate 3'-NADPH, and (d) by genetically determining AFN-1252's spontaneous resistance frequency and characterizing AFN-1252-resistant FabI mutants (2). In so-called time-kill assays, AFN-1252 caused a time-dependent reduction in the viability of *S. aureus* ATCC 29213 (MSSA) and *S. aureus* ATCC 43300 (MRSA), with similar magnitudes and rates of killing were obtained at 4 and 128 times the MIC (*i.e.*, 2.0- and 2.9-log<sub>10</sub> reductions) (2). 1. Karlowsky, Kaplan, Hafkin, *et al.* (2009) *Antimicrob. Agents Chemother.* **53**, 3544. 2. Parsons, Kukula, Jackson, *et al.* (2013) *Antimicrob. Agents Chemother.* **57**, 2182.

### Afoxolaner

This orally active isoxazoline-based pesticide (FW = 901.18 g/mol; CAS 1093861-60-9; IUPAC Name: 4-[5-[3-chloro-5-(trifluoromethyl)phenyl]-4,5-dihydro-5-(trifluoromethyl)-3-isoxazolyl]-*N*-[2-oxo-2-[(2,2,2-trifluoroethyl)amino]ethyl]-1-naphthalenecarboxamide, is highly active against fleas (*Ctenocephalides felis*) and ticks (*Dermacentor variabilis*) in dogs. Afoxolaner is more potent, when tested *in vitro*, than any other compound ever tested in the membrane feeding system, including the avermectins. At an oral dose of 2.5 mg/kg, afoxolaner reaches pharmacologically effective plasma concentrations (0.1–0.2 μg/mL), blocking native and expressed insect GABA-gated chloride channels with nanomolar potency. Afoxolaner has comparable potency between wild-type channels as well as channels

possessing the dieldrin resistance-conferring Alanine-302-Serine mutation. Lack of cyclodiene cross-resistance for afloxolaner suggests that afloxolaner blocks GABA-gated chloride channels by binding at a site topologically distinct from the cyclodienes. 1. Shoop, Hartline, Gould, *et al.* (2014) *Vetern. Parasitol.* **201**, 179.

#### Afuresertib

This potent and orally bioavailable pan-AKT inhibitor (FW<sub>free-base</sub> = 427.32 g/mol; CAS 1047644-62-1; Soluble in DMSO) is ATP-competitive and targets AKT1 ( $K_i = 0.08$  nM), AKT1<sup>E17K</sup> ( $K_i = 0.2$  nM), AKT2 ( $K_i = 2$  nM), and AKT3 ( $K_i = 2.6$  nM), a family of serine-threonine kinase in the PI3K-AKT pathway, which is often dysregulated in many human malignancies, leading to increased cell survival, growth and proliferation (1). PIP3 lipids tether these kinases to the membrane via their plextrin homology domain, enabling activation by Thr308 phosphorylation by PDK1 and Ser473 phosphorylation by the mTORC2 complex. Activated AKT in turn phosphorylates FOXO, TSC1/2, PRAS40, and GSK3 $\beta$ . Combination of Lapatinib with Afuresertib (or Uprosertib) is synergistic in HER2<sup>+</sup>/PIK3CA<sup>mut</sup> cell lines, but not in HER2<sup>+</sup>/PIK3CA<sup>wild-type</sup> cell lines (2). Measured changes in phosphoprotein levels in 15 cell revealed that p-S6RP levels were less well attenuated by lapatinib in HER2<sup>+</sup>/PIK3CA<sup>mut</sup> cells compared to HER2<sup>+</sup>/PIK3CA<sup>wild-type</sup> cells and that Lapatinib plus Afuresertib (or Uprosertib) reduced p-S6RP levels to those achieved in HER2<sup>+</sup>/PIK3CA<sup>wild-type</sup> cells with lapatinib alone. There is also compensatory up-regulation of p-HER3, and p-HER2 is blunted in PIK3CA(mut) cells, following Lapatinib plus Afuresertib (or Uprosertib) treatment (2). **See also Uprosertib** **Other Targets:** P70SK6 (IC<sub>50</sub> = 251 nM), PKA (IC<sub>50</sub> = 1.3 nM), PKC $\alpha$  (IC<sub>50</sub> = >1000 nM), PKC $\beta$ 1 (IC<sub>50</sub> = 430 nM), PKC $\beta$ 2 (IC<sub>50</sub> = >1000 nM), PKC $\delta$  (IC<sub>50</sub> = 1000 nM), PKC $\gamma$  (IC<sub>50</sub> = >1000 nM), PKC $\epsilon$  (IC<sub>50</sub> = >1000 nM), PKC $\theta$  (IC<sub>50</sub> = 510 nM), PKC $\eta$  (IC<sub>50</sub> = 210 nM), PKC $\xi$  (IC<sub>50</sub> = >1000 nM), PKG1 $\alpha$  (IC<sub>50</sub> = 0.9 nM), PKG1 $\beta$  (IC<sub>50</sub> = 4 nM), ROCK (IC<sub>50</sub> = 100 nM), RSK1 (IC<sub>50</sub> = 320 nM). 1. #### AG957

This tyrosine kinase inhibitor (FW = 273.28 g/mol; CAS 140674-76-6; Soluble in 5 mg/mL DMSO) targets BCR/ABL tyrosine kinase activity, restores  $\beta$ 1 integrin-mediated cell adhesion, and alters inhibitory signaling in chronic myelogenous leukemia hematopoietic progenitors (1-3). AG957 selectively blocks the tyrosine kinase activity of human p210<sup>bcf-abl</sup> ( $K_i = 750$  nM) versus p140<sup>c-abl</sup> ( $K_i = 10$   $\mu$ M). It also decreases p210<sup>bcf-abl</sup> phosphorylation in viable K562 cells at concentrations and durations of exposure that likewise inhibit cell proliferation. AG957 alters the physical state of p210<sup>bcf-abl</sup> and the association of p210<sup>bcf-abl</sup> with Shc and Grb2 in K562 cells. 1. ### Agmatine

This arginine metabolite (FW<sub>free-base</sub> = 130.19 g/mol), also known as 4-(aminobutyl)guanidine, is a putative endogenous agonist at imidazoline receptors and a ligand for α<sub>2</sub>-adrenergic receptors. Agmatine is also a precursor in the biosynthesis of a phosphagen (*i.e.*, phosphoagmatine) in certain invertebrates. In addition, agmatine blocks NMDA-activated channels in hippocampal neurons. Agmatine is a product of the reactions catalyzed by arginine decarboxylase, diguanidinobutanase, and acylagmatine amidase. **Target(s):** GfMEP thermostable lysine-specific metalloendopeptidase (1); polyamine oxidase (2,18); trypsin (2); nitric-oxide synthase (2,13,14,34); ancrod (3); diamine oxidase, weakly inhibited (4); Arginase (5,16,25); arginine 2-monooxygenase (7); guanidinobutyrase (8,22); *N*-methyl-D-aspartate (NMDA) receptors (10,19); *S*-adenosylmethionine decarboxylase (11,12); cyanophycin synthetase (15); voltage-gated Ca<sup>2+</sup> channels (10,17,19); arginine decarboxylase (11); ornithine decarboxylase (20,21); arginine deaminase (23,24); peptidyl-Lys metalloendopeptidase (26); venombin A<sub>3</sub>; arginine kinase (27,28); guanidinoacetate kinase (29); deoxyhypusine synthase (30); spermidine synthase (31); arginine *N*-succinyltransferase (32); ornithine carbamoyltransferase (33). 1. ### AH6809

This substituted xanthene (FW<sub>free-acid</sub> = 298.30 g/mol; CAS 33458-93-4), named systematically as 6-isopropoxy-9-oxoxanthene-2-carboxylic acid, is an antagonist that binds to EP<sub>1</sub> and EP<sub>2</sub> receptors (1,3) and DP receptors (2-4). AH6809 inhibits prostaglandin E<sub>2</sub> and D<sub>2</sub>-stimulated increases in cyclic AMP. 1. Woodward, Pepperl, Burkey & Regan (1995) *Biochem. Pharmacol.* **50**, 1731. 2. Crider, Griffin & Sharif (1999) *Brit. J. Pharmacol.* **127**, 204. 3. Chan, Jones & Lau (2000) *Brit. J. Pharmacol.* **129**, 589. 4. Keery & Lumley (1988) *Brit. J. Pharmacol.* **94**, 745.

### AH 23848

This prostaglandin analogue (FW<sub>free-acid</sub> = 477.60 g/mol; CAS 81496-19-7), also named (4*Z*)-*rel*-7-[(1*R*,2*R*,5*S*)-5-([1,1'-biphenyl]-4-ylmethoxy)-2-(4-morpholinyl)-3-oxocyclopentyl]-4-heptenoic acid, is a potent, specific thromboxane receptor-blocking drug that is orally active and has a long duration of action (1-4). It also blocks the action of Prostaglandin E<sub>2</sub> (PGE<sub>2</sub>), which activates four E-prostanoid receptors, EP<sub>1</sub>, EP<sub>2</sub>, EP<sub>3</sub>, and EP<sub>4</sub>. AH-23848 is a dual antagonist of TP<sup>1</sup> and EP<sub>4</sub> receptors (5). It inhibits TXA<sub>2</sub>-induced platelet aggregation, IC<sub>50</sub> = 0.26 μM (1) and the contraction of human bronchial smooth muscle induced by the TP agonist U-46619 (6). AH-23848 also impairs PGE<sub>2</sub>-mediated relaxation of piglet saphenous vein by antagonizing the PGE<sub>2</sub> receptor EP<sub>4</sub> (5) by inhibiting EP<sub>4</sub>, it likewise suppresses serum-induced cAMP generation, cyclin A synthesis, and the proliferation of fibroblasts (7). Accumulation at G<sub>0</sub>/G<sub>1</sub> after AH-6809 treatment appears to depend on intracellular Ca<sup>2+</sup> concentration, because a 6-h treatment with thapsigargin (1 μM) allowed G<sub>0</sub>/G<sub>1</sub>-arrested cells to enter S phase. Similarly, treatment with 20 μM forskolin for 6 h allowed S-phase and G<sub>2</sub>/M progression of AH-23848B-treated cells. Antagonism of the EP<sub>4</sub> receptor with either AH23848 or ONO-AE3-208 reduced breast cancer metastasis as compared with vehicle-treated controls (8). The therapeutic effect was comparable to that observed with the dual COX-1/COX-2 inhibitor indomethacin. EP<sub>3</sub> antagonism had no effect on tumor metastasis. Mammary tumor cells migrated in vitro in response to PGE and this chemotactic response was blocked by EP receptor antagonists (8). 1. ### Ajoene

This asymmetric disulfide (FW = 234.41 g/mol; CAS 92285-01-3), the major sulfur-containing compound purified from garlic, exhibits antiplatelet activity and has a possible role in the prevention and treatment of cancer. It has also been reported to inhibit prenylation of proteins. **Target(s):** lipases (1); trypsin-like activity of the 20S proteasome (2); glutathione-disulfide reductase (3); trypanothione reductase (3); protein-tyrosine phosphatase (4); soybean lipoxygenase (5). 1. Ransac, Gargouri, Marguet, *et al.* (1997) *Meth. Enzymol.* **286**, 190. 2. Xu, Monsarrat, Gairin & Girbal-Neuhauser (2004) *Fundam. Clin. Pharmacol.* **18**, 171. 3. Belman, Solomon, Segal, Block & Barany (1989) *Biochem. Toxicol.* **4**, 151.

#### AK 295

This unusual  $\alpha$ -ketoamide (FW<sub>free-base</sub> = 504.63 g/mol) inhibits calpain ( $K_i$  = 41  $\mu$ M), providing a significant dose-dependent neuroprotective effect after focal brain ischemia in rats. **Target(s):** calpain-1 (1,2); calpain-2 (2); cathepsin B, weakly inhibited (2). 1. Bartus, Hayward, Elliott, *et al.* (1994) *Stroke* **25**, 2265. 2. Li, Ortega-Vilain, Patil, *et al.* (1996) *J. Med. Chem.* **39**, 4089.

**Akt Inhibitor, See specific inhibitor; e.g., 1-L-6-Hydroxymethyl-chiro-inositol 2-(R)-2-O methyl-3-O-octadecylcarbonate**

#### Akti-1/2

This dual Akt1/Akt2 inhibitor (FW = 551.64 g/mol; CAS 612847-09-3; Soluble to 20 mM in DMSO with gentle warming), also named 1,3-dihydro-1-[1-[[4-(6-phenyl-1H-imidazo[4,5-g]quinoxalin-7-yl)phenyl]-methyl]-4-piperidinyl]-2H-benzimidazol-2-one, targets Protein kinase B (PKB) isoforms Akt1 ( $IC_{50}$  = 50 nM) and Akt2 ( $IC_{50}$  = 210 nM), serine/threonine-specific protein kinases that play a key role in multiple cellular processes such as glucose metabolism, apoptosis, cell proliferation, transcription and cell migration. Akti-1/2 is selective for Akt1 and 2 over a panel of other tyrosine and serine/threonine kinases (1-3). It also sensitizes LnCaP cells to TRAIL (TNF-related apoptosis-inducing ligand) induced apoptosis. Complete inhibition is achieved in liver cells treated with 1-10  $\mu$ M (4). Akti-1/2 also blocks insulin regulation of PEP carboxykinase and glucose 6-phosphatase expression (4). 1. Barnett, *et al.* (2005) *Biochem. J.* **385**, 399. 2. DeFeo-Jones, *et al.* (2005) *Mol. Cancer Ther.* **4**, 271. 3. Lindsley, Zhao, Leister, *et al.* (2005) *Bioorg. Med. Chem. Lett.* **15**, 761. 4. Logie, Ruiz-Alcaraz, Keane, *et al.* (2007) *Diabetes* **56**, 2218.

#### Akt Inhibitor II

This phosphatidylinositol analogue (FW<sub>free-acid</sub> = 598.76 g/mol), also known as SH-5, inhibits the proto-oncogenic serine/threonine kinase Akt (protein kinase B), inducing apoptosis. Specific inhibition of Akt by these compounds validates ligand design targeted to the PH domains of crucial signaling proteins, thus providing a unique class of possible cancer therapeutics. 1. Kozikowski, Sun, Brognard & Dennis (2003) *J. Amer. Chem. Soc.* **125**, 1144.

**Akt Inhibitor III, Similar in action to Akt Inhibitor II**

#### Akt-I-1

This reversible, cell-active protein kinase inhibitor (FW = 378.51 g/mol; CAS 473382-39-7) targets Akt1,  $IC_{50}$  = 4.6  $\mu$ M, showing linear mixed-type inhibition against ATP and peptide substrate. Akt/PKB (protein kinase B) is a serine/threonine kinase that plays a key role in regulating cell survival and proliferation. Akt1, Akt2 and Akt3 possess an N-terminal PH (pleckstrin homology) domain as well as a kinase domain, separated by a 39-amino-acid hinge region. Akt-I-1 is virtually inactive against Akt2 ( $IC_{50}$  > 250  $\mu$ M) or Akt3 ( $IC_{50}$  > 250  $\mu$ M). It also blocks the phosphorylation and activation of Akt1 by PDK1 (Phosphoinositide-Dependent Kinase-1). Akt-I-1 blocks Akt phosphorylation at Thr-308 and Ser-473 and reduces the levels of active Akt within cells, as well as blocking phosphorylation of known Akt substrates and promoting TRAIL- (or Tumour-necrosis-factor-Related Apoptosis-Inducing Ligand-) induced apoptosis in LNCap prostate cancer cells. This inhibitor is weakly active ( $IC_{50}$  > 250  $\mu$ M) against  $\Delta$ PH-Akt1, a form lacking its pleckstrin homology domain. In fact, antibodies to the Akt PH domain or hinge region block Akt-I-1 inhibition of Akt. 1. Barnett, DeFeo-Jones, Fu, *et al.* (2005) *Biochem. J.* **385** (Part 2), 399.

**Al, See Aluminum and Aluminum Ions**

#### AL-8810

This prostaglandin PGF<sub>2</sub> $\alpha$  analogue (FW<sub>free-acid</sub> = 402.51 g/mol; CAS 246246-19-5), also named (5Z,13E)-(9S,11S,15R)-9,15-dihydroxy-11-fluoro-15-(2-indanyl)-16,17,18,19,20-pentanoic-5,13-prostadienoate, is a strong and selective FP prostanoid receptor antagonist:  $K_i$  = 400-500 nM. AL 8810 is an 11 $\beta$ -fluoro analogue of PGF<sub>2</sub> $\alpha$  which acts as a potent and selective antagonist at the FP receptor (1). AL 8810 exhibits weak intrinsic agonist activity on FP receptor preparations in the 200-300 nM range, but fully antagonizes the activity of the potent FP receptor agonist fluprostenol ( $EC_{50}$  = 430 nM). AL-8810 fully antagonizes the bimatoprost-induced calcium mobilization in Swiss 3T3 fibroblasts at 100  $\mu$ M, indicating that bimatoprost acts as an FP agonist in this preparation (2). Its  $K_i$  for inhibiting several potent agonists at the cloned human ciliary body FP receptor is in the range of 1-2  $\mu$ M (3). 1. Griffin, Klimko, Crider & Sharif (1999) *J. Pharmacol. Exp. Ther.* **290**, 1278. 2. Sharif, Williams & Kelly (2001) *Eur. J. Pharmacol.* **432**, 211. 3. Sharif, Kelly & Crider (2002) *J. Ocul. Pharmacol* **18**, 313.

**[Ala286]-Calmodulin-Dependent Protein Kinase II Fragment 281-301 Amide, See Calmodulin-Dependent Protein Kinase II Fragment 281-301**

#### Alamethicin

These voltage-dependent, channel-forming, peptaibol antibiotics (MW<sub>Alamethicin F-30</sub> = 1964.40; CAS 27061-78-5) from the soil fungus *Trichoderma viride* NRRL 3199 are membrane-active oligopeptides isolated from that exhibit anti-bacterial and anti-fungal properties (1,2). Peptaibols are amphipathic, usually highly helical in structure, and typically form voltage dependent ion channels that uncouple oxidative phosphorylation (3,4), often attended by in bacterial and fungal cell death. Alamethicin F-30 has the sequence Ac-Aib-Pro-Aib-Ala-Aib-Ala-Gln-Aib-Val-Aib-Gly-Leu-Aib-Pro-Val-Aib-Aib-Glu-Gln-Phe-OH; Alamethicin F-50 has the sequence Ac-Aib-Pro-Aib-Ala-Aib-Ala-Gln-Aib-Val-Aib-Gly-Leu-Aib-Pro-Val-Aib Aib-Gln-Gln-Phe-OH; and Alamethicin II has the

sequence Ac-Aib-Pro-Aib-Ala-Aib-Aib-Gln-Aib-Val-Aib-Gly-Leu-Aib-Pro-Val-Aib-Aib-Glu-Gln-Phe-OH. *Note*: The name "peptaibol" is derived from the prefix "pep-", the central syllable "aib", and the suffix "-ol" to designate its peptide structure, the presence of an  $\alpha$ -aminoisobutyryl unit, and the C-terminal alcohol. 1. Rinehart, Gaudio, Moore, *et al.* (1981) *J. Amer. Chem. Soc.* **103**, 6517. 2. Brueckner & Przybylski (1984) *J. Chrom.* **296**, 263. 3. Reed (1979) *Meth. Enzymol.* **55**, 435. 4. Das, Basu & Baram (1985) *Biochem. Int.* **11**, 357.

### L-Alanosine

This antibiotic and aspartate/asparagine analogue (FW = 149.11 g/mol; CAS 5854-93-3), also named L-2-amino-3-(*N*-hydroxy-*N*-nitrosoamino) propionic acid, isolated from fermentation broths of *Streptomyces alanosinicus* (1,2), inhibits adenylosuccinate synthetase, disrupting *de novo* synthesis of AMP in both malignant and normal cells. That alanosine inhibits the adenylosuccinate synthetase reaction, the first step in the conversion of IMP to AMP, is evidenced by the accumulation of IMP, but not adenylosuccinate, in treated cells (3). L-Alanosine's action is potentiated in methylthioadenosine phosphorylase (MTAP) deficiency. Clinical use is limited by its toxicity. At a concentration as low as 2.7  $\mu$ M, L-alanosine completely inhibits the incorporation of hypoxanthine into adenosine triphosphate by cultured Novikoff rat hepatoma cells. A related agent, L-alanosyl-5-aminoimidazole-4-carboxylic acid ribonucleotide (*or* alanosyl-AICOR) has been synthesized enzymatically using 4-(*N*-succino)-5-aminoimidazole-4-carboxamide ribonucleotide (*or* SAICAR) synthetase in conjunction with 5-aminoimidazole-4-carboxylic acid ribonucleotide and alanosine (4). Alanosyl-AICOR is not a substrate of adenylosuccinate lyase from rat skeletal muscle, but it was an apparent competitive inhibitor in both reactions catalyzed by the enzyme (4). 1. Murthy, Thiemann, Coronelli, Sensi (1966) *Nature* **211**, 1198. 2. Thiemann & Beretta (1966) *J. Antibiot.* (Tokyo) **19**, 155. 3. Graff & Plegemann (1976) *Cancer Res.* **36**, 1428. 4. Casey & Lowenstein (1987) *Biochem. Pharmacol.* **36**, 705.

### 1-Alaninechlamydocin

This  $\beta$ -amino acid-containing cyclic tetrapeptide (FW = 427.62 g/mol; CAS 141446-96-0), from a Great Lakes-derived *Tolypocladium* sp. fungal isolate, showed potent antiproliferative/cytotoxic activities in a human MIA PaCa-2 pancreatic cancer cell line ( $GI_{50}$  = 5.3 nM,  $GI_{100}$  = 8.8 nM,  $LC_{50}$  22 nM). L-Alanine-chlamydocin induced G<sub>2</sub>/M cell-cycle arrest and apoptosis. Its inhibitory effects are believed to result from inhibition of histone deacetylase (HDAC). 1. Du, Risinger, King, Powell & Cichewicz (2014) *J. Nat. Prod.* **77**, 1753.

### Alaproclate

This ester (FW<sub>free-base</sub> = 255.74 g/mol; CASs = 60719-82-6 (free base) and 60719-83-7 (hydrochloride)), also known as GAE-654 and DL-alanine 2-(4-chlorophenyl 0-1,1-dimethylethyl ester), is a serotonin-uptake inhibitor (1), an NMDA (*N*-methyl-D-aspartate) receptor antagonist (2,4), and a K<sup>+</sup> channel blocker (3,4). 1. Lindberg, Thorberg, Bengtsson, *et al.* (1978) *J. Med. Chem.* **21**, 448. 2. Wilkinson, Courtney, Westlind-Danielsson, Hallnemo & Akerman (1994) *J. Pharmacol. Exp. Ther.* **271**, 1314. 3.

Hedlund (1987) *Neuropharmacology* **26**, 1535. 4. Svensson, Werkman & Rogawski (1994) *Neuro-pharmacology* **33**, 795.

### Alatrofloxacin

This fourth-generation fluoroquinolone-class antibiotic (FW = 558.51 g/mol; CAS 146961-76-4; quickly hydrolyzes to form trovafloxacin), also named 7-[(1*R*,5*S*)-6-[[[(2*S*)-1-[[[(2*S*)-2-aminopropanoyl]amino]-1-oxopropan-2-yl]amino]-3-azabicyclo[3.1.0]hexan-3-yl]-1-(2,4-difluorophenyl)-6-fluoro-4-oxo-1,8-naphthyridine-3-carboxylic acid, is a systemic antibacterial that targets Type II DNA topoisomerases (gyrases) required for bacterial replication and transcription. This fluoroquinolone shows an extensive *in vitro* antibiotic spectrum, with high activity against Gram-positive coccus, anaerobic and atypical pneumonia-producing bacteria (1). (For the prototypical member of this antibiotic class, *See Ciprofloxacin*) Intravenous alatrofloxacin, followed by oral trovafloxacin (TVX), is safe and well tolerated. Alatrofloxacin also lacks the phototoxicity, cardiovascular toxicity, and hemolytic anemia associated with earlier fluoroquinolones. Given its metabolism to trovafloxacin, it should be noted that the latter significantly increases the formation of nitrotyrosine in mice that are heterozygous for mitochondrial superoxide dismutase-2 (2). Using the NO-selective probe DAF-2, TVX also increases the production of mitochondrial NO in immortalized human hepatocytes. Similarly, mitochondrial Ca<sup>2+</sup> is increased by TVX, suggesting calcium ion-dependent activation of mitochondrial NOS activity. The relationship between these observations and trovafloxacin-induced leukopenia remains to be explored. 1. Hsiao, Younis & Boelsterli (2010) *Chem. Biol. Interact.* **188**, 204.

### Albiglutide

This GLP-1 agonist and anti-diabetic drug (MW = 72.9 kDa; CAS 782500-75-8), marketed as Eperzan<sup>®</sup> and Tanzeum<sup>®</sup>, by GlaxoSmithKline (GSK) is a dipeptidyl peptidase-4-resistant glucagon-like peptide-1 dimer fused to human albumin. Albiglutide has a half-life of 4-7 days, commencing it for biweekly or weekly administration in the treatment of Type 2 diabetes. The half-life is considerably longer than exenatide (Byetta<sup>®</sup>) and liraglutide (Victoza<sup>®</sup>).

### L-Albizzini

This L-glutamine analogue (FW = 147.13 g/mol; CAS 1483-07-4; IUPAC: L-( $-$ )-2-amino-3-ureidopropionic acid; CAS: 1483-07-4), also known as L-2-amino-3-ureidopropionic acid, from *Albizzia julibrissin* seeds inhibits many glutamine-dependent enzymes. **Target(s)**: asparaginase (1); glutaminase (1); asparagine synthetase (2,13,14); glutamate synthase (3,4); glutaminase (5,6); glutamine: fructose-6-phosphate aminotransferase (isomerizing), *or* glucosamine-6 phosphate synthase (7); glutaminyl-tRNA synthetase (8); phosphoribosyl-formylglycinamide synthetase, *or* formylglycinamide ribotide amidotransferase (9-12,15); carbamoyl-serine ammonia lyase, weakly inhibited (16); 4-methyleneglutaminase (17,18). 1. Kovalenko, Tsvetkova & Nikolaev (1977) *Vopr. Med. Khim.* **23**, 618. 2. Choraz, Andruszkiewicz & Borowski (1985) *Biochim. Biophys. Acta* **870**, 357. 3. Horowitz & Meister (1972) *J. Biol. ### Albumin, Bovine Serum

This abundant blood protein (MW = 66,463 Da; CAS 9048-46-8) regulates osmotic pressure and serves as a binding protein for fatty acid hormone,  $\text{Ca}^{2+}$ ,  $\text{K}^+$ ,  $\text{Na}^+$ , bilirubin, and many hydrophobic and amphipathic pharmaceuticals. The ease of purification made led to its use as a protein standard in biochemistry. BSA is frequently used (at 1–2 mg/mL) to stabilize proteins and enzymes by exerting what is called the protective colloid effect. BSA often protects against dilution-induced dissociation/inactivation of susceptible. BSA also reduces enzyme adsorption to the surfaces of plastic labware. Because BSA binds a wide variety of substances (including substrates, cofactors, or other components of the reaction mixture), it may inhibit enzyme activity, and one should run control experiments before using BSA indiscriminantly. **1.** Purich (2010) *Enzyme Kinetics: Catalysis & Control*, Academic Press (Elsevier), New York.

### Aldehyde-Containing Protease Inhibitors

The catalytic mechanisms of serine and cysteine proteases are multi-step catalytic process, of which a key step is the formation of oxygen- or thiol-ester intermediate. Nested around that intermediate is a manifold of transitory species, including any tetrahedral adducts leading to and from that covalent acyl-enzyme. Papain, for example, is a thiol proteinase that is strongly inhibited by aldehydes resembling carboxylic acids that are released upon enzyme-catalyzed hydrolysis of specific substrates. Westerik & Wolfenden (1) found that at pH 5.5, approximately one mol acetyl-L-phenylalanyl-amino-acetaldehyde is bound per mol papain ( $K_1 = 4.6 \times 10^{-8}$  M). These aldehydes protect the Enzyme-SH against inactivation by the thiol-modifying reagent *N*-ethylmaleimide, presumably as a consequence of the enzyme forming an unusually stable thiohemiacetal with stereoelectronic features resembling tetrahedral intermediates in enzyme-catalyzed substrate hydrolysis. Such ideas have guided the design of countless peptide aldehydes that have proved to be especially effective inhibitors. The objective is to achieve specificity by capitalizing on knowledge of a target enzyme's preference for side-chains in the peptide substrate, while relying on reversible formation of hemiacetal or hemithioacetal adducts to gain potency. **1.** Westerik & Wolfenden (1972) *J. Biol. Chem.* **247**, 8195.

### Aldicarb

This insecticide (FW = 190.26 g/mol; CAS 116-06-3), also known systematically as 2-methyl-2-(methylthio)propanal *O*-(*N*-methylcarbamoyl)oxime, inhibits acetyl-cholinesterase (1-6), aryl acylamidase (7), and carboxylesterase (8). It also binds to the nicotinic acetylcholine receptor (1). **CAUTION:** Exposure to high amounts of aldicarb can cause muscle weakness, blurred vision, headache, nausea, tearing, sweating, and tremors. High doses can be fatal to humans as a consequence of its ability to paralyze the respiratory system. Application of aldicarb should be undertaken only by qualified operators, heeding all guidelines and safety devices. **1.** Smulders, Bueters, Van Kleef & Vijverberg (2003) *Toxicol. Appl. Pharmacol.* **193**, 139. **2.** Payne, Stansbury & Weiden (1966) *J. Agric. ### Alectinib

This potent, selective, and orally available ALK inhibitor (FW = 482.62 g/mol; CAS 1256580-46-7; Soluble in DMSO, not in  $\text{H}_2\text{O}$ ), also known as AF 802, CH5424802, RO5424802, and 9-ethyl-6,6-dimethyl-8-(4-morpholinopiperidin-1-yl)-11-oxo-6,11-dihydro-5*H*-benzo[*b*]carbazole-3-carbonitrile, exhibits antitumor activity against cancers with ALK (IC<sub>50</sub> = 1.9 nM) and mutant forms, as seen in nonsmall cell lung cancer (NSCLC) cells expressing EML4-ALK fusion, and anaplastic large-cell lymphoma (ALCL) cells expressing NPM-ALK fusion *in vitro* and *in vivo* (1,2). Alectinib inhibits ALK<sup>L1196M</sup> (IC<sub>50</sub> = 1.56 nM), the common resistance-conferring gatekeeper mutation that defeats the action of many kinase inhibitors, and blocks EML4-ALK<sup>L1196M</sup>-driven cell growth. **1.** Sakamoto, Tsukaguchi, Hiroshima, *et al.* (2011) *Cancer Cell* **19**, 679. **2.** Kinoshita, Asoh, Furuichi, *et al.* (2012) *Bioorg. ### Alefacept

This recombinant immunosuppressive protein (FW = 51800 g/mol; CAS 222535-22-0), marketed under the trade name Amevive<sup>®</sup>, reduces the number of psoriasis-associated T lymphocytes, thereby alleviating an underlying cause of the disorder. Alefacept is indicated in patients with moderate to severe chronic plaque psoriasis. The dimeric fusion protein consists of the extracellular CD2-binding portion of the human Leukocyte Function Antigen-3 (*or* LFA-3) linked to the Fc (hinge, C<sub>1</sub>2 and C<sub>H</sub>3 domains) portion of human IgG<sub>1</sub> (1). Amevive is a fully humanized toxin that binds to CD2 and blocks costimulatory signaling, selectively inducing apoptosis of activated memory T cells involved in the pathogenesis of psoriasis. Alefacept has a slow onset of action, peaking approximately 18 weeks after the first injection of a 12-week course (2). Because psoriasis is a chronic disorder, patients require lifelong access to injectable biologic agents targeting specific immune mediators, raising concerns about their long-term safety. Alefacept is only effective in a small proportion of patients, and its maximal efficacy is not achieved until 4-6 weeks after a treatment course. **1.** Cooper, Morgan & Harding (2003) *Eur. J. Immunol.* **33**, 666. **2.** Hodak & David (2004) *Dermatol. Ther.* **17**, 383.

### Alendronate

This widely used methylenebisphosphonate bone resorption inhibitor (FW<sub>free-acid</sub> = 249.10 g/mol; CAS 66376-36-1 (disodium salt)), also known by the trade name Fosamax<sup>®</sup> and systematically named 4-amino-1-hydroxybutylidene-1,1-bisphosphonic acid, remains the drug of choice for treating osteoporosis. Alendronate shows preferential uptake at sites of bone resorption, where it blocks osteoclastic activity by inhibiting ruffled border formation (1). Alendronate is also the treatment of choice for hypercalcemia of malignancy, where a single infusion will normalize serum calcium in 80% of the patients. Paget's disease also shows an excellent long-term response to alendronate. **Inhibition of Bone Resorption:** Alendronate is a polyanion that binds firmly to positively charged calcium ions at active resorption sites of bone surfaces. Unlike pyrophosphate,

however, bisphosphonates cannot be hydrolyzed by inorganic pyrophosphatase to orthophosphate. Instead, alendronate ion forms a multidendrate  $\text{Ca}^{2+}$  complex that binds tenaciously at physiologic pH. Under therapy, normal bone mineralization is unimpeded, with alendronate deposited onto and incorporated within the bone-matrix in a pharmacologically latent form. During osteoclast-mediated bone resorption, actin filament-rich podosomes allow osteoclasts to contact the bone surface, allowing the local hydrogen ion concentration to increase, lowering the pH to  $\sim 5.5$ . This process facilitates local hydroxyapatite hydrolysis, with release of  $\text{Ca}^{2+}$ , phosphate, and alendronate. Alendronate uptake by osteoclasts requires fluid-phase endocytosis and is enhanced by  $\text{Ca}^{2+}$  ions. Subsequent transfer of alendronate from endocytic vesicles to the cytosol requires endosomal acidification. Liberated in this manner, the drug retards further resorption by inhibiting farnesyl-diphosphate synthase as well as prenylation of Rac and Rho. Posttranslational modification of these small GTPases is required for tether these regulators to the peripheral membrane, where they activate actin polymerization and promote podosome formation. By inhibiting podosome assembly, alendronate suppresses the activation of vacuolar ATPase (or  $\text{H}^+$ -transporting proton pump), thus preventing proton export to the bone surface and further hydrolytic erosion of hydroxyapatite (1,2). **Pharmacokinetics:** After oral administration, systemic alendronate bioavailability is low, amounting to  $\sim 0.6\%$  under fasting conditions. Once absorbed, about half binds to exposed bone surfaces, with the remainder excreted unchanged within 4-6 hours by the kidney. When taken with meals and beverages (other than water), alendronate's bioavailability is greatly reduced. When administered at the directed amount, it inhibits bone resorption without affecting bone mineralization. Alendronate is not cytotoxic for osteoclasts. Alendronate also appears to be without effect on the dynamics of vascular calcification. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Amelioration of Elastase-induced Emphysema:** In mice, delivery of the alendronate via aerosol inhalation (not orally administered) relieves elastase-induced emphysema, inhibiting airspace enlargement after elastase instillation (3). Aerosol inhalation induces macrophage apoptosis in bronchoalveolar fluid via caspase-3- and mevalonate-dependent pathways. Cytometry indicates that the  $\text{F4/80}^{\text{high}}\text{CD11b}^{\text{high}}\text{CD11c}^{\text{mid}}$  population characterizing inflammatory macrophages, and the  $\text{F4/80}^{\text{mid}}\text{CD11b}^{\text{mid}}\text{CD11c}^{\text{high}}$  population defining resident alveolar macrophages take up substantial amounts of the bisphosphonate imaging agent OsteoSense680 after aerosol inhalation (3). Alendronate also inhibits macrophage migratory and phagocytotic activities and blunts the inflammatory response of alveolar macrophages by inhibiting nuclear factor- $\kappa\text{B}$  (NF $\kappa\text{B}$ ) signalling. **Acid/Base Properties:**  $\text{pK}_1 = 2.6$  (at 298 K) and  $2.76$  (at 310 K),  $\text{pK}_2 = 6.7$  (at 298 K) and  $6.8$  (at 310 K),  $\text{pK}_3 = 11.5$  (at 298 K) and  $11.3$  (at 310 K), and  $\text{pK}_4 = 12.4$  (at 298 K) and  $11.8$  (at 298 K). **Target(s):** protein-tyrosine phosphatase (4,6-8); geranyltrans-ferase, or farnesyl diphosphate synthase (9-13,17-19); alkaline phosphatase (14); interstitial collagenase, or MMP-1 (15); gelatinase A, or MMP-2 (15); stromelysin-1, or MMP-3 (15); neutrophil collagenase, or MMP-8 (15); gelatinase B, or MMP-9 (15); macrophage elastase, or MMP-12 (15); collagenase-3, or MMP-13 (15); enamelysin, or MMP-20 (15); pyrophosphate-dependent phosphofructo-kinase, or diphosphate: fructose-6-phosphate 1-phosphotransferase (16); geranyl-diphosphate synthase (20); protein-tyrosine phosphatases (PTPs), most likely as an alendronate-metal ion complex, inasmuch as alendronate inhibition is suppressed by EDTA (21). 1. #### Alfentanil

This potent analgesic (FW = 416.52 g/mol; CAS 71195-58-9), also known by its code name R-39209 and trade names Alfenta<sup>®</sup> and Rapifen<sup>®</sup>, is a synthetic, short-acting  $\mu$ -opioid agonist (1). Rat liver alfentanil oxidation was increased threefold by treatment with pregnenolone 1- $\alpha$ -carbonitrile, a CYP3A inducer, but not by treatment with phenobarbital,  $\beta$ -naphthoflavone, or pyrazole, which are CYP2B, CYP1A, and CYP2E1 inducers, respectively (2). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Komatsu, Turan & Orhan-Sungur (2007) *Anaesthesia* **62**, 1266. 2. Kharasch & Thummel (1993) *Anesth. Analg.* **76**, 1033.

#### Alirocumab

This humanized anti-PCSK9 monoclonal antibody (MW = 146 kDa; CAS 1245916-14-6), developed as REGN727 (Regeneron Pharmaceuticals) and SAR236553 and Praluent<sup>®</sup> in cooperation with Sanofi, inhibits atherosclerosis, improves plaque morphology, and enhances statin effects (1-4). Its target, Pro-protein Convertase Subtilisin/Kexin type 9 (or PCSK9), is a secreted pro-protein convertase. Inhibition of PCSK9 increases hepatic Low-Density Lipoprotein Receptors (LDLRs), thereby enhancing hepatic LDL clearance. PCSK9 undergoes autocatalytic processing of its pro-domain within the endoplasmic reticulum, and its inhibitory pro-peptide segment remains associated with it following subsequent secretion. PCSK9 phosphorylation at Ser-47 in its pro-peptide and Ser-688 in its C-terminal domain by a Golgi casein kinase-like protein kinase appears to stabilize secreted PCSK9. The level of circulating PCSK9 appears to be inversely related to blood HDL levels, and it is understandable that cholesterol-lowering statins have the effect of increasing PCSK9 gene expression as well as the circulating level of PCSK9. Alirocumab binds to circulating PCSK9, blocking the latter's action on surface LDLR. Alirocumab dose-dependently decreases plasma lipids and atherosclerosis progression, and it enhances the beneficial effects of atorvastatin in ApoE3-Leiden transgenic mice. (See also Evolocumab) 1. #### Alisertib

This orally available protein kinase inhibitor (FW = 518.92 g/mol; CAS 1028486-01-2; Solubility: 1 mg/mL DMSO, <1mg/mL H<sub>2</sub>O), also known by its code name MLN8237 and its systematic name 4-[[9-chloro-7-(2-fluoro-6-methoxyphenyl)-5H-pyrimido[5,4-d][2]benzazepin-2-yl]amino]-2-methoxybenzoic acid, targets Aurora A, or AAK (IC<sub>50</sub> = 1.2 nM),

showing >200x selectivity over Aurora B, or ABK (1). **Mode of Inhibitory Action:** Alisertib produces a dose-dependent decrease in bipolar and aligned chromosomes in the HCT-116 xenograft model, a drug-induced phenotype consistent with AAK inhibition (1). Targeting Aurora A kinase activity with the investigational agent alisertib likewise increases the efficacy of cytarabine through a FOXO-dependent mechanism (2). MLN8237 likewise induces polyploidization and expression of mature megakaryocyte markers in acute megakaryocytic leukemia (AMKL) blasts and displayed potent anti-AMKL activity *in vivo* (3). **Drug Formulation:** Typically prepared in an inert solubilizing carrier (2-hydroxypropyl- $\beta$ -cyclodextrin, 10% weight/volume) in sodium bicarbonate, 1% weight/volume). 1. Manfredi, Ecsedy, Chakravarty, *et al.* (2011) *Clin. Cancer Res.* **17**, 7614. 2. Kelly, Nawrocki, Espitia, *et al.* (2012) *Int. J. Cancer* **131**, 2693. 3. Wen, Goldenson, Silver, *et al.* (2012) *Cell* **150**, 575.

### Aliskiren

This first-in-class oral renin inhibitor (FW = 551.76 g/mol; CAS 173334-57-1) also known by its alternate code name SPP100, its trade names: Tekturma™ and Rasilez™; and its IUPAC name, (2*S*,4*S*,5*S*,7*S*)-5-amino-*N*-(2-carbamoyl-2,2-dimethylethyl)-4-hydroxy-7-[[4-methoxy-3-(3-methoxy propoxy)phenyl]methyl]-8-methyl-2-(propan-2-yl)nonanamide, targets renin ( $IC_{50}$  = 0.6 nM; *in vivo*  $t_{1/2}$  = 40 hours; bioavailability = 2.6%) and is effective in treating hypertension. Aliskiren not only blocks renin but also binds to prorenin, inducing a conformational change. In this respect, aliskiren can be employed to titrate prorenin concentrations. Among renin/angiotensinogen blocking agents, direct renin inhibitors show excellent efficacy in hypertension control and also exhibit pharmacologic tolerance comparable with other renin-angiotensin suppressors. Aliskiren is effective in controlling blood pressure as monotherapy or in combination with other antihypertensive drugs, irrespective of patient's age, ethnicity or sex (2). (See VTP-27999) **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Nussberger, Wuerzner, Jensen, *et al.* (2003) *Biochem. Biophys. Res. Commun.* **308**, 698. 2. Juncos (2013) *Ther. Adv. Cardiovasc. Dis.* **7**, 153.

### Alizarin

This anthraquinone dye (FW = 240.22 g/mol; CAS 72-48-0), also called Mordant Red 11, is a natural product from the madder plant (*Rubia tinctorium*), where it is glycosidically linked to primeverose. **Target(s):** steroid 5 $\alpha$ -reductase (1); CYP1A1 (2); CYP1A2 (2); CYP1B1 (2); HIV-1 proteinase (3); glutathione *S*-transferase (4,5,8); cystathionine  $\beta$ -synthase (6); [myosin light-chain] kinase (7); procollagen-proline 4-dioxygenase,  $IC_{50}$   $\approx$  79  $\mu$ M (9). 1. ### Allicin

This naturally occurring sulfoxide and antibacterial and antifungal agent (FW = 162.28 g/mol; CAS 539-86-6), also known as diallyl thiosulfinate, and 2-propene-1-sulfinothioic acid *S*-2-propenyl ester, has the fragrance of freshly crushed garlic (*Allium sativum*). **Target(s):** urease (1-3); papain (2,4,10); amylase (2); succinate dehydrogenase (4); xanthine oxidase (4); glyceraldehyde-3-phosphate dehydrogenase (4); choline oxidase (4); hexokinase (4); cholinesterase (4,13); glyoxylase (4); alcohol dehydrogenase (4,9,10); lactate dehydrogenase (4); tyrosinase (4); alkaline phosphatase (2); RNA biosynthesis (5); prostaglandin-E synthase, or prostaglandin-H<sub>2</sub> isomerase (6); acetyl-CoA synthetase, or acetate:CoA ligase (7); lanosterol 14 $\alpha$ -demethylase (8); histolysin and/or amoebapain (9); alcohol dehydrogenase, NAD<sup>+</sup>-dependent (10); protein farnesyltransferase (11); protein geranylgeranyltransferase (11); CYP1A2 (12); CYP2C9 (12); CYP2C19 (12); CYP2D6 (12); CY3A4 (12); acetylcholinesterase (13); 5-lipoxygenase, or arachidonate 5-lipoxygenase (14). 1. ### L-Alloisoleucine

This isoleucine isomer (FW = 131.17 g/mol; CAS 1509-34-8; Symbol, L-alle), named systematically as (2*S*,3*R*)-2-amino-3-methylpentanoic acid, is a diastereoisomer of the proteogenic amino acid, L-isoleucine. Alloisoleucine is observed in the blood plasma and urine of patients with maple syrup urine disease and other disorders associated with metabolic pathways of the branched chain amino acids (1,2). Alloisoleucine is also a component of the antibiotics malformin B<sub>1</sub> and globomycin. **Target(s):** threonine deaminase (3). 1. Schadewaldt, Bodner-Leidecker, Hammen & Wendel (1999) *Clin. Chem.* **45**, 1734. 2. Matthews, Ben-Galim, Haymond & Bier (1980) *Pediatr. Res.* **14**, 854. 3. Ahmed, Bollon, Rogers & Magee (1976) *Biochimie* **58**, 225.

### Allopurinol

This purine analogue (FW = 136.11 g/mol; CAS 315-30-0), also known by the trade names Zyloprim™ and Lopurin™ and by its systematic name 4-hydroxypyrazolo(3,4-*d*)pyrimidine, is used mainly to treat gout by inhibiting xanthine oxidase, thereby limiting the build-up of uric acid.

Allopurinol and oxipurinol are metabolically converted by purine nucleoside phosphorylase to their corresponding L-ribosyl derivatives that are then phosphorylated. **History:** Seeking to retard the breakdown of the anticancer drug mercaptopurine, which is used to treat acute lymphoblastic leukemia, Nobelist Gertrude Elion and coworkers synthesized allopurinol to enhance mercaptopurine's action. Allopurinol is a slowly catalyzed alternative substrate for xanthine oxidase, which produces oxipurinol (**See Oxipurinol**). Because oxipurinol dissociates extremely slow ( $t_{1/2} = 300$  min) from the enzyme, oxipurinol is a potent xanthine oxidase product inhibitor.

**Therapeutic Use:** Allopurinol is dispensed as 30-mg and 100-mg tablets. Its long-term use is generally unremarkable, but both allopurinol and oxipurinol cause orotic aciduria (from < 2 mg/day to 6-30 mg/day) and orotidinuria (from < 3 mg/day to 24-55 mg/day), while also increasing orotidine:PRPP transferase and orotidylate decarboxylase activity, for which they are inhibitors. **Allopurinol Hypersensitivity:** Allopurinol-derived oxipurinol is a common cause of severe cutaneous adverse drug reactions (SCAR), including Stevens-Johnson Syndrome (SJS) and Toxic Epidermal Necrolysis (TEN). A strong association between "allopurinol"-induced SCAR and the Human Leukocyte Antigen HLA-B\*5801 was observed in a Han Chinese population, with high frequency of this allele, whereas there is only a moderate association was observed in European and Japanese populations, where this allele has a low frequency. Although genotyping is now required to identify individuals susceptible to SJS prior to starting abacavir and carbamazepine therapy (**See Abacavir and Carbamazepine**), no such screening is advocated for allopurinol, in part due to the lack of rapid/inexpensive screening for the HLA-B\*58:01 allele. **Pharmacokinetics:** After oral dosage, the PK parameters of allopurinol include an oral bioavailability of 79%, an elimination  $t_{1/2}$  of 1.2 hours, an apparent oral clearance of 15.8 mL/min/kg, and an apparent volume of distribution of 1.31 L/kg (1). Assuming that 90 mg of oxipurinol is formed from every 100mg of allopurinol, the pharmacokinetic parameters of oxipurinol in subjects with normal renal function are a  $t_{1/2}$  of 23 hours, CL/F of 0.31 mL/min/kg,  $V_d/F$  of 0.59 L/kg, and renal clearance (relative to creatinine) of 0.19. Oxipurinol is cleared almost entirely by urinary excretion (1). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011).

**Target(s):** xanthine oxidase, slow, tight-binding inhibitor (1-5,8,9,14,19-23); orotate phosphoribosyl-transferase (6); purine nucleoside phosphorylase (7,15); tryptophan pyrrolase, or tryptophan 2,3-dioxygenase (10,16); salicylhydroxamic acid reductase (11); guanine deaminase (12); glutamine:D-fructose-6-phosphate aminotransferase (13); xanthine phosphoribosyl-transferase (17,18); hypoxanthine(guanine) phosphoribosyl-transferase (18); xanthine dehydrogenase (24-29); orotidine:PRPP transferase and orotidylate decarboxylase (30). 1. ### Allopurinol Ribonucleoside 5'-Monophosphate

This unnatural nucleotide (FW<sub>free-acid</sub> = 348.21 g/mol) is an AMP and IMP analogue that inhibits orotidylate decarboxylase, or orotidine-5'-phosphate decarboxylase (1-5); GMP reductase (6), adenylosuccinate synthetase (7), and amidophosphoribosyl-transferase (8). 1. Silva & Hatfield (1978) *Meth. Enzymol.* **51**, 143. 2. Jones, Kavipurapu & Traut (1978) *Meth. Enzymol.* **51**, 155. 3. Porter & Short (2000) *Biochemistry* **39**, 11788. 4. ### Allosamidin

This glycoside (FW = 622.63 g/mol; CAS 103782-08-7), first isolated from a species of *Streptomyces* in 1987, is the first naturally occurring chitinase inhibitor identified. It inhibits insect class-18 chitinases as well as chitinase CiX1 of *Coccidioides immitis*,  $K_i = 60$  nM (1-7). **Target(s):** chitinase (1-7); chitotriosidase (8); hevamine, a chitinase from the rubber tree *Hevea brasiliensis* (5). 1. Milewski, O'Donnell & Gooday (1992) *J. Gen. Microbiol.* **138**, 2545. 2. Sakuda, Isogai, Matsumoto & Suzuki (1987) *J. Antibiot.* **40**, 296. 3. Bortone, Monzingo, Ernst & Robertus (2002) *J. Mol. ### L-Allothreonine

This nonproteogenic diastereoisomer of L-threonine (FW = 119.12 g/mol; CAS 28954-12-3) is found in the antibiotics telomycin, syringostatin, globomycin, enduracidins A and B, and lysobactin. **Target(s):** serine hydroxymethyl-transferase, or glycine Hydroxymethyltransferase (1,6); L-threonine 3-dehydrogenase, also an alternative substrate (2); threonine dehydratase, inhibited by racemic mixture (3); L-serine dehydratase, inhibited by racemic mixture (4); and kynureninase, weakly inhibited by racemic mixture (5); 3-phosphoglycerate dehydrogenase (6). 1. Liu, Reig, Nasrallah & Stover (2000) *Biochemistry* **39**, 11523. 2. Green & Elliott (1964) *Biochem. J.* **92**, 537. 3. Maeba & Sanwal (1966) *Biochemistry* **5**, 525. 4. Ramos & Wiame (1982) *Eur. J. Biochem.* **123**, 571. 5. Jakoby & Bonner (1953) *J. Biol. Chem.* **205**, 709. 6. Schirch & Gross (1968) *J. Biol. Chem.* **243**, 5651.

### Alloxan

This sulfhydryl reagent (FW = 142.07 g/mol; CASs = 50-71-5 (free base) and 2244-11-3 (monohydrate)), also named as 2,4,5,6-tetraoxypyrimidine, is an unstable tetraoxypyrimidine that induces diabetes by selectively destroying pancreatic  $\beta$ -cells in laboratory animals upon selective uptake via the GLUT2 transporter. **Protocol for Using Alloxan to Induce Diabetes:** *Step-1:* Weigh and measure baseline blood glucose level of mice (Age: 6 weeks or older), adhering to the IACUC Guidelines for Glucose Monitoring of Blood. *Step-2:* Inject i.v. or i.p. with alloxan (70-90 mg/kg). *Step-3:* Beginning the day after the alloxan injection, blood glucose levels of each mouse should be checked daily or every other day for 5-7 days. Within 2-3 days after onset of diabetes (as indicated by blood glucose levels), mice should be implanted with an insulin-secreting pellet, when long-term study is necessary. Pellets typically release 0.1 U each 24 hr for >30 days. Mice weighing less than 25 grams require one insulin pellet; larger mice typically receive two insulin pellets to restore normoglycemia.

**Target(s):** hexokinase (1,5,24-28,59); glucokinase (2,60,63,64, 66); succinate dehydrogenase (3,4,41,56); phosphofructokinase (6,9,26); alcohol dehydrogenase, yeast (7); glucose-6 phosphatase (8,23); aconitase (10,57,65); ATPase (11,12); arylamine acetyltransferase (13,14); carbonic anhydrase, weakly inhibited (15); choline acetyltransferase (16); choline dehydrogenase (17); choline oxidase (18); cytochrome oxidase (19,20); fructose-1,6-bisphosphatase (21); galactonolactone dehydrogenase (22); alkaline phosphatase (29,30,50); phosphoglucomutase (23,31); glyceraldehyde-3-phosphate dehydrogenase (32); phosphoprotein phosphatase (33,52); pyrophosphatase (11,12,34,49,51); pyruvate decarboxylase (36-38); rhodanese, or thiosulfate sulfurtransferase (39); sedoheptulokinase (40); succinate oxidase (42,43); urease (44); xanthine oxidase (45,73); adenylate cyclase, *Phycomyces blakesleeana* (47); stearate dehydrogenase (48); acid phosphatase (50,72); allantoinase, weakly inhibited (53); oxidative phosphorylation, moderately inhibited (54); protein O-linked N-acetylglucosaminyl-transferase (55); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (56); calmodulin-dependent protein kinase (58,67); Ca<sup>2+</sup>-dependent ATPase (61,62); isocitrate dehydrogenase, NAD (65); glutamate dehydrogenase (65);  $\alpha$ -ketoglutarate dehydrogenase (65); succinyl-CoA synthetase (65); fumarase (65); citrate synthase, moderately inhibited (65); isocitrate dehydrogenase, NADP (65); phosphate transport (68); xanthine dehydrogenase (69); papain (70); cathepsin (70); barbiturase (71). 1. ### Alogliptin

This orally available DPP-IV inhibitor (FW = 339.39 g/mol; CAS 850649-62-6), also known as 2-({6-[(3R)-3-aminopiperidin-1-yl]-3-methyl-2,4-dioxo-3,4-dihydropyrimidin-1(2H)-yl}methyl)benzonitrile and by its trade name Nesina<sup>®</sup> targets dipeptidyl peptidase IV, or DPP-4, thereby retarding the inactivation of incretin hormones GLP-1 (glucagon-like peptide-1) and GIP (glucose-dependent insulinotropic peptide), both of which play a role in regulating blood glucose levels (1). Alogliptin inhibition is competitive,  $K_i = 24$  nM (2). In 2013, alogliptin received FDA approval for the treatment of type II diabetes mellitus. DPP-4 inhibitors have become widely accepted in clinical practice because of their low risk of hypoglycemia, favorable adverse-effect profile, and once-daily dosing. The only reported side-effect is mild hypoglycemia, suggesting that some individuals may benefit from a slightly lower dose. Other DPP-4 inhibitors include sitagliptin phosphate (Januvia<sup>®</sup>) and saxagliptin (Onglyza<sup>®</sup>). DPP-4 inhibition has been associated with enhanced  $\beta$ -cell survival and neogenesis in streptozotocin-treated diabetic rats (See also *Streptozotocin*) (3). Significantly, the addition of alogliptin resulted in clinically significant reductions in HbA<sub>1c</sub> (typically from 1.4 to 1%), without increased incidence of hypoglycemia, in type 2 diabetes patients who are inadequately controlled by glyburide monotherapy (4). 1. ### Allyl (5S,6S)-6-[(R)-Acetoxyethyl]penem-3-carboxylate

This penicillin-like ester (FW = 297.33 g/mol), containing an 2,3-unsaturated thiazolidine ring, is a potent inhibitor of *Escherichia coli* leader peptidase I (1-3). Signal peptidase (SPase) I is responsible for the cleavage of signal peptides of many secreted proteins in bacteria. Because of its

unique physiological and biochemical properties, it serves as a potential target for development of novel antibacterial agents. SPase I belongs to a novel class of serine protease that utilize a serine and a lysine to form a unique catalytic dyad for peptide hydrolysis (2). Because of this unique catalytic mechanism, they are not sensitive to the classic protease inhibitors. (5S,6S)-penem is covalently bound as an acyl-enzyme intermediate to the  $\gamma$ -oxygen of a serine residue at position-90, demonstrating that this residue acts as the nucleophile in the hydrolytic mechanism of signal-peptide cleavage (2). 1. Carlos, Paetzel, Klenotic, Strynadka & Dalbey (2002) *The Enzymes*, 3rd ed., 22, 27. 2. Paetzel, Dalbey & Strynadka (1998) *Nature* 396, 186. 3. Allsop, Brooks, Edwards, Kaura & Southgate (1996) *J. Antibiot.* 49, 921.

#### Allyl Alcohol

This extremely hazardous hydroxyalkene (FW = 58.08 g/mol; CAS 107-18-6; M.P. = -50°C; B.P. = 96-97°C; Solubility: Miscible with water and ethanol; Lachrymator), also known as 2-propen-1-ol, is a mechanism-based irreversible inhibitor of yeast alcohol dehydrogenase. In mammals, allyl alcohol requires activation by alcohol dehydrogenases (ADH) to form the highly reactive and toxic metabolite acrolein, which shows similar toxicity in zebrafish embryos and adults. *Note:* Allyl alcohol is more toxic than related alcohols, and its threshold limit value (TLV) is 2 ppm. 1. Rando (1977) *Meth. Enzymol.* 46, 28. 2. Rando (1974) *Biochem. Pharmacol.* 23, 2328. 3. Trivic & Leskovic (1999) *Biochem. Mol. Biol. Int.* 47, 1.

#### Allylamine

This toxic aminoalkene (FW<sub>free-base</sub> = 57.095 g/mol; B.P. = 55-58°C; Miscible with Water and Ethanol), also known as 2-propen-1-amine targets monoamine oxidase (1-4,8,9), methylamine dehydrogenase (5,11), diamine oxidase, or amine oxidase (copper-containing) (6), alanine aminotransferase (7), aspartate aminotransferase (7), mitochondrial electron transport, weakly inhibited (10). 1. Rando (1977) *Meth. Enzymol.* 46, 28. 2. Maycock (1980) *Meth. Enzymol.* 66, 294. 3. Ator & Ortiz de Montellano (1990) *The Enzymes*, 3rd ed., 19, 213. 4. #### 2-(3-Allylamino-5-chloro-2-oxo-6-phenyl-2H-pyrazin-1-yl)-N-(4-amino(imino)-methyl)benzyl)acetamido

This substituted pyrazinone (FW = 451.93 g/mol) inhibits coagulation factor VIIa (IC<sub>50</sub> = 0.7  $\mu$ M) and thrombin (IC<sub>50</sub> = 8.7  $\mu$ M). The pyrazinone core orients the substituents in the correct spatial arrangement to probe the S<sub>1</sub>, S<sub>2</sub>, and S<sub>3</sub> pockets within the active site of the enzyme. 1. Parlow, Case, Dice, *et al.* (2003) *J. Med. Chem.* 46, 4050.

#### 4-(Allylamino)-3-hydroxy-2,2-dimethyl-3,4-dihydro-2H-benzo[g]chromene-5,10-dione

This quinone (FW = 313.35 g/mol) inhibits indoleamine 2,3-dioxygenase, with an IC<sub>50</sub> value of 0.186  $\mu$ M for the *cis* isomer and 0.183  $\mu$ M for the *trans*. Indoleamine 2,3-dioxygenase (IDO) is emerging as an important new therapeutic target for the treatment of cancer, chronic viral infections, and other diseases characterized by pathological immune suppression. 1. Kumar, Malachowski, DuHadaway, *et al.* (2008) *J. Med. Chem.* 51, 1706.

#### 1-Allyl-2-[3-(benzylamino)propoxy]-9H-carbazole

This derivative (FW = 382.51 g/mol), also known as YM 75440, inhibits squalene synthase (IC<sub>50</sub> = 150 and 63 nM for the rat and human enzymes, respectively). It significantly reduced both plasma total cholesterol and plasma triglyceride levels following oral dosing to rats with a reduced tendency to elevate plasma transaminase levels. 1. Ishihara, Kakuta, Moritani, Ugawa & Yanagisawa (2004) *Bioorg. Med. Chem.* 12, 5899.

#### 3(S)-Allyl-4(S)-benzyl-2-oxoazetidine-1-carboxylic Acid (4-Pyridinylmethyl)amide

This  $\beta$ -lactam (FW = 335.42 g/mol) inhibits human pancreatic elastase, human leukocyte elastase, and chymotrypsin, with IC<sub>50</sub> values of 4.7, 0.3, and 6  $\mu$ M, respectively. It also targets human cytomegalovirus protease. Modest antiviral activity was found in a plaque reduction assay. 1. Yoakim, Ogilvie, Cameron, *et al.* (1998) *J. Med. Chem.* 41, 2882.

#### L-C-Allylglycine

This amino acid (FW = 115.13 g/mol), also known as L-2-amino-4-pentenoic acid, is a convulsant and inhibits glutamate decarboxylase. **Target(s):** cystathionine  $\gamma$ -lyase (1); cysteine desulfurase (2); cysteine sulfinate decarboxylase, or sulfinoalanine decarboxylase, weakly inhibited (3); glutamate decarboxylase (4-7); protein biosynthesis (8); UDP-*N*-acetylmuramate:L-alanine ligase, weakly inhibited (9). 1. Beeler & Churchich (1978) *Biochim. Biophys. Acta* 522, 251. 2. Zheng, White, Cash & Dean (1994) *Biochemistry* 33, 4714. 3. Heinamaki, Peramaa & Piha (1982) *Acta Chem. Scand. B* 36, 287. 4. Liger, Masson, Blanot, van Heijenoort & Parquet (1995) *Eur. J. Biochem.* 230, 80.

### 3-Allyl-4-[3-(isopropylamino)propoxy]biphenyl

This biphenyl derivative (FW = 308.45 g/mol) inhibits squalene synthase ( $IC_{50}$  = 93 nM for the rat enzyme), significantly reducing both plasma total cholesterol and plasma triglyceride levels following oral dosing to rats with a reduced tendency to elevate plasma transaminase levels. 1. Ishihara, Kakuta, Moritani, Ugawa & Yanagisawa (2004) *Bioorg. Med. Chem.* **12**, 5899.

### 1-Allyl-2-[3-(isopropylamino)propoxy]-9H-carbazole

This carbazole derivative (FW = 308.45 g/mol) inhibits squalene synthase ( $IC_{50}$  = 66 nM for the rat enzyme), significantly reducing both plasma total cholesterol and plasma triglyceride levels following oral dosing to rats with a reduced tendency to elevate plasma transaminase levels. 1. Ishihara, Kakuta, Moritani, Ugawa & Yanagisawa (2004) *Bioorg. Med. Chem.* **12**, 5899.

### 4-Allyl-2-methoxyphenyl Benzoate

This eugenol ester (FW = 268.31 g/mol), also known as eugenyl benzoate, inhibits 15-lipoxygenase ( $IC_{50}$  = 4.4  $\mu$ M). Other esters also inhibit (e.g., 2-pyridinecarboxylate ( $IC_{50}$  = 33.3  $\mu$ M), nicotinate ( $IC_{50}$  = 1.7  $\mu$ M), isonicotinate ( $IC_{50}$  = 2.3  $\mu$ M), 2-fluorobenzoate ( $IC_{50}$  = 6.7  $\mu$ M), 3-fluorobenzoate ( $IC_{50}$  = 2.1  $\mu$ M), and 4-fluorobenzoate ( $IC_{50}$  = 7.2  $\mu$ M), 2-chlorobenzoate ( $IC_{50}$  = 168  $\mu$ M), 3-chlorobenzoate ( $IC_{50}$  = 5.2  $\mu$ M), and 4-chlorobenzoate ( $IC_{50}$  = 134.3  $\mu$ M), 2-methylbenzoate ( $IC_{50}$  = 77  $\mu$ M), 3-methylbenzoate ( $IC_{50}$  = 11  $\mu$ M), and 4-methylbenzoate ( $IC_{50}$  = 15  $\mu$ M), 3-( $IC_{50}$  = 23  $\mu$ M), 4-methoxybenzoate ( $IC_{50}$  = 19  $\mu$ M), cyclohexanecarboxylate ( $IC_{50}$  = 2.2  $\mu$ M), and adamantanecarboxylate ( $IC_{50}$  = 0.017  $\mu$ M). 1. Sadeghian, Seyedi, Saberi, Arghiani & Riazi (2008) *Bioorg. Med. Chem.* **16**, 890.

### [4-[6-(Allylmethylamino)hexyloxy]phenyl](4-nitrophenyl) methanone

This orally active non-terpenoid inhibitor (FW<sub>free-base</sub> = 396.49 g/mol) targets human lanosterol synthase ( $IC_{50}$  = 1.9 nM), with demonstrated efficacy in lowering plasma total cholesterol (TC) and plasma low-density lipoprotein cholesterol (LDL-C) in hyperlipidemic hamsters. 1. Dehmlow, Aebi, Jolidon, et al. (2003) *J. Med. Chem.* **46**, 3354.

### N-( $\alpha$ (R)-Allyl-4-methylbenzylaminocarbonyl) 4(S)-(4-Carboxymethylphenoxy)-3,3-diethylazetidin-2-one

This alkylazetidinone (FW<sub>free-acid</sub> = 464.56 g/mol), also known as L-680755, inactivates human, green monkey, dog, and rat leukocyte elastase (1). Its specificity toward human pancreatic elastase versus porcine pancreatic elastase is consistent with the differences in substrate specificity reported for these enzymes (2). 1. Knight, Green, Chabin, et al. (1992) *Biochemistry* **31**, 8160. 2. Zimmerman & Ashe (1977) *Biochim. Biophys. Acta* **480**, 241

### 1-Allyl-2-thiourea

This substituted thiourea (FW = 116.19 g/mol), also known as thiosinamine, is a noncompetitive inhibitor of ammonia monooxygenase. **Target(s):** methane monooxygenase (1); photosynthesis (2); tyrosinase (3); cytochrome *c* oxidase (3); succinate dehydrogenase (3); ammonia monooxygenase (4,5); alkane monooxygenase (6). 1. Tonge, Harrison & Higgins (1977) *Biochem. J.* **161**, 333. 2. Green, McCarthy & King (1939) *J. Biol. Chem.* **128**, 447. 3. DuBois & Erway (1946) *J. Biol. Chem.* **165**, 711. 4. Rasche, Hyman & Arp (1991) *Appl. Environ. Microbiol.* **57**, 2986. 5. Juliette, Hyman & Arp (1993) *Appl. Environ. Microbiol.* **59**, 3728. 6. Hamamura, Yeager & Arp (2001) *Appl. Environ. Microbiol.* **67**, 4992.

### Almorexant

This orally available, dual orexin (*or* hypocretin) antagonist (FW = 549.02 g/mol; CAS 913358-93-7; Solubility: 79 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O; Dose: ~300 mg/kg body weight, administered in polyethylene glycol 400 or 0.25% methylcellulose in water), also named (*R*)-2-((*S*)-1-(4-(trifluoromethyl)phenethyl)-6,7-dimethoxy-3,4-dihydroisquinolin-2(1*H*)-yl)-*N*-methyl-2-phenylacetamide·HCl, targets for OX<sub>1</sub> ( $IC_{50}$  = 6.6 nM) and OX<sub>2</sub> ( $IC_{50}$  = 3.4 nM) receptors, decreased cell proliferation and neurogenesis specifically in the ventral hippocampus (1,2). Mounting evidence suggests that an increase of orexin receptor signaling is likely to underlie the pathophysiology of major depression. These receptors (**See also Orexins A & B; Fluoxetine; IPSU**) 1. Brisbare-Roch, Dingemans, Koberstein, et al. (2007) *Nature Med.* **13**, 150. 2. Nollet, Gaillard, Tanti, et al. ## Alpelisib

This orally bioavailable phosphatidylinositol 3-kinase (PI3K) inhibitor (FW = 441.47 g/mol; CAS 1217486-61-7; Soluble in DMSO), also named BYL719 and (S)-N<sup>1</sup>-(4-methyl-5-(2-(1,1,1-trifluoro-2-methylpropan-2-yl)pyridin-4-yl)thiazol-2-yl)pyrrolidine-1,2-dicarboxamide, targets PIK3 in the PI3K/AKT kinase (or Protein Kinase B) signaling pathway, thereby blocking the activation of the PI3K signaling pathway and impeding tumor cell growth/survival in susceptible tumor cells, including PIK3CA-mutant breast cancer. Dysregulated PI3K signaling is believed to be a contributing factor in tumor resistance to antineoplastic agents. 1. Azab, Vali, Abraham, *et al.* (2014) *Brit. J. Haematol.* **165**, 89. 2. ## Alprazolam

This potent benzodiazepine-class depressant and anxiolytic drug (FW = 308.77 g/mol; CAS 28981-97-7), known by the trade name Xanax<sup>®</sup> and by its IUPAC name, 8-chloro-1-methyl-6-phenyl-4H-[1,2,4]triazolo[4,3-a][1,4]benzodiazepine, exhibit wide-ranging properties that commend its use as a highly effective sedative, hypnotic, skeletal muscle relaxant, anticonvulsant, and amnestic properties. When given daily at a dosage of 0.5 to 4.0 mg, it is as effective an anxiolytic agent as diazepam and chlordiazepoxide. Protracted use, however, results in tolerance, requiring higher doses to maintain efficacy. Among the most frequently abused CNS depressants, alprazolam is classified as a controlled substance (Schedule IV) by the U.S. Drug Enforcement Agency. **Primary Mode of Action:** Alprazolam targets the GABA<sub>A</sub> receptor, of which there are numerous subtypes, each showing varying interactions with alprazolam. Located different regions of the brain, diazepam-type GABA<sub>A</sub> receptor agonists cause hyperpolarization and inhibition of neuronal excitability as a consequence of chloride ion influx. **Pharmacokinetics:** When given orally or intravenously, only 1% of alprazolam reaches the brain, as detected with [<sup>11</sup>C]-alprazolam and positron emission tomography (2). The mean kinetic parameters (1) for intravenous and oral alprazolam administration, respectively, were: volume of distribution of 0.72 and 0.84 L/kg; elimination *t*<sub>1/2</sub> of 11.7 and 11.8 hour; clearance rate of 0.74 and 0.89 mL/min/kg (2). There were no significant differences between intravenous and oral alprazolam in terms of V<sub>d</sub>, *t*<sub>1/2</sub>, or AUC. The mean fraction absorbed after oral administration was 0.92. With the exception of rapidity of onset, the pharmacodynamic profiles of intravenous and oral alprazolam are similar for a 1-mg dose (2). In humans, alprazolam is metabolized by CYP3A4 to 4-hydroxyalprazolam and  $\alpha$ -hydroxyalprazolam. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Dobbs, Banks, Fleishaker, *et al.* (1995) *Nucl. Med. Biol.* **22**, 459. 2. Smith, Kroboth, Vanderlugt, Phillips & Juhl (1984) *Psychopharmacol.* (Berlin) **84**, 452.

## Alrestatin

This aldose reductase inhibitor and drug (FW<sub>free-acid</sub> = 255.23 g/mol; CAS 51411-04-2), also known as 1,3-dioxo-1H-benz[de]isoquinoline-2(3H)-acetic acid) suppresses diabetes-associated, osmotic cell and tissue damage by inhibiting aldose reduction and thereby reducing the accumulation intracellular sorbitol. **Primary Mode of Action of Aldose Reductase Inhibitors:** A major cause of diabetic neuropathy is the intraneural osmotic pressure that builds up as a consequence of the over-accumulation of sorbitol, a polyol formed by aldose reductase (*Reaction:* Glucose + NADPH  $\rightleftharpoons$  Sorbitol + NADP<sup>+</sup> + H<sup>+</sup>). Similar considerations apply to cataract formation in the lens, another tissue rich in aldose reductase. In diabetes, aldose reductase activity increases as the concentration of glucose rises in the lens, peripheral nerves and glomerulus (tissues that are insulin-insensitive); because sorbitol lacks a membrane carrier, its contributes to intracellular osmotic pressure, disrupting cell-cell interactions (especially synapses), eventually leading to retinopathy and neuropathy. The additive effects of aldose reductase (AR) and polyol dehydrogenase in producing sorbitol from glucose and fructose, acting in combination with age-dependent decreased hexokinase is believed to account for diabetic cataract formation in human lenses under high glucose stress. AR's *K*<sub>m</sub> for glucose of AR is roughly 200 mM, whereas its *K*<sub>m</sub> for NADPH is 0.06 mM. NADP inhibits human lens AR noncompetitively and has a *K*<sub>i</sub> that is roughly equal to the *K*<sub>m</sub> for NADPH. Notably, the *K*<sub>m</sub> for fructose is 40 mM and that for NADH is 0.02 mM in the polyol dehydrogenase (PD) reaction. Therefore, although sorbitol formation is modest during normoglycemia, such is not the case for diabetic hyperglycemia. Moreover, the recent increased reliance on high-fructose corn syrup as a sweetener is problematic, in that glucose-sensing mechanisms in humans are largely unresponsive to fructose. Because sorbitol is not transported out of the lens, any increase in intracellular sorbitol must be compensated osmotically by the considerable uptake of water, a well-characterized cataractogenic event. By inhibiting sorbitol dehydrogenase, alrestatin lowers the undesirable net accumulation of sorbitol during hyperglycemic episodes. At high enough concentrations, alrestatin also inhibits PD. **Target(s):** aldose reductase, or aldehyde reductase (1-3,6-10); 4-aminobutyrate aminotransferase (4); carbonyl reductase (5); succinate-semialdehyde dehydrogenase (4); polyol dehydrogenase, weakly inhibited, except at elevated concentrations (6); hexonate dehydrogenase, or glucuronate reductase (8). 1. ## Alsterpallone

This cell-permeable GSK3 $\beta$  (FW = 293.28 g/mol; CAS 237430-03-4), also named NSC 705701 and 9-nitro-7,12-dihydroindolo[3,2-d][1]benzazepin-6(5H)-one, targets cyclin-dependent kinases (CDKs) and glycogen synthase kinase 3 $\beta$  potently, reversibly, and ATP competitively. Displays remarkable antitumor activity *in vitro*. Alsterpallone inhibits growth of the colon cancer cell line HCT-116, with an IC<sub>50</sub> in the nanomolar range. **Target(s):** cyclin-dependent kinase, or cyclin-dependent protein kinase 2/cyclin A, IC<sub>50</sub> = 0.08  $\mu$ M (1,4); glycogen synthase kinase 3 $\beta$ , or [tau protein] kinase; IC<sub>50</sub> = 0.11  $\mu$ M (1,3,5); lymphocyte kinase, IC<sub>50</sub> = 0.47  $\mu$ M (1); cyclin-dependent protein kinase 1/cyclin B, IC<sub>50</sub> = 0.035  $\mu$ M (2,5); cyclin-dependent protein kinase 5/p25 (3,5); mitogen-activated protein kinase (1); protein kinase C, weakly inhibited (1); cAMP-dependent protein kinase, or protein kinase A; weakly inhibited (1); non-specific serine/threonine protein kinase (1); protein-tyrosine kinase, or non-specific protein-tyrosine kinase (1), Lck protein-tyrosine kinase (1). 1. Bain, McLauchlan, Elliott & Cohen (2003) *Biochem. J.* **371**, 199. 2. Schultz, Link, Leost, *et al.* (1999) *J. Med. Chem.* **42**, 2909. 3. Leost, Schultz, Link, *et al.* (2000) *Eur. J. ### (-)-Altenuene

This mycotoxin (FW = 292.28 g/mol; CAS 889101-41-1) from *Alternaria tenuis* (an endophytic fungus associated with *Vinca rosea*, or *Catharanthus roseus*) partially inhibits acetylcholinesterase (maximal inhibition = 78%) and butyrylcholinesterase (maximal inhibition = 73%). Other *Alternaria* mycotoxins include tenuazonic acid, alternariol monomethyl ether, alternariol, and altertoxin I. **See Tenuazonic Acid 1.** Bhagat, Kaur, Kaur, *et al.* (2016) *J. Appl. Microbiol.* **121**, 1015.

### Altoprane

This phenyltropane derivative (FW = 429.27 g/mol; CAS 180468-34-2), also known as O-587, IACFT, and 2β-carbomethoxy-3β-(4-fluorophenyl)-N-((E)-3-iodoprop-2-enyl)tropane, is a dopamine reuptake inhibitor that displays high affinity and specificity both *in vitro* and *in vivo* in laboratory animals (1). The favorable binding properties of altoprane, together with its rapid entry into primate brain and highly localized distribution in dopamine-rich brain regions, suggest it is a suitable iodinated probe for monitoring the dopamine transporter *in vitro* and *in vivo* by SPECT or PET imaging (2). Altoprane also shows promise for treating attention deficit hyperactivity disorder (ADHD). **1.** Elmaleh, Fischman, Shoup, *et al.* (1996) *J. Nucl. Med.* **37**, 1197. **2.** Madras, Meltzer, Liang, *et al.* (1998) *Synapse* **29**, 93.

**Aluminum Chloride, See Aluminum and Aluminum Ions**

### Aluminum(III)-ATP Complex

This one-to-one, exchange-stable complex, forms as a consequence of the much tighter binding of trivalent  $Al^{3+}$  to nucleoside triphosphates than with divalent magnesium or calcium ions.  $Al(III)ATP$  inhibits a number of ATP-dependent enzymes (1-6) and is likely to act in a similar manner with many more. Solheim & Fromm (7) describe a simple method for removing aluminum from ATP. **Target(s):** hexokinase, slow-binding inhibition (1-6); glycerokinase (2,4). **1.** Morrison (1982) *Trends Biochem. Sci.* **7**, 102. **2.** Viola, Morrison & Cleland (1980) *Biochemistry* **19**, 3131. **3.** Macdonald & Martin (1988) *Trends Biochem. Sci.* **13**, 15. **4.** Furumo & Viola (1989) *Inorg. ### Aluminum Ion ( $Al^{3+}$ )

This trivalent inorganic ion, derived from its parent Group IIIB metal, readily forms the amphoteric species aluminum hydroxide  $[Al(OH)_3]$  that hydrates to the insoluble hexacoordinate species  $[Al(OH)_3(H_2O)_3]$ . Insoluble aluminum hydroxide can be formed by the addition of hydroxide ion,  $OH^-$  to form a soluble salt of  $Al^{3+}$  (*Reaction:*  $[Al(H_2O)_6]^{3+}(aq) + 3 OH^-(aq) \rightarrow Al(OH)_3(OH)_3(s) + 3 H_2O(l)$ ). The insoluble metal hydroxide can act as a base, since it can be redissolved upon reaction with an acid (*Reaction:*  $Al(OH)_3(H_2O)_3(s) + 3 H_3O^+(aq) \rightarrow [Al(H_2O)_6]^{3+}(aq) + 3 H_2O(l)$ ). Alternatively, the metal hydroxide can act as an acid, since it can react with a base (*Reaction:*  $Al(OH)_3(H_2O)_3(s) + OH^-(aq) \rightarrow [Al(OH)_4(H_2O)_2]^{-}(aq) + H_2O(l)$ ). pH therefore strongly influences the aqueous species that form, as does temperature and ionic strength. **Nature of Enzyme-Bound Aluminum Ions:** The amphoteric nature of aluminum ions is strongly influenced by the presence of other ligands, including amines, carboxylic acids, and phosphoric acid species. For this reason, the best way

to determine the enzyme-bound species is through the use of X-ray crystallography or NMR structures of the enzyme-aluminum species in a buffer that approximates the solution properties used in assays of enzymatic activity. Because the enzyme is likely to provide one or more ligands, the precise solution species that first combines with the enzyme is necessarily conjectural. **Aluminum Exposure & Neurodegenerative Disease:** Various lines of evidence, mostly conjectural, have associated aluminum exposure to such disorders as dialysis encephalopathy, amyotrophic lateral sclerosis, Parkinson Disease in the Kii Peninsula and Guam, and Alzheimer's disease (AD). The complex characteristics of aluminum bioavailability make it difficult to evaluate its toxicity, and a direct causal relationship remains to be established. Given that protein misfolding and associated oligomerization and/or polymerization appears to be an emerging theme in protein folding disorders, one cannot discount a role of aluminum ions in promoting such protein structural rearrangements. **Sources:** Anhydrous  $AlCl_3$  (Sigma-Aldrich 563919 and Fisher-Acros AC36481-0100 (both are 99.999% trace metals basis); CAS 7446-70-0;  $MW_{anhydrous} = 133.34$  g/mol);  $AlCl_3$  Hydrate (Sigma-Aldrich 229393 (99.999% on trace metals basis); CAS 10124-27-3). **Caution:** Anhydrous  $AlCl_3$  reacts violently with water, generating considerable heat. The recommended practice for hydrolysis is to allow anhydrous  $AlCl_3$  to hydrate slowly (over a few days) in a moist atmosphere. This can be accomplished by placing two beakers, one containing the anhydrous powder and the other a few mL of water in an otherwise empty desiccator. (The anhydrous powder essentially serves as the desiccant.) Another simple method is to expose a weighed sample of anhydrous powder to the ambient atmosphere for a few days, allowing it to absorb ambient humidity. Unless highly experienced, it is advisable to prepare only a small quantity (0.2-0.5 g) at a time. **Target(s):** phospholipase C (10,43,121,122); phosphorylase phosphatase (2); Ferroxidase (3,42,152); acetylcholinesterase (14,42,52); apyrase, starting from aluminum chloride (5);  $H^+$  ATPase (6);  $K^+$  channels (7); porphobilinogen synthase, or  $\delta$ -aminolevulinic acid dehydratase; starting with  $AlCl_3$  (8,14,18); hexokinase (9,16,34,40,41,42); phospholipase D (10,119,120); butyrylcholinesterase (11,42); ras p21 (12); catalase (13); nitrogenase, starting with aluminum fluoride (15); trypsin (17,53); chymotrypsin (17); isocitrate dehydrogenase, NAD (19); isocitrate dehydrogenase, NADP (19,20); acid phosphatase (21,22,126-128); alkaline phosphatase, starting from aluminum chloride (22,35,42); protein kinase C (23); calpain (24);  $H^+$ -translocating ATPase (25); superoxide dismutase (26); glucose-6-phosphate dehydrogenase (27,28); transducin (29,30); GTPase (29,30); adenylate cyclase, activated and inhibited under different conditions (31,32); porphobilinogen deaminase (33); mannan endo-1,4- $\beta$ -mannosidase (34); aquacobalamin reductase (38); aquacobalamin reductase, NADPH (37,38,153); secretory tomato ribonucleases (39); glycerokinase (41); 3',5'-cyclic-nucleotide phosphodiesterase (42); catechol *O*-methyltransferase (42); amidase (44); phospholipase  $A_2$  (45); ascorbate peroxidase (46); tyrosinase (47);  $TF_1$  ATPase (48,49); nucleotide diphosphatase, nucleotide pyrophosphatase (50); aminoacylase (51); pyruvate decarboxylase (52); 6-carboxyhexanoyl-CoA synthetase, or 6-carboxyhexanoate: CoA ligase (54); mannose isomerase (55); indoleacetaldoxime dehydratase (56); isocitrate lyase (57); acetylenedicarboxylate decarboxylase, starting from  $Al(NO_3)_3$  (58); uroporphyrinogen decarboxylase (59); aromatic-L-amino-acid decarboxylase, or dopa decarboxylase (60,61); phloretin hydrolase (72);  $Mg^{2+}$ -importing ATPase (63); NAD diphosphatase (64); exopolyphosphatase (65); GTP cyclohydrolase I (66); guanosine deaminase (67); D-arginase (68); arginine deaminase (69); arginase II (70); calpain-2, or m-calpain (71); calpain-1,  $\mu$ -calpain (71); IgA-specific serine endopeptidase (72); prolyl oligopeptidase (73); cystinyl aminopeptidase, oxytocinase (74); leucyl aminopeptidase (75); microsomal epoxide hydrolase (weakly inhibited (76)); soluble epoxide hydrolase (76);  $\alpha$ -glucuronidase (77); glucan 1,4- $\alpha$ -maltotetraosidase, weakly inhibited (78); fructan  $\beta$ -fructosidase (79); inulinase (79); galacturan 1,4- $\alpha$ -galacturonidase (80); levanase (81); glucan 1,4- $\alpha$ -maltotetrahydrolase (82);  $\beta$ -N-acetylhexosaminidase (83,84); pullulanase (85); xylan 1,4- $\beta$ -xylosidase (86); hyaluronoglucosaminidase, or hyaluronidase (87); xylan endo-1,3- $\beta$ -xylosidase (88,89);  $\alpha$ -D-trehalase (90,91);  $\beta$ -galactosidase (92);  $\beta$  glucosidase (93);  $\alpha$ -glucosidase (94,95); chitinase, starting from by  $AlCl_3$  (96); endo-1,4- $\beta$ -xylanase (97,98); glucan 1,4- $\alpha$ -glucosidase, glucoamylase (99,100);  $\beta$ -amylase (101,102);  $\alpha$ -amylase (103-108); *Basidobolus hapto*sporous nuclease (nuclease Bh1) (109,111); ribonuclease IX (110); Arylsulfatase, starting from by  $AlCl_3$  (112,113); 3',5'-cyclic-nucleotide phosphodiesterase (114-117); sphingomyelin phospho-diesterase, or neutral sphingomyelinase (118); 4-phytase (123,125); 3- or 4-phytase (124); phospholipase  $A_1$  (129);

- Lysophospholipase (129,132,133); 1,4-lactonase (130); pectinesterase (131); lipase, *or* triacylglycerol lipase (134); acetate kinase (135); pantothenate kinase, starting from by  $AlCl_3$  (136); dihydroxyphenylalanine aminotransferase (137); alanine aminotransferase (138); hydroxymethylbilane synthase (139); 3-phosphoshikimate 1-carboxyvinyltransferase, *or* 3-enolpyruvoylshikimate-5 phosphate synthase (140); galactose-6-sulfurylase (141); 1,4- $\beta$ -D-xylan synthase (142); nicotinate nucleotide diphosphorylase, carboxylating (143,144); anthocyanin 3'-O- $\beta$ -glucosyltransferase (145); xyloglucan:xyloglucosyl transferase (146); sucrose:sucrose fructosyltransferase (147); galactinol: sucrose galactosyltransferase, *or* raffinose synthase (148); cyclomaltodextrin glucanotransferase (149,150); dextranase (151); polyphenol oxidase (154); tyrosinase, monophenol monooxygenase (154); stizolobate synthase (155); stizolobate synthase (155); protocatechuate 3,4 dioxygenase (156); catechol 1,2-dioxygenase (157); L-ascorbate peroxidase (158,159); peroxidase (160,161); laccase (162,163); catechol oxidase (164); polyphenol oxidase (164). 1. ### Aluminum Tetrafluoride

This aqueous aluminum fluoride anion is a presumptive geometric analogue of an associated intermediate formed in  $S_N2$ -type nucleophilic mechanisms, as observed with many phosphoryl transferases and phosphate ester hydrolases. Tightly bound fluoride substituents exhibit exceptional hydrogen-bonding capacity, a property that is likely to explain why  $AlF_4^-$  species interact as strongly as they do with enzyme-bound water molecules and other hydrogen-donating groups within the active sites of enzymes binding nucleoside 5'-triphosphates. This fluoroaluminate complex is readily formed by mixing aqueous solutions of sodium fluoride and aluminum chloride (*see below*). The dihydrate  $[AlF_4(H_2O)_2]^{2-}$  is the most likely species in water. Either of the two water molecules may be displaced by a nucleophile,  $R-O^-$  in the structure shown above, thereby yielding a dianion. Analogous tightly bound inorganic fluorides include beryllium fluoride ( $BeF_n$ ), scandium fluoride ( $ScF_n$ ), and gallium fluoride ( $GaF_n$ ).  $AlF_4^-$  activates members of the heterotrimeric G-protein ( $G\alpha\beta\gamma$ ) family by binding to inactive  $G\alpha \cdot GDP$  complex near the site occupied by the  $\gamma$ -phosphate in  $G\alpha \cdot GTP$  complex (1). Recent work (2), however, illustrates the need for caution in interpreting the mode of  $AlF_4^-$  action. These investigators found that p190 RhoGAP forms a high-affinity complex with Rho GTPases in the presence of fluoride ions *without* any requirement for aluminum ions or even guanine nucleotide. Thus, fluoride may play a role other than as a  $\gamma$ -phosphate mimic. This finding supports the results of an earlier study by Murphy & Coll (3), who found that fluoride is a slow, tight-binding inhibitor of the calcium ATPase of sarcoplasmic reticulum. Any role for aluminum was ruled out by the observation that the addition of EGTA to 10 mM or aluminum sulfate to 0.2 mM or of deferoxamine to 0.5 mM produced no significant change in  $k_{obs}$  for fluoride inactivation of the pump ATPase. Investigators should carefully consider alternative modes of action when a requirement for aluminum or guanine nucleotide has not yet been demonstrated. One should also question any assumption that enzymes passively bind  $AlF_4^-$  as a tightly bound competitive inhibitor. The phosphoryl oxygens of active-site nucleotides may combine with  $AlF_4^-$  to form species resembling the structure presented above. Other active-site changes can occur. Yousafzai & Eady (4), for example, found that incubation of MoFe (Kp1) and Fe (Kp2) component proteins of *Klebsiella pneumoniae* nitrogenase are incubated with MgADP and  $AlF_4^-$  in the presence of the reducing agent dithionite produces a stable transition-state complex. The EPR signal associated with reduced Kp2 was not detectable; yet, Kp1 retained the  $S = 3/2$  EPR signal arising from the dithionite reduced state of the protein's MoFe cofactor center. This observation suggested that the  $[Fe_4S_4]$  center was somehow oxidized. No satisfactory explanation for the fate of the electrons lost by Kp2 has been forthcoming. In a later report, Yousafzai and Eady (5) demonstrated that  $H_2$  was evolved; likewise, they observed the formation of  $H_2$  by nitrogenase in the absence of  $AlF_4^-$  in reaction mixtures containing MgADP, but not MgATP. **Preparation:**  $AlF_4^-$  is generated by combining aqueous  $Al_2(SO_4)_3$  and NaF solutions at a 4:1

fluorine:aluminum ratio. If a pH buffer is required, sulfonic acid buffers, such as HEPES or MES, should be used. Avoid Tris buffer, because primary amines may interact with aluminum fluoride. **Target(s):**  $F_1$  ATPase, via MgADP-fluoroaluminate complex (6-10); RecA ATPase (11);  $Ca^{2+}$ -transporting ATPase (12); myosin ATPase (13,18); nitrogenase (14,16);  $CF_1$  ATPase (15); dynamin GTPase (17);  $H^+$ -exporting ATPase (19); exopolyphosphatase (20); acetate kinase (21). 1. ### Alvespimycin

This potent Hsp90 inhibitor (FW<sub>HCl-salt</sub> = 653.21 g/mol; CAS 467214-21-7), also named 17-DMAG and 17-demethoxy-17-[[2-(dimethylamino)ethyl]amino]geldanamycin, targets Heat Shock Protein-90 (IC<sub>50</sub> = 62 nM in a cell-free assay). (**See also** *Ansamycin*; *Deguelin*; *Derrubone*; *Ganetespib*; *Geldanamycin*; *Herbimycin*; *Macbecin*; *Radicicol*; *Tanespimycin*; and the *nonansamycin Hsp90 inhibitor KW-2478*) 1. Ge, Normant, Porter, *et al.* (2006) *J. Med. Chem.* **49**, 4606. 2. Lang, Klein, Moser, *et al.* (2007) *Mol. Cancer Ther.* **6**, 1123.

### Alvocidib, See Flavopiridol

### AM251

This CB<sub>1</sub> inverse agonist (FW = 555.24 g/mol; CAS 183232-66-8; Solubility: 100 mM in DMSO; Fluorescent Derivative: Tocrifluor T1117), also named 1-(2,4-dichlorophenyl)-5-(4-iodophenyl)-4-methyl-N-(1-piperidyl)pyrazole-3-carboxamide, binds to the cannabinoid-1 receptor, potentially blocking ( $K_i = 7.5$  nM; IC<sub>50</sub> = 8 nM) the action of endocannabinoids (**See** *Anandamide*). AM251 potentiates the forskolin-stimulated accumulation of cAMP, and it reduces the basal levels of inositol phosphate production in cells expressing the CB<sub>2</sub> receptors. Such findings demonstrate that AM251 acts as inverse agonists at the human CB<sub>2</sub> receptor acting via pathways coupled to members of the  $G_q$  family of GPCRs. 1. Lan, Liu, Fan, *et al.* (1999) *J. Med. Chem.* **42**, 769.

### AM803, See GSK2190915

**AM-1155, See Gatifloxacin** **$\alpha$ -Amanitin**

This bicyclic octapeptide toxin (FW = 918.98 g/mol; CAS 23109-05-9; LD<sub>50</sub> = 0.1 mg/kg *i.p.* in albino mice) from the death-cap fungus *Amanita phalloides* binds very tightly to eukaryotic RNA polymerase II ( $K_i \approx 10$  nM) and less tightly to eukaryotic RNA polymerase III ( $K_i \approx 1$   $\mu$ M), blocking mRNA synthesis and inducing cytolysis of hepatocytes and kidney cells.  $\alpha$ -Amanitin is stable at room temperature, soluble in water and ethanol, and melts with decomposition at 254-255°C. **Caution:** Gloves should be worn, and measures should be taken to avoid inhalation. Symptoms of a toxic dose may not appear for 6-15 hours after exposure. More than 90% of deaths caused by mushroom poisonings are due to *A. phalloides* and related species. **Target(s):** RNA polymerase II (1-4,8); RNA polymerase III (1-3,7); yeast RNA polymerase B (2); RNA polymerase I (7); certain plant RNA polymerases (e.g., plant RNA polymerase II (2); DNA-directed DNA polymerase (5); DNA-directed RNA polymerase (1-4,6-8). 1. **Amastatin**

This peptide analogue (FW = 474.56 g/mol; CAS 100938-10-1), also known as (2S,3R)-3-amino-2-hydroxy-5-methylhexanoyl-L-valyl-L-valyl-L-aspartate, is a high-affinity, reversible competitive inhibitor of human serum and porcine kidney aminopeptidase ( $K_i \approx 1-2$   $\mu$ M). Prepare as a 1 mM stock solution in methanol or ethanol, store at -20 °C for one month, and use at final concentrations of 2-20  $\mu$ M. At room temperature, aqueous solutions are stable for one day. **Target(s):** leucyl aminopeptidase (1,9,17,22,27,55,66-74); membrane alanyl aminopeptidase, or aminopeptidase M, or aminopeptidase N (1,2,19, 22,28,48,60-65); glutamyl aminopeptidase, or aminopeptidase A (3,18,42-48); cystinyl aminopeptidase, or oxytocinase (4,54-59); insulin-regulated membrane aminopeptidase (5); aminopeptidase PS (6); aminopeptidase B (7,49-52); nardilysin (8,15,24,25); aminopeptidase Y, or aminopeptidase Co (10,11,37); *Vibrio* aminopeptidase (12); aminopeptidase T (13); Xaa-Trp aminopeptidase, or aminopeptidase W (14,34-36); acyl amidase-like leucyl aminopeptidase (16); L-to-D-amino-acid-residue isomerase (20,21); bacterial leucyl aminopeptidase (12,22); biotinidase (23); mitochondrial intermediate peptidase (26); pyroglutamyl peptidase I, weakly inhibited (27); dipeptidyl-peptidase III, moderately inhibited (29); cytosol nonspecific dipeptidase (30); aminopeptidase I (31-33); cytosol alanyl aminopeptidase (38); Xaa-Pro aminopeptidase, or aminopeptidase P (39-41); prolyl aminopeptidase, *Aneurinibacillus* sp. (53); leucyl aminopeptidase/cystinyl aminopeptidase (55). 1. Rich, Moon & Harbeson (1984) *J. Med. Chem.* **27**, 417. 2. Turner (1998) in *Handb. ### Ambrisentan

This orally active endothelin receptor antagonist (FW = 378.42 g/mol; CAS 177036-94-1), also known by its code names LU-208075, BSF-208075, its trade names Letairis™ and Volibris™, and by its IUPAC name (2*S*)-2-[(4,6-dimethylpyrimidin-2-yl)oxy]-3-methoxy-3,3-diphenylpropanoic acid, is a FDA-approved, once-daily drug for treating pulmonary hypertension. Because endothelin constricts blood vessels and elevates blood pressure, endothelin receptor antagonists (ETRA) prevent constriction/narrowing of blood vessels, thereby enhancing blood flow. There are no known interactions between ambrisentan and cytochrome P450 isoenzymes (metabolism, induction or inhibition) that might alter the activity of P450-metabolized drugs. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) ### AMD3100, See Plerixafor

### Amdinocillin

This amidino-penicillin (FW = 325.43 g/mol), also known as mecillinam, is a semi-synthetic antibacterial that inhibits certain penicillin-binding proteins, indirectly blocking cell division. **Target(s):** penicillin-binding protein 5, a serine-type D-Ala-D-Ala carboxypeptidase (1); penicillin-binding protein 4 (2); penicillin-binding protein 1 (3); penicillin-binding protein 2 (4-7,9); *Actinomadura* R39 D-alanyl-D-alanine-cleaving serine peptidase (8). Under laboratory selection conditions, frequencies of mutation to amdinocillin resistance in *Escherichia coli* varied from  $8 \times 10^{-8}$  to  $2 \times 10^{-5}$  per cell, depending on the amdinocillin concentration (9). Of the genes demonstrated to confer amdinocillin resistance, eight novel genes in amdinocillin resistance encode functions involved in the respiratory chain, the ribosome, cysteine biosynthesis, tRNA synthesis, and pyrophosphate metabolism. **1.** Wilkin (1998) in *Handb. ### Amentoflavone

This biflavonoid (FW = 538.47 g/mol; CAS 1617-53-4), also known as 3',8''-biapegenin, from *Ginkgo biloba*, *Taxodium mucronatum*, and St. John's wort (*Hypericum perforatum*), scavenges superoxide radicals, inhibits lipid peroxidation, and has anti-inflammatory properties. **Target(s):** CYP1A1 (1); CYP1B1 (1); 3',5'-cyclic-nucleotide phosphodiesterase, or cAMP phosphodiesterase; IC<sub>50</sub> = 22 μM (2,6); RNA-directed DNA polymerase (3); avian myeloblastosis reverse transcriptase (3); Rous-associated virus-2 reverse transcriptase (3); Maloney murine leukemia virus reverse transcriptase (3); phospholipase Cγ1 (4); cyclooxygenase (however, see ref. 11) (5,11); α-glucosidase (7); α-amylase (7); phospholipase A<sub>2</sub> (8); DNA topoisomerase I (9); CYP2C9 (10); cathepsin B (12); 3',5'-cyclic-GMP phosphodiesterase (13); phosphodiesterase 5 (13); inositol-trisphosphate 3 kinase (14). **1.** Chaudhary & Willett (2006) *Toxicology* **217**, 194. **2.** Beretz, Briancon-Scheid, Stierle, et al. ### Amezinium

This sympathomimetic and antihypertensive drug (FW = 313.32 g/mol; CAS 30578-37-1), also named 4-amino-6-methoxy-1-phenyl-pyridazinium methyl sulfate, amezinium-metilsulfate, LU 1631, and Regulton®, increases the arterial blood pressure and heart rate of anesthetized animals and of pithed rats by stimulating vascular α-adrenoceptors and cardiac β<sub>1</sub>-adrenoceptors (1). This action is unaffected by ganglionic blockade with hexamethonium. The α-adrenergic blocking drug phentolamine antagonizes the blood pressure increasing effect of amezinium, and the β-adrenergic blocking drug propranolol antagonizes the heart rate increasing effect. Noradrenaline depletion by pretreatment with reserpine reduces the pressor effect of amezinium to approximately the same extent as it reduces the effect of tyramine. It completely abolished the heart rate increasing effect. Under such conditions, high doses of amezinium reduced the heart rate (1). Amezinium is taken up by adrenergic neurons. Amezinium also inhibits intraneuronal monoamine oxidase, with IC<sub>50</sub> values of 5 μM and >1mM for MAO-A and MAO-B, respectively (1,2). **1.** Araújo, Caramona & Osswald (1983) *Eur. J. Pharmacol.* **90**, 203. **2.** Lenke, Gries & Kretzschmar (1981) *Arzneimittel-Forschung* **31**, 1558.

**AMF-26**

This novel anticancer agent (FW = 403.55 g/mol), also known as (2*E*,4*E*)-5-((1*S*,2*S*,4*aR*,6*R*,7*S*,8*S*,8*aS*)-7-hydroxy-2,6,8-trimethyl-1,2,4*a*,5,6,7,8,8*a*-octahydronaphthalen-1-yl)-2-methyl-*N*-(pyridin-3-ylmethyl)penta-2,4-dienamide, is a powerful cell growth inhibitor ( $GI_{50} = 12$  nM) and equally potent Golgi disruptor ( $EC_{50} = 27$  nM), inhibiting activation of ADP-ribosylation factors (or Arfs) by its guanine nucleotide exchange factors (GEFs). Arfs are Ras superfamily small GTPases that play a major role in mediating vesicular transport in the secretory and endocytic pathways. Molecular dynamics (MD) simulations suggest that AMF-26 binds to the contact surface of the Arf1-Sec7 domain near the site for brefeldin A. AMF-26 strongly affected membrane traffic, including the *cis*-Golgi and *trans*-Golgi networks, and the endosomal systems. When tested with a panel of 39 cancer cell lines, the  $GI_{50}$  was consistently below 40 nM. The total synthesis of AMF-26 has also been described (2). 1. Ohashi, Iijima, Yamaotsu, *et al.* (2012) *J. Biol. Chem.* **287**, 3885. 2. Shiina, Umezaki, Ohashi, *et al.* (2013) *J. Med. Chem.* **56**, 150.

**AMG-1**

This protein kinase inhibitor (FW = 556.58 g/mol; CAS 913376-84-8), targets human c-Met (or hepatocyte growth factor receptor (HGFR)) and RON (or *Recepteur d'Origine Nantais*) kinase, with  $IC_{50}$  values of 4 nM and 9 nM respectively. 1. Araki, Karasawa, Kawashima, *et al.* (1989) *Meth. Find. Exp. Clin. Pharmacol.* **11**, 731.

**AMG-47a**

This selective protein kinase inhibitor (FW = 535.60 g/mol; CAS 882663-88-9; Soluble in DMSO), also named 3-(2-(2-morpholinoethylamino)quinazolin-6-yl)-*N*-(3-(trifluoromethyl)phenyl)-4-methylbenzamide, targets Lck (or Lymphocyte-specific kinase), showing a sub-nM  $IC_{50}$ , and low (<10 nM) inhibition of so-called hard-to-inhibit kinases (e.g., KDR, Src, and MAPK $\alpha$  (or p38 $\alpha$ )). AMG-47 is effective against the Lck mediated anti-inflammatory activity ( $ED_{50} = 11$  mg/kg, or 630nM) *in vivo*. 1. Carver, Dexheimer, Hsu, *et al.* (2014) *PLoS One* **9**, e103836.

**AMG-51**

This protein kinase inhibitor (FW = 629.65 g/mol; CAS 890019-63-3; Solubility: 15 mM in DMSO), also known as 5-(3-fluoro-4-(6-methoxy-7-(3-morpholinopropoxy)quinolin-4-yloxy)phenyl)-2-(4-fluorophenylamino)-

3-methylpyrimidin-4(3*H*)-one, targets c-Met, or hepatocyte growth factor receptor (HGFR), a protein tyrosine kinase that plays a key role in several cellular processes and is overexpressed or mutated in different human cancers. AMG-51 shows the enzyme selectivity of c-Met with a ( $K_i = 4.9$  nM), with off-targets, such as IGFR ( $K_i = 22$ nM), Ron or Recepteur d'Origine Nantais kinase ( $K_i = 28$ nM), and KDR ( $K_i = 139$  nM). 1. D'Angelo, Bellon, Booker, *et al.* (2008) *J. Med. Chem.* **51**, 5766.

**AMG-145, See Evolocumab****AMG 162, See Denosumab****AMG-319**

This PI3K $\delta$  inhibitor (FW = 385.40 g/mol; CAS 1608125-21-8; Solubility: 77 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named *N*-((*S*)-1-(7-fluoro-2-(pyridin-2-yl)quinolin-3-yl)ethyl)-9*H*-purin-6-amine, potently and selectively targets phosphatidylinositol-4,5-bisphosphate 3-kinase ( $IC_{50} = 16$  nM in whole blood), an intracellular signal-transducing enzyme that phosphorylates the position-3 hydroxyl in phosphatidylinositol (PtdIns). **Other Target(s)**: PI3K $\gamma$  ( $IC_{50} = 850$  nM); PI3K $\beta$  ( $IC_{50} = 2.7$  $\mu$ M); and PI3K $\alpha$  ( $IC_{50} = 33$   $\mu$ M). 1. Cushing, Hao, Shin, *et al.* (2015) *J. Med. Chem.* **58**, 480.

**AMG-458**

This potent c-Met protein kinase inhibitor (FW = 539.58 g/mol; CAS 913376-83-7; Solubility: 21 mg/mL DMSO; ~1 mg/mL H<sub>2</sub>O), also named 1-(2-hydroxy-2-methylpropyl)-*N*-(5-(7-methoxyquinolin-4-yloxy)pyridin-2-yl)-5-methyl-3-oxo-2-phenyl-2,3-dihydro-1*H*-pyrazole-4-carboxamide, targets the *MET* proto-oncogene product c-Met, which is the hepatocyte growth factor receptor possessing tyrosine-kinase activity. The primary single-chain precursor protein is posttranslationally cleaved to produce the  $\alpha$  and  $\beta$  subunits that are disulfide linked to form the mature receptor. Various mutations in the *MET* gene are associated with papillary renal carcinoma. AMG-458 preferentially inhibits c-Met ( $K_i = 1.2$  nM), showing ~350-fold greater potency than VEGFR2 in cells (1). AMG-458 significantly inhibited tumor growth in the NIH3T3/TPR-Met and U-87 MG xenograft models with no adverse effect on body weight (1). AMG 458 binds covalently to liver microsomal proteins from rats and humans, even in the absence of NADPH. When [<sup>14</sup>C]AMG-458 is incubated with liver microsomes in the presence of glutathione or *N*-acetyl cysteine, quinolone-type thioether adducts can be detected by radiochromatography

and LC/MS/MS analysis (2). AMG-458 was more effective in cells that expressed higher levels of c-Met/p-Met, suggesting that higher levels of c-Met and p-Met in non-small cell lung cancer (NSCLC) tissue may classify a subset of tumors that are more sensitive to molecular therapies against this receptor (3). 1. Liu, Siegmund, Xi *et al.* (2008) *J. Med. Chem.* **51**, 3688. 2. Teffera, Colletti, Harmange, *et al.* (2008) *Chem. Res. Toxicol.* **21**, 2216. 3. Li, Torossian, Sun, *et al.* (2012) *Int. J. Radiat. Oncol. Biol. Phys.* **84**, e525.

**AMG 706**, See *Motesanib*

#### AMG-900

This potent and highly selective mitotic protein kinase inhibitor (FW = 503.58 g/mol; CAS 945595-80-2; Solubility: 100 mg/mL DMSO), also named *N*-(4-(3-(2-aminopyrimidin-4-yl)pyridin-2-yloxy)phenyl)-4-(4-methylthiophen-2-yl)phthalazin-1-amine, targets Aurora A (IC<sub>50</sub> = 5 nM), Aurora B (IC<sub>50</sub> = 4 nM), and Aurora C (IC<sub>50</sub> = 1 nM) protein kinases, with >10-fold selectivity versus p38α, Tyk2, JNK2, Met and Tie2 (1). The modal tumor cell response to AMG 900 treatment is aborted cell division without prolonged mitotic arrest, ultimately resulting in cell death (1). AMG 900 exhibits acceptable PK properties in preclinical species and is predicted to have low clearance in humans (2). Male rats metabolize AMG 900 primarily through hydroxylation with subsequent sulfate conjugation on the pyrimidinyl-pyridine side-chain, whereas female rats favor oxidation on the thiophene ring's methyl group, which is then metabolized to a carboxylic acid, attended by conjugation to an acyl glucuronide (3). At low-nM concentrations, AMG 900, whether administered alone or in combination with microtubule-targeting drugs (paclitaxel or ixabepilone), may be an effective intervention strategy for the treatment of metastatic breast cancer and provide potential therapeutic options for patients with multidrug-resistant tumors (4). It is, in fact, also active against taxane-resistant tumor cell lines (5). 1. Payton, Bush, Chung, *et al.* (2010) *Cancer Res.* **70**, 9846. 2. Huang, Be, Berry, *et al.* (2011) *Xenobiotica* **41**, 400. 3. Waldon, Berry, Lin, *et al.* (2011) *Drug Metab. Lett.* **5**, 290. 4. Bush, Payton, Heller, *et al.* (2013) *Mol Cancer Ther.* **12**, 2356. 5. Payton, Bush, Chung, *et al.* (2010) *Cancer Res.* **70**, 9846.

#### AMG-Tie2-1

This highly potent signal transduction inhibitor (FW = 479.75 g/mol; CAS 870223-96-4; Solubility: 15 mM in DMSO), also named 3-(3-(2-(methylamino)pyrimidin-4-yl)pyridin-2-yloxy)-*N*-(3-(trifluoromethyl)phenyl)-4-methylbenzamide, targets the intrinsic protein tyrosine kinase of Tie2, a receptor that binds angiopoietin-1 and mediates signaling pathway(s) in embryonic vascular development. Tie-2 possesses a unique extracellular region that contains two immunoglobulin-like domains, three epidermal growth factor (EGF)-like domains and three fibronectin type III repeats. AMG-Tie2-1 exhibits >30-fold selectivity over a panel of kinases, good oral exposure, and *in vivo* inhibition of Tie-2 autophosphorylation. 1. Hodous, Geuns-Meyer, Hughes, *et al.* (2007) *J. Med. Chem.* **50**, 611.

#### Amicetins

These pyrimidine-containing glycoside antibiotic (FW<sub>Amicetin-A</sub> = 617.69 g/mol (free base); CAS 17650-86-1; FW<sub>Amicetin-B</sub> = 532.59 g/mol (free base)) from *Streptomyces vinaceus-drappus* and *S. fasciculatus* inhibits protein biosynthesis, exerting its bacteriostatic most potently on Gram-positive bacteria. Amicetin B, also called plicacetin, was isolated from *Streptomyces plicatus* and has the identical structure minus the α-methylseryl residue. It is weaker in action compared to amicetin A. **Target(s):** peptidyltransferase (1-5,9-11,14-17); peptidyl-tRNA hydrolase, or aminoacyl-tRNA hydrolase (6); ribonuclease P (7,8); protein biosynthesis (1-5,9-14). 1. #### Amifloxacin

This fluoroquinolone-class antibiotic (FW = 334.31 g/mol; CAS 86393-37-5) is a broad-spectrum systemic agent that targets Type II DNA topoisomerases (gyrases) required for bacterial replication and transcription (1). Ninety percent of *Escherichia coli*, *Klebsiella* species, *Aeromonas*, *Salmonella*, *Shigella*, *Citrobacter*, *Enterobacter* species, *Proteus mirabilis*, *Serratia marcescens*, and *Morganella morganii* were inhibited by ≤ 0.5 μg/mL (2). Amifloxacin inhibited *Branhamella*, *Haemophilus*, and *Neisseria* at ≤ 0.25 μg/mL, and 90% of *Pseudomonas aeruginosa*, including gentamicin and carbencillin-resistant isolates, at 4 ≤ μg/mL (2). It also inhibited *Staphylococci*, including methicillin-resistant isolates, but was less active against *Streptococci* and *Bacteroides* species. For mechanism of action, see Ciprofloxacin, which is the prototypical member of this antibiotic class. 1. Johnson & Benzinger (1985) *Antimicrob. Agents Chemother.* **27**, 774. 2. Neu & Labthavikul (1985) *Diagnost. Microbiol. Infect. Dis.* **3**, 469.

**Amikacin**

This aminoglycoside-class antibiotic (FW = 585.60 g/mol; CAS 37517-28-5) is a broad-spectrum semisynthetic derivative of kanamycin A that has become a go-to drug for treating hospital-acquired infections by multidrug-resistant, Gram-negative bacteria (e.g., *Pseudomonas aeruginosa*, *Acinetobacter*, *Enterobacter*, as well as *Serratia marcescens* and *Providencia stuartii*). (**For additional mechanistic details, See Neomycins**) Because amikacin is not absorbed orally, it must be delivered intravenously or by an intranasal using liposomes as carriers. Test results revealed that 60.5% of the isolates were resistant to tobramycin (at 8 µg/mL), 67.1% to gentamicin (at 8 µg/mL), 86.2% to kanamycin A (at 20 µg/mL), but only 8.6% to amikacin (at 20 µg/mL). Amikacin's broad spectrum comports with the fact that it is a poor substrate for most enzymes that inactivate other aminoglycosides through O-phosphorylation, O-adenylation, or N-acetylation (1). **Pharmacokinetics:** A dose of 300 mg/m<sup>2</sup> intramuscularly produced a highest mean serum concentration of 25.4 µg/mL with a mean serum concentration of 3.1 µg/mL at 8 hours (2). The same dose intravenously produced a mean serum concentration of 52 µg/mL with a mean serum concentration of 2 µg/mL at 8 hours. The mean urinary excretion during the first 6 hours was 75 and 66%, respectively. When administered at 150 mg/m<sup>2</sup> every 6 hours, there was evidence of some drug accumulation (2). A loading dose of 150 mg/m<sup>2</sup> administered IV over 30 min, followed by a continuous infusion at 200 mg/m<sup>2</sup> every 6 hours to maintain serum concentrations of 8 µg/mL. No major toxicity was observed with any of these drug regimens (2). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Price, Pursiano & DeFuria (1974) *Antimicrob. Agents Chemother.* 5, 143. 2. Bodey, Valdivieso, Feld & Rodriguez (1974) *Antimicrob. Agents Chemother.* 5, 508.

**Amiloride**

This potassium-sparing diuretic (FW = 229.63 g/mol; CAS 2016-88-8; Absorbance at 10 mg/mL (water) = 642 at 212 nm, 555 at 285 nm, and 617 at 362 nm; pK<sub>a</sub> = 8.7; Soluble in hot water (50 mg/mL), yielding a clear, yellow-green solution), also known as MK 870, Midamor<sup>®</sup>, and 3,5-diamino-6-chloro-N-(diaminomethylene)pyrazine-2-carboxamide, is an epithelial sodium channel (or ENaC) blocker used to manage hypertension and congestive heart failure (1-4). Two classes of Na<sup>+</sup> transporters are sensitive to this drug: (a) the conductive Na<sup>+</sup> entry pathway found in electrically high resistance epithelia and (b) a Na<sup>+</sup>-H<sup>+</sup> electroneutral exchange system found in certain leaky epithelia, such as the renal proximal tubule. Amiloride exhibits a K<sub>i</sub> value of <1 µM for the kidney transporter and approximately 1 mM in the colon. Midamor is a potassium-conserving (antikaliuretic) drug that possesses weak (compared with thiazide diuretics) natriuretic, diuretic, and antihypertensive activity. Like other potassium-conserving agents, amiloride may cause hyperkalemia (i.e., serum K<sup>+</sup> levels >5.5 mEq/L), which, if uncorrected, can be fatal. Amiloride-induced hyperkalemia occurs in ~10% of patients, when used without a kaliuretic diuretic. This complication is more frequent in patients showing evidence of renal impairment and diabetes mellitus. When used along with a thiazide diuretic in patients without these complications, the risk of Amiloride-induced hyperkalemia drops to 1-2%. Amiloride is not metabolized by the liver and is instead excreted unchanged by the kidney. Amiloride displaces both adenosine A<sub>1</sub> receptor agonist and antagonist binding with a K<sub>i</sub> value in the low micromolar range, when assayed in calf brain membranes (5). Inhibition is counteracted by NaCl and protons. Amiloride (IC<sub>50</sub> = 0.25 mM) and 5-(N-ethyl-N-isopropyl)amiloride (IC<sub>50</sub> = 0.11 mM) also inhibit coxsackievirus B<sub>3</sub> RNA polymerase in a single-nucleotide incorporation assay (6,7), although the argument that amiloride

competes with incoming nucleoside triphosphates is unconvincing. A high-fidelity RNA dependent CVB<sub>3</sub> RNA polymerase (RdRp) variant is amiloride-resistant (7). 1. Baer, Jones, Spitzer & Russo (1967) *J. Pharm. Exper. Ther.* 157, 435. 2. Baba, Lant, Smith, Townsend & Wilson (1968) *Clin. Pharmacol. Therapeut.* 9, 318. 3. Smith & Smith (1973) *Brit. J. (2010) *PLoS Pathog.* 6, e1001163.

**Amineptine**

This synthetic dopamine reuptake inhibitor (FW = 338.47 g/mol; CAS 57574-09-1), also known by the trade names Survector<sup>®</sup>, Maneon<sup>®</sup>, Directim<sup>®</sup>, Neolior<sup>®</sup>, Provector<sup>®</sup>, and Viaspera<sup>®</sup> as well as its IUPAC name, 7-[(10,11-dihydro-5H-dibenzo[a,d]cyclohept-5-yl)amino]heptanoic acid, significantly reduces the effect of 6-hydroxy-dopamine on brain dopamine, increases striatal homovanillic acid concentrations, and shows cross-tolerance (1). Despite these amphetamine-like properties, amineptine does not alter brain noradrenaline or acetylcholine concentrations, suggesting amineptine is a new type of antidepressant with a brain biochemical profile differing from that of other drugs used in depressive disorders. Amineptine is also a norepinephrine reuptake inhibitor (2). This agent is also ineffective in reducing amphetamine withdrawal symptoms or craving (3). Amineptine failed to secure FDA approval and is not a duly authorized drug in the U.S. 1. Samanin, Jori, Bernasconi, Mopugo & Garattini (1977) *J. Pharm. Pharmacol.* 29, 555. 2. Invernizzi & Garattini (2004) *Prog. Neuropsychopharmacol. Biol. Psychiatry* 28, 819. 3. Shoptaw, Kao, Heinzerling & Ling (2009) *Cochrane Database Syst. Rev.* CD003021.

**4-Aminobutyraldehyde, See 4-Aminobutanol****2-Aminobutyrate (2-Aminobutyric Acid)**

This water-soluble amino acid (FW = 103.12 g/mol), also called α-aminobutyric acid and 2-aminobutanoic acid, is an alanine homologue that has often been used to probe substrate specificity. **Target(s):** tryptophanase, by the L-enantiomer (1); 4-aminobutyrate aminotransferase (2); arginase, weakly inhibited (3); L-alanine aminotransferase, by the L-enantiomer (4,10); homoserine kinase (5,9,23,24); D-alanyl-poly(phosphoribitol) synthetase, or D-alanine:poly(phosphoribitol) ligase, inhibited by the D-enantiomer (6); saccharopine dehydrogenase (7); methionyl-tRNA synthetase (8); kynureninase, by DL-2-aminobutyrate (11); UDP-N-acetylmuramate:L-alanine ligase (inhibited by the L-enantiomer (12,13); cysteinyl-tRNA synthetase, also weak alternative substrate (14); D-lysine 5,6-aminomutase (15); 2-aminohexano-6-lactam racemase, inhibited by both D- and L-isomers (16); methionine γ-lyase (17); 1-aminocyclopropane-1-carboxylate deaminase, inhibited by the L-enantiomer (18,19); arginine deaminase, inhibited by the L-enantiomer (20); [glutamine-synthetase] adenylyltransferase (21); aspartate kinase, inhibited by the L-enantiomer (22); (R)-3-amino-2 methylpropionate: pyruvate aminotransferase, by L-2-aminobutyrate (25); asparagine:oxo-acid aminotransferase, weakly (26); acetolactate synthase, inhibited by the L-enantiomer (27); ornithine carbamoyltransferase, inhibited by the L-enantiomer (28-31); aminocyclopropane-carboxylate oxidase, inhibited by D-isomer (32). 1. #### 4-Aminobutyrate (4-Aminobutyric Acid)

This neurotransmitter (FW = 103.12 g/mol; CAS 56-12-2;  $pK_1 = 4.03$  and  $pK_2 = 10.56$ ; Very Soluble in H<sub>2</sub>O), commonly referred to as  $\gamma$ -aminobutyric acid (GABA), is synthesized by pyridoxal 5'-phosphate-dependent decarboxylation of L-glutamate, stored in vesicles within a neuron's synaptic terminal, and, upon release, is an agonist for the GABA<sub>A</sub> and GABA<sub>B</sub> receptors. GABA<sub>A</sub> receptors are ligand-activated chloride channels: when activated by GABA, they allow the flow of chloride ions across the membrane of the cell. GABA is the chief inhibitory neurotransmitter in the mammalian Central Nervous System, where its principal role is to reduce neuronal excitability throughout the nervous system. In humans, GABA is also directly responsible for the regulation of muscle tone. **Target(s):** ornithine carbamoyltransferase (1); pyrroline-5-carboxylate dehydrogenase (2,6); pantothenate synthetase, *or* pantoate:  $\beta$ -alanine ligase (3,11); putrescine carbamoyltransferase (4); carboxypeptidase B (5); L-carnitine uptake (7); D-alanyl-D-alanine synthetase (D-alanine:D-alanine ligase (8); methionyl-tRNA synthetase (9); pyridoxal kinase (10); lysyl-tRNA synthetase (12); D-lysine 5,6-aminomutase (13); ornithine decarboxylase (14); guanidinopropionase (15); guanidinobutyrase (15); acetylspermidine deacetylase, weakly inhibited (16);  $\beta$ -ureidopropionase (17); 2-aminoethylphosphonate:pyruvate aminotransferase, weakly inhibited (18); ornithine  $\delta$  aminotransferase (19,20); carnitine acetyltransferase (21). **1.** Nakamura & Jones (1970) *Meth. **$\gamma$ -Aminobutyryne**, See 2,4-Diaminobutyrate and 2,4-Diaminobutyric Acid

#### $\gamma$ -Aminobutyryl-L-alanylglycine

This glutathione analogue (FW = 231.25 g/mol) weakly inhibits glutathionylspermidine synthetase from *Crithidia fasciculata*, which, like other trypanosome, synthesizes trypanothione enzymatically synthesized from spermidine and glutathione through the consecutive action of the ATP-dependent carbon-nitrogen ligases, glutathionylspermidine synthetase and trypanothione synthetase. **1.** De Craecker, Verbruggen, Rajan, *et al.* (1997) *Mol. Biochem. Parasitol.* **84**, 25.

**$\alpha$ -Aminocaproate ( $\alpha$ -Aminocaproic Acid)**, See *Norleucine*

**$\epsilon$ -Amino-*n*-caproate ( $\epsilon$ -Amino-*n*-caproic Acid)**, See 6-Aminohexanoate (6-Aminohexanoic Acid)

**$\epsilon$ -Aminocaproic Acid Hydrochloride *p*-Carbomethoxy-phenyl Ester**, See *p*-Carbomethoxyphenyl  $\epsilon$ -Amino-caproate

***N*-(Aminocarbonyl)-L-phenylalanine**, See *N*-Carbamoyl-L-phenylalanine

#### *N*-(3-Aminocarbonylphenyl)-4-(2-chlorophenoxy)piperidine-1-carboxamide

This orally bioavailable piperidine derivative (FW = 372.83 g/mol) inhibits stearoyl-CoA 9-desaturase (mouse, IC<sub>50</sub> = 10 nM), a well-known druggable target in the management of fat metabolism and weight-gain. **1.** Xin, Zhao, Serby, *et al.* (2008) *Bioorg. Med. Chem. Lett.* **18**, 4298.

#### 2(S)-Amino-3-[4-(4-carboxybenzyl)oxyphenyl]-1-propanethiol

This amino thiol (FW = 317.41 g/mol) inhibits leukotriene-A<sub>4</sub> hydrolase (IC<sub>50</sub> = 12  $\mu$ M). The *m*-carboxy analogue has an IC<sub>50</sub> value of 6  $\mu$ M. The free thiol group is necessary for sub-micromolar binding and the enzyme prefers the *R*-enantiomer over the *S*-enantiomer. **1.** Ollmann, Hogg, Muñoz, *et al.* (1995) *Bioorg. Med. Chem.* **3**, 969.

#### 2-(4-Amino-4-carboxybutyl)aziridine-2-carboxylate

This metabolically activated species (FW = 202.21 g/mol), formed by spontaneous hydrolysis of  $\alpha$ -(halomethyl)diaminopimelic acids, is a potent irreversible inhibitor of *Escherichia coli* diaminopimelate epimerase (EC 5.1.1.7). Under physiological conditions, 2-(4-amino-4-carboxybutyl)aziridine-2-carboxylate (aziridino-DAP) reacts quickly with and inactivates this non-pyridoxal enzyme. **1.** Gerhart, Higgins, Tardif & Ducep (1990) *J. Med. Chem.* **33**, 2157. **2.** Scapin & Blanchard (1998) *Adv. Enzymol. Relat. Areas Mol. Biol.* **72**, 279.

**(4*R*\*,5*S*\*,6*S*\*)-4-Amino-5-[(1-carboxyethyl)oxy]-6-hydroxycyclohex-1-enecarboxylate**

This substrate analogue (FW = 243.22 g/mol) inhibits *Escherichia coli* *p*-aminobenzoate synthase, anthranilate synthase, and isochorismate synthase ( $K_i = 2.3$ , 0.38, and 0.027  $\mu\text{M}$ , respectively, when normalized for axial and equatorial conformations). **Target(s):** *p*-aminobenzoate synthase (1); anthranilate synthase (1); isochorismate synthase (1); 4-amino-4-deoxychorismate synthase,  $K_i = 5.6$   $\mu\text{M}$  (2). 1. Kozlowski, Tom, Seto, Sefer, & Bartlett (1995) *J. Amer. Chem. Soc.* **117**, 2128. 2. He, Stigers Lavoie, Bartlett & Toney (2004) *J. Amer. Chem. Soc.* **126**, 2378.

**(*R*)-*S*-(2-Amino-2-carboxyethyl)-L-homocysteine, See L-Cystathionine**

**N<sup>ε</sup>-(DL-2-Amino-2-carboxyethyl)-L-lysine**

This nephrotoxic amino acid analogue (FW = 233.27 g/mol), also known as lysinoalanine, is also a metal ion chelator. This property demands the experimenter to carry out measurements at a constant free metal ion concentration to differentiate enzyme inhibition effects from metal ion chelation effects. **Target(s):** lysyl-tRNA synthetase (1); carboxypeptidase A (2,3); carboxypeptidase B (2); alcohol dehydrogenase, yeast (2); cytochrome *c* oxidase (3). 1. Lifsey, Farkas & Reyniers (1988) *Chem. Biol. Interact.* **68**, 241. 2. Hayashi (1982) *J. Biol. Chem.* **257**, 13896. 3. Friedman, Grosjean & Zahnley (1986) *Adv. Exp. Med. Biol.* **199**, 531.

**2-Amino-4-{O-[4-(carboxymethyl)phenyl]-O-methylphosphono}butanoic Acid**

This  $\gamma$ -phosphono diester analogue (FW = 329.29 g/mol) of glutamate inactivates *Escherichia coli* and human  $\gamma$ -glutamyl transpeptidase, or  $\gamma$ -glutamyltransferase, or GGT (EC 2.3.2.2). By detoxifying xenobiotics and reactive oxygen species, GGT plays a role in cancer cell drug resistance and metastasis. It is also implicated in Parkinson's Disease, neurodegenerative disease, diabetes, and cardiovascular diseases. 1. Han, Hiratake, Kamiyama & Sakata (2007) *Biochemistry* **46**, 1432.

**(*R*,*S*)-2-Amino-4-[2-(carboxymethylsulfanyl)ethylsulfanyl]butyrate**

This homocysteine derivative (FW = 221.35 g/mol) inhibits betaine: homocysteine *S*-methyltransferase, or BHMT (IC<sub>50</sub> = 96 nM). The 2-(carboxymethylsulfonide)ethyl analogue is a weaker inhibitor. BHMT is very sensitive to the structure of substituents on the sulfur atom of homocysteine. The *S*-carboxybutyl and *S*-carboxypentyl derivatives are the most potent inhibitors, and an additional sulfur atom in the alkyl chain is well tolerated. The respective (*R,S*)-5-(3-amino-3-carboxy-propylsulfanyl)-pentanoic, (*R,S*)-6-(3-amino-3-carboxy-propylsulfanyl)-hexanoic, and (*R,S*)-2-amino-4-(2-carboxymethylsulfanylethylsulfanyl)-butyric acids are also very potent inhibitors and among the strongest ever reported. 1. Jiracek, Collinsova, Rosenberg, *et al.* (2006) *J. Med. Chem.* **49**, 3982.

**3(*S*)-[[[(1*S*)-5-Amino-1-carboxypentyl]amino]-2,3,4,5-tetrahydro-2-oxo-1*H*-1-benzazepine-1-acetic Acid**

This benzazepineone derivative (FW = 363.41 g/mol) is a potent inhibitor of peptidyl-dipeptidase A, or human angiotensin I-converting enzyme (IC<sub>50</sub> = 7 nM) and is especially potent, when tested in dogs for inhibition of angiotensin I pressor response, having an ID<sub>50</sub> of 0.07 mg/kg orally. 1. Stanton, Watthey, Desai, *et al.* (1985) *J. Med. Chem.* **28**, 1603.

**(3*R*,4*S*)-4-(3'(*S*)-Amino-3'-carboxypropyl-thiomethyl)-1-[(9-deazaadenin-9-yl)-methyl]-3-hydroxypyrrolidine**

This immucillin-based *S*-adenosylhomocysteine analogue (FW = 369.47 g/mol) inhibits ( $K_i = 6$  pM) 5'-methylthioadenosine/*S*-adenosylhomocysteine nucleosidase, which recycles 5'-methylthio-adenosine from the polyamine pathway via adenine phosphoribosyl-transferase as well as recycling adenine and 5-methylthioriboseto methionine. 1. Singh, Evans, Lenz, *et al.* (2005) *J. Biol. Chem.* **280**, 18265.

***N*-[[[(2*S*,3*R*)-3-Amino-5-carboxyl-2-sulfhydryl]-pentanoyl]-L-isoleucyl-L-aspartate**

This peptide analogue (FW = 421.47 g/mol), also known as *N*-{[(2*S*,3*R*)-3-amino-5-carboxy-2-mercapto]pentanoyl}-L-isoleucyl-L-aspartate, inhibits glutamyl aminopeptidase ( $K_i = 3.56$  nM), neprilysin ( $K_i = 4$  nM), and peptidyl-dipeptidase A ( $K_i = 1800$  nM). The (2*R*,3*S*)-, (2*S*,3*S*)-, and (2*R*,3*R*)-diastereoisomers also inhibit glutamyl aminopeptidase ( $K_i = 16$ , 13, 267 nM, respectively). The (2*R*,3*S*)- and (2*S*,3*S*)-isomers also inhibit membrane alanyl aminopeptidase ( $K_i = 3900$  and 120 nM, respectively). **Target(s):** glutamyl aminopeptidase, or aminopeptidase A; membrane alanyl aminopeptidase; neprilysin; peptidyl-dipeptidase A (angiotensin I-converting enzyme). 1. David, Bischoff, Meudal, *et al.* (1999) *J. Med. Chem.* **42**, 5197.

**Aminocarnitine**

This carnitine isostere and fatty acid oxidation inhibitor (FW = 161.23 g/mol; CAS 98063-21-9), also known as 3-amino-4-(trimethyl-ammonio)-butyric acid, is a strong inhibitor of carnitine *O*-palmitoyltransferase. Aminocarnitine is a hypoglycemic and antiketogenic agent that alters lipid metabolism by inhibiting both carnitine acetyltransferase (CAT) and carnitine palmitoyltransferase (CPT). The (*R*)-stereoisomer, also known as emeramine, has been isolated from a fungus. **Target(s):** carnitine *O*-

palmitoyltransferase (1,2,4-7); carnitine *O*-octanoyltransferase, moderately inhibited (3). 1. Jenkins & Griffith (1985) *J. Biol. Chem.* **260**, 14748. 2. Kanamaru, Shinagawa, Asai, *et al.* (1985) *Life Sci.* **37**, 217. 3. Chung & Bieber (1993) *J. Biol. Chem.* **268**, 4519. 4. Hertel, Gellerich, Hein & Zierz (1999) *Adv. Exp. Med. Biol.* **466**, 87. 5. Traufeller, Gellerich & Zierz (2004) *Biochim. Biophys. Acta* **1608**, 149. 6. Murthy, Ramsay & Pande (1990) *Biochem. Soc. Trans.* **18**, 604. 7. Murthy, Ramsay & Pande (1990) *Biochem. J.* **267**, 293.

### 7-Aminocephalosporanic Acid

This  $\beta$ -lactam (FW = 272.28 g/mol; CAS 957-68-6), obtained by mild hydrolysis of cephalosporin C, is a precursor in the preparation of synthetic cephalosporins. **Target(s):** D-stereospecific aminopeptidase (1,8);  $\gamma$ -aminobutyrate aminotransferase (2); serine-type D-Ala-D-Ala carboxypeptidase (3); zinc D-Ala-D-Ala carboxypeptidase (3); glutathione S-transferase  $\pi$  (4);  $\beta$ -lactamase, also weak alternative substrate (5); glutaryl-7-aminocephalosporanic acid acylase, product inhibition (6,7). 1. Asano (1998) in *Handb. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.), p. 430, Academic Press, San Diego. 2. Hopkins & Silverman (1992) *J. Enzyme Inhib.* **6**, 125. 3. Asano, Kato, Yamada & Kondo (1992) *Biochemistry* **31**, 2316.

### (2R,4R)-2-Amino-4-[(3-chloro)-2-benzo[b]thienyl]methyl-pentanedioate

This D-glutamate derivative (FW = 292.34 g/mol), also known as 4R-[(3-chloro)-2-benzo[b]thienyl]methyl-D-glutamic acid, potently inhibits glutamate racemase ( $K_i = 16$  nM). It shows potent whole cell antibacterial activity against *S. pneumoniae* PN-R6, with good correlation between minimal inhibitory concentration and inhibition of enzyme assay. 1. de Dios, Prieto, Martín, *et al.* (2002) *J. Med. Chem.* **45**, 4559.

### (R)-7-Amino-2-(4-(4-chlorobiphenyl)ylsulfonyl)-1,2,3,4-tetrahydroisoquinolin-3-carboxylic Acid

This isoquinoline derivative (FW = 442.92 g/mol) inhibits human neutrophil collagenase, or matrix metalloproteinase 8,  $IC_{50} = 7$  nM. Docking studies of a reference compound are based on crystal structures of MMP-8 complexed with peptidic inhibitors to propose a model of its bioactive conformation, and this model was validated by a 1.7-Å crystal structure of MMP-8's catalytic domain. The weaker zinc ion-binding properties of carboxylates was compensated by introducing an optimally fitting P1' residue. 1. Matter, Schwab, Barbier, *et al.* (1999) *J. Med. Chem.* **42**, 1908.

### 2-Amino-3-chlorobutyrate

This valine analogue (FW = 137.57 g/mol; CAS 14561-56-9), also known as *threo*- $\alpha$ -amino- $\beta$ -chlorobutyric acid and 2-amino-3-chlorobutanoic acid, is an alternative substrate and competitive inhibitor of valyl-tRNA synthetase (1).  $\beta$ -Chlorovaline is also incorporated into the hemoglobin  $\alpha$ - and  $\beta$ -chains in rabbit reticulocytes, reducing the protein's half-life to ten minutes, instead of its normal value of 120 days. **Target(s):** valyl-tRNA synthetase, inhibited by DL- and D-*allo*-isomers (1); aspartate 4-decarboxylase, inhibited by the L-*threo*-isomer (3). 1. Bergmann, Berg & Dieckmann (1961) *J. Biol. Chem.* **236**, 1735. 2. Rabinovitz & Fisher (1964) *Biochim. Biophys. Acta* **91**, 313. 3. Tate, Relyea & Meister (1969) *Biochemistry* **8**, 5016.

### 7-Amino-4-chloro-3-ethoxyisocoumarin

This substituted isocoumarin (FW = 239.66 g/mol) is a strong inactivator of human leukocyte elastase. The half-life of this isocoumarin is about 216 minutes at pH 7.5 and 25°C. **Target(s):** leukocyte elastase (1-3); pancreatic elastase (1); cathepsin G (1); chymotrypsin (1); chymase (1); trypsin (1); streptogrisin A (1); thrombin (1); coagulation factor XIIa (1); plasma kallikrein (1); trypsin (1); myeloblastin (3). 1. Harper & Powers (1985) *Biochemistry* **24**, 7200. 2. Kerrigan, Oleksyszyn, Kam, Selzler & Powers (1995) *J. Med. Chem.* **38**, 544. 3. Kam, Kerrigan, Dolman, *et al.* (1992) *FEBS Lett.* **297**, 119.

### 4-Amino-N-(3-chloro-4-fluorophenyl)-N'-hydroxy-1,2,5-oxadiazole-3-carboximidamide

This carboximidamide (FW = 271.64 g/mol) is a competitive inhibitor of human indoleamine 2,3-dioxygenase ( $IC_{50} = 67$  nM). In mice, this agent demonstrated pharmacodynamic inhibition of the dioxygenase, as measured by decreased plasma kynurenine levels and dose-dependent efficacy against GM-CSF-secreting B16 melanoma tumors. 1. Yue, Douy, Wayland, *et al.* (2009) *J. Med. Chem.* **52**, 7364.

### 7-Amino-4-chloro-3-methoxyisocoumarin

This yellow isocoumarin (FW = 225.63 g/mol; Melting Point = 163-165°C), also known as  $\gamma$  secretase inhibitor XI and JLKG, inhibits a number of proteases as well as  $\gamma$ -secretase and blocks the production of both amyloid- $\beta$ 40 and - $\beta$ 42 ( $IC_{50} < 100$   $\mu$ M). The half-life for this isocoumarin is about 200 minutes at 25°C in 100  $\mu$ M HEPES, 500  $\mu$ M NaCl, 10% dimethyl sulfoxide, and pH 7.5. **Target(s):** leukocyte elastase (1-3); pancreatic elastase (2); cathepsin G (1,2); chymotrypsin (1,2); chymase (2); trypsin (2); streptogrisin A (2);  $\gamma$ -secretase (4); granzyme B (5); complement factor D (6). 1. Powers & Kam (1994) *Meth. Enzymol.* **244**, 442. 2. Harper & Powers (1985) *Biochemistry* **24**, 7200. 3. Kerrigan, Oleksyszyn, Kam, Selzler & Powers (1995) *J. Med. Chem.* **38**, 544. 4. Kam, Oglesby, Pangburn, Volanakis & Powers (1992) *J. Immunol.* **149**, 163.

**1-(4-{5-[6-Amino-5-(4-chlorophenyl)pyrimidin-4-ylethynyl]pyridin-2-yl}piperazin-1-yl)ethanone**

This pyrimidine (FW = 432.92 g/mol) inhibits ( $IC_{50}$  = 1 nM) cytosolic adenosine kinase, a key intracellular enzyme regulating intracellular and extracellular concentrations of adenosine (ADO), itself a powerful endogenous modulator of intercellular signalling that reduces cell excitability during tissue stress and trauma. Adenosine levels increase at seizure foci as part of a negative feedback mechanism that controls seizure activity through adenosine receptor signaling. Agents that inhibit adenosine kinases increase/sustain site-/event-specific adenosine surges, thereby providing anti-seizure activity akin to that of adenosine receptor agonists, but with fewer dose-limiting cardiac side effects. **1.** Matulenko, Paight, Frey, *et al.* (2007) *Bioorg. Med. Chem.* **15**, 1586.

**(R)- $\alpha$ -Amino-5-chloro-1-(phosphonomethyl)-1H-benzimidazole-2-propanoic Acid**

This structurally complex amino acid (FW = 333.67 g/mol), also known as (*R*)- $\alpha$ -amino-5-chloro-1-(phosphonomethyl)-1H-benzimidazole-2-propanoic acid hydrochloride and EAB-318, is an antagonist for NMDA (*N*-methyl-D-aspartate) and AMPA ( $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid) receptors. EAB-318 also protects neurons against ischemia induced cell death. **1.** Sun, Chiu, Kowal, *et al.* (2004) *J. Pharmacol. Exp. Ther.* **310**, 563.

**2-Amino-5-chlorotetralin**

This conformationally rigid phenylethylamine substrate analogue (FW = 181.67 g/mol) competitively inhibits ( $K_i$  = 0.2  $\mu$ M) phenylethanolamine *N*-methyltransferase, *or* norepinephrine *N*-methyltransferase ( $IC_{50}$  = 5.2  $\mu$ M). (Its 6-, 7-, and 8-chlorinated analogues are slightly weaker inhibitors.) 2-Amino-5-chlorotetralin inhibits the reuptake of serotonin and norepinephrine, and likely induces their release. **1.** Fuller & Molloy (1977) *Biochem. Pharmacol.* **26**, 446.

**22-Aminocholesterol**

This cholesterol derivative (FW<sub>free-base</sub> = 401.67 g/mol; CAS 50921-65-8) inhibits cholesterol monooxygenase (side-chain-cleaving), *or* CYP11A1,

where the (22*R*)-stereoisomer ( $IC_{50}$  = 25 nM) is the stronger inhibitor than the (22*S*)-isomer ( $IC_{50}$  = 13  $\mu$ M). **1.** Vickery (1991) *Meth. Enzymol.* **206**, 548. **2.** Nagahisa, Foo, Gut & Orme-Johnson (1985) *J. Biol. Chem.* **260**, 846. **3.** Jacobs, Singh & Vickery (1987) *Biochemistry* **26**, 4541.

**1-Aminocyclobutane-1-carboxylate**

This NMDA receptor partial agonist (FW = 115.13 g/mol; CAS 22264-50-2; Symbol: ACBC; Soluble to 100 mM in water) is a specific antagonist of the *N*-methyl-D-aspartate receptor-coupled glycine receptor (1,2). Unfortunately, ACBC is rapidly eliminated ( $t_{1/2}$  = 5 min in mouse brain;  $t_{1/2}$  = 5-4 min in rat cerebrospinal fluid), rendering it of questionable utility *in vivo*. **1.** Hood, Sun, Compton & Monahan (1989) *Eur. J. Pharmacol.* **161**, 281. **2.** Rao, Cler, Compton, *et al.* (1990) *Neuropharmacol.* **29**, 305.

**cis-1-Aminocyclobutane-1,3-dicarboxylate**

This potent, competitive and selective transport inhibitor (FW = 159.14 g/mol; CAS 73550-55-7; Symbol: *cis*-ACBD; Soluble to 100 mM with addition of 1 equivalent of NaOH) targets synaptosomal glutamate transporters ( $K_i$  = 8  $\mu$ M), reducing uptake of glutamic acid. **1.** Allan, *et al.* (1990) *J. Med. Chem.* **33**, 2905. **2.** Fletcher, *et al.* (1991) *Neurosci. Lett.* **121**, 133. **3.** Koch, *et al.* (1999) *Mol. Pharmacol.* **56**, 1095.

**cis-3-Aminocyclohex-4-ene-1-carboxylate**

This conformationally constrained amino-acid (FW = 140.16 g/mol) is a mechanism-based enzyme inhibitor that is an analogue of the antiepilepsy drug vigabatrin, inactivating porcine 4-aminobutyrate aminotransferase, a key enzyme in  $\gamma$ -aminobutyrate metabolism. An energy-minimized computer model of vigabatrin bound to PLP indicated that the major Michael addition pathway could only occur if the vinyl group could rotate by 180°. Further study revealed that the agent inactivates by an enamine pathway. (See *Vigabatrin*) **1.** Choi, Storici, Schirmer & Silverman (2002) *J. Amer. Chem. Soc.* **124**, 1620.

**(2S)-1-[(2S)-2-Amino-2-cyclopentylacetyl]-2-cyanopyrrolidine**

This pyrrolidone (FW = 220.30 g/mol), also known as (2*S*)-1-[( $\alpha$ *S*)- $\alpha$ -cyclopentylglycyl]-2-cyanopyrrolidine, inhibits human dipeptidyl-peptidase IV ( $K_i$  = 1 nM), a target for diabetes therapy due to its indirect regulatory role in modulating plasma glucose concentration. Dipeptidyl peptidase IV (DPP-IV) belongs to a family of serine peptidases. Its indirect regulatory role in plasma glucose modulation makes it an attractive druggable target for diabetes therapy. DPP-IV inactivates the glucagon-like peptide (GLP-1) and several other naturally produced bioactive peptides that contain preferentially a proline or alanine residue in the second amino acid sequence position by cleaving the N-terminal dipeptide. **1.** Longenecker, Stewart, Madar, *et al.* (2006) *Biochemistry* **45**, 7474.

**1-Amino-1-cyclopropanecarboxylate**

This unusual conformationally confined amino acid (FW = 101.11 g/mol; CAS 68781-13-5) is an intermediate in the production of ethene from L-methionine. It is a product of the reaction catalyzed by 1-aminocyclopropane-1-carboxylate synthase and is a substrate for aminocyclopropanecarboxylate oxidase and 1-aminocyclopropane-1-carboxylate deaminase. 1-Amino-1-cyclopropanecarboxylate is also an NMDA (*N*-methyl-D-aspartate) receptor agonist, binding at the glycine co-agonist site. **Target(s):** 2,2-dialkylglycine decarboxylase (pyruvate) (1-3). 1. Malashkevich, Strop, Keller, Jansonius & Toney (1999) *J. Mol. Biol.* **294**, 193. 2. Zhou, Kay & Toney (1998) *Biochemistry* **37**, 5761. 3. Sun, Bagdassarian & Toney (1998) *Biochemistry* **37**, 3876.

### 1-Aminocyclopropanol

This cycloalkyl-hemiaminal (FW<sub>free-base</sub> = 73.09 g/mol) inhibits aldehyde dehydrogenases. The active agent is cyclopropanone hydrate, formed by hydrolysis of 1-aminocyclopropanol (*t*<sub>1/2</sub> = 30 min at 27°C and pH 7.4). 1. Tottmar & Lindberg (1977) *Acta Pharmacol. Toxicol. (Copenhagen)* **40**, 476. 2. Marchner & Tottmar (1978) *Acta Pharmacol. Toxicol. (Copenhagen)* **43**, 219. 3. Wiseman & Abeles (1979) *Biochemistry* **18**, 427.

### 1-Amino-2-cyclopropene-1-carboxylate

This substrate analogue (FW = 84.10 g/mol) inactivates 1-aminocyclopropanecarboxylate (ACC) oxidase (Reaction: ACC + Ascorbate + O<sub>2</sub> ⇌ Ethylene + Cyanide + Dehydroascorbate + CO<sub>2</sub> + 2 H<sub>2</sub>O). Ring-opening of enzyme-bound ACC is believed to result in the elimination of ethylene together with an unstable intermediate, cyanofornate ion, which then decomposes to cyanide ion and carbon dioxide. 1-Amino-2-cyclopropene-1-carboxylate most likely intercepts an active-site nucleophile. 1. Pirrung (1999) *Acc. Chem. Res.* **32**, 711.

### 3-Amino-1-(cyclopropylamino)heptan-2-one

This transition-state analogue (FW<sub>free-base</sub> = 184.28 g/mol) inhibits *Staphylococcus aureus* methionyl aminopeptidase (IC<sub>50</sub> = 7 μM), by mimicking the tetrahedral intermediate for amide bond hydrolysis. 1. Douangamath, Dale, D'Arcy, *et al.* (2004) *J. Med. Chem.* **47**, 1325.

### 1-Amino-2-cyclopropylcyclopropane-1-carboxylate

This substrate analogue (FW = 141.17 g/mol) is a mechanism-based inactivator of aminocyclopropanecarboxylate oxidase (Reaction: 1-Aminocyclopropane-1-carboxylate + Ascorbate + O<sub>2</sub> ⇌ Ethylene + Cyanide + Dehydroascorbate + CO<sub>2</sub> + 2 H<sub>2</sub>O). 1. Pirrung (1999) *Acc. Chem. Res.* **32**, 711.

### 2-Amino-2-deoxy-D-glucitol 6-Phosphate

This reduced aminosugar-phosphate (FW = 261.17 g/mol) inhibits glutamine:fructose-6-phosphate aminotransferase (isomerizing), with a *K<sub>i</sub>* value of 0.2 μM for the *Escherichia coli* enzyme. **Target(s):** glutamine:fructose-6-phosphate aminotransferase (isomerizing), *or* glucosamine 5-phosphate deaminase, *or* glucosamine-6-phosphate isomerase (1-11); and glucose-6-phosphate isomerase (7). 1. Montero-Morán, Lara-González, Alvarez-Añorve, Plumbridge & Calcagno (2001) *Biochemistry* **40**, 10187. 2. Lara-Lemus & Calcagno (1998) *Biochim. Biophys. Acta* **1388**, 1. 3. Midelfort & Rose (1977) *Biochemistry* **16**, 1590. 4. Bustos-Jaimes, Sosa-Peinado, Rudiño-Piñera, Horjales & Calcagno (2002) *J. Mol. Biol.* **319**, 183. 5. Steimle, Lindmark & Jarroll (1997) *Mol. Biochem. Parasitol.* **84**, 149. 6. Olchoway, Jedrzejczak, Milewski & Rypniewski (2005) *Acta Crystallogr. Sect. F* **61**, 994. 7. Milewski, Janiak & Wojciechowski (2006) *Arch. Biochem. Biophys.* **450**, 39. 8. Floquet, Richez, Durand, *et al.* (2007) *Bioorg. Med. Chem. Lett.* **17**, 1966. 9. Wojciechowski, Milewski, Mazerski & Borowski (2005) *Acta Biochim. Pol.* **52**, 647. 10. Badet-Denisot, Leriche, Massiere & Badet (1995) *Bioorg. Med. Chem. Lett.* **5**, 815. 11. Bearne (1996) *J. Biol. Chem.* **271**, 3052.

### (3S)-3-Amino-1-diaminophosphinyl-2-pyrrolidinone

This sulphostin analogue (FW<sub>free-base</sub> = 166.14 g/mol) inhibits dipeptidyl-peptidase IV (IC<sub>50</sub> = 11 nM). All the functional groups on the piperidine ring appear to be crucial for DPP-IV inhibition. 1. Abe, Akiyama, Umezawa, *et al.* (2005) *Bioorg. Med. Chem.* **13**, 785.

### 4-Amino-4,5-dideoxy-L-arabinose Imine

This L-rhamnose analogue (FW = 115.13 g/mol) noncompetitively inhibits α-L-rhamnosidase (*K<sub>is</sub>* = 0.14 μM, *K<sub>ii</sub>* = 1.2 μM). Substitution on the nitrogen atom shifted the inhibition mechanism from mixed to competitive. 1. Provencher, Steensma & Wong (1994) *Bioorg. Med. Chem.* **2**, 1179.

### 2-Amino-4,5-dihydro-8-phenylimidazole[2,1-b]thiazolo[5,4-g]benzothiazole

This benzothiazole (FW<sub>free-base</sub> = 324.43 g/mol), also known as YJA20379-1, inhibits gastric H<sup>+</sup>/K<sup>+</sup> ATPase, with IC<sub>50</sub> values of 21 and 24 μM at pH 6.4 and 7.4, respectively. Oral administration of YJA20379-1 also prevented the formation of ethanol-, indomethacin-, and water immersion stress-induced gastric lesions as well as mepirizole-induced duodenal ulcers in rats. YJA20379-1 accelerated the healing of acetic acid-induced chronic gastric ulcers in rats. Such results suggest YJA20379-1 is a potent

inhibitor of gastric  $H^+K^+$  ATPase, with much shorter duration of antisecretory action than omeprazole. 1. Sohn, Chang, Choi, *et al.* (1999) *Can. J. Physiol. Pharmacol.* **77**, 330.

**(2S,3R,12RS)-2-Amino-3,12-dihydroxy-2-hydroxymethylstearate**

This sphingosine analogue (FW = 365.51 g/mol) inhibits serine C-palmitoyltransferase reaction ( $IC_{50}$  = 3.2 nM), the first step of the biosynthesis of sphingolipids that modulate various cellular proliferation, differentiation, and apoptosis. 1. Yamaji-Hasegawa, Takahashi, Tetsuka, Senoh & Kobayashi (2005) *Biochemistry* **44**, 268.

**1-[4-Amino-2,6-di(isopropyl)phenyl]-3-[1-butyl-4-(3-methoxyphenyl)-2(1H)-oxo-1,8-naphthyridin-3-yl]urea**

This orally available naphthyridinylurea (FW = 541.70 g/mol), also known as SMP-797, inhibits rat cholesterol *O*-acyltransferase, or ACAT ( $IC_{50}$  = 8.3 nM), with inducible effect on the expression of low-density lipoprotein receptor. SMP-797 also increased low-density lipoprotein receptor expression in HepG2 cells like atorvastatin, an HMG-CoA reductase inhibitor, although other acyl-coenzyme A: cholesterol acyltransferase inhibitor had no effect, suggesting that the increase of low-density lipoprotein receptor expression by SMP-797 was independent of its acyl-coenzyme A: cholesterol acyltransferase inhibitory action and did not result from the inhibition of hepatic cholesterol synthesis. The 3-amino analogue also inhibits ( $IC_{50}$  = 14 nM). 1. Ban, Muraoka, Ioriya & Ohashi (2006) *Bioorg. Med. Chem. Lett.* **16**, 44.

**(S)-2-Amino-3-(4-{5-[3,4-dimethoxybenzylamino]pyrazin-2-yl}phenyl)propanoic Acid**

This amino acid (FW = 406.44 g/mol) inhibits ( $IC_{50}$  = 69 nM) tryptophan 5-monooxygenase, thereby providing the promise of novel treatments for gastrointestinal disorders associated with dysregulation of the serotonergic system, such as chemotherapy-induced emesis and irritable bowel syndrome. 1. Shi, Devasagayayaraj, Gu, *et al.* (2008) *J. Med. Chem.* **51**, 3684.

**2-Amino-5-[(2,5-dimethoxyphenyl)sulfanyl]-6-methylthieno[2,3-d]pyrimidin-4(3H)-one**

This thienopyrimidine (FW = 337.42 g/mol) is a dual inhibitor of dihydrofolate reductase ( $IC_{50}$  = 22  $\mu$ M) and human thymidylate synthase ( $IC_{50}$  = 4.6  $\mu$ M). The  $IC_{50}$  value for *Toxoplasma gondii* dihydrofolate reductase is 56 nM. 1. Gangjee, Qiu, Li & Kisliuk (2008) *J. Med. Chem.* **51**, 5789.

**4-(2-Aminoethyl)benzenesulfonyl Fluoride**

This yellow sulfonyl fluoride (FW<sub>hydrochloride</sub> = 239.70 g/mol; CAS 30827-99-7; Solubility: 100 mM in  $H_2O$ ; 100 mM in DMSO), also named 4-(2-aminoethyl)benzenesulfonyl fluoride hydrochloride, often abbreviated AEBSF and Pefabloc SC hydrochloride, is a potent and irreversible inhibitor of many serine proteases and esterases. It is more soluble in water than phenylmethanesulfonyl fluoride (PMSF) and less toxic (aqueous solutions are stable for one-to-two months at 4°C). AEBSF slowly hydrolyzes above pH 8. **Target(s):**  $\alpha$ -lytic protease (1); kedarcidin chromoprotein (2); chymotrypsin (17); kallikrein (15,25); plasmin (16); trypsin (3,20); platelet-activating-factor: sphingosine acetyltransferase (4); proteasome (5); thrombin (6,7); chymase (8); t-plasminogen activator (9,38); *Pseudoalteromonas* protease CP1 (10); *Sarcocystis* *neuro*na merozoite serine protease (11); platelet activating factor-degrading acetylhydrolase (12); phospholipase  $A_2$  (12,18); cinnamoyl esterase (13); NADPH oxidase (14); Z-Pro prinalin-insensitive Z-Gly-Pro-, or 7-amino-4-methylcoumarin-hydrolyzing peptidase (19); cinnamoyl ester hydrolase (21); dipeptidyl-peptidase II (22,47,48); dipeptidyl-peptidase IV (23,46); complement component C1a (24); aromatic-L-amino-acid decarboxylase, filarial nematode (*Dirofilaria immitis*) (26); N-acyl-D-amino-acid deacylase (27); amidase (28); envelysin (29); site-1 protease (30); mannan-binding lectin-associated serine protease-2 (31); hepacivirin, or hepatitis C virus NS3 serine proteinase (32); oligopeptidase B (33,34); myeloblastin (35-37); complement factor I (39); cucumisins (40); pyroglutamyl-peptidase II (41); cyanophycinase (42); Xaa-Xaa-Pro tripeptidyl peptidase, or prolyltri-peptidyl aminopeptidase (43-45); aminopeptidase B (49,50); membrane alanyl aminopeptidase, or aminopeptidase N (51); calcivirin (52); feruloyl esterase (53); 1-alkyl-2 acetylglucosphosphocholine esterase, or platelet-activating-factor acetylhydrolase (54,55); vinoreline synthase (56); platelet-activating factor acetyltransferase (57); phosphatidylcholine:sterol *O*-acyltransferase, or LCAT (58). 1. #### [1(RS)-Aminoethyl][2(RS)-benzyl-2-carboxy-1-ethyl]phosphinate

This pentavalent phosphinate-containing transition-state analogue ( $FW_{\text{hydrochloride}} = 307.71$  g/mol) inhibits D-alanyl-D-alanine synthetase, or D-alanine:D-alanine ligase. A mechanism for the inhibition of D-Ala-D-Ala ligase by these compounds is proposed to involve an ATP-dependent formation of phosphorylated inhibitor within the enzyme's active site. The antibacterial activities of these compounds are modest although their spectra include both Gram-positive and Gram-negative susceptible organisms. **1.** Parsons, Patchett, Bull, et al. (1988) *J. Med. Chem.* **31**, 1772.

#### (S)-2-Amino-3-(4-{5-[9-ethyl-9H-carbazol-3-yl)methylamino]pyrazin-2-yl}phenyl)propanoic Acid

This amino acid ( $FW = 465.56$  g/mol) inhibits tryptophan hydroxylase (TPH), or tryptophan 5-monoxygenase ( $IC_{50} = 31$  nM). This class of TPH inhibitors exhibits excellent potency in *in vitro* biochemical and cell-based assays, and it selectively reduces serotonin levels in the murine intestine after oral administration without affecting levels in the brain. Such inhibitors may provide novel treatments for gastrointestinal disorders associated with dysregulation of the serotonergic system, such as chemotherapy-induced emesis and irritable bowel syndrome. **1.** Shi, Devasagaraj, Gu, et al. (2008) *J. Med. Chem.* **51**, 3684.

#### [1(S)-Aminoethyl][2-carboxy-2(RS)-heptyl-1-ethyl]phosphinate

This pentavalent phosphinate-containing transition-state analogue ( $FW_{\text{hydrochloride}} = 315.76$  g/mol) is a strong inhibitor of D-alanyl-D-alanine synthetase, or D-alanine:D-alanine ligase. **1.** McDermott, Creuzet, Griffin, et al. (1990) *Biochemistry* **29**, 5767. **2.** Duncan & Walsh (1988) *Biochemistry* **27**, 3709. **3.** Parsons, Patchett, Bull, et al. (1988) *J. Med. Chem.* **31**, 1772.

#### [1(RS)-Aminoethyl][2(RS)-carboxy-1-hexyl]phosphinate

This pentavalent phosphinate-containing transition-state analogue ( $FW_{\text{hydrochloride}} = 273.70$  g/mol) inhibits D-alanyl-D-alanine synthetase, or D-alanine:D-alanine ligase. A mechanism for the inhibition of D-Ala-D-Ala ligase by these compounds is proposed to involve an ATP-dependent formation of phosphorylated inhibitor within the enzyme's active site. The antibacterial activities of these compounds are modest although their spectra include both Gram-positive and Gram-negative susceptible organisms. **1.** Parsons, Patchett, Bull, et al. (1988) *J. Med. Chem.* **31**, 1772.

#### [1(S)-Aminoethyl][2-carboxy-2(R)-methyl-1-ethyl]phosphinate

This aminoalkyl dipeptide analogue and pentavalent phosphinate-containing transition-state analogue ( $FW_{\text{hydrochloride}} = 231.62$  g/mol) is an ATP-dependent, slow-binding inhibitor of the D-Ala:D-Ala ligase (*i.e.*, D-alanyl-D-alanine synthetase) from *Salmonella typhimurium*. After ATP-dependent phosphorylation, dissociation of the enzyme-bound inhibitor has a half-life of 17 days at 37°C. The mechanism of inhibition is analogous to that of glutamine synthetase by methionine sulfoximine and phosphinothricin. McDermott et al. (1) used rotational resonance, then a newly developed solid-state NMR method, for structural studies of an inhibited complex formed by reaction of the enzyme with ATP and the aminoalkyl dipeptide analogue. The measured NMR coupling properties indicate that the two species are bridged in a P-O-P linkage, with a P-P through-space distance of  $2.7 \pm 0.2$  Å, unambiguously demonstrating that the inactivation mechanism involves phosphorylation of enzyme-bound inhibitor by ATP to form a phosphoryl-phosphinate adduct. **1.** McDermott, Creuzet, Griffin, et al. (1990) *Biochemistry* **29**, 5767. **2.** Parsons, Patchett, Bull, et al. (1988) *J. Med. Chem.* **31**, 1772. **3.** Fan, Park, Walsh & Knox (1997) *Biochemistry* **36**, 2531. **4.** Shi & Walsh (1995) *Biochemistry* **34**, 2768.

#### N-(2-Aminoethyl)-5-chloroquinoline-8-sulfonamide

This arylsulfonamide protein kinase inhibitor ( $FW_{\text{free-base}} = 285.75$  g/mol), also known as CKI-7, targets casein kinase 1 ( $K_i = 8.5$  μM) and casein kinase 2 ( $K_i = 70$  μM). **Target(s):** casein kinase 1 (1-9); casein kinase 2 (1-3); non-specific serine/threonine protein kinase (1-9). **1.** Hidaka, Watanabe & Kobayashi (1991) *Meth. Enzymol.* **201**, 328. **2.** Eriksson, Toivola, Sahlgren, Mikhailov & Härmälä-Braskén (1998) *Meth. Enzymol.* **298**, 542. **3.** Chijiwa, Hagiwara & Hidaka (1989) *J. Biol. Chem.* **264**, 4924.

### S-( $\beta$ -Aminoethyl)-L-cysteine

This L-lysine analogue (FW<sub>dihydrochloride</sub> = 237.14 g/mol), also known as L-4-thialysine, inhibits a number of lysine-dependent enzymes. This thioether is also formed upon acid hydrolysis of thiol-containing proteins previously treated with ethyleneimine to introduce additional trypsin-cleavage sites.

**See Ethyleneimine Target(s):** L-lysine 2,3-aminomutase (1,7,11); peptidyl-Lys metalloendopeptidase, *or Armillaria mellea* protease (2,18);  $\alpha$ -amino adipate-semialdehyde dehydrogenase (3); D-lysine 5,6 aminomutase (4,10); lysyl-tRNA synthetase (5,8,9); aspartate kinase (5,6,19,20); dihydrodipicolinate synthase (12-15); diaminopimelate decarboxylase (16); kynureninase (17); hydroxylysine kinase (21); homocitrate synthase (22-25). 1. ### N-(2-Aminoethyl)-5-isoquinolinesulfonamide

This substituted isoquinoline (FW<sub>free-base</sub> = 251.31 g/mol), commonly referred to as H-9, inhibits a number of protein kinases: *e.g.*, protein kinase G ( $K_i$  = 0.87  $\mu$ M), protein kinase A ( $K_i$  = 1.9  $\mu$ M), protein kinase C ( $K_i$  = 18  $\mu$ M), and myosin light-chain kinase ( $IC_{50}$  = 70  $\mu$ M). 1. Inagaki, Watanabe & Hidaka (1985) *J. Biol. Chem.* **260**, 2922.

### S-(2-Aminoethyl)isothiurea & S-(2-Aminoethyl)isothiuronium Cation

This substituted isothiurea (FW<sub>free-base</sub> = 119.19 g/mol; *Abbreviation:* AET), inhibits nitric-oxide synthase, with respective  $K_d$  values of 12  $\mu$ M and 3  $\mu$ M for the endothelial and inducible enzymes. **Target(s):** nitric oxide synthase (1,2,4); arginase (3); glutamate decarboxylase (5);

creatinase (6). 1. Southan, Szabo & Thiemermann (1995) *Brit. J. Pharmacol.* **114**, 510. 2. Southan, Zingarelli, O'Connor, Salzman & Szabo (1996) *Brit. J. Pharmacol.* **117**, 619. 3. ### N,N-(2-Aminoethyl)-D-mannoamidine

This half-chair mannosidase transition-state mimic (FW = 219.24 g/mol) inhibits several glycosidases:  $\alpha$ -mannosidase ( $K_i$  = 6 nM),  $\beta$ -mannosidase ( $K_i$  = 9 nM),  $\alpha$ -glucosidase ( $K_i$  = 81  $\mu$ M),  $\beta$ -glucosidase ( $K_i$  = 6600  $\mu$ M),  $\alpha$ -galactosidase ( $K_i$  = 218  $\mu$ M),  $\beta$ -galactosidase ( $K_i$  = 82  $\mu$ M),  $\alpha$ -fucosidase ( $K_i$  = 6  $\mu$ M), and  $\beta$ -N acetylhexosaminidase ( $K_i$  = 99  $\mu$ M). 1. Heck, Vincent, Murray, *et al.* (2004) *J. Amer. Chem. Soc.* **126**, 1971.

### 4-(5-(3-Amino-3-ethylpentyl)thiophen-2-yl)-N-[4-(4-pyrrolidin-1-ylpiperidin-1-yl)carbonyl]phenyl]pyrimidin-2-amine

This substituted pyrimidine (FW = 546.78 g/mol) inhibits human I $\kappa$ B kinase 1 and 2, with  $IC_{50}$  values of 0.03 and 0.06  $\mu$ M, respectively, demonstrating significant *in vivo* activity in an acute model of cytokine release. 1. Waelchli, Bollbuck, Bruns, *et al.* (2006) *Bioorg. Med. Chem. Lett.* **16**, 108.

### D-3-[(1-Aminoethyl)phosphinyl]-D-2-ethylpropionic Acid

This phosphinate-containing dipeptide analogue (FW = 209.18 g/mol) is a slow-binding inhibitor of *Enterococcus faecium* D-Ala-D-Ala dipeptidase ( $K_i^*$  = 90 nM) a D-,D-dipeptidase required for vancomycin resistance in *Enterococcus faecium*. This inhibitor showed a time-dependent onset of inhibition of VanX and a time-dependent return to uninhibited steady-state rates upon dilution of the enzyme/inhibitor mixture. 1. Wu & Walsh (1995) *Proc. Natl. Acad. Sci. U.S.A.* **92**, 11603.

### D-3-[(1-Aminoethyl)phosphinyl]-2-heptylpropionic Acid

This phosphinate-containing dipeptide analogue (FW<sub>hydrochloride</sub> = 315.78 g/mol) is converted by enzymatic phosphorylation from a low-affinity inhibitor form to an extremely tightly bound analogue of a D-alanyl-D-alanine synthetase reaction intermediate. This compound is a potent active site-directed inhibitor and is competitive with D-alanine ( $K_i$  = 1.2  $\mu$ M), exhibiting time-dependent inhibition in the presence of ATP. Kinetic analysis revealed a rapid onset of steady-state inhibition ( $k_{on}$  =  $1.35 \times 10^4$  M<sup>-1</sup> s<sup>-1</sup>), followed by very slow dissociation of inhibitory complex(es) with a half-life of 8.2 h. 1. Duncan & Walsh (1988) *Biochemistry* **27**, 3709.

**(R)-(+)-trans-4-(1-Aminoethyl)-N-4-pyridyl)cyclohexane carboxamide**

This pyridine derivative (FW<sub>free-base</sub> = 247.34 g/mol; CAS 146986-50-7; Water-soluble;  $\lambda_{\text{max}}$  = 269.6 nm), also known as Y-27632, binds specifically to the ROCK family of protein kinases and inhibits their activity (1-5). Y-27632 is also a smooth muscle relaxant, inhibits stress fiber formation, and inhibits lysophosphatidate-induced neurite retraction (2). **Target(s):** Rho-dependent protein kinase (ROCK-I and ROCK-II) (1-5); mitogen- and stress- activated protein kinase 1, mildly inhibited (3); [mitogen-activated protein kinase]-activated protein kinase-1, weakly inhibited (3); phosphorylase kinase, weakly inhibited (3). 1. Amano, Fukata, Shimokawa & Kaibuchi (2000) *Meth. Enzymol.* **325**, 149. 2. Narumiya, Ishizaki & Uehata (2000) *Meth. Enzymol.* **325**, 273. 3. Davies, Reddy, Caivano & Cohen (2000) *Biochem. **4-Amino-5-fluoropentanoate**

This  $\gamma$ -amino acid (FW = 135.14 g/mol) is a mechanism-based inhibitor that inactivates  $\gamma$ -aminobutyrate aminotransferase (1-8) by an enamine mechanism first suggested by Metzler and co-workers (9). **Target(s):**  $\gamma$ -aminobutyrate aminotransferase (1-9,12); hypotaurine aminotransferase (2); glutamate 1-semialdehyde 2,1-aminomutase, *or* glutamate-1-semialdehyde aminotransferase (10,11). 1. **2-[5-Amino-2-(4-fluorophenyl)-6-oxo-1,6-dihydro-1-pyrimidinyl]-N-[2-methyl-1-(4,4,5,5-tetramethyl-1,3,2-dioxaborolan-2-yl)propyl]acetamide**

This substituted 5-aminopyridine-6-one (FW = 444.31 g/mol) inhibits human leukocyte elastase,  $K_i$  = 6.2 nM. This compound contains a boronic acid moiety that binds covalently to the Ser-195 hydroxyl of the enzyme. 1. Veale, Bernstein, Bryant, *et al.* (1995) *J. Med. Chem.* **38**, 98

**8-Amino-9-(2-furylmethyl)guanine**

This synthetic purine nucleoside (FW = 246.23 g/mol) inhibits calf spleen purine nucleoside phosphorylase (IC<sub>50</sub> = 92 nM). **See also Immucillins** 1. **3-Aminoglutarate, See  $\beta$ -Glutamate****DL-Aminogluthethimide**

This substituted glutarimide (FW = 232.28 g/mol), also known as 2-(4-aminophenyl)-2-ethylglutarimide, inhibits many steroid monooxygenases. Aminogluthethimide blocks adrenal steroid biosynthesis and the production of estrogens in extraglandular tissues. **Target(s):** aromatase, *or* CYP19, IC<sub>50</sub> values for the (+)-*R*- and (-)-*S*-stereoisomers are 0.86 and 23.15  $\mu$ M, respectively (1-3,7,10,16,19); steroid 11 $\beta$ -monooxygenase (4,9); calcidiol 1-monooxygenase, *or* 25-hydroxycholecalciferol 1 $\alpha$ -monooxygenase (5); cholesterol monooxygenase, side-chain-cleaving (6,9-11,17,18); ecdysone 20-monooxygenase (8); steroid 7 $\alpha$ -monooxygenase, *or* cholesterol 7 $\alpha$ -monooxygenase (12,13); estradiol 2-monooxygenase (14,16); estradiol 16 $\alpha$ -monooxygenase (14); cholestanetriol 26-monooxygenase, *or* 5 $\beta$ -cholestane-3 $\alpha$ ,7 $\alpha$ ,12 $\alpha$ -triol 27-hydroxylase, weakly inhibited (15). 1. **Aminoguanidine**

This substituted hydrazine (FW<sub>hydrochloride</sub> = 110.55 g/mol; CAS 79-17-4), also named pimagedine, is a strong inhibitor of diamine oxidases as well as nitric oxide synthase. Note that aminoguanidine also inhibits the formation of advanced glycosylation end-products, reportedly by reacting with and trapping Amadori rearrangement-derived fragmentation products in solution. In view of this property, aminoguanidine has often been used to treat complications associated with chronic diabetes. **Target(s):** amine

oxidase (copper-containing), or diamine oxidase (1,2,6,8,9,13,18,19,25); methylamine dehydrogenase (3); tryptophan tryptophylquinone enzymes (3); nitric-oxide synthase (4,10,14-16,20,26,27);  $\beta$ -fructofuranosidase, or invertase (5); monoamine oxidase, or amine oxidase (7,10); histidine decarboxylase (9,12,25); aldose reductase (10); catalase (11); formation of advanced glycosylation end products (17); adenosylmethionine decarboxylase (21); arginine deaminase (22); arginine kinase (23); aspartate aminotransferase (24); histamine *N*-methyltransferase (25). 1. ### 6-Aminohexanoate

This  $\epsilon$ -amino acid (FW = 131.17 g/mol; CAS 60-32-2; *Abbreviation*:  $\epsilon$ Ahx), also known as  $\epsilon$ -amino-*n*-caproic acid, is a lysine derivative/analogue that inhibits many peptidases and likewise retards fibrinolysis. 6-Aminohexanoate is soluble in water and has  $pK_a$  values of 4.43 and 10.75. Note that 6-aminohexanoic acid is the subunit of the polymer nylon 6. **Target(s)**: plasmin (1,2,10,19,25,40); pyrroline-5-carboxylate dehydrogenase (3); u-plasminogen activator, or urokinase (4,5,10,14,19,23,24); lysine carboxypeptidase, or lysine(arginine) carboxypeptidase, or carboxypeptidase N (6,7,42,44-47); carboxypeptidase B (8,9,11-13,42,48-50); coagulation factor VIIa (15); leukocyte phagocytosis and clumping (16,17); penicillopepsin (18); crayfish carboxypeptidase (20,21); lysyl endopeptidase (22); trypsin (25); complement component C<sub>1</sub> (26); pantothenate synthetase, or pantoate: $\beta$ -alanine ligase, slightly inhibited (27); lysyl-tRNA synthetase (28); D-lysine 5,6-aminomutase (29); lysine decarboxylase (30); ornithine decarboxylase (31); guanidinobutyrase (32); acetylsermidine deacetylase (33); peptidyl-Lys metalloendopeptidase (34); procollagen C endopeptidase (35); cathepsin D (36); t-plasminogen activator (37); complement factor I, weakly inhibited (38); acrosin (39); carboxypeptidase U (41-43); carboxypeptidase M (42); carboxypeptidase E (42); cytosol alanyl aminopeptidase (51); membrane alanyl aminopeptidase (52); 2,3,4,5-tetrahydropyridine-2,6-dicarboxylate *N*-succinyltransferase (53); ceruloplasmin (54); ferroxidase (54); lysine 2-monooxygenase (55). 1. ### *N*-(6-Aminoethyl)-5-chloro-1-naphthalenesulfonamide

This naphthylsulfonamide (FW<sub>hydrochloride</sub> = 377.33 g/mol), often referred to as W-7, is a calmodulin antagonist that inhibits a number of calmodulin-dependent reactions. **Target(s)**: 3',5'-cyclic-nucleotide phosphodiesterase (1-4,9,11), [myosin light-chain] kinase (1-4,6,13,14); calmodulin (1-3); protein kinase C (3,5,8,10); Ca<sup>2+</sup>-exporting ATPase (3); cAMP-dependent protein kinase (3,4); cGMP-dependent protein kinase (3,4); casein kinase I (3); casein kinase II (3); pyruvate dehydrogenase, pea (7); [3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)] kinase (12); Ca<sup>2+</sup>/calmodulin-dependent protein kinase (15-19); diphosphoinositol-pentakisphosphate kinase (20); NAD<sup>+</sup> kinase (21); thymidine kinase (22); fatty-acid *O*-methyltransferase (23); nitric-oxide synthase (24,25). 1. ### (2S,3R)-2-Amino-3-hydroxy-2-hydroxymethyl-12-oxostearate

This sphingosine analogue (FW = 347.50 g/mol) inhibits serine C-palmitoyltransferase ( $IC_{50} = 3.5$  nM), the enzyme that catalyzes the first step of the biosynthesis of all sphingolipids. The methyl ester is a slightly weaker inhibitor ( $IC_{50} = 17$  nM). **1.** Yamaji-Hasegawa, Takahashi, Tetsuka, Senoh & Kobayashi (2005) *Biochemistry* **44**, 268.

### 2-Amino-4-hydroxypteridine-6-aldehyde

This yellow pteridine (FW = 191.15 g/mol), also known as 6-pteridylaldehyde, pterin-6-aldehyde, and 2-amino-4-hydroxy-6-pteridinecarboxaldehyde, is a photoproduct that inhibits xanthine oxidase, for which it is a slow substrate, producing the 6-carboxylate. It also exhibits a superoxide anion radical scavenging activity (7). **Note:** This derivative is a frequent contaminant in folic acid solutions, as a consequence of unrecognized photodegradation. **Target(s):** xanthine oxidase, or pterin oxidase (1-12,15); guanine deaminase, or guanase (4,14); quinine oxidase (6,13); xanthine dehydrogenase (16). **1.** Theorell (1951) *The Enzymes*, 1st ed., **2** (part 1), 335. **2.** Bray (1963) *The Enzymes*, 2nd ed., **7**, 533. **3.** Bray (1975) *The Enzymes*, 3rd ed., **12**, 299. **4.** Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. **2**, Academic Press, New York. **5.** Terada, Leff & Repine (1990) *Meth. ### 5-Amino-1H-imidazole-4-carboxamide

This free-base of a key purine nucleotide biosynthesis intermediate (FW<sub>free-base</sub> = 126.12 g/mol;  $\lambda_{max}$  = of 266 nm at pH 7, with  $\epsilon = 12700$  M<sup>-1</sup>cm<sup>-1</sup>;  $\lambda_{max}$  = 277 nm at pH 13, with  $\epsilon = 12500$  M<sup>-1</sup>cm<sup>-1</sup>), also known as 4-amino-5-imidazolecarboxamide, enzymatically undergoes PRPP-dependent conversion into AICAR, the actual purine nucleotide biosynthetic pathway intermediate. (See next entry). **Target(s):** guanine deaminase (1-4,7,8,10-15); adenosine deaminase (5); adenine deaminase (6); NAD(P)H dehydrogenase (quinone), or DT diaphorase (9); xanthine phosphoribosyltransferase (16,17); hypoxanthine (guanine) phosphoribosyltransferase (17); urate-ribonucleotide phosphorylase, weakly inhibited (18); glutaminyl-peptide cyclotransferase, weakly inhibited (1). **9** Glantz &

### 5-Amino-1H-imidazole-4-carboxamide riboside

This key purine nucleotide precursor and Type-2 diabetes prodrug (FW<sub>free-base</sub> = 126.12 g/mol;  $\lambda_{max}$  = of 266 nm at pH 7, with  $\epsilon = 12700$  M<sup>-1</sup>cm<sup>-1</sup>;  $\lambda_{max}$  = 277 nm at pH 13, with  $\epsilon = 12500$  M<sup>-1</sup>cm<sup>-1</sup>; Abbreviation: AICARiboside), also known as Acadesine® and 4-amino-5-imidazolecarboxamide ribonucleoside, is phosphorylated to form 5-Amino-1H-imidazole-4-carboxamide ribonucleoside 5'-phosphate (AICAR), an allosteric activator of AMP-stimulated protein kinase (AMPK). (Other reports attribute AMPK activation by AICAR to the latter's conversion to XMP.) Addition of 50-500  $\mu$ M acadesine to suspensions of isolated rat hepatocytes results in the accumulation of millimolar concentrations of the AICAR (1). AMP-activated protein kinase is a multisubstrate protein kinase that, in liver, inactivates both acetyl-CoA carboxylase, the rate-limiting enzyme of fatty acid synthesis, and 3-hydroxy-3-methyl-glutaryl-CoA reductase, the rate-limiting enzyme of cholesterol synthesis. AICAR stimulates rat liver AMP-activated protein kinase up to 10-fold, with a half-maximal effect at approximately 5 mM (1). This was accompanied by a dose-dependent inactivation of both acetyl-CoA carboxylase and 3-hydroxy-3-methylglutaryl-CoA reductase. Addition of 50-500  $\mu$ M acadesine to hepatocyte suspensions incubated in the presence of various substrates, including glucose and lactate/pyruvate, caused a parallel inhibition of both fatty acid and cholesterol synthesis (1). Acadesine also stimulates glucose uptake and increases the activity of p38 mitogen-activated protein kinases  $\alpha$  and  $\beta$  in skeletal muscle tissue. 5-Aminoimidazole-4-carboxamide riboside is also a competitive inhibitor of adenosine deaminase,  $K_i = 0.36$  mM (2). AICAR activation of the p53 pathway is attenuated by rapamycin, an immunosuppressant that inhibits mTOR kinase. **1.** Henin, Vincent, Gruber & Van den Berghe (1985) *FASEB J.* **9**, 541. **2.** Baggott, Vaughn & Hudson (1986) *Biochem. J.* **236**, 193.

### 6-[(2-Aminoimidazol-1-yl)methyl]-5-bromouracil

This substituted uracil (FW = 287.10 g/mol) is a potent inhibitor of thymidine phosphorylase ( $IC_{50} = 20$  nM). The 4-amino analogue is a weaker inhibitor. **1.** Reigan, Gbaj, Stratford, Bryce & Freeman (2008) *Eur. J. Med. Chem.* **43**, 1248. **2.** Reigan, Edwards, Gbaj, et al. (2005) *J. Med. Chem.* **48**, 392. **3.** Gbaj, Edwards, Reigan, et al. (2006) *J. Enzyme Inhib. Med. Chem.* **21**, 69.

**N-[2-((4-((Amino(imino)methyl)amino)-1(S)-carboxybutyl)amino)propyl)-L-histidine**

This histargin homologue and ACE1 inhibitor (FW = 358.42 g/mol), consisting of L-histidine and L-arginine linked by a propylene bridge to their  $\alpha$ -amino groups, targets carboxypeptidase B, lysine carboxypeptidase (or lysine(arginine) carboxypeptidase, carboxypeptidase N, and peptidyl-dipeptidase A (or angiotensin I-converting enzyme). 1. Moriguchi, Umeda, Miyazaki, *et al.* (1988) *J. Antibiot.* **41**, 1823.

**2-Aminoindan-2-phosphonate**

This conformationally constrained phenylalanine analogue (FW<sub>hydrochloride</sub> = 249.63 g/mol) is a slow-binding, inhibitor of phenylalanine ammonia-lyase, with a  $K_i$  of 7 nM for the *Petroselinum crispum* enzyme). The corresponding carboxylic acid is a weak alternative substrate and competitive inhibitor. 1. Appert, Zon & Amrhein (2003) *Phytochemistry* **62**, 415. 2. Dubery & Smit (1994) *Biochim. Biophys. Acta* **1207**, 24. 3. Campbell & Ellis (1992) *Plant Physiol.* **98**, 62. 4. Kim, Kronstad & Ellis (1996) *Phytochemistry* **43**, 351. 5. Hisaminato, Murata & Homma (2001) *Biosci. Biotechnol. Biochem.* **65**, 1016.

**4-Amino-5-iodo-7-( $\beta$ -D-erythro-furanosyl)pyrrolo[2,3-d]pyrimidine**

This tubercidin analogue (FW = 362.12 g/mol) inhibits human adenosine kinase ( $IC_{50}$  = 6 nM), a key intracellular enzyme regulating intracellular and extracellular concentrations of adenosine (ADO), itself an powerful endogenous modulator of intercellular signalling that reduces cell excitability during tissue stress and trauma. 1. Boyer, Ugarkar, Solbach, *et al.* (2005) *J. Med. Chem.* **48**, 6430.

**5-Aminolevulinate (5-Aminolevulinic Acid)**

This key metabolic precursor (FW = 131.13 g/mol; CAS 106-60-5;  $pK_a$  values = 4.05 and 8.90 at 25°C; Symbol: ALA), also known as  $\delta$ -aminolevulinic acid, is essential for the biosynthesis of metal ion-binding tetrapyrrole ring systems (porphyrins, chlorophylls, and cobalamins). In non-photosynthetic eukaryotes (animals, insects, fungi, protozoa, and alphaproteobacteria),  $\delta$ -aminolevulinic acid is produced by the enzyme ALA synthase, using glycine and succinyl CoA as substrates. In plants, algae, bacteria, and archaea, it is produced from glutamyl-tRNA and

glutamate-1-semialdehyde. 5-Aminolevulinic acid inhibits (*R*)-3-amino-2-methylpropionate:pyruvate aminotransferase. **ALA Phototherapy:** Protoporphyrin IX, the immediate heme precursor is a highly effective tissue photosensitizer that is synthesized in four steps from 5-aminolevulinic acid. ALA synthesis is regulated via a feedback inhibition and gene repression mechanism linked to the concentration of free heme. In certain cell and tissue types, addition of exogenous ALA bypasses these regulation mechanisms, inducing uptake and synthesis of photosensitizing concentrations of Protoporphyrin IX, or PpIX. Topical application of ALA to certain malignant and non-malignant skin lesions, for example, can induce a clinically useful degree of lesion-specific photosensitization (*e.g.*, superficial basal cell carcinomas show high response rate (~79%) after a single phototherapy treatment). ALA also induces localized tissue-specific photosensitization, when injected intradermally. In this sense, ALA and its methyl ester (methyl aminolevulinate, or MAL; trade name: Metvix<sup>®</sup>) are prodrugs that increase the amounts of the active drug (PpIX). 1. Kontani, Kaneko, Kikugawa, Fujimoto & Tamaki (1993) *Biochim. Biophys. Acta* **1156**, 161.

**Aminomalonnate (Aminomalonic Acid)**

This amino dicarboxylic acid (FW<sub>hydrochloride</sub> = 155.54 g/mol), which readily undergoes decarboxylation in aqueous solutions, inhibits  $\delta$ -aminolevulinatase (1-3,14,15), aspartate 4-decarboxylase, as an alternative substrate (4,8); asparagine synthetase (5,6,9,10), serine hydroxymethyl-transferase (or glycine hydroxymethyltransferase) (1,7); glycine acyltransferase, weakly inhibited (1), phosphoribosylglycinamide synthetase (phosphoribosylamine:glycine ligase, weakly inhibited (1), aspartyl-tRNA synthetase (11), serine-sulfate ammonia-lyase (13), and glycine C-acetyltransferase (16). 1. **N-[2(S)-[2(R)-Amino-3-mercaptopropylamino]-3-methylbutyl]-L-phenylalanyl-L-methionine**

This cell-permeable Cys-Val-Phe-Met peptidomimetic (FW = 470.70 g/mol), also known as FTase inhibitor 1, is a potent inhibitor of protein farnesyltransferase ( $IC_{50}$  = 21 nM). It will also inhibit protein geranylgeranyltransferase at higher concentrations ( $IC_{50}$  = 0.79  $\mu$ M). 1. Garcia, Rowell, Ackermann, Kowalczyk & Lewis (1993) *J. Biol. Chem.* **268**, 18415. 2. Cox, Garcia, Westwick, *et al.* (1994) *J. Biol. Chem.* **269**, 19203.

**N-4-[2(R)-Amino-3-mercaptopropyl]amino-2-naphthylbenzoyl-L-leucine**

This peptidomimetic (FW = 465.62 g/mol), often called GGTI-297, inhibits protein geranylgeranyltransferase type I,  $K_i = 56$  nM (1-5) and protein farnesyltransferase,  $K_i = 200$  nM (6). 1. Sebti & Hamilton (2000) *Meth. Enzymol.* **325**, 381. 2. Gibbs (2001) *The Enzymes*, 3rd ed., **21**, 81. 3. Yokoyama & Gelb (2001) *The Enzymes*, 3rd ed., **21**, 105. 4. Chem.* **273**, 26497.

**N-4-[2(R)-Amino-3-mercaptopropyl]amino-2-phenylbenzoyl-L-leucine**

This protein farnesyltransferase inhibitor (FW = 415.56 g/mol), often referred to as GGTI-287, is a leucine-containing L-cysteinylyl-L-valyl-L-leucyl-L-leucine peptidomimetic, in which the two central aminoacyl residues are replaced with 2-phenyl-4-aminobenzoic acid. It inhibits protein geranylgeranyltransferase I ( $IC_{50} = 5$  nM) and protein farnesyltransferase ( $IC_{50} = 25$  nM). 1. Lerner, Qian, Hamilton & Sebti (1995) *J. Biol. Chem.* **270**, 26770. 2. Qian, Vogt, Vasudevan, Sebti & Hamilton (1998) *Bioorg. Med. Chem.* **6**, 293.

**N-[3-(Aminomethyl)benzyl]acetamidine**

This slow, tight-binding inhibitor (FW<sub>dihydrochloride</sub> = 250.17 g/mol), targets the inducible nitric-oxide synthase, or iNOS ( $K_d = 7$  nM). The  $K_d$  values for the human brain and endothelial enzymes are 2 and 50  $\mu$ M, respectively. 1. Kankuri, Vaali, Knowles, *et al.* (2001) *J. Pharmacol. Exp. Ther.* **298**, 1128. 2. Thomsen, Scott, Topley, *et al.* (1997) *Cancer Res.* **57**, 3300. 3. Laszlo & Whittle (1997) *Eur. J. Pharmacol.* **334**, 99. 4. Garvey, Oplinger, Furfine, *et al.* (1997) *J. Biol. Chem.* **272**, 4959.

**2-[[[(1-Amino-3-methylbutyl)hydroxyphosphinyl]methyl]-4-methylpentanoate**

This peptide analogue (FW = 279.32 g/mol), also known as LeuP[CH<sub>2</sub>]Leu, inhibits leucyl aminopeptidase ( $K_i = 65$  nM) and membrane alanyl aminopeptidase, or aminopeptidase N ( $K_i = 1.02$   $\mu$ M). 1. Grembecka, Mucha, Cierpicki & Kafarski (2003) *J. Med. Chem.* **46**, 2641.

**trans-1-Amino-4-methylcyclohexane**

This sterically constrained cycloalkylamine (FW = 113.20 g/mol; CAS 2523-55-9), also known as *trans*-4-methylcyclohexylamine, inhibits spermidine synthase (*Reaction*: *S*-Adenosyl 3-(methylthio)propylamine + Putrescine  $\rightleftharpoons$  5'-*S*-Methyl-5'-thioadenosine + Spermidine), with the *cis* isomer a weaker inhibitor as is 1-amino-3-methylcyclohexane. 1. Ikeguchi, Bewley & Pegg (2006) *J. Biochem.* **139**, 1. 2. Shirahata, Takahashi, Beppu, Hosoda & Samejima (1993) *Biochem. Pharmacol.* **45**, 1897. 3. Goda, Watanabe, Takeda, *et al.* (2004) *Biol. **1-Amino-3-methylcyclopentane**

A sterically constrained cycloalkylamine (FW = 99.18 g/mol), consisting of a racemic mixture of *cis* and *trans* isomers, inhibits spermidine synthase ( $IC_{50} = 15$   $\mu$ M). The active site has a relatively large hydrophobic cavity adjacent to a negatively charged binding site, with which a protonated amino group of putrescine interacts, while putrescine's other amino group is situated in the hydrophobic cavity as a free form to be aminopropylated by decarboxylated *S*-adenosylmethionine. 1. Shirahata, Morohoshi, Fukai, Akatsu & Samejima (1991) *Biochem. Pharmacol.* **41**, 205.

**Aminomethylenebisphosphonate**

This pyrophosphate analogue (FW = 190.01 g/mol) inhibits vacuolar H<sup>+</sup>-translocating inorganic pyrophosphatase. Proton-translocating pyrophosphatases of from bacteria and plants are competitively inhibited by aminomethylene-diphosphonate and have inhibition constants below 2  $\mu$ M, whereas liver mitochondrial pyrophosphatase is two orders of magnitude less sensitive to this compound, but extremely sensitive to imidodiphosphate. Aminomethylene-bisphosphonic acid derivatives also have herbicidal properties. 1. Zhen, Baykov, Bakuleva & Rea (1994) *Plant Physiol.* **104**, 153. 2. Gordon-Weeks, Parmar, Davies & Leigh (1999) *Biochem. J.* **337**, 373. 3. Drozdowicz, Shaw, Nishi, *et al.* (2003) *J. Biol. Chem.* **278**, 1075. 4. McIntosh & Vaidya (2002) *Int. J. Parasitol.* **32**, 1.

**1-Amino-S-methylisothiourea**

This thiourea derivative, (FW<sub>free-base</sub> = 105.16 g/mol; frequently supplied as the *p*-toluenesulfonate salt, with FW = 277.36 g/mol; *Abbreviation*: AMITU), also known as *S*-methylisothiosemicarbazide, is a strong, irreversible inhibitor of neuronal nitric-oxide synthase ( $IC_{50} = 3$   $\mu$ M). It is a somewhat weaker inhibitor of the inducible ( $IC_{50} = 24$   $\mu$ M) and endothelial ( $IC_{50} = 103$   $\mu$ M) isozymes. **Target(s)**: catalase (1); nitric-oxide synthase (2). 1. Feinstein, Seaholm & Ballonoff (1964) *Enzymologia* **27**, 30. 2. Wolff, Gauld, Neulander & Southan (1997) *J. Pharmacol. Exp. Ther.* **283**, 265.

**2-Amino-6-methyl-5-(2-naphthylsulfanyl)thieno[2,3-d]pyrimidin-4(3H)-one**

This dual TS-DHFR inhibitor (FW = 339.44 g/mol) inhibits human thymidylate synthase ( $IC_{50} = 0.12 \mu\text{M}$ ) and dihydrofolate reductase ( $IC_{50} = 2.9 \mu\text{M}$ ). The  $IC_{50}$  value for *Toxoplasma gondii* dihydrofolate reductase is 44 nM. 1. Gangjee, Qiu, Li & Kisliuk (2008) *J. Med. Chem.* **51**, 5789.

**N-[4-[(2-Amino-6-methyl-4-oxo-3,4-dihydro-thieno[2,3-d]pyrimidin-5-yl)sulfanyl]benzoyl]-L-glutamate**

This dual TS-DHFR inhibitor (FW = 462.51 g/mol) inhibits dihydrofolate reductase (human,  $IC_{50} = 20 \text{ nM}$ ) and thymidylate synthase (human,  $IC_{50} = 40 \text{ nM}$ ). The  $IC_{50}$  value for *Toxoplasma gondii* dihydrofolate reductase is 8 nM. Such dual inhibitors of the one-carbon folate cycle promise to exert enhanced pharmacologic potency as antineoplastic agents. 1. Gangjee, Qiu, Li & Kisliuk (2008) *J. Med. Chem.* **51**, 5789.

**(S)-2-Amino-2-methyl-4-phosphonobutyrate**

This glutamate isostere and presynaptic depressant (FW = 197.13 g/mol; FW<sub>hydrochloride</sub> = 232. g/mol; CAS 157381-42-5; Solubility: 100 mM in H<sub>2</sub>O), also known as MAP4 and L-2-amino-4-phosphonobutyrate (L-AP4), is a selective Group III metabotropic glutamate receptor antagonist in some electrophysiological systems, but also acts as Group II/Group III agonist in certain neurochemical systems. MAP4 selectively and competitively antagonizes the depression of monosynaptic excitation produced by L-AP4,  $K_d = 22 \mu\text{M}$  (1). At 10x higher concentrations, MAP4 also antagonizes synaptic depression produced by L-CCG-I, but in an apparently non-competitive manner. MAP4 was virtually without effect on depression produced by (1S,3R)- or (1S,3S)-1-aminocyclopentane-1,3-dicarboxylate (4). Given the fact that mammalian glutamine synthetases bind both D- and L-glutamate as well as accommodate bulky side-chains on the  $\alpha$ -carbon (5), one must consider the likelihood that (S)-2-amino-2-methyl-4-phosphonobutyrate will inhibit glutamine synthetase. Similar considerations may be at play for enzymes catalyzing the oligo-glutamylolation of folates. 1. Knöpfel, Lukic, Leonard, *et al.* (1995) *Neuropharmacology* **34**, 1099. 2. Pharmacol.* **112**, 809. 5. Purich (1998) *Adv. Enzymol.* **72**, 9.

**2-Amino-2-methyl-1,3-propanediol**

This pH-buffer compound (FW<sub>free-base</sub> = 105.14 g/mol; Solubility: 250 g per 100 mL at 20°C; Abbreviation: AMPD) is a structural analogue of the common laboratory buffer known as Tris and is itself an effective buffer ( $pK_a = 8.79$  at 25°C;  $dpK_a/dT = -0.029$ ). **Target(s):** D-arabinose isomerase (1,2); L-fucose isomerase (1,2); sucrose  $\alpha$ -glucosidase, *or* sucrase-isomaltase (3,7); oligo-1,6-glucosidase, *or* isomaltase (7); choline oxidase (4,5); D-serine ammonia lyase (6); amylo- $\alpha$ -1,6-glucosidase/4- $\alpha$ -glucanotransferase, *or* glycogen debranching enzyme (8); acid phosphatase (9); lysine 2-monooxygenase (10). 1. Garrido, Lisa & Domenech (1988) *Mol. Cell. Biochem.* **84**, 41.

**2-Amino-4-methyl-6-propylpyridine**

This substituted pyridine (FW = 150.23 g/mol) is a non-selective inhibitor of nitric-oxide synthase (human inducible, endothelial, and neuronal  $IC_{50} = 0.01, 0.05, \text{ and } 0.01 \mu\text{M}$ , respectively), demonstrating that flipping of the pyridine ring in these new inhibitors allows the piperidine to interact with different residues and confer excellent selectivity. 1. Connolly, Aberg, Arvai, *et al.* (2004) *J. Med. Chem.* **47**, 3320.

**4-Amino-N<sup>10</sup>-methylpteroyl-L-aspartate**

This folic acid analogue (FW<sub>free-acid</sub> = 440.42 g/mol), which is identical to methotrexate, albeit with an aspartate residue in place of a glutamate substituent, is a weak inhibitor of many folate-dependent enzymes. **See also Methotrexate** 1. Baker (1967) *Design of Active-Site-Directed Irreversible Enzyme Inhibitors*, Wiley, New York. 2. Mead, Greenberg, Schrecker, Seeger & Tomcufcik (1965) *Biochem. Pharmacol.* **14**, 105.

**4-Amino-N<sup>10</sup>-methylpteroyl-L-glutamate, See Methotrexate****2-Amino-4-methylpyridine**

This substituted pyridine, (FW = 108.14 g/mol), also known as 2-amino-4-picoline, is a strong inhibitor of inducible ( $K_d = 59$  nM), neuronal ( $K_d = 111$  nM), and endothelial ( $K_d = 136$  nM) nitric oxide synthase. The inducible isozyme within RAW 264.7 cells has an  $IC_{50}$  value of 6 nM. 1. Faraci, Nagel, Verdries, *et al.* (1996) *Brit. J. Pharmacol.* **119**, 1101. 2. Boer, Ulrich, Klein, *et al.* (2000) *Mol. Pharmacol.* **58**, 1026. 3. Connolly, Aberg, Arvai, *et al.* (2004) *J. Med. Chem.* **47**, 3320.

**3-[(2-Amino-6-methyl-3-pyridinyl)methyl-5-(2-hydroxyethyl)-4-methylthiazolium]methyl-5-(2-hydroxyethyl)-4-methylthiazolium Pyrophosphate**

This thiamin pyrophosphate analogue (FW<sub>hydrochloride</sub> = 459.78 g/mol) selectively inhibits transketolase,  $K_i = 33$  nM (1). When tested in nude mice xenografted with HCT-116 tumor cells and dosed with this inhibitor, transketolase activity is almost totally suppressed in blood, spleen, and tumor cells, with little effect on  $\alpha$ -ketoglutarate dehydrogenase or glucose-6-phosphate dehydrogenase, two other thiamine-utilizing enzymes (2). 6-Trifluoromethyl, 6-cyano, 6-ethyl, 6-chloro, and 6-demethyl analogues also inhibit, with  $K_i$  values of 104, 57, 10, 46, and 36 nM, respectively (1). 4-Ethylthiazolium, 4-(hydroxymethyl)-thiazolium, 2-methylthiazolium, 2-ethyl-4-methyl-thiazolium, and 2,4-dimethylthiazolium derivatives show  $K_i$  values of 40, 25, 36, 75, and 25 nM, respectively (1). The 1-(R) stereoisomer is only weakly inhibitory. 1. Esakova, Meshalkina, Golbik, Hübner & Kochetov (2004) *Eur. J. Biochem.* **271**, 4189. 2. Thomas, Le Huerou, De Meese, *et al.* (2008) *Bioorg. Med. Chem. Lett.* **18**, 2206.

**4-Amino-1,8-naphthalimide**

This PARP inhibitor (FW = 212.21 g/mol) is a strong inhibitor of NAD:ADP-ribosyltransferase or poly(ADP-ribose) polymerase ( $IC_{50} = 0.18$   $\mu$ M). In addition, 4-Amino-1,8-naphthalimide is a radiation sensitizer at non-toxic and low concentrations. 1. Thiemermann, Bowes, Myint & Vane (1997) *Proc. Natl. Acad. Sci. U.S.A.* **94**, 679. 2. Banasik, Komura, Shimoyama & Ueda (1992) *J. Biol. Chem.* **267**, 1569. 3. Schlicker, Peschke, Burkle, Hahn & Kim (1999) *Int. J. Radiat. Biol.* **75**, 91.

**4-Amino-N-[4-(3-nitrophenyl)thiazol-2-yl]benzenesulfonamide**

This sulfonamide (FW = 348.40 g/mol) inhibits kynurenine 3-monooxygenase ( $IC_{50} = 40$  nM), blocking rat and gerbil kynurenine 3-hydroxylase after oral administration, with an  $ED_{50}$  value of 3-5  $\mu$ mol/kg in gerbil brain. 1. Röver, Cesura, Huguenin, Kettler & Szente (1997) *J. Med. Chem.* **40**, 4378.

**8-Amino-2'-nordeoxyguanosine**

This nucleoside analogue (FW = 270.25 g/mol), also known as 9-(1,3-dihydroxy-2-propoxymethyl)-8-methylguanine, 2,8-dimethyl-9-(1,3-dihydroxy-2-propoxymethyl)-6-hydroxypurine and 8-aminoganciclovir, is a moderately strong inhibitor of human purine-nucleoside phosphorylase;  $K_i = 0.26$   $\mu$ M. 1. Stein, Stoeckler, Li, *et al.* (1987) *Biochem. Pharmacol.* **36**, 1237.

**L-2-Amino-4-oxo-5-chloropentanoate**

This chloromethyl ketone (FW = 165.58 g/mol), also known as 5-chloro-4-oxo-L-norvaline (CONV), is a glutamine and asparagine analogue that inactivates many glutamine-dependent biosynthetic enzymes by alkylating an active-site cysteinyl residue in the glutamine-hydrolyzing subunit.

**Target(s):** carbamoyl-phosphate synthetase II, glutamine-hydrolyzing (1,5,8,10,15,19); glutamate synthase (2,5);  $\gamma$ -glutamylcysteine synthetase (3,5,6,12,14,26); asparagine synthetase (4, 7,16,17,20-23); anthranilate synthetase (5,18,27); glutaminase (5,11); phosphoribosylformylglycinamide synthetase (5); CTP synthetase (5); glutamine transport (9); aspartate- $\beta$  semialdehyde dehydrogenase (13); GMP synthetase (24); carbamoyl-phosphate synthetase I (25); asparaginase (28); amidophosphoribosyl-transferase (29). 1. **N-[4-[4-(2-Amino-4-oxo-4,7-dihydro-3H-pyrrolo[2,3-d]pyrimidin-6-yl)butyl]benzoyl]-L-glutamate**

This glutamate-containing folate/pemetrexed analogue (FW = 453.46 g/mol) inhibits the *de novo* purine biosynthesis by targeting phosphoribosyl glycinamide formyltransferase ( $IC_{50} = 6.8$  nM). Its combined properties (e.g., selective FR targeting, lack of transport by the reduced folate carrier,

and GARFTase inhibition) making it a promising antitumor agent. 1. Deng, Wang, Cherian, *et al.* (2008) *J. Med. Chem.* **51**, 5052.

**N-[3-[4-Amino-2-oxo-1-(1H-pyrazol-5-ylmethyl)-1,2-dihydropyrimidin-5-yl]prop-2-yn-1-yl]ethanesulfonamide**

This substituted pyrimidine (FW = 337.38 g/mol) inhibits 4-(cytidine-5'-diphospho)-2-C-methyl-D-erythritol kinase, an enzyme in the non-mevalonate pathway for isoprenoid biosynthesis ( $K_i = 1.6 \mu\text{M}$  for the *Mycobacterium tuberculosis* enzyme). 1. Hirsch, Lauw, Gersbach, *et al.* (2007) *ChemMedChem* **2**, 806.

**Aminoxyacetate**

This amino acid analogue (FW<sub>free-acid</sub> = 91.07 g/mol; CAS 645-88-5), also known as aminoxyacetic acid *O*-(carboxymethyl)hydroxylamine, is a good nucleophile that readily reacts with the aldehyde functional group in the vitamin B<sub>6</sub> cofactor pyridoxal 5-phosphate (PLP), thereby inhibiting numerous PLP-dependent systems, especially transaminases (aminotransferases). Like methoxyhydroxylamine, this hydroxylamine analogue also reacts rapidly (<10 seconds) at pH 5 to form complexes having absorption maxima in the 370-390 nm range. 1. Roberts (1952) *J. Biol. Chem.* **198**, 95. 2. Roberts & Simonsen (1963) *Biochem. Pharmacol.* **12**, 113.

**6-Aminopenicillanate**

This  $\beta$ -lactam (FW = 216.26 g/mol; CAS 551-16-6; Abbreviation: 6-APS), also known as 6-aminopenicillanic acid and (2*S*,5*R*,6*R*)-6-amino-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylic acid, is a common starting reagent in the preparation of semi-synthetic penicillins and as an intermediate in the biosynthesis of naturally occurring penicillins. Note that 6-APS possesses no antibiotic activity on its own. 6-Aminopenicillanate is a product of the reaction catalyzed by penicillin amidase. The structure and chemistry of this metabolite was first determined by Ernst Chain, who shared the Nobel Prize in Physiology or Medicine in 1945 for his work on penicillins. **Target(s):** serine-type D-Ala-D-Ala carboxypeptidase, *or* penicillin-binding protein-5 (1,12); D-stereospecific aminopeptidase (2,13); penicillin-binding protein-4 (3);  $\gamma$ -aminobutyrate aminotransferase (4); cytosol alanyl aminopeptidase (5); D-alanine carboxypeptidase (6,8); penicillin amidase (7,9-11). 1. Wilkin (1998) in *Handb. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.), p. 418, Academic Press, San Diego. 2. Asano (1998) in *Handb. **(S)-2-Aminopentane-1,5-dithiol**

This dithiol (FW = 151.30 g/mol), also known as EC27, inhibits membrane alanyl aminopeptidase ( $K_i = 32 \text{ nM}$ ). 1. Zini, Fournie-Zaluski, Chauvel, *et al.* (1996) *Proc. Natl. Acad. Sci. U.S.A.* **93**, 11968. 2. Llorens-Cortes (1998) *C. R. Seances Soc. Biol. Fil.* **192**, 607. 3. Bauvois & Dauzonne (2006) *Med. Res. Rev.* **26**, 88.

**p-Aminophenylarsine Oxide**

This toxic thiol-reactive arsenical, (FW = 183.04 g/mol; CAS 73791-39-6 (for the dehydrate)), also known as reduced Atoxyl, inhibits many enzymes. In 1905, Thomas and Breinl reported the successful use of Atoxyl in the treatment of trypanosomiasis, albeit at high doses. **CAUTION:** Avoid inhalation of dry powder. **Target(s):** D-amino-acid oxidase (1-3);  $\beta$ -amylase (4); choline oxidase (5); cytochrome *c* oxidase (6); lipase (2,3); monoamine oxidase (3); nicotinamide methyltransferase (7); papain (8); pyruvate decarboxylase (3); succinate oxidase (3); urease (9); protein-disulfide isomerase (10); pantetheine hydrolase (11); amylo- $\alpha$ -1,6-glucosidase/4- $\alpha$ -glucano-transferase, *or* glycogen debranching enzyme (12); arginyltransferase (13). 1. **m-Aminophenylboronic Acid**

This arylboronic acid (FW = 136.95 g/mol; CAS 280563-63-5), also known as *m*-aminobenzenboronic acid and *m*-aminophenylboron dihydroxide, inhibits many enzymes, including microbial  $\beta$ -lactamases. Affinity chromatography on *m*-aminophenylboronic acid agarose columns also affords a simple way to measure glycosylated albumin. **Target(s):** lecithin:cholesterol acyltransferase (1); lipase, *or* triacylglycerol lipase (2,3);  $\beta$ -lactamase (4,7,9-11); lipoprotein lipase (5); pantothenase (6,12); ADP-ribosyltransferase (8); pancreatic elastase (13); NAD nucleosidase, *or* NADase (8); peptidyltransferase (14); glycerol-3-phosphate *O*-acyltransferase (15). 1. #### 2-[[[(1-Amino-3-phenylpropyl)hydroxyphosphinyl]methyl]-3-phenylpropionate

This new class of highly potent transition-state analogue (FW = 361.38 g/mol), also known as hPheP[CH<sub>2</sub>]Phe and 2-[[[(1-amino-3-phenylpropyl)hydroxyphosphinyl]methyl]-3-phenylpropionic acid, most likely mimics a catalytically required tetrahedral adduct, thereby inhibiting leucyl aminopeptidase ( $K_i = 66$  nM) and aminopeptidase N ( $K_i = 276$  nM). The X-ray structure of bovine lens leucine aminopeptidase complexed with the phosphonic acid analogue of leucine (LeuP) guided the structure-based design of novel inhibitors and for the analysis of their interactions with the substrate binding site. These inhibitors were designed by modification of phosphonic group in the LeuP structure to account for the docking of substituents located at the S' side of the enzyme. **1.** Grembecka, Mucha, Cierpicki & Kafarski (2003) *J. Med. Chem.* **46**, 2641.

#### 4-(2-Aminophenylthio)butylphosphonate

This phosphonate (FW<sub>free-acid</sub> = 261.28 g/mol), also known as 4-(2-aminophenylthio)butylphosphonic acid, is a transition-state analogue that inhibits *Salmonella typhimurium* tryptophan synthase (IC<sub>50</sub> = 178 nM). This and related inhibitors were designed to mimic the transition state formed during the  $\alpha$ -reaction of the enzyme and, as expected, have affinities much greater than that of the natural substrate indole-3-glycerol phosphate or its nonhydrolyzable analogue indole propanol phosphate (IPP). **1.** Sachpatzidis, Dealwis, Lubetsky, *et al.* (1999) *Biochemistry* **38**, 12665.

#### DL-E-2-Amino-5-phosphono-3-pentenoate

This substituted  $\alpha$ -amino acid (FW<sub>hydrochloride</sub> = 231.57 g/mol) is an irreversible inhibitor of threonine synthase,  $K_i = 0.4$  mM,  $k_{inact} = 0.25$  min<sup>-1</sup> (**1**) and a strong competitive inhibitor of cystathionine  $\gamma$ -synthase,  $K_i = 1.1$   $\mu$ M (**2-4**). The Z-isomer is a stronger inhibitor of *Escherichia coli* threonine synthase. **1.** Laber, Gerbling, Harde, *et al.* (1994) *Biochemistry* **33**, 3413. **2.** Krefl, Townsend, Pohlenz & Laber (1994) *Plant Physiol.* **104**, 1215. **3.** Clausen, Wahl, Messerschmidt, *et al.* (1999) *Biol. Chem.* **380**, 1237. **4.** Steegborn, Laber, Messerschmidt, Huber & Clausen (2001) *J. Mol. Biol.* **311**, 789.

#### N-[[[(2S,3R)-3-Amino-5-phosphono-2-sulfhydryl]pentanoyl]-L-isoleucyl-L-aspartate

This phosphonopeptide (FW = 457.44 g/mol), also known as N-[[[(2S,3R)-3-amino-2-mercapto-5-phosphono]pentanoyl]-L-isoleucyl-L-aspartate, inhibits glutamyl aminopeptidase ( $K_i = 12$  nM), neprilysin ( $K_i = 5.4$  nM), and peptidyl-dipeptidase A ( $K_i = 2200$  nM). The (2R,3R) diastereoisomer also inhibits glutamyl aminopeptidase ( $K_i = 910$  nM). **1.** David, Bischoff, Meudal, *et al.* (1999) *J. Med. Chem.* **42**, 5197.

#### 1-Aminoproline

These N-substituted amino acids (FW = 130.15 g/mol), a component of the naturally occurring vitamin B<sub>6</sub> antagonist linatine (N- $\gamma$ -L-glutamyl)amino-D-proline; CAS 10139-06-7), inactivates D-lysine 5,6-aminomutase, a pyridoxal 5-P/adenosylcobalamin-dependent enzyme that catalyzes the reversible and nearly isoenergetic transformation of D-lysine into 2,5-diaminohexanoate (2,5-DAH) and of l- $\beta$ -lysine into 3,5-diaminohexanoate (3,5-DAH). **1.** Morley & Stadtman (1972) *Biochemistry* **11**, 600. **2.** Stadtman (1972) *The Enzymes*, 3rd ed., **6**, 539.

#### $\beta$ -Aminopropionitrile

This veterinary antirheumatic drug (FW = 70.09 g/mol; CAS 151-18-8; Symbol: BAPN), also known as 2-cyanoethylamine, targets lysyl oxidase (LOX; IC<sub>50</sub> = 10  $\mu$ M), a Cu(II)-containing amine oxidase that catalyzes the oxidation of the  $\epsilon$ -amino group of peptidyl lysine to peptidyl aldehyde, consuming O<sub>2</sub> and H<sub>2</sub>O, and producing ammonia and H<sub>2</sub>O<sub>2</sub> (**1**).  $\beta$ -Aminopropionitrile also decreases tissue colonization by MDA-MB-231-Luc2 cells following their intracardiac administration (**2**). BAPN pretreatment significantly reduces the number of metastases that develop as well as the whole animal tumor burden. The former result suggests that the numbers of cells 'seeding' a given tissue site is reduced by BAPN pretreatment (**2**). When BAPN initiated 3 hours after tumor cell injection, there is less of an inhibition on metastasis development, suggesting that this agent is most effective when it acts on tumor cells and/or host tissues during the initial phase of the extravasation process (**2**).  $\beta$ -aminopropionitrile also attenuates body weight increase and fat mass increase otherwise observed in obese animals, shifting adipocyte size toward smaller adipocytes (**3**). Reference (**4**) describes prodrugs that can release BAPN selectively under hypoxic conditions. *Note:* Because BAPN metabolism yields cyanide, the specificity of this agent may be compromised (**See Cyanide**). **1.** Narayanan, Siegel & Martin (1972) *Biochem. Biophys. Res. Commun.* **46**, 745. **2.** Bondareva, Bondy, Ayres, *et al.* (2009) *PLoS One* **4**, e5620. **3.** Miana, Galán, Martínez-Martínez, *et al.* (2015) *Dis. Model Mech.* **8**, 543. **4.** Granchi, Funaioli, Erler, (2009) *ChemMedChem.* **4**, 1590.

#### N-(3-Aminopropyl)-exo-2-aminonorbornane

This substrate analogue (FW = 169.29 g/mol) inhibits spermine synthase (IC<sub>50</sub> = 0.27  $\mu$ M). The *endo* analogue is a much weaker inhibitor (IC<sub>50</sub> = 10  $\mu$ M). The active site possesses a relatively large hydrophobic cavity lying adjacent to a negatively charged site, to which a protonated amino group of putrescine binds, with another amino group of putrescine being situated in the hydrophobic cavity as a free form to be aminopropylated by decarboxylated S-adenosylmethionine. **1.** Shirahata, Morohohi, Fukai, Akatsu & Samejima (1991) *Biochem. Pharmacol.* **41**, 205. **2.** Shirahata, Takahashi, Beppu, Hosoda & Samejima (1993) *Biochem. Pharmacol.* **45**, 1897.

**2-[(2-[(3-Aminopropyl)amino]phenyl)sulfonyl]amino]-5,6,7,8-tetrahydro-1-naphthalenecarboxylic Acid**

This orally active anthranilic acid sulfonamide (FW = 403.50 g/mol) reversibly inhibits methionyl aminopeptidase ( $IC_{50}$  = 13 nM), showing good cellular activity in both proliferation and methionine processing assays. 1. Sheppard, Wang, Kawai, *et al.* (2006) *J. Med. Chem.* **49**, 3832.

**N-(3-Aminopropyl)-1,4-diaminobut-2-ene**

This spermidine analogue (FW<sub>free-base</sub> = 144.24 g/mol) inhibits human deoxyhypusine synthase (EC 2.5.1.46), the enzyme that catalyzes the posttranslational modification of in Eukaryotic Translation Initiation Factor 5A-1, converting a lysyl residue into deoxyhypusine [*or* *N*-(4-amino-2-hydroxybutyl)-lysine]. The synthase transfers the 4-aminobutyl moiety from spermidine to a specific lysine residue in the eIF5A precursor protein, forming the deoxyhypusine-containing eIF5A intermediate. Both the *cis* and *trans* isomers of *N*-(3-aminopropyl)-1,4-diaminobut-2-ene are inhibitory. 1. Park, Wolff, Folk & Park (2003) *J. Biol. Chem.* **278**, 32683.

**N,N-(3-Aminopropyl)-D-glucoamidine**

This glucose analogue (FW = 232.26 g/mol) inhibits  $\alpha$ -mannosidase ( $K_i$  = 90 nM),  $\beta$ -mannosidase ( $K_i$  = 0.41  $\mu$ M),  $\alpha$ -glucosidase ( $K_i$  = 14  $\mu$ M),  $\beta$ -glucosidase ( $K_i$  = 71  $\mu$ M),  $\alpha$ -galactosidase ( $K_i$  = 44  $\mu$ M),  $\beta$ -galactosidase ( $K_i$  = 44  $\mu$ M),  $\alpha$ -fucosidase ( $K_i$  = 91  $\mu$ M), and  $\beta$ -*N* acetylhexosaminidase ( $K_i$  = 252  $\mu$ M). Its likely mode of action is that protonation of the ring nitrogen forms a positively charged mimic of oxocarbenium ion intermediates formed in enzyme-catalyzed hydrolysis of glycosides. 1. Heck, Vincent, Murray, *et al.* (2004) *J. Amer. Chem. Soc.* **126**, 1971.

**5-(2-Aminopropyl)indole**

This psychoactive stimulant (FW = 174.25 g/mol; CAS 3784-30-3; *Symbol*: 5-IT) is a recreationally abused substance associated with fatal and non-fatal intoxications, showing acute symptoms of monoaminergic (*e.g.* serotonin) toxicity, resulting from increased circulating serotonin levels (1,2). 5-IT targets the type A isozyme of human monoamine oxidase, *or* MAO-A ( $IC_{50}$  = 1.6  $\mu$ M and  $K_i$  = 0.25  $\mu$ M), whereas MAO-B inhibition is not observed, even at 500  $\mu$ M (2). For reference, clorgyline, harmaline, toloxatone, and moclobemide have  $IC_{50}$  values of 16 nM, 20 nM, 6.7  $\mu$ M and >500  $\mu$ M. In Sweden, 5-IT is scheduled as a hazardous substance

(September, 2012), with prohibitions on possession and sale. Its isomer, 3-(2-aminopropyl)indole (*or*  $\alpha$ -methyltryptamine, AMT) may represent yet another factor in 5-IT toxicity. 1. Coppola & Mondola (2013) *Am. J. Psychiatry* **170**, 226. 2. Herraiz & Brandt (2013) *Drug Test Anal.* **6**, 607.

**6-Amino-9-D-psicofuranosylpurine, See Psicofuranine**

**Aminopterin**

This folate antagonist (FW<sub>free-acid</sub> = 440.42 g/mol; CAS 54-62-6; Solubility: 50 mg/mL in 2 M NaOH (store for 1-2 days at 4°C)), also known as 4-amino-4-deoxyfolate and 4-aminofolate, was the first antifolate drug used clinically in the treatment of acute lymphoblastic leukemia, beginning in the late 1940s. (**See also Methotrexate**) Upon transport into cells via the folate transporter, aminopterin is polyglutamylated, which in turn, inhibits dihydrofolate reductase. Although considerably more potent than methotrexate, aminopterin is also far more toxic. Indeed, aminopterin has been used as a rodenticide. Aminopterin-polyglutamate is degraded intracellularly by  $\gamma$ -glutamyl hydrolase. **Target(s):** dihydrofolate reductase (1-6,23,32); dihydropterine reductase (7,9); dihydropterine reductase, NADPH-dependent (8); GTP cyclohydrolase I, weakly inhibited (10); NAD(P)H dehydrogenase, quinone-dependent (11); NADPH dehydrogenase, quinone-dependent (11); glutamate dehydrogenase (12); lactate dehydrogenase (12); malate dehydrogenase (12); serine hydroxymethyltransferase, *or* glycine hydroxymethyl-transferase (13,31); mandelate 4-monooxygenase (14); phenylalanine 4-monooxygenase (15); xanthine oxidase (16,17,21); choline oxidase (19); purine-nucleoside phosphorylase (22); formimidoyltetrahydrofolate cyclodeaminase (24); sepiapterin deaminase (25,26); methenyltetrahydrofolate cyclohydrolase, weakly inhibited (27); methionyl-tRNA formyltransferase (28); deoxycytidylate 5-hydroxymethyltransferase (29); glutamate formimidoyltransferase (30); thymidylate synthase (32-36); anthranilate 3-monooxygenase (37); benzoate 4-monooxygenase, weakly inhibited (38). 1. ## 2-Aminopurine

This substituted purine (FW = 135.13 g/mol) is a mutagen for many organisms. It is metabolized to 2-aminopurine-2'-deoxyriboside 5'-triphosphate and incorporated into DNA. Aminopurine is also a competitive inhibitor with respect to ATP of double-stranded RNA-dependent protein kinase. **Target(s):** adenosine deaminase (1); double-stranded RNA-dependent protein kinase (2-5); Ca<sup>2+</sup>/calmodulin-dependent protein kinase (6); casein kinase (7); nonspecific serine/threonine protein kinase (7); methionine *S*-adenosyltransferase, weakly inhibited (8); hypoxanthine(guanine) phosphoribosyltransferase (9); xanthine phosphoribosyltransferase (9). 1. Akedo, Nishihara, Shinkai, Komatsu & Ishikawa (1972) *Biochim. Biophys. Acta* **276**, 257. 2. De Benedetti, Williams & Baglioni (1985) *J. Virol.* **54**, 408. 3. De Benedetti & Baglioni (1983) *J. ## 2-Aminopurine 9-β-D-Ribofuranoside

This adenosine analogue (FW = 267.24 g/mol), also known as 2-amino-9-β-D-ribofuranosylpurine, inhibits adenosine deaminase,  $K_i = 4 \mu\text{M}$  (1) and adenosine kinase (2). The latter is a key intracellular enzyme regulating intracellular and extracellular concentrations of adenosine (ADO), itself an powerful endogenous modulator of intercellular signalling that reduces cell excitability during tissue stress and trauma. 1. Simon, Bauer, Tolman & Robins (1970) *Biochemistry* **9**, 573. 2. Miller, Adamczyk, Miller, *et al.* (1979) *J. Biol. Chem.* **254**, 2346.

## 8-Aminopurine 9-β-D-Ribofuranoside

This nucleoside (FW = 267.24 g/mol) inhibits adenosine kinase, a purine salvage enzyme that phosphorylates adenosine to AMP. In *Mycobacterium tuberculosis*, adenosine kinase also catalyzes an essential step in the conversion of 2-methyl-Ado to a compound with selective antimycobacterial activity. This study revealed the presence of a hydrophobic pocket near the N<sup>6</sup>- and N<sup>1</sup>-positions that can accommodate substitutions at least as large as a benzyl group. 1. Long & Parker (2006) *Biochem. Pharmacol.* **71**, 1671.

## N-((E)-3-[(2R,3S,4R,5R)-5-(6-Amino-6H-purin-9-yl)-3,4-dihydroxytetrahydrofuran-2-yl]prop-2-enyl)-2,3-dihydroxy-5-nitrobenzene-1-carboxamide

This bisubstrate analogue (FW = 473.40 g/mol) inhibits catechol *O*-methyltransferase (IC<sub>50</sub> = 9 nM), a druggable target for the treatment of Parkinson's Disease. There is a large dependence of binding affinity on inhibitor preorganisation and the length of the linker between nucleoside and catechol moieties. This bisubstrate analogue exhibits competitive kinetics for the SAM and mixed inhibition kinetics for the catechol binding site. Its bisubstrate binding mode was confirmed by X-ray structure analysis of the ternary complex formed by the inhibitor, COMT and a Mg<sup>2+</sup> ion. 1. Lerner, Masjost, Ruf, *et al.* (2003) *Org. Biomol. Chem.* **1**, 42.

## Aminopurvalanol A

This cell-permeable purvalanol derivative (FW = 403.92 g/mol), also named (2*R*)-2-[[[6-[(3-Amino-5-chlorophenyl)amino]-9-(1-methylethyl)-9*H*-purin-2-yl]amino]-3-methyl-1-butanol], targets cdk1/cyclin B (IC<sub>50</sub> = 0.033 μM), cdk2/cyclin A (IC<sub>50</sub> = 0.033 μM), cdk2/cyclin E (IC<sub>50</sub> = 0.028 μM), and cdk5/p35 (IC<sub>50</sub> = 0.020 μM). It also inhibits ERK1 (IC<sub>50</sub> = 12 μM) and ERK2 (IC<sub>50</sub> = 3.1 μM), with 3000-times greater selectivity versus a range of other protein kinases (IC<sub>50</sub> > 100 μM). Aminopurvalanol A arrests cell cycle at G<sub>2</sub>/M boundary (IC<sub>50</sub> = 1.25 μM), and induces apoptosis at concentrations > 10 μM (1). 1. Gompel, Soulié, Ceballos-Picot & Meijer (2004) *Neurosignals* **13**, 134. 2. Rosania, Merlie, Gray, *et al.* (1999) *Proc. Natl. Acad. Sci. U.S.A.* **96**, 4797. 3. Lu & Schulz-Gahnen (2006) *J. Med. Chem.* **49**, 3826.

## 4-Aminopyrazolo[3,4-d]pyrimidine

This adenine/allopurinol analogue (FW = 135.18 g/mol; CAS 2380-63-4) is taken up by many cells, where it is transformed into its corresponding nucleoside 5'-mono-, di, and tri-phosphates. **Target(s):** adenine phosphoribosyltransferase, alternative substrate (1); xanthine oxidase (2,5); ribosomal-inactivating proteins RNA-*N*-glycosidase activity (*e.g.*, Shiga toxin I, ricin, gelonin, *etc.*) (3); adenine deaminase (4). 1. Dewey & Kidder (1977) *Can. J. Biochem.* **55**, 110. 2. Sheu, Lin & Chiang (1997) *Anticancer Res.* **17**, 1043. 3. Brigotti, Rizzi, Carnicelli, L. Montanaro & S. Sperti (2000) *Life Sci.* **68**, 331. 4. Jun & Sakai (1979) *J. Ferment. Technol.* **57**, 294. 5. Hsieh, Wu, Yang, Choong & Chen (2007) *Bioorg. Med. Chem.* **15**, 3450.

## 4-Aminopyridine

This substituted pyridine (FW = 94.116 g/mol; CAS Registry Number = 504-24-5; M.P. = 158-159°C), also known as fampridine, inhibits chymotrypsin and is also a K<sup>+</sup> channel blocker. 4-Aminopyridine is used in the treatment of multiple sclerosis. **Target(s):** chymotrypsin,  $K_i = 2.9 \text{ mM}$  (1); K<sup>+</sup> channels, *or* Kv channels (2,3,5-11); Ca<sup>2+</sup> transporting ATPase (4); steroid 11β-monooxygenase (12); Na<sup>+</sup> channels (13). 1. Pharmacol.* **207**, 275.

### 3-Aminopyridine Adenine Dinucleotide

This NAD<sup>+</sup> analogue (FW = 636.43 g/mol) inhibits numerous dehydrogenases and NAD<sup>+</sup>-dependent enzymes, including NAD<sup>+</sup> nucleosidase, or NADase (1,3,4), alcohol dehydrogenase (2,3), lactate dehydrogenase (3), glucose-6-phosphate dehydrogenase, weakly inhibited (3), and malate dehydrogenase (3). 1. Anderson & Yuan (1980) *Meth. Enzymol.* **66**, 144. 2. Brändén, Jörnvall, Eklund & Furugren (1975) *The Enzymes*, 3rd ed., **11**, 103. 3. Fisher, Vercellotti & Anderson (1973) *J. Biol. Chem.* **248**, 4293. 4. Muller-Steffner, Slama & Schuber (1996) *Biochem. Biophys. Res. Commun.* **228**, 128.

### 3-Aminopyridine Adenine Dinucleotide Phosphate

This NADP<sup>+</sup> analogue (FW = 716.41 g/mol) inhibits a number of NADP<sup>+</sup>-dependent dehydrogenases, including glucose-6-phosphate dehydrogenase (1), methenyl-tetrahydrofolate cyclohydrolase (2), phenylacetone monooxygenase (3; 4), and hydroxyacetophenone monooxygenase (4,5). 1. Anderson, Yuan & Vercellotti (1975) *Mol. Cell. Biochem.* **8**, 89. 2. Pelletier & MacKenzie (1994) *Biochemistry* **33**, 1900. 3. Fraaije, Kamerbeek, Heidekamp, Fortin & Janssen (2004) *J. Biol. Chem.* **279**, 3354. 4. van den Heuvel, Tahallah, Kamerbeek, *et al.* (2005) *J. Biol. Chem.* **280**, 32115. 5. Kamerbeek, Fraaije & Janssen (2004) *Eur. J. Biochem.* **271**, 2107.

### 6-(6-Aminopyridin-3-ylethynyl)-5-(4-chlorophenyl)-pyrimidin-4-ylamine

This pyrimidine (FW = 321.77 g/mol) inhibits cytosolic adenosine kinase, IC<sub>50</sub> = 14 nM. Adenosine levels increase at seizure foci as part of a negative feedback mechanism that controls seizure activity through adenosine receptor signaling. Agents that inhibit adenosine kinases increase/sustain site/event-specific adenosine surges, thereby providing anti-seizure activity akin to that of adenosine receptor agonists, but with fewer dose-

limiting cardiac side effects. 1. Matulenko, Paight, Frey, *et al.* (2007) *Bioorg. Med. Chem.* **15**, 1586.

### 3-[[6-Amino-3-pyridinyl)methyl-5-(2-hydroxyethyl)-4-methylthiazolium Chloride Pyrophosphate

This pyridine analogue of thiamin pyrophosphate (FW<sub>chloride</sub> = 433.75 g/mol) inhibits transketolase (K<sub>i</sub> = 7 nM). 2-Amino-3-pyridinyl and 4-amino-3-pyridinyl analogues are slightly weaker inhibitors (K<sub>i</sub> = 36 and 64 nM, respectively). Transketolase activity was almost completely suppressed in blood, spleen, and tumor cells, but there was little effect on the activity of the other thiamine-utilizing enzymes α-ketoglutarate dehydrogenase or glucose-6-phosphate dehydrogenase. 1. Thomas, Le Huerou, De Meese, *et al.* (2008) *Bioorg. Med. Chem. Lett.* **18**, 2206.

### 6-Amino-2-[[quinolin-4-ylmethyl)amino]-8H-imidazo[4,5-g]quinazolin-8-one

This substrate analogue (FW = 357.38 g/mol) inhibits tRNA-guanine transglycosylase (K<sub>i</sub> = 27 nM) a newly recognized target for disease-causing *Shigella* bacteria. Crystallographic and pK<sub>a</sub> data suggest that the aminoimidazole moiety of the central *lin*-benzoguanine scaffold is protonated and binding is stabilized by charge-assisted hydrogen bonding. 1. Hörtnert, Ritschel, Stengl, *et al.* (2007) *Angew. Chem.* **46**, 8266.

### 2-Amino-5-(β-D-ribofuranosyl)-2,5-dihydro[1,5,2]diazaphosphorin-6(1H)-one 2-oxide

This phosphopyrimidine nucleoside (FW = 279.19 g/mol) is a potent, slow-binding inhibitor of *Escherichia coli* cytidine deaminase, most likely by mimicking a pentavalent associative transition-state species bearing both the in-coming nucleophile and its nascent exiphile. 1. Ashley & Bartlett (1984) *J. Biol. Chem.* **259**, 13621. 2. Ashley & Bartlett (1982) *Biochem. Biophys. Res. Commun.* **108**, 1467.

### 4-Aminosalicylate

This aromatic acid (FW<sub>free-acid</sub> = 153.14 g/mol; CAS 2066-89-9; *Abbreviation*: PAS), also known by the trade name Paser<sup>®</sup> as well as 4-aminosalicylic acid or *p*-aminosalicylic acid, is an analogue of *p*-aminobenzoate, an essential intermediate in the bacterial folate synthesis. PAS potentially inhibits the growth of *Mycobacterium bovi*, *M. smegmatis*, and *M. tuberculosis*. It is also used for the treatment of such inflammatory bowel diseases as ulcerative colitis and Crohn's disease, most likely by

inhibiting NF- $\kappa$ B. **Primary Mode of Antimicrobial Action:** Although in use clinically for over 60 years, *p*-aminosalicylate's inhibitory mechanism had proved elusive. Recent studies, however, demonstrated that PAS is prodrug, one that targets dihydrofolate reductase, or DHFR (1). PAS is first converted by dihydropteroate synthase (DHPS) and dihydrofolate synthase (DHFS) to a hydroxyl-dihydrofolate antimetabolite, which in turn inhibits DHFR. PAS is about as efficient a DHPS substrate as its natural substrate pABA, and inhibition of DHPS or mutation in DHFS prevents the formation of the antimetabolite and confers resistance to PAS.

***N*-[[(2*S*,3*R*)-3-Amino-2-sulfhydryl-5-sulfonate]pentanoyl]-L-isoleucyl-L-aspartate**

This peptide analogue (FW = 441.53 g/mol; *N*-{[(2*S*,3*R*)-3-amino-2-mercapto-5-sulfonate]pentanoyl}-L-isoleucyl-L-aspartate) inhibits glutamyl aminopeptidase ( $K_i = 3.2$  nM), neprilysin ( $K_i = 22$  nM), and peptidyl-dipeptidase A ( $K_i = 1200$  nM). The (2*R*,3*S*)-, (2*S*,3*S*)-, and (2*R*,3*R*)-diastereoisomers also inhibit glutamyl aminopeptidase ( $K_i = 50, 20,$  and  $53$  nM, respectively). The (2*S*,3*S*)-isomer also weakly inhibits membrane alanyl aminopeptidase ( $K_i = 23$   $\mu$ M). Replacing the L-isoleucyl residue with its D-enantiomer weakens the inhibition ( $K_i = 14.7$  nM for the (2*S*,3*R*)-isomer and glutamyl aminopeptidase). The analogue containing D-aspartate is a strong inhibitor of glutamyl aminopeptidase ( $K_i = 5.36$  nM).  $\alpha$ -L-Aspartamide analogues are weaker inhibitors ( $K_i = 15$  nM for the (2*S*,3*R*)-isomer and glutamyl aminopeptidase). 1. David, Bischoff, Meudal, *et al.* (1999) *J. Med. Chem.* **42**, 5197.

**5-Aminosulfonyl-1-(3,4-dichlorobenzyl)isatin 3-(*O*-Acetyl)oxime**

This acylated isatin oxime (FW = 442.28 g/mol) inhibits ubiquitin thiolesterase ( $IC_{50} = 12$   $\mu$ M), an enzyme linked to Parkinson Disease, progression of certain nonneuronal tumors, as well as neuropathic pain. Certain lung-derived tumor cell lines express the enzyme, which it is not expressed in normal lung tissue. 1. Liu, Lashuel, Choi, *et al.* (2003) *Chem. Biol.* **10**, 837.

**9-Amino-1,2,3,4-tetrahydroacridine**

This acetylcholinesterase inhibitor (FW<sub>free-base</sub> = 198.27 g/mol; CAS 321-64-2 and 1684-40-8 (HCl)), also known as Tacrine and 1,2,3,4-tetrahydro-5-aminoacridine, was the first orally available, centrally-acting cholinesterase inhibitor approved for the treatment of Alzheimer's disease. Its use in the U.S. was discontinued out of concerns about its side effects, mainly hepatotoxicity and gastrointestinal discomfort. This agent is also a likely DNA intercalator. **Target(s):** acetylcholinesterase,  $K_i = 25$  nM (1-3,6,8,12-17); cholinesterase, or butyrylcholinesterase (2,3,5,6,13,15,16); aldehyde oxidase (4); ion channels (7);  $K^+$  current (8,9); histamine *N*-methyltransferase (10,18-20); apyrase, or ATP diphosphohydrolase (11); aryl-acylamidase (13). 1. Harel, Schalk, Ehret-Sabatier, *et al.* (1993) *Proc.*

**2-Aminotetralin**

This conformationally constrained cyclohexylamine (FW = 147.22 g/mol; CAS 2954-50-9, 1743-01-7 (HCl), 21880-87-5 (*S*-isomer), 21966-60-9 (*R*-isomer)), also called  $\beta$ -tetrahydronaphthylamine, and its many derivatives are inhibitors of serotonin and norepinephrine transport and likely induces their release as well. **Target(s):** monamine oxidase, or amine oxidase (1); 5-hydroxytryptamine transport (2); norepinephrine transport (2,3); phenylethanolamine *N*-methyltransferase (4). 1. Blaschko (1963) *The Enzymes*, 2nd ed., **8**, 337. 2. Bruinvels (1971) *Brit. J. Pharmacol.* **42**, 281. 3. Knepper, Grunewald & Rutledge (1988) *J. Pharmacol. Exp. Ther.* **247**, 487. 4. **17-(2-Amino-4-thiazolyl)androsta-5,16-dien-3 $\beta$ -ol**

This synthetic steroid (FW<sub>free-base</sub> = 370.56 g/mol) inhibits 17 $\alpha$ -hydroxyprogesterone aldolase, or steroid C17(20) lyase, or Cytochrome P450 17A1 ( $IC_{50} = 63$  nM (1), key enzyme in the steroidogenic pathway that produces progestins, mineralocorticoids, glucocorticoids, androgens, and estrogens, as well as steroid 17 $\alpha$ -monooxygenase (2). These studies confirmed that steroids bearing a heteroaromatic substituent at C-17 were designed as inhibitors of C17(20) lyase. 1. Burkhart, Gates, Laughlin, Resvick & Peet (1996) *Bioorg. Med. Chem.* **4**, 1411. 2. Njar & Brodie (1999) *Curr. Pharm. Des.* **5**, 163.

**3-Amino-1-(3-trifluoromethyl)phenyl-2-pyrazoline**

This substituted pyrazoline (FW = 229.20 g/mol), also known as 4,5-dihydro-1-[3-(trifluoromethyl)phenyl]-1*H* pyrazol-3-amine and BW755C, inhibits both the cyclooxygenase and lipoxygenase pathways. **Target(s):** 12-lipoxygenase, or arachidonate 12-lipoxygenase; (1, 3,13,14; however, see 8); cyclooxygenase, or prostaglandin-endoperoxide synthase (2,6,8);

lipoxygenase (4,5,15); 5-lipoxygenase, *or* arachidonate 5-lipoxygenase (2,7-12); 15-lipoxygenase, *or* arachidonate 15-lipoxygenase (8). **1.** Koshishara, Murota, Petasis & Nicolaou (1982) *FEBS Lett.* **143**, 13. **2.** Coutts, Khandwala & Vaninwegen (1985) in *Prostaglandins, Leukotrienes, and Lipoxins* (Bailey, ed.), pp. 627-637, Plenum Press, New York. **3.** Higgs, Flower & Vane (1979) *Biochem. ### Amiodarone

This photosensitive benzofuran (FW<sub>free-base</sub> = 645.32 g/mol; CAS 19774-82-4 (HCl)), also known as Nexterone and systematically as (2-{4-[(2-butyl-1-benzofuran-3-yl)carbonyl]-2,6-diiodophenoxy}ethyl)diethylamine, is a non-selective ion channel blocker and an  $\alpha$ - and  $\beta$ -adrenergic receptor agonist and antiarrhythmic agent used for various types of cardiac dysrhythmias, both ventricular and atrial. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** Na<sup>+</sup> channels (1); phospholipase A<sub>1</sub> (2); calmodulin-dependent action (3-5); protein kinase C (4); Ca<sup>2+</sup> channels (6,10,16); carnitine palmitoyltransferase (17); K<sup>+</sup> channels (8,9,15); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (11,12); lysosomal phospholipases (13); phospholipase A<sub>2</sub> (14,18); phospholipase C (14); cholesterol  $\Delta$ -isomerase, *or* sterol  $\Delta^{7,8}$ -isomerase (17); phosphatidylglycerol-selective phospholipase A<sub>2</sub> (18); retinyl ester hydrolase (19). **1.** Revenko, Khodorov & Avrutskii (1980) *Biull. ### Amiton

This toxic organothiophosphate (FW<sub>free-base</sub> = 269.35 g/mol; CAS 78-53-5), also known as Tetram and *O,O*-diethyl-*S*-(2 diethylaminoethyl) phosphorothiolate, inhibits acetylcholinesterase and has been used as an insecticide. Amiton has also been classified as a chemical warfare agent and has been given the designation VG. **CAUTION:** Extreme care must be exercised in handling this agent. A single drop on the skin is often lethal. There are no confirmed reports of amiton having been used in combat. **Target(s):** acetylcholinesterase (1-6); butyrylcholinesterase (6,7). **1.** Froede & Wilson (1971) *The Enzymes*, 3rd ed., **5**, 87. **2.** Bracha & O'Brien (1968) *Biochemistry* **7**, 1545. **3.** Aharoni & O'Brien (1968) *Biochemistry* **7**, 1538. **4.** Ellison (2000) *Handbook of Chemical and Biological Warfare Agents*, CRC Press, Boca Raton. **5.** Iverson & Main (1969) *Biochemistry* **8**, 1889. **6.** Main (1969) *J. ### Amitriptyline

This tricyclic antidepressant (FW<sub>free-base</sub> = 277.41 g/mol; CAS 50-48-6 (free base) and 549-18-8 (hydrochloride)), marketed under Tryptomer, Elavil, Tryptizol, Laroxyl, Saroten, Sarotex, Lentizol, Endep, and systematically named 3-(10,11-dihydro-5*H*-dibenzo[*a,d*]cycloheptene-5-ylidene)-*N,N*-dimethylpropan-1-amine, is widely used to treat depressive disorders, anxiety disorders, attention deficit hyperactivity disorder, migraine prophylaxis, eating disorders, bipolar disorder, post-herpetic neuralgia, and insomnia. The pK<sub>a</sub> = 9.4, and its hydrochloride salt is freely soluble in water. (See *Mianserin*) **Target(s):** Ca<sup>2+</sup>-dependent cyclic nucleotide phosphodiesterase (1); monoamine oxidase (2,8); norepinephrine transporter (3,4); serotonin reuptake (4-6); K<sup>+</sup> channels (7,10,11); Na<sup>+</sup> channels, voltage dependent (9,13,14); butyrylcholinesterase, *or* cholinesterase (12); glucuronosyltransferase (15). **1.** Hidaka, Inagaki, Nishikawa & Tanaka (1988) *Meth. ### Amlodipine

This long-acting, dihydropyridine-class calcium channel blocker (FW = 408.88 g/mol; CAS 88150-42-9), also known by the trade name Norvasc<sup>TM</sup> is an antihypertensive agent indicated for the treatment of angina pectoris. **Primary Mode of Action:** Amlodipine acts by relaxing arterial wall smooth muscle, thereby decreasing total resistance in peripheral circulation and lowering blood pressure. Amlodipine toxicity is the leading cause of drug overdose, often leading to profound hypotension and shock. **Pharmacokinetics:** Intravenous amlodipine administration (single dose = 10

mg) results in a mean plasma  $t_{1/2}$  of 34 hours, with a mean clearance of 7 mL min<sup>-1</sup>kg<sup>-1</sup> and a mean apparent volume of distribution of 21 L/kg (1). Oral administration of single 10-mg dose gives a mean systemic availability of 64% and a mean plasma half-life of 36 hours. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Faulkner, McGibney, Chasseaud, Perry & Taylor (1986) *Brit. J. Clin. Pharmacol.* **22**, 21.

### Ammonia (Ammonium Ion)

This important nitrogenous metabolite (FW = 17.031 g/mol) is extremely soluble in water, with which it readily forms hydrogen bonds, often abstracting a proton to become ammonium ion (Ionic Radius = 1.43 Å). Although aqueous ammonia solutions are commonly called ammonium hydroxide solutions, NH<sub>4</sub>OH is unlikely to exist to any significant degree. In fact, a 1 M ammonia solution only contains 0.0042 M ammonium and hydroxide ions. Because  $pK_a = 14 - pK_b$ , the  $pK_a$  for the reaction of ammonium ion with water to yield ammonia and water is 9.25 ( $K_a = 5.62 \times 10^{-10}$  M). Ammonia protonation and ammonium ion deprotonation occur on the sub-nanosecond timescale, as first demonstrated in the chemical relaxation experiments by Nobelist Manfred Eigen. Ammonia is also an excellent nucleophile, and the rapidity of forming and breaking hydrogen bonds in aqueous solution permits ammonia to react well with electrophilic centers in nucleophilic displacement reactions. Ammonium ion itself is inert in nucleophilic reactions. At normal blood pH ( $\approx 7.4$ ), nearly 99% of all circulating ammonia is in the ammonium ion form. Ammonium ion is converted to glutamine in the glutamine synthetase reaction, which serves to deprotonate this metabolite at neutral pH. Enzymes requiring reactive ammonia then hydrolyze the  $\gamma$ -amide of glutamine to generate what is called "nascent ammonia". Such enzymes possess an endogenous glutaminase activity that is usually tightly coupled by means of an ammonia transfer tunnel to ammonia consumption in subsequent biosynthetic reaction steps, thereby avoiding futile hydrolysis of this amid nitrogen donor. Protected transfer of nascent ammonia is accomplished by a tunnel that excludes water and proton donors. For humans, ammonia toxicity refers to the effects on the brain that arise due to depletion of  $\alpha$ -keto-glutarate (by means of the glutamate dehydrogenase (NADPH-dependent) and glutamine synthetase reactions) and the collapse of certain transmembrane proton gradients when circulating ammonia rises above 0.5 mM. Although ammonia and ammonium ions inhibit over two hundred enzyme-catalyzed reactions, none are listed here. Such effects are generally nonphysiologic, characterized by millimolar inhibition constants.

**AMN107, See Nilotinib**

### Amodiaquine

This antimalarial and anti-inflammatory agent (FW = 355.87 g/mol; CAS 86-42-0), also known by the trade names Camoquin<sup>®</sup> and Flavoquine<sup>®</sup> as well as its systematic name 4-[(7-chloroquinolin-4-yl)amino]-2-[(diethylamino)methyl]phenol, is more effective than in inhibiting chloroquine-resistant *Plasmodium falciparum* infections. Amodiaquine binds to the parasite DNA, preventing replication, transcription, and translation. It is active against the asexual erythrocytic forms of *Plasmodium* species. While not marketed in the United States, amodiaquine is widely available in Africa. **See Artemisinin; Chloroquine**

### Amoxicillin

This semi-synthetic, moderate-spectrum  $\beta$ -lactam antibiotic (FW = 365.40 g/mol; CAS 26787-78-0; Abbreviation: Amox) also known as 2*S*,5*R*,6*R*)-6-[[[(2*R*)-2-amino-2-(4-hydroxyphenyl)-acetyl]amino]-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-24-carboxylate, is bacteriolytic at 10  $\mu$ g/mL, or less, for many bacterial pathogens, including *Streptococcus*, *Bacillus subtilis*, *Enterococcus*, *Haemophilus*, *Helicobacter*, and *Moraxella*. Clinically, amoxicillin is effective in eradicating bacteriuria due to susceptible organisms and is well tolerated (1). Its stability in gastric acid and rapid uptake after oral administration commend its use for treating *Helicobacterium pylori*, the major causative agent in the occurrence of peptic ulcers and gastric cancer in humans. Treatment typically involves a two- or three-antibiotic cocktail that almost always includes amoxicillin. **Mode of Inhibitory Action:** Amoxicillin binds to Penicillin-Binding Protein 1*A*, or PBP-1*A*, which is situated inside the bacterial cell wall. Like many other  $\beta$ -lactam antibiotics, amoxicillin acylates the penicillin-sensitive transpeptidase C-terminal domain, a process attended by  $\beta$ -lactam ring opening. Enzyme inactivation blocks cross-link formation between nearby linear peptidoglycan strands, thereby inhibiting bacterial cell wall synthesis, with subsequent lysis mediated by autolysins. **Amoxicillin Resistance:** Certain bacteria (e.g., *Citrobacter*, *Klebsiella* and *Pseudomonas aeruginosa*) are highly resistant to amoxicillin, and *Escherichia coli* and most clinical isolates of *Staphylococcus aureus* have already developed resistance to amoxicillin to varying degrees. Amox resistance is typically multifactorial, as illustrated for the case of *H. pylori* (2). Progression of spontaneous genetic mutations contributing to *H. pylori* resistance, when exposed to increasing amoxicillin concentrations *in vitro*, revealed that mutations in a number of genes (notably *pbp1*, *pbp2*, *hefC*, *hopC*, and *hofH*). Five isolates, each expressing multiple mutated genes, and four transformed strains expressing individually mutated *pbp1*, *hefC*, or *hofH*, were characterized using minimum inhibitory concentrations, amoxicillin uptake, and efflux studies (2). Mutations in *pbp1*, *hefC*, *hopC*, *hofH*, and possibly *pbp2* contribute to high-level amoxicillin resistance in *H. pylori*. Such findings indicate the complex evolution of amoxicillin resistance, with certain families of genes appearing to be more susceptible to resistance mutations (2). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Handsfield, Clark, Wallace, Holmes & Turck (1973) *Antimicrob. Agents Chemother.* **3**, 262. 2. Qureshi, Gallaher & Schiller (2014) *Microb. Drug Resist.* **20**, 509.

**AMPCPP, See  $\alpha,\beta$ -Methyleneadenosine 5'-Triphosphate**

**AMPD, See 2-Amino-2-methyl-1,3-propanediol**  
**Amphetamine**

This psychostimulant and drug (FW<sub>free-base</sub> = 135.21 g/mol; CAS 300-62-9 (free base) and 60-13-9 (sulfate (2:1))), also known as 1-phenyl-2-aminopropane and by its IUPAC name (2*S*)-1-phenylpropan-2-amine, increases one's sense of wakefulness and improves focus, with attendant decreases in fatigue and appetite. Amphetamine inhibits catecholamine release, inhibits monoamine oxidase, and acts as an adrenergic receptor agonist. The salt (e.g., the hydrochloride) is very soluble in water. (*Note:* The terms dextroamphetamine and dexamphetamine refer to the (+)-(*S*)-enantiomer, the more physiologically active form of the two stereoisomers.) **Mechanism of Amphetamine Action:** To regulate the extracellular dopamine, the presynaptic dopamine transporter (DAT)

utilizes the chemiosmotic energy of the  $\text{Na}^+/\text{Cl}^-$  gradient to drive the reuptake of released dopamine, thereby conserving dopamine and decreasing the need for *de novo* synthesis of dopamine to replenish vesicular dopamine stores. In the Facilitated Exchange Diffusion Model, dopamine efflux results from the translocation of amphetamine into the cell, which is attended by outward movement of dopamine into the extracellular space. In the Vesicle Depletion Model, amphetamine induces dopamine reverse transport by elevating the cytoplasmic its concentration, thus altering the transmembrane dopamine gradient. Amphetamine and similarly acting drugs compete with dopamine for uptake and also induce DAT-mediated dopamine efflux. **Caution:** In view of its so-called performance-enhancing effects, amphetamine has become a recreational drug, the abuse of which has become a matter of great medical and societal concern. Drug tolerance raises the risk for using ever-higher doses, thus increasing the likelihood of amphetamine addiction/dependence. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** alcohol dehydrogenase (1); dopamine  $\beta$ -monooxygenase (2); CYP2D6 (3); hemoglobin S polymerization (4); monoamine oxidase (5,6,8); aldehyde dehydrogenase (7); norepinephrine uptake (9); phenylalanyl-tRNA synthetase,  $K_i = 12 \mu\text{M}$  (10); lysine 2-monooxygenase (11). 1. ### Amphotericin B

This polyene macrolide (FW = 924.09 g/mol; CAS 1397-89-3) is a fungicide produced by *Streptomyces nodosus* M4575. Amphotericin B acts by permeabilizing sterol-containing membranes; hence, it is not active against mitochondrial membranes. It binds selectively to ergosterol in the cell membrane of susceptible fungi, resulting in cell death. Amphotericin B is used to treat serious systemic fungal infections. Ambisome for Injection is a sterile, non-pyrogenic lyophilized form of amphotericin B suitable for intravenous infusion. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York. **Target(s):** photosystem I (1); photosynthetic electron transport (2,3); chitin synthase, the methyl ester also inhibits (4,7); DNA biosynthesis (5);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (6); sterol 24-C methyltransferase, inhibits at concentrations above 60 nM (8); sterol 14-demethylase, or CYP51 (9). 1. ### Ampicillin

This semisynthetic penicillin-based antibiotic (FW = 349.41 g/mol; CAS 69-53-4), also named (2S,5R,6R)-6-([(2R)-2-amino-2-phenylacetyl]amino)-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylate, inhibits peptidoglycan synthesis needed for bacterial proliferation. It has an increased resistance to acidic pH and a wider antibacterial spectrum than most penicillins. It is also effective against many Gram-negative species. Ampicillin was the first semisynthetic penicillin analogue to be administered orally in clinical practice. An ampicillin resistance gene (abbreviated *ampR*) is often employed as a selectable marker by molecular biologists. **Target(s):** muramoylpentapeptide carboxypeptidase (1); glycopeptide transpeptidase (1); serine-type D-Ala-D-Ala carboxypeptidase, or penicillin-binding protein-5 (2,3,10,11); D-stereospecific aminopeptidase (4,12); penicillin-binding protein-4 (5); neprilysin, or enkephalinase (6);  $\beta$ -lactamase, or cephalosporinase (7); lysostaphin, or glycylglycine endopeptidase (8); acylaminoacyl-peptidase (9); cytosol ananyl aminopeptidase (13);  $\alpha$ -amino-acid esterase, weak alternative substrate (14); deacetoxycephalosporin-C synthase (15). 1. ### Amprenavir

This peptide analogue (FW = 505.64 g/mol; CAS 161814-49-9), also known as K VX-478, VX-478, and by its trade name as Agenerase™ is an antiviral agent that inhibits human immunodeficiency virus-1 protease ( $K_i = 0.6$  nM). With its relatively long *in vivo* half-life of 7-9 hours, amprenavir requires less frequent administration. **1.** Kim, Baker, Dwyer, *et al.* (1995) *J. Amer. Chem. Soc.* **117**, 1181. **2.** Clemente, Coman, Thiaville, *et al.* (2006) *Biochemistry* **45**, 5468. **3.** Specker, Böttcher, Brass, *et al.* (2006) *ChemMedChem* **1**, 106. **4.** Surleraux, de Kock, Verschuere, *et al.* (2005) *J. ### Ampullosporins

This set of at eight or more peptaibol antibiotics are membrane-active oligopeptides isolated from soil fungi and exhibit anti-bacterial and anti-fungal properties. They contain  $\alpha$ -aminoisobutyryl residues; hence, the "aib" in the class name) and usually end in a C-terminal alcohol (thus, the "ol" in the class name). The peptaibols are amphipathic, usually highly helical in structure, and typically form voltage-dependent ion channels. This will often lead to cell death. Ampullosporin has the sequence Ac-Trp-Ala-Aib-Leu-Aib-Gln-Aib-Aib-Gln-Leu-Aib-Gln-Leu-OH, ampullosporin B is Ac-Trp-Ala-Aib-Aib-Leu-Aib-Gln-Ala-Aib-Gln-Leu-Aib-Gln-Leu-OH, ampullosporin C is Ac-Trp-Ala-Aib-Aib-Leu-Aib-Gln-Aib-Ala-Aib-Gln-Leu-Aib-Gln-Leu-OH, ampullosporin D is Ac-Trp-Ala-Aib-Aib-Leu-Aib-Gln-Aib-Aib-Ala-Gln-Leu-Aib-Gln-Leu-OH, and ampullosporin E1 has the sequence Ac-Trp-Ala-Aib-Aib-Leu-Aib-Gln-Ala-Aib-Aib-Gln-Leu-Ala-Gln-Leu-OH where Ac refers to the *N*-acetyl group, Aib refers to an  $\alpha$ -aminoisobutyryl residue, and Leu-OH refers to L-leucinol. The ampullosporins are isolated from *Sepedonium ampullosporum*. **1.** Ritzau, Heinze, Dornberger, *et al.* (1997) *J. Antibiot.* **50**, 722. **2.** Kronen, Kleinwachter, Schlegel, Hartl & Grafe (2001) *J. Antibiot.* **54**, 175.

### Amrinone

This 2-pyridinone (FW = 187.20 g/mol; CAS 60719-84-8), also known by the trade name Inocor® and its systematic name, 5-amino-3,4'-bipyridin-6(1H)-one, is a noncatechol, nonglycoside phosphodiesterase-3 inhibitor that retards the breakdown of both cAMP and cGMP. The vasodilator

mechanisms of amrinone do not involve the opening of either ATP-sensitive  $K^+$  ( $K_{ATP}$ ) and large-conductance  $Ca^{2+}$ -activated  $K^+$  (or  $KCa$ ) channels. **1.** Orito, Satoh & Taira (1994) *Tohoku J. Exp. Med.* **172**, 163.

**m-AMSA**, See Amsacrine

### Amsacrine

This 9-anilinoacridine, (FW<sub>free-base</sub> = 393.47 g/mol; CAS 51264-14-3), also known as *m*-AMSA, is a cytostatic intercalating agent that stimulates and stabilizes the complex formed between DNA and DNA topoisomerase II. The *o*-analogue is a slightly weaker inhibitor of the *Sulfolobus shibatae* enzyme. Amsacrine is used to treat acute myelogenous leukemia. **Target(s):** DNA topoisomerase II (1,2,5-14); aldehyde oxidase (3); HERG (human ether-a-go go-related gene)  $K^+$  currents (4). **1.** McDonald, Eldredge, Barrows & Ireland (1994) *J. Med. Chem.* **37**, 3819. **2.** Nelson, Tewey & Liu (1984) *Proc. Natl. Acad. Sci. U.S.A.* **81**, 1361. **3.** Gormley, Rossitch, D'Anna & Cysyk (1983) *Biochem. Biophys. Res. ### Amuvatinib

This potent, multi-target signal transduction inhibitor (FW = 447.51 g/mol; CAS 850879-09-3; Solubility: 32 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as MP-470, is highly effective against c-Kit, IC<sub>50</sub> = 10 nM; PDGFR $\alpha$  IC<sub>50</sub> = 40 nM; and Flt3, IC<sub>50</sub> = 81 nM (1-4). Whether alone or in combination with erlotinib, amuvatinib inhibits prostate cancer *in vitro* and *in vivo*, with an IC<sub>50</sub> in the low- $\mu$ M range. **1.** Mahadevan, Cooke, Riley, *et al.* (2007) *Oncogene* **26**, 3909. **2.** Qi, Cooke, Stejskal, *et al.* (2009) *BMC Cancer* **9**, 142. **3.** Welsh, Mahadevan, Ellsworth, *et al.* (2009) *Radiat. Oncol.* **4**, 69. **4.** Zhao, Luoto, Meng, Bristow, *et al.* (2011) *Radiother. Oncol.* **101**, 59-65.

### Amygdalin

This cyanogenic glycoside (FW = 457.43 g/mol; CAS 29883-15-6) a constituent of bitter almonds as well as the seeds of peaches and apricots, inhibits trehalase. Often called laetrile by the nonscientific community, this substance was the focus of bogus claims in the 1970s and 1980s that it is effective in curing cancer. Numerous clinical investigations discount any

idea that amygdalin is effective as a cancer treatment. Hydrolysis of amygdalin is attended by the release of cyanide, a property accounting for its toxicity and mild cytostatic properties. The hydrolysis of amygdalin by emulsin in 1830 was one of the first chemical studies on enzyme catalysis.

**Target(s):**  $\alpha$ , $\alpha$ -trehalase (1,2);  $\beta$ -galactosidase, *Tenebrio molitor* (3); thioglucosidase, or myrosinase, or sinigrinase (4-6); cyclomaltodextrin glucanotransferase (7). 1. Silva, Terra & Ferreira (2006) *Comp. Biochem. Physiol. B Biochem. Mol. Biol.* **143**, 367. 2. Silva, Terra & Ferreira (2004) *Insect Biochem. Mol. Biol.* **34**, 1089. 3. Chem.* **33**, 1315. 6. Tani, Ohtsuru & Hata (1974) *Agric. Biol. Chem.* **38**, 1623. 7. Bovetto, Villette, Fontaine, Sicard & Bouquetlet (1992) *Biotechnol. Appl. Biochem.* **15**, 59.

### Amylin

This 37-residue pancreatic  $\beta$ -cell hormone (MW = 3.9 kDa; Sequence: KCNTATCATQRLANFLVHSSNFGAILSTNVGSNTY), also called Islet Amyloid Polypeptide (IAPP), is co-secreted with insulin and plays a role in glycemic regulation by retarding gastric emptying and promoting satiety. Amylin helps to prevent post-prandial spikes in blood glucose. Amylin potently inhibits ( $EC_{50}$  = 18 pM) amino acid-stimulated glucagon secretion. (Note: Human amylin is amyloidogenic, whereas the synthetic hormone known as Pramlintide (MW = 3951.41g; CAS 151126-32-8; Sequence: KCNTATCATQRLANFLVHSSNFGPILPPTNVGSNTY-NH<sub>2</sub>; Tradename: Symlin<sup>®</sup>) contains three prolyl residues that are found in Rat Amylin (Sequence: KCNTATCATQRLANFLVRSNNLGPVLPPTNGSNTY) and is nonamyloidogenic.) 1. Young (2005) *Adv. Pharmacol.* **52**, 151.

### Anabasine & Anabaseine

Anabasine (FW = 162.23 g/mol; CAS 40774-73-0) is a piperidine-containing alkaloid and natural insecticide found in the Tree Tobacco *Nicotiana glauca* (1,2). As a potent partial agonist of nicotinic acetylcholine receptors, it produces a depolarizing block at autonomic ganglionic and neuromuscular synapses, resulting in nicotine-like symptoms. Anabaseine (FW = 160.22 g/mol; CAS 3471-05-4), isolated from the marine worm *Paranemertes peregrina* Coe (3) and *Aphaenogaster* ants (4), interacts preferentially with  $\alpha_7$  nicotinic receptors, inducing half-maximal probability of channel opening at 10  $\mu$ M (5). Anabaseine undergoes pH-dependent ring opening, and, because only 29% is cyclic at pH 7.4 (6), its closed ring form is likely to be a more potent partial agonist than anabasine. Receptor interactions of Anabasine and Anabaseine inform the design of receptor-selective nicotinic agonists (See GTS-21). 1. Pyriki & Oehler (1954) *Pharmazie* **9**, 685. 2. Feinstein & McCabe (1950) *Science* **112**, 534. 3. Kem, Abbott & Coates (1971) *Toxicol.* **9**, 15. 4. Wheeler, Olubajo, Storm & Duffield (1981) *Science* **211**, 1051. 5. Kem, Mahnr, Papke & Lingle (1997) *J. Pharmacol. Exp. Ther.* **283**, 979. 6. Zoltewicz, Bloom, Kem (1989) *J. Org. Chem.* **54**, 4462.

### Anacardic Acids

These urushiol-related phenolic lipids (IUPAC Name: 2-hydroxy-6-pentadecylbenzoic acid; FW = 348.52 g/mol; CAS 16611-84-0; IUPAC Name: 2-hydroxy-6-[(8Z,11Z)-pentadeca-8,11,14-trienyl]benzoic acid; FW = 342.47 g/mol; CAS 11034-77-8), first isolated from the shell of the Indian cashew nut *Anacardium occidentale*, consists of salicylic acid with an 15 or 17 carbon atom alkyl chain. The first is a potent inhibitor of p300 and p300/CBP-associated factor histone acetyltransferases, also showing antimicrobial activity as well as inhibition of prostaglandin synthase, tyrosinase and lipoxygenase. The second is active against *Streptococcus mutans* and methicillin-resistant *Staphylococcus aureus*. 1. Izzo & Dawson (1949) *J. Org. Chem.* **14**, 1039. 2. Symes & Dawson (1953) *J. Amer. Chem. Soc.* **75**, 4952. 3. Paul & Yeddanapalli (1954) *Nature* **174**, 604.

### Anacetrapib

This cholesteryl ester transfer protein (or CETP) inhibitor (FW = 637.51 g/mol; CAS 875446-37-0), also known by the code name MK-0859, reduces plasma cholesterol concentrations, thereby increasing serum high-density lipoprotein levels and preventing cardiovascular disease associated with hypercholesteremia (1,2). X-ray crystal studies suggest that CETP is a crescent-shaped protein with a 6-nm hydrophobic tunnel traversing its core (3). Both of the tunnel's two entrances face the protein's concave surface, which most likely is the interaction platform for binding HDL particles and engaging its lipoprotein constituents. CETP mediates the reciprocal transfer of neutral lipids (e.g., cholesteryl esters and triglycerides) and phospholipids between different lipoprotein fractions in blood plasma. Anacetrapib is unlike many CETP inhibitors, which increase systolic blood pressure. Anacetrapib also exhibits a low-to-moderate degree of absorption after oral dosing and majority of the absorbed dose is eliminated via oxidation to a series of hydroxylated metabolites that undergo conjugation with glucuronate before excretion into bile (2). Unlike torcetrapib, another CETP inhibitor, anacetrapib does not elevate blood pressure, alter electrolytes, or cause any significant side effects. 1. Krishna, Anderson, Bergman, et al. (2007) *Lancet* **370**, 1907. 2. Tan, Hartmann, Chen, et al. (2010) *Drug Metab. Dispos.* **38**, 459. 3. Qiu, Mistry, Ammirati, et al. (2007) *Nature Struct. Mol. Biol.* **14**, 106.

### Anagrelide

This potent platelet aggregation inhibitor (FW = 256.09 g/mol; CAS 68475-42-3), also known as 6,7-dichloro-1,5-dihydroimidazo[2,1-b]quinazolin-2(3H)-one, BL-4162A, and Agrylin<sup>®</sup>, blocks the action of a variety of aggregating agents added platelet rich plasma,  $EC_{50}$  < 1  $\mu$ g/mL, or 4 nM (1). **Primary Mode of Action:** Although the exact mechanism of its selective inhibition of megakaryocyte (MK) production of platelets remains uncertain, anagrelide is known to be a potent inhibitor of phosphodiesterase-II ( $IC_{50}$  = 36 nM) and lipoprotein-associated phospholipase A<sub>2</sub> (or Lp-PLA<sub>2</sub>), the latter also known as platelet-activating factor acetylhydrolase (or PAF-AH). PDE-II hydrolyzes both cGMP and cAMP. Binding of cGMP to its regulatory GAF-B domain favors cAMP hydrolysis to 5'-AMP, thereby reducing cGMP hydrolysis to 5'-GMP. This property, which facilitates cross-regulation of the cAMP and cGMP pathways, suggests that a potent PDE-II inhibitor should potentiate the effects of cAMP and/or cGMP, the concentrations of which should increase in anagrelide-sensitive cells. Lp-PLA<sub>2</sub> plays pivotal role in platelet maturation by specifically hydrolyzing Platelet-Activating Factor (PAF = acetyl-glycerol-ether-phosphorylcholine) as well as other glycerophos-

pholipids containing short, truncated, and/or oxidized fatty acyl groups at the *sn*-2 position of the glycerol backbone. At a final concentration of 100 ng/mL, anagrelide selectively blocks *in vitro* MK maturation, resulting in a 50% decrease in the total number of CD41a<sup>+</sup> MKs (2). In humans, anagrelide has the intriguing ability to promote as a species-specific platelet-lowering activity at dose levels lower than those required to inhibit platelet aggregation (3). **Target(s):** collagen- and immune complex-induced platelet aggregation and release (4); suppresses megakaryocytopoiesis by reducing the expression levels of the transcription GATA-1 and FOG-1 via a PDEIII-independent mechanism that is differentiation context-specific but does not involve inhibition of MPL-mediated early signal transduction events (5). 1. Fleming & Buyniski (1979) *Thromb. Res.* **15**, 373. 2. Lane, Hattori, Dias, *et al.* (2001) *Exp. Hematol.* **29**, 1417. 3. Tefferi, Silverstein, Pettit, Mesa & Solberg (1997) *Semin. Thromb. Hemost.* **23**, 379. 4. Clark, Reid, Tevaarwerk (1981) *Thromb. Res.* **21**, 215. 5. Ahluwalia, Donovan, Singh, Butcher & Erusalimsky (2010) *J. Thromb. Haemost.* **8**, 2252.

#### Anandamide

This lipid neurotransmitter and endocannabinoid receptor ligand (FW = 347.54 g/mol; CAS 94421-68-8), also known as arachidonyl ethanolamide, inhibits calcium ion currents and activates the MAP kinase signaling pathway. Anandamide is a naturally occurring effector of central and peripheral nervous systems, as mediated by CB<sub>1</sub> and CB<sub>2</sub> cannabinoid receptors, respectively. (These receptors were originally characterized as binding Δ<sup>9</sup>-tetrahydrocannabinol, *or* THC, marijuana's major psychoactive ingredient.) Anandamide, 2-arachidonoylglycerol, and congeners (*N*-oleoylethanolamide and *N*-palmitoylethanolamide) are lipophilic signalling molecules with multiple physiological roles in learning and memory, neuroinflammation, oxidative stress, neuroprotection and neurogenesis. Anandamide likewise plays a role in regulating uterine implantation of the early-stage embryo (blastocyst). Anandamide synthesis occurs from *N*-acetylphosphatidylethanolamine by multiple pathways that include phospholipase A<sub>2</sub>, phospholipase C, and NAPE-hydrolyzing phospholipase D (*or* NAPE-PLD). **Target(s):** adenylate cyclase (1,2); Na<sup>+</sup> channels (3,4); α<sub>7</sub>-nicotinic acetylcholine receptor (5); 5 HT<sub>3</sub> receptors (6); Ca<sup>2+</sup> channels (7,8,10,11); K<sup>+</sup> channels, voltage-gated (9); acylglycerol lipase, *or* monoacylglycerol lipase (12). 1. #### Anastrozole

This non-steroidal aromatase inhibitor and breast cancer adjuvant (FW = 293.37 g/mol; CAS 120511-73-1), also known by its code name ZD1033, its proprietary name Arimidex™ and its systematic name 2,2'-[5-(1*H*-1,2,4-triazol-1-ylmethyl)-1,3-phenylene]bis(2-methylpropanenitrile), is a FDA-approved drug for treating breast cancer after surgery, with or without radiotherapy. **Mechanism of Inhibitory Action:** Arimidex is an orally available drug for the treatment of postmenopausal women with hormone receptor-positive or hormone receptor-unknown locally advanced or metastatic breast cancer and for the treatment of postmenopausal women with advanced breast cancer that has progressed following treatment with tamoxifen. It is a reversible competitive aromatase inhibitor (IC<sub>50</sub> of 15 nM) that limits the conversion of androgens to estrogens in extragonadal tissues (1). At 0.5 μM, anastrozole does not elevate plasma 11-deoxycorticosterone in monkeys, and at 1.5 μM, does not affect plasma aldosterone levels or Na<sup>+</sup>/K<sup>+</sup> excretion in rats, plasma K<sup>+</sup> concentrations in dogs, or cause adrenal hypertrophy in rats or dogs. Anastrozole is without discernible effect on adrenocorticoid hormone synthesis *in vivo*, even at high multiples of its maximally effective aromatase-inhibiting dose. **Pharmacokinetics:** Anastrozole is rapidly absorbed, with maximum plasma concentrations occurring within 2 hour after oral administration (2). Plasma concentrations of anastrozole rose with increasing doses of the drug. The elimination *t*<sub>1/2</sub> of Anastrozole in humans ranged from 30-60 hours. Consistent with anastrozole's long plasma *t*<sub>1/2</sub>, steady-state plasma concentrations were 3-4x higher than plasma concentrations observed after single administration of 1, 3, 5, or 10 mg (2). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York. 1. Dukes, Edwards, Large, Smith & Boyle (1996) *J. Steroid Biochem. Mol. Biol.* **58**, 439. 2. Plourde, Dyroff, Dowsett, *et al.* (1995) *J. Steroid Biochem. Mol. Biol.* **53**, 175.

#### 5α-Androstan-17-one

This steroid (FW = 274.45 g/mol), which, except for the absence of a hydroxyl group, is otherwise identical to 3α-hydroxy-5α-androstan-17-one (*or* androsterone), inhibits rat mammary glucose-6-phosphate dehydrogenase (*K*<sub>i</sub> = 0.3 μM). 1. Raineri & Levy (1970) *Biochemistry* **9**, 2233.

#### 5-Androstene-3β,17β-diol

This sterol (FW = 290.45 g/mol), also referred to simply as androstenediol, is a metabolite of dehydroepiandrosterone (prasterone) isolated independently in the laboratories of Butenandt and Ruzicka, who were awarded the Nobel Prize in Chemistry in 1939. **Target(s):** glucose-6-phosphate dehydrogenase (1); steroid 16α-monooxygenase (2); 17β hydroxysteroid dehydrogenase, also alternative substrate (3); 17-ketosteroid reductase (4); estrone sulfotransferase (5). 1. Criss & McKerns (1969) *Biochim. Biophys. Acta* **184**, 486. 2. Sano, Shibusawa, Yoshida, *et al.* (1980) *Acta Obstet. Gynecol. Scand.* **59**, 245. 3. Bonney, Reed & James

(1983) *J. Steroid Biochem.* **18**, 59. 4. MacIndoe, Hinkhouse & Woods (1990) *Breast Cancer Res. Treat.* **16**, 261. 5. Rozhin, Huo, Zemlicka & Brooks (1977) *J. Biol. Chem.* **252**, 7214.

#### 4-Androstene-3,17-dione

This androgen (FW = 286.41 g/mol), also referred to simply as androstenedione, is synthesized in the adrenal gland, testis, and ovary as a testosterone and estrone precursor. Androstenedione exhibits approximately one-fifth the androgenic activity of testosterone. **Target(s):** steroid 21-monooxygenase (1,14); steroid demethylase (2); glucose-6-phosphate dehydrogenase,  $K_i = 60.7 \mu\text{M}$  (3,4,8,9); 3-keto-5 $\beta$ -steroid 4-dehydrogenase (5); glutamate dehydrogenase (6); 3 $\beta$ -hydroxysteroid dehydrogenase (7); 6-phosphogluconate dehydrogenase (8); isocitrate dehydrogenase (8); steroid sulfatase (10); steroid  $\Delta$ -isomerase (11); steroid *O*-acyltransferase, or cholesterol *O*-acyltransferase, or ACAT (12); arylamine *N*-acetyltransferase (13). 1. #### Androsterone

This steroid (FW = 290.45 g/mol), also known as 5 $\alpha$ -androstane-3 $\alpha$ -ol-17-one and 3 $\alpha$ -hydroxy-5 $\alpha$ -androstane-17-one, is a weak androgen (approximately one-tenth that of testosterone). Androsterone was first isolated by Adolph Butenandt and coworkers in 1929-1931. Leopold Ruzicka showed that cholesterol could be converted to androsterone, and the two shared the 1939 Nobel Prize in Chemistry. **Target(s):** 3-keto-5 $\beta$ -steroid 4-dehydrogenase (1); 21-hydroxysteroid dehydrogenase (2,4,7,8); steroid acyltransferase, or cholesterol acyltransferase (3); glucose-6-phosphate dehydrogenase (5,6); steroid sulfatase (9); steroid sulfotransferase, also alternative substrate showing substrate inhibition (10); glucuronosyltransferase (11). 1. #### Anecortave Acetate

This novel angiogenesis pro-drug (FW = 386.48 g/mol; CAS 7753-60-8) is taken up and metabolically de-esterified to form the anecortave, a synthetic steroid that suppresses the development and elongation of neovascular sprouts and tip cell motility in a VEGF-treated retinal explant model in a dose-dependent manner (1). Whether used as monotherapy or in combination with sub-therapeutic doses of cisplatin, anecortave acetate significantly controlled tumor burden in a murine retinoblastoma model (2). 1. Sci.* **47**, 1264.

#### 2,2'-Anhydro-1-(arabinofuranosyl)-5-ethyluracil

This nucleoside analogue (FW = 253.23 g/mol), misnamed 2,2'-anhydro-5-ethyluridine, inhibits rat uridine phosphorylase ( $K_i = 25 \text{ nM}$ ). This anhydropyrimidine nucleoside has little or no flexibility about the *N*-glycosidic bond, as confirmed by NMR spectroscopy. 1. Veres, Neszmélyi, Szabolcs & Dénes (1988) *Eur. J. #### 2,6-Anhydro-3-deoxy-2 $\beta$ -phosphonylmethyl-8-phosphate-D-glycero-D-talo-octonate

This isosteric phosphonate analogue (FW = 410.20 g/mol) inhibits 3-deoxy-8-phosphooctulonate synthase ( $K_i = 5 \mu\text{M}$ ). 1. Baasov, Sheffer-Dee-Noor, Kohen, Jakob & Belakhov (1993) *Eur. J. Biochem.* **217**, 991.

## 1,5-Anhydro-D-glucitol

This naturally occurring sugar ether (FW = 164.15 g/mol; CAS 154-58-5; Symbol: 1,5-AG), also known as 1-deoxy-D-glucose and GlycoMark<sup>®</sup>, is a metabolically inert polyol that competes with glucose for reabsorption in the kidneys. 1,5-AG is rapidly depleted as blood glucose levels exceed the renal threshold for glucosuria. 1,5-AG is prepared by LiAlH<sub>4</sub> reduction of 1-bromo- $\alpha$ -D-glucopyranose 2,3,4,6-tetraacetate. **Biomarker for Glycemic Control:** Although still regarded as the gold standard in diabetes management, glycated hemoglobin (*or* HbA1c) is not a direct index of recent glycemic control (*i.e.*, excursions from normoglycemia over immediately preceding days or weeks). The plasma level of 1,5-AG reflects episodes of acute hyperglycemia more sensitively than HbA1c does and is correlated with fasting plasma glucose (FPG) and postprandial hyperglycemic peaks. In this regard, 1,5-AG levels appear to be a useful index of short-term glucose status, postprandial hyperglycemia, and glycemic variability (1-3). 1,5-AG predicts rapid changes in glycemia more accurately than HbA1c or fructosamine. It is also more tightly associated with glucose fluctuations and postprandial glucose. 1,5-AG provides information that is complementary information to A1C. Guidelines in Diabetes Assessment: >10  $\mu$ g 1,5-AG per mL (*or* 60  $\mu$ M) = Well Controlled; 5-10  $\mu$ g 1,5-AG per mL (*or* 30-60  $\mu$ M) = Moderately Controlled; 2-5  $\mu$ g 1,5-AG per mL (*or* 12-30  $\mu$ M) = Poorly Controlled; <2  $\mu$ g 1,5-AG per mL (*or* <12  $\mu$ M) = Very Poorly Controlled. *Note:* Because 1,5-anhydroglucitol is transported by sodium-glucose cotransporter, 1,5-AG assays may provide inaccurate assessment of glycemic control in T2DM patients treated with an (SGLT2) inhibitor, such as canagliflozin (4). **Target(s):** concanavalin A (5); hexokinase, as a weakly inhibiting alternative substrate (6,7); aldose 1-epimerase, *or* mutarotase (8-11); glucose 1-oxidase (11); trehalose (12); glucokinase (11);  $\beta$ -glucosidase ( $K_i$  = 60 mM for the sweet almond enzyme (12));  $\alpha,\alpha$ -trehalose phosphorylase, configuration-retaining (13); cellobiose phosphorylase (14). 1. ## 2,5-Anhydro-D-glucitol 1,6-Bisphosphate

This glucitol analogue (FW<sub>free-acid</sub> = 324.12 g/mol) of the  $\alpha$ -anomer of D-fructose 1,6-bisphosphate and inhibits fructose-1,6-bisphosphate aldolase and fructose-1,6 bisphosphatase, with respective  $K_i$  values of 13 and 0.55  $\mu$ M. **Target(s):** fructose-1,6-bisphosphate aldolase (1); fructose-1,6-bisphosphatase (2,3); pyrophosphate-dependent phospho-fructokinase, *or* diphosphate: fructose-6-phosphate 1-phosphotransferase (4). 1. Hartman & Barker (1965) *Biochemistry* **4**, 1068. 2. Marcus (1976) *J. Biol. Chem.* **251**, 2963. 3. Villeret, Huang, Zhang & Lipscomb (1995) *Biochemistry* **34**, 4307. 4. ## 1,5-Anhydro-D-glucitol 6-Phosphate

This glucitol derivative (FW<sub>free-acid</sub> = 244.14 g/mol) is an analogue of D-glucose 6-phosphate. **Target(s):** glucose-6-phosphate isomerase (1,2); hexokinase (2,3,4,6-13); phosphoglucomutase (2); glucokinase (4); inositol-3-phosphate synthase, *or* inositol-1-phosphate synthase (5). 1. Noltmann (1972) *The Enzymes*, 3<sup>rd</sup> ed., **6**, 271. 2. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. **2**, Academic Press, New York. 3. Kosow & Rose (1968) *J. Biol. ## 2,5-Anhydro-D-mannitol 1,6-Bisphosphate

This mannitol derivative (FW<sub>free-acid</sub> = 324.12 g/mol) is an analogue of the  $\beta$ -anomer of D-fructose 1,6-bisphosphate and inhibits fructose-1,6-bisphosphate aldolase and fructose-1,6 bisphosphatase ( $K_i$  = 30  $\mu$ M and 33 nM, respectively). **Target(s):** fructose-1,6-bisphosphatase (1-5); fructose-1,6-bisphosphate aldolase (6); pyrophosphate-dependent phospho-fructokinase, *or* diphosphate: fructose-6-phosphate 1-phosphotransferase (7). 1. Pilkis, Claus, Kountz & El-Maghrabi (1987) *The Enzymes*, 3<sup>rd</sup> ed., **18**, 3. 2. Marcus (1976) *J. Biol. Chem.* **251**, 2963. 3. ## N-(4-(Anilinoacetyl)phenylsulfonyl)-2-(benzofuran-2-yl)tryptamine

This modified tryptamine (FW = 519.63 g/mol) inhibits 15-lipoxygenase, *or* arachidonate 15-lipoxygenase, IC<sub>50</sub> = 15 nM. Compounds with aryl substituents at C-2 of the indole core of tryptamine and homotryptamine sulfonamides proved to be potent inhibitors of the isolated enzyme. 1. Weinstein, Liu, Gu, *et al.* (2005) *Bioorg. Med. Chem. Lett.* **15**, 1435.

### Anipamil

This novel, orally active phenylalkylamine derivative (FW = 520.79 g/mol; CAS 83200-10-6; IUPAC: 2-(3-methoxyphenyl)-2-[3-[2-(3-methoxyphenyl)ethylmethylamino]-propyl]tetradecanenitrile, exhibits calcium channel-blocking activity that is confined peculiarly to myocardial muscle. **1.** Raddino, Poli, Pasini & Ferrari (1992) *Naunyn. Schmiedeberg's Arch. Pharmacol.* **346**, 339.

### Anisomycin

This ribotoxin, antibiotic and famous amnesic agent (FW<sub>free-base</sub> = 265.31 g/mol; CAS 22862-76-6; alkali-labile; also slowly decomposes in acid), systematically named (2*R*,3*S*,4*S*)-4-hydroxy-2-(4-methoxybenzyl)-pyrrolidin-3-yl acetate, from *Streptomyces griseolus* and *S. roseochromogenes*, inhibits protein biosynthesis by binding to the 3'-end of the large (23S/28S) ribosomal RNA, a region directly involved in the three sequential steps of translational elongation, namely aminoacyl-tRNA binding, peptidyl transfer, and ribosomal translocation (1-8). **Structural Features:** The large ribosomal subunit of *Haloarcula marismortui* has provided 3-Å resolution structural data on antibiotic binding site(s) and the poses taken by anisomycin, blasticidin S, chloramphenicol, sparsomycin, and virginiamycin when they are bound to ribosomes (8). Two hydrophobic crevices, one located at the peptidyl transferase center and the other situated at the entrance to the peptide exit tunnel play roles in antibiotic binding. The aromatic ring of anisomycin binds to the active-site hydrophobic crevice, as does the aromatic ring of puromycin, while the aromatic ring of chloramphenicol binds to the exit tunnel hydrophobic crevice (8). These antibiotics bind at sites that overlap with either peptidyl-tRNA or aminoacyl-tRNA sites, consistent with their functioning as competitive inhibitors of peptide bond formation. **In vitro Mechanism of Action:** Anisomycin's inhibitory mechanism has been investigated using an *in vitro* rabbit reticulocyte system, using preformed Complex C (consisting of rabbit reticulocyte ribosomes, *E. coli* AcPhe-tRNA, and polyU) that reacts with excess puromycin and catalyzes peptide bond formation between AcPhe and puromycin in a pseudo-first-order, non-elongating reaction. A detailed kinetic investigation (9) showed that AcPhe-puromycin is produced in a pseudo-first-order reaction from the preformed AcPhe-tRNA/poly(U)/80S ribosome complex (designated Complex C) and excess of puromycin serving as substrate. Anisomycin acts as a mixed noncompetitive inhibitor ( $K_i = 6 \times 10^{-7}$  M;  $K_{ii} = 12 \times 10^{-7}$  M), with the product, AcPhe-puromycin, is derived only from Complex C, according to the puromycin reaction. **Amnesic Properties:** One well known characteristic of long-term memory is its apparent sensitivity to anisomycin, when the latter is administered directly to the brain at or around the time of training (10). About an hour or more after ending a training, memory enters a long-term, anisomycin-insensitive phase. Even beyond this period, however, there appear to be time windows during which later expression of memory is impaired by injection of this inhibitor (11). Anisomycin is also known to disrupt traumatic memory consolidation, attenuating posttraumatic stress response in experimental animals (12). Because anisomycin was first shown to be a ribosome inhibitor that blocks translation, these observations led to the now long-held conclusion that the consolidation of memory somehow requires protein synthesis. More recently, however, anisomycin was also shown to activate certain stress-activated protein kinases (SAPKs), including c-Jun amino-terminal kinases (JNKs), thereby altering the efficiency of their associated signal

transduction pathways (12,13). Other amino-hexose pyrimidine nucleoside antibiotics that bind to the anisomycin-binding region of ribosomes likewise activate SAPK/JNK1. Consistent with this finding is the separate observation that ribosomes that are active at the time of exposure to Ricin A chain and  $\alpha$ -Sarcin can initiate signal transduction from the damaged 28S rRNA to SAPK/JNK1, whereas inactive ribosomes cannot (12,13). Recent studies have shown that anisomycin also significantly inhibits mammalian cell proliferation by activating the P53/P21/P27 signaling to decrease the expression of ICBP90, thereby inhibiting expression of P-CDK2 and blocking cells in S and G<sub>2</sub>/M phases (14). **Target(s):** ribosomal peptidyltransferase (1-8); tyrosine hydroxylase (15); acetylcholine esterase (16,17);  $\alpha$ -L-rhamnosidase,  $K_i = 52 \mu\text{M}$  for the 2*S*,3*S*,4*S*-isomer of anisomycin [structure shown above] (18). **1.** Fernandez-Muñoz, Monro & Vazquez (1971) *Meth. ### Anthracimycin

This first-in-class polyketide antibiotic (FW = 396.28 g/mol), isolated from a marine-derived *Streptomyces* species (Strain CNH365) from near-shore sediments off the California coast and cultured in saline, shows significant activity against *Bacillus anthracis* (MIC = 31 ng/mL *in vitro*). Anthracimycin's antibiotic spectrum includes Gram-positive staphylococci, enterococci, and streptococci. Its X-ray structure showed the enol proton to be virtually equidistant between each oxygen atom, suggesting a rapid keto-enol tautomerization, with pseudo-ring formation (See inset in structure above). **1.** Jang, Nam, Locke, *et al.* (2013) *Angew. Chem. (Internat. Ed.)* **52**, 7822.

### Anthranilate (Anthranilic Acid)

This tryptophan biosynthetic intermediate (FW<sub>free-acid</sub> = 137.14 g/mol; CAS 118-92-3;  $pK_1 = 2.05$ ,  $pK_2 = 4.95$ ), also known as 2-aminobenzoic acid, is a product of the anthranilate synthase reaction (Chorismate + L-glutamine  $\rightleftharpoons$  anthranilate + pyruvate + L-glutamate). It is also an alternative substrate for 4-aminobenzoate 1-monooxygenase. **Target(s):** arylformamidase (1,24-26); indole-3-glycerol-phosphate synthase (2); 3-hydroxyanthranilate 3,4-dioxygenase (3); D-amino-acid oxidase (4,10-12,16,18,19); 3-hydroxyanthranilate oxidase (5); tryptophanase, or tryptophan indole-lyase (6,14,20); acetoin dehydrogenase (7); alcohol dehydrogenase, NADP-dependent (7); carbonyl reductase (7); glutamine synthetase, *Neurospora crassa* (8); phenoxazinone synthase, or *o*-aminophenol oxidase (9); esterase (13); alanine aminotransferase (15); L-amino-acid oxidase (17); 4,5-dihydroxyphthalate decarboxylase (21); *o*-pyrocatechuate decarboxylase (22); kynureninase, as product inhibitor (23); kynurenine:

oxoglutarate amino-transferase, weakly inhibited (27); orotate phosphoribosyl-transferase, weakly inhibited (28); 3' dimethylstaurosporine O-methyltransferase (29); kynurenine 3-monooxygenase, weakly inhibited (30); phenylalanine 2-monooxygenase (31); 3-hydroxyanthranilate 3,4-dioxygenase (32); o-aminophenol oxidase (33). 1. ### Anthrax Lethal Toxin

This potentially death-causing, zinc metalloproteinase, (*Abbreviation:* LeTx), produced by *Bacillus anthracis*, is a holocomplex consisting of (a) Anthrax Lethal Factor (*or* ATL F), a zinc-metalloproteinase; (b) Protective Antigen (*or* PA), an 83-kDa bacterial component; and (c) Anthrax Edema Factor, an adenylate cyclase that also associates with PA to form Anthrax Edema Toxin. Upon binding to a cell surface receptor, PA<sup>83</sup> undergoes proteolysis to PA<sup>63</sup>, the latter a 63-kDa fragment that then self-assembles into a heptameric membrane channel that mediates the entry of Lethal Factor and/or Edema Factor into the host cell. Once within the cytosol of target cells, ATL F cleaves mitogen-activated protein kinase kinase 1 (MEK1) and other targets. Proteasome inhibitors (*e.g.*, *N*-acetyl-Leu-Leu-Norleucinal, MG132, and Lactacystin) efficiently block ATL F cytotoxicity, whereas other protease inhibitors ineffective (1). Inhibitor concentrations needed to block ATL F cytotoxicity are similar to those required to inhibit the proteasome-dependent IκB-α degradation, as induced by lipopolysaccharide. Proteasome inhibitors do not interfere with the subsequent proteolytic cleavage of MEK1 within LeTx-treated cells, indicating that they do not directly block the protease activity of ATL F. (That said, the proteasome inhibitors also prevent ATP depletion, a well known early effect of LeTx.) LeTx inhibition of actin assembly is mediated by blockade of Hsp27 phosphorylation, and can be reproduced by treating cells with the p38 mitogen-activated protein (MAP) kinase inhibitor SB203580 (2). Nonphosphorylated Hsp27 inhibits actin-based *Listeria* motility in cell extracts, most likely by binding to and sequestering actin monomers. **Structural Features:** Peptide substrates and small-molecule inhibitors bind to ATL F in the space between Domains-3 and -4. Domain-3 is attached on a hinge to Domain-2 and can move through an angular arc of >35° in response to ligand binding (3). Structures of ATL F-Inhibitor complexes reveal three frequently populated ATL F conformational states termed 'bioactive', 'open' and 'tight' (1). The bioactive position is observed with large substrate peptides, with all peptide-recognition subsites open and accessible. The tight state, which occurs in unliganded and small-molecule complex structures, has Domain-3 serving as a clamp, situated over certain substrate subsites and blocking access. The open position appears to be an intermediate state between these extremes and is observed owing to steric constraints imposed by specific bound ligands (1). 1. Tang & Leppa

### Antiamoebins

This set of at least sixteen peptide antibiotics are peptaibols, membrane-active oligopeptides isolated from soil fungi that exhibit anti-bacterial and anti-fungal properties. They contain α-aminoisobutyryl residues (thus, the "aib" in the class name) and usually end in a C-terminal alcohol (thus, the "ol" in the class name). The peptaibols are amphipathic, usually highly helical in structure, and typically form voltage-dependent ion channels. This will often lead to cell death. Antiamoebin-I sequence: Ac-Phe-Aib-Aib-Aib-Iva-Gly-Leu-Aib-Aib-Hyp-Gln-Iva-Hyp-Aib-Pro-Phe-OH, Antiamoebin-II: Ac-Phe-Aib-Aib-Aib-Iva-Gly-Leu-Aib-Aib-Hyp-Gln-Iva-Pro-Aib-Pro-Phe-OH, Antiamoebin-III: Ac-Phe-Aib-Aib-Aib-Aib-Gly-Leu-Aib-Aib-Hyp-Gln-Iva-Hyp-Aib-Pro-Phe-OH, and Antiamoebin-IV has the sequence Ac-Phe-Aib-Aib-Aib-Iva-Gly-Leu-Aib-Aib-Hyp-Gln-Iva-Hyp-Aib-Pro-Phe-OH, where Ac indicates an *N*-acetyl group, Aib refers to an α-aminoisobutyryl residue, Hyp represents a hydroxypropyl residue, Iva refers to an isovaleryl residue, and Phe-OH refers to L-phenylalaninol. Antiamoebins-I to-V are isolated from *Emericellopsis poonenensis*, *Emericellopsis synnematicola*, and *Cephalosporium pimprina* (1,2). Antiamoebins VI to XVI are isolated from *Stilbella erythrocephala*, *Stilbella fimetaria*, and *Glucoladium catenulatum* (3). **Likely Structure of the Active Ionophore:** Molecular dynamic simulations were carried out to obtain a structural model consistent with measured conductances (4). By counting ions crossing the channel and by solving the Nernst-Planck equation, the motion of ions inside the channel appears to be diffusive. The calculated conductance of octameric channels is markedly higher than observed in single channel recordings, and the tetramer appears to be nonconducting. The calculated conductance for a hexameric pore was 74 ± 20 pS at 75 mV, agreeing well with the 90-pS value measured at 75 mV. These findings suggest a six-monomer channel can accommodate K<sup>+</sup> and Cl<sup>-</sup>, while keeping their inner shells intact. The free energy barrier for K<sup>+</sup> is only 2.2 kcal/mol, and that for Cl<sup>-</sup> is nearly 5 kcal/mol, making the channel selective for cations. 1. ### α<sub>1</sub>-Antichymotrypsin

This glycoprotein (MW = 68000 Da) is a serpin that forms very long-lived, enzymatically inactive 1:1 complex (denoted E\*I\*) with chymotrypsin and other chymotrypsin-like proteases, but not trypsin or leukocyte elastase. **Mechanism of Action:** Serpins share a conserved tertiary structure, in which an exposed region of amino acid residues (called the Reactive Center Loop, *or* RCL) serves as "bait" for its target proteinase. Within E\*I\*, the serpin and protease are covalently linked (E\*-I\*) after nucleophilic attack by Ser-195 on the P<sub>1</sub> residue in the serpin RCL. While formally similar to acyl-enzyme in serine proteinase catalysis, subsequent hydrolysis of E\*-I\* is extremely slow as a result of structural changes within the enzyme leading to distortion of the active site. There is presently an ongoing debate about whether the enzyme, bound to P<sub>1</sub>, maintains its original position at the top of the serpin molecule (1) or translocates across the entire length of the serpin, attended by insertion of RCL residues P<sub>1</sub>-P<sub>14</sub> within β-sheet A as well as a large separation of the enzyme and RCL residue P<sub>1</sub>' (2). **Target(s):** chymotrypsin (3,9,12,14,16,25,30,44); pancreatic elastase I (14,17,19); cathepsin G (5,9,10,12-15,28,29,40-43); chymase (6,9,9,12,26,36-39); seaprose (7,27); prohormone thiol protease (8,24); DNA polymerase α (18); DNA primase (20,21); clippers (22); NADPH oxidase-enzyme complex (23); pappalysin-1 (31); kallikrein 8, *or* neuropsin, weakly inhibited (32); stratum corneum chymotryptic enzyme, *or* kallikrein-7 (33); semenogelase (34,35). 1. ### Antihypertensive Agents

These blood pressure-lowering substances are used to prevent the complications of high blood pressure, mainly stroke and myocardial infarction. **DIURETICS**, which facilitate excretion of excess salt and water from body fluids, include: **Loop Diuretics**, such as Bumetanide, Ethacrynic Acid, Furosemide, and Torsemide; **Thiazide Diuretics**, such as Epitizide, Hydrochlorothiazide, Chlorothiazide, and Bendroflumethiazide; **Thiazide-like Diuretics**, including Indapamide, Chlorthalidon, and Metolazone; as well as **Potassium-sparing Diuretics**, such as Amiloride, Spironolactone, and Triamterene. **CALCIUM CHANNEL BLOCKERS**, which block the entry of calcium into muscle cells in artery walls, include: **Dihydropyridines**, such as Amlodipine, Cilnidipine, Felodipine, Isradipine, Lercanidipine, Levamlodipine, Nicardipine, Nifedipine, Nimodipine, Nitrendipine, and **Non-dihydropyridines**, such as Diltiazem and Verapamil. **ACE INHIBITORS**, which target angiotensin-converting enzyme-mediated conversion of angiotensin I into angiotensin II, include Benazepril, Captopril, Enalapril, Fosinopril, Lisinopril, Perindopril, Quinapril, Ramipril, and Trandolapril. **ANGIOTENSIN II RECEPTOR ANTAGONISTS**, which work by inhibiting the activation of angiotensin receptors, include Candesartan, Eprosartan, Irbesartan, Losartan, Olmesartan, Telmisartan, and Valsartan. **Adrenergic Receptor Antagonists**, of which there are several subtypes:  **$\beta$ -BLOCKERS**, such as Atenolol, Metoprolol, Nadolol, Nebivolol, Oxprenolol, Pindolol, Propranolol, and Timolol;  **$\alpha$ -BLOCKERS**, such as Doxazosin, Phentolamine, Indoramin, Phenoxybenzamine, Prazosin, Terazosin, and Tolazoline; **MIXED  $\alpha/\beta$ -BLOCKERS**, which Bucindolol, Carvedilol, and Labetalol; **VASODILATORS**, which act directly on the smooth muscle of arteries to relax, include Sodium Nitroprusside and Hydralazine; **BENZODIAZEPINES**, which, as GABA<sub>A</sub> receptor agonists in brain, slow down neurotransmission and dilate blood vessels; **RENIN INHIBITORS**, Renin Inhibitors, which include Aliskiren; **ALDOSTERONE RECEPTOR ANTAGONISTS**, which include Eplerenone and Spironolactone; and  **$\alpha_2$ -ADRENERGIC RECEPTOR AGONISTS**, such as Clonidine, Guanabenz, Guanfacine, Methyl-DOPA, and Moxonidine. **See specific agent for details on mode of action.**

### Antimony Sodium Gluconate

This pentavalent antimony complex (FW = 925.90 g/mol; CAS 16037-91-5) has remained a first-line drug for treating leishmaniasis, a disease caused by a protozoan parasite of the genus *Leishmania*, transmitted to humans through the bite of sandflies that previously fed on an infected vertebrate reservoir (1). Entering by means of the phosphate transporter, Sb(V) accumulation is higher in axenic amastigotes than in promastigotes for a number of species. Gluconate competitively inhibits Sb(V) uptake in axenic amastigotes, and Sb(V) is believed to enter into the parasites by means of a protein recognizing a sugar moiety resembling gluconate (2). It is likely that pentavalent antimony is a pro-drug, undergoing metabolic reduction by a parasite-specific enzyme, thiol-dependent reductase to Sb(III), the highly toxic anti-leishmanial agent. The most likely reductant is trypanothione, main intracellular thiol in *Leishmania* parasites, containing two glutathione units joined by a spermidine (3). Potential molecular targets of Sb(III) are trypanothione reductase as well as zinc-finger proteins, the latter involved in DNA replication, structure and repair. Sodium stibogluconate, but not Sb(III), specifically inhibits type I DNA topoisomerase from *Leishmania donovani* (4). Treatment with sodium antimony gluconate at the therapeutic dose may result in minor side effects such as arthralgia, myalgia, transient elevation of hepatocellular enzyme levels, and minor changes in ECG (5). 1. ### Antimycin A

This mixture of four antibiotic components from *Streptomyces*, that inhibit electron transport (at complex III), mitochondrial oxidative phosphorylation (1-4,10,12-14,17) as well as photo-phosphorylation (5) Antimycin A<sub>1</sub> inhibits electron transfer in complex III by blocking the transfer of electrons between Cyt *b*<sub>H</sub> and Coenzyme Q bound at the Q<sub>N</sub> site. The antimycins also induce apoptosis. The two main components of this mixture are antimycin A<sub>1</sub> and A<sub>3</sub>. All four exhibit the same activity with respect to electron transport. The four antimycins differ only in the alkyl chain attached at the 8 position of the nine-membered ring: Antimycin A<sub>1</sub> (FW = 548.63 g/mol; CAS 642-15-9; M.P. = 149-150°C; R = *n*-hexyl); Antimycin A<sub>2</sub> (FW = 534.6 g/mol; CAS 27220-57-1) R = *n*-pentyl); Antimycin A<sub>3</sub>, (FW = 520.58 g/mol; M.P. = 170.5-171.5°C; R = *n*-butyl); and Antimycin A<sub>4</sub>, R = *n*-propyl. Antimycin A<sub>1</sub> is practically insoluble in water but is soluble in diethyl ether, ethanol, acetone, and chloroform. This is also true for antimycin A<sub>3</sub>. **Target(s)**: ubiquinol:cytochrome-*c* reductase (complex III) (1,2,8-10,12-16,19,29-48); oxidative phosphorylation (1-4,8-10,12-17); aldehyde oxidase (3); sarcosine oxidase (4); mitochondrial electron transport (1,8-10,15,19); chloroplast electron transport (5); photophosphorylation (5); succinate oxidase (6,19,20); NADH oxidase6; very-long-chain fatty acid  $\alpha$ -hydroxylase (7); calcidiol 1 monooxygenase, or 25-hydroxyvitamin D 1 $\alpha$ -hydroxylase (11,23-25); ATP  $\rightleftharpoons$  P<sub>i</sub> exchange activity in *Rhodospirillum rubrum* (18); steroid 21-monooxygenase, or CYP21A1, weakly inhibited (21); squalene monooxygenase, or squalene epoxidase (22); *trans*-cinnamate 4-monooxygenase (26); procollagen

proline 4-dioxygenase, weakly inhibited (27); hydrogen:quinone oxidoreductase (28). *Note:* The antimycin A-like molecules AAL<sub>1</sub> and AAL<sub>2</sub> inhibit cyclic electron transport around Photosystem I in ruptured chloroplasts (49). 1. ### Antipain

This peptide analogue and irreversible serine and cysteine protease inhibitor (FW = 604.70 g/mol; CAS 37691-11-5), also known as *N*-(*N*<sup>c</sup>-carbonyl-L-arginyl-L-valyl-L-arginal)-L-phenylalanine and [(*S*)-1-carboxy-2-phenylethyl]carbamoyl-L-arginyl-L-valyl-L-arginal, is produced by certain *Streptomyces* species (1,2). When bound to wheat carboxypeptidase (3) and *Leishmania* major oligopeptidase B (4), the backbone carbonyl of antipain's terminal arginine forms a covalent bond to the active site serine, giving detailed information on the enzyme active site and extended substrate binding pockets. A 10-mM stock solution is stable for one week at 4°C. **Target(s):** Over 200 proteinases are inhibited by antipain. 1. Suda, Aoyagi, Hamada, Takeuchi & Umezawa (1972). *J. Antibiot.* **25**, 263. 2. ### $\alpha_2$ -Antiplasmin

This fast-acting lycoprotein serpin (MW = 58 kDa (452 aminoacid residues); however, on SDS-gel, *Mr* is 67000) single-chain rapidly binds to plasmin ( $k_{on} = 2 \times 10^7 \text{ M}^{-1}\text{s}^{-1}$ ) to form a high-affinity 1:1 complex. Efficient binding requires the presence of a free active site and free lysine-binding site(s) on plasmin (or plasminogen). (*For a discussion of the likely mechanism of inhibitory action, See Serpins; also  $\alpha_1$ -Antichymotrypsin*) **Target(s):** plasmin (1,2,8-10,13-17,19,20,24,25); coagulation factor XIIa (3); coagulation factor Xia, slow interaction (4,17); limulus clotting factor B (5,11,22); limulus clotting enzyme (6,12); limulus coagulation factor G (7); trypsin (8,16,18); chymotrypsin, slow interaction (8,16,18); t-plasminogen activator, slow interaction (8,23); thrombin, slow interaction (16,17); plasma kallikrein, slow interaction (17); matriptase (21). 1. ### Antipyretic Agents

These substances have the effect of directly or indirectly overriding prostaglandin-induced increase in temperature. Commonly used antipyretics include: Acetylsalicylic acid (Aspirin) and Salicylate Salts (*e.g.*, Choline Salicylate, Magnesium Salicylate, and Sodium Salicylate); Phenazone; Non-Steroidal Anti-Inflammatory Drugs, or NSAIDs (*e.g.*, Ibuprofen, Naproxen, Ketoprofen, Nimesulide); Paracetamol (also known as Acetaminophen); Metamizole (now banned for causing agranulocytosis) and Nabumetone.

### Antisauvagine-30

This highly selective CRF<sub>2</sub> antagonist (MW = 3650.29 g/mol; CAS 220673-95-0; Sequence: D-Phe-His-Leu-Leu-Arg-Lys-Met-Ile-Glu-Ile-Glu-Lys-Gln-Glu-Ala-Ala-Asn-Asn-Arg-Leu-Leu-Leu-Asp-Thr-Ile-NH<sub>2</sub>; Solubility: 5 mg/mL H<sub>2</sub>O; Alternate Name: [D-Phe<sup>11</sup>,His<sup>12</sup>]-Sauvagine (11-40)) targets human Corticotropin-Releasing hormone (CRH) Receptor-2 subtypes CRF<sub>2B</sub> ( $K_i = 1.4 \text{ nM}$ ), with a much higher value of 154 nM for CRF<sub>1</sub> (1-3). (*See also Astressin; K41448*) Type-2 GPCRs reside in plasma membranes of hormone-sensitive cells and bind CRH, a peptide hormone and neurotransmitter involved in stress responses. Antisauvagine-30 blocks ( $pA_2 = 8.49$ ) sauvagine-stimulated accumulation of cAMP in HEK-mCRF<sub>2B</sub> cells. It also prevents stress-enhanced fear conditioning and MEK1/2-dependent activation of ERK1/2 in mice and suggesting a role for protein kinase signaling in the hippocampus and its modulation by CRF<sub>2</sub> as a possible link between stress and fear memory. 1. ### Antisense Drugs/Effectors

These short DNA- or RNA-like analogues (consisting of 12-21 bases, with molecular weight values that are typically below 2,000) hybridize with specific mRNA molecules, thereby preventing synthesis of a protein (wild

type or mutant), whose presence results in or promotes a metabolic disorder, infection, or degenerative disease. Some antisense drugs direct their inhibitory effects on the expression of a particular mRNA splice-variant. Still others combine the extreme sequence-specificity of antisense oligonucleotides with the mRNA-cleaving power of catalytic RNA (ribozymes) in search-and-destroy strategies aimed at degrading target mRNA molecules. To minimize hydrolysis and inactivation, antisense oligonucleotides are synthesized with nuclease-resistant phosphorothioate linkages. Use of suitably derivatized purine and pyrimidine bases can also improve pharmacokinetics. (See *Mipomersen*) 1. Phillips, ed. ### Anti-Siglec-15 Antibodies

These monoclonal antibodies target Siglec-15, a functionally important, but little-studied, sialic acid-binding receptor located on the outer surface of bone-resorbing osteoclasts. At the molecular level, Siglec-15 interacts with the adapter protein DAP12 (or DNAX Activation Protein of 12 kDa) to activate Akt (also known as "protein kinase B", or PKB), when clustered on the cell surface of osteoclasts. This key regulatory interaction controls osteoclast differentiation and downstream activity of RANKL (or Receptor Activator of Nuclear factor Kappa-B Ligand). Antibody-mediated receptor dimerization is followed by rapid internalization, lysosomal targeting, and degradation, resulting in inhibition of functional osteoclast differentiation *in vitro*. Treatment of mice with these antibodies markedly increases bone mineral density, a finding that is likewise consistent with inhibition of osteoclast activity. Significantly, osteoblast numbers were maintained despite the anti-resorptive activity of these antibodies, supporting the further development of Siglec-15 antibodies as a novel class of bone loss therapeutics. 1. Stuitable, Moraitis, Fortin, *et al.* (2014) *J. Biol. Chem.* **289**, 6498.

### Antithrombin

This human plasma serpin (MW = 50.2 kDa; CAS 9000-94-6; Abbreviation: AT), also known as human plasma-derived antithrombin, antithrombin III, ATIII, and by its trade name ATryn<sup>®</sup>, plays a central role in hemostasis, serving as the principal inhibitor of thrombin (Reaction: Fibrinogen + H<sub>2</sub>O ⇌ Fibrin + Fibrinopeptides *a* and *b*) and Factor Xa (Reaction: Prothrombin + H<sub>2</sub>O ⇌ Thrombin). Given that AT is one of the major naturally occurring inhibitors of coagulation, acquired or hereditary deficiencies of this protein result in excessive thrombin generation. Use of ATryn is indicated for prophylactic treatment of patients with congenital antithrombin deficiency, a disorder that is manifested by dysregulated coagulation, abnormal blood clotting, and deep vein thrombosis. (For a discussion of the likely mechanism of inhibitory action, See *Serpins*; also *α<sub>1</sub>-Antichymotrypsin*) **Other Target(s):** AT also inhibits Factors IXa, XIa, and XIIa, in addition to kallikrein and plasmin. **Primary Mode of Inhibitory Action:** Antithrombin is a liver-derived glycoprotein that neutralizes the catalytic activities of thrombin and Factor Xa by forming a complex that is rapidly removed from the circulation. It is essentially unreactive with Factor IXa in the absence of heparin (*i.e.*,  $k_{on} \approx 10 \text{ M}^{-1}\text{s}^{-1}$ ) but undergoes a remarkable approximately one million-fold enhancement in reactivity with this proteinase to the physiologically relevant range (*i.e.*,  $k_{on} \approx 10^7 \text{ M}^{-1}\text{s}^{-1}$ ), when activated by heparin in the presence of physiologic levels of calcium. This enhancement results from: (a) allosteric activation of antithrombin by a sequence-specific heparin pentasaccharide (300-500x enhancement), (b) allosteric activation of factor IXa by calcium ions (4-8x enhancement), and (c) heparin bridging of antithrombin and factor IXa, as augmented by calcium ions (130-1000x, depending on heparin chain length (1). **Structural Features:** Antithrombin is a 432-residue protein that contains three disulfide bonds and four canonical glycosylation sites. Exosite interactions are responsible for the unusual specificity of antithrombin and heparin for thrombin, Factor IXa, and Factor Xa, each with quite distinct substrate specificities. Antithrombin circulates in blood in two major isoforms,  $\alpha$  and  $\beta$  differing in their glycosylation, a property that is linked to differences in their affinities for heparin. Kinetic studies suggest that similar induced-fit mechanisms determine pentasaccharide binding to native and latent antithrombins, and kinetic simulations support a three-step mechanism of allosteric activation of native antithrombin involving successive conformational changes. Equilibrium binding studies of pentasaccharide interactions with native and latent antithrombins and the salt dependence of these interactions suggest that each conformational change is associated

with distinct spectroscopic changes and is driven by a progressively better fit of the pentasaccharide in the binding site (3). **Use of Transgenics in Antithrombin Production:** Given its complex structure, antithrombin III resisted expression by standard bacterial or yeast protocols. ATryn is thus the first-ever transgenically produced therapeutic protein (4) and the first transgenically produced recombinant antithrombin to be approved in the U.S. ATryn is purified from the milk of a genetically modified goat, after introduction of the antithrombin III gene into the nucleus of its fertilized egg. The glycosylation profile differs from plasma-derived antithrombin, resulting in increased heparin affinity and a higher clearance rate. 1. ### $\alpha_1$ -Antitrypsin

This plasma serpin (MW = 51 kDa; Abbreviation: A1AT; Accession Number: NP 001121173; Gene: *SERPINA1*; Chromosome Location: 14q32.1) chiefly inhibits neutrophil elastase, but also shows broader action (hence its alternative name:  $\alpha_1$ -proteinase inhibitor, or API). Although elastase is its physiologic target, A1AT was designated as antitrypsin in recognition of its ability to irreversibly inactivate trypsin, the prototypical serine protease. (For a discussion of the most likely mechanism of action, See *Serpins*; *α<sub>1</sub>-Antichymotrypsin*)  $\alpha_1$ -Antitrypsin protects the lungs from neutrophil elastase, an enzyme that disrupts connective tissue.  $\alpha_1$ -Antitrypsin deficiency, an autosomal codominant hereditary disorder, is characterized by the accumulation of the inactive (misfolded/aggregated) A1AT polypeptide within the liver, leading to chronic uninhibited tissue breakdown and proceeding to cirrhosis of the liver (and, in smokers, pulmonary emphysema). Normal  $\alpha_1$ -antitrypsin blood levels range from 1.0 to 2.7 g/L, but, in individuals with PiSS, PiMZ and PiSZ genotypes, circulating A1AT levels can fall by 40–60%. While such lower levels are sufficient to protect the lungs of nonsmokers from the effects of elastase, those who smoke suffer the consequential oxidation of Methionine-382, with loss of serpin activity and progression to emphysema. A naturally occurring Methionine-358-Arginine (M358R) mutant has reduced inhibition of neutrophil elastase, while significantly enhancing inhibition of thrombin, factor XIa, and kallikrein. **Target(s):** trypsin (1,15,18,19,24,31); pancreatic elastase (2,18,23,24,61); pancreatic elastase II (3,49,61); pancreatic endopeptidase E (4,50); leukocyte elastase (5,17,18,26,31, 42,58-60,66,69,73); cathepsin G (6,16,18,26,67-71); myeloblastin (7,28,39-44); sheep mast cell proteinase (18); tissue kallikrein (9,10,18,21,62); however, inhibition is slow, 21); semenogelase (11); coagulation factor Xia (12,20,25); protein C (activated) (13,51-53,63); glutamyl endopeptidase II (14); chymotrypsin (18,26); thrombin (18,32); plasmin (18,73); acrosin (18,72); collagenase (18,23); tryptase (22); *Coccidioides* endopeptidase (27); granzyme A (29); granzyme B (30,38); kexin (by  $\alpha_1$ -antitrypsin Pittsburgh) (33); coagulation factor Xa (34); t plasminogen activator (48); u-plasminogen activator (urokinase) (35,47,48); kallikrein 8 (neurosin), weakly inhibited (36); matriptase (37); furin, inhibited by  $\alpha_1$ -antitrypsin Pittsburgh, *i.e.*, Met35Arg (45,46); chymase (54-57); plasma kallikrein, inhibited by altered  $\alpha_1$ -antitrypsin (63); complement subcomponent C1, inhibited by altered  $\alpha_1$ -antitrypsin (63); coagulation factor XIIa, inhibited by altered  $\alpha_1$ -antitrypsin (63); brachyuran (64); prolyl oligopeptidase, partially inhibited (65). 1. ### Antofloxacin

This novel 8-amino derivative of levofloxacin (FW = 376.49 g/mol; Symbol: AFX and AX) is a long-lived (and hence dosed daily) fluoroquinolone antibiotic displaying broad-spectrum *in vitro* activity, with high effectiveness against *Staphylococcus aureus* (1). The fact that cyclosporin A, probenecid, erythromycin and cimetidine all inhibit the biliary excretion of AFX glucuronide suggests that multiple transporters are likely to mediate the biliary excretion of AFX (2). Using phenacetin as a microsomal CYP1A2 substrate, antofloxacin was found to require NADPH for greatest inhibition (3). When studied by whole-cell patch-clamp technique in transiently transfected HEK293 cells, the administration of AX caused voltage- and time-dependent inhibition of HERG K<sup>+</sup> current ((HERG/MiRP1)) in a concentration-dependent manner, but does not

markedly modify the properties of channel kinetics, including activation, inactivation, deactivation and recovery from inactivation as well (4). 1. Xiao & Xiao (2008) *Acta Pharmacol. Sin.* **29**, 1253. 2. Hu, Liu, Xie, Wang & Liu (2007) *Xenobiotica* **37**, 579. 3. Zhu, Liao, Xie, Wang & Liu (2009) *Xenobiotica* **39**, 293. 4. Guo, Han, Liu, *et al.* (2010) *Basic Clin. Pharmacol. Toxicol.* **107**, 643.

### AP5

This NMDA antagonist (FW = 197.13 g/mol; CAS 76326-31-3; Solubility: 10 mM in H<sub>2</sub>O; 100 mM, when combined with 1 equivalent NaOH), also known as APV and (2R)-amino-5-phosphonovaleric acid, targets the N-methyl-D-aspartate receptor ( $K_d = 1.4 \mu\text{M}$ ), binding competitively at the ligand (glutamate) binding site. Although AP5 is isosteric with  $\gamma$ -glutamyl-P, an intermediate in the glutamine synthetase catalysis (3), there have been no reports on how AP5 affects glutamine synthetases. 1. Davies & Watkins (1982) *Brain Res.* **235**, 378. 2. Evans, Francis, Jones, Smith & Watkins (1982) *Brit. J. Pharmacol.* **75**, 65.

### AP22161

This Src SH2 binding disruptor (FW = 577.68 g/mol; CAS 268741-42-0) targets the cysteine residue in the phosphotyrosine-binding pocket of the Src SH2 domain in Src family tyrosine kinases (*e.g.*, Src, Fyn, Yes, Yrk, Lyn, Hck, Fgr, Blk, Lck, Frk/Rak and Iyk/Bsk). A fluorescence-polarization-based competitive binding assay was utilized to determine the IC<sub>50</sub> of AP-22161 binding to the Src SH2 domain, the Yes SH2 domain and the tandem ZAP SH2 domains. Src has been implicated in the regulation of osteoclast functional activity, and AP 22161 inhibits resorption of dentine. AP22161 demonstrates no sign of toxicity at tested concentrations, as monitored by the presence of tartrate-resistant acid phosphatase (TRAP)-positive cells and surrounding fibroblasts. **See also** UCS15A; pYEEI; and  $\zeta$ -ITAM peptide. **Target(s)**: Src SH2 (IC<sub>50</sub> = 0.24  $\mu\text{M}$ ); YES SH2 (IC<sub>50</sub> = 29.4  $\mu\text{M}$ ); ZAP SH2 (IC<sub>50</sub> = 422  $\mu\text{M}$ ); dentine resorption by rabbit osteoclasts (IC<sub>50</sub> = 43  $\mu\text{M}$ ). 1. Violette, Shakespeare, Bartlett, *et al.* (2000) **7**, 225.

### AP23573, See Ridaforolimus

### AP26113

This potent ALK inhibitor (FW = 529.02 g/mol; CAS 1197958-12-5; Solubility: 45 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 5-chloro-N2-

[4-[4-(dimethylamino)-1-piperidinyl]-2-methoxyphenyl]-N4-[2-(dimethylphosphinyl)phenyl]-2,4-pyrimidinediamine, inhibits wild type Lymphoma Kinase, or ALK ( $K_i = 0.62$  nM) and overcomes crizotinib resistance in non-small cell lung cancers harboring the fusion oncogene EML4-ALK. Cells often develop the L1196M gatekeeper mutation within the kinase domain, a changes that renders them resistant to crizotinib, even at higher drug doses (1  $\mu$ M). AP26113 is highly active against these resistant cancer cells, both *in vitro* and *in vivo*. 1. Katayama, Khan, Benes, *et al.* (2011) *Proc. Natl. Acad. Sci. U.S.A.* **108**, 7535.

### Apamin

This bee venom octadecapeptide toxin (FW = 2027.34 g/mol; CAS 24345-16-2; NCBI Reference Sequence: NP\_001011612.1) potently blocks the small-conductance  $Ca^{2+}$ -activated potassium ion (or SK) channels hSK1 as well as rSK2, with  $IC_{50}$  values of 3.3 nM and 83 pM. It shows greater effectiveness at the SK2 channel ( $IC_{50} = 0.06$ -0.4 nM) than SK1 ( $IC_{50} = 1$ -12 nM). SK3 ( $IC_{50} = 1$ -13 nM), and SK4 ( $IC_{50} = 1$   $\mu$ M) channels (1-3), and is active against channels within neurons, vascular endothelium, bladder smooth muscle, and certain cancers (4,5). Apamin does not inhibit human cardiac  $Na^+$  current, L-type  $Ca^{2+}$  current or other major  $K^+$  currents (6). Structurally, apamin forms a stable structure, consisting of a C-terminal  $\alpha$ -helix and two reverse turns, that is stabilized by two disulfide bonds connecting Cys-1 to Cys-11 and Cys-3 to Cys-15. A minor constituent of venom of the bee (*Apis mellifera*), apamin amounts to only 2-3% (w/w) of its dry venom. The smallest known neurotoxic polypeptide, apamin is derived by proteolytic processing of the 48-residue pre-pro-protein (7-9). The precursors of the bee venom constituents apamin and MCD peptide are encoded by two genes in tandem which share the same 3'-exon (10). 1. Maylie, Bond, Herson, *et al.* (2004) *J. ### APCIN

This Cdc20 inhibitor (FW = 438.65 g/mol; CAS 300815-04-7; Solubility: 100 mM in DMSO), also named 3-(2-methyl-5-nitroimidazol-1-yl)-N-(2,2,2-trichloro-1-phenylaminoethyl)propionamide, targets substrate interaction of Cell division control protein 20, blocking substrate-mediated Cdc20 loading onto the Anaphase-Promoting Complex (1,2). APC is a 13-subunit ubiquitin ligase that initiates the metaphase-anaphase transition and mitotic exit by targeting proteins such as securin and cyclin B<sub>1</sub> for ubiquitin-dependent destruction by the proteasome. APC regulates cell cycle progression by forming APC-Cdc20 and APC-Cdh1, two closely related, but functionally distinct, E<sub>3</sub> ubiquitin ligase sub-complexes. Cdh1 and Cdc20 have opposing functions in tumorigenesis, with the former largely functioning as a tumor suppressor, and the latter exhibiting an oncogenic function. Because blocking mitotic exit is an effective approach for inducing tumour cell death, the APC/C represents a potential novel target for cancer therapy. APC/C activation during mitosis requires Cdc20 binding, forming a co-receptor with the APC/C to recognize substrates containing a destruction box (D-box). APC/C-dependent

proteolysis and mitotic exit can be synergistically inhibited by simultaneously disrupting two protein-protein interactions within the APC/C-Cdc20-substrate ternary complex. APC inhibitor, or Apcin, binds to Cdc20, competitively inhibiting ubiquitylation of D-box-containing substrates. Analysis of the crystal structure of the apcin-Cdc20 complex suggests that apcin occupies the D-box-binding pocket on the side face of the WD40-domain. The ability of Apcin to block mitotic exit is enhanced by co-addition of tosyl-L-arginine methyl ester (See TAME), a small molecule that blocks the APC/C-Cdc20 interaction (3). Apcin also inhibits APC-dependent ubiquitylation and prolongs mitotic duration in RPE1 cells, when administered in combination with proTAME, a prodrug of TAME *in vitro* (See pro-TAME). 1. ### APEX57219

This HIV-1 RT inhibitor (FW = 424.36 g/mol), first identified using a FRET-based high-throughput screening for the AZT-MP excision repair activity, has  $K_i = 140$  nM for wild-type reverse transcriptase, 220 nM for [M41L/L210W/T215Y]-RT, 207 nM for [D67N/K70R]-RT, and 242 nM for [D67N/K70R/T215F/K219Q]-RT. In the RNA-dependent DNA polymerase assay, APEX57219 gave a  $K_i$  value of 330 nM for wild-type RT. APEX57219 is a competitive inhibitor with respect to template/primer binding, and a non-competitive inhibitor with respect to dNTP binding. That APEX57219 abrogates the interactions between enzyme and its nucleic acid substrate is indicated by its ability to inhibit all of HIV-1 RT activities (*i.e.*, DNA polymerase, RNase H and NRTI-MP excision), while retaining activity against common NNRTI resistance mutations. APEX57219 also inhibits HIV replication and the level of reverse transcription. 1. Bago, Malik, Munson, *et al.* (2014) *Biochem. J.* **462**, 425.

### Aphidicolin

This photosensitive diterpenoid (FW = 338.49 g/mol; CAS 38966-21-1; M.P. = 227-232°C; IUPAC: (3R,4R,4aR,6aS,8R,9R,11aS,11bS)tetradeca hydro-3,9-dihydroxy-4,11b-dimethyl-8,11a-methano-11aH-cyclohepta[a] naphthalene-4,9-dimethanol) from *Cephalosporium aphidicola* and *Nigrospora oryzae* inhibits many nuclear replicative DNA polymerases, thereby arresting the cell cycle in the S phase. Inhibition of DNA polymerase  $\alpha$  is noncompetitive with respect to dATP, dGTP, dTTP as well as DNA, but is competitive relative to dCTP. Certain cells become aphidicolin-resistant by any one of the following adaptations: (a) a mutation in DNA polymerase  $\alpha$  that greatly decreases affinity for the drug; (b) overproduction of DNA polymerase  $\alpha$ ; or (c) increased synthesis of dCTP. Replication of mitochondrial and chloroplast DNA is unaffected by aphidicolin. **Target(s)**: DNA polymerase  $\alpha$  (1-3,5,7,10,12,17,21-23,26);  $\phi$ 29 DNA polymerase (4,7); DNA polymerase  $\delta$  (3,6,7,8,21-23,26,27,29,32); DNA polymerase  $\zeta$  (28); bacteriophage T4 DNA polymerase (7,16); DNA polymerase  $\epsilon$  (7,11,12,20-23); *Pyrococcus furiosus* DNA polymerase BI (9); Herpes simplex-induced DNA polymerase (10,12); *Vaccinia*-induced DNA polymerase (10,12); plant cell

$\alpha$ -like DNA polymerase (10); yeast DNA polymerase I (10); yeast DNA polymerase II (10). 1. Hubermann (1981) *Cell* **23**, 647. 2. Ward & Weissbach (1986) *Meth. Enzymol.* **118**, 97. 3. ### Apicidin

This fungal metabolite and potential oral chemotherapeutic agent (FW = 623.79 g/mol; CAS 183506-66-3), also known as [cyclo(*N*-*O*-methyl-L-tryptophanyl-L-isoleucinyl-L-D-pipecolinyl-L-2-amino-8-oxodecanoyl)], is an antiproteolytic agent. It is cell permeable and is a strong inhibitor of histone deacetylase (IC<sub>50</sub> = 0.7 nM). Apicidin also inhibits proliferation of tumor cells *via* induction of p21WAF1/Cip1 and gelsolin. Apicidin's low bioavailability of apicidin is mainly due to the P-glycoprotein-mediated efflux (3). 1. Han, Ahn, Park, et al. (2000) *Cancer Res.* **60**, 6068. 2. Darkin-Rattray, Gurnett, Myers, et al. (1996) *Proc. Natl. Acad. Sci. U.S.A.* **93**, 13143. 3. Shin, Yoo, Kim, et al. (2014) *Drug Metab. Dispos.* **42**, 974.

### Apixaban

This oral factor Xa inhibitor (FW = 459.51 g/mol; CAS 503612-47-3), also named Eliquis® and 1-(4-methoxyphenyl)-7-oxo-6-[4-(2-oxopiperidin-1-yl)phenyl]-4,5-dihydropyrazolo[5,4-c]pyridine-3-carboxamide, directly and

selectively targets coagulation Factor Xa. With its extremely low IC<sub>50</sub> of 80 pM for human FXa, apixaban has >30,000-fold selectivity for FXa over other human coagulation proteases (1). (See also Heparin, Clopidogrel Dabigatran, Rivaroxaban, and Warfarin) **Mode of Inhibitor Action:** Direct FXa inhibitors constitute a class of anticoagulant drugs acting directly, without requiring antithrombin as a mediator.) With association rate constant of 20 μM<sup>-1</sup>s<sup>-1</sup>, apixaban produces rapid-onset FXa inhibition, inhibiting both free as well as prothrombinase- and clot-bound FXa activity *in vitro* (2). When human tissue factor (TF) plus 7.5 mM CaCl<sub>2</sub> was added to platelet-rich plasma, aggregometry confirmed that TF-induced platelet aggregation was inhibited by apixaban, IC<sub>50</sub> = 4 nM (2). **Pharmacodynamics:** Apixaban is FDA-approved for the prevention of venous thromboembolism after elective hip or knee replacement. Apixaban has good bioavailability, low clearance, and a small volume of distribution (2). Although warfarin's anticoagulative action can be reversed (See Warfarin), there is no known substance that will rapidly reverse apixaban's inhibitory action. Apixaban shows only a low potential for drug-drug interactions, but it is a substrate for both CYP3A4 and P-gp. As such, inhibitors of these enzymes can be expected to alter apixaban exposure. See other direct Factor Xa inhibitors: Rivaroxaban, or Xarelto®; Betrixaban; Daxetaban (discontinued); Edoxaban, or Lixiana®; and Otamixaban injectable (discontinued). 1. Pinto, Orwat, Koch, et al. (2007) *J. Med. Chem.* **50**, 5339. 2. Wong, Pinto, Zhang (2011) *J. Thromb. Thrombolysis* **31**, 478. 3. Wong & Jiang (2010) *Thromb. Haemost.* **104**, 302.

### Apocynin

This neutrophil oxidative burst antagonist and potent anti-inflammatory agent (FW = 166.17 g/mol; CAS 4098.02-2; slight vanilla fragrance), also named 1-(4-hydroxy-3-methoxyphenyl)ethanone, from the root of Canadian hemp *Apocynum cannabinum* and the perennial Nepalese herb *Picrorhiza kurroa*, targets NADPH oxidase (IC<sub>50</sub> = 10-15 μM), which in activated polymorphonuclear (PMN) leukocytes catalyzes NADPH-dependent O<sub>2</sub> reduction to superoxide, the latter employed by immune cells to kill bacteria and fungi (1). Apocynin effectively prevents superoxide production in white blood cells or neutrophilic granulocytes, but does not affect phagocytic or other defense roles of granulocytes. Oxygen uptake by neutrophils incubated with 300 μM apocynin was completely inhibited at 7 min upon addition of serum-treated zymosan (STZ), with a lagtime of inhibition of 2-3 min (1). However, the capacity of neutrophils for intracellular killing of *Staphylococcus aureus* was not impaired by apocynin (1). Such selective inhibition makes apocynin a tool for modulating NADPH oxidase without interfering with other immune system actions. Apocynin is rapidly absorbed after oral administration at 50 mg/kg in rats, reaching peak plasma level within 5 min (2). Its presence in plasma is detectable for up to 48 hours. Apocynin bioavailability is 8.3%. When measured *in vitro*, plasma protein binding was found to be 83-86% and 71-73% in rat and human plasma, respectively. Apocynin is stable in gastric (pH 1.2), intestinal (pH 6.8) and physiological (pH 7.4) fluids, including microsomal (rat and human) stability studies (2). IIIHyQ, a related trimer hydroxylated quinone, inhibits endothelial NADPH oxidase, IC<sub>50</sub> = ~30 nM. *In vitro*, IIIHyQ disrupts the interaction between p47<sub>phox</sub> and p22<sub>phox</sub>, thereby blocking the activation of the Nox2 isoform. A key cysteine residues in p47<sub>phox</sub> is the IIIHyQ target (3). **Other Target(s):** Arachidonic acid-induced aggregation of bovine platelets, possibly by inhibiting thromboxane formation (4); angiotensin II-induced endothelin-1 expression (5); ischemia-reperfusion lung injury, but the mechanism of protection remains unclear (6). 1. ### Apolipoprotein C-III

This 79-residue lipid-binding protein (MW = 8,750 Da), also known as Apo-CIII and ApoC3, is a major component of HDL, triglyceride-rich lipoproteins (TRL) (*i.e.*, VLDL and chylomicrons), and, to a lesser extent,

LDL. Apo-CIII inhibits lipoprotein lipase and hepatic lipase, thereby delaying the uptake and metabolism of triglyceride-rich particles in liver. While Apo-CIII promotes assembly and secretion of triglyceride-rich VLDL particles from hepatic cells under lipid-rich conditions, its over-expression of human apoC-III in the plasma of transgenic mice results in hypertriglyceridemia. Indeed, high apoC-III levels are linked to hypertriglyceridemia, inflammation, atherosclerosis, and metabolic syndrome. Rare mutations that disrupt *APOC3* function are associated with lower levels of plasma triglycerides and ApoC3 (1,2), and carriers of these mutations show a reduced risk of coronary heart disease. Changes in apoC-III levels are directly associated with changes in cardiovascular risk and the atherogenicity of the lipoproteins on which apoC-III resides (3). Emerging roles of apoC-III include influencing the atherogenicity of high-density lipoprotein, trafficking of intestinal dietary triglycerides, and modulating pancreatic  $\beta$ -cell survival (3). 1. Do, Willer, Schmidt, *et al.* (2013) *Nature Genetics* **45**, 1345. 2. TG & HDL Working Group, NHLBI Exome Sequencing Project (2014) *New. Engl. J. Med.* **371**, 22.. 3. Kohan (2015) *Curr. Opin. Endocrinol. Diabetes Obes.* **22**, 119.

### Apoptin

This 121-residue nucleocytoplasmic shuttling protein (MW = 13.6 kDa; GenBank: AAO45416.1), from Chicken Anemia Virus (CAV) and Human Gyrovirus Type 1, associates with APC (anaphase-promoting complex), inducing G<sub>2</sub>/M cell-cycle arrest and apoptosis in the absence of p53. When grown *in vitro*, CAV only replicates in transformed chicken cell lines, suggesting that at least a part of the CAV life-cycle requires transformation-like cellular events (1). Apoptin triggers programmed cell death by activating the mitochondrial pathway (*or* intrinsic apoptosis), acting independently of the death receptor pathway (*or* extrinsic apoptosis). Synthesis of apoptin alone induces apoptosis in various human transformed and/or tumorigenic cell lines, but not in normal human diploid cells (1). Apoptin also interacts with the SH3 domain of the BCR-ABL1 fusion protein, inhibiting BCR-ABL1 kinase and its downstream targets (2). A chimeric protein (Dose: 1  $\mu$ M), consisting of apoptin fused the Tat cell-penetrating sequence, as well as the apoptin-derived decapeptide (*Sequence*: PKPPSKKRSC; Dose: 1-2  $\mu$ M), but not the sequence-scrambled peptide PRPPSRSPKC, is effective in treating chronic myelogenous leukemia (CML) by inhibiting the BCR-ABL1 down-stream target, c-Myc, with an efficacy comparable to full-length apoptin and imatinib (*See Imatinib*). Synthetic apoptin inhibits cell proliferation in murine 32Dp210 cells and human K562 cells, and is also effective *ex vivo* in both imatinib-resistant and imatinib-sensitive CML patient samples (3). 1. Noteborn (2004) *Vet. Microbiol.* **98**, 89. 2. Panigrahi, Stetefeld, Jangamreddy *et al.* (2012) *PLoS One* **7**, e28395. 3. Jangamreddy, Panigrahi, Lotfi, *et al.* (2014) *Oncotarget* **5**, 7198.

### Apoptosis Inhibitor of Macrophages

This novel murine macrophage-derived soluble factor (MW  $\approx$  40 kDa; *Symbol*: AIM), also known as Spz and Api6, belongs to the scavenger receptor cysteine-rich domain superfamily of glycoproteins secreted by tissue macrophages in the spleen, lymph node, thymus, bone marrow, liver and fetal liver. AIM confers apoptosis resistance to macrophages exposed to various pro-apoptotic signals, including cytotoxic oxidized-low density lipoprotein (oxLDL), dexamethasone, irradiation, Fas/CD95, and fulminant hepatitis (1,2). 1. Miyazaki, Hirokami, Matsuhashi, Takatsuka & Naito (1999) *J. Exp. Med.* **189**, 413. 2. Arai, Shelton, Chen, *et al.* (2005) *Cell Metab.* **1**, 201.

**Apoptosis Repressor with CARD, See ARC**

### Apremilast

This thalidomide-like psoriasis drug (FW = 460.50 g/mol; CAS 608141-41-9; Solubility: 90 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as CC-

10004, Otezla<sup>®</sup> and *N*-[2-[(1*S*)-1-(3-ethoxy-4-methoxyphenyl)-2-(methylsulfonyl)ethyl]-2,3-dihydro-1,3-dioxo-1*H*-isoindol-4-yl]acetamide, is a potent, orally active phosphodiesterase inhibitor that targets phosphodiesterase PDE4 (IC<sub>50</sub> = 74 nM), itself a proinflammatory mediator, and TNF- $\alpha$ , IC<sub>50</sub> = 77 nM (1-3). Apremilast inhibits PBMC production of the chemokines CXCL9 and CXCL10, cytokines interferon- $\gamma$  and tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), and interleukins IL-2, IL-12 and IL-23 from human rheumatoid synovial membrane cultures (3). Apremilast significantly reduces clinical scores in both murine models of arthritis over a ten-day treatment period and maintains healthy joint architecture in a dose-dependent manner. Unlike rolipram, however, apremilast demonstrated no adverse behavioral effects in naïve mice (4). Otezla is specifically indicated by the Food & Drug Administration for the treatment of patients with moderate to severe plaque psoriasis who are typically candidates for phototherapy or systemic therapy. That said, the specific mechanism(s) for therapeutic action in psoriatic arthritis patients and psoriasis patients is unclear. 1. Man, Schafer, Wong, *et al.* (2009) *J. Med. Chem.* **52**, 1522. 2. Muller, Shire, Wong, *et al.* (1998) *Bioorg. Med. Chem. Lett.* **8**, 2669. 3. Schafer, Parton, Gandhi, *et al.* (2010) *Brit. J. Pharmacol.* **159**, 842. 4. McCann, *et al.* (2010) *Arthritis Res. Ther.* **12**, R107.

### Aprepitant

This anti-emetic (FW = 534.43 g/mol; CAS 170729-80-3), also known by its code names MK 869 (*or* MK 0869) and L 754030, its trade name Emend<sup>®</sup> and its systematic name 5-(((2*R*,3*S*)-2-((*R*)-1-[3,5-bis(trifluoromethyl)phenyl]ethoxy)-3-(4-fluorophenyl)morpholino)methyl)-1*H*-1,2,4-triazol-3(2*H*)-one, is a selective high-affinity Substance P antagonist (*or* SPA) that acts by blocking Substance P binding to the Neurokinin 1 (NK<sub>1</sub>) receptor (IC<sub>50</sub> = 0.12 nM). NK<sub>1</sub> is a G-protein-coupled receptor in the central and peripheral nervous systems, and is especially abundant in the vomiting center. (*See prodrug Fosaprepitant*) In preclinical studies, aprepitant did not interact with monoamine systems in the manner seen with established antidepressant drugs (1). Once daily oral administration of MK-869 was effective in reducing delayed emesis and nausea after high-dose Cisplatin (2). At 5-70  $\mu$ M, aprepitant also elicits growth cell inhibition in a concentration-dependent manner in all tumor cell lines studied (3). Aprepitant moderately inhibits CYP3A4 in humans, as measured with midazolam as a probe drug (4). **See Orvepitant; Rolapitant** **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York. 1. Kramer, Cutler, Feighner, *et al.* (1998) *Science* **281**, 1640. 2. Campos, Pereira, Reinhardt, *et al.* (2001) *J. Clin. Oncol.* **19**, 1759. 3. Muñoz & Rosso (2010) *Invest. New Drugs* **28**, 187. 4. Majumdar, McCrea, Panebianco, *et al.* (2003) *Clin. Pharmacol. Ther.* **74**, 150.

### Apricoxib

This oral COX-2 inhibitor (FW = 356.44 g/mol; CAS 162011-90-7), also named CS-706 and 4-[2-(4-ethoxyphenyl)-4-methyl-1*H*-pyrrol-1-yl]-benzene sulfonamide, targets Cyclooxygenase-2 (1), which is over-

expressed in advanced stage non-small-cell lung cancer (NSCLC), possibly as a result of elevated levels of COX-2-dependent prostaglandin E<sub>2</sub> (PGE<sub>2</sub>). That said, a randomized, double-blind, placebo-controlled, multicenter phase II study (2) found little evidence of efficacy of apicoxib in combination with either docetaxel or pemetrexed in patients with biomarker-selected NSCLC. **See also Rofecoxib 1.** Kirane (2012) *Clin. Cancer Res.* **18**, 5031. **2.** Edelman, Tan, Fidler, *et al.* (2015) *J. Clin. Oncol.* **33**, 189.

### Aprotinin

This serine protease inhibitor (MW ≈ 6.5 kDa; CASs = 9087-70-1 and 9004-04-0; Solubility: 10 mg/mL or 1.5 mM), also called bovine pancreatic trypsin inhibitor or Trasylol™, is a naturally occurring 58-residue oligopeptide, with disulfides joining Cys-5 to Cys-55, Cys-14 to Cys-38, and Cys-30 to Cys-51) that potently inhibits trypsin, ( $K_i = 60$  fM), chymotrypsin ( $K_i = 10$  nM), kallikrein ( $K_i = 1$ -2 nM), plasmin ( $K_i = 5$  nM), elastase ( $K_i = 4$ -5 μM), and urokinase ( $K_i = 8$ -10 μM). Aprotinin forms extremely stable complexes at neutral pH, but binding is reversible, with most aprotinin-enzyme complexes dissociating slowly at pH >10 or <3. Given the great diversity of proteases and their substrates, aprotinin can be an invaluable tool in unraveling the action of serine proteases in the posttranslational processing of peptide/protein ligands in signal transduction pathways.

### AR-A014418

This ATP-competitive protein kinase inhibitor (FW = 308.31 g/mol; CAS 487021-52-3; Solubility: 62 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O) selectively targets glycogen synthase kinase 3β (GSK3β), with IC<sub>50</sub> = 104 nM;  $K_i = 38$  nM. Attesting to its high specificity for GSK3, AR-A014418 does not significantly inhibit Cdk2 or Cdk5 (IC<sub>50</sub> > 100 μM) or 26 other kinases (1). AR-A014418 inhibits phosphorylation of the microtubule-associated protein Tau at Ser-396 (*i.e.*, the GSK3-specific site) in cells stably expressing human four-repeat Tau (1). AR-A014418 protects N2A neuroblastoma cells against cell death mediated by inhibition of the phosphatidylinositol 3-kinase/protein kinase B survival pathway. AR-A014418 inhibits neurodegeneration mediated by β-amyloid peptide in hippocampal slices (1). Treatment of neuroblastoma cell lines with AR-A014418 reduced the level of GSK-3α phosphorylation at Tyr-279 compared to GSK-3β phosphorylation at Tyr-216, and attenuated growth via the maintenance of apoptosis. (2). AR-A014418-dependent antinociceptive effects are induced by modulation of the glutamatergic system through metabotropic and ionotropic (NMDA) receptors and the inhibition of TNF-α and IL-1β cytokine signaling (3). **1.** Bhat, Xue, Berg, *et al.* (2003) *J. Biol. Chem.* **278**, 45937. **2.** Carter, Kunnimalaiyaan, Chen, Gamblin & Kunnimalaiyaan (2014) *Cancer Biol. Ther.* **15**, 510. **3.** Martins, *et al.* (2011) *J. Pain.* **12**, 315.

### Arachidonyl-2'-chloroethylamide

This synthetic CB<sub>1</sub> receptor agonist and anandamide (*N*-arachidonylethanolamide) analogue (FW = 365.99 g/mol; CAS 220556-69-

4; Symbol: ACEA) is a selective agonist of cannabinoid receptor-1 ( $K_i = 1.4$  nM) but has low affinity to the cannabinoid receptor 2 ( $K_i = 3.1$  μM). ACEA inhibits forskolin-induced cAMP accumulation in Chinese hamster ovary cells expressing the human CB<sub>1</sub> receptor. It also increases the binding of [<sup>35</sup>S]GTPγS to cerebellar membranes and inhibits electrically evoked contractions of the mouse vas deferens. ACEA produces hypothermia in mice, an effect that is inhibited by co-administration of the CB<sub>1</sub> receptor antagonist SR141716A. **1.** Hillard, Manna, Greenberg, *et al.* (1999) *J. Pharmacol. Exp. Ther.* **289**, 1427.

### 2-Arachidonoylglycerol

This potent endocannabinoid (FW = 378.30 g/mol; CAS 53847-30-6; Symbol: 2-AG), also known as 1,3-dihydroxy-2-propanyl (5Z,8Z,11Z,14Z)-5,8,11,14-eicosatetraenoate, is an endogenous agonist of the CB<sub>1</sub>, the G-protein-coupled Cannabinoid receptor type-1 found primarily in the central and peripheral nervous system. 2-AG is found at highest concentrations in the CNS, where it exerts its cannabinoid-like neuromodulatory effects (1,2). Found in milk, 2-AG plays a role in sustaining infant suckling, and the selective CB<sub>1</sub> receptor antagonist SR141617A (*N*-(piperidin-1-yl)-5-(4-chlorophenyl)-1-(2,4-dichlorophenyl)-4-methyl-1*H*-pyrazole-3-carboxamide) permanently prevents milk ingestion in a dose-dependent manner, when administered to mouse pups, within 1 day of birth (3). 2-AG is formed by phospholipase C (PLC) and diacylglycerol lipase (DAGL) from arachidonic acid-containing diacylglycerol (DAG). In the CNS, three serine-hydrolases, monoacylglycerol lipase (MAGL), α,β-hydrolase-domain-6 (ABHD6) and α,β-hydrolase-domain 12 (ABHD12) are responsible for inactivation of the primary 2-arachidonoylglycerol. Irreversible ABHD6 inhibitors show exceptional potency and selectivity in cells (<5 nM) and, at equivalent doses in mice (1 mg/kg), acting as systemic and peripherally restricted inhibitors, respectively (1). Indeed, selective knockdown of ABHD6 in metabolic tissues protects mice from high-fat-diet-induced obesity, hepatic steatosis, and systemic insulin resistance (2). **1.** Hsu, Tsuboi, Chang, *et al.* (2013) *J Med Chem.* **56**, 8270. **2.** Thomas, Better, Lord, *et al.* (2013) *Cell Rep.* **5**, 508. **3.** Fride, Foox, Rosenberg, *et al.* (2003) *Eur. J. Pharmacol.* **461**, 27.

### Aranidipine

This calcium channel blocker (FW = 388.37 g/mol; CAS 86780-90-7), also named MPC-1303, Sapresta® and the methyl-2-oxopropyl 1,4-dihydro-2,6-dimethyl-4-(2-nitrophenyl)-3,5-pyridine-dicarboxylate, exhibits antihypertensive effects that were more potent than other dihydropyridines, and its pharmacologically active metabolites displayed antihypertensive effects comparable to other dihydropyridines. **1.** Kanda, Haruno, Miyake, & Nagasaka (1992) *J. Cardiovasc. Pharmacol.* **20**, 723.

### ARC

This 208-residue skeletal and cardiac muscle protein (MW = 22629.46 g; Protein Accession Number AAC34993; Isoelectric Point = 4.11), known fully as Apoptosis Repressor with CARD (*or* Caspase recruitment domain), is an endogenous inhibitor of apoptosis that is induced by caspase-8 and CED-3, but not caspase-9. Significantly, the enzymatic activity of caspase-8 is inhibited by ARC in 293T cells (1). Consistent with the inhibition of caspase-8, ARC attenuates apoptosis induced by FADD and TRADD as well as that triggered by stimulation of caspase-8 death receptors (*e.g.*, CD95/Fas, tumor necrosis factor-R1, and TRAMP/DR3) (1). ARC also antagonizes both the extrinsic (death receptor) and intrinsic

(mitochondrial/ER) pathways. ARC also inhibits TNF $\alpha$ -induced necrosis when overexpressed in its wild-type form, but not by a CARD mutant defective for inhibiting apoptosis. Conversely, knockdown of ARC exacerbated TNF $\alpha$ -induced necrosis, an effect that was rescued by reconstitution with wild type ARC, but not with CARD-defective ARC. A likely mechanism for these effects involves the interaction of ARC with TNF Receptor-1, interfering with recruitment of RIP1, a critical mediator of TNF $\alpha$ -induced regulated necrosis. Induction of hypoxia-inducible factors (HIFs) is needed for tumor cell to adapt to a low-oxygen environment, and ARC expression is itself induced in a HIF1-dependent manner (3). 1. Koseki, Inohara, Chen & Núñez (1998) *Proc. Natl. Acad. Sci. U.S.A.* **95**, 5156. 2. Kung, Dai, Deng & Kitsis (2014) *Cell Death Differ.* **21**, 634. 3. Razorenova, Castellini, Colavitti, *et al.* (2013) *Mol. Cell Biol.* **34**, 739.

### Arctigenin

This plant lignan (FW = 372.41 g/mol; CAS 7770-78-7; IUPAC: (3*R*,4*R*)-4-[(3,4-dimethoxy-phenyl)methyl]-3-[(4-hydroxy-3-methoxyphenyl)methyl]-2-tetrahydrofuranone) is a functional ingredient of several traditional Chinese herbs and dose-dependently reduces proliferation of human dermal microvascular endothelial cells without altering their migratory and tube-forming capacity. Arctigenin treatment also resulted in a decreased cellular expression of phosphorylated serine/threonine protein kinase AKT, vascular EGFR2, and proliferating cell nuclear antigen and inhibited vascular sprouting from aortic rings. 1. Gu, Scheuer, Feng, Menger & Laschke (2013) *Anticancer Drugs* **24**, 781.

### Arecoline

This CNS-active alkaloid (FW = 155.19 g/mol; CAS 63-75-2; p*K<sub>a</sub>* ~ 6.8), also named methyl 1-methyl-1,2,5,6-tetrahydropyridine-3-carboxylate, from the areca nut (*Areca catechu*), is a partial agonist of muscarinic M<sub>1</sub>, M<sub>2</sub>, M<sub>3</sub>, and M<sub>4</sub> acetylcholine receptors, giving rise to its well-known parasympathetic effects, including pupillary and bronchial constriction (1-3). (Note: Some muscarinic agonists also cause cause significant receptor internalization and down-regulation; others are allosteric ligands. In this respect, the action of arecoline may not be that of a classical partial agonist acting at a receptor's primary binding site.) Arecoline induces dose-dependent antinociception (0.3-1 mg/kg, *i.p.*) that can be prevented by muscarinic antagonists: pirenzepine (0.1  $\mu$ g/mouse, *i.c.v.*) or *S*-(-)-ET-126 (0.01  $\mu$ g/mouse, *i.c.v.*) (1). Arecoline excites rat *locus coeruleus* neurons by activating the M<sub>2</sub>-muscarinic receptor (2). It also excites the colonic smooth muscle motility via M<sub>3</sub> receptors in rabbits (3). In some Asian countries, the areca nut is chewed along with betel leaf for its stimulating effects. This practice can have devastating long-term consequences, including aggressive oral cancer. Oral submucous fibrosis (OSF), a chronic inflammatory disease characterized by the accumulation of excess collagen, is a condition occurring often in individuals who frequently chew areca nuts (4). Notably, arecoline markedly induces morphologic change in HaCaT cells (transformed human epithelial cells derived from adult skin), but has no obvious effect on He1 cells (human embryo fibroblasts) (4). Arecoline also attenuates the 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD)-induced CYP1A1 activation, mainly via down-regulation of AhR expression in human hepatoma cells, suggesting the possible involvement of arecoline in the AhR-mediated metabolism of environmental toxicants in liver (5). 1. Ghelardini, Galeotti, Lelli & Bartolini (2001) *Farmaco* **56**, 383. 2. Yang YR, Chang, Chen & Chiu (2000) *Chin. J. Physiol.* **43**, 23. 3. Xie, Chen, Liu, *et al.* (2004) *Chin. J. Physiol.* **47**, 89. 4. Li, Gao, Zhou, *et al.* (2014) *Oncol. Rep.* **31**, 2422. 5. Chang, Miao, Lee, *et al.* (2007) *J. Hazard. Mater.* **146**, 356.

### Argadin

This cyclopentapeptide (FW = 674.70 g/mol; CAS 289665-92-5), found in fungal cultures of a species of *Clonostachys*, inhibits insect chitinases (*e.g.*, blowfly [*Lucilia cuprina*] chitinase: IC<sub>50</sub> = 0.15  $\mu$ M at 37°C and 3.4 nM at 20°C). The *K<sub>i</sub>* value for chitinase B of *Serratia marcescens* is 20 nM. 1. Arai, Shiomi, Yamaguchi, *et al.* (2000) *Chem. Pharm. Bull.* **48**, 1442. 2. Houston, Shiomi, Arai, *et al.* (2002) *Proc. Natl. Acad. Sci. U.S.A.* **99**, 9127.

### Argatroban

This anticoagulant (FW = 508.64 g/mol; CAS 74863-84-6), also named (2*R*,4*R*)-4-methyl-1-*N*2-[(3-methyl-1,2,3,4-tetrahydro-8-quinolyl)sulfonyl]-L-arginyl-2-piperidine carboxylic acid, Novastan<sup>®</sup>, and MD-805, is a direct thrombin inhibitor (1-11) that is an effective treatment for heparin-induced thrombocytopenia (HIT), an immunoglobulin-mediated adverse drug reaction characterized by platelet activation, thrombocytopenia, and a high risk of thrombotic complications among patients who are receiving or have recently received heparin. HIT is an autoimmune-like disorder, with the target antigen a multimolecular complex of the "self" protein, Platelet Factor-4, and heparin. Continued use of heparin is ill-advised and dangerous. Argatroban is also indicated for the treatment of heparin-induced thrombocytopenia and thrombosis syndrome (HITTS), an immune-mediated response to the administration of heparin that results in life-threatening thrombosis. Argatroban is one of four FDA-approved parenteral direct thrombin inhibitors, the others being lepirudin, desirudin, and bivalirudin. Argatroban is metabolized in the liver (*t*<sub>1/2</sub> = ~50 min). Other DTI's include recombinant hirudins, bivalirudin, and ximelagatran, either alone or in combination with melagatran (2). Argatroban is a significantly weaker inhibitor of trypsin, *K<sub>i</sub>* = 4.3  $\mu$ M (6,11), plasmin (*K<sub>i</sub>* = 800  $\mu$ M), coagulation factor Xa, and plasma kallikrein (*K<sub>i</sub>* = 2 mM). Commercial sources often supply a mixture of 21(*R*) and 21(*S*) Diastereoisomers. The latter is more potent. 1. Koster, Fischer, Harder & Mertzluft (2007) *Biologics* **1**, 105. 2. ### D-Arginine

This amino acid (FW<sub>free-base</sub> = 174.20 g/mol), named systematically as (*R*)-2-amino-5-guanidinopentanoic acid, is the enantiomer of the more abundant and proteogenic amino acid. **Target(s):** arginine *N*-succinyltransferase (1); ribosomal peptidyltransferase (2); arginine decarboxylase (3,4,10-12); carboxypeptidase B (5,16); clostripain (6); arginine 2-monooxygenase, weakly inhibited (7); acetylcholinesterase, weakly inhibited (8); tyrosine:arginine ligase, or kyotorphin synthetase (9); arginine deaminase (13); Arginase (14); lysine carboxypeptidase, or lysine(arginine) carboxypeptidase, or carboxypeptidase N (15); aminopeptidase B (17); arginine kinase (18-20). 1. ### L-Arginine

This basic proteogenic amino acid and nitric oxide precursor (FW<sub>monohydrochloride</sub> = 210.66 g/mol; FW<sub>free-base</sub> = 174.20 g/mol; pKa values of 1.82, 8.99, and 12.48 (guanido) at 25°C), also called (*S*)-2-amino-5-guanidinopentanoate, is symbolized by Arg or R. There are six codons for arginine: AGA, AGG, CGU, CGC, CGA, and CGG. (The first two are not in the mitochondria of mammals, and AGA is also not in the mitochondria of *Drosophila melanogaster*). The guanidino group reacts with a number of reagents (e.g., phenylglyoxal and 1,2-cyclohexanedione), often resulting in loss of catalytic activity for enzymes with active-site arginine residues. Arginine is also converted into creatine and creatinine. **Target(s):** amino-acid *N*-acetyltransferase (*N*-acetylglutamate synthase; arginine is an activator of the mammalian and frog enzymes) (1,79,85-92); *N*-acetylglutamate kinase (2,7,15,17,28,73,78); omptin (3,11); procollagen C-endopeptidase (4,56,57); peptidyl-Lys metalloendopeptidase, or *Armillaria mellea* protease, weakly inhibited (5,54,55); GfMEP, thermostable lysine-specific metalloendopeptidase (5,55); anicrod (6); ribosomal peptidyltransferase (8); putrescine carbamoyltransferase (9); lysine carboxypeptidase, or lysine(arginine) carboxypeptidase, or carboxypeptidase N (10,64); ornithine carbamoyltransferase (12,93-95); carboxypeptidase B (13); clostripain (14); carbamate kinase (16); homoserine kinase, weakly inhibited (18,22); saccharopine dehydrogenase (19); argininosuccinate synthetase (20,35); Xaa-Arg Dipeptidase, or aminoacyl-lysine Dipeptidase (27); aminopeptidase B (23,66-68);  $\gamma$ -glutamyl transpeptidase, weakly inhibited (24,25); group I self-splicing intron (26); kynureninase (27); asparagine synthetase, weakly inhibited (29); alkaline phosphatase (30); acetylcholinesterase (31); glutamate decarboxylase, weakly inhibited (32); urate oxidase, weakly inhibited (33); carbamoyl-phosphate synthetase (34); glutamine synthetase (36,37); lysyl-tRNA synthetase (38); 2-aminohexano-6-lactam racemase (39); threonine ammonia-lyase, or threonine hydratase (40); hyaluronate lyase (41); dihydrodipicolinate synthase (42-45); lysine transport (46); 5-guanidino-2-oxopentanoate decarboxylase, or  $\alpha$ -ketoarginine decarboxylase; weakly inhibited (47); ornithine decarboxylase (48-50); kynureninase (51); agmatine deaminase (52); agmatinase (53); oligopeptidase B (58); venombin A (60); acrosin (59-62); carboxypeptidase E (63); membrane alanyl aminopeptidase, or aminopeptidase N (65,69,70); [citrate lyase] deacetylase (71); guanidinoacetate kinase, weakly inhibited (78);

homoserine kinase (86); ornithine aminotransferase (87); spermidine synthase (88); homocitrate synthase (89); leucyltransferase. 1. Powers-Lee (1985) *Meth. Enzymol.* **113**, 27. 2. #### L-Arginine Methyl Ester

This amino acid ester (FW<sub>dihydrochloride</sub> = 261.15 g/mol) has the following inhibitory targets: alkaline phosphatase (1); cyanophycin synthetase (2); hyaluronate lyase (3); arginine decarboxylase (4,5); protein-arginine deiminase (reference probably meant *N*<sup>ω</sup>-nitro-L-arginine methyl ester) (6); aminopeptidase B, weakly inhibited (7); [protein ADP-ribosylarginine] hydrolase, weakly inhibited (8); arginine kinase (9); *N*-acetylglutamate kinase (10); leucyltransferase (11). **1**. #### Argininic Acid

This  $\alpha$ -hydroxy arginine analogue (FW = 175.19 g/mol; CAS 157-07-3), also known as  $\alpha$ -hydroxy- $\delta$ -guanidinovaleric acid, has the following inhibitor targets: carboxypeptidase B (1-4); arginase (5,13); lysine carboxypeptidase, *or* lysine(arginine) carboxypeptidase (6); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (7,8); arginine decarboxylase, inhibited by the L-enantiomer (9,10,12); 5-guanidino-2-oxopentanoate decarboxylase, *or*  $\alpha$  ketoarginine decarboxylase; weakly inhibited, *K*<sub>i</sub> = 6.9 mM (11). **1**. #### L-Argininosuccinate

This Urea Cycle intermediate (FW = 290.27 g/mol; CAS 2387-71-5; p*K*<sub>a</sub> values: 1.62, 2.70, 4.26, 9.58, and >12), also known as (*N*<sup>ω</sup>-L-arginino)-succinic acid and *N*<sup>ω</sup>-(1,2-dicarboxylethyl)arginine, is a nonproteinogenic L-amino acid formed by argininosuccinate synthetase (*Reaction*: Citrulline + MgATP<sup>2-</sup> + L-Aspartate  $\rightleftharpoons$  L-Argininosuccinate + AMP + PP<sub>i</sub>) and is subsequently converted to arginine by argininosuccinate lyase. **Target(s)**: arginyl-tRNA synthetase (1,2,9; but see ref. 2); diacylglycerol cholinephosphotransferase (3); nitric oxide synthase (4,5); adenylosuccinate synthetase (6,7); histidyl tRNA synthetase, weakly inhibited (8). **1**. #### L-Arginyl-L-alanylglycyl-L-phenylalanyl-L-alanyl-L-prolyl-L-phenylalanyl-L-arginine

This octapeptide (FW = 835.96 g/mol; Sequence: RAGFAPFA), also known as [des-Pro<sup>3</sup>,Ala<sup>2</sup>,6]-bradykinin, inhibits peptidyl-dipeptidase A, *or* angiotensin I-converting enzyme: (*K*<sub>i</sub> = 30 nM), giving better inhibition than captopril. **1**. Chaturvedi, Huelar, Gunthorpe, *et al.* (1993) *Pept. Res.* **6**, 308.

#### D-Arginyl-L-homophenylalanyl-L-arginine 2-(3,3,3-Trifluoro)ethoxymethyl Ketone

This tripeptide analogue (FW = 588.66 g/mol) inhibits plasma kallikrein, *or* PK (*K*<sub>i</sub> = 54 nM, showing good selectivity for PK versus tissue kallikrein, thrombin and plasmin. **1**. Evans, Jones, Pitt, *et al.* (1996) *Immunopharmacology* **32**, 115.

#### L-Arginyl-L-lysyl-L-tyrosyl-L-tyrosyl-L-arginyl-L-arginyl-L-lysineamide

This nonapeptide amide, also known as Peptide-18 (FW = 1324.62 g/mol; Sequence: RKKYKYRRK-NH<sub>2</sub>), inhibits [myosin light-chain] kinase (*K*<sub>i</sub> = 52 nM). **1**. Lukas, Mirzoeva, Slomczynska & Watterson (1999) *J. Med. Chem.* **42**, 910. **2**. Deng, Williams & Schultz (2005) *Dev. Biol.* **278**, 358.

#### L-Arginyl-D-tryptophanyl-N-methyl-L-phenylalanyl-D-tryptophanyl-L-leucyl-L-methioninamide

This hexapeptide amide (FW = 951.21 g/mol), also known as Antagonist G and [Arg<sup>6</sup>,D-Trp<sup>7,9</sup>,N-Me-Phe<sup>8</sup>]-Substance P fragment 6-11, is a broad spectrum neuropeptide growth factor antagonist used in the treatment of small-cell lung cancer. **1**. Jones, Cummings, Langdon, MacLellan & Smyth (1995) *Biochem. Pharmacol.* **50**, 585. **2**. Laufer, Wormser, Friedman, *et al.* (1985) *Proc. Natl. Acad. Sci. U.S.A.* **82**, 7444.

#### Argyrol

This silver-gelatin colloid (MW = undefined), prepared by a proprietary process, in which silver nitrate, sodium hydroxide, and gelatin are combined, inhibits the erosive growth of *Neisseria gonorrhoeae* introduced into a neonate's eyes during passage through an infected birth canal. The preparation was perfected and commercialized by Philadelphia physician, Albert Coombs Barnes, who used the proceeds to amass one of the finest private collections of Impressionist paintings, now comprising the world-famous Barnes Collection. **Note**: Despite claims to the contrary, some microorganisms manage to resist silver toxicity by expressing ATP-dependent cation pumps that export Ag<sup>+</sup>. **1**. Bruns (1906) *Trans. Am. Ophthalmol. Soc.* **11**, 28. **2**. Lancaster (1920) *Trans. Am. Ophthalmol. Soc.* **18**, 151.

#### Arietin

This cysteine-rich disintegrin (*M*<sub>r</sub> = 8500) from the snake *Bitis arietans* contains an RGD loop that facilitates tight binding to integrins in a manner that inhibits platelet aggregation stimulated by ADP, thrombin, collagen,

and U46619, with  $IC_{50}$  = 130-270 nM. At 65 nM, arietin blocks fibrinogen-induced aggregation of elastase-treated platelets. 1. Huang, Wang, Teng & Ouyang (1991) *Biochim. Biophys. Acta* **1074**, 144. 2. Huang, Wang, Teng, Liu & Ouyang (1991) *Biochim. Biophys. Acta* **1074**, 136.

### Aripiprazole

This antipsychotic drug (FW = 448.39 g/mol; CAS 129722-12-9; Solubility = 90 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), known also by its code name OPC-145977, its trade name Ambifyl<sup>®</sup>, and its systematic name (4-[4-(2,3-dichlorophenyl)-1-piperazinyl]butyloxy)-3,4-dihydro-2(1H)-quinolinone, is a dual dopamine autoreceptor agonist and postsynaptic D<sub>2</sub> receptor antagonist (1). (See *Brexiprazole*) Ambifyl is indicated for the treatment of schizophrenia in individuals age 13 years and older and for bipolar disorder in individuals age 10 years and older. It is considered to be safe, effective, and well tolerated for treating both positive and negative symptoms in schizophrenia and schizoaffective disorder. Aripiprazole is also the first non-D<sub>2</sub> receptor antagonist with evident antipsychotic effects, representing a novel treatment for such disorders. Aripiprazole is a partial agonist of human 5-HT<sub>1A</sub> receptor,  $K_i$  = 4.2 nM (2). Coadministration with medications that inhibit (*e.g.*, paroxetine and fluoxetine) or induce (*e.g.*, carbamazepine) CYP2D6 and CYP3A4 has the effect of increasing and decreasing plasma aripiprazole levels, respectively. (See also *Amisulpride*; *Aripiprazole*; *Olanzapine*; *Quetiapine*; *Remoxipride*; *Risperidone*; *Sertindole*; *Ziprasidone*; *Zotepine*) **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York. **Other Target(s):** 5-HT<sub>1B</sub> serotonin receptor,  $K_i$  = 830 nM; 5-HT<sub>1D</sub> receptor,  $K_i$  = 66 nM; 5-HT<sub>2A</sub> receptor,  $K_i$  = 8.7 nM; 5-HT<sub>2B</sub> receptor,  $K_i$  = 0.36 nM; 5-HT<sub>2C</sub> receptor,  $K_i$  = 22 nM, partial agonist; 5-HT<sub>3</sub> receptor,  $K_i$  = 630 nM; 5-HT<sub>5A</sub> receptor,  $K_i$  = 1200 nM; 5-HT<sub>6</sub> receptor,  $K_i$  = 640 nM; 5-HT<sub>7</sub> receptor,  $K_i$  = 10 nM, weak partial agonist; D<sub>1</sub> receptor,  $K_i$  = 1200 nM; D<sub>2</sub> receptor,  $K_i$  = 1.6 nM, partial agonist; D<sub>3</sub> receptor,  $K_i$  = 5.4 nM, partial agonist; D<sub>4</sub> receptor,  $K_i$  = 510 nM, partial agonist; D<sub>5</sub> receptor,  $K_i$  = 2100 nM;  $\alpha_{1A}$ -adrenergic receptor,  $K_i$  = 26 nM;  $\alpha_{1B}$ -adrenergic receptor,  $K_i$  = 34 nM;  $\alpha_{2A}$ -adrenergic receptor,  $K_i$  = 74 nM;  $\alpha_{2B}$ -adrenergic receptor,  $K_i$  = 100 nM;  $\alpha_{2C}$ -adrenergic receptor,  $K_i$  = 38 nM;  $\beta_1$ -adrenergic receptor,  $K_i$  = 140 nM;  $\beta_2$ -adrenergic receptor,  $K_i$  = 160 nM; H<sub>1</sub> receptor,  $K_i$  = 28 nM; M<sub>1</sub> receptor,  $K_i$  = 6800 nM; M<sub>2</sub> receptor,  $K_i$  = 3500 nM; M<sub>3</sub> receptor,  $K_i$  = 4700 nM; M<sub>4</sub> receptor,  $K_i$  = 1500 nM; M<sub>5</sub> receptor,  $K_i$  = 2300 nM; SERT,  $K_i$  = 1100 nM; NET,  $K_i$  = 2100 nM; and DAT,  $K_i$  = 320 nM. 1. Kikuchi, Tottori, Uwahodo, *et al.* (1995) *J. Pharmacol. Exp. Ther.* **274**, 329. 2. Jordan, Koprivica, Chen, *et al.* (2002) *Eur. J. Pharmacol.* **441**, 137.

### Aristeromycin

This adenosine analogue (FW = 265.27 g/mol CAS 19186-33-5), also known as carbocyclic adenosine and 9-[2,3-dihydroxy-4-(hydroxymethyl)cyclopentyl]adenine, inhibits purine biosynthesis as well as *S*-adenosylhomocysteine hydrolase, or adenosylhomocysteinase (1-5). 1. Mizutani, Masuoka, Imoto, Kawada & Umezawa (1995) *Biochem. Biophys. Res. Commun.* **207**, 69. 2. Chiang (1987) *Meth. Enzymol.* **143**, 377. 3. Guranowski & Jakubowski (1987) *Meth. Enzymol.* **143**, 430. 4. Guranowski, Montgomery, Cantoni & Chiang (1981) *Biochemistry* **20**, 110. 5. Ishikura, Nakamura, Sugawara, *et al.* (1983) *Nucl. Acids Symp. Ser.* (12), 119.

### Arjunolate (Arjunolic Acid)

This pentacyclic triterpenoid (FW = 488.70; CAS 465-00-9), also known as 2 $\alpha$ ,3 $\beta$ ,23-trihydroxyolean-12-en-28-oic acid, from several plants, including flowers of *Campsis grandiflora*, inhibits cholesterol *O*-acyltransferase (1) and tyrosinase, the latter with an  $IC_{50}$  value of 1  $\mu$ M (2). The methyl ester also inhibits tyrosinase ( $IC_{50}$  = 2.3  $\mu$ M). 1. Kim, Han, Chung, *et al.* (2005) *Arch. Pharm. Res.* **28**, 550. 2. Ullah, Hussain, Hussain, *et al.* (2007) *Phytother. Res.* **21**, 1976.

### Armodafinil

This vigilance-promoting, or eugeroic, drug (FW = 287.38 g/mol; CAS 112111-43-0), also known by its trade name Nuvigil<sup>®</sup> and its systematic name (-)-2-[(*R*)-(diphenylmethyl)sulfinyl]acetamide, is the (*R*)-enantiomer of modafinil and has FDA approval for the treatment of excessive sleepiness caused either by narcolepsy or shift-worker sleep disorder. Armodafinil is a unique dopamine uptake inhibitor that binds to the dopamine transporter (DAT), inhibiting DA uptake less potently than cocaine. *R*-modafinil has ~3x higher affinity for DAT than its enantiomer, a property thought, on the basis molecular docking studies, to arise from differences in binding modes (1). *R*-modafinil was significantly less potent in the DAT-Y156F mutant compared with wild-type DAT, whereas *S*-modafinil was less affected (1). Studies on Y335A DAT also showed that the *R*- and *S*-enantiomers tolerated the inwardly facing conformation better than cocaine, a finding that was further supported by the reactivity of [2-(trimethylammonium)ethyl]-methanethio-sulfonate reactivity with the DAT-E2C/1159C double-mutant. Both *R*- and *S*-enantiomers increase extracellular DA concentrations in the nucleus accumbens shell less efficaciously than cocaine, but with a longer duration of action (1). Loland, Mereu, Okunola, *et al.* (2012) *Biol. Psychiatry* **72**, 405.

### ARN 272

This FLAT inhibitor (FW = 432.47 g/mol; CAS 488793-85-7), also named 4-[4-(4-hydroxy-phenyl)-1-phthalazinyl]amino]-*N*-phenylbenzamide, targets the FAAH-Like Anandamide Transporter ( $IC_{50}$  = 1.8  $\mu$ M), a catalytically silent variant of fatty acid amide hydrolase-1 (FAAH-1) that

drives anandamide transport. **Mode of Action:** The intensity and duration of anandamide signaling appear to be controlled by a two-step elimination process, in which the anandamide or an anandamide-like substance is first internalized by neurons and astrocytes through the action of FLAT and then undergoes hydrolysis through the action of the intracellular membrane-bound amidases, FAAH-1 and FAAH-2. ARN-272 attenuates anandamide internalization, thereby reducing its deactivation. ARN272 competitively antagonizes [<sup>3</sup>H]-anandamide binding to FLAT (IC<sub>50</sub> = 1.8 μM) and inhibits [<sup>3</sup>H]-anandamide accumulation in both FLAT-expressing Hek293 cells (IC<sub>50</sub> ≈ 3 μM) and primary cultures of cortical neurons prepared from rats or wild-type mice. By contrast, ARN272 is without significant effect on the residual [<sup>3</sup>H]-anandamide accumulation observed in cortical transport system may also facilitate the release of this lipid mediator from cells. It also exhibits analgesic effects in rodent models of CB<sub>1</sub> endocannabinoid receptor-mediated nociceptive and inflammatory pain. 1. Fu, Bottegoni, Sasso, *et al.* (2011) *Nature Neurosci.* **15**, 64.

#### ARN398 & ARN14988

These sphingolipid-signaling inhibitors (FW<sub>ARN398</sub> = 307.27 g/mol; FW<sub>ARN14988</sub> = 373.83 g/mol) target human acid ceramidase, with IC<sub>50</sub> values of 7.7 and 12.8 nM, respectively, thereby increasing cellular ceramide levels and decreasing sphingosine 1-phosphate, and synergizing with several antitumor agents. Compared to normal melanocytes, ceramide production is suppressed in melanoma cells, and elevation of ceramide levels enhances the cytotoxic effects of chemotherapeutic drugs on proliferative melanoma cells in culture. ARN398 is unstable, showing a plasma half-life of 1 min and an *in vitro* half-life of 120 min at pH 4.5. ARN14988 is more stable, showing a plasma half-life of 300 min and an *in vitro* half-life of 140 min at pH 4.5. 1. Realini, Palese, Pizzirani, *et al.* (2015) *J. Biol. Chem.* **291**, 2422.

#### Arphamenine A

This dipeptide analogue (FW<sub>di-Arphamenine-Sulfate</sub> = 738.85 g/mol; CAS 144110-37-2), isolated from *Chromobacterium violaceum*, strongly inhibits aminopeptidase B. Stock solutions are stable for about one month at -20°C. **Target(s):** aminopeptidase B (1,2,9-13); leukotriene A<sub>4</sub> hydrolase aminopeptidase activity (3); dipeptide transport (4); leucyl aminopeptidase, *Leishmania* sp. and *Psoroptes cuniculi* (5,6); Xaa-Trp aminopeptidase, or aminopeptidase W (7); cytosol alanyl aminopeptidase (8); prolyl aminopeptidase, from *Grifola frondosa* (14); membrane alanyl aminopeptidase, aminopeptidase N (15). 1. Foulon, Cadel & Cohen (1998) in *Handb. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.), p.

#### ARQ 197, See Tivantinib

#### AR-R17477

This neuronal NOS-specific inhibitor (FW = 369.91 g/mol), also known as *N*-(4-(2-((3-chlorophenylmethyl)amino)ethyl)phenyl)-2-thiophenecarboxamide, inhibits neuronal nitric-oxide synthase (rat IC<sub>50</sub> = 35 nM). It is a weaker inhibitor of the inducible and endothelial synthases. Crystal structures of iNOS<sub>oxy</sub> and nNOS<sub>oxy</sub> complexed with AR-R17477 suggest that specificity is provided by the interaction of the chlorophenyl group with an isoform-unique substrate access channel residue (L337 in rat neuronal NOS, N115 in mouse inducible NOS). This is confirmed by biochemical analysis of site-directed mutants. AR-R 17477 also blocks some effects of phencyclidine, while having no observable behavioural effects when given alone (2). 1. Federov, Vasani, Ghosh & Schlichting (2004) *Proc. Natl. Acad. Sci. U.S.A.* **101**, 5892. 2. Johansson, Deveney, Reif & Jackson (1999) *Pharmacology & Toxicology* **84**, 226.

#### Arrestin

This rod outer-segment protein (MW = 48-kDa) inhibits the dephosphorylation of photolyzed rhodopsin by binding preferentially to the phosphorylated protein and blocking dephosphorylation. Arrestin mediates the quenching of phototransduction. **Target(s):** G protein-coupled receptor/G protein coupling (1); protein phosphatase 2A, or opsin phosphatase (2); rhodopsin kinase (3). 1. Mundell, Orsini & Benovic (2002) *Meth. Enzymol.* **343**, 600. 2. Palczewski, McDowell, Jakes, Ingebritsen & Hargraves (1989) *J. Biol. Chem.* **264**, 15770. 3. #### ARRY-162, See Binimetinib

#### ARRY-142886, See Selumetinib

#### ARRY 334543

This ErbB1/2 inhibitor (FW = 466.94 g/mol; CAS 845272-21-1), also named (*R*)-*N*-(3-chloro-4-(thiazol-2-ylmethoxy)phenyl)-*N*-(4-methyl-4,5-dihydrooxazol-2-yl)quinazoline-4,6-diamine, selectively targets the intrinsc protein kinase activities of ErbB1, or Epidermal Growth Factor Receptor (EGFR), IC<sub>50</sub> = 7 nM and ErbB2, or Human Epidermal growth factor Receptor (HER2), IC<sub>50</sub> = 2 nM (1). ARRY-334543 also reverses

multidrug resistance by antagonizing the activity of ATP-binding cassette subfamily G member 2 (2). 1. Rabindran, Discifani, Rosfjord, *et al.* (2004) *Cancer Res.* 64, 3958. 2. Wang, Patel, Sim, *et al.* (2014) *J. Cell Biochem.* 115, 1381.

**ARRY-438162**, See *Binimetinib*

***p*-Arsanilate (*p*-Arsanilic Acid)**

This toxic arsenical (FW<sub>free-acid</sub> = 217.06 g/mol; CAS 202-674-3), also known as *p*-arsanilic acid, (4-aminophenyl)arsonic acid, atoxylic acid, and atoxyl, is a precursor in the chemical synthesis of many pharmaceuticals. The sodium salt is used as an anthelmintic in farm animals. The free acid is slightly soluble in cold water while the sodium salt is soluble in about six parts water. Nobelist Robert Koch reported in 1906 on the effectiveness of atoxyl on human trypanosomiasis, and Nobelist Paul Ehrlich determined the structure of atoxyl. **Target(s)**: subtilisin (1,3); esterase (2,4,5); chymotrypsin (3); trypsin (3); triacylglycerol lipase (6,10,12,14-16); cholesterol esterase (7); lipoprotein lipase (8); carboxylesterase (2,4,5,9); amidase (11); aryl esterase (12); cholinesterase (13); thioesterase (19). 1. **Arsenate**

This inorganic dianion HAsO<sub>4</sub><sup>2-</sup> (FW<sub>dianion</sub> = 139.93 g/mol) and conjugate base of arsenic acid, H<sub>3</sub>AsO<sub>4</sub> (FW<sub>free-acid</sub> = 141.94 g/mol; CAS 7778-39-4), is an environmental hazard that acts as a phosphate analogue in many enzyme-catalyzed reactions. The similarity of arsenate and phosphate is evident in their pK<sub>a</sub> values: 2.25, 6.77, and 11.60 (at 18°C) for the former, and 2.15, 7.20, and 12.33 (at 25°C) for the latter. The As–O bond length and bond angle are 1.6–2.0 Å and 100° (compare to 1.5 Å and 117° for P<sub>i</sub>). As such, arsenate enters most cells and compartments via phosphate transporters, albeit at somewhat lower rates. Once within, arsenate is incorporated into many metabolites, forming glucose 1-arsenate by the action of glycogen phosphorylase, glyceraldehyde 3-arsenate by glyceraldehyde 3-P dehydrogenase, and ADP-arsenate by ATP synthase. Similarly, reactions like polynucleotide phosphorylase produce arsenate esters. A key property of arsenate esters (*i.e.*, R–O–AsO<sub>3</sub><sup>2-</sup>), however, is their kinetic and thermodynamic instability, readily undergoing hydrolysis in aqueous solutions. As such, arsenate forms product-like compounds that persist within an enzyme's active sites, but, once released from the enzyme's surface, rapidly hydrolyze to ROH and HAsO<sub>4</sub><sup>2-</sup>. One also cannot discount the likelihood that arsenate is an effective competitive inhibitor for many enzymes, and, given the well-known phosphate attenuation of glucose-6-P inhibition of brain hexokinase, one may also anticipate higher rates of glycolysis in the presence of arsenate. Arsenate contamination in drinking water poses serious worldwide health threats, producing multiple adverse effects in humans. Indeed, certain geographical regions have intolerably high levels of arsenate pollution. (*Note*: Arsenate is also redox-active, with an oxidation-reduction potential of +139 mV (compare to P<sub>i</sub> value of –690 mV), a property exploited by some microorganisms as a source of metabolic energy.) **Target(s)**: deoxyribonuclease (11,25); glycerol-2-phosphatase (2); exopolyphosphatase (3); ribulose-bisphosphate

carboxylase (4); fatty-acid synthase (5); steroid 11β-monooxygenase (6); aspartate carbamoyltransferase (7); AMP nucleosidase (8,67); nucleoside-diphosphate kinase (9,27); trehalose-phosphatase (10,81); cholesterol esterase (11); photo-phosphorylation uncoupler, in the presence of ADP (12); triose-phosphate isomerase (13,55-57); alkaline phosphatase (14,20,22,24,28,29,32,47,95-98); luciferase, firefly (*Photinus*-luciferin 4-monooxygenase (15,120-123); putrescine carbamoyltransferase (16); flagellar motor (17); arylformamidase (18); Ca<sup>2+</sup>-transporting ATPase (19); 3-phosphoglycerate kinase (21); acid phosphatase (22,23,30,33,35, 36,38,39,84-94); polynucleotide phosphorylase (26); glucose-6-phosphatase (31,45); carbonic anhydrase, *or* carbonate dehydratase (34); phosphoprotein phosphatase (37); glycerol-1-phosphatase (40); methylglyoxal synthase (41); pyrophosphatase, *or* inorganic diphosphatase (42); phosphoglucomutase (43); xylose oxidase (44); malic enzyme, NAD<sup>+</sup>-dependent (decarboxylating) (46); oxidative phosphorylation (48); adenylosuccinate synthetase (49); asparagine synthetase (ADP-forming) (50); carboxy-*cis,cis*-muconate cyclase (51); phosphopentomutase (52); protein-disulfide isomerase (53); xylose isomerase (54); pectin lyase (58); xenobiotic-transporting ATPase, multidrug-resistance protein (59,60); trimetaphosphatase, slightly inhibited (61); sorbose reductase (62); cyanoalanine nitrilase (63); Arginase (64); 4-methyleneglutaminase, weakly inhibited (65); aryl-acylamidase (66); glucan 1,3-β-glucosidase (68); β-D-fucosidase (69); inulinase (70); 2-,3'-cyclic-nucleotide 3'-phosphodiesterase (71); phosphodiesterase I, *or* 5'-exonuclease, weakly inhibited (72); protein-tyrosine-phosphatase (73); 3-phosphoglycerate phosphatase (74); 4 phytase (75); 3-phytase (76,77); phosphoprotein phosphatase (78); histidinol-phosphatase (79); methylphosphothioglycerate phosphatase (80); glucose-1-phosphatase (82); 5'-nucleotidase (83); cephalosporin-C deacetylase (99); ribose-5-phosphate adenylyltransferase (100); sulfate adenylyltransferase (ADP) (101,102); ammonia kinase (103); nucleoside phosphotransferase (104); riboflavin phosphotransferase (105); pantothenate kinase (106); hexokinase (107); arylamine glucosyltransferase, weakly inhibited (108); glycogen phosphorylase (109); homocitrate synthase (110); phosphate acetyltransferase (111-114); transketolase (115); ornithine carbamoyltransferase (116); aspartate carbamoyltransferase (117); glutamate formimidoyl-transferase, weakly inhibited (118); cyclohexanone monooxygenase (119); gentisate 1,2-dioxygenase (124); protocatechuate 3,4 dioxygenase (125); L-ascorbate peroxidase (126); *o*-aminophenol oxidase (127); glutathione:cystine transhydrogenase (128); sulfite oxidase (129,130). 1. ### Arsenic Trioxide

This toxic inorganic oxide  $As_2O_3$  (FW = 197.84 g/mol; CAS 1327-53-3; Solubility = 37 g/L  $H_2O$  at 20°C and 115 g/L  $H_2O$  at 100°C), a commercially useful precursor employed in the synthesis of other arsenic compounds, including organoarsenic compounds, has enjoyed great interest in view of its ability to induce clinical remission in patients with acute promyelocytic leukemia (APL), particularly those who have relapsed after retinoic acid treatment. Although no longer produced in the U.S., arsenic trioxide has been employed as a herbicide, pesticide, and rodenticide. **Mechanism of  $As_2O_3$  Action:** APL is characterized by a specific reciprocal chromosome translocation t(15;17) that generates the *PML-RAR $\alpha$*  fusion gene and expression of its oncoprotein PML-RAR $\alpha$ . Upon dimerization, (PML-RAR $\alpha$ )<sub>2</sub> binds the histone-deacetylase recruiting co-repressor complex with higher affinity than the wild-type RAR $\alpha$ . Fortunately, that co-repressor complex can be dissociated by pharmacological doses of all-trans retinoic acid (ATRA), providing complete remission for roughly 90% of APL patients, especially when combined with chemotherapy. For the remaining 10%, who are refractory to ATRA treatment, relief has been achieved through arsenic trioxide-induced proteolysis of PML-RAR $\alpha$  (1,2). For such purposes, arsenic trioxide is marketed under the trade name Trisenox<sup>®</sup>.  **$As_2O_3$ -Mediated Reactivation of Methylation-Silenced Genes in Human Cancer:** DNA (cytosine-5)-methyltransferases help establish and regulate tissue-specific DNA methylation patterns, thereby maintaining tissue integrity and preventing both tumorigenesis and developmental abnormalities. In cancer, tumor suppressor genes are silenced by oncomethylation, and reactivation of them occurs when 5-azacytidine and 5-aza-2'-deoxycytidine selectively and rapidly induce proteasome-mediated degradation of maintenance DNA methyltransferase-1. Arsenic trioxide inhibits DNA methyltransferase and restores methylation-silenced genes in human liver cancer cells. Upon treatment of HepG2 and Huh-7 cells with 2–10  $\mu$ M  $As_2O_3$  for 24, 48, and 72 hours, arsenic trioxide decreased DNMT1 mRNA expression of DNMT1 and dose-dependently inhibited catalytic activity of DNMT1 (3).  **$As_2O_3$  Toxicity:** The considerable cytotoxicity of arsenic trioxide appears to be linked to its ability to induce oxidative stress, reducing glutathione stores and generating reactive oxygen species, the latter evidenced by increased malondialdehyde, a marker of lipid peroxidation.  $As_2O_3$  also significantly increases the levels of antioxidant enzymes, among them superoxide dismutase and catalase. Arsenic trioxide-exposed cells show increased levels of reactive oxygen species, lipid peroxidation, suggesting that oxidative stress might be the primary mechanism for arsenic trioxide toxicity in humans (4). **Chemical Properties:** Arsenic trioxide undergoes slow hydrolysis to form  $As(OH)_3$ , a pyramidal molecule consisting of three hydroxyl groups bonded  $sp^3$  to arsenic. In humans,  $As_2O_3$  is metabolized to arsenate, mono-methylarsonate and di-methylarsinate, the latter two formed by the action of liver methyltransferases. **Caution:** Care should be exercised in handling all arsenicals, including use of face mask to avoid airborne particulates and chemically resistant rubber gloves with liquids. (In 1858, an estimated 200 people in Bradford, England were poisoned, with twenty succumbing, when arsenic trioxide was accidentally added to some candies. That incident led to the British Pharmacy Act of 1868, recognizing the druggist as the legal custodian of all listed poisons.) **Target(s):** Acetyl-CoA acetyltransferase (5); acetyl-CoA acyltransferase (6); pyruvate dehydrogenase (7); cystathionine  $\gamma$ -lyase, or cysteine desulfhydrase (8); catalase (9,10); thiaminase (11); I $\kappa$ B kinase (12); formaldehyde transketolase (13); 2-hydroxypyridine 5-monooxygenase (14); iodide peroxidase, or thyroid peroxidase (15). **1.** Gambacorti-Passerini, Grignani, et al. #### Arspenammine

This organoarsenic (FW<sub>disodium-salt</sub> = 458.04 g/mol; CAS 1936-28-3; IUPAC Name: 4,4'-(1,2-diarsenediyl)bis[2-aminophenol]), more famously as “Ehrlich’s 606” or Salvarsan, was found to be highly effective against syphilis, culminating a determined search by Nobelist Paul Ehrlich for a “magic bullet” against the spirochete recently discovered by Schaudinn and Hoffmann. Ehrlich had his associate, Sahachiro Hata, noted the effectiveness of what was the 606<sup>th</sup> drug to be tested on syphilis-infected rabbits. Mass spectral analysis (1) later demonstrated that the actual structure is almost certainly a mixture of the cyclic trimer and pentamer, with no evidence of an As=As double bond. Salvarsan is likely to be a slow-release formulation, giving rise to the bioactive species R–As(OH)<sub>2</sub> (1). While other agents (notably, penicillin) have long-since supplanted Salvarsan in the treatment of syphilis, its discovery remains a landmark in the history of chemotherapy, one that led to the development of many other antiprotozoal and antibacterial agents (2). 1. Lloyd, Morgan, Nicholson & Ronimus (2005) *Angew. Chem. Int. Ed. Engl.* **44**, 941. 2. Purich (2010) *Enzyme Kinetics: Catalysis & Control*, pp. 486-487, Academic Press-Elsevier, New York.

#### Artemisinin

This first-line antimalarial (FW = 282.34 g/mol; CAS 63968-64-9), also known as quinhaosu, is an endoperoxy sesquiterpene lactone that is active at nanomolar concentrations *in vitro* against both chloroquine-sensitive and resistant strains of *Plasmodium falciparum*. It was isolated from the ancient medicinal herb *Artemisia annua* (or *Qinghao*) by Nobelist Youyou Tu (屠呦呦). The principal advantage of artemisinin over antimalarial drugs is that they accelerate parasite clearance by clearing young, circulating, ring-stage parasites, thereby preventing further maturation and parasite sequestration (1,2). Various mechanisms for its toxic effects on *falciparum* have been proposed, including heme alkylation and/or inactivation (3). In areas of resistance to mefloquine (the second-line treatment for chloroquine-sensitive or resistant malaria), combination therapy with artemisinin or its derivatives appears to improve sustained parasite clearance compared with either drug alone (4). **Primary Mode of Action:** Artemisinin brings about a rapid and dramatic increase reactive oxygen species (ROS) in yeast and malarial mitochondria, but not in mammalian mitochondria (5). The presence of ROS scavengers ameliorates artemisinin’s effects. Lacking a crucial endoperoxide bridge, deoxy-artemisinin is without effect on malarial mitochondrial membrane potential of ROS production. A distantly related antimalarial endoperoxide, OZ209, also causes ROS production and depolarizes isolated malarial mitochondria. Interference of the mitochondrial electron transport system (ETS) by desferrioxamine also alters the artemisinin sensitivity of *P. falciparum* and reduces the extent of artemisinin-induced ROS production (5). Such results strongly implicate the parasite mitochondrion as the major, if not the sole, target for artemisinin’s therapeutic action on *P. falciparum*. **Artemisinin Resistance:** Various models have been advanced to explain how malarial organisms gain resistance to antimalarial drugs. One idea is that one or more of these drugs is inactivated by the cytochrome P450 (or CYP) system. What seems more likely is that ATP-binding cassette (ABC)-type transporters confer multi-drug resistance (MDR) through their ability to

actively export such antimalarials as chloroquine, mefloquine, and artemisinin. Resistance is, in fact, marked by increased copy numbers of the *P. falciparum* (Pf) multidrug-resistance gene *PfMDR1*. Resistance is manifested as slow *in vivo* clearance of the parasite without evidence of reduction in conventional *in vitro* susceptibility tests (6). **Global Plan for Containing Artemisinin Resistance:** Artemisinin-based combination therapies (ACTs) represent the most potent weapon in treating malaria arising from *P. falciparum*. Given that pockets of resistance to artemisinin have emerged along the Cambodia-Thailand border, the World Health Organization (WHO) and Roll Back Malaria (RBM) have advanced a five-step action plan: (a) stop the spread of resistant parasites; (b) increase monitoring and surveillance for artemisinin resistance; (c) improve access to malaria diagnostic testing and rational treatment with ACTs; (d) invest in artemisinin resistance-related research; and (e) motivate action and mobilize resources. The success of this global plan will depend on a well-coordinated and adequately funded response from many stakeholders acting globally, regionally, nationally, and locally. **Artemisinin Derivatives:** Unlike most other anti-malarials, this conformationally constrained and highly oxygenated sesquiterpene lactone peroxide lacks nitrogen-containing heterocyclic rings. Even so, artemisinin is only sparingly soluble in water or oil as well as poor GI absorption – features emphasizing the opportunity for improvement. Artemisinin has proved to be a remarkably versatile scaffold for the semi-synthesis of many pharmacologically active derivatives. Chaturvedi, *et al.* (7) present a thorough review of the synthesis, chemical and physical properties, and structure–activity relationships of artemisinin derivatives for use as anti-malarial, immunosuppressant, and anti-cancer agents. **Antineoplastic Properties:** Artemisinin has selective anticancer activities in various types of cancers, both *in vitro* and *in vivo*. Artemisinin derivatives induce iron-dependent cell death (ferroptosis) in tumor cells (12). In human cervical cancer cells, artemisinin induces apoptosis and represses cell proliferation by inhibiting the telomerase subunit ERα and downstream components like VEGF (13).

**Target(s):** dihydroorotate dehydrogenase (8); glutathione *S*-transferase (9,10); K<sup>+</sup> current (11). 1. Kuile, White, Holloway, Pasvol & Krishna (1993) *Exp. Parasitol.* **76**, 85. 2. #### Arzanol

This phloroglucinol  $\alpha$ -pyrone (FW = 402.44 g/mol; CAS 32274-52-5), also known as 3-[[3-acetyl-2,4,6-trihydroxy-5-(3-methyl-2-buten-1-yl)phenyl]methyl]-6-ethyl-4-hydroxy-5-methyl-2H-pyran-2-one from a Mediterranean plant *Helichrysum italicum* (ssp. *Microphyllum*; family Asteraceae) exhibits anti-inflammatory, anti-HIV, and antioxidant activities (1). Arzanol also protects linoleic acid against free-radical attack in assays of autoxidation and EDTA-mediated oxidation (1). At noncytotoxic concentrations, arzanol also showed a strong inhibition of TBH-induced oxidative stress in VERO cells. It also protects low density lipoprotein (LDL) against the oxidative modification induced by Cu<sup>2+</sup>, inhibiting the increase of oxidative products, such as conjugated dienes, fatty acid hydroperoxides, 7 $\beta$ -hydroxycholesterol, and 7-ketocholesterol (2). Moreover, its cell-penetrating properties commend its use as a lipid-protecting antioxidant (2). Arzanol inhibited 5-lipoxygenase and related leukotriene formation in neutrophils, as well as the activity of cyclooxygenase-1 (COX-1) and formation of COX-2-derived prostaglandin

PG-E<sub>2</sub> *in vitro*, IC<sub>50</sub> = 2-9 μM (3). 1. Rosa, Deiana, Atzeri, *et al.* (2007) *Chem. Biol. Interact.* **165**, 117. 2. Rosa, Pollastro, Atzeri, *et al.* (2011) *Chem. Phys. Lipids* **164**, 24. 3. Bauer, Koeberle, Dehm, *et al.* (2011) *Biochem. Pharmacol.* **81**, 259.

#### AS252424

This potent and selective PI3K inhibitor (FW = 305.28 g/mol; CAS 900515-16-4), also known as (5Z)-5-[[5-(4-fluoro-2-hydroxyphenyl)-2-furanyl]methylene]-2,4-thiazolidinedione, targets human recombinant PI3K $\alpha$  (IC<sub>50</sub> = 30 nM), with far weaker inhibition of PI3K $\beta$  (IC<sub>50</sub> = 940 nM), PI3K $\gamma$  (IC<sub>50</sub> = 20,000 nM), and PI3K $\delta$  (IC<sub>50</sub> = 20,000 nM). These intracellular signal-transducing enzymes phosphorylate the position-3 hydroxyl in phosphatidylinositol (PtdIns). Oral administration of AS252424 in a mouse model for acute peritonitis led to a significant reduction of leukocyte recruitment. 1. Pomel, Klicic, Covini, *et al.* (2006) *J. Med. Chem.* **49**, 3857.

#### AS703569, See MSC1992371A1

#### AS703026

This novel and orally bioavailable MEK1/2 inhibitor (FW = 431.20 g/mol; CAS 1236699-92-5), also known as (S)-N-(2,3-dihydroxypropyl)-3-(2-fluoro-4-iodophenyl)amino-isonicotinamide, selectively targets MEK1/2 (noncompetitive, with IC<sub>50</sub> values of 5-11 nM). AS703026 reduces the growth and survival of multiple myeloma (MM) cells. It also inhibits cytokine-induced osteoclast differentiation about 10x more potently than AZD6244. Inhibition of proliferation by AS703026 leads to G<sub>0</sub>-G<sub>1</sub> cell cycle arrest, attended by reduction in MAF oncogene expression. AS703026 also induces apoptosis (via Caspase-3) as well as poly(ADP-ribose) polymerase (PARP) cleavage in MM cells, whether in the absence or presence of bone marrow stromal cells (BMSCs). Importantly, AS703026 also sensitizes MM cells to other anti-MM therapies employing dexamethasone, melphalan, lenalidomide, perifosine, bortezomib, or rapamycin. Growth reduction in mice bearing H929 MM xenograft tumors correlates with down-regulated pERK1/2, induced PARP cleavage, and decreased microvasculature. BMSC-induced viability of MM patient cells was similarly blocked within the same dose range. 1. Kim, Kong, Fulciniti, *et al.* (2010) *Brit. J. Hematol.* **149**, 537.

#### Ascaris Aspartic Proteinase Inhibitor Protein

This inhibitory protein (MW ~ 17000) from a pig intestinal parasitic worm is highly specific (K<sub>i</sub> of 0.5 nM) for pig pepsin, and reacts more weakly with other proteases. **Target(s):** pepsin A, human (1,8); gastricsin, human (1); pepsin, pig (1,3-10); gastricsin, pig (1,6); cathepsin E (2-4,7,11,12); pepsin A, chicken (6). 1. #### Ascomycin

This antifungal antibiotic (FW = 792.02 g/mol; CAS 104987-12-4; Solubility: 50 mM in DMSO), also known as FK520, isolated from *Streptomyces hygroscopicus*, is also a powerful immunosuppressant. Note that ascomycin is a structural analogue of tacrolimus (*or* FK506) and, as such, operates by a similar mechanism of action (See *Tacrolimus*). Ascomycin inhibits allogenic T-lymphocyte proliferation and calcineurin phosphatase activity. 1. Petros, Kawai, Luly & Fesik (1992) *FEBS Lett.* **308**, 309. 2. Ivery & Weiler (1997) *Bioorg. Med. Chem.* **5**, 217. 3. Salowe & Hermes (1998) *Arch. Biochem. Biophys.* **355**, 165.

#### Ascorbate (Ascorbic Acid)

This water-soluble vitamin and anti-Scurvy factor (FW<sub>free-acid</sub> = 176.13 g/mol; CAS 50-81-7), also known as vitamin C, is structurally the  $\gamma$ -lactone of 2-oxo-L-gulonic acid. It was discovered as a major constituent of Hungarian paprika, affording Nobel Laureate Albert Szent-Györgyi the means for its isolation (1) and subsequent chemical and physiologic analysis. One hydroxyl group of the ene-diol is more acidic than acetic acid (*i.e.*, pK<sub>a</sub> of 4.17 for ascorbic acid versus pK<sub>a</sub> of 4.76 for acetic acid). Its second pK<sub>a</sub> is 11.6, with a redox potential ( $E^{\circ}$ ) of 0.058 V at pH 7. With its reducing and chelating properties, ascorbic acid is also an efficient enhancer of non-heme iron absorption. It protects unsaturated fatty acids (and their esters) from peroxidation and converts lipid peroxyl radicals and alkoxy radical into lipid hydroperoxides and lipid hydroxides, respectively. **Roles as an Enzyme Cofactor:** Humans cannot synthesize ascorbate, because we lack the enzyme catalyzing the last step of its biosynthesis (*i.e.*, oxidation of l-gulonolactone to L-ascorbic acid by l-gulonolactone oxidase, an endoplasmic reticulum enzyme). Ascorbate is also an electron donor for numerous enzymes and thereby plays an important role in a wide variety of biochemical processes, including collagen formation, norepinephrine biosynthesis, and mitochondrial fatty acid transport. As an essential cofactor in reactions catalyzed by Cu<sup>+</sup>-dependent monooxygenases and Fe<sup>2+</sup>-dependent dioxygenases, vitamin C is required by  $\gamma$ -butyrobetaine dioxygenase, procollagen-proline dioxygenase, pyrimidine-deoxynucleoside 2'-dioxygenase, procollagen-lysine 5-dioxygenase, thymine dioxygenase, procollagen-proline 3-dioxygenase, trimethyllysine dioxygenase, flavanone 3-dioxygenase, pyrimidine-deoxynucleoside 1'-dioxygenase, hyoscyamine (6S)-dioxygenase, 6 $\beta$ -hydroxyhyoscyamine epoxidase, gibberellin 3 $\beta$ -dioxygenase, taurine dioxygenase, phytanoyl CoA dioxygenase, leucocyanidin oxygenase, desacetoxylindole 4-hydroxylase, flavone synthase, and 2-acetolactate mutase. Ascorbic acid is a required Fe(III)-reducing cofactor for prolyl hydroxylase and lysyl hydroxylase, the enzymes responsible for the hydroxylation of proline and lysine residues in tropocollagen. **Effects on the Efficacy of Anticancer Agents:** Pharmacologic concentrations of intracellular vitamin C antagonize the therapeutic cytotoxic effects of antineoplastic chemotherapeutic agents (2). Given the current widespread use of vitamin C as a nutritional supplement, one may anticipate adverse consequences in patients who are receiving cancer chemotherapy. Vitamin C enters the mitochondria where it may play a role in quenching local reactive oxygen species (ROS). Alternatively, because some tissues cannot absorb ascorbate, but do concentrate dehydroascorbate (DHA), the latter may act as an oxidant, paradoxically increasing the level of ROS in those cells that take up DHA. As the fully oxidized form of vitamin C,

dehydroascorbate is reduced spontaneously by glutathione as well as enzymatically in reactions requiring glutathione or NADPH. (See also *Dehydroascorbate for additional details*) **Target(s):** steroid 11 $\beta$ -monooxygenase (3,117); phosphodiesterase I (4); steroid 21 monooxygenase, or CYP21A1 (5,44,99,100); *o*-aminophenol oxidase (6); ecarin (7); catalase (8,16,37,38,58); 6 phosphofructokinase (9); lactate dehydrogenase (9); adenylate kinase (9,30,86);  $\beta$ -amylase (10,36,47); papain (11,42); carboxylesterase (12); lipoygenase (13); urate oxidase, or uricase (14); neuraminidase, or sialidase (15); GTP cyclohydrolase I (20); hyaluronoglucosaminidase, or hyaluronidase (22,34); hyaluronate lyase (22,49); tyrosine 3-monooxygenase (23,25); thyroxine deiodinase, or iodothyronine deiodinase (24); dihydrodiol dehydrogenase (2,24); alkaline phosphatase (26); L-galactose dehydrogenase (27); 3-hydroxy-3-methylglutaryl-CoA reductase (29);  $\beta$ -glucuronidase (30); lactoylglutathione lyase (31); NADH oxidase (33,39); pyrophosphatase, or inorganic diphosphatase (39); catechol oxidase (40); dipeptidyl-peptidase I, or cathepsin C (45); xanthine oxidase (46); GDP-mannose 3,5-epimerase, mildly inhibited (48); isocitrate lyase, in the presence of Fe<sup>2+</sup> (50); trimethylamine oxide aldolase (51); fructose-1,6-bisphosphate aldolase (52); nucleotide diphosphatase (53); arylacetone nitrilase (54); 3- $\beta$ -hydroxy-5 $\alpha$ -steroid dehydrogenase (55); acid phosphatase (56,81); alkaline phosphatase, in the presence of copper (56); 1,5-anhydro-D-fructose reductase (57); arylformamidase (59); cathepsin D (60); glutamate carboxypeptidase (61); thioglucosidase, or myrosinase, an activator for several thioglucosidases (62-64); levansase (65,66);  $\beta$ -N-acetylhexosaminidase, in the presence of Cu<sup>2+</sup> (67);  $\beta$ -glucuronidase (68,69);  $\beta$ -fructofuranosidase, or invertase (70);  $\alpha$ -galactosidase (71);  $\beta$ -glucosidase (72); dextranase (73); cerebrosidase-sulfatase, or arylsulfatase A (73,75); glycerophosphocholine cholinephosphodiesterase (76); phosphodiesterase I, or 5'-exonuclease; weakly inhibited (77); 4-phytase (78); 5'-nucleotidase (79); acid phosphatase (80-82); S-formylglutathione hydrolase (83); acetyl-CoA hydrolase (84); lipase, or triacylglycerol lipase (85); alanine aminotransferase (87); aspartate aminotransferase (88); glutathione S-transferase (89); glutamyl-peptide cyclotransferase (90); naringenin-chalcone synthase (91); 1-alkylglycerophosphocholine O acetyltransferase (92); arylamine N-acetyltransferase (93); catechol O-methyltransferase (94,95); xanthine oxidase (96,97); deoxyhypusine monooxygenase (98); catechol oxidase (102,103,105,106,139-144,146-150); polyphenol oxidase (105-112,115,139-144,146-150); tyrosinase, or monophenol monooxygenase (100-105,107-115,145); phenylalanine 4-monooxygenase (116); *trans*-cinnamate 4-monooxygenase (118); phenol 2-monooxygenase (119); salicylate 1-monooxygenase, weakly inhibited (120); clavaminic synthase (121); proline 4-dioxygenase (122); 3-hydroxy-2-methylquinolin-4-one 2,4-dioxygenase, weakly inhibited (123); 3-hydroxy-4-oxoquinoline 2,4-dioxygenase (123); 2,3-dihydroxyindole 2,3 dioxygenase (124); lipoygenase (125); homogentisate 1,2-dioxygenase (126,127); catechol 1,2 dioxygenase (128); manganese peroxidase (129,130); peroxidase (131-134); peroxidase, horseradish (132); NADPH peroxidase (135); *o*-aminophenol oxidase (136,137); laccase (138); ubiquinol:cytochrome-*c* reductase, complex III (151,152). **1.** Szent-Györgyi (1928) *Biochem. ### Asenapine

This atypical antipsychotic agent (FW = 285.77 g/mol; CAS 65576-45-6), marketed under the trade names Saphris<sup>®</sup>, and also known as Org 5222 and (3*a*RS,12*b*RS)-*rel*-5-chloro-2,3,3*a*,12*b*-tetrahydro-2-methyl-1*H*-dibenz[2,3:6,7]-oxepino-[4,5-*c*]pyrrole, is multi-receptor antagonist with the following spectrum of binding interactions: serotonin 5-HT<sub>1A</sub> receptor,  $K_i = 2.5$  nM; serotonin 5-HT<sub>1B</sub> receptor,  $K_i = 4.0$  nM; serotonin 5-HT<sub>2A</sub> receptor,  $K_i = 0.06$  nM; serotonin 5-HT<sub>2B</sub> receptor,  $K_i = 0.16$  nM; serotonin 5-HT<sub>2C</sub> receptor,  $K_i = 0.03$  nM; serotonin 5-HT<sub>5A</sub> receptor,  $K_i = 1.6$  nM; serotonin 5-HT<sub>6</sub> receptor,  $K_i = 1.5$  nM; serotonin 5-HT<sub>7</sub> receptor,  $K_i = 0.13$  nM;  $\alpha_1$ -Adrenergic receptor,  $K_i = 1.2$  nM;  $\alpha_{2A}$ -Adrenergic receptor,  $K_i = 1.2$  nM;  $\alpha_{2B}$ -Adrenergic receptor,  $K_i = 0.25$  nM;  $\alpha_{2C}$ -Adrenergic receptor,  $K_i = 1.2$  nM; dopamine D<sub>1</sub>-receptor,  $K_i = 1.4$  nM; dopamine D<sub>2</sub>-receptor,  $K_i = 1.3$  nM; dopamine D<sub>3</sub>-receptor,  $K_i = 0.4$  nM; dopamine D<sub>4</sub>-receptor,  $K_i = 1.1$  nM; histamine H<sub>1</sub>-receptor,  $K_i = 1.0$  nM; and histamine H<sub>2</sub>-receptor,  $K_i = 6$  nM (1,2). Like other atypical antipsychotic drugs, asenapine preferentially enhances dopamine and acetylcholine efflux in the rat medial prefrontal cortex and hippocampus. See Reference-x for asenapine's UV, IR, NMR, and mass spectra as well as X-ray analysis, thermal properties, solubilities and partition coefficient (3). **1.** Shahid, Walker, Zorn & Wong (2009) *J.*

### ASP2151

This structurally novel oxadiazolephenyl-class helicase/primase inhibitor (FW = 482.16 g/mol; CAS 841301-32-4), also known as amenamevir, is not a nucleoside and, as such, bypasses drug-resistance mechanisms associated with nucleoside transport and phosphorylation as well as the broad spectrum of inhibition that limit the efficacy of nucleoside 5'-di- and tri-phosphate purine and pyrimidine analogues as anticancer agents. ASP2151 possesses potent antiviral activity not only against HSV-1 and HSV-2 but also against VZV. ASP2151 is selective with low cytotoxicity *in vitro*. It is also orally available and well tolerated. ASP2151 inhibited the single-stranded DNA-dependent ATPase, helicase and primase activities associated with the HSV-1 helicase-primase complex. Antiviral assays revealed that ASP2151, unlike other known HSV helicase/primase inhibitors (HPI's), exerts equipotent activity against VZV, HSV-1 and HSV-2 through prevention of viral DNA replication. Further, the anti-VZV activity of ASP2151 ( $EC_{50} = 0.038 - 0.10$   $\mu$ M) was more potent against all strains tested than that of aciclovir ( $EC_{50} = 1.3 - 27$   $\mu$ M). ASP2151 was also active against aciclovir-resistant VZV. Amino acid substitutions were found in helicase and primase subunits of ASP2151-resistant VZV. In a mouse zosteriform-spread model, ASP2151 was orally active and inhibited disease progression more potently than valaciclovir. **1.** Hono, Katsumata, Kontani, *et al.* (2010) *J. Antimicrob. Chemother.* **65**, 1733.

### ASP3026

This potent signal transduction inhibitor (FW = 580.74 g/mol; CAS 1097917-15-1; Solubility: 14 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as *N*<sup>2</sup>-[2-methoxy-4-[4-(4-methyl-1-piperazinyl)-1-piperidinyl]phenyl]-*N*<sup>4</sup>-[2-[(1-methylethyl)sulfonyl]phenyl]-1,3,5-triazine-2,4-diamine, targets ALK, the Activin receptor-Like Kinase activity of Transforming Growth Factor- $\beta$  (TGF- $\beta$ ) receptors, with  $IC_{50}$  of 3.5 nM. ASP3026 inhibits ALK in an ATP-competitive manner with an inhibitory spectrum that differs from crizotinib, a dual ALK/MET inhibitor. In patients with non-small cell lung cancer, a therapeutic target is the EML4-ALK fusion protein, which is formed between echinoderm microtubule-associated protein like 4 and ALK as a consequence of the rearrangement of ALK and EML4 genes. In mice xenografted with EML4-ALK-expressing NCI-H2228 cells, orally administered ASP3026 is well absorbed in tumor tissues, reaching concentrations >10-fold higher than those in plasma, and induces tumor regression with a wide therapeutic margin between efficacious and toxic doses. In the same mouse model, ASP3026 enhances the antitumor activities of paclitaxel and pemetrexed without affecting body weight. ASP3026 also showed potent antitumor activities, including tumor

shrinkage to a undetectable level, in hEML4-ALK transgenic mice and prolonged survival in mice with intrapleural NCI-H2228 xenografts. Finally, ASP3026 exhibited potent antitumor activity against cells expressing EML4-ALK<sup>L1196M</sup>, a mutation conferring resistance to crizotinib. 1. Mori, Ueno, Konagai, *et al.* (2014) *Mol. Cancer Ther.* **13**, 329.

#### D-Asparagine

This amino acid (FW = 132.12 g/mol; FW<sub>monohydrate</sub> = 150.13 g/mol), also called (*R*)-2-amino-3-carbamoylpropanoate, is the enantiomer of the nonproteogenic amino acid L-asparagine. D-Asparagine found in certain bacterial cell wall peptidoglycans as well as in a form of bacitracin A.

**Target(s):** L-asparaginase (1-4,8-10); allantoicase (5); D-alanine aminotransferase (6); glutamin (asparagin-)ase (7). 1. Sobis & Mikucki (1991) *Acta Microbiol. Pol.* **40**, 143. 2. #### L-Asparagine

This proteogenic amino acid (FW = 132.12 g/mol; FW<sub>monohydrate</sub> = 150.13 g/mol) has pK<sub>a</sub> values of 2.14 and 8.72 at 25°C), also called (*S*)-2-amino-3-carbamoylpropanoate, has a polar side chain that, when incorporated in a protein, is most often found on the surface. L-asparaginyl residues in proteins can undergo racemization as well as deamidation to produce a mixture of D- and L-aspartyl residues as well as isoaspartyl residues. Asparaginyl residues are also the sites for *N*-glycosylation in the formation of glycoproteins. The asparaginyl residue modified is usually in one of the following sequences: -Asn-Xaa-Cys-, -Asn-Xaa-Ser-, or -Asn-Xaa-Thr-, where Xaa is any residue other than proline. **Target(s):** hemoglobin S polymerization (1); kynureninase, weakly inhibited (2); glutamate synthase (3); acetylcholinesterase (4); glutamine synthetase (5); allantoicase (6); theanine hydrolase (7); N<sup>4</sup>-(β-*N*-acetylglucosaminyl)-L-asparaginase, also alternative substrate (8); leucyl aminopeptidase (9); [citrate lyase] deacetylase, weakly inhibited (10); serine:glyoxylate aminotransferase, also alternative substrate (11); ornithine carbamoyltransferase, weakly inhibited (12). 1. #### L-Asparaginyl-L-isoleucyl-L-valyl-L-asparaginyl-L-valyl-L-serinyl-L-leucyl-L-valyl-L-lysine

This non-toxic, nine-residue peptide (FW = 985.19 g/mol; Sequence: NIVNVS LVK; Isoelectric Point = 8.75) inhibits insulin fibrillation, a phenomenon limiting long-term insulin storage and reducing insulin efficacy in treating Type II diabetes. Insulin oligomer dissociation into monomers is the key step for onset of fibrillation, and time-course of insulin fibrillation at 62°C (based on the fluorescence-generating binding of the amyloid cross-β-sensitive dye Thioflavin-T) shows an increase in the

lag-time from 120 min in the absence peptide, as compared to 236 min in its presence. Transmission electron micrographs show branched insulin fibrils in its absence and less inter-fibril association in its presence. Both size-exclusion chromatography and dynamic light scattering show that insulin primarily exists as trimer, the conversion of which into a monomer is resisted by the peptide. Saturation transfer difference nuclear magnetic resonance confirms that the hydrophobic residues in the peptide are in close contact with an insulin hydrophobic groove. Significantly, insulin aggregation appears to be related to the interplay of B-chain Phe-24 and B-chain Tyr-26. 1. Banerjee, Kar, Datta, *et al.* (2013) *PLoS One* **8**, e72318.

#### L-Asparaginyl-L-seryl-L-phenylalanyl-L-threonyl-L-leucyl-L-aspartyl-L-alanyl-L-aspartyl-L-phenylalanine

This acetylated nonapeptide (Sequence: Ac-NSFTLDADF; FW = 1072.12 g/mol) inhibits mammalian ribonucleotide reductase. The sequence corresponds to the C-terminus of the R2 subunit of the reductase. 1. Cory, Cory & Downes (1995) in *Purine and Pyrimidine Metabolism in Man*, 8th ed. (Sohota & Taylor, eds.), p. 631.

#### Asparagusate (Asparagusic Acid)

This naturally occurring dithiolane (FW = 150.21 g/mol; CAS 2224-02-4), systematically named 1,2-dithiolane-4-carboxylic acid, is present in asparagus and may well be the metabolic precursor to characteristically odorous thiols associated with the consumption of this vegetable. The reduced form is likely to have the same protein disulfide reducing properties as dithiothreitol (DTT) and dithioerythritol (DTE). It also structurally resembles oxidized lipoic acid. Asparagusate's biological function remains uncertain, but it may prevent fungal growth and repel insect attack (1). It also possesses a considerable nematocidal activity (2,3) In plants, asparagusic acid is most abundant in apical regions of the emerging shoots and other vulnerable areas, decreasing markedly in woody parts of plants (4). Other 1,2-dithiolanes, especially those isolated from mangroves (4-hydroxy-1,2-dithiolane, its sulphoxide and sulfone), exhibit potent antibacterial and insecticidal activities. Asparagusic acid is also a growth inhibitor in other higher plants (similar in potency to abscisic acid), perhaps preventing overcrowding and/or competition for scarce nutrients by adjacent plants. 1. #### Aspartame

This popular artificial sweetener (FW = 294.31 g/mol), also known as *N*-(L-α-aspartyl)-L-phenylalanine methyl ester and EQUAL<sup>®</sup>, is a dipeptide ester that is ~160x sweeter than in aqueous sucrose. Aspartame exhibits dose-dependent inhibition of L-glutamate binding to the *N*-methyl-D-aspartate (NMDA) receptor in rat brain synaptosomes (1). **Target(s):** peptidyl-dipeptidase A, or angiotensin-converting enzyme; weakly inhibited (2); thrombin, weakly inhibited (3); acetylcholinesterase, weakly inhibited (4). *Note:* L-Aspartyl-L-phenylalanine, formed by the action of esterases, inhibits Angiotensin Converting Enzyme from rabbit lung (*K<sub>i</sub>* = 11 μM, comparable to the IC<sub>50</sub> of 12 μM for 2-D-methyl-succinyl-L-proline, an orally active antihypertensive agent in rats (5)). 1. ## D-Aspartate

This conjugate base ( $FW_{\text{free-acid}} = 133.10$  g/mol;  $FW_{\text{monosodium salt}} = 155.09$  g/mol;  $pK_a$  values of 1.99, 3.90 ( $\beta$ -carboxyl), and 9.90 at 25°C;  $dpK_a/dT = -0.022$ ), also known as (*R*)-2-aminobutanedioic acid, is the less common enantiomer of the proteogenic amino acid L-aspartate. D-Aspartyl residues can be found in bacitracin A and in bacterial cell walls. **Target(s)**: argininosuccinate synthetase (1,5); adenylosuccinate synthetase (2); D-alanine aminotransferase (3); glutamine synthetase, weakly inhibited (4); UDP-*N*-acetylmuramoyl-L-alanine:D-glutamate ligase, weakly inhibited (6); asparagine synthetase (7); aspartate ammonia lyase (8,9); glutamate decarboxylase, weakly inhibited (10); L-asparaginase (11);  $\gamma$ -D-glutamyl-meso diaminopimilate, weakly inhibited (12); tyrosine aminotransferase, weakly inhibited (13). 1. ## L-Aspartate

This conjugate base ( $FW_{\text{free-acid}} = 133.10$  g/mol;  $FW_{\text{monosodium salt}} = 155.09$  g/mol;  $pK_a$  values of 1.99, 3.90 ( $\beta$ -carboxyl), and 9.90 at 25°C;  $dpK_a/dT = -0.022$ ). Aspartic acid is soluble in water (0.5 g/100 mL at 25°C and 2.87 g/100 mL at 75°C; the solubility increases with pH) and easily forms supersaturated solutions. It is more soluble in salt solutions. It is slightly soluble in ethanol (0.00016 g/100 mL at 25°C) and insoluble in diethyl ether. It is stable in hot acid solutions. **Target(s)**: pyruvate carboxylase (1-3,14,30-34); glutamate dehydrogenase (4); carbamoyl phosphate synthetase(5); phosphoenolpyruvate carboxylase (6,7,9,15,40-59) glycosylasparaginase (8);  $\beta$ -glucuronidase (10); pantothenate synthetase, or pantoate: $\beta$ -alanine ligase 9-11); arginase, weakly inhibited (12); malic enzyme, or malate dehydrogenase (decarboxylating) (13); L-lactate dehydrogenase, particularly LDH-X (16); glutamate decarboxylase, weakly inhibited (17,18,19,60); succinate dehydrogenase (19); glutamine synthetase (20,29,36-38);  $\gamma$ -glutamyl transpeptidase, weakly inhibited (21,22); *N*-methylglutamate dehydrogenase (23); kynureninase, weakly inhibited (34); glutamate synthase (25); alkaline phosphatase (26); pyrophosphatase, or inorganic diphosphatase (27); acetylcholinesterase (28); 4-methyleneglutamate synthetase, or 4-methyleneglutamate:ammonia ligase (35); serine-sulfate ammonia-lyase (weakly inhibited)48); theanine hydrolase (61); *N*<sup>2</sup>-( $\beta$ -*N*-acetylglucosaminy)-L-asparaginase (62,63); gametolysin (64); glutamate carboxypeptidase II (65); glutamate carboxypeptidase, weakly inhibited (66); dipeptidase E (67); glutamyl aminopeptidase, or aminopeptidase A (68); phosphoenolpyruvate phosphatase (69); [citrate lyase] deacetylase (70,71); acetylcholinesterase, weakly inhibited (72); arginine kinase (73,74); pyruvate kinase (75); homoserine kinase, weakly inhibited (76); phosphoribulokinase (77); asparagine:oxo-acid aminotransferase, weakly inhibited (78,79); kynurenine:oxoglutarate aminotransferase (80); tyrosine aminotransferase (81); nicotinate-nucleotide diphosphorylase, carboxylating (82,83); arginyltransferase, weakly inhibited (84); aspartyltransferase (85); glutamate formimidoyltransferase (86); cysteine dioxygenase (87); catalase (88,89). 1. #### L-Aspartate $\beta$ -Semialdehyde

This semialdehyde (FW = 117.10 g/mol), also known as L-aspartic acid  $\beta$ -semialdehyde, is an intermediate in the biosynthesis of L-lysine, L-threonine, and L-methionine. It is a product of the reaction catalyzed by  $\beta$ -aspartate semialdehyde dehydrogenase and a substrate for dihydropicolinate synthase and homoserine dehydrogenase. *Escherichia coli* aspartate ammonia-lyase catalyzes the deamination of the semialdehyde to produce fumarate semialdehyde and ammonium ion; the semialdehyde product partitions between subsequent release or irreversible enzyme inactivation. This semialdehyde is unstable as a solid or in neutral solutions; hence, solutions should be freshly prepared (aqueous solutions are stable for several days at 4°C in 0.25-4 M HCl, and especially in an inert atmosphere). **Target(s):** asparaginase (1); aspartate ammonia-lyase (2-5); aspartate kinase (6); homoserine kinase (7). **1.** Westerik & Wolfenden (1974) *J. Biol. Chem.* **249**, 6351. **2.** Tokushige (1985) *Meth. Enzymol.* **113**, 618. **3.** Giorgianni, Beranova, Wesdemiotis & Viola (1997) *Arch. Biochem. #### ASS234

The multi-target enzyme inhibitor (FW = g/mol), also known as *N*-((5-(3-(1-benzylpiperidin-4-yl)propoxy)-1-methyl-1*H*-indol-2-yl)methyl)-*N*-methylprop-2-yn-1-amine, bears the MAO-inhibiting propargyl group attached to a cholinesterase-inhibiting donepezil moiety retains the ability to inhibit human acetyl- and butyryl-cholinesterases as well as monamine oxidases. With a  $k_{inact}/K_i$  value of  $3 \times 10^6 \text{ min}^{-1} \text{ M}^{-1}$ , ASS234 inhibition of MAO A and MAO B by ASS234 is almost as effective as clorgyline. It also forms the same  $N^5$ -adduct with the isalloxazine ring of the FAD cofactor. The kinetic studies demonstrate that ASS234 is not only a reversible inhibitor of both acetyl and butyryl-cholinesterases with  $\mu\text{M}$  affinity, but is also a highly potent irreversible inhibitor of MAO A similarly to clorgyline. **1.** Estebana, Allanb, Samadi, *et al.* (2014) *Biochim. Biophys. Acta* **1844**, 1104.

#### Astemizole

This once-daily, orally bioavailable, second-generation antihistamine (FW = 458.57 g/mol; CAS 68844-77-9), also known as R43512, Hismanal<sup>®</sup> and 1-[(4-fluorophenyl)methyl]-*N*-[1-[2-(4-methoxyphenyl)ethyl]-4-piperidyl]benzimidazol-2-amine, is selective  $H_1$  receptor inverse agonist, with rapid onset of action. With the withdrawal of both astemizole and terfenadine

(which produce unexpected and significant prolongation of the cardiac QT interval, with other more serious cardiac effects) from the U.S. and European markets, current widely available second-generation antihistamines include, loratadine, cetirizine, and fexofenadine (1). Because histamine favors the proliferation of normal and malignant cells, several anti-histamine drugs, including astemizole, inhibit tumor cell proliferation (2). Astemizole has also drawn interest by binding to ether  $\alpha$ -go 1 (Eag1) and Eag-related gene (Erg) potassium channels, two important protein targets in cancer progression (2). **1.** Van Wauwe, Awouters, Neimegeers, *et al.* (1981) *Arch. Int. Pharmacodyn. Ther.* **251**, 39. **2.** García-Quiroz & Camacho (2011) *Anticancer Agents Med. Chem.* **11**, 307.

#### Astressin

This novel CRF antagonist (MW = 3663.20 g/mol; CAS 170809-51-5; Sequence: D-Phe-His-Leu-Leu-Arg-Glu-Val-Leu-Glu-Nle-Ala-Arg-Ala-Glu-Gln-Ala-Gln-*cyclo*-( $\gamma$ -Glu-Ala-His- $\epsilon$ -Lys)Asn-Arg-Leu-Leu-Mle-Glu-Ile-Ile-NH<sub>2</sub>; Solubility: 1 mg/mL in Acetic acid/water (10% vol/vol); Alternate Name: [D-Phe<sup>12</sup>, Nle<sup>21,38</sup>, Glu<sup>30</sup>, Lys<sup>33</sup>]-CRF (12-41)) targets human Corticotropin-Releasing hormone (CRH) Receptor subtypes CRF<sub>2a</sub> ( $K_i$  = 1.5 nM) and CRF<sub>2b</sub> ( $K_i$  = 1 nM), with a comparable value (2 nM) for CRF<sub>1</sub>. (**See also Antisauvagine-30; K41448**) These type-2 GPCRs reside in plasma membranes of hormone-sensitive cells and bind CRH, a peptide hormone and neurotransmitter involved in stress responses. Astressin is a structurally constrained and competitive antagonists of corticotropin-releasing factor (1). Astressin is neuroprotective in the hippocampus when administered after a seizure (2). Peripheral injection of astressin blocks peripheral CRF- and abdominal surgery-induced delayed gastric emptying in rats (3). A related antagonist is Astressin 2B (FW = 4041.69 g/mol; CAS 681260-70-8; Sequence: Ac-Asp-Leu-Ser-D-Phe-His- $\alpha$ -methyl-Leu-Leu-Arg-Lys-Nle-Ile-Glu-Ile-Glu-Lys-Gln-Glu-Lys-Glu-Lys-Gln-Gln-Ala-*cyclo*-( $\gamma$ -Glu-Ala-Asn- $\epsilon$ -Lys)Leu-Leu-Leu-Asp- $\alpha$ -methyl-Leu-Ile-NH<sub>2</sub>). Astressin 2B is a potent and selective antagonist of CRF<sub>2</sub> ( $IC_{50}$  = 1.3 nM) and CRF<sub>1</sub> ( $IC_{50}$  > 500 nM) (4-6). **1.** Gulyas, *et al.* (1995) *Proc. Natl. Acad. Sci. U.S.A.* **92**, 10575. **2.** Maecker, *et al.* (1997) *Brain Res.* **744**, 166. **3.** Martinez, *et al.* (1999) *J. Pharmacol. Exp. Ther.* **290**, 629. **4.** Rivier, *et al.* (2002). *J. Med. #### Astressin 2B

This Astressin analogue (FW = 4041.69 g/mol; CAS 681260-70-8; Sequence: Ac-Asp-Leu-Ser-D-Phe-His- $\alpha$ -methyl-Leu-Leu-Arg-Lys-Nle-Ile-Glu-Ile-Glu-Lys-Gln-Glu-Lys-Glu-Lys-Gln-Gln-Ala-*cyclo*-( $\gamma$ -Glu-Ala-Asn- $\epsilon$ -Lys)Leu-Leu-Leu-Asp- $\alpha$ -methyl-Leu-Ile-NH<sub>2</sub>) is a potent and selective antagonist of CRF<sub>2</sub> ( $IC_{50}$  = 1.3 nM) and CRF<sub>1</sub> ( $IC_{50}$  > 500 nM) (1-3). (**See also Antisauvagine-30; Astressin; K41448**) **1.** Rivier, *et al.* (2002). *J. Med. Chem.* **45**, 4737. **2.** Hoare, *et al.* (2005) *Peptides* **26**, 457. **3.** Henry, *et al.* (2006) *J. Neurosci.* **26**, 9142.

#### Asunaprevir

This highly selective HCV antiviral (FW = 748.29 g/mol; CAS 630420-16-5; Symbol: ASV), also named BMS-650032, targets NS3 protease, a serine proteinase required for Hepatitis C Virus (HCV) polyprotein processing, showing good antiviral activity against replicons based on HCV Genotype 1a ( $EC_{50}$  = 4 nM), Genotype 1b ( $EC_{50}$  = 1.2 nM), Genotype 4 ( $EC_{50}$  = 1.8 nM), Genotype 5 ( $EC_{50}$  = 1.7 nM), and Genotype 6 ( $EC_{50}$  = 0.9 nM) (1). It is far less effective against Genotype 2 ( $EC_{50}$  = 67 nM) and Genotype 3 ( $EC_{50}$  = >1100 nM). Asunaprevir is a peptidomimetic that occupies the

active site, inhibiting the HCV NS3/4A serine protease, with little or no action against related viruses (1). The average  $K_i$  for ASV is approximately 0.4 nM and 0.2 nM for Genotype 1a and Genotype 1b, respectively. Its acylsulfonamide moiety interacts noncovalently with the NS3 protease – unlike telaprevir's  $\alpha$ -ketoamide moiety, which is linked covalently to NS3/4A's catalytic serine and reverses slowly over time. ASV exhibits an excellent selectivity index (>40,000x) against all serine/cysteine proteases evaluated, including human leukocyte elastase, porcine pancreatic elastase, and three members of the chymotrypsin family (1). Although ASV shows a low barrier to resistance, it can be combined with daclatasvir to achieve a very high rate of viral eradication in both naïve and treatment-experienced patients, showing a sustained virological response rate of 80%-90% (2,3). 1. McPhee, Sheaffer, Friberg, *et al.* (2012) *Antimicrob. Agents Chemother.* **56**, 5387. 2. Lok, Gardiner, Lawitz, *et al.* (2012) *New Engl. J. Med.* **366**, 216. 3. Gentile, Buonomo, Zappulo, *et al.* (2014) *Ther. Clin. Risk Manag.* **10**, 493.

### Asymmetric Dimethylarginine

This endogenous dimethylated amino acid (FW = 202.26 g/mol; CAS 30315-93-6; *Symbol*: ADMA), also named *N,N*-dimethylarginine and 2-amino-5-[(amino-*N,N*-dimethylaminomethylene)amino]pentanoic acid, is formed by the proteolysis of posttranslationally *N,N*-dimethylated arginine-containing proteins, with up to 10 mg excreted daily in the urine. ADMA targets cellular L-arginine uptake and nitric oxide synthase, thereby reducing the rate of NO formation (1). Elevated plasma ADMA levels are detected in patients or experimental animals with hypercholesterolemia, renal failure, atherosclerosis, hypertension, thrombotic microangiopathy, peripheral arterial occlusive disease and in the regenerated endothelial cells after angioplasty (3). Within endothelial cells, NO induces DDAH2 expression *via* a cGMP-mediated process, thereby reducing both ADMA and *N*-monomethylarginine (*or* MMA). When acting in concert, these enzymes constitute a positive feedback loop that maintains NO levels in endothelial cells (4). A high circulating ADMA level has also emerged as an independent risk marker predicting future CVD (cardiovascular disease) events (5). ADMA and its metabolizing enzymes also show significant temporal changes after Traumatic Brain Injury (TBI) and may be new targets in TBI treatment (6). **Pharmacologic Manipulation of ADMA Concentration:** PD-404182 potently inhibits dimethylarginine dimethylaminohydrolase isoform-1 (DDAH1), the human enzyme that degrades ADMA (See PD-404182) (7). On the other hand, chloroketone-containing peptide C21 irreversibly inhibits protein arginine methyltransferase 1 (PRMT1), the human enzyme that catalyzes the *S*-adenosyl-methionine-dependent post-translational methylation of arginine residues (See C21). PRMT1 generates the majority of protein-bound ADMA that represents the ultimate source of ADMA. 1. Vallance, Leone, Calver, Collier & Moncada (1992). *J. Cardiovasc. Pharmacol* **20**, S60. 2. ### AT7519

This novel small-molecule multi-CDK inhibitor (FW = 382.24 g/mol; CAS 844442-38-2, 902135-91-5 (HCl), 902135-89-1 (methanesulfonate); Solubility: 10 mg/mL DMSO; <1 mg/mL Water; Formulation: Dissolved in 0.9% saline), named systematically as 4-(2,6-dichlorobenzamido)-*N*-(piperidin-4-yl)-1*H*-pyrazole-3-carboxamide, targets cyclin dependent kinases CDK1/cyclin B, CDK2/Cyclin A, CDK3/Cyclin E, CDK4/Cyclin D1, CDK5/p35 and CDK6/Cyclin D3 with  $IC_{50}$  values of 210 nM, 47 nM, 360 nM, 100 nM, 13 nM and 170 nM, respectively (1). AT7519 is inactive against all non-CDK kinases with the exception of GSK3 $\beta$  ( $IC_{50}$  = 89 nM) (2). AT7519 displays potent cytotoxicity and apoptosis in multiple myeloma (MM) models, resulting *in vivo* tumor growth inhibition and prolonged survival (3). AT7519 inhibits CDK-mediated phosphorylation of RNA polymerase II (RNA pol II), attended by reduced RNA synthesis. AT7519 inhibits glycogen synthase kinase-3 $\beta$  phosphorylation, and pretreatment with a selective GSK-3 inhibitor as well as shRNA GSK-3 $\beta$  knockdown restores MM survival, suggesting the involvement of GSK-3 $\beta$  in AT7519-induced apoptosis. GSK-3 $\beta$  activation was independent of RNA pol II dephosphorylation, as confirmed by  $\alpha$ -amanitin, a specific RNA pol II inhibitor. 1. Squires, *et al.* (2009) *Mol. Cancer Ther.* **8**, 324. 2. Santo, *et al.* (2010) *Oncogene* **29**, 2325. 3. Santo, Vallet, Hideshima, *et al.* (2010) *Oncogene* **29**, 2325.

### AT7867

This potent ATP-competitive inhibitor (FW = 337.85; CAS 857531-00-1; Solubility: 68 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), known systematically as 4-(4-(1*H*-pyrazol-4-yl)phenyl)-4-(4-chlorophenyl)piperidine, targets Akt1, Akt2 and Akt3 Protein Kinases B (*or* PKB), with  $IC_{50}$  values of 32 nM, 17 nM and 47 nM, respectively. AT7867 also inhibits the structurally related AGC kinases, p70S6K and PKA, with  $IC_{50}$  values of 20 nM and 85 nM, respectively. 1. Grimshaw (2010) *Mol. Cancer Ther.* **9**, 1100.

### AT9283

This potent JAK protein kinase inhibitor (FW = 381.43 g/mol; CAS 896466-04-9; Solubility = 76 mg/mL DMSO), also named 1-cyclopropyl-3-(3-(5-(morpholinomethyl)-1*H*-benzo[*d*]imidazol-2-yl)-1*H*-pyrazol-4-yl)urea, targets JAK3 ( $IC_{50}$  = 1.1 nM), JAK2 ( $IC_{50}$  = 1.2 nM), Aurora A ( $IC_{50}$  = 3 nM), Aurora B ( $IC_{50}$  = 3 nM), and Abl (T3151). 1. Howard, Berdini, Boulstridge, *et al.* (2009) *J. Med. Chem.* **52**, 379. 2. Qi, Liu, Cooke, *et al.* (2012) *Int. J. Cancer* **130**, 2997.

### AT-13387

This selective and potent chaperone inhibitor (FW = 409.53 g/mol; CAS 912999-49-6; Solubility: 25 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also named 2,4-dihydroxy-5-isopropylphenyl-[5-(4-methylpiperazin-1-ylmethyl)-1,3-dihydroisoindol-2-yl]methanone, targets Hsp90 $\alpha$ ,  $K_i$  = 18 nM. Like other Hsp90 inhibitors, AT-13387 interacts with the N-terminal ATP-binding site to prevent ATP binding and stop the chaperone cycle, leading to degradation of multiple client proteins involved in tumor progression. AT13387 displays a long duration of action *in vitro* and *in vivo* in non-small cell lung cancer (2). It is also effective against imatinib-sensitive and -resistant gastrointestinal stromal tumor models (3). The total synthesis of AT13387 has been reported (4). 1. Woodhead, Angove, Carr, *et al.*

(2010) *J. Med. Chem.* **53**, 5956. 2. Graham, Curry, Smyth, *et al.* (2012) *Cancer Sci.* **103**, 522. 3. Smyth, Van Looy, Curry, *et al.* (2012) *Mol. Cancer Ther.* **11**, 1799. 4. Patel & Barrett (2012) *J. Org. Chem.* **77**, 11296.

### Ataluren

This reported translation modulator (FW = 284.24 g/mol; CAS 775304-57-9), also known as PTC124 and 3-[5-(2-fluorophenyl)-[1,2,4]oxadiazol-3-yl]-benzoate, reportedly induces dose- and time-dependent ribosomal readthrough of premature stop codons with greater potency than gentamicin (1,2). There is nonetheless some question as to whether the *Photinus pyralis* firefly luciferase (FLuc) reporter assay is an artifact. Importantly, FLuc inhibition and stabilization results from formation of an inhibitory product of the FLuc-catalyzed reaction between ATP and ataluren (3). A 2.0-Å cocrystal structure reveals the inhibitor to be the acyl-AMP mixed-anhydride adduct ataluren-AMP, which is a high-affinity ( $K_d = 120$  pM) multisubstrate geometrical inhibitor. Biochemical assays, liquid chromatography/mass-spectrometry, and near-attack conformer modeling demonstrate that formation of this inhibitor depends upon precise positioning and reactivity of a key meta-carboxylate of ataluren within the FLuc active site. The inhibitory activity of ataluren-AMP is relieved by free coenzyme A, a component present at high concentrations in luciferase detection reagents used for cell-based assays. This finding explains why ataluren can appear to increase, instead of inhibit, FLuc activity in cell-based reporter gene assays. To test the ability of PTC124 to read through nonsense mutations, McElroy *et al.* (4) comparing ataluren's efficacy with that of the classical aminoglycoside antibiotic read-through agent, geneticin (G418) across a diverse range of *in vitro* reporter assays. That study confirmed the off-target FLuc activity of PTC124, but found that, while G418 exhibits varying activity in every read-through assay, there is no evidence of activity for PTC124. 1. Welch, Barton, Zhuo, *et al.* (2007) *Nature* **447**, 87. 2. Hirawat, Welch, Elfring, *et al.* (2007) *J. Clin. Pharmacol.* **47**, 430. 3. Auld, Lovell, Thorne, *et al.* (2010) *Proc. Natl. Acad. Sci. U.S.A.* **107**, 4878. 4. McElroy, Nomura, Torrie, *et al.* (2013) *PLoS Biol.* **11**, e1001593.

### Atazanavir

This antiviral peptide drug (FW = 704.88 g/mol; CAS 198904-31-3), also known as BMS-232632, Rayataz, and systematically as methyl *N*-[[(1*S*)-1-[(2*S*,3*S*)-3-hydroxy-4-[(2*S*)-2-[(methoxycarbonyl)amino]-3,3-dimethyl-*N'*-[[4-(pyridin-2-yl)phenyl]methyl]butanehydrazido]-1-phenylbutan-2-yl]-carbamoyl]-2,2-dimethyl-propyl]carbamate, is a potent inhibitor of HIV-1 protease, particularly of indinavir- and saquinavir-resistant strains. Proof-of-principle studies indicate BMS-232632 blocks cleavage of viral precursor proteins in HIV-infected cells, demonstrating its function as an HIV Prt inhibitor. BMS-232632 is generally more potent than the five currently approved HIV-1 Prt inhibitors. BMS-232632 is highly selective for HIV-1 Prt and exhibits cytotoxicity only at concentrations 6,500- to 23,000-fold higher than required for anti-HIV activity. One mechanism that contribute to reduced atazanavir concentrations is the expression of ATP-binding cassette drug efflux transporters, especially P-glycoprotein multi-drug resistance factor. Because atazanavir is a substrate of the cytochrome P450 3A4 isoenzyme, it may alter serum concentrations of other drugs metabolized by the CYP3A4 pathway, such as rifabutin, clarithromycin, and lipid-lowering agents. **Key Pharmacokinetic Parameters:** See Appendix

II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York. **Target(s):** HIV-1 retropepsin (1,4,5); glucuronosyl-transferase, or UDPglucuronosyltransferases: UGT1A1, UGT1A3, and UGT1A4 (2); CYP3A (3); P-glycoprotein (3). 1. ### ATB-346

This H<sub>2</sub>S-liberating naproxen analogue and nonsteroidal anti-inflammatory drug, or NSAID (FW = 365.44 g/mol; CAS 1226895-20-0; Soluble in DMSO, not in water), also named 4-carbamothioylphenyl 2-(6-methoxynaphthalen-2-yl)propanoate, is an anti-inflammatory agent with properties similar to naproxen, suppressing gastric prostaglandin E<sub>2</sub> synthesis as effectively, but with substantially reduced gastrointestinal toxicity (1,2). NSAID-induced gastroenteropathy is a significant limitation to the use of this class of drugs, and hydrogen sulfide is known to be an important mediator of gastric mucosal defense. ATB-346 inhibits cyclooxygenase-2 (COX2), suppressing leukocyte infiltration more effectively than naproxen. ATB-346 is as effective as naproxen in adjuvant-induced arthritis in rats, with a more rapid onset of activity. Unlike naproxen, ATB-346 does not elevate blood pressure in hypertensive rats. (See also *Naproxen*; NCX 429) 1. Wallace, Caliendo, Santagada & Cirino (2010) *Brit. J. Pharmacol.* **159**, 1236. 2. Blackler, Syer, Bolla, Ongini & Wallace (2012) *PLoS One* **7**, e35196.

### Atenolol

This selective β<sub>1</sub> receptor antagonist, or β-blocker (FW = 266.34 g/mol; CAS 29122-68-7), also known as Tenormin<sup>®</sup> and (*R,S*)-2-[(2-hydroxy-3-(propan-2-ylamino)propoxy)phenyl]-acetamide, is a widely used drug that slows the heart and reduces its workload. Unlike propranolol, atenolol does not penetrate the brain barrier and thus avoids the latter's well-known CNS side-effects. β-Blockers are no longer the recommended first-line therapy for primary hypertension, in view of data indicating that β-blockers are inferior to other antihypertensives and no better than placebo, in spite of its blood pressure-reducing action (1). Atenolol is useful in the prevention of angina pectoris, particularly in patients in whom there is associated arterial hypertension (2). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Ripley & Saseen (2014) *Ann. Pharmacother.* **48**, 723. 2. Hernández-Cañero, González, Cardonne, Pérez-Medina & Garcia-Barreto (1972) *Cor. Vasa.* **20**, 99.

### Atomoxetine

This ADHD drug (FW<sub>free-base</sub> = 255.36 g/mol; FW<sub>hydrochloride</sub> = 291.81 g/mol; CAS 83015-26-3), also known as LY139603, Strattera<sup>®</sup>, and systematically as (*3R*)-*N*-methyl-3-(2-methylphenoxy)-3-phenylpropan-1-amine; (*R*)-*N*-

methyl-3-phenyl-3-(*o*-tolylloxy)-propan-1-amine, potently inhibits the presynaptic norepinephrine transporter,  $K_i = 4.5$  nM (1-3) and is used to treat depression and attention-deficit/hyperactivity disorder (4). In 2002, Strattera became the first FDA-approved nonstimulant for the treatment of ADHD. The mechanism of action is related to its selective inhibition of presynaptic norepinephrine reuptake in the prefrontal cortex (5). Atomoxetine demonstrates high affinity and selectivity for norepinephrine transporters, but little or no affinity for neurotransmitter receptors. Atomoxetine demonstrates preferential binding to areas of known high distribution of noradrenergic neurons, such as the fronto-cortical subsystem. Atomoxetine undergoes extensive biotransformation, which is affected by poor metabolism by cytochrome P450 (CYP2D6) in a small percentage of the population (5). (Note: Atomoxetine was originally named tomoxetine, but was changed to avoid any potential confusion with tamoxifen.) **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York. 1. Farid, Bergstrom, Ziege, Parli & L. Lemberger (1985) *J. Clin. Pharmacol.* **25**, 296. 2. Zerbe, Rowe, Enas, *et al.* (1985) *J. Pharmacol. Exp. Garnock-Jones & Keating (2009) *Pediatr. Drugs* **11**, 203.

### Atopaxar

This novel orally active thrombin receptor antagonist (FW = 528.62 g/mol; CAS 751475-53-3), also known as E-5555, reversibly inhibits protease-activated receptor-1, or PAR-1 ( $IC_{50} = 19$  nM). The inhibition of thrombin-mediated platelet activation by means of protease-activated receptor-1 inhibitors represents an attractive therapeutic option for patients with atherothrombotic disease processes. (See *Vorapaxar*) 1. Kogushi, *et al.* (2011) *Eur. J. Pharmacol.* **657**, 131. 2. Marion, *et al.* (2006) *J. Clin. Pharmacol.* **46**, Abstract 102. 3. Takeuchi, *et al.* (2007) *Eur. Heart J.* **28** (Suppl. 1), Abstract 264. 4. Goto, *et al.* (2010) *Eur. Heart J.* **31**, 2601.

### Atorvastatin

This widely used statin (FW<sub>free-acid</sub> = 558.65 g/mol; CAS 134523-00-5), also known as Lipitor™ and systematically named (3*R*,5*R*)-7-[2-(4-fluorophenyl)-3-phenyl-4-(phenylcarbamoyl)-5-propan-2-ylpyrrol-1-yl]-3,5-dihydroxy-heptanoic acid, is a potent inhibitor of 3- hydroxy-3-

methylglutaryl-CoA reductase,  $IC_{50} = 8$  nM (1-4). When taken with a low-fat diet, atorvastatin reduces the risk of heart attack, stroke, certain kinds of heart surgeries, and chest pain in patients with heart disease or several common heart disease risk factors (*i.e.*, family history of heart disease, high blood pressure, age, low HDL cholesterol, and smoking). *Note:* Because atorvastatin is a CYP3A4-metabolized statin, co-administration of a CYP3A4 inhibitors can result in adverse drug interactions. (See *Statin Side Effects*) **Pharmacokinetics & Metabolism:** Atorvastatin PK and metabolism are well characterized in humans. *Absorption:* Atorvastatin is rapidly absorbed after oral administration, reaching maximum plasma concentrations within 1-2 hours. Its extent of absorption increases in proportion to atorvastatin dose, with an absolute bioavailability of ~14% and a systemic availability of HMG-CoA reductase inhibitory activity at ~30%. The low systemic availability of atorvastatin is attributed to pre-systemic clearance in gastrointestinal mucosa and/or hepatic first-pass metabolism. Although food decreases the rate and extent of drug absorption by approximately 25% and 9%, respectively, as assessed by  $C_{max}$  and AUC parameters, LDL-C reduction is similar whether atorvastatin is given with or without food. Plasma atorvastatin concentrations are lower (~30% for  $C_{max}$  and AUC) following evening drug administration compared with morning. *Distribution:* The mean volume of distribution of atorvastatin is approximately 381 L. More than 98% of atorvastatin binds to plasma proteins. A blood/plasma ratio of ~0.25 indicates poor drug penetration into red blood cells. *Metabolism:* Atorvastatin is extensively metabolized to ortho- and para-hydroxylated derivatives and various  $\beta$ -oxidation products, but the *in vitro* inhibition of HMG-CoA reductase by these metabolites is equivalent to that of atorvastatin, and ~70% of circulating inhibitory activity for HMG-CoA reductase is attributed to active metabolites. *In vitro* studies suggest the importance of atorvastatin metabolism by cytochrome P450 3A4, consistent with increased plasma concentrations of atorvastatin in humans following coadministration with erythromycin, a known inhibitor of this cytochrome isozyme. *Excretion:* Atorvastatin and its metabolites are eliminated primarily in bile following hepatic and/or extra-hepatic metabolism; however, the drug does not appear to undergo enterohepatic recirculation. The mean plasma elimination half-life of atorvastatin in humans is ~14 hours, but the half-life of inhibitory activity for HMG-CoA reductase is 20-30 hours, mainly the result of the contribution of active metabolites. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York. 1. Istvan & Deisenhofer (2001) *Science* **292**, 1160. 2. Baumann, Butler, Deering, *et al.* (1992) *Tetrahedron Lett.* **33**, 2283. 3. ### Attractyloside

This toxic mitochondrial ATP-ADP translocation inhibitor and proapoptotic agent (FW = 802.98 g/mol for the dipotassium salt; CAS 102130-43-8), first isolated from the Mediterranean thistle *Attractylis gummifera*, blocks nucleotide binding to the carrier, thereby, inhibiting mitochondrial import of ADP and reducing oxidative phosphorylation. The amount of attractyloside required for achieving half-maximal inhibition is approximately one nmol attractyloside per mg mitochondrial protein. The dissociation constant for attractyloside for the ATP-ADP translocase is about  $5 \times 10^{-8}$  M. Rat heart studies indicate that Attractyloside inhibits chloride channels within the mitochondrial membrane. (See *Bongkrekic Acid*; *Carboxyatractyloside*) **CAUTION:** Attractyloside poisoning is an infrequent but often fatal form of herbal poisoning, which occurs worldwide but especially in Africa and the Mediterranean regions. **Target(s):** ATP/ADP antiport or translocator, or adenine nucleotide translocator (1-8); 2,3'

cyclic-nucleotide 3'-phosphodiesterase (9); and oxidative phosphorylation (10). 1. Slater (1967) *Meth. Enzymol.* **10**, 48. 2. Vignais, Brandolin, Lauquin & Chabert (1979) *Meth. ### Atrazine

This herbicide (FW = 215.68 g/mol; CAS 1912-24-9), also known as 2-chloro-4-(2-propylamino)-6-ethylamino-*s*-triazine, is a chloroplast electron transport inhibitor and popular selective herbicide. Atrazine is used to eliminate pre- and post-emergence broadleaf and grassy weeds from corn fields. **Target(s):** photosynthetic electron transport (1-3); photosystem II (4); *s*-triazine hydrolase (5); cyclic-nucleotide phosphodiesterase (6,7); unspecific monooxygenase (8). 1. Izawa & Good (1972) *Meth. Enzymol.* **24**, 355. 2. Dodge (1977) *Spec. Publ., Chem. Soc.* **29**, 7. 3. Tischer & Strotmann (1977) *Biochim. Biophys. Acta* **460**, 113. 4. ### Atropine

This parasympatholytic alkaloid (FW = 289.37 g/mol; CAS 51-55-8; White solid; M.P. = 114-116°C; Solubility: 2.2 mg/mL H<sub>2</sub>O; Atropine HCl is highly soluble in water), also called (±)-hyoscamine, can be isolated from the deadly nightshade (*Atropa belladonna*) and related organisms. Atropine is a racemic mixture, with hyoscamine is the 3*S*-isomer. (See also *Hyoscyamine*) When delivered promptly, atropine can be an effective antidote for nerve agent poisoning and other cholinesterase inhibitors (e.g., organophosphorus insecticides). Atropine is a competitive nonselective antagonist at central and peripheral muscarinic acetylcholine receptors. Its ability to block the effects of vagal stimulation was noted in 1867. **Target(s):** acid phosphatase (1); [β-adrenergic-receptor] kinase (2); cholinesterase, or butyrylcholinesterase (3); β-fructofuranosidase, or invertase (4); muscarinic acetylcholine receptors (5,6); phospholipase A<sub>2</sub> (7); tropinesterase (8); urease, reportedly inhibited by the free base (9). 1. ### Auranofin

This gold-containing anti-rheumatic (FW = 679.49 g/mol; CAS 34031-32-8; photosensitive and thermolabile), also known as SK&F D-39162 and 1-thio-β-D-glucopyranosatriethylphosphine gold-2,3,4,6-tetraacetate, is gold compound intended to improve on gold thioglucose and gold thiomalate as a treatment for rheumatoid arthritis as well as other inflammatory and proliferative diseases. **Mechanism(s) of Action:** Auranofin potently inhibits the release of lysosomal enzymes from leukocytes *in vitro* (1). At 1-10 μM, auranofin produces a dose-dependent reduction in extracellular levels of the lysosomal marker enzymes, β-glucuronidase and lysozyme, which are selectively released from rat leukocytes during phagocytosis of zymosan particles. The reduction in extracellular levels of lysosomal enzymes appears to be caused by inhibition of their selective cellular release, since effective concentrations of auranofin does not produce leukocyte cytotoxicity or inhibition of cell-free lysosomal enzyme activity (1). Morphologic and biochemical evidence indicated that auranofin also interferes with phagocytosis of zymosan particles. Another auranofin target is Vascular Endothelial Growth Factor Receptor-3, an endothelial cell (EC) surface receptor that is essential for angiogenesis and lymphangiogenesis (2). In both primary EC as well as EC cell lines, auranofin down-regulates VEGFR3 in a dose-dependent manner. At doses ≥ 1 μM, auranofin decreases the cellular survival protein thioredoxin reductase (TrxR2), TrxR2-dependent Trx2, and transcription factor NF-κB. At low doses (≤ 0.5 μM), however, auranofin specifically down-regulates VEGFR3 and VEGFR3-mediated EC proliferation and migration, two steps that are required for *in vivo* lymphangiogenesis. Auranofin-induced VEGFR3 down-regulation is blocked by antioxidant *N*-acetyl-L-cysteine (NAC) and the lysosome inhibitor chloroquine, but is promoted by proteasomal inhibitor MG132. Such results suggest auranofin induces VEGFR3 degradation through a lysosome-dependent pathway (2). **Effect on Diphtheria Toxin Processing:** Another auranofin target is diphtheria toxin, which delivers its catalytic domain DTA from acidified endosomes into the cytosol in a process that requires reduction of the disulfide bond linking DTA to the transport domain (3). Thioredoxin reduces this disulfide, and thioredoxin reductase (TrxR) is part of a cytosolic complex facilitating DTA-translocation. As a TrxR-selective inhibitor, auranofin prevents DTA delivery into the cytosol and intoxication of HeLa cells by diphtheria toxin (3). **Target(s):** thioredoxin reductase (2-4,9,28); glutathione peroxidase (5,24); glutathione-disulfide reductase (5); nitric-oxide synthase (6); phosphofructo-kinase (7); 5-lipoxygenase (8,21); trypsin-like neutral protease (10,11); cathepsins (11,26,27); histamine release (12,20); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (13); neutrophil collagenase (14,15); bile acid uptake (16); protein kinase C (17-19); phospholipase C, moderately inhibited (22); adenylate cyclase (23); IκB kinase (25). 1. ### Aureobasidin A

This cyclic depsipeptide antibiotic (FW<sub>Aureobasidin-A</sub> = 1101.43; CAS 127785-64-2) from *Aureobasidium pullulans* R106 is toxic (typically at 0.1-0.5 µg/mL) against *Saccharomyces cerevisiae*, *Schizosaccharomyces pombe*, *Candida glabrata*, *Aspergillus nidulans*, and *A. niger*. Aureobasidin A inhibits inositolphosphoryl-ceramide synthase. Note that the antibiotic contains *N*-methyl-L-valine, L-alloisoleucine, *N*-methyl-L-phenyl-alanine, and *N*-methyl-3-hydroxy-L-valine. **Target(s):** inositolphosphoryl-ceramide synthase, *or* ceramide inositolphosphoryltransferase, inhibited by aureobasidin A (1,2). **1.** Fischl, Liu, Browdy & Cremesti (2000) *Meth. Enzymol.* **311**, 123. **2.** Lynch (2000) *Meth. Enzymol.* **311**, 130.

**Auristatin, See Dolastatin 10; Monomethyl auristatin E**

### Aurothiomalate

This immunosuppressive (FW = 390.08 g/mol; CAS 12244-57-4; Symbol: AuTM), also known as sodium aurothiomalate, gold sodium thiomalate, Myocrisin<sup>®</sup>, and sodium 2-(auriosulfanyl)-3-carboxypropanoate, is an orally active nonsteroidal anti-inflammatory agent for treating rheumatism. **See also Auranofin** Even so, the demonstrated effectiveness of low-dose methotrexate (MTX) has led to a significant decline in using sodium aurothiomalate (1). **Mode of Action:** AuTM markedly inhibits DNA binding by the transcription factor AP-1, with less potent effects for AP-2, NF-1 and TFIID (2). In studies of the interactions of the progesterone receptor (*or* PR) with its DNA response element (*or* PRE), AuTM was found to regulate gene expression, again suggesting that inhibition of binding of a transcription factor to DNA is a likely mechanism (3). Electrophoretic mobility-shift assays showed that AP-1 DNA binding is inhibited by gold(I) thiolates and selenite, with IC<sub>50</sub> values occurring of 5 µM and 1 µM, respectively. Thiomalate was without effect in the absence of gold(I), and other metal ions inhibited at higher concentrations, in a rank order correlating with their thiol binding affinities. Cysteine-to-serine mutants demonstrated that these effects of Au(I) and selenite require Cys272 and Cys154 in the DNA-binding domains of Jun and Fos, respectively (3). Gold(I) thiolates and selenite did not inhibit nonspecific protein binding to the AP-1 site and were at least an order of magnitude less potent as inhibitors of sequence-specific binding to the AP-2, TFIID, or NF1 sites compared with the AP-1 site (3). **Note:** Given the chemical reactivity of AuTM, it is likely that this agent may inhibit other thiol-dependent processes within cells. **1.** Kean & Kean (2008) *Inflammopharmacol.* **16**, 112. **2.** Handel, Sivertsen, Watts, Day & Sutherland (1993) *Agents Actions Suppl.* **44**, 219. **3.** Handel, Watts, deFazio, Day & Sutherland (1995) *Proc. ### AV-412

This second-generation, oral dual kinase inhibitor (FW = 507.01 g/mol; CAS 451492-95-8), also known as *N*-(4-(3-chloro-4-fluorophenylamino)-7-(3-methyl-3-(4-methylpiperazin-1-yl)but-1-ynyl)quinazolin-6-yl)acrylamide, targets both EGFR and ErbB2 tyrosine kinases, including EGFR<sup>L858R</sup> and EGFR<sup>T790M</sup> mutants that are clinically resistant to the EGFR-specific kinase inhibitors, such as erlotinib and gefitinib. AV-412 inhibited EGFR variants and ErbB2 in the nM range, with over 100x selectivity over other kinases; however, ABL and FLT1 are both moderately sensitive. In cells, AV-412 inhibited autophosphorylation of EGFR and ErbB2 with respective IC<sub>50</sub> values of 43 and 282 nM. In animal studies using cancer xenograft models, AV-412 (30 mg/kg) demonstrated complete inhibition of tumor growth of the A431 and BT-474 cell lines, which overexpress EGFR and ErbB2, respectively. **1.** Suzuki, Fujii, Ohya, *et al.* (2007) *Cancer Sci.* **98**, 1977.

### Avian Erythrocyte NAD<sup>+</sup>-dependent ADP-ribosyltransferase

This ribosyltransferase catalyzes the reaction of NAD<sup>+</sup> with an acceptor substrate to produce nicotinamide and the ADP-ribosylated acceptor. *Cholera* enterotoxin catalyzes the mono(ADP-ribosylation) of a number of GTP-binding proteins. The avian erythrocyte enzyme has been shown to modify both tubulin and MAP-2 and impair microtubule assembly. **1.** Purich & Scaife (1988) in *Enzyme Dynamics and Regulation* (Chock, Huang, Tsou & Wang, eds.), pp. 217-223, Springer-Verlag, New York. **2.** Scaife, Wilson & Purich (1992) *Biochemistry* **31**, 310. **3.** Raffaelli, Scaife & Purich (1992) *Biochem. Biophys. Res. Commun.* **184**, 414.

### Avibactam

This non-β-lactam inhibitor of β-lactamase (FW = 261.27 g/mol; CAS 1192500-31-4), also known as NLX104 and AVE1330A, shows a spectrum of action against Classes A and C β-lactamase as well as selected Class D β-lactamase, enzymes that often confer resistance to β-lactam antibiotics. By forming a high-affinity complex with its target enzymes, avibactam enhances the antibacterial activity of certain β-lactam drugs, such as ceftaroline. With over 1000 known β-lactamase, the action of avibactam is apt to depend on the individual active-site interactions. **Mode of Action:** Acylation and deacylation rates have been measured for the clinically important enzymes CTX-M-15, KPC-2, *E. cloacae* AmpC, *P. aeruginosa* AmpC, OXA-10, and OXA-48 (1). The efficiency of acylation ( $k_{on}/K_i$ ) varies across the enzyme spectrum, from  $1.1 \times 10^4 \text{ M}^{-1}\text{s}^{-1}$  for OXA-10 to  $1.0 \times 10^5 \text{ M}^{-1}\text{s}^{-1}$  for CTX-M-15. Inhibition of OXA-10 was shown to follow a reversible covalent mechanism (see below), and the acylated OXA-10 displayed the longest residence time for deacylation, with a half-life of greater than 5 days. The inhibited enzyme forms are stable to hydrolysis for all enzymes with the exception of KPC-2, which displays slow hydrolytic route that involved fragmentation of the acyl-avibactam complex. In the case of TEM-1 lactamase, avibactam slowly covalently acylates its target, and the acylated enzyme subsequently undergoes slow deacylation ( $k_{off} = 0.045 \text{ min}^{-1}$ ) regenerating avibactam intact (2). **Use as a Combined Drug:** Combination of avibactam with extended-spectrum cephalosporins *or*

aztreonam shows promise in inhibiting *Klebsiella pneumoniae* (KP) isolates harboring carbapenemases, or KPCs (3). Given abundant experience with ceftazidime and the significant improvement avibactam provides against contemporary  $\beta$ -lactamase-producing Gram-negative pathogens, this combination will likely play a role in the treatment of complicated urinary tract infections (as monotherapy) and complicated intra-abdominal infections (in combination with metronidazole) caused (or suspected to be caused) by otherwise resistant pathogens, such as extended spectrum  $\beta$ -lactamase-, AmpC-, or *Klebsiella pneumoniae* carbapenemase-producing *Enterobacteriaceae* and multidrug-resistant *P. aeruginosa* (4). 1. Ehmann, Jahic, Ross, *et al.* (2013) *J. Biol. Chem.* **288**, 27960. 2. Ehmann, Jahic, Ross, *et al.* (2012) *Proc. Natl. Acad. Sci.* **109**, 11663. 3. Endimiani (2009) *Antimicrob. Agents Chemother.* **53**, 3599. 4. Lagacé-Wiens, Walkty & Karlowsky (2014) *Core Evid.* **9**, 13.

### Avidin

This bacteriostatic egg-white glycoprotein (MW = 54.7 kDa; CAS 1405-69-2; Abs<sub>10mg/mL</sub> = 15.5 at 282nm) contains four identical subunits, each containing a ultrahigh-affinity binding site ( $K_d \approx 10^{-15}$  M) for biotin, a coenzyme essential in many carboxylation reactions. The avidin-biotin interaction is among the strongest known noncovalent interactions, making it the constant subject of biophysical inquiry. By binding ~15  $\mu$ g biotin per mg, avidin (which makes up ~0.05% of total egg protein, or around 1.8 mg/egg) deprives invading microorganisms of this vital coenzyme. Many microorganisms partly by-pass this effect by possessing enzymes that covalently link biotin to  $\epsilon$ -NH<sub>2</sub> groups of active-site lysyl residues within biotin-dependent carboxylases. Upon cooking, biotin-free avidin is fully denatured, thus imparting no effect on those consuming cooked eggs. **Applications in Cytology:** The avidin-biotin interaction provides a simple and sensitive immunoenzymatic method to localize antigens (Ag) in formalin-fixed tissues, typically involving a biotin-labeled secondary antibody (Ab), followed by the addition of avidin-biotin-peroxidase complex, and affording superior results over the use of unlabeled antibodies (1). The availability of biotin-binding sites in the Ab-Ag complex is created by the incubation of a relative excess of avidin with biotin-labeled peroxidase. The oligomeric structure of avidin serves to bridge biotin-labeled peroxidase molecules to biotin-labeled peroxidase molecules. When compared on a mol-for-mol basis, the extreme affinity of avidin-biotin interactions rivals or exceeds that of nearly all known Ab-Ag interactions (See also *Streptavidin*). **Biochemical Applications with Recombinant Fusion Proteins:** In *Escherichia coli*, the biotin carboxy carrier protein (BCCP) is biotinylated by BirA, a biotin ligase that covalently attaches a biotin to the amino group of a lysine residue present within the recognition sequence within BCCP. A minimal biotinylation sequence has been found from screens of combinatorial peptide libraries; this 13-residue peptide (Sequence: GLNDIFEAQKIEW), along with a 13-residue long variant (Sequence: GLNDIFEAQKIEWHE), termed the AviTag™, have been identified as effective *in vivo* and *in vitro* substrates for the BirA enzyme (2). When target proteins are fused to the AviTag and co-expressed *in vivo* along with BirA, they can be biotinylated in bacteria, yeast, insect, or mammalian cells. Furthermore, when recombinant proteins are fused to the AviTag and incubated *in vitro* with purified BirA, they can be biotinylated efficiently on the central lysine residue in the AviTag. 1. Hsu, Raine & Fanger (1981) *J. Histochem. Cytochem.* **29**, 577. 2. Kay, Thai & Volgina (2009) *Meth. Mol. Biol.* **498**, 185.

### AVL-301, See Rociletinib

### AVN-944

This orally available antineoplastic agent (FW = 310.36 g/mol; CAS 297730-17-7), also known as VX-944 and (R)-1-cyanobutan-2-yl-(S)-1-(3-(3-(3-methoxy-4-(oxazol-5-yl)phenyl)ureido)phenyl)ethyl)carbamate, inhibits inosine 5'-monophosphate dehydrogenase (IMPDH), the enzyme catalyzing the conversion of IMP into XMP, leading to the biosynthesis of GMP, GDP, GTP, and ultimately dGTP. IMPDH is overexpressed in some cancer cells, particularly in hematological malignancies, and AVN944 appears to have a selective cytotoxic effect on cancer cells (1). Reduction of GTP in normal cells results in a temporary slowing of cell growth only.

AVN944 treatment results in dose-dependent cell growth inhibition in all studied prostate cancer cells, independently of their androgen sensitivity (1). AVN944 treatment arrests LNCaP cells in G<sub>1</sub>-phase and androgen-independent 22Rv1, DU145 and PC-3 cells in S-phase (1). AVN-944 treatment leads to the rapid disappearance of nucleostemin, a positive regulator of cell proliferation that is highly expressed in a variety of stem cells, tumors, and tumor cell lines (2). 1. Floryk & Thompson (2008) *Int. J. Cancer* **123**, 2294. 2. Huang, Itahana, Zhang & Mitchell (2009) *Cancer Res.* **69**, 3004.

### Avosentan

This potent, selective and orally available endothelin A receptor blocker (FW = 479.51 g/mol; CAS 290815-26-8; Soluble in DMSO), also known by its code names SPP301 and Ro 67-0565, induces the dose-dependent reduction in the fractional renal excretion of sodium (up to 8.7% at 50 mg avosentan), with a paralleled dose-related increase in proximal sodium reabsorption. Avosentan reduces albuminuria, when added to standard treatment in patients with type 2 diabetes and overt nephropathy, but induces significant fluid overload and congestive heart failure (2). 1. Smolander, Vogt, Maillard, *et al.* (2009) *Clin. Pharmacol. Ther.* **85**, 628. 2. Mann, Green, Jamerson, *et al.* (2010) *J. Am. Soc. Nephrol.* **21**, 527.

### Axitinib

This orally bioavailable anti-angiogenesis agent (FW = 386.47 g/mol; CAS 319460-85-0), also known by its code name AG013736, its trade name Inlyta®, and its systematic name N-methyl-2-[[3-[(E)-2-pyridin-2-ylethenyl]-1H-indazol-6-yl]sulfanyl]benzamide, is a tyrosine kinase inhibitor that targets vascular endothelial growth factor receptors VEGFR-1 (IC<sub>50</sub> = 0.1 nM), VEGFR-2 (IC<sub>50</sub> = 0.3 nM), and VEGFR-3 (IC<sub>50</sub> = 0.1-0.3 nM), as well as platelet-derived growth factor receptor, or PDGFR (IC<sub>50</sub> = 1.6 nM), and cKIT, or CD117 (IC<sub>50</sub> = 1.7 nM). Axitinib is cytostatic in xenograft models for breast cancer, renal cell carcinoma, and other tumors, presumably by acting as a vasculature-disrupting agent, or VDA (1-7). After inhibition of VEGF signaling, some normal capillaries regress in a systematic sequence of events initiated by a cessation of blood flow and followed by apoptosis of endothelial cells, migration of pericytes away from regressing vessels, and formation of empty basement membrane sleeves that can facilitate capillary regrowth (1). A Phase-3 trial indicates its superiority in prolonging progression-free survival (PFS) in previously treated renal cell carcinoma (RCC) patients, with axitinib-treated patients exhibiting a median PFS of 6.7 months versus 4.7 months for sorafenib (8). Axitinib potently inhibits CYP1A2, K<sub>i</sub> = 0.11  $\mu$ M (9). 1. Baffert, Le, Sennino, *et al.* (2006) *Am. J. Physiol. Heart Circ. Physiol.* **290**, H547. 2. Hu-Lowe, Zou, Grazzini, *et al.* (2008) *Clin. Cancer Res.* **14**, 7272. 3. Rossler, Monnet, Farace, *et al.* (2011) *Int. J. Cancer* **128**, 2748. 4. Porta, Tortora, Linassier, *et al.* (2012) *Med. Oncol.* **29**, 1896. 7. Rini, Escudier, Tomczak, *et al.* (2011) *Lancet* **378**, 1931. 8. Mittal, Wood & Rini (2012) *Biol. Ther.* **2**, 5. 9. Gu, Hibbs, Ong, Edwards & Murray (2014) *Biochem. Pharmacol.* **88**, 245.

## AZ20

This novel potent inhibitor (FW = 412.51 g/mol; CAS 1233339-22-4; Solubility: 83 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named AZ 20 and 4-[4-[(3*R*)-3-methyl-4-morpholinyl]-6-[1-(methylsulfonyl)cyclopropyl]-2-pyrimidinyl]-1*H*-indole, selectively targets ATR kinase, a serine/threonine-protein kinase also known as ataxia telangiectasia and Rad3-related protein (*or* ATR) kinase with IC<sub>50</sub> of 5 nM, 8-fold selectivity over mTOR. **1.** Foote, Blades, Cronin, *et al.* (2013) *J. Med. Chem.* **56**, 2125.

## AZ-27

This RSV inhibitor (FW = 633.77 g/mol) targets Respiratory Syncytial Virus, inhibiting both mRNA transcription and genome replication in cell-based mini-genome assays, suggesting it targets a step common to both of these RNA synthesis processes. Analysis in an *in vitro* transcription run-on assay, containing RSV nucleocapsids, showed that AZ-27 inhibits (IC<sub>50</sub> ≈ 15 nM) the synthesis of transcripts from the 3'-end of the genome to a greater extent than those from the 5'-end, indicating that it inhibits transcription initiation. In experiments assaying polymerase activity on the promoter, AZ-27 inhibits transcription and replication initiation. The RSV polymerase also utilizes the promoter sequence to perform a back-priming reaction. Addition of AZ-27 has no effect on the addition of up to three nucleotides by back-priming, but inhibits further extension of the back-primed RNA. These findings suggest that the RSV polymerase is likely to adopt different conformations to execute its separate functions at the promoter. **1.** Tiong-Yip, Aschenbrenner, Johnson, *et al.* (2014) *Antimicrob. Agents Chemother.* **58**, 3867. **2.** Noton, Nagendra, Dunn, *et al.* (2015) *J. Virol.* **89**, 7786.

## AZ191

This potent and selective DYRK inhibitor (FW = 429.53 g/mol), also systematically named *N*-(2-methoxy-4-(4-methylpiperazin-1-yl)phenyl)-4-(1-methyl-1*H*-pyrrolo[2,3-*c*]pyrimidin-3-yl)pyrimidin-2-amine, selectively targets DYRK1B, a *Dual* specificity tyrosine-phosphorylation-regulated kinase, with an IC<sub>50</sub> value of 17 nM, or about 5x and 110x higher affinity than for DYRK1A and DYRK2. AZ191 is effective both *in vitro* and in cells. DYRK1B has also been proposed to promote the turnover of Cyclin D<sub>1</sub>, a key regulator of mammalian G<sub>1</sub>-S-phase transitions. Cyclin D<sub>1</sub> is phosphorylated on Thr-286 by GSK3β (*or* glycogen synthase kinase 3β), thereby promoting its degradation. **1.** Ashford, Oxley, Kettle, *et al.* (2014) *Biochem. J.* **457**, 43.

## AZ3146

This selective inhibitor (FW = 452.55 g/mol; CAS 1124329-14-1; Solubility: 28 mg/mL DMSO; <1 mg/mL Water), also known as 9-cyclopentyl-2-(2-methoxy-4-(1-methylpiperidin-4-yloxy)phenylamino)-7-methyl-7*H*-purin-8(9*H*)-one, inhibits MPS1 protein kinases (IC<sub>50</sub> = 35 nM), which are found widely, but not ubiquitously, in eukaryotes and regulate kinetochore in both the chromosome attachment and the spindle checkpoints. MPS1 kinases also regulate centrosome function. **1.** Hewitt, Tighe, Santaguida, *et al.* (2010) *J. Cell Biol.* **190**, 25.

## AZ3976

This small molecule PAI-1 inhibitor (FW = 317.35 g/mol) targets Plasminogen Activator Inhibitor type-1 (IC<sub>50</sub> = 26 μM, in enzyme assays; IC<sub>50</sub> = 16 μM, in a plasma clot lysis assay), not by binding to active PAI-1, but to latent PAI-1 (K<sub>d</sub> = 0.29 μM at 35 °C). The observed binding stoichiometry (0.94 mol AZ3976 per mol PAI-1) was determined by isothermal calorimetry. The X-ray structure of AZ3976-PAI-1<sub>latent</sub> revealed that the inhibitor is lodged within the flexible-joint region, with the entrance to the cavity located between α-helix D and β-strand 2A. AZ3976 inhibits PAI-1 by enhancing the latency transition of active PAI-1, and, because AZ3976 only has measurable affinity for latent PAI-1, the likely mechanism of inhibition entails AZ3976 binding to the small fraction of PAI-1<sub>latent</sub> in equilibrium with PAI-1<sub>active</sub>. These findings suggest new routes for designing small molecule drugs that target PAI-1. **1.** Fjellström, Deinum, Sjögren, *et al.* (2013) *J. Biol. Chem.*, **288**, 873.

## AZ 6102

This moderately orally available TNKS2/TNKS1 inhibitor (FW = 428.53 g/mol; CAS 1645286-75-4; Solubility: 50 mM in DMSO), also named *rel*-2-[4-[6-[(3*R*,5*S*)-3,5-dimethyl-1-piperazinyl]-4-methyl-3-pyridinyl]phenyl]-3,7-dihydro-7-methyl-4*H*-pyrrolo[2,3-*d*]pyrimidin-4-one, targets tankyrase TNKS2 (IC<sub>50</sub> = 1 nM) and TNKS1 (IC<sub>50</sub> = 3 nM), exhibiting >100x greater selectivity for TNKS1/2 over PARP-1 (IC<sub>50</sub> = 2.0 μM), PARP-2 (IC<sub>50</sub> = 0.5 μM) and PARP-6 (IC<sub>50</sub> = 3.0 μM). Tankyrases are poly-ADP-ribosyltransferases that are involved in Wnt signaling pathway, telomere length, and vesicle trafficking. They activate the Wnt signaling pathway by poly-ADP-ribosylating AXIN1 and AXIN2, which are key components of the β-catenin destruction complex, such that poly-ADP-ribosylated target proteins are recognized by RNF146, the latter mediating their ubiquitination and later degradation. Germ-line mutations of several Wnt pathway components (*e.g.*, Axin, APC, and β-catenin), are known to be oncogenic. Inhibition of the poly(ADP-ribose) polymerase (PARP) catalytic domain of the tankyrases (TNKS1 and TNKS2) is known to inhibit the Wnt pathway via increased stabilization of Axin. AZ-6102 inhibits Wnt signaling in DLD-1 cells (IC<sub>50</sub> = 5 nM). **1.** Johannes, Almeida, Barlaam, *et al.* (2015) *ACS Med. Chem. Lett.* **6**, 254.

## AZ 10606120

This P2X<sub>7</sub> purine receptor antagonist (FW = 422.57 g/mol; CAS 607378-18-7; Solubility: 100 mM in DMSO), also named *N*-[2-[[2-[(2-hydroxyethyl)amino]ethyl]amino]-5-quinolinyl]-2-tricyclo[3.3.1.1<sup>3,7</sup>]dec-1-ylacetamide, exhibits *K*<sub>d</sub> values of 1.4 and 19 nM for human and rat receptors respectively. P2X<sub>7</sub> is a ligand-gated Ca<sup>2+</sup>/Mg<sup>2+</sup> cation channel that opens in response to the binding of extracellular ATP, resulting in cell depolarization. 1. Michel, *et al.* (2007) *Brit. J. Pharmacol.* **151**, 103. 2. Michel & Fonfria (2007) *Brit. J. Pharmacol.* **152**, 523. 3. Michel, *et al.* (2008) *Brit. J. Pharmacol.* **153**, 737. 4. Adinolfi, *et al.* (2012) *Cancer Res.* **72**, 2957.

## 8-Azaadenine

This bioavailable adenine analogue (FW = 136.12 g/mol) inhibits xanthine oxidase, *K*<sub>i</sub> = 0.66 μM. When incorporated in DNA, 8-azaadenine base pairs with thymine (also with cytosine), and *ab initio* calculations suggest these base-pairs may be 7 kcal/mol more stable than Adenine:Thymine base pairs. **Target(s):** hypoxanthine(guanine) phosphoribosyl-transferase (1); xanthine oxidase (2); xanthine phosphoribosyltransferase (1); xanthine dehydrogenase (3,4). 1. Naguib, Iltzsch, el Kouni, Panzica & el Kouni (1995) *Biochem. Pharmacol.* **50**, 1685. 2. Sheu, Lin & Chiang (1997) *Anticancer Res.* **17**, 1043. 3. Aretz, Kaspari & Klemme (1981) *Z. Naturforsch. C* **36**, 933. 4. Pérez-Vicente, Alamillo, Cárdenas & Pineda (1992) *Biochim. Biophys. Acta* **1117**, 159.

## 25-Azacholesterol

This cholesterol analogue (FW<sub>free-base</sub> = 387.65 g/mol; CAS 1973-61-1) inhibits sterol 25-*C*-methyltransferase, or cycloartenol 24-*C*-methyltransferase, *K*<sub>i</sub> = 10 nM (1,3-8) and cholesterol Δ<sup>7,8</sup>-isomerase, or sterol Δ<sup>7,8</sup>-isomerase (2). 1. Oehlschlager, Angus, Pierce, Pierce & Srinivasan (1984) *Biochemistry* **23**, 3582. 2. Nes, Zhou, Dennis, *et al.* (2002) *Biochem. J.* **367**, 587. 3. Mangla & Nes (2000) *Bioorg. Med. Chem.* **8**, 925. 4. Nes (2000) *Biochim. Biophys. Acta* **1529**, 63. 5. Venkatramesh, Guo, Jia & Nes (1996) *Biochim. Biophys. Acta* **1299**, 313. 6. Biophys.* **342**, 68.

## 25-Azacycloartenol

This cycloartenol analogue (FW<sub>free-base</sub> = 429.73 g/mol), also known as 25-azacycloartenol, inhibits plant sterol biosynthesis and cycloartenol 24-*C*-methyltransferase (*Prototheca wickerhamii* *K*<sub>i</sub> = 3 nM). 1. Rahier, Bouvier, Cattel, Narula & Benveniste (1983) *Biochem. Soc. Trans.* **11**, 537. 2. Zhao & Nes (2003) *Arch. Biochem. Biophys.* **420**, 18. 3. Nes, Song, Dennis, *et al.* (2003) *J. Biol. Chem.* **259**, 15215. 7. Nes, Guo & Zhou (1997) *Arch. Biochem. Biophys.* **342**, 68.

## 5-Azacytidine

This nucleoside antibiotic (FW = 244.21 g/mol), also known as 1-β-D-ribofuranosyl-5-azacytosine, is a natural product of *Streptovorticillius ladakanus* that is effective against Gram-negative organisms, inhibiting the biosynthesis of DNA and RNA. Observations that 5-azacytidine was incorporated into DNA (1) and that, when present in DNA, inhibited DNA methylation, led to widespread use of 5-azacytidine and 5-aza-2'-deoxycytidine (Decitabine) to demonstrate the correlation between loss of methylation in specific gene regions and activation of the associated genes. Upon incorporation into DNA results in instability. Azacytidine resistance in myelodysplastic syndrome and acute myeloid leukemia appears to reverse azacytidine-mediated activation of apoptosis signaling and to the re-establish G<sub>2</sub>/M checkpoint (2). Independently of its DNA methylation effects, 5-AzaC selectively and potently reduces expression of PCSK9, HMGCR, FASN, which are key genes in cholesterol and lipid metabolism, and this effect is observed in all tested cell lines and *in vivo* in mouse liver (3). Treatment with 5-AzaC perturb subcellular cholesterol homeostasis, impeding activation of sterol regulatory element-binding proteins (SREBPs). Through inhibition of UMP synthase, 5-AzaC also strongly induces expression of 1-acylglycerol-3-phosphate *O*-acyltransferase 9 (AGPAT9) and promoted triacylglycerol synthesis and cytosolic lipid droplet formation. Remarkably, complete reversal was obtained by co-addition of either UMP or cytidine (3). **Target(s):** protein biosynthesis (4,5); DNA biosynthesis (5); tRNA (cytosine-5) methyltransferase (7,8); DNA (cytosine-5) methyltransferase (9-11); adenosine deaminase (12); UTP synthase (3). 1. (3*R*,4*S*)-1-[(8-Aza-9-deazaadenin-9-yl)methyl]-4-(benzylthiomethyl)-3-hydroxy-pyrrolidine

This immucillin nucleoside analogue (FW = 359.47 g/mol), which mimics a highly dissociative transition-state possessing ribooxacarbenium ion character, potently inhibits 5'-methylthioadenosine/*S*-adenosyl-homocysteine nucleosidase, *K*<sub>i</sub><sup>o</sup> = 400 fM (1) and *S*-methyl-5'-thioadenosine phosphorylase, *K*<sub>i</sub> = 55 nM (2). When the ring nitrogen is protonated, this analogue mimics the charge of oxa-carbenium ion

intermediate that forms transiently in many glycosidase reactions. This property results in tight binding. 1. Singh, Evans, Lenz, *et al.* (2005) *J. Biol. Chem.* **280**, 18265. 2. Evans, Furneaux, Lenz, *et al.* (2005) *J. Med. Chem.* **48**, 4679.

### 5-Aza-2'-Deoxycytidine

This 2'-deoxycytidine analogue (FW = 228.21 g/mol; CAS 2353-33-5), also known generically as Decitabine, by its trade name Dacogen<sup>®</sup> and systematically as 4-amino-1-(2-5'-deoxy-β-D-erythro-pentofuranosyl)-1,3,5-triazin-2(1H)-one, is a powerful DNA methylase inhibitor. Dacogen is specifically indicated for the treatment of multiple types of myelodysplastic syndromes, including previously treated and untreated, de novo and secondary myelodysplastic syndromes (MDS) of all French-American-British subtypes. **Primary Mode of Action:** Upon metabolic phosphorylation and direct incorporation into DNA, the modified DNA inhibits DNA methyltransferase, bringing about hypomethylation, cellular differentiation, and/or apoptosis. Decitabine also inhibits DNA methylation *in vitro*, which is achieved at concentrations that do not suppress DNA synthesis. Decitabine-induced hypomethylation in neoplastic cells may restore normal function to genes that are critical for the control of cellular differentiation and proliferation. In rapidly dividing cells, the cytotoxicity of decitabine may also be attributed to the formation of covalent adducts between DNA methyltransferase and decitabine incorporated into DNA. Non-proliferating cells are relatively insensitive to decitabine. **Effect on Inorganic Phosphorus-Induced Mineralization of Vascular Smooth Muscle Cells:** 5-aza-dC increase the expression and activity of alkaline phosphatase (ALP) and reduce DNA methylation in the ALP promoter region in the Human Aortic Smooth Muscle Cells, *or* HASMCs (5). Treatment with 5-aza-dC and downregulation of the DNMT1 expression both promotes P<sub>i</sub>-induced mineralization of HASMCs. Moreover, both treatment with phosphonoformic acid (*or* PFA), a sodium-dependent phosphate transporter inhibitor, and suppression of the ALP expression inhibits the 5-aza-dC-promoted mineralization of HASMCs. 1. Adams, Fulton & Kirk (1982) *Biochim. Biophys. Acta* **697**, 286. 2. Paluska, Hrubá, Madar, *et al.* (1982) *Immunobiology* **162**, 288. 3. ### 5-Aza-5,6-dihydro-2'-deoxycytidine

This pro-drug (FW = 115.12 g/mol), also known as KP1212, undergoes metabolic phosphorylation to the deoxynucleoside triphosphate, followed by its RNA-directed DNA polymerase-catalyzed incorporation into HIV DNA, causing lethal A-to-G and G-to-A mutations in the viral genome, both in tissue culture and in HIV positive patients on KP1212 monotherapy. KP1212 base pairs promiscuously with A and G, and variable-temperature NMR and 2-dimensional infrared spectroscopy shows that KP1212 exists as a broad ensemble of interconverting tautomers, which its enolic forms dominating. KP1212's mutagenic properties were assessed empirically by *in vitro* and *in vivo* replication of a single-stranded vector containing a single KP1212. It was found that KP1212 paired ambiguously with both A (10% of the time) and G (90% of the time), a mutation frequency that is sufficient for pushing a viral population over its error catastrophe limit. 1. Li, Fedeles, Singh, *et al.* (2014) *Proc. Natl. Acad. Sci. USA* **111**, E3252.

### 25-Aza-24,25-dihydrozosterol

This cholesterol analogue (FW<sub>free-base</sub> = 387.65 g/mol) inhibits sterol 24-C-methyltransferase (*Saccharomyces cerevisiae*, K<sub>i</sub> = 5 nM). 1. Pierce, Mueller, Unrau & Oehlschlager (1978) *Can. J. Biochem.* **56**, 794. 2. Oehlschlager, Angus, Pierce, Pierce & Srinivasan (1984) *Biochemistry* **23**, 3582. 3. Nes (2000) *Biochim. Biophys. Acta* **1529**, 63.

### 3-Azageranylgeranyl Diphosphate

This analogue of geranylgeranyl diphosphate (FW = 454.46 g/mol) has a K<sub>i</sub> value of 15 nM for protein geranylgeranyltransferase, type I (1,2) and inhibits farnesyltransferase, *or* geranylgeranyl-diphosphate synthase (3-5). 1. Yokoyama & Gelb (2001) *The Enzymes*, 3rd ed., **21**, 105. 2. Zhang, Moomaw & Casey (1994) *J. Biol. Chem.* **269**, 23465. 3. Sagami, Korenaga, Ogura, Steiger, Pyun & Coates (1992) *Arch. Biochem. ### 8-Azaguanine

This toxic guanine analogue (FW = 152.12 g/mol; CAS 134-58-7; Soluble in dilute acid), also known as pathocidin and 5-amino-1,4-dihydro-7H-1,2,3-triazolo[4,5-d]pyrimidin-7-one, is readily incorporated into ribonucleic acids and acts as a purine antimetabolite. In most cases, 8-azaguanine inhibits translation and/or causes translation errors. Subsequent to its laboratory synthesis, 8-azaguanine was found to be a natural antibiotic produced by *Streptomyces spectabilis*. **Target(s):** xanthine oxidase (1-3); adenosine deaminase (3-5); methionine S adenosyltransferase (6,21); GTP cyclohydrolase I (7); xanthine dehydrogenase (8,24,25); translation (9); pterin deaminase (10,18,19); rRNA maturation (11); ribonucleotide reductase (12); DNA biosynthesis (12); protein biosynthesis (13-15); uricase (16); sepiapterin deaminase (17); agmatine deaminase (20); tRNA guanine transglycosylase, also alternative substrate (21); hypoxanthine(guanine) phosphoribosyltransferase (22,23); xanthine phosphoribosyltransferase (22). 1. ### 8-Aza-immucillin-H

This nucleotide analogue (FW = 266.24 g/mol), also known as (1*S*)-1-(7-hydroxy-1*H*-pyrazolo[4,3-*d*]pyrimidin-3-yl)-1,4-dideoxy-1,4-imino-D-ribose, is a high-affinity transition-state mimic for purine nucleosidase. When the ring nitrogen is protonated, this analogue mimics the charge of oxa-carbenium ion intermediate that forms transiently in many glycosidase reactions. This property results in tight binding. **1.** Versées, Barlow & Steyaert (2006) *J. Mol. Biol.* **359**, 331.

### 1-Azakenpauillone

This cell-permeable protein kinase inhibitor (FW = 328.17 g/mol; CAS 676596-65-9; Solubility: 66 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 9-bromo-7,12-dihydro-pyrido[3,2':2,3]azepino[4,5-*b*]indol-6(5*H*)-one, selectively and potently targets glycogen synthase kinase 3β, or GSK3β (IC<sub>50</sub> = 18 nM) with 100x less inhibitory action against cyclin-dependent kinases (CDKs) (1-3). 1-Azakenpauillone has become a gold standard for GSK3 inhibition (3). **1.** Zaharevitz, Gussio, Leost, *et al.* (1999) *Cancer Res.* **59**, 2566. **2.** Schultz, Link, Leost, *et al.* (1999) *J. Med. Chem.* **42**, 2909. **3.** Kunick, Lauenroth, Leost, Meijer & Lemcke (2004) *Bioorg. Med. Chem. Lett.* **14**, 413.

### 25-Azalanosterol

This steroid analogue (FW = 429.73 g/mol) inhibits sterol 24-C-methyltransferase ( $K_i$  = 7 nM). **1.** Mangla & Nes (2000) *Bioorg. Med. Chem.* **8**, 925. **2.** Venkatramesh, Guo, Jia & Nes (1996) *Biochim. Biophys. Acta* **1299**, 313. **3.** Nes, Jayasimha & Song (2008) *Arch. Biochem. ### Azalanstat

This imidazole-containing agent (FW = 429.96 g/mol), also known as RS-21607, inhibits both inducible heme oxygenase-1 and constitutive heme oxygenase-2 (rat IC<sub>50</sub> = 5.3 and 24.5 μM, respectively). The *m*-aminophenyl analogue is a slightly stronger inhibitor of heme oxygenase-1 (IC<sub>50</sub> = 1 μM). Azalanstat is a stronger inhibitor of lanosterol 14α-demethylase (rat and human  $K_i$  = 2.5 and 0.79 nM, respectively). The other three stereoisomers are weaker inhibitors of the demethylase. **Target(s):** aromatase, or CYP19 (3,4); cholestanetriol 26-monooxygenase, or cholesterol 27-monooxygenase (4); cholesterol 7α-monooxygenase (CYP7)3,4; cholesterol monooxygenase, side-chain cleaving (4); CYP1A1 (4); CYP1A2 (4); CYP2C9 (4); CYP2D6 (4); heme oxygenase (1,2,5-7); progesterone 6β-monooxygenase, or CYP3A (3,4); progesterone 16α-monooxygenase (4); steroid 11β monooxygenase (3,4); steroid 17α-monooxygenase, or steroid 17α/20-lyase (3,4); steroid 21 monooxygenase (4); sterol 14-demethylase, or CYP5 (1); lanosterol 14α-demethylase (3,4,8). **1.** Roman, Riley, Vlahakis, *et al.* (2007) *Bioorg. Med. Chem.* **15**, 3225. **2.** Vlahakis, Kinobe, Bowers, *et al.* (2005) *Bioorg. Med. Chem. Lett.* **15**, 1457. **3.** Walker, Kertesz, Rotstein, *et al.* (1993) *J. Med. ### L-Azaserine

This substituted serine (FW = 173.13 g/mol; CAS 115-02-6), also known as *O*<sup>3</sup>-(diazooacetyl)-L-serine and 3-[(diazooacetyl)oxy]alanine, is an L-glutamine analogue and inhibits many glutamine-dependent enzymes. Azaserine is also produced by species of *Streptomyces*. Solutions must always be freshly prepared. **Target(s):** phosphoribosyl-formylglycinamide synthetase, or formylglycinamide ribonucleotide amidotransferase (1,8,10-13,16-20,24-27,29,32); amido-phosphoribosyl-transferase (1,7,11,12, 15,16,31,54); γ-glutamyl transpeptidase, or γ-glutamyltransferase (2,3,14,21,23,55-57); NAD<sup>+</sup> synthetase (glutamine-hydrolyzing) (4,5,11,15,16,51); carbamoyl-phosphate synthetase (6,11); glutamine:fructose-6-phosphate aminotransferase, isomerizing (7,52,53); anthranilate synthase (9,15,30,33); CTP synthetase (11); GMP synthetase (11,28,35,50); phosphoribosyl-formylglycinamide cyclo-ligase (12); glutaminase (15); glutamine uptake (22); glutamin-(asparagin)-ase, or glutaminase-asparaginase (34,36,37); glutamate synthase (38,39); γ-glutamyl peptide-hydrolyzing enzyme (40); γ-glutamyl hydrolase41; glutamate synthase (ferredoxin) (42-45); asparagine synthetase (46-49). **1.** Buchanan (1982) *Meth. ### Azathioprine

This mercaptopurine cancer agent, proliferation inhibitor, and immunosuppressant (FW = 277.27 g/mol; CAS 446-86-6 and 55774-33-9 (sodium salt);  $\lambda_{\text{max}}$  at 276 nm in 0.1 N HCl ( $\epsilon = 18200 \text{ M}^{-1}\text{cm}^{-1}$ ) and 280 nm in 0.1 N NaOH ( $\epsilon = 17300 \text{ M}^{-1}\text{cm}^{-1}$ )), also named 6-[(1-methyl-4-nitro-1H-imidazol-5-yl)sulfanyl]-7H-purine, is a 6-mercaptopurine pro-drug. Prior to the advent of cyclosporin an FK506, azathioprine was often used in combination with prednisone as an immunosuppressant in kidney transplantation. **Mechanism of Inhibitory Action:** In the presence of glutathione, azathioprine is converted nonenzymatically to the active drug, 6-mercaptopurine (See 6-Mercaptopurine). Azathioprine has a superior therapeutic index relative to 6-mercaptopurine. Its major adverse effect is bone marrow suppression, one that can prove life-threatening in individuals with a deficiency in thiopurine S-methyltransferase (*Reaction: S-Adenosyl-L-Methionine + 6-Mercaptopurine*  $\rightleftharpoons$  6-S-Methylpurine + S-Adenosyl-L-Homoserine). Azathioprine's metabolite S-methyl-6-thioinosine monophosphate also mimics the action of IMP in the allosteric feedback inhibition of the first step in purine biosynthesis, a reaction catalyzed by amidophosphoribosyl-transferase. **Pharmacokinetics:** Azathioprine bioavailability varies between 30-90%, owing to individual variability in its inactivation within the liver. Highest plasma concentrations are reached after one to two hours, with an average plasma half-life of 26-80 minutes for azathioprine and 200-300 minutes for drug plus metabolites. 6-

Mercaptopurine is converted to its nucleotide form by HGPRT and eventually gives rise to thioguanosine triphosphate and thio-deoxyguanosine triphosphate by metabolism of thioinosine monophosphate. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York. **Target(s):** methionine S-adenosyltransferase (1); phosphoribosylamino-imidazole-carboxamide formyltransferase (2). **1.** Berger & Knodel (2003) *BMC Microbiol.* **3**, 12. **2.** Ha, Morgan, Vaughn & Baggott (1990) *Biochem. J.* **272**, 339.

### 6-Azathymine

This thymine analogue (FW = 127.10 g/mol; CAS 932-53-6) has the following inhibitor targets: (S)-3-amino-2-methylpropionate:pyruvate aminotransferase, or L-3-aminoisobutyrate aminotransferase (1); DNA biosynthesis (2); 4-aminobutyrate aminotransferase (3,6); D-3-aminobutyrate aminotransferase (4); (R)-3-amino-2-methylpropionate:pyruvate aminotransferase, or D-3-aminoisobutyrate aminotransferase, weakly inhibited (5). **1.** Tamaki, Fujimoto, Sakata & Matsuda (2000) *Meth. Acta* **1156**, 161. **6.** Buu & van Gelder (1974) *Can. J. Physiol. Pharmacol.* **52**, 674.

### 6-Azauracil

This uracil analogue (FW = 113.08 g/mol; CAS 461-89-2), also known as 1,2,4-triazine-3,5-(2H,4H)-dione, inhibits 3-amino-isobutyrate and 4-aminobutyrate aminotransferases. **Target(s):** (R)-3-amino-2-methylpropionate:pyruvate aminotransferase, or D-3-aminoisobutyrate aminotransferase (1,3,7); (S)-3-amino-2-methylpropionate:pyruvate aminotransferase, or L-3-aminoisobutyrate aminotransferase (1); 4-aminobutyrate amino-transferase (2,8); orotidine-5'-phosphate decarboxylase (4);  $\beta$ -alanine aminotransferase (5); uracil DNA glycohydrolase (6); alanine:glyoxylate aminotransferase (7); orotate phosphoribosyltransferase (9). **1.** Tamaki, Fujimoto Sakata & Matsuda (2000) *Meth. Enzymol.* **324**, 376. **2.** Tamaki, Kubo, Aoyama & Funatsuka (1983) *J. Biochem.* **93**, 955. **3.** Tamaki, Kaneko, Mizota, Kikugawa & Fujimoto (1990) *Eur. J. ### 6-Azauridine 5'-Monophosphate

This nucleotide analogue (FW<sub>free-acid</sub> = 325.17 g/mol) inhibits orotidylate decarboxylase and blocks pyrimidine biosynthesis. With protonation at N3, this analogue may resemble a putative zwitterionic intermediate preceding decarboxylation. **Target(s)**: orotidine-5'-phosphate decarboxylase, *or* orotidylate decarboxylase,  $K_i = 7 \times 10^{-7}$  M for yeast enzyme (1-5,7-22); orotate phosphoribosyltransferase (2); IMP dehydrogenase (6). 1. ## 24-Azazymosterol

This steroid analogue (FW = 387.65 g/mol) inhibits cycloartenol 24-C-methyltransferase, *or* SMT ( $K_i = 15$  nM), or about four orders of magnitude more tightly the substrate cycloartenol ( $K_m = 28$   $\mu$ M), supporting the likely intermediacy of the carbenium ion reaction intermediate (1,2). Ergosterol (but not cholesterol or sitosterol) inhibits this methyltransferase ( $K_i = 80$   $\mu$ M). This combination of results suggests that the interrelationships of substrate functional groups within the active center of a  $\Delta^{24^{25}}$  to  $\Delta^{25^{27}}$ -SMT could be approximated, thereby facilitating the rational design and testing of novel C-methylation inhibitors (2). In the earlier study (1), an isosteric analogue of the natural substrate zymosterol, in which the 26/27-gem-dimethyl groups were joined to form a cyclopropylidene function was found to be a potent irreversible mechanism-based inactivator of SMT enzyme activity that exhibits competitive-type inhibition ( $K_i = 80$   $\mu$ M;  $k_{inact} = 1.5$  min<sup>-1</sup>). 1. Mangla & Nes (2000) *Bioorg. Med. Chem.* **8**, 925. 2. Nes, Guo & Zhou (1997) *Arch. Biochem. Biophys.* **342**, 68.

## 25-Azazymosterol, Similar in action to 24-Azazymosterol

AZD0530, See Saracatinib

## AZ 628

this pan-Raf inhibitor (FW = 451.52 g/mol; CAS 878739-06-1; Solubility: 90 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also named 3-(2-cyanopropan-2-yl)-N-(4-methyl-3-(3-methyl-4-oxo-3,4-dihydroquinazolin-6-ylamino)-

phenyl)benzamide, targets the proto-oncogene B-Raf, *or* BRAF, *or*, more formally, serine/threonine-protein kinase B-Raf (IC<sub>50</sub> = 105 nM), BRAF<sup>V600E</sup> (IC<sub>50</sub> = 34 nM), and c-Raf-1 (IC<sub>50</sub> = 29 nM), with off-target inhibition of VEGFR2, DDR2, Lyn, Fli1, FMS, and others (1). **Mechanism of Action**: Frequently mutated in human cancer, MAPK/ERK pathway consists of a RAS family GTP protein that is activated in response to extracellular signaling and recruits a RAF kinase family member to the cell membrane. Once activated, RAF signals through MAP/ERK kinase to activate ERK and its downstream effectors to regulate cell differentiation, proliferation, senescence, and survival. Mutations in BRAF (especially BRAF<sup>V600E</sup>) are found in approximately 30% of all human cancers (melanoma, colorectal, and thyroid cancers), making the BRAF pathway a druggable target for therapy. 1. Montagut, Sharma, Shioda, *et al.* (2008) *Cancer Res.* **68**, 4853.

## AZ-960

This potent and selective JAK2 protein kinase inhibitor (FW = 354.36 g/mol; CAS 905586-69-8; Solubility = 70 mg/mL DMSO), also named 5-fluoro-2-[[[(1S)-1-(4-fluorophenyl)ethyl]amino]-6-[(5-methyl-1H-pyrazol-3-yl)amino]-3-pyridinecarbonitrile], targets Janus-associated kinase-2 kinase. The JAK2<sup>V617F</sup> mutation is thought to play a critical role in the pathogenesis of polycythemia vera, essential thrombocythemia, and idiopathic myelofibrosis. AZ960 inhibits JAK2 kinase ( $K_i = 0.45$  nM, *in vitro*). Treatment of TEL-JAK2 driven Ba/F3 cells with AZ960 blocks STAT5 phosphorylation and potently inhibits cell proliferation (GI<sub>50</sub> = 25 nM). AZ960 demonstrates selectivity for TEL-JAK2-driven STAT5 phosphorylation and cell proliferation when compared with cell lines driven by similar fusions of the other JAK kinase family members. JAK2 inhibition induces apoptosis by direct and indirect regulation of the anti-apoptotic protein BCL-xL. 1. Gozgit, Bebernit, Patil, *et al.* (2008) *J. Biol. Chem.* **283**, 32334.

AZD217, See Cediranib

## AZD1080

This orally active, brain-permeable protein kinase inhibitor (FW = 334.37 g/mol; CAS 612487-72-6), also named 2-hydroxy-3-[5-(4-morpholinylmethyl)-2-pyridinyl]-1H-indole-5-carbonitrile, selectively targets human GSK3 $\alpha$  ( $K_i = 6.9$  nM) and GSK3 $\beta$  ( $K_i = 31$  nM), showing >14x lower inhibitory action against CDK2, CDK5, CDK1 and Erk2. AZD1080 inhibits human tau phosphorylation. The inhibitory pattern on tau phosphorylation reveals a prolonged pharmacodynamic effect predicting less frequent dosing in humans. Subchronic but not acute, administration with AZD1080 reverses MK-801-induced deficits, as measured by long-term potentiation in hippocampal slices and in a cognitive test in mice. Such findings suggest that reversal of synaptic plasticity deficits in dysfunctional systems requires longer term modifications of proteins downstream of GSK3 $\beta$  signaling. 1. Georgievska, Sandin, Doherty, *et al.* (2013) *J. Neurochem.* **125**, 446.

AZD1152, See *Barasertib*

AZD1208

This orally available protein kinase inhibitor (FW = 379.48 g/mol; CAS 1204144-28-4; Soluble in DMSO, Insoluble in H<sub>2</sub>O), also named 5-[[2-[(3*R*)-3-aminopiperidin-1-yl]biphenyl-3-yl]methylidene]-1,3-thiazolidine-2,4-dione, targets the proto-oncogene serine/threonine-protein kinases PIM-1, PIM-2 and PIM-3, often interrupting the G<sub>1</sub>/S cell cycle transition and inducing apoptosis in PIM-overexpressing cells. Pim kinases are downstream effectors of ABL, JAK2, and Flt-3 oncogenes that are critical for driving tumorigenesis (1). PIM1, PIM2 and PIM3 were first recognized as pro-viral integration sites for the Moloney Murine Leukemia virus (2). Unlike other kinases, they possess a hinge region which creates a unique binding pocket for ATP. Absence of a regulatory domain makes these proteins are constitutively active once transcribed. Upregulation of Pim kinases is observed in several types of leukemias (especially Acute Myelogenous Leukemia (AML)) and lymphomas, with PIM-1, PIM-2 and PIM-3 promoting cancer cell proliferation and survival. AZD1208, demonstrates efficacy in preclinical models of acute myeloid leukemia (2). 1. Keeton, McEachern, Dillman, *et al.* (2013) *Blood* **123**, 905. 2. Swords, Kelly, Carew, *et al.* (2011) *Curr. Drug Targets* **12**, 2059.

AZD1480

This ATP-competitive protein kinase inhibitor (FW = 348.77 g/mol; CAS 935666-88-9) targets Janus kinases JAK1 (IC<sub>50</sub> = 1.3 nM) and JAK2 (IC<sub>50</sub> = 0.26 nM), inducing arrest at the G<sub>2</sub>/M junction and cell death by its inhibition of Aurora kinases. AZD1480 suppresses the growth of human solid tumor xenografts harboring persistent Stat3 activity, a downstream target of JAK2 (1). Through its inhibition of phosphorylation of JAK2, STAT3 and MAPK signaling proteins, AZD1480 (at low- $\mu$ M concentrations) blocks proliferation and induces apoptosis in myeloma cell lines (2). AZD1480 likewise inhibits constitutive and stimulus-induced phosphorylation of JAK2 and STAT-3 in glioblastoma multiforme, a devastating and presently incurable disease (3). AZD1480 effectively inhibits tumor angiogenesis and metastasis, as mediated by STAT3 in stromal cells as well as tumor cells (4). Treatment of HCT116, HT29 and SW480 human colorectal cancer cell lines with AZD-1480 results in decreased phosphorylated JAK2 and phosphorylated STAT3, as well as the decreased expression of STAT3-targeted genes c-Myc, cyclin D2 and IL-6 (5). 1. Hedva, Huszar, Herrmann, *et al.* (2009) *Cancer Cell* **16**, 487. 2. Scuto, Krejci, Popplewell, *et al.* (2011) *Leukemia* **25**, 538. 3. McFarland, Ma, Langford, *et al.* (2011) *Mol. Cancer Ther.* **10**, 2384. 4. Xin, Herrmann, Reckamp, *et al.* (2011) *Cancer Res.* **71**, 6601. 5. Wang, Hu, Guo, *et al.* (2014) *Oncol. Rep.* **32**, 1991.

AZD-2281, See *Olaparib*

AZD2624

This neurokinin receptor antagonist (FW = 459.56 g/mol; CAS 941690-55-7) selectively targets Neurokinin 3, or NK<sub>3</sub>, receptors, which are driven by tachykinins released from intrinsic primary afferent neurones (IPANs). AZD shows high selectivity for NK<sub>3</sub> receptors ( $K_i$  = 2 nM; calcium flux IC<sub>50</sub> = 2.6 nM) with >100x selectivity over a 184 other receptors, enzymes, and ion channels, including NK<sub>2</sub>R, NK<sub>1</sub>R, and CCK<sub>2</sub>R. The major human metabolite, AZ12592232, has only slightly weaker human NK3R antagonist potency (calcium flux IC<sub>50</sub> = 9.0 nM), with >10x selectivity of toward NK<sub>2</sub>R. CYP3A4 and CYP3A5 appear to be the primary enzymes forming the pharmacologically active ketone metabolite (M<sub>1</sub>), whereas CYP3A4, CYP3A5, and CYP2C9 form the hydroxylated metabolite (M<sub>2</sub>). Apparent  $K_m$  values are 1.5 and 6.3  $\mu$ M for the formation of M<sub>1</sub> and M<sub>2</sub> in human liver microsomes, respectively. 1. Li, Zhou, Ferguson, *et al.* (2010) *Xenobiotica* **40**, 721.

AZD2858

This selective protein kinase inhibitor (FW = 453.52 g/mol; CAS 486424-20-8; Solubility: 7 mg/mL DMSO), also named 3-amino-6-[4-[(4-methyl-1-piperazinyl)sulfonyl]phenyl]-*N*-3-pyridinyl-2-pyrazine carboxamide, targets glycogen synthase kinase-3 (or GSK-3), IC<sub>50</sub> = 68 nM, thereby activating Wnt signal transduction pathway. Treatment of human osteoblast cells with 1  $\mu$ M AZD2858 *in vitro* increased  $\beta$ -catenin levels (1). In rats, oral AZD2858 treatment caused a dose-dependent increase in trabecular bone mass compared to control after a two-week treatment (1). AZD2858 produced time-dependent changes in serum bone turnover biomarkers and increased bone mass over 28 days exposure in rats (2). AZD2858 likewise drives mesenchymal cells into the osteoblastic pathway, leading to direct bone repair in an otherwise unstable fracture milieu (3). 1. Marsell, Sisask, Nilsson, *et al.* (2012) *Bone* **50**, 619. 2. Gilmour, O'Shea, Fagura, *et al.* (2013) *Toxicol. Appl. Pharmacol.* **272**, 399. 3. Sisask, Marsell, Sundgren-Andersson, *et al.* (2013) *Bone* **54**, 126.

AZD3293

This orally active  $\beta$ -secretase "sheddease" inhibitor (FW = 412.54 g/mol), also named 4-methoxy-5'-methyl-6'-[5-(prop-1-yn-1-yl)pyridin-3-yl]-3'*H*-dispiro[cyclohexane-1,2'-indene-1',2''-imidazole]-4"-amine and LY3314814, targets BACE1 (or  $\beta$ -site Amyloid Precursor Protein Cleaving Enzyme or Memapsin-2), an aspartic-acid protease important in the formation of myelin sheaths in peripheral nerve cells and in the pathogenesis of Alzheimer's disease. BACE1 cleaves the APP protein to release the C99

fragment, itself a substrate for subsequent  $\gamma$ -secretase cleavage to form A $\beta$  peptide, reducing amyloid-related toxicity in Alzheimer's disease. AZD3293 is a blood-brain barrier (BBB) penetrating BACE1 inhibitor with unique slow off-rate kinetics (1). The in vitro potency of AZD3293 was demonstrated in several cellular models, including primary cortical neurons. In vivo in mice, guinea pigs, and dogs, AZD3293 displayed significant dose- and time-dependent reductions in plasma, cerebrospinal fluid, and brain concentrations of A $\beta$ 40, A $\beta$ 42, and sA $\beta$ PP $\beta$  (1). The in vitro potency of AZD3293 in mouse and guinea pig primary cortical neuronal cells was correlated to the in vivo potency expressed as free AZD3293 concentrations in mouse and guinea pig brains (1). AZD3293 is the only BACE1 inhibitor for which prolonged suppression of plasma A $\beta$  with a QW dosing schedule has been reported (2). 1. Eketjäll, Janson, Kaspersson, *et al.* (2016) *J. Alzheimers Dis.* **50**, 1109. 2. Cebers, Alexander, Haerberlein, *et al.* (2017) *J. Alzheimers Dis.* **55**, 1039.

#### AZD3463

This novel, orally bioavailable ALK inhibitor (FW = 448.95 g/mol; CAS 1356962-20-3; Solubility: 24 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named *N*-[4-(4-amino-1-piperidinyl)-2-methoxyphenyl]-5-chloro-4-(1*H*-indol-3-yl)-2-pyrimidinamine, inhibits Anaplastic Lymphoma Kinase (ALK) with a *K<sub>i</sub>* of 0.75 nM and overcomes multiple mechanisms of acquired crizotinib resistance. AZD3463 inhibits ALK in cells as demonstrated by its ability to decrease ALK autophosphorylation in tumor cell lines containing ALK fusions, including DEL (ALCL NPM-ALK), H3122 (NSCLC EML4-ALK) and H2228 (NSCLC EML4-ALK) mutant forms. Inhibition of ALK is associated with perturbations in downstream signaling including ERK, AKT and STAT3 pathways leading to preferential inhibition of proliferation in the ALK fusion containing cell lines in vitro. AZD3463 also demonstrates the ability to dose dependently inhibit pALK in xenograft tumors in vivo resulting in stasis or regression. **Other Target(s):** AZD3463 also inhibits additional receptor tyrosine kinases including insulin growth factor receptor (IGF1R) with equivalent potency. 1. Drew, Cheng, Engelman, *et al.* (2013) *Cancer Res.* **73**, Suppl. 1, Abstr. 919.

#### AZD3965

This orally bioavailable MCT1 inhibitor (FW = 515.51 g/mol; CASs = 733809-45-5 and 1448671-31-5), also named (*S*)-5-(4-hydroxy-4-methylisoxazolidine-2-carbonyl)-1-isopropyl-3-methyl-6-((3-methyl-5-(trifluoromethyl)-1*H*-pyrazol-4-yl)methyl)-thieno[2,3-*d*]pyrimidine-2,4(1*H*, 3*H*)-dione, selectively targets the Monocarboxylate Transporter-1 (IC<sub>50</sub> = 1.6 nM) and is ~6x less active toward MCT2. AZD3965 does not inhibit MCT4, even at 10  $\mu$ M. MCT1 and MCT4 are primarily involved in lactate transport, targeting highly glycolytic cancer cells, especially those that are hypoxic. The latter property suggests that the combined use with a vascular-disrupting anticancer agent (such as combrestatin) may improve the inhibitory action of AZD-3965 against cancer cells. 1. Polański, Hodgkinson, Fusi, *et al.* (2014) *Clin. Cancer Res.* **20**, 926.

#### AZD4547

This potent and selective FGFR inhibitor (FW = 463.57 g/mol; CAS 1035270-39-3; Solubility (25°C) = 92 mg/mL DMSO; <1 mg/mL water), also known as *N*-(5-(3,5-dimethoxyphenethyl)-1*H*-pyrazol-3-yl)-4-((3*S*,5*R*)-3,5-dimethylpiperazin-1-yl)benzamide, is active against the receptor-coupled tyrosine kinase activity of both the wild-type and mutant forms of fibroblast growth factor receptors (1). AZD4547 exhibits weaker activity against FGFR4, and VEGFR2(KDR), with little activity observed against IGFR, CDK2, and p38. A 1.65 Å resolution structure of AZD4547 bound to the kinase domain of FGFR1 reveals extensive drug-protein interactions, an integral network of water molecules, and tight closure of the FGFR1 P-loop, the latter forming a long, narrow crevice into which AZD4547 binds (2). Such findings likely explain the sub-nM *K<sub>i</sub>* for its action as a FGFR1 inhibitor. **Targets:** FGFR1, *K<sub>i</sub>* = 0.2 nM; FGFR1, *K<sub>i</sub>* = 2.5 nM; FGFR1, *K<sub>i</sub>* = 1.8 nM (1). 1. Gavine, *et al.* (2012) *Cancer Res.* **72**, 2045. 2. Yosaatmadja, Patterson, Smail & Squire (2015) *Acta Crystallogr. D Biol. Crystallogr.* **71**, 525.

#### AZD5438

This cyclin kinase-directed inhibitor (FW = 371.46 g/mol; CAS 602306-29-6; Solubility: 70 mg/mL DMSO; <1 mg/mL Water; Formulation: dissolve in hydroxy-propyl-methyl-cellulose), systemically named 4-(1-isopropyl-2-methyl-1*H*-imidazol-5-yl)-*N*-(4-(methylsulfonyl)phenyl)-pyrimidin-2-amine, targets CDK1, CDK2 and CDK9 with IC<sub>50</sub> values of 16 nM, 6 nM, and 20 nM, respectively, inducing cell cycle arrest in a range of tumor cell lines. AZD5438 also inhibits the kinase activity of p25-cdk5 and glycogen synthase kinase 3 $\beta$  with IC<sub>50</sub> of 14 nM and 17 nM, respectively. **Cyclin Target Selectivity:** Cdk1 (weak, if any), Cdk2 (weak, if any), Cdk3 (weak, if any), Cdk4 (weak, if any), Cdk5 (weak, if any), Cdk6 (weak, if any), Cdk7 (++) , Cdk8 (weak, if any), Cdk9 (weak, if any), Cdk10 (weak, if any). 1. Byth, *et al.* (2009) *Mol. Cancer Ther.* **8**, 1856.

#### AZD 5582

This potent dimeric Smac mimetic (FW = 1088.21 g/mol; Solubility: 100 mM in H<sub>2</sub>O; 100 mM in DMSO), also named 3,3'-[2,4-hexadiene-1,6-diylbis[oxy[(1*S*,2*R*)-2,3-dihydro-1*H*-indene-2,1-diyl]]]bis[*N*-methyl-L-alanyl-(2*S*)-2-cyclohexylglycyl-L-prolinamide, targets  $\chi$ -linked Inhibitor of

Apoptosis Protein (*or* XIAP) and cellular Inhibitor of Apoptosis Proteins 1 and 2 (cIAP1 and cIAP2), with IC<sub>50</sub> values of 15, 15 and 21 nM for XIAP, cIAP1 and cIAP2, respectively. A protein that promotes cytochrome *c*-dependent activation by eliminating the inhibition via IAP, Smac is normally found in mitochondria, but escapes into the cytosol when a cell is primed for apoptosis during the final so-called execution step of caspase activation. When administered intravenously to MDA-MB-231 xenograft-bearing mice, AZD5582 results in cIAP1 degradation and caspase-3 cleavage within tumor cells, resulting in substantial tumor regression after two weekly doses of 3.0 mg/kg. Antiproliferative effects are observed with AZD 5582 in only a small subset of the over 200 cancer cell lines examined, consistent with other published IAP inhibitors. AZD 5582 binds to the BIR3 domain of XIAP to prevent interaction with caspase-9. Causes degradation of cIAP1 and cIAP2 and induces apoptosis in MDA-MB-231 breast cancer cells. 1. Hennessy, Adam, Aquila, *et al.* (2013) *J. Med. Chem.* **56**, 9897.

**AZD6140**, See *Ticagrelor*

**AZD6244**, See *Selumetinib*

**AZD6738**

This orally active, and selective ATR kinase inhibitor (FW = 412.51 g/mol; CAS 1352226-88-0; Solubility: 80 mg/mL DMSO; < 1 mg/mL H<sub>2</sub>O) targets Ataxia Telangiectasia/Rad3-related kinase (IC<sub>50</sub> = 1 nM), a serine/threonine protein kinase that activates checkpoint signaling upon genotoxic stresses (*e.g.*, ionizing radiation, ultraviolet light, or replication stalling), thereby serving as a DNA damage sensor. In a model consisting of primary human Chronic Myelogenous Leukemia (CL) cells with biallelic TP53 or ATM inactivation xenotransplanted into NOD/Shi-scid/IL-2R $\gamma$  mice, AZD6738 provides potent and specific inhibition of ATR signalling with compensatory activation of ATM/p53 pathway in cycling CLL cells in the presence of genotoxic stress (1). In p53 or ATM-defective cells, AZD6738 treatment results in replication fork stalls and accumulation of unrepaired DNA damage, as evidenced by  $\gamma$ H2AX and 53BP1 foci formation, carried through into mitosis and resulting in cell death by mitotic catastrophe (1). AZD6738 displays selective cytotoxicity towards ATM- or p53-deficient CLL cells (1). AZD6738 also potentiates cisplatin and gemcitabine cytotoxicity in Non-Small-Cell Lung Carcinoma (NSCLC) cell lines with intact ATM kinase signaling. It also potently synergizes with cisplatin in ATM-deficient NSCLC cells (2). When used in combination, cisplatin and AZD6738 resolve ATM-deficient lung cancer xenografts. 1. Kwok, Davies, Agathangelou, *et al.* (2015) *Lancet* **385**, Suppl. 1, S58. 2. Vendetti, Lau, Schamus, *et al.* (2015) *Oncotarget* **6**, 44289.

**AZD7545**

This [pyruvate dehydrogenase] kinase-2 inhibitor (FW = 478.88 g/mol) maintains the active dephospho-form of pyruvate dehydrogenase *in vivo*, thereby improving blood glucose control in Type II diabetes. 1. Mayers, Butlin, Kilgour, *et al.* (2003) *Biochem. Soc. Trans.* **31**, 1165. 2. Kato, Li, Chuang & Chuang (2007) *Structure* **15**, 992. 3. Roche & Hiromasa (2007) *Cell. Mol. Life Sci.* **64**, 830. 4. Mayers, Leighton & Kilgour (2005) *Biochem. Soc. Trans.* **33**, 367. 5. Tuganova, Klyuyeva & Popov (2007) *Biochemistry* **46**, 8592.

**AZD8931**

This signal transduction kinase inhibitor (FW = 473.94 g/mol; CAS 848942-61-0), also named 2-(4-[4-(3-chloro-2-fluorophenylamino)-7-methoxyquinazolin-6-yloxy]piperidin-1-yl)-*N*-methylacetamide, reversibly inhibits EGFR (IC<sub>50</sub> = 4 nM), erbB2 (IC<sub>50</sub> = 3 nM), and erbB3 (IC<sub>50</sub> = 4 nM) phosphorylation in cells. In proliferation assays, AZD8931 is significantly more potent than gefitinib or lapatinib in specific squamous cell carcinoma of the head and neck and non-small cell lung carcinoma cell lines. *In vivo*, AZD8931 inhibits xenograft growth in a range of models, while significantly affecting EGFR, erbB2, and erbB3 phosphorylation and downstream signaling pathways, apoptosis, and proliferation. In EGF and HRG ligand-driven cell systems, AZD8931 is more potent than gefitinib or lapatinib. Metabolic disposition of AZD8931 (2). 1. Hickinson, Klinowska, Speake, *et al.* (2010) *Clin. Cancer Res.* **16**, 1159. 2. Ballard, Swaisland, Malone, *et al.* (2014) *Xenobiotica* **44**, 1083.

**AZD9272**

This orally bioavailable and brain-penetrant potent and selective mGlu<sub>5</sub> antagonist (FW = 284.22 g/mol; CAS 327056-26-8; Solubility: 50 mM in DMSO), also named 3-fluoro-5-[3-(5-fluoro-2-pyridinyl)-1,2,4-oxadiazol-5-yl]benzotrile, with IC<sub>50</sub> values are 2.6 and 7.6 nM for rat and human receptors, respectively. AZD9272 exhibits >3900-fold selectivity for mGlu<sub>5</sub> over other mGlu receptors. AZD9272 does not share discriminative effects with drugs of abuse of the cocaine, benzodiazepine, or NMDA antagonist types. A partial (-)- $\Delta^9$ -THC-like effect was found. AZD9272 caused a partial but dose-dependent increase in (-)- $\Delta^9$ -THC-appropriate responding, with a maximal effect of 37.39%, and then a decrease with no dose-dependent effects on response rates. 1. Raboisson, Breitholtz-Emanuelsson, Dahllöf, *et al.* (2012) *Bioorg. Med. Chem. Lett.* **22**, 6974.

**AZD9291**

This novel third-generation TKI (FW = 499.62 g/mol; CAS 1421373-65-0), also named osimertinib and Tagrisso<sup>®</sup>, is an orally available antineoplastic agent that selectively and irreversibly inhibits both EGFR<sup>m</sup>-sensitizing and EGFR<sup>T790M</sup> resistance-conferring mutants, while sparing wild-type EGFR (1,2). When studied *in vitro*, AZD9291 had IC<sub>50</sub> values of 1, 12, 5, and 184 nM toward EGFR<sup>L858R/T790M</sup>, EGFR<sup>L858R</sup>, EGFR<sup>L861Q</sup>, and wild-type EGFR (1). AZD-9291 binds to the EGFR kinase, forming a covalent bond with Cysteine-797 in the ATP binding site (3). This mono-anilino-pyrimidine compound is structurally distinct from other third-generation EGFR TKIs and, in preclinical studies, likewise irreversibly inhibits signaling pathways and cellular growth in both EGFR<sup>m</sup> and EGFR<sup>m</sup>/T790M<sup>+</sup> mutant cell lines *in vitro*, showing lower activity against

wild-type EGFR lines. The result is profound and sustained tumor regression in *EGFR*-mutant tumor xenograft and transgenic models. In clinical trials, AZD 9291 was highly active in *EGFR*<sup>T790M</sup> lung cancer patients experiencing disease progression during prior therapy with other *EGFR*-directed TKIs (4). **Binding Characteristics:** X-ray structural models of AZD9291 bound to *EGFR* showed (a) that its pyrimidine core forms two hydrogen bonds to Met-793 in the hinge region, (b) that its indole group is favorably oriented relative to an adjacent gatekeeper residue, (c) that its amine moiety occupies the solvent channel, and (d) that its acrylamide moiety is situated near Cys-797, the nucleophile with which it reacts to form a covalent adduct (1). While sharing a number of structural features with the other third-generation TKIs, such as WZ4002 and CO-1686, (e.g., location of the thiol-reactive electrophile, positioning of heteroatom-linked pyrimidine 4-substituents, and the presence of a pyrimidine 5-substituent), AZD9291 is architecturally unique (1). Indeed, its electrophile resides on the pyrimidine C-2 substituent ring, its pyrimidine 4-substituent is C-linked and heterocyclic, and the pyrimidine 5-position on AZD9291 is unsubstituted (1). 1. ### Azelnidipine

This dihydropyridine-class calcium channel antagonist (FW = 582.64 g/mol; CAS 123524-52-7), also known as Calblock<sup>®</sup> and *O*<sup>3</sup>-[1-[di(phenyl)methyl]azetid-3-yl]-*O*<sup>2</sup>-propan-2-yl-2-amino-6-methyl-4-(3-nitrophenyl)-1,4-dihydropyridine-3,5-dicarboxylate, selectively inhibits L-type calcium channels and is indicated for the treatment of patients with hypertension. 1. Wellington & Scott (2003) *Drugs* **63**, 2613.

### 3-O-(2(S)-Azetidinylmethoxy)pyridine

This hygroscopic pyridine, also known as A-85380 (FW<sub>free-base</sub> = 164.21 g/mol), is a neuronal nicotinic acetylcholine receptor agonist (1,2). For the human  $\alpha_4\beta_2$  neuronal acetylcholine receptor,  $K_i$  = 50 pM. 1. Sullivan, Donnelly-Roberts, Briggs, *et al.* (1996) *Neuropharmacology* **35**, 725. 2. Abreo, Lin, Garvey, *et al.* (1996) *J. Med. Chem.* **39**, 817.

### 6 $\beta$ -Azido-7 $\alpha$ -acetoxysteroid-4-ene-3,17-dione

This steroid (FW = 385.46 g/mol) inhibits CYP19, or aromatase,  $K_i$  = 14 nM. Inhibitors of human placental aromatase (P-450<sup>arom</sup>) may be useful in treating estrogen-dependent diseases, including breast cancer. 1. Njar, Grun & Hartmann (1995) *J. Enzyme Inhib.* **9**, 195.

### 2-Azidoadenosine 5'-Diphosphate

This purine-2 position photoreactive ADP analogue (FW<sub>free-acid</sub> = 468.22 g/mol) will covalently modify adenine nucleotide-dependent reactions/processes. **Target(s):** CF<sub>1</sub> ATPase (1,3,5,11); F<sub>1</sub> ATPase (2,4,7-10); ADP/ATP transporter (6). 1. Colman (1990) *The Enzymes*, 3rd ed., **19**, 283. 2. Garin, Vincon, Gagnon & Vignais (1994) *Biochemistry* **33**, 3772. 3. Czarnecki, Abbott & Selman (1982) *Proc. Natl. Acad. Sci. ### 8-Azido-ADP-glucose

This photoaffinity labeling reagent and sugar-nucleotide derivative (FW<sub>free-acid</sub> = 630.36 g/mol) inhibits glucose-1-phosphate adenylyltransferase, or ADPglucose synthase. In the dark, the synthase utilizes 8-azido-ADPglucose as a substrate. When illuminated at 254 nm, however, this analogue specifically and covalently modifies the enzyme, with concomitant loss of catalytic activity. ADPglucose also protects the enzyme from covalent modification by the photoreagent. **1.** Colman (1990) *The Enzymes*, 3rd ed., **19**, 283. **2.** Lee, Mukherjee & Preiss (1986) *Arch. Biochem. Biophys.* **244**, 585.

#### $\gamma$ -(*p*-Azidoanilide)adenosine 5'-Triphosphate

This photoaffinity labeling reagent and ATP analogue (FW<sub>free-acid</sub> = 623.31 g/mol) inhibits several ATP dependent enzymes. Not all aminoacyl-tRNA synthetases are inhibited by this amidate. **Target(s):** tryptophanyl-tRNA synthetase (1,2,5); phenylalanyl-tRNA synthetase (3,5); arginine kinase (4); creatine kinase4,6; arginyl-tRNA synthetase5; valyl-tRNA synthetase5; isoleucyl-tRNA synthetase (5); leucyl-tRNA synthetase (5,7); threonyl-tRNA synthetase (5); K<sup>+</sup> channel, ATP-sensitive (8). **1.** Kisselev, Favorova & Kolaleva (1979) *Meth. Enzymol.* **59**, 234. **2.** Akhveridan, Kiselev, Knorre, Lavrik & Nevinskii (1976) *Dokl. Akad. Nauk. #### 4-Azidochalcone Oxide

This photoaffinity labeling reagent (FW = 265.27 g/mol) inhibits soluble epoxide hydrolase (IC<sub>50</sub> = 1.6  $\mu$ M). The 4'-azido analogue also inhibits (IC<sub>50</sub> = 4.8  $\mu$ M). **1.** Prestwich & Hammock (1985) *Proc. Natl. Acad. Sci. U.S.A.* **82**, 1663.

#### 2'-Azido-2'-deoxycytidine 5'-Diphosphate

This nucleotide (FW<sub>free-acid</sub> = 428.19 g/mol) inhibits ribonucleotide reductase. **1.** Brush & Kozarich (1992) *The Enzymes*, 3rd ed., **20**, 317. **2.** Thelander, Hobbs & Eckstein (1977) *Meth. #### 3'-Azido-3'-deoxythymidine

This pro-drug (FW = 267.24 g/mol; *Abbreviation:* AZT), also known as Zidovudine and 3'-azido-2',3'-dideoxythymidine, is metabolically transformed to its 5'-triphosphate, which then potently inhibits HIV replication. AZT was the first drug found to be effective in treating individuals with HIV-AIDS, and provided much-needed relief until other, more effective antivirals came on line. SLC28A1, the Na<sup>+</sup>-dependent nucleoside transporter selective for pyrimidine nucleosides and adenosine, also transports Zidovudine. **Target(s):** HIV-1 reverse transcriptase, inhibited by the triphosphate (1-3,5,9); avian myeloblastosis virus reverse transcriptase, inhibited by the triphosphate (4); poly(ADP-ribose) polymerase (6); cytidine deaminase (7); 5'-nucleotidase (8); RNA-directed DNA polymerase (1-5,9); dTMP kinase, or thymidylate kinase (10-12); deoxynucleoside kinase (13); thymidine kinase (13,14); phosphorylase, weakly inhibited (15); uridine phosphorylase, rat K<sub>i</sub> = 56  $\mu$ M (15); glucuronosyl-transferase, substrate for UGT2B7 (16). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** Le Grice, Cameron & Benkovic (1995) *Meth. Enzymol.* **262**, 130. **2.** Wilson, Porter & Reardon (1996) *Meth. #### 3'-Azido-3'-deoxythymidine 5'-Diphosphate

This dideoxynucleotide (FW = 426.19 g/mol), often abbreviated AzddTDP and AZTDP and also called 3'-azido-2',3'-dideoxythymidine 5'-diphosphate, is a dTDP analogue and inhibits viral Rauscher murine leukemia virus reverse transcriptase, or RNA-directed DNA polymerase. **1.** Ono, Nakane, Herdewijn, Balzarini & De Clercq (1988) *Nucl. Acids Res.* **20**, 5.

**3'-Azido-3'-deoxythymidine 5'-Monophosphate**

This modified nucleotide (FW<sub>free-acid</sub> = 347.22 g/mol) inhibits DNA polymerase. **Target(s):** simian virus 40 origin-dependent replication (1); DNA polymerase-associated 3'→5' exonuclease activity (2); ribonuclease H (3); dTMP kinase, or thymidylate kinase (4-6). 1. Bebenek, Thomas, Roberts, Eckstein & Kunkel (1993) *Mol. Pharmacol.* **43**, 57. 2. Bridges, Faraj & Sommadossi (1993) *Biochem. Pharmacol.* **45**, 1571. 3. **8-Azidoguanosine 5'-Triphosphate**

This photoaffinity labeling reagent and GTP analogue (FW<sub>free-acid</sub> = 564.19 g/mol) photolabels RNA polymerase II and elongation factor-2, while inhibiting cytosolic phosphoenolpyruvate carboxykinase (GTP) without photolabeling. **Target(s):** DNA-dependent RNA polymerase II (1,2); elongation factor-2 (3); transglutaminase (4); phosphoenolpyruvate carboxykinase, GTP-requiring (5); glutamate dehydrogenase (6,7); GTP cyclohydrolase IIa (8). 1. **3-Azido-5-methoxy-2-methyl-6-(3,7-dimethyloctyl)-1,4-benzoquinone**

This photoaffinity labeling reagent and quinone analogue (FW = 333.43 g/mol), also known as azido-Q and 3-azido-2-methyl-5-methoxy-6-(3,7-dimethyl[<sup>3</sup>H]octyl)-1,4-benzoquinone, inhibits plastoquinol:plastocyanin reductase (*Reaction*: plastoquinol + 2 oxidized plastocyanin + 2 H<sup>+</sup><sub>[Side-1]</sub> ⇌ plastoquinone + 2 reduced plastocyanin + 2 H<sup>+</sup><sub>[Side-2]</sub>). Maximum inactivation (~45%) is observed when 30 mol azido-Q is used per mol cytochrome f (or cytochrome b<sub>6</sub>f complex). The extent of the decrease in activity upon illumination correlates with the amount of azido-Q incorporated into the protein. 1. Doyle, Li, Yu & Yu (1989) *J. Biol. Chem.* **264**, 1387.

**2A-Azido-NAD<sup>+</sup>**

This photoaffinity labeling reagent and (NAD<sup>+</sup>) derivative (FW = 704.45 g/mol) photolabels NAD<sup>+</sup>-dependent oxidoreductases. **Target(s):** NAD<sup>+</sup>-dependent enzymes (1); 15-hydroxyprostaglandin dehydrogenase (2); glutamate dehydrogenase (3-5); NAD(P)H:quinone oxidoreductase (6); isocitrate dehydrogenase, NADP<sup>+</sup>-dependent (7). (See **2-Azidoadenosine for location of azido group**) 1. Colman (1997) *Meth. Enzymol.* **280**, 186. 2. Ensor & Tai (1997) *Meth. Enzymol.* **280**, 204. 3. Kim & Haley (1990) *J. Biol. **3'-O-[3-(4-Azido-2-nitroanilino)propionyl]adenosine 5'-Triphosphate**

This photoaffinity labeling reagent and substituted ATP (FW<sub>free-acid</sub> = 740.37 g/mol), also known as arylazido- $\beta$ -alanine-adenosine 5'-triphosphate, inhibits myosin ATPase (1), F<sub>1</sub> ATPase (1,2), and oxidative phosphorylation (3). 1. Guillory & Jeng (1977) *Meth. Enzymol.* **46**, 259. 2. Schäfer (1986) *Meth. Enzymol.* **126**, 649. 3. Schäfer, Lücken & Lübken (1986) *Meth. Enzymol.* **126**, 682.

#### Azilsartan & Azilsartan Medoxomil

pro-drug

active drug

This angiotensin II receptor antagonist and its membrane-permeant pro-drug (FW<sub>drug</sub> = 456.45 g/mol; CAS 147403-03-0; FW<sub>pro-drug</sub> = 568.53 g/mol; CAS 863031-21-4), also named TAK-536 (drug) and TAK-491 (pro-drug), Edarbi™, and (5-methyl-2-oxo-1,3-dioxol-4-yl)methyl 2-ethoxy-1-([2'-(5-oxo-4,5-dihydro-1,2,4-oxadiazol-3-yl)biphenyl-4-yl]methyl)-1*H*-benzimidazole-7-carboxylate, lowers blood pressure by blocking the binding of the vasopressor hormone, angiotensin II, to the angiotensin Type-1 receptor (or AT<sub>1</sub>-receptor), IC<sub>50</sub> = 45 nM (1). Blocking of AT<sub>1</sub> receptors reduces blood pressure by promoting vasodilation, decreasing vasopressin secretion, and reducing aldosterone production/secretion. The pro-drug is hydrolyzed to the active moiety in the gastrointestinal (GI) tract during the absorption phase. The estimated absolute bioavailability of azilsartan is 60%. Absorption is unaffected by food, and peak plasma concentrations are reached within several hours before its eventual deactivation by cytochrome P450 (CYP2C9), biological  $t_{1/2} \approx 11$  hours. The U.S. FDA approved Edarbi for the treatment of high blood pressure in adults in February, 2011. 1. Ojima, Igata, Tanaka, *et al.* (2011) *J. Pharmacol. Exp* **336**, 801.

#### Azimilide

This class III antiarrhythmic drug and ion channel blocker (FW = 457.95 g/mol; CAS 149908-53-2), also known by the code name NE-10064 and systematic name, 1-((*E*)-[5-(4-chlorophenyl)furan-2-yl]methylidene)amino-3-[4-(4-methylpiperazin-1-yl)butyl]-imidazolidine-2,4-dione, blocks both the slow-activating I<sub>Ks</sub> and rapidly activating I<sub>Kr</sub> components of the delayed rectifier potassium current, distinguishing its action from conventional potassium channel blockers such as sotalol and dofetilide,

which block only I<sub>Kr</sub> (1). Azimilide prolongs the cardiac refractory period in a dose-dependent manner, as manifested by increases in action potential duration, QTc interval, and effective refractory period. 1. Karam, Marcello, Brooks, Corey & Moore (1998) *Am. J. Cardiol.* **81**, 40D.

#### Aziridine, See Ethylenimine

#### Azithromycin

This orally active erythromycin derivative (FW = 749.00 g/mol; CAS 83905-01-5; Solubility: 100 mM in DMSO), also known by the trade names Zithromax<sup>®</sup>, Azyth<sup>®</sup>, Sumamed<sup>®</sup>, is a macrolide antibiotic that targets the assembly of 50S ribosomal subunits and inhibits the transpeptidation step in many Gram-positive and Gram-negative microorganisms. Azithromycin's large volume of distribution (23 L/kg) and peak serum level (0.4  $\mu\text{g/mL}$ ) indicate an extensive tissue distribution, allowing it to achieve high, bacteriocidal levels at sites of infection. It is also taken up by cells (even phagocytes), localizing mainly in cell granules and cytosol and allowing it to be effective against such intracellular pathogens as *Listeria monocytogenes*. Azithromycin is also effective against respiratory, urogenital, and dermal infections. **Microbial Targets:** Aerobic & Facultative Gram-positive Microorganisms: *Staphylococcus aureus* (including MRSA), *Streptococcus agalactiae*, *S. pneumoniae*; *S. pyogenes*; Aerobic & Facultative Gram-negative Microorganisms: *Haemophilus influenzae*, *Neisseria gonorrhoeae*, *Bordetella pertussis*, *Legionella pneumophila*. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York. 1. Girard, *et al.* (1987) *Antimicrob. Agents Chemother.* **31**, 1948. 2. Retsema, *et al.* (1987) *Antimicrob. Agents Chemother.* **31**, 1939. 3. Champney & Burdine (1995) *Antimicrob. Agents Chemother.* **39** 2141. 4. Parnham, Erakovic, Giamarellos-Bourboulis, *et al.* (2014) *Pharmacol Ther.* **143**, 225. **IUPAC:** 13-[(2,6-dideoxy-3-C-methyl-3-O-methyl- $\alpha$ -L-ribohexopyranosyl)oxy]-2-ethyl-3,4,10-trihydroxy-3,5,6,8,10,12,14-heptamethyl-11-[[3,4,6-trideoxy-3-(dimethylamino)- $\beta$ -D-xylohexopyranosyl]oxy]-1-oxa-6-azacyclopentadecan-15-one.

#### Azoramide

This first-in-class, dual-function UPR modulator (FW = 308.83 g/mol; CAS 932986-18-0; Soluble to 100 mM in DMSO), also named *N*-[2-[2-(4-chlorophenyl)-4-thiazolyl]ethyl]butanamide, is a orally bioavailable drug that displays the unique ability to modulate the unfolded protein response by acutely increasing the output of endoplasmic reticulum (ER) protein folding, while also inducing chaperone expression and chronically promoting ER homeostasis. Treatment of cells with azoramide is strongly protective against chemically induced (e.g., by thapsigargin or tunicamycin), hypoxia-induced, lipotoxicity-induced, and protein misfolding-induced ER stress. When used at 1-25  $\mu\text{M}$ , azoramide stimulates the expression of multiple chaperone proteins, enhancing ER chaperone capacity and inducing phosphorylation of eukaryotic translation initiation factor 2 $\alpha$  subunit (eIF2 $\alpha$ ), thereby reducing protein biosynthesis. At 150 mg/kg, azoramide exerts antidiabetic activity in stress are associated both *ob/ob* and diet-induced obese mice, improving insulin sensitivity and glucostasis, as well as protecting pancreatic  $\beta$ -cells against ER stress.

Azoramide thus improves insulin sensitivity, glucose tolerance, and  $\beta$ -cell function in multiple obese mouse preclinical models. ER plays a critical role in protein, lipid, and glucose metabolism as well as cellular calcium signaling and homeostasis. Perturbation of ER function and chronic ER with many pathologies ranging from diabetes and neurodegenerative diseases to cancer and inflammation. Such proof-of-principle data show that small-molecule modulators of adaptive UPR pathways can be identified with functional phenotypic screens targeting the ER and confer

benefits in the treatment of ER stress-mediated pathologies. Azoramide was also effective in preventing the death of cells expressing a mutant form of rhodopsin-identified in autosomal dominant human retinitis pigmentosa and associated with protein misfolding and ER stress. 1. Fu, Yalcin, Lee, *et al.* (2015) *Sci. Transl. Med.* 7, 292ra98.

# - B -

## B581

This cell-permeable CAAX peptidomimetic (FW = 470.70 g/mol; FW<sub>trifluoroacetate-salt</sub> = 583.71 g/mol; CAS 149759-96-6), named as *N*-[2(*S*)-(2(*R*)-2-amino-3-mercaptopropylamino)-3-methylbutyl]-*L*-phenylalanyl-*L*-methionine), binds to and prevents protein farnesyltransferase (IC<sub>50</sub> = 21 nM) from interacting with C-terminal L-Cys-L-Val-L-Phe-L-Met substrate-recognition sequences that are present in its natural substrates. Otherwise hydrophilic proteins associate with membranes by means of enzymatic attachment of hydrophobic moieties to their C-termini. Whereas prenylation occurs in the cytosol, post-prenylation processing is accomplished on the cytoplasmic surface of the endoplasmic reticulum and Golgi apparatus. B581 inhibits prenylation and processing of H-ras and lamin A. B581 specifically blocks farnesylated, but not geranylgeranylated or myristylated, oncogenic ras signaling and transformation. 1. Cox, Garcia, Westwick, *et al.* (1994) *J. Biol. Chem.* **269**, 19203. 2. Garcia, Rowell, Ackermann, Kowalczyk & Lewis (1993) *J. Biol. Chem.* **268**, 18415.

## Baccharin

This anti-leukemia agent (FW = 562.61 g/mol; CAS 61251-97-6), also named (2'*S*,3'*R*,4'*S*, 7'*R*,9'*R*,10'*S*)-7'-deoxy-2'-deoxy-2',3',9,10-bisoxo-9,10-dihydro-4'-hydroxy-7'-[(*R*)-1-hydroxyethyl]verrucarin A, from the toxic South American plant known as green propolis (*Baccharis megapotamica*), is a likely mycotoxin that was later modified by *Baccharis megapotamica* (1,2). Baccharin is also a potent competitive inhibitor (*K*<sub>i</sub> = 56 nM) of human Aldo-keto reductase (AKR) 1C3, also known as 17β-hydroxysteroid dehydrogenase (Type 5) and prostaglandin F synthase. AKR is regarded as a druggable target in the treatment of prostate and breast cancers. Baccharin shows no significant inhibition toward the AKR1C1, AKR1C2, and AKR1C4 isoforms (3). Moreover, non-prenyl analogues of baccharin as selective and potent inhibitors for AKR1C3 (4). 1. Kupchan, Jarvis, Dailey *et al.* (1976) *J. Am. Chem. Soc.* **98**, 7092. 2. ## Bacillus A

This novel antibiotic (FW = 1157.58 g/mol) from *Bacillus amyloliquefaciens* AP183, is a macrodiolide composed of dimeric 4-hydroxy-2-methoxy-6-alkenylbenzoic acid lactones with conjugated pentaene-hexahydroxy polyketide chains. Head-to-head comparisons of antibiotics against methicillin-resistant *Staphylococcus aureus* (ATCC 33591) are: Bacillus A (Minimal Inhibitory Concentration = 1.2 μg/mL); Vancomycin (MIC = 1.6 μg/mL); Ciprofloxacin (MIC = 0.4 μg/mL), and Methicillin (MIC > 100 μg/mL). Head-to-head comparisons of antibiotics against methicillin-resistant *Enterococcus faecium* (ATCC 700221) are: Bacillus A (MIC = 0.6 μg/mL); Vancomycin (MIC > 100 μg/mL); Ciprofloxacin (MIC > 100 μg/mL), and Methicillin (MIC > 100 μg/mL). 1. Ravu, Jacob, Chen, *et al.* (2015) *J. Nat. Prod.* **78**, 924.

## Bacillus thuringiensis Crystal Proteins

These bioproteins are *B. thuringiensis*-derived protein toxins, also known as Bt Toxins, that are composed of parasporal crystalline inclusions containing so-called Crystal (*or* Cry) and Cytolytic (*or* Cyt, also known as δ-endotoxins) toxins, which are cytotoxic/cytostatic toward a wide range of insect orders, nematodes as well as human-cancer cells. Cry and Cyt toxins are biosynthesized at the onset of sporulation and during stationary growth phase, mainly forming parasporal crystalline inclusions. Upon ingestion by susceptible insects, the protein crystals are solubilized in the midgut, followed by proteolytic activation by midgut proteases. They then bind to specific insect cell membrane receptors, resulting in cell disruption and insect death. More than 700 *cry* gene sequences have been identified, most often located on large plasmids. Cry proteins contain: Domain I, a seven α-helix cluster membrane-perforating domain; a central or middle Domain II, consisting of three antiparallel β-sheets that play an important role in toxin-receptor interactions; and a galactose-binding Domain III, consisting of a two-antiparallel β-sheet sandwich that is also involved in receptor binding and pore formation. The extended pro-region in Cry proteins comprises the less well defined Domains IV, V, VI, and VII. Cyt proteins constitute a smaller, distinct group of crystal proteins with insecticidal activity against several dipteran larvae, particularly mosquitoes and black flies. 1. ## Bacitracins

This group of oligopeptide antibiotics, produced by *Bacillus subtilis* and *B. licheniformis*, inhibits cell wall peptidoglycan synthesis (1,5,8,11). Most commercial sources of bacitracin contain at least nine distinct components, the most common being bacitracin A (FW = 1422.71 g/mol; containing both D- and L-aminoacyl residues; Very soluble in water, methanol, and ethanol). It is relatively stable in acidic conditions but is unstable above pH 9. Bacitracin A inhibits the dephosphorylation of undecapenyl diphosphate and dolichyl diphosphate, thereby inhibiting cell wall biosynthesis. Bacitracin A also inhibits many peptidases and proteinases, of which a few are listed below. It has also been reported to activate aminopeptidase B. **Target(s):** pyroglutamyl-peptidase, bacterial (2); insulysin (3,36-40); ptilysin, *or* protease Pi (4,10,36,41); protein glycosylation (1,5,8,11); 4-hydroxybenzoate polyprenyltransferase (6); dolichyl-diphosphatase, *or* dolichyl pyrophosphate phosphatase (7,8,24,28,32-34); dipeptidyl peptidase IV, *or* post-proline dipeptidyl aminopeptidase (9,21,46); dolichyl-phosphate *N*

acetylglucosaminyltransferase (11); protein-disulfide isomerase (12,13,29, 30); thermitase (14,42); savinase (14); subtilisin (14,42); *Treponema denticola* oligopeptidase (15); *Neurospora crassa* insulinase (16); leucyl aminopeptidase (17,45); enkephalin aminopeptidase (18); membrane-bound alanyl aminopeptidase (19); dolichyl-monophosphate phosphatase (20); receptor-mediated endocytosis of  $\alpha_2$ -macroglobulin-protease complexes (22); extracellular protease of *Bacillus licheniformis* (23); undecaprenyl-diphospho-muramoylpentapeptide  $\beta$ -N-acetylglucos-aminyl transferase, weakly inhibited (25); dolichol kinase (26); geranyltransferase, or farnesyl-diphosphate synthase (27); oligosaccharide-diphosphodolichol diphosphatase (31); undecaprenyl-diphosphatase (35); peptidase K, or proteinase K (42); prolyl oligopeptidase (43,44); tripeptide aminopeptidase (47); CDP-glycerol glycerophospho-transferase (48); N-acetylglucosaminyl-diphosphodolichol N-acetylglucosaminyl-transferase (49); cellulose synthase, UDP-forming (50); protein-disulfide reductase (glutathione) (51,52). 1. ### Baclofen

This  $\gamma$ -aminobutyric acid (GABA) derivative (FW = 213.66 g/mol; CAS 1134-47-0), also named (*RS*)-4-amino-3-(4-chlorophenyl)butanoic acid, is a GABA<sub>B</sub> receptor agonist marketed under the trade names Kemstro<sup>®</sup>, Lioresal<sup>®</sup>, Liofen<sup>®</sup>, Gablofen<sup>®</sup>, Beklo<sup>®</sup> and Baclosan<sup>®</sup> for the treatment of spasticity and early research stages of alcoholism. Baclofen increases expression of GABA<sub>B</sub> receptors has been detected in several human cancer cells and tissues, baclofen inhibits tumor growth in rat models (1). GABA<sub>B</sub> receptor activation not only induces suppressing the proliferation and migration of various human tumor cells but also results in inactivation of cAMP-responsive element binding protein (CREB) and ERK in tumor cells (1). P-type Ca<sup>2+</sup> channels in cerebellar Purkinje neurons were inhibited by GABA as well as baclofen (2). In cross-chopped rat cortical slice preparations, (–)-baclofen inhibits forskolin-stimulated adenylyl cyclase activity and augments noradrenaline-stimulated adenylyl cyclase activity (3). Baclofen inhibition of the hyperpolarization-activated cation current in rat substantia nigra zona compacta neurons appears to be secondary to potassium current activation (4). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) ### Bafilomycin A<sub>1</sub>

This toxic macrolide antibiotic (FW = 622.84 g/mol; CAS 88899-55-2) from *Streptomyces griseus*, potently inhibits the proton-pumping vacuolar ATPase, or V-ATPase (IC<sub>50</sub> = 0.44 nM), thereby blocking acid influx (1). Bafilomycin not only dissipates the low endosomal pH but also blocks transport from early to late endosomes in HeLa cells. At doses of 0.1-1  $\mu$ M, Bafilomycin A<sub>1</sub> completely inhibits lysosomal acidification. Bafilomycin A<sub>1</sub> also prevents maturation of autophagic vacuoles by inhibiting fusion between autophagosomes and lysosomes in rat hepatoma cell line, H-4-II-E cells (2). Inhibition of the fusion was reversible, and the autophagosomes changed into autolysosomes after the removal of the inhibitor. Bafilomycin A<sub>1</sub> also prevented the appearance of endocytosed horse radish peroxidase in autophagic vacuoles. These results suggested that acidification of the luminal space of autophagosomes or lysosomes by V-ATPase is important for the fusion between autophagosomes and lysosomes (2). **Target(s):** Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase, moderately inhibited (1); Ca<sup>2+</sup>-transporting ATPase, moderately inhibited (1); K<sup>+</sup>-transporting ATPase (1,4-6); vesicle-fusing ATPase (2); cadmium-exporting ATPase (7). 1. ### Baicalein

This flavone (FW = 270.24 g/mol; CAS 491-67-8), also known as 5,6,7-trihydroxy-2-phenyl-chromen-4-one, is formed upon metabolic hydrolysis of baicalin, a flavone prodrug found in the Chinese medicinal herb *Huang-chin*

(See *Baicalin*). It inhibits leukotriene biosynthesis and is also a free radical scavenger. Alkaline solutions have a greenish-brown color, while strong acidic solutions are yellow with a green fluorescence. Baicalein inhibits CYP2C9 ( $K_i \approx 2 \mu\text{M}$ ), a cytochrome P450 that metabolizes many drugs, including NSAIDs (Celecoxib, Ibuprofen, Naproxen), Sulfonylureas (Glipizide, Glibenclamide, Glimepiride), Angiotensin II receptor antagonists (Irbesartan and Losartan), Warfarin, Sildenafil, and Tamoxifen. **Target(s):** 12-lipoxygenase, or arachidonate 12-lipoxygenase,  $K_i = 0.14 \mu\text{M}$  (1,13,43-48); 17 $\beta$ -hydroxysteroid dehydrogenase (2); NADP<sup>+</sup>-dependent malic enzyme (3); phosphoenolpyruvate carboxylase (3); thyroid type I deiodinase (4); steroid 5 $\alpha$ -reductase (5); aromatase, or CYP19 (6); RNA directed DNA polymerase (7,8); aldose reductase (9,12); 5-lipoxygenase, or arachidonate 5 lipoxygenase (10,21,40-42); aryl hydrocarbon hydroxylase, unspecific monooxygenase (11,25); sialidase, mouse liver (14); NAD(P)H dehydrogenase, or DT-diaphorase (15,18); DNA polymerase  $\gamma$  (16); DNA polymerase I, *Escherichia coli* (16); hyaluronidase (17); xanthine oxidase (19); UDP glucuronosyltransferase (20);  $\alpha$ -glucosidase, or sucrase (22,29); Raf-1 protein kinase (23,27); integrase, HIV-1 (24); CYP3A4, or testosterone 6 $\beta$ -hydroxylation (25); CYP1A2, caffeine *N*-demethylation (25); VHR dual-specificity protein-tyrosine phosphatase (26); 15-lipoxygenase, or arachidonate 15-lipoxygenase;  $K_i = 0.18 \mu\text{M}$  (28,43-45); lipoxygenase, soybean (28,49); protein kinase CK2 (30); lactoylglutathione lyase, or glyoxalase I (31); membrane alanyl aminopeptidase, or aminopeptidase N (32); DNA-directed DNA polymerase (16,33); inositol-trisphosphate 3-kinase (34); glycogen phosphorylase (35); fatty-acid synthase (36); 1-alkylglycerophosphocholine *O*-acetyltransferase (37,38); tyrosinase, monophenol monooxygenase (39); 8-lipoxygenase, or arachidonate 8-lipoxygenase (40). 1. ### Baicalin

This baicalein glucuronide (FW = 446.36 g/mol; CAS 21967-41-9), also known as 5,6-dihydroxy-4-oxygen-2-phenyl-4*H*-1-benzopyran-7- $\beta$ -D-glucopyranose acid, is a flavone prodrug found in the Chinese medicinal herb Huang-chin (*Scutellaria baicalensis*) that is hydrolyzed to baicalein (See *Baicalein*). Baicalin is a slow, tight-binding inhibitor of Jack Bean urease, rapidly forming initial BA-urease complex ( $K_i = 3.9 \times 10^{-3}$  M) that slowly isomerizes to the final complex (overall inhibition constant of  $K_i^* = 0.15 \times 10 \mu\text{M}$ ). Inhibition can be reversed by dithiothreitol but not dilution of substrate. Baicalin also inhibits prolyl oligopeptidase (2), a cytosolic serine peptidase that hydrolyzes proline-containing peptides at the carboxy terminus of proline residues and is associated with schizophrenia, bipolar affective disorder, and related neuropsychiatric disorders. ### Balofloxacin

This carboxyquinolone-class antibiotic (FW = 389.42 g/mol; CAS 127294-70-6; Symbol: BLFX), also named 1-cyclopropyl-6-fluoro-8-methoxy-7-(3-methylaminopiperidin-1-yl)-4-oxoquinoline-3-carboxylate, is active against *Staphylococcus aureus* (MIC<sub>90</sub> = 0.2  $\mu\text{g/mL}$ ), methicillin-resistant *S. aureus* (MIC<sub>90</sub> = 6.25  $\mu\text{g/mL}$ ), *Staphylococcus epidermidis* (MIC<sub>90</sub> = 0.2  $\mu\text{g/mL}$ ), *Streptococcus pneumoniae* (MIC<sub>90</sub> = 0.4  $\mu\text{g/mL}$ ), and *Streptococcus pyogenes* (MIC<sub>90</sub> = 0.4  $\mu\text{g/mL}$ ). For 82 ciprofloxacin-resistant staphylococci (MIC<sub>90</sub> = 100  $\mu\text{g/mL}$ ), Q-35 was the most active of the new quinolones tested (MIC<sub>90</sub> = 6.25  $\mu\text{g/mL}$ ). The MIC<sub>90</sub> values for *Escherichia coli*, *Enterobacter aerogenes*, and *Pseudomonas aeruginosa* were 0.2, 0.78, and 12.5  $\mu\text{g/mL}$ , respectively. 1. Ito, Otsuki & Nishino (1992) *Antimicrob. Agents Chemother.* **36**, 1708.

### BAM15

This novel mitochondrial uncoupler (FW = 340.29 g/mol), also named (2-fluorophenyl)-{6-[(2-fluorophenyl)amino]-(1,2,5-oxadiazolo[3,4-e]pyrazin-5-yl)amine, exhibits a broad effective range of H<sup>+</sup> gradient-dissipating action without affecting plasma membrane electrophysiology. With FCCP as an equipotent positive control, BAM15 was found to be fully able to increase mitochondrial respiration in the presence of oligomycin over a broader concentration range than FCCP in both myoblasts and hepatocytes. BAM15 and FCCP had similar effects on mitochondrial depolarization in L6 myoblasts treated with concentrations of each uncoupler at 1 and 10  $\mu\text{M}$ , as measured by tetramethylrhodamine (TMRM) fluorescence. Neither FCCP nor BAM15 donates electrons to the Electron Transport Chain. Although some non-protonophoric uncouplers increase proton transport into the matrix via interaction with the mitochondrial inner membrane adenine

nucleotide translocase (ANT), neither BAM15 nor FCCP requires the ANT to increase mitochondrial respiration. **1.** Kenwood, Weaver, Bajwa, *et al.* (2013) *Mol. Metab.* **3**, 114.

### Bambuterol

This  $\beta_2$ -adrenergic agonist pro-drug and long-acting bronchodilator (FW = 367.44 g/mol; CAS 81732-46-9), also named (*RS*)-5-[2-(*tert*-butylamino)-1-hydroxyethyl]benzene-1,3-diyl bis(dimethylcarbamate), is used in the management of asthma and chronic obstructive pulmonary disease (1,2). (See also *Formoterol*; *Salmeterol*) Bambuterol is an extremely effective inhibitor (*i.e.*, weak alternative substrate) of cholinesterase, when assayed with butyrylthiocholine as the substrate ( $IC_{50} = 1.7 \times 10^{-8}$  M), but is 2400-fold less efficient in inhibiting cholinesterase (with acetylthiocholine as substrate,  $IC_{50} = 4.1 \times 10^{-5}$  M) (3). However, preincubation of blood with bambuterol in the absence of thiocholine ester substrate is essential for obtaining maximal inhibition. The inhibition exerted by bambuterol after such preincubation was reversible and noncompetitive (3). Because butyrylthiocholine is the preferred substrate for cholinesterase (EC 3.1.1.8) and acetylthiocholine for acetylcholinesterase (EC 3.1.1.7), such results indicate that bambuterol is a selective and potent inhibitor of cholinesterase. Such findings facilitated the discovery that bambuterol is the inactive *bis-N,N*-dimethylcarbamate prodrug of the active  $\beta_2$ -adrenoceptor agonist terbutaline (FW = 225.28 g/mol; CAS 23031-25-6; IUPAC: (*RS*)-5-[2-(*tert*-butylamino)-1-hydroxyethyl]-benzene-1,3-diol). The latter is formed through hydrolytic and/or oxidative pathways catalyzed by plasma cholinesterase (EC 3.1.1.8) and cytochrome P450 (CYP) enzymes. Terbutaline itself is a fast-acting bronchodilator that is often used as a short-term asthma treatment; it is also used as a tocolytic agent to delay premature labor. Note that the complex bambuterol-to-terbutaline biotransformation is likely to be a factor contributing to the long duration of action of bambuterol. Cholinesterases also share homologies with cell adhesion molecules, and *in vitro* neurite growth from various neuronal tissues of the chick embryo can be modified by the action of bambuterol (4). **1.** Pedersen, Laursen, Gnosspeilius, Faurischou & Weeke (1985) *Eur. J. Clin. Pharmacol.* **29**, 425. **2.** Holstein-Rathlou, Laursen, Madsen, *et al.* (1986) *Eur. J. Clin. Pharmacol.* **30**, 7. **3.** Tunek & Svensson (1988) *Drug Metab. Dispos.* **16**, 759. **4.** Layer, Weikert & Alber (1993) *Cell Tissue Res.* **273**, 219.

### b-AP15

This deubiquitinase inhibitor (FW = 421.31 g/mol; CAS 1009817-63-3), also named 3,5-bis[(4-nitrophenyl)methylene]-1-(1-oxo-2-propen-1-yl)-(3*E*,5*E*)-4-piperidinone, targets two proteasome-associated ubiquitin carboxyl-terminal hydrolase-14, or USP14, and Ubiquitin Carboxyl-terminal Hydrolase isozyme L5 UCHL5,  $IC_{50} = 2.1$   $\mu$ M, resulting in a rapid accumulation of high-molecular-weight ubiquitin conjugates and functional shutdown of proteasome. Interestingly, b-AP15 displays several differences with respect to bortezomib including insensitivity to over-expression of the anti-apoptotic mediator Bcl-2 and anti-tumor activity in solid tumor models.

Inhibition of DUBs blocked the processing and release of interleukin IL-1 $\beta$  in both mouse and human macrophages. DUB activity was necessary for inflammasome association as DUB inhibition also impaired ASC oligomerization and caspase-1 activation without directly blocking caspase-1 activity. These data reveal the requirement for DUB activity in a key reaction of the innate immune response and highlight the therapeutic potential of DUB inhibitors for chronic auto-inflammatory diseases. (See also *Bortezomib*, *Eeyarestatin I*) **1.** Lopez-Castejon, Luheshi, Compan, *et al.* (2013) *J. Biol. Chem.* **288**, 2721.

**BAPN**, See  $\beta$ -Aminopropionitrile

### BAPTA

This calcium ion chelator (FW<sub>free-acid</sub> = 476.44 g/mol), also known as 1,2-bis(*o*-aminophenoxy)-ethane-*N,N,N',N'*-tetraacetic acid, has high affinity of  $Ca^{2+}$ , with a  $K_d$  of 110 nM in 0.1 M KCl (1) The  $K_d$  value for  $Mg^{2+}$  is 17 mM. BAPTA has a  $\lambda_{max}$  at 254 nm ( $\epsilon = 16000$   $M^{-1}cm^{-1}$ ), which, upon binding of  $Ca^{2+}$ , shifts to 274 nm ( $\epsilon = 4200$   $M^{-1}cm^{-1}$ ). BAPTA is much less affected to changes in pH than EGTA: two  $pK_a$  values are below 4 and the other two are 5.47 and 6.36. Note that, while one may suspect that BAPTA would be an effector with  $Ca^{2+}$ -dependent systems, it may also be a modulator in  $Ca^{2+}$ -independent systems: *e.g.*, it has been reported that BAPTA exhibits a potent  $Ca^{2+}$ -independent actin and microtubule depolymerizing activity in most cell types. The tetrakis(acetoxymethyl ester), often abbreviated BAPTA-AM (FW = 764.69 g/mol), is a commercially available, membrane permeable agent that is de-esterified to BAPTA within the cell. **Target(s):** phosphoinositide phospholipase C (2); tubulin polymerization, microtubule assembly (3); actin polymerization (3); RNA biosynthesis (4); mannosyl-oligosaccharide 1,2- $\alpha$  mannosidase, or mannosidase I (5);  $Ca^{2+}$ /calmodulin-dependent protein kinase II (6); phosphatidylinositol-4-phosphate 3-kinase (7); 1,3- $\beta$ -glucan synthase (8). **1.** Tsien (1980) *Biochemistry* **19**, 2396. **2.** Hardie (2005) *Cell Calcium* **38**, 547. **3.** Saoudi, Rousseau, Doussiere, *et al.* (2004) *Eur. ### Barbourin

This platelet aggregation activation inhibitor (MW = 7700.52 g/mol; CAS 135402-55-0; Accession Number = P22827; Sequence: EAGEECDGSP ENPCCDAATCKLRPGAQCADGLCCDQCRFMKKGTVCRVAKGDWN DDTCTGQSADCPNGLYG) was isolated from the venom of the Southeastern Pigmy Rattlesnake (*Sistrurus miliaris barbouri*), the only of 52 venoms specific for integrin GPIIb-IIIa versus other integrins. Barbourin is highly homologous to other peptides of the viper venom GPIIb-IIIa antagonist family, but contains a Lys-Gly-Asp (KGD) in place of the canonical Arg-Gly-Asp (RGD) sequence needed to inhibit receptor function. Barbourin represents a new structural model for designing potent and GPIIb-

IIIa-specific, platelet aggregation inhibitors (See *Eptifibatid* for details on *Mechanism of Action*). 1. Scarborough, Rose, His, *et al.* (1991) *J. Biol. Chem.* **266**, 9359.

### Barasertib

This highly selective Aurora kinase inhibitor (FW = 507.56 g/mol; CAS 722544-51-6; Solubility: 102 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), alternatively named AZD1152-AQPA and systematically as 2-(5-(7-(3-(ethyl(2-hydroxyethyl)amino)propoxy) quinazolin-4-ylamino)-1H-pyrazol-3-yl)-N-(3-fluorophenyl)acetamide, targets Aurora B (IC<sub>50</sub> = 0.37 nM) and inhibits proliferation of malignant hematopoietic cells (*e.g.*, HL-60, NB4, MOLM13, PALL-1, PALL-2, MV4-11, EOL-1, THP-1, and K562 cells, with IC<sub>50</sub> values of 3-40 nM). Aurora kinases are serine/threonine protein kinases that play various roles in mitosis. Aurora B helps to regulate chromosome alignment, kinetochore-microtubule bi-orientation, spindle assembly checkpoint activation, and cytokinesis. Its higher expression levels and activity correlate with malignancy of solid tumors in prostate, colon, pancreas, breast, and thyroid. **Target(s):** AZD1152 shows 3000x lower activity against Aurora A (IC<sub>50</sub> = 1.37 μM), with even less activity against fifty other serine-threonine and tyrosine kinases, including FLT3, JAK2, and Abl. 1. Yang, Ikezoe, Nishioka, *et al.* (2007) *Blood* **110**, 2034. 2. Wilkinson, Odedra, Heaton, *et al.* (2007) *Clin. Cancer Res.* **13**, 3682.

### Bardoxolone Methyl

This oleanane triterpenoid (FW = 505.70 g/mol; CAS 218600-53-4; Solubility: 1 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as RTA 402, TP-155, NSC 713200, CDDO Methyl Ester, and 2-cyano-3,12-dioxooleana-1,9(11)-dien-28-oic acid methyl ester, targets Inhibitor of nuclear factor Kappa-B Kinase subunit β, or IKKβ, a key component of the cytokine-activated intracellular signaling pathway that triggers immune responses (1). Significantly, CDDO methyl ester inhibits proliferation of myeloid leukemia cells, inducing both differentiation and apoptosis (2). CDDO-Me induces loss of mitochondrial membrane potential, induction of caspase-3 cleavage, increase in annexin V binding, and DNA fragmentation – all suggesting induction of apoptosis (2). CDDO-Me induces pro-apoptotic Bax protein that preceded caspase activation. CDDO-Me also inhibits ERK1/2 activation, as indicated by inhibition of mitochondrial ERK1/2 phosphorylation and blocking of Bcl-2 phosphorylation, rendering the latter less anti-apoptotic (2). CDDO-Me inhibits NF-κB through inhibition of IκBα kinase, resulting in the suppression of expression of NF-κB-regulated gene products (*Readouts*: IAP2, cFLIP, TRAF1, survivin, and Bcl-2) as well as inhibition of proliferation (*Readouts*: cyclin d<sub>1</sub> and c-myc), and angiogenesis (*Readouts*: VEGF, Cox-2, and MMP-9) (3). CDDO-Me thus enhances apoptosis induced by TNF and chemotherapeutic agents (3). Bardoxolone methyl exhibits potent pro-apoptotic and anti-inflammatory activity, potentially inhibiting interferon γ-induced nitric oxide synthesis in mouse macrophages, IC<sub>50</sub> = 0.1 nM (4). Bardoxolone methyl pretreatment uniquely confers protection against lipopolysaccharide (LPS) challenge by modulating the *in vivo* immune response to LPS, indicating that it represents a novel oral agent for use in LPS-mediated inflammatory diseases. Significantly, a number of well-recognized naturally occurring or synthetic

anti-inflammatory compounds possessing a Michael-type acceptor (*e.g.*, thymoquinone (TQ), the paracetamol metabolite NAPQI, the 5-LO inhibitor AA-861, and bardoxolone methyl) are all direct covalent 5-LO enzyme inhibitors that target the catalytically relevant Cysteines 416 and 418 (6). Their action as irreversible Michael acceptor moiety that interact with required cysteines of proteins/enzymes may explain why they are effective and sustained enzyme activity modulators. 1. ### Baricitinib

This selective, ATP-competitive protein kinase inhibitor (FW = 371.42 g/mol; CAS 1187594-09-7; Solubility: 70 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known by its code names LY3009104 and INCB028050 as well as its systematic name 1-(ethylsulfonyl)-3-[4-(7H-pyrrolo[2,3-d]pyrimidin-4-yl)-1H-pyrazol-1-yl]-3-azetidineacetone, targets JAK1 and JAK2, with respective IC<sub>50</sub> values of 5.9 nM and 5.7 nM, showing little effect on JAK3 (IC<sub>50</sub> = 560 nM) (1-3). In cell-based assays, INCB028050 proved to be a potent inhibitor of JAK signaling and function. **Primary Mode of Inhibitory Action:** Janus kinases JAK1, JAK2, JAK3, and the related enzyme TYK2 are critical components of signaling mechanisms used by many cytokines and growth factors, including several that are elevated in patients with RA. Cytokines such as interleukin-6, -12 and -23 and both type 1 and type 2 interferons signal through these pathways. JAK-dependent cytokines have been implicated in the pathogenesis of inflammatory and autoimmune diseases, suggesting that JAK inhibitors may be useful for the treatment of a broad range of inflammatory conditions. At concentrations <50 nM, baricitinib inhibits intracellular signaling of multiple proinflammatory cytokines including IL-6 and IL-23 (3). Significant efficacy, as assessed by improvements in clinical, histologic and radiographic signs of disease, was achieved in a rat adjuvant arthritis model with baricitinib providing partial and/or periodic inhibition of JAK1/JAK2 and no inhibition of JAK3. Such findings suggest that fractional inhibition of JAK1 and JAK2 may be sufficient for significant pharmacological activity in autoimmune diseases, such as rheumatoid arthritis. A related JAK inhibitor, Tofacitinib, is approved in the U.S. for the treatment of RA. **Target(s):** Baricitinib shows moderate (~10x) selectivity against Tyk2 (IC<sub>50</sub> = 53 nM) and marked selectivity over the unrelated c-Met (IC<sub>50</sub> > 10,000 nM) and Chk2 (IC<sub>50</sub> > 1,000 nM) kinases as well as ~100x higher IC<sub>50</sub> values against Abl, Akt1, AurA, AurB, CDC2, CDK2, CDK4, CHK2, c-kit, EGFR, EphB4, ERK1, ERK2, FLT-1, HER2, IGF1R, IKKα, IKKβ, JNK1, Lck, MEK1, p38α, p70S6K, PKA, PKCα, Src, and ZAP70. 1. ### Barium Ions

This Group 2 stable alkali earth element (Atomic Weight = 137.33; Atomic Number = 56; Symbol: Ba; Atomic radius = 222 pm; Covalent radius = 215 pm; Van der Waals radius = 268 pm) forms divalent ions (Radius = 149.57 pm (compare to 114.21 pm for Ca<sup>2+</sup>)) and lies two rows beneath calcium in the Periodic Table, shares other properties with members of its group. Barium can be highly toxic to plants and animals upon acute and chronic exposure. Inhaled dust containing insoluble barium compounds can accumulate in the lungs, causing a benign condition called baritosis. Generated in many industrial processes, barium targets the potassium inward rectifier channels (IRCs) in the KCNJx gene family. Extracellular barium enters the potassium-conducting pore, blocking potassium conduction. As a competitive potassium channel antagonist, divalent barium ion blocks the passive efflux of intracellular potassium, resulting in a shift of extracellular

K<sup>+</sup> into intracellular compartments, resulting in a significant decrease of K<sup>+</sup> in the blood plasma. Although relatively insoluble in water, barium carbonate (Formula = BaCO<sub>3</sub>; FW = 197.34 g; CAS 513-77-9) becomes toxic when hydrolyzed stomach acid, allowing further absorption of Ba<sup>2+</sup> within the gastrointestinal tract. (Other insoluble barium compounds (notably barium sulfate) are inefficient sources of Ba<sup>2+</sup> ion and are of little concern in humans.) Ingestion of BaCO<sub>3</sub> often results in gastrointestinal effects (vomiting, diarrhea), cardiovascular effects (e.g., arrhythmias and hypertension), neuromuscular (e.g., abnormal reflexes and paralysis), respiratory effects (e.g., arrest and even failure), as well as metabolic effects (e.g., hypokalemia). Treatment of barium poisoning uses sodium sulfate (administered orally) to form insoluble barium sulfate in the intestinal tract, with potassium supplementation.

### Batimastat

This potent, broad-spectrum matrix metalloprotease, or MMP, inhibitor (FW = 477.64 g/mol; CAS 130370-60-4; Solubility: 96 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known by its code name BB-94 and its systematic name (2*R*,3*S*)-*N*<sup>4</sup>-hydroxy-*N*<sup>1</sup>-[(1*S*)-2-(methylamino)-2-oxo-1-(phenylmethyl)ethyl]-2-(2-methylpropyl)-3-[(2-thienylthio)methyl]butanediamide, targets MMP-1 (IC<sub>50</sub> = 3 nM), MMP-2 (IC<sub>50</sub> = 4 nM), MMP-9 (IC<sub>50</sub> = 4 nM), MMP-7 (IC<sub>50</sub> = 6 nM) and MMP-3 (IC<sub>50</sub> = 22 nM). Matrix metalloproteinases have been implicated in the growth and spread of metastatic tumors, and Batimastat not only prevents colonization of secondary organs by B16-BL6 cells, but limits the growth of solid tumors (1). Animals receiving BB-94 (30 mg/kg, i.p., once daily for 60 days, followed by 3 times weekly) show a reduction in the median primary tumor weight from 293 mg in the control group to 144 mg in the treated group (3). BB-94 treatment also reduces the incidence of local and regional invasion. Batimastat also reduces *in vivo* growth of experimental hemangiomas, most probably by blocking endothelial cell recruitment by the transformed cells or by interfering with cell organization in vascular structures (3). **Target(s):** *Trimeresurus mucrosquamatus* (Taiwan habu) venom metalloproteinases (4); matrix metalloproteinases (5); interstitial collagenase, or MMP1 (5,15); stromelysin, or MMP3 (5,10); matrilysin, or MMP7 (5,20); gelatinase A, or or MMP2 (5); gelatinase B, or or MMP9 (5); neutrophil collagenase, or MMP8 (6,19); atrolysin C, or *Crotalus atrox* metalloendopeptidase c (10); membrane-type 1 matrix metalloproteinase, or MMP14 (11,12,20); membrane-type 3 matrix metalloproteinase, or MMP-16 (12,17); ADAM 17 endopeptidase, or tumor necrosis factor- $\alpha$  converting enzyme; TACE (13-15);  $\alpha$ -secretase (15); ADAM TS-4 endopeptidase, or aggrecanase (16); macrophage elastase, or MMP12 (18). 1. ### Batrachotoxin

This lipid-soluble neurotoxin (FW = 526.67 g/mol; CAS 23509-16-2; LD<sub>50</sub> = ~2 µg/kg mouse body weight.), isolated from the skin of the Columbian poison-dart frog *Phylllobates aurotaenis*, enhances Na<sup>+</sup> conductance, promoting opening of voltage-gated Na<sup>+</sup> channels, inducing depolarization of the resting membrane potential (1,2). It does so by binding to the sodium channel, keeping the membrane permeable to sodium ions in an all-or-none manner. This results in hyperexcitability of excitable tissues, followed by convulsions, paralysis, and death in animals. The most common use of batrachotoxin is in darts for blowguns used in hunting by the Noanamá Chocó and Emberá Chocó Indians of western Colombia. Batrachotoxin has also been identified in the feathers of the passerine birds of New Guinea *Pitohui dichrous*, *Pitohui kirhocephalus*, and *Ifrita kowaldi* (3). The less toxic batrachotoxin A is the deesterified steroid. 1. Conn (1983) *Meth. Enzymol.* **103**, 401. 2. Wang & Wang (2003) *Cell Signal* **15**, 151. 3. Dumbacher, Spande & Daly (2000) *Proc. Natl. Acad. Sci. U.S.A.* **97**, 12970.

### Batroxostatin

This cysteine-rich, 71-residue disintegrin (MW = 7602.46 g/mol; CAS 130357-67-4), from the snake *Bothrops atrox* (*Barba amarilla*) contains an RGD loop that facilitates high-affinity binding to integrins in a manner that inhibits ADP-induced platelet aggregation (IC<sub>50</sub> = 133 nM), about 1000-times higher than that of Arg-Gly-Asp-Ser tetrapeptide. In addition, batroxostatin was about 400-times more potent than Arg-Gly-Asp-Ser at inhibiting melanoma cell adhesion to fibronectin. When covalently attached to plastic culture dishes, batroxostatin promoted adhesion of melanoma cells. 1. Rucinski, Niewiarowski, Holt, Soszka & Knudsen (1990) *Biochim. Biophys. Acta* **1054**, 257.

### *Bauhinia unguolata* Factor Xa Inhibitor

This secreted Kunitz-type inhibitor (MW = 19,238 g/mol, based on primary sequence), isolated from *Bauhinia unguolata* (orchid tree) seeds, is a potent inhibitor of plasma kallikrein (K<sub>i</sub> = 6.9 nM) and coagulation factor Xa (K<sub>i</sub> = 18.4 nM) (1,2). **Target(s):** chymotrypsin (2); coagulation factor Xa (1,2); coagulation factor XIIa (2); plasma kallikrein (1-3); plasmin (2); trypsin (2). 1. Oliva, Andrade, Batista, *et al.* (1999) *Immunopharmacol.* **45**, 145. 2. Oliva, Andrade, Juliano, *et al.* (2003) *Curr. Med. Chem.* **10**, 1085. 3. Oliva, Santomauro-Vaz, Andrade, *et al.* (2001) *Biol. Chem.* **382**, 109.

### Bax Inhibitor-1

This evolutionarily conserved integral membrane protein (MW = 26538 g/mol; Accession Number = P55061; Abbreviation: BI-1) is an anti-apoptotic factor (1), mediating a calcium leak, or safety valve, that provides for Ca<sup>2+</sup> homeostasis by balancing active Ca<sup>2+</sup> uptake by the endoplasmic reticulum (2). BI-1 represents the highly conserved and widely distributed Transmembrane Bax Inhibitor Motif (or TMBIM) proteins that share a canonical seven-transmembrane-helix fold featuring two triple-helix sandwiches wrapped around a central C-terminal helix (2). Structures show a pH-dependent switch that reversibly interconverts closed and open conformations, as governed by the pK<sub>a</sub> of a perturbed pair of conserved aspartate residues and allowing pH to regulate Ca<sup>2+</sup> influx in proteoliposomes (2). 1. ### BAY 11-7082

This protein kinase inhibitor (FW = 207.31 g/mol; CAS 19542-67-7; λ<sub>max</sub> = 251 nm), also named 3-[(4-methylphenyl)sulfonyl]-(2*E*)-propenenitrile, targets NF-κB activation, selectively and irreversibly blocking TNF- $\alpha$ -induced phosphorylation of IκB- $\alpha$  without affecting phosphorylation of

constitutive I $\kappa$ B- $\alpha$  (1). **Mechanism of Inhibitory Action:** NF- $\kappa$ B transcription factor regulates expression of inflammatory cytokines, various chemokines and immunoreceptors, as well as cell adhesion molecules. When stationed within the cytoplasm, NF- $\kappa$ B is kept inactive through its binding to the inhibitory factor I $\kappa$ B; however, certain stimuli result in I $\kappa$ B phosphorylation and ubiquitin-mediated degradation, freeing NF- $\kappa$ B for translocation to the nucleus. In endothelial cells, I $\kappa$ B- $\alpha$  phosphorylation and degradation occur within 15 min of TNF $\alpha$  treatment, allowing NF- $\kappa$ B to translocate to the nucleus to activate gene expression. Treatment of human vascular endothelial cells (HUVEC) with TNF $\alpha$  results in rapid loss of I $\kappa$ B- $\alpha$  from the cytoplasm (1). BAY11-7082 stabilizes I $\kappa$ B- $\alpha$  in a dose-dependent manner (IC<sub>50</sub>  $\approx$  10  $\mu$ M). There is a clear correlation between the concentration of drug that stabilizes I $\kappa$ B- $\alpha$ , the concentration that inhibits nuclear levels of NF- $\kappa$ B, and the concentration that inhibits adhesion molecule expression. More recent studies (2) demonstrate that BAY 11-7082 prevents ubiquitin conjugation to Ubc13 and Ubch7 by forming a covalent adduct with their cysteine residues via Michael addition at the C-3 atom of BAY 11-7082, followed by the release of 4-methylbenzenesulfinate. BAY 11-7082 stimulated Lys48-linked polyubiquitin chain formation in cells and protected Hypoxia-Inducible Factor-1 $\alpha$  (HIF1 $\alpha$ ) from proteasomal degradation, suggesting it inhibits the proteasome. These results indicate that the anti-inflammatory effects of BAY 11-7082, its ability to induce B-cell lymphoma and leukemic T-cell death and to prevent the recruitment of proteins to sites of DNA damage are exerted via inhibition of components of the ubiquitin system— not by inhibiting NF- $\kappa$ B (2). BAY11-7082 also inhibits proliferation and promotes apoptosis in breast carcinoma MCF-7 cells by inhibiting phosphorylation of ATP citrate lyase (3). 1. **BAY 12-9566, See Tanomastat**

**BAY 43-9006, See Sorafenib**

**BAY 57-1293**

This prototypical primase-helicase inhibitor (FW = 402.49 g/mol; CAS 348086-71-5; IUPAC Name: *N*-[5-(aminosulfonyl)-4-methyl-1,3-thiazol-2-yl]-*N*-methyl-2-[4-(2-pyridinyl)phenyl]acetamide), also known as Pritelivir, represents a new class of antiviral compounds inhibits replication of herpes simplex virus (HSV) Types 1 and 2 in the nanomolar range *in vitro* by interfering with the enzymatic activity of the viral primase-helicase complex. In rodent models of HSV infection, the antiviral activity of BAY 57-1293 *in vivo* was found to be superior compared to all compounds currently used to treat HSV infections (1,2). BAY 57-1293 is well tolerated, significantly reduces time to healing, prevents rebound of disease after cessation of treatment and, most importantly, reduces the frequency and severity of recurrent disease. Indeed, Pritelivir reduces the rates of genital HSV shedding and days with lesions in a dose-dependent manner in otherwise healthy men and women with genital herpes (3). Variants resistant to BAY 57-1293 retained sensitivity to the nucleoside analogue, ACV. Moreover, single amino acid substitutions in the HSV-1 helicase protein that confer resistance to BAY 57-1293 are associated with increased or decreased virus growth characteristics in tissue culture (4). BAY 57-1293 also reduces the formation of Alzheimer's disease-like  $\beta$ -amyloid (A $\beta$ ) and abnormal tau (P-tau) in HSV-1 infected cells in culture (5). 1. Kleymann, Fischer, Betz, *et al.* (2002) *Nature Med.* **8**, 392. 2. Betz, Fischer, Kleymann, *et al.* (2002) *Antimicrob. Agents Chemother.* **46**, 1766. 3. Wozniak, Frost & Itzhaki (2013) *Antiviral Res.* **99**, 401.

**BAY 59-7939, See Rivaroxaban**

**BAY 60-7550**

This selective cGMP/cAMP phosphodiesterase PDE2A inhibitor (FW = 476.60 g/mol; CAS 439083-90-6; Solubility: 10 mM DMSO), systematically named 2-[(3,4-dimethoxyphenyl)methyl]-7-[(1*R*)-1-hydroxyethyl]-4-phenylbutyl]-5-methyl-imidazo[5,1-*f*][1,2,4]triazin-4(1*H*)-one, targets Type 2 cyclic nucleotide phosphodiesterase (human, IC<sub>50</sub> = 4.7 nM; bovine, IC<sub>50</sub> = 2.0 nM), a dual-function enzyme that, when stimulated by 3',5'-cyclicGMP (cGMP), preferentially catalyzes hydrolysis of 3',5'-cyclicAMP (cAMP). BAY 60-7550 is 50x more selective for PDE2 than PDE1 and >100x selective relative to PDE5, PDE3B, PDE4B, PDE7B, PDE8A, PDE9A, PDE10A, and PDE11A (1). Use of BAY-60-7550 also indicates that PDE2 is responsible for the degradation of newly synthesized cGMP in cultured neurons and hippocampal slices (1). Inhibition of PDE2 enhanced long-term potentiation of synaptic transmission without altering basal synaptic transmission. Inhibition of PDE2 also improved the performance of rats in social and object recognition memory tasks, and reversed MK801-induced deficits in spontaneous alternation in mice in a T-maze (1). Treatment of mice with L-buthionine-(*S,R*)-sulfoximine (300 mg/kg) induces oxidative stress and also causes anxiety-like behavioral effects in elevated plus-maze, open-field, and hole-board tests, most likely through the NADPH oxidase pathway (2). These effects are antagonized by Bay 60-7550 (3 mg/kg), which decreases oxidative stress and expression of NADPH oxidase subunits in amygdala, hypothalamus, and cultured neurons. The resulting increase in cGMP also promotes phosphorylation of vasodilator-stimulated phosphoprotein (VASP) at Ser-239, suggesting a role of cGMP-Protein Kinase G signaling in the reduction of anxiety (2). PDE inhibitors also enhance object recognition, and the effects of PDE inhibition on cognitive functions may result from higher cerebrovascular function (3). In the spatial location task, PDE5 inhibition of cGMP hydrolysis by vardenafil only enhances early-phase consolidation, and PDE4 inhibition of cAMP hydrolysis by rolipram only enhances late-phase consolidation; on the other hand, PDE2 inhibition of cAMP and cGMP hydrolysis by Bay 60-7550, enhances both (3). These results underscore the specific effects of cAMP and cGMP on memory consolidation (object and spatial memory) and provide evidence that the underlying mechanisms of PDE inhibition on cognition are independent of cerebrovascular effects. Bay 60-7550 treatment also indicates that phosphodiesterase 2A is a major negative regulator of iNOS expression in lipopolysaccharide-treated mouse alveolar macrophages (4). BAY 60-7550 reverses functional impairments induced by brain ischemia by decreasing hippocampal neurodegeneration and enhancing hippocampal neuronal plasticity (5). 1. Boess, Hendrix, van der Staay, *et al.* (2004) *Neuropharmacol.* **47**, 1081. 2. Masood, Nadeem, Mustafa & O'Donnell (2008) *J. Pharmacol. Exp. Ther.* **326**, 369. 3. **BAY 73-4506, See Regorafenib**

**BAY 85-3934, See Molidustat**

**BAY 87-2243**

This Hif1 $\alpha$  inhibitor (FW = 525.53 g/mol; CAS 1227158-85-1; Solubility: <1 mg/mL DMSO or H<sub>2</sub>O) targets the transcription factor hypoxia-inducible factor-1 (HIF-1), which plays an essential role in tumor development, tumor progression, and resistance to chemo- and radiotherapy. BAY 87-2243 inhibits HIF-1 $\alpha$  and HIF-2 $\alpha$  accumulation under hypoxic conditions in the H460 Non-Small Cell Lung Cancer (NSCLC) cell line but is without effect on HIF-1 $\alpha$  protein levels that are induced by such hypoxia mimetics asdesferrioxamine or cobalt chloride. BAY 87-2243 has no effect on HIF target gene expression levels in RCC4 cells lacking Von Hippel-Lindau (VHL) activity; nor does it affect the activity of HIF prolyl hydroxylase-2. Antitumor activity of BAY 87-2243, suppression of HIF-1 $\alpha$  protein levels, and reduction of HIF-1 target gene expression *in vivo* have been demonstrated in a H460 xenograft model. BAY 87-2243 does not inhibit cell proliferation under standard conditions. Upon glucose depletion, a condition favoring mitochondrial ATP generation as energy source, BAY 87-2243 inhibits cell proliferation in the low-nM range. In a mouse model for BRAF-mutant melanoma, BAY 87-2243-mediated complex I inhibition induces melanoma cell death *in vitro* and reduces melanoma tumor growth in various mouse models *in vivo* (2). This effect is mediated through BAY 87-2243-induced stimulation of mitochondrial ROS production, leading to oxidative damage and subsequent cell death. BAY 87-2243 displays increased antitumor efficacy compared to single agent treatment, when combined with the BRAF inhibitor vemurafenib in nude mice with BRAF mutant melanoma xenografts. 1. **Bayer-2502, See Nifurtimox**

**BAY U6751**

This dihydropyridine (FW = 407.85 g/mol), also known as (-)-(*S*)-3-isopropyl 4-(2-chlorophenyl)-1,4-dihydro-1-ethyl-2-methylpyridine-3,5,6-tricarboxylate and BAY W1807, inhibits glycogen phosphorylase ( $K_i = 1.6$  nM). It is competitive with respect to AMP. Note that the term BAY U6751 refers to the racemic mixture, of which the active enantiomer is BAY W1807. 1. Gregus & Némethi (2007) *Toxicol. Sci.* 100, 44. 2. Zographos, Oikonomakos, Tsitsanou, *et al.* (1997) *Structure* 5, 1413. 3. Bergans, Stalmans, Goldmann, Vanstapel (2000) *Diabetes* 49, 1419.

**BAZ2-ICR**

This selective bromodomain inhibitor (FW = 357.41 g/mol; Solubility: 100 mM in DMSO), named 4-[4-(1-methyl-1H-pyrazole-4-yl)-1-[2-(1-methyl-1H-pyrazol-4-yl)ethyl]-1H-imidazol-5-yl]benzotrile, targets BAZ2A ( $K_d = 109$  nM) and BAZ2B ( $K_d = 170$  nM), showing 15x selectivity for the BAZ2 bromodomain over the CERC2 bromodomain as well as >100-fold selectivity over other bromodomain inhibitors. BAZ2A/B belong to a ubiquitously expressed bromodomain containing protein family characterized by a C-terminal bromodomain that lies adjacent to a PHD finger and a WACZ motif. BAZ2B is believed to regulate nucleosome mobilization by the ATP-dependent chromatin remodeling factor ISWI. 1. Drouin, McGrath, Vidler, *et al.* (2015) *J. Med. Chem.* 58, 2553.

**Bazedoxifene**

This potent and selective estrogen receptor modulator, or SERM (FW = 530.65 g/mol; CAS 198481-33-3; Solubility: 00 mM in DMSO), also named 1-[[4-[2-(hexahydro-1H-azepin-1-yl)ethoxy]phenyl]methyl]-2-(4-hydroxyphenyl)-3-methyl-1H-indol-5-ol, selectivity targets the estrogen receptor ER $\alpha$  ( $IC_{50} = 26$  nM), with weaker action against ER $\beta$  ( $IC_{50} = 99$  nM), inhibiting 17 $\beta$ -estradiol-induced proliferation of MCF-7 cells. Bazedoxifene represents a promising new treatment for osteoporosis, one with a potential for less uterine and vasomotor effects than selective estrogen receptor modulators now used clinically. 1. Komm, Kharode, Bodine *et al.* (2005) *Endocrinology* 146, 3999.

**BC21, See  $\beta$ -Catenin/Tcf Inhibitor V**

**Bcl-xL Anti-apoptotic Factor**

This Bcl-2 family member (MW = 26063 g), also known as B-cell lymphoma-extra large, is 233-residue pro-survival mitochondria transmembrane protein that prevents cytochrome *c* release and is often overexpressed in cancer cells. This *Bcl-xL* gene was first recognized through its involvement in the t(14;18) chromosomal translocations found in B-cell lymphomas, where it contributes to neoplastic cell expansion by preventing cell turnover due to programmed cell death. BCL-2 overexpression also occurs in many other types of human tumors (*e.g.*, prostate cancer, colon cancer, and lung cancer) and has been associated with chemoresistance and radioresistance in some malignant cell types. Its overexpression is an indicator of a poor prognosis for recovery.

**BCX-1777, See Immucillin-H**

**Bedaquiline**

This diarylquinoline-class anti-tuberculosis drug (FW = 554.43 g/mol; CAS 843663-66-1), also known by the tradename Sirturo<sup>®</sup> and code names TMC207 and R207910, is the first new antibiotic against multi-drug-resistant tuberculosis (1). *Mycobacterium tuberculosis* represents a global threat, with >2 billion people harboring latent TB and >9 million new TB cases. Two million die of TB every year, and ~500,000 become multidrug-resistant. A single dose of bedaquiline inhibits mycobacterial growth for 1 week, and plasma levels associated with efficacy in mice are well tolerated in healthy human volunteers (1). Mutants selected *in vitro* suggest that the drug targets the proton pump of ATP synthase. Six distinct mutations (*e.g.*, Asp-28-Gly, Asp-28-Ala, Leu-59-Val, Glu-61-Asp, Ala-63-Pro, and Ile-66-Met) within ATP Synthase subunit *c* confer resistance against some diarylquinoline drugs (2). 1. Andries, Verhasselt, Guillemont, *et al.* (2005) *Science* 307, 223. 2. Segala, Sougakoff, Nevejans-Chauffour, Jarlier & Petrella (2012) *Antimicrob. Agents Chemother.* 56, 2326.

**BeKm 1**

This ERG channel inhibitor (FW = 4091.65 g/mol; CAS 524962-01-4; Soluble to 1 mg/mL in H<sub>2</sub>O), from the Central Asian scorpion *Buthus eupeus*, targets human K<sub>v</sub>11.1 Ether-a-go-go-Related Gene potassium ion currents (1,2). BeKm-1 inhibits hERG1 channels (IC<sub>50</sub> = 3.3 nM), but has little or no effect, even at 100 nM, on hEAG, hSK1, rSK2, hIK, hBK, KCNQ1/KCNE1, KCNQ2/3, and KCNQ4 channels. BeKm-1 shares a molecular scaffold (consisting of a short  $\alpha$ -helix and a triple-stranded antiparallel  $\beta$ -sheet) in common with other short scorpion toxins (3). Site-directed mutagenesis identified Tyr-11, Lys-18, Arg-20, and Lys-23 as key residues for binding to hERG channels. All four are located in the  $\alpha$ -helix and its following loop, whereas the canonical functional site of other short scorpion toxins lies within the  $\beta$ -sheet (3). BeKm-1 significantly prolongs QTc intervals in isolated rabbit hearts (4.7 at 10 nM, 16.3% at 100 nM), concentrations that inhibit hERG1 channels (4). **1.** Fillipov, Kozlov, Pluzhnikov, Grishin & Brown (1996) *FEBS Lett.* **384**, 277. **2.** Korolkova, Kozlov, Lipkin, *et al.* (2001) *J. ### Belinostat

This synthetic epigenetic modulator (FW = 318.35 g/mol; CAS 866323-14-0), also known as PXD101 and the IUPAC name, (2*E*)-*N*-hydroxy-3-[3-(phenylsulfamoyl)phenyl]prop-2-enamide, inhibits histone deacetylase (IC<sub>50</sub> = 27 nM) and induces a concentration-dependent increase (over the 0.2–5  $\mu$ M range) in histone H4 acetylation and alters expression of genes located on DNA associated with its parent histone octamer (1). A simple and sensitive high-performance liquid chromatography ultraviolet method has been developed for the quantification of PXD101 in human plasma (2). In Rhesus monkeys, belinostat is cleared rapidly from plasma with a half-life of 1.0 h, a mean residence time of 0.47 h, and a clearance of 425 mL/min/m<sup>2</sup> (3). CSF drug exposure is <1% of plasma drug exposure and <10% of free (non-protein bound) plasma drug exposure. The DNA-methylation inhibitor decitabine and histone-deacetylase inhibitor belinostat increases the efficacy of chemotherapeutic agents in tumors that acquired drug resistance due to DNA methylation and gene silencing (4). **1.** Plumb, Finn, Williams, *et al.* (2003) *Mol. Cancer Ther.* **2**, 721. **2.** Zhang, Goh, Khoo, Yeo & Lee (2007) *Ther. Drug Monit.* **29**, 231. **3.** Warren, McCully, Dvinge, *et al.* (2008) *Cancer Chemother. ### Benazepril

This ACE-directed pro-drug (FW<sub>free-acid</sub> = 424.50 g/mol; CAS 86541-75-5), also known as 3-((1-(ethoxycarbonyl)-3-phenylpropyl)amino)-2,3,4,5-tetrahydro-2-oxo-(*S*-(*R*\*,*R*\*)-1*H*-1-benzazepine-1-acetic acid, Lotensin and CGS 14824A, is rapidly metabolized to its diacid benazeprilat (CGS 14831; FW<sub>free-diacid</sub> = 396.44 g/mol), the latter a potent, long-acting inhibitor of peptidyl-dipeptidase A, or angiotensin I-converting enzyme, IC<sub>50</sub> = 1.7 nM (1,2). Lotensin is used to treat hypertension, congestive heart failure, and chronic renal failure. The antihypertensive effects of benazepril begin as early as 30 min after a single dose, and those effects during consecutive dosing are also sustained for 24 h with a lesser diurnal variation in blood pressure (3). **1.** Wattley, Stanton, Desai, Babiarz & Finn (1985) *J. Med. Chem.* **28**, 1511. **2.** Van Dyck, Novakova, Van Schepdael & Hoogmartens (2003) *J. Chromatogr. A* **1013**, 149. **3.** Shionoiri, Ueda, Minamisawa, *et al.* (1992) *J. Cardiovasc. Pharmacol.* **20**, 348.

**Benazeprilat, See Benazepril**

### Bendamustine

This nitrogen mustard and anticancer drug (FW<sub>free-acid</sub> = 358.26 g/mol; CAS 16506-27-7), also known by its code name SDX-105, its trade names Treanda<sup>TM</sup>, Treakisym<sup>TM</sup>, Ribomustin<sup>TM</sup>, and Levact<sup>TM</sup>, as well as by its systematic name 4-[5-[bis(2-chloroethyl)amino]-1-methylbenzimidazol-2-yl]butanoic acid, is a relatively nonspecific DNA alkylating agent that causes intra- and inter-strand cross-links. Bendamustine is used in the treatment of chronic lymphocytic leukemia (CLL), Hodgkin's disease, non-Hodgkin's lymphoma, multiple myeloma and lung cancer. **Pharmacokinetics:** After intravenous infusion, >95% of the drug becomes protein-bound, mainly to albumin; however, only free bendamustine is active. Bendamustine is metabolized by liver cytochrome p450, and elimination (renal) is biphasic, with an initial half-life of 6–10 minutes and a terminal half-life of approximately 30 minutes. **1.** Tageja, Nishant, Nagi & Jasdeepsa (2010) *Cancer Chemother. Pharmacol.* **66**, 413.

### Bengamide

This potent NF- $\kappa$ B activation inhibitor and anti-inflammatory and anti-tumor agent (FW = 598.81 g/mol; CAS 104947-69-5; Soluble in DMSO), also named (6*E*)-6,7,8,9-tetradecoxy-*N*-[(3*S*,6*S*)-hexahydro-1-methyl-2-oxo-6-[(1-oxotetradecyl)oxy]-1*H*-azepin-3-yl]-8-methyl-2-*O*-methyl-D-gulonon-6-enamide, is a novel sponge-derived marine natural product with broad spectrum antitumor activity, decreasing I $\kappa$ B $\alpha$  phosphorylation and attenuating LPS-induced nitric oxide production as well as expression of TNF- $\alpha$ , IL-6 and MCP. Bengamide also suppresses HeLa and HCT116 cell proliferation. **1.** Hu, Dang, Tenney, *et al.* (2007) *Chem. Biol.* **14**, 764.

### Benidipine

This oral, once-daily antihypertensive agent (FW = 505.57 g/mol; CAS 105979-17-7), also known by its code name KW-3049, trade name Coniel<sup>®</sup>, and systematic name *O*<sup>2</sup>-methyl,*O*<sup>3</sup>-[(3*R*)-1-(phenylmethyl)piperidin-3-yl] 2,6-dimethyl-4-(3-nitrophenyl)-1,4-dihydropyridine-3,5-dicarboxylate, is a dihydropyridine-class calcium ion blocker that is effective against L-, N-, and T-channels, with potent and selective inhibitory action on cardiac slow calcium channels (1). Benidipine bound stereospecifically to nitrendipine binding sites of rat myocardium with high affinity ( $K_i$  = 0.13 nM) and to the rat brain  $\alpha_1$ -adrenergic receptor ( $K_i$  = 1.2  $\mu$ M). KW-3049 exhibited no remarkable binding affinity to  $\alpha_2$  adrenergic,  $\beta$ -adrenergic, D<sub>2</sub> dopamine, H<sub>1</sub> histamine, S<sub>2</sub> serotonin, A<sub>1</sub> adenosine, A<sub>2</sub> adenosine and muscarinic cholinergic receptors at 100  $\mu$ M (2). **1.** Yoshitake, Kubo, Ikeda, *et al.* (1986) *Nihon. Yakurigaku Zasshi.* **88**, 179. **2.** Ishii, Nishida, Oka & Nakamizo (1988) *Arzneimittelforschung.* **38**, 1677.

### Benocyclidine

This piperazine-class psychostimulant and dopamine reuptake inhibitor (FW = 620.82 g/mol) also known as BCP, BTCP, and benzothienopyridine-cyclohexylpiperidine, is highly selective, showing negligible affinity for the NMDA receptor and lacking anticonvulsant, anesthetic, hallucinogenic, or dissociative effects (1,2). Its high-affinity interactions with dopamine transporters commend it for use as a cellular localization reagent (3,4). 1. Vignon, Pinet, Cerruti, Kamenka & Chicheportiche (1998) *Eur. J. Pharmacol.* **148**, 427. 2. Chaudieu, Vignon, Chicheportiche, et al. (1989) *Pharmacol. Biochem. Behav.* **32**, 699. 3. Filloux, Hunt, Wamsley (1989) *Neurosci. Lett.* **100**, 105. 4. Maurice, Vignon, Kamenka & Chicheportiche (1989) *Neurosci Lett.* **101**, 234.

### Benomyl

This benzimidazole-based fungicide (FW = 290.32 g/mol) inhibits tubulin polymerization and strongly suppresses microtubule dynamic instability *in vitro* (1-3) The active component is its methyl *N*-(benzimidazol-2-yl)carbamate (or, carbendazim; FW = 191.19 g/mol), which inhibits 1-3-polygalacturonase (4) and cellulase (4). Carbendazim interferes with initial events of MT polymerization, possibly GTP binding, with microtubule-associated proteins (MAPs) moderating this effect (5). Another downstream metabolite, *S*-methyl *N*-butylthiocarbamate sulfoxide (FW = 163.24 g/mol), inhibits aldehyde dehydrogenase (6,7). 1. Friedman & Platzer (1978) *Biochim. Biophys. Acta* **544**, 605. 2. Kilmartin (1981) *Biochemistry* **20**, 3629. 3. Gupta, Bishop, Peck, et al. (2004) *Biochemistry* **43**, 6645. 4. Ohazurike (1996) *Nahrung* **40**, 150. 5. Pharmacol.* **58**, 1467.

### Bentazon

This thiadiazinone (FW = 240.28 g/mol; CAS 25057-89-0), also known as Basagran<sup>®</sup> and 3-(1-methylethyl)-1*H*-2,1,3 benzothiadiazin-4(3*H*)-one 2,2-dioxide, is a selective post-emergence herbicide used to control the growth of cocklebur, Canada thistle, and yellow nutsedge. Bentazon is a contact herbicide, meaning that it injures only to the parts of the plant to which it is applied. **Target(s):** photosystem II, as primary mode of herbicidal action (1); acetyl-CoA carboxylase, weakly inhibited (2). 1. Silverman, Petracek, Heiman, Ju, Fledderman & Warrior (2005) *J. Agric. Food Chem.* **53**, 9769. 2. Rendina & Felts (1988) *Plant Physiol.* **86**, 983.

### Benzalkonium Chloride

This cationic surface-active disinfectant and preservative (FW<sub>lauryl-homologue</sub> = 340.00 g/mol; CAS 8001-54-5; Soluble in Ethanol and Acetone), also named alkyldimethylbenzyl-ammonium chloride, refers to several cationic detergents that are widely used in various pharmaceutical preparations, including eye, ear, and nasal drops as well as leave-on antiseptics. (**See also specific agent**) Benzalkonium chloride has also been used in the isolation and purification of proteins and as an antimicrobial agent. Commercial sources typically contain a mixture of alkyl homologues, predominantly with a dodecyl (lauryl) side-chain. Standard concentrates are manufactured as 50% and 80% w/w solutions, and sold under trade names such as BC50, BC80, BAC50, and BAC80. **Target(s):** acetylcholinesterase, esterase activity (1); butyrylcholinesterase, esterase activity (but activates the aryl acylamidase activity) (1); trypsin (2); chymotrypsin (2); histamine release (3); G proteins (4); serralyisin (5); chitosanase (6). 1. ### Benzamide Riboside

Benzamide Riboside

Benzamide Riboside 5'-Triphosphate

Benzamide Riboside Adenine Dinucleotide (BAD<sup>+</sup>)

This pseudonucleoside and pro-drug (FW = 253.25 g/mol; CAS 3804827-0; IUPAC Name: (2*R*,3*S*,4*R*,5*R*)-2-(hydroxymethyl)-5-[6-[[[(*Z*)-4-hydroxy-2-methylbut-2-enyl]amino]purin-9-yl]oxolane-3,4-diol]), also known as norzeatin riboside, is a synthetic nicotinamide riboside analogue (1) that is taken up by human cells and metabolically activated to form benzamide riboside 5'-mono-, di- and tri-phosphates as well as benzamide riboside-adenine dinucleotide (or BAD<sup>+</sup>). The latter is a potent inhibitor of IMP dehydrogenase, IC<sub>50</sub> = 2 μM (2). Phosphorylation to BR 5'-P (BRMP) is catalyzed by adenosine kinase, and conversion of the latter to benzamide riboside-adenine dinucleotide (or BAD<sup>+</sup>) is catalyzed by NMN adenylyltransferase. BAD<sup>+</sup> is a more potent inhibitor of IMPDH than either BR and BRMP, the cytotoxicity of BR is thus more closely connected with the metabolism to BAD<sup>+</sup>. While a weak PARP inhibitor, BAD<sup>+</sup> is an extremely potent inhibitor of cell proliferation. Survival-relevant genes (e.g., cdc25A, akt, bcl-2, and transferrin receptor) are repressed by BR, whereas the expression level of the apoptosis enforcing gene c-myc persists (3). At high BR concentrations, DNA double-strand breaks occur hours before necrosis. There is also a dramatic decrease of intracellular ATP. Restoration of ATP by addition of adenosine or provision of sufficient glucose prevents BR-promoted necrosis and favors apoptosis instead (3). By inhibiting nicotinamide adenine dinucleotide kinase, BAD<sup>+</sup> also reduces cellular pools of NADP<sup>+</sup> and NADPH, the lack of which destabilizes dihydrofolate reductase (4). Likely effects of BAD<sup>+</sup> on NAD<sup>+</sup>-dependent histone deacetylase have yet to be reported. BAD<sup>+</sup> also inhibits cell growth by down-regulating DHFR protein. Supporting this mode of action is the finding that CCRF-CEM/R human T-cell lymphoblastic leukemia cells (which are MTX-resistant as a consequence of DHFR gene amplification and overexpression) are more resistant to BR than are parental cells. BAD<sup>+</sup> reduces cellular levels of NADP<sup>+</sup> and NADPH by inhibiting nicotinamide

adenine dinucleotide kinase (NADK), depleting NADPH, and destabilizing DHFR. NADK inhibition therefore represents another approach for down-regulating DHFR and inhibiting cancer cell growth (5) **Target(s)**: IMP dehydrogenase (2,5); malate dehydrogenase (3); dihydrofolate reductase (4); nicotinamide adenine dinucleotide kinase, or NADK (5). **1.** Krohn, Heins, Wielckens (1992) *J. Med. Chem.* **35**, 511. **2.** Jayaram, Gharehbaghi, Jayaram, *et al.* (1992) *Biochem. Biophys. Res. Commun.* **186**, 1600. **3.** Polgar, Gfatter, Uhl, *et al.* (2002) *Curr. Med. Chem.* **9**, 765. **4.** Roussel, Johnson-Farley, Kerrigan, *et al.* (2012) *Cancer Biol. Ther.* **13**, 1290. **5.** Roussel, Johnson-Farley, Kerrigan, *et al.* (2012) *Cancer Biol. Ther.* **13**, 1290.

### 3-(2-Benzamidoethyl)-5-(pyridin-3-ylmethyl)-1-benzenepropionate

This sulfonamide (FW<sub>free-acid</sub> = 374.46 g/mol) inhibits human thromboxane-A synthase (IC<sub>50</sub> = 22 nM) and is also a thromboxane receptor antagonist. Oral administration at a dose of 5 mg/kg to conscious dogs produces long-lasting thromboxane synthase inhibition and thromboxane receptor blockade, as measured by inhibition of U46619-induced platelet aggregation *ex vivo*. **1.** Dickinson, Dack, Long & Steele (1997) *J. Med. Chem.* **40**, 3442.

### Benzbromarone

This CaCC blocker (FW = 424.08 g/mol; CAS 3562-84-3; Solubility: 100 mM in DMSO), also named (3,5-dibromo-4-hydroxyphenyl)(2-ethyl-3-benzofuranyl)methanone, targets transmembrane proteins 16A and 16B (or TMEM16A and TMEM16B), which are activated by uncomplexed intracellular Ca<sup>2+</sup> and by Ca<sup>2+</sup>-mobilizing stimuli. Benzbromarone inhibits ATP-induced mucin secretion and metacholine-induced airway smooth muscle contraction *in vitro*. **1.** Huang, *et al.* (2012) *Proc. Natl. Acad. Sci. U.S.A.* **109**, 16354. **2.** Gallos, *et al.* (2013) *Am. J. Physiol. Lung Cell Mol. Physiol.* **305**, 625.

### (R)-2-(Benzenesulfonyl)-1,2,3,4-tetrahydro-isoquinolin-3-carboxylic Acid Hydroxamate

This isoquinoline derivative (FW = 331.37 g/mol) inhibits human neutrophil collagenase, matrix metalloproteinase-8, IC<sub>50</sub> = 20 nM. The hydroxamate moiety most likely forms a coordination complex with an active-site Zn<sup>2+</sup>. A 1.7-Å resolution X-ray structure of the catalytic domain of MMP-8 was used to make highly predictive 3D-QSAR models of the steric, electrostatic, and hydrophobic complementarity of enzyme and inhibitor. It was possible to compensate the weaker zinc binding properties of carboxylates by introducing optimal fitting at P1' residues. The final QSAR model agrees with all experimental data for the binding topology and provides clear guidelines and accurate activity predictions for novel MMP-8 inhibitors. **1.** Matter, Schwab, Barbier, *et al.* (1999) *J. Med. Chem.* **42**, 1908.

### N-1H-Benzimidazol-2-yl-N'-(3-bromo-5-chloro-6-ethoxybenzyl)propane-1,3-diamine

This substituted benzimidazole (FW = 437.77 g/mol) inhibits *Staphylococcus aureus* methionyl-tRNA synthetase, or MRS (IC<sub>50</sub> = 3.8 nM), showing very good antibacterial activity against panels of antibiotic-resistant *Staphylococci* and *Enterococci*. Its design was guided by a Structure-Activity Relationship (SAR) study suggesting that the righthand side pharmacophore for MRS inhibition has now been defined as an NH-C-NH functionality in the context of a bicyclic heteroaromatic system. **1.** Jarvest, Armstrong, Berge, *et al.* (2004) *Bioorg. Med. Chem. Lett.* **14**, 3937.

### Benznidazole

This orally available 5-nitrofurans and anti-trypanosomal agent (FW = 260.25 g/mol; CAS 22994-85-0), known by its trade name Rochagan® and Radanil® as well as its systematic name *N*-benzyl-2-(2-nitro-1H-imidazol-1-yl)acetamide, is the front-line treatment used against American trypanosomiasis, a parasitic infection caused by *Trypanosoma cruzi* and the trypanosomal diseases, Chagas Disease and Sleeping Sickness. While benznidazole activation was once thought to generate reductive metabolites that damage DNA and deplete thiols, recent studies suggest benznidazole activation is likely to involve trypanosomal type I nitroreductase catalysis of a NADH-dependent, oxygen-insensitive reaction to form 4,5-dihydro-4,5-dihydroxyimidazole (1). Breakdown of this product releases glyoxal, a reactive dialdehyde that, in the presence of guanosine, generates guanosine-glyoxal adducts with attendant toxicity. **1.** Hall & Wilkinson (2012) *Antimicrob. Agents Chemother.* **56**, 115.

### Benzocaine

This widely used local anesthetic (FW = 165.19 g/mol; CAS 94-09-7), known systematically as ethyl 4-aminobenzoate, is a common ingredient in topical pain-relieving formulations, including the gel used by dentists to numb gums prior to injection of nerve blocks as well as in cough drops and cough syrup. Benzocaine is a membrane-permeable NaV1.5-directed anesthetic that stops the propagation of an action potential. Its lower affinity (IC<sub>50</sub> ~800 μM) is most likely the consequence of its neutral charge (pK<sub>a</sub> = 3.5), making it unable to replicate π-cation binding interactions typical of lidocaine (pK<sub>a</sub> = 7.7) and other tertiary amine-containing anesthetics (1). At 2 mM benzocaine, Q<sub>max</sub> is 0.85 of control values, V<sub>1/2</sub> is shifted from -62 mV to -76 mV, and the slope factor *s* is flattened from -12 mV to -17 mV, suggesting that benzocaine acts similarly to lidocaine, albeit without use-dependence (2). Benzocaine-associated methemoglobinemia is reversed by methylene blue treatment, most often with clinical recovery (3). **1.** Becker & Reed (2006) *Anesth. Prog.* **53**, 98. **2.** Hanck, Nikitina, McNulty, *et al.* (2009) *Circ. Res.* **105**, 492. **3.** Taleb, Ashraf, Valavoor & Tinkel (2013) *Am. J. Cardiovasc. Drugs* **13**, 325.

### Benzoate (Benzoic Acid)

This naturally occurring aromatic acid (FW<sub>free-acid</sub> = 122.12 g/mol; CAS 65-85-0; MP = 122.4°C, pK<sub>a</sub> = 4.19) is metabolized by butyrate-CoA ligase, forming *S*-benzoyl-CoA, which is further metabolized to hippuric acid through the action of glycine *N*-acyltransferase. Because benzoate is metabolically conjugated to glycine (a nonessential amino acid) to form hippurate (*N*-benzoylglycine), it has been used for decades as a therapeutic regimen to reduce ammonia toxicity in patients with inborn defects in Urea Cycle enzymes. Benzoic acid is also an efficient peroxide scavenger, forming benzoyl peroxide, and nontoxic food additive that inhibits the growth of mold, yeast and some bacteria. Benzoic acid is, however, ineffective against common meat-spoilage bacteria, including *Brochothrix thermosphacta*, *Carnobacterium piscicola*, *Lactobacillus curvatus*, *Lactobacillus sake*, *Pseudomonas fluorescens*, and *Serratia liquefaciens*. Acceptable daily intake, as established by the World Health Organization, is 5 mg/kg in healthy human subjects. **Target(s):** D-amino-acid oxidase (1,2,7,8,11,15,20,23,26,27, 29,33,38,47); L-amino-acid oxidase (3,9,11,15, 23,39); UDP-glucuronosyl-transferase (4); amine oxidase (5); tyrosinase, or monophenol monooxygenase (6,23,25,36,71-76); carboxypeptidase A (10,13); diamine oxidase (12); xanthine oxidase (14); phenylalanine ammonia-lyase (16,54); creatine kinase (17); aspartate aminotransferase (18); salicylate monooxygenase (19); chymotrypsin, weakly inhibited (21,22,28,31,42,51); catechol oxidase (23,44,86,87); polyphenol oxidase (86,87); lactate dehydrogenase, weakly inhibited (23,24); glucose dehydrogenase, weakly inhibited (23,24);  $\gamma$ -butyrobetaine dioxygenase,  $\gamma$ -butyrobetaine hydroxylase, K<sub>i</sub> = 2.6 mM (30);  $\gamma$ -glutamyl transpeptidase, transfer activity (32); acetoin dehydrogenase (34); mandelonitrile lyase (35,57,58); carbonyl reductase (34); esterase (37); peroxidase (40); pyrophosphatase or inorganic diphosphatase (41); choline acetyltransferase (43); leucyl aminopeptidase (45); urease (46); pyruvate carboxylase (48); mandelate racemase (49,50); L-3-cyanoalanine synthase, or  $\beta$ -cyanoalanine synthase (52); serine-sulfate ammonia-lyase (53); hydroxymandelonitrile lyase (55,56); 4,5-dihydroxyphthalate decarboxylase (59); *o*-pyrocatechuate decarboxylase, weakly inhibited (60,61); haloacetate dehalogenase (62); nicotinamide (63); peptidyl-dipeptidase A, angiotensin I-converting enzyme (64); 5'-nucleotidase (65); tyrosine-ester sulfotransferase (66); nicotinate phosphoribosyltransferase (67); nicotinate glucosyltransferase (68); nicotinate *N*-methyltransferase (69); 4-methoxybenzoate monooxygenase, or *O*-demethylating (70); catechol oxidase (74); polyphenol oxidase (75); 4 hydroxybenzoate 3-monooxygenase (77-80); salicylate 1-monooxygenase (81); procollagen-lysine 5-dioxygenase (82); procollagen-proline 3-dioxygenase (82); procollagen-proline 4-dioxygenase (82,83); 15 lipoxygenase, or arachidonate 15-lipoxygenase (84); catechol 2,3-dioxygenase (85). 1. **N-[(1,3-Benzodioxol-5-yl)methyl]-1-[6-chloro-2-(1H-imidazol-1-yl)pyrimidin-4-yl]piperazine-2-acetamide**

This synthetic pyrimidine (FW = 455.90 g/mol) is a potent inhibitor of nitric-oxide synthase activity (IC<sub>50</sub> = 1.1 nM), blocking dimerization of the inducible enzyme. This agent displays a 1000-times greater selectivity for inhibiting iNOS versus endothelial NOS dimerization in a cell-based assay. The crystal structure of inhibitor bound to the monomeric iNOS oxygenase domain revealed the inhibitor-heme interaction, substantially perturbing the substrate binding site as well as the dimerization interface. These studies demonstrated that this small molecule acts by allosterically disrupting protein-protein interactions at the dimer interface. I. McMillan, Adler, Auld, et al. (2000) *Proc. Natl. Acad. Sci. U.S.A.* 97, 1506.

**2-(Benzofuran-2-yl)-N-(4-(cyclohexylaminocarbonyl)phenylsulfonyl)tryptamine**

This modified tryptamine (FW = 541.66 g/mol) potently inhibits 15-lipoxygenase ( $IC_{50}$  = 12 nM), demonstrating that highly potent 15-LO inhibitors may be generated by introducing aryl and heteroaryl substituents at the indole C-2 position of simple tryptamine and homotryptamine precursors. Many substituents are tolerated on the aryl-sulfonamide region of the molecule, providing a potential handle for modulating their binding properties. The unprecedented potency and lipoxygenase selectivity profiles of the tryptamine sulfonamides make them attractive lead molecules for optimizing pharmacokinetic properties and assessing models of 15-LO-mediated diseases, including atherosclerosis. 1. Weinstein, Liu, Gu, *et al.* (2005) *Bioorg. Med. Chem. Lett.* **15**, 1435.

**5-(Benzofuran-2-yl)-6-(6-morpholin-4-ylpyridin-3-ylethynyl)pyrimidin-4-ylamine**

This pyrimidine (FW = 397.44 g/mol) inhibits cytosolic adenosine kinase ( $IC_{50}$  = 1 nM). Because the use of adenosine receptor agonists is plagued by dose-limiting cardiovascular side effects, there is great interest in developing adenosine kinase inhibitors (AKIs) as a means for raising steady-state adenosine concentrations. 1. Matulenko, Paight, Frey, *et al.* (2007) *Bioorg. Med. Chem.* **15**, 1586.

**(2S)-2-[[[3aS,6S,6aR)-4-(1,3-Benzothiazol-2-yl)-6-methyl-5-oxohexa-hydropyrrolo[3,2-b]pyrrol-1(2H)-yl]carbonyl]-N-(4-isopropylphenyl)pyrrolidine-1-carboxamide**

This pyrrolidine-5,5'-*trans*-lactam (FW = 530.67 g/mol) inhibits human cytomegalovirus assemblin ( $K_i$  = 10 nM). The combination of high potency against HCMV  $\Delta^{Aba}$  protease and high human plasma stability produced compounds with significant *in vitro* antiviral activity against human cytomegalovirus, with potency equivalent that of ganciclovir. 1. Borthwick, Davies, Ertl, *et al.* (2003) *J. Med. Chem.* **46**, 4428.

**4-((3E)-1-(1H-Benzotriazol-1-yl)-1-(4-(difluoro(phosphono)methyl)benzyl)-4-phenylbut-3-en-1-yl)benzoic acid Methyl Ester**

This phosphonate (FW = 601.55 g/mol) inhibits protein-tyrosine-phosphatase ( $IC_{50}$  = 39 nM) through a conformation-assisted inhibition mechanism that accounts for its considerable selectivity for protein-tyrosine phosphatase-1B over T-cell protein-tyrosine phosphatase. Its design exploited the conservative L119V substitution between the two enzymes to synthesize a PTP-1B inhibitor that is an order of magnitude more selective over TCPTP. 1. Asante-Appiah, Patel, Despons, *et al.* (2006) *J. Biol. Chem.* **281**, 8010.

**N-(Benzoylaminothiocarbonyl)-N-(4-nitrobenzyl)-β-alanine Hydroxamate**

This hydroxamate (FW = 402.43 g/mol) inhibits interstitial collagenase ( $K_i$  = 32 nM), gelatinase A ( $K_i$  = 2 nM), neutrophil collagenase ( $K_i$  = 1.8 nM), gelatinase B ( $K_i$  = 1.6 nM), and microbial collagenase ( $K_i$  = 15 nM). Its 4-nitrobenzyl moiety is an efficient P<sub>2</sub>'-anchoring moiety, and the β-alanyl scaffold is a promising replacement for the α-amino acyl to obtain potent MMP/ChC inhibitors. 1. Scozzafava, Ilies, Manole & Supuran (2000) *Eur. J. Pharm. Sci.* **11**, 69.

**(E,E)-8-O-(4-Benzoylbenzyl)-3,7-dimethyl-2,6-octadien-1,8-diol Diphosphate**

This substrate analogue (FW = 524.44 g/mol) targets protein farnesyltransferase ( $K_i$  = 45 nM). The 3-benzoylbenzyl analogue also inhibits ( $K_i$  = 49 nM). Crystallographic analysis of one of these analogues bound to PFTase reveals that the diphosphate moiety and the two isoprene units bind in the same positions occupied by the corresponding atoms in FPP when bound to PFTase. However, the benzophenone group protrudes into the acceptor protein binding site and prevents the binding of the second (protein) substrate. 1. Turek-Etienne, Strickland & Distefano (2003) *Biochemistry* **42**, 3716.

**N-Benzoyl-N-(4-cyano-3-(naphthalen-1-yl)phen-1-yl)-N-(3-methyl-3H-imidazol-4-ylmethyl)amine**

This imidazole-containing agent (FW = 442.52 g/mol) inhibits rat protein farnesyltransferase ( $IC_{50}$  = 14 nM). An X-ray crystal structure of the inhibitor bound to rat farnesyltransferase is also presented. 1. Curtin, Florjancic, Cohen, *et al.* (2003) *Bioorg. Med. Chem. Lett.* **13**, 1367.

### 6-Benzoylheteratisine

This benzoylated diterpene alkaloid (FW<sub>free-base</sub> = 495.62 g/mol), structurally related to aconitine, has been identified in different *Aconitum* species, which are utilized as analgesics in traditional Chinese folk medicine. 6-Benzoylheteratisine suppresses the spread of seizure activity and has an anticonvulsive potential. It also inhibits voltage-gated Na<sup>+</sup> channels in rat brain synaptosomes. Note that this alkaloid is photosensitive and should be stored in the dark. 6-Benzoylheteratisine is structurally related to aconitine, and patch-clamp studies on cultured rat hippocampal pyramidal cells revealed an inhibitory action of 6-Benzoylheteratisine on whole cell Na<sup>+</sup> currents, suggesting that 6-Benzoylheteratisine is a naturally occurring antagonist of the Na<sup>+</sup> channel activator aconitine (2). **See Aconitine** 1. Gutser & Gleitz (1998) *Neuropharmacol.* **37**, 1139. 2. Ameri & Simmet (1999) *Eur. J. Pharmacol.* **386**, 187.

### N<sup>1</sup>-Benzoyl-N<sup>1</sup>-[N-(4-methoxybenzoyl)-L-valyl-L-prolyl]-1,4(S)-diamino-2,2-difluoro-5-methyl-3-oxohexane

This orally bioavailable peptide analogue (FW = 613.68 g/mol) inhibits leukocyte elastase ( $K_i$  = 6.4 nM). Development of such compounds demonstrates that peptidyl trifluoromethyl ketone inhibitors can achieve high levels of oral activity and bioavailability, commending their use as therapeutic agents in the treatment of elastase-associated disorders. 1. Veale, Bernstein, Bohnert, *et al.* (1997) *J. Med. Chem.* **40**, 3173.

### (R)-2-(4-Benzoylphenylsulfonyl)-1,2,3,4-tetrahydroisoquinoline-3-carboxylic Hydroxamate

This isoquinoline (FW = 593.93 g/mol) inhibits human neutrophil collagenase, or matrix metalloproteinase-8,  $IC_{50}$  = 3 nM. (R)-2-(4-benzoylphenylsulfonyl)-1,2,3,4-tetrahydro-isoquinolin-3-carboxylic acid, by contrast, has an  $IC_{50}$  value of 300 nM. 1. Matter, Schwab, Barbier, *et al.* (1999) *J. Med. Chem.* **42**, 1908.

### N-{N-[3-(2(S)-Benzoylpyrrolidine-1-carbonyl)benzoyl]-L-prolyl}pyrrolidine

This dipeptide analogue (FW = 501.58 g/mol) inhibits pig prolyl oligopeptidase ( $IC_{50}$  = 18 nM). In the series of compounds where the N-acyl group was a Boc group, the 5(R)-tert-butyl group increased the potency strongly. A similar effect is not observed for the 5(S)-tert-butyl group. In the series of compounds, where the N-acyl group was a 4-phenylbutanoyl group, the 5(R)-tert-butyl, 5(R)-methyl and 5(S)-methyl groups was found to be ineffective. 1. Wallén, Christiaans, Saarinen, *et al.* (2003) *Bioorg. Med. Chem.* **11**, 3611.

### 5-Benzylacyclouridine

This substituted uracil (FW = 276.29 g/mol), also known as 5-benzyl-1-(2'-hydroxy-ethoxy-methyl)uracil, inhibits uridine phosphorylase,  $K_i$  = 98 nM. **Target(s):** uridine phosphorylase (1-7); nucleoside transport (8); thymidine phosphorylase (9). 1. Jimenez, Kranz, Lee, Gero & O'Sullivan (1989) *Biochem. Pharmacol.* **38**, 3785. 2. Niedzwicki, Chu, el Kouni, Rowe & Cha (1982) *Biochem. Pharmacol.* **31**, 1857. 3. Bu, Settembre, el Kouni & Ealick (2005) *Acta Crystallogr. D Biol. Crystallogr.* **61**, 863. 4. Naguib, el Kouni, Chu & Cha (1987) *Biochem. Pharmacol.* **36**, 2195. 5. Bu, Settembre, el Kouni & Ealick (2005) *Acta Crystallogr. Sect. D* **61**, 863. 6. Temmink, de Bruin, Turksma, *et al.* (2007) *Int. J. Biochem. Cell Biol.* **39**, 565. 7. el Kouni, el Kouni & Naguib (1993) *Cancer Res.* **53**, 3687. 8. Lee, el Kouni, Chu & Cha (1984) *Cancer Res.* **44**, 3744. 9. Liu, Cao, Russell, Handschumacher & Pizzorno (1998) *Cancer Res.* **58**, 5418.

### α-Benzylaminobenzylphosphonic Acid

This phosphonic acid (FW<sub>free-acid</sub> = 277.26 g/mol) inhibits human prostatic acid phosphatase ( $IC_{50}$  = 4 nM). The enhanced potency is thought to be the consequence of four interaction sites, including the phosphate binding region, hydrophobic moieties in the benzylamino and phenylphosphonic acid, as well as rigidity produced by an internal salt bridge between the phosphonate and the α-amino group. 1. Beers, Schwender, Loughney, *et al.* (1996) *Bioorg. Med. Chem.* **4**, 1693.

### (E)-7-[4-[4-[(Benzylamino)carbonyl]-2-oxazoly]phenyl]-7-(3-pyridyl)hept-6-enoate

This substituted oxazolecarboxamide (FW<sub>free-acid</sub> = 481.55 g/mol) inhibits human thromboxane-A synthase (IC<sub>50</sub> = 25 nM) and is a thromboxane receptor antagonist (K<sub>d</sub> = 135 nM). 1. Takeuchi, Kohn, True, *et al.* (1998) *J. Med. Chem.* **41**, 5362.

**2-Benzylamino-2-deoxy-D-glucosyl- $\alpha$ 1,6-D-myoinositol-1-phosphoryl-sn-1,2-dipalmitoylglycerol**

This substrate analogue (FW = 1063.33 g/mol) inhibits *Trypanosoma brucei* N-acetylglucosaminylphosphatidylinositol deacetylase (IC<sub>50</sub> = 8 nM), showing that (a) the de-N-acetylases show little specificity for the lipid moiety; (b) the 3'-OH group of the GlcNAc residue is needed for substrate recognition, whereas the 6'-OH group is dispensable and the 4'-OH, while not required for recognition, cannot be epimerized or substituted; (c) the parasite enzyme acts on analogues containing  $\beta$ GlcNAc or aromatic N-acyl groups, whereas the human enzyme cannot; (d) three GlcNR-PI analogues are de-N-acetylase inhibitors, one of which is a suicide inhibitor; (e) the suicide inhibitor most likely forms a carbamate or thiocarbamate ester to an active-site hydroxy-amino acid or Cys or residue such that inhibition is reversed by certain nucleophiles. 1. Smith, Crossman, Borissow, *et al.* (2001) *EMBO J.* **20**, 3322.

**6-(Benzylamino)-2-(3-hydroxypropyl)purine**

This purine (FW = 283.34 g/mol) inhibits cytokinin 7 $\beta$ -glucosyltransferase. The most effective inhibitors are the cytokinin analogues 3-methyl-7-n-pentylaminopyrazolo[4,3-d]pyrimidine, which act competitively (K<sub>i</sub> = 22  $\mu$ M), and the diaminopurine, 6-benzylamino-2-(2-hydroxyethylamino)-9-methylpurine (K<sub>i</sub> = 3.3  $\mu$ M). However these compounds were ineffective as inhibitors of the cytokinin-alanine synthase which was inhibited competitively by IAA (K<sub>i</sub> = 70  $\mu$ M) and related compounds, especially 5,7-dichloro-IAA (K<sub>i</sub> 0.4  $\mu$ M). Certain urea derivatives were moderately effective inhibitors of the enzymes (K<sub>i</sub> = 100 $\mu$ M). 1. Parker, Entsch & Letham (1986) *Phytochemistry* **25**, 303.

**2-[[[Benzylamino]methyl](hydroxyphosphinoyl)methyl]pentanedioic Acid**

This phosphinic acid (FW = 329.29 g/mol) inhibits glutamate carboxypeptidase II (IC<sub>50</sub> = 59 nM) and prevents neurodegeneration in a middle cerebral artery occlusion model of cerebral ischemia. In addition, in the chronic constrictive model of neuropathic pain, it significantly attenuates the hypersensitivity observed with saline-treated animals. 1. Jackson, Tays, Maclin, *et al.* (2001) *J. Med. Chem.* **44**, 4170.

**N-(R,S)-2-Benzyl-3[(S)-(2-amino-4-methylthiobutylidithio)-1-oxopropyl]-L-phenylalanine, See RB 101**

**5-(3-Benzylaminophenyl)-1H-1,2,3-triazole**

This aryl-1,2,3-triazole (FW = 250.30 g/mol), also known as N-benzyl-3-(1H-1,2,3-triazol-5-yl)aniline, inhibits human methionyl aminopeptidase type 2 (K<sub>i,app</sub> = 29 nM for the Co(II)-substituted protein). 1. Kallander, Lu, Chen, *et al.* (2005) *J. Med. Chem.* **48**, 5644.

**N<sup>1</sup>-Benzyl-N<sup>4</sup>-[N-(benzyloxycarbonyl)-L-valyl-L-prolyl]-1,4(S)-diamino-2,2-difluoro-5-methyl-3-oxohexane**

This peptide analogue (FW = 599.70 g/mol) inhibits leukocyte elastase (K<sub>i</sub> = 1.6 nM), a chymotrypsin-like serine proteinase that is secreted by neutrophils and macrophages during inflammation, thereby destroying both invasive bacteria and host tissue. 1. Veale, Bernstein, Bohnert, *et al.* (1997) *J. Med. Chem.* **40**, 3173.

**[(2R,4R,5S)-2-Benzyl-5-(N-(t-butoxycarbonyl)-amino)-4-hydroxy-6-phenyl-hexanoyl]-L-leucyl-L-phenylalaninamide**

This tetrapeptide isostere (FW = 672.87 g/mol), also known as L-685458 and  $\gamma$ -secretase inhibitor X, inhibits amyloid  $\beta$ -protein precursor  $\gamma$ -secretase activity: IC<sub>50</sub> = 17 nM. It is a 100-fold weaker inhibitor of cathepsin D. Note that the hydroxyethylene dipeptide isostere has the opposite stereochemistry as required for inhibition of the HIV-1 aspartyl protease. 1. Shearman, Behr, Clarke, *et al.* (2000) *Biochemistry* **39**, 8698. 2. Li, Lai, Xu, *et al.* (2000) *Proc. Natl. Acad. Sci. U.S.A.* **97**, 6138.

**Benzyl (S)-1-((2S,3R)-4-((R)-4-(tert-butylcarbonyl)thiazolidin-3-yl)-3-hydroxy-1-phenylbutan-2-ylamino)-4-amino-1,4-dioxobutan-2-ylcarbamate**

This peptide analogue (FW = 599.75 g/mol) inhibits HIV-1 retropepsin (K<sub>i</sub> = 6 nM) and HIV-2 retropepsin (K<sub>i</sub> = 25 nM). Although the sequences of the proteinases from HIV-1 and HIV-2 are less than 50% identical overall, their enzymatic properties are quite similar. There are only five active-site residues that are different between the two proteinases, and this report focuses on homo- and hetero-dimer effects on inhibitor binding. 1. Griffiths, Tomchak, Mills, *et al.* (1994) *J. Biol. Chem.* **269**, 4787.

**2-Benzyl-5-(6-(4-(2-chlorophenoxy)piperidin-1-yl)pyridazin-3-yl)1,3,4-oxadiazole**

This potent, selective, orally bioavailable pyridazine derivative (FW = 447.93 g/mol) inhibits stearoyl-CoA 9-desaturase (IC<sub>50</sub> = 12 nM, mouse). It and related SCD1 inhibitors are based on a common pyridazine carboxamide template. 1. Liu, Lynch, Freeman, *et al.* (2007) *J. Med. Chem.* **50**, 3086.

**N-Benzyl-N-(4-chlorophenylsulfonyl-aminocarbonyl)-glycine hydroxamate**

This tight-binding hydroxamate-based protease inhibitor (FW = 397.84 g/mol) targets proteases, including: interstitial collagenase, matrix metalloproteinase-1, or MMP-1 ( $K_i = 143$  nM; gelatinase A, or matrix metalloproteinase-2,  $K_i = 10$  nM; gelatinase B, or matrix metalloproteinase-9,  $K_i = 15$  nM; neutrophil collagenase, or matrix metalloproteinase-8 ( $K_i = 15$  nM), and microbial collagenase ( $K_i = 15$  nM). 1. Ilies, Banciu, Scozzafava, *et al.* (2003) *Bioorg. Med. Chem.* **11**, 2227.

**Benzyl Cyanide**

This nitrile (FW = 117.15 g/mol; CAS 140-29-4), also known as phenylacetonitrile, occurs naturally in plants (*e.g.*, garden cress). It is an oily liquid (melting point =  $-23.8^\circ\text{C}$ ; boiling point =  $233.5^\circ\text{C}$ ) that has a very low solubility in water. It is miscible with ethanol. Benzyl cyanide is a courtship-inhibition pheromone for mature gregarious male desert locusts, *Schistocerca gregaria*. Benzyl cyanide is also an anti-aphrodisiac, a chemical agent or pheromone passed from males to females of the butterfly *Pieris brassicae* during mating, rendering the recipient less attractive to conspecific males. Wings and legs, in particular the fore wings, have been identified as the main releasing sites. Given its utility in the chemical synthesis of phenobarbital, methylphenidate, and other amphetamines, benzyl cyanide appears on List I of the U.S. Drug Enforcement Agency. **Target(s):** monoamine oxidase (1); courtship (2,3); dopamine  $\beta$ -monoxygenase (4). 1. Bright & Porter (1975) *The Enzymes*, 3rd ed. (Boyer, ed.), **12**, 421. 2. Seidelmann, Weinert & Ferenz (2003) *J. Insect Physiol.* **49**, 1125. 3. Fatouros, Huigens, van Loon, Dicke & Hilker (2005) *Nature* **433**, 704. 4. Colombo, Rajashekar, Giedroc & Villafranca (1984) *J. Biol. Chem.* **259**, 1593.

**N-Benzyl-N-(4-cyano-3-(naphthalen-1-yl)phen-1-yl)-N-(3-methyl-3H-imidazol-4-ylmethyl)amine**

This highly substituted imidazole-containing biphenyl (FW = 428.54 g/mol) inhibits rat protein farnesyltransferase ( $\text{IC}_{50} = 1.5$  nM). This and several of these analogues, are potent inhibitors of farnesyltransferase ( $K_i < 1$  nM), showing >300-fold selectivity over geranylgeranyltransferase and cellular  $\text{IC}_{50}$  values  $\leq 80$  nM. An X-ray crystal structure of the inhibitor bound to rat farnesyltransferase is also presented. 1. Curtin, Florjancic, Cohen, *et al.* (2003) *Bioorg. Med. Chem. Lett.* **13**, 1367.

**N-[(R)-2-Benzyl-5-cyano-4-oxopentanoyl]-L-phenylalanine**

This acylated amino acid (FW<sub>free-acid</sub> = 378.43 g/mol) is a mechanism-based inactivator of human neutral endopeptidase 24.11, or neprilysin, with inactivation occurring via a ketenimine intermediate that is then intercepted by an active-site nucleophile to irreversibly generate an enzyme-inhibitor compound. Inactivation is likely to result from NEP-catalyzed formation of ketenimine intermediates, which are subsequently trapped by an active-site nucleophile. 1. Levy, Taibi, Mobashery & Ghosh (1993) *J. Med. Chem.* **36**, 2408.

**1-Benzylcyclopropylamine**

This cyclopropylamine (FW<sub>free-base</sub> = 147.22 g/mol) is a mechanism-based inactivator of monoamine oxidase, with one mole of the enzyme inactivated (at an active-site cysteine) for every 2.3 moles of the amine converted to product. Monoamine oxidase B is inactivated more rapidly than monoamine oxidase A. 1. Brush & Kozarich (1992) *The Enzymes*, 3rd ed. (Sigman, ed.), **20**, 317. 2. Silverman & Zieske (1985) *J. Med. Chem.* **28**, 1953. 3. Silverman & Hiebert (1988) *Biochemistry* **27**, 8448.

**9-Benzyl-9-deazaguanine**

This pseudonucleoside analogue (FW = 240.26 g/mol) inhibits calf spleen purine-nucleoside phosphorylase ( $K_i = 12$  nM). 1. Bennett, Allan, Noker, *et al.* (1993) *J. Pharmacol. Exp. Ther.* **266**, 707. 2. Parker, Allan, Niwas, Montgomery & Bennett (1994) *Cancer Res.* **54**, 1742. 3. Kimble, Hadala, Ludewig, *et al.* (1995) *Inflamm. Res.* **44** Suppl. 2, S181. 4. Castilho, Postigo, de Paula, *et al.* (2006) *Bioorg. Med. Chem.* **14**, 516. 5. Bzowska, Kulikowska & Shugar (2000) *Pharmacol. Ther.* **88**, 349.

**(2S,3R)-2-Benzyl-3,4-epoxybutanoic Acid**

This epoxide (FW<sub>free-acid</sub> = 192.21 g/mol) irreversibly inhibits carboxypeptidase A, covalently modifying Glu270 in the process. The (2R,3S)-enantiomer acts likewise, but the other diastereoisomers are ineffective. 1. Lee & Kim (2002) *Bioorg. Med. Chem.* **10**, 913. 2. Kim & Kim (1991) *J. Amer. Chem. Soc.* **113**, 3200. 3. Yun, Park, Kim, *et al.* (1992) *J. Amer. Chem. Soc.* **114**, 2281. 4. Ryu, Choi & Kim (1997) *J. Amer. Chem. Soc.* **119**, 38. 5. Cho, Kim, Lee & Choi (2001) *Biochemistry* **40**, 10197.

**O<sup>4</sup>-Benzylfolic acid**

This modified folate (FW = 521.53 g/mol) inhibits methylated-DNA:[protein]-cysteine *S*-methyltransferase, or *O*<sup>6</sup>-alkylguanine DNA alkyltransferase. The activity of *O*<sup>4</sup>-benzylfolic acid is particularly noteworthy, because it is roughly 30-times more active than *O*<sup>6</sup>-

benzylguanine against the wild-type alkyltransferase. It is also capable of inactivating the P140K mutant alkyltransferase that is resistant to inactivation by *O*<sup>6</sup>-benzylguanine. **1.** McMurry (2007) *DNA Repair* **6**, 1161. **2.** Nelson, Loktionova, Pegg & Moschel (2004) *J. Med. Chem.* **47**, 3887.

### *N*-Benzyl-β-D-galactosylamine

This synthetic *N*-glycoside (FW<sub>free-base</sub> = 269.30 g/mol) is a potent inhibitor of β-galactosidase (*K*<sub>i</sub> = 9.5 nM). Acid catalysis of *O*-galactoside hydrolysis and tight binding of basic inhibitors is observed only when Mg<sup>2+</sup> is bound to the enzyme. Formation of an ion-pair by proton transfer from the acidic group required for catalysis to the bound galactosylamine is proposed as the cause of the enhanced affinity. The magnitude of the observed effects indicates strong shielding of the active site from the aqueous environment. The pH-dependence of *K*<sub>i</sub> for 1-d-galactosylpiperidine and d-galactosylbenzene shows that no deprotonation from the active site occurs up to pH 10. The hydrophobic nature of the aglycon site inferred from earlier studies was confirmed by the high affinity of *N*-benzyl- (*K*<sub>i</sub> = 9 × 10<sup>-9</sup>M) and *N*-heptyl-β-d-galactosylamine (*K*<sub>i</sub> = 0.6 × 10<sup>-9</sup>M). Such results suggest a model for catalysis, wherein the charge of an essential carboxylate group is neutralized by an adjacent cationic group. **1.** Mooser (1992) *The Enzymes*, 3rd ed., **20**, 187. **2.** Legler & Herrchen (1983) *Carbohydr. Res.* **116**, 95.

### *O*<sup>6</sup>-Benzylguanine

This modified guanine (FW = 241.25 g/mol) inactivates human *O*<sup>6</sup>-alkylguanine-DNA alkyltransferase via the formation of an *S*-benzyl-L-cysteinyl residue and stoichiometric guanine. **Target(s):** DNA helicase, weakly inhibited (1); methylated-DNA:[protein]-cysteine *S*-methyltransferase, IC<sub>50</sub> = 0.2 μM (2-11); nucleoside triphosphatase, weakly inhibited (1). **1.** Borowski, Niebuhr, Mueller, *et al.* (2001) *J. Virol.* **75**, 3220. **2.** Pegg, Boosalis, Samson, *et al.* (1993) *Biochemistry* **32**, 11998. **3.** Goodtzova, Crone & Pegg (1994) *Biochemistry* **33**, 8385. **4.** Elder, Margison & Rafferty (1994) *Biochem. J.* **298**, 231. **5.** McMurry (2007) *DNA Repair* **6**, 1161. **6.** Nelson, Loktionova, Pegg & Moschel (2004) *J. Med. Chem.* **47**, 3887. **7.** Walter, Sung, Intano & Walter (2001) *Mutat. Res.* **493**, 11. **8.** Terashima, Kawata, Sakumi, Sekiguchi & Kohda (1997) *Chem. Res. Toxicol.* **10**, 1234. **9.** Sabharwal & Middleton (2006) *Curr. Opin. ### 2(S)-Benzyl-3-[hydroxy(1'(R)-aminoethyl)phosphinyl]propanoyl-L-phenylalanine

This phosphinate-containing peptidomimetic (FW = 416.41 g/mol) resemble a required tetrahedral catalytic intermediate, making it a potent transition-state inhibitor of membrane alanyl aminopeptidase, *or* aminopeptidase N (*K*<sub>i</sub> = 0.59 nM). **1.** Noble, Luciani, Da Nascimento, *et al.* (2000) *FEBS Lett.* **467**, 81. **2.** Jardinaud, Banisadr, Noble, *et al.* (2004) *Biochimie* **86**, 105.

### (*RS*)-2-Benzyl-3-mercaptopropionic Acid

This β-mercaptoacid (FW<sub>free-acid</sub> = 196.27 g/mol), also known as SQ 14603 and (*RS*)-2-(mercaptomethyl)-3-phenylpropionic acid, is a strong inhibitor of carboxypeptidase A, but more weakly inhibits carboxypeptidase B and angiotensin-converting enzyme. **Target(s):** carboxypeptidase A, *K*<sub>i</sub> = 11 nM (1-4); carboxypeptidase B, *K*<sub>i</sub> = 163 μM (1); β-lactamase (metallo-β-lactamase) (5); peptidyl-dipeptidase A, *or* angiotensin-converting enzyme, *K*<sub>i</sub> = 58 μM (1). **1.** Ondetti, Condon, Reid, *et al.* (1979) *Biochemistry* **18**, 1427. **2.** Park & Kim (2002) *J. Med. Chem.* **45**, 911. **3.** Lee & Kim (2003) *Bioorg. Med. Chem.* **11**, 4685. **4.** Chung & Kim (2001) *Bioorg. Med. Chem.* **9**, 185. **5.** Jin, Arakawa, Yasuzawa, *et al.* (2004) *Biol. Pharm. Bull.* **27**, 851.

### *N*<sup>1</sup>-Benzyl-*N*<sup>4</sup>-[*N*-(4-methoxybenzoyl)-L-valyl-L-prolyl]-1,4(S)-diamino-2,2-difluoro-5-methyl-3-oxohexane

This peptide analogue (FW = 600.71 g/mol) inhibits leukocyte elastase (*K*<sub>i</sub> = 0.35 nM). This and related compounds demonstrate peptidyl trifluoromethyl ketone inhibitors can achieve high levels of oral bioavailability, indicating they may prove to be useful as agents for treating elastase-associated diseases. **1.** Veale, Bernstein, Bohnert, *et al.* (1997) *J. Med. Chem.* **40**, 3173.

### 3-(3-Benzyl-1,2,4-oxadiazol-5-yl)-6-(4-(2-fluorophenoxy)piperidin-1-yl)pyridazine

This pyridazine derivative (FW = 431.47 g/mol) inhibits stearoyl-CoA 9-desaturase (mouse IC<sub>50</sub> = 7 nM). Stearoyl-CoA desaturase 1 (SCD1) catalyzes the committed step in the biosynthesis of monounsaturated fatty acids from saturated, long-chain fatty acids. Studies with SCD1 knockout mice have established that these animals are lean and protected from leptin deficiency-induced and diet-induced obesity, with greater whole body insulin sensitivity than wild-type animals. **1.** Liu, Lynch, Freeman, *et al.* (2007) *J. Med. Chem.* **50**, 3086.

### *N*<sup>1</sup>-[2-(Benzyloxy)benzyl]-4-oxo-4-(1-piperidinyl)-1,3-(S)-butanediamine

This substituted piperidine (FW = 382.53 g/mol) is a strong inhibitor of dipeptidyl-peptidase II (IC<sub>50</sub> = 0.39 nM). The 4-(benzyloxy)benzyl analogue also inhibits (IC<sub>50</sub> = 0.41 nM; this analogue is also a weak inhibitor of dipeptidyl-peptidase IV; IC<sub>50</sub> = 192 μM). **1.** Senten, van der Veken, De Meester, *et al.* (2004) *J. Med. Chem.* **47**, 2906.

**O-[[[(1R)-[[N-(Benzyloxycarbonyl)-L-alanyl]amino]ethyl]hydroxy phosphinyl]-L-3-phenyllactate**

This peptidomimetic phosphonate ester (FW = 402.34 g/mol) is a potent tetrahedral transition-state analogue and inhibitor of bovine carboxypeptidase A, or CPA ( $K_i = 3$  pM). Additional enzyme-inhibitor interactions for tripeptide phosphonates secure a binding mode in which a Pi portion of the inhibitor is clearly bound by the corresponding Si binding subsite. The phosphinyl groups of these phosphonates coordinate to the active-site zinc in a manner that has been proposed as a characteristic feature of the general-base ( $Zn^{2+}$ -hydroxyl or  $Zn^{2+}$ -water) mechanism for the CPA-catalyzed reaction. 1. Kim & Lipscomb (1991) *Biochemistry* **30**, 8171.

**1-(N-Benzyloxycarbonyl-L-alanyl)-5-(N-Benzyloxycarbonyl)-L-leucyl)carbohydrazide**

This carbohydrazide (FW = 542.59 g/mol) strongly inhibits cathepsin K ( $K_i = 1$  nM) and cathepsin S ( $K_i = 44$  nM), but exerts little inhibition on cathepsins B and L. X-ray, MS, and NMR data indicate that different intermediates or transition states are being represented that are dependent on the conditions of measurement and the specific groups flanking the carbonyl in the inhibitor. The species observed crystallographically are most consistent with tetrahedral intermediates that may be close approximations of those that occur during substrate hydrolysis. Initial kinetic studies suggest the possibility of irreversible and reversible active-site modification. 1. Thompson, Halbert, Bossard, *et al.* (1997) *Proc. Natl. Acad. Sci. U.S.A.* **94**, 14249.

**N-[1-[[[(Benzyloxycarbonyl)amino]phenyl]ethyl]-hydroxyphosphinyl]-L-leucyl-L-alanine**

This tetrahedral reaction intermediate analogue (FW = 519.54 g/mol), also named *N*-(benzyloxycarbonyl)-phenylalanyl[PO<sub>2</sub>NH]-L-leucyl-L-alanine, is a strong inhibitor of thermolysin ( $K_i = 68$  pM). 1. Christianson & Lipscomb (1988) *J. Amer. Chem. Soc.* **110**, 5560. 2. Holden, Tronrud, Monzingo, Weaver & Matthews (1987) *Biochemistry* **26**, 8542. 3. Baltora-Rosset, Aboubeker, Dupradeau, *et al.* (1999) *J. Biomol. Struct. Dyn.* **16**, 1061.

**N-[N-[N-(Benzyloxycarbonyl)-L-asparaginy]-L-(3S-amino-2R-hydroxy-4-phenylbutyl)]piperidine-2(S)-carboxylic t-Butyl Amide**

This pseudopeptide (FW = 595.74 g/mol), also known as Z-Asn-Phe[CH(OH)CH<sub>2</sub>N]PIC-NhtBu, contains a tetrahedral mimic, making it a powerful inhibitor of HIV-1 protease ( $IC_{50} = 18$  nM). Antiviral activity was observed in the nM range in three different cell systems, as assessed by p24

antigen and syncytium formation. 1. Roberts, Martin, *et al.* (1990) *Science* **248**, 358.

**N-(Benzyloxycarbonyl)-D-aspartic Acid**

This modified amino acid (FW<sub>free-acid</sub> = 267.24 g/mol) inhibits aspartoacylase. Canavan disease, an autosomal recessive disorder, is characterized biochemically by N-acetylaspartic aciduria and aspartoacylase (*N*-acyl-L-aspartate amidohydrolase; EC 3.5.1.15) deficiency. Aspartoacylase is localized to white matter, whereas the *N*-acetylaspartic acid concentration is threefold higher in gray matter than in white matter. 1. Kaul, Casanova, Johnson, Tang & Matalon (1991) *J. Neurochem.* **56**, 129.

**N<sup>4</sup>-(Benzyloxycarbonyl)-L-aspartyl-L-glutamyl-L-valyl-L-aspartate α-Semialdehyde**

This potent tetrapeptide aldehyde (FW = 594.57 g/mol) is a potent inhibitor of caspase-8 ( $K_i = 2$  nM). Aldehyde inhibitors can bind reversibly, forming adducts with the active-site residues. Caspase-8 initiates the Fas-mediated pathway, in which the downstream executioner caspase-3 is a physiological target. These cysteine proteases are specific for substrates possessing an aspartic acid residue at the P<sup>1</sup> position and a four-residue recognition motif lying N-terminal to the cleavage site. The aldehyde warhead of this inhibitor forms a tetrahedral thioacetal that mimics the catalytic transition state. 1. Blanchard, Donepudi, Tschopp, *et al.* (2000) *J. Mol. Biol.* **302**, 9.

**N-(Benzyloxycarbonyl)glutathione**

This glutathione derivative (FW<sub>free-acid</sub> = 441.46 g/mol) inhibits hydroxyacylglutathione hydrolase, or glyoxalase II or GLX2-2 ( $K_i = 5.6$  μM). Analysis of site-directed mutants of GLX2-2 demonstrated that tight binding of these inhibitors is not due to interactions of the protecting groups with hydrophobic amino acids on the surface of the enzyme. Instead, MM2 calculations predict that the lowest energy structures of the unbound, doubly substituted inhibitors are similar to those of a bound inhibitor. 1. Yang, Sobieski, Carenbauer, *et al.* (2003) *Arch. Biochem. Biophys.* **414**, 271.

**N-(Benzyloxycarbonyl)-L-isoleucyl-L-(glutamyl-O-t-butylester)-L-alanyl-L-leucinal**

This tetrapeptide aldehyde (FW = 618.77 g/mol), also known as proteasome inhibitor I (PSI) and Z-IE(*O*-*t*-Bu)AL CHO, inhibits the chymotrypsin-like activity of the mammalian proteasome. Aldehyde inhibitors can bind reversibly, forming adducts with the active-site residues. It also prevents activation of NF-κB and stabilizes a newly phosphorylated form of I κB-α that is still bound to NF-κB. 1. Gonzalez-Flores, Guerra-Araiza, Cerbon, Camacho-Arroyo & Etgen (2004) *Endocrinology* **145**, 2328. 2. Figueiredo-Pereira, Berg & Wilk (1994) *J. Neurochem.* **63**, 1578. 3. **1-(*N*<sup>c</sup>-Benzyloxycarbonyl-L-leucylamino)-3-(phenoxyphenyl sulfonamido)-2-propanone**

This substituted diaminopropanone (FW = 567.66 g/mol) is a strong reversible inhibitor of cathepsin K (apparent  $K_i$  = 1.8 nM), a key enzyme in osteoclast-mediated bone resorption. Its design is based on the poorly electrophilic 1,3-bis(acetylamino)-2-propanone scaffold. **1.** Yamashita, Smith, Zhao, *et al.* (1997) *J. Amer. Chem. Soc.* **119**, 11351.

**1-(*N*<sup>c</sup>-Benzyloxycarbonyl-L-leucyl-L-leucyl-L-leucinal**

This cell-permeable tripeptide aldehyde (FW = 475.63 g/mol), also known as MG-132 and Cbz-Leu-Leu-Leu-CHO, is a strong inhibitor of the chymotrypsin-like activity of the 26S proteasome ( $K_i$  = 4 nM). It also inhibits cathepsin K ( $K_i$  = 1.4 nM), activates c-Jun N-terminal kinase and thus initiating apoptosis, and inhibits NF- $\kappa$ B activation ( $IC_{50}$  = 3  $\mu$ M). In addition, it inhibits both  $\beta$ - and  $\gamma$ -secretase. **Target(s):** proteasome endopeptidase complex (1,2,4,9-12); cathepsin K (3);  $\beta$ -secretase (5);  $\gamma$  secretases (5-7); DNA-directed DNA polymerase (8); DNA polymerase  $\alpha$  (8); DNA polymerase  $\beta$  (8); DNA polymerase  $\gamma$  (8); DNA polymerase I (8); DNA nucleotidyltransferase, weakly inhibited (8). **1.** Rock, Gramm, Rothstein, *et al.* (1994) *Cell* **78**, 761. **2.** Grisham, Palombella, Elliott, *et al.* (1999) *Meth. **1-(*N*<sup>c</sup>-Benzyloxycarbonyl-L-leucyl-L-phenylalanyl-(3-acetamido)-L-alaninal**

This aldehyde-containing transition-state analogue (FW = 524.62 g/mol), also known as AG6084, inhibits picornain 3C (rhinovirus 3C protease),  $K_i$  = 6 nM. **1.** Patick & Potts (1998) *Clin. Microbiol. Rev.* **11**, 614. **2.** Webber, Okano, Little, *et al.* (1998) *J. Med. Chem.* **41**, 2786.

**((S)-1-[(3*R*,*S*)-(S)-2-Benzyloxycarbonyl(methyl)-amino-4-methylpentanoylamino)-4-oxopyrrolidin-1-yl]methanoyl)-3-methylbutyl)carbamic Acid Benzyl Ester**

This acyclic ketone-based inhibitor (FW = 605.71 g/mol) targets cathepsin K ( $K_{i,app}$  = 0.6 nM), consistent with reaction of the active-site thiol at the ketone to form a hemithioacetal adduct. **1.** Marquis, Ru, Zeng, *et al.* (2001) *J. Med. Chem.* **44**, 725.

**1-(*N*-Benzyloxycarbonyl-L-phenylalanine Chloromethyl Ketone**

This halomethyl ketone (FW = 331.80 g/mol), often abbreviated zPCK, is a site-specific inhibitor of chymotrypsin, particularly bovine chymotrypsin *Ay*. **Target(s):** chymotrypsin (1,8,13); Rt41A protease, *Thermus* strain (2); nicotinamidase (3); thermomycolin (4); carboxypeptidase C, or carboxypeptidase Y (5,6,11,16,17); *Thermomonospora* protease (7); subtilisin (9,10,13); nicotinamidase (12); thermitase (13); endopeptidase La (14); peptidyl glycinamidase, or carboxamidopeptidase (15). **1.** Shaw (1972) *Meth. **1-(N-Benzoyloxycarbonyl-D-phenylalanyl-L-prolyl-boro-(methoxypropyl)-glycine-pinanediol**

This peptide analogue (FW = 659.59 g/mol) inhibits thrombin ( $K_i$  = 8.9 nM) but is a much weaker inhibitor of both trypsin ( $K_i$  = 1.1  $\mu$ M) and plasmin ( $K_i$  = 15.7  $\mu$ M). **1.** Tapparelli, Metternich, Ehrhardt, *et al.* (1993) *J. Biol. Chem.* **268**, 4734.

**N-[N-(Benzoyloxycarbonyl)thiopropyl]thioprolinal**

This peptide analogue (FW = 366.46 g/mol) inhibits prolyl oligopeptidase,  $K_i$  = 0.01 nM. Aldehyde warhead inhibitors can bind reversibly, forming adducts with the active-site residues. **1.** Yoshimoto & Ito (1998) in *Handb. **N<sup>z</sup>-(Benzoyloxycarbonyl)-L-valyl-L-alanyl-L-aspartate Fluoromethyl Ketone**

This tripeptide halomethyl ketone (FW<sub>free-acid</sub> = 467.49 g/mol; Soluble to 9.35 mg/ml in DMSO; CAS RegistryNumber = 187389-52-2), also known as Z-VAD-FMK and caspase inhibitor VI, is a broad-spectrum caspase inhibitor that blocks caspase-mediated apoptosis. Z-VAD-FMK inhibits caspase processing (IC<sub>50</sub> = 0.0015–5.8 mM, depending on enzyme and cell type). The aspartate methyl ester derivative (FW = 467.49 g/mol), also known as caspase inhibitor I, is far more cell-permeable. **Target(s):** caspases (1-7,11); caspase-1 (11); caspase-2 (11); caspase-3 (11); caspase-4 (11); caspase 5 (11); caspase-6 (11,14); caspase-7 (11); caspase-8 (11-13); caspase-9 (8,9,11); caspase-10 (10). **1.** Thornberry (1998) in *Handb. **Benzoyloxycarbonyl-L-valyl-L-phenylalaninal**

This potent, cell-permeable, aldehyde-containing peptidomimetic (FW = 382.45 g/mol; CAS 88191-84-8; Sequence: z-Val-Phe-al; Solubility = 26 mg/mL DMSO, <<1 mg/mL H<sub>2</sub>O), also known as MDL 28170, targets calpain I and II inhibitor, protects rat erythrocyte membrane-associated cytoskeletal proteins from proteolytic degradation (IC<sub>50</sub> = 1 microM) which occurs when the cells are rendered permeable to Ca<sup>2+</sup> (1). Calpain I and II is a Ca<sup>2+</sup>-activated non-lysosomal protease. MDL 28170 reduces capsaicin-mediated cell death in cultured dorsal root ganglion neurons (2). Although calpain I and protein kinase C (PKC) is known to form a complex in rabbit skeletal muscle, MDL 28170 does not block the activation of the purified PKC by Ca<sup>2+</sup> and phosphatidylserine (3). When tested in two models of experimental Parkinson Disorder induced by the neurotoxin 1-methyl-4-phenyl 1,2,3,6-tetrahydropyridine and the environmental toxin, rotenone, treatment with MDL-28170 prevents neuronal death and restore functions (4). **1.** Mehdi, Angelastro, Wiseman & Bey (1988) *Biochem. Biophys. Res. Commun.* **157**, 1117. (Erratum in: *Biochem. Biophys. Res. Commun.* **159**, 371.) **2.** Chard, Bleakman, Savidge & Miller (1995) *Neuroscience* **65**, 1099. **3.** Savart, Pallet, Letard, Bossuet & Ducastaing (1991) *Biochimie* **73**, 1409. **4.** Samantaray, Ray & Banik (2008) *CNS Neurol. Disord. Drug Targets* **7**, 305.

**(E)-7-[4-[4-[[2-(Benzoyloxy)ethyl]amino]carbonyl]-2-oxazolyl]phenyl]-7-(3-pyridyl)-hept-6-enoate**

This substituted oxazolecarboxamide (FW<sub>free-acid</sub> = 525.60 g/mol) inhibits human thromboxane-A synthase (IC<sub>50</sub> = 48 nM) and is a thromboxane receptor antagonist ( $K_d$  = 156 nM). **1.** Takeuchi, Kohn, True, *et al.* (1998) *J. Med. Chem.* **41**, 5362.

**5-(4-Benzoyloxyphenyl)-4S-(7-phenylheptanoylamino)pentanoate**

This sPLA<sub>2</sub> inhibitor (FW<sub>free-acid</sub> = 487.64 g/mol), also known as 5-(4-benzoyloxyphenyl)-4S-(7-phenylheptanoyl-amino)pentanoic Acid, targets secretory phospholipase A<sub>2</sub>; IC<sub>50</sub> = 29 nM for the human nonpancreatic enzyme. **1.** Arumugam, Arnold, Proctor, *et al.* (2003) *Brit. J. Pharmacol.* **140**, 71. **2.** Hansford, Reid, Clark, *et al.* (2003) *Chem. Bio. Chem.* **4**, 101.

**4-(Benzoyloxypropoxy)-3-[(naphth-2-yl)methoxy]piperidine**

This substituted piperidine (FW = 481.63 g/mol) is a strong inhibitor of human renin, with an IC<sub>50</sub> value of 8 nM for the recombinant protein. **1.** Vieira, Binggeli, Breu, *et al.* (1999) *Bioorg. Med. Chem. Lett.* **9**, 1397.

#### N-(1-Benzyl-4-piperidinyl)-2,4-dichlorobenzamide

This anticonvulsant (FW = 363.28 g/mol) inhibits betaine/GABA transporter-1 (BGT-1), a recently recognized target for treating epilepsy. While a selective noncompetitive inhibitor of the human BGT-1, BPDBA exhibits no significant inhibitory activity against the three human  $\gamma$ -aminobutyrate transporter subtypes GAT-1, GAT-2 and GAT-3. GABA transporters are essential regulators of GABAergic neurons through the continuous uptake of the neurotransmitter from the synaptic cleft and extrasynaptic space. (See *Tiagabine*) **1.** Kragholm, Kvist, Madsen, *et al.* (2013) *Biochem. Pharmacol.* **86**, 521.

#### 5'-(Benzylthio)-immucillin-A

This pseudonucleoside analogue (FW = 357.46 g/mol), systematically known as (1S)-5-(benzylthio)-1-(9-deazaadenin-9-yl)-1,4-dideoxy-1,4-imino-D-ribose, inhibits 5'-methylthioadenosine/S-adenosylhomocysteine nucleosidase, K<sub>i</sub>' = 12 pM (1) and S-methyl-5'-thioadenosine phosphorylase, K<sub>i</sub> = 26 nM (2). **1.** Singh, Evans, Lenz, *et al.* (2005) *J. Biol. Chem.* **280**, 18265. **2.** Evans, Furneaux, Schramm, Singh & Tyler (2004) *J. Med. Chem.* **47**, 3275.

#### N-Benzyl-N-(2-toluenesulfonylamino)glycine Hydroxamate

This hydroxamate (FW = 376.41 g/mol) inhibits a number of metalloproteinases: interstitial collagenase (K<sub>i</sub> = 162 nM), gelatinase A (K<sub>i</sub> = 18 nM), neutrophil collagenase (K<sub>i</sub> = 25 nM), gelatinase B (K<sub>i</sub> = 24 nM), and microbial collagenase (K<sub>i</sub> = 17 nM). **Target(s):** gelatinase A, or matrix metalloproteinase 2; gelatinase B, or matrix metalloproteinase 9; interstitial collagenase, or matrix metalloproteinase; microbial collagenase; neutrophil collagenase, or matrix metalloproteinase 8. **1.** Ilies, Banciu, Scozzafava, *et al.* (2003) *Bioorg. Med. Chem.* **11**, 2227.

#### Bepridil

This substituted pyrrolidine (FW<sub>free-base</sub> = 366.55 g/mol) is a calcium channel blocker that inhibits the Na<sup>+</sup>/Ca<sup>2+</sup> exchange, exhibiting antiarrhythmic, antianginal, and vasodilatory properties. Bepridil inhibits the growth of certain brain tumors *in vitro*. Bepridil also binds to troponin C. **Target(s):** Ca<sup>2+</sup> channels (1,2); ATP-sensitive K<sup>+</sup> channels (3); Na<sup>+</sup>-activated K<sup>+</sup> channels (3). **1.** Galizzi, Borsotto, Barhanin, Fosset & Lazdunski (1986) *J.*

*Biol. Chem.* **261**, 1393. **2.** Yatani, Brown & Schwartz (1986) *J. Pharmacol. Exp. Ther.* **237**, 9. **3.** Li, Sato & Arita (1999) *J. Pharmacol. Exp. Ther.* **291**, 562.

#### Berbamine

This antihypertensive alkaloid (FW = 608.72 g/mol; CAS 478-61-5; *Symbol*: BBM) from *Berberis lyceum* and *Mahonia swaseyi* is a dihydropyridine-class calcium ion blocker (1). Berbamine also inhibits KM3 cell growth by inducing G<sub>1</sub> arrest as well as apoptosis, by blocking NF- $\kappa$ B signaling through up-regulation of A20, down-regulation of IKK $\alpha$ , p-I $\kappa$ B $\alpha$ , and then inhibition of p65 nuclear translocation, all with a resultant decrease in the expression of the downstream targets of NF- $\kappa$ B (2). BBM potently suppresses liver cancer cell proliferation and induces cancer cell death by targeting Ca<sup>2+</sup>/calmodulin-dependent protein kinase II (CAMKII). BBM likewise inhibits *in vivo* tumorigenicity of liver cancer cells in NOD/SCID mice. These effects are recapitulated by short hairpin RNA-mediated CAMKII knockdown, whereas CAMKII overexpression promotes cancer cell proliferation and increases the resistance of liver cancer cells to BBM. CAMKII was hyperphosphorylated in liver tumors compared with the paired peri-tumor tissues, supporting a role of CAMKII in promoting human liver cancer progression and the clinical potential of BBM in liver cancer therapies (3). **1.** Khan, Qayum & Qureshi (1969) *Life Sci.* **8**, 993. **2.** Liang, Xu, Zhang & Zhao (2009) *Acta Pharmacol Sin.* **30**, 1659. **3.** Meng, Li, Ma, *et al.* (2013) *Mol. Cancer Ther.* **12**, 2067.

#### Beraprost

This orally active epoprostenol analogue (FW = 398.50 g/mol; CAS 88475-69-8; Soluble to 25 mM in DMSO), also named TRA-418 and 2,3,3a,8b-tetrahydro-2-hydroxy-1-(3-hydroxy-4-methyl-1-octen-6-yn-1-yl)-1H-cyclopenta[b]benzofuran-5-butanoic acid, is a potent agonist for the Prostacyclin Receptor, a member of the G-protein coupled receptor family. Prostacyclin, the major product of cyclooxygenase in macrovascular endothelium, elicits a potent vasodilation and inhibition of platelet aggregation through binding to this receptor. Beraprost potently inhibits ADP-induced platelet aggregation (pIC<sub>50</sub> = 8.26) and P-selectin expression *in vitro* (pIC<sub>50</sub> = 8.56). It also increases vasodilation and reduces pulmonary hypertension *in vivo*. TRA-418 inhibited platelet GPIIb/IIIa activation as well as induction of P-selectin expression by adenosine 5'-diphosphate, Thrombin Receptor Agonist Peptide 1-6 (Ser-Phe-Leu-Leu-Arg-Asn-NH<sub>2</sub>), and U-46619 in the presence of epinephrine (2). TRA-418 also inhibits platelet aggregation induced by those platelet-stimulants in Ca<sup>2+</sup>-chelating anticoagulant, citrate and in nonchelating anticoagulant, *d*-phenylalanyl-L-prolyl-L-arginyl-chloromethyl ketone (PPACK). The TP-receptor antagonist SQ-29548 inhibited only U-46619+epinephrine-induced GPIIb/IIIa activation, P-selectin expression, and platelet aggregation. The IP-receptor agonist beraprost sodium inhibited platelet activation. Beraprost also inhibited platelet aggregation induced by platelet stimulants we tested in citrate and in PPACK (2). The GPIIb/IIIa inhibitor abciximab blocked GPIIb/IIIa activation and platelet aggregation. However, abciximab showed slight inhibitory effects on P-selectin expression. TRA-418 is more advantageous as an antiplatelet agent than TP-receptor antagonists or IP-receptor agonists separately used. TRA-418 showed a different inhibitory

profile from abciximab in the effects on P-selectin expression (2). 1. Saito, Tatsumi, Kasahara, Tani & Kuriyama (1995) *Nihon. Kyobu. Shikkan. Gakkai. Zasshi*. **33**, 497. 2. Miyamoto, Yamada, Ikezawa, *et al.* (2003) *Br. J. Pharmacol.* **140**, 889.

### Berberine

This yellow isoquinoline-based alkaloid (FW<sub>free-base</sub> = 336.37 g/mol; FW<sub>chloride</sub> = 371.82 g/mol; CAS 2086-83-1) is an acetylcholinesterase inhibitor that also induces apoptosis in promyelocytic leukemia HL-60 cells, modulates the expression and function of P-glycoprotein 170 (multi-drug resistance transporter) in hepatoma cells, and inhibits platelet aggregation induced by ADP, arachidonate, and collagen in rats. It is a fluorescent stain for heparin in mast cells. Berberine inhibits  $\beta$ -catenin transcriptional activity and attenuates anchorage-independent growth, reducing cellular levels of active  $\beta$ -catenin and increasing the expression of E-cadherin (1). A screen of synthetic 13-arylalkyl berberine derivatives identified compounds exhibiting activities superior to those of the naturally occurring parent substance with more than 100-fold lower EC<sub>50</sub> values for Wnt-repression. Berberine is also a partial agonist of  $\alpha_2$  adrenoceptors. With rat cerebral cortex synaptosomes, berberine inhibits the release of glutamate evoked by the K<sup>+</sup> channel blocker 4-aminopyridine, an effect that can be prevented by the chelating extracellular Ca<sup>2+</sup> ions or by the vesicular transporter inhibitor bafilomycin A<sub>1</sub> (2). Berberine inhibition is insensitive to the glutamate transporter inhibitor DL-threo- $\beta$ -benzyl-oxyaspartate. The inhibitory effect of berberine on glutamate release is associated with a reduction in the depolarization-induced increase in cytosolic free Ca<sup>2+</sup> (2). Berberine is a component of the Chinese herb medicine Huanglian (*Coptis chinensis*). *Note*: Tetrahydroberberine is canadine (See Canadine). **Target(s)**: lactate dehydrogenase (3); malate dehydrogenase (4); acetylcholinesterase (4,7); alcohol dehydrogenase (5,10); (RS)-norcoclaurine 6-O-methyltransferase (6); electron transport (8); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (9); diamine oxidase (11); microbial collagenase (12); elastase (13); K<sup>+</sup> channels (IK1, IK, and HERG channels) (14,16,18,24); HIV-1 reverse transcriptase (15);  $\beta$ -fructofuranosidase, or invertase (17); Ca<sup>2+</sup> channels, L- and T-type (19); arylamine N-acetyltransferase (20,21,22); lipase, or triacylglycerol lipase (22); monoamine oxidase (23); telomerase (25); sortase (26); reticuline oxidase (27); mitogen-activated protein kinase kinase (28); (S)-tetrahydroprotoberberine N-methyltransferase (30); (S)-scoulerine 9-O-methyltransferase (31); 3'-hydroxy-N-methyl-(S)-coclaurine 4'-O-methyltransferase (32). 1. ### Berninamycin A

This fungal antibiotic (FW = 1146.12 g/mol; CAS 58798-97-3; Soluble in DMSO), also known as Antibiotic U27810, from *Streptomyces bernensis* inhibits protein biosynthesis by binding to a complex formed by ribosomal 23S and the L11 protein, thereby disrupting the function of the ribosome's A site and inhibiting protein synthesis in Gram-positive bacteria (1,2). In this respect, it has the same mode of action as thiostrepton. *Streptomyces bernensis* and *Streptomyces azureus*, which produce berninamycin and thiostrepton, respectively, possess similar ribosomal RNA methylases that mediate specific pentose-directed methylation of 23S ribosomal RNA, rendering the modified ribosomes resistant to these antibiotics (2). 1. Reusser (1969) *Biochemistry* **8**, 3303. 2. Thompson, Cundliffe & Stark (1982) *J. Gen. Microbiol.* **128**, 875.

### Berterion

This sulfurophane analogue and antimetastatic agent (FW = 175.43 g/mol; CAS 4430-42-6; Physical State = Liquid; Soluble in ethanol, DMSO, and chloroform; Store at -20° C; M.P. = 155-156° C), also named 5-methylthiopentyl isothiocyanate, is found in cruciferous vegetables (including Chinese cabbage and rucola leaves) and mustard oil. Berteroin inhibits LPS-induced degradation of Inhibitor of  $\kappa$ B $\alpha$  (or  $\kappa$ B $\alpha$ ) as well as NF- $\kappa$ B p65 translocation into the nucleus and DNA binding. Berteroin also suppresses degradation of IL-1 Receptor Associated Kinase and phosphorylation of Transforming Growth Factor  $\beta$ -Activated Kinase-1. Berteroin also inhibits LPS-induced phosphorylation of p38 MAPK, ERK1/2, and AKT. 1. Jung, Jung, Cho, *et al.* (2014) *Int. J. Mol. Sci.* **15**, 20686.

### Beryllium & Beryllium Ions

This Group 2 (or IIA) alkaline element (Symbol: Be; Atomic Number = 4; Atomic Weight = 9.012182; CAS CAS No. 7440-41-7), positioned directly above magnesium in the Periodic Table, has oxidation states of 0, 1, and 2, with ionic radii of 0.44 and 0.35 Å for Be<sup>+</sup> and Be<sup>2+</sup>, respectively (1-3). Beryllium fluoride ion is frequently employed as an isostere of phosphoryl and metaphosphate intermediates that form by various phosphotransferases,

phosphohydrolases, transporters, and molecular motors. **CAUTION:** Epidemiological studies indicate an increased risk of lung cancer in occupational groups exposed to beryllium or beryllium compounds, a finding that is consistent with the carcinogenicity of beryllium and beryllium compounds in humans. While sweet to the taste, is extremely toxic.

**Target(s):** myosin ATPase, inhibited by  $\text{BeF}_x$  (4,17,54); calcium-exporting ATPase (6);  $\beta$ -galactosidase (7,29); peptidyltransferase (8,9); thymidine kinase (10,22); [glycogen synthase] kinase (11); nitrogenase (12); P-glycoprotein ATPase (13); gelsolin severing of F-actin (14); adenylate kinase (15); inositol-phosphate phosphatase, or myo-inositol monophosphatase (16,56,57); bromoperoxidase (18); cytochrome P450 (19); casein kinase-1 (20); phosphatase (21);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (23,24); phosphoglucomutase (25,26,34,50,51); triokinase (27); creatine kinase (28); alkaline phosphatase (30,32,36,40) (42,44,45,47,61); enolase (31); pancreatic ribonuclease, or ribonuclease A, by  $\text{BeCl}_2$ , (33); phosphatidate phosphatase, by  $\text{BeCl}_2$  (35); phospholipase D, by  $\text{BeCl}_2$  (36); lipase (38); pyrophosphatase, or inorganic diphosphatase (39); glucose-6-phosphate isomerase (43); hexokinase (46); phosphomannomutase (48); phosphoacetylglucosamine mutase, or N-acetylglucosamine-phosphate mutase (49); pyruvate decarboxylase (52); nitrogenase, by  $\text{BeF}_2$  (53); Xaa-Pro Dipeptidase, or prolidase, or imidodipeptidase (55); histidinol-phosphatase (58); phosphatidate phosphatase (59); acid phosphatase (60). 1. ### Besifloxacin

This fourth-generation, fluoroquinolone-class antibiotic (FW = 393.84 g/mol; CAS 141388-76-3), also known as Besivance<sup>®</sup>, BOL-303224-A, SS734, and 7-[(3R)-3-aminoazepan-1-yl]-8-chloro-1-cyclopropyl-6-fluoro-4-oxo-1,4-dihydroquinoline-3-carboxylic acid, displays activity in *in vitro* antimicrobial efficacy studies as well as efficacy in an *in vivo* murine infection model (1). BOL-303224-A demonstrates excellent ocular pharmacokinetics in rabbits, with ocular mean residence times >7 hours, reaching conjunctival concentrations that exceed the MIC<sub>90</sub> for nonresistant ophthalmic isolates for >12 hours following a single dose (1). Besifloxacin acts as an anti-inflammatory agent in monocytes *in vitro*, a property that may enhance its efficacy in ocular infections (2). It exhibits broad-spectrum *in vitro* activity against aerobic and anaerobic bacteria, based on studies on 2,690 clinical isolates representing 40 species (3). 1. Ward, Lepage & Driot (2007) *J. Ocul. Pharmacol. Ther.* **23**, 243. 2. Zhang & Ward (2008) *J. Antimicrob. Chemother.* **61**, 111. 3. Haas, Pillar, Zurenko, et al. (2009) *Antimicrob. Agents Chemother.* **53**, 3552.

### Bestatin

This potent aminopeptidase inhibitor (FW = 308.38 g/mol; CASs = 8970-76-6 (free acid) and 65391-42-6 (HCl salt); pK<sub>1</sub> = 3.1; pK<sub>2</sub> = 8.1), also known by the nonproprietary name, ubenimex, and systematically as (2S,3R)-3-amino-2-hydroxy-4-phenylbutanoyl-L-leucine, is usually effective in the 1–25 nM range, and, except for nardilysin, is without effect on endoproteinases. Bestatin inhibits the enzymatic degradation of oxytocin, vasopressin, and enkephalins. It also potentially inhibits arginyl aminopeptidase (or aminopeptidase B), leukotriene A<sub>4</sub> hydrolase, alanyl aminopeptidase (or aminopeptidase M/N), leucyl/cystinyl aminopeptidase (or oxytocinase, vasopressinase), and membrane dipeptidase (or leukotriene D<sub>4</sub> hydrolase). Aqueous solutions are stable for about one day, but 1 mM stock solutions in methanol are stable for one month at –20°C. The D-leucine analogue is a slightly weaker inhibitor of leucyl aminopeptidase and aminopeptidase B. The (2S,3S)-3-amino-2-hydroxy-4-phenylbutanoyl-L-leucine and D-leucine stereoisomers also inhibit these two aminopeptidases. **Target(s):** membrane alanyl aminopeptidase, or aminopeptidase M, or aminopeptidase N (1,2,21,24,27,29,43,73,83,108-120); leucyl aminopeptidase (3,11,12,20,24,39,57,58,73,96,102, 104,121-137); bacterial pyroglutamyl-peptidase (4); cystinyl aminopeptidase, or oxytocinase (5,104-107); aminopeptidase PS (6); yeast aminopeptidase Ape2 (7); leukotriene-A<sub>4</sub> hydrolase (8,23,28,138-144); aminopeptidase B, also inhibited by the 3S-amino-and-D-leucine stereoisomer (9,20,22,24,82-96); aminopeptidase Ey (10,63); aminopeptidase Y, or aminopeptidase Co (13,67,68); bacterial leucyl aminopeptidase, or *Vibrio* aminopeptidase (14,70-74); aminopeptidase T (15); tripeptide aminopeptidase, or tripeptidyl-peptidase (16,47,98-103); Xaa-Trp aminopeptidase, or aminopeptidase W (17,29,65,66); cytosol nonspecific dipeptidase (18,30,51,102); nardilysin (19,32-34); mouse ascites tumor dipeptidase (24,25); lysine-specific aminopeptidase (26); glutamyl aminopeptidase, or aminopeptidase A (29,81); biotinidase (31); mitochondrial intermediate peptidase (35); envlysin (36); cathepsin H (37); chymase (38); glutamate carboxypeptidase II, or N-acetylated-γ-linked-acidic dipeptidase (40); tripeptidyl-peptidase I, weakly inhibited (41); dipeptidyl-peptidase IV (42); dipeptidyl-peptidase III, weakly inhibited (44); dipeptidyl-peptidase II, weakly inhibited (45,46); β-Ala-His Dipeptidase, or carnosinase (48); membrane Dipeptidase, or renal Dipeptidase, or dehydropeptidase (49; however, see 50); Xaa-Pro Dipeptidase, or prolidase, or imidodipeptidase (52,77); Xaa-methyl-His

- Dipeptidase, or anserinase, or N-acetylhistidine deacetylase, weakly inhibited (53); PepB aminopeptidase (peptidase B) (54); aminopeptidase (17,55,56,59-62); methionyl aminopeptidase (64); cytosol alanyl aminopeptidase (69); Xaa-Pro aminopeptidase, or aminopeptidase P (75-80); prolyl aminopeptidase, or *Aneurinibacillus* sp. (97); leucyl aminopeptidase/cystinyl aminopeptidase (104); *Salmonella enterica serovar Typhimurium* Peptidase B (137). 1. Tate (1985) *Meth. Enzymol.* **113**, 471. 2. Turner (1998) in *Handb. ### Betahistine

This vasodilator (FW<sub>free-base</sub> = 136.20 g/mol; CAS 5638-76-6) is a structural analogue of histamine, a weak histamine H<sub>1</sub> receptor agonist, and a more potent H<sub>3</sub> receptor antagonist (1). Betahistine improves vestibular compensation in animal models of unilateral vestibular dysfunction. Betahistine has been used to treat Meniere's disease, vertigo, and peripheral vascular arterial disease (2). **1.** Lacour & Sterkers (2001) *CNS Drugs* **15**, 853. **2.** Allison & Barnes (1971) *Tex. Med.* **67**, 85.

### Betaxolol

This selective β<sub>1</sub>-receptor blocker (FW = 307.43 g/mol; CAS 63659-18-7; IUPAC: (R*S*)-1-[4-[2-(cyclopropylmethoxy)ethyl]phenoxy]-3-(isopropylamino)propan-2-ol), also known by the trade names Betoptic<sup>®</sup>, Betoptic S<sup>®</sup>, Lokren<sup>®</sup>, and Kerlone<sup>®</sup>, is used to treatment of hypertension and glaucoma (1). Given its selective, it has fewer systemic side-effects than non-selective β-blockers, for example, not causing bronchospasm (mediated by beta2 receptors) as timolol may. Betaxolol shows greater affinity for β-receptors than metoprolol. In addition to its effect on the heart, betaxolol reduces the intraocular pressure, an effect thought to be caused by reducing the production of the aqueous humor within the eye. Reduction in intraocular pressure reduces the risk of damage to the optic nerve and loss of vision in patients with elevated intraocular pressure due to glaucoma. **1.** Buckley, Goa & Clissold, (1990) *Drugs* **40**, 75.

### Bevacizumab

This humanized monoclonal antibody (MW = 149.2 kDa; CAS 216974-75-3), known by the tradename Avastin<sup>®</sup>, is an angiogenesis inhibitor that targets vascular endothelial growth factor A (VEGF-A). Because VEGF is the key angiogenic factor in tumors, blocking VEGF signal transduction can lead to tumor growth arrest and inhibition of metastasis. The rationale for Avastin therapy is premised on findings that high VEGF expression correlates with (a) reduced overall survival, (b) disease progression, (c) greater risk of relapse, (d) lymph node involvement, and (e) malignant pleural effusion. By binding directly bind to VEGF-A, Avastin blocks its interaction with endothelial cell VEGF receptors, thereby inhibiting neovascularization and depriving cancer cells of vital nutrients and oxygen. Avastin is approved for: *metastatic colorectal cancer* (mCRC), when started with the first or second intravenous 5-FU-based chemotherapy for metastatic cancer; advanced-stage *nonsquamous, non-small cell lung cancer* (NSCLC), when administered in combination with carboplatin and paclitaxel in patients who have not received chemotherapy for their advanced disease; *metastatic renal cell cancer* (mRCC) when used with interferon-α; and *glioblastoma multiforme* (GBM) in adult patients whose cancer has progressed after prior treatment.

### Bevantolol

This antihypertensive agent (FW = 345.43 g/mol; CAS 59170-23-9), also known by the code name NC-1400 and systematically as (R*S*)-[2-(3,4-dimethoxyphenyl)ethyl]-[2-hydroxy-3-(3-methylphenoxy)propyl]amine, is a dual-action β-blocker and calcium ion channel blocker. Bevantolol is a selective β<sub>1</sub>-adrenoceptor blocker with some blocking activity of α<sub>1</sub>-adrenoceptors (1). **1.** Gross, Buck, Wartier & Hardman (1979) *J. Cardiovasc. Pharmacol.* **1**, 139. **2.** Takayanagi, Kizawa, Iwasaki & Nakagoshi (1987) *Gen. Pharmacol.* **18**, 87.

### Bevirimat

This first-in-class, natural product-based antiviral (FW = 584.83 g/mol; CAS 174022-42-5; *Abbreviation*: BVM), also known as 3-*O*-(3',3'-dimethylsuccinyl)betulinic acid (DSB), 3β-(3-carboxy-3-methyl-butanoyloxy)-lup-20(29)-en-28-oic acid, PA-457, and MPC-4326, is a novel HIV-1 maturation inhibitor that blocks proteolytic processing of the Gag capsid precursor (CA-SP1) into mature capsid (CA) protein. Bevirimat binds to the Gag polypeptide at the CA/SP1 cleavage site. The net result of BVM treatment is the release of immature, noninfectious viral particles. Despite its promising mode of action, about half of all patients have viruses containing genetic polymorphisms in the Gag SP1 (at positions 6 to 8) protein do not respond to BVM treatment. **1.** Lu, Salzwedel, Wang, *et al.* (2011) *Antimicrob. Agents Chemother.* **55**, 3324.

### Bexarotene

This third-generation retinoid receptor X agonist and antineoplastic agent (FW = 348.48 g/mol; CAS 153559-49-0), also named LGD1069, Targretin<sup>®</sup> and 4-[1-(5,6,7,8-tetrahydro-3,5,5,8,8-pentamethyl-2-naphthalenyl)ethenyl]benzoate, is a first-line therapy for early-stage Cutaneous T-Cell Lymphomas (CTCLs), a group of relatively uncommon lymphoproliferative disorders characterized by the presence of a malignant population of T cells that is localized to the skin at presentation (1). Bexarotene is a retinoid X receptor (RXR) agonist (EC<sub>50</sub> = 24, 25 and 33 nM for RXRβ, RXRγ and RXRα, respectively) that blocks cell cycle progression, induces apoptosis and differentiation, prevents multidrug resistance, and inhibits angiogenesis and metastasis. In clinical trials, bexarotene gel demonstrated efficacy for the topical treatment of cutaneous lesions in Stage IA or IB CTCL patients with refractory or persistent disease following other therapies or who cannot tolerate other therapies, including: topical corticosteroids; topical chemotherapy with mechlorethamine or carmustine; local and total skin electron beam therapy; and UV-A or UV-B phototherapy (1,2). A promising development was the finding that bexarotene also blocks calcium-permeable ion channels formed by neurotoxic Alzheimer's β-amyloid peptides (3). **1.** Bischoff, Gottardis, Moon, *et al.* (1998) *Cancer Res.* **58**, 4479. **2.** Martin (2003) *J. Drugs Dermatol.* **2**, 155. **3.** Fantini, Di Scala, Yahi, *et al.* (2014) *ACS Chem. Neurosci.* **5**, 216.

**BEZ235**

This ATP site-competitive, dual pan-PI3K/mTOR and antineoplastic agent (FW = 469.55; CASs = 915019-65-7 (free base) and 1028385-32-1 (4-methylbenzenesulfonate salt); Solubility (25°C): 1 mg/mL DMSO, <1 mg/mL Water), IUPAC: 2-methyl-2-(4-(3-methyl-2-oxo-8-(quinolin-3-yl)-2,3-dihydro-imidazo[4,5-c]quinolin-1-yl)phenyl)propane-nitrile, targets phosphoinositide 3-kinases in the PI3K/mTOR signaling pathway, inhibiting PI3K p110 $\alpha$  (IC<sub>50</sub> = 4 nM), PI3K p110 $\gamma$  (IC<sub>50</sub> = 5 nM), PI3K p110 $\delta$  (IC<sub>50</sub> = 7 nM), and PI3K p110 $\beta$  (IC<sub>50</sub> = 75 nM) (1). In cellular settings using human tumor cell lines, this inhibitor effectively and specifically blocks the dysfunctional activation of the PI3K pathway, inducing G<sub>1</sub> cell-cycle arrest in *in vivo* models of human cancer. BEZ235 also significantly reduces phosphorylation of the mTOR-activated kinase p70S6K (2,3). *In vivo* NVP-BEZ235 treatment of colonic tumors resulted in a 56% decrease in cellular proliferation, but the absence of an induction in apoptosis. Although induction of apoptosis by NVP-BEZ235 treatment has been reported in lung, breast, renal cell carcinoma, and ovarian models, the absence of apoptosis has been found after treatment of glioma and sarcoma models. Furthermore, *in vivo* NVP-BEZ235 treatment of colonic tumors resulted in a 75% decrease in microvessel density after NVP-BEZ235 treatment (2). Use of NVP-BEZ235 and sorafenib has greater antitumor benefit compared to either drug alone and thus provides a strategy for treating metastatic renal cell carcinoma (3). 1. Maira, Stauffer, Breuggen, *et al.* (2008) *Mol. Cancer Ther.* 7, 1851. 2. Roper, *et al.* (2011) *PLoS One* 6, e25132. 3. Roulin, *et al.* (2011) *Mol. Cancer* 10, 90.

**BFA, See Brefeldin A****BGB324, See R428****BGC 638**

This nonpolyglutamatable folate (FW = 631.64 g/mol), also known as 6S-CB300638, inhibits thymidylate synthase ( $K_i$  = 0.24 nM) and is transported into  $\alpha$ -folate receptor-overexpressing tumors (1,2). The low expression of the  $\alpha$ -FR in normal tissues, particularly those sensitive to TS inhibitors, together with BGC638's low affinity for the reduced-folate carrier, suggests it may have potential as an antitumor agent and is likely to have a high therapeutic index (1). 1. Theti, Bavetsias, Skelton, *et al.* (2003) *Cancer Res.* 63, 3612. 2. Gibbs, Theti, Wood, *et al.* (2005) *Cancer Res.* 65, 11721.

**BGC 945, See ONX-0801****BGT226**

This novel Class I PI3K/mTOR inhibitor (FW<sub>free-base</sub> = g/mol; FW<sub>maleate-salt</sub> = 650.60 g/mol; CAS 1245537-68-1; Solubility: 30 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as NVP-BGT226 and 8-(6-methoxy-pyridin-3-yl)-3-methyl-1-(4-(piperazin-1-yl)-3-(trifluoromethyl)phenyl)-1H-imidazo[4,5-c]quinolin-2(3H)-one, targets PI3K $\alpha$  (IC<sub>50</sub> = 4 nM), PI3K $\beta$  (IC<sub>50</sub> = 63 nM), and PI3K $\gamma$  (IC<sub>50</sub> = 38 nM). BGT226 is active against all tested cancer cell lines, and cross-resistance is not observed in the cisplatin-resistant cell line (1). Activation of the AKT/mTOR signal cascade is suppressed by BGT226 in a concentration- and time-dependent manner, with cells accumulating in the G<sub>0</sub>-G<sub>1</sub> phase, attended by concomitant loss in the S-phase. TUNEL assays and analysis of caspase 3/7 and PARP indicate that BGT226 induces cancer cell death through an apoptosis-independent pathway (1). BGT226 induces autophagy, as indicated by the aggregation and upregulation of the microtubule-associated protein light chain 3B-II, and p62 degradation. Gene silencing of Beclin1 or cotreatment of the autophagosome inhibitor, 3-methyladenine, inhibits the BGT226-induced autophagy and led to the retrieval of colony survival (1). In a xenografted animal model, BGT226 delays tumor growth in a dose-dependent manner, along with suppressed cytoplasmic expression of p-p70 S6 kinase and the presence of autophagosome formation (1). BGT226 inhibits growth in common myeloma cell lines and primary myeloma cells at nM-concentrations in a time-dependent and dose-dependent manner (2). BGT226 also has a potent cytotoxic effect on normoxic and hypoxic hepatocarcinoma cells, inactivating p-Akt and p-S6 at less than 10 nM (3). 1. Chang, Tsai, Wu, *et al.* (2011) *Clin. Cancer Res.* 17, 7116. 2. Baumann, Schneider, Mandl-Weber, Oduncu & Schmidmaier (2012) *Anticancer Drugs* 23, 131. 3. Simioni, Cani, Martelli, *et al.* (2015) *Oncotarget* 6, 6597.

**BI397, See Dalbavancin****BI 2536**

This protein kinase inhibitor (FW = 521.66 g/mol; CASs = 755038-02-9, 876126-71-5; Solubility: 100 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named (R)-4-(8-cyclopentyl-7-ethyl-5-methyl-6-oxo-5,6,7,8-tetrahydropteridin-2-ylamino)-3-methoxy-N-(1-methylpiperidin-4-yl)benzamide, targets the Polo-like serine/threonine kinase Plk1 (IC<sub>50</sub> = 0.83 nM), bringing about G<sub>2</sub>/M cell-cycle arrest and cell death. 1. Steegmaier, *et al.* (2007) *Curr. Biol.* 17, 316. 2. Nappi, *et al.* (2009) *Cancer Res.* 69, 1916.

**BI-7273, Similar in action to BI-9564****BI-9564**

This potent, selective and cell-permeable BRD9 and BRD7 inhibitor (FW = 353.41 g/mol; CAS 1883429-22-8; Solubility: 20 mM in DMSO; 10 mM in 1 eq. HCl, with gentle warming), also named 4-[4-[(dimethylamino)methyl]-2,5-dimethoxyphenyl]-2-methyl-1,2-dihydro-2,7-naphthyridin-1-one, targets Bromodomain-containing proteins 9 and 7, with respective  $K_d$  values of 14 and 239 nM, and exhibiting higher selectivity for BRD9/7 versus 48 other bromodomains, 324 kinases, and 55 GPCRs. BRD9/7 are components of SWI/SNF (*or* *switch/sucrose nonfermentable*), a chromatin remodelling complex that also plays a role in oncogenesis. In acute leukemias, it was found that the SWI/SNF complex supports an oncogenic transcriptional program. In the absence of the SWI/SNF ATPase Brg1, leukemic cells arrest in G<sub>1</sub> and differentiate. Notably, BI-9564 shows efficacy in a xenograft model for acute myelogenous leukemia (AML). 1. Karim & Schönbrunn (2016) *J. Med. Chem.* 59, 4459. 2. Martin, Koegl, Bader, *et al.* (2016) *J. Med. Chem.* 59, 4462.

## BI 224436

This novel non-catalytic-site HIV integrase inhibitor (MW = 441.51 g/mol) targets the 3'-processing step, blocking interaction of LTR DNA with the enzyme as well as the interaction between the enzyme and the transcriptional coactivator LEDGF, without inhibiting strand-transfer (1). When tested against different laboratory strains of HIV-1, antiviral EC<sub>50</sub> values are below 15 nM. A 6000x higher BI 224436 concentration is required to evoke cytotoxicity. Antiviral potency is reduced by a factor of ~2.1 in the presence of 50% human serum. By virtue of its steep dose-response curve slope, however, BI 224436 exhibits serum-shifted EC<sub>50</sub> values ranging from 22 to 75 nM. This latter property reflects the fact that binding of BI 224436 is highly cooperative. EC<sub>50</sub> values are therefore only ~2.4x higher than their corresponding EC<sub>50</sub> values (*i.e.*, % Inhibition =  $\{I_{\max} \times [I]\} / \{[I]^n + (EC_{50})^n\}$ , with a Hill coefficient *n* of 4). Passage of virus in the presence of inhibitor gives rise to resistance substitutions mapping to a conserved allosteric pocket near the integrase's catalytic core. BI 224436 also retains full antiviral activity against recombinant viruses encoding well-known INSTI resistance substitutions. BI 224436 exhibits drug-like ADME properties *in vitro*. 1. Fenwick, Amad, Bailey, *et al.* (2014) *Antimicrob. Agents Chemother.* **58**, 3233.

## Biapenem

This novel, broad-spectrum carbapenem antibiotic (FW = 350.39 g/mol; CAS 120410-24-4), also named LJC10,627 and (4*R*,5*S*,6*S*)-3-(6,7-dihydro-5*H*-pyrazolo[1,2-*a*][1,2,4]triazol-8-ium-6-ylsulfanyl)-6-(1-hydroxyethyl)-4-methyl-7-oxo-1-azabicyclo[3.2.0]hept-2-ene-2-carboxylate, exhibits MIC values ranging from 0.1–25 µg/mL for 90% of tested members of the family *Enterobacteriaceae*, including ceftazidime-resistant strains (1). Biapenem is more stable than imipenem, meropenem and panipenem to hydrolysis by human renal dihydropeptidase-I (DHP-I), and therefore does not require the coadministration of a DHP-I inhibitor (2). Upon intravenous administration, biapenem penetrates well into various tissues (*e.g.*, lung tissue) and body fluids (*e.g.*, sputum, pleural effusion, abdominal cavity fluid). 1. Ubukata, Hikida, Yoshida M, *et al.* (1990) *Antimicrob. Agents Chemother.* **34**, 994. 2. Perry & Ibbotson (2002) *Drugs* **62**, 2221.

## Bicalutamide

This synthetic androgen (FW = 430.37 g/mol; CAS 90357-06-5; Solubility: 86 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known by its trade names Casodex<sup>®</sup>, Cosudex<sup>®</sup>, Calutide<sup>®</sup>, Kalumid<sup>®</sup>, and its systematic name, *N*-[4-cyano-3-(trifluoromethyl)phenyl]-3-[(4-fluorophenyl)sulfonyl]-2-hydroxy-2-methylpropanamide, is an androgen receptor antagonist (IC<sub>50</sub> = 0.16 µM), preventing binding of testosterone and other androgens, and has been used in the treatment of prostate cancer. Casodex does not cross the blood-brain barrier exists, excluding this antiandrogen from CNS sites of androgen negative feedback and accounting for its peripherally selective antihormonal profile. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Furr, Valcaccia, Curry, *et al.* (1987) *J. Endocrinol.* **113**, R7. 2. Freeman, Mainwaring & Furr (1989) *Brit. J. Cancer* **60**, 664.

## Bicarbonate

This carbonic acid monoanion (FW<sub>NaHCO<sub>3</sub></sub> = 84.01 g/mol CAS 144-55-8 (NaHCO<sub>3</sub> Salt); FW<sub>KHCO<sub>3</sub></sub> = 100.12 g/mol, CAS 298-14-6 (KHCO<sub>3</sub> Salt); FW<sub>NH<sub>4</sub>HCO<sub>3</sub></sub> = 79.06 g/mol, CAS 1066-33-7 (NH<sub>4</sub>HCO<sub>3</sub> Salt); and apparent pK<sub>a1</sub> of carbonic acid is 6.35 [Note that the true value is ~3.8.] and pK<sub>a2</sub> is 10.33 at 25°C) is a key physiological buffer in all living organisms. (**See also Carbon Dioxide; Carbonic Acid**) Aqueous solutions of sodium bicarbonate form carbon dioxide and sodium carbonate spontaneously ~20°C. **Target(s):** membrane dipeptidase (1); succinate dehydrogenase (2,6); glycosyl-phosphatidylinositol phospholipase D, *or* glycoprotein phospholipase D (3,28); glutamyl endopeptidase (4); glucose-6-phosphatase (5,17); *Ustilago sphaerogena* ribonuclease (7); ATP synthesis (8); glutamate dehydrogenase (9); aconitase (10,11); aspartate aminotransferase (12); carbonic anhydrase (13,18); *Clostridium pasteurianum* F<sub>1</sub>F<sub>0</sub> ATP synthase (14); creatine kinase (15); phosphoenolpyruvate carboxykinase (16); glucose-6-phosphate dehydrogenase (19,23); adenylo-succinate synthetase (20); acetyl-CoA synthetase, *or* acetate:CoA ligase (21); phosphoenolpyruvate mutase (22); threonine ammonia-lyase, *or* threonine dehydratase (24); oxaloacetate decarboxylase (25); fumarylacetoacetase (26); AMP deaminase (27); adenosine deaminase (27); phosphoprotein phosphatase (29); pyrophosphate-dependent phosphofructokinase, *or* diphosphate:fructose-6-phosphate 1-phosphotransferase (30); starch phosphorylase, weakly inhibited (31); glycine amidinotransferase (32); ferredoxin:NADP<sup>+</sup> reductase (33). 1. **BI-D1870**

This cell-permeant, ATP-competitive inhibitor (FW = 391.42 g/mol; CAS 501437-28-1; Solubility = 78 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as 2-[(3,5-difluoro-4-hydroxyphenyl)amino]-7,8-dihydro-5,7-dimethyl-8-(3-methylbutyl)-6(5H)-pteridinone, targets the p90 Ribosomal protein S6 Kinase α-1, 2, 3, and 4, or RSK1, RSK2, RSK3, and RSK4, with IC<sub>50</sub> values of 31 nM, 24 nM, 18 nM, and 15 nM, respectively (1). RSK isoforms are activated by Extracellular-signal-Regulated Kinases ERK1 and ERK2 in response to growth factors, phorbol esters and other agonists. BI-D1870 shows 10x to 100x selectivity for RSK over MST2, GSK-3β, MARK3, CK1 and Aurora B protein kinases. When tested *in vitro*, BI-D1870 exhibits IC<sub>50</sub> values for inhibits RSK1, RSK2, RSK3 and RSK4 are in the 10–30 nM (1). Although assumed to be a remarkably specific inhibitor of RSK isoforms, with a >500-fold greater selectivity over nine other AGC kinases, later work assessing the ability of BI-D1870 to protect enzyme active sites from alkylation demonstrated that several other kinases interact with BI-D1870 (2). Subsequent direct activity assays confirmed that SIK, Lok and Mst1 protein kinases are inhibited by BI-D1870 and that phosphorylation of some of their substrates is blocked by BI-D1870 in living cells (2). Such results suggest that the specificity of BI-D1870 cannot be taken for certain. 1. Gopal, Sapkota, Cummings & Newell (2007) *Biochem. J.* **401** (Pt 1), 29. 2. Edgar, Trost, Watts & Zaru (2013) *Biosci. Rep.* **34**, e00091.

**BIIB021**

This purine scaffold-based, orally available HSP90 inhibitor (FW = 318.76 g/mol; CAS 848695-25-0), known as 6-chloro-9-((4-methoxy-3,5-dimethylpyridin-2-yl)methyl)-9H-purin-2-amine and CNF2024, inhibits HSP90 with K<sub>i</sub> and EC<sub>50</sub> of 1.7 nM and 38 nM, respectively. **Primary Mode of Action:** BIIB021 binds within the ATP-binding pocket of Hsp90, interfering with its chaperone function and resulting in client protein degradation (including HER-2, Akt, and Raf-1), with consequential tumor growth inhibition. BIIB021 inhibits tumor cell proliferation with IC<sub>50</sub> from 0.06-0.3 μM. BIIB021 up-regulates expression of the heat shock proteins Hsp70 and Hsp27. BIIB021 depletes NF-κB and sensitizes Hodgkin's lymphoma cells

for natural killer cell-mediated cytotoxicity (2). BIIB021 also shows preferential cytotoxicity towards Kaposi's sarcoma-associated herpesvirus-associated primary effusion lymphomas (PEL) cells, as compared to non-PEL cells. BIIB021's cytotoxic effect against PEL is associated with induction of cell-cycle arrest and apoptosis (1). BIIB021 blocks the expression of a number of cellular proteins involved in cell cycle regulation and apoptosis. BIIB021 also blocks constitutive NF-κB activity present in PEL cells in part by blocking the interaction of vFLIP K13 with the IKK complex subunits. 1. Lundgren, Zhang, Brekken, *et al.* (2009) *Mol. Cancer Ther.* **8**, 921. 2. Böll, Eltaib, Reiners, *et al.* (2009) *Clin. Cancer Res.* **15**, 5108. 3. Gopalakrishnan, Matta & Chaudhary (2013) *Clin. Cancer Res.* **19**, 5016.

**BIIB037, See Aducanumab****Bikinin**

This ATP-competitive Arabidopsis GSK-3 inhibitor, (FW = 273.08 g/mol; CAS 188011-69-0), also named 4-(5-bromopyridin-2-ylamino)-4-oxobutanoic acid, is a strong activator of brassinosteroid (BR) signaling (1). Bikinin directly binds the GSK3 BIN2 and also inhibits the activity of six other Arabidopsis GSK3s. Genome-wide transcript analyses demonstrate that simultaneous inhibition of seven GSK3s is sufficient to activate BR responses (1). inhibited the SnRK2.3 kinase activity and its T180 phosphorylation *in vivo* by blocking BIN2 phosphorylation of SnRK2.3 on Thr-180 (2). 1. De Rybel, Audenaert, Vert, *et al.* (2009) *Chem Biol.* **16**, 594. 2. Cai, Liu, Wang, *et al.* (2014) *Proc. Natl. Acad. Sci. U.S.A.* **111**, 9651.

**Bilirubin**

This photosensitive tetrapyrrole metabolite (FW<sub>free-acid</sub> = 584.67 g/mol), also known as bilirubin IX<sub>α</sub>, is the primary bile pigment that is formed in heme degradation in the biliverdin reductase reaction. Billirubin is a free radical scavenger that protects membrane lipids and neurons from oxidatively generated radicals. **Target(s):** HIV-1 protease, K<sub>i</sub> = 0.8 μM (1); protoporphyrinogen oxidase (2,28); electron transport, as an uncoupler (3,12); glutathione S-transferase (4,5,7,15,17,29,31-34); prostaglandin-D synthase (6,22); lactoylglutathione lyase, or glyoxalase I (8); alcohol dehydrogenase (9); glutamate dehydrogenase (10); isocitrate dehydrogenase, NAD<sup>+</sup> (11); malate dehydrogenase (13,16,25); protein kinase A (14); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (18); 5'-nucleotidase (19); phospholipase A<sub>2</sub> (20); nitric-oxide synthase (21); protein kinase C (23,26); coproporphyrinogen III oxidase (24); aspartate aminotransferase (25); glycerol-3-phosphate dehydrogenase, mildly inhibited (25); uroporphyrinogen I synthase (27); biliverdin reductase, mildly inhibited (30); glucuronosyltransferase, substrate for UGT1A1 (35-38); 5-aminolevulinatase synthase (39). 1. ### Bilobalide

This plant natural product (FW = 326.30 g/mol; CAS 33570-04-6) from the ginkgo tree (*Ginkgo biloba*) is a terpene trilactone that exhibits anticonvulsant properties (1). Bilobalide has multiple mechanisms of action (e.g., acting as a GABAA receptor antagonist (1), preserving mitochondrial ATP synthesis, inhibiting staurosporine-induced apoptotic damage, suppressing hypoxia-induced membrane deterioration in the brain, and increasing the expression the mitochondrial DNA-encoded COX III subunit of cytochrome *c* oxidase and the ND1 subunit of NADH dehydrogenase). Bilobalide was later synthesized in E. J. Corey's laboratory in the late 1980s (2,3). **1.** Ivic, Sands, Fishkin, *et al.* (2003) *J. Biol. Chem.* **278**, 49279. **2.** Corey & Su (1987) *J. Amer. Chem. Soc.* **109**, 7534. **3.** Corey & Su (1988) *Tetrahedron Lett.* **29**, 3423.

**BIMT-17**, See *Flibanserine*

### Binimetinib

This MEK inhibitor (FW = 441.23 g/mol; CAS 606143-89-9; Solubility: 88 mg/mL DMSO, when warmed), also named MEK162, ARRY-162, ARRY-438162, and 5-((4-bromo-2-fluorophenyl)amino)-4-fluoro-*N*-(2-hydroxyethoxy)-1-methyl-1*H*-benzo[*d*]imidazole-6-carboxamide, targets Mitogen-Activated Protein Kinase Kinase (MAPKK), also known as MAP2K and MEK, which phosphorylates Mitogen-Activated Protein Kinase (MAPK). (IC<sub>50</sub> = 12 nM) and is the first targeted therapy to show activity in patients with NRAS -mutated melanoma. **1.** Ascierto, Schadendorf, Berking, *et al.* (2013) *Lancet Oncol.* **14**, 249.

**BIO**, See (2*Z*,3*E*)-6-Bromoindirubin-3'-oxime

### BIO 5192

This selective integrin inhibitor (FW = 832.82 g/mol; CAS Number = 327613-57-0; Soluble to 100 mM in DMSO and to 50 mM in 1eq. NaOH) targets integrin  $\alpha_4\beta_1$ , also known as Very Late Antigen-4 (VLA-4) with a  $K_d$  < 10 pM and IC<sub>50</sub> value of 1.8 nM. BIO 5192 shows high selectivity for  $\alpha_4\beta_1$  versus integrins  $\alpha_9\beta_1$  (IC<sub>50</sub> = 138 nM),  $\alpha_2\beta_1$  (IC<sub>50</sub> = 1053 nM),  $\alpha_4\beta_7$  (IC<sub>50</sub> > 500 nM), and  $\alpha_{11b}\beta_3$  (IC<sub>50</sub> > 10,000 nM). Integrin  $\alpha_4\beta_1$  plays an important role in inflammatory processes by regulating the migration of lymphocytes into inflamed tissues, suggesting that BIO 5192 offers a new way to treat human inflammatory diseases. Significantly, interruption of the Vascular Cell Adhesion Molecule-Very Late Antigen-4 (or VCAM-1/VLA-4) axis with BIO5192 results in a 30-fold increase in mobilization of murine hematopoietic stem and progenitors (HSPCs) over basal levels. A 3x enhancement of HSPC mobilization was observed when plerixafor (AMD3100), a small molecule inhibitor of the CXCR-4/SDF-1 axis, was combined with BIO5192. (See *Plerixafor*) Furthermore, the combination of granulocyte colony-stimulating factor (G-CSF), BIO5192, and plerixafor enhanced mobilization by 17x compared with G-CSF alone. **1.** Leone, Giza, Gill, *et al.* (2003) *J. Pharmacol. Exp. Ther.* **305**, 1150. **2.** Ramirez, Rettig, Uy, *et al.* (2009) *Blood* **114**, 1340. **IUPAC:** (2*S*)-2-[[[(2*S*)-1-[(3,5-dichlorophenyl)sulfonyl]-2-pyrrolidinyl]carbonyl]-amino]-4-[[[(2*S*)-4-methyl-2-[methyl[2-[4-[[[(2-methyl-phenyl)amino]carbonyl]-amino]phenyl]acetyl]amino]-1-oxopentyl]amino]butanoate

### Bipinnatins

Bipinnatin A

Bipinnatin B

Bipinnatin C

These furanocembrenolide-class diterpenes (FW<sub>Bipinnatin-A</sub> = 488.49 g/mol; CAS (Bipinnatin A) = 99552-28-0; FW<sub>Bipinnatin-B</sub> = 458.46 g/mol; CAS (Bipinnatin B) = 99552-24-6; FW<sub>Bipinnatin-C</sub> = 460.48 g/mol; CAS (Bipinnatin C) = 123483-20-5), isolated from the bipinnate sea plume *Antillogorgia bipinnata*, a sea fan found in the eastern Caribbean Sea, are naturally occurring marine neurotoxins that irreversibly inhibit nicotinic acetylcholine receptors by forming a covalent bond with Tyrosine-190 in the  $\alpha$ -subunit of the receptor (See also *Lophotoxin*). The parent species of the bipinnatins display little, if any, affinity for the nicotinic receptor. Preincubation of the toxins appeared to produce a single, relatively stable, active toxin species that irreversibly inhibited the two acetylcholine-binding sites on the nicotinic receptor with two distinguishable apparent pseudo first-order rates. The difference in the rates of irreversible inhibition of the two binding sites on the receptor was exploited to selectively inhibit one site for the pharmacological investigation of the other. The bipinnatins preferentially inhibited the binding site near the  $\alpha\delta$ -subunit interface that displays low affinity for metocurine and high affinity for acetylcholine. The bimolecular reaction constants for the interaction of the bipinnatins with the nicotinic receptor decreased in the order: Bipinnatin-B > Bipinnatin-A > Bipinnatin-C, for both acetylcholine-binding sites. The ratio of the bimolecular reaction constants for the two binding sites on the receptor was not the same for the three bipinnatins, suggesting that the reaction of the bipinnatins with the nicotinic receptor is sensitive to differences in the structure of the two acetylcholine-binding sites. 1. Groebe, Dumm & Abramson (1994) *J. Biol. Chem.* **269**, 8885.

### Birinapant

This rotationally symmetric SMAC mimetic antagonist and anticancer agent (FW = 806.94 g/mol; CAS 1260251-31-7) targets cellular Inhibitor of Apoptosis Protein (or cIAP1;  $K_d$  of <1 nM), arguably the most potent mammalian caspase inhibitor, showing single-agent efficacy due to its pan-IAP antagonism and causing rapid cIAP1 degradation, caspase activation, PARP cleavage, and NF- $\kappa$ B activation (1). When administered in combination with TNF- $\alpha$ , Birinapant is effective against a melanoma cell line with acquired resistance to BRAF inhibitors (2). 1. Allensworth, Sauer, Lyerly, Morse & Devi (2013) *Breast Cancer Res. Treat.* **137**, 359. 2. Krepler, et al. (2013) *Clin. Cancer Res.* **19**, 1784.

### 1,5-Bis(4-allyldimethylammoniumphenyl)pentan-3-one

This extremely hazardous quaternary amine (FW<sub>dibromide</sub> = 566.42 g/mol), also known as BW284c51, is a potent and selective inhibitor of acetylcholinesterase. It has also been used to ascertain the tissue localization of acetylcholinesterases in many organisms. **Target(s):** acetylcholine esterase (1-10); nicotinic acetylcholine receptors (11,12); cholinesterase, or butyrylcholinesterase (13-17); aryl-acylamidase (9). 1. ### trans-1,4-Bis(2-chlorobenzylaminomethyl)-cyclohexane

This cholesterol biosynthesis inhibitor (FW<sub>free-base</sub> = 151.16 g/mol), often referred to as AY-9944, selectively inhibits 7-dehydrocholesterol reductase (1,2,4-6), but also inhibits sterol  $\Delta^{24}$ -reductase (3) and cholesterol  $\Delta$  isomerase, or sterol  $\Delta^{7,8}$ -isomerase (7). 1. ### bis(2-Chloroethyl)ethylamine

This strong vesicant and chemical warfare agent (FW<sub>free-base</sub> = 170.08 g/mol), also known as nitrogen mustard, HN-1, and (2,2'-dichloro)triethylamine, is a liquid with a melting point of  $-34^{\circ}\text{C}$ . While the free base is only slightly soluble in water, the hydrochloride is very soluble. Bis(2-chloroethyl)ethylamine has a faint odor of fish and exhibits strong vesicant activity, albeit not as potent as sulfur mustard. HN-1 is reported to be a DNA and RNA alkylating agent, inhibit both transcription and translation. Although there are no reports that bis(2-chloroethyl)ethylamine has ever been used on the battlefield, several nations currently have stockpiles of sulfur and nitrogen mustards. **CAUTION:** Strong vesicant! Special training is required for safe handling. The free base of bis(2-chloroethyl)ethylamine should only be handled in a suitably vented chemical hood, and use of a gas mask is recommended. Fully protective clothing should be worn to prevent any possibility of contact with skin. **Target(s):** hexokinase (1,2); choline dehydrogenase (3,4). 1. McDonald (1955) *Meth. Enzymol.* **1**, 269. 2. Colowick (1951) *The Enzymes*, 1st ed. (Sumner & Myrbäck, eds.), **2** (Part 1), 114. 3. Singer (1963) *The Enzymes*, 2nd ed. (Boyer, Lardy & Myrbäck, eds.), **7**, 345. 4. Hatefi & Stiggall (1976) *The Enzymes*, 3rd ed. (Boyer, ed.), **13**, 175.

### 1,6-Bis(cyclohexyloximinocarbonylamino)hexane

This reagent (FW = 394.51 g/mol), also known as RHC-80267, RG 80267, and 1,6-di(O-(carbamoyl)cyclohexanone oxime)hexane, is a potent and selective inhibitor of diacylglycerol lipase activity in canine platelets ( $I_{50}$  = 4  $\mu\text{M}$ ) and in a variety of mammalian cells (1,2). It also inhibits glucose- and carbachol-induced insulin release from intact islets (3) and is an inhibitor of angiotensin II- and ATP-induced synthesis of 6-keto-prostaglandin F $1\alpha$ . **Target(s):** diacylglycerol lipase (1-8); lipase, or triacylglycerol lipase (8); lipoprotein lipase (8). 1. Shinoda, Suzuki, Oiso & Kozawa (1997) *Arterioscler. Thromb. Vasc. Biol.* **17**, 295. 2. Shinoda, Kozawa, Suzuki, et al. (1997) *Eur. J. Endocrinol.* **136**, 207. 3. ### Bisdethio-bis(methylthio)gliotoxin

This naturally occurring indole derivative (FW = 356.47 g/mol; CAS 74149-38-5), also known as bis(methylthio)gliotoxin and dimethylgliotoxin, is a platelet-activating factor (PAF) antagonist that inhibits PAF-induced platelet aggregation (1). The parent compound, gliotoxin is a dual inhibitor of farnesyltransferase and geranylgeranyl-transferase. Bisdethio-bis(methylthio)gliotoxin is a minor metabolite of *Gliocladium deliquescens*. Radiocarbon tracer experiments showed it is formed, apparently irreversibly, from gliotoxin (2). It has also been synthesized from gliotoxin by reduction and methylation. Bisdethio-bis(methylthio)gliotoxin also binds  $\text{Cu}^+$  and  $\text{Ag}^+$  ions. 1. Okamoto, Yoshida, Uchida, *et al.* (1986) *Chem. Pharm. Bull.* **34**, 340. 2. Kirby, Robins, Sefton & Talekar (1980) *J. Chem. Soc., Perkin Trans. 1*, 119.

### 1-(2-[Bis(4-fluorophenyl)methoxy]ethyl)-4-(3-phenylpropyl)piperazine

This piperazine derivative (FW<sub>free-base</sub> = 450.57 g/mol; supplied as the dihydrochloride salt), also known as GBR 12909 and vanoxerine, inhibits dopamine transport ( $K_i = 9$  nM). This high-affinity dopamine reuptake inhibitor was originally prepared in the late 1970s as a potential antidepressant, but was later considered for its use in treating cocaine addiction. **Target(s):** dopamine reuptake (1-3,6); TTX-sensitive  $\text{Na}^+$  channels (4; CYP2D1 (5)). 1. Borowsky & Kuhn (1993) *Brain Res.* **613**, 251. 2. Heikkila & Manzino (1984) *Eur. J. Pharmacol.* **103**, 241. 3. Reith, Coffey, Xu & Chen (1994) *Eur. J. Pharmacol.* **253**, 175. 4. Drugs* **1**, 241.

### (2R,3R,4R,5R)-N<sup>1</sup>,N<sup>6</sup>-Bis[(1S,2R)-2-hydroxy-1-indanyl]-2,5-bis[(2E)-3-(3,4-methylenedioxyphenyl)-2-propenyloxy]-3,4-dihydroxyhexane-1,6-diamide

This peptide analogue (FW = 788.81 g/mol) inhibits hemoglobin-degrading aspartic proteases, plasmepsin I and plasmepsin II ( $K_i = 0.5$  and 14 nM, respectively). It shows no measurable affinity to the human enzyme cathepsin D. 1. Ersmark, Feierberg, Bjelic, *et al.* (2004) *J. Med. Chem.* **47**, 110.

### (1 $\alpha$ ,2 $\beta$ ,3 $\alpha$ )-9-[2,3-Bis(hydroxy-methyl)-cyclobutyl]-guanine

This carbocyclic guanosine analogue (FW = 265.27 g/mol), also known as lobucavir, inhibits a number of viral DNA polymerases, after metabolism to form the triphosphate metabolite. It is also a carbocyclic analogue of oxetanocin G and has been used in the treatment of certain viral infections (*e.g.*, hepatitis B virus). **Target(s):** viral DNA polymerases (1-3); HSV-1 and HSV-2 replication (1,2); *Varicella zoster* virus replication (1,2); human cytomegalovirus replication (1,2). 1. Prisbe & Chen (1996) *Meth. Enzymol.* **275**, 425. 2. Field, Tuomari, McGeever-Rubin, *et al.* (1990) *Antiviral Res.* **13**, 41. 3. Terry, Cianci & Hagen (1991) *Mol. Pharmacol.* **40**, 591.

### 9-[2,3-Bis(hydroxymethyl)cyclobutyl]guanine Triphosphate

This carbocyclic analogue (FW<sub>free-acid</sub> = 504.20 g/mol) of oxetanocin G triphosphate, also known as lobucavir triphosphate, is likewise an analogue of guanosine 5'-triphosphate and a nonobligate chain terminator in viral DNA biosynthesis. **Target(s):** telomerase (1); DNA polymerase, viral (2-4); HIV reverse transcriptase (2). 1. Takahashi, Amano, Saneyoshi, Maruyama & Yamaguchi (2003) *Nucl. Acids Res. Suppl.* (3), 285. 2. Izuta, Shimada, Kitagawa, *et al.* (1992) *J. Biochem.* **112**, 81. 3. Seifer, Hamatake, Colono & Standing (1998) *Antimicrob. Agents Chemother.* **42**, 3200. 4. Terry, Cianci & Hagen (1991) *Mol. Pharmacol.* **40**, 591.

### Bislysine

This symmetric lysine analogue (FW = 348.49 g/mol) inhibits dihydrodipicolinate synthase (DHDPS), which catalyzes the condensation of pyruvate and  $\beta$ -aspartate semialdehyde (ASA) to form a cyclic product that dehydrates to form dihydrodipicolinate, the latter required for bacterial peptidoglycan biosynthesis in *Campylobacter jejuni*. DHDPS is allosterically regulated by lysine. This novel inhibitor is a mixed partial inhibitor with respect to pyruvate (the first substrate) and a noncompetitive partial inhibitor with respect to ASA. Bislysine binds to all forms of the enzyme with a  $K_i$  near 200 nM, >300x more tightly than lysine. Hill plots show its inhibition is cooperative, indicating that the allosteric sites are not independent, despite their distal locations on opposite sides of the protein tetramer. DHDPS<sup>Y110F</sup>, a mutant enzyme that is resistant to lysine inhibition, is strongly inhibited by this novel inhibitor, suggesting bislysine-based agents may be a promising strategy for antibiotic development. 1. Skovpen, Conly, Sanders & Palmer (2016) *J. Am. Chem. Soc.* **138**, 2014.

## 4,5-Bis(4-methoxyphenyl)-1,2-selenazole

This isoselenazole inhibits cyclooxygenase-1 ( $IC_{50} = 6$  nM), cyclooxygenase-2 ( $IC_{50} = 8$   $\mu$ M), and 5-lipoxygenase, or arachidonate 5-lipoxygenase ( $IC_{50} = 8$   $\mu$ M), portending their use as multi-target non-steroidal anti-inflammatory drugs (MTNSAIDs) which can intervene into the inflammatory processes via different mechanisms of action. 1. Scholz, Ulbrich & Dannhardt (2008) *Eur. J. Med. Chem.* **43**, 1152.

## 1,2-Bis(methylsulfonyl)-1-(2-chloroethyl)-2-[(methylamino)carbonyl]hydrazine

This antitumor prodrug (FW = 272.33 g/mol), also known as VNP40101M, generates a chloroethylating agent that alkylates DNA at the  $O^6$ -position of guanine residues. It also produces a carbamoylating agent, methyl isocyanate, which inhibits  $O^6$ -alkylguanine-DNA alkyltransferase. 1. Baumann, Shyam, Penketh, et al. (2004) *Cancer Chemother. Pharmacol.* **53**, 288.

## Bisoprolol

This oral cardio-specific  $\beta$ -blocker (FW<sub>free-base</sub> = 325.45 g/mol; CAS 66722-44-9; IUPAC: (RS)-1-[4-[(2-isopropoxyethoxy)methyl]phenoxy]-3-(isopropylamino)propan-2-ol), also named Zebet<sup>®</sup> (oral tablets as fumarate salt), selectively targets  $\beta_1$ -adrenergic receptors, blocking epinephrine stimulation of  $\beta_1$ -adrenoreceptors that are concentrated in the heart muscle cells and heart conduction tissue as well as kidney juxtaglomerular cells. Bisoprolol is used to treat hypertension, coronary heart disease, arrhythmias, ischemic heart diseases, and myocardial infarction after the acute event. Given such versatility, bisoprolol is understandably included in the World Health Organization's List of Essential Medicines. **Pharmacokinetics:** Bioavailability > 90%; Hepatic metabolism (50%) by CYP2D6 and CYP3A4; Biological  $t_{1/2} = 10$ -12 hours. 1. Bühring, Sailer, Faro, et al. (1986) *J. Cardiovasc. Pharmacol.* **8** (Supplement 11), S21-8. 3. Leopold (1986) *J. Cardiovasc. Pharmacol.* **8** (Supplement 11), S16-20. 2. Horikiri, Suzuki & Mizobe (1998) *J. Pharmaceut. Sci.* **87**, 289.

## Bis(oxalato)platinate(II), Potassium

This platinum(II) complex (FW = 449.32 g/mol; FW<sub>dihydrate</sub> = 485.35 g/mol; CAS 14244-64-5) slowly inactivates D-alanyl-D-alanine carboxypeptidase (or DD-peptidase) with a second-order rate constant of about  $0.06$   $M^{-1}s^{-1}$  at a single binding site near the active-site  $Zn^{2+}$ . 3-Mercaptopropionate (racemic) and 3-mercaptoisobutyrate (L-isomer) inhibit the enzyme competitively with  $K_i$  values  $\sim 5$  nM, whereas classical  $\beta$ -lactam compounds are very weak inhibitors. 1. Charlier, Dideberg, Jamoulle, et al. (1984) *Biochem. J.* **219**, 763.

## 2,3-Bis(phospho)-D-glycerate

This  $O_2$  transport modulator (FW<sub>free-acid</sub> = 266.04 g/mol; CAS 138-81-8), also called D-2,3-bisphosphoglycerate (2,3-BPG), D-glycerate 2,3-bisphosphate, and formerly 2,3-diphosphoglycerate, is an important intermediate (cofactor) in the reaction catalyzed by phosphoglycerate mutase (*Reaction:* 1,3-BPG  $\rightleftharpoons$  2,3-BPG), an enzyme unique to erythrocytes and placental cells. 2,3-BPG synthesis is enhanced at lower pH, a condition occurring during altitude-induced acidosis (hypoxia). The Bohr Effect, which defines the reciprocal binding of  $H^+$  and  $O_2$ , also suggests how preferential binding of 2,3-BPG to deoxygenated human hemoglobin A, thereby reducing the latter's affinity for  $O_2$ . By dumping a greater fraction of transported  $O_2$ , 2,3-BPG helps to attenuate circulatory and cerebral edema associated with severe bouts of Mountain Sickness. Phosphoglycerate mutase possesses a phosphatase activity, which is likely to reduce 2,3-BPG content at lower altitude or normal pH. (Diamox treatment favors the lowering of blood pH and elevation in 2,3-BPG within red blood cells). *Note:* 2,3-BPG also activates 3-hydroxy-3 methylglutaryl-CoA reductase, the rate-controlling enzyme (NADH-dependent, EC 1.1.1.88; NADPH-dependent, EC 1.1.1.34) in the mevalonate pathway producing cholesterol and other essential isoprenoids.

**Target(s):** 6-phosphofructokinase (1,13,18,35); acylphosphatase, or 1,3-diphosphoglycerate phosphatase (2,43,44); AMP deaminase (3,32,45); 3-phosphoglycerate kinase (4,59-61); casein kinase I (5); casein kinase II (6,7,21,24-26); hemoglobin oxygenation (8,9); inositol-polyphosphate 5-phosphatase, or inositol-1,4,5 trisphosphate 5-phosphatase (12,20,27,46-52); glucose-6-phosphate dehydrogenase (14); pyruvate kinase (15,19,30,66-68); phospholipase D (16); inositol 1,3,4-trisphosphate 5/6-kinase (17); phytase (22); 3-deoxy-7-phosphoheptulonate synthase, or 3-deoxy-D-arabinoheptulonate-7-phosphate synthetase (28); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (29,36,56-58); hexokinase (31,70,71); phosphoglucomutase (33,38-40); transaldolase (34); phosphopentomutase (37); aspartate ammonia-lyase,  $K_i = 1.1$  mM (41,42); phosphoinositide 5 phosphatase (53); [ $\beta$ -adrenergic-receptor] kinase, weakly inhibited (54,55); inositol-trisphosphate 3 kinase (62); glucose-1,6-bisphosphate synthase (63-65); glycerate kinase (69); glycogen synthase (72); starch phosphorylase (73); 1-deoxy-D-xylulose-5-phosphate synthase (74). 1. #### Bisulfite Ion

This anionic food preservative (FW = 104.06 g/mol (Sodium Salt); CAS 7631-90-5; Solubility = 0.42 g/mL) is a powerful antioxidant and food additive (E222 on the European Scale) that likewise inhibits many enzymes. Bisulfite ion has the same geometry as bicarbonate and metaphosphate. In winemaking and dried fruit preservation, sodium bisulfite releases sulfur dioxide gas to increase its bacterial and fungal killing action. (See also *Sulfur Dioxide; Metabisulfite*) In erythrocytes, anion transport of bisulfite and diffusion of its conjugate acid in the form of SO<sub>2</sub> make the rate of bisulfite influx through the anion exchange pathway at least 100-fold faster than sulfate ion. **Bisulfite Sequencing:** Providing the ability to analyze the methylation state of every cytosine accurately, bisulfite sequencing has become the gold standard for DNA methylation analysis. When coupled with next-generation sequencing technology, it allows for an unbiased genome-wide analysis of DNA methylation and various analyses can be performed on the altered sequence. Combining bisulfite treatment and high-throughput sequencing generates high-accuracy methylome, providing reference for differential DNA methylation analysis across large-scale samples. **Note:** Because bisulfite slowly oxidizes in air to form sulfate, reagent bottles should be tightly closed. Replace reagent after one year. **Target(s):** mannitol-1-phosphate dehydrogenase (1); hydroxylamine reductase (2); ethanolamine oxidase (3); acetoacetate decarboxylase (4); histidine ammonia-lyase (5,17,45,46); L-2-aminoadipate-6-semialdehyde dehydrogenase (6,22); amine oxidase (7,11); mannosidostreptomycin hydrolase (8); arylformamidase (9,50-53); urease (12); L-lactate dehydrogenase (13,27); glucose oxidase (14); cytochrome *c* oxidase, complex IV (15); carbonic anhydrase (16,36,38,39); aminomalotate decarboxylase, or aspartate 4-decarboxylase (18); cystathionine  $\gamma$ -lyase, or cysteine desulfhydrase (19,43); *Clostridium pasteurianum* F<sub>1</sub>F<sub>0</sub> ATP synthase (20); Lactoperoxidase (21); lipase (23); pyruvate decarboxylase (10,24); Arylsulfatase (25); formate dehydrogenase (26); glycogen phosphorylase (28); starch phosphorylase (28); papain (29); DNA

polymerase I (30); phospholipase A, lysosomal (31); phospholipase C (31,34); Lactoperoxidase (32); lysozyme (33); xanthine oxidase (35); F<sub>1</sub>F<sub>0</sub> ATP synthase, *Clostridium pasteurianum* (37); homogentisate dioxygenase (40); kynureninase (41); bisphosphoglycerate mutase (42); phenylalanine ammonia-lyase (44); urocanate hydratase, or urocanase (47); sphinganine-1-phosphate aldolase (48); acetoacetate decarboxylase (49); adenosylhomocysteinase (54); bisphosphoglycerate phosphatase (55); leucine aminotransferase (56); catechol oxidase (57); tyrosinase, or monophenol monooxygenase (57); nitronate monooxygenase (58); laccase (59); catechol oxidase (60-62); polyphenol oxidase (60-62); nitrate reductase, cytochrome (63). **1.** Wolff & Kaplan (1955) *Meth. #### Bivalirudin

This intravenously administered, direct thrombin inhibitor (FW = 2180.29 g/mol; CAS 128270-60-0; Sequence: FFRPGGGNGDFEEIPEEYL, with N-terminal D-phenylalanine), also known by its trade name Angiomax™, is a hirudin analogue and potent anticoagulant, exhibiting high potency (K<sub>i</sub> = 2 nM) by simultaneously occupying the fibrinogen-binding region of thrombin's active site and its anion-binding exosite. Angiomax is indicated

as a thrombin-specific anticoagulant to be used in patients taking aspirin with unstable angina undergoing percutaneous transluminal coronary angioplasty (PTCA). By inhibiting both thrombin's catalytic and exosite domains, bivalirudin enjoys antithrombotic potency that is a thousand times greater than achieved by inhibitors acting at either domain alone, (1). Bivalirudin is particularly at sites of deep arterial injury, and because it degraded proteolytically, its action ceases within 1 hour of its last dose. 1. Kelly, Maraganore, Bourdon, Hanson & Harker (1992) *Proc. Natl. Acad. Sci. U.S.A.* **89**, 6040.

**BIX01294**

This histone methyltransferase inhibitor ( $FW_{\text{free-base}} = 490.65 \text{ g/mol}$ ;  $FW_{\text{tri-HCl}} = 600.00 \text{ g/mol}$ ; CAS 935693-62-2; IUPAC: 2-(hexahydro-4-methyl-1H-1,4-diazepin-1-yl)-6,7-dimethoxy-N-[1-(phenylmethyl)-4-piperidinyl]-4-quinazolinamine) selectively targets G9a HMTase,  $IC_{50} = 1.7 \mu\text{M}$  (1), with lower inhibitory effectiveness against HMTase G9a-like protein (GLP;  $IC_{50} = 38 \mu\text{M}$ ). BIX01294 has little or no inhibitory effect on other known HMTases (1). Methylation of histone H3 at lysine 9 (H3K9) occurs in heterochromatin, which requires H3K9me<sub>3</sub>, and in euchromatin, which requires H3K9me<sub>1</sub> and H3K9me<sub>2</sub>, formed mainly by G9a and GLP. H3K9me<sub>1</sub> and H3K9me<sub>2</sub> are the only silencing marks lost when tumor suppressor genes in colorectal and breast cancer cells are reactivated after treatment with the DNA demethylation drug, 5-aza-2'-deoxycytidine. G9a HMTase and GLP are thus considered to be important druggable targets. Moreover, when used along with the calcium channel activator BayK8644, BIX01294 also facilitates the *in vitro* generation of induced pluripotent stem cells from somatic cells (2). The structural basis for BIX-01294 inhibition of G9a-like protein lysine methyltransferase is well understood (3). 1. Kubicek, O'Sullivan, August, *et al.* (2007) *Mol. Cell* **25**, 473. 2. Shi, Despoints, Do, *et al.* (2008) *Cell Stem Cell* **3**, 568. 3. Chang, Zhang, Horton, *et al.* (2009) *Nature Struct. Mol. Biol.* **16**, 312.

**BIX 02189**

This selective MEK/ERK pathway inhibitor ( $FW = 440.54 \text{ g/mol}$ ; CAS 1265916-41-3; Solubility: 100 mM in DMSO; 100 mM for monohydrochloride salt), also named (3Z)-3-[[[3-[(dimethylamino)methyl]phenyl]amino]phenylmethylene]-2,3-dihydro-N,N-dimethyl-2-oxo-1H-indole-6-carboxamide, targets Mitogen/Extracellular signal-regulated Kinase-5, or MEK5 ( $IC_{50} = 1.5 \text{ nM}$ ), and Extracellular-signal-Regulated Kinase, or ERK5 ( $IC_{50} = 59 \text{ nM}$ ), showing far weaker effects on MEK1 ( $IC_{50} = 6200 \text{ nM}$ ), MEK2 ( $IC_{50} = >6200 \text{ nM}$ ), ERK1 ( $IC_{50} >6200 \text{ nM}$ ), JNK2 ( $IC_{50} >6200 \text{ nM}$ ), TGF $\beta$ R1 ( $IC_{50} = 580 \text{ nM}$ ), EGFR ( $IC_{50} >6300 \text{ nM}$ ), and STK16 ( $IC_{50} >6300 \text{ nM}$ ) (1). **Pharmacology:** ERK5 is an atypical MAPK that is activated in the heart by pressure overload. ERK5 regulates cardiac hypertrophy and hypertrophy-induced apoptosis, and silencing ERK5 expression or inhibiting its kinase activity with BIX02189 reduces Myocyte Enhancer Factor-2 (MEF2) transcriptional activity and blunted hypertrophic responses in neonatal rat cardiomyocytes, or NRCMs (2). By applying BIX02189 to NRCMs, ERK5 phosphorylation is blocked without affecting other MAP kinases (2). BIX02189 induces apoptosis in acute

myeloid leukemia tumor cells without affecting T cells from healthy donors (3). 1. Tatakae, O'Neill, Kennedy, *et al.* (2008) *Biochem. Biophys. Res. Commun.* **377**, 120. 2. Kimura, Jin, Zi, *et al.* (2010) *Circ. Res.* **106**, 961. 3. Lopez-Royuela, Rathore, Allende-Vega, *et al.* (2014) *Int. J. Biochem. Cell Biol.* **53C**, 253.

**BKM-120, See Buparlisib****BKT140**

This orally bioavailable, disulfide cross-linked, polyphemusin-II-derived peptide antagonist (sequence shown above, with Nal = naphthylamine, Cit = citrulline, D-Lys = D-Lysine, and Cys = half-cystine), also known as 4-F-benzoyl-TN14003 and BL-8040, targets CXC Chemokine Receptor-4 (CXCR4), a G-protein-coupled receptor that is directly involved in tumor progression, tumor angiogenesis, metastasis, and cancer cell survival (1,2). **Primary Mode of Inhibitory Action:** CXCR4 is over-expressed in more than 70% of human cancers and its expression often correlates with disease severity. BKT140 exhibits high affinity ( $K_i = 0.8 \text{ nM}$ ) and a low rate of dissociation from its receptor. BKT140 prevents the binding of stromal derived factor-1 (SDF-1 or CXCL12) to CXCR4 activation, resulting in decreased tumor cell proliferation and migration. In addition, inhibition of CXCR4 may mobilize hematopoietic cell egress from the bone marrow and into blood. BKT140 significantly and preferentially stimulates multiple myeloma apoptotic cell death, as indicated by induced morphological changes, phosphatidylserine externalization, decreased mitochondrial membrane potential, caspase-3 activation, sub-G<sub>1</sub> cell-cycle arrest, as well as DNA double-stranded breaks (2). 1. **BL-4162A, See Anagrelide****BL-8040, See BKT140****Blasticidin S**

This pyrimidine antibiotic ( $FW = 422.43 \text{ g/mol}$ ; CAS 2079-00-7) from *Streptomyces griseochromogenes* inhibits protein biosynthesis through its action as a mixed-type noncompetitive inhibitor of the peptidyltransferase (1-10). Blasticidin S has been used to suppress rice blast disease. Structures of the large ribosomal subunit of *Haloarcula marismortui* at 3.0Å resolution indicate the poses taken by bound anisomycin, chloramphenicol, sparsomycin, blasticidin S, and virginiamycin M (9). Two hydrophobic crevices, one at the peptidyl transferase center and the other at the entrance to the peptide exit tunnel play roles in antibiotic binding. Blasticidin S base pairs with the P-loop and thereby mimics C74 and C75 of a P-site bound tRNA. Most ribotoxic antibiotics bind to sites that overlap those of either peptidyl-tRNA or aminoacyl-tRNA, consistent with their functioning as competitive inhibitors of peptide bond formation (13). The cytidine moiety of blastocidin S makes a Watson-Crick base-pair with the corresponding guanine base at the P-site of the 50S ribosome. Blasticidin S is enzymatically deaminated to its uracil-containing form, which cannot bind to the P-site and likewise lacks antibiotic activity. **Target(s):** peptidyltransferase (1-13); DNA biosynthesis (14); arginase (15); TMV RNA biosynthesis (16); ribonuclease P (17); cytidine deaminase (18). 1. ### (-)-Blebbistatin

This selective, cell-permeant, nonmuscle myosin II inhibitor (FW = 292.34 g/mol; CAS 674289-55-5) binds to myosin II, altering van der Waals contacts, destroying a critical salt bridge, and blocking the myosin's mechanochemical action. Blebbistatin inhibits contraction of the cleavage furrow without disrupting mitosis or contractile ring assembly (1). Blebbistatin therefore blocks cell blebbing rapidly and reversibly (1,2). Illumination of blebbistatin-treated bovine aortic endothelial cells at 365 and 450-490 nm, but not 510-560 or 590-650 nm, caused dose-dependent cell death (3). Illumination of blebbistatin alone at 365 and 450-490 nm changed its absorption and emission spectra, suggesting that the structure had been changed. While nontoxic, the resultant photochemicals no longer disrupted myosin distribution in cells, indicating consequential loss of blebbistatin's pharmacological activity. Fluorescence microscopy also demonstrated that upon illumination, blebbistatin became bound to cells and to protein-coated glass, suggesting its toxicity may arise, at least in part, from light-induced reactions. Blebbistatin should be used in a manner that controls for these photochemical effects. **Target(s):** myosin II ATPase,  $IC_{50} = 2 \mu M$  (1); [myosin light-chain] kinase (2). **1.** Straight, Cheung, Limouze, et al. ### Bleomycins

This set of glycopeptide antibiotics and anticancer agents (Bleomycin A<sub>1</sub>: FW = 1415.55 g/mol; CAS 11056-06-7; R = -NH(CH<sub>2</sub>)<sub>3</sub>-SOCH<sub>3</sub>); Bleomycin A<sub>2</sub>, R = -NH(CH<sub>2</sub>)<sub>3</sub>-S<sup>-</sup>CH<sub>3</sub>); Bleomycin B<sub>1</sub>, R = -NH(CH<sub>2</sub>)<sub>4</sub>-NCH(=NH)NH<sub>2</sub>); Bleomycin A<sub>5</sub>, R = -NH(CH<sub>2</sub>)<sub>3</sub>-NH(CH<sub>2</sub>)<sub>4</sub>-NH<sub>2</sub>); and Bleomycin A<sub>6</sub>, R = -NH(CH<sub>2</sub>)<sub>3</sub>-NH(CH<sub>2</sub>)<sub>4</sub>-NH(CH<sub>2</sub>)<sub>3</sub>-NH<sub>2</sub>), often abbreviated BLM and produced by *Streptomyces verticillus*, are DNA strand-breaking agents that exploit their interaction with Fe(II) ion. More than two-hundred bleomycins have been isolated from different strains of *Streptomyces*, with molecular weights ranging from 1000 to 10,000. Bleomycin's activity is associated with single-strand DNA cleavage through the generation of hydroxyl free radicals. Although the exact *in vivo* mechanism of bleomycin's action as an antineoplastic agent is unknown, available evidence indicates that the main mode of action is the inhibition of DNA synthesis with lesser effects arising from effects on RNA and protein synthesis. Bleomycin can stop the cell cycle at G<sub>2</sub> and is often used to induce synchrony in cell cultures. **Primary Mode of Action:** Bleomycin forms chelation complexes with Fe<sup>2+</sup>, Co<sup>2+</sup>, Cu<sup>2+</sup>, Ni<sup>2+</sup>, and Zn<sup>2+</sup>. Upon binding of a bleomycin-Fe<sup>2+</sup>-O<sub>2</sub> complex to DNA, the coplanar bithiazole moiety intercalates in the minor groove of DNA, whereupon the iron is oxidized to

Fe<sup>3+</sup>, and the resulting complex of bleomycin acts on deoxyribose. Bleomycin interacts with either Fe(II) and O<sub>2</sub> or Fe(III) and H<sub>2</sub>O<sub>2</sub> to form an activated complex that attacks DNA (1). Under aerobic conditions, both reactions yield similar quantities of free bases as well as products consisting of the base plus deoxyribose carbon-atoms 1 to 3. Under anaerobic conditions, activated bleomycin releases only free base. The yield of free base is the same under aerobic or anaerobic conditions, when DNA is in excess. When DNA concentration is limiting, more base is released under anaerobic than under aerobic conditions. Drug self-destruction proceeds as quickly and completely in the presence or absence of O<sub>2</sub>. **Pharmacokinetics:** Bleomycin is rapidly absorbed following intramuscular (IM) or subcutaneous (SC), administration reaching peak plasma concentrations in 30 to 60 minutes and exhibiting a systemic bioavailability of 100% (IM) and 70% (SC). Upon IV bolus administration, bleomycin is widely distributed, with a mean volume of distribution of 17.5 L/m<sup>2</sup>. Protein binding has not been studied. Bleomycin is inactivated by a cytosolic cysteine proteinase enzyme, bleomycin hydrolase, which is widely distributed in normal tissues (exception: skin and lungs, where toxicity is highest). **Target(s):** DNA polymerase (2,5,7,8,12); protein-glutamine  $\gamma$ -glutamyltransferase (transglutaminase), by bleomycin alone or copper-bleomycin (3); RNA polymerase (2,6,11); DNA ligase (4,7); dopamine  $\beta$ -monooxygenase (9); tyrosine monooxygenase (10). **1.** Burger, Peisach & Horwitz (1982) *J. ### BMN 673

This novel, orally bioavailable poly(ADP-ribose) polymerase, or PARP, inhibitor (FW = 380.35 g/mol; CAS 1207456-01-6), also known as (8*S*,9*R*)-5-fluoro-8-(4-fluorophenyl)-9-(1-methyl-1*H*-1,2,4-triazol-5-yl)-8,9-dihydro-2*H*-pyrido[4,3,2-*de*]phthalazin-3(7*H*)-one, targets PARP-mediated DNA repair pathway. By enhancing the accumulation of DNA strand breaks, BMN 673 promotes genomic instability, eventually leading to apoptosis. BMN 673 exhibits selective anti-tumor cytotoxicity and elicits DNA repair biomarkers at much lower concentrations than earlier generation PARP1/2 inhibitors, including olaparib, rucaparib and veliparib. BMN 673 shows remarkable anti-tumor activity *in vivo*, with strong action against xenografted tumors carrying defects in DNA repair due to BRCA mutations or PTEN deficiency. Synergistic or additive anti-tumor effects are observed, when BMN 673 was combined with temozolomide, SN38 or platinum drugs. **1.** Shen, Rehman, Feng, et al. (2013) *Clin. Cancer Res.* **19**, 5003.

### BMS-232632, See Atazanavir

### BMS-265246

This cyclin D-directed inhibitor (FW = 345.34 g/mol; CAS 582315-72-8; Solubility: 20 mg/mL DMSO; <1 mg/mL Water), also known systematically

as (4-butoxy-1*H*-pyrazolo[3,4-*b*]pyridin-5-yl)(2,6-difluoro-4-methylphenyl) methanone, targets CDK1/cyclin B and CDK2/cyclin E with  $IC_{50}$  of 6 nM and 9 nM, respectively. **Cyclin Target Selectivity:** Cdk1 (+++), Cdk2 (+++), Cdk3 (weak, if any), Cdk4 (+), Cdk5 (weak, if any), Cdk6 (weak, if any), Cdk7 (weak, if any), Cdk8 (weak, if any), Cdk9 (weak, if any), Cdk10 (weak, if any). **1.** Misra, *et al.* (2003) *Bioorg. Med. Chem. Lett.* **13**, 2405. **2.** Sutherland, *et al.* (2011) *Mol. Cancer Ther.* **10**, 242.

**BMS 566419**

This IMPDH inhibitor (FW = 487.58 g/mol; CAS 566161; Solubility: 50 mM in H<sub>2</sub>O (mono-HCl salt); 100 mM in DMSO (free base)), also named *N*-[1-[6-(4-ethyl-1-piperaziny)-3-pyridinyl]-1-methylethyl]-2-fluoro-9,10-dihydro-9-oxo-3-acridinecarboxamide, targets inosine monophosphate dehydrogenase isoform-2, a key enzyme in *de novo* guanosine nucleotide synthesis and required for neuron survival. Steady-state kinetics showed that BMS 566419 is a reversible uncompetitive inhibitor relative to IMP ( $K_i = 25$  nM). **1.** Watterson, Chen, Zhao, *et al.* (2007) *J. Med. Chem.* **50**, 3730.

**BMS-626529**

This novel small-molecule HIV-1 attachment inhibitor (FW = 473.49 g/mol; CAS 701213-36-7) is active against both CCR5- and CXCR4-tropic viruses and functions (1). HIV-1 attachment inhibitors represent a new class of drug candidates that prevent the initial interaction between virus and host cell by binding to the viral envelope protein gp120 and blocking attachment of the virus to the CD4 receptor on CD4<sup>+</sup> T-cells. The efficacy of BMS-626529 is virus-dependent, due to heterogeneity within gp120 (1). Genotypic substitutions in HIV-1 gp120 (*e.g.*, mainly Met-426-Leu or Ser-375-Met, with Met-434-Ile and Met-475-Ile contributing to a lesser extent) confer phenotypic resistance to BMS-626529 (2). A prodrug (**See BMS-663068**) is currently in clinical development. Administration of BMS-663068 for 8 days with or without ritonavir resulted in substantial declines in plasma HIV-1 RNA levels and was generally well tolerated (2). **1.** Nowicka-Sans, Gong, McAuliffe, *et al.* (2012) *Antimicrob. Agents Chemother.* **56**, 3498. **2.** Zhou, Nowicka-Sans, McAuliffe, *et al.* (2013) *J. Antimicrob. Chemother.* **69**, 573.

**BMS-663068**, See *Fostemsavir*

**BMS-707035**

This specific integrase (IN) inhibitor (FW = 410.42 g/mol; CAS 729607-74-3; Solubility: 38 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as *N*-[(4-fluorophenyl)methyl]-1,6-dihydro-5-hydroxy-1-methyl-6-oxo-2-(tetrahydro-1,1-dioxido-2*H*-1,2-thiazine-4-pyrimidinecarboxamide, targets HIV-1

integrase,  $IC_{50} = 15$  nM (1,2). **1.** Dicker, Samanta, Li, *et al.* (2007) *J. Biol. Chem.* **282**, 31186. **2.** Langley, Samanta, Lin, *et al.* (2008) *Biochemistry* **47**, 13481.

**BMS-708163**

This orally bioavailable, selective protease inhibitor (FW = 520.88 g/mol; CAS 1146699-66-2; Solubility: 100 mg/mL DMSO; <1 mg/mL Water; Formulation for Animal Studies: 99% PEG-400, 1% Tween-80 (in rats) or 94% labrafil-1944, 5% ethanol, 1% tween-80 (in dogs)), known as Avagacestat and (2*R*)-2-(*N*-(2-fluoro-4-(1,2,4-oxadiazol-3-yl)benzyl)-4-chlorophenylsulfonamido)-5,5,5-trifluoropentanamide, targets  $\gamma$ -secretase (GS), thereby inhibiting the formation of A $\beta$ 40 and A $\beta$ 42, with  $IC_{50}$  values of 0.3 nM and 0.27 nM, respectively. **1.** Gillman, Starrett, Parker, *et al.* (2010) *Med. Chem. Lett.* **1**, 120.

**BMS-790052**, See *Daclatasvir*

**BMS-791325**

This potent allosteric inhibitor (FW = 673.87 g/mol) targets hepatitis C virus NS5B polymerase  $IC_{50} < 0.5$  nM (biochemical assay) and  $EC_{50} = 0.8$ -6 nM (replicon assay). Unlike prior cyclopropyl-fused indolobenzazepine inhibitors, BMS-791325 has improved solubility and membrane permeability properties as well as reduced off-target activities, directed most notably against human pregnane X receptor (hPXR) transactivation. **1.** Gentles, Ding, Bender, *et al.* (2014) *J. Med. Chem.* **57**, 1855.

**BMS-936558**, See *Nivolumab*

**BMS-986001**

This nucleoside reverse transcriptase inhibitor, or NRTI (FW = 248.24 g/mol; CAS 1097733-37-3; *Symbol*: 4'-Ed4T), also known as 4'-ethynyl-d4T, OBP-601, festinavir, and 1-[(2*R*,5*R*)-5-ethynyl-5-(hydroxymethyl)-2*H*-furan-2-yl]-5-methylpyrimidine-2,4-dione, is a powerful anti-HIV-1 agent that is more active than the parent compound stavudine (d4T), while much less toxic to host cells (1). 4'-Ed4T is also to mitochondrial DNA synthesis. BMS-986001 is a better substrate for human thymidine kinase than d4T and is very much more resistant to catabolism by thymidine phosphorylase (1). Administration of BMS-986001 for 10 days resulted in substantial decreases

in plasma HIV-1 RNA levels for all dose groups and was generally well tolerated. (2). 1. Tanaka, Haraguchi, Kumamoto, Baba & Cheng (2005) *Antivir. Chem. Chemother.* **16**, 217. 2. Cotte, Dellamonica, Raffi, *et al.* (2013) *J. Acquir. Immune Defic. Syndr.* **63**, 346.

### Bocprevir

This oral HCV inhibitor (FW = 519.69 g/mol; CAS 394730-60-0), also named (1*R*,5*S*)-*N*-[3-amino-1-(cyclobutylmethyl)-2,3-dioxopropyl]-3-[2-(*S*)-[[[(1,1-dimethylethylamino) carbonyl]amino]-3,3-dimethyl-1-oxobutyl]-6,6-dimethyl-3-azabicyclo[3.1.0]hexane-2(*S*)-carboxamide, SCH 503034, and Victrelis™, selectively targets hepatitis C virus non-structural protein 3 (NS3) serine protease (1). **Primary Mode of Action:** The NS3 protease is required for cleavage and processing of most nonstructural hepatitis C proteins. SCH-503034 is a nonpeptidomimetic drug that initially binds to NS3/4A protease to form a low-affinity, reversible E-I complex ( $K_i = 5 \mu\text{M}$ ), followed by formation of a second higher-affinity (covalent) E-I complex ( $K_i = 20 \text{ nM}$ ). This increase in potency can be explained by its slow dissociation rate, forming complexes with a 5-hour dissociation half-life (2). Inhibitor potency correlated with changes in the buried surface area upon its binding to the active site, with greatest contributions to the binding energy arising from hydrophobic interactions of the P<sub>1</sub> and P<sub>2</sub> groups as they bind to the S<sub>1</sub> and S<sub>2</sub> pockets (3). 1. Venkatraman, Bogen, Arasappan, *et al.* (2006) *J. Med. Chem.* **49**, 6074. 2. Flores, Strawbridge, Ciaramella & Corbau (2009) *Biochim. Biophys. Acta* **1794**, 1441. 3. Madison, Prongay, Guo, *et al.* (2008) *J. Synchrotron Radiat.* **15** (Part 3), 204.

### BOL-303224-A, See Besifloxacin

### Bongkreic Acid

This toxic tricarboxylic acid (FW<sub>free-acid</sub> = 486.61 g/mol; CAS 11076-19-0), produced *Pseudomonas cocovenenans*, is a potent competitive inhibitor of the mitochondrial ATP-ADP translocator, effectively blocking nucleotide binding to the carrier (1-7). The name is derived from bongkreke, a moldy coconut product produced in Indonesia. The toxin accumulates when *P. cocovenenans* outgrows the mold. Klingenberg *et al.* (3) investigated bongkreke binding to mitochondrial membrane to examine the reorienting site mechanism. The inferred mode of inhibition requires bongkreke to bind to the single carrier site only from the inner face of the mitochondrial membrane (*i.e.*, the matrix side). They confirmed the pH-dependent accumulation of [<sup>3</sup>H]bongkreke inside the mitochondria which superimposes onto the binding at carrier sites. By breaking the membrane with Lubrol or sonication, binding to the carrier sites could be titrated, and a  $K_d$  value of approximately  $5 \times 10^{-8} \text{ M}$  was determined. The presence of ADP or ATP increases the amount of binding but does not alter the  $K_d$ . [<sup>35</sup>S]Atractylate is displaced by [<sup>3</sup>H]bongkreke at a 1:1 molar ratio; this displacement is dependent on ADP concentration with the  $K_m = 0.5 \times 10^{-6} \text{ M}$ . **See also Atractylaside** The isomer known as isobongkreic acid, which has a *cis*-double bond at the dicarboxylic acid end of the molecule, has similar biological activity. **Target(s):** Adenine nucleotide translocator, ADP/ATP carrier (1-5); ATPase (6); bromelain, stem (7); papain (7); ficain, or ficin (7). 1. ### Borate (Boric Acid)

This conjugate base (FW = 61.83 g/mol; CAS 11129-12-7) of boric acid is the likely consequence of boric acid acting as a Lewis acid (*i.e.*, as an electron pair acceptor), as does boron trifluoride, to form  $\text{B}(\text{OH})_4^-$ . Borate is soluble in cold water (1 g/18 mL) and inhibits many enzymes. The neutral species has been shown to inhibit urease by bridging the enzyme's pair of catalytic nickel ions. Boric acid also forms a complex with serine that inhibits  $\gamma$ -glutamyl transpeptidase. (**See also Serine-Borate Complex**) Sodium borate  $\text{Na}_2\text{B}_4\text{O}_7$ , also called sodium tetraborate, is often used as an antiseptic and detergent. The decahydrate is known as Borax. **Dionex BorateTrap™:** Because borate can be leached from borosilicate laboratory glassware, and because borate binds to vicinal hydroxyl groups in many carbohydrates, one cannot discount the possibility of borate effects on carbohydrate-utilizing enzymes. The Dionex BorateTrap is a  $4 \times 50 \text{ mm}$  column placed between the eluent pump and an HPLC injection valve to remove borate contamination from eluents. Its placed prior the injection valve assures that the trap will have no effect on the efficiencies or retention times of the carbohydrate analytes. The trap itself is packed 20- $\mu\text{m}$  high-capacity resin that has high selectivity for borate. The resin used in the BorateTrap is functionalized with a polyol capable of complexing borate in the presence of hydroxide. The BorateTrap eliminates peak tailing for mannose, fructose, and reduced monosaccharides, resulting from contamination of the eluent from borate. Therefore, the BorateTrap is highly recommended for optimal performance during carbohydrate analysis. **Target(s):** L-Iditol dehydrogenase (1); deoxyribonuclease I (2); glycerol-2-phosphatase (3); 5'-nucleotidase (4,32,76); steryl-sulfatase (5); aspartate-semialdehyde dehydrogenase (6);  $\gamma$ -glutamyltransferase, plant (7); clostripain (8,11); L-gulonolactone oxidase (9); dehydro-L-gulonate decarboxylase (10); catechol *O*-methyltransferase (12); alcohol dehydrogenase (13,28,41,51); catechol oxidase, or *o*-diphenol oxidase (14); arginase (15,18,19,56-59); peptide-*N*<sup>4</sup>-(*N*-acetyl- $\beta$  glucosaminyl)asparaginase (16); glutamyl endopeptidase (17); glutaminase (20); alkaline phosphatase (21,25,31); glycogen synthase (22); xanthine oxidase (23); carboxypeptidase B, above pH 8 (24); acid phosphatase (26,77-79); glucose-6-phosphatase (27); urease (29,36-38,55); formimidoylglutamase, or formimino-glutamase (30); phosphodiesterase (31); arylsulfatase A, or cerebroside-sulfatase (33); arylsulfatase B, or *N*-acetylgalactosamine-4-sulfatase (33); cholinesterase (34);  $\beta$ -lactamase (35); tyrosinase (40); glyceraldehyde-3-phosphate dehydrogenase (43); venom exonuclease (44); kynureninase, weakly inhibited (45); tetrahydrofolate synthetase (46,47); carboxy-*cis*-*mu*-conate cyclase, under acidic conditions (48); cyclamate sulfohydrolase (49); nucleotide diphosphatase (50); cytidine deaminase (52); methylenediurea deaminase (53); allantate deaminase (54); 4-methyleneglutaminase (60-62); pantothenase (63); bacterial leucyl aminopeptidase, weakly inhibited (64); aminopeptidase B (65); *N*-acetylgalactosamine-4-sulfatase, or arylsulfatase B (66,67); glycosulfatase (68); steryl-sulfatase, inhibited by metaborate and tetraborate (69-71); Arylsulfatase (72,73); 3-phosphoglycerate phosphatase (74); 3- or 4-phytase (75); alkaline phosphatase (80,81); arginine kinase (82); arginine:pyruvate transaminase (83); peptidyltransferase, weakly inhibited (84); protein-histidine *N*-methyltransferase, weakly inhibited (85); cyclopropane-fatty-acyl-phospholipid synthase (86); xanthine oxidase (87); 4 hydroxybenzoate 3-monooxygenase (88); lysine 2-monooxygenase (89); catechol 2,3-dioxygenase (90); catalase, weakly inhibited (91); catechol oxidase (92); polyphenol oxidase (92) 1. ### S-(2-Boronoethyl)-L-cysteine

This boronic acid-containing arginine analogue (FW = 190.00 g/mol; CAS 63107-40-4; *Abbreviation*: BEC) is a slow, tight-binding competitive inhibitor of arginase (*Reaction*: L-Arginine + H<sub>2</sub>O ⇌ Urea + L-Ornithine), the binuclear manganese metalloenzyme catalyzing the last step in the Urea Cycle. Upon binding, the boronic acid moiety undergoes nucleophilic attack by the enzyme's metal-bridging hydroxide ion, yielding a tetrahedral boronate anion that bridges the binuclear manganese cluster and mimics the tetrahedral intermediate (or a flanking transition state configuration) in arginase catalysis (1). BEC is also a potent inhibitor of human arginase II with *K<sub>i</sub>* values of 0.31 μM and 30 nM at pH 7.5 and 9.5, respectively (2). Inhibition of arginase by BEC increases the circulating concentration of arginine, thereby increasing nitric oxide synthesis and significantly enhancing NO-dependent smooth muscle relaxation in human penile corpus cavernosum. Arginase is thus a potential druggable target for the treatment of erectile dysfunction. 1. Kim, Cox, Baggio, *et al.* (2001) *Biochemistry* **40**, 2678. 2. Colleluori & Ash (2001) *Biochemistry* **40**, 9356.

### Bortezomib

This FDA-approved alkyl boronate drug for relapsed multiple myeloma (FW = 384.24 g/mol; CAS 179324-69-7; Solubility: 75 mg/mL DMSO; <1 mg/mL Water), also known as PS-341, Velcade, and [(1*R*)-3-methyl-1-((2*S*)-3-phenyl-2-[(pyrazin-ylcarbonyl)amino]propanoyl)amino]butyl] boronic acid, is a potent proteasome inhibitor. *K<sub>i</sub>* = 0.6 nM (1). **Mechanism of Action**: Bortezomib is an *N*-protected dipeptide and can be written as Pyz-Phe-boroLeu, where Pyz- is pyrazinonic acid, Phe is phenylalanine, and the last residue is a leucine analogue with a boronic acid in place of a carboxylic acid. It is the *sp*<sup>3</sup> orbital hybridization of the boronate that is thought to mimic a tetrahedral reaction intermediate, thereby conferring high-affinity binding (*K<sub>i</sub>* = 0.6 nM). **Pharmacodynamics**: Bortezomib-mediated 26S proteasome inhibition causes cell-cycle arrest and induces apoptosis in CD-30<sup>+</sup> anaplastic large cell lymphoma (2). Bortezomib-treated cells form aggregates of ubiquitin-conjugated proteins ("aggresomes") *in vitro* and *in vivo*, resulting in apoptosis. Bortezomib reverses defective G-CSF-triggered granulocytic differentiation of CD34<sup>+</sup> cells from CN patients *in vitro*, an effect that was accompanied by restoration of Lymphoid Enhancer-binding Factor-1 (LEF-1) protein levels and LEF-1 mRNA autoregulation. This inhibitory effect helped to define a novel mechanism of LEF-1 down-regulation in CN patients via enhanced LEF-1 protein ubiquitination and degradation by hyperactivated Signal Transducer/Activator of Transcription-5 (STAT5) (3). Bortezomib is currently used to eliminate malignant plasma cells in multiple myeloma patients. It is also effective in depleting both alloreactive plasma cells in acute Ab-mediated transplant rejection and their autoreactive counterparts in animal models of lupus and myasthenia gravis (MG). Significantly, bortezomib (at 10 nM or higher) kills long-lived plasma cells in cultured thymus cells from nine early-onset MG patients, consistently halting their spontaneous production of autoantibodies against the acetylcholine receptor, but also of total IgG (4). Bortezomib appears to be a promising treatment for MG and possibly other Ab-mediated autoimmune or allergic disorders, especially when given in short courses at modest doses before the standard immunosuppressive drugs have taken effect (4). 1. ### Botulinum Toxin

This bacterial toxin and neurotoxin (FW = 149.3 kDa; CAS 93384-43-1; abbreviated as BTX or BoNT) from Gram-positive *Clostridium botulinum* are ADP-ribosyltransferases and proteases that give rise to the clinical manifestations of botulism. **Classification:** BTX consists of seven antigenically and serologically distinct neurotoxins (types A, B, C<sub>1</sub>, C<sub>2</sub>, C<sub>3</sub>, D, E, F, and G) that are otherwise functionally and structurally similar. Human botulism is caused mainly by types A, B, E, and (rarely) F. Types C and D cause toxicity only in animals. Each botulinum toxin possesses individual potencies, necessitating special care to avoid medication errors. Recent changes to the established drug names by the FDA were intended to reinforce these differences and prevent medication errors. They include the following: exotoxins, which inhibit the release of catecholamines from the adrenal medulla and block the release of acetylcholine at neuromuscular junctions. The seven distinct types of exotoxin are now labeled A through G, each consisting of two peptide chains linked by a disulfide bond. Chain I of botulinum toxin C<sub>2</sub> catalyzes the ADP-ribosylation of G-actin and prevents actin polymerization. **Neurotoxic Effects:** Following the attachment of the botulinum toxin's heavy chain to one or more proteins on the exterior surface of axon terminals, the toxin is taken by neurons via endocytosis. The light chain cleaves endocytotic vesicles and enters the cytoplasm, where it proteolytically degrades the SNAP-25 protein, a type of SNARE protein involved in vesicle trafficking. SNAP-25 is essential for vesicle fusion, a step that is required for release of neurotransmitters, particular acetylcholine, from the axon endings. Botulinum toxin thereby prevents neurosecretory vesicles from docking/fusing with the nerve synapse plasma membrane and releasing their neurotransmitters. **Clinical Applications:** Injectable formulations of OnabotulinumtoxinA (INN generic name) are now used to treat blepharospasm or strabismus, to relieve neck pain, resulting from cervical dystonia, and for muscle stiffness in the elbow, wrist, and finger muscles in adult patients with upper limb spasticity. Botox is often employed to prevent chronic migraine and cosmetically to improve the appearance of deep facial lines or furrows between eyebrows and creases in the skin around the eyes. Patients with urinary incontinence and overactive bladder can also benefit from appropriate application. **Target(s):** catecholamine release (1,2); acetylcholine release (1,2); actin polymerization (3). 1. Wictome & Shone (1998) *Symp. Ser. Soc. Appl. Microbiol.* **27**, 87S. 2. Dressler, Saberi & Barbosa (2005) *Arq. Neuropsiquiatr.* **63**, 180. 3. Wille, Just, Wegner & Aktories (1992) *J. Biol. Chem.* **267**, 50.

### Botulinum Toxin C3 ADP-ribosyltransferase

This 211-residue bacterial toxin (MW = 23.5 kDa) catalyzes the ADP-ribosylation of small GTPases, particularly Rho-like proteins that control actin polymerization, cell motility, and related aspects of cancer cell metastasis. Treatment of cells with a cell-permeable chimeric C3 toxin led to complete localization of modified Rho to the cytosolic fraction based on the complexation of ADP-ribosylated Rho with the Guanin-nucleotide Dissociation Inhibitor-1 (GDI-1) (3). The modified complex was resistant to phosphatidyl-inositol 4,5-bisphosphate- and GTPγS-induced release of Rho from GDI-1. ADP-ribosylation therefore leads to entrapment of Rho in the GDI-1 complex. Note also that covalent modification is not the only mode of C3 action. Indeed, C3 transferases from *Clostridium botulinum* and *C.*

*limosum* form a GDI-like complex with the Ras-like low molecular mass GTPase Ral, inhibiting its action *without* ADP-ribosylation (4). 1. Aktories & Frevert (1987) *Biochem. J.* **247**, 363. 2. Schmiedebergs Arch. Pharmacol.* **374**, 347.

### Bouvardin

This cyclic hexapeptide antitumor agent (FW = 772.86 g/mol; CAS 64755-14-2), from *Bouvardia ternifolia* (scarlet bouvardia or trumpetilla), also known as NSC 259968, inhibits protein synthesis in intact eukaryotic cells and cell-free systems. Bouvardin inhibits EF<sub>1</sub>-dependent binding of aminoacyl-tRNA and EF<sub>2</sub>-dependent translocation of peptidyl-tRNA but does not affect the nonenzymic translocation since this reaction does not require EF<sub>2</sub>. Bouvardin contains L- and D-alanine, and N-methyl-L-tyrosine. 1. Jolad, Hoffman, Torrance, *et al.* (1977) *J. Amer. Chem. Soc.* **99**, 8040. 2. Chitnis, Alate & Menon (1981) *Chemotherapy* **27**, 126. 3. Zaera, Santamaria, Zalacain & Jimenez (1982) *Rev. Esp. Oncol.* **29**, 587. 4. Zalacain, Zaera, Vazquez & Jimenez (1982) *FEBS Lett.* **148**, 95.

### Bovine Pancreatic Trypsin Inhibitor

This monomeric 58-residue polypeptide (MW = 6511.44 g/mol; CAS 9087-70-1; Isoelectric Point = pH 10.5), known as Trasylol, forms an extremely tight complex with trypsin, chymotrypsin, kallikrein, and plasmin, blocking substrate access to their active sites (1-4). BPTI is a member of the pancreatic trypsin inhibitor (Kunitz) family, which is a family of serine protease inhibitors. (See *Trypsin Inhibitors; Aprotinin*) These proteins usually have conserved cysteine residues that participate in forming disulfide bonds at Cys<sub>5</sub>-Cys<sub>55</sub>, Cys<sub>14</sub>-Cys<sub>38</sub>, and Cys<sub>30</sub>-Cys<sub>51</sub>. One of the most stable proteins known, BPTI is inert to urea-, thermal- and acid-denaturation, the latter exhibiting a mid-point at 80 °C at pH 2.1 Surprisingly, this cationic protein also blocks magnesium channels required for growth by *Saccharomyces cerevisiae* and the human pathogen *Candida albicans* (5). **Mechanism of Inhibition:** BPTI may be classified as a slow-binding, active site-directed inhibitor. Bond angles in about seven residues near the BPTI N-terminus are distorted in such a way that they mimic key geometric aspects of substrate binding in trypsin's catalytic transition state. Stopped-flow kinetic studies using the prflavin-displacement assay (6), indicate that, at neutral pH, BPTI binds to trypsin in a diffusion-controlled reaction, with an initial dissociation constant of 10<sup>-5</sup> M, followed by slow isomerization to the final complex (*k* = 350 sec<sup>-1</sup>). The pre-equilibrium step contributes about one-third of the overall Gibbs energy change for formation of the final complex. The pH-dependence for BPTI-trypsin binding is explained by assuming that binding requires the unprotonated histidine residue in trypsin's active site. **Target(s):** trypsin (1,2,4); kallikrein (3,4); plasmin (3,4); chymotrypsin (4). 1. Kassell, Radicevic, Berlow, Peanasky & Laskowski (1963) *J. Biol. Chem.* **238**, 3274. 2. Kassell, Radicevic, Ansfield & Laskowski (1965) *Biochem. Biophys. Res. Commun.* **18**, 255. 3. ### Bowman-Birk Protease Inhibitors

These plant serpins (MW = ~8 kDa; CAS 37330-34-0) belong to MEROPS serine proteinase inhibitor family I12, clan IF and mainly inhibit serine peptidases of the S1 family, but also inhibit S3 peptidases (1-3). BBI family members have a duplicated structure, consisting of two topologically distinct inhibitory sites. They interact with target enzymes via an exposed surface loop that adopts the canonical proteinase inhibitory conformation. The net result is formation of an inactive noncovalent (or a cleaved and extremely tightly bound) protease-inhibitor complex. The interaction loop is a particularly well-defined, disulfide-linked, short β-sheet region (2), and

synthetic peptide mimics of the BBI have been prepared and investigated (4,5). 1. Rawlings, Tolle & Barrett (2004) *Biochem. J.* **378**, 705. 2. Brauer, Nievo, McBride, *et al.* (2003) *J. Biomol. ### Bozepinib

This potent antitumor agent (FW = 521.33 g/mol), systematically known as (*RS*)-2,6-dichloro-9-[1-(*p*-nitrobenzenesulfonyl)-1,2,3,5-tetrahydro-4,1-benzoxazepin-3-yl]-9*H*-purine, induces apoptosis in breast and colon cancer cells via inhibition ( $IC_{50}$  = 0.3–2  $\mu$ M) of the the double-stranded RNA-dependent protein kinase, PKR, but not p53. Moreover, interferon enhances cytotoxicity of bozepinib in colon and breast cancer cells by increasing apoptotic cell death. 1. Marchal, Carrasco, Ramirez, *et al.* (2013) *Drug Des. Devel. Ther.* **7**, 1301.

### BPTES

This synthetic allosteric inhibitor (FW = 524.68 g/mol; CAS 314045-39-1; Soluble to 20 mM in DMSO), also known as *N,N'*-[thiobis(2,1-ethanediy-1,3,4-thiadiazole-5,2-diy)]bisbenzeneacetamide, selectively targets glutaminase GLS1 ( $IC_{50}$  = 3.3  $\mu$ M), with weaker action against GLS2 and  $\gamma$ -glutamyl transpeptidase. The level of a splice variant of GLS1 (GAC) is elevated in certain cancers. BPTES induces cell death of P493 human lymphoma B cells *in vitro* and reduces tumor volume of P493 cell xenografts in mice. 1. Shukla, Ferraris, Thomas, *et al.* (2012) *J. Med. Chem.* **55**, 10551. 2. DeLaBarre, Gross, Fang, *et al.* (2011) *Biochemistry* **50**, 10764.

### BR-A-657, See Fimasartan

### Bradykinin Potentiating Peptide 5a

This snake venom pentapeptide (*Sequence: pyro-EKWAP*; FW = 611.69 g/mol) from *Bothrops jararaca* selectively potentiates the action of bradykinin and acts as a substrate inhibitor for angiotensin I-converting enzyme ( $K_i$  = 0.09  $\mu$ M for the human testicular enzyme). BPP<sub>5a</sub> is also a weak inhibitor (not substrate) of pyroglutamyl-peptidase II ( $K_i$  = 1.05 mM).

**Target(s):** peptidyl-dipeptidase A, or angiotensin I-converting enzyme (1-6); pyroglutamyl peptidase II (7). 1. Farias, Sabatini, Sampaio, *et al.* (2006) *Biol. Chem.* **387**, 611. 2. ### Bradykinin Potentiating Peptide 9a

This snake venom nonapeptide (FW = 1101.26 g/mol), also known as teprotide, V-6-1, and SQ-20881, from the venom of *Bothrops jararaca* potentiates the action of bradykinin, while inhibiting angiotensin I-converting enzyme ( $IC_{50}$  = 0.01  $\mu$ M for the human testicular enzyme). The corresponding octapeptide lacking one C-terminal proline residues also inhibits. 1. Farias, Sabatini, Sampaio, *et al.* (2006) *Biol. Chem.* **387**, 611. 2. Takada, Hiwada & Kokubu (1981) *J. ### Brassinazole

This triazole-type inhibitor (FW = 327.81; CAS 224047-41-0; Brz2001), systematically named 4-(4-chlorophenyl)-2-phenyl-3-[[1,2,4]triazol-1-yl]butan-2-ol, targets brassinosteroid biosynthesis. The latter are plant steroids and phytohormones that promote organ growth through their combined effect on cell expansion and division, plant architecture, vascular differentiation, fertility and flowering, photo-morphogenesis, tolerance to biotic and abiotic stresses, as well as senescence. Brassinazole's inhibitory action is reversed by brassinolide, which showed good recovery after addition brassinazole-treated plants. Although brassinazole is structurally similar to pacrobutrazol, a gibberellin biosynthesis inhibitor, it does not show any evidence of recovery upon addition of gibberellin. Brassinazole also induces morphological changes in dark-grown *Arabidopsis*. 1. Asami, Min, Nagata *et al.* (2000) *Plant Physiol.* **123**, 93.

### Brefeldin A

This fungal metabolite (FW = 280.36 g/mol; CAS 20350-15-6; Symbol: BFA; Solubility: 4 mg/mL (14 mM) DMSO; <1 mg/mL (<1 mM) H<sub>2</sub>O), isolated from *Penicillium brefeldianum*, *P. decumbens*, and *P. cyaneum*, inhibits activation of ADP-ribosylation factor (Arf), thereby disrupting the structure and function of the Golgi apparatus and inhibiting protein secretory traffic. Its effects are not limited to the Golgi apparatus, but are evident throughout the central vacuolar system, mainly by inducing tubule formation (or "tubulation") of the endosomal membrane vesicle system, the trans-Golgi network, and lysosomes. While BFA only modestly affects endocytic membrane transport in cultured fibroblasts, it profoundly alters endocytic pathways within polarized cells, such as MDCK cells. **Mechanism of Action:** ADP-ribosylation factors are found ubiquitously in eukaryotic cells. Although Arfs are initially formed as soluble elements within the cytosol, they undergo N-terminal myristoylation, allowing them to become firmly associated with Golgi and vesicle membranes. Arfs function as regulators of vesicular traffic and actin remodeling. A canonical GDP/GTP phosphoryl switch undergoes conformational changes within Arf Switch-1 and Arf Switch-2 regions, which tightly bind to the  $\gamma$ -phosphoryl of GTP, but only weakly, or not at all, bind GDP. Arf-GTP undergoes hydrolysis to generate Arf-GDP-P<sub>i</sub>, and the latter must dissociate and be replaced by GTP for the secretory interaction cycle to start anew. Unassisted Arf GDP-GTP exchange is very slow, however, requiring catalysis by a family of guanine nucleotide-exchange factors. Formation of transport vesicles carrying cargo proteins between the plasma membrane, the trans-Golgi network (TGN) and endosomes relies in part on vesicle coats containing clathrin and adaptor protein (AP) complexes. AP-1 is mainly found at the TGN, but also on endosomes and specialized granules, depending on the cell type. AP-3 is present on endosomal compartments and is involved in the trafficking of cargo proteins to lysosomes and lysosome-related organelles. Association of AP-1 and -3, but not AP-2, with the membrane of endosomes or the TGN is mediated by Arf1. Arfs contain a Sec7 domain that binds brefeldin A and disrupts trafficking and induces organelle disintegration. The net effect is that BFA alters membrane transport by inhibiting the association of vesicle coat proteins, thereby blocking the formation of transport vesicles. **Glucose Transporter Trafficking:** Brefeldin A also appears to regulate the trafficking of the GLUT4 glucose transporter, inducing its relocation from intracellular stores to the cell surface and inducing apoptosis in human cancer cells (operating on a p53-independent manner). GLUT4 redistribution is normally regulated by insulin-mediated signaling. BFA causes the activation of the insulin receptor, IRS-1, Akt-2, and AS160 components of the insulin

pathway. This response is mediated through phosphoinositol-3-kinase (PI3K) and Akt kinase, and BFA-mediated activation of the insulin pathway results in Akt-mediated phosphorylation of the insulin-responsive transcription factor FoxO1. This event leads to exclusion of FoxO1 from the nucleus, decreasing transcription of the insulin-responsive gene SIRT-1.

**Target(s):** guanine nucleotide-exchanging proteins (1-3); protein transport and processing (4,5); memapsin (6). 1. Pacheco-Rodriguez, Moss & Vaughan (2001) *Meth. Enzymol.* **329**, 300. 2. ### Brentuximab vedotin

This antibody-drug conjugate, *or* ADC (MW  $\approx$  151 kDa; CAS 914088-09-8; *Symbol*: cAC10-vcMMAE), also known by the trade name Adcetris<sup>®</sup>, is directed against CD30, a cell surface protein expressed in classical Hodgkin lymphoma (*or* HL) and systemic anaplastic large cell lymphoma (*or* sALCL). The chimeric monoclonal antibody cAC10 induces growth arrest of CD30<sup>+</sup> cell lines *in vitro* and has pronounced antitumor activity in severe combined immunodeficiency (SCID) mouse xenograft models of Hodgkin disease. Adcetris comprises an anti-CD30 monoclonal antibody joined by a protease-cleavable linker to monomethyl auristatin E (*or* MMAE), a cytotoxic agent. (See *Monomethyl Auristatin E*) The linker is stable in the bloodstream but releases MMAE upon internalization into CD30-expressing tumor cells, resulting in death of targeted cells. 1. Francisco, Cerveny, Meyer, *et al.* (2003) *Blood* **102**, 1458.

### Brevetoxins

This collection of cyclic polyether natural products (CASs = 98225-48-0 and 98112-41-5; *Symbol*: Btx or PbTx-2) from the dinoflagellate *Karenia brevis* consists of neurotoxins that bind to voltage-gated sodium channels, giving rise to neurotoxic shellfish poisoning. Symptoms include nausea, vomiting, slurred speech. Brevetoxins bind at a common binding site (*i.e.*, receptor-site 5) on the  $\alpha$ -subunit of this neuronal transmembrane protein. Once bound, the sodium channels remain permanently opened, at the resting membrane potential, which produces a continuous entry of sodium ions in most excitable cells. Such a sodium entry has various consequences on sodium-dependent physiological mechanisms, consisting in a membrane depolarization that, in turn, causes spontaneous and/or repetitive action potential discharges and thereby increases membrane excitability. These neuronal discharges may be transient or continuous depending on the preparation and the toxin tested (1-3). **Brevetoxin Types:** Btx-1 (*or* PbTx-1) = Btx A + R =  $-\text{CH}_2\text{C}(\text{=CH}_2)\text{CHO}$ , FW = 853.05 g/mol; Btx-2 (*or* PbTx-2) = Btx B + R =  $-\text{CH}_2\text{C}(\text{=CH}_2)\text{CHO}$ , FW = 881.06 g/mol; Btx-3 (*or* PbTx-3) = Btx B + R =  $-\text{CH}_2\text{C}(\text{=CH}_2)\text{CH}_2\text{OH}$ , FW = 852.98 g/mol; Btx-5 (*or* PbTx-5) = Btx B (acetylated at Position-38) + R =  $-\text{CH}_2\text{C}(\text{=CH}_2)\text{CH}_2\text{OH}$ , FW = 895.04 g/mol; Btx-6 (*or* PbTx-6) = Btx B (epoxide in place of double-bond at C27 & C28) + R =  $-\text{CH}_2\text{C}(\text{=CH}_2)\text{CH}_2\text{OH}$ , FW = 897.06 g/mol; Btx-7 (*or* PbTx-7) = Btx A + R =  $-\text{CH}_2\text{C}(\text{=CH}_2)\text{CH}_2\text{OH}$ , FW = 855.07 g/mol; Btx-8 (*or* PbTx-8) = Btx B + R =  $\text{CH}_2\text{COCH}_2\text{Cl}$ , FW = 903.50 g/mol; Btx-9 (*or* PbTx-9) = Btx B + R =  $-\text{CH}_2\text{CH}(\text{CH}_3)\text{CH}_2\text{OH}$ , FW = 885.09 g/mol; and Btx-10 (*or* PbTx-10) = Btx A + R =  $-\text{CH}_2\text{CH}(\text{-CH}_3)\text{CH}_2\text{OH}$ , FW = 857.08 g/mol. 1. ### Brevilin A

This naturally occurring sesquiterpenoid (FW = 346.40 g/mol; CAS 16503-32-5) from the volatile oils of the plant *Centipeda minima* inhibits (IC<sub>50</sub> = 10  $\mu\text{g/mL}$ ) STAT3 phosphorylation in the Jak/STAT transduction pathway of A549R cells. Brevilin A showed high specificity on Janus Kinase activity and following STAT3 signaling without directly affecting some other signals, including p65, AKT and GSK-3 $\beta$  phosphorylation, as well as Src kinase activity. Brevilin A is also an antibiotic with activity against *Giardia* (IC<sub>50</sub> = 16  $\mu\text{M}$ ) and *Entamoeba histolytica* (IC<sub>50</sub> = 4–9  $\mu\text{M}$ ). 1. Chen X, Du Y, Nan, *et al.* (2013) *PLoS One* **8**, e63697.

### Brexpiprazole

This serotonin-dopamine activity modulator, *or* SDAM (FW = 433.60 g/mol; CAS 913611-97-9), also known as OPC-34712, Rexulti<sup>®</sup>, 7-{4-[4-(1-benzothiophen-4-yl)piperazin-1-yl]butoxy}quinolin-2(1H)-one, is an atypical antipsychotic drug that acts as a dopamine D<sub>2L</sub> ( $K_i$  = 1.1 nM) and D<sub>3</sub> ( $K_i$  = 0.3 nM) receptor partial agonist and a partial agonist of 5-HT<sub>1A</sub> receptors ( $K_i$  = 0.12 nM). Brexpiprazole is also an antagonist of the 5-HT<sub>2A</sub> ( $K_i$  = 0.47 nM), 5-HT<sub>2B</sub> ( $K_i$  = 1.9 nM), 5-HT<sub>7</sub> ( $K_i$  = nM),  $\alpha_{1B}$ -adrenergic ( $K_i$  = 0.17 nM),  $\alpha_{2C}$ -adrenergic ( $K_i$  = 0.59 nM), and histamine H<sub>1</sub> receptors ( $K_i$  = 19 nM). It has negligible affinity for the mACh receptors. Rexulti is an FDA-approved add-on medication for major depressive disorder in adults. See *Aripiprazole* 1. Maeda, Sugino, Akazawa, *et al.* (2014) *J. Pharmacol. Exp. Ther.* **350**, 589.

### Brilacidin

This membrane-lyzing defensin mimetic (FW = 932.98 g/mol; CAS 1224095-98-0; IUPAC: *N,N'*-bis[3-[[5-(carbamimidoylamino)pentanoyl]amino]-2-[(3R)-pyrrolidin-3-yloxy]-5-(trifluoromethyl)phenyl]pyrimidine-4,6-dicarboxamide) is bactericidal (not simply bacteriostatic like most antibiotic) toward a broad spectrum of bacteria, but not mammalian cells. Brilacidin kills many Gram-positive bacteria including methicillin-resistant *Staphylococcus aureus* (MRSA) and *Enterococcus faecium* as well as Gram-negative bacteria, including *Escherichia coli* and *Klebsiella pneumoniae* (NDM). This action of this drug commend it for use in controlling Acute Bacterial Skin and Skin Structure Infections (ABSSSI). A five-day treatment course is usually effective in the treatment of many infections, and, given its direct membrane-disrupting action, bacteria are highly unlikely to acquire resistance to brilacidin. 1. Mensa, Howell, Scott & DeGrado (2014) *Antimicrob. Agents Chemother.* **58**, 5136.

**Brincidofovir**, See *Cidofovir*

### Brivanib

This ATP-competitive VEGFR inhibitor (FW = 370.38 g/mol; CAS 649735-46-6; Solubility: 74 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also named (*R*)-1-(4-(4-fluoro-2-methyl-1*H*-indol-5-yloxy)-5-methylpyrrolo[1,2-*f*][1,2,4]triazin-6-yloxy)propan-2-ol and Brivanib<sup>®</sup>, targets human Vascular Endothelial Growth Factor-2 Receptor, or VEGFR-2 (IC<sub>50</sub> = 25 nM; K<sub>i</sub> = 26 nM), with VEGFR-1 (IC<sub>50</sub> = 0.38 μM) and FGFR-1 (IC<sub>50</sub> = 0.148 μM) (1). Because brivanib has a high oral dose (60 mg/kg) relative to its intravenous dose (10 mg/kg), its alanine ester is a more effective oral drug (See *Brivanib Alanate*) (2). BMS-540215 is only weakly active against PDGFRβ, EGFR, LCK, PKCα or JAK-3, all with IC<sub>50</sub> values >1.9 μM. BMS-540215 selectively inhibits VEGF- and FGF-stimulated endothelial cell (HUVEC) proliferation *in vitro*, with respective IC<sub>50</sub> values of 40 and 276 nM (1). Furthermore, brivanib-induced growth inhibition was associated with a decrease in phosphorylated VEGFR-2 at Tyr(1054/1059), increased apoptosis, reduced microvessel density, inhibition of cell proliferation, and down-regulation of cell cycle regulators. The levels of FGFR-1 and FGFR-2 expression in these xenograft lines were positively correlated with its sensitivity to brivanib-induced growth inhibition (2). It also shows broad-spectrum *in vivo* antitumor activity over multiple dose levels and induces stasis in large tumors, with potential for treating hepatocellular carcinoma (HCC). 1. Bhide, Cai, Zhang, *et al.* (2006) *J. Med. Chem.* **49**, 2143. 2. Huynh, Ngo, Fargnoli, *et al.* (2008) *Clin. Cancer Res.* **14**, 6146.

### Brivanib Alanate

This dual VEGFR/FGFR inhibitor (FW = 441.46 g/mol; CAS 649735-63-7), also named (*S*)-(*R*)-1-((4-(4-fluoro-2-methyl-1*H*-indol-5-yl)oxy)-5-methylpyrrolo[2,1-*f*][1,2,4]triazin-6-yl)oxy)propan-2-yl 2-aminopropanoate, targets vascular endothelial growth factor receptor and fibroblast growth factor receptor tyrosine kinases, inducing growth inhibition in mouse models of human hepatocellular carcinoma (1). Brivanib-induced growth inhibition is associated with inactivation of VEGFR-2, increased apoptosis, a reduction in microvessel density, inhibition of cell proliferation, and down-regulation of cell cycle regulators, including cyclin D<sub>1</sub>, Cdk-2, Cdk-4, cyclin B1, and phospho-*c*-Myc. 1. Huynh, Ngo, Fargnoli, *et al.* (2008) *Clin. Cancer Res.* **14**, 6146.

### Brodifacoum

This potent vitamin K antagonist (FW = 523.43 g/mol; CAS 56073-10-0), also named Bromfenacoum, Superwarfarin, WBA 8119, and its IUPAC

name 3-[3-[4-(4-bromophenyl)phenyl]-1,2,3,4-tetrahydronaphthalen-1-yl]-2-hydroxychromen-4-one, is famously lethal 4-hydroxycoumarin anticoagulant and biologically active ingredient in rodenticides and rat baits, such as D-Con<sup>®</sup>, Prufe I<sup>®</sup> and Prufe II<sup>®</sup>, Ramik<sup>®</sup>, Talon-G<sup>®</sup>, Ratak<sup>®</sup>, and Contract<sup>®</sup>. (See *Dicumarol*) Its toxic potency is about 200x greater than warfarin, with a half-life as much as 60x longer. Such lethal and powerful action as a blood clotting inhibitor requires care to protect house pets and unintended animal targets. Baiting with medium oatmeal or wheat containing brodifacoum (0.0005–0.002 % wt/wt) completely controls infestations of warfarin-resistant rats on farms, when maintained until no longer required (1). Acute LD<sub>50</sub> values: rats (oral), 0.27 mg/kg body weight; mice (oral), 0.40 mg/kg; rabbits (oral), 0.30 mg/kg; cats (oral), 0.25 mg/kg; and dogs (oral), 0.25 mg/kg. Such potency led to its designation as extremely toxic. Moreover, its long biological half-life also qualifies brodifacoum as noxious environmental pollutant. In humans, brodifacoum is poorly responsive to the administration of vitamin K (2). 1. Rennison & Dubock (1978) *J. Hygiene (London)* **80**, 77. 2. Wallace, Worsnop, Paull & Mashford (1990) *Austral. New Zeal. J. Med.* **20**, 713.

### Bromazepam

This lipophilic valium-like benzodiazepine (FW = 316.20 g/mol; CAS 1812-30-2; IUPAC Name: 7-bromo-5-(pyridin-2-yl)-1*H*-benzo[e][1,4]diazepin-2(3*H*)-one), is a long-lasting anxiolytic agent used to treat anxiety or panic states. Like diazepam, bromazepam is a positive allosteric modulator of GABA<sub>A</sub> receptors, promoting GABA binding, which in turn increases the total conduction of chloride ions across the neuronal cell membrane. Like other benzodiazepines, bromazepam also inhibits the acetylcholine receptor-operated potassium current. Bromazepam is mainly metabolized by oxidative pathways within the liver. 1. Marketed as Lectopam<sup>®</sup>, Lexotan<sup>®</sup>, Lexilium<sup>®</sup>, Lexaurin<sup>®</sup>, Brazepam<sup>®</sup>, Rekotmil<sup>®</sup>, Bromaze<sup>®</sup>, Somalium<sup>®</sup> and Lexotanil<sup>®</sup>.

### Bromelain Inhibitors

This set of eight isoforms (MW = 5,700-5,900 g/mol, based on SDS polyacrylamide gel electrophoresis), from pineapple stem, inhibits bromelain. These inhibitors consist of a light chain (10 or 11 residues) and a heavy chain (40 or 41 residues) that are cross-linked with disulfide bonds. There are two distinct domains, each of which is formed by a three-stranded anti-parallel β-sheet. They are structurally related to the Bowman-Birk trypsin/chymotrypsin inhibitor. The K<sub>i</sub> value for bromelain inhibitor VI is 270 nM. **Target(s):** stem bromelain (1-3); papain (1); ficain (1). 1. Heinrikson & Kézdy (1976) *Meth. Enzymol.* **45**, 740. 2. Hatano, Sawano & Tanokura (2002) *Biol. Chem.* **383**, 1151. 3. Reddy, Keim, Heinrikson & Kézdy (1975) *J. Biol. Chem.* **250**, 1741.

### 2-Bromoacetamide

This alkylating agent (FW = 137.96 g/mol; CAS 683-57-8; MP = 88–90°C; Water-soluble) is a potent irreversible inhibitor of enzymes containing reactive thiols, ε-amino groups, and/or imidazole side-chain groups. In certain instances, methionyl residues also undergo alkylation. The reaction is typically a bimolecular process showing no evidence of the rate-saturation kinetics characteristic of affinity labeling reagents. The reactivity of sulfhydryl groups is usually highest, increasing in proportion to the fraction of the more nucleophilic thiolate species (optimal between pH 6 and 8.5). However, solution pH in excess of 8.5 should be avoided to minimize side-reactions, particularly with deprotonated amino groups. Because bromoacetamide slowly decomposes in aqueous solutions, fresh stock solutions should be prepared. **Note:** This compound must not be confusing with CH<sub>3</sub>-C(=O)N(H)Br, the common brominating agent N-

bromoacetamide. **Target(s):** alcohol dehydrogenase(1-3); arylamine *N*-acetyltransferase (4); papain (5). 1. Plapp (1982) *Meth. Enzymol.* **87**, 469. 2. Shaw (1970) *The Enzymes*, 3rd ed. (Boyer, ed.), **1**, 91. 3. Woronick (1961) *Acta Chem. Scand.* **15**, 2062. 4. Wang, Vath, Gleason, Hanna & Wagner (2004) *Biochemistry* **43**, 8234. 5. Glazer & Smith (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), **3**, 501.

#### **N<sup>6</sup>-(*p*-Bromoacetamidobenzyl)adenosine 5'-Monophosphate**

This haloacetylated nucleotide (FW<sub>free-acid</sub> = 573.30 g/mol) irreversibly inactivates dehydrogenases and kinases through its action at their respective NAD<sup>+</sup> and ATP binding. It also irreversibly labels the allosteric AMP activator site on muscle glycogen phosphorylase *b* with an attendant increase in enzyme activity. 1. Colman (1990) *The Enzymes*, 3rd ed., **19**, 283. 2. Suzuki, Eguchi & Imahori (1977) *J. Biochem.* **81**, 1147.

#### **2(R)-[2-(4'-Bromobiphenyl-4-yl)ethyl]-4(S)-(n-butyl)-1,5-pentanedioic Acid 1-(α(S)-tert-Butylglycine Methylamide) Amide**

This substituted peptidomimetic (FW = 531.58 g/mol), also known as 2(R)-[2-[4-(4-bromophenyl)phenyl]ethyl]-4(S) butylpentanedioate 1-((S)-tert-butylglycine methylamide) amide, inhibits gelatinase A (*K*<sub>i</sub> = 17 nM) and stromelysin 1 (*K*<sub>i</sub> = 11 nM). 1. Esser, Bugianesi, Caldwell, *et al.* (1997) *J. Med. Chem.* **40**, 1026.

#### **6-Bromo-2-(4-bromophenyl)-4-quinolinecarboxylic Acid**

This substituted quinoline analogue (FW<sub>free-acid</sub> = 407.06 g/mol) is a strong inhibitor of *Candida albicans* prolyl-tRNA synthetase (IC<sub>50</sub> = 25 nM, with high selectivity over the corresponding human enzyme). 1. Yu, Hill, Yu, *et al.* (2001) *Bioorg. Med. Chem. Lett.* **11**, 541.

#### **4S-[(6-Bromo-2H-chromene-3-carbonyl)amino]-5-(2-oxopyrrolidin-3S-yl)pent-2-enoic Acid Ethyl Ester**

This Michael acceptor-containing ester (FW = 462.08 g/mol) irreversibly inhibits picornain 3C. No cytotoxicity is observed at the limits of the assay concentration. A crystal structure of one of the more potent inhibitors covalently bound to HRV-2 3CP is also provided. 1. Johnson, Hua, Luu, *et al.* (2002) *J. Med. Chem.* **45**, 2016.

#### **Bromocolchicine**

This halogenated mitotic spindle poison (FW = 478.34 g/mol) is a highly specific affinity label for tubulin, blocking tubulin polymerization and microtubule assembly (See also Colchicine). 1. Schmitt & Atlas (1976) *J. Mol. Biol.* **102**, 743. 2. Atlas & Schmitt (1977) *Meth. Enzymol.* **46**, 567.

#### **Bromocriptine**

This nonspecific monoamine receptor agonist and lactation inhibitor (FW = 654.60 g/mol; CAS 25614-03-3), also known as (5 $\alpha$ )-2-bromo-12'-hydroxy-5'-2-methylpropyl)-3',6',18-trioxo-2'-(propan-2-yl)-ergotaman, inhibits the release of glutamate, by reversing the glutamate GLT1 transporter (1). An ergoline derivative, bromocriptine dose-dependently inhibits d-[<sup>3</sup>H]aspartate release elicited by chemical anoxia or high KCl, while no changes occurred in uptake. The inhibitory action of bromocriptine is unaffected by sulpiride, a dopamine D<sub>2</sub> receptor antagonist. On the other hand, bromocriptine is without effect on swelling-induced d-[<sup>3</sup>H]aspartate release, which is mediated by volume-regulated anion channels. *In vivo*, bromocriptine suppresses the excessive elevation of glutamate levels in gerbils subjected to transient forebrain ischemia in a manner similar to DHK. Taken together, such results provide evidence that bromocriptine inhibits excitatory amino acid release via reversed operation of GLT-1 without altering forward transport (1). In Europe, use of bromocriptine to inhibit lactation is restricted to situations in which breastfeeding must be stopped for medical reasons. **Agonist Targets:** Dopamine Receptor Family: D<sub>1</sub> (*K*<sub>i</sub> = 680 nM); D<sub>2</sub> (*K*<sub>i</sub> = 500 nM); D<sub>2</sub> (*K*<sub>i</sub> = 3 nM); D<sub>3</sub> (*K*<sub>i</sub> = 5.4 nM); D<sub>4</sub> (*K*<sub>i</sub> = 330 nM); Serotonin Receptor Family: 5-HT<sub>1A</sub> (*K*<sub>i</sub> = 13 nM); 5-HT<sub>1B</sub> (*K*<sub>i</sub> = 355 nM); 5-HT<sub>1D</sub> (*K*<sub>i</sub> = 11 nM); 5-HT<sub>2A</sub> (*K*<sub>i</sub> = 107 nM); 5-HT<sub>2B</sub> (*K*<sub>i</sub> = 56 nM); 5-HT<sub>2C</sub> (*K*<sub>i</sub> = 740 nM); 5-HT<sub>6</sub> (*K*<sub>i</sub> = 33 nM); Adrenergic  $\alpha$  Receptor Family:  $\alpha_{1A}$  (*K*<sub>i</sub> = 4 nM);  $\alpha_{1B}$  (*K*<sub>i</sub> = 1.4 nM);  $\alpha_{1D}$  (*K*<sub>i</sub> = 1.1 nM);  $\alpha_{2A}$  (*K*<sub>i</sub> = 11 nM);  $\alpha_{2B}$  (*K*<sub>i</sub> = 35 nM);  $\alpha_{2C}$  (*K*<sub>i</sub> = 28 nM); Adrenergic  $\beta$  Receptor Family:  $\beta_1$  (*K*<sub>i</sub> = 590 nM); and  $\beta_2$  (*K*<sub>i</sub> = 740 nM). 1. Shirasaki, Sugimura, Sato, *et al.* (2010). *Eur. J. Pharmacol.* **643**, 48.

**5-Bromo-2'-deoxyuridine**

This pyrimidine nucleoside (FW = 307.10 g/mol), abbreviated as 5BrdU and also known as broxuridine, is metabolized to 5-bromo-2'-deoxyuridine 5'-triphosphate (**See below**), which is enzymatically incorporated into DNA, replacing thymidine in the process and rendering the DNA product sensitive to visible light (1). 5BrdU also inhibits cell differentiation. **Indirect Detection of Intracellular DNA Synthesis:** 5-Bromodeoxyuridine substitutes for pyrimidine bases during DNA synthesis, a property permitting the detection of cells in S-phase using BrdU-specific antibodies: **Step-1.** Incubate cells with 10  $\mu$ M BrdU for 30-120 min. **Step-2.** Wash three times with 2-3 mL PBS (One liter containing 8.01 g/L sodium chloride, 0.2g KCl; 1.78g  $\text{Na}_2\text{HPO}_4 \cdot 2\text{H}_2\text{O}$ , 0.27g  $\text{KH}_2\text{PO}_4$ , adjusted to pH 7.4). **Step-3.** Fix cells in 2-4% paraformaldehyde for 5 min. **Step-4.** Wash again in PBS. **Step-5.** Denature with 2 M HCl for 30 min at 37°C. **Step-6.** Rinse away HCl. **Step-7.** Neutralize by washing three times with one mL borate buffer (0.1 M, pH 8.5, 5 min). **Step-8.** Wash three more times with PBS. **Step-9.** Wash again PBS, containing 0.1% (w/v) Tween-20 and 2% Serum, incubating for 30 min at 37°C. **Step-10.** Aspirate away the buffer, and incubate with anti-BrdU antibody (Pierce Monoclonal Antibody BU-1 Catalog Number MA3-071; Nominal titer = 1:1,000 to 1:2,000) for 1-2 hr at room temperature. **Step-11.** Remove antibody by three washes with PBS/Tween-20. **Step-12.** Incubate with secondary antibody, for 30-40 at room temperature. **Step-13.** Wash three more times with PBS/Tween-20. **Step-14.** Stain with DAPI, wash, and mount. **Target(s):** viral DNA polymerase, via its 5'-triphosphate (2); dihydroorotase (3); thymidine kinase (4,5,12-14); DNA biosynthesis (6,7); deoxycytidine deaminase (8); cytidine deaminase (9); dTMP kinase, or thymidylate kinase (10,11);  $\text{NAD}^+$  ADP-ribosyltransferase, or (poly(ADP-ribose) polymerase (15); thymidine phosphorylase (16). **See also 5-Ethynyluridine** 1. **5-Bromo-2'-deoxyuridine 5'-Triphosphate**

This halogenated dUTP derivative (FW<sub>free-acid</sub> = 547.04 g/mol; Soluble in water), often abbreviated 5-Br-dUTP, is a useful probe of DNA biosynthesis (**See entry above**). Brominated nucleotides inhibit DNA replication by acting as poor alternative substrates, resulting in their incorporation into DNA. Modified DNA is produced and cell growth is inhibited. 5-Br-dUTP should be stored in a desiccator in the cold and protected from light. **Target(s):** dCMP deaminase (1); DNA polymerase (2); thymidine kinase (3). 1.

**S-(4-Bromo-2,3-dioxobutyl)-Coenzyme A**

This haloketone-containing acyl-CoA analogue (FW = 884.47 g/mol) is an irreversible inhibitor for several enzymes that bind short-chain fatty-acyl-CoA substrates (1-8). Note that the fatty acid-like chain is joined to Coenzyme A by a thioether linkage, not a thiolester bond. A convenient chemical synthesis has been described (3). **Target(s):** acetyl-CoA carboxylase (1,3); fatty-acid synthase (2,3,5-7); citrate synthase (3,4); acetyl-CoA hydrolase (3); acetoacetyl-CoA thiolase (3); 3-hydroxy-3-methylglutaryl-CoA reductase (4);  $\beta$ -oxoacyl synthase (condensing) (5,6);  $\beta$ -oxoacyl reductase (5);  $\beta$ -hydroxyacyl dehydratase (5); enoyl reductase (5); carnitine *O*-palmitoyltransferase (8). 1. **2-(4-Bromo-2,3-dioxobutylthio)adenosine 2',5'-Bisphosphate**

This synthetic nucleotide (FW<sub>free-acid</sub> = 622.24 g/mol) is an affinity label for isocitrate dehydrogenase ( $\text{NADP}^+$ ). Biphasic inactivation kinetics are observed, with a fast initial phase resulting in partially active enzyme (6-7% residual activity), followed by a slower phase leading to total inactivation. The inactivation rate constant exhibits a nonlinear dependence on reagent concentration, consistent with the formation of a reversible complex with the enzyme prior to irreversible modification. The enzyme incorporates this reagent to a limited extent and is protected against inactivation by  $\text{NADP}^+$  and NADPH. 1. Bailey & Colman (1987) *Biochemistry* **26**, 6858.

**Bromo-enol lactone**

This alkylating agent (FW = 317.18 g/mol; CAS 88070-98-8;  $\lambda_{\text{max}}$  = 224 nm; Symbol = BEL) inactivates phospholipase  $\text{A}_2$ , or  $\text{PLA}_2$ , in a linear, time-dependent manner. Inactivation of the  $\text{PLA}_2$  by 5,5'-dithiobis(2-nitrobenzoic acid) before treatment with [ $^3\text{H}$ ]BEL results in the near complete lack of radiolabel incorporation, a finding that is fully consistent with covalent irreversible suicide inhibition of the enzyme. Labeling of the 80-kDa band rather than 40-kDa band distinguishes the macrophage  $\text{Ca}^{2+}$ -independent  $\text{PLA}_2$ , providing strong evidence that the 80-kDa protein is the catalytic subunit (1). BEL also inhibits cellular phosphatidic acid phosphohydrolase (PAP) activity in P388D1 macrophages ( $\text{IC}_{50}$  = 8  $\mu$ M), blocking incorporation of exogenous arachidonate and palmitate into diacylglycerol and triacylglycerol (2). 1. #### 4-(4-Bromo-2-fluorophenylamino)-3-fluoro-1-methyl-pyridin-2(1H)-one 5-(O-cyclopropylmethyl)hydroxamate

This methylpyridinone (FW = 428.23 g/mol) inhibits mitogen-activated protein kinase kinase (IC<sub>50</sub> = 6.8 nM). This inhibitor exhibits excellent cellular potency and good pharmacokinetic properties. It inhibits ERK phosphorylation in HT-29 tumors from mouse xenograft studies. 1. Wallace, Lyssikatos, Blake, *et al.* (2006) *J. Med. Chem.* **49**, 441.

#### 4-Bromo-3-hydroxybenzoyloxamine

This substituted hydroxylamine (FW = 218.05 g/mol), also known as *O*-(4-bromo-3-hydroxybenzyl)hydroxylamine,  $\alpha$ -(aminooxy)-6-bromo-*m*-cresol, NSD 1055, Brocresine, and Bromcresine, inhibits 5-aminolevulinic acid aminotransferase (1), arginine decarboxylase (2,15,16), histidine decarboxylase (3,6,7,9), diamine oxidase (3), phosphatidylserine decarboxylase (4), aromatic-L-amino-acid decarboxylase (Dopa decarboxylase (5,7,14), *S*-adenosylmethionine decarboxylase (8,12,13), threonine ammonia-lyase, or threonine dehydratase (10), phenylalanine decarboxylase (11), and dihydroxyphenylalanine aminotransferase (17). 1. #### 6-Bromoindirubin-3'-oxime

These protein kinase inhibitors (FW<sub>BIO</sub> = 356.19 g/mol; CAS 667463-62-9; Solubility: 70 mg/mL DMSO, <1mg/mL H<sub>2</sub>O), also known as BIO, 6BIO, and systematically as 6-bromo-3-[(3*E*)-1,3-dihydro-3-(hydroxyimino)-2*H*-indol-2-ylidene]-1,3-dihydro-(3*Z*)-2*H*-indol-2-one, targets glycogen synthase kinase-3 (or GSK-3), with an IC<sub>50</sub> value of 5 nM for  $\alpha$  and  $\beta$  forms. BIO also shows greater than 16x selectivity over CDK5 and is also a weaker pan-JAK inhibitor, with IC<sub>50</sub> values of 30 nM, 1.5  $\mu$ M, 8.0  $\mu$ M, and 0.5  $\mu$ M for TYK2, JAK1, JAK2 and JAK3 (1,2). (See the structural related inhibitor 1-Azakenpaullone) BIO, but not 1-methyl-BIO, closely mimicked Wnt signaling in *Xenopus* embryos (1,2). BIO-induced apoptosis of human melanoma cells is associated with reduced phosphorylation of JAKs and STAT3 in both dose- and time-dependent manners. Consistent with inhibition of STAT3 signaling, expression of the anti-apoptotic protein Mcl-1 was down-regulated. **Maintaining Embryonic Stem Cells Pluripotency:** Human and mouse embryonic stem cells (ESCs) self-renew indefinitely

while maintaining the ability to generate all three germ-layer derivatives. Importantly, Wnt pathway activation by BIO is sufficient to maintain the undifferentiated phenotype in both types of ESCs and sustains expression of the pluripotent state-specific transcription factors Oct-3/4, Rex-1 and Nanog (3). Such results suggest that BIO and related GSK-3-specific inhibitors may offer practical advantages in regenerative medicine. Bio can also participate in controlling the proliferative capability of the highly differentiated cardiomyocytes (4). Activation of Wnt/ $\beta$ -catenin and inhibition of Notch signaling pathways, as mediated by simultaneous co-application of BIO and the  $\gamma$ -secretase inhibitor *N*-[(3,5-difluorophenyl)acetyl]-L-alanyl-2-phenylglycine-1,1-dimethylethyl ester (or DAPT), efficiently induces intestinal differentiation of ESCs cultured on feeder cells. These findings that Wnt and Notch signaling function to pattern the anterior-posterior axis of the DE and control intestinal differentiation (5). **6-Bromoindirubin-3'-acetoxime:** This cell-permeable BIO analogue (FW<sub>BIO-acetoxime</sub> = 398.21 g/mol; CAS 667463-85-6) is active against herpes simplex virus-1 (HSV-1) infection in human oral epithelial cells, the latter representing a natural target cell type. BIO-acetoxime reduces viral yields and the expression of different classes of viral proteins. BIO-acetoxime may suppress viral gene expression and protect oral epithelial cells from HSV-1 infection. **Tyrian Purple:** BIO's indirubin nucleus is related to the famous Tyrian purple dye that the Phoenicians isolated from the gastropod mollusk *Hexaplex trunculus* and gained favor in antiquity, because it did not fade, actually becoming more brilliant upon weathering and exposure to sunlight. The inhibitory properties of BIO suggest that 6-bromoindirubin provides a new scaffold for the development of selective and potent pharmacological inhibitors of GSK-3 (1). 1. #### 2-Bromolysergic Acid Diethylamide

This halogenated LSD derivative (FW = 402.33 g/mol), also known as bromolysergide and bromo-LSD, is a serotonin antagonist that lacking the powerful hallucinogenic effects exhibited by LSD. **Target(s):** histamine *N*-methyltransferase (1,2); serotonin receptor (3); aryl-acylamidase (4,5). 1. Axelrod (1971) *Meth. Enzymol.* **17B**, 766. 2. Brown, Tomchick & Axelrod (1959) *J. Biol. Chem.* **234**, 2948. 3. Bennett & Snyder (1975) *Brain Res.* **94**, 523. 4. Paul & Halaris (1976) *Biochem. Biophys. Res. Commun.* **70**, 207. 5. Hsu, Paul, Halaris & Freedman (1977) *Life Sci.* **20**, 857.

#### 2-Bromopalmitate

This  $\alpha$ -halofatty acid (FW = 335.33 g/mol; CAS 18263-25-7; Symbols: 2-BP and Br-C16) inhibits palmitate oxidation by approximately 40% and 60%, when added at 50 and 100  $\mu$ M (1). Pretreatment with both concentrations also inhibited lipolysis in washed cells (1). Br-C16 also inhibits human palmitoyl acyltransferases (2), a family of enzymes sharing a conserved DHHC (or Asp-His-His-Cys) motif (3). Actively inhibitory forms of 2-bromopalmitate are the CoA and carnitine esters, which are also extremely powerful and specific inhibitors of mitochondrial fatty acid oxidation (4). Indeed, 2-bromopalmitoyl-CoA, when added as such or formed from 2-bromopalmitate, inhibits the carnitine-dependent mitochondrial oxidation of palmitate or palmitoyl-CoA, but not the oxidation of palmitoylcarnitine. 2-Bromopalmitoylcarnitine inhibits the oxidation of palmitoylcarnitine as well as that of palmitate or palmitoyl-CoA, but has no effect on succinate oxidation. Significantly, 2-bromopalmitate also inhibits palmitoylation of

Phospholipid **Scramblase-1** (or PLSCR1), a  $\text{Ca}^{2+}$ -binding, endofacial plasma membrane protein contributing to the trans-bilayer movement (or "scrambling") of phosphatidylserine and other phospholipids normally present on cytoplasmic face of membrane bilayers to the outer leaflet, upon influx of calcium ion (5). Accumulation of PS in outer leaflet is suppressed by ATP-dependent flippases, and loss of ATP formation in apoptotic cells allows PS to accumulate to levels that initiate phagocytosis and clearance by mononuclear macrophages. PLSCR1's cysteine-rich sequence (184-CCCPC-189) is required for palmitoylation, and mutation of these five cysteines abrogates PLSCR1 trafficking to the plasma membrane, keeping nearly all of the expressed protein in the nucleus. **Other Target(s):** 2-Bromopalmitate also increases expression of Uncoupling Protein-2 (or UCP2), a mitochondrial protein involved in controlling energy expenditure (6). This  $\alpha$ -halofatty acid also inhibits sex pheromone production, after topical treatment of pheromonal glands with 2-bromopalmitate (in DMSO), in the lepidopteran insects *Spodoptera littoralis*, *Thaumotopoea pityocampa*, and *Bombyx mori* (7). 2-Bromopalmitate reduces protein deacylation by inhibition of acyl-protein thioesterase enzymatic activities (8). Mass spectrometry analysis of enriched 2-bromopalmitate targets identified PAT enzymes, transporters, and many palmitoylated proteins, with no observed preference for CoA-dependent enzymes. Such findings raise uncertainty whether 2-bromopalmitate or 2-bromopalmitoyl-CoA blocks S-palmitoylation by inhibiting protein acyl transferases, or by blocking palmitate incorporation by direct covalent competition, highlighting the likely promiscuity of 2BP (9). 1. #### 4-[(3-Bromophenyl)amino]-6,7-dimethoxyquinazoline

This potent tyrosine protein kinase inhibitor (FW = 360.21 g/mol), also known as tyrphostin AG 1517, PD 153035, compound 32, and SU 5271, inhibits epidermal growth factor receptor (EGFR) protein-tyrosine kinase,  $K_i = 6$  pM (1-5). 1. #### N-[2-((3-(4-Bromophenyl)-2-propenyl)amino)ethyl]-5-isoquinolinesulfonamide

This substituted isoquinoline (FW<sub>free-base</sub> = 446.37 g/mol), commonly referred to as H-89 and N-[2-((p-bromocinnamyl)amino)ethyl]-5-isoquinolinesulfonamide, inhibits a number of protein kinases. H-89 also inhibits phosphatidylcholine biosynthesis in HeLa cells. **Target(s):** cAMP-dependent protein kinase, or protein kinase A ( $K_i = 0.048$   $\mu\text{M}$ ) (1-10); mitogen- and stress activated protein kinase (12); p70 ribosomal protein S<sub>6</sub> kinase (2); Rho-dependent protein kinase II (2); checkpoint kinase (2); AMP-activated protein kinase (2); [mitogen-activated protein kinase]-activated protein kinase 2 (2); cGMP-dependent protein kinase, or protein kinase G (3); [myosin light-chain] kinase ( $K_i = 28.3$   $\mu\text{M}$ ) (3); casein kinase I ( $K_i = 38.3$   $\mu\text{M}$ ) (3); casein kinase II ( $K_i = 30$   $\mu\text{M}$ ) (3); protein kinase C ( $K_i =$

31.7  $\mu\text{M}$ ) (3);  $\text{Ca}^{2+}$ /calmodulin-dependent protein kinase II (3); *Renilla-luciferin* 2-monooxygenase (11). 1. Hidaka, Watanabe & Kobayashi (1991) *Meth. #### Bromophycolide A

This *Callophycus serratus* natural product (FW = 665.30 g/mol) and its natural and synthetic analogues target the crystallization of heme that is released during the life cycle of the human malaria parasite. **Mechanism of Inhibitory Action:** Plasmodium parasites produce and excrete plasmepsin, a pepsin-like enzyme that degrades hemoglobin to supply essential nutrients to the parasite, with concomitant release of  $\alpha$ -hematin. The latter, also known as ferriprotoporphyrin IX, is a toxic pro-oxidant that catalyzes reactive oxygen species production. This substance is itself toxic to the parasite, which relies on heme crystallization to reduce its toxicity. Bromophycolide A binds to  $\alpha$ -hematin ( $K_d = 1.8 \times 10^{-5}$  M), thereby inhibiting the crystallization/detoxification process. 1. Stout, Cervantes, Prudhomme, et al. (2011) *Chem. Med. Chem.* **6**, 1572. 2. Teasdale, Prudhomme, Torres, et al. (2013) *ACS Med. Chem. Lett.* **4**, 989.

#### Bromopyruvate (Bromopyruvic Acid)

This  $\alpha$ -halo-keto acid (FW<sub>free-acid</sub> = 166.96 g/mol; CAS 1113-59-3; Symbol: 3BrPA) is an active-site-directed irreversible enzyme inhibitor and lactate/pyruvate transport inhibitor. A classical example is *Escherichia coli* isocitrate lyase (*Reaction*: Isocitrate  $\rightleftharpoons$  Glyoxylate + Succinate), where, upon reaction with 3-bromopyruvate, Cys-195 is alkylated with full loss of catalytic activity. Inactivation by 3BrPA exhibits saturation kinetics, with protection against inactivation exerted by isocitrate and glyoxylate, but not succinate (1). Touted to be a molecular "Trojan horse" in cancer chemotherapy, 3-bromopyruvate is a lactate analogue that is thought to selectively enter those cancerous cells exhibiting the Warburg effect, whereupon it quickly dissipates glycolytic and mitochondrial ATP production, resulting in tumor destruction without apparent harm to the animals (2,3). Although hexokinase-II was once thought to be responsible for 3BrPA inhibition of glycolysis, pyruvylation of glyceraldehyde 3-phosphate dehydrogenase (GAPDH) by 3BrPA not only inhibits glycolysis, but also appears to be the primary intracellular target in 3BrPA-mediated cancer cell death (4). At higher concentrations, however, bromopyruvate is apt to be indiscriminant in its cytotoxicity, most likely the result of nonspecific enzyme alkylation. Given its large number of targets, the cellular action of bromopyruvate is far from straightforward. **Target(s):** ribonuclease A, or pancreatic ribonuclease (5,17,80); 3-phosphoglycerate dehydrogenase (6,26); 2-dehydro-3-deoxy-6-phosphogluconate aldolase, or 6-phospho-2-dehydro-3-deoxygluconate aldolase, or 2-keto-3-deoxy-6-phosphogluconate aldolase (7,8,12,14,16,20,31,35,38,40); pyruvate, orthophosphate dikinase (9,105); aspartate aminotransferase

(10,11,34,39,40); 6-phospho-2-dehydro-3-deoxygalactonate aldolase (12,14,45); isocitrate lyase (12,21,60,81); 3-dehydroquinate synthase (12); carbonic anhydrase I (12,18,63); *N*-acetylneuraminase lyase (12,32,94-96); pyruvate carboxylase (12); glutamate decarboxylase (12,42,47,50,100); malic enzyme (12,41,48,53); malonyl-CoA decarboxylase (9); alcohol dehydrogenase (15); 2-dehydro-3-deoxyphosphoheptonate aldolase, or 3-deoxy-D-*arabino*-heptulosonate 7-phosphate synthase (16); fructose-1,6-bisphosphate aldolase (19,86); L-lactate dehydrogenase (22,25); succinate dehydrogenase (23,36); glycerate dehydrogenase (24); pyruvate kinase (27,51,83); pyruvate dehydrogenase complex (28,30,37,46,57,58); phosphoenolpyruvate carboxylase (29,52,64); pyruvate decarboxylase (30); glutamate dehydrogenase (33); serine hydroxymethyltransferase, or glycine hydroxymethyltransferase (44,111); flavocytochrome b (29,54); choline transport (55); phosphoenolpyruvate carboxykinase (56); 3-phosphoshikimate 1-carboxyvinyltransferase, or 5-enolpyruvylshikimate-3-phosphate synthase (59,73,108); octopine dehydrogenase (9); tryptophanase, or tryptophan indole-lyase (62); dipeptide transporter (65); acetylactate synthase, or acetohydroxyacid synthase (66); phosphofructo-1-kinase (67); glutathione *S*-transferase (68); fatty acid synthase (69); lactate oxidase (70); pyruvate:ferredoxin oxidoreductase (71); 2-keto-4-hydroxyglutarate aldolase (72); arginase (74); 4-aminobutyrate aminotransferase (75); histidine aminotransferase (76); dihydrodipicolinate synthase (77); 4-oxalocrotonate tautomerase (78); 3-deoxy-D-*manno*-octulosonic acid 8-phosphate synthase (79); 2-methylisocitrate lyase (82,85); malate synthase (81); anthranilate synthase (87); GMP synthetase (88); dihydrodipicolinate synthase (89,90); methylisocitrate lyase (91); 4-hydroxy-2-oxoglutarate aldolase (92,93); 2-dehydro-3-deoxy-6-phosphogalactonate aldolase (95); threonine aldolase (96); malonyl-CoA decarboxylase (101,102); pantotheine hydrolase (103); *N*-acyl-D-amino-acid deacylase (104); phosphoenol-pyruvate:protein phosphotransferase (103); 3-deoxy-8-phosphooctulonate synthase (107); UDP-*N*-acetylglucosamine 1-carboxyvinyltransferase (109); acetylactate synthase (110). 1. #### N-Bromosuccinimide

This common protein-modifying reagent (FW = 178 g/mol; CAS 128-08-5; Abbreviatin: NBS; water solubility = 0.015 g/mL, M.P. = 173-175°C) reacts somewhat selectively under acidic conditions (pH ≤ 4, typically using acetate or formate buffers) with tryptophanyl residues in peptides/proteins. Indole-ring oxidation (detected as an absorbance loss at 280 nm or a gain at 261 nm;  $\epsilon = 10,300 \text{ M}^{-1}\text{cm}^{-1}$  in the latter case) induces peptide-bond cleavage on its carboxyl side. (Note: No cleavage occurs at or above neutral pH.) NBS treatment often oxidizes the sulfur atom(s) in cysteinyl, cystinyl, and methionyl residues; histidyl and tyrosyl residues are also oxidized by NBS, albeit more slowly. Accordingly, the proximal cause of lost biological

activity of an NBS-treated peptide/protein is often initially uncertain. **Note:** *N*-Bromosuccinimide is an eye and skin irritant, necessitating appropriate handling. Avoid inhalation of the easily dispersed dry powder.

#### O<sup>6</sup>-(4-Bromothienyl)-8-aza-7-deazaguanine

This modified guanine (FW = 327.19 g/mol) inactivates methylated-DNA:[protein]-cysteine *S*-methyltransferase, or *O*<sup>6</sup>-alkylguanine-DNA alkyltransferase ( $I_{50} = 6$  nM). The methyl transferase active site also tolerates *O*<sup>6</sup>-substituted guanines, where the side chain can be quite large. However, it does not tolerate those with an aromatic or heteroaromatic ring with an "ortho" substituent. **1.** McMurry (2007) *DNA Repair* **6**, 1161.

#### O<sup>6</sup>-(4-Bromothienyl) guanine

This modified guanine (FW = 327.19 g/mol), also known as lomeguatrib, inactivates methylated-DNA:[protein]-cysteine *S*-methyltransferase, or *O*<sup>6</sup>-alkylguanine-DNA alkyltransferase ( $I_{50} = 3.4$  nM). The 5-bromo analogue also inhibits ( $I_{50} = 4.5$  nM). Note that the *O*<sup>6</sup>-(4-bromothien-3-ylmethyl)-guanine isomer is a weaker inhibitor. **1.** McMurry (2007) *DNA Repair* **6**, 1161. **2.** Verbeek, Southgate, Gilham & Margison (2008) *Brit. Med. Bull.* **85**, 17. **3.** Shibata, Glynn, McMurry, *et al.* (2006) *Nucl. Acids Res.* **34**, 1884. **4.** Juillerat, Heinis, Sielaff, *et al.* (2005) *ChemBioChem* **6**, 1263.

#### 5-(5-Bromothien-2-yl)-2'-deoxyuridine

This nucleoside (FW = 389.23 g/mol) is an antiherpetic agent that inhibits viral DNA polymerase. It also inhibits herpes simplex virus type 1 thymidine kinase ( $IC_{50} = 3.5$   $\mu$ M; the 3 bromothien-2-yl) analogue is a weaker inhibitor). **Target(s):** DNA polymerase, via its 5'-triphosphate (1,2); thymidine kinase (3). **1.** Prisce & Chen (1996) *Meth. Enzymol.* **275**, 425. **2.** Wigerinck, Pannecouque, Snoeck, *et al.* (1991) *J. Med. Chem.* **34**, 2383. **3.** Creuven, Evrard, Olivier, *et al.* (1996) *Antiviral Res.* **30**, 63.

#### 5-Bromotryptophan

This halogenated amino acid (FW = 283.12 g/mol; CAS 6548-09-0) is a relatively potent inhibitor of sickle hemoglobin polymerization (1,2), indoleamine 2,3-dioxygenase, also alternative substrate (3,4), and tyrosine 3-monooxygenase (5,6). **1.** Li, Lin & Johnson (1995) *Biochem. J.* **308**, 251. **2.** De Croos, Sangdee, Stockwell, *et al.* (1990) *Med. Chem.* **33**, 3138. **3.** Southan, Truscott, Jamie, *et al.* (1996) *Med. Chem. Res.* **6**, 343. **4.** Macchiarulo, Camaioni, Nuti & Pellicciari (2009) *Amino Acids* **37**, 219. **5.**

Moore & Dominic (1971) *Fed. Proc.* **30**, 859. **6.** McGeer, McGeer & Peters (1967) *Life Sci.* **6**, 2221.

#### 5-Bromouracil

This halogenated thymine analogue (FW = 190.98 g/mol; CAS 51-20-7) can be incorporated into DNA and is a powerful mutagen for a number of organisms. **Target(s):** dihydropyrimidine dehydrogenase (1); glucose-6-phosphate dehydrogenase (2,3); orotate phosphoribosyltransferase (4); pancreatic ribonuclease (5); thymidine phosphorylase, rabbit liver,  $I_{50} = 180$   $\mu$ M (6-9,17,18); uracil-DNA glycosylase (10); uracil phosphoribosyltransferase (16); uridine phosphorylase,  $K_i = 230$   $\mu$ M (11-13); (*R*)-3-amino-2-methylpropionate:pyruvate aminotransferase, weakly inhibited (14);  $NAD^+$  ADP-ribosyltransferase, or poly(ADP-ribose) polymerase (15); thymine dioxygenase (19). **1.** Porter, Chestnut, Merrill & Spector (1992) *J. Biol. Chem.* **267**, 5236. **2.** Noltmann & Kuby (1963) *The Enzymes*, 2nd ed., 7, 223. **3.** Hochster (1961) *Biochem. Biophys. Res. C* **52**, 670. **19.** Bankel, Lindstedt & Lindstedt (1977) *Biochim. Biophys. Acta* **481**, 431.

#### 5-Bromouridine

This halogenated pyrimidine nucleoside (FW = 323.10 g/mol; CAS 957-75-5) is a thymidine analogue that can be incorporated (via the 5'-triphosphate) into polynucleic acids. (See also 5-Bromo-2' deoxyuridine) **Target(s):** pancreatic ribonuclease (1); dihydroorotase (2); pre-mRNA splicing (3); cytidine deaminase (4);  $NAD^+$  ADP-ribosyltransferase, or poly(ADP-ribose) polymerase (5). **1.** Richards & Wyckoff (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), 4, 647. **2.** Bresnick & Blatchford (1964) *Biochim. Biophys. Acta* **81**, 150. **3.** Sierakowska, Shukla, Dominski & Kole (1989) *J. Biol. Chem.* **264**, 19185. **4.** Cacciamani, Vita, Cristalli, *et al.* (1991) *Arch. Biochem. Biophys.* **290**, 285. **5.** Banasik, Komura, Shimoyama & Ueda (1992) *J. Biol. Chem.* **267**, 1569.

#### 5-Bromouridine 5'-Triphosphate

This halogenated UTP derivative (FW = 563.04 g/mol; CAS 93882-11-2), often abbreviated 5-Br-UTP, is often used in the study of RNA and DNA biosynthesis. Acting as an inhibitor of DNA replication, this brominated nucleotide is incorporated into RNA and DNA, producing mismatched DNA and inhibiting normal cell proliferation. **Target(s):** CTP synthetase, *Escherichia coli* (1,2); transcription termination (3); UMP kinase (4);  $\alpha$ -1,3-mannosyl-glycoprotein 2- $\beta$ -N-acetylglucosaminyl-transferase (5). 1. Scheit & Linke (1982) *Eur. J. Biochem.* **126**, 57. 2. Scheit & Linke (1981) *Nucl. Acids Res.* **9**, 229. 3. Shuman & Moss (1989) *J. Biol. Chem.* **264**, 21356. 4. #### (E)-5-(2-Bromovinyl)-2'-deoxyuridine

This halogenated nucleoside (FW = 333.14 g/mol), also known as brivudine and 5-[(E)-2-bromoethenyl]-2'-deoxyuridine, is an antiherpetic agent that inhibits viral DNA polymerase. BvdU is a highly potent and selective inhibitor of herpes simplex virus type 1 and varicella-zoster virus infections. **Target(s):** DNA polymerase, viral, via the 5'-triphosphate (1-4); HSV-1 replication (1-4); 5' nucleotidases (5); dTMP kinase, or thymidylate kinase (6-8); deoxynucleoside kinase, also alternative substrate (9,10); thymidine kinase (9,11). 1. Prisbe & Chen (1996) *Meth. Enzymol.* **275**, 425. 2. Wigerinck, Pannecouque, Snoeck, et al. (1991) *J. Med. Chem.* **34**, 2383. 3. De Clercq (2005) *Med. Res. Rev.* **25**, 1. 4. #### BS-181

This cyclin kinase inhibitor (FW<sub>free-base</sub> = 416.99 g/mol; CAS 1092443-52-1); Solubility: 83 mg/mL DMSO; 3 mg/mL H<sub>2</sub>O; Formulation: Dissolve in 10% DMSO/50 mM HCl/ 5% Tween 20/85% saline, systematically as named N<sup>6</sup>-(6-aminohexyl)-N<sup>7</sup>-benzyl-3-isopropylpyrazolo[1,5-a]pyrimidine-5,7-diamine, targets CDK7 with IC<sub>50</sub> value of 21 nM. Testing of other CDKs as well as another 69 kinases showed that BS-181 only inhibited CDK2 at concentrations lower than 1  $\mu$ M, with CDK2 being inhibited 35-fold less potently (IC<sub>50</sub> = 880 nM) than CDK7. **Cyclin Target Selectivity:** Cdk1 (+++), Cdk2 (++), Cdk3 (weak, if any), Cdk4 (weak, if any), Cdk5 (weak, if any), Cdk6 (weak, if any), Cdk7 (weak, if any), Cdk8 (weak, if any), Cdk9 (++), Cdk10 (weak, if any). 1. Ali, et al. (2009) *Cancer Res.* **69**, 6208.

#### BSc2118

This potent aldehyde-containing tripeptide mimetic (FW = 533.31 g/mol; CAS 863924-64-5) targets the 20 S proteasome (with lowest IC<sub>50</sub> values of 58 nM (chymotrypsin-like activity), 53 nM (trypsin-like activity), and 100 nM (caspase-like activity)), forming covalent adducts to active-site threonines (1). Given its critical role in protein turnover with effect on vital cellular pathways, the ubiquitin-proteasome system advanced to a promising new target in cancer treatment. Cell cycle regulating peptides, pro- and anti-apoptotic proteins as well as transcription factors, all necessary for cell survival, are degraded proteasome-dependently. Proteasomal inhibition results in accumulation of myriad of regulatory proteins, leading to confounding signals toward cell cycle progression and induction of apoptosis. In OPM-2, RPMI-8226, U266 multiple myeloma (MM) cell lines and primary MM cells, BSc2118 causes dose-dependent growth inhibitory effects (2). After 48 hours, dose-dependent apoptosis occurs both in cell lines and primary myeloma cells. G<sub>2</sub>-M cell cycle arrest occurs after 24 hours, also causing marked inhibition of intracellular proteasome activity, an increase in intracellular p21 levels, and an inhibition of NF- $\kappa$ B activation (2). 1. Braun, Umbreen, Groll, et al. (2005) *J. Biol. Chem.* **280**, 28394. 2. Sterz, Jakob, Kuckelkorn, et al. (2010) *Eur. J. Hematol.* **85**, 99.

#### BSF-208075, See Ambrisentan

#### BTB-1

This mitotic kinesin inhibitor (FW = 297.71 g/mol; CAS 86030-08-2; Solubility: 100 mM in DMSO), also known as 4-chloro-2-nitro-1-(phenylsulfonyl)-benzene, targets Kif18A inhibitor (IC<sub>50</sub> = 1.7  $\mu$ M), a cytoskeletal motor that is frequently overexpressed in solid tumors (1). Kif18A reduces the amplitude of preanaphase oscillations and slows poleward movement during anaphase (2). BTB-1 is ATP-competitive and microtubule- (or MT-) uncompetitive and is selective, showing much weaker action against Kif4, Eg5, MKLP-1, MKLP-2, MPP1, CENP-E and MCAK (1). Kif18A's *in vitro* MT-gliding activity is also blocked reversibly (1). BTB-1 only inhibits the ATPase activity of the MT-bound motor protein. 1. Catarinella, Grüner, Strittmatter, Marx & Mayer (2009) *Angew. Chem. Int. Ed. Engl.* **48**, 9072. 2. Braun, Möckel, Strittmatter, et al. (2015) *ACS Chem. Biol.* **10**, 554.

#### BTB06584

This (FW = 417.82 g/mol; CAS 219793-45-0; Solubility: 84 mg/mL DMSO; < 1 mg/mL H<sub>2</sub>O), also named 2-nitro-5-(phenylsulfonyl)phenyl 4-chlorobenzoate, inhibits F<sub>1</sub>F<sub>0</sub>-ATPase activity, with no effect on mitochondrial membrane potential ( $\Delta\Psi_m$ ) or O<sub>2</sub> consumption. ATP consumption was significantly slowed after inhibition of respiration, and ischemic cell death was reduced. BTB efficiency was increased by IF<sub>1</sub> overexpression, and reduced by silencing the protein. 1. Ivanov, Faccenda, Gatiloff (2014) *Brit. J. Pharmacol.* **171**, 4193.

**Budesonide**

This glucocorticosteroid (FW = 430.53 g/mol; CAS 51333-22-3), also known as Rhinocort™, Pulmicort™, Budacort™, Ucerus™, and 16,17-(butylidenebis(oxy))-11,21-dihydroxy-(11 $\beta$ ,16 $\alpha$ )-pregna-1,4-diene-3,20-dione, reduces inflammation in the respiratory and digestive tract, depending on its mode of administration (1). Compared to prednisolone, budesonide has been associated with less bone density loss, and has little influence on the hypothalamic-pituitary-adrenal axis, with lower incidence of systemic manifestations than similar medications. The [22*R*]-epimer was more susceptible to liver biotransformation than the [22*S*]-epimer (2). Interleukins IL-2 and IL-4 counteract budesonide inhibition of GM-CSF and IL-10, but not of IL-8, IL-12 or TNF- $\alpha$  production by human mononuclear blood cells (3). 1. Thalén & Brattsand (1979) *Arzneimittel-forschung*. 29, 1687. 2. Andersson, Edsbäcker, Ryrfeldt & von Bahr (1982) *J. Steroid Biochem.* 16, 787. 3. Larsson, Löfdahl & Linden (1999) *Br. J. Pharmacol.* 127, 980.

**Bufalin**

This cardioactive C-24 steroid (FW = 386.52 g/mol; CAS 465-21-4; Solubility: 5 mg/mL chloroform, 25 mg/mL DMSO), also named 3,14-dihydroxybufa-20,22-dienolide;5 $\beta$ ,20(22)-bufadienolide-3 $\beta$ ,14-diol and 3 $\beta$ ,14-dihydroxy-5 $\beta$ ,20(22)-bufadienolide, is the major digoxin-like immunoreactive component of *Chansu*, a traditional Chinese medicine prepared from the skin and venom-containing parotid gland of a poisonous toad (1). Bufalin increases the doubling time of three prostate cancer cell lines, inducing apoptosis and the caspase-3 activity. Expression of other proapoptotic factors, such as mitochondrial Bax and cytosolic cytochrome *c*, were also increased. Bufalin also reduces serum-induced invasiveness of human hepatocellular cancer SK-Hep1 cells, markedly inhibiting MMP-2 and MMP-9 activities (2). It also attenuates phosphoinositide-3-kinase (PI3K) and AKT phosphorylation was associated with reduced levels of NF- $\kappa$ B. Bufalin also suppresses protein levels of FAK, Rho A, VEGF, MEKK3, MKK7, and uPA. Such observations indicate that bufalin is as an antiinvasive agent that inhibits MMP-2 and -9 and alters PI3K/AKT and NF- $\kappa$ B signaling pathways (2). 1. Takai, Kira, Ishii, *et al.* (2012) *Asian Pacific J. Cancer Prev.* 13, 399. 2. Chen, Lu, Hsu, *et al.* (2015) *Environ. Toxicol.* 30, 74.

 **$\alpha$ -Bungarotoxin**

This 74-residue snake neurotoxin (MW = 7983 Da; Accession Number = 720920A; CAS 11032-79-4; Symbol: Bgt) from the venom of the many-banded krait *Bungarus multicinctus* is a nicotinic cholinergic receptor antagonist that prevents opening of post-synaptic nicotinic receptor ion channels.  $\alpha$ -Bungarotoxin is far more selective for the  $\alpha_7$  receptor (IC<sub>50</sub> = 1.6 nM) than  $\alpha_3\beta_4$  receptor (IC<sub>50</sub> > 3  $\mu$ M). Because fluorescently tagged  $\alpha$ -bungarotoxin binds to the nAChR with high affinity and defined stoichiometry, it may be employed to determine the location and amount of nAChR on the surface of muscle cells. 1. Berg, Kelly, Sargent, Williamson & Hall (1972) *Proc. Natl. Acad. Sci. U.S.A.* 69, 147. 2. Harvey, ed. (1991) *Snake Toxins*, Pergamon.

 **$\beta$ -Bungarotoxin**

This snake neurotoxin (MW = 15 kDa; CAS 12778-32-4) from the venom of the many-banded krait (*Bungarus multicinctus*) is a presynaptic terminus-seeking phospholipase A<sub>2</sub> (of which there are two forms, designated  $\beta_1$  and  $\beta_2$ ) catalyzing phospholipid hydrolysis, thereby impairing acetylcholine release. 1. Chen & Lee (1970) *Virchows Arch B Cell Pathol.* 6, 318. 2. Howard (1975) *Biochem. Biophys. Res. Commun.* 67, 58. 3. Strong, Goerke, Oberg & Kelly (1976) *Proc. Natl. Acad. Sci. USA* 73, 178.

**Buparlisib**

This orally available, pan-class I PI3K inhibitor (FW = 410.17; CAS 944396-07-0; Solubility: 82 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O) also known as NVP-BKM-120 and BKM-120, as well as 5-[2,6-di(4-morpholinyl)-4-pyrimidinyl]-4-(trifluoromethyl)-2-pyridinamine, targets all four class I PI3K isoforms in biochemical assays with at least 50-fold selectivity against other protein kinases (1). Buparlisib displays mixed-type inhibition, affecting both the *V*<sub>max</sub> and the *K*<sub>m</sub> for ATP. It is also active against the most common somatic PI3K $\alpha$  mutations, but does not significantly inhibit the related class III (Vps34) and class IV (mTOR, DNA-PK) PI3K kinases (1). Consistent with this mechanism of action, NVP-BKM120 decreases the cellular levels of p-Akt in mechanistic models and relevant tumor cell lines, as well as downstream effectors in a concentration-dependent and pathway-specific manner. NVP-BKM120 demonstrated anti-proliferative activity in 11 human gastric cancer cell lines by decreasing mTOR downstream signaling (2). In studies of human glioblastoma multiforme (GBM) cells *in vitro* and *in vivo*, Koul, *et al.* (3) observed a differential sensitivity pattern with respect to p53 status, with cells containing wild-type p53 proving to be more sensitive than those with mutated or deleted p53. NVP-BKM120 showed differential forms of cell death on the basis of p53 status of the cells with p53 wild-type cells undergoing apoptotic cell death and p53 mutant/deleted cells having a mitotic catastrophe cell death. NVP-BKM120 mediates mitotic catastrophe mainly through Aurora B kinase (3). Knockdown of p53 in p53 wild-type U87 glioma cells displayed microtubule misalignment, multiple centrosomes, and mitotic catastrophe cell death (3). 1. Maira, Pecchi, Huang, *et al.* (2012) *Mol. Cancer Ther.* 11, 317. 2. Park, *et al.* (2012) *Int. J. Oncol.* 40, 1259. 3. Koul, *et al.* (2012) *Clin. Cancer Res.* 18, 184.

**Buprenorphine**

This semi-synthetic thebaine-based prodrug (FW = 467.44 g/mol; CAS 52485-79-7) is metabolized to norbuprenorphine (FW = 415.55 g/mol; CAS 78715-23-8), the pharmacologically active form that acts as an  $\mu$ -opioid receptor antagonist (or more accurately a partial agonist). Buprenorphine is a strong analgesic with marked narcotic antagonist activity, producing side effects similar to those observed with other morphine-like compounds, including respiratory depression (3). Buprenorphine is used (a) at lower dosages (~200  $\mu$ g) to control moderate acute pain in non-opioid-tolerant individuals, (b) at dosages ranging from 20-70  $\mu$ g/hour to control moderate chronic pain, and (c) at higher dosages (>2 mg) to treat opioid addiction.

Buprenorphine is also employed to maintain sobriety. Dependence liability of buprenorphine may be lower than that of other older morphine-like drugs. Due to its partial agonist properties, buprenorphine offers advantages over methadone in managing opioid addiction (*i.e.*, decreased respiratory depression, less sedation, less withdrawal symptoms, lower risk of toxicity, and decreased risk of diversion). **Targets:** Buprenorphine is a nonselective, mixed agonist/antagonist opioid receptor modulator, acting at the  $\mu$ -Opioid Receptor (*or* MOR),  $K_i = 1.5$  nM; Intrinsic Activity = 28.7%; the  $\kappa$ -Opioid Receptor (*or* KOR),  $K_i = 2.5$  nM, Intrinsic Activity = 0%;  $\delta$ -Opioid Receptor (*or* DOR):  $K_i = 6.1$  nM, Intrinsic Activity = 0%; and Nociceptin Receptor (*or* ORL-1),  $K_i = 77.4$  nM; Intrinsic Activity = 15.5%. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1. Buprenorphine IUPAC Name:** (2*S*)-2-[(5*R*,6*R*,7*R*,14*S*)-9 $\alpha$ -cyclopropylmethyl-4,5-epoxy-6,14-ethano-3-hydroxy-6-methoxymorphinan-7-yl]-3,3-dimethylbutan-2-ol; **Norbuprenorphine IUPAC Name:** (5 $\alpha$ ,6 $\beta$ ,14 $\beta$ ,18*R*)-18-[(1*S*)-1-hydroxy-1,2,2-trimethylpropyl]-6-methoxy-18,19-dihydro-4,5-epoxy-6,14-ethenomorphinan-3-ol. **2.** Dum & Herz (1981) *Brit. J. Pharmacol.* **74**, 627. **3.** Heel, Brogden, Speight & Avery (1979) *Drugs* **17**, 81.

### Bupropion

This  $\beta$ -ketoamphetamine-type antidepressant and smoking cessation aid (FW = 239.74 g/mol; CAS 34841-39-9), also known as Wellbutrin<sup>®</sup>, Zyban<sup>®</sup>, and ( $\pm$ )-2-(*tert*-butylamino)-1-(3-chlorophenyl)propan-1-one, is said to be a norepinephrine and dopamine reuptake inhibitor, although its weak effect on dopamine levels calls into question the latter action (1). Bupropion also acts noncompetitively as a neuronal acetylcholine receptor antagonist. Unlike many antidepressants, however, bupropion shows no serotonergic activity. It also lacks typical antidepressant side effects, *e.g.*, sexual dysfunction, weight gain, and sedation (2). **Pharmacokinetics:** Upon oral administration, bupropion is rapidly absorbed with first-order kinetics and subsequently eliminated via biphasic kinetics, with a redistribution  $t_{1/2}$  of  $\sim$ 1 hour and an elimination  $t_{1/2}$  of 11-14 hours. Widely distributed throughout the body, bupropion is extensively metabolized, both oxidatively and reductively, to form as many as six metabolites, of which some are pharmacologically active. While bupropion does not inhibit monoamine oxidase, it exerts no effect on serotonin uptake. It minimally alters the reuptake of norepinephrine at presynaptic sites. Importantly, bupropion does not act on postsynaptic  $\beta$ -adrenergic down-regulation or presynaptic dopamine uptake. Gene variants in CYP2C19 are associated with altered *in vivo* bupropion pharmacokinetics (3). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** Soroko, Mehta, Maxwell, Ferris & Schroeder (1977) *J. Pharm. Pharmacol.* **29**, 767. **2.** Stahl, Pradko, Haight, *et al.* (2004) *Prim. Care Companion J. Clin. Psychiatry.* **6**, 159. **3.** Zhu, Zhou, Cox, *et al.* (2014) *Drug Metab. Dispos.* **42**, 1971.

### Buspirone

This non-benzodiazepine serotonin receptor partial agonist (FW = 385.50 g/mol; CAS 36505-84-7) targets 5-HT<sub>1A</sub> receptors, exerting both anxiolytic and antidepressant effects (1). Buspirone differs from benzodiazepines, inasmuch as it fails to stimulate or inhibit <sup>3</sup>H-benzodiazepine binding and does not affect GABA binding/uptake (2). Buspirone lacks anticonvulsant activity, interacts minimally with CNS depressants, and does not cause muscle relaxation. In animal models, its tranquilizing activity is characterized by the ability to tame aggression, to block conditioned avoidance responses, to inhibit shock-induced fighting, and to attenuate shock-induced suppression of drinking (2). Because it lacks the anticonvulsant, sedative, and muscle-relaxant properties associated with other anxiolytics, buspirone has been termed "anxiolytic" (3).

Moreover, in contrast to the benzodiazepines, buspirone operates on a matrix of neural targets (see below) to treat anxiety effectively, while preserving arousal and attentional processes (4). *In vitro*, buspirone is metabolized by CYP3A4. Moreover, its active metabolites show a mechanism of action different from that of the parent compound (5). Given that buspirone appears to be useful in various neurological and psychiatric disorders (*e.g.*, attenuating side-effects of Parkinson's disease therapy, ataxia, depression, social phobia, and behaviour disturbances following brain injury, Alzheimer's disease, dementia and attention deficit disorder), it is unfortunate that buspirone's mechanism(s) of action are incompletely defined (6). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** 5-HT<sub>1A</sub> receptors,  $K_d = 29$  nM, as an agonist; 5-HT<sub>2A</sub> receptors,  $K_d = 138$  nM, as an agonist; 5-HT<sub>2B</sub> receptors,  $K_d = 214$  nM, as an agonist; 5-HT<sub>2C</sub> receptors,  $K_d = 490$  nM, as an agonist; D<sub>2</sub> receptors, moderate an antagonist; D<sub>3</sub> receptors, as an antagonist; D<sub>4</sub> receptors, as an antagonist;  $\alpha_1$  receptors, as an agonist; and  $\alpha_{1D}$  receptors, as an agonist. **1.** Goldberg & Finnerty (1979) *Am. J. Psychiatry* **136**, 1184. **2.** Riblet, Taylor, Eison & Stanton (1982) *J. Clin. Psychiatry* **43**, 11. **3.** Taylor, Eison, Riblet & Vandermaelen (1985) *Pharmacol. Biochem. ### Busulfan

This antineoplastic drug (FW = 246.30 g/mol; CAS 55-98-1), also known as Myleran<sup>®</sup>, Busulfex IV<sup>®</sup>, and 1,4-butanediol dimethanesulfonate, is a cell cycle non-specific DNA alkylating agent that penetrates cancer cells and induces apoptosis. (See also the water-soluble analogue, Treosulfan) Busulfan undergoes nucleophilic attack by the N<sup>7</sup>-atom of guanine, forming intra-strand DNA-DNA crosslinks between guanine and nearby adenine bases as well as between guanine and nearby guanine bases. By preventing replication as well as the action of DNA repair enzymes, busulfan-treated cells undergo programmed cell death. Initially developed to treat chronic myelogenous leukemia in view of its suppressive effect on peripheral granulocyte counts, Busulfan was later found to exert broad myelosuppressive effects. Indeed, high doses of busulfan produce myeloablation, depleting bone marrow precursors upon repeated dosing. In combination with Cyclophosphamide, Busulfan is an alternative to total-body irradiation for allogeneic bone marrow transplantation. Given its low solubility, busulfan exhibits erratic busulfan absorption, necessitating close monitoring to achieve predictable myelosuppressive levels. Busulfan is now the cornerstone for high-dose treatment of various hematologic malignancies and immunodeficiencies. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** Elson, Galton & Till (1958) *Brit. J. Hematol.* **4**, 355.

### L-Buthionine Sulfoximine

Butathione Sulfoximine

Butathione Sulfoximine Phosphate

This transition-state analogue precursor (FW = 222.31 g/mol; CAS 5072-26-4; *Symbol:* BSO), also known as *S*-*n*-butyl-homocysteine sulfoximine, undergoes ATP-dependent phosphorylation to the transition-state analogue L-buthionine sulfoximine phosphate, the latter potently inhibiting  $\gamma$ -glutamylcysteine synthetase. This reagent is without effect on glutamine

synthetase (**See instead** *L*-Methionine Sulfoximine and *L*-Methionine Sulfoximine Phosphate). **Depletion of Cellular Glutathione Content:** Treatment of many cell types of buthionine sulfoximine results in a depletion of intracellular glutathione. In fed male mice, liver and kidney GSH levels are depleted by BSO in a dose-dependent manner, with maximum effect (*i.e.*, reduction to 35% of initial levels) occurring at intraperitoneal doses of 0.8-1.6 g/kg body weight. At such doses, maximum effects on  $\gamma$ -glutamylcysteine synthetase ( $\gamma$ -GCS) and GSH are observed 2-4 hours after BSO administration, with initial  $\gamma$ -GCS activity and GSH restored ~16 hours post-BSO. Because cellular glutathione plays essential protective roles against radiation-induced cell death, BSO also increases radiation sensitivity. **1.** Griffith (1982) *J. Biol. Chem.* **257**, 13704. **2.** Seelig & Meister (1985) *Meth. Enzymol.* **113**, 379. **3.** Griffith (1987) *Meth. Enzymol.* **143**, 286. **4.** Meister (1995) *Meth. ### Butoconazole

This fungicide (FW = 411.78 g/mol; CAS 64872-77-1), also known as Femstat™, Femstat-3™, Gynazole-1™, and systematically as 1-[4-(4-chlorophenyl)-2-[(2,6-dichlorophenyl)sulfonyl]butyl]-1H-imidazole (\* = chiral center), is believed to inhibit steroid synthesis, targeting the conversion of lanosterol to ergosterol and modifying membrane composition/function. At 80  $\mu$ M, butoconazole was strictly fungistatic against early stationary-phase *Candida albicans* cells. During early log-phase growth, butoconazole were highly lethal at 20  $\mu$ M (1). In 1995, butoconazole was approved for treatment of vaginal yeast infections. **1.** Beggs (1985) *J. Antimicrob. Chemother.* **16**, 397.

### *N*-[*N*-(*t*-Butoxycarbonyl)-*L*-alanyl]-(*R*)-7-amino-2-(4-methoxybenzenesulfonyl)-1,2,3,4-tetrahydroisoquinolin-3-carboxylic acid hydroxamate

This isoquinoline derivative (FW = 548.62 g/mol) inhibits human neutrophil collagenase, or MMP-8 ( $IC_{50}$  = 2 nM), fitting well with catalytic site, based on steric, electrostatic, and hydrophobic complementarity. **1.** Matter, Schwab, Barbier, *et al.* (1999) *J. Med. Chem.* **42**, 1908.

### *N*-[3-(*t*-Butoxycarbonylamino)-4-methoxyphenylsulfonyl]-*N*-(4-nitrobenzyl)- $\beta$ -alanine hydroxamate

This hydroxamate-based protease inhibitor (FW = 507.54 g/mol) inhibits interstitial collagenase ( $K_i$  = 24 nM), gelatinase A ( $K_i$  = 4 nM), neutrophil collagenase ( $K_i$  = 7 nM), gelatinase B ( $K_i$  = 6 nM), and microbial collagenase ( $K_i$  = 11 nM). **1.** Scozzafava, Iliés, Manole & Supuran (2000) *Eur. J. Pharm. Sci.* **11**, 69.

### (2*R*,3*S*,11'*S*,8'*S*)-3-[*t*-Butoxycarbonylamino]-4-phenyl-1-[7',10'-dioxo-8'-(1-methylpropyl)-2'-oxa-6',9'-diazabicyclo[11.2.2]heptadeca-13',15',16'-trien-11'-yl]amino]butan-2-ol

This hydrolytically stable macrocyclic peptidomimetic agent (FW = 596.77 g/mol) is a potent inhibitor of HIV-1 protease:  $K_i$  = 4 nM. Such cyclic analogues are potent inhibitors of HIV protease, and the crystal structures show them to be structural mimics of acyclic peptides, binding in the active site of HIV protease via the same interactions. Each macrocycle is restrained to adopt a  $\beta$ -strand conformation which is preorganized for protease binding. An unusual feature of the binding of C-terminal macrocyclic inhibitors is the interaction between a positively charged secondary amine and a catalytic aspartate of HIV protease. A bicyclic inhibitor binds similarly through its secondary amine that lies between its component N-terminal and C-terminal macrocycles. **1.** Abbenante, March, Bergman, *et al.* (1995) *J. Amer. Chem. Soc.* **117**, 10220. **2.** Martin, Begun, Schindeler, *et al.* (1999) *Biochemistry* **38**, 7978.

### *N*-[*N*-(*t*-Butoxycarbonyl)-*L*-phenylalanyl-*L*-histidyl]- (4-amino-5-cyclohexyl-2,2-difluoro-3-oxopentanoyl)-*L*-isoleucyl-2-pyridylmethylamide

This peptidomimetic (FW<sub>free-base</sub> = 836.98 g/mol) inhibits renin ( $IC_{50}$  = 2.5 nM). The readily hydrated fluoro ketone is thought to mimic the tetrahedral intermediate that forms during the enzyme-catalyzed hydrolysis of a peptidic bond. The fluoro ketone is shown to be a much more effective inhibitor than the corresponding nonfluorinated ketone, which acts as a pseudosubstrate. **1.** Thaisrivongs, Pals, Kati, *et al.* (1986) *J. Med. Chem.* **29**, 2080.

### *N*-(*t*-Butoxycarbonyl)-*D*-phenylalanyl-*L*-prolyl-*L*-boroarginine

This boronyl-tripeptide (FW<sub>chloride</sub> = 554.88 g/mol) is a potent inhibitor of thrombin ( $K_i$  = 3.6 pM), but a much weaker inhibitor of plasma kallikrein ( $K_i$  = 0.4 nM), coagulation factor Xa ( $K_i$  = 0.94 nM), plasmin ( $K_i$  = 0.46 nM), and t-plasminogen activator ( $K_i$  = 5.7 nM). Peptides containing alpha-aminoboronic acids with neutral side chains are highly effective reaction intermediate analog inhibitors of the serine proteases leukocyte elastase, pancreatic elastase, and chymotrypsin. **1.** Kettner, Mersinger & Knabb (1990) *J. Biol. Chem.* **265**, 18289.

***N*-(*t*-Butoxycarbonyl)-L-valyl-L-methionyl-[(2*R*,4*S*,5*S*)-5-amino-4-hydroxy-2,7-dimethyl-octanoyl]-L-valine Benzylamide**

This pentapeptide analogue (FW = 722.01 g/mol), also known as GT-1017, contains a nonhydrolyzable  $-(S)CH(OH)CH_2-$ , a hydroxyethylene isostere often denoted by  $\Psi$ , that replaces the peptide bond between the Leu-3 and Ala-4 residues. GT-1017 inhibits memapsin-2 ( $\beta$ -secretase;  $K_i = 2.5$  nM) and memapsin-1 ( $K_i = 1.2$  nM (1-3). Note that the methionine sulfone analogue (GT-1026) also inhibits, with respective  $K_i$  values of 9.4 and 44.7 nM. 1. Ghosh, Hong & Tang (2002) *Curr. Med. Chem.* **9**, 1135. 2. Ghosh, Bilcer, Harwood, *et al.* (2001) *J. Med. Chem.* **44**, 2865. 3. Turner, Loy, Nguyen, *et al.* (2002) *Biochemistry* **41**, 8742.

***N*<sup>ω</sup>-[4-[2-(*t*-Butylaminosulfonyl)phenyl]-2-methyl-benzoyl]-L-boroarginine *O*,*O*-(+)-pinanediol ester**

This transition-state mimic (FW<sub>hydrochloride</sub> = 704.55 g/mol) potently inhibits thrombin and trypsin, with  $K_i$  values of 0.21 and 0.70 nM, respectively. Modified peptides possessing a boronate functional group in place of the carboxyl group are "sticky" for many proteases. 1. Quan, Wityak, Dominguez, *et al.* (1997) *Bioorg. Med. Chem. Lett.* **7**, 1595.

**Butylated hydroxytoluene**

This radical scavenger and widely used antioxidant (FW = 220.36 g/mol; CAS 128-37-0; IUPAC Name: 2,6-bis(1,1-dimethylethyl)-4-methylphenol; Symbol: BHT; Soluble in most oils) inhibits food spoilage by terminating free radical reactions through the conversion of peroxy radicals ( $R-O_2^*$ ) to hydroperoxides ( $R-OOH$ ). This is accomplished by donating a hydrogen atom (*Reaction*:  $R-O_2^* + BHT-OH \rightarrow ROOH + BHT-O^*$ ), where R is alkyl or aryl, and where BHT-OH indicates the hydroxyl group of butylated hydroxytoluene. The key to BHT's effectiveness is the formation of a highly stabilized oxygen free radical that is poorly reactive due to steric constraints.

***t*-Butyl-bicyclo[2.2.2]-phosphorothionate**

This highly hindered, membrane-permeant phosphorothioate (FW = 222.25 g/mol) is a potent convulsant, GABA<sub>A</sub> receptor antagonist (1,2) and chloride channel blocker (3). While slightly soluble in water, solubility is increased in the presence of nonionic detergents. TBPS is also soluble in dimethyl sulfoxide. **CAUTION:** Avoid inhalation and contact with skin contact, especially when dissolved in DMSO). 1. Casida, Palmer & Cole (1985) *Mol. Pharmacol.* **28**, 246. 2. Squires, Casida, Richardson & Saederup (1983) *Mol. Pharmacol.* **23**, 326. 3. Tehrani, Vaidyanathaswamy, Verkade & Barnes (1986) *J. Neurochem.* **46**, 1542.

***n*-Butylboronic Acid**

This hygroscopic boronic acid (FW = 101.94 g/mol; CAS 69190-62-1; M.P. = 94-96°C), also known as butaneboronic acid and butylboron dihydroxide, inhibits a number of hydrolytic enzymes. The respective  $K_i$  values for cholesterol esterase and cutinase is 223 and 3.2  $\mu$ M. **Target(s):** bacterial leucyl aminopeptidase, *or Aeromonas* aminopeptidase (1,2,8-11); cholesterol esterase (3,4); chymotrypsin (5); lipoprotein lipase (4); methionyl aminopeptidase (6); lipase, *or* triacylglycerol lipase (7); cutinase (12). 1. Prescott, Wagner, Holmquist & Vallee (1985) *Biochemistry* **24**, 5350. 2. Baker & Prescott (1985) *Biochem. Biophys. Res. Commun.* **130**, 1154. 3. Feaster & Quinn (1997) *Meth. ***N*-Butyl-1-deoxygalactonojirimycin**

This sugar analogue (FW<sub>free-base</sub> = 219.28 g/mol) is a strong inhibitor of glycolipid biosynthesis but has no effect on the maturation of *N*-linked oligosaccharides or on lysosomal glucocerebrosidase. When the ring nitrogen is protonated, this analogue mimics the charge of oxa-carbenium ion intermediate that forms transiently in many glycosidase reactions, a property that results in tight binding. It has been effective in depleting glycosphingolipids in Type I Gaucher disease patients. **Target(s):** ceramide glucosyltransferase (1);  $\alpha$ -galactosidase A (2,3);  $\beta$ -galactosidase (4); lactase/phlorizin-hydrolaseglycosylceramidase (5,6). 1. Platt, Neises, Karlsson, Dwek & Butters (1994) *J. Biol. Chem.* **269**, 27108. 2. Fan, Ishii, Asano & Suzuki (1999) *Nat. Med.* **5**, 112. 3. Asano, Ishii, Kizu, *et al.* (2000) *Eur. J. Sesink, Arts, Faassen-Peters & Hollman (2003) *J. Nutr.* **133**, 773.

***N*-Butyl-1-deoxyojirimycin**

This sugar analogue (FW = 219.28 g/mol), also known as Miglustat, Vevesca, and Zavesca, inhibits processing  $\alpha$ -glucosidases as well as ceramide glucosyltransferase. Because the ring nitrogen is protonated, this analogue mimics the charge of oxa-carbenium ion intermediate that forms transiently in many glycosidase reactions, a property that very often results in tight binding. Its oral administration prevents lysosomal accumulation of glucocerebrosidase that occurs in patients with Type I Gaucher's disease. *N*-

Butyl-1- deoxynojirimycin also inhibits human immunodeficiency virus (HIV) replication ( $EC_{50} = 56 \mu\text{M}$ ) by inhibiting processing  $\alpha$ -glucosidase activities. **Target(s):** ceramide glucosyltransferase (1,2,9-11); mannosyl-oligosaccharide glucosidase, or glucosidase I (2-5); glucan 1,3- $\alpha$ -glucosidase, or glucosidase II, or mannosyl-oligosaccharide  $\alpha$ -glucosidase II (2-4,6); acid  $\alpha$ -glucosidase (4);  $\alpha$ -1,6- glucosidase (4); glucosylceramidase (7,8). 1. ### Butyrate (Butyric Acid)

This HDAC inhibitor ( $FW_{\text{free-acid}} = 88.11 \text{ g/mol}$ ; CAS 107-92-6;  $FW_{\text{Na-salt}} = 110.09 \text{ g/mol}$ ; CAS 156-54-7), also known as butanoate (the conjugate base of butanoic acid), is a major colonic lumen metabolite formed by bacterial fermentation of dietary fiber. Butyrate also serves as a critical mediator of inflammatory response in the colon. Its action as a histone deacetylase inhibitor is believed to underlie its ability to suppress colonic inflammation by inhibition of IFN- $\gamma$ /STAT1 signaling pathways. **Discovery of HDAC Inhibition:** The discovery of butyrate inhibition of histone deacetylases followed early reports that sodium butyrate halts DNA synthesis, arrests cell proliferation, alters cell morphology and increases or decreases gene expression (1). This finding was followed by the discovery that *n*-butyrate causes histone modification in HeLa and Friend erythroleukemic cells (2) and that sodium butyrate inhibits histone deacetylation in cultured cells (3). Later papers added evidence that butyrate suppresses histone deacetylation, both *in vivo* and *in vitro* (4,5), leading to accumulation of multi-acetylated forms of histones H3 and H4 and increased DNase I-sensitivity of the associated DNA sequences (6). HDAC8 action on a histone H4 peptide substrate, for example, is inhibited by sodium butyrate, as is deacetylation of nucleosomal core histones (7). **Effect on Fetal Hemoglobin Production:** Intermittent therapy in which butyrate is administered for 4 days, followed by 10-24 days without drug, induces fetal globin gene expression in 9 of every 11 patients, with the mean Hb F in this group increased 7-21 % over the course of 39 weeks (8). Butyrate is likewise a HDAC inhibition-mediated fetal globin gene inducer in patients with  $\beta$ -thalassemia (9). **Other Actions of Butyrate on Histone Acetylation:** Butyrate inhibition of HDAC activity affects the expression of ~2% of mammalian genes. Promoters of butyrate-responsive genes have butyrate response elements, and a model has been proposed in which inhibition of Sp1/Sp3-associated HDAC activity leads to histone hyperacetylation and transcriptional activation of the p21(Waf1/Cip1) gene, with the latter inhibiting cyclin-dependent kinase 2 activity and thereby arresting cell cycling (10). 1. ### Butyrolactone I

This natural product ( $FW = 424.45 \text{ g/mol}$ ), first identified in species of *Aspergillus* and named systematically as 2,5-dihydro-4-hydroxy 2-[(4-hydroxy-3-(3-methyl-2-butenyl)phenyl)methyl]-3-(4-hydroxyphenyl)-5-oxo-2-furancarboxylic acid methyl ester, competes with ATP in cyclin-dependent kinase reactions. The  $IC_{50}$  values for these kinases are typically 0.6-1.5  $\mu\text{M}$ . Butyrolactone I also inhibits cell proliferation by the inhibiting pRb phosphorylation in IMR32 cells, causing both  $G_1$  and  $G_2$  arrest and stimulating apoptosis. **Target(s):** cyclin-dependent kinases 1 and 2 (1,2,4); cdk5 (1); protein kinase C (1); protein kinase A (1); MAP kinase (1); casein kinase II (1); [tau protein] kinase (3). 1. ### BX-795

This nonselective signal transduction inhibitor and antineoplastic agent ( $FW = 591.47 \text{ g/mol}$ ; CAS 702675-74-9; Solubility: 120 mg/mL DMSO; <1 mg/mL Water), systematically named *N*-(3-(5-iodo-4-(3-(thiophene-2-carboxamido)propylamino)pyrimidin-2-ylamino)phenyl)pyrrolidine-1-carboxamide, targets the phosphoinositide 3-kinase/3-phosphoinositide-dependent kinase 1 (PDK1)/Akt signaling pathway plays a key role in cancer cell growth, survival, and tumor angiogenesis and represents a promising target for anticancer drugs. BX-795 targets TBK1 ( $IC_{50} = 6 \text{ nM}$ ), IKK $\epsilon$  ( $IC_{50} = 41 \text{ nM}$ ), PDK-1 ( $IC_{50} = 111 \text{ nM}$ ), and ERK8 ( $IC_{50} = 140 \text{ nM}$ ), but acts more broadly by inhibiting MARK1 ( $IC_{50} = 55 \text{ nM}$ ), MARK2 ( $IC_{50} = 53 \text{ nM}$ ), MARK4 ( $IC_{50} = 19 \text{ nM}$ ), NUA1 ( $IC_{50} = 5 \text{ nM}$ ), VEGFR ( $IC_{50} = 157 \text{ nM}$ ), MLK1 ( $IC_{50} = 50 \text{ nM}$ ), MLK2 ( $IC_{50} = 46 \text{ nM}$ ), MLK3 ( $IC_{50} = 42 \text{ nM}$ ). BX795 also inhibits the phosphorylation of JNK1/2 and p38 $\alpha$  MAPK in MEFs stimulated with IL-1 $\alpha$  or TNF $\alpha$ . The effect of BX795 on the activation of JNK1/2 and p38 $\alpha$  MAPK does not result from the inhibition of TBK1/IKK $\epsilon$ . 1. Feldman, et al. (2005) *J. Biol. Chem.* **280**, 19867. 2. ## C1 Esterase Inhibitor (or C1 Inhibitor)

This serpin (CAS 80295-38-1; *Abbreviation*: C1 INH), known commercially as Cinryze<sup>®</sup>, is the only known plasma inhibitor of the activated homologous serine proteases C1s and C1r in the complement cascade. C1-INH is also a major inhibitor of plasma kallikrein and factor XIIa. Hereditary angioedema (HAE), a rare genetic deficiency in functional C1-esterase inhibitor, is characterized by recurrent episodes of angioedema in the absence of associated urticaria. Therapy includes use of plasma-derived and recombinant C1 inhibitors, kallikrein inhibitors, and bradykinin B<sub>2</sub>-receptor antagonists. Prophylactic measures include use of plasma-derived C1 inhibitors, attenuated androgens, and antifibrinolytic agents, albeit with significant adverse events. **Primary Mode of Action**: C1-INH regulates the activation of the classical complement pathway, and genetic or acquired deficiencies of C1-INH result in recurrent episodes of angioedema (1-3). Like many other serpins, C1 INH is a slow-binding inhibitor ( $K_i = 0.03$  nM) that target proteases by forming a stable covalent serpin-enzyme complex (or SEC), resulting in the cleavage of the P<sub>1</sub>-P<sub>1'</sub> bond with the reactive center loop of the serpin, generating a COOH-terminal peptide ( $M_r = 4152$ ). This large-scale structural rearrangement exposes a binding site for low-density lipoprotein receptor-related protein (LRP), a multifunctional endocytic receptor that mediates the cellular uptake of the C1 INH-C1s and C1 IHN-C1r complexes, as well as other SEC's and unrelated ligands, such as lipoproteins, lipoprotein lipase, proteinase- or methylamine-activated  $\alpha_2$ -macroglobulin, bacterial toxins, and lactoferrin. Early blockade of complement activation by recombinant human C1-inhibitor prevents acute antibody-mediated rejection in pre-sensitized recipients (4). (For a discussion of the likely mechanism of inhibitory action, See *Serpins*; also  $\alpha_1$ -Antichymotrypsin) **Beriner P<sup>™</sup>**: This purified, pasteurized, and lyophilized concentrate of human plasma-derived C1 esterase inhibitor is an FDA-approved intravenous treatment for acute abdominal or facial attacks of hereditary angioedema (HAE) in adult and adolescent patients (5,6). **1.** Arlaud & Thielens (1993) *Meth. ## C-1

This PKC inhibitor and vasodilator (FW = 277.34 g/mol; CAS 84468-24-6; Solubility: 100 mM in DMSO), also named 1-(5-isoquinoline sulfonyl)piperazine, targets protein kinase C at  $\mu$ M concentrations, markedly inhibiting the release of superoxide anion from human PMN stimulated with phorbol myristate acetate or the synthetic diacylglycerol, 1-oleoyl-2-acetyl glycerol. This action agrees with previous findings that protein kinase C is the intracellular target for these agonists. In contrast, superoxide anion production (stimulated by the complement anaphylatoxin peptide C5a or the synthetic chemotaxin formyl-methionyl-leucyl-phenylalanine (f-Met-Leu-Phe)) were not inhibited by C-1. These observations suggest that the agonist-stimulated respiratory burst of human neutrophils employs parallel pathways, of which only one utilizes the calcium and phospholipid-dependent protein kinase. **1.** Gerard, McPhail, Marfat, *et al.* (1986) *J. Clin. Invest.* **77**, 61.

## C21

This selective PRMT inhibitor (FW = 2166.94 g/mol; CAS 1229236-78-5; Soluble: 2 mg/mL H<sub>2</sub>O; Sequence: Acetyl-SGXGKGGKGLGKGG

AKRHRKV, where X = N<sup>ε</sup>-(2-chloro-1-iminoethyl)-ornithine) targets Protein Arginine Methyl-Transferase 1, or PRMT1 (IC<sub>50</sub> = 1.8  $\mu$ M), with 5x selectivity for PRMT1 over PRMT6 and >250x over PRMT3 and CARM1 (1). Protein arginine methyltransferases catalyze the S-adenosyl-methionine-dependent post-translational methylation of arginine residues, with PRMT1 the major isozyme that generates most of the asymmetrically dimethylated arginine (See *Asymmetric Dimethylarginine*) subsequently liberated *in vivo* by proteolysis. C21 is a chloroacetam<sup>'''</sup>idine-containing peptide irreversibly modifies an active-site and inactivates the enzyme selectively. Plots of the pseudo first order rate constants of inactivation versus C21 concentration are saturable, consistent with a standard two-step inactivation process: *Reaction 1*: E + I  $\rightleftharpoons$  E·I; *Reaction 2*: E·I  $\rightarrow$  E-I, where E·I is a reversible complex, and E-I is the resulting covalent adduct,  $K_i = [E][I]/[E\cdot I] \leq 0.8$   $\mu$ M,  $k_{inact} = 3.1$  min<sup>-1</sup>, and  $k_{inact}/K_i = 4.6 \times 10^6$  M<sup>-1</sup>min<sup>-1</sup>. The fact that higher substrate concentrations protects against inactivation strongly suggests that enzyme inactivation involves modification of an active-site nucleophile. No inactivation is observed no inhibition was observed with H21, a control peptide lacking the chloro group. **1.** Obianyo, Causey, Osborne, *et al.* (2010) *Chembiochem.* **11**, 1219.

## C36

This thiazolium-based AGE breaker (FW = 310.19 g/mol), also known as 3-benzyloxy-carbonylmethyl-4-methylthiazol-3-ium bromide, selectively cleaves glucose-derived protein cross-links both *in vitro* and *in vivo*, when administered at 30-50 mg/kgilogram. Formation of Advanced Glycation End-products, or AGE, is a normal aging process, one that is accelerated in diabetes and likely to contribute to Alzheimer's Disease. AGE cross-links accumulate on long-lived proteins, especially collagen and elastin, often with harmful consequences for cardiovascular and renal systems. Proteins are mainly cross-linked as  $\alpha$ -dicarbonyl adducts (also called Amadori diones), and, akin to the well-known coenzyme thiamin pyrophosphate, C36 acts catalytically to cleave these  $\alpha$ -dicarbonyl cross-links, thus freeing the proteins. In so doing, C36 also blocks AGE fibrosis-associated gene expression and improves diabetes-associated cardiovascular dysfunction in rat models. (Given the high circulating concentrations of thiamin, one cannot discount the vitamin's role in mitigating AGE cross-link accumulation.) **1.** Cheng, Wang, Long, *et al.* (2007) *Br. J. Pharmacol.* **152**, 1196.

## C75

This fatty acyl lactone (FW<sub>free-acid</sub> = 254.33 g/mol; CAS 191282-48-1), systematically named as tetrahydro-4-methylene-2R-octyl-5-oxo-3S-furancarboxylic acid, inhibits fatty-acid synthase (1-5). C75 is also cytotoxic to many human cancer cell lines, an effect believed to be mediated by the accumulation of malonyl-coenzyme A in cells with an upregulated FAS pathway. **See also C75-CoA Target(s)**: enoyl-[acyl-carrier-protein] reductase (1); fatty-acid synthase (1-5);  $\beta$ -ketoacyl [acyl-carrier-protein] synthase I (1); thiolesterase (1). **1.** Rendina & Cheng (2005) *Biochem. C646

This potent cell-permeable p300/CBP histone acetyltransferase (HAT) inhibitor (FW = 445.42 g/mol; CAS 328968-36-1; Solubility: 30 mM in DMSO), named systematically as (*Z*)-4-(4-((5-(4,5-dimethyl-2-nitrophenyl)furan-2-yl)methylene)-3-methyl-5-oxo-4,5-dihydro-1*H*-pyrazol-1-yl)benzoic acid, competes at the acetyl-CoA binding pocket (IC<sub>50</sub> ~400 nM), selectively inducing cell-cycle arrest and apoptosis and blocking the growth of human melanoma, leukemia, lung, and prostate cancer cells *in vitro* (1-3). **Mechanism of Action:** Histone acetylation (*Reaction:* Histone + Acetyl-S-CoA  $\rightleftharpoons$  *N*<sup>ε</sup>-lysyl-Histone + CoASH) leads to charge neutralization of lysines residues, thereby reducing the affinity of acetylated histone tails for DNA by creating a more open state for transcription and forming binding sites for other effector molecules. C646 blocks dynamic acetylation of histone H3 Lys-4 trimethylation in mouse and fly cells, and locally across the promoter and start-site of inducible genes in the mouse, thereby disrupting RNA polymerase II association and the activation of these genes. The histone acetyltransferase p300 promotes self-renewal of acute myelogenous leukemia cells by acetylating AML1-ETO fusion protein (AE) and facilitating its downstream gene expression as a transcriptional co-activator, suggesting that p300 may be a potential therapeutic target for AE-positive AML (3). C646 inhibited cellular proliferation, reduced colony formation, evoked partial cell cycle arrest in G<sub>1</sub> phase, and induced apoptosis in AE-positive AML cell lines and primary blasts isolated from leukemic mice and AML patients (3). 1. Cabazitaxel

This semi-synthetic taxane (taxoid) (FW = 835.93 g/mol; CAS 183133-96-2), also known as XRP-6258 and Jevtana<sup>®</sup>, is a microtubule- (MT) stabilizing drug that, like Paclitaxel (Taxol), interrupts normal MT

cytoskeletal dynamics and forms a deranged cytoskeleton. Cabazitaxel binds to and stabilizes MTs, thereby inhibiting cell division, inducing cell-cycle arrest at G<sub>2</sub>/M, and inhibiting tumor cell proliferation. When used in combination with prednisone, cabazitaxel is highly effective in treating hormone-refractory prostate cancer. It is also effective against multidrug- and docetaxel-resistant cancer cell lines, demonstrating a survival benefit over mitoxantrone and prednisone in patients who failed docetaxel-based chemotherapy. Unlike paclitaxel, cabazitaxel is a poor substrate for the P-glycoprotein multidrug resistance transporter. 1. Galsky, Dritselis, Kirkpatrick & Oh (2010) *Nature Rev. Drug Discov.* **9**, 677.

Cabergoline

This long-acting dopamine D<sub>2</sub> receptor agonist (FW = 451.60 g/mol; CAS 81409-90-7), also named 6*aR*,9*R*,10*aR*)-*N*-[3-(dimethylamino)propyl]-*N*-(ethylcarbamoyl)-7-prop-2-enyl-6,6*a*,8,9,10,10*a*-hexahydro-4*H*-indolo[4,3-*fg*]quinoline-9-carboxamide, is used to treat: hyperprolactinemia; adjunctive therapy of prolactin-producing pituitary gland tumors; early-phase Parkinson's disease (as a monotherapy) and progressive-phase Parkinson's disease (in a combination with levodopa and carbidopa). Prolactin-lowering effects occur rapidly and, after a single dose, were evident at the end of follow up (21 days) in puerperal women, and up to 14 days in patients with hyperprolactinaemia (1). **Targets:** Serotonin 5-HT<sub>1A</sub> Receptor, K<sub>i</sub> = 20 nM (as agonist); Serotonin 5-HT<sub>1B</sub> Receptor, K<sub>i</sub> = 480 nM (action unknown); Serotonin 5-HT<sub>1D</sub> Receptor, K<sub>i</sub> = 8.7 nM (action unknown); Serotonin 5-HT<sub>2A</sub> Receptor, K<sub>i</sub> = 6.2 nM (as agonist); Serotonin 5-HT<sub>2B</sub> Receptor, K<sub>i</sub> = 1.2 nM (as agonist); Serotonin 5-HT<sub>2C</sub> Receptor, K<sub>i</sub> = 690 nM (as agonist); Adrenergic α<sub>1A</sub> Receptor, K<sub>i</sub> = 288 nM (action unknown); Adrenergic α<sub>1B</sub> Receptor, K<sub>i</sub> = 60 nM (action unknown); Adrenergic α<sub>1D</sub> Receptor, K<sub>i</sub> = 166 nM (action unknown); Adrenergic α<sub>2A</sub> Receptor, K<sub>i</sub> = 12 nM (action unknown); Adrenergic α<sub>2B</sub> Receptor, K<sub>i</sub> = 70 nM (as antagonist); Adrenergic α<sub>2C</sub> Receptor, K<sub>i</sub> = 22 nM (action unknown); Adrenergic β<sub>1</sub> Receptor, K<sub>i</sub> >10,000 nM (action unknown); Adrenergic β<sub>2</sub> Receptor, K<sub>i</sub> >10,000 nM (action unknown); Dopamine D<sub>1</sub> Receptor, K<sub>i</sub> = 214 nM (as agonist); Dopamine D<sub>2S</sub> Receptor, K<sub>i</sub> = 0.6 nM (as agonist); Dopamine D<sub>2L</sub> Receptor, K<sub>i</sub> = 0.9 nM (as agonist); Dopamine D<sub>3</sub> Receptor, K<sub>i</sub> = 0.8 nM (as agonist); Dopamine D<sub>4</sub> Receptor, K<sub>i</sub> = 56 nM (as agonist); Dopamine D<sub>5</sub> Receptor, K<sub>i</sub> = 22.4 nM (action unknown). 1. Rains, Bryson & Fitton (1995) *Drugs* **49**, 255.

Cabozantinib

This oral, pan-tyrosine kinase inhibitor and antiangiogenic agent (FW = 501.51 g/mol; CAS 849217-68-1; Soluble to 100 mM in DMSO), also known as XL184, Cometriq<sup>®</sup>, Cabometyx<sup>®</sup>, and *N*-(4-((6,7-dimethoxyquinolin-4-yl)oxy)phenyl)-*N*-(4-fluorophenyl)-cyclopropane-

1,1-dicarboxamide, targets angiogenesis and metastasis in cancers with dysregulated mitogenic and angiogenic signaling pathways, particularly within the VEGFR and MET transduction cascades. In 2012, cabozantinib was approved by FDA for the treatment of metastatic medullary thyroid cancer. Cabometyx is also approved by FDA for the treatment of patients with advanced renal cell carcinoma who have received prior antiangiogenic therapy. A simple, rapid and sensitive HPLC-MS/MS method for detecting and quantifying cabozantinib is available (3). **Target(s):** VEGFR (IC<sub>50</sub> = 0.035 nM); c-Met (IC<sub>50</sub> = 1.3 nM); KIT (IC<sub>50</sub> = 4.6 nM); RET (IC<sub>50</sub> = 5.2 nM); FLT4 (IC<sub>50</sub> = 6 nM); Axl (IC<sub>50</sub> = 7 nM); Flt3 (IC<sub>50</sub> = 11.3 nM); Flt1 (IC<sub>50</sub> = 12 nM); and Tie2 (IC<sub>50</sub> = 14.3 nM). 1. ### Cacodylate

This organoarsenical (FW<sub>sodium-salt</sub> = 159.98 g/mol; CAS 124-65-2; MP = 195-196°C; Solubility = 0.2 g/mL; pK<sub>a</sub> = 6.27 at 25°C), also known as dimethylarsinate, is the conjugate base of cacodylic acid and is a common pH buffer salt. Given its structural similarity to orthophosphate and phosphate esters, care should be exercised when phosphate is a substrate or product. Cacodylate is also redox-active at pH < 6.5, inhibiting many sulfhydryl-dependent enzymes (1). **Caution:** Avoid contact with skin. Cacodylate and cacodylic acid are toxic to most animals and plants. Combined in a 4:1 ratio (w/w), sodium cacodylate and cacodylic acid were widely employed by the U.S. military under the name Agent Blue to kill grasses and rice plants. The aim was defoliate supply routes and reduce foodstuffs used by the North Vietnamese. **Target(s):** adenosine-phosphate deaminase (2,9); aspartate aminotransferase (3); galactosyltransferase (4); nitrogenase (5); phenylalanyl-tRNA synthetase (6); *Ustilago sphaerogena* ribonuclease (7); galactarate dehydratase (8); acetyltransferase (10). 1. ### Cadaverine

This toxic diamine (FW<sub>free-base</sub> = 102.18 g/mol; CAS 462-94-2; pK<sub>a</sub> values of 9.13 and 10.25), also known as pentamethylenediamine and 1,5-diaminopentane, is formed by lysine decarboxylase. It is an excellent substrate for amine oxidase. Cadaverine has a putrid odor, contributing to the odor of decaying meat. Indeed, decaying carcasses produce putrescine and cadaverine, both of which are volatile chemottractants for vultures. These facts that remind us to keep this substance in a desiccator, preferably above a sulfuric acid trap. Cadaverine in its free base form readily absorbs atmospheric CO<sub>2</sub>, and aqueous solutions must be freshly prepared and kept in tightly sealed vessels. **Target(s):** tRNA adenylyltransferase (1); spermidine synthase (putrescine aminopropyltransferase, also an alternative substrate (2,42-45); kynureninase (3,29); porins (4-7); lipoxigenase-18, *or* ornithine decarboxylase (9,10,27,28); histamine *N*-methyltransferase (11); protein kinase C (12); conversion of proacrosin to acrosin (13); agmatinase (14); arginine decarboxylase (15,26); T<sub>4</sub> polynucleotide ligase (16); ouabain-sensitive and K<sup>+</sup>-dependent *p*-nitrophenyl-phosphatase (17); amino-acid *N*-acetyltransferase, *or N*-acetylglutamate synthetase (18,49); pyridoxal kinase (19); RNA-directed RNA polymerase (20); putrescine oxidase (21); indolethylamine *N*-methyltransferase, *or* amine *N*-methyltransferase (22); lysyl-tRNA synthetase (23,24); diaminopimelate decarboxylase (25); agmatine deaminase (30-32); acetyltransferase

(33); pyridoxal kinase (34); aminolevulinic acid aminotransferase, mildly inhibited (35); ornithine δ-aminotransferase (36,37); deoxyhypusine synthase, weakly inhibited (38); homospermidine synthase, spermidine specific (39); homospermidine synthase (40,41); protein-glutamine γ-glutamyltransferase, *or* transglutaminase; also as an alternative substrate (46,47); diamine *N*-acetyltransferase (48); putrescine *N*-methyltransferase (50,51); deoxyhypusine monooxygenase, weakly inhibited (52). 1. ### Cadazolid

This fluoroquinolone-class antibiotic (FW = 585.55 g/mol; CAS 1025097-10-2), also named 1-cyclopropyl-6-fluoro-7-[4-(2-fluoro-4-[(5R)-5-(hydroxymethyl)-2-oxo-1,3-oxazolidin-3-yl]phenoxy)methyl]-4-hydroxypiperidin-1-yl]-4-oxo-1,4-dihydroquinolin-3-carboxylate, is a broad-spectrum systemic antibacterial agent that targets Type II DNA topoisomerases (gyrases), which are required for bacterial replication and transcription. Cadazolid is effective against *Clostridium difficile*, a major

cause of drug resistant diarrhea in the elderly. (For the prototypical member of this antibiotic class, **See Ciprofloxacin**) 1. Rashid, Dalhoff, Weintraub & Nord (2014) *Anaerobe* 28, 216.

### Caffeic Acid

This yellow-colored anti-oxidant (FW<sub>free-acid</sub> = 180.16 g/mol), also known as 3,4-dihydroxycinnamic acid, is typically found in plants in conjugated form. Caffeic acid is a key intermediate in the biosynthesis of lignin, a major contributor to plant biomass. Caffeic inhibits leukotriene biosynthesis and stimulates low-density lipoprotein oxidation. It also significantly reduces lipid peroxidation and decreases DNA damage in UVB-irradiated cells. **Target(s):** xanthine oxidase (1,6,12,30,53); phenylalanine ammonia-lyase (2,16,23,36-40); *N*-acetylxanthine oxidase (3); indoleacetate oxidase (4); horseradish peroxidase (5); aromatic-amino-acid decarboxylase, or dopa decarboxylase (7,19,21);  $\gamma$ -butyrobetaine dioxygenase, or  $\gamma$ -butyrobetaine hydroxylase;  $K_i$  = 6  $\mu$ M (8);  $\alpha$ -amylase (9,27,42);  $\beta$ -amylase (9); 5-lipoxygenase, or arachidonate 5-lipoxygenase (10,11,59); glutathione *S*-transferase (13,14); DNA methyltransferase (15); starch synthase (17); thiamin transport (18); vitamin D<sub>3</sub> 1 $\alpha$ -monooxygenase (20); vitamin D<sub>3</sub> 24-monooxygenase (20); lipase, pancreatic (22); arylamine *N*-acetyltransferase (24); phosphorylase kinase (25); protein kinase A (25); protein kinase C (25); neutrophil elastase (26); trypsin (27); gelatinase B (matrix metalloproteinase 9) (28); sucrose, weakly inhibited (29); 4-coumaroyl-CoA synthetase, or 4-coumarate:CoA ligase (31,32); DNA topoisomerase I (33); chorismate mutase (34); phenylpyruvate tautomerase (35); peptidyl-dipeptidase A, or angiotensin I-converting enzyme, weakly inhibited (41); chlorogenate hydrolase (43); phenol sulfotransferase, or aryl sulfotransferase (44); shikimate kinase (45); 3-deoxy-7-phosphoheptulonate synthase (46); anthocyanin 5-*O*-glucoside 6''-*O*-malonyltransferase (47); quinate *O*-hydroxycinnamoyltransferase (48); arylamine *N*-acetyltransferase (49-51); catechol *O*-methyltransferase (52); tyrosinase, or monophenol monooxygenase (54,55); phenylalanine 4-monooxygenase (56); hyoscamine (6*S*)-dioxygenase (57); procollagen-proline 4-dioxygenase (58); 15-lipoxygenase, or arachidonate 15-lipoxygenase (60); 12-lipoxygenase, or arachidonate 12-lipoxygenase (61); 3,4-dihydroxyphenylacetate 2,3-dioxygenase (62); lipoxygenase (63); protocatechuate 3,4-dioxygenase (64,65). 1. ### Caffeine

This naturally occurring CNS stimulant and diuretic (FW = 194.19 g/mol; CAS 58-08-2), also known as 1,3,7-trimethylxanthine, is a secondary metabolite in coffee (*Coffea arabica* and *Coffea canephora*) and tea (*Camellia sinensis*) plants. It competitively inhibits 3',5'-cyclic AMP phosphodiesterase, thereby sustaining the cAMP concentration, which stimulates Protein Kinase (PKA). In this way, caffeine maintains the high phosphorylation state of PKA's protein substrates. Elevated cAMP concentrations also activate popeye domain-containing proteins (or Popdc), cyclicAMP-gated ion channels as well as Exchange Proteins Activated by cAMP (or EPAC), including RAPGEF3. (See Adenosine 3',5'-Cyclic Monophosphate) **Other Actions of Caffeine:** Caffeine is also a nonselective low-affinity adenosine receptor antagonist. Adenosine generally inhibits adenylyl cyclase (AC) through the action of high-affinity A<sub>1</sub> receptors and stimulates AC via low-affinity A<sub>2</sub> receptors. Caffeine binds to adenosine receptors without activating them, thereby acting as a competitive inhibitor and reversing the latter's effects on the release of acetylcholine, dopamine, norepinephrine, GABA, and serotonin. Caffeine is also known to inhibit DNA repair. First isolated from coffee beans in 1821, it was later synthesized by Nobelist Emil Fischer (see References. 10 & 11). **Caffeine Consumption:** Caffeine is widely used to ward off drowsiness, restore alertness, and elevate mood. While mildly habit-forming, moderate caffeine consumption has no direct link to any serious health risks. Caffeine is classified by the Food and Drug Administration as "Generally Recognized as Safe", with toxic doses >10 g for adults, much higher than typically consumed (300-500 mg per day). An 8-ounce cup of brewed coffee contains 90-200 mg caffeine, whereas a 12-ounce can of Coca Cola® contains 32 mg (DietCoke®, 42 mg). Generally regarded as safe when consumed by healthy adults, high consumption is ill-advised for cardiac patients and pregnant women. **Pharmacokinetics:** Caffeine is rapidly and

nearly completely absorbed from caffeinated beverages, reaching peak blood levels within 30-60 min. The apparent first-order caffeine elimination rate constant ( $0.16 \text{ hour}^{-1}$ , when administered as a 50-mg initial intravenous dose, and  $0.10 \text{ hour}^{-1}$  for 750 mg) decreases linearly with dose (1). The total body clearance rate of  $0.98 \text{ mL/min/kg}$  is dose-independent. The apparent volume of distribution is high and trends upwards with increasing dose (1). Primary metabolites are paraxanthine, theobromine and theophylline, dimethylxanthines that also contribute to caffeine's pharmacological effects (See also *Theophylline*). Caffeine activates the PI3K/Akt pathway and prevents apoptotic cell death in a Parkinson's disease model of SH-SY5Y cells (2). **Target(s):** 3',5'-cyclic-nucleotide phosphodiesterase (3-5,25-28); purine-nucleoside phosphorylase (6,11); D-amino-acid oxidase (7,10); photoalkylated DNA endonuclease, or DNA (apurinic or apyrimidinic site) lyase (8); DNA insertase (8); dATP(dGTP)-DNA purinetransferase (13,34); adenosine receptor (14); ATP diphosphatase, or ATP pyrophosphatase (15); adenosine receptor (16,17); acetylcholinesterase (18); guanylate cyclase (19); lactoylglutathione lyase, or glyoxalase I (20); adenosine deaminase (21); purine nucleosidase, weakly inhibited (22); adenine deaminase (22); hypoxanthine(guanine) phosphoribosyltransferase (22,38); 2',3'-cyclic-nucleotide 3'-phosphodiesterase (23); 3',5'-cyclic-GMP phosphodiesterase, or cGMP phospho-diesterase (24, 25, 28); alkaline phosphatase (29); hydroxyacylglutathione hydrolase, or glyoxalase II (20); phosphatidylinositol-4-phosphate 3-kinase (29); 1-phosphatidylinositol 4 kinase (33); thymidine kinase (33,34);  $\text{NAD}^+$  ADP-ribosyltransferase, or poly(ADP-ribose) polymerase (35-37); xanthine phosphoribosyltransferase (38); glycogen synthase (39); glycogen phosphorylase (40-46).

### Calcineurin Autoinhibitory Peptide

This specific calcineurin inhibitor (FW = 2930.35 g/mol; CAS 148067-21-4; *Sequence*: ITSFEEAKGLDRINERMPRRDAMP), corresponding to residues 457-482 of the calmodulin-binding domain of calcineurin (PP2B), inhibits  $\text{Mn}^{2+}$ -stimulated calcineurin activity ( $\text{IC}_{50} = 10 \mu\text{M}$ , with  $^{32}\text{P}$ -myosin light chain as a substrate). Calcineurin autoinhibitory peptide has no effect on  $\text{Ni}^{2+}$ -stimulated enzyme activity. It does not inhibit CaM kinase II, protein phosphatase 1 or 2A. 1. Hashimoto, *et al.* (1990) *J. Biol. Chem.* **265**, 1924. 2. Yokoyama & Wang (1994) *FEBS Lett.* **337**, 128. 3. Perrino, *et al.* (1995) *J. Biol. Chem.* **270**, 340.

### Calcipotriol

This vitamin D<sub>3</sub> analogue and anti-psoriasis drug (FW = 412.61 g/mol; CAS 112828-00-9), also named (1*R*,3*S*,5*E*)-5-{2-[(1*R*,3*aS*,4*Z*,7*aR*)-1-[(2*R*,3*E*)-5-cyclopropyl-5-hydroxypent-3-en-2-yl]-7*a*-methyloctahydro-1*H*-inden-4-ylidene]ethylidene}-4-methylidene-cyclohexane-1,3-diol and calcipotriene, is a vitamin D receptor ligand that inhibits epidermal cell proliferation and enhances cell differentiation. Psoriasis is characterized by hyperproliferation and abnormal differentiation of epidermal keratinocytes resulting from a disordered immune response. In patients with chronic plaque psoriasis, calcipotriol (applied as an ointment twice daily) is significantly more effective than betamethasone valerate and dithranol. Topically applied calcipotriol has low hypercalcemic potential (1). Enstilar<sup>®</sup> (calcipotriene and betamethasone dipropionate) is an FDA-approved aerosol foam for the topical treatment of plaque psoriasis in patients 18 years of age and older. 1. Murdoch & Clissold (1992) *Drugs* **43**, 415.

### Calcitonin

CGNLSTCMLGTYTQDFNKFHTFPQTAIGVGAP-NH<sub>2</sub>

Human Calcitonin

CGNLSTCVLGLKLSQELHLKLTYPRTNTGSGTP-NH<sub>2</sub>

Salmon Calcitonin

This calcium-regulating hormone and antiresorptive drug (MW = 3548 g), also known as thyrocalcitonin, is FDA-approved, intravenously or intranasally administered drug (prepared synthetically, based on the salmon sequence) for inhibiting bone loss in osteoporosis. Calcitonin lowers blood calcium ion levels in four ways: by reducing  $\text{Ca}^{2+}$  absorption by the intestine, by inhibiting osteoclast activity in bones, by stimulating osteoblastic activity in bones, and by reducing renal tubular cell reabsorption of  $\text{Ca}^{2+}$ , followed by urinary excretion. Calcitonin has a short absorption half-life (10-15 minutes) and a somewhat longer elimination half-life (50-80 minutes). **Mechanism of Action:** Calcitonin reduces blood  $\text{Ca}^{2+}$  and opposes the action of parathyroid hormone (PTH). In humans, calcitonin is produced by thyroid parafollicular cells (C-cells). Calcitonin protects the skeleton during episodes of increased calcium demand for growth, pregnancy and lactation. Calcitonin exerts its bone-sparing effects by targeting osteoclasts, but not odontoclasts, suiting it as an inhibitor bone loss without altering the dynamics of dental root surface remodeling.

activating the G-proteins often found on osteoclasts. **Calcitonin Receptor:** Found on osteoclasts, kidney and regions of the spine and brain, the calcitonin receptor is a G protein-coupled receptor, which is coupled by Gs (*i.e.*, cAMP) to adenylate cyclase and thereby to the generation of cAMP in target cells. It also binds to G<sub>q</sub>-coupled (*i.e.*, phospholipase-linked) transduction pathways to regulate calcium homeostasis. **Salmon Calcitonin:** Sharing structural features with calcitonins, salmon calcitonin also has 32 residues, terminating in prolinamide and containing a cystine linkage between Cys-1 and Cys-7 (1). Although differing in their sequences, human, porcine, bovine and salmon calcitonins are homologous in nine of their thirty-two positions. Moreover, to exert its hypocalcemic effect, all 32 residues are required. The much higher biological potency of salmon calcitonin commends its use as a drug. Nasal salmon calcitonin exerted a significant hypocalcemic effect, but did not interfere with antigen- or mitogen-induced expansion of T-lymphocytes, suggesting it is unlikely that nasal salmon calcitonin affects cell-mediated immunity in healthy subjects (2). Salmon calcitonin is effective in relieving pain associated with postmenopausal osteoporosis, especially in resolving pain during the first month following a vertebral bone crush (3). 1. ### Calcium Ion

This alkaline earth ion (Symbol, Ca; Atomic Number = 20; Atomic Weight = 40.08; Pauling Ionic Radius = 1.14 Å) is a group 2 (or group IIA) element, situated directly beneath magnesium in the Periodic Table. [Note: The Shannon-Prewitt Scale for effective ionic radius takes into account that the effective ionic radius *r* depends on the coordination number, such that for *n* = 6, *r* = 1.00 Å; for *n* = 7, *r* = 1.06 Å; for *n* = 8, *r* = 1.12 Å; for *n* = 9, *r* = 1.18 Å; for *n* = 10, *r* = 1.23 Å; ; for *n* = 12, *r* = 1.34 Å.] Calcium is an essential element in all living organisms (although some fungi may be exceptions). It is a major constituent of bones, teeth, shells, and other hard tissues. It is involved in the regulation of a number of enzymes and binds to quite a few proteins; *e.g.*, calmodulin, calcium-dependent ATPases, myosin, and calcium pumps. A significant number of proteins use calcium ions as a cofactor, including tryptophan dehydrogenase, protein-glutamine  $\gamma$ -glutamyltransferase, [myosin light-chain] kinase, calcium/calmodulin-dependent protein kinase, 1-D-*myo*-inositol-trisphosphate 3-kinase, phospholipase A<sub>2</sub>, calpain, leucolysin, envelysin, stromelysins, gelatinases, neutrophil collagenase, russelsysin, macrophage elastase, apyrase, and 3-ketoalidoxylamine C-N-lyase. Calcium ions are messengers in nerve and muscle responses and they initiate chemotropic responses in pollen. The high degree of spatial and temporal precision of calcium ion control of cellular processes requires the highly coordinated interplay of calcium ion channels, stores, and oscillations. Accumulators of calcium include mammalian bone, many invertebrate shells, and some red algae. **Radioisotopes:** The nuclide with the longest half-life is <sup>41</sup>Ca: 1.03 x 10<sup>5</sup> years (via nuclear disintegration by electron capture: 0.421 MeV). Calcium-47 (half-life = 4.536 days;  $\beta$ -emitter, 1.988 MeV) is used in a number of metabolic studies, as is calcium-45, a  $\beta$ -emitter (0.257 MeV) with a half-life of 162.7 days. A special note of precaution should be presented here. **Caution:** Bone is the critical organ in terms of calcium dose, and the effective biological half-life of calcium ion in humans is nearly twenty years. The experimenter using radioactive calcium is at risk, and double-gloving and great caution is recommended for those working with radioactive calcium. **Inhibitory Targets:** Divalent calcium cation (Ionic Radius = 0.99 Å) combines readily with oxygen ligands (chiefly water, phosphates, polyphosphates, and carboxylates to reversibly form stable metal ion complexes. More than 300 enzymes are known to be inhibited by divalent calcium, far too many to list here. For most, the inhibitory effect occurs at calcium ion concentrations well above the physiologic range found in most cells.

### Calcium Ion Channel Blockers

In search of desired pharmacologic outcomes over the last half century, researchers have uncovered the unique properties of a wide spectrum of calcium ion channel blockers. The following partial list tallies calcium ion blockers and modulators that are described in this reference. **See also** Amlodipine; Amrinone; Anandamide; Anipamil; Aranidipine; Azelnidipine; Azimilide; Benidipine; Bepidil; Berbamine; Bevantolol; Canadine; Carboxyamidotriazole; Caroverine; Cilnidipine; Cinnarizine; Clevidipine; Conotoxins; Fantofarone; Fasudil; Flunarizine; Gabapentin; Magnesium ion; Manoalide; Mibefradil; Naftopidil;

Nicardipine; Niguldipine; Nimodipine; Ochratoxin A; Oxodipine; Pregabalin; Prenylamine; Valproate; Valpromide; Verapamil.

### Calmidazolium Chloride

This calmodulin antagonist (FW = 687.71 g/mol; CAS 57265-65-3), also known as compound R-24571, inhibits calmodulin-dependent cyclic nucleotide phosphodiesterase 1 (IC<sub>50</sub> = 0.01  $\mu$ M) and skeletal muscle sarcoplasmic reticulum Ca<sup>2+</sup>-exporting ATPase (K<sub>i</sub> = 0.06  $\mu$ M). Stock solutions are typically prepared in dimethyl sulfoxide and are stable for several weeks. When in aqueous solutions, calmidazolium chloride binds to borosilicate laboratory glassware. **Target(s):** 3',5'-cyclic-nucleotide phospho-diesterase (1,5,9,23); Ca<sup>2+</sup>-transporting ATPase (1,4,9,11,22); calpains (2); adenylate cyclase (3,15,16,20); Na<sup>+</sup> channels (6); Ca<sup>2+</sup>-dependent protein kinase (7,10,11); Ca<sup>2+</sup> channels (8); NADH: semidehydroascorbate oxidoreductase (12); myosin light-chain kinase (13,19); phosphatidylinositol-specific phospholipase C (14); calmodulin-stimulated protein phosphatase (17); F<sub>1</sub> ATPase (18); inositol-1,4,5-trisphosphate 5-phosphatase (21); Ca<sup>2+</sup>/calmodulin dependent protein kinase (24); NAD<sup>+</sup> kinase (25); calmodulin-lysine *N*-methyltransferase (26,27); heme oxygenase (28); nitric-oxide synthase (29-32). 1. ### Calmodulin-Dependent Protein Kinase II, Fragment 281-309

This 29-residue fragment (MW = 3374.09 g; Sequence: MHRQET VDCLKKFNARRKLLKGAILTTML; Isoelectric Point = 10.45) is a tight-binding inhibitor of Ca<sup>2+</sup>/calmodulin-dependent protein kinase II (IC<sub>50</sub> = 80

nM). The oligopeptide contains elements of the calmodulin-binding, inhibitory, and autophosphorylation domains of the protein kinase. It is also an alternative substrate of protein kinase C, undergoing phosphorylation at Thr-286. Replacement of this residue (*i.e.*, [Thr-286-Ala]-calmodulin-dependent protein kinase II fragment 281-309) results in a synthetic peptide that also inhibits the kinase ( $IC_{50} = 2 \mu M$ ). 1. Colbran, Fong, Schworer & Soderling (1988) *J. Biol. Chem.* **263**, 18145. 2. Colbran, Smith, Schworer, Fong & Soderling (1989) *J. Biol. Chem.* **264**, 4800. 3. Fukunaga, Stoppini, Miyamoto & Muller (1993) *J. Biol. Chem.* **268**, 7863.

#### Calmodulin-Dependent Protein Kinase II, Fragment 290-309

This peptide (MW = 2202.78 g; *Sequence*: LKKFNARRKLGAILTTL; Isoelectric Point = 12.03) is a tight-binding inhibitor of  $Ca^{2+}$ /calmodulin-dependent protein kinase II ( $IC_{50} = 52$  nM). The oligopeptide contains the calmodulin-binding, inhibitory, and autophosphorylation domains of the protein kinase. **Target(s)**:  $Ca^{2+}$ /calmodulin-dependent protein kinase II (1-3); calmodulin-lysine *N*-methyltransferase (4). 1. Payne, Fong, Ono, *et al.* (1988) *J. Biol. Chem.* **263**, 7190. 2. Basavappa, Mangel, Scott & Liddle (1999) *Biochem. Biophys. Res. Commun.* **254**, 699. 3. #### Calpastatin

This naturally occurring non-lysosomal protein (MW = 126 kDa; Accession: BAA03747) inhibits calpains, the calcium-activated proteases that control steps in cell fusion, mitosis and meiosis. Calpains are heterodimers of a small regulatory subunit and one of three large catalytic subunits, designated Calpain 1, Calpain 2 and Calpain p94. The three subdomains of this intrinsically disordered protein bind to wrap around calpain, making contact with three non-active-site regions and blocking substrate access. Seven isoforms of the human protein are produced by alternative splicing. The  $K_i$  value reported with  $\mu$ -calpain (calpain I) is 32 nM. **Target(s)**: calpain-1, or  $\mu$ -calpain (1,3-12,14); calpain-2, or m-calpain (2-12); picornain 3C, weakly inhibited (13). 1. #### Calpeptin

This potent dipeptide aldehyde inhibitor (FW = 362.47 g/mol; CAS 117591-20-5; Soluble to 72 mg/mL in DMSO), also known as *N*<sup>z</sup>-(benzyloxycarbonyl)-L-leucyl-L-norleucinal and Z-LNle-CHO, targets calpain-1 ( $IC_{50} = 52$  nM), calpain-2 ( $IC_{50} = 34$  nM), and papain ( $IC_{50} = 138$  nM). Peptide aldehyde hydrates most often resemble tetrahedral intermediates formed by  $H_2O$  attack on peptide substrates. Alternatively, these inhibitors may form adducts with an active-site nucleophile, again by resembling intermediates in a double-displacement mechanism. Calpeptin also modulates the processing of the  $\beta$ -amyloid precursor protein. Calpeptin is cell-permeable and soluble in dimethyl sulfoxide and dimethylformamide. It is also a weak inhibitor of HIV protease ( $IC_{50} = 160$

$\mu M$ ). **Target(s)**: calpain-1,  $\mu$ -calpain (1,2); calpain-2, or m-calpain (2,6,7); papain (1); protein-tyrosine phosphatase (3); peptide deformylase (*N*-formylmethionylaminoacyl-tRNA deformylase (4); HIV retropepsin, weakly inhibited (5); cathepsin V (8); cathepsin K (9); phosphatidylinositol-4-phosphate 3-kinase (10). 1. Tsujinaka, Kajiwara, Kambayashi, *et al.* (1988) *Biochem. Biophys. Res. Commun.* **153**, 1201. 2. Saito & Nixon (1993) *Neurochem. Res.* **18**, 231. 3. Schoenwaelder & Burridge (1999) *J. Biol. Chem.* **274**, 14359. 4. Durand, Green, O'Connell & Grant (1999) *Arch. Biochem. Biophys.* **367**, 297. 5. Sarubbi, Seneci, Angelastro, *et al.* (1993) *FEBS Lett.* **319**, 253. 6. Brömme, Li, Barnes & Mehler (1999) *Biochemistry* **38**, 2377. 9. Brömme, Okamoto, Wang & Biroc (1996) *J. Biol. Chem.* **271**, 2126. 10. Crljen, Volinia & Banfic (2002) *Biochem. J.* **365**, 791.

#### Calphostin C

This red-colored naturally occurring polycyclic (FW = 790.78 g/mol; CAS 121263-19-2) from *Cladosporium cladosporioides*, named (2*R*)-1-[3,10-dihydroxy-12-[(2*R*)-2-(4-hydroxyphenoxy)carbonyloxypropyl]-2,6,7,11-tetramethoxy-4,9-dioxoperylen-1-yl]propan-2-yl benzoate, selectively inhibits protein kinase C,  $IC_{50} = 50$  nM. It is a weaker inhibitor of other protein kinases: *e.g.*, protein kinase A ( $IC_{50} > 50 \mu M$ ), protein kinase G ( $IC_{50} > 25 \mu M$ ), p60v-src ( $IC_{50} > 50 \mu M$ ), and [myosin light-chain] kinase ( $IC_{50} > 5 \mu M$ ). Calphostin C absorbs light strongly in the visible and ultraviolet range of the spectra. Inhibition by calphostin C is dependent on exposure to light: ordinary fluorescent light is sufficient for full activation of the inhibitor. Light-activated calphostin C inhibits protein kinase C isozymes by covalent modification of the lipid binding regulatory domain. **Target(s)**: protein kinase C (1-7,11,12); cGMP-dependent protein kinase (1,2); [myosin-light chain] kinase (1,2); cAMP-dependent protein kinase (1,2); p60v-aro protein kinase (1,2); phospholipase D (8,9); L-type  $Ca^{2+}$  channels (10); inositol-trisphosphate 3-kinase (13). 1. Kobayashi, Nakano, Morimoto & Tamaoki (1989) *Biochem. Biophys. Res. Commun.* **159**, 548. 2. Tamaoki & Nakano (1990) *Biotechnology* **8**, 732. 3. Gopalakrishna, Chen & Gundimeda (1995) *Meth. #### Calycanthine

This highly toxic alkaloid (FW<sub>free-base</sub> = 346.48 g/mol) from *Calycanthus floridus* (Carolina allspice), *C. glaucus* (Eastern sweetshrub), *Chimonanthus praecox* (wintersweet), *Idiospermum australiense* (a primitive flowering plant), and *Psychotria colorata*, is a very powerful convulsant and poison. It has been proposed its convulsant action arises from the inhibition of  $\gamma$ -aminobutyrate release as a result of interactions with L-type Ca<sup>2+</sup> channels and by inhibiting  $\gamma$ -aminobutyrate-mediated chloride currents at GABA<sub>A</sub> receptors. 1. Chebib, Duke, Duke, *et al.* (2003) *Toxicol. Appl. Pharmacol.* **190**, 58.

### Calyculin A

This marine toxin (FW<sub>free-acid</sub> = 1009.18 g/mol) from the sponge *Discodermia calyx* is a phosphorylated polyketide that has an IC<sub>50</sub> value of 1-2 nM for protein phosphatase 1 and < 1 nM for protein phosphatase 2A. Calyculin A is an antitumor agent and has been observed to prevent apoptosis in Burkitt's lymphoma cell line BM13674. **Target(s):** [myosin-light-chain] phosphatase (1); protein phosphatase type 1 (2-7,9, 10); protein phosphatase type 2A (2-4,6,10); phosphoprotein phosphatase (2-13); protein phosphatase type 4 (10,13); protein phosphatase type 5 (10). 1. Acta* **742**, 419.

### (S)-(+)-Camptothecin

This alkaloid (FW = 348.36 g/mol; CAS 7689-03-4; unstable when stored in frozen aqueous solutions) from the Chinese tree *Camptotheca acuminata* intercalates into DNA, rendering the latter unstable toward alkali. This alkaloid binds to a transient topoisomerase-DNA complex and inhibit the resealing of a single-strand nick that the enzyme creates to relieve superhelical tension in duplex DNA. The inactive complex is then ubiquitinated and hydrolyzed by proteasomes, thus depleting the cell of DNA topoisomerase I (See also CPT-11). Camptothecin induces apoptosis in a variety of cells. **Target(s):** DNA topoisomerase I (1-6); DNA topoisomerase II (7,8); sphinganine kinase, or sphingosine kinase (9); PARP-1 (10; Note: Camptothecin inhibition of poly(ADP-ribose) polymerase-1 converts PARP1 into a dominant-negative molecule that poisons the ability of DNA repair machinery to participate in either PARP1-dependent or PARP1-independent repair of camptothecin-induced DNA damage.). 1. ### Canagliflozin

This orally available Type-2 diabetes drug (FW = 444.52 g/mol; CAS 842133-18-0; Symbol: CNF), also known by the trade name: Invokana<sup>®</sup> and systematically as (1S)-1,5-anhydro-1-(3-{[5-(4-fluorophenyl)-2-thienyl]methyl}-4-methylphenyl)-D-glucitol, inhibits the sodium-glucose transporter, Subtype 2 (SGLT2), a carrier responsible for >90% of kidney glucose reabsorption (1-3). Canagliflozin lowers fasting plasma glucose and hemoglobin A<sub>1c</sub> levels in a dose-dependent manner. **Primary Mode of Inhibitory Action:** SGLT2 inhibitors block glucose reabsorption in the proximal tubule, thereby lowering the renal threshold for glucose, increasing urinary glucose excretion, and reducing serum glucose in hyperglycemic patients. Canagliflozin improves glycemic control in an insulin-independent fashion through inhibition of glucose reuptake in the kidney. This novel mechanism of action offers potential advantages over other antihyperglycemic agents, including a relatively low hypoglycemia risk and weight loss-promoting effects. **Pharmacokinetics:** Canagliflozin shows high oral bioavailability (~85%). Its half-life is 10.6 hours at a 100-mg oral dose and 13.1 hours with a 300-mg dose, attaining peak plasma concentrations in 1-2 hours and steady-state levels within 4-5 days. **Other Targets:** CNF inhibits all UDP-glucuronosyltransferase UGT1A subfamily enzymes, but the greatest inhibition is observed with UGT1A1, UGT1A9,

and UGT1A10 ( $IC_{50} \leq 10 \mu\text{M}$ ) (4). CNF also inhibits recombinant and human liver microsomal UGT1A9, with  $K_i$  values ranging from 1.4–3.0  $\mu\text{M}$ , depending on the substrate (propofol/4-methylumbelliferone).  $K_i$  values for CNF inhibition of UGT1A1 were approximately 3-fold higher (4). Given such findings, CNF inhibition of UGT1A1 and UGT1A9 *in vivo* cannot be discounted as a source of potential drug-drug interactions (4).

**Anion Gap Ketoacidosis:** In some subjects, canagliflozin therapy can give rise to severe anion gap metabolic acidosis and euglycemic diabetic ketoacidosis, or DKA (5). This form of metabolic acidosis is characterized by a high anion gap (*i.e.*, a medical value based on the concentrations of ions in a patient's serum). An anion gap is usually considered to be high if the value exceeds 11 mEq/L. High anion gap metabolic acidosis is caused generally by the body producing too much acid or not producing enough bicarbonate. This is often due to an increase in lactic acid or ketoacids, or it may be a sign of kidney failure. DKA can develop when insulin levels are too low or during prolonged fasting. (See also *Dapagliflozin; Empagliflozin, Tofogliflozin, Luseogliflozin*) 1. Nomura, Sakamaki, Hongu, *et al.* (2010) *J. Med. Chem.* **53**, 6355. 2. ### Canakinumab

This humanized anti-human IL-1 $\beta$  monoclonal IgGk antibody (MW = 145.2 kDa; CAS 914613-48-2) is also known by its code name ACZ885 and trade name Ilaris<sup>®</sup>. **Primary Mode of Inhibitory Action:** Canakinumab binds to IL-1 $\beta$  ( $K_d = 30\text{--}50 \text{ pM}$ ), blocking its interaction with IL-1 receptor, without binding to IL-1 $\alpha$  or IL-1 receptor antagonist (1). Interleukin-1 is a pro-inflammatory cytokine causing fever, anorexia, joint destruction, and tissue damage/remodeling, which are reversed/reduced by specific IL-1 blockers. Ilaris is an FDA-approved drug specifically indicated for treating cryopyrin-associated periodic syndrome (CAPS), a spectrum of autoinflammatory syndromes, including familial cold autoinflammatory syndrome (FCAS), the Muckle-Wells syndrome (MWS), and neonatal-onset multisystem inflammatory disease (NOMID). All are associated with mutations in *NLRP3*, the gene encoding cryopyrin, an adaptor protein that is essential for inflammasome activation in response to signalling pathways triggered by ATP, nigericin, maitotoxin, *Staphylococcus aureus*, or *Listeria monocytogenes*. **Clinical Applications:** Treatment with subcutaneous canakinumab once every eight weeks was associated with rapid remission of symptoms in most patients with CAPS (2). Ilaris is also approved for the treatment of active Systemic Juvenile Idiopathic Arthritis (SJIA) in patients aged two and older. Biweekly administration offers advantages over treatment with the human IL-1 receptor antagonist Anakinra, which must be injected daily and is often poorly tolerated (3). Canakinumab is also effective in the prophylaxis and management of acute gout, reducing its pain and risk of new attacks. Its long *in vivo* half-life contributes to its prolonged anti-inflammatory effects (4). 1. Dhimolea (2010) *MAbs* **2**, 3. 2. Lachmann, Kone-Paut, Kuemmerle-Deschner, *et al.* (2009) *New Engl. J. ### L-Canaline

This ornithine analogue (FW = 134.14 g/mol; CAS 496-93-5), also known as L-2-amino-4-(aminoxy)butyric acid, is an inhibitor of many pyridoxal-dependent enzymes, reacting with the coenzyme to form a covalently-bound oxime that inactivates the enzyme. Hydroxylamines are known to possess enhanced nucleophilicity, especially toward aldehydes, acyl anhydrides, and acyl-phosphates. The D-enantiomer also inactivates ornithine and alanine transaminases, albeit more slowly. L-Canaline reductase catalyzes an NADPH-dependent reductive cleavage of L-canaline to L-homoserine and ammonia. L-Canaline is found in many legumes, including the jack bean (*Canavalia ensiformis*). In higher plants, canaline inhibits production of ethylene, a key metabolic signaling molecule. **Target(s):** ornithine carbamoyltransferase (1,7); tyrosine aminotransferase (1,11,16,31); ornithine  $\delta$ -aminotransferase (1,4,5,8,14,15, 26-30); ornithine decarboxylase (1,6,24); aromatic-amino-acid decarboxylase (1); diamine oxidase (1); 1-aminocyclopropane-1-carboxylate synthase (2,21); alanine

aminotransferase (3); serine hydroxymethyl-transferase, or glycine hydroxymethyltransferase (9);  $\gamma$ -cystathionase, or cystathionine  $\gamma$ -lyase (10);  $\gamma$ -aminobutyrate aminotransferase, GABA aminotransferase (12); lysine transport, weakly inhibited (13); aspartate aminotransferase (17); methionine aminotransferase (18); arginase (20); cystathionine  $\beta$ -lyase (22); adenosyl-methionine decarboxylase, weakly inhibited (23); pyridoxal kinase (25). 1. ### L-Canavanine

This toxic L-arginine analogue (FW = 176.18 g/mol; CAS 543-38-4;  $pK_a = 2.35$  for carboxyl;  $pK_a = 7.01$  for hydroxyguanidine group;  $pK_a = 9.22$  for the amino groups), also known as L-2-amino-4-(guanidinoxy)butyric acid, from the jack bean (*Canavalia ensiformis*). When incorporated into proteins, many of the latter are non-functional, because the hydroxyguanidine moiety has very different electrostatics. L-Canavanine also inhibits the growth of certain bacterial strains. L-Canavanine is an alternative substrate and competitive inhibitor for many arginine-utilizing enzymes, including nitric-oxide synthases. **Target(s):** N-acetylglutamate kinase (1,6,37); arginine decarboxylase, as alternative substrate (2,10,12,24-28); argininosuccinate lyase (3,4); ornithine aminotransferase (5,38,39); alcohol dehydrogenase, particularly the yeast enzyme (7); arginine deaminase, mechanism-based inhibitor (8,9,14,29,30); arginine transport, competitive (11,13); lysine permease, competitive (13); nitric-oxide synthase,  $K_i = 11.1 \mu\text{M}$  (15-18,20,21,40); group I self-splicing intron (19); arginyl-tRNA synthetase (23); Arginase (31-33); arginine kinase (34-36). 1. ### Cancerous Inhibitor of Protein Phosphatase 2A

This 905-residue human protein (MW = 102,185 g; NCBI Reference Sequence = NP 065941.2; Symbol = CIP2A) targets Protein Phosphatase 2A (PP2A), an enzyme that dephosphorylates *c-Myc*, a constitutively expressed form of *Myc* transcription factor in many cancer cell types. CIP2A is overexpressed in most human cancers is associated with altered expression of epithelial-mesenchymal transition markers, increased lymph node metastasis, and poorer prognosis in pancreatic ductal adenocarcinoma (1). CIP2A strongly interacts with NIMA-related kinase 2 (NEK2 serine/threonine kinase) during the G<sub>2</sub>/M phase, thereby enhancing NEK2 kinase activity and facilitate centrosome separation in a PP1 and PP2A-independent manner (2). stage. CIP2A depletion impairs cell-cycle progression, resulting in aberrant centrosome separation, altered mitotic spindle dynamics, and SAC activation. CIP2A plays a role in regulating centrosome separation through the activation of NEK2A. **1.** Wang, Gu, Ma, Zhang, Bian & Cao (2013) *Tumor Biol.* **34**, 2309. **2.** Jeong, Lee, Park, *et al.* (2014) *J. Biol. Chem.* **289**, 28.

### Candesartan & Candesartan Cilexetil

Candesartan

Candesartan Cilexetil

This angiotensin II receptor antagonist (FW = 440.45 g/mol; CAS 139481-59-7), also known as 2-ethoxy-1-((4-[2-(2*H*-1,2,3,4-tetrazol-5-yl)phenyl]phenyl)methyl)-1*H*-1,3-benzodiazole-7-carboxylic acid, is an antihyper-

tensive agent. Its prodrug candesartan cilexetil (FW = 610.67 g/mol) is marketed under the trade names Blopress<sup>®</sup>, Atacand<sup>®</sup>, Amias<sup>®</sup>, and Ratacand<sup>®</sup>. Candesartan exhibits strong receptor binding affinity, with slow dissociation (1,2). Candesartan cilexetil is metabolized by esterases in the intestinal wall, attended by absorption of candesartan. The clinical benefits of candesartan may extend beyond its proven antihypertensive effects to a wider range of complications across the cardiovascular continuum, including diabetes, left ventricular hypertrophy, atherosclerosis and stroke (3). (**See also** Eprosartan; Irbesartan; Losartan; Olmesartan; Telmisartan; Valsartan) **Pharmacological Parameters:** Bioavailability = 42 %; Food Effect? NO; Drug *t*<sub>1/2</sub> = 3.5–4 hours; Metabolite *t*<sub>1/2</sub> = 3–11 hours; Drug's Protein Binding = 99.5 %; Metabolite's Protein Binding = very low; Route of Elimination = 33 % Renal, 67 % Hepatic. **1.** Mizuno, Niimura, Tani, *et al.* (1992) *Life Sci.* **51**, PL183. **2.** Shibouta, Inada, Ojima, *et al.* (1993) *J. Pharmacol. Exp. Ther.* **266**, 114. **3.** Meredith (2007) *Curr. Med. Res. Opin.* **23**, 1693.

### Cangrelor

This antiplatelet drug (FW = 776.36 g/mol; CAS 163706-06-7), also known as Kengreal<sup>®</sup>, potently inhibits P2Y<sub>12</sub>, the G<sub>i</sub> class of ADP-chemosensing G protein-coupled receptors that promote platelet aggregation (1). Although cangrelor is itself an ATP derivative, it does not require metabolic conversion (nor, as a dichloromethylphosphonate, can it be) to the ADP species for its pharmacodynamics properties. Cangrelor rapidly achieves steady-state concentrations, showing a clearance rate of 50 L/h and a *t*<sub>1/2</sub> ≈ 3 minutes. Kengreal is indicated for reducing thrombotic cardiovascular events in patients with coronary artery disease and as a bridging therapy in patients with acute coronary syndrome, or with stents, who face an increased risk for thrombotic events (*e.g.*, stent thrombosis) when oral P2Y<sub>12</sub> therapy is interrupted because of surgery (2). IUPAC: also named [dichloro-[[[(2*R*,3*S*,4*R*,5*R*)-3,4-dihydroxy-5-[6-(2-methylsulfanylethyl amino)-2-(3,3,3-trifluoropropyl-sulfanyl)purin-9-yl]oxolan-2-yl]methoxy hydroxyphosphoryl]oxyhydroxy-phosphoryl]methyl]phosphonate **1.** Ingall, Dixon, Bailey, *et al.* (1999) *J. Med. Chem.* **42**, 213. **2.** Lhermusier, Baker & Waksman (2015) *Am. J. Cardiol.* **115**, 1154.

### Cannabidiol

This natural product (FW = 314.46 g/mol; CAS 13956-29-1), comprising some 40% of the dry extract weight of the Marijuana plant *Cannabis sativa*, is a non-psychotomimetic agent that induces anxiolytic- and antipsychotic-like effects that are mediated by facilitation of the endocannabinoid system or by activation of 5-HT<sub>1A</sub> (serotonin) receptors. Cannabidiol exhibits low affinity for cannabinoid CB<sub>1</sub> and CB<sub>2</sub> receptors (1), but can block anandamide reuptake (2) as well as its metabolism by fatty acid amide hydrolase (3). **1.** Thomas, Gilliam, Burch, Roche & Seltzman (1998) *J. Pharmacol. Exp. Ther.* **285**, 285. **2.** Bisogno, Hanus,

De Petrocellis *et al.* (2001) *Br. J. Pharmacol.* **134**, 845. 3. Watanabe, Ogi, Nakamura, *et al.* (1998) *Life Sci.* **62**, 1223.

### Cantharidin

This terpene carboxylic anhydride and PP2A inhibitor (FW = 196.20 g/mol; CAS 56-25-7; Symbol: CA; IUPAC Name: 2,6-dimethyl-4,10-dioxatricyclo[5.2.1.0<sup>2,6</sup>]decane-3,5-dione), from the Spanish fly (*Lytta vesicatoria*), is a poisonous blister agent used topically to remove warts and tattoos as well as to treat the small papules of *Molluscum contagiosum*. **Identification as Phosphoprotein Phosphatase-2A Inhibitor:** The toxic effects of cantharidin as well as those of its herbicidal analogue, endothal, are attributable to their highly affine and specific interactions with cantharidin-binding protein, *or* CBP (1). The latter is the protein phosphatase 2A (PP2A), an  $\alpha\beta$  heterodimer ( $\alpha$ -subunit, 61-kDa  $\beta$ -subunit, 39-kDa). CBP catalyzes the dephosphorylation of phosphorylase *a*, a reaction that is sensitive not only to okadaic acid, cantharidin and its analogues. Indeed, okadaic acid is a potent inhibitor of [<sup>3</sup>H]cantharidin binding to CBP (1,2). The PP2A inhibitory properties of a series of anhydride modified cantharidin analogues indicates that only those analogues that can undergo facile ring opening of the anhydride moiety display significant inhibition (3). NMR experiments suggest that 7-oxobicyclo[2.2.1]heptane-2,3-dicarboxylic acid was the sole species under PP2A assay conditions (3).

**Role in Insect Defense:** Cantharidin is secreted by the male blister beetle as a copulatory gift during mating. The female recipient then cover her eggs with cantharidin, which imparts a disagreeable odor to ward off predators, EC<sub>50</sub> ≈ 10  $\mu$ M (4). **Mode of Vesicant Action:** Cantharidin is readily absorbed by epidermal cell membranes, activation the release of serine proteases that cleave disintegrate desmosomal plaques, resulting in tonofilament detachment and skin blistering that eventually heals without scarring. That said, the widespread presence of PP2A in animals and plants, and its inhibition ( $K_i$  = 80 nM in rat brain) by cantharidin is likely to underlie many of the toxic effects of cantharidin and its analogues. The vesicant action of cantharidin is thought to account for the notorious use of Spanish fly as an aphrodisiac. **Antineoplastic Properties:** Based on its use in traditional Chinese medicine, cantharidin was found to be a potent antitumor agent. Such action goes beyond its inhibition of PP2A. Indeed, cantharidin induces cancer cell death, with an IC<sub>50</sub> value of 4.2  $\mu$ M by blocking Heat Shock Factor 1 (HSF1) binding to promoters and inhibiting expression of Heat Shock Protein 70, *or* HSP70, as well as Bcl-2-associated athanogene domain-3, *or* BAG3 (5). However, cantharidin does not inhibit NF- $\kappa$ B luciferase reporter activity, suggesting it is not a general transcription inhibitor. Moreover, PP2A siRNA or okadaic acid fails to block HSF1 activity, again suggesting cantharidin inhibits HSF1 in a PP2A-independent manner (5). 1. Li & Casida (1992) *Proc. Natl. Acad. Sci. U.S.A.* **89**, 11867. 2. Eldridge & Casida (1995) *Toxicol. Appl. Pharmacol.* **130**, 95. 3. McCuskey, Keane, Mudgee, *et al.* (2000) *Eur. J. Med. Chem.* **35**, 957. 4. ### Capillarisin & "Thiocapillarisin"

This naturally occurring flavone from *Artemisia capillaris* (FW = 316.26 g/mol; CAS 56365-38-9; Symbol: CPS), also named 5,7-dihydroxy-2-(4-hydroxyphenoxy)-6-methoxychromen-4-one, exerts a relaxing effect on rabbit penile corpus cavernosum (PCC) by activating the NO-cGMP and adenylyl cAMP signaling pathways. Capillarisin may well become an alternative medicine for patients wishing to use natural products to improve erectile function or in those who do not respond adequately to cGMP phosphodiesterase isozyme-5 inhibitors (1). Capillarisin also specifically inhibits both constitutive and inducible STAT3 activation at tyrosine-705, but not at serine-727, in human multiple myeloma cells (2). CPS also blocks STAT3 constitutive activity and nuclear translocation, as mediated through the inhibition of activation of upstream JAK1, JAK2, and c-Src kinases (2). Capillarisin also inhibits aldol reductase (3). Its thio analogue is [(4-hydroxyphenyl)thio]-7-isopropoxy-5,6-dimethoxy-4H-chromen-4-one (FW = 332.33 g/mol) (4). 1. Kim, Choi, Bak, *et al.* (2011) *Phytotherapy Res.* **26**, 805. 2. Lee, Chiang, Nam, *et al.* (2013) *Cancer Lett.* **345**, 130. 3. ### Capecitabine

This orally bioavailable 5-fluorouracil pro-drug (FW<sub>free-acid</sub> = 359.35 g/mol; CAS 154361-50-9), systematically named pentyl [1-(3,4-dihydroxy-5-methyltetrahydrofuran-2-yl)-5-fluoro-2-oxo-1H-pyrimidin-4-yl]carbamate, is enzymatically transformed to 5-FU, whereupon it is then metabolized to form the potent thymidylate synthase inhibitor, 5-fluoro-dUMP. Capecitabine activation follows a pathway employing three enzymatic steps and two intermediates, 5'-deoxy-5-fluorocytidine (5'-dFCR) and 5'-deoxy-5-fluorouridine (5'-dFUR). The N<sup>4</sup>-pentylloxycarbonyl group is hydrolytically removed by liver carboxylesterases to form 5'-deoxy-5-fluorocytidine, which suffers subsequent enzymatic deamination to 5'-deoxy-5-fluorouridine. Absent any susceptibility to 5' phosphorylation, the latter is instead converted by thymidine phosphorylase into 5-fluorouracil. (See *Fluorouracil*) **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Parker (2009) *Cmem. Rev.* **109**, 2880.

### Capsaicin

This pungent secondary plant metabolite (FW = 305.42 g/mol; CAS 404-86-4), also known as 8-methyl-N-vanillyl-6-nonenamide, is the primary irritant found in hot chilies and red peppers, giving them and their powdered forms (*e.g.*, paprika, and cayenne) a stinging sensation and spiciness. **Primary Mode of Action:** At sub-micromolar concentrations, capsaicin targets certain pain-sensing neurons, activating the mammalian Transient Receptor Potential Vanilloid-1 (TRPV1) receptor involved in nociception. At micro- to millimolar concentrations, capsaicin is used in clinical and *in vitro* studies, modulating the function of a large number of seemingly unrelated membrane proteins. Capsaicin also regulates voltage-dependent sodium channels by altering lipid bilayer elasticity, promoting channel inactivation, similar to other amphiphiles that decrease bilayer stiffness. By activating TRPV1, capsaicin allows more QX-314 (membrane-impermeant lidocaine derivative) to enter primary sensory nociceptor neurons, thereby synergizing lidocaine's anesthetic effects (See *Lidocaine*). Birds reportedly express a capsaicin-insensitive vanilloid receptor, relieving them capsaicin's sting and allowing them to serve as far-flying vectors for seed dispersal. **Capsaicin Patch:** Containing 8% capsaicin by weight, a transdermal patch marketed under the trade name Qutenza™ relieves pain by targeting neurons in the area of skin where pain is being experienced. In 2009, Qutenza received FDA approval for the use of capsaicin to relieve neuropathic pain associated with post-herpetic

neuralgia. **Target(s):** voltage-dependent Na<sup>+</sup> channels (1); NADH dehydrogenase, or complex I (2-4,8,9); CYP2A2 (5); CYP3A1 (5); CYP2C1 (5); CYP2B1 (5); CYP2B (25); CYP2C6 (5); tyrosyl-tRNA synthetase (6); 5-lipoxygenase, or arachidonate 5-lipoxygenase (10,11); inhibits chloride secretion in colonic epithelial cells independently of TRPV1 (12); human platelet aggregation and thromboxane biosynthesis (13); blocks constitutive and interleukin-6-inducible STAT3 activation (14); inhibits protein synthesis in TRPV1-expressing HEK cells, IC<sub>50</sub> = 15.6 nM (15); stimulates microtubule depolymerization within 10 min (16); inhibits catecholamine secretion and synthesis by blocking Na<sup>+</sup> and Ca<sup>2+</sup> influx through a vanilloid receptor-independent pathway in bovine adrenal medullary cells (17); inhibits VEGF-induced vessel sprouting in rat aortic ring and Matrigel plug assays (18); inhibits lipid peroxidation via the radical scavenging properties of capsaicin's C7-benzyl carbon (19); inhibits activation of voltage-gated sodium currents in capsaicin-sensitive trigeminal ganglion neurons (20); inhibits NADH-ubiquinone oxidoreductases (21); blocks Ca<sup>2+</sup> channels in isolated rat trigeminal and hippocampal neurons (22); disrupts axoplasmic transport in sensory neurons by disorganizing microtubules and neurofilaments (23). **1.** Lundbaek, Birn, Tape, *et al.* (2005) *Mol. ### Captopril

This antihypertensive drug, (FW<sub>free-acid</sub> = 217.29 g/mol; CAS 62571-86-2) also called (2*S*)-1-(3-mercapto-2-methylpropionyl)-L-proline, D-2-methyl-3-mercapto-propanoyl-L-proline, and SQ-14225, is a reversible competitive

inhibitor of LTA<sub>4</sub> hydrolase (IC<sub>50</sub> = 11 mM) and angiotensin I-converting enzyme, or peptidyl-dipeptidase A; IC<sub>50</sub> = 23–35 nM. The first orally active ACE inhibitor, Captopril also inhibits angiogenesis and slows the growth of experimental tumors in rats. It also inhibits apoptosis in human lung epithelial cells (IC<sub>50</sub> = ~320 nM). Significantly, a study of 5492 patients (aged 25-66 years; with diastolic blood pressure ≥100 mm Hg measured on two occasions) randomly assigned Captopril or conventional antihypertensive treatment (*i.e.*, diuretics or β-blockers) showed that captopril did not differ from conventional treatment in efficacy in preventing cardiovascular morbidity and mortality (72). **Target(s):** peptidyl-dipeptidase A, or angiotensin I-converting enzyme (1,2,9-12,14,17,18,31,33,57); leukotriene-A<sub>4</sub> hydrolase (3,66-69); invertebrate peptidyl-dipeptidase A<sub>4</sub>, or peptidyl-dipeptidase Dcp (dipeptidyl carboxypeptidase) (5,13); tripeptide aminopeptidase (6,65); peptidyl-dipeptidase B (7,32); *Streptomyces* peptidyl-dipeptidase (8); tripeptidyl carboxypeptidase activity of peptidyl dipeptidase A (14); Xaa-Pro aminopeptidase, or aminopeptidase P (19,60,61,63); β-lactamase, or metallo-β lactamase (20,21); bontoxilysin (22-26); tentoxilysin (24,25); saccharolysin (27); nephrosin (28); meprin A (29); lysine carboxypeptidase (30); carboxypeptidase A, weakly inhibited; K<sub>i</sub> = 620 μM (31); Xaa-Trp aminopeptidase, or aminopeptidase W (58,59); Xaa-Pro dipeptidase (62); glutamyl aminopeptidase, or aminopeptidase A, K<sub>i</sub> = 29 μM (64); tyrosinase, or monophenol monooxygenase (70); catechol oxidase (70); lactoperoxidase (71); peroxidase (71). **1.** Cushman, Cheung, Sabo & Ondetti (1977) *Biochemistry* **16**, 5484. **2.** Corvol & Williams (1998) in *Handb. ### Carbamazepine

This common antiepileptic drug (AED) and neuropathic pain drug (FW = 236.27 g/mol; CASs = 298-46-4 and 85756-57-6; IUPAC Name: 5*H*-dibenzo[*b,f*]azepine-5-carboxamide; Abbreviation: CBZ (*not* Cbz for carbobenzoxy), also known as Tegretol<sup>®</sup>, binds to and stabilizes the inactivated state of voltage-gated sodium channels, making fewer channels available for subsequent opening. Carbamazepine is also a GABA receptor agonist, potentiating those made up of  $\alpha_1$ ,  $\beta_2$ , and  $\gamma_2$  subunits. **Note:** Dangerous and potentially carbamazepine hypersensitivity, presenting as Stevens-Johnson syndrome and toxic epidermal necrolysis, occurs in carbamazepine-treated individuals possessing the human leukocyte antigen allele, HLA-B\*1502. **Drug Interactions:** Carbamazepine is one of the most commonly prescribed antiepileptic drugs and is also used in the treatment of trigeminal neuralgia and psychiatric disorders, particularly bipolar depression. Because of its widespread and long term use, carbamazepine is frequently prescribed in combination with other drugs, leading to the possibility of drug interactions (1). Carbamazepine is a potent inducer of CYP3A4 and other oxidative enzyme system in the liver, and it may also increase glucuronyltransferase activity. This results in the acceleration of the metabolism of concurrently prescribed anticonvulsants, particularly valproic acid, clonazepam, ethosuximide, lamotrigine, topiramate, tiagabine and remacemide (1). The metabolism of many other drugs such as tricyclic antidepressants, antipsychotics, steroid oral contraceptives, glucocorticoids, oral anticoagulants, cyclosporin, theophylline, chemotherapeutic agents and cardiovascular drugs can also be induced, leading to a number of clinically relevant drug interactions (1). **Comparison of Carbamazepine & Oxcarbazepine Pharmacodynamics:** Oxcarbazepine (FW = 252.27 g/mol; CAS 28721-07-5; IUPAC: 10,11-dihydro-10-oxo-5*H*-dibenzo[*b,f*]azepine-5-carboxamide; Symbol: OXC, also known as Trileptal<sup>®</sup>) is a so-called modern antiepileptic drug (AED) that is used as both monotherapy and adjunctive therapy for the treatment of partial seizures with or without secondary generalization in adults and children older than 4 years (USA) or 6 years (Europe) (2). Although OXC is a structural variant of carbamazepine, there are significant differences between the two drugs. The mechanism of action of OXC involves mainly blockade of sodium currents, but differs from CBZ by modulating different types of calcium channels (2). In contrast to CBZ, which is oxidized by the cytochrome P-450 system, OXC undergoes reductive metabolism at its keto moiety to form the monohydroxy derivative (MHD), which is

glucuronidated and excreted in the urine. The involvement of the hepatic cytochrome P-450-dependent enzymes in the metabolism of OXC is minimal, making why it might be more effectively combined with other AEDs that show drug interactions with CBZ. Such findings indicate that OXC and CBZ are distinctly different medications (2). **Target(s):** Carbamazepine strongly attenuates lipopolysaccharide-induced production of NO and iNOS protein at concentrations of 5, 10, and 20  $\mu$ M (3). Carbamazepine also directly inhibits adipocyte differentiation through activation of the ERK 1/2 pathway (4). It inhibits agonist-stimulated inositol lipid metabolism in rat hippocampus (5). CBZ increases acetylation of histone H4 in the HepG<sub>2</sub> liver carcinoma cell line by inhibiting both HDAC 3 and HDAC 7, which respectively represent class I and II histone de-acetylases respectively (6). The IC<sub>50</sub> of ~2 mM is considerably lower than therapeutic plasma levels of 25–50 mM typically achieved in CBZ-treated patients. **1.** Spina, Pisani & Perucca (1996) *Clin. ### N-Carbamoyl-L-Glutamate

This *N*-acetyl-glutamate isostere (FW = 190.15 g/mol; CAS 1188-38-1), also known as carglumatic acid and Carbaglu<sup>®</sup>, is used in the treatment of hyperammonemia resulting from primary and secondary deficiencies in *N*-acetyl-L-glutamate synthase (*or* NAGS), the mammalian mitochondrial enzyme that catalyzes acetyl transfer from Acetyl-CoA to L-glutamate (1,2). (NAGS deficiency is, in fact, the rarest Urea Cycle disorder.) **Primary Mode of Action:** *N*-Acetyl-L-glutamate is required by liver cells to allosterically activate Carbamoyl-Phosphate Synthase I (CPS-I), the first committed step in the Urea Cycle. Any impairment in the synthesis of *N*-acetyl-glutamate results in lower CPS-I activity, attended by hyperammonemia. In contrast to *N*-acetyl-glutamate, carbaglu is taken up by liver cells and readily transported into the mitochondrial compartment (3), where it can activate CPS-I. At constant urea production, carbaglu decreases the concentration of ammonia; whereas, at constant ammonia concentrations, it increases urea production (4). Carbaglu should, in principle, also be effective for treating hyperammonemia that is incidental to mutations in CPS-I that lower its affinity for *N*-acetyl-glutamate. **Human Studies:** The efficacy of Carbaglu in the treatment of hyperammonemia due to NAGS deficiency was evaluated in a retrospective review of the clinical course of 23 NAGS deficiency patients who received Carbaglu treatment for a median of 7.9 years (Range: 0.6 – 20.8 years) (1). Short-term efficacy was evaluated using mean and median change in plasma ammonia levels from baseline to days 1 to 3. Persistence of efficacy was evaluated using long-term mean and median change in plasma ammonia level. **Likely Inhibitory Targets:** As a *N*-acetyl-glutamate isostere, carbaglu is likely to inhibit those enzymes known to be inhibited by *N*-acetyl-glutamate, including *N*-formylglutamate deformylase, 4-methyleneglutaminase, glutamate carboxypeptidase II, glutamate carboxypeptidase, and glutamate formimidoyltransferase (See *N*-acetyl-glutamate). **1.** CARBAGLU (carglumatic-acid) NDA 022562 by ORPHAN EUROPE. **2.** Caldovic, Morizono & Daikhin (2004) *J. Pediatr.* **145**, 552. **3.** Rubio & Grisolia (1981) *Enzyme (Basel)* **26**, 233. **4.** Meijer, Lof, Ramos & Verhoeven (1985) *Eur. J. Biochem.* **148**, 189.

### Carbamoyl Phosphate

This key Urea Cycle and Pyrimidine Nucleotide Biosynthesis intermediate (FW<sub>free-acid</sub> = 141.02 g/mol; CAS 90-55-6), also known as carbamyl

phosphate, is an important precursor of arginine and urea biosynthesis as well as pyrimidine nucleotides. It was identified as the naturally occurring carbamoyl group donor by Nobelist Lipmann and coworkers Mary Ellen Jones and Leonard Spector. Carbamoyl phosphate is a product of the reactions catalyzed by carbamoyl phosphate synthetase-I, or CPSI (using mitochondrial ammonia in the first committed step of the Urea Cycle), carbamoyl-phosphate synthetase-II, or CPSII (cytoplasmic glutamine in the first committed step in the Pyrimidine Nucleotide Pathway). It is also formed by carbamate kinase. Carbamoyl-P is a substrate for aspartate carbamoyltransferase, ornithine carbamoyltransferase, oxamate carbamoyltransferase, putrescine carbamoyltransferase, 3-hydroxymethylcephem carbamoyltransferase, and lysine carbamoyltransferase. It is also an alternative substrate for a number of enzymes (e.g., glucose-6-phosphatase and biotin carboxylase). **Stability:** Carbamoyl-P decomposes nonenzymatically in water, with the rate of orthophosphate release dependent on pH. In acidic conditions, the products are ammonium ions, orthophosphate, and carbon dioxide. In basic conditions the products are orthophosphate, water, and cyanate. pH-rate profile studies and use of isotopic probes indicate that different hydrolytic mechanisms operate for the monoanion and dianion forms, resulting in P-O and C-O bond cleavage, respectively (See Ref. 9). **Target(s):** glutamine synthetase (1,2,7,8,13,20-22,25); pyruvate kinase (3); acylphosphatase (4); nitrate reductase (5); threonine dehydratase (6,18); nitrogenase (10,16; however, see 17); formyltetrahydrofolate synthetase (11); hemoglobin S polymerization (12); carbonic anhydrase (14); alanine aminotransferase (18); glutamate dehydrogenase (19); aspartate aminotransferase (18); threonine deaminase (18); asparagine synthetase (23); adenylosuccinate synthetase (24); ornithine decarboxylase, inhibited at elevated concentrations (26). 1. ### Carba-NAD<sup>+</sup>

This NAD<sup>+</sup> analogue (FW<sub>free-acid</sub> = 662.47 g/mol), also known as carbanicotinamide adenine dinucleotide, has a D-2,3-dihydroxycyclopentyl moiety in place of the D-ribose residue in NAD<sup>+</sup> and inhibits NADase. Carba-NAD<sup>+</sup> is reduced to Carba-NADH by yeast and horse liver alcohol dehydrogenase. **Target(s):** NAD<sup>+</sup> Nucleosidase, or NADase, or NAD<sup>+</sup> glycohydrolase (1-3,5); cholera toxin ADP-ribose transferase (3); poly(ADP-ribose) polymerase (4). 1. Oppenheimer & Handlon (1992) *The Enzymes*, 3rd ed., **20**, 453. 2. Slama & Simmons (1988) *Biochemistry* **27**, 183. 3. Slama & Simmons (1989) *Biochemistry* **28**, 7688. 4. ### Carbenicillin

This semisynthetic penicillin-based antibiotic (FW = 378.41 g/mol; CAS 4697-36-3), also known as  $\alpha$ -phenyl(carboxymethylpenicillin), inhibits peptidoglycan biosynthesis. While the free acid is sparingly soluble in water, sodium and potassium salts are very soluble. Although more resistant than ampicillin to degradation by  $\beta$ -lactamases, carboxypenicillins are still susceptible. **Target(s):** neprilysin, or enkephalinase (1,6); plasmin, weakly inhibited (2); urokinase (3); serine type D-Ala-D-Ala carboxypeptidase (4,5,10,11);  $\beta$ -lactamase, or cephalosporinase (7,8); muramoylpentapeptide carboxypeptidase (9). 1. ### Carbenoxolone

This anti-inflammatory glucocorticoid (FW<sub>free-acid</sub> = 570.77 g/mol; CAS 5697-56-3 (free acid), 74203-92-2 (dicholine salt), and 7421-40-1 (disodium salt)), also known as (3 $\beta$ ,20 $\beta$ )-3-(3-carboxy-1-oxopropoxy)-11-oxoolean-12-en-29-oic acid and 18 $\beta$ -glycyrrethric acid hydrogen succinate, is a water-soluble derivative of glycyrrhetic acid. **Target(s):** 11 $\beta$ -hydroxysteroid dehydrogenase type (11,2,8,9,12,13,16,20); pepsin (3,4,7); cAMP phosphodiesterase (5); cGMP phosphodiesterase (5); 15-hydroxyprostaglandin dehydrogenase (6,7);  $\Delta^{13}$ -prostaglandin reductase (6); trypsin (7); chymotrypsin (7); elastase (7);  $\Delta^5$ -reductase (7); 3 $\alpha$ -hydroxysteroid dihydrogenase (10); 3 $\alpha$ - (or, 20 $\beta$ -) hydroxysteroid dehydrogenase (11,14,20); cis-retinol/androgen dehydrogenase (15,19); linoleate Desaturase (17); 7 $\alpha$ -hydroxysteroid dehydrogenase (18); Ca<sup>2+</sup> channels, voltage-gated (21); DNA polymerase  $\beta$  (22). 1. ### Carbidopa

This nonmetabolizable L-DOPA isostere and Parkinson drug (FW = 225.22 g/mol; CAS 28860-95-9), also named (2S)-3-(3,4-dihydroxyphenyl)-2-hydrazino-2-methylpropanoic acid, inhibits aromatic-L-amino-acid decarboxylase (or DOPA decarboxylase), a required enzyme in both tryptophan to serotonin biosynthesis as well as in the conversion of L-DOPA to Dopamine (DA). Although L-DOPA can cross the blood brain barrier, dopamine cannot. By preventing peripheral DDC catalysis of L-DOPA conversion to dopamine, carbidopa can be used to treat Parkinson Disease (PD), a condition arising from dopaminergic neuron death located within the substantia nigra. It thus enhances entry of L-DOPA into dopamine-deficient regions of PD brains. Blood-brain barrier to carbidopa (MK-486) and Ro 4-4602, peripheral dopa decarboxylase inhibitors. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) ### Carbinoxamine

This antihistamine (FW = 290.79 g/mol; CAS 486-16-8), also known by its trade names Clistin<sup>®</sup>, Palgic<sup>®</sup>, Rondec<sup>®</sup>, and Rhinopront<sup>®</sup>, and Rotoxamine<sup>®</sup> (the latter as the maleate salt of the (-)-enantiomer), as well as systematically as 2-[(4-chlorophenyl)-pyridin-2-ylmethoxy]-N,N-dimethylethanamine, targets histidine H<sub>1</sub> receptors. 1. ### Carbon Monoxide

This colorless and odorless metabolic signaling gas (FW = 28.01 g/mol; CAS 630-08-0; M.P. = -199°C; B.P. = -191.5°C; bond length = 0.113 nm; shown above are contributing resonance forms) binds to and inhibits a wide range of metalloproteins, particularly heme proteins and enzymes, displaying very high affinity for hemoglobin (Hb), myoglobin, neuroglobin, cytochrome *c* oxidase, and CYP's. Carbon monoxide's linear diatomic structure allows its vacant *p*-orbitals to form an end-on coordinate bond with suitable metal ions, especially Fe(II) coordinated to heme.

Carbon monoxide binding to heme proteins is also photolabile, and excitation of HbCO by a single 6-psec pulse of 530-nm light results in prompt photodissociation (first-order constant =  $0.9 \times 10^{11} \text{ sec}^{-1}$ ). That heme-bound carbon monoxide photodissociates has proven to be an important tool in the characterization of heme proteins and their involvement in electron transport chains that create the proton motive force driving both photophosphorylation and oxidative phosphorylation. **Binding to Hemoglobin:** With >250-300 times greater affinity than diatomic oxygen for adult hemoglobin (HbA), carbon monoxide can fully displace hemoglobin-bound O<sub>2</sub>. At sub-saturating levels, however, carbon monoxide has the seemingly paradoxical effect of greatly increasing hemoglobin's apparent affinity for O<sub>2</sub>. This property, which is anticipated in the Monod-Wyman-Changeux concerted transition model for allostery, explains Claude Bernard's observation of substantial levels of hemoglobin-bound O<sub>2</sub> in the venous circulation of individuals exposed to subsaturating CO. In the concerted transition model, hemoglobin exists in an all-or-nothing dynamic equilibrium between ligand-free R<sub>0</sub> and T<sub>0</sub> states, as defined by the allosteric constant  $\mathcal{L}$ , equal to  $[T_0]/[R_0] \approx 700-800$ . O<sub>2</sub> binds preferentially to R<sub>0</sub>, generating R<sub>1</sub> (i.e., (Hb(O<sub>2</sub>)<sub>1</sub>), which then binds a second, third and fourth O<sub>2</sub> molecule to form R<sub>2</sub> (i.e., (Hb(O<sub>2</sub>)<sub>2</sub>), then R<sub>3</sub> (i.e., (Hb(O<sub>2</sub>)<sub>3</sub>), and finally R<sub>4</sub> (i.e., (Hb(O<sub>2</sub>)<sub>4</sub>). Note further that the affinity of R<sub>1</sub>, R<sub>2</sub>, R<sub>3</sub>, and R<sub>4</sub> for O<sub>2</sub> are all equivalent, and cooperative binding only occurs, because T<sub>0</sub> is far more stable than R<sub>0</sub>. This property indicates that hemoglobin resists oxygenation, except at high O<sub>2</sub> pressure within the lung (where pO<sub>2</sub> is ~100 mm Hg) and that hemoglobin undergoes substantial deoxygenation in peripheral circulation (where pO<sub>2</sub> is ~30 mm Hg). This results in an S-shaped O<sub>2</sub> saturation curve, where little binding occurs at low O<sub>2</sub> pressure. The inflection point (or "tipping point") is defined O<sub>2</sub> partial pressure needed for  $\sum[R_i]/\sum[T_i] = 1$ . This condition is attained when the oxygen partial pressure high enough to fully form Hb(O<sub>2</sub>)<sub>1</sub> and partially form Hb(O<sub>2</sub>)<sub>2</sub>. However, because CO binds with much higher affinity than O<sub>2</sub>, binding of a single CO molecule drives hemoglobin into the R state, increasing the the concentration of ligand-free subunits that are available for O<sub>2</sub> binding. **Role in Metabolic Signaling:** CO also plays an a significant role as a cellular messenger in mammals in a manner akin to nitric oxide, and CO is a likely alternative activator for guanylate cyclase. Heme oxygenase and 3,4-dihydroxyquinoline 2,4-dioxygenase catalyze reactions that produce CO as a second messenger for CO-activated guanylate cyclases, thereby abetting 3'5'-cyclicGMP synthesis. Enzymes utilizing CO as a substrate include carbon monoxide oxygenase (or, cytochrome *b*-561), carbon monoxide oxidase, and carbon monoxide dehydrogenase. Neurons contain neuroglobin, a myoglobin-like CO-binding protein that is thought to play a role in modulating CO-dependent processes. **Target(s):** tryptophan 2,3-dioxygenase (1,8,9,137); catechol oxidase (2); hydrogenase (3,20,28,29,33); steroid 21-monooxygenase (4,37); cytochrome *c* oxidase, or Complex IV (5,6,17,18,27, 32,36,45-47,51,165-172); steroid 11b-monooxygenase (7,37,55,83-86); corticosterone 18 monooxygenase (7); steroid 21-monooxygenase (7); sulfite reductase (10,35); sulfite reductase (NADPH) (11,35); dopamine β-monooxygenase (12,34,82); mitochondrial electron transport (5,27); photosynthetic electron transport (13); nitrogenase (14,15,38,58-64,66); heme oxygenase (16); cytochrome *a*<sub>3</sub> (19,32); cytochrome *a*<sub>1</sub> (19); cytochrome *o* (19); cytochrome *d* (19); cytochrome *c* (19); cytochrome *c*' (19); cytochrome P450 systems (19,34,37,40,41); ferredoxin:nitrite reductase (21); caliciol 1-monooxygenase, or 25-hydroxyvitamin D<sub>1</sub> α-hydroxylase (22,123); leukotriene B<sub>4</sub> 20-hydroxylase (24); cholesterol 7α-monooxygenase (25); hemoglobin (26,52); lipoxygenase (31); nitrite reductase (e.g., from *Achromobacter fischeri*) (35); cholesterol monooxygenase, side-chain-cleaving, or CYP11A1 (37,56); steroid 17α-monooxygenase (37); cystathionine *b* synthase (39); flavin-containing monooxygenase, or dimethylaniline-*N*-oxide aldolase (40,41); lanosterol 14 α-demethylase (42); nitrogen fixation (43); nitric oxide synthase (44); catalase (48); carbonic anhydrase (49,50); formate hydrogen-lyase (53); aliphatic

### Carboplatin

This platinum-based antineoplastic agent (FW = 371.25 g/mol; CAS 41575-94-4), also known by NSC-241-240 and its IUPAC name *cis*-diammine(cyclobutane-1,1-dicarboxylate-*O,O'*)platinum(II), is a cisplatin analogue that damages DNA. It is considerably less nephrotoxic, ototoxic, and neurotoxic than its parent compound, cisplatin. Its main drawback is its myelosuppressive effect, causing blood cell and platelet output of bone marrow to decrease to as low as 10% the usual output. **Primary Mode of Action:** Carboplatin primarily considered as a DNA-damaging anticancer drug, forming different types of bifunctional adducts with cellular DNA (1-4). While cisplatin and carboplatin are structurally distinct, they form similar adducts at the same sites of the DNA that are recognized by a number of cellular proteins. (See *Cisplatin*; *Oxaliplatin*) Mismatch repair proteins and some damage-recognition proteins may show selectivity, contributing to the differences in its cytotoxicity and tumor range relative to other platinum-based antineoplastic agents. (The last reference deals with metal complexes in medicine with a focus on enzyme inhibition.) **Carboplatin Cytotoxicity:** Toxicity arises from its interference with transcription and/or DNA replication mechanisms, damaging tumors *via* induction of apoptosis (possibly by means of generating Reactive Oxygen Species, or ROS), as mediated by the activation of various signal transduction pathways, including calcium signaling, death-receptor signaling, and mitochondrial apoptotic pathways. Its cytotoxicity and apoptosis are not exclusively induced in cancer cells; thus, carboplatin might also lead to diverse side-effects such as neuro- and/or renal-toxicity or bone marrow-suppression. **Mechanisms of Drug Resistance:** These include changes in cellular uptake, drug efflux, increased detoxification, inhibition of apoptosis and increased DNA repair. To minimize carboplatin

resistance, combinatorial therapies have proven more effective to defeat cancers. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** Frezza, Hindo, Chen, *et al.* (2010) *Pharm. Des.* **16**, 1813. **2.** Rosenberg (1980) in *Nucleic Acid-Metal Ion Interactions* (Spiro, ed.) ### Carbovir

This carbocyclic 2',3'-dideoxy-2',3'-didehydroguanosine analogue (FW = 249.27 g/mol; CAS 118353-05-2; Symbol: CBV) is metabolized to its 5'-triphosphate at concentrations sufficient to inhibit HIV reverse transcriptase. There was no evidence of CBV degradation by purine nucleoside phosphorylase, and the  $t_{1/2}$  of CBV-triphosphate is 2.5 h, similar to that of zidovudine 5'-triphosphate (AZT-triphosphate). Unlike the latter, however, CBV-triphosphate levels decline without evidence of a plateau. CBV did not affect the metabolism of AZT; nor does AZT affect CBV metabolism. The small fraction of CBV that is incorporated into DNA is increased by incubation with mycophenolic acid, an IMP dehydrogenase inhibitor. CBV specifically inhibits the incorporation of nucleic acid precursors into DNA, but is without effect on the incorporation of radiolabeled precursors into RNA or protein. **Mode of Action:** Carbovir-TP is a potent inhibitor of HIV-1 reverse transcriptase, with  $K_i$  values (0.09  $\mu$ M with 16S rRNA template; 0.05  $\mu$ M with gapped duplex DNA template) are similar to that observed by AZT-TP, ddGTP, and ddTTP. The kinetic constants for incorporation of these nucleotide analogues into DNA ( $K_m$  = 0.96  $\mu$ M with 16S rRNA template; 0.74  $\mu$ M with gapped duplex DNA template) by HIV-1 reverse transcriptase are similar to those seen for their respective natural nucleotides. In addition, the incorporation of either carbovir-TP or AZT-TP in the presence of dGTP or dTTP, respectively, indicates that the mechanism of inhibition by these two nucleotide analogs is due to their incorporation into the DNA resulting in chain termination. **Target(s):** Carbovir-TP is not a potent inhibitor of DNA polymerases  $\alpha$ ,  $\beta$ , or  $\gamma$ , or DNA primase. CBV does not decrease the level of TTP, dGTP, dCTP, or dATP, indicating that the cytotoxicity of CBV was due to inhibition of DNA synthesis. **1.** Parker, White, Shaddix, *et al.* (1991) *J. Biol. Chem.* **266**, 1754. **2.** Parker, Shaddix, Bowdon, *et al.* (1993) *Antimicrob. Agents Chemother.* **37**, 1004.

### Carboxin

This well-established, globally registered Electron Transport System Complex-II inhibitor (FW = 235.30 g/mol; CAS 5234-68-4; IUPAC: 5,6-dihydro-2-methyl-1,4-oxathiine-3-carboxanilide), marketed under the trade names Vitavax<sup>®</sup>, Anchor<sup>®</sup>, Vitflo<sup>®</sup> and Provax<sup>®</sup>, is a broad-spectrum succinate dehydrogenase inhibitor (or SDHI) fungicide. Carboxin is especially effective on bunts and rhizoctonia and is used on wheat, barley, oats, rye, triticale, rice, maize, cotton, sugar beets, peanuts, soybeans, peas, sunflower, linseed, flax, rapeseed and potatoes. Carboxin and its primary metabolite (carboxin sulfoxide) are absorbed by germinating seeds, traveling upward in the plant by transpiration system and moving into the lower stem and first leaves. Carboxin does not redistribute into new growth as the plant develops and is not found in the seeds or upper leaves of crops grown from treated seed. Animals excrete carboxin and its degradation products rapidly, and no accumulation in tissues has been reported. In mammals, carboxin shows low-level, acute oral, dermal and inhalational

toxicity; without skin or eye irritation. It is, however, a skin sensitizer. Carboxin also inhibits dichlorophenol indophenol (DCIP) reductase activities by these membranes in a manner both qualitatively and quantitatively similar to the inhibition of oxidation of the various substrates. 1. Tucker & Lillich (1974) *Antimicrob. Agents Chemother.* **6**, 572.

### Carboxyamidotriazole

This indirect PRPP synthetase inhibitor and calcium channel blocker (FW = 424.67 g/mol; CAS 99519-84-3), also known by its code name L-651,582 and its systematic name 5-amino-1-[4-(4-chlorobenzoyl)-3,5-dichlorobenzyl]-1,2,3-triazole-4-carboxamide, is an antiproliferative and antiparasitic agent that inhibits mammalian nucleotide metabolism (1). It inhibits  $^3\text{H}$ -hypoxanthine,  $^{14}\text{C}$ -adenine, and  $^{14}\text{C}$ -formate incorporation into nucleotide pools, suggesting depletion of phosphoribosyl pyrophosphate stores required for *de novo* nucleotide synthesis. L-651,582 also inhibits  $^3\text{H}$ -hypoxanthine incorporation into nucleotide pools with glucose, uridine, or ribose as the carbon source, suggesting a block at PRPP synthetase. Drug treatment does not kill cells, but instead reduces the fraction of cells in S and G<sub>2</sub>/M, while increasing the population in G<sub>1</sub> (1). L651582 also blocks muscarinic m<sub>5</sub> receptor-stimulated  $^{45}\text{Ca}^{2+}$  influx and release of arachidonic acid at low micromolar concentrations, suggesting it is an effective calcium ion blocker (2). Attesting to carboxyamidotriazole's action as a calcium antagonist is its ability to block L-type calcium channels in a voltage-dependent manner, with the apparent dissociation constant for the high affinity state is 0.5  $\mu\text{M}$ . The IC<sub>50</sub> for blocking T-type calcium channels is 3.5  $\mu\text{M}$ . The inhibition of cellular proliferation and the production of arachidonate metabolites by L-651,582 may be the result of its nearly equipotent blockade of receptor-operated and voltage-gated calcium channels (3). 1. Hupe, Behrens & Boltz (1990) *J. Cell Physiol.* **144**, 457. 2. Felder, Ma, Liotta & Kohn (1991) *J. Pharmacol. Exp. Ther.* **257**, 967. 3. Hupe, Boltz & Cohen, *et al.* (1991) *J. Biol. Chem.* **266**, 10136.

### 2-Carboxyarabinitol 1-phosphate

This endogenous diurnal regulator (FW = 258.12 g/mol; CAS 106777-19-9; *Symbol*: CA 1-P), also known as (2-C-phosphohydroxymethyl)-D-ribonic acid, inhibits ribulose-bisphosphate carboxylase by binding tightly ( $K_d = 32$  nM) to the carbamoylated form of the enzyme (1). This inhibitor was extracted from leaves and copurified with the Rbu-1,5-P<sub>2</sub> carboxylase of the leaves. Further purification by ion-exchange chromatography, adsorption to purified Rbu-1,5-P<sub>2</sub> carboxylase, barium precipitation, and HPLC separation yielded a phosphorylated compound that was a strong inhibitor of Rbu-1,5-P<sub>2</sub> carboxylase. GC/MS as well as  $^{13}\text{C}$ - and  $^1\text{H}$ -NMR proved its structure. This compound differs from the Rbu-1,5-P(2) carboxylase transition-state analogue, 2-carboxyarabinitol 1,5-bisphosphate ( $K_d = 10$  pM), only by its lack of the C-5 phosphate group. In *Phaseolus vulgaris*, dark/light regulation of Rubisco activity is principally achieved by synthesis/degradation of CA 1-P (2). **See also** 2-Carboxyarabinitol 1,5-bisphosphate 1. Berry, Lorimer, Pierce, *et al.* (1987) *Proc. Natl. Acad. Sci. U.S.A.* **84**, 734. 2. Holbrook, Turner & Polans (1992) *Photosynth. Res.* **32**, 37.

### 2-Carboxyarabinitol 1,5-bisphosphate

This transition-state inhibitor (FW = 258.12 g/mol; *Symbol*: CA 1,5-P<sub>2</sub>), targets ribulose-bisphosphate (Rbu-1,5-P<sub>2</sub>) carboxylase by binding extremely tightly. Diurnal change in carboxylase activity is regulated by an endogenous inhibitor that binds tightly to the activated (carbamoylated) form of Rbu-1,5-P<sub>2</sub> carboxylase. When extracted from leaves of *Phaseolus vulgaris*, the inhibitor copurified with the carboxylase, and further purification yielded 2-carboxy-arabinitol 1-phosphate [(2-C-phosphohydroxymethyl)-D-ribonic acid]. Synthetic 2-carboxy-D-arabinitol 1-phosphate, but not 2-carboxy-D-arabinitol 5-phosphate, was kinetically identical to that of the isolated, naturally occurring compound. Note that the isolated compound differs from the transition-state analogue (2-carboxyarabinitol 1,5-bisphosphate) by lacking a C-5 phosphate group, resulting in lower affinity for the monophosphate ( $K_d = 32$  nM) than the bisphosphate ( $K_d < 10$  pM). The less tightly bound compound is active in a light-dependent, reversible regulation of Rbu-1,5-P<sub>2</sub> carboxylase *in vivo*. **See also** 2-Carboxyarabinitol 1-phosphate 1. Berry, Lorimer, Pierce, *et al.* (1987) *Proc. Natl. Acad. Sci. U.S.A.* **84**, 734.

### Carboxyatractyloside

This toxic glycoside (FW<sub>dipotassium salt</sub> = 847.01 g/mol; CAS 33286-30-5; M.P. = 270-275°C; Soluble in water but insoluble in ethanol), also called gummiferin, is more effective ( $K_d = 10^{-7}$  M) than atractyloside in inhibiting the adenine nucleotide translocator (1-4), thereby inhibiting oxidative phosphorylation. Unlike atractyloside, carboxyatractyloside inhibits the translocase noncompetitively. In addition, plant mitochondria are significantly more sensitive to carboxyatractyloside than atractyloside. Note that carboxyatractyloside can be converted to atractyloside by pyrolysis. 1. Vignais, Brandolin, Lauquin & Chabert (1979) *Meth. Enzymol.* **55**, 518. 2. Luciani (1971) *Life Sci.* **10**, 961. 3. Vignais, Vignais & Defaye (1973) *Biochemistry* **12**, 1508. 4. Silva Lima & Denslow (1979) *Arch. Biochem. Biophys.* **193**, 368.

### S-(4-Carboxybutyl)-L-homocysteine

This dual-substrate analogue (FW = 235.30 g/mol) binds with high affinity to the active site of the human hepatic betaine:homocysteine S-methyltransferase ( $K_i = 6.5$   $\mu\text{M}$ ), presumably due to the L-isomer only. The corresponding sulfoxide and sulfone are both weaker inhibitors. 1. Skiba, Wells, Mangum & Awad (1987) *Meth. Enzymol.* **143**, 384. 2. Awad, Whitney, Skiba, Mangum & Wells (1983) *J. Biol. Szegedi, Castro, Koutmos & Garrow (2008) *J. Biol. Chem.* **283**, 8939.

### (S)- $\gamma$ -Carboxyglutamate

This clotting enzyme-derived amino acid (FW = 191.14 g/mol;  $pK_a$  values = 1.7, 3.2, 4.75, and 9.9; Symbol: Gla) is obtained principally from the proteolytic degradation of posttranslationally carboxylated  $Ca^{2+}$ -binding enzymes and proteins, mainly those in the blood coagulation cascade (e.g., prothrombin, and coagulation factors VII, IX, and X) (1-4). Carboxyglutamate is also found in the bone mineralization protein osteocalcin, in invertebrate ion channel blockers (e.g., conotoxins) and in NMDA receptor antagonists (e.g., conantokins). It is produced via vitamin K-dependent carboxylation of specific glutamyl residues in protein substrates.  $\gamma$ -Carboxyglutamate was first identified as a component of prothrombin in 1974 (3,4). The free amino acid is relatively stable in alkaline solutions, but decomposes in acidic solutions ( $t_{1/2}$  = 10 minutes in 0.05 M HCl at 100° C). Note: Because  $\gamma$ -carboxyglutamate is a calcium ion chelator, one should test a putative target enzyme's activity in the presence of other calcium-ion chelators to exclude susceptibility to other metal ion chelator before inferring that carboxyglutamate binds to a inhibitor site on that enzyme. **Target(s):** group II metabotropic glutamate receptors1; group III metabotropic glutamate receptors1; glutamate dehydrogenase,  $K_i$  = 0.38  $\mu$ M (2). 1. Schoepp, Jane & Monn (1999) *Neuropharmacology* **38**, 1431. 2. Federici, Ricci, Matarese, *et al.* (1979) *Arch. Biochem. Biophys.* **196**, 304. 3. **N-[(2R)-2-(Carboxymethyl)-4-methylpentanoyl]-L-tryptophan-(S)-methyl-benzamide**

This peptidomimetic (FW<sub>free-acid</sub> = 463.58 g/mol), also known as GM 1489, is a potent inhibitor of certain matrix metalloproteinases (MMPs), including MMP-1 (or interstitial collagenase,  $K_i$  = 0.2 nM), MMP-2 (or gelatinase A,  $K_i$  = 0.5  $\mu$ M), MMP-3 (or stromelysin 1,  $K_i$  = 20  $\mu$ M), MMP-8 (or neutrophil collagenase,  $K_i$  = 0.1  $\mu$ M), and MMP-9 (or gelatinase B,  $K_i$  = 0.1  $\mu$ M). 1. Holleran, Galardy, Gao, *et al.* (1997) *Arch Dermatol Res.* **289**,138.

**2-[[[1-(Carboxymethyl)-2,3,4,5-tetrahydro-5-hydroxy-2-oxo-1H-1-benzazepine-3-yl]amino]-4-phenylbutanoate**

This benzazepinone derivative (FW<sub>free-acid</sub> = 412.44 g/mol) is a potent inhibitor of human peptidyl-dipeptidase A, or angiotensin-I-converting enzyme,  $IC_{50}$  = 8 nM. 1. Ksander, Erion, Yuan, *et al.* (1994) *J. Med. Chem.* **37**, 1823.

**[4S-[14 $\alpha$ ,7 $\alpha$ (R\*),12b $\beta$ ]]-7-[S-(1-Carboxy-3-phenylpropyl)amino]-1,2,3,4,6,7,8,12b-octahydro-6-oxopyrido[2,1-a]-[2]benzazepine-4-carboxylate**

This tricyclic peptidomimetic (FW<sub>free-acid</sub> = 436.51 g/mol) of a substrate C-terminal dipeptide linked with a 4-phenylbutanoic acid fragment, also known as MDL 27,088, inhibits peptidyl-dipeptidase A, or angiotensin I converting enzyme with  $K_i$   $\approx$  4 pM. The structurally related compound MDL 27,788 inhibits angiotensin I-converting enzyme with  $K_i$   $\approx$  46 pM. 1. Giroux, Beight, Dage & Flynn (1989) *J. Enzyme Inhib.* **2**, 269.

**2-[[[2-Carboxy-3-phenylpropyl]hydroxyphosphinoyl]methyl]pentanedioate**

This phosphinate-containing tricarboxylic acid (FW = 372.31 g/mol) inhibits glutamate carboxypeptidase II ( $IC_{50}$  = 2 nM), presumably by mimicking the tetrahedral adduct formed during catalysis. In this case, a methylene also serves as a mimic for the amino that would be present in a glutamate containing peptide. 1. Jackson, Tays, Maclin, *et al.* (699Å) *J. Med. Chem.* **44**, 4170.

**(3R,4S,5R)-5-((R)-1-Carboxy-1-phosphonoethoxy)-4-hydroxy-3-phosphono-oxycyclohex-1-enecarboxylate**

This tetrahedral-intermediate analogue (FW = 405.17 g/mol) targets phosphoshikimate 1 carboxyvinyltransferase, or 3-enolpyruvoyldhikimate-5 phosphate synthase ( $K_i$  = 16 nM). The (S)-1-carboxy-1-phosphonoethoxy analogue is a slightly weaker inhibitor ( $K_i$  = 75 nM). 1. Priestman, Healy, Becker, *et al.* (2005) *Biochemistry* **44**, 3241. 2. Alberg & Bartlett (1989) *J. Amer. Chem. Soc.* **111**, 2337.

**2-C-Carboxy-D-ribitol 1,5-Bisphosphate**

This modified ribitol (FW<sub>free-acid</sub> = 356.12 g/mol) inhibits ribulose-bisphosphate carboxylase ( $K_d$  = 1.5  $\mu$ M). 1. Calvin (1954) *Fed. Proc., Fed. Amer. Soc. Exp. Biol.* **13**, 697. 2. Wishnick, Lane & Scrutton (1970) *J. Biol. Chem.* **245**, 4939. 3. Siegel & Lane (1975) *Meth. Enzymol.* **42**, 472. 4. Schloss, Phares, Long, *et al.* (1982) *Meth. **Cardamonin**

This chalconoid and Wnt/ $\beta$ -catenin inhibitor (FW = 270.27 g/mol; CAS 19309-14-9; IUPAC Name: (*E*)-1-(2,4-dihydroxy-6-methoxyphenyl)-3-phenylprop-2-en-1-one) from the seeds of *Alpinia katsumadai hayata* inhibits RANKL-induced NF- $\kappa$ B activation, with its suppressive effects correlating with inhibition of I $\kappa$ B $\alpha$  kinase and inhibition of phosphorylation and degradation of I $\kappa$ B $\alpha$ , an inhibitor of NF- $\kappa$ B (1). Furthermore, cardamonin also down-regulated RANKL-induced phosphorylation of MAPK including ERK and p38 MAPK. Cardamonin suppresses the RANKL-induced differentiation of monocytes to osteoclasts in a dose-dependent and time-dependent manner, suggesting that cardamonin may prove to be a valuable agent in suppressing osteoporosis. Cardamonin also inhibits pigmentation in melanocytes by suppressing the Wnt/ $\beta$ -catenin, key elements in a signaling pathway that regulates stem cell pluripotency and fate decisions during development by integrating signals from other pathways, including retinoic acid, FGF, TGF- $\beta$ , and BMP. Wnt ligand is a secreted glycoprotein that binds to Frizzled receptors, triggering displacement of the multifunctional kinase GSK-3 $\beta$  from a regulatory APC/Axin/GSK-3 $\beta$ -complex. Cardamonin also reduces COX and iNOS expression by inhibiting p65NF- $\kappa$ B nuclear translocation and I- $\kappa$ B phosphorylation in RAW 264.7 macrophage cells (3). 1. Sung, Prasad, Yadav, *et al.* (2013) *PLoS One* **8**, e64118. 2. Cho, Ryu, Jeong, *et al.* (2009) *Biochem. Biophys. Res. Commun.* **390**, 500. 3. Israf, Khaizurin, Syahida, Lajis & Khozirah (2007) *Mol. Immunol.* **44**, 673.

**Cardiotonic Steroids**

These digitalis-like inhibitors, or CTS, exert their effects on cardiac cells by binding to specific binding sites on the extracellular loops connecting transmembrane helices TM<sub>1</sub> to TM<sub>2</sub>, TM<sub>3</sub> to TM<sub>6</sub>, and TM<sub>7</sub> to TM<sub>8</sub> of the  $\alpha$ -subunit of the Na<sup>+</sup>/K<sup>+</sup>-ATPase. Originally considered to regulate renal sodium transport and arterial pressure, these substances are now known to regulate cell growth, differentiation, apoptosis, and fibrosis, the modulation of immunity and of carbohydrate metabolism as well as CNS function and human behavior. Remarkably, digitalis-like cardiotonic steroids were constituents of herbal remedies administered to cardiac patients in Roman times. Those in the bufadienolide class were routinely used in clinical practice more than 1000 years ago. **See also:** *Ouabain*, *Digitoxin*, *Digoxin*, *Convallatoxin*, *SC4453*, *Bufalin*, *Gitoxin*, *Digoxigenin*, *Actodigin*, *Oleandrin*, *Digitoxigenin*, *Gitoxin*, *Strophanthidin*, *Gitoxigenin*, *Lanatosides A, B and C*, and *Methyl-digoxin*.

**Cardizem, See Diltiazem****Carfilzomib**

This epoxyketone-containing tetrapeptide (FW = 719.91 g/mol; CASs = 868540-17-4, 1140908-84-4 (TFA salt), 1140908-85-5 (methanesulfonate); Solubility: 50 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O; Animal Studies Formulation: 10% sulfobutylether  $\beta$ -cyclodextrin in 10 mM citrate, pH 3.5), also known as PR-171, selectively and irreversibly inhibits the chymotrypsin-like activity of proteasomes (IC<sub>50</sub> < 5 nM). Inhibition of proteasome-mediated proteolysis results in a build-up of misfolded and polyubiquitinated proteins, including consequentially dysfunctional chaperonins, which may cause cell cycle arrest, apoptosis, and inhibition of tumor growth. Carfilzomib inhibits proliferation in a variety of cell lines

and patient-derived neoplastic cells, including multiple myeloma, and induced intrinsic and extrinsic apoptotic signaling pathways and activation of c-Jun-N-terminal kinase (JNK). This second-generation proteasome inhibitor, based on the naturally occurring epoxomicin, is intended to be a potential treatment for patients with multiple myeloma and solid tumors. (**See also** *Bortezomib*; *Ixazomib*; *Oprozomib*) IUPAC: ( $\alpha$ S)- $\alpha$ -[[2-(4-morpholinyl)acetyl]amino]benzenebutanoyl-L-leucyl-N-[(1S)-3-methyl-1-[[2(R)-2-methyl-2-oxiranyl]carbonyl]butyl]-L-phenylalaninamide 1. Kuhn, *et al.* (2007) *Blood* **110**, 3281. 2. Kuhn, *et al.* (2011) *Curr. Cancer Drug Targets* **11**, 285.

**Cariporide**

This orally bioavailable Na<sup>+</sup>/H<sup>+</sup> exchange inhibitor (FW = 283.35 g/mol; CAS 159138-80-4; Soluble to 100 mM in DMSO), also named *N*-(aminoiminomethyl)-4-(1-methylethyl)-3-(methylsulfonyl)benzamide and HOE 642, selectively targets NHE1 (IC<sub>50</sub> = 0.05  $\mu$ M), with much weaker action against NHE3 (IC<sub>50</sub> = 3  $\mu$ M) and NHE2 (IC<sub>50</sub> = 1000  $\mu$ M) (1). Subtype specificity was determined by <sup>22</sup>Na<sup>+</sup> uptake inhibition in a fibroblast cell line separately expressing subtype Isoforms 1, 2 or 3. Cariporide attenuates ischemia-induced cardiomyocyte apoptosis *in vitro* and reduces cardiac arrhythmia *in vivo* (1). Although mild, apoptosis can be rapidly induced in isolated hearts by a relatively brief period of ischemia without reperfusion. Loss of mitochondrial membrane potential is a critical step of the death pathway, and cariporide prevents H<sub>2</sub>O<sub>2</sub>-induced loss of mitochondrial membrane potential (3). Significantly, cariporide sensitizes leukemic cells to tumor necrosis factor related apoptosis-inducing ligand by up-regulating Death Receptor-5 via the endoplasmic reticulum stress-CCAAT/enhancer binding protein homologous protein-dependent mechanism (4). **See** *Zoniporide* 1. Scholz, Albus, Counillon, *et al.* (1995) *Cardiovasc. Res.* **29**, 260. 2. Chakrabarti, Hoque & Karmazyn (1997) *J. Mol. Cell Cardiol.* **29**, 3169. 3. Teshima, Akao, Jones & Marbán (2003) *Circulation* **108**, 2275. 4. Li, Chang, Wang, *et al.* (2014) *Leuk. Lymphoma* **55**, 2135.

**Cariprazine**

This orally active, brain-penetrant dopamine D<sub>3</sub> receptor partial agonist (FW = 427.41 g/mol; CAS 839712-12-8), also known as *N*'-[*trans*-4-[2-[4-(2,3-dichlorophenyl)-1-piperazinyl]-ethyl]cyclohexyl]-*N,N*-dimethylurea, RGH-188, and Vraylar<sup>®</sup>, is specifically indicated for treatment of schizophrenia and acutely as a treatment for manic or mixed episodes associated with bipolar I disorder. For the former, Vraylar's efficacy was demonstrated at 1.5 to 9 mg/day, and, for the latter, efficacy was shown at 3 to 12 mg/day. Unlike many D<sub>2</sub> and 5-HT<sub>2A</sub> receptor-targeting antipsychotics, cariprazine is a D<sub>2</sub> and D<sub>3</sub> partial agonist, showing higher affinity for the latter (1). D<sub>2</sub> and D<sub>3</sub> receptors are regarded as important targets treating schizophrenia, inasmuch as overstimulation of dopamine receptors is believed to be a possible causative factor of schizophrenia. Acting as an antagonist, aripiprazole inhibits overstimulated dopamine receptors, but, acting as an agonist, it stimulates the same receptors, when endogenous dopamine levels are low. In animal studies using acute phencyclidine (PCP) treatment to model the cognitive deficits of schizophrenia, cariprazine pretreatment significantly diminished PCP-triggered cognitive deficits, and studies on knockout mice show that dopamine D<sub>3</sub> receptors contribute to this effect (2). Activation of dopamine D<sub>2</sub> receptors (D<sub>2</sub>R) modulates G-protein/cAMP-dependent signaling and engages Akt-GSK-3 signaling through D<sub>2</sub>R/ $\beta$ -arrestin 2 scaffolding of Akt and PP2A (3). This G protein-independent pathway may be important in mediating the antimanic effects of mood stabilizers and antipsychotics. The mood stabilizer lithium influences behavior and Akt/GSK-3 signaling in mice and many antipsychotics have been shown to more potently antagonize the activity of the  $\beta$ -arrestin-2 pathway relative to the G protein-

dependent pathway. Cariprazine was more potent than aripiprazole in inhibiting isoproterenol-induced cAMP although both compounds showed similar maximum efficacy. In assays of D<sub>2</sub>R/ $\beta$ -arrestin 2-dependent interactions, cariprazine showed very weak partial agonist activity, unless the levels of receptor kinase were increased; as an antagonist it showed similar potency to haloperidol and around five times greater potency than aripiprazole (3). Although D<sub>2</sub> and D<sub>3</sub> receptor agonists (e.g., dopamine, pramipexole, apomorphine, 7-OH-DPAT, quinpirole) fully activate [<sup>35</sup>S]GTP $\gamma$ S binding in membrane preparation from rat striatum, HEK293-D<sub>2</sub>, and CHO-D<sub>3</sub> cells, cariprazine and aripiprazole did not show G-protein activation at concentrations up to 10  $\mu$ M (1). **Pharmacodynamic Profile:** Serotonin 5-HT<sub>1A</sub> receptor, K<sub>i</sub> = 3 nM (acting as a partial agonist); 5-HT<sub>2A</sub> receptor, K<sub>i</sub> = 19 nM (acting as an inverse agonist); 5-HT<sub>2B</sub> receptor, K<sub>i</sub> = 0.58 nM (acting as an inverseagonist); 5-HT<sub>2C</sub> receptor, K<sub>i</sub> = 134 nM (acting as an inverse agonist); 5-HT<sub>7</sub> receptor, K<sub>i</sub> = 111 nM (acting as an antagonist); Dopamine D<sub>2L</sub> receptor, K<sub>i</sub> = 0.49 nM (acting as a partial agonist); D<sub>2S</sub> receptor, K<sub>i</sub> = 0.69 nM (acting as a partial agonist); D<sub>3</sub> receptor, K<sub>i</sub> = 0.09 nM (acting as a partial agonist); Histamine H<sub>1</sub> receptor, K<sub>i</sub> = 23 nM (acting as an inverse agonist). 1. Kiss, Horváth, Némethy, *et al.* (2010) *J. Pharmacol. Exp. Ther.* 333, 328. 2. Zimnisky, Chang, Gyertyán *et al.* (2013) *Psychopharmacol. (Berl)* 226, 91. 3. ### Carmustine

This mustard gas-related  $\beta$ -chloronitrosourea anticancer drug (FW = 214.05 g/mol; CAS 154-93-8; *Abbreviation:* BCNU), also known as 1,3-bis(2-chloroethyl)-1-nitrosourea, is a cell cycle-independent DNA alkylating agent that forms interstrand crosslinks, thereby preventing DNA replication and transcription (1,2). Given its ability to cross the blood-brain barrier, carmustine is often used to treat brain tumors. A single BCNU dose (50 mg/kg i.p.) to mice significantly inhibited glutathione reductase activity in liver within 10 min, and in lung and heart within 30 min (3). Maximal inhibition was reached at 4 h in all tissues, and glutathione reductase activity remained significantly depressed for 48 h in liver and for 96 h in lung and heart. BCNU doses <25 mg/kg were without effect on reductase activity. As noted elsewhere (See *Nitrosoureas*), cell redox mechanisms greatly influence cell susceptibility of nitrosoureas. 1. Ahmann, Hahn & Bisel (1972) *Cancer Chemother. Rep.* 56, 93. 2. Carter, Schabel, Broder & Johnston (1972) *Adv. Cancer Res.* 16, 273. 3. Kehrer (1983) *Toxicol. Lett.* 17, 63.

### L-Carnitine

This hydrophilic quaternary amine and key fatty acid-conjugating metabolite (FW<sub>inner-salt</sub> = 161.20 g/mol; carboxyl group pK<sub>a</sub> = 3.80 at 25°C), also known as (R)-(-)-carnitine is found in high abundance in skeletal muscle, liver, and yeast, where participates in the transport of acyl groups across the mitochondrial membrane. Carnitine facilitates the transport of long-chain fatty acids (as fatty acyl-carnitine) into the mitochondrial matrix, where they undergo  $\beta$ -oxidation to acetyl CoA and the citric acid cycle. Carnitine is not metabolized, is excreted in urine, and undergoes highly efficient renal reabsorption. Carnitine is itself a product of the reactions catalyzed by acylcarnitine hydrolase and carnitinamidase. Because L-carnitine can deplete cellular acetyl-CoA stores via carnitine acetyl transferase (*Reaction:* Carnitine + Acetyl-CoA  $\rightleftharpoons$  Acetyl-carnitine + CoA), it would be expected to reduce histone acetylation. On the contrary, L-carnitine actually increases histone acetylation and induces accumulation of acetylated histones both in normal thymocytes and cancer cells. This effect appears to result from its inhibition of histone deacetylases HDAC-I and HDAC-II by binding to their active sites (1). **Target(s):** caspase-3 (2); caspase-7 (2); caspase-8 (2); D-carnitine dehydrogenase (3); phosphatidylcholine:sterol acyltransferase, *or* LCAT (4); succinate:3-hydroxy-3-methylglutarate CoA-transferase (5); glycerophosphocholine cholinephosphodiesterase (6); palmitoyl-CoA hydrolase, *or* acyl-CoA

hydrolase, activated at low concentrations (7); lysophospholipase (8); choline sulfotransferase (9); hydroxylysine kinase (10); glycerone-phosphate *O*-acyltransferase, *or* dihydroxyacetone-phosphate *O*-acyltransferase, inhibited by DL-carnitine (11). 1. Huang, Liu, Guo, *et al.* (2012) *PLoS One* 7, e49062. 2. Mutomba, Yuan, Konyavko, *et al.* (2000) *FEBS Lett.* 478, 19. 3. Hanschmann & Kleber (1997) *Biochim. Biophys. Acta* 1337, 133. 4. ### Caroverine

This N-type calcium channel blocker (FW = 365.47 g/mol; CAS Registry = 23465-76-1), also known as Spasmium<sup>®</sup>, Spadon<sup>®</sup>, and 1-[2-(diethylamino)ethyl]-3-(4-methoxybenzyl)quinoxalin-2(1H)-one, is a spasmolytic drug and an oto-neural protective agent that is also a competitive antagonist of AMPA receptors, a noncompetitive antagonist of NMDA receptors, and a potent antioxidant. 1. Nohl, Bieberschulte, Dietrich, *et al.* (2003) *BioFactors* 19, 79.

### Carvedilol

This potent receptor antagonist and cardiovascular drug (FW = 406.48 g/mol; CAS 72956-09-3; Solubility: 100 mM in DMSO), also known 1-(9H-carbazol-4-yloxy)-3-[[2-(2-methoxyphenoxy)ethyl]amino]-2-propanol and BM 14190, targets the  $\beta_1$ -adrenoceptor (K<sub>i</sub> = 0.81 nM),  $\beta_2$ -adrenoceptor (K<sub>i</sub> = 0.96 nM), and  $\alpha_1$ -adrenoceptor (K<sub>i</sub> = 2.2 nM), displaying both antihypertensive and peripheral vasodilatory activity. Carvedilol also blocks cardiac inward-rectifier K<sup>+</sup> (K<sub>IR</sub>) channels and voltage-dependent Ca<sup>2+</sup> channels. It also exhibits antioxidant properties at much higher concentrations. Carvedilol also produced a concentration-dependent inhibition of vascular smooth muscle cell migration induced by platelet-derived growth factor, with an IC<sub>50</sub> value of 3  $\mu$ M. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Ohlstein, Douglas, Sung, *et al.* (1993) *Proc. Natl. Acad. Sci. U.S.A.* 90, 6189. 2. Pönicke, Heinroth-Hoffmann & Brodde (2002) *J. Pharmacol. Exp. Ther.* 301, 71.

### $\alpha$ S1-Casomorphin

This  $\kappa$ -acting opioid agonist (*Sequence:* Tyr-Val-Pro-Phe-Pro; FW = 621.73 g/mol; CAS 51871-47-7) is a noncompetitive inhibitor of nitric oxide synthase (1). This pentapeptide was isolated from hydrolysis of human S1 casein (residues: 158-162). Both the pentapeptide and its amide inhibit the proliferation of Thr47Asp human breast cancer cells (2). 1. Kampa, Hatzoglou, Notas, *et al.* (2001) *Cell Death Differ.* 8, 943. 2. Kampa, Loukas, Hatzoglou, *et al.* (1996) *Biochem. J.* 319, 903.

### Castanospermine

This indolizine alkaloid (FW = 189.21 g/mol; CAS 79831-76-8), also named (1*S*,6*S*,7*R*,8*R*,8*aR*)-1,2,3,5,6,7,8,8*a*-octahydroindolizine-1,6,7,8-tetrol, from the seeds of *Castanospermum australe*, is a potent glucosidase inhibitor with antiviral activity. In liver, both neutral (pH 6.5) and acidic (pH 4.5)  $\alpha$ -glucosidase activities are inhibited, but the former is more susceptible (1). Castanospermine is also a potent inhibitor of  $\alpha$ -glucocerebrosidase in fibroblast extracts, whereas other lysosomal glycosidases (*i.e.*,  $\alpha$ - or  $\beta$ -galactosidase,  $\alpha$ - or  $\beta$ -mannosidase,  $\beta$ -*N*-acetylhexosaminidase,  $\beta$ -glucuronidase,  $\alpha$ - or  $\beta$ -L-fucosidase) are insensitive to castanospermine (2). Castanospermine inhibits the processing of the oligosaccharide portion of the influenza viral hemagglutinin (3). Castanospermine is a competitive inhibitor of amyloglucosidase at both pH 4.5 and 6.0, when assayed with the *p*-nitrophenyl- $\alpha$ -D-glucoside (4). It is also a competitive inhibitor of almond emulsin  $\beta$ -glucosidase at pH 6.5; however, inhibition was of the mixed type at pH 4.5 to 5.0 (4). In all cases, castanospermine was a much better inhibitor at pH 6.0 to 6.5 than at lower pH values, and the  $pK_a$  for castanospermine is 6.09. The authors suggest that the alkaloid is probably more active in its unprotonated form, which comports with the finding that the *N*-oxide of castanospermine, while still a competitive inhibitor, is 50-100x less active than was castanospermine. The latter's activity is not markedly altered by pH. These results probably explain why castanospermine is a good inhibitor of the glycoprotein processing enzyme, glucosidase I, since which is a neutral hydrolase (4). It should also be noted that bicyclic iminosugars, such as castanospermine and Celgosivir<sup>®</sup>, inhibit Dengue virus production by inhibiting endoplasmic reticulum  $\alpha$ -glucosidases, and not by reducing the activity of glycolipid-processing enzymes (5). **See also Celgosivir** 1. Saul, Ghidoni, Molyneux & Elbein (1985) *Proc. Natl. Acad. Sci. U.S.A.* **82**, 93. 2. Saul, Molyneux & Elbein (1984) *Arch. Biochem. Biophys.* **230**, 668. 3. Pan, Hori, Saul, *et al.* (1983) *Biochemistry* **22**, 3975. 4. Saul, Molyneux & Elbein (1984) *Arch. Biochem. Biophys.* **230**, 668. 5. Sayce, Alonzi, Killingbeck, *et al.* (2016) *PLoS Negl. Trop. Dis.* **10**, e0004524.

### $\beta$ -Catenin/Tcf Inhibitor V

This cell-permeable, dimeric copper complex (FW = 378.60 g/mol; CAS 691005-38-6), also known as BC21, is a Wnt signaling inhibitor that binds to  $\beta$ -catenin, thereby competitively and reversibly blocking the  $\beta$ -catenin/Tcf4 interaction ( $IC_{50}$  = 5.0  $\mu$ M). Named for *Drosophila* Wingless-Type proteins, Wnts are secreted glycolipoproteins that regulate embryonal development and tissue homeostasis. Wnt binds to certain receptors, resulting in the inactivation of the  $\beta$ -catenin destruction complex to initiate Wnt-responsive gene expression after associating with TCF (T-cell factor) in the nucleus and activating cell proliferation.  $\beta$ -Catenin over-activation/over-expression is often observed in tumorigenesis. By disrupting key regulatory steps, BC21 decreases the viability of  $\beta$ -catenin overexpressing HCT116 colon cancer cells that harbor the  $\beta$ -catenin mutation, and more significantly, it inhibits the clonogenic activity of these cells (1). 1. Tian, Han, Yan, *et al.* (2012) *Biochemistry* **51**, 724.

### Caudatin

This natural product and potential antitumor agent (FW = 490.63 g/mol; CAS 38395-02-7), also named (3 $\beta$ ,12 $\beta$ ,14 $\beta$ ,17 $\alpha$ )-12-[[*(E)*-3,4-dimethyl-1-oxo-2-pentenyl]oxy]-3,8,14,17-tetrahydroxypregn-5-en-20-one, from the

traditional Chinese herbal medicine *bai shou wu*, the root tuber of *Cynanchum auriculatum* Royle ex Wight, inhibits carcinomic human alveolar basal epithelial cell growth and angiogenesis through modulating GSK3 $\beta$ / $\beta$ -catenin pathway (1). In HepG2 cells treated with caudatin, Western blotting indicated that the levels of Bcl-2 are down-regulated after caudatin treatment, whereas the expression of Bax is up-regulated (2). Furthermore, caudatin-induced apoptosis is accompanied by activation of caspase-3, -9, and poly(ADP-Ribose) Polymerase (PARP) (2). Treatment with caudatin also induced phosphorylation of extracellular-signal regulating kinase (ERK) and c-Jun N-terminal kinase (JNK). Such results demonstrate caudatin inhibits cell proliferation via DNA synthesis reduction and induces caspase-dependent apoptosis in HepG2 cells (2). 1. Fei, Cui, Zhang, Zhao & Wang (2012) *J. Cell Biochem.* **113**, 3403. 2. Fei, Chen, Xiao, Chen & Wang (2012) *Mol. Biol. Rep.* **39**, 131.

### CB-839

This potent, orally bioavailable glutaminase inhibitor (FW = 571.58 g/mol) binds reversibly at an allosteric site on both KGA and GAC splice forms of the ubiquitously expressed mitochondrial enzyme glutaminase, or GLS (1). CB-839 does not inhibit the related enzyme glutaminase 2 (GLS2), whose expression is restricted primarily to liver. **Rationale:** Inhibition of mitochondrial glutaminase activity, as achieved by small molecule inhibitors or genetic knockdown, exerts anti-tumor activity across a variety of tumor types, including lymphoma, glioma, breast, pancreatic, non-small cell lung, and renal cancers. Development of CB-839 as a GLS inhibitor exploits knowledge that BPTES (*bis*-2-(5-phenylacetamido-1,2,4-thiadiazol-2-yl)ethyl sulfide) forms inactive glutaminase homodimer through the binding of two inhibitor molecules at the interface between a pair of homodimers. CB-839 is most likely a slow, tight-binding inhibitor, and  $IC_{50}$  values < 50 nM following  $\geq$  1-hour pre-incubation with recombinant human GAC-GLS, or  $\sim$ 13x lower than with BPTES. 1. Gross, Demo, Dennison, *et al.* (2014) *Mol. Cancer Ther.* **13**, 890.

### CB 300945, See ONX-0801

### CBR 5884

This small-molecule anti-cancer agent (FW = 336.39 g/mol; CAS 681159-27-3; Soluble to 100 mM in DMSO), also named ethyl 5-[(2-furanylcarbonyl)amino]-3-methyl-4-thiocyanato-2-thiophenecarboxylate, targets 3-phosphoglycerate dehydrogenase ( $IC_{50}$  = 33  $\mu$ M), thereby reducing the *de novo* serine synthesis in cancer cells and inhibiting proliferation of cancer cell lines characterized by high PHGDH expression levels. CBR-5884 is a time-dependent noncompetitive inhibitor that disrupts enzyme oligomerization. CBR-5884 was identified by screening a library of 800,000 drug-like compounds. 1. Mullarky, Lucki, Beheshti Zavareh, *et al.* (2016) *Proc. Natl. Acad. Sci. U.S.A.* **113**, 1778.

### CC-223

This potent and orally bioavailable mTOR inhibitor (FW = 397.47 g/mol; CAS 1228013-30-6; Solubility: 80 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 7-(6-(2-hydroxypropan-2-yl)pyridin-3-yl)-1-((*trans*)-4-methoxycyclohexyl)-3,4-dihydropyrazino[2,3-*b*]pyrazin-2(1*H*)-one, selectively targets mTOR kinase (IC<sub>50</sub> = 16 nM), with >200-fold selectivity over the related PI3K- $\alpha$  (IC<sub>50</sub> = 4.0  $\mu$ M). Of the PI3K-related kinases tested, CC-223 shows no significant inhibition of ATR or SMG1, but inhibits DNA-PK (IC<sub>50</sub> = 0.84  $\mu$ M). When screened in a single-point assay against a commercially available panel of 246 kinases, only FLT4 (IC<sub>50</sub> = 0.65  $\mu$ M) and cFMS (IC<sub>50</sub> = 28 nM) were substantially inhibited below 1  $\mu$ M. The kinase selectivity of CC-223 was confirmed upon evaluation in cellular systems using ActivX KiNativ profiling. Other than mTOR kinase, no kinase target was identified when HCT 116 or A549 cells were treated for 1 hour with 1  $\mu$ mol/L CC-223 and assayed for kinase activity. Like rapamycin, CC-223 inhibits the direct and indirect mTORC1 substrates p-p70S6K and pS6RP. However, unlike rapamycin, CC-223 more fully inhibits mTORC1 activity, demonstrating a concentration-dependent reduction in the direct marker p-4EBP1<sup>T46</sup>. CC-223 also demonstrates inhibition of the mTORC2 complex, as assessed by reduction in phosphorylation of the direct substrate AKT<sup>S473</sup> and the downstream markers PRAS40<sup>T246</sup> and GSK3 $\beta$ <sup>S9</sup>. Using a panel consisting of twenty-three diffused large B-cell lymphoma (DLBCL), four follicular lymphoma (FL), 5 acute myelogenous leukemia (AML), six mantle cell lymphoma (MCL), and two anaplastic large cell lymphoma (ALCL) lines, potent growth inhibitory effects were observed with GI<sub>50</sub> < 0.7  $\mu$ M in 33 of 40 lines and GI<sub>50</sub> values between 1-5  $\mu$ M in the remaining lines. 1. Mortensen, Fultz, Xu, *et al.* (2015) *Mol. Cancer Ther.* 14, 1295.

#### CC 0651

This allosteric Cdc34 inhibitor (FW = 442.29 g/mol; CAS 1319207-44-7; Solubility: 100 mM in 1eq. NaOH; 100 mM in DMSO), also named (2*R*,3*S*,4*S*)-5-[4-(3,5-dichlorophenyl)phenyl]-2,3-dihydroxy-4-(2-methoxyacetamido)pentanoate, targets human Cdc34-mediated ubiquitination of p27<sup>Kip1</sup> (IC<sub>50</sub> = 1.72  $\mu$ M), with selectivity over Uba1, Ube2G1, UbcH7, UbcH5, Ube2N (Ubc13), Ube2R2, SMURF2, SspH1 and Rnf168. Structure determination revealed that CC0651 inserts into a cryptic binding pocket on hCdc34 distant from the catalytic site, causing subtle but wholesale displacement of E2 secondary structural elements (1). CC0651 analogues also inhibit proliferation of human cancer cell lines and caused accumulation of the SCF (*or* Skp2) substrate p27 (*or* Kip1). CC0651 does not affect hCdc34 interactions with E<sub>1</sub> or E<sub>3</sub> enzymes or the formation of the ubiquitin thioester but instead interferes with the discharge of ubiquitin to acceptor lysine residues. E<sub>2</sub> enzymes are thus susceptible to noncatalytic site inhibition and may represent a viable class of drug target in the UPS (1). CC-0651 traps a weak interaction between ubiquitin and the E<sub>2</sub> donor ubiquitin-binding site (2). A structure of the ternary CC0651-Cdc34A-ubiquitin complex revealed that the inhibitor engages a composite binding pocket formed from Cdc34A and ubiquitin. CC0651 also suppresses the spontaneous hydrolysis rate of the Cdc34A-ubiquitin thioester without decreasing the interaction between Cdc34A and the RING domain subunit of the E<sub>3</sub> enzyme (2). Stabilization of otherwise weak interactions between ubiquitin and UPS enzymes by small molecules appears to be a strategy for selectively inhibiting different UPS activities (2). 1. Ceccarelli, Tang, Pelletier, *et al.* (2011) *Cell* 145, 1075. 2. Huang, Ceccarelli, Orlicky, *et al.* (2014) *Nature Chem. Biol.* 10, 156.

CC-10004, See Apremilast

#### CCCP

This mitochondria/chloroplast-inhibiting protonophore, *or* small-molecule transmembrane carrier (FW = 204.62 g/mol; CAS 555-60-2), also known as carbonyl cyanide *m*-chlorophenyl hydrazone, is cytotoxic, dissipating the proton motive forces needed to drive oxidative phosphorylation and photophosphorylation, gradually causing cell destruction and death (1-3). CCCP inhibits chloroplast function as well as plant mitochondria by uncoupling of the proton chemiosmotic gradient established by the photon capture and the electron transport chain, thereby reducing or blocking ATP synthase. (See FCCP) **Intracellular Target:** Although oxidative phosphorylation is blocked by CCCP, the agent's actual target is the cytochrome *c* oxidase complex. CCCP binds to the cytochrome *a*<sub>3</sub>,  $K_d$  = 0.27  $\mu$ M, with weaker binding to other sites in the cytochrome *c* oxidase complex (4). The electrostatic interaction between CCCP and cytochrome *c* oxidase involves an ionizable group ( $pK_a$  = 6.64) on cytochrome *c* oxidase. CCCP's interaction at low-affinity binding sites of cytochrome *c* oxidase induces the shift of the anion spectrum of CCCP toward the UV (4). **Mechanism of Protonophore Action:** After binding within a phospholipid membrane bilayer, each protonophore resides within that membrane throughout multiple rounds, shuttling protons one-by-one, forth or back across the membrane, depending on the transmembrane potential. This mechanism explains the efficiency of protonophore, which relies on rapid protonation/deprotonation rather than carrier desorption after each round of proton transport. In the following model, transmembrane proton transport is facilitated by intramembrane-resident weak acids like CCCP. In such a scheme, there are four relevant parameters:  $\beta_A$  and  $\beta_{HA}$ , describing the proton binding to and release from the weak acid's anionic and neutral forms, respectively, and  $\kappa_A$  and  $\kappa_{HA}$ , the rate constants for the movement of A<sup>-</sup> and HA within and across the membrane's interior.

In this diagram (*excerpted from (5) with permission of the authors and publisher, AEPress, Bratislava, Slovakia*), the circled positive and negative signs indicate an implied potential difference across the membrane. The rate constants  $k_R$  and  $k_D$  refer to the heterogeneous reassociation and dissociation, respectively, of an aqueous proton with an anion carrier molecule adsorbed to the membrane. The rate constants  $k'_A$  and  $k''_A$  refer to the voltage-dependent translocation of the anion A<sup>-</sup> from the *i*-(memb/aq)-interface to the *ii*-(memb/aq)-interface. The rate constant  $k_{HA}$  refers to the movement of HA between the two interfaces. The parameters  $\beta_A$ ,  $\beta_{HA}$ ,  $\kappa_A$ , and  $\kappa_{HA}$  were determined by equilibrium dialysis, electrophoretic mobility, membrane potential, membrane conductance, and spectrophotometric measurements (5). Based on these equilibrium and steady-state measurements on diphtanoyl phosphatidylcholine/ chlorodecane membranes,  $\beta_A = \beta_{HA} = 1.4 \times 10^{-3}$  cm,  $\kappa_A = 175$  s<sup>-1</sup> and  $\kappa_{HA} = 12,000$  sec<sup>-1</sup>. The model predicts a single exponential decay of the current in a voltage-clamp experiment. The model also predicts that the decay in the voltage across the membrane following an intense current pulse of short duration (approximately 50 nsec) can be described by the sum of two exponentials. The magnitudes and time constants of the relaxations that we observed in both voltage-clamp and charge-pulse experiments agree well with the predictions of the model for all values of pH, voltage and CCCP concentrations. **CCCP Effects on Autophagy:** Treatment of HeLa cells with CCCP causes redistribution of mitochondrially targeted dyes (*e.g.*, DiOC6, TMRM, MTR, and MTG) from mitochondria to cytosol, and then to lysosomal compartments (6). Relocalization of mitochondrial dyes to lysosomal compartments was brought about by retargeting the dye, rather than mitochondrial component delivery to the lysosome. CCCP interfered with lysosomal function and autophagosomal degradation in both yeast and

mammalian cells, inhibited starvation-induced mitophagy in mammalian cells, and blocked the induction of mitophagy in yeast cells. Such results demonstrate that CCCP inhibits autophagy at both the initiation and lysosomal degradation stages. In addition, our data demonstrated that caution should be taken when using organelle-specific dyes in conjunction with strategies affecting membrane potential. **Effect on Chloramphenicol & Ciprofloxacin:** Although chloramphenicol and ciprofloxacin are highly effective against *Enterobacter aerogenes*, certain clinical isolates possess the highly active AcrAB drug efflux pump that reduces their intracellular concentrations to noncytostatic levels (). The MICs are reduced in drug-insensitive isolates, but not sensitive bacterial strains, when CCCP is added as an uncoupling agent for systems maintaining transmembrane ion gradients. The intracellular chloramphenicol concentration, for example, rises 2.3x in the presence of CCCP, suggesting that transport energization or the organization of the efflux channel is impaired (7,8). 1. #### CCEP-32496

This potent BRAF/cRaf inhibitor (FW = 517.46 g/mol; CAS 1188910-76-0; Solubility: 9 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named *N*-[3-[(6,7-dimethoxy-4-quinazolinyloxy)phenyl]-*N*-[5-(2,2,2-trifluoro-1,1-dimethylethyl)-3-isoxazolyl]urea, targets wild type BRAF ( $K_d = 36$  nM), BRAF<sup>V600E</sup> ( $K_d = 14$  nM) and c-Raf ( $K_d = 39$  nM), but is also against Abl-1, c-Kit, Ret, PDGFR $\beta$  and VEGFR2 (1,2). Affinity for MEK-1, MEK-2, ERK-1 and ERK-2 is insignificant. Notably, cellular expression of mutant BRAF<sup>V600E</sup> results in constitutive activation of the MAPK pathway, which can lead to uncontrolled growth. Significant oral efficacy was observed in a 14-day BRAF<sup>V600E</sup>-dependent human Colo-205 tumor xenograft mouse model, upon dosing at 30 and 100 mg/kg BID (1). CEP-32496 exhibits single oral dose (10-55 mg/kg) pharmacodynamic inhibition of both pMEK and pERK in BRAF<sup>V600E</sup> colon carcinoma xenografts in nude mice (2). Moreover, sSustained tumor stasis and regressions are observed with oral administration (30-100 mg/kg twice daily) against BRAF<sup>V600E</sup> melanoma and colon carcinoma xenografts, with no adverse effects (2). 1. Rowbottom, Faraoni, Chao, *et al.* (2012) *J. Med. Chem.* **55**, 1082. 2. James, Ruggeri, Armstrong, *et al.* (2012) *Mol. Cancer Ther.* **11**, 930.

#### CCI-779, See Temsirolimus

#### CCT128930

This potent, ATP-competitive inhibitor (F.Wt. = 341.84; CAS 885499-61-6; Solubility (at 25°C): 65 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), known systematically as 4-(4-chlorobenzyl)-1-(7H-pyrrolo[2,3-d]pyrimidin-4-yl)piperidin-4-amine, targets Akt2 (also known as Protein Kinase B, or PKB), PKA, and p70S6K, with IC<sub>50</sub> values of 6 nM, 168 nM, and 120 nM, respectively. CCT128930 exhibits marked antiproliferative activity and inhibits phosphorylation of AKT substrates in multiple tumor cell lines *in vitro*, consistent with its action as an AKT inhibitor. CCT128930 also causes a G<sub>1</sub> arrest in PTEN-null U87MG human glioblastoma cells,

consistent with AKT pathway blockade. CCT128930 also blocks phosphorylation of several downstream AKT biomarkers in U87MG tumor xenografts, indicating AKT inhibition *in vivo*. Antitumor activity is observed with CCT128930 in U87MG and HER2-positive, PIK3CA-mutant BT474 human breast cancer xenografts, behavior that is consistent with its pharmacokinetic and pharmacodynamic properties. 1. Yap, Walter, Hunter *et al.* (2011) *Mol. Cancer Ther.* **10**, 360.

#### CCT 241533

This potent Chk inhibitor (FW = 515.41 g/mol; CAS 1262849-73-9; Soluble to 10 mM in H<sub>2</sub>O (with gentle warming); 100 mM in DMSO), also known as (3*R*,4*S*)-4-[[2-(5-fluoro-2-hydroxyphenyl)-6,7-dimethoxy-4-quinazoliny]amino]- $\alpha,\alpha$ -dimethyl-3-pyrrolidinemethanol, targets the serine/threonine-protein checkpoint kinase Chk2 (IC<sub>50</sub> = 3 nM), showing >63-fold selectivity over Chk1. CCT 241533 inhibits Chk2 activation in response to etoposide-induced DNA damage in HT29 cells. It also blocks ionizing radiation-induced apoptosis of mouse thymocytes. 1. Caldwell, Welsh, Matijssen, *et al.* (2011) *J. Med. Chem.* **54**, 580.

#### CDN 1163

This allosteric SERCA2 activator (FW = 320.38 g/mol; CAS 892711-75-0; Soluble to 100 mM in DMSO), also known as 4-(1-methylethoxy)-*N*-(2-methyl-8-quinoliny)benzamide, targets the Sarco/Endoplasmic Reticulum Ca<sup>2+</sup>-ATPase, or SR Ca<sup>2+</sup>-ATPase, a divalent cation pump that mediates the ATP-dependent transfer of Ca<sup>2+</sup> from the cytosol to the lumen of the SR during muscle relaxation. Dysregulation of ER Ca<sup>2+</sup> homeostasis triggers ER stress, leading to insulin resistance in obesity and diabetes. Impaired SERCA function has emerged as a major contributor to ER stress. CDN-1163 increases Ca<sup>2+</sup>-ATPase activity and Ca<sup>2+</sup> uptake by ER microsomes from obese mice, rescuing HEK cells from ER stress-induced cell death. It also reduces fasting glucose levels and adipose tissue weight, and increases energy expenditure in *ob/ob* mice. CDN1163 also improves glucose tolerance and reverses hepatic steatosis in *ob/ob* mice. 1. Kang, Dahl, Hsieh, *et al.* (2016) *J. Biol. Chem.* **291**, 5185.

#### CDP-choline

This metabolite and anti-senility drug (FW<sub>zwitterion</sub> = 488.33 g/mol; CAS 987-78-0; Water-soluble; UV/Visible Spectrum is that of CDP), also called cytidine-5'-diphosphocholine, Citicoline, and Cognizin<sup>®</sup>, is required for the biosynthesis of phospholipids and sphingomyelins (1,2). CDP-choline is a ready source of the choline needed by cholinergic neurons, improving the cognitive and memory disturbances which are observed after a head

trauma. CDP-choline activates the biosynthesis of structural phospholipids in the neuronal membranes, increases cerebral metabolism and acts on the levels of various neurotransmitters. Thus, it has been experimentally proven that CDP-choline increases noradrenaline and dopamine levels in the CNS. It also restores the activity of mitochondrial ATPase and of membranal Na<sup>+</sup>/K<sup>+</sup> ATPase. It also accelerates the reabsorption of cerebral edema in various experimental models. CDP-choline also stimulates acetylcholinesterase and Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase reactions (3) It inhibits phospholipase A<sub>2</sub> activation (4). Heating CDP-choline in 1.0 M H<sub>2</sub>SO<sub>4</sub> for eighteen minutes results in 50% conversion to CMP and phosphocholine. **Target(s):** ethanolamine phospho-transferase (1,7-10); choline kinase (2,12); glycogenin glucosyltransferase (5,14); FAD diphosphatase (6); nucleotide diphosphatase (6); choline-phosphate cytidylyl-transferase, product inhibition (11); 1,4-β-D-xylan synthase (13). 1. #### CDP-ethanolamine

This metabolite (FW<sub>zwitterion</sub> = 446.25 g/mol; CAS 3036-18-8; Soluble in water; UV/Visible Spectrum is that of CDP), also called cytidine-5'-diphosphoethanolamine, inhibits diacylglycerol choline-phosphotransferase (1-4) and ethanolamine-phosphate cytidylyltransferase, product inhibition (5). 1. Coleman & Bell (1977) *J. Biol. Chem.* **252**, 3050. 2. Kanoh & Ohno (1981) *Meth. Enzymol.* **71**, 536. 3. Kanoh & Ohno (1976) *Eur. J. Biochem.* **66**, 201. 4. Sparace, Wagner & Moore (1981) *Plant Physiol.* **67**, 922. 5. Sundler (1975) *J. Biol. Chem.* **250**, 8585.

#### CDP-D-glucose

This metabolite (FW<sub>free-acid</sub> = 565.32 g/mol; CAS 2906-23-2; Soluble in water; UV/Visible Spectrum is that of CDP), is an intermediate in lipopolysaccharide biosynthesis. CDP-D-glucose is a product of the reaction catalyzed by glucose-1-phosphate cytidylyltransferase and is a substrate for CDP-glucose 4,6-dehydratase. **Target(s):** UDP-glucuronate 4-epimerase (1,3,4); glycogenin glucosyltransferase (2,9); UDP sugar diphosphatase (5); [protein-P<sub>II</sub>] uridylyltransferase (6); glucose-1-phosphate cytidylyltransferase, by product inhibition (7,8); β-1,4-mannosyl-glycoprotein 4-β-N-acetylglucosaminyltransferase (10); ceramide glucosyl-transferase, weakly inhibited (11). 1. Gaunt, Ankel & Schutzbach (1972) *Meth. Enzymol.* **28**, 426. 2. Manzella, Ananth, Oegema, et al. (1995) *Arch. Biochem. Biophys.* **320**, 361. 3. Gaunt, Maitra & Ankel (1974) *J. Biol. Ikeda, Koyota, Ihara, et al. (2000) *J. Biochem.* **128**, 609. 11. Shukla & Radin (1990) *Arch. Biochem. Biophys.* **283**, 372.

#### CDP-glycerol

This nucleotide alcohol (FW<sub>free-acid</sub> = 477.26 g/mol), also known as cytidine 5'-diphosphate glycerol, is a component in lipid metabolism, the diacyl derivative being an intermediate in the biosynthesis of phosphatidylinositol. Note that this metabolite is unstable in acidic and alkaline conditions. Treatment for thirty minutes in 1 M HCl at 100°C produces a mixture of CMP, *sn*-glycerol 3-phosphate, and *sn*-glycerol 2-phosphate. Treatment with concentrated ammonia at 100°C for one hour forms CMP and glycerol 2,3-cyclic phosphate. **Target(s):** CDP-ribitol ribitolphosphotransferase, weakly inhibited (1); teichoic acid synthase (1); glycerol-3-phosphate cytidylyltransferase (2,3). 1. Fiedler & Glaser (1974) *J. Biol. Chem.* **249**, 2684. 2. Park, Sweitzer, Dixon & Kent (1993) *J. Biol. Chem.* **268**, 16648. 3. Badurina, Zolli-Juran & Brown (2003) *Biochim. Biophys. Acta* **1646**, 196.

#### CE3F4

This potent cAMP-binding protein inhibitor (FW = 351.01 g/mol; CAS 143703-25-7; Soluble to 100 mM in DMSO), also named 5,7-dibromo-6-fluoro-2-methyl-1,2,3,4-tetrahydroquinoline-1-carbaldehyde, (with positions numbered for any tetrahydroquinoline skeleton, targets Epac (or Exchange protein directly activated by 3',5'-cyclic-AMP)). The latter has two isoforms, each consisting of a cAMP-binding regulatory region and a GTP Exchange Factor (or GEF) region that catalyzes GTP exchange for GDP bound to the Ras-like small GTPases Rap1 and Rap2. Epac proteins contain Dishevelled, Egl-10, and pleckstrin domains, followed by an evolutionally conserved cAMP-binding domain (similar to that found in PKA) and bacterial transcriptional factor cAMP-receptor protein. In the absence of cAMP, the regulatory region containing the cAMP-binding domain directly interacts with the catalytic region, blocking its GEF activity. CE3F4 blocks Epac1 guanine nucleotide exchange reaction on Rap1 in intact cells. Because CE3F4 did not exert its antagonism by directly competing with cAMP for binding to Epac1, it is difficult to predict whether it could also inhibit Epac2. CE3F4 proved useful in demonstrating that Epac1 promotes autophagy during cardiomyocyte hypertrophy (2). 1. Courilleau, Bissierier & Jullian (2012) *J. Biol. Chem.* **287**, 44192. 2. Laurent, et al. (2015) *Cardiovasc. Res.* **105**, 55.

#### Cediranib

This indole-ether quinazoline-based vascular-disrupting agent and pan-VEGF receptor tyrosine kinase inhibitor (FW = 450.51 g/mol; CAS 288383-20-0; Solubility: 90 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known by its code names AZD2171 and NSC-732208, its trade name Recentin<sup>®</sup>, and by its IUPAC name 4-[(4-fluoro-2-methyl-1*H*-indol-5-yl)oxy]-6-methoxy-7-[3-(pyrrolidin-1-yl)propoxy]quinazoline, is a highly potent vascular endothelial growth factor receptor-2 tyrosine kinase (VEGFR2) inhibitor, IC<sub>50</sub> = 0.5 nM (1). Once-daily oral administration of AZD2171 shows promise in limiting the progression of solid malignancies by suppressing tumor-induced angiogenesis. Cediranib inhibits Flt1 and Flt4, with IC<sub>50</sub> values of 5 nM and ≤3 nM; however, when assayed with ELISA to measure phosphorylated products, 10 μM Cediranib showed little or no inhibition of KDR, c-Kit, PDGFRα, PDGFRβ, CSF-1R, FGFR1, Src, Abl, epidermal growth factor receptor (EGFR), ErbB2, Aurora A, or Aurora B activity in the presence of 100 μM ATP. Cediranib reverses ABCB1- and ABCC1-mediated MDR by directly inhibiting drug efflux (2). 1. Wedge, Kendrew, Hennequin, *et al.* (2005) *Cancer Res.* **65**, 4389. 2. Tao, Liang, Wang, *et al.* (2009) *Cancer Chemother. Pharmacol.* **64**, 961.

#### Ceefourin 1

This MRP4 inhibitor (FW = 293.42 g/mol; CAS 315702-40-0; Solubility: 100 mM in DMSO), also named 5-[(2-benzothiazolylthio)methyl]-2,4-dihydro-4-methyl-3*H*-1,2,4-triazole-3-thione, selectively targets Multidrug Resistance-associated Protein-4 (IC<sub>50</sub> = 2.6 μM). It and the structurally related compound Ceefourin 2 were discovered using high-throughput screening and were found to be highly selective for MRP4 over other ABC transporters, including P-glycoprotein (P-gp), ABCG2 (Breast Cancer Resistance Protein; BCRP) and MRP1 (multidrug resistance protein 1; ABCC1). Both compounds are more potent MRP4 inhibitors in cellular assays than MK-571, the most widely used inhibitor, and they require lower concentrations for a comparable level of inhibition. Ceefourin 1 and Ceefourin 2 have low cellular toxicity, and high microsomal and acid stability. Sensitizes MRP4 over-expressing cells to the DNA topoisomerase-1 inhibitor SN 38, which is formed metabolically from the pro-drug CPT-11 (See CPT-11). 1. Cheung, Flemming, Watt, *et al.* (2014) *Biochem. Pharmacol.* **91**, 97.

CEP-18770, See Delanzornib

#### Cefadroxil

This broad-spectrum cephalosporin-class antibiotic (FW = 363.39 g/mol; CAS 66592-87-8), also known as Duricef and (6*R*,7*R*)-7-[[2*R*]-2-amino-2-(4-hydroxyphenyl)acetyl]amino]-3-methyl-8-oxo-5-thia-1-azabicyclo[4.2.0]oct-2-ene-2-carboxylic acid, is highly effective against Gram-positive and Gram-negative bacterial infections (*e.g.*, *Escherichia coli*, (MIC = 8 μg/mL), *Staphylococcus aureus*, (MIC = 1-2 μg/mL), and *Streptococcus pneumoniae* (MIC = 1-10 μg/mL). Oral cefadroxil in doses of 0.6-1.8 g per day given on twice or three times daily schedules was effective in the treatment of thirty-six patients with infections such as abscesses, carbuncles, cellulitis, furunculosis and impetigo (1). Cefadroxil is almost completely absorbed from the gastrointestinal tract. After doses of 500 mg and 1 g by mouth, peak plasma concentrations of about 16 and 30

micrograms/mL, respectively, are obtained after 1.5 to 2 hours. 1. Cordero (1976) *J. Int. Med. Res.* **4**, 176.

#### Cefepime

This fourth-generation cephalosporin antibiotic (FW = 480.56 g/mol; CAS 88040-23-7; Route: Intravenous or Intramuscular) is highly effective against *Pseudomonas aeruginosa*, *Staphylococcus aureus*, *Streptococcus pneumoniae*, and certain *Enterobacteriaceae* (1,2). Unlike other cephalosporins, which are readily degraded by many plasmid- and chromosome-mediated β-lactamases, cefepime is stable. Upon intravenous infusion, cefepime reaches peak plasma concentrations of 193 μg/mL during the 30-min infusion (3). The mean plasma elimination *t*<sub>1/2</sub> is 2.1 hours. Penetration into inflammatory fluid is rapid, with mean peak levels of 91.5 μg/mL at 0.9 hour post-infusion. Urinary elimination accounted for 98.9% of the dose within 8 h. Therapeutic plasma levels (>2 μg/mL) are present for >8 hours after infusion, suggesting that 2 or 3 doses daily would be sufficient to treat infections due to susceptible organisms (3). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Okamoto, Nakahiro, Chin & Bedkian (1993) *Clin. Pharmacokinet.* **25**, 88. 2. Clynes, Scully & Neu (1989) *Diagn. Microbiol. Infect. Dis.* **12**, 257. 3. Nye, Shi, Andrews & Wise (1989) *J. Antimicrob. Chemother.* **24**, 23.

#### Cefixime

This third-generation cephalosporin (FW = 455.46 g/mol; CAS 79350-37-1), also named Suprax and (6*R*,7*R*)-7-[[2-(2-amino-1,3-thiazol-4-yl)-2-(carboxymethoxyimino)acetyl]amino]-3-ethenyl-8-oxo-5-thia-1-azabicyclo[4.2.0]oct-2-ene-2-carboxylic acid, is an orally active antibiotic that is often used to treat bacterial infections of the ear, urinary tract, and upper respiratory tract. Its broad spectrum of antimicrobial action includes both gram-positive and -negative bacteria including many beta-lactamase-producing strains of streptococci, *Haemophilus influenzae*, *Neisseria gonorrhoeae*, and the majority of the *Enterobacteriaceae* (1). Activity of cefixime against *Staphylococcus aureus*, *Enterococci*, *Listeria monocytogenes*, and *Pseudomonas* spp. is poor. It is especially active against *Escherichia coli* (MIC = 15 ng/mL to 4 μg/mL), *Haemophilus influenzae* (MIC ≤4 ng/mL to 4 μg/mL) and *Proteus mirabilis* (MIC 8 to 60 ng/mL). 1. Shimada K. (1987) *Japan J. Antibiot.* **40**, 1537.

**Cefotaxime**

This third-generation cephalosporin (FW = 455.47 g/mol; CAS 63527-52-6), also known by the trade name Claforan<sup>®</sup>, is a broad-spectrum antibiotic that is active against both Gram-positive and Gram-negative bacteria. It is slightly less active than cefazolin against *Staphylococcus aureus*, but 4x to 300x as active as carbenicillin against gram-negative organisms, including *Pseudomonas aeruginosa*, *Pseudomonas cepacia*, *Enterobacter cloacae*, and *Serratia marcescens* (2). Cefotaxime was the most active compound against *Enterobacteriaceae* members and 20x to 100x more active than cefoxitin against the indole-positive *Proteus* group. 1. Braveny, Dickert & Machka (1979) *Infection* 7, 231. 2. Masuyoshi, Arai, Miyamoto & Mitsuhashi (1980) *Antimicrob Agents Chemother.* 18, 1.

**Ceftaroline Fosamil**

This advanced-generation cephalosporin antibiotic (FW = g/mol; CAS 866021-48-9 and 400827-46-5), also known by its code names PPI-0903 and TAK-599, its trade names Teflaro<sup>®</sup> in the U.S. and Zinforo<sup>®</sup> in the Europe, and its IUPAC name (1). is active against Methicillin-Resistant *Staphylococcus aureus* (MRSA) and broad-spectrum activity against Gram-positive bacteria (2-4). In 2010, ceftaroline is approved by the FDA for the treatment of community-acquired bacterial pneumonia and acute bacterial skin infections. 1. (6*R*,7*R*)-7-[(2*Z*)-2-ethoxyimino-2-[5-(phosphonoamino)-1,2,4-thiazol-3-yl]acetyl]amino]-3-[4-(1-methylpyridin-1-ium-4-yl)-1,3-thiazol-2-yl]sulfanyl]-8-oxo-5-thia-1-azabicyclo[4.2.0]oct-2-ene-2-carboxylate. 2. Andes & Craig (2006) *Antimicrob. Agents Chemother.* 50, 1376. 3. Jacqueline, Caillon, Le Mabecque, et al. (2007) *Antimicrob. Agents Chemother.* 51, 3397. 4. Stee & Rybak (2010) *Pharmacotherapy* 30, 375.

**Ceftazidime**

This third-generation cephalosporin (FW = 546.58 g/mol; CAS 72558-82-8), also named Fortaz<sup>®</sup>, Tazicef<sup>®</sup>, GR-20263, and (6*R*,7*R*,*Z*)-7-(2-(2-

aminothiazol-4-yl)-2-(2-carboxypropan-2-yloxyimino)acetamido)-8-oxo-3-(pyridinium-1-ylmethyl)-5-thia-1-azabicyclo[4.2.0]oct-2-ene-2-carboxylate, is bacteriocidal (MIC = 60-500 ng/mL) for *Enterobacteriaceae*, *Haemophilus influenzae*, *Neisseria gonorrhoeae*, and Lancefield group A  $\beta$ -hemolytic *Streptococci*, but acts far more weakly against *Pseudomonas aeruginosa* (MIC = 2  $\mu$ g/mL), *Staphylococcus aureus* (MIC = 16  $\mu$ g/mL), and *Bacteroides fragilis* (MIC > 128  $\mu$ g/mL) (1). When administered i.m. or i.v., ceftazidime is widely distributed in body fluids and tissues, exhibiting relatively low binding to serum proteins (2). It is eliminated primarily through the urine and, depending upon the type of infection, can be administered every 8-12 hours. Because of its broad spectrum and its activity against penicillin-resistant and aminoglycoside-resistant *Pseudomonas*, ceftazidime can be used as a single agent in place of combination therapy in patients with cystic fibrosis (2). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Wise, Andrews & Bedford (1980) *Antimicrob. Agents Chemother.* 17, 884. 2. Smith (1984) *Clin. Pharm.* 3, 373.

**Ceftobiprole**

This so-called fifth-generation cephalosporin antibiotic (FW = 534.57 g/mol; CASs = 209467-52-7 and 252188-71-9), also known by its code name BAL9141 and by trade names Zeftera<sup>®</sup> and Zevtera<sup>®</sup>, is highly effective against methicillin-resistant *Staphylococcus aureus*, penicillin-resistant *Streptococcus pneumoniae*, *Pseudo-monas aeruginosa*, and certain enterococci. It also comparable to a vancomycin/ceftazidime combination for treating skin and soft tissue infections. 1. Entenza, Hohl, Heinze-Krauss, Glauser & Moreillon (2002) *Antimicrob. Agents Chemother.* 46, 171. 2. Zbinden, Pünter & von Graevenitz (2002) *Antimicrob. Agents Chemother.* 46, 871. 3. Dauner, Nelson & Taketa (2010) *Am. J. Health Syst. Pharm.* 67, 983.

**Ceftriaxone**

This third-generation cephalosporin (FW = 554.58 g/mol; CAS 73384-59-5), also known as Ro 13-9904 and Rocephin<sup>®</sup>, demonstrates broad-spectrum activity against Gram-positive bacteria as well as many Gram-negative bacteria. It is commonly used intravenously to treat sexually transmitted infections caused by *Neisseria gonorrhoeae*. Ceftriaxone inhibits bacterial cell wall synthesis by inhibiting the transpeptidation reaction in the synthesis of peptidoglycan elements of the bacterial cell

wall. Many  $\beta$ -lactam antibiotics are transcriptional activators of the Excitatory Amino Acid Transporter-2 (or EAAT2), resulting in increased EAAT2 protein levels (2). Treatment of animals with ceftriaxone increases EAAT2 expression and glutamate transport activity in brain. CEF has neuroprotective effects in both *in vitro* and *in vivo* models based on its ability to inhibit neuronal cell death by preventing glutamate excitotoxicity. Although ceftriaxone has also been used as a treatment for attenuating attenuates cue-induced cocaine relapse (3), its cerebral penetration in surgery patients is quite low, amounting to <2% of serum concentrations (4). Clavulanic acid may be a better alternative (5). (See *Clavulanic Acid*)

**Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Neu, Meropol & Fu (1981) *Antimicrob. Agents Chemother.* **19**, 414. 3. Kim, Lee, Kegelman (2011) *J. Cell Physiol.* **226**, 2484. 3. ### Celecoxib

This cyclooxygenase inhibitor and non-steroidal anti-inflammatory drug (FW = 381.38 g/mol; CAS 169590-42-5; *Symbol*: CE), also known by its code name SC-58635, its trade names Celebrex™ or Celebra™ (for arthritis) and Onsenal™ (for polyps) and systematically as 4-[5-phenyl-3-(trifluoromethyl)-1H-pyrazol-1-yl]benzenesulfonamide, is a significantly better inhibitor of COX-2 (IC<sub>50</sub> = 32 nM) than COX-1 (IC<sub>50</sub> = 55  $\mu$ M). In mice, low doses of celecoxib [(0.5-1 mg/kg), but *not* a higher dose (5 mg/kg)] attenuate inflammation-associated gut barrier failure, thereby reducing entry of pathogenic bacteria (6). Celecoxib is a highly permeable drug that is readily absorbed throughout the GI tract, such that dissolution of solid dosage forms may be a rate-limiting factor for absorption. *Note*: Replacement of the methyl group on the phenyl ring by a second trifluoromethyl group abrogates COX-2 inhibition, but enhances other anti-inflammatory properties (See *4-Trifluoromethyl-Celecoxib*)

**Other Targets:** cyclooxygenase (1,4,5); steroid sulfotransferase (or SULT2A1), celecoxib switches steroid sulfation from the 3-*O*-position to the 17 $\beta$ -*O*-site (2); thiopurine *S*-methyltransferase (3); 5-lipoxygenase, or arachidonate 5-lipoxygenase (5). In prostate cancer cells, CE also inhibits the protein kinase B/Akt pathway (7,8), a signal transduction route known to play a significant role in cancer cell growth and survival. CE, but not rofecoxib, also inhibits cell growth in human prostate cell lines that do not produce COX2 (9). Kulp et al. (2004) used CE and a COX2 inactive analogue to study their effect on prostate cancer cells. By inhibiting ER Ca<sup>2+</sup>-ATPases, CE increase intracellular calcium in prostate cancer cells and osteoblasts, unlike other NSAIDs (10,11). CE also inhibits adenyl cyclase (11).

### Celgosivir

This castanospermine prodrug (FW = 259.30 g/mol; CAS 121104-96-9), also named 6-*O*-butanoylcastanospermine and (1*S*,6*S*,7*S*,8*R*,8*aR*)-1,7,8-trihydroxyoctahydro-6-indoliziny butyrate, is most likely taken up by cells where it is hydrolyzed to castanospermine, a potent glucosidase inhibitor that inhibits Dengue virus production *in vitro* by inhibiting endoplasmic reticulum  $\alpha$ -glucosidases, not by reducing the activity of glycolipid-processing enzymes (1). Dengue infection is the most common mosquito-borne viral disease worldwide. Although celgosivir is an antiviral agent in a lethal mouse model of antibody-enhanced DENV infection, results of a recent clinical trial in humans suggest celgosivir does not significantly reduce viral load or fever burden in patients with dengue (2). See also *Castanospermine* 1. Sayce, Alonzi, Killingbeck, et al. (2016) *PLoS Negl. Trop. Dis.* **10**, e0004524. 2. Low, Sung, Wijaya, et al. (2014) *Lancet Infect. Dis.* **14**, 706.

**CEM-101, See Solithromycin**

### Centimitor-1

This cytostatic anticancer agent (FW<sub>free-acid</sub> = 466.34 g/mol; Abbreviation: Centi-1), also known as *N*'-(3-bromo-4-hydroxybenzylidene)-2-(9-oxo-10(9*H*)-acridinyl)acetohydrazide, reduces microtubule (MT) dynamics and disrupts mitosis (1). Cent-1's actions phenocopy those of Rigosertib, a related inhibitor said to target PI3K and PLK signaling pathways (See *Rigosertib*). Depending on the target cell, Cent-1 induces a transient mitotic arrest, followed by abnormal exit from M-phase and/or cell death. Cent-1 also induces multipolarity and centrosome fragmentation. Notably, Cent-1 and rigosertib modulate microtubule dynamics and the behavior of proteins that bind to microtubule (+)-ends. Although Cent-1 and rigosertib do not show any obvious effects on the appearance of MTs at low concentrations, identical treatments cause discernable changes in the localization of MT end-binding protein EB1 in interphase cells, with EB1 comets appearing to be much shorter and fragmented. In A549 EGFP- $\alpha$ -tubulin cells, 6-hour exposure to 5  $\mu$ M Cent-1 caused a similar phenotype as in HeLa cells (e.g., chromosome misalignment, multipolarity, and prolonged mitotic delay). The same concentration only shows minor effects on interphase MTs. (These cells were much more sensitive to rigosertib treatment than HeLa cells, and treatment with 0.25  $\mu$ M rigosertib completely abolished microtubules; at 0.55  $\mu$ M, rigosertib did not eliminate MTs but was sufficient for mitotic arrest.) Both Cent-1 and rigosertib cause centrosome fragmentation and reduced the amount of centrosome-associated  $\gamma$ -tubulin. They also significantly retard MT dynamics in interphase cells, shorten spindle length in mitosis, and decrease tension across sister kinetochores in mitotic chromosomes. They also cause the delocalization of NuMA and

EB1 in mitotic cells. Taken together, these data suggest Cent-1 and rigosertib impair MT-mediated processes during M phase. Acentrosomal spindle poles, reduced interkinetochore tension, mislocalization of MT end-tracking proteins, and chromosome misalignment are consequences of treating cells with low doses of well-studied MT drugs, again supporting the inference that these compounds may modulate microtubule dynamics. Taken together, these data suggest Cent-1 and rigosertib impair MT-mediated processes during M phase. It is noteworthy that neither Cent-1 nor Rigosertib perturb MT self-assembly *in vitro*. Moreover, the current findings do not distinguish between direct and indirect drug-induced mechanisms for altering microtubule processes and thereby hindering mitosis. 1. Mäki-Jouppila, Laine, Rehnberg, *et al.* (2014) *Mol. Cancer Ther.* **13**, 1054.

#### Centrinone B

This PLK4 inhibitor (FW = 631.67 g/mol; CAS 1798871-31-4; Solubility: 50 mM DMSO), also named 2-[[2-fluoro-4-[[2-(2-fluoro-3-nitrophenyl)methyl]sulfonyl]phenyl]thio]-5-methoxy-*N*-(5-methyl-1*H*-pyrazol-3-yl)-6-(1-piperidinyl)-4-pyrimidinamine, targets the Polo-like Kinase-4 ( $K_i = 0.6$  nM), depleting centriole and centrosome levels *in vitro*. Centrinone induces cell cycle arrest in normal human cell lines in a p53-dependent manner. 1. Wong, Anzola, Davis, *et al.* (2015) *Science* **348**, 1155.

#### CEP-32215

This potent, selective, and orally bioavailable inverse agonist (FW = 383.49 g/mol), also known as 3-(1'-cyclobutylspiro[4*H*-1,3-benzodioxine-2,4'-piperidin]-6-yl)-5,5-dimethyl-1,4-dihydro-pyridazin-6-one, targets the histamine  $H_3$  receptor (*or*  $H_{3R}$ ), a G-coupled histamine receptor that affects wakefulness. Histaminergic neurons are located exclusively in the tuberomammillary nucleus of the posterior hypothalamus and project to most regions of the brain. The wake-promoting effects of histamine are modulated via  $H_1$  receptors, as indicated by the ability of brain-penetrant  $H_1$  antagonists to induce sedation. Histamine also produces similar effects via  $H_3R$  activation, which results in the inhibition of histamine synthesis and release via the autoreceptor mechanism. CEP-32215 exhibits drug-like properties, with high affinity for human  $H_{3R}$  ( $K_i = 2.0$  nM) and rat  $H_{3R}$  ( $K_i = 3.6$  nM) (1,2). It is an antagonist ( $K_b = 0.3$  nM) and inverse agonist ( $EC_{50} = 0.6$  nM) in binding assays employing [ $^{35}$ S]guanosine 5'-*O*-( $\gamma$ -thio)-triphosphate. Upon oral dosing, occupancy of  $H_{3R}$  by CEP-32215 can be estimated in *ex vivo* binding measurements on rat cortical slices ( $ED_{50} = 0.1$  mg/kg, p.o.). Functional antagonism is also demonstrable in brain as inhibition of *R*- $\alpha$ -methylhistamine-induced drinking in the rat dipsogenia model ( $ED_{50} = 0.92$  mg/kg). CEP-32215 also significantly increases wake duration in the rat EEG model at 3-30 mg/kg, p.o. (1). Increased motor activity, sleep rebound or undesirable events (such as spike wave or seizure activity) is not observed following doses up to 100 mg/kg p.o., indicating an acceptable therapeutic index. CEP-32215 may have potential utility in the treatment of a variety of sleep disorders (1). Wang, Przyuski, Roemmele, *et al.* (2) describe the synthesis of CEP-

32215 and provide details on the formation of its key spiroketal moiety as well as discovery of a novel Suzuki coupling approach for synthesis of the backbone of the molecule. 1. Hudkins, Gruner, Radditz, *et al.* (2016) *Neuropharmacol.* **106**, 37. 2. Haas & Panula (2016) *Neuropharmacol.* **106**, 1. 3. Wang, Przyuski, Roemmele, *et al.* (2013) *Org. Proc. Res. Develop.* **17**, 846.

#### Cephalexin

This orally active semi-synthetic cephalosporin antibiotic (FW<sub>free-acid</sub> = 347.39 g/mol; CAS 15686-71-2), also known by the Lilly tradename Keflex<sup>TM</sup> and by the systematic name, (6*R*,7*R*)-7-[[2-(*R*)-2-amino-2-phenylacetyl]amino]-3-methyl-8-oxo-5-thia-1-azabicyclo-[4.2.0]oct-2-ene-2-carboxylate, inhibits bacterial peptidoglycan biosynthesis. Oligopeptidic drugs, such as this  $\beta$ -lactam antibiotic and angiotensin-converting enzyme inhibitors, often rely on the same carriers to gain entry into human and animal cells, a property that can give rise to competitive pharmacokinetic interactions. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** serine-type D-Ala-D-Ala carboxypeptidase, *or* penicillin-binding protein-5 (1,5,8); penicillin-binding protein-4 (2,6); penicillin-binding protein-3 (3,7); peptidoglycan biosynthesis (4,5); penicillin-binding protein-1 (7); penicillin-binding protein-2 (7). 1. Wilkin (1998) in *Handb. Proteolytic Enzymes*, p. 418, Academic Press, San Diego. 2. Wilkin (1998) in *Handb. Proteolytic Enzymes*, p. 435, Academic Press, San Diego. 3. Coyette, Perkins, Polachek, Shockman & Ghuyesen (1974) *Eur. J. Biochem.* **44**, 459.

#### Cephalosporin C

This antibiotic (FW = 415.42 g/mol; CAS 28240-09-7 (potassium salt)), originally obtained from a species of *Cephalosporium*, but made synthetically (1,2), inhibits peptidoglycan and cell wall biosynthesis. Cephalosporin C has pKa values of < 2.6, 3.1, and 9.8. **Target(s):** serine-type D-Ala-D-Ala carboxypeptidase, *or* penicillin-binding protein-5 (2,8); penicillin-binding protein-4 (4);  $\beta$ -lactamase, *or* penicillinase (5); peptide-glycan biosynthesis (6); glutaryl 7-aminoccephalosporic-acid acylase, also a weak substrate (7); undecaprenyldiphospho-muramoylpentapeptide  $\beta$ -*N*-acetylglucosaminyl-transferase, *or* MurG transferase (9). 1. Woodward, Heusler, Gosteli, *et al.* (1966) *J. Amer. Chem. Soc.* **88**, 852. 2. Woodward (1966) *Science* **153**, 487. 3. Wilkin (1998) in *Handb. **Cerebratulus Toxin A-III**

This marine worm toxin (MW = 9.8 kDa), one of four homologous *Cerebratulus lacteus* protein toxins, consists of a 95-residue polypeptide, cross-linked by three disulfide bonds and mainly consisting of  $\alpha$ -helix. Toxin A-III permeabilizes a variety of cells as well as liposomes made from a variety of phospholipids, apparently forming large pores permitting release of large proteins almost as rapidly as small organic molecules and inorganic ions. At sublytic concentrations, the toxin also inhibits protein kinase C and endogenous voltage-gated cation-selective sodium, potassium channels in nervous and cardiovascular systems. In view of its small size and helical structure, A-III remains a promising probe for investigating pore-forming protein toxin insertion into biological membranes and the ensuing steps in pore formation. 1. Kem (1994) *Toxicol.* **87**, 189.

**Ceritinib**

This potent EML4-ALK signal transduction inhibitor and antineoplastic agent (FW = 558.14 g/mol; CAS 1032900-25-6; Solubility: 56 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as LDK378, Zykadia<sup>®</sup>, and 5-chloro-*N*<sup>1</sup>-[2-[(1-methylethyl)sulfonyl]phenyl]-*N*<sup>2</sup>-[5-methyl-2-(1-methylethoxy)-4-(4-piperidinyl)phenyl]-2,4-pyrimidinediamine, targets ALK, the Activin receptor-Like Kinase activity of Transforming Growth Factor- $\beta$  (TGF- $\beta$ ) receptors, with IC<sub>50</sub> of 0.2 nM, showing 40x and 35x selectivity against IGF-1R and InsR, respectively. Zykadia inhibits autophosphorylation of ALK, ALK-mediated phosphorylation of the downstream signaling protein STAT3, as well proliferation of ALK-dependent cancer cells in *in vitro* and *in vivo* assays. Non-small cell lung cancers often harbor anaplastic lymphoma kinase (ALK) mutations (*e.g.*, Leu-1196-Met, Gly-1269-Ala, Ile-1171-Thr, and Ser-1206-Tyr) that invariably lead to crizotinib resistance; however, ceritinib can overcome several crizotinib-resistant mutations and is potent against several *in vitro* and *in vivo* laboratory models of acquired resistance to crizotinib (3,4). Ceritinib was approved by the FDA Zykadia for the treatment of patients with anaplastic lymphoma kinase (ALK)-positive metastatic non-small cell lung cancer who have progressed on or are intolerant to crizotinib. Brain accumulation of ceritinib is restricted by P-glycoprotein (P-GP/ABCB1) and breast cancer resistance protein (BCRP/ABCG2), but ceritinib export can be specifically inhibited by zosuquidar (ABCB1 inhibitor) and Ko143 (ABCG2 inhibitor) (5). 1. Marsilje, Pei, Chen, *et al.* (2013) *J. Med. Chem.* **56**, 5675. 2. Chen, Jiang & Wang (2013) *J. Med. Chem.* **56**, 5673. 3. **Cerivastatin**

This cholesterol-reducing statin (FW<sub>free-acid</sub> = 459.56 g/mol; CAS 145599-86-6; IUPAC Name: (3*R*,5*S*,6*E*)-7-[4-(4-fluorophenyl)-5-(methoxymethyl)-2,6-bis(propan-2-yl)pyridin-3-yl]-3,5-dihydroxyhept-6-enoic acid, potentially inhibits 3-hydroxy-3-methylglutaryl-CoA reductase: *K*<sub>i</sub> = 5.7 nM at 37°C. (Cerivastatin was withdrawn from the market in August, 2001 due to risk of serious rhabdomyolysis.) Cerivastatin inhibits cholesterol biosynthesis in the human cell lines with a similar IC<sub>50</sub> value. At daily doses of 0.2 mg/day, low density lipoprotein-cholesterol, total cholesterol, and triacylglycerol levels were significantly reduced in individuals with type IIa hypercholesterolemia. In addition, high density lipoprotein-cholesterol levels increased. **Target(s):** 3-hydroxy-3-methylglutaryl-CoA reductase (1,2); CYP2C8 (3). 1. Istvan & Deisenhofer (2001) *Science* **292**, 1160. 2. Carbonell & Freire (2005) *Biochemistry* **44**, 11741. 3. Tornio, Pasanen, Laitila, Neuvonen & Backman (2005) *Basic Clin. Pharmacol. Toxicol.* **97**, 104.

**CEP-701, See Lestaurtinib****Certolizumab pegol**

This anti-TNF $\alpha$  drug (MW = 91 kDa; CAS 428863-50-7; *Abbreviation:* CZP), also known as CDP870 and the trade name Cimzia<sup>™</sup>, is monoclonal antibody approved for the treatment of rheumatoid arthritis (RA) and Crohn's Disease (CD). Composed of a humanized antigen-binding fragment (Fab) conjugated to polyethylene glycol, CZP lacks an Fc fragment and is thus unlike other agents. Pegylation increases certolizumab's plasma half-life to ~14 days. In mice with collagen-induced arthritis, CZP penetrated inflamed joint tissue to a greater extent and for a longer time period than either adalimumab or infliximab and the degree of penetration correlated better with the level of inflammation within the tissue (1). Unlike other anti-TNF $\alpha$  agents (*e.g.*, infliximab, adalimumab, and etanercept), certolizumab pegol does not stimulate apoptosis in a variety of *in vitro* assays, a finding that suggests apoptosis is not essential for the efficacy of anti-TNF $\alpha$  agents in Crohn's Disease (2). 1. Horton, Sudipto Das, Paul Emery (2011) *Int. J. Clin. Rheumatol.* **6**, 517. 2. Nesbitt, Fossati & Bergin (2007) *Inflamm. Bowel Dis.* **13**, 1323.

**Cerulenin**

This antifungal antibiotic and irreversible protein acylation inhibitor (FW = 223.27 g/mol; CAS 17397-89-6), also named (2*R*,3*S*)-3-[(4*E*,7*E*)-nona-4,7-dienoyl]oxirane-2-carboxamide, inhibits fatty acid and steroid biosynthesis, targeting  $\beta$ -keto-acyl-ACP synthase (*k* = 88 M<sup>-1</sup>s<sup>-1</sup> at 0 °C and pH 6.5, or ~90x faster than by iodoacetamide) in the Fatty Acid Synthase and blocking its interactions with malonyl-CoA (1,2). The enzyme was protected against inhibition by prior treatment with acetyl-CoA but not malonyl-CoA. Cerulenin has no effect on the malonyl-CoA decarboxylase activity of the iodoacetamide-treated enzyme (2). When the enzyme is first incubated with cerulenin, malonyl-CoA decarboxylase activity is not detectable, even after treatment of the enzyme with iodoacetamide, suggesting cerulenin reacts with the peripheral SH-groups, leading to inactivation (2). The structure of the complex between the antibiotic cerulenin and its target,  $\beta$ -ketoacyl-acyl carrier protein synthase has been published (3). Both cerulenin (~10  $\mu$ g/ml) and TOFA (~1  $\mu$ g/ml) are effective in blocking the incorporation of radiolabeled acetate into palmitate; however, TOFA reduces malonyl-CoA levels, rather than elevating them. Cerulenin inhibits growth of yeast-type fungi and several kinds of filamentous fungi, with *Candida stellatoidea* most sensitive among them. This antifungal activity is not reversed by amino acids, and purine and pyrimidine derivatives, but it is reversed by ergocalciferol, and to a lesser extent by retinol, thiamine, pantothenic acid, lauric acid and oleic acid (4). Cerulenin also suppresses expression of the p185(HER2) oncoprotein and tyrosine-kinase activity in breast and ovarian HER2 overexpressors (5). Cerulenin is also a potent inhibitor of antigen processing by antigen-presenting cells (6). 1. Vance, Goldberg, Mitsuhashi & Bloch (1972) *Biochem. Biophys. Res. Commun.* **48**, 649. 2. ### Cetirizine

This once-daily, orally bioavailable, second-generation antihistamine (FW = 366.69 g/mol; CAS 83881-51-0), also known as Zyrtec<sup>®</sup> and Reactine<sup>®</sup> and (±)-[2-[4-[(4-chlorophenyl)phenylmethyl]-1-piperazinyl]ethoxy]acetic acid, is selective H<sub>1</sub> receptor inverse agonist, with rapid onset of action. Cetirizine is a major human metabolite of hydroxyzine, another histamine H<sub>1</sub>-antagonist. Unlike its parent compound, cetirizine only poorly penetrates the blood-brain barrier, thereby minimizing the sedative and anticholinergic effects observed with hydroxyzine (1). At a nominal dose of 5–20 mg in adult humans, cetirizine provides greater protection against histamine-induced bronchospasm than hydroxyzine, which is oxidized to cetirizine by the action of liver alcohol dehydrogenase (See *Hydroxyzine*) (1). Compared to placebo, cetirizine significantly decreased the eosinophil attraction at skin sites challenged with grass pollen and compound 48/80 (2). With the FDA-mandated withdrawal of both terfenadine and astemizole (which produce unexpected and significant prolongation of the cardiac QT interval, with other more serious cardiac effects) from the U.S. market, current widely available second-generation antihistamines include, loratadine, cetirizine, and fexofenadine. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Brik, Tashkin, Gong, Dauphinee & Lee (1987) *J. Allergy Clin. Immunol.* **80**, 51. 2. Fadel, Herpin-Richard, Rihoux & Henocq (1987) *Clin. Allergy* **17**, 373.

### CFTR Modulators

Lumacaftor

Ivacaftor

These agents (marketed in combination as Orkambi<sup>®</sup>) target Phe<sup>506</sup>-deleted Cystic Fibrosis Transmembrane Conductance Regulator (CFTR<sup>ΔF508</sup>), a chloride channel present on the epithelial cells of multiple organs. CFTR<sup>ΔF508</sup> is misfolded, resulting in defective cellular processing/trafficking as well as proteasome-mediated degradation. Lumacaftor (FW = 452.41 g/mol; CAS 936727-05-8; also named VX-809 and 3-{6-[[1-(2,2-difluoro-1,3-benzodioxol-5-yl)cyclopropyl]carbonyl]amino}-3-methylpyridin-2-yl}benzoate) increases the conformational stability of CFTR<sup>ΔF508</sup>, resulting in increased processing/trafficking of mature protein to the cell surface. Ivacaftor (FW = 392.49 g/mol; CAS 873054-44-5; also named N-(2,4-di-*tert*-butyl-5-hydroxyphenyl)-4-oxo-1,4-dihydroquinoline-3-carboxamide and VX-770) is a CFTR potentiator that facilitates increased chloride transport by increasing the channel-open probability of the CFTR protein, once incorporated into the cell surface. *In vitro* experiments showed that lumacaftor and ivacaftor act directly on the CFTR in primary human bronchial epithelial cultures, resulting in increased chloride ion transport. Orkambi received FDA's breakthrough therapy designation

because the sponsor demonstrated through preliminary clinical evidence that the drug may offer a substantial improvement over available therapies.

### CGP-33101, See Rufinamide

### CGP-37157

This widely employed benzothiazepine-based calcium ion blocker (FW = 342.22 g/mol; CAS 75450-34-9; *Symbol* = CGP), also known as 7-chloro-5-(2-chlorophenyl)-1,5-dihydro-4,1-benzothiazepin-2(3*H*)-one, selectively inhibits the Na<sup>+</sup>-Ca<sup>2+</sup> exchanger of cardiac mitochondria (IC<sub>50</sub> = 0.36 μM), without affecting the L-type voltage-dependent calcium channel, the Na<sup>+</sup>-Ca<sup>2+</sup> exchanger, or the Na<sup>+</sup>-K<sup>+</sup>-ATPase of the cardiac sarcolemma, or the Ca<sup>2+</sup>-ATPase of the cardiac sarcoplasmic reticulum (1,2). Mitochondrial Na<sup>+</sup>-Ca<sup>2+</sup> exchange activity is determined by monitoring intramitochondrial [Ca<sup>2+</sup>]<sub>free</sub> in isolated heart mitochondria loaded with the Ca<sup>2+</sup>-sensitive fluorophore fura-2. CGP-37157 had no effect on the calcium current, recorded by whole-cell voltage clamp in isolated neonatal ventricular myocytes. CGP-37157, at or below 10 μM, was without effect on the activities of the Na<sup>+</sup>-Ca<sup>2+</sup> exchanger and Na<sup>+</sup>-K<sup>+</sup>-ATPase in isolated cardiac sarcolemmal vesicles or on activity of the Ca<sup>2+</sup>-ATPase in isolated cardiac sarcoplasmic reticulum vesicles. Such findings data suggest CGP-37157 is a potent, selective, and specific inhibitor of mitochondrial Na<sup>+</sup>-Ca<sup>2+</sup> exchange when used at or below 10 μM. CGP37157 also modulates mitochondrial Ca<sup>2+</sup> homeostasis in cultured rat dorsal root ganglion neurons (3). CGP37157 was also useful in demonstrating that mitochondria accumulate Ca<sup>2+</sup> following intense glutamate stimulation of cultured rat forebrain neurons. **Other Target(s):** CGP-37157 also directly modulates ryanodine receptor channels (RyRs) and/or sarco/endoplasmic reticulum Ca<sup>2+</sup>-stimulated ATPase (SERCA) by CGP (5). In the presence of ruthenium red (an inhibitor of RyRs), CGP decreased SERCA-mediated Ca<sup>2+</sup> uptake of cardiac and skeletal sarcoplasmic reticulum (SR) microsomes, with IC<sub>50</sub> values of 6.6 and 9.9 μM, respectively. The CGP effects on SERCA activity correlated with a decreased V<sub>max</sub> of ATPase activity of SERCA-enriched skeletal SR fractions. CGP (≥ 5 μM) also increased RyR-mediated Ca<sup>2+</sup> leak from skeletal SR microsomes. Planar bilayer studies confirmed that both cardiac and skeletal RyRs are directly activated by CGP-37157, with EC<sub>50</sub> values of 9.4 and 12.0 μM, respectively. Therefore, the reported action of CGP on cellular Ca<sup>2+</sup> homeostasis of cardiac, skeletal muscle, and other nonmuscle systems requires further analysis to take into account the contribution of other CGP-sensitive Ca<sup>2+</sup> transporters. 1. ### CGP 41251

This staurosporine derivative (FW = 556.64 g/mol), also known as PKC412 and 4'-*N*-benzoylstaurosporine, selectively inhibits *in vitro* protein kinase C (1). PKC $\alpha$  (IC<sub>50</sub> = 24 nM), PKC $\beta$ I (IC<sub>50</sub> = 17 nM), PKC $\beta$ II (IC<sub>50</sub> = 32 nM), PKC $\gamma$  (IC<sub>50</sub> = 18 nM), PKC $\delta$  (IC<sub>50</sub> = 360 nM), PKC $\eta$  (IC<sub>50</sub> = 60 nM), and PKC $\epsilon$  (IC<sub>50</sub> = 4.5  $\mu$ M). PKC $\zeta$  is very weakly inhibited. **Target(s)**: phosphatidylinositol 3-kinase (1); protein kinase C (2-4); vascular endothelial growth factor (VEGF) receptor kinase (4). **1.** Berggren, Gallegos, Dressler, Modest & Powis (1993) *Cancer Res.* **53**, 4297. **2.** Marte, Meyer, Stabel, *et al.* (1994) *Cell Growth Differ.* **5**, 239. **3.** Kessels, Krause & Verhoeven (1993) *Biochem. J.* **292**, 781. **4.** Fabbro, Buchdunger, Wood, *et al.* (1999) *Pharmacol Ther.* **82**, 293.

#### CGP 52622A

This hydroxylamine derivative (FW<sub>free-base</sub> = 130.19 g/mol) competitively inhibits *Plasmodium falciparum* ornithine decarboxylase (K<sub>i</sub> = 20.4 nM). **1.** Birkholtz, Joubert, Neitz & Louw (2003) *Proteins* **50**, 464. **2.** Das Gupta, Krause-Ihle, Bergmann, *et al.* (2005) *Antimicrob. Agents Chemother.* **49**, 2857. **3.** Krause, Lüersen, Wrenger, *et al.* (2000) *Biochem. J.* **352**, 287.

#### CGP-57148, See Imatinib

#### CGP 74514A

This cell-permeable CDK/cyclin inhibitor (FW = 385.89 g/mol; CAS 1173021-98-1), also named 2-*N*-(2-aminocyclohexyl)-6-*N*-(3-chloro phenyl)-9-ethylpurine-2,6-diamine, potently and selectively targets CDK/cyclin B (IC<sub>50</sub> = 25 nM) and shows weaker action against PKC $\alpha$  (IC<sub>50</sub> = 6.1  $\mu$ M), PKA (IC<sub>50</sub> = 125  $\mu$ M) and EGFR (IC<sub>50</sub> > 10  $\mu$ M). In human leukemia cells, CGP74514A induces complex changes in cell cycle-related proteins accompanied by extensive mitochondrial damage, caspase activation, and apoptosis (1). Exposure of U937 monocytic leukemia cells to minimally toxic concentrations of CGP74514A for 3 hours along with the PI3K inhibitor LY294002 markedly decreases Akt phosphorylation (2). **1.** Dai, Dent & Grant (2002) *Cell Cycle* **1**, 143. **2.** Yu, Rahmani, Dai, *et al.* *Cancer Res.* **63**, 1822.

#### CGS 9343B

This potent, selective and cell-permeable calmodulin antagonist (FW = 544.61 g/mol; CAS 109826-27-9; Soluble to 50 mM in DMSO), also known as Zaldaride® and 1,3-dihydro-1-[1-[(4-methyl-4*H*,6*H*-pyrrolo[1,2-*a*][4,1]benzoxazepin-4-yl)methyl]-4-piperidinyl]-2*H*-benzimidazol-2-one, targets calmodulin-stimulated cAMP phosphodiesterase activity (IC<sub>50</sub> = 3.3  $\mu$ M). CGS 9343B is 3.8 times more potent than trifluoperazine (IC<sub>50</sub> = 12.7

$\mu$ M) as an inhibitor of calmodulin activity (1). CGS 9343B does not inhibit protein kinase C activity at concentrations up to 100  $\mu$ M, whereas trifluoperazine inhibits protein kinase C activity (IC<sub>50</sub> = 44  $\mu$ M (1). CGS 9343B weakly displaces [<sup>3</sup>H]spiperone from postsynaptic dopamine receptors with an IC<sub>50</sub> value of 4.8  $\mu$ M, while IC<sub>50</sub> for trifluoperazine is 18 nM (1). CGS-9343B reversibly blocks voltage-activated Ca<sup>2+</sup>, Na<sup>+</sup>, and K<sup>+</sup> currents in differentiated rat pheochromocytoma (PC12) cells (2). It also inhibits nicotinic acetylcholine receptor (nAChR) channel currents, but not inward ion currents evoked by extracellular ATP. Depolarization-induced intracellular Ca<sup>2+</sup> transients are almost completely inhibited in growth cones and cell bodies by CGS 9343B (2). CGS9343B also prevents estrogen-induced transcriptional activation by the estrogen receptor (ER), without altering basal transcription (3). The inhibition is dose-dependent and independent of the time of estrogen stimulation. **1.** Norman, Ansell, Stone, Wennogle & Wasley (1987) *Mol. Pharmacol.* **31**, 535. **2.** Neuhaus & Reber (1992) *Eur. J. Pharmacol.* **226**, 183. **3.** Li, Li & Sacks (2003) *J. Biol. Chem.* **278**, 1195.

#### CGS 13945, See Pentopril (and Pentoprilat)

#### CGS 14824A, See Benazepril

#### CGS27023A, See MMI270

#### CH5132799

This orally active PI3K inhibitor (FW = 377.42 g/mol; CAS 1007207-67-1; Solubility: 12 mg/mL DMSO) selectively targets PI3K $\alpha$  (IC<sub>50</sub> = 14 nM), PI3K $\beta$  (IC<sub>50</sub> = 120 nM), PI3K $\delta$  (IC<sub>50</sub> = 500 nM), PI3K $\gamma$  (IC<sub>50</sub> = 36 nM), but shows less inhibition of class II PI3Ks, class III PI3k and mTOR and also no inhibitory activity (IC<sub>50</sub> > 10  $\mu$ M) against twenty-six protein kinases. PI3K phosphorylates PtdIns(4,5)P<sub>2</sub>, producing phosphoinositide PtdIns(3,4,5)P<sub>3</sub>, which plays a central role in cell proliferation and human cancer survival. **1.** Ohwada, Ebiike, Kawada, *et al.* (2011) *Bioorg. Med. Chem. Lett.* **21**, 1767. **2.** Tanaka, Yoshida, Tanimura, *et al.* (2011) *Clin. Cancer Res.* **17**, 3272.

#### CH5164840

This anti-proliferative agent (FW = 385.49 g/mol) targets the molecular chaperone Hsp90 (Heat shock protein 90), inducing the degradation of cell-stabilizing and oncogenic client proteins, altering the proliferation and/or survival of treated cells. CH5164840 exhibits potent antitumor efficacy with regression in NCI-N87 and BT-474 tumor xenograft models and significantly enhances antitumor efficacy against gastric and breast cancer models, when used in combination with the HER2-directed agents, trastuzumab and lapatinib. CH5164840 binds tightly to Hsp90 $\alpha$  (k<sub>on</sub> = 5.6 x 10<sup>5</sup> M<sup>-1</sup>s<sup>-1</sup>; k<sub>off</sub> = 2.9 x 10<sup>-4</sup> s<sup>-1</sup>; K<sub>d</sub> = 0.52 nM) and Hsp90 $\beta$  (k<sub>on</sub> = 6.6 x 10<sup>5</sup> M<sup>-1</sup>s<sup>-1</sup>; k<sub>off</sub> = 9.2 x 10<sup>-4</sup> s<sup>-1</sup>; K<sub>d</sub> = 1.4 nM). Hsp90 is considered an attractive target in anticancer therapy for several reasons; first, its role in the regulation of its client proteins, many of which are cancer-related proteins,

such as kinases, transcription factors, and steroid receptors. Hsp90 inhibition induces degradation of these clients, leading to the inhibition of multiple signaling pathways that regulate tumor cell proliferation and survival. 1. Ono, Yamazaki, Nakanishi, *et al.* (2012) *Cancer Sci.* **103**, 342.

#### CH5183284

This selective and orally available mitogen-activated protein kinase kinase (MEK) inhibitor, or phosphoinositide 3-kinase (PI3K) inhibitor (FW = 356.38 g/mol; CAS 1265229-25-1; Solubility: 71 mg/mL DMSO; < 1 mg/mL H<sub>2</sub>O), also named Debio-1347 and (5-amino-1-(2-methyl-3H-benzof[d]-imidazol-5-yl)-1H-pyrazol-4-yl)(1H-indol-2-yl)methanone, targets fibroblast growth factor receptors FGFR1 (IC<sub>50</sub> = 9.3 nM), FGFR2 (IC<sub>50</sub> = 7.6 nM), FGFR3 (IC<sub>50</sub> = 22 nM), and FGFR4 (IC<sub>50</sub> = 290 nM) (1). The FGFR family consists of FGFR1, FGFR2, FGFR3, and FGFR4, each of which is bound by a subset of 22 fibroblast growth factor (FGF) ligands. FGFRs are activated by ligand-dependent or ligand-independent dimerization that leads to intermolecular phosphorylation. FGFR substrate 2 (FRS2) is a key adaptor protein that is phosphorylated by FGFR. Phosphorylated FRS2 recruits several other adaptor proteins and activates the mitogen-associated protein kinase (MAPK) or PI3K/AKT pathways. In FGFR-altered cancer cells, Dual-Specificity Phosphatase 6 (DUSP6) was more significantly suppressed by CH5183284 than by CH5126766. CH5126766 suppressed phospho-ERK, but not the downstream ERK effector DUSP6, suggesting that CH5126766 does not strongly suppress MAPK, resulting in the resistance of FGFR-altered cancer cells to MEK inhibition. It thus appears that CH5183284 exerts its inhibitory effects by suppressing ERK signaling without feedback activation of the MAPK pathway via FGFR (2). 1. Nakanishi, Akiyama, Tsukaguchi, *et al.* (2014) *Mol. Cancer Ther.* **3**, 2547. 2. Nakanishi, Mizuno, Sase, *et al.* (2015) *Mol. Cancer Ther.* **14**, 2831.

#### CH5424802, See *Alectinib*

#### Chaetomelic Acid A

This natural product (FW<sub>free-acid</sub> = 326.48 g/mol; CAS 148796-51-4) from *Chaetomella acutiseta* inhibits protein farnesyltransferase (IC<sub>50</sub> = 55 nM), competitively with respect to farnesyl diphosphate and noncompetitive with respect to Ras). At higher concentrations, it will also inhibit protein geranylgeranyltransferases I and II (IC<sub>50</sub> values of 92 and 34 μM, respectively). **Target(s):** protein farnesyltransferase (1-3,5); protein geranylgeranyltransferase type I (2); protein geranylgeranyltransferase type II (2); rubber *cis*-polyprenyltransferase (4); penicillin binding protein-1b (6); peptidoglycan glycosyltransferase (6). 1. Gibbs (2001) *The Enzymes*, 3rd ed., **21**, 81. 2. Gibbs, Pompliano, Mosser, *et al.* (1993) *J. Biol. Chem.* **268**, 7617. 3. Lingham, Silverman, Bills, *et al.* (1993) *Appl. Microbiol. Garneau, Qiao, Chen, Walker & Vederas (2004) *Bioorg. Med. Chem.* **12**, 6473.

#### Charybdotoxin

This 37-residue neurotoxin (FW = 4295.95 g/mol; CAS 95751-30-7; Symbol: ChTX) from the venom of the Deathstalker scorpion (*Leiurus quinquestratus hebraeus*) is a relatively specific inhibitor of the big conductance Ca<sup>2+</sup>-activated K<sup>+</sup> channel (1). This channel is activated by depolarizing voltages and has a voltage-sensitivity that is modulated by cytoplasmic Ca<sup>2+</sup> levels. Its conduction is also unusual, showing high ionic

selectivity and a very high unitary conductance (1). Purified ChTX potently and selectively inhibits the 220-pS Ca<sup>2+</sup>-activated K<sup>+</sup> channel present in GH3 anterior pituitary cells and primary bovine aortic smooth muscle cells (2). It reversibly blocks channel activity by interacting at the external pore of the channel protein (K<sub>d</sub> = 2.1 nM). The ChTX primary structure is similar to neurotoxins of diverse origin, suggesting ChTX is a member of a superfamily of ion-channel modifiers (2). ChTX-sensitive K<sub>Ca</sub> channels were highly activated to regulate the myogenic tone in the resting state of carotid, femoral and mesenteric arteries from spontaneously hypertensive rats (SHR). The increased K<sub>Ca</sub> channel functions in SHR arteries appeared to be secondary to the increased Ca<sup>2+</sup> influx via L-type voltage-dependent Ca<sup>2+</sup> channels in the resting state of these arteries (3). ChTX blocks homotetrameric, voltage-gated K<sup>+</sup> channels and its Shaker channel (*i.e.*, His replacing wild-type Phe-425) by binding near the outer entrance to the pore in one of four indistinguishable orientations (4). (See also *Paxilline*) 1. Miller, Moczydlowski, Latorre & Phillips (1985) *Nature* **313**, 316. 2. Gimenez-Gallego, Navia, Reuben, *et al.* (1988) *Proc. Natl. Acad. Sci. USA* **85**, 3329. 3. #### Chemical Synthetic Lethality

This chemotherapeutic strategy has its roots in phenomenon known as Synthetic Lethality, which requires the experimentally or environmentally imposed co-occurrence of two genetic events (*e.g.*, gene fusions, mutations, and deletions) for an organism or cell to die. Two genes are said to be synthetic lethal, if a mutation in either is compatible with viability, but mutations in both genes results prove lethal. In genetics, synthetic lethal interactions provide insights into the functional relationships between/among genes that are relatively easy to score in screens. In the analogous phenomenon, known as Chemical Synthetic Lethality (CSL), death occurs when a particular gene fusion, deletion, or mutation(s), but not the corresponding wild-type allele, confers lethality in the presence of a particular drug. CSL experiments often provide (a) insights into the pathophysiologic role(s) of a particular gene product, (b) elucidation of mechanism(s) for a pharmacologic effect, and (c) new strategies for treating cancers by inducing mutations that confer drug lethality. The classical example is the action of imatinib on cancer cells expressing the Bcr-Abl fusion protein (See *Imatinib*). Many protein kinase-directed inhibitors also show enhanced cell killing in the presence of mutations within their ATP binding domains. Many cancers respond to chemotherapy by mutations placed under strongly selective conditions when cultured in the presence of a chemotherapeutic agent.

#### Chemotactic Factor Inactivator

This serum protein (often abbreviated CFI), first isolated from the α-globulin fraction of human serum, inhibits chemotactic factor C5a-directed neutrophil chemotaxis by binding to the C5a cochemotaxin Gc-globulin, a vitamin-D-binding protein, and inhibiting the capacity of Gc-globulin to enhance the chemotactic activity of C5a (1). Small amounts (10<sup>-10</sup> mol) of purified human CFI suppress leukocytic infiltration, permeability changes, and hemorrhage associated with acute immune complex-induced injury in rats (2). *In vitro*, human CFI inhibits the chemotactic activity generated in complement-activated rat serum. The inhibitory effects of human CFI are not seen if it is first heat inactivated. The highly chemotactic synthetic peptide Met-Leu-Phe is completely hydrolyzed by CFI preparations, indicating that CFI is most likely an aminopeptidase that inhibits the activity of chemotactic substrates by catalyzing their proteolytic turnover (3). The observed heterogeneity in CFI activity released by phagocytosing neutrophils suggests that the predominant inactivator activity of the C5 chemotactic fragment is most likely elastase and/or cathepsin G (4). 1. #### CHF-2819, See *Ganstigmine*

#### Chidamide

This synthetic benzamide-type HDAC inhibitor (FW = 390.40 g/mol; CAS 743420-02-2), also known by the code names CS055 and HBI-8000 and systematically as *N*-(2-amino-5-fluorophenyl)-4-[[[1-oxo-3-(3-pyridinyl)-2-propen-1-yl]amino]methyl]benzamide, mainly targets Class I HDACi, potently inhibiting histone deacetylases HDAC-1, -2 and -3, all at low nanomolar concentrations and inducing G<sub>1</sub> arrest (1). The results showed that at low concentrations (<1 μM), CS055. At moderate concentrations (0.5–2 μM), CS055 induced differentiation of primary myeloid leukemia cells, as determined by the increased expression of the myeloid differentiation marker CD11b. At relatively high concentrations (2–4 μM), CS055 potently induced caspase-dependent apoptosis. Co-treatment with the ROS (reactive oxygen species) scavengers *N*-acetyl-L-cysteine or Tiron blocked CS055-induced cell differentiation and apoptosis, suggesting an essential role for ROS in these effects. Chidamide treatment leads to increased acetylation of histone H3 at Lys9/Lys18 and H4 at Lys8, resulting ultimately in activation of gene transcription (2). 1. Gong, Xie, Yi & Li (2012) *Biochem. J.* **443**, 735. 2. Ning, Li, Newman *et al.* (2012) *Cancer Chemother. Pharmacol.* **69**, 901.

### Ching001

This tubulin polymerization inhibitor and spindle poison (FW = 438.42 g/mol; Solubility: dissolve in DMSO, then dilute 20x into buffer or growth medium) shows specific cytotoxic action against lung cancer cell lines, with little effect against normal lung cells (1). IC<sub>50</sub> values for various cell lines were: CL1-0, 2 μM; CL1-5, 1.9 μM; A549, 1.2 μM; H1299, 2.6 μM; and MRC5, 8.3 μM for cells treated with Ching001 for 48 h. Aurora B, survivin and p-MPM2 remained high after Ching001 treatment compared with DMSO control, a result indicating M-phase arrest. Significantly, Ching001 inhibits *in vivo* xenograft growth by mitotic arrest and apoptosis, but without inducing apoptosis in host tissue surrounding of xenograft. Consistent with the general observation that prolong M-phase arrest leads to chromosome segregation failure and death, results with Ching001 are consistent with M-phase arrest followed by DNA damage and apoptotic cell death. **See also Podophyllotoxin; Colchicine; Vinblastine** 1. ### CHIR-258

This benzimidazole (FW = 392.44 g/mol), also known as TKI258, inhibits fibroblast growth factor receptor-3 kinase, IC<sub>50</sub> = 5 nM (1-3). **Target(s):** fibroblast growth factor receptor kinase (2,3); platelet-derived growth factor receptor β kinase (3); polo kinase (1); receptor protein-tyrosine kinase (2); signal-regulated kinase (2); vascular endothelial growth factor receptor kinase (3). 1. Johnson, Stewart, Woods, Giranda & Luo (2007) *Biochemistry* **46**, 9551. 2. Trudel, Wei, Wiesmann, *et al.* (2005) *Blood* **105**, 2941. 3. Lee, Lopes de Menezes, Vora, *et al.* (2005) *Clin. Cancer Res.* **11**, 363.

### CHIR-99021

This GSK-3 inhibitor (F.Wt. = 465.34; CAS 252917-06-9; Solubility (25°C): 1 mg/mL DMSO, <1 mg/mL Water), also known as CT99021 and systematically named 6-(2-(4-(2,4-dichlorophenyl)-5-(4-methyl-1H-imidazol-2-yl)pyrimidin-2-ylamino)ethylamino)nicotinonitrile, targets glycogen synthase kinase 3α and 3β, with IC<sub>50</sub> values of 10 nM and 7 nM, respectively. Glycogen synthase kinase-3 can negatively regulate several aspects of insulin signaling, and elevated levels of GSK-3 have been reported in skeletal muscle from diabetic rodents and humans. CHIR 99021 stabilizes free cytosolic β-catenin and inhibits adipogenesis by blocking Inducing CCAAT/Enhancer-binding Protein-α and Peroxisome Proliferator-activated Receptor-γ (1). Preadipocyte differentiation is inhibited when 3T3-L1 cells are exposed to CHIR 99021 for any 24-hour period during the first 3 days of adipogenesis. 1.
