This conjugated unsaturated fatty acid (FW<sub>free-acid</sub> = 278.44 g/mol), also known as 9*Z*,11*E*,13*Z*-octadecatrienoic acid, from *Punica granatum* inhibits DNA-directed DNA polymerase, DNA polymerase α, and DNA topoisomerase II (1). **1.** Mizushima, Tsuzuki, Eitsuka, *et al.* (2004) *Lipids* **39**, 977.

### Purine

This heterocyclic base (FW = 120.11 g/mol; CAS 120-73-0) is the structural foundation for a wide variety of naturally occurring compounds. It is soluble in water and absorbs light in the ultraviolet. Purine was first synthesized, characterized, and named in the late nineteenth century by Emil Fischer, the 1902 Nobel Laureate in Chemistry. **Target(s):** adenine deaminase (1-3); adenosine deaminase (4-6); 5-phosphoribosylamine synthetase, *or* ribose-5-phosphate:ammonia ligase (7); xanthine dehydrogenase, weakly inhibited (8); xanthine oxidase (9); and xanthine phosphoribosyltransferase (10). **1.** Hartenstein & Fridovich (1967) *J. ### Purmorphamine

This Smo activator (FW = 520.62 g/mol; CAS 483367-10-8; Solubility: 4 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 9-cyclohexyl-*N*-[4-(4-morpholinyl)phenyl]-2-(1-naphthalenylloxy)-9*H*-purin-6-amine, targets Smoothed and blocks BODIPY-cyclopamine binding (IC<sub>50</sub> ~ 1.5 μM). Purmorphamine is also an inducer of osteoblast differentiation (EC<sub>50</sub> = 1 μM). **1.** Sinha, *et al.* (2006) *Nature Chem. Biol.* **2**, 29. **2.** Wu, *et al.* (2002) *J. Am. Chem. Soc.* **124**, 14520. **3.** Wu, *et al.* (2004) *Chem. Biol.* **11**, 1229.

### Puromycin

Puromycin

3'-O-Tyrosyl-adenosine

This tyrosylated aminonucleoside antibiotic (FW<sub>free-base</sub> = 471.52 g/mol) from *Streptomyces alboniger*, named systematically as 3'-((2-amino-3-(4-methoxyphenyl)-1-oxopropyl)amino)-3'-deoxy-*N,N*-dimethyl-(*S*)-adenosine, is a potent protein biosynthesis inhibitor (1,2). It is highly cytotoxic and is unselective in its action against both prokaryotes and eukaryotes. Puromycin resistance is conferred by the *Pac* gene, which encodes a puromycin *N*-acetyl-transferase (PAC), in its *Streptomyces* producer strain. The multi-paper description of its synthesis was reported in 1954 by B. R. Baker and coworkers in Issue 4 of Vol 19 of *The Journal of Organic Chemistry*. **Mechanism of Action:** Puromycin binds at the A-site on the ribosome and is incorporated into the growing polypeptide chain. (Note the similarity in structure to the aminoacyl-adenylyl terminus of aminoacyl-tRNAs.) The carboxyl group of the growing peptide is linked by a peptide bond to the amino group of the puromycin side chain. Protein synthesis is then terminated and the puromycinyl peptide is released from the ribosome. The free base form is sparingly soluble in water whereas the dihydrochloride and monosulfate are readily soluble. **Key Role in mRNA Display Technique:** This peptide- and protein-selection approach, which provides a way to carry out both ligand discovery and interaction analysis, utilizes encoded peptide and protein libraries that are covalently fused to their own mRNA (3). Indeed, the mRNA display technique has been used to discover novel peptide and protein ligands for RNA, small molecules and proteins, as well as to define cellular interaction partners of proteins and drugs. In this method, puromycin serves as a chemically stable, small-molecule mimic of aminoacyl tRNA. Synthetic oligonucleotide containing a 3'-puromycin molecule is ligated to the 3'-end of an mRNA, and the product is translated in rabbit reticulocyte lysate. The sequence present in the peptide is therefore encoded in the covalently attached mRNA, allowing the sequence information in the protein to be read and recovered after selection via RT-PCR, such that exceedingly small amounts of material can be amplified and analyzed. **Properties:** The pK<sub>a</sub> values are 6.8 and 7.2. The nucleoside also absorbs light significantly in the ultraviolet: λ<sub>max</sub> in 0.1 N HCl is 267.5 nm (ε = 19500 M<sup>-1</sup>cm<sup>-1</sup>) whereas the value in 0.13 M NaOH is 275 nm (ε = 20300 M<sup>-1</sup>cm<sup>-1</sup>). **Target(s):** acetylcholinesterase (4,5); aminopeptidase B (41,42); aminopeptidase PS (6); aminopeptidase, rat brain (5); aromatic-hydroxylamine *O*-acetyltransferase (60); arylacylamidase (7,8); biotinidase (10); bleomycin hydrolase (11); cathepsin H, weakly inhibited (12,13); 3',5'-cyclic-nucleotide phosphodiesterase (14); [cytochrome *c*]-lysine *N*-methyltransferase (61); cytosol alanyl aminopeptidase (39); *O*-demethylpuromycin *O*-methyltransferase, product inhibition (62); dipeptidyl-peptidase I, *or* cathepsin C (15); dipeptidyl-peptidase II (16-23); dipeptidyl-peptidase III (24-26); dipeptidyl-peptidase IV, *or* post-proline dipeptidyl aminopeptidase (27); glutamate carboxypeptidase II (28); glutamyl aminopeptidase, *or* aminopeptidase A (40); leucyl aminopeptidase (43,51-53); leucyl aminopeptidase/cystinyl aminopeptidase (43); leucyltransferase, *or* leucyl-tRNA:protein leucyltransferase (29,57-59); membrane alanyl aminopeptidase, *or* aminopeptidase N (30-33,40,44-50); nepriylsin (34); protein biosynthesis,

or elongation (1-3,35-37); pyroglutamyl-peptidase I (9); ribonuclease P (54-56); subtilopeptidase A, or *Bacillus subtilis* protease, type 8 (38); and tripeptidyl-peptidase (15). 1. #### Puromycin Aminonucleoside

This aminoribose-containing nucleoside (FW = 294.31 g/mol), also known as 3'-amino-3'-deoxy- $N^6,N^6$ -dimethyladenosine, inhibits RNA biosynthesis. Because the use of adenosine receptor agonists is plagued by dose-limiting cardiovascular side effects, there is great interest in developing adenosine kinase inhibitors (AKIs) as a means for raising steady-state adenosine concentrations. **Target(s):** adenosine deaminase (1); adenosine kinase (2); aminopeptidase PS (3); dipeptidyl-peptidase II (4); protein biosynthesis (5); protein degradation (5); and RNA biosynthesis (6,7). 1. #### Purpurin

This red/orange pigment (FW = 256.21 g/mol), also known as 1,2,4-trihydroxyanthraquinone, is found with alizarin in madder root (*Rubia tinctorum*) and related plants. Purpurin produces a yellow solution in water and diethyl ether and a red solution in ethanol. It forms colored chelates with metal ions and is used in the detection of boron. *Note:* The term purpurin has also been used to refer to a lectin from *Dictyostelium purpureum*. In addition, a 20-kDa protein from neural retina adherens is referred to as retinal purpurin. **Target(s):** CYP1A1 (1); CYP1A2 (1); CYP2A6, weakly inhibited (1); CYP1B1 (1); CYP2E1, weakly inhibited (1); inositol-trisphosphate 3-kinase (2); [myosin light-chain] kinase (3); protein kinase A (4); protein-tyrosine kinase, or non-specific protein-tyrosine kinase (5); and xanthine oxidase (6). 1. #### Purpurogallin

This aglycone (FW = 220.18 g/mol) of a number of glycosides (e.g., dryophantin) from several nutgalls. Purpurogallin is a scavenger of polymorphonuclear leukocyte-derived oxyradicals and acts as a cardioprotector. **Target(s):** catechol *O*-methyltransferase (1,2); cystathionine  $\beta$ -synthase (3); glutathione-disulfide reductase (4); glutathione *S*-transferase (4-7); HIV-1 integrase (8); lactoylglutathione lyase, or glyoxalase I (9,10); 3-phosphoglycerate kinase (11); prolyl endopeptidase (12); protein-tyrosine kinase (13); and xanthine oxidase (14). 1. ## Purvalanol A and B

This highly substituted adenine/valanol conjugate and cell-permeable inhibitor ( $FW_A = 388.90$  g/mol), also known as (2*R*)-2-[[6-[(3-chlorophenyl)amino]-9-(1-methylethyl)-9*H*-purin-2-yl]amino]-3-methyl-1-butanol, targets cyclin-dependent kinases and is ATP-competitive.  $IC_{50}$  values are 4, 70, 35, 850 and 75 nM for Cdc2/Cyclin B, Cdk2/Cyclin A, Cdk2/Cyclin E, Cdk4/Cyclin D1 and Cdk5-p35 respectively. Purvalanol reversibly arrests synchronised cells in  $G_1$  and  $G_2$ , inhibiting cell proliferation and inducing cell death. Purvalanol B ( $FW_B = 431.91$ ) is more water-soluble and therefore less cell-permeant. **Target(s):** ABC transporter ABCG2 (1); cAMP-dependent protein kinase, or protein kinase A, weakly inhibited (2); cyclin-dependent kinase, or cdk2,  $IC_{50} = 0.1$   $\mu$ M (2-5); dual-specificity kinase, or dual-specificity, tyrosine-phosphorylated and regulated kinase 1A, abbreviated DYRK1A,  $IC_{50} = 0.3$   $\mu$ M (2); Lck protein-tyrosine kinase (2); mitogen-activated protein kinase, or p42/p44 MAPK (2,6); non-specific serine/threonine protein kinase (2); protein-tyrosine kinase, or non-specific protein-tyrosine kinase (2); and ribosomal S6 kinase 1, abbreviated RSK1,  $IC_{50} = 1.5$   $\mu$ M (2). 1. ## Putrescine

This diamine ( $FW_{free-base} = 88.15$  g/mol; CAS 110-60-1; colorless oil; M.P. = 23-24°C; B.P. = 158-160°C), also known as tetramethylenediamine, 1,4-diaminobutane, and 1,4-butanediamine, is produced by the decarboxylation of ornithine and is a precursor for the polyamines spermidine and spermine. Putrescine has a strong odor similar to that of piperidine. It is very soluble in water and ethanol. The dihydrochloride ( $FW = 161.07$  g/mol) has a melting point of about 280°C, at which it decomposes. The  $pK_a$  values at 20°C are 9.35 and 10.80 (at 30°C are 9.04 and 10.50). **Target(s):** acetylcholinesterase (1,44,45); adenosylmethionine decarboxylase (32); adenylate cyclase (2); agmatinase (3); agmatine deiminase (40-42); *Agropyron elongatum* nuclease (48); amino-acid *N*-acetyltransferase (63); 1-amino-cyclopropane-1-carboxylate synthase (31); amylo- $\alpha$ -1,6-glucosidase/4- $\alpha$ -glucanotransferase, or glycogen debranching enzyme (47); arginine decarboxylase (4,33-39); arginine deiminase (5,43); arginyltransferase, weakly inhibited (62); carbamoyl-phosphate synthetase, glutamine-hydrolyzing (6,7); carbonic anhydrase, or carbonate dehydratase (8); deoxyhypusine monooxygenase, weakly inhibited (69); deoxyhypusine synthase (54); DNA (cytosine-5-)-methyltransferase (66); DNA-directed RNA polymerase (9); glucose-6-phosphate dehydrogenase (8); glutamate dehydrogenase (10,11); glutamate:ethylamine ligase, or theanine synthetase, weakly inhibited (12); indolethylamine-*N*-methyltransferase (13); kynureninase (14); lipoxigenase-1 (15); lysine 5,6-aminomutase (16,17); methionine *S*-adenosyltransferase (18,57); nitric-oxide synthase (19,20); ornithine aminotransferase (52,53); ornithine carbamoyltransferase (64,65); pancreatic ribonuclease, ribonuclease A (21); phosphatidylinositol 3-kinase (22); phospholipase C (23); phosphoprotein phosphatase I, *e.g.*, phosphorylase phosphatase (24); polynucleotide adenylyltransferase, or poly(A) polymerase (50); protein-arginine *N*-methyltransferase (25); protein-glutamine  $\gamma$ -glutamyltransferase, or transglutaminase; also alternative substrate (58-61); protein kinase C (26); pyridoxal kinase (27,51); ribonuclease (21); RNA-directed RNA polymerase (49); spermine synthase, or spermidine aminopropyltransferase (28,29,55,56); tRNA (adenine-*N*1-)-methyltransferase (67); tRNA adenylyltransferase (30); tRNA (cytosine-5-)-methyltransferase (67); tRNA (uracil-5-)-methyltransferase (68); and tubulinyl-tyrosine carboxypeptidase, inhibited

## PX-866

This orally active antifungal and antineoplastic agent (FW = 541.60 g/mol; CAS 502632-66-8; Solubility: 40 mg/mL DMSO, water-insoluble; stable for six months, when stored in a refrigerated desiccator) is a chemically stable wortmannin derivative that potently and irreversibly inhibits phosphoinositide 3-kinase ( $IC_{50} = 0.1$  nM) and phosphoinositide-3-kinase-dependent signaling (1). PX-866 blocks PtdIns-3-kinase signaling, as measured by phospho-Ser<sup>473</sup>-Akt levels in HT-29 colon cancer cells ( $IC_{50} = 20$  nM). PX-866 also overcomes resistance to the EGFR inhibitor gefitinib in A-549 human non-small cell lung cancer xenografts (2). 1. Ihle, Williams, Chow, *et al.* (2004) *Mol. Cancer Ther.* **3**, 763. 2. Ihle, Paine-Murrieta, Berggren *et al.* (2005) *Mol. Cancer Ther.* **4**, 1349.

**PXD101**, See *Belinostat*

**PXS-4681A**

This SSAO/VAP-1-directed anti-inflammatory agent (FW = 342.84 g/mol) is a potent and selective mechanism-based inhibitor ( $K_i = 37$  nM;  $k_{inact} = 0.26$  min<sup>-1</sup>) of Semicarbazide-Sensitive Amine Oxidase (SSAO), or Vascular Adhesion Protein-1 (VAP-1), a copper-dependent amine oxidase associated with various forms of inflammation and fibrosis (1). SSAO/VAP-1 catalyzes the oxidation of primary amine substrates (including benzylamine, tyramine, methylamine, *n*-decylamine, histamine, tryptamine or  $\beta$ -phenylethylamine) to aldehydes, releasing ammonia and hydrogen peroxide upon regeneration of its 6-hydroxy-dopa-quinone (TPQ) co-factor. PXS-4681A is highly selective for SSAO/VAP-1, when profiled against related amine oxidases, ion channels and 7-TM receptors, superior to inhibitors reported previously. While the exact physiological role of this enzyme is presently not well understood, PXS-4681A (at 2 mg/kg) attenuates neutrophil migration, TNF- $\alpha$  and IL-6 levels in mouse models of lung inflammation and localized inflammation. Such findings suggest SSAO inhibition leads to decreased neutrophil rolling/extravasation, resulting in a reduction in inflammation. See also PXS-4728A 1. Foot, Yow, Schilter, *et al.* (2013) *J. Pharmacol. Exp. Ther.* **347**, 365.

**PXS-4728A**

This potent and highly selective mechanism-based VAP-1-inhibitor (FW<sub>HCl</sub> salt = 316.80 g/mol; Solubility: >10 mg/mL H<sub>2</sub>O) targets Semicarbazide-Sensitive Amine Oxidase, or Vascular Adhesion Protein-1 ( $K_i = 175$  nM;  $k_{inact}$  of 0.68 min<sup>-1</sup>). PXS-4728A provides >90% inhibition for 24 hours after a single oral dose. PXS-4728A in development for the treatment of cardiometabolic diseases like the liver-related disease Nonalcoholic Steatohepatitis (NASH), which is common to people who are overweight or obese. Given the increasing rate of obesity around the world, made worse by sedentary lifestyles and poor food choices, the condition is likely to become a major cause of liver disease and transplantations in coming years. PXS-4728A exhibits an  $IC_{50}$  of <10 nM against the human VAP-1/SSAO, and this activity was maintained across all the mammalian species tested. It is 500x selective for VAP-1/SSAO versus related human amine oxidases. It shares the excellent potency, selectivity with PXS-4681A, but has a more balanced blood/plasma ratio (1.2 for human and dog, 1.45 for rat) due to substitution of the sulfonamide group with an amide, thereby removing all inhibition of carbonic anhydrase II and thus avoiding the potential for sequestration by erythrocytes in whole blood. Like PXS-4681A, PXS-4728A is stable in human, rat and dog plasma (>90% remaining after 1 hour incubation) and has high water solubility >10 mg/mL at pH 7.4. See also PXS-4681A 1. Schilter, Collison, Russo, *et al.* (2015) *Respir. Res.* **16**, 42.

**Pygenic Acid A**

This triterpene (FW<sub>free-acid</sub> = 492.12 g/mol) inhibits rabbit muscle glycogen phosphorylase,  $IC_{50} = 213$   $\mu$ M. X-ray analysis indicates that the inhibitor binds at the allosteric activator site, where the physiological activator AMP binds. 1. Wen, Sun, Liu, *et al.* (2008) *J. Med. Chem.* **51**, 3540.

**Pyocyanine**

This natural pigment (FW = 210.24 g/mol), which has an antifungal activity, is a secretory agent produced by *Pseudomonas aeruginosa* (formerly *P. pyocyanea* and *Bacillus pyocyaneus*). It is a blue solid that is soluble in chloroform and pyridine generates reactive oxygen species, such as superoxide and hydrogen peroxide. Pyocyanine is slightly soluble in cold water and the aqueous blue solution can be decolorized under alkaline conditions upon the addition of glucose or sodium hydrosulfite. **Target(s):** catalase (1); cytochrome P450 leukotriene B<sub>4</sub>  $\omega$ -oxidation (2); and diamine oxidase (3,4). 1. O'Malley, Reszka, Rasmussen, *et al.* (2003) *Amer. J. Physiol. Lung Cell Mol. Physiol.* **285**, L1077. 2. Muller & Sorrell (1992) *Infect. Immun.* **60**, 2536. 3. Zeller (1951) *The Enzymes*, 1st ed. (Sumner & Myrback, eds.), **2** (part 1), 536. 4. Zeller (1963) *The Enzymes*, 2nd ed. (Boyer, Lardy & Myrback, eds.), **8**, 313.

**PYR-41**

This cell-permeable pyrazole (FW = 425.40 g/mol; CAS 418805-02-4), also known as 4-(4-(5-nitrofuranyl)methylene)-3,5-dioxo-pyrazolidin-1-yl)benzoic acid ethyl ester, irreversibly inhibits the ubiquitin-activating enzyme E<sub>1</sub> activity ( $IC_{50} < 10$   $\mu$ M in cell-free E<sub>1</sub> ubiquitination assays) but exhibits little or no activity against E<sub>3</sub>, E<sub>2</sub>, or caspase enzymatic activity. PYR-41 blocks ubiquitination-dependent protein degradation and other ubiquitination-mediated cellular activities. Unexpectedly, in addition to blocking ubiquitylation, PYR-41 increases total sumoylation in cells. Although the molecular basis for this effect is unknown, increased sumoylation is also observed in cells harboring a temperature-sensitive form of E<sub>1</sub>. PYR-41 attenuates cytokine-mediated NF $\kappa$ B activation. This behavior correlates with inhibition of nonproteasomal (Lys-63) ubiquitylation of TRAF6, a protein that is essential to I $\kappa$ B kinase activation. PYR-41 also prevents the downstream ubiquitylation and proteasomal degradation of I $\kappa$ B. (See also NSC624206) Later studies demonstrated not only PYR-41 inhibited UBE<sub>1</sub> but also had equal or greater inhibitory activity against several deubiquitinases (DUBs) within intact cells and purified Ubiquitin-Specific Peptidase 5 (USP5) *in vitro* (2). Both UBE<sub>1</sub> and DUB inhibition are mediated through covalent protein cross-linking, which parallels the inhibition of the target proteins enzymatic activity. PYR-41 also mediates cross-linking of specific protein kinases (Bcr-Abl, Jak2) to inhibit their

signaling activity (2). Degradation of Repressor Element 1-Silencing transcription factor (REST), itself is a major neuronal and tumor suppressor, is blocked by both PYR-41 and the proteasome inhibitor MG-132, but not by the nuclear export inhibitor leptomycin B (3). 1. Yang, Kitagaki, Dai, *et al.* (2007) *Cancer Res.* **67**, 9472. 2. Kapuria, Peterson, Showalter, *et al.* (2011) *Biochem. Pharmacol.* **82**, 341. 3. Guan & Ricciardi (2012) *J. Virol.* **86**, 5594.

### Pyrazinamide

This pyrazinecarboxamide (FW = 123.11 g/mol), is an important tuberculosis-sterilizing drug that helps to shorten the duration of current chemotherapy regimens for tuberculosis. Pyrazinamide, which is hydrolyzed by an amidase to pyrazinoic acid, has a  $pK_a$  value of 0.5 and is soluble in water (15 mg/mL). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** fatty-acid synthase (1-4); NAD<sup>+</sup> ADP-ribosyltransferase, or poly(ADP-ribose) polymerase,  $IC_{50}$  = 0.13 mM (5); nicotinamide, also alternative substrate (6,7); and nicotinate *N*-methyltransferase (8). 1. Schroeder, de Souza, Santos, Blanchard & Basso (2002) *Curr. Pharm. Biotechnol.* **3**, 197. 2. Zimhony, Cox, Welch, Vilcheze & Jacobs, Jr. (2000) *Nature Med.* **6**, 1043. 3. Pyrazinecarboxamide, See Pyrazinamide

### 2-(Pyrazin-2-yl)-1H-benzimidazole

This substituted benzimidazole (FW = 196.21 g/mol) inhibits *Escherichia coli* methionyl aminopeptidase *in vitro* ( $IC_{50}$  = 4.6  $\mu$ M) by binding to an additional Co(II) ion situated at the entrance of the active site. This unexpected finding explains the inactivity of this and other compounds under *in vivo* conditions.. 1. Schiffmann, Neugebauer & Klein (2006) *J. Med. Chem.* **49**, 511.

### Pyrazofurin

This pyrimidine nucleoside (FW = 261.23 g/mol), also known as pyrazomycin, exhibits antineoplastic activity and inhibits cell proliferation and DNA synthesis in cells by inhibiting orotidylate decarboxylase (uridine 5'-phosphate synthase). Pyrazofurin, also known as 3,β-D-ribofuranosyl-4-hydroxypyrazole-5-carboxamide, is the prodrug of the 5'-phosphate derivative. **Target(s):** adenosylhomocysteinase (1); 5-aminoimidazole-4-carboxamide-1-β-D-ribofuranosyl 5'-monophosphate formyltransferase (2); orotate phosphoribosyltransferase (3); orotidylate decarboxylase, or UMP synthase (4). 1. Guranowski, Montgomery, Cantoni & Chiang (1981) *Biochemistry* **20**, 110. 2. Worzalla & Sweeney (1980) *Cancer Res.* **40**, 1482. 3. Krungkrai, Aoki, Palapac, *et al.* (2004) *Mol. Biochem. Parasitol.* **134**, 245. 4. Ringer, Howell & Etheredge (1991) *J. Biochem. Toxicol.* **6**, 19.

### Pyrazofurin 5'-Phosphate

This nucleotide (FW<sub>free-acid</sub> = 341.21 g/mol), itself a five-membered ring analogue of orotidine 5'-phosphate (OMP), inhibits orotidylate decarboxylase, or UMP synthase (1-3). 1. Jones, Kavipurapu & Traut (1978) *Meth. Enzymol.* **51**, 155. 2. Ringer, Howell & Etheredge (1991) *J. Biochem. Toxicol.* **6**, 19. 3. Suttle & Stark (1979) *J. Biol. Chem.* **254**, 4602.

### 1H-Pyrazole-1-carboximidine

This pyrazole derivative (FW<sub>free-base</sub> = 110.12 g/mol) inhibits nitric-oxide synthase,  $IC_{50}$  = 0.2  $\mu$ M (1,2). 1. Southan, Gauld, Lubeskie, *et al.* (1997) *Biochem. Pharmacol.* **54**, 409. 2. Lee, Martasek, Roman & Silverman (2000) *Bioorg. Med. Chem. Lett.* **10**, 2771.

1,9-Pyrazoloanthrone, See SP 600125

### Pyrazoloisoguanine

This allopurinol-like, guanine analogue (FW = 151.13 g/mol), also known as 4-amino-6-hydroxypyrazolo[3,4-d]pyrimidine, inhibits xanthine oxidase (1,2). Pyrazoloisoguanine can be produced by the action of xanthine oxidase on pyrazoloadenine. 1. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 279, Academic Press, New York. 2. Feigelson, Davidson & Robins (1957) *J. Biol. Chem.* **226**, 993.

### Pyrazolo[4,3-b]olean-12-en-28-oate

This oleanolic acid derivative (FW = 466.71 g/mol), or pyrazolo[4,3-b]olean-12-en-28-oic acid, inhibits rabbit muscle glycogen phosphorylase,  $IC_{50}$  = 9.9  $\mu$ M. 1. Chen, Gong, Liu, *et al.* (2008) *Chem. Biodivers.* **5**, 1304.

### 17-(3'-Pyrazolyl)androsta-5,16-dien-3β-ol

This synthetic steroid (FW = 334.46 g/mol) inhibits steroid 17 $\alpha$ -monooxygenase, or CYP17, human IC<sub>50</sub> = 42 nM (1-3). The 17-(1H-pyrazol-1-yl) analogue is a weaker inhibitor. 1. Ling, Li, Liu, *et al.* (1997) *J. Med. Chem.* **40**, 3297. 2. Njar, Kato, Nnane, *et al.* (1998) *J. Med. Chem.* **41**, 902. 3. Njar & Brodie (1999) *Curr. Pharm. Des.* **5**, 163.

**Pyrazon, See Chloridazon**

### 1-Pyrenylglyoxal

This pyrenylated derivative of glyoxal (FW = 258.28 g/mol) is an irreversible inhibitor of E<sub>1</sub> of the pyruvate dehydrogenase complex; an arginyl residue at the active site is modified. **See also Phenylglyoxal**  
**Target(s):** phosphoenolpyruvate carboxykinase (1); and pyruvate dehydrogenase (2). 1. Bazaes, Silva, Goldie, Cardemil & Jabalquinto (1993) *J. Protein Chem.* **12**, 571. 2. Eswaran, Ali, Shenoy, *et al.* (1995) *Biochim. Biophys. Acta* **1252**, 203.

### N-(1-Pyrenyl)maleimide

This fluorescent labeling reagent (FW = 297.31 g/mol) is a *N*-arylmaleimide derivative that reacts with thiol groups to produce fluorescently tagged natural products. Pyrenyl-actin has proven to be a remarkably valuable tool in filament assembly studies, because the filamentous form is some 20-25 times more fluorescent than unpolymerized actin. Nonetheless, modification of actin by this reagent greatly reduces monomeric actin's affinity for profilin and thymosin  $\beta$ 4 (1). **Target(s):** acylglycerol lipase, or monoacylglycerol lipase (2); desulfoglucosinolate sulfotransferase (3); H<sup>+</sup>-translocating pyridine nucleotide transhydrogenase (4); H<sup>+</sup>-translocating pyrophosphatase, vacuolar (5); and 6-phosphofructo-2-kinase (6,7). 1. Kang, Purich & Southwick (1999) *J. Biol. Chem.* **274**, 36963. 2. Saario, Salo, Nevalainen, *et al.* (2005) *Chem. Biol.* **12**, 649. 3. Biophys.* **376**, 313.

### Pyrethrins

These plant-derived insecticides are the active constituents of *Chrysanthemum cinerariaefolium* (or *Pyrethrum cinerariaefolium*). Pyrethrin I (FW = 328.45 g/mol), systematically named as (2Z)-(1S)-2-methyl-4-oxo-3-(penta-2,4-dienyl)cyclopent-2-enyl (+)-*trans*-chrysanthe-mate, is a viscous liquid that oxidizes readily and is quickly inactivated in air and must be stored in the dark and cold. Pyrethrin II (FW = 372.46 g/mol), systematically named as (2Z)-(1S)-2-methyl-4-oxo-3-(penta-2,4-dienyl)cyclopent-2-enyl pyrethrate, is also a viscous liquid that is likewise oxidized in air. Both pyrethrins are practically insoluble in water. These esters also inhibit multidrug-resistant *Mycobacterium tuberculosis*. Formed by the action of chrysanthemyl diphosphate synthase on two molecules of dimethylallyl pyrophosphate, pyrethrins concentrate mainly in the seed cases, where they ward off invasive insects. *Note:* The term pyrethrins also refers to a mixture of natural insecticides that contain various amounts of cinerin I, cinerin II, jasmolin I, jasmolin II, pyrethrin I, and pyrethrin II. **See also synthetic pyrethroids (e.g., Permethrin; Cypermethrin; Deltamethrin)** 1. Kakkko, Toimela & Tahti (2000) *Chemosphere* **40**, 301.

### Pyridine

This aromatic nitrogen heterocycle (FW = 79.101 g/mol; CAS 110-86-1; colorless; M.P. = -41.5° C; B.P. = 115.25° C; unpleasant odor; weak base; pK<sub>a</sub> = 5.23 at 25° C, with dpK<sub>a</sub>/dT = -0.014) has many uses in organic synthesis and analytical chemistry. Pyridine should only be used in a fume hood or where there is sufficient ventilation. Miscible with water, pyridine has a larger dipole moment (2.37 versus 1.87 for water), and a dielectric constant of 12.4 (a sixth that of water). **Target(s):** acid phosphatase (1); adenain (2); alcohol dehydrogenase (3-7); D-amino-acid oxidase, weakly inhibited (8); aromatase, or CYP19 (9); carbonic anhydrase, or carbonate dehydratase, K<sub>i</sub>  $\approx$  0.5 M (10); catechol 2,3-dioxygenase (11,12); chymotrypsin (13); dimethylaniline-*N*-oxide aldolase (14); glucose dehydrogenase, weakly inhibited (15); histidine decarboxylase, K<sub>i</sub> = 1.4 mM (16-18); lipase, or triacylglycerol lipase (19,20); nicotinate phosphoribosyltransferase (21); and xyloglucan:xyloglucosyl transferase (22). 1. **Pyridine-3-aldehyde, See 3-Pyridinecarboxaldehyde**

### 3-Pyridinealdehyde Adenine Dinucleotide

This NAD<sup>+</sup> analogue (FW<sub>ion</sub> = 646.40 g/mol) is an alternative substrate for many oxidoreductases and an inhibitor of others (1-3). The aldehyde moiety

forms a thiohemiacetal linkage with an active-site cysteinyl residue of glyceraldehyde-3-phosphate dehydrogenase and inhibits the dehydrogenase and esterase activities of that enzyme (4). **Target(s):** aldehyde dehydrogenase (5); dihydrolipoamide dehydrogenase (1); glyceraldehyde-3-phosphate dehydrogenase (4,6,7); lactate dehydrogenase (8); NAD<sup>+</sup> kinase (9,10); nicotinamide phosphoribosyl-transferase (2); and nitrate reductase (3). 1. Koike & Hayakawa (1970) *Meth. Enzymol.* **18A**, 298. 2. Dietrich (1971) *Meth. Enzymol.* **18B**, 144. 3. Trimboli & Barber (1994) *Arch. Biochem. Biophys.* **315**, 48. 4. ### 3-Pyridinecarboxaldehyde

This photosensitive aldehyde (FW = 107.11 g/mol; CAS 500-22-1), also known as pyridine-3-aldehyde, 3-pyridylcarboxaldehyde, and nicotin-aldehyde, inhibits xanthine oxidase. **Target(s):** nicotinamidase (1,2); nicotinate phosphoribosyltransferase (3); starch phosphorylase (4); and xanthine oxidase (5). 1. Johnson & Gadd (1974) *Int. J. Biochem.* **5**, 633. 2. Yan & Sloan (1987) *J. Biol. Chem.* **262**, 9082. 3. Imsande (1964) *Biochim. Biophys. Acta* **85**, 255. 4. ### 3-Pyridinecarboxaldehyde N',N'-(Dibenzyl)hydrazine

This substituted hydrazine (FW = 301.39 g/mol) inhibits glucose-6-phosphatase, IC<sub>50</sub> = 3.7 μM (1). The 2- and 4-pyridinecarboxaldehyde analogues are weaker inhibitors, with IC<sub>50</sub> values of 10 and 17 μM, respectively. 1. Madsen, Jakobsen & Westergaard (2001) *Bioorg. Med. Chem. Lett.* **11**, 2165.

### Pyridine-2-carboxaldehyde Thiosemicarbazone

This thiosemicarbazone (FW = 166.23 g/mol) is a strong inhibitor of ribonucleoside-diphosphate reductase. Cell cycle arrest and cell death produced by simple chemicals like N-hydroxyurea and hydroxamates can be traced back to their interaction with metal ions within the ribonucleotide reductase active site. 1. Lammers & Follmann (1983) *Struct. Bonding* **54**, 27.

### Pyridine-2-carboxylic Acid Thiazol-2-ylamide

This amide (FW = 205.24 g/mol), also known as N-1,3-thiazol-2-ylpyridine-2-carboxamide, inhibits *Escherichia coli*, *Saccharomyces cerevisiae*, and human methionyl aminopeptidase, with an IC<sub>50</sub> value of 1.3 μM for the human enzyme (1-5). 1. ### Pyridine-2,4-dicarboxylic Acid

This dicarboxylic acid (FW<sub>free-acid</sub> = 167.12 g/mol), also known as lutidinic acid, is a structural analogue of α-ketoglutarate and accordingly inhibits a number of α-ketoglutarate-dependent enzymes. **Target(s):** γ-butyrobetaine dioxygenase, or γ-butyrobetaine hydroxylase, K<sub>i</sub> = 0.2 μM (1); deoxyhypusine monooxygenase (2,3); flavanone 3-dioxygenase, or flavone 3-dioxygenase (4-6); flavone synthase (6); flavonol synthase (5); homocitrate synthase (7); 6β-hydroxyhyoscyamine epoxidase (8); hyoscyamine (6S)-dioxygenase (9); α-ketoglutarate dehydrogenase (10); nicotinate-nucleotide diphosphorylase (carboxylating), weakly inhibited (11); peptide-aspartate β-dioxygenase (12,13); procollagen-lysine 5-dioxygenase (10); procollagen-proline 3-dioxygenase (10,14); procollagen-proline 4-dioxygenase, or prolyl 4-hydroxylase (10,13,15-25); and proline 4-dioxygenase (26). 1. ### Pyridine-2,5-dicarboxylic Acid

This dicarboxylic acid (FW<sub>free-acid</sub> = 167.12 g/mol), also known as isoinchomeronic acid, is a structural analogue of α-ketoglutarate and will

inhibit a number of  $\alpha$ -ketoglutarate-dependent enzymes. When heated above its melting point of 254°C, this dicarboxylic acid sublimes as nicotinic acid. **Target(s):**  $\gamma$ -butyrobetaine dioxygenase, or  $\gamma$ -butyrobetaine hydroxylase,  $K_i = 14 \mu\text{M}$  (1); deoxyhypusine monoxygenase (2,3); flavanone 3-dioxygenase, or flavone 3-dioxygenase, or naringenin 3-dioxygenase (4); flavonol synthase (5); homocitrate synthase (6);  $\alpha$ -ketoglutarate dehydrogenase (7); nicotinate-nucleotide diphosphorylase (carboxylating), weakly inhibited (8); peptide-aspartate  $\beta$ -dioxygenase (9); procollagen-lysine 5-dioxygenase (7); procollagen-proline 3-dioxygenase (7,10); procollagen-proline 4-dioxygenase, or prolyl 4-hydroxylase (7,9,11-18); and proline 4-dioxygenase (19). 1. **4-Pyridine Disulfide, See 4,4'-Dithiopyridine**

**4,4'-[2,6-Pyridinediylbis(oxy)]bis(benzamidine)**

This substituted benzamidine ( $\text{FW} = 349.39 \text{ g/mol}$ ) inhibits coagulation factor Xa, thrombin, and trypsin, with  $K_i$  values of 400, 550, and 2800 nM, respectively (1,2). 1. Phillips, Davey, Eagen, *et al.* (1999) *J. Med. Chem.* **42**, 1749. 2. Liang, Light, Kochanny, *et al.* (2003) *Biochem. Pharmacol.* **65**, 1407.

**3-Pyridinepropanol, See 3-(3-Pyridyl)-1-propanol**

**Pyridine-3-sulfonamide**

This sulfonamide ( $\text{FW} = 158.18 \text{ g/mol}$ ) inhibits carbonic anhydrase, or carbonate dehydratase (1,2). 1. van Goor (1948) *Enzymologia* **13**, 73. 2. Taylor, King & Burgen (1970) *Biochemistry* **9**, 2638.

**Pyridine-3-sulfonic Acid**

This water-soluble analogue of nicotinic acid ( $\text{FW} = 159.17 \text{ g/mol}$ ), also called 3-pyridylsulfonic acid, is a nicotinamide antagonist in some organisms. Pyridine-3-sulfonic acid is corrosive and decomposes at about 357°C. **Target(s):** alcohol dehydrogenase (1,2); glucose (3); L-lactate dehydrogenase (3); NADase, weakly inhibited (4); and nicotinate phosphoribosyltransferase (5). 1. van Eys & Kaplan (1957) *Biochim. Biophys. Acta* **23**, 574. 2. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 498, Academic Press, New York. 3. von Euler (1942) *Ber.* **75**, 1876. 4. **2-[(Pyridin-2-yl)amino]ethylidene-1,1-bis(phosphonate)**

This bisphosphonate ( $\text{FW}_{\text{ion}} = 280.11 \text{ g/mol}$ ), also known as NE 11808, inhibits geranyltransferase, or farnesyl-diphosphate synthase (1,2). 1. Dunford, Thompson, Coxon, *et al.* (2001) *J. Pharmacol. Exp. Ther.* **296**, 235. 2. Dunford, Kwaasi, Rogers, *et al.* (2008) *J. Med. Chem.* **51**, 2187.

**2-[[2-[[2-(4-Pyridinyl)ethyl]amino]phenyl]sulfonyl]amino]-5,6,7,8-tetrahydro-1-naphthalenecarboxylic Acid**

This substituted anthranilic acid sulfonamide ( $FW_{ion} = 451.54$  g/mol) inhibits methionyl aminopeptidase,  $IC_{50} = 0.016$   $\mu$ M (1). The 2-(2-pyridinyl)ethyl analogue is a slightly weaker inhibitor ( $IC_{50} = 0.053$   $\mu$ M). 1. Sheppard, Wang, Kawai, *et al.* (2006) *J. Med. Chem.* **49**, 3832.

**2-(3-Pyridinyl)ethylidene-1,1-phosphonocarboxylic Acid**

This risedronate analogue ( $FW_{ion} = 228.12$  g/mol), in which a second phosphonate is replaced by a carboxyl group, inhibits protein geranylgeranyltransferase type II. 1. Coxon, Ebetino, Mules, *et al.* (2005) *Bone* **37**, 349.

**2-(Pyridin-4-yl)-1-hydroxyethane-1,1-bis(phosphonic Acid), See 1-Hydroxy-2-(pyridin-4-yl)ethylidene-1,1-bis(phosphonate)**

**2-(3-Pyridinyl)-1-hydroxyethylidene-1,1-phosphonocarboxylate**

This risedronate analogue ( $FW_{ion} = 245.13$  g/mol), also known as NE10790, inhibits geranyltransferase, or farnesyl-diphosphate synthase (1) and protein geranylgeranyltransferase type II (2,3). 1. Dunford, Kwaasi, Rogers, *et al.* (2008) *J. Med. Chem.* **51**, 2187. 2. Coxon, Ebetino, Mules, *et al.* (2005) *Bone* **37**, 349. 3. Wu, Waldmann, Reents, *et al.* (2006) *ChemBiochem* **7**, 1859.

**8-[2-(3-Pyridinyl)-1H-indol-1-yl]octanoic Acid 1-(Carboxymethyl)-3-[[1-carboxy-3-phenylpropyl]-amino]-2,3,4,5-tetrahydro-2-oxo-1H-1-benzazepin-5-yl Ester**

This benzazepinone derivative ( $FW_{free-acid} = 744.89$  g/mol) is a potent inhibitor of peptidyl-dipeptidase A, or human angiotensin-I-converting enzyme ( $IC_{50} = 90$  nM) and thromboxane-A synthase ( $IC_{50} = 20$  nM). 1. Ksander, Erion, Yuan, *et al.* (1994) *J. Med. Chem.* **37**, 1823.

**5-(3'-Pyridinylmethyl)benzofuran-2-carboxylic Acid**

This benzofuran ( $FW_{free-acid} = 253.26$  g/mol), also known as U-63557A, is a potent human thromboxane-A synthase inhibitor in platelets (1-3). A single oral dose of 3.0 mg/kg U-63557A inhibits the platelet thromboxane

synthase in macaques approximately 80% for at least twelve hours. 1. Jones & Fitzpatrick (1991) *J. Biol. Chem.* **266**, 23510. 2. Gorman, Johnson, Spilman & Aiken (1983) *Prostaglandins* **26**, 325. 3. Hall, Tuan & Venton (1986) *Biochem. J.* **233**, 637.

**N-(Pyridin-2-ylmethyl)-N'-(1,3-thiazol-2-yl)oxamide**

This diamide ( $FW = 250.28$  g/mol), also known as *N*-(pyridin-2-ylmethyl)-*N'*-1,3-thiazol-2-ylethanedi-*amide*, inhibits the Co(II) and Mn(II) forms of methionyl aminopeptidase, particularly the former. Intriguingly, although methionine aminopeptidases require a divalent metal ion, such as Mn(II), Fe(II), Co(II), Ni(II), or Zn(II), to catalyze the removal of the *N*-terminal methionine from newly synthesized proteins, it is uncertain which of these ions is most important *in vivo*. 1. Ye, Xie, Huang, *et al.* (2004) *J. Amer. Chem. Soc.* **126**, 13940.

**2-[3-(Pyridin-4-yloxy)benzoylamino]benzoic Acid**

This benzoic acid derivative ( $FW_{ion} = 333.32$  g/mol) inhibits *Enterococcus faecalis*  $\beta$ -ketoacyl-[acyl-carrier-protein] synthase III,  $IC_{50} = 10$   $\mu$ M (1,2). 1. Nie, Perretta, Lu, *et al.* (2005) *J. Med. Chem.* **48**, 1596. 2. Ashek, San Juan & Cho (2007) *J. Enzyme Inhib. Med. Chem.* **22**, 7.

**Pyridin-3-ylpropyl  $\alpha$ -Cyano-3,4-dihydroxycinnamate**

This caffeic acid derivative ( $FW = 425.14$  g/mol) inhibits 12-lipoxygenase (or arachidonate 12-lipoxygenase) and 15-lipoxygenase (or arachidonate 15-lipoxygenase), with respective  $IC_{50}$  values of 0.47 and 3.93  $\mu$ M. 1. Cho, Ueda, Tamaoka, *et al.* (1991) *J. Med. Chem.* **34**, 1503.

**5-(Pyridin-2-yl)-1H-1,2,3-triazole**

This aryl-1,2,3-triazole ( $FW = 145.15$  g/mol) inhibits human methionyl aminopeptidase type 2,  $K_{i,app} = 41$  nM for the Co(II)-substituted protein (1). The 5-(pyridin-3-yl) analogue is a weaker inhibitor ( $K_{i,app} = 260$  nM). 1. Kallander, Lu, Chen, *et al.* (2005) *J. Med. Chem.* **48**, 5644.

**Pyridochromanones**

These so-called chromones are strong inhibitors of *Escherichia coli* and *Mycobacterium tuberculosis*  $NAD^+$ -dependent DNA ligases. Shown above is the most active known chromone ( $FW = 273.22$  g/mol), which exhibits an  $IC_{50}$  value of 0.04  $\mu$ M for the *E. coli* enzyme (1,2). 1. Gong, Martins, Bongiorno, Glickman & Shuman (2004) *J. Biol. Chem.* **279**, 20594. 2. Brötzer-Oesterheld, Knezevic, Bartel, *et al.* (2003) *J. Biol. Chem.* **278**, 39435.

**Pyridoglutethimide, See Rogletimide**

**$\alpha$ -Pyridone, See 2-Hydroxypyridine**

**Pyridostigmine Bromide**

This hygroscopic pyridinium salt (FW = 261.12 g/mol) is a reversible cholinesterases inhibitor, with a  $K_d$  value of 5.5  $\mu$ M for acetylcholinesterase (1-5). It is soluble in water and ethanol and almost insoluble in acetone and diethyl ether. Pyridostigmine is effective in protecting against irreversible inhibitors of acetylcholinesterase such as organophosphates and chemical warfare agents (e.g., soman). **Target(s):** acetylcholinesterase (1-5); catalytic antibody with acetylcholinesterase activity (5); cholinesterase, or butyrylcholinesterase (2,6,7); and microtubule assembly, or tubulin polymerization (8). 1. Forsberg & Puu (1984) *Eur. J. Biochem.* **140**, 153. 2. Xia, Wang & Pei (1981) *Fundam. Appl. Toxicol.* **1**, 217. 3. Laine-Cessac, Turcant, Premel-Cabic, Boyer & Allain (1993) *Res. Commun. Chem. Prasad, Scotch, Chaudhuri, et al. (2000) *Neurochem. Res.* **25**, 19.

**Pyridoxal**

This photosensitive aldehyde form of vitamin B<sub>6</sub> (FW = 167.16 g/mol), systematically referred to as 3-hydroxy-5-(hydroxymethyl)-2-methyl-4-pyridinecarboxaldehyde, is the immediate precursor to the coenzyme pyridoxal 5'-phosphate (PLP) and is often a weaker competitive inhibitor of PLP binding to PLP-dependent enzymes). Pyridoxal is soluble in water (1 g/2 mL) and sensitive to heat, particularly at alkaline pH. The pK<sub>a</sub> values are 4.23 (phenol OH), 8.70 (pyridinium NH<sup>+</sup>), and 13.0. Pyridoxal has a  $\lambda_{\text{max}}$  value of 252 nm at pH 7.0 ( $\epsilon = 8200 \text{ M}^{-1}\text{cm}^{-1}$ ). It is typically supplied as the hydrochloride. **Target(s):** O-acetylhomoserine aminocarboxyltransferase, or O-acetylhomoserine (thiol)-lyase (1); alanine racemase (2); aldehyde dehydrogenase (3); arginine decarboxylase (4,5,25); cystathionine  $\beta$ -lyase, or cystine lyase (6); cysteine synthase (34); dextranucrase (7);  $\beta$ -fructofuranosidase, or invertase (8-10,27-32); glutamate dehydrogenase (11-13); hemoglobin S polymerization (14,15); hydroxyacyl-glutathione hydrolase, or glyoxalase II (16); kynurenine 3-monooxygenase (37); lactoylglutathione lyase, or glyoxalase I (16); NMN nucleosidase (26); phosphopantothenoylcysteine decarboxylase (17-19); porphobilinogen synthase, or  $\delta$ -aminolevulinatase (20); pyridoxal kinase (21); pyridoxal phosphatase, weakly inhibited (33); starch phosphorylase (35); thiamin phosphatase (22); tyrosinase (23); and xanthine dehydrogenase (24,36). 1. **Pyridoxal 5'-Phosphate**

This vitamin B<sub>6</sub>-derived coenzyme (FW<sub>free-acid</sub> = 247.14 g/mol; CAS 853645-22-4), often abbreviated PLP, plays a central role in metabolism. In addition to facilitating aminotransfer reactions, PLP is a coenzyme in reactions involving: (a) loss of the  $\alpha$ -proton, resulting in racemization, cyclization, or  $\beta$ -elimination/replacement (e.g., alanine racemase, 1-aminocyclopropane-1-carboxylate synthase, and serine dehydratase, respectively); (b) loss of the  $\alpha$ -carboxylate as carbon dioxide (e.g., glutamate decarboxylase); (c) removal/replacement of a group by aldol cleavage (e.g., threonine aldolase); and (d) catalysis via ketimine intermediates (e.g., selenocysteine lyase). PLP is also often employed as an inhibitor and site-directed, conformationally sensitive reporter group for studying the environment of reactive amino groups within proteins. PLP forms aldimine adducts that can be reduced with nucleophilic reducing reagents such as sodium borohydride or sodium cyanoborohydride. Solid

PLP is light-sensitive, and solutions should be prepared fresh. There are four  $pK_a$  values associated with this coenzyme: a  $pK_a < 2.5$  and another at 6.20 for the phosphate group, a  $pK_a$  of 4.14 for the hydroxyl group, and a  $pK_a$  of 8.69 for the pyridinium group. The coenzyme has an ultraviolet/visible spectrum:  $\lambda_{max} = 330$  nm and 388 nm ( $\epsilon = 2500$  and 4900  $M^{-1}cm^{-1}$ , respectively) in 50 mM phosphate buffer at pH 7.0;  $\lambda_{max} = 305$  nm and 388 nm ( $\epsilon = 1100$  and 6550  $M^{-1}cm^{-1}$ , respectively) in 100 mM NaOH. Pyridoxal 5'-phosphate may also be used as a photosensitizing agent to modify nearby aminoacyl residues (e.g., histidyl residues in 6-phosphogluconate dehydrogenase and tryptophanase). **Target(s):** acetylcholinesterase (143,160); acetyl-CoA carboxylase (2); acetyl-CoA synthetase, or acetate:CoA ligase (3); *N*-acetylneuraminyl 4-*O*-acetyltransferase (190); acyl-[acyl-carrier-protein]:UDP-*N*-acetylglucosamine *O*-acyltransferase, followed by  $NaBH_4$  reduction (188); acylphosphatase (4,5); adenylate cyclase (6-8); [ $\beta$ -adrenergic-receptor] kinase (9,17); alanine racemase (10,11); alcohol dehydrogenase, followed by  $NaBH_4$  reduction (12); alcohol sulfotransferase (170); aldose reductase (13); allantoinase (159); *N*-(5-amino-5-carboxypentanoyl)-L-cysteiny-D-valine synthetase (14); 5-aminolevulinic synthase, in the presence of borohydride (191); aryl-acylamidase (160); aspartate carbamoyltransferase (15-17); aspartyl aminopeptidase (162); ATP-dependent deoxyribonuclease (18); *Bgl*I restriction endonuclease, type II site-specific deoxyribonuclease (19); biliverdin reductase (20); carbonic anhydrase, or carbonate dehydratase (151); casein kinase II (21,22); catechol *O*-methyltransferase (23); cathepsin B (24,161); cathepsin K (24,161); cathepsin L (24,161); cathepsin S (24,161);  $Ca^{2+}$ -transporting ATPase (25); cerebroside sulfotransferase (26); cholesterol monooxygenase, side-chain cleaving, or cytochrome P450<sup>sc</sup> (27);  $\zeta$ -crystallin/NADPH:quinone oxidoreductase (28); cytosine deaminase (157,158); dextranucrase (29,30,185); dipeptidyl-peptidase I, or cathepsin C (161); DNA-directed DNA polymerase (31-36,173);  $\phi 29$  DNA polymerase (37); DNA topoisomerase I (36); DNA topoisomerase II (36); dopa decarboxylase (38); estrone sulfotransferase (170); exodeoxyribonuclease V (39);  $F_1$  ATPase, or  $H^+$ -transporting two-sector ATPase (40); fatty-acid synthase, at enoyl-[acyl-carrier protein] reductase (41-43,189); fatty-acyl-CoA synthase, yeast, at 3-ketoacyl-[acyl-carrier protein] reductase step (43); flavin-containing monooxygenase (197);  $\beta$ -fructofuranosidase, or invertase (44,164); fructose-1,6-bisphosphate aldolase (15,45-47,152); fructose-6-phosphate 2-kinase/fructose-2,6-bisphosphatase (48);  $\alpha 1 \rightarrow 3$  fucosyltransferase (49); galactosylceramide sulfotransferase (169); glucan 1,4- $\alpha$ -glucosidase, or glucoamylase, weakly inhibited (166); glucose-6-phosphatase (50); glucose-1-phosphate adenyltransferase (172); glucose-6-phosphate dehydrogenase (51-53);  $\alpha$ -glucosidase (165); glucuronate reductase (54); glutamate decarboxylase (55,56); glutamate dehydrogenase (57-61); glutathione-disulfide reductase (62,63); glutathione synthetase, slowly inhibited (64); glyceraldehyde-3-phosphate dehydrogenase (65-67); glycerol-1,2-cyclic-phosphate phosphodiesterase (167); glycerol dehydrogenase (68); glycogen phosphorylase (69); glycolipid sulfotransferase (70); glycoprotein *N*-acetylglucosaminyltransferase (71); glycoprotein 6- $\alpha$ -L-fucosyltransferase (183); glycoprotein galactosyltransferase (71); glycoprotein sialyltransferase (71); hemoglobin S polymerization (72); hexokinase (73); HIV (human immunodeficiency virus) reverse transcriptase (74,75);  $H^+/K^+$ -exchanging ATPase (76); homoserine kinase (176);  $H^+$ -transporting ATPase, chloroplast (77); 2'-hydroxybiphenyl-2-sulfinate desulfinate (156);  $\omega$ -hydroxy-fatty-acid:NADP<sup>+</sup> oxidoreductase (78); hydroxyindole-*O*-methyltransferase (acetylserotonin *O*-methyltransferase (79,80); hydroxymethylbilane synthase (180); 4-hydroxyphenylpyruvate dioxygenase (19,80); inositol-phosphate phosphatase (168); inositol-3-phosphate synthase, or inositol-1-phosphate synthase (81); integrase, HIV (173);  $\alpha$ -ketoglutarate carrier (82);  $\alpha$ -ketoglutarate dehydrogenase (83); kynurenine 3-monooxygenase (195,196); lactate dehydrogenase (84); lactoylglycathione lyase, or glyoxalase I (144); malate dehydrogenase (85); malate synthase (187); methanol:5-hydroxybenzimidazolylcobamide *C*-methyltransferase (192); mevalonate kinase (86); murine leukemia virus reverse transcriptase (87); myosin ATPase (88); NAD(P)<sup>+</sup> transhydrogenase (89);  $Na^+/K^+$ -exchanging ATPase (90); neuraminidase (91); NMN nucleosidase, weakly inhibited (163); nucleoside-diphosphatase (92); pancreatic ribonuclease, or ribonuclease A (93-101); phenol 2-monooxygenase (102); phenol sulfotransferase, or aryl sulfotransferase (103); phenylalanyl-tRNA synthetase (104); phosphoenolpyruvate carboxylase (105); phosphofructokinase (106-108); phosphogluconate dehydrogenase (109-111); phosphoglucose isomerase (112-114); 3-phosphoglycerate kinase (115); phospholipase C (116); phosphomevalonate

kinase (174); phosphopantothenoylcysteine decarboxylase (117,118,153-155); phosphoribulokinase (119,177); porphobilinogen synthase, or  $\delta$ -aminolevulinic dehydratase (149,150); pyridoxamine:oxaloacetate aminotransferase (178,179); pyridoxine 4-oxidase (120); pyruvate dehydrogenase (121); pyruvate kinase (122,175); pyruvate,orthophosphate dikinase (123,124); retinal oxidase (125); ribonuclease A (93-101); ribonucleoside-diphosphate reductase (126,193,194); ribosomal proteins (127); ribulose-1,5-bisphosphate carboxylase (128,129); RNA-directed DNA polymerase, or reverse transcriptase (130,131); RNA polymerase (132-134); serine-sulfate ammonia-lyase (145); starch phosphorylase (186); starch synthase (184); succinic-semialdehyde dehydrogenase (135); thiamin-phosphate pyrophosphorylase (136); thymidylate synthase (137,138); tissue-specific transcription factor HNF1 (139); tryptophanase (140); tryptophan synthase (15); uracilylalanine synthase (181,182); urocanase (141); uroporphyrinogen-III synthase (146-148); xanthine dehydrogenase, *Drosophila melanogaster* (142). 1. #### Pyridoxal-5'-phosphate-6-azo(benzene-2,4-disulfonic Acid)

This reagent (FW<sub>ion</sub> = 330.35 g/mol), often abbreviated PPADS and also known as 4-[[4-formyl-5-hydroxy-6-methyl-3-[(phosphonoxy)methyl]-2-pyridinyl]-azo]-1,3-benzenedisulfonic acid, is a functionally selective antagonist of P2 purinoceptors. **Target(s):** apyrase (1); ecto-ATPase (1-5); nucleotide diphosphatase, ecto-nucleotide pyrophosphatase (5-7); and P2 purinoceptor (8). **1.** Ziganshin, Zigashina, Bodin, Bailey & Burnstock (1995) *Biochem. **Pyridoxal-5'-phosphate- $\gamma$ -L-Glutamyl Hydrazone**

This amino acyl hydrazone ( $FW_{ion} = 386.26$  g/mol) inhibits glutamate decarboxylase (1). 1. Tapia & Salazar (1991) *Neurochem. Res.* **16**, 263.

**Pyridoxal-5'-phosphate-6-(2'-naphthylazo-6'-nitro-4',8'-disulfonate, See PPNDS****Pyridoxal 5'-Phosphate Oxime**

This oxime of pyridoxal 5'-phosphate ( $FW = 259.13$  g/mol), which is practically insoluble in water, ethanol, and diethyl ether, inhibits aromatic-L-amino-acid decarboxylase, or DOPA decarboxylase (1), pyridoxamine-phosphate oxidase (2), and pyridoxine 4-oxidase (3). 1. Gonnard, Camier, Boigne, Duhault & Nguyen-Philippon (1965) *Enzymologia* **28**, 211. 2. Merrill, Kazarinoff, Tsuge, Horiike & McCormick (1979) *Meth. Enzymol.* **62**, 568. 3. Korytnyk & Ikawa (1970) *Meth. Enzymol.* **18A**, 524.

**Pyridoxal 5'-Phosphate Oxime-O-acetic Acid**

This pyridoxal 5'-phosphate derivative ( $FW_{ion} = 317.17$  g/mol), which is readily prepared by the reaction of pyridoxal 5'-phosphate with (aminoxy)acetic acid (i.e., carboxymethoxylamine), inhibits glutamate decarboxylase and is believed to be an analogue of the aldimine intermediate. 1. Tapia & Sandoval (1971) *J. Neurochem.* **18**, 2051.

**Pyridoxal Semicarbazone**

This semicarbazone ( $FW = 224.22$  g/mol) inhibits pyridoxal kinase (1-3). 1. Korytnyk & Ikawa (1970) *Meth. Enzymol.* **18A**, 524. 2. Webb (1966)

*Enzyme and Metabolic Inhibitors*, vol. 2, p. 564, Academic Press, New York. 3. McCormick & Snell (1961) *J. Biol. Chem.* **236**, 2085.

**Pyridoxal 5'-Sulfate**

This pyridoxal 5'-phosphate analogue ( $FW_{ion} = 246.22$  g/mol) inhibits glutamate decarboxylase (1) and hemoglobin S polymerization (2). 1. Korytnyk & Ikawa (1970) *Meth. Enzymol.* **18A**, 524. 2. Benesch, Benesch & Yung (1974) *Proc. Natl. Acad. Sci. U.S.A.* **71**, 1504.

**Pyridoxal 5'-Triphospho-5'-adenosine, See ATP-Pyridoxal****Pyridoxal 5'-Triphospho-5'-guanosine, See GTP-pyridoxal****Pyridoxamine**

This photosensitive vitamer ( $FW_{dihydrochloride} = 241.12$  g/mol; CAS 524-36-7; Solubility:  $\sim 0.5$  g/mL  $H_2O$ ;  $pK_a$  values: 3.54 (the unusually acidic phenolic OH group), 8.21 (pyridinium NH), and 10.63 (primary amine)), also known as 4-(aminomethyl)-5-(hydroxymethyl)-2-methylpyridin-3-ol, is formed during digestion by enzymatic hydrolysis of dietary pyridoxamine-5-P and absorbed within the jejunum. The ionized phenolic hydroxyl and the methylamino groups probably account for the ability of pyridoxamine to coordinate with Cu(II) and Fe(II) ions. The 3'-hydroxyl group of pyridoxamine is thought to play an important role in scavenging free radicals. Pyridoxamine also blocks the formation of advanced glycation end-products formed by the Maillard reaction and associated with medical complications in diabetes. Pyridoxamine is believed to trap intermediates in the formation of Amadori products released from glycated proteins. Pyridoxamine is commonly supplied as the dihydrochloride and should be stored in tightly closed containers in desiccator. **Target(s):** alanine racemase (1); amine oxidase (2,3); dextranucrase (4);  $\beta$ -fructofuranosidase, or invertase (5-8); hydroxyacylglutathione hydrolase, or glyoxalase II (9); lactoylglutathione lyase, or glyoxalase I (9); pyridoxal dehydrogenase (10,11); pyridoxamine-5-phosphate oxidase (12); starch phosphorylase (13); and tyrosinase (14). 1. Olivard & Snell (1955) *J. Biol. Chem.* **213**, 203. 2. Tabor, Tabor & Rosenthal (1955) *Meth. Enzymol.* **2**, 390. 3. Zeller (1951) *The Enzymes*, 1st ed. **Pyridoxamine 5-Phosphate**

This vitamin B<sub>6</sub> metabolite (FW = 248.18 g/mol) is derived biosynthetically from pyridoxamine and by transamination from pyridoxal 5'-phosphate. The hygroscopic solid is light-sensitive, and solutions should be prepared freshly, despite their stability when stored cold and in the absence of light. Solutions are more labile under alkaline conditions. There are four pK<sub>a</sub> values associated with this coenzyme: a value less than 2.5 and a value of 5.76 for the phosphate group, 3.69 for the hydroxyl group, 8.61 for the pyridinium group, and 10.92 for the primary amine. The coenzyme has an ultraviolet/visible spectrum: λ<sub>max</sub> = 254 nm and 327 nm (ε = 5200 and 9400 M<sup>-1</sup>cm<sup>-1</sup>, respectively) at pH 7.2; λ<sub>max</sub> = 244 nm and 312 nm (ε = 7500 and 8300 M<sup>-1</sup>cm<sup>-1</sup>, respectively) at pH 10. (**See also Pyridoxal 5'-Phosphate**) **Target(s):** dextranucrase (1); glutamine:fructose-6-phosphate aminotransferase, isomerizing (2,3); phenol 2-monooxygenase, weakly inhibited (4); phosphomevalonate kinase (5); phosphoprotein phosphatase, weakly inhibited (6); porphobilinogen synthase, or δ-aminolevulinate dehydratase (7); pyridoxal kinase (8); pyridoxal phosphatase, also as an alternative substrate (9); pyridoxamine:oxaloacetate aminotransferase (10,11); starch phosphorylase (12); tyrosinase (13); and tyrosine aminotransferase (14). 1. Thaniyavarn, Taylor, Singh & Doyle (1982) *Infect. Immun.* **37**, 1101. 2. Pogell (1962) *Meth. Enzymol.* **5**, 408. 3. Gryder & Pogell (1960) *J. Biol. Chem.* **235**, 558. 4. #### 4-Pyridoxic Acid

This oxidized derivative (FW = 171.15 g/mol) of pyridoxal is the chief catabolic product of pyridoxine, pyridoxal, and pyridoxamine degradation; it can be isolated from human urine. The carboxyl group has a pK<sub>a</sub> value of 5.50 while the phenolic OH has a value of 9.75. 4-Pyridoxic acid has a blue fluorescence which is maximal between pH 3 and 4. Heating 4-pyridoxic acid in 0.5 N acid will convert the metabolite to its lactone, which has an even stronger fluorescence. **Target(s):** dextranucrase (1); glucose dehydrogenase (2,3); pyridoxal dehydrogenase (4,5); and pyridoxamine-phosphate oxidase (6). 1. Thaniyavarn, Taylor, Singh & Doyle (1982) *Infect. Immun.* **37**, 1101. 2. Streckler (1955) *Meth. Enzymol.* **1**, 335. 3. Brink (1953) *Acta Chem. Scand.* **7**, 1090. 4. Burg (1970) *Meth. Enzymol.* **18A**, 634. 5. Burg & Snell (1969) *J. Biol. Chem.* **244**, 2585. 6. Wada & Snell (1961) *J. Biol. Chem.* **236**, 2089.

#### 5-Pyridoxic Acid

This pyridoxine metabolite (FW = 171.15 g/mol), also known as 3-hydroxy-4-hydroxymethyl-2-methylpyridine-5-carboxylate and isopyridoxic acid, inhibits 3-hydroxy-2-methylpyridinecarboxylate dioxygenase (1-3). 1. Burg (1970) *Meth. Enzymol.* **18A**, 634. 2. Sparrow, Ho, Sundaram, *et al.* (1969) *J. Biol. Chem.* **244**, 2590. 3. Kishore & Snell (1981) *J. Biol. Chem.* **256**, 4234.

#### Pyridoxine

This essential nutritional factor vitamin B<sub>6</sub> (FW<sub>free-base</sub> = 169.18 g/mol), also called pyridoxol, is a white solid that is typically supplied as the hydrochloride (the two pK<sub>a</sub> values are 4.94 and 8.89). (*Note:* The term vitamin B<sub>6</sub> actually refers to a mixture of pyridoxine, pyridoxal, and pyridoxamine.) Pyridoxine is stable in light and air, but is somewhat photolabile in neutral and alkaline solutions. It is soluble in water (1 g/4.5 mL) and has λ<sub>max</sub> values at 253 and 325 nm at pH 7 in phosphate buffer (ε = 3700 and 7100 M<sup>-1</sup>cm<sup>-1</sup>, respectively). Pyridoxine is a substrate of the reactions catalyzed by pyridoxine 4-dehydrogenase, pyridoxine 4-oxidase, pyridoxine 5-dehydrogenase, and pyridoxine 5'-O-β-D-glucosyltransferase. **Target(s):** alanine racemase (1); arginine decarboxylase (2,3); dextranucrase (4); β-fructofuranosidase, or invertase (5-10); glycogen phosphorylase b (11); hydroxymethylpyrimidine kinase, also alternative substrate, K<sub>i</sub> = 2.7 μM (12); pyridoxal dehydrogenase (13,14); pyridoxamine-5-phosphate oxidase (15); pyridoxamine: pyruvate aminotransferase (13,16); tyrosinase (17). 1. #### N-(4-Pyridoxyl)-L-alanine

This amino acid-vitamin B<sub>6</sub> conjugate (FW<sub>ion</sub> = 240.26 g/mol) strongly inhibits pyridoxamine:pyruvate aminotransferase, K<sub>i</sub> = 0.18 μM (1-4). 1. Dempsey & Snell (1963) *Biochemistry* **2**, 1414. 2. Korytnyk & Ikawa (1970) *Meth. Enzymol.* **18A**, 524. 3. Burg (1970) *Meth. Enzymol.* **18A**, 634. 4. Wolfenden (1977) *Meth. Enzymol.* **46**, 15.

#### Pyridoxal-5'-phosphate-6-azo(benzene-2,4-disulfonic Acid)

This PLP adduct (FW = 507.35 g/mol), often abbreviated PPADS and also known as 4-[4-formyl-5-hydroxy-6-methyl-3-[(phosphonoxy)methyl]-2-pyridinyl]azo]-1,3-benzenedisulfonic acid, is a functionally selective antagonist of P2 purinoceptors. **Target(s):** apyrase (1); ecto-ATPase (1-5); nucleotide diphosphatase, ecto-nucleotide pyrophosphatase (5-7); and P2 purinoceptor (8). 1. Ziganshin, Zigashina, Bodin, Bailey & Burnstock (1995) *Biochem. Mol. Biol. Int.* **36**, 863. 2. Yegutkin & Burnstock (2000) *Biochim. Biophys. Acta* **1466**, 234. 3. Chen & Lin (1997) *Biochem. Pharmacol.* **217**, 217.

#### Pyridoxal-5'-phosphate-6-(2'-naphthylazo-6'-nitro-4',8'-disulfonate, See PPNDS

#### Pyridoxal 5'-Phosphate Oxime

This oxime of pyridoxal 5'-phosphate (FW = 260.14 g/mol), which is practically insoluble in water, ethanol, and diethyl ether, inhibits aromatic-L-amino-acid decarboxylase, or DOPA decarboxylase (1), pyridoxamine-phosphate oxidase (2), and pyridoxine 4-oxidase (3). 1. Gonnard, Camier, Boigne, Duhault & Nguyen-Philippon (1965) *Enzymologia* **28**, 211. 2. Merrill, Kazarinoff, Tsuge, Horiike & McCormick (1979) *Meth. Enzymol.* **62**, 568. 3. Korytnyk & Ikawa (1970) *Meth. Enzymol.* **18A**, 524.

#### Pyridoxal Semicarbazone

This semicarbazone (FW = 224.22 g/mol), formed by the combination of pyridoxal and semicarbazide, inhibits pyridoxal kinase (1-3). 1. Korytnyk & Ikawa (1970) *Meth. Enzymol.* **18A**, 524. 2. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 564, Academic Press, New York. 3. McCormick & Snell (1961) *J. Biol. Chem.* **236**, 2085.

#### Pyridoxamine

This key metabolite (FW<sub>dihydrochloride</sub> = 241.12 g/mol; CAS 524-36-7; photosensitive; deliquescent, Solubility ~0.5 g/mL H<sub>2</sub>O, pK<sub>a</sub> values of 3.54 (the unusually acidic phenolic OH group), 8.21 (pyridinium NH), and 10.63 (primary amine)) is formed from vitamin B<sub>6</sub>. The ionized phenolic hydroxyl and the methylamino groups probably account for its ability to coordinate with Cu(II) and Fe(II) ions. The 3'-hydroxyl group is thought to play an important role in scavenging free radicals. Pyridoxamine also blocks formation of advanced glycation end-products that are formed by the Maillard reaction. Pyridoxamine is believed to trap intermediates in the formation of Amadori products released from glycated proteins. Pyridoxamine is commonly supplied as the dihydrochloride and should be stored in tightly closed containers in desiccator. **Target(s):** alanine racemase (1); amine oxidase (2,3); dextranucrase (4); β-fructofuranosidase, or invertase (5-8); hydroxyacylglutathione hydrolase, or glyoxalase II (9);

lactoylglutathione lyase, or glyoxalase I (9); pyridoxal dehydrogenase (10,11); pyridoxamine-5-phosphate oxidase (12); starch phosphorylase (13); and tyrosinase (14). 1. Olivard & Snell (1955) *J. Biol. Chem.* **213**, 203. 2. Tabor, Tabor & Rosenthal (1955) *Meth. Enzymol.* **2**, 390. 3. Zeller (1951) *The Enzymes*, 1st ed. (Sumner & Myrbäck, eds.), **2** (part 1), 536. 4. Agric. Food Chem.* **51**, 2733.

#### Pyridoxamine 5'-Phosphate

This vitamin B<sub>6</sub> metabolite (FW = 248.18 g/mol; CAS 529-96-4) is derived biosynthetically from pyridoxamine and by transamination from pyridoxal 5'-phosphate. The hygroscopic solid is light-sensitive, and solutions should be prepared freshly, despite their stability when stored cold and in the absence of light. Solutions are more labile under alkaline conditions. There are four pK<sub>a</sub> values associated with this coenzyme: a value less than 2.5 and a value of 5.76 for the phosphate group, 3.69 for the hydroxyl group, 8.61 for the pyridinium group, and 10.92 for the primary amine. The coenzyme has an ultraviolet/visible spectrum: λ<sub>max</sub> = 254 nm and 327 nm (ε = 5200 and 9400 M<sup>-1</sup>cm<sup>-1</sup>, respectively) at pH 7.2; λ<sub>max</sub> = 244 nm and 312 nm (ε = 7500 and 8300 M<sup>-1</sup>cm<sup>-1</sup>, respectively) at pH 10. **See also Pyridoxal 5'-Phosphate Target(s):** dextranucrase (1); glutamine:fructose-6-phosphate aminotransferase, isomerizing (2,3); phenol 2-monooxygenase, weakly inhibited (4); phosphomevalonate kinase (5); phosphoprotein phosphatase, weakly inhibited (6); porphobilinogen synthase, or δ-aminolevulinic acid dehydratase (7); pyridoxal kinase (8); pyridoxal phosphatase, also as an alternative substrate (9); pyridoxamine:oxaloacetate aminotransferase (10,11); starch phosphorylase (12); tyrosinase (13); and tyrosine aminotransferase (14). 1. #### 4-Pyridoxic Acid

This oxidized derivative (FW<sub>ion</sub> = 180.14 g/mol) of pyridoxal is the chief catabolic product of pyridoxine, pyridoxal, and pyridoxamine degradation; it can be isolated from human urine. The carboxyl group has a pK<sub>a</sub> value of 5.50 while the phenolic OH has a value of 9.75. 4-Pyridoxic acid has a blue fluorescence which is maximum between pH 3 and 4. Heating 4-pyridoxic acid in 0.5 N acid will convert the metabolite to the lactone, which has a stronger fluorescence. **Target(s):** dextranucrase (1); glucose dehydrogenase (2,3); pyridoxal dehydrogenase (4,5); and pyridoxamine-phosphate oxidase (6). 1. Thaniyavarn, Taylor, Singh & Doyle (1982) *Infect. Immun.* **37**, 1101. 2. Strecker (1955) *Meth. Enzymol.* **1**, 335. 3.

#### 5-Pyridoxic Acid

This pyridoxine metabolite (FW = 183.16 g/mol), also known as 3-hydroxy-4-hydroxymethyl-2-methylpyridine-5-carboxylate and isopyridoxic acid, inhibits 3-hydroxy-2-methylpyridinecarboxylate dioxygenase. It is a substrate for 5-pyridoxate dioxygenase. **Target(s):** 3-hydroxy-2-methylpyridinecarboxylate dioxygenase (1-3). **1.** Burg (1970) *Meth. Enzymol.* **18A**, 634. **2.** Sparrow, Ho, Sundaram, *et al.* (1969) *J. Biol. Chem.* **244**, 2590. **3.** Kishore & Snell (1981) *J. Biol. Chem.* **256**, 4234.

#### Pyridoxine

This nutritionally essential factor (FW<sub>free base</sub> = 169.18 g/mol; CAS 65-23-6), also called vitamin B<sub>6</sub> and pyridoxol, is a white solid that is typically supplied as the hydrochloride (the two pK<sub>a</sub> values are 4.94 and 8.89). (*Note:* The term vitamin B<sub>6</sub> actually refers to a mixture of pyridoxine, pyridoxal, and pyridoxamine.) Pyridoxine is stable in light and air, but is somewhat photolabile in neutral and alkaline solutions. It is soluble in water (1 g/4.5 mL) and has λ<sub>max</sub> values at 253 and 325 nm at pH 7 in phosphate buffer (ε = 3700 and 7100 M<sup>-1</sup>cm<sup>-1</sup>, respectively). Pyridoxine is a substrate of the reactions catalyzed by pyridoxine 4-dehydrogenase, pyridoxine 4-oxidase, pyridoxine 5-dehydrogenase, and pyridoxine 5'-O-β-D-glucosyltransferase. **Target(s):** alanine racemase (1); arginine decarboxylase (2,3); dextranucrase (4); β-fructofuranosidase, *or* invertase (5-10); glycogen phosphorylase *b* (11); hydroxymethylpyrimidine kinase, also alternative substrate; K<sub>i</sub> = 2.7 μM (12); pyridoxal dehydrogenase (13,14); pyridoxamine-5-phosphate oxidase (15); pyridoxamine:pyruvate aminotransferase (13,16); and tyrosinase (17). **1.** Olivard & Snell (1955) *J. #### N-(4-Pyridoxyl)-L-alanine

This amino acid-vitamin B<sub>6</sub> conjugate (FW = 224.26 g/mol) strongly inhibits pyridoxamine:pyruvate aminotransferase, K<sub>i</sub> = 0.18 μM (1-4). **1.**

Dempsey & Snell (1963) *Biochemistry* **2**, 1414. **2.** Korytnyk & Ikawa (1970) *Meth. Enzymol.* **18A**, 524. **3.** Burg (1970) *Meth. Enzymol.* **18A**, 634. **4.** Wolfenden (1977) *Meth. Enzymol.* **46**, 15.

#### N-(4-Pyridoxylidene)phenethylamine

This pyridoxal-phenethylamine adduct (FW = 270.33 g/mol), which has been identified in the urine of individuals with phenylketonuria, inhibits pyridoxal kinase (1-2). **1.** Korytnyk & Ikawa (1970) *Meth. Enzymol.* **18A**, 524. **2.** Loo & Whittaker (1967) *J. Neurochem.* **14**, 997.

#### N-(4-Pyridoxyl-5'-phosphate)-L-dopa

This pyridoxal 5'-phosphate conjugate (FW = 426.32 g/mol), also known as N-(5'-phospho-4-pyridoxyl)-L-dopa and N-(4-pyridoxyl-5'-phosphate)-L-3,4-dihydroxy-phenylalanine, inhibits aromatic-L-amino-acid decarboxylase, *or* dopa decarboxylase. **1.** Jung (1986) *Bioorg. Chem.* **14**, 429.

**(R)-(+)-N-(4-Pyridyl)-4-(1-aminoethyl)benzamide**, See **(R)-(+)-4-(1-Aminoethyl)-N-(4-pyridyl)benzamide**

#### 17-(3-Pyridyl)androsta-5,16-dien-3β-ol

This synthetic steroid (FW = 351.26 g/mol) inhibits steroid 17α-monooxygenase, human IC<sub>50</sub> = 4 nM (1,2). The 2-pyridyl and 4-pyridyl analogues are weaker inhibitors (human IC<sub>50</sub> = 270 and 4000 nM, respectively). **1.** Njar & Brodie (1999) *Curr. Pharm. Des.* **5**, 163. **2.** Potter, Barrie, Jarman & Rowlands (1995) *J. Med. Chem.* **38**, 2463.

#### 4-(2-Pyridylazo)resorcinol

This metal ion chelator (FW<sub>free-acid</sub> = 215.21 g/mol), which has been used in the determination of trace amounts of Cr<sup>3+</sup>, inhibits many metalloenzymes, including: alcohol dehydrogenase (1); collagenase (2); 4-methoxybenzoate monooxygenase (*O*-demethylating), weakly inhibited (3); and protein-S-prenylcysteine *O*-methyltransferase (4). **1.** Zhang & Zhou (1996) *J. Enzyme Inhib.* **10**, 239. **2.** Springman, Nagase, Birkedal-Hansen & Van Wart (1995) *Biochemistry* **34**, 15713. **3.** Bernhardt, Nastainczyk & Seydewitz (1977) *Eur. J. **1-[N<sup>α</sup>-(4-Pyridylcarboxy)-L-leucylamino]-3-(phenoxyphenylsulfonamido)-2-propanone**

This substituted diaminopropanone (FW = 538.62 g/mol) is a strong reversible inhibitor of cathepsin K, apparent  $K_i = 13$  nM. 1. Yamashita, Smith, Zhao, *et al.* (1997) *J. Amer. Chem. Soc.* **119**, 11351.

**3-(2-Pyridyl)-5,6-diphenyl-1,2,4-triazine-4',4''-disulfonate**

This chelator, also known as ferrozine (FW<sub>free-acid</sub> = 470.49 g/mol), binds cobalt, silver, copper, nickel, and iron ions, the latter with particularly high affinity. **Target(s):** CMP-*N*-acetylneuraminase monooxygenase (1-5). 1. Schlenzka, Shaw, Schneckeburger & Schauer (1994) *Glycobiology* **4**, 675. 2. Schlenzka, Shaw & Schauer (1993) *Biochim. Biophys. Acta* **1161**, 131. 3. Gollub & Shaw (2003) *Comp. Biochem. Physiol. B Biochem. Mol. Biol.* **134**, 89. 4. Gollub, Schauer & Shaw (1998) *Comp. Biochem. Physiol. B Biochem. Mol. Biol.* **120**, 605. 5. Shaw, Schneckeburger, Carlsen, Christiansen & Schauer (1992) *Eur. J. Biochem.* **206**, 269.

**Pyridyldithioethylamine**

This sulfhydryl-reactive reagent (FW<sub>free-base</sub> = 186.30 g/mol) inhibits the phospholipid-translocating ATPase, also known as flippase (1,2) and inhibits taurine transport (3). In general, the pyridine-thiolate is the leaving group in a reaction that transfers a thioethylamine to a reactive thiol on susceptible enzyme targets. 1. Connor & Schroit (1991) *Biochim. Biophys. Acta* **1066**, 37. 2. Connor & Schroit (1988) *Biochemistry* **27**, 848. 3. Dumaswala & Brown (1996) *Placenta* **17**, 329.

**(S)-1-(4-Pyridyl)ethyl 1-Adamantanecarboxylate**

This ester (FW = 270.35 g/mol) inhibits human steroid 17 $\alpha$ -monooxygenase,  $IC_{50} = 3.3$  nM, and aromatase, *or* CYP19,  $IC_{50} = 5.6$   $\mu$ M (1). The (*R*)-1-(4-pyridyl)ethyl epimer is a weaker inhibitor ( $IC_{50} = 340$  nM and 16  $\mu$ M, respectively). In addition, the corresponding 3-pyridylethyl analogues are weaker inhibitor ( $IC_{50} = 840$  nM and 4.6  $\mu$ M, respectively, for the (*S*)-epimer and 580 nM and 36  $\mu$ M for the (*R*)-epimer). 1. Chan, Potter, Barrie, *et al.* (1996) *J. Med. Chem.* **39**, 3319.

**2-Pyridylferrocene**

This ferrocene derivative (FW = 293.19 g/mol) inhibits rat brain DNA topoisomerase II,  $IC_{50} = 0.1$  mM. Thiomorpholide amido methyl ferrocene shows higher inhibition of catalytic activity ( $IC_{50} = 50$   $\mu$ M) against topoisomerase II $\beta$ , when compared to azalactone ferrocene. Analysis of protein-DNA intermediates formed in the presence of these two compounds suggests that azalactone ferrocene readily induces formation of cleavable complex in a dose-dependent manner, in comparison with thiomorpholide amido methyl ferrocene. Both the compounds show significant inhibition of DNA-dependent ATPase activity of enzyme 1. Sai Krishna, Panda & Kondapi (2005) *Arch. Biochem. Biophys.* **438**, 206.

**N-(3-Pyridyl)indomethacinamide**

This indomethacin derivative (FW = 433.89 g/mol; Symbol = N-3Py1A), also named *N*-(3-pyridyl)-1-(4-chlorobenzoyl)-5-methoxy-2-methyl-1*H*-indole-3-acetamide, potently inhibits human cyclooxygenase-2,  $IC_{50} = 52$  nM, but is more than 300-fold less effective on human cyclooxygenase-1 (1). *N*-(3-Pyridyl)indomethacinamide could be a useful tool for determining whether a COX metabolite plays a downstream signaling role in mediating a cellular process of interest. It has, for example been employed to probe whether bradykinin-mediated contraction of the pig iris sphincter muscle is mediated by cyclooxygenase-2 metabolites (2). Another example is the demonstration that  $\alpha$ -linolenic acid inhibits human renal cell carcinoma cell proliferation in part through COX-2 inhibition (3). There is less selectivity with respect to the ovine cyclooxygenases ( $IC_{50}$  values of 50 and 75  $\mu$ M for COX-2 and COX-1, respectively). 1. Kalgutkar, Marnett, Crews, Rimmel & Marnett (2000) *J. Med. Chem.* **43**, 2860. 2. El Sayah & Calixto (2003) *Eur. J. Pharmacol.* **458**, 175. 3. Yang, Yuan, Liu, *et al.* (2013) *Oncol. Lett.* **6**, 197.

**(2*R*,3*S*)-*N*-{[(1*S*)-4-(2-Pyridylsulfonyl)guanyl-1-[(1,3-thiazol-2-ylamino)-carbonyl]-butyl]-3-[formyl(hydroxy)-amino]-2-isobutylhexanamide**

This metalloproteinase inhibitor (FW = 610.76 g/mol) inhibits: ADAM 17 endopeptidase, *or* tumor necrosis factor- $\alpha$  converting enzyme, *or* TACE,  $IC_{50} = 6$  nM; interstitial collagenase, *or* matrix metalloproteinase 1,  $IC_{50} = 76$  nM; gelatinase B, *or* matrix metalloproteinase 9,  $IC_{50} = 43$  nM; and stromelysin 1, *or* matrix metalloproteinase 9,  $IC_{50} = 84$  nM (1). 1. Rabinowitz, Andrews, Becherer, *et al.* (2001) *J. Med. Chem.* **44**, 4252.

**Pyrilamine**

This antihistamine (FW<sub>free-base</sub> = 285.39 g/mol), first prepared and used as an antihistamine in the mid-1940s in the laboratory of Nobelist Daniel Bovet, is a potent H<sub>1</sub> histamine receptor antagonist. The free base is an oily liquid, but the commercially available hydrochloride and maleate salts are highly water-soluble. **Target(s):** H<sub>1</sub> histamine receptor (1); histamine N-methyltransferase (2). 1. Haley (1983) *J. Pharm. Sci.* **72**, 3. 2. Thithapandha & Cohn (1978) *Biochem. Pharmacol.* **27**, 263.

#### Pyrimethamine

This folate antagonist (FW = 248.71 g/mol; slightly soluble in ethanol (~9 g/L) and dilute HCl (~5 g/L)), also known as 2,4-diamino-5-(p-chlorophenyl)-6-ethylpyrimidine, 5-(p-chlorophenyl)-2,4-diamino-6-ethylpyrimidine, as well as Daraprim<sup>®</sup>, is an antiprotozoal and antimalarial agent first synthesized in the early 1950s by Nobelist George Hitchings and coworkers (1). While primarily active against *Plasmodium falciparum*, it is also active against *P. vivax*. Other antifolates (e.g., methotrexate and trimethoprim) potentiate the action of pyrimethamine and can lead to folate deficiency anemia and other blood dyscrasias. Resistance to pyrimethamine is widespread, mainly resulting from mutations in the malarial dihydrofolate reductase that decrease binding affinity via loss of required hydrogen bonds and steric interactions **Target(s):** dihydrofolate reductase,  $K_i = 17$  nM (1-10); glutathione S-transferase (11); and histamine N-methyltransferase (12). 1. #### 2-Pyrimidinone

This hygroscopic pyrimidine (FW = 96.09 g/mol), also known as 2-hydroxypyrimidine and 2-pyrimidinol, inhibits cytosine deaminase (1-3) and pancreatic ribonuclease (4), the latter weakly. 1. Kornblatt & Tee (1986) *Eur. J. Biochem.* **756**, 297. 2. Ko, Lin, Hu, et al. (2003) *J. Biol. Chem.* **278**, 19111. 3. Hsu, Hu, Lin & Liaw (2003) *Acta Crystallogr. Sect. D* **59**, 950. 4. Richards & Wyckoff (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), **4**, 647.

#### 2-Pyrimidinone Nucleosides

These 5-substituted deoxythymidine analogues (including 5-methyl-2-pyrimidinone, FW<sub>MPdR</sub> = 226.23 g/mol; 5-iodo-2-pyrimidinone, FW<sub>IPdR</sub> = 338.10 g/mol; 5-ethynyl-2-pyrimidinone, FW<sub>EPdR</sub> = 336.23 g/mol; and 5-propynyl-2-pyrimidinone, FW<sub>PPdR</sub> = 250.25 g/mol) target Herpes Simplex Virus Types 1 and 2 (HSV-1 and HSV-2), viruses that induce type-specific thymidine kinase (TK) in virus-infected cells. HSV TKs have a broader substrate specificity than host TK, suggesting that unusual 2-pyrimidinone

nucleosides can be activated to their nucleotide derivatives in HSV-laden cells and selectively exert their cytotoxic effects. 1. Lewandowski, Grill, Fisher, et al. (1989) *Antimicrob. Agents Chemother.* **33**, 340.

#### 4-Pyrimidinone

This hygroscopic pyrimidine, also known as 4-hydroxypyrimidine and 4-pyrimidinol (FW = 96.09 g/mol), inhibits both hypoxanthine(guanine) and xanthine phosphoribosyltransferases (1). 1. Naguib, Iltzsch, el Kouni, Panzica & el Kouni (1995) *Biochem. Pharmacol.* **50**, 1685.

#### N<sup>1</sup>-(2-Pyrimidyl)sulfanilamide, See Sulfadiazine

#### Pyriminil

This substituted urea-based rodenticide (FW = 272.26 g/mol), also known as Vacor and named systematically as N-(4-nitrophenyl)-N'-(3-pyridinylmethyl)urea, inhibits, acetylcholinesterase (1), insulin release (2), and NADH:ubiquinone reductase activity of mitochondrial complex I, or NADH dehydrogenase (3). 1. Devi & Krishnamoorthy (1979) *Indian J. Physiol. Pharmacol.* **23**, 285. 2. Taniguchi, Yamashiro, Chung, et al. (1989) *J. Endocrinol. Invest.* **12**, 273. 3. Esposti, Ngo & Myers (1996) *Diabetes* **45**, 1531.

#### Pyripropene A

This fungal sesquiterpene (FW = 580.65 g/mol), first isolated from *Aspergillus fumigatus*, inhibits sterol O-acyltransferase, or cholesterol O-acyltransferase, abbreviated ACAT (1-3). 1. Ohshiro, Rudel, Ômura & Tomoda (2007) *J. Antibiot.* **60**, 43. 2. Ômura, Tomoda, Kim & Nishida (1993) *J. Antibiot.* **46**, 1168. 3. Das, Davis, Tomoda, Ômura & Rudel (2008) *J. Biol. Chem.* **283**, 10453.

#### Pyrithiamin

This thiamin analogue (FW<sub>bromide/hydrobromide salt</sub> = 420.15 g/mol; hygroscopic solid; M.P. = 205-210°C) soluble in water, chloroform, and ethanol, also known as pyrithiamine and neopyrithiamin, is a thiamin antagonist in many

organisms. **Target(s):** esterase, weakly inhibited (1); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (2-4); thiaminase (5); thiamin kinase (6); thiamin diphosphokinase (7-14); thiamin oxidase (15); thiamin-phosphate kinase (16); thiamin transport (17-19); and thiamin-triphosphatase (20). 1. Muftic (1954) *Enzymologia* **17**, 123. 2. Matsuda, Iwata & Cooper (1985) *Biochim. Biophys. Acta* **817**, 17. 3. Matsuda, Iwata & Cooper (1984) *J. Biol. Chem.* **259**, 3858. 4. ### Pyrogallol

This poisonous substance (FW = 126.11 g/mol; M.P. = 131-133°C; solubility, or 1 g per 1.7 mL water), also called 1,2,3-trihydroxybenzene and pyrogallol, is a white solid that turns gray upon exposure to light and air. Aqueous solutions also darken when exposed to air and light, becoming alkaline in pH. Autooxidation of pyrogallol also generates several reactive oxygen species, including superoxide anion. **Target(s):** aldehyde dehydrogenase (1); catechol 1,2-dioxygenase (2); catechol O-methyltransferase (3-7); 3-demethylubiquinone-9 3-O-methyltransferase, weakly inhibited (8); dihydroceramide desaturase (9); 1,2-dihydroxynaphthalene dioxygenase (10); histidine decarboxylase (11); hydroxyquinol 1,2-dioxygenase (12); lipoxygenase (13); nitronate monooxygenase (14); procollagen-lysine 5-dioxygenase (15); protocatechuate 4,5-dioxygenase (16); RNA-directed RNA polymerase (17); shikimate dehydrogenase (18); tannase (19); and urease (20). 1. **Pyroglutamic Acid, See 5-Oxoproline**

### L-Pyroglutamyl-L-asparaginyl-L-prolinamide

This thyrotropin-releasing factor analogue (FW = 339.35 g/mol) is not hydrolyzed by pyroglutamyl-peptidase II (thyrotropin-releasing hormone-degrading ectoenzyme) but is an inhibitor, K<sub>i</sub> = 17.5 μM (1). The free acid (i.e., L-pyroglutamyl-L-asparaginyl-L-proline) is a weaker inhibitor, K<sub>i</sub> = 750 μM (2). 1. Kelly, Slator, Tipton, Williams & Bauer (2000) *J. Biol. Chem.* **275**, 16746. 2. O'Connor & O'Cuinn (1985) *Eur. J. Biochem.* **150**, 47.

### L-Pyroglutamyl-L-asparaginyl-L-proline 7-Amido-4-methylcoumarin

This thyrotropin-releasing factor analogue (FW = 497.19 g/mol) is not hydrolyzed by pyroglutamyl-peptidase II, or thyrotropin-releasing hormone-degrading ectoenzyme, but is an inhibitor, K<sub>i</sub> = 0.97 μM (1). 1. Kelly, Slator, Tipton, Williams & Bauer (2000) *J. Biol. Chem.* **275**, 16746.

**L-Pyroglutamyl-L-asparaginy-L-tryptophan**

This naturally occurring tripeptide (FW<sub>free-acid</sub> = 429.43 g/mol) inhibits adamalysin (1), atrolysin E,  $K_i = 11 \mu\text{M}$  (3), and *Trimeresurus mucrosquamatus* (Taiwan habu) venom metalloproteinase,  $K_i = 0.16 \mu\text{M}$  (4,5). 1. **L-Pyroglutamyl-L-histidyl-L-tryptophanyl-L-seryl-L-tyrosylglycyl-L-tryptophan**

This heptapeptide (Sequence: pGHTSTGW (where pG = pyroglutamyl); FW = 726.75 g/mol), corresponding to the N-terminus of salmon gonadotropin-releasing hormone and also known as luteinizing hormone releasing hormone (LHRH), is not hydrolyzed by pyroglutamyl-peptidase II but does inhibit ( $K_i = 60.3 \mu\text{M}$ ). 1. Gallagher & O'Connor (1998) *Int. J. Biochem. Cell Biol.* **30**, 115.

**L-Pyroglutamyl-L-lysyl-L-tryptophan**

This naturally occurring tripeptide (FW = 443.50 g/mol) inhibits *Trimeresurus mucrosquamatus* (Taiwan habu) venom metalloproteinase,  $K_i = 0.124 \mu\text{M}$  (1,2). 1. Huang, Hung, Wu & Chiou (1998) *Biochem. Biophys.*

**Pyromellitic Acid**

This aromatic tetracarboxylic acid (FW<sub>free-acid</sub> = 254.15 g/mol), also known as 1,2,4,5-benzenetetracarboxylic acid, is converted to the dianhydride upon heating to its melting point (281-281.5°C). **Target(s)**: aconitase, or aconitate hydratase (1); fumarase, or fumarate hydratase (2,3); phosphofructokinase (4); and phosphoglycerate mutase (5). 1. Glusker (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), **5**, 413. 2. Ueda, Yumoto, Tokushige, Fukui & Ohya-Nishiguchi (1991) *J. Biochem.* **109**, 728. 3. Beeckmans & Kanarek (1977) *Eur. J. **1,2-Pyrone-5-carboxylic Acid**, See *Coumalic Acid*

**1,4-Pyrone-2,6-dicarboxylic Acid**, See *Chelidonic Acid*

**Pyronin Y**

This cationic dye (FW<sub>ion</sub> = 267.35 g/mol), also known as puronine Y and pyronine G, is used to selectively demonstrate RNA (red) in contrast to DNA (green) in the Unna-Pappenheim stain. **Target(s)**: F<sub>1</sub> ATPase, or H<sup>+</sup>-transporting two-sector ATPase (1,2). 1. Bullough, Ceccarelli, Roise & Allison (1989) *Biochim. Biophys. Acta* **975**, 377. 2. Mai & Allison (1983) *Arch. Biochem. Biophys.* **221**, 467.

**Pyrophosphate**

This conjugate base (also called diphosphate and previously inorganic pyrophosphate; abbreviated PP<sub>i</sub>) of pyrophosphoric acid (FW = 177.98 g/mol;  $pK_1 = 0.85$ ,  $pK_2 = 1.96$ ,  $pK_3 = 6.60$ , and  $pK_4 = 9.41$  (at 25°C);  $pK_a$  values sensitive to changes in ionic strength) is commonly supplied as its crystalline sodium salts that are very soluble in water. Pyrophosphate anion hydrolyzes to orthophosphate, but much more slowly pyrophosphoric acid. Pyrophosphate binds many metal ions quite tightly. This property alone often accounts for its inhibition of numerous enzymes. The  $\text{Mg}^{2+}$ - $\text{HP}_2\text{O}_7^{3-}$  stability constant is reported to be  $1200 \text{ M}^{-1}$ . Values for  $\text{Ni}^{2+}$ ,  $\text{Cu}^{2+}$ ,  $\text{Co}^{2+}$ , and  $\text{Zn}^{2+}$  are higher.

**Pyroquilon**

This fungicide (FW = 173.21 g/mol), also known as 1,2,5,6-tetrahydro-4H-pyrrolo[3,2,1-*ij*]quinolin-4-one, inhibits melanin biosynthesis in *Pyricularia oryzae* and has been used in the treatment of rice blast disease.

**Target(s):** scytalone dehydratase (1); tetrahydroxynaphthalene reductase (2); and trihydroxynaphthalene reductase (2,3). 1. Wheeler & Greenblatt (1988) *Exp. Mycol.* **12**, 151. 2. Liao, Thompson, Fahnestock, Valent & Jordan (2001) *Biochemistry* **40**, 8696. 3. Liao, Basarab, Gatenby, Valent & Jordan (2001) *Structure* **9**, 19.

**Pyrostatins**

These *N*-acetyl- $\beta$ -D-glucosaminidase inhibitors (Pyrostatin A, FW<sub>ion</sub> = 159.17 g/mol; Pyrostatin B, FW<sub>ion</sub> = 143.17 g/mol), also named systematically as 4-hydroxy-2-imino-1-methylpyrrolidine-5-carboxylate and (2-imino-1-methylpyrrolidine-5-carboxylate, respectively, were isolated from a species of *Streptomyces*. Their respective *K<sub>i</sub>* values are 1.7 and 2.0  $\mu$ M (1). 1. Aoyama, Kojima, Imada, *et al.* (1995) *J. Enzyme Inhib.* **8**, 223.

**Pyrobutamine**

This antihistamine (FW = 311.86 g/mol; CAS 91-82-7), also known as 1-[(2*E*)-4-(4-chlorophenyl)-3-phenylbut-2-en-1-yl]pyrrolidine, inhibits histamine *N*-methyltransferase. 1. Thithapandha & Cohn (1978) *Biochem. Pharmacol.* **27**, 263.

**Pyrrole-2-carboxylic Acid**

This derivative of pyrrole (FW<sub>free-acid</sub> = 111.10 g/mol; melting point = 204-208°C [decomposes]) can be regarded as an unsaturated, planar analogue of proline, albeit with substantial  $\pi$ -orbital electron density. **Target(s):** D-amino-acid oxidase (1-3); CTP synthase, weakly inhibited (4); 4-hydroxyproline epimerase (5,6); procollagen N-endopeptidase (7); and proline racemase (8-11). 1. Yagi (1971) *Meth. Enzymol.* **17B**, 608. 2. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 342, Academic Press, New York. 3. Klein & Austin (1953) *J. Biol. Chem.* **205**, 725. 4. **Pyrrolidine**

This colorless liquid (FW<sub>free-base</sub> = 71.122 g/mol; B.P. = 88.5-89°C), also known as tetrahydropyrrole, is the structural foundation of many biomolecules, including proline. Pyrrolidine has also been reported in

tobacco and carrot leaves. Pyrrolidine is miscible in water and is a strong base ( $pK_a = 11.27$  at 25°C). **Target(s):** D-amino-acid oxidase, weakly inhibited (1); and prolyl-tRNA synthetase (2). 1. Dixon & Kleppe (1965) *Biochim. Biophys. Acta* **96**, 368. 2. Norris & Fowden (1972) *Phytochemistry* **11**, 2921.

**Pyrrolidine-2-carboxylic Acid, See L-Proline; D-Proline****L-trans-Pyrrolidine-2,4-dicarboxylic Acid**

This L-proline derivative (FW = 145.11 g/mol), also known as *trans*-4-carboxy-L-proline, inhibits glutamate transport (1,2) and kynurenine:oxoglutarate aminotransferase (3). 1. Bridges, Stanley, Anderson, Cotman & Chamberlin (1991) *J. Med. Chem.* **34**, 717. 2. Balcar (1992) *FEBS Lett.* **300**, 203. 3. Battaglia, Rassoulpour, Wu, *et al.* (2000) *J. Neurochem.* **75**, 2051.

**2-Pyrrolidinemethanol, See Prolinol****3-Pyrrolidinol**

This alcohol (FW = 87.122 g/mol) inhibits 4-hydroxyproline epimerase (1,2). *Note:* 3-Pyrrolidinol is the decarboxylated analogue of both 3-hydroxy- and 4-hydroxyproline. 1. Adams (1971) *Meth. Enzymol.* **17B**, 266. 2. Finlay & Adams (1970) *J. Biol. Chem.* **245**, 5248.

**7-(4'-(Pyrrolidin-1-yl)but-2-ynoxy)chromen-2-one**

This chromenone, also known as 7-(4'-(*N*-pyrrolidinyl)but-2-ynoxy)chromen-2-one (FW<sub>free-base</sub> = 283.33 g/mol), inhibits *Alicyclobacillus acidocaldarius* squalene:hopene cyclase, IC<sub>50</sub> = 5  $\mu$ M (1,2) and *Saccharomyces cerevisiae* lanosterol synthase, IC<sub>50</sub> = 10.3  $\mu$ M (1). 1. Oliaro-Bosso, Viola, Matsuda, *et al.* (2004) *Lipids* **39**, 1007. 2. Cravotto, Balliano, Tagliapietra, Palmisano & Penoni (2004) *Eur. J. Med. Chem.* **39**, 917.

**2-Pyrrolidone**

This toxic lactam (FW = 85.106 g/mol), also called 2-pyrrolidinone, is soluble in water and many organic solvents. **Target(s):** cholinesterase, weakly inhibited (1); prolyl-tRNA synthetase (2); and pyroglutamyl-peptidase I (3-7). 1. Fitch (1963) *Biochemistry* **2**, 1221. 2. Norris & Fowden (1972) *Phytochemistry* **11**, 2921. 3. McKeon & O'Connor (1998) in *Handb. **$\Delta^1$ -Pyrroline-5-carboxylic Acid**

This metabolite (FW<sub>free-acid</sub> = 113.12 g/mol) is an intermediate in L-proline biosynthesis, is rapidly formed in aqueous solutions from glutamate  $\gamma$ -semialdehyde, the equilibrium favoring the cyclic structure by roughly 20-to-1. **See also L-Glutamate  $\gamma$ -Semialdehyde Target(s):** CTP synthetase, moderately inhibited (1); glutamine:fructose-6-phosphate aminotransferase, isomerizing, *or* glucosamine-6-phosphate synthase (2,3). 1. Bearne, Hekmat & MacDonnell (2001) *Biochem. J.* **356**, 223. 2. Bearne & Wolfenden (1995) *Biochemistry* **34**, 11515. 3. Badet-Denisot, Leriche, Massière & Badet (1995) *Bioorg. Med. Chem. Lett.* **5**, 815.

**Pyrrolnitrin**

This photosensitive chloropyrrole (FW = 257.08 g/mol), also known as 3-chloro-4-(2'-nitro-3'-chlorophenyl)pyrrole, is an antifungal agent that inhibits electron transport. **Target(s):** complex I, *or* NADH dehydrogenase (1); complex II, *or* succinate dehydrogenase (1); and electron transport (1-4). 1. el-Banna & Winkelmann (1998) *J. Appl. Microbiol.* **85**, 69. 2. Rapoport & Schewe (1977) *Trends Biochem. Sci.* **2**, 186. 3. Lambowitz & Slayman (1972) *J. Bacteriol.* **112**, 1020. 4. Warden & Edwards (1976) *Eur. J. Biochem.* **71**, 411.

**3-(1H-Pyrrol-2-ylmethylene)-1,3-dihydroindol-2-one**

This indole derivative (FW = 210.24 g/mol), also known as oxindole I, is a potent and selective inhibitor of the vascular endothelial growth factor (VEGF) receptor protein-tyrosine kinase Flk-1 (*i.e.*, fetal liver kinase-1), IC<sub>50</sub> = 390 nM (1,2), but a weaker inhibitor of platelet-derived growth factor receptor (PDGFR) protein-tyrosine kinase, IC<sub>50</sub> = 12  $\mu$ M. In addition, it also inhibits certain cyclin-dependent kinases: cyclin D1/cdk4 enzyme (IC<sub>50</sub> = 4.9  $\mu$ M) > cyclin E/cdk2 (IC<sub>50</sub> = 10  $\mu$ M) and cyclin B/cdk1 (IC<sub>50</sub> = 10.2  $\mu$ M). 1. Kent, Hull-Campbell, Lau, *et al.* (1999) *Biochem. Biophys. Res. Commun.* **260**, 768. 2. Sun, Tran, Tang, *et al.* (1998) *J. Med. Chem.* **41**, 2588.

**Pyruvaldehyde, See Methylglyoxal**

**Pyruvamide**

This synthetic activator (FW = 87.08 g/mol) of *Kluyveromyces lactis* and *Saccharomyces cerevisiae* pyruvate decarboxylase actually becomes a mixed-type inhibitor at elevated concentrations. **Target(s):** pyruvate decarboxylase (1,2); pyruvate dehydrogenase (acetyl-transferring) complex (3); and [pyruvate dehydrogenase (acetyl-transferring)] kinase (4). 1. **Pyruvate (Pyruvic Acid)**

This pivotal  $\alpha$ -keto acid metabolite (FW<sub>free-acid</sub> = 88.06 g/mol) is found as its conjugate, pyruvate, in almost every cell as an important intermediate in both the catabolism and biosynthesis of carbohydrates and amino acids. Pyruvic acid was the first  $\alpha$ -keto acid synthesized in the laboratory (by Berzelius in 1835). The free acid is a liquid at room temperature (M.P. = 11.8°C; B.P. (with decomposition) = 165°C), has a pK<sub>a</sub> value of 2.39 at 25°C, and is very soluble in water and ethanol. In concentrated solutions, the free acid polymerizes. Aqueous solutions of the free acid exist primarily in the *gem*-diol form (CH<sub>3</sub>C(OH)<sub>2</sub>COOH), typically at 54–71%. By contrast, aqueous solutions of the anion form consists of only 3–5% *gem*-diol. Aqueous solutions polymerize on storage to DL- $\gamma$ -hydroxy- $\gamma$ -methyl- $\alpha$ -ketoglutaric acid and higher molecular weight compounds. The aldol dimer and aldol trimer of pyruvic acid have also been called meta- and parapyruvic acid, respectively. **See also Parapyruvic Acid Target(s):** acetoacetate decarboxylase (2); acetyl-CoA synthetase, *or* acetate:CoA ligase (3); *N*-acetylglucosamine 2-epimerase (4); alanine racemase (5); 4-aminobutyrate aminotransferase (101);  $\delta$ -aminolevulinic synthase (6); 8-amino-7-oxononanoate synthase (109); asparaginase, weakly inhibited (69); asparagine synthetase, weakly inhibited (7); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, *or* [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (8,80,81);  $\gamma$ -butyrobetaine dioxygenase, *or*  $\gamma$ -butyrobetaine hydroxylase, K<sub>i</sub> = 1.4 mM (9); catalase (1); choline acetyltransferase (10,11); cystathionine  $\gamma$ -lyase, *or* cysteine desulfhydrase (12); deacetylcephalosporin-C acetyltransferase (108); 2-dehydro-3-deoxy-L-arabinonate dehydratase (13); exo- $\alpha$ -sialidase, *or* neuraminidase, *or* sialidase (71); fructose-1,6-bisphosphate aldolase (14); fructose-2,6-bisphosphate 2-phosphatase (72); fumarase, *or* fumarate hydratase (54); fumarylacetoacetase (64); gluconate 2-dehydrogenase (15); glucose-1-phosphate adenylyltransferase (95); glutaminase (16,17,68); glycerate dehydrogenase (18); glycerate kinase (97,98); glycogen synthase (19); glyoxylate reductase (20); guanylate cyclase (21); hexose oxidase (22); histidine ammonia-lyase (23); 3-hydroxybutyrate dehydrogenase (24); 4-hydroxy-2-ketoglutarate aldolase (25); indolepyruvate decarboxylase, also alternative substrate (59); inositol oxygenase (114); [isocitrate dehydrogenase (NADP<sup>+</sup>)] kinase (26,77-79); isocitrate lyase (27,55-57); isopenicillin-N synthase, weakly inhibited (65); kynurenine 3-monooxygenase (28); lactase-phlorizin hydrolase, *or* glycosylceramidase (70); malate dehydrogenase (29,30); malate synthase (102-107); *N*-methylglutamate dehydrogenase (31); 3-methyl-2-ketobutanoate hydroxymethyltransferase, *or* 3-methyl-2-oxobutanoate hydroxymethyltransferase (32); 3-mercaptopyruvate sulfurtransferase (33,73-76); NAD<sup>+</sup> kinase, weakly inhibited (99); oxaloacetate tautomerase (34); pantothenase (66,67); phenylalanine monooxygenase (35); phosphoenolpyruvate carboxylase (61-63); phosphoenolpyruvate:protein phosphotransferase (96); phosphoenolpyruvate decarboxylase, pyruvate is also a slow alternative substrate (58); procollagen-lysine 5-dioxygenase (110); procollagen-proline 3-dioxygenase (110); procollagen-proline 4-dioxygenase (110-113); proline dehydrogenase (36); pyrophosphatase, inorganic diphosphatase (37); [pyruvate dehydrogenase, acetyl-transferring] kinase (1,38-44,82-94); ribulose-bisphosphate carboxylase/oxygenase (60); saccharopine dehydrogenase (46); L-serine ammonia-lyase, *or* L-serine dehydratase (47); serine:glyoxylate aminotransferase (100); tartronate-semialdehyde reductase, *or* 2-hydroxy-3-oxopropionate reductase, weakly inhibited (48); thiosulfate sulfurtransferase, rhodanase (45); threonine ammonia-lyase, threonine dehydratase (49-51); D-threonine dehydrogenase (52); and tyrosine 2,3-aminomutase (53). 1. # — Q —

**Q**, Symbol for Glutamine; Quinine

**Q-58**, See 2-(*N,N*-Dimethyl-*N*-heptylammonium Bromide)-*p*-methan-1-ol

**Q-64**, See 2-(*N,N*-Dimethyl-*N*-octylammonium Bromide)-*p*-methan-1-ol

**Qc 1**

This embryonic stem cell-selective inhibitor (FW = 455.46 g/mol; CAS 403718-45-6; Soluble: 50 mM in DMSO; 1,2,3,4-tetrahydro-4-oxo-*N*-(phenylmethyl)-2-thioxo-3-[3-(trifluoromethyl)phenyl]-7-quinazolinocarboxamide, selectively targets threonine dehydrogenase (IC<sub>50</sub> ~ 0.5 μM, reversible noncompetitive), inducing autophagy and inhibiting cell proliferation in mouse embryonic stem (ES) cells. Significantly, ES cells use a mitochondrial threonine dehydrogenase to catabolize threonine into glycine and acetyl-CoA, expressing >1,000x higher levels of TDH mRNA than any of seven other mouse tissues tested. Moreover, when cell culture medium is deprived of threonine, ES cells rapidly discontinue DNA synthesis, arrest cell division, and eventually die. Because glycine is required in purine nucleotide metabolism, TDH inhibition is likely to result in a shortage of nucleotides required for DNA replication, energy metabolism, and signal transduction. 1. Alexander, Wang & McKnight (2011) *Proc. Natl. Acad. Sci. U.S.A.* **108**, 15828.

**QNZ**

This signal transduction inhibitor (FW = 356.42 g/mol; CAS 545380-34-5; Solubility: 5 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as EVP4593 and *N*<sup>4</sup>-[2-(4-phenoxyphenyl)ethyl]-4,6-quinazolinodiamine, potently inhibits both NF-κB activation and TNF-α production with IC<sub>50</sub> values of 11 nM and 7 nM, respectively (1-3). QNZ was useful in demonstrating that NF-κB enhances the potassium currents elicited by treatment with the growth related oncogene (CXCL1) chemokine in nociceptive neurons (3). 1. Tobe, Isobe, Tomizawa, *et al.* (2003) *Bioorg. Med. Chem.* **11**, 383. 2. Li, Whiteman & Moore (2009) *J. Cell Mol. Med.* **13**, 2684. 3. Yang, Strong & Zhang (2009) *Mol. Pain* **28**, 26.

**QO 58**

This potassium channel opener (FW = 443.18 g/mol; CAS 1259536-62-3; Solubility: Soluble to 50 mM in DMSO), also named 5-(2,6-dichloro-5-fluoro-3-pyridinyl)-3-phenyl-2-(trifluoromethyl)pyrazolo[1,5-*a*]pyrimidin-

7(4*H*)-one, targets K<sub>v</sub>7.4 (EC<sub>50</sub> = 0.6 μM), K<sub>v</sub>7.2 (EC<sub>50</sub> = 1.0 μM), K<sub>v</sub>7.3/7.5 (EC<sub>50</sub> = 5.2 μM), and K<sub>v</sub>7.1 (EC<sub>50</sub> = 7.0 μM) channels, thereby increasing the threshold for neuropathic pain in a sciatic nerve CCI *in vivo* model. Voltage-gated K<sub>v</sub>7/KCNQ/M-potassium channels play a pivotal role in controlling neuronal excitability and are involved in epilepsy and arrhythmia. A chain of amino acids (Val<sup>224</sup>Val<sup>225</sup>Tyr<sup>226</sup>) in K<sub>v</sub>7.2 appears to be important for QO-58 activation of this channel (2). 1. Qi, Zhang, Mi, *et al.* (2011) *Eur. J. Med. Chem.* **46**, 934. 2. Zhang, Mi, Qi, *et al.* (2013) *Br. J. Pharmacol.* **168**, 1030.

**Quaternary Amiton**, See *O,O*-Diethyl *S*-[2-(*N,N,N*-Triethylammonio)-ethyl]thiophosphate Cation

**Quazinone**

This cardiotonic agent (FW = 235.67 g/mol; CAS 70018-51-8), known also as Dozonone and (*R*)-6-chloro-1,5-dihydro-3-methylimidazo[2,1-*b*]quinazolin-2[3*H*]-one, exerts its vasodilative properties by inhibiting cyclic-GMP phosphodiesterase, acting selectively on the type-III isozyme, IC<sub>50</sub> = 0.6 μM (1,2). 1. Holck, Thorens, Muggli & Eigenmann (1984) *J. Cardiovasc. Pharmacol.* **6**, 520. 2. Osinski & Schror (2000) *Biochem. Pharmacol.* **60**, 381.

**Queen Substance**

This honeybee pheromone (FW<sub>free-acid</sub> = 184.24 g/mol; M.P. = 54.5-55.5°C), also known as 9-oxo-*trans*-2-decenoic acid and Queen Mandibular Pheromone, is secreted by the queen bee to block ovary formation in worker bees and to attract male suitors (1,2). Synthetic and natural 9-oxodecenoic acid have the same biological activity (3). The methyl ester of 9-oxodecenoic acid is also active. As pointed out by Velthuis (4), Queen Substance accounts, at least in part, for the dominant status of a queen within the hive, as indicated by the attention paid her by worker bees and by the reactions of the colony to her departure as a consequence of swarming or regicide. By secreting this volatile agent, the queen bee identifies herself in the hive, thereby maintaining the social hierarchy and order. More recent work suggests that queen-worker pheromone communication is a multi-component, labile dialogue between the castes, rather than a simple, fixed signal-response system (5). QS also inhibits tRNA methyltransferases (6). The other inhibitory factor, known simply as 'Queen Scent', does not completely inhibit queen rearing; however, when combined with 9-oxodecenoic acid, the two cause complete inhibition (3). 1. Seances Acad. Sci. D* **288**, 1335.

**Quercetagetin**

This flavone (FW = 318.24 g/mol; CAS 90-18-6), the yellow pigment (as the glycoside) of the French and African marigold, exhibits anti-inflammatory and anti-microbial properties. In the marigold, quercitrin is

concentrated in its UV-absorbing, insect-attracting petal zones (known also as "nectar guides"). The latter are visible to certain insects (not humans), providing them pollination-facilitating orientation cues. (See *Quercetin*)

**Inhibitory Target(s):** aldose reductase (1); DNA polymerase (2,3); glycogen phosphorylase (4); lipoxygenase (5); [myosin light-chain] kinase (6); phospholipase A<sub>2</sub> (7); reverse transcriptase, HIV (2,3); reverse transcriptase, Rauscher murine leukemia virus (3); RNA-directed DNA polymerase (2,3); and RNA polymerase (2,3). 1. ### Quercetin

This plant flavonoid (FW = 302.24 g/mol; CAS 117-39-5;  $\lambda_{\text{max}}$  at 258 nm and 375 nm), also known as quercitin, quercetol, and quertine, and named systematically as 2-(3,4-dihydroxyphenyl)-3,5,7-trihydroxy-4H-chromen-4-one, exhibits anti-thrombotic and anti-inflammatory properties, and also inhibits numerous enzymes. Quercetin inhibits phosphatidylinositol (PtdIns) 3-kinase ( $IC_{50} \approx 4 \mu\text{M}$ ), an enzyme implicated in growth factor signal transduction by associating with receptor and nonreceptor tyrosine kinases, including the platelet-derived growth factor receptor. Given the nonspecificity of quercetin, it seems that other, more specific quercetin-derived PtdIns 3-kinase inhibitors (*e.g.*, LY294002) will prove more useful in exploring the function and regulatory mechanisms of the enzyme. See also *Quercitrin*; **Quercitin Target(s):** adenosine deaminase (1); alcohol dehydrogenase, NADP<sup>+</sup>-dependent (2); aldose reductase, or aldehyde reductase (3-7); 1-alkylglycerophosphocholine *O*-acetyltransferase (150,151); amine sulfotransferase (122); AMP-activated protein kinase (8); aromatase, or CYP19 (9,10); arylamine *N*-acetyltransferase (152,153); ATPase (11,101); ATP synthase (12,13); avian myeloblastosis reverse transcriptase (14); Ca<sup>2+</sup>/calmodulin-dependent protein kinase (129); caffeine *O*-methyltransferase (154); calmodulin (15); carbonyl reductase (16-19);  $\beta$ -carotene 15,15'-monooxygenase (163); casein kinase (28); casein kinase type G (20); catechol *O*-methyltransferase (155-160); CF<sub>1</sub> ATP synthase, or chloroplast H<sup>+</sup>-transporting two-sector ATPase (21); chalcone isomerase (103); chitin synthase II (23); chymotrypsin (24); creatine kinase (133); 3',5'-cyclic-GMP phosphodiesterase, or cGMP phosphodiesterase (22), although (27) reports little inhibition; 3',5'-cyclic-nucleotide phosphodiesterase (22,25-27,142); cyclin-dependent kinase, *e.g.*, Cdk1/B, Cdk5, and Cdk6 (126); CYP1A2 (28); CYP3A4 (28); CYP2C9 (28); cystathionine  $\beta$ -synthase (109); diacylglycerol kinase (137); DNA-dependent protein kinase (29); DNA-directed DNA polymerase (132); DNA topoisomerase I (30); DNA topoisomerase II (30,102,136); dopamine  $\beta$ -hydroxylase (31); ecdysone 20-monooxygenase (32); endopeptidase La (33,116,117); epidermal growth-factor receptor protein-tyrosine kinase (131); estrone sulfatase (34); estrone sulfotransferase (123,124); 7-ethoxycoumarin *O*-deethylase activity, cytochrome P450 (35,36); ethoxyresorufin deethylase, cytochrome P450 (37,38); eukaryotic initiation factor 2 $\alpha$  kinases, or interferon-inducible double-stranded RNA-dependent kinase (39); fatty-acid synthase (40,149); flavanone 7-*O*-glucoside 2''-*O*- $\beta$ -L-rhamnosyltransferase (145);  $\beta$ -D-glucuronidase (42,43); glutathione-disulfide reductase (44,45); glutathione *S*-transferase (45,143,144); glycogen phosphorylase (146-148); [glycogen synthase] kinase-3, or [tau protein] kinase (126); hexokinase (46); HIV-1 retropepsin (47); H<sup>+</sup>-transporting ATPase (41,100); hyaluronoglucosaminidase, or hyaluronidase (43,120); 17 $\beta$ -hydroxysteroid dehydrogenase (48); I $\kappa$ B kinases  $\alpha$  and  $\beta$  (49); inositol-trisphosphate 3-kinase (136); integrase, HIV (50); iodothyronine deiodinase, type I (51);  $\beta$ -lactamase (24,114); lactate dehydrogenase (52); lactoylglutathione lyase, or glyoxalase I (104-106);

leucoanthocyanidin reductase (161,162); lipoxygenase (53-55); 5-lipoxygenase (56,57); 15-lipoxygenase (58); lysozyme (43); malate dehydrogenase (24); malic enzyme, NADP<sup>+</sup>-dependent (59); 3-methylbutanal reductase113; mitogen-activated protein kinase60; [mitogen-activated protein kinase]-activated protein kinase (18); Moloney murine leukemia virus reverse transcriptase (14,61); [myosin light-chain] kinase (128); NADH oxidase (101); NADPH diaphorase (62); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (63-65); nitric-oxide dioxygenase (167); nucleoside diphosphate kinase (66); nucleoside-triphosphatase (112); 5'-nucleotidase (67); ornithine decarboxylase (55); peptidyl-dipeptidase A, or angiotensin I-converting enzyme; weakly inhibited (118); P-glycoprotein (110,111); phenol sulfotransferase, or aryl sulfotransferase (122,125); phenylalanine ammonia-lyase (68,107,108); 1-phosphatidylinositol 3-kinase, or (PtdIns) 3-kinase,  $IC_{50} = 3.8 \mu\text{M}$  (8,69,70,134,135); 1-phosphatidylinositol 4-kinase (13, 9-141); 1-phosphatidyl-inositol-4-phosphate 5-kinase (71,138); phosphodiesterase (127); phosphodiesterase (227); phosphodiesterase 3 (27); phosphodiesterase 4 (27); phosphoenolpyruvate carboxylase (72,73); phospholipase A<sub>2</sub> (74-76); phosphorlyase kinase (77,127); p70 ribosomal protein S6 kinase (8); prostaglandin endoperoxide synthase, or cyclooxygenase (56,78); prostaglandin E<sub>2</sub>-reductase (79); prostaglandin F synthase (80); proteasome endopeptidase complex (115); protein kinase (8,20,29,69,81-84); protein kinase C (69,81,84,85); protein-tyrosine kinase, or non-specific protein-tyrosine kinase (69,77,82,86-89,130); pyruvate kinase (52,90); receptor protein-tyrosine kinase (131); RNA-directed DNA polymerase (14,61); RNA polymerase II (91); Rous-associated virus-2 reverse transcriptase (14); Rous sarcoma virus src gene product pp60src protein kinase (83); soluble epoxide hydrolase (119); sorbitol dehydrogenase, or L-iditol dehydrogenase (59); steroid sulfotransferase (121); steroid 5 $\alpha$ -reductase (92); succinoxidase (101); sulfotransferase (93-95); tyrosinase, or monophenol monooxygenase (43,96,164-166); xanthine oxidase (97-99); and xenobiotic-transporting ATPase, or multidrug-resistance protein (110,111). 1. #### Quercetin-3-O-rutinoside, See Rutin

#### Quercitrin

This plant arylglycoside and antioxidant (FW = 448.38 g/mol; CAS 522-12-3;  $\lambda_{\max}$  at 258 and 350 nm), also known as 2-(3,4-dihydroxyphenyl)-5,7-dihydroxy-3-[[[(2S,3R,4R,5R,6S)-3,4,5-trihydroxy-6-methyl-2-tetrahydropyran-2-yl]oxy]-4-chromenone], inhibits many enzymes: acetoacetyl dehydrogenase (1); NADP<sup>+</sup>-dependent alcohol dehydrogenase (1); aldose reductase, or aldehyde reductase (2-4); ATP synthase (5); carbonyl

- acetylspermidine deacetylase (111); alcohol dehydrogenase (3); aldehyde oxidase (4-7); allohydroxy-D-proline oxidase (8); amine oxidase (9-11,105); D-amino-acid oxidase (12-16); L-amino-acid oxidase (17); asparaginase (112); ATPase (18,19); benzoate 4-monooxygenase (122); biotin sulfoxide reductase (20); bontoxilysin (113);  $\gamma$ -butyrobetaine:2-oxoglutarate dioxygenase (21); Ca<sup>2+</sup>-dependent ATPase (22); catechol oxidase (23); cGMP phosphodiesterase (24); cholest-5-ene-3 $\beta$ ,7 $\alpha$ -diol 3 $\beta$ -dehydrogenase (25); choline dehydrogenase (26); cholinesterase1,2; cyclohexanone monooxygenase (121); cyclooxygenase (27); cytochrome *c* oxidase (28); cytochrome *c* reductase (28); cytochrome *c*-554 reductase (29); diamine oxidase (11,30); diferric-transferrin reductase (119); DNA ligase, NAD<sup>+</sup>-dependent (31); DNA methylases (32); DNA polymerase (33,34); ethanolamine oxidase (35,36); F<sub>1</sub> ATPase, or F<sub>1</sub>F<sub>0</sub> ATP synthase, or H<sup>+</sup>-transporting two-sector ATPase (37); ferroxidase (38); galactonolactone dehydrogenase (39); glucose dehydrogenase (40,41); glucose-6-phosphate dehydrogenase (28,42,43); glutaminase (44-49); hexokinase (50), however (19) lists quinacrine as a stimulator; histamine *N*-methyltransferase (51,52,116); hydrogenase (53); L-2-hydroxyacid oxidase (54); hydroxylamine oxidase (55); hydroxylamine reductase, NADH-dependent (56); 4-hydroxymandelate oxidase (57); 4-hydroxyproline epimerase (108); 2-hydroxyquinoline 5,6-dioxygenase, weakly inhibited (123); ITPase (58); lactate dehydrogenase (59,60); L-lactate oxidase (61,62); lactate racemase (107); lipase, or aliesterase (43); 5-lipoxygenase (63); malate dehydrogenase (3,64); malate dehydrogenase (acceptor), or malate: vitamin K reductase (65); L-mandelate dehydrogenase (104); 4-methoxybenzoate monooxygenase, *O*-demethylating (120); myeloperoxidase (66); myosin ATPase (67); NADH dehydrogenase, or NADH:cytochrome *c* reductase (3,28,68-72); NAD(P)H dehydrogenase (quinone), or diaphorase (73-76,106); nicotinate dehydrogenase (117); nitrate reductase (29,77-79); nitrite reductase (56,80); nitroaryl nitroreductase (81); oxidative (mitochondrial) and photophosphorylation uncoupler (18); phospholipase A<sub>1</sub> (114); phospholipase A<sub>2</sub> (82-87,114); phospholipase C (24); L-pipecolate dehydrogenase (88); *Plasmodium falciparum* aminopeptidase (90); platelet-activating factor acetyltransferase (116); polyamine oxidase (90); protein-disulfide reductase (91); retinal oxidase, or retinene oxidase (92); riboflavin transglucosidase (93); RNA nucleotidyltransferase (94); rubredoxin:NAD<sup>+</sup> reductase (110); spermidine dehydrogenase (95); succinate dehydrogenase (96); sulfite reductase (53,97); sulfur reductase (109); taurine dehydrogenase (98); thiosulfate reductase (53,97); thyroxine deiodinase (99); trypanothione reductase (100); xanthine dehydrogenase (118); and xanthine oxidase (101-103). 1. **Quinacrine Mustard**

This chloro-substituted quinacrine (FW<sub>free-base</sub> = 468.85 g/mol; CAS 4213-45-0) is an alkylating agent that inactivates bovine heart F<sub>1</sub> ATPase, labeling the β-subunit in the process. Quinacrine mustard exhibits cytostatic and cytotoxic effects and is used as a DNA-labeling reagent. **Target(s):** F<sub>1</sub> ATPase, or F<sub>1</sub>F<sub>0</sub> ATP synthase, or H<sup>+</sup>-transporting two-sector ATPase (1-6); histamine N-methyltransferase (7); TF<sub>1</sub> ATPase (4,5); vacuolar H<sup>+</sup>-translocating ATPase (1); and ATPase, *Escherichia coli* (5). 1. **Quinaldate**

This tryptophan catabolite (FW<sub>free-acid</sub> = 173.127 g/mol; CAS 93-10-7), also known as quinaldic acid, quinaldonic acid and 2-quinolinecarboxylic acid, forms complexes with a number of metal ions, especially zinc and copper ions. **Target(s):** aconitase, or aconitate hydratase (1,2); alcohol dehydrogenase (3); dopamine β-hydroxylase (4); D-glyceraldehyde-3-phosphate dehydrogenase (5-7); kynureninase (8); lactate dehydrogenase (3,6); and pyruvate oxidase (9). 1. **Quinalizarin**

This red dye (FW = 272.21 g/mol; CAS 81-61-8; M.P. > 275°C), named systematically as 1,2,5,8-tetrahydroxyanthraquinone, inhibits HIV-1 integrase (1), inositol-trisphosphate 3-kinase (2), [myosin light-chain] kinase (3), and protein kinase C (3). With a panel of 140 kinases, quinalizarin is one of the most selective inhibitors of CK2, superior to silmitasertib (CX-4945), a first-in-class CK2 inhibitor in clinical trials for cancer treatment (4). Quinalizarin discriminates between the isolated CK2 catalytic subunit (CK2α) and CK2 holoenzyme (CK2αβ<sub>2</sub>). 1. Hong, Neamati, Winslow, et al. (1998) *Antivir. Chem. **Quinapril & Quinaprilat****Quinapril****Quinaprilat**

This substituted isoquinoline (FW<sub>free-acid</sub> = 438.52 g/mol; CAS 85441-61-8), also known as (3S)-2-[(2S)-2-[(1S)-1-(ethoxycarbonyl)-3-phenylpropyl]amino]-1-oxopropyl]-1,2,3,4-tetrahydro-3-isoquinolinecarboxylic acid, is an antihypertensive prodrug that, like other ACE inhibitors, decreases systemic vascular resistance without increasing heart rate. The actual active agent is the diacid metabolite, quinaprilat (FW<sub>free-acid</sub> = 410.46 g/mol; CAS 82768-85-2), targets peptidyl-dipeptidase A, or angiotensin I-converting enzyme, IC<sub>50</sub> = 8.3 nM (1-3). Due to reduced angiotensin production, plasma concentrations of aldosterone are likewise reduced, resulting in increased sodium ion excretion in the urine and an increased blood potassium ion level. With different chemical structures and susceptibilities to activation in the liver, ACE prodrugs differ in their bioavailability, plasma half-life, route of elimination, and volume of distribution. This is true for moexipril, which is the 6,7-dimethoxy analogue of quinapril. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) **Quinate**

This cyclic polyol carboxylic acid (FW<sub>free-acid</sub> = 192.17 g/mol; CAS 60321-02-0; M.P. = 162-163°C), also known as quinic acid and named systematically as (1R,3R,4S,5R)-1,3,4,5-tetrahydroxycyclohexanecarboxylic acid, is found in many plants, especially cinchona bark, tobacco leaves, carrot leaves, and some fruits. While initially thought to be pharmacologically inert, quinic acid is now believed to displace binding of the mu opioid receptor antagonists. **Target(s):** α-amylase (1,2); chitin synthase (3); kynurenine aminotransferase, weakly inhibited (4); lysozyme (1); and trypsin (1). 1. ## Quinidine

This triboluminescent quinine diastereoisomer (FW<sub>free-base</sub> = 324.42 g/mol; CAS 56-54-2; M.P. = 174-175°C), found in a number of plants (often with quinine), exhibits cardiac anti-arrhythmic effects, mainly by blocking the fast inward Na<sup>+</sup> current (I<sub>Na</sub>), but also blocking the slow-inactivating, tetrodotoxin-sensitive Na<sup>+</sup> current, the slow inward Ca<sup>2+</sup> current (I<sub>Ca</sub>), the rapid (I<sub>Kr</sub>) and slow (I<sub>Ks</sub>) components of the delayed K<sup>+</sup> rectifier current, the inward K<sup>+</sup> rectifier current (I<sub>K1</sub>), the ATP-sensitive K<sup>+</sup> channel (I<sub>KATP</sub>) and I<sub>to</sub>.

**Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011).

**Target(s):** acetylcholinesterase (1-3); adenylate cyclase (4); ATPase (5); cholesterol 24-hydroxylase, moderately inhibited (6); cholinesterase, or butyrylcholinesterase (1,2,7,8); CYP2C3 (9); CYP2D6 (10-14); debrisoquine 4-hydroxylase (15,16); ecdysone 20-monoxygenase (17); 7-esterase, nonspecific (2); ethoxyresorufin *O*-deethylase (18); K<sup>+</sup> channel blocker (19); 4-nitrophenol 2-monoxygenase, or CYP2E1, weakly inhibited (20); steroid 21-monoxygenase (21); and strictosidine synthase (22). 1. ## Quinine

This quinidine diastereoisomer (FW<sub>free-base</sub> = 324.42 g/mol; CAS 130-95-0; M.P. = 174-177 °C; triboluminescent crystals; pK<sub>1</sub> = 4.13 and pK<sub>2</sub> = 8.3)

from the bark of the cinchona is a potassium channel blocker. Quinine has been widely used in the treatment and prevention of malaria. Quinine is believed to be useful in treating some muscular disorders, especially nocturnal leg cramps and myotonia congenital, affecting muscle membrane depolarization by acting directly on sodium channels. The refreshing quality of quinine-containing drinks are may have a similar explanation. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** acetylcholinesterase (1,2); D-amino-acid oxidase (3-6); aminopyrine *N*-demethylase (7); benzoate 4-monoxygenase (8); bontoxilysin, weakly inhibited (9); carboxylesterase, esterase (10,11); cholinesterase (11,12); choline exchanger (13); choline oxidase (14); cyclohexanone monoxygenase (15); CYP3A4 (16,17); CYP2C8 (18); CYP2D1 (19,20); debrisoquine 4-hydroxylase (21,22); ecdysone 20-monoxygenase (23); 7-ethoxyresorufin *O*-deethylase (24); F<sub>0</sub>F<sub>1</sub> ATP synthase, or H<sup>+</sup>-transporting two-sector ATPase, *Streptococcus pneumoniae* (25); β-fructofuranosidase, or saccharase (26); or invertase (26); α-glucosidase (27); heme polymerase (28); D-hydroxybutyrate dehydrogenase (29); K<sup>+</sup> channels (30); lipase (31-35); phenylpyruvate tautomerase (36); sorbose reductase (37); strictosidine synthase (38); and urease (39). 1. ## Quinlobelane

This water-soluble lobelane analogue (FW = 445.03 g/mol), also named *N*-methyl-*cis*-2,6-diphenethylpiperidine, inhibits vesicular monamine transporter-2, or VMAT2 (*K*<sub>i</sub> = 51 nM), the membrane carrier responsible for sequestering cytosolic dopamine (DA) into synaptic vesicles (See *Dopamine*), thereby preventing dopamine degradation by monoamine oxidase. Quinlobelane is therefore some 1000-times more potent than lobelane (1). Interesting, structure-activity studies with quinlobelane and

structurally related molecules showed that their affinity for the VMAT2 binding site does not necessarily predict their ability to inhibit dopamine transport by VMAT2 (1). Such findings also suggest that a ligand-induced conformational change, mimicking that of dopamine and other transport substrates, is a requirement for effective transport inhibition. 1. Vartak, Deaciuc, Dwoskin, & Crooks (2010) *Bioorg. Med. Chem. Lett.* **20**, 3584.

#### Quinoid 6(S)-Methyldihydropterin

This product analogue (FW = 179.18 g/mol) is a strong competitive inhibitor of rat liver 4a-hydroxytetrahydro-biopterin dehydratase:  $K_i = 1.5 \mu\text{M}$ . 1. Rebrin, Bailey, Boerth, Ardell & Ayling (1995) *Biochemistry* **34**, 5801.

#### Quinolate

This dicarboxylic acid (FW<sub>free-acid</sub> = 167.12 g/mol; CAS 89-00-9;  $\lambda_{\text{max}}$  = 268 nm;  $\epsilon = 4000 \text{ M}^{-1}\text{cm}^{-1}$  in acid), also known as quinolinic acid and pyridine-2,3-dicarboxylic acid, is an intermediate in the formation of NAD<sup>+</sup> from tryptophan. Quinolate is also an NMDA (*N*-methyl-D-aspartate) agonist and differentiates between cerebellar and forebrain NMDA receptors. Spectral analysis also confirms that quinolate complexes with Fe<sup>2+</sup>.

**Target(s):** aspartate 4-decarboxylase (1);  $\gamma$ -butyrobetaine hydroxylase, or  $\gamma$ -butyrobetaine:2-oxoglutarate dioxygenase,  $K_i = 0.15 \text{ mM}$  (2); deoxyhypusine monooxygenase (3); glutamate carboxypeptidase II (4); homocitrate synthase (5); 3-hydroxyanthranilate 3,4-dioxygenase (6); kynurenine:oxoglutarate aminotransferase, weakly inhibited (7,8); monoamine oxidase (9); nicotinamide-nucleotide amidase (10); nicotinate phosphoribosyltransferase (11); phosphoenolpyruvate carboxykinase, ATP-dependent (12); PEP carboxykinase, GTP-dependent (13-15); phosphoenolpyruvate carboxylase (16); and pyridoxal kinase (17,18). 1. Quinolinic Acid, See *Quinolate*

2-Quinololinol, See *2-Hydroxyquinoline*

8-Quinololinol, See *8-Hydroxyquinoline*

*N*-[*N*-(2-Quinolinylicarbonyl)-L-valyl]-*(2S,3R)*-2-amino-4-((2*S,4R*)-2-(*tert*-butylcarbamoyl)-4-(pyridin-2-ylthio)piperidin-1-yl)-3-hydroxy-1-phenylbutane

This pseudopeptide linkage-containing peptide analogue (FW = 699.94 g/mol) inhibits HIV-1 and HIV-2 retropepsins, with respective  $K_i$  values of 1.9 and 1.8 nM. X-ray crystallography reveals that the substrate flap and residues 79-81 in the S<sub>1</sub> substrate-binding pocket undergo conformational changes upon inhibitor binding. Residues 29 and 30 also adapt their conformation to accommodate certain inhibitors, showing that HIV protease flexibility plays an important role in inhibitor binding. 1. Tong, Pav, Mui, *et al.* (1995) *Structure* **3**, 33.

*N*-Quinoln-4-yl-3-(1*H*-imidazol-4-yl)propanamine

This imidazole derivative (FW = 252.31 g/mol) is a histamine H<sub>3</sub> receptor antagonist ( $K_i = 4.1 \text{ nM}$ ) and inhibits histamine *N*-methyltransferase (IC<sub>50</sub> = 24 nM), making this derivative a valuable pharmacological tool for further development of dual-action drugs that inhibit histamine *N*-methyltransferase (HMT) and antagonizing histamine H<sub>3</sub> receptors. The *N*-quinoln-6-yl analogue is a weaker effector ( $K_i = 71 \text{ nM}$  and IC<sub>50</sub> = 6.1  $\mu\text{M}$  for the receptor and transferase, respectively). 1. Grabmann, Apelt, Sippl, *et al.* (2003) *Bioorg. Med. Chem.* **11**, 2163.

Quinomycin A, See *Echinomycin*

*p*-Quinone

This quinone (FW = 108.10 g/mol; CAS 106-51-4; M.P. = 115.7°C), also known as *p*-benzoquinone and 1,4-benzoquinone, is a common laboratory reagent used as an oxidizing agent and in organic syntheses. Care should be exercised in its handling, as its vapors can cause eye and skin irritation. *p*-Quinone also reacts with amino groups in proteins to produce 1,4-disubstituted adducts. If quinone-reactive amino group(s) of an enzyme is(are) catalytically essential, its biological activity may be inhibited. **See also Hydroquinone** **Target(s):** alanine:oxomalonate aminotransferase (62); aldehyde:nitrate oxidoreductase (1); aldehyde oxidase (2); alkaline phosphatase (3,4); amidase (5); amine oxidase (6); D-amino-acid oxidase (7);  $\alpha$ -amylase (8-10);  $\beta$ -amylase (10,11); aryl-acylamidase (59,60); arylamine glucosyltransferase (64); aspartate aminotransferase (12); carbonic anhydrase (13); catalase (7,10,14); cholinesterase (15); *trans*-cinnamate 4-monooxygenase (66); complement system, guinea pig (16); cytochrome oxidase (17); dihydroxy-acid dehydratase (57); DNA topoisomerase II (18,55,56); fructose-1,6-bisphosphatase (19); glucose dehydrogenase (20,21); glutaminase (22-25); glyceraldehyde-3-phosphate dehydrogenase (26);  $\alpha$ -glycerophosphatase (27); homogentisate oxidase, or homogentisate 1,2-dioxygenase (28); hyaluronoglucosaminidase, or hyaluronidase (61); lactate dehydrogenase (29); lipoxigenase (7,30,31); lysozyme (8); magnesium-protoporphyrin IX monomethyl ester (oxidative) cyclase (65); NAD<sup>+</sup> ADP-ribosyltransferase, or poly(ADP-ribose) polymerase (63); nicotinate oxidase (32); oxalate oxidase (5); papain (33-35); peroxidase, horseradish (36); polyphenol oxidase (10); pyruvate

decarboxylase (37-39); pyruvate oxidase (40); succinate dehydrogenase (41-45); succinate oxidase (7,41,45); triose-phosphate isomerase (46); trypsin (8); tryptophan pyrrolase, or tryptophan 2,3-dioxygenase (47); urease (48-51,58); xanthine oxidase (52); and xylose isomerase (53,54). 1. ### Quinovose

This deoxy hexose (FW = 164.16 g/mol; CAS 7658-08-4), also known as chinovose, D-*epirhamnose*, and D-*isorhamnose*, and 6-deoxy-D-glucose, is a structural component of chloroplast glycolipids and certain cardiac glycosides. Quinovose is soluble in water and ethanol and melts at 146°C. In D<sub>2</sub>O at 44°C, quinovose exists primarily in the  $\beta$ -pyranose form (64% vs. 36%  $\alpha$ -pyranose and 0.002% aldehyde). **Target(s)**: aldose 1-epimerase, or

mutarotase (1);  $\alpha$ -glucosidase, *Entamoeba histolytica* (2,3);  $\beta$ -glucosidase, weakly inhibited (4); hexokinase (5); and  $\alpha$ -L-rhamnosidase (6,7). 1. Keston (1964) *J. Biol. ### 2-Quinoxalinecarboxamide-N-adamantan-1-yl, See NPS 2390

### (±)-3-Quinuclidinyl Benzilate

This powerfully incapacitating chemical warfare agent (FW<sub>free-base</sub> = 337.42 g/mol; CAS 6581-06-2; Symbol: QNB; M.P. = 164-165°C;  $\lambda_{max}$  = 207.4 nm in methanol ( $\epsilon$  = 13500 M<sup>-1</sup>cm<sup>-1</sup>)), commonly referred to as BZ, is a non-selective, competitive antagonist of muscarinic cholinergic receptors, that has been used to investigate acetylcholine receptors (1). One target, the M<sub>2</sub> muscarinic acetylcholine receptor, is essential for controlling cardiovascular function by activating G-protein-coupled inwardly rectifying potassium channels. In M<sub>2</sub> receptors, QNB binds in the orthosteric binding pocket, in the middle of a long aqueous channel extending approximately two-thirds of the way through the membrane (2). A layer of tyrosine residues forms an aromatic cap that restricts dissociation of the bound ligand. This channel is formed by amino acids found to be identical in all five muscarinic receptor subtypes. This binding site also shares structural homology with other functionally unrelated acetylcholine binding proteins from different species (2). When given to rats in the passive avoidance task, either before training (a memory acquisition test), immediately post-training (a memory consolidation test) or 24-hours pre-retention (a memory retrieval test), QNB greatly impairs acquisition in the water maze at doses 0.5-5.0 mg/kg as well as the acquisition of passive avoidance task (3). In contrast, consolidation and retrieval were unaffected by QNB, indicating that QNB specifically affects the stage of acquisition (3). **CAUTION:** Symptoms of QNB overexposure include dizziness, tachycardia, headaches, disorientation, and hallucinations. Decontamination can be accomplished by washing the skin vigorously with soap and water. 1. Saunders, Hough & Chuang (1996) *Brain Res.* **713**, 29. 2. Haga, Kruse, Asada, *et al.* (2012) *Nature* **482**, 547. 3. Misik, Vanek, Musilek & Kassa (2014) *Behav. Brain Res.* **266**, 193.

### Quinupristin

This antibiotic (FW = 1022.23 g/mol; CAS 120138-50-3), also named N-{{(6R,9S,10R,13S,15aS,18R,22S,24aS)-18-[[[(3S)-1-azabicyclo[2.2.2]oct-3-ylthio]methyl]-22-[4-(dimethylamino)benzyl]-6-ethyl-10,23-dimethyl-5,8,12,15,17,21,24-heptaoxo-13-phenyl-docosahydro-12H-pyrido[2,1-f]pyrrolo[2,1-l][1,4,7,10,13,16]oxapentaazacyclononadecin-9-yl]-3-hydroxy-

pyridine-2-carboxamide, is used in combination with dalfoipristin (marketed as Synercid®), which shows a selective spectrum of antibacterial activity, mainly against gram-positive aerobic bacteria. Synercid has been assessed primarily in emergency-use protocols, in hospitalized patients with skin and skin-structure infections, and in patients with vancomycin-resistant *Enterococcus faecium* (VREF) bacteremia. **1.** Allington & Rivey (2001) *Clin. Ther.* **23**, 24.

### Quisinostat

This broad-spectrum histone deacetylase inhibitor (FW = 394.48 g/mol; CAS 875320-29-9, 875320-30-2 (TFA), 875320-31-3 (2HCl); Solubility: 80 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O; Formulation for Animal Studies: 2 mg/mL in 20% hydroxypropyl-β-cyclodextrin (final pH 8.7)), also known as JNJ-26481585 and systematically as *N*-hydroxy-2-(4-(((1-methyl-1*H*-indol-3-yl)methylamino)methyl)piperidin-1-yl)pyrimidine-5-carboxamide, targets HDAC1, HDAC2, HDAC4, HDAC10 and HDAC11 with *IC*<sub>50</sub> values of 0.11 nM, 0.33 nM, 0.64 nM, 0.46 nM and 0.37 nM, respectively. JNJ-26481585 exhibits broad-spectrum anti-proliferative activity in solid and hematologic cancer cell lines (e.g., lung, breast, colon, prostate, brain, and ovarian tumor cell lines), with *IC*<sub>50</sub> values ranging from 3 to 250 nM. **1.** Arts, *et al.* (2009) *Clin. Cancer Res.* **15**, 6841. **2.** Stühmer T, *et al.* (2010) *Brit. J. Haematol.* **149**, 529.

### L-Quisqualate

This glutamate analogue (FW = 189.13 g/mol), also known as L-quisqualic acid and 3-(3,5-dioxo-1,2,4-oxadiazolidin-2-yl)-L-alanine; is an excitatory amino acid used to identify certain receptors. **Target(s):** aspartate aminotransferase (1); choline *O*-acetyltransferase (2); *N*-formylglutamate deformylase, or *N*-β-citrylglutamate deacylase (3); glutamate carboxypeptidase II (4-10); and kynurenine:oxoglutarate aminotransferase (11-13). **1.** Guidetti, Amori, Sapko, Okuno & Schwarcz (2007) *J. ### Quizalofop

This herbicide (FW<sub>free-acid</sub> = 344.75 g/mol; CAS 76578-14-8) and several of its esters are inhibitors of plant acetyl-CoA carboxylase (1-4). *Note:* Its ethyl ester is known as Targa™, and its 2-isopropylideneamino-oxyethyl ester is known as Agil™. **1.** Dehaye, Alban, Job, Douce & Job (1994) *Eur. J. Biochem.* **225**, 1113. **2.** Herbert, Cole, Pallett & Harwood (1996) *Pestic. Biochem. Physiol.* **55**, 129. **3.** Zuther, Johnson, Haselkorn, McLeod & Gornicki (1999) *Proc. Natl. Acad. Sci. U.S.A.* **96**, 13387. **4.** Price, Herbert, Moss, Cole & Harwood (2003) *Biochem. J.* **375**, 415.

### Quizartinib

This second-generation FLT3 inhibitor (FW = 560.67 g/mol; CAS 950769-58-1), also known as AC220 and 1-(5-(*tert*-butyl)isoxazol-3-yl)-3-(4-(7-(2-morpholinoethoxy)benzo[*d*]imidazo[2,1-*b*]thiazol-2-yl)phenyl)urea, exerts low-nM potency in biochemical and cellular assays as well as exceptional kinase selectivity, (**See also G749**). In animal models, AC220 is efficacious at doses as low as 1 mg/kg given orally once daily. **Rationale:** Activating mutations in the FLT3 receptor tyrosine kinase occur ~30% of acute myeloid leukemia (AML) patients, with the most common class of internal tandem duplications (ITDs) in the juxtamembrane domain, resulting in lead constitutive, ligand-independent activation of the kinase (1). FLT3 has thus become an attractive druggable target. First-generation FLT3 inhibitors include: CEP-701, MLN-518, PKC-412, sorafenib, and sunitinib. **1.** Zarrinkar, Gunawardane, Cramer, *et al.* (2009) *Blood* **114**, 2984. **2.** Chao, Sprankle, Grotzfeld, *et al.* (2009) *J. Med. Chem.* **52**, 7808.

### Q-VD-Oph

This cell-permeable, pan-caspase inhibitor (FW = 513.49 g/mol; CAS 1135695-98-5; Solubility = 10 mM in DMSO; IUPAC: *N*-(2-quinolyl)valyl-*O*-methylaspartyl-(2,6-difluorophenoxy)methyl ketone; *Symbol:* QVD; selectively protects cells from caspase-dependent apoptosis. The difluorophenoxymethyl ketone moiety serves as the warhead for reaction with the catalytic nucleophile, displacing the *o*-difluorophenol leaving group (*pK*<sub>a</sub> = 6.3) in the process. Compared to ZVA-D-fmk or Boc-D-fmk, Q-VD-OPH is more effective in preventing apoptosis mediated by caspase 9/3, caspase 8/10, and caspase 12, with the following inhibitory action: caspase-3 (*IC*<sub>50</sub> = 25 nM), caspase-1 (*IC*<sub>50</sub> = 50 nM), caspase-8 (*IC*<sub>50</sub> = 100 nM) and caspase-9 (*IC*<sub>50</sub> = 430 nM). **1.** Caserta, Smith, Gultice, Reedy, Brown (2003) *Apoptosis* **8**, 345.

# - R -

## R, See Arginine

### R16 Peptide

This high-affinity peptide antagonist and apoptosis inducer (FW = 2309.69 g/mol; Sequence = PHCVPRDLSWLDLEANMCLP; CAS 211364-78-2; Soluble to 1 mg/mL in H<sub>2</sub>O), first identified through the use of phage display techniques, targets the binding of 14-3-3 protein to signal transduction proteins that control key aspects of cell proliferation, transformation, and apoptosis. The ability of the R16 peptide to inhibit Bad and other proapoptotic proteins suggests that 14-3-3 promotes/maintains cell survival. R-16 peptide blocks the ability of 14.3.3 proteins to bind to Raf-1, Bad, ASK1 and exoenzyme S, thereby inducing apoptosis. **1.** Wang, *et al.* (1999) *Biochemistry* **38**, 12499. **2.** Masters & Fu (2001) *J. Biol. Chem.* **276**, 45193. **3.** Masters, *et al.* (2002) *Biochem. Soc. Transact.* **30**, 360.

### R106, See Aureobasidins

### R428

This Axl inhibitor (FW = 506.64 g/mol; CAS 1037624-75-1; Solubility: 24 mg/mL DMSO, with warming), also known as BGB324 and 1-(6,7-dihydro-5H-benzo[6,7]cyclohepta[1,2-c]pyridazin-3-yl)-N<sup>3</sup>-(7S)-6,7,8,9-tetrahydro-7-(1-pyrrolidinyl)-5H-benzocyclohept-2-yl]-1H-1,2,4-triazole-3,5-diamine, targets tyrosine-protein kinase receptor UFO (IC<sub>50</sub> = 14 nM), an enzyme that transduces extracellular matrix signals into the cytoplasm by binding Growth Arrest-Specific 6 (or GAS6) and regulating many physiological processes, including cell survival, cell proliferation, migration, and differentiation (1,2). Axl is a novel regulator of endothelial cell haptotactic migration towards the matrix factor vitronectin (3). R428 shows >100-fold selective toward Axl *versus* Abl. Selectivity for Axl is also greater than Mer and Tyro3 (50x to 100x more selective) and InsR, EGFR, HER2, and PDGFRβ (100x more selective). **1.** Holland, Pan, Franci, *et al.* (2010) *Cancer Res.* **70**, 1544. **2.** Ghosh, Secreto, Boysen, *et al.* *Blood* **117**, 1928. **3.** Holland, Powell, Franci, *et al.* (2005) *Cancer Res.* **65**, 9294.

### R547

This cyclin kinase-directed inhibitor (FW = 441.46 g/mol; CAS 741713-40-6), named systematically as 4-amino-2-(1-methanesulfonylpiperidin-4-ylamino)pyrimidin-5-yl]-(2,3-difluoro-6-methoxyphenyl)methanone, targets CDK1/cyclin B, CDK2/cyclin E, and CDK4/cyclin D1 ( $K_i = 1-3$  nM) and was inactive ( $K_i > 5,000$  nM) against a panel of >120 unrelated kinases in cell-free assays. The growth-inhibitory activity is characterized by a cell cycle block at G<sub>1</sub> and G<sub>2</sub> phases and induction of apoptosis. **Cyclin Target Selectivity:** Cdk1 (++++), Cdk2 (++++), Cdk3 (weak, if any), Cdk4 (++++), Cdk5 (weak, if any), Cdk6 (weak, if any), Cdk7 (weak, if any), Cdk8 (weak, if any), Cdk9 (weak, if any), Cdk10 (weak, if any). **1.** DePinto, *et al.* (2006) *Mol. Cancer Ther.* **5**, 2644.

### R 715

This potent, selective and metabolically stable bradykinin antagonist (FW = 1140.35 g/mol; CAS 185052-09-9; Sequence = Acetyl-KRPPGFSXI, where X = D-β-Nalidixic Acid; Solubility: 5 mg/mL H<sub>2</sub>O) targets B<sub>1</sub> receptors (IC<sub>50</sub> ≈ 3 nM), with no activity toward B<sub>2</sub> receptors. R715 reduces mechanical hyper-nociception in a mouse model of neuropathic pain. **1.** Gobeil, *et al.* (1996) *Hypertension* **28**, 833. **2.** Abdouh, *et al.* (2008) *Brit. J. Pharmacol.* **154**, 136. **3.** Quintao, *et al.* (2008) *J. Neurosci.* **28**, 2856.

### R 830, See 2,6-Di(t-butyl)-4-(2'-thenoyl)phenol

### R-848, See Resiquimod

### R 1485

This selective, high-affinity and brain-penetrant serotonin antagonist (FW<sub>free-base</sub> = 377.48 g/mol; FW<sub>di-HCl</sub> = 450.35 g/mol; Solubility: 100 mM dihydrochloride in H<sub>2</sub>O; 100 mM free base in DMSO), also named 4-[(2-fluorophenyl)sulfonyl]-3,4-dihydro-8-(1-piperazinyl)-2H-1,4-benzoxazine dihydrochloride, targets 5-HT<sub>6</sub> receptors (pK<sub>i</sub> = 8.9), with low hERG inhibition and >100x selectivity against a panel of 50 targets, including other 5-HT receptor subtypes. **1.** Zhao, Berger, Clark, *et al.* (2007) *Bioorg. Med. Chem. Lett.* **17**, 3504. **2.** Liu, *et al.* (2009) *Drug Des. Rev.* **70**, 145.

### R 1530

This potent and orally available multi-kinase inhibitor (FW = 356.79 g/mol; CAS 882531-87-5; Solubility: 100 mM in DMSO), also named 5-(2-chlorophenyl)-7-fluoro-1,2-dihydro-8-methoxy-3-methylpyrazolo[3,4-b][1,4]benzodiazepine, targets Checkpoint Kinase-2, or Chk2 (IC<sub>50</sub> = 24 nM), Kinase insert Domain Receptor kinase, or KDR (IC<sub>50</sub> = 34 nM), fibroblast growth factor receptor kinase, or FGFR (IC<sub>50</sub> = 50 nM), Aurora A kinase (IC<sub>50</sub> = 58 nM), and Cyclin-dependent kinase Cdk2 (IC<sub>50</sub> = 88 nM), with weaker action against VEGFR-2 ( $K_d = 15$  nM), FGFR1 ( $K_d = 61$  nM) and PDGFRβ ( $K_d = 88$  nM). R1530 induces polyploidy, interfering with tubulin polymerization as well as mitotic checkpoint function in cancer cells, leading to abortive mitosis, endo-reduplication and polyploidy (1). R1530-induced polyploid cancer cells undergo apoptosis or become senescent, whereas normally proliferating cells are resistant to R1530-induced polyploidy, a finding favoring its use in treating cancers (1). R1530 also displays antiproliferative activity *in vitro*, inhibiting both mitosis and angiogenesis (2). **1.** Tovar, Higgins, Deo, *et al.* (2010) *Cell Cycle* **9**, 3364. **2.** Liu, *et al.* (2013) *ACS Med. Chem. Lett.* **4**, 259.

### R 7050

This cell-permeable TNFα receptor antagonist (FW = 380.77 g/mol; CAS 303997-35-5), also named 8-chloro-4-(phenylthio)-1-(trifluoromethyl)[1,2,4]triazolo[4,3-a]quinoxaline, targets TNFα receptor 1, blocking its

association with with **TNF $\alpha$  Receptor-Associated Death Domain protein** (or TRADD) and **Receptor Interacting Protein 1** (or RIP1) in the initial intracellular signaling event following TNF $\alpha$  stimulation (1). It also inhibits TNF $\alpha$ -induced NF- $\kappa$ B and MAPK signaling pathway activation. R-7050 attenuates intracerebral hemorrhage-induced neurovascular injury in mice (2). 1. Gururaja, Yung, Ding, *et al.* (2007) *Chem. Biol.* **14**, 1105. 2. King, Alleyne & Dhandapani (2013) *Neurosci. Lett.* 2013 May 10;542:92

**RA 839**

This Nrf2 activator (FW = 452.57 g/mol; CAS 1832713-02-6; Solubility: 100 mM in DMSO), also known as (3S)-1-[4-[[[(2,3,5,6-tetramethylphenyl)sulfonyl]amino]-1-naphthalenyl]-3-pyrrolidinyl]propanoate, is an anti-inflammatory agent that inhibits Nrf2/Keap1 interaction ( $K_d = 6 \mu\text{M}$ ), suppressing lipopolysaccharide (LPS) induction of iNOS expression and hence nitric oxide formation in macrophages. The transcription factor NF-E2-related factor 2 (Nrf2) is a basic leucine zipper (bZIP) protein that serves as a master regulator of the antioxidant response by regulating the expression of antioxidant proteins that protect against oxidative damage triggered by injury and inflammation. The multi-domain Keap1 (Kelch-like ECH-associated protein 1) contains a stress-sensing cysteinyl residue (C151). Absent stressors, the activity of Nrf2 is inhibited by its interaction with the Keap1. Similar to the activation of Nrf2 by either silencing of Keap1 expression or by the reactive compound CDDO-Me (2-cyano-3,12-dioxooleana-1,9-dien-28-oic acid methyl ester), RA839 prevents induction of both inducible nitric-oxide synthase expression and nitric oxide release in response to lipopolysaccharides in macrophages. In mice, RA839 acutely induced Nrf2 target gene expression in liver. RA839 is a selective inhibitor of the Keap1/Nrf2 interaction and a useful tool compound to study the biology of Nrf2. 1. Winkel, Engel, Margerie, *et al.* (2015) *J. Biol. Chem.* **290**, 28446.

#### **Rab GDP Dissociation Inhibitor**

This monomeric cytosolic protein ( $MW_{\text{isoform-}\alpha} = 50,500$ ;  $MW_{\text{isoform-}\beta} = 50,700$ ), often abbreviated Rab GDI, inhibits exchange of GTP with Rab-GDP complex by preventing GDP dissociation from small G proteins and subsequent the binding of GTP (1-7). GDI is required to maintain a cytosolic pool of Rab proteins. Rab GDI also inhibits intra-cisternal

transport between the Golgi stacks and participates in the removal of Rab proteins from the Golgi. Rab GDI only interacts with lipid-modified GDP-Rab3A. Other Rab family members that can be acted on include Rab1, Rab2, and Rab4. **See also Rho GDP Dissociation Inhibitor**. 1. Takai, Kaibuchi, Kikuchi & Sasaki (1995) *Meth. Enzymol.* **250**, 122. 2. #### **(S)-Raclopride**

This CNS-acting dopamine receptor antagonist ( $FW_{\text{free-base}} = 347.24$  g/mol; CAS 84225-95-6; Solubility: 100 mM in DMSO), also known as 3,5-dichloro-*N*-(1-ethylpyrrolidin-2-ylmethyl)-2-hydroxy-6-methoxybenzamide, selectively targets  $D_2$  ( $K_i = 1.8$  nM) and  $D_3$  ( $K_i = 3.5$  nM) receptors, reacting much more weakly with  $D_4$  ( $K_i = 2.4 \mu\text{M}$ ) and  $D_1$  ( $K_i = 1.8 \mu\text{M}$ ) receptors. (**See also Remoxipride**) 1. Protais, Chagraoui, Arbaoui & Mocaer (1994) *Eur. J. Pharmacol.* **271**, 167. 2. Kohler, Hall, Ogren & Gawell (1985) *Biochem. Pharmacol.* **34**, 2251.

## RAD001, See Everlimus

## Radicicol

This photosensitive antifungal macrolide (FW = 364.78 g/mol; CAS 12772-57-5), also called monorden, from *Diheterospora chlamydosporia* and *Monosporium bonorden* inhibits p60v-src protein-tyrosine kinase activity,  $IC_{50} = 0.27$  nM. Radicicol also acts as a cell differentiation modulator, suppresses the expression of mitogen-inducible cyclooxygenase, and inhibits receptor-mediated activation of p85 phosphatidylinositol 3-kinase. Radicicol inhibits [pyruvate dehydrogenase] kinase (PDK) activity by binding directly to the ATP-binding pocket of PDK3, similar to Hsp90 and Topo VI from the same ATPase/kinase superfamily. **Target(s):** ATP:citrate lyase, or ATP:citrate synthase, showing noncompetitive inhibitor of ATP citrate lyase with  $K_i$  values for citrate and ATP of 13 and 7  $\mu$ M (1); [branched-chain  $\alpha$ -keto acid dehydrogenase] kinase, or [3-methyl-2-oxobutyrate dehydrogenase (acetyl-transferring)] kinase (2); heat shock protein 90-kDa ATPase (2-4); nonchaperonin molecular chaperone ATPase (4); protein-histidine kinase, Sln1 yeast (2); protein-tyrosine kinase (5,6); and [pyruvate dehydrogenase (acetyl-transferring)] kinase (7). 1. ## Raffinose

This nonreducing trisaccharide (FW = 504.44 g/mol; CAS 17629-30-0), also known as  $\beta$ -D-fructofuranosyl- $O$ - $\alpha$ -D-galactopyranosyl-(1 $\rightarrow$ 6)- $\alpha$ -D-glucopyranoside, melitose, and melitriose, occurs widely in higher plants, often functioning as a transport carbohydrate. **Raffinose Space:** Raffinose is not taken up by most animal cells, a property that makes radiolabeled raffinose an especially useful tool in investigations of ion and metabolite transport investigations. One may estimate the volume of extracellular space ( $V_e$ ) by determining the dilution (in cpm/mL) after a given volume  $V_0$  (units mL) of radiolabel of known concentration (say  $C_0 = \text{cpm}_{\text{initial}}/\text{mL}$ ) is mixed with a tissue, followed by centrifugation to recover some of the fluid. All dilutions follow the equation:  $C_0 V_0 = C_f V_f$ , where  $V_f = (V_0 + V_e)$ . Therefore, measurement of  $C_f$  (or cpm $_{\text{final}}/\text{mL}$ ), allows one to correct for the amount of ion or metabolite present extracellularly (*i.e.*, in the interstitial space), which is often called the "raffinose space". Such corrections can be substantial (*e.g.*, rabbit muscle has an interstitial space of 23.5 mL per 100 g tissue). This method for the estimating the raffinose space is essentially the same as the time-honored inulin method (1). **Target(s):**  $\alpha$ -galactosidase (2,3);  $\beta$ -galactosidase, weakly inhibited (2,4,5);  $\alpha$ -glucosidase (2,6); inulinase (7); and phosphoenolpyruvate-dependent sucrose phosphotransferase system (8). 1. ## Rafoxanide

This anthelmintic (FW = 626.02 g/mol; CAS 22662-39-1), known as Disalan<sup>TM</sup> Flukanide<sup>TM</sup>, MK 990, Rafoxanid<sup>TM</sup>, and Ranide<sup>TM</sup>, and named systematically as *N*-(3-chloro-4-(4-chlorophenoxy)phenyl)-2-hydroxy-3,5-diiodobenzamide, is often used to treat grazing livestock. This fasciolocidic agent inhibits cystathionine  $\beta$ -synthase and is a proton ionophore. Rafoxanide is also used to treat fluke, hookworm and other infestations. **Target(s):** cystathionine  $\beta$ -synthase (1); fumarate reductase (2); oxidative phosphorylation (3); and succinate dehydrogenase (2). 1. Walker & Barrett (1992) *Exp. Parasitol.* **74**, 205. 2. Kaur & Sood (1983) *Vet. Parasitol.* **13**, 333. 3. Martin (1997) *Vet. J.* **154**, 11.

## Raloxifene

This second-generation selective estrogen receptor modulator (FW = 473.59 g/mol; CAS 84449-90-1) is effective in the treatment of osteoporosis in postmenopausal women. While exerting estrogen agonist effects on bone and cholesterol metabolism, raloxifene behaves as a complete estrogen antagonist on mammary gland and uterine tissue. It is also a potent inhibitor of aldehyde oxidase, which catalyzes the oxidation of aldehydes (*Reaction:* Aldehyde +  $H_2O + O_2 \rightleftharpoons$  Carboxylate +  $H_2O_2 + H^+$ ) as well as the hydroxylation of some heterocycles. Aldehyde oxidase also catalyzes the oxidation of intermediate products in both CYP450 and monoamine oxidase (MAO) reactions. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** aldehyde oxidase,  $IC_{50} = 2.9$  nM (1); CYP3A4 (2); estrogen receptor (3,4); LDL oxidation (5); and myeloperoxidase (5); anoxic xanthine oxidoreductase-catalyzed reduction of  $NO_2^-$  to  $^*NO$ ,  $EC_{50} = 64$   $\mu$ M (6). In the latter case, Exposure of purified XO to raloxifene (PBS, pH 7.4) resulted in a dose-dependent (12.5-100  $\mu$ M) inhibition of xanthine oxidation to uric acid. Although Dixon plot analysis suggested a competitive inhibition,  $K_i = 13$   $\mu$ M (6), Dixon Plots cannot distinguish between competitive inhibition and certain kinds of mixed-type competitive inhibition (7). 1. Obach, Huynh, Allen & Beedham (2004) *J. Clin. Pharmacol.* **44**, 7. 2. Chen, Ngui, Doss, *et al.* (2002) *Chem. Res. Toxicol.* **15**, 907. 3. Kellen (2001) *Curr. Drug Targets* **2**, 423. 4. ## Raltegravir

This potent integrase inhibitor (FW = 444.42 g/mol; CAS 518048-05-0; Solubility: 89 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O; pK<sub>a</sub> = 6.7), also known as MK-0518, Isentress, and *N*-(4-fluorobenzyl)-5-hydroxy-1-methyl-2-(2-(2-methyl-1,3,4-oxadiazole-5-carboxamido)propan-2-yl)-6-oxo-1,6-dihydropyrimidine-4-carboxamide, targets wild-type HIV integrase (IC<sub>50</sub> = 90 nM) and Prototype Foamy Virus (PFV) intasome IN<sup>S217Q</sup> (IC<sub>50</sub> = 40 nM) (1-3). Targeting the strand transfer step of viral integration, efficiently blocking viral replication *in vitro*, and suppressing viremia in patients, raltegravir is the first FDA-approved human HIV-1 integrase drug. Notably, HIV-1 IN<sup>Q148H/G140S</sup> and HIV-1 IN<sup>N155H</sup> and the analogous PFV IN<sup>S217H</sup> and PFV IN<sup>N224H</sup> display reduced sensitivity to raltegravir *in vitro* (1). Because raltegravir undergoes nonhepatic glucuronidation, the potential for drug-drug interactions is decreased (2). Raltegravir lipophilicity is reduced as pH increases from 5 to 9 (3). Cellular permeability of raltegravir is lower in the presence of magnesium and calcium. Cellular retention of raltegravir is increased by inhibiting the ABCB1 transporter and by lowering extracellular pH from pH 8 to 5 (3). Raltegravir binds to the IN active site, causing it to disengage from the deoxyadenosine at the 3'-end of viral DNA (4). This inhibitor occupies contacts the β<sub>4</sub>-α<sub>2</sub> loop of the catalytic core domain (4). 1. Hare, Vos, Clayton, *et al.* (2010) *Proc. Natl. Acad. Sci. U.S.A.* **107**, 20057. 2. Pharmacol.* 2011, 80(4), 565.

## Raltitrexed

This antifolate and antineoplastic agent (FW = 456.48 g/mol; CAS 112887-68-0), known also as Tomudex™ as well as ZD-1694, and systematically named as *N*-(5-(*N*-(3,4-dihydro-2-methyl-4-oxoquinazolin-6-ylmethyl)-*N*-methylamino)-2-thienoyl)-L-glutamic acid, inhibits thymidylate synthase (1-4). Once within cells, raltitrexed is rapidly polyglutamated, and the pentaglutamate analogue is also inhibitory. 1. Tong, Liu-Chen, Ercikan-Abali, *et al.* (1998) *J. Biol. Chem.* **273**, 11611. 2. Marsham, Hughes, Jackman, *et al.* (1991) *J. Med. Chem.* **34**, 1594. 3. Bijnsdorp, Comijn, Padron, Gmeiner & Peters (2007) *Oncol. Rep.* **18**, 287. 4. Hekmat-Nejad & Rathod (1996) *Antimicrob. Agents Chemother.* **40**, 1628.

## Ramipril

This long-lasting antihypertensive prodrug (FW = 416.52 g/mol; CAS 87333-19-5), variously known as H.OE-498, Acovil™, Altace™, Carasel™, Delix™, Ramace™, Triatec™, Tritace™, Vesdil™, Zabien™, and named systematically as 2-[*N*-[(*S*)-1-ethoxycarbonyl-3-phenylpropyl]-L-alanyl]-[(1*S*,3*S*,5*S*)-2-azabicyclo[3.3.0]octane-3-carboxylic acid, undergoes hepatic conversion to ramiprilat, a potent inhibitor of peptidyl-dipeptidase A, or angiotensin I-converting enzyme, IC<sub>50</sub> = 4 nM (1-3). (**See active drug Ramiprilat**) **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*,

12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. van Griensven, Schoemaker, Cohen, *et al.* (1995) *Eur. J. Clin. Pharmacol.* **47**, 513. 2. ## Ramiprilat

This long-lasting antihypertensive (FW<sub>free-acid</sub> = 388.46 g/mol; CAS 87269-97-4), also known as 2-[*N*-[(*S*)-1-carboxy-3-phenylpropyl]-L-alanyl]-[(1*S*,3*S*,5*S*)-2-azabicyclo[3.3.0]octane-3-carboxylate, is not assimilated directly and must be formed by hepatic metabolism of its prodrug form ramipril. Ramiprilat exists as slowly interconverting *cis* and *trans* geometric isomers with respect to the amide bond. The *trans* isomer is the most potent enzyme inhibitor of angiotensin-converting enzyme (K<sub>i</sub> = 7 pM), first rapidly binding to the enzyme to form an initially weak enzyme-inhibitor complex, which then undergoes a slow isomerization. The *cis* isomer exhibits a very low inhibitory effect. (**See prodrug Ramipril**) **Target(s):** peptidyl-dipeptidase A, or angiotensin I-converting enzyme (1-6); and Xaa-Pro aminopeptidase, or aminopeptidase P (7-9). 1. Baudin & Beneteau-Burnat (1999) *J. Enzyme Inhib.* **14**, 447. 2. Bunning (1987) *J. Cardiovasc. Pharmacol.* **10** Suppl. 7, S31. 3. Skoglof, Gothe & Deinum (1990) *Biochem. J.* **272**, 415. 4. ## Ramoplanins

These glycolipopeptide antibiotics (FW = 2254.06; CAS 76168-82-6 for Ramoplanin A<sub>1</sub>), including Ramoplanin A<sub>1</sub>: R<sub>1</sub> = octa-2(*Z*),4(*E*)-dienoyl and R<sub>2</sub> = OH; Ramoplanin A<sub>2</sub>: R<sub>1</sub> = 7-methylocta-2(*Z*),4(*E*)-dienoyl and R<sub>2</sub> = OH; Ramoplanin A<sub>3</sub>: R<sub>1</sub> = 9-methyldeca-2(*Z*),4(*E*)-dienoyl and R<sub>2</sub> = OH; and Ramoplanose: R<sub>1</sub> = 7-methylocta-2(*Z*),4(*E*)-dienoyl; R<sub>2</sub> = D-mannose, are isolated from the cell-culture broths of actinomycetes (genus *Actinoplanes*, strain ATCC 33076) and their undecaridin congenitors. Ramoplanins are powerful inhibitors of cell wall biosynthesis (1-4), exhibiting promising properties for treating vancomycin- and methicillin-resistant enterococci as well as *Clostridia difficile*. These inhibitors sequester peptidoglycan biosynthetic lipid intermediates by blocking late-stage cell wall synthesis catalyzed by MurG (or undecaprenyldiphospho-

muramoylpentapeptide  $\beta$ -*N*-acetyl-glucosaminyltransferase) and related transglycosylases. Ramoplanins are functionally related to mersacidin and vancomycin. **Target(s):** transglycosylases, bacterial (1,5); undecaprenyl-diphosphomuramoylpentapeptide  $\beta$ -*N*-acetyl-glucosaminyltransferase, or MurG transferase (1,2,6). 1. McCafferty, Cudic, Frankel, *et al.* (2002) *Biopolymers* **66**, 261. 2. Crouvoisier, Mengin-Lecreux & van Heijenoort (1999) *FEBS Lett.* **449**, 289. 3. Branstrom, Midha, Longley, *et al.* (2000) *Anal. Biochem.* **280**, 315.

### Ramosetron

This 5-HT<sub>3</sub> receptor antagonist and antiemetic (FW = 279.33 g/mol; CAS 132907-72-3; IUPAC: (1-methyl-1*H*-indol-3-yl)[(5*R*)-4,5,6,7-tetrahydro-1*H*-benzimidazol-5-yl]methanone) targets the 5-hydroxytryptamine type-3 (serotonin) receptor ( $K_d = 0.15$  nM,  $B_{max} = 653 \pm 30$  fmol/mg protein), with higher affinity than [<sup>3</sup>H]granisetron ( $K_d = 1.17$  nM,  $B_{max} = 427 \pm 43$  fmol/mg protein). Kinetic studies revealed that dissociation rate constant ( $k_{off}$ ) for [<sup>3</sup>H]ramosetron was also lower than that for [<sup>3</sup>H]granisetron (1). These results suggest that ramosetron is a highly potent 5-HT<sub>3</sub>-receptor antagonist. Ramosetron is used to treat irritable bowel syndrome (IBS), a highly prevalent functional bowel disorder. Serotonin (5-HT) regulates gastrointestinal function, and, in experimental studies, 5-HT<sub>3</sub> receptor antagonists slow colon transit, blunt gastrocolonic reflex, and reduce rectal sensitivity (2). 1. Akuzawa, Ito & Yamaguchi (1998) *Japanese J. Pharmacol.* **78**, 381. 2. Min & Rhee (2015) *Therap. Adv. Gastroenterol.* **8**, 136.

### Ramucicromab

This VEGF receptor 2 inhibitor (MW = 143.6 kDa; CAS 947687-13-0), also known by its code name IMC-1121B, is a fully human IgG<sub>1</sub> monoclonal antibody intended for the treatment of solid tumors, particularly as a second-line option for patients with advanced gastric or gastroesophageal junction cancer.

### Ranakinin

This undecapeptide amide KPNPERFYGLM-NH<sub>2</sub> (MW = 1349 g/mol; CAS 139446-71-2), first isolated from the brain of the frog *Rana ridibunda*, binds to the NK<sub>1</sub> tachykinin receptor, inhibiting the binding of mammalian substance P (1). Ranakinin also stimulates phospholipase C activity in the frog adrenal gland. The stimulatory action of ranakinin on inositol phosphate formation (with concomitant decrease in membrane polyphosphoinositides) and corticosteroid secretion is mediated through activation of a phospholipase C positively coupled to a pertussis toxin-sensitive G protein (2). 1. O'Harte, Burcher, Lovas, *et al.* (1991) *J. Neurochem.* **57**, 2086. 2. Kodjo, Desruets, Lavagno, *et al.* (1998) *Endocrinology* **139**, 505.

### Ranibizumab

This first-in-class angiostatic agent (MW = 48 kDa; CAS 347396-82-1), known by the trade name Lucentis®, is a humanized, affinity-matured anti-VEGF Fab antibody fragment with anti-angiogenic properties. The splice variant VEGF<sub>165</sub> increases the permeability of retinal endothelial cells, often resulting in diabetic macular edema; however, capillary barrier function can be restored by treating affected patients with the ranibizumab. Derived from the same parent mouse antibody used to prepare bevacizumab (Avastin®), ranibizumab is the first FDA-approved anti-angiogenic agent for the treatment of "wet" type, age-related macular degeneration. Ranibizumab is administered as an intravitreal injection on a monthly schedule.

### Ranitidine

This furanyl derivative (FW<sub>free-base</sub> = 314.41 g/mol; CAS 66357-35-5; M.P. = 69-70°C; Soluble to 50 mM in water), also known as Zantac™ and *N*-[2-[[[5-[(dimethylamino)methyl]-2-furanyl]methyl]thio]ethyl]-*N'*-methyl-2-nitro-1,1-ethanediamine hydrochloride, is a potent, competitive and selective antagonist (IC<sub>50</sub> = 3.3 μM) of histamine H<sub>2</sub> receptors, thereby blocking gastric acid secretion. By 1982, only three years after receiving FDA approval, Zantac sales reached \$1 billion, making it the largest selling prescription drug in the world. Zantac has since largely been superseded by the even more effective proton pump inhibitors, with omeprazole becoming the biggest-selling drug. [Ranitidine was widely used to treat ulcers prior to the discovery of *Helicobacter pylori* (formerly *Campylobacter pylori*).] **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** acetylcholine esterase,  $K_i = 2.1$  μM (1); butyrylcholinesterase,  $K_i = 61$  μM (1); histamine H<sub>2</sub> receptor (2-4); and monoamine oxidase B (5). 1. Laine-Cessac, Turcant, Premel-Cabic, Boyer & Allain (1993) *Res. Commun. Chem. Pathol. Pharmacol.* **79**, 185. 2. van der Goot & Timmerman (2000) *Eur. J. Med. Chem.* **35**, 5. 3. Smit, Leurs, Alewijnse, *et al.* (1996) *Proc. Natl. Acad. Sci. U.S.A.* **93**, 6802. 4. Hill, Ganellin, Timmerman, *et al.* (1997) *Pharmacol. Rev.* **49**, 253. 5. Lu & Silverman (1993) *J. Enzyme Inhib.* **7**, 43.

### Ranolazine

This orally active antianginal (FW<sub>free-base</sub> = 427.54 g/mol; CAS 95635-55-5), known by its trade name Ranexa™, its code name RS-43285 and its systematic name (*RS*)-*N*-(2,6-dimethylphenyl)-2-[4-[2-hydroxy-3-(2-methoxyphenoxy)propyl]piperazin-1-yl]acetamide, also reduces myocardial infarct size and cardiac troponin T release in the rat. **Action on Inward Sodium Current:** The depolarizing inward sodium current ( $I_{Na}$ ) initiates the cardiac action potential, and the main ion channel that conducts  $I_{Na}$  in cardiac cells is  $Na_v1.5$ , the tetrodotoxin-resistant, pore-forming  $\alpha$ -subunit of the voltage-gated sodium channel (VGSC). In cardiac myocytes, ranolazine not only blocks peak  $Na_v$  current, but also inhibits the response of  $Na_v1.5$  channels to mechanical stimulation, very likely by altering membrane partitioning (1). Its effects on  $Na_v1.7$  and  $Na_v1.8$  sodium channels suggest its potential utility in treating neuropathic pain. Ranolazine is also a partial fatty acid  $\beta$ -oxidation inhibitor, inhibiting 3-ketoacyl coenzyme A thiolase and thereby shifting the energy substrate preference away from fatty acid metabolism and toward glucose metabolism (2). It also improves left ventricular function by blocking uptake of free fatty acids by the heart while shifting metabolism to anaerobic glycolysis during myocardial ischemia. Note that ranolazine activates pyruvate dehydrogenase. Persistent current blockers of voltage-gated sodium channels, like ranolazine, are also receiving greater attention in the face of mounting evidence that metastatic progression in carcinomas is accompanied, perhaps even preceded, by upregulation of voltage-gated sodium channels, which enhance invasiveness (3). **Target(s):** acetyl-CoA C-acyltransferase (2);  $\beta$ -adrenoceptor, weak antagonist (4); fatty acid  $\beta$ -oxidation (2,5); HERG and  $IsK$  currents (6); late sodium current (7); NADH dehydrogenase, or complex I, uncompetitive inhibition with respect to ubiquinone-1, IC<sub>50</sub> > 350 μM (8). (Note that rotenone displaces ranolazine from its binding site, a property that may explain ranolazine's anti-ischemic activity.) 1. Beyder, Stregre, Reyes, *et al.* (2012) *Circulation* **125**, 2698. 2. Fragasso, Spoladore, Cuko & Pallosi (2007) *Curr. Clin. Pharmacol.* **2**, 190. 3. Djamgoz & Onkal (2013) *Recent*

**Ranunculeate, See Columbinatae**

### Rapamycin

This macrocyclic antifungal agent and immunosuppressant (FW = 914.19 g/mol; CAS 53123-88-9; Soluble to 50 mM in DMSO), also known as Sirolimus and Rapamune, from *Streptomyces hygroscopicus* potently inhibits interleukin-2- (or IL-2-) dependent T-cell proliferation (1-9). Its chief advantage is that, unlike calcineurin inhibitors, transplant patients can be maintained long-term on the latter without developing impaired kidney function or chronic renal failure. **Primary Mode of Inhibitory Action:** Mammalian target of rapamycin (or mTOR) is a Ser/Thr protein kinase that is conserved in all eukaryotes that plays a key role in cell growth and is likewise a central effector of several pathways regulating essential cell functions. Hyperactivation of the mTOR-dependent signalling pathway occurs in many human diseases, making it a druggable target. However, the dual nature of mTOR, existing in two multiprotein complexes mTORC1 and mTORC2, which is driven by different feedback loops, modulating rapamycin's therapeutic effects. Rapamycin's antiproliferative effect is mediated through the formation of an active complex with the cytosolic receptor protein FKBP12, inhibiting the translation of mRNAs encoding ribosomal proteins and elongation factors, thereby decreasing protein biosynthesis. Rapamycin also inhibits the cyclin-dependent kinase cdk2-cyclin E complex, which functions as a crucial regulator of G<sub>1</sub>/S cell cycle transition. Therefore, although it exerts a suppressive effect on the immune system that is similar to that of tacrolimus (FK506), sirolimus's (rapamycin's) action directly binds the mTOR Complex1 (mTORC1) without involving calcineurin. Recent work suggests that the amino acid sequence comprising a phosphorylation site is a likely factor in determining why certain mTORC1 sites are rapamycin-insensitive (10). Rapamycin also strongly augments lentiviral (LV) transduction of human stem cells (HSCs) *in vitro* and *in vivo*, dramatically enhancing marking frequency within long-term engrafting cells in mice (11). Mechanistically, rapamycin enhances post-binding endocytic events, leading to increased levels of LV cytoplasmic entry, reverse transcription, and genomic integration. **Use in Combination Chemotherapy:** Inhibition of the mammalian target of rapamycin (mTOR) signaling pathway promotes the initiation of autophagy, and the Mitogen-Activated Protein Kinase/Extracellular signal-Regulated protein Kinase (or MAPK/ERK) is well known to induce autophagy, a self-defense mechanism of cancer cells subjected to antitumor agents. Blocking autophagy, rapamycin triggers apoptosis, and application of the MEK inhibitor U0126 offers an effective treatment for Malignant Fibrous Histiocytoma, or MFH (12). Significantly, Rapamycin reverses insulin resistance (IR) in high-glucose medium without causing IR in normoglycemic medium (13). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF*

*THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** cyclin-dependent kinase, by binding FK506-rapamycin complex (1-3); p33<sup>cdk2</sup> kinase (2); p34<sup>cdk2</sup> kinase (2,3); p70 S6 kinase (4-6); and peptidylprolyl isomerase (7-9). 1. **Ras Inhibitory Peptide, See L-Valyl-L-prolyl-L-prolyl-L-prolyl-L-valyl-L-prolyl-L-prolyl-L-arginyl-L-arginyl-L-arginine**

### Rasagiline

This irreversible monoamine oxidase inhibitor and early Parkinson monotherapy (FW = 171.24 g/mol; CAS 1875-50-9), also known as AGN 1135, TVP 1012, Azilect<sup>®</sup>, and (R)-N-(prop-2-ynyl)-2,3-dihydro-1H-inden-1-amine, forms stoichiometric N<sup>5</sup>-flavocyanine adducts with the FAD moieties within monoamine oxidase, Types A and B (1). The telling observation that no H<sub>2</sub>O<sub>2</sub> is produced during monoamine oxidase A and B inactivation indicates that covalent addition occurs within a single catalytic round. Rasagiline has a specificity index ( $k_{inact}/K_i$ ) that is ninety times greater for MAO B than MAO A (2). Rasagiline rescues degenerating dopamine neurons by inhibiting death signal transduction that is initiated by increased mitochondrial permeability and induction of antiapoptotic Bcl-2 (signaling through PKC) and Glial cell line-derived neurotrophic factor (GDNF) (3). When given prior to the dopaminergic neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP), rasagiline protected mice against neurotoxicity, supporting the oxidation of MPTP to 1-methyl-4-phenyl-pyridinium (MPP<sup>+</sup>) as an important feature of the neurotoxic process (4). (See also *Ladostigil*) 1. Youdim & Finberg (1987) *Adv. Neurol.* **45**, 127. 2. Hubálek, Binda, Li, *et al.* (2004) *J. Med. Chem.* **47**, 1760. 3. ### Raubasine

This alkaloid (FW<sub>free-base</sub> = 352.43 g/mol; CAS 483-04-5), also known as  $\delta$ -yohimbine, ajmalicine, and (19 $\alpha$ )-16,17-didehydro-19-methoxyayohimban-16-carboxylic acid methyl ester, isolated from *Corynanthe johimbe* and *Rauwolfia serpentina* is an  $\alpha_1$ -adrenergic blocker (1-3) that is structurally similar to  $\alpha$ -yohimbine (or rauwolscine). Like corynanthine, it acts as a  $\alpha_1$ -adrenergic receptor antagonist with preferential actions over  $\alpha_2$ -adrenergic receptors, underlying its hypotensive rather than hypertensive effects (4). 1. Rimele, Rooke, Aarhus & Vanhoutte (1983) *J. Pharmacol. Exp. Ther.* **226**, 668. 2. Demichel, Gomond & Roquebert (1981) *Brit. J. Pharmacol.* **74**, 739. 3. Roquebert (1986) *Arch. Int. Pharmacodyn. Ther.* **282**, 252. 4. Roquebert & Demichel (1984) *Eur. J. Pharmacol.* **106**, 203.

**Rauwolfia Serpentina Root**

This tranquilizing and antihypertensive powder, prepared from the root of the Indian snakeroot (*sarpagandha* in Hindi and *shégēn mù* in Chinese), also known as Insanity Herb, contains variable amounts of psychoactive substances, including reserpine, yohimbine, ajmaline, deserpidine, rescinnamine, and serpentinine. As the major alkaloid of the root, reserpine was one of the earliest recognized tranquilizers and also found broad application in the treatment of paranoia and schizophrenia. Its antihypertensive properties are well described (1). The root enjoys a long history in India, where medicine men still use it to treat both mental illness and snakebite. *Note:* Although having received FDA action on January 28, 1954 (NDA 009276), there are no Indications of Approved Use or designated Therapeutic Equivalents. 1. Genest, Adamkiewics, Robillard & Tremblay (1955) *London Med. Assoc. J.* **72**, 483.

**Rauwolscine**

This alkaloid (FW<sub>free-base</sub> = 356.42 g/mol; CAS 6211-32-1), also known as  $\alpha$ -yohimbine, from the tree bark of *Rauwolfia serpentina*, *R. canescens*, and *Corynanthe yohimbe* is an  $\alpha_2$ -adrenergic antagonist as well as a 5-HT<sub>1A</sub> serotonergic receptor agonist. Rauwolscine diastereoisomers include yohimbine, corynanthine, and *allo*-yohimbine. **See also** *Yohimbines* **Target(s):**  $\alpha_2$ -adrenergic receptor. 1. Perry & U'Prichard (1981) *Eur. J. Pharmacol.* **76**, 461.

**Raventoxin**

These venom toxins from the spider *Macrothele raventi* target voltage-gated sodium channels, shifting to a hyperpolarized state and slowing recovery. They include: Raventoxin-I (MW = 4840.11 Da); Raventoxin-II (MW = 3021.56 Da); Raventoxin-III (MW = 3286.58 Da); Raventoxin-V (MW = 3133.48 Da); and Raventoxin-VI (MW = 5371.60 Da). The crude venom was found to be neurotoxic in mice (LD<sub>50</sub> = 2.8 mg/kg) (1). Raventoxin-I appears to exert an effect of first exciting and then inhibiting the contraction of mouse diaphragm muscle caused by electrically stimulating the phrenic nerve (1). Venom potently and selectively suppresses the growth of K562 chronic myelogenous leukemia cells, inducing apoptosis via Caspase 3- and Caspase 8- mediated signaling pathways (2). 1. Zeng, Xiao & Liang (2003) *Toxicol.* **41**, 651. 2. Liu, Zhao, Li, *et al.* (2012) *Leuk. Res.* **36**, 1063.

**Ravuconazole**

This antifungal agent (FW = 437.47 g/mol; CAS 170864-29-6; *Abbreviation:* RAV), also known as ER-30306 and systematically named as 3-(4-(4-cyanophenyl)thiazol-2-yl)-2-(2,4-difluorophenyl)-1-(1*H*-1,2,4-triazol-1-yl)-2-butanol, inhibits sterol 14-demethylase, or CYP51 (1). Ravuconazole is a broad-spectrum triazole with *in vitro* activity against most *Candida* and *Aspergillus* species, some non-*Aspergillus* species of filamentous fungi, *Cryptococcus*, dermatophytes, and fungi that cause the endemic mycoses. The sterol biosynthesis pathway has received attention as a target for the development of new drugs for Chagas disease, and inhibitors

of sterol 14-demethylase are shown to be extremely active on *Trypanosoma cruzi*, both in *in vitro* and in animal experiments. **Prodrug:** In the orally administered, water soluble ravuconazole prodrug known as E1224, the hydrogen of the -OH group is replaced by -CH<sub>2</sub>OPO<sub>3</sub>H<sup>-</sup>. 1. Mellado, Garcia-Effron, Buitrago, *et al.* (2005) *Antimicrob. Agents Chemother.* **49**, 2536.

**Razoxane**

This racemic iron-chelating antimetastatic agent (FW<sub>free-base</sub> = 268.27 g/mol; CAS 21416-87-5), also known as ICRF-159, is a cyclized methyl-EDTA derivative that inhibits topoisomerase II by blocking the enzyme reaction cycle at the stage where the enzyme forms a closed clamp conformation around DNA, thereby interfering with transcription (or other DNA metabolic processes) and resulting in cell death. *Note:* Razoxane has a central chiral carbon, and its (+)- and (-)-enantiomers, often called dexrazoxane (Zinecard<sup>®</sup>) and levorazoxane, have the pharmaceutical code names ICRF-187 and ICRF-186, respectively. **Target(s):** collagen-peptidase (1); and DNA topoisomerase II (2-10). 1. Boggust & McGauley (1978) *Brit. J. Cancer* **38**, 329. 2. Hammonds, Maxwell & Jenkins (1998) *Antimicrob. Agents Chemother.* **42**, 889. 3. **RB 38A**

This peptidase inhibitor (FW<sub>free-acid</sub> = 370.41 g/mol; CAS 105831-46-7; (*R*)-[3-(*N*-hydroxycarboxamido)-2-benzylpropanoyl]-L-phenylalanine) targets neprilysin (1,2) and membrane alanyl aminopeptidase, or aminopeptidase N, with respective *K<sub>i</sub>* values of 0.9 and 120 nM. RB 38A is relatively poor at crossing the blood-brain barrier. Membrane alanyl aminopeptidase degrades a number of small secreted peptides, among them, amyloid  $\beta$ -peptide which has been implicated as a causative factor of Alzheimer's disease. Aminopeptidase N is responsible for the processing of peptide hormones, such as angiotensin III and IV, neuropeptides, and chemokines. It also cleaves antigen peptides bound to major histocompatibility complex class II molecules of presenting cells and degrades certain neurotransmitters at synaptic junctions. 1. Roques, Noble, Crine & Fournié-Zaluski (1995) *Meth. Enzymol.* **248**, 263. 2. Bauvois & Dauzonne (2006) *Med. Res. Rev.* **26**, 88. 3. Noble, Luciani, Da Nascimento, *et al.* (2000) *FEBS Lett.* **467**, 81. 4. Luciani, Marie-Claire, Ruffet, *et al.* (1998) *Biochemistry* **37**, 686.

## RB 101

This double-prodrug (FW = 492.73 g/mol; CAS 135949-60-9), also called *N*-(*R,S*)-2-benzyl-3[(*S*)-(2-amino-4-methylthiobutylidithio)-1-oxopropyl]-L-phenylalanine, generates the following two specific inhibitors upon cleavage of its disulfide bond: *N*-[(*R,S*)-2-mercaptomethyl-1-oxo-3-phenylpropyl]-L-phenylalanine, a neprilysin inhibitor ( $K_i = 2$  nM), and (*S*)-2-amino-1-mercapto-4-methylthiobutane, an aminopeptidase N (or membrane alanyl aminopeptidase) inhibitor ( $K_i = 11$  nM). It was the first systemically-active mixed inhibitor of enkephalin-degrading enzymes. *Note*: The benzyl ester of the prodrug has also been referred to as RB 101. **Target(s)**: membrane alanyl aminopeptidase, or aminopeptidase N (1-3); and neprilysin (1-3). 1. Roques, Noble, Crine & Fournié-Zaluski (1995) *Meth. Enzymol.* **248**, 263. 2. Ruiz-Gayo, Baamonde, Turcaud, Fournié-Zaluski & Roques (1992) *Brain Res.* **571**, 306. 3. Bauvois & Dauzonne (2006) *Med. Res. Rev.* **26**, 88.

## RB 104

This peptide analogue (FW<sub>free-acid</sub> = 526.33 g/mol; CAS 145253-48-1), also called 2-((3-iodo-4-hydroxy)phenylmethyl)-4-*N*-[3-(hydroxyamino-3-oxo-1-phenylmethyl)propyl]amino-4-oxobutanoic acid, inhibits neprilysin ( $K_i = 27$  pM). **Target(s)**: *Aplysia* neutral endopeptidase (1); neprilysin (2-4); peptidyl-dipeptidase A, or angiotensin I-converting enzyme; weakly inhibited,  $K_i = 15$  μM (3). 1. Bawab, Aloyz, Crine, Roques & DesGroseillers (1993) *Biochem. J.* **296**, 459. 2. Roques, Noble, Crine & Fournié-Zaluski (1995) *Meth. Enzymol.* **248**, 263. 3. Fournié-Zaluski, Soleilhac, Turcaud, et al. (1992) *Proc. Natl. Acad. Sci. U.S.A.* **89**, 6388. 4. Landry, Santagata, Bawab, et al. (1993) *Biochem. J.* **291**, 773.

## Reactive Blue 4

This blue dye (FW<sub>free-acid</sub> = 637.44 g/mol; CAS 13324-20-4;  $\lambda_{max} = 595$  nm), also known as Procion Blue MX-R, Procion Royal Blue MX-R, Procion Blue MX-3G, Procion Blue M-3GS, and Procion Brilliant Blue RS, is a triazine stain. *Note*: There is some confusion concerning the nomenclature and structure. Some sources, including commercial vendors, such as Aldrich, refer to the upper structure, whereas many of the literature sources refer to the lower structure. For example, the anthraquinone dye (bottom) is the electrophilic dichlorotriazine precursor of Cibacron Blue. It is an irreversible inhibitor of NAD(P)H:(quinone-acceptor) oxidoreductase, or quinone reductase;  $K_i = 16$  nM,  $k_3 = 0.03$  min<sup>-1</sup> (1). This inactivation is blocked by Cibacron Blue. **Target(s)**: alcohol dehydrogenase (2); choline-phosphate cytidyltransferase (3);  $\alpha$ 1,6-fucosyltransferase (4); glucokinase (5); glucose-6-phosphate dehydrogenase (6); glycerol kinase (5); NAD(P)H:(quinone-acceptor) oxidoreductase, inhibited by Procion Blue M-3GS (1); polyphosphate:glucose phosphotransferase (7); pyruvate kinase (8,9); and ricin A chain (10). 1. Pretera, Prochaska & Talalay (1992) *Biochemistry* **31**, 824. 2. Small, Lowe, Atkinson & Bruton (1982) *Eur. J. Biochem.* **128**, 119. 3. Hunt & Postle (1986) *Biochem. Soc. ## Reboxetine

This oral antidepressant (FW<sub>free-base</sub> = 313.40 g/mol; CAS 98769-81-4, for mesylate salt; Solubility: 50 mM in H<sub>2</sub>O; 50 mM in DMSO), known also as Vestra™ and named systematically as 2-((2-ethoxyphenoxy)benzyl)morpholine methanesulfonate, is the first selective noradrenaline (norepinephrine) reuptake inhibitor. Reboxetine is a potent and selective inhibitor of noradrenalin transporter, or NET ( $K_i = 1.1$  nM), with weaker action against SERT ( $K_i = 129$  nM) and DAT ( $K_i > 10000$  nM), and displaying > 1000x selectivity over  $\alpha$ -adrenoceptors, 5-HT, dopamine and muscarinic ACh receptors. It also prevents clonidine-induced hypothermia in mice. 1. Kasper, el Giamal & Hilger (2000) *Expert Opin. Pharmacother.* **1**, 771. 2. Sacchetti, et al. (1999) *Brit. J. Pharmacol.* **128**, 1332. 3. Wong, et al. (2000) *Biol. Psychiatry* **47**, 818. 4. Millan, et al. (2001) *J. Pharmacol. Exp. Ther.* **298**, 565. 5. Owen & Whitton (2003) *Neurosci. Lett.* **348**, 171.

## Recoverin

This retinal/pineal-specific calcium binding protein (MW = 23 kDa; CAS 135844-11-0) participates in visual signal transduction and is tethered to

membranes by means of its *N*-terminal myristoyl group. A surge in intracellular calcium ion forms Ca<sup>2+</sup>-bound recoverin, which then combines with rhodopsin kinase to form a Ca<sup>2+</sup>-recoverin-rhodopsin kinase ternary complex that is stabilized by its membrane association, resulting in effective suppression of rhodopsin kinase activity (1-12). Half-maximal inhibition occurs at 1.5-3 μM free Ca<sup>2+</sup>, with a Hill coefficient of ~2. A drop in free calcium ion following illumination is thus a key regulatory step during photoresponse recovery and light adaptation. **See also S-Modulin** 1. Chen & Hurley (2000) *Meth. Enzymol.* **315**, 404. 2. Kawamura, Hisatomi, Kayada, Tokunaga & Kuo (1993) *J. Biol. Chem.* **268**, 14579. 3. Gorodovikova, Gimelbrant, Senin & Philippov (1994) *FEBS Lett.* **349**, 187. 4. **Regorafenib**

This orally active, multi-kinase inhibitor (FW = 482.82 g/mol; CAS 755037-03-7), also known as BAY 73-4506, Stivarga®, and 4-[4-(4-chloro-3-(trifluoromethyl)phenyl)carbamoyl]amino-3-fluorophenoxy]-*N*-methylpyridine-2-carboxamide hydrate, targets angiogenic, stromal, and oncogenic receptor tyrosine kinase-mediated processes, mainly through its inhibitory action on the anti-angiogenic activity of VEGFR2-TIE2 tyrosine kinases. Treatment of advanced-stage cancer patients with regorafenib has adverse hepatic, cardiovascular, cutaneous, gastrointestinal, thyroid, neurological and haematological effects, as well as infections and bleeding (2). These adverse effects are severe in about 40% of patients. A Phase I dose escalation study suggests that regorafenib has an acceptable safety profile as well as antitumor activity in patients with solid tumors (3). **Target(s)**: VEGFR1 (IC<sub>50</sub> = 13 nM), VEGFR2 (IC<sub>50</sub> = 4.2 nM), VEGFR3 (IC<sub>50</sub> = 46 nM), PDGFRβ (IC<sub>50</sub> = 22 nM), Kit (IC<sub>50</sub> = 7 nM), RET (IC<sub>50</sub> = 1.5 nM) and Raf-1 (IC<sub>50</sub> = 2.5 nM). 1. **REGN727**, **See Alirocumab**

**Regucalcin**

This Ca<sup>2+</sup> and GTP binding protein (FW = 33250 g/mol; Accession: BAA84082.1; Symbol: RGN) participates in maintaining intracellular Ca<sup>2+</sup> homeostasis due to activating Ca<sup>2+</sup> pump enzymes in the plasma membrane (basolateral membrane), microsomes (endoplasmic reticulum), and the mitochondria of many cell types. Because its expression is down-regulated with aging, RGN is also known as senescence marker protein-30. Beyond its well-known role in Ca<sup>2+</sup> homeostasis, RGN has been linked to the control of an oxidative stress, cell proliferation, apoptosis, and signal transduction (4). RGN has antioxidant properties, reducing ROS production while increasing antioxidant defenses. RGN also suppresses cell proliferation through regulation of oncogene and tumor suppressor gene expression (4). **Target(s)**: phosphoprotein phosphatase (1); protein kinase C (2); and protein-tyrosine-phosphatase (2,3). 1. Ichikawa, Tsurusaki & Yamaguchi (2004) *Int. J. Mol. Med.* **13**, 289. 2. Yamaguchi (2005) *Int. J. Mol. Med.* **15**, 371. 3. Fukaya & Yamaguchi (2004) *Int. J. Mol. Med.* **14**, 427. 4. Vaz, Correia, Cardoso, *et al.* (2016) *Curr. Mol. Med.* **16**, 607.

**Remazol Brilliant Blue R**

This reactive anthraquinone dye (FW<sub>disodium-salt</sub> = 626.55 g/mol; CAS 2580-78-1; λ<sub>max</sub> = 592 nm), also known as reactive blue 19 and named systematically as, 1-amino-9,10-dihydro-9,10-dioxo-4-((3-(2-(sulfoxyethyl)sulfonyl)phenyl)amino)-2-anthracenesulfonic acid, is frequently linked to polysaccharides or polymeric proteinase substrates to form chromagenic substrates. **Target(s)**: lactate dehydrogenase (1,2); and Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (2). 1. Bohacova, Docolomansky, Breier, Gemeiner & Ziegelhoffer (1998) *J. Chromatogr. B Biomed. Sci. Appl.* **715**, 273. 2. Durisova, Vrbanova, Ziegelhoffer & Breier (1990) *Gen. Physiol. Biophys.* **9**, 519.

**Remikiren**

This peptide (FW<sub>free-base</sub> = 630.85 g/mol; CAS 135669-48-6), also known as Ro 42-5892 and named systematically as (S)-α-((S)-α-((*t*-butylsulfonyl)methyl)hydrocinnamamido)-*N*-((1*S*,2*R*,3*S*)-1-(cyclohexylmethyl)-3-cyclopropyl-2,3-dihydropropyl)imidazole-4-propionamide, is a potent inhibitor of human renin, IC<sub>50</sub> = 0.7 nM (1,2). It was the first orally active renin inhibitor, albeit with low oral absorption. 1. Fischli, Clozel, el Amrani, *et al.* (1991) *Hypertension* **18**, 22. 2. Mathews, Doebli, Pruschy, *et al.* (1996) *Protein Expr. Purif.* **7**, 81.

**Remoxipride**

This now discontinued atypical antipsychotic (FW = 371.27 g/mol; CAS 117591-79-4), also named Roxiam® and systematically as 3-bromo-*N*-[[2-(2*S*)-1-ethylpyrrolidin-2-yl]methyl]-2,6-dimethoxybenzamide, had been used in Europe to treat schizophrenia and acute mania. It also has marked affinity for central sigma receptors. Remoxipride was withdrawn in 1993 due to high incidence of aplastic anemia in treated patients. Remoxipride acts as a selective D<sub>2</sub> and D<sub>3</sub> receptor antagonist and also has high affinity for the sigma receptor, possibly playing a role in its atypical neuroleptic action. 1. Wadworth & Heel (1990) *Drugs* **40**, 863. (Erratum: *Drugs* (1991) **41**, 532.)

**Renilla Luciferin**, **See Coelenterazine**

**Renin Inhibitor H142**

This pseudopeptide-containing inhibitor (MW = 1208.5 g/mol; Sequence = PPHPFHL[CH<sub>2</sub>-NH]VIHK, where the linkage between Leu-6 and Val-7 is a "reduced" peptide bond (as a mimic of the presumptive tetrahedral intermediate)) targets endothiapepsin,  $K_i = 160$  nM (1-4) and renin,  $K_i = 10$  nM (3-6). 1. Hallett, Jones, Atrash, *et al.* (1985) in *Aspartic Proteinases and Their Inhibitors* (Kostka, ed.), *Proc. FEBS Advanced Course* 84/07, pp. 467-478, Walter de Gruyter & Co., Berlin. 2. **RepSox**

This potent and selective ALK inhibitor (FW = 287.33 g/mol; CAS 446859-33-2; Solubility: 57 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as E-616452, SJN-2511, and 2-[3-(6-methyl-2-pyridinyl)-1*H*-pyrazol-4-yl]-1,5-naphthyridine, targets TGFβR-1/ALK5 with IC<sub>50</sub> values of 23 nM and 4 nM for ATP binding to ALK5 and ALK5 autophosphorylation (1,2). RepSox replaces Sox2 by inhibiting Tgf-β signaling in cultures containing stable intermediate cells trapped in a partially reprogrammed state. The resulting sustained transcription of Nanog demonstrates the feasibility of replacing the central reprogramming transgenes with small molecules that modulate discrete cellular pathways or processes rather than by globally altering chromatin structure (2). 1. Gellibert, Woolven, Fouchet, *et al.* (2004) *J. Med. Chem.* **47**, 4494. 2. Ichida, Blanchard, Lam, *et al.* (2009) *Cell Stem Cell* **5**, 491.

**RES 701-1**

This endothelin type B receptor antagonist (MW = 2045.20 g/mol; CAS 151308-34-8), a cyclopeptide from *Streptomyces* sp RE-701, has the sequence GNWHGTAPDWFNYYW, wherein an isopeptide bond joins Glycine-1 and Aspartate-9. RES-701-1 blocks endothelin binding (IC<sub>50</sub> = 10 nM) (1-3). 1. Morishita, Chiba, Tsukuda, *et al.* (1994) *J. Antibiot.* **47**, 269. 2. **Reserpine**

This catecholamine-depleting alkaloid (FW<sub>free-base</sub> = 608.69 g/mol CAS 50-55-5; Source: *Rauwolfia*), also known as (3β,16β,17α,18β,20α)-11,17-dimethoxy-18-[(3,4,5-trimethoxy-benzoyl)oxy]yohimban-16-carboxylic acid methyl ester, is both an antihypertensive agent and a tranquilizer. Reserpine irreversibly blocks the Vesicular Monoamine Transporter (VMAT) that transports free intracellular norepinephrine, serotonin, and dopamine within the presynaptic nerve terminal into presynaptic vesicles for their subsequent exocytotic release into the synaptic cleft. Reserpine thereby reduces catecholamine and serotonin stores, altering catecholaminergic- and serotonergic-dependent neuronal processes. **Target(s)**: aldehyde dehydrogenase (1); Ca<sup>2+</sup> transport (5,6); dopamine uptake (4); hyaluronoglucosaminidase, or hyaluronidase (9); multidrug efflux pumps (5,8); NAD<sup>+</sup> ADP-ribosyltransferase, or poly(ADP-ribose) polymerase (10); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (6); oxidative phosphorylation (7); and xenobiotic-transporting ATPase, or multidrug-resistance protein (8). 1. **Resiquimod**

This immune response modifier (FW = 314.39 g/mol; CAS 144875-48-9; Solubility: 200 mM in DMSO), also known as R-848 and 4-amino-2-(ethoxymethyl)-α,α-dimethyl-1*H*-imidazo[4,5-*c*]quinoline-1-ethanol, is a potent toll-like receptor-7 (TLR 7) and -8 (TLR8) agonist. Resiquimod mimics effects of the T-dependent CD40 signal in both mouse and human B cell lines. Toll-like receptors (TLRs) play an important role in the innate immune response to pathogens. TLRs detect PAMPs (pathogen-associated molecular patterns) and stimulate immune cells *via* the MyD88-dependent interleukin-1 receptor (IL-1R)-TLR signaling pathway, which leads to activation of the transcription factor NF-κB. Like CD40, resiquimod stimulates antibody secretion, cytokine production, protects cells from apoptosis, and upregulates CD80. In addition, it shows synergy with signals delivered by the B-cell antigen receptor and heightens CD40-mediated B cell activation, demonstrating that resiquimod can enhance antigen-specific responses in B lymphocytes. 1. Bishop, Ramirez, Baccam, *et al.* () *Cellular Immunol.* **208**, 9.

**Resorcinol**

This common redox-active reagent (FW = 110.11 g/mol; CAS 108-46-3; white solid; M.P. = 109-111°C) is less frequently known as 1,3-quinol, 1,3-hydroquinone, resorcin, and 1,3-dihydroxybenzene. *Note*: Resorcinol

decomposes (turning pink) upon exposure to light, air, and iron. Solutions should always be freshly prepared and protected from light. Resorcinol is also a key component in the Seliwanoff test for the qualitative determination of ketoses. **Target(s):**  $\gamma$ -butyrobetaine hydroxylase, or  $\gamma$ -butyrobetaine:2-oxoglutarate dioxygenase (1); cAMP phosphodiesterase (2); carboxylase (3,4); catalase (5); catechol oxidase (6,7); complement component C'3, guinea pig (8); 2,6-dihydropyridine 3-monooxygenase (9); esterase (10); glyoxalase I, or lactoylglutathione lyase (11); lipase, weakly inhibited (12); lipoxygenase (13); papain (14); pyrogallol hydroxytransferase (15); starch phosphorylase (16); tannase (17); tyrosinase, alternative substrate (6,18); and tyrosine phenol-lyase (19). 1. **Restrictocin. See Ribotoxins**

**Resveratrol**

This *trans*-stilbene derivative (FW = 228.25 g/mol; CAS 501-36-0, for *trans*-isomer), also known as 3,4',5'-trihydroxy-*trans*-stilbene, is the phenolic antioxidant found in red wine, grape skins, peanuts, and cranberries. Resveratrol modulates lipid metabolism and inhibits platelet aggregation. It is also an antagonist of the aryl hydrocarbon (Ah) receptor. Other studies indicate resveratrol exhibits vasodilative, and anti-inflammatory properties. **Target(s):** aldehyde dehydrogenase (1); Ca<sup>2+</sup> influx (2); casein kinase II (31); creatine kinase (3); cyclooxygenase, or peroxidase activity, IC<sub>50</sub> = 15  $\mu$ M for COX-1 and 200  $\mu$ M for COX-2 (4-9); CYP1A1 (10,11); CYP1A2 (10); CYP3A5 (12); CYP1B1 (10,13-15); CYP2B1 (16); CYP2C19 (17); CYP2D (18); CYP2E1 (19,20); CYP3A4 (12,17,20); DNA-directed DNA polymerase (21); DNA topoisomerase II (37); electron transport (22); estrone sulfotransferase (41,42); fatty-acid synthase (47); F<sub>1</sub>F<sub>0</sub> ATPase, or ATP synthase, or H<sup>+</sup>-transporting two-sector ATPase (22-25); glutathione S-transferase (46); I $\kappa$ B kinase (43); lipoxygenase (6,26); mitogen-activated protein kinase (27); monoamine oxidase A (28); peptidyl-dipeptidase A, or angiotensin I-converting enzyme; weakly inhibited (39); phenylpyruvate tautomerase (38); 1-phosphatidylinositol 4-kinase (45); prostaglandin H synthase (17); protein kinase C (29,30); protein kinase CKII, or casein kinase II (31); protein kinase D (30,32); non-specific protein-tyrosine kinase (33,34,44); steroid 21-monooxygenase (49); sterol esterase, or cholesterol esterase (40); succinate dehydrogenase, weakly inhibited (22); tyrosinase, or monophenol monooxygenase (35,36,50,51); and xanthine oxidase (28,48). 1. ### Retapamulin

This pleuromutilin-class topical antibiotic (FW = 517.77 g/mol; CAS 224452-66-8), also named SB-275833, Altanax<sup>®</sup>, Altargo<sup>®</sup>, and mutilin 14-(*exo*-8-methyl-8-azabicyclo[3.2.1]oct-3-yl)sulfanylacetate, is a translational inhibitor that binds to domain V of 23S rRNA on the bacterial ribosome's 50S subunit, thereby directly blocking peptide formation by interfering with substrate binding (1). Retapamulin has demonstrated efficacy against certain Gram-positive bacteria, including methicillin-resistant *Staphylococcus aureus* (MRSA). The MIC<sub>90</sub> for retapamulin is 0.12 µg/mL for *Staphylococcus aureus* and ≤ 0.03 µg/mL for *Streptococcus pyogenes*. There is no cross-resistance for microorganism subsets that are resistant to oxacillin, erythromycin, or mupirocin. Compared to tiamulin, retapamulin appears to be uniformly eightfold more potent. 1. Jones, Fritsche, Sader & Ross (2006) *Antimicrob. Agents Chemother.* **50**, 2583.

### *all-trans*-Retinal

This aldehyde (FW = 284.44 g/mol; CAS 116-31-4; orange solid; M.P. = 61-64°C; light exposure generates various *cis*-isomers), commonly known as vitamin A aldehyde and systematically named as (2*E*,4*E*,6*E*,8*E*)-3,7-dimethyl-9-(2,6,6-trimethylcyclohex-1-en-1-yl)nona-2,4,6,8-tetraenal, is an essential component of the visual cycle. Retinal is a substrate of the reaction catalyzed by retinal dehydrogenase, retinal oxidase, and retinal isomerase. Retinal formation is catalyzed by retinol dehydrogenase and β-carotene 15,15'-dioxygenase. **Target(s):** CYP1A1 (1); NAD<sup>+</sup> ADP-ribosyltransferase, or poly(ADP-ribose) polymerase; IC<sub>50</sub> = 0.45 mM (2) 1. Inouye, Mae, Kondo & Ohkawa (1999) *Biochem. Biophys. Res. Commun.* **262**, 565. 2. Banasik, Komura, Shimoyama & Ueda (1992) *J. Biol. Chem.* **267**, 1569.

### *all-trans*-Retinoate

This bioactive acid (FW<sub>free-acid</sub> = 300.44 g/mol; CAS 302-79-4; yellow solid; M.P. = 180-182°C; soluble in methanol, ethanol, and dimethyl sulfoxide; λ<sub>max</sub> = 350 nm in ethanol (ε = 45400 M<sup>-1</sup>cm<sup>-1</sup>), also known as *all-trans*-retinoic acid, (2*E*,4*E*,6*E*,8*E*)-3,7-dimethyl-9-(2,6,6-trimethylcyclohex-1-en-1-yl)nona-2,4,6,8-tetraenoic acid and vitamin A<sub>1</sub> acid, regulates gene expression by binding to the retinoic acid receptor. Retenoate plays a major role in development, cell proliferation, and in morphogenic changes. Retinoate is produced from retinal by either retinal dehydrogenase or retinal oxidase. It is also a substrate for a number of cytochrome P450 monooxygenases (*e.g.*, CYP2C8). **Target(s):** CYP1A1 (1); diferric-transferrin reductase (2); estrone sulfotransferase (3); β-glucuronidase (4); glutamate dehydrogenase (4); guanidinobenzoate (5); lipoxygenase (6); prostaglandin-D synthase (7); retinol acyltransferase (8); retinyl-palmitate esterase (9); and ribonuclease P (10). 1. ### 13-*cis*-Retinoate

This naturally occurring vitamin A metabolite (FW<sub>free-acid</sub> = 300.44 g/mol; CAS 4759-48-2; M.P. = 174-175°C; λ<sub>max</sub> = 354 nm; ε = 39800 M<sup>-1</sup>cm<sup>-1</sup>), also known as 13-*cis*-retinoic acid, isotretinoin and (2*Z*,4*E*,6*E*,8*E*)-3,7-dimethyl-9-(2,6,6-trimethylcyclohex-1-en-1-yl)nona-2,4,6,8-tetraenoic acid,

inhibits sebum production and is used as an antiacne agent. **Target(s):** lipoxygenase (1); retinol dehydrogenase, or 3 $\alpha$ -hydroxysteroid dehydrogenase (2,3); retinyl-palmitate esterase (4); ribonuclease P (5); and thioredoxin reductase (6,7). 1. Goldreich, Grossman, Sofer, Breitbart & Sklan (1997) *Int. J. Vitam. Nutr. Res.* **67**, 4. 2. Karlsson, Vahlquist, Kedishvili & Torma (2003) *Biochem. Biophys. Res. Commun.* **303**, 273. 3. #### all-trans-Retinol

This essential nutrient and potential signaling molecule (FW = 286.46 g/mol; CAS 11103-57-4;  $\lambda_{\max}$  = 325 nm in ethanol ( $\epsilon$  = 52480 M<sup>-1</sup>cm<sup>-1</sup>); photolabile; readily oxidized in air), commonly called vitamin A, can be obtained from carotenoids. It is also unstable in acidic conditions. Retinol is stabilized by the presence of antioxidants such as hydroquinone or  $\alpha$ -tocopherol. Retinol is also stabilized by esterification (e.g., retinyl palmitate). **Target(s):** arylsulfatase A, or cerebroside-sulfatase (1); cathepsin D (2); CYP1A1 (3);  $\beta$ -glucuronidase (4); glutamate dehydrogenase (4); GTPase (5); hemoglobin S polymerization (6); and lipoxygenase (7). 1. #### all-trans-Retinyl Bromoacetate

This retinol ester (FW = 407.39 g/mol) is a potent irreversible inhibitor of phosphatidylcholine:retinol *O*-acyltransferase:  $K_i$  = 12.1  $\mu$ M and the pseudo-first-order inactivation rate constant ( $k_{\text{inh}}$  = 8.2 x 10<sup>-4</sup> s<sup>-1</sup>). **Target(s):** phosphatidylcholine:retinol *O*-acyltransferase (1-6); retinol *O*-fatty-acyltransferase (5). 1. Ruiz & Bok (2000) *Meth. Enzymol.* **316**, 400. 2. Shi, Furuyoshi, Hubacek & Rando (1993) *Biochemistry* **32**, 3077. 3. Trehan, Canada & Rando (1990) *Biochemistry* **29**, 309. 4. **Retrothiorphan, See 3-[(R)-1-(Mercaptomethyl)-2-phenylethyl]amino-3-oxopropanoate**

**Retrovir, See 3'-Azido-3'-deoxythymidine**

#### REV 5367

This aryl methyl phenyl ether (FW = 328.41 g/mol) is a structural analogue of 15-hydroxy-(5Z,8Z,11Z,13E)-eicosatetraenoic acid (15-HETE), which is produced from arachidonate in the 15-lipoxygenase pathway. REV-5367 inhibits 5-lipoxygenase with  $I_{50}$  = 3  $\mu$ M. *Note:* 15-HETE also inhibits 5-lipoxygenase. 1. Coutts, Khandwala, Van Inwegen, et al. (1985) in *Prostaglandins, Leukotrienes, and Lipoxins* (Bailey, ed.), p. 627, Plenum Press, New York.

#### Revaprazan

This novel proton pump antagonist (FW<sub>free-base</sub> = 362.44 g/mol; CAS 178307-42-1; FW<sub>HCl</sub> = 398.90 g/mol), also known by the code name YH1885 and systematically as *N*-(4-fluorophenyl)-4,5-dimethyl-6-(1-methyl-3,4-dihydro-1H-isoquinolin-2-yl)pyrimidin-2-amine, targets H<sup>+</sup>/K<sup>+</sup>-ATPase, thereby controlling gastric acid secretion. It also exerts anti-inflammatory action against *Helicobacter pylori*-induced COX-2 expression by inhibiting I $\kappa$ B- $\alpha$  degradation as well as Akt inactivation, resulting in attenuation of COX-2 expression (1). Plasma concentrations of YH1885 reached peak levels 1.3 to 2.5 hours after single-dose administration and then declined monoexponentially with a terminal half-life of 2.3 hours in dosage groups up to 200 mg in the single-dose study. YH1885 showed little accumulation after multiple administrations (2). The parent drug was not detected in urine, indicating its likely first-pass absorption and metabolism (2). Revaprazan also alleviates ER stress (i.e., accumulation of unfolded proteins in the endoplasmic reticulum), often accompanied by drastic apoptosis (3). 1. Lee, Cho, Song, Kim & Hahm (2012) *J. Clin. Biochem. Nutr.* **51**, 77. 2. Kim, Park, Cheung, et al. (2010) *J. Gastroenterol. Hepatol.* **25**, 1618. 3. Kim, Kim, Ock, et al. (2012) *J. Gastroenterol. Hepatol.* **27**, 120.

#### Reveromycin A

This polyketide antibiotic (FW<sub>free-acid</sub> = 660.80 g/mol; CAS 134615-37-5), isolated from a species of *Streptomyces*, inhibits cell-cycle G<sub>1</sub> phase and also induces apoptosis specifically in osteoclasts (1,2). Reveromycin A also inhibits isoleucyl-tRNA synthetase (3). 1. Takahashi, Osada, Koshino, et al. (1992) *J. Antibiot.* **45**, 1414. 2. Takahashi, Osada, Koshino, et al. (1992) *J. Antibiot.* **45**, 1409. 3. Miyamoto, Machida, Mizunuma, et al. (2002) *J. Biol. Chem.* **277**, 28810.

#### RG108

This potent, specific and cell-permeant DNA methylation inhibitor and epigenetic reprogramming agent (FW = 334.33 g/mol; CAS 48208-26-0; Solubility = 67 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known as *N*-phthalyl-L-tryptophan, targets human DNA methyltransferase, or DNMT, IC<sub>50</sub> = 115 nM (1-3). RG108 inhibits the free DNA methyltransferase, whereas 5-azacytidine needs to be incorporated into DNA. Other experiments showed

that increasing concentrations of RG108 resulted in increasing amounts of unprotected BstUI restriction fragments, representing the first example for pharmacologic inhibition of a purified DNA methyltransferase *in vitro* (1). Treatment of various cancer cell lines with RG108 results in net demethylation of DNA, attended by reactivation of tumor suppressor genes and inhibition of human tumor cell proliferation (3). 1. Brueckner, Boy, Siedlecki, *et al.* (2005) *Cancer Res.* **65**, 6305. 2. Schirmacher, *et al.* (2006) *Bioconjug. Chem.* **17**, 261. 3. Pasha, *et al.* (2011) *PLoS One* **6**, e23667.

### RG2833

This brain-penetrant HDAC inhibitor (FW = 339.43 g/mol; CAS 1215493-56-3; Solubility: 68 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as *N*-(6-(2-aminophenylamino)-6-oxohexyl)-4-methylbenzamide and RGFPI09, targets HDAC1 (IC<sub>50</sub> = 60 nM; K<sub>i</sub> = 32 nM) and HDAC3 (IC<sub>50</sub> = 50 nM; K<sub>i</sub> = 5 nM). Friedreich's ataxia (FRDA), the most common recessive ataxia in Caucasians, is linked to severely reduced levels of frataxin resulting from a large GAA triplet repeat expansion within the first intron of the *FXN* gene. In FRDA patients' peripheral blood mononuclear cells, RG2833 is highly potent in upregulating frataxin, supporting the concept that HDAC3 selectivity correlates with this property (1). RG2833 also shows a good dose-response correlation, with a 4-9x up-regulation in frataxin mRNA at 10 μM (1). These findings suggest that RG2833 decondenses the chromatin structure at the *FXN* gene, restoring frataxin levels in cells from FRDA patients. In a GAA-repeat expansion mutation-containing YG8R FRDA mouse model, RG2833 treatment improves motor coordination and increases locomotor activity (2). RGFPI09 also attenuates L-DOPA-induced dyskinesia in the MPTP-lesioned marmoset (3). 1. Rai, Soragni, Chou, *et al.* (2010) *PLoS One* **5**, e8825. 2. ### RH-34

This potent and selective 5-HT<sub>2A</sub> partial agonist (FW = 325.36 g/mol; CAS 1028307-48-3) targets the serotonin subtype-2A receptor. RH-34 is a ketanserin derivative, with the latter's 4-(*p*-fluorobenzoyl)-piperidine moiety replaced by the *N*-(2-methoxybenzyl) pharmacophore already described for the potent 5-HT<sub>2A</sub> agonists known as NBOMe-2C-B and NBOMe-2C-I. See also *Ketanserin*; *Pimavanserin*; *Risperidone*; *Ritanserin*; *Setoperone*; *Volinanserin*. 1. Silva, Heim, Strasser, Elz & Dove (2011) *J. Comput. Aided Mol. Des.* **25**, 51.

### L-Rhamnose

This deoxyhexose (FW = 164.16 g/mol; CAS 3615-41-6), also known as 6-deoxy-L-mannose, is a bacterial polysaccharide that is a common constituent in plant glycosides as well as gums and mucilages. Rhamnose is also found in free form in a number of plants (*e.g.*, poison sumac, *Rhus toxicodendron*). The α-pyranose form, shown above, is the prevalent species in aqueous solutions (60% at 44°C in D<sub>2</sub>O; 87% in dimethyl sulfoxide). The α-anomer has a very sweet taste. The β-crystal is hygroscopic and undergoes mutarotation upon exposure to moist air. L-Rhamnose is very soluble in water (57 g/100 mL at 18°C; 109 g/100 mL at 40°C). The epimers of L-rhamnose are 6-deoxy-L-glucose (L-quinovose), 6-deoxy-L-altrose, 6-deoxy-L-talose, and 6-deoxy-D-glucose. **Target(s):** β-fructofuranosidase, or invertase, inhibited by β-anomer (1); α-L-fucosidase (2); β-glucosidase, K<sub>i</sub> = 110 mM for the sweet almond enzyme (3); α-L-rhamnosidase, product inhibition (4-16). 1. ### Rhein

This yellow anthraquinone purgative and antirheumatic (FW<sub>free-acid</sub> = 284.22 g/mol; CAS 478-43-3), also known as 9,10-dihydro-4,5-dihydroxy-9,10-dioxo-2-anthracenecarboxylic acid and 1,8-dihydroxyanthraquinone-2-carboxylic acid, is found in rhubarb, Senna leaves, and other higher plants. **Target(s):** activator protein-1 activity and cell transformation through the inhibition of a c-Jun NH<sub>2</sub>-terminal kinase-dependent mechanism (1); arylamine *N*-acetyltransferase (2); CYP1A1 (3); electron transport (4,5); glucose uptake (6); inositol-trisphosphate 3-kinase (7); NADH dehydrogenase (4,8); and Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (9). 1. ### Rhazinilam

This microtubule poison (FW = 294.39 g/mol; CAS 36193-36-9; IUPAC Name: (3*aR*)-3*a*-ethyl-2,3,3*a*,4,5,7-hexahydroindolino[8,1-*ef*][1]benzazon in-6(1*H*)-one) from the *Melodinus australis* and *Rhazya stricta* protects assembled microtubules from cold-induced disassembly, but not from Ca<sup>2+</sup>-induced disassembly (1). Incubation of tubulin with rhazinilam at both 373 K and 410 K induced formation of anomalous tubulin polymeric spirals. The latter is prevented by maytansine and vinblastine, but not colchicine. Preferential saturable and stoichiometric incorporation of radiolabeled rhazinilam into these spirals,  $K_d = 5 \mu\text{M}$ , but binding is blocked by vinblastine and maytansine (1). Specific binding of radioactive rhazinilam to microtubules is not observed. Omission of GTP, causes a major change in the morphology in (-)-rhazinilam-induced tubulin polymers, with half of the observed polymer microtubule-like and the other half spirals (2). **See Colchicine; Epothilone; Maytansine; Paclitaxel (Taxol); Podophyllotoxin; Taxotere; Vinblastine** **1.** David, Sévenet, Morgat, *et al.* (1994) *Cell Motil. Cytoskeleton* **28**, 317. **2.** Edler, Yang, Jung, *et al.* (2009) *Arch. Biochem. Biophys.* **487**, 98.

### Rhizobitoxine

This toxic substance (FW<sub>dihydrochloride</sub> = 263.12 g/mol), also known as 1-2-amino-4-(2'-amino-3'-hydroxypropoxy)-*trans*-3-butenoic acid, is produced by *Rhizobium japonicum* that inhibits cystathionine  $\beta$ -lyase, apparent  $K_i = 220 \text{ nM}$ . Rhizobitoxine inhibits a number of pyridoxal-5'-phosphate-dependent enzymes. This phytotoxin also inhibits ethylene production. **Target(s):** 1-aminocyclopropane-1-carboxylate synthase (1-3); and cystathionine  $\beta$ -lyase (4-10). **1.** Adams & Yang (1981) *Trends Biochem. Sci.* **6**, 161. **2.** Yasuta, Satoh & Minamisawa (1999) *Appl. Environ. Microbiol.* **65**, 849. **3.** Jakubowicz (2002) *Acta Biochim. Pol.* **49**, 757. **4.** Guggenheim (1971) *Meth. Acta* **158**, 219. **9.** Giovanelli, Owens & Mudd (1972) *Plant Physiol.* **51**, 492. **10.** Ravel, Job & Douce (1996) *Biochem. J.* **320**, 383.

### Rhizoxin

This macrocyclic lactone (FW = 625.76 g/mol; CAS 90996-54-6) inhibits mitosis by interfering with microtubule self-assembly (1-4) and appears to be effective against vincristine-resistant human and murine tumor cells (5). In evidence of its substantial effect on tubulin conformation, rhizoxin blocks intrachain covalent cross-linking in the  $\beta$ -tubulin subunit by *N,N*-

methylene-bis(iodoacetamide).  $\beta$ -tubulin may also be irreversibly modified with the photoaffinity agent azidodansyl-rhizoxin. Plant and fungal tubulins also bind rhizoxin in a manner that inhibits *de novo* microtubule assembly and promotes depolymerization of preexisting microtubules. Rhizoxin is stable for up to several years, when stored at 0°C. Solutions may be prepared in dimethyl sulfoxide or ethanol and are stable for several weeks in the cold. (**See also** *Maytansine, Vinblastine, Vincristine*) **1.** Sawada, Kobayashi, Hashimoto & Iwasaki (1993) *Biochem. Pharmacol.* **45**, 1387. **2.** Takahashi, Iwasaki, Kobayashi, *et al.* (1987) *Biochim. Biophys. Acta* **926**, 215. **3.** Takahashi, Iwasaki, Kobayashi, *et al.* (1987) *J. ### Rhodionin

This flavone glycoside (FW = 432.38 g/mol; CAS 85571-15-9), isolated from species of *Rhodiola*, inhibits (IC<sub>50</sub> = 22  $\mu\text{M}$ ) prolyl oligopeptidase, or PEP (EC. 3.4.21.26), an enzyme that plays a role in the metabolism of proline-containing neuropeptide that is involved in learning and memory. **1.** Fan, Tezuka, Ni & Kadota (2001) *Chem. Pharm. Bull. (Tokyo)* **49**, 396.

**Rhodosin**, similar in action to *Rhodionin*

**Rhodium(II) Acetate Dimer**, See *Tetrakis(m-acetato)dirhodium(II,II)*

### Rhodomyces

These DNA-intercalating antibiotics (FW<sub>Rhodomyces-A</sub> = 701.78 g/mol; CAS 1401-16-7) from *Streptomyces purpurascens* and a red-pigmented mutant of *Streptomyces griseus*, selectively inhibit DNA and RNA biosynthesis by forming complexes with the polynucleic acids (1,2). It is likely that protonation of the tertiary amine facilitates DNA binding, with the flattened anthracycline ring intercalating between base-pairs, and the positively charged glycone binding to the phosphodiester backbone. Rhodomyces inhibit cancer cell proliferation, clonogenicity, motility, and invasiveness, underscoring that they are likely to be nonspecific in their actions. Indeed, rhodomyces A renders gefitinib-resistant lung adenocarcinoma cells more sensitive to gefitinib treatment, implying a synergistic effect of the combination therapy. Our data also reveal that the inhibitory effect of rhodomyces A on lung cancer progression may act through suppressing the Src-related multiple signalling pathways, including PI3K, JNK, Paxillin, and p130cas (3). Related anthracycline antitumor drugs include daunorubicin (DNR) and doxorubicin (DXR). **1.** Shockman & Waksman (1951) *Antibiot. Chemother. (Northfield)* **1**, 68. **2.** Oki (1977) *Jpn. J. **Rhodoviolascin**, See *Spirilloxanthin*

**Rho GDP Dissociation Inhibitor (RhoGDI)**

These guanine dissociation inhibitors ( $MW_{\text{Human-Isoform-A}} = 23.2$  kDa;  $MW_{\text{Human-Isoform-B}} = 18.2$  kDa;  $MW_{\text{Human-Isoform-C}} = 25.8$  kDa;  $MW_{\text{Human-Isoform-D}} = 36.6$  kDa) block GDP dissociation from Rho GTPases, locking these small GTPases in an inactive GDP-bound state (1-4). RhoGDI interacts with lipid-modified GDP-RhoA and GDP-RhoB. Other targets include Rac1, Rac2, and Cdc42 (**See also Rab GDP Dissociation Inhibitor**). RhoGDI is made up of two domains: a flexible N-terminal domain of about 70 residues and a folded 134-residue C-terminal domain (4). Two regions (residues 9-120 and 36-58) tend to form helices, and *in vitro* and *in vivo* functional assays with truncated proteins indicate that first 30 residues are not needed for inhibition of GDP dissociation; instead, they appear to be important for GTP hydrolysis (4) Removal of the first 41 residues completely abolishes RhoGDI inhibition of GDP dissociation from Rho. Structural and functional studies also explain why RhoGDI and D4GDI can interact in similar ways with GDP-bound GTPase, yet differ in their regulation of GTP-bound forms. Two transient helices appear to exert different effects, providing an example of structure-activity relationships within a flexible protein domain (4). **Role in Phagocyte NADPH Oxidase System:** 'Professional' phagocytic cells employ the the NADPH Oxidase System (*or* Phage Ox System) to form superoxide in the lumen of phagocytes, thereby promoting microbial killing by myeloperoxidase. GDI-1 indirectly activates the phagocyte superoxide-generating NADPH oxidase, a process requiring the membrane-associated cytochrome  $b_{559}$  with the cytosolic components, p47-phox, p67-phox and GDI-1, the latter forming a heterodimeric p21rac1-GDI complex, *or*  $\sigma_1$  (5). 1. #### Ribavirin 5'-Monophosphate

This antiviral nucleotide ( $FW_{\text{free-acid}} = 324.19$  g/mol), also known as virazole 5'-monophosphate and formed by enzymatic phosphorylation of the nucleoside ribavirin (CAS 36791-04-5), inhibits adenylosuccinate lyase (1) and IMP dehydrogenase (2). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Shaw, Thomas, Patey & Thomas (1979) *J. Chem. Soc. Perkin Trans.* **1**, 1415. 2. Prosis, Wu & Luecke (2002) *J. Biol. Chem.* **277**, 50654.

#### Ribavirin 5'-Triphosphate

This antiviral nucleotide ( $FW_{\text{free-acid}} = 484.15$  g/mol), formed by metabolic phosphorylation of the nucleoside ribavirin, inhibits mRNA guanylyltransferase (1), mRNA (nucleoside-2'-*O*-)-methyltransferase (2), nucleoside-triphosphatase/ DNA helicases (3-6), RNA-directed DNA polymerase (7), and visna virus reverse transcriptase (7). 1. #### RHPS 4

This acridine-based DNA intercalator and quadruplex-stabilizing telomerase inhibitor ( $FW = 458.11$  g/mol; CAS 390362-78-4; Solubility: 10 mM in H<sub>2</sub>O with gentle warming; 20 mM in DMSO), also named 3,11-difluoro-6,8,13-trimethylquino[4,3,2-*kl*]acridinium methyl sulfate, induces telomere injury and promotes apoptosis (1-3). RHPS-4 inhibits growth of UXF1138L cells (uterus carcinoma cells with short telomeres), medulloblastoma and glioblastoma cells *in vitro* (with  $IC_{50}$  of 2-3  $\mu$ M, depending on cell type) and blocks growth of CG5 breast cancer xenografts in mice. **Mechanism of Antiproliferative Action:** The pentacyclic acridinium methosulfate salt RHPS4 induces the 3' single-stranded guanine-rich telomeric overhang to fold into a G-quadruplex structure. Stabilization of the latter is incompatible with an attachment of telomerase to the telomere and thus G-quadruplex ligands can effectively inhibit both the catalytic and capping functions of telomerase. Repetitive TTAGGG sequences at the ends of chromosomes allow cells to distinguish between natural chromosome ends and double-strand DNA breaks, and the perpetual maintenance of this telomeric DNA allows cancer cells to have unlimited replicative potential. Activated telomerase maintains telomere length homeostasis in ~85% of human cancers, motivating anti-cancer strategies that target components of the telomerase holoenzyme. One strategy is to use a G-quadruplex (G4) ligand to critically erode chromosome end(s), resulting in telomere shortening and/or telomere uncapping. Because telomerase requires the 3'-telomeric end to be in a single-stranded configuration, sequestering of the telomere in a four-stranded structure by small molecules that can compete with telomere-associated proteins, should inhibit telomerase binding to telomere ends. The resulting loss of telomere maintenance should activate DNA damage response and arrest growth. 1. Phatak, *et al.* (2007) *Br. J. Cancer* **96**, 1223. 2. Salvati, *et al.* (2007) *J. Clin. Invest.* **117**, 3236. 3. Lagah, Tan, Radhakrishnan, *et al.* (2014) *PLoS One* **9**, e86187.

#### 9-( $\beta$ -D-Ribofuranuronic)adenine Monophosphate Mixed Anhydride

This carboxylic-phosphoric mixed anhydride ( $FW_{\text{free-acid}} = 361.21$  g/mol) is an AMP isostere that inactivates adenylosuccinate lyase (1). A carboxylic-phosphoric mixed anhydride was synthesized, in which the 5'-methylene group of ATP is replaced by a carbonyl group (2). This compound does not inhibit rabbit adenylate kinase, but rapidly inactivates rabbit pyruvate kinase. The latter effect was prevented by ATP, ADP and phosphoenolpyruvate, indicating that it appears to be ATP-site-directed. The analogous anhydride isosteric with adenosine 5'-phosphate (AMP) rapidly inactivated rabbit AMP aminohydrolase, with inactivation prevented

by an equimolar level of AMP (2). Such findings suggest these anhydrides are powerful and potentially useful reagents for adenine nucleotide binding sites of enzymes. 1. Hampton & Harper (1971) *Arch. Biochem. Biophys.* **143**, 340. 2. Hampton, Harper, Sasaki, Howgate & Preston (1975) *Biochem. Biophys. Res. Commun.* **65**, 945.

### 9-( $\beta$ -D-Ribofuranuronic)adenine Triphosphate Mixed Anhydride

This carboxylic-phosphoric mixed anhydride (FW<sub>free-acid</sub> = 521.17 g/mol) is an ATP isostere that inhibits pyruvate kinase. 1. Hampton, Harper, Sasaki, Howgate & Preston (1975) *Biochem. Biophys. Res. Commun.* **65**, 945.

### Ribonuclease Inhibitor RPI

This acidic cytoplasmic protein (MW = 49,973; pI = 4.7) forms a high-affinity ( $K_i = 35$ -44 fM) with pancreatic RNase. The porcine inhibitor has a value of 4 fM for porcine ribonuclease-4. Ribonuclease protein inhibitor (RPI) is inactivated by *p*-hydroxymercuribenzoate. *Note*: Each animal species studied to date contains only a single ribonuclease inhibitor. **Target(s)**: angiogenin (1,2); Onconase™ (1); pancreatic ribonuclease, *or* ribonuclease A, also known as seminal ribonuclease (1-13); ribonuclease-2, eosinophil-derived neurotoxin (1); ribonuclease-3 (1); ribonuclease-4, porcine (1); ribonuclease-6, *or* poly-(U)-specific ribonuclease (14); and RNA lariat debranching enzyme (15). 1. ### Ribonuclease Inhibitors

Given the pervasive presence of numerous ribonucleases in nearly all cell types and their ability to rapidly hydrolyze messenger RNA, ribonuclease inhibitors are of paramount significance in experiments requiring intact mRNA (1). In fact, ribonucleases are surprisingly difficult to remove completely from samples or to inactivate during RNA isolation. RNases are so ubiquitous that they are often introduced into samples, even in deionized laboratory water. **Reversible Low-Molecular-Weight RNase Inhibitors**: These substances bind within RNase active sites, including: (a) Vanadyl ribonucleoside complexes, which resemble transition-state analogue and consist of a 1:1 complex of oxovanadium ion and a ribonucleosides. These complexes may be added before or during cell lysis solutions to inhibit the endogenous RNase activity of the cells. Such complexes bind to a broad range of RNases, typically exhibiting a  $K_i$  of 10  $\mu$ M for pancreatic RNase, *or* RNase A. However, these vanadyl complexes also inhibit reverse transcriptase (thereby affecting RT-PCR assays) as well as *in vitro* translation. (b) 5'-Diphosphoadenosine 3'-phosphate exhibits a 1- $\mu$ M  $K_i$ , among the strongest reversible low-molecular-weight inhibitor. (c) Simple nucleotides (including 2'-CMP, 2'-UMP, 4-thiouridine 3'-phosphate, thymidine 3',5'-diphosphate, and pAp) that have  $K_i$  values of 1-10  $\mu$ M, depending on assay conditions. (d) Other RNase A inhibitors are di-ribonucleoside 2'-5' monophosphates (2'-5'-GpG, 2'-5'-CpG, and 2'-5'-UpG, as well as such di-ribonucleoside 3'-5' monophosphates as ApU, ApC, and GpU. (e) Guanylyl-2',5'-guanosine (2',5'-GpG) and 2'-guanylic acid (2'-GMP), arguably the most potent RNase inhibitors, especially for RNase T1. **Irreversible Low-Molecular-Weight RNase Inhibitors**: These agents covalently modify active-site residues required for RNase catalysis. The most widely applied reagent is diethyl pyrocarbonate, which inactivates RNases. DEPC is typically added to buffers and water used in mRNA preparations, usually

with 0.1% v/v DEPC for >1 hour at 37°C, followed by autoclaving at least 15 min to inactivate any remaining traces of DEPC. **High-Molecular-Weight RNase Inhibitors**: The angiogenic RNase inhibitor PRI binds very tightly to RNase A and to angiogenin, exhibiting  $K_i$  values in the 10<sup>-14</sup> to 10<sup>-16</sup> M range. In the presence of sodium dodecyl sulfate, proteinase K will digest many RNases, with consequential loss of enzymatic activity. 1. Pasloske (2000) *Meths. Molec. Biol.* (Schein, ed.) **160**, 105.

### D-Ribose

This aldopentose (FW = 150.13 g/mol; CAS 50-69-1), a component of RNA, nucleotides, certain coenzymes and glycosides, and intermediates in carbohydrate metabolism. Note that the majority of free D-ribose is in the pyranose forms rather than the furanose structure typically observed in nucleotides. In D<sub>2</sub>O at 31°C, D-ribose is 21.5%  $\alpha$ -pyranose, 58.5%  $\beta$ -pyranose, 6.5%  $\alpha$ -furanose, and 13.5%  $\beta$ -furanose (the corresponding percentages in dimethyl sulfoxide at 25°C are 18%, 57%, 6% and 9%). The normal crystal form is  $\beta$ -D-ribofuranose (M.P. = 86-87°C). **Target(s)**: aldose 1-epimerase (1); aspartate carbamoyltransferase (2); cytidine deaminase,  $K_i = 12$  mM (3); formaldehyde transketolase (4);  $\beta$ -galactosidase (5);  $\alpha$ -glucosidase (6,7); ketohexokinase, *or* hepatic fructokinase (8); lactose synthase (9); orotidine-5'-phosphate decarboxylase, weakly inhibited (10); prodigiosin formation (11); purine nucleosidase, product inhibition (12-14); ribose-5-phosphate isomerase (15); superoxide dismutase, Cu/Zn (16); uridine nucleosidase (17,18); and xylose isomerase (19,20). 1. ### D-Ribose 1,5-Bisphosphate

This bisphosphorylated aldopentose (FW<sub>free-acid</sub> = 310.09 g/mol) is a regulator of carbohydrate metabolism that relieves phosphofructokinase from ATP inhibition and increased the affinity for fructose 6-phosphate. This sugar phosphate is also a cofactor of phosphoribomutase (phosphopentomutase). **Target(s)**: fructose-1,6-bisphosphatase (1); and pyruvate kinase (2). 1. Ozaki, Mitsui, Sugiya & Furuyama (2000) *Comp. Biochem. Physiol. B Biochem. Mol. Biol.* **125**, 97. 2. Lin, Turpin & Plaxton (1989) *Arch. Biochem. Biophys.* **269**, 228.

**D-Ribose 5-Diphosphate**

This phosphorylated aldopentose ( $FW_{\text{free-acid}} = 326.09$  g/mol;  $\beta$ -anomer shown above) inhibits RNA polymerase. Ribose and deoxyribose 5' pyro- and tri-phosphates are potent substrate-competitive inhibitors for an *in vitro* transcription system containing either calf thymus or T<sub>7</sub> DNA as template, and the *E. coli* RNA polymerase [E.C.2.7.7.6]. Each analogue gave  $K_i \sim 25$   $\mu\text{M}$ , essentially the same as the  $K_m$  values ( $\sim 15$   $\mu\text{M}$ ) for the substrates. In contrast, the ribose and deoxyribose 5'-monophosphates, ribonucleosides, deoxynucleoside mono and triphosphates gave no significant inhibition. The data are consistent with the interpretation that the enzyme binds the substrate primarily through the 3'-endo ribose polyphosphate moiety. 1. Sylvester & Dennis (1977) *Biochem. Biophys. Res. Commun.* **75**, 667.

**D-Ribose 1-Phosphate**

This phosphorylated aldopentose ( $FW_{\text{free-acid}} = 230.11$  g/mol) is produced by a number of enzymes (e.g., uridine phosphorylase and purine-nucleoside phosphorylase) and is a product inhibitor in many of these catalyzed reactions. The  $\alpha$ -anomer shown above and the product of the phosphorylases is not as stable as the  $\beta$ -anomer and is rapidly hydrolyzed in strong acid (50% in 3.5 hours at 20°C in 10 mM HCl or 2.5 minutes at 25°C in 500 mM HCl). The  $\beta$ -epimer is 50% hydrolyzed in 4 hours at 26°C in 100 mM HCl. **Target(s):** *S*-methyl-5'-thioadenosine phosphorylase (1); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase, weakly inhibited (2); thymidine phosphorylase (3,4); and triose-phosphate isomerase (5). 1. Garbers (1978) *Biochim. Biophys. Acta* **523**, 82. 2. Fox & Kelley (1972) *J. Biol. Chem.* **247**, 2126. 3. Schwartz (1978) *Meth. Enzymol.* **51**, 442. 4. Blank & Hoffee (1975) *Arch. Biochem. Biophys.* **168**, 259. 5. Noltmann (1972) *The Enzymes*, 3rd ed., **6**, 271.

**D-Ribose 5-Phosphate**

This phosphorylated aldopentose ( $FW_{\text{free-acid}} = 230.11$  g/mol), a component of many nucleotides, is also an intermediate in the pentose phosphate pathway and in photosynthesis. This reducing sugar is slightly soluble in water and more soluble in dilute mineral acids. It is slowly hydrolyzed by acids: 59% is hydrolyzed in two hours at 100°C by 1.0 M HCl. The half-life in 10 mM acid at 100°C is about seventeen hours. The sodium salt is hygroscopic and should be stored in a desiccator. D-Ribose 5-P is a product of the reactions catalyzed by transketolase, ribokinase, AMP nucleosidase, pyrimidine-5'-nucleotide nucleosidase, inosinate nucleosidase, NMN nucleosidase, ADP-ribose pyrophosphatase, and phosphopentomutase. Ribose 5-P is a substrate for acetoin:ribose-5-phosphate transaldolase, phosphoribokinase, ribose-phosphate pyrophosphokinase, ribose-5-phosphate adenylyltransferase, pseudouridylylase synthase, ribose 5-phosphate epimerase (ribose-5-phosphate isomerase), and ribose-5-phosphate:ammonia ligase. Ribose 5-P is an activator of *Bacillus*

*stearothermophilus* pyruvate kinase but an inhibitor of the chloroplastic *Selenastrum minutum* enzyme. **Target(s):** D-amino-acid oxidase, weakly inhibited (1); arabinose-5-phosphate isomerase (2); aspartate carbamoyltransferase (3,4); 2-carboxy-D-arabinitol-1-phosphatase, weakly inhibited (5); 2-dehydro-3-deoxyphosphooctonate aldolase (6); 3-deoxy-8-phosphooctulonate synthase, or 3-deoxy-D-manno-2-octulosonate-8-phosphate synthase (7,8); fructose-1,6-bisphosphate aldolase (9,10); glucose dehydrogenase (11-13); glucose-6-phosphate dehydrogenase, weakly inhibited (13); glucose-6-phosphate isomerase (14,15); glycerate kinase (16); IMP dehydrogenase (17); *myo*-inositol-1-phosphate synthase (18); L-*myo*-inositol-1-phosphatase (19); mannose-6-phosphate isomerase (14); NMN Nucleosidase, product inhibition (19); orotate phosphoribosyltransferase (20); orotidine-5'-phosphate decarboxylase, or orotidylate decarboxylase (21-23); 6-phosphogluconate dehydrogenase (24); phosphoglycolate phosphatase (25,26); phospho-protein phosphatase (27); pyruvate kinase, chloroplastic *Selenastrum minutum*, an activator for other pyruvate kinases (28); ribulose-bisphosphate carboxylase, oxygenase activity (29); and uridine nucleosidase (30). 1. D-Ribulose 1,5-Bisphosphate

This bis-phosphorylated ketopentose ( $FW_{\text{free-acid}} = 310.09$  g/mol), known formerly as D-ribulose 1,5-diphosphate, is a product of the reaction catalyzed by phosphoribulokinase and is a substrate for ribulose-bisphosphate carboxylase/oxygenase in the carbon dioxide fixation segment of the Calvin cycle. The more acid-labile C1-phosphate monoester exhibits a 12-min half-life for hydrolysis in 0.1 M acid at 100°C. **Target(s):** fructose-1,6-bisphosphatase (1); fructose-1,6-bisphosphate aldolase (2); glyceralate kinase (3); pyruvate kinase, chloroplastic (4); ribose-5-phosphate isomerase (5); and sedoheptulose-bisphosphatase (6). 1. D-Ribulose 1,5-Diphosphate, See D-Ribulose 1,5-Bisphosphate

D-Ribulose 5-Phosphate

This phosphorylated ketose ( $FW_{\text{free-acid}} = 230.11$  g/mol), a component of the pentose phosphate pathway and the  $CO_2$  assimilation pathway in photosynthesis, is a product of the reactions catalyzed by 6-phosphogluconate dehydrogenase (decarboxylating), ribitol-5-phosphate 2-dehydrogenase, D-ribulokinase, ribose 5-phosphate epimerase, and arabinose-5-phosphate isomerase. It is a substrate for phosphoribulokinase, ribulose-phosphate 3-epimerase, and transketolase. The half-life for the hydrolysis of the phosphate group in 0.5 M  $H_2SO_4$  at 100°C is 40 minutes. Note that the L-enantiomer also occurs naturally. **Target(s):** glucose-6-phosphate isomerase (1-4); 6-phosphogluconate dehydrogenase, product inhibition (5-6); and uridine nucleosidase (8). 1. Noltmann (1972) *The Enzymes*, 3rd ed. (Boyer, ed.), **6**, 271. 2. Sangwan & Singh (1990) *Indian J. Biochem. Biophys.* **27**, 23. 3. Sangwan & Singh (1989) *J. Biosci.* **14**, 47. 4. 9-β-D-Riburonosyladenine, See 9-(β-D-Ribofuranuronic)adenine

Riccardin C

This bis(benzyl)-containing macrocycle ( $FW = 424.49$  g/mol; CAS 84575-08-6), itself a secondary metabolite from the Siberian cowslip (*Primula veris* subsp. *Macrocalyx*), *Reboulia hemisphaerica*, and Chinese liverwort (*Plagiochasma intermedium*), is a Liver X Receptor (or LXRα) agonist and an LXRβ antagonist that enhances ABCA1 and ABCG1 expression as well as cellular cholesterol efflux in THP-1 cells (1). LXRα and LXRβ form heterodimers with the obligate partner 9-cis retinoic acid receptor (RXR), and the LXR/RXR heterodimer can be activated by oxysterols (e.g., 22(R)-hydroxycholesterol, 24(S)-hydroxycholesterol, 27-hydroxycholesterol, and cholestenic acid) or the RXR agonist 9-cis-retinoic acid. Upon activation, LXR binds to the LXR response element (LXRE) within target gene promoters. Riccardin C thus provides a novel tool for identifying LXR subtype and probing receptor function. 1. Tamehiro, Sato, Suzuki, et al. (2005) *FEBS Lett.* **579**, 5299.

Rice α-Amylase/Subtilisin Inhibitor

This plant protein (MW = 21 kDa; often abbreviated RASI, isoelectric point = 9.05) inhibits subtilisin strongly but inhibits germinating rice seed α-amylase from weakly. RASI inhibits rice α-amylase more than barley α-amylase, and the inhibition of rice α-amylase was greater at higher pHs. RASI did not inhibit trypsin, chymotrypsin, cucumisin, or mammalian α-amylase (1-3). 1. Nielsen, Bonsager, Fukuda & Svensson (2004) *Biochim. Biophys. Acta* **1696**, 157. 2. Ohtsubo & Richardson (1992) *FEBS Lett.* **309**, 68. 3. Yamagata, Kunimatsu, Kamasaka, Kuramoto & Iwasaki (1998) *Biosci. Biotechnol. Biochem.* **62**, 978.

Ricin

This heterodimeric toxin and type-II ribosome-inactivating protein (CAS 9009-86-3) from the seeds of *Ricinus communis* consists of an enzymatic A chain (267 residues; MW = 30 kDa) and a Gal/GalNAc-binding B chain (262 residues; MW = 32 kDa), joined by a single disulfide bond. **Mode of**

**Cell Entry:** Ricin's A-chain is the active *N*-glycosidase, and Ricin B-chain is a lectin that facilitates tight binding to the cell surface glycoconjugates of target cells and facilitates internalization/translocation of the toxin to the cytosol. The toxin binds to the cell surface via its B-chain, followed by retrograde trafficking through intracellular compartments to the ER, where the A-chain is transported across the ER membrane using cellular proteins involved in the disposal of aberrant ER proteins, a process known as Retrograde Translocation. **Mode of Ribosomal Inactivation:** The ricin A chain possesses rRNA *N*-glycosidase activity that catalyzes depurination of A4256 in the 28S ribosomal RNA, interfering with the interaction of eEF-2 with the ribosome and inhibiting protein biosynthesis (1). When separated from the B-chain and administered parenterally to animals, the toxicity of the ricin A-chain is reduced >1,000-times compared to ricin holotoxin. Upon depurination, changes occur in domains I, II and V of 28 S rRNA as well as in 5 S rRNA. Changes were found in functional regions of the rRNAs, such as the regions involved in peptidyltransferase activity, subunit interaction and in the binding of elongation factors. Most of these structural changes make the rRNAs less accessible for chemical modification, suggesting that the ribosomal particles become less flexible after ricin treatment (2). Depurination in the ricin loop (5'-AGUACGAGAGGA-3', where the bold-type shows A4256) also affects the structure of the 3' major domain in 18 S rRNA. Ricin is about 60-100x less potent than the related plant toxin (*See Abrin*) having a maximal ribosome-inactivation rate constant of around 1500 s<sup>-1</sup>. **Discovery of Ricin's *N*-Glycosidase Activity:** Ricin was first recognized as a protein toxin in 1888, when Richard Stillmark isolated a toxin-enriched extract. Three years later, Paul Ehrlich showed that mice could be immunized against ricin. Even so, the work of Endo & Tsurugi (3) was definitive. To determine whether ricin A-chain releases any bases from 28 S rRNA, they incubated rat liver ribosomes with a catalytic amount of the toxin, and a fraction containing free bases and nucleosides was prepared by means of ion-exchange column chromatography. Thin-layer chromatographic analysis of this fraction revealed a release of one mol of adenine per mol of ribosome. When the ribosomes or naked total RNAs were treated with ricin A-chain in the presence of [<sup>32</sup>P]-phosphate, little incorporation of the radioactivity into 28 S rRNA was observed, indicating that the release is not mediated by phosphorolysis. This evidence and the results of an earlier paper (4) indicated that the ricin A-chain inactivates the ribosomes by cleaving the *N*-glycosidic bond of A4324 of 28 S rRNA in a hydrolytic fashion. This catalytic activity of ricin A-chain was also observed when naked 28 S rRNA is used as a substrate, showing that the toxin directly acts on the RNA. Similar activity on 28 S rRNA is also exhibited by ricin-related toxins (abrin and modeccin), suggesting a general mechanistic pathway for ribosome inactivation by these lectin toxins. **Catalytic Mechanism:** The sarcin/ricin loop containing A4256 of the ribosome docks into a cleft comprising ricin's active site, such that its adenine is sandwiched between Tyrosine-80 and Tyrosine-123 in a base-stacking interaction. The leaving group (*i.e.*, adenine) is protonated by Arginine-180, thereby promoting C-1'-N-9 bond scission, forming an oxacarbenium ion on the ribose of A4256. The resulting transition-state is stabilized by an ion-pairing interaction with Glutamate-177. A water molecule (presumably polarized by Arginine-180) is then delivered to the reaction center, attacking the sugar carbonium intermediate and completing the catalytic round. **Transition-State Inhibition:** These features agree with kinetic and structural studies the potent inhibitor cyclic-G(9-DA)GA-2'-OMe, a transition state mimic that contains the tetranucleotide sequence of the GAGA sarcin-ricin loop, but with its ricin-susceptible adenosine replaced by DADMe-Immucillin-A (5). A methylene bridge between azasugar and adenine group (circled below) in the transition state analogue mimics the geometry of the dissociative transition state.

The design of this inhibitor is based on studies of the catalytic properties of a related plant toxin (*See Saporin-L1 Toxin*), which exhibits robust depurinating activity against defined nucleic acid substrates and mammalian ribosomes (6). Low-molecular-weight transition-state analogues, with adenosine replaced with the transition-state mimic 9-deazaadenine-9-methylene-*N*-hydroxy-pyrrolidine (DADMeA), were found to be powerful, slow-onset inhibitors. Linear, cyclic, and stem-loop oligonucleotide inhibitors containing DADMeA and based on the GAGA sarcin-ricin tetranucleotide loop gave slow-onset tight-binding, with inhibition constants  $K_i^*$  values of 2.3–8.7 nM under physiological conditions, or about 4000-times tighter than corresponding RNA substrates (6). **Caution:** Ricin is extremely toxic, and care must be exercised when working with this agent. Within 12 hours of ingestion, symptoms of ricin toxicity are nonspecific (*e.g.*, nausea, vomiting, diarrhea, and abdominal pain), often progressing to hypotension, liver failure, renal dysfunction, and death due to multi-organ failure and/or cardiovascular collapse. Within 8 hours after ricin inhalation, symptoms include cough, dyspnea, arthralgia, and fever, eventually progressing to respiratory distress and death, often without involving other organs. The U.S. Center for Disease Control advises that ricin may cause severe allergic reactions and that exposure to milligram quantities of ricin can prove fatal. Ricin toxin is classified as a select agent, requiring registration with CDC for ricin possession, use, storage or transfer. 1. Jiménez (1976) *Trends Biochem. Sci.* **1**, 28. 2. ### Ricinine

This toxic alkaloid (FW = 164.16 g/mol; CAS 524-40-3; M.P. = 201°C), also known as ricinine and 1,2-dihydro-4-methoxy-1-methyl-2-oxo-3-pyrimidinocarbonitrile, from the leaves and seeds of the castor plant (*Ricinus communis*) induces seizures, when administered to mice at doses higher than 20 mg/kg. Ricinine inhibits toyocamycin nitrile hydratase. 1. Uematsu & Suhadolnik (1975) *Meth. Enzymol.* **43**, 759.

### Ricinolate, See Ricinoleate

### Ricinoleate

This hydroxylated derivative (FW<sub>free-acid</sub> = 298.47 g/mol; CAS 5323-95-5) of oleic acid, also known as ricinoleic acid and (9*Z*,12*R*)-12-hydroxy-9-octadecenoic acid and ricinolic acid, is found in large quantities (as the triacylglycerol triricinolein) in castor oil (indeed, ~90% of the total triacylglycerols in castor oil is triricinolein). The free acid is a liquid at room temperature (melting point of the  $\alpha$ -form is 5.5°C while the  $\beta$ -crystal form melts at 16°C). The *trans*-isomer of ricinoleic acid, also known as ricinelaidic acid, melts at 53°C. Note: Castor oil, which is obtained by expressing castor seeds (*Ricinus communis*), contains some triacylglycerols with oleoyl, linoleoyl, palmitoyl, stearoyl, and dihydroxystearoyl residues. **Target(s):** alanine absorption (1); cholesterol biosynthesis (2); chondroitin AC lyase (3); chondroitin B lyase (3); and hyaluronate lyase (3). 1. Hajjar,

### Ridaforolimus

This mTOR inhibitor (FW = 958.22 g/mol; CAS 572924-54-0), formerly as deforolimus and also known by AP23573 and MK-8669, inhibits mammalian Target of Rapamycin (or mTOR), a protein kinase within the phosphatidylinositol 3-kinase (PI3K)/Akt signalling cascade. The latter plays a central role in controlling cell proliferation, survival, mobility and angiogenesis. Dysregulation of mTOR pathway has been observed in many human tumors, making everolimus a promising new anticancer drug whose action leads to cell cycle arrest in the G<sub>1</sub> phase, with inhibition of tumor angiogenesis by reducing VEGF formation. 1. Rubio-Viqueira & Hidalgo (2006) *Curr. Opin. Investig. Drugs* **7**, 501. 2. Wan, Shen, Mendoza, Khanna & Helman (2006) *Neoplasia* **6**, 394.

### Ridogrel

This oral antithrombotic agent (FW<sub>free-acid</sub> = 366.34 g/mol; CAS 110140-89-1), also known as R 68070, inhibits human thromboxane-A synthase, IC<sub>50</sub> = 4-14.7 nM (1-5) and is also a thromboxane receptor antagonist, K<sub>d</sub> = 1.7-8 μM (1-3,5). In humans, ridogrel is absorbed within 30-60 min, with a half-life of 6-9 hours. At the oral dose of 300 mg b.i.d., steady state is reached within 3 days. 1. Takeuchi, Kohn, True, *et al.* (1998) *J. Med. Chem.* **41**, 5362. 2. De Clerck, Beetens, de Chaffoy de Courcelles, *et al.* (1989) *Prog. Clin. Biol. Res.* **301**, 567. 3. ### Rifalazil

This antimicrobial agent (FW = 941.08 g/mol; CAS 129791-92-0), a semisynthetic derivative of rifamycin S, inhibits bacterial DNA-directed RNA polymerase (1,2). **See Rifamycin** 1. Chopra (2007) *Curr. Opin. Invest. Drugs* **8**, 600. 2. Fujii, Saito, Tomioka, Mae & Hosoe (1995) *Antimicrob. Agents Chemother.* **39**, 1489.

**Rifamide, See Rifamycin B N,N-Diethylamide**

### Rifampicin

This semisynthetic antibiotic (FW = 822.95 g/mol; CAS 13292-46-1), also called rifampin and rifamycin AMP, is prepared chemically from one of the rifamycins isolated from *Streptomyces mediterranei* (formerly called *Nocardia mediterranei*). Rifampicin inhibits bacterial transcription at very low concentrations (*e.g.*, 0.01 μg/mL). It was first marketed as a treatment for tuberculosis in 1957. RNA biosynthesis is inhibited by the binding of rifampicin to the β subunit of RNA polymerase. At higher concentrations (*e.g.*, 1 μg/mL), mitochondrial and chloroplast transcription can be affected as well. No effect is observed with eukaryotic RNA polymerase at 100 μg/mL. Rifampicin will also inhibit the assembly of DNA and protein into mature virus particles and is used in the removal of plasmids in bacteria (*i.e.*, plasmid curing). It also activates the human glucocorticoid receptor and acts as an immunodepressant. **Drug Interactions:** Rifampicin is a powerful known inducer of hepatic cytochrome P450 enzyme system, increasing the cellular content of CYP2B6, CYP2C8, CYP2C9, CYP2C19, CYP3A4, CYP3A5, and CYP3A7. As a consequence, rifampicin speeds up the metabolism of many drugs (including cyclosporine (CYP3A4), simvastatin (CYP3A4), rosiglitazone (CYP2C9), warfarin (CYP2C9), and bupropion (CYP2B6)) making them less effective or ineffective. **Properties:** Rifampicin is a stable, red-orange solid (decomposes at 183-188°C) that is soluble in dimethyl sulfoxide, ethyl acetate, and chloroform. It is slightly soluble in water (at pH < 6). It should be protected from light and stored in the dark. It is zwitterionic in nature with a 4-hydroxy pK<sub>a</sub> of 1.7 and 3-piperazine pK<sub>a</sub> of 7.9. The λ<sub>max</sub> values at pH 7.38 are 237, 255, 334, and 475 nm (the corresponding molar extinction coefficients are 33200, 32100, 27000, and 15400 M<sup>-1</sup>cm<sup>-1</sup>, respectively). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** DNA-directed DNA polymerase (1); DNA-directed RNA polymerase (2-10); 16α-hydroxyprogesterone dehydratase (11); polynucleotide adenyllyltransferase, or poly(A) polymerase (12-14); RNA polymerases, certain mitochondrial (15); RNA polymerases, certain plant (15); tubulin polymerization (16). 1. ### Rifamycins

These antibiotics (CAS 14487-05-9 for rifamycin B) from *Streptomyces mediterranei* are highly effective against Gram-positive organisms and *Mycobacterium tuberculosis*, with significantly weaker action on Gram-negative bacteria. Rifamycins bind to the  $\beta$ -subunit of prokaryotic RNA polymerase and inhibit chain initiation (but not elongation after elongation has commenced). **Target(s):** DNA-directed DNA polymerase (1); DNA-directed RNA polymerase (2,3); ribonuclease H (4,5); and RNA-directed DNA polymerase (6,7). 1. Müller, Yamazaki & Zahn (1972) *Enzymologia* **43**, 1. 2. Lal & Lal (1994) *Bioessays* **16**, 211. 3. Riva & Silvestri (1972) *Ann. Rev. Microbiol.* **26**, 199. 4. ### Rifamycin AF/05

This semi-synthetic antibiotic (FW = 907.03 g/mol), also known as rifamycin SV 3'-formyl-diphenylmethyloxime, inhibits certain nucleic acid polymerases. Solutions of rifamycin AF/05 should contain reducing reagents (such as ascorbic acid) that suppress formation of the quinone. **Target(s):** DNA polymerase (1); polynucleotide adenyltransferase, or poly(A) polymerase (1); ribonuclease H (2); and RNA polymerase (1,3). 1. Sethi & Okano (1976) *Biochim. Biophys. Acta* **454**, 230. 2. Sekeris & Roewekamp (1972) *FEBS Lett.* **23**, 34. 3. Meilhac, Tysper & Chambon (1972) *Eur. J. Biochem.* **28**, 291.

### Rifamycin AF/013

This semi-synthetic antibiotic (FW = 853.02 g/mol), derived from rifamycin SV and known as rifamycin SV 3'-formyl-n-octyloxime, inhibits certain nucleic acid polymerases. Solutions of rifamycin AF/013 should contain

reducing reagents (such as ascorbic acid) to prevent formation of the quinone. Rifamycin AF/013 inhibits initiation and destabilizes the nucleosome. **Target(s):** cyclic-nucleotide independent, heparin-sensitive nuclear protein kinase (1); DNA polymerase (2-5); polynucleotide adenyltransferase, or poly(A) polymerase (2,6,7,15-18); ribonuclease H (8,9); RNA polymerase (2,7,10-14); RNA polymerase I (11); RNA polymerase II (7,10,11); and RNA polymerase III (10). 1. ### Rifamycin SV

This semi-synthetic antibiotic (FW = 697.78 g/mol) inhibits certain nucleic acid polymerases and is derived from rifamycin S. Solutions of rifamycin SV should contain reducing reagents (such as ascorbic acid) to prevent reformation of rifamycin S (*i.e.*, the quinone form). **Target(s):** DNA-directed RNA polymerase (1-3); polynucleotide adenyltransferase, or poly(A) polymerase (4,5); polynucleotide phosphorylase, or polyribonucleotide nucleotidyltransferase (6,7); and RNA-directed DNA polymerase (8). 1. Bacteriol.* **130**, 869. 8. Ting, Yang & Gallo (1972) *Nature New Biol.* **236**, 163.

### Rifaximin

This semisynthetic rifamycin-class antibiotic (FW = 885.89 g/mol; CAS 80621-81-4), also known as Xifaxan<sup>®</sup>, binds to the  $\beta$ -subunit of bacterial RNA polymerase, thereby blocking transcription by interfering with the

translocation step that must follow the formation of the first phosphodiester bond (See *Rafamycin*). The poor absorption properties of rifaximin commend its use in gut-specific infections, including those associated with irritable bowel disorder (with diarrhea). Rifaximin has a low level of resistance selection, but may select stable highly resistant mutants in a single step; periodic surveillance of rifaximin resistance should detect the appearance of rifaximin-resistant clinical isolates (1). **Antibacterial Spectrum:** *Campylobacter jejuni*, MIC<sub>90</sub> = 32 µg/mL; *Clostridium difficile*, MIC<sub>90</sub> = 128 µg/mL; *Escherichia coli*, MIC<sub>90</sub> = 32 µg/mL; *Helicobacter pylori*, MIC<sub>90</sub> = 4 µg/mL; *Salmonella jejuni*, MIC<sub>90</sub> = 64 µg/mL; *Sigella*, MIC<sub>90</sub> = 64 µg/mL; *Vibrio cholerae*, MIC<sub>90</sub> = 4 µg/mL; *Yersinia enterocolitica*, MIC<sub>90</sub> = 32 µg/mL; *Campylobacter jejuni*, MIC<sub>90</sub> = 16 µg/mL. 1. Ruiz, Mensa, Pons, Vila & Gascon (2008) *J. Antimicrob. Chemother.* **61**, 1016.

Rigoserb (ON 01910)

Inactive Control (ON 01911)

This multi-mode chemotherapeutic agent (FW<sub>free-acid</sub> = 451.50 g/mol; FW<sub>Sodium-Salt</sub> = 473.47 g/mol; CAS 1225497-78-8), also known as ON-01910, is likely to inhibit PI3K/Akt and PLK signaling (1,2) as well as to disrupt mitosis, the latter by reducing microtubule (MT) dynamics (3). PI3K signaling promotes the growth/survival under stressful conditions, such as the low oxygen levels found in solid tumors. If the PI3K pathway is over-active, apoptosis is diminished, leading to excessive proliferation. By inhibiting the PI3K pathway, rigosertib promotes tumor cell apoptosis. Rigosertib also influences signals along the PI3K pathway, such as those leading to the production of cyclin D<sub>1</sub>. The PLK pathway plays a critical role in maintaining proper organization and sorting of chromosomes during cell division. Excessive PLK activity in cancer cells can result in uncontrolled proliferation. By inhibiting polo-like kinase 1 (IC<sub>50</sub> = 9 nM) in cancer cells, rigosertib also inhibits cellular division, leading to chromosome disorganization and death. Recent work on Rigoserb and Cent-1 (See *Centimitor-1*) provides new clues about the likely mode of action of these agents during M phase (3). Both cause centrosome fragmentation and reduced the amount of centrosome-associated  $\gamma$ -tubulin. They also significantly retard MT dynamics in interphase cells, shorten spindle length in mitosis, and decrease tension across sister kinetochores in mitotic chromosomes. They also cause the delocalization of NuMA and EBI in mitotic cells. Taken together, these data suggest Cent-1 and rigosertib impair MT-mediated processes during M-phase. Acentrosomal spindle poles, reduced interkinetochore tension, mislocalization of MT end-tracking proteins, and chromosome misalignment are consequences of treating cells with low doses of well-studied MT drugs, again supporting the inference that these compounds alter microtubule dynamics. It is noteworthy that neither Rigoserb nor Cent-1 perturb MT self-assembly *in vitro*. Current findings do not distinguish between direct and indirect drug-induced mechanisms for altering microtubule processes and thereby hindering mitosis. Adding to the dispute over the mode of action is the finding that ON 01910 does not induce consistent activation or only delayed activation of proteins traditionally associated with this DNA damage-response, whereas both doxorubicin and camptothecin provided prompt activation of Chk1, Chk2, and histone H2A.X (4). Instead, ON-01910 induced hyperphosphorylation of RanGAP1-SUMO1, and the latter correlated with accumulation of mitotic cells, prolonged M-phase arrest, and apoptotic cell death. A pharmacologically inactive analogue (ON-01911, See structure above) fails to induce RanGAP1-SUMO1 phosphorylation (4). Given ON 01910's inhibitory action on cancer cells *in vitro*, on tumor xenografts, and on some clinical cancers, determination of its molecular target(s) is of paramount importance. 1. ### Rilonacept

This soluble receptor decoy for IL-1 and long-acting anti-inflammatory (MW  $\approx$  251 kDa; CAS 501081-76-1), also known as Arcalyst<sup>®</sup> and IL-1 Trap<sup>®</sup>, binds IL-1, thereby neutralizing the latter's pro-inflammatory actions. Rilonacept is a dimeric fusion protein consisting of the ligand-binding domains in the extracellular domains of the human interleukin-1 receptor component (IL-1R<sub>1</sub>) and IL-1 receptor accessory protein (IL-1RAcP), both linked in tandem to the Fc region of a human IgG1 that binds IL-1. Rilonacept binds IL-1 $\beta$ , IL-1 $\alpha$ , and IL-1 receptor antagonist (IL-1ra) with high affinity, thereby preventing the activation of IL-1 receptors, attenuating inflammatory responses and other effects secondary to IL-1 excess. Rilonacept (final concentration = 80 mg/mL; initial dose = 4 mL; maximum weekly dose = 2 mL) is administered subcutaneously. It is indicated for the treatment of cryopyrin-associated periodic syndromes (or CAPS). The latter are rare, inherited, inflammatory disorders resulting from a mutation in the *NLRP3* gene, which codes for cryopyrin, a regulator in the acute immune reaction. Rilonacept's terminal half-life is 8.6 days in adults and 6.3 days in pediatric patients. Because an IL-1 blockade may interfere with immune response to infection, some added risk of infection may occur during rilonacept treatment.

### Rilpivirine

This substituted pyrimidine (FW = 366.43 g/mol; CAS 500287-72-9), also known as TMC278, is a non-nucleoside inhibitor that targets HIV-1 reverse transcriptase and RNA-directed DNA polymerase (1-3). Rilpivirine undergoes oxygenation reactions catalyzed primarily by CYP3A4 and CYP3A5 (4). 1. El Safadi, Vivet-Boudou & Marquet (2007) *Appl. Microbiol. Biotechnol.* **75**, 723. 2. Janssen, Lewi, Arnold, et al. (2005) *J. Med. Chem.* **48**, 1901. 3. Fang, Bauman, Das, et al. (2008) *Proc. Natl. Acad. Sci. U.S.A.* **105**, 1472. 4. Lade, Avery & Bumpus (2013) *Antimicrob. Agents Chemother.* **57**, 5067.

### Riluzole

This neuroprotecting glutamate antagonist (FW = 234.20 g/mol; CAS 1744-22-5), also known as 2-amino-6-(trifluoromethoxy)benzothiazole, exhibits anti-excitotoxic action and protects against nonexcitotoxic oxidative neuronal injury. Riluzole affects neurons by inhibiting excitatory amino acid release, inhibiting events following stimulation of excitatory amino acid receptors, and stabilizing the inactivated state of voltage-dependent, tetrodotoxin-sensitive sodium channels. Riluzole (as Rilutek<sup>®</sup> tablets) was the first drug to be approved by the FDA for treating amyotrophic lateral sclerosis. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):**  $\gamma$ -aminobutyrate (GABA) uptake (1); glutamate and aspartate release (2); Na<sup>+</sup> channels (3,4); and protein kinase C (5). 1. Mantz, Laudenbach, Lecharny, Henzel & Desmonts (1994) *Eur. J. Pharmacol.* **257**, R7. 2. Martin, Thompson & Nadler (1993) *Eur. J. Pharmacol.* **250**, 473. 3. Yokoo, Shiraishi, Kobayashi, et al. **Rimantadine**

This antiviral agent (FW<sub>hydrochloride</sub> = 215.77 g/mol; CAS 13392-28-4), also known as remantadine and  $\alpha$ -methyl-1-adamantanemethylamine, inhibits the influenza virus M2 ion channel, a transmembrane protein that regulates pH during infection (1-3). Reversal potentials were close to equilibrium potentials for transmembrane pH gradients and not to those for Na<sup>+</sup>, K<sup>+</sup> or Cl<sup>-</sup> concentration gradients. M2 permeability to Na<sup>+</sup> relative to H<sup>+</sup> was estimated to be less than  $6 \times 10^{-7}$ . The M2 conductance increased as external pH decreased below 8.5 and approached saturation at an external pH of 4, effects attributable to increased permeability due to increased driving potential and to activation by low external pH. **See also Amantadine** 1. Chizhakov, Geraghty, Ogden, *et al.* (1996) *J. Physiol.* **494**, 329. 2. Karginov, Blinov, Safronov, Mamaev & Golovin (1987) *Bioorg. Khim.* **13**, 1638. 3. Lin, Heider & Schroeder (1997) *J. Gen. Virol.* **78**, 767.

**Rimonabant**

This once-popular anorectic anti-obesity drug (FW = 462.08 g/mol; CAS 158681-13-1), also known as SR141716, Acomplia<sup>®</sup>, Zimulti<sup>®</sup>, and 5-(4-chlorophenyl)-1-(2,4-dichlorophenyl)-4-methyl-*N*-(piperidin-1-yl)-1*H*-pyrazole-3-carboxamide, is an inverse agonist for the CB<sub>1</sub> cannabinoid receptor ( $K_i$  = 2 nM), with no discernible action at CB<sub>2</sub> receptors. Rimonabant is also an inverse agonist of adenylyl cyclase, reversing inhibition by WIN 55,212-2. Its undesirable clinical side-effects (*e.g.*, severe depression and suicidal thoughts) that led to its withdrawal from the EU market. Rimonabant is the first drug to target the endocannabinoid (CB) pathway by inhibiting the actions of anandamide and 2-archidonyl-glycerol on CB<sub>1</sub> receptors. Rimonabant is also a  $\mu$ -opioid receptor antagonist. CB<sub>1</sub> receptor blockade decreases in appetite and has direct actions in adipose tissue and liver to improve glucose, fat and cholesterol metabolism, thereby improving insulin resistance, triglycerides and high-density lipoprotein cholesterol (HDL-C) and in some patients, blood pressure. Despite its removal from the market, rimonabant remains a valuable tool for the pharmacologic investigation of cannabinoid receptors. Rimonabant is also an inverse agonist of adenylyl cyclase, reversing inhibition by WIN 55,212-2. 1. Rinaldi-Carmona, *et al.* (1994) *FEBS Lett.* **350** 240. 2. Rinaldi-Carmona, *et al.* (1995) *Life Sci.* **56**, 1941. 3. Colombo, *et al.* (1998) *Life Sci.* **63**, 113. 4. Janiak, *et al.* (2007) *Kidney Int.* **72**, 1345.

**Riociguat**

This first-in-class, oral vasodilator (FW = 422.22 g/mol; CAS 625115-55-1; Solubility: 84 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known by its code name BAY 63-2521, its trade name Adempas<sup>®</sup> and its systematic name, methyl *N*-[4,6-diamino-2-[1-[(2-fluorophenyl)methyl]-1*H*-pyrazolo[3,4-*b*]pyridin-3-yl]-5-pyrimidinyl]-*N*-methylcarbaminate, stimulates soluble guanylate cyclase, both independently of endogenously generated vasodilator nitric oxide and in synergy with NO to produce its anti-aggregatory, anti-proliferative, and vasodilatory effects. Riociguat stimulates soluble guanylate cyclase (sGC) in a dose-dependent manner, increasing its catalysis by as much as 73-fold (1). In October 2013, riociguat received FDA approval to reduce mean pulmonary arterial pressure in the treatment of persistent/recurrent Chronic Thromboembolic Pulmonary Hypertension, *or* CTEPH (WHO Group 4) after surgical treatment or inoperable CTEPH to improve exercise capacity. Riociguat is rapidly absorbed, reaching a maximum plasma concentration within 0.5–1.5 h, after which it is eliminated with a 5–10 hour half-life. **Targets:** P-gp ( $f_2$ -value = 12  $\mu$ M), BCRP (IC<sub>50</sub> = 46  $\mu$ M), OATP1B1 (IC<sub>50</sub> = 34  $\mu$ M), OATP1B3 (IC<sub>50</sub> = 50  $\mu$ M), CYP2D6 (IC<sub>50</sub> = 12  $\mu$ M), and CYP2C19 (IC<sub>50</sub> = 46  $\mu$ M). Riociguat also induces mRNA expression of BCRP/ABCG2 (3-times at 20  $\mu$ M) and to a lesser extent of CYP3A4 (2.3-times at 20  $\mu$ M), UGT1A4, and ABCB11 (2). 1. Mittendorf, Weigand, Alonso-Alija, *et al.* (2009) *ChemMedChem.* **4**, 853. 2. Rickert, Haefeli & Weiss (2014) *Pulm. Pharmacol. Ther.* **28**, 130.

**Ripasudil**

This potent ROCK inhibitor (FW = 395.88 g/mol; CAS 887375-67-9; 4-fluoro-5-[[[2*S*]-hexahydro-2-methyl-1*H*-1,4-diazepin-1-yl]sulfonyl]isoquinoline and K-115, which targets the Rho-associated, coiled-coil containing protein kinases ROCK1 (IC<sub>50</sub> = 51 nM) and ROCK2 (IC<sub>50</sub> = 19 nM), respectively, is used in the treatment of glaucoma and ocular hypertension. ROCK is a key regulator of actin organization and thus a regulator of cell migration. 1. Nakagawa, Koizumi, Okumura, Suganami & Kinoshita (2015) *PLoS One* **10**, e0136802.

**Risedronate**

This bisphosphonate (FW<sub>free-acid</sub> = 283.11 g/mol; CAS 115436-72-1), also known by the trade names Actonel<sup>®</sup>, Atelvia<sup>®</sup>, and Benet<sup>®</sup>, as well as risedronate and (1-hydroxy-1-phosphono-2-pyridin-3-ylethyl)phosphonate, targets farnesyl pyrophosphate synthase. Like analogous bisphosphonates (ibandronate, pamidronate, alendronate, and zoledronate) risedronate mimics isoprenoid diphosphate lipids, thereby inhibiting FPP synthase, an enzyme in the mevalonate pathway. Bisphosphonates show remarkable affinity for hydroxyapatite, accounting for their bone-homing propensity. Inhibition of FPP synthase in osteoclasts reduces the levels of FPP and GGPP, which are needed for the post-translational farnesylation and geranylgeranylation of small GTPase signalling proteins and essential for osteoclast podosome assembly, V-ATPase acidification of bone surfaces, and consequential resorption/turnover of bone. In postmenopausal women, risedronate reduces the elevated rate of bone turnover, often resulting in a regain of bone mass. Risedronate is thus an osteoclast-mediated bone-resorption inhibitor and is used to treat Paget's disease. **Target(s):** dimethylallyl-*tran*sferase, *or* geranyl-diphosphate synthase (1); farnesyl-*tran*sferase, *or* geranylgeranyl-diphosphate synthase (2,3); geranyl-*tran*sferase, *or* farnesyl-diphosphate synthase (3-13); hypoxanthine:guanine phosphoribosyltransferase (14); protein geranylgeranyl-

transferase (15); protein geranylgeranyltransferase type II (16); pyrophosphatase, or inorganic diphosphatase (17); pyrophosphate-dependent phosphofructokinase, or diphosphate:fructose-6-phosphate 1-phosphotransferase (18); and vacuolar H<sup>+</sup>-transporting pyrophosphatase (17). 1. ### Risperidone

This atypical antipsychotic/antischizophrenic drug (FW = 410.49 g/mol; CAS 106266-06-2; Solubility: 3 mg/mL DMSO, 1 mg/mL H<sub>2</sub>O), also known by its code name R-64766, its trade name Risperdal<sup>®</sup> and its systematic name, 4-[2-[4-(6-fluorobenzo[d]isoxazol-3-yl)-1-piperidyl]-ethyl]-3-methyl-2,6-diazabicyclo[4.4.0]deca-1,3-dien-5-one, is a dopamine antagonist that also exhibits antiserotonergic, antiadrenergic, and antihistaminergic properties (1,2). Risperidone shows very high binding affinity for Serotonin-2, or 5-HT<sub>2</sub>, receptors,  $K_i = 0.16$  nM, with a slow dissociation,  $t_{0.5} = 31$  min (1). Risperidone likewise potently blocks serotonin-induced phosphatidic acid formation in human blood platelets (IC<sub>50</sub> = 0.5 nM). Risperidone also shows high-affinity binding for dopamine-D<sub>2</sub> receptors,  $K_i = 3.1$  nM, and rapid dissociation,  $t_{0.5} = 2.7$  min (1). It also displays high-affinity binding to  $\alpha_1$ -adrenergic ( $K_i = 0.8$  nM), histamine-H<sub>1</sub> ( $K_i = 2.2$  nM) and  $\alpha_1$ -adrenergic ( $K_i = 7.5$  nM) receptors (1). In rats (2), risperidone's potent central 5-HT<sub>2</sub> and catecholamine actions account for its potent and complete antagonism of an LSD (dose = 0.16 mg/kg). The CYP2D6 poor metabolizer phenotype appears to be associated with risperidone adverse drug response and discontinuation (4,5). (**See Paliperidone**) **Note:** Atypical neuroleptics are defined as dopamine (DA) receptor blockers that differ from typical neuroleptics in that they show a markedly lower propensity to induce parkinsonian side-effects of tardive dyskinesias. Some, but not all, are also more effective in treating schizophrenic patients with negative symptoms or who resist classical treatments. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **See also** Ketanserin; Pimavanserin; RH-34; Ritanserin; Setoperone; Volinanserin. **Targets:** Serotonin 5-HT<sub>1A</sub> Receptor,  $K_i = 423$  nM (as antagonist); Serotonin 5-HT<sub>1B</sub> Receptor,  $K_i = 14.9$  nM (as antagonist); Serotonin 5-HT<sub>1D</sub> Receptor,  $K_i = 84.6$  nM (as antagonist); Serotonin 5-HT<sub>2A</sub> Receptor,  $K_i = 0.17$  nM (as inverse agonist); Serotonin 5-HT<sub>2B</sub> Receptor,  $K_i = 61.9$  nM (as inverse agonist); Serotonin 5-HT<sub>2C</sub> Receptor,  $K_i = 12.0$  nM (as inverse agonist); Serotonin 5-HT<sub>5A</sub> Receptor,  $K_i = 206$  nM (as antagonist); Serotonin 5-HT<sub>6</sub> Receptor,  $K_i = 2,060$  nM (as antagonist); Serotonin 5-HT<sub>7</sub> Receptor,  $K_i = 6.60$  nM (as irreversible antagonist); Dopamine D<sub>1</sub> Receptor,  $K_i = 244$  nM (as antagonist); Dopamine D<sub>2</sub> Receptor,  $K_i = 3.57$  nM (as antagonist); Dopamine D<sub>2S</sub> Receptor,  $K_i = 4.73$  nM (as antagonist); Dopamine D<sub>2L</sub> Receptor,  $K_i = 4.16$  nM (as antagonist); Dopamine D<sub>3</sub> Receptor,  $K_i = 3.6$  nM (as inverse agonist); Dopamine D<sub>4</sub> Receptor,  $K_i = 4.66$  nM (as antagonist); Dopamine D<sub>5</sub> Receptor,  $K_i = 290$  nM (as antagonist); Adenergetic  $\alpha_{1A}$  Receptor,  $K_i = 5.0$  nM (as antagonist); Adenergetic  $\alpha_{1B}$  Receptor,  $K_i = 9.0$  nM (as antagonist);  $\alpha_{2A}$  Receptor,  $K_i =$

16.5 nM (as antagonist);  $\alpha_{2B}$  Receptor,  $K_i = 108$  nM (as antagonist); Adenergetic  $\alpha_{2C}$  Receptor,  $K_i = 1.3$  nM (as antagonist); muscarinic Acetylcholine Receptors (mAChRs) >10,000 nM; Histamine H<sub>1</sub> Receptor,  $K_i = 20.1$  nM (as inverse agonist); Histamine H<sub>2</sub> Receptor,  $K_i = 120$  nM (as inverse agonist). 1. ### Ristocetin

These *Nocardia lurida* glycopeptide antibiotics (Ristocetin A (shown above); FW<sub>free-base</sub> = 2067.95 g/mol; CAS 1404-55-3; unstable above pH 7), also known as ristomycin, containing a variable number of carbohydrate substituents, inhibits cell wall biosynthesis in Gram-positive bacteria (1). Ristocetin is also a platelet aggregation agent. **Target(s):** CDP-glycerol glycerol-phosphotransferase (1); CDP-ribitol ribitolphospho-transferase (2); muramoylpentapeptide carboxypeptidase (3); penicillin-binding protein 1b (4); peptidoglycan biosynthesis (5); peptidoglycan glycosyltransferase (4); phospho-N-acetylmuramoyl-pentapeptide-transferase (6); and undecaprenyldiphospho-muramoyl-pentapeptide  $\beta$ -N-acetylglucosaminyltransferase (7). 1. ### RITA

This symmetrical DNA-damaging thiophene (FW = 292.37 g/mol; CAS 213261-59-7; Miscible with Water; Protect from light and heat) also known as NSC 652287, SOS Bismethanol, and systematically as 2,5-bis(5-hydroxymethyl-2-thienyl)furan, inhibits hypoxia-inducible factor-1 $\alpha$  and vascular endothelial growth factor expression *in vivo* and induces tumor cell apoptosis in normoxia and hypoxia, the latter by activation of a novel p53-dependent S-phase checkpoint involving CHK-1. In studies with a renal carcinoma cell line, RITA induced both DNA-protein and DNA-DNA cross-links with no detectable DNA single-strand breaks. Because NSC 652287 does not cross-link purified DNA or mammalian topoisomerase I, it is likely that metabolic activation is required for cross-linking (1). **Toxic Agent:** Moderate to severe irritant to the skin and eyes. This

pharmaceutically active agent should only be handled by trained personnel. 1. Nieves-Neira, Rivera, Kohlhagen, *et al.* (1999) *Mol. Pharmacol.* 56, 478.

**Ritalin, See Methylphenidate**

### Ritanserin

This antidepressant (FW<sub>free-base</sub> = 477.58 g/mol; CAS 87051-43-2) is a potent 5-HT<sub>2A</sub> serotonin receptor antagonist that can cross the blood-brain barrier (1,2). **See also Ketanserin; Pimavanserin; RH-34; Risperidone; Setoperone; Volinanserin.** 1. Leysen, Gommeren, Van Gompel, *et al.* (1985) *Mol. Pharmacol.* 27, 600. 2. Shi, Nathaniel & Bunney (1995) *J. Pharmacol. Exp. Ther.* 274, 735.

### Ritodrine

This tocolytic drug (FW<sub>free-base</sub> = 287.36 g/mol; CAS 26652-09-5) is a  $\beta_2$ -adrenergic agonist that also inhibits uterine muscle contraction and the Ca<sup>2+</sup>-ATPase, inhibiting labor, prolonging pregnancy, and allowing time for the fetus (mainly lungs) to mature. Maternal side-effects include metabolic hyperglycemia, hyperinsulinemia, hypokalemia, antidiuresis, altered thyroid function, physiologic tremor, palpitations, nervousness, nausea, vomiting, fever, and hallucinations. Fetal and neonatal side-effects include tachycardia, hypotension, hypoglycemia, hypocalcemia, hyperbilirubinemia, and intraventricular hemorrhage. 1. Plenge-Tellechea, Soler & Fernandez-Belda (1998) *Arch. Biochem. Biophys.* 357, 179.

### Ritonavir

This pseudopeptide bond-containing peptide analogue (FW = 720.96 g/mol; CAS 155213-67-5), also known as Norvir™, Abbott 84538 and ABT-538, is an antiviral agent that inhibits HIV-1 ( $K_i$  = 0.1 nM *in vitro*, EC<sub>50</sub> = 22-130 nM) and HIV-2 (EC<sub>50</sub> = 160 nM) proteases, blocking polyprotein cleavage in human immunodeficiency virus (1-12). Ritonavir shows high and sustained plasma concentrations after oral administration. Ritonavir produces CYP3A inhibition equivalent to or greater than ketoconazole, and is the best index CYP3A inhibitor alternative to ketoconazole (13). **Target(s):** calpain-1, or  $\mu$ -calpain (1); calpain-2, or m-calpain (1); candidapepsin (2); CYP3A, or cytochrome P450 (3); glucuronosyltransferases, or UDP-glucuronosyltransferases known as UGT1A1, UGT1A3, and UGT1A4 (4); and HIV-1 retropepsin (2,5-12). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Wan & DePetrillo (2002) *Biochem. Pharmacol.* 63, 1481. 2. Tossi, Benedetti, Norbedo, *et al.* (2003) *Bioorg. Med. Chem.* 11, 4719. 3. ### Rivaroxaban

This synthetic, first-in-class, orally available anticoagulant (F.W. = 435.88 g/mol; CAS 366789-02-8; Solubility = 12.5 mg/mL DMSO), also known by tradenames BAY 59-7939 and Xarelto®, and its IUPAC name, (S)-5-chloro-N-[[2-oxo-3-[4-(3-oxomorpholin-4-yl)-phenyl]oxazolidin-5-yl]methyl]-thiophene-2-carboxamide, competitively inhibits blood-clotting Factor Xa ( $K_i$  = 0.4 nM), showing >10,000 times greater selectivity for it over other serine proteases (1-3). Rivaroxaban also inhibits prothrombinase activity (IC<sub>50</sub> = 2.1 nM). **Mode of Action:** The prothrombinase complex (consisting of Factor Xa, Factor Va, Ca<sup>2+</sup>, and phospholipids) rapidly converts prothrombin to thrombin. The membrane-dependent protease activation process requires multiple binding steps including Factor Xa binding to tissue factor-bearing cells and platelets through specific binding sites and receptors, limiting inhibitor access to the two dimensional membrane surface (4). Factor Xa catalyzes peptide-bond cleavage after an arginine residue, with a preferred cleavage site: Ile-(Glu or Asp)-Gly-Arg.) Rivaroxaban's anticoagulant action is exerted by inhibiting thrombin formation, thereby preventing thrombi formation. Rivaroxaban also appears to provide more consistent anticoagulation *versus* vitamin antagonists (VKAs) in atrial fibrillation as well as for the treatment and prevention of venous thromboembolism (3). Without the need for mandatory monitoring and with only few drug interactions, rivaroxaban and other direct Factor Xa inhibitors are appealing alternatives to VKAs in patients for these indications (4). There is a close correlation between the plasma rivaroxaban concentration and prolongation of prothrombinase-induced clotting time and reduction in endogenous thrombin potential (4). Rivaroxaban strongly inhibits platelet-induced thrombin generation, after activation of either platelets or the coagulation pathway, even in the presence of minimal Factor Xa inhibition in plasma (5). **Reversal of Inhibition:** Although there is currently no reliable way to reverse rivaroxaban's anticoagulant action acutely, polyphosphate is a promising agent. This potent and naturally occurring hemostatic regulator accelerates blood coagulation by activating the contact pathway and by promoting factor V activation, in turn attenuating the anticoagulant function of tissue factor pathway inhibitor (6). Indeed, 100  $\mu$ M polyphosphate significantly shortens the clotting time of normal plasma containing 1  $\mu$ g/mL rivaroxaban (6). **See other direct Factor Xa inhibitors:** Apixaban, or Eliquis®; Betrixaban; Darexaban (discontinued); Edoxaban, or Lixiana®; and Otamixaban injectable (discontinued). 1. ### Rivastigmine

This unusual ester (FW<sub>free-base</sub> = 250.34 g/mol; CAS 123441-03-2), also known as Exelon™, is a brain cholinesterase inhibitor used to treat mild to moderate Alzheimer's disease. *Torpedo californica* acetylcholinesterase is carbamoylated very slowly, whereas the bimolecular rate constant for reaction of rivastigmine with human acetylcholinesterase is much higher. For human butyrylcholinesterase and for *Drosophila melanogaster* acetylcholinesterase, carbamoylation is even more rapid. For all four enzymes, spontaneous reactivation is very slow. The Exelon Patch™ consists of four layers: an outer shell, an inner layer containing rivastigmine (4.6 mg initial dose; 9.5 mg maintenance dose), an adhesive layer, and a

peel-off layer protecting the adhesive. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). (**See also Ladostigil**) **Target(s):** acetylcholine esterase (1-5); cholinesterase, or butyrylcholinesterase (2-5). **1.** Amstutz, Enz, Marzi, Boelsterli & Walkinshaw (1990) *Helv. Chim. Acta* **73**, 739. **2.** Darvesh, Walsh, Kumar, *et al.* (2003) *Alzheimer Dis. Assoc. Disord.* **17**, 117. **3.** Luo, Yu, Zhan, *et al.* (2005) *J. Med. #### RK-682

This cell-impermeable agent (FW = 368.51 g/mol; CAS 154639-24-4) from species of *Streptomyces*, inhibits protein-tyrosine phosphatases (*e.g.*, CD45, IC<sub>50</sub> = 54 μM, and vaccinia VHR, IC<sub>50</sub> = 2 μM, *in vitro* (1-3). RK-682 also exerts mammalian cell cycle arrest in the G<sub>1</sub> phase. **1.** Fujii, Kato, Furuse, *et al.* (1995) *Neurosci. Lett.* **187**, 130. **2.** Fujii, Ito, Osada, *et al.* (1995) *Neurosci. Lett.* **187**, 133. **3.** Hamaguchi, Sudo & Osada (1995) *FEBS Lett.* **372**, 54.

#### RKI-1447

This potent, cell-permeable protein kinase inhibitor (FW = 326.37 g/mol; CAS 1342278-01-6; Solubility: 65 mg/mL DMSO; < 1 mg/mL H<sub>2</sub>O), also named *N*-[(3-hydroxyphenyl)methyl]-*N'*-[4-(4-pyridinyl)-2-thiazolyl]urea, targets the Rho-associated kinases ROCK1 (IC<sub>50</sub> = 14.5 nM) and ROCK2 (IC<sub>50</sub> = 6.2 nM) by binding the ATP binding site through interactions with its hinge region and DFG motif (1,2). Importantly, RKI-1447 suppresses phosphorylation of ROCK substrates (MLC-2 and MYPT-1) in human cancer cells, but is without effect on AKT, MEK, and S6 kinase at concentrations as high as 10 μM (1). Consistent with Rho's involvement in actin-based motility, RKI-1447 inhibits migration, invasion and anchorage-independent tumor growth of breast cancer cells. RKI-1447 is also a highly effective inhibitor of mammary tumor outgrowth in a transgenic mouse model (1). **1.** Patel, Forinash, Pireddu, *et al.* (2012) *Cancer Res.* **72**, 5025. **2.** Pireddu, Forinash, Sun, *et al.* (2012) *Med. #### RNA

Aside from the occasional report that of mRNA or tRNA inhibiting enzyme catalysis by blocking the binding a negatively charged substrate to an oppositely charged active site, there are several far more important and extremely generalizable forms of inhibitory RNA. **Antisense RNA:** These small RNA molecules hybridize with specific messenger RNA molecules to form high-affinity complexes that block translation (1-3). Such a mode of action is possible because mRNA is a single-stranded polynucleotide, often referred to as the "sense" strand, because its translation results in a gene product (protein). The unpaired nucleotides of mRNA must hybridize by forming hydrogen-bonded hybrids with the anticodons of aminoacylated transfer RNA molecules as the ribosome proceeds in translating the mRNA sequence into a defined polypeptide sequence. By increasing their length, one can increase the binding energy associated with antisense RNA interaction with its cognate mRNA, thereby increasing affinity and lowering its *K<sub>i</sub>* value. For example, because tomatoes must be shipped to distant markets before they ripen, and because ripening gas ethylene is required for ripening, transgenic tomatoes have been engineered to carry an artificial

gene within their genome, and transcription of that gene into an antisense RNA that complementary to the mRNA for an enzyme involved in ethylene production. Such tomatoes make <10% of the normal amount of the enzyme, thereby greatly prolonging ripening and potential spoilage. One limitation of antisense RNA is that some are degraded by intracellular nucleases. A second limitation is that sufficient antisense RNA must be present to sequester the mRNA as an inactive hybridization complex with its specific antisense RNA. **Catalytic RNA:** These low-molecular-weight RNA molecules, also known as ribozymes, catalyze hydrolase-type reactions that can be engineered to optimize their action within living cells. RNA-cleaving ribozymes achieve their target specificity from Watson-Crick base-pairing between the ribozyme's specificity-conferring binding-arm sequences as well as other sequences flanking the cleavage site within the target RNA (4). Once bound, the cleavage mechanism involves attack of the 2'-OH lying 5' to the scissile bond in the target, thus destabilizing the target RNA's phosphate backbone. Upon cleavage, the hydrolysis products dissociate from the ribozyme complex and the ribozyme is released and may bind and cleave other targets again. The cleavage event renders the mRNA untranslatable and leads to further degradation of the target by cellular ribonucleases. Liu & Altman (5), for example, converted catalytic RNA subunit (known as M1 RNA) of *Escherichia coli* RNase P to an endoribonuclease that specifically cleaves the mRNA encoding the thymidine kinase (TK) of herpes simplex virus 1 (HSV-1). Covalent attachment to the 3' end of M1 RNA of a sequence complementary to TK mRNA resulted in very efficient cleavage of the target RNA *in vitro*. When cultured mouse cells expressing the novel M1 RNA construct were infected with HSV-1, the levels of both TK mRNA and TK protein were reduced to ~20% that found in mock-treated HSV-1-infected cells. Introduction of a library of active ribozymes into specific cells and subsequent screening for phenotypic changes, allows the rapid identification of gene function (6). By destroying a targeted mRNA or directly disrupting their genes, catalytic RNA and DNA are particularly attractive tools for rational design. For the determination of gene function, ribozyme technology complements another RNA-based tool that is based on libraries of small interfering RNAs. **Small Interference RNA:** This class of inhibitory RNA, known as small interfering RNA (siRNA) or silencing RNA, is double-stranded RNA molecules involved in the RNA interference pathway, wherein expression of a specific gene is greatly, but most often incompletely, suppressed (7-10). This technique for inactivating genes within cell relies on the introduction of double-stranded RNA (dsRNA), because animal cells selectively destroy dsRNA. Therefore, if a segment of dsRNA has the same sequence as part of a gene, its introduction into a cell will trigger mRNA destruction, thereby silencing gene expression. This inhibitory mechanism may have evolved as a defense against retroviruses, including HIV, in which genetic information is stored as double-stranded RNA. Small interfering RNAs typically consist of a short (most often 21-nucleotide) double-strand of RNA, with two-nucleotide 3'-overhangs located on either end. Each strand also has a 5'-phosphomonoester group and a 3'-hydroxyl group, resulting from processing by the enzyme, known as dicer, which either converts long double-stranded RNAs or small hairpin RNA's into siRNAs. Because they are so small, siRNA enjoy the advantages that they can be rapidly transcribed from their genes, and there is no requirement for translation into a protein product for inhibition to take place. When introduced into cells by transfection, siRNAs specifically block the expression of a target gene, with targeting based on sequence complementarity with appropriately tailored siRNA. By using two or three different siRNAs, each designed for the very same target, their combined effect is often >80-90% reduction in target gene expression at 48 hours post-transfection, when the latter is carried out at final concentrations of ~5 nM of both siRNAs. **Targets:** Because antisense RNA, catalytic RNA, and small interference RNA are most effective when optimized for a particular enzyme target in a given organism and cell type, and because these techniques do not target conserved binding sites on enzyme targets *per se*, the reader is advised to search PubMed for details on specific applications of RNA inhibitors for a desired enzyme target. Commercial sources (*e.g.*, Ambion.com, Dharmacon.com, GenScript.com, Origene.com, Scbt.com, siRNA.com, *etc.*) also rely on their own well-tested proprietary approaches, including statistical and clustering approaches, for designing highly effective inhibitory RNAi and ribozymes. Finally, one should also consider the possibility of employing RNA therapeutics to increase the therapeutic efficacy of active-site-directed enzyme inhibitors (*i.e.*, reversible and irreversible inhibitors, transition-state mimics, *etc.*). **1.** Green, Pines & Inouye (1986) *Annu. #### Ro 8-4304

This voltage-independent, non-competitive NMDA receptor antagonist (FW<sub>free-base</sub> = 370.42 g/mol; CAS 195988-65-9) exhibits a state-dependent mode of action similar to that described for ifenprodil, when tested in cultured rat cortical neurons. Its apparent affinity for the NMDA receptor increases in a manner that depends on NMDA concentration, inhibiting 10 and 100  $\mu\text{M}$  NMDA responses with respective IC<sub>50</sub> values of 2.3 and 0.36  $\mu\text{M}$ . Currents elicited by 1  $\mu\text{M}$  NMDA were slightly potentiated in the presence of 10  $\mu\text{M}$  Ro 8-4304, and Ro 8-4304 binding slowed the rate of glutamate dissociation from NMDA receptors. Such behavior suggests that Ro 8-4304 exhibits a 14 and 23 times higher affinity for the activated and desensitized states of the NMDA receptor, respectively, relative to the agonist-unbound resting state. Ro 8-4304 binding also results in a 3–4 fold increase in receptor affinity for glutamate site agonists. **1.** Kew, Trube & Kemp (1998) *Brit. J. Pharmacol.* **123**, 463.

**Ro-8-6837**, See *Methiothepin*

#### RO9021

This novel ATP-competitive protein tyrosine kinase inhibitor (FW = 355.45 g/mol), also named systematically as 6-((1*R*,2*S*)-2-aminocyclohexylamino)-4-(5,6-dimethylpyridin-2-ylamino)pyridazine-3-carboxylic acid amide, targets Spleen tyrosine kinase, or SYK ( $K_i$  = 5.6 nM), a key integrator of intracellular signals triggered by activated immunoreceptors, including B-cell and Fc receptors that are important for lymphoid cell development and function. Significantly, RO9021 blocks osteoclastogenesis from mouse bone marrow macrophages *in vitro*. Toll-like Receptor-9 (TLR9) signaling in human B-cells is inhibited by RO9021, decreasing levels of plasmablasts, immunoglobulin (Ig) M and IgG upon B-cell differentiation. RO9021 also potently inhibits type I interferon production by human plasmacytoid dendritic cells (pDC) upon TLR9-specific activation. RO9021 does not inhibit TLR4- or JAK-STAT-mediated signaling. **1.** Liao, Hsu, Kim, *et al.* (2013) *Arthritis Res. Ther.* **15**, R146.

**Ro 13-9904**, See *Ceftriaxone*

#### Ro 15-4513

This benzodiazepine-based ethanol antagonist (FW = 326.31 g/mol; CAS 91917-65-6), also known as ethyl 8-azido-6-dihydro-5-methyl-6-oxo-4*H*-imidazo[1,5-*a*][1,4]benzodiazepine-3-carboxylate, is a partial, inverse agonist of benzodiazepine receptors and a potent antagonist of ethanol-stimulated chloride uptake into brain vesicles (1,2). However, Ro 15-4513 fails to antagonize either pentobarbital- or muscimol-stimulated <sup>36</sup>Cl<sup>-</sup> uptake. In addition, horse liver alcohol dehydrogenase is inactivated after forming a binary complex with LADH ( $K_d$  = 8.6 mM at pH 7.0). **1.** Langeland & McKinley-McKee (1994) *Arch. Biochem. Biophys.* **308**, 367. **2.** Suzdak, Glowa, Crawley, *et al.* (1986) *Science* **234**, 1243.

#### Ro 25-6981

This NR2B subunit-selective NMDA receptor antagonist (FW<sub>free-base</sub> = 339.48 g/mol; FW<sub>maleate-salt</sub> = 455.55 g/mol; CAS 1312991-76-6; Soluble to 10 mM in water with gentle warming and to 100 mM in DMSO), systematically named ( $\alpha$ *R*, $\beta$ *S*)- $\alpha$ -(4-hydroxyphenyl)- $\beta$ -methyl-4-(phenylmethyl)-1-piperidinepropanol maleate, is a potent and selective activity-dependent antagonist for the NR1C/NR2B-type NMDA receptor (IC<sub>50</sub> = 9 nM), with much weaker action against the NR1C/NR2A-type NMDA receptor (IC<sub>50</sub> = 52  $\mu\text{M}$ ), when both were cloned and expressed in *Xenopus* oocytes. Ro 25-6981 exerts neuroprotectant effects both *in vitro* and *in vivo*, albeit little or no protection against kainate toxicity (exposure to 500  $\mu\text{M}$  for 20 h) and only weak activity in blocking Na<sup>+</sup> and Ca<sup>2+</sup> channels, activated by exposure of cortical neurons to veratridine (10  $\mu\text{M}$ ) and potassium (50 mM), respectively (1). Ro-25-6981 shares structural determinants with ifenprodil and other modulators in the NR2B subunit (2). Ro 25-6981 (10 mg/kg *i.p.* in rats) significantly potentiated the nicotine-induced dopamine (DA) release, although it has no effect on DA release when given alone, suggesting that, compared with other subunits of the NMDA receptor, the NR2B subunit might play a different role in the reinforcing effects of nicotine (3). **1.** Fischer, Mutel, Trube, *et al.* (1997) *J. Pharmacol. Exp. Ther.* **283**, 1285. **2.** Lynch, Shim, Seifert, *et al.* (2000) *Eur. J. Pharmacol.* **416**, 185. **3.** Kosowski & Liljequist (2004) *J. Pharmacol. Exp. Ther.* **311**, 560.

#### Ro 31-8220

This maleimide derivative (FW<sub>free-base</sub> = 457.56 g/mol; CAS 125314-64-9), also known as bisindolylmaleimide IX, Ro 318220, and 2-(1-[3-(amidinothio)propyl]-1*H*-indol-3-yl)-3-(1-methylindol-3-yl)maleimide, is a strong inhibitor of protein kinase C, exhibiting some preference for certain isozymes (e.g., the IC<sub>50</sub> value for PKC $\alpha$  is 5 nM and the value for PKC $\gamma$  is 27 nM). In addition, Ro 31-8220 inhibits the growth factor-stimulated expression of MAP kinase phosphatase-1 and c-Fos, but strongly stimulates c-Jun expression and also activates Jun N-terminal kinase. Ro 31-8220 is often supplied as the methanesulfonate salt. **Target(s):** Akt-3 serine/threonine protein kinase (1); glycogen-synthase kinase III, or [tau protein] kinase (2,3); [mitogen-activated protein kinase]-activated protein kinase-1 (3,4); mitogen- and stress-activated protein kinase (3); Na<sup>+</sup>-channels, voltage-dependent (5); non-specific serine/threonine protein kinase (1,3,4); protein kinase C (3,6-8); and ribosomal protein S6 kinase, p70 (3,4). 1. ## Ro 41-1049

This thiazolecarboxamide (FW<sub>free-base</sub> = 265.31 g/mol; CAS 127500-84-9), also known as *N*-(2-aminoethyl)-5-(3-fluorophenyl)-4-thiazolecarboxamide, is a potent and selective reversible inhibitor of monoamine oxidase A (1,2). 1. Da Prada, Kettler, Keller, *et al.* (1990) *J. Neural Transm. Suppl.* **29**, 279. 2. Fernandes & Soares-da-Silva (1990) *J. Pharmacol. Exp. Ther.* **255**, 1309.

## Ro 42-5892, See Remikiren

## Ro 48-8071

This orally active benzophenone (FW<sub>free-base</sub> = 448.38 g/mol; CAS 161582-11-2; typically supplied as the 1:1 fumarate salt) inhibits human lanosterol synthase, *or* 2,3-oxidosqualene:lanosterol cyclase,  $IC_{50} \approx 6.5$  nM (1-5) and squalene:hopene cyclase (6-9). Oxidosqualene cyclase (OSC) catalyzes the cyclization of monooxidosqualene to form lanosterol in the cholesterol synthetic pathway. Ro 48-8071 is an inhibitor of oxidosqualene cyclase (OSC) that has LDL cholesterol-lowering activity similar to the HMG-CoA inhibitor simvastatin. It inhibits human liver microsomal OSC ( $IC_{50} = 6.5$  nM) and HepG2 cells ( $IC_{50} = 1.5$  nM). Ro 48-8071 is readily photodegraded. 1. Morand, Aebi, Dehmlow, *et al.* (1997) *J. ## Rociletinib

This orally available mutant-selective EGFR kinase inhibitor (FW = 555.56 g/mol; CAS 1374640-70-6; Solubility: 100 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), named CO-1686, CNX-419, AVL-301, and *N*-[3-[[2-[[4-(4-acetyl-1-piperazinyl)-2-methoxyphenyl]amino]-5-(trifluoromethyl)-4-pyrimidinyl]amino]phenyl]-2-propanamide, irreversibly targets EGFR<sup>L858R/T790M</sup> ( $K_i = 21.5$  nM) and EGFR<sup>WT</sup> ( $K_i = 21.5$  nM) respectively. After inhibitor binding, the enzyme is covalently modified at the conserved Cys797 within the ATP-

binding pocket of EGFR's kinase domain. Potency is expressed by the ratio ( $k_{\text{inact}}/K_i$ ), where  $k_{\text{inact}}$  is the inactivation rate constant and  $K_i$  is the binding constant. For EGFR<sup>L858R/T790M</sup> kinase,  $k_{\text{inact}}/K_i$  equals  $2.41 \times 10^5 \text{ M}^{-1}\text{s}^{-1}$  and is approximately 22x more selective than with WT EGFR, for which  $k_{\text{inact}}/K_i$  equals  $1.12 \times 10^4 \text{ M}^{-1}\text{s}^{-1}$ . For comparison, erlotinib, a first-generation tyrosine kinase inhibitor, potently inhibits EGFR<sup>WT</sup> ( $K_i = 0.40 \text{ nM}$ ), but with little activity against EGFR<sup>L858R/T790M</sup> ( $K_i = 98.0 \text{ }\mu\text{M}$ ). CO-1686 also demonstrates a favorable selectivity profile when profiled against 434 kinases. Twenty-three targets (representing 14 different kinases) were identified to be inhibited more than 50% at 0.1  $\mu\text{M}$  CO-1686. EGFR  $\Delta 19$ -, T790M-, L858R/T790M-, and L858R-mutant kinases demonstrate the highest degree of inhibition, indicating the specificity of CO-1686. Other kinase targets are inhibited at lower potency, including focal adhesion kinase (FAK), CHK2, ERBB4, and Janus-activated kinase 3 (JAK3). 1. Walter, Sjin, Haringsma, *et al.* (2013) *Cancer Discov.* 3, 1304.

### Rofecoxib

This once widely used anti-inflammatory agent (FW = 314.36 g/mol; CAS 162011-90-7), also known as Vioxx<sup>TM</sup> and MK-0966 and systematically as 4-(4'-methylsulfonylphenyl)-3-phenyl-2-(5H)-furanone, is a potent, orally active cyclooxygenase-2 inhibitor (1,2). No significant inhibition of cyclooxygenase-1 is observed, even at oral doses of 1000 mg (1,2). On September 30, 2004, the FDA issued a Public Health Advisory on Vioxx, announcing that Merck was withdrawing the drug after the safety monitoring board overseeing a long-term study of this drug recommended identified the increased risk of serious cardiovascular events, including heart attacks and strokes, in patients taking Vioxx compared to those receiving placebo. This unfortunate episode in modern drug discovery teaches the risks of assuming a particular enzyme only has a single major role in human metabolism and that extremely high affinity drugs can be safely developed absent a detailed understanding of the diverse and often vital roles of the target enzyme in different tissues. **Likely Effects on Arterial Elasticity:** The actions of orally administered [<sup>14</sup>C]-rofecoxib and two other COX-2 inhibitors, [<sup>14</sup>C]-celecoxib and [<sup>14</sup>C]-apricoxib, were assessed in rats by whole-body autoradioluminography and quantitative determination of the tissue concentrations (3). These experiments showed that considerable radioactivity is retained by and accumulated in the thoracic aorta of rats after oral administration of [<sup>14</sup>C]-rofecoxib, but not [<sup>14</sup>C]-celecoxib or [<sup>14</sup>C]-apricoxib. Acid, organic solvent, and proteolytic enzyme treatments of aorta retaining high levels of radioactivity from [<sup>14</sup>C]-rofecoxib demonstrated that most of the radioactivity is covalently bound to elastin (3). In agreement with this result, the radioactivity was found to be highly localized on the elastic fibers in the aorta by microautoradiography. The retention of radioactivity on the elastic fibers was also observed in the aortic arch and the coronary artery. These findings indicate that rofecoxib and/or its metabolite(s) are covalently bound to elastin in the arteries. Subsequent work demonstrated that rofecoxib, but not other COX-2 inhibitors, is capable of covalently binding to the aldehyde group of allysine in human elastin (4). These data are consistent with the suggestion of modified arterial elasticity leading to an increased risk of cardiovascular impairment after long-term treatment with rofecoxib (3). 1. ### Rogletimide

This aminoglutethimide analogue (FW = 218.26 g/mol; CAS 121840-95-7), also known as pyridoglutethimide and 3-ethyl-3-(4-pyridyl)piperidine-2,6-dione, is a potent aromatase inhibitor. Both enantiomers inhibit, with IC<sub>50</sub>

values of 24.58 and 24.43  $\mu\text{M}$  for the (+)-R- and (-)-S-stereoisomers, respectively (1). **Target(s):** aromatase, or CYP19 (1,2); cholesterol monooxygenase, side-chain-cleaving, or CYP11A1, weakly inhibited (3). 1. Ogbunude & Aboul-Enein (1994) *Chirality* 6, 623. 2. Kitawaki, Yamamoto, Urabe, *et al.* (1990) *Acta Endocrinol. (Copenhagen)* 122, 592. 3. Ahmed (2000) *Biochem. Biophys. Res. Commun.* 274, 821.

### Rolapitant

This selective CNS-penetrant NK<sub>1</sub>R antagonist (FW<sub>free-base</sub> = 500.48 g/mol; FW<sub>HCl-salt</sub> = 536.94 g/mol; CAS 552292-08-7 (free base); 914462-92-3 (HCl monohydrate); Soluble in DMSO, not in water), also known as Varubi<sup>®</sup>, SCH619734, SCH-619734, SCH 619734, and (5S,8S)-8-(((R)-1-(3,5-bis(trifluoromethyl)phenoxy)methyl)-8-phenyl-1,7-diazaspiro[4.5]decan-2-one), targets neurokinin (tachykinin) NK<sub>1</sub> receptor and shows behavioral effects in animals models of emesis. *In vitro* studies suggest that rolapitant has a high affinity for the human NK1 receptor ( $K_i = 0.66 \text{ nM}$ ), showing a high selectivity of >1000-fold over the human NK2 and NK3 subtypes. Rolapitant is a functionally competitive antagonist, as measured by calcium efflux, with a calculated  $K_b$  of 0.17 nM. Varubi is an FDA-approved medication that is specifically indicated for use in combination with other antiemetic agents in adults to prevent the delayed nausea and vomiting associated with initial and repeat courses of emetogenic cancer chemotherapy. **See also Aprepitant** 1. ### Rolipram

This potent cell-permeable 3',5'-cGMP phosphodiesterase inhibitor and antidepressant (FW = 275.35g/mol; CASs = 61413-54-5, 85416-74-6; Solubility: 55 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as ZK 62711, SB 95952 and 4-[3-(cyclopentylloxy)-4-methoxyphenyl]-2-pyrrolidinone, targets the Type-4 phosphodiesterase isoform (PDE4), IC<sub>50</sub> = 1  $\mu\text{M}$  (1-5). Rolipram also promotes neuronal survival (6) and exerts antipsychotic effects in mice (7). **Target(s):** reduces inflammation by suppressing leukocyte function, blocking C5a-stimulated leukotriene C<sub>4</sub> synthesis in eosinophils, IC<sub>50</sub> = 200 nM (8); inhibits lipopolysaccharide-induced TNF synthesis in monocytes, IC<sub>50</sub> = 360 nM (9); prevents bone loss in ovariectomized rats (10). 1. Thomas, Francis & Corbin (1990) *J. Biol. Chem.* 265, 14964. 2. Manganiello, Degerman & Elks (1988) *Meth. Enzymol.* 159, 504. 3. Wachtel (1983) *Neuropharmacology* 22, 267. 4. **Rosenthal's Inhibitor, See Dimethyl-DL-2,3-distearoyloxypropyl(2-hydroxyethyl)-ammonium Acetate**

**Rosiglitazone**

This orally active antidiabetic agent (FW = 357.43 g/mol; CAS 122320-73-4; Solubility: 100 mM in DMSO and to 100 mM in leq. HCl), also known as BRL-49653 and 5-[4-[2-(methyl-2-pyridinylamino)ethoxy]phenyl]-methyl]-2,4-thiazolidinedione, is a PPAR-γ inhibitor (EC<sub>50</sub> = 60 nM) that targets Peroxisome Proliferator Activated Receptor (Type γ) in fat cells, rendering them more responsive to insulin (1,2). (Rosiglitazone exhibits no activity at PPARα and PPARβ.) Rosiglitazone is marketed as a stand-alone drug Avandia™, in combination with metformin, as Avandamet™, and in combination with glimeperide (as Avandaryl™). In 2007, an Advisory Committee of the Food and Drug Administration concluded that rosiglitazone use appeared to carry a greater risk of myocardial ischemic events and heart attacks than a placebo; however, several long-term, prospective clinical trials showed that, when compared to metformin or sulfonylurea, there was added risk of heart attack. The FDA issued a finding that the association between rosiglitazone and myocardial ischemia was inconclusive. Thus, despite its sustained effects on glycemic control, rising concerns about an elevated risk of myocardial infarction and other cardiopathy have reduced the clinical use of rosiglitazone. Rosiglitazone also appears to exert anti-inflammatory effects. **Target(s):** CYPC17, weakly inhibited (3); 3β-hydroxysteroid dehydrogenase type II, weakly inhibited (3); lipoprotein lipase (4); long-chain-fatty-acyl-CoA synthetase, or long-chain-fatty-acid:CoA ligase (5). 1. Lehmann, *et al.* (1995) *J. Biol. Chem.* **270**, 12953. 2. Willson, *et al.* (1996) *J. Med. Chem.* **39**, 665. 3. Arlt, Auchus & Miller (2001) *J. Biol. Chem.* **276**, 16767. 4. **Rosinduline, See Azocarmine G**

**Rosolic Acid, See Aurin**

**Rosuvastatin**

This 3-hydroxy-3-methylglutaryl-CoA reductase inhibitor (FW<sub>free-acid</sub> = 481.55 g/mol; CAS 287714-41-4), also known as Crestor® and (3*R*,5*S*,6*E*)-7-[4-(4-fluorophenyl)-2-(*N*-methylmethanesulfonamido)-6-(propan-2-yl)pyrimidin-5-yl]-3,5-dihydroxyhept-6-enoate, is employed in the chronic treatment of hyperlipidemia, inhibits (1,2), Rosuvastatin reduces low-density lipoprotein-cholesterol (LDL-C) and very low-density lipoprotein-cholesterol (VLDL-C) levels, thereby retarding progression of atherosclerosis and improving the outcomes of coronary heart disease. **Mode of Inhibitor Action:** HMG-CoA reductase is the rate-controlling step in the

biosynthesis of cholesterol and other isoprenoids. Reversible binding of rsvastatin to HMG-CoA reductase involves formation of an initial complex ( $K_1 \approx 1$  nM), which then undergoes a slow transition over 0.5-6 min to yield a tighter complex ( $K_1^* \approx 0.1$  nM). At steady state, rosuvastatin is at least as potent as atorvastatin, cerivastatin, and simvastatin, while being more potent than fluvastatin and pravastatin (2). **Effects on Vascular Cell Dynamics:** Rosuvastatin significantly suppresses PDGF-BB-induced migration of vascular smooth muscle cells (VSMCs), with likely inhibitory effects on expression of matrix metalloproteinases MMP2 and MMP9 (3). It also inhibits mitogen-activated protein kinase (MAPK) signaling by downregulating extracellular signal-regulated kinase (ERK) and p38 MAPK, although the phosphorylation level of c-Jun N-terminal kinase (c-JNK) is not altered (3). **Key Pharmacokinetic Parameters:** The approximate elimination half-life is 19 hours, and the time to peak plasma concentration is reached in 3-5 hours following oral administration. ### Rotenone

This insecticide and fish poison (FW = 394.42 g/mol; CAS 83-79-4), which is found in a number of East Asian and South American plants and used by indigenous tribes as a arrow tip poison, interferes with ubiquinone reduction by binding to (saturable,  $K_d = 15$ -55 nM; Hill coefficient = 1) and inhibiting on the "oxygen side" of NADH dehydrogenase (or Complex I) by blocking electron transfer from the Fe-S centers in Complex I to ubiquinone. By impeding mitochondrial electron transport rotenone poisons terminal respiration, and ATP depletion induces oxidative stress in cells. The latter accounts for rotenone's ability to induce apoptosis in a variety of cell types through activation of the Jun N-terminal kinase pathway, caspase-activated DNAase, p53 relocalization, and activation of Bad. **Note:** Rotenone readily decomposes upon exposure to light and air. **Plant Sources:** Rotenone producers include: Hoary pea, or goat's rue (*Tephrosia virginiana*); Jicama (*Pachyrhizus erosus*); Cubé plant, or lancepod (*Lonchocarpus utilis*); Barbasco (*Lonchocarpus urucu*); Tuba plant (*Derris elliptica*); Jewel vine (*Derris involuta*); Cork-bush (*Mundulea sericea*); Florida fishpoison tree (*Piscidia piscipula*). Little is known about how plants escape rotenone poisoning. **Target(s):** alliin lyase (1); corticosterone 18-monooxygenase (2); electron transport (3-8); glutamate dehydrogenase (9); 25-hydroxyvitamin D  $1\alpha$ -hydroxylase, or calcidiol 1-monooxygenase (10); 2-ketoisovalerate dehydrogenase (11); 4-methoxybenzoate monooxygenase, *O*-demethylating (12); NADH dehydrogenase, or complex I, or NADH:ubiquinone reductase (3-8,13); NADH dehydrogenase, plant inner surface (14); and squalene monooxygenase, or squalene epoxidase (15); tubulin polymerization,  $IC_{50} = 3$   $\mu$ M (16). 1. ### Rottlerin

This natural dye (FW = 518.52 g/mol; CAS 82-08-6) from *Mallotus philippinensis* (or *Rottlera tinctoria*), is a reddish-brown solid also named mallotoxin and (*E*)-1-[6-[(3-acetyl-2,4,6-trihydroxy-5-methylphenyl)-methyl]-5,7-dihydroxy-2,2-dimethyl-2*H*-1-benzopyran-8-yl]-3-phenyl-2-propen-1-one. Rottlerin inhibits different isozymes of protein kinase C, with an  $IC_{50}$  value of 3-6  $\mu$ M for the  $\delta$ -isozyme, whereas the  $IC_{50}$  value is 30-42  $\mu$ M for the  $\alpha$ -,  $\beta$ -, and  $\gamma$ -proteins, and 80-100  $\mu$ M for protein kinase C- $\epsilon$ , - $\eta$ , and - $\zeta$ . The  $IC_{50}$  value for calmodulin-dependent kinase III (also called elongation factor-2 kinase) is 5.3  $\mu$ M. Rottlerin potently stabilizes the channel-open conformation of large conductance potassium channel (BKCa<sup>+</sup>), which is found in the inner mitochondrial membrane of cardiomyocytes. Opening of these channels is beneficial for post-ischemic changes in vasodilation. **Target(s):** Abl1 kinase (1); CaM kinase-III (2-4); chymotrypsin (1); [glycogen-synthase] kinase III, or [tau protein] kinase (4); inositol-trisphosphate 3-kinase (5);  $\beta$ -lactamase (1); malate dehydrogenase (1); [mitogen-activated protein kinase]-activated protein kinase (2-4); mitogen- and stress-activated protein kinase (1-4); p38-regulated/activated protein kinase (4); and protein kinase C (2,4,6-9). 1. McGovern & Shoichet (2003) *J. Med. Chem.* **46**, 1478. 2. Gschwendt, Muller, Kielbassa, *et al.* (1994) *Biochem. Biophys. Res. Commun.* **199**, 93. 3. ### Roussin's Black Salt

This black polynuclear NO-containing, iron-sulfur compound (FW<sub>Potassium-Salt</sub> = 568.73 g/mol; Chemical Formula: K[Fe<sub>4</sub>S<sub>3</sub>(NO)<sub>7</sub>]; CAS 12518-87-5) is photolabile, water soluble, and can release nitric oxide when exposed to light (1). **Target(s):** alcohol dehydrogenase, yeast (2); carbonic anhydrase, or carbonate dehydratase (3); cellular respiration (4). 1. Bourassa, Lee, Bernard, Schoonover & Ford (1999) *Inorg. Chem.* **38**, 2947. 2. Sund & Theorell (1963) *The Enzymes*, 2nd ed. (Boyer, Lardy & Myrback, eds.), **7**, 25. 3. Lindskog, Henderson, Kannan, *et al.* (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), **5**, 587. 4. Hurst, Chowdhury & Clark (1996) *J. Neurochem.* **67**, 1200.

### Roxarsone

This feed-efficiency enhancer and coccidiostatic agent (FW = 263.04 g/mol; CAS 121-19-7), also known as 4-hydroxy-3-nitrobenzenearsonic acid and (4-hydroxy-3-nitrophenyl)arsonic acid, targets bile salt hydrolase (BSH), an

intestinal bacterial enzyme (taurodeoxycholate hydrolase and taurocholate hydrolase activities) that reduces host fat digestion and utilization (1). Synthesized from cholesterol and conjugated to either glycine or taurine in the liver, bile acids pass into the intestine, where it is hydrolyzed by BSH (produced by *Bacteroides*, *Clostridium*, *Enterococcus*, *Bifidobacterium*, and *Lactobacillus*), freeing taurine to function as an electron acceptor. BSHs may also decrease the toxicity of conjugated bile acids for bacteria. Deconjugated bile acids also have decreased solubility and diminished detergent activity, and maybe less toxic to certain GI bacteria. Although one of four FDA-approved arsenicals (*others*: nitarson, arsanilic acid, and carbarsone) for use in poultry and/or swine, roxarsone is metabolized to arsenate in chickens, leading to arsenate accumulation in the liver (2). In 2013, the USFDA withdrew approval of roxarsone, carbarsone, and arsanilic but is reviewing nitarson. 1. Moser & Savage (2001) *Appl. Environ. Microbiol.* 67, 3476. 2. U.S. Food and Drug Administration (September 20, 2011) *FDA Response to Citizen Petition on Arsenic-based Animal Drugs*.

### Roxithromycin

This semi-synthetic antibiotic (FW<sub>free-base</sub> = 837.06 g/mol; CAS 80214-83-1), which is prepared from erythromycin, is similar in action to that parent antibiotic and is predominantly bacteriostatic and is ineffective against Gram-negative bacilli. **Target(s):** CYP3A4 (1); and protein biosynthesis (2). 1. Yamazaki & Shimada (1998) *Drug Metab. Dispos.* 26, 1053. 2. Champney, Tober & Burdine (1998) *Curr. Microbiol.* 37, 412.

### RP 67580

This substance P receptor antagonist (FW<sub>free-base</sub> = 438.57 g/mol; CAS 135911-02-3), also known as (3*aR*,7*aR*)-7,7-diphenyl-2-[1-imino-2-(2-methoxyphenyl)ethyl]perhydroisoindol-4-one, targets the neurokinin-1 receptor ( $K_i$  = 2.9 nM), exerting antidepressant, anxiolytic, and antiemetic properties (1). Its enantiomer (RP 67581) is without effect. *Note*: RP-67580 has high affinity for the NK<sub>1</sub> receptor in rats and mice, but not in humans. RP 67580 also inhibits dactylisin,  $K_i$  = 190 μM (2). 1. Garret, Carruette, Fardin, *et al.* (1991) *Proc. Natl. Acad. Sci. U.S.A.* 88, 10208. 2. ### RPL-554

This experimental bronchodilator and anti-inflammatory drug (FW = 477.55 g/mol), also known as LS-193,855 and named *N*-{2-[(*2E*)-2-(mesitylimino)-9,10-dimethoxy-4-oxo-6,7-dihydro-2*H*-pyrimido[6,1-*a*]isoquinolin-3(4*H*)-yl]ethyl]urea is a long-acting inhibitor of PDE-3 and PDE-4, dual cAMP and cGMP phosphodiesterases, with clinically significant roles in regulating cardiac and vascular smooth muscle as well as platelet aggregation. 1. Boswell-Smith, Spina, Oxford, *et al.* (2006) *J. Pharmacol. Exp. Ther.* 318, 840.

### RPR 107393

This quinuclidine derivative (FW = 340.43 g/mol; CAS 89567-03-38) inhibits squalene synthase,  $IC_{50}$  = 68 nM for the rat enzyme (1). It significantly reduced both plasma total cholesterol and plasma triglyceride levels following oral dosing to rats with a reduced tendency to elevate plasma transaminase levels. 1. Ishihara, Kakuta, Moritani, Ugawa & Yanagisawa (2004) *Bioorg. Med. Chem.* 12, 5899.

### RPR 120844

This substituted pyrrolidinone (FW = 460.58 g/mol) is a potent inhibitor of coagulation factor Xa ( $K_i$  = 7 nM), but a weaker inhibitor of thrombin, trypsin, protein C (activated), plasmin, and t-plasminogen activator, with respective  $K_i$  values of 1, 0.53, 2.4, 4.4, and 8.6 μM. 1. Leadley (2001) *Curr. Top. Med. Chem.* 1, 151. 2. Ewing, Becker, Manetta, *et al.* (1999) *J. Med. Chem.* 42, 3557.

### RPR 130737

This substituted benzamidine (FW = 471.56 g/mol), also known as 4-hydroxy-3-[2-oxo-3(*S*)-(5-pyridin-3-ylthiophene-2-sulfonylamino)pyrrolidin-1-ylmethyl]benzamidine, is a potent inhibitor of human coagulation factor Xa ( $K_i$  = 2.4 nM) and a weak inhibitor of thrombin, activated protein C, plasmin, t-plasminogen activator, and trypsin, with respective  $K_i$  values of 2.8 μM, > 18.5 μM, 2.9 μM, 6.7 μM, and 2.9 μM. 1. Chu, Brown, Colussi, *et al.* (2000) *Thromb. Res.* 99, 71.

RS 25259-197, See Palonosetron

RS-25560-197, See Nepicastat

RSVA 405

This small-molecule resveratrol analogue and AMPK activator (FW = 312.37 g/mol; CAS 140405-36-3; Solubility: 50 mM in DMSO), also named 2-[[4-(diethylamino)-2-hydroxyphenyl]methylene]hydrazide-4-pyridinecarboxylic acid, facilitates CaMKKβ-dependent activation of AMP-activated protein Kinase (EC<sub>50</sub> = 1 μM), inhibits mTOR (mammalian Target of Rapamycin), and promotes autophagy to increase Alzheimer Aβ-peptide degradation by lysosomes, with an apparent EC<sub>50</sub> ~ 1 μM (1). RSVA405 thus inhibits acetyl-CoA carboxylase (ACC), a target of AMPK and a key regulator of fatty acid biogenesis in nondifferentiated and proliferating adipocytes (2). RSVA 405 also potently inhibits Signal Transducer and Activator of Transcription 3 (*or* STAT3), a key mediator of the inflammatory responses of macrophages and other immune cell types. It also inhibits constitutive STAT3 activity in HEK293 cells and stimulated STAT3 activity lipopolysaccharide-stimulated RAW 264.7 macrophages (3). These effects on STAT3 phosphorylation are prevented by inhibitors of protein tyrosine phosphatases, indicating that RSVA405 promotes STAT3 dephosphorylation by protein tyrosine phosphatases. 1. Vingtdeux, Chandakkar, Zhao, *et al.* (2011) *FASEB J.* **25**, 219. 2. Vingtdeux,

Chandakkar, Zhao, Davies & Marambaud (2011) *Mol. Med.* **17**, 1022. 3. Capiralla, Vingtdeux, Venkatesh (2012) *FEBS J.* **279**, 3791.

RTA-408, See Omaveloxolone

RTI-55

This methylecgonidine derivative (FW = 385.24 g/mol; CAS 136794-86-0), also known systematically as methyl (1*R*,2*S*,3*S*)-3-(4-iodophenyl)-8-methyl-8-azabicyclo[3.2.1]octane-2-carboxylate, is a non-selective dopamine reuptake inhibitor. 1. Boja, Patel, Carroll, *et al.* (1991) *Eur. J. Pharmacol.* **194**, 133.

RTI-229

This neurotransmitter reuptake inhibitor (FW = 424.32 g/mol; CAS 160948-17-4), also known systematically as [(1*R*,2*S*,3*S*,5*S*)-3-(4-iodophenyl)-8-methyl-8-azabicyclo[3.2.1]octan-2-yl]-pyrrolidin-1-ylmethanone, exhibits a K<sub>i</sub> value of 0.35 nM for dopamine and a K<sub>i</sub> value of 20 nM for norepinephrine. 1. Rothman, Baumann, Dersch, *et al.* (2001) *Synapse* **39**, 32.

RTX Toxin

These cytotoxic Gram-negative bacterial proteins encompass >1000 members exhibit characteristic glycine and aspartate-rich repeats and extracellular secretion by the type I secretion system (TISS), which prevents RTX toxin accumulation in the periplasmic space. RTX toxins may be divided into pore-forming leukotoxins and multifunctional autoprocessing RTX toxins (MARTX). The prototypical RTX toxin is α-hemolysin (HlyA), a virulence factor produced by uropathogenic *Escherichia coli* (UPEC). Enterohemorrhagic *E. coli* (EHEC Serotype O157:H7) produces the RTX toxin known as EHEC hemolysin (EHEC-Hly). Likewise, *Vibrio* RtxA inhibits the actin cytoskeleton by targeting Rho GTPases. 1. Lally, Hill, Kieba & Korostoff (1999) *Trends Microbiol.* **7**, 356. 2. Benz (2015) *Biochim. Biophys. Acta* **1858**, 526.

RU 486, RU-486, or RU486, See Mifepristone

RU2390, See Nilutamide

RU 23345

This desoxyimino-3-cephem antibiotic (FW = 412.44 g/mol) inhibits serine-type D-Ala-D-Ala carboxypeptidase and is a β-lactamase substrate. Interestingly, the *Streptomyces albus* G Zn<sup>2+</sup>-containing D-alanyl-D-alanine-cleaving peptidase (a highly penicillin-resistant enzyme) remains highly resistant to all compounds tested. 1. Laurent, Durant, Frère, Klein & Ghuysen (1984) *Biochem. J.* **218**, 933.

## RU-28318

This potent and selective mineralocorticoid receptor (MR) antagonist (FW<sub>free-acid</sub> = 402.58 g/mol; FW<sub>potassium-salt</sub> = 440.67 g/mol; CAS 76676-34-1), also known as potassium oxprenolate and (7 $\alpha$ ,17 $\alpha$ )-17-hydroxy-3-oxo-7-propylpregn-4-ene-21-carboxylate, inhibits aldosterone production and secretion. A dose-related inhibition of aldosterone production is observed for doses ranging from 10<sup>-5</sup> to 10<sup>-3</sup> M of RU 28318, and an intermediate dose (10<sup>-4</sup> M) causes 70% inhibition (1). Long-term infusion (8 hours) results in to significant, stable and reversible inhibition of aldosterone production. Acute treatment of adrenalectomized rats with RU28318 (10-50 mg/kg) selectively decreased ex-vivo available MR binding in the hippocampus (2). Intracerebroventricular injection of RU28318 causes significant decrease in systolic blood pressure within 8 hours, demonstrating that brain mineralocorticoid receptors participate in blood pressure and renal function control. 1. Perroteau, Netchitailo, Delarue, *et al.* (1984) *J. Steroid Biochem.* **20**, 853. 2. Kim, Cole, Kalman & Spencer (1998) *J. Steroid Biochem. Mol. Biol.* **67**, 213. 3. RU 38486, See *Mifepristone*

## RU 44004

This peptide analogue (FW = 280.39 g/mol) inhibits neprilysin ( $K_i$  = 200 nM), an endothelial membrane-bound Zn<sup>2+</sup> metallopeptidase found in brain, kidneys, lungs, gastrointestinal tract, heart, and peripheral vasculature. NEP degrades and inactivates a number of endogenous peptides, including enkephalins, circulating bradykinin, angiotensin peptides, and natriuretic peptides. 1. Roques, Noble, Crine & Fournié-Zaluski (1995) *Meth. Enzymol.* **248**, 263.

Rubeanic Acid, See *Dithiooxamide*

Rubidazone, See *Zorubicin*

Rubomycin, See *Daunorubicin*

## Ruboxistaurin

This orally available *N*-*N'*-bridged bis-indolylmaleimide-based macrocycle (FW = 468.56 g/mol; CAS 169939-94-0; *Symbol*: RBX), also known by its

trade name Arxxant<sup>®</sup> and systematic name (9*S*)-9-[(dimethylamino)methyl]-6,7,10,11-tetrahydro-9*H*,18*H*-5,21:12,17-di(metheno)-dibenzo[*e,k*]pyrrole-[3,4-*h*][1,4,13]oxadiazacyclohexadecine-18,20-dione, is an investigational drug for the treatment of diabetic peripheral retinopathy. Ruboxistaurin inhibits the PKC  $\beta$ 1 (IC<sub>50</sub> = 4.7 nM) and PKC  $\beta$ II (IC<sub>50</sub> = 5.9 nM) isozymes and is 76x and 61x more selective than compared to PKC  $\alpha$  (2). PKC  $\beta$  is a druggable target for treating diabetic peripheral neuropathy (DPN). This drug is also likely to exert beneficial effects in preventing the development of diabetic nerve dysfunction by its action on the endoneurial microvasculature (3). The benefit of RBX for peripheral neuropathy has not been successfully demonstrated in Phase III trials. 1. 2. Jirousek, Gillig, Gonzalez, *et al.* (1996) *J. Med. Chem.* **39**, 2664. 3. Nakamura, Kato, Hamada, *et al.* (1999) *Diabetes* **48**, 2090.

## Rubratoxin B

This lactone-containing bisanhydride metabolite (FW = 518.52 g/mol; CAS 21794-01-4) of certain toxigenic molds (*e.g.*, *Penicillium rubrum* and *P. purpurogenum*) is a hepatotoxin that inhibits gap junction intracellular communication, induces nuclear and internucleosomal fragmentation, and induces apoptosis. **Target(s)**: cytochrome P450 (1); electron transport (2); and Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (3). 1. Siraj & Hayes (1979) *Toxicol. Appl. Pharmacol.* **48**, 351. 2. Hayes (1976) *Toxicology* **6**, 253. 3. Phillips, Hayes, Ho & Desai (1978) *J. Biol. Chem.* **253**, 3487.

## Rubrofusarin B

This phytotoxin, isolated from the fungus *Guanomyces polythrix*, inhibits calmodulin-dependent cyclic-nucleotide phosphodiesterase and NAD<sup>+</sup> kinase, with respective IC<sub>50</sub> values of 4.7 and 13.3  $\mu$ M, as well as NAD<sup>+</sup> kinase (1) and xanthine oxidase (2). 1. Mata, Gamboa, Macias, *et al.* (2003) *J. Agric. Food Chem.* **51**, 4559. 2. Song, Li, Ye, *et al.* (2004) *FEMS Microbiol Lett.* **241**, 67.

## Rucaparib

This PARP inhibitor (FW = 323.37 g/mol; FW<sub>Phosphate-Salt</sub> = 421.36 g/mol; CAS 459868-92-9; Solubility = 200 mM in DMSO), also known as AG-014699, PF-01367338, and 8-fluoro-5-(4-((methylamino)methyl)phenyl)-3,4-dihydro-2*H*-azepino[5,4,3-*cd*]indol-1(6*H*)-one, targets the poly(ADP-ribose) polymerase PARP-1 ( $K_i$  = 1.4 nM), a nuclear enzyme that promotes the base excision repair within DNA breaks. Rucaparib inhibition of PARP-1 greatly enhances the efficacy of DNA alkylating agents, topoisomerase I poisons, and ionizing radiation. Rucaparib binding is also detected with eight other PARP domains (*e.g.*, PARP-2, PARP-3, PARP-4, PARP-10,

PARP-15, PARP-16, TNKS1 and TNKS2). The phosphate salt has improved aqueous solubility and is used in clinical trials. Rucaparib inhibits myosin light chain kinase 10x more potently than ML-9, producing an additive relaxation above that achievable with ML-9 (2). This finding suggested MLCK inhibition is not solely responsible for dilation. That rucaparib possesses a nicotinamide-like pharmacophore also raises the possibility it may inhibit other NAD<sup>+</sup>-dependent processes (2). 1. Thomas, Calabrese, Batey, *et al.* (2007) *Mol. Cancer Ther.* **6**, 945. 2. McCrudden, O'Rourke, Cherry, *et al.* (2015) *PLoS One* **10**, e0118187.

#### Rufinamide

This anticonvulsant drug (FW = 238.19 g/mol; CAS 106308-44-5), also known as CGP-33101, RUF-331, Inovelon™, Banzel™ and 1-(2,6-difluorobenzyl)-1H-1,2,3-triazole-4-carboxamide, is indicated as an adjunctive, second/third-line treatment for seizures associated with Lennox-Gastaut syndrome in adults and children who are four years and older. Rufinamide appears to limit the firing of sodium-dependent action potentials in neurons, consistent with the stabilization of the sodium channel inactive state, thereby maintaining these ion channels in a closed state. 1. Perucca, Cloyd, Critchley & Fuseau (2008) *Epilepsia* **49**, 1123. 2. Glauser, Kluger, Sachdeo, *et al.* (2008) *Neurology* **70**, 1950. 3. Cheng-Hakimian, Anderson & Miller (2006) *Internat. J. Clin. Pract.* **60**, 1497.

#### Rufloxacin

This fluoroquinolone-class antibiotic (FW = 363.41 g/mol; CAS 101363-10-4 and 106017-08-7; IUPAC Name: 9-fluoro-10-(4-methylpiperazin-1-yl)-7-oxo-2,3-dihydro-7H-[1,4]thiazino[2,3,4-ij]quinoline-6-carboxylate), marketed under the trade names Ruflox®, Monos®, Qari®, Tebraxin®, Uroflox®, and Uroclar®, is a broad-spectrum systemic antibacterial agent that targets Type II DNA topoisomerases (gyrases), which are required for bacterial replication and transcription. Rufloxacin has a broad spectrum of activity in vitro against clinically important gram-positive and gram-negative aerobes (37, 54). The pharmacokinetics are characterized by a mean level of plasma protein binding of 60%, a long elimination half-life of about 30-35 hours, low renal clearance, and good tissue penetration. In rats, ~60% of the dose was absorbed. After an oral dose of 200 mg, humans reach maximum plasma levels of ~4 µg/mL in 3-5 hours, and steady-state serum concentrations within 4-5 days. Urine excretion of rufloxacin is 25-50% of the dose, and renal clearance is about 20 mL/min. For the prototypical member of this antibiotic class. See Ciprofloxacin 1. Schito, Acar, Bauernfeind, *et al.* () *J. Antimicrob. Chemother.* **38**, 627. 2. Wise, Andrews, Matthews & Wolstenholme (1992) *J. Antimicrob. Chemother.* **29**, 649.

#### Rupatadine

This orally active, dual-receptor antagonist and second-generation antihistamine (FW = 532.03 g/mol (fumarate salt); CAS 182349-12-8;

Solubility: 10 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), named systematically as 8-chloro-6,11-dihydro-11-[1-[(5-methyl-3-pyridinyl)methyl]-4-piperidin-ylidene]-5H-benzo[5,6]cyclohepta[1,2-b]pyridine), targets the platelet-activating factor receptor PAFR (a G-protein coupled receptor that binds platelet-activating factor) and histamine (H<sub>1</sub>) receptor (a Rhodopsin-like G-protein coupled receptor that binds histamine) with K<sub>i</sub> values of 550 and 102 nM, respectively. Rupatadine competitively inhibited histamine-induced guinea pig ileum contraction, without affecting contraction induced by ACh, serotonin or leukotriene D<sub>4</sub>. It also competitively inhibited PAF-induced platelet aggregation in washed rabbit platelets and in human platelet-rich plasma (IC<sub>50</sub> = 0.68 µM), while not affecting ADP- or arachidonic acid-induced platelet aggregation. 1. Merlos, *et al.* (1997) *J. Pharmacol. Exp. Ther.* **280**, 114. 2. Queralt, *et al.* (2000) *Inflamm. Res.* **49**, 355. 3. Barbanjoj, *et al.* (2004) *Neuropsychobiology* **50**, 311. 4. Sudhakara Rao, *et al.* (2009) *Indian J. Otolaryngol. Head Neck Surg.* **61**, 320.

#### Rupintrivir

This peptidomimetic (FW = 598.67 g/mol; CAS 223537-30-2), also known as AG 7088, is a potent irreversible inhibitor of picornain 3C, with a k<sub>obs</sub>/[I] value of 1.47 x 10<sup>6</sup> M<sup>-1</sup>s<sup>-1</sup> for HRV 14 (1-3). Rupintrivir exhibits potent *in vitro* activity against all HRV serotypes and HEV strains. 1. Dragovich, Prins, Zhou, *et al.* (1999) *J. Med. Chem.* **42**, 1213. 2. Patick, Binford, Brothers, *et al.* (1999) *Antimicrob. Agents Chemother.* **43**, 2444. 3. Matthews, Dragovich, Webber, *et al.* (1999) *Proc. Natl. Acad. Sci. U.S.A.* **96**, 11000.

#### RU-SKI 43

This Sonic Hedgehog (Shh) signaling pathway inhibitor (FW<sub>free-base</sub> = 386.55 g/mol; FW<sub>hydrochloride</sub> = 423.01 g/mol; CAS 1043797-53-0; Solubility: 93 mM in DMSO), also named 2-(2-methylbutylamino)-1-(4-(*m*-tolylloxymethyl)-6,7-dihydrothieno[3,2-*c*]pyridin-5(4H)-yl)ethanone-HCl, targets hedgehog acyltransferase (HhAT), blocking Sonic Hedgehog signal transduction (See also Wnt-C59). **Mode of Inhibitor Action:** Several lines of evidence suggest RU-SKI 43 is a specific inhibitor of Shh palmitoylation. First, neither palmitoylation of H-Ras and Fyn nor myristoylation of c-Src is affected by when cells are treated RU-SKI 43. Second, RU-SKI 43 treatment is without effect on fatty acylation of Wnt3a12 by Porcupine, another member of the MBOAT family, whereas Wnt C59 (itself a Porcupine inhibitor) blocked radiolabel incorporation. Third, overexpression of Hhat reduced the ability of RU-SKI 43 to inhibit Shh palmitoylation in transfected COS-1 cells, whereas overexpression of Porcupine had no effect. Fourth, RU-SKI 43 inhibited palmitoylation of Shh by endogenous Hhat in COS-1 cells. Lastly, RU-SKI 43 did not alter Shh autoprocessing, steady-state levels of Shh and Hhat, or subcellular localization of Shh and Hhat. 1. Petrova, Rios-Esteves, Ouerfelli, Glickman, & Resh (2013) *Nature Chem Biol.* **9**, 24.

### Russell's Viper Venom Proteinase Inhibitors

These Kunitz-type proteinase inhibitors and exert antihemorrhagic agents (MW  $\approx$  7.2 kDa), isolated from the venom of Russell's viper (*Daboia russelli*), show  $K_i$  values of 0.8 nM for bovine trypsin, 0.1 nM for bovine chymotrypsin, 0.3 nM for bovine plasma kallikrein, and 1 nM for bovine plasmin. **See also Trypsin Inhibitors** 1. Iwanaga, Takahashi & Suzuki (1976) *Meth. Enzymol.* **45**, 874. 2. Kurachi & Davie (1981) *Meth. Enzymol.* **80**, 211.

### Rustmicin

This lactone (FW = 380.48 g/mol; CAS 100227-57-4) from a *Micromonospora* exhibits potent antifungal activity against phytopathogenic fungi but has no effect on lipid biosynthesis in mammalian cells. Rustmicin has a relatively short half-life in aqueous solutions (<1 hour below pH 4 or above pH 7; longer at pH 5.5). **Target(s):** inositolphosphoryl-ceramide synthase, or ceramide inositol phosphoryltransferase (1,2). 1. Fischl, Liu, Browdy & Cremesti (2000) *Meth. Enzymol.* **311**, 123. 2. Mandala & Harris (2000) *Meth. Enzymol.* **311**, 335.

### Rutaecarpine

This quinoxalinocarboline alkaloid (FW = 287.32 g/mol; CAS 20575-76-2), also called rutaecarpine, from the fruit of *Evodia rutaecarpa* and *Hortia arborea* is a vasodilator and a delayed rectifier  $K^+$  channel blocker. **Target(s):** COX-2, or cyclooxygenase (1); CYP1A1 (2); CYP1A2 (2); CYP3A4 (3); and delayed rectifier  $K^+$  channel (4). 1. Moon, Murakami, Kudo, *et al.* (1999) *Inflamm. Res.* **48**, 621. 2. Ueng, Jan, Lin, *et al.* (2002) *Drug Metab. Dispos.* **30**, 349. 3. ### Rutamycin A

This macrolide antibiotic (FW = 777.05 g/mol; CAS 1404-59-7), also known as oligomycin D and 26-demethyloligomycin A, strongly inhibits fungal mitochondrial  $F_0F_1$  ATP synthase, or  $H^+$ -transporting two-sector ATPase (1-5). Rutamycin B, isolated from *Streptomyces aureofaciens*, likewise inhibits mitochondrial ATP synthase. 1. Stiggall, Galante & Hatefi (1979) *Meth. Enzymol.* **55**, 308. 2. Racker (1979) *Meth. Enzymol.* **55**, 315. 3. Linnett & Beechey (1979) *Meth. Enzymol.* **55**, 472. 4. Lardy, Witonsky & Johnson (1965) *Biochemistry* **4**, 552. 5. Kageyama, Tamura, Nantz, *et al.* (1990) *J. Amer. Chem. Soc.* **112**, 7407.

### Rutecarpine, See Rutaecarpine

### Rutin

This remarkably abundant plant flavonoid (FW = 610.53 g/mol; CAS 153-18-4; hygroscopic solid that darkens upon light exposure) is the 3'-rutinoside of quercetin found in many plants (*e.g.*, buckwheat, hydrangea, eucalyptus, pansies, tobacco, and forsythia). This natural free-radical scavenger, occasionally referred to as vitamin P, has a protective antioxidant effect in cells and protects cells with carcinogen-induced DNA damage. **Target(s):** aldose reductase, or aldehyde reductase (1,2); ATPase, weakly inhibited (3);  $Ca^{2+}$ -exporting ATPase (4); carbonyl reductase (5,6); catechol *O*-methyltransferase (24); chitin synthase (7); DNA-directed DNA polymerase (23); dopamine  $\beta$ -hydroxylase (8); hyaluronoglucosaminidase, or hyaluronidase (9-11); iodothyronine deiodinase, type I (12); leucoanthocyanidin reductase (26); [myosin light-chain] kinase (22); NADH oxidase, weakly inhibited (3); NAD(P)H:quinone reductase (13); P-glycoprotein (14); phosphoenolpyruvate carboxylase (15,16); phospholipase  $A_2$  (17,18); protein kinase C (19); pyruvate kinase (20); succinoxidase, weakly inhibited (3); tyrosinase, or monophenol monooxygenase (10,27,28); xanthine oxidase (21,25); and xenobiotic-transporting ATPase, or multidrug-resistance protein (14). 1. #### Ruxolitinib

This Janus-associated kinase inhibitor (F.Wt. = 306.43 g/mol; CAS 941678-49-5; Soluble in DMSO; Water < 1 mg/mL), also known as (*R*)-3-(4-(7*H*-pyrrolo[2,3-*d*]pyrimidin-4-yl)-1*H*-pyrazol-1-yl)-3-cyclopentylpropanenitrile and NCB018424, acts selectively, with IC<sub>50</sub> values of 2.7 nM, 4.5 nM, and 322 nM for JAK1, JAK2, and JAK3 (1). The rationale for its therapeutic action is the observation that most polycythemia vera patients carry the JAK2-Val617Phe mutation (2). Ruxolitinib is an oral Janus kinase (JAK) 1/JAK2 inhibitor approved in the US for the treatment of intermediate-or high-risk myelofibrosis (MF); however, because thrombopoietin and erythropoietin signal through JAK2, dose-dependent cytopenias are expected with treatment (3). Ruxolitinib treatment dose-dependently alleviates CCL<sub>4</sub>-induced hepatic injury and necroinflammation, as indicated by biochemical markers of injury and histopathology (4). **1.** Williams, *et al.* (2008) *Ann. Rheum. Dis.* **67** (Suppl II), 62. **2.** Quintás-Cardama, Vaddi, Liu, Manshouri, *et al.* (2010) *Blood* **115**, 3109. **3.** Verstovsek, Gotlib, Gupta, *et al.* (2013) *Onco Targets Ther.* **7**, 13. **4.** Hazem, Shaker, Ashamallah & Ibrahim (2014) *Chem. Biol Interact.* **220**, 116.

**RWJ-17021, See Topiramate**

#### RWJ-37947

This topiramate analogue (FW = 361.35 g/mol), also known as RWJ-37497, inhibits carbonic anhydrase, or carbonate dehydratase, with IC<sub>50</sub> = 36 nM for the human II isozyme (1,2). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** Recacha, Costanzo, Maryanoff, Maryanoff & Chatto-padhyay (2002) *Biochem. J.* **361**, 437. **2.** Maryanoff, Costanzo, Northey, *et al.* (1998) *J. Med. Chem.* **41**, 1315.

#### RWJ-50353

This arginine-containing derivative (FW = 551.72 g/mol), known as *N*-methyl-D-phenylalanyl-*N*-[5-[(aminoiminomethyl)amino]-1-[[2-(benzothiazolyl)carbonyl]butyl]-L-prolinamide], inhibits thrombin,  $K_i = 0.19$  nM (1-3), trypsin,  $K_i = 3.1$  nM (2,4), and trypsin  $K_i = 6.5$  nM (4). **1.** Matthews, Krishnan, Costanzo, Maryanoff & Tulinsky (1996) *Biophys. J.* **71**, 2830. **2.** Costanzo, Maryanoff, Hecker, *et al.* (1996) *J. Med. Chem.* **39**, 3039. **3.** Recacha, Costanzo, Maryanoff, *et al.* (2000) *Acta Crystallogr. Sect. D* **56**, 1395. **4.** Costanzo, Yabut, Almond, Jr., *et al.* (2003) *J. Med. Chem.* **46**, 3865.

#### RWJ-51084

This arginine-containing derivative (FW = 387.51 g/mol), a dipeptide-based transition-state analogue containing a benzothiazole ketone, inhibits trypsin ( $K_i = 30$  nM) and trypsin ( $K_i = 88$  nM) (1,2). Aerosol administration of RWJ-58643 to allergic sheep effectively antagonized antigen-induced asthmatic responses, with substantial blockade of the early response and complete ablation of the late response and airway hyperresponsiveness. **1.** Costanzo, Yabut, Almond, Jr., *et al.* (2003) *J. Med. Chem.* **46**, 3865. **2.** Recacha, Carson, Costanzo, *et al.* (1999) *Acta Crystallogr. D Biol. Crystallogr.* **55**, 1785.

#### RWJ-51438

This phenylalanylprolylarginine-containing benzothiazole (FW = 593.69 g/mol) is thrombin inhibitor ( $K_i = 1.1$  nM) that becomes covalently linked to the hydroxyl group of Ser195, forming a tetrahedral intermediate, hemiketal structure. **1.** Recacha, Costanzo, Maryanoff, *et al.* (2000) *Acta Crystallogr. Sect. D* **56**, 1395.

**RWJ-355871, See 2-[3-[*N*-Methyl-*N*-(*N*-(*b*-naphthoyl)piperidin-4-yl)carbamoyl]-naphthalene-2-yl]-1-(naphthalene-1-yl)-2-oxoethylphosphonate**

#### RXP 407

This phosphinic peptide (FW = 440.44 g/mol), also known as *N*-Acetyl- $\alpha$ -aspartyl-3-[(1-amino-2-phenylethyl)hydroxyphosphinyl]-2-methylpropanoylalaninamide or *N*-acetyl-L-aspartyl-L-phenylalanyl $\Psi$ [PO<sub>2</sub>-CH<sub>2</sub>]-L-

alanyl-L-alaninamide (where  $\psi$  indicates a pseudopeptide linkage), is a potent inhibitor of peptidyl-dipeptidase A, or angiotensin I-converting enzyme. RXP 407 is the first inhibitor reported to differentiate between the two active sites of the two homologous domains of this enzyme, with a  $K_i$  value of 12 nM for the active site in the N-terminal domain and a  $K_i$  value of 25  $\mu$ M for the C-terminal domain (1). Cotton, Hayashi, Cuniasse, *et al.* (2002) *Biochemistry* **41**, 6065. 2. Dive, Cotton, Yiotakis, *et al.* (1999) *Proc. Natl. Acad. Sci. U.S.A.* **96**, 4330.

### Ryanodine

This poisonous alkaloid and potent insecticide (FW = 493.55 g/mol; CAS 15662-33-6) from *Ryania speciosa* binds to large, high conductance  $\text{Ca}^{2+}$  channels (ryanodine receptors) controlling the release of  $\text{Ca}^{2+}$  from an intracellular compartment (*i.e.*, the sarco/endoplasmic reticulum). At nM concentrations, ryanodine locks the receptor in a half-open state; however, at  $\mu$ M concentrations, the receptor closes fully. Ryanodine binds with such high affinity that it was used as a radiolabel the receptor, thereby permitting purification of this class of ion channels. Mammalian tissues express three closely related ryanodine receptors. 1. Feher & Lipford (1985) *Biochim. Biophys. Acta* **813**, 77. 2. Marban & Wier (1985) *Circ. Res.* **56**, 133.

# - S -

## S3QEL 2

This cell-permeable substituted allopurinol (FW = 323.44 g/mol; CAS 890888-12-7; Solubility: 20 mM in DMSO, with gentle warming), also named 1-(3,4-dimethylphenyl)-*N,N*-dipropyl-1*H*-pyrazolo[3,4-*d*]pyrimidin-4-amine, suppresses superoxide production by mitochondrial Complex III (IC<sub>50</sub> = 1.7 μM), without affecting normal electron flux or cellular oxidative phosphorylation. S3QEL-2 also suppresses HIF-1α accumulation and enhances survival and function of primary pancreatic islets *in vitro*. Superoxide production by respiratory complex III is implicated in diverse signaling events and pathologies, but its role remains controversial. 1. Orr, Vargas, Turk, *et al.* (2015) *Nature Chem. Biol.* **11**, 834.

**S-13**, See 2',5-Dichloro-3-*tert*-butyl-4'-nitrosalicylanilide

**S-2720**, See 6-Chloro-3,3-dimethyl-4-(isopropenyl-oxycarbonyl)-3,4-dihydroquinoxalin-2(1*H*)-thione

## S 2101

This LSD1 inhibitor (FW<sub>HCl-Salt</sub> = 311.75 g/mol; CAS 1239262-36-2; Soluble to 50 mM in H<sub>2</sub>O; 100 mM in DMSO), also named (1*R*,2*S*)-*rel*-2-[3,5-difluoro-2-(phenylmethoxy)phenyl]cyclopropanamine HCl, targets Lysine-Specific Demethylase 1A, a flavin-dependent monoamine oxidase that catalyzes the demethylation of mono- and di-methylated lysines, specifically acting on histone 3, lysines 4 and 9 (IC<sub>50</sub> = 990 nM; K<sub>i</sub> = 610 nM). S-2101 exhibits selectivity for LSD1, as compared to monoamine oxidases MAO-A (K<sub>i</sub> = 110 μM) and MAO-B (K<sub>i</sub> = 17 μM). LSD1 plays critical roles in embryogenesis and tissue-specific differentiation, as well as oocyte growth. 1. Mimasu, Umezawa, Sato, *et al.* (2010) *Biochemistry* **49**, 6494.

## S-3483

This chlorogenic acid derivative (FW<sub>free-acid</sub> = 502.14 g/mol) is a reversible, linear competitive inhibitor of the glucose-6-phosphatase (Glc-6-Pase) system within rat renal microsomes and rat and human liver microsomes (1). The K<sub>i</sub> value of 129 nM for S-3483 in rat liver microsomes is three orders of magnitude lower than that for chlorogenic acid. At concentrations

up to 100 μM, S-3483 had no direct effect on the Glc-6-Pase enzyme activity or on its inorganic pyrophosphatase activity (*i.e.*, on T<sub>2</sub>, the P<sub>i</sub>/inorganic pyrophosphate transporter). Thus, like chlorogenic acid, S-3483 appears to be a site-specific inhibitor of T<sub>1</sub>, the Glc-6-P transporter of renal and liver microsomes (2). 1. Simon, Herling, Preibisch & Burger (2000) *Arch. Biochem. Biophys.* **373**, 418. 2. Arion, Canfield, Ramos, *et al.* (1998) *Arch. Biochem. Biophys.* **351**, 279.

## S 07662

This CAR inverse agonist (FW = 300.38 g/mol; CAS 883226-64-0; Solubility = 100 mM in DMSO), also named *N*-[(2-methyl-3-benzofuranyl)methyl]-*N'*-(2-thienylmethyl)urea, S-07662, and S07662, targets the orphan nuclear Constitutive Androstane Receptor (*or* CAR) via recruitment of nuclear receptor co-repressor (*or* NCoR). In addition to being one of the key regulators of xenobiotic and endobiotic metabolism, CAR also influences a variety of physiological functions, such as gluconeogenesis, metabolism of xenobiotics, fatty acids, bilirubin, bile acids, hormonal regulation, *etc.* 1. Küblbeck, Jyrkkärinne, Molnár, *et al.* (2011) *Mol. Pharm.* **8**, 2424.

**S-16257**, See *Ivabradine*

## S 17625

This quinolinone-phosphonic acid (FW<sub>free-acid</sub> = 294.03 g/mol), also known as 6,7-dichloro-2(1*H*)-oxoquinoline-3-phosphonic acid, is an AMPA (*or* α-amino-3-hydroxy-5-methylisoxazole-4-propionic acid) receptor antagonist. Replacement of the chlorine in position-6 by a sulfonylamine led to very potent AMPA antagonists endowed with good *in vivo* activity and lacking nephrotoxicity potential. 1. Cordi, Desos, Ruano, *et al.* (2002) *Farmaco* **57**, 787.

## S 23515

This imidazole-like agent (FW = 271.11 g/mol) has a high affinity for non-adrenergic imidazole receptor binding sites and will induce hypotension (1). S23515 also specifically inhibits cholesterol synthesis in cultured rodent and primate hepatocytes in a dose-dependent manner, and this hypocholesterolemic effect was likely due to the inhibition of the oxido:lanosterol cyclase (OSC), a rate-limiting enzyme in the cholesterol biosynthetic pathway (2). Partial OSC inhibition induced by S23515 led to the generation of 24(*S*),25-epoxycholesterol, a potent ligand for the liver X receptor (LXR). Such results suggest that S-23515, and potentially other imidazole-like drugs, exert hypolipidemic effects in addition to their hypotensive activities. 1. Venteclef, Guillard & Issandou (2005) *Biochem.*

*Pharmacol.* **69**, 1041. **2.** Ventecief, Guillard & Issandou (2005) *Biochem. Pharmacol.* **69**, 1041.

### S 25585

This potent NPY receptor antagonist (FW = 528.50 g/mol; CAS 263849-50-9; Soluble to 100 mM in DMSO), also systematically named 1-benzoyl-2-[[*trans*-4-[[[2-nitro-4-(trifluoro-methyl)phenyl]sulfonyl]amino]methyl]-cyclohexyl]carbonyl]hydrazine, targets neuropeptide Y<sub>5</sub> receptor (IC<sub>50</sub> = 5.4 nM), with weaker action against Y<sub>1</sub> (IC<sub>50</sub> > 1000 nM), Y<sub>2</sub> (IC<sub>50</sub> > 10000 nM), and Y<sub>4</sub> (IC<sub>50</sub> > 10000 nM) receptors. S-25585 displays no affinity for over 40 other receptors, channels or uptake systems (1). S 25585 does not induce a conditioned taste aversion, does not significantly alter need-induced sodium appetite, and does not induce pica, suggesting that at this dose, it did not induce illness or malaise. Significantly, S25585 inhibits NPY-induced feeding. Although S 25585 appears to influence a physiological system controlling appetite, its action does not involve the Y<sub>5</sub> receptor, because it markedly reduces food intake in the NPY Y<sub>5</sub> knockout mouse (1). Such results show that the activity of any new NPY Y<sub>5</sub> antagonist must be assessed in a Y<sub>5</sub> knockout mouse, before assuming an effect is due to blockade of this receptor. **1.** Della-Zuana, Revereault, Beck-Sickinger, *et al* (2004) *Int. J. Obes.* **28**, 628.

### S 35047

This cytotoxic indenoindole derivative (FW<sub>free-base</sub> = 495.58 g/mol) inhibits human DNA topoisomerase II. The growth of human leukemia cells is strongly reduced in the presence of the S 35047, with an IC<sub>50</sub> value in the 50 nM range. Cytotoxicity is attributed to cell cycle arrest at the G2/M junction as well as apoptosis, the latter evidenced by extensive internucleosomal DNA cleavage. **1.** Bal, Baldeyrou, Moz, *et al.* (2004) *Biochem. Pharmacol.* **68**, 1911.

### S49076

This orally active anticancer agent (FW = 424.53 g/mol), named 3-[(3-[[4-(4-morpholinylmethyl)-1H-pyrrol-2-yl]methylene]-2-oxo-2,3-dihydro-1H-indol-5-yl)methyl]-1,3-thiazolidine-2,4-dione, inhibits MET, AXL and FGFRs, receptor tyrosine kinase that are associated with tumor progression in a wide variety of human malignancies. With MET, the on-rate constant was 1.27 × 10<sup>6</sup> M<sup>-1</sup>s<sup>-1</sup>, the off-rate constant was 1.62 s<sup>-1</sup>, and the calculated K<sub>d</sub> was 1.3 nM. With the other tyrosine kinase, the IC<sub>50</sub> was about 200 nM. Attesting to the selectivity of S49076 was the observation that VEGFR2 was not inhibited. S49076 also lowers viability, motility, and three-dimensional colony formation in tumor cell lines bearing MET, AXL and FGFR. **1.** Burbridge, Bossard, Saunier *et al.* (2013) *Molec. Cancer Therap.* [Published On-line]

**S-265744, See GSK1265744**

### SA 57

This dual FAAH/MAGL inhibitor (FW = 338.83 g/mol; CAS 1346169-63-8; Soluble to 25 mM in DMSO), systematically named 4-[2-(4-chlorophenyl)ethyl]-1-piperidinecarboxylic acid 2-(methylamino)-2-oxoethyl ester, targets human and mouse fatty acid amide hydrolase, *or* FAAH (IC<sub>50</sub> < 10 nM) as well as mouse and human monoacylglycerol lipase, *or* MAGL (IC<sub>50</sub> = 410 nM and 1.4 μM, respectively) (1). FAAH and MAGL catalyze the hydrolysis of anandamide (AEA) and 2-arachidonoylglycerol (2-AG), two major endocannabinoids. FAAH and MAGL inhibitors elevate brain AEA and 2-AG levels, respectively, thereby reducing pain, anxiety, and depression in rodents, but without the psychotropic behavioral effects observed with direct cannabinoid receptor-1 (CB<sub>1</sub>) agonists. Significantly, SA-57 reduces abrupt withdrawal in morphine-dependent mice and is likewise effective in an *in vitro* model of opioid withdrawal (2). **1.** Niphakis, Johnson, Ballard, Stiff & Cravatt (2012) *ACS Chem. Neurosci.* **3**, 418. **2.** Ramesh, Gamage, Vanuytsel, *et al.* (2013) *Neuropsychopharmacol.* **38**, 1039.

### SA751

This peptidomimetic (FW<sub>free-acid</sub> = 465.55 g/mol), also known as *N*-(1(*R*)-carboxyethyl)- $\alpha$ -(*S*)-(4-phenyl-3-butynyl)glycyl-L-*O*-methyltyrosine *N*-methylamide, is a selective inhibitor of neutrophil collagenases, *or* matrix metalloproteinase 8, K<sub>i</sub> = 2 nM, with K<sub>i</sub> of >10,000 nM against MMP-3 and MMP-1 (1). The latter are part of the 'aggrecanase' activity that degrades the aggregating cartilage proteoglycan, or aggrecan, which along with type II collagen gives rise to the mechanical properties of articular cartilage. Aggrecan core protein cleavage at the Glu<sup>373</sup>-Ala<sup>374</sup> bond apparently plays a critical role in cartilage matrix degradation. **1.** Arner, Decicco, Cherney & Tortorella (1997) *J. Biol. Chem.* **272**, 9294.

### SA 862

This antithrombotic benzamidine derivative, also known as 3-(3-carbamimidoyl-phenyl)-isoxazole-4-carboxylic acid (2'-sulfamoyl)biphenyl-

4-yl)amide, noncovalently inhibits coagulation factor Xa (*i.e.*, Stuart-Prower factor or prothrombinase (EC 3.4.21.6),  $K_i = 0.15$  nM, but is relatively non-inhibitory for the closely related proteases thrombin ( $K_i = 2800$  nM) and trypsin ( $K_i = 21$  nM). Further optimization in the pyrazole series resulted in the discovery of fXa inhibitors such as SN429 with picomolar factor Xa affinity. 1. Pinto, Orwat, Wang, *et al.* (2001) *J. Med. Chem.* **44**, 566.

**Saccharate**, See *D-Glucarate*

### Saccharin

This nonnutritive sweetener (FW = 183.19 g/mol; CAS: 81-07-2 and 128-44-9; Solubility (sodium salt) = 1 g/mL), also known as 1,2-benzisothiazol-3(2H)-one 1,1-dioxide and 2H-1λ<sup>6</sup>,2-benzothiazol-1,1,3-trione, is ~500 times sweeter than sucrose. The hydrogen atom on the nitrogen atom is quite acidic ( $pK_a \sim 2$ ), readily forming sodium and calcium salts. **ACME:** Because saccharin is nearly fully ionized at physiological pH in body fluids, it is more completely absorbed from the stomachs of animals having low pH (guinea pig, pH 1.4; rabbit, pH 1.9) than from those with higher pH (rat, pH 4.2). When present at the higher pH of the intestine, it is slowly absorbed. Saccharin is rapidly eliminated in the urine. Following administration of a single oral dose of saccharin in humans, peak plasma levels of saccharin are rapidly achieved; however, saccharin clearance from the plasma is prolonged. Saccharin binds reversibly to plasma proteins. The presence of food in the gut is associated with a reduced initial peak plasma concentration. **Carcinogenesis:** Modest promotion of bladder carcinogens by high dietary concentrations of sodium saccharin is only observed in rats. Malignant transformation of cultured human foreskin fibroblasts occurred in cells exposed to a non-toxic concentration of sodium saccharin (50 μg/mL) after release from the G<sub>1</sub> cell-cycle phase, followed by exposure to either *N*-ethyl- or *N*-methyl-nitrosourea. Despite suggestions that saccharin induces and/or promotes carcinogenesis in experimental animals, subsequent work suggests it would be inappropriate to consider the bladder tumors induced in male rats by sodium saccharin to be a relevant to hazard to humans. **Target(s):** adenylyl cyclase (1); carbonic anhydrase (2); glucose-6-phosphatase (competitively) (3,4); tubulin polymerization, or microtubule assembly (5); urease (6); guanylate cyclase (7). 1. Dib, Wisez, el Jamali, Lambert & Correz (1997) *Cell Signal* **9**, 431. 2. Wilson, Tanko, Wendland, *et al.* (1998) *Physiol. Chem. Phys. Med. NMR* **30**, 149. 3. Lygre (1976) *Can. J. ### *Saccharomyces cerevisiae* Killer Toxins

These toxic proteins, which are encoded by a double-stranded RNA virus residing within the cytoplasm of *S. cerevisiae*, first appear as translated preproteins that proteolytically processed and released to the medium, where they then may then bind to and kill susceptible yeast. In *S. cerevisiae*, the two most studied toxins are: K1 toxin (*or* M1-1 Toxin), which binds to the β-1,6-D-glucan receptor on the target cell wall, entering the host where it then binds to the plasma membrane receptor Kre1p to form a cation-selective ion channel that is lethal to the cell; and K28 toxin, which uses the α-1,6-mannoprotein receptor to gain entry to target cells. K28 then utilizes the secretory pathway in reverse by displaying the endoplasmic reticulum HDEL signal. From the ER, K28 moves into the cytoplasm and shuts down DNA synthesis in the nucleus, triggering apoptosis. K1, K2, and K28 killer toxins are genetically encoded by medium-sized, double-stranded RNA (dsRNA) viruses grouped into three types: M1 (1.6 kb), M2 (1.5 kb), and M28 (1.8 kb). Only the positive strand has coding capacity, and the 5'-end region contains an open reading frame that encodes the preprotoxin (*or* ptox), which also provides immunity. The three toxin-coding M dsRNAs show no sequence homology to each other. The phenomenon of killer yeast attacking susceptible brewing yeast cultures was first noted by Pasteur in 1877, the system has provided great insights into the nature of yeast viruses

as well as their remarkable pathogenic mechanisms. 1. Schmitt & Breinig (2006) *Nature Rev. Microbiol.* **4**, 212.

### (*R*)-Saclofen

This competitive GABA antagonist (FW = 249.72 g/mol; CAS 125464-42-8; Soluble to 10 mM in H<sub>2</sub>O), also named (*R*)-3-amino-2-(4-chlorophenyl)propylsulfonic acid, targets GABA<sub>B</sub>, seven-helix receptor that couples to the G<sub>i/o</sub> class of heterotrimeric G-proteins. Saclofen is an analogue of the GABA<sub>B</sub> agonist baclofen. The *S*-enantiomer is inactive. The *S*-enantiomer is inactive. Saclofen's antiepileptic action is likely to be the consequence of its GABA<sub>B</sub> effect, which is coupled to excitation in the thalamo-cortical circuits, lowering the threshold for T-type Ca<sup>2+</sup> channel opening. 1. Kerr, Ong, Vaccher (1996) *European Journal of Pharmacology* **308**, R1.

### Sacubitril

This oral antihypertensive pro-drug (FW = 411.49 g/mol; CAS 149709-62-6; Solubility: 100 mM in DMSO; compounded as the hemi-calcium salt), also known as AHU.377 and 4-[[[(2*S*,4*R*)-1-(4-biphenyl)-5-ethoxy-4-methyl-5-oxo-2-pentanyl]amino]-4-oxobutanoate, undergoes metabolic desterification to form the active neprilysin inhibitor, IC<sub>50</sub> = 5 nM (1). Neprilysin is a neutral endopeptidase and its inhibition increases bioavailability of natriuretic peptides, bradykinin, and substance P, resulting in natriuretic, vasodilatory, and anti-proliferative effects. Entresto® (Code name: LCZ696) is a drug combining the actions of valsartan and sacubitril, as a first-in-class angiotensin II-receptor and neprilysin inhibitor for the treatment of heart failure and as a drug that may exert a preferential effect on systolic pressure (2). (See *Valsartan*). 1. Ksander, Ghai, de Jesus, *et al.* (1995) *J. Med. Chem.* **38**, 1689. 2. Bavishi, Messerli, Kadosh, Ruilope & Kario (2015) *Eur. Heart J.* **36**, 1967.

### Sal 003

This ER-stress/UPR modulator (FW = 463.21 g/mol; CAS 1164470-53-4; Soluble to 100 mM in DMSO), also named 3-phenyl-N-(2,2,2-trichloro-1-(((4-chlorophenyl)amino)carbonothioyl)amino)ethyl)acrylamide, targets enzymes (EC<sub>50</sub> ~ 20 μM) catalyzing the dephosphorylation of eukaryotic translation Initiation Factor 2 subunit α (eIF2α), thereby protecting cells from Endoplasmic Reticulum stress-induced (also called Unfolded Protein Response-induced) apoptosis (1). Sal-003 is a salubrinal analogue possessing improved aqueous solubility (See *Salubrinal*). Sal-003 prevents long-term potentiation (LTP) and long-term memory formation (LTM) in mice. 1. Baltzis, Pluquet, Papadakis, *et al.* (2007) *J. Biol. Chem.* **282**, 31675. 2. Costa-Mattioli, Gobert, Stern, *et al.* (2007) *Cell* **129**, 195.

### Salacinal

This sulfonium ion-containing monosaccharide analogue (FW = 320.34 g/mol; CAS 200399-47-9) from the stems and roots of kothalahimbutu (*Salacia reticulata*) inhibits α-glucosidase activities. Water left overnight in a cup made of kothalahimbutu wood is used as a traditional medicine in Sri Lanka and India for treating diabetes. **Target(s):** α-amylase (1); glucoamylase (2); α-glucosidase (3-5); isomaltase (3); maltase (3); α-mannosidase (5); mannosyl-oligosaccharide 1,3-1,6-α-mannosidase, *or* mannosidase II (6); and sucrose (3). 1. Ghavami, Johnston, Jensen, Svensson & Pinto (2001) *J. Amer. Chem. Soc.* **123**, 6268. 2. Johnson, Jensen, Svensson & Pinto (2003) *J. Amer. Chem. Soc.* **125**, 5663. 3. ### Salermide

This SIRT inhibitor (FW = 394.47 g/mol; CAS 1105698-15-4; Soluble to 100 mM in DMSO), also named N-[3-[[[2-hydroxy-1-naphthalenyl]-methylene]amino]phenyl]-α-methylbenzeneacetamide, targets class III histone/protein deacetylases (sirtuins) SIRT1 and SIRT2, with a stronger inhibitory effect on SIRT2 than on SIRT1 *in vitro*. Salermide induces the reactivation of proapoptotic genes repressed by SIRT1, resulting in massive apoptosis in cancer cells within 24 hours (1,2). Salermide likewise prompts tumor-specific cell death in a wide range of human cancer cell lines that is independent of global tubulin and K16H4 acetylation, ruling out a putative Sirt2-mediated apoptotic pathway and suggesting an *in vivo* mechanism involving Sirt1. Indeed, RNA interference-mediated knockdown of Sirt1, but not Sirt2, induces apoptosis in cancer cells. 1. Mai, Massa, Lavu, *et al.* (2005) *J. Med. Chem.* **48**, 7789. 2. Lara, Mai, Calvanese, *et al.* (2009) *Oncogene* **28**, 781.

### Salicin

This naturally occurring, non-reducing glucoside (FW = 286.28 g/mol; CAS 138-52-3; M.P. = 199-202°C; water soluble 40 mg/mL at 25°C), also known as saligenin β-D-glucopyranoside, from the bark of poplar and willow, is frequently used as an alternative substrate for β-glucosidases and often acts as a competitive inhibitor of glucosidases. **Target(s):** cellobiase, *Neocallimastix frontalis* (1); cyclomaltodextrin glucanotransferase (2); β-glucosidase, *Thermomyces lanuginosus* (3); phosphoenolpyruvate-dependent phosphotransferase system, *Staphylococcus carnosus* (4); sucrose synthase (5); thioglucosidase, *or* myrosinase; *or* sinigrinase (6-9); and α,α-trehalase (10). 1. ### Salicylaldoxime

This metal ion chelator (FW = 137.14 g/mol; CAS 94-67-7), also known as 2-hydroxybenzaldehyde oxime and 2-hydroxybenzaldoxime, forms high-affinity complexes with Ni<sup>2+</sup>, Cu<sup>2+</sup>, and Co<sup>2+</sup> (*K*<sub>formation</sub> = 6300 M<sup>-1</sup>, 16000 M<sup>-1</sup>, and 1.3 × 10<sup>8</sup> M<sup>-1</sup>, respectively). The solid (melting point = 57°C) is slightly soluble in cold water, more soluble in hot water, and has p*K*<sub>a</sub> values of 8.9 and 11.1. Salicylaldoxime decomposes on heating to form salicylaldehyde and hydroxylamine. **Target(s):** alcohol dehydrogenase (1); anthranilate 3-monooxygenase (deaminating), *or* anthranilate 2,3-dioxygenase (deaminating) (2-4); arylformamidase (5); ascorbate oxidase (6,7); catechol oxidase (8-10); complement component C<sub>3</sub>, guinea pig (11); cytochrome *c* oxidase, complex IV (12); 2,3-dihydroxybenzoate 2,3-dioxygenase (13); DNA topoisomerase II, inhibited by Co(II)salicylaldoxime complex (14); electron transport, chloroplast (15-20); Hill reaction (15); hydroxylamine reductase (21); K<sup>+</sup> and Ca<sup>2+</sup> currents (22); nitroaryl nitroreductase (23); photosynthesis (15,24); tyrosinase, *or* monophenol monooxygenase (10,25,26); and xanthine oxidase (27). 1. ### Salicylate (Salicylic Acid)

This sweet-tasting phytohormone and aspirin breakdown product (FW<sub>free-acid</sub> = 138.12 g/mol; CAS 69-72-7; White Solid; M.P. = 159 °C; pK<sub>a</sub> = 2.9 and 13.1; sodium salt Solubility: 1.25 g/mL H<sub>2</sub>O) is often found as an ester in many plants, especially sweet birch bark and wintergreen leaves. In plants, salicylate plays diverse roles, affecting growth and development, photosynthesis, transpiration, ion transport, and morphogenetically by regulating leaf anatomy and chloroplast structure. Although derived chiefly from phenylalanine, some plants (e.g. *Arabidopsis thaliana*) synthesize salicylate by a second pathway. Salicylate also activates adenosine monophosphate-activated protein kinase (AMPK), a signal-transducing enzyme that controls the activity of many energy-consuming biosynthetic reactions. The net effect of AMPK activation is enhancement of hepatic fatty acid oxidation, ketogenesis, skeletal muscle fatty acid oxidation as well as inhibition of cholesterol synthesis, lipogenesis, and triglyceride formation, adipocyte lipolysis and lipogenesis, as well as modulation of insulin secretion by pancreatic β-cells. **Metal Ion Interactions:** Salicylate is also a metal ion chelator, forming reasonably high-affinity chelate complexes with Mn<sup>2+</sup> (K<sub>assoc</sub> = 7.9 × 10<sup>5</sup> M<sup>-1</sup>), Be<sup>2+</sup> (K<sub>assoc</sub> = 20000 M<sup>-1</sup>), iron (K<sub>assoc</sub> = 4.0 × 10<sup>6</sup> M<sup>-1</sup>), Co<sup>2+</sup> (K<sub>assoc</sub> = 5.0 × 10<sup>6</sup> M<sup>-1</sup>), Ni<sup>2+</sup> (K<sub>assoc</sub> = 1.0 × 10<sup>7</sup> M<sup>-1</sup>), and Cu<sup>2+</sup> (K<sub>assoc</sub> = 4.0 × 10<sup>10</sup> M<sup>-1</sup>). As a consequence, one must always entertain the possibility that its inhibitory action results from its metal ion-sequestering ability and depletion of catalytically essential active-site metal ion. (For *Pharmacokinetics & Metabolism*, See *Acetylsalicylate*) **Target(s):** alanine aminotransferase (1); alcohol dehydrogenase (2,3); aldose reductase (4); D-amino-acid oxidase (5,6); L-amino-acid oxidase (7-9); arginase (10,11); arylamine N-acetyltransferase (12); ascorbate peroxidase (13); aspartate aminotransferase (1,14); ATPase, mitochondrial (15); benzoyl-CoA synthetase, or benzoate:CoA ligase, also weak alternative substrate (69); γ-butyrobetaine hydroxylase, or γ-butyrobetaine:2-oxoglutarate dioxygenase; K<sub>i</sub> = 1.3 mM (16); cathepsin L, weakly inhibited (80);

cholesterol sulfotransferase (17); creatine kinase (18,19); L-3-cyanoalanine synthase (72); 4,5-dihydroxyphthalate decarboxylase (75); esterase (20); estrone sulfotransferase (89,90); gentisate 1,2-dioxygenase (21); glucose transport (22); glutamate decarboxylase (23); glutamate dehydrogenase (24,25); L-glutamine:D-fructose-6-phosphate aminotransferase (26,27); glutamyl-tRNA synthetase (28); glycerol dehydratase (29); 3-hydroxyanthranilate 3,4-dioxygenase (30); N-hydroxyarylamine O-acetyltransferase (31); 4-hydroxybenzoate 4-O-β-glucosyltransferase (93); 4-hydroxybenzoate 3-monoxygenase (NAD(P)H) (32); γ-hydroxybutyrate dehydrogenase (33); IκB kinase, weakly inhibited (91); imidazoleacetate phosphoribosyltransferase (34); lactate dehydrogenase (5,24,25,35,36); lipase, or triacylglycerol lipase (37); long-chain 3-hydroxyacyl-CoA dehydrogenase (38); mandelate racemase (70,71); medium-chain fatty-acyl-CoA synthetase, or butyryl-CoA synthetase (39-43); 6-methylsalicylate decarboxylase (44); monoamine oxidase (45); myeloperoxidase (46); NAD<sup>+</sup> nucleosidase, or NADase (82,83); NAD(P)H dehydrogenase (quinone), or DT diaphorase (47); NADPH oxidase, neutrophil (48); nicotinate N-methyltransferase (95); nicotinate phospho-ribosyltransferase (92); orsellinate decarboxylase (49); pectate lyase (73,74); peptidyl-dipeptidase A, or angiotensin I-converting enzyme (81); peroxidase (50); phenol sulfotransferase, or aryl sulfotransferase (12,51,52,90); phenylalanine ammonia-lyase (53); phosphatase, acid (85); 3-phosphoglycerate kinase (54,55); phospholipase A<sub>2</sub> (87); phyloquinone epoxide reductase (56); polyphenol oxidase (96); propionyl-CoA synthetase (57); prostaglandin H<sub>2</sub> synthase (58); protein-tyrosine-phosphatase 1B, weakly inhibited (84); o-pyrocatechuate decarboxylase (59,76-78); RNA polymerase (60); short-chain 3-hydroxyacyl-CoA dehydrogenase (38); steryl sulfatase (61); sulfate transport (62); tannase (86); thyroxine 5'-deiodinase (63,64,79); tyrosinase, or monophenol monoxygenase (5,96); tyrosine-ester sulfotransferase (88); urease (65); vitamin K epoxide reductase (66); and xanthine oxidase (67,68). Salicylic acid also inhibits enzymatic browning of fresh-cut Chinese chestnut (*Castanea mollissima*) by competitively inhibiting polyphenol oxidase (97). 1. Hanninen & Hartiala (1965) *Biochem. **Salicylazosulfapyridine, See Sulfasalazine**

### Salicylhydroxamic Acid

This hydroxamic acid (FW = 153.14 g/mol; CAS 89-73-6;  $pK_a$  value of 4.19 at 25°C), also known as SHAM and 2-hydroxybenzhydroxamic acid, inhibits a number of oxidoreductases. **Target(s):** alternative oxidase in plant and algal mitochondria (cyanide-insensitive respiration) (1-4); cytochrome  $bc_1$  complex (5); cytochrome  $c$  oxidase (6);  $\Delta^6$ -desaturase (7); electron transport (8); glycerol-3-phosphate dehydrogenase (9); lathosterol oxidase, or  $\delta^7$ -sterol  $C^{5(6)}$ -desaturase (10,11); lipoxygenase (12-16); mucopolysaccharide sulfotransferase (17); myeloperoxidase (18-22); NAD(P)H dehydrogenase (23); NAD(P)H:quinone oxidoreductase (24); peroxidase (18-22,25,26); phenol sulfotransferase (17); polyphenol oxidase (27); ribonucleoside-diphosphate reductase (28,29); tyrosinase, or monophenol monooxygenase (26,30,31); and xanthine dehydrogenase (32,33). **1.** Shepherd, Chin & Sullivan (1978) *Arch. **Salicylyl Phosphate, See 2-Carboxyphenyl Phosphate**

**Saligenin  $\beta$ -D-Glucopyranoside, See Salicin**

### Salinomycin

This polyether ionophore antibiotic and oxidative phosphorylation inhibitor (FW<sub>free-acid</sub> = 791.84 g/mol; CAS 53003-10-4), from *Streptomyces albus*, binds monovalent cations such as potassium ion. Salinomycin is an effective agent against coccidiosis and is used as a feed additive in animal husbandry. The unusual tricyclic spiroketal moiety represents a daunting challenge for chemical synthesis of salinomycin. **Note:** The fact that salinomycin is some 100 times more effective than taxol in killing human breast cancer cells suggests that this ionophore may have toxic side effects in mammals. **Target(s):** oxidative phosphorylation (1-3). **1.** Reed (1979) *Meth. Enzymol.* **55**, 435. **2.** Mitani, Yamanishi, Miyazaki & Otake (1976) *Antimicrob. Agents Chemother.* **9**, 655. **3.** Mitani, Yamanishi & Miyazaki (1975) *Biochem. Biophys. Res. Commun.* **66**, 1231.

### Salinosporamide A

This cytotoxic marine natural product (FW = 313.78 g/mol), also named Marizomib, NPI-0052, and (4*R*,5*S*)-4-(2-chloroethyl)-1-((1*S*)-cyclohex-2-enyl(hydroxy)methyl)-5-methyl-6-oxa-2-azabicyclo[3.2.0]heptane-3,7-dione, from *Salinospora* strains present in ocean sediments, shows high affinity (IC<sub>50</sub> = 1.3 nM) for 20S proteasomes, covalently modifying an

active-site threonine residue (1). The first stereoselective synthesis was reported in 2004 (2). 1. Feling, Buchanan, Mincer, *et al.* (2003) *Angewan. Chem., Inter. Ed.* **42**, 355. 2. Leleti & Corey (2004) *J. Am. Chem. Soc.* **126**, 6230.

### Salirasib

This Ras protein inhibitor (FW = 358.54 g/mol; CAS 162520-00-5; Soluble to 100 mM in DMSO and to 50 mM in 1eq. NaOH), also named 2-[[*(2E,6E)*-3,7,11-trimethyl-2,6,10-dodecatrien-1-yl]thio]benzoic acid, displaces active Ras ( $EC_{50}$  = 10-15  $\mu$ M) from the plasma membrane, thereby impairing downstream signaling and inhibiting endometrial carcinoma cell proliferation. Salirasib also facilitates Ras degradation and likewise induces autophagy in several human cancer cell lines. 1. Haklai, Weisz, Elad, *et al.* (1998) *Biochemistry* **37**, 1306. 2. Faigenbaum, Haklai, Ben-Baruch & Kloog (2013) *Oncotarget* **4**, 316. 3. Schmukler, Grinboim, Schokoroy, *et al.* (2013) *Oncotarget* **4**, 142.

### Salmeterol

This bronchodilator (FW = 415.57 g/mol; CAS 89365-50-4), also named (*RS*)-2-(hydroxymethyl)-4-{1-hydroxy-2-[6-(4-phenylbutoxy)hexylamino]ethyl}phenol, is a structural analogue of albuterol and is a  $\beta_2$ -adrenergic agonist. Its lipophilic aryl alkyl group makes it  $\beta_2$ -selective. Like other long-acting  $\beta_2$ -adrenoceptor agonists, which include formoterol and bambuterol, salmeterol is used in the management of asthma and chronic obstructive pulmonary disease (COPD). **Target(s):** aldehyde oxidase (1); and CYP2C8 (2). 1. Obach, Huynh, Allen & Beedham (2004) *J. Clin. Pharmacol.* **44**, 7. 2. Walsky, Gaman & Obach (2005) *J. Clin. Pharmacol.* **45**, 68.

### Salsolinol

This dopamine-derived alkaloid (FW<sub>free-base</sub> = 179.22 g/mol; CAS 57256-34-5; Solubility: 25 mM in H<sub>2</sub>O), also known as 6,7-dihydroxy-1-methyl-1,2,3,4-tetrahydroisoquinoline, induces DNA damage and chromosomal aberrations and also inhibits calcium binding. Both the (+)-(*R*)-salsolinol (shown above) and (-)-(*S*)-salsolinol of this tetrahydroisoquinoline are alternative substrates for soluble and membrane-bound catechol *O*-methyltransferases, thereby accounting for their action as competitive inhibitors of dopamine methylation. **Target(s):** catechol *O*-methyltransferase (1-3); complex II, mitochondrial, or succinate:ubiquinone reductase (4); dihydropteridine reductase (5); monoamine oxidase (2,6-8); tryptophan 5-monoxygenase, inhibited by both enantiomers (9); and tyrosine 3-monoxygenase, inhibited by both enantiomers (8,10). 1. Hotzl & Thomas (1997) *Chirality* **9**, 367. 2. Giovine, Renis & Bertolino (1976) *Pharmacology* **14**, 86. 3. Tunnicliff & Ngo (1983) *Int. J. Biochem.* **15**, 733. 4. Patsenka & Antkiewicz-Michaluk (2004) *Pol. J. Pharmacol.* **56**, 727. 9. Ota, Dostert, Hamanaka, Nagatsu & Naoi (1992) *Neuropharmacology* **31**, 337. 10. Minami, Takahashi, Maruyama, *et al.* (1992) *J. Neurochem.* **58**, 2097.

### Salubrinal

This cell-permeable, ER-stress/UPR modulator (FW = 479.81 g/mol; CAS 405060-95-9; Soluble to 100 mM in DMSO), also known as 3-phenyl-N-[2,2,2-trichloro-1-[[*(8*-quinolinylamino)thioxomethyl]amino]ethyl]-2-propenamide, targets enzymes ( $EC_{50}$  ~ 15  $\mu$ M) catalyzing the dephosphorylation of eukaryotic translation Initiation Factor 2 subunit  $\alpha$  (eIF2 $\alpha$ ), thereby protecting cells from Endoplasmic Reticulum stress-induced (also called Unfolded Protein Response-induced) apoptosis (1). Salubrinal blocks eIF2 $\alpha$  dephosphorylation mediated by a Herpes Simplex virus protein, thereby inhibiting viral replication (1). Salubrinal also interacts with the anti-apoptotic protein Bcl-2, thereby inhibiting binding of the non-peptidic antagonist HA14-1 and of a porphycene that catalyzes Bcl-2 photodamage. As a result, salubrinal offers protection from the apoptotic and autophagic effects that can result from loss of Bcl-2 function (2). It also delays the formation of insoluble aggregates of the mutant superoxide dismutase-1 (SOD1) and suppresses the mutant-induced cell death (3). The hypothesis that sleep is facilitated by signals associated with the ER stress response is supported, in part, by the finding that intracerebroventricular (ICV) infusion of salubrinal increases phospho-eIF2 $\alpha$  by inhibiting its dephosphorylation and likewise increases deep slow-wave sleep by 255%, reduces active waking by 49%, increases non-rapid eye movement (NREM) sleep, and reduces power in the  $\sigma$ ,  $\beta$ , and  $\gamma$  bands during NREM sleep (4). Cyclosporine-triggered ER stress induces endothelial cells to undergo endothelial phenotypic changes suggestive of a partial endothelial-to-mesenchymal transition, and salubrinal stabilizes the endothelial phenotype (5). Taken together, salubrinal should be cytoprotective against cytostatic/cytotoxic effects of drugs inducing ER stress. 1. Boyce, Bryant, Jousse, *et al.* (2005) *Science* **307**, 935. 2. Kessel (2006) *Biochem. Biophys. Res. Commun.* **346**, 1320. 3. Oh, Shin, Yuan & Kang (2008) *J. Neurochem.* **104**, 993. 4. Methippara, Bashir, Kumar, *et al.* (2009) *Am. J. Physiol. Regul. Integr. Comp. Physiol.* **296**, R178. 5. Bouvier, Flinois, Gilleron, *et al.* (2009) *Am. J. Physiol. Renal Physiol.* **296**, F160.

### (+)-Salutaridine

This alkaloid (FW<sub>free-base</sub> = 327.38 g/mol; CAS 1936-18-1), itself an intermediate in the biosynthesis of morphine, inhibits salutaridinol 7-*O*-acetyltransferase. The (-)-isomer is also called sinoaculine. Salutaridinol-7-*O*-acetyltransferase catalyzes the stoichiometric transfer of the acetyl group from acetyl-CoA to the 7-OH group of salutaridinol yielding salutaridinol-7-*O*-acetate, which is a new intermediate in morphine biosynthesis. Salutaridinol-7-*O*-acetate undergoes a subsequent spontaneous allylic elimination at pH 8-9, leading to the formation of thebaine, the first morphinan alkaloid with the complete pentacyclic ring system, or at pH 7 leading to dibenz[*d,f*]azone alkaloids that contain a nine-membered ring. Acetylation and subsequent allylic elimination is a new enzymic mechanism in alkaloid biosynthesis, which in the poppy plant can transform one precursor into alkaloids possessing markedly different ring systems, depending on the reaction pH. 1. Lenz & Zenk (1995) *J. Biol. Chem.* **270**, 31091.

**Salubrinal**

This phosphoprotein phosphatase inhibitor (FW = 479.81 g/mol; CAS 405060-95-9; Solubility: 96 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 3-phenyl-*N*-[2,2,2-trichloro-1-[(8-quinolinylamino)thioxomethyl]amino]-ethyl]-(*2E*)-propenamide, protects cells (EC<sub>50</sub> = ~15 μM) from ER stress-mediated apoptosis (1). Salubrinal likewise inhibits viral replication by blocking herpes simplex virus protein-mediated eIF2α dephosphorylation (1). **Mode of Inhibitory Action:** ER-assisted folding (ERAF) within the lumen of the endoplasmic reticulum (ER) is tightly coupled to protein-synthesis pathways operating on the outer surface of the ER, a process that is regulated in part by the translation initiation factor eIF2α. Imbalance of these events is associated with numerous misfolding diseases that directly or indirectly trigger the Unfolded Protein Response (UPR). By selectively blocking dephosphorylation of the ribosomal initiation protein eIF2α, salubrinal reprograms the kinetics of protein synthesis and chaperone-assisted folding, thereby providing a novel approach for rebalancing ER-protein load with cellular-folding capacity, in some cases correcting a underlying mechanism of pathogenesis (2). Arrest of protein synthesis is thus a first-line defense against the accumulation of unfolded or misfolded proteins in the ER. **Other Actions of Salubrinal:** Selective inhibition of eIF2α dephosphorylation also potentiates fatty acid-induced ER stress, causing pancreatic β-cell dysfunction and apoptosis (3). By interacting with the anti-apoptotic protein Bcl-2, salubrinal inhibits the actions of HA14-1, a non-peptidic Bcl-2 antagonist (**See HA14-1**) and porphycene, which catalyzes Bcl-2 photodamage (**See Porphycene**), thereby protecting cells from the apoptotic and autophagic effects resulting from loss of Bcl-2 function (4). Salubrinal also increases deep slow-wave sleep by 255%, reduces active waking by 49%, and increases the amount of p-eIF2α in both cholinergic and noncholinergic neurons (5). The latter is more widespread among the noncholinergic neurons. Salubrinal also induces c-Fos activation of GABAergic neurons within the sleep-promoting rostral median preoptic nucleus, while simultaneously reducing c-Fos activation of wake-promoting lateral hypothalamic orexin-expressing neurons and magnocellular BF cholinergic neurons (6). Such findings suggest ER stress plays a role in NREM sleep homeostasis in response to sleep deprivation and provides a mechanistic explanation for the sleep modulation by molecules signaling the need for brain protein synthesis (6). Accumulation α-synuclein within ER leads to chronic ER stress conditions that contribute to neurodegeneration in α-synucleinopathies, and salubrinal significantly attenuates disease manifestations in both the A53TαS Tg mouse model and the adeno-associated virus-transduced rat model of A53TαS-dependent dopaminergic neurodegeneration (7). 1. Boyce, Bryant, Jousse, *et al.* (2005) *Science* **307**, 935. 2. Wiseman & Balch (2005) *Trends Mol. Med.* **11**, 347. 3. Cnop, Ladrerie, Hekerman, *et al.* (2007) *J. Biol. **Salvicine**

This cytotoxic agent (FW = 330.42 g/mol; CAS 133276-80-9), which can induce apoptosis, is a structurally modified *o*-quinone derived from *Salvia prionitis*. It promotes the formation of the [DNA topoisomerase II]-DNA complex and inhibits pre- and post-strand DNA religation, IC<sub>50</sub> = 3 μM (1-3). 1. Meng, Zhang & Ding (2001) *Biochem. Pharmacol.* **62**, 733. 2. Meng, He, Zhang & Ding (2001) *Acta Pharmacol. Sin.* **22**, 741. 3. Hu, Zuo, Xiong, *et al.* (2006) *Mol. Pharmacol.* **70**, 1593.

**Salyrgan, See Mersalyl****SAM, See S-Adenosyl-L-methionine****Samarium-ATP, See Sm<sup>3+</sup>-ATP****Sampatrilat**

This substituted tyrosine (FW = 584.68 g/mol; CAS 129981-36-8), also known as UK 81252, is a potent inhibitor of both angiotensin-converting enzyme (*or* peptidyl-dipeptidase A) and neprilysin (1,2). 1. Wallis, Ramsay & Hettiarachchi (1998) *Clin. Pharmacol. Ther.* **64**, 439. 2. Kirk & Wilkins (1996) *Brit. J. Pharmacol.* **119**, 943.

**Sangivamycin**

This nucleoside antibiotic (FW = 309.28 g/mol; CAS 18417-89-5), also known as 4-amino-5-carboxamide-7-(D-ribofuranosyl)pyrrrolo[2,3-*d*]pyrimidine and 7-deaza-7-carbamoyl-adenosine, is similar in structure to toyocamycin, but the latter is not a strong protein kinase C inhibitor. **Target(s):** adenosine kinase (1); [β-adrenergic-receptor] kinase (2); histone H1 kinase, *or* nuclear protein kinase (3); protein biosynthesis (4); protein kinase C, K<sub>i</sub> = 11 μM (5-8); and rhodopsin kinase, K<sub>i</sub> = 180 nM (7,9-11). Sangivamycin's amidine derivative (FW<sub>free-base</sub> = 308.30 g/mol) inhibits rhodopsin kinase: K<sub>i</sub> = 2.2 μM (10-11). Its corresponding amidoxime derivative (FW = 324.30 g/mol) has a K<sub>i</sub> = 1.0 μM (10-11). 1. Long & Parker (2006) *Biochem. Pharmacol.* **71**, 1671. 2. Benovic (1991) *Meth. Palczewski, Kahn & Hargrave (1990) *Biochemistry* **29**, 6276.

**Sanguinarine**

This alkaloid (FW<sub>HCl-Salt</sub> = 367.78 g/mol; CAS 2447-54-3), also known as pseudochelerythrine (*or*, ψ-chelerythrine) and 13-methyl[1,3]benzodioxolo [5,6-*c*]-1,3-dioxolo[4,5-*i*]phenanthridinium, is widely distributed in plants, particularly in poppy-fumaria species. The chloride dihydrate exhibits antiplaque activity and is frequently incorporated into mouthrinses and toothpaste. Sanguinarine intercalates DNA, thereby inhibiting DNA biosynthesis and reverse transcriptase. **Target(s):** acetylcholinesterase (1,2); alanine aminotransferase (3); amine oxidase (copper-containing), *or* diamine oxidase (4,5); aminopeptidase N, *or* membrane alanyl

aminopeptidase (6);  $\alpha$ -amylase (7); aromatic-amino-acid decarboxylase (8); butyryl-cholinesterase (2);  $\text{Ca}^{2+}$ -dependent ATPase (9); cation-transporting ATPases (10); choline acetyltransferase (2); deoxyribonuclease I (11); dipeptidyl-peptidase IV (6,12); DNA ligase (ATP), human,  $\text{IC}_{50} = 127 \mu\text{M}$  (13); elastase (14); glutamate decarboxylase (15); lipase, *Candida rugosa* (16); 5-lipoxygenase (17); 12-lipoxygenase (17); monoamine oxidase (18); myosin-light-chain kinase (19);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (20-24); NF- $\kappa\text{B}$  activation (25); protein kinase A (19); protein kinase C (19,26); and reverse transcriptase, or RNA-directed DNA polymerase (2). 1. #### SANT-1

This Smo antagonist (FW = 373.49 g/mol; CAS 304909-07-7), also named *N*-[(3,5-dimethyl-1-phenyl-1*H*-pyrazol-4-yl)methylene]-4-(phenylmethyl)-1-piperazinamine, potently and selectively inhibits cyclopamine- and jervine-mediated ciliary translocation of Smoothed (IC<sub>50</sub> = 20 nM; K<sub>i</sub> = 1.2 nM), a distant relative of G protein-coupled receptors, which mediates Hedgehog (Hh) signaling during embryonic development and initiates/transmits ligand-independent pathway activation in tumorigenesis (1,2). With neoplastic pancreatic cells, SANT-1 enhances the induction of apoptosis, cell-cycle arrest at the G<sub>0</sub>/G<sub>1</sub> junction, and ductal epithelial differentiation (3). (**Other Hedgehog inhibitors include:** GANT61; BMS-833923; Purnormamine; PF-5274857; LY2940680; Cyclopamine, LDE225, or NVP-LDE225, or Erismodegib; Vismodegib, or GDC-0449) 1. Chen, Taipale, Young, Maiti & Beachy (2002) *Proc. Natl. Acad. Sci. USA* **99**, 14071. 2. Wilson, Chen & Chuang (2009) *PLoS One* **4**, e5182. 3. Chun, Zhou & Yee (2009) *Cancer Biol. Ther.* **8**, 1328.

#### SANT-2

This allosteric Smo antagonist and Sonic hedgehog signal disruptor (FW = 479.96 g/mol; CAS 329196-48-7; Soluble to 100 mM in DMSO), also known as *N*-[3-(1*H*-benzimidazol-2-yl)-4-chlorophenyl]-3,4,5-triethoxybenzamide, potently and selectively inhibits Smoothed receptor (K<sub>i</sub> = 12 nM), a distant relative of G protein-coupled receptors. SANT-2 displaces smo-[<sup>3</sup>H]SAG-1.3 and smo-[<sup>3</sup>H]cyclopamine binding, with respective K<sub>i</sub> values of 7.8 nM and 8.4 nM (1,2). The finding that SANT-1 and SANT-2 only partially inhibit SAG-1.3 binding to Smo was rationalized with an allosteric model accounting for their action (2). Subtle differences in binding of allosteric ligands such as SANT-1 and SANT-2 may result in unique phenotypes because they may change the way smoothed receptors interact with accessory proteins (2). 1. Chen, et al. (2002) *Proc. Natl. Acad. Sci.* **99**, 14071. 2. Rominger, Bee, Copeland, et al. (2009) *J. Pharmacol. Exp. Ther.* **329**, 995.

#### Sapanisertib

This ATP-competitive mTOR inhibitor (FW = 308.14 g/mol; CAS 1224844-38-5; Soluble in DMSO), also known as TAK-228, MLN0128, INK 128, and 1-isopropyl-3-(2-methylbenzo[d]oxazol-5-yl)-1*H*-pyrazolo[3,4-*d*]pyrimidin-4-amine, potently and selectively targets mammalian Target of Rapamycin (IC<sub>50</sub> = 1 nM), with some 200-times weaker action against Class I PI3K isoforms. As TORC1/2 inhibitor, sapanisertib inhibits the phosphorylation of both the translational regulator S6 Kinase 1 (S6K1) and 4EBP1, the latter a translational suppressor eIF4E binding protein that functions as a key regulator in cellular growth, differentiation, apoptosis and survival. Both S6 and 4EBP1 are downstream substrates of TORC1, and selectively inhibits AKT phosphorylation at Ser473, the downstream substrate of TORC2. Sapanisertib also shows potent inhibition in cell lines resistant to rapamycin and pan-PI3K inhibitors. In a ZR-75-1 breast cancer xenograft model, it shows tumor growth inhibition efficacy at a dose of 0.3 mg/kg/day. Daily oral administration also inhibits angiogenesis and tumor growth in multiplexxenograft models (2). Functional evaluation of rapamycin and sapanisertib on HRG-dependent signaling activities, uncovered a necessary role for mTORC2 in the regulation of the AKT/TSC2/mTORC1 axis by affecting the phosphorylation of AKT at the PDK1(PDPK1)-dependent site (Thr-308) as well as at the mTORC2-dependent site (Ser-473) (3). These findings suggest the potential benefits of targeting mTORC2 in HRG/ErbB2-induced breast cancer (3). mTOR inhibitors (*i.e.*, both rapalogs and kinase inhibitors) has been investigated as a co-therapy (with either trastuzumab or lapatinib) for cancers that are refractory to ErbB2-directed monotherapies, inasmuch as aberrant PI3K/AKT/mTOR activity is a hallmark of resistance to ErbB2 therapy resistance. 1. Garcia-Garcia, Ibrahim, Serra, et al. (2012) *Clin. Cancer Res.* **18**, 2603. 2. Liu, Thoreen, Wang, et al. (2009) *Drug Disc. Today: Therapeut. Strat.* **6**(2), 47-55. 3. Lin, Rojas, Cerione & Wilson (2014) *Mol. Cancer Res.* **12**, 940.

#### Saposins

This group of lipid-transfer and sphingolipid activator glycoproteins (which include Saposin A, 84 residues; Saposin B, 84 residues; Saposin C, 80 residues; and Saposin D, 83 residues) are required for the lysosomal degradation of sphingolipids and for the loading of lipid antigens onto antigen-presenting molecules of the CD1 type. Sap-A assists in the degradation of galactosylceramide by galactosylceramide-beta-galactosidase *in vivo*, which takes place at the surface of intra-endosomal/intra-lysosomal vesicles. Sap-A is believed to mediate the interaction between the enzyme and its membrane-bound substrate. The stimulatory effect of saposins A, C, and D on acid sphingomyelinase activity is greatly influenced by the physical environment of the enzyme. Saposin D is an inhibitor of alkaline ceramidase, or *N*-acylsphingosine

deacetylase and an activator of acid ceramidase (1). In the absence of a detergent, saposin D inhibited the purified acid sphingomyelinase (2). Pro-saposin is synthesized as a 53-kDa precursor protein that is then glycosylated to yield a 70 kDa secretory product. This latter undergoes partial proteolysis to produce saposin A, B, C, and D (MW = 12-14 kDa). Each member acts in conjunction with hydrolase enzymes to facilitate the breakdown of glycosphingolipids within the lysosome. The saposins modify the environment of target lipids to make them accessible to the active sites of specific enzymes. Saposin B also binds and transfers coenzyme Q<sub>10</sub> (CoQ<sub>10</sub>), an essential, but highly hydrophobic, antioxidant and redox component that is required for ATP production. 1. Nikolova-Karakashian & Merrill, Jr. (2000) *Meth. Enzymol.* **311**, 194. 2. Tayama, Soeda, Kishimoto, *et al.* (1993) *Biochem. J.* **290**, 401.

**Sapropterin, See (6R)-Tetrahydrobiopterin**

### Saquinavir

This statine-containing HIV protease inhibitor (FW = 670.85 g/mol; CAS 127779-20-8), also known as Ro 31-8959, inhibits many HIV-1 and HIV-2 proteases with a  $K_i$  of 0.3 nM. The methanesulfonate salt is known as Invirase<sup>®</sup>. The  $K_i$  values showed that its potency towards the V82F, L90M, I84V and G48V mutant proteinases respectively was 2-, 3-, 17- and 27-fold less than against the wild-type proteinase. Designed on the basis of the protease's three-dimensional structure, saquinavir became the first pharmaceutical approved for human use in 1996. Saquinavir inhibition prevents cleavage of the viral polyproteins resulting in the formation of immature non-infectious viral particles. Protease inhibitors are almost always used in combination with at least two other anti-HIV drugs. Saquinavir is poorly absorbed and is rapidly degraded by CYP3A4. **Target(s):** glucuronosyl-transferase, or UDP glucuronosyltransferases: UGT1A1, UGT1A3, and UGT1A4 (1); HIV-1 retropepsin, or human immunodeficiency virus I protease (2-12); HIV-2 retropepsin, or human immunodeficiency virus 2 protease (7); and proteasome (13). 1. ### SAR156497

This highly potent tricyclic aurora kinase inhibitor (FW = 467.52 g/mol) targets Aurora A, Aurora B, and Aurora C, shows exquisite selectivity versus other protein kinases (1). When tested in female SCID mice bearing human colon adenocarcinoma HCT116 xenografts, continuous subcutaneous infusion with ALZET<sup>®</sup> mini-pump (24 or 48 h at 25 or 50 mg/kg/day) was highly effective in suppressing tumor growth. The X-ray

structure of the bound inhibitor indicates that the DFG motif of Aurora A displays an "in" conformation and that the enzyme adopts an  $\alpha$ -Helix "Glu out" (or inactivated) conformation. Gln-185, an amino acid residue within the  $\alpha$ C Helix, is highly selective for Aurora kinases, making it a major determinant for target selectivity. 1. Carry, Clerc, Minoux, *et al.* (2014) *J. Med. Chem.* **58**, 362.

### SAR 216471

This reversible antithrombotic agent (FW = 599.51 g/mol; CAS 1279829-64-9; Solubility: 20 mM in DMSO, with gentle warming), also named 5-chloro-N-[6-[5-methyl-4-(1-oxobutyl)-1H-pyrazol-1-yl]-3-pyridazinyl]-1-[2-(4-methyl-1-piperazinyl)-2-oxoethyl]-1H-indole-3-carboxamide-HCl, targets the P2Y<sub>12</sub> receptor, acting as an antagonist and blocking ADP-induced platelet aggregation. Adenosine 5'-diphosphate (ADP) liberated from damaged red blood cells or endothelial cells is a key mediator of activation and aggregation of platelets. ADP could bind two purinergic receptors P2Y<sub>1</sub> and P2Y<sub>12</sub>. P2Y<sub>1</sub> is implicated in platelet shape changes, whereas P2Y<sub>12</sub> is involved in platelet aggregation, thrombin generation, microparticles release, and thrombus stabilization. 1. Boldron, Besse, Bordes, *et al.* (2014) *J. Med. Chem.* **57**, 729.

### Saracatinib

This orally active tyrosine protein kinase inhibitor (FW = 542.03 g/mol; CAS 379231-04-6; Solubility: 184 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known as AZD0530 and N-(5-chlorobenzo[d][1,3]dioxol-4-yl)-7-(2-(4-methylpiperazin-1-yl)ethoxy)-5-(tetrahydro-2H-pyran-4-yloxy)quinazolin-4-amine, is an investigational drug that targets Src (IC<sub>50</sub> = 2.7 nM) and also potently inhibits Fyn, c-Yes, Lyn, Blk, Fgr and Lck, with weaker action against Abl and the L858R and L861Q mutants of EGFR. Because the tyrosine kinase Fyn is activated via cell surface binding of Alzheimer-related A $\beta$ -oligomers to cellular prion protein, and because Fyn also interacts with both A $\beta$  and the microtubule-associated axonal protein Tau, AZD0530 is likewise under investigation for its potentially beneficial effects in Alzheimer's Disorder (8). 1. Chang, *et al.* (2008) *Oncogene* **27**, 6365. 2. Green, *et al.* (2009) *Mol. Oncol.* **3**, 248. 3. Purnell, *et al.* (2009) *J. Thorac. Oncol.* **4**, 448. 4. de Vries, *et al.* (2009) *Mol. ### Saralasin

This peptidic angiotensin antagonist (FW = 909.11 g/mol; CAS 34273-10-4; Sequence: XRVYVHPA (Modification: X = Sar); Soluble to 1 mg/mL in

H<sub>2</sub>O) competitively and non-selectively targets the angiotensin II receptor, enlarging microvascular diameters and increasing glomerular blood flow (1). Saralasin also exerts antiarrhythmic effects in myocardial reperfusion by a mechanism independent of circulatory and central actions (2). 1. Steinhäuser, Kücherer, Parekh, *et al.* (1986) *Kidney Int.* **30**, 56. 2. Thomas, Howlett & Ferrier (1995) *J. Pharmacol. Exp. Ther.* **274**, 1379.

**Sarcine**, See *Hypoxanthine*

### Sarcodictyin A & B

These microtubule-stabilizing agents (Sarcodictyin A [R = -CH<sub>3</sub>], MW<sub>SD-A</sub> = 496.60 g/mol; Sarcodictyin B [R = -CH<sub>2</sub>CH<sub>3</sub>], MW<sub>SD-B</sub> = 510.63 g/mol) from the Japanese soft coral *Bellonella albiflora* exhibit IC<sub>50</sub> values in the 200-500 nM range, considerably more weakly than paclitaxel (IC<sub>50</sub> < 10 nM, except in resistant cell lines) and eleutherobin and epothilone A, (IC<sub>50</sub> = 10-40 nM). 1. Hamel, Sackett, Vourloumis & Nicolaou (1999) *Biochemistry* **38**, 5490.

**Sarcosylsine**, See *Melphalan*

### Sarcosine

This methylated amino acid and endogenous glycine transporter GlyT1 inhibitor (FW = 89.09 g/mol; CAS 127779-20-8; pK<sub>a</sub>'s = 2.12 and 10.2; Soluble to 100 mM in water; Abbreviation: Sar), also known as *N*-methylglycine, is an intermediate in choline metabolism and a regulator of the *S*-adenosyl-*L*-methionine and *S*-adenosyl-*L*-homocysteine concentrations via the actions of glycine *N*-methyltransferase, dimethylglycine dehydrogenase, sarcosine oxidase, and sarcosine dehydrogenase. A sarcosyl moiety is also present in the structure of actinomycin D. **Target(s)**: L-alanine dehydrogenase (1,2); dimethylglycine *N*-methyltransferase (3); glycine transport (4); 4-hydroxyproline epimerase (5,6); proline racemase (7); and prolyl-tRNA synthetase (8). 1. ### Sarilesin

This angiotensin II receptor analogue (FW = 968.15 g/mol; CAS 37827-06-8; *Sequence*: Sar-Arg-Val-Phe-Ile-His-Pro-Ile, where Sar represents sarcosine (*i.e.*, *N*-methylglycine), also inhibits cAMP phosphodiesterase (1-

4). 1. Koziarz & Moore (1989) *Proc. West Pharmacol. Soc.* **32**, 79. 2. Matsoukas, Agelis, Wahhab, *et al.* (1995) *J. Med. Chem.* **38**, 4660. 3. Sharma (2003) *Ind. J. Biochem. Biophys.* **40**, 77. 4. Sharma, Smith & Moore (1991) *Biochem. Biophys. Res. Commun.* **179**, 85.

### Sarin

This lethal chemical warfare (CW) agent (FW = 140.09 g/mol; CAS 107-44-8; clear and odorless liquid, M.P. = -57°C; B.P. = 147°C), also known as methylisopropoxyfluorophosphine oxide and *O*-isopropyl methylphosphonofluoridate, frequently called *Agent GB*, was an insecticide first synthesized in 1937 by Schrader, Ambrose, Rüdiger, and van der Linde in Germany, hence the name. Sarin was soon found to be an extremely potent nerve agent and was produced in large quantities during World War II. Germany, however, refrained from using sarin as a chemical warfare weapon, most likely out of fear of worldwide condemnation and certain reprisal. (On March 20, 1995, members of the cult movement Aum Shinrikyo carried out the Tokyo Subway Sarin Incident (地下鉄サリン事件), an act of domestic terrorism that killed 12, severely injured 50, and temporarily impaired the vision of 5,000 others.) **Caution**: Sarin is extremely toxic and vapors can be readily absorbed through the skin and eyes. The transdermal LD<sub>50</sub> in human is 100-300 mg, death almost always occurring within fifteen minutes. The i.p. LD<sub>50</sub> in mice is 0.42 mg/kg. The LC<sub>50</sub> (*i.e.*, the concentration in air that is lethal in 50% of exposed individuals) is 0.6-1.2 ppm. Sarin is a substrate for a number of carboxylesterases and is a potent inhibitor of acetylcholinesterase and cholinesterase. At low concentrations, sarin inhibits the evoked release of  $\gamma$ -aminobutyrate in rat hippocampal slices (1). Interestingly, sarin has been used in the treatment of leprosy and of AIDS. **Cyclosarin**: This structurally related toxin (FW = 180.16 g/mol; B.P. = 239 °C), also named cyclohexyl methyl-phosphonofluoridate and (fluoro-methyl-phosphoryl)-oxycyclohexane, has comparable properties to sarin as a nerve gas, albeit far less volatile. **Target(s)**: acetylcholinesterase (2-12); carboxylesterase (9); cholinesterase, *or* butyrylcholinesterase (2,6,9,12-15); chymotrypsin (9);  $\alpha$ -lytic endopeptidase (16); thrombin (17,18); and trypsin (9). 1. ### Sarpogrelate

This serotonin 5HT<sub>2A</sub> and 5-HT<sub>2B</sub> receptor antagonist (FW = 429.51 g/mol; CAS 125926-17-2), also known by code names MCI-9042 and LS-187118, trade name Anplag<sup>®</sup>, and systematic name, 4-[2-(dimethylamino)-1-({2-[2-

(3-methoxyphenyl)ethyl]phenoxy}methyl)ethoxy]-4-oxobutanoic acid, blocks serotonin-induced platelet aggregation and has been used to treat diabetic nephropathy and neuropathy, Buerger's disease (or thromboangiitis obliterans), Raynaud's disease, coronary artery disease, angina, and atherosclerosis. Sarpogrelate has a  $K_i$  value of 8.4 nM with 5HT<sub>2</sub> receptors (1). (The  $pK_i$  values are 8.52, 7.43 and 6.57 for antagonist action on 5-HT<sub>2A</sub>, 5-HT<sub>2C</sub> and 5-HT<sub>2B</sub> receptors, respectively.) (*R,S*)-1-[2-[2-(3-Methoxyphenyl)ethyl]phenoxy]-3-(dimethylamino)-2-propanol (or M-1), its major metabolite, is more active ( $K_i$  = 1.7 nM). Both sarpogrelate and M-1 show no affinity for 5-HT<sub>1A</sub> receptors, but these substances, at a concentration of 10  $\mu$ M, displace the specific binding of [<sup>125</sup>I]iodocyanopindolol to the 5-HT<sub>1B</sub> receptors, with respective  $K_i$  values of 0.88 and 0.86  $\mu$ M. Sarpogrelate, (*R,S*)-M-1, (*R*)-M-1 and (*S*)-M-1 are competitive antagonists of rat tail artery 5-HT<sub>2A</sub> receptors, showing  $pA_2$  values of 8.53, 9.04, 9.00 and 8.81, respectively (2). 1. Nishio, Inoue & Nakata (1996) *Arch. Int. Pharmacodyn. Ther.* **331**, 189. 2. Pertz & Elz (1995) *J. Pharm. Pharmacol.* **47**, 310.

#### Saucerneol B

This lignan (FW = 534.60 g/mol) inhibits cholesterol *O*-acyltransferase,  $IC_{50}$  = 43  $\mu$ M for human ACAT-1 (1). **Target(s):** HIV-1 protease (1); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, also known as ACAT (2,3). 1. Lee, Huh, Kim, Hattori & Otake (2010) *Antiviral Res.* **85**, 425. 2. Jeong, Kim, Yu, *et al.* (2005) *Bioorg. Med. Chem. Lett.* **15**, 385. 3. Lee, Lee, Baek, *et al.* (2004) *Bioorg. Med. Chem. Lett.* **14**, 3109.

#### Sauvagine

This corticotropin-releasing factor (CRF) receptor agonist (FW = 4599.35 g/mol; CAS 74434-59-6; Sequence: XGPPISIDLSLELLLRKMIEIEKQEK EKQQAANNRLLDITI (Modifications: X-1 = pGlu, Ile-40 = C-terminal amide); Store desiccated at -20°C) inhibits of [<sup>125</sup>I]-[D-Tyr<sup>1</sup>]astressin binding to hCRF-R1 ( $K_i$  = 9.4 nM), rCRF-R2a ( $K_i$  = 9.9 nM), and mCRF-R2b ( $K_i$  = 3.8 nM). Sauvagine was first isolated from the skin of *Phyllomedusa sauvagei*, a frog of Central and South America (1). 1. Montecucchi & Henschen (1981) *Int. J. Pept. Protein Res.* **18**, 113. 2. Eckart, *et al.* (1999) *Curr. Med. Chem.* **6**, 1035. 3. Perrin & Vale (1999) *Ann. N.Y. Acad. Sci.* **885**, 312.

#### Savignin

This coagulation-modulating protein (MW = 12.4 kDa) from the tick *Ornithodoros savignyi* is a potent thrombin inhibitor,  $K_i$  = 4.9 pM for  $\alpha$ -thrombin and 22 nM for  $\gamma$ -thrombin (1,2). Savignin is a competitive, slow, tight-binding inhibitor, requiring thrombin's fibrinogen-binding exo-site for optimal inhibition. 1. Nienaber, Gaspar & Neitz (1999) *Exp. Parasitol.* **93**, 82. 2. Mans, Louw & Neitz (2002) *Insect Biochem. Mol. Biol.* **32**, 821.

#### Saxagliptin

This substituted pyrrolidone (FW = 315.41 g/mol; CAS 361442-04-8), also known as BMS-477118 and marketed under the tradename Onglyza™, is a potent, selective, and orally active inhibitor ( $K_i$  = 0.6 nM) of dipeptidyl-peptidase IV, or DPP-4 (1,2). By limiting proteolysis of the gastrointestinal

hormones, glucagon-like peptides 1 and 2 (GLP-1 and GLP-2), saxagliptin is a so-called incretin enhancer that indirectly maintains insulin secretion and suppresses glucagon release. Saxagliptin has good oral bioavailability and enjoys the added advantage of not being significantly influenced by food intake. Moreover, its prolonged *in vivo* half-life and its efficient inhibition of DPP-4 permit a single oral dose for daily management of Type-2 diabetes (3). Saxagliptin is a P450 substrate that is metabolized by CYP3A4/A5. Finally, because dipeptidyl-peptidase IV has diverse physiologic roles (*e.g.*, angiogenesis, vascular remodeling, inflammation, regulation of Na<sup>+</sup>/H<sup>+</sup> exchanger isoform activity in proximal tubule cells, attenuation of blood pressure, *etc.*), one may anticipate that high-potency DPP-4 inhibitors will elicit a range of side-effects. See *Sitagliptin, Vildagliptin* 1. Augeri, Robl, Betebenner, *et al.* (2005) *J. Med. Chem.* **48**, 5025. 2. Metzler, Yanchunas, Weigelt, *et al.* (2008) *Protein Sci.* **17**, 240. 3. Scheen (2010) *Diabetes Obes. Metab.* **12**, 648.

#### Saxitoxin

This selective Na<sup>+</sup> channel blocker (FW<sub>dihydrochloride</sub> = 370.2 g/mol; CAS 35523-89-8; hygroscopic), produced by red tide dinoflagellates of *Gonyaulax* species, is a paralytic toxin that accumulates in shellfish, often reaching levels that can result in severe poisoning of humans consuming affected shellfish. Saxitoxin inhibits sodium ion transport by binding to a site at/near the extracellular face of the sodium channel's pore (1-4). In each of the six species studied, a single class of high-affinity receptor sites was detected with  $B_{max}$  values of 1.7–12 fmol/mg (wet weight) and  $K_d$  values of 0.3–7.5 nM for STX, compared to a value of 3.5–10.4 nM for tetrodotoxin. For example, saxitoxin inhibits the action potential Na<sup>+</sup> ionophore of electrically excitable neuroblastoma cells with a  $K_i$  of 3.7 nM. Binding experiments detect a single class of saturable binding sites with  $K_d$  of 3.9 nM and a  $B_{max}$  of 156 fmol/mg of cell protein (~78 sites per  $\mu$ m<sup>2</sup> of cell surface) (5). Saturable binding is completely inhibited by tetrodotoxin but is unaffected by scorpion toxin or batrachotoxin. No saturable binding is observed in cultures of clone N103, a variant neuroblastoma clone lacking the action potential Na<sup>+</sup> response (5). Saxitoxin is thus a valuable tool in neurochemical investigations on voltage-gated channels. The oral LD<sub>50</sub> for humans is 5.7  $\mu$ g/kg. 1. Catterall (1986) *Ann. Rev. Biochem.* **55**, 953. 2. Cheymol, Bourillet, Long & Roch-Arveiller (1968) *Arch. Int. Pharmacodyn. Ther.* **174**, 393. 3. Evans (1969) *Brit. Med. Bull.* **25**, 263. 4. #### Sazetidine A

This subtype-selective nicotinic acetylcholine receptor ligand (FW = 333.25 g/mol; CAS 1197329-42-2; Soluble to 50 mM in H<sub>2</sub>O), also named 6-[5-(2*S*)-2-azetidinylmethoxy]-3-pyridinyl]-5-hexyn-1-ol di-HCl, targets  $\alpha_5\beta_2$

receptor ( $K_i = 0.26$ ), with 200x greater affinity than for the  $\alpha_3\beta_4$  receptor ( $K_i = 54$  nM). Depending on subunit composition, Sazetidine A acts either as a silent desensitizer or as an agonist, with an  $EC_{50}$  of 1.1 nM for nAChR-stimulated dopamine release. It also exhibits analgesic activity *in vivo* and significantly reduces nicotine self-administration in a rat model. 1. Xiao, *et al.* (2006) *Mol. Pharmacol.* **70**, 1454. 2. Cucchiaro, *et al.* (2008) *Anesthesiology* **109**, 512. 3. Zwart, *et al.* (2008) *Mol. Pharmacol.* **73**, 1843. 4. Levin, *et al.* (2010) *J. Pharmacol. Exp. Ther.* **332**, 933.

**SB 202190**

This substituted imidazole (FW = 331.35 g/mol; CAS 152121-30-7), also known as (4-(4-fluorophenyl)-2-(4-hydroxyphenyl)-5-(4-pyridyl)-1*H*-imidazole, is structurally similar to SB 203580. SB 202190 inhibits p38 stress activated protein kinase 2a and p38 stress-activated protein kinase 2b, IC<sub>50</sub> values of 50 and 100 nM, respectively (1-5). *Note*: SB 202474 (4-ethyl-2(*p*-methoxyphenyl)-5-(4'-pyridyl)-1*H*-imidazole), in which the 4-fluorophenyl group of SB 202190 has been replaced with an ethyl moiety and the hydroxyl group is methylated, is often used as a negative control in investigations of mitogen-activated protein kinase. 1. **SB 203186**

This potent serotonin antagonist (FW = 308.81 g/mol; CAS 207572-69-8; Soluble to 100 mM in water), also named 1-piperidinylethyl-1*H*-indole-3-carboxylate hydrochloride, targets 5-HT<sub>4</sub> receptors, with high affinity for human atrial receptors. 1. Midhurst & Kaumann (1993) *Brit. J. Pharmacol.* **110**, 1023. 2. McLean & Coupar (1995) *Naunyn. Schmiedebergs Arch. Pharmacol.* **352**, 132. 3. Parker, *et al.* (1995) *Naunyn. Schmiedebergs Arch. Pharmacol.* **353**, 28.

**SB 203207**

This isoleucyl derivative (FW = 474.54 g/mol), from a strain of *Streptomyces*, inhibits *Staphyococcus aureus* and rat liver isoleucyl-tRNA synthetases, IC<sub>50</sub> = 1.7 and < 2 nM, respectively (1-3). Note that the semi-synthetic leucyl and valyl analogues inhibit their cognate aminoacyl-tRNA synthetases. **Target(s)**: isoleucyl-tRNA synthetase (1-3); leucyl-tRNA synthetase, moderately inhibited (1); and valyl-tRNA synthetase, moderately inhibited (1,2). 1. Crasto, Forrest, Karoli, *et al.* (2003) *Bioorg. Med. Chem.* **11**, 2687. 2. Stefanska, Cassels, Ready & Warr (2000) *J. Antibiot.* **53**, 357. 3. Houge-Frydrych, Gilpin, Skett & Tyler (2000) *J. Antibiot.* **53**, 364.

**SB 203347**

This sulfonamide (FW = 573.39 g/mol; CAS 169527-42-8) inhibits human type II phospholipase A<sub>2</sub> (IC<sub>50</sub> = 0.5 μM) inhibits human glycerophospholipid arachidonyltransferase (CoA-independent), IC<sub>50</sub> = 23 μM (1) and phospholipase A<sub>2</sub> (2,3). 1. Winkler, Eris, Sung, *et al.* (1996) *J. Pharmacol. Exp. Ther.* **279**, 956. 2. Anderson, Roshak, Winkler, McCord & Marshall (1997) *J. Biol. Chem.* **272**, 30504. 3. Marshall, Hall, Winkler, *et al.* (1995) *J. Pharmacol. Exp. Ther.* **274**, 1254.

**SB 203386**

This tripeptide analogue (FW = 507.68 g/mol) inhibits HIV-1 and HIV-2 retropepsin,  $K_i = 18$  and 1280 nM, respectively (1). SB 203386 inhibition prevents cleavage of the viral polyproteins resulting in the formation of immature non-infectious viral particles. Protease inhibitors are almost always used in combination with at least two other anti-HIV drugs. 1. Swairjo, Towler, Debouck & Abdel-Meguid (1998) *Biochemistry* **37**, 10928.

## SB 203580

This anti-inflammatory (FW<sub>free-base</sub> = 377.44 g/mol; CAS 152121-47-6; Solubility: 25 mM in DMSO as free base; 100 mM as mono-HCl salt), also known as 4-(4-fluorophenyl)-2-(4-methylsulfonylphenyl)-5-(4-pyridyl)-1H-imidazole, is a selective inhibitor of p38 mitogen-activated protein kinase SAPK2/p38 (IC<sub>50</sub> = 50 nM) and SAPK2b/p38β2 (IC<sub>50</sub> = 500 nM), displaying 100-500x selectivity over LCK, GSK3β and PKBa (1-15). SB 203580 inhibits interleukin-2-induced T-cell proliferation, cyclooxygenase-1 and -2, and thromboxane synthase. SB 203580 suppresses the activation of MAPKAP kinase-2 and inhibits the phosphorylation of heat shock protein 27. As a SAPK2 pathway inhibitor, SB 203580 treatment results in the phosphorylation of such AP1 transcription factors c-Jun. Its solubility in dimethyl sulfoxide is 50 mg/mL. **Target(s):** cRaf protein kinase (16); cyclooxygenases, COX-I and II (17); [glycogen-synthase] kinase III (4); Jun N-terminal kinase, especially JNK2 and JNK3 (18); lymphocyte kinase (4); mitogen-activated protein kinase (or p38 MAP kinase/reactivating kinase), p38 stress-activated protein kinase 2a, and p38 stress-activated protein kinase 2b, with IC<sub>50</sub> values of 50 and 500 nM, respectively (1-15); protein kinase B (4); and thromboxane-A synthase (17). 1. ## SB 203580 Sulfone

This SB 203580 derivative (FW = 393.44 g/mol), known systematically as 4-(4-fluorophenyl)-2-(4-methylsulfonylphenyl)-5-(4-pyridyl)-1H-imidazole, is a strong inhibitor of mitogen-activated protein kinase, or p38 stress-activated protein kinase (IC<sub>50</sub> = 30 nM). 1. Gallagher, Seibel, Kassis, *et al.* (1997) *Bioorg. Med. Chem.* **5**, 49.

## SB 204070

This potent and selective serotonin receptor antagonist (FW = 382.88 g/mol; CAS 148688-01-1; Soluble to 100 mM in DMSO), also named (1-Butyl-4-piperidinyl)methyl 8-amino-7-chloro-1,4-benzodioxane-5-carboxylate hydrochloride, 5-HT<sub>4</sub> receptor antagonist (IC<sub>50</sub> = 90 nM). SB 204070 displays >5000x selectivity for 5-HT<sub>4</sub> versus 5-HT<sub>1A</sub>, 5-HT<sub>1D</sub>, 5-HT<sub>1E</sub>, 5-HT<sub>2A</sub>, 5-HT<sub>2C</sub>, and 5-HT<sub>3</sub> receptors. SB 204070 exhibits anxiolytic activity upon systemic administration *in vivo*. 1. Gaster *et al.* (1993) *J. Med. Chem.* **36**, 4121. 2. Bingham, *et al.* (1995) *J. Pharm. Pharmacol.* **47**, 219. 3. Prins, *et al.* (2000) *Brit. J. Pharmacol.* **129**, 1601.

## SB 204144

This phosphinate-containing peptidomimetic (FW = 768.85 g/mol), also named (1R)-bis[2-phenyl-1-[(carbobenzoxy)valyl]aminoethyl]phosphinic acid (FW<sub>free-acid</sub> = 770.86 g/mol; melting point = 236-238°C), is a potent tetrahedral-adduct transition-state mimic that inhibits HIV-1 protease, K<sub>i</sub> = 2.8 nM, at pH 6.0. 1. Ringe (1994) *Meth. Enzymol.* **241**, 157. 2. Kempf (1994) *Meth. Enzymol.* **241**, 334. 3. Abdel-Meguid, Zhao, Murthy, *et al.* (1993) *Biochemistry* **32**, 7972.

## SB 204741

This serotonin antagonist (FW = 286.35 g/mol; CAS 152239-46-8; Soluble to 100 mM in DMSO), also named N-(1-methyl-1H-indolyl-5-yl)-N''-(3-methyl-5-isothiazolyl)urea, targets 5-HT<sub>2B</sub> receptor antagonist (pA<sub>2</sub> = 7.95), displaying greater than 100x selectivity versus 5-HT<sub>2C</sub> (pK<sub>i</sub> = 5.82), 5-HT<sub>2A</sub> (pK<sub>i</sub> < 5.2), 5-HT<sub>1A</sub>, 5-HT<sub>1D</sub>, 5-HT<sub>1E</sub>, 5-HT<sub>3</sub> and 5-HT<sub>4</sub> receptors. 1. Bonhaus, *et al.* (1995) *Brit. J. Pharmacol.* **115**, 622. 2. Forbes, *et al.* (1995) *J. Med. Chem.* **38**, 855. 3. Glusa & Pertz (2000) *Brit. J. Pharmacol.* **130**, 692. 4. Ebrahimkhani, *et al.* (2011) *Nature Med.* **17**, 1668.

## SB 205952

This pseudomonic/monic acid analogue (FW = 478.50 g/mol) is a strong inhibitor of isoleucyl-tRNA synthetase as well as a substrate for bacterial NAD(P)H-dependent reductases (1-4). 1. Pope, Moore, McVey, *et al.* (1998) *J. Biol. Chem.* **273**, 31691. 2. Pope, McVey, Fantom & Moore (1998) *J. Biol. Chem.* **273**, 31702. 3. Broom, Cassels, Cheng, *et al.* (1996) *J. Med. Chem.* **39**, 3596. 4. Wilson, Oliva, Cassels, O'Hanlon & Chopra (1995) *Antimicrob. Agents Chemother.* **39**, 1925.

## SB 212047

This β-lactam (FW = 497.37 g/mol), also named 4-methoxybenzyl (3S,4R)-6-bromo-6-[(1-methyl-1,2,3-triazol-4-yl)hydroxymethyl]penicillanate, irreversibly inhibits human CoA-independent glycerophospholipid arachidonoyltransferase (or CoA-IT), a key mediator of arachidonate

remodeling that moves arachidonate into 1-ether-containing phospholipids. Blockade of CoA-IT blocks release of arachidonate in stimulated neutrophils and inhibits production of eicosanoids and platelet-activating factor. Evidence of irreversibility (namely that extensive washing does not restore activity) is unconvincing. 1. Winkler, Sung, Chabot-Flecher, *et al.* (1998) *Mol. Pharm.* **53**, 322.

**SB 214357**

This penem antibiotic derivative (FW = 297.33 g/mol) inhibits certain signal peptidases. *Note:* Some literature sources have mislabeled this inhibitor as SB 216357. **Target(s):** chloroplast and cyanobacterial signal peptidase 1 (1,2); C-terminal processing peptidase, *or* tsp peptidase (3); and *Escherichia coli* leader peptidase (4). 1. Howe & Floyd (2002) *The Enzymes*, 3rd ed. (Dalbey & Sigman, eds.), **22**, 101. 2. Barbrook, Packer & Howe (1996) *FEBS Lett.* **398**, 198. 3. Chaal, Ishida & Green (2003) *Plant Mol. Biol.* **52**, 463. 4. Perry, Ashby & Elsmere (1995) *Biochem. Soc. Trans.* **23**, 548S.

**SB 216357, See SB 214357****SB 216477, See 4-(Phenylthio)-N-(4-phenyl-2-oxobutyl)azetidin-2-one****SB 216763**

This substituted maleimide (FW = 371.22 g/mol; CAS 280744-09-4) inhibits [glycogen synthase] kinase-3 (GSK3),  $IC_{50} = 34$  nM, protecting both central and peripheral nervous system neurons in culture from death induced by reduced PI3-kinase pathway activity. The inhibition of neuronal death mediated by SB-216763 correlates with inhibition of GSK-3 activity and modulation of GSK-3 substrates Tau protein and  $\beta$ -catenin. 1. Cross, Culbert, Chalmers, *et al.* (2001) *J. Neurochem.* **77**, 94. 2. Coghlan, Culbert, Cross, *et al.* (2000) *Chem. Biol.* **7**, 793.

**SB 220025**

This photosensitive p38 inhibitor (FW = 338.39 g/mol; IUPAC: 5-(2-amino-4-pyrimidinyl)-4-(4-fluorophenyl)-1-(4-piperidinyl)imidazole, targets p38 MAP kinase,  $IC_{50} = 60$  nM (human), with and 50x to 1000x

selectivity versus other kinases tested (1,2). SB 220025 binds in an extended pocket within the active site and is complementary to the open domain structure of the low-activity form of p38. 1. Jackson, Bolognese, Hillegass, *et al.* (1998) *J. Pharmacol. Exp. Ther.* **284**, 687. 2. Wang, Canagarajah, Boehm, *et al.* (1998) *Structure* **6**, 1117.

**SB 222657 & SB 223777****SB-222657****SB-223777**

These mechanism-based azetidinones (FW = 460.02 g/mol) inhibit lipoprotein-associated phospholipase  $A_2$ , platelet-activating factor acetylhydrolase, with  $K_i$  values of 40 nM and 6.3  $\mu$ M for SB-222657 and SB-223777, respectively, based on the reversible phase prior to inactivation. Stereoselectivity is also observed in the second-order rate constants for inactivation:  $k_{obs}/[I] = 6.6 \times 10^5 \text{ M}^{-1} \cdot \text{s}^{-1}$  for SB-222657, and  $k_{obs}/[I] = 1.6 \times 10^4 \text{ M}^{-1} \cdot \text{s}^{-1}$  for SB-223777. SB-222657 is completely inactive against the human synovial fluid Type IIa  $PLA_2$ , which, unlike Lp- $PLA_2$ , is a  $Ca^{2+}$ -dependent  $PLA_2$  and lacks an active-site serine residue and is therefore not expected to be inhibited. These inhibitors are unique tools for investigating the role of Lp- $PLA_2$  in the altered phospholipid metabolism during oxidative modification of lipoproteins. These findings also demonstrate unequivocally that Lp- $PLA_2$  is solely responsible for the elevation of lyso-PtdCho found within oxidized LDL. 1. MacPhee, Moores, Boyd, *et al.* (1999) *Biochem. J.* **338**, 479.

**SB 225002**

This potent and selective CXCR2 antagonist (FW = 352.14 g/mol; CAS 182498-32-4; Solubility: 100 mM in DMSO), systematically named *N*-(2-bromophenyl)-*N'*-(2-hydroxy-4-nitrophenyl)urea, blocks Interleukin-8 (IL-8) binding to the CXCR2 chemokine receptor ( $IC_{50} = 22$  nM). SB 225002 displays more than 150x selectivity for CXCR2 over CXCR1 receptors. CXC chemokine receptors are G-coupled, seven-helix integral membrane proteins that bind cytokines in the CX chemokine family. *In vitro*, SB 225002 potently inhibits human and rabbit neutrophil chemotaxis induced by both IL-8 and  $GRO\alpha$ . *In vivo*, SB 225002 selectively blocks IL-8-induced neutrophil margination in rabbits (1). SB 225002 also inhibits HIV-1 replication in both T lymphocytes and macrophages, indicating potential therapeutic uses for CXCR2 antagonists in limiting HIV-1 infection and AIDS (2). This inhibitory effect on  $A\beta_{40}$  and  $A\beta_{42}$  formation is mediated by  $\gamma$ -secretase through reduction in expression of presenilin, a  $\gamma$ -secretase substrate. SB225002 also inhibits angiogenic activity of IL-8 by blocking its binding with CXCR2 in the early stage of experimentally induced choroidal neovascularization (CNV), which may provide a potential new therapeutic strategy for CNV (3). Cell cycle analysis, immunocytometry, immunoblotting, and RNA interference reveal that SB225002 induces

mitotic checkpoint serine/threonine-protein kinase BubR1-dependent mitotic arrest (4). SB225002 also possesses a microtubule-destabilizing activity, as evidenced by Bcl<sub>2</sub> and Bcl<sub>xL</sub> hyperphosphorylation, suppression of microtubule polymerization, and induction of a prometaphase arrest. Molecular docking studies suggest that SB225002 should have a good affinity toward vinblastine binding site on  $\beta$ -tubulin subunit. By contrast, SB265610, exhibits potent IL-8RB antagonistic activity but does not exhibit a similar antimitotic activity. The antitumor activity of SB225002 is unaffected by P-glycoprotein-mediated multidrug resistance. 1. White, Lee, Young, *et al.* (1998) *J. Biol. Chem.* **273**, 10095. 2. Lane, Lore, Bock, *et al.* (2001) *J. Virol.* **75**, 8195. 3. Qu, Zhou & Xu. (2009) *Zhonghua Yan Ke Za Zhi.* **45**, 742. 4. Goda, Koyama, Sowa, *et al.* (2013) *Biochem. Pharmacol.* **85**, 1741.

#### SB 239063

This highly substituted imidazole (FW = 368.41 g/mol), also known as *trans*-1-(4-hydroxycyclohexyl)-4-(4-fluorophenyl)-5-(2-methoxypyrimidin-4-yl)imidazole, is a strong inhibitor of the  $\alpha$ - and  $\beta$ -isoforms of p38 mitogen-activated protein kinase (IC<sub>50</sub> = 44 nM) and exhibits anti-inflammatory/antiallergic activity, commending it for the treatment of asthma and other inflammatory disorders. 1. Underwood, Osborn, Kotzer, *et al.* (2000) *J. Pharmacol. Exp. Ther.* **293**, 281.

#### SB 243545

This L-tyrosine-containing metabolite (FW<sub>free-base</sub> = 487.51 g/mol) is a potent inhibitor of bacterial tyrosyl-tRNA synthetase, IC<sub>50</sub> = 0.2 nM for the *Staphylococcus aureus* enzyme. The inhibitor occupies the known substrate binding sites as well as an affinity-enhancing butyl binding pocket. 1. Qiu, Janson, Smith, *et al.* (2001) *Protein Sci.* **10**, 2008.

#### SB 252218, See Tranilast

#### SB 269970

This brain-penetrant serotonin antagonist (FW = 388.95 g/mol; CAS 261901-57-9; Soluble to 20 mM in H<sub>2</sub>O and to 100 mM in DMSO), also named (2*R*)-1-[(3-hydroxyphenyl)sulfonyl]-2-[2-(4-methyl-1-piperidinyl)ethyl]pyrrolidine hydrochloride, potently and selectively targets 5-HT<sub>7A</sub> receptors (pK<sub>i</sub> = 8.9), with weaker action against 5-HT<sub>5A</sub> (pK<sub>i</sub> = 7.2), and 5-HT<sub>5B</sub> (pK<sub>i</sub> = 6.0) receptors and showing pK<sub>i</sub> values < 6.0 for 5-HT<sub>1A</sub>, 5-HT<sub>1D</sub>, 5-HT<sub>1E</sub>, 5-HT<sub>1F</sub>, 5-HT<sub>2A</sub>, 5-HT<sub>2B</sub>, 5-HT<sub>2C</sub>, 5-HT<sub>4</sub> and 5-HT<sub>6</sub> receptors. 1. Hagan, *et al.* (2000) *Brit. J. Pharmacol.* **130**, 539. 2. Lovell, *et al.* (2000) *J. Med. Chem.* **43**, 342. 3. Kogan, *et al.* (2002) *Eur. J. Pharmacol.* **449**, 105.

**SB-275833, See Retapamulin**

#### SB 284485

This L-tyrosine-containing metabolite (FW = 400.39 g/mol) is a potent inhibitor of bacterial tyrosyl-tRNA synthetase, with an IC<sub>50</sub> of 4 nM for the *Staphylococcus aureus* enzyme. The inhibitor occupies the known substrate binding sites in unique ways that reveal a so-called butyl binding pocket. 1. Qiu, Janson, Smith, *et al.* (2001) *Protein Sci.* **10**, 2008.

#### SB 332235

This CXCR2 antagonist (FW = 410.66 g/mol; CAS 276702-15-9; Solubility: 100 mM in DMSO), also named 6-chloro-3-[[[(2,3-dichlorophenyl)amino]carbonyl]amino]-2-hydroxybenzenesulfonamide, targets C-X-C motif Chemokine Receptor 2 (1). The CXCR2 binds interleukin 8 (IL8) with high affinity, transducing the signal through a G-protein-activated second messenger system. This receptor also binds to chemokine (C-X-C motif) ligand 1 (*or* CXCL1/MGSA), a protein with melanoma growth-stimulating activity required for serum-dependent melanoma cell growth. CXCR2 mediates neutrophil migration to sites of inflammation, and receptor knockout studies in mice suggest it controls oligodendrocyte precursor positioning in developing spinal cord by arresting their migration. SB-332235 inhibits binding of <sup>125</sup>I-labeled human IL-8 (IC<sub>50</sub> = 40.5 nM) as well as human IL-8-induced calcium mobilization by rabbit CXCR2 (IC<sub>50</sub> = 7.7 nM), but not the corresponding binding of human IL-8 to rabbit CXCR1 (IC<sub>50</sub> > 1000) or human IL-8-induced calcium mobilization by rabbit CXCR1 (IC<sub>50</sub> = 2200 nM). Such findings suggest the rabbit is an appropriate species for examining anti-inflammatory effects of human CXCR2-selective antagonists (1). When tested *in vitro*, SB332235 potentially inhibited human IL-8-induced chemotaxis of rabbit neutrophils (IC<sub>50</sub> = 0.75 nM), suggesting that inhibition of leukocyte migration into the knee joint is a likely mechanism by which the CXCR2 antagonist modulates disease (1). CXCR2 is also significantly increased in MDS CD34<sup>+</sup> cells from a large clinical cohort and was predictive of increased transfusion dependence (2). High CXCR2 expression is also an adverse prognostic factor in the Cancer Genome Atlas AML cohort, again pointing to a critical role of the IL8-CXCR2 axis in AML/MDS. CXCR2 knockdown and pharmacologic inhibition significantly reduce proliferation in several leukemic cell lines and in primary MDS/AML samples by inducing G<sub>0</sub>/G<sub>1</sub> cell-cycle arrest. 1. Podolin, Bolognese, Foley, *et al.* (2002) *J. Immunol.* **169**, 6435. 2. Schinke, Giricz, Li, *et al.* (2015) *Blood* **125**, 3144.

**SB 334867, Similar in action to SB 408124**

## SB 408124

This non-peptide, orexin receptor antagonist (FW = 356.37 g/mol; CAS 288150-92-5), also known as Tocris-1963 and named systematically as *N*-(6,8-difluoro-2-methyl-4-quinoliny)-*N'*-[4-(dimethylamino)phenyl]urea, selectively targets the human OX<sub>1</sub> receptor ( $K_i$  = 22 nM), with much low affinity for the OX<sub>2</sub> receptor ( $K_i$  = 1.4 nM). Orexin, a peptide neurotransmitter (known also as hypocretin) produced by 10,000-20,000 cells within the hypothalamus, regulates arousal, wakefulness, and appetite. SB 408124 blocks the orexin-A induced grooming in rats following oral administration *in vivo*. **1.** Langmead, Jerman, Brough, *et al.* (2004) *Brit. J. Pharmacol.* **141**, 340.

## SB 415286

This substituted maleimide (FW = 359.73 g/mol; CAS 264218-23-7; Soluble in DMSO), also known as 3-(3-chloro-4-hydroxyphenylamino)-4-(2-nitrophenyl)-1*H*-pyrrole-2,5-dione, inhibits both GSK $\alpha$  and GSK $\beta$ , or [glycogen synthase] kinase, with IC<sub>50</sub> and  $K_i$  values of 71 nM and 31 nM, respectively (1). **Mode of Inhibitory Action:** GSK is a serine/threonine protein kinase, that is inhibited by a variety of extracellular stimuli including insulin, growth factors, cell specification factors and cell adhesion. As a result, GSK-3 inhibition is a druggable target for altering numerous signalling pathways that control a wide range of cellular responses. Although lithium ion has been most commonly used to investigate the effects of GSK-3 $\beta$  inhibition, it is nonspecific and may produce results due to other kinase inhibition (See *Lithium Ion*); in contrast, SB415286 is potent and highly specific GSK-3 $\beta$  inhibitor, acting in an ATP-competitive manner (1). **Cellular Effects:** SB-415286 stimulates glycogen synthesis in human liver cells and induces expression of a  $\beta$ -catenin-LEF/TCF regulated reporter gene in HEK293 cells (1). It inhibits cellular GSK-3 activity, as assessed by activation of glycogen synthase (GS), which is a direct target of this kinase (1). SB415286 also protects both central and peripheral nervous system neurons in culture from cell death induced by reducing PI 3-kinase pathway activity, and its inhibitory action correlates with inhibition of GSK-3 phosphorylation of the microtubule-associated Tau protein and  $\beta$ -catenin (2). In L6 myotubes, SB-415286 induces a much greater activation of GS (6.8x) compared to that elicited by insulin (4.2x) or lithium ion (4x) (3). In adipocytes, insulin, lithium ion and SB-415286 all cause comparable activation of GS, despite a substantial differentiation-linked reduction in GSK3 expression, indicating that GSK3 is an important determinant of GS activation in fat cells (3). SB-415286 was also used to show that GSK3 $\beta$  plays an important role in rapamycin-mediated cell cycle regulation and chemosensitivity, thereby potentiating rapamycin's antitumor effects (4). Likewise, this inhibitor aided in showing that that Coxsackievirus B3 (CVB3) infection stimulates GSK3 $\beta$  activity by a tyrosine kinase-dependent mechanism that contributes to CVB3-induced cytopathic effects and apoptosis through dysregulation of  $\beta$ -catenin (5). SB-415286 exerts neuroprotective effects on hydrogen peroxide-induced cell death in B65 rat neuroblastoma cells and neurons (6). GSK-3 inhibitors like SB-415286 also provide new ways to enhance the anti-tumor

activity of Tumor necrosis factor-Related Apoptosis-Inducing Ligand (TRAIL) in hepatocellular carcinoma (HCC) (7). SB-415286 effects also suggest that GSK-3 regulates multiple myeloma cell growth and bortezomib-induced cell death (8) as well as cell death, apoptosis, and *in vivo* tumor growth delay in neuroblastoma Neuro-2A cell line (9). **1.** Coghlan, Culbert, Cross, *et al.* (2000) *Chem. Biol.* **7**, 793. **2.** Cross, Culbert, Chalmers *et al.* (2001) *J. Neurochem.* **77**, 94. **3.** MacAulay, Hajduch, Blair, *et al.* (2003) *Eur. J. ## SB 418011

This substituted indole carboxylate (FW = 443.33 g/mol) inhibits *Escherichia coli*, *Streptococcus pneumoniae*, and *Hemophilus influenzae*  $\beta$ -ketoacyl-[acyl-carrier-protein] synthase, with IC<sub>50</sub> values of 1.2, 0.016, and 0.59  $\mu$ M, respectively. In the bacterial type II fatty acid synthase system,  $\beta$ -ketoacyl-acyl carrier protein (ACP) synthase III (FabH) catalyzes the condensation of acetyl-CoA with malonyl-ACP. **1.** Khandekar, Gentry, Van Aller, *et al.* (2001) *J. Biol. Chem.* **276**, 30024.

## SB 431542

This potent antitumor agent (FW = 384.39 g/mol; CAS 301836-41-9; Solubility: 77 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 4-(benzo[*d*][1,3]dioxol-5-yl)-5-(pyridin-2-yl)-1*H*-imidazol-2-yl)benzamide, inhibits transforming growth factor- $\beta$  superfamily type 1 activin receptor-like kinase (ALK) receptors ALK-4, -5, and -7, selectively targeting ALK5 with an IC<sub>50</sub> of 94 nM in a cell-free assay. SB431542 shows 100-fold more selective for ALK5 over p38 MAPK and other kinases (1-3). SB-431542 is a selective inhibitor of endogenous activin and TGF- $\beta$  signaling, but has no effect on bone morphogenetic proteins (BMPs) signaling. B-431542 is without effect on ERK, JNK, or p38 MAP kinase pathways or on signaling pathways activated in response to serum. **1.** Laping, Grygielko, Mathur, *et al.* (2002) *Mol. Pharmacol.* **62**, 58. **2.** Inman, Nicolas, Callahan, *et al.* (2002) *Mol. Pharmacol.* **62**, 65. **3.** Halder, Beauchamp & Datta (2005) *Neoplasia* **7**, 509.

## SB505124

This selective TGF $\beta$ R inhibitor (FW = 335.40 g/mol; CAS 694433-59-5; Solubility: 67 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O; 2-(4-(benzo[d][1,3]dioxol-5-yl)-2-*tert*-butyl-1*H*-imidazol-5-yl)-6-methylpyridine) potently targets the Activin receptor-Like Kinase activities of Transforming Growth Factor- $\beta$  (TGF- $\beta$ ) receptors: ALK4 (IC<sub>50</sub> = 129 nM) and ALK5 (IC<sub>50</sub> = 47 nM), also inhibiting ALK7, but not ALK1, 2, 3, or 6 (1). Docking studies point to specificity-conferring hydrogen bond interactions between SB-505124 and amino acids His-283 and Ser-280 of ALK-5 (2). SB505124 brings about concentration-dependently inhibitions ALK4-, ALK5-, and ALK 7-dependent activation of downstream cytoplasmic signal transducers, Smad2 and Smad3, and of TGF- $\beta$ -induced mitogen-activated protein kinase pathway components but does not alter ALK1, ALK2, ALK3 or ALK6-induced Smad signaling. SB-505124 also inhibits more complex endpoints of TGF- $\beta$  action, as evidenced by its ability to abrogate cell death caused by TGF- $\beta$ 1 treatment (1). SB-505124 blocks TGF- $\beta$ -induced cytoskeletal alterations (*i.e.*, filipodia formation and F-actin assembly) in endothelial cells linked to nitric oxide generation and cell-cell interactions (3). Likewise, migration and invasion by MCF-7-M5 cells are suppressed by SB-505124, whereas anti-estrogens do not suppress the motile properties of these cells (4). 1. DaCosta, Byfield, Major, Laping & Roberts (2004) *Mol. Pharmacol.* **65**, 744. 2. Sapiro, Dunmire, Scott, *et al.* (2010) *Mol. Vis.* **16**, 1880. 2. Hu, Ramachandrarao, Siva, *et al.* (2005) *Am. J. Physiol. Renal Physiol.* **289**, F816. 3. Goto, Hiyoshi, Ito, *et al.* (2011) *Cancer Sci.* **102**, 1501.

#### SB 706504

This p38 inhibitor (FW = 492.46 g/mol; CAS 911110-38-8; Solubility: 100 mM in DMSO), also named *N*-cyano-*N'*-[2-[[8-(2,6-difluorophenyl)-4-(4-fluoro-2-methylphenyl)-7,8-dihydro-7-oxopyrido[2,3-*d*]pyrimidin-2-yl]amino]ethyl]guanidine, targets p38 mitogen-activated protein kinase (MAPK), a signaling enzyme known to be increased in macrophages of individuals with chronic obstructive pulmonary disease (COPD). Extracellular stimuli, including the TOLL-like receptor (TLR) 4 ligand lipopolysaccharide and cytokines activate p38 MAPK signaling, up-regulating production of proinflammatory cytokines and chemokines by activating such transcription factors as NF $\kappa$ B and Activating Transcription Factor 2 or by altering chromatin structure to allow NF $\kappa$ B binding to the promoter regions of inflammatory genes. When LPS-stimulated monocyte-derived macrophages (MDMs) and alveolar macrophages (AMs) are cultured with dexamethasone and/or SB706504, the latter causes transcriptional inhibition of a range of cytokines and chemokines in COPD MDMs. Combined use of SB706504 and dexamethasone caused greater suppression of gene expression (-8.90), when compared to SB706504 alone (-2.04) or dexamethasone (-3.39). SB706504 significantly inhibits LPS-stimulated TNF $\alpha$  production from COPD and smoker AMs, with near-maximal suppression caused by targeting a subset of inflammatory macrophage genes and when used with dexamethasone causes effective suppression of these genes. 1. Kent, Smyth, Plumb, *et al.* (2009) *J. Pharmacol. Exp. Ther.* **328**, 458.

#### SB-715992, See *Ispinesib*

#### SB 743921

This selective cell-cycle inhibitor (FW = 553.52 g/mol; CAS 940929-33-9 (hydrochloride), 618430-39-0 (free base); Solubility: 110 mg/mL DMSO; 20 mg/mL H<sub>2</sub>O), also known as (*R*)-*N*-(3-aminopropyl)-*N'*-(1-(3-benzyl-7-chloro-4-oxo-4*H*-chromen-2-yl)-2-methylpropyl)-4-methylbenzamide hydrochloride, inhibits Kinesin Spindle Protein (KSP), a member of the kinesin superfamily of microtubule-based motors that plays a critical role in mitosis by mediating centrosome separation and bipolar spindle assembly and maintenance. Inhibition of KSP function leads to cell cycle arrest at mitosis with the formation of monoastrial microtubule arrays, and ultimately, to cell death. The *K<sub>i</sub>* values for SB 743921 inhibition of human and mouse KSP are 0.1 nM and 0.12 nM, respectively, while the *K<sub>i</sub>* values for inhibition of other kinesins (including MKLP1, and Kin2) exceed 70  $\mu$ M. **Note:** The target KSP must not be confused with the neurofilament-directed protein kinases that phosphorylate KSPXXXX (or Lys-Ser-Pro-Xaa-Xaa-Xaa-Xaa) sequences in light, medium- and high-molecular weight neurofilament proteins. 1. Sakowicz, Finer, Beraud *et al.* (2004) *Cancer Res.* **64**, 3276.

#### SB-3CT, See (4-Phenoxyphenylsulfonyl)methylthiirane

#### SB-RA-2001

This taxane (FW = 319.32 g/mol) inhibits the proliferation of *Bacillus subtilis* 168 and *Mycobacterium smegmatis*, with minimum inhibitory concentrations of 38 and 60  $\mu$ M, respectively. The lengths of these microorganisms increase remarkably in the presence of SB-RA-2001, indicating inhibition of cytokinesis. SB-RA-2001 also perturbs formation of FtsZ ring in *B. subtilis* 168 cells and also altered the mid-cell localization of the late cell division protein, DivIVA. Flow cytometric analysis of the SB-RA-2001-treated *B. subtilis* cells indicated that the compound did not affect DNA replication. SB-RA-2001 does not affect the localization of the chromosome-partitioning protein, Spo0J, along the two ends of the nucleoids and is without discernable effect on the nucleoid segregation. *In vitro*, SB-RA-2001 binds to FtsZ with modest affinity, promotes assembly and bundling of FtsZ protofilaments, and reduces FtsZ GTPase activity. GTP did not alter SB-RA-2001 binding to FtsZ. Instead of binding to the nucleotide site, SB-RA-2001 binds in a cleft region between the C-terminal domain and H<sup>1</sup> helix, resembling FtsZ interactions with PC190723, a well-

characterized inhibitor of FtsZ. The findings suggest SB-RA-2001 inhibits bacterial proliferation by targeting FtsZ assembly dynamics of and this can be exploited further to develop potent FtsZ targeted antimicrobials. (See PC190723) 1. Singh, Bhattacharya, Rai, *et al.* (2014) *Biochemistry* **53**, 2979.

## SC-236

This sulfonamide (FW = 401.80 g/mol), known systematically as 4-[5-(4-chlorophenyl)-3-(trifluoromethyl)-1H-pyrazol-1-yl]benzenesulfonamide, is a strong inhibitor of cyclooxygenase-2 ( $IC_{50} = 0.01 \mu\text{M}$ ), exhibiting a preference over cyclooxygenase-1,  $IC_{50} = 17.8 \mu\text{M}$  (1-4). SC-236 also inhibits angiogenesis in a dose-dependent manner. 1. Castano, Barrtons & Gil (2000) *J. Pharmacol. Exp. Ther.* **293**, 509. 2. Masferrer, Koki & Seibert (1999) *Ann. N. Y. Acad. Sci.* **889**, 84. 3. Penning, Talley, Bertenshaw, *et al.* (1997) *J. Med. Chem.* **40**, 1347. 4. Gierse, McDonald, Hauser, *et al.* (1996) *J. Biol. Chem.* **271**, 15810.

## SC-514

This orally active, ATP-competitive IKK-2 inhibitor (FW = 224.30 g/mol; CAS 354812-17-2; Solubility: 44 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also named 4-amino[2,3'-bithiophene]-5-carboxamide, blocks NF- $\kappa$ B-dependent gene expression ( $IC_{50} = 3\text{-}12 \mu\text{M}$ ), without affecting other IKK isoforms or other serine-threonine and tyrosine kinases. **Mode of Inhibitor Action:** NF $\kappa$ B-induced gene expression contributes significantly to the pathogenesis of inflammatory diseases, such as arthritis. The I $\kappa$ B kinase is an upstream component of the NF- $\kappa$ B signal transduction cascade, I $\kappa$ B $\alpha$  (or Inhibitor of  $\kappa$ B) is a protein that inactivates NF- $\kappa$ B transcription factor by masking its nuclear localization signals. SC-514 does not inhibit the phosphorylation and activation of the IKK complex. Its action is characterized by a delay, but not a complete blockade, in I $\kappa$ B $\alpha$  phosphorylation and degradation. There is also slightly slowed p65 nuclear import as well as faster export from the nucleus. IKK-2I has comparable  $K_m$  and  $k_{cat}$  values for  $\kappa$ B $\alpha$  and p65 as substrates, and SC-514 likewise inhibits their phosphorylation to a similar degree. 1. Kishore, Sommers, Mathialagan, *et al.* (2003) *J. Biol. Chem.* **278**, 32861.

## SC-558

This substituted pyrazole (FW = 446.25 g/mol), also known as 4-[5-(4-bromophenyl)-3-(trifluoromethyl)-1H-pyrazol-1-yl]benzenesulfonamide, is a strong inhibitor of cyclooxygenase-2,  $IC_{50} = 9.3 \text{ nM}$ , exhibiting a preference over cyclooxygenase-1,  $IC_{50} = 17.7 \mu\text{M}$  (1,2). 1. Chavatte, Yous, Marot, Baurin & Lesieur (2001) *Bioorg. Med. Chem.* **44**, 3223. 2. Kurumbail, Stevens, Gierse, *et al.* (1996) *Nature* **384**, 644.

## SC-560

This orally active agent (FW = 352.74 g/mol; CAS 188817-13-2), also known as 5-(4-chlorophenyl)-1-(4-methoxyphenyl)-3-trifluoromethyl pyrazole, is a selective inhibitor of cyclooxygenase-1,  $IC_{50} = 9 \text{ nM}$ , showing markedly weaker action against cyclooxygenase-2,  $IC_{50} = 6.3 \mu\text{M}$ . SC-560 does not inhibit COX-2-derived PGs in the lipopolysaccharide-induced rat air pouch. Therapeutic or prophylactic administration of SC-560 in the rat carrageenan footpad model does not affect acute inflammation or hyperalgesia at doses that markedly inhibits *in vivo* COX-1 activity. 1. Smith, Zhang, Koboldt, *et al.* (1998) *Proc. Natl. Acad. Sci. U.S.A.* **95**, 13313.

## SC 19220

This selective EP<sub>1</sub> receptor antagonist (FW = 331.76 g/mol; CAS 19395-87-0; Soluble to 100 mM in DMSO), also named 8-chlorodibenz[b,f][1,4]oxazepine-10(11H)-carboxylic 2-acetylhydrazide, targets human prostaglandin EP<sub>1</sub> receptor, with an  $IC_{50}$  value of 6.7  $\mu\text{M}$  for inhibiting binding of [<sup>3</sup>H]-PGE<sub>2</sub> to EP<sub>1</sub> transfected COS cells. 1. Sanner (1972) *Intra-Science Chem. Report* **6**, 1. 2. Funk *et al.* (1993) *J. Biol. Chem.* **268**, 26767. 3. Botella, *et al.* (1995) *J. Pharmacol. Exp. Ther.* **273**, 1008.

## SC12267, See 4SC-101

## SC 26196

This desaturase inhibitor (FW = 423.55 g/mol; CAS 218136-59-5; Soluble to 25 mM in DMSO), also named  $\alpha,\alpha$ -diphenyl-4-[(3-pyridinylmethylene)amino]-1-piperazinepentanenitrile, targets  $\Delta^6$ -desaturase ( $IC_{50} = 0.2 \mu\text{M}$ , *in vitro*), the rate-limiting step in the polyunsaturated fatty acid (PUFA) biosynthetic pathway. It displays 1000x selectivity over  $\Delta^5$  and  $\Delta^9$  desaturases ( $IC_{50}$  values are >200  $\mu\text{M}$ ). That the antiinflammatory properties of SC-26196 are consistent with its action *in vivo* as a  $\Delta^6$ -desaturase inhibitor is evidenced by: (a) the strong correlation between liver  $\Delta^6$ -desaturase inhibition and decreased edema; (b) the time-dependent decreased in edema upon SC-26196 administration; (c) SC-26196's dose-dependent action in reducing arachidonate in liver, plasma and peritoneal cells; and (d) the reversal of changes resulting from SC-26196 inhibition

upon controlled refeeding of arachidonic acid, but not oleic acid (1). SC-26196 also impedes intestinal tumorigenesis (2). 1. Obukowicz, Welsch, Salsgiver, *et al.* (1998) *J. Pharmacol. Exp. Ther.* **287**, 157. 2. Hansen-Petrik, McEntee, Johnson, *et al.* (2002) *Cancer Lett.* **175**, 157.

**SC-52551**

This pseudopeptide-containing peptidomimic (FW = 604.75 g/mol) is a potent inhibitor of human immunodeficiency virus I retropepsin, *or* HIV-I protease, with a *K*<sub>i</sub> value for the *R*-stereoisomer is 6.1 nM (1,2). SC-52551 inhibition prevents cleavage of the viral polyproteins resulting in the formation of immature non-infectious viral particles. Protease inhibitors are almost always used in combination with at least two other anti-HIV drugs. 1. Vacca (1994) *Meth. Enzymol.* **241**, 311. 2. Getman, DeCrescenzo, Heintz, *et al.* (1993) *J. Med. Chem.* **36**, 288.

**SC-58125**

This substituted pyrazole (FW = 384.35 g/mol), also known as 1-[(4-methylsulfonyl)phenyl]-3-trifluoromethyl-5-(4-fluorophenyl)pyrazole, irreversibly inhibits cyclooxygenase-2, IC<sub>50</sub> = 0.05 μM, showing a preference over cyclooxygenase-1, IC<sub>50</sub> > 10 μM (1-3). 1. Gierse, McDonald, Hauser, *et al.* (1996) *J. Biol. Chem.* **271**, 15810. 2. Seibert, Zhang, Leahy, *et al.* (1994) *Proc. Natl. Acad. Sci. U.S.A.* **91**, 12013. 3. Patrignani, Panara, Sciuilli, *et al.* (1997) *J. Physiol. Pharmacol.* **48**, 623.

**SC-58272**

This substituted dipeptide (FW<sub>free-base</sub> = 596.81 g/mol) is a potent inhibitor of glycolipid *N*-tetradecanoyltransferase, *or* protein *N*-myristoyltransferase, IC<sub>50</sub> = 56 nM (1-3). 1.  2. Vogt, Rice, Settineri, *et al.* (1998) *J. Pharmacol. Exp. Ther.* **287**, 806.

**4SC-101**

This uridine biosynthesis inhibitor (FW = 355.37 g/mol), also named 2-(3-fluoro-3'-methoxybiphenyl-4-carbamoyl)cyclopent-1-enecarboxylic acid and formerly as SC12267, targets dihydroorotate dehydrogenase, or DHODH, which catalyzes the fourth step in the *de novo* pyrimidine biosynthesis, converting dihydroorotate to orotate. *De novo* pyrimidine biosynthesis is essential for supplying DNA precursors in rapidly proliferating cells, and DHODH inhibition suppresses the rapid expansion of autoreactive lymphocytes in autoimmune diseases. 4SC-101 also inhibits the proliferation of phytohemagglutinin-stimulated lymphocytes (IC<sub>50</sub> ≈ 13 μM) and phytohemagglutinin-induced interleukin-17 secretion from human peripheral blood mononuclear cells, or PBMCs (IC<sub>50</sub> ≈ 6 μM), but independently of lymphocyte proliferation (1,2). 4SC-101 acts as a novel immunosuppressive drug, inhibits IL-17, attenuating colitis in two murine models of inflammatory bowel disease (3). **Mode of Inhibitory Action:** Structural studies indicate that the  $\alpha$ - and  $\beta$ -barrel domains of DHODH form a tunnel through which substrates gain access to the active site, and compounds interacting with the  $\alpha$ - and the  $\beta$ -barrel domains are known to block DHODH activity. (See also *Leflunomide*) 4SC-101 likewise binds in this region, IC<sub>50</sub> = 134 nM (1,2).

**4SC-207**

This microtubule-directed antineoplastic agent (FW = 382.44 g/mol; Solubility: 25 mM in DMSO), also known as (*E*)-ethyl 3-cyano-2-(3-(pyridin-3-yl)acrylamido)-4,5-dihydrothieno[2,3-*c*]pyridine-6(7*H*)-carboxylate, inhibits tubulin polymerization *in vivo*, strongly reducing both the rate and extent of microtubule self-assembly. Cells treated with 4SC-207 are delayed in mitosis, unable to complete chromosome alignment, or to maintain a metaphase plate. In many cells, spindles are disorganized, unstable, and marked by the appearance of extra poles. 4SC-207 also shows strong anti-proliferative activity in a large panel of tumor cell lines (average GI<sub>50</sub> ≈ 11nM). Importantly, 4SC-207 is active in multi-drug-resistant cell lines (*e.g.*, HCT-15 and ACHN), suggesting it is a poor substrate for drug

efflux pumps. 4SC-207 inhibits microtubule growth *in vivo* and promotes mitotic delay/arrest in a dose-dependent manner, followed by apoptosis or aberrant divisions due to chromosome misalignment and multi-polar spindle formation. 4SC-207 exhibits a low propensity towards bone marrow toxicity at concentrations that inhibit tumor growth in paclitaxel-resistant xenograft models.

SCH 44342

This substituted piperidine (FW = 429.95 g/mol), known systematically as (1-(4-pyridylacetyl)-4-(8-chloro-5,6-dihydro-11*H*-benzo[5,6]cyclohepta[1,2-*b*]pyridin-11-ylidene)piperidine, was one of the earliest nonpeptidic, nonthiol inhibitors of both rat brain and recombinant human protein farnesyltransferases with an IC<sub>50</sub> value of ~250 nM. SCH 44342 also weakly inhibits rat brain protein geranylgeranyltransferase type 1, IC<sub>50</sub> > 115 μM. SCH 44342 behaves as a competitive inhibitor with respect to the protein substrate (1-3). 1. Gibbs (2001) *The Enzymes*, 3rd ed., **21**, 81. 2.

Bishop, Bond, Petrin, *et al.* (1995) *J. Biol. Chem.* **270**, 30611. 3.  
Yokoyama, Trobridge, Buckner, *et al.* (1998) *J. Biol. Chem.* **273**, 26497.

**SCH 47896**

This small peptide (FW<sub>free-acid</sub> = 430.46 g/mol), known systematically as *N*-[*N*-[1-(*S*-carboxyl-3-(4-hydroxyphenyl)propyl)]-(*S*)-phenylalanyl]-(*S*)-isoserine, inhibits neutral endopeptidase, *or* neprilysin ( $K_i$  = 85.1 nM), the neutral metalloendopeptidase (EC 3.4.24.11) that rapidly degrades atrial natriuretic peptide (ANP), with the kidney being a major site of ANP clearance. 1. Kanazawa, Casley, Sybertz, Haslanger & Johnston (1992) *J. Pharmacol. Exp. Ther.* **261**, 1231.

**SCH48446**

This peptidomimetic (FW<sub>free-acid</sub> = 682.25 g/mol), known systematically as *N*-[*N*-[1-(*S*-carboxyl-3-(4-hydroxy-3,5-diiodophenyl)propyl)]-(*S*)-phenylalanyl]-(*S*)-isoserine, inhibits neutral endopeptidase, *or* neprilysin ( $K_i$  = 43.3 nM), the enzyme responsible for degrading Atrial natriuretic peptide (ANP) in the kidney (1). Neprilysin activity in rat kidney was inhibited by specific NEP inhibitors (phosphoramidon, thiorphan, SCH39370, SCH47896 and SCH48446) at  $\mu$ M concentrations. SCH48446 is the di-iodo analogue of SCH47896, which itself is a phenolic derivative of SCH39370. Autoradiography with [<sup>125</sup>I]SCH47896 demonstrated that maximal binding occurs in the outer stripe of the outer medulla and to the inner cortex, a finding that is consistent with binding to the deep proximal tubules. Moreover, these results indicate that degradation of ANP by neprilysin occurs mainly in the deep proximal tubules and that the proximal convoluted tubule within the outer cortex is unlikely to be a major site of neprilysin. 1. Kanazawa, Casley, Sybertz, Haslanger & Johnston (1992) *J. Pharmacol. Exp. Ther.* **261**, 1231. 2. Kanazawa, Yasujima, Kohzuki & Abe (1994) *Nihon. Jinzo. Gakkai. Shi.* **36**, 791.

**SCH 51866**

This purine derivative (FW = 389.15 g/mol) inhibits 3',5'-cyclic-GMP phosphodiesterases, *or* cGMP phosphodiesterase (1-8); cGMP phosphodiesterase-12 (4,8), cGMP phosphodiesterase-5 (3,4); cGMP phosphodiesterase-7 (5,6), and cGMP phosphodiesterase-9 (1,2,7). 1. **SCH 53239**

This nucleotide exchange inhibitor (FW = 520.55 g/mol; CAS 188480-51-5) targets Ras-GDP, binding to the critical switch II region in the Ras protein, based on intra- and inter-molecular NOE distance constraints. Ras protein exists in two conformations that are in slow exchange on the NMR timescale. Reversible conformational changes occur mainly in the GDP-binding pocket, within the switch I and the switch II regions. 1. Ganguly, Wang, Pramanik, *et al.* (1998) *Biochemistry* **37**, 15631.

**SCH58235, See Ezetimibe****SCH58261**

This adenosine receptor antagonist (FW = 345.36 g/mol; CAS 160098-96-4; Solubility: 69 mg/mL; < 1 mg/mL H<sub>2</sub>O), also named [7-(2-phenylethyl)-5-amino-2-(2-furyl)pyrazolo[4,3-*e*]-1,2,4-triazolo[1,5-*c*]pyrimidine], potently and selectively targets A<sub>2A</sub> receptors ( $K_i$  = 2.3 nM, rat;  $K_i$  = 2 nM, bovine) (1). SCH 58261 does not show affinity for either the A<sub>3</sub> receptors or other receptors at concentrations up to 1  $\mu$ M (1). Saturation experiments on rat A<sub>1</sub> and A<sub>2a</sub> adenosine receptors indicated the competitive nature of the antagonism. SCH 58261 antagonizes competitively the effects induced by the A<sub>2a</sub> adenosine-selective agonist CGS 21680 as a rabbit platelet aggregation inhibitor and porcine coronary artery relaxation (1). SCH58261 protects against spinal cord injury through peripheral and central effects (2). 1. Zocchi, Ongini, Conti, *et al.* (1996) *J. Pharmacol. Exp. Ther.* **276**, 398. 2. Paterniti, Melani, Cipriani, *et al.* (2011) *J. Neuroinflam.* **8**, 31.

**SCH66336, See Lonafarnib****SCH79797**

This nonpeptide receptor antagonist (FW<sub>free-base</sub> = 371.21 g/mol; FW<sub>dihydrochloride</sub> = 444.41 g/mol; CAS 245520-69-8; Solubility: 50 mM in DMSO), also known as *N*<sup>3</sup>-cyclopropyl-7-[[4-(1-methylethyl)phenyl]methyl]-7*H*-pyrrolo[3,2-*f*]quinazoline-1,3-diamine dihydrochloride, potently and selectively targets the Protease-Activated Receptor-1, *or* PAR<sub>1</sub> (IC<sub>50</sub> = 70 nM), inhibiting haTRAP-induced platelet aggregation, but having no effect on  $\gamma$ -thrombin-, ADP- or collagen-induced aggregation. SCH79797 also selectively blocks PAR<sub>1</sub> agonist- or thrombin-induced

increases in cytosolic  $\text{Ca}^{2+}$  in vascular smooth muscle cells (1-4). **Antiamnesic Properties:** Minimal Traumatic Brain injury (mTBI) is associated with retrograde amnesia and microscopic bleeds, the latter containing activated coagulation factors. In an mTBI model, intracerebroventricular injection of thrombin or a PAR-1 agonist (1 hour after memory acquisition) induces amnesia through its receptor PAR<sub>1</sub>. Long-term potentiation, measured in hippocampal slices 24 h after mTBI, ICV thrombin or the PAR-1 agonist, was significantly impaired and this effect was completely reversed by the PAR-1 antagonist. Such findings reveal a novel therapeutic target for the cognitive effects of brain trauma. Significantly, SCH79797 completely blocks the amnesic effects of thrombin and the PAR-1 agonist in a Minimal Traumatic Brain injury (mTBI). 1. Ahn, Arik, Boykow, *et al.* (1999) *Bioorg. Med. Chem. Lett.* **9**, 2073. 2. Ahn, Foster, Boykow, *et al.* (2000) *Biochem. Pharmacol.* **60**, 1425. 3. Lidington, Steinberg, Kinderlerer, *et al.* (2005) *Am. J. Physiol. Cell Physiol.* **289**, C1437. 4. Itzekson, Maggio, Milman, *et al.* (2013) *J. Mol. Neurosci.* **53**, 87.

**SCH 351125**

This oral first-in-class retroviral entry inhibitor (FW = 557.50) is a HIV-1 co-receptor CCR antagonist. While SCH-C exhibits potent activity against clinical HIV-1 R5 isolates, both *in vitro* and in mouse models, it shows no effectiveness against HIV-1 X4 isolates. In view its dose-dependent prolongation of the corrected cardiac QT interval, further development of SCH 351125 was abandoned in favor of developing more effective agents. Other similarly acting viral entry inhibitors include: aplaviroc, viviviroc, TAK-779, and Maraviroc. By contrast, the entry inhibitor PRO 140 is a human monoclonal antibody to the CCR5 receptor. 1. Strizki, Xu, Wagner, *et al.* (2001) *Proc. Natl. Acad. Sc. U.S.A.* **98**, 12718.

**SCH 530348, See Vorapaxar**

**SCH619734, See Rolapitant**

**SCH727965, See Dinaciclib**

**SCH 772984**

This novel ATP-competitive protein kinase inhibitor (FW = 587.67 g/mol; CAS 942183-80-4; Solubility: <1 mg/mL DMSO or H<sub>2</sub>O), also named (*R*)-1-(2-oxo-2-(4-(4-(pyrimidin-2-yl)phenyl)piperazin-1-yl)ethyl)-*N*-(3-(pyridin-4-yl)-1*H*-indazol-5-yl)pyrrolidine-3-carboxamide, specifically targets both Extracellular-signal-Regulated Kinase ERK1 (IC<sub>50</sub> = 4 nM) and ERK2 (IC<sub>50</sub> = 1 nM). SCH772984 has nanomolar cellular potency in tumor cells with mutations in BRAF, NRAS, or KRAS and induces tumor regressions in xenograft models at tolerated doses. Importantly, SCH772984 effectively inhibited MAPK signaling and cell proliferation in BRAF or MEK inhibitor-resistant models as well as in tumor cells resistant to concurrent

treatment with BRAF and MEK inhibitors. 1. Morris, Jha, Restaino, *et al.* (2013) *Cancer Discov.* **3**, 742. 2. Nissan, Rosen & Solit (2013) *Cancer Discov.* **3**, 719.

**SCH 900776**

This cyclin kinase-directed inhibitor (FW = 376.25 g/mol; CAS 891494-63-6; Solubility: 75 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O; Formulation: Dissolve in 20% hydroxypropyl β-cyclodextrin), systematically named 6-bromo-3-(1-methyl-1*H*-pyrazol-4-yl)-5-((*R*)-piperidin-3-yl)pyrazolo[1,5-*a*]pyrimidin-7-amine, selectively targets the serine-threonine, cell-cycle checkpoint kinase Chk1 inhibitor with IC<sub>50</sub> of 3 nM and also inhibits CDK2 with IC<sub>50</sub> of 160 nM. Chk1 is essential for maintenance of replication fork viability during exposure to DNA antimetabolites. **Cyclin Target Selectivity:** Cdk1 (weak, if any), Cdk2 (weak, if any), Cdk3 (weak, if any), Cdk4 (weak, if any), Cdk5 (weak, if any), Cdk6 (weak, if any), Cdk7 (weak, if any), Cdk8 (weak, if any), Cdk9 (weak, if any), Cdk10 (weak, if any), CHK1 (+++). 1. Guzi, *et al.* (2011) *Mol. Cancer Ther.* **10**, 591. 2. Montano, *et al.* (2012) *Mol. Cancer Ther* **11**, 427. 3. Schenk, *et al.* (2012) *Clin. Cancer Res.* **18**, 5364.

**Scopolamine**

(-)-Scopolamine

This nonselective antimuscarinic agent (FW<sub>free-base</sub> = 303.36 g/mol; CAS 51-34-3), also known as L-hyosicine and scopolamine tropate, is the competitive antagonist (IC<sub>50</sub> = 55 nM) of acetylcholine and other muscarinic agonists. Scopolamine induces amnesia and has also been used as a truth serum for extracting information. The free base decomposes upon standing at room temperature, whereas the hydrochloride is much more stable at room temperature. **Target(s):** cholinesterase, *or* butyrylcholinesterase (1); muscarinic cholinergic receptors (2). 1. Nagasawa, Sugisaki, Tani & Ogata (1976) *Biochim. Biophys. Acta* **429**, 817. 2. Frey & Howland (1992) *J. Pharmacol. Exp. Ther.* **263**, 1391.

**Scopolamine N-Oxide**

This scopolamine derivative (FW = 319.36 g/mol; CAS 97-75-6; HBr salt is soluble to 10 g/100 mL H<sub>2</sub>O), also known as hyosicine *N*-oxide, and systematically as [(1α,2β,4β,5α)-9-methyl-3-oxa-9-azatricyclo[3.3.1.0<sup>3,4</sup>]-nonane 9-oxide]-7β-yl (*S*)-α-(hydroxy-methyl)-benzeneacetate, is a muscarinic receptor antagonist. Under the same conditions, the p*K*<sub>a</sub> of hyosicine *N*-oxide is 5.78, with the unprotonated form inactive on

muscarinic receptors in the ileum. By contrast, the protonated form is highly active with  $-\log K$  estimated to be 9.9, at least as active as hyosine methobromide ( $-\log K = 9.85$ ). 1. Barlow & Winter (1981) *Brit. J. Pharmacol.* **72**, 657.

### Scopoletin

This hydroxycoumarin (FW = 192.17 g/mol; CAS 92-61-5; Slightly soluble in H<sub>2</sub>O;  $\lambda_{\max}$  at 230 nm ( $\epsilon_M = 12900 \text{ M}^{-1}\text{cm}^{-1}$ ), 254 nm ( $\epsilon_M = 4790 \text{ M}^{-1}\text{cm}^{-1}$ ), 260 nm ( $\epsilon_M = 4270 \text{ M}^{-1}\text{cm}^{-1}$ ), 298 nm ( $\epsilon_M = 4790 \text{ M}^{-1}\text{cm}^{-1}$ ), and 346 nm ( $\epsilon_M = 11700 \text{ M}^{-1}\text{cm}^{-1}$ ), also known as 7-hydroxy-6-methoxy-2H-1-benzopyran-2-one, inhibits cell proliferation and induces apoptosis. **Target(s):** arylamine *N*-acetyltransferase (1,2); monoamine oxidase (3); nitric-oxide synthase (4); phenylalanine ammonia-lyase (5); phenylpyruvate tautomerase (6); and xanthine oxidase (7,8). 1. Kukongviriyapan, Phromsopha, Tassaneeyakul, *et al.* (2006) *Xenobiotica* **36**, 15. 2. Makarova (2008) *Curr. Drug Metab.* **9**, 538. 3. Yun, Lee, Ryoo & Yoo (2001) *J. Nat. Chang & Chiang (1995) *Anticancer Res.* **15**, 1969. 8. Chang, Chang, Lu & Chiang (1994) *Anticancer Res.* **14**, 501.

### SCR7

This DNA ligase IV and NHEJ inhibitor (FW = 332.38 g/mol; CAS 14892-97-8; Solubility: 100 mM in DMSO), also named 2,3-dihydro-6,7-diphenyl-2-thioxo-4(1H)-pteridinone, when present at 1  $\mu\text{M}$ , targets Nonhomologous End-Joining, thereby significantly enhancing the efficiency of Clustered Regularly Interspaced Short Palindromic Repeat-Cas-9 (or CRISPR-Cas9)-mediated homology-directed repair (HDR) *in vitro* (1-3). CRISPR-Cas9 is a prokaryotic immune system that confers resistance to foreign genetic elements such as plasmids and phages, and provides a form of acquired immunity. Insertion of precise genetic modifications by genome editing tools such as CRISPR-Cas9 is limited by the relatively low efficiency of homology-directed repair (HDR) compared with the higher efficiency of the NHEJ pathway (1). Indeed, NHEJ is an alternative DNA repair pathway that directly competes with homology-directed repair (HDR) (2). **Selectivity:** Scr7 targets the DNA binding domain of DNA Ligase IV, reducing its affinity for DSBs and inhibiting its function (4). It also inhibits DNA Ligase III (but not DNA Ligase I), albeit less efficiently (1) Treatment of mice with Scr7 affects lymphocyte development, as DNA Ligase IV plays a key role in the joining of coding ends during V(D)J recombination via C-NHEJ (1). 1. Srivastava, *et al.* (2012) *Cell.* **151**:1474. 2. Maruyama, Dougan, Truttmann, *et al.* (2015) *Nature Biotechnol.* **33**, 538. 3. Chu, Weber, Wefers, *et al.* (2015) *Nature Biotechnol.* **33**, 543.

### Scriptaid

This active-site-directed, high-affinity hydroxamate (FW = 326.35 g/mol; CAS 287383-59-9), also known as Scriptide<sup>®</sup>, GCK 1026, and *N*-hydroxy-1,3-dioxo-1H-benz[de]isoquinoline-2(3H)-hexanamide, inhibits histone

deacetylase, showing a greater effect on acetylated H4 than H3 (1). Use of Scriptaid (optimally at 6–8  $\mu\text{M}$ ) results in a one hundred times increase in histone acetylation in cultured cells, confirming HDAC inhibition. The hydroxamic acid group coordinates to the zinc atom in HDAC's polar pocket within the HDAC-Zn<sup>2+</sup>-TSA complex (2). The hydroxamic acid group on a Scriptaid analogue extends from a 5-carbon aliphatic chain spanning a narrow tube-like pit formed by the surface of HDAC (2). Nanomolar concentrations of suberoylanilide hydroxamic acid (SAHA), suberic bishydroxamic acid (SBHA), Scriptaid (IC<sub>50</sub> = 39 nM), and trichostatin A (TSA) inhibited *Toxoplasma gondii* tachyzoite proliferation. Scriptaid was the most potent hydroxamic acid inhibitor. For comparison, other carboxylate histone deacetylase inhibitors (such as sodium valproate, sodium butyrate, and 4-phenylbutyrate) were far less potent, IC<sub>50</sub> range = 1–5 mM (3). Quantitative Real-Time PCR showed 2000–20,000x increase of estrogen receptor  $\alpha$  (ER) mRNA transcript in three cell lines after a 48-hour treatment with Scriptaid (4). Moreover, Scriptaid and AZA co-treatment is more effective in inducing ER than Scriptaid or AZA alone. Scriptaid induces the growth inhibition of endometrial and ovarian cancer cells, decreasing the proportion of cells in the S phase and increased the proportion in the G<sub>0</sub>/G<sub>1</sub> and/or G<sub>2</sub>/M phases (5). Induction of apoptosis is confirmed by annexin V staining of externalized phosphatidylserine and loss of the transmembrane potential of mitochondria. Scriptaid elicited a dose-dependent decrease in lesion size at 1.5 to 5.5 mg/kg and a concomitant attenuation in motor and cognitive deficits when delivered 30 minutes postinjury in a model of moderate traumatic brain injury, or TBI (6). 1. Su, Sohn, Ryu & Kern (2000) *Cancer Res.* **60**, 3137. 2. Finnin, Donigian, Cohen, *et al.* (1999) *Science* **401**, 188. 3. Strobl, Cassell, Mitchell, *et al.* (2007) *J. Wang, Jiang, Pu, *et al.* (2013) *Neurotherapeutics* **10**, 124.

### SCS

This GABA receptor antagonist (FW = 256.26 g/mol; CAS 3232-36-8; Soluble to 50 mM in DMSO) shows sub-type selectivity in targeting the  $\beta_1$  subunit-containing GABA<sub>A</sub> receptors, with respective IC<sub>50</sub> values of 4.5, 5.3, and 7.9 nM for  $\alpha_2\beta_1\gamma_1\theta$ ,  $\alpha_2\beta_1\gamma_1$  and  $\alpha_2\beta_1\gamma_2$  GABA<sub>A</sub> receptor sub-types. 1. Thompson, Wheat, Brown, *et al.* (2004) *Brit. J. Pharmacol.* **142**, 97.

### Scutellarein

This yellow flavonol (FW = 286.24 g/mol; CAS 529-53-3), also known as 4',5,6,7-tetrahydroxyflavone, is the aglycon of scutellarin. Care should be exercised when searching the literature to avoid confusing scutellarein and scutellarin with scutellarin, an endopeptidase from *Oxyuranus scutellatus*. **Target(s):** avian myeloblastosis reverse transcriptase (1); cAMP phosphodiesterase (2); Maloney murine leukemia virus reverse transcriptase (1); RNA-directed DNA polymerase (1); and Rous-associated virus-2 reverse transcriptase (1). 1. Spedding, Ratty & Middleton, Jr. (1989) *Antiviral Res.* **12**, 99. 2. Kuppusamy & Das (1992) *Biochem. Pharmacol.* **44**, 1307.

### Scyptolin A and B

These depsipeptides (for Scyptolin A, FW = 981.54 g/mol, where R = H; for Scyptolin B (FW = 1139.72 g/mol), where R = *N*-butyryl-L-alanine) from the terrestrial cyanobacterium *Scytonema hofmanni* PCC 7110, inhibit pancreatic elastase (1,2). Note the presence of a *cis*-peptide bond between the L-threonyl and *N*-methyl-3'-chloro-L-tyrosyl residues. 1. Matern, Schleger, Jelakovic, Weckesser & Schulz (2003) *Chem. Biol.* **10**, 997. 2. Matern, Oberer, Falchetto, *et al.* (2001) *Phytochemistry* **58**, 1087.

### Scytonemin

This cyanobacter-derived pigment (FW = 544.57 g/mol; CAS 112793-66-5) inhibits human polo-like kinase-1 (IC<sub>50</sub> = 2  $\mu$ M). Scytonemin has an extracellular photoprotective role in certain cyanobacteria, absorbing strongly and broadly. 1. Zhang, Su, Feng, *et al.* (2007) *Mol. Reprod. Dev.* **74**, 1247. 2. ### S-2E-CoA

This acyl-coenzyme A derivative (FW = 1117.07 g/mol), which is formed by metabolic conversion of commercially available (*S*)-(+)-4-[1-(4-*tert*-butylphenyl)-2-oxopyrrolidin-4-yl]methoxybenzoic acid within the liver, noncompetitively inhibits acetyl-CoA carboxylase ( $K_i$  = 69  $\mu$ M) and 3-hydroxy-3-methylglutaryl-CoA reductase ( $K_i$  = 18  $\mu$ M). 1. Ohmori, Yamada, Yasuda, *et al.* (2003) *Eur. J. Pharmacol.* **471**, 69.

### Secobarbital

This barbiturate (FW<sub>free-acid</sub> = 238.29 g/mol; CAS 76-73-3; sodium salt, very soluble in H<sub>2</sub>O), also known as Seconal and 5-(1-methylbutyl)-5-(2-propenyl)-2,4,6-(1*H*,3*H*,5*H*)-pyrimidinetrione, is a short-acting hypnotic that is often used as a sedative. It also possesses anesthetic, anticonvulsant, and anxiolytic properties. By depressing sensory cortex and motor activity, secobarbital produces drowsiness, sedation, and hypnosis. Barbiturates of this type also inhibit AP-1 complex formation as well as AP-1-dependent gene expression at clinically relevant doses. They act by suppressing the activity of mitogen-activated protein (MAP) kinase, which in turn regulates AP-1 complex formation. (In the United Kingdom, Seconal is known as Quinalbarbitone.) **Caution:** This once widely abused and habit-forming drug is now classified as a Schedule-2 controlled substance. It is also prescribed under physician-assisted euthanasia laws in Oregon, Washington, Vermont, and New Mexico. **Target(s):** acetylcholine receptor (1,2); CYP2B (3); enkephalinase A, or neprilysin (4,5); NADH dehydrogenase, or complex I, or NADH:ubiquinone reductase (6-8); phosphatidylinositol kinase (9); phosphatidylinositol 4-phosphate kinase (9); and protein kinase C (9). 1. ### $\beta$ -Secretase Inhibitor

This term refers to a class of moderately high-affinity  $\beta$ -secretase inhibitors, of which many incorporate a statine (Sta) moiety into a substrate analogue sequence, such as: L-Lys-L-Thr-L-Glu-L-Glu-L-Ile-L-Ser-L-Glu-L-Val-L-Asn-[Sta]-L-Val-L-Ala-L-Glu-L-Phe, and often exhibiting IC<sub>50</sub> values of 10–30 nM (1,2) **See specific inhibitor** 1. ### Secretory Leukocyte Protease Inhibitor

This 132-residue serine proteinase inhibitor (MW = 14,326 g; GenBank = CAA28187.1; Isoelectric Point = 9.11; Symbol = SLPI) is a non-glycosylated serpin that prevents neutrophils from attacking the underlying fibronectin or elastin components in the extracellular matrix (1,2). SLPI is an antimicrobial peptide and an anti-inflammatory molecule that targets elastase and cathepsin G from neutrophils, chymase and trypsin from mast cells, as well as trypsin and chymotrypsin from pancreatic acinar cells. **Primary Mechanism of Action:** Human neutrophils undergo actin-based chemotaxis and degranulation of proteolytic enzymes in response to changes in cytosolic calcium Ca<sup>2+</sup>, with the latter mediated inositol 1,4,5-triphosphate (IP<sub>3</sub>) production in response to G-protein-coupled receptor stimuli. Once released, neutrophil proteases rapidly degrade extracellular matrix proteins, especially fibronectin or elastin, by directing the protease's hydrolytic action to sites of cell-substrate contact (3). SLPI (~0.5  $\mu$ M) significantly inhibits fMet-Leu-Phe- (fMLP-) and interleukin-8-induced neutrophil chemotaxis and decreased degranulation of matrix metalloproteinase-9 (MMP-9), hCAP-18, and myeloperoxidase (3). SLPI is released by cells possessing mucosal surfaces (e.g., bronchia, cervix, nasal mucosa) as well as saliva and seminal fluid. Its inhibitory effect contributes to the immune response by protecting epithelial surfaces from attack by endogenous proteases. As such, Secretory Leukocyte Protease Inhibitor is a major barrier to tissue destruction by polymorphonuclear leukocytes (PMNs). SLPI is a significant component of the anti-neutrophil elastase (anti-NE) shield in the lung, with a different reactivity from, and is therefore complementary to, the anti-NE action of  $\alpha_1$ -proteinase inhibitor (4). 17 $\beta$ -Estradiol inhibits IL-8 in cystic fibrosis by upregulating secretory leukoprotease inhibitor (5). SLPI also modulates monocyte/macrophage function through inhibition of NF- $\kappa$ B signaling. **Structural Features:** SLPI has a four-disulfide core that is thought to stabilize that compensates for the absence of a typical hydrophobic core and helix or sheet secondary structure. X-ray crystallography (6) and site-directed mutagenesis (7)

identify Leu72-Met73 in human SLPI as the reactive site for inhibition of elastase, trypsin, and chymotrypsin. **Other Actions:** SLPI modulates the inflammatory and immune responses after bacterial infection, and after infection by the intracellular parasite *Leishmania major*. SLPI down-regulates host cell response to bacterial lipopolysaccharide (LPS); Plays a role in regulating the activation of NFκB and inflammatory response. SLPI exhibits antimicrobial activity against *Mycobacteria*, but not *Salmonella*. Finally, SLPI is required for wound healing, most likely by preventing tissue damage by limiting protease activity. **Targets(s):** human leukocyte elastase (EC 3.4.21.37); cathepsin G (EC 3.4.21.20); human trypsin (EC 3.4.21.4). 1. #### Secukinumab

This whole human monoclonal G1κ immunoglobulin (FW = 147.9 kDa; CASs = 875356-43-7 (heavy chain), 875356-44-8 (light chain)), also known by the trade name Cosentyx<sup>®</sup>, binds to interleukin IL-17A, blocking its receptor signaling and demonstrating efficacy in the systemic treatment of moderate-to-severe plaque psoriasis. The latter is a chronic and disabling inflammatory skin disease, the pathogenesis of which is linked to several cytokines and chemokines, particularly IL-17A. Increased helper T cells (T<sub>H</sub>17) and elevated levels of IL-17A are found in psoriatic plaques, and increased levels of T<sub>H</sub>17 are likewise present in the plasma of psoriasis patients. Elevated IL-17A also induces neutrophilia, inflammation, and angiogenesis. IL-17A also plays a key role in host defense, particularly in mucocutaneous immunity against *Candida albicans*, as well as in hematopoiesis, the latter through stimulation of granulopoiesis and neutrophil trafficking. While IL-17A is a key product of T<sub>H</sub>17 cells, it is also produced by neutrophils, mast cells and Tc17 cells. Each of these cell types is found in psoriatic lesions. IL-17A acts on keratinocytes to increase expression of chemokines (*e.g.* CCL20, CXCL1, CXCL3, CXCL5, CXCL6 and CXCL8) involved in recruiting myeloid dendritic cells, Th17 cells and neutrophils to the lesion site. IL-17A induces production of antimicrobial peptides and proinflammatory cytokines that, in turn, may help sustain immune responses in the skin. Secukinumab is also under investigation for treating uveitis, rheumatoid arthritis, ankylosing spondylitis, and psoriatic arthritis. 1. Yamauchi & Bagel (2015) *J. Drugs Dermatol.* **14**, 244.

**Securines A and B, See Securamines A and B**

#### Sedanolid

This mosquitocidal, nematocidal, and antifungal agent (FW = 194.27 g/mol; CAS 6415-59-4) from celery seed oil, known systematically as 3-butyl-3a,4,5,6-tetrahydro-1(3H)-isobenzofuranone, topoisomerases I and II, and prostaglandin H endoperoxide synthase-I. 1. Momin & Nair (2002) *Phytomedicine* **9**, 312.

#### D-Sedoheptulose 1,7-Bisphosphate

This phosphorylated sedoheptulose derivative (FW = 366.11 g/mol), an alternative product of fructose-bisphosphate aldolase and a substrate of sedoheptulose-bisphosphatase, inhibits 3-deoxy-7-phosphoheptulonate synthase, *or* 2-keto-3-deoxy-D-arabino-heptonate-7-phosphate synthase (1,2), fructose-1,6-bisphosphatase (3,4), ribose-5-phosphate isomerase (5), and ribulose-bisphosphate carboxylase (6). 1. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 413, Academic Press, New York. 2. Srinivasan & Sprinson (1954) *J. Biol. Chem.* **234**, 716. 3. #### Selamectin

This topical veterinary endectocide, parasiticide and antihelminthic (FW = 769.96 g/mol; CAS 220119-17-5), also known by the tradenames Revolution<sup>®</sup> and Stronghold<sup>®</sup> and systematically as 25-cyclohexyl-25-de-(1-methylpropyl)-5-deoxy-22,23-dihydro-5-(hydroxyimino)avermectin B<sub>1</sub> monosaccharide, activates the chloride current without desensitization, thereby permitting chloride ions to enter the nerve cells and causing neuromuscular paralysis, impaired muscular contraction, and eventual death. It prevents infections of heartworms (*Dirofilaria immitis*), fleas (*Ctenocephalides felis felis*), ear mites, scabies, and certain types of ticks (*Ixodes ricinus*) in dogs as well as adult ascarids (*Toxocara cati*) and adult hookworms (*Ancylostoma tubaeforme*) in cats. Consult reference (3) for the pharmacokinetics of selamectin following intravenous, oral and topical

administration in cats and dogs. 1. Jacobs (2000) *Vet. Parasitol.* **91**, 161. 2. Pacey, Dutton, Monday, Ruddock & Smith (2000) *J. Antibiot.* (Tokyo) **53**, 301. 3. Sarasola, Jernigan, Walker, *et al.* (2010) *J. Vet. Pharmacol. Ther.* **25**, 265.

### Selective Serotonin Re-uptake Inhibitors

This class of antidepressants (or SSRIs), also called serotonin-specific reuptake inhibitors, are most often used to treat depression, anxiety disorders, and some personality disorders. Drugs in this class include (trade names in parentheses): **Citalopram** (Celexa<sup>®</sup>, Cipramil<sup>®</sup>, Cipram<sup>®</sup>, Cital<sup>®</sup>, Citox<sup>®</sup>, Dalsan<sup>®</sup>, Emocal<sup>®</sup>, Recital<sup>®</sup>, Sepram<sup>®</sup>, Seropram<sup>®</sup>); **Dapoxetine** (Priligy<sup>®</sup>); **Escitalopram** (Lexapro<sup>®</sup>, Cipralext<sup>®</sup>, Seroplex<sup>®</sup>, Esertia<sup>®</sup>); **Fluoxetine** (Depex<sup>®</sup>, Prozac<sup>®</sup>, Fontex<sup>®</sup>, Fluctin<sup>®</sup>, Fluox<sup>®</sup> (New Zealand), Flutop<sup>®</sup>, Ladose<sup>®</sup>, Lovan<sup>®</sup> (Australia), Motivest<sup>®</sup>, Prodep<sup>®</sup> (India), Sarafem<sup>®</sup>, Seromex<sup>®</sup>, Seronil<sup>®</sup>); **Fluvoxamine** (Dumyrox<sup>®</sup>, Faverin<sup>®</sup>, Favoxil<sup>®</sup>, Fevarin<sup>®</sup>, Floxyfral<sup>®</sup>, Luvox<sup>®</sup>, Movox<sup>®</sup>); **Indalpine** (Upstene<sup>®</sup>, discontinued); **Paroxetine** (Paxil<sup>®</sup>, Seroxat<sup>®</sup>, Sereupin<sup>®</sup>, Aropax<sup>®</sup>, Deroxat<sup>®</sup>, Divarius<sup>®</sup>, Rexetin<sup>®</sup>, Xetanor<sup>®</sup>, Paroxat<sup>®</sup>, Loxamine<sup>®</sup>, Deparoc<sup>®</sup>); **Sertraline** (Zolof<sup>®</sup>, Lustral<sup>®</sup>, Serlain<sup>®</sup>, Asentra<sup>®</sup>, Tresleen<sup>®</sup>); and **Zimelidine** (Zelmid<sup>®</sup>, Normud<sup>®</sup>).

### Selenate

The free acid H<sub>2</sub>SeO<sub>4</sub> (FW = 144.97 g/mol; deliquescent solid; M.P. = 58°C; B.P. = 260°C) is very soluble in water. Selenate may be reduced by many common reagents, including HBr, HI, H<sub>2</sub>S, phenylhydrazine, formic acid, oxalic acid, malonic acid, pyruvic acid, and several metals. Selenate salts (SeO<sub>4</sub><sup>2-</sup>) are isomorphous with the corresponding sulfates, but selenate is toxic substance that has been used as an insecticide. **Target(s)**: arsenite methyltransferase (1) 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase (2); 3-phosphoglycerate kinase (3); polynucleotide 5'-hydroxyl-kinase (4); protein kinase C (5); ribose-5-phosphate adenylyltransferase (6); sulfate adenylyltransferase (7); sulfate adenylyltransferase (ADP-forming) (8); and sulfate transport (9). 1. Zakharyan, Wu, Bogdan & Aposhian (1995) *Chem. Res. Toxicol.* **8**, 1029. 2. Kountz, McCain, el-Maghrabi & Pilkis (1986) *Arch. Biochem. Biophys.* **251**, 104. 3. Joao & Williams (1993) *Eur. J. Biophys. Acta* **123**, 1. 9. Shennan & Boyd (1986) *Biochim. Biophys. Acta* **859**, 122.

### Selenazofurin

This selenazole analogue of tiazofurin (FW = 307.16 g/mol; CAS 83705-13-9), also known as 2-β-D-ribofuranosylselenazole-4-carboxamide, is transported into animal cells, where it is metabolically converted to its nucleoside mono-, di, and tri-phosphate analogues as well as the corresponding NAD<sup>+</sup> analogue. (See also *Benzamide Riboside*; *Tiazofurin*) Selenazofurin 5'-monophosphate is an IMP analogue that specifically inhibits IMP dehydrogenase activity in cultured cells. The dose-dependence for this inhibition correlates with the relative cytotoxicity of the drug, indicating that the inhibition of IMP dehydrogenase by the selenazole analog is primarily responsible for its cytotoxicity (1). Although

selenazofurin is a highly potent antiviral agent *in vitro*, its antiviral activity is readily reversed by the addition of exogenous guanosine (2). Selenazofurin adenine dinucleotide competes with NAD<sup>+</sup> and inhibits many oxidoreductase reactions as well as the NAD-dependent enzyme, poly(ADP-ribose) polymerase (3). 1. Streeter & Robins (1983) *Biochem. Biophys. Res. Commun.* **115**, 544. 2. Robins, Revankar & McKernan (1985) *Adv. Enzyme Regul.* **24**, 29. 3. Berger, Berger, Catino, Petzold & Robins (1985) *J. Clin. Invest.* **75**, 702.

### Selenite

The free acid H<sub>2</sub>SeO<sub>3</sub> (FW = 128.97 g/mol; pK<sub>1</sub> = 2.46 and pK<sub>2</sub> = 8.31 at 25°C), also known as selenous acid, is a deliquescent solid that decomposes at 70°C with the release of water and selenium dioxide. note that it has a significant vapor pressure at room temperature. **Target(s)**: alcohol dehydrogenase, yeast (1); arsenite methyltransferase (3,34); aryl hydrocarbon hydroxylase (2); Ca<sup>2+</sup>-dependent ATPase (4); caspase-3 (5); c-Jun N-terminal kinase/stress-activated protein kinase (6); deoxyribonuclease I (7); DNA methylases, or DNA-cytosine methyltransferase (8-10); DNA polymerase, inhibited in the presence of sulfhydryl compounds (11,12); glycerol-3-phosphate dehydrogenase (13); IκB kinase (14); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (15); nuclear factor-κB (14); pancreatic ribonuclease, or ribonuclease A (23,32); phosphatase, acid (33); porphobilinogen synthase, or δ-aminolevulinatase dehydratase (16,17); prostaglandin-D synthase, or prostaglandin H<sub>2</sub>-D-isomerase (18-20); protein disulfide reduction by thioredoxin systems (21); protein kinase C (22); ribonucleotide reductase (21); RNA polymerase, inhibited in the presence of sulfhydryl compounds (11,12,24); squalene monooxygenase (25,26); succinate dehydrogenase, or succinate oxidase (27-29); tubulin polymerization, or microtubule assembly (30); and UDP-N-acetylglucosamine 2-epimerase (31). 1. ### Seleno-coenzyme M

This selenium-containing coenzyme (FW<sub>free-acid</sub> = 189.09 g/mol) irreversibly inhibits *Methanobacterium marburgensis* coenzyme-B sulfoethylthio-transferase, or methyl-CoM reductase. The natural substance, Ccoenzyme M, is the C1 donor in bacterial methanogenesis, where it is converted to

propyl coenzyme M-thioester. Nickel-requiring methyl-coenzyme M reductase (MCR) catalyses the reduction of methyl-coenzyme M ( $\text{CH}_3\text{-S-CoM}$ ) with coenzyme B ( $\text{HS-CoB}$ ) to methane and  $\text{CoM-S-S-CoB}$ . Coenzyme M reacts with Coenzyme B, 7-thioheptanoylthreonine-phosphate, to give a homodisulfide, releasing methane (*Reaction*:  $\text{CH}_3\text{-S-CoM} + \text{HS-CoB} \rightarrow \text{CH}_4 + \text{CoB-S-S-CoM}$ ). This enzyme contains the nickel porphyrinoid  $\text{F}_{430}$  prosthetic group that, for catalysis, must be  $\text{Ni(I)}$ . 1. Goenrich, Mahlert, Duin, *et al.* (2004) *J. Biol. Inorg. Chem.* **9**, 691.

### Selenocystamine

This selenium-containing cystamine analogue (FW<sub>free-base</sub> = 246.06 g/mol) catalyzes the oxygen-mediated oxidation of excess glutathione to glutathione disulfide at neutral pH and ambient  $\text{pO}_2$ . Selenocystamine can also catalyze the decomposition of such *S*-nitrosothiols as *S*-nitroso-glutathione and *S*-nitroso-*N*-acetyl-DL-penicillamine in the presence of different thiols (such as glutathione) to generate nitric oxide. **Target(s)**:  $\gamma$ -glutamylcysteine synthetase (1); and hydroxyindole *O*-methyltransferase (2). 1. Seelig & Meister (1984) *J. Biol. Chem.* **259**, 3534. 2. Sugden & Klein (1987) *J. Biol. Chem.* **262**, 6489.

### L-Selenocysteine

This selenium-containing cysteine analogue (FW = 168.05 g/mol; CAS 3614-08-2) is found at the active site of a number of redox-active selenoproteins. Selenocysteine is readily oxidized to selenocystine. R-SeH has a  $\text{p}K_a = 5.2$ , the much lower than 8.3 value for cysteine's thiol. At neutral pH, selenocysteine is largely present as  $\text{R-Se}^-$ , whereas cysteine is largely R-SH. **Metabolic Properties**: Selenocysteine is widely recognized as the 21st amino acid, participating in ribosome-mediated protein synthesis. Its specific incorporation into polypeptides is directed by the UGA codon. Unique tRNAs that have complementary UCA anticodons are aminoacylated with serine, with seryl-tRNA converted to selenocysteyl-tRNA (1). The latter binds specifically to a special elongation factor and is delivered to the ribosome. Recognition elements within the mRNAs are essential for translation of UGA as selenocysteine. A reactive oxygen-labile compound, selenophosphate, is the selenium donor required for synthesis of selenocysteyl-tRNA. Selenophosphate synthetase, which forms selenophosphate from selenide and ATP, is found in various prokaryotes, eukaryotes, and archaeobacterial (1). **Roles in Catalysis**: Selenocysteine-containing enzymes (*e.g.*, glutathione peroxidase, thioredoxin reductase, and iodothyronine deiodinase) play prominent roles in metabolism. Artificial selenoenzymes, such as selenosubtilisin, have been produced by chemical modification. Genetic engineering techniques also have been used to replace cysteine residues with selenocysteine. Selenocysteine plays mechanistic roles in glutathione peroxidase, the 5'-deiodinases, formate dehydrogenases, glycine reductase, and a few hydrogenases. In a few cases, a marked decrease in catalytic activity of an enzyme is observed when a selenocysteine residue is replaced with cysteine. This substitution causes complete loss of glycine reductase selenoprotein A activity. **Target(s)**: cysteine desulfurase, also as an alternative substrate (2); cysteinyl-tRNA synthetase, also as an alternative substrate (3); glycerol-3-phosphate dehydrogenase (4); and L-serine dehydratase, by DL-selenocysteine (5). 1. Stadtman (1996) *Ann. Rev. Biochem.* **65**, 83. 2. Lacourciere & Stadtman (1998) *J. Biol. Chem.* **273**, 30921. 3. Burnell & Whatley (1977) *Biochim. Biophys. Acta* **481**, 266. 4. Kim, Park, Kang, Choi & Kim (2002) *Biochim. Biophys. Acta* **1569**, 67. 5. Suda & Nakagawa (1971) *Meth. Enzymol.* **17B**, 346.

### L-Selenocystine

This cystine analogue (FW = 334.09 g/mol; CAS 1464-43-3) is readily produced by oxidation of selenocysteine and inhibits cystine transport (1) and squalene monooxygenase,  $\text{IC}_{50} = 65 \mu\text{M}$  (2). 1. Greene, Marcusson, Morell & Schneider (1990) *J. Biol. Chem.* **265**, 9888. 2. Gupta & Porter (2001) *J. Nutr.* **131**, 1662.

**Selenoethanolamine, See Selenocysteamine**

**Selenolysine, See Se-( $\beta$ -Aminoethyl)-L-seleno-cysteine**

### L-Selenomethionine

This selenium-containing L-methionine analogue (FW = 196.11 g/mol) can replace L-methionyl residues in proteins. The presence of selenomethionyl residues in proteins is an important tool in X-ray crystallography, where its anomalous dispersion solves the phase problem. L-Selenomethionine has an antioxidant activity, can activate glutathione peroxidase, and is soluble in water. **Target(s)**: cystine transport (1); glycerol-3-phosphate dehydrogenase (2); homoserine *O*-acetyltransferase (3); methionine *S*-adenosyltransferase (4); methionine *S*-methyltransferase (5); methionyl-tRNA synthetase, also acts as an alternative substrate (6); squalene monooxygenase, weakly inhibited (7); and tRNA (guanine- $\text{N}^2$ -methyltransferase (8)). 1. ### Selenopurine

This hypoxanthine analogue (FW = 199.08 g/mol; CAS 226-088-2) is five times more active than mercaptopurine in inhibiting the growth of mouse leukemia L5178 cells in tissue culture (1). Selenopurine is considerably more active than mercaptopurine as an inhibitor of chicken kidney xanthine dehydrogenase (2). When injected into mice bearing L5178-Y mouse lymphoma cells or S-180 tumor cells, 6-selenopurine had lower antitumor activity and greater host toxicity than equimolar amounts of 6-mercaptopurine (3). However, when injected into L1210-bearing mice, 6-selenopurine and 6-mercaptopurine exhibit similar antitumor activities at all dose levels (3). Like 6-mercaptopurine, methylation decreases 6-selenopurine's antitumor activity. 1. Clarke, Philips, Sternberg, *et al.* (1953) *Cancer Res.* **13**, 593. 2. Galton (1957) in *The Chemistry and Biology of Purines*. Boston: Little, Brown & Co. 2. Mautner & Jaffe (1958) *Cancer Res.* **18**, 294.

### Seleno-Salacinal

This salacinal analogue (FW = 367.23 g/mol) inhibits mannosyl-oligosaccharide 1,3-1,6- $\alpha$ -mannosidase, or mannosidase II. 1. Kuntz, Ghavami, Johnston, Pinto & Rose (2005) *Tetrahedron Asymmetry* **16**, 25.

### Selenotaurine

This selenium-containing taurine analogue (FW = 172.04 g/mol; CAS 16698-41-2) inhibits hypotaurine aminotransferase. At alkaline pH,

selenocystamine undergoes autoxidation, entirely transformed into selenohypotaurine in the presence of cupric ions. 1. Fellman (1987) *Meth. Enzymol.* **143**, 183.

**Selenous Acid, See Selenite**

### Selinexor

This orally bioavailable and selective CRM1 inhibitor (FW = 443.31 g/mol; CAS 1393477-72-9; Solubility = <1 mg/mL DMSO or H<sub>2</sub>O), also known as KPT-330 and (Z)-3-(3-(3,5-bis(trifluoromethyl)phenyl)phenyl)-1H-1,2,4-triazol-1-yl)-N'-(pyrazin-2-yl)acryloylhydrazide, targets the nuclear export Chromosome Region Maintenance-1, or CRM1 (also called Exportin-1, or XPO1) and displays selective anticancer activity in preclinical models of T-cell acute lymphoblastic leukemia and acute myeloid leukemia (ED<sub>50</sub> < 200 nM), reducing growth in MOLT-4, Jurkat, HBP-ALL, KOPTK-1, SKW-3, and DND-41 cell lines, with IC<sub>50</sub> values ranging from 34 to 203 nM (1,2). KPT-330 suppresses the growth of T-acute lymphoblastic leukemia (T-ALL) cells (*i.e.*, MOLT-4) and acute myelogenous leukemia (AML) cells (*i.e.*, MV4-11) *in vivo*, with little toxicity to normal haematopoietic cells (1). In SCID mice with diffuse human multiple myeloma (MM) bone lesions, KPT-330 inhibits tumor-induced bone lysis, prolonging survival. KPT-330 also impairs osteoclastogenesis and bone resorption by blocking RANKL-induced NF-κB and NFATc1, with minimal impact on osteoblasts and bone marrow stem cells (BMSCs). Tumor-suppressor proteins are inactivated by nuclear exclusion by CRM-1, and increased tumor levels of CRM-1 correlate with poor prognosis for pancreatic cancer patients. Selective Inhibitors of Nuclear Export (SINEs) bind to CRM-1 to irreversibly inhibit (most probably by alkylation of the essential thiol at Cysteine-528) its ability to export proteins. Oral administration of KPT-330 to mice reduced growth of subcutaneous and orthotopic xenograft tumors without major toxicity (3). Analysis of tumor remnants showed that KPT-330 disrupted the interaction between CRM-1 and PAR-4, activated PAR-4 signaling, and reduced proliferation of tumor cells (3). 1. Etchin, Sanda, Mansour, *et al.* (2013) *Brit. J. Hematol.* **161**, 117. 2. Tai, Landesman, Acharya, *et al.* (2013) *Leukemia* **28**, 155. 3. Azmi, Aboukameel, Bao, *et al.* (2013) *Gastroenterology* **144**, 447.

### Selumetinib

This orally bioavailable, potent and highly selective protein kinase inhibitor (FW = 457.68; CAS 606143-52-6; Solubility (25°C): 92 mg/mL DMSO, <1 mg/mL Water), also known as AZD6244, ARRY-142886 and 6-(4-bromo-2-chloro-phenylamino)-7-fluoro-N-(2-hydroxyethoxy)-3-methyl-3H-benzod[*d*]imidazole-5-carboxamide, targets MEK1 (IC<sub>50</sub> = 14 nM) and ERK1/2 phosphorylation (tight-binding, uncompetitive inhibitor; IC<sub>50</sub> = 10 nM), with little or no inhibition of p38α, MKK6, EGFR, ErbB2, ERK2, or B-Raf (1-3). Treatment of primary hepatocellular carcinoma (HCC) cells with AZD6244 led to growth inhibition, elevation of the cleavage of caspase-3 and caspase-7, and cleaved poly(ADP)ribose polymerase, but inhibition of ERK1/2 and p90RSK phosphorylation (1). AZD6244 also exhibited sub-mM IC<sub>50</sub> values in 5 of 31 human breast cancer cell lines and

15 of 43 human non-small cell lung cancer (NSCLC) cell lines, with a correlation between sensitivity and raf mutations in breast cancer cell lines ( $P = 0.022$ ) and ras mutations in NSCLC cell lines ( $P = 0.045$ ) (2). Treatment with AZD6244 results in the growth inhibition of several cell lines containing B-Raf and Ras mutations but has no effect on a normal fibroblast cell line (3). When dosed orally, ARRY-142886 was capable of inhibiting both ERK1/2 phosphorylation and growth of HT-29 xenograft tumors in nude mice. Treatment of primary HCC cells with the mitogen-activated protein/extracellular signal-regulated kinase (ERK) kinase 1/2 inhibitor AZD6244 (ARRY-142886) plus doxorubicin led to synergistic growth inhibition and apoptosis (4). AZD6244 has potential to inhibit proliferation and induce apoptosis and differentiation, but the response varies between different xenografts (5). Enhanced antitumor efficacy can be obtained by combining AZD6244 with the cytotoxic drugs irinotecan or docetaxel (5). *In vitro*, treatment with selumetinib and vorinostat synergistically inhibited proliferation and spheroid formation in both colorectal cancer (CRC) cell lines (6). This inhibition was associated with an increase in apoptosis, cell-cycle arrest in G<sub>1</sub>, reduced cellular migration, and VEGF-A secretion (6). *In vivo*, the combination resulted in additive tumor growth inhibition. Treatment of renal cell carcinoma RCC 786-0 cells with combined sorafenib/AZD6244 resulted in G<sub>1</sub> cell cycle arrest and blockade of serum-induced cell migration (7). Sorafenib/AZD6244 also induced apoptosis in primary RCC 08-0910 cells at low concentrations. *In vivo* addition of AZD6244 to sorafenib significantly augmented the antitumor activity of sorafenib and allowed dose reduction of sorafenib without compromising its antitumor activity. Thyroid cancers with BRAF mutation are preferentially sensitive to AZD6244 and other MEK inhibitors (8). In melanoma cells, most mutations conferring resistance to the MEK inhibitor AZD6244 *in vitro* populated the allosteric drug binding pocket or α-helix C and showed robust (~100x) resistance (9). BRAF Val-600-Glu disrupts AZD6244-induced abrogation of negative feedback pathways between extracellular signal-regulated kinase and Raf proteins (10). AZD6244 enhances the anti-tumor activity of sorafenib in ectopic and orthotopic models of human hepatocellular carcinoma (HCC) cells (11). 1. Huynh, Soo, Chow & Tran (2007) *Mol. Cancer Therapy* **6**, 138. 2. Garon, Finn, Hosmer, *et al.* (2010) *Mol. Cancer Ther.* **9**, 1985. 3. Yeh, Marsh, Bernat, *et al.* (2007) *Clin. Cancer Res.* **13**, 1576. 4. Hepatol.* **52**, 79.

### Semagacestat

This γ-secretase inhibitor (FW = 361.43 g/mol; CAS 425386-60-3), known also as LY-450139 and named systematically as 2-hydroxy-3-methyl-N-[1-methyl-2-oxo-2-[(2,3,4,5-tetrahydro-3-methyl-2-oxo-1H-3-benzazepin-1-yl)amino]ethyl]butanamide, was once a leading AD drug candidate because a single oral dose (0.1-10 mg/kg) reduced CSF levels of Aβ40 and Aβ43 peptides, the chief constituents of amyloid plaques (1,2). Its inhibitory target, γ-secretase, mediates intramembrane proteolysis of Notch and other essential proteins. Semagacestat is rapidly absorbed ( $t_{max} \approx 0.5$  hour), and eliminated from systemic circulation, with a  $t_{1/2}$  of 2.4 hour (3). Semagacestat failed to slow AD progression in large clinical trials comparing semagacestat with placebo in more than 2600 patients with mild-to-moderate AD. Semagacestat actually worsened both cognition and the ability to perform activities of daily living, leading its developer Lilly to withdraw this experimental agent from further clinical examination. While casting doubt on the amyloid plaque hypothesis, γ-secretase may have other poorly understood roles within the brain. 1. Best, Jay, Otu, *et al.* (2005) *J.*

*Pharmacol. Exp. Ther.* **313**, 902. **2.** Lanz, Karmilowicz, Wood, *et al.* (2006) *J. Pharmacol. Exp. Ther.* **319**, 924. **3.** Yi, Hadden, Kulanthaivel, *et al.* (2010) *Drug Metab Dispos.* **38**, 554.

### Semapimod

This macrophage arginine transporter inhibitor (FW<sub>tetra-HCl</sub> = 890.72 g/mol; FW<sub>free-base</sub> = 744.91 g/mol; CAS 164301-51-3 and 352513-83-8), also named CNI-1493 and *N,N'*-bis[3,5-bis[*N*-(diaminomethylideneamino)-*C*-methylcarbonimidoyl]phenyl]decanediamide, also exhibits anti-inflammatory, immunomodulatory, anti-cytokine, antiviral, and antimalarial properties. **Mode of Action:** Upon activation by cytokines, macrophages increase L-arginine transport to support the production of NO by NOS. Because endothelial cells do not require additional arginine transport to produce NO, semapimod is a competitive inhibitor of cytokine-inducible L-arginine transport that does not inhibit Endothelial-Derived Relaxing Factor (EDRF) activity in blood vessels. CNI-1493 to be a selective inhibitor of cytokine-inducible arginine transport and NO production, but does not inhibit EDRF activity (1). **Other Actions:** CNI-1493 prevents lipopolysaccharide (LPS)-induced NO production, even when added in concentrations 10-fold less than required to competitively inhibit L-arginine uptake (2). CNI-1493's action is independent of extracellular L-arginine and NO production, and it is not restricted to induction by LPS. As a selective inhibitor of macrophage activation that prevents TNF production, this tetravalent guanidylhydrazone shows promise as a cytokine-suppressive agent for treating diseases mediated by overproduction of cytokines (2). Semapimod inhibits the biosynthesis of the 26-kDa membrane form of TNF, indicating altered translational regulation (3). Both 5'- and 3'-untranslated regions of the TNF gene are required to elicit maximal translational suppression by CNI-1493 (3). **1.** Bianchi, Ulrich, Bloom, *et al.* (1995) *Mol. Med.* **1**, 254. **2.** Bianchi, Bloom, Raabe, *et al.* (1996) *J. Exp. Med.* **183**, 927. **3.** Cohen, Nakshatri, Dennis, *et al.* (1996) *Proc. Natl. Acad. Sci. USA* **93**, 3967.

### Semaxinib

This experimental-stage cancer therapeutic (FW = 238.29 g/mol; CAS 194413-58-6), also known as SU5416 and named systematically as (3*Z*)-3-[(3,5-dimethyl-1*H*-pyrrol-2-yl)methylidene]-1,3-dihydro-2*H*-indol-2-one, is a potent and selective synthetic inhibitor of the Flk-1/KDR vascular endothelial growth factor (VEGF) receptor tyrosine kinase. SU5416 was shown to inhibit vascular endothelial growth factor-dependent mitogenesis of human endothelial cells without inhibiting the growth of a variety of tumor cells *in vitro*. In contrast, systemic administration of SU5416 at nontoxic doses in mice resulted in inhibition of subcutaneous tumor growth of cells derived from various tissue origins. It targets the VEGF pathway and has demonstrated antiangiogenic potential both *in vivo* and *in vitro*. The antitumor action of SU5416 was accompanied by the appearance of pale white tumors that were resected from drug-treated animals, supporting the antiangiogenic property of this agent. **Status:** Based on consequence of discouraging results, Pharmacia/Sugen terminated Phase-III clinical trials of Semaxinib in the treatment of advanced colorectal cancer in early 2002. **1.** Fong, Shawver, Sun, *et al.* (1999) *Cancer Res.* **59**, 99

### Semicarbazide

This common laboratory reagent and urea analogue (FW<sub>hydrochloride</sub> = 111.53 g/mol; CAS 537-47-3) reacts with aldehydes and ketones, the product of which is a semicarbazone. By reacting with free and enzyme-bound pyridoxal 5-P, semicarbazide characteristically inhibits nearly all pyridoxal-phosphate-requiring enzymes (1). Semicarbazide breaks the Schiff base of PLP by transamination and is nearly independent of pH over the physiologic range. The highly stable semicarbazone of PLP, which emits strongly at 460 nm, when excited at 380 nm. The Schiff base is inherently 30-times more reactive than pyridoxal phosphate toward semicarbazide, but is much less reactive than protonated Schiff bases, as judged from studies on morpholine-catalyzed pyridoxal phosphate semicarbazone formation. The latter reaction proceeds via a cationic imine intermediate (1). Semicarbazide also reacts with pyrroloquinoline quinone (PQQ) found in enzymes like methylamine dehydrogenase (primary-amine:(acceptor) oxidoreductase (deaminating), EC 1.4.99.3 (2)). **1.** Cordes and Jencks (1962) *Biochemistry* **1**, 773. **2.** Van der Meer, Jongejan, and Duine (1987) *FEBS Lett.* **2**, 299.

### Senexin A

This ATP-competitive cdk inhibitor (FW = 310.78 g/mol; Solubility: 100 mM in DMSO), also named 4-[(2-phenylethyl)amino]-6-quinazolinecarbonitrile, targets cyclin-dependent kinase 8, or CDK8 (IC<sub>50</sub> = 280 nM) and also binds to cdk19 isoform. This CDK8 inhibitor suppresses damage-induced tumor-promoting paracrine activities of tumor cells and normal fibroblasts and reverses the increase in tumor engraftment and serum mitogenic activity in mice pretreated with a chemotherapeutic drug. It also increases the efficacy of chemotherapy against xenografts formed by tumor cell/fibroblast mixtures. **1.** Porter, Farmaki, Altilia, *et al.* (2012) *Proc. Natl. Acad. Sci. U.S.A.* **109**, 13799.

### Sepantronium bromide

This small-molecule, pro-apoptotic antineoplastic agent (FW<sub>HBr salt</sub> = 443.29 g/mol; CAS 781661-94-7 and 753440-91-4 (free base); Solubility: 60 mg/mL DMSO; 90 mg/mL H<sub>2</sub>O), also known as YM155 and named systematically as 4,9-dihydro-1-(2-methoxyethyl)-2-methyl-4,9-dioxo-3-(2-pyrazinylmethyl)-1*H*-naphth[2,3-*d*]imidazolium bromide, selectively inhibits (IC<sub>50</sub> = 0.54 nM) survivin gene expression in tumor cells, resulting in inhibition of survivin's anti-apoptotic activity (via extrinsic and intrinsic apoptotic pathways) as well as tumor cell apoptosis. A member of the inhibitor-of-apoptosis (IAP) gene family, survivin is expressed during embryonal development, but is absent in most normal, terminally differentiated tissues. Survivin is also up-regulated in a number of human cancers, with its expression associated with aggressive-phenotype tumors as well as shorter survival times and lower responsiveness to chemotherapy. YM155 potently inhibits human cancer cell lines (mutated or truncated p53) including PC-3, PPC-1, DU145, TSU-Pr1, 22Rv1, SK-MEL-5 and A375

with  $IC_{50}$  from 2.3 to 11 nM, respectively. 1. Nakahara, *et al.* (2007) *Cancer Res.* **67**, 8014. 2. Iwasa, *et al.* (2008) *Clin. Cancer Res.* **14**, 6496.

### Sephin 1

This protein phosphatase localization inhibitor (FW<sub>carbonate-salt</sub> = 258.66 g/mol; Soluble to 100 mM in DMSO), also named (2E)-2-[(2-chlorophenyl)methylene]hydrazinecarboximidamide, selectively targets the stress-induced PPP1R15A, which recruits the serine/threonine-protein phosphatase PP1 to dephosphorylate the translation initiation factor eIF-2A/EIF2S1, thereby reversing the shut-off of protein synthesis initiated by stress-inducible kinases and facilitating recovery from stress. Sephin-1 is without effect on the related and constitutive PPP1R15B. Upon oral administration at 1 or 10 mg/kg, Sephin 1 rapidly disappeared from plasma, and was concentrated in the nervous system, reaching concentrations 7–44 times higher in the brain and sciatic nerve (up to ~ 1  $\mu$ M) than in plasma. In mice, chronic treatment (1 mg/kg for 1 month) was tolerable, with no measurable adverse effects on body weight. When tested *in vivo*, Sephin1 safely prevents the motor, morphological, and molecular defects of two otherwise unrelated protein-misfolding diseases in mice, Charcot-Marie-Tooth 1B, and amyotrophic lateral sclerosis. 1. Das, Krzyzosiak, Schneider, *et al.* (2015) *Science* **348**, 239.

### Sepiapterin

This pterin (FW = 237.22 g/mol; CAS 17094-01-8) is a precursor in the biosynthesis of tetrahydrobiopterin via the pterin salvage pathway. **Target(s):** dihydropteridine reductase (1); GTP cyclohydrolase I (1-4); nitric-oxide synthase (5); and tRNA-guanine transglycosylase (6). 1. Shen, Zhang & Perez-Polo (1989) *J. Enzyme Inhib.* **3**, 119. 2. Jacobson & Manos (1989) *Biochem. J.* **260**, 135. 3. Shen, Alam & Zhang (1988) *Biochim. Biophys. Acta* **965**, 9. 4. Farkas, Jacobson & Katze (1984) *Biochim. Biophys. Acta* **781**, 64.

### Sepimostat

This aminobenzoate derivative (FW<sub>free-base</sub> = 373.41 g/mol), known in brief as FUT-187 and systematically as 6-amidino-2-naphthyl [4-(4,5-dihydro-1H-imidazol-2-yl)amino]benzoate, is an orally active serine proteinase inhibitor, acting competitively toward trypsin ( $K_i$  = 0.097  $\mu$ M), pancreatic kallikrein ( $K_i$  = 0.029  $\mu$ M), plasma kallikrein ( $K_i$  = 0.61  $\mu$ M), plasmin ( $K_i$  = 0.57  $\mu$ M), thrombin ( $K_i$  = 2.5  $\mu$ M), coagulation factor Xa ( $K_i$  = 20.4  $\mu$ M), and complement subcomponent C1r ( $K_i$  = 6.4  $\mu$ M). Sepimostat is a noncompetitive inhibitor for coagulation factor XIIa ( $K_i$  = 0.021  $\mu$ M) and an uncompetitive inhibitor for complement subcomponent C1s ( $K_i$  = 0.18  $\mu$ M). The complement-mediated hemolyses in the classical and alternative

pathways were also inhibited by sepimostat with  $IC_{50}$  values of 0.17 and 3.5  $\mu$ M, respectively. **Target(s):** alternative-complement-pathway C3/C5 convertase (1); classical-complement-pathway C3/C5 convertase (1); coagulation factor Xa (2); coagulation factor XIIa (1); complement subcomponent C1r (1,2); complement subcomponent C1s (1,2); kallikrein (1,2); plasmin (1,2); thrombin (1,2); and trypsin (1,2). 1. ### Septamycin

This polyether ionophore and antibiotic (FW<sub>free-acid</sub> = 913.20 g/mol; CAS 55924-40-8), from *Streptomyces hygroscopicus* NRRL 5678, forms complexes with metal ions and inhibits oxidative phosphorylation (1,2), especially active against Gram-positive bacteria and *Eimeria tenella* (chicken coccidiosis). 1. Reed (1979) *Meth. Enzymol.* **55**, 435. 2. Keller-Juslen, King, Kis & von Wartburg (1975) *J. Antibiot.* **28**, 854.

[Ser4,Glu8]-Oxytocin, See *Glumitocin*

### D-Serine

This neuroactive amino acid (FW = 105.09 g/mol; CAS 312-84-5), systematically known as (R)-2-amino-3-hydroxypropanoic acid, is found in silkworms and earthworms as well as in such antibiotics as tolaasin and the polymyxins. D-Serine is most likely the endogenous ligand for the glycine modulatory binding site on the NR1 subunit of N-methyl-D-aspartate receptors, serving as a neuromodulator by coactivating NMDA receptors and facilitating their opening when they bind glutamate. The D-serine concentrations within neurons are regulated by its synthesis and degradation by serine racemase (a fully reversible enzymatic reaction) as well as by its oxidation by D-amino acid oxidase. (**See L-Serine**) **Target(s):** D-alanine aminotransferase (1); D-alanyl-poly(phosphoribitol) synthetase, or D-alanine:poly(phosphoribitol) ligase (2); l-aminocyclopropane-1-carboxylate deaminase (3-5); aspartate 1-decarboxylase (6,7); aspartate 4-decarboxylase, or aminomalotate decarboxylase (8); diphosphate:serine phosphotransferase (9); kynureninase (10); phosphoserine phosphatase (11-13); pyruvate kinase (14); L-serine ammonia-lyase, or L-serine dehydratase (15-20); serine:glyoxylate aminotransferase (21); and threonine ammonia-lyase, or threonine dehydratase (22,23). 1. ### L-Serine

This hydrophilic proteogenic amino acid (FW = 105.09 g/mol; CAS 56-45-1;  $pK_1 = 2.19$ , and  $pK_2 = 9.21$  at 25°C;  $pK_3 \approx 15$ ), systematically known as (S)-2-amino-3-hydroxypropanoic acid is encoded by six codons (UCU, UCC, UCA, UCG, AGU, and AGC) is usually found on the surfaces of proteins. When buried in the interior of a protein, the hydroxyl side-chain is usually hydrogen-bonded to an oxygen atom of a peptide bond. Seryl residues tend to favor  $\alpha$ -helical structures and are often located at the ends of helices or reverse turns. L-Serine has a specific rotation of +15.1° at 25°C of the D line for 2.0 g/100 mL in 5 M HCl (-7.5° in distilled water) and is soluble in water (25 g/100 mL at 20°C). Many enzymes use D- or L-serine as alternative substrates (and hence competitive inhibitors), including L-amino-acid dehydrogenase, the amino acid oxidases, D-amino-acid dehydrogenase, alanopine dehydrogenase, alanine:oxo-acid aminotransferase, ornithine:oxo-acid aminotransferase, asparagine:oxo-acid aminotransferase, tryptophanase, tyrosine phenol-lyase, threonine dehydratase, diaminopropionate ammonia-lyase, and amino-acid racemase. **See also D-Serine; Serine-Borate Complex** **Target(s):** D-alanine 2-hydroxymethyl-transferase (1,63); D-amino-acid aminotransferase (53); 1-aminocyclopropane-1-carboxylate deaminase (38-40); aminomalate decarboxylase, or aspartate  $\beta$ -decarboxylase (2); 8-amino-7-oxononanoate synthase (3,60,61); asparagine:oxo-acid aminotransferase (54,55); aspartate 1-decarboxylase (4,37); aspartate 4-decarboxylase (2,36); choline kinase (5,51); cystathionine  $\gamma$ -lyase, or cysteine desulfhydrase (6-8); cysteine lyase (9); cysteine synthase (58); glutamine synthetase (10-18);  $\gamma$ -glutamyl transpeptidase, or  $\gamma$ -glutamyltransferase (19,20,59); D-glycerate dehydrogenase (21); glycine aminotransferase (57); glycine dehydrogenase (cytochrome) (22); glycine:oxaloacetate aminotransferase (52); glycyl-tRNA synthetase (23); homoserine dehydrogenase (24); homoserine kinase (49,50); kynureninase (25); ornithine aminotransferase (56); ornithine carbamoyltransferase (62); 3-phosphoglycerate dehydrogenase (21,26,27); phosphoglycerate phosphatase (41); phosphoglycolate phosphatase (42); phosphoserine phosphatase (43-48); propionyl-CoA carboxylase, *Myxococcus Xanthus* (28); D-serine ammonia-lyase, or D-serine dehydratase (29-31); threonine ammonia-lyase, or threonine dehydratase (32-34); and UDP-N-acetylmuramate:L-alanine ligase (35). 1. ### Serine-Borate Complex

This molecular entity, which forms upon binding of serine to  $\gamma$ -glutamyl transpeptidase in the presence of borate anion (10 mM), represents a transition state-like bridge complex between the serine hydroxyl group and a putative active-site hydroxyl group. L-Serine binds roughly 8.5-fold more tightly than with D-serine ( $K_i$  values of 20 and 170  $\mu$ M). **Target(s):** D-alanine  $\gamma$ -glutamyltransferase (1); and  $\gamma$ -glutamyl transpeptidase, or  $\gamma$ -glutamyltransferase (2-4). 1. ### L-Serine Hydroxamate

This N-acylhydroxamate analogue of serine (FW<sub>ion</sub> = 121.12 g/mol; CAS 31697-35-5) reacts with ATP on seryl-tRNA synthetase to form a tightly bound seryl-hydroxamate-adenylate (1-5). This inhibitor design should suffice for other amino acyl tRNA synthetases, provided the Because acyl hydroxamates is available. Note: Acylhydroxamates readily chelate Fe<sup>3+</sup>, such experiments should be conducted in the presence of a chelating agent. Alternatively, the hydroxamate should be freed of metal ions by passage over a cation exchange column or Chelex resin. 1. Söll & Schimmel (1974) *The Enzymes*, 3rd ed. (Boyer, ed.), **10**, 489. 2. SERP-1, See *Myxoma Virus Serine Proteinase Inhibitor*

Serpasil, See *Reserpine*

**Serpentine**

This alkaloid (FW = 348.40 g/mol; CAS 18786-24-8) from the roots of *Rauwolfia serpentina* is a DNA-intercalating alkaloid that stabilizes the formation of topoisomerase II-DNA covalent complex, thereby stimulating DNA scission without any preference for cutting at a specific base (1). Serpentine also inhibits CYP2D6 (2) and 3- $\alpha$ -(*S*)-strictosidine  $\beta$ -glucosidase (3,4). 1. Dassonneville, Bonjean, De Pauw-Gillet, et al. (1999) *Biochemistry* **38**, 7719. 2. SERPIN A1, See  $\alpha_1$ -Antitrypsin

SERPIN B5, See *Maspin*

**Serpin b6b**

This 377-residue serpin (*Official Name:* Serine (or cysteine) Proteinase Inhibitor, Clade B, Member 6b) is specific intracellular inhibitor of mouse Granzyme A (mGzMA), but not human Granzyme A (hGzMA). Serpinb6b utilizes an unusual exosite interaction that depends on the dimeric nature of mGzMA, and its mechanism of action indicates evolutionary divergence in cytotoxic potential and physiological function between mouse and human enzymes. (*For a discussion of serpin mechanisms, See also Serpins;  $\alpha_1$ -Antichymotrypsin*) 1. Kaiserman, Stewart, Plasman, et al. (2014) *J. Biol. Chem.* **289**, 9408.

**Serpin b12**

This 405-residue serine protease inhibitor (MW<sub>predicted</sub> = 46,276), expressed by numerous tissues (e.g., brain, bone marrow, lymph node, heart, lung, liver, pancreas, testis, ovary, and intestine) inhibits plasmin and trypsin. (*For a discussion of the likely mechanism of inhibitory action, See Serpins; also  $\alpha_1$ -*

*Antichymotrypsin*) 1. Askew, Pak, Luke, *et al.* (2001) *J. Biol. Chem.* **276**, 49320

**SERPINB13**, See *Headpin*

**Serpin Proteinase Inhibitor 9**, See *P19*

### Serpins

These serine proteinase inhibitors form catalytically inactive complexes with their target protease, and, upon binding to the target enzyme's active site, undergo P<sup>1</sup>-P<sup>1'</sup> cleavage to form high-affinity complexes that dissociate extremely slowly. (See *specific serpin*:  $\alpha_1$ -Antitrypsin, Antithrombin, Bopamin, Complement C1 inhibitor, crmA, Plasminogen Activator Inhibitors, *etc.*) **RCL Recognition**: A key structural element in the action of this class of inhibitors is thus a conformationally mobile reactive-center loop that enables the serpin to form a virtually irreversible, high-affinity complex with their target proteinase. The inhibitory mechanism of serpin-class inhibitors relies on its exposed region, called the Reactive Center Loop (or RCL) to mimic the specific substrate of the target protease. RCL cleavage by the target protease initiates a conformational change in the serpin fold that captures the protease in a 1:1 covalent complex (1). Canonical sequences serpin RCLs are thus critical determinants of protease inhibition, and they closely resemble the substrate's sequence at a cleavage site. **Detailed Serpin Mechanism for Antichymotrypsin Interactions with Chymotrypsin**: O'Malley *et al.* (2) demonstrated that antichymotrypsin (I) binds to chymotrypsin (E) to form an E\*I\* complex via a three-step mechanism:  $E + I \rightleftharpoons E \cdot I \rightleftharpoons E^* \cdot I^*$ . In this scheme, E'I' retains the P<sup>1</sup>-P<sup>1'</sup> linkage and is formed in a partly, or largely, rate-determining step. Using rapid quench-flow assay for post-complex fragment formation, Nair & Cooperman (3) determined that the E:I encounter complex of serpin and enzyme forms both E\*-I\* and the post-complex fragment with the same rate constant, indicating that both species arise from E'I' conversion to E\*-I\*. These results indicate (a) that the peptide bond remains intact within the E'I' complex, and (b) that E\*-I\* is likely to be either the acyl-enzyme or the tetrahedral intermediate formed after water attack on acyl-enzyme (4). (For further discussion of the likely mechanism of inhibitor action, See  $\alpha_1$ -Antichymotrypsin) 1. Gettins (2002) *Chem. Rev.* **102**, 4751. 2. O'Malley, Nair, Rubin & Cooperman (1997) *J. ### *Serratia marcescens* Proteinase Inhibitor

This *Serratia marcescens* polypeptide (MW = 10 kDa) from is localized in the periplasmic space, where it inhibits the proteinase serralyisin (1-3). 1. Kim, Kim, Kim, Byun & Shin (1995) *Appl. Environ. Microbiol.* **61**, 3035. 2. Suh & Benedik (1992) *J. Bacteriol.* **174**, 2361. 3. Bae, Kim, Kim, Shin & Byun (1998) *Arch. Biochem. Biophys.* **352**, 37.

### Sertraline

This widely used antidepressant (FW<sub>free-base</sub> = 306.23 g/mol; CAS 79617-96-2; pK<sub>a</sub> = 9.48), known also as Zoloft<sup>®</sup> and its IUPAC name (1S,4S)-N-methyl-4-(3,4-dichlorophenyl)-1,2,3,4-tetrahydro-1-naphthylamine, is a selective (and competitive) serotonin reuptake inhibitor, or SSRI, K<sub>i</sub> = 3.3 nM. Also available in generic forms (*i.e.*, the U.S. patent expired in 2006), sertraline is prescribed throughout the world for the treatment of depression, obsessive compulsive disorder (OCD), panic disorder, posttraumatic stress disorder (PTSD), social anxiety disorder, and premenstrual dysphoric disorder (PMDD). **Likely Mechanism of Action**: Sertraline's antidepressant action is presumed to be rooted in its inhibition of CNS neuronal uptake of serotonin (5HT) (1-7). Studies at clinically relevant doses show that Sertraline blocks serotonin uptake into human platelets. *In vitro* studies in animals also suggest that Sertraline is a potent and selective inhibitor of neuronal serotonin reuptake and has only very weak effects on

norepinephrine and dopamine neuronal reuptake. *In vitro* studies confirm that Sertraline has no significant affinity for  $\alpha_1$ -adrenergic receptors,  $\alpha_2$ -adrenergic receptors,  $\beta$ -adrenergic receptors, cholinergic receptors, GABA receptors, dopaminergic receptors, histaminergic receptors, serotonergic (5-HT<sub>1A</sub>, 5-HT<sub>1B</sub>, 5-HT<sub>2</sub>) receptors, or benzodiazepine receptors. On the other hand, Sertraline preferentially does block the inwardly rectifying astroglial K<sup>+</sup> channel Kir4.1, but not Kir1.1 or Kir2.1 channels, an action that may be implicated in its therapeutic and/or adverse actions (8). **Key Pharmacokinetic Parameters**: See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s)**: Sertraline is a mixed-type inhibitor of Dynamin-1 with respect to both GTP and L- $\alpha$ -phosphatidyl-L-serine (PS) *in vitro*, also inhibiting synaptic vesicle endocytosis via inhibition of Dynamin GTPase in human neuroblastoma SH-Sy5Y cells and HeLa cells (9). In mitochondria isolated from rat liver, sertraline uncoupled mitochondrial oxidative phosphorylation and inhibited the activities of oxidative phosphorylation complexes I and V (10). Additionally, sertraline induced Ca<sup>2+</sup>-mediated mitochondrial permeability transition (MPT), and the induction was prevented by bongkreik acid (BA), a specific MPT inhibitor targeting adenine nucleotide translocator (ANT), implying that the MPT induction is mediated by ANT (10). Sertraline (1.5-25  $\mu$ M) progressively inhibits the rise in Na<sup>+</sup> and the release of pre-loaded [<sup>3</sup>H]Glu as well as the release of endogenous 5-HT (11). Glu and GABA (as detected by HPLC) induced by veratridine depolarization either under external Ca<sup>2+</sup>-free conditions or in the presence of external Ca<sup>2+</sup> (10). Sertraline also inhibits insulin-induced Tyr phosphorylation of insulin receptor substrate (IRS)-2 protein and the activation of its downstream targets Akt and the ribosomal protein S6 kinase-1 (S6K1) (12). Inhibition was dose-dependent with half-maximal effects at ~15-20  $\mu$ M. It correlated with a rapid dephosphorylation and activation of the IRS kinase GSK3 $\beta$ . **Drug Interactions**: When assayed in the presence of NADPH, incubation of human liver microsomes with sertraline markedly decreases testosterone 6 $\beta$ -hydroxylation activities, indicating that sertraline metabolism leads to CYP3A4 inactivation (13). This inactivation required NADPH and was not protected by glutathione. No significant inactivation was observed for other P450 enzymes. Spectroscopic evaluation revealed that microsomes with and without sertraline in the presence of NADPH gave a Soret peak at 455 nm, suggesting formation of complexes of sertraline metabolite(s) with reduced form of P450 (13). No significant inactivation was observed with other P450 enzymes. 1. Koe, Weissman, Welch & Browne (1983) *J. Pharmacol. Exp. Ther.* **226**, 686. 2. Bogetto, Albert & Maina (2002) *Eur. ### Sertindole

This phenylindole-class antipsychotic (FW = 440.94 g/mol; CAS 106516-24-9), also known by tetrad names Serdolect<sup>®</sup> and Serlect<sup>®</sup> as well as 1-[2-[4-[5-chloro-1-(4-fluorophenyl)indol-3-yl]-1-piperidyl]ethyl]imidazole-2-one, is active at both dopamine and serotonin receptors and is used to treat schizophrenia. (See also *Quetiapine*; *Remoxipride*; *Risperidone*; *Zotepine*) **Targets**: Dopamine D<sub>2</sub> Receptor, 2.4 nM; Dopamine D<sub>3</sub> Receptor, 2.3 nM; Dopamine D<sub>4</sub> Receptor, 4.9 nM; Serotonin 5-HT<sub>1A</sub> Receptor, K<sub>i</sub> = 280 nM; Serotonin 5-HT<sub>1B</sub> Receptor, K<sub>i</sub> = 60 nM; Serotonin 5-HT<sub>1D</sub> Receptor, K<sub>i</sub> = 96 nM; Serotonin 5-HT<sub>1E</sub> Receptor, K<sub>i</sub> = 430 nM; Serotonin 5-HT<sub>1F</sub>

Receptor,  $K_i = 360$  nM; Serotonin 5- $H_{2A}$  Receptor,  $K_i = 0.4$  nM; Serotonin 5-HT<sub>2C</sub> Receptor,  $K_i = 0.9$  nM; Serotonin 5-HT<sub>6</sub> Receptor,  $K_i = 5.4$  nM; Serotonin 5-HT<sub>7</sub> Receptor,  $K_i = 28$  nM. 1. Muscatello, Bruno, Micali-Bellinghieri, Pandolfo & Zoccali (2014) *Expert Opin. Pharmacother.* **15**, 1943.

**L-Seryl-L-alanyl-L-alanyl-(5(S)-amino-4(S)-hydroxy-6-(4'-hydroxyphenyl)hexanoyl)-L-valyl-L-valine Methyl Ester**

This hydroxyethylene isostere-containing peptidomimetic (FW<sub>free-base</sub> = 680.80 g/mol) inhibits HIV-1 protease, or HIV-1 retropepsin, apparent  $K_i = 79$  nM. This peptide prevents cleavage of the viral polyproteins resulting in the formation of immature non-infectious viral particles. Protease inhibitors are almost always used in combination with at least two other anti-HIV drugs. 1. Dreyer, Metcalf, Tomaszek, Jr., et al. (1989) *Proc. Natl. Acad. Sci. U.S.A.* **86**, 9752.

**L-Seryl-L-alanyl-L-alanyl-(5(S)-amino-4(S)-hydroxy-6-phenylhexanoyl)-L-valyl-L-valine Methyl Ester**

This hydroxyethylene isostere-containing peptidomimetic (FW<sub>free-base</sub> = 664.80 g/mol) inhibits HIV-1 protease, or HIV-1 retropepsin, apparent  $K_i = 62$  nM. This peptide prevents cleavage of the viral polyproteins resulting in the formation of immature non-infectious viral particles. Protease inhibitors are almost always used in combination with at least two other anti-HIV drugs. 1. Dreyer, Metcalf, Tomaszek, Jr., et al. (1989) *Proc. Natl. Acad. Sci. U.S.A.* **86**, 9752.

**L-Seryl-L-alanyl-L-alanyl-(4(S)-amino-3(S)-hydroxy-5-phenylpentanoyl)-L-valyl-L-valine Methyl Ester**

This pseudopeptide bond-containing peptide analogue (FW<sub>free-base</sub> = 650.77 g/mol) inhibits HIV-1 protease, or HIV-1 retropepsin, apparent  $K_i = 0.81$  μM. This peptide prevents cleavage of the viral polyproteins resulting in the formation of immature non-infectious viral particles. Protease inhibitors are almost always used in combination with at least two other anti-HIV drugs. 1. Dreyer, Metcalf, Tomaszek, et al. (1989) *Proc. Natl. Acad. Sci. U.S.A.* **86**, 9752.

**Sesamin**

This water-soluble natural product (FW = 354.36 g/mol; CAS 607-80-7), known systematically as 5,5'-(tetrahydro-1*H*,3*H*-furo[3,4-*c*]furan-1,4-

diyl)bis-1,3-benzodioxole, is isolated from sesame oil, the barks of species of *Fagara*, and from fruit of *Piper lowong*. Sesamin is a noncompetitive inhibitor of fatty acid Δ<sup>5</sup>-desaturase (1-3), lysophosphatidylcholine acyltransferase (4), and tocopherol ω-hydroxylase, or CYP4F2 (5). 1. Shimizu, Akimoto, Shinmen, et al. (1991) *Lipids* **26**, 512. 2. Umeda-Sawada, Takahashi & Igarashi (1995) *Biosci. Biotechnol. Biochem.* **59**, 2268. 3. Sontag & Parker (2002) *J. Biol. Chem.* **277**, 25290.

**Sespendole**

This fungal indole (FW = 517.75 g/mol), isolated from *Pseudobotrytis terrestris*, inhibits sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, or ACAT (1). Sespendole also inhibits inhibitor of lipid droplet formation in macrophages by inhibiting the synthesis of cholesteryl ester and triacylglycerol with IC<sub>50</sub> values of 4.0 and 3.2 μM, respectively. 1. Ohshiro, Rudel, Omura & Tomoda (2007) *J. Antibiot.* **60**, 43.

**Sethoxydim**

This selective post-emergence herbicide (FW = 326.48 g/mol; CAS 74051-80-2), also known as 2-[1-(ethoxyimino)butyl]-5-[2-(ethylthio)propyl]-3-hydroxy-2-cyclohexen-1-one and Poast (FW = 327.49 g/mol), is a potent inhibitor of acetyl-CoA carboxylase (1-8), with an IC<sub>50</sub> value of 0.96 μM for the wheat enzyme. Note that commercial preparations often are the (*RS*),(*EZ*)-mixture. Sethoxydim is often used to control annual and perennial grass weeds. **Target(s):** acetyl-CoA carboxylase (1-8); and 4-hydroxyphenylpyruvate dioxygenase (9). 1. Lin & Yang (1999) *Bioorg. Med. Chem. Lett.* **9**, 551. 2. Burton, Gronwald, Somers, et al. (1987) *Biochem. Biophys. Res. Commun.* **148**, 1039. 3. Harwood (1988) *Trends Biochem. Sci.* **13**, 330. 4. Dotray, DiTomaso, Gronwald, Wyse & Kochian (1993) *Plant Physiol.* **103**, 919. 5. Egli, Gengenbach, Gronwald, Somers & Wyse (1993) *Plant Physiol.* **101**, 499. 6. Zagnitko, Jelenska, Tevadze, Haselkorn & Gornicki (2001) *Proc. Natl. Acad. Sci. U.S.A.* **98**, 6617. 9. Lin & Yang (1999) *Bioorg. Med. Chem. Lett.* **9**, 551.

**Setipiprant**

This potent CRTH2 antagonist (FW = 402.43 g/mol; CAS 866460-33-5), also named ACT-129968 and 2-(2-(1-naphthoyl)-8-fluoro-3,4-dihydro-1*H*-pyrido[4,3-*b*]indol-5(2*H*)-yl)acetic acid, targets Chemoattractant Receptor on Th2 cells (CRTH2), a G-coupled, prostaglandin D<sub>2</sub> (PGD<sub>2</sub>) receptor with important roles in allergic inflammation. **Mode of Inhibitory Action:** T helper type 2 cells (or Th2 cells) are a distinct lineage of CD4<sup>+</sup> effector T cells that secrete interleukins (e.g., IL-4, IL-5, IL-9, IL-13, and IL-17E/IL-

25) and coordinate immune responses to large extracellular pathogens. Produced by the mast cells, PGD<sub>2</sub> is a key mediator in various inflammatory diseases, including allergy and asthma. PGD<sub>2</sub> binds CRTH2 on the surface of blood-borne cells, inducing chemotaxis in Th2 cells, basophils, and eosinophils, and stimulating cytokine release from these cells. Pre-clinical data showed that setiprant potently inhibits migration of eosinophils towards PGD<sub>2</sub> in vitro as well as in an in vivo rat model of lung eosinophilia. **1.** Baldoni, Mackie, Gutierrez, Theodor & Dingemans (2013) *Clin. Ther.* **35**, 1842. **2.** Satoh, Moroi, Aritake, Urade, *et al.* (2006) *J. Immunol.* **177**, 2621. **3.** Diamant, Singh, O'Connor, *et al.* (2012) *Am. J. Respir. Crit. Care Med.* **185**, A3957.

### Setoperone

This serotonin antagonist (FW = 401.50 g/mol; CAS 86487-64-1), also known as 6-[2-[4-(4-fluorobenzoyl)piperidin-1-yl]ethyl]-7-methyl-2,3-dihydro[1,3]thiazolo[3,2-a]pyrimidin-5-one, 5-HT<sub>2A</sub> receptor is pharmacologically characterized by its potent serotonin and moderate dopamine receptor blocking properties. Blockade of serotonin receptors may be related to improvement of autistic behaviour, dysphoria, and parkinson-like symptoms. **See also** Ketanserin; Pimavanserin; RH-34; Risperidone; Ritanserin; Volinanserin. **1.** Ceulemans, Gelders, Hoppenbrouwers, Reyntjens & Janssen (1985) *Psychopharmacology* (Berlin) **85**, 329.

### Sevin, See Carbaryl

### Sevoflurane

This sweet-smelling inhalation anesthetic (FW = 200.06 g/mol; CAS 28523-86-6), also known as 1,1,1,3,3,3-hexafluoro-2-(fluoromethoxy)propane, is a nonflammable, highly fluoroalkyl ether that induces and maintains general anesthesia. Along with desflurane, sevoflurane is replacing isoflurane and halothane in modern anesthesiology, and is frequently co-administered with nitrous oxide and oxygen. With an oil/gas partition coefficient of 47.2, the Minimum Alveolar Concentration (MAC) of sevoflurane is 2.05%. Its potency is considerably lower than that of halothane and isoflurane, but is about three times more potent than desflurane (1). About 2-5% of the drug taken up by the liver is metabolized. Demonstrating less irritation to mucous membranes, sevoflurane is now preferred over desflurane. **1.** Behne, Wilke & Harder (1999) *Clin. Pharmacokinet.* **36**, 13.

### SF2809 Compounds

These indole derivatives: SF2809-I (FW = 387.46 g/mol), R<sub>1</sub> = -H and R<sub>2</sub> = -NHCOCH<sub>3</sub>), SF2809-II (FW = 362.55 g/mol), R<sub>1</sub> = -C<sub>6</sub>H<sub>4</sub>(*p*-OH) and R<sub>2</sub> = -NHCOCH<sub>3</sub>); SF2809-III (FW = 346.41 g/mol), R<sub>1</sub> = -H and R<sub>2</sub> = -OH); SF2809-IV (FW = 438.50 g/mol, R<sub>1</sub> = -C<sub>6</sub>H<sub>4</sub>(*p*-OH) and R<sub>2</sub> = -OH); SF2809-V (FW = 463.56 g/mol), R<sub>1</sub> = -C<sub>6</sub>H<sub>5</sub> and R<sub>2</sub> = -NHCOCH<sub>3</sub>); and SF2809-VI (FW = 422.50 g/mol, where R<sub>1</sub> = -C<sub>6</sub>H<sub>5</sub> and R<sub>2</sub> = -OH)) from the fermentation broth of *Dactylosporangium* sp. strain SF2809, inhibit chymase, with IC<sub>50</sub> values of 7.3, 0.041, 2.1, 0.081, 0.043, and 0.014 mM

for SF2809-I, -II, -III, -IV, -V, and -VI, respectively. **1.** Tani, Gyobu, Sasaki, *et al.* (2004) *J. Antibiot.* **57**, 83.

### SF6847, See 3,5-Di-tert-butyl-4-hydroxybenzylidenemalononitrile

### SGC707

This potent, selective, and cell-active PRMT3 inhibitor (FW = 298.34 g/mol; CAS 1687736-54-4; Solubility: 59 mg/mL in DMSO), also named *N*-6-isoquinolinyl-*N'*-[2-oxo-2-(1-pyrrolidinyl)ethyl]urea, targets protein arginine methyltransferase 3 (IC<sub>50</sub> = 31 nM; K<sub>d</sub> = 53 nM). SGC707 exhibits outstanding selectivity versus 31 other methyltransferases and >250 non-epigenetic targets. Mechanism of action studies and crystal structure of the PRMT3-SGC707 complex confirm its allosteric inhibition mode. SGC707 engages PRMT3 and potently inhibits its methyltransferase activity in cells. It is also bioavailable and suitable for animal studies, making it an excellent tool to investigate the role of PRMT3 in health and disease. **1.** Kaniskan, Szweczyk, Yu, *et al.* (2015) *Angew. Chem. Int. Ed. Engl.* **54**, 5166.

### SGI-110

This 5-aza-2'-dC-containing demethylating pro-drug (FW = 579.39 g/mol; CAS 929901-49-5), also known as S-110 and 2'-deoxy-5-azacytidyl-(3'→5')-2'-deoxyguanosine, is a novel DNA hypomethylating dinucleotide antimetabolite, consisting of a decitabine (**See Decitabine**) joined via a phosphodiester bond to 2'-deoxyguanosine (1-5). SGI-110 is also a "chemosensitizer", making cancer cells more susceptible to the action of other anticancer agents like Cisplatin, especially those cells that are Cisplatin-resistant. For example, in a mouse xenoplant model for human ovarian cancer, DNA damage induced by Cisplatin was increased by SGI-110, as measured by ICP-mass spectrometry analysis of DNA adduct formation and repair of Cisplatin-induced damage (6). **Mechanism of Inhibitory Action:** DNA methyltransferases (DNMTs) are a family of nuclear enzymes catalyzing methylation of CpG dinucleotides, resulting in epigenetic methylomes distinguishing normal cells from those observed in diseases, such as cancer. SGI-110 is a potential anticancer agent that, following metabolic phosphorylation and incorporation into DNA, inhibits DNA methyltransferase, thereby causing genome-wide and non-specific hypomethylation, inducing cell cycle arrest at S-phase. Significantly, SGI-110 is resistant to cytidine deaminase, resulting in gradual decitabine release, both extracellularly and intracellularly, to provide prolonged decitabine exposure to susceptible cells. SGI-110 treatment results in the up-regulation of Melanoma Antigen family A members (*e.g.*, MAGE-A1, MAGE-A2, MAGE-A3, MAGE-A4, MAGE-A10) and G-antigen family members (*e.g.*, GAGE 1-2, GAGE 1-6), as well as NY-ESO-1 and SSX 1-5 in all cancer cell lines studied, both at mRNA and at protein levels. (*Note:* The chemical nature of the pharmacologically active form(s) remain uncertain, and SGI-110 may first undergo hydrolysis to generate the well known DNMT inhibitor 5-aza-2'-deoxycytidine, or Decitabine). **1.** Foulks, Parnell, Ni, *et al.* (2012) *J. Biomol. Screen.* **17**, 2. **2.** Foulks & Parnell, Nix, *et al.* (2012) *J. Biomol. Screen.* **17**, 2. **3.** Coral, Parisi, Nicolay, *et al.* (2013) *Cancer Immunol. Immunother.* **62**, 605. **4.** Singh, Sharma, Capalash (2013) *Curr. Cancer Drug Targets* **13**, 379. **5.** Tellez, Grimes, Picchi, *et al.* (2014) *Int. J. Cancer.* **135**, 2223. **6.** Fang, Munck, Tang, *et al.* (2014) *Clin Cancer Res.* **20**, 6504.

**S/GI-1027**

This DNMT inhibitor (FW = 461.52 g/mol; CAS 1020149-73-8; Solubility: 92 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as *N*-[4-[(2-amino-6-methyl-4-pyrimidinyl)amino]phenyl]-4-(4-quinolinylamino)benzamide, targets DNA (cytosine-5)-methyltransferases DNMT1 (IC<sub>50</sub> = 6 μM), DNMT3A (IC<sub>50</sub> = 8 μM), and DNMT3B (IC<sub>50</sub> = 7.5 μM), enzymes that help establish and regulate tissue-specific DNA methylation patterns, thereby maintaining tissue integrity and preventing both tumorigenesis and developmental abnormalities. In cancer, tumor suppressor genes are silenced by oncomethylation, and reactivation of them occurs when 5-azacytidine and 5-aza-2'-deoxycytidine selectively and rapidly induce proteasome-mediated degradation of maintenance DNA methyltransferase-1. Treatment of various cancer cell lines with SGI-1027 results in selective degradation of DNMT1, with minimal or no effects on DNMT3A and DNMT3B (1). At a concentration of 2.5-5 μM (similar range as that of decitabine), complete degradation of DNMT1 protein is achieved within 24 hours, without significantly affecting its mRNA level. MG132 blocked SGI-1027-induced depletion of DNMT1, indicating the involvement of proteasomal pathway (1). SGI-1027 4 can now be synthesized using as palladium-catalyzed Ar-N bond formation reactions carried out in a sequential or convergent manner (2). 1. Datta, Ghoshal, Denny, *et al.* (2009) *Cancer Res.* **69**, 4277. 2. Garcia-Domínguez, Dell'aversana, Alvarez, Altucci & de Lera (2013) *Bioorg. Med. Chem. Lett.* **23**, 1631.

**S/GI-1776**

This ATP-competitive protein kinase inhibitor (FW = 405.42 g/mol; CAS 1025065-69-3; Solubility = 80 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known as *N*-((1-methylpiperidin-4-yl)methyl)-3-(3-(trifluoromethoxy)phenyl)imidazo[1,2-*b*]pyridazin-6-amine, targets the proto-oncogene serine/threonine-protein kinase Pim1 (IC<sub>50</sub> = 7 nM), Pim2 (IC<sub>50</sub> = 363 nM), Pim3 (IC<sub>50</sub> = 69 nM), and the Fms-like tyrosine kinase 3, or Flt3 (IC<sub>50</sub> = 44 nM). Expressed mainly in spleen, thymus, bone marrow, prostate, oral epithelial, hippocampus and fetal liver cells, Pim-1 is present at high levels in human tumor cell cultures. SGI-1776 induces apoptosis in chronic lymphocytic leukemia (CLL) cells (1). Unlike in replicating cells, phosphorylation of traditional Pim-1 kinase targets, phospho-Bad (Ser112) and histone H3 (Ser10), and cell-cycle proteins were unaffected by SGI-1776, suggesting an alternative mechanism in CLL. Levels of antiapoptotic proteins Bcl-2, Bcl-X(L), XIAP, and proapoptotic Bak and Bax were unchanged; however, a significant reduction in Mcl-1 was observed that was not caused by caspase-mediated cleavage of Mcl-1 protein. Later work showed that PIM-3 kinase is a positive regulator of STAT3 signaling, suggest that PIM-3 inhibitors like SGI-1776 cause growth inhibition of cancer cells by down-regulating pSTAT3(Tyr705) expression. Treatment of acute myeloid leukemia (AML) cells with SGI-1776 results in a concentration-dependent induction of apoptosis, again significantly reducing Mcl-1 expression (3). SGI-1776 decreases cell surface expression of P-glycoprotein (ABCB1) and breast cancer resistance protein (ABCG2) and drug transport by Pim-1-dependent and -independent mechanisms (4). By contrast, SGI-1776 treatment in myeloma cell lines and CD138+ myeloma cells elicits its deleterious effects through inhibition of translation and induction of autophagy (5). 1. Chen, Redkar, Bearss, Wierda & Gandhi (2009) *Blood* **114**, 4150. 2. Chang, Kanwar, Feng, *et al.* (2010) *Mol. Cancer Ther.* **9**, 2478. 3. **S/GSK1349572, See Dolutegravir****Shermilamine C**

This pyridoacridine alkaloid (FW = 430.53 g/mol) from two marine species of *Cystodytes* and *Trididemnum* inhibits DNA topoisomerase II. These results suggest that disruption of the function of TOPO II, subsequent to intercalation, is a probable mechanism by which pyridoacridines inhibit the proliferation of HCT cells by disrupting DNA and RNA synthesis with little effect on protein biosynthesis. DNA is the primary cellular target of the pyridoacridine alkaloids, a behavior that is consistent with the action of DNA intercalators. 1. McDonald, Eldredge, Barrows & Ireland (1994) *J. Med. Chem.* **37**, 3819.

**Shiga Toxins**

This family of bacterial cytotoxins Stx1 and Stx2 are produced by the bacteria *Shigella dysenteriae* and the Shigatoxigenic group of *Escherichia coli* (STEC), respectively. The structurally related toxin has five β-subunits (MW = 7.7 kDa) and one α-subunit (MW = 32 kDa), linked together by a disulfide bond. The β-subunits combine to form a pentameric ring that binds binding with the globotriaosylceramide receptor (Galα(1→4)Galβ(1→4)-glucosyl ceramide (*or* Gb3) in the peripheral membranes of target cells. (A variant binds to the globotetraosylceramide receptor (*or* Gb4), accounting for its ability to target other cell types.) The complex enters by way of clathrin-coated cavities and is taken up by the endoplasmic reticulum (ER) via retrograde transport. Once within the ER, the disulfide bond releasing the α-subunit, an active *N*-glycosidase that catalyzes ricin-like depurination of 28S rRNA of the 60S subunit of host cell ribosomes, and, in the process, releasing adenine and inactivating the modified ribosome. *Escherichia coli* strains that produce Stx2 are isolated from hemolytic-uremic syndrome (HUS) cases more frequently than are strains that produce both Stx1 and Stx2, whereas strains that produce only Stx1 are rarely isolated from HUS cases. Studies have implicated Stx2 as the sole contributor to acute kidney failure and other systemic complications in humans. The most common Shiga toxin-producing organism causing disease in North America is *E. coli* O157:H7, accounting for nearly 90% of all diarrhea-associated HUS cases.

**Shikimate (Shikimic Acid)**

This metabolite (FW = 174.15 g/mol; CAS 138-59-0; λ<sub>max</sub> = 213 nm, ε = 8900 M<sup>-1</sup>cm<sup>-1</sup> in ethanol) is a key intermediate in the biosynthesis of tyrosine, phenylalanine, tryptophan, folic acid, the tocopherols, ubiquinone, and certain antibiotics. Known systematically as (3*R*,4*S*,5*R*)-3,4,5-trihydroxy-1-cyclohexene-1-carboxylic acid, shikimate inhibits chitin synthase (1) and 3-deoxy-7-phosphoheptulon synthase (2). 1. Hwang, Ahn, Lee, *et al.* (2001) *Planta Med.* **67**, 501. 2. Wu, Shefflyan & Woodard (2005) *Biochem. J.* **390**, 583.

**Shikimate-5-enolpyruvate 3-Phosphate, See 5-O-(1-Carboxyvinyl)-3-phosphoshikimate**

**Shikonin**

This naphthoquinone (FW = 288.30 g/mol; CAS 517-89-5), also known as (+)-5,8-dihydroxy-2-[(1R)-1-hydroxy-4-methyl-3-pentenyl]-1,4-naphthalenedione, from the Chinese herb *Shiunko* exhibits significant antibacterial, anti-inflammatory, and antitumor activities (1). Shikonin inhibits TNF- $\alpha$ -induced and B-16 melanoma-induced angiogenesis in mice (2). It also blocks the expression of integrin  $\alpha v\beta 3$  and inhibits endothelial cell proliferation and migration *in vitro*. Shikonin will induce apoptosis in HL60 human promyelocytic leukemia cell line (3). **Target(s)**: alkaline phosphatase (4); chemokine binding to CC chemokine receptor-1 (5); DNA topoisomerase I (6); leukotriene B<sub>4</sub> biosynthesis (7); photosynthetic electron transfer (8); ribonuclease H (9); sterol *O*-acyltransferase, or ACAT (10); and telomerase (11). 1. **SHK-186**, See *Dalazatide*

**ShK-Dap22**

This semi-synthetic potassium channel toxin and immunosuppressive polypeptide (MW = 4.1 kDa), also named Potassium Channel Toxin  $\kappa$ -Stichotoxin-She1a, targets K<sub>v</sub>1.3, the voltage-gated potassium channel in T lymphocytes, an important molecular target for immunosuppressive agents. It is prepared from the parent polypeptide ShK (from the sea anemone *Stichodactyla helianthus*) by site-directed substitution of the non-natural amino acid diaminopropionic acid in place of lysine at the critical residue-22. ShK-Dap22 potently inhibits K<sub>v</sub>1.3 ( $K_d = 11$  pM) and also blocks K<sub>v</sub>1.1, K<sub>v</sub>1.4, and K<sub>v</sub>1.6 at sub-nM concentrations. At sub-nM concentrations, ShK-Dap22 also suppresses anti-CD3-induced human T-lymphocyte [<sup>3</sup>H]thymidine incorporation *in vitro*. Its toxicity is low in a rodent model (median paralytic i.v. dose  $\approx$  200 mg/kg body weight). 1. Kalman, Pennington, Lanigan, *et al.* (1998) *J. Biol. Chem.* **273**, 32697.

**Showdomycin**

This water-soluble nucleoside-like antibiotic (FW = 229.19 g/mol; CAS 16755-07-0), also known as 2-( $\beta$ -D-ribofuranosyl)maleimide, from *Streptomyces showdoensis* is structurally related to uridine and pseudouridine. The double-bond in the maleimide moiety of showdomycin reacts with catalytically essential sulfhydryl groups, thereby inactivating target enzymes. **Target(s)**: *N*-acetylglucosaminyl diphosphodolichol *N*-acetylglucosaminyltransferase (1-3); adenosine transport, Na<sup>+</sup>-linked (4); amino acid transport (5); DNA-directed RNA polymerase (6); dolichylphosphate  $\beta$ -glucosyltransferase (7-10); dolichylphosphate  $\beta$ -D-

mannosyltransferase (11); 1,3- $\beta$ -glucan synthase (12); GTP cyclohydrolase II (13); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (14,15); poly(ADPribose) polymerase, or NAD<sup>+</sup> ADP-ribosyltransferase (16); protein glycosylation (7-9,17); sugar transport (5); thymidylate synthase (18,19); UDP-*N*-acetylglucosamine:dolichylphosphate *N*-acetylglucosaminylphosphotransferase (20); UDP-glucose dehydrogenase (8,9); and UDP-glucose 4-epimerase (21). 1. **SHP099**

This selective and orally bioavailable small-molecule SHP2 inhibitor (FW<sub>free-base</sub> = 352.26 g/mol; FW<sub>HCl-Salt</sub> = 388.72 g/mol; CAS 1801747-11-4 (HCl salt) and 801747-42-1 (Free Base); Soluble in DMSO; IUPAC: 6-(4-amino-4-methylpiperidin-1-yl)-3-(2,3-dichlorophenyl)pyrazin-2-amine) targets the non-receptor protein tyrosine phosphatase SHP2 (IC<sub>50</sub> = 71 nM), also known as Protein Tyrosine-Phosphatase Non-receptor type 11 (PTPN11), Protein-Tyrosine Phosphatase 1D (PTP-1D) and Protein-Tyrosine Phosphatase 2C (PTP-2C). Indeed, SHP2 is ubiquitously expressed and regulates cell survival and proliferation primarily through activation of the RAS-ERK signalling pathway. This enzyme plays important roles in signal transduction occurring downstream of growth factor receptor signaling. SHP2 was the first reported oncogenic tyrosine phosphatase, and it is also a key mediator in the Programmed cell Death-1 (PD-1) and B- and T-Lymphocyte Attenuator (BTLA) immune-checkpoint pathways. **Mode of Inhibitory Action**: SHP099 stabilizes SHP2 in an auto-inhibited conformation by binding concurrently to the interface of the N-terminal SH2, C-terminal SH2, and protein tyrosine phosphatase domains, thereby allosterically inhibiting SHP2's phosphatase activity. It also suppresses RAS-ERK signaling, thereby inhibiting proliferation of receptor-tyrosine-kinase-driven human cancer cells *in vitro* and in mouse tumor xenograft models, the latter achieved after a single oral dose (100 mg per kg) of SHP099. 1. Chen, LaMarche, Chane, *et al.* (2016) *Nature* **535**, 148.

**Siaastatin B**

This *Streptomyces*-derived piperidine (FW = 218.21 g/mol; CAS 54795-58-3), known systematically as (3*S*,4*S*,5*R*,6*R*)-6-(acetylamino)-4,5-dihydroxy-

3-piperidinecarboxylic acid, is a broad-spectrum inhibitor of bacterial exo- $\alpha$ -sialidase, or neuraminidase (1-3). The charge distribution in the siastatin B zwitterion is thought to resemble that in the *N*-acetylneuraminic oxocarbenium ion, a proposed intermediate in the sialidase-catalyzed reaction. 1. Miyagi, Hata, Hasegawa & Aoyagi (1993) *Glycoconj. J.* **10**, 45. 2. Umezawa, Aoyagi, Komiyama, Morishima & Hamada (1974) *J. Antibiot.* **27**, 963. 3. Knapp & Zhao (2000) *Org. Lett.* **2**, 4037.

### Sibutramine

This centrally-acting neurotransmitter reuptake inhibitor and anorectic agent (FW = 279.85 g/mol; CAS 106650-56-0), also known by the trade names Reductil<sup>®</sup>, Meridia<sup>®</sup>, and Sibutrex<sup>®</sup>, as well as the systematic name ( $\pm$ )-dimethyl-1-[1-(4-chlorophenyl)cyclobutyl]-*N,N,N*,3-trimethylbutan-1-amine, is a  $\beta$ -phenethylamine that targets the serotonin transporter ( $K_i = 0.3 \mu\text{M}$ ), norepinephrine transporter ( $K_i = 5.4 \mu\text{M}$ ), and dopamine transporter ( $K_i = 0.94 \mu\text{M}$ ), thereby increasing their levels within synaptic clefts and enhancing satiety. Sibutramine is metabolized by CYP3A4 into two pharmacologically-active primary and secondary amines (called active metabolites 1 and 2) with half-lives of 14 and 16 hours, respectively. Although sibutramine had been widely marketed, an associated high risk of cardiovascular events, strokes, and death led to its withdrawal in many countries. 1. Araújo, Silva, Cruz & Falcão-Reis (2014) *J. Glaucoma* **23**, 415.

### Sideromycins

These naturally occurring  $\text{Fe}^{3+}$ -siderophores and antibacterial agents are covalently linked to an antibiotic moiety, the former accounting for their efficient cellular uptake and the latter explaining their substantial cytotoxic/cytostatic antibacterial action (1). Shown above is Albomycin  $\delta_2$ . Siderophores and sideromycins compete for common uptake systems, which transport of  $\text{Fe}^{3+}$ -siderophores across the outer membrane, driven by the cytoplasmic membrane's proton-motive force and transduced by the Ton protein complex, consisting of TonB, ExbB, and ExbD proteins. As a consequence, their minimal inhibitory concentration is at least 100-fold lower than that of antibiotics entering cells by diffusion. One such sideromycin is albomycin (the hexacoordinate,  $\text{Fe}^{3+}$ -hydroxamate-containing complex shown above), which consists of a siderophore that is structurally similar to ferrichrome and a thioribosyl pyrimidine antibiotic. 1. Braun, Pramanik, Gwinner, Köberle & Bohn (2009) *Biometals* **22**, 3.

**Siguazodan**, See SKF 94836

**Silencing RNA**, See Small Interfering RNA

### Sildenafil

This prototypical erectile dysfunction (ED) drug (FW<sub>free-base</sub> = 474.58 g/mol; CAS 139755-83-2; M.P. = 187-189°C), also named 1-[4-ethoxy-3-(6,7-dihydro-1-methyl-7-oxo-3-propyl-1*H*-pyrazolo[4,3-*d*]pyrimidin-5-yl)phenyl sulfonyl]-4-methylpiperazine, targets the type-5 isozyme of 3',5'-cyclicGMP phosphodiesterase, resulting in the sustained phosphorylation of protein targets of 3',5'-cyclicGMP-stimulated protein kinase, attended by prolonged vasodilation (1-8). **Mode of Inhibitory Action:** Both sildenafil and zaprinast are competitive inhibitors, and double-inhibition analysis shows that they bind to PDE5 in a mutually exclusive manner (2). Site-directed mutagenesis of each of 23 conserved amino acid residues in the catalytic domain of PDE5 show that the pattern of change in the  $\text{IC}_{50}$  values for sildenafil or UK-122764 were found to be similar to that for zaprinast. However, among the three inhibitors, sildenafil exhibits the most similar pattern of changes in the  $\text{IC}_{50}$  to that found for the affinity of cGMP, implying similar interactions with the catalytic domain (2). This may explain the stronger inhibitory potency of sildenafil for wild-type PDE5 (i.e., sildenafil ( $K_i = 1 \text{ nM}$ ) > UK-122764 ( $K_i = 5 \text{ nM}$ ) > zaprinast ( $K_i = 130 \text{ nM}$ ) (2). The affinity of each inhibitor is much higher than for cGMP ( $K_m = 2 \mu\text{M}$ ). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). Sildenafil citrate is the formulation known by the proprietary name Viagra<sup>™</sup>. It is also a potent stimulator of angiogenesis, achieved through upregulation of pro-angiogenic factors and by regulation of cGMP concentration. 1. Gopal, Francis & Corbin (2001) *Eur. J. ### Silibinin

This benzodioxin (FW = 482.44 g/mol; CAS 22888-70-6), also known as silybin and named systematically as 2,3-dihydro-3-(4-hydroxy-3-methoxyphenyl)-2-(hydroxymethyl)-6-(3,5,7-trihydroxy-4-oxobenzopyran-2-yl)benzodioxin, is the principal component of silymarin isolated from the seeds of the milk thistle (*Silybum marianum*). This flavonoid possesses antioxidant, anti-inflammatory and cancer-preventive activities. **Target(s):** CYP3A4 (1,2); CYP2C9 (2); CYP2D6 (1,2); CYP2E1 (1);  $\beta$ -glucuronidase (3); and glucuronosyltransferase (4). Silibinin also exhibits inhibitory effects on basal and cytokine-induced expression of Secreted Phospholipase A<sub>2</sub> (sPLA<sub>2</sub>) in cancer cells (5). 1. Zuber, Modriansky, Dvorak, et al. (2002) *Phytother. Res.* **16**, 632. 2. Beckmann-Knopp, Rietbrock, Weyhenmeyer, et al. (2000) *Pharmacol. Toxicol.* **86**, 250. 3. ### Silodosin

This  $\alpha_{1a}$ -adrenoceptor antagonist (FW = 495.53 g/mol; CAS 160970-54-7), also known by its code name KMD-3213, its trade names Rapaflo<sup>™</sup> (in USA) and Silodyx<sup>™</sup> (in Europe), Rapilif<sup>™</sup> (in India), and Urief<sup>™</sup> (in Japan) as well as its systematic name, 1-(3-hydroxypropyl)-5-[(2*R*)-{(2-[2-(2,2,2-trifluoroethoxy)phenoxy]ethyl)amino}propyl]indoline-7-

carboxamide) is a uroselective muscle relaxant used to treat reduced urinary flow associated with benign prostatic hyperplasia, or BPH (1,2). Silodosin binds to cloned human  $\alpha_{1a}$ -AR ( $K_i = 0.036$  nM), but exhibits 583x and 56x lower potency  $\alpha_{1b}$ -AR and  $\alpha_{1a}$ -AR, respectively. KMD-3213 also inhibits norepinephrine-induced increases in intracellular  $Ca^{2+}$  concentrations in  $\alpha_{1a}$ -AR-expressing Chinese hamster ovary (CHO) cells, with an  $IC_{50}$  of 0.32 nM, again with much weaker effects on  $\alpha_{1b}$ - and  $\alpha_{1a}$ -ARs (1). 1. Shibata, Foglar, Horie, *et al.* (1995) *Mol. Pharmacol.* 48, 250. 2. Moriyama, Akiyama, Murata *et al.* (1997) *Eur. J. Pharmacol.* 331, 39.

### Siltuximab

This mouse/human chimeric anti-IL-6 monoclonal antibody (MW = 145.0 kDa; CAS 541502-14-1), also known as CNTO 328 and Sylvant<sup>®</sup>, binds to human interleukin-6, a multifunctional, proinflammatory cytokine produced by various cells such as T-cells, B-cells, monocytes, fibroblasts, and endothelial cells. IL-6 overproduction in activated B cells within affected lymph nodes is linked to multicentric Castleman's disease. Siltuximab is indicated for treating Castleman's patients, who are HIV-/HHV-8-negative. Treatment of therapy-resistant prostate cancer cells with Sylvant induces apoptosis and down-regulation of Myeloid cell leukemia-1 (Mcl-1) protein, an antiapoptotic member in the Bcl-2 family (1). IL-6 also stimulates inflammatory cytokine production, tumor angiogenesis, and the tumor macrophage infiltrate in ovarian cancer, actions that can be inhibited by Sylvant (2). Siltuximab also completely inhibits STAT3 tyrosine phosphorylation in H1650 cells, resulting in inhibition of lung cancer cell growth *in vivo* (3). 1. Cavarretta, Neuwirt, Untergasser, *et al.* (2007) *Oncogene* 26, 2822. 2. Coward, Kulbe, Chakravarty, *et al.* (2011) *Clin. Cancer Res.* 17, 6083. 3. Song, Rawal, Nemeth & Haura (2011) *Mol. Cancer Ther.* 10, 481.

### Silver Ion

This well-known bactericidal agent  $Ag^+$  (most often supplied as the soluble (2.16 g/mL at 20 °C), but nonhygroscopic mononitrate salt,  $AgNO_3$ ; FW = 169.87 g/mol) is frequently used to stain proteins and RNA in polyacrylamide gels. Silver ions react with sulfhydryl groups, accounting for its inhibitory action on a large number of enzymes requiring free active-site thiols for catalysis. Silver ion will often replace a Cu(I) in certain copper-dependent proteins, and a  $Ag_2Zn$ -superoxide dismutase has been reported. The antimicrobial properties of silver were first recognized thousands of years ago, when silver containers were found to be highly effective for preserving potable water. (See also *Argyrol*, for use in prevention of gonorrheal blindness) Another product, SILVADUR<sup>™</sup> ET, is Dow Chemical's silver-based antimicrobial that uses a patented delivery system for transporting and binding silver to articles of clothing, thereby inhibiting the growth of microbes. This proprietary technology controls the release of the silver, thereby avoiding discoloration and reducing unnecessary loss of the bound silver. SILVADUR<sup>™</sup> ET may be applied to both organic and inorganic surfaces using standard coating methods such as saturation, spray, foam, printing or exhaust. Approved applications are the preservation of non-food contact coatings and films, as well as woven and nonwoven fibers commonly used in industry and homes.

### Silver Sulfadiazine, See Sulfadiazine

### Simazine

This pre-emergence herbicide and algacide (FW = 201.66 g/mol; CAS 122-34-9; water solubility  $\approx 30$   $\mu$ M), widely known as Princep<sup>™</sup> and named systematically either as 2-chloro-4,6-bis(ethylamino)-s-triazine, 2,4-bis(ethylamino)-6-chloro-s-triazine or 6-chloro-*N,N'*-diethyl-1,3,5-triazine-2,4-diamine, inhibits photosynthetic electron transport. Simazine is absorbed through the roots and accumulates in the leaves and the meristem of plants. Its toxicity requires exposure to light, and plants kept in the dark are virtually unaffected. Simazine was introduced as a herbicide in the early 1950s, but its use is now restricted to reduce ground-water contamination **Target(s)**: alcohol dehydrogenase (1); and photosynthetic electron transport (2,3). 1. Leblova, Galociova & Cerovska (1983) *Environ. Res.* 30,

389. 2. Izawa & Good (1972) *Meth. Enzymol.* 24, 355. 3. Dodge (1977) *Spec. Publ., Chem. Soc.* 29, 7.

### Simeprevir

This hepatitis C protease inhibitor (FW = 748.95 g/mol; CAS 923604-59-5), also known as TMC435, TMC435350, Olysio<sup>®</sup> and (2*R*,3*aR*,10*Z*,11*aS*,12*aR*,14*aR*)-*N*-(cyclopropylsulfonyl)-2-[[2-(4-isopropyl-1,3-thiazol-2-yl)-7-methoxy-8-methyl-4-quinolinyloxy]-5-methyl-4,14-dioxo-2,3,3*a*,4,5,6,7,8,9,11*a*,12,13,14-tetradecahydrocyclopenta[*c*]cyclopropano[1,6]diazacyclotetradecine-12*a*(1*H*)-carboxamide, is an FDA-approved treatment for chronic hepatitis C (Genotype 1) infection, when used in combination with pegylated-interferon  $\alpha$  and ribavirin (two other FDA-approved treatments for chronic hepatitis C) in adult patients with compensated liver disease (including cirrhosis) who are treatment-naïve or who have failed previous interferon therapy (pegylated or non-pegylated) with or without ribavirin. Simeprevir is a potent inhibitor of HCV NS3/4A protease ( $K_i = 0.36$  nM) and viral replication (replicon  $EC_{50} = 7.8$  nM). 1. Raboisson, de Kock, Rosenquist, *et al.* (2008) *Bioorg. Med. Chem. Lett.* 18, 4853

### Simvastatin

This cholesterol-reducing statin (FW = 418.57 g/mol; CAS 79902-63-9; tradename: Zocor<sup>™</sup>), a synthetic derivative of a fermentation product of *Aspergillus terreus*, targets 3-hydroxy-3-methylglutaryl-CoA reductase ( $IC_{50} = 11$  nM), the rate-controlling reaction in the biosynthesis of cholesterol and other isoprenoids (1-3). When taken along with a low-fat diet, simvastatin reduces the risk of heart attack, stroke, certain kinds of heart surgeries, as well as chest pain in patients with heart disease or several common heart disease risk factors (*i.e.*, family history of heart disease, high blood pressure, age, low HDL cholesterol, and smoking). Simvastatin has also been reported to modify the cholesterol exchange between plasma and the erythrocyte membrane. **Note**: Because Simvastatin is metabolized by CYP3A4, co-administration of a CYP3A4 inhibitor can lead to adverse drug interactions. Strong CYP3A4 inhibitors include itraconazole, ketoconazole, posaconazole, erythromycin, clarithromycin, telithromycin, HIV protease inhibitors, boceprevir, telaprevir, nefazodone, gemfibrozil, cyclosporine, and danazol. **Antineoplastic Action**: Commonly used statins (including lovastatin, fluvastatin, and simvastatin) are known to inhibit proliferation of cancer cells. Simvastatin inhibits cell proliferation in a dose-dependent manner in both endometrial cancer cell lines and 5/8 primary cultures of endometrial cancer cells. Simvastatin treatment arrests cell cycle at  $G_1$ , reduces HMG-CoA reductase activity, induces apoptosis as well as DNA damage and cellular stress (4). Simvastatin treatment also inhibits MAPK pathway signalling and shows differential effects on the AKT/mTOR pathway in the ECC-1 and Ishikawa cells. Minimal change in AKT phosphorylation was seen in both cell lines. Treatment also reduces cell adhesion and invasion in these cell lines (4). Simvastatin enhances phosphorylation of the endogenous Akt substrate endothelial nitric oxide synthase (eNOS), inhibited apoptosis and accelerated vascular structure

formation in vitro in an Akt-dependent manner (5). Similar to vascular endothelial growth factor (VEGF) treatment, simvastatin administration and enhanced Akt signaling in the endothelium promoted angiogenesis in ischemic limbs of normocholesterolemic rabbits. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** 3-hydroxy-3-methylglutaryl-CoA reductase (1-3); cyclin-dependent kinase, or Cdk2 (6); acetylcholinesterase (7); cholinesterase, or butyrylcholinesterase (7); CYP3A4 (8); CYP2C9 (8); CYP2D6 (8). 1. **SIN-1, See 3-Morpholinopyridone**

### Sinapate

This coumarate derivative (FW<sub>free-acid</sub> = 224.21 g/mol; CAS 530-59-6), also known as sinapinic acid and 4-hydroxy-3,5-dimethoxycinnamic acid, antioxidant-exhibiting precursor in the biosynthesis of sinapyl alcohol. Sinapic acid is often used as a matrix in MALDI-TOF mass spectroscopy.

**Target(s):** activator-protein 1, or AP-1 (1);  $\alpha$ -amylase, weakly (2); lipase, or triacylglycerol lipase, weakly (3); peroxidase, horseradish (4); phenol sulfotransferase, or aryl sulfotransferase (5); and phenylalanine ammonia-lyase, weakly (6). 1. Jorin & Dixon (1990) *Plant Physiol.* **92**, 447.

### Sinefungin

This *S*-adenosyl-L-homocysteine analogue and antibiotic (FW = 381.39 g/mol; CAS 58944-73-3; pK<sub>1</sub> = 2.9, pK<sub>2</sub> = 3.9, pK<sub>3</sub> = 8.9, and pK<sub>4</sub> = 10.2 in *N,N*-dimethylformamide, 66% vol/vol;  $\lambda_{\max}$  = 259 nm;  $\epsilon$  = 15,400 M<sup>-1</sup>cm<sup>-1</sup>), also known as A-9145, adenosylornithine and 6,9-diamino-1-(6-amino-9H-purin-9-yl)-1,5,6,7,8,9-hexadeoxy-D-glycero- $\alpha$ -L-talo-decofuranuronic acid, is produced by *Streptomyces griseolus* NRRL 3739. Sinefungin inhibits a many methyltransferases, including those catalyzing methylation of

residues in mRNA and DNA. **Target(s):** acyl-homoserine-lactone synthase (41); adenosyl-fluoride synthase, weakly (40); adenosyl-homocysteinase, or *S*-adenosylhomocysteine hydrolase (1,38); 1-aminocyclopropane-1-carboxylate synthase (2,3,36,37); calmodulin-lysine *N*-methyltransferase (62); CheR methyltransferase (4); catechol *O*-methyltransferase (5,66,68); cycloartenol 24-*C*-methyltransferase (32); cyclopropane-fatty-acyl-phospholipid synthase (6,54-56); [cytochrome *c*]-arginine *N*-methyltransferase (46); [cytochrome *c*]-methionine *S*-methyltransferase (46); demethylmacrocin *O*-methyltransferase, weakly (47); 3'-demethylstaurosporine *O*-methyltransferase (42); DNA (adenine)-methyltransferase *M.Dam* (7); DNA (adenine)-methyltransferase *M.Eca* (18); DNA (adenine)-methyltransferase *M.EcoRI* (9,57); DNA (adenine)-methyltransferase *MmeI* (10); DNA (adenine)-methyltransferase *M.TaqI* (11); DNA (adenine)-methyltransferase, *Streptomyces* (12); DNA (cytosine-5)-methyltransferase *M.MspI* (13); DNA (cytosine-)-methyltransferase, *Streptomyces* (12); DNA methyltransferase *M.KpnI* (14); guanidinoacetate *N*-methyltransferase (15,69,70); histamine methyltransferase (16,66); histone-arginine *N*-methyltransferase (43-45); histone-lysine *N*-methyltransferase (17,18); homarine synthase (19); macrocin *O*-methyltransferase (48); magnesium protoporphyrin IX methyltransferase (67); meromycolic acid-[acyl-carrier protein] methyltransferase (20); 5'-methylthioadenosine nucleosidase (21,39); mRNA (guanine-*N*<sup>7</sup>-)-methyltransferase (18,22,63,64); mRNA (nucleoside-2'-*O*-)-methyltransferase (18,22,63); [myelin basic protein]-arginine *N*-methyltransferase (43); norepinephrine *N*-methyltransferase (18,66); phenylethanolamine *N*-methyltransferase (16,66); protein-arginine methyltransferase (18,23,24); protein-glutamate *O*-methyltransferase (18,25,53); protein-*S*-isoprenylcysteine *O*-methyltransferase (18,26,27,49-52); RNA (adenine-1)-methyltransferase, *Streptomyces* (28); RNA, or adenine-*N*<sup>6</sup>-methyltransferase, *Streptomyces* (28); RNA (guanine-7)-methyltransferase, *Streptomyces* (28); rRNA (adenine-*N*<sup>6</sup>-)-methyltransferase *ErmC*<sup>29</sup>; site-specific DNA-methyltransferase (adenine-specific) (7-12,57-61); spermidine synthase (30); splice-leader RNA methyltransferase (31); sterol 24-*C*-methyltransferase (32,65); thioether *S*-methyltransferase (33); thiopurine methyltransferase (34); and type IV pilin *N*-methyltransferase (35). 1. ### Sirtinol

This cell-permeable hydroxynaphthaldehyde-containing sirtuin (FW = 394.47 g/mol; CAS 410536-97-9; Soluble to 100 mM in DMSO), also named 2-[[[2-(2-hydroxy-1-naphthalenyl)-methylene]amino]-N-(1-phenylethyl)benzamide], inhibits members of the sirtuin family of NAD<sup>+</sup>-dependent deacetylases (SIRT1, IC<sub>50</sub> = 131 μM, and SIRT2, IC<sub>50</sub> = 38 μM), including the yeast Sir2p transcriptional silencing activity (1). Sirtinol inhibits Hepatitis A Virus (HAV) replication by inhibiting HAV internal ribosomal entry site activity (2). Spectroscopic and structural data reveal that this compound is also an iron chelator forming high-spin ferric species *in vitro* and in cultured leukemia cells (3). Sirtinol-induced senescence-like growth arrest was accompanied by impaired activation of mitogen-activated protein kinase (MAPK) pathways, namely, extracellular-regulated protein kinase, c-jun N-terminal kinase and p38 MAPK, in response to epidermal growth factor (EGF) and insulin-like growth factor-I (IGF-I) (4). Active Ras was reduced in sirtinol-treated senescent cells compared with untreated cells. However, tyrosine phosphorylation of the receptors for EGF and IGF-I and Akt/PKB activation were unaltered by sirtinol treatment (4). **Other Target(s):** inhibits neutrophil elastase activity, attenuating lipopolysaccharide-mediated acute lung injury in mice (5); attenuates trauma hemorrhage-induced hepatic injury through Akt-dependent pathway in rats (6); modulates adhesion molecule expression and monocyte adhesion on activated primary human dermal microvascular endothelial cells (HDMEC) (7). **1.** Grozinger, Chao, Blackwell, Moazed & Schreiber (2001) *J. Biol. Chem.* **276**, 38837. **2.** Kanda, Sasaki, Nakamoto, *et al.* (2015) *Biochem. Biophys. Res. Commun.* **466**, 567. **3.** Gautam, Akam, Astashkin, Loughrey & Tomat (2015) *Chem. Commun. ### Sisomicin

This aminoglycoside antibiotic (FW<sub>free-base</sub> = 447.53 g/mol; CAS 53179-09-2) from *Micromonospora inyoensis* consists of 2-deoxystreptamine linked covalently to sisosamine and garosamine. Sisomicin exhibits bactericidal activity against a wide range of Gram-negative bacteria (*e.g.*, *Escherichia coli*, *Pseudomonas aeruginosa*, and species of *Enterobacter*, *Klebsiella*, and *Proteus*). Although active against staphylococci, most streptococci are usually resistant (except when β-lactam antibiotics are present). Anaerobic organisms are not sensitive. Sisomicin is structurally closely related to gentamicin Cla, which contains a purpurosamine component in place of sisosamine. *In vitro* studies have shown it to have superior activity to gentamicin against *P. aeruginosa*, while still possessing the high activity of gentamicin against *Serratia* and other Gram-negative rods. Sisomicin is inactivated by virtually all bacterial enzymes which inactivate gentamicin and tobramycin. **Target(s):** gentamicin 3'-acetyltransferase (1); phospholipases (2); and protein biosynthesis (3). **1.** Haas & Dowding (1975) *Meth. Enzymol.* **43**, 611. **2.** Carlier, Laurent, Claes, Vanderhaeghe & Tulkens (1983) *Antimicrob. Agents Chemother.* **23**, 440. **3.** Cavallo & Martinetto (1981) *G. Bacteriol. Virol. Immunol.* **74**, 335.

### Sitafloxacin

This fluoroquinolone-class antibiotic (FW = 409.82 g/mol; CAS 127254-12-0), also known as DU-6859a, inhibits bacterial DNA topoisomerase II. (For the prototypical member of this antibiotic class, **See Ciprofloxacin**) **Target(s):** DNA topoisomerase II, or DNA gyrase (1-3); and DNA topoisomerase IV (2,3). **1.** Akasaka, Kurosaka, Uchida, *et al.* (1998) *Antimicrob. Agents Chemother.* **42**, 1284. **2.** Onodera, Uchida, Tanaka & Sato (1999) *J. Antimicrob. Chemother.* **44**, 533. **3.** Onodera, Okuda, Tanaka & Sato (2002) *Antimicrob. Agents Chemother.* **46**, 1800.

### Sitagliptin

This orally bioavailable antihyperglycemic agent (FW = 407.31 g/mol; CAS 654671-77-9, 486460-32-6 (free base), 654671-78-0 (phosphate); Solubility: 100 mg/mL DMSO; 100 mg/mL Water; Formulation: 0.5% aqueous hydroxyethylcellulose), also known as MK-0431 or Januvia<sup>®</sup> and named systematically as (2*R*)-4-oxo-4-[3-(trifluoromethyl)-5,6-dihydro[1,2,4]triazolo[4,3-*a*]pyrazin-7(8*H*)-yl]-1-(2,4,5-trifluorophenyl)butan-2-amine, is a potent competitive inhibitor of dipeptidyl-peptidase IV, or DDP-

4,  $IC_{50} = 18$  nM. DDP-4 cleaves the incretins, a group of gastrointestinal hormones that increase insulin release, even before blood glucose levels become elevated. By limiting proteolysis of the gastrointestinal hormones glucagon-like protein-1 and -2 (GLP-1 and GLP-2), sitagliptin indirectly maintains insulin secretion and suppresses glucagon release (1). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). See *Incretin Hormone Enhancers; Saxagliptin* 1. Kim, Wang, Beconi, *et al.* (2005) *J. Med. Chem.* **48**, 141.

#### Sitaxentan

This orally active, highly selective  $ET_A$  antagonist (FW<sub>free-acid</sub> = 454.90 g/mol; FW<sub>Na-salt</sub> = 476.89 g/mol; CAS 210421-74-2; Solubility: 40 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as TBC11251 and *N*-(4-chloro-3-methyl-1,2-oxazol-5-yl)-2-[2-(6-methyl-2*H*-1,3-benzodioxol-5-yl)acetyl]thiophene-3-sulfonamide, targets the endothelin A receptor ( $IC_{50} = 1.4$  nM;  $K_i = 0.43$  nM), exhibiting 7000x selectivity over  $ET_B$  receptors ( $IC_{50} = 9800$  nM) and inhibiting ET-1-induced stimulation of phosphoinositide turnover with a  $K_i$  of 0.686 nM (1). Three weeks after rats were first treated with a single subcutaneous injection of monocrotaline (MCT), sitaxentan dose dependently (10 and 50 mg/kg per day in the drinking water) attenuated right ventricular systolic pressure, right heart hypertrophy, and pulmonary vascular remodeling (1-3). [Note: Administration of small doses of MCT or its active metabolite, monocrotaline pyrrole (MCTP), causes delayed and progressive lung injury characterized by pulmonary vascular remodeling, pulmonary hypertension, and compensatory right heart hypertrophy (4).] Systemic administration of this  $ET_A$  receptor antagonist significantly attenuates cerebral vasospasm after subarachnoid hemorrhage (SAH), thus providing additional support for the role of ET-1 in vasospasm (5). 1. Wu, Chan, Stavros, *et al.* (1997) *J. Med. Chem.* **40**, 1690. 2. Tilton, Munsch, Sherwood, *et al.* (2000) *Pulm. Pharmacol. Ther.* **13**, 87. 3. Holm (1997) *Scand. Cardiovasc. J. #### β-Sitosterol

This phytosterol (FW = 414.72 g/mol), also known as (3β)-stigmast-5-en-3-ol, is commonly found in many plants (*e.g.*, soy beans, rice embryos, wheat germ, corn oil, rye germ oil, cottonseed oil, pine bark, potatoes, sugar cane wax, tobacco, *etc.*). **Target(s):** cholesterol 7α-hydroxylase, weak alternative substrate (1); cholesterol uptake (2-4); complement component C1 (5); cycloartenol 24-*C*-methyltransferase (6,7); protein-tyrosine kinase activation (8,9); steroid 5α-reductase (10); sterol acyltransferase, or cholesterol acyltransferase (11); sterol 27-monooxygenase (12); and steryl-β-glucosidase (13). 1. Shefer, Salen, Nguyen, *et al.* (1988) *J. Clin. Invest.* **82**, 1833. 2. Wong (2001) *Can. J. Cardiol.* **17**, 715. 3. Ikeda, Tanaka, Sugano, Vahouny & Gallo (1988) *J. Amer. Physicians* **110**, 32. 13. Kalinowska & Wojciechowski (1978) *Phytochemistry* **17**, 1533.

#### Sivelestat

This peptide analogue (FW<sub>free-acid</sub> = 434.46 g/mol; CAS 201677-61-4), also known by the code name ONO-5046, the trade name Elaspot<sup>®</sup>, and *N*-[2-[4-(2,2-dimethylpropionyloxy)phenyl-sulfonylamino]aminoacetic acid, inhibits neutrophil elastase,  $K_i = 200$  nM,  $IC_{50} = 44$  nM (1) and is used to treat pulmonary fibrosis and idiopathic interstitial pneumonia. Human neutrophil elastase (HNE) is a serine protease, which plays a major role in the COPD inflammatory process. Sivelestat also inhibits the growth of human lung cancer cell lines in SCID mice. 1. Kawabata, Suzuki, Sugitani, *et al.* (1991) *Biochem. Biophys. Res. Commun.* **177**, 814.

#### Sizukacillin, See Suzukacillin

#### SJ 172550

This reversible MDMX inhibitor (FW = 428.87 g/mol; CAS 431979-47-4; Solubility: 100 mM DMSO), also named 2-[2-chloro-4-[(1,5-dihydro-3-methyl-5-oxo-1-phenyl-4*H*-pyrazol-4-ylidene)methyl]-6-ethoxyphenoxy]-acetic acid methyl ester, binds MdmX ( $EC_{50} = 2.3$  μM), which inhibits p53 through Mdm2-dependent and independent mechanisms. MDM2 and MDMX (also known as HDMX and MDM4) proteins are dysregulated in many human cancers, exerting oncogenic activity by inhibiting the p53 tumor suppressor. MdmX is regulated by DNA damage signaling events, indicating its involvement in the p53 response to DNA damage SJ-172550 inhibits the MDMX-p53 interaction in cultured retinoblastoma cells, freeing p53 to induce apoptosis. The effect of SJ-172550 is additive when combined with an MDM2 inhibitor. Results from a series of biochemical and structural modeling studies suggest SJ-172550 binds to the p53-binding pocket of MDMX, thereby displacing p53. 1. Reed, Shen, Shelat, *et al.* (2010) *J. Biol. Chem.* **285**, 10786.

#### Skepinone-L

This protein kinase inhibitor (FW = 425.42; CAS 1221485-83-1), also named 2-[(2,4-difluorophenyl)amino]-7-[(2*R*)-2,3-dihydroxypropoxy]-10,11-dihydro-5*H*-dibenzo[*a,d*]-cyclohepten-5-one and CEP-32496, targets p38 $\alpha$ -MAPK (IC<sub>50</sub> = 5 nM), wild-type BRAF (K<sub>d</sub> = 36 nM), BRAF<sup>V600E</sup> (K<sub>d</sub> = 14 nM) and c-Raf (K<sub>d</sub> = 39 nM). Skepinone-L inhibits HSP27 phosphorylation at Ser82 by the p38 MAPK (IC<sub>50</sub> = 25 nM) (1,2). Skepinone-L (at 1  $\mu$ M) almost completely blocked phosphorylation of platelet p38 MAPK substrate Hsp27 after stimulation with C-Reactive Protein (CRP) at 1  $\mu$ g/ml, thrombin at 5 mU/mL, or the thromboxane A<sub>2</sub> analogue U-46619 at 1  $\mu$ M (2). Skepinone-L significantly blunted activation-dependent platelet secretion and aggregation following threshold concentrations of CRP, thrombin and thromboxane A<sub>2</sub> analogue U-46619. Skepinone-L did not impair platelet Ca<sup>2+</sup> signaling but prevented agonist-induced thromboxane A<sub>2</sub> synthesis through abrogation of p38 MAPK-dependent phosphorylation of platelet cytosolic phospholipase A<sub>2</sub>, or cPLA<sub>2</sub> (2). Skepinone-L further markedly blunted thrombus formation under low and high arterial shear rates. 1. Koeberle, Romir, Fischer, *et al.* (2011) *Nature Chem. Biol.* **8**, 141. 2. Borst, Walker, Münzer, *et al.* (2013) *Cell Physiol. Biochem.* **31**, 914.

**SK549**

This antithrombotic agent (FW<sub>ion</sub> = 546.59 g/mol) inhibits coagulation factor Xa, K<sub>i</sub> = 0.52 nM, but is a weaker inhibitor of thrombin, trypsin, and plasmin, with respective K<sub>i</sub> values of 400 nM, 45 nM, and 890 nM. 1. Leadley, Jr. (2001) *Curr. Top. Med. Chem.* **1**, 151. 2. Quan, Ellis, Liauw, *et al.* (1999) *J. Med. Chem.* **42**, 2760. 3. Wong, Quan, Crain, *et al.* (2000) *J. Pharmacol. Exp. Ther.* **292**, 351. **Alternate Identifiers:** SK549, SK-549

**Skatole**

This foul-smelling indole (FW = 131.18 g/mol; CAS 83-34-1; M.P. = 95°C), also known as 3-methyl-1*H*-indole, is a degradation product of indoleacetate and tryptophan that is soluble in hot water, ethanol, and benzene. Skatole has a fecal odor that readily permeates clothing. While many bacteria metabolize tryptophan to indole and indole acetic acid (IAA), only a few gut bacteria, mainly from the *Clostridium* and *Bacteroides* genera, catalyze the conversion of IAA to skatole. **Target(s):** chymotrypsin (1,2); lipid peroxidation (3); and tryptophanase (4). 1. **SKF 93944**, See *Temelastine*

**SKF 94836**

This substituted guanidine (FW = 284.32 g/mol), also known as Siguzodan, inhibits cAMP phosphodiesterase III,  $K_i = 1-3 \mu\text{M}$  (1,2). Time course studies indicated that SK&F 94836-induced relaxation of trachealis strips contracted with 0.1  $\mu\text{M}$  methacholine was accompanied by an activation of cAMP-dependent protein kinase (cAMP-PK). In subsequent experiments, trachealis strips were contracted with three concentrations of methacholine (0.1, 1.0 or 3.0  $\mu\text{M}$ ) or two concentrations of histamine (10 or 300  $\mu\text{M}$ ) before being relaxed by the cumulative addition of SKF-94836. The relaxant response to SKF-94836 ( $EC_{50} = 1-10 \mu\text{M}$ ) decreases progressively as tissues are contracted with higher concentrations of methacholine. In parallel with its inhibitory effect on SKF-94836-induced relaxation, methacholine suppresses the ability of SKF-94836 to activate cAMP-PK. Inhibition of cAMP-PK activity is not accompanied by a significant inhibition of SK&F 94836-stimulated cAMP accumulation. The concentration of histamine used to contract tissues has no effect on SKF-94836-induced relaxation or cAMP-PK activation. To determine the effect of SKF-94836 on the mechanical and biochemical responses to the  $\beta$ -adrenoceptor agonist isoproterenol, tissues are first contracted with 3.0  $\mu\text{M}$  methacholine and then incubated with 0, 0.3, 3.0 or 30  $\mu\text{M}$  SKF-94836 before being relaxed by the cumulative addition of isoproterenol. SKF-94836 potentiates isoproterenol-induced relaxation, cAMP accumulation and cAMP-PK activation in a concentration-dependent manner. 1. Torphy, Burman, Huang & Tucker (1988) *J. Pharmacol. Exp. Ther.* **246**, 843. 2. Tomkinson, Karlsson & Raeburn (1993) *Brit. J. Pharmacol.* **108**, 57.

**SKF 95282**, See *Zolantidine*

**SKF 96022**, See *Pantoprazole*

**SKF 96365**

This calcium ion antagonist and Store-operated  $\text{Ca}^{2+}$  entry (or SOCE) inhibitor (FW<sub>hydrochloride</sub> = 402.92 g/mol; CAS 130495-35-1; Solubility: 100 mM in  $\text{H}_2\text{O}$ , as HCl salt), also named 1-( $\beta$ -[3-(4-methoxyphenyl)propoxy]-4-methoxyphenethyl)-1H-imidazole, is structurally distinct from known  $\text{Ca}^{2+}$  antagonists and selectively blocks Receptor-Mediated Calcium entry, or RMCE, compared with receptor-mediated internal  $\text{Ca}^{2+}$  release (1). SK&F 96365 gave  $IC_{50}$  values of 8.5  $\mu\text{M}$  or 11.7  $\mu\text{M}$  for ADP- and thrombin-activated platelets, but does not affect internal  $\text{Ca}^{2+}$  release (1). Similar effects of SK&F 96365 are observed in suspensions of neutrophils and endothelial cells. SK&F 96365 also inhibits agonist-stimulated  $\text{Mn}^{2+}$  entry in platelets and neutrophils. Voltage-gated  $\text{Ca}^{2+}$  entry in fura-2-loaded

GH3 pituitary cells and rabbit ear-artery smooth-muscle cells held under voltage-clamp is also inhibited by SK&F 96365, but the ATP-gated  $\text{Ca}^{2+}$ -permeable channel of arterial smooth-muscle cells is unaffected by SK&F 96365. Unlike 'organic  $\text{Ca}^{2+}$  antagonists', SK&F 96365 shows no selectivity between voltage-gated  $\text{Ca}^{2+}$  entry and RMCE, although the lack of effect on ATP-gated channels indicates that it discriminates between different types of RMCE. Because SK&F 96365 is not as potent ( $IC_{50} \sim 10 \mu\text{M}$ ) and nonselectively inhibits voltage-gated  $\text{Ca}^{2+}$  entry, caution must be exercised for unambiguous use of this agent. SKF-96365 exhibits potent anti-neoplastic activity by inducing cell-cycle arrest and apoptosis in colorectal cancer cells (2). It also induces cytoprotective autophagy to delay apoptosis by preventing the release of cytochrome *c* (cyt *c*) from the mitochondria into the cytoplasm (2). Mechanistically, SKF-96365 treatment inhibited the calcium/calmodulin-dependent protein kinase II $\gamma$  (CaMKII $\gamma$ )/AKT signaling cascade *in vitro* and *in vivo*. Overexpression of CaMKII $\gamma$  or AKT abolished the effects of SKF-96365 on cancer cells, suggesting a critical role of the CaMKII $\gamma$ /AKT signaling pathway in SKF-96365-induced biological effects (2). (See also *Maitotoxin*; *Palytoxin*) SKF 96365 also inhibits tubulin polymerization (microtubule self-assembly) *in vitro* (3). 1. Merritt, Armstrong, Benham, *et al.* (1990) *Biochem. J.* **271**, 515. 2. Jing, Sui, Yao, *et al.* (2016) *Cancer Lett.* **372**, 226. 3. Mitsui-Saito, Nakahata & Ohizumi (2000) *Jpn. J. Pharmacol.* **82**, 269.

**SKF 98625**

This phosphonate diester (FW<sub>ion</sub> = 531.66 g/mol) is a strong inhibitor of human glycerophospholipid arachidonyl-transferase (CoA-independent),  $IC_{50} = 9 \mu\text{M}$  (1-4). 1. Winkler, Eris, Sung, *et al.* (1996) *J. Pharmacol. Exp. Ther.* **279**, 956. 2. Winkler, Sung, Marshall & Chilton (1996) *Adv. Exp. Med. Biol.* **416**, 11. 3. **SKI II**

This highly selective ATP-noncompetitive inhibitor (FW = 302.74 g/mol; CAS 312636-16-1), also known as 2-(4-hydroxyanilino)-4-(4-chlorophenyl)thiazole, targets the sphingosine-1-phosphate receptor kinase ( $IC_{50} = 0.5 \mu\text{M}$ ), with little or no inhibitory action on other kinases, including PI3K, PKC $\alpha$  and ERK2. SK inhibitors were anti-proliferative toward a panel of tumor cell lines, including lines with the multidrug resistance phenotype because of overexpression of either P-glycoprotein or multidrug resistance phenotype 1, and were shown to inhibit endogenous human SK activity in intact cells (1). SKI II-inhibited human cancer cell lines include: T-24 ( $IC_{50} = 4.6 \mu\text{M}$ ), MCF-7 ( $IC_{50} = 1.2 \mu\text{M}$ ), MCF-7/VP ( $IC_{50} = 0.9 \mu\text{M}$ ), and NCI/ADR ( $IC_{50} = 1.3 \mu\text{M}$ ). In mice, SKI-II is orally bioavailable and can be detected in the blood for >8 hours after administration (2). SKI II ameliorates antigen-induced bronchial smooth muscle hyper-responsiveness in mice, but not airway inflammation (3). SKI-II appears to be a novel activator of Nuclear factor erythroid 2-related factor 2 (Nrf2) signalling via the inactivation of Keap1. The latter is a negative regulator of Nrf2 expression, and the effect of SKI II is independent of sphingosine kinase inhibition (4). 1. **SL 327**

These photosensitive isomeric phenylacetone nitriles (FW = 335.35 g/mol) inhibit MEK1 and MEK2, with  $IC_{50}$  values of 180 and 220 nM for the *E*- and *Z*-isomers, respectively, and block fear conditioning and learning in rats. *Note*: Commercial sources often supply a mixture of the *E*- and *Z*-isomers. 1. Salzmann, Marie-Claire, Le Guen, Roques & Noble (2003) *Brit. J. Pharmacol.* **140**, 831. 2. Selcher, Atkins, Trzaskos, Paylor & Sweatt (1999) *Learn Mem.* **6**, 478.

**Slotoxin**

This 37-residue peptide (MW = 4092 g/mol; CAS 144026-79-9; *Sequence*: TFIDVDCTVSKECWAPCKAAFGVDRGKCMGKKCKCYV) from the venom of the scorpion *Centruroides noxius* blocks the MaxiK (hSlo) pore-forming  $\alpha$  subunit reversibly,  $K_d = 1.5$  nM (1). 1. Garcia-Valdes, Zamudio, Toro, Possani & Possani (2001) *FEBS Lett.* **505**, 369.

**$\mu$ -SLPTX-Ssm6a**

This unique 46-residue peptide and neurotoxin from the venom of the predatory centipede *Scolopendra subspinipes mutilans* potently inhibits the voltage-gated sodium channel,  $Na_v1.7$ . **Mode of Inhibitory Action**: The  $Na_v1.7$  channel amplifies membrane depolarizations, and when the membrane potential difference reaches a specific threshold, the neuron fires. In sensory neurons, multiple voltage-dependent sodium currents are differentiated by their voltage dependence and by their sensitivity to tetrodotoxin, the classical voltage-gated sodium-channel blocker.  $\mu$ -SLPTX-Ssm6a has high affinity for the  $Na_v1.7$  channel ( $IC_{50} \approx 23$  nM), exhibiting >150x selectivity over all other human  $Na_v$  subtypes, with the exception of  $Na_v1.2$ , for which its selectivity is 32x.  $\mu$ -SLPTX-Ssm6a is a more potent analgesic than morphine in a rodent chemical-induced pain model and is equipotent with morphine in rodent thermal and acid-induced pain models. **Structural Features**:  $\mu$ -SLPTX-Ssm6a contains three disulfide bonds, exhibiting a unique disulfide connectivity pattern.  $\mu$ -SLPTX-Ssm6a has no significant sequence homology with any known peptide or protein. 1. **SM-19712**

This sulfonamide (FW = 437.84 g/mol), named systematically as 4-chloro-*N*-[[[(4-cyano-3-methyl-1-phenyl-1*H*-pyrazol-5-yl)amino]carbonyl]benzenesulfonamide, sodium salt, inhibits rat lung endothelin-converting enzyme,  $IC_{50} = 42$  nM. At concentrations ranging from 10 to 100  $\mu$ M, no effect was reported for other metalloproteases. 1. Umekawa, Hasegawa, Tsutsumi, *et al.* (2000) *Jpn. J. Pharmacol.* **84**, 7.

**SM-324405**

This potent TLR7 agonist (FW = 385.42 g/mol; CAS 677773-91-0; Solubility: 100 mM in DMSO), also named methyl 3-[[[(6-amino-2-butoxy-7,8-dihydro-8-oxo-9*H*-purin-9-yl)methyl]benzeneacetate, targets Toll-like Receptor-7 ( $EC_{50} = 50$  nM), which recognises single-stranded RNA in endosomes, the latter a common feature of viral genomes that are internalized by macrophages and dendritic cells. Exhibits selectivity for TLR7 over TLR8. SM-324405 treatment induces both IFN- $\alpha$  and IFN- $\gamma$  expression in human peripheral blood mononuclear cells (PBMCs) as well as mouse splenocytes, and it also inhibits IL-5 production in human PBMCs *in vitro*. SM-324405 is rapidly metabolized to acid metabolite ( $t_{1/2} = 2.6$  min in human plasma). 1. Kurimoto, Hashimoto, Nakamura, *et al.* (2010) *J. Med. Chem.* **53**, 2964.

**Small Interfering RNA**, See *RNA*

**SMER3**

This Small-Molecule Enhancer of Rapamycin (FW = 224.14 g/mol; CAS 67200-34-4) is an inhibitor of the Skp1-Cullin-F-box, or SCF (Met30) ubiquitin ligase ( $IC_{50} = 51$  nM) *in vivo* and *in vitro*, but not the closely related SCF(Cdc4). SMER3 also diminishes binding of the F-box subunit Met30 to the SCF core complex *in vivo* by binding directly to Met30. 1. Aghajani, Jonai, Flick, *et al.* (2010) *Nature Biotechnol.* **28**, 738.

**SMI-4a**

This novel small-molecule protein kinase inhibitor (FW = 273.23 g/mol; CAS 438190-29-5; Solubility = 55 mg/mL DMSO) targets Pim1 kinase ( $IC_{50} = 17$  nM), a serine/threonine protein kinase that is up-regulated in specific hematologic neoplasms. A screen of 60 other serine, threonine, and tyrosine protein kinases indicates that SMI-4a and related benzylidene-thiazolidine-2,4-diones are highly specific inhibitors of the Pim protein kinase. SMI-4a is cytotoxic against both myeloid and lymphoid cell lines, particularly precursor T-cell lymphoblastic leukemia/lymphoma cells (*or* pre-T-LBL cells). Incubation of such cells with SMI-4a induced  $G_1$  phase cell-cycle arrest and dose-dependent induction of p27<sup>Kip1</sup>, mitochondrial pathway-mediated apoptosis, and inhibition of the mammalian target of rapamycin C1 (mTORC1) pathway. The phosphatidylinositol/Akt/mTOR pathway is often activated in leukemia and lymphoma downstream of a variety of oncogenes including receptor tyrosine kinases. Treatment of these cells with SMI-4a also induces phosphorylation of extracellular signal-related kinase1/2 (ERK1/2), and the combination of SMI-4a and a mitogen-activated protein kinase kinase 1/2 (MEK1/2) inhibitor was highly synergistic in killing pre-T-LBL cells. Addition of Pim inhibitors to several prostate and leukemic cell lines induces a  $G_1$  cell cycle block, although, in other cell lines, especially in low-serum conditions, these inhibitors are capable of inducing apoptosis. 1. Beharry, Zemskova, Mahajan, *et al.*

(2009) *Mol. Cancer Ther.* **8**, 1473. 2. Lin, Beharry, Hill, *et al.* (2010) *Blood* **115**, 824.

### SMIFH2

This actin cytoskeletal motor inhibitor (FW = 377.21 g/mol; CAS 340316-62-3; Soluble to 100 mM in DMSO), also named 1-(3-bromophenyl)-5-(2-furanylmethylene)dihydro-2-thioxo-4,6(1*H*,5*H*)-pyrimidinedione, targets Formin Homology-2 (FH2) domains, preventing both formin-mediated actin nucleation (IC<sub>50</sub> = 5-10 μM) and processive barbed end elongation as well as decreasing formin affinity for filament barbed-ends (1,2). Formins are actoclampin-type (+)-end-tracking molecular motors that exploit processive actin monomer insertion to generate propulsive forces (3,4). At low-μM concentrations, SMIFH2 disrupts formin-dependent, but not Arp2/3 complex-dependent, actin cytoskeletal structures in fission yeast and mammalian NIH 3T3 fibroblasts. 1. ### SN-38

SN-38

Etirinotecan Pegol

This topoisomerase I inhibitor (FW = 392.40 g/mol; CAS 86639-52-3), also named 7-ethyl-10-hydroxycamptothecin, is the active drug formed via hydrolysis of its prodrug Etirinotecan Pegol (MW = 23 kDa; CAS 1193151-09-5), a polyethylene glycol-encapsulated irinotecan that is eventually hydrolyzed by carboxylesterases. The active drug, SN-38, inhibits topoisomerase I activity by stabilizing the cleavable Topoisomerase-DNA

complex, resulting in DNA breaks that inhibit DNA replication and trigger apoptosis. Eventually glucuronidated by UGT1A1, the resulting SN38-glucuronide is incorporated into the bile and feces. Pegylation improves drug penetration into tumors and also retards drug clearance, thereby increasing therapeutic exposure and duration, while reducing its toxicity. Complications include diarrhea and myelosuppression in a fourth of those receiving the prodrug. 1. Atyabi, Farkhondehfar, Esmaili & Dinarvand (2009) *Acta Pharm.* **59**, 133. 2. **Sodium Dodecyl Sulfate**

This common laboratory detergent (FW = 288.38 g/mol; CAS 151-21-3; Abbreviation: SDS), also known as sodium lauryl sulfate, is a powerful denaturing agent. Originally used to solubilize proteins from cell membranes, the denaturing power of SDS often precludes such use. This anionic detergent is a white powder with a cmc (critical micelle concentration) value of about 8.2 mM in water (0.52 mM in 0.5 M NaOH). SDS also exhibits a bactericidal activity, particularly at low pH. Note also that enzymes inhibited by free fatty acids are often inhibited by non-denaturing concentrations of SDS. Sodium dodecyl sulfate is also used in polyacrylamide gel electrophoresis to obtain a rough estimate of protein molecular mass. This is possible because the alkyl portion of SDS binds tightly and extensively to most proteins (1.4 g SDS per gram of protein), such that the detergent-bound polypeptides minimize electrostatic repulsion by adopting an elongated rod-like shape that is hydrodynamically well-behaved during electrophoresis.

**Sodium Borate**, See *Borax*

**Sodium Dodecyl Sulfonate**

This ionic surfactant (FW = 272.38 g/mol), also called sodium lauryl sulfonate, inhibits various lipases by directly binding in place of lipid substrates and/or by altering lipid and phospholipid micellization in a manner that changes enzyme binding at the lipid-water interface. **See also Sodium Dodecyl Sulfate Target(s):** arylsulfatase (1); lipid-phosphate phosphatase (2); lysozyme (3); soluble epoxide hydrolase, or phosphatase activity (2). 1. **Sodium Tetraborate**, See *Borax*

**Sofosbuvir**

This cell-penetrating HCV pro-drug (FW = 529.46 g/mol; CAS 1190307-88-0), also known as isopropyl (2*S*)-2-[[[(2*R*,3*R*,4*R*,5*R*)-5-(2,4-dioxypyrimidin-1-yl)-4-fluoro-3-hydroxy-4-methyl-tetrahydrofuran-2-yl]methoxyphenoxyphosphoryl]amino]propanoate, PSI-7977, GS-7977, and Sovaldi<sup>®</sup>, is taken up by cells and efficiently hydrolyzed through the action of human cathepsin A and/or carboxylesterase 1 (1,2). The resulting 2'-deoxy-2'- $\alpha$ -fluoro- $\beta$ -C-methyluridine-5'-monophosphate is itself a pro-drug that must undergo metabolic phosphorylation to its triphosphate form, which then inhibits Hepatitis C virus NS5B RNA polymerase, causing chain termination during replication of the HCV genome. Sofosbuvir is a pan-genotype, direct-acting antiviral for hepatitis C virus infection. Oral sofosbuvir has been approved by the FDA and the European Medicines Agency's Committee for Medicinal Products for Human Use for the treatment of chronic hepatitis C. Despite its high barrier to developing drug resistance, sofosbuvir is almost always used in combination with another HCV inhibitor, most often daclatasvir. (Harvoni<sup>®</sup>, for instance, contains ledipasvir and sofosbuvir.) High rates of sustained virological response (SVR) are observed with interferon-free drug combinations, particularly with genotypes 1 and 2. In patients with hepatocellular carcinoma who received sofosbuvir for extended treatment duration, while awaiting liver transplantation, the Leu-159-Phe mutation emerged in those infected with Genotype 1a or 2b. Sofosbuvir's safety profile is favorable in both cirrhotic and noncirrhotic patients (3). While sofosbuvir's game-changing 90% success rate commends it as the treatment-of-choice for HCV, its controversial high cost (*i.e.*, \$84,000 for a 12-week treatment course in 2014) has placed it well beyond the affordability of many patients and healthcare systems. That the high price is unrelated to production costs is strongly suggested by a recent agreement between its manufacturer and India, where the same 12-week course will be 50-60 times less expensive. 1. Sofia, Bao, Chang, *et al.* (2010) *J. Med. Chem.* **53**, 7202. 2. Murakami, Tolstykh, Bao, *et al.* (2010) *J. Biol. Chem.* **285**, 34337. 3. Stedman (2014) *Therap. Adv. Gastroenterol.* **7**, 131.

**Solanidine**

This  $\alpha$ -solanine aglycone (FW<sub>free-base</sub> = 397.64 g/mol; CAS 80-78-4; M.P. = 218-219°C; soluble in benzene and chloroform, but insoluble in water), named for its abundance in sprouts of the common potato *Solanum tuberosum*, inhibits butyrylcholinesterase (1) and sterol 24-C-methyltransferase, or cycloartenol 24-C-methyl-transferase; *K*<sub>i</sub> = 2  $\mu$ M (2-4). 1. Nigg, Ramos, Graham, *et al.* (1996) *Fundam. Appl. Toxicol.* **33**, 272. 2. Nes, Guo & Zhou (1997) *Arch. Biochem. Biophys.* **342**, 68. 3. Mangla & Nes (2000) *Bioorg. Med. Chem.* **8**, 925. 4. Nes (2000) *Biochim. Biophys. Acta* **1529**, 63.

**$\alpha$ -Solanine**

This glycoalkaloid (FW<sub>free-base</sub> = 867.09 g/mol; CAS 20562-02-1; soluble in hot ethanol, but poorly soluble in water (25 mg/L)), found in several potato species (genus *Solanum*), contains the branched trisaccharide solaratriose comprised of D-glucose, D-galactose, and L-rhamnose). Because  $\alpha$ -solanine is toxic and is present in elevated concentrations potato shoots, the latter cannot be used as a food source. **Target(s):** acetylcholinesterase (1); and butyrylcholinesterase (2-4). 1. Nigg, Ramos, Graham, *et al.* (1996) *Fundam. Appl. Toxicol.* **33**, 272. 2. Nes, Guo & Zhou (1997) *Arch. Biochem. Biophys.* **342**, 68. 3. Mangla & Nes (2000) *Bioorg. Med. Chem.* **8**, 925. 4. Nes (2000) *Biochim. Biophys. Acta* **1529**, 63.

**Solasodine**

This steroidal alkaloid (FW = 413.64 g/mol; CAS 126-17-0), also known as (22*R*,25*R*)-spirosol-5-ene-3 $\beta$ -ol is an aglycone of  $\alpha$ -solanine present in several species of *Solanum* that inhibits sterol 24-*C*-methyltransferase, or cycloartenol 24-*C*-methyltransferase (1-3). 1. Nes, Guo & Zhou (1997) *Arch. Biochem. Biophys.* **342**, 68. 2. Mangla & Nes (2000) *Bioorg. Med. Chem.* **8**, 925. 3. Nes (2000) *Biochim. Biophys. Acta* **1529**, 63.

**Solithromycin**

This oral fluoroketolide antibiotic (FW = 845.01 g/mol; CAS 760981-83-7), also known by the code names CEM-101 and OP-1068, is under

development for treating community-acquired pneumonia as well as infections by other Gram-positive pathogens. Solithromycin binds tightly to the large 50S subunit of the ribosome, thereby inhibiting both protein biosynthesis and further synthesis of the 50S subunit (1). Among 1363 strains of *Streptococcus pneumoniae*, 99.9% display a minimal inhibitory concentration (MIC)  $\leq$  0.5  $\mu$ g/mL, and 100% were inhibited at 1  $\mu$ g/mL (2). Solithromycin demonstrates activity and potency against *Haemophilus influenzae* (MIC<sub>50%</sub> = 1 mg/L and MIC<sub>90%</sub> = 2  $\mu$ g/mL), comparable to that of azithromycin (2). 1. Rodgers, Frazier & Champney (2013) *Antimicrob. Agents Chemother.* **57**, 1632. 2. Farrell, Castanheira, Sader & Jones (2010) *J. Infect.* **61**, 476.

**Soman**

This chemical warfare agent and acetylcholinesterase inhibitor (FW = 182.18 g/mol; CAS 96-64-0), often designated GD and also known as methylpinacolylloxyfluorophosphine oxide and pinacolyl methylphosphorofluoridate, has four stereoisomers, of which the two *P*(-)-stereoisomers are more effective than the *P*(+)-isomers (1). Nobelist Richard Kuhn's group discovered soman at the Kaiser Wilhelm Institute for Medical Research (Heidelberg). Soman inhibits AChE, cholinesterase, and certain carboxylesterases. A soman-hydrolyzing enzyme has been reported (2). **Caution:** Soman is extremely toxic (even exceeding tabun and sarin). As a vapor, it is readily absorbed through the skin and eyes. Inhalation or absorption of a lethal dose will result in death in one to ten minutes (LD<sub>50</sub> = 0.35 g). The LC<sub>50</sub> (*i.e.*, the concentration in air that proves lethal to 50% of exposed individuals) is 0.5-0.9 ppm. To improve survival (even if the smallest drop contacts the skin), one must immediately flood the affected area with bleach and dilute alkali. In mice, the *i.p.* LD<sub>50</sub> is 0.6 mg/kg. **Target(s):** acetylcholinesterase (1,3-11); carboxylesterase (3,12); choline acetyltransferase (13); cholinesterase, or butyrylcholinesterase (3,9,10,14-17); chymotrypsin (3,9); and trypsin (3). 1. **Somatoliberin, See Growth Hormone Releasing Factor**

**Somatostatin-14 & Somatostatin-28**

These inhibitory hormones Somatostatin-14 (MW = 1640; CAS 38916-34-6; pI = 8.9) and Somatostatin-28 (MW = 3261; CAS 75037-27-3; pI = 9.85) inhibit the release of somatotropin as well as other secretory proteins. Somatostatin is also known as Growth Hormone-Inhibiting Hormone (GHIH), Somatotropin Release-Inhibiting Factor (SRIF), and Somatotropin Release-Inhibiting Hormone. The SRIF system, including SRIF ligand and receptors, regulates anterior pituitary gland function. Its main role is to inhibit hormone secretion. SRIF-14 binds to G-protein-coupled receptor subtypes 1-5, activating many targets, among them adenylyl cyclase, MAPK, ion channel-dependent pathways. **Target(s):** Somatostatin's actions within the anterior pituitary gland include: inhibition of Growth Hormone release (thereby opposing the effects of Growth Hormone-

Releasing Hormone), inhibition of thyroid-stimulating hormone (TSH), inhibition of adenyl cyclase in parietal cells, and inhibition of prolactin release. Its actions within the gastrointestinal tract include inhibition of gastrin release, inhibition of cholecystokinin release, inhibition of secretin release, inhibition of motilin release, inhibition of vasoactive intestinal peptide release, inhibition of gastric inhibitory polypeptide release, inhibition of gastrointestinal hormone(s) release, and inhibition of enteroglucagon, cystinyl aminopeptidase, or oxytocinase (1); protein-disulfide isomerase (2); and serotonin *N*-acetyltransferase (3). 1. Burbach, De Bree, Terwel, *et al.* (1993) *Peptides* **14**, 807. 2. Morjana & Gilbert (1991) *Biochemistry* **30**, 4985. 3. Klein & Namboodiri (1982) *Trends Biochem. Sci.* **7**, 98.

### Sonidegib (Erismodegib)

This orally active Hedgehog signaling pathway inhibitor (FW = 485.50 g/mol; CAS 1218778-77-8), also known as LDE225, Odomzo<sup>®</sup>, and *N*-[6-[(2*S*,6*R*)-2,6-dimethylmorpholin-4-yl]pyridin-3-yl]-2-methyl-3-[4-(trifluoromethoxy)phenyl]benzamide, is a Smoothed antagonist and anticancer agent, first identified by a cell-based phenotypic high-throughput screen (1). Blockade of aberrant hedgehog (Hh) signaling shows great promise in cancer chemotherapy, and LDE225 represses tumor growth and prolongs survival in a transgenic mouse model of islet cell neoplasias (2). 1. Pan, Wu, Jiang, *et al.* (2010) *ACS Med. Chem. Lett.* **1**, 130. 2. Fendrich, Wiese, Waldmann, *et al.* (2011) *Ann. Surg.* **254**, 818.

### Sophoraflavanone G

This biodefensive flavanone (FW = 432.38 g/mol; IUPAC: (2*S*)-2-(2,4-dihydroxyphenyl)-5,7-dihydroxy-8-[(2*R*)-5-methyl-2-(prop-1-en-2-yl)hex-4-en-1-yl]-2,3-dihydro-4*H*-chromen-4-one) noncompetitively inhibits invasive protozoa, fungi, and bacteria affecting its organism of origin (*Sophora flavescens*). Sophoraflavanone G inhibits tyrosinase, or monophenol monooxygenase,  $K_i = 7.7 \mu\text{M}$ . 1. Ryu, Westwood, Kang, *et al.* (2008) *Phytomedicine* **15**, 612.

### Sophorose

This rare disaccharide (FW = 342.30 g/mol; CAS 534-46-3; M.P. = 196-198°C), also known as 2-*O*-β-D-glucopyranosyl-D-glucopyranose, from *Sophora japonica*, is a component of the sweetener stevioside. Sophorose is a substrate for many β-glucosidases. **Target(s):** membrane-oligosaccharide glycerophospho-transferase (1). 1. Goldberg, Rumley & Kennedy (1981) *Proc. Natl. Acad. Sci. U.S.A.* **78**, 5513.

### Sorafenib

This oral apoptosis-promoting agent (FW = 464.83 g/mol; CAS 284461-73-0), also known as BAY 43-9006, inhibits Raf kinase and has been used in the treatment of colorectal and breast cancers, hepatocellular carcinomas, and non-small-cell lung cancer. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** c-kit (1); p38 (1); platelet-derived growth factor receptor B kinase (1); polo kinase (2); Raf kinase (1,3-5); vascular endothelial growth factor receptor 2 kinase (1); and vascular endothelial growth factor receptor 3 kinase (1). 1. Ahmad & Eisen (2004) *Clin. Cancer Res.* **10**, 6388S. 2. Johnson, Stewart, Woods, Giranda & Luo (2007) *Biochemistry* **46**, 9551. 3. Hilger, Kredke, Hedley, *et al.* (2002) *Int. J. Clin. Pharmacol. Ther.* **40**, 567. 4. Lyons, Wilhelm, Hibner & Bollag (2001) *Endocr. Relat. Cancer* **8**, 219. 5. Lee & McCubrey (2003) *Curr. Opin. Investig. Drugs* **4**, 757.

### Sorangicins

Sorangin A

These antimicrobial agents (FW = 773.98 g/mol for Sorangicin A; CAS 100415-25-6), isolated from the myxobacterium *Sorangium cellulosum*, inhibit bacterial DNA-directed RNA polymerase (1,2). This antibiotic acts mainly against Gram-positive bacteria, including mycobacteria, with MIC values between 0.01-0.1 μg/mL. Higher concentrations (MIC 3-30 μg/ml) Gram-negatives are also inhibited. Yeasts and molds are completely resistant. Sorangicin is a specific inhibitor of eubacterial RNA polymerase which it blocks, but, only if added before RNA polymerization has commenced. 1. Chopra (2007) *Curr. Opin. Invest. Drugs* **8**, 600. 2. Irschik, Jansen, Gerth, Höfle & Reichenbach (1987) *J. Antibiot.* **40**, 7.

### Sorbic Acid

This unsaturated carboxylic acid (FW<sub>free-acid</sub> = 112.13 g/mol; CAS 16577-94-9; p*K<sub>a</sub>* = 4.76 at 25°C; M. P. = 134.5°C; water solubility = 2.5 g/L at 30°C), also known as (2*E*,4*E*)-hexadienoic acid, inhibits the growth of molds and yeast, and it is frequently used as a fungastatic agent in food containers. Sorbate should be stored at temperatures below 40°C. **Target(s):** catalase (1). 1. Troller (1965) *Can. J. Microbiol.* **11**, 611.

**Sorbinil**

This spirohydantoin (FW = 236.20 g/mol; CAS 68367-52-2), also known as (4*S*)-6-fluorospiro(chroman-4,4'-imidazolidine)-2',5'-dione, is a strong inhibitor of aldose reductase, the enzyme responsible for formation and accumulation of sorbitol in the human lens and retina. Sorbinil acts primarily by binding to aldose reductase complexed with oxidized nicotinamide dinucleotide phosphate (E•NADP<sup>+</sup>) to form a ternary dead-end complex, thereby preventing its turnover in the steady state. **Target(s):** alcohol dehydrogenase, NADP<sup>+</sup>-requiring (1); aldose reductase, aldehyde reductase (2-5); 4-aminobutyrate aminotransferase (6); hexonate dehydrogenase (7); and succinate-semialdehyde dehydrogenase (6). 1. Whittle & Turner (1981) *Biochem. Pharmacol.* **30**, 119. 2. Wermuth & von Wartburg (1982) *Meth. Enzymol.* **89**, 181. 3. Ramana, Chandra, Srivastava, Bhatnagar & Srivastava (2003) *Chem. Biol. Interact.* **143-144**, 587. 4. Bohren & Grimshaw (2000) *Biochemistry* **39**, 9967. 5. De Jongh, Schofield & Edwards (1987) *Biochem. J.* **242**, 143. 6. Whittle & Turner (1978) *J. Neurochem.* **31**, 1453. 7. Poulson (1986) *Biochem. Pharmacol.* **35**, 2955.

**L-Sorbinose, See L-Sorbosose**

**Sorbitan Laurate**

This nonionic liquid surfactant (FW = 346.46 g/mol; CAS 1338-39-2), also known as Span 20 and 1,4-anhydro-D-glucitol 6-dodecanoate, is often used to solubilize membrane-interacting proteins. **Target(s):** bis(2-ethylhexyl)phthalate esterase (1); and steryl-sulfatase, *or* arylsulfatase C (2). 1. Gniot-Szulzycka & Komoszynski (1972) *Enzymologia* **42**, 11. 2. Krell & Sandermann, Jr. (1984) *Eur. J. Biochem.* **143**, 57.

**D-Sorbitol**

This common sugar alcohol (FW = 182.17 g/mol; CAS 50-70-4), also known as D-glucitol (note that D-glucitol is identical to L-gulitol), is produced in the aldose reductase by the reduction of the C1 aldehyde of D-glucose. The latter reaction is problematic in diabetic hyperglycemia, where excessive accumulation of sorbitol results in osmotic damage in diabetic retinopathy. When heated in the presence of acids, D-sorbitol converts to several cyclic ethers (*e.g.*, 1,4-sorbitan). **Target(s):** acetyl-CoA synthetase, *or* acetate:CoA ligase, weakly (1); aldose 1-epimerase, *or* mutarotase (2-4);  $\alpha$ -amylase (5); D-arabinose isomerase (6); dihydrodiol dehydrogenase (7); ferredoxin:NADP<sup>+</sup> reductase, inhibited by elevated concentrations (8); L-fucose isomerase (6); glucan 1,4- $\alpha$ -glucosidase, *or* glucoamylase; weakly inhibited (9); mannonate dehydratase (10,11); naringinase, weakly (12); sorbitol-6-phosphatase (13); thioglucosidase, *or* myrosinase (14); and xylose isomerase, *or* glucose isomerase (15-25). 1. Roughan & Ohlrogge

**D-Sorbitol 1,6-Bisphosphate**

This phosphorylated sugar alcohol (FW<sub>free-acid</sub> = 342.13 g/mol), also known as D-glucitol 1,6-bisphosphate and D-glucitol 1,6-diphosphate, inhibits fructose-1,6-bisphosphate aldolase,  $K_i = 12 \mu\text{M}$  (1,2). 1. Hartman & Barker (1965) *Biochemistry* **4**, 1068. 2. Ginsburg & Mehler (1966) *Biochemistry* **5**, 2623.

**D-Sorbitol 6-Phosphate**

This phosphorylated sugar alcohol (FW<sub>free-acid</sub> = 262.15 g/mol), also known as D-glucitol 6-phosphate, is a substrate for sorbitol-6-phosphate 2-dehydrogenase, aldose-6-phosphate reductase (NADPH), and sorbitol-6-phosphatase. **Target(s):** glucokinase, in the presence of the regulatory protein (1-3); glucose-6-phosphate isomerase (4-7); glutamine:fructose-6-phosphate aminotransferase, isomerizing (7-9); inositol-3-phosphate synthase, *or* inositol-1-phosphate synthase (10-12); mannose-6-phosphate isomerase (4); phosphofructokinase-2 (13); pyrophosphate-dependent phosphofructokinase, *or* diphosphate:fructose-6-phosphate 1-phosphotransferase (14). 1. #### Sorivudine

This antiviral agent (FW = 349.14 g/mol; CAS 77181-69-2), also known systematically as 1- $\beta$ -D-arabinofuranosyl-5-[(1E)-2-bromoethenyl]-2,4(1H,3H)-pyrimidinedione, is a synthetic analogue of thymidine. Sorivudine exhibits antiviral activity against varicella zoster virus, herpes simplex type 1 virus, and Epstein-Barr virus. While shown to be a potent agent for treating varicella zoster infections, sorivudine's use has been discontinued in a number of nations in view of toxic responses and deaths, particularly when administered along with fluoropyrimidine drugs. **Target(s)**: dihydropyrimidine dehydrogenase (1,2); DNA-directed DNA polymerase, as the 5'-triphosphate (3); DNA polymerase I, as the 5'-triphosphate (3); thymidine kinase (4,5); varicella zoster virus replication (6,7); viral DNA polymerase, as the 5'-triphosphate (5). **1**. #### Sotalol

This water-soluble sulfonamide (FW<sub>free-base</sub> = 272.37 g/mol; CAS 3930-20-9), also known as Sotacor and *N*-[4-[1-hydroxy-2-[(1-methylethyl)amino]ethyl]phenyl]methanesulfonamide, is a potent  $\beta$ -adrenergic receptor antagonist (1-5), predominantly as the (-)-enantiomer (*i.e.*, *l*-sotalol). The dextrorotatory isomer of sotalol (*i.e.*, (+)- or *d*-sotalol) is a class III antiarrhythmic that prolongs cardiac repolarization by inhibiting the fast component of the delayed outward rectifying potassium channel. The *l*-(-)-enantiomer has both  $\beta$ -blocking (class II) activity and potassium-channel-blocking (class III) properties. The *d*-(+)-enantiomer has class III properties similar to those of *l*-sotalol; however, the affinity of *d*-sotalol for  $\beta$ -adrenergic receptors is 30-60 times lower than the affinity of *l*-sotalol. **Key Pharmacokinetic Parameters**: See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) #### Sotrastaurin

This potent pan-Protein Kinase C (pan-PKC) inhibitor (F.Wt. = 438.48 g/mol; CAS 425637-18-9 and 1058706-32-3 (HCl); Solubility: DMSO = 87 mg/mL; Water < 1 mg/mL), also known as AEB071 and systematically as 3-(1H-indol-3-yl)-4-(2-(4-methylpiperazin-1-yl)quinazolin-4-yl)-1H-pyrrole-2,5-dione, inhibits the PKC $\theta$  isozyme slightly more potently (1). **Targets**: PKC $\alpha$  (IC<sub>50</sub> = 0.95 nM); PKC $\beta$  (IC<sub>50</sub> = 0.64 nM); PKC $\delta$  (IC<sub>50</sub> = 2.1 nM); PKC $\epsilon$  (IC<sub>50</sub> = 3.2 nM); PKC $\eta$  (IC<sub>50</sub> = 1.8 nM); and PKC $\theta$  (IC<sub>50</sub> = 0.22 nM). Sotrastaurin (<10 $\mu$ M) blocks early T-cell activation (indicated by interleukin-2 secretion and CD25 expression) in primary human and mouse T cells. AEB071 (200 nM) inhibits the CD3/CD28 antibody- and alloantigen-induced T-cell proliferation responses in the absence of nonspecific antiproliferative effects. AEB071 (< 3  $\mu$ M) markedly inhibits lymphocyte function-associated antigen-1-mediated T-cell adhesion (1). AEB071 (<20  $\mu$ M) selectively impairs CD79 mutant ABC-DLBCL cell proliferation, with decreased NF- $\kappa$ B signaling (1). AEB071 (5  $\mu$ M) induces G<sub>1</sub> cell-cycle arrest and/or cell death in CD79 mutant cells (2). **1**. Evenou, *et al.* (2009) *J. Pharmacol. Exp. Ther.* **330**, 792. **2**. #### Soybean Trypsin Inhibitor (Kunitz)

This 181-aminoacyl residue polypeptide (Mr = 28,964; CAS 9035-81-8; pI = 5.35) is a nutrient protein in soybeans that strongly inhibits trypsin ( $K_i$  = ~ 10 pM). They will also inhibit chymotrypsin, albeit with a larger  $K_i$  value (approximately 10  $\mu$ M). Note that soybeans and other plants contain other trypsin and chymotrypsin inhibitors that are not members of this Kunitz family; hence, the designation Kunitz should be present. **See Trypsin Inhibitor; Bowman-Birk Inhibitor** **1**. Birk (1996) *Arch. Latinoam. Nutr.* **44**, Suppl. 1, 26S.

#### SP 600125

This cell-permeable, c-Jun N-terminal kinase inhibitor (FW = 220.23 g/mol (HCl Salt); CAS 129-56-6, 67072-00-8 (potassium salt); Solubility: 44 mg/mL DMSO; <1 mg/mL Water), also known as JNK inhibitor II, anthra[1,9-*cd*]pyrazol-6(2H)-one, and 1,9-pyrazoloanthrone, targets JNK1, JNK2, JNK3, Aurora A, Flt3, and TRKA kinases, with IC<sub>50</sub> of 40 nM, 40 nM, 90 nM, 60 nM, 90 nM, and 70 nM, respectively. SP600125 inhibits the phosphorylation of c-Jun with IC<sub>50</sub> of 10  $\mu$ M (1-7). It also inhibits Mps1 (*or* Monopolar spindle-1), also known as TTK, a dual-specificity protein kinase that phosphorylates tyrosine, serine, or threonine residues. Mps1 is activated during mitosis and is essential for centrosome duplication, mitotic checkpoint signaling, and the maintenance of chromosomal instability, *or* CIN (8). **Target(s)**: AMP-activated protein kinase (1); casein kinase 1 $\delta$  (1); c-Jun N-terminal kinase  $\alpha$ 1, IC<sub>50</sub> = 5.8  $\mu$ M (1,2); c-Jun N-terminal kinase  $\alpha$ 2, IC<sub>50</sub> = 6.1  $\mu$ M; cyclin-dependent protein kinase; dual-specificity, tyrosine-phosphorylated and regulated kinase; p70 ribosomal protein S6

cell types, binds preferentially to duplex DNA or RNA and interacts at K<sup>+</sup> and Na<sup>+</sup> binding sites on numerous proteins. Spermidine also stimulates T<sub>4</sub> polynucleotide kinase. The fact that spermidine has so many inhibitory effects suggests that within cells the free (unbound) spermidine level must be quite low to prevent such promiscuous inhibition. Measurements of the free spermidine concentration in tissues have not been reported. **Target(s):** adenosine deaminase, or RNA-adenosine deaminase (74); adenosylmethionine decarboxylase (54-56); adenylate cyclase (1-3); [ $\beta$ -adrenergic-receptor] kinase (4); agmatine deaminase (75-78); *Agropyron elongatum* nuclease (82); amino-acid N-acetyltransferase (100); 1-aminocyclopropane-1-carboxylate synthase (53); arginine decarboxylase (5,57-66); arginine N-succinyltransferase (98); arginyltransferase (6); *BamHI* restriction endonuclease (7); Ca<sup>2+</sup>-dependent ATPase (8); carbamoyl-phosphate synthetase, glutamine hydrolyzing (9,10); carnosine synthetase (50); deoxyhypusine monooxygenase (11); CDP-glycerol glycerophosphotransferase (89); DNA (cytosine-5-)-methyltransferase (105,106); DNA ligase, ATP-dependent (12-14); DNA-3-methyladenine glycosylase I (81); DNA polymerase (15,16); DNA polymerase III, however, stimulation of the complex or holoenzyme (17); DNA topoisomerase I (51,52); dsRNA-dependent protein kinase (18); *EcoRI* restriction endonuclease (7,19); epidermal-growth-factor-receptor protein-tyrosine kinase (20); exopolyphosphatase (73); F<sub>1</sub> ATPase, or H<sup>+</sup>-transporting two-sector ATPase (21); glutamate dehydrogenase (22,23); *HindIII* restriction endonuclease (7); histone acetyltransferase (99); homospermidine synthase (93); *HpaI* restriction endonuclease (7); inositol 1,4,5-trisphosphate receptor (24); K<sub>ATP</sub> channels (25); lipoxigenase-1 (26); methionine S-adenosyltransferase (27,94); 3-methyladenine-DNA glycosylase (28); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (29); nitric-oxide synthase(30); *OmpF* and *OmpC* bacterial porins (31); ornithine aminotransferase (32); ornithine carbamoyl-transferase (102-104); ornithine decarboxylase (33,67-72); papain (34); pepsin (35,36); phosphatidate phosphatase, weakly inhibited (86); phospholipase C (37); phosphoprotein phosphatase (38,39); photosystem II (40); polynucleotide adenylyltransferase, or poly(A) polymerase (91); protein-arginine N-methyltransferase (41); protein-glutamine  $\gamma$ -glutamyltransferase, or transglutaminase, also alternative substrate (95-97); protein kinase C (42,43); protein-tyrosine-phosphatase (85); *PstI* restriction endonuclease (7); putrescine carbamoyltransferase (101); pyridoxal kinase, weakly inhibited (92); rhodopsin kinase (88); ribonuclease H (83); ribonuclease U<sub>2</sub>, or *Ustilago sphaerogena* ribonuclease (48); [RNA-polymerase]-subunit kinase (87); semenogelase (44,79); T<sub>4</sub> polynucleotide ligase (45); tRNA (adenine-N<sup>1</sup>-)-methyltransferase (107); tRNA adenylyltransferase (46,90); tRNA cytidyltransferase (90); tRNA (cytosine-5-)-methyltransferase (109); tRNA nucleotidyltransferase (90); tRNA (uracil-5-)-methyltransferase (108); *Trypanosoma cruzi* protein kinases (47); tubulinylyl-tyrosine carboxypeptidase, inhibited above 1 mM (80); vacuolar ion channels (49); and yeast ribonuclease, weakly inhibited (84). 1. **Spermidine Diacridine, See Diacridines**

## Spermine

This polyamine (FW<sub>free-base</sub> = 202.34 g/mol; CAS 71-44-3; M.P. = 55-60°C; deliquescent solid), known systematically as *N,N*-bis(3-aminopropyl)-1,4-butanediamine, is found in all tissues and is required for growth. Spermine is a mixed NMDA (*N*-methyl-D-aspartate) receptor agonist/antagonist, participates in cellular proliferation and differentiation, and also exhibits neuroprotective effects. (The fact that spermine has so many inhibitory effects suggests that within cells the free (unbound) spermine level must be quite low to prevent such promiscuous inhibition. NMR measurements of the free spermine concentration in tissues have not been reported.) *Note*: Solutions of the water-soluble free base will absorb atmospheric carbon dioxide; thus, containers of spermine must be kept tightly closed, and spermine solutions should be freshly prepared. **Target(s)**: acetylspermidine deacetylase, alternative product (1,99,100); adenosylmethionine decarboxylase (2,79-81); adenylate cyclase (3-6); [ $\beta$ -adrenergic-receptor] kinase, weakly inhibited (7,8); agmatine deaminase (95-98); *Agropyron elongatum* nuclease (103); alfalfa leaf protease (9); amino-acid *N*-acetyltransferase (128); 1-aminocyclopropane-1-carboxylate synthase (78); arginine decarboxylase (10,82-87); arginyltransferase (11); *Bam*HI restriction endonuclease (12); bis(5'-adenosyl)-triphosphatase (94); Ca<sup>2+</sup>-dependent ATPase (13,14); carbamoyl-phosphate synthetase, glutamine-hydrolyzing (15,16); cyclic-nucleotide phosphodiesterase (17-19); deoxyhypusine monooxygenase (20); deoxyhypusine synthase, weakly inhibited (119); DNA (cytosine-5-)-methyltransferase (129,130); DNA ligase (ATP) (21,22); DNA polymerase (23,24); dsRNA-dependent protein kinase (25); *Eco*RI restriction endonuclease (12,26); epidermal-growth-factor-receptor protein-tyrosine kinase (27); exoribonuclease II, or ribonuclease II, weakly inhibited (105); F<sub>1</sub> ATPase, or H<sup>+</sup>-transporting two-sector ATPase (28); glutamate dehydrogenase (29,30); [glycogen synthase] kinase 3 (31); glycyl-tRNA synthetase (77); GTPase activity of G<sub>i</sub> proteins (32); H<sup>+</sup> ATPase (33); *Hind*III restriction endonuclease (12); homoserimidine synthase, spermidine-specific (120); *Hpa*I restriction endonuclease (12); inositol 1,3,4-trisphosphate 5/6-kinase (34); inositol 1,4,5-trisphosphate receptor (35); K<sub>ATP</sub> channels (36); K<sup>-</sup>-dependent phosphatase (37); lipoxigenase-1 (38); methionine *S*-adenosyltransferase (39,122); 3-methyladenine-DNA glycosylase (40); Na<sup>+</sup>/K<sup>+</sup> exchanging ATPase (41-43); nardilysin (44,101); nicotinamide mononucleotide glycohydrolase (45); nicotinic acetylcholine receptor (46); nitric-oxide synthase (47,48); nuclear protein kinase NI (49); *OmpF* and *OmpC* bacterial porins (50); ornithine aminotransferase (51); ornithine decarboxylase (52,88-93); papain (53,54); pepsin (55); peptidyltransferase (56,126,127); phosphatidate phosphatase (109,110); phosphatidylinositol 3-kinase (57); 1-phosphatidylinositol-4-phosphate 5-kinase (117); phosphoinositide phospholipase C (106); phospholipase A<sub>2</sub> (58); phospholipase C (58,59); phosphoprotein phosphatase, including [phosphorylase] phosphatase (60-63,108); photosystem II (64); polynucleotide adenyltransferase, or poly(A) polymerase (65,114,115); polynucleotide 5'-hydroxyl-kinase, activated at 1 mM spermine, but inhibited at elevated concentrations (116); protein-arginine *N*-methyltransferase (66); protein-glutamine  $\gamma$ -glutamyltransferase, or transglutaminase, also alternative substrate (123-125); protein kinase C (67,68); protein-tyrosine-phosphatase (107); *Pst*I restriction endonuclease (12); pyridoxal kinase, weakly inhibited (118); rhodopsin kinase, also activated at low concentrations (111); ribonuclease H (104); ribonuclease U<sub>2</sub>, *Ustilago sphaerogena* ribonuclease (75); RNA-directed RNA polymerase (112,113); RNA ligase ribozyme (69); spermidine synthase (121); T<sub>4</sub> polynucleotide ligase (70); transglutaminase (71); tRNA adenyltransferase (72); tRNA (cytosine-5-)-methyltransferase (131,132); *Trypanosoma cruzi* protein kinases (73); tubulinin-tyrosine carboxypeptidase, inhibited above 0.06 mM (102); tyrosine monooxygenase (74); and vacuolar ion channels (76). 1. **Spheroidine, See Tetrodotoxin**

### Sphinganine

This long-chain alkylamino diol precursor of sphingosine (FW<sub>free-base</sub> = 301.51 g/mol; CAS 764-22-7), also known as D-erythro-2-amino-1,3-octadecanediol and D-erythro-dihydro-sphingosine, has surfactant properties, binds to membranes, and inhibits various lipid-processing enzymes. *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **See also threo-Dihydro-sphingosine Target(s):** 2-acylglycerol *O*-acyltransferase, or monoacylglycerol *O*-acyltransferase (1); CDP-diacylglycerol:serine *O*-phosphatidyltransferase, or phosphatidylserine synthase (2); ceramidase (3-6); ceramide kinase (7); 1,3-β-glucan synthase (8); [myosin light-chain] kinase (9); NADPH oxidase (10); phosphatidate phosphatase (11-14); phospholipase A<sub>2</sub> (15); phospholipase D (15); protein kinase C, IC<sub>50</sub> = 2.8 μM (16,17); and sphinganine kinase, or sphingosine kinase, inhibited by D-(+)-threo-, L-(-)-erythro-, and L-threo-(-)-sphinganine (18,19). **1.** Bhat, Wang & Coleman (1995) *Biochemistry* **34**, 11237. **2.** Yamashita & Nikawa (1997) *Biochim. ### Sphingomyelins

This entire class of sphingolipids (general structure: *N*-acyl-4-sphinganyl-1-*O*-phosphorylcholine) first identified in animal cell membranes, especially those comprising the myelin sheath surrounding the axons of neurons. Sphingomyelins contain a saturated or unsaturated fatty acid linked as an amide to the nitrogen of sphingosine, with the terminal hydroxyl group esterified to phosphocholine. Often the fatty acyl group is twenty carbons long or longer. In view of the spectrum of acyl groups, the inhibitory properties are likely to depend on the source and homogeneity of a particular sphingomyelin preparation. *Note:* Because this substance readily forms micelles, one must take care to determine whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **See specific sphingomyelin Target(s):** β-*N*-acetylhexosaminidase (1); acyl-CoA synthetase (2); acylglycerol kinase, or monoacylglycerol kinase (10); ceramidase (3,4); cerebroside-sulfatase, or arylsulfatase A (5); choline-phosphate cytidyltransferase (6); glycosyl-phosphatidylinositol phospholipase D (7); 3-hydroxybutyrate dehydrogenase (8); lysophospholipase (9); monoacylglycerol kinase (10); phosphatidate phosphatase (11); phosphatidylcholine:sterol *O*-acyltransferase, or LCAT (12,13); phosphatidylinositol diacylglycerol-lyase (14); phosphoinositide phospholipase C (14-17); phospholipase C, inhibited by increasing interlipid hydrogen bonding and by decreasing membrane hydration (15-18); and protein-tyrosine sulfotransferase, weakly inhibited (19). **1.** Frohwein & Gatt (1967) *Biochemistry* **6**, 2783. **2.** Koshlukova, Momchilova-Pankova, Markovska & Koumanov (1992) *J. ### Sphingosine

This long-chain alkylamino diol (FW<sub>free-base</sub> = 299.50 g/mol; CAS 1670-26-4; M.P. = 82.5-83°C; essentially insoluble in water and soluble in acetone, chloroform, and ethanol), also known as D-erythro-sphingosine, D-erythro-4-trans-sphingene and (2*S*,3*R*,4*E*)-2-amino-4-octadecene-1,3-diol, is an important component of biomembranes. Sphingosine is typically not found in free form in high concentrations but as a component of sphingomyelins, cerebrosides, gangliosides, etc. *Note*: Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **See also Phytosphingosine Target(s)**: β-N-acetylhexosaminidase (1); 2-acylglycerol O-acyltransferase, or monoacylglycerol O-acyltransferase (19); [β-adrenergic-receptor] kinase (2); Ca<sup>2+</sup>/calmodulin-dependent phosphodiesterase (3); Ca<sup>2+</sup>/calmodulin-dependent protein kinase (3); ceramidase, inhibited by all four stereoisomers (4,41-48); ceramide glycanase (5); ceramide kinase (63,64); cholesterol monooxygenase, or cholesterol side-chain-cleavage enzyme (6); choline-phosphate cytidylyltransferase (7,8,61,62); diacylglycerol O-acyltransferase (66); diacylglycerol kinase (9); DNA primase (10,11); 7-ethoxycoumarin O-deethylase, or cytochrome P450 (12); β-galactosidase (13); galactosylceramidase (13-15); glucosylceramidase, the *threo*-analogue also inhibits (5,16,49,50); 2-hydroxyacylsphingosine 1-β-galactosyltransferase, or cerebroside synthase (17,65); insulin receptor protein-tyrosine kinase (18); [myosin light-chain] kinase (3,59); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (7,20); nitric-oxide synthase (21); phosphatidate phosphatase (7,22,23,54-58); phospholipase A<sub>2</sub> (24); phosphoinositide phospholipase C (53); phospholipase D (24); protein kinase C, IC<sub>50</sub> = 2.8 μM (3,7,25-36); protein-tyrosine kinase, insulin receptor (18); protein-tyrosine sulfotransferase (37); sodium-calcium exchange (39); sphingomyelin phosphodiesterase, or sphingomyelinase (39,51,52); sphingomyelin synthase (60); telomerase, weakly inhibited (40). 1. ### Sphingosine 1-Phosphate

This powerful sphingolipid agonist (FW = 378.47 g/mol) of receptor-mediated signal transduction culminates in endothelial cell proliferation and chemotaxis. *Note*: Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **Target(s)**: acid sphingomyelinase (1); alkylglycerophosphoethanolamine phosphodiesterase, or lysophospholipase D (2); and phosphatidate phosphatase (3). 1. Gomez-Munoz, Kong, Salh & Steinbrecher (2003) *FEBS Lett.* **539**, 56. 2. van Meeteren, Ruurs, Christodoulou, et al. (2005) *J. Biol. Chem.* **280**, 21155. 3. Nanjundan & Possmayer (2000) *Exp. Lung Res.* **26**, 361.

### Sphingosylphosphocholine

This lipid mediator (FW = 465.64 g/mol), also known as lysosphingomyelin, potently attenuates calcium entry via voltage-operated calcium channels. Sphingosyl-phosphocholine also stimulates mitogen-activated protein kinase and casein kinase II and inhibits platelet aggregation. *Note*: Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **Target(s)**: choline-phosphate cytidylyltransferase (1); phosphatidylinositol diacylglycerol-lyase, or phosphatidylinositol-specific phospholipase C (2); sphingomyelin phosphodiesterase or sphingomyelinase (3,4); and voltage-operated calcium channels (5). 1. Sohal & Cornell (1990) *J. Biol. Chem.* **265**, 11746. 2. Dawson, Hemington & Irvine (1985) *Biochem. J.* **230**, 61. 3. Sloan (1972) *Meth. Enzymol.* **28**, 874. 4. ### 4-Sphingynine

This sphingosine analogue (FW = 376.45 g/mol) inhibits glucosylceramidase (1). *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). 1. Greenberg, Merrill, Liotta & Grabowski (1990) *Biochim. Biophys. Acta* **1039**, 12.

### SPI-3

This serpin produced by orthopoxviruses modulates cell-cell fusion during virus infection. It is a glycoprotein with a molecular mass of about 50 kDa (the amino acid sequence predicts a mass of 42 kDa). **Target(s):** plasmin (1); tissue-type plasminogen activator (1); and urokinase-type plasminogen activator. (For further discussion of the likely mechanism of inhibitor action, See  $\alpha_1$ -Antichymotrypsin) 1. Turner, Baquero, Yuan, Thoennes & Moyer (2000) *Virology* **272**, 267.

### Spilanthol

This bioactive *N*-isobutylamide (FW = 221.34 g/mol; CAS 25394-57-4) from the traditional medicinal plant *Acmella oleracea*, also named (2*E*,6*Z*,8*E*)-*N*-isobutyl-2,6,8-decatrienamamide, is a fatty acid amide with antimalarial properties. In bioassays against the yellow fever mosquito *Aedes aegypti*, spilanthol has a 24-hour LD<sub>100</sub> of 12 µg/mL and a LD<sub>50</sub> of 6 µg/mL. Spilanthol is likely to account for the local anesthetic properties of plant extracts, often imparting a tingling or numbing sensation when imbibed as a flower bud extract. 1. Ramsewak, Erickson & Nair (1999) *Phytochem.* **51**, 729. 2. Spelman, Depoix, McCray, et al. (2011) *Phytother. Res.* **25**, 1098.

### Spinorphin

This endogenous nonclassical opioid (*Heptapeptide Sequence*: LVVYPWT; MW = 877.05 g/mol; CAS 137201-62-8; Storage: Desiccate at -20°C), also called LVV-hemorphin-4, from bovine spinal cord is a potent P2X3 receptor antagonist, IC<sub>50</sub> = 8.3 pM (1). Spinorphin also inhibits enkephalin-degrading enzymes and blocks fMet-Leu-Phe-induced neutrophil chemotaxis by acting as a specific antagonist at the *N*-formylpeptide receptor subtype FPR. It also displays antinociceptive effects in mice. Rather remarkably, the sequence of spinorphin exactly matches a highly conserved sequence in  $\beta$ -hemoglobin (32-LVVYPWT-39). **Target(s):** dipeptidyl-peptidase III (2-4); peptidyl-dipeptidase A (angiotensin I-converting enzyme (2); and neprilysin (2). 1. Jung, Moon, Lee, et al. (2007) *J. Med. Chem.* **50**, 4543. 2. Nishimura & Hazato (1993) *Biochem. Biophys. Res. Commun.* **194**, 713. 3. Yamamoto, Ono, Ueda, et al. (2002) *Curr. Protein Pept. Sci.* **3**, 587. 3. Chiba, Li, Yamane, et al. (2003) *Peptides* **24**, 773.

### Spiroperone

This antipsychotic (FW<sub>free-base</sub> = 395.48 g/mol; CAS 749-02-0; Store at RT), also called spiroperidol, is a selective D<sub>2</sub> receptor antagonist (respective K<sub>i</sub> values are 0.06, 0.6, 0.08, ~ 350, ~ 3500 nM for D<sub>2</sub>, D<sub>3</sub>, D<sub>4</sub>, D<sub>1</sub> and D<sub>5</sub> receptors) as well as an  $\alpha_{1B}$ -adrenergic receptor antagonist and a mixed 5-HT<sub>2A</sub>/5-HT<sub>1</sub> serotonin antagonist. **Target(s):**  $\alpha_{1B}$ -adrenoceptor (1); dopamine D<sub>2</sub>-like receptors (2); dopamine-stimulated adenylate cyclase (3,4); and 5-HT<sub>2A</sub> and 5-HT<sub>1</sub> serotonin receptor (5). 1. Testa, Guarneri, Poggese, et al. (1995) *Brit. J. Pharmacol.* **114**, 745. 2. Amenta, Bronzetti,

Felici, Ricci & Tayebati (1999) *J. Auton. Pharmacol.* **19**, 151. 3. Iversen (1975) *Science* **188**, 1084. 4. Iversen (1976) *Trends Biochem. Sci.* **1**, 121. 5. Metwally, Dukat, Egan, et al. (1998) *J. Med. Chem.* **41**, 5084.

### Spiramycin

These structurally related antibiotics: (CAS 8025-81-8; Spiramycin I: FW<sub>free-base</sub> = 843.07 g/mol, R = H; Spiramycin II: FW<sub>free-base</sub> = 885.10 g/mol, R = COCH<sub>3</sub>; and Spiramycin III: FW<sub>free-base</sub> = 899.13 g/mol, R = COCH<sub>2</sub>CH<sub>3</sub>), also called foronacids, are produced by *Streptomyces ambofaciens*. These antibiotics inhibit the peptidyltransferase activity in prokaryotic protein biosynthesis (1-6) by inhibiting the binding of the donor and the acceptor substrates. They also induce rapid turnover of polyribosomes as well as stimulate the peptidyl-tRNA dissociation from ribosomes during translocation (7). 1. Poulsen, Kofoed & Vester (2000) *J. Mol. Biol.* **304**, 471. 2. Dinos, Synetos & Coutsogeorgopoulos (1993) *Biochemistry* **32**, 10638. 3. Pestka (1974) *Meth. Enzymol.* **30**, 261. 4. Jiménez (1976) *Trends Biochem. Sci.* **1**, 28. 5. ### Spirolactone

This orally bioavailable, K<sup>+</sup>-sparing, synthetic steroid and aldosterone receptor antagonist (FW = 416.58 g/mol; CAS 50-01-7), also called Aldactone and known systematically as (7 $\alpha$ ,17 $\alpha$ )-7-(acetylthio)-17-hydroxy-3-oxopregn-4-ene-21-carboxylic acid  $\gamma$ -lactone and, exhibits anti-mineralocorticoid activity (1), and is used as a diuretic and antagonist of aldosterone receptors. Spirolactone is used to treat high blood pressure. Administration often prevents bone loss. Spirolactone is metabolized to canrenone (also an anti-mineralocorticoid agent) via loss of the acetylthio moiety and insertion of a double bond at position-6,7. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** aldosterone receptor (2); carbonic anhydrase (3); CYP3A (4); dehydroepiandrosterone sulfotransferase (5); 3 $\alpha$ / $\beta$ ,20 $\beta$ -hydroxysteroid dehydrogenase (6); steroid 11 $\beta$ -monoxygenase (7-10); steroid 17 $\alpha$ -monoxygenase (1); and steroid 18-monoxygenase (9). 1. ### Spiro-17 $\beta$ -oxiranyl-4-androsten-3-one

This steroid (FW = 300.44 g/mol) inactivates steroid  $\Delta$ -isomerase, a key enzyme in the biosynthesis and metabolic transformation of steroids. **1.** Kayser, Bounds, Bevins & Pollack (1983) *J. Biol. Chem.* **258**, 909.

**Spiro-17 $\beta$ -oxiranylestro-1,3,5(10),6,8-pentaen-3-ol.** See (17S)-*Spiro[estro-1,3,5(10),6,8-pentaene-17,2'-oxiran]-3-ol*

### 3 $\beta$ -Spirooxiranyl-5 $\alpha$ -pregnan-20 $\beta$ -ol

This synthetic steroid (FW = 332.53 g/mol) inactivates steroid  $\Delta$ -isomerase in a time-dependent manner. The inactivated enzyme may be dialyzed without regain of activity, indicating a stable covalent bond forms between the inhibitor and the enzyme. Inactivation follows pseudo-first-order kinetics, and at higher inhibitor concentrations, saturation was observed. The competitive inhibitor 17  $\beta$ -oestradiol protects against the inactivation. **1.** Penning (1985) *Biochem. J.* **226**, 469.

**Spiroperidol.** See *Spiperone*

**(3 $\beta$ ,25R)-Spirost-5-en-3-ol.** See *Diosgenin*

### Spiruchostatin A

This novel HDAC prodrug (FW = 473.61 g/mol; CAS 328548-11-4; Soluble in DMSO, not in H<sub>2</sub>O), also known as OBP-801 and YM753 as well as systematically as (1S,5S,6R,9S,15E,20R)-5-hydroxy-20-methyl-6-(propan-2-yl)-2-oxa-11,12,dithia-7,19,22-triazabicyclo[7.7.6]docos-15-ene-3,8,18,21-tetrone, targets histone deacetylase *in vitro* (IC<sub>50</sub> = 2.0 nM, in the presence of dithiothreitol). Upon entry into tumor cells, the disulfide

linkage in Spiruchostatin A is reductively cleaved, whereupon the product inhibits HDAC, inducing the accumulation of acetylated histones. The latter is attended by p21WAF1/Cip1 gene expression, tumor cell growth inhibition, and tumor-selective cell death. In an *in vitro* washout experiment, YM753 prolongs the accumulation of acetylated histones in WiDr human colon carcinoma cells. YM753 administration to mice harboring WiDr xenografts likewise reduces tumor growth. While YM753 rapidly disappears from the plasma, its reduced form remains within the tumor tissue. **1.** Shindoh, Mori, Terada, *et al.* (2014) *Int. J. Oncol.* **32**, 545.

### SPL 334

This *S*-nitrosogluthatione modulator (FW = 433.50 g/mol; CAS 688347-51-5; Solubility: 100 mM in DMSO; 4-[[2-[(2-cyanophenyl) methyl]thio]-4-oxothieno[3,2-*d*]pyrimidin-3(4*H*)-yl]methyl]benzoate, inhibits *S*-nitrosogluthatione reductase, an enzyme that was originally identified in plants and other organisms as formaldehyde dehydrogenase (FALDH), a type III alcohol dehydrogenase. Nitric oxide (NO) reacts with glutathione (GSH) to form *S*-nitrosogluthatione (GSNO), which in turn transfers its NO group to other cellular thiols to form *S*-nitrosothiols (SNOs). This NO adduct has been proposed to contribute significantly to NO regulatory mechanisms, particularly in *S*-nitrosylation of proteins. Interstitial lung disease (ILD), a disorder characterized by pulmonary fibrosis and inflammation. Daily administration of SPL-334 (at 0.3, 1.0, or 3.0 mg/kg i.p.) in a mouse model of bleomycin-induced ILD is without effect on animal body weight, appearance, behavior, total and differential bronchoalveolar lavage (BAL) cell counts, or collagen accumulation in the lungs, demonstrating little or no toxicity of this agent. Similar administration of SPL-334 for 7 days before, followed by an additional 14 days after bleomycin exposure, results in a preventive protective effect on the bleomycin challenge-induced decline in total body weight and changes in total and differential BAL cellularity. Administration of SPL-334 at days 7-21 after bleomycin challenge attenuates levels of profibrotic cytokines interleukin-6, monocyte chemoattractant protein-1, and transforming growth factor- $\beta$  (TGF- $\beta$ ). Related experiments in cell cultures of primary normal human lung fibroblast also demonstrate attenuation of TGF- $\beta$ -induced up-regulation in collagen, suggesting SPL-334 is a potential therapeutic agent for ILD. **1.** Luzina, Lockett, Todd, *et al.* (2015) *J. Pharmacol. Exp. Ther.* **355**, 13.

### Spliceostatin A

This FR901464 derivative (FW = 505.65 g/mol; CAS 391611-36-2) targets the spliceosome, a multicomponent complex that assembles on the newly synthesized pre-mRNA and catalyzes the removal of intervening sequences from transcripts (See also E7107, FR901464; Meayamyacin; Pladienolide B). Spliceostatin A inhibits *in vitro* splicing and promotes pre-mRNA accumulation by binding to SF3b, a subcomplex of the U2 small nuclear ribonucleoprotein in the spliceosome. Treatment of cells with this agent results in leakage of (unspliced) pre-mRNA to the cytoplasm, where it is

translated. Knockdown of SF3b by small interfering RNA induced phenotypes similar to those seen with spliceostatin A treatment. SF3b appears to have two functions, first in the splicing pre-mRNA and in retaining it. **1.** Kaida, Motoyoshi, Tashiro, *et al.* (2007) *Nature Chem. Biol.* **3**, 576.

### Splitomicin

This cell-permeable lactone (FW = 198.22 g/mol; CAS 5690-03-9; Soluble to 100 mM in DMSO), also named 1,2-dihydro-3*H*-naphtho[2,1-*b*]pyran-3-one, inhibits the histone deacetylase activity of Sir2p, or silent information regulator (IC<sub>50</sub> = 60 μM), required for chromatin-dependent silencing in yeast. **1.** Bedalov, Gatbonton, Irvine, Gottschling & Simon (2001) *Proc. Natl. Acad. Sci. U.S.A.* **98**, 15113.

### SQ 28133

This high-affinity proteinase inhibitor (FW<sub>free-acid</sub> = 309.43 g/mol), also named *N*-[2-(mercaptomethyl)-1-oxo-3-phenylpropyl]-L-leucine, inhibits neprilysin, *K<sub>i</sub>* = 4.5 nM, and peptidyl-dipeptidase A, *K<sub>i</sub>* = 55 nM. SQ-28133 elicits significant depressor activities in both conscious spontaneously hypertensive rats (SHRs) and in DOCA/salt hypertensive rats during inhibition of angiotensin-converting enzyme (ACE) by captopril or SQ 27,519 (*i.e.*, the free acid form of the prodrug fosinopril) (2). **1.** Roques, Noble, Crine & Fournié-Zaluski (1995) *Meth. Enzymol.* **248**, 263. **2.** Seymour, Swerdel & Abboa-Offei (1991) *J. Cardiovasc. Pharmacol.* **17**, 456.

### SQ 29548

This hygroscopic acid (FW<sub>free-acid</sub> = 387.48 g/mol), also known as 1*S*-(1α,2β(5*Z*),3β,4α)-7-[3-[[2-[(phenylamino)carbonyl]hydrazino]methyl]-7-oxabicyclo[2.2.1]hept-2-yl]-5-heptenoic acid, is a potent and specific thromboxane A<sub>2</sub> receptor antagonist (1-3). **1.** Ogletree, Harris, Greenberg, Haslanger & Nakane (1985) *J. Pharmacol. Exp. Ther.* **234**, 435. **2.**

### Squalamine

This aminosterol (FW = 601.94 g/mol; CAS 148717-90-2) is an antibiotic isolated from shark tissue (*e.g.*, from the stomach of the spiny dogfish shark [*Squalus acanthias*]). It is water soluble and is effective against protozoa and Gram-positive and Gram-negative bacteria. It also causes changes in endothelial cell shape and is a natural antiangiogenic sterol (1). **Target(s):** Na<sup>+</sup>/H<sup>+</sup> exchanger isoform NHE32. **1.** Marwick (2001) *J. Natl. Cancer Inst.* **93**, 1685. **2.** Akhter, Nath, Tse, *et al.* (1999) *Amer. J. Physiol.* **276**, C136.

### Squalene-maleimide

This thiol-reactive squalene analogue (FW = 465.72 g/mol) inhibits lanosterol synthase (1) and squalene:hopene cyclase (2). **1.** Cattel, Ceruti, Balliano, *et al.* (1995) *Lipids* **30**, 235. **2.** Milla, Lenhart, Grosa, *et al.* (2002) *Eur. J. Biochem.* **269**, 2108.

**Squalestatin 1, See Zaragozates**

### Squamous Cell Carcinoma Antigen 2

This serpin (often abbreviated SCCA2) from human cervical squamous carcinoma cells inhibits a number of chymotrypsin-like serine proteinases. (*For further discussion of the likely mechanism of inhibitor action, See α<sub>1</sub>-Antichymotrypsin*) **Target(s):** cathepsin G (1,2); and mast cell chymase (1,2). **1.** Silverman, Bartuski, Cataltepe, *et al.* (1998) *Tumour Biol.* **19**, 480. **2.** Schick, Kamachi, Bartuski, *et al.* (1997) *J. Biol. Chem.* **272**, 1849.

### Squarate (Squaric Acid)

This diacid (FW = 114.06 g/mol; CAS 2892-51-5), also known as 3,4-dihydroxy-3-cyclobutene-1,2-dione, inhibits glyoxalase I, or lactoylglutathione lyase (1-3). **1.** Kraus & Castaing (1989) *Res. Commun. Chem. Pathol. Pharmacol.* **65**, 105. **2.** Kraus, Pernice & Ponce (1988) *Res. Commun. Chem. Pathol. Pharmacol.* **59**, 419. **3.** Douglas & Nadvi (1979) *FEBS Lett.* **106**, 393.

**SR 202, See Mifobate**

**SR-4233, See Tirapazamine**

### SR 8278

This Rev-Erba antagonist (FW = 361.48 g/mol; CAS 1254944-66-5; Soluble to 100 mM in DMSO), also named 1,2,3,4-tetrahydro-2-[[5-(methylthio)-2-thienyl]carbonyl]-3-isoquinoline carboxylic acid ethyl ester, inhibits Rev-Erba transcriptional repression,  $EC_{50} = 0.47 \mu\text{M}$ . REV-ERBa is a member of the nuclear receptor superfamily that functions as a receptor for the porphyrin heme. REV-ERBa suppresses transcription of its target genes in a heme-dependent manner. In HEK293 cells, SR 8278 blocks activity of Rev-Erba agonist GSK 4112, the first nonporphyrin synthetic ligand for REV-ERBa. It also increases expression of the glucose-regulating enzymes, G6Pase and PEPCK, in HepG2 cells. 1. Kojetin, Wang, Kamenecka & Burris (2011) *ACS Chem. Biol.* 6, 131.

## SR 9238

This LXR inverse agonist (FW = 595.73 g/mol; CAS 1416153-62-2; Soluble to 100 mM in DMSO), also named ethyl 5-[[[3'-(methylsulfonyl)[1,1'-biphenyl]-4-yl]methyl]-[(2,4,6-trimethylphenyl)sulfonyl]-amino]methyl]-2-furancarboxylate, potently and selectively targets Liver X Receptors LXR $\alpha$  ( $IC_{50} = 43 \text{ nM}$ ) and LXR $\beta$  ( $IC_{50} = 214 \text{ nM}$ ), a subfamily of the nuclear receptors that form obligate heterodimers with retinoid X receptors (RXRs) and regulate expression of target genes containing LXR response elements (1). Treatment of diet-induced obese mice with SR9238 suppressed plasma cholesterol levels (1). SR9238 is also effective in reducing hepatic steatosis, inflammation and fibrosis in an animal model of NASH. These results have important implications for the development of therapeutics for treatment of non-alcoholic steatohepatitis (NASH) in humans (2). 1. Griffett, Solt, El-Gendy, Kamenecka & Burris (2013) *ACS Chem. Biol.* 8, 559. 2. Griffett, Welch, Flaveny, *et al.* (2015) *Mol. Metab.* 4, 353.

## SR 12813

This bisphosphonate ester (FW = 504.34 g/mol; CAS 126411-39-0; Store at +4°C; Soluble to 100 mM in DMSO), also known as tetraethyl 2-(3,5-di-*tert*-butyl-4-hydroxyphenyl)ethyl-1,1-bisphosphonate, indirectly inhibits cholesterol biosynthesis by enhancing the degradation of 3-hydroxy-3-methylglutaryl-CoA reductase. SR 12813 *does not* inhibit the reductase directly. SR 12813 is also an agonist for the human nuclear xenobiotic PXR (NR 112) receptor ( $EC_{50}$  values are 200 and 700 nM for human and rabbit PXR respectively). SR 12813 also activates the farnesoid X receptor (FXR) at  $\mu\text{M}$  concentrations. 1. Berkhout, Simon, Patel, *et al.* (1996) *J. Biol. Chem.* 271, 14376.

## SR 13800

This MCT1 inhibitor (FW = 435.58 g/mol; CAS 227321-12-2; Solubility: 100 mM DMSO), named 2,6-dihydro-7-[(3-hydroxypropyl)thio]-2-methyl-4-(2-methylpropyl)-6-(1-naphthalenylmethyl)-1*H*-pyrrolo[3,4-*d*]pyridazin-1-one, targets H<sup>-</sup>-coupled Monocarboxylate transporter 1 (Gene Name: *SLC16A1*), blocking proliferation of Raji lymphoma cells *in vitro* ( $IC_{50} = 0.5 \text{ nM}$ ). MCT1 catalyzes rapid transport across the plasma membrane of many monocarboxylates (*e.g.*, lactate, pyruvate, branched-chain oxo-acids derived from leucine, valine and isoleucine, as well as acetoacetate,  $\beta$ -hydroxybutyrate and acetate. Depending on the tissue and on circumstances, MCT1 mainly mediates the import or export of lactic acid and ketone bodies. SR-13800 also inhibits lactate uptake in breast cancer cells *in vitro*. Inhibition of MCT1 during T lymphocyte activation results in selective and profound inhibition of the extremely rapid phase of T cell division essential for an effective immune response (1). 1. Murray, Hutchinson, Bantick *et al.* (2005) *Nature Chem. Biol.* 1, 371.

SR 33557, See *Fantofarone*

SR-46349, See *Eplivanserin*

## SR 59230A

This aryloxypropanolaminotetralin (FW = 415.49 g/mol), also known as 3-(2-ethylphenoxy)-1-[(1*S*)-1,2,3,4-tetrahydronaphth-1-ylaminol]-2-*S*-propanol, was the first  $\beta_3$ -adrenergic receptor antagonist (1-3). The *RR*-enantiomer (SR 59483) is inactive. 1. De Ponti, Gibelli, Croci, *et al.* (1996) *Brit. J. Pharmacol.* 117, 1374. 2. Manara, Badone, Baroni, *et al.* (1996) *Brit. J. Pharmacol.* 117, 435. 3. Nisoli, Tonello, Landi & Carruba (1996) *Mol. Pharmacol.* 49, 7.

SR 90107A, See *Fondaparinux*

## SR141617A

This selective CB<sub>1</sub> receptor antagonist (FW = 463.93 g/mol), also named as (*N*-(piperidiny-1-yl)-5-(4-chlorophenyl)-1-(2,4-dichlorophenyl)-4-methyl-1*H*-pyrazole-3-carboxamide), inhibits the binding of 2-arachidonylglycerol to the Cannabinoid receptor Type-1 receptor (1,2) and permanently prevents milk ingestion in a dose-dependent manner, when administered to mouse pups, within one day of birth (3). Cannabinoids affected performance in a dose-x-delay-dependent manner, with the synthetic cannabinoid WIN-2 showing a potency more than four times that of  $\Delta^9$ -THC, but these effects

were eliminated if SR141617A was preadministered, but doses of the antagonist alone had no effect on performance (1). (**See also** *Arachidonyl-2'-chloroethylamide*) 1. Hampson & Deadwyler (2000) *J. Neurosci.* **20**, 8932. 2. Esteban & Garcia-Sevilla (2012) *Prog. Neuro-psychopharmacol. Biol. Psych.* **38**, 78. 3. Fride, Foox, Rosenberg, *et al.* (2003) *Eur. J. Pharmacol.* **461**, 27.

**SR141716**, *See Rimonaban*

#### SR 144528

This orally bioavailable CB<sub>2</sub> receptor-selective inverse agonist (FW = 476.05 g/mol; CAS 192703-06-3; Soluble to 100 mM in DMSO), also named 5-(4-chloro-3-methylphenyl)-1-[(4-methylphenyl)methyl]-N-[(1*S*,2*S*,4*R*)-1,3,3-trimethylbicyclo[2.2.1]hept-2-yl]-1*H*-pyrazole-3-carboxamide, targets rat spleen and human CB<sub>2</sub> inverse agonist ( $K_i = 0.6$  nM). SR 144528 exhibits >700-fold selectivity for CB<sub>2</sub> ( $K_i = 400$  nM) over CB<sub>1</sub> receptors (1). Based on both its binding and functional properties, SR 144528 as the first-in-class, highly potent, selective and orally active CB<sub>2</sub> receptor antagonist (1). It also blocks the effects of CP 55,940, a cannabinoid agonist that is considerably more potent than  $\Delta^9$ -THC, on forskolin-sensitive adenylyl cyclase activity and MAPK in CHO cells expressing CB<sub>2</sub> receptors. Also blocks CP 55,940-induced B-cell activation. By means of its binding to the CB<sub>2</sub> receptors, SR 144528 blocks the direct activation of the G<sub>i</sub> protein by mastoparan analog in Chinese hamster ovary CB<sub>2</sub> cell membranes (2). Sustained treatment with SR 144528 induced an up-regulation of the cellular G<sub>i</sub> protein level, as demonstrated in Western blotting as well as in confocal microscopic experiments (2). This up-regulation occurred with a concomitant loss of SR 144528 ability to inhibit the insulin or lysophosphatidic acid-induced MAPK activation (2). Subsequent studies demonstrated the importance of hydrogen bonding and aromatic stacking in SR 144528's affinity and efficacy as a cannabinoid receptor ligand (3). 1. Rinaldi-Carmona, Barth, Millan, *et al.* (1998) *J. Pharmacol. Exp. Ther.* **284**, 644. 2. Bouaboula, Desnoyer, Carayon, Combes & Casellas (1999) *Mol. Pharmacol.* **55**, 473. 3. Kotsikorou, Navas, 3rd, Roche, *et al.* (2003) *J. Med. Chem.* **56**, 6593.

#### Src i1

This competitive dual-site protein tyrosine kinase inhibitor (FW = 373.40 g/mol; CAS 179248-59-0; Soluble to 100 mM in DMSO), also named 6,7-dimethoxy-*N*-(4-phenoxyphenyl)-4-quinazolinamine, targets human pp60c-src kinase, with IC<sub>50</sub> values of 44 and 88 nM for Src and Lck, respectively, by binding to ATP and peptide binding sites. Src-11 inhibits VEGFR2 and c-fms at much higher concentrations, exhibiting IC<sub>50</sub> values are 0.32 and 30  $\mu$ M, respectively. Structural modeling of Src tyrosine kinase (Src TK) with inhibitor and peptide substrate bound indicated a direct atomic-level clash between the bulky 4-position group and the hydroxy of the peptide tyrosyl to which the  $\gamma$ -phosphoryl of ATP is transferred during the kinase reaction (1). This atomic conflict would likely prevent simultaneous binding of both

inhibitor and peptide, an action that is consistent with the observed kinetic competitiveness of the inhibitor with peptide. Such dual-site inhibitors appear to have enhanced potency and selectivity for Src TK (1,2). 1. Tian, Cory, Smith & Knight (2001) *Biochemistry* **40**, 7084. 2. Bain, Plater, Elliott, *et al.* (2007) *Biochem. J.* **408**, 297.

**SRIF (Somatotropin Release-Inhibiting Factor)**, *See Somatostatin*

#### SRPIN340

This SRPK arginine (FW = 349.35 g/mol; CAS 218156-96-8; Soluble to 100 mM in DMSO and to 50 mM in 1 eq. HCl), also named *N*-[2-(1-piperidinyl)-5-(trifluoromethyl)-phenyl]-4-pyridinecarboxamide, selectively targets Serine arginine protein kinase-1, or SRPK1 ( $K_i = 0.89$   $\mu$ M), with action against SRPK2 only at much higher concentrations. SRPIN340 does not significantly inhibit other SRPKs, such as CLK1 and CLK4, or other classes of SR kinases. SRPIN340 down-regulates expression of VEGF<sub>165</sub> but is without effect on VEGF<sub>165b</sub> expression. 1. Fukuhara, Hosoya, Shimizu, *et al.* (2006) *Proc. Natl. Acad. Sci. U.S.A.* **103**, 11329. 2. Oltean, Gammons, Hulse, *et al.* (2012) *Biochem. Soc. Trans.* **40**, 831. 3. Gammons, Dick, Harper & Bates (2013) *Invest. Ophthalmol. Vis. Sci.* **54**, 5797.

**SRS**, *See Leukotriene C<sub>4</sub>; Leukotriene D<sub>4</sub>; Leukotriene E<sub>4</sub>*

#### SRT1720

This putative SIRT1 activator, or STAC (FW = 469.56 g/mol; CAS 925434-55-5), also named *N*-[2-[3-(piperazin-1-ylmethyl)imidazo[2,1-*b*][1,3]thiazol-6-yl]phenyl]quinoxaline-2-carboxamide, was thought to target the NAD<sup>+</sup>-dependent deacetylase Sirtuin-1 (1). However, SRT1720 and structurally related compounds (SRT2183 and SRT1460), as well as resveratrol, do not activate SIRT1 with native peptide or full-length protein substrates, but instead activate SIRT1 with peptide substrate containing a covalently attached fluorophore. NMR, surface plasmon resonance (SPR), and isothermal calorimetry evidence indicates that these compounds directly interact with fluorophore-containing peptide substrates. Furthermore, SRT1720 neither lowers plasma glucose nor improves mitochondrial capacity in mice fed a high fat diet. SRT1720, SRT2183, SRT1460, and resveratrol exhibit multiple off-target activities against receptors, enzymes, transporters, and ion channels. Taken together, SRT1720, SRT2183, SRT1460, and resveratrol are not direct activators of SIRT1 (2). 1. Milne, Lambert, Schenk, *et al.* (2007) *Nature* **450**, 712. 2. Pacholec, Bleasdale, Chrnyk, *et al.* (2010) *J. Biol. Chem.* **285**, 8340.

## SSR69071

This substituted pyrido[1,2-*a*]pyrimidine (FW = 580.66 g/mol; CAS 344930-95-6), known systematically as 2-(9-(2-piperidinoethoxy)-4-oxo-4*H*-pyrido[1,2-*a*]pyrimidin-2-yl)oxymethyl)-4-(1-methylethyl)-6-methoxy-1,2-benzisothiazol-3(2*H*)-one-1,1-dioxide, is a potent inhibitor of human leukocyte elastase, or HLE ( $K_i = 17$  pM). SSR-69071 is a potent inhibitor of HLE, with the inhibition constant of 168 pM, an association rate constant of  $0.183 \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$ , and a dissociation rate constant of  $3.1 \times 10^{-6} \text{ s}^{-1}$ . Bronchoalveolar lavage fluid from mice orally treated with SSR69071 inhibits HLE (*ex vivo*), and in this model, SSR69071 has a dose-dependent efficacy with an  $\text{ED}_{50} = 10.5 \text{ mg/kg p.o.}$  1. Kapui, Varga, Urban-Szabó, *et al.* (2003) *J. Pharmacol. Exp. Ther.* **305**, 451. **Alternate Identifiers:** SSR69071, SSR-69071

## SSR128129E

This orally-active allosteric FGFR1 inhibitor (FW<sub>free-acid</sub> = 324.24 g/mol; FW<sub>NaSalt</sub> = 346.31 g/mol; CAS 848318-25-2; Solubility: 69 mg/mL DMSO, 1 mg/mL H<sub>2</sub>O), also named 2-amino-5-[(1-methoxy-2-methyl-3-indolizinyloxy)carbonyl]benzoate, targets Fibroblast Growth Factor Receptor 1 (FGFR1), also known as Basic Fibroblast Growth Factor Receptor 1 (IC<sub>50</sub> = 1.9 μM), with little effect on other related RTKs. 1. Bono, De Smet, Herbert, *et al.* (2013) *Cancer Cell* **23**, 477. 2. Dol-Gleizes F1, Delesque-Touchard N, Marès A, *et al.* (2013) *PLoS One* **8**, e80027.

## SSR 180711

This  $\alpha_7$  nAChR partial agonist and antidepressant (FW<sub>free-base</sub> = 325.21 g/mol; CAS 446031-79-4; Soluble to 100 mM in H<sub>2</sub>O (HCl Salt) or DMSO (free base)), also named 4-bromophenyl 1,4-diazabicyclo[3.2.2]nonane-4-carboxylate, targets  $\alpha_7$  nicotinic acetylcholine receptors, enhancing episodic memory and reversing MK-801-induced deficits in retention of episodic memory (1). Selectivity of SSR180711 was confirmed as these effects were abolished by 3 mg/kg (i.p.) or 1 mg/kg (i.v.) methyllycaconitine, a selective  $\alpha_7$  n-AChR antagonist (1). SSR180711 displays high affinity for rat  $\alpha_7$  n-AChRs ( $K_i = 22$  nM) and human  $\alpha_7$  n-AChRs ( $K_i = 14$  nM) (2). *Ex vivo* [<sup>3</sup>H]- $\alpha$ -bungarotoxin binding experiments demonstrate that SSR180711 rapidly penetrates into the brain (ID<sub>50</sub> = 8 mg/kg p.o.). In functional studies performed with human  $\alpha_7$  n-AChRs expressed in *Xenopus* oocytes or GH4C1 cells, SSR180711 shows partial agonism (Intrinsic activities of 51 and 36%, and EC<sub>50</sub> values of 4.4 and 0.9 μM, respectively) (2). 1. Pichat, Bergis, Terranova, *et al.* (2007) *Neuropsychopharmacol.* **32**, 17. 2. Biton, Bergis, Galli, *et al.* (2007) *Neuropsychopharmacol.* **32**, 1.

## SSR-591813, See Dianicline

## SSRI, See Selective Serotonin Re-uptake Inhibitors

## ST 638

This tyrosine kinase inhibitor (FW = 354.43 g/mol; photosensitive), also known as  $\alpha$ -cyano-(3-ethoxy-4-hydroxy-5-phenylthiomethyl)cinnamide, exhibits an IC<sub>50</sub> value of 0.37 μM. ST 638 also inhibits (hepatocyte growth factor)-induced mitogen-activated protein (MAP) kinase activation in hepatocytes and phospholipase D activity in human neutrophils. **Target(s):** (hepatocyte growth factor)-induced mitogen-activated protein (MAP) kinase activation (1); inositol-trisphosphate 3-kinase (2); and protein-tyrosine kinase (1,3). 1. Adachi, Nakashima, Saji, Nakamura & Nozawa (1996) *Hepatology* **23**, 1244. 2. Mayr, Windhorst & Hillemeier (2005) *J. Biol. Chem.* **280**, 13229. 3. Shiraishi, Kameyama, Imai, *et al.* (1988) *Chem. Pharm. Bull.* **36**, 974.

## Stachybotrylactone

This spirocyclic drimane (FW = 348.44 g/mol; CAS 149691-31-6), originally isolated from the culture broth of the fungus *Stachybotrys cylindrospora*, is a strong inhibitor of rat  $\beta$ -galactoside  $\alpha$ -2,3-sialyltransferase ( $K_i = 10$  μM). 1. Lin, Chang, Chen & Tsai (2005) *Biochem. Biophys. Res. Commun.* **331**, 953.

## Stallimycin, See Distamycin A

## Stampidine

This nucleotide analogue (FW = 550.28 g/mol) is a prodrug form of stavudine 5'-triphosphate, which inhibits HIV-1 reverse transcriptase (1,2). 1. El Safadi, Vivet-Boudou & Marquet (2007) *Appl. Microbiol. Biotechnol.* **75**, 723. 2. Uckun, Pendergrass, Venkatachalam, Qazi & Richman (2002) *Antimicrob. Agents Chemother.* **46**, 3613.

Stanolone, See 5 $\alpha$ -Androstan-17 $\beta$ -ol-3-one

**Stanozolol**

This anabolic steroid (FW = 328.50 g/mol; CAS 10418-03-8), also known as androstanozole and 17 $\beta$ -hydroxy-17 $\alpha$ -methylandrostanol[3,2-*c*]pyrazole, is a controlled substance exhibiting one of the largest anabolic/androgenic ratios of the common steroids. Stanozolol also possesses substantial fibrinolytic properties. **Target(s):** steroid 17 $\alpha$ -hydroxylase/C17,20-lyase, or CYP17A1. 1. Nakajin, Takahashi & Shinoda (1989) *Chem. Pharm. Bull.* 37, 1855.

**Staphicillin, See Methicillin**

**Staphylococcus aureus Exfoliative Toxins**

These "epidermolytic" toxins (MW = 30 kDa) are extremely specific serine proteases (serotypes ETA and ETB) that recognize and cleave desmosomal cadherins within the superficial layers of the skin and are directly responsible for the clinical manifestation of staphylococcal scalded skin syndrome (SSSS). The target protein, desmoglein 1, is recognized through an interaction at the classical P1 site and by additional features in the tertiary structure, located away from the site of hydrolysis. The cleavage of Dsg-1 results in the destruction of desmosomal cell-cell attachments in a superficial layer of the skin. 1. Bukowski, Wladyka & Dubin (2010) *Toxins (Basel)* 2, 1148.

**Statin: A Confusing Nomenclature**

Use of 'statin' as a suffix is both confusing and arbitrary. Even so, there is little likelihood for a self-consistent remedy. In the broadest sense, a statin is an agent that maintains or holds steady a metabolic or physiologic process through some activity-modulating effect. In layman usage, statin most often refers to an LDL-cholesterol-reducing drug acting as an inhibitor of the hydroxymethyl-CoA reductase reaction (**See Statin Drugs: LDL Cholesterol-Reducing**). Many other peptidomimetics (e.g., pepstatin) are protease inhibitors, particularly those containing the tetrahedral transition-state mimic known as statine (**See Statine**). Still other inhibitors contain "statin" in their suffix (e.g., pancreastatin is derived by proteolytic processing of the glycoprotein chromogranin A). Readers must therefore exercise care to avoid confusing the modes of action of these agents.

**Statins: LDL Cholesterol-Reducing Drugs**

These high-affinity inhibitors target hydroxymethylglutaryl-coenzyme A (or HMGCoA) reductase (*Reaction: (S)-3-Hydroxy-3-methylglutaryl-CoA + 2 NADPH  $\rightleftharpoons$  (R)-Mevalonate + 2 NADP<sup>+</sup>*), which catalyzes the rate-determining step in the mevalonate pathway. Most manufacturers recommend that statins be taken at night, on the basis of physiological studies show most cholesterol is synthesized when dietary cholesterol intake is at its nadir. **METABOLIC ASPECTS:** Formation of mevalonate leads to the synthesis of cholesterol and other isoprenoids, including various steroids, coenzyme Q<sub>10</sub>, isopentenyl pyrophosphate (IPP), dolichol pyrophosphate, farnesyl pyrophosphate (FPP) and geranylgeranyl pyrophosphate (GGPP). The last two are especially critical in the membrane-anchoring posttranslational modification reactions involving proteins essential for cell proliferation and differentiation. The latter include the small GTP-binding proteins known as Ras, Rac, and Rho. The mevalonate pathway also contributes to multidrug resistance (MDR), a major challenge to durable tumor eradication by chemotherapy. **COMMONLY USED STATINS:** Advicor<sup>®</sup>, a combination of lovastatin and extended-release niacin; Altprev<sup>®</sup>, or extended-release lovastatin; Caduet<sup>®</sup>, or amlodipine and atorvastatin; Crestor<sup>®</sup>, or rosuvastatin; Juvivinc<sup>®</sup>, or sitagliptin and simvastatin; Lescol<sup>®</sup>, or fluvastatin; Lescol XL<sup>®</sup>, extended-release fluvastatin; Lipitor<sup>®</sup>, or atorvastatin; Livalo<sup>®</sup>, or pitavastatin; Mevacor<sup>®</sup>, or lovastatin; Pravachol<sup>®</sup>, or pravastatin; Simcor<sup>®</sup>, a combination of simvastatin and extended-release niacin; Vytorin<sup>®</sup>, or ezetimibe/simvastatin; and Zocor<sup>®</sup>, or simvastatin. **SIDE-EFFECTS OF STATIN THERAPY:** Often exhibiting significant biochemical and physiologic side effects, HMGCoA reductase inhibitors are far from being entirely benign. Mild effects include: constipation, stomach pain, nausea, headache, memory loss, forgetfulness, and confusion. More

serious side effects include: muscle pain, tenderness, or weakness; decreased urination; lack of energy, tiredness, or weakness; loss of appetite; stomach pain; fever, chills, and/or flushing; skin blisters, rash, hives, itching; swelling of the face, throat, tongue, lips, eyes, hands, feet, ankles, or lower legs; difficulty breathing or swallowing; hoarseness; joint pain; as well as sensitivity to light. **Impact of Mevalonate Depletion:** On average, humans produce about 20 mmol mevalonate each day, with about 80-90% ultimately converted to cholesterol, and the remainder forming other isoprenoids. By greatly reducing mevalonate biosynthesis, statins deplete cellular stores of steroids, geranyl-PP, geranylgeranyl-PP, farnesyl-PP, Coenzyme Q<sub>10</sub>, and other less abundant isoprenoids. Cellular processes relying on these metabolites are therefore negatively impacted during statin therapy. For example, all statins cause an accumulation of unprenylated signal transduction GTP-regulatory proteins, thereby blocking their membrane tethering and limiting their effectiveness in signal transduction. **Physiologic Effects:** Among the most common physiologic effects are myalgia/rhabdomyolysis, gastrointestinal intolerance, and an increase in hepatic aminotransferases. Symptoms of statin-induced myopathy include fatigue, muscle pain, muscle tenderness, muscle weakness, nocturnal cramping, and tendon pain. There is increased muscle cell apoptosis, often taxing the kidney as a consequence of muscle protein turnover. **Lipophilic versus Hydrophilic Statins:** Statin pharmacodynamics and pharmacokinetics are also influenced by the inhibitors lipophilic or hydrophilic character. Lipophilic statins appear to evoke the greatest complaint of muscle pain. Lovastatin and simvastatin are the most lipophilic, followed by atorvastatin, fluvastatin, rosuvastatin and pravastatin. *Note:* The mevalonate pathway is also inhibited by aminobisphosphonates (NBPs), which target FPP synthase (FPPS) selectively. NBPs are commonly used to inhibit the activity of osteoclasts in patients affected by bone metastases or other causes of bone fragility (e.g., osteoporosis). Zoledronic acid (ZA) is the most potent NBP currently available for clinical use.

**Statine**

This unusual  $\gamma$ -amino acid (FW = 175.23 g/mol; CAS 49642-07-1), when incorporated in peptides/polypeptides, becomes a potent transition-state inhibitor for many aspartic proteinases (1,2). The inhibitory action of these peptidomimetics often becomes selective, when the sequence matches the specificity-conferring subsites in the target proteinase (3). (**See Pepstatin, Pancreastatin**) 1. Umezawa, Aoyagi, Morishima, Matsuzaki & Hamada (1970). *J. Antibiot.* 23, 259. 2. Marcinişzyn, Hartsuck & Tang (1976) *J. Biol. Chem.* 251, 7088. 3. Jupp, Dunn, Jacobs, *et al.* (1990) *Biochem. J.* 265, 871.

**Stattic**

This small-molecule protein kinase inhibitor (FW = 211.19 g/mol; CAS 19983-44-9; Solubility = 45 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also named 6-nitrobenzo[*b*]thiophene 1,1-dioxide, inhibits (IC<sub>50</sub> = 5.1  $\mu$ M) STAT3 (or Signal Transducer and Activator of Transcription factor 3) activation, dimerization, and nuclear translocation, thereby increasing apoptosis in STAT3-dependent breast cancer cells (1). Later work provided preclinical proof-of-principle that STAT3 is a good druggable target (2). Direct inhibition of STAT3 with short hairpin RNA suppressed cancer cell growth in a manner associated with apoptosis, repression of STAT3 target genes, and inhibition of a tumor-promoting microenvironment. Such results indicate STAT3 inhibition may be a promising approach in its therapy. Binding of Stattic to the unphosphorylated STAT3 $\beta$ tc (U-STAT3) protein is attended by alkylation of at least four cysteine residues (3). This finding not only bears on its mechanism of inhibitory action but also raises concerns about specificity and clinical suitability. Indeed, a preview to the original paper mentions this inhibitor's likely susceptibility to Michael addition (4). A study of signal transduction pathways within dendritic cells recently demonstrated that cell type and/or cytokine-specific effects can modulate

the selectivity of Stattic toward STAT3 (5). These investigators emphasize the need for interrogating an inhibitor's action against anticancer targets within a microenvironment likely to surround the tumor *in situ* (5; *See also reply*, 6). Given its modest size, Stattic is likely to lack sufficient specificity-conferring determinants seen in inhibitors with formula weights 2-3x higher. 1. ### Staurosporine

This antibiotic alkaloid (FW = 466.54 g/mol; CAS 62996-74-1; water-insoluble; soluble to 50 mM in DMSO; photosensitive), produced by a number of *Streptomyces* species, is a broadly acting and potent protein kinase inhibitor, with strongest effects ( $IC_{50} = 3$  nM) on the PKC  $\beta$ II isoform. Other inhibited include protein kinase A ( $IC_{50} = 7$  nM), p<sup>60v-src</sup> tyrosine protein kinase ( $IC_{50} = 6$  nM) and CaM kinase II ( $IC_{50} = 20$  nM). Staurosporine is effective against fungi and yeasts, but is ineffective against bacteria. In higher organisms, it wreaks havoc by reducing the phosphorylation of multiple proteins. For example, even when used in low concentrations (1-10 nM), staurosporine causes the complete collapse and loss of hair bundles in postnatal mouse cochlear cultures, without provoking hair-cell death, as judged by lack of TUNEL labelling or reactivity to anti-activated caspase-3 (1). Staurosporine exposure results in the fusion of the hair bundle's stereocilia, resorption of the parallel actin filament bundles of the stereocilia into the cytoplasm of the hair cell, detachment of the apical, non-stereociliary membrane of the hair cell from the underlying cuticular plate, and severing of hair-bundle's rootlets from the actin cores with stereocilia. Staurosporine does not block membrane retrieval at the apical pole of the hair cells, nor does it elicit the externalisation of phosphatidylserine. Notably, it reduces the levels of the phosphorylated forms of ezrin, radixin and moesin in cochlear cultures during the period of hair-bundle loss, indicating the integrity of the hair bundle may be maintained by the phosphorylation status of these proteins. The take-home lesson is that staurosporine is evoking many changes in the phosphorylation state of numerous proteins (1). **IUPAC Name:** [9S-(9 $\alpha$ ,10 $\beta$ ,11 $\beta$ ,13 $\alpha$ )]-2,3,10,11,12,13-hexahydro-10-methoxy-9-methyl-11-(methylamino)-9,13-epoxy-1H,9H-diindolo[1,2,3-gh:3',2',1'-lm]pyrrolo[3,4-j][1,7]-benzodiazonin-1-one. **Target(s):** AfsK serine/ threonine protein kinase (28); Akt-3 serine/threonine protein kinase (29); Bruton's protein-tyrosine kinase (32); Ca<sup>2+</sup>/calmodulin-dependent protein kinase (2,19); cAMP-dependent protein kinase, *or* protein kinase A (11,12,24,25); cGMP-dependent protein kinase, *or* protein kinase G (23); cyclin-dependent kinases Cdk1 and Cdk2,  $IC_{50} = 9$  and 7 nM, respectively (3-5); dual-specificity kinase (6,7); I $\kappa$ B kinases (8); inositol-trisphosphate 3-kinase (35); Lyn protein-tyrosine kinase (31); mitogen-activated protein kinase (9); non-specific serine/threonine protein kinase (26-30); phosphatidylinositol 3-kinase (34); phosphorylase kinase (10); PknH serine/threonine protein kinase (27); polo kinase (33); protein kinase C (7,11-18,20-22); protein-tyrosine kinase (7,11,12,31,32); PstA serine/threonine protein kinase (26); receptor protein-tyrosine kinase (7); Rho-associated kinase (17); and StkP serine/threonine protein kinase (30). 1. ### Stavudine 5'-Triphosphate

This nucleotide derivative (FW<sub>free-acid</sub> = 464.16 g/mol), also known as 2',3'-didehydro-2',3'-dideoxythymidine 5'-triphosphate and often abbreviated d4TTP, inhibits HIV-1 reverse transcriptase *in vitro*,  $K_i = 5$  nM. The nucleotide will not enter cells, and the action reported below is *in vitro*

assays. **See Staudine for in vivo agent Target(s):** avian myeloblastosis virus reverse transcriptase (1); DNA helicases (2); DNA-directed DNA polymerase (1,3); DNA polymerase I (1); DNA polymerase  $\beta$ ,  $IC_{50} = 1.0 \mu\text{M}$  (1,3); DNA polymerase  $\gamma$  (3); HIV-1 reverse transcriptase (3-5); nucleoside-triphosphatase, as alternative substrate (2); Rauscher murine leukemia virus reverse transcriptase (6); Raus sarcoma virus reverse transcriptase (1), or RNA-directed DNA polymerase (1,3-6); and terminal deoxynucleotidyltransferase (1). **1.** Dyatkina, Minassian, Kukhanova, *et al.* (1987) *FEBS Lett.* **219**, 151. **2.** Locatelli, Gosselin, Spadari & Maga (2001) *J. ### Stearamide

This amide (FW = 283.49 g/mol; CAS 124-26-5) inhibits microsomal epoxide hydrolase,  $IC_{50} = 20 \mu\text{M}$ . *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **1.** Morisseau, Newman, Dowdy, Goodrow & Hammock (2001) *Chem. Res. Toxicol.* **14**, 409.

### Stearate (Stearic Acid)

This carboxylic acid (FW = 284.48 g/mol; CAS 57-11-4;  $pK_a \approx 4.8$ ; M.P. = 69-70°C; B.P. = 383°C; water insoluble; slightly soluble in benzene (2.5 g per 100 mL), also called *n*-octadecanoic acid, is a long-chain fatty acid widely distributed in nature. Stearic acid is a solid at room temperature (benzene (2.5 g per 100 mL), ethyl acetate, and acetone. It is very soluble in diethyl ether. Chemist Paul Sabatier (Nobel Laureate, 1912), used catalytic hydrogenation to chemically convert oleic acid to stearic acid, forming the basis of the margarine and oil hydrogenation in the food industry. *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **Target(s):** alcohol dehydrogenase (1); D-amino-acid oxidase (2,3); choline oxidase (3); chondroitin AC lyase (18); chondroitin B lyase, weakly inhibited (18); chymase (4,20); dihydroorotate dehydrogenase (5); dimethylaniline monooxygenase (6); DNA-directed DNA polymerase (7,8); DNA polymerases  $\alpha$ ,  $\gamma$ ,  $\delta$ , and  $\epsilon$  (7,8); 7-ethoxycoumarin *O*-deethylase, or cytochrome P450 (9); firefly luciferase, or *Photinus*-luciferin 4-monooxygenase,  $IC_{50} = 0.63 \mu\text{M}$  (10,27);  $\beta$ -galactoside  $\alpha$ -2,6-sialyltransferase (25); 1,3- $\beta$ -glucan synthase (26); glucose-6-phosphate dehydrogenase (11); glutathione *S*-transferase (12); glycerol-3-phosphate dehydrogenase (13); hexokinase (24); hyaluronate lyase (18); leukocyte elastase, or neutrophil elastase (19); Lysophospholipase (23); microbial collagenases (19); palmitoyl-CoA synthetase, or palmitate:CoA ligase (14); phospholipase D (22); *Photinus*-luciferin 4-monooxygenase (10); prostaglandin dehydrogenase (15,16); prostaglandin  $D_2$  dehydrogenase (16); prostaglandin D synthetase (16); sphingomyelin phosphodiesterase, weakly inhibited (21); succinate oxidase, weakly inhibited (3); and L-threonine dehydrogenase (17). **1.** Winer & Theorell (1960) *Acta Chem. ### Stearidonate

This long-chain fatty acid (FW<sub>free-acid</sub> = 276.42 g/mol; CAS 20290-75-9), also called stearidonic acid and named systematically as (*Z,Z,Z*)-6,9,12,15-octadecatetraenoic acid, is an  $\omega$ -3 fatty acid that is biosynthesized from  $\alpha$ -linolenic acid. Stearidonic acid is also a precursor to a number of long-chain unsaturated acids (*e.g.*, eicosapentaenoic acid). *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **Target(s):** DNA topoisomerase II,  $IC_{50} = 60 \mu\text{M}$  (1); and 5-lipoxygenase (2). **1.** Mizushima, Tsuzuki, Eitsuka, *et al.* (2004) *Lipids* **39**, 977. **2.** Guichardant, Trautler, Spielmann, Sprecher & Finot (1993) *Lipids* **28**, 321.

### Stearoyl-CoA

This thioester (FW = 1034.01 g/mol; CAS 362-66-3), also known as *n*-octadecanoyl-CoA, is a substrate of stearoyl-CoA 9-desaturase, icosanoyl-CoA synthase (or, eicosanoyl-CoA synthase), and many acyltransferases. *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **Target(s):** acetyl-CoA carboxylase,  $K_i = 0.71 \mu\text{M}$  for the rat liver enzyme (1,2); acetyl-CoA synthetase, or acetate:CoA ligase (3); AMP deaminase (4); aralkylamine *N*-acetyltransferase (23); ATP:citrate lyase, or ATP:citrate synthase (5,6); choline kinase (7-9); cyclooxygenase (10); ethanolamine kinase (8); fatty-acid synthase (11); glucose-6-phosphatase (12,13); glucose-6-phosphate dehydrogenase (14,15); glycerol-3-phosphate dehydrogenase (16); isocitrate dehydrogenase (NADP<sup>+</sup>) (17); lipoxygenase (10); phosphate-activated glutaminase (18,19); protein-palmitoyl acyltransferase (20); [pyruvate dehydrogenase (acetyl-transferring)] kinase (21); and RNA polymerase (22). **1.** Tanabe, Nakanishi, Hashimoto, *et al.* (1981) *Meth. ### 1-Stearoylglycerol

This monoacylglycerol (FW = 358.56 g/mol; CAS 22610-63-5; M.P. = 74.4°C), also known as 1-monostearoylglycerol and 1-monostearin, is often supplied commercially as the racemic mixture (*e.g.*, 1-stearoyl-*rac*-glycerol). *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **See also 2-Stearoylglycerol** **Target(s):** alcohol *O*-acetyltransferase (1); 7-ethoxycoumarin *O*-deethylase, or cytochrome P450 (2); sphingomyelin phosphodiesterase, inhibited by the racemic mixture (3). **1.** Yoshioka & Hashimoto (1981) *Agric. Biol. Chem.* **45**, 2183. **2.** Muller-Enoch, Fintelmann, Nicolaev & Gruler (2001) *Z. Naturforsch. [C]* **56**, 1082. **3.** Liu, Nilsson & Duan (2002) *Lipids* **37**, 469.

### 2-Stearoylglycerol

This monoacylglycerol (FW = 358.56 g/mol; M.P. = 74.4°C), also known as 2-monostearoylglycerol and 2-monostearin, inhibits diacylglycerol lipase. *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **Target(s):** diacylglycerol lipase (1). **1.** Moriyama, Urade & Kito (1999) *J. Biochem.* **125**, 1077.

### Steviol

This diterpene, (FW<sub>free-acid</sub> = 318.46 g/mol; CAS 471-80-7; M.P. = 215°C.) also known as (4 $\alpha$ )-13-hydroxykaur-16-en-18-oate, is the aglycon of stevioside **See Stevioside** **Target(s):** *p*-aminohippurate transport (1); ATPase (2); glucose absorption (3); glutamate dehydrogenase (2); oxidative phosphorylation (2); and succinate dehydrogenase (2). **1.** Chatsudhipong & Jutabha (2001) *J. Pharmacol. Exp. Ther.* **298**, 1120. **2.** Kelmer Bracht, Alvarez & Bracht (1985) *Biochem. Pharmacol.* **34**, 873. **3.** Toskulkao, Sutteerawattananon & Piyachaturawat (1995) *Toxicol. Lett.* **80**, 153.

### Stevioside

This non-nutritive glycosylated diterpene sweetener (FW = 804.88 g/mol; CAS 57817-89-7; hygroscopic solid; M.P. = 198°C) from the leaves of the South America bush *Stevia rebaudiana* is about 300-times as sweet as cane

sugar. **Target(s):** *p*-aminohippurate transport (1,2); ATPase (3); Ca<sup>2+</sup> influx (4); glutamate dehydrogenase (3); long-chain fatty acid transport (5); oxidative phosphorylation (3); and succinate dehydrogenase (3). **1.** Chatsudhipong & Jutabha (2001) *J. Pharmacol. Exp. Ther.* **298**, 1120. **2.** Jutabha, Toskulkao & Chatsudhipong (2000) *Can. J. Physiol. Pharmacol.* **78**, 737. **3.** Kelmer Bracht, Alvarez & Bracht (1985) *Biochem. ### STF-118804

This highly specific NAMPT inhibitor (FW = 461.53 g/mol; CAS 894187-61-2; Solubility = <1 mg/mL DMSO or H<sub>2</sub>O), also known as 4-[5-methyl-4-[[[4-methylphenyl)sulfonyl]methyl]-2-oxazolyl]-*N*-(3-pyridinylmethyl) benzamide, targets nicotinamide phospho-ribosyl transferase, or NAMPT (*Reaction:* Nicotinamide + PRPP  $\rightleftharpoons$  NMN + PP<sub>i</sub>), a rate-limiting enzyme in the biosynthesis of NAD<sup>+</sup>, a coenzyme for many biochemical processes, including cytoplasmic and mitochondrial redox reactions, telomere poly(adenosine diphosphate-ribose) polymerase (*or* PARP), and the chromatin-silencing NAD-dependent histone deacetylases (*or* Sirtuins). STF-118804 is a highly specific NAMPT inhibitor, improves survival in an orthotopic xenotransplant model of high-risk acute lymphoblastic leukemia, and targets leukemia stem cells (IC<sub>50</sub> range: 3-60 nM). **1.** Matheny, Wei, Bassik, *et al.* (2013) *Chem. Biol.* **20**, 1352. **2.** Mei & Brenner (2013) *Chem. Biol.* **20**, 1307.

### Stibogluconate, Sodium

This phlebotoxic antileishmanial drug (FW = 336.87 g/mol, but 907.88 g/mol, also known as Pentostam<sup>®</sup> and 2,4:2',4'-*O*-(oxydistibylidene)bis[D-gluconic acid] *Sb*,*Sb*'-dioxide trisodium salt nonahydrate, irreversibly inhibits protein-tyrosine phosphatase. When formulated as the water-soluble trisodium *Sb*(III) monogluconate salt, it is known as Triostam<sup>™</sup>. Pentavalent antimonials have been used to treat leishmaniasis for well over a half-century. While *Sb*(V) is thought to be a prodrug that is converted to the toxic *Sb*(III), direct involvement by pentavalent antimony has not been excluded. **Target(s):** DNA topoisomerase I (1,2); protein-tyrosine phosphatase (3); and trypanothione reductase (4). **1.** Chakraborty & Majumder (1988) *Biochem. Biophys. Res. Commun.* **152**, 605. **2.** Walker & Saravia (2004) *J. Parasitol.* **90**, 1155. **3.** Pathak & Yi (2001) *J. Immunol.* **167**, 3391. **4.** Cunningham & Fairlamb (1995) *Eur. J. Biochem.* **230**, 460.

### Stichodactyla Toxin

This naturally occurring 35-residue peptide (FW = 4054.84 g/mol; CAS 172450-46-3; *Sequence:* RSCIDTIPKSRCTAFQCKHSMKYRLSFCRKTCTGTC, with disulfide linkages indicated above), also known as ShK peptide, from the Caribbean Sea anemone, *Stichodactyla heliantus*, is among the most potent blockers of Kv1.3 voltage-gated potassium ion channel, IC<sub>50</sub>  $\approx$  10 pM (1). Its therapeutic application in autoimmune diseases is compromised by its lack of selectivity against other channels, particularly Kv1.1 channels, IC<sub>50</sub>  $\approx$  10 pM. Several analogues with altered selectivity (*e.g.*, ShK-Dap22, ShK-F6CA, and ShK-192), have been developed by using non-natural amino acids and/or adducts. Another analogue, ShK-186,

contains a phosphorylated Tyr residue. **See also Dalazitide 1.** Pennington, Mahnir, Krafte, *et al.* (1996) *Biochemistry* **35**, 16407. **2.** Tudor, Pallaghy, Pennington & Norton (1996) *Nature Struct. Biol.* **3**, 317.

**Stigmast-5-ene-3 $\beta$ -ol**, similar in action to *Stigmast-5-ene-3 $\beta$ ,26-diol*

#### Stigmasterol

This phytosterol (FW = 412.70 g/mol; CAS 83-48-7; M.P. = 170°C; very low water solubility), also known as stigmasta-5,22-dien-3 $\beta$ -ol, found in calabar beans, soybeans, carrots, and almond hulls, inhibits cholesterol absorption (1); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (2); sterol acyltransferase, *or* cholesterol acyltransferase (3); and sterol  $\Delta^24$ -reductase (4). **1.** Vahouny, Connor, Subramaniam, Lin & Gallo (1983) *Amer. J. Clin. Nutr.* **37**, 805. **2.** Hirano, Homma & Oka (1994) *Planta Med.* **60**, 30. **3.** Billheimer (1985) *Meth. Enzymol.* **111**, 286. **4.** Fernandez, Suarez, Ferruelo, Gomez-Coronado & Lasuncion (2002) *Biochem. J.* **366**, 109.

#### Stigmatellin A

This antibiotic (FW = 514.66 g/mol; CAS 91682-96-1; decomposes below pH 5) from *Stigmatella aurantiaca* inhibits microbial electron transport at the *bc*<sub>1</sub> complex by binding to the heme *b*<sub>L</sub> domain of cytochrome *b* as well as to the iron-sulfur protein. In plants, stigmatellin inhibits electron transport by binding to the quinol oxidation (*Q<sub>o</sub>*) site of the cytochrome *bc*<sub>1</sub> complex in mitochondria and the cytochrome *b<sub>6</sub>f* complex of thylakoid membranes. (**See also Myxothiazol**) **Target(s):** inositol-trisphosphate 3-kinase (1); nitrate reductase A (2); plastoquinol:plastocyanin reductase, *or* cytochrome *b<sub>6</sub>f* complex (3,4); and ubiquinol:cytochrome *c* reductase, *or* complex III (5-10). **1.** Mayr, Windhorst & Hillemeier (2005) *J. #### *cis*- and *trans*-Stilbene Oxide

This oxidized stilbene (FW = 196.25 g/mol; M.P. = 38-40°C (*cis*-isomer); M.P. = 65-67°C (*trans*-isomer), also known as *trans*-1,2-diphenyloxirane, inhibits cholesterol-5,6-oxide hydrolase, by *trans* isomer (1); microsomal epoxide hydrolase, by *cis* isomer (2); soluble epoxide hydrolase, also alternative substrate (3,4). **1.** Levin, Michaud, Thomas & Jerina (1983) *Arch. Biochem. Biophys.* **220**, 485. **2.** Oesch (1974) *Biochem. J.* **139**, 77. **3.** Morrisseau, Archelas, Guittou, *et al.* (1999) *Eur. J. Biochem.* **263**, 386. **4.** Blée & Schubert (1992) *Biochem. J.* **282**, 711.

#### Stilbestrol

This notorious endocrine-disrupting chemical (FW = 212.25 g/mol; CAS 13425-53-1), also known as stilboestrol, 4,4'-dihydroxystilbene, and 4,4'-[(1*E*)-1,2-ethenediyl]bisphenol, is a nonsteroidal estrogenic agent that was once used as a growth promoter in farm animals, but is now banned in most nations. **Note:** The term stilbestrol has also been used as a synonym for diethylstilbestrol. **See Diethylstilbestrol Target(s):** glucose-6-phosphate dehydrogenase (1,2); 3 $\alpha$ / $\beta$ -hydroxysteroid dehydrogenase (3,4); and steroid 11 $\beta$ -monooxygenase (5). **1.** McKerns & Kaleita (1960) *Biochem. Biophys. Res. Commun.* **2**, 344. **2.** Criss & McKerns (1969) *Biochim. Biophys. Acta* **184**, 486. **3.** Nakajin, Ishii & Shinoda (1994) *Biol. Pharm. Acta* **1203**, 215.

**Stilboestrol**, **See Stilbestrol; Diethylstilbestrol**

#### STO 609

This 1,8-naphthylene benzimidazole-3-carboxylic acid (FW = 315.01 g/mol), also known as 7-oxo-7*H*-benzimidazo[2,1-*a*]benz[*de*]isoquinoline-3-carboxylic acid, inhibits Ca<sup>2+</sup>/calmodulin-dependent protein kinase kinase (1,2). STO-609 inhibits the activities of recombinant CaM-KK $\alpha$  and CaM-KK $\beta$  isoforms, with *K<sub>i</sub>* values of 0.25 and 0.05  $\mu$ M, respectively, and also inhibits their autophosphorylation activities. Comparison of the inhibitory potency of the compound against various protein kinases revealed that STO-609 is highly selective for CaM-KK without any significant effect on the downstream CaM kinases (CaM-KI and -IV), and the IC<sub>50</sub> against CaM-KII is ~0.03  $\mu$ M. STO-609 inhibits constitutively active CaM-KK $\alpha$  (glutathione S-transferase (GST)-CaM-KK-(84-434)) as well as the wild-type enzyme. Kinetic analysis indicates STO-609 is a competitive inhibitor

of ATP. In transfected HeLa cells, it suppresses the  $\text{Ca}^{2+}$ -induced activation of CaM-KIV in a dose-dependent manner. In agreement with this observation, the inhibitor significantly reduces the endogenous activity of CaM-KK in SH-SY5Y neuroblastoma cells at a concentration of 1  $\mu\text{g}/\text{ml}$  (~80% inhibitory rate). Such results indicate that STO-609 is a selective and cell-permeable inhibitor of CaM-KK and that it may be a useful tool for evaluating the physiological significance of the CaM-KK-mediated pathway *in vivo* as well as *in vitro* (1). The distinct sensitivity of CaM-KK isoforms to STO-609 arises from a single Val/Leu substitution in the ATP-binding pocket, as confirmed by the generation of a STO-609-resistant CaM-KK mutant that might be useful for validating the pharmacological effects and specificity of STO-609 *in vivo* (2). 1. Tokumitsu, Inuzuka, Ishikawa, *et al.* (2002) *J. Biol. Chem.* **277**, 15813. 2. Ishikawa, Tokumitsu, Inuzuka, *et al.* (2003) *FEBS Lett.* **550**, 57.

### Streptavidin

This tetrameric biotin-binding protein ( $M_r = 18,834$ ; CAS 9013-20-1;  $pI = 5.5$ ) from *Streptomyces avidinii* binds biotin ( $K_d = 40$  fM, at pH 7 and  $25^\circ\text{C}$ ) (1-4). Streptavidin is frequently used in biotin-binding immunosorbent assays, protein blotting, radioimmuno-assays, and as a DNA probe, when the macromolecule of interest has been biotinylated **See also Avidin** **Target(s)**: glycoprotein 6- $\alpha$ -L-fucosyltransferase (4); 3-methylcrotonoyl-CoA carboxylase (5); and urease, ATP-hydrolyzing (1). 1. Chaiet & Wolf (1964) *Arch. Biochem. Biophys.* **106**, 1. 2. Green (1990) *Meth. Enzymol.* **184**, 51. 3. Bayer, Ben-Hur & Wilchek (1990) *Meth. Enzymol.* **184**, 80. 4. Shao, Sokolik & Wold (1994) *Carbohydr. Res.* **251**, 163. 5. Baldet, Alban, Axiotis & Douce (1992) *Plant Physiol.* **99**, 450.

### Streptidine

This component of the antibiotic streptomycin ( $\text{FW}_{\text{free-base}} = 262.27$  g/mol; CAS 85-17-6), also known as 1,3-diguanido-2,4,5,6-cyclohexanetetrol, inhibits diamine oxidase (EC 1.4.3.6), the first enzymatic reaction in putrescine degradation. 1. Cubria, Ordonez, Alvarez-Bujidos, Negro & Ortiz (1991) *Comp. Biochem. Physiol. B* **100**, 543.

### Streptococcal $\text{NAD}^+$ -Glycohydrolase Inhibitor

This thermostable 161-residue protein ( $\text{MW} = 18.8$  kDa), also known as IFS, competitively inhibits streptococcal  $\text{NAD}^+$  glycohydrolase, or  $\text{NADase}$  (1). *Streptococcus pyogenes*  $\text{NAD}^+$ -glycohydrolase (SPN) is itself a toxic enzyme, introduced into *Streptococcus*-infected host cells by the cytolysin-mediated translocation pathway. *S. pyogenes* protects itself from SPN self-toxicity by means of  $\text{NAD}^+$ -glycohydrolase inhibitor, the small inhibitory protein localized in the bacterial cytoplasmic compartment. IFS combines with one-to-one stoichiometry relative to SPN, thereby inhibiting SPN's otherwise toxic  $\text{NAD}^+$ -glycohydrolase activity. IFS is the first molecularly characterized endogenous inhibitor of a bacterial  $\beta$ - $\text{NAD}^+$ -consuming toxin, the protective mechanism underlying SPN-mediated streptococcal pathogenesis (2). 1. Kimoto, Fujii, Hirano, Yokota & Taketo (2006) *J. Biol. Chem.* **281**, 9181. 2. Meehl, Pinkner, Anderson, Hutgren & Caparon (2005) *PLoS* **1**, E35.

### Streptolydigin

This antibiotic ( $\text{FW} = 600.71$  g/mol; CAS 7229-50-7), also known as portamycin, from *Streptomyces lydicus* inhibits bacterial RNA polymerase without affecting the fidelity of transcription. The product of the polymerase reaction does not dissociate from the inhibitor-bound translocated ternary complex. **Target(s)**: DNA-directed RNA polymerase (1-9); DNA nucleotidyltransferase, or terminal deoxyribonucleotidyltransferase (10); and oxidative phosphorylation (11). 1. Chamberlin (1974) *The Enzymes*, 3rd ed., **10**, 333. 2. Jin & Zhou (1996) *Meth. Enzymol.* **273**, 300. 3. von der Helm & Krakow (1972) *Nature New Biol.* **235**, 82. 4. Res. Commun.* **72**, 1343. 11. Reusser (1969) *J. Bacteriol.* **100**, 1335.

### Streptomyces Subtilisin Inhibitor

This serine proteinase inhibitor ( $\text{MW}_{\text{calculated}} = 11,483$  g; Abbreviation: SSI) is a homodimeric protein, with each subunit consisting of 113 residues and two disulfide bridges. many protein protease inhibitors are susceptible to hydrolysis inflicted by the protease. Ganz *et al.* (1) engineered SSI to resist proteolysis by adding an interchain -S-S- bond and removing a subtilisin cleavage site at Leu-63. When combined with changes optimizing subtilisin affinity SSI affinity, the resulting inhibitor provided complete protease stability for at least 5 months at  $31^\circ\text{C}$  in a subtilisin-containing liquid laundry detergent, while allowing full recovery of subtilisin activity upon dilution in the was cycle of North American washing machine. **Target(s)**: *Aspergillus* serine proteinase (2); aqualysin I (3,4); mycolysin (5); oryzin (6); streptogrisin A (7,8); streptogrisin B (8,9); and subtilisin (10-13). 1. Ganz, Bauer, Sun, *et al.* (2004) *Prot. Eng. Des. Select.* **17**, 333. 2. Markaryan, Beall & Kolattukudy (1996) *Biochem. Biophys. Res. Commun.* **220**, 372. 3. ### Streptomycin

This aminoglycoside antibiotic ( $\text{FW}_{\text{free-base}} = 581.58$  g/mol; CAS 57-92-1) inhibits protein biosynthesis, binding to the 16S ribosomal RNA of the 30S ribosomal subunit, and inhibits initiation and causes misreading. This antibiotic is composed of three components: streptidine (*i.e.*, 1,3-diguanido-2,4,5,6-cyclohexanetetrol), streptose (5-deoxy-3-C-formyl-L-lyxose), and *N*-methyl-L-glucosamine, with the last two components linked glycosidically are occasionally referred to as streptobiosamine. Streptomycin was the first antibiotic identified by Waksman (Nobel

Laureate, 1952) in the soil bacterium *Streptomyces griseus*, but has been isolated from other *Streptomyces* species. *S. biliniensis*, *S. olivaceus*, *S. mashuensis*, *S. galbus*, *S. rameus*, and *S. glovisporus streptomycine*. Streptomycin first associates with the cell surface of the microorganism and diffuses through the outer membrane into the periplasmic space. It then enters the cytosol using the electron-transport system in an energy-dependent process. **Antibiotic Resistance:** Once inside the microorganism, streptomycin binds to the 30S ribosomal subunit (specifically nucleotides 911-915 of the 530 loop within 16S ribosomal RNA of *Escherichia coli*). An abnormal initiation complex is subsequently formed, fixing the ribosomal complex at the start codon of the mRNA. Streptomycin resistance arises from alteration of the 530 loop of the 16S ribosomal RNA, one of the most highly conserved part of the aminoacyl-tRNA binding site (A-site), and is manifested by greatly attenuated affinity for streptomycin. **Chemical Properties:** Streptomycin is usually supplied as the salt (e.g., the trihydrochloride, pantothenate, or sesquisulfate). These salts are hygroscopic and deliquesce when exposed to air. As expected, these formulations are very soluble in water (for example, more than 20 mg of the trihydrochloride or sesquisulfate can dissolve in 1 mL of water at 28°C). **Target(s):** alcohol dehydrogenase, yeast (1); D-amino acid oxidase (2); aspartyltransferase (3); CDP-glycerol glycerophospho-transferase (4); diamine oxidase (5,6); 2,5-diaminovalerate aminotransferase, weakly inhibited (7); group I ribozymes (8,9); peptidyl-tRNA hydrolase, or aminoacyl-tRNA hydrolase (10); phosphatidylinositol-specific phospholipase C (11,12); phospholipase D (13); protein biosynthesis (10,14-17); ribonuclease (18); and urate oxidase (19). 1. ### Streptonigrin

This antibiotic and antineoplastic agent (FW<sub>free-acid</sub> = 508.48 g/mol; CAS 3930-19-6; dark brown solid; M.P. = 262-263°C; slightly soluble in water) from *Streptomyces flocculus* requires iron activation for its antibiotic action. In the presence of certain metal ions, streptonigrin causes DNA cleavage and chromosome damage via the production of free radicals. Streptonigrin also induces apoptosis in the presence of NF-κB. **Target(s):** avian myeloblastosis virus reverse transcriptase (1,2); DNA topoisomerase II (3); phosphoenolpyruvate carboxykinase (4); and RNA-directed DNA polymerase (1,2,5). 1. Hafuri, Takemori, Oogose, *et al.* (1988) *J. Antibiot.* **41**, 1471. 2. Okada, Inouye & Nakamura (1987) *J. Antibiot.* **40**, 230. 3. Antibiot.* **40**, 702.

### Streptothricin

These antibiotics from *Actinomyces lavendulae* (FW = 502.526 g/mol; CAS 11076-96-3), which differ with respect to the number (i.e., one to seven) of β-lysyl residues, were originally thought to be a single substance, when isolated by Nobel Laureate Selman Waksman. For streptothricin B, *n* = 5, and for streptothricin F, *n* = 1. *Note:* The sugar component is a derivative of D-gulosamine. **Target(s):** EF-G-dependent translocation, inhibited by streptothricin F (1); and EF-Tu-dependent binding of aminoacyl-tRNA to the ribosome, inhibited by streptothricin F (1); and phosphatidylinositol phospholipase C, inhibited by streptothricin B (2). 1. Haupt, Jonak, Rychlik & Thrum (1980) *J. Antibiot.* **33**, 636. 2. Hill, Bonjouklian, Powis, *et al.* (1994) *Anticancer Drug Des.* **9**, 353.

### Streptovaricins

These ansamycin-type macrolide antibiotics (CASs = 1404-74-6 for general class; for Streptovaricin C: FW = 769.84 g/mol; CAS 23344-17-4) from *Streptomyces spectabilis* inhibit RNA and protein synthesis in microorganisms, particularly in Gram-positive bacteria and also inhibits *in vitro* RNA synthesis catalyzed by DNA-dependent RNA polymerase. Unlike other RNA polymerase-directed antibiotics, the streptovaricins target the polymerase and not its DNA template. This antibiotic group includes: Streptovaricin A (FW = 770.81 g/mol): R = COOCH<sub>3</sub>, R' = OCOCH<sub>3</sub>, W = OH, X = Ac, Y = OH, Z = OH; Streptovaricin B (FW = 754.81 g/mol): R = COOCH<sub>3</sub>, R' = OCOCH<sub>3</sub>, W = OH, X = Ac, Y = OH, Z = H; Streptovaricin C (the antibiotic component; (FW = 729.78 g/mol): R = COOCH<sub>3</sub>, R' = OCOCH<sub>3</sub>, W = OH, X = H, Y = OH, Z = H; Streptovaricin D (FW = 713.78 g/mol): R = COOCH<sub>3</sub>, R' = OCOCH<sub>3</sub>, W = H, X = H, Y = OH, Z = H; Streptovaricin E (FW = 628.77 g/mol): R = COOCH<sub>3</sub>, R' = OCOCH<sub>3</sub>, W = OH, X = H, Y = O, Z = H; Streptovaricin G (FW = 7766.77 g/mol): R = COOCH<sub>3</sub>, R' = OCOCH<sub>3</sub>, W = OH, X = H, Y = OH, Z = OH; Streptovaricin J (FW = 755.82 g/mol): R = COOCH<sub>3</sub>, R' = OCOCH<sub>3</sub>, W = OH, X = H, Y = OAc, Z = H; and Streptovaricin K (FW = 773.67 g/mol): (R = COOCH<sub>3</sub>, R' = OCOCH<sub>3</sub>, W = OH, X = H, Y = OAc, Z = OH). **Target(s):** DNA-directed RNA polymerase (1-8); and RNA-directed DNA polymerase, RNA tumor viruses (2,9,10). 1. Chamberlin (1974) *The Enzymes*, 3rd ed. (Boyer, ed.), 10, 333. 2. Ooka, Tanaka, Ishikawa & Kato (1999) *Biol. Pharm. Bull.* **22**, 107. 3. Logan, Zhang, Davis & Ackerman (1989) *DNA* **8**, 595. 4. ### Streptoviridins

These nucleoside-containing antibiotics (Streptovirudin A<sub>1</sub> (shown above); FW<sub>Streptovirudin-A1</sub> = 788.89 g/mol; CAS 51330-28-0), consisting of at least ten metabolites from *Streptomyces griseoflavus*, are structurally related to tunicamycin. There are two distinct subcategories of streptoviridins: series 1 contain a dihydrouracil moiety (Streptovirudin A<sub>1</sub>, B<sub>1</sub>, C<sub>1</sub>, and D<sub>1</sub>) whereas series 2 contains a uracil (Streptovirudins A<sub>2</sub>, B<sub>2</sub>, C<sub>2</sub>, and D<sub>2</sub>). *Note*: Streptovirudin C<sub>2</sub> is identical to tunicamycin A. All are relatively stable antibiotics that are slightly soluble in water and have an inhibitory effect on Gram-positive microorganisms, mycobacteria, and a number of viruses. **Target(s)**: protein glycosylation (1-4); and UDP-*N*-acetylglucosamine: dolichyl-phosphate *N*-acetylglucosamine phosphotransferase (1,2,4) 1. Elbein (1983) *Meth. Enzymol.* **98**, 135. 2. Elbein (1987) *Meth. Enzymol.* **138**, 661. 3. Elbein (1984) *CRC Crit. Rev. Biochem.* **16**, 21. 4. Keenan, Hamill, Occolowitz & Elbein (1981) *Biochemistry* **20**, 2968.

### Streptozotocin

This nitrosourea-containing antibiotic (FW = 265.22 g/mol; CAS 18883-66-4; abbreviated STZ), also known as streptozocin and 2-deoxy-2-[[[(methylnitrosoamino)carbonyl]amino]-D-glucopyranose], is also an antineoplastic agent and a diabetes-causing agent originally isolated from *Streptomyces achromogenes*. Its action in inducing experimental diabetes in laboratory animals has been attributed to its selective uptake by the GLUT2 transporter, the main glucose transporter of pancreatic  $\beta$ -cells. Although the inactivation of superoxide dismutase should be toxic, the exact lethal action of streptozotocin on  $\beta$ -cells has not been unambiguously established. STZ is also a nonspecific DNA-alkylating agent *in vitro* and is an FDA-approved treatment for metastatic islet cell cancer. **Induction of Experimental Diabetes**: Males of various mouse strains are differentially susceptible to STZ-induced diabetes. The following multiple low-dose STZ protocol induces diabetes in susceptible males. Mice receive daily IP injections (50 mg STZ/kg body weight) for five consecutive days, with age-matched controls receiving only buffer injections. Because mice metabolize STZ for at least 24 hours post-injection, experimental and control mice are housed separately in disposable cages, using appropriate absorbent bedding and supplying food and water *ad libitum*. At post-injection day-10, pancreatic islet cells are totally absent or severely depleted. Mice are weighed and their blood glucose levels determined. They are deemed to be diabetic, if their non-fasted blood glucose levels exceed 300-400 mg/dL. **Target(s)**: *N*-acetyl- $\beta$ -D-glucosaminidase, *O*-GlcNAc-selective (1);  $\beta$ -glucosidase (2); stearoyl-CoA desaturase (3); and superoxide dismutase (4). 1. ### Strobilurin A

This antifungal antibiotic (FW = 258.32 g/mol; CAS 65105-52-4), commonly known as mucidin and systematically as (*E,Z,E*)-2-(methoxymethylene)-3-methyl-6-phenyl-3,5-hexadienoic acid methyl ester, from wood-rotting mushrooms (*e.g.*, *Strobilurus tenacellus*) inhibits mitochondrial respiration at the cytochrome *bc*1 step. It has a low solubility in water and is soluble in many organic solvents. The molar extinction coefficients at 230, 237, and 294 nm in ethanol are 16900, 15330, and 21850 M<sup>-1</sup>cm<sup>-1</sup>, respectively. Strobilurin A is the parent compound of a large class of naturally occurring and synthetic compounds frequently used as agricultural antifungal agents. **Target(s)**: chitin synthase (1); and ubiquinol:cytochrome *c* reductase, *or* complex III (2-4). 1. Pfefferle, Anke, Bross & Steglich (1990) *Agric. Biol. Chem.* **54**, 1381. 2. Von Jagow & Link (1986) *Meth. Enzymol.* **126**, 253. 3. Wood & Hollomon (2003) *Pest Manag. Sci.* **59**, 499. 4. Von Jagow, Gribble & Trumpower (1986) *Biochemistry* **25**, 775.

### Strobilurin B

This antifungal antibiotic (FW = 321.78 g/mol) inhibits mitochondrial respiration at the cytochrome *bc*1 step. **Target(s)**: chitin synthase (1); and ubiquinol:cytochrome *c* reductase (2). 1. Pfefferle, Anke, Bross & Steglich (1990) *Agric. Biol. Chem.* **54**, 1381. 2. Von Jagow & Link (1986) *Meth. Enzymol.* **126**, 253.

**Stromelysin I Inhibitor**, *See specific inhibitor; e.g., N<sup>6</sup>-Acetyl-L-arginyl-L-cysteinylglycyl-L-valyl-L-prolyl-L-aspartate a-Amide*

### Strontium (II) (or Sr<sup>2+</sup>) Ion

This divalent cation from the Group II alkaline earth element acts either directly as an inhibitory metal ion and/or Sr<sup>2+</sup>-ligand/metabolite complex. Strontium commonly occurs in nature and is the 15<sup>th</sup> most abundant element (~360 parts per million) in the Earth's crust. Strontium(II) acts as an alternative metal ion cofactor for many (*but not all*) calcium ion-dependent biological processes. For example, Sr<sup>2+</sup> is reported to have similar kinetics with respect to the sarcoplasmic reticulum calcium ATPase (1) and can induce Ca<sup>2+</sup> release via cyclic ADP-ribose (2). **Target(s)**: *N*-acetylneuraminidase (3); adenylate cyclase (3); alkaline phosphatase (57,58); 4-aminobutyrate aminotransferase (67);  $\alpha$ -amylase (51-53); arylalkyl-phosphatase, *or* paraoxonase (61); arylesterase (62); asparagine synthetase (4); calcidiol 1-monooxygenase (5); calpain-1, *or*  $\mu$ -calpain (16); chitinase (47); creatine kinase (7,8); dextranase (48); dextranucrase (69); dipeptidyl-peptidase IV (9); diphosphate:serine phosphotransferase, weakly inhibited (64); DNA-directed DNA polymerase (10); enolase (11,12); exo- $\alpha$ -sialidase, *or* neuraminidase, *or* sialidase (45); glucan 1,4- $\alpha$ -glucosidase, *or* glucoamylase (49,50); glucan 1,4- $\alpha$ -maltohexaosidase (13,14);  $\beta$ -glucosidase (43,44); glucose-6-phosphate isomerase (15); glycine *C*-acetyltransferase (70); GTP cyclohydrolase I (16); H<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (17); isocitrate lyase (18,19); 3-

ketovalidoxylamine C-N-lyase (20);  $\alpha$ -mannosidase (42); methylaspartate ammonia-lyase, or  $\beta$ -methylaspartase (21,22); micrococcal nuclease (23); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (24);  $\alpha$ -neogaro-oligosaccharide hydrolase (25); nicotinate-nucleotide diphosphorylase, carboxylating (68); oryzin (26); oxidative phosphorylation (27); pantothenate synthetase, or pantoate: $\beta$ -alanine ligase, slightly inhibited (28); pectate lyase, weakly inhibited (29); phosphatidylinositol diacylglycerol-lyase (30); phospholipase A<sub>2</sub> (31-33,59,60); phospholipase C (34,35); phospholipase D (54); 3- or 4-phytase (55); polygalacturonidase, or pectinase (46); pullulanase (36); pyruvate decarboxylase, slightly inhibited (37); pyruvate kinase (65); riboflavin kinase (66); ribonuclease, plant (38); RNA ligase ribozyme (39); thioglucosidase, or myrosinase (40); thymidine kinase (41); trehalose-phosphatase (56); and trehalose-phosphate synthase (56). 1. ### Strophanthidin

This toxic sterol (FW = 404.50 g/mol; CAS 66-28-4), also known as (3 $\beta$ ,5 $\beta$ )-3,5,14-trihydroxy-19-oxocard-20(22)-enolide, is the aglycon on *k*-strophanthin (Note:  $\gamma$ -Strophanthin is ouabain), from *Strophanthus kombe* inhibits Ca<sup>2+</sup>-transporting ATPase (1), H<sup>+</sup>/K<sup>+</sup>-transporting ATPase (1), H<sup>-</sup>-transporting ATPase (1), and Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (2-4). 1. Xu (1992) *Biochim. Biophys. Acta* **1159**, 109. 2. Ruoho & Kyte (1977) *Meth. Enzymol.* **46**, 523. 3. Glynn (1964) *Pharmacol. Rev.* **16**, 381. 4. Hokin & Yoda (1964) *Proc. Natl. Acad. Sci. U.S.A.* **52**, 454.

### Strophanthidin-3-bromoacetate

This steryl haloacetate (FW = 525.44 g/mol) is an irreversible inhibitor of Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase, binding at the same site where cardiotonic steroids bind. 1. Hokin, Mokotoff & Kupchan (1966) *Proc. Natl. Acad. Sci. U.S.A.* **55**, 797.

### Strychnine

This toxic, bitter-tasting alkaloid and seizurogenic agent (FW<sub>free-base</sub> = 334.42 g/mol; CAS 57-24-9) from the seeds of *Strychnos nux-vomica* (the dog button plant) and *Strychnos ignatii* (Saint Ignatius bean) exhibits convulsion-inducing properties. Rather than directly affecting excitatory neurotransmission, strychnine (2 mg/kg in mice) blocks the inhibitory regulation of neurotransmission by antagonism of inhibitory glycine synapses (primarily) and GABA synapses (secondarily). Strychnine-sensitive glycine receptors are primarily localized in the brainstem and spinal cord where they are the major mediators of postsynaptic inhibition (1). Such receptors are ligand-gated ion channels arranged as five 4-helix subunits surrounding a central pore. LD<sub>50</sub> values are 0.16 mg/kg in rats and 1–2 mg/kg in humans (orally). In most cases of lethal strychnine poisoning, the patient dies before ever reaching the hospital. Little or no activity against seizures is produced by other chemical convulsants (bicuculline;

quinolinic acid; mercaptopropionic acid); by electrical stimuli (maximal electroshock); or by sensory stimuli (audiogenic seizure susceptible mice) (1). The glycine receptor agonist MDL 27,531 (or 4-methyl-3-methylsulphonyl-5-phenyl-4H-1,2,4-triazole), however, successfully blocks strychnine-induced tonic extensor seizures in mice following either intraperitoneal ( $ED_{50} = 12.8$  mg/kg; 30 min) or oral ( $ED_{50} = 7.3$  mg/kg; 30 min) administration (1). **Target(s):** cholinesterase, or acetylcholinesterase (2,3); esterase, nonspecific (3); glycine receptor (4-8); and lactate dehydrogenase (9). 1. Kehne, Kane, Miller, *et al.* (1992) *Brit. J. Pharmacol.* **106**, 910. 2. Augustinsson (1950) *The Enzymes*, 1st ed. (Sumner & Myrbäck, eds.), **1** (part 1), 443. 3. ### Styrene

This hazardous and versatile organochemical starting reagent (FW = 104.15 g/mol; CAS 100-42-5; slightly soluble in water, but soluble in most methanol, diethyl ether, ethanol, and acetone) for organic chemical synthesis is a colorless liquid (M.P. =  $-30.6^{\circ}\text{C}$ ; B.P. =  $145-146^{\circ}\text{C}$ ). On exposure to light, styrene slowly undergoes free radical-mediated polymerization, and many commercial sources of styrene contain the styrene polymerization inhibitor 4-(*t*-butyl)catechol as an additive. **Target(s):** acetylcholinesterase (1); ATPase (2,3);  $\delta$ -aminolevulinic acid dehydratase, or porphobilinogen synthase, observed inhibition may occur by contaminating styrene oxide (4,5); dopamine transport (6); monoamine oxidase A (7); and  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (8). 1. Korpela & Tahti (1986) *Arch. Toxicol. Suppl.* **9**, 320. 2. Vaalavirta & Tahti (1995) *Clin. Exp. Pharmacol. Physiol.* **22**, 293. 3. Vaalavirta & Tahti (1995) *Life Sci.* **57**, 2223. 4. ### Styrene Oxide

This oxidized styrene metabolite FW = 120.15 g/mol; CAS 96-09-3, also known as oxidostyrene, phenyloxirane, and styrene 7,8-oxide, inhibits a variety of enzymes, including alcohol dehydrogenase (1). Styrene oxide also stimulates formation of alkali-sensitive, DNA single-strand breaks and is a cancer-suspect agent. **Target(s):**  $\delta$ -aminolevulinic acid dehydratase, or porphobilinogen synthase (2,3); dopamine transport (4); glutathione *S*-transferase (5); mandelate racemase (6); microsomal epoxide hydrolase, also as a substrate (7);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (8); soluble epoxide hydrolase, weak alternative substrate (9-14). 1. Klinman, Welsh & Hogue-Angeletti (1977) *Biochemistry* **16**, 5521. 2. Mori, Fujishiro & Inoue (1988) *J. UOEH* **10**, 269. 3. Fujita, Koizumi, Hayashi & Ikeda (1986) *Biochim. Biophys. **SU 101, See Leflunomide**

### SU 1498

This acrylonitrile (FW = 390.53 g/mol), also known as (*E*)-3-(3,5-diisopropyl-4-hydroxyphenyl)-2-[(3-phenyl-*n*-propyl)aminocarbonyl]acrylonitrile, SU1498, and SU-1498, is a potent and selective inhibitor of Flk-1 kinase,  $IC_{50} = 0.7$   $\mu\text{M}$  (1-3), a vascular endothelial-growth-factor-receptor (VEGFR) protein-tyrosine kinase. SU 1498 also reduces the expression of *ets-1*, a transcription factor stimulated by the vascular endothelial growth factor receptor (1). It has a weak inhibitory effect on PDGF-receptor ( $IC_{50} > 50$  nM), EGF-receptor ( $IC_{50} > 100$  nM), and HER2 ( $IC_{50} > 100$  nM) kinases. It has also been shown to act as an angiogenesis inhibitor. 1. Arbiser, Larsson, Claesson-Welsh, *et al.* (2000) *Amer. J. Pathol.* **156**, 1469. 2. Strawn, McMahon, App, *et al.* (1996) *Cancer Res.* **56**, 3540. 3. Jin, Zhu, Sun, *et al.* (2002) *Proc. Natl. Acad. Sci. U.S.A.* **99**, 11946.

### SU 4312

This substituted indolinone (FW = 264.33 g/mol), also named SU4312 and SU-4312, inhibits EGF receptor protein-tyrosine kinase. Note that commercial sources often supply a mixture of the *E* and *Z* isomers. **Target(s):** endothelial growth factor receptor protein-tyrosine kinase (1); platelet derived growth factor receptor protein-tyrosine kinase (1); protein-tyrosine kinase (1). 1. Kendall, Rutledge, Mao, *et al.* (1999) *J. Biol. Chem.* **274**, 6453.

**SU 5271, See 4-[(3-Bromophenyl)amino]-6,7-dimethoxy-quinazoline**

### SU 5402

This potent multi-target receptor tyrosine kinase inhibitor (FW = 296.32 g/mol; CAS 215543-92-3; Solubility: 59 mg/mL DMSO; <1 mg/mL  $\text{H}_2\text{O}$ ), also named 3-(4-methyl-2-((2-oxoindolin-3-ylidene)methyl)-1H-pyrrol-3-yl)propanoic acid, SU5402 and SU-5402, acts on VEGFR2 ( $IC_{50} = 20$  nM), FGFR1 ( $IC_{50} = 30$  nM), and PDGF-R $\beta$  ( $IC_{50} = 510$  nM) (1). SU5416 inhibits vascular endothelial growth factor-dependent mitogenesis in human endothelial cells without inhibiting the growth of a variety of tumor cells *in vitro* (2). Systemic administration of SU5416 at nontoxic doses in mice results in inhibition of subcutaneous tumor growth of cells derived from various tissue origins (2). The antitumor effect of SU5416 was accompanied by the appearance of pale white tumors that were resected from drug-treated animals, supporting the antiangiogenic property of this agent (2). 1. Sun,

Tran, Liang, *et al.* (1999) *J. Med. Chem.* **42**, 5120. 2. Fong, Shawver, Sun, *et al.* (1999) *Cancer Res.* **59**, 99.

**SU5416**, See *Semaxinib*

#### SU 5614

This indolinone (FW = 272.73 g/mol), also known as 5-chloro-3-[(3,5-dimethylpyrrol-2-yl)methylene]-2-indolinone, SU5614, and SU-5614, is a selective inhibitor of vascular-endothelial-growth-factor receptor protein-tyrosine kinase Flk-1,  $IC_{50}$  = 1.2  $\mu$ M (1,2) and PDGF receptor protein-tyrosine kinase,  $IC_{50}$  = 2.9  $\mu$ M (1). SU 5614 is without effect on the EGF and IGF receptor protein tyrosine kinases. SU 5614 also inhibits the VEGF-driven mitogenesis of human umbilical vein endothelial cells,  $IC_{50}$   $\approx$  0.7  $\mu$ M). 1. Sun, Tran, Tang, *et al.* (1998) *J. Med. Chem.* **41**, 2588. 2. Yee, O'Farrell, Smolich, *et al.* (2002) *Blood* **100**, 2941. 3. Spiekermann, Dirschinger, Schwab, *et al.* (2003) *Blood* **101**, 1494.

#### SU 6656

This photosensitive sulfonamide (FW = 371.46 g/mol), also known as 2-oxo-3-(4,5,6,7-tetrahydro-1H-indol-2-ylmethylene)-2,3-dihydro-1H-indole-5-sulfonic acid dimethylamide, is a selective src family kinase inhibitor used to probe growth factor signaling. **Target(s):** AMP-activated protein kinase (1); dual-specificity, tyrosine phosphorylated and regulated kinase 1A (1); Fyn protein-tyrosine kinase,  $IC_{50}$  = 0.17  $\mu$ M (2); lymphocyte protein kinase,  $IC_{50}$  = 0.04  $\mu$ M (1,3); phosphorylase kinase (1); platelet-derived growth factor receptor protein-tyrosine kinase, weakly inhibited,  $IC_{50}$  > 10  $\mu$ M (3); protein-tyrosine kinase (1-6); ribosomal S6 kinase 1 (1); src protein-tyrosine kinase,  $IC_{50}$  = 0.28  $\mu$ M (3-6); Yes protein tyrosine kinase,  $IC_{50}$  = 0.02  $\mu$ M (2,5). 1. Bain, McLauchlan, Elliott & Cohen (2003) *Biochem. J.* **371**, 199. 2. Sanguinetti, Cao & Mastick (2003) *Biochem. J.* **376**, 159. 3. Blake, Broome, Liu, *et al.* (2000) *Mol. Cell Biol.* **20**, 9018. 4. Okutani, Lodyga, Han & Liu (2006) *Amer. J. Physiol. Lung Cell Mol. Physiol.* **291**, L129. 5. Meyn III, Schreiner, Dumitrescu, Nau & Smithgall (2005) *Mol. Pharmacol.* **68**, 1320. 6. Sirvent, Boureux, Simon, Leroy & Roche (2007) *Oncogene* **26**, 7313.

#### SU6668

This tyrosine kinase inhibitor, *or* TKI (FW = 323.14 g/mol; CAS 210644-62-5), also known as (Z)-3-[2,4-dimethyl-5-(2-oxo-1,2-dihydroindol-3-ylidenemethyl)-1H-pyrrol-3-yl]propionate, is an ATP-competitive inhibitor of Flk-1 transphosphorylation ( $K_i$  = 2.1  $\mu$ M), FGFR1 trans-phosphorylation ( $K_i$  = 1.2  $\mu$ M), and PDGFR autophosphorylation ( $K_i$  = 0.008  $\mu$ M). SU6668 has greatest potency against PDGFR autophosphorylation, but also strongly inhibits Flk-1 and FGFR1 trans-phosphorylation (1). In contrast, SU6668 does not inhibit EGFR kinase activity at concentrations up to 100  $\mu$ M. The biochemical  $IC_{50}$  values of SU6668 against EGFR, insulin-like

growth factor 1 receptor, Met, Src, Lck, Zap70, Abl, and cyclin-dependent kinase 2 are at least 10  $\mu$ M, indicating that it shows a high level of selectivity against other tyrosine and serine/threonine kinases (1). Although HUVECs stimulated by VEGF exhibit an increase in tyrosine phosphorylation of KDR, treatment with SU6668 inhibits this increase in a dose-dependent manner. SU6668 also inhibits PDGF-stimulated PDGFR $\beta$  tyrosine phosphorylation in NIH-3T3 cells overexpressing PDGFR $\beta$  at a minimum concentration of 0.03–0.1  $\mu$ M. SU6668 inhibits acidic FGF-induced phosphorylation of the FGFR1 substrate 2 (FRS-2) at concentrations of 10  $\mu$ M. However, SU6668 has no detectable effect on epidermal growth factor-stimulated EGFR tyrosine phosphorylation in NIH-3T3 cells overexpressing EGFR at concentrations of up to 100  $\mu$ M. These cellular data demonstrate that SU6668 inhibits Flk-1/KDR, PDGFR, and FGFR but has no activity against EGFR at the concentrations tested (1). As would be expected of an inhibitor of Flk-1, FGFR1, and PDGFR kinase activity, SU6668 demonstrated significant antitumor activity against a wide range of xenografts. SU6668 may influence tumor growth by multiple mechanisms including inhibition of endothelial cell proliferation and/or survival as well as tumor cell and stromal cell proliferation. 1. Laird, Vajkoczy, Shawver, *et al.* (2000) *Cancer Res.* **60**, 4152.

#### SU 9516

This substituted indoline (FW = 241.25 g/mol), also known as 3-[1-(3H-imidazol-4-yl)-meth-(Z)-ylidene]-5-methoxy-1,3-dihydroindol-2-one, SU9516, and SU-9516, inhibits cyclin-dependent kinase-2 (Cdc2),  $IC_{50}$  = 22 nM (1-3). SU 9516 also induces apoptosis and promotes the accumulation of high molecular weight E2F complexes in human colon carcinoma cells. It will also kill human leukemia cells via down-regulation of Mcl-1 through a transcriptional mechanism. 1. Lane, Yu, Rice, *et al.* (2001) *Cancer Res.* **61**, 6170. 2. Moshinsky, Bellamacina, Boisvert, *et al.* (2003) *Biochem. Biophys. Res. Commun.* **310**, 1026. 3. Bukczynska, Klingler-Hoffmann, Mitchelhill, *et al.* (2004) *Biochem. J.* **380**, 939.

**SU 10603**, See 3-(1,2,3,4-Tetrahydro-1-oxo-7-chloro-2-naphthyl)pyridine; 3-(1,2,3,4-Tetrahydro-4-oxo-7-chloro-2-naphthyl)pyridine

#### SU11652

This potent cell-permeable, multi-targeted receptor tyrosine kinase inhibitor, *or* RTKI (FW = 416.95 g/mol; CAS 326914-10-7), also known by its systematic name *N*-(2-diethylaminoethyl)-5-[(Z)-5-chloro-2-oxo-1H-indol-3-ylidenemethyl]-2,4-dimethyl-1H-pyrrole-3-carboxamide, targets PDGF and VEGF receptors. (See also *Sunitinib*) SU11652 acts as an ATP-competitive tyrosine kinase receptor and angiogenic inhibitor that exhibits greater selectivity for PDGFR $\beta$  ( $IC_{50}$  = 3 nM), VEGFR2 ( $IC_{50}$  = 27 nM), FGFR1 ( $IC_{50}$  = 170 nM), and Kit family members ( $IC_{50}$  ~ 10 to 500 nM) over EGFR ( $IC_{50}$  > 20  $\mu$ M) (1). FLT3-ITD and FLT3-TKD mutations are frequently found in acute myeloid leukemia (AML), and inhibition of these mutants by makes SU11652 a highly attractive inhibitor for AML drug development (7). **Modes of Inhibitory Action:** SU11652 inhibits all receptors for platelet-derived growth factor (PDGF) and vascular endothelial growth factor (VEGF), both of which play essential roles in tumor angiogenesis and tumor cell proliferation. Simultaneous inhibition of these targets reduces tumor vascularization and promotes cancer cell death. SU11652 and its fluoro-substituted congener, Sunitinib, kill HeLa cervix carcinoma, U-2-OS

osteosarcoma, Du145 prostate carcinoma and WEHI-S fibrosarcoma cells at low micromolar concentrations by accumulating rapidly in lysosomes, disturbing their pH regulation and ultrastructure, and ultimately leading to lysosomal protease leakage into the cytosol (8). Lysosomal destabilization was preceded by an early inhibition of acid sphingomyelinase (ASM), a lysosomal lipase that promotes lysosomal membrane stability (8). 1. Johnson, Stewart, Woods, Giranda & Luo (2007) *Biochemistry* **46**, 9551. 2. Schmidt-Arras, Böhmer, Markova, *et al.* (2005) *Mol. Cell. Biol.* **25**, 3690. 3. #### Suberoylanilide Hydroxamic Acid

This hydroxamic acid (FW = 264.32 g/mol; *Symbol*: SAHA) inhibits histone deacetylase, thereby inducing tumor cell differentiation, apoptosis, and/or growth arrest in several *in vitro* and *in vivo* experimental models. SAHA also enhances radiosensitivity and suppresses lung metastasis of triple-negative breast cancer (TNBC), the latter defined by the absence of an estrogen receptor, progesterone receptor, and human epidermal growth factor receptor 2 expression (4). Other studies have demonstrated that the expression of matrix metalloproteinase-9 (MMP-9) has been associated with a high potential of metastasis in several human carcinomas including breast cancer, and some HDAC inhibitors retard lung cancer cell migration via reduced activities of MMPs, RhoA, and focal adhesion complex. **Target(s)**: amidase, or histone-deacetylase-like amidohydrolase (1); and histone deacetylase (2,3). 1. Hildmann, Ninkovic, Dietrich, *et al.* (2004) *J. Bacteriol.* **186**, 2328. 2. Butler, Agus, Scher, *et al.* (2000) *Cancer Res.* **60**, 5165. 3. Richon, Emiliani, Verdin, *et al.* (1998) *Proc. **Substance K**, See  *$\alpha$ -Neurokinin*

#### Substance P

This undecapeptide amide (MW = 1348 g/mol; *Sequence*: RPKPQQFFGLM-NH<sub>2</sub>; CAS 33507-63-0; *Symbol*: SP), first discovered by von Euler and Gaddum in 1931, has a major role in hypertension and vasodilation in many vertebrates. The endogenous substance P receptor is the Neurokinin 1 Receptor (NK1 Receptor, NK1R), belonging to the tachykinin receptor sub-family of G-Protein-Coupled Receptors. Three second-messenger pathways are activated upon agonist binding to NK-1 receptors: (a) phospholipase C-mediated stimulation of phosphatidyl

inositol turnover, thereby mobilizing calcium ion release from both intra- and extracellular stores; (b) phospholipase A<sub>2</sub>-mediated mobilization of arachidonate, and adenylate cyclase-mediated stimulation of cAMP synthesis. Substance P also stimulates intestinal contractions as well as secretion of saliva. It is also a neuromodulator participating in the transmission of pain (1) and is a tachykinin NK-1 receptor agonist (2). Because SP promotes the proliferation of tumor cells, angiogenesis and the migration of tumor cells, SP receptor antagonists show promise in combating cancer. **Target(s)**: carboxypeptidase E (3); glutamyl aminopeptidase, or aminopeptidase A (4); membrane alanyl aminopeptidase, or aminopeptidase N,  $K_i = 0.44$   $\mu$ M (5,6); neurolysin, alternative substrate (7,8); and peptidyl-dipeptidase A (9). 1. #### Succinate (Succinic Acid)

This dicarboxylic acid (FW = 118.09 g/mol; CAS 110-15-6), also known as butanedioic acid and ethanedicarboxylic acid, is a key intermediate in the tricarboxylic acid cycle and the glyoxylate cycle. The free acid is soluble in water (6.8 g/100 mL at 20°C; the sodium and potassium salts are considerably more soluble), has a melting point of 185-187°C, and decomposes at 235°C with a partial conversion to succinic anhydride. The  $pK_a$  values are 4.21 and 5.72 at 25°C (the  $dpK_a/dT$  value for  $pK_{a1}$  is -0.0018). **Target(s):** 2-(acetamidomethylene)-succinate hydrolase (92);  $N^4$ -( $\beta$ -*N*-acetylglucosaminyl)-L-asparaginase (33); aconitase, or aconitate hydratase (74); adenine phosphoribosyltransferase (1); adenosine-phosphate deaminase (2,88); adenylosuccinate synthetase (3,57-59); aerobactin synthase (61); alanine aminotransferase (110); alanopine dehydrogenase (5);  $\beta$ -alanyl-CoA ammonia-lyase (6); amidase, or half-amidase (94); amino-acid *N*-acetyltransferase (116); D-amino-acid aminotransferase, or D-alanine aminotransferase (4,107); 4-aminobutyrate aminotransferase (7,108); aminolevulinic acid aminotransferase (106); AMP deaminase (2); AMP nucleosidase (98); argininosuccinate lyase (65,66); aspartate aminotransferase (8-10,110-113); aspartate ammonia-lyase, weakly inhibited (68-70); aspartate carbamoyltransferase (11-14,117-123); aspartate 1-decarboxylase (15,84); aspartate 4-decarboxylase (16,82,83); aspartate kinase (103); D-aspartate oxidase (17-19);  $\gamma$ -butyrobetaine hydroxylase, or  $\gamma$ -butyrobetaine:2-oxoglutarate dioxygenase,  $K_i = 0.07$  mM (20); carbamoyl-phosphate synthetase (21,56); carboxymethylene-butenolidase (102); carboxy-*cis,cis*-muconate cyclase (63); carboxypeptidase A,  $K_i = 4$  mM (22); carboxypeptidase B,  $K_i = 28$  mM (22,96); choline acetyltransferase (23); creatinase (89); cutinase (24); cyanate hydratase, or cyanase (71); dehydro-L-gulonate decarboxylase (25); dehydrogluconate dehydrogenase (26); 3-dehydroquinone dehydratase (27,73); deoxyribonuclease II, or spleen acid deoxyribonuclease (52,99); dichloromuconate cycloisomerase (62); 5-formyltetrahydrofolate cycloligase, or 5,10-methylenetetrahydrofolate synthetase (60); fumarase, or fumarate hydratase (28-30,75); glutamate decarboxylase,  $K_i = 0.29$  mM (31,32); glutamate formimidoyltransferase (124); glutaminase (95); (S)-2-hydroxy-acid oxidase (34);  $\alpha$ -ketoglutarate dehydrogenase (35); kynurenine:2-oxoglutarate aminotransferase (36); L-lactate dehydrogenase, particularly LDH-X (37); leucine aminotransferase (109); maleimide hydrolase, alternative product inhibition (90); malic enzyme, or malate dehydrogenase (decarboxylating) (38-40); 2-methyleneglutarate mutase (41); *N*-methylglutamate dehydrogenase (42); (S)-2-methylmalate dehydratase (43,72); myosin ATPase (87); nicotinate-nucleotide diphosphorylase (carboxylating) (114,115); oxaloacetate decarboxylase (85,86); pantothenase (93); peptidyl-dipeptidase A, or angiotensin I-converting enzyme (97); phosphoenolpyruvate carboxykinase (GTP), weakly inhibited (77); phosphoenolpyruvate carboxylase (44,78-81); phosphoenolpyruvate phosphatase (100); 6-phosphofructokinase (45-47,105); 3-phosphoglycerate kinase (48,104); [phosphorylase] phosphatase (101); pyrophosphatase, or inorganic diphosphatase (49); pyruvate kinase (50); serine-sulfate ammonia-lyase, weakly inhibited (67); tartrate decarboxylase (76); taupine dehydrogenase (53); theanine hydrolase (91); thiosulfate sulfurtransferase, or rhodanese (51); triose-phosphate isomerase (54,64); and urocanate hydratase (55). 1. ### Succinate Semialdehyde

This monoaldehyde of succinic acid ( $FW_{\text{free-acid}} = 102.09$  g/mol), also known as 4-oxobutanoic acid, is an intermediate in the metabolism of  $\gamma$ -aminobutyric acid. Succinate semialdehyde is a product of the reversible reactions catalyzed by 4-hydroxybutyrate dehydrogenase and 4-aminobutyrate aminotransferase as well as a product of 2-(acetamidomethylene)succinate hydrolase and  $\alpha$ -ketoglutarate decarboxylase. It is a substrate of the succinate-semialdehyde dehydrogenases. This water-soluble and viscous liquid (B.P. = 134-136°C at 14 mm Hg) tends to polymerize; nevertheless, aqueous solutions are stable below pH 6 at 2°C for at least three months. **Target(s)**: aminolevulinate aminotransferase (1,2); *N*-carbamoylsarcosine amidase (3); dihydrodipicolinate synthase (4); and malonate-semialdehyde dehydrogenase (5). **1**. ### Succinic Monohydroxamic Acid

This hydroxamic acid ( $FW_{\text{free-acid}} = 133.10$  g/mol) inhibits ADAM 17 endopeptidase, *or* tumor necrosis factor- $\alpha$  converting enzyme; TACE (1) and 3-ketoacid CoA-transferase (2). **1**. **N<sup>6</sup>-Succinyl-L-alanyl-L-alanyl-L-prolyl-L-phenylalanine Chloromethyl Ketone**

This tetrapeptide halomethyl ketone ( $FW_{\text{free-acid}} = 537.01$  g/mol) inhibits cuticle degrading endopeptidase, *Metarhizium* (1). Note that *N<sup>6</sup>*-succinyl-L-alanyl-L-alanyl-L-prolyl-L-phenylalanine *p*-nitroanilide is a substrate for chymotrypsin, cathepsin G, and peptidyl-prolyl isomerase. **1**. St. Leger (1998) in *Handb. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.), p. 325, Academic Press, San Diego.

### Succinylcholine

This potent nicotinic cholinergic receptor antagonist ( $FW_{\text{dication}} = 234.38$  g/mol; CAS 6101-15-1, for the dichloride dehydrate; Halide salts are water-soluble (~1 g/mL)), also known by its generic name Suxamethonium chloride (*or* "SUX"), its trade names Anectine<sup>®</sup> and Quelicin<sup>®</sup>, and 2,2'-[(1,4-dioxobutane-1,4-diyl)bis(oxy)]bis(*N,N,N*-trimethylethanaminium ion), induces persistent receptor activation, blocking synaptic transmission at myoneural junctions (1-3). Succinylcholine is often used to as a muscle relaxant to induce short-term paralysis, especially to facilitate tracheal intubation. Neuromuscular transmission is inhibited as long as an adequate succinylcholine concentration remains at the receptor site. Onset of flaccid paralysis is rapid (<1 minute after intravenous administration), and with single administration lasts approximately 4-6 minutes. Its utility as a muscle relaxant was first investigated by Nobel Laureate Daniel Bovet (Physiology and Medicine, 1957). Aqueous solutions are unstable (particularly above pH 9 and at elevated temperature) and should be prepared freshly. Succinylmonocholine (SMC), which is the product of the inefficient hydrolysis of succinylcholine by butyrylcholinesterase, is a forensic marker for succinylcholine poisoning. The post-mortem half-life for plasma SMC is 1-3 hours, putting the reliable detection interval of 8-24 hours (4). The following drugs enhance the neuromuscular blocking by succinylcholine: promazine, oxytocin, aprotinin, certain non-penicillin antibiotics, quinidine,  $\beta$ -adrenergic blockers, procainamide, lidocaine, trimethaphan, lithium carbonate, quinine, chloroquine, isoflurane, and desflurane. Its neuromuscular effects may be enhanced by drugs reducing plasma cholinesterase activity (*e.g.*, oral contraceptives, glucocorticoids, and monoamine oxidase inhibitors) or by agents that inhibit plasma cholinesterase irreversibly. **1**. ### Succinyl-CoA

This citric acid cycle intermediate ( $FW_{\text{ion}} = 866.61$  g/mol) is a potent product inhibitor of the  $\alpha$ -ketoglutarate dehydrogenase complex. As with most acyl derivatives of coenzyme A, succinyl-CoA is unstable at neutral pH at room temperature ( $t_{1/2} = 1-2$  hours in bicarbonate buffer at pH 7.5).

Complete hydrolysis occurs within two minutes at 100°C. On the other hand, succinyl-CoA solutions are relatively stable at pH 1. **Target(s):** acyl-CoA carboxylase (1,12); arylamine *N*-acetyltransferase (30); butyrate:acetoacetate CoA-transferase (21); carnitine *O*-palmitoyltransferase (2,3); citrate (*si*)-synthase (4,5); 3-hydroxy-3-methylglutaryl-CoA lyase (6); 3-hydroxy-3-methylglutaryl-CoA reductase, weakly inhibited (7); 3-hydroxy-3-methylglutaryl-CoA synthase (27,28);  $\alpha$ -ketoglutarate dehydrogenase complex (8,9); malonyl-CoA decarboxylase (10-13); [acyl-carrier-protein] *S*-malonyltransferase (29); malyl-CoA synthetase, or malate:CoA ligase, alternative product inhibition (14); methylmalonyl-CoA decarboxylase (15); methylmalonyl-CoA epimerase (16); (*S*)-methylmalonyl-CoA hydrolase (24); [3-methyl-2-oxobutanoate dehydrogenase, or 2-methylpropanoyl-transferring] phosphatase ([branched-chain- $\alpha$ -keto-acid dehydrogenase] phosphatase (22,23); oxaloacetate decarboxylase, weakly inhibited (17); 3-oxoacid CoA-transferase (25); pantothenate kinase (26); phosphoprotein phosphatase (23); propionyl-CoA carboxylase (18); and pyruvate kinase (19,20). 1. ### *O*-Succinylhomoserine

This metabolite (FW<sub>hydrochloride</sub> = 219.19 g/mol; CAS 1492-23-5), an intermediate in the biosynthesis of L-methionine, inhibits *O*-acetylhomoserine aminocarboxypropyltransferase, inhibited by the racemic mixture (1,2), *O*-acetylserine/*O*-acetylhomoserine sulfhydrylase, inhibited by the racemic mixture (3), and homoserine *O*-acetyltransferase, weakly inhibited (4). 1. Murooka, Kakahara, Miwa, Seto & Harada (1977) *J. Bacteriol.* **130**, 62. 2. Yamagata (1971) *J. Biochem.* **70**, 1035. 3. Yamagata (1987) *Meth. Enzymol.* **143**, 478. 4. Yamagata (1987) *J. Bacteriol.* **169**, 3458.

### *N*<sup>ε</sup>-Succinyl-L-prolyl-L-leucyl-L-phenylalanine Chloromethyl Ketone

This halomethyl ketone (FW<sub>free-acid</sub> = 508.01 g/mol) inhibits cathepsin G (1,2); chymase, mast cell protease I (1-3), chymotrypsin (1,2), and trypsin (1,2). 1. Powers, Tanaka, Harper, et al. (1985) *Biochemistry* **24**, 2048. 2. Yoshida, Everitt, Neurath, Woodbury & Powers (1980) *Biochemistry* **19**, 5799. 3. Woodbury, Everitt & Neurath (1981) *Meth. Enzymol.* **80**, 588.

### Sucralfate

This cytoprotective agent and oral gastrointestinal medication (FW = 2111 g/mol; CAS 54182-58-0) is a basic aluminum sucrose sulfate complex (R = -SO<sub>3</sub>[Al<sub>2</sub>(OH)<sub>5</sub>]) is an antiulcer drug that inhibits peptic hydrolysis. Sucralfate binds to the mucosa, creating a physical barrier that impairs diffusion of hydrochloric acid within the gastrointestinal tract and preventing degradation of mucus by acid hydrolysis. Sucralfate also inhibits Ca<sup>2+</sup> channels (1,2), glycoprotein *N*-palmitoyltransferase, *K<sub>i</sub>* = 0.91 μM (3), glycosulfatase (4), and urease (5). 1. Liu, Slomiany & Slomiany (1992) *Gen. Pharmacol.* **23**, 1129. 2. Slomiany, Liu & Slomiany (1992) *Biochem. Int.* **28**, 1125. 3. Slomiany, Liao, Mizuta & Slomiany (1987) *Biochem. Int.* **42**, 155.

### Sucralose

This non-nutritive sweetener (FW = 397.64 g/mol; CAS 56038-13-2), also known as Splenda®, Zerocal®, Sukrana®, SucraPlus®, Candys®, Cukren®, Nevella®, and 1,6-dichloro-1,6-dideoxy-β-D-fructofuranosyl-4-chloro-4-deoxy-α-D-galactopyranoside, is 320 to 1,000 sweeter than sucrose. **Inhibitory Target(s):** fructosyltransferase and glucosyltransferase. 1. Young & Bowen (1990) *J. Dent. Res.* **69**, 1480.

### Sucrose

This nonreducing disaccharide (FW = 342.30 g/mol; CAS 57-50-1) is the common commercial sugar used as a sweetener and is obtained primarily from sugar cane (*Saccharum officinarum*) or sugar beet (*Beta vulgaris*). **Target(s):** acetyl-CoA:α-glucosaminide *N*-acetyltransferase, or heparan-α-glucosaminide *N*-acetyltransferase (1); acetyl-CoA synthetase, or

acetate:CoA ligase (2);  $\beta$ -*N*-acetylhexosaminidase (27); aldose 1-epimerase (3);  $\alpha$ -amylase (4); calcdiol 1-monooxygenase (64); concanavalin A (5); cyclomaltodextrin glucanotransferase (61); cytochrome *c* oxidase, weakly inhibited (6); exoribonuclease II, ribonuclease II, weakly inhibited (46); 2,1-fructan:2,1-fructan 1-fructosyltransferase (58,59); fructan  $\beta$ -fructosidase (7,8); fructan  $\beta$ -(2,1)-fructosidase (8-11); fructan  $\beta$ -(2,6)-fructosidase (11-13);  $\beta$ -fructofuranosidase, *or* invertase; inhibited by elevated concentrations of sucrose (14,15);  $\beta$ -D-fucosidase (28); fucosterol-epoxide lyase (16);  $\alpha$ -galactosidase (38);  $\beta$ -galactosidase, weakly inhibited (36,37); glucan 1,4- $\alpha$ -glucosidase, *or* glucoamylase (41,45);  $\alpha$ -glucosidase (40-43);  $\beta$ -glucosidase (39);  $\beta$ -glucuronidase (29); glycogen phosphorylase *b* (17); guanylate cyclase (18); hyaluronan synthase (57); inulinase (19); levanase, weakly inhibited (20); naringinase (21); pectinesterase (54);  $\alpha$ , $\alpha$ -phosphotrehalase, *or* trehalose-6-phosphate hydrolase (22); polynucleotide phosphorylase, *or* polyribonucleotide nucleotidyltransferase (56); procollagen galactosyltransferase (23); procollagen glucosyltransferase (23,60); sucrose-phosphatase (47-53); sucrose-6-phosphate hydrolase (24); sucrose-phosphate synthase (62,63); thioglucosidase, *or* myosinase (25);  $\alpha$ , $\alpha$ -trehalase (26,30-35); and UTP:glucose-1-phosphate uridylyltransferase (55). 1. ### Sulbactam

This water-soluble, semi-synthetic  $\beta$ -lactam (FW<sub>free-acid</sub> = 233.25 g/mol; CAS 68373-14-8; M.P. = 148-151°C), also known as penicillanic acid sulfone and penicillanic acid 1,1-dioxide, is an irreversible  $\beta$ -lactamase inhibitor that is often used to maintain the therapeutic action of other  $\beta$ -lactam antibiotics, most often penicillin. (In the U.S., sulbactam is combined with cefoperazone to form cefoperazone/sulbactam (MAGNEX<sup>®</sup>) and ampicillin to form ampicillin/sulbactam (Unasyn<sup>®</sup>.) While effective against most forms of  $\beta$ -lactamase, sulbactam does not inhibit amPC cephalosporinase, conferring little protection against *Pseudomonas aeruginosa*, *Citrobacter*, *Enterobacter*, and *Serratia*. 1. Walsh (1983) *Trends Biochem. Sci.* **8**, 254. 2. Mantoku & Ogawara (1981) *J. Antibiot.* **34**, 1347. 3. Kemal & Knowles (1981) *Biochemistry* **20**, 3688. 4. Neu & Fu (1980) *Antimicrob. ### Sulconazole

This antifungal agent (FW = 397.75 g/mol; CAS 61318-90-9), also known as [2-[[4-(4-chlorophenyl)methyl]thio]-2-(2,4-dichlorophenyl)ethyl]-1H-imidazole, inhibits CYP1A2 (1), CYP2B6 (1), CYP2C9 (1), CYP2C19 (1), CYP2D6 (1), and CYP19, *or* aromatase (2). Its mechanism of action is unknown. Sulconazole is the indicated topical treatment for *tinea corporis* (Ringworm-of-the-Body), *tinea cruris* (ringworm of the groin, *or* Jock Itch), and *tinea pedis* (ringworm of the foot, *or* Athlete's Foot) caused by *Trichophyton rubrum*, *T. mentagrophytes*, *Epidermophyton floccosum*, and *Microsporum canis*. 1. Zhang, Ramamoorthy, Kilicarlan, *et al.* (2002) *Drug Metab. Dispos.* **30**, 314. 2. Kragie, Turner, Patten, Crespi & Stresser (2002) *Endocr. Res.* **28**, 129.

### Sulfacetamide

This sulfonamide antibiotic (FW = 214.25 g/mol; CAS 144-80-9; pK<sub>1</sub> = 1.8 for amino group, and pK<sub>1</sub> = 5.4 for sulfonamide), also known as *N*-[(4-aminophenyl)sulfonyl]acetamide and *N*-acetylsulfanilamide, has a low lipid solubility. The sodium salt is very soluble in water (one part in 1.5 parts water). When formulated as complexes with Ag(I) and Zn(II), sulfacetamide is an effective against *Aspergillus* and *Candida spp.*, with minimum inhibitory concentrations in the 0.3 – 0.5  $\mu$ g/mL range. The mechanism of antifungal action of these complexes does not appear to be connected with inhibition of lanosterol-14- $\alpha$ -demethylase, since sterol levels in the fungi cultures are unaffected by Ag(I) sulfacetamide complex

or Zn(II) sulfacetamide complex. *Note:* Sulfacetamide should not be confused with *N*<sup>1</sup>-acetylsulfanilamide. **Target(s):** carbonic anhydrase, or carbonate dehydratase (1); and dihydropteroate synthase (2-5). 1. Lanir & Navon (1972) *Biochemistry* **11**, 3536. 2. Prabhu, Lui & King (1997) *Phytochemistry* **45**, 23. 3. Kasekarn, Sirawaraporn, Chahomchuen, Cowman & Sirawaraporn (2004) *Mol. Biochem. Agents Chemother.* **49**, 741.

### Sulfachloropyridazine

This antibacterial sulfonamide (FW = 284.73 g/mol; CAS 80-32-0), also known as sulfachloropyridazine and 4-amino-*N*-(6-chloro-3-pyridazinyl)-benzenesulfonamide, is frequently used clinically to combat enteric infections. **Target(s):** dihydropteroate synthase (1-5). 1. Hong, Hossler, Calhoun & Meshnick (1995) *Antimicrob. Agents Chemother.* **39**, 1756. 2. Kasekarn, Sirawaraporn, Chahomchuen, Cowman & Sirawaraporn (2004) *Mol. Biochem. Parasitol.* **137**, 43. 3. Berglez, Iliades, Sirawaraporn, Coloe & Macreadie (2004) *Int. J. Parasitol.* **34**, 95. 4. Iliades, Meshnick & Macreadie (2005) *Antimicrob. Agents Chemother.* **49**, 741. 5. Fernley, Iliades & Macreadie (2007) *Anal. Biochem.* **360**, 227.

### Sulfadiazine

This antibacterial agent (FW = 250.28 g/mol; CAS 68-35-9), also known as 4-amino-*N*-2-pyrimidinylbenzenesulfonamide, was developed by Roblin et al. (1) in 1940 and is most often used along with other antibiotics, such as trimethoprim. Sulfadiazine is a white solid (M.P. = 252-256°C) that is slightly soluble in water (200 mg/100 mL at 37°C and pH 7.5). **Target(s):** D-amino-acid oxidase (2); ATPase, inhibited by silver sulfadiazine (3); bontoxilysin, inhibited by silver sulfadiazine (4); dihydroorotase, *K<sub>i</sub>* = 0.19 mM (5); dihydropteroate synthase (6-12); glucose-6-phosphate dehydrogenase, weakly inhibited (13); mannose-6-phosphate isomerase, inhibited by silver sulfadiazine (14). 1. Roblin, Williams, Winnek & English (1940) *J. Amer. Chem. Soc.* **62**, 2002. 2. Hellerman, Lindsay & Bovarnick (1946) *J. Biol. Chem.* **163**, 553. 3. Nechay & Saunders (1984) *J. Environ. Pathol. Chem.* **166**, 149. 14. Wells, Scully, Paravicini, Proudfoot & Payton (1995) *Biochemistry* **34**, 7896.

### Sulfadimethoxine

This water-soluble sulfonamide (FW = 310.33 g/mol; CAS 122-11-2), also known as 4-amino-*N*-(2,6-dimethoxy-4-pyrimidinyl)benzenesulfonamide, is frequently used as an antibacterial agent, in conjunction with other pharmaceuticals such as trimethoprim. **Target(s):** CYP2C9 (1); and dihydropteroate synthase (2-4). 1. Zweers-Zeilmaker, Horbach & Witkamp (1997) *Xenobiotica* **27**, 769. 2. Kasekarn, Sirawaraporn, Chahomchuen, Cowman & Sirawaraporn (2004) *Mol. Biochem. Parasitol.* **137**, 43. 3. Berglez, Iliades, Sirawaraporn, Coloe & Macreadie (2004) *Int. J. Parasitol.* **34**, 95. 4. Iliades, Meshnick & Macreadie (2005) *Antimicrob. Agents Chemother.* **49**, 741.

### Sulfadoxine

This water-soluble sulfonamide (FW = 310.33 g/mol; CAS 2447-57-6) is a structural analogue of sulfadimethoxine and is frequently used as an antibacterial agent in conjunction with other antibiotics. Sulfadoxine/pyrimethamine is widely used in Africa for treating chloroquine-resistant *Plasmodium falciparum* malaria. (See also Dapsone; Sulfadiazine) **Target(s):** Dihydropteroate synthase (DHPS) is the primary target of sulfone and sulfonamide drugs, which are used extensively in the control of many infections including *P. falciparum* (1-5). Sequencing of the DHPS gene in 10 isolates from Thailand identified a new allele of DHPS that has a previously unidentified amino acid difference (5). Eight alleles of *P. falciparum* PPPK-DHPS have been expressed in *Escherichia coli* and purified to homogeneity (5). Strikingly, the *K<sub>i</sub>* for sulfadoxine varies by almost three orders of magnitude from 0.14 μM for the DHPS allele from sensitive isolates to 112 μM for an enzyme expressed in a highly resistant isolate. Comparison of the *K<sub>i</sub>* values of different sulfonamides and the sulfone dapsone suggests that amino acid differences in DHPS are likely to confer cross-resistance to these compounds (5). Mutations in the DHPS gene of sulfadoxine-resistant isolates of *P. falciparum* are thus central to the mechanism of resistance to sulfones and sulfonamides (5). Other targets include 2-amino-4-hydroxy-6-hydroxymethylidihydropteridine diphosphokinase (1), CYP2C9 (6), and dihydrofolate reductase (7). 1. Kasekarn, Sirawaraporn, Chahomchuen, Cowman & Sirawaraporn (2004) *Mol. Biochem. Parasitol.* **137**, 43. 2. Triglia, Menting, Wilson & Cowman (1997) *Proc. Natl. Acad. Sci. U.S.A.* **94**, 13944. 3. Sirawaraporn & Yuthavong (1986) *Antimicrob. Agents Chemother.* **29**, 899.

### Sulfaethidole

This thiazole antibacterial (FW = 284.36 g/mol; CAS 94-19-9), known systematically as sulfaethylthiazole and 4-amino-*N*-(aminoimino-methyl)benzenesulfonamide, also inhibits glucose-6-phosphatase. 1. Jasmin & Johnson (1959) *J. Amer. Pharm. Assoc.* **48**, 113.

### Sulfaguanidine

This sulfonamide derivative (FW<sub>free-base</sub> = 214.25 g/mol; M.P. = 190-193°C; CAS 57-67-0; water solubility = 1 g/L at 25°C), also known as *N*<sup>1</sup>-amidinosulfanilamide, *N*<sup>1</sup>-guanylsulfanilamide, and 4-amino-*N*-(aminoimino-methyl)benzenesulfonamide, is an antibacterial agent.

**Target(s):** L-amino-acid oxidase (1); 2-amino-4-hydroxy-6-hydroxy-methylidihydropteridine pyrophosphokinase (2); carbonic anhydrase, or carbonate dehydratase,  $K_i = 1.9$  mM (3); and dihydropteroate synthase (2,4). 1. Zeller & Maritz (1945) *Helv. Chim. Acta* **28**, 365. 2. Walter & Königk (1980) *Meth. Enzymol.* **66**, 564. 3. Pocker & Stone (1968) *Biochemistry* **7**, 2936. 4. ### Sulfamethoxazole

This membrane-permeant sulfonamide (FW = 253.28 g/mol; CAS 723-46-6), also known as 4-amino-*N*-(5-methyl-3-isoxazolyl)benzenesulfonamide, targets dihydropteroate synthase (Reaction: (2-amino-4-hydroxy-7,8-dihydropteridin-6-yl)methylidiphosphate + 4-aminobenzoate  $\rightleftharpoons$  dihydropteroate + PP<sub>i</sub>) and is highly effective antibiotic for treating intracellular pathogens (e.g., *Listeria* and *Shigella*), especially when used in combination with trimethoprim (1). **Pharmacokinetics:** Sulfamethoxazole is rapidly absorbed when administered orally, distributing into most tissues and accumulating in sputum, vaginal fluid, and middle-ear fluid. Seventy percent of circulating drug is bound to plasma proteins. The time to reach maximum plasma concentration is 1–4 hours after, and the mean serum half-life is 10 hours. About 50–70% of oral sulfamethoxazole undergoes hepatic metabolism, forming at *N*<sup>4</sup>-acetyl-, *N*<sup>4</sup>-hydroxy-, 5-methylhydroxy-, *N*<sup>4</sup>-acetyl-5-methylhydroxy-derivatives as well as its *N*-glucuronide conjugate (15–20%). CYP2C9 catalyzes the formation of the *N*<sup>4</sup>-hydroxy derivative. Sulfamethoxazole is not a substrate of the P-glycoprotein transporter. It is primarily excreted as glomerular filtrate and tubular secretion. See also Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** CYP2C9 (2); and dihydropteroate synthase (3–12). 1. Southwick & Purich (1996) *New Engl. J. Med.* **334**, 770. 2. Wen, Wang, Backman, Laitila & Neuvonen (2002) *Drug Metab. Dispos.* **30**, 631. 3. Hong, Hossler, Calhoun & Meshnick (1995) *Antimicrob. Agents Chemother.* **39**, 1756. 4. ### Sulfamethoxy-pyridazine

This sulfonamide (FW = 280.31 g/mol; CAS 80-35-3), also known as 4-amino-*N*-(6-methoxy-3-pyridazinyl)benzenesulfonamide, inhibits dihydropteroate synthase (1–4). 1. Hong, Hossler, Calhoun & Meshnick (1995) *Antimicrob. Agents Chemother.* **39**, 1756. 2. Nopponpunth, Sirawaraporn, Greene & Santi (1999) *J. Bacteriol.* **181**, 6814. 3. ### Sulfamidochrysoidine

This red dye and antibiotic prodrug (FW<sub>free-base</sub> = 291.33 g/mol; CAS 103-12-8; IUPAC Name: 2,4-diaminophenylazobenzene-4'-sulfonamide) was first synthesized by Bayer chemists Klarer and Mietzsch and found by Domagk (Nobel Prize, 1939) to be a lethal antibiotic for many Gram-positive bacteria. In 1935, Pasteur Institute researchers Fournau, Tréfouël, Bovet (Nobel, 1955; for discovery of neurotransmitters and antihistamines) and Nitti found that it is metabolized to sulfanilamide (*p*-aminobenzenesulfonamide), a potent competitive inhibitor of enzymes acting on *p*-aminobenzoic acid. The hydrochloride (FW = 327.79 g/mol), known as Prontosil, is an orange-red solid that is slightly soluble in water (1 g/400 mL). This dye binds tightly to carbonic anhydrase and is often used as a stain for that enzyme in polyacrylamide gels. Prontosil-dextran are also inhibitors of carbonic anhydrase. **Target(s):** carbonic anhydrase, or carbonate dehydratase (1,2). 1. Siffert, Teske, Gartner & Gros (1983) *J. Biochem. Biophys. Methods* **8**, 331. 2. van Goor (1948) *Enzymologia* **13**, 73.

### Sulfamisterin

This fungal metabolite (FW<sub>ion</sub> = 438.56 g/mol), first obtained from a strain of *Pycnididiella*, suppresses sphingolipid biosynthesis by inhibiting serine C-palmitoyltransferase, IC<sub>50</sub> = 3 nM. Sulfamisterin markedly inhibits sphingolipid biosynthesis in CHO cells and *Saccharomyces cerevisiae*, as monitored by incorporation of radioactive precursors into sphingolipids. Unlike cell-free experiments, 10 μM sulfamisterin was needed for complete inhibition of sphingolipid biosynthesis in intact cells. 1. Yamaji-Hasegawa, Takahashi, Tetsuka, Senoh & Kobayashi (2005) *Biochemistry* **44**, 268.

### Sulfamoxole

This antibacterial (FW = 267.31 g/mol; CAS 729-99-7; Solubility: 160 mg/100 mL in 10 mM HCl; 200 mg/100 mL in 10 mM NaOH), also known as 4-amino-*N*-(4,5-dimethyl-2-oxazolyl)benzenesulfonamide, inhibits CYP2C (1) and dihydropteroate synthase (2–4). 1. Zweers-Zeilmaker, Horbach & Witkamp (1997) *Xenobiotica* **27**, 769. 2. Kasekarn, Sirawaraporn, Chahomchuen, Cowman & Sirawaraporn (2004) *Mol. Biochem. Parasitol.* **137**, 43. 3. ### Sulfanilamide

This *p*-aminobenzoate mimic and antibacterial (FW = 172.21 g/mol; CAS 63-74-1; Soluble in boiling water = 0.5 g/mL), also known as 4-aminobenzenesulfonamide, exhibits wide-spectrum of action against most Gram-positive and many Gram-negative organisms. Exogenous folic acid restores optimal growth in most strains. Sulfanilamide was first synthesized by Austrian chemist Paul Gelmo in 1908, but its antibacterial activity was first noted by Domagk (Nobel Laureate, 1939). Many bacteria were later found to develop sulfanilamide resistance. By examining the effects of sulfanilamide on dihydropteroate synthetase activity in genetically transformed mutants of *Diplococcus pneumoniae*, Hotchkiss and Evans (1)

concluded that drug resistance was achieved by changes in dihydropteroate synthetase structure, resulting in reduced binding affinity for sulfanilamide, but not for the natural substrate, *p*-aminobenzoic acid (or PABA). This conclusion was later confirmed by kinetic measurements on dihydropteroate synthetase from naturally occurring clinical isolates of *Neisseria meningitidis* and *Neisseria gonorrhoeae* (2). Additional resistance mechanisms have been now identified, including increased expression of the pABA synthase and dihydropteroate synthetase genes. **Target(s):** alkaline phosphatase (3,4); D-amino-acid oxidase (5); 2-amino-4-hydroxy-6-hydroxymethyl-dihydropteridine pyrophosphokinase (6); aminopeptidase B (7); carbonic anhydrase, or carbonate dehydratase (8-26,40-42); catalase (27); catechol oxidase (28); dihydrofolate synthase (29,39); dihydroorotase,  $K_i = 3.4$  mM (30); dihydropteroate synthase, *clinical target* (6,29,31,32,39,43-48); glucose-6-phosphate dehydrogenase (33,34); glutamate decarboxylase, mildly inhibited (35); histidine decarboxylase (36); lactate dehydrogenase, weakly inhibited (34); luciferase, bacterial, or alkanal monooxygenase (37); and peroxidase, horseradish (38). 1. ### Sulfanilate

This arylsulfonic acid (FW<sub>free-acid</sub> = 173.19 g/mol; CAS 121-57-3; acid has low water solubility (0.01 g/mL at 20°C), but sodium salt is freely soluble), also known as sulfanilic acid and 4-aminobenzenesulfonic acid, inhibits  $\alpha$ -amylase, *Bacillus subtilis* (1,2) dihydropteroate synthase (3);  $\beta$ -fructofuranosidase, or invertase (4); and glutathione S-transferase (5). 1. ### Sulfaquinoxaline

This sulfonamide (FW = 300.34 g/mol; CAS 967-80-6), also known as 4-amino-*N*-2-quinoxalinylnbenzenesulfonamide and *N*<sup>1</sup>-(2-quinoxalinyln)-sulfanilamide, is a potent ( $K_i = 1 \mu\text{M}$ ) inhibitor of the dithiothreitol-dependent reduction of both vitamin K epoxide and vitamin K quinone by rat liver microsomes *in vitro*. The inhibition by sulfaquinoxaline resembles inhibition by coumarin anticoagulants and by hydroxynaphthoquinones. Sulfaquinoxaline has a low solubility in water (0.75 mg/100 mL at pH 7.0; however, the deliquescent sodium salt is much more soluble. Note that aqueous solutions absorb atmospheric carbon dioxide resulting in decreased solubility of the sulfonamide. **Target(s)**: dihydropteroate synthase (1-4); vitamin K epoxide reductase (5); and vitamin K quinone reductase (5). 1. Kasekarn, Sirawaraporn, Chahomchuen, Cowman & Sirawaraporn (2004) *Mol. Biochem. Parasitol.* **137**, 43. 2. Berglez, Iliades, Sirawaraporn, Coloe & Macreadie (2004) *Int. J. Preusch, Hazelett & Lemasters (1989) *Arch. Biochem. Biophys.* **269**, 18.

### Sulfasalazine

This brownish-yellow sulfonamide and efficient free radical scavenger (FW<sub>free-acid</sub> = 398.40 g/mol; CAS 599-79-1; Low H<sub>2</sub>O solubility), also known as 2-hydroxy-5-[[4-[(2-pyridinylamino)sulfonyl]phenyl]azo]benzoic acid and salicylazosulfapyridine, is widely used for the treatment of ileitis and colitis. Its pharmacologic action has been attributed to 5-aminosalicylic acid, a primary breakdown product. **Target(s)**: cystine transport (1); dihydrofolate reductase (2);  $\gamma$ -glutamyl hydrolase (3); glutathione *S*-transferase and leukotriene C<sub>4</sub> synthase (4-6); HIV-1 integrase (7); 9-hydroxyprostaglandin dehydrogenase (8); 15-hydroxyprostaglandin dehydrogenase (9,10); I $\kappa$ B kinases  $\alpha/\beta$  (11,26,27); lipoxigenase (12); lipoxigenase, soybean (13, however, reference 1 reports no inhibition); lyso-(platelet-activating factor):acetyl-CoA acetyltransferase (15); myeloperoxidase (16); NF- $\kappa$ B (nuclear factor  $\kappa$ B) activation (17-20); 3-phosphoglycerate kinase (21,28); AICAR transformylase, *or* phosphoribosylaminoimidazole carboxamide formyltransferase (2); serine hydroxymethyl-transferase, *or* glycine hydroxymethyl-transferase (22); thiopurine *S*-methyltransferase (23,24,29,30); thromboxane synthase (25); and folate transport (30,31). 1. ### Sulfate

This inorganic anion SO<sub>4</sub><sup>2-</sup> (FW<sub>ion</sub> = 96.06 g/mol) is an essential and ubiquitous metabolite in all living organisms, participates in a wide variety of processes, and is a product and/or inhibitor of many sulfatases. In renal failure, sulfoesters accumulate and hypersulfatemia contributes directly to the unmeasured anion gap characteristic of the condition. Sulfate weakly inhibits over 150 enzymes, with inhibition constants ranging in the 0.1–5 mM range.

### Sulfathiazole

This sulfanilamide derivative (FW = 255.32 g/mol; CAS 72-14-0), also called *N*<sup>1</sup>-2-thiazolylsulfanilamide and 4-amino-*N*-2-thiazolylbenzene sulfonamide, inhibits folic acid biosynthesis and exerts antibacterial activity. **Target(s)**: D-amino acid oxidase (1); 2-amino-4-hydroxy-6-hydroxymethyldihydropteridine diphosphokinase (2,3); carbonic anhydrase, *or* carbonate dehydratase, weakly inhibited (4); catechol oxidase (5); dihydropteroate synthase (2,3,6-14); glucose-6-phosphate dehydrogenase (15);  $\gamma$ -glutamyl transpeptidase (16); peroxidase, horseradish (17); pyruvate carboxylase (18); and tyrosinase (19). 1. ### Sulfide Ions

This dianion S<sup>2-</sup> (Na<sub>2</sub>S; FW = 78.05 g/mol; very hygroscopic; solubility = 18.6 g/100 g H<sub>2</sub>O at 20°C; K<sub>2</sub>S; FW = 110.26 g/mol; unstable and may explode on percussion or upon rapid heating), decomposes in air to produce hydrogen sulfide. The sulfide ion can be thought of as a conjugate base of hydrogen sulfide. H<sub>2</sub>S has pK<sub>a</sub> values of 7.04 and 14.9, and at typical alkaline pH values, the main species in aqueous solutions is HS<sup>-</sup>. **See also Hydrogen Sulfide Target(s)**: aconitase (1,2); alcohol dehydrogenase (3,4); alkaline phosphatase (5); amine oxidase (6); ascorbate oxidase (7); bacterial leucyl aminopeptidase (60); carbonic anhydrase, *or* carbonate dehydratase (8-15,54); carboxypeptidase A (16-18); catalase (19,20); cysteinyl-tRNA synthetase (21,22); cytochrome *c* oxidase, *or* complex IV (23-26); cytosol alanyl aminopeptidase (59); formate dehydrogenase (27);

### Sulfinpyrazone

This potent uricosuric drug (FW = 404.48 g/mol; CAS 57-96-5), also known as 1,2-diphenyl-4-[2-(phenylsulfinyl)ethyl]-3,5-pyrazolidinedione, scavenges free radicals and inhibits platelet aggregation by blocking degranulation. Sulfinpyrazone may be used to treat gout by competitively inhibiting uric acid reabsorption by the kidney proximal tubule. **Target(s):** cadmium-transporting ATPase (1); cathepsin G (2,3); cyclooxygenase (4-10); CYP2C9 (11,12); CYP2C6 (13); elastase (2,3); glutathione-transporting ATPase (1); urate transport (14); and xenobiotic-transporting ATPase, *or* multidrug-resistance protein (15). 1. ### Sulfisoxazole

This antibacterial agent (FW = 267.31 g/mol; CAS 127-69-5), also known as 4-amino-N-(3,4-dimethyl-5-isoxazolyl)benzenesulfonamide, inhibits folate biosynthesis and is a selective endothelin receptor ETA antagonist (also an antagonist at ETB at higher concentrations). It has a water solubility of 0.13 mg/mL at 25°C; however, the salt is far more soluble. **Target(s):** dihydropteroate synthase (1-3); and endothelin receptor, *or* ETA (4). 1. ### Sulfite Ion

This redox-active dianion (FW<sub>ion</sub> = 80.06 g/mol; FW<sub>disodium-salt</sub> = 126.06 g/mol; CAS 7757-83-7) inhibits enzymes in a multiple ways, often by acting as a sulfate analogue or as a reducing agent. Sodium sulfite reacts reversibly with FAD and FMN (1,2), and the ability to form covalent N<sup>5</sup>-flavin adducts with oxidases distinguishes these enzymes from other classes of flavoproteins. At high concentration, sulfite reacts with disulfide bonds, especially at elevated pH, to produce an S-substituted sulfite (R-S-SO<sub>3</sub><sup>-</sup>) and a free thiol. Metal ions (particularly Cu<sup>2+</sup>) facilitate sulfitolysis by forming a complex with the thiol anion product. Sulfite is also a substrate in reactions catalyzed by the sulfite reductases, sulfite dehydrogenase, sulfite oxidase, UDP-sulfoquinovose synthase, and cysteine lyase. It is also a product of the reactions catalyzed by the phosphoadenylyl-sulfate reductases, the adenylyl-sulfate reductases, sulfur dioxygenase, taurine dioxygenase, 4-sulfobenzoate 3,4-dioxygenase, thiosulfate sulfurtransferase (rhodanese), thiosulfate:thiol sulfurtransferase, thiosulfate:dithiol sulfurtransferase, 2-(2-hydroxyphenyl)-benzenesulfinate hydrolase, and sulfoacetaldehyde lyase. **Target(s):** 2-(acetamido-methylene)succinate hydrolase (3); N-acetylgalactosamine-4-sulfatase, *or* arylsulfatase B (4,5); N-acetylgalactosamine-6-sulfatase (67); N-acetylglucosamine-6-sulfatase (6); acid phosphatase (77); adenylylsulfatase (54); adenylylsulfate reductase (7); alcohol dehydrogenase (8); AMP nucleosidase (63); Arylsulfatase (5,9-14,70-75); aspartate 4-decarboxylase (15); catalase (16,17); cerebroside-sulfatase, *or* arylsulfatase A (4,5,12,65); chaperonin ATPase (53); choline-sulfatase (13,18,19,66); creatine kinase (20); cyanate hydratase, *or* cyanase

(43); cyclamate sulfohydrolase (52); diiodophenylpyruvate reductase (21); disulfoglucosamine-6-sulfatase (64); dopamine  $\beta$ -monoxygenase (88); F<sub>1</sub>F<sub>0</sub> ATP synthase, or H<sup>+</sup>-transporting two-sector ATPase (22,23); formate dehydrogenase (24);  $\beta$ -fructofuranosidase, or invertase (25); fructose-1,6-bisphosphate aldolase (26); L-galactono-1,4-lactone oxidase (27); glucose-6-phosphate dehydrogenase (17); glucosinolate sulfatase (9); glutathione peroxidase (17); glyceraldehyde-3-phosphate dehydrogenase, or acetylphosphatase activity (28); D- $\beta$ -hydroxybutyrate dehydrogenase (29); 2-(hydroxymethyl)-3-(acetamidomethylene)succinate hydrolase (61); 4-hydroxyphenyllactate dehydrogenase, or aromatic  $\alpha$ -keto acid reductase (30); iodothyronine-5'-deiodinase (31); malate dehydrogenase (32-34); methanol:5-hydroxybenzimidazolylcobamide Co-methyltransferase (87); oxalate decarboxylase (50); peptidylglycine monoxygenase (88); peroxidase (35); phosphoenolpyruvate mutase (36); phosphonate dehydrogenase, or phosphite dehydrogenase (57-59); phosphonoacetaldehyde hydrolase (51); propanediol-phosphate dehydrogenase (37); pyrophosphate-dependent phosphofructokinase, or diphosphate:fructose-6-phosphate 1-phosphotransferase (86); rubredoxin:NAD<sup>+</sup> reductase (60); steryl-sulfatase (9,68,69); streptopain (62); sucrose carrier (39); sulfate adenyltransferase (85); sulfoacetaldehyde lyase, product inhibition (40); sulfur reductase (56); superoxide dismutase (17); tetrachloroethene reductive dehalogenase (55); thiosulfate:dithiol sulfurtransferase, or thiosulfate reductase (41); thiosulfate sulfurtransferase, or rhodanese (38,80-84); thiosulfate:thiol sulfurtransferase, or thiosulfate reductase (42,78,79); and urocanate hydratase, or urocanase (44-49). 1. ### 3-Sulfo-L-alanine, See L-Cysteate

### S-Sulfocysteine

Both enantiomers of S-sulfocysteine (FW = 200.22 g/mol), also known as cysteine S-sulfate, rapidly inactivate rat kidney  $\gamma$ -glutamylcysteine synthetase, but are reversible inhibitors of sheep brain glutamine synthetase (1). The binding of the inhibitor to the enzyme induces formation of a very stable enzyme-inactivator complex, stabilized from interactions involving the sulfonyl sulfur atom of the S-sulfo amino acid and an active-site thiol group of the enzyme. **Target(s):** cysteine synthase (1-3); glutamine synthetase (4);  $\gamma$ -glutamylcysteine synthetase (4-7); and serine-sulfate ammonia-lyase, weakly inhibited (8). 1. **1-O-(3-O-Sulfo-β-D-galactopyranosyl)ceramide**, See  
*Galactosylceramide 3-O-Sulfate*  
**Sulfoglycolate**

This bisulfite addition compound (FW<sub>disodium-salt</sub> = 200.08 g/mol), formed by the combination of sodium glyoxylate and sodium bisulfite, inhibits glycolate oxidase. See also *Hydroxymethanesulfonate*; *Glycolate 2-Sulfate* 1. Zelitch (1957) *J. Biol. Chem.* **224**, 251.

### S-Sulfohomocysteine

This thiol-reactive amino acid analogue (FW = 215.25 g/mol; CAS 28715-19-7) rapidly inactivates rat kidney  $\gamma$ -glutamylcysteine synthetase, and both enantiomers reversibly inhibit sheep brain glutamine synthetase (1). The binding of the inhibitor to  $\gamma$ -glutamylcysteine synthetase induces formation of a very stable enzyme-inactivator complex, stabilized from interactions involving the sulfenyl sulfur atom of the S-sulfo amino acid and an active-site thiol group of the enzyme. **Target(s)**: glutamine synthetase (1); and  $\gamma$ -glutamylcysteine synthetase (1-4). 1. Moore, Weiner & Meister (1987) *J. Biol. Chem.* **262**, 16771. 2. Meister (1995) *Meth. Enzymol.* **252**, 26. 3. Huang, Moore & Meister (1988) *Proc. Natl. Acad. Sci. U.S.A.* **85**, 2464. 4. ### Sulfopyruvate

This metabolite (FW<sub>free-acid</sub> = 168.13 g/mol), an intermediate in the biosynthesis of plant sulfolipids and coenzyme M, is produced by the action of (*R*)-2-hydroxyacid dehydrogenase and is a substrate of sulfopyruvate decarboxylase. Note: Sulfopyruvate is an isoelectronic analogue of oxaloacetate and phosphoenolpyruvate. It is an alternative substrate of malate dehydrogenase. **Target(s)**: phosphoenolpyruvate carboxykinase (GTP) (1,2); phosphoenolpyruvate mutase, K<sub>i</sub> = 22 μM (3); phosphonopyruvate decarboxylase, sulfopyruvate is also a slow alternative substrate (4); and phosphonopyruvate hydrolase (5). 1. ### Sulfur Dioxide

This colorless gas SO<sub>2</sub> (FW = 64.065 g/mol; CAS 7446-09-5; M.P. = -72°C; B.P. = -10°C) reacts with water to form sulfurous acid H<sub>2</sub>SO<sub>3</sub> and bisulfite HSO<sub>3</sub><sup>-</sup>. SO<sub>2</sub> reversibly inhibits noncyclic photophosphorylation in isolated, envelope-free chloroplasts (1). Inhibition is competitive relative to phosphate, K<sub>i</sub> = 0.8 mM. The same inhibition characteristics are observed when phosphoglycerate (PGA)- or ribulose-1,5-bisphosphate (RuBP)-dependent oxygen evolution is examined in a reconstituted chloroplast system in the presence of SO<sub>3</sub><sup>2-</sup>. See also *Bisulfite* **Target(s)**: ascorbate oxidase (2); ATPase (3); DNA polymerase I (4); and sucrose carrier (5). 1. Cerović, Kalezić, Plesničar, *et al.* (1982) *Planta* **156**, 249. 2. ### Sulindac

This anti-inflammatory agent (FW<sub>free-acid</sub> = 356.42 g/mol; CAS 38194-50-2; pK<sub>a</sub> = 4.7 at 25°C), also known as Clinoril<sup>®</sup> and systematically as (1Z)-5-fluoro-2-methyl-1-[[4-(methylsulfinyl)phenyl]methylene]-1H-indene-3-acetic acid, is slightly soluble in water (3 mg/mL at pH 7). Sulindac is actually a prodrug that is converted in the liver to an active nonsteroidal anti-inflammatory drugs (NSAID) that is excreted in the bile and subsequently reabsorbed from the intestine. This route maintains a relatively constant blood level of the resulting COX-1 and/or COX-2 inhibitor. **See also Sulindac Sulfide; Sulindac Sulfone** **Target(s):** aldose reductase (1-5); arylamine *N*-acetyltransferase (6); collagenases (7); cyclic-nucleotide phosphodiesterase (8); cyclooxygenase (9-12); dihydrofolate reductase (13); elastase (14); estrone sulfotransferase (15); 15-hydroxyprostaglandin dehydrogenase, NAD<sup>+</sup>-dependent (16); phenol sulfo-transferase, or aryl sulfotransferase (15); and phosphoribosylaminoimidazolecarboxamide formyltransferase, or AICAR transformylase (13). 1. #### Sulindac Sulfide

This reduced form of sulindac (FW<sub>free-acid</sub> = 340.42 g/mol; CAS 32004-67-4), known systematically as (Z)-5-fluoro-2-methyl-1-[*p*-(methylthio)benzylidene]indene-3-acetic acid, inhibits cell growth and induces apoptosis, perhaps as a consequence of its ability to block Ras activation of Raf-1. Sulindac sulfide also inhibits cyclooxygenase-1, IC<sub>50</sub> = 0.5 μM, exhibiting a selectivity over cyclooxygenase-2, IC<sub>50</sub> = 14 μM. Sulindac sulfide also prevents cell transformation and slow cancer cell growth by triggering the endoplasmic reticulum stress response (ERSR), as revealed by upregulation of molecular chaperones such as GRP78 and C/EBP homologous protein, or CHOP (1). Because sulindac sulfide has good brain bioavailability, lower COX-2 inhibition, and no mitochondrial effects, it represents an appealing candidate for treating malignant gliomas through gliotoxicity arising from activation of the ERSR (1). **See also Sulindac; Sulindac Sulfone** **Target(s):** aldose reductase (2); cyclooxygenase, or prostaglandin-endoperoxide synthase (3-6); cyclic-nucleotide phosphodiesterase (7); elastase (8); epidermal growth factor-induced phosphorylation of extracellular-regulated kinase and Bad (9); 15-hydroxyprostaglandin dehydrogenase, NAD<sup>+</sup>-dependent (10); IκB kinase (11); and phospholipase A<sub>2</sub>, weakly inhibited (12); Ras signaling (13); and γ-secretase (14). 1. 2. #### Sulmazole

This inotropic agent (FW = 287.34 g/mol; M.P. = 203-205°C), also known as 2-[2-methoxy-4-(methylsulfinyl)phenyl]-1H-imidazo[4,5-*b*]pyridine, is often used as a cardiotoxic agent. **Target(s):** A<sub>1</sub> adenosine receptor (1); and cyclic-nucleotide phosphodiesterase (2-4). 1. Parsons, Ramkumar & Stiles (1988) *Mol. Pharmacol.* **33**, 441. 2. Schuhmacher, Greeff & Noack (1982) *Arzneimittel-forschung* **32**, 80. 3. el Allaf, D'Orio & Carlier (1984) *Arch. Int. Physiol. Biochim.* **92**, S69. 4. Scholz & Meyer (1986) *Circulation* **73**, III 99.

#### (S)-(-)-Sulpiride

This dopamine antagonist (FW = 341.43 g/mol; CAS 15676-16-1; Solubility: 100 mM in DMSO), also known as *S*-(*-*)-5-aminosulfonyl-*N*-[(1-ethyl-2-pyrrolidinyl)methyl]-2-methoxybenzamide, selectively targets D<sub>2</sub>, D<sub>3</sub>, D<sub>4</sub>, D<sub>1</sub> and D<sub>5</sub> receptors, with respective K<sub>i</sub> values of ~15 nM, ~13 nM, 1 μM, ~45 μM, and ~77 μM. Dopamine receptors are the primary targets in the treatment of schizophrenia, Parkinson's disease, and Huntington's chorea. **Primary Mode of Inhibitory Action:** Although sulpiride has a high affinity for dopamine receptors involved in emesis and prolactin secretion, it lacks part of the behavioral and biochemical profiles of the classical dopamine receptor antagonist neuroleptics (1). In the cardiovascular system, sulpiride is a potent prejunctional dopamine receptor antagonist, but has variable effectiveness in post-junctional dopamine receptor models (1). Sulpiride, but not haloperidol, up-regulates γ-hydroxybutyrate receptors *in vivo* and in cultured cells (2). **Pharmacokinetics:** Oral bioavailability is low (25–35% with marked inter-individual differences), absorbed slowly from the GI tract and reaching peak plasma concentrations in 4–5 hours. Sulpiride's *in vivo* half-life is 6–8 hours, with 92% excreted unchanged in the urine. The serum half-life of the terminal slope following intravenous administration averaged 5.3 hours (range 3.7–7.1 hours) according to the two-compartment model. In two subjects the half-lives were 11.0 and 13.9 hours, when the three-compartment model was applied (3). **Target(s):** mesolimbic and mesocortical D<sub>2</sub> dopamine receptors (1-10); D<sub>3</sub> dopamine receptors (9,10); carbonic anhydrase, 1-20 nM, depending on enzyme isotype (11,12). 1. ### Sunitinib

This orally bioavailable multi-targeted receptor tyrosine kinase inhibitor, *or* RTKI (FW = 400.23 g/mol; CAS 341031-54-7), also known by its code name SU11248 and its systematic name *N*-(2-diethylaminoethyl)-5-[(*Z*)-(5-fluoro-2-oxo-1*H*-indol-3-ylidene)methyl]-2,4-dimethyl-1*H*-pyrrole-3-carboxamide, targets all receptors for platelet-derived growth factor (PDGF) and vascular endothelial growth factor (VEGF), both of which play essential roles in tumor angiogenesis and tumor cell proliferation (1). (**See also SU11652**) **Primary Mode of Inhibitory Action:** Simultaneous inhibition of these targets reduces tumor vascularization and promotes cancer cell death. SU11248 treatment of mice bearing subcutaneously implanted NCI-H526 tumors resulted in significant tumor growth inhibition, with the reduced levels of phospho-KIT levels correlating with efficacy (3). This RTK inhibitor does not induce regression of primary tumors but slows the progression of tumor growth, suggesting the greatest role for VEGF antagonists may be to prevent the formation of new blood vessels, during and after conventional therapy is given to existing neoplastic disease (4). Sunitinib and its chloro-substituted congener, SU11652, kill HeLa cervix carcinoma, U-2-OS osteosarcoma, Du145 prostate carcinoma and WEHI-S fibrosarcoma cells at low micromolar concentrations by accumulating rapidly in lysosomes and disturbing their pH regulation and ultrastructure, and eventually leading to the leakage of lysosomal proteases into the cytosol (5). Lysosomal destabilization was preceded by an early inhibition of acid sphingomyelinase (ASM), a lipase that promotes lysosomal membrane stability (5). **Drug Interactions:** Sunitinib interacts with CYP3A4 inducers, inhibitors and substrates as well as with P-glycoprotein and ABCG2 substrates (6). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** Mendel, Laird, Xin, *et al.* (2003) *Cancer Res.* **9**, 327. **2.** Sun, Liang, Shirazian, *et al.* (2003) *J. Med. ### Superoxide Anion

This paramagnetic radical anion  $O_2^-$ , which is generated in a number of biochemical processes, is formally equivalent to the addition of an unpaired electron to dioxygen. Because of the spin restriction, univalent  $O_2$  reduction to  $O_2^-$  is facile, and  $O_2^-$  production by spontaneous and enzyme-catalyzed reactions is well-documented.  $O_2^-$  is the product of the reaction catalyzed by xanthine oxidase. Superoxide is a strong oxidizing agent and can have significant effects on a cell (1-3). Although  $O_2^-$  can initiate and propagate free radical oxidations of leukoflavins, tetrahydropterins, catecholamines, and related compounds and can inactivate [4Fe-4S]-containing dehydratases, it does not significantly attack polyunsaturated lipids or DNA. In what Fridovich (4) referred to as the "*in vivo* Haber-Weiss reaction,"  $O_2^-$  increases "free" iron by oxidizing the [4Fe-4S] center of dehydratases such as dihydroxy acid dehydrase, 6-phosphogluconate dehydrase, fumarases A and B, and aconitase. The released iron is maintained in its reduced state by cellular reductants, and the Fe(II) reacts with  $H_2O_2$ , as in the Fenton

reaction, to yield Fe(III) +  $HO^\cdot$  or its formal equivalent, Fe(II)O. This was proposed to provide an explanation for the enhanced  $O_2$ -dependent mutagenesis exhibited by *sodA sodB E. coli*, and it has been experimentally verified. The importance of release of iron by  $O_2^-$  from [4Fe-4S] clusters of dehydratases was underscored by the recent observation of the complementation of *sodA sodB E. coli* by insertion and overexpression of rubredoxin reductase. Several superoxide dismutases (EC 1.15.1.1) catalyze the dismutation of superoxide:  $2 O_2^- + 2 H^+ \rightarrow O_2 + H_2O_2$ . In aqueous solutions,  $O_2^-$  is highly hydrated. The oxygen-oxygen bond length is slightly longer (0.133 nm) in superoxide than in dioxygen. Stable ionic superoxides are formed by certain alkali metals. Transient levels of superoxide in aqueous solution can be generated a number of ways. **Target(s):** guanylate cyclase (1); and 6-phosphogluconate dehydratase (2,3). **1.** Bruene, Schmidt & Ullrich (1990) *Eur. J. Biochem.* **192**, 683. **2.** Gardner & Fridovich (1991) *J. Biol. Chem.* **266**, 1478. **3.** Rodriguez, Wedd & Scopes (1996) *Biochem. Mol. Biol. Int.* **39**, 783. **4.** Fridovich (1997) *J. Biol. Chem.* **272**, 18515.

### Suplatast

This orally active T-helper cell-2 (*or* Th2) cytokine inhibitor and anti-allergy drug (FW = 209.20 g/mol; CAS 94055-76-2 (for tosylate salt); Solubility: 100 mM in  $H_2O$ ; 100 mM in DMSO), also named [3-[[4-(3-ethoxy-2-hydroxypropoxy)phenyl]amino]-3-oxopropyl]dimethylsulfonium ion, attenuates IL-2, IL-5 and IL-13 production, but is without effect on IFN- $\gamma$  production. Suplatast is an immunoregulator that suppresses IgE production, eosinophil infiltration and histamine release. It also exhibits anti-asthmatic, anti-inflammatory and anti-fibrotic activity *in vivo*. Suplatast tosylate inhibits histamine signaling by direct and indirect down-regulation of histamine  $H_1$  receptor gene expression through suppression of histidine decarboxylase and IL-4 gene transcription (4). **1.** Kurokawa, Kawazu, Asano, *et al.* (2001) *Mediators Inflamm.* **10**, 333. **2.** Hsu, Yang, Goto, *et al.* (2007) *Transpl. Immunol.* **18**, 108. **3.** Furonaka, Hattori, Tanimoto, *et al.* (2009) *J. Pharmacol. Exp. Ther.* **328**, 55. **4.** Shahriar, Mizuguchi, Maeyama, *et al.* (2009) *J Immunol.* **183**, 2133.

### Suprafenacine

This colchicine site-directed ligand (FW = 282.35 g/mol; IUPAC: 4,5,6,7-tetrahydro-1*H*-indazole-3-carboxylic acid [1*p*-tolyl-meth-(*E*)-ylidene]hydrazide; Abbreviation: SRF), first identified by *in silico* screening of annotated chemical libraries, binds to tubulin and inhibits its polymerization (*i.e.*, microtubule self-assembly). Suprafenacine treatment of human cancer cell lines (*e.g.*, HeLa ( $IC_{50}$  = 0.20  $\mu M$ ), MDA-MB-231 ( $IC_{50}$  = 0.25  $\mu M$ ), A549 ( $IC_{50}$  = 0.23  $\mu M$ ), HCT15 ( $IC_{50}$  = 0.24  $\mu M$ ), Jurkat ( $IC_{50}$  = 0.21  $\mu M$ ), and SH-SY5Y ( $IC_{50}$  = 0.08  $\mu M$ )) as well as CCL-116 ( $IC_{50}$  = 0.21  $\mu M$ ) and WI-38 ( $IC_{50}$  = 0.22  $\mu M$ ) human fibroblast cell lines leads to  $G_2/M$  cell cycle arrest and subsequent cell death by a mitochondria-mediated apoptotic pathway. Significantly, SRF bypasses the p-glycoprotein multi-drug resistance system, explaining why it is more potent than taxol in inhibiting SH-SY5Y neuroblastoma and HCT-15 colorectal adenocarcinoma cells, as both these cancer cell types express elevated levels of P-gp protein. Despite

the structural dissimilarity, SRF and colchicine share tubulin binding site, suggesting a similar role in disrupting microtubule self-assembly (**See Colchicine**). 1. Choi, Chattopadhyaya, Thanh, *et al.* (2014) *PLoS One* **9**, e110955.

### Suprofen

This anti-inflammatory agent (FW<sub>free-acid</sub> = 260.31 g/mol; pK<sub>a</sub> = 3.91; soluble in methanol and ethanol), also known as  $\alpha$ -methyl-4-(2-thienylcarbonyl)benzeneacetic acid, is an orally effective non-narcotic analgesic having a potent inhibitory action on prostaglandin biosynthesis. **Target(s)**: anandamide deamidase (1); carbonyl reductase (2); cyclooxygenase, *or* prostaglandin-endoperoxide synthase (3-6); and  $3\alpha$ -hydroxysteroid dehydrogenase (7). 1. ### Suramin

This hygroscopic hexasulfonated naphthylurea (FW<sub>hexasodium-salt</sub> = 1429.19 g/mol; CAS 129-46-4), also known as Bayer 205, is a strong inhibitor of a wide variety of enzymes. Suramin is also known to inhibit the binding of growth factors (*e.g.*, epidermal growth factor, platelet-derived growth factor, and tumor growth factor- $\beta$ ) to their receptors and thus antagonize the ability of these factors to stimulate growth of tumor cells *in vitro*. Suramin readily binds to plasma proteins, suggesting that it may enter *T. brucei* by some form of receptor-mediated endocytosis, possibly bound to LDL. That said, suramin's actual mode of inhibitory action remains uncertain, as do its therapeutic targets. Suramin is also a non-selective P<sub>2</sub> purinergic receptor antagonist. It likewise blocks calmodulin binding to recognition sites and G-protein coupling to GCPRs. Increases open probability of ryanodine receptor (RyR) channels. **Clinical Applications**: Suramin is a trypanocide used to combat the early stages of African trypanosomiasis. It is also an effective anthelmintic used to treat onchocerciasis. Suramin is ineffective against early stage of *Trypanosoma brucei* gambiense and late-stages of both Human African Trypanosomiasis, *or* HATs. As a result of campaigns of coordinated surveillance and treatment programs using suramin and other drugs (**See also** Pentamidine, Melarsoprol, and Eflornithine), the number of people succumbing to HAT has fallen considerably, now to around 70,000 annually. (**See also** NF062, NF127, *etc.*) **Target(s)**: acid amyloglucosidase (1); acrosin (92); O<sup>6</sup>-alkylguanine-DNA alkyltransferase (2); apyrase (3,85-89); arylsulfatase A, weakly inhibited (4); ascorbate oxidase (5); ATPase, Mg<sup>2+</sup> (6,7); bis(5'-adenosyl)-triphosphatase (82); bis(5'-nucleosyl)-tetraphosphatase, asymmetrical (82); cathepsin G (8); cellulose 1,4- $\beta$ -cellobiosidase, weakly inhibited (93); choline acetyltransferase (9); choline dehydrogenase (5); chymase10; chymosin, *or* renin (5); citrate synthase (11); complement factor I (91); cyclin-dependent kinases (12); cytochrome c oxidase (5); diadenosine polyphosphate hydrolase (13,14); DNA-dependent protein kinase (15); DNA polymerase (16-20); DNA primase (17,20); DNA topoisomerase II (21-23,75); duck hepatitis B virus reverse

transcriptase (18); ecto-ATPase (24-31); ectonucleotide diphosphohydrolase, *or* nucleotide diphosphatase (32,83); folicypolyglutamate synthetase (33);  $\beta$ -fructofuranosidase, *or* invertase (34,35); fructose-1,6-bisphosphate aldolase (77-79); fumarase (36);  $\beta$ -galactocerebrosidase, weakly inhibited (4);  $\alpha$ -galactosidase, weakly inhibited (1,4); glucocerebrosidase, weakly inhibited (4); glucose-6-phosphate dehydrogenase (37); glucose-6-phosphate isomerase (38); glyceraldehyde-3-phosphate dehydrogenase (39); glycerol-3-phosphate dehydrogenase (40); GM<sub>3</sub>-sialidase (4,41); heparanase (42,43); heparin-sulfate lyase (76); hexokinase (5,44);  $\beta$ -hexosaminidase (4,45); HIV reverse transcriptase (46-49); hyaluronidase (50); iduronate-2-sulfatase (94); lactate dehydrogenase (51,52); lysozyme (53); malate dehydrogenase (51); malic enzyme (54); methenyltetrahydrofolate cyclohydrolase (90); monoamine oxidase (55); NADPH oxidase (56); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (80); neutrophil elastase (8); nucleotide diphosphatase (32,83,84); papain (5); pepsin (5); 6-phosphogluconate dehydrogenase (57); 3-phosphoglycerate kinase (58,97-99); phospholipase D (59); phospholipid-translocating ATPase, *or* flippase (81); prostate-specific membrane antigen, *or* glutamate exocarboxypeptidase (60); proteinase (38); protein kinase I (61); protein kinase C (62,63); protein-tyrosine-phosphatase (64,65,95); ribonuclease H (48); RNA-directed DNA polymerase, *or* reverse transcriptase (17,18,46-49,66,96); RNA polymerase (17); simian immunodeficiency virus reverse transcriptase (96); sphingomyelinase (4); steroid 5 $\alpha$ -reductase (67); succinate dehydrogenase (5,68); telomerase (69); thymidine kinase (100); thymidylate synthase (70); triose-phosphate isomerase (71); trypsin (5,72); vacuolar H<sup>+</sup>-ATPase (73); and urease (5,74). 1. ### Surfactin

This lipopeptide antibiotic (FW<sub>free-acid</sub> = 1036.34 g/mol; CAS 24730-31-2) from *Bacillus subtilis* is a potent surfactant and can cause lysis of erythrocytes and bacteria (1). Surfactin is produced and contains  $\beta$ -hydroxy-fatty acid of 13-to-15 carbon atoms in length, depending upon the composition of the fermentation medium. **Target(s):** phospholipase A<sub>2</sub>, platelet (2). **1.** Arima, Kakinuma & Tamura (1968) *Biochem. Biophys. Res. Commun.* **31**, 488. **2.** Kim, Jung, Lee, *et al.* (1998) *Biochem. Pharmacol.* **55**, 975.

### Survivin

This caspase-inhibiting homodimer and anti-apoptotic factor (MW = 34 kDa) is a structurally unique member of the Inhibitors-of-Apoptosis Protein (IAP) family and plays a role in controlling cell division and inhibiting apoptosis. The respective  $K_i$  values for surviving survivin inhibition of caspase-3 and caspase-7 are 36 and 16 nM (1,2). The shared structural feature of all IAP family members is a 70-amino acid motif, termed BIR,

that is present in one to three copies. Survivin expression is a predictor of both poor prognosis and decreased survival time in cancer therapy. In view of its likely role in conferring chemotherapeutic and radiotherapeutic resistance, survivin expression should prove to be a druggable target. **1.** Deveraux, Welsh & Reed (2000) *Meth. Enzymol.* **322**, 154. **2.** Shin, Sung, Cho, *et al.* (2001) *Biochemistry* **40**, 1117.

### Suvorexan

This orally bioavailable, dual orexin (hypocretin) receptor antagonist (FW = 450.92 g/mol; CAS 1030377-33-3; Solubility: 10 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known by the proprietary name Belsontra<sup>®</sup>, its codename MK-4305 and IUPAC name 5-chloro-2-[(5R)-5-methyl-4-[5-methyl-2-(2H-1,2,3-triazol-2-yl)benzoyl]-1,4-diazepan-1-yl]-1,3-benzoxazole, targets OX<sub>1</sub> and OX<sub>2</sub> receptors, with  $K_i$  values of 0.55 nM and 0.35 nM, respectively (1,2). **Pharmacokinetics:** Bioavailability is 82%, with circulating suvorexan highly protein-bound. Food delays the time to maximum plasma concentration. Suvorexan is metabolized by the liver. It is excreted renally (23% unchanged) and through feces (66% unchanged), with an elimination half-life of 12 hours. EMPA, suvorexan, almorexant and TCS-OX-29 all bind to the OX<sub>2</sub> receptor with moderate to high affinity, with  $pK_i$  values  $\geq 7.5$ , whereas the primarily OX<sub>1</sub> selective antagonists SB-334867 and SB-408124 displayed low affinity, with  $pK_i$  values  $\sim 6$  (2). Competition kinetic analysis showed that the compounds displayed a range of dissociation rates from very fast (TCS-OX2-29,  $k_{off} = 0.22 \text{ min}^{-1}$ ) to very slow (almorexant,  $k_{off} = 0.005 \text{ min}^{-1}$ ). There is a clear correlation between association rate and affinity (2). Given CYP3A's role in suvorexan metabolism, dosage should be reduced when other drugs (*e.g.*, verapamil, erythromycin, diltiazem, or dronedarone) are in use. **Structural Basis of Suvorexant-Receptor Interactions:** A 2.5-Å resolution structure reveals that suvorexant adopts a  $\pi$ -stacked horseshoe-like conformation when bound deep in the orthosteric pocket of the receptor (3). Those interactions are stabilized by a network of extracellular salt bridges and blocking transmembrane helix motions necessary for activation. Computational docking suggests that other classes of synthetic antagonists may interact with the receptor at a similar position in an analogous  $\pi$ -stacked fashion (3). The hOX<sub>1</sub>R structures also reveal a conserved amphipathic  $\alpha$ -helix, in the extracellular N-terminal region, that interacts with orexin-A and is essential for high-potency neuropeptide activation at both receptors (4). Human receptors OX<sub>1</sub>R and OX<sub>2</sub>R are 64% identical in sequence and have overlapping, but distinct, physiological functions and therapeutic profiles (4). **(Other Orexin Receptor Antagonists include:** Almorexant, Filorexant, Lemborexant, and SB-649868) **1.** Cox, Breslin, Whitman, *et al.* (2010) *J. Med. Chem.* **53**, 5320. **2.** Mould, Brown, Marshall & Langmead (2014) *Brit. J. **Suxamethonium Ion, See Succinylcholine**

### SW 033291

This high-affinity 15-PGDH inhibitor (FW = 412.58 g/mol; CAS 459147-39-8; Soluble to 100 mM in DMSO), also named 2-(butylsulfanyl)-4-phenyl-6-(2-thienyl)thieno[2,3-*b*]pyridin-3-amine, targets 15-hydroxy-prostaglandin dehydrogenase ( $K_i = 0.1$  nM), increasing PGE<sub>2</sub> levels in A549 cells *in vitro* and in bone marrow, colon, lung and liver in mice. Prostaglandin PGE<sub>2</sub>, a lipid signaling molecule that supports expansion of several types of tissue stem cells, is a candidate therapeutic target for promoting tissue regeneration *in vivo*. SW-033291 also promotes tissue regeneration in mouse models of colon and liver injury. Moreover, tissues from 15-PGDH-null mice demonstrate similar increased regenerative capacity. 1. Zhang, Desai, Yang, *et al.* (2015) *Science* **348**, 2340.

### Swainsonine

This indolizidine alkaloid (FW<sub>free-base</sub> = 173.21 g/mol; CAS 72741-87-8), isolated from *Swainsona canescens* and spotted locoweed (*Astragalus lentiginosus*), inhibits  $\alpha$ -mannosidases, leading to the accumulation of mannose-rich oligosaccharides in the lysosomal system. Its epimers are milder inhibitors. Swainsonine prevents complex glycoprotein formation in cultured cells, apparently by inhibiting the mannosyl trimming process. It blocks the synthesis of complex *N*-linked glycoproteins by inhibiting Golgi mannosidase, an enzyme that normally acts on glycoproteins containing GlcNAcMan<sub>3</sub>GlcNAc<sub>2</sub> groups. Ingestion of *Swainsona* sp. induces mannosidosis, a condition resembling hereditary lysosomal storage disease. Swainsonine and swainsonine *N*-oxide are likewise believed to be causative agents of locoism, a chronic neurological disorder. **Target(s):**  $\beta$ -D-arabinosidase, moderately inhibited (1); arylmannosidase (2,3);  $\beta$ -galactosidase, moderately inhibited (1);  $\alpha$ -glucosidase, moderately inhibited (1);  $\beta$ -glucuronidase, moderately inhibited (1); glycoprotein processing (4-10);  $\alpha$ -mannosidase (1,2,4-6,11-18,36-45);  $\alpha$ -1,2-mannosidase, *Trypanosoma cruzi* and *Vigna umbellata* (34,35); mannosyl-oligosaccharide 1,3-1,6- $\alpha$ -mannosidase, mannosidase II (1,2,4-6,19-33,35); and  $\beta$ -D-xylosidase, moderately inhibited (1). 1. ### Swertifrancheside

This flavonoxanthone *C*-glucoside (FW = 720.60 g/mol; CAS 155740-03-7), known systematically as 1,5,8-trihydroxy-3-methoxy-7-(5',7',3",4"-tetrahydroxy-6'-*C*- $\beta$ -D-glucopyranosyl-4'-oxy-8'-flavyl)xanthone, from *Swertia franchetiana* inhibits DNA ligase (ATP), human, IC<sub>50</sub> = 11  $\mu$ M (1), HIV-1 reverse transcriptase, IC<sub>50</sub> = 43  $\mu$ M (2,3), and RNA-directed DNA polymerase (2,3). 1. Tan, Lee, Lee, *et al.* (1996) *Biochem. J.* **314**, 993. 2. Pengsuparp, Cai, Constant, *et al.* (1995) *J. Nat. Prod.* **58**, 1024. 3. Wang, Hou, Liu, *et al.* (1994) *J. Nat. Prod.* **57**, 211.

### Swinholide A

This marine toxin (FW = 1387.92 g/mol; CAS 95927-67-6) from the sponge *Theonella swinhoi* is a 44-carbon, dimeric dilactone macrolide with a C<sub>2</sub> axis of symmetry. At concentrations as low as 80 nM, swinholide A causes rounding of cultured mouse embryo fibroblast cells within one hour, attended by massive loss of the actin cytoskeletal network, as evidenced by treatment with fluorescently labeled phalloidin, the latter binding only to filamentous actin (1). At 10–50 nM swinholide, partial cell retraction and diminution of filament bundles (stress fibers) commences after 2–4 hours, with complete loss by 5–7 hours. Swinholide action is the consequence of efficient actin filament severing (1). At much higher concentrations,

swinholid A binds very tightly to actin dimers with unit stoichiometry, a behavior that may underlie its filament-severing action. 1. Bubb & Spector (1998) *Meth. Enzymol.* **298**, 26. 2. Bubb, Spector, Bershadsky & Korn (1995) *J. Biol. Chem.* **270**, 3463. 3. Saito, Watabe, Ozaki, *et al.* (1998) *J. Biochem.* **123**, 571.

**SX 001**

This protein kinase inhibitor (FW = 483.96 g/mol; CAS 309913-42-6; Soluble to 100 mM in DMSO), also named 6-chloro-5-[[4-[(4-fluorophenyl)methyl]-1-piperidinyl]carbonyl-*N,N,N*-trimethyl-*α*-oxo-1*H*-indole-3-acetamide, selectively targets p38 $\alpha$  (IC<sub>50</sub> = 9 nM), with weaker inhibition of p38 $\beta$  (IC<sub>50</sub> = 90 nM) and JNK-2 (IC<sub>50</sub> = 100 nM) and insignificant inhibition of p38 $\gamma$ , p38 $\delta$ , ERK-2, and JNK-1. 1. Lee & Dominguez (2005) *Curr. Med. Chem.* **12**, 2979.

**SXN101959**

This recombinant Targeted Secretion Inhibitor (MW = 105 kDa) is a proprietary recombinant protein that inhibits growth hormone (GH) hypersecretion from the benign pituitary tumor responsible for acromegaly. **Mode of Inhibitor Action:** SXN10195 consists of covalently linked botulinum toxin light chain designed to target GHRH receptor-rich somatotrophs, thereby allowing internalization of the endopeptidase (light chain) and leading to potent inhibition of vesicular secretion of growth hormone. The expressed single-chain polypeptide is activated by proteolytic cleavage into a 100-kDa heavy chain (HC) and a 50-kDa light chain (LC), linked together by a single disulfide bond. In TSIs, three distinct protein domains play key roles in inhibiting vesicle fusion in target neurons: a binding domain and a membrane-translocation domain (both located in the HC) and an endopeptidase domain (located in the LC) (1,2). The binding domain confers high-affinity selective binding to the target neurons, linking to the membrane translocation domain via a peptide bond. Noncovalent interactions and a single disulfide linking translocation and endopeptidase domains, facilitating entry assist into a target cell's cytosol, where it is released (presumably through the action of reduced glutathione). The endopeptidase then cleaves SNARE proteins, which play an essential role in vesicle docking and enable secretion of its contents. By cleaving them, the endopeptidase prevents formation of a productive SNARE complex and inhibits neurotransmitter secretion (3-5). The duration of that inhibition can range from less than a month to over six months depending on the LC and the specific SNARE protein that is cleaved. In acromegaly, GH hypersecretion is presently treated with somatostatins to reduce secretion, but over one-half of the patients are refractory to this treatment (6). In principle, Syntaxin's TSI strategy, which provides a unique and potentially longer-lasting treatment for inhibiting GH release, is generalizable to other vesicle secretion disorders. 1. Swaminathan (2011) *FEBS J.* **278**, 4467. 2. Lacy & Stevens (1999) *J. Mol. Biol.* **291**, 1091. 3. Simpson (1980) *J. Pharmacol. Exp. Ther.* **212**, 16. 4. Schiavo, *et al.* (1992) *Nature* **359**, 832. 5. Montecucco & Schiavo (1994) *Mol. Microbiol.* **13**, 1. 6. Melmed (2006) *New Engl. J. Med.* **355**, 2558.

**SYM 2206**

This AMP<sub>A</sub> receptor antagonist and anticonvulsant (FW = 366.42 g/mol; CAS 173952-44-8; Soluble to 100 mM in DMSO), also named (±)-4-(4-aminophenyl)-1,2-dihydro-1-methyl-2-propylcarbamoyl-6,7-methylene-dioxiphthalazine, targets the  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor, *or* AMP<sub>A</sub> receptor (IC<sub>50</sub> = 2.8  $\mu$ M), acting allosterically at the same regulatory site as GYKI 52466, GYKI 53655, and other benzodiazepines, but does not bind directly to the diazepam binding site. SYM 2206 is selective for AMP<sub>A</sub> relative to kainate receptor sub-types. 1. Pelletier, *et al.* (1996) *J. Med. Chem.* **39**, 343. 2. Li, *et al.* (1999) *Nature* **397**, 161. 3. Bleakman, *et al.* (2002) *Curr. Pharm. Des.* **8**, 873.

**Symadex**

This DNA topoisomerase II inhibitor, also known as C-1311 (FW<sub>free-base</sub> = 350.42 g/mol; CAS 138154-39-9), induces cell death by mitotic catastrophe in human colon carcinoma cells (1,2). Although most topoisomerase II inhibitors are recognized by the P-glycoprotein, a few are either poor substrates for the P-glycoprotein (amsacrine, mitoxantrone) or, in the case of Symadex, not recognized at all (1). Vincristine-resistant cells were 4- to 20-times cross-resistant to tested topoisomerase II inhibitors than are parental cells. Vincristine-resistant cells were also cross-resistant to ICRF-187, a topoisomerase II inhibitor that stabilizes noncovalent, rather than covalent complexes between DNA and topoisomerase II (2). 1. Skladanowski, Plisov, Konopa & Larsen (1996) *Mol. Pharmacol.* **49**, 772. 2. Skladanowski, Come, Sabisz, Escargueil & Larsen (2005) *Mol. Pharmacol.* **68**, 625.

**Syn-A<sub>2</sub>**

This synthetic, amphiphilic peptide amide (FW = 2774 g/mol; Sequence: MLSRLSLRLLSRLSRLLSRYLL-NH<sub>2</sub>) inhibits bovine heart mitochondrial F<sub>1</sub> ATPase, *or* H<sup>+</sup>-transporting two-sector ATPase, IC<sub>50</sub> = 40 nM (**See also** Syn-C). The order of effectiveness of the peptide inhibitors (expressed as IC<sub>50</sub> values is: Syn-A<sub>2</sub> (40 nM), Syn-C (54 nM), and melittin (5  $\mu$ M). Rhodamine B, rhodamine 123, dequalinium, melittin, and Syn-A<sub>2</sub> all showed noncompetitive inhibition, whereas other inhibitors (rhodamine 6G, rosaniline, malachite green, coriphosphine, acridine orange, and-Syn-C) showed mixed inhibition. With the exception of Syn-C, for which the slope replot was hyperbolic and the intercept replot was parabolic, steady-state kinetic analyses indicated that inhibition by the other inhibitors was complete. The inhibition constants obtained by steady-state kinetic analyses were in agreement with the IC<sub>50</sub> values for each inhibitor. Rhodamine 6G, rosaniline, dequalinium, melittin, Syn-A<sub>2</sub>, and Syn-C all protected F<sub>1</sub> against inactivation by the aziridinium form of quinacrine mustard in agreement with experimentally determined IC<sub>50</sub> values. 1. Bullough, Ceccarelli, Roise & Allison (1989) *Biochim. Biophys. Acta* **975**, 377.

**Syncurine, See Decamethonium Bromide**

**p-Synephrine**

This adrenergic receptor agonist (FW<sub>free-base</sub> = 167.09 g/mol; CAS 94-07-5), also known as sympatol, oxedrine, and 4-[1-hydroxy-2-(methylamino)ethyl]phenol, is a simple alkaloid that is biosynthesized in various *Citrus*

species (*Likely Pathway*: Tyrosine → Tyramine → *N*-Methyltyramine → Synephrine) through the successive action of tyrosine decarboxylase, tyramine *N*-methyltransferase, and *N*-methyl-tyramine- $\beta$ -hydroxylase. Synephrine exhibits distinct preference for the  $\alpha_1$  over the  $\alpha_2$  subtype, but its potency at these receptors is relatively low. It also has weak activity at 5-HT receptors and the Trace Adrenergic Amine Receptors TAAR1. Synephrine is a weak substrate for rat brain mitochondrial monoamine oxidase ( $K_m = 0.25$  mM). Synephrine significantly inhibits IL-4-induced eotaxin-1 expression, an effect that is mediated through the inhibition of STAT6 phosphorylation in the JAK/STAT signaling pathway (1). *p*-Synephrine also significantly stimulates glycogenolysis, glycolysis, gluconeogenesis, and oxygen uptake, and these effects are mediated by both  $\alpha$ - and  $\beta$ -adrenergic signaling, requiring simultaneous participation of both  $Ca^{2+}$  and cAMP (2). 1. Roh, Kim, Kim, *et al.* (2014) *Molecules* **19**, 11883. 2. de Oliveira, Comar, de Sá-Nakanishi, Peralta & Bracht (2014) *Mol. Cell Biochem.* **388**, 135.

### Synergistin A

This antibiotic (CAS 11126-45-7), also known as PA114A, is a polyunsaturated cyclic macrolactone from *Streptomyces olivaceus* that binds to the 50S ribosomal subunit and inhibits protein biosynthesis (chain elongation; peptidyltransferase). Synergistin A is reportedly identical to virginiamycin M<sub>1</sub>. See *Virginiamycin M<sub>1</sub>*. 1. Pestka (1974) *Meth. Enzymol.* **30**, 261.

### Synergistin B

This antibiotic (CAS 3131-03-1), also known as PA114B, is a cyclic hexadepsipeptide from *Streptomyces olivaceus* that binds to the 50S ribosomal subunit and inhibits protein biosynthesis (chain elongation; peptidyltransferase). Synergistin B is reportedly identical to pristinamycin IA. See *Pristinamycin IA*. 1. Pestka (1974) *Meth. Enzymol.* **30**, 261.

### Synip

This 553-residue cytoplasmic regulatory protein (MW = 61,662 Da), also known as Syntaxin 4-interacting protein and STX4-interacting protein, is an insulin-regulated syntaxin 4-binding protein that mediates the translocation of GLUT4-laden vesicles within adipocytes. Synip arrests SNARE-dependent membrane fusion, thereby preventing initiation of ternary SNARE complex assembly (1). It binds to GLUT4 exocytic SNAREs and inhibits the docking, lipid mixing, and content mixing phases of the vesicle fusion reaction. Synip is also phosphorylated on Ser-99 by PKB/Akt2 after treatment with insulin. Ser-99-Ala-Synip, a phosphorylation-deficient mutant, inhibits insulin-stimulated Glut4 translocation and 2-deoxyglucose uptake in adipocytes, demonstrating that Ser-99 phosphorylation is required for Glut4 translocation as well as glucose uptake in both adipocytes and podocytes (3) This study further suggests that defects in Synip phosphorylation may underlie insulin resistance and associated diabetic neuropathy (3). 1. Min, Okada, Kanzaki, *et al.* (1999) *Mol. Cell* **3**, 751. 2. Yu, Rathore & Shen (2013) *J. Biol. Chem.* **288**, 18885. 3. Yamada, Saito, Okada, *et al.* (2014) *Endocr J.* **61**, 523.

### Synthalin

This cationic reagent (FW<sub>dihydrochloride</sub> = 329.32 g/mol; CAS 301-15-5; Soluble to 5 mM in H<sub>2</sub>O; Symbol: bisG10), also known as decamethylenediguanidine, *N,N'*-1,10-decanediyl-bis(guanidine), and 1,10-bis(guanidino)-*n*-decane, will act as a potassium ion channel blocker and inhibit diamine oxidase. **Target(s)**:  $Ca^{2+}$  release (1); cytochrome *c* oxidase (2); diamine oxidase (3-5);  $K^+$  channels (6,7); *N*-methyl-D-aspartate receptor (8,9); and photophosphorylation (10). 1. Allard, Moutin & Ronjat (1992) *FEBS Lett.* **314**, 81. 2. Slater (1967) *Meth. Enzymol.* **10**, 48. 3. Zeller (1938) *Helv. Chim. Acta* **21**, 1645. 4. Reynolds, Baron & Edwards (1991) *J. Pharmacol. Exp. Ther.* **259**, 626. 10. Izawa & Good (1972) *Meth. Enzymol.* **24**, 355.

### Syringate

This benzoic acid derivative (FW<sub>free-acid</sub> = 198.18 g/mol; M.P. = 206-209°C), also known as 4-hydroxy-3,5-dimethoxybenzoic acid and 3,5-dimethoxy-4-hydroxybenzoic acid, is found in most angiosperms. **Target(s)**: 3-galactosyl-*N*-acetylglucosaminide 4- $\alpha$ -L-fucosyltransferase (1); glycoprotein 3- $\alpha$ -L-fucosyltransferase, weakly inhibited (1); hemoglobin S polymerization (2); lipase, or triacylglycerol lipase (3); and phenol sulfotransferase, or aryl sulfotransferase (4). 1. Niu, Fan, Sun, *et al.* (2004) *Arch. Biochem. Biophys.* **425**, 51. 2. Gamaniel, Samuel, Kapu, *et al.* (2000) *Phytomedicine* **7**, 105. 3. Karamac & Amarowicz (1996) *Z. Naturforsch. [C]* **51**, 903. 4. Yeh & Yen (2003) *J. Agric. Food Chem.* **51**, 1474.

### Syringolin A

This plant pathogen virulence factor and irreversible proteasome inhibitor (FW = 493.60 g/mol; CAS 212115-96-3; Symbol: SylA), also systematically named *N*-[1-[(3*E*,9*Z*)-5-isopropyl-2,7-dioxo-1,6-diazacyclododeca-3,9-dien-8-yl]carbamoyl]-2-methylpropylcarbamoyl]-valine, isolated from the bacterial pathogen *Pseudomonas syringae*, is a nonribosomal cyclic peptide that targets the  $\beta 1$  caspase-like activity that cleaves after acidic residues, the  $\beta 2$  trypsin-like activity that cleaves after basic residues, and the  $\beta 5$  chymotrypsin-like activity that cleaves after hydrophobic residues (1). Syringolin A also preferentially inhibits  $\beta 2$  and  $\beta 5$  of the proteasome from *Arabidopsis thaliana*, both *in vitro* and *in vivo* (2). Syringolin A-negative mutants, which induce stomatal closure, can be complemented by exogenous addition of not only syringolin A but also MG132, a well-characterized and structurally unrelated proteasome inhibitor (See *MG132*), demonstrating that proteasome activity is crucial for guard cell function. The dipeptide tail of SylA contributes to  $\beta 2$  specificity, and the subunit selectivity can be explained on the basis of crystallographic findings (2). 1. Groll, Schellenberg, Bachmann, *et al.* (2008) *Nature* **452**, 755. 2. Schellenberg, Ramel & Dudler (2010) *Mol. Plant Microbe Interact.* **23**, 1287.

### SZL P1-41

This Skp2 inhibitor (FW = 420.52 g/mol; CAS 222716-34-9; Soluble to 20 mM in 1eq. HCl and to 5 mM in DMSO with gentle warming), also named 3-(2-benzothiazolyl)-6-ethyl-7-hydroxy-8-(1-piperidinylmethyl)-4*H*-1-benz

opyran-4-one, interferes with the assembly of Skp2-Skp1 complexes, selectively suppressing Skp2 SCF E<sub>3</sub> ligase activity, but without effect on the activity of other SCF complexes. SZL P1-41 also inhibits Skp2-mediated p27 and Akt ubiquitination *in vivo* and *in vitro*. It phenocopies the effects observed upon genetic Skp2 deficiency, such as suppressing survival

and Akt-mediated glycolysis and triggering p53-independent cellular senescence. SZL P1-41 also suppresses survival of cancer cell and cancer stem cells by triggering cell senescence and inhibiting glycolysis. SZL P1-41 exhibits antitumor effects in multiple animal models and cancer cell lines. I. Chan, Morrow, Li, *et al.* (2013) *Cell* **154**, 556.

**T**, See *L*-Threonine; Thymine; Tocopherol

**2,4,5-T**, See (2,4,5-Trichlorophenoxy)acetate

**T2AA**

This nonhormonal T<sub>3</sub> thyronine analogue (FW = 511.10 g/mol; CAS 1380782-27-3), also named (βS)-β-amino-4-(4-hydroxyphenoxy)-3,5-diiodobenzeneopropanol, inhibits (IC<sub>50</sub> ~1 μM) the binding of a PIP-box sequence peptide (*i.e.*, N-terminal 5-carboxyfluorescein-labeled SAVLQKKITDYFHPKK) to Proliferating Cell Nuclear Antigen (or PCNA) protein by competing for the same binding site, as evidenced by the co-crystal structure of the PCNA-T<sub>3</sub> complex at 2.1-Å resolution (1). PCNA is an essential component of the DNA replication apparatus and the DNA damage response pathway, supporting translesion DNA synthesis (TLS) by interacting with TLS polymerases through PIP-box interaction. The impetus for synthesizing this analogue was the discovery that 3,3',5'-triiodothyronine (T<sub>3</sub>) inhibits binding of a PIP-box sequence peptide to PCNA. T2AA abolishes PCNA binding to DNA polymerase δ within cellular chromatin. *De novo* DNA synthesis is also inhibited by T2AA, arresting cells in S-phase. T2AA inhibited growth of cancer cells with induction of early apoptosis. In cells lacking nucleotide-excision repair activity, T2AA inhibits reactivation of a reporter plasmid that is globally damaged by cisplatin, suggesting that the inhibitors blocked the translesion DNA synthesis (TLS) that allows replication of the plasmid. 1. Punchihewa, Inoue, Hishiki, *et al.* (2012) *J. Biol. Chem.* **287**, 14289. 2. Actis, Inoue, Evison, *et al.* (2013) *Bioorg. Med. Chem.* **21**, 1972.

**T-705**, See Favipiravir-β-ribosyl-triphosphate

**T70907**

This potent PPAR inhibitor (FW = 277.66 g/mol; CAS 313516-66-4) targets nuclear Peroxisome Proliferator-Activated Receptor γ, PPARγ (IC<sub>50</sub> = 1 nM) by reacting irreversibly with an active-site thiol at Cys-313 (1). T0070907 displays >800x selectivity over PPARα and PPARδ. In experiments on MDA-MB-231 and MCF-7 breast cancer cells, T0070907 inhibits proliferation, invasion and migration, but does not significantly affect apoptosis (2). T0070907 also mediates a dose-dependent decrease in PPARγ phosphorylation, DNA binding, and mitogen-activated protein kinase signaling. 1. Lee, Elwood, McNally, *et al.* (2002) *J. Biol. Chem.* **277**, 19649. 2. Zaytseva, Wallis, Southard & Kilgore (2011) *Anticancer Res.* **31**, 813.

**T0901317**

This cholesterol absorption inhibitor (FW = 481.30 g/mol; CAS 293754-55-9; λ<sub>max</sub> at 227, 265, 272 nm; Solubility: 96 mg/mL DMSO), also named *N*-(2,2,2-trifluoroethyl)-*N*-[4-[2,2,2-trifluoro-1-hydroxy-1-(trifluoromethyl)ethyl]phenyl]benzenesulfonamide, is a potent and selective agonist for the Liver X Receptor (LXR), EC<sub>50</sub> = ~50 nM, the Farnesoid X receptor (FXR), EC<sub>50</sub> = 5 μM, and the receptor pregnane X receptor (PXR). **Role as Cholesterol Absorption Inhibitor:** LXRα and LXRβ are nuclear hormone receptors that bind 22(*R*)-hydroxy-cholesterol and regulate the oxysterol-induced expression of cholesterol 7α-hydroxylase (CYP7A1), which catalyzes the rate-limiting step in bile acid synthesis (1). Acting through LXR, T0901317 increases expression of the ABCA1 reverse cholesterol transporter, thus increasing cholesterol efflux from enterocytes and having the overall effect of inhibiting cholesterol absorption. T0901317 activates (EC<sub>50</sub> = ~5 μM) bile acid FXRs, with ~10x more potency than natural ligand chenodeoxycholate (2). T0901317 induces PXR target gene expression in cells and animals, including the scavenger receptor CD36 (3). It also decreases amyloid-β production in cultured primary neurons (4). By binding to RORα (K<sub>i</sub> = 132 nM) and RORγ (K<sub>i</sub> = 51 nM), T0901317 modulates their interactions with transcriptional cofactor proteins (5). 1. Kumar, Solt, Conkright, *et al.* (2010) *Mol. Pharmacol.* **77**, 228.

**T-5601640**

This selective LIM kinase inhibitor (FW = 389.33 g/mol; CAS 924473-59-6; Solubility: 50 mM in DMSO), systematically named 3-methyl-*N*-[3-[[[3-(trifluoromethyl)phenyl]amino]carbonyl]phenyl]-5-isoxazolecarboxamide, targets LIM Kinase 2, or LIMK2. The latter directly phosphorylates and thereby inactivates cofilin family members, resulting in stabilization of filamentous (F)-actin. Some 40 eukaryotic LIM proteins are so named, because they share a highly conserved cysteine-rich structures containing 2 zinc fingers. LIMK1 and LIMK2 belong to a small subfamily with a unique combination of 2 N-terminal LIM motifs and a C-terminal protein kinase domain. Lim kinases are activated by signaling through small GTPases of the Rho family. T5601640 reduces cofilin phosphorylation in cells overexpressing LIMK2, but not LIMK1. It also attenuates the growth of several cancer cell lines (IC<sub>50</sub> = 10-30 μM), reducing phospho-cofilin levels and Panc-1 tumor size in a mouse xenograft model. 1. Rak, Haklai, Elad-Tzfadia, *et al.* (2014) *Oncoscience* **1**, 39.

**Tabtoxinine β-Lactam**

This lactam-containing glutamine analogue (FW = 188.18 g/mol), also named 2-amino-4-[3-hydroxy-2-oxo-azacyclobutan-3-yl]butanoate, from produced from tabtoxin in several *Pseudomonas syringae* pathovars, is an active site-directed, irreversible inhibitor of glutamine synthetase, wherein ATP is required for inactivation (1-3). The lactam ring is essential for inhibition. Tabtoxinine-β-lactam is generated by combining a 4-carbon fragment, a 2-carbon fragment, and a single carbon atom. The 4-carbon

fragment arises from aspartic acid, and the 2-carbon unit is donated from carbons 2 and 3 of pyruvate. The 6-carbon backbone of tabtoxinine- $\beta$ -lactam arises from the condensation of fragments from aspartate and pyruvate, most likely by using reactions analogous to the initial steps in the pathway of lysine biosynthesis. 1. Langston-Unkefer, Robinson, Knight & Durbin (1987) *J. Biol. Chem.* **262**, 1608. 2. Knight, Durbin & Langston-Unkefer (1986) *J. Bacteriol.* **166**, 224. 3. Thomas & Durbin (1985) *J. Gen. ### Tabun

This nerve poison (FW = 162.13 g/mol; CAS 77-81-6; M.P. =  $-50^{\circ}\text{C}$ ; B.P. =  $240\text{-}246^{\circ}\text{C}$ ), also known as ethyl-*N*-dimethyl phosphoramidocyanidate, was first developed as an insecticide in Germany in 1936. The first nerve agent to be synthesized, tabun's primary targets are acetylcholinesterase (1-7) and cholinesterase, or butyrylcholinesterase (1,2,7-9). Also known by its chemical warfare designation GA, tabun is a clear liquid with a slightly fruity odor (similar to that of bitter almonds, perhaps originating from the presence of contaminating cyanide). Tabun is extremely toxic, and vapors are readily absorbed through the skin, eyes, and nasal mucosa. The skin absorption  $\text{LD}_{50}$  in man is 1-1.5 g. The i.p.  $\text{LD}_{50}$  in mice is considerably lower (0.6 mg/kg). The  $\text{LC}_{50}$  (i.e., the concentration in air that is lethal to 50% of exposed individuals) is 1-2 ppm. This chemical warfare agent was reportedly used by Iraq in its war with Iran in March of 1984. A United Nations investigation team verified tabun use, and Iran had reported prior use of nerve agents, dating back to 1980. 1. Holmstedt (1959) *Pharmacol. Rev.* **11**, 567. 2. ### Tacedinaline

An orally bioavailable, antineoplastic agent (FW = 269.32 g/mol; CAS 112522-64-2, 1299346-14-7 (HCl), 1353653-79-8 (TFA)); Solubility: 50 mg/mL DMSO; <1 mg/mL  $\text{H}_2\text{O}$ ), also known as CI994, PD-123654 and systematically named 4-(acetylamino)-*N*-(2-aminophenyl)benzamide, inhibits histone deacetylation ( $\text{IC}_{50}$  = 0.57  $\mu\text{M}$ ), resulting in histone hyperacetylation, induction of cell differentiation, inhibition of cell proliferation, and apoptosis in susceptible tumor cell populations. 1. Methot, et al. (2008) *Bioorg. Med. Chem. Lett.* **18**, 973. 2. Loprevite, et al. (2005) *A. Oncol. Res.* **15**, 39. 3. Gediya, et al. (2008) *Bioorg. Med. Chem.* **16**, 3352. 4. LoRusso, et al. ### Tacrine, See 9-Amino-1,2,3,4-tetrahydroacridine

### (RS)-( $\pm$ )-Tacrine(10)-hupyrindone

This dicationic alkylene-linked alkaloid (FW = 502.74 g/mol), consisting of tacrine (See 9-Amino-1,2,3,4-tetrahydroacridine) and hupyrindone, inhibits acetylcholinesterase (AChE) with far greater affinity than with either tacrine or hupyrindone alone. One unit of the pseudodimeric inhibitor is bound at the "anionic" subsite of the active site, situated near the bottom of the active-site gorge, as observed for the *Torpedo californica* AChE complex. The second unit interacts with the peripheral "anionic" site (PAS) located at the top of the gorge, where it is hydrogen-bonded to the side-chains of residues belonging to an adjacent, symmetry-related AChE molecule covering the gorge entrance. 1. Haviv, Wong, Greenblatt, et al. (2005) *J. Amer. Chem. Soc.* **127**, 11029.

### Tacrolimus, See FK-506

### Tadalafil

This orally active phosphodiesterase inhibitor (FW = 377.40 g/mol; CAS 171596-29-5), systematically named (6*R-trans*)-6-(1,3-benzodioxol-5-yl)-2,3,6,7,12,12a-hexahydro-2-methylpyrazino[1',2':1,6]pyrido[3,4-*b*]indole-1,4-dione) and marketed under the tradename Cialis<sup>TM</sup>, is a potent, long-lasting vasodilator that is widely used to treat erectile dysfunction and pulmonary arterial hypertension. Tadalafil exhibits high selectivity for 3',5'-cyclic-GMP phosphodiesterase Type 5 over the other phosphodiesterases. PDE5 inhibition within the corpus cavernosum increases intracellular cGMP levels, facilitating relaxation of smooth muscle and resulting in penile erection. Tadalafil is also cardiomyoprotective in cases of ischemia/reperfusion injury, doxorubicin cardiotoxicity, ischemic/diabetic cardiomyopathy, and cardiac hypertrophy, acting to increase the expression of nitric oxide synthases, activating protein kinase G (PKG), to stimulate PKG-dependent hydrogen sulfide generation, and to enhance phosphorylation of glycogen synthase kinase-3 $\beta$ , the latter a master switch immediately proximal to mitochondrial permeability transition pore as well as the end-effector of cardioprotection. An increase in Bcl2/Bax during early-phase and transcriptional upregulation of PKG-I by STAT3 during late-phase were responsible for stem cell protection by tadalafil against ischemic injury (11). Tadalafil also appears to beneficially modulate the tumor micro- and macro-environment in patients with head and neck squamous cell carcinoma (HNSCC) by lowering myeloid-derived suppressor cells (MDSC) and regulatory T (Treg) cells and by increasing tumor-specific CD8(+) T cells in a dose-dependent fashion (12). **Pharmacokinetic Parameters:** In healthy subjects, tadalafil is absorbed rapidly, with a mean  $C_{\text{max}}$  of 378  $\mu\text{g}\cdot\text{Liter}^{-1}$  for a 20-mg dose at 2 hours, declining exponentially ( $t_{1/2}$  = 17.5 hours) (12). The mean oral clearance (CL/F) is 2.48  $\text{Liters}\cdot\text{hour}^{-1}$  and apparent volume of distribution is 62.6 Liters. There is no clinically meaningful effect of BMI, age, gender or smoking. Exposure is also substantially unaffected by time of dosing. Food has negligible effects on bioavailability, as assessed by  $C_{\text{max}}$  and AUC (12). Parameters were proportional to dose, indicating that doubling the dose doubled exposure. Steady-state is attained by day-5 after once-daily administration, with an accumulation that is consistent with its  $t_{1/2}$  (13). 1. Rotella (2002) *Nat. Rev. Drug Discov.* **1**, 674. 2. ## TAE684

This ALK protein kinase inhibitor (FW = 614.21 g/mol; CAS 761439-42-3; Solubility: 3 mg/mL DMSO; < 1 mg/mL H<sub>2</sub>O), also known as NVP-TAE684 and systematically named 5-chloro-*N*<sup>4</sup>-(2-(isopropylsulfonyl)phenyl)-*N*<sup>2</sup>-(2-methoxy-4-(4-(4-methylpiperazin-1-yl)piperidin-1-yl)phenyl)pyrimidine-2,4-diamine, targets Nucleophosmin-Anaplastic Lymphoma Kinase (NPM-ALK), an oncogenic fusion protein that is formed by (2;5)(p23;q35) translocation and is constitutively overexpressed and/or activated in anaplastic large-cell lymphomas (ALCLs) and thereby drives tumor cell survival and proliferation. NVP-TAE684 blocks the growth of ALCL-derived and ALK-dependent cell lines with IC<sub>50</sub> values between 2-10 nM (1). NVP-TAE684 treatment results in rapid and sustained inhibition of NPM-ALK phosphorylation and its downstream effectors, with subsequent induction of apoptosis and cell-cycle arrest. *In vivo*, TAE684 suppresses lymphomagenesis in two independent models of ALK-positive ALCL and induces regression of established Karpas-299 lymphomas (1). TAE-684 is also active against crizotinib-resistant (even at 1 μM) cells harboring the L1196M gatekeeper mutation within the kinase domain. Other constitutively active ALK mutations (e.g., G1128A, I1171N, F1174L, R1192P, F1245C and R1275Q) can be blocked by crizotinib and/or TAE684, although some mutants require high levels of inhibitor (3). Unlike crizotinib, the sulfonated aniline moiety of TAE684 makes hydrophobic interactions with the Gly1123-His1124 segment, a property likely to account for the latter's actions (4). NPM-ALK is also a Hsp90-client tyrosine kinase, whose expression and tyrosine phosphorylation is down-regulated in ALK<sup>+</sup> CD30<sup>+</sup> lymphoma cells treated with the Hsp90 antagonist 17-allylamino,17-demethoxygeldanamycin (5). 1. Galkin, Melnick, Kim, *et al.* (2007) *Proc. Natl. Acad. Sci. U.S.A.* **104**, 270. *Erratum: Proc. Natl. Acad. Sci. U.S.A.* **104**, 2025. 2. Katayama, Khan, Benes, *et al.* (2011) *Proc. Natl. Acad. Sci. U.S.A.* **108**, 7535. 3. Schönherr, Ruuth, Yamazaki, *et al.* (2011) *Biochem. J.* **440**, 405. 4. Bossi, Saccardo, Ardini, *et al.* (2010) *Biochemistry* **49**, 6813. 5. Bonvini, Gastaldi, Falini & Rosolen (2002) *Cancer Res.* **62**, 1559.

## Tafamidis

This TTR amyloidosis drug (FW = 308.12 g/mol; CAS 594839-88-0), also named Fx-1006A, Vyndaqel<sup>®</sup>, and 2-(3,5-dichlorophenyl)-1,3-benzoxazole-6-carboxylate, binds to stabilizes the natively folded tetrameric form of the transthyretin (TTR). Tafamidis ameliorates transthyretin-related hereditary amyloidosis, also called familial amyloid polyneuropathy (FAP). In this rare but deadly neurodegenerative disorder, TTR dissociates in the rate-limiting step for amyloid fibril formation, causing failure of the autonomic nervous system and/or the peripheral nervous system (neurodegeneration) initially and later failure of the heart. (See also Tolcapone) 1. Bulawa, Connelly, DeVit, *et al.* (2012) *Proc. Natl. Acad. Sci. U.S.A.* **109**, 9629.

## Taflopiside

This antineoplastic agent (FW<sub>free-acid</sub> = 1116.72 g/mol; CAS 179067-42-6), also known as the 2'',3''-bispentafluorophenoxyacetyl-4'',6''-ethylidene-β-D-glucoside of 4'-phosphate-4'-demethylepipodophyllotoxin and F11782, is a dual inhibitor of DNA topoisomerases I and II (1,2). While most topo inhibitors typically favor either topo I or topo II, a smaller number that can act against both enzymes fall three classes: first, those drugs that bind to DNA via intercalation (e.g., benzopyridoindole intoplicine, TAS-103, XR11576, and NSC 366140; second, hybrid molecules, such as camptothecin-epipodophyllotoxin and ellipticine-distamycin hybrids, that consist of physically linked topo I and topo II pharmacophores; third, those that recognize structural motifs present in both topo I and II (e.g., NK 109, BN 80927 and F-11782). While DNA intercalation also factors into the action of some topo inhibitors, F11782 does not intercalate into DNA. 1. Kruczynski, Barret, van Hille, *et al.* (2004) *Clin. Cancer Res.* **10**, 3156. 2. Perrin, van Hille, Barret, *et al.* (2000) *Biochem. Pharmacol.* **59**, 807.

## D-Tagatose 1,6-Bisphosphate

This substrate analogue (FW<sub>free-acid</sub> = 340.11 g/mol; CAS 55529-38-9) weakly inhibits pyrophosphate-dependent phosphofructokinases from the facultative anaerobic bacterium *Propionibacterium freudenreichii* (K<sub>i</sub> = 0.82 mM) and the mung bean *Phaseolus aureus*. The dissociation constants for D-psicose 6-phosphate, D-tagatose 6-phosphate, and L-sorbose 6-phosphate are >10x that for D-fructose 6-phosphate, suggesting the stringent steric requirement for the D-threo (trans) configuration at the two nonanomeric furan ring hydroxyl groups. 1. Bertagnolli, Younathan, Voll, Pittman & Cook (1986) *Biochemistry* **25**, 4674.

## Tagetitoxin

This bacterial phytotoxin (FW = 416.30 g/mol; CAS 87913-21-1; *Symbol*: TGT) from *Pseudomonas syringae* *pv. tagetis* (1) inhibits multi-subunit RNA polymerases chloroplasts and bacteria (2) as well as eukaryotic pol III (3), all with low  $\mu\text{M}$  inhibition constants. This agent disrupts the ability of these enzymes to catalyze nucleotide addition reaction cycles consisting of phosphodiester bond formation, translocation, and binding of the subsequent nucleotide (4-6). A unique property of TGT is that it retards nucleotide addition in a sequence-dependent manner, but only at certain positions of the template (7). It neither alters the chemistry of RNA synthesis nor induces backward translocation. What's more, TGT does not compete with the nucleoside triphosphate (NTP) in the active center. Instead, it appears to increase the stability of the pre-translocated state of elongation complex, thus slowing down addition of the next nucleotide (7). The extent of inhibition directly depends on the intrinsic stability of the pre-translocated state on the target enzyme. What's more, the dependence of translocation equilibrium on the transcribed sequence results in a wide distribution (1-10<sup>3</sup> times) the inhibitory effect of TGT at different positions of the template, thus explaining sequence-specificity of TGT action (7). *Note*: Pralidoxime (or 2-[(hydroxyimino)methyl]-1-methylpyridin-1-ium) is often used, along with the muscarinic antagonist atropine, to reduce the parasympathetic effects of organophosphate poisoning. Pralidoxime is only effective in organophosphate toxicity and has no effect if the acetylcholinesterase is carbamylated, as occurs with neostigmine or physostigmine. 1. **Tagit**, See 3-(4-Hydroxyphenyl)propionic Acid N-Hydroxysuccinimide Ester

#### TAK-063

This orally active PDE inhibitor and potential schizophrenia drug (FW = 428.43 g/mol), also known as 1-[2-fluoro-4-(1H-pyrazol-1-yl)phenyl]-5-methoxy-3-(1-phenyl-1H-pyrazol-5-yl)pyridazin-4(1H)-one, selectively targets (IC<sub>50</sub> = 0.3 nM) phosphodiesterase 10a (PDE10A), a dual substrate (cAMP/cGMP) enzyme in the medium spiny neurons of the striatum, a region strongly associated with motor and cognitive functions. TAK-063 shows favorable pharmacokinetics, including high brain penetration, in mice. Oral administration elevated striatal 3',5'-cyclic adenosine monophosphate (cAMP) and 3',5'-cyclic guanosine monophosphate (cGMP) levels at 0.3 mg/kg (in mice), showing potent suppression of phencyclidine (PCP)-induced hyperlocomotion at a minimum effective dose (MED) of 0.3 mg/kg. Other PDE10A-selective inhibitors include PF-2545920 (or MP-10), OMS824, RG7203, and FRM-6308 (formerly EVP-6308). **Target(s)**: PDE1A, IC<sub>50</sub> = 12000 nM (range: 9800–14000 nM); PDE2A<sub>3</sub>, IC<sub>50</sub> > 30000 nM; PDE3A, IC<sub>50</sub> = >30000 nM; PDE4D2, IC<sub>50</sub> = 5500 nM (range: 5000–6100 nM); PDE5A1, IC<sub>50</sub> = 5700 nM (range: 4700–6900 nM); PDE6AB, IC<sub>50</sub> = 6800 nM (range: 5300–8900 nM); PDE7B, IC<sub>50</sub> = 19000 nM (range: 18000–21000 nM); PDE8A<sub>1</sub>, IC<sub>50</sub> > 30000 nM; PDE9A<sub>2</sub>, IC<sub>50</sub> > 30000 nM; PDE10A<sub>2</sub>, IC<sub>50</sub> = 0.30 nM (range: 0.22–0.40 nM); PDE11A<sub>4</sub>, IC<sub>50</sub> > 30000 nM. 1. Kunitomo, Yoshikawa, Fushimi, *et al.* (2014) *J. Med. Chem.* **57**, 9627.

#### TAK 165

This (FW = 470.50 g/mol; CAS 366017-09-6; Soluble to 75 mM in DMSO and to 5 mM in Ethanol), also named 1-[4-[4-[[2-[(1E)-2-[4-(trifluoromethyl)phenyl]ethenyl]-4-oxazolyl]methoxy]phenyl]butyl]-1H-1,2,3-triazole, is a potent, irreversible human epithelial growth factor receptor 2 (ErbB2) inhibitor (IC<sub>50</sub> = 6 nM), displaying > 4000x selectivity over EGFR, FGFR, PDGFR, JAK1 and Src. TAK-165 also exhibits potent antiproliferative effects in ErbB2-overexpressing cancer in BT474 breast cancer cells (IC<sub>50</sub> = 5 nM) and significantly inhibits growth of bladder, breast and prostate cancer xenografts. 1. Nagasawa, *et al.* (2006) *Int. J. Urol.* **13**, 585. 2. Spector, *et al.* (2007) *Breast Cancer Res.* **9**, 205.

#### TAK-632

This novel 1,3-benzothiazole and potent pan-RAF inhibitor (FW = 554.51 g/mol; CAS 1228591-30-7), also known as N-(7-cyano-6-(4-fluoro-3-(2-(3-(trifluoromethyl)phenyl)acetamido)-[phenoxy]benzo[d]thiazol-2-yl)cyclopropanecarboxamide, targets BRAF<sup>wild-type</sup> (IC<sub>50</sub> = 8.3 nM, with slow off-rate (assayed *in vitro*), BRAF<sup>V600E</sup> (IC<sub>50</sub> = 2.4 nM, *in vitro*), CRAF (IC<sub>50</sub> = 1.4 nM, *in vitro*), pMEK, or A375, (IC<sub>50</sub> = 12 nM *in vitro*), and pMEK, or HMVII (IC<sub>50</sub> = 49 nM *in vitro*). TAK-632 demonstrates antitumor efficacy against both A375 (BRAF<sup>V600E</sup>) and HMVII (NRAS<sup>O61K</sup>) tumor xenografts in rats. 1. Okaniwa, Hirose, Arita, *et al.* (2013) *J. Med. Chem.* **56**, 6478.

#### TAK-715

This orally available MAPK inhibitor (FW = 399.51 g/mol; CAS 303162-79-0), also named N-[4-[2-ethyl-4-(3-methylphenyl)-5-thiazolopyridin-2-yl]benzamide, targets p38 mitogen-activated protein kinase, an enzyme in the proinflammatory cytokine signal pathway associated with chronic inflammatory disorders, including rheumatoid arthritis and inflammatory bowel disease. TAK-715 potently inhibits p38 $\alpha$  (IC<sub>50</sub> = 7.1 nM), LPS-stimulated release of TNF- $\alpha$  from THP-1 (IC<sub>50</sub> = 48 nM), LPS-induced TNF- $\alpha$  production in mice, 87.6% inhibition at 10 mg/kg, oral dose, with no inhibitory action against major CYPs, including CYP3A4 (1). Although TAK-715 had been thought to affect Wnt-3 $\alpha$ -stimulated  $\beta$ -catenin signaling, two highly selective and equally potent p38 inhibitors, VX-745 and Scio-469, do not. Moreover, profiling of TAK-715 against 200 kinases revealed inhibition of casein kinases  $\delta$  and  $\epsilon$ , enzymes that are known activators of Wnt/ $\beta$ -catenin signaling. This lack of TAK-715 specificity weighs against a role of p38 in Wnt/ $\beta$ -catenin signaling. 1. Miwatashi, Arikawa, Kotani, *et al.* (2005) *J. Med. Chem.* **48**, 5966. 2. Verkaar, van der Doelen, Smits, Blankestijn & Zaman (2011) *Chem. Biol.* **18**, 485.

## TAK-773

This potent allosteric-site inhibitor (FW = 504.23 g/mol; CAS 1035555-63-5; Solubility: 100 mg/mL DMSO), also named (*R*)-3-(2,3-dihydroxypropyl)-6-fluoro-5-(2-fluoro-4-iodophenylamino)-8-methylpyrido[2,3-*d*]pyrimidine-4,7(3*H*,8*H*)-dione, selectively targets MEK1 (IC<sub>50</sub> = 3.2 nM), with no discernible effect on Abl1, AKT3, c-RAF, CamK1, CDK2, or c-Met. TAK-773. It also exhibits broad antitumor activity in mouse xenograft models for human cancer including models of melanoma, colorectal, NSCLC, pancreatic and breast cancer. TAK-773 is also well tolerated, with pharmacokinetics and pharmacodynamics that support once-daily oral dosing in humans. **1.** Dong, Dougan, Gong *et al.* (2011) *Bioorg. Med. Chem. Lett.* 21, 1315.

## TAK-779

This nonpeptide CCR5 receptor antagonist (FW = 531.13 g/mol) prevents HIV-1 from entering and infecting peripheral blood CD4<sup>+</sup> immune cells, when present at 2-4 nM (1). CCR5 is a member of G-protein-coupled, seven transmembrane segment receptors, also known as C-C motif chemokine receptor-5. TAK-779 also antagonizes the binding of RANTES (*or* Regulated on Activation, Normal T cell Expressed and Secreted) cytokine to CCR5-expressing Chinese hamster ovary cells and blocked CCR5-mediated Ca<sup>2+</sup> signaling, again at nanomolar concentrations (2). **Primary Mechanism of Inhibitory Action:** TAK-779 inhibits HIV-1 replication at the membrane fusion stage by blocking the interaction of the viral surface glycoprotein gp120 with CCR5, and alanine scanning mutagenesis of the transmembrane domains revealed that the binding site for TAK-779 on CCR5 is located near the extracellular surface of the receptor, within a cavity formed between transmembrane helices 1, 2, 3, and 7 (2). The efficiency of entry of cell-attached infectious HIV-1 appears to be controlled by three different kinetic processes (3). The first shows lag-phase kinetics, caused in part by the concentration-dependent reversible association of virus with CD4 and CCR5, forming an equilibrium manifold of complexes. In the second, this assembly step lowers, but does not eliminate, a large activation energy barrier for a rate-limiting, CCR5-dependent conformational change in gp41. The rate of infection therefore depends on the fraction of infectious virions that have enough CCR5 to undergo this conformational change and surmount the energy barrier. While only a small fraction of fully assembled viral complexes overcome this barrier per hour, the later steps of entry are rapidly completed within 5-10 min. Thus, this barrier limits the overall rate for virion attachment and entry, but it is without effect on the already mentioned lag time. Third, there follows a relatively rapid and kinetically dominant process of viral inactivation, which partly involves endocytosis and competes with infectious viral entry. Other similarly acting viral entry inhibitors include aplaviroc, viviviroc, maraviroc, and SCH-C (*or* SCH 351125). By contrast, the entry inhibitor PRO-140 is a human monoclonal antibody to the CCR5 receptor. This chemokine receptor antagonist is protective against ischemic brain injury (4). **1.** Baba, Nishimura, Kanzaki, *et al.* (1999) *Proc. Natl. Acad. Sci. U.S.A.* 96, 5698. **2.** Dragic, Trkola, Thompson, *et al.* (2000) *Proc. Natl. Acad. Sci. U.S.A.* 97, 5639. **3.** Platt, Durnin & Kabat (2005) *J. Virol.* 79, 4347. **4.** Takami, Minami, Katayama, *et al.* (2002) *J. Cereb. Blood Flow Metab.* 22, 780.

## TAK-802

This novel acetylcholinesterase inhibitor (FW<sub>hydrochloride</sub> = 456.99 g/mol), also known as 8-[3-[1-[(3-fluoro-phenyl)methyl]-4-piperidinyl]-1-oxo-propyl]-1,2,5,6-tetrahydro-4*H*-pyrrolo[3,2,1-*ij*]-quinolin-4-one, shows high selectivity for acetylcholinesterase over butyryl-cholinesterase. TAK-802 inhibits human-erythrocyte-derived acetylcholinesterase activity (IC<sub>50</sub> = 1.5 nM), with 30x and 250x higher affinity than neostigmine and distigmine, respectively (1). TAK-802 increases isovolumetric bladder contractions, with a minimum effective dose (MED) of 10 µg/kg i.v. in rats and guinea pigs, and this effects is completely abolished by atropine. Such results suggest TAK-802 and can effectively increase reflex bladder contractions by increasing the efficacy of acetylcholine released by nerve impulses. **1.** Nagabukuro, Okanishi, Imai, *et al.* (2004) *Eur. J. Pharmacol.* 485, 299.

## Talampanel

This oral benzodiazepine (FW = 337.38 g/mol; CAS 161832-65-1; Soluble to 100 mM in DMSO), also known as GYKI 53773, LY 300164, and (8*R*)-7-acetyl-5-(4-aminophenyl)-8,9-dihydro-8-methyl-7*H*-1,3-dioxolo[4,5-*h*][2,3]benzodiazepine, is a noncompetitive antagonist of the α-amino-3-hydroxy-5-methylisoxazolepropionic acid (AMPA) receptor (1). LY 300164 potentiates the protective action of diazepam in some animal models of seizures, suggesting a new approach for treating drug-resistant epilepsy or status epilepticus (2) **1.** Solyom & Tamawa (2002) *Curr. Pharm. Des.* 8, 913. **2.** Borowicz, Kleinrok & Czuczwar (2000) *Naunyn. Schmiedebergs Arch. Pharmacol.* 361, 629.

## Talniflumate

This CaCC blocker and anti-inflammatory agent (FW = 414.34 g/mol; CAS 66898-62-2; Soluble to 25 mM in DMSO), also named 1,3-dihydro-3-oxo-1-isobenzofuran-2-yl-[[3-(trifluoromethyl)phenyl]amino]-3-pyridine carboxylate, targets calcium-activated chloride channels (CaCC), including hCLCA1 and mCLCA3, reducing mucin synthesis and release in cell culture and animal models (1,2). Talniflumate's anti-inflammatory actions relate to its inhibitory effects on cyclooxygenases. It also inhibits the Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchanger activity, increasing survival in a cystic fibrosis mouse model of distal intestinal obstructive syndrome (3). **1.** Sanchez, *et al.* (1982) *J. Appl. Toxicol.* 2, 42. **2.** Knight (2004) *Curr. Opin. Invest. Drugs* 5, 557. **3.** Walker, *et al.* (2006) *J. Pharmacol. Exp. Ther.* 317, 275.

## Talopram

This potent and selective transport inhibitor and antidepressant ( $FW_{\text{HCl-Salt}} = 331.88$  g/mol; CAS 7013-41-4; Solubility: 50 mM in  $H_2O$ , 100 mM in DMSO), known also as Lu 3-010 and 1,3-dihydro-*N*,3,3-trimethyl-1-phenyl-1-isobenzofuranpropanamine, targets the noradrenalin transporter, or norepinephrine transporter NET ( $IC_{50} = 2.9$  nM), showing selectivity for NET versus SERT (5-HT transporters) and DAT (dopamine transporters) (1-3). The basis for such selectivity is the observation that only small amines are accommodated at the 5-HT-uptake site, whereas larger amines such as piperazine are accommodated both at the DA- and NE-uptake sites. The synthesis and evaluation of [ $^{11}C$ ]talopram is relevant to its use in positron emission tomography (2). (See *Talsupram*) 1. Bogesø, Christensen, Hyttel & Liljefors (1985) *J. Med. Chem.* **28**, 1817. 2. Schou, Sóvágó, Pike, *et al.* (2006) *Mol. Imaging Biol.* **8**, 1. 3. Eildal, Andersen, Kristensen, *et al.* (2008) *J. Med. Chem.* **51**, 3045.

## Talsupram

This potent and selective transport inhibitor and antidepressant ( $FW_{\text{HCl-Salt}} = 347.95$  g/mol; CAS 25487-28-9; Solubility: 20 mM in  $H_2O$ , 100 mM in DMSO; 1,3-dihydro-*N*,3,3-trimethyl-1-phenylbenzo[*c*]thiophene-1-propanamine) targets the noradrenalin transporter, or norepinephrine transporter, NET ( $IC_{50} = 0.8$  nM), showing selectivity for NET versus SERT, or 5-HT transporters ( $IC_{50} = 850$  nM) and DAT, or dopamine transporters ( $IC_{50} = 9300$  nM). (See *Talopram*) 1. Schou, Sóvágó, Pike, *et al.* (2006) *Mol. Imaging Biol.* **8**, 1.

## TAME

This amino-substituted L-arginine ester and well-known synthetic protease inhibitor ( $FW_{\text{hydrochloride}} = 378.88$  g/mol; CAS 1784-03-8; hydrolyzes nonenzymatically above pH 9), also known as *N*<sup>ε</sup>-(*p*-Tosyl)-L-arginine methyl ester, is an alternative substrate that is useful for quantifying the esterase activity of many neutral proteinases, including trypsin, plasmin, and papain (1-10). Depending on the target enzyme, TAME actions as a slow alternative substrate (*i.e.*, both low  $K_m$  and low  $k_{\text{cat}}$ ) results in competitive inhibition the peptide-hydrolyzing activities of proteases. **Pharmacologic Inhibition of Anaphase-Promoting Complex in Mitosis:** Microtubule inhibitors that induce mitotic arrest by activating the Spindle Assembly Checkpoint

(SAC), which in turn inhibits the ubiquitin ligase activity of the Anaphase-Promoting Complex (APC). TAME binds to the APC, preventing proteolytic activation by Cdc20 and Cdh1. A cell-permeable prodrug (See *pro-TAME*) arrests cells in metaphase without perturbing the spindle, properties that commend its development as an anticancer drug (11). **Target(s):** barrierpepsin, above pH 6 (1); *N*-benzoyl-D-arginine-4-nitroanilide amidase (2); dactylisin, weakly inhibited (3); mitochondrial intermediate peptidase (4); scutellarin (5); signal peptidase II (6,7); thrombin (8,9); u-plasminogen activator, or urokinase (10). 1. ## Tamoxifen

This mixed antagonist/partial-agonist and breast cancer drug ( $FW = 371.52$  g/mol; CAS 10540-29-1; Hygroscopic; UV-sensitive; Soluble to 100 mM in DMSO with gentle warming; IUPAC Name: (Z)-2-[4-(1,2-diphenyl-1-butenyl)phenoxy]-*N,N*-dimethylethanamine), also known as Nolvadex<sup>TM</sup>, Istubal<sup>TM</sup>, and Valodex<sup>TM</sup>, is an estrogen receptor (ER) antagonist, with effects that vary, depending on an organism's species and tissue type. In addition to its effects on estrogen homeostasis, tamoxifen inhibits many enzymes and induces apoptosis in susceptible cell lines. Tamoxifen is also neuroprotective in female rats. **Metabolic Activation:** A prodrug with little affinity for the estrogen receptor, tamoxifen is metabolized by liver cytochromes CYP2D6 and CYP3A4 to **Afimoxifene** ( $FW = 387.51$  g/mol; CAS 68392-35-8; Alternative Name: 4-hydroxytamoxifen) and **Endoxifen** ( $FW = 373.49$  g/mol; CAS 112093-28-4; Alternative Name: *N*-demethyl-4-hydroxytamoxifen). With 30x-100x greater estrogen receptor affinity than tamoxifen, these metabolites compete with estrogen for the estrogen receptor. In breast tissue, 4-hydroxytamoxifen acts as an estrogen receptor antagonist that inhibits transcription of estrogen-responsive genes. Tamoxifen is currently used to treat both early and advanced ER<sup>+</sup> (estrogen receptor-positive) breast cancer in pre- and post-menopausal women and as the most common hormone treatment for male breast cancer. Tamoxifen is a high-affinity agonist at the membrane estrogen receptor GPR30, an orphan receptor unrelated to nuclear estrogen receptors, has all the binding and signaling characteristics of a membrane ER. GPR30 is structurally unrelated to the recently discovered family of GPCR-like membrane progesterin receptors. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** [ $\beta$ -adrenergic-receptor] kinase (1); aldehyde oxidase (2); aromatase, or CYP19 (3,4); ceramide glycanase (5,6); cholesterol  $\Delta$ -isomerase, or sterol  $\Delta^{7,8}$ -isomerase (7-11a) at the so-called emopamil-insensitive site (11b); CYP3A4 (12); CYP3B1 (12); glucucosyltransferase (13); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (14); nitric-oxide synthase (15); protein kinase C (16-18); sterol  $\Delta^{14}$ -reductase (8); and sterol  $\Delta^{24}$ -reductase (8). 1. ### Tamsulosin

This selective  $\alpha_{1A}/\alpha_{1D}$ -receptor antagonist and muscle relaxant (FW<sub>free-base</sub> = 408.51 g/mol; FW<sub>hydrochloride</sub> = 433.96; CAS 106133-20-4), widely known as Flomax<sup>®</sup> and (*R*)-5-(2-[[2-(2-ethoxyphenoxy)ethyl]amino]propyl)-2-methoxybenzene-1-sulfonamide, is used to treat benign prostatic hyperplasia (BPH) symptomatically and to promote passage of moderately sized kidney stones, by increasing blood flow in small blood vessels as well as urine flow through the ureter (1). Tamsulosin decreases resting maximal urethral pressure, with negligible effect on mean arterial blood pressure. The specific binding of [<sup>3</sup>H]tamsulosin in human prostatic membranes is saturable, showing high affinity ( $K_d = 0.04$  nM), and the density of binding sites (measured as  $B_{max}$  in Scatchard plots) was 409 fmol/mg protein (2). This antagonist has  $pK_i$  values are 9.97, 9.64 and 8.86 for  $\alpha_{1A}$ ,  $\alpha_{1B}$  and  $\alpha_{1D}$  subtypes, respectively. Tamsulosin is metabolized by the liver cytochrome system and should not be used in combination with warfarin or strong CYP3A4 inhibitors (*e.g.*, ketoconazole, erythromycin, fluconazole, grapefruit juice, and omeprazole). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Yazawa, Takanashi, Sudoh, Inagaki & Honda (1992) *J. Pharmacol. Exp. Ther.* **263**, 201. 2. Yamada, Tanaka, Ohkura, *et al.* (1994) *Urol. Res.* **22**, 273.

### Tandospirone

This serotonin receptor partial agonist and anxiolytic agent (FW = 419.95 g/mol; CAS 99095-10-0), also named (3*aR*,4*S*,7*R*,7*aS*)-*rel*-hexahydro-2-[4-[4-(2-pyrimidinyl)-1-piperazinyl]butyl]-4,7-methano-1*H*-isoindole-1,3(2*H*)-dione, targets 5-HT<sub>1A</sub> ( $K_i = 27$  nM), displaying great selectivity over 5-HT<sub>2</sub>, 5-HT<sub>1C</sub>,  $\alpha_1$ ,  $\alpha_2$ , D<sub>1</sub> and D<sub>2</sub> receptors, for which  $K_i$  values range from 1.3 to 41  $\mu$ M (1). Saturation and competition studies using 3H-tandospirone also suggest that the drug interacts with 5-HT<sub>1A</sub> receptor binding sites in rat cortical membranes ( $K_D = 4.5$  nM;  $B_{max} = 2.2$  pmol/g tissue). Based on adenylate cyclase studies, which measure 5-HT<sub>1A</sub> receptor-mediated effects, tandospirone displays ~60% of the agonist effect of 8-OH-DPAT, a selective 5-HT<sub>1A</sub> agonist. Tandospirone is qualitatively similar to the other azapirone anxiolytics buspirone, gepirone and ipsapirone, but is different from sedative-hypnotic anxiolytics (2). Serotonin-1A receptors are distributed throughout the brain with their highest concentrations in the frontal cortex, subthalamic nucleus and entopeduncular nucleus as well as the dorsal and median raphe nucleus. There is growing evidence that 5-HT<sub>1A</sub> receptor agonists have an antidepressant effect in individuals with major depressive disorders (3). 1. Matsubara, Shimizu, Suno, *et al.* (2006) *Brain Res.* **1112**, 126.

### Tanespimycin

This potent heat shock protein inhibitor and antineoplastic agent (FW = 585.69 g/mol; CAS 75747-14-7; Solubility = 100 mg/mL DMSO, and <1 mg/mL H<sub>2</sub>O; Symbol: 17-AAG), also known as 17-demethoxy-17-(2-propenylamino)geldanamycin and [(3*S*,5*S*,6*R*,7*S*,8*E*,10*R*,11*S*,12*E*,14*E*)-21-(allylamino)-6-hydroxy-5,11-dimethoxy-3,7,9,15-tetramethyl-16,20,22-tri-oxo-17-azabicyclo[16.3.1]docosa-8,12,14,18,21-pentaen-10-yl] carbamate, targets HSP90, displaying an IC<sub>50</sub> value of 5 nM. The natural product HSP90 inhibitors, like geldanamycin and radicicol, exert their antitumour effects by inhibiting HSP90's intrinsic ATPase activity, resulting in degradation of HSP90 client proteins by the ubiquitin/proteasome pathway. Indeed, tanespimycin inhibition of this chaperone protein results in the depletion of such oncogenic proteins as Raf-1, mutant p53, and Bcr-Abl (1). Tanespimycin also depletes N-ras, Ki-ras, and c-Akt and also inhibits c-AKT phosphorylation in human colon adenocarcinoma cells, thereby inducing cytotostasis and apoptosis (2). Tanespimycin also enhances tumor cell radiosensitivity, often enhancing the killing action by factors ranging from 1.3 to 1.7. Enzyme-catalyzed reduction of 17-AAG by NAD(P)H:quinone oxidoreductase 1 (NQO1) generates 17-allylamino-demethoxygeldanamycin hydroquinone (17-AAGH<sub>2</sub>), a relatively stable hydroquinone that exhibits superior Hsp90 inhibition (4). Significantly, tanespimycin also associates with the mitochondrial membrane voltage-dependent anion channel (VDAC) via a hydrophobic interaction that is independent of HSP90 (5). *In vitro*, tanespimycin functions as a Ca<sup>2+</sup> mitochondrial regulator akin to benzoquinone-ubiquinones like Ub0. In contrast, the HSP90 inhibitor radicicol, which lacks a benzoquinone moiety, has no measurable effect on cationic current and is less effective in influencing intercellular Ca<sup>2+</sup> concentration (5). Recent work suggests that tanespimycin mainly causes a cytostatic antiproliferative effect, rather than cell death, and further suggests that BAX status may not alter the overall clinical response to HSP90 inhibitors (6). ### Tanomastat

This synthetic inhibitor (FW<sub>free-acid</sub> = 410.92 g/mol; CAS 179545-77-8), also known as BAY 12-9566, targets a matrix metalloproteinase and is relatively selective for gelatinase A, or matrix metalloproteinase-2 ( $K_i = 11$  nM). Higher BAY 12-9566 concentrations also inhibit stromelysin 1 ( $K_i = 140$  nM), gelatinase B ( $K_i = 300$  nM), collagenase-3 ( $K_i = 1.5$   $\mu$ M), and interstitial

collagenase ( $K_i = 5 \mu\text{M}$ ). Tanomastat induces extracellular matrix degradation, and inhibits angiogenesis, tumor growth and invasion, and metastasis. **1.** Leung, Abbenante & Fairlie (2000) *J. Med. Chem.* **43**, 305.

### Tanshinone

This antioxidant and anti-inflammatory agent (FW = 294.34 g/mol; CAS 568-72-9; Soluble to 5 mM in DMSO with gentle warming), also named 6,7,8,9-tetrahydro-1,6,6-trimethylphenanthro[1,2-*b*]furan-10,11-dione, from *Salvia miltiorrhiza*, inhibits NF- $\kappa$ B and AP-1 binding to DNA and cytotoxic activity for a number of different cancer cells (1,2). Tanshinone also inhibits human aortic smooth muscle cell migration and MMP-9 activity through AKT signaling pathway (2,3). Tanshinone inhibits  $\beta$ -amyloid aggregation and protects PC12 cells from  $\beta$ -amyloid<sub>25-35</sub>-induced apoptosis via PI3K/Akt signaling pathway (4). **1.** Wang, Wang, Jiang, *et al.* (2007) *J. Neurooncol.* **82**, 11. **2.** Jin, Suh, Chang, *et al.* (2008) *J. Cell Biochem.* **104**, 15. **3.** Lee, Sher, Chen, *et al.* (2008) *Mol. Cancer Ther.* **7**, 3527. **4.** Dong, Mao, Wei, *et al.* (2012) *Mol. Biol. Rep.* **39**, 6495.

### Tapentadol

This powerful analgesic (FW<sub>free-base</sub> = 221.34 g/mol; CAS 175591-09-0), also known by the trade names Nucynta<sup>®</sup>, Palexia<sup>®</sup>, and Tapal<sup>®</sup> as well as the systematic name 3-[(1*R*,2*R*)-3-(dimethylamino)-1-ethyl-2-methylpropyl]-phenol, is a CNS analgesic with dual action as a  $\mu$ -opioid receptor agonist and a norepinephrine reuptake inhibitor (1,2). Tapentadol is also an agonist of the  $\sigma_2$  receptor, but the role of this receptor is unclear. It shows high efficacy in acute nociceptive, acute and chronic inflammatory, as well as in chronic neuropathic pain. **Pharmacokinetics:** In four healthy male subjects receiving a single 100-mg oral dose of 3-<sup>[14C]</sup>-labeled tapentadol, the serum pharmacokinetics and excretion kinetics of tapentadol and its conjugates were assessed, as was tolerability (3). Absorption was rapid, with a mean serum [C<sub>max</sub>] of 2.45  $\mu\text{g-eq/mL}$  and a time-to-C<sub>max</sub> value of 75-90 minutes. The drug was present mainly (24:1) as conjugated metabolites. Excretion of radiocarbon was rapid and complete (>95% within 24 hours; 99.9% within 5 days) and almost exclusively renal (99%: 69% as conjugates; 27% as other metabolites; 3% in unchanged form). No severe adverse events or clinically relevant changes in vital signs, laboratory measurements, electrocardiogram recording, or physical examination findings were reported (2). Tapentadol is metabolized to *N*-demethyltapentadol. With no active metabolites and minimal protein binding, tapentadol provides improved tolerability with a lower potential for pharmacokinetic drug-drug interactions or accumulation with impaired renal or hepatic function when compared with oxycodone (4). (**See Oxycodone; Tramadol**) **Other Actions:** Tapentadol also inhibits K<sup>+</sup>-stimulated Calcitonin Gene-Related Peptide (CGRP) release from the rat brainstem in vitro through a mechanism involving an increase in 5-HT levels in the system and the subsequent activation of 5-HT<sub>3</sub> receptors (5). Notably, the  $\alpha_2$ -antagonist yohimbine does not counteract the effects of tapentadol. Moreover, neither NA nor the  $\alpha_2$ -agonist clonidine per se inhibits K<sup>+</sup>-stimulated CGRP release, thereby indicating that the effects of tapentadol are not mediated through the block of NA reuptake. 5-HT and tramadol (the latter inhibiting both NA and 5-HT reuptake) significantly reduces K<sup>+</sup>-stimulated CGRP release. **See also Calcitonin** **1.** Tzschentke, Christoph, Kögel, *et al.* (2007) *J. ### Tartradiamide

This diamide of tartaric acid (FW = 148.12 g/mol), which can exist as one of three possible stereoisomers (D, L, and *meso*) inhibits acid phosphatase (IC<sub>50</sub>  $\approx$  17 mM). **Target(s):** acid phosphatase (1,2). **1.** Hollander (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), **4**, 449. **2.** Kilsheimer & Axelrod (1957) *J. Biol. Chem.* **227**, 879.

### Tartrate

This  $\alpha$ -hydroxy acid (FW<sub>free-acid</sub> = 120.06 g/mol), also known as hydroxymalonic acid and hydroxypropanedioic acid, is a water-soluble dicarboxylic acid with pK<sub>a</sub> values of 2.42 and 4.54 at 25°C. **Target(s):** acid phosphatase, weakly inhibited (1,2); D-aspartate oxidase (3,4); cyanate hydratase, or cyanase (5); D-2-hydroxyacid dehydrogenase (6); isocitrate lyase (7-9); D-lactate dehydrogenase (cytochrome) (10); L-lactate dehydrogenase (11-13); L-malate dehydrogenase (14-18); malic enzyme (19-23); phosphoenolpyruvate carboxykinase (GTP), weakly inhibited (24,25); 3-phosphoglycerate kinase (26); serine 3-dehydrogenase (27); D(-)-tartrate dehydratase (28); L(+)-tartrate dehydratase (29,30); *meso*-tartrate dehydratase (28); tartronate semialdehyde reductase, or 2-hydroxy-3-oxopropionate reductase (31); D-threonine dehydrogenase (32); L-threonine dehydrogenase (33). **1.** Hollander (1971) *The Enzymes*, 3rd ed. **D-Tartronate Semialdehyde 2-Phosphate**

This metabolite (FW<sub>free-acid</sub> = 184.04 g/mol), named systematically as 3-oxo-2-phosphonoxy-propanoic acid, is produced by the action of pyruvate kinase on  $\beta$ -hydroxyppyruvate, first as the enol form, which then tautomerizes to the aldehyde and becomes hydrated. Both the enolate and the aldehyde forms are potent inhibitors of yeast enolase (1-4). Brewer *et al.* (5) determined the kinetics of the reaction of human neuronal enolase and yeast enolase 1 with the slowly-reacting chromophoric substrate D-tartronate semialdehyde phosphate (TSP). All data were biphasic, fitting either two successive first-order reactions or two independent first-order reactions, with higher  $Mg^{2+}$  concentrations reducing the relative magnitude of the slower reaction. The results suggest a catalytically significant interaction between the enzyme's two subunits (5). **1.** Spring (1970) Ph.D. Thesis, Univ. of Minnesota, Minneapolis. **2.** Wold (1975) *Meth. **Tartronic Semialdehyde, See Tartronate Semialdehyde**

**TAS-102, See Tipiracil**

**TAS-106, See 3'-Ethylnyl-Cytosine**

**TAS 301**

This synthetic indole derivative (FW = 357.40 g/mol; CAS 193620-69-8; Solubility: 40 mg/mL DMSO) inhibits smooth muscle cell migration and proliferation, inhibiting intimal thickening after balloon injury to rat carotid arteries (1). TAS-301 also blocks receptor-operated calcium influx and inhibits rat vascular smooth muscle cell proliferation induced by basic fibroblast growth factor and platelet-derived growth factor. **1.** Muranaka, Yamasaki, Nozawa, *et al.* (1998) *J. Pharmacol. Exp. Ther.* **285**, 1280. **2.** Sasaki, Nozawa, Miyoshi, *et al.* (2000) *Jpn. J. Pharmacol.* **84**, 252.

**Taselisib**

This orally bioavailable phosphatidylinositol 3-kinase (or PI3K) inhibitor (FW = 459.55 g/mol; CAS 1282512-48-4), also called GDC-0032, RG7604, and 2-(4-(2-(1-isopropyl-3-methyl-1H-1,2,4-triazol-5-yl)-5,6-dihydrobenzo[*f*]imidazo[1,2-*d*][1,4]oxazepin-9-yl)-1H-pyrazol-1-yl)-2-methylpropanamide, selectively targets PI3K $\alpha$  ( $K_i$  = 0.2 nM), with reduced inhibitory activity against PI3K $\beta$  (1,2). Mean single-dose pharmacokinetic parameters, determined by an LC-MS/MS method, for a Phase I/II clinical trial were:  $C_{max}$  = 35.2 ng/mL,  $AUC_{0-inf}$  = 1570 ng-hour/mL, and  $t_{1/2}$  = 39.3 hours (3). **1.** Lopez, Schwab, Cocco, *et al.* (2014) *Gynecol. Oncol.* **135**, 312. **2.** Ndubaku, Heffron, Staben, *et al.* (2013) *J. Med. Chem.* **56**, 4597. **3.** Ding, Faber, Shi, *et al.* (2016) *J. Pharm. Biomed. Anal.* **126**, 117.

**TAT-cyclo-(CLLFVY)**

This disulfide-linked membrane-penetrating derivative of *cyclo*-(Cys-Leu-Phe-Val-Tyr) (FW = g/mol; CAS 1446322-66-2) is a selective HIF-1 dimerization inhibitor that blocks protein-protein interaction of recombinant HIF-1 $\alpha$  (but not HIF-2 $\alpha$ ) with HIF-1 $\beta$ . TAT-*cyclo*-(CLLFVY) exploits the presence of the TAT protein sequence, which facilitates direct cellular uptake. Once within cells, TAT-*cyclo*-(CLLFVY) is cleaved by reduced glutathione to produce *cyclo*-(CLLFVY), which then inhibits hypoxia-induced HIF-1 activity, and decreases VEGF and CAIX expression in osteosarcoma and breast cancer cells *in vitro*. TAT-*cyclo*-(CLLFVY) also inhibits capillary tubularization of hypoxic HUVECs. Hypoxia inducible factor-1 (HIF-1) is a heterodimeric transcription factor that acts as the master regulator of cellular response to reduced oxygen levels, thus playing a key role in the adaptation, survival, and progression of tumors. Identified from a library of 3.2 million cyclic hexapeptides, this inhibitor blocks (IC<sub>50</sub> = 1.3  $\mu$ M) the HIF-1 $\alpha$ /HIF-1 $\beta$  protein-protein interaction *in vitro* and in cells. **1.** Packham, Eccles & Tavassoli (2013) *J. Am. Chem. Soc.* **135**, 10418.

**Taurine**

This water-soluble cysteine metabolite (FW = 125.15 g/mol; CAS 107-35-7; pK<sub>a</sub> = 1.5 & 8.74), also known as 2-aminoethanesulfonate, is a  $\beta$ -aminosulfonic acid that is abundant in brain. The thiol group of cysteine is oxidized to cysteine sulfonic acid (by cysteine dioxygenase), decarboxylated to hypotaurine (by sulfinoalanine decarboxylase), and then oxidized to taurine spontaneously or enzymatically. Taurine functions in many metabolic reactions and processes, the latter including osmoregulation, bile salt formation, and as an apoptosis modulator in some cells. Taurine is conjugated via its amino terminal group with chenodeoxycholic acid and cholic acid to form the bile salts known as sodium taurochenodeoxycholate and sodium taurocholate. Taurine also exhibits diuretic properties, facilitating the movement of potassium, sodium, and calcium in and out of the cell. **Target(s):** 4-aminobutyrate aminotransferase (1); 2-aminohexano-6-lactam racemase (2); bile acid acyl glucuronosyltransferase (3);  $\gamma$ -glutamyl transpeptidase, or weakly inhibited (4); K<sup>+</sup> channel, ATP-sensitive (5); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (6); pantothenate synthetase, or pantoate: $\beta$ -alanine ligase (7,8); partial agonist at the inhibitory glycine receptor, with low concentrations competitively inhibiting glycine responses, whereas higher concentrations elicit a significant membrane current (9). **1.** Sulaiman, Suliman & Barghouthi (2003) *J. ### Taurocholate

This amphipathic bile salt and bio-detergent (FW<sub>sodium-salt</sub> = 537.69 g/mol; CAS 145-42-6; p*K*<sub>a</sub> = 1.9), an amide conjugate of cholic acid with taurine, has a critical micelle concentration of 3-11 mM and an aggregation number of four. For many of the following enzymes, the inhibitor is the micellar form, not monomeric taurocholate. **Target(s):**  $\beta$ -*N*-acetylhexosaminidase (1); 2-acylglycerol *O*-acyltransferase, or monoacylglycerol *O*-acyltransferase (59,60); alkaline phosphatase (2); bile-acid-CoA:amino acid *N*-acyltransferase (57,58); bis(2-ethylhexyl)phthalate esterase (46); carbonic anhydrase (3-5); carboxylesterase, or esterase (13,14,52); cholesterol acyltransferase (6); cholesterol esterase (7); cholesterol 7 $\alpha$ -monooxygenase, or CYP7A1 (8-10); choloyl-CoA synthetase, or cholate:CoA ligase (36); CYP7B1, or oxysterol 7 $\alpha$ -monooxygenase (11); diacylglycerol *O*-acyltransferase (61); dolichyl esterase (12);  $\alpha$ -*L*-fucosidase (15);  $\alpha$ -galactosidase (39); galactosylceramidase (37); galactosylgalactosylglucosylceramidase (16); glucose-6-phosphatase (17);  $\beta$ -glucosidase (40-42);  $\gamma$ -glutamyl transpeptidase, weakly inhibited (18); *sn*-glycerol-3-phosphate dehydrogenase (19); glycine *N*-choloyltransferase, alternative product (20); glycolipid 2- $\alpha$ -mannosyltransferase (55); guanidoacetate methyltransferase (21); 2-hydroxyacylsphingosine 1 $\beta$ -galactosyltransferase, or cerebroside synthase (22); 3-hydroxy-3-methylglutaryl-CoA reductase (9,23); lipase, or triacylglycerol lipase (24-26,51); lipoprotein lipase (27); lipoxigenase (28); lysophospholipase (29); lysozyme (30);  $\beta$ -mannosidase (31,38); phosphoglyceride: lysophosphatidylglycerol *O*-acyltransferase (32); phospholipase A<sub>2</sub> (50); phospholipase D (45); pyridoxine-5'- $\beta$ -D-glucoside  $\beta$ -glucosidase (33); retinol *O*-fatty-acyltransferase (34,56); sphingomyelin phosphodiesterase, or sphingomyelinase (44); sterol esterase, or cholesterol esterase (47-49); sterol 3 $\beta$ -glucosyltransferase (53,54); and steryl-sulfatase (35,43). 1. ### Taurodehydrocholate

This bile acid analogue (FW = 509.66 g/mol; CAS 517-37-3), also known as 5 $\beta$ -cholanic acid-3,7,12-trione *N*-(2-sulfoethyl)amide, inhibits bile-salt sulfotransferase. 1. Chen (1982) *Biochim. Biophys. Acta* **717**, 316.

### Taurodeoxycholate

This bile salt and bio-detergent (FW<sub>sodium-salt</sub> = 521.69 g/mol; CAS 81-24-3), a product of the conjugation of deoxycholic acid with taurine, is a major constituent of bile in most mammals. Taurodeoxycholate is frequently employed in the isolation of membrane proteins. Taurodeoxycholate has a critical micelle concentration of 1-4 mM and an aggregation number of six. For many of the following enzymes, the inhibitor is the micellar form, not monomeric taurocholate. **Target(s):**  $\beta$ -*N*-acetylhexosaminidase (1); alkaline phosphatase (2); bile-acid-CoA:amino acid *N*-acyltransferase (3); ceramidase (4); CYP7B1, or oxysterol  $7\alpha$ -monooxygenase (5); endoglycosylceramidase (6,7);  $\gamma$ -glutamyl transpeptidase, weakly inhibited (8); 2-hydroxyacyl sphingosine  $1\beta$ -galactosyltransferase, or cerebroside synthase (9); lipase, or triacylglycerol lipase (10-14); *N*-(long-chain-acyl)ethanolamine deacylase (15); *trans*-octaprenyltransferase (16); phospholipase A<sub>1</sub> (17); phospholipase D (18); proteasome endopeptidase complex (19); and squalene:hopene cyclase (20-22). 1. #### Tauroolithocholate 3-Sulfate

This sulfated bile salt (FW<sub>ion</sub> = 549.75 g/mol) inhibits the phosphatase activity of soluble epoxide hydrolase (IC<sub>50</sub> = 5  $\mu$ M) and lipid-phosphate phosphatase. Soluble epoxide hydrolase is involved in the metabolism of arachidonic acid epoxides, endogenous chemical mediators that play important roles in blood pressure regulation, cell growth, and inflammation. This sulfated bile salt inhibits through a noncompetitive inhibition mechanism involving a new binding site on the C-terminal domain. 1. Tran, Aronov, Tanaka, et al. (2005) *Biochemistry* **44**, 12179.

#### Tautomycin

This spiroketal-containing polyketide (FW = 809.05 g/mol), a dialkyl maleic anhydride derivative from *Streptomyces verticillatus*, exhibits IC<sub>50</sub> values of 0.21 nM and 0.94 nM, respectively, for phosphoprotein phosphatases 1 and 2A (1-11). Tautomycin also induces apoptosis (12) and inhibit smooth muscle endogenous phosphatase (13). **Target(s):** [myosin-light-chain] phosphatase (14); phosphoprotein phosphatase (1-11); protein phosphatase (11); protein phosphatase 2A (1-3); protein phosphatase (48); smooth muscle endogenous phosphatase (13). 1. #### Taxifolin

This phytoflavonoid and superoxide scavenger (FW = 304.26 g/mol; CAS 480-18-2), also called dihydroquercetin and 3,3',4',5,7-pentahydroxyflavanone, also inhibits numerous enzymes, including aldose reductase (1); creatine kinase (2); fatty-acid synthase (3); inositol-trisphosphate 3-kinase (4); lipoxygenase (15); Moloney murine leukemia virus reverse transcriptase (6); protein kinase C (7); and RNA-directed DNA polymerase (8). 1. #### Tazobactam

This triazolyl-substituted penicillanic acid sulfone (FW<sub>free-acid</sub> = 300.30 g/mol; CAS 89786-04-9), often used clinically with a broad-spectrum penicillin (e.g., piperacillin), is an effective inhibitor against class A  $\beta$ -lactamases and some Class-C  $\beta$ -lactamases (1-12). Tazobactam first acylates the reactive seryl residue of its target, and the acylated enzymes then partitions between a hydrolysis and inactivation pathway involving interaction with other enzyme nucleophiles. Because the hydrolytic rate is high, thousands of hydrolytic turnovers may actually occur until inhibition is achieved. **See also** LM-1-255 1. Perilli, Franceschini, Bonfiglio, et al. (2000) *J. **TB21007**

This brain-penetrant GABA<sub>A</sub> receptor inverse agonist (FW = 339.50 g/mol; CAS 207306-50-1; Soluble to 100 mM in DMSO), also named 6,7-dihydro-3-[(2-hydroxyethyl)thio]-6,6-dimethyl-1-(2-thiazolyl)benzo[*c*]thiophen-4(5*H*)-one, selectively targets selective for the  $\alpha_5$ -subtype ( $K_i = 1.6$  nM), with weaker affinity for subtypes  $\alpha_2$  ( $K_i = 16$  nM),  $\alpha_1$  ( $K_i = 20$  nM) and  $\alpha_3$  ( $K_i = 20$  nM). TB-21007 enhances cognitive performance in rats in the delayed 'matching-to-place' Morris water maze test following i.p. administration. 1. Chambers, Attack, Broughton, *et al.* (2003) *J Med Chem.* **46**, 2227.

**TBB**, See 4,5,6,7-Tetrabromobenzotriazole

**TBC11251**, See Sitaxentan

**DL-TBOA**

This amino acid transport inhibitor (FW = 239.23 g/mol; CAS 205309-81-5; Soluble to 100 mM in DMSO and to 5 mM in H<sub>2</sub>O with gentle warming), also known as DL-threo- $\beta$ -benzyloxy-L-aspartic acid (with \* marking the second asymmetric carbon), is a competitive, non-transportable blocker of excitatory amino acid transporters EAAT<sub>1</sub> (IC<sub>50</sub> = 70  $\mu$ M), EAAT<sub>2</sub> (IC<sub>50</sub> = 70  $\mu$ M), EAAT<sub>3</sub> (IC<sub>50</sub> = 6  $\mu$ M), EAAT<sub>4</sub> ( $K_i = 4.4$   $\mu$ M) and EAAT<sub>5</sub> ( $K_i = 3.2$   $\mu$ M), with low selectivity for ionotropic and metabotropic glutamate receptors.

**TBPS**, See *t*-Butylbicyclo[2.2.2]phosphorothionate

**TC 1**

This high-affinity  $\sigma_1$  receptor ligand (FW = 297.37 g/mol; CAS 362512-81-0; Soluble to 50 mM in DMSO and to 50 mM in ethanol, both with gentle warming), also named (*N*-(3'-fluorophenyl)ethyl-4-azabicyclo[5.4.1.0<sup>2,6</sup>.0<sup>3,10</sup>.0<sup>5,9</sup>.0<sup>8,11</sup>]dodecan-3-ol, displays selectivity, with  $K_i$  values of 10 and 370 nM, respectively, for  $\sigma_1$  and  $\sigma_2$  receptors (1). TC-1 exhibits low affinity for: dopamine transporters, or DAT ( $K_i > 10$   $\mu$ M); serotonin transporters, or SERT ( $K_i > 10$   $\mu$ M); noradrenalin transporters, or NET ( $K_i > 10$   $\mu$ M); and dopamine D<sub>2</sub> receptors ( $K_i = 1226$  nM). TC-1 attenuates cocaine-induced locomotor activity in mice. 1. Liu, Banister, Christie, *et al.* (2007) *Eur. J. Pharmacol.* **555**, 37.

**TC 1698**

This neuroprotective nicotinic receptor agonist (FW = 275.22 g/mol; CAS 787587-06-8; Soluble to 100 mM in water), also named 2-(3-pyridinyl)-1-azabicyclo[3.2.2]nonane dihydrochloride, selectively targets  $\alpha_7$  receptor agonist (EC<sub>50</sub> = 440 nM) and displays weak partial agonist/antagonist activity at  $\beta$ -subunit-containing receptors (1,2). Its neuroprotective effect is prevented

through angiotensin receptor activation of the protein tyrosine phosphatase SHP-1. (1). 1. Marrero, Papke, Bhatti, Shaw & Bencheri (2004) *J. Pharmacol. Exp. Ther.* **309**, 16. 2. Papke, McCormack, Jack, *et al.* (2005) *Eur. J. Pharmacol.* **524**, 11.

**TC 2559**

This partial nicotinic acetylcholine receptor agonist (FW<sub>free-base</sub> = 206.14 g/mol; FW<sub>di-Fumarate-Salt</sub> = 438.43 g/mol; CAS 212332-35-9), also named 4-(5-ethoxy-3-pyridinyl)-*N*-methyl-(3*E*)-3-buten-1-amine, is subtype-selective for  $\alpha_4\beta_2$  receptor (EC<sub>50</sub> = 0.18  $\mu$ M), showing weaker interactions with  $\alpha_4\beta_4$  (EC<sub>50</sub> = 12.5  $\mu$ M),  $\alpha_2\beta_4$  (EC<sub>50</sub> = 14.0  $\mu$ M),  $\alpha_3\beta_4$  (EC<sub>50</sub> > 30  $\mu$ M),  $\alpha_3\beta_2$  (EC<sub>50</sub> > 100  $\mu$ M), and  $\alpha_7$  (EC<sub>50</sub> > 100  $\mu$ M) subtypes. TC 2559 displays selectivity for ( $\alpha_4$ )<sub>2</sub>( $\beta_2$ )<sub>3</sub> receptor stoichiometry and enhanced central versus peripheral nervous system (CNS-PNS) selectivity ratio. TC-2559 competes effectively with nicotine binding ( $K_i = 5$  nM), but not with bungarotoxin ( $K_i > 50$   $\mu$ M) (1-3). Dopamine release from striatal synaptosomes and ion flux from thalamic synaptosomes indicate that TC-2559 is potent and efficacious in the activation of CNS receptors and significantly reduced glutamate-induced neurotoxicity *in vitro*. TC-2559 has no detectable effects on muscle and ganglion-type nicotinic acetylcholine receptors at concentrations up to 1 mM. TC-2559 significantly attenuates scopolamine-induced cognitive deficits in a step-through passive avoidance task (1). TC 2559 attenuates scopolamine-induced cognitive deficits in a step-through passive avoidance task. Two glutamate receptor antagonists (6-cyano-7-nitroquinoxaline-2,3-dione and D(-)-2-amino-5-phosphonopentanoic acid) fail to reduce TC-2559-induced responses, suggesting that the TC-2559-induced increase in DA cell firing is caused by direct postsynaptic depolarization *via* activation of  $\alpha_4\beta_2$  receptors, and not by enhancement of glutamate release (2). The EC<sub>50</sub> for TC-2559 is unchanged in *Xenopus* oocytes that manipulated to express exclusively ( $\alpha_4$ )<sub>2</sub>( $\beta_2$ )<sub>3</sub> nicotinic acetylcholine receptors, however, the maximum effect of TC-2559 was dramatically enhanced. These results suggest that TC-2559 is a selective agonist of ( $\alpha_4$ )<sub>2</sub>( $\beta_2$ )<sub>3</sub> nicotinic acetylcholine receptor. 1. Bencherif, Bane, Miller, Dull & Gatto (2000) *Eur. J. Pharmacol.* **409**, 45. 2. Chen, Sharples, Phillips, *et al.* (2003) *Neuropharmacology* **45**, 334. 3. Zwart, Broad, Xi, *et al.* (2006) *Eur. J. Pharmacol.* **539**, 10.

**TC-2153**

This potent STEP inhibitor (FW<sub>free-base</sub> = 354.86 g/mol), also named 8-(trifluoromethyl)-1,2,3,4,5-benzopentathiepin-6-amine, targets Striatal-Enriched protein tyrosine Phosphatase, or STEP (IC<sub>50</sub> = 25 nM), a neuron-specific enzyme regulating *N*-methyl-D-aspartate receptor (NMDAR) and  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid receptor (AMPA) trafficking, as well as ERK1/2, p38, Fyn, and Pyk2 activity. STEP is overactive in several neuropsychiatric and neurodegenerative disorders, including Alzheimer's disease (AD). Although the elemental sulfur allotrope S<sub>8</sub> was found to be a STEP inhibitor, it suffers from low water-solubility and an inability to be modified with the goal of improving its physicochemical properties, redox activity, binding affinity, and selectivity. By contrast, TC-2153 is a derivative with more desirable properties that may even serve as a lead for inhibitor development. This cyclic polysulfide forms a reversible covalent bond with the catalytic cysteine, thereby blocking STEP catalysis. TC-2153 increased tyrosine phosphorylation of STEP substrates ERK1/2, Pyk2, and GluN2B, and exhibited no toxicity in cortical cultures. In cell-based assays, TC-2153 increased tyrosine phosphorylation of STEP substrates ERK1/2, Pyk2, and GluN2B, and exhibited no toxicity in cortical cultures. TC-2153 improves cognitive function in several cognitive tasks in 6 and 12 month-old triple transgenic AD (3xTg-AD) mice, with no change in  $\beta$ -amyloid and phospho-Tau protein levels. 1. Xu, Chatterjee, Baguley, *et al.* (2014) *PLoS Biol.* **12**, e1001923.

This PRMT inhibitor (FW = 401.26 g/mol; CAS 17328-16-4; Soluble to 50 mM in DMSO), also named *N,N'*-(sulfonyldi-4,1-phenylene)bis(2-chloroacetamide), selectively targets protein arginine methyl-transferase-1, or PRMT1 (IC<sub>50</sub> = 1.5 μM), with no inhibitory activity against CARM1 and the lysine methyltransferase Set7/9. PRMT catalyzes methylation of arginine residues, transferring methyl groups from *S*-adenosyl-L-methionine to its terminal guanidino nitrogen atoms. TC-E 5003 inhibits growth of MCF7a breast cancer cells and LNCaP prostate cancer cells. It also attenuates androgen-induced gene expression in LNCaP cells. Given the susceptibility of α-chloroacetamido groups to nucleophilic displacement by active-site thiol and imidazole groups, TC-E 5003 most likely irreversibly inactivates PRMT1. **1.** Bissinger, Heinke, Spannhoff (2011) *Bioorg. Med. Chem.* **19**, 3717.

#### TC-E 5005

This potent and selective PDE inhibitor (FW = 270.33 g/mol; CAS 959705-64-7; Soluble in H<sub>2</sub>O to 100 mM as HCl salt), also named 2-methoxy-6,7-dimethyl-9-propyl-imidazo[1,5-a]pyrido[3,2-e]pyrazine, selectively targets phosphodiesterase PDE10A (IC<sub>50</sub> = 7.28 nM), with far lower affinity for PDE2A (IC<sub>50</sub> = 239 nM), PDE11A (IC<sub>50</sub> = 779 nM), PDE5A (IC<sub>50</sub> = 919 nM), PDE7B (IC<sub>50</sub> = 3100 nM) and PDE3A (IC<sub>50</sub> = 3700 nM), with IC<sub>50</sub> values >5000 nM for PDE1B, PDE4A, PDE6, PDE8A and PDE9A). **1.** Höfgen, Stange, Schindler, *et al.* (2010) *J. Med. Chem.* **53**, 4399.

#### TC-F 2

This potent, reversible FAAH inhibitor (FW = 439.51 g/mol; CAS 1304778-15-1; Soluble to 100 mM in DMSO), also named 1-[(3*S*)-1-[4-(2-benzofuranyl)-2-pyrimidinyl]-3-piperidinyl]-3-ethyl-1,3-dihydro-2*H*-benzimidazol-2-one, targets fatty acid amide hydrolase, or FAAH, with respective IC<sub>50</sub> values of 28 and 100 nM for human and rat enzymes. Also known as oleamide hydrolase and anandamide amidohydrolase, FAAH plays a central role in inactivating endocannabinoids, such as *N*-arachidonyl-ethanolamide (anandamide). TC-F 2 shows far lower affinity (IC<sub>50</sub> > 20 μM) for cannabinoid-related targets like the CB<sub>1</sub> and CB<sub>2</sub> cannabinoid receptors as well as the Transient Receptor Potential cation channel subfamily V member 1 (TrpV1). **1.** Gustin, Ma, Min, *et al.* (2011) *Bioorg. Med. Chem. Lett.* **21**, 2492. **2.** Min, Thibault, Porter, *et al.* (2011) *Proc. Natl. Acad. Sci. U.S.A.* **108**, 7379.

#### TC-G 1004

This potent receptor antagonist (FW = 421.50 g/mol; CAS 1061747-72-5; Soluble to 100 mM (as HCl salt) and to 100 mM in DMSO), also named *N*-[2-(3,5-dimethyl-1*H*-pyrazol-1-yl)-6-[6-(4-methoxy-1-piperidinyl)-2-pyridinyl]-4-pyrimidinyl]acetamide, targets adenosine A<sub>2A</sub> receptors (K<sub>i</sub> = 0.44 nM), with >100-fold selectivity compared to A<sub>1</sub> receptors (K<sub>i</sub> = 85 nM)

and potentiates L-DOPA-induced rotational behavior in 6-hydroxydopamine- (or 6-OHDA-) lesioned rats. **1.** Zhang, Tellew, Luo, *et al.* (2008) *J. Med. Chem.* **51** 7099.

#### TC-G 24

This potent, brain-penetrating protein kinase inhibitor (FW = 330.73 g/mol; CAS 1257256-44-2; Soluble to 10 mM in DMSO, with gentle warming), also named *N*-(3-chloro-4-methylphenyl)-5-(4-nitrophenyl)-1,3,4-oxadiazol-2-amine, targets GSK-3β (IC<sub>50</sub> = 17 nM), displaying selectivity versus CDK2 (~22% inhibition at 10 μM). TC-G 24 increases liver glycogen reserves in rodents. **1.** Khanfar, Hill, Kaddoumi & El Sayed (2001) *J. Med. Chem.* **53**, 8534.

#### TC-H 106

This brain-penetrant, Class I HDAC inhibitor (FW = 339.43 g/mol; CAS 937039-45-7; Soluble to 100 mM in DMSO and to 50 mM in Ethanol) targets HDAC1 (IC<sub>50</sub> = 150 nM), HDAC3 (IC<sub>50</sub> = 370 nM), HDAC2 (IC<sub>50</sub> = 760 nM) and HDAC8 (IC<sub>50</sub> = 5000 nM), with no activity against class II HDACs. TC-H 106 is a slow, tight-binding inhibitor for HDAC1, with *k*<sub>1</sub> = 4.9 × 10<sup>4</sup> M<sup>-1</sup> min<sup>-1</sup>, *k*<sub>-1</sub> = 0.0072 min<sup>-1</sup>; K<sub>i</sub> = 148 nM (1). **1.** Chou, *et al.* (2008) *J. Biol. Chem.* **283**, 35402. **2.** Rai, *et al.* (2008) *PLoS ONE* **3**, e1958. **3.** Xu, *et al.* (2009) *Chem. Biol.* **16**, 980.

#### TC HSD 21

This potent 17β-hydroxysteroid dehydrogenase inhibitor (FW = 422.32 g/mol; CAS 330203-01-5; Soluble: 100 mM in DMSO), also named 5-[(3-bromo-4-hydroxyphenyl)methylene]-3-(4-methoxyphenyl)-2-thioxo-4-thiazolidinone, targets human 17β-HSD isozyme-3 (IC<sub>50</sub> = 6 nM) and mouse 17β-HSD3 (IC<sub>50</sub> = 40 nM), with no activity toward 17β-HSD1, 17β-HSD2, or the estrogen receptor α (ERα), androgen receptors, or glucocorticoid receptors. **1.** Harada, Kubo, Tanaka & Nishioka (2012) *Bioorg. Med. Chem. Lett.* **22**, 504.

#### TC-I 15

This potent α<sub>2</sub>β<sub>1</sub> integrin inhibitor (FW = 520.62 g/mol; CAS 916734-43-5; Solubility: 100 mM in DMSO; 25 mM as the sodium salt), also named *N*-[[[(4*R*)-5,5-dimethyl-3-(phenylsulfonyl)-4-thiazolidinyl]carbonyl]-3-[[[(phenylmethyl)amino]carbonyl]amino]-L-alanine, blocks human platelet adhesion to type I collagen under static (IC<sub>50</sub> = 12 nM) and under flow (IC<sub>50</sub> = 715 nM) conditions. TC-I 15 displays selectivity for α<sub>2</sub>β<sub>1</sub>, with an IC<sub>50</sub> value >1000 nM for α<sub>v</sub>β<sub>3</sub>, α<sub>5</sub>β<sub>1</sub>, α<sub>6</sub>β<sub>1</sub> and α<sub>IIb</sub>β<sub>3</sub>. It also reduces collagen IV production in mesangial cells. **1.** Miller, Basra, Kulp, *et al.* (2009) *Proc. Natl. Acad. Sci. U.S.A.* **106**, 719. **2.** Borza, Su, Chen, *et al.* (2012) *J. Am. Soc. Nephrol.* **23**, 1027.

## TCID

This membrane-permeable UCH inhibitor (FW = 283.92 g/mol; CAS 30675-13-9; Solubility: 50 mM in DMSO), also named 4,5,6,7-tetrachloro-1H-indene-1,3(2H)-dione, selectively targets ubiquitin C-terminal hydrolase-L3 (UCH-L3) inhibitor ( $IC_{50}$  = 0.6  $\mu$ M), exhibiting >100x selectivity for UCH-L3 over UCH-L1 (1). **Pharmacologic Action:** Inhibitory glycinergic neurotransmission is terminated by Na<sup>+</sup>/Cl<sup>-</sup>-dependent glycine transporters (or GlyT's), with the glial GlyT1 mainly responsible for completion of inhibitory neurotransmission, and the neuronal GlyT2 mediating reuptake of the neurotransmitter. Protein Kinase C accelerates GlyT2 endocytosis by increasing its ubiquitination, and this process is in turn regulated by the deubiquitinating enzyme (or DUB) known as ubiquitin C-terminal hydrolase-L1 (UCHL1). TCID diminishes glycine transporter GlyT2 ubiquitination in brain stem and spinal cord primary neurons (2). 1. Liu, Lashuel, Choi, *et al.* (2003) *Chem Biol.* **10**, 837. 2. de Juan-Sanz, Núñez, López-Corcuera & Aragón (2013) *PLoS One* **8**, e58863.

## TC LPA5 4

This LPA receptor antagonist (FW = 410.89 g/mol; CAS 1393814-38-4; Soluble to 100 mM in DMSO), also named 5-(3-chloro-4-cyclohexylphenyl)-1-(3-methoxyphenyl)-1H-pyrazole-3-carboxylic acid, targets the G protein-coupled, lysophosphatidic acid receptor-5 (LPA<sub>5</sub>) receptor antagonist ( $IC_{50}$  = 0.8  $\mu$ M), with great selectivity compared to eighty other screened targets. TC-LPA5-4 also inhibits LPA-induced aggregation of isolated human platelets. 1. Kozian, Evers, Florian, *et al.* (2012) *Bioorg. Med. Chem. Lett.* **22**, 5239.

## TC-MCH 7c

This orally active, brain-penetrant MCH<sub>1</sub>R antagonist (FW = 408.47 g/mol; CAS 864756-35-4; Solubility: 100 mM in water (as HCl salt); 50 mM in DMSO), also named 4-[(4-fluorophenyl)methoxy]-1-[4-[2-(1-pyrrolidinyl)ethoxy]phenyl]-2(1H)-pyridinone, potently and selectively targets the melanin-concentrating hormone receptor 1 (or MCH<sub>1</sub>R) antagonist ( $IC_{50}$  = 5.6 nM, in hMCH<sub>1</sub>R-expressing CHO cells). Melanin-concentrating hormone (MCH), which is a neuropeptide expressed in the hypothalamus of the brain, is involved in regulating feeding behavior and energy homeostasis. TC-MCH 7c displays selectivity for MCH<sub>1</sub>R over MCH<sub>2</sub>R receptors ( $IC_{50}$  = > 10  $\mu$ M). It also decreases body weight in a mouse model of diet-induced obesity. 1. Ito, Ishihara, Gomori, *et al.* (2009) *Eur. J. Pharmacol.* **624**, 77. 2. Haga, Mizutani, Naya, *et al.* (2011) *Bioorg. Med. Chem.* **19**, 883.

## TC Mps1 12

This orally active Mps1 inhibitor (FW = 324.38 g/mol; CAS 1206170-62-8; Solubility: 100 mM in DMSO), also named 4-[[4-amino-5-cyano-6-[(1,1-dimethylethyl)amino]-2-pyridinyl]amino]benzamide, potently and selectively targets monopolar spindle-1, or Mps1 ( $IC_{50}$  = 6.4 nM), a kinetochore-associated protein kinase involved in both chromosome attachment and spindle checkpoint control. Mps1 kinases also function at centrosomes, with wider impact on development, cytokinesis, and several different signaling pathways. By virtue of its unusual flipped-peptide conformation, TC Mps1 12 exhibits high selectivity for Mps1 when tested with a panel of 95 kinases, including JNK. It also inhibits A549 lung carcinoma cell proliferation and attenuates A549 cell xenograft growth in mice. 1. Kusakabe, Ide, Daigo, *et al.* (2012) *ACS Med. Chem. Lett.* **3**, 560.

## TCN-201

This NMDA receptor antagonist (FW = 461.89 g/mol; CAS 852918-02-6; Soluble to 100 mM in DMSO) display sub- $\mu$ M and  $\mu$ M potency at NR1 and NR2A receptors, respectively, although they did not show activity at NR2B-containing receptor up to 50  $\mu$ M concentration (1-4). NR1 and NR2A represent a subtype of N-methyl-D-aspartate receptors (NMDARs) that are glutamate- and glycine-gated Ca<sup>2+</sup>-permeable channels and are highly expressed in the central nervous system. Antagonists that are sufficiently selective to preferentially block GluN2A-containing NMDA receptors (NMDARs) over GluN2B-containing NMDARs are few in number. Electrophysiological recordings from chimeric and mutant rat NMDA receptors suggest that TCN-201 binds to a novel allosteric site located at the dimer interface between the GluN1 and GluN2 agonist binding domains. Furthermore, we demonstrate that occupancy of this site by TCN-201 inhibits NMDA receptor function by reducing glycine potency. Addition of 1 mM glycine, but not 1 mM L-glutamate, surmounts the inhibitory effects of TCN-201 in the FLIPR NR1/NR2A assay. However, TCN-201 displaces the glutamate-site antagonist CGP 39653 to a greater extent than the glycine site antagonist MDL 105,519 in rat brain cortex binding assay. 1. Bettini, Sava, Griffante, *et al.* (2010) *J. Pharm. Exp. Ther.* **335**, 644. 2. Shin, Kim & Thayer (2012) *Brit. J. Pharmacol.* **166**, 1002. 3. Edman, McKay, Macdonald, *et al.* (2012) *Neuropharmacology* **63**, 441. 4. Hansen, Ogden & Traynelis (2012) *J. Neurosci.* **32**, 6197.

## TC-N 1752

This channel blocker and experimental analgesic (FW = 516.52 g/mol; CAS 1211866-85-1), also named N-[2-methyl-3-[[4-[4-[[4-(trifluoromethoxy)phenyl]methoxy]-1-piperidinyl]-1,3,5-triazin-2-yl]amino]phenyl]acetamide, targets voltage-gated sodium channels: NaV1.7 channels ( $IC_{50}$  = 0.17  $\mu$ M) values are 0.17, 0.3, 0.4 and 1.1  $\mu$ M at hNav1.7, hNav1.3 ( $IC_{50}$  = 0.3  $\mu$ M), hNav1.4 ( $IC_{50}$  = 0.4  $\mu$ M) and hNav1.5 ( $IC_{50}$  = 1.1  $\mu$ M). TC-N 1752 also inhibits tetrodotoxin-sensitive sodium channels. 1. Bregman H1, Berry L, Buchanan

**Tc $\alpha$ -19402**, See *Large Clostridial Cytotoxins*

**TC OT 39**

This nonpeptide OT/V2 partial agonist (FW = 600.78 g/mol; CAS 479232-57-0; Solubility: 100 mM in 1 eq. HCl; 100 mM in DMSO), also named (2*S*)-*N*-[[4-[(4,10-dihydro-1-methylpyrazolo[3,4-*b*][1,5]benzodiazepin-5(1*H*)-yl)carbonyl]-2-methylphenyl)methyl]-2-[(hexahydro-4-methyl-1*H*-1,4-diazepin-1-yl)thioxomethyl]-1-pyrrolidinecarboxamide, targets oxytocin (*or* OT) ( $K_i = 147$  nM) and vasopressin  $V_2$  ( $K_i > 1000$  nM) receptors, while acting as an antagonist of  $V_{1a}$  receptors, ( $K_i = 300$  nM). TC OT 39 stimulates uterine contraction in rats. **1.** Pitt, Batt, Haigh, *et al.* (2004) *Bioorg. Med. Chem. Lett.* **14**, 4585. **2.** Frantz, Rodrigo, Boudier, *et al.* (2010) *J. Med. Chem.* **2010** **53**, 1546.

**TC-P 262**

This diaminopyrimidine (FW = 258.32 g/mol; CAS 873398-67-5; Soluble to 100 mM in DMSO), also named 5-[5-methyl-2-(1-methylethyl)phenoxy]-2,4-pyrimidinediamine, is a selective purinergic receptor antagonist that targets  $P2X_3$  ( $pIC_{50} = 7.39$ ) and  $P2X_{2/3}$  ( $pIC_{50} = 6.68$ ) receptors. The latter are cation-permeable ligand gated ion channels that open in response to the binding of extracellular ATP. TC-P-262 displays no detectable activity at  $P2X_1$ ,  $P2X_2$ ,  $P2X_4$  and  $P2X_7$  receptors, for which  $pIC_{50}$  values are less than 4.7. Whole-cell voltage clamp electrophysiology confirmed these results. **1.** Ballini, Virginio, Medhurst, *et al.* (2011) *Brit. J. Pharmacol.* **163**, 1315.

**TCS 46b**

This NMDA receptor antagonist (FW = 345.44 g/mol; CAS 302799-86-6; Soluble to 100 mM in DMSO), also named 1,3-dihydro-5-[3-[4-(phenylmethyl)-1-*H*-benzimidazol-2-one], targets the NR1A/NR2B ( $IC_{50} = 5.3$  nM), NR1A/2A ( $IC_{50} = 35000$  nM), and NR1A/2C ( $IC_{50} = 100000$  nM) subtypes of the *N*-methyl-D-aspartate receptor. Oral administration of at 10 and 30 mg/kg TCS 46b also potentiates the effect of L-DOPA in unilaterally 6-hydroxydopamine-lesioned (6-OHDA) rats. **1.** Wright, Gregory, Kesten, *et al.* (2000) *J. Med. Chem.* **43**, 3408. **2.** Roger, Lagnel, Besret, *et al.* (2003) *Bioorg. Med. Chem.* **11**, 5401.

**TCS 183**

This short peptide (FW = 1425.58 g/mol; Sequence: MSGRPRTTSFAES-NH<sub>2</sub>; CAS unassigned; Soluble to 1 mg/mL H<sub>2</sub>O), corresponding to residues 1-13 of human and mouse GSK-3 $\beta$ , is a competitive inhibitor (possibly even an alternative phosphoryl-accepting substrate) for enzymes catalyzing phosphorylation of Ser-9 in GSK-3 $\beta$ . This GSK isoform is unusual, because its kinase activity is primarily determined by the phosphorylation status of Ser-9. Dephosphorylation of this residue by Ser/Thr protein phosphatases activates GSK3 $\beta$ , whereas phosphorylation of Ser-9 inhibits its activity. In glycogen metabolism, for example, insulin stimulates PI3K, which leads to activation of Akt (*or* Protein Kinase B), which catalyzes GSK3 $\beta$  phosphorylation of GSK3 $\beta$ , favoring dephosphorylation of glycogen synthase and stimulation of glycogen synthesis. The sequence-scrambled version of TCS 183 that serves as a control for nonspecific effects. **1.** Peineau, Taghibiglou, Bradley, *et al.* (2007) *Neuron* **53**, 703.

**TCS 359**

This potent receptor-type tyrosine-protein kinase inhibitor (FW = 360.43 g/mol; CAS 301305-73-7; Solubility: 15 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 2-[(3,4-dimethoxybenzoyl)amino]-4,5,6,7-tetrahydrobenzo[*b*]thiophene-3-carboxamide, targets Fetal Liver Kinase FLT3, with an  $IC_{50}$  value of 27 nM for the isolated enzyme and 42 nM for the proliferation of MV4-11 cells. **1.** Patch, Baumann, Liu, *et al.* (2006) *Bioorg. Med. Chem. Lett.* **16**, 3282.

**TCS 401**

This orally available and selective protein-tyrosine phosphatase inhibitor (FW<sub>HCl-Salt</sub> = 306.72 g/mol; CAS 243966-09-8), also named 2-[(carboxycarbonyl)amino]-4,5,6,7-tetrahydrothieno[2,3-*c*]pyridine-3-carboxylic acid hydrochloride, targets PTP1B ( $K_i = 0.29$  nM), with far less affinity for CD45 D1D2 ( $K_i = 59$  nM), PTP $\beta$  ( $K_i = 560$  nM), PTP $\epsilon$  D1 ( $K_i = 1100$  nM), SHP-1 ( $K_i > 2000$  nM), PTP $\alpha$  D1 ( $K_i > 2000$  nM), and LAR D1D2 ( $K_i > 2000$  nM). **1.** Iversen, *et al.* (2000) *J. Biol. Chem.* **275**, 10300. **2.** Andersen *et al.* (2002) *J. Med. Chem.* **45**, 4443.

**TCS 1102**

This potent, dual orexin receptor antagonist, *or* DORA (FW = 470.59 g/mol; CAS 916141-36-1; Soluble to 100 mM in DMSO and to 100 mM in Ethanol), also named *N*-[1,1'-biphenyl]-2-yl-1-[2-[(1-methyl-1*H*-benzimidazol-2-yl)thio]acetyl]-2-pyrrolidinedicarboxamide, targets OX<sub>2</sub> ( $K_i = 0.2$  nM) and

OX<sub>1</sub> ( $K_i = 3$  nM) receptors. 1. Bergman, Roecker, Mercer, *et al.* (2008) *Bioorg. Med. Chem. Letts.* **18**, 1425. 2. Winrow, Tanis, Reiss, *et al.* (2010) *Neuropharmacology* **58**, 185.

**TCS 2002**

This potent and orally available GSK-3 $\beta$  inhibitor (FW = 338.38 g/mol; CAS 1005201-24-0; Soluble to 100 mM in DMSO), systematically named 2-methyl-5-[3-[4-(methylsulfinyl)phenyl]-5-benzofuranyl]-1,3,4-oxadiazole, targets Glycogen Synthase Kinase-3 $\beta$  ( $IC_{50} = 35$  nM). TCS-2202 shows a good pharmacokinetic profile, including favorable blood-brain barrier (BBB) penetration. TCS-2202 inhibits stress-induced hyperphosphorylation of the microtubule-associated protein Tau in mouse brain. 1. Saitoh, Kunitomo, Kimura, *et al.* (2009) *J. Med. Chem.* **52**, 6270.

**TCS 2312**

This protein kinase inhibitor (FW = 412.49 g/mol; CAS 838823-31-7; Solubility: 20 mM in DMSO), also named 4'-[5-[[3-[(cyclopropylamino)methyl]phenyl]amino]-1H-pyrazol-3-yl]-[1,1'-biphenyl]-2,4-diol, potently and selectively targets Checkpoint Kinase 1, *or* chk1 ( $K_i = 0.38$  nM,  $EC_{50} = 60$  nM). TCS 2312 enhances the cell killing activity of gemcitabine in breast and prostate cancer cell lines and displays antiproliferative effects *in vitro*. 1. Teng, Zhu, Johnson, Chen, *et al.* (2007) *J. Med. Chem.* **50**, 5253.

**TCS 2314**

This integrin very late antigen-4 (VLA-4;  $\alpha_4\beta_1$ ) antagonist (FW = 522.59 g/mol; CAS 317353-73-4; Soluble to 100 mM in DMSO and to 50 mM in ethanol), also systematically named 1-[[[(3S)-4-[2-[4-[[[(2-methylphenyl)amino]carbonyl]amino]phenyl]acetyl]-3-morpholinyl]carbonyl]-4-piperidinediacetic acid, blocks ( $IC_{50} = 4.4$  nM) the activation of inflammatory cells. The integrin very late antigen-4 (VLA-4, R4 $\beta$ 1, CD49d/CD29) is intrinsically involved in the pathogenesis of inflammatory and autoimmune diseases such as asthma, rheumatoid arthritis, type 1 diabetes, psoriasis, multiple sclerosis (MS), inflammatory bowel disease, and hepatitis C. A heterodimeric glycoprotein receptor that is constitutively expressed on the surface of nearly all leukocytes. VLA-4 binds vascular cell adhesion molecule-1 (VCAM-1, CD106) expressed on cytokine-stimulated endothelial cells and the alternatively spliced portion of the type-III connecting segment of fibronectin (FN), and mediates the process of adhesion, migration, and activation of inflammatory cells at the site of inflammation. Therefore, the blockade of the

interaction of VLA-4 with the ligands should alleviate the inappropriate cellular signaling processes and would thus be expected to be useful in the treatment of inflammatory and autoimmune diseases. TCS 2312 demonstrates excellent efficacy in models of asthma and PK profiles in rats, dogs, and monkeys. 1. Muro, Iimura, Sugimoto, *et al.* (2009) *J. Med. Chem.* **52**, 7974.

**TC-S 7003**

This orally active, potent and selective protein kinase inhibitor (FW = 530.62 g/mol; CAS 847950-09-8; Soluble to 100 mM in DMSO) targets Lymphocyte specific kinase, *or* Lck ( $IC_{50} = 7$  nM), Lyn ( $IC_{50} = 21$  nM), Src ( $IC_{50} = 42$  nM), and Syk ( $IC_{50} = 200$  nM). TC-S 7003 displays >1000x selectivity for Lck *versus* MAPK, CDK and RSK family representatives. TC-S 7003 inhibits T-cell proliferation *in vitro* and inhibits arthritis in two *in vivo* models. 1. Martin, Newcomb, Nunes, *et al.* (2008) *J. Med. Chem.* **51**, 1637.

**TC-S 7005**

This potent and selective serine/threonine protein kinase inhibitor (FW = 359.38 g/mol; CAS 1082739-92-1; Soluble to 100 mM in DMSO), also named 3-(1,3-benzodioxol-5-yl)-N-[(1S)-1-phenylethyl]isoxazolo[5,4-c]pyridin-5-amine, targets Polo-Like Kinase 2, *or* PLK2 ( $IC_{50} = 4$  nM), with weaker action against PLK3 ( $IC_{50} = 24$  nM), and PLK1 ( $IC_{50} = 214$  nM). Polo-like kinases play fundamental roles in regulating cell division, and treatment of cells with PLK inhibitors results in multiple mitotic defects, often attended by cell death. These enzymes are thus promising targets for cancer therapy, especially in view of their frequent overexpression in human tumors. TC-S 7005 induces mitotic arrest and cell death in HCT 116 colorectal cells. 1. Hanan, Fucini, Romanowski, *et al.* (2008) *Bioorg. Med. Chem. Lett.* **18**, 5186.

**TCS 21311**

This potent JAK inhibitor (FW = 526.51 g/mol; CAS 1260181-14-3; Soluble to 100 mM in DMSO), also named 3-[5-[4-(2-hydroxy-2-methyl-1-oxopropyl)-1-piperazinyl]-2-(trifluoromethyl)phenyl]-4-(1H-indol-3-yl)-1H-pyrrole-2,5-dione, targets Janus Kinase-3, *or* JAK3 ( $IC_{50} = 8$  nM), with much weaker action against JAK1 ( $IC_{50} = 1017$  nM), JAK2 ( $IC_{50} = 2550$  nM), and TYK2 ( $IC_{50} = 8055$  nM). TCS 21311 is only moderately selective inasmuch as it also inhibits GSK-3 $\beta$  ( $IC_{50} = 3$  nM), PKC $\alpha$  ( $IC_{50} = 13$  nM) and PKC $\theta$  ( $IC_{50} = 68$  nM). 1. Thoma, Nuninger, Falchetto, *et al.* (2010) *J. Med. Chem.* **54**, 284.

## TCS 5861528

This TRP<sub>A1</sub> channel blocker (FW = 369.42 g/mol; CAS 332117-28-9; Soluble to 100 mM in DMSO and to 10 mM in ethanol), also named 2-(1,3-dimethyl-2,6-dioxo-1,2,3,6-tetrahydro-7H-purin-7-yl)-N-[4-(1-methylpropyl)phenyl]-acetamide, antagonizes AITC- and 4-HNE-evoked calcium influx (IC<sub>50</sub> values of 14.3 and 18.7 μM respectively) and attenuates diabetic hypersensitivity in *in vivo* rat model. The TRP<sub>A1</sub> ion channel modulates excitability of nociceptors, and it may be activated by compounds resulting from oxidative insults. Diabetes mellitus produces oxidative stress and sensory neuropathy. 1. Wei, Hämäläinen, Saarnilehto, Koivisto & Pertovaara (2009) *Anesthesiology* **111**, 147. 2. Wei, Hämäläinen, Saarnilehto, Koivisto & Pertovaara (2010) *Neuropharmacology* **58**, 578. 3. Wei, Koivisto & Pertovaara (2010) *Neurosci. Letts.* 479 253.

## TCS ERK 11e

This orally bioavailable and potent ERK inhibitor (FW = 500.35 g/mol; CAS 896720-20-0; Soluble to 100 mM in DMSO) selectively targets Extracellular signal-Related Kinase 2, or ERK2 (K<sub>i</sub> < 2 nM), with much weaker action against GSK-3 (K<sub>i</sub> = 395 nM), Aurora Kinase A (K<sub>i</sub> = 540 nM) and Cdk2 (K<sub>i</sub> = 852 nM). Specificity for ERK was optimized following the discovery of a conformational change for this drug, when bound to ERK2, relative to anti-target GSK3. A selective subnanomolar ERK2 inhibitor with potent cellular activity was obtained by stabilizing the ERK-bound conformation through the introduction of additional functionality. TCS ERK 11e also potently blocks proliferation of HT29 cells (IC<sub>50</sub> = 48 nM). 1. Aronov, Tang, Martinez-Botella, *et al.* (2009) *J. Med. Chem.* **52**, 6362.

## TcsH-82, See Large Clostridial Cytotoxins

## TCS JNK 5a

This selective protein inhibitor (FW = 332.42 g/mol; CAS 312917-14-9; Soluble to 100 mM in DMSO), also named N-(3-cyano-4,5,6,7-tetrahydrobenzo[b]thienyl-2-yl)-1-naphthalenecarboxamide, targets c-Jun N-terminal kinases JNK3 (pIC<sub>50</sub> = 6.7), JNK2 (pIC<sub>50</sub> = 6.5), JNK1 (pIC<sub>50</sub> < 5.0), and p38α (pIC<sub>50</sub> < 4.8), without significant activity at a range of other protein kinases, including EGFR, ErbB2, cdk2, PLK-1 and Src, for which pIC<sub>50</sub> is < 5.0. 1. Angell, Atkinson, Brown, *et al.* (2007) *Bioorg. Med. Chem. Letts.* **17**, 1296.

## TCS JNK 6o

This selective ATP-competitive protein inhibitor (FW = 356.38 g/mol; CAS 894804-07-0; Solubility: 100 mM in DMSO), also named N-(4-amino-5-cyano-6-ethoxy-2-pyridinyl)-2,5-dimethoxybenzeneacetamide, targets c-Jun N-terminal kinase (JNK) inhibitor (IC<sub>50</sub> = 2 nM), 4 and 52 nM for JNK1 (IC<sub>50</sub> = 2 nM), JNK2 (IC<sub>50</sub> = 4 nM), and JNK3 (IC<sub>50</sub> = 52 nM), with >1000x selectivity over other kinases, including ERK2 and p38. TCS JNK 6o also inhibits c-Jun phosphorylation (EC<sub>50</sub> = 920 nM) and prevents collagen-induced platelet aggregation *in vitro*. 1. Szczepankiewicz, *et al.* (2006) *J. Med. Chem.* **49**, 3563. 2. Kauskot, *et al.* (2007) *J. Biol. Chem.* **282**, 31990.

## TcsL-82, See Large Clostridial Cytotoxins

## TCS OX2 29

This potent OX<sub>2</sub> antagonist (FW<sub>HCl-Salt</sub> = 433.97 g/mol; CAS 372523-75-6; Soluble to 100 mM in H<sub>2</sub>O and to 25 mM in DMSO), also named (2S)-1-(3,4-dihydro-6,7-dimethoxy-2(1H)-isoquinolinyl)-3,3-dimethyl-2-[(4-pyridinylmethyl)amino]-1-butanone, targets orexin 2 receptor, or OX<sub>2</sub>R (IC<sub>50</sub> = 40 nM), displaying >250c selectivity over OX<sub>1</sub> and fifty other receptors, ion channels and transporters. 1. Hirose, Egashira, Goto, *et al.* (2003) *Bioorg. Med. Chem. Lett.* **13**, 4497.

## TCS PIM-1 1

This selective, ATP-competitive Pim kinase inhibitor (FW = 367.20 g/mol; CAS 491871-58-0; Soluble to 100 mM in DMSO), also named 3-cyano-4-phenyl-6-(3-bromo-6-hydroxy)phenyl-2(1H)-pyridone, targets Pim-1 (IC<sub>50</sub> = 50 nM), displaying 400x selectivity over Pim-2 (IC<sub>50</sub> = 20000 nM) and MEK1/2 (IC<sub>50</sub> > 20000 nM). 1. Cheney, Yan, Appleby, *et al.* (2007) *Bioorg. Med. Chem. Lett.* **17**, 1679.

## TCS PIM-1 4a

This selective, ATP-competitive Pim kinase inhibitor (FW = 273.23 g/mol; CAS 438190-29-5; Soluble to 100 mM in DMSO), also named SMI-4a and (5Z)-5-[[3-(trifluoromethyl)phenyl]-methylene]-2,4-thiazolidinedione,

targets Pim-1 ( $IC_{50} = 24$  nM) and Pim-2 ( $IC_{50} = 100$  nM), displaying  $>150\times$  selectivity over a panel of fifty other kinases tested. TCS PIM-1 4a inhibits ( $IC_{50} = 17$   $\mu$ M) cell growth and is cytotoxic to PC3 prostate carcinoma cells *in vitro*. 1. Xia, Knaak, Ma, *et al.* (2009) *J. Med. Chem.* **52**, 74.

#### TCS PrP Inhibitor 13

This antiprion agent (FW = 281.27 g/mol; CAS 34320-83-7; Soluble to 100 mM in DMSO), also named 2,4-dihydro-5-(4-nitrophenyl)-2-phenyl-3H-pyrazol-3-one, potently inhibits ( $IC_{50} = 3$  nM) accumulation of protease-resistant prion protein (PrP-res) in two models for prion-infected mouse neuroblastoma cell lines. Although its mechanism of action remains uncertain, the antiprion action of this compound does not correlate with any antioxidant activities, any hydroxyl radical-scavenging activities, or any SOD-like activities. 1. Kimata, Nakagawa, Ohyama, *et al.* (2007) *J. Med. Chem.* **50**, 5053.

#### TC-T 6000

This potent ENT inhibitor (FW = 504.71 g/mol; CAS 949467-71-4; Soluble to 20 mM in DMSO), targets the Equilibrative Nucleoside Transporter 4, or ENT4 passive transporter ( $IC_{50} = 74.4$  nM), with 20- and 80-fold selectivity over ENT2 and ENT1, respectively. Structure-activity relationship suggests that nitrogen-containing monocyclic rings and noncyclic substituents at the 4- and 8-positions of the pyrimido[5,4-d]pyrimidine are important for the inhibitory activity against hENT4. The most potent and selective hENT4 inhibitors tend to have a 2,6-di(*N*-monohydroxyethyl) substitution on the pyrimidopyrimidine ring system. ENT4 exhibited a novel, pH-dependent adenosine transport activity optimal at acidic pH, with apparent  $K_m$  values 0.78 and 0.13 mM, respectively, at pH 5.5, which was absent at pH 7.4. Its cardiac abundance suggests contribution to regulation of extracellular adenosine concentrations under ischemia conditions. 1. Wang, Lin, Playa, *et al.* (2013) *Biochem. Pharmacol.* **86**, 1531.

#### dTDP-D-Glucose

This nucleoside diphosphosugar (FW = 564.33 g/mol; CAS 2196-62-5), also known as thymidine 5'-diphospho- $\alpha$ -D-glucopyranose, is formed from dTTP and  $\alpha$ -D-glucose 1-P by glucose-1-phosphate thymidyl-transferase. **Target(s):** CMP-*N*-acetylneuraminatase phospho-diesterase (1); 1,3- $\beta$ -glucan

synthase (2); glucose-1-phosphate thymidyltransferase, by product inhibition (3); glucose-1-phosphate uridylyltransferase, or UDPglucose pyrophosphorylase (4); glycogenin glucosyltransferase (5); glycogen phosphorylase (6,7);  $\beta$ -1,4-mannosyl-glycoprotein 4- $\beta$ -*N*-acetylglucosaminyltransferase (8); UDP-glucuronate 4-epimerase (9); xyloglucan 4-glucosyltransferase, weakly inhibited (11). 1. #### Tebipenem & Tebi-pivoxil

**Tebipenem (R = H)**  
**Tebi-pivoxil (R = CH<sub>2</sub>-O-CO-*t*-Butyl)**

This first-in-class, orally available carbapenem antibiotic (1) (FW = 383.48 g/mol; CAS 161715-21-5) is a slow substrate that inhibits *Mycobacterium tuberculosis*  $\beta$ -lactamase,  $K_m < 2$   $\mu$ M and  $k_{cat} \approx 0.04$  min<sup>-1</sup> (2). FT-ICR mass spectrometry showed that the tebipenem acyl-enzyme complex remains stable for  $>90$  min, existing as mixture of covalently bound drug and bound retro-aldol cleavage product. This low rate of deacylation (via hydrolysis of the lactamase-tebipenem covalent adduct) permits structural analysis of the covalent intermediate by soaking apoenzyme crystals with tebipenem. Its prodrug form tebi-pivoxil (FW = 497.62 g/mol; CAS 211558-19-9) is membrane-permeant and is hydrolyzed to tebipenem. 1. Sato, Kijima, Koresawa, *et al.* (2008) *Drug Metab. Pharmacokin.* **23**, 434. 2. Hazra, Xu & Blanchard (2014) *Biochemistry* **53**, 3671.

#### Tecoviramat

This oral synthetic antiviral (FW = 376.33 g/mol; CAS 816458-31-8), also named *N*-[3,5-dioxo-4-azatetracyclo[5.3.2.0<sup>2,6</sup>.0<sup>8,10</sup>]dodec-11-en-4-yl]-4-(trifluoromethyl)benzamide and ST-246, is active against orthopoxviruses (including smallpox, vaccinia, monkeypox, camelpox, cowpox, mousepox (ectromelia), and variola viruses) by targeting virus p37, which is needed for vaccinia virus envelopment and secretion of extracellular (infective) forms (1-3). Proteins associated with the late endosome (LE) appear to play a central role in the envelopment of a number of taxonomically diverse viruses. ST-246 prevents formation of extracellular virus by inhibiting the formation of a putative wrapping complex derived from virus-modified LE membranes. The LE is enriched for Rab9 protein that mediates recycling of Cation-Dependent Mannose-6-Phosphate Receptor (CD-MPR) and Cation-Independent Mannose-6-Phosphate Receptor (CI-MPR) from the LE to the Trans-Golgi Network (TGN). The wrapping complex catalyzes the envelopment of intracellular mature virus particles to produce egress-competent forms of the

R = -C(=O)-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>(CH<sub>3</sub>)-CH<sub>3</sub>-CH<sub>3</sub>; A<sub>2</sub>-5, R = -C(=O)-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-CH<sub>2</sub>-(CH<sub>3</sub>)<sub>2</sub>. Teicoplanin variants possess a common aglycone core, consisting of seven amino acids that are bound by peptide and ether bonds, thereby forming a four-ring system. Teicoplanin has a longer half-life than vancomycin and can be administered intravenously (as a bolus dose) or by intramuscular injection, with rare nephrotoxicity and ototoxicity. **Primary Mode of Inhibitory Action:** Teicoplanins inhibit peptidoglycan polymerization, resulting in inhibition of Gram-positive bacteria cell walls synthesis and consequent cell death. When given as an intravenous bolus dose, serum and urine teicoplanin concentrations exceeded the minimal inhibitory concentration (typical MIC ≈ 0.02–2 µg/mL) on many pathogenic organisms for at least one day after administration (2). With side effects that do not require close monitoring, its longer serum half-life commends teicoplanin as a valuable vancomycin alternative, making it the glycopeptide antibiotic of choice in many hospitals. 1. Cynamon & Granato (1982) *Antimicrob. Agents Chemother.* **21**, 504. 2. Traina & Bonati (1984) *J. Pharmacokinet. Biopharm.* **12**, 119.

#### Teijin Compound 1

This chemokine receptor antagonist (FW = 476.32 g/mol; CAS 1313730-14-1; Soluble to 10 mM in water and to 100 mM in DMSO), also named N-[2-[[[(3R)-1-[(4-chlorophenyl)methyl]-3-pyrrolidinyl]amino]-2-oxoethyl]-3-(trifluoromethyl)benzamide hydrochloride, targets the CCR2b receptor (IC<sub>50</sub> = 180 nM) and potently inhibits cell chemotaxis induced by MCP-1 (EC<sub>50</sub> = 24 nM). 1. Moree, *et al.* (2004) *Bioorg. Med. Chem. Letts.* **14**, 5413. 2. Moree, Kataoka, Ramirez-Weinhouse, *et al.* (2008) *Bioorg. Med. Chem. Letts.* **18**, 1869. 3. Hall, Mao, Nicolaidou, *et al.* (2009) *Mol. Pharmacol.* **75**, 1325.

#### Teixobactin

This first-in-class, low/no-resistance antibiotic (FW = 1242.47 g/mol; CAS1613225-53-8), isolated from the previously unculturable bacteria *Eleftheria terrae*, exhibits broad action against Gram-positive bacteria by binding to a highly conserved motif of Lipid II and Lipid III, essential peptidoglycan precursors involved in cell wall biosynthesis. In wide-ranging studies, no mutants of *Staphylococcus aureus* or *Mycobacterium tuberculosis* were found to be resistant to teixobactin (1). That resistance has not developed suggests that the target is not a protein, inasmuch as a teixobactin binding site on a protein would be subject to affinity-reducing mutations (1). Given the presence of a metal ion-chelating macrolide ring, another likely mechanism is sequestration of essential metal ions, either in their free or bound forms. **Minimal Inhibitory Concentrations:** (from Reference 1) *Staphylococcus aureus* (MSSA), 0.25 µg/mL; *S. aureus* + 10% serum, 0.25 µg/mL; *S. aureus* (MRSA), 0.25 µg/mL; *Enterococcus faecalis* (VRE), 0.5 µg/mL; *Enterococcus faecium* (VRE), 0.5 µg/mL; *Streptococcus pneumoniae* (penicillin-resistant), ≤ 0.03 µg/mL; *Streptococcus pyogenes*, 0.06 µg/mL; *Streptococcus agalactiae*, 0.12 µg/mL; *Viridans group streptococci*, 0.12 µg/mL; *Bacillus anthracis*, ≤ 0.06 µg/mL; *Clostridium difficile*, 0.005 µg/mL; *Propionibacterium acnes*, 0.08 µg/mL; *Mycobacterium tuberculosis*, 0.125 µg/mL; *Haemophilus influenzae*, 4 µg/mL; *Moraxella catarrhalis*, 2 µg/mL; *Escherichia coli*, 25 µg/mL; *Escherichia coli* (asmB1), 2.5 µg/mL; *Pseudomonas aeruginosa*, > 32

µg/mL; and *Klebsiella pneumoniae*, > 32 µg/mL. 1. Ling, Schneider, Peoples, *et al.* (2015) *Nature* **517**, 455.

#### Telaprevir

This orally available serine protease-directed antiviral (FW = 697.84 g/mol; CAS 402957-28-2 and 569364-34-7; Solubility: 136 mg/mL DMSO; <1 mg/mL Water), also known as VX-950 and systematically as (1*S*,3*aR*,6*aS*)-2-[(2*S*)-2-[[[(2*S*)-2-cyclohexyl-2-(pyrazine-2-carboxylamino)acetyl]amino]-3,3-dimethylbutanoyl]-*N*-[(3*S*)-1-(cyclopropylamino)-1,2-dioxohexan-3-yl]-3,3*a*,4,5,6,6*a*-hexahydro-1*H*-cyclopenta[*c*]pyrrole-1-carboxamide, inhibits hepatitis C virus NS3.4A serine protease (1). In studies with protease domain mutants A156T, D168V and R155Q of full-length NS3 protease, VX-950 was the only known NS3-directed antiviral to inhibit the D168V enzyme more efficiently than the wild type NS3 (2). Telaprevir induces a median 4-log decline of HCV RNA after two weeks of therapy (3) and, when combined with cyclosporine, is highly effective against the recurrence of hepatitis C in liver transplant patients (4). One must avoid co-administration of telaprevir and simvastatin, inasmuch as there is an undesirable drug interaction due to telaprevir inhibition of CYP3A4-mediated simvastatin clearance, increasing plasma concentration by as much as 30x. 1. Lin, Lin, Luong, *et al.* (2004) *J. Biol. Chem.* **279**, 17508. 2. Dahl, Sandström, Akerblom & Danielson (2007) *Antivir. Ther.* **12**, 733. 3. Gentile, Viola, Borgia *et al.* (2009) *Curr. Med. Chem.* **16**, 1115. 4. Kikuchi, Okuda, Ueda, *et al.* (2013) *Biol. Pharm. Bull.* **37**, 417.

#### Telavancin

This semi-synthetic vancomycin derivative (FW = 1755.63 g/mol; CAS 372151-71-8), also known by its trade name Vibativ<sup>®</sup>, is a bactericidal lipopeptide used to treat methicillin-resistant *Staphylococcus aureus* (MRSA) and other Gram-positive infections, including hospital-acquired and ventilator-associated pneumonia caused by *S. aureus*. Telavancin exhibits concentration-dependent bactericidal effects *in vitro* via a dual mechanism of action of inhibition of bacterial cell wall synthesis and disruption of bacterial cell membrane barrier functions (1). Like its parent compound, telavancin inhibits bacterial cell wall synthesis by binding to the D-Ala-D-Ala terminus of the peptidoglycan in the growing cell wall (See Vancomycin). Telavancin is approved in the United States and Canada for the treatment of adult patients with complicated skin and skin structure infections (cSSSI) due to susceptible gram-positive pathogens, especially hospital-acquired bacterial pneumonia (HABP) such as ventilator-associated bacterial pneumonia (VABP) due to susceptible isolates of *S. aureus* (MRSA). Telavancin shows a higher rate of kidney failure than vancomycin. 1. Lunde, Hartouni, Janc, *et al.* (2009) *Antimicrob. Agents Chemother.* **53**, 3375.

**Telbivudine**

This synthetic L-nucleoside analogue of thymidine (FW = 242.23 g/mol; CAS 3424-98-4), also named Tyzeka<sup>®</sup> and 1-(2-deoxy-β-L-erythro-pentofuranosyl)-5-methylpyrimidine-2,4-(1*H*,3*H*)-dione, is converted metabolically to telbivudine-triphosphate, a potent inhibitor of Hepatitis B reverse transcriptase. Removal or substitution of the 3'OH group results in loss of inhibition. Moreover, Telbivudine is highly selective for HBV DNA and inhibits viral DNA synthesis with no effect on human DNA or other viruses. Compared to Lamivudine, Telbivudine showed a statistically significantly greater reduction in HBV DNA, a greater proportion of alanine aminotransferase normalization, a greater histological response, fewer cases of treatment failure, and less virological resistance. (**See also Adefovir & Adefovir Dipivoxil; Entecavir; Lamivudine; Tenofovir; Emtricitabine**) 1. Nash (2009) *Adv. Ther.* **26**, 155.

**Telenzepine**

This selective M<sub>1</sub> muscarinic receptor antagonist (FW = 370.48 g/mol; CAS 80880-90-6) inhibits gastric acid secretion. Telenzepine specifically blocks the so-called M<sub>1</sub> receptors located in the ganglia of the myenteric plexus. It represents an attractive alternative to the H<sub>2</sub> blockers, because M<sub>1</sub> receptor blockers are virtually devoid of the untoward reactions typical of atropine-like compounds, e.g., dry mouth, mydriasis, tachycardia, etc. (1). Telenzepine binds with high affinity ( $K_{\text{assoc}} = 3 \times 10^9 \text{ M}^{-1}$ ) to a subpopulation of muscarinic binding sites in rat cerebral cortex, which has high affinity for pirenzepine (2). When compared head to head with pirenzepine (i.e., on a molar basis), telenzepine proved to be 25x and 50x more potent as an inhibitor of gastric and salivary secretion, respectively (3). 1. Bertaccini & Coruzzi (1989) *Pharmacol. Res.* **21**, 339. 2. Eveleigh, Hulme, Schudt & Birdsall (1989) *Mol. Pharmacol.* **35**, 477. 3. Londong, Londong, Meierl, & Voderholzer (1987) *Gut* **28**, 888.

**Telithromycin**

This first-in-class ketolide macrolide antibiotic and nAChR ligand (FW = 790.10 g/mol; CAS 191114-48-4), also known as RU-66647 and Ketek<sup>®</sup>, inhibits translation by binding to the bacterial ribosome 50S subunit, blocks progression of the growing polypeptide chain. Telithromycin exhibits >10x higher affinity than erythromycin. It also binds strongly to two domains in the 23S RNA core, whereas older macrolides bind strongly to one domain,

and only weakly to the second domain. Telithromycin also inhibits the assembly of 50S and 30S subunits. Unlike erythromycin, telithromycin is acid-stable resists gastric acids (1). RU-66647 is more active than erythromycin and azithromycin against oxacillin-resistant *Staphylococcus* spp., vancomycin-resistant enterococci, and *Klebsiella pneumoniae*. Adverse effects have limited the clinical use of telithromycin. Telithromycin preferentially inhibits nicotinic acetylcholine receptors located at the neuromuscular junction ( $\alpha_3\beta_2$  AChR), ciliary ganglion of the eye ( $\alpha_3\beta_4$  and  $\alpha_7$  AChRs), and vagus nerve innervating the liver ( $\alpha_7$  AChR), accounting in part for its capacity to exacerbate myasthenia gravis, induce visual disturbances, and give rise to liver failure (2). Telithromycin also reduces *N*-demethylation of oxycodone by inhibiting CYP3A4, suggesting that telithromycin use in patients receiving multiple doses of oxycodone for pain relief may increase the risk of opioid adverse effects (3). Some 121 drugs (represented by 341 brand and generic products) are known to have major interactions with telithromycin. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Jones & Biedenbach (1997) *Diagn. Microbiol. Infect. Dis.* **27**, 7. 2. Bertrand, Bertrand, Neveu & Fernandes (2010) *Antimicrob. Agents Chemother.* **54**, 5399. 3. Grönlund, Saari, Hagelberg, et al. (2010) *J. Clin. Pharmacol.* **50**, 101.

**Tellurium(IV) Bis(citrate)**

This organotellurium(IV) compound (FW = 507.81 g/mol) inhibits papain, presumably by means of a nucleophilic displacement reaction, leading to formation of a Te-S bond to its active-site thiol. 1. Albeck, Weitman, Sredni & Albeck (1998) *Inorg. Chem.* **37**, 1704.

**Tellurium Dioxide, See Tellurite****Telmisartan**

This substituted benzimidazole (FW<sub>free-acid</sub> = 514.63 g/mol; CAS 144701-48-4; Soluble to 20 mM in DMSO), also named 4'-[(1,4'-dimethyl-2'-propyl[2,6'-bi-1*H*-benzimidazol]-1'-yl)methyl]-[1,1'-biphenyl]-2-carboxylic acid, is an angiotensin II type 1 (AT<sub>1</sub>) receptor antagonist,  $K_i = 3.7 \text{ nM}$  (1-3). Telmisartan also has an insulin-sensitizing action, involving adipose tissue-independent down-regulation of peroxisome proliferator-activated receptor-γ (PPAR-γ) regulated genes, thereby ameliorating fatty liver (4). Intriguingly, telmisartan diminishes deleterious effects of chronic restraint stress on memory in a statistically significant manner ( $p < 0.01$ ), as evaluated in a passive avoidance (PA) situation and in an object recognition test (ORT) (5). Surprisingly, telmisartan (at 5mg/kg) also displays antiinflammatory activity by modulating TNF-α, IL-10, and RANK/RANKL in a rat model of ulcerative colitis (6). (**See also Candesartan; Eprosartan; Irbesartan; Losartan; Olmesartan; Valsartan**) **Pharmacological Parameters:** Bioavailability = 43 %; Food Effect? NO; Drug  $t_{1/2} = 24$  hours; Metabolite  $t_{1/2} =$  not determined; Drug's Protein Binding = >99 %; Route of Elimination = 0.5 % Renal and >97 % Hepatic. 1. Ries, Mihm, Narr, et al. (1993) *J. Med. Chem.* **36**, 4040. 2. Wiene, Huel, Van Meel, et al. (1993) *Brit. J. Pharmacol.* **110**, 245. 3. Maillard, Perregaux, Centeno, et al. (2002) *J. Pharmacol. Exp. Ther.* **302**, 1089. 4. Rep.* **67**, 520.

**Temelastine**

This nonsedating agent (FW = 444.38 g/mol; CAS 86181-42-2), also known as SK&F 93944, is a potent and selective histamine H<sub>1</sub> receptor antagonist, K<sub>i</sub> = 0.32 nM (1-3). Temelastine was found to be a weak noncompetitive antagonist of carbachol on the guinea-pig ileum, but was devoid of measurable anticholinergic activity *in vivo*. 1. Hill, Ganellin, Timmerman, *et al.* (1997) *Pharmacol. Rev.* **49**, 253. 2. Alexander, Stote, Allison, *et al.* (1986) *J. Int. Med. Res.* **14**, 200. 3. Ter Laak, Donne-Op den Kelder, Bast & Timmerman (1993) *Eur. J. Pharmacol.* **232**, 199.

**Temozolomide**

This orally bioavailable radio-sensitizing/chemotherapeutic agent (FW = 194.15 g/mol; CAS 85622-93-1; Symbol: TMZ), also known by the trade names Temodar™, Temodal™ and Temcad™ and by its systematic names 3,4-dihydro-3-methyl-4-oxoimidazo[5,1-d][1,2,3,5]tetrazine-8-carboxamide and 4-methyl-5-oxo-2,3,4,6,8-pentazabicyclo[4.3.0]nona-2,7,9-triene-9-carboxamide, is taken up by cells and metabolized to 3-methyl-(triazene-1-yl)imidazole-4-carboxamide (MTIC), the latter a highly effective DNA-alkylating agent that preferentially methylates guanine at its O<sup>6</sup> and N<sup>7</sup> atoms, thereby triggering cell death, especially in the presence of a alkylation-sensitizing PARP inhibitor (**See also Veliparib**). Because of its small size and lipophilic properties, TMZ crosses the blood-brain barrier, entering the cerebrospinal fluid. *In vitro*, temozolomide has demonstrated schedule-dependent antitumor activity against highly resistant malignancies, including high-grade glioma (1). In clinical studies, TMZ demonstrates noncumulative minimal myelosuppression that is rapidly reversible, with activity against a variety of solid tumors in both children and adults. The standard therapy for glioblastoma multiforme (GBM), the most common primary brain tumour in adults, is maximal surgical resection followed by radiotherapy with concurrent and adjuvant TMZ. This agent has been associated with anemia, lymphopenia, neutropenia, and severe thrombocytopenia. **Primary Mode of Inhibitory Action:** Temozolomide is [an analogue of 5-(3,3-dimethyl-1-triazeno)imidazole-4-carboxamide that does not require metabolic activation. Instead, it rearranges nonenzymatically to produce methyl diazonium ion, a highly reactive alkylating agent is formed by temozolomide breakdown, mainly forming O<sup>6</sup>- and N<sup>7</sup>-methylguanine (2,3).

Of these, O<sup>6</sup>-methylguanine formation is more cytotoxic, because DNA mismatch repair enzymes try, but fail, to excise O<sup>6</sup>-methylguanine, in the process generating single- and double-strand breaks that lead to the activation of apoptotic pathways. Among the damage to DNA is methylation at the N<sup>7</sup> position of guanine, followed by methylation at the O<sup>3</sup> position of adenine and the O<sup>6</sup> position of guanine. Although the N<sup>7</sup>-methylguanine and O<sup>3</sup>-methyladenine adducts both contribute to TMZ's antitumor activity in some, if not all, sensitive cells, their role is controversial. Because TMZ does not cross-link DNA, it is less toxic to bone marrow hematopoietic progenitor cells than DNA cross-linkers like nitrosoureas (*i.e.*, carmustine and lomustine), platinum compounds (*i.e.*, cisplatin and carboplatin), and procarbazine. **Resistance:** Inherent and acquired glioma cell resistance to TMZ is caused by enhanced levels of O<sup>6</sup>-methylguanine DNA methyltransferase (MGMT) as well as overexpression of epidermal growth factor receptor (EGFR), galectin-1, murine double minute 2 (Mdm2), p53 and phosphatase and tensin homolog (PTEN) mutations (4). To reduce acquired resistance, different therapeutic molecules have been developed, for example, O<sup>6</sup>-benzyl-guanine which inhibits MGMT, tyrosine kinase inhibitors that act on EGFR, nutlin-3 which inhibits Mdm2, which contributes to the restoration of p53 activity (4). **Pharmacokinetics:** Peak plasma MTIC concentrations of 0.07–0.61 µg/mL were observed approximately 1 hour after an oral TMZ dose (5). Appearance and disappearance (t<sub>1/2</sub> = 88 min) of the reactive metabolite paralleled the appearance and disappearance of TMZ in plasma. The mean values of the metabolite peak plasma concentration and AUC were 2.6% (range: 1.6–4.6%) and 2.2% (range: 0.8–3.6%), respectively, of the TMZ values. MTIC does not accumulate in plasma, even after five consecutive daily doses of TMZ. 2. O'Reilly, Newlands, Glaser, *et al.* (1993) *Eur. J. Cancer* **29**, 940. 1. Today*. **20**, 899. 5. Reid, Stevens, Rubin & Ames (1997) *Clin. Cancer Res.* **3**, 2393.

**Temsirolimus**

This intravenously administered antineoplastic agent (FW = 1030.28 g/mol; CAS 162635-04-3), also known as CCI-779 and Torisel®, inhibits mammalian Target of Rapamycin (or mTOR), a protein kinase operating within the phosphatidylinositol 3-kinase (PI3K)/Akt signalling cascade. The latter plays a central role in controlling cell proliferation, survival, mobility and angiogenesis. Dysregulation of mTOR pathway has been observed in many human tumors, making temsirolimus a promising new anticancer drug, the action of which leads to cell cycle arrest in the G<sub>1</sub> phase as well as inhibition of tumor angiogenesis by reducing VEGF formation. Temsirolimus binds to FKBP, a cytosolic protein that subsequently inhibits mTOR. Inhibition of mTOR blocks a number of signal transduction pathways that suppress translation of several key proteins regulating the cell cycle. **Pharmacokinetic Parameters:** In the treatment of advanced renal cell carcinoma, temsirolimus is administered as a 30- to 60-minute IV infusion once weekly at a flat dose of 25 mg. This dosage results in high peak temsirolimus concentrations and limited immunosuppressive activity. Temsirolimus shows activity on its own, but it is also known to be converted to rapamycin *in vivo*. Its activity may thus be more attributed to its metabolite rather than the prodrug itself. [See also Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011).] 1. ### Tenascin

This 2199-residue major chondroitin sulfate proteoglycan (MW = 240,718 g/mol; EMBL Accession: X56160.1), produced abundantly in the extracellular matrix of developing vertebrate embryos and reappearing around healing wounds and in the stroma of some tumors (1), inhibits axon regeneration within the injured central nervous system, presumably by binding to growth cone receptors (Rc), via inhibition of Rho family GTP-regulatory proteins and disruption of the actin cytoskeleton, resulting in growth cone collapse/repulsion (2). Tenascin C promiscuously binds growth factors via its fifth fibronectin type III-like domain (3). **Structural Features:** The monomer consists of four major domains: the N-terminal domain, which mediates hexamerization by forming a coiled structure with interchain disulfide bonds; a series of 14.5 epidermal growth factor-like (EGFL) repeats, each 30-50 amino acids long and containing six cysteines; a series of up to 15 fibronectin type III-like (TNCIII) repeats, each ~90 amino acids long that form two sheets of antiparallel  $\beta$ -strands, serving as cell-adhesive, integrin-binding sites that promote cell adhesion; and a fibrinogen-like globular domain at the C-terminus. 1. Dou & Levine (1994) *J. Neurosci.* **14**, 7616. 2. Sandvig, Berry, Barrett, *et al.* (2004) *Glia* **46**, 225. 3. De Laporte, Rice, Tortelli & Hubbell (2013) *PLoS One* **8**, e62076.

### Tendamistat

This 74-residue polypeptide (MW = 7961.77 g) from *Streptomyces tendae* forms a 1:1 complex with mammalian  $\alpha$ -amylase, inhibiting the latter with  $K_i = 9$  pM (1-4). It is, however, without effect on plant and microbial  $\alpha$ -amylases. Tendamistat contains six  $\beta$ -sheets and two disulfide bridges between Cys11-Cys27 and Cys45-Cys73. 1. Wiegand, Epp & Huber (1995) *J. Mol. Biol.* **247**, 99. 2. Vertesy, Oeding, Bender, Zepf & Nesemann (1984) *Eur. J. Biochem.* **141**, 505. 3. Ono, Umezaki, Tojo, *et al.* (2001) *J. ### Tenidap

This novel cytokine-modulating anti-inflammatory and antiarthritic agent (FW = 320.75 g/mol; CAS 120210-48-2; Soluble to 100 mM in DMSO), also known by its code name CP-66,248 and its systematic name 5-chloro-2-hydroxy-3-(2-thienylcarbonyl)-1*H*-indole-1-carboxamide, displays symptomatic efficacy superior to nonsteroidal anti-inflammatory drugs (NSAIDs) and is equivalent to combinations of NSAIDs and second-line agents (1-3). Tenidap preferentially inhibits COX-1 ( $IC_{50} < 0.03$   $\mu$ M), COX-2 ( $IC_{50} = 1.2$   $\mu$ M), and 5-lipoxygenase ( $IC_{50} > 30$   $\mu$ M). Tenidap inhibits formation of pro-inflammatory arachidonic acid metabolites in isolated human peripheral polymorphonuclear leukocytes. It potently inhibits leukotriene B<sub>4</sub> and prostanoid synthesis in human polymorphonuclear leukocytes *in vitro* (1). Tenidap, but not NSAIDs, also causes rapid and sustained acidification of the cytoplasmic compartment, but does not act as a proton ionophore or dissipate the low lysosomal pH (2). Tenidap does not alter  $pH_{internal}$  via inhibition of the sodium-proton antiporter, but instead inhibits chloride-bicarbonate exchangers, as does UK5099, a known anion-transport inhibitor that likewise lowers  $pH_{internal}$ , suggesting that the  $pH_{internal}$  change is coupled to anion transport inhibition. Tenidap also inhibits mannose 6-phosphate receptor-mediated endocytosis and protein synthesis, stimulating leucine accumulation (2). Tenidap is a potent channel opener, acting on the inwardly rectifying K<sup>+</sup> channel hKir2.3 (4). Down-regulation of the Kir2.3 channel expression is believed to contribute to the pathogenesis of pilocarpine-induced temporal lobe epilepsy (TLE), a condition that may be ameliorated by the administration of tenidap (5). 1. ### Tenofovir

This reverse transcriptase inhibitor and antiretroviral drug (FW = 287.21 g/mol; CAS 147127-20-6), also known as Viread<sup>®</sup> and (*R*)-9-[2-(phosphonomethoxy)propyl]adenine, and its membrane-permeant prodrug (FW = 635.51 g/mol; CAS 202138-50-9), also known as tenofovir disoproxil and Reviro<sup>®</sup>, target the reverse transcriptases of Human Immunodeficiency Virus-1 (HIV-1) and hepatitis B virus. Tenofovir alone, or in combination with emtricitabine, has enjoyed growing demand as a pre-exposure prophylactic, one that significantly decreases the risk of contracting HIV. In adult humans, tenofovir has a volume of distribution of 0.813 L/kg, is minimally bound to plasma protein (7.2%), has a plasma elimination half-life of 12-14 hours, and is mainly excreted unchanged in urine (70%-80%) (2). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Kearney, Yale, Shah, Zhong & Flaherty (2006) *Clin. Pharmacokinet.* **45**, 1115. 2. Fung, Stone & Piacenti (2002) *Clin. Ther.* **24**, 1515.

### Tenovin-1

This small-molecule p53 activator (FW = 369.38 g/mol; CAS 380315-80-0; Solubility: 74 mg/mL DMSO) binds to and protects (when present at 10  $\mu$ M) p53 against MDM2-mediated degradation, a process involving ubiquitination and acting through inhibition of protein-deacetylating activities of NAD<sup>+</sup>-

dependent histone deacetylases, Sirtuins-1 and -2 (or SirT1 and SirT2). 1. Lain, Hollick, Campbell, *et al.* (2008) *Cancer Cell* **13**, 454.

#### Tenoxicam

This anti-inflammatory drug (FW = 337.38 g/mol; CAS 59804-37-4; M.P. = 209-213°C; Solubility = 45 µg/mL; IUPAC Name: 4-hydroxy-2-methyl-N-2-pyridinyl-2H-thieno[2,3-e]-1,2-thiazine-3-carboxamide) inhibits cyclooxygenase 1 and 2 (1,2). 1. Ther.* **281**, 1005.

**Tenox PG**, See *n-Propyl Gallate*

#### Tentoxin

This cyclic tetrapeptide antibiotic (FW = 414.50 g/mol; CAS 28540-82-1; Sequence: cyclo-(L-MeAla<sup>1</sup>-L-Leu<sup>2</sup>-MeA<sup>3</sup>Phe<sup>3</sup>-Gly<sup>4</sup>) from the phytopathogenic fungus *Alternaria alternata* induces chlorosis (*i.e.*, insufficient chlorophyll production, with lightening of leaf color) in several germinating seedlings (1-3). Tentoxin inactivates photophosphorylation in a sensitive species (lettuce) by binding ( $K_d = 50-750$  nM) to Coupling Factor-1 (CF<sub>1</sub>) ATPase at a single site (1). Tentoxin increases the binding of ATP even under conditions where the ATPase activity is activated by light plus dithiothreitol (2). The effect of tentoxin on CF<sub>1</sub>, however, is more complex than simply decreasing the efficiency of the conversion of State I to State II. Tentoxin markedly decreases the magnitude of the rapid phase ( $t_{1/2} = 20$  msec) of binding in the dark associated with the back reaction of State II to State I and decreases the total amount of adenine nucleotides that bind in the dark. Moreover, at concentrations greater than  $5 \times 10^{-7}$  M selectively increases potassium ion conductivity across lipid bilayers, whereas dihydrotentoxin, another naturally occurring derivative, has no such effect. Current-voltage curves, zero-current potential and charge-pulse measurements suggest that tentoxin dimerize in order to bind and transport K<sup>+</sup> ion (4). This model contradicts the earlier conclusion that tentoxin is a pore-forming peptide antibiotic (5). Tentoxin is without effect on the mammalian mitochondrial complex (6-9). **Target(s):** chloroplast ATP synthase, or chloroplast H<sup>+</sup>-transporting two-sector ATPase (6-9); and 4-phytase, weakly inhibited (10). 1. Steele, Uchytel, Durbin, Bhatnagar & Rich (1976) *Proc. Natl. Acad. Sci. U.S.A.* **73**, 2245. 2. Shoshan & Selman (1979) *J. Biol. Chem.* **254**, 8808. 3. #### Tenuazonic Acid

This *Alternaria tenuis* and *A. alternata* mycotoxin (FW = 196.23 g/mol; CAS 610-88-8; low water solubility; freely soluble in chloroform, acetone, ethanol), named systematically as 3-acetyl-1,5-dihydro-4-hydroxy-5-(1-methylpropyl)-2H-pyrrol-2-one, inhibits mammalian protein biosynthesis by suppressing the release of newly formed polypeptide from the ribosomes. It is without effect on yeast. **Target(s):** DNA synthesis (1); protein biosynthesis (elongation) (2,3). 1. Friedman, Aggarwal & Lester (1975) *Res. Commun. Chem. Pathol. Pharmacol.* **11**, 311. 2. Carrasco, Battaner & Vazquez (1974) *Meth. Enzymol.* **30**, 282. 3. Jiménez (1976) *Trends Biochem. Sci.* **1**, 28. **See also** (-)-*Altenuene*

#### Temafloxacin

This fluoroquinolone-class antibiotic (FW = 417.38 g/mol; CAS 108319-06-8), also named 1-(2,4-difluorophenyl)-6-fluoro-7-(3-methylpiperazin-1-yl)-4-oxoquinoline-3-carboxylate, is a broad-spectrum systemic antibacterial agent that targets Type II DNA topoisomerases (gyrases), which are required for bacterial replication and transcription. FDA-approved and marketed as Omniflox<sup>®</sup>, temafloxacin was withdrawn within the same year, after it was shown to give rise to serious allergic reactions and hemolytic anemia. For the prototypical member of this antibiotic class, **See** *Ciprofloxacin*

#### Tenuiorin

This tridepside secondary 3-orscinol metabolite (FW = 467.41 g/mol; CAS 570-07-0), derived from, from species of *Pseudocypbellaria*, *Lobaria* and *Peltiger* inhibits 5-lipoxygenase and 15-lipoxygenase. The term has been used to refer to either the trimer of *o*-orsellinic acid (or the methyl ester of this trimer) or to the polymer. 1. Ingoldsdottir, Gudmundsdottir, Ogmundsdottir, *et al.* (2002) *Phytomedicine* **9**, 654.

#### Tepoxalin

This nonsteroidal anti-inflammatory (FW = 385.85 g/mol), also known as 5-(4-chlorophenyl)-*N*-hydroxy-(4-methoxyphenyl)-*N*-methyl-1*H*-pyrazole-3-ropamide and marketed under the brand name Zubrin<sup>™</sup>, inhibits both COX-1 and COX-2 cyclooxygenases as well as 5-lipoxygenase (1,2). Tepoxalin also indirectly inhibits nuclear factor-κB activation (3). 1. Kirchner, Aparicio, Argentieri, Lau & Ritchie (1997) *Prostaglandins Leukot. Essent. Fatty Acids* **56**, 417. 2. Tam, Lee, Wang, Munroe & Lau (1995) *J. Biol. Chem.* **270**, 13948. 3. J. I. Lee & G. J. Burckart (1998) *J. Clin. Pharmacol.* **38**, 981.

### Terazosin

This orally available  $\alpha_1$ -adrenergic receptor antagonist (FW<sub>free-base</sub> = 387.44 g/mol; CAS 63590-64-7; water solubility = 24 mg/mL for the hydrochloride dihydrate), known systematically as [4-(4-amino-6,7-dimethoxyquinazolin-2-yl)piperazin-1-yl]-(oxolan-2-yl)methanone, targets  $\alpha_{1A}$ ,  $\alpha_{1B}$ ,  $\alpha_{1D}$ ,  $\alpha_{2B}$ ,  $\alpha_{2A}$  and  $\alpha_{2C}$  receptors, with  $K_i$  values are 3.3, 0.7, 1.1, 7.7, 1510 and 78.2 nM, respectively (1-3). Terazosin induces apoptosis and reduces prostate tumor vascularity in benign and malignant prostate cells. Terzosin also suppresses prostate growth without affecting cell proliferation (3-6). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):**  $\alpha_1$ -adrenergic receptor (2). 1. Anglin, Glassman & Kyprianou (2002) *Prostate Cancer Prostatic Dis.* **5**, 88. 2. Kyncl (1993) *J. Clin. Pharmacol.* **33**, 878. 3. Maruyama, et al. (1994) *Biol. Pharm. Bull.* **17**, 1126. 4. Kyncl (1986) *Am. J. Med.* **80**, 12. 5. Maruyama, et al. (1994) *Biol. Pharm. Bull.* **17**, 1126. 6. Hancock, et al. (1995) *J. Recept. Signal Transduct. Res.* **15**, 863.

### Terbacil

This uracil derivative (FW = 216.67 g/mol; CAS 5902-51-2; Properties: white, crystalline, odorless solid, which is wetttable, noncorrosive and nonflammable), also known as Sinbar<sup>®</sup> and 5-chloro-3-(1,1-dimethylethyl)-6-methyl-2,4(1*H*,3*H*)-pyrimidinedione, is a selective herbicide for controlling the growth of annual grasses, broad-leaved weeds, and some perennial weeds. Its principal mode of action is the inhibition of photosynthetic electron transport (1). 1. Dodge (1977) *Spec. Publ., Chem. Soc.* **29**, 7.

### Terbogrel

This guanidine derivative (FW<sub>free-acid</sub> = 405.50 g/mol; CAS 149979-74-8), also known as (5*E*)-6-(3-(2-cyano-3-*tert*-butylguanidino)phenyl)-6-(3-pyridyl)hex-5-enoic acid, inhibits human thromboxane-A synthase (IC<sub>50</sub> = 4 nM) and is a thromboxane receptor antagonist (IC<sub>50</sub> = 11 nM). Note that the 5*Z*-isomer is a weaker inhibitor (IC<sub>50</sub> = 1.6 and 2.6  $\mu$ M for the synthase and receptor, respectively). **Target(s):** thromboxane-A synthase (1,2); thromboxane receptor (1,2). 1. Soyka, Guth, Weisenberger, Luger & Müller (1999) *J. Med. Chem.* **42**, 1235. 2. Michaux, Norberg, Dogne, et al. (2000) *Acta Crystallogr. C* **56**, 1265.

### Terbutryn

This triazine-based plant control agent (FW = 241.36 g/mol; CAS 886-50-0), also known as terbutryne and *N*-(1,1-dimethylethyl)-*N'*-ethyl-6-(methylthio)-1,3,5-triazine-2,4-diamine, is a selective pre- and post emergent herbicide for most grasses and many annual broadleaf weeds. It is used in crops of wheat, barley, sorghum, sugarcane, sunflowers, peas, and potatoes. Terbutryn is a competitive inhibitor of quinone binding at bacterial photosynthetic reaction centers. **Target(s):** photosynthetic electron transport (1); photosynthetic reaction center (2,3). 1. Dodge (1977) *Spec. Publ., Chem. Soc.* **29**, 7. 2. Kirmaier, Laible, Hanson & Holten (2003) *Biochemistry* **42**, 2016. 3. Stein, Castellvi, Bogacz & Wraight (1984) *J. Cell Biochem.* **24**, 243.

### Terephthalate

This aromatic dicarboxylic acid (FW<sub>free-acid</sub> = 166.13 g/mol; CAS 3198-30-9), also called *p*-carboxybenzoic acid and *p*-phthalic acid is only soluble in slightly alkaline solutions. **Target(s):** D-amino-acid oxidase (1-3);  $\gamma$ -butyrobetaine hydroxylase, or  $\gamma$ -butyrobetaine:2-oxoglutarate dioxygenase, weakly inhibited (4); 4,5-dihydroxyphthalate decarboxylase (5); glutamate decarboxylase, weakly inhibited (6); kynurenine aminotransferase, weakly inhibited (7); monophenol monooxygenase (1,8); procollagen-proline:2-oxoglutarate 4-dioxygenase (9); serine-sulfate ammonia-lyase, or weakly inhibited (10); succinate dehydrogenase (1,11). 1. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, Academic Press, New York. 2. Bartlett (1948) *J. Amer. Chem. Soc.* **70**, 1010. 3. Frisell, Lowe & Hellerman (1956) *J. Biol. Chem.* **223**, 75. 4. Ng, Hanauske-Abel & Englard (1991) *J. Biol. Chem.* **266**, 1526. 5. Nakazawa & Hayashi (1978) *Appl. Environ. Microbiol.* **36**, 264. 6. ### Terfenadine

This first-in-class, non-sedating antihistamine (FW = 471.68 g/mol; CAS 50679-08-8; Soluble to 100 mM in DMSO; solid has three polymorphic forms, with melting points at 142-144°C, 146-148°C, and 149-152°C; sparingly soluble in H<sub>2</sub>O (1 mg/100 mL at 30°C, but has higher solubility (0.11 g/100 mL) in 0.1 M citric acid), also known as  $\alpha$ -[4-(1,1-dimethylethyl)phenyl]-4-(hydroxy-diphenylmethyl)-1-piperidinebutanol and Seldane<sup>™</sup>, is a histamine-H<sub>1</sub> receptor antagonist. In addition to its antihistamine effects, terfenadine also acts as a K<sub>v</sub>11.1 potassium channel blocker (encoded by the gene *hERG*). Terfenadine is also an alternative

substrate for CYP3A4 and CYP2D6. **See also** Loratadine; Fexofenadine  
**Target(s):** calcium channel (1); histamine H<sub>1</sub> receptor,  $K_i = 80$  nM (2-5); 5-lipoxygenase (6); potassium currents (7,8); and sodium currents (9). 1. Liu, Melchert & Kennedy (1997) *Circ. Res.* **81**, 202. 2. Masheter (1993) *Clin. Rev. Allergy* **11**, 5. 3. Zhang & Timmerman (1993) *Pharm. World Sci.* **15**, 186. 4. ### Tergitol

This class of nonionic detergents (MW = 264.41 for  $n = 7$ , but depending on value of  $n$ ), known also as  $n$ -nonylphenoxypolyethoxyethanols, was originally produced by Union Carbide. Tergitol NP-10, a light yellow liquid (M. P. = 6°C; B. P. = 250°C) is a polyoxyethylene, with a  $p$ -nonylphenyl moiety located on the  $\alpha$ -position and a hydroxyl group at the  $\omega$ -position. **Note:** Tergitol is a skin irritant; avoid contact with skin. **Target(s):** 5-aminolevulinic acid synthase (1); diacylglycerol *O*-acyltransferase, inhibited by Tergitol NP-40 (2); and triacylglycerol lipase (3). 1. Murthy & Woods (1974) *Biochim. Biophys. Acta* **350**, 240. 2. Grigor & Bell (1982) *Biochim. Biophys. Acta* **712**, 464. 3. Khoo & Steinberg (1975) *Meth. Enzymol.* **35**, 181. **See also** Triton N-101; Niaproof 4

### Teriflunomide

This orally active MS drug (FW = 270.21 g/mol; CAS 163451-81-8), also known by the code name A771726, A771726 HMR-1726, trade name Aubagio<sup>®</sup>, and its systematic name (2*Z*)-2-cyano-3-hydroxy-*N*-[4-(trifluoromethyl)phenyl]but-2-enamide, is *de novo* pyrimidine nucleotide synthesis inhibitor, targeting dihydroorotate dehydrogenase (DHODH) **Reaction:** Dihydroorotate + NAD<sup>+</sup>  $\rightleftharpoons$  Orotate + NADH. Inhibition of DHODH has a cytostatic effect on actively dividing B- and T-cells. Salvage pathways allow the proliferation of more slowly dividing cells (*e.g.*, memory T-cells and haematopoietic cells) that are not as susceptible to DHODH inhibition and are able to sustain pyrimidine synthesis, thus maintaining the patient's immune response. Teriflunomide reduces lymphocyte proliferation and exerts immunomodulatory affecting the progression of multiple sclerosis. While cytostatic, teriflunomide is not cytotoxic, and does not affect resting or slowly dividing lymphocytes. Teriflunomide inhibits T cell receptor (TCR)/CD3-mediated calcium mobilization, with little effect on other critical T cell signaling events, such as MAPK activation and NF- $\kappa$ B activation (1,2). Teriflunomide interfered strikingly with TCR/CD3-triggered integrin- $\beta_{11}$  avidity and integrin-mediated costimulation (*i.e.*, outside-in signaling). Teriflunomide is the active metabolite of leflunomide, a potent disease-modifying antirheumatic drug that exhibits antiinflammatory, antiproliferative, and immunosuppressive effects (**See** Leflunomide). 1. Zeyda, Poglitsch, Geyeregger, *et al.* (2005) *Arthritis Rheum.* **52**, 2730. 2. Garnock-Jones (2013) *CNS Drugs* **27**, 1103.

### Terpendole C and E

These fungal metabolites, particularly terpendole C (FW = 519.67 g/mol; CAS 164323-42-6) and terpendole E (FW = 437.60 g/mol; CAS 167427-23-8; Alternate Name: 1' $\alpha$ -hydroxy-paspaline), abbreviated TerC and TerE, from *Albophoma yamanashiensis* (Strain FO-2546) arrest at cell-cycle M-phase by inhibiting kinesin Eg5. TerE does not affect microtubule integrity in interphase, but induces formation of a monoastrial spindle. TerE also inhibits both kinesin motor Eg5, but does not affect conventional kinesins from either *Drosophila* or bovine brain. Although terpendoles have been reported as inhibitors of acyl-CoA:cholesterol *O*-acyltransferase (ACAT), the Eg5 inhibitory activity of TerE was independent of ACAT inhibition. **Target(s):** microtubule-stimulated ATPase, inhibited by terpendole E (1); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase (ACAT) (2,3). 1. Nakazawa, Yajima, Usui, *et al.* (2003) *Chem. Biol.* **10**, 131. 2. Ohshiro, Rudel, Omura & Tomoda (2007) *J. Antibiot.* **60**, 43. 3. Huang, Tomoda, Nishida, Masuma & Omura (1995) *J. Antibiot.* **48**, 1.

### Terpestacin

This fungal metabolite (FW = 402.58 g/mol; CAS 146436-22-8), isolated from *Arthrinium sp.* FA1744, binds to the 13.4-kDa subunit (UQCRB) of mitochondrial Complex III, resulting in inhibition of hypoxia-induced reactive oxygen species generation, blocking hypoxia-inducible factor activation and tumor angiogenesis *in vivo*, without inhibiting mitochondrial respiration. 1. Jung, Shim, Lee, *et al.* (1999) *Bioorg. Med. Chem. Lett.* **9**, 2279.

### Tertiapin

This basic honey bee venom toxin (MW = 2459.1 g/mol; CAS 252198-49-5; **Sequence:** ALCNCNRIIPHMCWKKCGKK-NH<sub>2</sub>) is a potent inhibitor of the inward-rectifier K<sup>+</sup> channels, binds specifically to different subunits of the inward rectifier potassium channel (Kir), namely GIRK1 (Kir 3.1), GIRK4 (Kir 3.4) and ROMK1 (Kir 1.1), inducing a dose-dependent block of the potassium current. It is thought that tertiapin binds to the Kir channel with its  $\alpha$ -helix situated at the C-terminal of the peptide. This  $\alpha$ -helix is plugged into the external end of the conduction pore, thereby blocking the channel. The N-terminal of the peptide sticks out of the extracellular side. Tertiapin has a high affinity for Kir channels with approximately  $K_d = 8$  nM for GIRK1/4 channels and  $K_d = 2$  nM for ROMK1 channels. **Target(s):** calmodulin activating activity (3); inward-rectifier K<sup>+</sup> channels (1,2). 1. Jin & Lu (1998) *Biochemistry* **37**, 13291. 2. Schultz, Czachurski, Volk, Ehmke & Seller (2003) *Brain Res.* **963**, 113. 3. Miroshnikov, Boikov, Snezhkova, Severin & Shvets (1983) *Bioorg. Khim.* **9**, 26.

### Tertiapin-Q

This air oxidation-resistant analogue (FW = 2295.82 g/mol; CAS 252198-49-5) of honey bee venom toxin tertiapin (**Sequence:** ALCNCNRIIPHQ CWKKCGKK-NH<sub>2</sub>, with Cys<sup>2</sup>-S-S-Cys<sup>14</sup> and Cys<sup>2</sup>-S-S-Cys<sup>18</sup> disulfide bridges and with Q replacing M at residue-13) blocks the ROMK1 (Kir1.1) channel and the G-protein-gated K<sup>+</sup> channel, or GIRK1/4 ( $K_{ir}$ 3.1/3.4) with  $K_i$  values are 1.3 and 13.3 nM respectively (1,2). Tertiapin-Q shows selective over  $K_{ir}2.1$  channels. Note that the methionine residue in Tertiapin is sensitive to oxidation, reducing the ability to block the ionic channels; this problem is alleviated in Tertiapin-W, wherein the methionine is replaced by glutamine. 1. Sackin, Vasilyev, Palmer & Krambis (2003) *Biophys. J.* **84**, 910. 2. Jin, Klem, Lewis & Lu (1999) *Biochemistry* **38**, 14294.

### Tessulin

This 81-residue cysteine-rich polypeptide (MW = 9 kDa) from the duck leech *Theromyzon tessulatum* inhibits trypsin,  $K_i = 1$  pM, and chymotrypsin,  $K_i =$

150 pM (1). Tessulin also decreases the lipopolysaccharide-induced activation of human monocytes and granulocytes, but does not inhibit elastase or cathepsin G. When acting in conjunction with other *Theromyzon* serine-protease inhibitors, namely therin and theromin, tessulin significantly diminishes the level of human granulocyte and monocyte activation induced by lipopolysaccharides (10 µg), and the combined level of inhibition is higher than that of aprotinin. Such properties commend its use as an anti-inflammatory agent. 1. Chopin, Stefano & Salzet (1998) *Eur. J. Biochem.* **258**, 662.

**Testane, See 5 $\alpha$ -Androstane**

### Testosterone

This androgenic steroid (FW = 288.43 g/mol; CAS 58-22-0; water solubility = 0.13 mM;  $\lambda_{\text{max}}$  = 239 nm;  $\epsilon$  = 17000 M<sup>-1</sup>cm<sup>-1</sup>), also known as  $\Delta^4$ -androst-17 $\beta$ -ol-3-one, is synthesized in Leydig cells of the testes. Testosterone is converted to 5 $\alpha$ -dihydrotestosterone by steroid 5 $\alpha$ -reductase, a metabolite that is required for normal male sexual differentiation. Testosterone also has an antigluccorticoid activity (1). **Target(s):** aldehyde dehydrogenase (2); D-amino-acid oxidase (3); cortisol sulfotransferase (4,5); F<sub>1</sub>F<sub>0</sub> ATPase, or H<sup>+</sup>-transporting two-sector ATPase (6); glucose-6-phosphate dehydrogenase (7); glucuronosyltransferase (8-10); glutamate dehydrogenase (2); hydroxyindole O-methyltransferase (11); 21-hydroxysteroid dehydrogenase (NAD<sup>+</sup>) (12-14); isocitrate dehydrogenase, weakly inhibited (15); 6-phosphogluconate dehydrogenase, weakly inhibited (15); steroid  $\Delta$ -isomerase (16-18); steroid 21-monooxygenase (19); steroid sulfotransferase (20); sterol O-acyltransferase, or cholesterol O-acyltransferase; ACAT (21,22); sterol demethylase (23); sterol esterase, or cholesterol esterase (24); and steryl sulfatase (25). 1. **cis-Testosterone, See Epitestosterone**

### Testosterone Acetate

This steroid ester (FW = 330.47 g/mol; CAS = 1045-69-8; M.P. = 140-141°C), also known as 4-androst-17 $\beta$ -ol-3-one 17-acetate and inhibits *aromatase* or CYP19 (1) and steroid  $\Delta$ -isomerase (2,3). 1. Danisova,

Sebokova & Kolena (1987) *Exp. Clin. Endocrinol.* **89**, 165. 2. Jones & Ship (1972) *Biochim. Biophys. Acta* **258**, 800. 3. Weintraub, Vincent, Baulieu & Alfsen (1977) *Biochemistry* **16**, 5045.

### Tetanus Toxin

This powerful bacterial neurotoxin (MW<sub>pre-protein</sub> = 150,317 Da; GenBank: AAK72964.2; Symbol: TeTx), also known as tetanospasmin, from the Gram-positive spore-forming bacillus *Clostridium tetani* has an LD<sub>50</sub> of 1 ng/mL, second only to Botulinum Toxin in its deadliness. The toxin induces violent recurrent spasms/paralysis, or tetany, marked by inhibition of glycine-mediated and GABA-ergic neurotransmission (1) as well as involuntary contraction of peripheral skeletal muscles, with death often arising from respiratory failure. **Mechanism of Inhibitory Action:** For activation, a single precursor is proteolyzed to form a disulfide-linked heterodimer consisting of 50 kDa A-Chain and a 100 kDa B-Chain (2,3). The A-chain is a Zn<sup>2+</sup>-metalloprotease (4), whereas B-chain is a membrane-docking component that binds to neuron and facilitates endocytosis. The main target of TeTx is the central nervous system, where it blocks synaptic function by several mechanisms. The first involves selective proteolysis of the integral membrane proteins synaptobrevin II (also known as the Vesicle-Associated Membrane Protein (VAMP) or its homologue cellubrevin (5). A second entails TeTx activation Ca<sup>2+</sup>-dependent, GTP-modulated transglutaminases that cross-link synapsin, a phosphoprotein involved in neurotransmission (6,7). Two forms of TeTx-activated transglutaminase are found in nerve endings (i.e., one in the cytosol and the other on synaptic vesicles). A third mechanism exploits TeTx's ability to block synapsin phosphorylation after depolarizing rat brain synaptosomes (8). TeTx also markedly decreased the translocation of synapsin I from the small synaptic vesicles and the cytoskeleton into the cytosol, on depolarization of synaptosomes. The effect of TeTx on synapsin I phosphorylation was both time and TeTx concentration dependent and required active toxin. A fourth mechanism relates to the discovery that TeTx exerts a time- and dose-dependent inhibition of Na<sup>+</sup>-dependent serotonin (5-HT) uptake in CNS synaptosomes, an effect found in all CNS tryptaminergic areas, but highest in the hippocampus and occipital cortex (9). Notably, fenfluramine (IC<sub>50</sub> = 11 µM), paroxetine (IC<sub>50</sub> = 33 µM), and imipramine (IC<sub>50</sub> = 90 µM) are 1,000 to 10,000 times less potent serotonin transport inhibitors than TeTx (IC<sub>50</sub> = 9 nM). The TeTx effect on serotonin accumulation may be responsible for some tetanic symptoms (9). The Hc fragment of TeTx inhibits both basal and stimulated serotonin uptake in primary neuronal cultures, effects that parallel the activation of phosphoinositide-phospholipase C activity and PKC activation (10). 1. ### 1,2,3,4-Tetra(adenosine-5'-O-phospho)erythritol

This unusual oligonucleotide conjugate (FW<sub>ion</sub> = 1385.95 g/mol) inhibits both symmetrical and asymmetrical bis(5'-nucleosyl)tetrakisphosphatases. Dinucleoside 5',5''-P<sup>1</sup>,P<sup>2</sup>-polyphosphates (particularly the diadenosine compounds) have been implicated in extracellular purinergic signalling and

in various intracellular processes, including DNA metabolism, tumour suppression and stress responses. If permitted to accumulate, they may also be toxic. Adenosine-5'-*O*-phosphorothioylated polyols were generally stronger inhibitors than their adenosine-5'-*O*-phosphorylated counterparts. 1. Guranowski, Starzynska, McLennan, Baraniak & Stec (2003) *Biochem. J.* **373**, 635.

#### Tetra(*p*-amidinophenoxy)-*neo*-pentane

This aromatic tetrabenzamidine derivative (FW<sub>free-base</sub> = 608.70 g/mol; Symbol: TAPP) inhibits coagulation factor Xa (1); plasmin (1); thrombin (1,2); tissue kallikrein (1,2); and trypsin (1,2). Over the pH range from 2 to 8, values of *K<sub>i</sub>* for TAPP binding to  $\alpha$ -thrombin, Factor Xa, Lys77-Plasmin and  $\beta$ -Kallikrein-B may be described as depending on the p*K*-shift, upon inhibitor association, of two equivalent proton-binding amino acid residues. 1. Menegatti, Ferroni, Scalia, *et al.* (1987) *J. Enzyme Inhib.* **2**, 23. 2. Menegatti, Ferroni, Nastruzzi, *et al.* (1991) *Farmaco* **46**, 1297.

#### Tetrabenazine

This orally available dopamine-depleting drug (FW = 317.43 g/mol; CAS 58-46-8; Symbol = TBZ; Soluble to 30 mM in ethanol and to 100 mM in DMSO), also known by the trade names Nitoman<sup>®</sup> and Xenazine<sup>®</sup> and as (*SS,RR*)-3-isobutyl-9,10-dimethoxy-1,3,4,6,7,11*b*-hexahydro-pyrido[2,1-*a*]isoquinolin-2-one, is a Vesicular Monoamine Transporter-2 (or VMAT2) inhibitor that is especially effective in promoting dopamine depletion within the striatum. Tetrabenazine is an FDA-approved drug used to treat the symptomatic hyperkinesia associated with Huntington's chorea. **Mode of Inhibitory Action:**  $\alpha$ -DTBZ inhibits monoamine uptake, as driven by transmembrane proton electrochemical gradients generated by an ATP-hydrolyzing proton pump. TBZ is a reversible high-affinity inhibitor of monoamine uptake into granular vesicles of presynaptic neurons (1). It is also a weak D<sub>2</sub> postsynaptic receptor blocker in high doses (2), decreasing voluntary movements. TBZ depletes serotonin, norepinephrine, and especially dopamine (3). In rats and mice, TBZ also induces tremulous jaw movements (TJMs), which have many characteristics of Parkinsonian tremors in humans (4). Treatment of TJM, with deprenyl, a selective monoamine oxidase-B inhibitor, shows a dose-related suppression of TBZ-induced TJMs. (See Deprenyl) 1. Pettibone, Totaro & Pflueger (1984) *Eur. J. #### Tetrabromoaurate(III), Potassium

This KAuBr<sub>4</sub> dihydrate (FW = 591.71 g/mol; CAS 14323-32-1; reddish-brown solid) is a planar d<sup>8</sup> tetracoordinate Au(III) complex formed by slow hydrolysis/aquation of H[Au(III)Cl<sub>4</sub>·(H<sub>2</sub>O)<sub>3</sub>] in the presence of excess HBr

(typically requiring >24 hours incubation prior to use) to form the inhibitor (1,2). **Target(s):** acid phosphatase (2);  $\beta$ -glucuronidase (2); and L-malate dehydrogenase (3). 1. Catalini, Chessa, Michelin, *et al.* (1985) *Inorg. Chem.* **24**, 3409. 2. Lee, Ahmed & Friedman (1989) *J. Enzyme Inhib.* **3**, 23. 3. Friedman, Chasteen, Shaw, Allen & McAuliffe (1982) *Chem. Biol. Interact.* **42**, 321.

#### 4,5,6,7-Tetrabromobenzotriazole

This aromatic triazole (FW = 434.71 g/mol; CAS 17374-26-4; Symbol: TBB; Soluble to 100 mM in DMSO and to 15 mM in Ethanol), also known as 4,5,6,7-tetrabromo-2-azabenzimidazole, is a potent inhibitor of casein kinase-2: IC<sub>50</sub> = 0.9  $\mu$ M for the rat liver enzyme. TBB acts in an ATP/GTP-competitive manner, with 10x to 100x selectivity over a panel of 33 protein kinases. **Target(s):** casein kinase-2 (1-6); DNA helicases (7); and non-specific serine/threonine protein kinase (1-6). 1. Sarno, Reddy, Meggio, *et al.* (2001) *FEBS Lett.* **496**, 44. 2. Szyszka, Grankowski, Felczak & Shugar (1995) *Biochem. Biophys. Res. Commun.* **208**, 418. 3. #### Tetrabromocinnamic Acid

This CK2 inhibitor (FW = 463.74 g/mol; CAS 934358-00-6), also known as TBCA and (*2E*)-3-(2,3,4,5-tetrabromophenyl)-2-propenoate, targets Casein Kinase-2 (IC<sub>50</sub> = 0.11  $\mu$ M) and exhibits selectivity over CK1, DYRK1A, or Dual-specificity tyrosine phosphorylation-regulated kinase-1A (IC<sub>50</sub> = 24.5  $\mu$ M), and a panel of 27 other kinases. The most widely employed CK2 inhibitor is 4,5,6,7-tetrabromobenzotriazole, or TBB (IC<sub>50</sub> = 0.54  $\mu$ M), which exhibits a comparable efficacy toward another kinase, DYRK1a. Abnormally high constitutive activity of protein kinase CK2 are suspected to underlie its pathogenesis of vertrain cancers. TBCA reduces the viability of Jurkat cells more efficiently than TBB through enhancement of apoptosis. 1. Pagano, Poletto, Di Maira, *et al.* (2007) *Chembiochem.* **8**, 129.

#### Tetracaine

This local anesthetic (FW<sub>hydrochloride</sub> = 300.83 g/mol; CAS 136-47-0; solubility = 1 part in 7.5 parts water at 20°C), also known as 4-(butylamino)benzoic acid 2-(dimethylamino)ethyl ester, blocks the voltage-sensitive release of calcium ions from the sarcoplasmic reticulum. **Target(s):** acetylcholinesterase (1-8); 1-acylglycerol-phosphocholine *O*-acyltransferase, or lysophosphatidyl-choline *O*-acyltransferase (49);  $\beta_2$ -adrenergic receptor (9); amino acid transport (10); Ca<sup>2+</sup>-dependent cyclic nucleotide phosphodiesterase (11); Ca<sup>2+</sup>/Mg<sup>2+</sup>-dependent ATPase (12); Ca<sup>2+</sup> release channel (13-15); choline-phosphate cytidyltransferase, or CTP:phosphocholine cytidyltransferase (42,48); cholinesterase (5,19); cytochrome *c* oxidase (20), electron transport (21,22); F<sub>1</sub> ATP synthase, or

mitochondrial ATPase; H<sup>+</sup>-transporting two-sector ATPase (7,23-28); GABA<sub>A</sub> receptors (29); D-3-hydroxybutyrate dehydrogenase (30); K<sup>+</sup>/Cl<sup>-</sup> cotransport (31); kinesin (32); lecithin:cholesterol acyltransferase, or LCAT (33); luciferase (20,34); N-methyl-D-aspartate receptor (35); monoamine oxidase (36); NADPH:ferrihemoprotein reductase (37); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (7,38); nicotinic acetylcholine receptors (39,40); μ-, κ-, and δ-opioid receptors (41); phospholipase A<sub>2</sub> (43); phospholipid-dependent protein kinase (44); protein kinase C (45,46); quaternary-amine-transporting ATPase (47); stearoyl-CoA Desaturase (37); and sterol O-acyltransferase, or cholesterol O-acyltransferase, ACAT (16-18). 1. al-Jafari, Kamal, Duhaiman & Alhomida (1996) *J. **2,2',3,3'-Tetrachlorobiphenyl**

This polychlorinated biphenyl or PCB congener (FW = 291.99 g/mol; CAS 52663-59-9; Abbreviation: 2,2',3,3'-TCB and 2,2',3,3'-TCBP) is a

membrane-permeant environmental pollutant that inhibits uroporphyrinogen decarboxylase (1). In all, there are 169 congeners that contain four or more chlorine atoms. Virtually all are toxic. PCBs were widely used for many applications, especially as dielectric fluids in transformers and capacitors, but their toxicity and biological persistence led to current bans on PCB production in the United States Congress since 1979. 1. Kawanishi, Seki & Sano (1983) *J. Biol. Chem.* **258**, 4285.

**2,3,7,8-Tetrachlorodibenzo-p-dioxin**, See **TCDD**

**Tetrachloro-p-hydroquinone**

This quinol and porphyrin synthesis inhibitor (FW = 247.89 g/mol; CAS 87-87-6), itself a hydroxylation metabolite of pentachlorophenol, targets both porphyrinogen carboxy-lyase (1,2) and uroporphyrinogen decarboxylase (3). 1. **4,5,6,7-Tetrachloroindan-1,3-dione**

This substituted indane (FW = 283.93 g/mol; CAS 606-23-5 and 30675-13-9; orange solid) is a novel inhibitor of ubiquitin C-terminal hydrolase L3, or UCH-L3 (IC<sub>50</sub> = 0.6 μM), displaying 125x greater selectivity for UCH-L3 than for UCH-L1 (IC<sub>50</sub> = 75 μM). 1. Liu, Lashuel, Choi, et al. (2003) *Chem. Biol.* **10**, 837. 2. Love, et al. (2007) *Nature Chem. Biol.* **3**, 697.

**Tetrachloropalladate dianion**

These inorganic reagents [Na<sub>2</sub>PdCl<sub>4</sub>] (FW = 294.21 g/mol; CAS 14349-67-8) and K<sub>2</sub>PdCl<sub>4</sub> (FW = 326.43 g/mol) are planar d<sup>8</sup>-tetracoordinate Pd(II) dianionic complexes that inhibit the sarcoplasmic reticulum Ca<sup>2+</sup>/Mg<sup>2+</sup>-dependent ATPase (1) and electron transport (2). 1. Tat'ianenko, Sokolova & Moshkovskii (1982) *Vopr. Med. Khim.* **28**, 126. 2. Biagini, Moorman & Winston (1982) *Toxicol Lett.* **12**, 165.

**Tetrachloroplatinate, Potassium**

This water-soluble, ruby-red, planar d<sup>8</sup>-tetracoordinate Pt(II) dianionic complex K<sub>2</sub>[PtCl<sub>4</sub>] (FW = 415.09 g/mol) is an irreversible inhibitor of dihydropteridine reductase (1), fructose-1,6-bisphosphate aldolase (2), glucose-6-phosphate dehydrogenase (2), glyceraldehyde-3-phosphate dehydrogenase (2), and malate dehydrogenase (3,4). 1. Armarego & Ohnishi (1987) *Eur. J. Biochem.* **164**, 403. 2. Aull, Allen, Bapat, et al. (1979) *Biochim. Biophys. Acta* **571**, 352. 3. Friedman, Otwell & Tegginis (1975) *Biochim. Biophys. **4,5,6,7-Tetrachloro-2'-trifluoromethylbenzimidazole**

This weakly acidic, membrane-permeant halogenated benzimidazole (FW = 323.92 g/mol;  $pK_a = 5.6$ ), often abbreviated TTFB or TCFB, is a potent proton gradient-dissipating agent that uncouples mitochondrial oxidative phosphorylation and chloroplast electron transport (1-3). **See Uncouplers** 1. Heytler (1979) *Meth. Enzymol.* **55**, 462. 2. Hanstein (1976) *Trends Biochem. Sci.* **1**, 65. 3. Beechey (1966) *Biochem. J.* **98**, 284.

**Tetracycline**

The antibiotic (FW = 444.44 g/mol; CAS 60-54-8; solubility = 1.7 mg/mL at 28°C), systematically named [4*S*-(4 $\alpha$ ,4 $\alpha$ ,5 $\alpha$ ,6 $\beta$ ,12 $\alpha$ )]-4-(dimethylamino)-1,4,4 $\alpha$ ,5,5 $\alpha$ ,6,11,12 $\alpha$ -octahydro-3,6,10,12,12 $\alpha$ -pentahydroxy-6-methyl-1,11-dioxo-2-naphthacene-carboxamide, from *Streptomyces* spp. inhibits binding of aminoacyl-tRNA to ribosomal acceptor site (A-site). Tetracycline-sensitive organisms are those that are most readily affected by this class of antibiotics. Tetracycline-resistant organisms exhibit diminished cellular accumulation of the antibiotic. Two transposons in enteric bacteria that carry genes associated with tetracycline resistance. In Gram-positive bacteria, resistance reportedly involves a translation attenuation mechanism. **Target(s)**: catalase (1); fructose-1,6-bisphosphate aldolase (2); gingipain R (3); glutamate racemase (4); GTP diphosphokinase (5,6); guanosine-3',5'-bis(diphosphate) 3'-diphosphatase (7); guanosine 3',5'-polyphosphate synthetase (6); lipase, or triacylglycerol lipase (8-11); nucleotide diphosphokinase (12); peptidyl-tRNA hydrolase, or aminoacyl-tRNA hydrolase (13); protein biosynthesis, at elongation and termination (14-19); protein-synthesizing GTPase (elongation factor) (19); streptomycin 3'-adenylyltransferase (20). **See also** *Chlortetracycline*; *Oxytetracycline* 1. **O-(*n*-Tetradecyl) Methylphosphonofluoridate**

This *n*-alkyl methylphosphonofluoridate (FW = 278.39 g/mol) irreversibly inhibits acetylcholinesterase and 1-alkyl-2-acetylglucero-phosphocholine esterase, or platelet-activating-factor acetylhydrolase. Platelet-activating factor (PAF) is a potent endogenous phospholipid modulator of diverse biological activities, including inflammation and shock. PAF levels are primarily regulated by PAF acetylhydrolases (PAF-AHs). These enzymes are candidate secondary targets of organophosphorus (OP) pesticides and related toxicants. Ultra-high potency and selectivity are achieved with *N*-alkyl methylphosphonofluoridates (long-chain sarin analogues): mouse brain and testes  $IC_{50} < \text{or} = 5$  nM for C<sub>8</sub>-C<sub>18</sub> analogues and 0.1-0.6 nM for C<sub>13</sub> and C<sub>14</sub> compounds; human plasma  $IC_{50} \leq 2$  nM for C<sub>13</sub>-C<sub>18</sub> analogues. Acetylcholine esterase (AChE) inhibitory potency decreases as chain length increased with maximum brain PAF-AH/AChE selectivity (>3000x) for C<sub>13</sub>-C<sub>18</sub> compounds. 1. Quistad, Fisher, Owen, Klintonberg & Casida (2005) *Toxicol. Appl. Pharmacol.* **205**, 149.

**5-(Tetradecyloxy)-2-furanoyl-CoA**

This acylated coenzyme A (FW = 1091.00 g/mol), produced by the action of fatty acyl-CoA synthetases on 5-(tetradecyloxy)-2-furoic acid, inhibits acetyl-CoA carboxylase, thereby indirectly stimulating fatty acid oxidation and inhibiting glycolysis. **Target(s)**: acetyl-CoA carboxylase (1,2); and adenine nucleotide translocase (1). 1. Harris & McCune (1981) *Meth. Enzymol.* **72**, 552. 2. Halvorson & McCune (1984) *Lipids* **19**, 851.

**Tetradecyl Sulfate**, See *Myristyl Sulfate*

**Tetradecyltriphenylphosphonium Bromide**

This phosphonium salt (FW<sub>ion</sub> = 539.58 g/mol) inhibits glycylpeptide *N*-tetradecanoyltransferase, or protein *N*-myristoyltransferase (1). 1. Selvakumar, Lakshmi-kuttyamma, Shrivastav, et al. (2007) *Prog. Lipid Res.* **46**, 1.

**Tetraethylammonium Chloride**

This quaternary amine salt (FW = 165.71 g/mol; CAS 56-34-8; soluble in water, ethanol, ether, and acetone; *Symbol* = TEA chloride) is the prototypical ganglionic blocking agent that inhibits K<sup>+</sup> channels and nicotinic acetylcholine neurotransmission by blocking the receptor-mediated K<sup>+</sup>

currents (**See Ganglionic Blocking Agents**). Tetraethylammonium bromide (FW = 210.16 g/mol; CAS 71-91-0; *Symbol* = TEA bromide) is likewise a ganglionic blocking agent and has been shown to inhibit acetylcholinesterase. **Target(s)**: acetylcholinesterase (1-6); acid phosphatase (7); choline kinase (8); cholinesterase, *or* butyrylcholinesterase (9-12); K<sup>+</sup> channels (13) 1. #### Tetraethylenepentamine

This toxic oligoamine (FW<sub>free-base</sub> = 189.30 g/mol; CAS 112-57-2), often abbreviated TEPA, usually supplied as the pentahydrochloride) is a metal chelator that tightly binds zinc and copper ions, often depriving metalloenzymes of a required metal ion. Containing both primary and secondary amines, TEPA also reacts with aldehydes, acids and chlorinated hydrocarbons. **Target(s)**: adenosylhomocysteinase (1); *Aeromonas caviae* metalloproteinase (2); *Agkistrodon acutus* (hundred-pace snake) Ac3-proteinase (3); *Agkistrodon halys* hemorrhagic toxin I (4); *Calloselasma rhodostoma* hemorrhagic protease (5); fibrolase (6,7); leucyl aminopeptidase (8); β-lytic metalloendopeptidase (9); ptilirysin, *or* protease Pi (10); pseudolysin (12); *Pseudomonas aeruginosa* LasA, *or* extracellular proteinase (12); serralyisin (13); *Serratia marcescens* 56K protease (14); staphylolysin (15); and Cu/Zn superoxide dismutase (16,17). 1. #### Tetraethyllead

This toxic organolead compound (FW = 323.4 g/mol; CAS 78-00-2; B.P. ≈ 200°C) was previously employed as a gasoline additive that increases the effective octane number and reduces engine knocking. When absorbed by an organism, tetraethyllead is converted to triethyllead cation *via* cytochrome P450 systems, and this metabolite is the cause of the symptoms of tetraethyllead poisoning. By the mid-1970s, however, when tetraethyllead

usage reached its peak, environmentalists succeeded in banning this additive in the United States and Europe. **Target(s)**: γ-aminobutyrate (GABA) uptake, Na<sup>+</sup>-dependent, inhibited by triethyllead cation (1,2); Ca<sup>2+</sup>-channel, voltage-dependent, inhibited by triethyllead cation (3); cerebroside biosynthesis (4); cytokinesis (5,6); DNA biosynthesis (4); oxidative phosphorylation (7); porphobilinogen synthase, *or* δ-aminolevulinate dehydratase, inhibited by triethyllead cation (8); sulfatide biosynthesis (4); tubulin polymerization (microtubule assembly), inhibited by triethyllead cation (9,10) **See also Triethyl lead Chloride** 1. #### Tetraethyl Pyrophosphate

This toxic insecticide (FW = 290.19 g/mol; CAS 107-49-3), abbreviated TEPP and systematically named tetraethyl diphosphate, is a hygroscopic liquid that inhibits cholinesterases. TEPP also reacts very slowly with chymotrypsin (and even slower with trypsin). Once inactivated by TEPP, acetylcholine esterase will slowly reactivate, regaining 75% of its activity in 3 days, when incubated with saturating choline. Reactivation is faster, when carried out in the presence of 1-2 M freshly prepared neutral hydroxylamine. In the latter case, the likely nucleophile is the hydroxyl group of hydroxylamine. *Note*: TEPP is miscible with water, but quickly hydrolyzes to ethanol and orthophosphate (*t*<sub>1/2</sub> = 7 hours at 25°C of a 1:1 solution). **Target(s)**: acetylcholinesterase (1-9); acetylsterase (10,11); arylformamidase (12); cholinesterase (3,13,14); chymotrypsin (14-16); esterase (11); glucose-6-phosphate dehydrogenase, weakly inhibited (17); lipase (14); lipoprotein lipase (18); 6-phosphogluconate dehydrogenase (17); and trypsin (15). 1. #### Tetraethylthiuram Disulfide

This disulfide (FW = 296.55 g/mol; Solubility: 2.82 g/100 mL ethanol and 7.14 g/100 mL diethyl ether), also known as Antabuse, disulfiram, and tetraethyldithiocarbamyl disulfide, is a natural product of the mushroom *Coprinus atramentarius* (inky cap) that is used in aversion therapy for controlling alcoholism. Tetraethylthiuram disulfide inhibits monomeric mitochondrial aldehyde dehydrogenase by inducing the formation of an

intramolecular disulfide bond (1). When alcohol is consumed, acetaldehyde is formed in the alcohol dehydrogenase, accumulating to toxic levels and manifested as a set of unpleasant sensations (referred to as the **Disulfiram-Ethanol Reaction**, or DER) that include flushing, tachycardia, nausea, and vomiting. The perceived threat of DER is thought to be dominant psychological factor in dissuading alcohol use. **Target(s):** alcohol dehydrogenase (2,3); aldehyde dehydrogenase (1,4-12); aldehyde reductase (13); D-amino-acid oxidase (14); ascorbate oxidase (15); caspase 1 (16); caspase 3 (16); carboxylesterase (17); cholesterol 7 $\alpha$ -monooxygenase (18,19); CYP2E1 (20-24); dopamine  $\beta$ -monooxygenase (25,26); glucose-6-phosphate dehydrogenase (27); glutathione S-transferase (28); guanylate cyclase (29); L-gulonolactone oxidase (30); inositol-phosphate phosphatase, or myo-inositol monophosphatase (31); inositol-polyphosphate 5-phosphatase, or myo-inositol-1,4,5-trisphosphate 5-phosphatase (31,32); lactate dehydrogenase (33); 5-lipoxygenase (34); microtubule assembly (tubulin polymerization) (35); 6-phosphogluconate dehydrogenase (27); 1-pyrroline-5-carboxylate dehydrogenase (36); salicylhydroxamic acid reductase (37); succinate dehydrogenase (38-41); Cu/Zn superoxide dismutase (42); 4-N-trimethylamino-butyraldehyde dehydrogenase (43); and xanthine oxidase (41,44). 1. #### S-(1,1,2,2-Tetrafluoroethyl)-L-cysteine

This toxic cysteine conjugate (FW = 221.18 g/mol), which is formed metabolically in mammals exposed to the industrial gas tetrafluoroethylene, is further metabolized to difluorothioacetate fluoride. The latter, which is thought to inhibit mitochondrial aconitase and the  $\alpha$ -

ketoglutarate dehydrogenase complex, also rapidly inactivates branched-chain-amino-acid aminotransferase. **Target(s):** aconitase, or aconitate hydratase (1); branched-chain-amino-acid aminotransferase (2); dihydroliipoamide dehydrogenase (3);  $\alpha$ -ketoglutarate dehydrogenase complex (3); and liipoamide succinyltransferase (3). 1. James, Gygi, Adams, et al. (2002) *Biochemistry* **41**, 6789. 2. Cooper, Bruschi, Conway & Hutson (2003) *Biochem. Pharmacol.* **65**, 181. 3. Bruschi, Lindsay & Crabb (1998) *Proc. Natl. Acad. Sci. U.S.A.* **95**, 13413.

#### DL-4,5,6,7-Tetrafluorotryptophan

This halogenated tryptophan (FW = 276.19 g/mol) competitively inhibits tryptophanyl-tRNA synthetase (1-3). 1. Kisselev, Favorova & Kolaleva (1979) *Meth. Enzymol.* **59**, 174. 2. #### Tetrahydrobenzo[h][1,6]naphthyridine-6-chlorotacrine Hybrids

These novel AChE inhibitors (Hybrid 5a: FW<sub>n=3</sub> = 596.56 g/mol; Hybrid 5b: FW<sub>n=4</sub> = 610.58 g/mol; Hybrid 5c: FW<sub>n=5</sub> = 624.60 g/mol; Hybrid 5d: FW<sub>n=6</sub> = 638.62 g/mol; Hybrid 5e: FW<sub>n=7</sub> = 652.64 g/mol; Hybrid 5f: FW<sub>n=8</sub> = 666.66 g/mol; Hybrid 5g: FW<sub>n=9</sub> = 680.68 g/mol), which bind simultaneously at the catalytic anionic site (CAS) and the peripheral anionic site (PAS) of cholinesterases, were designed by molecular hybridization of a novel 3,4-dihydro-2H-pyrido[3,2-

c]quinoline scaffold and the potent AChE CAS-directed inhibitor, 6-chlorotacrine (1). Hybrid 5a, the trimethylene-bridged analogue, is a remarkably tight inhibitor for human acetylcholine esterase, or hAChE ( $IC_{50} = 0.006$  nM), with much weaker effects on human butyrylcholine esterase, or hBChE ( $IC_{50} = 120$  nM), A $\beta$ 42 aggregation in *Escherichia coli* (52% inhibition at 10  $\mu$ M), and microtubule-associated protein Tau aggregation in *E. coli* (41% inhibition at 10  $\mu$ M). Hybrid 5b, the tetramethylene-bridged analogue, inhibits hAChE ( $IC_{50} = 14.2$  nM), hBChE ( $IC_{50} = 205$  nM), A $\beta$ 42 aggregation (56%), and Tau aggregation (59%). Hybrid 5c, the pentamethylene-bridged analogue, inhibits hAChE ( $IC_{50} = 14.2$  nM), hBChE ( $IC_{50} = 337$  nM), A $\beta$ 42 aggregation (54%), and Tau aggregation (58%). Hybrid 5d, the octamethylene-bridged analogue, inhibits hAChE ( $IC_{50} = 2$  nM), hBChE ( $IC_{50} = 286$  nM), A $\beta$ 42 aggregation (77%), and Tau aggregation (69%). *In vitro* studies using artificial membranes predict good brain permeability, indicating a potential for these hybrid to reach their intended CNS targets. 1. Di Pietro, Pérez-Areales, Juárez-Jiménez, *et al.* (2014) *Eur. J. Med. Chem.* **84**, 107.

**Tetrahydroberberine, See Canadine**

### (6R)-Tetrahydrobiopterin

This biopterin derivative (FW = 241.25 g/mol;  $\lambda_{max} = 265$  nm in 0.1 M HCl ( $\epsilon = 14000$  M $^{-1}$ cm $^{-1}$ ) and 300 nm at pH 6.8), also known as BH $_4$  and (6R)-L-erythro-5,6,7,8-tetrahydrobiopterin, is a cofactor for phenylalanine 4-monooxygenase, tyrosine 3-monooxygenase, anthranilate 3-monooxygenase, tryptophan 5-monooxygenase, glyceryl-ether monooxygenase, mandelate 4-monooxygenase, and nitric oxide synthase. In addition, BH $_4$  stimulates dopamine release from the rat striatum and PC12 pheochromocytoma cells as well as Ca $^{2+}$  channels in rat brain. PC12 cells are activated by tetrahydrobiopterin via a cAMP-dependent protein kinase pathway. Note that excess tetrahydrobiopterin will inhibit tyrosine 3-monooxygenase (1) and phenylalanine 4-monooxygenase. **Solution Preparation:** Tetrahydropterin stock solutions should be prepared daily, usually by dissolving the dihydrochloride salt in deionized water. BH $_4$  concentration is determined from the absorbance at 265 nm in 2 M perchloric acid ( $\epsilon = 18,000$  M $^{-1}$ cm $^{-1}$ ). BH $_4$  is rapidly oxidized in aqueous solutions, with a 6-min half-life at pH 6.8 and 24°C. **Other Target(s):** dihydropteridine reductase (2); GTP cyclohydrolase I (2-11); [phenylalanine monooxygenase] kinase (12); tRNA-guanine transglycosylase (13); and xanthine oxidase (14). 1. ### $\Delta^9$ -Tetrahydrocannabinol

This much abused psychotropic substance and CB $_1$ /CB $_2$  partial agonist (FW = 314.47 g/mol; CAS 1972-08-3;  $\lambda_{max} = 283$  and 276 nm ( $\epsilon = 1620$  and 1580

M $^{-1}$ cm $^{-1}$ , respectively, in Ethanol; Abbreviations:  $\Delta^9$ -THC and THC), also called (-)- $\Delta^1$ -3,4-*trans*-tetrahydrocannabinol, is the psychoactive principle in *Cannabis* (e.g., marijuana, hashish, or "pot").  $\Delta^9$ -THC has a  $K_i$  of 10 nM (partial agonist) for the CB $_1$  receptor and a  $K_i$  of 24 nM (partial agonist) for the CB $_2$  receptor. These G-protein-coupled receptors are activated by three major ligand types: endocannabinoids (e.g., oleylethanolamine), plant cannabinoids (e.g., THC), and synthetic cannabinoids (e.g., HU-210). The two known cannabinoid receptor subtypes, termed CB $_1$  and CB $_2$ , with the former mainly expressed in brain (but also in lung, liver, and kidney), and the latter in the immune and hematopoietic cells. Other effects include relaxation, alteration of visual, auditory, and olfactory senses, fatigue, and appetite stimulation. THC has marked antiemetic properties, the latter commending its use to suppress vomiting in HIV-AIDS patients. **Psychotomimetic Effects:**  $\Delta^9$ -THC is classified as a psychotomimetic (or psychotogenic) agent, one whose actions mimic the symptoms of psychosis, including delusions and/or delirium, as opposed to only hallucinations. In the case of  $\Delta^9$ -THC, the effects are numerous, a finding that suggests the drug's widespread influence over the Central Nervous System. Indeed, a recent study (1) found that  $\Delta^9$ -THC induces transient effects in healthy individuals, including positive symptoms, negative symptoms, perceptual alterations, euphoria, anxiety, as well as deficits in working memory, recall, and the executive control of attention without altering general orientation. Other symptoms include suspiciousness, paranoid and grandiose delusions, conceptual disorganization, and illusions. It also produces depersonalization, derealization, distorted sensory perceptions, altered body perception, feelings of unreality and extreme slowing of time.  $\Delta^9$ -THC produces blunted affect, reduced rapport, lack of spontaneity, psychomotor retardation, and emotional withdrawal (1). In the case of pot smoking, the main route for THC entry is via the lungs, eventually reaching the central nervous system, where it can bind to and stimulate CB $_1$  receptors. That said, the lipophilic nature leads to almost immediate sequestration of THC within lipid-rich biological membranes, followed by slow release, the latter accounting for its long-lasting psychotropic effects. THC binding gives rise to anxiolytic- and antidepressant-like effects. **Target(s):** adenylate cyclase (2,3); anandamide amidohydrolase (4); ATPase (5); cholesterol esterase (6,7); lysolecithin acyltransferase (8); NADH oxidase (9); and Na $^+$ /K $^+$ -exchanging ATPase (10). 1. ### (+)-S-4,5,6,7-Tetrahydro-9-chloro-5-methyl-6-(3-methyl-2-butenyl)imidazo[4,5,1-jk][1,4]benzodiazepine-2(1H)-thione

This benzodiazepine (FW = 321.87 g/mol), also known as R82913 and 9-chloro-TIBO, inhibits a number of viral reverse transcriptases by binding within a hydrophobic pocket in the enzyme-DNA complex near the active-site catalytic residues (1). **Target(s):** HIV-1 reverse transcriptase (1-6); RNA-directed DNA polymerase (1-6); and viral reverse transcriptase (2). 1. **Tetrahydrofolate**

This coenzyme (FW<sub>free-acid</sub> = 445.44 g/mol; CAS 29347-89-5), named systematically as (-)-5,6,7,8-tetrahydropteroyl-L-glutamate or *N*-[4-[[[(2-amino-3,4,5,6,7,8-hexahydro-4-oxopteridin-6-yl)methyl]amino]benzoyl]-L-glutamate, is a crucial one-carbon donor in the metabolism of L-methionine, glycine, L-serine, L-histidine, and the purines and pyrimidines. Tetrahydrofolate is slowly oxidized in solid form and must be stored in the dark and cold under vacuum conditions or an inert gas. The presence of heavy metal ions or extremes of pH accelerates decomposition, as will light. The half-life of a solution of tetrahydrofolate in phosphate buffer at 23°C is about 40 min; if a stabilizer, such as ascorbate or 2-mercaptoethanol, is added, the half-life is increased by 2-3 times. Stability also depends on the buffer: relatively unstable in phosphate buffers and more stable in Tris or triethanolamine. The most common biological form of tetrahydrofolate contains between three and seven glutamyl residues, linked via their  $\gamma$ -carboxyl groups. **Target(s):** dihydropteroate synthase (1); formiminotetrahydrofolate cyclodeaminase, or formimidoyl-tetrahydrofolate cyclodeaminase (2-4); glutamate dehydrogenase (5); GTP cyclohydrolase I, weakly inhibited (6); guanine deaminase (7-9); indoleacetaldoxime dehydratase (10); and methionyl-tRNA formyltransferase (11). **See also Tetrahydropteroyl-triglutamate** 1. **Tetrahydrohomofolate**

The homologues of tetrahydrofolate and tetrahydrofolate polyglutamates can serve as inhibitors of a number of folate-dependent systems. **Target(s):** methionyl-tRNA formyltransferase (1,2); phosphoribosylglycinamide formyltransferase (3,4); thymidylate synthase (4-7). 1. **Tetrahydrolipstatin**

This L-leucine derivative (FW = 495.74 g/mol; CAS 96829-58-2; M.P. = 43°C), also known by its proprietary name Orlistat<sup>®</sup>, has been used clinically to inhibit digestive lipases in individuals requiring weight reduction.

Tetrahydrolipstatin is a potent irreversible inhibitor of lipoprotein lipase, but it slowly turned over. **Target(s):** cholesterol esterase (1); diacylglycerol lipase (2); fatty-acid synthase (3); lipase, or triacylglycerol lipase (1,4-7); lipase-related protein (2); pancreatic (5); lipoprotein lipase (8-10); microbial lipases from *Chromobacterium viscosum* and *Rhizopus oryzae* (1). 1. **3-(1,2,3,4-Tetrahydro-4-oxo-7-chloro-2-naphthyl)pyridine**

This pyridine derivative (FW = 257.72 g/mol; CAS 786-97-0), also known as SU 10603 and systematically named as 3-(1,2,3,4-tetrahydro-4-keto-7-chloro-2-naphthyl)pyridine, inhibits steroid 17 $\alpha$ -monooxygenase (1). This oxidoreductase [EC 1.14.99.9] is a microsomal cytochrome P-450 that catalyzes steroid hydroxylation at the 17-position by accepting electrons from

NADPH via a flavoprotein. It participates in the synthesis of steroid hormones, including cortisol, androgens, and estrogens. The enzyme also possesses 17 $\alpha$ -hydroxyprogesterone aldolase activity. 17 $\alpha$ -Hydroxylase deficiency is an autosomal recessive trait that causes congenital adrenal hyperplasia (type V). SU-10603 produces a concentration-dependent (0.01-1.0 mM) inhibition of ethylmorphine demethylation, aniline hydroxylation, and benzo[a]pyrene hydroxylation. A concentration of 0.1-0.2 mM decreases the metabolism of all three substrates by approximately 50%. SU-10603 is a more potent inhibitor of ethylmorphine metabolism than metyrapone, and its relative potency is even greater with respect to aniline and benzo[a]pyrene metabolism. Similar results are obtained with guinea pig liver microsomes. *Note:* The very same code name (SU 10603) has been used to refer to the structural isomer 3-(1,2,3,4-tetrahydro-4-oxo-2-naphthyl)pyridine (*See next entry*). 1. **6,7,8,9-Tetrahydro-5H-tetrazolo[1,5-a]zepine, See Pentylene tetrazole**

**Tetrahydrothiamin Pyrophosphate**

This thiazolidine ring derivative of thiamin pyrophosphate (FW = 426.32 g/mol), also called tetrahydrothiamin diphosphate, is produced by borohydride reduction of the thiazolium ring, yielding four stereoisomers, due to the introduction of two chiral centers on the thiazolidine ring. The resulting racemic mixture inhibits the pyruvate decarboxylase component of the pyruvate dehydrogenase complex from *Escherichia coli* (1). **Target(s):** acetylacetyl synthase (2);  $\alpha$ -ketoglutarate dehydrogenase complex (3); pyruvate decarboxylase (1,4,5); and pyruvate dehydrogenase complex (1,4,5). 1. Lowe, Leeper & Perham (1983) *Biochemistry* **22**, 150. 2. Schloss & Van Dyk (1988) *Meth. Enzymol.* **166**, 445. 3. Marley, Meganathan & Bentley (1986) *Biochemistry* **25**, 1304. 4. **3,4,5,6-Tetrahydouridine**

This tetrahedral transition-state analogue (FW = 248.24 g/mol; CAS 18771-50-1) rapidly inhibits bacterial cytidine deaminase, whereas the human liver enzyme is inactivated slowly (1-8). With the latter, the rate constants for binding and release ( $k_{on} = 2.4 \times 10^4 \text{ M}^{-1}\text{sec}^{-1}$  and  $k_{off} = 5.6 \times 10^{-4} \text{ sec}^{-1}$ ) are in reasonable agreement with the  $K_i$  value of 29 nM measured separately under steady-state conditions. The slow onset of inhibition has been suggested to be due to structural reorganization preceding the formation of a stable enzyme-inhibitor complex (1). **Target(s):** cytidine deaminase, slow-binding inhibition (1-8); deoxycytidine deaminase (9); deoxycytidine kinase (10); and uracil phosphoribosyl-transferase (11). 1. Wentworth & Wolfenden (1975) *Biochemistry* **14**, 5099. 2. Cohen & Wolfenden (1971) *J. Biol. Chem.* **246**, 7561. 3. Wentworth & Wolfenden (1978) *Meth. Enzymol.* **51**, 401. 4. #### N,N,N',N'-Tetrakis(2-pyridylmethyl)ethylenediamine

This cell-penetrant chelator (FW = 424.55 g/mol; CAS 16858-02-9; IUPAC: *N,N,N',N'*-Tetrakis(2-pyridylmethyl)ethylenediamine) binds divalent cations, with selectivity toward Zn<sup>2+</sup>, Cu<sup>2+</sup>, and Fe<sup>2+</sup>, but not greatly perturbing Ca<sup>2+</sup> and Mg<sup>2+</sup> concentrations. *K*<sub>d</sub> values are 0.26 × 10<sup>-15</sup> M for Zn<sup>2+</sup>, 2.4 × 10<sup>-15</sup> M for Fe<sup>2+</sup>, 54 × 10<sup>-12</sup> M for Mn<sup>2+</sup>, 4 × 10<sup>-5</sup> M Ca<sup>2+</sup>, and 20 mM for Mg<sup>2+</sup>. TPEN was useful in demonstrating that mitotic progression and nuclear assembly are Ca<sup>2+</sup>-mediated processes that are not attributable to other ions. Related nonpenetrating sulfonates include (4-{[2-(bis-pyridin-2-ylmethylamino)ethylamino]methyl}phenyl)methanesulfonic acid (DPESA) and [4-{[2-(bis-pyridin-2-ylmethylamino)ethyl]pyridin-2-ylmethylamino}-methyl]phenyl)methanesulfonic acid (TPESA). **Target(s):** Cu<sup>2+</sup>-dependent ATPase (1); picornain 2A (2); protein kinase C translocation (3); quorum-quenching *N*-acyl-homoserine lactonase (4). TPEN also induces axon and dendrite degeneration (5), strip metalloproteins of zinc cofactors (6), and promote apoptosis (7-9). **1.** Burlando, Evangelisti, Dondero, *et al.* (2002) *Biochem. #### N,N,N',N'-Tetramethylazodicarboxamide

This unselective thiol oxidant (FW = 172.19 g/mol), commonly referred to as diamide and known systematically as 1,1'-azobis(*N,N*-dimethylformamide), converts thiol-containing substances to their disulfide form, such as the oxidation of glutathione to glutathione disulfide (1). **Target(s):** *N*-acetylglucosamine kinase (2); *N*-acylmannosamine kinase (2); β-amino acid transport (3); Ca<sup>2+</sup>-dependent ATPase (4,5); diphosphomevalonate decarboxylase (6); ferrochelatase (7); glyceraldehyde-3-phosphate dehydrogenase (8-10); D-β-hydroxybutyrate dehydrogenase (11); 3-hydroxy-3-methylglutaryl-CoA reductase (12); inositol-1,2,3,5,6-pentakisphosphate 5-phosphatase (13); insulin (14); iodothyronine 5'-deiodinase (15,16); leukotriene-A<sub>4</sub> hydrolase, weakly inhibited (17); Na<sup>+</sup>/Ca<sup>2+</sup> exchange (18); phospholipid-translocating ATPase, *or* flippase (19); phosphoprotein phosphatase (20); protein kinase (21-23); protein phosphatase 7 (20); protein-tyrosine phosphatase (24-27); and UDP-glucose 4-epimerase (28). **1.** Kosower, Kosower, Wertheim & Correa (1969) *Biochem. **Tetrandrine**

This bis-benzylisoquinoline alkaloid ( $FW = 622.76$  g/mol; CAS 518-34-3) from the Chinese medicinal *Radix stephania tetrandrae* inhibits vascular contraction induced by membrane depolarization with KCl or adrenoceptor activation with phenylephrine. It also inhibits the release of endothelium-derived nitric oxide as well as NO production by inducible nitric oxide synthase. Tetrandrine also inhibits multiple Ca<sup>2+</sup> entry pathways. **Target(s):** Ca<sup>2+</sup>-dependent ATPase (1,2); calcium channel (2-5); nicotinic acetylcholine receptors (6); tyrosine monooxygenase (7). **1.** Chen, Chen, Tian & Yu (2000) *Brit. **Tetrodotoxin**

This natural product ( $FW_{\text{free-base}} = 319.27$  g/mol; CAS 4368-28-9; Soluble to 3 mM in acidic buffer, pH 4.8), which is destroyed by strong acid or alkaline solutions, also called fugu toxin, spheridine, and tarichatoxin, is a toxin that exists in two tautomeric forms in the ovaries, skin, and liver of the fugu or

puffer fish. The structure was determined by the Nobelist R. B. Woodward (1). Tetrodotoxin essentially prevents affected nerve cells from firing by binding to the pores of the voltage-gated, fast sodium ion channels blocking the channels used in the process. Tetrodotoxin is a specific blocker of voltage-gated sodium channels. This extremely toxic agent is also found in the newt, octopus, and several starfish. Tetrodotoxin is slightly soluble in water and has a  $pK_a$  value of 8.76. **Target(s):**  $Na^+$  channels (2-6); and rubredoxin:NAD<sup>+</sup> reductase (7). 1. Woodward (1964) *Pure Appl. Chem.* **9**, 49. 2. Conn (1983) *Meth. Enzymol.* **103**, 401. 3. Prince (1988) *Trends Biochem. Sci.* **13**, 76. 4. Suehiro (1996) *Rev. Hist. Pharm. (Paris)* **44**(312 suppl), 379. 5. **TGX-221**

This potent ATP site-competitive inhibitor (F.W. = 364.44 g/mol; CAS 663619-89-4; Solubility: 12 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as 7-methyl-2-morpholino-9-(1-(phenylamino)ethyl)-4H-pyrido[1,2-a]pyrimidin-4-one, targets the phosphoinositide-3-kinase- $\beta$  (PI3K $\beta$ ), also known as p110 $\beta$ , (IC<sub>50</sub> = 7 nM), with IC<sub>50</sub> values of 0.1, 3.5 and 5  $\mu$ M, respectively, for the  $\delta$ ,  $\gamma$  and  $\alpha$  isoforms. TGX-221 also shows >1,000x selectivity for PIK $\beta$  over a wide range of other kinases. It also inhibits thrombus formation in animal models. 1. Chaussade, *et al.* (2007) *Biochem. J.* **404**, 449.

**TH-302**

This anticancer prodrug (FW = 449.04 g/mol; CAS 918633-87-1; Solubility: 90 mg/mL DMSO or 10 mg/mL H<sub>2</sub>O, the latter with warming) is reductively activated in hypoxic cells to generate the bromo-isophosphoramidate mustard.

Nitrogen mustards form cyclic aminium ions (aziridinium rings) by intramolecular displacement of the chloride by the amine nitrogen. This aziridinium group then alkylates DNA once it is attacked by the N-7 nucleophilic center on the guanine base. Upon displacement of the second chloride, a second alkylation results in the formation of interstrand cross-links (so-called 1,3-ICLs) in 5'-d(GNC) sequences. The strong cytotoxic effect of ICL formation elicits cell cycle arrest as well as formation of histone

$\gamma$ H2AX, a marker for DNA double-strand breaks. Under hypoxic conditions, TH-302 is cytotoxic in CHO cells deficient in homology-dependent DNA repair, but not in lines deficient in base excision, nucleotide excision, or nonhomologous end-joining repair. TH-302 is also effective against lines deficient in BRCA1, BRCA2, and FANCA. In studies with three-dimensional spheroid and multicellular layer models, TH-302 shows enhanced potency in H460 spheroids, when tested under normoxia. 1. Duan, Jiao, Kaizerman, *et al.* (2008) *J. Med. Chem.* **51**, 2412. 2. Meng, Evans, Bhupathi, *et al.* (2012) *Mol. Cancer Ther.* **11**, 740.

**Thalidomide**

S(-)-Thalidomide

R(+)-Thalidomide

This notorious sedative and immunomodulator (FW = 258.23 g/mol; CAS 50-35-1), named systematically as ( $\pm$ )-2-(2,6-Dioxo-3-piperidinyl)-1H-isoindole-1,3(2H)-dione, also blocks basic fibroblast growth factor (bFGF)-induced angiogenesis in cornea (1). Thalidomide also inhibits replication of the HIV-1 virus (2) and has been used to treat AIDS-related oral ulcers. Both enantiomers inhibit tumor necrosis factor  $\alpha$  (TNF- $\alpha$ ) release (3,4). Racemic thalidomide causes severe fetal abnormalities (thalidomide embryopathy), particularly stunted limb growth, when administered during pregnancy. Of the >10,000 thalidomide babies world-wide, two-thirds were in Germany, where thalidomide was approved for over-the-counter sale. The ability of the S-stereoisomer to intercalate into GC-rich regions of DNA appears to give rise to its teratogenic properties, whereas the R-stereoisomer exhibits the sedative properties. Even so, thalidomide racemizes rapidly *in vivo*, making it impossible for the human body to favor only one enantiomer. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** HIV-1 virus replication (2,5); I $\kappa$ B kinase (6). 1. D'Amato, Loughnan, Flynn & Folkman (1994) *Proc. Natl. Acad. Sci. U.S.A.* **91**, 4082. 2. S. Makonkawkeyoon, Limson-Pobre, Moreira, Schauf & Kaplan (1993) *Proc. Natl. Acad. Sci. U.S.A.* **90**, 5974. 3. Tramontana, Utaipat, Molloy *et al.* (1995) *Mol. **Thallium**

This Period 6, Group-13 "post-transition" element (Atomic Symbol: Tl; Atomic Number: 81; Atomic Weight: 204.38) is a nonessential metal in humans, with two principal oxidation states: thallose ion (Tl(I) or Tl<sup>+</sup>) and thallic ion (Tl(III) or Tl<sup>3+</sup>). **Thallium Toxicity:** Both Tl<sup>+</sup> and Tl<sup>3+</sup> are highly toxic. Given the ability of Tl<sup>+</sup> ions (radius = 1.47 Å) to mimic K<sup>+</sup> ions (radius = 1.33 Å), mammals absorb thallium, as do plants. Once within cells, Tl<sup>+</sup> interferes with potassium ion-dependent signaling and metabolism. Agonist-induced Tl<sup>+</sup> influx into acetylcholine receptor-rich membrane vesicles occurs on a millisecond time scale. Tl<sup>3+</sup> compounds resemble corresponding Al<sup>3+</sup> compounds, suggesting the likelihood of forming exchange-inert metal ion-ligand complexes with ATP and other di- and tri-phosphate-containing metabolites. Many thallium compounds are colorless, odorless and tasteless, properties commending their use in rodenticides. The toxic mechanism is incompletely understood. Thallium inhibits glycolysis, TCA cycle, and oxidative phosphorylation. Toxicity is attended by neuropathy and alopecia. Acute-exposure symptoms in humans include pain, nausea, vomiting, and angina. Chronic-exposure issues are hair loss and birth defects. Thallium poisoning is readily diagnosed and detected (the latter by atomic and mass spectroscopy). Forensic awareness of thallium toxicity is high, after a series of notorious murders in the U.S. and People's Republic of China. **Thallium Stress Test:** This nuclear imaging method evaluates how well blood flows

into the heart muscle, both at rest and during supervised activity, usually on an exercycle or treadmill. Radioactive thallium-201 is employed to image blood flow characteristics within patients suffering coronary artery disease. Thallium scans are also made to evaluate the success of bypass surgery or angioplasty. With a half-life of 73 hours,  $^{201}\text{Tl}$  decays by electron capture, emitting Hg X-rays at ~70–80 keV and photons at 135 and 167 keV. This radionuclide thus provides good imaging characteristics without excessive radiation exposure.

**THAM**, See *Tris(hydroxymethyl)aminomethane*

### Thapsigargin

This cell-penetrating and  $\text{IP}_3$ -independent sesquiterpene lactone (FW = 650.76 g/mol; CAS 67526-96-8) from the roots of the umbelliferous plant *Thapsia garganica* is a potent inhibitor of the sarcoplasmic reticulum  $\text{Ca}^{2+}$ -ATPases in mammalian cells,  $\text{IC}_{50}$  = 4–13 nM (1–4), but is without effect on the activities of plasma membrane  $\text{Ca}^{2+}$ -dependent ATPases, inositol-1,4,5-trisphosphate production, or protein kinase C. Calcium ion signaling relies on an intricate network of cellular channels and transporters to maintain a low resting calcium concentrations in the cytosol, with release/uptake producing amplitude- and/or frequency-encoded spikes in ion concentration in response to receptor-bound hormones and growth factors. Thapsigargin is often used to manipulate intracellular calcium ion levels and to increase  $\text{Ca}^{2+}$ -dependent  $\text{Na}^+$  influx. It also depletes the endoplasmic reticulum calcium ion stores, inducing the ER stress response. **Target(s):** ATP-diphosphohydrolases, wherein only the ATPase activity is inhibited (5);  $\text{Ca}^{2+}$ -transporting ATPase (1,4,6–8);  $\text{Mg}^{2+}$ -importing ATPase (8); and photophosphorylation (9); catalytic domain ErbB subfamily of protein tyrosine kinases **1**. ### Theaflavin digallate

This polyphenol antioxidant (FW = 868.71 g/mol), a constituent in black tea, often inhibits many viral and cellular processes *in vitro*. (See *Theaflavin*) Theaflavin digallate (1–10  $\mu\text{M}$ ) inhibits the infectivity of both influenza A virus and influenza B virus in Madin-Darby canine kidney (MDCK) cells *in vitro* (1). Electron microscopy also revealed that EGCG and TF3 agglutinated influenza viruses as well as did antibody, and that they prevented the viruses from adsorbing to MDCK cells. Theaflavin digallate xanthine oxidase and suppression of intracellular Reactive Oxygen Species (ROS) in HL-60 cells (2). It also inhibits 3CL<sup>Pro</sup> ( $\text{IC}_{50}$  = 7  $\mu\text{M}$ ), the virally encoded 3C-like protease that is critical for the viral replication of SARS-CoV, the causative agent of severe acute respiratory syndrome, or SARS (3). Theaflavin digallate inhibits SAM-mediated DNA methylation by DNA methyltransferase 3a (Dnmt3a), an enzyme that regulates osteoclastogenesis via epigenetic repression of anti-osteoclastogenic genes (4). In this context, theaflavin digallate abrogates bone loss in osteoporosis models. **1**. Nakayama, Suzuki, Toda, *et al.* (1993) *Antiviral Res.* **21**, 289. **2**. ### L-Theanine

This L-glutamine derivative (FW = 174.20 g/mol; CAS 34271-54-0), also called *N*<sup>ε</sup>-ethylglutamine and L-glutamic  $\gamma$ -ethylamide, is enriched in green tea. **Target(s):** glutamate transporter via the glutathione-*S*-conjugate export pump (1,2); glutaminase (3,4); glutaminyl-tRNA synthetase (5); 4-methylene-glutaminase, weakly inhibited (6). **1**. Sadzuka, Sugiyama, Suzuki & Sonobe (2001) *Toxicol. Lett.* **123**, 159. **2**. Sugiyama, Sadzuka, Tanaka & Sonobe (2001) *Toxicol. Lett.* **121**, 89. **3**. Hartman (1970) *Meth. ### Thebaine

This (–)-benzylisoquinoline alkaloid (FW = 311.38 g/mol; CAS 115-37-7), which is a precursor to codeine and morphine and is a constituent of opium, binds to  $\mu$  and  $\delta$  opioid receptors. Thebaine is also the starting reagent for the synthesis of such controlled substances as oxycodone, oxymorphone, nalbuphine, naloxone, naltrexone, buprenorphine and etorphine. *Note:* Thebaine is itself a controlled substance, and care must be exercised in its use. **Target(s):** salutaridinol 7-*O*-acetyltransferase (1). **1**. Lenz & Zenk (1995) *J. Biol. Chem.* **270**, 31091. **Theelin**, See *Estrone*

Theelol, See Estriol

### 1-(2'-Thenoyl)-3,3,3-trifluoroacetone

This high-affinity heavy metal ion chelator (FW = 222.19 g/mol; CAS 326-91-0; Melting Point = 40-44°C), also known as 4,4,4-trifluoro-1-(2-thienyl)-1,3-butanedione, is a strong inhibitor of complex II of the mitochondrial electron transport chain, but does not inhibit solubilized succinate dehydrogenase. **Target(s):** dihydroorotate dehydrogenase (1); electron transport, mitochondrial (2,3); fumarate reductase (4); glycerol-3-phosphate dehydrogenase (5); hexacyanoferrate III reductase (6); 4-hydroxyphenylpyruvate dioxygenase (7); malate dehydrogenase (8,9); NAD(P)H dehydrogenase (10); oleoyl-CoA saturase (11); photosystem II (12); semidehydroascorbate reductase, NADH-dependent (13); steroid 21-monoxygenase (14); succinate dehydrogenase, or complex II (2-4,15-20). 1. ### Theobromine

This dimethyl xanthine (FW = 180.17 g/mol; CAS 83-67-0; sparingly soluble in water), also called 3,7-dimethylxanthine and 3,7-dihydro-3,7-dimethyl-1H-purine-2,6-dione, is enriched in cacao beans, cola nuts, and tea. As a 3',5'-cyclicAMP phosphodiesterase inhibitor, theobromine prevents the conversion of cyclicAMP to 5'-AMP. Theobromine is a cardiac stimulator and vasodilator, a smooth muscle relaxant, and a diuretic. It is also a weak adenosine receptor antagonist. **Target(s):** adenosine deaminase (1); 3',5'-cyclic-nucleotide phosphodiesterase (2,3); hydroxyacylglutathione hydrolase, or glyoxalase II (4); inosine Nucleosidase (5); lactoylglutathione lyase, or glyoxalase I (4); NAD<sup>+</sup>-dependent ADP-ribosyltransferase, poly(ADP-ribose) polymerase (6,7); NAD<sup>+</sup> Nucleosidase, or NADase (8,9); and purine-nucleoside phosphorylase (5,10). 1. ### Theophylline

This naturally occurring dimethyl xanthine and smooth muscle relaxant (FW = 180.17 g/mol; CAS 58-55-9; M.P. = 274°C; Soluble to 25 mM in water and to 100 mM in DMSO), also known as 1,3-dimethylxanthine and 3,7-dihydro-1,3-dimethyl-1H-purine-2,6-dione, is found in tea and other plants. Theophylline produces vasodilation, cardiac stimulation, and diuresis. **Target(s):** adenosine deaminase (1); adenosine deaminase (2-4); alkaline phosphatase (5,6); 3',5'-cyclic-GMP phosphodiesterase (7,8,31,32,35); 2',3'-cyclic nucleotide 3'-phosphodiesterase (9,10); 3',5'-cyclic-nucleotide phosphodiesterase,  $K_i = 0.1$  mM (11-18,31-35); CYP1A2 (19); cytokinin  $\beta$ -glucosyltransferase (47); glycerol-1,2-cyclic-phosphate phosphodiesterase (20); glycogen synthase (48); hydroxyacylglutathione hydrolase, or glyoxalase II (22); 15-hydroxyprostaglandin dehydrogenase (21); hypoxanthine(guanine) phosphoribosyltransferase (1,46); lactoylglutathione lyase, or glyoxalase I (22); myeloperoxidase (23); NAD<sup>+</sup>-dependent ADP-ribosyltransferase, or poly(ADP-ribose) polymerase (42-45); NAD<sup>+</sup> Nucleosidase, or NADase (24,25); NAD<sup>+</sup>:protein-arginine ADP-ribosyltransferase (41); nucleoside-diphosphate kinase (37); 1-phosphatidylinositol 4-kinase (38); poly(ADP-ribose) polymerase (26); purine nucleosidase (1); purine-nucleoside phosphorylase (27,28); pyridoxal kinase (29,39); rhodopsin kinase (36); thymidine kinase (40); urate oxidase, or uricase (30). **See also Aminophylline** 1. ### 13-Thiaarachidonate

This long-chain, thioether-containing acid (FW<sub>free-acid</sub> = 322.51 g/mol) is a irreversible mechanism-based inhibitor of arachidonate 15-lipoxygenase. O<sub>2</sub> is required for inactivation. The corresponding sulfoxide is a competitive inhibitor but not an inactivator. **1.** Ator & Ortiz de Montellano (1990) *The Enzymes*, 3rd ed. (Sigman & Boyer, eds.), **19**, 213.

### Thiabendazole

This common fungicide and anthelmintic (FW = 201.25 g/mol; CAS 148-79-8; M.P. = 304-305°C; λ<sub>max</sub> = 298 nm (ε = 23330 M<sup>-1</sup>cm<sup>-1</sup> in methanol); fluorescence emission maximum in acid is 370 nm, when excited at 310 nm) inhibits growth of *Penicillium atrovirens*, when present at 8–10 μg/mL (1). TBZ completely inhibits the following systems of isolated heart or fungus mitochondria: reduced nicotinamide adenine dinucleotide oxidase, succinic oxidase, reduced nicotinamide adenine dinucleotide-cytochrome *c* reductase, and succinic-cytochrome *c* reductase at concentrations of 10, 167, 10, and 0.5 μg/mL, respectively (1). Cytochrome *c* oxidase was not inhibited (1). **Target(s):** CYP1A2 (2); fumarate reductase (3); glucose-6-phosphate dehydrogenase (4); malate dehydrogenase (4-6); methionyl aminopeptidase, K<sub>i</sub> = 0.4 μM (7); Cu/Zn superoxide dismutase (8,9); triacylglycerol lipase (4); and tubulin polymerization (10,11). **1.** Allen & Gottlieb (1970) *Applied Environ. Microbiol.* **20**, 919. **2.** Bapiro, Egnell, Hasler & Masimirembwa (2001) *Drug Metab. Dispos.* **29**, 30. **3.** Armson, Grubb & Mendis (1995) *Int. J. ### Thiacetazone

This well-known tuberculostatic (FW = 236.30 g/mol; CAS 104-06-3), also called 4'-formyl-acetanilide thiosemicarbazone, is a potent noncompetitive inhibitor of influenza A/WSN/33 neuraminidase, or *sialidase* (K<sub>i</sub> = 4 μM). Note that thiacetazone is highly specific in its inhibition; neuraminidases from other influenza strains are not inhibited (1). Thiacetazone should be stored in light-tight container, as it darkens upon exposure to light. **1.** Wu, Peet, Coutts, et al. (1995) *Biochemistry* **34**, 7154.

### 6-Thia-7-dehydro-(RS)-2,3-oxidosqualene

This oxidosqualene analogue (FW = 432.75 g/mol), also called S-6, inhibits rat liver lanosterol cyclase and *Alicyclobacillus acidocaldarius* squalene:hopene cyclase (K<sub>i</sub> = 520 and 127 nM, respectively). (See also 6,10-

*Dimethyl-9,10-epoxy-(5E)-undecen-2-yl 4',8',12'-Trimethyl-(3E,7E)-tridecatrienylyl Sulfide* **1.** Zheng, Abe & Prestwich (1998) *Biochemistry* **37**, 5981.

### 10-Thia-11-dehydro-(RS)-2,3-oxidosqualene

This oxidosqualene analogue also called S-10 (FW = 432.75 g/mol), inhibits rat liver lanosterol cyclase and *Alicyclobacillus acidocaldarius* squalene:hopene cyclase (K<sub>i</sub> = 2.1 and 0.97 μM, respectively). **Target(s):** lanosterol synthase (1); and squalene:hopene cyclase (1). See also 6,10-*Dimethyl-9,10-epoxy-(5E)-undecen-2-yl 4',8',12'-Trimethyl-(3E,7E)-tridecatrienylyl Sulfide* **1.** Zheng, Abe & Prestwich (1998) *Biochemistry* **37**, 5981.

### (7E,11Z,14Z,17Z)-5-Thiaeicosa-7,11,14,17-tetraenoate

This long-chain, thioether-containing acid (FW<sub>free-acid</sub> = 322.51 g/mol) inhibits cyclooxygenase and prostaglandin biosynthesis. The most potent COX-2-catalyzed prostaglandin biosynthesis inhibitor was all-(Z)-5-thia-8,11,14,17-icosatetraenoic acid, followed by eicosapentaenoic acid (EPA), docosahexaenoic acid (DHA), α-linolenic acid (α-LNA), linoleic acid (LA), (7E,11Z,14Z,17Z)-5-thiaeicosa-7,11,14,17-tetraenoic acid, all-(Z)-3-thia-6,9,12,15-octadecatetraenoic acid, and (5E,9Z,12Z,15Z,18Z)-3-oxaheneicosa-5,9,12,15,18-pentaenoic acid, with IC<sub>50</sub> values ranging from 3.9 to 180 μM. **1.** Ringbom, Huss, Stenholm, et al. (2001) *J. Nat. Prod.* **64**, 745.

### Thiamet G

This oral and blood brain barrier-permeable hexosamine analogue (FW = 248.30 g/mol; CAS 1009816-48-1; Soluble to 50 mM in DMSO; (3*aR*,5*R*,6*S*,7*R*,7*aR*)-2-(ethylamino)-3*a*,6,7,7*a*-tetrahydro-5-(hydroxymethyl)-5*H*-pyrano[3,2-*d*]thiazole-6,7-diol, is a sterically constrained mechanism-inspired inhibitor that potently and selectively targets human Protein *O*-GlcNAcase (Reaction: [Protein]-3-*O*-(*N*-acetyl-β-D-glucosaminy)-L-(serine/threonine) + H<sub>2</sub>O ⇌ [Protein]-L-(serine/threonine) + *N*-acetyl-D-glucosamine), with a K<sub>i</sub> value of 21 nM. Given the observed reciprocal relationship between the states phosphorylation and *O*-GlcNAc modification of the microtubule-associated protein Tau as well as the reduced extent of *O*-GlcNAc in Alzheimer Tau, there is justifiably great motivation for generating potent and selective *O*-GlcNAcase inhibitors. Thiamet-G decreases Tau phosphorylation in PC-12 pheochromocytoma cells, an NGF-activatable cell line of neural crest origin. Moreover, attenuated phosphorylation occurs at the pathologically relevant sites, Thr-231 and Ser-396 (1). Thiamet-G also efficiently reduces Tau phosphorylation at Thr-231, Ser-396 and Ser-422 in both rat cortex and hippocampus, revealing the rapid and dynamic relationship between *O*-GlcNAc-Tau and Tau phosphorylation *in vivo*. Indeed, Thiamet G-induced increases in Tau *O*-GlcNAcylation reduces pathological Tau without affecting its normal phosphorylation in a mouse tauopathy model (2). **1.** Yuzwa, Macauley, Heinonen, et al. (2008) *Nature Chem. Biol.* **4**, 483. **2.** Graham, Gray, Joyce, et al. (2014) *Neuropharmacology* **79**, 307.

**Thiamethoxam**

This broad-spectrum systemic insecticide (FW = 291.71 g/mol; CAS 153719-23-4), also named 3-(2-chloro-5-thiazolylmethyl)tetrahydro-5-methyl-2-nitro-4H-1,3,5-oxadiazin-4-imine, is a neonicotinoid that blocks nicotinic acetylcholine receptors, paralyzing the muscles and resulting in death. As a systemic insecticide, it is absorbed quickly by plants and is transported throughout, including pollen, thereby deterring insects from feeding on susceptible plant parts. Neonicotinoid-class insecticides generally have favorable safety profiles, because they preferentially target nicotinic receptor (nAChR) subtypes in insects and poorly penetrate the mammalian blood-brain barrier. Low application rates also limit risk of toxicity in humans. 1. Sheets, Li, Minnema, *et al.* (2016) *Crit. Rev. Toxicol.* **46**, 153.

**Thiamin**

This essential nutrient (FW<sub>HCl-salt</sub> = 300.81 g/mol; CAS 59-43-8), also known as vitamin B<sub>1</sub>, is a water-soluble vitamin containing UV-absorbing pyrimidine and thiazole rings, the latter essential for its biochemical function (1-3). At pH 7 and above, thiamin has two bands ( $\lambda_{\text{max}}$  at 235 and 267 nm, with  $\epsilon = 11300$  and  $8300 \text{ M}^{-1}\text{cm}^{-1}$ , respectively). At and below pH 5.5, there is one UV band ( $\lambda_{\text{max}} = 247 \text{ nm}$ ;  $\epsilon = 14200 \text{ M}^{-1}\text{cm}^{-1}$ ). **Metabolic Forms:** Thiamin is the transport form of the vitamin, mainly associated with albumin. Within cells, thiamin is converted to: thiamine monophosphate (ThMP); thiamine diphosphate (ThDP), also called thiamine pyrophosphate (TPP); thiamine triphosphate (ThTP), adenosine thiamine triphosphate (AThTP), and adenosine thiamine diphosphate (AThDP). **Chemical Properties:** Thiamin chloride is readily hydrated, and aqueous solutions are stable at pH 3.5; however, above pH 5, solutions are less stable to heat and, above pH 7, solutions are unstable, even at room temperature. Accordingly, thiamin solutions should always be freshly prepared and kept cold. **Target(s):** acetylcholinesterase (4,5); acid phosphatase (6); ascorbate oxidase (7); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase, or [3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring)] kinase (8); cholinesterase (4); diamine oxidase (9,10);  $\beta$ -fructofuranosidase, or invertase (11); glycogen phosphorylase *b* (12); intron (group I) self-splicing (13); sulfoacetaldehyde acetyltransferase (14); thiamin-phosphate kinase (15); thiamin pyridinylase, or thiaminase I, reversibly inactivated by the natural substrate (16-19); and thiamin pyrophosphatase (20,21). 1. **Thiamin Diphosphate, See Thiamin Pyrophosphate****Thiamin Monophosphate**

Thiamin monophosphate (FW<sub>free-acid</sub> = 380.79 g/mol; CAS 22457-89-2), abbreviated ThMP, is an intermediate in thiamin pyrophosphate metabolism that can also be prepared by sulfuric acid hydrolysis of thiamin pyrophosphate. **Target(s):** intron (group I) self-splicing (1); thiamin diphosphokinase (2-4); thiamin pyrophosphatase (5); thiamin transport (6,7); and thiamin-triphosphatase (8). 1. Ahn & Park (2003) *Int. J. Biochem. Cell Biol.* **35**, 157. 2. Mitsuda, Takii, Iwami, Yasumoto & Nakajima (1979) *Meth. Enzymol.* **62**, 107. 3. Mitsuda, Takii, Iwami & Yasumoto (1975) *J. Nutr. Hashitani & Cooper (1972) *J. Biol. Chem.* **247**, 2117.

**Thiamin Pyrophosphate**

This key metabolite (FW<sub>ion</sub> = 425.31 g/mol; CAS 532-40-1), also known as thiamin diphosphate and abbreviated TPP, serves as a coenzyme for many enzymes. TPP absorbs light significantly in the ultraviolet: in phosphate buffer at pH 8, it has  $\lambda_{\text{max}}$  values of 233 and 267 nm ( $\epsilon = 10800$  and  $7800 \text{ M}^{-1}\text{cm}^{-1}$ , respectively). Thiamin pyrophosphate is soluble in water and is slightly less stable than thiamin; therefore, solutions should always be freshly prepared and stored in the cold until needed. **Target(s):** [branched-chain  $\alpha$ -ketoacid dehydrogenase] kinase, or 3-methyl-2-oxobutanoate dehydrogenase (acetyl-transferring) kinase (1-6); 3',5'-cyclic-nucleotide phosphodiesterase (7); diamine oxidase (8,9); FAD diphosphatase (10); glycogen phosphorylase *b* (11); intron (group I) self-splicing (12); nucleotide diphosphatase (13); [pyruvate dehydrogenase (acetyl-transferring)] kinase (14-21); thiamin diphosphokinase, product inhibition (22-24); thiamin pyridinylase, or thiaminase I (25). 1. ### Thiazolidine-4-carboxylate

This heterocyclic proline analogue (FW = 133.17 g/mol; soluble in hot water and in acids and bases), also known as thiaproline, thioproline, and timonacic, is prepared upon reaction of formaldehyde and cysteine. Thiaproline exhibits the ability to reverse the transformation of certain tumor cells to a normal cellular phenotype. **Target(s):** cysteinyl-tRNA synthetase (1);  $\gamma$ -glutamyl kinase, or glutamate 5-kinase, weakly inhibited (2); proline transport (3); prolyl-tRNA synthetase, as alternative substrate (4); and pyrroline-5-carboxylate reductase (5,6). **1.** Bunjun, Stathopoulos, Graham, *et al.* (2000) *Proc. ### 1-(2-Thiazolyl)-4-(1-(4-bromophenylsulfonyl)piperazin-4-ylcarbonyl)piperidine

This piperidine derivative (FW = 501.47 g/mol) potently and selectively inhibits rat 2,3-oxidosqualene cyclase-lanosterol synthase (OSC) (IC<sub>50</sub> = 0.4  $\mu$ M for rat and 0.11  $\mu$ M for human enzyme), resulting in selective oral inhibition of rat cholesterol biosynthesis (ED<sub>80</sub> = 1.2  $\pm$  0.3 mg/kg). Piperidinopyrimidine OSC inhibitors have a significantly lower pK<sub>a</sub> than the corresponding pyridine or the previously reported quinuclidine OSC inhibitor series. **1.** Brown, Hollinshead, Stokes, *et al.* (2000) *J. Med. Chem.* **43**, 4964.

**N<sup>1</sup>-2-Thiazolylsulfanilamide**, See *Sulfathiazole*

### Thiazovivin

This potent protein kinase inhibitor and vasodilator (FW = 432.37 g/mol for the monohydrochloride; CAS 864082-47-3; Solubility: 15 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known systematically as *N*-benzyl-2-(pyrimidin-4-ylamino)thiazole-4-carboxamide, targets RhoA/Rho kinases (IC<sub>50</sub> = 0.5  $\mu$ M). Abbreviated ROCK, these kinases play important roles in mediating vasoconstriction and vascular remodeling in the pathogenesis of pulmonary hypertension. **1.** Xu Y, *et al.* (2010) *Proc. Natl. Acad. Sci. USA* **107**, 8129. **2.** Lin, *et al.* (2009) *Nat. Methods* **6**, 805. **3.** Hu, *et al.* (2011) *Blood* **117**, e109.

### Thienamycin

This  $\Delta^2$ -penem-class antibiotic (FW = 273.33 g/mol; CAS 59995-64-1) from *Streptomyces cattleya*, is the first member of the penem family of antibiotics containing a thioethylamine moiety on an enamine five-membered ring. The  $\beta$ -lactam ring is unusually sensitive to hydrolysis above pH 8 and to reaction with nucleophiles, such as hydroxylamine and cysteine. The primary amine

of the antibiotic itself may also act as a nucleophile (1). **Target(s):**  $\beta$ -lactamase (2-4); muramoyltetrapeptide carboxypeptidase (or murein tetrapeptide LD-carboxypeptidases) from *Escherichia coli* and *Gaffkya homari* (5,6); and peptidoglycan transpeptidase (7,8). **See also Imipenem** 1. ### Thioacetamide

This hepatotoxic/hepatocarcinogenic agent (FW = 75.13 g/mol; CAS 62-55-5; M.P. = 113-114°C; Solubility = 0.17 g/mL H<sub>2</sub>O at 25°C; Symbol: TA; LD<sub>50</sub> of 300 mg/kg in rats and mice) was once widely used in qualitative inorganic analysis as a source for sulfide ions. Treatment of aqueous solutions of many metal cations (M = Ni, Pb, Cd, Hg) with aqueous thioacetamide yields the corresponding metal sulfide (Reaction: M<sup>2+</sup> + CH<sub>3</sub>C(S)NH<sub>2</sub> + H<sub>2</sub>O  $\rightarrow$  MS + CH<sub>3</sub>C(O)NH<sub>2</sub> + 2 H<sup>+</sup>). **Toxicity & Experimental Cirrhosis:** Cirrhosis is a slowly progressing disease, wherein healthy tissue is replaced with scar tissue, eventually preventing the liver from functioning properly. In humans, it is most often associated with excessive and chronic consumption to alcohol, but is chronic and not easily induced. Thioacetamide may be employed to induce experimental cirrhosis in rats. Even a single dose can often cause hepatic centrolobular necrosis, attended by dramatic increases in plasma transaminases and bilirubin. TA is oxidatively metabolized (bioactivated) to its S-oxide (FW = 91.13 g/mol; CAS 2669-09-2; IUPAC: thioacetamide-S-oxide; Symbol: TASO) and then to its highly reactive S,S-dioxide (FW = 106.12 g/mol; IUPAC: 1-iminoethanesulfinate; Symbol: TASO<sub>2</sub>), with the latter capable of modifying amine-lipids and proteins (1). TA itself is nontoxic, even at concentrations up to 50 mM for 40 hours (1). TASO,

however, is highly toxic to isolated hepatocytes, as indicated by LDH release, changes in cellular morphology, as well as loss of vital staining with Hoechst 33342/propidium iodide. TASO toxicity was partially blocked by the CYP2E1 inhibitors diallyl sulfide and 4-methylpyrazole and was strongly inhibited by TA (1). **Other Targets:** adenylylsulfatase (2); aldehyde dehydrogenase (3); amidase (4);  $\delta$ -aminolevulinatase synthase (5,6); methane monooxygenase (7); nitrile hydratase (8); trimethylamine oxidase (9). 1. Hajovsky, Hu, Koen, *et al.* (2012) *Chem. Res. Toxicol.* **25**, 1955. 2. Li & Schiff (1991) *Biochem. J.* **274**, 355. 3. RPatel, Hou, Derelanko & Felix (1980) *Arch. Biochem. **2-Thioacetate, See Thioglycolate**

### Thiobarbituric Acids

Two thiobarbituric acids (FW = 144.15 g/mol) contain a single sulfur atom in replace of the oxygen atom in barbituric acid. 2-Thiobarbituric acid, also known as 4,6-dihydroxy-2-mercaptopyrimidine (decomposes at 245°C), is frequently used to detect lipid hydroperoxides and lipid oxidation as well as to quantitate lipopolysaccharides, sialic acids, and carrageenans. **Target(s):** dihydroorotate dehydrogenase, inhibited by 6-thiobarbiturate (1);  $\gamma$ -glutamyl transpeptidase ( $\gamma$ -glutamyltransferase (2,3); orotate phosphoribosyltransferase, inhibited by 2-thiobarbiturate,  $K_i = 41 \mu\text{M}$  (4). 1. **Thioctate, See Lipoate; Dihydrolipoate**

**Thioctic Acid Amide, See Lipoamide; Dihydrolipoamide**

### Thiocyanate

This cyanate isostere (FW<sub>Na-salt</sub> = 80.07 g/mol; CAS 540-72-7; FW<sub>K-salt</sub> = 97.18 g/mol; CAS 333-20-0) is a potent competitive inhibitor of the thyroid sodium-iodide symporter, decreasing iodide transport into the thyroid follicle and reducing thyroxine production. Also called rhodanide, thiocyanate is formed from cyanide in the rhodanese reaction. *Note:* Inasmuch as thiocyanate shares its negative charge almost equally between its sulfur and nitrogen atoms, it acts as a nucleophile at either sulfur or nitrogen, making it an ambidentate ligand 1. Braverman, He, Pino, *et al.* (2005) *J. Clin. Endocrinol. Metab.* **90**, 700.

**Thiocyanate Radical Anion, See Di(thiocyanate) Radical Anion**

**6-Thio-7-deaza-2'-deoxyguanosine 5'-Triphosphate, See 7-Deaza-2'-deoxy-6-thioguanosine 5'-Triphosphate**

### 6-Thio-2'-deoxyguanosine

This thiothymine deoxynucleoside (FW = 283.31 g/mol; CAS 789-61-7; Solubility: 59 mg/mL DMSO; <1mg/mL H<sub>2</sub>O) is taken up by many cells and metabolically phosphorylated to its 5'-triphosphate, which is then bound by telomerase and incorporated into *de novo*-synthesized telomeres, leading to telomere dysfunction in cells expressing telomerase. 6-Thio-dG, but not 6-thioguanine, induces telomere dysfunction in telomerase-positive human cancer cells and hTERT-expressing human fibroblasts, but not in telomerase-negative cells. Treatment with 6-thio-dG results in rapid cell death for the vast majority of the cancer cell lines tested, whereas normal human fibroblasts and human colonic epithelial cells are largely unaffected. In A549 lung cancer cell-based mouse xenograft studies, 6-thio-dG caused a decrease in the tumor growth rate in a manner that is superior to that observed with 6-thioguanine. In addition, 6-thio-dG increased telomere dysfunction in tumor cells *in vivo*. Such findings suggest that 6-thio-dG may provide a new telomere-targeting anticancer strategy. *Note:* 6-thioguanosine monophosphate is further metabolized to 6-thio-2'-deoxyguanosine 5'-triphosphate by kinases and RNA reductases, which eventually may be incorporated into DNA strands during DNA replication. DNA-incorporated 6-thioguanine may also generate reactive oxygen species, which may cause additional damage to DNA, proteins and other cellular macromolecules, and thus block cellular replication. 1. Mender, Gryaznov, Dikmen, Wright & Shay (2015) *Cancer Discov.* **5**, 82.

### Thiodiglycolate (Thiodiglycolic Acid)

This dicarboxylic acid (FW<sub>free-acid</sub> = 150.16 g/mol; soluble in water and ethanol), also known as 2,2'-thiodiacetic acid and 2,2'-thiobis(acetic acid), is often used in the detection of copper, lead, mercury, and silver, is produced

in such detoxification of breakdown products of vinyl chlorides. **Target(s):** glutamate dehydrogenase (1,2); pyrimidine-deoxynucleoside 2'-dioxigenase, or thymidine:2-oxoglutarate dioxigenase (3). 1. Smith, Austen, Blumenthal & Nyc (1975) *The Enzymes*, 3rd ed. (Boyer, ed.), **11**, 293. 2. Rogers (1971) *J. Biol. Chem.* **246**, 2004. 3. Bankel, Lindstedt & Lindstedt (1972) *J. Biol. Chem.* **247**, 6128.

#### **N-(1-Thiododecyl)-4 $\alpha$ ,10-dimethyl-8-aza-trans-decal-3 $\beta$ -ol**

This thioamide (FW = 381.67 g/mol) inhibits cholesterol biosynthesis in HepG2 cells via inhibition of 2,3-oxidosqualene cyclase. While the initial strategy for making a high-affinity inhibitor focused on amine-containing analogues of the putative transition-state intermediate, later work determined that the amine is not required. 1. Wannamaker, Waid, Van Sickle, *et al.* (1992) *J. Med. Chem.* **35**, 3581.

#### **2-Thioethanesulfonate, See Coenzyme M**

#### **2-Thioflavin Mononucleotide**

This FMN analogue (FW = 472.42 g/mol) inhibits rat FAD synthetase (ATP:FMN adenylyltransferase, EC 2.7.7.2),  $K_i = 106 \mu\text{M}$ . The C=O group at position-2, the NH group at position-3, and a five-carbon side chain at the  $N^{10}$  position seem to be most crucial for flavin substrate binding to enzyme. 1. Bowers-Komro, Yamada & McCormick (1989) *Biochemistry* **28**, 8439.

#### **Thioflavin T**

This well-known histologic staining agent (FW = 318.86 g/mol; CAS 2390-54-7), also named 4-(3,6-dimethyl-1,3-benzothiazol-3-ium-2-yl)-*N,N*-dimethylaniline chloride, binds to so-called cross- $\beta$  structures consisting of small and densely packed  $\beta$ -sheet structures, including those in amyloid- $\beta$  and Tau aggregates. Upon binding to such aggregates, thioflavin T displays enhanced fluorescence and a characteristic red shift of its emission spectrum. The related compound Thioflavin S, a homogeneous mixture of compounds, resulting from methylation of dehydrothiotoluidine, is also used to stain amyloid plaques. Like Thioflavin T, it binds to amyloid fibrils – not monomers, increasing in fluorescence. Unlike Thioflavin T, however, it does not produce a characteristic shift in the excitation or emission spectra, resulting in high background fluorescence and making thioflavin S unsuitable for quantifying of fibril formation. Note that thioflavin T also dimerizes, a property allowing it to intercalate into DNA as well as bind to the minor and major grooves of DNA (2). 1. LeVine (1999) *Methods in Enzymology*. **309**, 274. 2. Biancardi, Biver, Burgalassi *et al.* (2014) *Phys. Chem. Chem. Phys.* **16**, 20061.

#### **5-Thio-L-fucose**

This sugar analogue (FW = 182.22 g/mol) inhibits  $\alpha$ -L-fucosidase,  $K_i = 0.05 \text{ mM}$ . Peracetylated 5-thio-L-fucose (5T-Fuc) is taken up by cancer cells and converted to GDP-5T-Fuc, which blocks  $\alpha$ 1,3-fucosyltransferase (FUT) activity and limits sLe<sup>x</sup> presentation on HepG2 cells, with a low- $\mu\text{M}$  EC<sub>50</sub> (2). 5T-Fuc also impairs adhesion to immobilized adhesion molecules and human endothelial cells (2). 5T-Fuc is thus a useful probe for modulating sLe<sup>x</sup> levels in cells, allowing one to evaluate the consequences of inhibiting FUT-mediated sLe<sup>x</sup> formation (2). (Note: sLe<sup>x</sup> is a tetrasaccharide that serves as a ligand for cell adhesion proteins known as selectins, enabling adhesion of leukocytes and cancer cells to endothelial cells within capillaries, resulting in their extravasation into tissues. The last step in sLe<sup>x</sup> biosynthesis is the FUT-catalyzed transfer of an L-fucose residue to carbohydrate acceptors. GDP-5T-Fuc is not transferred by either FUT3 or FUT7.) 1. #### **5-Thio-D-glucose**

5-thio- $\alpha$ -D-glucopyranose

This sulfur-containing D-glucose analogue (FW = 196.22 g/mol; melting point = 135-136°C), also known as 5-deoxy-5-thio-D-glucose, interferes with glucose transport (1) and, other than a hormone or alkylating reagent, was the first reagent to alter spermatogenesis. **Target(s):** amylo- $\alpha$ -1,6-glucosidase/4- $\alpha$ -glucanotransferase, or glycogen debranching enzyme (2); catechol oxidase (2); glucose transport (3,4);  $\beta$ -glucosidase (5); hexokinase (3,6-8); protein- $N^{\epsilon}$ -phosphohistidine:sugar phosphotransferase (9); and xylose isomerase (10). 1. #### **6-Thioguanine**

This prototypical anticancer and immunosuppressive agent (FW = 167.19 g/mol; CAS 154-42-7; Water-insoluble), also known as 2-amino-6-mercaptapurine, is incorporated into DNA, where it inhibits DNA replication. Thioguanine is a prodrug that requires uptake and conversion to its 6-thio-GMP through the purine salvage enzyme, hypoxanthine:guanine phosphoribosyltransferase. 6-TG is often used to treat both immune disorders and leukemia during their rapid proliferative phases. 6-TG displays cytotoxic and antineoplastic properties and disrupts cytosine methylation by DNA methyltransferases, after incorporation into DNA. 6-Thioguanine also selectively kills BRCA2-defective tumors in a xenograft model. It also facilitates proteasome-mediated degradation of DNA (cytosine-5)-methyltransferase 1 (DNMT1). The immunosuppressive action of this thiopurine arises because, like liver, immune cells are major sites of de novo nucleotide biosynthesis, the latter needed for rapid clonal expansion of these

cell types. Thioguanine was first synthesized by Elion and Hitchings (1955), who shared the 1988 Nobel Prize in Medicine and Physiology for their germinal work in cancer chemotherapy. **Target(s):** cytidine deaminase (2); guanosine phosphorylase, or purine-nucleoside phosphorylase, by alternative product inhibition (3); hypoxanthine(guanine) phosphoribosyltransferase, as weak alternative substrate (4-6); tRNA-guanine transglycosylase (7); xanthine oxidase (8,9); and xanthine phosphoribosyltransferase (4). 1. ### 6-Thioguanosine

This sulfur-containing guanosine analogue (FW 299.31 g/mol; CAS 85-31-4;  $\lambda_{max}$  at 257 ( $\epsilon = 8820 \text{ M}^{-1}\text{cm}^{-1}$ ) and 342 nm ( $\epsilon = 24800 \text{ M}^{-1}\text{cm}^{-1}$ )), also known as 6-mercaptoguanosine, inhibits adenosine deaminase (1) and sorbitol dehydrogenase (2). 1. Agarwal & Parks, Jr. (1978) *Meth. Enzymol.* **51**, 502. 2. Lindstad & McKinley-McKee (1996) *Eur. J. Biochem.* **241**, 142.

### 6-Thioguanosine 5'-Monophosphate

This sulfur-containing guanine nucleotide analogue (FW<sub>free-acid</sub> = 395.4 g/mol), also known as 6-thioguanilate and 2-amino-6-mercaptapurine ribonucleoside 5'-monophosphate, inhibits adenylosuccinate synthetase (1,2), amidophospho-ribosyltransferase (3) GMP reductase, the latter via formation of a disulfide-linked enzyme adduct (4,5), GMP synthetase (6), and guanylate kinase (7-10). 1. ### 6-Thioinosine

This inosine analogue (FW = 284.31 g/mol; CAS 574-25-4), also known as 6-mercaptapurine ribonucleoside, is formed upon conversion of 6-mercaptapurine by guanine(hypoxanthine) phosphoribosyltransferase. **Target(s):** adenosine deaminase,  $K_i = 370 \mu\text{M}$  for calf muscle enzyme (1-3); adenosine kinase (4,5); GMP synthetase, weakly (6); hypoxanthine(guanine) phosphoribosyltransferase (7); inosine nucleosidase

(8); methionine *S*-adenosyltransferase (9); 5'-nucleotidase (10,11); and sorbitol dehydrogenase, weakly (12). 1. Agarwal & Parks, Jr. (1978) *Meth. Enzymol.* **51**, 502. 2. **Thiolacetate, See Thioglycolate**

### Thiolactomycin

This broad-spectrum, naturally occurring antibiotic (FW = 210.30 g/mol), first isolated from *Nocardia*, is active against both Gram-positive and Gram-negative bacteria as well as *Mycobacterium tuberculosis*. Thiolactomycin (TLM) inhibits  $\beta$ -ketoacyl-[acyl-carrier-protein] synthase in fatty-acid synthase II and the elongation step involved in the synthesis of  $\alpha$ -mycolates

and oxygenated mycolates (1-3). **Target(s):** [acyl-carrier-protein] S-acyltransferase (4,5); fatty-acid synthase, acyl carrier-protein dependent (1,6-9); fatty-acyl-CoA synthase (9); N-hydroxyarylamine O-acyltransferase (10);  $\beta$ -ketoacyl-[acyl-carrier-protein] synthase I (2,3,11,12);  $\beta$ -ketoacyl-[acyl-carrier protein] synthase II (1,2,12-15); and  $\beta$ -ketoacyl-[acyl-carrier-protein] synthase III (4,11,12,16-20). 1. **Thionicotinamide Adenine Dinucleotide**

This sulfur analogue of NAD<sup>+</sup> (FW<sub>free-acid</sub> = 680.50 g/mol; often abbreviated S-NAD<sup>+</sup>) is an alternative substrate for many oxidoreductases (*e.g.*, glutamate dehydrogenase). In most of the cases, the reaction velocity is slower with this modified coenzyme. Note that the reduced form, *i.e.* S-NADH, has an absorbance maxima at 400 nm, offering a convenient assay.

**Target(s):** ADP-ribose diphosphatase (1); alcohol dehydrogenase (2,3); aldehyde dehydrogenase (4,5); glucose-6-phosphate dehydrogenase (6); L-lactate dehydrogenase (7-9); NAD<sup>+</sup> nucleosidase, or NADase (10-13); NMN nucleosidase (14); nicotinamide phosphoribosyltransferase (15,16); 1-pyrroline-5-carboxylate reductase (17); rubredoxin:NAD<sup>+</sup> reductase (18); and UDP-glucuronate decarboxylase (19). 1. **Thionicotinamide Adenine Dinucleotide Phosphate**

This sulfur-containing NADP<sup>+</sup> analogue (FW<sub>free-acid</sub> = 759.47 g/mol) is a weak alternative substrate for many oxidoreductases (*e.g.*, glutamate dehydrogenase and transhydrogenase). Note that the reduced form, *i.e.* S-NADPH, has an absorbance maxima at 400 nm. S-NADP<sup>+</sup> also blocks nicotinate adenine dinucleotide phosphate-induced calcium release (1).

**Target(s):** glucose-6-phosphate dehydrogenase (2,3); nicotinate adenine dinucleotide phosphate-induced calcium release (1); and 1-pyrroline-5-carboxylate reductase (4). 1. Gupta, Quirk, Venning, *et al.* (1998) *Biochim. Biophys. Acta* **1409**, 25. 2. Noltmann & Kubly (1963) *The Enzymes*, 2nd ed. (Boyer, Lardy & Myrback, eds.), **7**, 223. 3. **Thionine**

This chromatin- and mucin-staining thiazine dye (FW<sub>chloride</sub> = 263.75 g/mol; CAS 78338-22-4;  $\lambda_{\text{max}} = 602.5 \text{ nm}$ ), also known as thionin, Lauth's violet, and 3,7-diaminophenothiazine (also formerly referred to as 3,6-

diaminophenothiazine), is structurally similar to proflavine. Thionine is a blackish-green solid that is soluble in hot water, initially producing a blue solution that eventually turns violet. Solutions become bluer upon addition of HCl. *Note:* (a) Care must be exercised when encountering this term in the literature; (b) thionin also refers to a class of small and toxic plant proteins; and (c) thionein is the apoprotein of metallothionein and would be expected to inhibit a number of metalloenzymes. **Target(s):** glutathione-disulfide reductase (1); and trypsin (2-4). 1. Luond, McKie, Douglas, Dascombe & Vale (1998) *J. Enzyme Inhib.* **13**, 327. 2. Walsh (1970) *Meth. Enzymol.* **19**, 41. 3. Glazer (1967) *J. Biol. Chem.* **242**, 3326. 4. ## 2-Thio-6-oxo-1,6-dihydropyrimidine

This dihydropyrimidine (FW = 475.94 g/mol) inhibits lactate dehydrogenase isozyme A, or LDH<sub>A</sub> (IC<sub>50</sub> = 8.8  $\mu$ M), an enzyme believed to support glycolysis in tumor cells. Consistent with its known ordered ternary complex kinetic mechanism (with the coenzyme binding first), the inhibitor required simultaneous binding of the NADH cofactor. Although bound within the enzyme's active site, this and structurally related inhibitors made no direct contacts with the majority of enzyme residues involved in LDH<sub>A</sub> catalysis. 1. Dragovich, Fauber, Corson, et al. (2013) *Bioorg. Med. Chem. Lett.* **23**, 3186.

**2-Thio-6-oxypurine**, See *2-Thioxanthine*

## Thiopental

This short-acting barbiturate (FW = 228.31 g/mol; CAS 76-75-5), also known as 5-ethyl-5-(1-methylbutyl)-2-thiobarbituric acid and Sodium Pentothal® (Abbott), is used to rapidly induce anesthesia. Thiopental crosses the blood brain barrier rapidly, and its short duration of action arises from its redistribution to muscle and fat tissue, mainly the latter. Hepatic metabolism forms pentobarbital, 5-ethyl-5-(1'-methyl-3'-hydroxybutyl)-2-thiobarbiturate, and 5-ethyl-5-(1'-methyl-3'-carboxypropyl)-2-thiobarbiturate. **Target(s):** acetylcholinesterase (1);  $\gamma$ -aminobutyrate aminotransferase (2); ATP/K<sup>+</sup> channel (3); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (4,5);  $\alpha_7$  nicotinic acetylcholine receptor (6); and phosphofructokinase (7). 1. ## Thiopeptin

This sulfur-containing peptide antibiotic complex (FW<sub>Thiopeptin-B</sub> = 1670.05 g/mol; CAS 37339-66-5) potentially inhibits protein biosynthesis. The complex consists of several components, the major component being thiopeptin B, which contains dehydroalanine residues. It inhibits elongation factor (EF)-Tu-dependent GTP hydrolysis and binding of aminoacyl-tRNA to the ribosome. The peptidyl transferase-catalyzed puromycin reaction is not significantly affected by the antibiotic. Thiopeptin inhibits EF-G-associated GTPase reaction, and translocation of peptidyl-tRNA and mRNA from the acceptor site to the donor site. Thiopeptin Bb is a faint yellow solid that is insoluble in water and hexane and soluble in methanol, acetone, and ethyl acetate. **See also Thiostrepton Target(s):** protein biosynthesis, elongation and GTPase activity (1-4). 1. ## Thiophosphate, Sodium

This corrosive inorganic reagent (Na<sub>3</sub>SP<sub>3</sub>; FW = 180.01 g/mol; CAS 12609-84-6), also called sodium phosphorothioate, cleaves disulfide bonds in proteins and also reacts with cystine and glutathione disulfide (1). Thiophosphate is also an orthophosphate analogue and competitively inhibits such enzymes such as protein-tyrosine phosphatase (2). **Target(s):** alkaline phosphatase (3,4); cytochrome *c* oxidase (5); inositol-phosphatase phosphatase (6); photophosphorylation (7); and protein-tyrosine phosphatase (2). 1. Neumann & Smith (1967) *Arch. Biochem. Biophys.* **122**, 354. 2. Zhao (1996) *Biochem. Biophys. Res. Commun.* **218**, 480. 3. Denier, Vergnes, Brisson-Lougarre, et al. (1996) *Ann. Clin. ## Thioridazine

This phenothiazine antipsychotic and peroxisomal  $\beta$ -oxidation inhibitor (FW<sub>free-base</sub> = 370.58 g/mol; CAS 50-52-2) is a dopamine D<sub>2</sub> antagonist and Ca<sup>2+</sup> channel blocker (1). The hydrochloride salt is soluble in water (one part in nine) and has an ultraviolet spectra (in 0.1 N HCl,  $\lambda_{max}$  = 264 ( $\epsilon$  = 42371 M<sup>-1</sup>cm<sup>-1</sup>) and 305 nm ( $\epsilon$  = 5495 M<sup>-1</sup>cm<sup>-1</sup>). Phenothiazine antipsychotics such as thioridazine also prevent Tousled-like kinase- (TLK-) mediated phosphorylation of Rad9(S328), impairing checkpoint recovery and double-

strand break (or DSB) repair as well as potentiating radiomimetic tumor killing, especially when used in combination with other chemotherapeutics (1). The Tousled-like kinases (TLKs) are involved in chromatin assembly, DNA repair, and transcription, thereby maintaining genomic stability. Two human TLKs exist, often with dysregulated gene expression in cancer, phosphorylate Asf1 and Rad9 and regulate DSB repair and the DNA damage response (or DDR). *In vivo* administration of thioridazine, inhibits hepatic peroxisomal  $\beta$ -oxidation in mice. In starving animals, 3-hydroxybutyrate concentration is not decreased by thioridazine treatment, suggesting its use as a tool for simulating pathological conditions in which peroxisomal  $\beta$ -oxidation is impaired. **Receptor Binding:** Thioridazine also shows substantial affinity for dopamine receptors (D<sub>1</sub>, IC<sub>50</sub> = 94.5 nM; D<sub>2</sub>, IC<sub>50</sub> = 0.4 nM (responsible for antipsychotic action); D<sub>3</sub>, IC<sub>50</sub> = 1.5 nM; D<sub>4</sub>, IC<sub>50</sub> = 1.5 nM; and D<sub>5</sub>, IC<sub>50</sub> = 258 nM) (3).

**Target(s):** acetylcholinesterase (4); adenosyl-methionine decarboxylase (5); adenylate cyclase, dopamine-stimulated (6); aryl hydrocarbon hydroxylase (17); ATPase (8,9); calcineurin (10); cAMP phosphodiesterase (11); cholesterol 7 $\alpha$ -hydroxylase (12); cholinesterase, or butyrylcholinesterase (13); CYP1A2 (14); CYP3A2 (14); CYP2D6 (15); cytochrome *c* oxidase (16); cytochrome P450-dependent activities, such as 7-pentoxerysoruflin *O*-depentylase and 7-ethoxyresoruflin *O*-deethylase (17); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (8,18); pyruvate dehydrogenase (19); [pyruvate dehydrogenase (acetyl-transferring)]-phosphatase (20); retinyl ester hydrolase (21); and peroxisomal  $\beta$ -oxidation (22). 1. ### Thiosemicarbazide

This thioamide (FW = 91.14 g/mol; CAS 79-19-6; MP = 182-184°C; soluble in water and ethanol), also called hydrazine carbothioamide, is used in the detection and extraction of metal ions. Semicarbazide derivatives (e.g., semicarbazones and thiosemicarbazones) display antiviral, anti-infective and antineoplastic actions, presumably through binding to copper or iron within cells. **Target(s):** alanine aminotransferase (1); alcohol dehydrogenase, yeast (2); aromatic-L-amino-acid decarboxylase, or dopa decarboxylase (3); aspartate aminotransferase (4-6); branched-chain amino-acid aminotransferase (7); catalase (8,9); glutamate decarboxylase (10-12); leucine aminotransferase (13); lysyl oxidase, or protein-lysine 6-oxidase, collagen cross-linking (14,15); methane monooxygenase (16); phosphatidylserine decarboxylase (17); and RNA-directed DNA polymerase (18). 1. ### Thiostrepton

This sulfur- and dehydroalanyl-containing peptide antibiotic (FW = 1664.9 g/mol; CAS 1393-48-2), also known as bryamycin and thiactin, from *Streptomyces azureus* inhibits protein biosynthesis and peptide translocation by preventing GTP binding to the 50S ribosomal subunit, thus inhibiting the mechanochemical events linked to GTP hydrolysis. Thiostrepton also prevents the binding of elongation factor G to the ribosome. **See also Thiopeptin Target(s):** GTP diphosphokinase (4,5); guanosine-3',5'-bis(diphosphate) 3'-diphosphatase (6); guanosine 3',5'-polyphosphate synthetase I (5); IF-2-dependent ribosomal GTPase (7); initiation factor (18); and protein biosynthesis (1-3,9). 1. ### Thiosulfate

This dianionic reducing agent and sulfate analogue (FW<sub>NaSalt</sub> = 158.11 g/mol; CAS 7772-98-7; S-O bond-length = 147 pm; S-S bond-length = 201 pm) is a redox-active substrate for thiosulfate dehydrogenase, thiosulfate sulfurtransferase, or rhodanese, thiosulfate:thiol sulfurtransferase, and thiosulfate:dithiol sulfurtransferase as well as a product of the reaction catalyzed by trithionate hydrolase. Thiosulfate is an intermediate in the sulfur cycle in anoxic marine and freshwater sediments, where partakes in reduction, oxidation, and disproportionation pathways. It is also a potential respiratory electron acceptor for bacteria living in anoxic environments or at the anoxic/oxic interface. The ability to respire thiosulfate is conferred by the enzyme thiosulfate reductase (*Reaction: S<sub>2</sub>O<sub>3</sub><sup>2-</sup> + 2H<sup>+</sup> + 2e<sup>-</sup> → HS<sup>-</sup> + HSO<sub>3</sub><sup>-</sup>*) (1,2). In sulfate-reducing bacteria, the sulfite produced in the thiosulfate reductase reaction is further reduced to sulfide by sulfite reductase. For *Salmonella enterica* (serovar: *Typhimurium*), thiosulfate reduction is catalyzed by the membrane-bound enzyme thiosulfate reductase. Experiments with quinone biosynthesis mutants show that menaquinol is the sole electron donor to thiosulfate reductase (2). The reduction of thiosulfate by menaquinol is highly endergonic under standard conditions ( $\Delta E^{\circ} = -328$  mV), and thiosulfate reductase activity was found to depend on the proton motive force (PMF) across the cytoplasmic membrane (2). Sulfite reduction is an energy-yielding reaction that is also the final step in sulfate respiration. (**See also Dithionite Target(s):** N-acetylglucosamine-4-sulfatase, or arylsulfatase B (3); N-acetylglucosamine-6-sulfatase (4); N-acetylglucosamine-6-sulfatase (5); adenylylsulfatase (6); alcohol dehydrogenase (7); aminopeptidase B (8); cyanate hydratase, or cyanase (9);

### 2-Thioxanthine

This urate analogue (FW = 168.18 g/mol; CAS 2487-40-3;  $\text{pK}_a = 5.9$ ), also called 2-thio-6-oxypurine, inhibits glycine amidino-transferase (1,2); hypoxanthine(guanine) phosphoribosyltransferase (3,4); urate oxidase, *or* uricase (5); urate-ribonucleotide phosphorylase (6); and xanthine

phosphoribosyltransferase (3,7). **Mechanism-based Inactivation of Myeloperoxidase (MPO):** 2-Thioxanthines are mechanism-based inactivators of MPO that modify the heme prosthetic groups of the enzyme, exhibiting good specificity and undergoing limited oxidation before the enzyme is fully inactivated (8). They exert only a moderate effect on bacterial killing by neutrophils even at concentrations that completely blocked extracellular production of hypochlorous acid. 2-Thioxanthines inhibit hypochlorous acid production by both the purified enzyme and isolated neutrophils. The  $\text{IC}_{50}$  values with neutrophils were better than those for other inhibitors, including numerous nonsteroidal anti-inflammatory drugs. Indeed, TX2 and TX4 are the best known inhibitors of the chlorination activity of MPO ( $\text{IC}_{50} = 0.2 \mu\text{M}$ ) that do not act by converting the enzyme to compound II (8). 2-Thioxanthines are mechanism-based inactivators of MPO, because they promote inactivation of the enzyme to a far greater extent in the presence of added hydrogen peroxide than in its absence. Inactivation results from modification of the heme through covalent attachment of the 2-thioxanthine, as evident from the increase in mass of the modified heme and the X-ray crystal structure of the inactivated enzyme (8). 1. Ratner (1962) *The Enzymes*, 2nd ed. (Boyer, Lardy & Myrback, eds.), **6**, 267. 2. Walker (1957) *J. Biol. Chem.* **224**, 57. 3. Naguib, Iltzsch, el Kouni, Panzica & el Kouni (1995) *Biochem. ### 6-Thioxanthosine 5'-Monophosphate

This XMP analogue and guanine nucleotide-depleting agent (FW<sub>free-acid</sub> = 380.28 g/mol; CAS 3237-49-8), also named 6-thio-6,9-dihydro-1H-purin-2(3H)-one-β-D-ribofuranose 5'-phosphate, inhibits *Escherichia coli* GMP synthetase, acting as a weak alternative substrate (1,2), as well as IMP dehydrogenase (3). 1. Spector, Miller, Fyfe & Krenitsky (1974) *Biochim. Biophys. Acta* **370**, 585. 2. Spector (1975) *J. Biol. Chem.* **250**, 7372. 3. Pfefferkorn, Bzik & Honsinger (2001) *Exp. Parasitol.* **99**, 235.

### L(+)-Threonate (or L(+)-Threonic Acid)

This aldonic acid ( $FW_{\text{free-acid}} = 136.10$  g/mol; CAS 7306-96-9), also known as (2*R*,3*S*)-Trihydroxybutyric acid, inhibits acid phosphatase (1,2) and L-(+)-tartrate dehydratase (3). 1. Hollander (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), 4, 449. 2. Kilsheimer & Axelrod (1957) *J. Biol. Chem.* **227**, 879. 3. Hurlbert & Jakoby (1965) *J. Biol. Chem.* **240**, 2772.

### L-Threoninamide

This L-threonine amide ( $FW_{\text{free-base}} = 118.14$  g/mol; CAS 2280-40-2) inhibits aspartokinases (1) and bacterial leucyl aminopeptidase (2). L-Threonine amide also substitutes for L-threonine as an allosteric feedback inhibitor of aspartokinase. 1. McCarron & Chang (1978) *J. Bacteriol.* **134**, 483. 2. Baker, Wilkes, Bayliss & Prescott (1983) *Biochemistry* **22**, 2098.

This octadecapeptide amide ( $MW = 1927.17$  g/mol; Sequence = TTYAAFIASGRTGRRNAI-NH<sub>2</sub>) inhibits cAMP-dependent protein kinase:  $K_i = 8$  nM (1). 1. Walsh & Glass (1991) *Meth. Enzymol.* **201**, 304.

**L-Threonyl-L-threonyl-L-tyrosyl-L-alanyl-L-aspartyl-L-phenylalanyl-L-isoleucyl-L-alanyl-L-serylglycyl-L-arginyl-L-threonylglycyl-L-arginyl-L-arginyl-L-asparaginyll-L-alanyl-L-isoleucinamide**

This octadecapeptide ( $MW = 1968.0$  g/mol; TTYADFIASGRTGRRNAI-NH<sub>2</sub>), known commercially as WIPTIDE, is a potent cAMP-dependent protein kinase inhibitor,  $K_i = 3.1$  nM (1). 1. Walsh & Glass (1991) *Meth. Enzymol.* **201**, 304.

**L-Threonyl-L-threonyl-L-tyrosyl-L-alanyl-L-aspartyl-L-phenylalanyl-L-isoleucyl-L-alanyl-L-serylglycyl-L-arginyl-L-threonylglycyl-L-arginyl-L-arginyl-L-asparaginyll-L-alanyl-L-isoleucyl-L-histidyl-L-aspartate**, See *Protein Kinase A Inhibitor Fragment 5-24*

### D-Threose 2,4-Bisphosphate

This doubly phosphorylated form of D-threose ( $FW_{\text{free-acid}} = 280.06$  g/mol), formerly called D-threose 2,4-diphosphate is a noncompetitive inhibitor of glyceraldehyde-3 phosphate dehydrogenase (1-4). 1. ### Thrombin-Activatable Fibrinolysis Inhibitor

This plasma pro-enzyme ( $MW = 48.4$  kDa;  $M_r = 60,000$ ; NCBI Reference Sequence: NP\_001863.3; Symbol: TAFI), also known as plasma carboxypeptidase B, or pCPB (so designated for its ability to cleave after basic amino residues), carboxypeptidase B<sub>2</sub>, or CPB2, and carboxypeptidase U (or CPU), is synthesized in the liver but circulates as a plasminogen-bound zymogen. When activated by proteolysis at Arg92, as catalyzed by the thrombin/thrombomodulin complex, TAFI exhibits carboxypeptidase activity that reduces fibrinolysis by removing the fibrin C-terminal residues needed for binding and activating plasminogen. The pre-protein consists of a 22-residue signal peptide, a 92-residue activation peptide, and a 309-residue catalytic domain. 6-Amino-*n*-hexanoic acid, or εACA (See *6-Aminohexanoate*), a well-known competitive inhibitor of basic carboxypeptidases, selectively limits trypsin cleavage of pro-pCPB (2). In the

presence of εACA, trypsin cleavage at Arg-330 is significantly limited while the cleavage at Arg-92 is unaffected (2). Elevated TAFI levels form a mild risk factor for venous thrombosis (3). Such levels are found in 9% of healthy controls and in 14% of patients with a first deep vein thrombosis. Elevated TAFI levels do not enhance the thrombotic risk associated with Factor V (Leiden) but may interact with high Factor VIII levels (3). 1. Eaton, Malloy, Tsai, Henzel & Drayna (1991) *J. Biol. Chem.* **266**, 21833. 2. Tan & Eaton (1995) *Biochemistry* **34**, 5811. 3. Van Tiiburg, Rosendaal & Bertina (2000) *Blood* **95**, 2855.

### Thrombospondin-1

This 1170-residue, homodimeric platelet glycoprotein ( $MW = 129.4$  kDa; Isoelectric Point = 4.71) is released from platelet α-granules in response to thrombin stimulation and inhibits cathepsin G,  $K_i = 1.2$  nM and leukocyte elastase,  $K_i = 60$  nM. Upon release from platelets, thrombospondin-1 binds to platelet membranes, and the resulting complex acts as an adhesion protein participating in cell-cell and cell-matrix interactions. Thrombospondin-1 also binds to fibrinogen, type V collagen, fibronectin, and laminin (1). **Target(s):** cathepsin G (2); leukocyte elastase (3,4). 1. Sage & Bornstein (1991) *J. Biol. Chem.* **266**, 14831. 2. Hogg, Owensby & Chesterman (1993) *J. Biol. Chem.* **268**, 21811. 3. Bieth (1998) in *Handb. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.), p. 5. 4. Academic Press, San Diego. 4. Hogg, Owensby, Mosher, Misenheimer & Chesterman (1993) *J. Biol. Chem.* **268**, 7139.

### α-Thujaplicin

This hydroxylated tropolone ( $FW = 164.20$  g/mol; CAS 1946-74-3), also known as 2-hydroxy-3-(1-methylethyl)-2,4,6-cycloheptatrien-1-one, inhibits carboxypeptidase A (1), exoribonuclease H (2), HIV-1 reverse transcriptase (2), ribonuclease H (2), and RNA-directed DNA polymerase (2). 1. Morita, Matsumura, Tsujibo, et al. (2001) *Biol. Pharm. Bull.* **24**, 607. 2. Budihas, Gorshkova, Gaidamakov, et al. (2005) *Nucl. Acids Res.* **33**, 1249.

### β-Thujaplicin

This hydroxytropoloneone ( $FW = 164.20$  g/mol), also known as hinokitiol, 4-isopropyltropolone, and 2-hydroxy-4-(1-methylethyl)-2,4,6-cycloheptatrien-1-one, is a major component of *Thujopsis dolabrata*. β-Thujaplicin is also an iron chelator and induces cell differentiation and apoptosis in teratocarcinoma F9 cells. **Target(s):** arachidonate 12-lipoxygenase, or simply 12-lipoxygenase (1); exoribonuclease H, weakly (2); S-lactoylglutathione lyase (3); ribonuclease H, weakly (2); and tyrosine monooxygenase (4). 1. Suzuki, Ueda, Juranek, et al. (2000) *Biochem. Biophys. Res. Commun.* **275**, 885. 2. Budihas, Gorshkova, Gaidamakov, et al. (2005) *Nucl. Acids Res.* **33**, 1249. 3. Barnard & Honek (1989) *Biochem. Biophys. Res. Commun.* **165**, 118. 4. Goldstein, Gang & Anagnoste (1967) *Life Sci.* **6**, 1457.

### γ-Thujaplicin

This hydroxytropolone ( $FW = 164.20$  g/mol), also known as 2-hydroxy-5-(1-methylethyl)-2,4,6-cycloheptatrien-1-one, inhibits exoribonuclease H and ribonuclease H (1). 1. Budihas, Gorshkova, Gaidamakov, Wamiru, Bona, Parniak, Crouch, McMahon, Beutler & Le Grice (2005) *Nucl. Acids Res.* **33**, 1249.

## Thymidine

This DNA constituent (FW = 242.23 g/mol) absorbs light in the ultraviolet ( $\lambda_{\max} = 267$  nm at pH 7 ( $\epsilon = 9700$  M<sup>-1</sup>cm<sup>-1</sup>), abbreviated dT, inhibits acid phosphatase (1), ADP-ribose diphosphatase (2), aspartate carbamoyltransferase (3,4), cytidine deaminase (5-8), cytosine deaminase (9,10), dCMP deaminase (11); deoxycytidine kinase, weakly (12), dihydroorotase (13), dTMP kinase, or thymidylate kinase (14-20), NAD<sup>+</sup> ADP-ribosyltransferase, or poly(ADP-ribose) synthetase (21-28); NAD<sup>+</sup> nucleosidase (29); NAD<sup>+</sup>:protein-arginine ADP-ribosyltransferase (30), 5'-nucleotidase (3,31-33), pancreatic ribonuclease, or ribonuclease A (34); ribonuclease T<sub>2</sub> (35), ribonucleoside diphosphate reductase (36), and urate-ribonucleotide phosphorylase (37). **Double-Thymidine Block Method for G<sub>1</sub>/S Cell Synchronization:** The following seven-step protocol is optimized to achieve nearly complete synchronization of HeLa cells at the G<sub>1</sub>/S border, by keeping all cells in G<sub>1</sub>. **Procedure: Step-1.** Grow HeLa cells to about 40% confluence in standard Dulbecco's Minimal Essential Medium (DMEM) supplemented with 10% Fetal Bovine Serum (FBS). **Step-2.** Add sufficient thymidine (20 mM in Phosphate-Buffered Saline, or PBS) to a final concentration of 2mM in the media. **Step-3.** Incubate culture at 37° C for 19 hours. (Note: Strict time keeping is required in this step.) **Step-4.** Remove media, and wash cells three times with PBS. **Step-5.** Add fresh thymidine-free media, and incubate for 9 hours at 37° C. **Step-6.** Add thymidine (again at 2 mM final concentration) and incubate for additional 16 hours. **Step-7.** Wash cells with PBS, and add fresh thymidine-free media. The cells are now in G<sub>1</sub> and will be "released" to progress through the cell cycle over the ensuing 15 hours. The cells typically remain synchronized for about 1-2 cell divisions, after which their growth becomes asynchronous. **Note:** This protocol will not work on cell lines with intact p53 apoptotic responses (See *Methotrexate for another synchronization protocol*). 1. ## Thymidine 5'-Diphosphate

This 2'-deoxy-pyrimidine nucleotide (FW<sub>free-acid</sub> = 402.19 g/mol;  $\lambda_{\max} = 267$  nm at pH 7,  $\epsilon = 9600$  M<sup>-1</sup>cm<sup>-1</sup>), usually abbreviated dTDP, is a component of certain nucleoside diphosphosugars as well as an intermediate in the formation of dTTP (*i.e.*, a substrate for nucleoside diphosphate kinase). The ribonucleotide is far less common than the 2'-deoxy derivative. **Target(s):**  $\alpha$ -N-acetylneuraminate  $\alpha$ -2,8-sialyltransferase (1); cellulose synthase, UDP-forming (41); cytidylate kinase (2); dCMP deaminase, weakly inhibited (3); dCTP deaminase (4); deoxycytidine kinase (5-7); deoxyguanosine kinase (8,9); DNA-directed DNA polymerase (10); dTDP-glucose 4,6-dehydratase (11-13); dTMP kinase, or thymidylate kinase, by product inhibition (14-20); glucose-1-phosphate cytidyltransferase, weakly (21); glycoprotein 3- $\alpha$ -L-fucosyltransferase, weakly (22); glycoprotein 6- $\alpha$ -L-fucosyltransferase (40);  $\alpha$ -1,3-mannosyl-glycoprotein 2- $\beta$ -N-acetylglucosaminyl-transferase (39);  $\beta$ -1,4-mannosyl-glycoprotein 4- $\beta$ -N-acetylglucosaminyl-transferase (23); nicotinate-nucleotide diphosphorylase (carboxylating), weakly (24); 5'-nucleotidase (25); [protein-PII] uridylyltransferase (26); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (27,28); sinapate 1-glycosyltransferase (29); sucrose synthase (30); thymidine kinase (31-34); UDP-glucuronate decarboxylase (35); UDP-glucuronate 4-epimerase (36,37); xanthine phospho-ribosyltransferase, weakly (38). 1. **Thymidine 5'-Monophosphate *p*-Nitrophenyl Ester, See Thymidine 5'-*p*-Nitrophenyl Phosphate**

### Thymidine 3'-*p*-Nitrophenyl Phosphate

This pyrimidine 3'-nucleotide derivative ( $FW_{\text{free-acid}} = 443.31$  g/mol;  $\lambda_{\text{max}} = 270.5$  nm,  $\epsilon = 15400$  M<sup>-1</sup>cm<sup>-1</sup>), also known as thymidine 3'-monophosphate *p*-nitrophenyl ester and *p*-nitrophenyl thymidine 3'-phosphate, is an artificial chromogenic substrate for 3'-phosphodiesterases and micrococcal nuclease. Spleen phosphodiesterase readily hydrolyzes this alternative substrate to dT-3'-MP and *p*-nitrophenol (1), whereas it is not a substrate for venom phosphodiesterases. The sodium and potassium salts are readily soluble in water. The *p*-nitrophenol product, released via the action of spleen phosphodiesterase, has a yellow color in alkaline solutions ( $\lambda_{\text{max}} = 400$  nm at pH 9-10;  $\epsilon = 18300$  M<sup>-1</sup>cm<sup>-1</sup>). **See also Thymidine 3'-*p*-Nitrophenyl Phosphate 5'-Phosphate** **Target(s):** nucleotide diphosphatase (2); and staphylococcal nuclease, *or* micrococcal nuclease (3). **1.** Razzell & Khorana (1961) *J. Biol. Chem.* **236**, 1144. **2.** Byrd, Fearney & Kim (1985) *J. Biol. Chem.* **260**, 7474. **3.** Anfinsen, Cuatrecasas & Taniuchi (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), **4**, 177.

### Thymidine 5'-*p*-Nitrophenyl Phosphate

This pyrimidine nucleotide derivative ( $FW_{\text{free-acid}} = 443.31$  g/mol; water-soluble;  $\lambda_{\text{max}} = 270$  nm (pH 2);  $\epsilon = 16250$  M<sup>-1</sup>cm<sup>-1</sup> at), also known as thymidine 5'-monophosphate *p*-nitrophenyl ester, is an artificial chromogenic substrate for 5'-phosphodiesterases. Venom phosphodiesterases readily hydrolyze this substrate to dTMP and *p*-

nitrophenol (1). The *p*-nitrophenol product, released via the action of phosphodiesterase, has a yellow color in alkaline solutions ( $\lambda_{\max} = 400$  nm at pH 9-10;  $\epsilon_M = 18300 \text{ M}^{-1} \text{ cm}^{-1}$ ) **Target(s)**: alkylglycerophosphoethanolamine phosphodiesterase, or lysophospholipase D (2); and nucleotide diphosphatase (3). 1. Razzell & Khorana (1959) *J. Biol. Chem.* **234**, 2105 & 2114. 2. Xie & Meier (2004) *Cell. Signal.* **16**, 975. 3. Byrd, Fearney & Kim (1985) *J. Biol. Chem.* **260**, 7474.

### Thymidine 5'-Triphosphate

This nucleotide (FW<sub>free-acid</sub> = 482.17 g/mol;  $\lambda_{\max} = 267$  nm;  $\epsilon_M = 9600 \text{ M}^{-1} \text{ cm}^{-1}$  at pH 7), abbreviated dTTP, is a required DNA precursor. Although dTTP inhibits many enzymes, the most trivial mode of nucleoside 5'-triphosphate inhibition is the binding of a divalent ions, such as  $\text{Mg}^{2+}$ ,  $\text{Mn}^{2+}$ , or  $\text{Ca}^{2+}$ , that is required for enzymatic activity. **Target(s)**:  $\alpha$ -*N*-acetylneuraminate  $\alpha$ -2,8-sialyltransferase (113); Amidophosphoribosyltransferase, weakly inhibited (1,116); ATP:citrate lyase, or ATP:citrate synthase (120); CDP-diacylglycerol:inositol 3-phosphatidyltransferase (65,66); CDP reductase (2); cellulose synthase, UDP-forming (119); citrate (*si*)-synthase, weakly inhibited (121); 3',5'-cyclic-nucleotide phosphodiesterase (3); cytidine deaminase (4,5,61,62); cytidylate kinase (70); cytosine deaminase (4,6); dCMP deaminase, or deoxycytidylate deaminase (7-13,48-60); dCTP deaminase (14,15,45-47); dCTP deaminase, dUMP-forming (43); deoxycytidine kinase (86-89); deoxyguanosine kinase (83); deoxynucleoside kinase (77-82); deoxyribonuclease X (64); DNA-directed DNA polymerase (16); DNA helicases (40); DNA polymerase I, in the presence of ultraviolet light (16); dTDP-dihydrostreptose:streptidine-6-phosphate dihydrostreptosyltransferase (17); dTDP-glucose 4,6-dehydratase (18-20); dTMP kinase, or thymidylate kinase (71-76); dUTP diphosphatase (21-23); exopolyphosphatase (41); flavanone 7-*O*- $\beta$ -glucosyltransferase (118); fucokinase (90); glucokinase, also weak alternative substrate (110,111); glucose-1-phosphate cytidyltransferase (24); glucuronokinase (91); GTP cyclohydrolase I (44); lactose synthase (25); methionine *S*-adenosyltransferase (112); NADH peroxidase (26); nicotinate-nucleotide diphosphorylase (carboxylating), weakly inhibited (115); nucleoside-triphosphatase, alternative substrate (40); nucleotidases (41); 3'-nucleotidase (41); 5'-nucleotidase (27,41); nucleotide diphosphatase (42); polynucleotide 5'-hydroxyl-kinase (84,85); [protein-PII] uridylyltransferase (67); pyruvate carboxylase (29); *recA* enzyme of *Escherichia coli* (30); ribonucleoside-diphosphate reductase (31); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (28,69); RNA-directed RNA polymerase (68); *Serratia marcescens* nuclease (63); thymidine kinase (32-38,92-109); UDP-glucuronate decarboxylase (39); uracil phosphoribosyltransferase (117); and xanthine phosphoribosyltransferase, weakly inhibited (114). 1. ### L-Thymidine 5'-Triphosphate

This rare nucleotide (FW<sub>free-acid</sub> = 482.17 g/mol) contains 2'-deoxy-L-ribose as the sugar component. It inhibits a number of DNA polymerases. Although L-dTTP inhibits many enzymes, the most trivial mode of nucleoside 5'-triphosphate inhibition is the binding of a divalent ion, such as Mg<sup>2+</sup>, Mn<sup>2+</sup>, or Ca<sup>2+</sup>, that is required for enzymatic activity. **Target(s):** DNA-directed DNA polymerase (2); DNA helicases (1); DNA nucleotidyltransferase, or terminal deoxyribonucleotidyltransferase (2); DNA polymerase  $\alpha$  (2); DNA polymerase  $\gamma$  (2); DNA polymerase  $\delta$  (2); DNA polymerase  $\epsilon$  (2); DNA polymerase I (2); HIV-1 reverse transcriptase (2); HSV-1 DNA polymerase (2); nucleoside-triphosphatase (1); RNA-directed DNA polymerase (2); telomerase (3). **1.** Locatelli, Gosselin, Spadari & Maga (2001) *J. Mol. Biol.* **313**, 683. **2.** Focher, Maga, Bendiscioli, et al. (1995) *Nucl. Acids Res.* **23**, 2840. **3.** Yamaguchi, Yamada, Tomikawa, et al. ### Thymine

This major DNA constituent (FW = 126.11 g/mol;  $\lambda_{\max}$  = 264.5 nm (at pH 7)  $\epsilon$  = 7900 M<sup>-1</sup>cm<sup>-1</sup>); solubility = 4 g/L water at 25°C), known systematically as 2,6-dihydroxy-5-methylpyrimidine, is also found at low levels in certain tRNA. Thymine is an alternative substrate and competitive inhibitor of uracil dehydrogenase. **Target(s):** dihydrofolate reductase, weakly (1); hydroxyacylglutathione hydrolase, or glyoxalase II (2); lactoylglutathione lyase, or glyoxalase I (2); NADase (3-5); pancreatic ribonuclease, weakly inhibited (6); uracil dehydrogenase, as poor alternative substrate (7); urate-ribonucleotide phosphorylase (8); and uridine phosphorylase (9). **1.** Bertino, Perkins & Johns (1965) *Biochemistry* **4**, 839. **2.** Oray & Norton (1980) *Biochem. ### Thymoquinone

This superoxide scavenger (FW = 164.20 g/mol; CAS 490-91-5; Symbol: TQ), also known as 2-methyl-5-isopropyl-*p*-benzoquinone and 5-isopropyltoluquinone, is a major constituent of black cummin (*Nigella sativa*) seeds. TQ inhibits leukotriene C<sub>4</sub> synthase (1), 5-lipoxygenase (1), and pyruvate decarboxylase (2). In triple-negative breast cancer (TNBC) cells lacking functional p53 tumor suppressor, thymoquinone induces G<sub>1</sub> phase cell cycle arrest and apoptosis, the latter characterized by the loss of mitochondrial membrane integrity (3). TQ also inhibits tamoxifen-induced hepatic GSH depletion and renal lipid peroxidation (LPO) (4). It likewise normalizes the activity of SOD, inhibits the rise in TNF- $\alpha$ , and ameliorates histopathological changes. **1.** Mansour & Tornhamre (2004) *J. Enzyme Inhib. Med. ### Thymosin $\beta_4$

This highly abundant naturally occurring actin monomer-sequestering peptide (FW = 4963.49 g/mol; CAS 77591-33-4; Symbol: T $\beta_4$ ; Sequence: Acetyl-SDKPDMAEIEKFDKSKLKKTTETQEKPLPSKETIEQKQAGES) binds G-Actin (*i.e.*, Actin monomer) as a 1:1 binary complex,  $K_d$  = 0.7–1.0  $\mu$ M (1-3). Thymosin  $\beta_4$  serves to buffer the intracellular actin monomer levels, preferring to bind Actin·ATP over Actin·ADP. The Thymosin- $\beta_4$  concentration in human platelets is in the range of 200–500  $\mu$ M, which when combined with the high intracellular profilin concentrations, is more than enough to account for the pool of unpolymerized Actin within the cytosol. There was an extraordinary claim that Profilin promotes nonequilibrium filament assembly by accelerating the hydrolysis of filament-bound ATP, a property that was said to be more pronounced in the presence of Thymosin- $\beta_4$  (4). Using right-angle light scattering to directly measure polymer weight concentration, it proved possible to use Spectrin-4.1·Actin seeds to investigate (+)-end elongation solely, allowing profilin-mediated filament assembly to be examined in the absence and presence of Thymosin- $\beta_4$  (4). KINSIM-based modeling and Global Statistical Analysis allowed the evaluation of all pertinent rate and equilibrium constants (5). In the absence of T $\beta_4$ , both Actin·ATP and Profilin·Actin·ATP are equally competent in (+)-end polymerization, with  $k_{on}$   $\sim$  10  $\times$  10<sup>6</sup> M<sup>-1</sup>s<sup>-1</sup>. When measured in the absence of Profilin, Actin assembly curves (over a 0.7–4  $\mu$ M T $\beta_4$  concentration range) fit a simple monomer-sequestering model ( $K_d$  = 1  $\mu$ M) for T $\beta_4$ ·Actin (5). The corresponding constant for T $\beta_4$ ·pyrenyl-Actin, however, was significantly higher ( $K_d$  =  $\sim$ 9–10  $\mu$ M), suggesting that actin pyrenylation markedly weakens T $\beta_4$  binding, and selective enrichment of pyrenyl-Actin in the presence of T $\beta_4$  most likely caused erroneous fluorescence readings in the earlier study (5). Notably, actin filament assembly in presence of T $\beta_4$  and Profilin fits a simple thermodynamic energy cycle, without any hint of the nonequilibrium effects (5). These findings and earlier work carried out in the absence of T $\beta_4$  (6) indicate Profilin·Actin is directly incorporated at the (+)-end of actively polymerizing actin filaments, without selective facilitation of filament formation by Profilin. **1.** Safer, Elzinga & Nachmias (1991) *J. ### L-Thyroxine

This tetra-iodinated amino acid (FW = 776.87 g/mol; CAS 51-48-9;  $\lambda_{\max}$  = 295 nm ( $\epsilon$  = 4160 cm<sup>-1</sup>M<sup>-1</sup>; Symbol = Thx = T<sub>4</sub>) in 40 mM HCl; pK<sub>a</sub> values

of 2.2, 6.45 (phenol OH), and 10.1; photolabile), also known as L-3,3',5,5'-tetraiodothyronine and  $O^3$ -(4-hydroxy-3,5-diiodophenyl)-3,5-diiodotyrosine, is obtained by the proteolysis of thyroglobulin.  $T_4$  exhibits about one-fifth the biological activity of 3,5,3'-triiodothyronine (or  $T_3$ ). In mature organisms, the thyroid hormones increase oxygen consumption, elevate metabolic rates, increase thermogenesis, and induce RNA and protein synthesis. **See also 3,5,3'-Triiodothyronine Target(s):** acid phosphatase, no inhibition reported when *p*-nitrophenyl phosphate is the substrate (45); acylphosphatase (1,43); alanine aminotransferase (2); alcohol dehydrogenase (3-7); aromatase, or CYP19 (8); aspartate aminotransferase (9,10); bisphosphoglycerate mutase (11); cAMP-dependent protein kinase (12); cAMP phosphodiesterase (13,14); creatine kinase (15,16); cystathionine  $\gamma$ -lyase (17,18); dihydropteridine reductase (19); GABA<sub>A</sub> receptor (20); glucose-6 phosphate dehydrogenase (21,22); glutamate dehydrogenase (23,24); IMP dehydrogenase (25); inositol trisphosphate 3-kinase (46); iodothyronine deiodinase, type II (26); lipoprotein lipase (27); lysozyme (28); malate dehydrogenase (29-31); monoamine oxidase (32); NADPH:cytochrome  $c_2$  reductase (33); NAD(P)H dehydrogenase, or DT diaphorase (34-37); NAD(P)<sup>+</sup> transhydrogenase (38); nicotinamidase (39,44); phenylalanyl-tRNA synthetase (40); prostaglandin-D synthase (41); and tyrosine aminotransferase (42). **1.** Grisolia, Caravaca & Joyce (1958) *Biochim. ### Tiagabine

This anti-convulsant (FW = 375.55 g/mol; CAS 115103-54-3), also known by its code name NO-328, its trade name Gabitril<sup>®</sup>, and its systematic name (*R*)-1-[4,4-bis(3-methylthiophen-2-yl)but-3-enyl]piperidine-3-carboxylic acid, targets the GABA ( $\gamma$ -amino-butyrate) transporter GAT-1, a high-affinity, sodium- and chloride-dependent transporter located on presynaptic terminals and surrounding glial cells (1-4). GABA is the major inhibitory neurotransmitter in brain, and inhibition of its re-uptake from the synaptic cleft is an important way to enhance its neurotransmitter activity. Because the brain fails to take up radioiodine-labeled tiagabine to a sufficient degree, it cannot be used to localize cerebral GABA transporters (5). (**See also N-(1-Benzyl-4-piperidinyl)-2,4-dichlorobenzamide**) Gabitril is the first and currently only FDA-approved GAT inhibitor and is intended to treat partial seizures in adults and children age 12 and older. **1.** Nielsen, Suzdak, Andersen, et al. (1991) *Eur. J. Pharmacol.* **196**, 257. **2.** Andersen, Braestrup, Grønwald, et al. (1993) *J. Med. Chem.* **36**, 1716. **3.** Borden, Murali-Dhar, Smith, et al. (1994) *Eur. J. ### Tiazofurin

This pyridine nucleoside analogue (FW = 260.27 g/mol; CAS 60084-10-8) is an antineoplastic agent that inhibits IMP dehydrogenase (1-3), but only after undergoing phosphorylation by adenosine kinase, followed by ATP-dependent adenylylation by NMN adenylyltransferase (NMNAT) to form the NAD<sup>+</sup>-like analogue known as tiazole-4-carboxamide adenine dinucleotide (TAD). (**See Selenazofurin; Benzamide Riboside**) IMPDH is a rate-limiting step in the de novo synthesis of guanylates, including GTP and dGTP. TAD<sup>+</sup> inhibition of IMPDH depletes cells of GTP, thereby down-regulating G-protein function, inhibiting cell growth, and/or inducing apoptosis. Resistance to tiazofurin and related IMPDH inhibitors relates mainly to a decrease in NMNAT activity. **1.** Witters, Mendel & Colliton (1987) *Arch. Biochem. Biophys.* **252**, 130. **2.** Jayaram, Cooney & Grusch (1999) *Curr. Med. Chem.* **6**, 561. **3.** Tricot, Jayaram, E. Lapis, et al. (1989) *Cancer Res.* **49**, 3696.

### Tibolone

This synthetic steroid (FW = 312.45 g/mol; CAS 5630-53-5), also named 17-hydroxy-7 $\alpha$ -methyl-19-nor-17 $\alpha$ -pregn-5(10)-en-20-yn-3-one, is used in the treatment of menopause to prevent bone-loss and relieve symptoms (often as effectively as estrogen). **Target(s):** aromatase (CYP19), however, earlier reports suggest stimulation (1); estrone sulfatase (2-7); estrone sulfotransferase, activated at low concentrations (8,9); and 17 $\beta$ -hydroxysteroid dehydrogenase (10). **1.** Raobaikady, Parsons, Reed & Purohit (2007) *J. ### TIC10

This orally active dual Akt/ERK inhibitor (FW = 386.49 g/mol; CAS 41276-02-2; IUPAC: 2,6,7,8,9,10-hexahydro-10-[(2-methylphenyl)methyl]-7-(phenylmethyl)imidazo[1,2-a]pyrido[4,3-d]pyrimidin-5(3H)-one) targets Foxo3a nuclear translocation, TRAIL gene induction, and displays potent antitumor effects. TRAIL is Tumor necrosis factor-Related Appoptosis-Inducing Ligand, an antitumor protein with considerable potential for therapeutic targeting in cancer. TIC10 inhibits kinases Akt and extracellular signal-regulated kinase (ERK), leading to the translocation of Foxo3a into the nucleus, where it binds to the TRAIL promoter to up-regulate gene transcription. A member of the forkhead transcription factor family, Foxo3a protects cells from oxidative stress by upregulating catalase and MnSOD. Like other members of its family, Foxo3a also is a pro-apoptotic factor. Significantly, TIC10 exhibits the capacity to cross the blood/brain barrier, offering the advantage of accessing CNS targets. **1.** Allen, Krigsfeld, Mayes, *et al.* (2013) *Sci. Transl. Med.* **5**, 171.

### Ticagrelor

This ADP receptor (subtype P2Y<sub>12</sub>) antagonist (FW = 522.56 g/mol; CAS 274693-27-5), known as AZD6140 and Brilinta™, is a potent platelet aggregation inhibitor with clinical outcome properties thought to be superior to clopidogrel (1). Unlike clopidogrel and prasugrel, ticagrelor is a thienopyridine, does not require *in vivo* biotransformation, and has a reversible mode of action (*t*<sub>1/2</sub> = 12 h). The first drug of a new chemical class called cyclopentyltriazolopyrimidines, ticagrelor is administered orally and is characterized by a rapid, greater and consistent antiplatelet effect with a favorable safety profile. By inhibiting adenosine uptake by red blood cells, ticagrelor increases adenosine plasma concentration (APC) in acute coronary syndrome (ACS) patients, compared with clopidogrel (2). Ticagrelor's ability to promote very rapid and reversible platelet inhibition makes it a promising treatment option. Side-effects include dyspnea, bradyarrhythmia, and increased serum levels of uric acid and creatinine (3). **1.** Wallentin, Becker, Budaj, Cannon, *et al.* (2009) *New Engl. J. Med.* **361**, 1045. **2.** Bonello, Laine, Kipson, *et al.* (2014) *J. Am. Coll. Cardiol.* **63**, 872. **3.** Schömig (2009) *New Engl. J. Med.* **361**, 1108.

### Ticarcillin

This carboxypenicillin (FW = 384.43 g/mol; CAS 34787-01-4), also named (2*S*,5*R*,6*R*)-6-[[*(2R)*-2-carboxy-2-(3-thienyl)acetyl]amino]-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylate, is an IV antibiotic for the treatment of Gram-negative bacteria, particularly *Pseudomonas aeruginosa*. Given its susceptibility to β-lactamases, ticarcillin is also often paired with a β-lactamase inhibitor, such as clavulanic acid (*e.g.*, Timentin®). It is also one of the few antibiotics that can be used to treat *Stenotrophomonas maltophilia* infections. Tolerability is good, with hypokalaemia the most frequently reported side-effect. **See also** Carbenicillin; Carindacillin; Temocillin

### Tick Anticoagulant Peptide

This peptide (TAP) from the South African soft tick (*Ornithodoros moubata*), a vector for swine fever, strongly inhibits coagulation factor Xa and trypsin (1-5). The peptide consists of a single chain of sixty residues. Two isoforms of the inhibitor have been reported, differing in only four residues. Both isoforms are slow, tight-binding inhibitors with *K*<sub>i</sub> values of 0.2 nM. A 15-kDa peptide isolated from the camel tick *Hyalomma dromedarii* also inhibits coagulation factor Xa (*K*<sub>i</sub> = 134 nM). **1.** Dinwiddie, L. Waxman, Vlasuk & Friedman (1993) *Meth. Enzymol.* **223**, 291. **2.** Leadley, Jr. (2001) *Curr. Top. Med. Chem.* **1**, 151. **3.** Ibrahim, Ghazy, Maharem & M. I. Khalil (2001) *Comp. Biochem. Physiol. ### Ticlopidine

This thienotetrahydropyridine (FW = 263.79 g/mol; CAS 55142-85-3), also known as 5-(2-chlorobenzyl)-4,5,6,7-tetrahydrothieno[3,2-*c*]pyridine and Ticlid®, is a prodrug that upon metabolic activation reduces ADP-mediated platelet activation (1).

By interfering with platelet function, ticlopidine prevents clots from forming on the inside of blood vessels. Anti-platelet effects begin within 2 days, reaching a maximum after 6 days of therapy. Ticlopidine's effects generally persist for 3 days upon discontinuing ticlopidine, but may take 1–2 weeks for normal platelet function to return. Because this medication affects platelets irreversibly, platelets must be formed before platelet function normalizes. UR-4509, the bioactive metabolite formed from ticlopidine, also inhibits CYP2Y12 (1); CYP2C19 (2-4); CYP2D6 (3). The main biliary metabolite of ticlopidine was characterized as a glutathione (GSH) conjugate

of ticlopidine S-oxide, in which conjugation had occurred at carbon 7a in the thienopyridine moiety. The main biliary metabolite of ticlopidine was characterized as a glutathione (GSH) conjugate of ticlopidine S-oxide, in which conjugation had occurred at carbon 7a in the thienopyridine moiety (5).. 1. Kam & Nethery (2003) *Anaesthesia* **58**, 28. 2. Ha-Duong, Dijols, Macherey, Dansette & D. Mansuy (2001) *Adv. Exp. Med. Biol.* **500**, 145. 3. Ko, Desta, Soukhova, Tracy & Flockhart (2000) *Brit. J. Clin. Pharmacol.* **49**, 343. 4. Donahue, Flockhart, Abernethy & Ko (1997) *Clin. Pharmacol. Ther.* **62**, 572. 5. Shimizu, Atsumi, Nakazawa, *et al.* (2009) *Drug Metab. Dispos.* **37**, 1904.

### Tideglusib

This potent ATP-noncompetitive GSK3 inhibitor (FW = 334.39; CAS 865854-05-3; Solubility (25°C): 10 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known as NP031112 and NP-12, as well as systematically as 4-benzyl-2-(naphthalen-1-yl)[1,2,4]thiazolidine-3,5-dione, targets Glycogen Synthase Kinase-3 (or "Tau Kinase"), with an IC<sub>50</sub> value of 60 nM. Sustained oral administration of tideglusib in a variety of animal models has the effect of decreasing Tau hyper-phosphorylation, lowering brain amyloid plaque, improving memory and learning, and preventing neuronal loss (1). Once bound, the inhibitor is held tightly by the enzyme – so strongly that there is no recovery of enzyme activity, even after the unbound drug has been removed from the reaction medium (2). Such behavior suggests tideglusib is either an irreversible enzyme inhibitor or a slow, tight-binding inhibitor with extreme affinity. Tideglusib protects neural stem cells against NMDA receptor overactivation and NMDA receptor-induced cell death (3). Tideglusib significantly decreased ROS production and membrane degradation, but did not change intracellular Ca<sup>2+</sup> levels following NMDA receptor activation. Moreover, the PPAR $\gamma$  antagonist GW9662 significantly inhibits the protective effect of tideglusib in NMDA/d-serine-treated cells. 1. Luna-Medina, Cortes-Canteli, Sanchez-Galiano, *et al.* (2007) *J. Neurosci.* **27**, 5766. 2. Domínguez, Fuertes, Orozco, *et al.* (2012) *J. Biol. Chem.* **287**, 893. 3. Armagan, Keser, Atalayın & Dagcı (2015) *Pharmacol. Rep.* **67**, 823.

### Tiglate

This necic acid (FW<sub>free-acid</sub> = 100.12 g/mol; CAS 80-59-1; M.P. = 63.5-64°C, B.P. = 198.5°C; Soluble in hot water), also known as (2E)-2-methyl-2-butenic acid and *cis*-dimethylacrylic acid, is a volatile, branched-chain fatty acid that is also found as an ester in many alkaloids. Angelic acid is its *trans* isomer. (Note: Tiglate is also a powerful vesicant.) **See also Angelate (or Angelic Acid) Target(s):** D-amino-acid oxidase (1); esterase (2); and malic enzyme, NAD<sup>+</sup>-dependent (3). 1. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 343, Academic Press, New York. 2. Weber & King (1935) *J. Biol. Chem.* **108**, 131. 3. Landsperger & Harris (1976) *J. Biol. Chem.* **251**, 3599.

### Tiglyl-CoA

This coenzyme A-based thioester (FW = 849.74 g/mol; CAS 6247-62-7), also known as (E)-2-methyl-2-butenyl-CoA and tigloyl-CoA, is an intermediate in isoleucine metabolism, where it is formed from methylbutyryl-CoA and subsequently converted to succinyl-CoA and acetyl-CoA. Tiglyl-CoA inhibits amino-acid N-acetyltransferase, or N-acetylglutamate synthase (1), glycine cleavage complex, or glycine synthase (2), and 3-methylcrotonoyl-CoA carboxylase, the latter weakly (3). 1. Coude, Sweetman & Nyhan (1979) *J. Clin. Invest.* **64**, 1544. 2. Hayasaka &

Tada (1983) *Biochem. Int.* **6**, 225. 3. Diez, Wurtele & Nikolau (1994) *Arch. Biochem. Biophys.* **310**, 64.

### Tilfrinib

This potent ATP-competitive Brk inhibitor (FW = 275.30 g/mol; CAS 1600515-49-8; Solubility: 100 mM in DMSO), systematically named 3-(9H-pyrido[2,3-b]indol-4-ylamino)phenol, selectively targets breast tumor kinase (IC<sub>50</sub> = 3.15 nM), or PTK6, a non-receptor tyrosine-protein kinase that operates in signaling pathways controlling differentiation and maintenance of normal epithelia, as well as tumor growth. PTK6 substrates include certain RNA-binding proteins (*e.g.*, KHDRBS1/SAM68, KHDRBS2/SLM1, KHDRBS3/SLM2 and SFPQ/PSF), transcription factors (*e.g.*, STAT3 and STAT5A/B), as well as signaling proteins, such as STAP2/BKS, PXN/paxillin, BTK/ATK, and ARHGAP35/ p190RhoGAP. 1. Mahmoud, Krug, Wersig, *et al.* (2014) *Bioorg. Med. Chem. Lett.* **24**, 1948.

### Tilorone

This fluorenone (FW<sub>free-base</sub> = 410.56 g/mol; CAS 27591-97-5), also known as 2,7-bis-[2-(diethylamino)ethoxy]-9H-fluoren-9-one and bis-DEAE-fluorenone, which was the first synthetic interferon-inducer (1,2), inhibits DNA polymerase (3,4). 1. Mayer & Krueger (1970) *Science* **169**, 1214. 2. Krueger & Mayer (1970) *Science* **169**, 1213. 3. Chandra, Will, Gericke & Gotz (1974) *Biochem. Pharmacol.* **23**, 3259. 4. Schafer, Chirigos & Papas (1974) *Cancer Chemother. Rep.* **58**, 821.

### Tilorone R10,556 DA

This symmetrical diester inducer of interferon (FW<sub>free-base</sub> = 518.65 g/mol), also called 2,7-bis(piperidinobutyl)-9H-fluoren-9-one, inhibits poly(ADP-ribose) glycohydrolase (1). 1. Tavassoli, Tavassoli & Shall (1985) *Biochim. Biophys. Acta* **827**, 228.

### Tiludronate

This bisphosphonate-based bone resorption inhibitor (FW<sub>free-acid</sub> = 318.61 g/mol; CAS 155453-10-4) inhibits protein-tyrosine phosphatase (1); pyrophosphatase, or inorganic diphosphatase (2); vacuolar H<sup>+</sup>-transporting ATPase (3); and vacuolar H<sup>+</sup>-transporting pyrophosphatase (2). 1. Murakami, Takahashi, Tanaka, *et al.* (1997) *Bone* **20**, 399. 2. McIntosh & Vaidya (2002) *Int. J. Parasitol.* **32**, 1. 3. David, Nguyen, Barbier & Baron (1996) *J. Bone Miner. Res.* **11**, 1498.

**Timolol**

This common vasodilator and antiglaucoma agent (FW<sub>free-base</sub> = 316.43 g/mol; CAS 26839-75-8), also known as Timoptic<sup>®</sup> and Blocadren<sup>®</sup>, is a  $\beta_1/\beta_2$ -adrenergic antagonist, with  $K_i$  values of 1.97 nM and 2.0 nM, respectively. Timolol is typically supplied as the water-/ethanol-soluble maleate salt. It has been proposed for use as an antihypertensive, antiarrhythmic, antiangina, and antiglaucoma agent. **Target(s):**  $\beta$ -adrenergic receptor (1); ATPase (2); carbonic anhydrase (3); cholinesterase, weakly inhibited (4);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (2,5); and phospholipase  $A_1$ , weakly inhibited (6). **1.** Karhuvaara, Kaila & Huupponen (1989) *J. Pharm. Pharmacol.* **41**, 649. **2.** Whikehart, Montgomery & Sorna (1992) *J. Ocul. Pharmacol.* **8**, 107. **3.** Puscas, Reznicek, Moldovan, Puscas & Sturzu (1985) *Med. Pharmacol.* **7**, 195. **6.** Pappu, Yazaki & Hostetler (1985) *Biochem. Pharmacol.* **34**, 521.

**Timonacic, See Thiazolidine-4-carboxylate**

**Tingitanine, See Lathyrine**

**Tinidazole**

This 5-nitroimidazole antibiotic pro-drug (FW = 247.27 g/mol; CAS 19387-91-8; IUPAC: 1-(2-ethylsulfonyl)ethyl-2-methyl-5-nitroimidazole), also known by the trade names Tindamax<sup>®</sup>, Fasigyn<sup>®</sup>, Simplotan<sup>®</sup>, and Sporinex<sup>®</sup>, is active *in vitro* against a wide variety of anaerobic bacteria and protozoa. It is indicated for the treatment of infections arising from amoebae, giardia and trichomonas. Tinidazole is one of the most active antibacterial agents against *Bacteroides fragilis*, one of the most resistant species of anaerobic bacteria. Tinidazole is an FDA-approved treatment of infections caused by *Trichomonas vaginalis*, *Entamoeba histolytica* and *Giardia lamblia*. Since tinidazole has no activity against aerobic bacteria, it must be combined with other antibacterial agents in the treatment of mixed infections involving aerobic and anaerobic bacteria. **See Metronidazole for details on pro-drug activation and mechanisms of action.** **1.** Nord & Kager (1983) *Infection* **11**, 54.

**Tin-mesoporphyrin**

This porphyrin derivative (FW<sub>free-acid</sub> = 683.39 g/mol; CAS 106344-20-1) competitively inhibits heme oxygenase (1-3), the rate-limiting enzyme in the heme catabolic pathway. It may be administered as a single intramuscular dose to very-low-birth-weight infants experiencing severe hemolytic hyperbilirubinemia. Tin-heme complexes (particularly Sn(II)-Protoporphyrin) accumulate in humans during severe iron deficiency anemia, wherein ferrochelatase inserts  $\text{Sn}^{2+}$  in the face of extremely low  $\text{Fe}^{2+}$  concentrations. **1.** Wagner, Hua, de Courten-Myers, *et al.* (2000) *Cell Mol. Biol. (Noisy-le-grand)* **46**, 597. **2.** Boni, Huch Boni, Galbraith, Drummond & Kappas (1993) *Pharmacology* **47**, 318. **3.** Delaney, Mauzerall, Drummond & Kappas (1988) *Pediatrics* **81**, 498.

**Tin-Protoporphyrin IX**

This tin-containing porphyrin derivative (FW<sub>free-acid</sub> = 679.36 g/mol) inhibits ferrochelatase (1) and heme oxygenase (2-5). The extent to which tin is incorporated into hemoglobin-bound protoporphyrin IX is an indicator of iron scarcity during bouts of iron deficiency anemia. **1.** Dailey, Jones & Karr (1989) *Biochim. Biophys. Acta* **999**, 7. **2.** Anderson, Simionatto, Drummond & Kappas (1984) *J. Pharmacol. Exp. Ther.* **228**, 327. **3.** Sardana & Kappas (1987) *Proc. Natl. Acad. Sci. **Tinzaparin**

This low-molecular-weight heparin, or LMWH (MW<sub>average</sub>  $\approx$  6600 g/mol; CAS 9005-49-6 (free acid) and 9041-08-1 (sodium salt)), marketed under the trade name Innohep<sup>™</sup>, is an FDA-approved, once-daily antithrombotic drug for the treatment and prophylaxis of deep-vein thrombosis and pulmonary embolism. Tinzaparin is a LMWH produced by heparinase digestion of heparin. Tinzaparin is believed to be safe during pregnancy and for treating critically ill patients experiencing renal failure. (*For a listing of likely off-target inhibitory effects, see Heparin*) **1.** Friedel & Balfour (1994) *Drugs* **48**, 638.

**Tiopronin**

This FDA-registered orphan drug (FW = 163.19 g/mol; CAS 217-778-4), also known as Tiopronin (TSH), chemically reduces cystine to cysteine (*Reactions:*  $\text{Cys-S-S-Cys} + \text{T-SH}_{\text{excess}} \rightleftharpoons \text{Cys-S-S-T} + \text{Cys-SH}$ ;  $\text{Cys-S-S-T} + \text{T-SH}_{\text{excess}} \rightleftharpoons \text{T-S-S-T} + \text{Cys-SH}$ ), thereby forming cysteine (Cys-SH), the more soluble amino acid, and lowering otherwise supersaturating levels of cystine (Cys-S-S-Cys) that drive the formation of cystine stones in the kidneys of patients with cystinuria. Owing to the chronic nature of this disorder, tiopronin treatment requires many months, and often years, of administration. It is also a ROS scavenger and is an investigational drug for treating rheumatoid arthritis. Tiopronin also is an inhibitor of glutathione peroxidase (3), a finding that explains the otherwise confounding finding that, despite its action an antioxidant, tiopronin can actually elevate oxidative stress. Tiopronin also elicits collateral sensitivity (*or* CS), a phenomenon of drug hypersensitivity that is defined by the ability of certain compounds to selectively target MDR cells, but not the drug-sensitive parent cells from which they were derived (4). Unlike other CS-promoting agents, however, tiopronin's action does not depend on the expression of P-gp in MDR cells (4). Instead, its CS activity is mediated through the generation of reactive oxygen species (ROS) and can be reversed by a variety of ROS-scavenging compounds. Moreover, tiopronin's selective toxicity of towards MDR cells is achieved by inhibition of glutathione peroxidase (GPx). The pharmacokinetics of tiopronin and its principal metabolite, 2-mercaptropionic acid (2-MPA) are complex, with delayed maximal absorption of tiopronin and high protein and tissue binding of the drug, making its bioavailability variable (5,6). **1.** Joly, Rieu, Méjean, *et al.* (1999) *Pediatr. **Tiotidine**

This cyanoguanidinium derivative (FW<sub>free-base</sub> = 312.42 g/mol; CAS 69014-14-8; Soluble to 100 mM DMSO), also known as ICI 125,211 and is a histamine H<sub>2</sub> receptor inverse agonist, showing negligible activity against H<sub>1</sub>- and H<sub>3</sub>- receptors (1-3). Tiotidine binds with high affinity to a form of the receptor coupled to G-protein that then remains inactive. It binds with high affinity to a site that no longer exists in the presence of GTPγS or in desensitized cells (4). Tiotidine binding leads to a dose-dependent decrease in cAMP basal levels in U-937 cells, an effect that is evident in both homologous and heterologous overexpression systems, as well as in forskolin pretreated cells (4). **Target(s):** aldehyde dehydrogenase (5); cytochrome P450 (6); and histamine H<sub>2</sub> receptor (7,8). 1. Hill (1990) *Pharmacol. Rev.* **42**, 45. 2. Trzeciakowski & Levi (1980) *J. Pharmacol. Exp. Ther.* **214**, 629. 3. Yellin, *et al.* (1979) *Life Sci.* **25**, 2001. 4. Richardson, Feldman, Brater & Welborn (1981) *Gastroenterology* **80**, 301.

**Tiotropium Bromide**

This long-acting muscarinic receptor antagonist (FW = 472.43 g/mol; CAS 136310-93-5; Soluble to 20 mM in water and to 100 mM in DMSO), also named (1 $\alpha$ ,2 $\beta$ ,4 $\beta$ ,7 $\beta$ )-7-[(hydroxydi-2-thienylacetyl)oxy]-9,9-dimethyl-3-oxa-9-azoniatricyclo[3.3.1.0<sup>2,7</sup>]nonane bromide and Spiriva<sup>®</sup>, binds to human muscarinic receptors: M<sub>1</sub> (found mediating slow EPSP at the ganglion in the postganglionic nerve, commonly in exocrine glands and in the CNS, M<sub>2</sub>, (found on cholinergic nerve terminals) and M<sub>3</sub> (found on airway smooth muscle), with K<sub>d</sub> values in the sub-nanomolar concentration range. Tiotropium bromide is widely used as a bronchodilator for treating chronic obstructive pulmonary disease. The dissociation rate constants k<sub>off</sub> are extremely low: 1.3 × 10<sup>-5</sup> s<sup>-1</sup>, 5.3 × 10<sup>-5</sup> s<sup>-1</sup>, and 5.6 × 10<sup>-6</sup> s<sup>-1</sup> for human receptors M<sub>1</sub>, M<sub>2</sub>, and M<sub>3</sub> (1). In this respect, tiotropium bromide exhibits “kinetic subtype selectivity”, manifested by a more rapid dissociation from human M<sub>2</sub> than from the M<sub>1</sub> and M<sub>3</sub> receptors. When examined *in vitro*, tiotropium exerts potent inhibitory effects against cholinergic nerve-induced contraction of guinea-pig and human airways, with a slower onset than atropine or ipratropium bromide. Upon washout, tiotropium bromide dissociates extremely slowly compared with atropine and ipratropium bromide. Spiriva demonstrates a prolonged protective effect against cholinergic agonists and cholinergic nerve stimulation in animal and human airways (2). 1. Disse, Reichl, Speck, *et al.* (1993) *Life Sci.* **52**, 537. 2. Barnes (2001) *Expert Opin. Investig. Drugs* **10**, 733.

**Tipiracil**

This novel thymidine phosphorylase inhibitor (FW = 242.67 g/mol; CAS 183204-74-2), also named 5-chloro-6-[(2-imino-1-pyrrolidinyl)methyl]-2,4(1H,3H)-pyrimidinedione, is a uracil derivative that is used in use in combination with trifluridine (*i.e.*, as the binary drug TAS-102 or Lonsurf<sup>®</sup>). TAS-102 is a novel oral nucleoside antitumor agent containing both trifluridine and tipiracil to improve overall survival of patients with unresectable advanced or recurrent colorectal cancer that are insensitive to standard chemotherapies. Trifluridine incorporation into DNA induces DNA

dysfunction, including DNA strand breaks (See 5-(Trifluoromethyl)-2'-deoxyuridine). Thymidine phosphorylase inhibition prevents metabolic inactivation of trifluridine. 1. Tanaka, Sakamoto, Okabe, *et al.* (2014) *Oncol. Rep.* **32**, 2319.

**Tipifarnib**

This orally bioavailable farnesyltransferase inhibitor (FW = 489.40 g/mol; CAS 192185-72-1; Solubility = 14 mg/mL DMSO), also known by its code name R115777, the trade name Zarnestra<sup>®</sup>, and its systematic name (R)-6-(amino(4-chlorophenyl)(1-methyl-1H-imidazol-5-yl)methyl)-4-(3-chlorophenyl)-1-methyl-quinolin-2(1H)-one, is intended as a treatment for acute myeloid leukemia (AML) in elderly patients who are not candidates for standard chemotherapy. **Mode of Action:** Ras is the most common human oncogene, and mutations that activate Ras are found in 20-25% of all human tumors, with up to 90% in certain cancers. Tipifarnib targets prenylation (IC<sub>50</sub> = 0.6 nM) of the CAAX motif (where C is cysteine residue, A and A are two aliphatic residues, and X is any C-terminal amino acid, depending on a particular prenyltransferase's substrate specificity) required for membrane localization of small GTPase Ras to bind to the membrane, where it subsequently switches on other proteins that ultimately turn on genes involved in cell growth, differentiation and survival. **Inhibition of Tumor Cell Growth:** When tested *in vitro*, R115777 competitively inhibits the farnesylation of lamin B and K-RasB peptide substrates, with IC<sub>50</sub> values of 0.86 nM and 7.9 nM, respectively (1). In a panel of 53 human tumor cell lines, the growth of nearly three-fourths were found to be sensitive to Tipifarnib. The majority of sensitive cell lines had a wild-type ras gene. Tumor cell lines bearing H-ras or N-ras mutations were among the most sensitive of the cell lines tested, with responses observed at nanomolar concentrations of R115777 (1). Tumor cell lines bearing mutant K-ras genes required higher concentrations for inhibition of cell growth, with 50% of the cell lines resistant to R115777 up to concentrations of 500 nM (1). Inhibition of H-Ras, N-Ras, and lamin B protein processing was observed at concentrations of R115777 that inhibited cell proliferation. R115777 also induces dose-dependent growth inhibition of the three myeloma cell lines, attended by significant and time-dependent apoptosis. Phosphorylation of both STAT3 and ERK1/2 induced by IL-6 was totally blocked at 15 μM of R115777 and partially blocked when R115777 was used at 10 and 5 μM. 1. End, Smets, Todd, *et al.* (2001) *Cancer Res.* **61**, 131. 2. Le Gouill, Pellat-Deceunynck & Harousseau (2002) *Leukemia* **16**, 1664.

**TIPP**

This conformationally constrained tetrapeptide (FW = 634.73 g/mol), also known as Tyr-Tic-Phe-Phe, is a δ-opioid receptor antagonist (1). This report also demonstrated that the tetrapeptide amide Tyr-D-Phe-Phe-Phe-NH<sub>2</sub> is a potent μ-selective opioid agonist, consisting entirely of aromatic amino acid residues that can be conformationally restricted in a number of ways. Substitution of the D- and L- enantiomers of the conformationally restricted phenylalanine analogues N<sup>ε</sup>-methylphenylalanine and tetrahydro-3-isoquinoline carboxylic acid (Tic) for D-Phe produces astonishing changes in receptor affinity and intrinsic activity. These structure-activity relationship studies defined a class of potent and selective antagonists, characterized by the N-terminal sequence H-Tyr-Tic-Phe-. 1. Schiller, Nguyen, Weltrowska, *et al.* (1992) *Proc. Natl. Acad. Sci. U.S.A.* **89**, 11871.

**Tipranavir**

This nonpeptidic HIV-1 protease inhibitor (FW = 602.66 g/mol; CAS 174484-41-4), also known as PNU-140690E, Aptivus™, and systematically as *N*-{3-[(1*R*)-1-[(2*R*)-6-hydroxy-4-oxo-2-(2-phenylethyl)-2-propyl-3,4-dihydro-2*H*-pyran-5-yl]propyl]phenyl}-5-(trifluoromethyl)pyridine-2-sulfonamide, targets the virus-specific processing of the viral Gag and Gag-Pol polyproteins in HIV-1 infected cells, thereby preventing the formation of mature virions (1-6). Tipranavir is orally available, especially potent ( $K_i = 8$  pM), and inhibits protease inhibitor-resistant clinical HIV-1 isolates. While the presence of five or fewer protease gene mutations or 1-2 protease inhibitor resistance-associated mutations (PRAMs) is enough to reduce most currently available protease inhibitors, 16-20 mutations (including three or more PRAMs) are needed to achieve resistance to tipranavir (7). Aptivus is used in combination with ritonavir to treat adult and pediatric HIV-1 infected patients infected with HIV-1 strains that are resistant to more than one protease inhibitor. 1. **TIQ-A**, See *Thieno[2,3-*c*]isoquinolin-5-one*

**Tirapazamine**

This hypoxia-induced cytotoxin and antineoplastic agent (FW = 178.15 g/mol; CAS 27314-97-2), also known as 3-amino-1,2,4-benzotriazine 1,4-dioxide and SR-4233, is a bioreductive drug that exploits tumor hypoxia to interrupt cell cycle progression and induce apoptosis. Tirapazamine is metabolized to form a transient oxidizing radical. In the absence of oxygen, this radical reacts with DNA to form DNA radicals, largely at C4' on the ribose ring, culminating in DNA strand breaks. **Target(s)**: DNA replication (1); DNA topoisomerase II (2); and oxidative phosphorylation (3). 1. Peters, Wang, Brown & Iliakis (2001) *Cancer Res.* **61**, 5425. 2. Peters & Brown (2002) *Cancer Res.* **62**, 5248. 3. Ara, Coleman & Teicher (1994) *Cancer Lett.* **85**, 195.

**Tiratricol**, See *3,3',5-Triiodothyroacetate*

**Tirofiban**

This platelet aggregation inhibitor (FW = 440.60 g/mol; CAS 144494-65-5), known initially as MK-383 and L-700,462, marketed under the trade names Aggrastat™, and systematically named as *N*-(butylsulfonyl)-*O*-(4-(4-piperidyl)butyl)-*L*-tyrosine, is a synthetic, nonpeptide antagonist of platelet glycoprotein (GP) IIb/IIIa receptors, thereby accounting for its anticoagulant action by blocking platelet aggregation (1,2). Based on a peptide in an

anticoagulant found in the venom of the saw-scaled viper *Echis carinatus*, tirofiban was the first in the first nonpeptide GPIIb/IIIa antagonist of this new class of antiplatelet agents. The plasma IC<sub>50</sub> for MK-383 in healthy volunteers is approximately 13 ng/mL, with a Hill coefficient  $n_H > 5$  (3). 1. Hartman, Egbertson, Halczenko, *et al.* (1992) *J. Med. Chem.* **35**, 4640. 2. Peerlinck, de Lepeleire, Goldberg *et al.* (1993) *Circulation* **88**, 1512. 3. Barrett, Murphy, Peerlinck *et al.* (1994) *J. Clin. Pharmacol. Ther.* **56**, 377.

**Tiron**

This metal ion chelator (FW<sub>disodium salt</sub> = 314.20 g/mol; CAS 149-45-1), also known as 4,5-dihydroxybenzene-1,3-disulfonate and catechol-3,5-disulfonate, forms high-affinity complexes with many heavy metal ions, particularly with Fe<sup>3+</sup>, and is thus a likely inhibitor of metalloenzymes. Tiron is used in colorimetric assays for iron, manganese, titanium, and molybdenum, but also binds cobalt, nickel, copper, and zinc ions. Complexes with heavy metals are water soluble and are typically colored: ferric chloride produces a deep blue color below pH 5, titanium salt complexes are orange, copper salts will generate a greenish yellow color, and Mo(VI) produces a complex with a canary yellow color. Tiron is a cell-permeable superoxide scavenger (1), and is oxidized to an EPR-visible semiquinone by the superoxide radical (2). The latter property provides a probe for determining whether the superoxide anion or molecular oxygen is the true substrate for a particular mono- or dioxygenase. Tiron likewise inhibits those processes that require the participation of the superoxide anion. **Target(s)**: aliphatic aldoxime dehydratase (3); arylacetone nitrilase, weakly inhibited (4); catechol 1,2-dioxygenase (5); catechol 2,3-dioxygenase (6); CMP-*N*-acetylneuraminatase hydroxylase (7); glycerol-3-phosphate dehydrogenase (8); 3-hexulose-6-phosphate synthase (9); indoleamine 2,3-dioxygenase (10); lactate racemase (11); NADH peroxidase (12); nitrile hydratase (13); nitrogenase (14,15); tryptophan 5-monooxygenase (16); and vanillate hydroxylase (17). 1. **Δ<sup>7</sup>-Tirucalol**

This triterpene (FW = 425.72 g/mol; CAS 514-46-5), also known as tirucalla-7,24-dien-3β-ol and a diastereoisomer of lanost-7,24-dien-3β-ol, isolated from the flowers of the genus *Compositae*, inhibits both chymotrypsin,  $K_i = 72$  μM, and trypsin,  $K_i = 152$  μM (1). 1. Rajic, Akihisa, Ukiya, *et al.* (2001) *Planta Med.* **67**, 599.

### Tissue Factor Pathway Inhibitor

This 276-residue glycoprotein (MW = 34-40 kDa, depending on site/extent of proteolysis; *Symbol*: TFPI), also known as Lipoprotein-Associated Coagulation Inhibitor, is a multivalent protease inhibitor that arrests coagulation factor Xa with slow, tight-binding kinetics. TFPI is itself a complex protein, consisting of a highly anionic N-terminal region, three tandem Kunitz domains, and a highly cationic C-terminus. It blocks the initiation of coagulation by inhibiting TF-activated factor VII, activated factor X, and early prothrombinase. Coagulation factor VIIa is also inhibited by the formation of a complex consisting of VIIa, Xa, tissue factor pathway inhibitor, and tissue factor (1-8). While TFPI inhibits the activity of factor Xa and the complex of tissue factor and factor VIIa, TFPI-2 does not inhibit factor Xa; it is instead a strong inhibitor of factor XIa, plasma kallikrein, plasmin, and trypsin (1,4,8). Prothrombinase inhibition by TFPI $\alpha$  is mediated through a high-affinity exosite interaction between the basic region of TFPI $\alpha$  and the FV acidic region, which is retained in FXa-activated FVa and platelet FVa (9). This inhibitory action is not mediated by TFPI $\beta$  and is lost upon removal of the acidic region of FVa by thrombin. These properties define an isoform-specific anticoagulant function for TFPI $\alpha$ , and, when combined with earlier evidence of differential expression patterns of TFPI $\alpha$  and TFPI $\beta$  in platelets and endothelial cells, suggest that TFPI isoforms have distinct mechanisms for inhibiting the initial stages of intravascular coagulation: TFPI $\beta$  dampens TF present on the surface of vascular cells, and TFPI $\alpha$  dampens the initial prothrombinase on the surface of activated platelets. Humans produce the 3' splice variants TFPI $\alpha$  and TFPI $\beta$  that are differentially expressed in endothelial cells and platelets and that possess distinct structural features affecting their inhibitory function. TFPI also undergoes alternative splicing of Exon-2 within its 5'-untranslated region (10). Exon-2 behaves as a molecular switch preventing translation of TFPI $\beta$ , and a 5'-untranslated region alternative splicing event alters translation of isoforms by independent 3' splicing events within the same gene. **Effect of LDL:** Addition of full-length free TFPI (TFPI $\alpha$ ) to plasma prolongs the clotting time, whereas low-density lipoprotein particles (LDL-TFPI) exclusively decreased the peak height of thrombin without effecting the lag phase (11). Steady-state and transient kinetics showed that LDL-TFPI was a more potent inhibitor of FXa than TFPI $\alpha$  and TFPI $_{1-161}$ , indicating that FXa inhibition was not rate-determining for the lag phase, whereas it affects thrombin generation during the propagation phase (11). Note: Activated coagulation factor XI (FXIa) neutralizes both endothelium- and platelet-derived Tissue Factor Pathway Inhibitor, or TFPI (itself an essential reversible inhibitor of activated Factor X (FXa) and the FVIIa-TF complex), cleaving the protein between the Kunitz K1 and K2 domains (at Lys86/Thr87) and at the active sites of the K2 domain (at Arg107/Gly108) and K3 domain (at Arg199/Ala200) (12). **Target(s):** cathepsin G (1); chymotrypsin (1); coagulation factor VIIa, when in the presence of factor Xa (2-4); coagulation factor Xa (5-7); coagulation factor Xia (8); kallikrein (1,8); plasmin (8); and trypsin (1,4,8). 1. ### Tissue Inhibitor of Metalloproteinase

This family of naturally occurring glycoproteins (*Symbol*: TIMP) target metalloproteinases (MMPs), the Zn<sup>2+</sup>-activated peptidases that degrade extracellular matrix (ECM) components, thereby promoting tumor growth, angiogenesis and metastatic disease in a wide range of cell types. **Human TIMP1** (MW = 23171 g/mol; Accession: CAG46779) forms binary complexes with target metalloproteinases, such as collagenases, irreversibly inactivating the latter by interacting with their catalytic zinc cofactor. TIMP1 inhibits MMP1, MMP2, MMP3, MMP7, MMP8, MMP9, MMP10, MMP11, MMP12, MMP13 and MMP16; however, it fails to inhibit MMP14. In some cases, TIMP1 acts as a growth factor, regulating cell differentiation, migration and cell death and activating cellular signaling cascades via CD63 and ITGB1. TIMP1 lays a role in integrin signaling. TIMP1 also promotes erythropoiesis *in vitro*, stimulating the growth and differentiation of human erythroid progenitor cells. **Human TIMP2** (MW = 16082 g/mol; Accession:

EAW89541) uniquely activate MMP-2, using its N-terminus to bind and inhibit MT1-MMP and employing its C-terminus to bind to secreted zymogen, pro-MMP-2. Upon binding of TIMP-2 to MT1-MMP, a neighboring uninhibited MMP-14 subunit can cleave and activate a bound pro-MMP-2, when bound to  $\alpha_v\beta_3$  integrin receptor on the cell surface. **Human TIMP3** (MW = 24145 g/mol; Accession: CAG30479) inhibiting Tumor-Necrosis Factor  $\alpha$  (TNF- $\alpha$ )-Converting Enzyme (or TACE, also known as ADAM17) controlling levels of TNF in the liver. **Human TIMP4** (MW = 25503 g/mol; Accession: AAC34422) is involved in regulation of platelet aggregation and recruitment and may play role in hormonal regulation and endometrial tissue remodeling. 1. Gomez, Alonso, Yoshiji & Thorgeirsson (1997) *Eur. J. Cell Biol.* **74**, 111.

**Tissue Inhibitor of Metalloproteinases 1, See TIMP-1**

**Tissue Inhibitor of Metalloproteinases 2, See TIMP-2**

### Tityustoxin-K $\alpha$

This oligopeptide toxin (MW = 3942 Da) from the Brazilian scorpion *Tityus serrulatus* increases Na<sup>+</sup> permeability (1) and potently and selectively inhibits the voltage-gated non-inactivating K<sup>+</sup> channel,  $K_d = 0.21$  nM (2). TsTX-K $\alpha$  does not interact with the gating of K<sub>v</sub>1.3 since it did not affect the voltage-dependence of channel activation (3). Given its photosensitivity, tityustoxin-K $\alpha$  should be stored in a light-tight plastic tube. 1. Conn (1983) *Meth. Enzymol.* **103**, 401. 2. Werkman, Gustafson, Rogowski, Blaustein & Rogawski (1993) *Mol. Pharmacol.* **44**, 430. 3. Rodrigues, *et al.* (2003) *Brit. J. Pharmacol.* **139**, 1180.

### Tivantinib

This synthetic non-ATP-competitive protein kinase inhibitor (FW = 369.32 g/mol; CAS 905854-02-6, 1000873-98-2, and 1228508-24-4; Solubility: 74 mg/mL DMSO, <1mg/mL H<sub>2</sub>O), also known as ARQ 197 and (3*R*,4*R*)-3-(2,3-dihydro-1*H*-pyrrolo[3,2-*i*]quinolin-6-yl)-4-(1*H*-indol-3-yl)pyrrolidine-2,5-dione, is an orally available selective human c-Met inhibitor (IC<sub>50</sub> = 0.1  $\mu$ M). Exposure of c-Met-expressing cancer cell lines to ARQ 197 inhibited proliferation and induced caspase-dependent apoptosis (1). These cellular responses to ARQ 197 were phenocopied by RNAi-mediated c-Met depletion (2). Combined use of tivantinib and its bisphosphate, zoledronate, also prevents tumor bone engraftment and inhibits progression of established bone metastases in a breast xenograft model (3). Tivantinib also suppresses oral squamous cell carcinoma (OSCC) cell proliferation and colony formation, but its anti-tumor activity is independent of the inhibition of MET signaling pathway (4). Tivantinib causes G<sub>2</sub>/M cell cycle arrest and caspase-dependent apoptosis in OSCC cell lines, dose-dependently suppressing FAK activation and expression (4). 1. Munshi, Jeay, Li, *et al.* (2010) *Mol. Cancer Ther.* **9**, 1544. 2. Comoglio, Giordano & Trusolino (2008) *Nat. Rev. Drug Discov.* **7**, 504. 3. ### Tivirapine

This non-nucleoside reverse transcriptase inhibitor (FW = 321.87 g/mol; CAS 137232-54-8), also known as R86183, 8-chloro-TIBO, and (+)-S-

**Tobramycin**

This aminoglycoside antibiotic (FW<sub>free-base</sub> = 467.52 g/mol; CAS 32986-56-4; Soluble in 1.5 parts water; pK<sub>a</sub> values indicated for each amino group), a component of the nebramycin complex from *Streptomyces tenebrarius*, inhibits bacterial protein synthesis (IC<sub>50</sub> = 9.7 μM) as well as enzymes of various classes. Tobramycin binds tightly to 30S and 50S ribosome subunits, thereby preventing formation of the 70S complex and inhibiting synthesis of bacterial proteins. (For additional mechanistic details) See Neomycins.

**Target(s):** N-acetyl-β-D-glucosaminidase, weakly inhibited (1); DNA-directed DNA polymerase, Klenow fragment (2); hepatitis delta virus genomic ribozyme self-cleavage (3); kanamycin kinase (4); leukocyte elastase, slightly inhibited (5); lysozyme (6); phospholipase A<sub>1</sub>, inhibition may be due to substrate depletion (7-11); phospholipase A<sub>2</sub> (8-10,12,13); phospholipase C (9,10,14,15); poly(A)-specific ribonuclease (2); bacterial protein biosynthesis, primarily by binding to the A site in the ribosome (16); protein kinase C (17); ribonuclease P (18); streptomycin 3''-adenylyltransferase (19). 1. **Tocilizumab**

This humanized anti-IL-6 receptor monoclonal antibody (MW = 145 kDa; CAS 375823-41-9), marketed by Genentech under the trade name Actemra<sup>®</sup>, binds specifically to interleukin-6 (IL-6) receptors, which bind the versatile pro-inflammatory cytokine IL-6, itself produced by a variety of cell types, including T- and B-cells, lymphocytes, monocytes and fibroblasts. IL-6 is implicated in the pathogenesis of autoimmune disorders, multiple myeloma, and prostate cancer. Unlike other cytokines, IL-6 activates target cells through membrane-bound (IL-6R) and soluble receptors (sIL-6R), widening the number of responsive cell types. Tocilizumab binds to both sIL-6R and mIL-6R, inhibiting IL-6 binding and blocking both sIL-6R and mIL-6R signaling but not that of other IL-6 family cytokines. Administered intravenously on a monthly schedule, tocilizumab has an *in vivo* half-life of 8-14 days, commending its use in the treatment of moderate to severe rheumatoid arthritis, especially in combination with methotrexate. 1. Mihara, Kasutani, Okazaki, et al. (2005) *Int. Immunopharmacol.* **5**, 1731. 2. Alten & Maleitke (2013) *Ann. Med.* **45**, 357.

**α-Tocopherol**

This methylated tocol (FW = 430.71 g/mol; CAS 1406-18-4; MP = 2.5-3.5°C; λ<sub>max</sub> = 292 nm (ε = 3260 M<sup>-1</sup>cm<sup>-1</sup>), strongly fluorescent with Emission<sub>max</sub> at 340 nm) is also called 5,7,8-trimethyltolcol and (2R)-3,4-

dihydro-2,5,7,8-tetramethyl-2-[(4R,8R)-4,8,12-trimethyl-tridecyl]-2H-1-benzopyran-6-ol. **Target(s):** ascorbate oxidase (1); ATPase (2); cyclooxygenase (3); glutathione S-transferase (4); lipoxigenase (5-9); 5-lipoxygenase (10,11); phospholipase A<sub>2</sub> (12); protein kinase C (12,13-17); retinyl-palmitate esterase, or retinyl esterase (18-21); sphingomyelinase (22); and urokinase, or u-plasminogen activator (23). 1. **α-Tocopherol Phosphate**

This phosphoester (FW<sub>free-acid</sub> = 510.69 g/mol), also known as α-tocopheryl phosphate, inhibits cytochrome c oxidase (1); NAD<sup>+</sup> nucleosidase, or NADase (2); phenylalanine 4-monooxygenase (3); succinate dehydrogenase (1,4,5); and succinate oxidase (1). 1. Rabinovitz & Boyer (1950) *J. Biol. Chem.* **183**, 111. 2. Spaulding & Graham (1947) *J. Biol. Chem.* **170**, 711. 3. Woo, Gillam & Woolf (1974) *Biochem. J.* **139**, 741. 4. **α-Tocopherol Succinate**

This α-tocopherol succinate ester (FW<sub>free-acid</sub> = 530.79 g/mol), also known as α-tocopherol acid succinate, is practically insoluble in water and is soluble in organic solvents such as diethyl ether, acetone, and chloroform. It is unstable in alkaline conditions. **See also α-Tocopherol** **Target(s):** adenylate cyclase (1); NF-κB transcriptional activity (2); and succinate dehydrogenase (3). 1. Sahu, Edwards-Prasad & Prasad (1987) *J. Cell Physiol.* **133**, 585. 2. Nakamura, Goto, Matsumoto & Tanaka (1998) *Biofactors* **7**, 21. 3. Basinski & Hummel (1947) *J. Biol. Chem.* **167**, 339.

**Tocris-1963, See SB408124****TOFA**

This irreversible fatty acid synthesis inhibitor (FW = 324.59 g/mol; CAS 54857-86-2; λ<sub>max</sub> = 278 nm), also named RMI 14514 and 5-(tetradecyloxy)-2-furancarboxylic acid, targets the synthesis of malonyl-CoA by acetyl-CoA carboxylase, or ACC, reduced food intake and body weight in mice treated with fatty acid synthase inhibitors (1) and resulting in cytotoxicity and

apoptosis in human cancer cell lines (2). (**See also Cerulenin**) Both cerulenin (~10 µg/ml) and TOFA (~1 µg/ml) are effective in blocking the incorporation of radiolabeled acetate into palmitate; however, TOFA reduces malonyl-CoA levels, rather than elevating them. TOFA is also relatively non-toxic to various cancer cell lines. TOFA attenuates inhibition of feeding, when FAS inhibitors like cerulenin are administered to obese *ob/ob* mice. 1. Loftus, Jaworsky, Frehywot, *et al.* (2000) *Science* **288**, 2379.

### Tofacitinib

This Janus kinase 3 inhibitor and immunosuppressant (FW = 311.39 g/mol; CAS 477600-75-2; Solubility: 100 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), known formerly as tasocitinib and also by its code name CP-690550, its trade name Xeljanz<sup>®</sup>, and its IUPAC name 3-[(3*R*,4*R*)-4-methyl-3-[methyl(7*H*-pyrrolo[2,3-*d*]pyrimidin-4-yl)amino]piperidin-1-yl]-3-oxopropanenitrile, is an FDA-approved drug for the treatment of rheumatoid arthritis and is under investigation for treatment of psoriasis, inflammatory bowel disease, and prevention of transplant organ rejection. **Mechanism of Inhibitory Action:** Janus kinase 3 (*or* JAK3) is expressed during allograft rejection, and, with a 1-nM *K<sub>i</sub>* for JAK3, tofacitinib delays allograft rejection, significantly prolonging kidney survival. Tofacitinib citrate inhibits interleukin-6-induced phosphorylation of STAT1 and STAT3 with IC<sub>50</sub> values of 23 nM and 77 nM, respectively. Tofacitinib inhibits IL-2-mediated human T-cell blast proliferation and IL-15-induced CD69 expression with IC<sub>50</sub> of 11 nM and 48 nM, respectively. When used in combination with the IMP dehydrogenase inhibitor mycophenolate mofetil to block *de novo* guanine nucleotide biosynthesis in leukocytes, Tofacitinib is even more efficient in preventing organ rejection (2). Co-administration of CP-690550 and methotrexate is also well tolerated in patients with rheumatoid arthritis without need for dose adjustment (3) (**See also Baricitinib**). **Pharmacokinetics in Humans:** Tofacitinib is rapidly absorbed, with plasma concentrations and total radioactivity peaking ~1 hour after oral administration (4). The mean terminal-phase *t*<sub>1/2</sub> was ~3.2 h for both parent drug and total radioactivity. Two-thirds of circulating radioactivity in plasma is the parent drug, with each tofacitinib metabolite <10% of total circulating radioactivity. Hepatic clearance is ~70% of total clearance, with renal clearance accounting for the remainder. Tofacitinib undergoes oxidation of its pyrrolopyrimidine and piperidine rings, oxidation of the piperidine ring side chain, *N*-demethylation, and glucuronidation (4). Consistent with clinical reports of likely drug interactions, tofacitinib is mainly metabolized by CYP3A4, albeit with some contribution from CYP2C19. 1. Changelian, Flanagan, Ball, *et al.* (2003) *Science* **302**, 875. 2. Borie, Larson, Flores, *et al.* (2005) *Transplantation* **80**, 1756. 3. ### Tofogliflozin

This Type-2 diabetes drug (FW = 404.45 g/mol; CAS 1201913-82-7; Code Name: CSG452; IUPAC Name: (1*S*,3'*R*,4'*S*,5'*S*,6'*R*)-6-(4-ethylbenzyl)-6'-(hydroxymethyl)-3',4',5',6'-tetrahydro-3*H*-spiro[2-benzofuran-1,2'-pyran]-3',4',5'-triole monohydrate) inhibits the sodium-glucose transporter (SGLT2), Subtype 2, a carrier responsible for >90% of kidney glucose reabsorption (1,2). Importantly, such reduction in renal glucose reabsorption only occurs during hyperglycemia, but not under hypo- or euglycemia. The other SGLT2 inhibitors include canagliflozin, dapagliflozin, empagliflozin, and luseogliflozin (3). 1. Suzuki, Honda, Fukazawa, *et al.* (2012) *J. Pharmacol. Exp. Ther.* **341**, 692. 2. Ohtake, Sato, Kobayashi, *et al.* (2012) *J. Med. Chem.*

**55**, 7828. 3. Nagata, Fukazawa, Honda, *et al.* (2013) *Am. J. Physiol. Endocrinol. Metab.* **304**, E414.

### Tolazoline

This vasodilator (FW = 160.22 g/mol; CAS 59-98-3) is an α<sub>2</sub>-adrenergic blocker, typically formulated as the water-soluble hydrochloride Prisolol, inhibits acetylcholinesterase (1,2) and α<sub>2</sub>-adrenergic receptor (3,4). 1. Augustinsson (1950) *The Enzymes*, 1st. ed. (Sumner & Myrbäck, eds.), **1** (part 1), 443. 2. Schär-Wüthrich (1943) *Helv. Chim. Acta* **26**, 1836. 3. Schwartz & Clark (1998) *J. Vet. Pharmacol. Ther.* **21**, 342. 4. Angel, Niddam & Langer (1990) *J. Pharmacol. Exp. Ther.* **254**, 877.

### Tolbutamide

This oral hypoglycemic sulfonylurea (FW = 270.35 g/mol; CAS 64-77-7; M.P. = 128.5-129.5°C), also known as Orinase<sup>®</sup>, *N*-butyl-*N'*-*p*-toluenesulfonylurea, 1-(*p*-tolylsulfonyl)-3-butylurea, and D-860, stimulates insulin release and is also a substrate for a number of cytochrome P450 systems. Tolbutamide activates 6-phosphofructo-2-kinase while inhibiting fructose-2,6-bisphosphate 2-phosphatase. **Target(s):** acetohexamide reductase, heart (1); ATP-sensitive K<sup>+</sup>-channel (2); cAMP-dependent protein kinase, *or* protein kinase A (3,4); cAMP phosphodiesterase (5,6); carnitine acyltransferase (7,8); carnitine palmitoyl-transferase (8,9); cholesterol biosynthesis (10,11); fructose-2,6-bisphosphate 2-phosphatase (12); glucose-6-phosphatase (13-16); glutamine:fructose-6-phosphate aminotransferase, isomerizing (17); hexose-phosphate aminotransferase (17); insulin (18); lathosterol oxidase (19); lipase (20); lipoprotein lipase, via inhibition of the activation of the enzyme (21); phosphoenolpyruvate carboxykinase (22); protein-glutamine γ-glutamyl-transferase, *or* transglutaminase (23); protein phosphatase (24); and urease (25). 1. ### Tolcapone

This orally bioavailable nitrocatechol (FW = 273.25 g/mol; CAS 134308-13-7; Soluble to 100 mM in ethanol and to 100 mM in DMSO), also known as Ro 40-7592, inhibits catechol *O*-methyltransferase (1,2) and is an FDA-approved drug in the treatment of Parkinson Disease. Tolcapone also binds

specifically to transthyretin (TTR) in human plasma ( $K_{d1} = 21$  nM;  $K_{d2} = 58$  nM), stabilizing the native tetramer *in vivo* in mice and humans and inhibiting TTR cytotoxicity. Crystal structures of tolcapone bound to wild-type TTR and to the V122I cardiomyopathy-associated variant show that it docks better into the TTR T4 pocket than tafamidis, the only drug on the market for treating TTR amyloidosis (3). (See *Tafamidis*) Already in clinical trials for familial amyloid polyneuropathy, tolcapone is a strong candidate for therapeutic intervention in such diseases, including those affecting the central nervous system (3). 1. Bonifácio, Palma, Almeida & Soares-da-Silva (2007) *CNS Drug Reviews* **13**, 352. 2. Zürcher, Keller, Kettler, *et al.* (1990) *Adv. Neurol.* **53**, 497. 3. Sant'Anna, Gallego, Robinson, *et al.* (2016) *Nature Commun.* **7**, 10787.

#### Tolfenamate

This oral nonsteroidal anti-inflammatory drug ( $FW_{\text{free-acid}} = 261.71$  g/mol; CAS 13710-19-5), also named 2-[(3-chloro-2-methylphenyl)amino] benzoate, is a derivative of anthranilic acid that inhibits COX, thereby blocking prostaglandin biosynthesis. **Target(s):** aromatic-amino-acid decarboxylase (1);  $Ca^{2+}$  influx (2); cyclooxygenase (3-7); phenol sulfotransferase (8); and thiopurine *S*-methyltransferase (9). 1. Pribova, Gregorova & Drsata (1992) *Pharmacol. Res.* **25**, 271. 2. Kankaanranta, Wuorela, Siltaloppi, *et al.* (1995) *Eur. J. Pharmacol.* **291**, 17. 3. Ricketts, Lund & Seibel (1998) *Amer. J. #### Tolnaftate

This nonprescription thiocarbamate-based antifungal ( $FW = 307.42$  g/mol; CAS 2398-96-1), also known as *O*-2-naphthyl methyl(3-methylphenyl)thiocarbamate and Tinactin™, inhibits the biosynthesis of sterols, an essential component of fungal membranes (1). Tolnaftate is essentially insoluble in water and soluble in organic solvents (*e.g.*, chloroform and acetone). **Target(s):** aflatoxin biosynthesis (2); and squalene monooxygenase, or squalene epoxidase (3-5). 1. Robinson & Raskin (1965) *Arch. Dermatol.* **91**, 372. 2. Khan, Maggon & Venkatasubramanian (1978) *Appl. Environ. Microbiol.* **36**, 270. 3. Favre & Ryder (1996) *Antimicrob. Agents Chemother.* **40**, 443. 4. Barrett-Bee & Dixon (1995) *Acta Biochim. Pol.* **42**, 465. 5. Georgopapadakou & Bertasso (1992) *Antimicrob. Agents Chemother.* **36**, 1779.

**Tolonium Chloride, See Toluidine Blue O**

#### Toloxatone

This orally bioavailable antidepressant ( $FW = 207.23$  g/mol; CAS 29218-27-7), also known as 5-hydroxymethyl-3-*m*-tolylloxazolidin-2-one, reversibly inhibits monoamine oxidase A, or MAO (1). After administration of tolaxatone, cerebral concentrations of MAO substrates noradrenaline, dopamine and 5-hydroxy-tryptamine increased, whereas their metabolite concentrations were reduced (2). Synaptosomal uptake processes of these amines were not changed by tolaxatone. 1. Coston, Gouret & Raynaud (1975) *Therapie* **30**, 725. 2. Keane, Kan, Sontag & Benedetti (1979) *J. Pharm. Pharmacol.* **31**, 752.

#### Tolserine

This cymserine analogue ( $FW_{\text{free-base}} = 351.45$  g/mol) crosses the blood-brain barrier and inhibits acetylcholine esterase and butyrylcholinesterase ( $IC_{50} = 10.3$  and  $1950$  nM, respectively) and is used in the treatment of individuals with Alzheimer's disease. **Target(s):** acetylcholinesterase (1,2); and cholinesterase, or butyrylcholinesterase (1,3). 1. Yu, Holloway, Utsuki, Bossi & Greig (1999) *J. Med. Chem.* **42**, 1855. 2. Kamal, Greig, Alhomida & Al-Jafari (2000) *Biochem. Pharmacol.* **60**, 561. 3. Cerasoli, Griffiths, Doctor, *et al.* (2005) *Chem. Biol. Interact.* **157-158**, 363.

#### Tolterodine

This muscarinic receptor antagonist ( $FW_{\text{L-tartrate-Salt}} = 475.57$  g/mol; CAS 124937-52-6), also named 2-[(1*R*)-3-[bis(1-methylethyl)amino]-1-phenylpropyl]-4-methylphenol, is active at all muscarinic receptors (*i.e.*, subtypes  $M_1$  through  $M_5$ ), showing  $K_i$  values of  $\sim 3$  nM. Tolterodine exhibits a greater effect on the bladder than salivary glands *in vivo*. Radioligand binding experiments showed that tolterodine binds with high affinity to muscarinic receptors in urinary bladder ( $K_i = 2.7$  nM), heart ( $K_i = 1.6$  nM), cerebral cortex ( $K_i = 0.75$  nM) and parotid gland ( $K_i = 4.8$  nM) from guinea pigs and in urinary bladder from humans ( $K_i = 3.3$  nM). This muscarinic receptor antagonist is intended for the treatment of urinary urge incontinence and other symptoms related to an overactive bladder. 1. Nilvebrant, Andersson, Gillberg, Stahl & Sparf (1997) *Eur. J. Pharmacol.* **327**, 195.

#### Toluene-3,4-dithiol

This reagent ( $FW = 156.27$  g/mol; MP =  $31^\circ\text{C}$ ; soluble in benzene and modestly alkaline solutions), also called 1,2-dimercapto-4-methylbenzene, 3,4-dimercaptotoluene, 3,4-dithioltoluene, binds heavy metal ions to form colored complexes that are slightly soluble in water. This reagent is also used in the detection of metals such as bismuth, molybdenum, rhenium, tin, and tungsten, and one should anticipate that toluene-3,4-dithiol would inhibit a number of metalloproteins. **Target(s):** alcohol dehydrogenase, yeast (1); carbonic anhydrase (2); cyclooxygenase (3); endothelin-converting enzyme (4,5); and lipoygenase (3,6,7). 1. Sund & Theorell (1963) *The Enzymes*, 2nd ed. (Boyer, Lardy & Myrback, eds.), **7**, 25. 2. Davis (1961) *The Enzymes*, 2nd ed. (Boyer, Lardy & Myrback, eds.), **5**, 545. 3. **2-(p-Toluidino)-6-naphthalenesulfonate**

This substituted naphthalene (FW<sub>potassium salt</sub> = 351.47 g/mol), abbreviated as TNS and also known as 6-(p-toluidino)-2-naphthalenesulfonate, is a frequently used extrinsic fluorescent probe, especially in conformational studies, e.g., fluoresces strongly when bound to hydrophobic regions (1). TNS has also been used to assess binding of inhibitors to proteins, e.g., binding of pesticides to glutathione S-transferase (2). **Target(s):** alcohol dehydrogenase (3); chymotrypsin (4); firefly luciferase, or luciferin 4-monooxygenase (5); and pyruvate decarboxylase (6). **1.** McClure & Edelman (1966) *Biochemistry* **5**, 1908. **2.** Di Ilio, Sacchetta, Iannarelli & Aceto (1995) *Toxicol. **2-p-Toluidynaphthalene-6-sulfonate, See 2-(p-Toluidino)-6-naphthalenesulfonate**

**Toluquinone**

This quinone (FW = 122.12 g/mol; MP = 67-70°C), also known as methyl-1,4-benzoquinone, inhibits alkaline phosphatase (1); α-amylase (2); β-amylase (2); catalase (3); α-glycerophosphatase (4); homogentisate oxidase, or homogentisate 1,2-dioxygenase (5); papain (6); pyruvate decarboxylase (7); succinate dehydrogenase (8); and succinate oxidase (8,9). **1.** Anderson (1961) *Biochim. **Tolvaptan**

This potent and orally active, vasopressin receptor antagonist (FW = 448.95 g/mol; CAS 150683-30-0; Solubility: 90 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known by the code name OPC-41061 and systematically named N-(4-[(5R)-7-chloro-5-hydroxy-2,3,4,5-tetrahydro-1H-1-benzazepin-1-yl]carbonyl)-3-methylphenyl-2-methylbenzamide, selectively and competitively targets Arginine Vasopressin Receptor 2 (or AVP2), with an IC<sub>50</sub> value of 1.28 μM for inhibition of AVP-induced platelet aggregation. OPC-41061 antagonizes [<sup>3</sup>H]-AVP binding to human V2-receptors (K<sub>i</sub> = 0.43 nM) more potently than AVP (K<sub>i</sub> = 0.78 nM) or OPC-31260 (K<sub>i</sub> = 9.42 nM). OPC-41061 also inhibited [<sup>3</sup>H]-AVP binding to human V1a-receptors (K<sub>i</sub> = 12.3 nM) but not to human V1b-receptors, indicating that OPC-41061 was 29 times more selective for V2-receptors than for V1a-receptors (2). Tolvaptan induces free water excretion without increasing sodium excretion, safely correcting mild or moderate hyponatremia in patients with syndrome of inappropriate secretion of antidiuretic hormone (SIADH). **1.** Yamamura,

Nakamura, Itoh, *et al.* (1998) *J. Pharmacol. Exp. Ther.* **287**, 860. **2.** Kondo, Ogawa H, Yamashita, *et al.* (1999) *Bioorg. Med. Chem.* **7**, 1743.

**Tomoxetine, See Atomoxetine**

**Tomudex, See Raltitrexed**

**Topa, See 2,4,5-Trihydroxyphenylalanine**

**Topiramate**

This orally active and structurally novel antiepileptic drug (FW = 339.36 g/mol; CAS 97240-79-4; Soluble to 100 mM in DMSO), also known as McN-4853 and RWJ-17021 and named systematically as 2,3:4,5-bis-O-(1-methylethylidene)-β-D-fructopyranose sulfamate, has at least five distinct modes of action: (a) modulation of the blocking of voltage-activated sodium ion channels; (b) potentiation of GABA-mediated inhibition of neurotransmission; (c) antagonism of APMA glutamate receptors; (d) inhibition of L-type calcium ion channels, and (e) inhibition of carbonic anhydrase isozymes II (K<sub>i</sub> = 0.2 μM) and IV (K<sub>i</sub> = 0.2 μM), thereby lowering intraneuronal pH. In mice pretreated with a cytochrome P450 enzyme inhibitor (SKF-525A), TPM's anticonvulsant potency was either increased or unaffected 0.5-2 h post-i.p. administration, suggesting topiramate itself (and not a derived metabolite) is likely to be the active agent. **1.** Maryanoff, Nortey, Gardocki, Shank & Dodgson (1987) *J. Med. Chem.* **30**, 880. **2.** Shank, Gardocki, Vaught *et al.* (1994) *Epilepsia* **35**, 450. **3.** Taverna, Sancini, Mantegazza, Franceschetti & Avanzini (1999) *J. Pharmacol. Exp. Ther.* **288**, 960.

**Torcetrapib**

This CETP inhibitor (FW = 600.47 g/mol; CAS 262352-17-0) targets cholesterylester transfer protein (CETP), EC<sub>50</sub> = 43 nM, which transfers cholesterol from HDL cholesterol to very low density lipoproteins (VLDL) or low density lipoproteins (LDL), thereby raising HDL levels (1). Significantly, CETP inhibition by torcetrapib increased with escalating dose, leading to elevations of HDL-C of 16% to 91%. It binds specifically to CETP with 1:1 stoichiometry and blocks both neutral lipid and phospholipid (PL) transfer activities. Torcetrapib increases CETP affinity for HDL by ~5x, most likely representing a shift to a lipid transfer-impermissive binding state (2). When used alone, torcetrapib reduces VLDL, IDL, and LDL apoB100 levels primarily by increasing the rate of apoB100 clearance (3). In contrast, when added to atorvastatin treatment, torcetrapib reduces apoB100 levels mainly by enhancing VLDL apoB100 clearance and reducing production of IDL and LDL apoB100 (3). The ambitious Phase-III ILLUMINATE study, which enrolled 15000 subjects, was designed to determine the clinical outcome of raising HDL by torcetrapib (60 mg) plus atorvastatin versus atorvastatin alone (10 to 80 mg). The study was abruptly terminated in view of an excess of deaths in the torcetrapib/atorvastatin versus atorvastatin groups (82 versus 51, respectively) and upon noting increased heart failure and angina for those on the drug combination (4). A novel, non-tetrahydroquinoline-containing torcetrapib analogue shows improved aqueous solubility (5). **1.** Clark, Sutfin, Ruggeri, *et al.* (2004) *Arterioscler. Thromb. Vasc. ### Topotecan

This water-soluble camptothecin derivative and antineoplastic agent (FW<sub>free</sub> = 421.45 g/mol; CAS 119413-54-6; Solubility: 90 mg/mL DMSO, 90 mg/mL Water, <1 mg/mL), also known as Hycamtin, NSC 609699, and systematically as (*S*)-10-[(dimethylamino)methyl]-4-ethyl-4,9-dihydroxy-1*H*-pyrano[3',4':6,7]indolizino[1,2-*b*]quinolone-3,14(*4H*,12*H*)-dione monohydrochloride, inhibits DNA topoisomerase I (1,2). This highly effective topoisomerase I inhibitor for MCF-7 Luc cells and DU-145 Luc cells with IC<sub>50</sub> values of 13 nM and 2 nM, respectively. Topotecan inhibition of poly(ADP-ribose) polymerase-1 converts PARP1 into a dominant-negative molecule that poisons the ability of DNA repair machinery to participate in either PARP1-dependent or PARP1-independent repair of topotecan-induced DNA damage (3). 1. Iyer & Ratain (1998) *Cancer Chemother. Pharmacol.* **42** Suppl., S31. 2. Kingsbury, Boehm, Jakas, *et al.* (1991) *J. Med. Chem.* **34**, 98. 3. Patel, Flatten, Schneider, *et al.* (2012) *J. Biol. Chem.* **287**, 4198.

### Torbafylline

This xanthine derivative (FW = 338.40 g/mol; CAS 105102-21-4), also named and 7-(ethoxymethyl)-1-(5-hydroxy-5-methylhexyl)-3-methyl-3,7-dihydro-1*H*-purine-2,6-dione and HWA-448, inhibits proteasome-mediated proteolysis and prevents accumulation of polyubiquitinated proteins in the myofibrillar fraction of muscles from cachectic rats, supporting the idea that the Ub pathway degrades actin and myosin. HWA 448 did not alter peripheral blood mononuclear cell viability, and has a longer serum half-life and presumably lower toxicity than pentoxifylline, which is commonly used in humans (See *Pentoxifylline*). 1. Combaret, Tilignac, Claustre, *et al.* (2002) *Biochem. J.* (2002) **361**, 185.

### Toremifene

This orally active selective estrogen receptor modulator, or SERM (FW = 405.97 g/mol; CAS 89778-26-7), also named 2-{4-[(1*Z*)-4-chloro-1,2-diphenyl-but-1-en-1-yl]phenoxy}-*N,N*-dimethylethanamine, is a tamoxifen derivative that competitively inhibits [<sup>3</sup>H]estradiol binding to to the Estrogen Receptor (IC<sub>50</sub> = 0.3 μM), reducing MCF-7 cell growth in a concentration-dependent manner and exhibiting cell-killing effects above 3 μM (1). (Marketed in the United States under the trade name Fareston®, toremifene is FDA-approved for use in advanced (metastatic) breast cancer.) The overall pharmacokinetic profile is remarkably similar to tamoxifen. Toremifene is

highly metabolized in the liver and is eliminated primarily in the feces following enterohepatic circulation. Some metabolites retain biological activity. Toremifene inhibits the growth of ER-negative, glucocorticoid sensitive, mouse uterine sarcoma in a dose-dependent manner. Its pharmacokinetics and metabolism resemble those of tamoxifen, but this chlorinated drug forms different metabolites. See also *Tamoxifen*; *Lasofloxifene* 1. Kangas (1990) *J. Steroid Biochem.* **36**, 191.

### Torin-1

This potent, cell-permeable, and ATP-competitive mTOR inhibitor (FW = 607.64 g/mol; CAS 1222998-36-8; Solubility = 2 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also named 1-[4-[4-(1-oxopropyl)-1-piperazinyl]-3-(trifluoromethyl)phenyl]-9-(3-quinolinyl)benzo[*h*]-1,6-naphthyridin-2(1*H*)-one, targets the mammalian target of rapamycin complexes, designated mTORC1 and mTORC2, with IC<sub>50</sub> of 2 nM and 10 nM, respectively, while exhibiting 1000x lower action against PI3K (1). **Mode of Inhibitory Action:** mTORC1 integrates mitogen and nutrient signals to control cell proliferation, size, cell cycle progression, and viability. Rapamycin is a potent allosteric inhibitor of mTORC1 with promising clinical applications as an immunosuppressant and anti-cancer agent. Torin1 directly inhibits both complexes, impairing cell growth and proliferation to a far greater degree than achievable with rapamycin (2). These effects are independent of mTORC2 inhibition and are instead, because of suppression of rapamycin-resistant functions of mTORC1 required for cap-dependent translation and suppression of autophagy (2). Notably, mTORC1 inhibition by rapamycin (a mTORC1 inhibitor), torin-1 (targeting both mTORC1 and mTORC2) or short hairpin RNA-mediated knockdown of mTOR, regulatory associated protein of mTOR (RAPTOR), and p70 S6 kinase (p70S6K), all increased basal NT release via upregulating NT gene expression in the human endocrine cell line BON cells. (3). mTORC1-specific inhibition helped to demonstrate that control of cell size and cell cycle progression appear to be independent in mammalian cells, whereas in lower eukaryotes, translation initiation factor 4E-binding proteins (4E-BPs) influence both cell growth and proliferation (4). 1. Liu, Chang, Wang, *et al.* (2010) *J. Med. Chem.* **53**, 7146. 2. Thoreen, Kang, Chang, *et al.* (2009) *J. Biol. Chem.* **284**, 8023. 3. Li, Liu, Song, *et al.* (2011) *Am. J. Physiol. ### Tosufloxacin

This fluoroquinolone-class antibiotic (FW = 404.34 g/mol; CAS 100490-36-6), also named Ozex® (marketed in Japan) and 7-(3-aminopyrrolidin-1-yl)-1-(2,4-difluorophenyl)-6-fluoro-4-oxo-1,4-dihydro-1,8-naphthyridine-3-carboxylate, is a broad-spectrum systemic antibacterial agent that targets Type II DNA topoisomerases (gyrases), which are required for bacterial replication and transcription (1). Depending on dosage, tosufloxacin can cause severe thrombocytopenia and nephritis (2). For the prototypical member of this antibiotic class, See *Ciprofloxacin* 1. Niki (2002) *J. Infect. Chemother.* **8**, 1. 2. Rubinstein (2001) *Chemotherapy* **47** (Supplement 3), 3.

**N<sup>ε</sup>-(p-Tosyl)-L-lysine Chloromethyl Ketone**

This widely used halo ketone-based protease inhibitor (FW<sub>hydrochloride</sub> = 369.31 g/mol), abbreviated TLCK also known as 1-chloro-3-tosylamido-7-amino-L-2-heptanone, was a product of the pioneering work of biochemist Eliot Shaw, who in the mid-1960s developed specific active-site-directed irreversible inhibitors of trypsin and trypsin-like enzymes (1-3). TLCK alkylates the histidyl residue in trypsin's catalytic triad. *Note:* This reagent also inhibits some enzymes reversibly, e.g., butyrylcholinesterase (4). TLCK also alkylates the sulfhydryl group in picornain 3C. Because this reagent is unstable above pH 7.5, stock solutions (10 mM) are prepared by dissolving TLCK in 1.0 mM HCl or methanol. **Target(s):** acrosin (5-8,130,164-168); adenain (94,96,97, however, see 95); adenosine deaminase, or RNA-adenosine deaminase (82); adenylate cyclase (9,10); AMP deaminase, *Candida albicans* (81);  $\alpha$ -amylase (182); arylesterase (186); arylsulfate sulfotransferase (80); *Aspergillus oryzae* aminoacylase (11); assemblin, herpesvirus (12); *N*-benzoyl-D-arginine-4-nitroanilide amidase (84); bleomycin hydrolase (93); brachyurins (13,159-162); bromelain, stem (14-17); butyrylcholinesterase (4); Ca<sup>2+</sup>-independent endoprotease (18); calpain-1, or  $\mu$ -calpain (89); calpain-2, or *m*-calpain (88,89); cAMP-dependent protein kinase (19); carboxylesterase (187); carboxypeptidase C, weakly inhibited (175,176); carboxypeptidase D (174); cathepsin B (118-128); cathepsin H (106-110); cathepsin L (111-115); cathepsin T (20,21,105); cephalosporin-C deacetylase (185); cGMP-dependent protein kinase (22); clostripain (6,23,24,116,117); cocoonase (6,25); complement subcomponent C1r, or moderately inhibited (157); crotalase (26); cruzipain (27); cystinyl aminopeptidase (181); *Dictyostelium discoideum* cysteine proteinase-7 (28); enteropeptidase (29,169);  $\alpha$ -velysin, weakly inhibited (87); *Fasciola* cysteine endopeptidases (30); ficain, or ficin (16,31,32); furin (139); gabonase, or venombin AB (33,151); gametolysin, weakly inhibited (86); *Giardia lamblia* proteinase (34); gingipain K (90-92); gingipain R (91,92,98); glucose-6-phosphatase (35); glucose-6-phosphate translocase (183);  $\gamma$ -glutamyl transpeptidase, or  $\gamma$ -glutamyltransferase (190,191); granzyme K (36); hepacivirin, or hepatitis C virus NS3 serine proteinase (131-133); histolysin, or histolysin (99); HtrA2 peptidase (129); kallikrein, urinary (37); lactosylceramide  $\alpha$ -2,3-sialyltransferase (189); leukocyte elastase, weakly inhibited (158); Lysophospholipase (38); *Locusta migratoria* serine proteinases (39,40); lysyl endopeptidase (41,152-156); 3-mercaptopyruvate sulfurtransferase (188); *Metarhizium anisopliae* cuticle-degrading protease (42); 5-methyltetrahydropteroyltriglutamate:homocysteine *S*-methyltransferase (193); mitochondrial intermediate peptidase (85); mouse submandibular nerve growth factor protease, possibly  $\gamma$ -renin (43); non-acrosin *p*-aminobenzamidine-sensitive acrosomal protease (44); okinaxobin II (150); oligopeptidase B (45-47,135-137); pancreatic elastase II (140); papain (3,16,17,48-51); peptidyl-glycinamidase, or carboxamidopeptidase

#### N<sup>α</sup>-(p-Tosyl)-DL-norleucine Diazomethyl Ketone

This active site-directed irreversible inhibitor (FW = 310.39 g/mol), also known as DL-1-diazo-3-tosylamido-2-heptanone, inhibits aspergillopepsin I and II, with concomitant covalent incorporation of approximately two

molecules per molecule of protein. 1. Chang, Horiuchi, Takahashi, Yamasaki & Yamada (1976) *J. Biochem.* **80**, 975.

#### N<sup>α</sup>-(p-Tosyl)-L-phenylalanine Chloromethyl Ketone

This widely used halo ketone-based protease inhibitor (FW = 351.85 g/mol; CAS 329-30-6; Symbol: TPCK; also known as (S)-1-chloro-3-tosylamido-4-phenyl-2-butanone and L-(1-tosylamido-2-phenyl)ethylchloro-methyl ketone, was a product of the pioneering work of biochemist Eliot Shaw, who in the mid-1960s developed specific active-site-directed irreversible inhibitors of chymotrypsin and chymotrypsin-like enzymes, via alkylation of the catalytic histidyl residue (1-4). TPCK also reportedly alkylates the SH group in picornain 3C protease. TPCK also blocks apoptosis (typically by inactivating the caspase "death" cascade); however, TPCK-modified caspase-11 still activates Aip1:cofilin-mediated (-)-end actin filament depolymerization and cell motility (5). *Note:* This chloromethyl ketone inhibits some enzymes reversibly, e.g., butyrylcholinesterase (6). **Target(s):** acid carboxypeptidases (7); adenain (71,73-75), however, see (72); aminopeptidase B (8); aminopeptidase I, weakly inhibited (124); aminotripeptidase (9); assemblin, herpesvirus (10); brachyurin, or *Paralithodes camtschatica* protease C (110); bromelain, stem (4,11-13); butyrylcholinesterase (6); calpain-2, or m-calpain (69); carboxylesterase (129,130); carboxypeptidase C (7,119,120); cathepsin B (7,88-96); cathepsin G (14,113,114); cathepsin H (81-84); cathepsin L (85,86); chymase, inhibited slowly (15,16,107,108); chymotrypsin (1-5,7,17-21,116,117); chymotrypsin C, or caldecrin (22); clostripain, weakly inhibited (87); *Coccidioides* endopeptidase (23); cystinyl aminopeptidase (127); *Dictyostelium discoideum* cysteine proteinase-7 (24); dipeptidyl-peptidase III (121,122); elongation factor, thus, inhibiting protein synthesis (25-32); endopeptidase La (106); endopeptidase So (33,34,102); envlysin (64-66); ficain, or ficin (4,35); gametolysin, weakly inhibited (62); *Giardia lamblia* proteinase (36); gingipain K (70); gingipain R (76); glucose-6-phosphatase (37); glucose-6-phosphate translocase (128); glutamyl endopeptidase II (100);  $\gamma$ -glutamyl transpeptidase, or  $\gamma$ -glutamyltransferase (132); glycerophospholipid arachidonyltransferase, CoA-independent (134); *hepacivirin*, *orhepatitis* C virus NS3 serine proteinase (97-99); histolysin, or histolysin (77); 2-hydroxyruconate-semialdehyde hydrolase (38); isoprenylated protein endopeptidase (39,40); kinin inactivating serine endopeptidase H2, or kininase (41,42); lactosylceramide  $\alpha$ -2,3-sialyltransferase (131); legumain (78); firefly luciferase, or *Photinus*-luciferin 4-monooxygenase (4,30,43); membrane alanyl aminopeptidase (121); 5-methyltetrahydropteyl-triglutamate:homocysteine S-methyltransferase (135); metridin (18,44,115); mitochondrial intermediate peptidase (61); nardilysin (45); omptin (23,67); pancreatic elastase II (109); papain (4,7,13,46-48); peptidyl-glycinamidase, or carboxamidopeptidase (118); picornain 2A (79,80); picornain 3C (49-51); polyporopepsin (68); prolyl aminopeptidase, or weakly inhibited (125); prolyl oligopeptidase (111,112); proteasome endopeptidase complex (52,53); proteinase I of *Sulfolobus solfataricus* (54); proteinase II of *Sulfolobus solfataricus* (54); semenogelase (55,101); subtilisin Sendai (103); thimet oligopeptidase, weakly inactivated (63); thromboxane synthase (56); trepolisin (57); tricorn protease (58); tripeptide aminopeptidase (126); tryptase, or weakly inhibited (104,105); tsp protease, or protease Re (34); tulip mosaic virus N1a protease (59); tymovirus endopeptidase (60); vignain (78); vinorine synthase (133); Xaa-His Dipeptidase, or carnosinase, weakly inhibited (123). 1. **Toxin A, *Pseudomonas aeruginosa***, See *Pseudomonas Exotoxin A*

#### **$\alpha$ -Toxin, *Clostridium perfringens***

This toxic zinc metalloenzyme (MW = 45,545 g/mol; GenBank: CAA35186.1), or Alpha Toxin, is a phospholipase C [Reaction: Phosphatidylinositol 4,5-bisphosphate (PIP<sub>2</sub>) + H<sub>2</sub>O → Diacylglycerol (DAG) + Inositol 1,4,5-trisphosphate (IP<sub>3</sub>)] from *Clostridium perfringens*, the anaerobic pathogen responsible for gas gangrene and myonecrosis in infected tissues. The cytokine storm induced by  $\alpha$ -toxin (mainly via the release of TNF- $\alpha$ ), plays an important role in the death and massive hemolysis. The toxin-induced release of TNF- $\alpha$  from neutrophils and macrophages is dependent on the activation of ERK1/2 signal transduction via the TrkA receptor (1). Significantly, there is complete suppression of  $\alpha$ -toxin activity by tetracycline, when *C. perfringens* is treated with metronidazole, rifampin, clindamycin, and chloramphenicol at concentrations equal to their respective MIC values, whereas  $\alpha$ -toxin activity persists at concentrations of penicillin equal to and above the MIC (2). **1.** Oda, Shihara, Ohmae, et al. (2012) *Biochim. Biophys. Acta* **1822**, 1581. **2.** Stevens, Maier & Mitten (1987) *Antimicrob. Agents Chemother.* **31**, 213.

**$\alpha$ -Toxin, *Staphylococcus aureus***, See  *$\alpha$ -Hemolysin, *Staphylococcus aureus**

#### **Toxoflavin**

This flavin-like yellow pigment (FW = 193.16 g/mol; CAS 84-82-2;  $E_0' = -0.049$  Volt), named systematically as 1,6-dimethylpyrimido[5,4-e][1,2,4]triazine-5,7(1H,6H)-dione, was first isolated from *Bacterium bongkreke* in 1934. Through the use of high-throughput screening (HTS), toxoflavins and deazaflavins were identified as the first reported sub-micromolar, selective inhibitors of the recently discovered enzyme tyrosyl-DNA phosphodiesterase 2 (TDP2), which has been implicated in the topoisomerase-mediated repair of DNA damage. **1.** Raouf, Depledge, Hamilton, et al. (2013) *J. Med. Chem.* **56**, 6352.

#### **Toyocamycin**

This antifungal antibiotic (FW = 291.27 g/mol; CAS: 606-58-6; Soluble to 100 mM in DMSO) also known as Antibiotic 1037 and 4-amino-7- $\beta$ -D-ribofuranosyl-7H-pyrrolo[2,3-d]pyrimidine-5-carbonitrile, isolated from *Streptomyces toyocaensis* (1), inhibits specific RNA self-cleavage, EC<sub>50</sub> = 0.18  $\mu$ M (Compare to 8-azadenosine, EC<sub>50</sub> = 3.6  $\mu$ M; Sangivamycin, EC<sub>50</sub> = 1.1  $\mu$ M; Tubericidin, EC<sub>50</sub> = 2.5  $\mu$ M; EC<sub>50</sub> = 2.5  $\mu$ M; Tubericidin monophosphate, EC<sub>50</sub> = 2.2  $\mu$ M; tubericidin triphosphate, EC<sub>50</sub> = 1.9  $\mu$ M; Nebularine, EC<sub>50</sub> = 10.2  $\mu$ M; Tricyclic nucleotide, EC<sub>50</sub> = 39.5  $\mu$ M) (2). It also suppresses thapsigargin-, tunicamycin- and 2-deoxyglucose-induced X-Box-binding Protein-1 (XBP1) mRNA splicing in HeLa cells without affecting activating transcription factor 6 (ATF6) and PKR-like ER kinase (PERK) activation (3). (Note: XBP1 acts as a transcription factor during endoplasmic reticulum (ER) stress by regulating the unfolded protein response, or UPR. Indeed, the IRE1 $\alpha$ -XBP1 pathway is a key component of ER stress response and is considered to be a critical regulator for survival of multiple myeloma (MM) cells.) Furthermore, although toyocamycin cannot inhibit IRE1 $\alpha$  phosphorylation, it prevents IRE1 $\alpha$ -induced XBP1 mRNA cleavage *in vitro*. Thus, toyocamycin is an inhibitor of IRE1 $\alpha$ -induced XBP1 mRNA cleavage (3). Toyocamycin inhibits not only ER stress-induced but also constitutive activation of XBP1 expression in MM lines as well as primary samples from patients. It shows synergistic effects with bortezomib, and induced apoptosis of MM cells including bortezomib-resistant cells at nanomolar levels in a dose-dependent manner (3). It also inhibits growth of xenografts in an *in vivo* model of human MM (3). **Target(s):** adenosine kinase, also weak alternative substrate (4); 1-phosphatidylinositol 4-kinase (5); rhodopsin kinase (6); and rRNA maturation (7-9). **1.** Aszalos, Lemanski, Robison, Davis & Berk (1966) *J. ## TPCA-1

This signal transduction inhibitor and antineoplastic agent (FW = 279.29 g/mol; CAS 507475-17-4; Solubility: 50 mg/mL DMSO; <1 mg/mL Water), systematically named 2-[(aminocarbonyl)amino]-5-(4-fluoro-phenyl)-3-thiophenecarboxamide, targets IKK-2 (inhibitor of nuclear factor  $\kappa$ -B kinase) with  $IC_{50}$  of 17.9 nM. TPCA-1 exhibits  $IC_{50}$  values of 400 and 3600 nM, respectively, against IKK-1 and JNK3. It also inhibits the production of TNF- $\alpha$ , IL-6, and IL-8 in a concentration-dependent manner, with respective  $IC_{50}$  values of 170, 290, and 320 nM (1). TPCA-1 inhibits glioma cell proliferation, as well as TNF-induced RelA (p65) nuclear translocation and NF $\kappa$ B-dependent IL8 gene expression. TPCA-1 also inhibits IFN-induced gene expression, completely suppressing MX1 and GBP1 gene expression, with only a minor effect on ISG15 expression (2). 1. Podolin, *et al.* (2005) *J. Pharmacol. Exp. Ther.* **312**, 373. 2. Du, *et al.* (2012) *J. Interferon Cytokine Res.* **32**, 368.

## TRAM-34

This clotrimazole-like ion channel blocker (FW = 344.84 g/mol; CAS 289905-88-0; Soluble to 2 mg/mL in DMSO; Water-insoluble), also named 1-[(2-chlorophenyl)diphenylmethyl]-1H-pyrazole, is a potent inhibitor of the intermediate-conductance  $Ca^{2+}$ -activated  $K^{+}$  channel,  $IC_{50}$  = 20 nM (1). Based on the use of the ratioetric calcium indicator Fura-2 AM, TRAM-34 was found to increase the frequency of rhythmical depolarizations and  $[Ca^{2+}]_{intra-cellular}$  in smooth muscle cells (2). Structure-activity studies (3) suggest that the side chain methyl groups of Thr(250) and Val(275) may lock the triarylmethanes in place via hydrophobic interactions with the  $\pi$ -electron clouds of the phenyl rings. Importantly, TRAM-34's reported advantage over clotrimazole (*i.e.*, lack of cytochrome P450 inhibition) has been convincingly refuted by findings that TRAM-34 inhibits recombinant rat CYP2B1, CYP2C6 and CYP2C11 and human CYP2B6, CYP2C19 and CYP3A4 with  $IC_{50}$  values ranging from 0.9  $\mu$ M to 12.6  $\mu$ M, but is without effect on recombinant rat CYP1A2, human CYP1A2, or human CYP19A1 at TRAM-34 levels up to 80  $\mu$ M (4). TRAM-34 treatment inhibits proliferation of human endometrial cancer (EC) cells, and blocks EC cell cycle at G<sub>0</sub>/G<sub>1</sub> phase (5). 1. Wulff, Miller, Hansel, *et al.* (2000) *Proc. Natl. Acad. Sci. U.S.A.* **97**, 8151. 2. Haddock & Hill (2002) *J. Physiol.* **545** (Part 2), 615. 3. Wulff, Gutman, Cahalan & Chandy (2001) *J. Biol. Chem.* **276**, 32040. 4. ## Tramadol

This centrally acting analgesic (FW = 263.4 g/mol; CAS 27203-92-5), also known as Ultram<sup>®</sup>, Conzip<sup>®</sup>, Ryzolt<sup>®</sup>, and Ultracet<sup>®</sup> (when combined with paracetamol), as well as 2-[(dimethylamino)methyl]-1-(3-methoxyphenyl)-

cyclohexanol, is a orally, rectally, intravenously, epidurally or intramuscularly administered benzenoid-class opioid agonist that binds to the  $\mu$ -opioid receptor but exerts many other effects (1-3). Intravenous tramadol (50-150 mg) is equivalent in analgesic efficacy to morphine (5-15 mg) in patients with moderate post-operative pain (1). When administered epidurally, tramadol was one-thirtieth as potent as morphine. Orally administered tramadol is an effective analgesic at Step 2 of WHO guidelines for treating patients with cancer pain (1). Tramadol is also a norepinephrine reuptake inhibitor (3), a serotonin reuptake inhibitor and releasing agent (4-7), a NMDA receptor antagonist ( $IC_{50}$  = 16.5  $\mu$ M) (8), 5-HT<sub>2C</sub> receptor antagonist ( $EC_{50}$  = 26 nM) (9),  $\alpha$ 7-nicotinic acetylcholine receptor antagonist (10), TRPV1 receptor agonist (11), and muscarinic M<sub>1</sub> and M<sub>3</sub> acetylcholine receptor antagonist (12-13). Tramadol is rapidly distributed in the body; plasma protein binding is about 20%. It undergoes hepatic metabolism by cytochromes CYP2B6, CYP2D6 and CYP3A4, and one metabolite, *O*-demethyltramadol, has 200x the  $\mu$ -opioid receptor affinity of (+)-tramadol, with an elimination half-life of nine hours, compared with six hours for tramadol. Clinical experience suggests that tramadol has a low potential for abuse or addiction. 1. Lee, McTavish & Sorkin (1993) *Drugs* **46**, 313. 2. ## Trametinib

This orally bioavailable and selective protein kinase inhibitor (FW = 615.39 g/mol; CAS 871700-17-3; Solubility: 5 mg/mL DMSO, <1 mg/mL Water; Drug Formulation: Dissolve in 10% Cremophor EL - 10% PEG400), also known as JTP-74057, GSK1120212 and Mekinist<sup>®</sup>, targets mitogen-activated protein kinase kinase (*or* MEK, *or* MAP2K) and is indicated for treatment of unresectable or metastatic melanoma with BRAF<sup>V600E</sup> or BRAF<sup>V600K</sup> mutation. Trametinib inhibits the phosphorylation of myelin basic protein, regardless of the Raf and MEK isotype, with  $IC_{50}$  values ranging from 0.92 nM to 3.4 nM, but does not inhibit c-Raf, B-Raf, ERK1 and ERK2 kinases. Attesting to its selectivity, GSK1120212 show weak or no inhibitory potential toward 98 other protein kinases. In enzymatic and cellular studies, GSK1120212 inhibits MEK1/2 kinase activity and prevents Raf-dependent MEK phosphorylation (at Ser-217 for MEK1), producing prolonged p-ERK1/2 inhibition (1). Potent cell growth inhibition was evident in most tumor lines with mutant BRAF or Ras. In xenografted tumor models, GSK1120212 orally dosed once daily had a long circulating half-life and sustained suppression of p-ERK1/2 for more than 24 hours; GSK1120212 also reduced tumor Ki67, increased p27(Kip1/CDKN1B), and caused tumor growth inhibition in multiple tumor models (1). The greatest antitumor effect was among tumors harboring mutant BRAF or Ras (1). In patients with advanced BRAF-mutated melanoma, treatment with a single daily oral dose of trametinib significantly decreased the rate of tumor progression by about 3 months, as compared with patients receiving cytotoxic chemotherapy (2). Significantly, trametinib exhibits antitumour activity in patients with BRAF<sup>K601E</sup> and BRAF<sup>L597Q</sup> mutation-positive metastatic melanoma (3). 1. **Trandolapril**

This ACE inhibitor and antihypertensive prodrug (FW<sub>free-acid</sub> = 430.54 g/mol; CAS 87679-37-6; MP = 125°C) is hydrolyzed physiologically to the active diacid trandolaprilat, a potent inhibitor of peptidyl-dipeptidase A, or angiotensin-converting enzyme, IC<sub>50</sub> = 0.93 nM, and exerting its antihypertensive effect through the renin-angiotensin-aldosterone system (1-6). **See Trandolaprilat** 1. Peters, Noble & Plosker (1998) *Drugs* **56**, 871. 2. Miyazaki, Kawamoto & Okunishi (1995) *Amer. J. Hypertens.* **8**, 63S. 3. Wiseman & McTavish (1994) *Drugs* **48**, 71. 4. **Trandolaprilat**

This dicarboxylic acid (FW<sub>free-acid</sub> = 402.49 g/mol; CAS 87679-71-8), formed by hydrolysis of trandolapril, is the primary agent in the inhibition of angiotensin I-converting enzyme (IC<sub>50</sub> = 0.93 nM (1-5) and protein biosynthesis (6). **See Trandolapril** 1. Corvol, Williams & Soubrier (1995) *Meth. Enzymol.* **248**, 283. 2. Wiseman & McTavish (1994) *Drugs* **48**, 71. 3. Conen & Brunner (1993) *Amer. Heart J.* **125**, 1525. 4. Uehara, Numabe, Kawabata, *et al.* (1993) *J. Hypertens.* **11**, 1073.

**Tranexamate (Tranexamic Acid)**

This antifibrinolytic agent (FW = 157.21 g/mol; CAS 1197-18-8; Solubility: 170 mg/mL H<sub>2</sub>O; Decomposes at 386-392°C), also called *trans*-4-(aminomethyl)cyclohexanecarboxylate, is a lysine analogue that blocks lysyl binding sites of plasminogen, thus inhibiting plasminogen activation (1). Tranexamic acid prevents plasmin binding to and preventing fibrinolysis, thereby stabilizing clots. Tranexamic acid possesses ~8x the antifibrinolytic activity of  $\epsilon$ -aminocaproic acid. **Target(s):** lysine carboxypeptidase, or lysine(arginine) carboxypeptidase, or carboxypeptidase N (2); plasmin (3-5); u-plasminogen activator, or urokinase (5). 1. Petersen, Brender & Suenson (1985) *Biochem. J.* **225**, 149. 2. Juillerat-Jeanneret, Roth & Bargetzi (1982) *Hoppe-Seyler's Z. Physiol. Chem.* **363**, 51. 3. Robbins & Summaria (1970) *Meth. **Tranilast**

This antiallergic, anti-inflammatory, and antiproliferative anthranilate derivative (FW<sub>free-acid</sub> = 327.34 g/mol; CAS 53902-12-8; Soluble in dimethyl sulfoxide; Photosensitive) potent inhibits vascular endothelial growth factor (VEGF-) and vascular permeability factor-induced angiogenesis as well as collagen synthesis. Tranilast inhibits VEGF- and PMA-stimulated (phorbol myristate acetate-stimulated) protein kinase C activity in retinal capillary endothelial cells without affecting the VEGF binding or VEGF receptor

phosphorylation. It induces Ca<sup>2+</sup> mobilization in vascular smooth muscle. **Note:** Whether the active agent is the *E* or *Z* geometric isomer remains unclear. **Target(s):** cyclin-dependent kinases Cdk2 and Cdk4 (1); glucuronosyltransferase (2); prostaglandin D synthase (3); thioltransferase (4); VEGF- and PMA-stimulated protein kinase C activity (5); and VEGF- and vascular permeability factor-induced angiogenesis and collagen synthesis (5-7). 1. **Trans-24**

This cell-permeable, mitotic inhibitor (FW = 423.47 g/mol; CAS 869304-55-2; Solubility: 10 mg/mL DMSO; Photosensitive), also known as (5*R*,11*aS*)-2-benzyl-5-(3-hydroxyphenyl)-6*H*-1,2,3,5,11,11*a*-hexahydroimidazo[1,5-*b*]β-carboline-1,3-dione, targets Eg5 (IC<sub>50</sub> = 650 nM), a mitotic kinesin that plays an essential role in centrosome separation and bipolar spindle formation. Unlike classical mitotic spindle poisons (*e.g.*, colchicine; vinblastine; podophyllotoxin, etc.), Trans-24 does not show any tendency to bind to tubulin. (**See also Monastrol**; HR22C16; Trityl-L-cysteine) 1. Sunder-Plassmann, Sarli, Gartner, *et al.* (2005) *Bioorg. Med. Chem.* **13**, 6094.

**Transplatin**

This light yellow solid (FW = 300.05 g/mol; CAS 14913-33-8), first synthesized by the Nobelist Alfred Werner, and also known as *trans*-diamminedichloroplatinum (II) and *trans*-dichlorodiammine platinum (II), forms slowly from cisplatin, a widely known anticancer drug (**See also Cisplatin**), in aqueous solutions. (**Note:** The *trans*-isomer is less soluble than the *cis* enantiomer.) While a weaker mutagen than cisplatin, transplatin interacts with DNA, but produces different adducts (*i.e.*, cisplatin forms 1,2-intrastrand crosslink's, whereas transplatin displays a greater variation in nucleobase donor sites). The 1,2-intrastrand adducts produced by cisplatin causes DNA kinking and leads to thermal destabilization. The effects of transplatin adducts are of greater variability, causing either thermal stabilization or destabilization. **Target(s):** adenosylhomocysteinase, or S-adenosyl-homocysteinase (1); chymotrypsin (2); dihydropteridine reductase (3); glyceraldehyde-3-phosphate dehydrogenase (4); lactate dehydrogenase (5); peroxidase (2); ribonucleoside-diphosphate reductase, weakly inhibited (6); thioredoxin reductase (7); thymidylate synthase (8); and trypsin (2). 1. **Transvaalin, See Scillaren A****Tranlycypromine**

This membrane-penetrating antidepressant/anxiolytic agent (FW<sub>free-base</sub> = 133.19 g/mol; CAS 95-62-5; Soluble to 100 mM in water and to 100 mM in

DMSO; Abbreviation: 2-PCPA), also known by its systematic name, (1*R*,2*S*)-*trans*-2-phenylcyclopropylamine, code name SKF *trans*-385, and trade names Parnate<sup>®</sup> and Jatrosom<sup>®</sup> (in Germany), is a mechanism-based, irreversible inhibitor of monoamine oxidase (1-9) and LSD1, a histone demethylase catalyzing demethylation of Lys-4 on histone H3 (10,11). Parnate also inhibits phenylethanolamine *N*-methyltransferase, which catalyzes the conversion of norepinephrine to epinephrine (8). The most likely basis for its antidepressant action is inhibition of monoamine oxidase, thereby preventing the breakdown of epinephrine, norepinephrine, and serotonin neurotransmitters and thereby increasing their availability and action. It is indicated for the treatment of major depressive episode without melancholia. This drug is best suited for patients who failed to respond to commonly administered drugs for depression. (Tranylcypromine was temporarily withdrawn from the market in 1964 due to deaths involving hypertensive crises and intracranial bleeding, but was reintroduced that same year with more limited indications and specific warnings.) Because MAOs have *in vivo* turnover times of 10-14 days, recovery from the action of irreversible MAOs typically exhibits a 3-5 day delay. **MAO Inhibition:** The apparent second order rate constant of inactivation of monoamine oxidase by D-PCPA at 30°C and pH 7.2, derived from pseudo-first order kinetics was  $5 \times 10^5 \text{ M}^{-1} \text{ min}^{-1}$ , with an apparent  $K_i$  of 4  $\mu\text{M}$  (6). Because the nonprotonated form of the inhibitor is the active species ( $\text{p}K_a = 8.2$ ), the actual  $K_i$  is 0.36  $\mu\text{M}$ . For L-PCPA, the apparent second order inactivation rate constant was  $6.5 \times 10^3 \text{ M}^{-1} \text{ min}^{-1}$ , with an apparent  $K_i$  of 300  $\mu\text{M}$ , and a pH-corrected value of 30  $\mu\text{M}$ . It was suggested that the imine (or ketone) formed on oxidation of the inhibitor by the flavin combines with the -SH group at the substrate binding site to form a thioaminoketal or thiohemiketal, and this structure is then stabilized by noncovalent interactions in the native enzyme but becomes labile and dissociable when the enzyme is unfolded (6). The fact that the flavin moiety of the enzyme remains reduced, even in air, may represent steric hindrance to the access of oxygen to the reduced flavin by the bulky phenylcyclopropyl group. Silverman (9,10) suggested an alternative mechanism that exploits the one-electron chemistry of MAOs as well as the propensity of cyclopropylaminy radicals to undergo homolytic cleavage. **LSD1 Inhibition:** The catalytic domain of the flavin-dependent human histone Lysine-Specific Demethylase 1 (LSD1) belongs to the same enzyme family as monoamine oxidase. A survey of MAOs as potential LSD1 inhibitors demonstrated that *trans*-2-phenylcyclopropylamine was highly potent,  $\text{IC}_{50} < 2 \mu\text{M}$  (10). 2-PCPA is a time-dependent, mechanism-based irreversible inhibitor of LSD1 with a  $K_i$  of 242  $\mu\text{M}$  and a  $k_{\text{inact}}$  of  $0.0106 \text{ s}^{-1}$  (12). 2-PCPA shows limited selectivity for human MAOs *versus* LSD1, with  $k_{\text{inact}}/K_i$  values only 16x and 2.4x higher for MAO B and MAO A, respectively (12). Profiles of LSD1 activity and inactivation by 2-PCPA as a function of pH are consistent with a mechanism of inactivation dependent upon enzyme catalysis. Mass spectrometric data indicates that FAD is covalent modified by 2-PCPA. In *Arabidopsis thaliana*, 2-PCPA mimics the loss-of-function phenotype for FLOWERING LOCUS D (RSII; *alias* FLD) a homologue of human histone demethylase required for Systemic Acquired Resistance, or SAR (13). (See also *cis*-2-Phenylcyclopropylamine) **Target(s):** cholesterol 24-hydroxylase (14); CYP2A6 (15,16); CYP2C19 (17,18); histamine and 5-hydroxytryptamine uptake (19); lysyl oxidase, or protein-lysine monooxygenase (20); prostaglandin-I synthase, or prostacyclin synthase, moderately inhibited (21-23). 1. **TRAP-Inhibitory Protein, See Anti-TRAP Protein**

### Trapoxin

This cyclotetrapeptide HDAC inhibitor (FW = 602.72 g/mol; CAS 133155-89-2), also named cyclo[(*S*)-phenylalanyl-(*S*)-phenylalanyl-(*R*)-pipercolinyl-(*2S,9S*)-2-amino-8-oxo-9,10-epoxydecanoyl-], first isolated from culture broth of *Helicoma ambiens* RF-1023, exhibits detransformation activities against *v-sis* oncogene-transformed NIH3T3 cells (*or sis*/NIH3T3) as antitumor agents (1,2). Actin stress fibers are evident after trapoxin treatment. Almost complete reversion into the flat phenotype was observed at 6 hours after the administration of trapoxin (2). This effect is reversible, when cultured cells are incubated for 24 hours after drug removal. The intracellular level of *sis*-mRNA did not decrease with trapoxin treatment at a concentration (50 ng/ml), sufficient to reverse the transformed morphology (2). Trapoxin was later found to cause accumulation of highly acetylated core histones in a variety of mammalian cell lines (3). *In vitro* experiments showed that a low concentration of trapoxin irreversibly inhibited deacetylation of acetylated histones. Chemical reduction of an epoxide group in trapoxin completely abolished the inhibitory activity, suggesting that trapoxin employs the epoxide to bind covalently to the histone deacetylase. By contrast, trichostatin A inhibits histone deacetylase reversibly. (See *Trichostatin A*; *Valproate*) 1. Itazaki, Nagashima, Sugita, et al. (1990) *J. Antibiot.* (Tokyo) 43, 1524. 2. Yoshida & Sugita (1992) *Japan J. Cancer Res.* 83, 324. 3. Kijima, Yoshida, Sugita, Horinouchi & Beppu (1993) *J. Biol. Chem.* 268, 22429.

**Trappin-2, See Elafin**

### Trazodone

This 5-HT<sub>2A</sub> receptor antagonist and antidepressant (FW = 371.87 g/mol; CAS 19794-93-5; IUPAC Name: 2-{3-[4-(3-chlorophenyl)piperazin-1-yl]propyl}[1,2,4]triazolo[4,3-*a*]pyridin-3(2*H*)-one), marketed under the tradenames Depyrel<sup>®</sup>, Desyrel<sup>®</sup>, Mesyrel<sup>®</sup>, Molipaxin<sup>®</sup>, Oleptro<sup>®</sup>, Trazodil<sup>®</sup>, Trazorel<sup>®</sup>, Trialodine<sup>®</sup>, and Trittico<sup>®</sup>, is a Serotonin Antagonist/Reuptake Inhibitor, or SARI, with anxiolytic and hypnotic effects. Lacking anticholinergic side effects, trazodone is especially useful in situations where antimuscarinic effects are problematic, such as in patients with prostatic hypertrophy, closed-angle glaucoma, or severe constipation. Trazodone's side effects and toxicity different considerably from monoamine oxidase inhibitors and tricyclic antidepressants. **ADME Properties:** After oral administration, trazodone is nearly completely absorbed; although food delays absorption and reduces peak serum concentration, total area under the plasma concentration-time curve is not altered. Trazodone has biphasic elimination, with a redistribution half-life of about one hour and an elimination half-life of 10-12 hours. Trazodone is nearly completely metabolized hepatically by hydroxylation and oxidation to metabolites that are probably inactive. **Targets:** Serotonin transporter (SERT), 370 nM; norepinephrine transporters (NET), >10000 nM; dopamine transporters DAT, >7000 nM; 5-serotonin HT<sub>1A</sub> receptor, 120 nM; serotonin 5-HT<sub>1B</sub> receptor, >10000 nM; serotonin 5-HT<sub>1D</sub> receptor, 110 nM; serotonin 5-HT<sub>1E</sub> receptor, >10000 nM; 5-HT<sub>2A</sub> receptor, 40 nM; serotonin 5-HT<sub>2B</sub> receptor, 80 nM; serotonin 5-HT<sub>2C</sub> receptor, 220 nM; serotonin 5-HT<sub>3</sub> receptor, >10000 nM; serotonin 5-HT<sub>5A</sub> receptor, >10000 nM; serotonin 5-HT<sub>6</sub> receptor, >10000 nM; serotonin 5-HT<sub>7</sub> receptor, 1800 nM;  $\alpha_{1A}$  receptor, 150 nM;  $\alpha_{1B}$

adrenergic receptor, ND;  $\alpha_{2A}$  adrenergic receptor, 730 nM;  $\alpha_{2B}$  adrenergic receptor, ND;  $\alpha_{2C}$  adrenergic receptor, 155 nM;  $\beta_1$  adrenergic receptor, >10000 nM;  $\beta_2$  adrenergic receptor, >10000 nM; dopamine D<sub>1</sub> receptor, 3700 nM; dopamine D<sub>2</sub> receptor, 4100 nM; dopamine D<sub>3</sub> receptor, ND, dopamine D<sub>4</sub> receptor, 700 nM; dopamine D<sub>5</sub> receptor, >10000 nM; benzodiazepine (BDZ) receptors, >10000 nM; Ca<sup>2+</sup> channel, >10000 nM; cannabinoid receptors, >10000 nM;  $\sigma_1$  receptor, >10000 nM;  $\sigma_2$  receptor, 540 nM; H<sub>1</sub> receptor, 220 nM; H<sub>2</sub> receptor, 3300 nM; H<sub>3</sub> receptor, >10000 nM; H<sub>4</sub> receptor, >10000 nM;  $\mu$ -opioid receptor, >10000 nM;  $\delta$ -opioid receptor, >10000 nM;  $\kappa$ -opioid receptor, >10000 nM; E<sub>3</sub> receptor, >10000 nM; E<sub>4</sub> receptor, >10000 nM. 1. ### Trastuzumab

This humanized recombinant IgG1 monoclonal antibody (MW = 145531.5 g/mol; CAS 180288-69-1), also known as Herceptin™ (Genentech/Hoffman-LaRoche), is a human epidermal growth factor receptor-2 (HER2) dimerization inhibitor (HER dimerization inhibitor) that lengthens remission time for breast cancers (1-3). Recent also suggests that the HER2-targeting antibodies Trastuzumab and Pertuzumab act synergistically to inhibit the survival of breast cancer cells growing *in vitro* (4). **Mechanism of Action:** Trastuzumab disrupts ligand-independent HER2/HER3 interactions in HER2-amplified cells, and the observed kinetics of dissociation parallel HER3 dephosphorylation and uncoupling from PI3K activity, leading to down-regulation of proximal and distal AKT signaling in a manner that correlates with trastuzumab's antiproliferative effects. The selective and potent PI3K inhibitor, GDC-0941, is highly efficacious both in combination with trastuzumab and in the treatment of trastuzumab-resistant cells and tumors (5). **For more details on mechanism of action, see Pertuzumab** 1. Adams, Allison, Flagella, *et al.* (2006) *Cancer Immunol. Immunother.* **55**, 717. 2. Agus, Gordon, Taylor, *et al.* (2005) *J. Clin. Oncol.* **23**, 2534. 3. ### Trastuzumab emtansine

This antineoplastic agent (Molecular Mass = 148.5 kDa; CAS 1018448-65-1) is an antibody-drug conjugate consisting of the monoclonal antibody trastuzumab (itself directed against recombinant anti-epidermal growth factor receptor 2, or HER2; **See Trastuzumab; Maytansine**) and the maytansinoid DM1 (a potent microtubule inhibitor of tubulin polymerization; **See DM1**) via a nonreducible thioether linkage (1). The trastuzumab component directs the conjugate to tumor cells possessing HER2, and upon internalization, undergoes cleavage to release the DM1 component, thereby disrupting microtubule assembly/disassembly dynamics and inhibiting proliferation of cancer cells overexpressing HER2. This binary antibody-drug therefore selectively inhibits cells rich in HER2, such as seen in HER2<sup>+</sup> metastatic breast cancer (2). Pharmacokinetics (3). Physicochemical stability (4). 1. Lewis-Phillips, Li, Dugger, *et al.* (2008) *Cancer Res.* **68**, 9280. 2. LoRusso, Weiss, Guardino, Girish, and Sliwkowski (2011) *Clin. Cancer Res.* **17**, 6437. 3. **Trasyolol**, **See Aprotinin**

### Trehazolin

This antibiotic pseudosaccharide and trehalose analogue (FW = 366.33 g/mol; CAS 132729-37-4), produced by *Micromonospora coriacea*, acts as an insecticide by inhibiting insect flight muscle trehalase, with an apparent  $K_i$  value of 10–100 nM. Pig kidney trehalase is also inhibited,  $IC_{50}$  = 19 nM. **Target(s):** glucosidase I, plant (*Note:* Trehazolin does not inhibit plant glucosidase II) (1); trehalase, slow tight-binding inhibition (2-5). 1. Zeng & Elbein (1998) *Arch. Biochem. Biophys.* **355**, 26. 2. Ando, Nakajima, Kifune, Fang & Tanzawa (1995) *Biochim. Biophys. Acta* **1244**, 295. 3. Kyosseva, Kyosseva & Elbein (1995) *Arch. Biochem. Biophys.* **316**, 821. 4. Wegener, Tschiedel, Schloder & Ando (2003) *J. Exp. Biol.* **206**, 1233. 5. Ando, Satake, Itoi, *et al.* (1991) *J. Antibiot.* **44**, 1165.

### Treosulfan

This antineoplastic drug (FW = 278.30 g/mol; CAS 299-75-2), also known as (2*S*,3*S*)-2,3-dihydroxybutane-1,4-diyl dimethanesulfonate, is a cell cycle non-specific DNA alkylating agent that penetrates cancer cells and induces apoptosis. (**For mechanism of action, See Busulfan**). Treosulfan is better tolerated by elderly patients. 1. Thigpen, Vance, Balducci & Khansur (1984) *Semin. Oncol.* **11**, 314. 2. Galaup & Paci (2013) *Expert Opin. Drug Metab. Toxicol.* **9**, 333.

### Trequinsin

This orally active cAMP phosphodiesterase inhibitor and antihypertensive agent (FW<sub>free-base</sub> = 405.50 g/mol; FW<sub>HCl-salt</sub> = 441.95 g/mol; CAS 78416-81-6; Soluble to 100 mM in DMSO), also known by the code name HL-725 and systematically as 2,3,6,7-tetrahydro-9,10-dimethoxy-3-methyl-2-[(2,4,6-trimethylphenyl)imino]-4*H*-pyrimido[6,1-*a*]isoquinolin-4-one hydrochloride, is an extremely potent inhibitor of human platelet aggregation, as induced *in vitro* by ADP, collagen, thrombin, and epinephrine. The aggregation induced by 0.5 mM arachidonic acid is inhibited about 50% with 50 pM HL-725, a potency that exceed that of prostacyclin, the most active natural aggregation inhibitor. Trequinsin targets cAMP phosphodiesterase-3, or PDE3 ( $IC_{50}$  = 250 pM), reducing systemic blood pressure in both normotensive and hypertensive animal models (1,2). If whole blood is pretreated with adenosine deaminase, there is no inhibitory effect of dipyridamole plus HL 725 on platelet aggregation, demonstrating that plasma adenosine also plays a crucial role in the anti-aggregatory actions of Trequinsin and several other inhibitors of cAMP PDE, both in human and rat blood (3). 1. Ruppert & Weithmann (1982) *Life Sci.* **31**, 2037. 2. Lal, Dohadwalla, Dadkar, D'Sa & de Souza (1984) *J. Med. Chem.* **27**, 1470. 3. Agarwal, Buckley & Parks (1987) *Thromb. Res.* **47**, 191. PMID: 2821650.

### 5-(3 $\alpha$ ,7 $\alpha$ ,12 $\alpha$ -Triacetoxy-5 $\beta$ -cholanamido)-1,3,4-thiadiazole-2-sulfonamide

This sulfonamide (FW = 694.60 g/mol) inhibits carbonic anhydrase, or carbonate dehydratase,  $IC_{50}$  = 66 nM for the human isozyme II (1,2). 1. Bülbul, Hisar, Beydemir, Çiftçi & Küfrevioğlu (2003) *J. Enzyme Inhib. Med. Chem.* **18**, 371. 2. Bülbul, Saraçoğlu, Küfrevioğlu & Çiftçi (2002) *Bioorg. Med. Chem.* **10**, 2561.

### *N,N,N'*-Triacetylchitotriose

This trisaccharide (FW = 627.60 g/mol) of *N*-acetyl-D-glucosamine has  $\beta$ 1 $\rightarrow$ 4 linkages and can form a stable complex with lysozyme. **Target(s):** *N*-acetyl-D-glucosamine-specific lectin from the ascidian *Didemnum ternatanum* (1);  $\beta$ -*N*-acetylhexosaminidase (2,3); *Bandeiraea simplicifolia* lectin II (4); cephalochordate *Branchiostoma lanceolatum* lectin (5); chitinase (6,7); chitin synthase (8); gorse (*Ulex europaeus*) phytohemagglutinin II (9); lysozyme (10-15); and stinging nettle (*Urtica dioica*) rhizome lectin (16). 1. **Triacantoate, See Melissate**

### Triacsin A

This naturally occurring long-chain fatty acid analogue (FW = 209.29 g/mol; CAS 76896-80-5; Soluble to 25 mM in DMSO), also named (2*E*,4*E*,7*E*)-2,4,7-undecatrienyl nitrosohydrazone, is one of four structurally related compounds from *Streptomyces* sp. SK-1894. Triacsin A specifically inhibits long-chain fatty acyl-CoA synthetases from widely different sources. Inhibition is competitive with respect to long-chain fatty acids. The *N*-hydroxytriazeno moiety, common to all triacsins, is essential for inhibition. Triacsins differ with respect to the number and sites of unsaturation (1-3). These inhibitors are especially useful in demonstrating an essential role of long chain acyl-CoA synthetase in animal cell proliferation. **See also Triacsins B, C, and D** 1. Omura, Tomoda, Xu, Takahashi & Iwai (1986) *J. Antibiot. (Tokyo)* **39**, 1211. 2. Tomoda, Igarashi & Omura (1987) *Biochim. Biophys. Acta* **921**, 595. 3. Tomoda, Igarashi, Cyong & Omura (1991) *J. Biol. Chem.* **266**, 4214.

### Triacsin B

This naturally occurring long-chain fatty acid analogue (FW = 205.26 g/mol; CAS 105201-47-6; MP = 144-147°C), one of four structurally related compounds from *Streptomyces* sp. SK-1894, inhibits specifically long-chain fatty acyl-CoA synthetases from widely different sources. Triacsin A inhibition is competitive with respect to long-chain fatty acids, and weaker than other triacsins. The *N*-hydroxytriazeno moiety, common to all triacsins, is essential for inhibition. Triacsins differ with respect to the number and sites of unsaturation (1,2). **See also Triacsins A, C, and D** 1. Tomoda, Igarashi & Omura (1987) *Biochim. Biophys. Acta* **921**, 595. 2. Tomoda, Igarashi, Cyong & Omura (1991) *J. Biol. Chem.* **266**, 4214.

### Triacsin C

This naturally occurring long-chain fatty acid analogue (FW = 207.28 g/mol; CAS 76896-80-5), one of four structurally related compounds from *Streptomyces* sp. SK-1894, potently inhibits specifically long-chain fatty acyl-CoA synthetases from widely different sources. Inhibition is competitive with respect to long-chain fatty acids. The *N*-hydroxytriazeno moiety, common to all triacsins, is essential for inhibition. Triacsins differ with respect to the number and sites of unsaturation. Note that one of the sites of unsaturation is not conjugated. In addition to blocking the biosynthesis of triacylglycerols and cholesterol esters, triacsin C will also block  $\beta$ -cell

apoptosis induced by fatty acids. **See also Triacsins A, B, and D** **Target(s):** arachidonyl-CoA synthetase, or arachidonate:CoA ligase (1-3); long-chain-fatty-acyl-CoA synthetase, or long-chain-fatty-acid:CoA ligase (1-9); medium-chain-fatty-acyl-CoA synthetase, or butyrate:CoA ligase, weakly inhibited (9). 1. Lewin, Kim, Granger, Vance & Coleman (2001) *J. Biol. Chem.* **276**, 24674. 2. Kim, Lewin & Coleman (2001) *J. Biol. Chem.* **276**, 24667. 3. Hartman, Omura & Laposata (1989) *Prostaglandins* **37**, 655. 4. Igal, Wang & Coleman (1997) *Biochem. J.* **324**, 529. 5. Omura, Tomoda, Xu, Takahashi & Iwai (1986) *J. Antibiot. (Tokyo)* **39**, 1211. 6. Tomoda, Igarashi & Omura (1987) *Biochim. Biophys. Acta* **921**, 595. 7. Van Horn, Caviglia, Li, et al. (2005) *Biochemistry* **44**, 1635. 8. ### Triacsin D

This naturally occurring long-chain fatty acid analogue (FW = 207.28 g/mol), one of four structurally related compounds from *Streptomyces* sp. SK-1894, weakly inhibits specifically long-chain fatty acyl-CoA synthetases from widely different sources. Inhibition is competitive with respect to long-chain fatty acids (1,2). The *N*-hydroxytriazeno moiety, common to all triacsins, is essential for inhibition. Triacsins differ with respect to the number and sites of unsaturation. 1. Tomoda, Igarashi & Omura (1987) *Biochim. Biophys. Acta* **921**, 595. 2. Tomoda, Igarashi, Cyong & Omura (1991) *J. Biol. Chem.* **266**, 4214.

### 1,2,3-Tri(adenosine-5'-O-phospho)glycerol

This unusual oligonucleotide (FW = 1078.71 g/mol) competitively inhibits bis(5'-nucleosyl)tetraphosphatase ( $K_i = 80$  nM), a hydrolase that degrades AppppA (or  $P^i, P^i$ -di(adenosine-5')tetraphosphate). The latter has been implicated in extracellular purinergic signalling and in various intracellular processes, including DNA metabolism, tumor suppression, and cellular stress responses. If permitted to accumulate, AppppA and related metabolites may also be cytotoxic. 1. Guranowski, Starzynska, McLennan, Baraniak & Stec (2003) *Biochem. J.* **373**, 635.

### Triadimefon

This common fungicide (FW = 293.75 g/mol; CAS 43121-43-3; MP = 82°C; slightly soluble in water) inhibits aromatase, or CYP19 (1), (*S*)-canadine synthase (2), and sterol 14-demethylase, or CYP51 (3,4). 1. Vinggaard, Hnida, Breinholt & Larsen (2000) *Toxicol. In Vitro* **14**, 227. 2. Rueffer & Zenk (1994) *Phytochemistry* **36**, 1219. 3. Joseph-Horne, Hollomon, Loeffler & Kelly (1995) *FEBS Lett.* **374**, 174. 4. Tröskén, Adamska, Arand, et al. (2006) *Toxicology* **228**, 24.

**Triadimenol**

This common fungicide (FW = 295.77 g/mol; CAS 55219-65-3; MP = 112-117°C) is the reduced derivative of triadimefon. The (1*S*,2*R*)-stereoisomer is the strongest inhibitor of sterol 14-demethylase. **Target(s):** aromatase, *or* CYP19 (1) and sterol 14-demethylase, CYP51 (2-5). 1. Vinggaard, Hnida, Breinholt & Larsen (2000) *Toxicol. In Vitro* **14**, 227. 2. Trösken, Adamska, Arand, *et al.* (2006) *Toxicology* **228**, 24. 3. Yoshida & Aoyama (1990) *Chirality* **2**, 10. 4. **Triallate**

This thiocarbamate (FW = 304.67 g/mol; CAS 2303-17-5; MP = 20-30°C), known commercially as Avadex BW and systematically as bis(1-methylethyl)carbamothioic acid *S* (2,3,3-trichloro-2-propenyl) ester, is a volatile and selective pre-emergence herbicide used to control grass weeds in field and pulse crops, particularly in the control of wild oats, black grass, and annual meadow grass. **Target(s):** aldehyde dehydrogenase (1); and fatty acid biosynthesis (2). 1. Quistad, Sparks & Casida (1994) *Life Sci.* **55**, 1537. 2. Dodge (1977) *Spec. Publ., Chem. Soc.* **29**, 7.

**Triamcinolone**

This synthetic glucocorticosteroid (FW = 394.44 g/mol; CAS 124-94-7), known systematically as 9α-fluoro-11β,16α,17α,21-tetrahydroxypregna-1,4-diene-3,20-dione, binds to glucocorticoid receptors, exerting powerful anti-inflammatory activity and affecting protein biosynthesis. Triamcinolone will also induce apoptosis and impair the tumor necrosis factor-induced degradation of κB-α. **Target(s):** chymotrypsin (1); corticosteroid acetyltransferase (2); pyruvate kinase (3); and trypsin (1). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Mayer, Neufeld & Finci (1982) *Biochem. Pharmacol.* **31**, 2989. 2. Purdy & Rao (1970) *Steroids* **16**, 649. 3. Johnson & Venezia (1980) *Biochemistry* **19**, 2195.

**Triamterene**

This pteridine derivative (FW = 253.27 g/mol; CAS 2303-17-5), also called 2,4,7-triamino-6-phenylpteridine, is a mild 'potassium-sparing' diuretic usually employed in combination with other more potent diuretics in the treatment of hypertension. Triamterene blocks sodium ion reuptake in the

kidney. **Target(s):** carbonic anhydrase, *or* carbonate dehydratase (1,2); dihydrofolate reductase, *K<sub>i</sub>* = 13 nM (3-7); folate transport (8); histamine *N*-methyltransferase (9); kallikrein, weakly inhibited (10); Na<sup>+</sup> channels (11-14); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (15,16); phosphodiesterase (17); tyrosine monooxygenase (18). 1. Pharmacol.* **327**, 119.

**Triapine**

This substituted pyridine (FW = 195.25 g/mol; CAS 236392-56-6; *Symbol*: 3-AP), also known as 3-aminopyridine-2-carboxaldehyde thiosemicarbazone, is an anticancer agent that induces apoptosis in cancer cells (1-5). Treatment of colon cancer cells with 3-AP activates the PERK, IRE1a and ATF6 endoplasmic reticulum stress pathways by phosphorylation of eIF2α and upregulation of ATF4 and ATF6 gene expression (6). After induction of the Unfolded Protein Response (UPR), significant upregulation of pro-apoptotic proteins is detected, including higher levels of the transcription factor CHOP as well as the BH3-only member protein Bim, itself an essential factor for ER stress-related apoptosis. Despite a recent report (7) suggesting that the structurally related thiosemicarbazone Dp44mT may, in part, exert cytotoxicity by targeting DNA topoisomerase IIα, the results of subsequent application of a variety of assays proved otherwise (8). Triapine was without effect on inhibited topoisomerase IIα decatenation, induced cleavage of pBR322 DNA in the presence of enzyme. In cells, Dp44mT did not stabilize topoisomerase IIα covalent binding to DNA using an immunoblot band depletion assay, an ICE assay, and a protein-DNA covalent complex forming assay. Dp44mT also failed to display cross-resistance to etoposide-resistant K562 cells containing reduced topoisomerase IIα levels. **Target(s):** ribonucleoside-diphosphate reductase (1-5); and ribonucleoside-triphosphate reductase (1,2). 1. Karp, Giles, Gojo, *et al.* (2008) *Leuk. Res.* **32**, 71. 2. Odenike, Larson, Gajiria, *et al.* (2008) *Invest. New Drugs* **26**, 233. 3. Cory, Cory, Rappa, *et al.* (1994) *Biochem. **3-(1,2,4-Triazol-3-yl)-DL-alanine**

This histidine isostere (FW = 156.14 g/mol) is a synthetic allosteric feedback inhibitor of ATP phosphoribosyl-transferase (1), the enzyme catalyzing the first step in bacterial histidine biosynthesis. 3-(1,2,4-Triazol-3-yl)-alanine also competitively inhibits histidine ammonia-lyase (2,3) and histidyl-tRNA synthetase (4,5). 1. Ohta, Fujimori, Mizutani, *et al.* (2000) *Plant Physiol.* **122**, 907. 2. Shibatani, Kakimoto & Chibata (1975) *Eur. J. Biochem.* **55**, 263. 3. ## 6-[(4H-1,2,4-Triazol-4-ylamino)methyl]uracil

This uracil derivative (FW = 208.18 g/mol) inhibits *Escherichia coli* thymidine phosphorylase,  $K_i = 0.5 \mu\text{M}$ , as well as thymidine phosphorylase/platelet derived endothelial cell growth factor (TP/PD-ECGF). **1.** Kalman & Lai (2005) *Nucleosides Nucleotides Nucleic Acids* **24**, 367.

## 17-(1H-1,2,3-Triazol-1-yl)androsta-4,16-dien-3-one

This synthetic steroid (FW = 337.47 g/mol) is a potent inhibitor of steroid  $17\alpha$ -monooxygenase, or CYP17,  $K_i = 8 \text{ nM}$  for human enzyme and steroid  $5\alpha$ -reductase,  $\text{IC}_{50} = 198 \text{ nM}$  for human enzyme (1). The 1H-1,2,4-triazol-1-yl analogue also inhibits steroid  $17\alpha$ -monooxygenase,  $K_i = 41 \text{ nM}$ , for human enzyme and steroid  $5\alpha$ -reductase,  $\text{IC}_{50} = 152 \text{ nM}$  for human enzyme. **1.** Njar, Kato, Nnane, *et al.* (1998) *J. Med. Chem.* **41**, 902.

**4-(1H-1,2,3-Triazol-5-yl)aniline**, See **5-(4-Amino-phenyl)-1H-1,2,3-triazole**

## Tribufos

This phosphorothioate-based plant defoliant (FW = 272.44 g/mol; CAS 78-48-8), also known as *S,S,S*-tributyl phosphorotrithioate, inhibits acylglycerol lipase, or monoacylglycerol lipase (1), 1-alkyl-2-acetylglucero-phosphocholine esterase, or platelet-activating-factor acetylhydrolase (2,3), acylpeptide hydrolase (4), butyrylcholinesterase (4), carboxylesterase (1,5), fatty acid amide hydrolase (1,6), lysophospholipase (1,7), neuropathy target esterase, weakly inhibited (1), and thrombin (3,8). **1.** Quistad, Klintonberg, Caboni, Liang & Casida (2006) *Toxicol. Appl. Pharmacol.* **211**, 78. **2.** Quistad, Fisher, Owen, Klintonberg & Casida (2005) *Toxicol. Appl. Pharmacol.* **205**, 149. **3.** Casida & Quistad (2005) *Chem. Biol. ## (Tributyl)tin Chloride &amp; (Tributyl)tin Acetate

These membrane-penetrating organometallic salts (FW<sub>chloride</sub> = 325.51 g/mol; CAS 688-73-3; colorless liquid; BP = 172°C at 5 mm Hg; moisture sensitive; FW<sub>acetate</sub> = 349.10 g/mol; Structure:  $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{Sn}^+\text{CH}_3\text{COO}^-$ ; white powder; MP = 86-87°C) are uncouplers of oxidative phosphorylation uncoupler. (Tributyl)tin acetate that is moisture sensitive. See also *Bis(tributyltin)oxide*; **Uncouplers** **Target(s)**: aromatase, or CYP19 (1,2); ATP synthase, or  $\text{F}_1\text{F}_0$  ATPase, or  $\text{H}^+$ -transporting two-sector ATPase (3-7); calmodulin (8,9); carboxylesterase (10); coproporphyrinogen oxidase (11); cytochrome *c* is released by the presence of these agents (12); electron transport, chloroplast (13); estrone sulfotransferase (33); ferrochelatase (14); glutathione *S*-transferase, by (tributyl)tin acetate (15,16,34-37);  $\text{H}^+$ -exporting ATPase (17,18);  $\text{H}^+/\text{K}^+$ -ATPase (19);  $\text{K}^+$ -ATPase (19,20); lipoxigenase (21); mitochondrial inner membrane anion channel (22);  $\text{Na}^+$ -dependent ATPase (20,23);  $\text{NAD(P)}^+$  transhydrogenase (24);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (20,25,26);  $\text{Na}^+$ -transporting two-sector ATPase (27); oxidative phosphorylation (4-6,12); phenol sulfotransferase, or aryl sulfotransferase (33); prostaglandin-D synthase (28); steroid  $5\alpha$ -reductase (29); tubulin polymerization, or microtubule assembly (30,31); and tyrosine monooxygenase (32). **1.** Cooke (2002) *Toxicol. ## Tricarballoylate

This tricarboxylic acid analogue of isocitric and citric acid (FW<sub>free-acid</sub> = 176.13 g/mol; CAS 99-14-9;  $\text{pK}_a$  values of 3.49, 4.58, and 5.83 at 30°C), also known as 1,2,3-propanetricarboxylic acid, is a powerful chelator of calcium and magnesium ions. **Target(s)**: aconitase, or aconitate hydratase (1-3); ATP: citrate lyase, or ATP: citrate synthase (4); glucose-1,6-bisphosphate synthase (5);  $\text{NADP}^+$ -dependent isocitrate dehydrogenase (6,7); kynurenine aminotransferase, weakly inhibited (8); 2-methylcitrate dehydratase (9); phosphofructokinase (10); and succinate dehydrogenase (11-13). **1.** Glusker (1971) *The Enzymes*, 3rd ed. ### Triciribine

This tricyclic adenine nucleoside analogue (F.Wt. = 320.3; CAS 1191951-57-1 and 35943-35-2; Solubility (25°C): 60 mg/mL DMSO; <1 mg/mL Water), also known as NSC-154020, TCN and API-2, and named systematically as 6-amino-4-methyl-8-(β-D-ribofuranosyl)-4*H*,8*H*-pyrrolo[4,3,2-*de*]pyrimido[4,5-*c*]pyridazine, is a late-phase inhibitor ( $IC_{50}$  = 20 nM) of human immunodeficiency virus type 1 (HIV-1) replication by a unique mechanism not involving inhibition of viral replication enzymes (1). Inhibition requires TCN phosphorylation to its 5'-phosphomonoester by intracellular adenosine kinase. Triciribine also inhibits the Akt ( $IC_{50}$  = 130 nM). TCN is highly selective for Akt and does not inhibit the activation of phosphatidylinositol 3-kinase, phosphoinositide-dependent kinase-1, protein kinase C, serum and glucocorticoid-inducible kinase, protein kinase A, signal transducer and activators of transcription 3, extracellular signal-regulated kinase-1/2, or c-Jun N-terminal kinase (3). TCN-5'-P also weakly inhibits (GTP more than ATP) purine nucleotide biosynthesis at reactions catalyzed by amidophosphoribosyltransferase,  $IC_{50}$  = 20 mM, and IMP dehydrogenase,  $IC_{50}$  = 5–8 μM (4,5). **1.** Kucera, *et al.* (1993) *AIDS Res Hum Retroviruses* **9**, 307. **2.** Gursel DB, *et al.* (2011) *Neuro. **Trichloroacetaldehyde, See Chloral Hydrate**

### Trichlorfon

This membrane-permeable organophosphate (FW = 257.44 g/mol; CAS 52-68-6; white solid; MP = 83–84°C; soluble in water (15.4 g/100 mL at 25°C), benzene, and ethanol), also known as *O,O*-dimethyl-2,2,2-trichloro-1-hydroxyethyl phosphonate, Neguvon, and metrifonate, is an anthelmintic agent. It has also been found to be effective in the treatment of the cognitive symptoms of Alzheimer's disease. The active metabolite of trichlorfon is actually *O,O*-dimethyl-2,2-dichlorovinyl phosphonate which irreversibly inhibits acetylcholinesterase. **Target(s):** acetylcholinesterase (1–4); arylesterase (5); carboxylesterase (6); cholinesterase, *or* butyrylcholinesterase, weakly inhibited (1,3,4,7); electron transport (8); glucose-6-phosphate dehydrogenase (9). **1.** Reiner, Krauthacker, Simeon & Skrinjaric-Spoljar (1975) *Biochem. Pharmacol.* **24**, 717. **2.** Ringman & Cummings (1999) *J. Clin. Psychiatry* **60**, 776. **3.** Darvesh, Walsh, Kumar, *et al.* (2003) *Alzheimer Dis. Assoc. ### Trichlormethine

This membrane-penetrating nitrogen mustard (FW<sub>free-base</sub> = 204.53 g/mol; CAS 555-77-1; MP = –4°C), abbreviated as HN-3, and tris(2-chloroethyl)amine, is a DNA and RNA alkylating agent and inhibits both transcription and translation. The hydrochloride is an antineoplastic drug used the treatment of Hodgkin's disease and leukemias), and the free base is a chemical warfare agent. **Caution:** The free base should only be used in a chemical hood or with a gas mask. Protective clothing should be worn to prevent contact with skin. Trichlormethine **See also Mechllorethamine; Bis(2-chloroethyl)ethylamine Target(s):** cholinesterase (1); and hexokinase (2). **1.** Peters (1947) *Nature* **159**, 149. **2.** McDonald (1955) *Meth. Enzymol.* **1**, 269.

### Trichloroacetate

This trihaloacid (FW = 163.39 g/mol; CAS 76-03-9;  $pK_a$  = 0.66 at 25°C; MP = 57–58°C; BP = 196–197°C) is frequently used precipitate proteins. **Note:** This extremely deliquescent solid should be kept in a tightly closed container and stored in cool, well-ventilated location. Dilute aqueous solutions should not be stored, because the acid slowly decomposes. **Target(s):** acid phosphatase (1); adenylosuccinate synthetase (2); creatine kinase (3); fumarylacetoacetase (4); glucose-6-phosphate dehydrogenase (5); pancreatic ribonuclease, *or* ribonuclease A (6); pantothenate synthetase (7); tyrosine decarboxylase (8); urease (9); and wax biosynthesis (10). **1.** Belfanti, Contardi & Ercoli (1935) *Biochem. J.* **29**, 517. **2.** Markham & Reed (1977) *Arch. Biochem. Biophys.* **184**, 24. **3.** Watts (1973) *The Enzymes*, 3rd ed. ### 2-([3-[(2,3,5-Trichlorobenzyl)amino]propyl]amino)quinolin-4(1*H*)-one

This substituted quinolinone (FW = 410.73 g/mol), first identified through analysis of Structure Activity Relationships, enantioselectively inhibits methionyl-tRNA synthetase,  $IC_{50}$  < 3 nM for the *Staphylococcus aureus* enzyme. **1.** Jarvest, Armstrong, Berge, *et al.* (2004) *Bioorg. Med. Chem. Lett.* **14**, 3937.

### 1,1,1-Trichloro-2,2-bis(*p*-chlorophenyl)ethane

This highly toxic and notorious polychlorinated pesticide (FW = 354.49 g/mol; MP = 108.5–109°C), widely known as DDT (for Dichloro Diphenyl Trichloroethane) was first synthesized in 1873. DDT was found to be a highly effective insecticide, and during World War II, DDT became extremely valuable in combating typhus and malaria. When DDT came into wider use in agriculture, its toxicity ( $LD_{50}$  = ~115 mg/kg in rats) quickly became evident, and Paul Müller was awarded the 1948 Nobel Prize in Physiology or Medicine for his discovery of its high efficiency as a contact poison. DDT accumulates in lipid-rich foodstuffs (*e.g.*, solubility ≈ 11 g/100 mL peanut oil) as a consequence of its nonpolar nature. Resistant to oxidation and ultraviolet/visible light, DDT persists within the food-chain, where its stereoisomeric properties reduce egg shell biomineralization to such an extent that the fragile eggs are prone to cracking and microbial infection. **Caution:** DDT is readily absorbed orally, transdermally and by inhalation.

Extreme caution must be exercised when handling DDT. **Target(s):** ATPase (1-5); Ca<sup>2+</sup>-dependent ATPase (6-11); calmodulin-stimulated cyclic nucleotide phosphodiesterase (12); carbonic anhydrase, or carbonate dehydratase (13); chitin synthase (14); F<sub>0</sub>F<sub>1</sub> ATP synthase, or H<sup>+</sup>-transporting two-sector ATPase (15-20); Hill reaction (21); K<sup>+</sup> uptake (22); lipase (23); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (24-27); photosynthetic electron transport and photophosphorylation (21,28-31); xanthine oxidase (32). 1. **2,6,3'-Trichloroindophenol**, See *2,6,3'-Trichlorophenolindophenol*

### 2,4,5-Trichlorophenol

This fungicide and bactericide (FW = 197.45 g/mol; CAS 95-95-4; MP = 67°C, has a low water solubility (< 0.2 g per 100 g H<sub>2</sub>O; pK<sub>a</sub> = 7.37 at 25°C); highly soluble in acetone (615 g per 100 g solvent) and methanol (also 615 g per 100 g solvent). **Target(s):** acetylcholinesterase (1); D-amino-acid oxidase (2); lipase (3); malate dehydrogenase (4); and NADPH dehydrogenase (quinone) activity of ζ-crystallin (5). 1. Matsumura, Matsuoka, Igisu & Ikeda (1997) *Arch. Toxicol.* **71**, 151. 2. Krahl, Keltch & Clowes (1940) *J. Biol. Chem.* **136**, 563. 3. Christensen & Riedel (1981) *Arch. Environ. Contam. ### 2,6,3'-Trichlorophenolindophenol

This widely used synthetic electron acceptor (FW<sub>sodium salt</sub> = 324.53 g/mol; E<sub>o</sub>' = +0.26 V), also called 2,6,3'-trichloroindophenol and abbreviated TCIP, functions as such for a wide variety of oxidation/reduction enzymes. At pH 7, aqueous solutions are blue when the reagent is oxidized, but colorless when reduced. The oxidized form inhibits photophosphorylation, perhaps acting both as a proton gradient dissipator as well as a redox mediator. *Note:* The solid will slowly decompose in light; hence, it should be stored in the dark. Aqueous solutions will decompose upon standing, particularly under acidic conditions. 1. Izawa & Good (1972) *Meth. Enzymol.* **24**, 355.

### (2,4,5-Trichlorophenoxy)acetate

This herbicide (FW<sub>free-acid</sub> = 255.48 g/mol; MP = of 153°C; free acid is water-insoluble; salts are water soluble) is a synthetic auxin and component of the notorious jungle defoliant Agent Orange. 2,4,5-T kills broad-leaf plants, but not grasses. *Note:* Caution should be exercised in its handling to avoid contact dermatitis and liver damage. The use of 2,4,5-T as a herbicide became controversial as many regarded it unsafe to animals, humans, and the environment. The U. S. Environmental Protection Agency restricted its use to rangelands and rice fields, but, in 1985, the same agency completely banned its use as a herbicide in the U.S. **Target(s):** benzoyl-CoA synthetase, or benzoate:CoA ligase (1); Ca<sup>2+</sup>-dependent ATPase (2); glutathione S-transferase (3,4); lactate dehydrogenase (5,6); ATP-dependent palmitoyl-CoA synthetase (7). 1. Gregus, Halasz & Klaassen (1999) *Xenobiotica* **29**, 547. 2. Thebault & Decaris (1983) *Comp. Biochem. Physiol. C* **75**, 369. 3. Singh & Awasthi (1985) *Toxicol. Appl. Pharmacol.* **81**, 328. 4. Vessey & Boyer (1984) *Toxicol. Appl. Pharmacol.* **73**, 492. 5. Baker (1967) *Design of Active-Site-Directed Irreversible Enzyme Inhibitors*, Wiley, New York. 6. Ottolenghi & Denstedt (1958) *Can. J. Biochem. Physiol.* **36**, 1075. 7. Roberts & Knights (1992) *Biochem. Pharmacol.* **44**, 261.

### 2,6,8-Trichloropurine

This urate analogue (FW = 223.45 g/mol; MP = 159-161°C; slightly soluble in water) inhibits urate oxidase, or uricase, K<sub>i</sub> = 0.8 μM (1-3). 1. Baum, Hübscher & Mahler (1956) *Biochim. Biophys. Acta* **22**, 514. 2. Mahler (1963) *The Enzymes*, 2nd ed. (Boyer, Lardy & Myrbäck, eds.), **8**, 285. 3. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. **2**, p. 284, Academic Press, New York.

**O-(2,3,5-Trichloropyrid-6-yl)-(O-methyl-O-n-butyl)phosphate**, See *O-(n-Butyl) O-Methyl O-(2,3,5-Trichloropyrid-6-yl)phosphate*

### Trichokirin

This ricin-like toxic 27-kDa enzyme from the seeds of *Trichosanthes kirilowii*, exhibits rRNA N-glycosylase activity and is classified as a type I ribosome-inactivating protein (1). Trichokirin catalyzes endohydrolysis of the N-glycosidic bond at one specific adenosine on the 28S rRNA. Trichokirin-S1 is the smaller 11-kDa protein (2). 1. Casellas, Dussosoy, Falasca, et al. (1988) *Eur. J. Biochem.* **176**, 581. 2. Li, Yang, Hu, et al. (2003) *Sheng Wu Hua Xue Yu Sheng Wu Wu Li Xue Bao (Shanghai)* **35**, 841.

### Trichostatin A

This iron-binding *Streptomyces hygroscopicus*-derived antifungal (FW = 302.37 g/mol; CAS 58880-19-6; Symbol: TSA), known systematically as [R-(E,E)]-7-[4-(dimethylamino)phenyl]-N-hydroxy-4,6-dimethyl-7-oxo-2,4-heptadienamides, is active against trychophytons and some fungi (1) and noncompetitively inhibits histone deacetylase, or HDAC (K<sub>i</sub> = 3.4 nM for the mouse mammary tumor enzyme) (2-5), disrupting chromatin function (6,7). HDAC8 is the only known HDAC that is unaffected by TSA. (**For further details, see Vorinostat**) Trichostatin A induces a variety of biological responses of cells (e.g., induced differentiation, reduced migration, and cell cycle arrest). TSA prevents new actin filament formation in hepatic stellate cells by down-regulating express of Arp2/3 nucleating proteins and by up-regulating expression of the filament-capping proteins adducin-like protein 70 (ADDL70) and gelsolin (8). RhoA also decreases following TSA exposure. Trichostatin A has proved to be a useful probe of histone

deacetylase structure as well as the roles of HDAC in chromatin structure and function. Trichostatin B (FW = 959.93 g/mol) is the ferric chelate formed by three trichostatin A molecules. Trichostatin C (FW = 464.51 g/mol) is the glucosyl hydroxamate of trichostatin A. **Target(s):** histone-deacetylase-like amidohydrolase (1); and histone deacetylase (2-6). 1. Tsuji, Kobayashi, Nagashima, Wakisaka & Koizumi (1976) *J. Antibiot. (Tokyo)* **29**, 1. 2. Hildmann, Ninkovic, Dietrich, *et al.* (2004) *J. Bacteriol.* **186**, 2328. 3. **Trichothecene, See specific mycotoxin; e.g., Nivalenol; T-2 Toxin; Trichothecin**

#### Trichothecin

This sesquiterpene antibiotic and mycotoxin (FW = 332.40 g/mol; CAS 6379-69-7; soluble in most organic solvents) from *Trichothecium roseum* inhibits peptide bond formation in protein biosynthesis, chain elongation (1,2). Aqueous solutions are stable for at least two days at pH 1-10. 1. Barbacid, Fresno & Vazquez (1975) *J. Antibiot. (Tokyo)* **28**, 453. 2. Jimenez & Vazquez (1975) *Eur. J. Biochem.* **54**, 483.

#### Tricine

This zwitterionic Good's buffer (FW = 179.17 g/mol; CAS 5704-04-1;  $pK_{a1} = 2.1$  and  $pK_{a2} = 8.15$  at 20°C;  $dpK_{a2}/dT = -0.021$  ph units/°C), known systematically as *N*-[tris(hydroxymethyl)methyl]glycine, also weakly chelates  $Zn^{2+}$  and  $Ca^{2+}$ , the latter with a formation constant of  $16 M^{-1}$  (1). *Note:* Chloroethane sulfonate is an essential ingredient in the chemical synthesis of ethane sulfonic acid-containing Good's Buffers, giving rise to variable contaminating levels oligovinylsulfonate (OVS) that inhibit ribonuclease (2) and are likely to act similarly with other enzymes that bind polyanions. **Target(s):** carbonic anhydrase, *or* carbonate dehydratase (3);  $H^+$ -transporting inorganic pyrophosphatase (4); mannosyl-oligosaccharide glucosidase, *or* glucosidase I (5); ornithine decarboxylase (6); quinate *O*-hydroxycinnamoyltransferase (7); and shikimate *O*-hydroxycinnamoyltransferase (7). 1. Good, Winget, Winter, *et al.* (1966) *Biochemistry* **5**, 467. 2. Smith, Soellner & Raines (203) *J. Biol. Chem.* **278**, 20934. 3. Hatch (1991) *Anal. Biochem.* **192**, 85. 4. Acta* **438**, 551. 7. Lotfy, Fleuriot & Macheix (1992) *Phytochemistry* **31**, 767.

#### Triclosan

This cell-permeant, antiseptic agent (FW = 289.54 g/mol; CAS 3380-34-5; IUPAC name: 2-hydroxy-2',4,4'-trichlorodiphenyl ether), which exhibits both bacteriostatic and fungicidal activities, is a common additive in many cosmetic and personal care products, including toothpaste. Triclosan inhibits ( $K_i = 7$  pM) fatty acid synthase at the enoyl-[acyl-carrier protein] reductase step by forming an enzyme-NAD<sup>+</sup>-triclosan ternary complex that is stabilized by well-placed hydrogen bonds and hydrophobic interactions

between triclosan and the enzyme and coenzyme (1-3). Triclosan is also both an alternative substrate and inhibitor of human liver 3'-phosphoadenosine 5'-phosphosulfate-sulfotransferases and UDP-glucuronosyltransferases (4). Apparent  $K_m$  and  $V_{max}$  values for triclosan sulfonation were 9  $\mu M$  and 0.1 nmol/min/mg protein, whereas  $K_m$  and  $V_{max}$  values for glucuronidation were 100  $\mu M$  and 0.7 nmol/min/mg protein. Triclosan inhibits hepatic cytosolic sulfonation of 3-hydroxybenzo(a)pyrene, bisphenol A, *p*-nitrophenol, and acetaminophen with  $IC_{50}$  concentrations of 2.9, 3.0, 6.5, and 18  $\mu M$ , respectively (4). Triclosan is also a potent inhibitor of both estradiol and estrone sulfonation, exhibiting an  $IC_{50}$  of 0.6 nM for the latter (5). Given its structure and  $pK_a$  value of 7.9, triclosan is also a likely to be an effective protonophoric uncoupler of oxidative phosphorylation. Isolated liver mitochondria (at 60 nmol triclosan per mg mitochondrial protein) exhibited decreased oxygen consumption typical of State-3 respiration, as well as a decreased  $\Delta\psi$  (6). Indeed, mitochondrial swelling, as driven by  $K^+$  diffusion potential in the presence of valinomycin, was also inhibited at triclosan concentrations greater than 10 nmol/mg protein (6). Triclosan also alters thyroid hormone receptor  $\alpha$  transcript levels in premetamorphic tadpole brain and induces transient weight loss (7). Triclosan is chemically and functionally related to the antiseptic hexachlorophene (*or* 2,2'-methylenebis[3,4,6-trichlorophenol]). Note also that triclosan resists biological turnover and is likely to accumulate in lipid-rich tissues. Long-term human health risks remain uncertain. **Target(s):** CYP1A or CYP2B (1); enoyl-[acyl-carrier protein] reductase (2,3,8-10); estrogen sulfotransferase (5); NADPH-dependent enoyl-[acyl-carrier protein] reductase (11); and fatty-acid synthase (12,13). 1. #### Tricyclazole

This fungicide (FW = 189.24 g/mol; CAS 41814-78-2), also known as 5-methyl-1,2,4-triazolo[3,4-*b*]benzothiazole, inhibits melanin biosynthesis and has been used to treat rice blast disease. **Target(s):** scytalone dehydratase (1); tetrahydroxynaphthalene reductase (2,3); and trihydroxynaphthalene reductase (2,4,5). 1. Wheeler & Greenblatt (1988) *Exp. Mycol.* **12**, 151. 2. Liao, Thompson, Fahnestock, Valent & Jordan (2001) *Biochemistry* **40**, 8696. 3. Thompson, Fahnestock, Farrall, *et al.* (2000) *J. Biol. ***O*-Tricyclo[5.2.1.0<sup>2,6</sup>]dec-9-yl Dithiocarbonate**

This hygroscopic dithiocarbonate (FW = 228.38 g/mol), frequently referred to as D609 or tricyclodecan-9-yl xanthogenate, is a selective inhibitor of phosphatidyl-choline-specific phospholipase C, but does not inhibit

phosphatidylinositol-specific phospholipase C or phospholipase A. D609 inhibits angiogenesis by preventing the synthesis of basement membrane. *Note:* Avoid using this reagent with HEPES buffer, because HEPES renders the reagent toxic. **Target(s):** basement membrane biosynthesis (1); herpes simplex virus type 1 replication (2); HIV-1 replication (3); Lysophospholipase (4); phospholipase C (5-7); phospholipase D, weakly inhibited (8); protein kinase C (2); and sphingomyelin synthase (9-13). 1. ### Tricyclohexyltin Hydroxide

This UV-sensitive organotin acaricide (FW = 385.18 g/mol; white solid; MP = 195-198°C), also called Plictran, tricyclohexylstannol, and cyhexatin, inhibits the adrenergic stimulated calcium pump, or Ca<sup>2+</sup>-dependent ATPase (1,2), ecto-ATPase, by tricyclohexyltin chloride (3); F<sub>0</sub>F<sub>1</sub> ATP synthase (4,5), and glutathione S-transferase (6). 1. ### Tridemorph

This fungicide (FW<sub>free-base</sub> = 297.52 g/mol; CAS 24602-86-6), also known as 2,6-dimethyl-N-tridecylmorpholine, inhibits chitin synthase (1); cholesterol Δ-isomerase, or sterol Δ<sup>7,8</sup>-isomerase, K<sub>i</sub> = 90 pM (2-5), cholesterol oxidase (6), cyclooleucenol cycloisomerase, or cyclooleucenol:obtusifoliol isomerase (7,8), and electron transport (9,10). 1. ### Tridiphane

This herbicide (FW = 320.43 g/mol; CAS 58138-08-2) is a substrate of epoxide hydrolases and glutathione S-transferases. The glutathione conjugate of tridiphane is a strong inhibitor of glutathione S-transferase (1,2) and

tabersonine 16-hydroxylase (3). 1. Deng & Hatzios (2002) *Pestic. Biochem. Physiol.* **72**, 10. 2. Lamoureux & Rusness (1986) *Pestic. Biochem. Physiol.* **26**, 323. 3. St-Pierre & De Luca (1995) *Plant Physiol.* **109**, 131.

### Triethanolamine

This frequently pH buffer component (FW<sub>free-base</sub> = 149.19 g/mol; CAS 102-71-6) is a hygroscopic and viscous liquid (melting point = 21.57°C; B.P. = 335.4°C) and has a pK<sub>a</sub> value of 7.76 at 25°C (dpK<sub>a</sub>/dT = -0.020 pH units/°C). **Target(s):** choline sulfotransferase (1); dipeptidase (2); formimino-tetrahydrofolate cyclodeaminase (3); nardilysin (4); oligo-1,6-glucosidase, or isomaltase (5); sucrose α-glucosidase, or sucrose-isomaltase (5). 1. ### (Triethyl)lead Chloride

This cytotoxic alkylated lead (FW = 329.8 g/mol; CAS 5224-23-7), which is the major metabolite of the once widely used gasoline anti-knocking additive (tetraethyl)lead, is known to disrupt neurofilaments within neurons. *Caution:* Exposure to this agent is known to cause permanent neurologic deficiencies in experimental animals. See also *Tetraethyllead*. **Target(s):** γ-aminobutyrate (GABA) uptake (1,2); δ-aminolevulinate dehydratase, or porphobilinogen synthase (3-5); Ca<sup>2+</sup>-channel, voltage-dependent (6); F<sub>0</sub>F<sub>1</sub> ATPase, or H<sup>+</sup>-transporting two-sector ATPase (7); glutathione S-transferase, or ligandin (8); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (7); oxidative phosphorylation (7,9); tubulin polymerization, or microtubule assembly (10,11). 1. ### Triethyloxonium Tetrafluoroborate

This moisture-sensitive reagent (FW = 189.99 g/mol; CAS 368-39-8) reacts, under acidic conditions, with carboxyl groups within proteins and enzymes to form ethyl esters. To control which carboxyl groups are esterified, one may

vary pH, ionic strength, or degree of active-site occupancy by a substrate, coenzyme, metal ion or regulatory effector. If the unmodified COOH group is essential for catalytic activity, then triethyloxonium tetrafluoroborate will behave as an active site-directed irreversible enzyme inhibitor. **Target(s):**  $\beta$ -lactamase I (1); lysozyme (2,3); trypsin (4); and  $\beta$ -xylosidase (5). 1. Waley (1975) *Biochem. J.* **149**, 547. 2. Parsons, Jao, Dahlquist, *et al.* (1969) *Biochemistry* **8**, 700. 3. Parsons & Raftery (1969) *Biochemistry* **8**, 4199. 4. ### Trifluoperazine

This phenothiazine antipsychotic (FW<sub>free-base</sub> = 407.50 g/mol; CAS 117-89-5) is a dopamine D<sub>2</sub> receptor and calmodulin antagonist, an inhibitor of cAMP-gated cation channels, and an inhibitor of the calmodulin stimulation of cAMP phosphodiesterase. The dihydrochloride is hygroscopic and freely soluble in water. The ultraviolet spectra (in ethanol) has  $\lambda_{\max}$  values of 258 nm ( $\epsilon = 31600 \text{ M}^{-1}\text{cm}^{-1}$ ) and 307.5 nm ( $\epsilon = 3200 \text{ M}^{-1}\text{cm}^{-1}$ ). **Target(s):** adenylate cyclase (1,2); [ $\beta$ -adrenergic-receptor] kinase (3); 1-alkylglycerophosphocholine *O*-acetyltransferase (42); 1-aminocyclopropane-1-carboxylate synthase (4); apyrase (5); ATPase and electron transport, plant (6); Ca<sup>2+</sup>/calmodulin-dependent protein kinase II (34); Ca<sup>2+</sup> channel, type I inositol 1,4,5-trisphosphate-sensitive (7); calmodulin (8-10); calmodulin-dependent glycogen synthase kinase (11); Ca<sup>2+</sup>-transporting ATPase (12); cholesterol  $\Delta$ -isomerase, or sterol  $\Delta^{7,8}$ -isomerase (13); choline-phosphate cytidylyltransferase (35); 3',5'-cyclic-nucleotide phosphodiesterase (8,9,14); diacylglycerol *O*-acyltransferase (44); fatty-acid *o*-methyltransferase (45); G-protein coupled receptor kinase 2 (15); helicase/ATPase (16); H<sup>+</sup>-exporting ATPase (17); [3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)] kinase (30); [acyl-carrier-protein] *S*-malonyltransferase (43); [myosin light-chain] kinase (11,18,33); NAD<sup>+</sup> kinase (38-41); nucleoside-triphosphatase (16); 1-phosphatidylinositol 4-kinase (37); 1-phosphatidylinositol-4-phosphate 5-kinase (36); phospholipase A<sub>2</sub> (19); phosphoprotein phosphatase (21,25-27); phosphorylase kinase (31,32); phosphoserine phosphatase (28,29); protein kinase C (9-11,20); protein phosphatase 2B (21,26); protein-tyrosine-phosphatase, weakly inhibited (22); stearyl-CoA 9-desaturase (46); ubiquitin-calmodulin synthetase, or ubiquitin:calmodulin ligase (23); Xaa-methyl-His Dipeptidase, or anserinase, or *N*-acetylhistidine deacetylase (24). 1. ***N*-(Trifluoroacetyl)-L-valyl-L-alanine *p*-(trifluoromethyl)anilide**, similar in action to *N*-(Trifluoroacetyl)-L-lysyl-L-leucine *p*-(Isopropyl)anilide

### 3,3,3-Trifluoroalanine

This modified alanine (FW = 143.07 g/mol; CAS 10065-69-7) is a mechanism-based inactivator. For example, inactivation of the alanine racemases from the Gram-negative organism *Salmonella typhimurium* and Gram-positive organism *Bacillus stearothermophilus* with 2,2,2-trifluoroalanine occurs with the same rate constant as that for formation of a broad 460-490-nm enzyme chromophore (1). Loss of two fluoride ions per mole of inactivated enzyme and retention of [1-<sup>14</sup>C]trifluoroalanine label accompany inhibition, suggesting a monofluoro enzyme adduct. Partial denaturation (1 M guanidine) leads to rapid return of the initial 420-nm chromophore, followed by a slower ( $t_{1/2} \approx 30 \text{ min}^{-1}$ ) loss of the fluoride ion and <sup>14</sup>CO<sub>2</sub> release. At this point, reduction by NaBH<sub>4</sub> and tryptic digestion yielded a single radiolabeled peptide, with lysine-38 covalently attached to the PLP cofactor. The likely mechanism for enzyme inactivation by trifluoroalanine entails nucleophilic attack of released aminoacrylate on the PLP aldimine leads to enzyme inactivation (1). For trifluoroalanine inactivation, nucleophilic attack of lysine-38 on the electrophilic 2,2-difluoro- $\alpha,\beta$ -unsaturated imine provides an alternative mode of inhibition for these enzymes. **Target(s):** alanine racemase (1-3); 8-amino-7-oxononanoate synthase (4); cystathionine  $\beta$ -lyase (5-8); cystathionine  $\gamma$ -lyase (8-12); cystathionine synthase (8); threonine dehydratase (8); tryptophan indole-lyase, or tryptophanase (8,13); tryptophan synthase (8,13); UDP-*N*-acetylmuramate-L-alanine ligase, inhibited by the DL-mixture (14,15). 1. **$\alpha$ -(3'-Trifluoromethylbenzylamino)benzylphosphonate**

This substituted phosphonic acid (FW<sub>free-acid</sub> = 345.26 g/mol) inhibits human prostatic acid phosphatase, IC<sub>50</sub> = 4.9 nM, amounting to a 3500-times improvement in potency over the carbon analogue,  $\alpha$ -phenylethyl. This enhanced potency is likely to result from a combination of favorable interactions with the phosphate binding region, the presence of the hydrophobic moieties of the benzylamino and phenylphosphonic acid, as well as a rigid conformer produced by an internal salt bridge between the phosphonate and the  $\alpha$ -amino group. Replacement of the phosphonic acid moiety with a phosphinic or carboxylic acid or the deletion of the benzyl substitution of the  $\alpha$ -amino group led to great reductions in potency. 1. Beers, Schwender, Loughney, *et al.* (1996) *Bioorg. Med. Chem.* **4**, 1693.

**4-Trifluoromethyl-Celecoxib**

This non-steroidal anti-inflammatory agent and celecoxib analogue (FW = 435.34 g/mol; Symbol: TFM-C), also named 4-[5-(4-trifluoromethylphenyl)-3-(trifluoromethyl)-1H-pyrazol-1-yl]benzenesulfonamide, displays 205-fold lower COX2-inhibition than celecoxib, yet is equally effective in inhibiting the secretion, but not transcription, of Interleukin-12 (IL-12 p35/p40 heterodimer) and p80 (p40/p40 homodimer) by a mechanism involving altered cytokine-chaperone interaction in the endoplasmic reticulum (ER) (1). Such behavior is consistent with findings that celecoxib inhibits experimental autoimmune encephalomyelitis (EAE) in COX-2-deficient mice, indicating action by a COX2-independent pathway. Noting that IL-12, p80, and IL-23 are structurally related cytokines sharing common p40 subunits, later investigation demonstrated that celecoxib and TFM-C also block secretion of IL-23 p40/p19 heterodimers (2). Significantly, TFM-C and celecoxib ameliorate EAE mouse model for multiple sclerosis with equal potency, coinciding with reduced IL-17 and IFN- $\gamma$  secretion by MOG-reactive T-cells and secretion of IL-23 and associated inflammatory cytokines by bone marrow-derived dendritic cells. These findings suggest that TFM-C is a promising drug candidate, one that retains celecoxib's beneficial effects in the EAE, but with greatly decreased COX2 inhibitory activity and less likelihood of exerting adverse cardiovascular effects. 1. **5-(Trifluoromethyl)-2'-deoxyuridine**

This thymidine nucleoside analogue (FW = 296.20 g/mol; CAS 70-00-8), also known by its trade name Viroptic<sup>®</sup> and by its alternative names trifluorothymidine and trifluridine, and the IUPAC name 1-[4-hydroxy-5-(hydroxymethyl)oxolan-2-yl]-5-(trifluoromethyl)pyrimidine-2,4-dione, is an

antiherpetic agent that inhibits viral DNA polymerase-catalyzed elongation. The active drug, trifluridine 5'-triphosphate, is formed after cellular uptake and enzyme-catalyzed phosphorylation. A likely contributing factor to its cytotoxicity is the failure to make correct base-pairing interactions. FTD incorporation into DNA induces DNA dysfunction, including DNA strand breaks. When combined with tipiracil to inhibit thymidine phosphorylase (which metabolically deactivates trifluridine), the resultant binary drug (known as Lonsurf<sup>®</sup>) is a promising treatment option for patients resistant to or intolerant of 5-FU-based fluoropyrimidines (See *Tipiracil*). **Target(s):** deoxycytidine kinase (1); viral DNA polymerase, via the 5'-triphosphate (2-4); thymidylate kinase, or dTMP kinase (5,6); and thymidylate synthase (7). 1. Krenitsky, Tuttle, Koszalka, *et al.* (1976) *J. Biol. Chem.* **251**, 4055. 2. Prisbe & Chen (1996) *Meth. Enzymol.* **275**, 425. 3. Satake, Takeda, Matsumura, *et al.* (1992) *Nucleic Acids Symp. **5-Trifluoromethyl-2'-deoxyuridine 5'-Monophosphate**

This modified deoxynucleotide (FW<sub>free-acid</sub> = 376.18 g/mol), also known as trifluorothymidine 5'-monophosphate, is a mechanism-based inhibitor of *Lactobacillus casei* thymidylate synthase. The inhibitor binds to the active site of the enzyme in the absence of the cofactor N<sup>5</sup>,N<sup>10</sup>-methylene tetrahydrofolate. Cys198 attacks C6 of the pyrimidine, thereby activating release of fluoride ion from the trifluoromethyl group. The activated heterocycle adduct then reacts with a nucleophile of the enzyme (Tyr146) to form a moderately stable covalent complex (1-5). 1. ### Triflupromazine

This tranquilizing, antipsychotic phenothiazine (FW = 352.42 g/mol; CAS 146-54-3), also known as (*N,N*-dimethyl-2-(trifluoromethyl)-10*H*-phenothiazine-10-propanamine), is similar, both in structure and action, to the more widely used trifluoperazine. **Target(s):** adenosylmethionine decarboxylase (1); apyrase (2); calmodulin (3); calmodulin-dependent 3'5'-cAMP phosphodiesterase (3); K<sup>+</sup> channel, ATP-sensitive (4); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (5); [pyruvate dehydrogenase (acetyl-transferring)]-phosphatase, weakly inhibited (6). 1. ### Trifluralin

This pre-emergence herbicide (FW = 335.28 g/mol; CAS 1582-09-8), also known as Treflan and  $\alpha,\alpha,\alpha$ -trifluoro-2,6-dinitro-*N,N*-dipropyl-*p*-toluidine, is a potent inhibitor of plant microtubule assembly and plant cell division. Dinitroaniline herbicides (such as trifluralin and oryzalin) have been developed for the selective control of weeds in arable crops. No effect of trifluralin on animal microtubule systems has been reported, suggesting that trifluralin's action reveals a pharmacological difference between plant and animal tubulins (1). Likewise, this agent is without effect on yeasts such as *Schizosaccharomyces pombe* (2). Mutation of a single residue (Thr239-to-Ile), situated at the dimer interface in the microtubule protofilaments, confers resistance to dinitroaniline herbicides (3). Trifluralin also inhibits photosynthetic electron transport (4). 1. Hess & Bayer (1977) *J. Cell Sci.* **24**, 351. 2. Walker (1982) *J. Gen. Microbiol.* **128**, 61. 3. **Trifluridine, See 5-(Trifluoromethyl)-2'-deoxyuridine**

### Trifop

This herbicide (FW = 326.27 g/mol; CAS 58594-74-4), also named (*RS*)-2-[4-( $\alpha,\alpha,\alpha$ -trifluoro-*p*-tolylxy)phenoxy]propionic acid, is a strong reversible inhibitor of acetyl-CoA carboxylase, with an IC<sub>50</sub> value of 0.26  $\mu$ M for the wheat enzyme (1,2). 1. Rendina, Craig-Kennard, Beaudoin & Breen (1990) *J. Agric. Food Chem.* **38**, 1282. 2. Rendina, Felts, Boudoin, *et al.* (1988) *Arch. Biochem. Biophys.* **265**, 219.

### Trigocherrierin A

This daphnane diterpenoid orthoester (FW = 598.69 g/mol) from leaves of the critically endangered New Caledonian plant *Trigonostemon cherrieri* is a potent and selective replication inhibitor of Chikungunya Virus, or CHIKV (EC<sub>50</sub> = 0.6  $\mu$ M). Its complex structure and stereochemical features were determined by mass spectroscopy, 1-D and 2-D NMR, as well as structural data already in the literature. 1. Bourjot, Leyssen, Neyts, Dumontet & Litaudon (2014) *Molecules* **19**, 3617.

### Trigonelline

This zwitterion nicotinate catabolite (FW = 137.14 g/mol; FW<sub>hydrochloride</sub> = 173.60 g/mol; CAS 535-83-1), also known as 3-carboxy-1-methylpyridinium inner salt and nicotinic acid *N*-methylbetaine, accumulates in plants, sea urchin, jellyfish, as well as the urine of humans after ingestion of nicotinic acid. Trigonelline is a cell cycle regulator in a number of organisms and causes G<sub>2</sub> cell-cycle arrest (1). It also inhibits D-amino-acid oxidase (2), acetylcholinesterase (3), DNA replication (1) and is a product of the reaction catalyzed by nicotinate *N*-methyltransferase. 1. Mazzuca, Bitonti, Innocenti & Francis (2000) *Planta* **211**, 127. 2. Nishina, Sato, Miura & Shiga (2000) *J. Biochem.* **128**, 213. 3. Bergmann, Wilson & Nachmansohn (1950) *J. Biol. Chem.* **186**, 693.

### Trihexyphenidyl Hydrochloride

This anti-parkinson disease agent (FW = 337.93 g/mol; hydrochloride is slightly soluble (1.0 g/100 mL at 25°C)), also known as 3-(1-piperidyl)-1-cyclohexyl-1-phenyl-1-propanol hydrochloride, is an anticholinergic agent (1-3). Both stereoisomers are biologically active and different isotopes of the muscarinic receptor display different degrees of preference for the two enantiomers. 1. Onali, Aasen & Olanas (1994) *Brit. J. Pharmacol.* **113**, 775. 2. Dorje, Wess, Lambrecht, *et al.* (1991) *J. Pharmacol. Exp. Ther.* **256**, 727. 3. Hudkins & DeHaven-Hudkins (1991) *Life Sci.* **49**, 1229.

### 2,10,11-Trihydroxyaporphine

This hygroscopic and photosensitive compound, also known as 2-hydroxyapomorphine (FW<sub>free-base</sub> = 283.33 g/mol), is a dopamine receptor agonist. **Target(s):** amyloid-beta fibril formation (1); and dihydropteridine reductase, inhibited by both the *R*(-) and *S*(+)-stereoisomers (2). 1. Lashuel,

Hartley, Balakhaneh, *et al.* (2002) *J. Biol. Chem.* **277**, 42881. 2. Shen, Smith, Davis & Abell (1984) *J. Biol. Chem.* **259**, 8994.

### 2,3,4-Trihydroxybenzoate

This aromatic acid (FW<sub>free-acid</sub> = 170.12 g/mol; CAS 56128-66-6) inhibits 4-hydroxybenzoate decarboxylase (1,2), protocatechuate decarboxylase, or 3,4-dihydroxybenzoate decarboxylase (3), *o*-pyrocatechuate decarboxylase (4,5), and xanthine oxidase (6). 1. Gallert & Winter (1992) *Appl. Microbiol. Biotechnol.* **37**, 119. 2. He & Wiegel (1995) *Eur. J. Biochem.* **229**, 77. 3. He & Wiegel (1996) *J. Bacteriol.* **178**, 3539. 4. ### 3,3',5'-Triiodo-L-thyronine

This amino acid (FW = 650.98 g/mol; pK<sub>a</sub> values of 2.2, 8.40 (phenol OH), and 10.1), symbolized by T<sub>3</sub>, is the principal thyroid hormone derived by proteolysis of thyroglobulin. T<sub>3</sub> is about five-fold more potent than T<sub>4</sub>. Much of its physiological role is associated with its binding to the thyroid hormone receptor, with resulting regulation of gene expression. In mature organisms, the thyroid hormones increase oxygen consumption, elevate metabolic rates, increase thermogenesis, and induce the biosynthesis of RNA and proteins (*e.g.*, mitochondrial glycerol-1-phosphate dehydrogenase). T<sub>3</sub> also inhibits oxidative phosphorylation (1,2). They also participate in embryogenesis, growth and development, and sexual maturation. Enzymes that can utilize 3,3',5'-triiodo-L-thyronine as a substrate or alternative substrate include thyroid-hormone aminotransferase, diiodotyrosine aminotransferase, and certain phenol sulfotransferases. This hormone absorbs UV light:  $\lambda_{\text{max}} = 295$  nm ( $\epsilon = 4090$  cm<sup>-1</sup>M<sup>-1</sup>) in 40 mM HCl; also,  $\lambda_{\text{max}} = 224$  nm ( $\epsilon = 49200$  cm<sup>-1</sup>M<sup>-1</sup>) and 320 nm ( $\epsilon = 4660$  cm<sup>-1</sup>M<sup>-1</sup>) in dilute NaOH. T<sub>3</sub> is also photosensitive and decomposes with attendant deiodination. **Target(s)**: alcohol dehydrogenase (3-5); aldehyde dehydrogenase (6); aromatase, or CYP19 (7); aspartate aminotransferase (8); cAMP-dependent protein kinase (9); 3',5'-cyclic-nucleotide phosphodiesterase (10-12); cystathionine  $\gamma$ -lyase (13,14); 15-hydroxyprostaglandin dehydrogenase (15); IMP dehydrogenase (16); glucose-6-phosphate dehydrogenase (17); glutamate dehydrogenase (18); malate dehydrogenase (19-21); monoamine oxidase (22); NAD(P)H dehydrogenase, or DT diaphorase (23-25); NAD(P)<sup>+</sup> transhydrogenase (26); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (27); oxidative phosphorylation (1,2); phenylalanyl-tRNA synthetase (28); prostaglandin-D synthase (29); protein-disulfide isomerase, inhibited by both D- and L-isomers (30,31); pyruvate kinase (32); thyroxine 5-deiodinase (33,34); and tyrosine aminotransferase (35). 1. **Trilostane**

This synthetic epoxy sterol (FW = 329.44 g/mol; CAS 13647-35-3, 27107-98-8, and 28414-46-2;  $\epsilon_{252\text{nm}} = 8300 \text{ M}^{-1}\text{cm}^{-1}$  in ethanol; Solubility: 70 mg/mL DMSO, <1 mg/mL Water), also known as Veteryl and systematically as 4 $\alpha$ ,5-epoxy-17 $\beta$ -hydroxy-3-oxo-5 $\alpha$ -androstane-2 $\alpha$ -carbonitrile, is an inhibitor of steroid biosynthesis and is used clinically as an adrenocortical suppressant and in the treatment of breast cancer. As a potent inhibitor of 3 $\beta$ -hydroxysteroid dehydrogenase (*Reaction*: 3 $\beta$ -hydroxy- $\Delta^5$ -steroid (or pregnenolone) + NAD<sup>+</sup>  $\rightleftharpoons$  3-oxo- $\Delta^5$ -steroid (or progesterone) + NADH + H<sup>+</sup>), trilostane is used in the treatment of Cushing's syndrome, or hypercortisolism. **Target(s)**: estrogen receptor (1); estrone sulfate sulfatase, weakly inhibited (2); 15-hydroxysteroid dehydrogenase (3); 3 $\beta$ -hydroxysteroid dehydrogenase/steroid  $\Delta$ -isomerase (4-12); and 3-ketosteroid reductase (13). **1.** Puddefoot, Barker, Glover, Malouire & Vinson (2002) *Int. **Trimetazidine**

This antianginal agent (FW<sub>free-base</sub> = 266.34 g/mol) inhibits acetyl-CoA C-acyltransferase (1,2), carnitine palmitoyltransferase (3,4), fatty acid oxidation (1-4), and Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (5). By assessing insulin resistance (measured by glucose/insulin tolerance test) and lipid metabolite content in the gastrocnemius muscle of trimetazidine-treated obese mice (15 mg/kg/day), a recent study (6) found a mild shift in substrate preference towards carbohydrates as an oxidative fuel source, as evidenced by an increase in the respiratory exchange ratio. This shift was accompanied by an accumulation of long-chain acyl CoA and an increase in triacylglycerol content in gastrocnemius muscle, without exacerbating high-fat diet (HFD)-induced insulin resistance. **1.** Fragasso, Spoladore, Cuko & Pallosi (2007) *Curr. **Trimethoprim**

This broad-spectrum, cell-penetrating antibiotic (FW = 290.32 g/mol; CAS 738-70-5), also known systematically as 2,4-diamino-5-(3',4',5'-trimethoxybenzyl)pyrimidine, inhibits enzymatic formylation and is a strong inhibitor of dihydrofolate reductase (*Reaction*: Dihydrofolate + NADPH  $\rightleftharpoons$

Tetrahydrofolate + NADP<sup>+</sup>), exhibiting 50,000–100,000-times greater affinity for the bacterial reductase than its mammalian counterpart (1-12). By denying bacteria of sufficient tetrahydrofolate to support the synthesis of required DNA precursors (especially dTMP), replication cannot proceed and death ensues. Trimethoprim is readily absorbed by the oral route and is widely distributed in body fluids and tissues, where it is active against a wide range of Gram-positive and Gram-negative aerobes. When combined with sulfamethoxazole, a cell-penetrating structural analogue of *p*-aminobenzoic acid that inhibits dihydropteroate synthetase, trimethoprim is highly effective against *Listeria monocytogenes* and *Shigella flexneri*, intracellular pathogens that rely on induced phagocytosis by nonprofessional phagocytes and subsequent lysis of the resulting pathogen-laden phagolysosome to enter the cytoplasm of host cells, where they multiply and undergo actin-based motility and cell-to-cell spread that are cardinal features in both listeriosis and shigellosis (13). Bacterial resistance to trimethoprim is due to a variety of mechanisms, including mobile genetic elements (plasmids, transposons and integrons) that encode trimethoprim resistance factors, some generating additional mutants in DHFR that are less sensitive to trimethoprim inhibition. Trimethoprim-resistance genes (*dfrA17* and *dfrA12*) are often found in clinical isolates of trimethoprim-resistant *Escherichia coli* and are also used as markers in cloning vectors. **Target(s)**: CYP2C8 and CYP2C9 (1); glutathione synthetase (14); thymidylate synthase (15,16). **Key Pharmacokinetic Parameters**: See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) **3,4,5-Trimethoxybenzamidoxime**

This hydroxyl radical scavenger and Fe<sup>3+</sup> chelator (FW = 184.2 g/mol; CAS 95933-74-7;  $\lambda_{\text{max}} = 214$  and 261 nm; stability > 2 years, when stored desiccated at -20<sup>o</sup> C), also known as trimidox and VF 233, potently inhibits ribonucleotide reductase ( $K_i = 5 \mu\text{M}$ ) or ~100x more effective than hydroxyurea (1) and induces apoptosis in cultured cells (2). Trimidox is also a candidate antineoplastic agent (3). **1.** Szekeres, Fritizer, Strobl, *et al.* (1994) *Blood* **84**, 4316. **2.** Kanno, Uwai, Tomizawa, *et al.* (2006) *Basic Clin. Pharmacol. **3,4,5-Trimethoxybenzoic Acid 8-(Dimethylamino)octyl Ester, See 8-(N,N-Diethylamino)octyl 3,4,5-Trimethoxybenzoate****4S-(3,4,5-Trimethoxy)benzyl-D-glutamic Acid, See (2R,4S)-2-Amino-4-(3,4,5-trimethoxy)benzylpentanedioate****Trimethylacetyl Phosphate, See 2,2-Dimethylpropionyl Phosphate****Trimethylamine**

This naturally occurring tertiary amine (FW = 59.11 g/mol; pK<sub>a</sub> = 9.9; Colorless gas; M.P. = -117.08 <sup>o</sup>C; B.P. = 2.87<sup>o</sup>C) is formed by gut bacteria

during the metabolic degradation of carnitine, choline, and other trimethylamine-containing metabolites (**See Trimethylamine N-oxide**). The free base has the odor of rotting fish. Trimethylammonium hydrochloride is a deliquescent solid that decomposes at 277-278°C and is very soluble in water and ethanol. **Target(s)**: acetylcholinesterase, inhibited by the cation (1-8); acid phosphatase (9); anthranilate synthase (10); choline dehydrogenase (11); choline-sulfatase (12); choline sulfotransferase (13); flavin monooxygenase, or *N,N*-dimethylaniline *N*-oxygenase, or thiobenzamide *S*-monooxygenase (14-16);  $\beta$ -glucosidase (17); quinoprotein methylamine dehydrogenase (18); trimethylamine-oxide aldolase (19-21), however, reference 21 reports no inhibition. 1. ### Trimethylamine N-Oxide

This water- and ethanol-soluble alkyl-nitrogen oxide (FW = 75.111 g/mol;  $pK_a = 4.65$  at 20°C), a natural osmolyte formed in the degradation of nitrogenous substances in many organisms, is a deliquescent solid that decomposes on heating to dimethylamine and formaldehyde. **Target(s)**:  $\alpha_1$ -antitrypsin, polymerization of M and Z variants (1); electron transport (2); and phosphorylase kinase (3). 1. Devlin, Parfrey, Tew, Lomas & Bottomley (2001) *Amer. J. Respir. Cell Mol. Biol.* 24, 727. 2. Suzuki, Kubo, Shinano & Takama (1992) *Microbios* 71, 145. 3. Chebotareva, Andreeva, Makeeva, Livanova & Kurganov (2004) *J. Mol. Recognit.* 17, 426.

### *N,N,N*-Trimethylaminomethaneboronic Acid

This boronate analogue of betaine (FW = 118.97 g/mol) competitively inhibits rat liver betaine:homocysteine *S*-methyltransferase (or BHMT),  $K_i = 45 \mu\text{M}$ . Since the  $K_m$  for betaine measured with the purified enzyme is near 0.1 mM, the boronic acid analogue of betaine appears to function more effectively as a substrate analogue inhibitor of BHMT. 1. Lee, Cava, Amiri, Ottoboni & Lindquist (1992) *Arch. Biochem. Biophys.* 292, 77.

### *p*-(Trimethylammonio)benzenediazonium Fluoroborate

This quaternary amine and diazonium salt is ligand for acetylcholine receptor (1) and an irreversible inhibitor of acetylcholinesterase (2-5). 1. Changeux, Podleski & Wofsy (1967) *Proc. Natl. Acad. Sci. U.S.A.* 58, 2063. 2. Shaw (1970) *The Enzymes*, 3rd ed. (Boyer, ed.), 1, 91. 3. Froede & Wilson (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), 5, 87. 4. Meunier & Changeux (1969)

*FEBS Lett.* 2, 224. 5. Wofsy & Michaeli (1967) *Proc. Natl. Acad. Sci. U.S.A.* 58, 2296.

### *m*-(Trimethylammonio)trifluoroacetophenone

This quaternary amine (FW<sub>chloride</sub> = 267.68 g/mol), also known as *m*-(*N,N,N*-trimethylammonio)-2,2,2-trifluoroacetophenone and TMTFA, is a highly potent, reversible, time-dependent, transition-state inhibitor of *Electrophorus electricus* acetylcholinesterase ( $K_i = 1.3 \text{ fM}$ ) and *Torpedo californica* acetylcholinesterase ( $K_i = 15 \text{ fM}$ ) (1-4). TMTFA therefore exhibits about  $10^{10}$ -times tighter binding to acetylcholinesterase than acetylcholine. 1. Brodbeck, Schweikert, Gentinetta & Rottenberg (1979) *Biochim. Biophys. Acta* 567, 357. 2. Massiah, Viragh, Reddy, et al. (2001) *Biochemistry* 40, 5682. 3. Ordentlich, Barak, Kronman, et al. (1998) *J. Biol. Chem.* 273, 19509. 4. ### *N*-(1,5,9-Trimethyldecyl)-4 $\alpha$ ,10-dimethyl-8-aza-*trans*-decal-3 $\beta$ -ol

This isoquinoline derivative (FW<sub>free-base</sub> = 365.64 g/mol), also known as (4 $\alpha$ ,5 $\alpha$ ,6 $\alpha$ ,8 $\alpha$ )-decahydro-5,8 $\alpha$ -dimethyl-2-(1,5,9-trimethyldecyl)-6-isoquinolinol, 4 $\alpha$ ,10-dimethyl-8-aza-*trans*-decal-3 $\beta$ -ol, and MDL 28815, inhibits phytosterol and cholesterol biosynthesis. It mimics the carbocation intermediates postulated for the enzymic cyclization of 2,3-oxidosqualene. Note MDL 28815 does not inhibit  $\beta$ -amyrin synthase. **Target(s)**: cholesterol  $\Delta$ -isomerase, or sterol  $\Delta^{7,8}$ -isomerase (1); cycloartenol synthase (2); cycloolecalenol cycloisomerase (3); and lanosterol synthase (2,4). 1. Moebius, Reiter, Bermoser, et al. (1998) *Mol. Pharmacol.* 54, 591. 2. Taton, Benveniste & Rahier (1986) *Biochem. Biophys. Res. Commun.* 138, 764. 3. ### 4,5',6-Trimethylpsoralen, See Trioxsalen

### Trimethylquinone, See Cumoquinone

### *N,N,N*-Trimethyl-1-(4-*trans*-stilbenoxy)-2-propylammonium Iodide

This oxystilbene derivative (FW = 422.33 g/mol), often referred to simply as F3, is a relatively potent and apparently competitive antagonist of nicotinic acetylcholine receptors. The *R*-stereoisomer is more potent ( $IC_{50} = 0.35 \mu\text{M}$ )

than the *S*-enantiomer ( $IC_{50} = 1.5 \mu\text{M}$ ). **1.** Di Angelantonio, Nistri, Moretti, Clementi & Gotti (2000) *Brit. J. Pharmacol.* **129**, 1771.

### (Trimethyl)tin Chloride

This synthetic organotin compound (FW = 199.27 g/mol; CAS 1066-45-1; B.P. = 148 °C; Soluble in chloroform and organic solvents, Miscible in H<sub>2</sub>O; *Symbol*: TMT; colorless-to-white granular solid; unpleasant odor), also known as chlorotrimethylstannane; chlorotrimethyltin, and trimethyl chlorostannane, is an insect, bacteria and fungus control agent that is used primarily to preserve wood, textiles, leather, and paints. **Caution: TMT is neurotoxic and causes irreversible brain damage in test animals.** A factor contributing to organotin toxicity is its ability to pass through membranes. TMT-induced cognitive dysfunction and exhibited significant decreases in JAK2/STAT3 signaling and M<sub>1</sub> muscarinic acetylcholine receptor (mAChR) expression, as well as other cholinergic parameters (1). TMT decreased intracellular pH and opened K<sup>+</sup> channels in renal intercalated cells, suggesting that it can directly inhibit the activity of H<sup>+</sup>/K<sup>+</sup>-ATPases in renal intercalated cells, reducing urine K<sup>+</sup> reabsorption and inducing hypokalemia (2). Trimethyltin inhibits the uptake of  $\gamma$ -aminobutyric acid (GABA), norepinephrine and serotonin by mouse forebrain synaptosomes with  $IC_{50}$  values of 75, 43 and 24  $\mu\text{M}$ , respectively (3). **Target(s):**  $\gamma$ -aminobutyrate uptake (1); ATPases (5-9), ATP synthase (6,8,10), Ca<sup>2+</sup>-dependent ATPase (7,9), calmodulin (11,12), K<sup>+</sup>-dependent ATPase (5), mitochondrial inner-membrane anion channel (6); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (5,8); protein biosynthesis (13); and tubulin polymerization, or microtubule assembly (14). **1.** Kim, Tran, Shin, *et al.* (2013) *Cell Signal.* **25**, 1348. **2.** Tang, Yang, Lai, *et al.* (2010) *Toxicology* **271**, 45. **3.** Doctor, Costa, Kendall & Murphy (1982) *Toxicology* **25**, 213. **4.** Costa (1985) *Toxicol. ### Trimetrexate

This lipophilic methotrexate analogue (FW = 369.42 g/mol; CAS 52128-35-5), also known as 2,4-diamino-5-methyl-6-[(3,4,5-trimethoxyanilino)methyl]quinazoline, is a tight-binding inhibitor ( $K_i = 40 \text{ pM}$ ) of dihydrofolate reductase (1-4). It differs from methotrexate in its transport and intracellular retention, and may be useful against tumors resistant to methotrexate because of impaired transport or deficient polyglutamylation. **1.** Elslager, Johnson & Werbel (1983) *J. Med. Chem.* **26**, 1753. **2.** Bertino, Sawicki, Moroson, Cashmore & Elslager (1979) *Biochem. Pharmacol.* **28**, 1983. **3.** Jackson, Fry, Boritzki, *et al.* (1984) *Adv. ### Trimipramine

This tricyclic antidepressant (FW<sub>free-base</sub> = 294.44 g/mol; CAS 739-71-9) increases rapid eye movement sleep and nocturnal prolactin secretion, while suppressing nocturnal cortisol secretion. Although trimipramine shares equivalent efficacy with doxepin, imipramine, maprotiline and amitriptyline, it possesses a different side-effect profile, including lower cardiotoxicity, lower epileptogenic potential, and differing neurotransmitter function/reuptake (1). Moreover, trimipramine only weakly inhibits noradrenaline and serotonin reuptake and does not down-regulate  $\beta_1$ -adrenoceptors and does not down-regulate  $\beta_1$ -adrenoceptors (1). **Target(s):**  $\gamma$ -aminobutyrate transport (2); Ca<sup>2+</sup>-dependent ATPase (3,4); lysosomal acid sphingomyelinase (5); and monoamine oxidase (6,7); Human serotonin transporter (SERT),  $K_i = 150 \text{ nM}$ ; Human norepinephrine transporter (NET),  $K_i = 2.4 \mu\text{M}$ ; Human dopamine transporter (DAT),  $K_i = 3.8 \mu\text{M}$ ; Human histamine H<sub>1</sub> receptor,  $K_i = 1.4 \text{ nM}$ ; Rat adrenergic  $\alpha_1$  receptor,  $K_i = 24 \text{ nM}$ ; Rat adrenergic  $\alpha_{2A}$  receptor,  $K_i = 1.4 \mu\text{M}$ ; Rat adrenergic  $\alpha_{2B}$  receptor,  $K_i = 0.4 \mu\text{M}$ ; Human muscarinic acetyl-choline receptors (mAChRs),  $K_i = 59 \text{ nM}$ ; Rat serotonin 5-HT<sub>2A</sub> receptor,  $K_i = 20 \text{ nM}$ ; Rat serotonin 5-HT<sub>2C</sub> receptor,  $K_i = 540 \text{ nM}$ ; Rat serotonin 5-HT<sub>3</sub> receptor,  $K_i = 9.1 \mu\text{M}$ ; Rat dopamine D<sub>1</sub> receptor,  $K_i = 350 \text{ nM}$ ; Rat dopamine D<sub>2</sub> receptor,  $K_i = 58 \text{ nM}$ . **1.** Gastpar (1989) *Drugs* **38**, Supplement 1, 43. **2.** Nakashita, Sasaki, Sakai & Saito (1997) *Neurosci. ### 2',3'-O-(2,4,6-Trinitrophenyl)uridine 5'-Monophosphate

This modified UMP (FW = 534.26 g/mol), also known as 2',3'-O-(2,4,6-trinitrocyclohexadienyl)uridine 5'-monophosphate, is a strong inhibitor of UDP-glucose 4-epimerase. The extreme sensitivity of the fluorescence emission spectrum of this analog to solvent polarity makes it an excellent probe for the study of the environment at the active site. **1.** Ray, Ali & Bhaduri (1992) *Indiana J. Biochem. Biophys.* **29**, 209.

### Triolein

This water-insoluble fatty acid triester (FW = 885.45 g/mol; MP = -4° C), also called 1,2,3-tri(*cis*-9-octadecenyl)-glycerol and glyceryl trioleate, is a triacylglycerol, in which all three fatty acyl components are oleoyl residues. Triolein inhibits retinyl-palmitate esterase (1), *all-trans*-retinyl-palmitate hydrolase (1); 11-*cis*-retinyl-palmitate hydrolase (1); sphingomyelin phosphodiesterase (2). **1.** Mata, Mata & Tsing (1996) *J. Lipid Res.* **37**, 1947. **2.** Liu, Nilsson & Duan (2002) *Lipids* **37**, 469.

### Tripelennamine

This pyridine/ethylenediamine-class antihistamine and psychoactive drug (FW = 255.36 g/mol; CAS 91-81-6 (free base) and 154-69-8 (monohydrochloride)), also known by the trade name Pyribenzamine<sup>®</sup> and systematic name *N*-benzyl-*N'*-dimethyl-*N*-2-pyridylethylenediamine, is a histamine H<sub>1</sub> receptor antagonist used to treat hay fever and other severe allergies. Tripelennamine was the first antihistamine ever synthesized, a feat accomplished by Djerassi, Huttner & Scholz in 1943 (U.S. Patent No. 2,406,594). A recent analysis of cationic amphiphilic drugs that are potent inhibitors of yeast sporulation revealed that tripelennamine induces sporulation-specific cytotoxicity and a strong inhibition of meiotic M phase (1). Moreover, chemical-genomic screening identified genes involved in autophagy as hypersensitive to tripelennamine (1). 1. Schlecht, St. Onge, Walther, François & Davis (2012) *PLoS One* 7, e42853.

### Tris(hydroxymethyl)aminomethane

This widely used primary amine-containing buffer (FW<sub>free-base</sub> = 121.14 g/mol; CAS 77-86-1), known commonly as Tris, is a weak base with a pK<sub>a</sub> of 8.3 at 20°C and 8.06 at 25°C, with dpK<sub>a</sub>/dT value of -0.028. Many enzymes that are inhibited by Tris. Moreover, certain pH electrodes are adversely affected by prolonged exposure to elevated Tris concentrations. Substrate and products can also interact with this buffer. The lack of enzymatic activity in Tris buffer for 2-dehydro-3-deoxyglucuronate aldolase, for example, is likely due to the reaction of the buffer with the substrate (1).

**Target(s):** acetyl-CoA C-acyltransferase (236); acetyl-CoA synthetase, *or* acetate:CoA ligase (2); acetylenecarboxylate hydratase (101); *N*-acetylmuramoyl-L-alanine amidase (109); acid phosphatase (207); adenosylhomocysteine nucleosidase (124); adenylosuccinate synthetase (3); alcohol dehydrogenase (4); alternansucrase (220); D-amino-acid aminotransferase (213); aminolevulinatase aminotransferase (210,211); 5-aminolevulinatase synthase (234); aminopeptidase PS (5);  $\alpha$ -amylase (6); amylo- $\alpha$ -1,6-glucosidase/4- $\alpha$ -glucanotransferase, *or* glycogen debranching enzyme;  $K_i$  = 12 mM (87,147-153); amylsucrase (229); D-arabinose isomerase (7,92); arylamine glucosyltransferase (223); asparaginyl-tRNA synthetase (88); aspartate-semialdehyde dehydrogenase (8); ATP Sulfurylase, *or* sulfate adenylyltransferase (9); bacterial leucyl aminopeptidase (122); biuret amidohydrolase (107); branched-chain-amino-acid aminotransferase (212); branched-chain- $\alpha$ -keto-acid dehydrogenase, yeast (10); carbamoyl-phosphate synthetase I, ammonia-utilizing (11); carnitine dehydratase (100); cellulose 1,4- $\beta$ -cellobiosidase (136); ceramide glucosyltransferase (222); cholesterol-5,6-oxide hydrolase (123); clostripain (12,13); cystathionine  $\gamma$ -lyase (14); cytochrome *b*<sub>5</sub> reductase (15); 2-dehydro-3-deoxyglucuronate aldolase, *or* 2-keto-3-deoxyglucuronate aldolase (1); 2-dehydro-3-deoxy-D-gluconate 6-dehydrogenase, *or* 2-keto-3-deoxy-D-gluconate dehydrogenase (16); 2-dehydropanoate aldolase (103); 3-dehydroquininate synthase (17); 2-deoxyglucosidase (131); 3-deoxy-mannooctulosonate-8-phosphatase (18); deoxyribonuclease I (203,204); deoxyribonuclease X (202); dextranucrase (19); 4,5-dihydroxyphthalate decarboxylase (104); dipeptidase (20,21); dipeptidyl-peptidase II (22,113-121); diphosphate:serine phosphotransferase, weakly (209); DNA  $\beta$ -glucosyltransferase (23); DNA nucleotidyltransferase, *or* terminal deoxyribonucleotidyltransferase (24,208); dodecenoyl-CoA isomerase, *or*  $\Delta^{3,2}$ -enoyl-CoA isomerase (95); ecdysone 20-monooxygenase (242); electron transport, chloroplast (25); enoyl-CoA hydratase (95); flavone 7-*O*- $\beta$ -glucosyltransferase (721); fructan  $\beta$ -fructosidase (139);  $\beta$ -fructofuranosidase, *or* invertase (26,163-165); L-fucose isomerase (7,92);  $\beta$ -D-fucosidase (144-146);  $\alpha$ -L-fucosidase (141); galactinol:raffinose galactosyltransferase, *or* stachyose synthase (224); galactose oxidase (27);  $\alpha$ -

galactosidase (28,168);  $\beta$ -galactosidase (167); glucan 1,3- $\alpha$ -glucosidase, *or* glucosidase II; (32) mannosyl-oligosaccharide glucosidase II, (32,137,138); glucan 1,4- $\alpha$ -glucosidase, *or* glucoamylase (29,200,201); 4- $\alpha$ -glucanotransferase (225);  $\alpha$ -glucosidase (30,31,176-196);  $\beta$ -glucosidase (169-175); glucosylceramidase (33);  $\beta$ -glucuronidase (154); glutamate dehydrogenase (34); glutamate formimidoyltransferase (35,241); glutamate mutase, *or* methylaspartate mutase (36);  $\gamma$ -glutamyl kinase, *or* glutamate 5-kinase (37); glyoxylate dehydrogenase, acylating (38); glyceraldehyde-3-phosphate dehydrogenase (39); glycine:oxaloacetate aminotransferase (40); glycosylceramidase (33); GMP synthetase, glutamine hydrolyzing, *or* XMP amidotransferase (41); guanosine phosphorylase (42); hemoglobin S polymerization (43); histidine *N*-acetyltransferase, weakly inhibited (235); H<sup>-</sup>-transporting inorganic pyrophosphatase (44); (*S*)-2-hydroxy-acid oxidase (45); 3-hydroxyacyl-CoA dehydrogenase (95); 3-hydroxybutyryl-CoA epimerase, *or* 3-hydroxyacyl-CoA epimerase (95); 16 $\alpha$ -hydroxyprogesterone dehydratase (99); isomaltase (46); isomaltulose synthase (90); 3-ketoacyl-CoA thiolase (95);  $\alpha$ -ketoisocaproate dioxygenase (47); kynureninase (48); kynurenine:oxoglutarate aminotransferase (214); lactase/phlorizin hydrolase, *or* glycosylceramidase (132,133,140); lactosylceramide  $\alpha$ -2,3-sialyltransferase (216); levanase (49); levansucrase (50);  $\beta$ -lysine 5,6-aminomutase (51,52); maltase (53); maltose  $\alpha$ -D-glucosyltransferase, *or* trehalose synthase (89); maly-CoA lyase (54,102);  $\beta$ -mannanase (55);  $\alpha$ -mannosidase (166); mannosyl-oligosaccharide glucosidase, *or* glucosidase I (134,135); mannosyl-oligosaccharide 1,2- $\alpha$ -mannosidase, *or* mannosidase IA and IB (32,56,127-130); mannotetraose 2- $\alpha$ -*N*-acetylglucosaminyltransferase (57); membrane alanine aminotransferase (58); methylamine:glutamate methyltransferase (59); *N*-methyl-2-oxoglutarate hydrolase (108); 5'-methylthioadenosine/S-adenosylhomocysteine Nucleosidase (124); NAD<sup>+</sup> nucleosidase (60); naringenin-chalcone synthase (233); nicotinate-nucleotide diphosphorylase, carboxylating (218); nucleoside deoxyribosyltransferase (61,219); oligo-1,6-glucosidase, *or* isomaltase (46,62,198,199); ornithine carbamoyltransferase (63,240); ornithine decarboxylase (64); 3-oxoacid CoA-transferase, *or* 3-ketoacid CoA-transferase (106); phenylalanine 4-monooxygenase (65,243); phenylalanyl-tRNA synthetase (66); phosphate acetyltransferase (237,238); phosphoenolpyruvate carboxykinase, diphosphate (67,105); phosphofructokinase (68); phospholipase C (69,205,206); polygalacturonidase, *or* pectinase (197); porphobilinogen synthase, *or*  $\delta$ -aminolevulinatase dehydratase (70); procollagen C-endopeptidase, inhibited at high concentrations (110); procollagen N-endopeptidase (111); pyroglutamyl-peptidase II (112); pyruvate carboxylase (71); pyruvate synthase (72); quinate *O*-hydroxycinnamoyltransferase (230-232); ribonuclease, *Ustilago sphaerogena* (73); sarcosine dehydrogenase (74); D-serine ammonia-lyase, *or* D-serine dehydratase (97,98); L-serine dehydratase (75); strictosidine synthase (96); styrene-oxide isomerase (91); sucrose  $\alpha$ -glucosidase, *or* sucrose-isomaltase (46,76,142,143); sucrose-phosphate synthase, weakly inhibited (226); sucrose synthase (227,228); sulfite:cytochrome *c* oxidoreductase (77); transaldolase (239);  $\alpha$ , $\alpha$ -trehalase (78,79,155-162); trehalose synthase (80); trimethylamine dehydrogenase (81); tryptophanase (82); uracilylalanine synthase (215); uridine Nucleosidase (125,126); vanillate hydroxylase (83); xylan 1,4- $\beta$ -xylosidase (84); xyloglucan 6-xylosyltransferase (217); and xylose isomerase (85,86,93,94). 1. ### Trisnorsqualene Cyclopropylamine

This squalene analogue (FW = 423.73 g/mol) inhibits squalene monooxygenase, or squalene epoxidase,  $IC_{50} = 2 \mu M$ . The shorter homologue tetranorsqualene cyclopropylamine also inhibits,  $IC_{50} = 4 \mu M$ . The *N*-methylated analogue trisnorsqualene *N*-methylcyclopropylamine is a significantly weaker inhibitor ( $IC_{50} = 100 \mu M$ ). Note that the corresponding *N*-oxide is also a weak inhibitor of oxidosqualene cyclase ( $IC_{50} = 40 \mu M$ ). **1.** Sen & Prestwich (1989) *J. Amer. Chem. Soc.* **111**, 8761.

### O,O,O-Tri(o-tolyl)phosphate

This phosphoric triester (FW = 368.37 g/mol; M.P. = 25.6°C; B.P. = 410°C), also called tri(*o*-cresyl) phosphate and tris(*o*-cresyl) phosphate, poisoned an estimated 50,000 in the U.S. in 1930, when an alcoholic extract of Jamaican

ginger was adulterated with this triester, with many crippled by irreversible paralysis. **Target(s):** ATPase, synapto-somal (1); carboxylesterase (2-4);  $Ca^{2+}$ -transporting ATPase (5); cholinesterase (6-8); and fatty-acyl ethyl-ester synthase (9,10). **1.** Brown & Sharma (1976) *Experientia* **32**, 1540. **2.** Chemnitz, Haselmeyer & Zech (1983) *Arch. ### Triton CF-54

This synthetic polyethylene glycol detergent (FW = indefinite polymer; CAS 51938-58-0) inhibits *N*-acetyllactosaminide  $\alpha$ -2,3-sialyltransferase (1), globoside  $\alpha$ -*N*-acetylgalactosaminyltransferase (2), lactosylceramide  $\alpha$ -2,3-sialyltransferase, activated at low concentrations (3). **1.** Kono, Ohyama, Lee, *et al.* (1997) *Glycobiology* **7**, 469. **2.** Kijimoto, Ishibashi & Makita (1974) *Biochem. Biophys. Res. Commun.* **56**, 177. **3.** Iber, van Echten & Sandhoff (1991) *Eur. J. Biochem.* **195**, 115.

### Triton N-101

This proprietary mixture of *n*-nonylphenoxypoly-ethoxyethanols (FW = 616.83 and 660.89 g/mol) has a critical micelle concentration of about 0.085 mM. Note that this detergent absorbs UV light and should be stored in glass containers at 0°C to minimize peroxidation. **Target(s):** diacylglycerol kinase (1-3); and reverse transcriptase, RNA-directed DNA polymerase (4). **1.** Daleo, Piras & Piras (1976) *Eur. J. Biochem.* **68**, 339. **2.** Yada, Ozeki, Kanoh & Nozawa (1990) *J. Biol. Chem.* **265**, 19237. **3.** Lundberg & Sommarin (1992) *Biochim. Biophys. Acta* **1123**, 177. **4.** Baltimore (1970) *Nature* **226**, 1209.

### Triton X-100

This proprietary surfactant (FW = indefinite composition CAS 9002-93-1; Critical Micelle Concentration = 0.22-0.24 mM; Aggregation Number = 100-155), consisting of two *t*-octylphenoxy-polyethoxy-ethanols, was originally formulated for secondary recovery of petroleum, but is widely used in solubilizing membrane proteins without solubilizing much membrane lipid. Triton X-100 has the virtue of exerting mild nondenaturing effects on non-membrane proteins. The *cloud point* (*i.e.*, the temperature at which micellar aggregates begin to form and come out of solution) is 64°C. Triton X-100 has proved to be of great value in the surface phospholipid dilution strategy for defining lipase action at water-phospholipid interfaces (1,2). In this experimental approach, the surface concentration of phospholipid in mixed micelles is reduced by the addition Triton as a neutral diluent, thereby increasing the average distance between phospholipids. This allows one to draw mechanistic inferences about the binding interactions of lipases and phospholipases with their lipid substrates (1). This detergent absorbs light in the ultraviolet region of the spectrum (reduced Triton X-100 is the cyclohexane analogue and does not absorb significantly in the ultraviolet). Triton should be stored in glass containers at 0°C to minimize peroxidation. **See Cutscum Target(s):** 2-acetyl-1-alkyl-glycerophosphocholine esterase, or platelet-activating factor acetylhydrolase (3); acetyl-CoA hydrolase (114); acetyl-CoA:long-chain-base acetyl-transferase (4);  $\alpha$ -*N*-acetylgalactos-

aminide  $\alpha$ -2,6-sialyltransferase (5); acetyl-galactosaminyl-*O*-glycosyl-glycoprotein  $\beta$ -1,3-*N*-acetyl-glucosaminyl-transferase (222,223); *N*-acetylglucosaminyl-diphosphoundecaprenol *N*-acetyl- $\beta$ -D-mannosaminotransferase (216); *N*-acetyl-neuraminate 4-*O*-acetyl-transferase (249); *N*-acetyl-neuraminate 7-*O*-(or, 9-*O*)-acetyltransferase (6,247,248); *N*-acetyl-neuraminylgalactosylglucosylceramide  $\beta$ -1,4-*N*-acetylgalactos-aminyl-transferase (220,221); acid phosphatase, or tadpole isozyme 1 (104); acyl-[acyl-carrier-protein]:UDP-*N*-acetyl-glucosamine *O*-acyltransferase (240); 2-acylglycerol *O*-acyltransferase, or monoacyl-glycerol *O*-acyltransferase (262,263); acylglycerol lipase (monoacylglycerol lipase, weakly inhibited (135,164); 1-acylglycerol-3-phosphate *O*-acyltransferase (244,245); 1-acylglycerophosphocholine *O*-acyltransferase, or lysophosphatidylcholine *O*-acyltransferase (241,259-261); [ $\beta$ -adrenergic-receptor] kinase (7); aldehyde oxidase (8,9); 1-alkenylglycerophosphocholine *O*-acyltransferase (241); alkenylglycerophosphocholine hydrolase (71); alkenyl-glycerophosphoethanolamine hydrolase (70-72); 1-alkyl-2-acetyl-glycerophosphate (94); 1-alkyl-2-acetyl-glycerophosphocholine esterase, or platelet-activating-factor acetylhydrolase (128); 1-alkylglycerophosphocholine *O*-acetyltransferase (243); alkylglycerophosphoethanolamine phosphodiesterase, or lysophospholipase D (77); arylamine *N*-acetyltransferase (279); arylesterase (166); asparaginase (63); bis(2-ethylhexyl)phthalate esterase (125); carboxylesterase (167); carnitine *O*-palmitoyltransferase (264-267); carotene 7,8-desaturase (286); catechol *O*-methyltransferase (285); CDP-diacylglycerol:glycerol-3-phosphate 3-phosphatidyltransferase (177,178); CDP-diacylglycerol:inositol-3-phosphatidyltransferase (10,174-176); ceramidase, activated at low concentrations (60); ceramide glucosyltransferase (226-228); ceramide kinase (11); chloramphenicol acetyltransferase (12); chlorophyllase (137,138); chlorophyllide *a* prenyltransferase (13); choline-phosphate cytidyltransferase (186); cholinesterase, or butyrylcholinesterase (145,146); choloyl-CoA synthetase, or cholate:CoA ligase (44); coagulation factor Xa (65); 3',5'-cyclic-GMP phosphodiesterase, or cGMP phosphodiesterase (78); CYP1A (114); cytochrome *c* oxidase (15,16); dehydrodolicyl diphosphate synthase (17); diacylglycerol *O*-acyltransferase (268-272); diacylglycerol cholinephosphotransferase (179-183); diacylglycerol kinase (18,190,191); diacylglycerol lipase (164); dimethylallyltransferase, or geranyl-diphosphate synthase (22,209); dipeptidyl-peptidase IV (66,67); DNA-(apurinic or apyrimidinic site) lyase (52); dolichol kinase, activated at low concentrations (189); dolichylphosphatase, activated at low concentrations (54,55,96); dolichyl esterase (19); dolichyl-phosphatase, inhibited at elevated concentrations (96); ecdysone 20-monooxygenase (287); endo- $\beta$ -*N*-acetylglucosaminidase L (20); endopeptidase La (64); fatty acyl-CoA reductase, hexadecanal dehydrogenase (21); ferredoxin:NADP<sup>+</sup> reductase (58); flavonoid 3',5'-hydroxylase (295);  $\beta$ -D-fucosidase (73); fucosterol-epoxide lyase (53); galactolipase (132-134); galactoside 2- $\alpha$ -L-fucosyltransferase (230); ganglioside galactosyltransferase (231); geranyl-transferase, or farnesyl-diphosphate synthase (207,208); globotriaosylceramide  $\alpha$ -galactosidase (23); glucan 1,4- $\alpha$ -glucosidase, or glucoamylase (76); 1,3- $\beta$ -glucan synthase (233,234); glucomannan 4- $\beta$ -mannosyltransferase (235);  $\beta$ -glucosidase (74); glucuronosyltransferase (236-238); glutaminase (62); glycerol-3-phosphate *O*-acyltransferase (273-278); glycerone-phosphate *O*-acyltransferase (dihydroxyacetone-phosphate *O*-acyltransferase (251-257); glyceryl-ether monooxygenase (293); glycoprotein 3- $\alpha$ -L-fucosyltransferase (211); glycosaminoglycan galactosyltransferase (229); glycosyl-phosphatidylinositol diacylglycerol-lyase (50); histone acetyltransferase (246); (hydroxyamino)-benzene mutase (49); 4-hydroxybenzoate nonaprenyltransferase (202-204); inositol-polyphosphate 5-phosphatase (95); isopenicillin-N synthase (57); juvenile hormone epoxide hydrolase (68); juvenile-hormone esterase (126,127); lipase (triacylglycerol lipase (40,158-165); long-chain-acyl-CoA hydrolase (24); *N*-(long-chain-acyl)ethanolamine deacylase (59); long-chain-fatty-acid:[acyl-carrier-protein] ligase (41-43); long-chain-fatty-acyl-CoA synthetase, or long-chain-fatty-acid:CoA ligase (45-47); lysophospholipase (25,147-154); microsomal epoxide hydrolase (68,69); mRNA (guanine-N<sup>7</sup>-)methyltransferase (283); NADH dehydrogenase, ubiquinone (26,27); NAD<sup>+</sup>:protein-arginine ADP-ribosyltransferase (210); nicotinamide (61); nuatigenin 3 $\beta$ -glucosyltransferase (213-215); *trans*-octaprenyltransferase (206); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (105-113); penicillin-binding protein 1b (224); peptidoglycan glycosyltransferase (224,225); phenylacetone monooxygenase (294); phosphatidate cytidyltransferase (28,184,185); phosphatidate phosphatase, weakly inhibited (103); phosphatidylcholine:dolichol *O*-acyltransferase (242); phosphatidylcholine:sterol *O*-acyltransferase (LCAT) (250); phosphatidylcholine synthase (171); phosphatidylethanolamine *N*-methyltransferase (10,284); phosphatidyl-glycerophosphatase, inhibited at elevated concentrations (99-102); phosphatidylinositol diacyl-glycerol-lyase (29,51); 1-phosphatidylinositol 3-kinase (188); 1-phosphatidylinositol 4-kinase (197-201); phosphatidylinositol-4-phosphate 3-kinase (187); 1-phosphatidylinositol-4-phosphate 5-kinase (196,197); phosphatidyl-*N*-methylethanolamine *N*-methyltransferase (281,282); phospho-*N*-acetylmuramoyl-pentapeptide-transferase (173); phosphoglyceride: lysophosphatidyl-glycerol *O*-acyltransferase (30); phosphoinositide 5-phosphatase (97,98); phosphoinositide phospholipase C, or phosphatidylinositol-specific phospholipase C (83); phospholipase A, exhibits both phospholipase A<sub>1</sub> and A<sub>2</sub> activities (131); phospholipase A<sub>1</sub> (129,130); phospholipase A<sub>2</sub> (155-157); phospholipase C (91-93); phospholipase D (31,32,84-90); phospholipid:lysophospholipid *O*-acyltransferase (33); phytoene synthase (205); polygalacturonidase, or pectinase (75); poly(3-hydroxybutyrate) depolymerase (120-124); poly(3-hydroxyoctanoate) depolymerase (115-119); protein-*S*-isoprenylcysteine *O*-methyltransferase (34,280); protein-tyrosine sulfotransferase (168); pyrophosphatase, or inorganic diphosphatase (56); retinol dehydrogenase, microsomal (35); SacI phosphatase (36); sarsapogenin 3 $\beta$ -glucosyltransferase (212); sphinganine kinase, or sphingosine kinase (192-195); sphingomyelin phospho-diesterase, or sphingomyelinase, Triton X-100 is an activator for many sphingomyelinases (79-82); squalene:hopene cyclase (48); squalene monooxygenase (288-290); steroid 5 $\alpha$ -reductase (37); sterol *O*-acyltransferase (cholesterol *O*-acyltransferase; ACAT (38,258); sterol esterase, or cholesterol esterase (139-144); sterol 3 $\beta$ -glucosyltransferase (217-219); tannase136; thiosulfate sulfurtransferase, or rhodanese; weakly inhibited (170);  $\gamma$ -tocopherol methyltransferase39;  $\alpha$ , $\alpha$ -trehalose-phosphate synthase (UDP-forming) (239); tyrosinase, or monophenol monooxygenase; polyphenol oxidase (291,292); tyrosine-ester sulfotransferase (169); UDP-*N*-acetylglucosamine:dolichyl-phosphate *N*-acetylglucosaminophosphotransferase (172); and undecaprenyl-phosphate mannosyltransferase (232). 1. ### Triton X-114

This proprietary mixture of two *t*-octylphenoxy-polyethoxyethanols (FW = 514.70 and 558.75 g/mol), also called oxynols has a low cmc value of 0.17-0.20 mM and is widely used to solubilize membrane proteins without extensively solubilizing much membrane lipid. Triton X-114 has a greater solubility in water at lower temperatures compared to Triton X-100 and has a low cloud point (*i.e.*, the temperature at which micellar aggregates begin to form and come out of solution) of 22-28°C. For this reason, Triton X-114 separates from water at higher temperatures to form a separate detergent phase, and this property has been exploited in the purification of detergent-solubilized proteins (1-3). Note that this detergent absorbs UV light and should be stored in glass containers at 0°C to minimize peroxidation. **Target(s)**: ceramide kinase (4); flavonoid 3',5'-hydroxylase (5); and glutacetyl-CoA decarboxylase (6). 1. ### S-Trityl-L-Cysteine

This potent tumor growth inhibitor (FW<sub>free-base</sub> = 363.47 g/mol; CAS 2799-07-7; Abbreviation STLC), commonly used in protective-group chemistry required in solid-phase peptide/protein synthesis, targets the mitosis-associated kinesin molecular motor Eg5. STLC does not prevent cell-cycle progression at the S or G<sub>2</sub> phases but instead inhibits both separation of the duplicated centrosomes as well as bipolar spindle formation, thereby stalling cells in the M phase with single-aster spindles. Upon removal of *S*-trityl-L-cysteine, cells exit mitosis normally. *In vitro*, *S*-trityl-L-cysteine targets Eg5's catalytic domain, inhibiting its basal and microtubule- (MT-) activated ATPase activity as well as the release of ADP. *S*-Trityl-L-cysteine qualifies as a tight binding inhibitor ( $K_{i,app} < 150$  nM) and binds more tightly than monastrol. STLC has an ~8-fold faster on-rate (*i.e.*, 6.1  $\mu\text{M}^{-1} \text{s}^{-1}$  versus 0.78  $\mu\text{M}^{-1} \text{s}^{-1}$ ) and ~4-fold slower off-rate (*i.e.*, 3.6  $\text{s}^{-1}$  versus 15  $\text{s}^{-1}$ ). (See Monastrol) *S*-Trityl-L-cysteine also reversibly inhibits Eg5-driven MT-sliding rate (IC<sub>50</sub> of 500 nM). HeLa cells cultured for several weeks at increasing concentrations of STLC generate clones that can grow in the presence of 20  $\mu\text{M}$  STLC, a concentration sufficient to fully inhibit Eg5 (2). Further analysis indicated that the majority of cells in these clones were able to assemble a bipolar spindle even in the presence of 20  $\mu\text{M}$  STLC, owing to compensating increase in nuclear envelope dynein. **Target(s)**: Among ten human kinesins (*e.g.*, Eg5, CENP-E, MKLP1, RabK6, KIFC1, Kid, KIF2A and KIF2C) that were tested, *S*-trityl-L-cysteine was specific for Eg5 (1). 1. Skoufias, DeBonis, Saoudi, et al. (2006) *J. Biol. Chem.* **281**, 17559. 2. Raaijmakers, van Heesbeen, Meaders, et al. (*EMBO J.*) **31**, 4179.

### Troglitazone

This once widely studied peroxisome PPAR agonist (FW = 441.55 g/mol) showed promising properties (*e.g.*, improving insulin sensitivity and decreasing hepatic glucose production) for treating type 2 diabetes, but was

withdrawn when its hepatotoxicity became evident. **Target(s):** aromatase, or CYP19 (1,2); CYP3A4 (3); CYP2C8 (3); CYP2C9 (3); CYP2C19 (3);  $\beta$ -hydroxysteroid dehydrogenase (4);  $K_{ATP}$  channel (5); glucuronosyltransferase (6,7); and long-chain-fatty-acyl-CoA synthetase, or long-chain-fatty-acid CoA ligase (8-10). 1. Rubin, Duong, Clyne, *et al.* (2002) *Endocrinology* **143**, 2863. 2. Mu, Yanase, Nishi, *et al.* (2000) *Biochem. Biophys. Res. Commun.* **271**, 710. 3. ### Troleandomycin

This semisynthetic antibiotic (FW = 813.98 g/mol; CAS 2751-09-9), also called oleandomycin triacetate ester, inhibits CYP3A4/5 (1-4) and quinine 3-monooxygenase (4-6). 1. Koyama, Sasabe & Miyamoto (2002) *Xenobiotica* **32**, 573. 2. Fowler, Taylor, Friedberg, Wolf & Riley (2002) *Drug Metab. ### Trolox

This water-soluble vitamin E analogue and antioxidant (FW = 250.29 g/mol; CAS 53188-07-1), also known as 3,4-dihydro-6-hydroxy-2,5,7,8-tetramethyl-2H-1-benzopyran-2-carboxylic acid, potently inhibited interleukin-1-induced osteoclast formation in bone marrow cell-osteoblast coculture by abrogating induction by Receptor Activator of NF- $\kappa$ B Ligand (or RANKL) of c-Fos protein by suppressing its translation (1). Consonant with this action is the finding that ectopic overexpression of c-Fos overcomes trolox inhibition of osteoclastogenesis in bone marrow macrophages (1). Trolox also suppresses interleukin-1-induced osteoclast formation and bone loss in mouse calvarial bone (1). Taken together, such findings show that trolox prevents osteoclast formation and bone loss by inhibiting both RANKL induction in osteoblasts and c-Fos expression in osteoclast precursors. Trolox also prevents the oxidative reactions initiated upon oxidation of the hemoprotein by  $H_2O_2$  and involving tyrosyl radicals, inhibiting covalent binding of protein to the heme group, while also inhibited dimerization of myoglobin, the latter process entailing the intermolecular covalent binding of tyrosines (2). Inhibition of both processes requires 20-50x higher trolox levels than needed to reduce the hypervalent heme iron to its ferric form. **Trolox Equivalent Antioxidant Capacity:** This analytical biochemical method employs 2,2'-azino-di-[3-ethylbenzthiazoline sulphinate], or ABTS, as a redox-active chromophore in a plate-based colorimetric assay at 405 or 750 nm to quantify the total antioxidant capacity of substances within foodstuffs, plasma, serum, urine, saliva, cell lysates, *etc.* The assay relies on the ability

of antioxidants within a sample to inhibit the oxidation of ABTS to the radical-cation  $ABTS^{+\cdot}$  upon reaction with met-myoglobin (3-6). The reliability of this method becomes quantitative by including measured quantities of trolox as an internal reference standard. This procedure has also been applied to the determination of physiological antioxidant compounds, including radical-scavenging drugs. 1. Lee, Kim, Yang, *et al.* (2009) *J. Biol. Chem.* **284**, 13725. 2. Giulivi & Cadenas (1993) *Arch. Biochem. Biophys.* **303**, 152. 3. Miller, Rice-Evans, Davies, *et al.* (1993) *Clin. Sci.* **84**, 407. 4. ### 3-Tropanyl 3,5-Dichlorobenzoate

This 5-HT<sub>3</sub> receptor antagonist (FW<sub>free-base</sub> = 314.21 g/mol; CAS 40796-97-2), also known as MDL 72222, targets peripheral neuronal 5-hydroxytryptamine receptors of mammals and suppresses voluntary ethanol consumption that is mediated by the 5-HT<sub>3</sub> receptor (1,2). 1. Higgins, Kilpatrick, Bunce, Jones & Tyers (1989) *Brit. J. Pharmacol.* **97**, 247. 2. Fozard (1984) *Naunyn Schmiedebergs Arch. Pharmacol.* **326**, 36.

### Tropicamide

This muscarinic receptor antagonist (FW = 284.36 g/mol; CAS 1508-75-4; Soluble to 100 mM in DMSO), systematically named *N*-ethyl-3-hydroxy-2-phenyl-*N*-(pyridinylmethyl)propanamide, is M<sub>4</sub>-selective, with a pIC<sub>50</sub> of 7.62. Its action is distinct from that expected for M<sub>1</sub>-selective compounds (*e.g.*, pirenzepine and telenzepine), M<sub>2</sub>-selective compounds (*e.g.*, himbacine and methoctramine), and M<sub>3</sub>-selective compounds (*e.g.*, hexahydro-siladifenidol and 4-diphenylacetoxy-*N*-methylpiperidine methiodide). 1. Lazareno, Buckley & Roberts (1990) *Mol. Pharmacol.* **38**, 805. 2. Hernández, Simonsen, Prieto, *et al.* (1993) *Brit. J. Pharmacol.* **110**, 1413.

### Tropisetron

This serotonin 5-HT<sub>3</sub> receptor antagonist (FW = 284.35 g/mol; CAS 89565-68-4 (free base) and 105826-92-4 (hydrochloride)), also known as Navoban<sup>®</sup>, 3-tropanylindole-3-carboxylate, and (1*R*,5*S*)-8-methyl-8-azabicyclo[3.2.1]octan-3-yl-1-methylindole-3-carboxylate, is an anti-emetic that is often used to reduce vomiting and nausea following a round of chemotherapy and to treat pain associated with fibromyalgia (1,2). Tropisetron is highly potent and selective competitive antagonist of 5-HT<sub>3</sub> receptors, the latter comprising a subclass of serotonin receptors located on peripheral neurons and within the central nervous system. Navoban has a 24-hour duration of action, allowing convenient once-daily administration. Its inhibitory effects on the glycine receptor chloride channel occur in the  $\mu$ M range, whereas its potentiating effects occur at femtomolar concentrations at the homomeric  $\alpha_1$  receptor. Tropisetron is also a partial agonist of  $\alpha_7$  nicotinic acetyl-choline receptors, or nAChR (3). 1. Shearman & Tolcsvai (1987) *Psychopharmacology (Berlin)* **92**, 520. 2. Yang, Ney, Cromer, *et al.* (2007) *J. Neurochem.* **100**, 758. 3. Papke, Porter-Papke & Rose (2004) *Bioorg. Med. Chem. Lett.* **14**, 1849.

**Tropolone**

This  $\alpha$ -hydroxy cyclic ketone (FW = 122.12 g/mol; CAS 533-75-5; M.P. = 51-54°C), also known as 2-hydroxy-2,4,6-cycloheptatrien-1-one, is a structural element of many drugs and metabolites, including colchicine and is also found in some organisms. **Target(s):** (*S*)-canadine synthase (1); catechol *O*-methyltransferase (2-10); 8-dimethyl-alltnaringenin 2'-hydroxylase (11); L-dopachrome isomerase (12); dopamine  $\beta$ -monooxygenase (13); exoribonuclease H (14); peroxidase (15); polyphenol oxidase (16); ribonuclease H (14); thiol *S*-methyltransferase (5); thiopurine *S*-methyltransferase,  $K_i$  = 0.85 mM (5,17,18); tyrosinase, or monophenol monooxygenase (16,19-25); and tyrosine 3-monooxygenase (26). 1. **Trovafloxacin**

This fluoroquinolone antibiotic (FW = 512.46 g/mol; CAS 147059-75-4; Solubility: 50 mM in H<sub>2</sub>O; 100 mM in DMSO), also known by CP-99,219 and 7-[(1 $\alpha$ ,5 $\alpha$ ,6 $\alpha$ )-6-amino-3-azabicyclo[3.1.0]hex-3-yl]-1-(2,4-difluorophenyl)-6-fluoro-1,4-dihydro-4-oxo-1,8-naphthyridine-3-carboxylic acid, inhibits bacterial DNA topoisomerase IV and DNA gyrase by forming a stable quinolone-DNA adduct with these enzymes, thereby reversibly inhibiting DNA synthesis (1,2). (For the prototypical member of this antibiotic class, **See Ciprofloxacin**) Trovafloxacin displays potent activity against Gram-positive and Gram-negative bacteria. Ninety percent of the *Proteus vulgaris*, *Providencia rettgeri*, *Providencia stuartii*, and *Serratia marcescens* isolates are inhibited by 0.5 to 2  $\mu$ g/mL. CP-99,219 inhibited 90% of the *Pseudomonas aeruginosa* and *Haemophilus influenzae* isolates at 1 and 0.015  $\mu$ g/mL, respectively. The drug inhibited methicillin-susceptible *Staphylococcus aureus* at 0.06  $\mu$ g/mL, whereas a ciprofloxacin concentration of 1  $\mu$ g/mL was required to inhibit these organisms. [See Table I of (1) for complete listing and comparison with Sparfloxacin, Tosufloxacin, Ciprofloxacin & Temafloxacin.] Trovafloxacin also increases the production

of mitochondrial NO in immortalized hepatocytes and increases mitochondrial Ca<sup>2+</sup> (2). Somewhat surprisingly, the plasma membrane pannexin-1 channel, known as PANX1, is a direct target of trovafloxacin at drug concentrations (IC<sub>50</sub> ~ 4  $\mu$ M) observed in human plasma (3). Inhibition of PANX1 led to dysregulated fragmentation of apoptotic cells. Genetic loss of PANX1 phenocopied trovafloxacin effects, revealing a non-redundant role for pannexin channels in regulating cellular disassembly during apoptosis. (3). 1. (2014) *Nature* **507**, 329.

**Trp Peptide Amide**

This acetylated oligopeptide amide Ac-RRKWQKTGHAVRAIGRL-NH<sub>2</sub> inhibits [myosin light-chain] kinase,  $K_d$  = 8.6 pM (1). Substitution of a tyrosyl residue for Trp4 weakens the inhibition ( $K_d$  = 7.3 nM). The deacetylated peptide ARRWQKTGHAVRAIGRLSS has a  $K_d$  value of 0.11 nM while RRRKWQKTGHAVRAIGRLSSS has a value of 1.6 nM. 1. Török, Cowley, Brandmeier, et al. (1998) *Biochemistry* **37**, 6188.

**TRU-016, See Oltretuzumab****Trusopt, See Dorzolamide****Trypan Blue**

This so-called vital stain (FW<sub>tetrasodium salt</sub> = 960.82 g/mol) is a water-soluble blue dye that is excluded up by living cells, but is taken up by dead cells. Note, however, that this dye stains viable macrophages. When dissolved in water, this acid dye forms a deep blue solution with a violet tinge ( $\lambda_{max}$  = 607 nm). **Target(s):** acid phosphatase (1-3);  $\beta$ -fructofuranosidase, or invertase (4); fumarase (5,6); guanidinobenzoate (7); hemolytic activity of oligonucleotide-streptolysin S complex (8); thrombin (9); and triose-phosphate isomerase (10). 1. **Trypanothione**

This N<sup>1</sup>,N<sup>10</sup>-bis(glutathionyl)spermidine disulfide (FW = 721.86 g/mol; CASA Registry Number = 96304-42-6), found in trypanosomatids, is reduced to the dithiol by trypanothione reductase. This product is one of the major thiols of trypanosomatids and functions in maintaining the redox balance of the cell. Trypanothione participates in the detoxification of hydrogen peroxide, utilizing the enzyme trypanothione reductase, tryparedoxin, and tryparedoxin peroxidase. Tryparedoxin is a thiol similar in action to thioredoxin and glutaredoxin. **Target(s):** glutathionylspermidine synthetase, inhibited by the reduced form of trypanothione (1); and tryparedoxin activity (2). 1. Smith, Nadeau, Bradley, Walsh & Fairlamb (1992) *Protein Sci.* **1**, 874. 2. Krauth-Siegel & Schmidt (2002) *Meth. Enzymol.* **347**, 259.

### Trypan Red

This water-soluble red dye (FW<sub>pentasodium salt</sub> = 1002.81 g/mol) is frequently used as a biological stain and a trypanocide. Trypan red was produced by Paul Ehrlich in the early twentieth century and shown by his assistant Shiga to be effective against trypanosomes. **Target(s):** fumarase (1); hemolytic activity of oligonucleotide-streptolysin S complex (2); neuraminidase, or sialidase (3). 1. Quastel (1931) *Biochem. J.* **25**, 1121. 2. Taketo & Taketo (1982) *Z. Naturforsch. [C]* **37**, 385. 3. Gottschalk & Bhargava (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), **5**, 321.

### Trypsamide

This light-sensitive antiprotozoal arsenical (FW<sub>sodium salt</sub> = 296.09 g/mol; solubility = 0.5 g/mL water), with particular action against the sleeping sickness-causing pathogen *Trypanosoma gambiense*, inhibits glyceraldehyde-3-phosphate dehydrogenase (1), lipase, or triacylglycerol lipase, weakly inhibited (2); urease, weakly inhibited (1). 1. Chen (1948) *J. Infect. Diseases* **82**, 226. 2. Gordon & Quastel (1948) *Biochem. J.* **42**, 337.

### Trypsin-Chymotrypsin Inhibitor, See Trypsin Inhibitors

#### Trypsin Inhibitors

These proteins form highly affine, albeit reversible, complex with trypsin and trypsin-like proteases to form complexes devoid of any proteolytic activity. Soybean trypsin inhibitors (Kunitz-type has  $K_i = 10$  pM, with 1,000,000-times weaker binding to chymotrypsin) are single polypeptide chains with 181-aminoacyl residues and two disulfide bonds. The 71-residue soybean Bowman-Birk inhibitor, itself containing seven disulfide bonds, has two active sites, one for trypsin and one for chymotrypsin. **See also** *a<sub>1</sub>-Antitrypsin*; *Aprotinin*; *a<sub>1</sub>-Antichymotrypsin*; *etc.* **Target(s):** acrosin (1-6,91,126-135); activated protein C (7); adenain (86); bacillopeptidase F (8); brachyurins (9,10,115-120); cathepsin G (12-14,123-125); cerevisin, weakly inhibited (103,104); chymase (15-17); chymotrypsin (2,3,6,18-29,151-154); chymotrypsin C, or caldecrin (11); clostripain (30,87); coagulation factor VIIa (31,122); coagulation factor Xa (32,142,143); coagulation factor Xia (33,34); coagulation factor XIIa (35,36,106); cocoonase (19,37,82); complement factor I (105); diacylglycerol *O*-acyltransferase (159); duodenase (38); enteropeptidase, (43,137-141), however, see also ref. 136; envelysin (83-85); follipain (44); granzyme A (45,46); granzyme B (47,93); kexin (99); leukocyte elastase (39-42,107,124); leucyl endopeptidase (53); limulus clotting enzyme (54); lysosomal Pro-Xaa carboxypeptidase (156,157); oviductin (88); pancreatic elastase (25,107,109); pancreatic elastase II (97,108); peptidyl-dipeptidase Dcp (158); peptidyl-glycinamidase, or carboxamidopeptidase (155); plasma kallikrein (2,18,19,28,29,48-50,112-114); plasmin (2-5,18,19,28,29,55-58,145); plasminogen activator (59); prolyl oligopeptidase (121); proteinase A, mouse (60); proteinase K, salivary gland (61); scutellarin (62,100); sea urchin cortical granule protease (63); semenogelase (64,94); sheep mast cell proteinase (138); snake venom factor V activator, or thrombocytin in the presence of heparin (65); spermosin (91); stratum corneum chymotryptic enzyme (66,89,90); streptogrisin A (92); streptogrisin B (92); subtilisin (21,29,98); thermomycolin (67); thrombin, weakly inhibited (144); tissue kallikrein (2,18,50-52,110,111); tonin (68); trepolsin (69); trypsin (2-6,18-29,42,58,70-82,145-150,154); tryptase (16,101,102,145); u-plasminogen activator, or urokinase (96); and venombin A (95). 1. ### Trypstatin

This mast cell protease inhibitor (CAS 97502-03-9), first purified from rat peritoneal mast cells, is a proteolytic fragment of the inter- $\alpha$ -trypsin inhibitor light chain, or bikunin (1). **Target(s):** chymase, partial inhibition (2); coagulation factor Xa (3); and trypsin (2-4). **1.** Itoh, Ide, Ishikawa & Nawa (1994) *J. Biol. Chem.* **269**, 3818. **2.** Kido, Fukusen & Katunuma (1985) *Arch. Biochem. Biophys.* **239**, 436. **3.** Kido, Yokogoshi & Katunuma (1988) *J. Biol. ### Tryptamine

This biogenic amine (FW<sub>hydrochloride</sub> = 196.68 g/mol; CAS 61-54-1; pK<sub>a</sub> = 10.2 at 25°C;  $\lambda_{\max}$  at 282 and 290 nm;  $\epsilon$  = 6000 and 5100 M<sup>-1</sup>cm<sup>-1</sup> in 95% ethanol, respectively), known systematically as 2-(3-indolyl)ethylamine, is formed by the pyridoxal-phosphate-dependent decarboxylation of tryptophan. While there is, as yet, no compelling evidence to support persistent speculation that tryptamine is itself a neurotransmitter, it is nonetheless the direct precursor of serotonin. Moreover, tryptamine is a weak alternative substrate for the serotonin transporter. Weak transport substrates can, in principle, have higher K<sub>m</sub> value (suggesting a lower affinity than the preferred transport substrate) and/or lower k<sub>cat</sub> values (indicating a longer than normal transport cycle). If the k<sub>cat</sub> is lower for tryptamine transport, it may play a neuromodulatory role by reducing the efficiency of serotonin transport. **Note:** The term "tryptamine" also refers to a broad class of classical or serotonergic hallucinogens (e.g., psilocybin, LSD, and recent designer hallucinogens) that, in humans, produce profound changes in sensory perception, mood and thought, primarily by acting as 5-HT<sub>2A</sub> receptor agonists. This term is based on the presence of a tryptamine nucleus in their structures, although some synthetic tryptamines do not. **Target(s):** acetylcholinesterase (1); agmatine deaminase (2-4); anthranilate synthase (5); aryl-acylamidase, weakly inhibited (6-8); chymotrypsin (9-11); CYP1A2 (12); CYP2A6 (12); CYP2E1 (13); deacetylindoline O-acetyltransferase (14); glutamate dehydrogenase (15);  $\gamma$ -glutamylhistamine synthetase (16); histamine N-methyltransferase (17); kynureninase, weakly inhibited (18); phenylalanine decarboxylase (19); pyridoxal kinase, perhaps combining with pyridoxal (20,21); 3- $\alpha$ -(S)-strictosidine  $\beta$ -glucosidase, weakly inhibited (22); tryptophanase, weakly inhibited (9,23); tryptophan 2,3-dioxygenase (9); tryptophanyl-tRNA synthetase (24-29); and tyramine N-feruloyltransferase, also alternative substrate (30). **1.** Krupka (1965) *Biochemistry* **4**, 429. **2.** Chaudhuri & Ghosh (1985) *Phytochemistry* **24**, 2433. **3.** Yanagisawa & Suzuki (1981) *Plant Physiol.* **67**, 697. **4.** Sindhu & Desai (1979) *Phytochemistry* **18**, 1937. **5.** Poulsen, Bongaerts & Verpoorte (1993) *Eur. ## Tryptamine-4,5-dione

This neurotoxin (FW<sub>free-base</sub> = 191.21 g/mol), formed via the oxidation of 5-hydroxytryptamine by reactive oxygen and reactive nitrogen species, is a strong electrophile that can covalently modify cysteinyl residues. Tryptamine-4,5-dione is formed by oxidation of 5-hydroxytryptamine by reactive oxygen and reactive nitrogen species. It is also a powerful electrophile that can covalently modify cysteinyl residues of proteins, perhaps deactivating key enzymes that play roles in the degeneration of serotonergic neurons in brain disorders, such as Alzheimer's disease or evoked by amphetamine drugs. Tryptamine-4,5-dione reacts with free cysteine, glutathione, *N*-acetylcysteine, and cysteamine. **Target(s):**  $\alpha$ -ketoglutarate dehydrogenase (1); pyruvate dehydrogenase (1); and tryptophan hydroxylase (2). 1. Jiang & Dryhurst (2002) *Chem. Res. Toxicol.* **15**, 1242. 2. Wrona & Dryhurst (2001) *Chem. Res. Toxicol.* **14**, 1184.

## D-Tryptophan

This nonproteogenic amino acid (FW = 204.23 g/mol), known systematically as (*R*)-2-Amino-3-(1*H*-indol-3-yl)propanoic acid, is found in the antibiotics tyrocidin C and tyrocidin D. (See *L*-Tryptophan) **Target(s):** anthranilate synthase (1); aromatic-L-amino-acid decarboxylase, or dopa decarboxylase (2,3); carboxypeptidase A (4,5); prephenate dehydratase (6); tryptophanase (7); tryptophan 2,3-dioxygenase (8); tryptophan synthase (9); tryptophanyl-tRNA synthetase (10-12); tyrosine phenol-lyase (13). 1. ## L-Tryptophan

This naturally occurring aromatic amino acid (Symbol = Trp = W; FW = 204.23 g/mol; p*K*<sub>a</sub> values of 2.46 and 9.41 at 25°C; UV spectrum:  $\lambda_{\max}$  = 218 nm ( $\epsilon$  = 33500 M<sup>-1</sup>cm<sup>-1</sup>), 278 nm ( $\epsilon$  = 5550 M<sup>-1</sup>cm<sup>-1</sup>), and 287.5 nm ( $\epsilon$  = 4550 M<sup>-1</sup>cm<sup>-1</sup>) in 0.1 M HCl; Specific Rotation = +2.8° at 25°C for the D line for 1.0-2.0 g/100 mL tryptophan in 1 M HCl and -33.7°; solubility = 1.14 g/100 mL water at 25°C), known systematically as (*S*)-2-amino-3-(1*H*-indol-3-yl)propanoic acid, is the least abundant of the twenty proteogenic amino acids and is a nutritionally essential amino acid in mammals. Most proteins have very few tryptophanyl residues, making tryptophan fluorescence a powerful probe of protein conformational changes. Many enzymes also use D- and L-tryptophan as weak alternative substrates (and thus competitive inhibitors for the natural substrate). These include L-amino-acid dehydrogenase, amino acid oxidases, peptide-tryptophan 2,3-dioxygenase, aspartate aminotransferase, ornithine:oxo-acid aminotransferase,  $\gamma$ -glutamyl transpeptidase (L-tryptophan is a weak  $\gamma$ -glutamyl acceptor substrate), aromatic amino acid transferase, and amino-acid racemase. **Target(s):** acetylcholinesterase (1); alkaline phosphatase (2,61); 2-aminohexano-6-

lactam racemase, weakly inhibited (36); aminopeptidase B, weakly inhibited (58); anthranilate phosphoribosyltransferase (3,14,86-89); anthranilate synthase (3-10,44-53); anthranilate synthase/anthranilate phosphoribosyltransferase complex (4,87,88); arginase (11,55); argininosuccinate synthetase (12); arylformamidase (56);  $\beta$ -cyclopiasonate dehydrogenase (54); cystathionine  $\gamma$ -lyase (13); cytosol alanyl aminopeptidase (57); 3'-demethylstaurosporine *O*-methyltransferase, activated at low concentrations (92); 3-deoxy-7-phosphoheptulonate synthase, or phospho-2-dehydro-3-deoxyheptanate aldolase (25,72-85); diphosphomevalonate decarboxylase (63); L-dopachrome isomerase (14); glutamate decarboxylase (15); glutamine synthetase, weakly inhibited (16-20,35); [glutamine-synthetase] adenyltransferase (62);  $\gamma$ -glutamyl transpeptidase, weakly inhibited (21,22); hemoglobin S polymerization (23); histidine decarboxylase (9); hydroxyacylglutathione hydrolase, or glyoxalase II (37); kynureninase, weakly inhibited (24); kynurenine:oxoglutarate aminotransferase (67-71); lactoylglutathione lyase, or glyoxalase I (37); membrane alanyl aminopeptidase, or aminopeptidase N (59,60); phenylalanine 4-monooxygenase (93); prephenate dehydratase (26,40-42); prephenate dehydrogenase (27); propionyl-CoA carboxylase, *Mycococcus xanthus* (28); pyridoxal 5'-phosphate hydrolase, or alkaline phosphatase (29); pyrophosphatase, or inorganic diphosphatase (30); pyruvate kinase (64-66); L-serine ammonia-lyase, or L-serine dehydratase (38,39); shikimate kinase (31); starch phosphorylase, inhibited by DL-tryptophan (90,91); tyrosine 3-monooxygenase (32,33); and tyrosine phenol-lyase (34,43). 1. ### Tryptophol

This naturally occurring plant auxin (FW = 161.20 g/mol), also known as indole-3-ethanol and 2-(3-indolyl)ethanol, is found in a wide variety of microorganisms, sponges (*Ircinia spinulosa*), plants and mammals. It is an effector of indoleamine 2,3-dioxygenase, which catalyzes the degradation of L-tryptophan to form *N*-formylkynurenine, with superoxide anion serving as an oxygen donor. Indoleamine 2,3-dioxygenase is the first and rate-limiting enzyme of tryptophan catabolism. In *Saccharomyces cerevisiae*, tryptophol is a quorum-sensing molecule that allows the yeast cells to synchronously sense changes in cell density and other growth cues and to adapt collectively to new conditions through pre-programmed physiological and morphological responses. *Note:* Tryptophol must not be confused with tryptophanol. **Target(s):** aralkylamine *N*-acetyltransferase, or serotonin *N*-acetyltransferase (2); chymotrypsin (3); and Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (4). **1.** Sono (1989) *Biochemistry* **28**, 5400. **2.** De Angelis, Gastel, Klein & Cole (1998) *J. Biol. Chem.* **273**, 3045. **3.** Valenzuela & Bender (1970) *Biochemistry* **9**, 2440. **4.** Stepp & Novakoski (1997) *Arch. Biochem. Biophys.* **337**, 43.

**Tryptophol Phosphate, See Indole-3-ethanol Phosphate**

**TS-071, See Luseogliflozin**

### TS-2 and TS-4

These 1,3-selenazines TS-2 (FW = 266.25 g/mol), known systematically as 4-ethyl-4-hydroxy-2-*p*-tolyl-5,6-dihydro-4*H*-1,3-selenazine, and TS-4 (FW

= 293.29 g/mol), known systematically as 4-hydroxy-6-isopropyl-4-methyl-2-*p*-tolyl-5,6-dihydro-4*H*-1,3-selenazine, inhibit [elongation factor 2] kinase, with IC<sub>50</sub> values of 0.36 and 0.31 μM (1,2). Both are much weaker inhibitors of protein kinase A, protein kinase C, protein-tyrosine kinase, calmodulin-dependent protein kinase, and *v-src* kinase. **1.** Gutzkow, Lähne, Naderi, *et al.* (2003) *Cell. Signal.* **15**, 871. **2.** Cho, Koketsu, Ishihara, *et al.* (2000) *Biochim. Biophys. Acta* **1475**, 20.

### Tsushimycin

This acidic acylpeptide antibiotic (FW = 1302.49 g/mol; CAS 11054-63-0; Structural Components: Itd = Δ<sup>3</sup>-isotetradecenoic acid; Dab = 2,3-diaminobutyric acid; Pip = pipercolinic acid; Map, β-methylaspartate.) is structurally related to amphomycin. **Target(s):** dolichyl-phosphate β-D-mannosyltransferase (1-4); phospho-*N*-acetylmuramoyl-pentapeptide-transferase (5); and protein glycosylation (1-4). **1.** Elbein (1983) *Meth. Enzymol.* **98**, 135. **2.** Elbein (1987) *Meth. Enzymol.* **138**, 661. **3.** Elbein (1984) *CRC Crit. Rev. Biochem.* **16**, 21. **4.** Elbein (1981) *Biochem. J.* **193**, 477. **5.** Tanaka, Oiwa, Matsukura, Inokoshi & Omura (1982) *J. Antibiot.* **35**, 1216.

### TTP 22

This high-affinity, ATP-competitive casein kinase inhibitor (FW = 330.42 g/mol; CAS 329907-28-0; Solubility: 100 mM in DMSO; 20 mM in Ethanol), also named 3-[[5-(4-methylphenyl)thieno[2,3-*d*]pyrimidin-4-yl]thio]propanoic acid, targets casein kinase 2 (CK2) (IC<sub>50</sub> = 0.1 μM, K<sub>i</sub> = 40 nM), displays no inhibitory effects, even at 10 μM, JNK3, ROCK1 and MET. **1.** Golub, Bdzhol, Briukhovetska, *et al.* (2011) *Eur. J. Med. Chem.* **46**, 870.

### TTT-3002

This novel protein tyrosine kinase inhibitor (FW<sub>free-base</sub> = 465.51 g/mol) targets the FMS-like tyrosine kinase-3, or FLT3 (IC<sub>50</sub> = 100–250 pM), a receptor tyrosine kinase that is expressed in hematopoietic stem/progenitor

cells. Upon binding the FLT3 ligand (*or* FL), the receptor dimerizes, thereby activating its kinase domain and undergoing autophosphorylation as well as catalyzing the phosphorylation of target proteins in the STAT5, PI3K/AKT, and RAS/MAPK pathways. Notably, >35% of acute myeloid leukemia (AML) patients harbor a constitutively activating mutation in FLT3. TTT-3002 shows potent cytostatic activity ( $IC_{50} = 490\text{--}920\ \mu\text{M}$ ) against these FLT3-associated leukemias, both *in vitro* and *in vivo*. TTT-3002 also potently inhibits *in vitro* kinase activity of Leucine-Rich Repeat Kinase-2, *or* LRRK2, wild-type and mutant proteins, attenuated phosphorylation of cellular LRRK2 and rescued neurotoxicity of mutant LRRK2 in transfected cells. Mutations in LRRK2 are most frequently associated with late-onset Parkinson disease (PD). TTT-3002 is ineffective against the neurodegenerative phenotype in transgenic *Caenorhabditis elegans* carrying the inhibitor-resistant A2016T mutation of LRRK2, suggesting it elicits its neuroprotective effects *in vivo* by targeting LRRK2 specifically. 1. Ma, Nguyen, Li, *et al.* (2014) *Blood* **123**, 1525. 2. Yao, Johnson, Gao, *et al.* (2013) *Hum. Mol. Genet.* **22**, 328.

### Tubacin

This selective tubulin deacetylase inhibitor (FW = 721.86 g/mol; CAS 1350555-93-9; Soluble to 10 mM in DMSO), also named *N*-[4-[(2*R*,4*R*,6*S*)-4-[[[(4,5-diphenyl-2-oxazolyl)thio]methyl]-6-[4-(hydroxymethyl)phenyl]-1,3-dioxan-2-yl]phenyl]-*N'*-hydroxyoctanediamide, reversibly inhibits Histone Deacetylase-6, *or* HDAC6 ( $EC_{50} = 2.5\ \mu\text{M}$ ), which catalyzes the deacetylation of  $\alpha$ -tubulin, thereby increasing  $\alpha$ -tubulin acetylation levels in cells (1). Tubacin does not alter histone acetylation, gene-expression patterns, or cell-cycle progression. In cultured cells, tubacin (10  $\mu\text{M}$ ) induces up to a 3x increase in the relative  $\alpha$ -tubulin-acetylation level. Niltubacin, the carboxylate analogue of tubacin, is without effect on  $\alpha$ -tubulin or histone acetylation and therefore may be used as a negative control. Requirement of the hydroxamic acid for inhibitory activity suggests that tubacin targets a metal-dependent hydrolase. Levels of total  $\alpha$ -tubulin and  $\alpha$ -tubulin containing a C-terminal tyrosine (which is decreased in stabilized microtubules) are unaffected by tubacin (1). Unlike taxol, which increases  $\alpha$ -tubulin acetylation by directly stabilizing assembled microtubules, tubacin has no overall effect on cell morphology. Tubacin treatment does not affect the stability of microtubules but does decrease cell motility (1). Endothelial barrier dysfunction (EBD) involves both microtubule disassembly and enhanced cell contractility, and, when HDAC6 deacetylates  $\alpha$ -tubulin, microtubules are destabilized. HDAC6 inhibition attenuates thrombin-induced microtubule disassembly, attended by an increase in Phosphorylated Myosin Light Chain 2 (P-MLC2) and contractility, reducing endothelial barrier dysfunction induced by thrombin (2). Tubacin completely blocks inflammatory tolerance, revealing the opposing effects between HDAC6 and Glycogen Synthase Kinase-3 (GSK3) in regulating tolerance and indicating how it may be possible to rebalance these opposing forces to obliterate or enhance tolerance to lipopolysaccharide (LPS) in astrocytes (3). Tubacin blocks deacetylation of  $\alpha$ -tubulin (and not other HDAC6 substrates) reduces cell motility to an extent that is equivalent to the effects of agents that block all NAD-independent HDACs (4). This selective action of tubacin helped to show that microtubule acetylation influences the subcellular distribution of vesicles associated with the kinesin KIF1C, as well as their directionality, velocity and run length (5). Tubulin acetylation alters the targeting frequency of microtubule plus ends on podosomes and influences the number of podosomes per cell and thus the matrix-degrading capacity of macrophages (5). 1. ### Tubastatin A

This potent HDAC inhibitor (FW = 335.31 g/mol; CAS 1239262-52-2), named systematically *N*-hydroxy-4-[(1,2,3,4-tetrahydro-2-methyl-5*H*-pyrido[4,3-*b*]indol-5-yl)methyl]benzamide, targets histone deacetylase-6, *or* HDAC6 ( $IC_{50} = 15\ \text{nM}$ ), demonstrating >1,000x selectivity versus all other HDAC isoforms ( $IC_{50}$ s >16  $\mu\text{M}$ ), whereas HDAC8 ( $IC_{50} = 0.9\ \mu\text{M}$ ) (1). Tubastatin A also conferred dose-dependent protection in primary cortical neuron cultures against glutathione depletion-induced oxidative stress (1). When present at 2.5  $\mu\text{M}$ , tubastatin A also induces hyperacetylation of  $\alpha$ -tubulin in primary cortical neuron cultures, consistent with its HDAC6 selectivity (1). In a model of oxidative stress induced by glutathione depletion, 5-10  $\mu\text{M}$  tubastatin A displays dose-dependent neuronal protection of primary cortical neuron cultures. 1. Butler, Kalin, Brochier, *et al.* (2010) *J. Am. Chem. Soc.* **132**, 10842.

### Tuberactinomycins

This group of cyclic peptide antibiotics from *Streptomyces griseovorticillus* are potent inhibitors of prokaryotic protein biosynthesis. In tuberactinomycin A,  $R_1 = \text{OH}$ , and  $R_2 = \text{OH}$ ; in tuberactinomycin B,  $R_1 = \text{H}$ , and  $R_2 = \text{OH}$ ; in tuberactinomycin C,  $R_1 = \text{OH}$ , and  $R_2 = \text{H}$ ; and in tuberactinomycin D,  $R_1 = \text{H}$ , and  $R_2 = \text{H}$ . Tuberactinomycin A (FW = 701.70 g/mol) is soluble in water and practically insoluble in most organic solvents. Tuberactinomycin B is also known as viomycin and the N antibiotic is enviomycin. **Target(s):** group I intron RNA splicing (1); hammerhead ribozyme, inhibited by tuberactinomycin A with positive cooperativity (2). 1. Wank, Rogers, Davies & Schroeder (1994) *J. Mol. Biol.* **236**, 1001. 2. Jenne, Hartig, Piganeau, *et al.* (2001) *Nat. Biotechnol.* **19**, 56.

### Tubercidin

This cytotoxic adenosine analogue (FW = 266.26 g/mol; CAS 69-33-0;  $\lambda_{\text{max}}$  of 270 nm,  $\epsilon = 12100\ \text{M}^{-1}\text{cm}^{-1}$ ; readily soluble in acidic or alkaline solutions), also known as 7-deazaadenosine, from *Streptomyces tubercidicus* is an antifungal and antibacterial agent that interferes with purine metabolism and glycolysis. Tubercidin also inhibits leukocyte adhesion to TNF-treated endothelial cells. Tubercidin is often a weak alternative substrate for adenosine kinase and other adenosine-dependent enzymes. It inhibits protein biosynthesis and the growth of many microorganisms, including *Mycobacterium tuberculosis*. Nucleic acids containing tubercidin are biologically inactive. **See also 5-Iodotubercidin Target(s):** adenosine kinase, also alternative substrate (1-6); adenosylhomocysteinase, *or* *S*-adenosylhomocysteine hydrolase (7-9); 2',3'-cyclic-nucleotide 3'-

phosphodiesterase (10); estrone sulfotransferase (11); GMP synthetase (12); purine Nucleosidase, or purine-specific nucleoside *N*-ribohydrolase (13-15); toyocamycin nitrile hydratase (16); and tRNA methyltransferases (17,18). 1. ### Tubercidin 5'-Monophosphate

This AMP analogue (FW<sub>free-acid</sub> = 346.24 g/mol), also known as 7-deazaadenosine 5'-monophosphate and 4-amino-7-(β-D-ribofuranosyl)pyrrolo[2,3-d]pyrimidine 5'-monophosphate, inhibits adenylate kinase (1), amidophosphoribosyltransferase (2), AMP Nucleosidase (3,4), and rhodopsin kinase (5), and toyocamycin nitrile hydratase (6). 1. Munier-Lehmann, Burlacu-Miron, Craescu, Mantsch & Schultz (1999) *Proteins Struct. Funct. Genet.* **36**, 238. 2. Hill & Bennett, Jr. (1969) *Biochemistry* **8**, 122. 3. Uematsu & Suhadolnik (1975) *Meth. Enzymol.* **43**, 759.

### Tubercidin 5'-Triphosphate

This ATP analogue (FW<sub>free-acid</sub> = 506.20 g/mol), also known as 7-deazaadenosine 5'-triphosphate, inhibits lysyl- and threonyl-tRNA synthetases (See *Tubercidin*). 1. Freist, Sternbach, von der Haar & Cramer (1978) *Eur. J. Biochem.* **84**, 499.

### S-Tubercidinyl-L-homocysteine

This *S*-adenosyl-L-homocysteine analogue (FW = 383.43 g/mol; CAS 57344-98-6), also known as *S*-(7-deazaadenosyl)-L-homocysteine, inhibits thiol methyltransferase (1) and is an inhibitor for many methyltransferases (2). It also inhibits 5'-methylthioadenosine/*S*-adenosylhomocysteine nucleosidase,  $K_i = 1.9 \mu\text{M}$  (3), catechol *O*-methyltransferase (2), histamine *N*-methyltransferase (2), hydroxyindole *O*-methyltransferase (2), indole-ethylamine *N*-methyl-transferase (2), 5'-methylthioadenosine/*S*-adenosylhomocysteine nucleosidase (3), mRNA (guanine-*N*<sup>7</sup>-)methyltransferase

(4,5), mRNA (nucleoside-2'-*O*-)methyltransferase (4), phenylethanolamine *N*-methyltransferase (2), and thiol *S*-methyltransferase (1). 1. Borchardt & Cheng (1978) *Biochim. Biophys. Acta* **522**, 340. 2. Borchardt, Huber & Wu (1976) *J. Med. Chem.* **19**, 1094. 3. Della Ragione, Porcelli, Carteni-Farina, Zappia & Pegg (1985) *Biochem. J.* **232**, 335. 4. Pugh & Borchardt (1982) *Biochemistry* **21**, 1535. 5. Pugh, Borchardt & Stone (1977) *Biochemistry* **16**, 3928.

### S-Tubercidinyl-L-methionine

This *S*-adenosyl-L-methionine analogue (FW<sub>chloride</sub> = 433.92 g/mol), also known as *S*-(7-deazaadenosyl)-L-methionine, inhibits spermidine synthase (1), spermine synthase (1), and thiol *S*-methyltransferase (2). 1. Hibasami, Borchardt, Chen, Coward & Pegg (1980) *Biochem. J.* **187**, 419. 2. Borchardt & Cheng (1978) *Biochim. Biophys. Acta* **522**, 340.

### Tubocurarine

This *bis*-benzyl-isoquinoline curare alkaloid (FW = 681.66 g/mol; CAS 57-94-3; Symbol: dTC), also known as dextrotubocurarine chloride (*d*-tubocurarine chloride, *not* D) from *Chondodendron tomentosum*, is the principal paralyzing agent in arrow-tip poisons used by certain indigenous South Americans, as first reported by European explorers in the 16th century. That curare produces a neuromuscular block was later determined by the French physiologist Claude Bernard in the mid-19th century. Since then and extending into modern times, tubocurarine has helped to establish the role of acetylcholine in neuromuscular transmission. Its use as a muscle relaxant during surgical anaesthesia in World War II. **Classification:** Tubocurarine is considered to be the prototypical neuromuscular-blocking drug, the potency of which is related to the separation distance between the two quaternary ammonium head-groups; LD<sub>50</sub> (dog) = 0.5 mg/kg. **Mode of Inhibitory Action:** Tubocurarine interacts with acetylcholine receptors and as a 5-HT<sub>3</sub> and GABA<sub>A</sub> receptor antagonist. Tubocurarine binds non-equivalently to the two agonist sites ( $K_d$  values of 30 nM and 8 μM) within the *Torpedo* nicotinic acetylcholine receptor (1). When nAChR-rich membranes equilibrated with [<sup>3</sup>H]dTC are irradiated with 254-nm UV light, [<sup>3</sup>H]dTC is covalently incorporated into the α-, γ-, and δ-subunits in a concentration-dependent and agonist-inhibitable manner, consistent with the localization of the high and low affinity dTC binding sites at the α-γ- and α-δ-subunit interfaces (1). amino acids contributing to high- and low-affinity d-tubocurarine sites have been identified (2). **Target(s):** acetylcholinesterase (3,4); acid phosphatase (5); choline acetyltransferase (6); cholinesterase (7); diamine oxidase (8); histamine *N*-methyltransferase, inhibited by tubocurarine of which the primary active component is tubocurarine (9). 1. Pedersen & Cohen (1990) *Proc. Natl. Acad. Sci. U.S.A.* **87**, 2785. 2. Chiara & Cohen (1997) *J. Biol. Chem.* **272**, 32940. 3. Zorko & Pavlic (1986) *Biochem. Pharmacol.* **35**, 2287. 4. Chem.* **234**, 2948. **IUPAC Name:** 2,3,13a,14,15,16,25,25a-Octahydro-9,19-dihydroxy-18,29-dimethoxy-1,14,14-trimethyl-13*H*-4,6:21,24-dietheno-8,12-metheno-1*H*-pyrido[3',2':1,4,15][1,11]dioxacycloecocino[2,3,4-*ij*]-isoquinolinium ion.

### Tubulysin A

This highly cytotoxic antimetabolic peptide (FW = 842.11 g/mol; CAS 205304-86-5) induces microtubule (MT) depletion, triggering apoptosis, and stalls cells in the G<sub>2</sub>/M phase (1,2). Tubulysin A inhibits tubulin polymerization more efficiently than vinblastine and induces depolymerization of MTs in cell-free systems or in cells, even after assembled MTs or cells are pre-incubated with the MT-stabilizing agents epothilone B and paclitaxel (2). In competition experiments, Tubulysin A strongly inhibits ( $K_i = 3 \mu\text{M}$ ) the binding of vinblastine to tubulin. Electron microscopy revealed that Tubulysin A induces the formation of rings, double rings, and pinwheel structures (2). The mode of action of Tubulysin A resembles that of peptide antimetabolites Dolastatin 10, Phomopsin A, Hemiasterlin, and Symplostatin. Folate-conjugated tubulysins are highly cytostatic in cancer cells containing large numbers of folate receptors (4). 1. Sasse, Steinmetz, Heil, Höfle & Reichenbach (2000) *J. Antibiot.* (Tokyo) **53**, 879. 2. Kaur, Hollingshead, Holbeck, *et al.* (2006) *Biochem J.* **396**, 235. 3. Khalil, Sasse, Lünsdorf, *et al.* (2006) *ChemBioChem* **7**, 678. 4. Reddy, Dorton, Dawson, *et al.* (2009) *Mol. Pharm.* **6**, 1518.

### Tumstatin

This 28-kDa fragment of type IV collagen is an endothelial cell-specific inhibitor of protein synthesis. Through a requisite interaction with  $\alpha\text{V}\beta 3$  integrin, tumstatin inhibits activation of focal adhesion kinase, phosphatidylinositol 3-kinase, protein kinase B, and the mammalian target of rapamycin. In addition, it prevents the dissociation of eukaryotic initiation factor 4E protein (eIF4E) from 4E-binding protein 1 (1). 1. Maeshima, Sudhakar, Lively, *et al.* (2002) *Science* **295**, 140.

### Tungstate (Tungstic Acid)

This conjugate base of tungstic acid (FW<sub>sodium-salt</sub> = 271.84 g/mol; CAS 11120-01-7; FW<sub>methylamine-salt</sub> = 311.97; CAS 55979-60-7), which is only slightly soluble in water, is often used to precipitate proteins. Indeed, through its strong association with proteins, its methyl amine salt serves as a contrast agent for visualizing protein structures by means of electron microscopy.

**Target(s):** acid phosphatase (1,2,26-29); alkaline phosphatase (2,3,30,31); aryl sulfatase (2); carbonic anhydrase, or carbonate dehydratase (4); dimethylsulfoxide reductase (5); fatty-acyl-CoA synthase, inhibited by the methylamine salt (33); glucan endo-1,3- $\beta$ -D-glucosidase (6); glucose-6-phosphatase (7,25); nitrogenase (8); phloretin hydrolase (9); 6-phosphofructo-2-kinase (10); phosphonoacetaldehyde hydrolase (11); phosphoprotein phosphatase (16,23,24); 3-phytase (12); 4-phytase (12-14); polynucleotide 5'-hydroxyl-kinase (15); protein-phosphatase 2B (24); protein-tyrosine phosphatase (17,18); pyrophosphate-dependent phosphofructokinase, or diphosphate:fructose-6-phosphate 1-phosphotransferase (32); sabinene-hydrate synthase (19); and selenate reductase (20-22). 1. ### 21-Tungsto-9-antimoniate Ammonium Salt

This transition metal complex (Formula:  $(\text{NH}_4)_{17}\text{Na}[\text{NaW}_{21}\text{Sb}_9\text{O}_{86}]\cdot 14\text{H}_2\text{O}$  (FW = 6937.5 g/mol), also known as HPA23, is an antiviral agent that has been shown to potently inhibit both human and murine DNA polymerase  $\alpha$  and murine DNA polymerase  $\gamma$ . 21-Tungsto-9-antimoniate also noncompetitively inhibits murine DNA polymerase  $\alpha$  ( $K_i = 24 \text{ nM}$ ) and competitively inhibits the  $\gamma$  enzyme,  $K_i = 20 \text{ nM}$  (1-3). 1. Ono, Nakane, Barre-Sinoussi & Chermann (1988) *Eur. J. Biochem.* **176**, 305. 2. Ono, Nakane, Matsumoto, Barre-Sinoussi & Chermann (1984) *Nucl. Acids Symp. Ser.* **1984** (15), 169. 3. ### Tunicamycin

These lipophilic analogues of UDP-N-acetylglucosamine and antiviral antibiotics (Tunicamycin A<sub>1</sub>,  $n = 8$ , FW = 816.90 g/mol; CAS 11089-65-9; Tunicamycin B<sub>2</sub>,  $n = 9$ , FW = 830.93 g/mol; Tunicamycin C<sub>1</sub>,  $n = 10$ , FW = 844.95 g/mol; CAS 73942-07-1; and Tunicamycin D<sub>2</sub>,  $n = 11$ , FW = 858.99 g/mol) from *Streptomyces lysosuperificus* inhibit protein glycosylation and protein palmitoylation, making them powerful tools in investigations on glycoprotein processing. Tunicamycin also inhibits capillary endothelial cell proliferation by inducing apoptosis. *Note:* The exact composition of commercial tunicamycin will vary from batch to batch, requiring an investigator to save the certificate of analysis for each preparation purchased.

**Target(s):** cellulose synthase, UDP-forming (1); dolichyl-phosphate  $\beta$ -glucosyltransferase (2,3); dolichyl-phosphate  $\beta$ -D-mannosyltransferase (2); lactose synthase (4); peptidoglycan glycosyltransferase (5); phosphatidylcholine:sterol O-acyltransferase, LCAT (6); phospho-N-acetylmuramoylpentapeptide-transferase (7-10); protein N-acetylglucosaminyltransferase (11); protein glycosylation (12-17); protein palmitoylation (16); UDP-N-acetylglucosamine:dolichyl-phosphate N-acetylglucosamine phosphotransferase (12-15,17-23); undecaprenyl-diphosphomuramoylpentapeptide  $\beta$ -N-acetylglucosaminyl-transferase, or MurG-transferase (24,25). 1. ### Turanose

This sweet-tasting reducing disaccharide (FW = 342.30 g/mol; CAS 547-25-1), known systematically as 3-*O*- $\alpha$ -D-glucopyranosyl-D-fructose, is an unusual sucrose isomer that is found in the plant trisaccharide melezitose found. **Target(s)**: concanavalin A (1);  $\beta$ -fructofuranosidase, or invertase (2); glucan 1,3- $\alpha$ -glucosidase, or glucosidase II, or mannosyl-oligosaccharide glucosidase II (3,4);  $\alpha$ -glucosidase,  $K_i$  = 2.8 mM for the rat liver enzyme (5-18); and sucrose-phosphatase (19). 1. ### ar-Turmerone

This natural sesquiterpenoid oil (FW = 216.32 g/mol; CAS 38142-58-4; B.P. = 159-160°C), isolated from the oil of turmeric (*Curcuma longa*), inhibits the prostaglandin cyclooxygenase COX-2 and inducible nitric-oxide synthase. 1. Lee, Hong, Huh, et al. (2002) *J. Environ. Pathol. Toxicol. Oncol.* **21**, 141.

### TW-37

This novel nonpeptide (FW = 573.7; CAS 877877-35-5; Solubility (25°C): 110 mg/mL DMSO), also known as 5-(2-isopropylbenzyl)-*N*-(4-(2-*tert*-butylphenylsulfonyl)phenyl)-2,3,4-trihydroxybenzamide, inhibits the pro-survival Bcl (B-cell lymphoma) proteins Bcl-2 ( $K_i$  = 0.29  $\mu$ M), Bcl-xL ( $K_i$  = 1.1  $\mu$ M), and Mcl-1 ( $K_i$  = 0.26  $\mu$ M), targets the Bcl-2 Homology domain- (or BH-) binding groove in Bcl-2, where proapoptotic Bcl-2 proteins are known to bind. 1. Mohammad, et al. (2007) *Clin. Cancer Res.* **13**, 2226. 2. Zeitlin, et al. (2006) *Cancer Res.* **66**, 8698.

### TX-1918

This potent eEF2K inhibitor (FW = 228.25 g/mol; CAS 503473-32-3; Solubility: 10 mg/mL in DMSO), also named 2-((3,5-dimethyl-4-hydroxyphenyl)methylene)-4-cyclopentene-1,3-dione, is a cell-permeable arylidene-cyclopentenedione-derived tyrostatin that potent inhibits eukaryotic elongation factor-2 kinase (eEF2K,  $IC_{50}$  = 440 nM). At higher concentrations, TX-1918 inhibits other kinases, including proto-oncogene tyrosine-protein kinase Src (c-SRC),  $IC_{50}$  = 4.4  $\mu$ M, protein kinases A and C ( $IC_{50}$  = 44  $\mu$ M in both cases), and Epidermal Growth Factor Receptor Kinase (EGFR-K,  $IC_{50}$  = 440  $\mu$ M). 1. Hori H, Nagasawa H, Ishibashi et al. (2002) *Bioorg. Med. Chem.* **10**, 3257.

**Tylenol™**, See *Acetaminophen*

### Tylocrebrine

This alkaloid and antileukemic agent (FW<sub>free-base</sub> = 393.48 g/mol; CAS 6879-02-3) inhibits protein biosynthesis at the translocation step (1). *Note*: The (-)-stereoisomer is isolated from *Tylophora crebriflora* whereas the (+)-isomer is reported in *Ficus septica*. 1. Jiménez (1976) *Trends Biochem. Sci.* **1**, 28. 2. Donaldson, Atkinson & Murray (1968) *Biochem. Biophys. Res. Commun.* **31**, 104. 3. Huang & Grollman (1972) *Mol. Pharmacol.* **8**, 538. 4. Gupta, Krepinsky & Siminovitch (1980) *Mol. Pharmacol.* **18**, 136.

### Tylosin

This macrolide antibiotic (FW<sub>free-base</sub> = 916.11 g/mol; CAS 1401-69-0) from a strain of *Streptomyces fradiae* inhibits protein biosynthesis by binding to the 50S ribosomal subunit (1). The disaccharide present at position 5 in the lactone 16-member ring of the macrolide is essential for inhibition of peptidyltransferase (2). In acidic conditions (pH < 4), tylosin is converted to desmycosin, which does not inhibit the peptidyltransferase of ribosomes (2). **Target(s)**: peptidyltransferase (2); protein biosynthesis (1-3); and rRNA (guanine- $N^1$ -)-methyltransferase (4). 1. Pestka (1974) *Meth. Enzymol.* **30**, 261. 2. Poulsen, Kofoed & Vester (2000) *J. Mol. Biol.* **304**, 471. 3. Dinos & Kalpaxis (2000) *Biochemistry* **39**, 11621. 4. Douthwaite, Crain, Liu & Poehlsgaard (2004) *J. Mol. Biol.* **337**, 1073.

**Tyloxapol**

This nonionic surfactant (FW = indefinite polymer; CAS 1401-69-0; R =  $(\text{CH}_2\text{CH}_2\text{O})_x\text{H}$ ,  $x = 8-10$ ,  $m < 6$ ), also known as Tyloxapol, Triton WR-1339, and Triton A-20, is slowly miscible with water. **Target(s):** 1-acylglycerophosphocholine *O*-acyltransferase (1); 1-alkenylglycerophosphocholine *O*-acyltransferase (1); cholesterol-5,6-oxide hydrolase (2); diacylglycerol *O*-acyltransferase (3); diacylglycerol cholinephospho-transferase (4); ethanolaninephosphotransferase (4); lipoprotein lipase (5-8); phosphoglyceride: lysophosphatidyl-glycerol *O*-acyltransferase (9); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, or ACAT (10,11). 1. Arthur & Choy (1986) *Biochem. J.* **236**, 481. 2. Watabe, Ozawa, Ishii, Chiba & Hiratsuka (1986) *Biochem. Biophys. Res. Commun.* **140**, 632. 3. Akao & Kusaka (1976) *J. Biochem.* **80**, 723. 4. Biochem. Physiol. B* **122**, 301.

**Tynorphin**

This pentapeptide VVYPW (FW<sub>zwitterion</sub> = 647.77 g/mol) inhibits dipeptidyl-peptidase III,  $K_i = 75$  nM (1-4). 1. Mazzocco, Fukasawa, Auguste & Puiroux (2003) *Eur. J. Biochem.* **270**, 3074. 2. Yamamoto, Hashimoto, Shimamura, Yamaguchi & Hazato (2000) *Peptides* **21**, 503. 3. Mazzocco, Gillibert-Duplantier, Neaud, et al. (2006) *FEBS J.* **273**, 1056. 4. Chiba, Li, Yamane, et al. (2003) *Peptides* **24**, 773.

**Tyramine**

This tyrosine decarboxylation product (FW<sub>free-base</sub> = 137.18 g/mol; CAS 51-67-2; M.P. = 164-165°C; p*K<sub>a</sub>* values of 9.74 and 10.52 at 25°C) also known as  $\beta$ -(*p*-hydroxyphenyl)ethylamine, does not cross the blood-brain-barrier, limiting its catecholamine-releasing effects to peripheral neurons, where it displaces stored monoamines (e.g., dopamine, norepinephrine, and epinephrine) from pre-synaptic vesicles. Tyramine is also synthesized by the decarboxylation of tyrosine within the CNS, where it may serve as a neurotransmitter. **Target(s):** aromatic-L-amino-acid decarboxylase, or dopa decarboxylase (1); arylsulfatase (2-4); dihydropteridine reductase (5,6); dopamine  $\beta$ -monoxygenase (7-9);  $\gamma$ -glutamylhistamine synthetase (10); histamine *N*-methyltransferase (11); pyridoxal kinase (12); tubulin:tyrosine ligase, also, weak alternative substrate (13); tyrosine aminotransferase (14); tyrosine decarboxylase (15); tyrosyl-tRNA synthetase,  $K_i = 5.6$   $\mu\text{M}$  for the *Escherichia coli* enzyme (16-19). 1. Nakazawa, Kumagai & Yamada (1987) *Agric. Biol. Chem.* **51**, 2531. 2. Okamura, Yamada, Murooka & Harada (1976) *Agric. Biol. Chem.* **40**, 2071. 3. Beil, Kehrl, James, et al. (1995) *Eur. J. **Tyrocidines**

This mixture consists of at least four cyclic decapeptide antibiotics by *Bacillus brevis* and related organisms. The predominant form tyrocidine A (MW = 1373.70 g/mol; CAS 8011-61-8) is cyclo(L-Leu-D-Phe-L-Pro-L-Phe-D-Phe-L-Asn-L-Gln-L-Tyr-L-Val-L-Orn-), where L-Orn refers to L-ornithine. In tyrocidine B (MW = 1312.03 g/mol), the L-phe at position-four is replaced with an L-trp. Tyrocidine C (MW = 1351.57 g/mol) is identical to tyrocidine B, except for D-trp in place of D-phe at position-five. Tyrocidine D (MW = 1374.61 g/mol) is identical to tyrocidine C, except for L-trp in place of L-tyr at position-eight. The relative yields of the four tyrocidines appears to depend on the concentrations of the aromatic amino acids in the growth media. Dubos first isolated tyrocidines in 1939 from *Bacillus brevis*, which itself is immune to their effects. Tyrocidines are cationic detergents that increase the permeability of bacterial cell membranes, rendering them particularly bactericidal with respect to Gram-positive microorganisms. The tyrocidines also uncouple oxidative phosphorylation (1) and inhibit RNA polymerase (2). **See Uncouplers** 1. Hunter & Schwartz (1967) in *Antibiotics I: Mode of Action* (Gottlieb & Shaw, eds.), p. 142, Springer-Verlag, New York. 2. Schazschneider, Ristow & Kleinkauf (1974) *Nature* **249**, 757.

**Tyromycin A**

This natural product (FW = 446.58 g/mol; CAS 141364-77-4), also known as 1,16-bis-(4-methyl-2,5-dioxo-3-furyl)hexadecane, from *Tyromyces lacteus* and inhibits cystinyl and leucyl aminopeptidases. 1. Weber, Semar, Anke, Bross & Steglich (1992) *Planta Med.* **58**, 56.

**Tyropeptin A**

This peptide aldehyde (FW = 511.62 g/mol), also known as *N*-(*n*-butyryl)-L-tyrosyl-L-leucyl-DL-tyrosinal, and isolated from the culture broth of a strain of *Kitasatospora*, is a cell-permeable peptide aldehyde that competitively inhibits the chymotrypsin-like and trypsin-like activities of the 20S proteasome with IC<sub>50</sub> values of 0.1  $\mu\text{g/mL}$  and 1.5  $\mu\text{g/mL}$ , respectively (1,2). Tyropeptin A does not inhibit the peptidylglutamyl-peptide hydrolyzing activity. **Target(s):** calpain (1); cathepsin L (1);  $\alpha$ -chymotrypsin (1); and proteasome (1-3). 1. Momose, Sekizawa, Hashizume, et al. (2001) *J. Antibiot.* **54**, 997. 2. Momose, Sekizawa, Hirosawa, et al. (2001) *J. Antibiot.* **54**, 1004. 3. Momose, Sekizawa, Iinuma & Takeuchi (2002) *Biosci. Biotechnol. Biochem.* **66**, 2256.

**Tyropeptin B**

This peptide aldehyde (FW = 511.62 g/mol), also known as *N*-(*n*-butyryl)-L-tyrosyl-L-leucyl-DL-tyrosinal, and isolated from the culture broth of a strain of *Kitasatospora*, is a cell-permeable peptide aldehyde that competitively inhibits the chymotrypsin-like and trypsin-like activities of the 20S proteasome with an activity about two-fold less than that of tyropeptin A

- (1,2). 1. Momose, Sekizawa, Hashizume, *et al.* (2001) *J. Antibiot.* **54**, 997  
 2. Momose, Sekizawa, Hirokawa, *et al.* (2001) *J. Antibiot.* **54**, 1004.

### L-Tyrosinamide

This amino acid amide (FW<sub>free-base</sub> = 180.21 g/mol; CAS 4985-46-0; pK<sub>a</sub> values of 7.33 (amino) and 10.4 (phenolic OH) at 25°C), which is frequently used in the chemical synthesis of natural products, inhibits bacterial leucyl aminopeptidase (1), tyramine *N*-feruloyltransferase (2), and tyrosyl-tRNA synthetase, K<sub>i</sub> = 0.31 mM for the *Escherichia coli* enzyme (3,4). 1. Baker, Wilkes, Bayliss & Prescott (1983) *Biochemistry* **22**, 2098. 2. Negrel & Javelle (1997) *Eur. J. Biochem.* **247**, 1127. 3. Calendar & Berg (1966) *Biochemistry* **5**, 1690. 4. Santi & Peña (1973) *J. Med. Chem.* **16**, 273.

### D-Tyrosine

This enantiomer of L-tyrosine (FW = 181.19 g/mol; CAS 556-02-5), known systematically as (*R*)-2-amino-3-(4-hydroxyphenyl)propanoic acid, is present as its *O*-methyl ether in the antibiotic cycloheptamycin. See **L-Tyrosine Target(s)**: aroenate dehydrogenase (1); carboxypeptidase A (2,3); phenylalanine ammonia-lyase (4,5); phenylalanine dehydrogenase (6); prephenate dehydrogenase (7,8); tyrosine aminotransferase, weakly inhibited (9). 1. Bonner & Jensen (1987) *Meth. Enzymol.* **142**, 488. 2. Giusti, Carrara, Cima & Borin (1985) *Eur. J. Pharmacol.* **116**, 287. 3. Elkins-Kaufman & Neurath (1948) *J. Biol. Chem.* **175**, 893. 4. ### L-Tyrosine

This proteogenic aromatic amino acid (FW = 181.19 g/mol; CAS 60-18-4; pK<sub>a</sub> values of 2.20, 9.21, and 10.46 (phenolic OH) at 25°C; Symbol = Tyr = Y), known systematically as (*S*)-2-amino-3-(4-hydroxyphenyl)propanoic acid, absorbs UV light (λ<sub>max</sub> = 223 nm (ε = 8200 M<sup>-1</sup>cm<sup>-1</sup>) and 274.5 nm (ε = 1340 M<sup>-1</sup>cm<sup>-1</sup>) in 0.1 M HCl; λ<sub>max</sub> = 240 nm (ε = 11050 M<sup>-1</sup>cm<sup>-1</sup>) and 293.5 nm (ε = 2330 M<sup>-1</sup>cm<sup>-1</sup>) in 0.1 M NaOH). Enzymes utilizing L-tyrosine as a substrate or product include: cyclohexadienyl dehydrogenase, tyrosine *N*-monoxygenase, phenylalanine 4-monoxygenase, tyrosine 3-monoxygenase, monophenol monoxygenase, tyrosine aminotransferase, tubulin:tyrosine ligase, tubuliny-Tyr carboxypeptidase, tyrosine decarboxylase, tyrosine phenol-lyase, tyrosine 2,3-aminomutase, tyrosyl-tRNA synthetase, and tyrosylarginine synthetase. Many enzymes use D- or L-tyrosine as alternative substrates, including L-amino-acid dehydrogenase, phenylalanine dehydrogenase, the amino acid oxidases, aspartate aminotransferase, aromatic amino acid transferase, aromatic-amino-acid:glyoxylate aminotransferase, phenylalanine decarboxylase, phenylalanine ammonia-lyase (albeit, not from all sources), and amino-acid racemase. **Target(s)**: alkaline phosphatase (1,2); chorismate mutase (3-7); cyclohexadienyl dehydrogenase, or aroenate dehydrogenase (8,9); cystinyl aminopeptidase, or oxytocinase (29); cytosol alanyl aminopeptidase (27,28); 3-deoxy-7-phosphoheptulonate synthase, or 3-deoxy-D-arabinoheptulonate-7-phosphate synthetase, or phospho-2-dehydro-3-deoxyheptulonate aldolase (10,11,21,37-50); dihydropteridine reductase (12,13); diphosphomevalonate decarboxylase (34); glutamine synthetase (14); histidine ammonia-lyase (15); histidine decarboxylase (16); leucyl aminopeptidase (32); membrane alanyl aminopeptidase, or aminopeptidase N (30,31); mimosinase (17); phenylalanine ammonia-lyase (16,18-20); prephenate dehydratase (3,22); prephenate dehydrogenase (3,4); propionyl-CoA carboxylase, *Myxococcus Xanthus* (23); protein-tyrosine-phosphatase (33); pyrophosphatase, or inorganic diphosphatase (24); pyruvate kinase

(35,36); shikimate kinase (25); starch phosphorylase (51-53); and tryptophan 5-monoxygenase (26,54). 1. Fernley (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), **4**, 417. 2. ### m-Tyrosine

This naturally occurring tyrosine isomer (FW = 181.19 g/mol; CAS 775-06-4), also called (3-hydroxyphenyl)alanine, is an alternative intermediate in the biosynthesis of certain catecholamines as well as many plant quinones. m-Tyrosine is also a marker of oxidative damage in motor neuron disease (1) as well as a marker of hydroxyl radical generation (2). **Target(s)**: aromatic-L-amino-acid decarboxylase, also alternative substrate (3,4); 3-deoxy-7-phosphoheptulonate synthase, or 3-deoxy-D-arabinoheptulonate-7-phosphate synthetase (5); phenylalanine ammonia-lyase (6); phenylalanine 4-monoxygenase (7); prephenate dehydratase (8); and tyrosine phenol-lyase, inhibited by the L-enantiomer (9,10). 1. **o-Tyrosine**

This naturally occurring tyrosine isomer (FW = 181.19 g/mol), also called (2-hydroxyphenyl)alanine, is a marker of oxidative damage in motor neuron disease (1), a marker of hydroxyl radical generation (2), and is most abundant in the human lens (3). **Target(s):** 3-deoxy-7-phosphoheptulonate synthase, or 3-deoxy-D-arabinoheptulonate-7-phosphate synthetase (4); glucose-6-phosphatase (5); phenylalanine ammonia-lyase (6); and prephenate dehydratase (7). 1. **L-Tyrosine Benzyl Ester**

This esterified amino acid (FW<sub>free-base</sub> = 271.32 g/mol) inhibits tyramine *N*-feruloyltransferase (1,2) and *Escherichia coli* tyrosyl-tRNA synthetase,  $K_i$  = 0.03 mM (3). 1. Negrel & Javelle (1997) *Eur. J. Biochem.* **247**, 1127. 2. Negrel & Javelle (2001) *Phytochemistry* **56**, 523. 3. Santi & Peña (1973) *J. Med. Chem.* **16**, 273.

**L-Tyrosine Ethyl Ester**

This amino acid ester (FW<sub>hydrochloride</sub> = 245.71 g/mol; CAS 949-67-7; M.P. = 166-168°C) is an alternative substrate for chymotrypsin. Hydrolysis of the ester is accompanied by a decrease in absorbance at 233.5 nm at pH 6.5. The ester undergoes slow nonenzymatic hydrolysis (4% in 24 hours at pH 7 and 4°C) in aqueous solution. **Target(s):** L-amino-acid oxidase (1); pepsin,  $K_i$  = 18 mM (2); tyramine *N*-feruloyltransferase (3); tyrosyl-tRNA synthetase,  $K_i$  = 0.1 mM for the *Escherichia coli* enzyme (4,5). 1. Zeller & Maritz (1945) *Helv. Chim. Acta* **28**, 365. 2. Inouye & Fruton (1968) *Biochemistry* **7**, 1611. 3. Negrel & Javelle (1997) *Eur. J. Biochem.* **247**, 1127. 4. Calendar & Berg (1966) *Biochemistry* **5**, 1690. 5. Santi & Peña (1973) *J. Med. Chem.* **16**, 273.

**L-Tyrosine Methyl Ester**

This esterified amino acid (FW<sub>free-base</sub> = 195.22 g/mol) inhibits tyramine *N*-feruloyltransferase (1) tyrosyl-tRNA synthetase,  $K_i$  = 0.09 mM for the *Escherichia coli* enzyme (2,3). 1. Negrel & Javelle (1997) *Eur. J. Biochem.* **247**, 1127. 2. Calendar & Berg (1966) *Biochemistry* **5**, 1690. 3. Santi & Peña (1973) *J. Med. Chem.* **16**, 273.

**L-Tyrosine  $\beta$ -Naphthylamide**

This derivative of L-tyrosine (FW<sub>free-base</sub> = 306.36 g/mol), used frequently in the assay of tyrosine aminopeptidases, is a potent inhibitor of tobacco and

potato tyramine *N*-feruloyltransferase,  $K_i$  values of 0.66 and 0.3  $\mu$ M, respectively, and *Escherichia coli* tyrosyl-tRNA synthetase,  $K_i$  = 96  $\mu$ M (2). 1. Negrel & Javelle (1997) *Eur. J. Biochem.* **247**, 1127. 2. Santi & Peña (1973) *J. Med. Chem.* **16**, 273.

**Tyrosine-Specific Protein Kinase Inhibitor**

This oligopeptide (FW = 2482.74 g/mol; Sequence: VAPSDSIQAEWYFG KITRRE), corresponding to a sequence in noncatalytic domain of p60<sup>V-src</sup>, inhibits the autophosphorylation of epidermal growth factor receptor/kinase and the tyrosine-specific protein phosphorylation in the acetylcholine receptor-rich membranes isolated from electroplax of *Narke japonica*. **Target(s):** p60<sup>V-src</sup> protein-tyrosine kinase (1). 1. Sato, Miki, Tachibana, et al. (1990) *Biochem. Biophys. Res. Commun.* **171**, 1152.

**L-Tyrosinol**

This reduced derivative of L-tyrosine (FW<sub>free-base</sub> = 167.21 g/mol; CAS 87745-27-5) binds within the active-site of tyrosyl-tRNA synthetase ( $K_i$  = 16  $\mu$ M for the *Escherichia coli* enzyme), but cannot undergo adenylation. **Target(s):** tyramine *N*-feruloyltransferase (1); and tyrosyl-tRNA synthetase (2-4). 1. Negrel & Javelle (1997) *Eur. J. Biochem.* **247**, 1127. 2. Monteilhet, Blow & Brick (1984) *J. Mol. Biol.* **173**, 477. 3. Calendar & Berg (1966) *Biochemistry* **5**, 1690. 4. Santi & Peña (1973) *J. Med. Chem.* **16**, 273.

**D-Tyrosinol Adenylylate**

This synthetic aminoacyl adenylylate mimic (FW = 496.42 g/mol), also known as D-tyrosinyl adenylylate, is a potent isosteric inhibitor of tyrosyl-tRNA synthetase. 1. Santi & Peña (1973) *J. Med. Chem.* **16**, 273.

**L-Tyrosinol 2'-Deoxyadenylylate**

This aminoacyl adenylylate mimic (FW = 480.42 g/mol), also known as L-tyrosinyl 2'-deoxyadenylylate, inhibits tyrosyl-tRNA synthetase (IC<sub>50</sub> = 100  $\mu$ M for the *Staphylococcus aureus* enzyme and 18  $\mu$ M for the *Bacillus stearothermophilus* protein) (1). **See L-Tyrosinol Adenylylate** 1. Brown, Richardson, Mensah, et al. (1999) *Bioorg. Med. Chem.* **7**, 2473.

**L-Tyrosinol 3'-Deoxyadenylylate**

This aminoacyl adenylylate mimic, also known as L-tyrosinyl 3'-deoxyadenylylate (FW = 480.42 g/mol), inhibits tyrosyl-tRNA synthetase (IC<sub>50</sub> = 140  $\mu$ M for the *Staphylococcus aureus* enzyme and 36  $\mu$ M for the *Bacillus stearothermophilus* protein) (1). **See L-Tyrosinol Adenylylate** 1. Brown, Richardson, Mensah, et al. (1999) *Bioorg. Med. Chem.* **7**, 2473.

**L-Tyrosinol 2',3'-O-Isopropylideneadenylate**

This aminoacyl adenylate mimic, also known as L-tyrosinyl 2',3'-O-isopropylidene adenylate (FW = 536.48 g/mol), inhibits *Staphylococcus aureus* tyrosyl-tRNA synthetase ( $IC_{50}$  = 26 nM). **See L-Tyrosinol Adenylate** 1. Brown, Richardson, Mensah, *et al.* (1999) *Bioorg. Med. Chem.* 7, 2473.

**L-Tyrosinol 1 $\beta$ -Naphthyl-1,4-Anhydro-D-ribose-5-O-phosphate**

This aminoacyl adenylate mimic (FW = 489.46 g/mol), also known as L-tyrosinyl 1,4-anhydro-D-ribose-5-O-phosphate, inhibits *Staphylococcus aureus* tyrosyl-tRNA synthetase ( $IC_{50}$  = 150 nM). **See L-Tyrosinol Adenylate** 1. Brown, Richardson, Mensah, *et al.* (1999) *Bioorg. Med. Chem.* 7, 2473.

**L-Tyrosinol Uridylate**

This aminoacyl adenylate mimic (FW = 473.38 g/mol), also known as L-tyrosinyl uridine-5'-O-phosphate, inhibits *Staphylococcus aureus* tyrosyl-tRNA synthetase ( $IC_{50}$  = 210 nM). **See L-Tyrosinol Adenylate** 1. Brown, Richardson, Mensah, *et al.* (1999) *Bioorg. Med. Chem.* 7, 2473.

**Tyrostatin**

This peptide aldehyde (FW = 525.65 g/mol) from *Kitasatospora*, also known as *N*-isovaleryl-L-tyrosyl-L-leucyl-L-tyrosinal (FW = 525.65 g/mol), was found to be a competitive inhibitor for kumamolysin,  $K_i$  = 2.8  $\mu$ M (1), pseudomonalisin,  $K_i$  = 2.6 nM (2-8), and xanthomonalisin,  $K_i$  = 2.1 nM (5,8-10). Tyrostatin forms a covalent bond to an active-site seryl residue *via* its hydrated aldehyde moiety, with the side-chains occupying subsites S1-S4 of the enzymes. **See also Pseudo-tyrostatin; Pseudo-iodotyrostatin; Iodotyrostatin** 1. Oyama, Hamada, Ogasawara, *et al.* (2002) *J. Biochem.* 131, 757. 2. Murao (1998) in *Handb. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.), p. 975, Academic Press, San Diego. 3. Oda, Ito, Uchida, *et al.* (1996) *J. Biochem.* 120, 564.

**L-Tyrosyl-L-alanine**

This dipeptide (FW = 252.27 g/mol) inhibits peptidyl-dipeptidase A (angiotensin I-converting enzyme;  $K_i$  = 0.06 mM). It also inhibits bovine tubulin:tyrosine ligase ( $K_i$  = 0.19 mM) and *Escherichia coli* tyrosyl-tRNA synthetase ( $K_i$  = 5  $\mu$ M). **Target(s):** alanine carboxypeptidase, alternative substrate (1); dipeptidyl-peptidase III, weakly inhibited (2); peptidyl-dipeptidase A, or angiotensin I-converting enzyme (3,4); tubulin:tyrosine ligase (5); and tyrosyl-tRNA synthetase (6). 1. Levy & Goldman (1969) *J. Biol. Chem.* 244, 4467. 2. Lee & Snyder (1982) *J. Biol. Chem.* 257, 12043. 3. Das & Soffer (1975) *J. Biol. Chem.* 250, 6762. 4. Soffer (1976) *Ann. Rev. **L-Tyrosyl-L-alanyl-L-aspartyl-L-phenylalanyl-L-isoleucyl-L-alanyl-L-serylglycyl-L-arginyl-L-threonylglycyl-L-arginyl-L-arginyl-L-asparaginyl-L-alanyl-L-isoleucyl-L-histidine-L-glutamate**

This 18-residue peptide (FW = 2034.22 g/mol; YADFIASGRTGRRNAIHE) inhibits cAMP-dependent protein kinase,  $K_i$  = 2 nM. 1. Walsh & Glass (1991) *Meth. Enzymol.* 201, 304.

**L-Tyrosyl-L-aspartyl-L-prolyl-L-prolyl-L-alanyl-L-isoleucyl-statinyl-L-isoleucyl-L-isoleucine**

This short peptide (FW = 1069.31 g/mol; Sequence: RDPPAI(Sta)II) inhibits bovine leukemia virus retropepsin (1-3) at nanomolar concentrations. If the statin residue is replaced with L-leucyl-L-prolyl, the resulting peptide is hydrolyzed by the same aspartic proteinase. 1. Ménard & Guillemain (1998) in *Handb. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.), p. 940, Academic Press, San Diego. 2. Ménard, Mamoun, Geoffre, *et al.* (1993) *Virology* 193, 680. 3. Précigoux, Geoffre, Léonard, *et al.* (1993) *FEBS Lett.* 326, 237.

**N-[3-(D-Tyrosyl-L-glutamyl-L-lysyl-L-glutamyl-L-arginyl-L-seryl-L-lysyl-L-arginyl)propionyl]-L-alanyl-L-leucyl-L-arginyl-L-aspartate**

This peptide analogue contains an Arg $\Psi$ (COCH<sub>2</sub>)Gly replacing ArgSer in a peptide substrate for furin and proprotein convertase 1, with  $K_i$  values of 2.4 and 7.2  $\mu$ M, respectively. 1. Jean, Basak, DiMaio, Seidah & Lazure (1995) *Biochem. J.* 307, 689.

**D-Tyrosyl-L-glutamyl-L-phenylalanyl-L-lysyl-L-arginine Chloromethyl Ketone**

This halomethyl ketone inhibits plasma kallikrein (1) and trypsin (2). 1. Paquin, Benjannet, Sawyer, *et al.* (1989) *Biochim. Biophys. Acta* 999, 103. 2. Cromlish, Seidah, Marcinkiewicz, *et al.* (1987) *J. Biol. Chem.* 262, 1363.

**L-Tyrosylglycine**

This dipeptide (FW = 222.24 g/mol) is a  $\gamma$ -glutamyl acceptor substrate and inhibitor of  $\gamma$ -glutamyl transpeptidase (1,2), tubulin:tyrosine ligase (3), and *Escherichia coli* tyrosyl-tRNA synthetase,  $K_i$  = 12  $\mu$ M (4). 1. Allison (1985) *Meth. Enzymol.* 113, 419. 2. Thompson & Meister (1977) *J. Biol. Chem.* 252, 6792. 3. Raybin & Flavin (1977) *Biochemistry* 16, 2189. 4. Santi & Peña (1973) *J. Med. Chem.* 16, 273.

**L-Tyrosylglycyl-L-arginine Chloromethyl Ketone**

This halomethyl ketone (FW<sub>free-base</sub> = 426.90 g/mol; Symbol: YGR-CMK) inhibits certain mammalian proteasome activities. 1. Rivett, Savory & Djaballah (1994) *Meth. Enzymol.* **244**, 331.

**L-Tyrosyl-L-leucyl-L-tyrosyl-L-glutamyl-L-isoleucyl-L-alanyl-L-arginine**

This heptapeptide (FW = 927.07 g/mol; Sequence: YLYEIAR), with a sequence corresponding to residues to 138–144 of human serum albumin (also known as acin-1), inhibits peptidyl-dipeptidase A or angiotensin I-converting enzyme, IC<sub>50</sub> = 16 μM (1-2). The hexapeptide lacking the C-terminal arginine is a weaker inhibitor (IC<sub>50</sub> = 500 μM), as is the octapeptide with an additional C-terminal arginine (IC<sub>50</sub> = 86 μM). 1. Nakagomi, Yamada, Ebisu, *et al.* (2000) *FEBS Lett.* **467**, 235. 2. Nakagomi, Fujimura, Ebisu, *et al.* (1998) *FEBS Lett.* **438**, 255.

**L-Tyrosyl-L-tyrosine**

This dipeptide (FW = 344.37 g/mol), often abbreviated YY, inhibits dipeptidyl-peptidase III-4; tubulin:tyrosine ligase, IC<sub>50</sub> = 23 μM (5); and staphylococcal tyrosyl-tRNA synthetase, IC<sub>50</sub> = 3.8 μM (6,7). 1. Chan, Jones, Sweeney & Toursarkissian (1987) *Exp. Mycol.* **11**, 27. 2. Sentandreu & Toldrá (1998) *J. Agric. Food Chem.* **46**, 3977. 3. Lee & Snyder (1982) *J. Biol. Chem.* **257**, 12043. 4. Lett.* **9**, 2859. 7. Santi & Peña (1973) *J. Med. Chem.* **16**, 273.

**Tyrphostins**

This class of protein-tyrosine kinase inhibitors, of which many are benzylidenemalononitrile derivatives, inhibit other processes, including lipoxygenases and oxidative phosphorylation. Most penetrate cell membranes slowly. A few examples are provided in the entries below. **See Uncouplers** **Target(s):** protein-tyrosine kinases (1,2) 1. Levitzki, Gazit, Osherov, Posner & Gilon (1991) *Meth. Enzymol.* **201**, 347. 2. Gazit, Yaish, Gilon & Levitzki (1989) *J. Med. Chem.* **32**, 2344.

**Tyrphostin 1**

This light-sensitive tyrosine phosphorylation inhibitor (FW = 184.20 g/mol; melting point = 115°C), also known as (4-methoxybenzylidene) malononitrile, tyrphostin A1, and tyrphostin AG9, is such a poor inhibitor of protein-tyrosine kinase, IC<sub>50</sub> > 1.25 mM (1), is frequently used as a negative control. 1. Gazit, Yaish, Gilon & Levitzki (1989) *J. Med. Chem.* **32**, 2344.

**Tyrphostin 9, See Tyrphostin A9****Tyrphostin 23**

This photosensitive tyrosine phosphorylation inhibitor (FW = 186.17 g/mol; melting point = 225°C), also known as (3,4-dihydroxybenzylidene) malononitrile, tyrphostin A23, tyrphostin AG18, and RG-50810, has an IC<sub>50</sub> for the EGF receptor protein-tyrosine kinase of 35 μM and K<sub>i</sub> value of 11 μM. Other protein-tyrosine kinases with relatively low IC<sub>50</sub> values include platelet-derived growth factor receptor kinase (IC<sub>50</sub> = 25 μM) and p210<sup>bcr-abl</sup>

(IC<sub>50</sub> = 75 μM). **Target(s):** calcineurin, ior phosphoprotein phosphatase (1); DNA topoisomerase I, IC<sub>50</sub> = 750 μM (2,3); EGF receptor protein-tyrosine kinase (4-6); guanylyl cyclase (7); PDGF receptor protein-tyrosine kinase (4,6); p210<sup>bcr-abl</sup> protein-tyrosine kinase (4); protein-tyrosine kinase (4,8,9); and receptor protein-tyrosine kinase (4-6,9). 1. Martin (1998) *Biochem. Pharmacol.* **56**, 483. 2. Markovits, Larsen, Segal-Bendirdjian, *et al.* (1994) *Biochem. Pharmacol.* **48**, 549. 3. Bendetz-Nezer, Gazit & Priel (2004) *Mol. Du, Gao, Lau, *et al.* (2004) *J. Gen. Physiol.* **123**, 427.

**Tyrphostin 25**

This photosensitive tyrosine phosphorylation inhibitor (FW = 202.17 g/mol; MP = 245°C), also known as (3,4,5-trihydroxybenzylidene)malononitrile, tyrphostin A25, and tyrphostin AG82, has an IC<sub>50</sub> for the EGF receptor protein-tyrosine kinase of 3 μM and it is one of the most frequently used inhibitors for that kinase. Tyrphostin also inhibits the GTPase activity of transducin (IC<sub>50</sub> = 7 μM) and the kinase activity of Abl p210<sup>bcr-abl</sup> (IC<sub>50</sub> = 3.6 μM). **Target(s):** Abl p210<sup>bcr-abl</sup> protein-tyrosine kinase (1); aldehyde dehydrogenase (2); Bruton's protein-tyrosine kinase (10); epidermal growth factor receptor protein-tyrosine kinase (3-6); guanylyl cyclase (7); neuromedin B-induced phosphorylation of p125(FAK) (focal adhesion kinase) (8); protein-tyrosine kinase (1,9,10); receptor protein-tyrosine kinase (3-6,9); and transducin GTPase (11). 1. Anafi, Gazit, Gilon, Ben-Neriah & Levitzki (1992) *J. Biol. Chem.* **267**, 4518. 2. Poole, Bowden & Halestrap (1993) *Biochem. Pharmacol.* **45**, 1621. 3. **Tyrphostin 46**

This photosensitive tyrosine phosphorylation inhibitor (FW = 204.19 g/mol; MP = 247°C), also known as 3,4-dihydroxy-α-cyanocinnamamide, tyrphostin A46, tyrphostin B40, and tyrphostin AG99, has an IC<sub>50</sub> value for the EGF receptor protein-tyrosine kinase of 10 μM (1-3) and also inhibits ErbB2/neu protein-tyrosine kinase (3). 1. Rosenshine, Ruschkowski & Finlay (1994) *Meth. Enzymol.* **236**, 467. 2. Gazit, Yaish, Gilon & Levitzki (1989) *J. Med. Chem.* **32**, 2344. 3. Gazit, Osherov, Posner, *et al.* (1991) *J. Med. Chem.* **34**, 1896.

**Tyrphostin 47**

This photosensitive tyrosine phosphorylation inhibitor (FW = 220.25 g/mol; MP = 213°C), also known as α-cyano-3,4-dihydroxythiocinnamamide, tyrphostin A47, and tyrphostin AG213, has an IC<sub>50</sub> for the EGF (epidermal growth factor) receptor protein-tyrosine kinase of 2.4 μM, but is a relatively

weak inhibitor of protein kinase C ( $IC_{50} = 60 \mu\text{M}$ ). **Target(s):** aldehyde dehydrogenase (1);  $\text{Ca}^{2+}$  entry channels (2); cell proliferation (3); dual-specificity kinase (4); EGF receptor protein-tyrosine kinase (5-9); guanylyl cyclase (10); PDGF receptor protein-tyrosine kinase (5,7); p210<sup>bcr-abl</sup> protein-tyrosine kinase,  $IC_{50} = 5.8 \mu\text{M}$  (5); protein-glutamine  $\gamma$ -glutamyltransferase, or transglutaminase (11); and protein-tyrosine kinase (5,12). 1. Poole, Bowden & Halestrap (1993) *Biochem. Pharmacol.* **45**, 1621. 2. Ohta, Yasuda, Hasegawa, Ito & Nakazato (2000) *Eur. J. Pharmacol.* **387**, 211. 3. Twaddle, Turbov, Liu & Murthy (1999) *J. #### Tyrphostin 48

This tyrosine phosphorylation inhibitor (FW = 236.23 g/mol; melting point = 225°C), also known as 3-amino-2,4-dicyano-5-(4'-hydroxyphenyl)pent-2,4-dienonitrile, tyrphostin A48, and tyrphostin AG112, is a broad-range inhibitor of EGF (epidermal growth factor) receptor protein-tyrosine kinase ( $IC_{50} = 0.125 \mu\text{M}$ ). **Target(s):** calcineurin, or phosphoprotein phosphatase (1); and EGF receptor protein-tyrosine kinase (2). 1. Martin (1998) *Biochem. Pharmacol.* **56**, 483. 2. Gazit, Yaish, Gilon & Levitzki (1989) *J. Med. Chem.* **32**, 2344.

#### Tyrphostin 51

This photosensitive tyrosine phosphorylation inhibitor (FW = 268.23 g/mol; MP = 275°C), also known as 2-amino-1,1,3-tricyano-4-(3',4',5'-trihydroxyphenyl)buta-1,3-diene, tyrphostin A51, and tyrphostin AG183, has an  $IC_{50}$  for the EGF (epidermal growth factor) receptor protein tyrosine kinase of 0.8  $\mu\text{M}$ . **Target(s):** EGF receptor protein-tyrosine kinase (1-3); inositol-trisphosphate 3-kinase (4); and receptor protein-tyrosine kinase (1-3,5). 1. Rosenshine, Ruschkowski & Finlay (1994) *Meth. Enzymol.* **236**, 467. 2. Gazit, Yaish, Gilon & Levitzki (1989) *J. Med. Chem.* **32**, 2344. 3. Levitzki (1990) *Biochem. Pharmacol.* **40**, 913. 4. Mayr, Windhorst & Hillemeier (2005) *J. Biol. Chem.* **280**, 13229. 5. Mergler, Dannowski, Bednarz, et al. (2003) *Exp. Eye Res.* **77**, 485.

#### Tyrphostin 63

This photosensitive tyrosine phosphorylation inhibitor (FW = 172.19 g/mol), also known as (4-hydroxybenzyl)malononitrile, tyrphostin A63, and tyrphostin AG43, has such a high  $IC_{50}$  value for EGF receptor protein-tyrosine kinase of 6.5 mM that it is frequently used as a negative control (1). 1. Gazit, Yaish, Gilon & Levitzki (1989) *J. Med. Chem.* **32**, 2344.

**Tyrphostin A1, See Tyrphostin 1**

**Tyrphostin A8, See Tyrphostin AG10**

#### Tyrphostin A9

This tyrosine phosphorylation inhibitor (FW = 282.39 g/mol; melting point = 135°C), also known as tyrphostin 9, tyrphostin AG17, RG 50852, and [[3,5-bis(1,1-dimethylethyl)-4-hydroxyphenyl]methylene]propanedinitrile, is a selective inhibitor of platelet-derived growth factor (PDGF) receptor protein-tyrosine kinase ( $IC_{50} = 0.5 \mu\text{M}$ ). Tyrphostin also reportedly uncouples oxidative phosphorylation. **Target(s):** PDGF receptor protein-tyrosine kinase (1,2); and receptor protein-tyrosine kinase (1,2). 1. Bilder, Krawiec, McVety, et al. (1991) *Amer. J. Physiol.* **260**, C721. 2. Wang, Buck, RYang, Macey & Neve (2005) *J. Neurochem.* **93**, 899.

**Tyrphostin AG9, See Tyrphostin 1**

#### Tyrphostin AG10

This tyrosine phosphorylation inhibitor (FW = 170.17 g/mol), also known as tyrphostin A8,  $\alpha$ -cyano-(4-hydroxy)cinnamonitrile, and 4-hydroxybenzylidene-malononitrile, inhibits the GTPase activity of transducin,  $IC_{50} = 45 \mu\text{M}$  (1) and also inhibits calcineurin activity,  $IC_{50} = 21 \mu\text{M}$  (2). 1. Wolbring, Hollenberg & Schnetkamp (1994) *J. Biol. Chem.* **269**, 22470. 2. Martin (1998) *Biochem. Pharmacol.* **56**, 483.

**Tyrphostin AG17, See Tyrphostin A9**

**Tyrphostin AG18, See Tyrphostin 23**

#### Tyrphostin AG30

This tyrosine phosphorylation inhibitor (FW<sub>free-acid</sub> = 205.17 g/mol), also known as  $\alpha$ -cyano-(3,4-dihydroxy)cinnamic acid, inhibits c-ErbB protein-tyrosine kinase (1). 1. Wessely, Mellitzer, von Lindern, et al. (1997) *Cell Growth Differ.* **8**, 481.

#### Tyrphostin AG34

This tyrosine phosphorylation inhibitor (FW = 216.20 g/mol; MP = 235°C), also called tyrphostin A24, inhibits casein kinase II (1); EGF receptor protein-tyrosine kinase (2); and protein-tyrosine kinase (2,3). 1. Kang, Huang & Liang (1997) *Zhongguo Yao Li Xue Bao* **18**, 56. 2. Gazit, Yaish, Gilon &

Levitzki (1989) *J. Med. Chem.* **32**, 2344. **3.** Schwartz, Lamprecht, Polak-Charcon, Niv & Kim (1995) *Oncol. Res.* **7**, 277.

**Tyrphostin AG82, See Tyrphostin 25**

**Tyrphostin AG99, See Tyrphostin 46**

**Tyrphostin AG112, See Tyrphostin 48**

#### Tyrphostin AG126

This tyrosine phosphorylation inhibitor (FW = 215.17 g/mol), also known as (3-hydroxy-4-nitrobenzylidene)-malononitrile, blocks the production of tumor necrosis factor- $\alpha$  and nitric oxide in macrophages. This inhibitory effect correlates with the ability of this tyrphostin to block the lipopolysaccharide-induced protein-tyrosine phosphorylation of a macrophage p42MAPK protein substrate (1). **Target(s):** EGF (epidermal growth factor) receptor protein-tyrosine kinase,  $IC_{50}$  = 450  $\mu$ M (2); protein-tyrosine kinase (1,2); and TNF- $\alpha$  production (1). **1.** Novogrodsky, Vanichkin, Patya, *et al.* (1994) *Science* **264**, 1319. **2.** Gazit, Yaish, Gilon & Levitzki (1989) *J. Med. Chem.* **32**, 2344.

**Tyrphostin AG183, See Tyrphostin 51**

**Tyrphostin AG213, See Tyrphostin 47**

#### Tyrphostin AG370

This tyrosine phosphorylation inhibitor (FW = 259.27 g/mol; melting point = 242°C), also known as 2-amino-4-(1H-indo-5'-yl)-1,1,3-tricyanobuta-1,3-diene and tyrphostin B7, inhibits certain protein-tyrosine kinases. AG370 was found to be the a potent blocker of PDGF-induced (platelet-derived growth factor-induced) mitogenesis,  $IC_{50}$  = 20-25  $\mu$ M (1). **Target(s):** PDGF protein-tyrosine kinase (1,2); and receptor protein-tyrosine kinase (1-3). **1.** Bryckaert, Eldor, Fontenay, *et al.* (1992) *Exp. Cell Res.* **199**, 255. **2.** Wang, Buck, Yang, Macey & Neve (2005) *J. Neurochem.* **93**, 899. **3.** Levitzki, Gazit, Osherov, Posner & Gilon (1991) *Meth. Enzymol.* **201**, 347.

#### Tyrphostin AG473

This tyrosine phosphorylation inhibitor (FW = 265.27 g/mol), also known as 3,4-dihydroxy( $\alpha$ -benzoyl)*cis*-cinnamonitrile, inhibits certain protein-tyrosine kinases (1). **1.** Levitzki, Gazit, Osherov, Posner & Gilon (1991) *Meth. Enzymol.* **201**, 347.

#### Tyrphostin AG490

This photosensitive tyrosine phosphorylation inhibitor (FW = 294.31 g/mol; MP = 215°C), also known as 2-cyano-3-(3,4-dihydroxyphenyl)-*N*-(benzyl)-2-propenamide and tyrphostin B42, is a selective inhibitor of Jak-2 protein-

tyrosine kinase,  $IC_{50}$  = 100 nM. Pretreating cells with tyrphostin AG490 abolishes protein-tyrosine phosphorylation of the p85 subunit of PI3 kinase induced by granulocyte-macrophage colony-stimulating factor, or GM-CSF (1). Tyrphostin AG490 also causes cells to arrest at late G1 and during S phase (2). **Target(s):** Cdk2 activation<sup>3</sup>; EGF (epidermal growth factor) receptor protein-tyrosine kinase,  $IC_{50}$  = 0.1  $\mu$ M (4); guanylyl cyclase (5); inositol-trisphosphate 3-kinase (6); and Jak-2 protein-tyrosine kinase (1,7,8). **1.** Al-Shami & Naccache (1999) *J. Biol. Chem.* **274**, 5333. **2.** Kleinberger-Doron, Shelah, Capone, Gazit & Levitzki (1998) *Exp. Cell Res.* **241**, 340. **3.** Osherov & Levitzki (1997) *FEBS Lett.* **410**, 187. **4.** Gazit, Osherov, Posner, *et al.* (1991) *J. Med. Chem.* **34**, 1896. **5.** Jaleel, Shenoy & Visweswariah (2004) *Biochemistry* **43**, 8247. **6.** Mayr, Windhorst & Hillemeier (2005) *J. Biol. Chem.* **280**, 13229. **7.** Meydan, Grunberger, Dadi, *et al.* (1996) *Nature* **379**, 645. **8.** Anastasiadou & Schwaller (2003) *Curr. Opin. Hematol.* **10**, 40.

#### Tyrphostin AG494

This tyrosine phosphorylation inhibitor (FW = 280.28 g/mol; MP = 258°C), also known as tyrphostin B48, *N*-phenyl-3,4-dihydroxybenzylidene-cyanoacetamide, and 3,4-dihydroxy( $\alpha$ -benzamido)-*cis*-cinnamonitrile, inhibits EGF-receptor phosphorylation (albeit, not in intact cells): the  $IC_{50}$  is 1.24  $\mu$ M. Tyrphostin AG494 also causes cells to arrest at late G1 and during S phase (1). **Target(s):** Cdk2 activation (2); cell proliferation (3); epidermal growth factor receptor protein-tyrosine kinase (1,4); and guanylyl cyclase (5). **1.** Kleinberger-Doron, Shelah, Capone, Gazit & Levitzki (1998) *Exp. Cell Res.* **241**, 340. **2.** Osherov & Levitzki (1997) *FEBS Lett.* **410**, 187. **3.** Twaddle, Turbov, Liu & Murthy (1999) *J. Surg. Oncol.* **70**, 83. **4.** Levitzki, Gazit, Osherov, Posner & Gilon (1991) *Meth. Enzymol.* **201**, 347. **5.** Jaleel, Shenoy & Visweswariah (2004) *Biochemistry* **43**, 8247.

#### Tyrphostin AG527

This tyrosine phosphorylation inhibitor (FW = 308.34 g/mol; MP = 135°C), also known as tyrphostin B44 and (-)-(R)-*N*-( $\alpha$ -methylbenzyl)-3,4-dihydroxybenzylidene-cyanoacetamide, inhibits EGF-receptor phosphorylation: the  $IC_{50}$  is 2.5  $\mu$ M (1). *Note:* The (+)-(*S*)-enantiomer of tyrphostin AG527 is tyrphostin AG835. **1.** Gazit, Osherov, Posner, *et al.* (1991) *J. Med. Chem.* **34**, 1896.

#### Tyrphostin AG528

This photosensitive tyrosine phosphorylation inhibitor (FW = 306.32 g/mol; MP = 215°C), also known as tyrphostin B66, inhibits EGF-receptor phosphorylation,  $IC_{50}$  is 12  $\mu$ M (1). **1.** Gazit, Osherov, Posner, *et al.* (1991) *J. Med. Chem.* **34**, 1896.

#### Tyrphostin AG537

This photosensitive tyrosine phosphorylation inhibitor (FW = 448.44 g/mol), also known as bis-tyrphostin, inhibits EGF (epidermal growth factor) receptor protein-tyrosine kinase,  $IC_{50}$  = 0.4  $\mu$ M and  $K_i$  = 60 nM. **Target(s):** EGF receptor protein-tyrosine kinase (1); inositol-trisphosphate 3-kinase (2); and protein-tyrosine kinase (3). **1.** Levitzki & Gilon (1991) *Trends*

*Pharmaceut. Sci.* **12**, 171. **2.** Mayr, Windhorst & Hillemeier (2005) *J. Biol. Chem.* **280**, 13229. **3.** Tardif, Dubé & Bailey (2003) *Biol. Reprod.* **68**, 207.

#### Tyrphostin AG538

This tyrosine phosphorylation inhibitor (FW = 297.27 g/mol), also known as  $\alpha$ -cyano-(3,4-dihydroxy)cinnamoyl-(3',4'-dihydroxyphenyl)ketone, inhibits insulin-like growth factor receptor protein-tyrosine kinase,  $IC_{50}$  = 0.4  $\mu$ M (1). **1.** Blum, Gazit & Levitzki (2000) *Biochemistry* **39**, 15705.

**Tyrphostin AG538 I-Ome, See 5-Iodo-3-Methoxy-tyrphostin AG538**

#### Tyrphostin AG555

This photosensitive tyrosine phosphorylation inhibitor (FW = 322.36 g/mol; melting point = 165°C), also known as tyrphostin B46 and *N*-(3'-phenylpropyl)-3,4-dihydroxy-benzylideneacyanoacetamide, inhibits epidermal growth factor receptor protein-tyrosine kinase:  $IC_{50}$  = 0.7  $\mu$ M. **Target(s):** Cdk2 activation (1); cell proliferation (2); DNA topoisomerase I,  $IC_{50}$  = 100  $\mu$ M (3,4); EGF receptor protein-tyrosine kinase (5); and inositol-trisphosphate 3-kinase (6). **1.** Osherov & Levitzki (1997) *FEBS Lett.* **410**, 187. **2.** Sion-Vardy, Vardy, Rodeck, *et al.* (1995) *J. Surg. Res.* **59**, 675. **3.** Markovits, Larsen, Segal-Bendirdjian, *et al.* (1994) *Biochem. Pharmacol.* **48**, 549. **4.** Bendetz-Nezer, Gazit & Priel (2004) *Mol. Pharmacol.* **66**, 627. **5.** Gazit, Osherov, Posner, *et al.* (1991) *J. Med. Chem.* **34**, 1896. **6.** Mayr, Windhorst & Hillemeier (2005) *J. Biol. Chem.* **280**, 13229.

#### Tyrphostin AG556

This photosensitive tyrosine phosphorylation inhibitor (FW = 336.39 g/mol; melting point = 180°C), also known as tyrphostin B56 and *N*-(4-phenylbutyl)-3,4-dihydroxy-benzylideneacyanoacetamide, inhibits EGF (epidermal growth factor) receptor protein-tyrosine kinase:  $IC_{50}$  = 5  $\mu$ M. Tyrphostin AG556 also blocks lipopolysaccharide-induced TNF- $\alpha$  production and ErbB-1 kinase. **Target(s):** EGF receptor protein-tyrosine kinase (1,2); guanylyl cyclase (3); and receptor protein-tyrosine kinase (1,2). **1.** Gazit, Osherov, Posner, *et al.* (1991) *J. Med. Chem.* **34**, 1896. **2.** Du, Gao, Lau, *et al.* (2004) *J. Gen. Physiol.* **123**, 427. **3.** Jaleel, Shenoy & Visweswariah (2004) *Biochemistry* **43**, 8247.

#### Tyrphostin AG658

This photosensitive tyrosine phosphorylation inhibitor (FW = 340.40 g/mol; MP = 184°C), also known as tyrphostin C6 and 4-hydroxy-3-methoxy-5-(phenylthiomethyl)benzylideneacyanoacetamide, inhibits EGF (epidermal

growth factor) receptor protein-tyrosine kinase,  $IC_{50}$  = 0.4  $\mu$ M (1). **1.** Gazit, Osherov, Posner, *et al.* (1993) *J. Med. Chem.* **36**, 3556.

#### Tyrphostin AG698

This photosensitive tyrosine phosphorylation inhibitor (FW = 308.34 g/mol; melting point = 185°C), also known as tyrphostin B52 and *N*-(2-phenylethyl)-3,4-dihydroxy-benzylideneacyanoacetamide, inhibits EGF receptor protein-tyrosine kinase,  $IC_{50}$  = 0.93  $\mu$ M. **1.** Gazit, Osherov, Posner, *et al.* (1991) *J. Med. Chem.* **34**, 1896.

#### Tyrphostin AG808

This tyrosine phosphorylation inhibitor (FW = 304.30 g/mol), also known as 2-cyano-3-(3',4'-dihydroxyphenyl)-1-(3''-indolyl)-3-oxo-1-propene, inhibits protein-tyrosine kinase. **1.** Romer, McLean, Turner & Burrige (1994) *Mol. Biol. Cell* **5**, 349.

#### Tyrphostin AG825

This tyrosine phosphorylation inhibitor (FW = 397.48 g/mol; MP = 268°C), also known as tyrphostin C15 and 5-[(benzothiazol-2-yl)thiomethyl]-4-hydroxy-3-methoxy-benzylideneacyanoacetamide, inhibits EGF (epidermal growth factor) receptor protein-tyrosine kinase ( $IC_{50}$  = 19  $\mu$ M). Note that this tyrphostin does not inhibit the IGF-1 receptor protein-tyrosine kinase activity. **Target(s):** EGF receptor protein-tyrosine kinase (1,2); and HER2 kinase, p185<sup>neu</sup> (2,3). **1.** Gazit, Osherov, Posner, *et al.* (1993) *J. Med. Chem.* **36**, 3556. **2.** Osherov, Gazit, Gilon & Levitzki (1993) *J. Biol. Chem.* **268**, 11134. **3.** Tsai, Levitzki, Wu, *et al.* (1996) *Cancer Res.* **56**, 1068.

#### Tyrphostin AG835

This photosensitive tyrosine phosphorylation inhibitor (FW = 308.34 g/mol; MP = 135°C), also known as tyrphostin B50 and (+)-*S*-*N*-( $\alpha$ -methylbenzyl)-3,4-dihydroxy-benzylideneacyanoacetamide, inhibits EGF-receptor (epidermal growth factor receptor) phosphorylation,  $IC_{50}$  = 0.86  $\mu$ M. **Note:** The (-)-*R*-enantiomer of tyrphostin AG835 is tyrphostin AG527. **Target(s):** cell proliferation (1); and EGF receptor protein-tyrosine kinase (2). **1.** Twaddle, Turbov, Liu & Murthy (1999) *J. Surg. Oncol.* **70**, 83. **2.** Gazit, Osherov, Posner, *et al.* (1991) *J. Med. Chem.* **34**, 1896.

## Tyrphostin AG879

This tyrosine phosphorylation inhibitor (FW = 316.47 g/mol; MP = 210°C), also known as  $\alpha$ -cyano-(3,5-di-*t*-butyl-4-hydroxy)thiocinnamide, inhibits protein-tyrosine kinase activity of the nerve factor receptor. **Target(s):** HER2 kinase (1,2); and nerve growth factor receptor p140c-*trk* protein-tyrosine kinase (1,2). 1. Nie, Mei, Malek, *et al.* (1999) *Mol. Pharmacol.* **56**, 947. 2. Ohmichi, Pang, Ribon, *et al.* (1993) *Biochemistry* **32**, 4650.

## Tyrphostin AG957

This tyrosine phosphorylation inhibitor (FW = 273.29 g/mol), also known as methyl 4-[*N*-(2',5'-dihydroxybenzyl)amino]benzoate, inhibits human p210 protein-tyrosine kinase, or p210<sup>*bcr-abl*</sup>, IC<sub>50</sub> = 0.75  $\mu$ M (1). Tyrphostin AG957 also inhibits epidermal growth factor receptor protein-tyrosine kinase, IC<sub>50</sub> = 0.25  $\mu$ M. **See also Lavendustin C; Lavendustin C Methyl Ester Target(s):** EGF receptor protein-tyrosine kinase (1); and p210 protein-tyrosine kinase, human (1,2). 1. Anafi, Gazit, Gilon, Ben-Neriah & Levitzki (1992) *J. Biol. Chem.* **267**, 4518. 2. Sun, Layton, Elefanty & Lieschke (2001) *Blood* **97**, 2008.

## Tyrphostin AG974

This tyrosine phosphorylation inhibitor (FW = 312.07 g/mol; melting point = 105°C) inhibits protein-tyrosine kinase (1) and DNA topoisomerase I, IC<sub>50</sub> = 750  $\mu$ M (2); and protein-tyrosine kinase (1). 1. Ohmichi, Pang, Ribon, *et al.* (1993) *Biochemistry* **32**, 4650. 2. Bendetz-Nezer, Gazit & Priel (2004) *Mol. Pharmacol.* **66**, 627.

## Tyrphostin AG1024

This tyrosine phosphorylation inhibitor (FW = 305.17 g/mol) inhibits protein-tyrosine kinases, particularly the insulin-like growth factor-1 (IGF-1) protein-tyrosine kinase, IC<sub>50</sub> = 57  $\mu$ M (1-2) and receptor protein-tyrosine kinase (1-3). 1. Ohmichi, Pang, Ribon, *et al.* (1993) *Biochemistry* **32**, 4650. 2. Parrizas, Gazit, Levitzki, Wertheimer & LeRoith (1997) *Endocrinology* **138**, 1427. 3. Mehdi, Azar & Srivastava (2007) *Cell Biochem. Biophys.* **47**, 1.

## Tyrphostin AG1222

This potent tyrosine phosphorylation inhibitor (FW = 274.28 g/mol) targets p210<sup>*bcr-abl*</sup> protein-tyrosine kinase (1) and casein kinase II (2). 1. Anafi, Gazit, Zehavi, Ben-Neriah & Levitzki (1993) *Blood* **82**, 3524. 2. Kang, Huang & Liang (1997) *Zhongguo Yao Li Xue Bao* **18**, 56.

## Tyrphostin AG1288

This tyrosine phosphorylation inhibitor (FW = 231.17 g/mol), also known as (3,4-dihydroxy-5-nitrobenzylidene)malononitrile, blocks the cytotoxicity associated with tumor necrosis factor- $\alpha$  (1) and inhibits guanylyl cyclase (1); protein-tyrosine kinase (2). 1. Jaleel, Shenoy & Visweswariah (2004) *Biochemistry* **43**, 8247. 2. Novogrodsky, Vanichkin, Patya, *et al.* (1994) *Science* **264**, 1319.

## Tyrphostin AG1295

This tyrosine phosphorylation inhibitor (FW = 234.30 g/mol), also known as 6,7-dimethyl-2-phenylquinoxaline, is a selective inhibitor of PDGF receptor protein-tyrosine kinase, IC<sub>50</sub> = 0.5  $\mu$ M (1). Tyrphostin AG1295 also inhibits PDGF-dependent DNA synthesis in 3T3 cells and in porcine aorta endothelial cells. **Target(s):** platelet-derived growth factor (PDGF) receptor protein-tyrosine kinase (1); and receptor protein-tyrosine kinase (1,2). 1. Kovalenko, Gazit, Bohmer, *et al.* (1994) *Cancer Res.* **54**, 6106. 2. Mehdi, Azar & Srivastava (2007) *Cell Biochem. Biophys.* **47**, 1.

## Tyrphostin AG1296

This tyrosine phosphorylation inhibitor (FW = 266.30 g/mol), also known as 6,7-dimethoxy-2-phenylquinoxaline, is a selective inhibitor of PDGF receptor protein-tyrosine kinase, IC<sub>50</sub> = 1  $\mu$ M. Tyrphostin AG1296 also inhibits PDGF-dependent DNA synthesis in 3T3 cells and in porcine aorta endothelial cells (1-3). In addition, AG1296 inhibits signaling of human PDGF  $\alpha$ - and  $\beta$ -receptors as well as of the related stem cell factor receptor (c-Kit). 1. Kovalenko, Gazit, Bohmer, *et al.* (1994) *Cancer Res.* **54**, 6106. 2. Schmidt-Arras, Bohmer, Markova, *et al.* (2005) *Mol. Cell. Biol.* **25**, 3690. 3. Ingram & Bonner (2006) *Curr. Mol. **U**, See *Uracil*; *Uridine*

## U-104

This potent inhibitory sulfonamide (FW = 309.32 g/mol; CAS 178606-66-1; Soluble to 100 mM in DMSO) targets carbonic anhydrases CA-XII ( $K_i$  = 4.5 nM), CA-IX ( $K_i$  = 45 nM), CA-I ( $K_i$  = 5.1  $\mu$ M) and CA-II ( $K_i$  = 9.6  $\mu$ M). Carbonic anhydrase IX (CA-IX) is a hypoxia and HIF-1-inducible protein that regulates intra- and extracellular pH under hypoxic conditions and promotes tumor cell survival and invasion within hypoxic microenvironments. Stable depletion of CAIX activity in MDA-MB-231 human breast cancer xenografts attenuates primary tumor growth. CAIX depletion in the 4T1 cells leads to caspase-independent cell death and reversal of extracellular acidosis under hypoxic conditions *in vitro*. 1. Lou, McDonald, Oloumi, *et al.* (2011) *Cancer Res.* **71**, 3364.

## U0126

This synthetic rotationally symmetric agent (FW<sub>free-base</sub> = 380.50 g/mol; CAS 1173097-76-1; Solubility: 85 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also named 1,4-diamino-2,3-dicyano-1,4-bis(*o*-aminophenylmercapto)butadiene, targets the intracellular Raf/MEK/ERK signaling pathway, inhibiting MEK1 (IC<sub>50</sub> = 0.07  $\mu$ M), MEK2 (IC<sub>50</sub> = 0.06  $\mu$ M), with 100-times higher affinity for MEK<sup>AN3-S218E/S222D</sup> than observed with the MAPKK inhibitor PD098059. U0126 induces apoptosis in cancer cells. (See *Rapamycin*) **Target(s)**: mitogen-activated protein kinase (1); [mitogen-activated protein kinase] kinase (2-10); [mitogen-activated protein kinase kinase] kinase (11); and stress-activated protein kinase 2a, mildly inhibited (4). U0126 also exhibits antiviral activity against pandemic H1N1v swine influenza A virus and highly pathogenic avian influenza virus (AIV), both *in vitro* and *in vivo* (13). Indeed, treatment of mice with U0126 via the aerosol route led to inhibition of MEK activation in the lung, reduction of progeny IAV titers compared to untreated controls, protection of IAV-infected mice against a 100x lethal viral challenge. 1. ## U-72409E

This statine-containing peptidomimetic (FW<sub>free-base</sub> = 848.02 g/mol) inhibits renin ( $K_d$  = 23 nM). Importantly, although the general mode of binding of these renin inhibitors is primarily driven by hydrophobic interactions, significant deviations from thermodynamic additivity and independent subsite model constraints are observed. Another determinant for binding is the conformation assumed by the peptide inhibitor in solution, suggesting that caution be exercised in using affinity constants to assess the

interactions of peptide inhibitors with human renin and possibly with other enzymes having extended binding sites. The thermodynamic parameters of a class of compounds provide more information as to the mode of binding of ligands to their respective receptors than do dissociation constants. 1. Epps, Cheney, Schostarez, *et al.* (1990) *J. Med. Chem.* **33**, 2080.

**U-73122****U-73122****U-73343**

This thiol-reactive steroid analogue (FW = 464.65 g/mol; CAS 142878-12-4; IUPAC: 1-[6-((17 $\beta$ -3-methoxyestra-1,3,5(10)-trien-17-yl)amino) hexyl]-1H-pyrrole-2,5-dione; *photosensitive*, protect from light), blocks G-protein coupling to human platelet and neutrophil phospholipase C, thereby inhibiting the latter. The thiol-unreactive analogue U-73343 (FW = 466.66 g/mol; CAS 142878-12-4; IUPAC: 1-[6-((17 $\beta$ -3-methoxyestra-1,3,5(10)-trien-17-yl)amino)hexyl]-2,5-pyrrolidinedione) may be used as a negative control. 1. Peptide Symp.* (June 16-21, 1991) (Smith & Rivier, eds.), pp. 413-414.

**U-85777E**

This synthetic peptide analogue (FW = 476.66 g/mol), also known as Ac-Leu $\psi$ [CH(OH)CH<sub>2</sub>]Val-Ile-Amp and *N*-(5-acetylamino-4-hydroxy-2-isopropyl-7-methyloctanoyl)-L-isoleucine 2-pyridylmethylamide, contains a hydroxyethylene isostere in place of the scissile bond and potently inhibits HIV-1 protease ( $K_i$  = 70 nM). Sawyer, Staples, Liu, *et al.* (1992) *Int. J. Pept. Protein Res.* **40**, 274.

**U-89360**

This peptide analogue (FW<sub>free-base</sub> = 596.77 g/mol) possesses a hydroxyethylene isostere in place of the scissile bond, allowing it to potentially inhibit HIV-1 protease with a  $K_i$  of 20 nM (1-4). 1. Lin, Lin, Hong, *et al.* (1995) *Biochemistry* **34**, 1143. 2. Bardi, Lague & Freire (1997) *Biochemistry* **36**, 6588. 3. Hong, Zhang, Hartsuck, Foundling & Tang (1998) *Adv. Exp. Med. Biol.* **436**, 59. 4. Hong, Hartsuck, Foundling, Ermoloeff & Tang (1998) *Protein Sci.* **7**, 300.

**U-89920E**

This hydroxyethylene isostere-containing peptide analogue (FW = 867.02 g/mol), also known as Ac-Gly-Ser-His-Leu $\psi$ [CH(OH)CH<sub>2</sub>]Val-Glu-Ala-Leu-NH<sub>2</sub> and *N*-[*N*-(*N*-acetylglycyl-L-seryl-L-histidyl)-5-amino-4-hydroxy-2-isopropyl-7-methyloctanoyl]-L-glutamyl-L-alanyl-L-leucinamide (FW<sub>HCl</sub> = 903.47 g/mol), mimics a tetrahedral reaction intermediate in HIV-1 protease catalysis, thereby potently inhibiting this enzyme ( $K_i = 10$  nM). 1. Sawyer, Staples, Liu, *et al.* (1992) *Int. J. Pept. Protein Res.* **40**, 274.

**U 93631**

This GABA<sub>A</sub> receptor antagonist (FW = 299.33 g/mol; CAS 152273-12-6), also named 4,5-dihydro-4,4-dimethylimidazo[1,5-*a*]quinoxaline-3-carboxylic acid 1,1-dimethylethyl ester, binds at the picrotoxin site ( $K_d = 2$   $\mu$ M), stabilizing the inactive form of the channel, and allosterically decreasing the probability of single-channel opening. U-93631 accelerates the decay of  $\gamma$ -aminobutyric acid-induced chloride ion currents, with little effect on peak amplitude (1,2). It also inhibits 5-HT<sub>3A</sub> receptors by an apparently similar mechanism (3). 1. Dillon, Im, Hamilton, *et al.* (1993) *Mol. Pharmacol.* **44**, 860. 2. Dillon, Im, Pregenzer, Carter & Hamilton (1995) *J. Pharmacol. Exp. Ther.* **272**, 597. 3. Das, Bell-Horner, Machu & Dillon (2003) *Neuropharmacol.* **44**, 431.

**U-93965**

This synthetic statine-containing peptide analogue (FW = 802.05 g/mol) inhibits human immunodeficiency virus type 1 polyprotein protease ( $K_i = 1.6$  nM at pH 5). Key site-directed mutants (e.g., V82N, V82E, V82A, V82S, V82D, V82Q, D30F, D30W, G48H, G48D, G48Y, and K45E) were analyzed to investigate mutational effects on enzyme kinetics and inhibition. The  $k_{cat}$  and  $K_m$  values of many Val82 mutants and Lys45 mutant are comparable to the native enzyme. Surprisingly, Gly48 mutations produce enzymes with catalytic efficiency superior to that of the wild-type enzyme by as much as 10-fold. Modeling of the structure of the mutants suggests that the high catalytic efficiency of some substrates is related to increase rigidity in the flap region. 1. Lin, Lin, Hong, *et al.* (1995) *Biochemistry* **34**, 1143.

**U 99194**

This selective D<sub>3</sub> antagonist (FW<sub>free-base</sub> = 277.41 g/mol; FW<sub>maleate-salt</sub> = 393.48 g/mol; CAS 234757-41-6; Soluble to 25 mM in water), also known as PNU 99194 and 2,3-dihydro-5,6-dimethoxy-*N,N*-dipropyl-1*H*-inden-2-amine, targets human dopamine D<sub>3</sub> ( $K_i = 160$  nM), D<sub>2</sub> ( $K_i = 2280$  nM), and D<sub>4</sub> ( $K_i = > 10$   $\mu$ M) receptors. 1. Audinot *et al.* (1998) *J. Pharmacol. Exp.*

*Ther.* **287**, 187. 2. Clifford and Waddington (1998) *Psychopharmacol.* **136**, 284. 3. LaHoste *et al.* (2000) *J. Neurosci.* **20**, 6666.

**UA 62784**

This microtubule assembly inhibitor (FW = 353.38 g/mol; CAS 313367-92-9; Soluble to 25 mM in DMSO), also named 4-[5-(4-methoxyphenyl)-2-oxazolyl]-9*H*-fluorene-9-one, interacts with tubulin dimers 10x more potently than colchicine, vinblastine, or nocodazole. Competition experiments revealed that UA62784 binds at or near the colchicine-binding site. Nanomolar doses of UA62784 promote the accumulation of mammalian cells in mitosis, forming aberrant mitotic spindles. Treatment of cancer cell lines with UA62784 activates apoptosis. When used at low concentrations, UA62784 and vinblastine potentiate each other's ability to inhibit cell proliferation. Contrary to an earlier report (2), UA62784 is NOT an inhibitor of centromere protein E kinesin-like protein (1). 1. Tcherniuk, Deshayes, Sarli, Divita & Abrieu (2011) *Chem. Biol.* **18**, 631. 2. Henderson, Shaw, Wang, *et al.* (2009) *Mol. Cancer Ther.* **8**, 36.

**UAMC 00039**

This potent, orally available dipeptidyl peptidase inhibitor (FW = 382.76 g/mol; CAS 697797-51-6), also known as (2*S*)-2-amino-4-[[[(4-chlorophenyl)methyl]amino]-1-(1-piperidinyl)-1-butanone dihydrochloride, selectively targets proline-specific dipeptidyl peptidase DPP-II (IC<sub>50</sub> = 0.48 nM), with much weaker action against DPP-9 (IC<sub>50</sub> = 79 nM), DPP-8 (IC<sub>50</sub> = 142 nM) and DPP-IV (IC<sub>50</sub> = 165  $\mu$ M). 1. Maes, Dubois, Brandt, *et al.* (2007) *J. Leukoc. Biol.* **81**, 1252. 2. Van Goethem, Matheussen, Joossens, *et al.* (2011) *J. Med. Chem.* **54**, 5737.

**Ubiquinone**

This isoprenoid-derived, lipid-soluble electron carrier (FW<sub>Ubiquinone-50</sub> = 863.36 g/mol; CAS 303-98-0), also known as Coenzyme Q<sub>2</sub>, is a polyprenylated benzoquinone that, along with its reduced form Ubiquinol (or Coenzyme QH<sub>2</sub>), is a required component in the the Electron tTransport Chain. These ubiquinones are 2,3-dimethoxy-5-methylbenzoquinones that contain a terpenoid chain at position-6, consisting of 1–12 *trans*-isoprenoid units. Ubiquinone-0 is 2,3-dimethoxy-5-methyl-*p*-benzoquinone. The most

common ubiquinone contains a fifty-carbon terpenoid component and is designated either Ubiquinone 50 (also called coenzyme Q<sub>50</sub>) or Ubiquinone 10 (coenzyme Q<sub>10</sub>), since there are ten isoprene units present in Ubiquinone 50. **Chemical & Physical Properties:** All ubiquinones are sensitive to dioxygen, sunlight, and ultraviolet light. They are insoluble in water but highly soluble in most organic solvents, including ethanol, petroleum ether, diethyl ether, and cyclohexane. They absorb light in the ultraviolet portion of the spectrum: ubiquinone 50 has a  $\lambda_{\text{max}}$  of 275 nm in ethanol ( $\epsilon = 14600 \text{ M}^{-1}\text{cm}^{-1}$ ). The melting points of ubiquinones increase with the size of the isoprenoid side-chain: Ubiquinone-30 (19–20°C), Ubiquinone-35 (31–32°C), Ubiquinone-40 (37–38°C), Ubiquinone-45 (44–45°C), and Ubiquinone-50 (49°C). Note that Ubiquinone-0 has a melting point of 59–60°C. **Role of Ubiquinone in Cellular Redox Reactions:** In the NADH:ubiquinone oxidoreductase (or NADH dihydro-genase) of Mitochondrial Complex I, two electrons are removed from NADH and transferred to ubiquinone (Q). The resulting reduced product, or ubiquinol (QH<sub>2</sub>) freely diffuses within the membrane, allowing Complex I to translocate four protons across the membrane, producing a proton gradient. Complex I is the main site for premature electron leakage to oxygen occurs and is thus being one of the main sites of superoxide production. Quinones are thus mobile, lipid-soluble carriers that shuttle electrons (and protons) between large, relatively immobile macromolecular complexes embedded in the membrane. Bacteria use ubiquinone and related molecules, including menaquinone. **Ubiquinone Inhibitors:** Structural analogues of ubiquinone and ubiquinol are often inhibitors of electron transport. Compounds that inhibit the NADH-ubiquinone reductase activity of Complex I are classified as follows: Type A are antagonists of the ubiquinone substrate; Type B displace the ubisemiquinone intermediate; and Type C are antagonists of the ubiquinol product (1). **Target(s):** Complex II, by Ubiquinone-0 (2); horseradish peroxidase, by Ubiquinone-0 (3); sphingomyelinase (4); vitamin K-dependent  $\gamma$ -glutamylcarboxylase, by Ubiquinone-9 and Ubiquinone-10 (5); vitamin K-epoxide reductase, by Ubiquinone-9 and -10 (5). 1. ### Ubiquitin Aldehyde

This form of recombinant ubiquitin (MW = 8.5 kDa; CAS 79586-22-4), containing an aldehyde group at the C-terminus, inhibits (as the respective aldehyde hydrate) the hydrolysis of ubiquitin conjugates of small molecules *via* ubiquitin C-terminal hydrolase and inhibits several enzymes that regenerate free ubiquitin from adducts with proteins and intermediates in protein degradation. **Handling:** Stable for at least two months when stored at 4°C; Soluble and stable in aqueous solution at pH < 7.0; Avoid presence of amino-containing compounds; Do not lyophilize; Do not neutralize until immediately prior to use. **Target(s):** ubiquitin-dependent proteolysis (1-3); ubiquitin thiolesterase, or ubiquitinyl hydrolase (1); ubiquitin C-terminal hydrolase,  $K_i = 2.5 \text{ nM}$  (1,2,4-11); and U1p1 peptidase (12). 1. Proteolytic Enzymes* (Barrett, Rawlings & Woessner, eds.) 2, p. 1340, Academic Press, San Diego.

### Ubiquitin Hydroxamate

This ubiquitin inhibitor (MW = 8579.86) targets both ubiquitin C-terminal hydrolase and the isopeptidase (1,2). Indeed, the ubiquitin C-terminal hydrolase (hereafter Enz) is also inactivated by millimolar concentrations of hydroxylamine, but only if Ub is present (1). Such a result suggests that the hydrolase mechanism is one of nucleophilic catalysis with an acyl-Ub-Enz intermediate. Inactivation in the presence of hydroxylamine of hydrolase occurs once during hydrolysis of 1200 molecules of Ub-hydroxamate by the enzyme. The hydrolysis/inactivation ratio is constant over the range of 10–50 mM hydroxylamine showing that forms of Enz-Ub with which hydroxylamine and water react are different and not in rapid equilibrium (1). The inactive enzyme may be an acylhydroxamate formed from an Enz-Ub mixed anhydride generated from the Enz-Ub (thiol) ester, the existence

of which was inferred from parallel borohydride trapping experiments (1,2).

1. Pickart & Rose (1986) *J. Biol. Chem.* 261, 10210. 2. Purich (2002) *Meth. Enzymol.* 354, 174.

### UBP 282

This N<sup>3</sup>-substituted willardiine analogue and AMPA receptor antagonist (FW = 333.30 g/mol; CAS 544697-47-4; Soluble to 100 mM in 1 equivalent NaOH and to 25 mM in 1 equivalent HCl), also known as 3-CBW and ( $\alpha$ S)- $\alpha$ -amino-3-[(4-carboxyphenyl)methyl]-3,4-dihydro-2,4-dioxo-1(2H)-pyrimidinepropanoic acid, targets  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (or AMPA) receptor, but not kainate receptor-mediated currents on spinal neonatal motoneurons, yet antagonizes kainate-induced responses on dorsal root C-fibers. 1. More, Troop & Jane (2002) *Brit. J. Pharmacol.* 137, 1125. 2. More, Troop, Dolman & Jane (2003) *Brit. J. Pharmacol.* 138, 1093.

### UBP 310

This receptor antagonist (FW = 353.35 g/mol; CAS 902464-46-4; Soluble to 100 mM in DMSO), also named (S)-1-(2-amino-2-carboxyethyl)-3-(2-carboxythiophene-3-ylmethyl)-5-methylpyrimidine-2,4-dione, targets the ionotropic kainate glutamate GLU<sub>K5</sub> receptor (IC<sub>50</sub> = 130 nM) and also blocks recombinant homomeric GLU<sub>K7</sub> receptors (1-3). Crystal structures indicate that this antagonist binds by a novel mechanism that does not directly contact the E723 side-chain, as suggested in all previously solved AMPA and kainate receptor agonist and antagonist complexes (1). There is instead a hyperextension of the ligand binding core, and, in dimer assemblies, there is a 22-Å extension of the ion channel linkers in the transition from antagonist- to glutamate-bound forms. This large conformational change suggests that glutamate receptors are capable of much larger movements than previously thought (1). It has an apparent K<sub>D</sub> value is 18 nM for depression of kainate responses on the dorsal root. UBP 310 displays 12,700x selectivity for GLU<sub>K5</sub> over GLU<sub>K6</sub>. UBP 310 exhibits no activity at mGlu group I or NMDA receptors at concentrations of up to 10  $\mu$ M. 1. Mayer, Ghosal, Dolman & Jane (2006) *J. Neurosci.* 26, 2852. 2. Dolman, More, Alt, *et al.* (2007) *J. Med. Chem.* 50, 1558. 3. Perrais, Pinheiro, Jane & Mülle (2009) *Neuropharmacology* 56, 131.

### UCB 35625

This potent chemokine CCR1/CCR3 receptor antagonist (FW = 655.44 g/mol; CAS 301648-08-8; Soluble to 100 mM in DMSO and to 50 mM in ethanol), also known as 1,4-*trans*-1-(1-cycloocten-1-ylmethyl)-4-[[2-(2,7-

dichloro-9*H*-xanthen-9-yl)carbonyl]amino]-1-ethyl-piperidinium iodide, inhibits MIP-1 $\alpha$ -induced chemotaxis in CCR1 transfectants, IC<sub>50</sub> = 9.6 nM, and eotaxin-induced chemotaxis in CCR3 transfectants, IC<sub>50</sub> = 94 nM (1,2). UCB 35625 antagonizes CCR3-mediated entry of HIV-1 isolate 89.6 into NP-2 cells (IC<sub>50</sub> = 57 nM). Its enantiomer, **J 113863** (FW = 655.44 g/mol; CAS 353791-85-2; IUPAC: 1,4-*cis*-1-(1-cycloocten-1-ylmethyl)-4-[[2,7-dichloro-9*H*-xanthen-9-yl)carbonyl]amino]-1-ethylpiperidinium iodide), is also a CCR1 antagonist, with IC<sub>50</sub> values are 0.9 and 5.8 nM for human and mouse CCR1 receptors respectively. It displays high selectivity for human, IC<sub>50</sub> = 0.58 nM, but not mouse CCR3 receptors, IC<sub>50</sub> = 460 nM (3,4). J-113863 improves paw inflammation, joint damage and dramatically reduces cell infiltration into joints in collagen-induced arthritis in mice (4). 1. Sabroe, Peck, Van Keulen, *et al.* (2000) *J. Biol. Chem.* **275**, 25985. 2. de Mendonça, da Fonseca, Phillips, *et al.* (2005) *J. Biol. Chem.* **280**, 4808. 3. Naya, Sagara, Ohwaki, *et al.* (2001) *J. Med. Chem.* **44**, 1429. 4. **UCB L059**, See *Levetiracetam*

**UCF1-C**, See *Manumycin A*

#### UCF-101

This 2-thiobarbituric acid derivative (FW = 494.52 g/mol) inhibits the mammalian high-temperature requirement protein A<sub>2</sub> serine proteinase (IC<sub>50</sub> = 9.5  $\mu$ M). It is a weaker inhibitor of coagulation factor Xa, t-plasminogen activator, u-plasminogen activator, and protein C (activated). UCF-102, -103, and -104 are weaker inhibitors (the 2-nitrophenyl component being replaced with 3-chloro-4-methoxyphenyl, 3-carboxyphenyl, and 2-methyl-5-nitrophenyl, respectively). **Target(s)**: coagulation factor Xa; HtrA2 peptidase; protein C (activated); t-plasminogen activator; u-plasminogen activator. 1. Cilenti, Lee, Hess, *et al.* (2003) *J. Biol. Chem.* **278**, 11489.

#### UCL 1684

This nonpeptidic, bis-quinolinium cyclophane blocker (FW = 654.44 g/mol; CAS 199934-16-2; Soluble to 10 mM in DMSO), also named 6,12,19,20,25,26-hexahydro-5,27:13,18:21,24-trietheno-11,7-metheno-7*H*-dibenzo[*b,n*][1,5,12,16]tetraazacyclotricosine-5,13-dium dibromide, targets apamin-sensitive Ca<sup>2+</sup>-activated K<sup>+</sup> channel (K<sub>Ca2.1</sub>), with an IC<sub>50</sub> value of 3 nM in rat sympathetic neurons (1). UCL 1684 also blocks hK<sub>Ca2.1</sub> and rK<sub>Ca2.2</sub> channels expressed in HEK 293 cells with IC<sub>50</sub> values of 762 and 364 pM respectively (2). UCL 1407's inhibitory action is characterized by (a) a Hill slope greater than unity, (b) sensitivity to an increase in external potassium ion concentration, and (c) a time-course of onset suggesting use-dependence. UCL 1684 also blocks small-conductance SK channels hSK1 with an IC<sub>50</sub> value of 762 pM and rSK2 with an IC<sub>50</sub> value of 364 pM. 1.

Campos, Galanakis, Piergentili, *et al.* (2000) *J. Med. Chem.* **43**, 420. 2. Malik-Hall, Ganellin, Galanakis & Jenkinson (2000) *Br. J. Pharmacol.* **129**, 1431. 3. Strobaek, Jørgensen, Christophersen, Ahring & Olesen (2000) *Br. J. Pharmacol.* **129**, 991.

#### UCL 2077

This sAHP channel blocker (FW = 350.46 g/mol; CAS 918311-87-2), also named *N*-trityl-3-pyridinemethanamine, reduces calcium-activated, slow after-hyperpolarization, a potassium conductance implicated in memory, aging, and epilepsy. The significance of sAHP stems from its exceedingly long time-course, a property that integrates action potential-induced calcium signals, controls neuronal excitability, and prevents runaway channel firing (2). UCL 2077 suppresses the sAHP present in hippocampal neurons in culture (IC<sub>50</sub> = 0.5  $\mu$ M) and in the slice preparation (IC<sub>50</sub>  $\approx$  10  $\mu$ M). UCL2077 was selective, having minimal effects on Ca<sup>2+</sup> channels, action potentials, input resistance and the medium afterhyperpolarization. UCL2077 also had little effect on heterologously expressed small conductance Ca<sup>2+</sup>-activated K<sup>+</sup> (or SK) channels. 1. Shah, Javadzadeh-Tabatabaie, Benton, *et al.* (2006) *Mol. Pharmacol.* **70**, 1494. 2. Kim, Kobayashi, Takamatsu & Tzingounis (2012) *Biophys. J.* **103**, 2446. 3. Zhang, Ouyang, Ganellin & Thomas (2013) *J. Neurosci.* **33**, 5006.

#### UCM 707

This potent endocannabinoid transport inhibitor (FW = 383.57 g/mol; CAS 390824-20-1; Solubility: 100 mM in DMSO), also named (5*Z*,8*Z*,11*Z*,14*Z*)-*N*-(3-Furanylmethyl)-5,8,11,14-eicosatetraenamide, blocks anandamide transport (IC<sub>50</sub> = 0.8  $\mu$ M), but more weakly inhibits (IC<sub>50</sub> = 0.8  $\mu$ M) Fatty Acid Amide Hydrolase (FAAH, EC 3.5.1.99), a member of the serine hydrolase family, also known as oleamide hydrolase and anandamide amidohydrolase. UCM-707 is an effective inhibitor of the cannabinoid receptor CB<sub>2</sub> (K<sub>i</sub> = 0.07  $\mu$ M), and displays K<sub>i</sub> values of 4.7 and >5  $\mu$ M for CB<sub>1</sub> and VR1 receptors respectively. UCM-707 also potentiates hypokinetic and the antinociceptive effects of anandamide *in vivo*. 1. López-Rodríguez, Viso, Ortega-Gutiérrez, *et al.* (2003) *Eur. J. Med. Chem.* **38**, 403. 2. López-Rodríguez, Viso, Ortega-Gutiérrez, *et al.* (2003) *J. Med. Chem.* **46**, 1512.

#### UCM 17197

This substituted benzimidazole (FW<sub>free-base</sub> = 304.78 g/mol), also known as (S)-(-)-*N*-(1-azabicyclo[2.2.2]oct-3-yl)-6-chlorobenzimidazole-4-carboxamide, is a serotonin 5-HT<sub>3</sub> receptor antagonist, K<sub>i</sub> = 0.13 nM. 1. Lopez-Rodríguez, Benhamu, Morcillo, *et al.* (1999) *J. Med. Chem.* **42**, 5020.

## UCN-01

This staurosporine analogue and checkpoint inhibitor (FW = 482.54 g/mol; CAS 112953-11-4; Alternate Name: 7-hydroxystaurosporine) from *Streptomyces* (1) is more selective than staurosporine, with IC<sub>50</sub> values of 29, 34, 30, 590, and 530 nM for α, βI, γ, δ, and ε protein kinase C forms, respectively, and K<sub>i</sub> values of 42 and 45 nM for protein kinase A and p60v-src protein-tyrosine kinase are 42 and 45 nM (2,3). UCN-01 has low water-solubility but dissolves in dimethyl sulfoxide and dimethylformamide. UCN-01 also targets cyclin-dependent kinases (4-6); protein kinase C (2,6); protein-tyrosine kinase (2). UCN-01 also inhibits nucleotide excision repair in response to the DNA damage initiated by cisplatin (7), and UCN-01 may interfere with required protein phosphorylation of DNA repair enzymes (8). 1. Takahashi, Kobayashi, Asano, Yoshida & Nakano (1987) *J. Antibiot. (Tokyo)* **40**, 1782. 2. Tamaoki (1991) *Meth. Enzymol.* **201**, 340. 3. Kawakami, Futami, Takahara & Yamaguchi (1996) *Biochem. Biophys. Res. Commun.* **219**, 778. 6. VanderWel, Harvey, McNamara, et al. (2005) *J. Med. Chem.* **48**, 2371. 7. Jiang & Yang (1999) *Cancer Res.* **59**, 4529. 8. Yamauchi, Keating & Plunkett (2002) *Mol. Cancer Ther.* **1**, 287.

## UCPH 101

This selective non-substrate EAAT inhibitor (FW = 422.48 g/mol; CAS 1118460-77-7; Soluble to 25 mM in DMSO), also named 2-amino-5,6,7,8-tetrahydro-4-(4-methoxyphenyl)-7-(naphthalen-1-yl)-5-oxo-4H-chromene-3-carbonitrile, targets Excitatory Amino Acid Transporter 1, or EAAT1 (IC<sub>50</sub> = 660 nM), with far lower affinity for EAAT2 (IC<sub>50</sub> > 300000 nM) and EAAT3 (IC<sub>50</sub> > 300000 nM). UCPH 101 also demonstrates no significant inhibition at EAAT4 or EAAT5 in a patch-clamp electrophysiology assay at 10 μM (2). The allosteric mode of UCPH-101 inhibition underlines the functional importance of the trimerization domain of the EAAT and demonstrates the feasibility of modulating transporter function through ligand binding to regions distant from its "transport domain" (3). 1. Jensen, Erichsen, Nielsen, et al. (2009) *J. Med. Chem.* **52**, 912. 2. Erichsen, Huynh, Abrahamsen, et al. (2010) *J. Med. Chem.* **53**, 7180. 3. Abrahamsen, Schneider, Erichsen, et al. (2013) *J. Neurosci.* **33**, 1068.

## UCS15A

This nonpeptide, protein-protein interaction disruptor (FW = 480.55 g/mol) inhibits src-specific phosphorylation of tyrosine residues within numerous proteins in v-src-transformed cells. Earlier disruptors of SH3-mediated protein-protein interactions were synthetic 10-residue, or longer, peptides based on the native target sequence or peptides selected from screening with degenerate peptide and phage display libraries. T consisted of 10 or more amino acid residues. UCS15A inhibits the following SH3-mediated protein-protein interactions *in vivo*: Src-Sam68, Sam68-Grb2, Sam68-PLCγ, cortactin-ZO1 and Grb2-Sos, as well as atypical SH3-mediated interactions, such as Grb2-Gab1. UCS15A fails to inhibit non-SH3-mediated protein-protein interactions found in the E-cadherin. UCS15A exerts its src-inhibitory effects by disrupting protein-protein interactions mediated by src. One of the biological consequences of src-inhibition by UCS15A was its ability to inhibit osteoclast-mediated bone resorption *in vitro* (1) UCS15A's effects are not restricted to Src-SH3 mediated protein-protein interactions, since it can disrupt the *in vivo* interactions of Sam68 with other SH3 domain containing proteins, such as Grb2 and PLCγ. UCS15A can also disrupt other typical SH3-mediated protein-protein interactions, such as Grb2-Sos1, cortactin-ZO1, as well as atypical SH3-mediated protein-protein interactions such as Grb2-Gab1 (2). UCS15A cannot, however, disrupt the non-SH3-mediated protein-protein interactions of β-catenin, with E-cadherin and α-catenin. In addition, UCS15A is without effect on the SH2-mediated interactions between Grb2 and activated Epidermal Growth Factor receptor (2). Thus, the ability of UCS15A, to disrupt protein-protein interactions appeared to be restricted to SH3-mediated protein-protein interactions. (1). (See also AP22161) 1. Sharma, Oneyama, Yamashita, et al. (2001) *Oncogene* **20**, 2068. 2. Oneyama, Nakano & Sharma (2002) *Oncogene* **21**, 2037.

## Udenafil

This PDE-5 inhibitor and erectile dysfunction drug (FW = 516.66 g/mol; CAS 268203-93-6; Solubility: >20 mg/mL DMSO), also known by its code name DA-8159, its trade name Zydena®, and its systematic name 3-(1-methyl-7-oxo-3-propyl-4,7-dihydro-1H-pyrazolo[4,3-d]pyrimidin-5-yl)-N-[2-(1-methylpyrrolidin-2-yl)ethyl]-4-propoxybenzenesulfonamide, targets the Type-5 isozyme of human 3',5'-cGMP phosphodiesterase. Reaching maximal plasma concentration within 1.0 to 1.5 hours and possessing a t<sub>1/2</sub> of 11 to 13 hours, udenafil enjoys properties commending its use in treating erectile dysfunction. Udenafil is metabolized to its major metabolite DA-8164 by CYP3A4, and ketoconazole, a known CYP3A4 inhibitor, alters udenafil pharmacokinetics, increasing its plasma concentration (2). Daily dosing with this PDE5 inhibitor also improves cognitive function, depression and somatization (3). 1. Oh, Kang, Ahn, Yoo & Kim (2000) *Arch. Pharm. Res.* **23**, 471. 2. Shin, Chung, Kim, et al. (2010) *Brit. J. Clin. Pharmacol.* **69**, 307. 3. Shim, Pae, Cho, et al. (2013) *Int. J. Impot Res.* **26**, 76.

## UDP-N-acetyl-D-galactosamine

This sugar nucleotide metabolite (FW<sub>free-acid</sub> = 607.36 g/mol; λ<sub>max</sub> = 261 nm; ε = 10100 M<sup>-1</sup>cm<sup>-1</sup> at pH 1 and 7 and ε = 7500 M<sup>-1</sup>cm<sup>-1</sup> at pH 12), also known as uridine diphosphate N-acetyl-D-galactosamine, is a key intermediate in the biosynthesis of sialic acid, certain glycoproteins, and lipopolysaccharides. **Target(s):** fucosylgalactoside 3-α-galactosyltransferase (1); hyaluronan synthase (2); lactosylceramide α-2,3-sialyltransferase, weakly inhibited (3); α-1,3-mannosyl-glycoprotein 2-β-N-acetylglucosaminyltransferase, weakly inhibited (4); α-1,3-mannosyl-

glycoprotein 4- $\beta$ -*N*-acetylglucosaminyltransferase (5); and protein *N*-acetylglucosaminyltransferase (6). 1. Carne & Watkins (1977) *Biochem. Biophys. Res. Commun.* **77**, 700. 2. Tlapak-Simmons, Baron & Weigel (2004) *Biochemistry* **43**, 9234. 3. Cambron & Leskawa (1993) *Biochem. Biophys. Res. Commun.* **193**, 585. 4. Nishikawa, Pegg, Paulsen & Schachter (1988) *J. Biol. Chem.* **263**, 8270. 5. Oguri, Minowa, Ihara, *et al.* (1997) *J. Biol. Chem.* **272**, 22721. 6. Haltiwanger, Blomberg & Hart (1992) *J. Biol. Chem.* **267**, 9005.

#### UDP-*N*-acetyl-D-glucosamine

This sugar nucleotide ( $FW_{\text{free-acid}} = 607.36$  g/mol;  $\lambda_{\text{max}} = 261$  nm;  $\epsilon = 10100$  M<sup>-1</sup>cm<sup>-1</sup> at pH 1 and 7;  $\epsilon = 7500$  M<sup>-1</sup>cm<sup>-1</sup> at pH 12), is a key intermediate in the biosynthesis of sialic acid, chitin, glycoprotein, and lipopolysaccharides. Although UDP-*N*-acetyl-D-glucosamine weakly inhibits many enzymes, its physiologic concentration is unlikely to be sufficient for substantial inhibition. **Target(s):**  $\alpha$ -*N*-acetylgalactosaminide  $\alpha$ -2,6-sialyltransferase (1); *N*-acetylglucosamine kinase (2,3); *N*-acetylglucosamine-6-phosphate deacetylase (4); *N*-acetylglucosamine-1-phosphodiester  $\alpha$ -*N*-acetylglucosaminidase (5-8); *N*-acylneuraminatase cytidyltransferase, weakly inhibited (9); CMP-*N*-acylneuraminatase phospho-diesterase (10,11);  $\beta$ -galactoside  $\alpha$ -2,3-sialyltransferase (1); globoside  $\alpha$ -*N*-acetylgalactosaminyltransferase (27); glucosamine-6-phosphate deaminase, weakly inhibited (12); glucuronosyltransferase (28-30); glutamine:fructose-6-phosphate aminotransferase (isomerizing), or fructose-6-phosphate amidotransferase (13-22); glycogenin glucosyltransferase (self-glucosylation) (23); glycolipid 2- $\alpha$ -mannosyltransferase, weakly inhibited (24); glycolipid 3- $\alpha$ -mannosyltransferase, weakly inhibited (25); and UDP-*N*-acetylglucosamine diphosphorylase, or *N*-acetylglucosamine-1-phosphate uridylyltransferase, weakly inhibited (26). 1. #### UDP-*N*-acetyl-D-glucosamine 6-Phosphate

This sugar nucleotide ( $FW_{\text{free-acid}} = 687.34$  g/mol;  $\lambda_{\text{max}} = 261$  nm;  $\epsilon = 10100$  M<sup>-1</sup>cm<sup>-1</sup> at pH 1 and 7 and  $\epsilon = 7500$  M<sup>-1</sup>cm<sup>-1</sup> at pH 12), also known as uridine diphosphate *N*-acetyl-D-glucosamine 6-phosphate, is a UDP derivative of the natural product of the reaction catalyzed by *N*-acetylglucosamine kinase. 1. Datta (1975) *Meth. Enzymol.* **42**, 58.

#### [(UDP-*N*-acetyl-D-glucosamine-3-yl)methyl](2-carboxypropyl) Phosphinate

This transition-state mimic ( $FW_{\text{free-acid}} = 774.03$  g/mol;  $\lambda_{\text{max}} = 261$  nm;  $\epsilon = 10100$  M<sup>-1</sup>cm<sup>-1</sup> at pH 1 and 7 and  $\epsilon = 7500$  M<sup>-1</sup>cm<sup>-1</sup> at pH 12, based on uridine's UV spectrum) inhibits *Escherichia coli* UDP-*N*-acetylmuramate:L-alanine ligase ( $IC_{50} = 49$  nM), the L-alanine adding enzyme (also known as MurC) of bacterial peptidoglycan biosynthesis. Note that the phosphinate moiety resembles the likely tetrahedral reaction intermediate. 1. Reck, Marmor, Fisher & Wuonola (2001) *Bioorg. Med. Chem. Lett.* **11**, 1451.

#### UDP-*N*-acetyl-D-muramate (UDP-*N*-acetyl-D-muramic Acid)

This sugar nucleotide ( $FW_{\text{free-acid}} = 679.4$  g/mol;  $\lambda_{\text{max}} = 261$  nm;  $\epsilon = 10100$  M<sup>-1</sup>cm<sup>-1</sup> at pH 1 and 7 and  $\epsilon = 7500$  M<sup>-1</sup>cm<sup>-1</sup> at pH 12, based on uridine's UV spectrum), also known as uridine diphosphate *N*-acetyl-D-muramic acid, is a product of the reaction catalyzed by UDP-*N*-acetylmuramate dehydrogenase and is the substrate for UDP-*N*-acetylmuramate:L-alanine ligase and is a key intermediate in the biosynthesis of a number of compounds, including peptidoglycans and lipopolysaccharides. **Target(s):** glucosamine-1-phosphate *N*-acetyltransferase (1); UDP-*N*-acetylglucosamine 1-carboxyvinyltransferase (2-4). 1. Mengin-Lecreulx & van Heijenoort (1994) *J. Bacteriol.* **176**, 5788. 2. Wickus & Strominger (1973) *J. Bacteriol.* **113**, 287. 3. Venkateswaran, Lugtenberg & Wu (1973) *Biochim. Biophys. Acta* **293**, 570. 4. Mizyed, Oddone, Byczynski, Hughes & Berti (2005) *Biochemistry* **44**, 4011.

#### UDP-*N*-acetylmuramoyl-L-alanyl- $\gamma$ -(D-glutamyl)-(meso-2,6-diaminopimelate)

This metabolite ( $\text{FW}_{\text{hydrochloride}} = 1088.3 \text{ g/mol}$ ;  $\lambda_{\text{max}} = 261 \text{ nm}$ ;  $\epsilon = 10100 \text{ M}^{-1}\text{cm}^{-1}$  at pH 1 and 7 and  $\epsilon = 7500 \text{ M}^{-1}\text{cm}^{-1}$  at pH 12, based on uridine's UV spectrum) is a feedback inhibitor of bacterial cell wall peptidoglycan biosynthesis. **Target(s):** UDP-*N*-acetylglucosamine 1-carboxyvinyltransferase (1,2). 1. Zemell & Anwar (1975) *J. Biol. Chem.* **250**, 3185. 2. Venkateswaran, Lugtenberg & Wu (1973) *Biochim. Biophys. Acta* **293**, 570.

#### UDP-*N*-acetylmuramoyl-L-alanyl- $\gamma$ -(D-glutamyl)-(L)-(meso-2,6-diaminopimeloyl)-D-alanyl-D-alanine

This bacterial metabolite ( $\text{FW}_{\text{hydrochloride}} = 1230.4 \text{ g/mol}$ ;  $\lambda_{\text{max}} = 261 \text{ nm}$ ;  $\epsilon = 10100 \text{ M}^{-1}\text{cm}^{-1}$  at pH 1 and 7 and  $\epsilon = 7500 \text{ M}^{-1}\text{cm}^{-1}$  at pH 12, based on uridine's UV spectrum), also called Park nucleotide (pimelate form), is a feedback inhibitor in the biosynthesis of cell wall peptidoglycan. Note that there are two forms of Park nucleotide, containing either an L-lysyl or meso-diaminopimelate residue. Gram-negative bacteria typically contain the pimelate form. **Target(s):** UDP-*N*-acetylglucosamine 1-carboxyvinyltransferase (1,2). 1. Zemell & Anwar (1975) *J. Biol. Chem.* **250**, 3185. 2. Venkateswaran, Lugtenberg & Wu (1973) *Biochim. Biophys. Acta* **293**, 570.

#### [1-(UDP-*N*-acetylmuramido)ethyl](2,4-dicarboxybutyl) Phosphinate

This substrate analogue ( $\text{FW}_{\text{free-acid}} = 914.60 \text{ g/mol}$ ;  $\lambda_{\text{max}} = 261 \text{ nm}$ ;  $\epsilon = 10100 \text{ M}^{-1}\text{cm}^{-1}$  at pH 1 and 7 and  $\epsilon = 7500 \text{ M}^{-1}\text{cm}^{-1}$  at pH 12, based on uridine's UV spectrum) inhibits UDP-*N*-acetylmuramoylalanine:D-glutamate ligase,  $\text{IC}_{50} < 1 \text{ nM}$ . 1. Gegnas, Waddella, Chabinb, Reddyb & Wong (1998) *Bioorg. Med. Chem. Lett.* **8**, 1643.

#### UDP-L-arabinose

This sugar nucleotide ( $\text{FW}_{\text{free-acid}} = 536.28 \text{ g/mol}$ ;  $\lambda_{\text{max}} = 261 \text{ nm}$ ;  $\epsilon = 10100 \text{ M}^{-1}\text{cm}^{-1}$  at pH 1 and 7 and  $\epsilon = 7500 \text{ M}^{-1}\text{cm}^{-1}$  at pH 12, based on uridine's UV spectrum), also known as uridine diphosphate L-arabinose, is a key intermediate in the biosynthesis of arabinoxylans. It is formed from UDP-D-xylose and is a structural analogue of UDP-D-galactose. **Target(s):** UDP-glucuronate decarboxylase, weakly inhibited (1); UDP-glucuronate 4-

epimerase, but enantiomer was unspecified (2). 1. Ankel & Feingold (1965) *Biochemistry* **4**, 2468. 2. Gu & Bar-Peled (2004) *Plant Physiol.* **136**, 4256.

#### UDP Chloroacetol, See Uridine 5'-Diphosphate Chloroacetol

#### UDP-2-deoxy-D-glucose

This structural analogue of UDPglucose ( $\text{FW}_{\text{free-acid}} = 550.31 \text{ g/mol}$ ;  $\lambda_{\text{max}} = 261 \text{ nm}$ ;  $\epsilon = 10100 \text{ M}^{-1}\text{cm}^{-1}$  at pH 1 and 7 and  $\epsilon = 7500 \text{ M}^{-1}\text{cm}^{-1}$  at pH 12, based on uridine's UV spectrum), also known as uridine diphosphate 2-deoxy-D-glucose, inhibits the formation of dolichyl-phospho-D-glucose but not the formation of dolichyl-phospho-D-mannose. **Target(s):** dolichyl-phosphate glucosyltransferase (1); and protein glycosylation (1,2). 1. Schwarz & Datema (1980) *Trends Biochem. Sci.* **5**, 65. 2. Schwarz, Schmidt & Lehle (1978) *Eur. J. Biochem.* **85**, 163.

#### UDP-D-galactosamine

This naturally occurring sugar nucleotide ( $\text{FW}_{\text{hydrochloride}} = 361.92 \text{ g/mol}$ ;  $\lambda_{\text{max}} = 261 \text{ nm}$ ;  $\epsilon = 10100 \text{ M}^{-1}\text{cm}^{-1}$  at pH 1 and 7 and  $\epsilon = 7500 \text{ M}^{-1}\text{cm}^{-1}$  at pH 12, based on uridine's UV spectrum), also known as uridine diphosphate D-galactosamine, inhibits UDPglucose dehydrogenase (1). 1. Bauer & Reutter (1973) *Biochim. Biophys. Acta* **293**, 11.

#### UDP-D-galactose

This naturally occurring alkali-labile sugar nucleotide ( $\text{FW}_{\text{free-acid}} = 566.31 \text{ g/mol}$ ;  $\lambda_{\text{max}} = 261 \text{ nm}$ ;  $\epsilon = 10100 \text{ M}^{-1}\text{cm}^{-1}$  at pH 1 and 7 and  $\epsilon = 7500 \text{ M}^{-1}\text{cm}^{-1}$  at pH 12, based on uridine's UV spectrum; Symbol: UDPGal), also known as uridine diphosphate D-galactose, is a key intermediate in D-galactose metabolism as well as in the formation of a number of other cellular components (e.g., cell wall polysaccharides, rhamnogalacturonans, etc.). Although UDP-*N*-galactose weakly inhibits many enzymes *in vitro*, it is unlikely that its physiologic concentration is sufficient for substantial inhibition within cells. **Target(s):**  $\alpha$ -*N*-acetylglactosaminide  $\alpha$ -2,6-sialyltransferase (1); *N*-acetylglactosaminide  $\beta$ -1,6-*N*-acetylglucosaminyltransferase (2); (*N*-acetylneuraminy)-galactosylglucosylceramide *N*-acetylglactosaminyltransferase (20); CMP-*N*-acyl-neuraminatase phosphodiesterase (3,4);  $\beta$ -galactoside  $\alpha$ -2,3-sialyltransferase (1); globoside  $\alpha$ -*N*-acetylglactos-aminyltransferase (21); glucuronosyltransferase (23); glycogenin glucosyltransferase (self-glycosylation) (5); glycogen synthase (24); glycolipid 2- $\alpha$ -mannosyl-transferase, weakly inhibited (19); glycoprotein-fucosyl-galactoside  $\alpha$ -*N*-acetylglactosaminyltransferase (22); hyaluronan synthase (6); lactosylceramide  $\alpha$ -2,3-sialyltransferase, weakly inhibited (7);  $\alpha$ -1,3-mannosyl-glycoprotein 4- $\beta$ -*N*-acetylglucosaminyltransferase (18); NDP-glucose:starch glucosyltransferase (8); nucleotide diphosphatase, also alternative substrate (9); UDP-glucose dehydrogenase (10); UDP-glucose:hexose-1-phosphate uridylyltransferase, product inhibition (11); UDP-glucuronate 4-epimerase (12); and UTP:glucose-1-phosphate uridylyltransferase (13-17). 1. Sadler, Beyer, Oppenheimer, et

al. (1982) *Meth. Enzymol.* **83**, 458. 2. Sakamoto, Taguchi, Tano *et al.* (1998) *J. Biol. Chem.* **273**, 27625. 3. van Dijk, Maier & van den Eijnden (1976) *Biochim. Biophys. ### UDP-D-galacturonate

This sugar nucleotide (FW<sub>free-acid</sub> = 580.29 g/mol;  $\lambda_{\max}$  = 261 nm;  $\epsilon$  = 10100 M<sup>-1</sup>cm<sup>-1</sup> at pH 1 and 7 and  $\epsilon$  = 7500 M<sup>-1</sup>cm<sup>-1</sup> at pH 12, based on uridine spectrum), also known as uridine diphosphate D-galacturonate, is formed via a reversible epimerization of UDP-D-glucuronate. It is required for capsular biosynthesis in a number of microorganisms and in the formation of rhamnogalacturonans. **Target(s):** chitin synthase (1); CMP-N-acetylneuraminate phosphodiesterase (2); glucuronosyltransferase (3,4); procollagen galactosyl-transferase (5); UDP-D-ribose/UDP-D-xylose synthase (6); UTP:glucose-1-phosphate uridylyltransferase, or glucose-1-phosphate uridylyltransferase (7-9). 1. Jan (1974) *J. Biol. Chem.* **249**, 1973. 2. Kean & Bighouse (1974) *J. Biol. Chem.* **249**, 7813. 3. Bock, Josting, Lilienblum & Pfeil (1979) *Eur. J. Biochem.* **98**, 19. 4. ### UDP-D-glucose

This sugar nucleotide (FW<sub>free-acid</sub> = 566.31 g/mol;  $\lambda_{\max}$  = 261 nm;  $\epsilon$  = 10100 M<sup>-1</sup>cm<sup>-1</sup> at pH 1 and 7 and  $\epsilon$  = 7500 M<sup>-1</sup>cm<sup>-1</sup> at pH 12; Symbol: UDPGlc), also known as uridine diphosphate D-glucose, is a key intermediate in the formation of polysaccharides, including glycogen, from D-glucose. Although UDP-glucose weakly inhibits many enzymes *in vitro*, it is unlikely that its physiologic concentration is sufficient for substantial inhibition within cells. **Target(s):**  $\alpha$ -N-acetylglucosaminide  $\alpha$ -2,6-sialyltransferase (1); N-acetyl-glucosamine-1-phosphodiester  $\alpha$ -N-acetylglucosaminidase (2); N-acetylglucosaminyl-diphosphodolichol N-acetylglucosaminyltransferase (39,40); N-acetyllactosaminidase  $\beta$ -1,6-N-acetylglucosaminyltransferase (38); ATP diphosphatase, weakly inhibited (3); carbamoyl-phosphate synthetase II (glutamine hydrolyzing) (4); chitin synthase (49); CMP-N-acetylneuraminate phosphodiesterase (5);  $\beta$ -galactoside  $\alpha$ -2,3-sialyltransferase (1); galactosyltransferase (6); globoside

$\alpha$ -N-acetylglucosaminyltransferase (45,46); glucose-1-phosphate adenyltransferase (30); glucose-1-phosphate thymidyltransferase (7); glucuronosyl-transferase (48); glutamine:fructose-6-phosphate aminotransferase (isomerizing), or fructose-6-phosphate amidotransferase (8,35); glycogen phosphorylase (9,10,50-60); glycolipid 2- $\alpha$ -mannosyltransferase, weakly inhibited (43); glycolipid 3- $\alpha$ -mannosyltransferase, weakly inhibited (42); glycoprotein 2- $\beta$ -D-xylosyltransferase (36); hexokinase (34); hyaluronan synthase (37); lactose synthase (6); maltose synthase (41);  $\alpha$ -1,3-mannosyl-glycoprotein 2- $\beta$ -N-acetylglucosaminyltransferase, weakly inhibited (44);  $\alpha$ -1,3-mannosyl-glycoprotein 4- $\beta$ -N-acetylglucosaminyltransferase (38); nucleotide diphosphatase, alternative substrate (11,12); [phosphorylase] phosphatase (13,14); procollagen galactosyltransferase (47); [protein-P11] uridylyltransferase (29); starch phosphorylase (52,61-67); UDP-N-acetylglucosamine:dolichol-phosphate N-acetylglucosamine-phosphotransferase (15,16); UDP-N-acetylglucosamine 2-epimerase (17); UDP-N-acetylglucosamine:lysosomal-enzyme N-acetylglucosamine-phosphotransferase (18-20); UDP-glucuronate decarboxylase (21-24); UDP-glucuronate 4-epimerase (25-27); UTP:glucose-1-phosphate uridylyltransferase, product inhibition (31-34); and zeatin O- $\beta$ -D-xylosyltransferase (28). 1. Sadler, Beyer, Oppenheimer, *et al.* (1982) *Meth. Enzymol.* **83**, 458. 2. Varki & Kornfeld (1980) *J. Biol. Chem.* **255**, 8398. 3. Torp-Pedersen, Flodgaard & Saermark (1979) *Biochim. Biophys. **UDP-D-glucos-6-yl**, See *P<sup>1</sup>-5'-Uridine-P<sup>2</sup>-glucose-6-yl Diphosphate*

#### UDP-D-glucuronate

This sugar nucleotide (FW<sub>free-acid</sub> = 580.29 g/mol;  $\lambda_{\max}$  = 261 nm;  $\epsilon$  = 10100 M<sup>-1</sup>cm<sup>-1</sup> at pH 1 and 7 and  $\epsilon$  = 7500 M<sup>-1</sup>cm<sup>-1</sup> at pH 12, based on uridine spectrum), also known as uridine diphosphate D-glucuronate, is a key intermediate in the formation of glucuronosides and is a substrate of several UDPglucuronosyltransferases. It is slightly unstable and slowly decomposes at room temperature. UDP-D-glucuronate is a product inhibitor for UDP-glucose dehydrogenase. **Target(s):** *N*-acetylglucosaminyltransferase (1); chitin synthase (2); CMP-*N*-acetylneuraminyl phosphodiesterase (3); dolichylphosphate-glucose phosphodiesterase (4); dolichyl-phosphate  $\beta$ -glucosyltransferase (5); glucuronokinase (6); glycogenin glucosyltransferase (self-glucosylation) (7);  $\alpha$ -1,3-mannosyl-glycoprotein 4- $\beta$ -*N*-acetylglucosaminyl-transferase (8); procollagen galactosyltransferase (9);  $\alpha$ , $\alpha$ -trehalose-phosphate synthase (UDP-forming) (10); UDP-galactose 4-epimerase, in the presence of D-fucose or L-arabinose (11); UTP:glucose-1-phosphate uridylyl-transferase, or glucose-1-phosphate uridylyltransferase (12-14); and 1,4- $\beta$ -D-xylan synthase (15). **1.** Sakamoto, Taguchi, Tano, *et al.* (1998) *J. #### UDP-pyridoxal

This pyridinyl nucleotide (FW<sub>hydrochloride</sub> = 589.77 g/mol), also known as uridine diphosphopyridoxal and pyridoxal 5'-diphospho-5'-uridine, is an active-site probe of UDPsugar-utilizing enzymes that reacts with a specific lysyl residue in rabbit muscle glycogen synthase. **Target(s):** glycogen synthase (1-4); UDP-glucose pyrophosphorylase (1). **1.** Fukui & Tanizawa (1997) *Meth. Enzymol.* **280**, 41. **2.** Colman (1990) *The Enzymes*, 3rd ed. (Sigman & Boyer, eds.), **19**, 283. **3.** Pitcher, Smythe & Cohen (1988) *Eur. J. #### UDP-D-xylose

This sugar nucleotide (FW<sub>free-acid</sub> = 536.28 g/mol; *Symbol* = UDPX;  $\lambda_{\max}$  = 261 nm;  $\epsilon$  = 10100 M<sup>-1</sup>cm<sup>-1</sup> at pH 1 and 7 and  $\epsilon$  = 7500 M<sup>-1</sup>cm<sup>-1</sup> at pH 12, based on uridine spectrum), also known as uridine diphosphate D-xylose, is a key intermediate in the biosynthesis of xylans, xyloglucans, arabinoxylans, and xylosylzeatin. UDPX is also the donor substrate in the xylosylation of proteins, flavonols, and dolichols. UDPX is a product of the reaction catalyzed by UTP:xylose-1-phosphate uridylyltransferase and is a substrate for 1,4- $\beta$ -D-xylan synthase, protein xylosyltransferase, dolichylphosphate D-xylosyltransferase, flavonol-3-*O*-glycoside xylosyltransferase, glycoprotein 2- $\beta$ -D-xylosyltransferase, xyloglucan 6-xylosyltransferase, and zeatin *O*- $\beta$ -D-xylosyltransferase. **Target(s):** chitin synthase (1); glucuronosyltransferase (2); glycogenin glucosyltransferase, in which UDP-xylose is also an alternative substrate (3,4); sinapate 1-glucosyltransferase, weakly inhibited (5); UDP-*N*-acetylglucosamine:dolichyl-phosphate *N*-

acetylglucosaminophosphotransferase (6); UDP-glucose dehydrogenase (7-10); UDP-glucuronate decarboxylase (11,12); UDP-glucuronate 4-epimerase (13-16); UTP:glucose-1-phosphate uridylyltransferase (17-20); UTP:hexose-1-phosphate uridylyltransferase (18); and xyloglucan 4-glucosyltransferase (21). 1. ### UFP-101

This potent and selective antinociceptive peptide (FW = 1908.19 g/mol; Sequence: *N*-(Bn)GGGFTGARKSARKRNQ-NH<sub>2</sub>; CAS 849024-68-6) is a competitive silent antagonist for the Nociceptin Receptor, or NOP Opioid Receptor (See *Nociceptin*). Nociceptin/orphanin FQ (N/OFQ) modulates several biological functions by activating a specific G-protein coupled receptor (NOP). UFP-101 binds to NOP with high affinity (pK<sub>i</sub> = 10.24), displaying > 3000x selectivity over δ, μ and κ opioid receptors. In isolated peripheral tissues of mice, rats and guinea-pigs, and in rat cerebral cortex synaptosomes pre-loaded with [<sup>3</sup>H]-5-HT, UFP-101 competitively antagonized the effects of N/OFQ with pA<sub>2</sub> values in the range of 7.3 - 7.7 (1). In the same preparations, the peptide was inactive alone and did not modify the effects of classical opioid receptor agonists. UFP-101 is also active in mice where it prevented the depressant action on locomotor activity and the pronociceptive effect induced by N/OFQ (1 nmol, as an intracerebroventricular injection (i.c.v.) (1). In male Swiss mice, i.c.v. injection of UFP-101 (1-10 nmol) dose-dependently reduced the immobility time, or 192 sec for control versus 91 sec for UFP-101 (2). The effect of 3 or 10 nmol UFP-101 was fully or partially reversed, respectively, by the coadministration of 1 nmol N/OFQ, which was inactive *per se* (2). UFP-101 does not stimulate GTPγS binding on its own, but does produce a concentration dependent and parallel rightward shift in the concentration response curves to all agonists (3). 1. Calo, Rizzi, Rizzi, *et al.* (2002) *Brit. J. Pharmacol.* **136**, 303. 2. Gavioli, Marzola, Guerrini, *et al.* (2003) *Eur. J. Neurosci.* **17**, 1987. 3. McDonald, Calo, Guerrini & Lambert (2003) *Naunyn Schmiedeberg Arch. Pharmacol.* **367**, 183.

### UK5099

This transport inhibitor (FW = 288.31 g/mol; CAS 56396-35-1; Solubility = >20 mg/mL DMSO), also known as UK-5099, UK 5099, and 2-cyano-3-(1-phenyl-1*H*-indol-3-yl)-2-propenoic acid, is a potent, cell-permeable inhibitor (IC<sub>50</sub> = 1-5 nM) of the mitochondrial pyruvate carrier (MPC), inhibiting pyruvate-dependent O<sub>2</sub> consumption rat heart mitochondria (IC<sub>50</sub> = 50 nM) and displaying excellent selectivity over monocarboxylates and anions. In castor bean mitochondria, MPC exhibits Michaelis-Menten kinetics, with a K<sub>m</sub> of 0.10 mM for pyruvate and a V<sub>m</sub> of 0.95 nmol/min per mg of mitochondrial protein (1). (See also *Zaprinast*) Two proteins, Mpc1 and Mpc2, appear to be essential for mitochondrial pyruvate transport in

yeast, *Drosophila*, and humans (2). Mpc1 and Mpc2 associate to form an ~150-kDa complex in the inner mitochondrial membrane. Yeast and *Drosophila* mutants lacking the *MPC1* gene display impaired pyruvate metabolism, with an accumulation of upstream metabolites and a depletion of tricarboxylic acid cycle intermediates. Mpc1 appears to be a key target for UK-5099. By screening for *MPC1* mutants that could grow in the presence of UK-5099, an Asp-118-Gly resistance-conferring substitution was identified in Mpc1 (2). (See also *α-Cyano-4-hydroxycinnamate*, another mitochondrial pyruvate transport inhibitor) 1. Brailsford, Thompson, Kaderbhai & Beechey (1986) *Biochem J.* **239**, 355. 2. Bricker, Taylor, Schell, *et al.* (2012) *Science* **337**, 96.

### UK33274, See Doxazosin

### UK 69578

This dicarboxylic acid (FW<sub>free-acid</sub> = 399.48 g/mol) is a selective inhibitor of neprilysin (also called enkephalinase): K<sub>i</sub> = 28 nM. 1. Roques, Noble, Crine & Fournié-Zaluski (1995) *Meth. Enzymol.* **248**, 263. 2. Danilewicz, Barclay, Barnish, *et al.* (1989) *Biochem. Biophys. Res. Commun.* **164**, 58.

### UK 76654, See Zamifenacin

### UK 81252, See Sempatriat

### UK 156406

This peptidomimetic (FW<sub>inner-salt</sub> = 539.66 g/mol), which has a plasma half-life of 48 minutes, inhibits thrombin (K<sub>i</sub> = 0.46 nM) as well as thrombin-induced fibroblast proliferation, procollagen production, and connective tissue growth factor mRNA levels, when used at equimolar concentration to thrombin. **Target(s):** thrombin (1,2); and trypsin (1). 1. Allen, Abel, Barber, *et al.* (1998) *215th ACS Natl. Meeting, Dallas, TX*, Abst. MEDI 200. 2. Howell, Goldsack, Marshall *et al.* (2001) *Amer. J. Pathol.* **159**, 1383.

### UK-427,857, See Maraviroc

### Ulinastatin

This 352-residue serine protease inhibitor (MW<sub>unglycosylated</sub> = 38,999 g; Isoelectric Point = 5.95) also known as α-1-microglobulin, AMBP, urinary trypsin inhibitor (UTI), urinary trypstatin, Bikunin<sup>®</sup> and Urinastatin<sup>®</sup>, is a urine-derived glycoprotein used to treat acute pancreatitis, chronic pancreatitis, toxic shock, Stevens-Johnson syndrome, burn patients, severe sepsis and toxic epidermal necrolysis. Circulating α-1-microglobulin is a monomer that forms complexes with IgA and albumin. In most cells, α-1-microglobulin occurs as a complex with trypstatin. **Background:** Inter-α-trypsin inhibitor, or ITI, is an abundant 220-kDa human plasma serine protease inhibitor (0.4-0.5 g/L) that is a complex of two heavy chains and a light one, the latter corresponding to the urinary trypsin inhibitor. Naturally occurring UTI is a proteoglycan containing a chondroitin sulfate side chain mainly synthesized in liver. UTI inhibits trypsin, elastase, and cathepsin G, the latter released by stimulated neutrophils. ITI is degraded into lower molecular weight derivatives present in plasma, among which UTI excreted in urine. During infection, cancer, tissue injury during surgery, kidney disease, vascular disease, coagulation, and diabetes, the concentrations of

Bikunin in plasma and urine are increased. **Other Targets:** Broadly active against serine proteases, including trypsin, thrombin, chymotrypsin, kallikrein, plasmin, elastase, cathepsin, Factors IXa, Xa, XIa, and XIIa. UTI's physiologic spectrum of inhibitory action is most likely determined by location and extent of biosynthesis. 1. Pugia, Valdes & Jortani (2007) *Adv. Clin. Chem.* **44**, 223.

#### Ulipristal acetate

This selective progesterone receptor modulator, or SPRM (FW = 475.62 g/mol; CAS 126784-99-4; *Symbol:* UPA; *IUPAC Name:* (8*S*,11*S*,13*S*,14*R*,17*R*)-17-acetoxy-11-[4-(dimethylamino)phenyl]-19-norpregna-4,9-diene-3,20-dione), also known as the contraceptive EllaOne® (in EU) and Ella® (in U.S) as well as Esmya® for uterine fibroid therapy, is effective and well-tolerated oral hormonal emergency contraceptive, when administered within 48-120 hours after unprotected intercourse (1,2). This agent delays or inhibits ovulation, but is without effect once luteinizing hormone has begun to increase. Animal studies show ulipristal acetate to be embryotoxic, making it necessary to be certain the recipient is not already pregnant. Ulipristal acetate is metabolized by CYP3A4 *in vitro* to two other pharmacologically active, but less potent forms. Because it is also likely to interact with other CYP3A4 substrates (*e.g.*, rifampicin, phenytoin, erythromycin, St John's wort, carbamazepine, and ritonavir), concomitant use alters UPA pharmacokinetics. **See also** *Levonorgestrel and Mifepristone* 1. Fine, Mathé, Ginde, *et al.* (2010) *Obstet Gynecol.* **115**, 257. 2. Bouchard, Chabbert-Buffet & Fauser (2011) *Fertil. Steril.* **96**, 1175.

#### Umbelliferone

This coumarin derivative (FW = 162.14 g/mol), also known as 7-hydroxycoumarin, is frequently found in plants (*e.g.*, the aglucon of skimmion) and is often used as a fluorescent label (solutions will exhibit a blue fluorescence) and a pH indicator. **Target(s):** chymotrypsin (1); cyclooxygenase (2); 17 $\beta$ -hydroxysteroid dehydrogenase (3); lipoxigenase (4); phenylalanine ammonia-lyase (5); phenylpyruvate tautomerase (6); and xanthine oxidase (7). 1. Ghani, Ng, Atta-ur-Rahman, *et al.* (2001) *J. Mol. Biol.* **314**, 519. 2. Lee, Bykadi & Ritschel (1981) *Arzneimittelforschung* **31**, 640. 3. Le Lain, Barrell, Saeed, *et al.* (2002) *J. Enzyme Inhib. Med. Chem.* **17**, 93. 4. Sekiya, Okuda & Arichi (1982) *Biochim. Biophys. Acta* **713**, 68. 5. Dubery (1990) *Phytochemistry* **29**, 2107. 6. Molnar & Garai (2005) *Int. Immunopharmacol.* **5**, 849. 7. Chang & Chiang (1995) *Anticancer Res.* **15**, 1969.

#### UNC549

This orally bioavailable pyrazolopyrimidine (FW = 396.50 g/mol; Solubility = 100 mg/mL DMSO), also known as 1-((*trans*-4-aminocyclohexyl)-methyl)-*N*-butyl-3-(4-fluorophenyl)-1*H*-pyrazolo[3,4-*d*]pyrimidin-6-amine, MERTK Inhibitor I, RP38 Inhibitor I, TAM Family RTK Inhibitor I, and

UNC-569, is a potent and reversible ATP-competitive Mer receptor tyrosine kinase inhibitor ( $IC_{50} = 2.9$  nM;  $K_i = 4.3$  nM), exhibiting ~10x greater selectivity over the TAM family kinases Axl ( $IC_{50} = 37$  nM) and Tyro3 ( $IC_{50} = 48$  nM). UNC549 also blocks Mer auto-phosphorylation in human Pre-B leukemia 697 cells,  $IC_{50} = 141$  nM. When present at 30 nM, UNC549 inhibits Flt3, MAPKAPK2, RET and Ret-Y791F by 82%, 92%, 59% and 56%, respectively. Treatment of acute lymphoblastic leukemia (ALL) cells with UNC569 reduces proliferation and survival in liquid culture, decreases colony formation in methylcellulose/soft agar, and increases sensitivity to cytotoxic chemotherapies (1). Upon activation by the ligands Gas6 and Protein S, Tyro3/Axl/Mer (TAM) receptor tyrosine kinases promote phagocytic clearance of apoptotic cells and downregulate immune responses initiated by Toll-like receptors and type I interferons, or IFNs (2). Many enveloped viruses display the phospholipid phosphatidylserine on their membranes, through which they bind Gas6 and Protein S and engage TAM receptors. Such findings suggest that agents like UNC-549 will be effective in modulating these processes (2). 1. Christoph, Deryckere, Schlegel, *et al.* (2013) *Mol. Cancer Ther.* **12**, 2367. 2. Bhattacharyya, Zagórska, Lew, *et al.* (2013) *Cell Host Microbe* **14**, 136.

#### UNC669

This malignant brain tumor inhibitor (FW = 338.24 g/mol; CAS 1314241-44-5; Solubility: 11 mg/mL DMSO), also named 2-(phenylamino)-1,4-phenylenebis((4-(pyrrolidin-1-yl)piperidin-1-yl)methanone), interfere with the binding of methyl-lysine binding proteins to *N*-CH<sub>3</sub>-lysine-containing regulatory proteins, such as p53 and Rb, thereby altering chromatin compaction and repressing transcription. 1. Herold, Wigle, Norris, *et al.* (2011) *J. Med. Chem.* **54**, 2504.

#### UNC1215

This MBT antagonist (FW<sub>free-base</sub> = 529.73 g/mol; CAS 1415800-43-9; Solubility: 100 mg/mL DMSO or Ethanol; <1 mg/mL H<sub>2</sub>O), also known as 1,1'-[2-(phenylamino)-1,4-phenylene]bis[1-[4-(1-pyrrolidinyl)-1-piperidinyl]methanone], potently and selectively targets the Malignant Brain Tumor L3MBTL3 with  $IC_{50}$  of 40 nM and  $K_d$  of 120 nM, exhibiting 50x tighter binding *versus* other members of the human MBT family. In cells, UNC1215 is nontoxic and binds directly to L3MBTL3 via the Kme-binding pocket of its MBT domains. UNC1215 increases the cellular mobility of GFP-L3MBTL3 fusion proteins. Moreover, point mutations disrupting the Kme-binding function of GFP-L3MBTL3 phenocopy the effects of UNC1215 on localization. UNC1215 was used to reveal a new Kme-dependent interaction of L3MBTL3 with BCLAF1, a protein implicated in DNA damage repair and apoptosis. 1. James, Baryte-Lovejoy, Zhong, *et al.* (2013) *Nature Chem. Biol.* **9**, 184.

#### Uncouplers (Gradient-Dissipating Proton Carriers)

These membrane-permeant proton carriers (protonophores) and mobile, membrane-permeant ion carriers (ionophores) shuttle protons or ions across excitable biomembranes (often with bilayer crossing frequencies of  $10^7$  sec<sup>-1</sup>, or higher), thereby dissipating their respective transmembrane proton or ion gradients and frequently defeating life-sustaining metabolic processes (1,2). An important property of uncouplers is that they do not interacting with respiratory chain components or the ATP synthase. Instead, protonophoric uncouplers inhibit oxidative phosphorylation by defeating the productive

mechanochemical coupling of the proton gradient (formed by the NADH oxidation-dependent Electron Transport System) to ATP synthase. Mitochondrial uncoupling refers to a condition in which protons cross the inner membrane back into the matrix, while bypassing ("short-circuiting") ATP synthase, with consequential reduction in the transmembrane potential,  $\Delta\psi$ . The unprotonated uncoupler ( $U^-$ ) combines with a proton  $H^+$  at the proton-rich face of the membrane, forming the protonated uncoupler (UH), which then moves across to the other face of the membrane, whereupon protonated uncoupler readily dissociates, thereby increasing the proton concentration on the proton-poor side of the membrane and dissipating the proton gradient.

A key feature of effective uncouplers is their ability to delocalize the negative charge of  $U^-$  to an extent that it can recross the membrane to reprotonate (2). Consider the case of salicylanilide:

Notice how the negative charge is spread throughout the central, hydrogen bond-containing ring. Uncouplers like SF6847 and S13 are highly effective in delocalizing their negative charge, and they shuttle protons with respective cycling rates of 800 and 400  $s^{-1}$ , at or near the theoretical limit of 1000  $s^{-1}$  (2). Note that interfacial proton transfer is extremely rapid, occurring on  $\mu s$  timescales, with an estimated bimolecular rate constant of  $2 \times 10^{11} M^{-1} s^{-1}$  (3). This property indicates that there is little or no kinetic barrier for proton transfer from the aqueous phase to the membrane-water interface. Absent the proton gradient acting as a driving force, ATP synthesis is inhibited. In a futile effort to maintain the transmembrane potential in the presence of a protonophoric uncoupler, ATP synthase operates in reverse, catalyzing ATP hydrolysis to liberate ADP,  $P_i$ , and a proton, a process attended by release of considerable heat. **Frequently Used Uncouplers:** *Carbonyl cyanide m-chlorophenylhydrazone* (Abbreviation: CCCP; Functional Group: Aminoguanidine; Effective Concentration: 110 nM,  $pK_a = 6.0$ ); *3,5-di-tert-Butyl-4-hydroxybenzylidene-malononitrile* (Abbreviation: SF-6847; Functional Group: Phenol; Effective Concentration: 10 nM,  $pK_a = 6.8$ ); *2,4-Dinitrophenol* (Abbreviation: 2,4-DNP; Functional Group: Phenol; Effective Concentration: 24  $\mu M$ ,  $pK_a = 4.1$ ); *Pentachlorophenol* (Abbreviation: PCP; Functional Group: Phenol; Effective Concentration: 1  $\mu M$ ,  $pK_a = 4.6$ ); *Salicylanilide* (Functional Group: 2-Hydroxybenzylidene; Effective Concentration: 200 nM,  $pK_a = 7.0$ ); *4,5,6,7-Tetrafluoro-2-trifluoromethylbenzimidazole* (Abbreviation: TTFB; Functional Group: Imidazole; Effective Concentration: 30 nM,  $pK_a = 5.5$ ); *Trifluorocarbonyl cyanide phenylhydrazone* (Abbreviation: FCCP; Functional Group: Aminoguanidine; Effective Concentration: 70 nM,  $pK_a = 6.2$ ). These agents are moderately hydrophobic, membrane-permeant weak acids, with  $pK_a$  values ranging from 3.5 to 7.5. Optimal uncoupling is observed with compounds having  $pK_a$  values near 4.0. For example, S-133 and SF6847 are highly effective uncouplers, even at 10 nM. Free fatty acids ( $pK_a \approx 4.8$ ) may also operate as mild uncouplers. Brown adipose tissue of in newborn and hibernating mammals as well as irisin-responsive white-fat adipose tissue utilizes its uncoupling protein *thermogenin* (See *Uncoupling Protein 1*), a protein that stimulates ATP hydrolysis, thereby warming the animal. Thermogenin is activated by fatty acids and inhibited by nucleotides. The anti-inflammatory activity of several drugs is also believed to depend on their ability to uncouple oxidative phosphorylation. Note also that some uncouplers dissipate transmembrane proton gradients and stimulate

vacuolar proton-translocating ATPases (*i.e.*, the so-called V-ATPases). Ionophoric uncouplers defeat productive mechanochemical coupling of the ion gradient formed by ATP-dependent membrane pumps. An ionophoric uncoupler combines with an ion at the ion-rich side of the membrane, moves across to the other face of the membrane, where the ion readily dissociates, thereby increasing the ion concentration on the ion-poor side of the membrane. An example is valinomycin, a membrane-permeant natural product that binds  $K^+$  roughly  $10^4$  times more tightly than  $Na^+$  and each valinomycin carries up to  $10^4 K^+$  ions per sec, thereby dissipating potassium ion gradients in many cells. (The antibiotic gramicidin, for comparison, forms a transmembrane channel that transport up to  $10^7 K^+$  ions per sec.) Valinomycin uncouples both oxidative- and photo-phosphorylation, especially when cells contain  $H^+/K^+$ -exchanging channels or ion pumps (4). By shuttling ions forth and back across their target membrane, uncouplers dissipate proton gradients, thus inhibiting ATP synthesis without directly interacting with respiratory chain components or the ATP synthase. In a futile effort to maintain the transmembrane potential, ATP synthase operates in reverse, catalyzing ATP hydrolysis. An example of a mixed uncoupler is nigericin, an antibiotic derived from *Streptomyces hygroscopicus*, that acts both as a protonophore and a  $K^+$ -ionophore. An important factor, when considering the action of a particular uncoupler, is its effect on  $\Delta pH$  and  $\Delta\psi$  components of the chemiosmotic driving force (3). Consider, for example, the action of nigericin, which when added to a suspension of vesicles containing the electron transport system, will exchange  $H^+$  for  $K^+$ , thus abolishing the pH gradient, while leaving the transmembrane potential intact. For similarly treated suspensions of mitochondria or chloroplast thylakoids, ATP synthesis is effectively uncoupled by nigericin; however, in bacterial preparations, such is not the case, because the system still retains sufficient membrane potential to drive ATP synthesis. Now consider the action of valinomycin: by moving potassium ions across a membrane, valinomycin destroys the membrane potential, while leaving the  $\Delta pH$  intact. Therefore, in the presence of  $K^+$ , valinomycin does not uncouple ATP synthesis unless a  $\Delta pH$ -dissipating agent, such as nigericin is also included. (See also *Dinitrophenol* (includes additional information on low-molecular-weight protonophores); *Carbonyl cyanide m-chlorophenylhydrazone* (CCCP)) Finally, as discussed by Terada (2), not all uncouplers are proton carriers. 1. Skidmore & Whitehouse (1965) *Biochem. Pharmacol.* **14**, 547. 2. Terada (1990) *Environ. Health. Perspect.* **87**, 213. 3. Maity & Krishnamoorthy (2007) *J. Biosci.* **20**, 573. 4. ### Uncoupling Protein-1

This mammalian mitochondrial protein ( $MW_{human} = 33004.50$  g/mol; Official Symbol: UCP1), also known as thermogenin, is found in Brown Adipose Tissue (BAT), where it uncouples the transmembrane proton gradient, dissipating the considerable Gibbs free energy of NADH oxidation as thermal energy, a process often referred called a proton leak. UCPs facilitate the transfer of anions from the inner to the outer mitochondrial compartment as well as the return transfer of protons from the outer to the inner mitochondrial compartment, thereby reducing the transmembrane potential. See also *Uncouplers (Gradient-Dissipating Proton Carriers)*

### Undecanoyl-CoA

This fatty-acyl-CoA ( $FW_{free-acid} = 935.82$  g/mol) inhibits glucose-6-phosphatase. Fatty-acyl-CoA esters with chain lengths  $\leq 9$  carbons do not inhibit Glc6Pase. Medium-chain fatty-acyl-CoA esters (10-14 carbons) inhibit Glc6Pase of untreated microsomes in a dose-dependent manner, with  $K_i$  values in the range 1-20  $\mu M$ . The inhibitory effect also depends on the acyl-chain length. The higher the chain-length, the stronger the inhibitory effect. 1. Methieux & Zitoun (1996) *Eur. J. Biochem.* **235**, 799.

### 2-Undecyl-4H-1,3,2-benzodioxaphosphorin 2-Oxide

This 2-substituted benzodioxaphosphorin oxide (FW = 324.40 g/mol) inhibits 1-alkyl-2-acetyl-glycerophospho-choline esterase, or platelet-activating-factor acetyl-hydrolase. Platelet-activating factor (PAF) is a potent endogenous phospholipid modulator of diverse biological activities, including inflammation and shock. PAF levels are mainly regulated by PAF acetylhydrolases, which are secondary targets of sarin-type organophosphorus (OP) pesticides (See *Sarin*). Inhibitors exhibiting ultrahigh potency and selectivity were achieved with *n*-alkyl methylphosphonofluoridates (*i.e.*, long-chain sarin analogues): mouse brain and testes  $IC_{50} \leq 5$  nM for C<sub>8</sub>-C<sub>18</sub> analogues, and 0.1-0.6 nM for C(13) and C(14) compounds; human plasma  $IC_{50} < \text{or} = 2$  nM for C<sub>13</sub>-C<sub>18</sub> analogues. AChE inhibitory potency decreased as chain length increased, with maximum brain PAF-AH/AChE selectivity (>3000-fold) for C<sub>13</sub>-C<sub>18</sub> compounds. The toxicity of i.p.-administered PAF (LD<sub>50</sub> ≈ 0.5 mg/kg) was increased less than 2-fold by pretreatment with tribufos or the C<sub>13</sub> *n*-alkyl methylphosphonofluoridate. Such studies indicate that PAF-AH is not a major secondary target of OP pesticide poisoning. 1. Quistad, Fisher, Owen, Klintonberg & Casida (2005) *Toxicol. Appl. Pharmacol.* **205**, 149.

#### O-(*n*-Undecyl) Ethylphosphonofluoridate

This *n*-alkyl methylphosphonofluoridate (FW = 266.34 g/mol) inhibits acetylcholinesterase and 1-alkyl-2-acetyl-glycerophosphocholine esterase, or platelet-activating-factor acetylhydrolase. See also 2-Undecyl-4*H*-1,3,2-benzodioxaphosphorin 2-Oxide 1. Quistad, Fisher, Owen, Klintonberg & Casida (2005) *Toxicol. Appl. Pharmacol.* **205**, 149.

#### 5-(*n*-Undecyl)-6-hydroxy-4,7-dioxobenzothiazole

This ubiquinone analogue (FW = 335.47 g/mol; pK<sub>a</sub> ≈ 6.5; Symbol: UHDBT) inhibits complex III of electron transport (1) and *Escherichia coli* cytochrome *o*-type oxidase, K<sub>i</sub> = 0.3 μM (2). **Target(s)**: cytochrome *bo*<sub>3</sub> ubiquinol oxidase complex (3); cytochrome *o*-type oxidase (2,3); plastoquinol:plastocyanin reductase (cytochrome *b<sub>6</sub>f* complex) (4); sulfide:quinone reductase (5); and ubiquinol:cytochrome *c* reductase (1). 1. von Jagow & Link (1986) *Meth. Enzymol.* **126**, 253. 2. Matsushita, Patel & Kaback (1986) *Meth. Enzymol.* **126**, 113. 3. Musser, Stowell, Lee, Rumbley & Chan (1997) *Biochemistry* **36**, 894. 4. Malkin (1988) *Meth. Enzymol.* **167**, 341. 5. Arieli, Padan & Shahak (1991) *J. Biol. Chem.* **266**, 104.

#### Undecylhydroxynaphthoquinone

This ubiquinone analogue (FW = 328.45 g/mol) inhibits the reoxidation of the iron-sulfur center and the reduction of cytochrome *b*<sub>1</sub> in complex III of electron transport. 1. von Jagow & Link (1986) *Meth. Enzymol.* **126**, 253.

#### Undecylsuccinate (Undecylsuccinic Acid)

This dicarboxylic acid (FW<sub>free-acid</sub> = 272.38 g/mol), also called 3-carboxytetradecanoic acid and 3-carboxy-physeteroic acid, inhibits succinate dehydrogenase (1). *Note*: Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or

micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). 1. Franke (1944) *Z. Physiol. Chem.* **280**, 76.

#### S-(3-Undecyloyl)-*N*-acetylcysteamine

This substituted cysteamine, also known as *N*-acetylcysteamine 3-undecynoate thioester (FW = 283.44 g/mol), is an analogue of an acylated acyl-carrier protein and inhibits 3-hydroxydecanoyl-[acyl-carrier-protein] dehydratase of the fatty acid synthase complex (1,2). 1. Bloch (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), **5**, 441. 2. Helmkamp, Rando, Brock & Bloch (1968) *J. Biol. Chem.* **243**, 3229.

#### Unguinol

This herbicide (FW = 326.35 g/mol; CAS 36587-59-4), systematically named 6-[(2*E*)-2-Buten-2-yl]-3,8-dihydroxy-1,9-dimethyl-11*H*-dibenzo [*b,e*][1,4]dioxepin-11-one, originally isolated from *Aspergillus unguis* and *A. nidulans*, inhibits pyruvate, orthophosphate dikinase. 1. Motti, Bourne, Burnell, *et al.* (2007) *Appl. Environ. Microbiol.* **73**, 1921.

#### Uniconazole

This plant growth retardant (FW = 291.78 g/mol; CAS 83657-22-1; IUPAC Name: (*E*)-(*RS*)-1-(4-chlorophenyl)-4,4-dimethyl-2-(1*H*-1,2,4-triazol-1-yl)pent-1-en-3-ol) is strong competitive inhibitor (K<sub>i</sub> = 8 nM) of *Arabidopsis* abscisic acid (ABA) 8'-hydroxylase (1). Uniconazole-treated plants showed enhanced drought tolerance. Uniconazole also inhibits trans-zeatin biosynthesis and targets CYP735As in *Arabidopsis* (2). 1. Saito, Okamoto, Shinoda, *et al.* (2006) *Biosci. Biotechnol. Biochem.* **70**, 1731. 2. Sasaki, Ogura, Takei, *et al.* (2013) *Phytochemistry* **87**, 30.

#### Utenmone A

This marine natural product (FW = 379.56 g/mol; methyl (1*R*,2*R*)-2-hexadecyl-2-hydroxy-5-oxo-3-cyclopentene-1-carboxylate) inhibits DNA polymerases α and β as well as DNA nucleotidylexotransferase. **Target(s)**: DNA-directed DNA polymerase; DNA polymerase α; DNA polymerase β; DNA nucleotidylexotransferase. *Note*: Because this substance readily forms micelles, one must take care to discriminate

whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). 1. Doncaster, Etechells, Kershaw, *et al.* (2006) *Bioorg. Med. Chem. Lett.* **16**, 2877.

**UPF596**, See (S)-2-(3'-Carboxybicyclo[1.1.1]pentyl)glycine

#### UPF 1069

This PARP-2 inhibitor (FW = 279.30 g/mol; CAS 1048371-03-4; Soluble to 100 mM in DMSO), also named 5-(2-oxo-2-phenylethoxy)-3,4-dihydroisoquinolin-1(2H)-one, selectively targets poly(ADP-ribose) polymerase-2 ( $IC_{50} = 0.3 \mu\text{M}$ ), with 27x weaker action against PARP-1 ( $IC_{50} = 8.0 \mu\text{M}$ ). Selective PARP-2 inhibitors increase post-Oxygen-Glucose Deprivation (post-OGD) cell death in a model characterized by loss of neurons through a caspase-dependent, apoptosis-like process (hippocampal slice cultures), but they reduced post-OGD damage and increased cell survival in a model characterized by a necrosis-like process (cortical neurons). UPF-1069 may be a valuable tool for exploring the function of PARP-2 in biological systems and examining the roles of PARP isoenzymes in cell death and survival. 1. Pellicciari, Camaioni, Costantino, *et al.* (2008) *Chem. Med. Chem.* **3**, 914. 2. Moroni, Formentini, Gerace, *et al.* (2009) *Brit. J. Pharmacol.* **157**, 854.

#### Uprosertib

This potent and orally bioavailable pan-AKT inhibitor (FW = 429.20 g/mol; CAS 1047634-65-0 (free base) 1047635-80-2 (HCl salt); Solubility: 93 mg/mL DMSO), also known as GSK2141795 and GSK795, is ATP-competitive and targets AKT1 ( $K_i = 0.066 \text{ nM}$ ), AKT1<sup>E17K</sup> ( $K_i = 0.2 \text{ nM}$ ), AKT2 ( $K_i = 1.4 \text{ nM}$ ), and AKT3 ( $K_i = 1.5 \text{ nM}$ ), together comprising a family of PI3K-AKT pathway serine-threonine kinases that are often dysregulated in many human malignancies, leading to increased cell survival, growth and proliferation (1). PIP3 lipids tether these kinases to the membrane via their plextrin homology domain, enabling activation by Thr308 phosphorylation by PDK1 and Ser473 phosphorylation by the mTORC2 complex. Activated AKT in turn phosphorylates FOXO, TSC1/2, PRAS40, and GSK3 $\beta$ . Combination of Lapatinib with Uprosertib (or Afuresertib) is synergistic in HER2<sup>+</sup>/PIK3CA<sup>mut</sup> cell lines, but not in HER2<sup>+</sup>/PIK3CA<sup>wild-type</sup> cell lines (2). See also Afuresertib Changes in phosphoprotein levels in 15 cell types revealed that p-S6RP levels were less well attenuated by lapatinib in HER2<sup>+</sup>/PIK3CA<sup>mut</sup> cells, as compared to HER2<sup>+</sup>/PIK3CA<sup>wild-type</sup> cells, and that Lapatinib plus Uprosertib (or Afuresertib) reduce p-S6RP levels to those achieved in HER2<sup>+</sup>/PIK3CA<sup>wild-type</sup> cells with lapatinib alone. There is also compensatory up-regulation of p-HER3, and p-HER2 is blunted in PIK3CA(mut) cells, following Lapatinib plus Uprosertib (or Afuresertib) treatment (2). Identification of AKT pathway dysregulation in ovarian cancer as a platinum resistance-specific event led to a comprehensive analysis of GSK2141795 *in vitro*, *in vivo* and in the clinic (3). Proteomic analysis of GSK2141795 *in vitro* and *in vivo* identified changes in AKT and p38 phosphorylation and total Bim, IGF1R, AR and YB1 levels. In patient biopsies, prior to treatment with GSK2141795 in a Phase I clinical trial, this signature was predictive of post-treatment changes in the response marker CA125, demonstrating the clinical importance of AKT inhibition for re-sensitisation of platinum resistant ovarian cancer to platinum (3). **Other Targets:** P70SK6 ( $IC_{50} = 50 \text{ nM}$ ), PKA ( $IC_{50} = 2.0 \text{ nM}$ ), PKC $\alpha$  ( $IC_{50} > 1000 \text{ nM}$ ), PKC $\beta$ 1 ( $IC_{50} = 56 \text{ nM}$ ), PKC $\beta$ 2 ( $IC_{50} = 86 \text{ nM}$ ), PKC $\delta$  ( $IC_{50} = 69 \text{ nM}$ ), PKC $\gamma$  ( $IC_{50} = 200 \text{ nM}$ ), PKC $\epsilon$  ( $IC_{50} > 1000 \text{ nM}$ ), PKC $\theta$  ( $IC_{50} = 64 \text{ nM}$ ), PKC $\eta$  ( $IC_{50} = 49$

nM), PKC $\xi$  ( $IC_{50} > 1000 \text{ nM}$ ), PKG1 $\alpha$  ( $IC_{50} < 1 \text{ nM}$ ), PKG1 $\beta$  ( $IC_{50} < 1 \text{ nM}$ ), ROCK ( $IC_{50} = 126 \text{ nM}$ ), RSK1 ( $IC_{50} = 200 \text{ nM}$ ) (1). 1. Cheraghchi-Bashi, Parker, Curry, *et al.* (2015) *Oncotarget* **6**, 41736.

#### Uracil

This pyrimidine base (FW = 112.09 g/mol), known systematically as 2,4(1*H*,3*H*)-pyrimidinedione, absorbs UV light ( $\lambda_{\text{max}} = 259.5 \text{ nm}$  ( $\epsilon = 8200 \text{ M}^{-1}\text{cm}^{-1}$ ) at pH 4 and 7; 284 nm ( $\epsilon = 6200 \text{ M}^{-1}\text{cm}^{-1}$ ) at pH 12), consistent with its predominant diketo tautomeric structure. **Target(s):** D-amino-acid oxidase, weakly inhibited (1); aspartate carbamoyltransferase (2); carbamoyl-phosphate synthetase (glutamine-hydrolyzing) (3); DNA-uracil glycosylase (4); dUTP diphosphatase (5,6); hydroxyacylglutathione hydrolase (glyoxalase II) (7); hypoxanthine(guanine) phosphoribosyltransferase (8); lactoylglutathione lyase (glyoxalase I) (7); orotate phosphoribosyltransferase (9-11); ribonuclease, pancreatic (12); thymidine phosphorylase (13-16); thymine, $\alpha$ -ketoglutarate dioxygenase, or thymine 7-hydroxylase (17); tRNA-guanine transglycosylase, weakly inhibited (18); urate-ribonucleotide phosphorylase (19); xanthine phosphoribosyltransferase (8,20). 1. **Uracil-4-acetate**, See 6-Carboxymethyluracil

#### Uracil 1- $\beta$ -D-Arabinofuranoside

This uridine analogue (FW = 244.20 g/mol; CAS 3083-77-0;  $\lambda_{\text{max}} = 261 \text{ nm}$ ;  $\epsilon = 10100 \text{ M}^{-1}\text{cm}^{-1}$  at pH 1 and 7 and  $\epsilon = 7500 \text{ M}^{-1}\text{cm}^{-1}$  at pH 12, based on uridine's UV spectrum), also known as 1- $\beta$ -D-arabinofuranosyluracil (ara-U) and spongouridine, was first isolated from the Caribbean sponge *Cryptotethya crypta*. **Target(s):** cytidine deaminase (1,2); deoxycytidine kinase, weakly inhibited (3,4); and deoxynucleoside kinase (5). 1. Hosono & Kuno (1973) *J. Biochem.* **74**, 797. 2. Cacciamani, Vita, Cristalli, Vincenzetti, Natalini, Ruggieri, Amici & Magni (1991) *Arch. Biochem. Biophys.* **290**, 285. 3. Krenitsky, Tuttle, Koszalka, *et al.* (1976) *J. Biol. Chem.* **251**, 4055. 4. Wang, Kucera & Capizzi (1993) *Biochim. Biophys. Acta* **1202**, 309. 5. Johansson, Van Rompay, Degrève, Balzarini & Karlsson (1999) *J. Biol. Chem.* **274**, 23814.

**Uracil-6-carboxylate**, See Orotate

**6-Uracil Methyl Sulfone**

This nonionizable orotate analogue (FW = 190.18 g/mol) only weakly inhibits orotate phosphoribosyltransferase (*Reaction*: Orotate + p-Rib-pp  $\rightleftharpoons$  OMP + PP<sub>i</sub>),  $K_i = 0.71$  mM (1-3). **1.** Flaks (1963) *Meth. Enzymol.* **6**, 136. **2.** Holmes (1956) *J. Biol. Chem.* **223**, 677. **3.** Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 473, Academic Press, New York.

**6-Uracilsulfonamide**

This nonionizable orotate analogue (FW = 191.17 g/mol) inhibits orotate phosphoribosyltransferase,  $K_i = 7$   $\mu$ M (1-3). 6-Uracilsulfonamide and 6-uracil methylsulfone noncompetitively inhibit the growth of two strains of *Lactobacillus bulgaricus* in media supplemented with orotate or with certain precursors of this compound, including carbamyl-DL-aspartate or L-dihydroorotate. In contrast to the marked effect of this compound on the growth of these organisms, the same analogues had little effect on the growth of *Leuconostoc citrovorum* (*Pediococcus cerevisiae*) 8081 and *Streptococcus jaecalis* 8043, organisms that do not need added orotate for growth. **1.** Flaks (1963) *Meth. Enzymol.* **6**, 136. **2.** Holmes (1956) *J. Biol. Chem.* **223**, 677. **3.** Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 473, Academic Press, New York.

**Uramil**

This barbituric acid derivative (FW = 143.10 g/mol; CAS 118-78-5), also known as 5-mino-2,4,6-trihydroxypyrimidine and 5-aminobarbituric acid, is obtained from derivatives of uric acid. Uramil inhibits glucokinase, a finding that suggests yet another off-target effect of barbiturates (1). **1.** Lenzen, Brand & Panten (1988) *Brit. J. Pharmacol.* **95**, 851.

**Uranium (and Uranium Ions)**

This unstable element (atomic symbol U and atomic number 92) is the heaviest of all naturally occurring elements. All isotopes are radioactive: <sup>234</sup>U ( $t_{1/2} = 2.45 \times 10^5$  years) has a natural abundance of 0.0055 %; <sup>235</sup>U ( $t_{1/2} = 7.04 \times 10^8$  years) has a natural abundance of 0.720 %; and <sup>238</sup>U ( $t_{1/2} = 4.46 \times 10^9$  years) has a natural abundance of 99.2745 %. Uranium exhibits oxidation states of 3, 4, 5, or 6 (the ionic radii for U<sup>4+</sup> and U<sup>6+</sup> are 0.97 and 0.80 Å, respectively). Uranyl cation (UO<sub>2</sub><sup>2+</sup>) inhibits numerous enzymes (1).

**Target(s):** acid phosphatase (2,3); S-adenosylmethionine synthase, by uranyl cations (4); ATPases, by uranyl nitrate (5); creatine kinase, by UO<sub>2</sub><sup>2+</sup> (6); dextranase, by UO<sub>2</sub><sup>2+</sup> (7); exopolysphatase, by UO<sub>2</sub><sup>2+</sup> (8);  $\beta$ -fructofuranosidase, or invertase, by UO<sub>2</sub><sup>2+</sup> (9);  $\alpha$ -glucosidase, by UO<sub>2</sub><sup>2+</sup> (10); hydroxylamine reductase, by uranyl acetate (11); hydroxymethylbilane synthase, by UO<sub>2</sub><sup>2+</sup> (12); lysozyme, by UO<sub>2</sub><sup>2+</sup> (13); NADH oxidase (14); peroxidase, horseradish (15); photosystem II, by uranyl cations (16); pyrophosphatase, by uranyl cations (17); tryptophan transport, by uranyl nitrate (18); and urease, by UO<sub>2</sub><sup>2+</sup> (19). **1.** Takusagawa, Kamitori, Misaki & Markham (1996) *J. **Urantide**

This UT antagonist (FW = 1075.26 g/mol; CAS 669089-53-6; Sequence: DXFWXYCV, with the following modifications: X-2 = Pen, X-5 = Orn, Trp-4 = D-Trp, disulfide bridge between positions 2 and 7; Solubility: 2 mg/mL in H<sub>2</sub>O) selectively and competitively targets urotensin-II ( $K_i = 5 \times 10^{-8}$  M). Urantide blocks hU-II induced contractions in thoracic aorta *ex vivo*. It exhibits no effect on noradrenaline or endothelin 1-induced contraction or on acetylcholine-induced relaxation. Urantide as a partial agonist in a calcium mobilization assay in CHO cells expressing hUT receptors. **1.** Patacchini, Santicioli, Giuliani, *et al.* (2003) *Brit. J. Pharmacol.* **140**, 1155. **2.** Carotenuto, Auriemma, Merlino, *et al.* (2014) *J. Med. Chem.* **57**, 5965.

**URB597**

This carbamate (FW = 338.41 g/mol; CAS 546141-08-6; Soluble to 50 mM in DMSO), also named cyclohexylcarbamate 3'-(aminocarbonyl)-[1,1'-biphenyl]-3-yl ester, selectively inhibits fatty acid amide hydrolase, with IC<sub>50</sub> values of 3 and 5 nM for human liver and rat brain enzymes, respectively (1,2). URB597 exhibits no significant inhibitory activity against a variety of receptors, ion channels and enzymes, including human cannabinoid receptors and rat monoacylglycerol lipase. It also displays antiallostatic and antihyperalgesic activity in an inflammatory pain model. When treated with URB597, adolescent and adult Sprague-Dawley rats displayed higher levels of social behavior and emitted more 50-kHz USVs than Wistar rats, enhancing social play behavior in adolescent Wistar rats under all experimental conditions (3). **1.** Fegley, Gaetani, Duranti, *et al.* (2005) *J.  **$\beta$ -Ureidoisobutyrate**

This metabolite (FW<sub>free-acid</sub> = 146.15 g/mol), also known as 2-(ureidomethyl)propionic acid, 2-methyl-N-carbamoyl- $\beta$ -alanine, and 2-methyl-3-ureidopropionic acid, is an intermediate in the degradation of

deoxythymidine and a precursor to  $\beta$ -aminoisobutyrate.  $\beta$ -Ureidoisobutyrate is also an alternative substrate and competitive inhibitor of maize  $\beta$ -ureidopropionase (1,2). 1. ### 5-Ureidouracil

This pyrimidine and H(G)PRT inhibitor (FW = 170.13 g/mol), often misnamed 2,4-dihydroxy-5-carboxamidopyrimidine, targets hypoxanthine (guanine) phosphoribosyl-transferase. 1. Miller, Ramsey, Krenitsky & Elion (1972) *Biochemistry* **11**, 4723.

### Urethane

This simple carbamate (FW = 89.09 g/mol; M.P. = 48–50°C; B.P. 182–184°C; highly water-soluble), also known as urethan, ethyl carbamate, ethylurethan, and carbamic acid ethyl ester, is cytotoxic and inhibits mitosis. Urethan also forms etheno and oxoethyl adducts when combined with DNA. (**Caution:** Carbamate is toxic, and one should avoid inhalation of the dry powder or contact of the powder or urethane solutions with skin.)

**Target(s):** arginine decarboxylase (1,2); bacterial luciferase, or alkanal monooxygenase (3); carbonic anhydrase (4); esterase (5); firefly luciferase, or *Photinus*-luciferin 4-monooxygenase (6); formate hydrogen lyase (7); glycerol-3-phosphate dehydrogenase (8); hydrogenase (9,10); D-3-hydroxybutyrate dehydrogenase (11); L-lactate dehydrogenase (12); lipoygenase (13); pyrophosphatase (14); and succinate dehydrogenase, or succinate oxidase (15-18). 1. ### Uric Acid

This purine catabolic end-product (FW = 168.11 g/mol; CAS 69-93-2; Solubility: 2 mg/100 mL H<sub>2</sub>O at 25°C; pK<sub>a</sub> values of 5.4 and 11.3) is formed in reactions catalyzed by xanthine oxidase (*Reaction:* Xanthine + H<sub>2</sub>O + O<sub>2</sub> ⇌ Uric acid + H<sub>2</sub>O<sub>2</sub>) or xanthine dehydrogenase (*Reaction:* Xanthine + NAD<sup>+</sup> + H<sub>2</sub>O ⇌ Urate + NADH + H<sup>+</sup>). While uric acid plays only a minor role in human nitrogen excretion, birds and reptiles are uricotelic, meaning that urate is the primary end-product. Although an

unobvious acid, uric acid exists as tautomers (*see above*), and the imido species has a pK<sub>a</sub> of 5.4, only slightly less acidic than acetic acid (pK<sub>a</sub> = 4.8).

While sodium urate is quite soluble in physiologic fluids, uric acid is not and forms paracrystalline masses that accumulate in joints, especially in the big toe. Indeed, in humans, excess uric acid formation leads to Gout, a disorder that is characterized by soreness in toe joints as well as the formation of tofi, sack-like malformations beneath the skin that are filled with crystalline, chalk-like deposits of uric acid. In gout, uric acid accumulation in joints initiates an inflammasome response, resulting in excruciating pain. Excessive uric acid formation and gouty deposits are also observed in Lesch-Nyhan Disorder, a condition associated with defects in the gene encoding hypoxanthine:guanine phosphoribosyltransferase (HGPRT). In humans, uric acid also affects endothelial and adipose cell function and has been linked to hypertension, metabolic syndrome, and cardiovascular disease. Hyperuricemia can, in some instances, stimulate onset of hypertension, most likely by generating an inflammatory cascade, where endothelial dysfunction, smooth muscle proliferation and development of renal afferent arteriosclerosis appear. **Target(s):** In the presence of peroxynitrite, uric acid is converted nonenzymatically to triuret (or 1,1'-carbonyl-bis-urea), which inhibits dipeptidyl peptidase IV *in vitro* (1). Uric acid inhibits arginase (2); methionine *S*-adenosyltransferase (3); phosphorylase *a*<sub>3</sub>; protein-tyrosine phosphatase, or low-molecular-mass phosphotyrosine protein phosphatase (4,5); sepiapterin deaminase, weakly inhibited (6); and xanthine phosphoribosyltransferase (7). 1. Mohandas, Sautina, Beem, *et al.* (2014) *Exp. Cell Res.* **326**, 136. 2. Rosenfeld, Dutta, Chheda & Tritsch (1975) *Biochim. Biophys. Acta* **410**, 164. 3. ### Uridine

This pyrimidine nucleoside and RNA precursor (FW = 244.20 g/mol;  $\lambda_{\max}$  is 261 nm;  $\epsilon = 10100 \text{ M}^{-1}\text{cm}^{-1}$  at pH 1 and 7 and  $\epsilon = 7500 \text{ M}^{-1}\text{cm}^{-1}$  at pH 12; pK<sub>a</sub> values = 9.2 and 12.5 at 25°C) is a component of ribonucleotides, RNA, and sugar nucleotides. Uridine is prepared from cytidine by treatment with nitrous acid to form the diazonium salt, followed by hydrolysis. *Note:* Xuriden<sup>®</sup> (FW<sub>uridine-triacetate</sub> = 370.3 g/mol; CAS 4105-38-8; IUPAC: (2*R*,3*R*,4*R*,5*R*)-2-(acetoxymethyl)-5-(2,4-dioxo-3,4-dihydropyrimidin-1(2*H*)-yl)tetrahydrofuran-3,4-diyl diacetate), is a membrane-permeant pro-drug that, upon oral administration, is deacetylated by nonspecific esterases throughout the body. Xuriden provides uridine to patients with hereditary orotic aciduria and cannot synthesize adequate quantities of uridine due to a genetic defect in OMP decarboxylase. **Target(s):** Acid phosphatase (1,2); adenosine kinase (3,4); adenosylhomocysteinase (5); AMP:thymidine kinase (6); CMP-*N*-acetylneuraminatase phosphodiesterase, weakly inhibited (7); cytidine deaminase (8,9); deoxycytidine deaminase (10); deoxycytidine kinase, weakly inhibited (11); dihydroorotase (12); globoside  $\alpha$ -*N*-acetylgalactosaminyltransferase (27,28); glycogen synthase (30); glycoprotein-fucosylgalactoside  $\alpha$ -*N*-acetylgalactosaminyltransferase (29); hydroxyacylglutathione hydrolase, or glyoxalase II (13); lactoylglutathione lyase, or glyoxalase II (13); NDP-glucose:starch glucosyltransferase14; nucleoside phosphotransferase (15); 5'-nucleotidase, weakly inhibited (16-18); pancreatic ribonuclease, or ribonuclease A (19); purine nucleosidase (20,21); ribonuclease T<sub>2</sub> (22); thymidine phosphorylase (23,24); UDP-*N*-acetyl-glucosamine diphosphorylase, or *N*-acetylglucosamine-1-phosphate uridylyltransferase (25); and urate-ribonucleotide phosphorylase (26). 1. #### Uridine 5'-(3-Acetamido-2,6-anhydro-1,3-dideoxy-D-arabino-hept-2-enitol-1-yl phosphono)-Phosphate

This phosphinate-containing bisubstrate analogue ( $F_{W_{free-acid}} = 603.6$  g/mol) inhibits UDP-acetylglucosamine 2-epimerase by mimicking the transition state for the second step of the reaction. To mimic the assumed first transition state of this reaction, novel UDP-exo-glycal derivatives were designed and synthesized. (See Uridine 5'-[(Z)-3-Acetamido-2,6-anhydro-1,3-dideoxy-D-gluco-hept-1-enitol-1-yl phosphono] Phosphate) **1.** Stolz, Reiner, Blume, Reutter & Schmidt (2004) *J. Org. Chem.* **69**, 665.

**Uridine 6-Carboxylate**, See *Orotidine*

**Uridine 2',3'-Dialdehyde 5'-Diphosphate**, See *Uridine 5'-Diphosphate 2',3'-Dialdehyde*

#### Uridine 5'-Diphosphate

This pyrimidine nucleotide ( $F_{W_{free-acid}} = 404.16$  g/mol), abbreviated UDP, is a biosynthetic precursor of UTP and serves as the activating group in many nucleoside diphospho-sugars. UDP absorbs ultraviolet light strongly ( $\lambda_{max}$  is 262 nm with  $\epsilon = 10000$   $M^{-1}cm^{-1}$  at pH 2 and 7; and  $\lambda_{max} = 261$  nm,  $\epsilon = 7900$   $M^{-1}cm^{-1}$  at pH 11). Note: UDP is a product of many glycosyltransferase reactions and acts as a product inhibitor. UDP is also an alternative substrate of guanosine-diphosphatase. **Target(s):**  $\alpha$ -N-acetylglactosaminide  $\alpha$ -2,6-sialyltransferase (1); N-acetylglucosaminyl-diphosphodolichol N-acetylglucosaminyltransferase (2);  $\alpha$ -N-acetylneuraminide  $\alpha$ -2,8-sialyltransferase, weakly inhibited (76); adenine phosphoribosyltransferase, weakly inhibited (83); adenylosuccinate synthetase (3); alcohol

O-cinnamoyltransferase (96); amidophosphoribosyltransferase, weakly inhibited (80); *Bacillus subtilis* ribonuclease, weakly inhibited (41); bis(5'-nucleosyl)-tetraphosphatase (39); [branched-chain  $\alpha$ -keto-acid dihydrogenase] kinase, or [3-methyl-2-oxobutanoate dehydrogenase (acetyltransfering)] kinase (50); carbamoyl-phosphate synthetase (glutamine-hydrolyzing) (5-7); CDP-diacylglycerol:inositol 3-phosphatidyltransferase (56,57); chitobiosyldiphospho-dolichol  $\beta$ -mannosyltransferase (2); CMP-N-acetylneuraminide phosphodiesterase (43); cytidylate kinase (63); deoxycytidine kinase (8,9,65-69); deoxyguanosine kinase (10); diacylglycerol kinase (64); dolichyl-phosphate  $\beta$ -D-mannosyltransferase (91); dUTP diphosphatase (37); fructose-1,6-bisphosphatase (47-49); galactolipid galactosyltransferase (87);  $\beta$ -galactoside  $\alpha$ -2,3-sialyltransferase (1); 1,3- $\beta$ -D-glucan synthase (11,12); glucomannan 4- $\beta$ -mannosyltransferase, weakly inhibited (93); glucose-6-phosphate dehydrogenase, weakly inhibited (35); glucuronokinase (70); glycogen phosphorylase (94,95); glycogen synthase (13,14); glycolipid 2- $\alpha$ -mannosyltransferase, weakly inhibited (89); glycolipid 3- $\alpha$ -mannosyltransferase, weakly inhibited (88); glycoprotein 3- $\alpha$ -L-fucosyltransferase, weakly inhibited (84-86); glycoprotein 6- $\alpha$ -L-fucosyltransferase (92); hexokinase, weakly inhibited (71-74); hypoxanthine(guanine) phosphoribosyltransferase, weakly inhibited (83); lactosyl-ceramide  $\alpha$ -2,3-sialyltransferase (75); [3-methyl-2-oxobutanoate dehydrogenase, or [branched-chain  $\alpha$ -keto-acid dehydrogenase] phosphatase (4,45); NAD<sup>+</sup> diphosphatase (38); nicotinate-nucleotide diphosphorylase (carboxylating), weakly inhibited (79); 5'-nucleotidase (15); nucleotide diphosphatase (40); oligonucleotidase (42); orotate phosphoribosyltransferase (16,81); orotidylate decarboxylase (17); phosphodiesterase I, or 5'-exonuclease (44); phosphoglucomutase (17); phosphoprotein phosphatase (46); procollagen galactosyltransferase (19); [protein-PII] uridylyltransferase (59); protein xylosyltransferase (77); pyruvate,orthophosphate dikinase (51); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (18,60-62); sucrose:sucrose fructosyltransferase (90); UDP-N-acetylglucosamine: dolichyl-phosphate N-acetylglucosaminephosphotransferase (54,55); UDP-N-acetylglucosamine 2-epimerase (20,28,29); UDP-N-acetylglucosamine:lysosomal-enzyme N-acetyl-glucosaminephosphotransferase (21,52,53); UDP-galactopyranose mutase (22); UDP-glucose 4-epimerase, inhibition often enhanced in the presence of a sugar (23,33,34); UDP-glucuronate decarboxylase (24-26,36); UDP-glucuronate 4-epimerase (27,30-32); undecaprenyl-phosphate galactose phosphotransferase, weakly inhibited (58); uracil phosphoribosyltransferase (82); and xanthine phosphoribosyltransferase (78); competitive antagonist at P2Y<sub>14</sub> receptors,  $K_i = 2$  nM (no antagonist activity was observed with ADP, CDP, or GDP, and other uracil analogs) (97). **1.** Sadler, Beyer, Oppenheimer, et al. #### Uridine 5'-Diphosphate Chloroacetyl

This modified nucleotide ( $FW_{\text{free-acid}} = 494.67$  g/mol) is an irreversible inhibitor of *Escherichia coli* UDPgalactose 4-epimerase:  $K_D = 0.110$  mM and  $k_{\text{inact}} = 0.84$  min<sup>-1</sup> at pH 8.5. A nucleotide-NAD<sup>+</sup> adduct is proposed to form via alkylation of the nicotinamide ring by the chloroacetyl enolate. **Target(s):** UDP-glucose dehydrogenase (1); UDP-glucose 4-epimerase, or UDP-galactose 4-epimerase (2). **1.** Campbell, Sala, I. van de Rijn & Tanner (1997) *J. Biol. Chem.* **272**, 3416. **2.** Flentke & Frey (1990) *Biochemistry* **29**, 2430.

#### Uridine 5'-Diphosphate 2',3'-Dialdehyde

This UDP derivative ( $FW_{\text{free-acid}} = 402.15$  g/mol), which is readily generated by treating UDP with stoichiometric amounts of periodate, followed by incubation with 0.1 M ethylene glycol to inactivate any unreacted periodate, binds to and irreversibly modifies several enzymes. **Target(s):** galactosyltransferase (1); lactosylceramide  $\alpha$ -2,3-sialyltransferase, or CMP-*N*-acetylneuraminyl:lactosylceramide ( $\alpha$ 2 $\rightarrow$ 3) sialyltransferase (2); sterol 3 $\beta$ -glucosyltransferase (3); UDP-*N*-acetylglucosamine 2-epimerase (4). **1.** Powell & Brew (1976) *Biochemistry* **15**, 3499. **2.** Cambron & Leskawa (1993) *Biochem. #### Uridine 2'-Monophosphate

This nucleotide ( $FW_{\text{free-acid}} = 324.18$  g/mol), which is obtained upon hydrolysis of RNA, is slightly more labile than 5'-UMP under alkaline conditions. 2'-UMP absorbs light strongly in the ultraviolet region of the spectrum ( $\lambda_{\text{max}}$  is 260 nm with  $\epsilon = 9900$  and  $10000$  M<sup>-1</sup>cm<sup>-1</sup> at pH 2 and 7, respectively; and  $\lambda_{\text{max}} = 261$  nm,  $\epsilon = 7300$  M<sup>-1</sup>cm<sup>-1</sup> at pH 12). **Target(s):** 2',3'-cyclic-nucleotide 3'-phosphodiesterase (1); pancreatic ribonuclease, or ribonuclease A (2-4); ribonuclease M (5); ribonuclease Rh (5); ribonuclease T<sub>1</sub> (6); ribonuclease T<sub>2</sub> (5,7). **1.** Díaz & Heredia (1996) *Biochim. ## Uridine 3'-Monophosphate

This nucleotide ( $FW_{\text{free-acid}} = 324.18 \text{ g/mol}$ ) is obtained as the limit-hydrolysate of RNase action and upon hydrolysis of RNA under alkaline conditions. Uridine 3'-Monophosphate is stable under alkaline conditions (e.g., 0.3 M KOH at 37°C for 16 hours). 3'-UMP absorbs light strongly in the ultraviolet region of the spectrum ( $\lambda_{\text{max}}$  is 262 nm with  $\epsilon = 10000 \text{ M}^{-1}\text{cm}^{-1}$  at pH 1 and 7; and  $\lambda_{\text{max}} = 261 \text{ nm}$ ,  $\epsilon = 7800 \text{ M}^{-1}\text{cm}^{-1}$  at pH 13).

**Target(s):** pancreatic ribonuclease, or ribonuclease A (1-3); phosphodiesterase I, or 5'-exonuclease, weakly inhibited (4); ribonuclease M (5); ribonuclease Rh (5); ribonuclease T<sub>1</sub> (6); ribonuclease T<sub>2</sub> (5,7); and ribose-5-phosphate isomerase (8). 1. ## Uridine 5'-Monophosphate

This nucleotide ( $FW_{\text{free-acid}} = 324.18 \text{ g/mol}$ ), a key intermediate in the biosynthesis of UTP, is produced by the action of orotidylate decarboxylase (on which UMP acts as a product inhibitor) and in a salvage pathway from uridine. UMP absorbs light strongly in the ultraviolet region of the spectrum ( $\lambda_{\text{max}}$  is 262 nm with  $\epsilon = 10000 \text{ M}^{-1}\text{cm}^{-1}$  at pH 2 and 7; and  $\lambda_{\text{max}} = 261 \text{ nm}$ ,  $\epsilon = 7800 \text{ M}^{-1}\text{cm}^{-1}$  at pH 11). **Target(s):**  $\alpha$ -N-acetylglucosaminidase  $\alpha$ -2,6-sialyl-transferase (1); N-acetylglucosaminyl-diphospho-dolichol N-acetylglucosaminyltransferase (2,96,97); N-acetylglucosaminyl-diphospho-undecaprenol N-acetyl- $\beta$ -D-mannos-aminyltransferase, weakly inhibited (90);  $\beta$ -N-acetyl-glucosaminylglycopeptide  $\beta$ -1,4-galactosyltransferase (112); N-acetylglucosaminyl synthase (102); N-acetyl-lactosaminidase  $\beta$ -1,6-N-acetylglucosaminyltransferase (95);  $\alpha$ -N-acetylneuraminidase  $\alpha$ -2,8-sialyltransferase, weakly inhibited (78); adenylyl-sulfate kinase (74); adenylyl-sulfate kinase (74); amidophosphoribosyltransferase, weakly inhibited (82); D-amino-acid oxidase (4); AMP Nucleosidase (51); asparagine synthetase, weakly inhibited (5); aspartate carbamoyltransferase (6-8); carbamate kinase (9); carbamoyl-phosphate synthetase II (glutamine-hydrolyzing) (10-15,37); CDP-diacylglycerol diphosphatase, weakly inhibited (46); cellulose synthase (UDP-forming) (119,120); chitin synthase (117); CMP-N-acetylneuraminidase phosphodiesterase (55,56); cytidylate kinase, alternative substrate inhibition (71); deoxycytidine kinase (73); deoxyguanosine kinase (72); diacylglycerol choline-phosphotransferase, weakly inhibited (65); dihydroorotase (16); dolichyl phosphate  $\beta$ -glucosyltransferase (17,98,99); dolichyl-phosphate  $\beta$ -D-mannosyltransferase (104); ethanolaninephosphotransferase, weakly inhibited (65); FAD diphosphatase, weakly inhibited

(47); fructokinase (75); fructose-1,6-bisphosphatase (61); galactolipid galactosyltransferase (91);  $\beta$ -galactosidase  $\alpha$ -2,3-sialyl-transferase (1); globoside  $\alpha$ -N-acetylglucosaminyl-transferase (103); 1,3- $\beta$ -glucan synthase (113,114); glucuronosyltransferase (16); glutamine synthetase (38); glycogen synthase (18-22,121,122); glycoprotein-fucosyl-galactosidase  $\alpha$ -N-acetylglucosaminyltransferase (1,110, 111); hexokinase, weakly inhibited (76,77); hyaluronan synthase (87); hydroxyacylglutathione hydrolase, or glyoxalase II (45); lactose synthase (23); lactoylglutathione lyase, or glyoxalase I (45);  $\alpha$ -1,3-mannosyl-glycoprotein 2- $\beta$ -N-acetylglucosaminyltransferase (1,24,100); NDP-glucose:starch glucosyltransferase (85); natigenin  $\beta$ -glucosyltransferase (89); nucleotide diphosphatase, weakly inhibited (48-50); 1,3- $\beta$ -oligoglucan phosphorylase (115); oligonucleotidase (54); orotate phosphoribosyltransferase (25,83); pancreatic ribonuclease, or ribonuclease A (26); phosphodiesterase I, or 5'-exonuclease (57-59); phosphoprotein phosphatase (60); 5-phosphoribosylamine synthetase, or ribose-5-phosphate:ammonia ligase, weakly inhibited (27); polygalacturonate 4- $\alpha$ -galacturonosyl-transferase (106); polypeptide N-acetylglucosaminyl-transferase (107-109); procollagen galactosyltransferase (105); protein N-acetylglucosaminyltransferase (101); [protein-P<sub>II</sub>] uridylyltransferase (66,67); protein xylosyl-transferase (79); pyrimidine-nucleoside phosphorylase (28); retinyl-phosphate glycosyltransferase (29); ribonuclease T<sub>2</sub> (53); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (69,70); ribose-5-phosphate isomerase (39); sarsapogenin  $\beta$ -glucosyltransferase (88); [Skp1-protein]-hydroxyproline N-acetylglucosaminyl-transferase (86); sphingomyelin phosphodiesterase, or sphingomyelinase (30); sterol  $\beta$ -glucosyltransferase (92,93); sucrose 6'- $\alpha$ -galactosyltransferase (94); sucrose synthase (31);  $\alpha$ , $\alpha$ -trehalose-phosphate synthase (118); UDP-N-acetylglucosamine diphosphorylase, or N-acetylglucosamine-1-phosphate uridylyltransferase (68); UDP-N-acetylglucosamine: dolichyl-phosphate N-acetylglucosaminophosphotransferase (62,63); UDP-N-acetylglucosamine 2-epimerase (32); UDP-glucose 4-epimerase, inhibition often enhanced in the presence of a sugar (33,42-44); UDP-glucuronate decarboxylase (34,35); UDP-glucuronate 4-epimerase (36,40,41); undecaprenyl-phosphate galactose phosphotransferase (64); uridine Nucleosidase (52); and 1,4- $\beta$ -D-xylan synthase (80,81). 1. ### Uridine 5'-Monophosphoric (1-Hexadecane-sulfonic) Anhydride

This UMP derivative ( $FW_{\text{free-acid}} = 612.68$  g/mol), also known as UMP-hexadecanesulfonic anhydride, inhibits pig polypeptide *N*-acetylgalactosaminyltransferase,  $IC_{50} = 160$   $\mu\text{M}$  (1). *Note:* Because this substance readily forms micelles, one must take care to discriminate whether the monomeric and/or micelle form(s) is(are) inhibitory, when present at concentrations above the critical micelle concentration (*cmc*). **1.** Hatanaka, Slama & Elbein (1991) *Biochem. Biophys. Res. Commun.* **175**, 668.

### Uridine 5'-Triphosphate

This pyrimidine nucleotide ( $FW_{\text{free-acid}} = 484.14$  g/mol) is a precursor in the biosynthesis of CTP, nucleic acids, and nucleotide sugars. UTP activates chloride channels in epithelial cells. Solid sodium and potassium salts of UTP are very soluble in water. The phosphoanhydride bonds are labile in acids (e.g., UTP is hydrolyzed quantitatively in fifteen minutes at  $100^\circ\text{C}$  in  $0.1$  N  $\text{H}_2\text{SO}_4$ , forming UMP and orthophosphate); the phosphate ester bond is not as labile. UTP absorbs light strongly in the ultraviolet region of the spectrum ( $\lambda_{\text{max}} = 262$  nm with  $\epsilon = 10000$   $\text{M}^{-1}\text{cm}^{-1}$  at pH 2 and 7; and  $\lambda_{\text{max}} = 261$  nm,  $\epsilon = 8100$   $\text{M}^{-1}\text{cm}^{-1}$  at pH 11). UTP forms tight complexes with many metal ions. The stability constants are reported to be similar to those for ATP (1), for which stability constants are for 73000, 35000, and 100000  $\text{M}^{-1}$  for  $\text{MgATP}^{2-}$ ,  $\text{CaATP}^{2-}$ , and  $\text{MnATP}^{2-}$ , respectively. **Target(s):**  $\alpha$ -*N*-acetylgalactosaminide  $\alpha$ -2,6-sialyltransferase (2); *N*-acetylglucosamine kinase (3,138); *N*-acetylglucosamine-6-phosphate deacetylase (94); *N*-acetylglucosaminidiphosphodolichol *N*-acetylglucos-aminyltransferase (178,179); *N*-acetylglucosaminide  $\beta$ -1,6-*N*-acetylglucosaminyltransferase (177); *N*-acetylneuraminide cytidyltransferase (111);  $\alpha$ -*N*-acetylneuraminide  $\alpha$ -2,8-sialyltransferase, weakly inhibited (155); adenylate cyclase (73); adenylsulfatase (78); amidophosphoribosyl-transferase, weakly inhibited (4,165); AMP deaminase (88); arylsulfate sulfotransferase (5); asparagine synthetase (64); aspartate carbamoyltransferase (6-10); ATP:citrate lyase (210); carbamate kinase (12); carbamoyl-phosphate synthetase (glutamine-hydrolyzing) (13-18); CDP-diacylglycerol:inositol 3-phosphatidyltransferase (108,109); cellulose synthase (UDP-forming) (19,204,205); chitin synthase (193-196); citrate (*sr*)-synthase, weakly inhibited (211); CMP-*N*-acetylneuraminide phosphodiesterase (97); 3',5'-cyclic-nucleotide phosphodiesterase (20,21); cytidine deaminase (22,89-91); cytidylate kinase (23,129); cytosine deaminase (92,93); deoxycytidine kinase (135); deoxyguanosine kinase (130,131); diacylglycerol kinase (24,132); dCMP deaminase, weakly inhibited (87); dolichyl-phosphate  $\beta$ -*D*-mannosyltransferase (183); exopolyphosphatase (80); 5'→3' exoribonuclease (25); flavanone 7-*O*-glucoside 2''-*O*- $\beta$ -*L*-rhamnosyltransferase (169); flavanone 7-*O*- $\beta$ -glucosyltransferase (173);  $\beta$ -fructofuranosidase, or invertase (95); fructose-1,6-bisphosphatase (26,105); fumarase (27);  $\beta$ -galactoside  $\alpha$ -2,3-sialyltransferase (2,156);  $\beta$ -galactoside  $\alpha$ -2,6-sialyltransferase (157); 1,3- $\beta$ -glucan synthase (189,190); glucokinase, also poor alternative substrate (150,151); glucomannan 4- $\beta$ -mannosyltransferase, weakly inhibited (191); glucose-1-phosphate cytidyltransferase (115); glucose-6-phosphate dehydrogenase (28,74); glucuronosyl-transferase (192); [glutamine-synthetase] adenyltransferase (29,112,113); glycogen synthase (30-32,206-208); glycolipid 3- $\alpha$ -mannosyltransferase, weakly inhibited (180); glycoprotein-fucosyl-galactoside  $\alpha$ -*N*-acetylgalactos-aminyltransferase (2); GTP cyclohydrolase (183-86); guanylate cyclase (33,71,72); hexokinase (34); hyaluronan

- synthase (35,171); hydroxyacylglutathione hydrolase, *or* glyoxalase II (75); 5-hydroxypentanoate CoA-transferase, weakly inhibited (82); *myo*-inositol oxidase (36); isocitrate dehydrogenase (NAD<sup>+</sup>) (37,38); lactose synthase (39); lactoylglutathione lyase (glyoxalase I) (75);  $\alpha$ -1,3-mannosylglycoprotein 2- $\beta$ -N-acetylglucosaminyl-transferase (2,40,181); membrane dipeptidase, *or* renal dipeptidase (41); methionine S-adenosyltransferase (152,153); [3-methyl-2-oxobutanoate dehydrogenase (2-methylpropanoyl-transferring)] phosphatase, *or* [branched-chain  $\alpha$ -ketoacid dehydrogenase] phosphatase (11,101); multiple inositol-polyphosphate phosphatase, *or* inositol-1,3,4,5-tetrakisphosphate 3-phosphatase (100); NAD<sup>+</sup> diphosphatase (79); NADH peroxidase (42); NAD(P)H dehydrogenase (43); nicotinate glucosyltransferase (172); nicotinate-nucleotide diphosphorylase (carboxylating) (163,164); nicotinate phosphoribosyltransferase, weakly inhibited (166); nucleotidases (80); 3'-nucleotidase (80); 5'-nucleotidase (44-46,80); nucleotide diphosphatase (81); oligonucleotidase, weakly inhibited (96); orotate phosphoribosyltransferase (47); orotidylate decarboxylase (47); phosphatidate cytidyltransferase (114); 1-phosphatidylinositol 4-kinase (136,137); phosphodiesterase I, *or* 5'-exonuclease (98,99); phosphoenolpyruvate carboxylase (77); 1-phosphofructokinase (139); 6-phosphofructokinase (148,149); phosphoglucomutase (48,65,66); phosphopantothenoylcysteine decarboxylase (49,76); phosphoprotein phosphatase (103,104); phosphorylase kinase, weakly inhibited (106); [phosphorylase] phosphatase (102); polygalacturonate 4- $\alpha$ -galacturonosyltransferase (185,186); polynucleotide adenyltransferase, *or* poly(A) polymerase (51,52,116-118); polynucleotide 5'-hydroxyl-kinase (133,134); polypeptide N-acetylglucosaminyltransferase (187,188); porphobilinogen synthase ( $\delta$ -aminolevulinic acid dehydratase) (53); procollagen glucosyltransferase (54,184); protein N-acetylglucosaminyltransferase (182); protein-glutamine  $\gamma$ -glutamyltransferase, *or* transglutaminase (212); protein xylosyltransferase (159); pyruvate carboxylase (55); pyruvate kinase (146,147); ribose-5-phosphate diphosphokinase, *or* phosphoribosyl-pyrophosphate synthetase (50,119,120); [Skp1-protein]-hydroxyproline N-acetylglucosaminyltransferase (170); starch phosphorylase (209); sterol 3 $\beta$ -glucosyltransferase (174-176); sucrose-phosphate synthase (198-200); sucrose synthase (56,201-203); thiamin-phosphate diphosphorylase (57,154);  $\alpha$ , $\alpha$ -trehalose-phosphate synthase (UDP-forming) (197); UDP-N-acetylglucosamine 2-epimerase (67); UDP-N-acetylglucosamine:lysosomal enzyme N-acetylglucosamine-phosphotransferase (107); UDP-glucose 4-epimerase (58,69,70); UDP-glucuronate decarboxylase (59); UDP-glucuronate 4-epimerase (60,68); UMP kinase (121-128); undecaprenyl-phosphate galactose phospho-transferase, weakly inhibited (110); uracil phosphoribosyl-transferase (167,168); uridine kinase (23,61-63,140-145); xanthine phosphoribosyltransferase (162); 1,4- $\beta$ -D-xylan synthase (160,161); xyloglucan 4-glucosyltransferase (158); and xyloglucan 6-xylosyltransferase (158). 1. #### Uridine-Vanadate Complex

This somewhat unstable one-to-one complex of uridine and vanadium(V) forms and remains bound within the active site of pancreatic ribonuclease, showing moderate affinity, with a  $K_i$  value of 0.45  $\mu\text{M}$  (1-4). When ribonuclease A is exposed to mixture of 10 mM uridine and 0.1 mM vanadium(V) at pH 7 complex formation results in occupancy of about 80% of the enzyme. The structure shown above is based on experiments employing vanadium NMR, X-ray crystallography, and neutron diffraction. Note that some minor distortion of the trigonal bipyramid geometry has been reported. **Target(s):** pancreatic ribonuclease, or ribonuclease A (1-3); and yeast Pac1 ribonuclease (4). **1.** Lindquist, Lynn & Lienhard (1973) *J. #### 5'-Uridylcobalamin, See 5'-Deoxyuridylcobalamin

#### URMC-099

This orally bioavailable, brain-penetrant MLK inhibitor (FW = 421.54 g/mol; CAS 1229582-33-5), also named 3-(1H-indol-5-yl)-5-[4-(4-methyl-1-piperazinyl)methyl]phenyl]-1H-pyrrolo[2,3-b]pyridine, targets the Mixed Lineage Kinases (with  $\text{IC}_{50}$  values of 19 nM, 42 nM, and 14 nM for MLK1, MLK2, and MLK3) as well as DLK ( $\text{IC}_{50}$  = 150 nM) (1). It also inhibits Leucine-Rich Repeat Kinase 2 (LRRK2), a novel regulator of microglial phagocytosis (2). MLK3 activation is associated with many of the pathologic hallmarks of HIV-associated neurocognitive disorders, making this enzyme a prime target for adjunctive therapy using small-molecule kinase inhibitors. **1.** Marker, Tremblay, Puccini, *et al.* (2013) *J. Neurosci.* **33**, 9998. **2.** Goodfellow, Loweth, Ravula, *et al.* (2013) *J. Med. Chem.* **56**, 8032.

## Urocanate

This metabolite ( $FW_{\text{zwitterion}} = 138.13$  g/mol), also known as 4-imidazoleacrylic acid, is an intermediate in the degradation of L-histidine. Urocanate has *cis* and *trans* isomers, and the *trans*-isomer is the product of histidine ammonia-lyase. *trans*-Urocanic acid has  $pK_a$  values at 25°C of 3.5 and 5.8 whereas the *cis*-isomer has values of 3.0 and 6.7. Irradiation of *trans*-urocanate with ultraviolet light will generate *cis*-urocanate. **Target(s):** histidine decarboxylase (1-4). 1. Huynh & Snell (1986) *J. Biol. Chem.* **261**, 4389. 2. Snell (1986) *Meth. Enzymol.* **122**, 128. 3. Snell & Guirard (1986) *Meth. Enzymol.* **122**, 139. 4. Yamagata & Snell (1979) *Biochemistry* **18**, 2964.

## [Orn5]-URP

This ornithine-containing urotensin analogue ( $FW = 1003.20$  g/mol; CAS 782485-03-4; Solubility: 1 mg/mL H<sub>2</sub>O) retains much of receptor binding affinity ( $EC_{50} = 75$  nM) of Urotensin II (UII), the most potent endogenous vasoconstricting peptide ligand of the orphan G-protein-coupled urotensinergic receptor GPR14 (1). [Orn5]-URP behaves as a pure antagonist (*i.e.*, exerts zero agonist action) in both rat aortic ring contraction and astrocyte cytosolic calcium ion concentration mobilization assays (2). 1. ## Ursodeoxycholate

This bile acid ( $FW_{\text{free-acid}} = 392.58$  g/mol; CAS 128-13-2; slightly water-soluble), also known as ursodiol and 3 $\alpha$ ,7 $\beta$ -dihydroxy-5 $\beta$ -cholanoic-24-acid, found in relatively high concentrations in bear bile (as is its taurine conjugate) and humans, inhibits bilirubin UDP-glucuronosyltransferase (1); glycochenodeoxycholate sulfotransferase (2-4); and pepsin (5). 1. Sanchez Pozzi, Luquita, Catania, Rodriguez Garay & Mottino (1994) *Life Sci.* **55**, 111. 2. Barnes, Buchina, King, McBurnett & Taylor (1989) *J. Lipid Res.* **30**, 529. 3. ## Ursolate (Ursolic Acid)

This naturally occurring pentacyclic triterpenoid carboxylate ( $FW_{\text{free-acid}} = 456.71$  g/mol; CAS 77-52-1; IUPAC: 3 $\beta$ -hydroxyurs-12-en-28-oiic acid) is widely distributed in leaves and in the skins of fruits (*e.g.*, in the waxy skin layer of apples, pears, cherries, and cranberries), appearing as the free acid, as esters, or as a saponin component. Ursolic acid is slightly soluble in methanol, moderately soluble in acetone, and has a very low solubility in water. Ursolic acid inhibits intracellular trafficking of proteins and reduces IL-1 $\alpha$ -induced cell-surface ICAM-1 expression in human cancer cell lines and human umbilical vein endothelial cells (1). By contrast, ursolic acid exerts weak inhibitory effects on the IL-1 $\alpha$ -induced ICAM-1 expression at the protein level. Remarkably, ursolic acid decreases the apparent molecular weight of ICAM-1 and altered the structures of ICAM-1-bound *N*-linked oligosaccharides. Upon treatment of cells with ursolic acid, high-mannose-type glycan-containing ICAM-1 accumulates in the ER, and the Golgi apparatus is fragmented into pieces and distributed throughout the cells (1). *Note:* Corosolic acid (*or* 2 $\alpha$ -hydroxyursolic acid), a pentacyclic triterpene acid from *Lagerstroemia speciosa*, is likely to have similar inhibitory targets. **Target(s):**  $\alpha$ -amylase (2); cAMP-dependent protein kinase (3); chitin synthase II (4); DNA-directed DNA polymerase (6-9); human DNA ligase (ATP),  $IC_{50} = 216$   $\mu$ M (5); DNA polymerase  $\alpha$  (6,7); DNA polymerase  $\beta$  (6-8); DNA topoisomerase I (6,9); DNA topoisomerase II (6,7,9); elastase (10-12); glycogen phosphorylase (13); HIV-1 retropepsin (14-16); leukocyte elastase (11,12); 5-lipoxygenase (17); 15-lipoxygenase (17); plant DNA polymerase II (6); and protein-tyrosine-phosphatase 1B (18,19). 1. Ursolate  $\beta$ -D-Glucopyranosyl Ester

This triterpene glycoside ( $FW = 618.85$  g/mol) inhibits rabbit muscle glycogen phosphorylase ( $IC_{50} = 97$   $\mu$ M). X-ray analysis revealed that this inhibitor binds at AMP allosteric activator site, making it and related compounds promising antidiabetic agents by exerting hypoglycemic effects, through inhibition of glycogenolysis. 1. Wen, Sun, Liu, *et al.* (2008) *J. Med. Chem.* **51**, 3540.

**Ursonate (Ursonic Acid)**

This triterpene (FW<sub>free-acid</sub> = 454.69 g/mol) inhibits rabbit muscle glycogen phosphorylase (IC<sub>50</sub> = 57 μM) by binding to the allosteric activator site for AMP. **1.** Wen, Sun, Liu, *et al.* (2008) *J. Med. Chem.* **51**, 3540.

**Urushiols**

- R** =  $-(\text{CH}_2)_{14}\text{CH}_3$   
**R** =  $-(\text{CH}_2)_7\text{CH}=\text{CH}(\text{CH}_2)_5\text{CH}_3$

**R** =  $-(\text{CH}_2)_7\text{CH}=\text{CHCH}_2\text{CH}=\text{CHCH}=\text{CHCH}_3\text{CH}_3$   
**R** =  $-(\text{CH}_2)_7\text{CH}=\text{CHCH}_2\text{CH}=\text{CHCH}_2\text{CH}=\text{CH}_2$

These skin-adherent oleo-resins (CAS 53237-59-5) and closely related substances are oily plant catechols that give rise to plant-associated allergic contact dermatitis resulting from contact of skin and clothing with the leaves, stems and fruit of poison ivy, poison oak, and poison sumac (1,2). Based on a thorough examination of the effects of various leaf extract constituents (3), the following compounds were found to be strong allergens: 3-pentadecyl catechol, 4-pentadecyl catechol, "urushiol" dimethyl ether, 3-pentadecenyl-1'-veratrole, 3-methyl catechol, and hydrourushiol dimethyl ether. **Mechanism of Action:** Poison oak urushiols consist of catechol rings with a hydrocarbon side chain at the 3-position. Most poison oak urushiols have 17-carbon chains containing 1–3 double bonds. Their long side-chains facilitate adsorption to the lipid-rich epidermis, allowing subsequent, deeper penetration into the dermis itself. Polyunsaturated side-arms are associated with the most severe allergic responses. An oxidized form of the catechol ring is thought to be responsible for adduct formation with target proteins, which then undergo proteolysis to form the true immunogen. Shortening of the aliphatic chain by β-oxidation (within peroxisomes and/or mitochondria) may also be required for antigen presentation. In this respect, the active agent responsible for severe dermatitis is not urushiol *per se*. Instead, the immunogen is a combination of an urushiol (acting as a hapten) and one or more self proteins (acting as an immunoadjuvant). This mechanism accounts for delayed eruption, beginning at sites of greatest exposure and only later at less affected sites. **1.** Symes & Dawson (1953) *Nature* **171**, 841. **2.** Byck & Dawson (1967) *J. Org. Chem.* **32**, 1084. **3.** Keil, Wasserman & Dawson (1944) *J. Exp. Med.* **80**, 275.

**Usnate (Usnic Acid)**

This dibenzofuranone (FW = 344.32 g/mol; CAS 125-46-2) is found both as (+)- and (–)-stereoisomers in a number of lichens: occur in nature. (+)- and (–)-Usnic acid exhibits low solubility in water, but recrystallize as yellow orthorhombic prisms from acetone (solubility of 0.77 g/100 mL at 25°C). **Target(s):** deoxyribonuclease I in the presence of Co<sup>2+</sup> (1); plant 4-hydroxyphenylpyruvate dioxygenase (2); oxidative phosphorylation, uncoupler (3); protophorphyrinogen oxidase (2); and urease (4,5). **See Uncouplers** **1.** McDonald (1955) *Meth. Enzymol.* **2**, 437. **2.** Romagni, Meazza, Nanayakkara & Dayan (2000) *FEBS Lett.* **480**, 301. **3.** Abo-Khatwa, al-Robai & al-Jawhari (1996) *Nat. Toxins* **4**, 96. **4.** Cifuentes, Garcia & Vicente (1983) *Z. Naturforsch. [C]* **38**, 273. **5.** Garcia, Cifuentes & Vicente (1980) *Z. Naturforsch. [C]* **35**, 1098.

**Ussuristatins**

These 71-residue, cysteine-rich disintegrins from the Chinese viper *Agkistrodon ussuriensis* contain a KGD loop that facilitates tight binding to integrins. Ussuristatin 1 inhibits platelet aggregation as well as platelet adhesion to fibronectin, IC<sub>50</sub> = 17–33 nM. **1.** Oshikawa & Terada (1999) *J. Biochem.* **125**, 31.

**Ustiloxins**

These structurally related cyclic peptides (FW<sub>Ustilotoxin-A</sub> = 673.73 g/mol; CAS 143557-93-1), designated Ustilotoxins A through F, from the rice pathogen *Ustilaginoida vires* inhibit tubulin polymerization by binding to a sub-site of the Vincblastine site that can also be occupied by phomopsis A and rhizoxin (1). Ustilotoxin A and B share the same cyclic peptide nucleus and R<sub>1</sub> side-chain (*e.g.*,  $-\text{S}(\text{O})\text{CH}_2\text{CH}(\text{OH})\text{CH}_2\text{CH}(\text{NH}_3^+)\text{COO}^-$ ), but differ with respect to R<sub>2</sub> (*i.e.*, Ustilotoxin A possessing  $-\text{CH}(\text{CH}_3)_2$  and Ustilotoxin B possessing  $-\text{CH}_3$  side-chains). Ustilotoxin C has the same cyclic peptide nucleus with R<sub>1</sub> =  $-\text{S}(\text{O})\text{CH}_2\text{CH}_2\text{OH}$  and R<sub>2</sub> =  $-\text{CH}_3$  side-chains, respectively. Ustilotoxin D likewise has the same cyclic peptide nucleus, but R<sub>1</sub> =  $-\text{H}$  and R<sub>2</sub> =  $-\text{CH}(\text{CH}_3)_2$ . **1.** Li, Koiso, Kobayashi, Hashimoto & Iwasaki (1995) *Biochem. Pharmacol.* **49**, 1367. **2.** Ranaivoson, Gigant, Berritt, Joullié & Knossow (2012) *Acta Crystallogr. D Biol. Crystallogr.* **68**, 927.

**Ustekinumab**

This human monoclonal antibody (MW = 145.64 kDa; CAS 815610-63-0), also known as Stelara®, binds to the shared p40 subunit of interleukin (IL)-12 and IL-23, blocking signaling of their cognate receptors. It is approved for the treatment of moderate to severe plaque psoriasis and also shows promise for treating sarcoidosis. Indeed, extensive immunologic and genomic research identified IL-12 and IL-23 of the Th1 and Th17 inflammatory pathways, respectively, as key mediators in psoriasis, a complex, multigenic immune/inflammatory-mediated disorder that variably affects the skin, nails, and joints.

**Uteroglobin**

This low-MW protein, also known as blastokinin, is a secretoglobin family 1A member 1 (SCGB1A1) that strongly inhibits phospholipase A<sub>2</sub> (1–4). UG is a secreted, disulfide-bridged, progesterone-induced homodimer with structural similarity with phospholipase A<sub>2</sub> and other PLA<sub>2</sub> inhibitory proteins like the lipocortins. These properties suggest that its physiological function as a PLA<sub>2</sub> inhibitor may be mainly immunomodulatory (5). **1.** Chowdhury, Mantile-Selvaggi, Kundu, *et al.* (2000) *Ann. N. Y. Acad. Sci.* **923**, 307. **2.** Miele, Cordella-Miele, Mantile, Peri & Mukherjee (1994) *J. Endocrinol. Invest.* **17**, 679. **3.** Miele, Cordella-Miele, Facchiano & Mukherjee (1990) *Adv. Exp. ## UVI 3003

This RXR antagonist (FW = 436.58 g/mol; CAS 847239-17-2; Solubility: 100 mM in DMSO; IUPAC Name: 3-[4-hydroxy-3-[5,6,7,8-tetrahydro-5,5,8,8-tetramethyl-3-(pentyloxy)-2-naphthalenyl]phenyl]-2-propenoate) targets the Retinoid X Receptor (*or* RXR), a nuclear receptor that is activated by *9-cis* retinoic acid. Binding of an agonist (referred to as a rexinoid) to the RX Receptor triggers the dissociation of a corepressor and recruitment of coactivator protein, promoting transcription of the downstream target gene into mRNA and eventually protein biosynthesis. The antagonist UVI-3003 does not affect the corepressor interaction capacity of the RAR $\alpha$  subunit within the context of the RAR-RXR heterodimer. **1.** Nahoum, Pérez, Germain, *et al.* (2007) *Proc. Natl. Acad. Sci. U.S.A.* **104**, 17323. **2.** Santin, *et al.* (2009) *J. Med. Chem.* **52**, 3150.

## Uzarin

This cardenolide (FW = 698.81 g/mol; CAS 20231-81-6) from *Gomphocarpus* sp. and the milkweed *Asclepias asperula* inhibits porcine kidney Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase,  $K_d = 4 \mu\text{M}$  (1). **1.** Abbott, Holoubek & Martin (1998) *Biochem. Biophys. Res. Commun.* **251**, 256.

## Vaccenate

These fatty acids (FW<sub>free-acid</sub> = 282.47 g/mol; CAS 1937-63-9), corresponding to *cis* or *trans* isomers of octadec-11-enoic acid, or a mixture thereof, inhibit numerous enzymes. *cis* or (*Z*)-octadec-11-enoic acid (18:1Δ<sup>11</sup>, *cis*), has a melting point of 13.5°C and, while found in many tissues) is the major unsaturated fatty acid of *Escherichia coli*. *trans* or (*E*)-octadec-11-enoic acid (18:1Δ<sup>11</sup>, *trans*), also reported in many tissues, has a melting point of 44°C. **Target(s)**: chondroitin AC lyase (1); chondroitin B lyase (1); Δ<sup>9</sup>-desaturase, by *cis* vaccenate (2); DNA-directed DNA polymerase (3); DNA polymerases α and β, both inhibited by *cis*-vaccenate (3); DNA α-polymerase, inhibited by *trans*-isomer (3); DNA topoisomerase I (4); DNA topoisomerase II (4); hyaluronate lyase (1); 4-hydroxybenzoate nonaprenyltransferase, by *cis*-vaccenate (5); linoleate isomerase, by both *cis*- and *trans*-isomers (6). 1. ## Vadimezan

This vascular-disrupting agent (VDA) and chemotherapeutic agent (FW = 282.30 g/mol; CAS 117570-53-3; λ<sub>max</sub> at 242, 270, and 338 nm), also known by its code names DMXAA and ASA404 as well as its systematic name, 2-(5,6-dimethyl-9-oxo-9H-xanthen-4-yl)acetic acid, is a multi-kinase inhibitor, with anti-VEGFR activity that exerts non-immune-mediated effects on the vasculature (capillary formation and endothelial barrier function), denying the availability of essential nutrients (including O<sub>2</sub>) to the core of solid tumors. Indeed, the tumor vascular endothelium is characterized by increased permeability, abnormal morphology, disorganized vascular networks, and variable density. VDAs induce rapid shutdown of tumor blood supply, causing subsequent tumor death from hypoxia and nutrient deprivation. Vadimezan potently activates the TANK-binding kinase 1-interferon regulatory factor 3 signaling pathway in leukocytes, inducing type-I-interferon production (1-3). In addition, DMXAA significantly inhibits several other kinases in endothelial cells, including the vascular endothelial growth factor receptors VEGFR1 (IC<sub>50</sub> = 119 μM) and VEGFR2 (IC<sub>50</sub> = 11 μM) (4). ASA404 also competitively inhibits DT-diaphorase (*Reaction*: NAD(P)H + H<sup>+</sup> + Quinone ⇌ Substrate NAD(P)<sup>+</sup> + Hydroquinone Product), with a K<sub>i</sub> value of 20 μM and an IC<sub>50</sub> value of 63 μM, respectively, without significantly affecting the activity of cytochrome *b*<sub>5</sub> reductase and cytochrome P450 reductase. When evaluated for their *in vivo* antitumor activity and cytokine production by stromal or cancer cells in xenografts, mono-methyl XAA analogues with substitutions at the seventh and eighth positions were the most active in stimulating IL-6

and IL-8 production in human cell lines, whereas 5- and 6-substituted analogues were the most active in murine systems, highlighting the need to use appropriate *in vivo* animal models in selecting promising clinical candidates (5). 1. Roberts, Goutagny, Perera, *et al.* (2007) *J. Exp. Med.* **204**, 1559. 2. Tang, Aoshi, Jounai, *et al.* (2013) *PLoS One* **8**, e60038. 3. Cancer* **108**, 1306.

## Valdecoxib

This non-steroidal anti-inflammatory agent (FW = 314.36 g/mol; CAS 181695-72-7), also known as Bextra<sup>®</sup> and 4-[5-methyl-3-phenylisoxazol-4-yl]benzenesulfonamide, inhibits cyclooxygenase-2, IC<sub>50</sub> = 5 nM. Concerns about its unacceptable risk of heart attack and stroke led to its voluntary withdrawal from the market in 2005. Indeed, the manufacturer (Pfizer) acknowledged its cardiotoxicity, responsibly suggesting that Bextra cannot be ethically tested in patients at high risk for heart disease. Its water-soluble and injectable prodrug Parecoxib (FW = 370.42 g/mol; CAS 202409-33-4; IUPAC: *N*-{[4-(5-methyl-3-phenylisoxazol-4-yl)phenyl]-sulfonyl} propanamide) is sold as Dynastat<sup>®</sup> in the European Union. 1. Talley, Brown, Carter, *et al.* (2000) *J. Med. Chem.* **43**, 775.

**Valepotriatum**, See *Valtratum*

## Valerate (Valeric Acid)

This short-chain fatty acid (FW<sub>free-acid</sub> = 102.13 g/mol; CAS 109-52-4; F.P. = -34.5°C; B.P. = 186-187°C, pK<sub>a</sub> = 4.81 at 25°C; unpleasant odor; Solubility: 0.03 mg/mL H<sub>2</sub>O), also known as *n*-pentanoic acid, is not a natural human metabolite, but is found naturally in the valerian, a perennial flowering plant (*Valeriana officinalis*), from which it derived its name. Valerate is likewise formed and degraded by fermentative microorganisms in ruminant animals. In 1904, the German chemist Franz Knoepf elucidated the steps in β-oxidation by feeding dogs odd- and even-chain ω-phenyl fatty acids, including ω-phenylvaleric acid and ω-phenylbutyric acid, cleverly using the phenyl group as a metabolic marker at a time when stable isotope and radioisotope tracers were entirely unavailable. Indeed, valeryl-CoA is an intermediate in the β-oxidation of medium-chain fatty acids found in butter and coconut oil. **Target(s)**: alcohol dehydrogenase, weakly inhibited (1); amidase (2); D-amino-acid oxidase (3-6); γ-aminobutyrate aminotransferase, weakly inhibited (7); *p*-aminohippurate transport (8); cutinase (9); cytosol alanyl aminopeptidase (10); glutamate decarboxylase (11); guanidinobutyrase (12); (S)-2-hydroxy-acid oxidase (13); L-lactate dehydrogenase (cytochrome), weakly inhibited (14); mandelonitrile lyase (15); *N*-methylglutamate dehydrogenase (16); nitrile hydratase (17); nitroalkane oxidase, or 2-nitropropane dioxygenase (18); ornithine aminotransferase (19); valine decarboxylase, or leucine decarboxylase (20). 1. #### Valeryl-Coenzyme A

This short-chain fatty acyl thiolester (FW = 852.67 g/mol; CAS 4752-33-4), also known as pentanoyl-CoA (CoA = Coenzyme A) and adenosine 3'-phosphoric acid, 5'-[diphosphoric acid P<sup>2</sup>-[2,2-dimethyl-3-hydroxy-3-[[2-[(valerylthio)-ethyl]-aminocarbonyl]-ethyl]-aminocarbonyl]-propyl]] ester, is a  $\beta$ -oxidative intermediate that also inhibits acetyl-CoA hydrolase (1,2), 3-hydroxyisobutyryl-CoA hydrolase (3,4), 3-methylcrotonoyl-CoA carboxylase, weakly (5) and (S)-methylmalonyl-CoA hydrolase (6). **1.** Nakanishi, Isohashi, Ebisuno & Sakamoto (1988) *Biochemistry* **27**, 4822. **2.** Nakanishi, Isohashi, Matsunaga & Sakamoto (1985) *Eur. #### Validamine

This amino-pyranose analogue (FW<sub>free-base</sub> = 177.20 g/mol; CAS 32780-32-8), also known as 6-amino-4-(hydroxymethyl)-4-cyclohexene-1,2,3-triol, inhibits glucan 1,3- $\alpha$ -glucosidase, *or* glucosidase II, *or* mannosyl-oligosaccharide glucosidase II (1), glucoamylase (2), isomaltase (2), maltase (2), mannosyl-oligosaccharide glucosidase, *or* glucosidase I (1), sucrase (2), and trehalose (2). **1.** Takeuchi, Kamata, Yoshida, Kameda & Matsui (1990) *J. Biochem.* **108**, 42. **2.** Takeuchi, Takai, Asano, Kameda & Matsui (1990) *Chem. Pharm. Bull.* **38**, 1970.

#### Validamycin

Validamycin A

These structurally related antifungal agents from *Streptomyces hygroscopicus*, represented by validamycin A (FW = 497.50 g/mol; CAS 37248-47-8; IUPAC (1*R*,2*R*,3*S*,4*S*,6*R*)-2,3-dihydroxy-6-(hydroxymethyl)-4-[[[(1*S*,4*S*,5*S*,6*S*)-4,5,6-trihydroxy-3-(hydroxymethyl)cyclohex-2-en-1-yl]amino]cyclohexyl  $\beta$ -D-glucopyranoside) consist of a trideoxyglucosyl residue, a *chiro*-aminoinositol residue, and a hydroxylated cyclohexane. Validamycin A reduces the maximum rate of hyphal extension and increases hyphal branching without affecting the growth rate. **Target(s):**  $\alpha$ , $\alpha$ -trehalase, by validoxylamine A (1-7);  $\alpha$ , $\alpha$ -trehalose phosphorylase (8); and  $\alpha$ , $\alpha$ -trehalose phosphorylase, configuration-retaining (9). **1.** Asano, Yamaguchi, Kameda & Matsui (1987) *J. #### Validoxylamine A

This pseudodisaccharide (FW = 335.35 g/mol; CAS 38665-10-0) component of validamycin A strongly inhibits the trehalases of *Rhizoctonia solani* and other fungi ( $K_i$  = 1.9 nM). The pig kidney trehalase has a  $K_i$  value of 0.52 nM. **Target(s):**  $\alpha$ , $\alpha$ -trehalase (1-5);  $\alpha$ , $\alpha$ -trehalose phosphorylase (6);  $\alpha$ , $\alpha$ -trehalose phosphorylase, configuration-retaining (7). **1.** Asano, Yamaguchi, Kameda & Matsui (1987) *J. Antibiot.* **40**, 526. **2.** Kameda, Asano, Yamaguchi & Matsui (1987) *J. Antibiot.* **40**, 563. **3.** Asano, Kato & Matsui (1996) *Eur. J. Biochem.* **59**, 1908. **7.** Goedel, Griessler, Schwarz & Nidetzky (2006) *Biochem. J.* **397**, 491.

#### Valienamine

This amino-hexose analogue (FW = 175.18 g/mol; CAS 38231-86-6), also known as (1*S*,2*S*,3*R*,6*S*)-6-amino-4-(hydroxymethyl)-4-cyclohexene-1,2,3-triol, is derived from *Streptomyces hygroscopicus* and inhibits glucosidases I and II. The presence of a double-bond in the six-membered ring doubtlessly imposes a flattened, half-chair conformation that mimics *oxa*-carbenium ion intermediates typically observed in glycosidase catalysis.

**Target(s):** glucan 1,3- $\alpha$ -glucosidase *or* glucosidase II *or* mannosyl-oligosaccharide glucosidase II (1); glucoamylase (4);  $\alpha$ -glucosidase (2,3); isomaltase (4); maltase (4); mannosyl oligosaccharide glucosidase *or* glucosidase I (1); sucrose  $\alpha$ -glucosidase *or* sucrase (4-6); trehalose (4). **1.** Takeuchi, Kamata, Yoshida, Kameda & Matsui (1990) *J. Biochem.* **108**, 42. **2.** Kameda, Asano, Yoshikawa, *et al.* (1984) *J. Antibiot.* **37**, 1301. **3.** Kameda, Asano, Yoshikawa & Matsui (1980) *J. #### D-Valine

This non-protein-forming amino acid (FW = 117.15 g/mol; CAS 640-68-6), also known as (*R*)-valine, is present in a number of peptide antibiotics (*e.g.*, actinomycin, valinomycin, tolaasin, and gramicidins A, B, C, and D). It is known to inhibit acetolactate synthase (1), actinomycin biosynthesis (2,3), and 3-methyl-2-ketobutanoate hydroxymethyltransferase *or* 3-methyl-2-oxobutanoate hydroxymethyltransferase (4). (**See L-Valine**) **1.** Huppertz & Casida (1985) *Z. Naturforsch. [C]* **40**, 652. **2.** Beaven, Barchas, Katz & Weissbach (1967) *J. Biol. Chem.* **242**, 657. **3.** Katz (1960) *J. Biol. Chem.* **235**, 1090. **4.** Powers & Snell (1976) *J. Biol. Chem.* **251**, 3786.

## L-Valine

This hydrophobic proteinogenic amino acid (FW = 117.15 g/mol; CAS 72-18-4;  $pK_1 = 2.29$ ;  $pK_2 = 9.74$ ; Codons: GUU, GUC, GUA, and GUG), known systematically as (S)-2-amino-3-methylbutanoic acid, inhibits numerous enzymes. **Target(s):** acetolactate synthase (1-5); 2-amino-3-oxobutanoate transaminase (39); arginase (6,10); argininosuccinate synthetase (11); arylformamidase, weakly inhibited (12); aspartate 4-decarboxylase, weakly inhibited (13); bacterial leucyl aminopeptidase (33); creatine kinase (35); cystathionine  $\gamma$ -lyase or cysteine desulfhydrase (14); cytosol nonspecific dipeptidase (15); glutamine synthetase (16);  $\gamma$ -glutamyl transpeptidase (17,18); homoserine kinase (19,37,38); isoleucyl-tRNA synthetase (20);  $\beta$ -isopropylmalate dehydrogenase (21); leucyl aminopeptidase (34); 3-methyl-2-ketobutanoate hydroxymethyltransferase, or 3-methyl-2-oxobutanoate hydroxymethyltransferase (22); ornithine aminotransferase (40-43); pantothenate synthetase, or pantoate: $\beta$ -alanine ligase (23); propionyl-CoA carboxylase, *Myxococcus Xanthus* (24); pyruvate kinase (36); saccharopine dehydrogenase, weakly inhibited (25); L-serine ammonia-lyase, or L-serine dehydratase (26); threonine ammonia-lyase, or threonine dehydratase (27-31); Xaa-Pro dipeptidase, or prolidase isozyme I (32). 1. ## L-Valine Hydroxamate

This aminoacylhydroxamate (FW<sub>free-base</sub> = 132.16 g/mol) inhibits a number of aminopeptidases, among them atrolysin A (4), bacterial leucyl aminopeptidase (1-3), leucyl aminopeptidase (1), and membrane ananyl

aminopeptidase (1-3). In metal ion-coordinating enzymes, *N*-substituted hydroxamic acid functional groups often exist as a mixture of *syn* and *anti* rotamers, with relative abundances depending on their  $pK_a$ , that might influence their effectiveness as enzyme ligands and inhibitors. Sulfonated derivatives of L-valine hydroxamate also inhibit *Clostridium histolyticum* collagenases (5). 1. Wilkes & Prescott (1983) *J. Biol. Chem.* **258**, 13517. 2. ## Valinol

This optically active alcohol analogue of valine (FW<sub>free-base</sub> = 103.16 g/mol; CAS 2026-48-4) also known as 2-amino-3-methyl-1-butanol, reacts with aldehydes to form imines as well as nitriles to form oxazolines. **Target(s):** isoleucyl-tRNA synthetase, by the L-enantiomer (1); nitric oxide synthase, by the L-enantiomer (2); and valyl-tRNA synthetase, by the L-enantiomer (3). 1. Freist & Cramer (1983) *Eur. J. Biochem.* **131**, 65. 2. Hrabak, Bajor & Temesi (1996) *Comp. Biochem. Physiol. B Biochem. Mol. Biol.* **113**, 375. 3. Kakitani, Tomomura & Hiromi (1987) *Biochem. ## Valinomycin

This cyclic, twelve-residue depsipeptide (FW = 1111.3 g/mol; CAS 2001-95-8) from *Streptomyces fulvissimus* is an ionophorous uncoupler of transmembrane potentials involving potassium ion (1-8). Valinomycin may be regarded as a cyclic trimer, with each unit consisting of a D-valine, L-valine, D-hydroxyvalerate, and L-lactate residue. Valinomycin has the effect of uncoupling both mitochondrial oxidative phosphorylation (3-10  $\mu\text{g/mL}$ ) and chloroplast photophosphorylation ( $\sim 2 \mu\text{g/mL}$ ). When treated with small doses ( $\sim 30 \text{ ng/mL}$ ) of valinomycin, human cells quickly show evidence of mitochondrial swelling and reduced viability. **Antibiotic Action Against *Mycobacterium tuberculosis*:** Valinomycin is a particularly effective antibiotic against the human pathogen *M. tuberculosis*, an organism that exhibits reduced ability to maintain internal pH towards neutrality at very acidic pH conditions (pH 3-5). This property and its valinomycin sensitivity may result from an increased proton permeability of the *M. tuberculosis* membrane or a decreased proton extrusion by the membrane-embedded ATPase (9). **Primary Mechanism of Action:** Valinomycin catalyzes the transport of  $\text{K}^+$  and other monovalent cations of similar radius (e.g.,  $\text{Rb}^+$  or  $\text{Cs}^+$ , but not  $\text{Na}^+$ ) as a charged species across biomembranes. Because rubidium, cesium, silver, and thallium ions are not abundant in living organisms, valinomycin is mainly a potassium ionophore (*Ion Selectivity*:  $\text{Rb}^+ > \text{K}^+ > \text{Cs}^+ > \text{Ag}^+ > \text{Tl}^+ \gg \text{NH}_4^+ > \text{Na}^+ \approx \text{Li}^+$ ). Potassium ion binds roughly  $10^4$  times tighter than sodium ion. Each valinomycin crosses the bilayer at a rate of roughly  $10^5$  per second. Transmembrane transfer of neutral, metal ion-free valinomycin between the membrane's surfaces is slower than the transfer of charged potassium ion-valinomycin complexes (10). Transfer of the complex is hastened either by the deformation of the membrane or transfer of a conformational change in the free carrier (10).

**Valinomycin Effects on Mitochondria:** In the presence of valinomycin, mitochondria will take up  $K^+$  at the expense of the proton gradient driven by coupled electron transfer or ATP hydrolysis. In the presence of excess  $K^+$ , the electrical component  $\Delta\psi$  of the transmembrane proton gradient collapse, at least during the time required to accumulate a substantial  $K^+$  gradient. Accumulation of potassium inside the mitochondria promotes an increase in the volume of matrix (as evidenced by swelling) and contacts between inner and outer mitochondrial membranes decrease. In valinomycin-induced stimulation of mitochondrial energy-dependent reversible swelling (supported by succinate oxidation, cytochrome *c* and sulfite oxidase (normally present in the mitochondrial intermembrane space) are released by mitochondria (11). This effect can be observed at valinomycin concentrations as low as 1 nM, and the rate of cytosolic NADH/cytochrome-*c* electron transport pathway is also greatly stimulated. Magnesium ions prevent at least in part the valinomycin effects. Rather than to the dissipation of membrane potential, the pro-apoptotic property of valinomycin can be ascribed to both the release of cytochrome-*c* from mitochondria to cytosol and the increased rate of cytosolic NADH coupled with an increased availability of energy in the form of glycolytic ATP, useful for the correct execution of apoptotic program (11). **Effect on Red Blood Cells:** Exposure of red blood cells to valinomycin, causes loss of KCl and water, resulting in cell dehydration and increasing cell density. While almost all normal valinomycin-treated RBC dehydrate, in sickle cell anemia a fraction of RBCs fail to dehydrate, indicating the existence of valinomycin-resistant RBC (12). **See Uncouplers Target(s):** ATP synthase (5); nitric-oxide synthase (13); photosynthetic electron flow (14,15). 1. #### Valiolamine

This glucose analogue (FW<sub>free-base</sub> = 193.20 g/mol; CAS 83465-22-9), named systematically as (1(OH),2,4,5/1,3)-5-amino-1-C-(hydroxymethyl) 1,2,3,4-cyclohexanetetrol, from *Streptomyces hygroscopicus* is a strong inhibitor of rat intestinal sucrose, maltase, glucoamylase, isomaltase, and trehalase ( $K_i$  = 0.32  $\mu$ M, 2.9  $\mu$ M, 1.2  $\mu$ M, 0.91  $\mu$ M, and 49  $\mu$ M, respectively). **See also Valienamine Target(s):** glucan 1,3- $\alpha$ -glucosidase, *or* glucosidase II (1); glucoamylase (2);  $\alpha$ -glucosidase (1,3); isomaltase (2,3); lysosomal  $\alpha$ -glucosidase, *or* glucan 1,4- $\alpha$ -glucosidase (1); maltase (1-3); mannosyl oligosaccharide glucosidase, *or* glucosidase I (1); sucrose (2,3); and trehalase (2). 1. #### Valium See Diazepam

#### Valproate (or Valproic Acid)

This broad-spectrum antiseizure drug and HDAC inhibitor (FW = 144.21 g/mol; CAS 1069-66-5 (sodium salt); colorless liquid; slightly soluble in

water;  $pK_a \approx 4.7$  at 25°C; *Abbreviation:* VPA), also known as 2-propylpentanoic acid and di(*n*-propyl)acetic acid, is a  $\gamma$ -aminobutyrate antagonist at plasma valproate concentrations of 50–100  $\mu$ g/mL and is also effective against pentylentetrazol-induced seizures. Glutamatergic transmission is another major target for VPA, which decreases brain levels of glutamate and aspartate, while increasing its taurine content (1). **Mechanism of Action:** Among its many actions, valproate inhibits sustained repetitive firing via depolarization of cortical and spinal neurons. While without effect on GABA-regulated responses, valproate also increases GABA levels by stimulating glutamate decarboxylase. Valproate is FDA-approved for treating certain types of epilepsy, manic episodes in bipolar disorder, and migraine headaches. Its pharmacokinetics include a 1-4 hour delay before reaching peak plasma concentration, with 90% bound to plasma proteins. In humans, its volume of distribution is roughly 0.2 L/kg. (Chronic use can be toxic to liver and pancreas, attended by excessive tiredness, lack of energy, weakness, stomach pain, appetite loss, nausea/vomiting, or swelling of the face.) **Role as a Histone Deacetylase Inhibitor:** The finding that VPA inhibits HDAC was demonstrated by analyzing the degree of histone acetylation *in vitro* and *in vivo* using an antibody against hyperacetylated histones H3 or H4 (15). While low-level histone acetylation is detected in untreated teratocarcinoma or HeLa cells, 0.25 mM VPA increases the amount of acetylated histone H4. Massive acetylation is found with 2 mM VPA. Such a degree of acetylation is observed at 5 mM butyrate or 100 nM trichostatin A. Valproic acid relieves HDAC-dependent transcriptional repression and causes hyperacetylation of histones in cultured cells and *in vivo*. VPA inhibition of HDAC activity *in vitro* occurs most likely by binding to the active sites of HDACs (15). Corepressor-associated HDACs mediate repression via transcription factors, and inappropriate repression of target genes is responsible for transformation of leukemic cells which harbor disease-associated translocations, leading to expression of the fusion proteins. VPA is also a potent class-selective HDAC inhibitor at nontoxic therapeutic concentrations, relieving HDAC-dependent transcriptional repression and causing histone hyperacetylation in cultured cells and *in vivo*. Valproic acid also induces differentiation of hematopoietic progenitor cells and leukemic blasts obtained from AML patients. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** acyl-CoA dehydrogenases (2); NADP<sup>+</sup>-alcohol dehydrogenase (3); aldehyde reductase (3-6); 4-aminobutyrate aminotransferase (7-9,24,25); carbonyl reductase (10); CYP2C9 (11); glycine synthase (12,13); [glycogen synthase] kinase-3 (14); histone deacetylase (15); inositol-3 phosphate synthase, *or* inositol-1-phosphate synthase (16);  $\alpha$ -ketoglutarate dehydrogenase (17); 3-methylbutanal reductase, weakly inhibited (18);  $\beta$ -oxidation (19); palmitoyl-CoA hydrolase, *or* acyl CoA hydrolase (20); succinate-semialdehyde dehydrogenase (9,21,22); and vitamin D<sub>3</sub> 25-monooxygenase (cytochrome P450) (23); HDAC6 (IC<sub>50</sub> = 0.3 mM), leading to tubulin hyper-acetylation and providing a rationale for VPA enhancement of paclitaxel's anticancer action (26). 1. **Valrubicin**

This antineoplastic drug (FW = 723.65 g/mol; CAS 56124-62-0), also named *N*-trifluoroacetyl-adriamycin 14-valerate, *N*-trifluoroacetyl-doxorubicin 14-valerate, and 2-oxo-2-[(2*S*,4*S*)-2,5,12-trihydroxy-7-methoxy-6,11-dioxo-4-({2,3,6-trideoxy-3-[(trifluoroacetyl)amino]hexopyranosyl}oxy)-1,2,3,4,6,11-hexahydrotetracen-2-yl]ethyl pentanoate, is a lipophilic analogue of adriamycin. It has been used in the treatment of urinary bladder carcinoma. **Target(s):** DNA topoisomerase II (1,2); protein kinase C (3); and RNA polymerase II (4). 1. Insaf, Danks & Witiak (1996) *Curr. Med. Chem.* **3**, 437. 2. Christmann-Franck, Bertrand, Goupil-Lamy, *et al.* (2004) *J. Med. Chem.* **47**, 6840. 3. Chuang, Kung, Israel & Chuang (1992) *Biochem. Pharmacol.* **43**, 865. 4. Chuang, Kawahata & Chuang (1980) *FEBS Lett.* **117**, 247.

**Valsartan**

This angiotensin receptor blocker, *or* ARB (FW = 435.52 g/mol; CAS 137862-53-4), also named (*S*)-3-methyl-2-[(*N*-{[2'-(2*H*-1,2,3,4-tetrazol-5-yl)biphenyl-4-yl]methyl}pentanamido)butanoic acid, is a potent, specific, highly selective antagonist of angiotensin II (AII) at the Type I (AT1) angiotensin receptor, but does not possess agonistic activity. It is an efficacious, orally active, blood pressure-lowering agent in conscious renal hypertensive rats and in conscious normotensive, sodium-depleted primates. The hypotensive effects of valsartan last longer than those of losartan. (See also *Candesartan*; *Eprosartan*; *Irbesartan*; *Losartan*; *Olmesartan*; *Telmisartan*) **Pharmacological Parameters:** Bioavailability = 25 %; Food Effect? YES; Drug  $t_{1/2}$  = 9 hours; Drug's Protein Binding = 95 %; Route of Elimination = 13 % Renal, 85 % Hepatic. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Criscione, de Gasparo, Bühlmyer, *et al.* (1993) *Brit. J. Pharmacol.* **110**, 761.

**Valspodar**

This P-gp-inhibiting chemosensitizer (FW = 1214.64 g/mol; CAS 121584-18-7), also known as PSC-833, which lacks the immunosuppressive and nephrotoxic properties of cyclosporin A, binds tightly to P-glycoprotein,

inhibits the latter's multidrug resistance-reversing activity, and is superior to cyclosporin A and verapamil. Valspodar is also a substrate of CYP3A (cytochrome P450 3A). **Target(s):** P-glycoprotein (1-3); and xenobiotic-transporting ATPase multidrug-resistance protein (2,3). 1. Achira, Suzuki, Ito & Sugiyama (1999) *AAPS PharmSci.* **1**, E18. 2. Paul, Breuninger & Kruh (1996) *Biochemistry* **35**, 14003. 3. Garrigues, Escargueil & Orłowski (2002) *Proc. Natl. Acad. Sci. **L-Valyl-L-asparaginyl-[(2*R*,4*S*,5*S*)-5-amino-4-hydroxy-2,7-dimethyloctanoyl]-L-alanyl-L-glutamyl-L-phenylalanine**

This heptapeptide analogue (FW = 763.41 g/mol; CAS 121584-18-7), also known as OM99-1, L-valyl-L-asparaginyl-L-leucyl-Ψ[CH(OH)CH<sub>2</sub>]-L-alanyl-L-alanyl-L-glutamyl-L-phenylalanine (*or* VNLΨAAEF), has a nonhydrolyzable hydroxyethylene peptide-bond isostere (–(*S*)-CH(OH)CH<sub>2</sub>–), denoted by Ψ, between Leu-3 and Ala-4 residues. OM99-1 inhibits memapsin-2, *or* β-secretase, with a  $K_i$  of 0.3 nM. The inhibitor sequence is based on the β-secretase cleavage site of Swedish β-amyloid precursor protein, with an Asp residue replaced by Ala. 1. Ghosh, Hong & Tang (2002) *Curr. Med. Chem.* **9**, 1135.

**L-Valyl-3-cyclohexyl-L-alanine *N*-butylamide**

This dipeptide amide (FW = 325.50 g/mol) inhibits tripeptidyl-peptidase II ( $K_i$  = 57 μM), an intermediate exopeptidase (EC 3.4.14.10) required for efficient protein turnover, showing broad sequence specificity and releasing tripeptides from the N-terminus of oligopeptides. 1. Ganellin, Bishop, Bambal, *et al.* (2000) *J. Med. Chem.* **43**, 664.

**L-Valyl-L-glutamyl-L-glutamate**

This tripeptides (FW = 375.38 g/mol; *Sequence*: VEE) inhibits glutamate carboxypeptidase II, also known as *N*-acetylated-γ-linked-acidic dipeptidase. 1. Robinson, Blakely, Couto & Coyle (1987) *J. Biol. Chem.* **262**, 14498.

**L-Valyl-L-leucyl-L-isoleucyl-L-valyl-L-proline**

This pentapeptide (FW = 539.72 g/mol; *Sequence*: VLIVP), obtained from hydrolysis of glycinin, inhibits peptidyl-dipeptidase A, also known as angiotensin I-converting enzyme ( $K_i$  = 4.5 μM). Mallikarjun Gouda, Gowda, Appu Rao & Prakash (2006) *J. Agric. Food Chem.* **54**, 4568.

**L-Valyl-L-prolyl-L-leucine**

This naturally occurring hydrophobic tripeptides (FW = g/mol), also called diprotin B and VPL, inhibits dipeptidyl aminopeptidase IV (1). Other investigators have reported that this tripeptide is actually an alternative substrate and is slowly hydrolyzed by the peptidase. **Target(s)**: dipeptidyl-peptidase IV, or dipeptidyl-aminopeptidase IV (1-6); and Xaa-Pro dipeptidyl-peptidase (7). 1. **L-Valyl-L-tryptophan**

This dipeptide (FW = 302.35 g/mol) inhibits peptidyl-dipeptidase A (angiotensin I-converting enzyme),  $K_i = 0.3 \mu\text{M}$  (1-3). 1. Cheung, Wang, Ondetti, Sabo & Cushman (1980) *J. Biol. Chem.* **255**, 401. 2. Kawamura, Kikuno, Oda & Muramatsu (2000) *Biosci. Biotechnol. Biochem.* **64**, 2193. 3. Ono, Hosokawa, Miyashita & Takahashi (2006) *Int. J. Food Sci. Technol.* **41**, 383.

**N-(L-Valyl-L-valyl)-(5-amino-4-hydroxy-2-isopropyl-7-methyloctanoyl)-L-isoleucine 2-pyridyl-methylamide**

This peptide analogue (FW = 632.49 g/mol), also known as Val-Val-Leuψ[CH(OH)CH<sub>2</sub>]Val-Ile-Amp, inhibits HIV 1 and HIV-2 protease, with  $K_i$  values of 7 and 3.5 nM, respectively. Sawyer, Staples, Liu, Tomasselli, et al. (1992) *Int. J. Pept. Protein Res.* **40**, 274.

**L-Valyl-L-valyl-L-seryl-L-valyl-L-leucyl-L-threonine**

This hexapeptide (MW = 616.76 g/mol; Sequence: VVSVLT), also known as Cabin-3, corresponds to residues 185-190 of human immunoglobulin G  $\gamma$ -chain and inhibits human cathepsin B,  $IC_{50} = 20 \mu\text{M}$  (1). 1. ### Vancomycin

This glycopeptide antibiotic (FW = 1449.27 g/mol; CAS 1404-93-9), once known as vancocin, inhibits cell wall peptidoglycan biosynthesis in Gram-positive bacteria (1,2). With D-Alanyl-D-alanine essential for bacterial cell wall synthesis (*i.e.*, in assembling one of the subunits used for peptidoglycan cross-linking), vancomycin binds (largely by means of specific hydrogen bonds) to the aminoacyl-D-Ala-D-Ala strand, thereby interfering with cross-linking required in the biosynthesis of bacterial cell walls. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Guidelines for Clinical Use:** Given the emergence of vancomycin-resistant enterococci, the U.S. Centers for Disease Control Hospital Infection Control Practices Advisory Committee issued guidelines restricting the vancomycin use to the following indications: (a) Treatment of serious infections caused by methicillin-resistant *Staphylococcus aureus* [MRSA], Multiresistant *S. epidermidis* (MRSE), or in individuals with life-threatening penicillin allergies; (b) Treatment of pseudomembranous colitis caused by *Clostridium difficile*, especially relapse infections that are unresponsive to metronidazole; (c) Treatment of infections caused by Gram-positive microorganisms in patients with serious allergies to  $\beta$ -lactam antimicrobials; (d) Antibacterial prophylaxis for endocarditis in penicillin-hypersensitive individuals; (e) Surgical prophylaxis for major procedures involving implantation of prostheses in institutions with high rates of MRSA or MRSE; and (f) Preemptive treatment for likely MRSA infection, while awaiting identification of the organism. **Target(s):** CDP-glycerol glycerophospho-transferase (3,4); CDP-ribitol ribitolphosphotransferase, weakly inhibited (5); muramoylpentapeptide carboxy-peptidase (6); penicillin-binding protein 1b (7,8); peptidoglycan glycosyltransferase (7-11); phospho-*N* acetylmuramoyl-pentapeptide-transferase (12); MurG transferase, or undecaprenyl-diphosphomuramoyl-pentapeptide  $\beta$ -*N*-acetylglucosaminyltransferase, IC<sub>50</sub> = 15.7  $\mu$ M (13-15). 1. ### Vandetanib

This PKI and anti-cancer agent (FW = 475.36 g/mol; CAS 443913-73-3; Code Name: ZD6474; IUPAC Name: *N*-(4-bromo-2-fluorophenyl)-6-methoxy-7-[(1-methylpiperidin-4-yl)methoxy]quinazolin-4-amine; Trade Name: Caprelsa<sup>®</sup>) targets the intrinsic protein tyrosine kinase activity of Vascular Endothelial Growth Factor Receptor-2 (IC<sub>50</sub> = 40 nM for VEGFR2 versus IC<sub>50</sub> = 110 nM for VEGFR3); Epidermal Growth Factor Receptor (EGFR3, IC<sub>50</sub> = 500 nM), and RET-tyrosine kinase. Vandetanib is not an effective inhibitor for PDGFR $\beta$ , Flt1, Tie-2 and FGFR1, with IC<sub>50</sub> values ranging from 1.1 to 3.6  $\mu$ M. It shows almost no inhibition of MEK, CDK2, c-Kit, erbB2, FAK, PDK1, Akt and IGF-1R, all with IC<sub>50</sub> values >10  $\mu$ M. Once-daily oral administration of ZD6474 to growing rats for 14 days produced a dose-dependent increase in the femoro-tibial epiphyseal growth plate zone of hypertrophy, which is consistent with inhibition of VEGF signaling and angiogenesis *in vivo* (1). Administration of 50 mg/kg/day Vandetanib (once-daily, *p.o.*) to athymic mice with intradermally implanted A549 tumor cells also inhibited tumor-induced neovascularization significantly. Oral administration of Vandetanib to athymic mice bearing established, histologically distinct (*e.g.*, human lung, prostate, breast, ovarian, colon, or vulval) tumor xenografts or after implantation of aggressive syngeneic rodent tumors (*e.g.*, lung, melanoma) in immunocompetent mice, produced a dose-dependent inhibition of tumor growth in all cases (1). Significantly, while the human ABCG2 plasma membrane glycoprotein is a xenobiotic transporter that confers multidrug resistance against gefitinib and pemetinib, ABCG2 is without effect on the intracellular action of vandetanib and neratinib (2). Such finding suggest that development of ABCG2 inhibitors might well improve the efficacy of other protein tyrosine kinase inhibitors. Combination of high-dose vandetanib and high-dose docetaxel resulted in antiproliferative effects that were lower than expected from the sum of individual drug effects. This finding further suggests vandetanib should not be used along with docetaxel in treatment-naive or docetaxel-resistant prostate cancer (3). Vandetanib suppresses VEGFR-2 phosphorylation in HUVECs and EGFR phosphorylation in hepatoma cells and inhibited cell proliferation (4). In tumor-bearing mice, vandetanib suppressed phosphorylation of VEGFR-2 and EGFR in tumor tissues, significantly reducing tumor vessel density, enhancing tumor cell apoptosis, suppressed tumor growth, improved survival, reduced number of intrahepatic metastases, and upregulated VEGF, TGF- $\alpha$ , and EGF in tumor tissues (4). Beyond inhibiting endothelial cell proliferation by blocking VEGF-induced signaling, vandetanib may also be able to inhibit cancer cell growth by blocking EGFR autocrine signaling. Such results provide also a rationale commending the clinical evaluation of vandetanib, especially when combined with taxanes in cancer patients (5). 1. ### Vanillate (Vanillic Acid)

This natural product (FW<sub>free-acid</sub> = 168.15 g/mol; CAS 121-34-6; M.P. = 210°C; highly water-soluble), also known as 4-hydroxy-3-methoxybenzoic acid, inhibits a variety of mechanistically unrelated enzymes. **Target(s):** chorismate lyase (1);  $\alpha$ -glucosidase (2); glycogen phosphorylase (2); 4-hydroxybenzoate 4-*O*- $\beta$ -glucosyltransferase (3); phenol sulfotransferase, or aryl sulfotransferase (4); phenylalanine ammonia-lyase (5); protocatechuate 3,4-dioxygenase (6); shikimate dehydrogenase (7). 1. ### Vanillin

This aromatic aldehyde (FW = 152.15 g/mol; CAS 121-33-5; M.P. = 80-81°C), also known as 4-hydroxy-3-methoxybenzaldehyde, has a solubility of about one gram per 100 mL of water at room temperature. Vanillin is photosensitive and should be stored in light-resistant containers. It is frequently used in analytical biochemistry; for example, in the detection of catecholamines, ornithine, sugar alcohols, and catechins. **Target(s):** 4-aminobutyrate aminotransferase (1); DNA-dependent protein kinase (2); hemoglobin S polymerization, mildly inhibited (3); malonyl-CoA decarboxylase (4); shikimate dehydrogenase (5,6); succinate dehydrogenase (7); and succinate-semialdehyde dehydrogenase (1). 1. Tao, Yuan, Tang, Xu & Yang (2006) *Bioorg. Med. Chem. Lett.* **16**, 592. 2. Durant & Karran (2003) *Nucl. Acids Res.* **31**, 5501. 3. Zaugg, Walder & Klotz (1977) *J. Biol. Chem.* **252**, 8542. 4. **Vanoxerine**

This piperazine-class dopamine reuptake inhibitor (FW<sub>free-base</sub> = 450.56 g/mol; FW<sub>di-HCl</sub> = 523.49 g/mol; CAS 67469-78-7), also known as GBR-12909 and systematically as 1-[2-[bis(4-fluorophenyl)methoxy]ethyl]-4-(3-phenylpropyl)piperazine, binds to transporter some 400-500 times higher affinity than cocaine, but also inhibits dopamine release. The net effect is that vanoxerine does not elevate synaptic dopamine levels significantly. Vanoxerine is a potent and selective inhibitor of synaptosomal dopamine uptake ( $K_i = 1$  nM), with a 20-fold lower affinity for the histamine H<sub>1</sub>-receptor and a more than 100-fold affinity for the noradrenaline and 5-HT uptake carriers, the dopamine D<sub>1</sub> receptor, D<sub>2</sub> receptor (1). 5-HT<sub>1</sub> receptor, 5-HT<sub>1A</sub> receptor, and  $\alpha_1$ -receptor as well as voltage-dependent sodium channels. GBR 12909 (3  $\mu$ M) was without effect on muscarinic,  $\alpha_2$ ,  $\beta_1$  and  $\beta_2$ ,  $\gamma$ -aminobutyric acid (GABA) and benzodiazepine receptors, and on choline and GABA uptake carriers. The selective dopamine uptake inhibitory profile of GBR 12909 was confirmed by *ex vivo* uptake experiments (1). GBR 12909 inhibited uptake *in vitro* in a competitive manner. GBR 12935 binding was competitively inhibited by GBR 12909 as well as by dopamine, cocaine and methylphenidate. GBR 12909 inhibits dopamine uptake with equal potency in nucleus accumbens and striatum. GBR 12909 is the only compound with this neurochemical profile, making it a valuable experimental tool and antidepressant. **See also 1-(2-[Bis(4-fluorophenyl)methoxy]ethyl)-4-(3-phenylpropyl)piperazine 1.** Andersen (1989) *Eur. J. Pharmacol.* **166**, 493.

**Vardenafil**

This purine derivative (FW = 474.59 g/mol; CAS: 224785-90-4), known commercially as Levitra™ and systematically as 2-[2-ethoxy-5-(4-ethylpiperazine-1-sulfonyl)phenyl]-5-methyl-7-propyl-3H-imidazo[5,1-f][1,2,4]triazin-4-one, strongly inhibits 3',5'-cyclic-GMP phospho-

diesterase, or cGMP phosphodiesterase, with greatest affinity for the Type-5 isozyme (1-7); cGMP phosphodiesterase Type-6 (6); cGMP phosphodiesterase Type-9 (6); cGMP phosphodiesterase Type-11, slightly inhibited (6,7). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Sung, Hwang, Jeon, *et al.* (2003) *Nature* **425**, 98. 2. Porst, Rosen, Padma-Nathan, *et al.* (2001) *Int. J. Impot. Res.* **13**, 192. 3. **Varenicline**

This smoking-cessation drug (FW = 211.27 g/mol; CAS 249296-44-4; 375815-87-5), known by the trade name Chantix® and systematic name, 6,7,8,9-tetrahydro-6,10-methano-6H pyrazino[2,3-*h*][3]benzazepine, is a  $\alpha_4\beta_2$  type-specific partial agonist of nicotinic receptors ( $EC_{50} = 2.3$   $\mu$ M), with an efficacy of 13.4 %, relative to acetylcholine (1-3). Whereas varenicline is a partial agonist at other heteromeric neuronal nicotinic receptors (*e.g.*,  $EC_{50} = 55$   $\mu$ M; Efficacy = 75 %, relative to acetylcholine for  $\alpha_3\beta_4$  nicotinic receptors), it is a full agonist at the homomeric  $\alpha_7$  receptor ( $EC_{50} = 18$   $\mu$ M; Efficacy = 93 %, relative to acetylcholine). Varenicline also seems to be a weak partial agonist of  $\alpha_3\beta_2$  and  $\alpha_6$ -containing receptors, with an efficacy <10%. Varenicline can be considered as a structural analogue of cytosine (**See Cytosine**). **Rationale:** Repeated exposure to nicotine develops neuroadaptation, resulting in tolerance to many of the effects of nicotine. A confounding behavior of nicotine's reinforcing effects is its stimulation of brain nicotinic receptors, especially  $\alpha_4\beta_2$  receptors, with release of dopamine in the meso-limbic area. Nicotine abstinence reduces dopamine release, accompanied by withdrawal symptoms and nicotine craving. By blocking nicotine receptors and simultaneously stimulating dopamine, varenicline is the first drug to modulate both nicotinic receptor action and dopamine release. Involvement of presynaptic  $\alpha_4$ - and  $\alpha_6$ -containing receptors in regulating dopamine release in the striatum makes the partial agonism of varenicline at these receptors an attractive potential mechanism (2). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Coe, Brooks, Vetelino, *et al.* (2005) *J. Med. Chem.* **48**, 3474. 2. Coe, Vetelino, Bashore, *et al.* (2005) *Bioorg. Med. Chem. Lett.* **15**, 2974. 3. Mihalak, Carroll & Luetje (2006) *Mol. Pharmacol.* **70**, 801.

**Varespladib**

This intravenously administered anti-inflammatory agent and experimental drug (FW = 380.40 g/mol; CAS 172732-68-2; Solubility: 75 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known as A-001, previously LY315920, S-5920, and 2-(3-(2-amino-2-oxoacetyl)-1-benzyl-2-ethyl-1H-indol-4-yloxy)acetic acid, targets IIa, V, and X isoforms of secretory phospholipase A<sub>2</sub> (sPLA<sub>2</sub>) and human non-secretory phospholipase A<sub>2</sub>, or hnsPLA ( $IC_{50} = 7$  nM), thereby inhibiting a key first step of the arachidonic acid pathway needed to trigger inflammation in atherosclerotic disease. The orally bioavailable, prodrug varespladib methyl (FW = 394.43 g/mol; CAS 172733-08-3) is rapidly metabolized to varespladib; both compounds

potently inhibit human secretory phospholipase groups IIa, V and X (2). In patients with recent Acute Coronary Syndrome, or ACS (*i.e.*, sudden blockage of blood flow to heart muscles), varespladib did not reduce the risk of recurrent cardiovascular events and actually increased significantly the risk of myocardial infarction (3). When administered at a once-daily dose of 500 mg (in addition to atorvastatin and other established therapies), varespladib does reduce adverse cardiovascular outcomes after ACS and may even prove to be harmful. 1. ### Vasopressin

[Arg<sup>8</sup>]-Vasopressin

This peptide amide hormone (FW = 1083.22 g/mol; CAS 9034-50-8), also known as antidiuretic hormone (ADH), which contains nine aminoacyl residues with an internal disulfide bridge and an amide at the C-terminal amide, regulates water balance by exerting antidiuretic action, and by inducing arteriole contraction (1,2). **Target(s)**: carboxypeptidase E (2); hydroxyindole *O*-methyltransferase (3); serotonin *N*-acetyltransferase (4). 1. Alescio-Lautier & Soumireu-Mourat (1998) *Prog. Brain Res.*, 501. 2. Hook & LaGamma (1987) *J. Biol. Chem.* **262**, 12583. 3. Sugden & Klein (1987) *J. Biol. Chem.* **262**, 6489. 4. Klein & Nambodiri (1982) *Trends Biochem. Sci.* **7**, 98.

[deamino-Cys1,D-Arg8]-Vasopressin, See *Desmopressin*

### Vasotocin

[Arg<sup>8</sup>]-Vasotocin

This vasoactive peptide amide hormone (MW = 1108.25 g/mol; CAS 113-80-4), which is closely related to vasopressin and oxytocin, also contains nine aminoacyl residues with an internal disulfide bridge as well as a C-terminal amide, also inhibits adenylate cyclase (1,2); androgen biosynthesis (3); arylalkylamine *N*-acetyltransferase, serotonin *N*-acetyltransferase (4,5); and hydroxyindole *O*-methyltransferase (6). 1. ### Vatalanib

This orally available TKI (FW = 346.82 g/mol; CAS 212142-18-2; Soluble to 100 mM in DMSO), also known as CGP 79787D, ZK 222584, PTK787, and 1-[4-chloroanilino]-4-[4-pyridylmethyl]-phthalazine succinate, blocks phosphorylation by vascular endothelial growth factor receptors (IC<sub>50</sub> = 77 nM for VEGFR-1; IC<sub>50</sub> = 37 nM for VEGFR-2) and is also active against platelet-derived growth factor receptor  $\beta$  protein-tyrosine kinase, c-Kit, and c-Fms at higher concentrations. Vatalanib also inhibits proliferation, migration and survival of HUVECs *in vitro* as well as the growth, vascularization and metastasis of VEGFR-expressing tumors in mouse xenograft models. It is also a potent aromatase inhibitor (IC<sub>50</sub> = 50 nM). **Target(s)**: platelet-derived growth factor receptor protein-tyrosine kinase (1,2); receptor protein-tyrosine kinase (1-3); and vascular endothelial cell growth factor (VEGF) receptor protein-tyrosine kinase (1-3). 1. Ozaki, Seo, Ozaki, Yamada, Yamada, Okamoto, Hofmann, Wood & Campochiaro (2000) *Amer. J. Pathol.* **156**, 697. 2. Wood, Bold, Buchdunger, Cozens, *et al.* (2000) *Cancer Res.* **60**, 2178. 3. Medinger & Dreves (2005) *Curr. Pharm. Des.* **11**, 1139.

### VDM-11

This potent AMT inhibitor (FW = 409.61 g/mol; CAS 313998-81-1; most often dissolved in Ethanol or as an emulsion in Tocrisolve™ 100 (Tocris Biosciences Cat. No. 1686)), also named (5Z,8Z,11Z,14Z)-*N*-(4-hydroxy-2-methylphenyl)-5,8,11,14-eicosatetraenamide, selectively targets the Anandamide (*N*-arachidonylethanolamine) Membrane Transporter (IC<sub>50</sub> = 4-11  $\mu$ M), displaying negligible activity at the human vanilloid (capsaicin), or hVR<sub>1</sub>, receptor. VDM-11 also shows very weak agonist action at CB<sub>1</sub> and CB<sub>2</sub> receptors, with *K<sub>i</sub>* values are greater than 5-10  $\mu$ M. This anandamide membrane transporter inhibitor can be used to distinguish between CB<sub>1</sub> or VR<sub>1</sub> receptor-mediated actions of anandamide (2). 1. De Petrocellis, Bisogno, Davis, Pertwee & Di Marzo (2000) *FEBS Lett.* **483**, 52. 2. De Petrocellis, Bisogno, Maccarrone, *et al.* (2001) *J. Biol. Chem.* **276**, 12856

### VE

This synthetic acetylcholinesterase inhibitor (FW<sub>free-base</sub> = 253.35 g/mol), also named *O*-ethyl *S*-(2-diethylamino)ethyl ethylphosphonothioate, is a second-generation chemical warfare (CW) agent. **Caution:** Extreme care must be exercised to avoid contact or inhalation. A droplet contacting the skin is sufficient to kill most humans. Ellison (2000) *Handbook of Chemical and Biological Warfare Agents*, CRC Press, Boca Raton.

### VE-821

This potent and selective ATP-competitive inhibitor (FW = 368.41 g/mol; CAS 1232410-49-9), also named 3-amino-6-[4-(methylsulfonyl)phenyl]-*N*-phenyl-2-pyrazinocarboxamide, targets the Ataxia Telangiectasia and Rad3-related protein kinase, or ATR (*K<sub>i</sub>* = 13 nM; IC<sub>50</sub> = 26 nM), inhibiting the phosphorylation of histon H2AX (*or* H2A histone family, member X), with inhibitory action against PIKKs ATM, DNA-PK, mTOR and PI3K $\gamma$ . The differential responses of cancer and normal cells highlights the great potential for ATR as a novel target for dramatically increasing the efficacy of many established drugs and ionizing radiation. 1. Reaper, Griffiths, Long, *et al.* (2011) *Nature Chem. Biol.* **7**, 428. 2. Charrier, Durrant & Golec, *et al.* (2011) *J. Med. Chem.* **54**, 2320.

### VE-822

This novel potent inhibitor (FW = 463.56 g/mol; CAS 1232416-25-9; Solubility: 36 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O or Ethanol), also named 3-[3-[4-[(methylamino)methyl]phenyl]-5-isoxazolyl]-5-[4-[(1-methylethyl)sulfonyl]phenyl]-2-pyrazinamine, selectively targets ATR kinase, a serine/threonine-protein kinase also known as ataxia telangiectasia and Rad3-related protein (*or* ATR) kinase with IC<sub>50</sub> of 19 nM. VE-822 decreases cell-cycle checkpoint maintenance, increases persistent DNA damage, and decreases homologous recombination in irradiated cancer cells (1). VE-822 decreases survival of pancreatic cancer cells but not normal cells in response to XRT or gemcitabine. VE-822 markedly prolongs growth delay of pancreatic cancer xenografts after XRT and gemcitabine-based chemoradiation without augmenting normal cell or tissue toxicity (1). 1. Fokas, Prevo, Pollard, *et al.* (2012) *Cell Death Dis.* **3**, e441. 2. Fokas, Prevo, Hammond, *et al.* (2013) *Cancer Treat. Rev.* S0305-7372.

**VE-13045**, See *N*-(Benzyloxycarbonyl)-L-valyl-L-alanyl-L-aspartic(O-ethyl ester) 2,6-Dichlorobenzoyl-oxymethyl Ketone

### Vecuronium Bromide

This well known paralyzing agent (FW = 637.74 g/mol; CAS 50700-72-6), also known as Norcuron<sup>®</sup> and 1-[(2β,3α,5α,16β,17β)-3,17-bis(acetyloxy)-2-(1-piperidinyl) androstan-16-yl]-1-methylpiperidinium bromide, is a muscle blocker that competitively inhibits cholinesterase (1,2) as well as histamine *N*-methyltransferase (3,4). By competing for the choline receptors on the motor end-plate, vecuronium bromide's muscle-relaxing properties can be used to aid general anesthetics. **See also Tubocurarine** 1. Whittaker & Britten (1980) *Clin. Chim. Acta* **108**, 89. 2. Popovic & Kunec-Vajic (1990) *Lijec Vjesn.* **112**, 142. 3. Futo, Kupferberg & Moss (1990) *Biochem. Pharmacol.* **39**, 415. 4. **Vegolysen**, See *Hexamethonium Bromide*

### Veliparib

This orally active and brain-permeable PARP inhibitor and anticancer drug (FW = 244.39 g/mol; CAS 912444-00-9), also known as ABT 888 and (*R*)-2-(2-methylpyrrolidin-2-yl)-1*H*-benzo[*d*]imidazole-4-carboxamide, targets poly(ADP-ribose) polymerase 1 and 2 (PARP1, *K*<sub>i</sub> = 5.2 nM; PARP2, *K*<sub>i</sub> = 2.9 nM), thereby potentiating the DNA-damaging effects of anticancer treatments using temozolomide, platinum, cyclophosphamide, as well as radiation in syngeneic and xenograft tumor models (**See Temozolomide**). Veliparib is inactive to SIRT2. Under acute hypoxia, it radiosensitizes malignant cells to a level similar to oxiradiosensitivity, demonstrating that inhibition of PARP activity can sensitize hypoxic cancer cells and the combination of IR-PARPi has the potential to improve the therapeutic ratio of radiotherapy (2). 1. Donawho, Luo, Luo, *et al.* (2007) *Clin. Cancer Res.* **13**, 2728. 2. Liu, Coackley, Krause, *et al.* (2008) *Radiother. Oncol.* **88**, 258.

### Velnacrine

This acetylcholinesterase inhibitor (FW = 214.3 g/mol; CAS 321-64-2), also known as 1-hydroxytacrine, has been used to treat Alzheimer's disease by increasing the strength and duration of acetylcholine that accumulates in the synaptic groove. There is compelling evidence for the selective degeneration in AD of acetylcholine-releasing neurons, the cell bodies of which lie in the basal forebrain and provide widespread innervation of the cerebral cortex and related structures affecting cognitive functions, especially memory. **Target(s):** acetylcholinesterase and cholinesterase (1-3); cytochrome P450 (4); and histamine methyltransferase (5). 1. Ebmeier, Hunter, Curran, *et al.* (1992) *Psychopharmacol.* **108**, 103. 2. Wesnes, Simpson, White, *et al.* (1991) *Ann. N. Y. Acad. Sci.* **640**, 268. 3. Prell, Morrishow, Duoyon & Lee (1997) *J. Neurochem.* **68**, 142.

**Velsicol 1068**, See *Chlordan*

### Vemurafenib

This first-in-class B-Raf protein kinase inhibitor (FW = 489.92; CAS 1029872-54-5), known as PLX-4032, RG7204, and Zelboraf<sup>®</sup>, as well as its systematic name *N*-(3-{{[5-(4-chlorophenyl)-1*H*-pyrrolo[2,3-*b*]pyridin-3-yl]carbonyl}-2,4-difluorophenyl}propane-1-sulfonamide, is the FDA- and European Commission-approved monotherapy for unresectable metastatic melanoma in adult BRAF<sup>V600E</sup>-positive patients (1-2). The BRAF<sup>V600E</sup> mutation leads to constitutive activation of the MAPK signaling pathway. Vemurafenib actually stimulates cells possessing the wild-type B-Raf protein kinase, thereby activating the ERK pathway and enhancing cell migration and proliferation of BRAF<sup>WT</sup> melanoma cells (3). **Vemurafenib Resistance:** Most BRAF<sup>V600E</sup>-positive melanoma patients treated with vemurafenib initially show good clinical responses, but eventually relapse from acquired resistance (4). *In vitro* induction of vemurafenib resistance in melanoma cells is associated with an increased malignancy phenotype, and such cells show a higher level of expression of genes coding for cancer stem cell markers (including JARID1B, CD271 and Fibronectin), genes involved in drug resistance (ABCG2), cell invasion, and genes associated with the promotion of metastasis (MMP-1 and MMP-2) (4). Drug-resistant melanoma cells also adhere better to and transmigrate more efficiently through lung endothelial cells than drug-sensitive cells. They also alter their microenvironment in a different manner from that of drug-sensitive cells. Among the established mechanisms of vemurafenib resistance are: (a) overexpression of β-type platelet-derived growth factor receptor, thereby affording an alternative survival pathway; (b) mutations in the NRAS oncogene that reactivate the normal BRAF survival pathway; (c) enhanced secretion or up-regulation of RTK ligands (*e.g.*, Hepatocyte Growth Factor (HGF), Epidermal Growth Factor (EGF), Fibroblast Growth Factor (FGF), Platelet-Derived Growth Factor (PDGF), Neuregulin-1 (NRG1) and Insulin-like Growth Factor (IGF)) that are widely expressed in tumors. In a papillary thyroid carcinoma model, long-term vemurafenib treatment drives inhibitor resistance through a spontaneous KRAS<sup>G12D</sup> mutation (5) in subpopulation of KTC1 cells after five months of treatment. Increases in activated AKT, ERK1/2, and EGFR are also observed in these cells. Resistant cells are less sensitive to combinations. **Note:** Vemurafenib is the first FDA-approved drug designed by fragment-based lead approaches. 1. ## Venetoclax

This highly potent, orally bioavailable small molecule (FW = 868.44 g/mol; CAS 1257044-40-8; Solubility: 100 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known by the trade name Venclexta® and codenames ABT-199, GDC-0199, and RG760, mimics BH3-only proteins, thereby inhibiting antiapoptotic members of the Bcl-2 family. Venetoclax received FDA Breakthrough Drug Status to treat Chronic Lymphocytic Leukemia (CLL) patients who have either relapsed or have been refractory to previous treatment (most often fludarabine) and have the 17p deletion genetic mutation (1). (Note: Drug resistance in CLL patients with the 17p deletion is most likely caused by the inactivation of p53 by mutation of the remaining *TP53* allele.) (Note: BCL-2 family proteins (sharing at least one of the four domains of BCL-2 homology: BH1–BH4) regulate the balance between cell life and death by facilitating mitochondria-to-cytoplasm transfer of apoptogenic factors such as Cytochrome *c*. Prosurvival members of the family (e.g., BCL-2, BCL-X<sub>L</sub>, BCL-W, MCL-1, and A1) sequester BAX and BAK, the pro-apoptotic members that act as “executioner” molecules. All prosurvival proteins sequester BAX, whereas only BCL-X<sub>L</sub> and MCL-1 bind to BAK. This anti-apoptotic activity is antagonized by the BH3-only members (e.g., NOXA, BAD and BIM), so named because they only possess the BH3 domain.) These proteins insert their  $\alpha$ -helical BH3 domain into the hydrophobic groove of prosurvival proteins, displacement BAX and BAK.) Although navitoclax is a selective inhibitor of BCL-2 and BCL-2-like-1, thrombocytopenia limits its efficacy. Venetoclax was therefore developed by re-engineering navitoclax into a BCL-2-selective inhibitor that restores apoptosis by binding directly to the BCL-2 protein, displacing pro-apoptotic proteins like BIM, triggering mitochondrial outer membrane permeabilization, and activating caspases, thereby inhibiting the growth of BCL-2-dependent tumors *in vivo*, while sparing platelets (1). Venetoclax targets Bcl-2 ( $K_i < 0.01$  nM), with a >4800x selectivity over Bcl-xL and Bcl-w, but showing no activity toward Mcl-1. A single dose of ABT-199 in three patients with refractory chronic lymphocytic leukemia resulted in tumor lysis within 24 hours. Although treatment of CLL patients with navitoclax (ABT-263) is complicated by thrombocytopenia as a consequence of BCL-XL inhibition, venetoclax's enhanced specificity avoids this problem and also overcomes stroma-mediated resistance to apoptosis (2). 1. Souers, Leverson, Boghaert, *et al.* (2013) *Nature Med.* **19**, 202. 2. Davids, Letai & Brown (2013) *Leuk. Lymphoma* **54**, 1823. **IUPAC Name:** 4-(4-{[2-(4-Chlorophenyl)-4,4-dimethyl-1-cyclohexen-1-yl]-methyl}-1-piperazinyl)-*N*-{[3-nitro-4-[(tetrahydro-2*H*-pyran-4-ylmethyl)-amino]-phenyl]-sulfonyl}-2-(1*H*-pyrrolo[2,3-*b*]-pyridin-5-yl)oxy)-benzamide

## Venlafaxine

This SNRI-type antidepressant (FW<sub>free-base</sub> = 277.41 g/mol; CAS 99300-78-4, hydrochloride), also known by trade names Effexor® or Efexor® and its IUPAC name (*RS*)-1-[2-dimethylamino-1-(4-methoxyphenyl)ethyl]-cyclohexanol, selectively inhibits reuptake of serotonin, norepinephrine, and, to a lesser extent, dopamine. In animal models, venlafaxine does not significantly inhibit muscarinic, histaminic, or adrenergic receptor activity and does not inhibit monoamine oxidase. Venlafaxine is rapidly absorbed and metabolized in the liver to its active metabolite, *O*-

desmethylvenlafaxine (ODV). Time-to-peak concentration is 1-2 h for Venlafaxine and 4-5 hours for ODV. Venlafaxine and its major active metabolite, *O*-desmethylvenlafaxine, exhibit linear kinetics with respective elimination half-lives of 5 and 11 hours. **Target(s):** CYP2D6, or cytochrome P450 2D6 (1,2); monoamine uptake (3); nicotinic acetylcholine receptor (4); and the sodium channel (5). 1. Alfaro, Lam, Simpson & Ereshefsky (2000) *J. Clin. Pharmacol.* **40**, 58. 2. Ball, Ahern, Scatina & Kao (1997) *Brit. J. Clin. Pharmacol.* **43**, 619. 3. Ther.* **291**, 280.

## Venturicidins

Venturicidin A, R = NH<sub>2</sub>CO; Venturicidin B, R = H

These antifungal antibiotics (Venturicidin A: FW = 749.98 g/mol, CAS 33538-71-5; and Venturicidin B: FW = 706.96 g/mol, CAS 33538-72-6), from *Streptomyces aureofaciens*, inhibit ATP synthase ( $K_i = 2-5$  nM), binding to the F<sub>0</sub> subunit and therefore acting as a partial inhibitor. Venturicidin appears to alter  $k_{cat}$ , allowing ATP hydrolysis and synthesis to proceed, albeit at a much lower rate (1). It specifically blocks proton translocation through F<sub>0</sub>, binding at the interface of subunit *a* and *c*-ring oligomer in a manner like oligomycin. Its action is not limited to mitochondrial ATP synthase, and it is also effective against bacterial and chloroplast ATP synthases as well as Na<sup>+</sup>-translocating ATP synthases. When F<sub>0</sub>-F<sub>1</sub> coupling is good, venturicidin blocks the F<sub>1</sub> activity, making its action a test of F<sub>0</sub>F<sub>1</sub> coupling efficiency. Venturicidin may be stored as a concentrated stock solution for a long time without loss of its inhibitory power. (**For comparison of Modes of Action, See Oligomycin, Tentoxin, Azide, DCCD, Efrapeptin, AlF<sub>4</sub><sup>-</sup>, or Fluoro-aluminatate**) **Target(s):** ATP synthase, or F<sub>1</sub>F<sub>0</sub> ATPase, or H<sup>+</sup>-transporting two-sector ATPase (1-6); H<sup>+</sup>-transporting ATPase (7); Na<sup>+</sup>-transporting two-sector ATPase (8). 1. ## VER 155008

This ATP-competitive chaperonin inhibitor (FW = 556.40 g/mol; CAS 1134156-31-2), also known as 5'-*O*-[(4-cyanophenyl)methyl]-8-[[[(3,4-dichlorophenyl)methyl]amino]adenosine, targets Heat Shock Protein 70, or Hsp70 (IC<sub>50</sub> = 0.5  $\mu$ M), impairing the folding of client proteins and inhibiting the *in vitro* cell proliferation of multiple human tumor cell lines (1-3). Grp78, the 78-kDa glucose-regulated HSP binds VER-155008,  $K_d = 60$  nM (3) Phenotypically, Hsc70/Hsp70-interaction inhibitors mimic the

cellular mode of action of a small molecule Hsp90 inhibitors, potentiating the apoptotic potential of Hsp90 inhibitors in certain cell lines (2). VER-155008 also binds to Hsc70 and Grp78, displaying low affinity against Hsp90 $\beta$ ,  $IC_{50} > 200 \mu\text{M}$  (1). VER-155008 inhibited the proliferation of human breast and colon cancer cell lines with  $GI_{50}$  values in the range 5.3–14.4  $\mu\text{M}$ , and induced Hsp90 client protein degradation in both HCT116 and BT474 cells (2). As a single agent, VER-155008 induced caspase-3/7 dependent apoptosis in BT474 cells and non-caspase dependent cell death in HCT116 cells. VER-155008 potentiated the apoptotic potential of a small molecule Hsp90 inhibitor in HCT116, but not HT29 or MDA-MB-468 cells. *In vivo*, VER-155008 demonstrated rapid metabolism and clearance, along with tumor levels below the predicted pharmacologically active level. 1. Williamson, Borgognoni, Clay, *et al.* (2009) *J. Med. Chem.* **52**, 1510. 2. Massey, Williamson, Browne, *et al.* (2009) *Cancer Chemother. Pharmacol.* **66**, 535. 3. Massey (2010) *J. Med. Chem.* **53**, 7280. 4. Macias, Williamson, Allen, *et al.* (2011) *J. Med. Chem.* **54**, 4034.

### Verapamil

This phenylalkylamine derivative and vasodilator ( $FW_{\text{free-base}} = 454.61 \text{ g/mol}$ ;  $FW_{\text{HCl-salt}} = 489.16 \text{ g/mol}$ ; CAS 52-53-9); IUPAC:  $\alpha$ -[3-[[[2-(3,4-dimethoxyphenyl)ethyl]methylamino]propyl]-3,4-dimethoxy- $\alpha$ -(1-methylethyl)benzeneacetonitrile], exhibits calcium ion blocking activity by inhibiting the movement of  $\text{Ca}^{2+}$  across biological membranes. Verapamil enjoys broad use in the treatment of supraventricular tachyarrhythmias as well as for hypertension and control of symptoms in angina pectoris, and cluster headaches. Its action resembles propranolol inasmuch as it reduces the  $\text{O}_2$  requirement of the heart and abolishes certain arrhythmias. Unlike propranolol, however, it does not antagonize cardiac  $\beta$ -adrenoreceptors. Verapamil is a P-glycoprotein inhibitor, and, as such, is likely to interfere with other drugs that are transported by this multidrug resistance factor. **Key Pharmacokinetic Parameters:** After either intravenous or oral drug administration, plasma concentrations correlate with both electrophysiological and haemodynamic activity, with considerable intra- and intersubject variation in the intensity of its pharmacological effects (1). Its actions depend on the route of administration, and, while verapamil is widely distributed throughout body tissues, drug distribution to target organs and tissues is different for parenteral versus oral administration. The drug is eliminated by hepatic metabolism, with excretion of inactive products in the urine and/or feces. Norverapamil, its *N*-demethylated metabolite, exerts weaker vasodilator effects *in vitro*. Upon intravenous administration, systemic clearance appears to approach liver blood flow. The high hepatic extraction results in low systemic bioavailability (20%) after oral drug administration. Because of the complex pharmacokinetics associated with multiple-dose administration and the variation in individual patient responsiveness to the drug, verapamil must be titrated to achieve a clinical end-point (1). Single-day sustained release verapamil formulations for oral administration are as effective in lowering blood pressure over 24 hours as equivalent doses of conventional verapamil formulations given three times daily (2). See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** aldehyde oxidase (3); cadmium-transporting ATPase (4); calcium channel (5); cholesterol  $\Delta$ -isomerase, or sterol  $\Delta^{7,8}$ -isomerase (6); CYP3A (7); nucleoside triphosphate diphosphohydrolase (8); phospholipid-translocating ATPase, or flippase (13); protein kinase C (14,15); xenobiotic-transporting ATPase, or multidrug-resistance protein (10-13,16,17). 1. ### Veratridine

This toxic alkaloid ( $FW = 673.80 \text{ g/mol}$ ; CAS 71-62-5), named systematically as: 4,9-epoxycevine-3,4,12,14,16,17,20-heptol 3-(3,4-dimethoxybenzoate), from the seeds of the lily family member *Schoenocaulon officinalis* and the rhizome of *Veratrum album*, causes  $\text{Na}^+$  channels to remain open during sustained membrane depolarization by abolishing inactivation. The consequential  $\text{Na}^+$  influx, either by itself or by causing a maintained depolarization, leads to many secondary effects such as increasing pump activity,  $\text{Ca}^{2+}$  influx, and in turn exocytosis. If the membrane is voltage-clamped in the presence of the alkaloid, a lasting depolarizing impulse induces, following the "normal" transient current, another much more slowly developing  $\text{Na}^+$  current that reaches a constant level after a few seconds. Repolarization then is followed by an inward tail current that slowly subsides. 1. Ulbricht (1998) *Rev. Physiol. Biochem. Pharmacol.* **133**, 1. 2. McKinney, Chakraverty & De Weer (1986) *Anal. ### Verdinexor

This orally bioavailable nuclear export inhibitor ( $FW = 442.32 \text{ g/mol}$ ; CAS 1392136-43-4), also known as KPT-335 and (2Z)-3-(3-(3,5-bis(trifluoromethyl)phenyl)-1*H*-1,2,4-triazol-1-yl)-*N'*-(pyridin-2-yl)prop-2-enediazide, blocks the activity of XPO1/CRM1, itself one of seven nuclear export proteins, forcing the nuclear retention of key tumor suppressor proteins (TSP) and leading to selective apoptosis of tumor cells. Canine tumor cell lines derived from non-Hodgkin lymphoma, mast cell tumor, melanoma and osteosarcoma exhibited growth inhibition and apoptosis in response to nanomolar concentrations of KPT-335, with  $IC_{50}$  values ranging from 2 to 42 nM (1). Nuclear export of influenza virus ribonucleoprotein (vRNP) from infected cells is mediated by Exportin 1 interaction with viral nuclear export protein tethered to vRNP. Verdinexor limits the replication of various strains of influenza A and B viruses, including a pandemic H1N1 influenza virus strain, a highly pathogenic H5N1 avian influenza virus strain, and an emerging H7N9 influenza virus strain (2). Orally administered verdinexor is efficacious in limiting lung virus burdens in influenza virus-infected mice, as well as limiting lung proinflammatory cytokine expression, pathology, and death. 1. London, Bernabe, Barnard, *et al.* (2014) *PLoS One* **9**, e87585. 2. Perwitasari, Johnson, Yan, *et al.* (2014) *J. Virol.* **88**, 10228.

**Vernamycin A, See Virginiamycin M1**

**Vernolate**

This alkylated thiocarbamate (FW = 203.35 g/mol; CAS 1929-77-7), also known as Vernam and dipropylcarbamothioic acid *S*-propyl ester, is a selective herbicide developed by the Stauffer Chemical Co. in the late 1950s (1). A liquid at room temperature, vernolate is slightly soluble in water (107 mg/L at 25°C), and readily soluble in organic solvents. Vernolate is toxic to germinating broadleaf and grassy weeds and is frequently used to control weeds in fields of soybeans, peanuts, and sweet potatoes. Care should be exercised when encountering this name in the literature since the term vernolate also refers to the conjugate base of vernolic acid. **Target(s):** aldehyde dehydrogenase (2,3). 1. Tilles (1959) *J. Amer. Chem. Soc.* **81**, 714. 2. Hart & Faiman (1995) *Biochem. Pharmacol.* **49**, 157. 3. Quistad, Sparks & Casida (1994) *Life Sci.* **55**, 1537.

**Verrucarin A**

This macrocyclic trichothecene toxin (FW = 502.56 g/mol; CAS 3148-09-2), also called muconomycin A, is produced by the soil fungi *Myrothecium verrucaria*. Verrucarin's phytotoxicity and cytotoxicity in mammalian cell lines and potent antifungal action arise from its inhibition of eukaryotic protein biosynthesis at the initiation stage, interacting with the large ribosomal subunit (1-3). **Caution:** All verrucarins are extremely toxic and should be handled with care. 1. Hernandez & Cannon (1982) *J. Antibiot.* **35**, 875. 2. Fresno & Vázquez (1979) *Meth. Enzymol.* **60**, 566. 3. Jiménez (1976) *Trends Biochem. Sci.* **1**, 28.

**Verteporfin**

This benzoporphyrin-based photosensitizer (FW = 718.85 g/mol; CAS 129497-78-5), also known by the tradename Visudyne®, is used in the photodynamic therapy (PDT) to ablate abnormal blood vessels within the eye, most often associated with the wet form of macular degeneration. Verteporfin also inhibits drug- and starvation-induced autophagic degradation and the sequestration of cytoplasmic materials into autophagosomes; however, verteporfin does not inhibit LC3/Atg-8 processing or membrane recruitment in response to autophagic stimuli (1). Mitochondrial photodamage occurs at low verteporfin concentrations ( $\leq 1 \mu\text{M}$ ) in murine hepatoma 1c1c7 cells (2). Significantly, apoptosis was not observed until several hours after irradiation of photosensitized cells.

Moreover, autophagy was cytoprotective, because PDT efficacy was significantly enhanced in a knockdown sub-line, in which the level of a critical autophagy protein (Atg7) was markedly reduced (2). Autophagy thus protects from phototoxicity, even when apoptosis is substantially delayed. Much higher concentrations ( $\geq 10 \mu\text{M}$ ) of verteporfin had previously been shown to inhibit autophagosome formation. Other sensitizers (e.g., porphycene (termed CPO) and mesochlorin) respectively localize in the endoplasmic reticulum and mitochondria (3). 1. Donohue, Tovey, Vogl, et al. (2011) *J. Biol. Chem.* **286**, 7290. 2. Andrzejak, Price & Kessel (2011) *Autophagy* **7**, 979. 3. Kessel & Reiners (2007) *Photochem. Photobiol.* **83**, 1024.

**Vesamicol**

This substituted piperidine (FW = 259.39 g/mol; CAS 22232-64-0), also known as 2-(4-phenylpiperidino)cyclohexanol, allosterically inhibits the vesicular acetylcholine transporter (VACHT; TC 2.A.1.2.13),  $\text{IC}_{50} \sim 50 \text{ nM}$ , but is not itself transported (1). Its binding site is fundamentally different from the ACh binding site(s) on VACHT (2). Vesamicol exhibits monophasic, high-affinity binding characteristic of strong and specific contacts between a single, substantially preformed binding site and its ligand (2). 1. Prior, Marshall & Parsons (1992) *Gen. Pharmacol.* **23**, 1017. 2. Khare, Mulakaluri & Parsons (2010) *J. Neurochem.* **115**, 984.

**VG, See Amiton**

**VI21497, See Merimepodib**

**Viagra™, See Sildenafil**

**Vibramycin, See Doxycycline**

**Vigabatrin****Vigabatrin****Glutamate**

This synthetic  $\gamma$ -amino acid and first-in-class anticonvulsant (FW = 129.15 g/mol; CAS 60643-86-9), also known as vinyl-GABA, CPP-115, Sabril® and 4-amino-5-hexenoic acid, is a glutamate analogue and irreversible Michael-type mechanism-based inactivator of  $\gamma$ -aminobutyrate aminotransferase (1,2). The *S*(+)-stereoisomer is pharmacologically active. (See also *cis*-3-Aminocyclohex-4-ene-1-carboxylate)  $\gamma$ -Aminobutyrate aminotransferase inhibition consequentially increases the level of GABA, a neurotransmitter that inhibits dopamine release. In 2009, FDA approved Sabril as second-line antiepileptic therapy for adult patients with refractory complex partial seizures (CPS) who have already responded inadequately to alternative treatments. **Primary Mode of Action:** Inactivation proceeds by two divergent mechanisms (2). The major pathway involves removal of the  $\gamma$ -proton, tautomerization into the PLP ring, followed by a Michael addition of an active-site lysine residue at the conjugated vinyl group to give a stable covalent adduct with the protein. The minor inactivation mechanism also involves  $\gamma$ -proton loss, but tautomerization occurs through the vinyl group, followed by an enamine rearrangement that leads to attachment of the inactivator to the PLP bound to the protein. The X-ray structure of GABA transaminase complexed to vigabatrin suggests likely steps in the Michael-type addition/inhibition process (9). **Target(s):** 4-aminobutyrate

transaminase (1-9); aspartate aminotransferase (8); glutamate 1-semialdehyde 2,1-aminomutase, or glutamate-1-semialdehyde aminotransferase (10); hypotaurine aminotransferase (11); and ornithine aminotransferase (8). 1. ### Vilazodone

This serotonergic antidepressant (FW = 441.52 g/mol; CAS 163521-12-8; IUPAC: 5-(4-[4-(5-cyano-1H-indol-3-yl)butyl]piperazin-1-yl)benzofuran-2-carboxamide), also known by its codename EMD 68843 and its tradename Viibryd<sup>®</sup>, is an FDA-approved treatment of major depressive disorder as well as for generalized anxiety disorder and obsessive compulsive disorder. Vilazodone inhibits serotonin reuptake ( $IC_{50} = 2.1$  nM;  $K_i = 0.1$  nM) and 5-HT<sub>1A</sub> receptor partial agonist ( $IC_{50} = 0.2$  nM; Agonist Efficacy = ~60–70%), with negligible affinity for serotonin 5-HT<sub>1D</sub>, 5-HT<sub>2A</sub>, and 5-HT<sub>2C</sub> receptors (1,2). Vilazodone also shows negligible inhibitory activity at the norepinephrine transporter, or NET ( $IC_{50} = 56$  nM) and dopamine transporter, or DAT ( $IC_{50} = 56$  nM). 1. Page, Cryan, Sullivan, et al. (2002) *J. Pharmacol. Exp. Therap.* **302**, 1220. 2. Hughes, Starr, Langmead, et al. (2005) *Europ. J. Pharmacol.* **510**, 49.

### Vildagliptin

This oral antihyperglycemic drug (FW = 304.41 g/mol; CAS 274901-16-5), also known as NVP-LAF237 and 1-[[[3-hydroxy-1-adamantyl) amino]acetyl]-2-cyano-(S)-pyrrolidine, inhibits dipeptidyl-peptidase IV ( $IC_{50} = 3.5$  nM). By limiting proteolysis of the gastrointestinal hormones, glucagon-like peptides 1 and 2 (GLP-1 and GLP-2), vildagliptin is a so-called incretin enhancer that indirectly maintains insulin secretion and suppresses glucagon release (See *Incretin Hormone Enhancers; Saxagliptin*). Vildagliptin also reduces levels of reactive oxygen species as well as mitochondrial swelling, thereby providing cardioprotection by reducing the infarct size and ameliorating cardiac dysfunction during ischemia-reperfusion (4). **Target(s):** cytosol nonspecific dipeptidase (prolyl dipeptidase)1; dipeptidyl-peptidase IV (1-3). 1. Jiang, Chen, Hsu, et al. (2005) *Bioorg. Med. Chem. Lett.* **15**, 687. 2. Villhauer, Brinkman, Naderi, et al. (2003) *J. Med. Chem.* **46**, 2774. 3. Brandt, Lambeir, Ketelslegers, et al. (2006) *Clin. Chem.* **52**, 82. 4. Chinda, Sanit, Chattipakorn & Chattipakorn (2013) *Diab. Vasc. Dis. Res.* **11**, 75.

### Vinblastine

This indole-indoline alkaloid and microtubule assembly/disassembly modulator (FW = 811 g/mol; CAS 865-21-4) from the periwinkle (*Catharanthus roseus*, formerly *Vinca rosea*) is a potent inhibitor of microtubule assembly and cellular processes depending on an organized microtubule cytoskeleton. Low concentrations (0.2–1  $\mu$ M) of this antiproliferative agent do not induce microtubule disassembly. The alkaloid instead binds to tubulin to form a high-affinity tubulin-vinblastine complex that is incorporated by limited copolymerization with drug-free tubulin into the ends of assembling microtubules, where it kinetically suppresses microtubule dynamics by modulating the gain and loss of terminally bound tubulin-GTP or tubulin-GDP·P<sub>i</sub>. By disrupting mitosis, vinblastine also triggers apoptosis in many cell lines, induces p53 expression, stimulates Raf-1 activation, and initiates phosphorylation of bcl-2 family proteins. Mounting evidence suggests that tumor cell apoptosis and checkpoint-linked apoptosis is synergistically enhanced by combined treatments with DNA- and cytoskeleton-damaging agents. When administered at a dose of 6 milligrams per square meter of body surface, vinblastine has a 1-day half-life in the bloodstream. Vinblastine has proven efficacy in the treatment of Hodgkin's disease, lymphocytic lymphoma, histiocytic lymphoma, advanced testicular cancer, advanced breast cancer, Kaposi's sarcoma, and Letterer-Siwe disease. Overexpression of Class III  $\beta$ -tubulin has emerged as a biomarker in a number of cancers, a prognostic indicator of more aggressive disease, and a predictor of resistance to taxanes and *Vinca* alkaloids (6). (See also *Vindesine; Vincristine; Vinorelbine*) **Target(s):** microtubule self-assembly and mitosis (1-6); xenobiotic-transporting ATPase, or multidrug-resistance protein (7-10); cadmium-transporting ATPase (11); CYP3A4, or cytochrome P450 3A4 (12); thromboxane synthetase (13). 1. ### Vinc-1 Head Fragment 840-849, Human

This decapeptide PDFPPPPDL (MW = 1091.23 g/mol) corresponding to a proline-rich register (residues 840-849) of human vinculin inhibits actin-based membrane protrusion, actin-based propulsion of *Listeria monocytogenes* and *Shigella flexneri* (1) by disrupting binding interactions between filament (+)-end-tracking motors and their cargo (2), when microinjected at sub- $\mu$ M concentrations. The analogous FEFPPPTDE register in *Listeria* ActA surface protein displaces human vasodilator-stimulated phosphoprotein (VASP) from FPPPP-containing proteins, suggesting that vinculin PDFPPPPDL has the analogous mode of action (See *ActA Peptide FEFPPPTDE; ABM-1 & ABM-2 Sequences in Actin-Based Motors*). 1. Laine, Zeile, Kang, Purich & Southwick (1997) *J. Cell Biol.* **138**, 1255. 2. Purich (2010) *Enzyme Kinetics: Catalysis and Control*, Academic Press, New York.

### Vincalocoblastin, See Vinblastine

**Vinclozolin**

This dicarboximide-class fungicide (FW = 286.11 g/mol; CAS 50471-44-8), known also by its IUPAC name (*RS*)-3-(3,5-dichlorophenyl)-5-methyl-5-vinylloxazolidine-2,4-dione and the trade names Ronilan<sup>®</sup>, Curalan<sup>®</sup>, Vorlan<sup>®</sup>, and Touche<sup>®</sup>, is used to control blights, rots and molds in vineyards (especially *Botrytis*) and on raspberries, lettuce, kiwi, snap beans, and onions (1). Its precise mode of action remains unclear. Vinclozolin inhibits mycelial growth much more than spore germination (2). Although chitin biosynthesis is inhibited by this fungicides, it was barely affected at the ED<sub>50</sub> concentrations (the concentration required to reduce the growth or germination of the test species by 50%) and is thus unlikely to be the primary target (2). Moreover, it is without effect on respiration, membrane permeability or RNA production. Vinclozolin metabolites M<sub>1</sub> and M<sub>2</sub> are effective antagonists of the androgen receptor in rats, exhibiting K<sub>i</sub> values of 92 and 9.7 μM respectively (3). 1. Pothuluri, Freeman, Heinze, *et al.* (2000) *J. Agric. Food Chem.* **48**, 6138. 2. Pappas & Fisher (1979) *Pesticide Sci.* **10**, 239. 3. Kelce, Monosson, Gamsick, *et al.* (1994) *Toxicol. Appl. Pharmacol.* **126**, 276.

**Vincristine**

This indole-indoline alkaloid and microtubule assembly/disassembly modulator (FW = 824.97 g/mol; CAS 57-22-7), from the periwinkle (*Catharanthus minor*, formerly *Vinca minor*), is a potent inhibitor of microtubule self-assembly and cellular processes requiring a well-structured and properly organized microtubule cytoskeleton. **Mode of Action:** Vincristine is likely to exert effects that are similar to the antiproliferative action of vinblastine, which at low concentrations result from changes of microtubule dynamics rather than from depolarization of the mitotic microtubules (1-3). (See *Vinblastine* for additional comments on mode of action) Marketed as Oncovin<sup>™</sup> by Eli Lilly, vincristine (serum t<sub>1/2</sub> of ~85 hours) is used to treat acute leukemia, rhabdomyosarcoma, neuroblastoma, Hodgkin's disease and other lymphomas. Typical one-weekly therapeutic dose is 1.4 mg/m<sup>2</sup> body surface. Because neurons unavoidably require microtubules to maintain their anisometric structure, sensory and neurotransmission functions, and because vincristine penetrates neurons and blocks MT processes, significant peripheral vincristine neuropathy is often dose-limiting. (See *Vinblastine*; *Vindesine*; *Vinorelbine*) **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Vincristine Resistance in Multiple Myeloma:** In vincristine-resistant RPMI8226/VCR multiple myeloma cells, multidrug resistance (MDR) involves the overexpression of MDR1 and survivin, exhibiting increased levels of activated ERK1/2, Akt, and NF-κB. By comparison, the levels of activated mTOR, p38MAPK, and JNK do not differ between RPMI8226/VCR cells and their vincristine-susceptible cells (4). Inhibition of ERK1/2, Akt, or NF-κB reverses drug-resistance of RPMI8226/VCR cells via the suppression of survivin expression, but does not affect MDR1 expression. RNA silencing of survivin expression completely reverses vincristine resistance, whereas MDR1 silencing only weakly suppresses vincristine resistance in RPMI8226/VCR cells (4). Such findings indicate that enhanced survivin expression via the activation of ERK1/2, Akt, and NF-κB plays a critical role in vincristine resistance in RPMI8226/VCR cells. **Target(s):**

CYP3A4, or cytochrome P450 3A4 (5); lactose synthase (6); thromboxane synthetase (7); xenobiotic-transporting ATPase, or multidrug-resistance protein (8). 1. Jordan, Thrower & Wilson (1991) *Cancer Res.* **51**, 2212. 2. Jordan, Thrower & Wilson (1992) *J. Cell. Sci.* **102**, 401. 3. Baumhake, Kasel, Rao-Schymanski, *et al.* (2001) *Int. J. Clin. Pharmacol. Ther.* **39**, 517. 6. West (1985) *Biochem. Soc. Trans.* **13**, 694. 7. Maguire & Csonka-Khalifah (1987) *Biochim. Biophys. Acta* **921**, 426. 8. Mao, Deeley & Cole (2000) *J. Biol. Chem.* **275**, 34166. 8. Loe, Deeley & Cole (1998) *Cancer Res.* **58**, 5130.

**Vindesine**

This semi-synthetic vinblastine derivative and microtubule assembly/disassembly modulator (FW = 753.94 g/mol; CAS 59917-39-4), marketed under the names Eldisine<sup>™</sup> and Fildesine<sup>™</sup>, binds rapidly to tubulin and thereby undergoes limited incorporation into the ends of microtubules, thereby altering microtubule self-assembly and suppressing microtubule dynamics (1). Vindesine is mainly used to treat melanoma, lung cancers (carcinomas), and certain uterine cancers (See also *Vinblastine*; *Vincristine*; *Vinorelbine*). 1. Jordan, Himes & Wilson (1985) *Cancer Res.* **45**, 2741.

**Vineomycin A<sub>1</sub>**

This *Streptomyces albogriseolus* natural product (FW = 934.99 g/mol; CAS 78164-00-8), also known as P-1894B, inhibits procollagen-proline 4-monooxygenase, or prolyl hydroxylase, K<sub>i</sub> = 1.6 μM. Inasmuch as hydroxyprolyl residues are essential to stabilize collagen, vineomycin A<sub>1</sub> is likely to reduce T<sub>m</sub>, the melting temperature for thermal denaturation of the tropocollagen triple helix, such that nonhydroxylated procollagen chains are degraded within the cell. Lacking suitable structural support, tissues, blood vessels, tendons, and skin become fragile. 1. Ishimaru, Kanamaru, Takahashi, Ohta & Okazaki (1982) *Biochem. Pharmacol.* **31**, 915. 2. Okazaki, Ohta, Kanamaru, Ishimaru & Kishi (1981) *J. Antibiot.* **34**, 1355.

**Vinorelbine**

This semi-synthetic *Vinca* alkaloid derivative and microtubule assembly/disassembly modulator (FW = 778.95 g/mol; CAS 71486-22-1) binds rapidly to tubulin and thereby undergoes limited incorporation into the ends of microtubules, thereby altering microtubule self-assembly and suppressing microtubule dynamics (1,2). It inhibits proliferation of multiple

human tumor cell lines ( $IC_{50} = 1.25$  nM in HeLa cells) and blocks metaphase/anaphase transition by suppression of microtubule dynamics ( $IC_{50} = 3.8$  nM). The most recent clinically approved *Vinca* alkaloid, Vinorelbine shows improved efficacy and reduced toxicity and is effective in non-small-cell lung cancer, metastatic breast cancer, and ovarian cancer. It also shows promise in the treatment of lymphoma, esophageal cancer, and prostatic carcinoma. Vinorelbine's similarly acting difluoro analogue, **vinflunine** (FW = 816.92 g/mol; CAS 162652-95-1), contains a  $-CF_2CH_3$  moiety in place of the ethyl group shown at the top of vinorelbine's structure. Vinflunine has 3x to 16x lower overall affinity for tubulin than vinorelbine, whereas vinorelbine has lower overall affinity than vinblastine under the conditions of the experiments, suggesting that their lower affinity for tubulin, may partly explain the high concentrations of drug required to block mitosis and cell proliferation (3,4). The lower potency and low tubulin binding affinity of vinflunine correlates well with the finding that it is the least cytotoxic of the *Vinca* alkaloids studied (5), and one cannot discount the possibility that drug clearance is strongly influenced by the off-rate constant for each of the *Vinca* alkaloid interactions with microtubules. Cellular uptake of *Vinca* alkaloids reaches peak intracellular drug concentrations (vinflunine, 4.2  $\mu$ M; vinorelbine, 1.3  $\mu$ M; vinblastine, 0.13  $\mu$ M) that are considerably in excess of the medium concentrations corresponding to its mitotic  $IC_{50}$  value (2). Such findings suggest that each drug's efficacy may also depend on metabolism and efflux mechanisms. (See also *Vinblastine*; *Vincristine*; *Vindesine*) **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Jordan, Himes & Wilson (1985) *Cancer Res.* **45**, 2741. 2. Ngan, Bellman, Hill, Wilson & Jordan (2001) *Mol. Pharmacol.* **60**, 225. 3. ### Vinpocetine

This nootropic vincamine derivative (FW = 350.46 g/mol; CAS 42971-09-5; photosensitive) exhibits vasodilating activity by inhibiting 3',5'-cyclic-nucleotide phosphodiesterase (1-8), phosphodiesterase 1,  $IC_{50} = 20$   $\mu$ M (1-5,7), and phosphodiesterase 11, slightly inhibited (6). Vinpocetine inhibits retrograde axoplasmic transport of nerve growth factor (NGF) in the peripheral nerve, resulting in transganglionic degenerative atrophy (TDA) in the segmentally related ipsilateral superficial spinal dorsal horn (9). The latter is characterized by depletion of the marker enzymes fluoride-resistant acid phosphatase (FRAP) and thiamine monophosphatase (TMP). inhibition of retrograde axoplasmic transport of nerve growth factor (NGF) in the peripheral nerve. Blockade of retrograde transport of NGF results in transganglionic degenerative atrophy (TDA) in the segmentally related ipsilateral superficial spinal dorsal horn, which is characterized by depletion of the marker enzymes fluoride-resistant acid phosphatase (FRAP) and thiamine monophosphatase (TMP). Vinpocetine also inhibits the rise in sodium and calcium induced by 4-aminopyridine in synaptosomes (10). It produces a concentration- and state-dependent inhibition of  $Na_v1.8$  sodium channel activity (11). Voltage-clamp experiments revealed a 3x increase in vinpocetine potency when whole-cell  $Na_v1.8$  conductances were elicited from relatively depolarized potentials (-35 mV;  $IC_{50} = 3.5$   $\mu$ M) compared with hyperpolarized holding potentials (-90 mV;  $IC_{50} = 10.4$   $\mu$ M). Vinpocetine also produced an approximately 22 mV leftward shift in the voltage dependence of  $Na_v1.8$  channel inactivation but did not affect the voltage range of channel activation (11). Vinpocetine-mediated stimulation of  $Ca^{2+}$ -activated  $K^+$  current ( $I_{KCa}$ ) may result from the direct activation of large-conductance  $Ca^{2+}$ -activated  $K^+$  ( $BK_{Ca}$ ) channels and indirectly from elevated cytosolic  $Ca^{2+}$  (12). The main mechanism involved in the neuroprotective action of vinpocetine in the CNS is unlikely to be due to a direct inhibition of  $Ca^{2+}$  channels or PDE enzymes, but rather the inhibition of presynaptic  $Na^+$  channel-activation unchained responses (13). 1. Han, Werber, Surana, Fleischer & Michaeli (1999) *J. Biol. Chem.* **274**, 22337. 2.

### Vintafolide

This novel anticancer drug (FW = 1903.03 g/mol; CAS 742092-03-1), also known as MK-8109, is a disulfide-linked (see dashed box) conjugate consisting of vinblastine and folic acid, the former acting as an anti-mitotic agent (See *Vinblastine*) and the latter targeting the conjugate to cancer cells that overexpress folate receptors (FRs). Once within the target cell, vinblastine is released nonenzymatically through the action of intracellular glutathione and/or cysteine (1-3). FR-overexpressing cells include ~80-90% of ovarian tumors, gynecological cancers, pediatric ependymal brain tumors, and mesothelioma, as well as breast, colon, renal and lung tumors. Etarfolatide, a non-invasive companion diagnostic imaging agent, may be used to identify folate receptor-positive tumor cells that are likely to be susceptible to vintafolide therapy. Vintafolide is currently under development for treating late-stage ovarian cancer and adenocarcinoma of the lung. Combination therapy using vintafolide plus pegylated liposomal doxorubicin (PLD) offers improved outcome *versus* standard therapy in a randomized trial of patients with platinum-resistant ovarian cancer (4). 1. $\gamma$ -Vinyl-GABA, See *Vigabatrin*

### L-Vinyglycine

This alkenyl amino acid (FW = 101.11 g/mol; CAS, 52773-87-2), also known as 2-amino-3-butenate, is a chiral mechanism-based enzyme inactivator of snake venom L-amino-acid oxidase by the L-stereoisomer (1,2) and D-alanine aminotransferase by the D-enantiomer. Vinylglycine (VG) is also an alternative substrate for threonine synthase (3). **Target(s):** alanine aminotransferase (4); alanine racemase (5); D-alanine

aminotransferase, by the D-enantiomer (6); venom L-amino-acid oxidase (1,2,7); 1-aminocyclopropane-1-carboxylate synthase (8-10); aspartate aminotransferase (4,11,12); cysteine desulfurase (13); heart  $\alpha$ -ketoglutarate dehydrogenase complex (14); threonine synthase (15); tryptophan 2-monooxygenase (16); UDP-N-acetylmuramate:L-alanine ligase, by the L-enantiomer (17,18). 1. ### Vinylglycolate

This  $\alpha$ -hydroxy acid (FW<sub>free-acid</sub> = 101.08 g/mol; CAS 6192-52-5), also known as vinylglycolic acid 2-hydroxy-3-butenic acid, is an alternative substrate for lactate oxidase and lactate dehydrogenase. Mandelate racemase catalyzes its racemization (1). **Target(s):** L- $\alpha$ -hydroxyacid oxidase (2); phosphoenolpyruvate:protein phosphotransferase, or phosphoenol-pyruvate:phosphate transferase system, *Escherichia coli* (3). 1. Garcia-Viloca, Gonzalez-Lafont & Lluch (2001) *J. Amer. Chem. Soc.* **123**, 709. 2. Walsh, Cromartie, Marcotte & Spencer (1978) *Meth. Enzymol.* **53**, 437. 3. Walsh & Kaback (1973) *J. Biol. Chem.* **248**, 5456.

### 4-Vinylpyridine

This substituted pyridine (FW = 105.14 g/mol; CAS 100-43-6), also known as 4-ethenylpyridine, reacts with sulfhydryl groups (1) and inactivates Fo ATP synthase component (2); 6-pyruvoyltetrahydropterin synthase (3); thioredoxin reductase (4); and transducin (5). (**Caution:** Care should be exercised in its use as it is corrosive and a lachrymator. There are reports of adverse skin reactions with 4-vinylpyridine.) 1. Cavins & Friedman (1970) *Anal. Biochem.* **35**, 489. 2. Huang, Kantham & Sanadi (1987) *J. Biol. Chem.* **262**, 3007. 3. Burgisser, Thöny, Redweik, *et al.* (1994) *Eur. J. Biochem.* **219**, 497. 4. ### Viomycin

This cyclic peptide antibiotic (FW = 685.70 g/mol; CAS 32988-50-4), also called tuberactinomycin B, from *Streptomyces* sp., inhibits prokaryotic protein biosynthesis (1,2), and seems to bind at least to the small ribosomal subunit because it competes partially with the binding of streptomycin (3).

However, viomycin does not induce misreading like streptomycin1, but promotes association of the ribosomal subunits, stabilises 70S couples (4), and blocks trans-location (5,6). Interestingly, resistant mutants have been found containing either an altered 30S or an altered 50S subunit (7-9). Viomycin strengthens the association of the sensitive subunits, but does not affect the association of subunits derived from resistant mutants (4). **Target(s):** group I intron RNA splicing (10); GTP diphosphokinase (10); protein biosynthesis, ribosomal elongation and translocation (10-15); protein-synthesizing GTPase (elongation factor) (15). (**See also Tuberactinomycins**) 1. Davies, Gorini & Davis (1965) *Molec. Pharmacol.* **1**, 93. 2. Tanaka & Igusa (1968) *J. Antibiot.* **21**, 239. 3. Masuda & Yamada (1976) *Biochim. Biophys. **Vioxx, See Rofecoxib**

### VIR-576

This anti-retroviral (FW = 4483.33 g/mol) is based on "VIRIP", a naturally occurring peptide corresponding to a 20-residue segment near the C-terminus of  $\alpha_1$ -antitrypsin ( $\alpha_1$ -AT). VIR-576 is a conformationally restricted, disulfide-linked tandem repeat that recapitulates, albeit with somewhat higher affinity, the inhibitory action of VIRIP against Human Immunodeficiency Virus Type-1 (HIV-1) entry into the target cells. VIRIP and VIR-576 directly inhibit CD4<sup>+</sup> T cell activation *in vitro*. 1. Forssmann, The, Stoll, *et al.* (2010) *Sci. Transl. Med.* **2**, 63re3.

**Viracept, See Nelfinavir**

**Virazole 5'-Monophosphate, See Ribavirin**

### Virginiamycin M<sub>1</sub>

This macrolactone antibiotic (FW = 529.59 g/mol; CAS 21411-53-0), also called vernamycin A, mikamycin A, ostreogrycin A, and streptogramin A, is produced by *Streptomyces virginiae* and inhibits protein biosynthesis (1-3). Virginiamycin M<sub>1</sub> inactivates the donor and acceptor sites of the peptidyltransferase (2). Greater inhibition is observed with ribosomes from Gram-positive microorganisms compared to those from Gram-negative bacteria (3). Virginiamycin is the active ingredient in veterinary medicine used to prevent laminitis, a painful hoof condition, in horses. Veterinary use of virginiamycin on poultry farms selectively controls the intestinal microflora in the upper small intestine, thereby preventing the bacterial

breakdown and promoting assimilation of essential amino acids and glucose, significant reducing feed costs. Given the use patterns of virginiamycin in intensive animal farming practices, there is mounting concern about the spread of virginiamycin-resistant animal bacteria to humans and the transfer of antibiotic resistance genes from animal bacteria to human pathogens. The UK Veterinary Medicines Directorate, for example, announced in 2012 that importation of virginiamycin for veterinary use will be phased out, with a complete ban starting in late 2014.

**Target(s):** peptidyltransferase (2); protein biosynthesis, initiation and elongation phases (1-5); and protein-synthesizing GTPase elongation factor (5). 1. Pestka (1974) *Meth. Enzymol.* **30**, 261. 2. Di Giambattista, Chinali & Cocito (1989) *J. Antimicrob. Chemother.* **24**, 485. 3. Jiménez (1976) *Trends Biochem. Sci.* **1**, 28. 4. ### Viridiofungins

Viridiofungin A

These tricarboxylic acids (FW<sub>free-acid</sub> = 591.7 g/mol for viridiofungin A) from *Trichoderma viride* are broad-spectrum antifungals that inhibit sphingolipid biosynthesis as well as other enzymes that act on di- and tricarboxylic acids (1). **Target(s):** geranylgeranyltransferase (1); serine palmitoyltransferase (1-3); and squalene synthase (1). 1. Mandala & Harris (2000) *Meth. Enzymol.* **311**, 335. 2. Dickson, Lester & Nagiec (2000) *Meth. Enzymol.* **311**, 3. 3. Mandala, Thornton, Frommer, Dreikorn & Kurtz (1997) *J. Antibiot.* **50**, 339.

### Viscumin

This toxic heterodimeric protein (MW = 60 kDa; consisting of Mr = 29,000 and 32,000 for its subunits) from mistletoe (*Viscum album*) potentially inhibits protein synthesis in cell-free systems. The smaller subunit, designated the A-chain, is the inhibitory component, catalytically deactivating the 60 S ribosomal subunit. While the heterodimer inhibits ribosomes are inhibited at 1 ng/mL viscumin, the isolated A-chain is some 60x less active. Viscumin is a lectin that binds to Sepharose 4B and can be eluted with lactose. 1. Olsnes, Stirpe, Sandvig & Pihl (1982) *J. Biol. Chem.* **257**, 13263.

### Vismodegib

This novel, orally bioavailable cyclopamine-competitive antagonist (FW = 421.30 g/mol; CAS 879085-55-9), also known by the code name GDC-0449, the trade name Erivedge® and as 2-chloro-N-(4-chloro-3-pyridin-2-ylphenyl)-4-methylsulfonylbenzamide, is potent, and specific hedgehog inhibitor (IC<sub>50</sub> = 3 nM) that also inhibits P-gp (IC<sub>50</sub> = 3.0 μM). **Mode of Inhibitory Action:** Mainly as a way to regulate body patterning and organ development during embryogenesis, the Hedgehog (Hh) signaling pathways is largely quiescent in adults. Exceptions include Hh signaling in tissue maintenance/repair as well as several cancers. Aberrant constitutive activation of Hedgehog pathway signaling as well as uncontrolled cellular proliferation are associated with mutations in the cell surface receptors PTCH and SMO, which bind hedgehog ligands. Vismodegib inhibits ATP-binding cassette transporters, the overexpression of which confers a multidrug resistance phenotype. Vismodegib is the first FDA-approved Hedgehog (Hh) signaling pathway targeting agent for treatment of basal-cell carcinoma (BCC) and is also undergoing trials for use in metastatic colorectal cancer, small-cell lung cancer, advanced stomach cancer, pancreatic cancer, medulloblastoma and chondrosarcoma (1,2). The Smoothed receptor (Smo) mediates Hh pathway signaling that is involved in the pathogenesis, self-renewal of stem cells, and chemotherapeutic resistance of BCC (3). It is ≥95% protein bound in plasma at clinically

relevant concentrations and has an approximately 200x longer single dose half-life in humans relative to rats. A strong linear relationship exists between plasma drug concentrations and α-1-Acid Glycoprotein (AAG), and vismodegib binds strongly to human AAG (K<sub>d</sub> = 13 μM) and with lower affinity to albumin (K<sub>d</sub> = 120 μM). Binding to rat AAG is ~20x weaker, whereas the binding affinity to rat and human albumin was similar (4). **Drug Interactions:** A clinical trial evaluating the effects of rabeprazole (a proton-pump inhibitor), itraconazole (a combined P-glycoprotein/ CYP3A4 inhibitor), and fluconazole (a CYP2C9 inhibitor) found that vismodegib can be administered along with these inhibitors absent risk of a clinically meaningful drug-drug interaction (5). **Other Hedgehog inhibitors:** GANT61; BMS-833923; Purmorphamine; PF-5274857; LY2940680; Cyclopamine, LDE225, or NVP-LDE225, or Erismodegib; SANT-1 1. ### Voglibose

This glucose analogue and oral antidiabetic agent (FW<sub>free-base</sub> = 267.3 g/mol; CAS 83480-29-9; M.P. = 162-163°C), also known as AO 128 and Basen, inhibits pig intestinal maltase and sucrase with IC<sub>50</sub> values of 15 and 4.6 nM, respectively. **Target(s):** α-glucosidase (1-3); maltase (3); and sucrase (3). 1. Goke, Fuder, Wieckhorst, et al. (1995) *Digestion* **56**, 493. 2. Oki, Matsui & Osajima (1999) *J. Agric. Food Chem.* **47**, 550. 3. Horii, Fukase, Matsuo, et al. (1986) *J. Med. Chem.* **29**, 1038.

### Volasertib

This ATP-competitive protein kinase inhibitor (FW<sub>free-acid</sub> = 618.81 g/mol; CAS 755038-65-4, 946161-17-7 (tri-HCl salt); Solubility: 50 mg/mL DMSO; <1 mg/mL Water), also known as BI6727 and systematically as N-((1R,4R)-4-(4-(cyclopropylmethyl)piperazin-1-yl)cyclohexyl)-4-((R)-7-ethyl-8-isopropyl-5-methyl-6-oxo-5,6,7,8-tetrahydropteridin-2-ylamino)-3-methoxybenzamide, targets the Polo-like kinase Plk1 (IC<sub>50</sub> = 0.87 nM), bringing about G<sub>2</sub>/M cell-cycle arrest and cell death. This agent exhibits synergistic antitumor activity in combination with other chemotherapeutic agents. Low nanomolar concentrations of BI6727 display potent inhibitory activity against neuroblastoma. 1. Rudolph, et al. (2009) *Clin. Cancer Res.* **15**, 3094. 2. Grinshtein, et al. (2011) *Cancer Res.* **71**, 1385. 3. Harris, et al. (2012) *BMC Cancer* **12**, 80.

### Volinanserin

This highly selective serotonin antagonist (FW = 373.46 g/mol; CAS 139290-65-6), also known as (R)-(2,3-dimethoxyphenyl)-[1-[2-(4-fluorophenyl)ethyl]-4-piperidyl]methanol and MDL-100,907, targets HT<sub>2A</sub> receptors, showing favorable properties as an antidepressant, antipsychotic,

and sleep aid. **See also** *Ketanserin*; *Pimavanserin*; *RH-34*; *Risperidone*; *Ritanserin*; *Setoperone*. **1.** Schmidt, Fadaye, Sullivan & Taylor (1992) *Eur. J. Pharmacol.* **223**, 65. **3.** Herth, Kramer, Piel, *et al.* (2009) *Bioorg. Medic. Chem.* **17**, 2989. **3.** Nic, Fox, Stutz, Rice & Cunningham (2009) *Behav. Neurosci.* **123**, 382.

### Volkensin

This highly toxic heterodimeric protein (MW = 62 kDa; subunits of  $M_r$  36 and 29 kDa) from the roots of *Adenia volkensii* is a galactose-specific lectin that inhibits protein synthesis in rabbit reticulocyte lysates and HeLa cells (1). In mice, the LD<sub>50</sub> is 1.38 µg per kg body weight. **Use in Inducing Motor Neuron Loss:** In as early as four days after volkensin injection (5.0 ng), rat peroneal or sciatic nerves degenerate in the ventral horn of the lumbar spinal cord and L<sub>4</sub> and L<sub>5</sub> dorsal root ganglia. By two weeks, no retrogradely labeled motoneurons can be found in the treated peroneal pool. Moreover, loss of motor neurons is accompanied by severe loss of muscle mass. **1.** Stirpe, Barbieri, Abbondanza, *et al.* (1985) *J. Biol. Chem.* **260**, 14589. **2.** Nógrádi & Vrbová (1992) *Neuroscience* **50**, 975.

### Vomitoxin

This trichothecene-class mycotoxin and probable carcinogen (FW = 296.32 g/mol; CAS 51481-10-8), also named deoxynivalenol (DON) and (3 $\alpha$ ,7 $\alpha$ )-3,7,15-trihydroxy-12,13-epoxytrichothec-9-en-8-one, is a secondary metabolite of *Fusarium graminearum* and *F. culmorum*, common grain contaminants that cause head blight in wheat and also damage maize. Vomitoxin is a ribotoxin that interrupts protein synthesis by binding to ribosomes and triggering a Ribotoxic Stress Response (RSR), in which mitogen-activated protein kinases (MAPKs) are activated (1). In mononuclear phagocytes, DON induces p38 mobilization to the ribosome, attended by phosphorylation (2). Other effects include anorexia, suppressed immune response to pathogens, and superinduction of cytokines by T-helper cells. Vomitoxin is hazardous and, as its name implies, induces violent vomiting when administered at elevated concentrations. At lower concentrations, vomitoxin also stimulates tryptophan uptake in the CNS, increasing serotonin synthesis and most likely accounting for its anorexic effects. **1.** Rotter, Prelusky & Pestka (1996) *J. Toxicol. Environ. Health* **48**, 1. **2.** Bae & Pestka (2008) *Toxicol. Sci.* **105**, 59.

### Vonoprazan

This Potassium-Competitive Acid Blocker, *or* P-CAB (FW = 461.46; CAS 1260141-27-2; Solubility: 62 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as TAK-438 and 5-(2-fluorophenyl)-*N*-methyl-1-(3-pyridinylsulfonyl)-1*H*-pyrrole-3-methanamine, reversibly inhibits the proton-pumping H<sup>+</sup>/K<sup>+</sup>, ATPase (IC<sub>50</sub> = 19 nM at pH 6.5), controlling gastric acid secretion (1). Its inhibitory potency is unaltered by ambient pH, whereas SCH28080 and lansoprazole inhibition is weaker at pH 7.5. The inhibition by vonoprazan and SCH28080 is reversible and achieved in a K<sup>+</sup>-competitive manner, an action that is quite different from that by lansoprazole. When administered at a dose of 4 mg/kg (as the free base) orally, completely inhibited basal and 2-deoxy-D-glucose-stimulated gastric acid secretion in rats, and its effect on both was stronger than that of lansoprazole (1). The drug is approved in Japan for the treatment of acid-related diseases, including erosive oesophagitis, gastric ulcer, duodenal ulcer, peptic ulcer, gastric reflux, reflux esophagitis and *Helicobacter pylori* eradication (2). **1.** Hori, Imanishi, Matsukawa, *et al.* (2010) *J. Pharmacol. Exp. Ther.* **335**, 231. **2.** Garnock-Jones (2015) *Drugs* **75**, 309.

### Vorapaxar

This himbacine-based thrombin receptor antagonist (FW = 492.98 g/mol; CAS 618385-01-6), also known as SCH 530348, Zontivity<sup>®</sup>, and ethyl *N*-[(3*R*,3*aS*,4*S*,4*aR*,7*R*,8*aR*,9*aR*)-4-[(*E*)-2-[5-(3-fluorophenyl)-2-pyridyl]-vinyl]-3-methyl-1-oxo-3*a*,4,4*a*,5,6,7,8,8*a*,9,9*a*-decahydro-3*H*-benzo[*f*]isobenzofuran-7-yl]carbamate, is an orally active and potent platelet-directed anticoagulant, binding with extreme affinity (1). Vorapaxar potently antagonizes the platelet thrombin receptor protease-activated receptor-1 (PAR-1), leaving intact thrombin's procoagulant function and demonstrating no effect on bleed time or coagulation parameters, high bioavailability and inhibited *ex vivo*. Thrombin Receptor-Activating Peptide- (*or* TRAP-) stimulates platelet aggregation in a potent and long-lasting manner (2). It is an FDA-approved treatment for acute coronary syndrome chest pain caused by coronary artery disease. Vorapaxar does not affect platelet aggregation, as induced by adenosine diphosphate (ADP), collagen or a thromboxane mimetic; nor does it alter coagulation parameters *ex vivo*. While PAR-1 receptors are also expressed in endothelial cells, neurons, and smooth muscle cells, vorapaxar's pharmacodynamic effects in these cell types have not been assessed. **1.** Chackalamanni, Wang, Greenlee, *et al.* (2008) *J. Med. Chem.* **51**, 3061. **2.** Oestreich (2009) *Curr. Opin. Investig. Drugs* **10**, 988.

### Voriconazole

This triazole antifungal (FW = 349.31; CAS 137234-62-9, 173967-54-9; Solubility: 70 mg/mL DMSO; <1 mg/mL Water), also known as systematically as (2*R*,3*S*)-2-(2,4-difluorophenyl)-3-(5-fluoropyrimidin-4-yl)-1-(1*H*-1,2,4-triazol-1-yl)butan-2-ol, is used to control serious infections by invasive fungal infections (*e.g.*, invasive candidiasis, aspergillosis, and other emerging fungal pathogens) typically infecting immunocompromised patients. **Mode of Action:** Voriconazole severely impairs growth by inhibiting sterol-14 $\alpha$ -demethylase (cytochrome P450 CYP51), thereby blocking production of brassinosteroids, a recently recognized class of steroidal phytohormones (1). The natural voriconazole resistance of the woodland strawberry *Fragaria vesca* is conferred by the specific voriconazole-resistant CYP51 variant (1). Voriconazole also targets CYP3A4 and P-glycoprotein, *or* P-gp (2). **See also related compound, Fluconazole Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** Rozhon, Husar, Kalaivanan *et al.* (2013) *PLoS One* **8**, e53650. **2.** Park, Song, Kang, *et al.* (2012) *Clin. Nephrol.* **78**, 412.

### Vorinostat

This histone deacetylase inhibitor (FW = 264.30 g/mol; CAS 149647-78-9; Solubility: 50 mg/mL DMSO; 1 mg/mL Water; *Abbreviation:* SAHA), also

known as MK-0683, suberoylanilide hydroxamic acid, and Zolinza, targets HDAC1 and HDAC3 with  $IC_{50}$  values of 10 nM and 20 nM, respectively, resulting in a marked hyperacetylation of histone H4 (1). X-ray crystal structures of the uncomplexed HDAC as well as its binary complexes with trichostatin A and SAHA reveal an active site consisting of a tubular pocket, a  $Zn^{2+}$  binding site, as well as two Asp-His charge-relay systems, suggesting a likely mechanism for HDAC inhibition (2). Active-site residues contacting these inhibitors are conserved across the HDAC family, suggesting a histone deacetylation mechanism that should provide a framework for developing HDAC-directed inhibitors as antitumor agents. Vorinostat inhibits the prostate cancer cell growth ( $EC_{50} = 2.5-7.5 \mu M$ ), inducing dose-dependent cell death (3). Vorinostat also inhibits the NF- $\kappa B$  pathway by suppressing the degradation of I- $\kappa B\alpha$  and attenuating NF- $\kappa B$  p65 translocation to the nucleus (4). Transcriptome analysis of prostate cancer PC3 cells identified a subset of NF- $\kappa B$  target genes reversibly regulated by Vorinostat, as well as a group of interferon (IFN)-stimulated genes (ISGs) (5). Consistent with the induction of NF- $\kappa B$  target genes, vorinostat-mediated enhancement of vesicular stomatitis virus (VSV) oncolysis increases hyper-acetylation of NF- $\kappa B$  RELA/p65, a signaling event that also increases expression of several autophagy-related genes. VSV replication and cell killing are suppressed, when NF- $\kappa B$  signaling was inhibited. Inhibition of autophagy by 3-methyladenine enhanced expression of ISGs, indicating that vorinostat stimulates NF- $\kappa B$  activity in a reversible manner by modulating RELA/p65, inducing autophagy, suppressing IFN-mediated responses, and then enhancing VSV replication and apoptosis (5). 1. Richon, *et al.* (1998) *Proc. Natl. Acad. Sci. USA* **95**, 3003. 2. Finnin, Donigian, Cohen, *et al.* (1999) *Nature* **401**, 188. 3. Butler, *et al.* (2000) *Cancer Res.* **60**, 5165. 4. Zhong, Ding, Chen & Luo (2013) *Int. Immunopharmacol.* **17**, 329. 5. Shulak, Beljanski, Chiang, *et al.* (2013) *J. Virol.* **88**, 2927.

#### Vorozole

This triazole derivative and orally available nonsteroidal aromatase inhibitor (FW = 324.8 g/mol; CAS 118949-22-7), also known by the code name R83842 and systematically as 6-[(4-chlorophenyl)(1,2,4-triazol-1-yl)methyl]-1-methylbenzotriazole, targets aromatase ( $IC_{50} = 1.4$  nM, competitive inhibitor), significantly reducing plasma estradiol levels in postmenopausal women. (Note: Aromatase is an adrenal enzyme that converts androstenedione and estrone to estrogen.) Vorozole is highly effective in the treatment of these women with advanced breast cancer. In pregnant mare serum gonadotropin- (PMSG)- primed female rats, plasma estradiol levels at 2 hours after single oral administration of vorozole were significantly reduced by doses  $\geq 1 \mu g/kg$ , with an  $ED_{50}$  of 3.4  $\mu g/kg$  (2). An added feature is that vorozole displays  $>10000\times$  selectivity for aromatase versus other cytochrome P450 enzymes (1). **See also Letrozole** 1. Wouters, Snoeck & De Coster (1994) *Breast Cancer Res. Treat.* **30**, 89. 2. Wouters, Van Ginckel, Krekels, Bowden & De Coster (1993) *J. Steroid Biochem. Mol. Biol.* **44**, 617.

#### Vortioxetine

This serotonin reuptake inhibitor (FW<sub>free-base</sub> = 298.45 g/mol; FW<sub>hydrobromide</sub> = 379.36 g/mol; CAS 508233-74-7), also known by its Code name Lu

AA21004, its trade name Brintellix<sup>®</sup>, and its systematic name 1-[2-(2,4-dimethylphenylsulfanyl)phenyl]piperazine, is an atypical antidepressant that targets the human 5-HT transporter (SERT) inhibitor ( $K_i = 1.6$  nM); 5-HT<sub>1A</sub> receptor, with high-efficacy partial agonist action ( $K_i = 15$  nM), the 5-HT<sub>1B</sub> receptor partial agonist ( $K_i = 33$  nM), the 5-HT<sub>1D</sub> receptor antagonist ( $K_i = 54$  nM), the 5-HT<sub>3A</sub> receptor antagonist ( $K_i = 3.7$  nM), the 5-HT<sub>7</sub> receptor antagonist ( $K_i = 19$  nM), and the norepinephrine transporter, or NET ( $K_i = 113$  nM) (1,2). Vortioxetine likewise displays moderately high affinity for the  $\beta_1$ -adrenergic receptor ( $K_i = 46$  nM). **Pharmacokinetics:** After oral administration, Lu AA21004 shows an extended absorption phase, a large volume of distribution, and a medium clearance rate, resulting in late  $t_{max}$  values and a mean elimination  $t_{1/2}$  of 57 hr (3). See reference (4) for drug interactions, especially dose adjustment required when vortioxetine is co-administered with bupropion or rifampicin. **Metabolism:** Lu AA21004 was found *in vitro* to be oxidized to a 4-hydroxy-phenyl metabolite (by CYP2D6 with some contribution from CYP2C9), a sulfoxide (by CYP3A4/5 and CYP2A6), an *N*-hydroxylated piperazine (by CYP2C9 and CYP2C19), and a benzylic alcohol (by CYP2D6) that is further oxidized to 3-methyl-4-(2-piperazin-1-ylphenylsulfanyl)benzoic acid. Benzylic alcohol oxidation to the corresponding benzoic acid is primarily catalyzed by alcohol dehydrogenase and aldehyde dehydrogenase. 1. Bang-Andersen, Ruhland, Jørgensen, *et al.* (2011) *J. Med. Chem.* **54**, 3206. 2. Mørk, Pehrson, Brennum, *et al.* (2012) *J. Pharmacol. Exp. Ther.* **340**, 666. 3. Areberg, Søgaard, Højer (2012) *Basic Clin. Pharmacol. Toxicol.* **111**, 198. 4. Chen, Lee, Højer, *et al.* (2013) *Clin. Drug Investig.* **33**, 727.

#### Voruciclib

This potent flavone-based CDK inhibitor (FW = 487.90 g/mol; CAS 1000023-04-0; Soluble in DMSO), also named P1446A-05 and 2-[2-chloro-4-(trifluoromethyl)phenyl]-5,7-dihydroxy-8-[(2R,3S)-2-(hydroxymethyl)-1-methyl-3-pyrrolidinyl]-4H-chromen-4-one, selectively targets Cyclin-Dependent Kinases 4 and 6, with activity in multiple BRAF-mutant and wild type cell lines. The addition of a CDK 4/6 inhibitor to BRAF inhibitors is supported by extensive preclinical data. 1. Diab, Martin, Simpson, *et al.* (2015) ASCO Annual Meeting, *J. Clin. Oncol.* **33**, Suppl. Abstr. 9076.

#### Voxtalisisb

This mTOR/PI3K dual inhibitor (FW = 270.30 g/mol; CAS 934493-76-2; Solubility: 200 mM in DMSO; < 1 mg/mL in H<sub>2</sub>O), also known as SAR245409, XL765, and 2-amino-8-ethyl-4-methyl-6-(1H-pyrazol-5-yl)pyrido[2,3-d]pyrimidin-7-one, targets p110 $\gamma$  ( $IC_{50} = 9$  nM), but also inhibits DNA-PK and mTOR. Voxtalisisb is pro-apoptotic to chronic lymphocytic leukemia (CLL) cells, irrespective of their ATM/p53 status, than PI3K $\alpha$  or PI3K $\delta$  isoform-selective inhibitors (2). SAR245409 also blocks CLL survival, adhesion and proliferation (2). Dual PI3K/mTOR inhibition results in increased anti-tumor activity, both *in vitro* and *in vivo*, in models of pancreatic adenocarcinoma (3). 1. Papadopoulos, Egile, Ruiz-Soto, *et al.* (2015) *Leuk. Lymphoma* **56**, 1763. 2. Thijssen, Ter Burg, van Bochove, *et al.* (2016) *Leukemia* **30**, 337. 3. Mirzoeva, Hann, Hom, *et al.* (2011) *J. Mol. Med. (Berlin)* **89**, 877.

VP-16-213, See *Etoposide*

### VPS34-IN1

This first-in-class, cell-permeable inhibitor (FW = 424.93 g/mol) targets recombinant, insect cell-expressed class III PI3K isoform known as Vps34 (Vacuolar protein sorting-34) with an  $IC_{50}$  ~25 nM, but does not significantly inhibit other lipid (or protein) kinases tested, including class I or class II phosphoinositide 3-kinases. PI3Ks phosphorylate the 3'-hydroxyl of the *D-myo*-inositol head group of phosphatidylinositol (PtdIns), thereby generating 3-phosphoinositides that orchestrate aspects of cell growth, proliferation and intracellular trafficking. Vps34 assists in controlling vesicular protein sorting, by forming a core complex with Vps15 (itself a serine/threonine protein kinase) and Beclin-1 (also known as Vps30 or ATG6) [24]. The resulting core complex then interacts with a growing list of proteins to form distinct complexes that regulate endosomal membrane trafficking processes, endosome-lysosome maturation, and autophagy. VPS34-IN1 also rapidly reduces endosomal PtdIns(3)P levels within 1 min of treatment. Use of VPS34-IN1 helped to demonstrate that Vps34 plays a role in regulating the phosphorylation and activity of the Serum- and Glucocorticoid-regulated protein Kinase-3 (SGK3), the only protein kinase known to possess a selective PtdIns(3)P-binding PX domain. That VPS34-IN1 suppresses Vps34 activity in cells is supported by the observed complete dispersal of PtdIns3P-binding GFP-labeled 2xFYVE<sub>HIS</sub> from endosomal membranes within 1-2 minutes. When present at 1  $\mu$ M, VPS34-IN1 does not appreciably inhibit the activity of 340 protein kinases or 25 lipid kinases, including all isoforms of Class I and II PI3Ks. Use of VPS34-IN1 revealed phosphatidylinositol 3-phosphate binding SGK3 protein kinase as a downstream target of Class III PI-3 kinase. Other Vps34 inhibitors (See Wortmannin, 3-Methyadenine, LY294002, KU55933, G66946) are not selective in their action. 1. Bago, Malik, Munson, *et al.* (2014) *Biochem. J.* **463**, 413.

### VR

This membrane-penetrating chemical warfare (CW) agent (FW = 267.37 g/mol; CAS 159939-87-4); IUPAC Name: *S*-(2-diethylaminoethyl) isobutylmethylphosphonothioate, also variously known as Russian VX, Soviet V-gas, Substance-33, and R-33, binds to and irreversibly inhibits acetylcholinesterase. VR has similar lethal dose (10–50 mg) levels to VX. Pre-treatment with pyridostigmine prior to exposure can reduce VR toxicity, but not death at high VR exposure. The oxime HI-6 is quite effective in reactivating acetylcholinesterase–VR adducts. The facile synthesis VR was conducive to production of so-called binary weapons, where less toxic precursors are combined while the CW projectile is in flight (4). 1. Worek, Thiermann, Szinicz & Eyer (2004) *Biochem. Pharmacol.* **68**, 2237. 2. Shih, Kan & McDonough (2005) *Chem. Biol. Interact.* **157-158**, 293. 3. (ISBN 978-1-4327-2566-2).

### VS-5584

This potent ATP-competitive dual-PI3K/mTOR inhibitor FW = 345.32 g/mol; CAS 1246560-33-7; Solubility: 71 mg/mL DMSO), also known as SB2343 and 5-[8-methyl-9-(1-methylethyl)-2-(4-morpholinyl)-9H-purin-6-yl]-2-pyrimidinamine, selectively targets mTOR ( $IC_{50}$  = 3.4 nM), PI3K $\alpha$  ( $IC_{50}$  = 2.6 nM), PI3K $\alpha$ -H1047 ( $IC_{50}$  = 3.3 nM), PI3K $\beta$  ( $IC_{50}$  = 21 nM), PI3K $\delta$  ( $IC_{50}$  = 2.7 nM), and PI3K $\gamma$  ( $IC_{50}$  = 3 nM), without relevant activity on 400 other lipid and protein kinases. VS-5584 likewise exhibits favorable pharmacokinetic properties after oral dosing in mice and is well tolerated. VS-5584 induces long-lasting and dose-dependent inhibition of PI3K/mTOR signaling in tumor tissue, leading to tumor growth inhibition in various rapalog-sensitive and -resistant human xenograft models. It also reduces the number of functional blood vessels in the tumor. 1. Hart, Novotny-Diermayr, Goh, *et al.* (2013) *Mol. Cancer Ther.* **12**, 151.

### VTP-27999

This renin inhibitor and antihypertensive (FW = 525.09 g/mol; CAS 942142-51-0) resembles aliskiren, showing a similar  $IC_{50}$  (0.3 nM) and  $t_{1/2}$  (30 hours), but having a 7-8x higher bioavailability (~20%). VTP-27999 blocks renin, but also binds to prorenin, the latter inducing a conformational change (like that induced by acid), thereby allowing its recognition in a renin-specific assay. (See Aliskiren). Notably, *in vitro* analysis demonstrated that VTP-27999 increases renin immunoreactivity for a given amount of renin by  $\geq 30\%$  without unfolding prorenin (1). It binds to acid-activated, intact prorenin, increasing immunoreactivity in a renin assay. No such increase in immunoreactivity is observed, when acid-activated prorenin bound to VTP-27999 is measured in a prosegment-directed assay (1). VTP-27999-induced increases in renin immunoreactivity is competitively prevented by aliskiren, and antibody displacement studies shows a higher affinity of the active site-directed antibodies in the presence of VTP-27999 (1). VTP-27999 accumulates at higher levels in HMC-1 cells than when on aliskiren, allowing this inhibitor to block intracellular renin at approximately five-fold lower medium levels (2). 1. Krop, Lu, Verdonk, *et al.* (2013) *Hypertension* **61**, 1075. 2. Lu, Krop, Batenburg, *et al.* (2014) *J. Hypertens.* **12**, 1255.

### VU 0409106

This potent and selective allosteric mGlu<sub>5</sub> inhibitor and anxiolytic (FW = 330.34 g/mol; CAS 1276617-62-9; Solubility: 100 mM in DMSO), also named 3-fluoro-*N*-(4-methyl-2-thiazoly)-5-(5-pyrimidinyl)oxy)benzamide, targets the metabotropic glutamate receptor-5 (IC<sub>50</sub> = 49 nM), a G protein-coupled receptor that in humans is encoded by the GRM5 gene. VTP-27999 differs from aliskiren regarding its level of intracellular accumulation and its capacity to interfere with renin signaling via the (Pro)Renin Receptor in rat vascular smooth muscle cells, and the (P)RR determines prorenin-angiotensin conversion and constitutive (but not regulated) (pro)renin release. **1.** Felts, Rodriguez, Morrison, *et al.* (2013) *Bioorg. Med. Chem. Lett.* **23**, 5779.

#### VUF 5574

This potent A<sub>3</sub> antagonist (FW = 371.40 g/mol; CAS 280570-45-8; IUPAC: *N*-(2-Methoxyphenyl)-*N'*-[2-(3-pyridinyl)-4-quinazolinyl]urea) selectively targets the adenosine A<sub>3</sub> receptor (K<sub>i</sub> = 4 nM), showing >2500-fold selectivity versus A<sub>1</sub> and A<sub>2A</sub> receptors. This GPCR couples to Gi/Gq and mediates a sustained cardioprotective action during cardiac ischemia. VUF 5574 competitively antagonizes the effect of an agonist in a functional A<sub>3</sub> receptor assay (*i.e.*, inhibition of cAMP production in cells expressing the human adenosine A<sub>3</sub> receptor). A<sub>3</sub> receptor stimulation is also deleterious during ischaemia, and treatment with VUF 5574 appears to increase the resistance of the CA1 hippocampal region to ischaemic damage (3). **1.** van Muijlwijk-Koezen, Timmerman, van der Goot, *et al.* (2000) *J. Med. Chem.* **43**, 2227. **2.** Baraldi & Borea (2000) *Trends Pharmacol. Sci.* **21**, 456. **3.** Pugliese, Coppi, Spalluto, Corradetti & Pedata (2006) *Brit. J. Pharmacol.* **147**, 524.

#### VX

This chemical warfare agent (FW<sub>free-base</sub> = 267.37 g/mol; CAS 50782-69-9; 51848-47-6; 53800-40-1, and 65143-05-7), also named *O*-ethyl *S*-(2-diisopropylaminoethyl)methylphosphonothioate, is a colorless, odorless, and amber liquid with a low volatility and motor oil-like consistency. Binary VX, also referred to as VX2, is formed by mixing *O*-(2-diisopropylaminoethyl) *O'*-ethyl methylphosphonite (Agent QL) with elemental sulfur (Agent NE) within chemical warfare munitions. VX was classified as a weapon of mass destruction by the UN Resolution 687, and its production and stockpiling are outlawed by the Chemical Weapons Convention of 1993. It is neutralized by reaction with aqueous sodium hydroxide and other nucleophiles, including hydroxylamine. **Caution:** The LD<sub>50</sub> of this irreversible cholinesterase inhibitor in rabbits is ~15 µg/kg subcutaneous and 7 µg/kg (intravenous) in rats. Its inhalation LC<sub>50</sub> is 30–

50 mg·min/m<sup>3</sup>. Extreme care must be exercised, as a small drop contacting the skin is sufficient to kill a human. **Target(s):** acetylcholinesterase (1-7); cholinesterase, *or* butyrylcholinesterase (1,5-10); and Na<sup>+</sup>/K<sup>+</sup> exchanging ATPase (11). **1.** Duysen, Li, Xie, *et al.* (2001) *J. Pharmacol. Exp. Ther.* **299**, 528. **2.** Friboulet, Rieger, Goudou, Amitai & Taylor (1990) *Biochemistry* **29**, 914. **3.** Forsberg & Puu (1984) *Eur. J. **VX-680, See MK-0457**

#### VX-745

This anti-inflammatory agent (FW = 436.27 g/mol) is a small-molecule inhibitor of mitogen activated protein kinase (p38 MAP), exhibiting an IC<sub>50</sub> value of 0.8 nM. **1.** Haddad (2001) *Curr. Opin. Investig. Drugs* **2**, 1070. **2.** Hideshima, Akiyama, Hayashi, *et al.* (2003) *Blood* **101**, 703. **3.** Stelmach, Liu, Patel, *et al.* (2003) *Bioorg. Med. Chem. Lett.* **13**, 277. **4.** Fitzgerald, Patel, Becker, *et al.* (2003) *Nature Struct. Biol.* **10**, 764.

#### VX-765

This oral interleukin (IL)-converting enzyme/caspase-1 inhibitor (FW = 508.99 g/mol; CAS 273404-37-8), also known as (*S*)-1-((*R*)-2-(4-amino-3-chlorobenzamido)-3,3-dimethylbutanoyl)-*N*-((2*S*,3*S*)-2-ethoxy-5-oxotetrahydrofuran-3-yl)pyrrolidine-2-carboxamide, selectively targets caspase-1 (K<sub>i</sub> = 0.8 nM) and exhibits potent anti-inflammatory activities by inhibiting the release of IL-1β and IL-18. **1.** Wannamaker, Davies, Namchuk, *et al.* (2006) *J. Pharmacol. Exp. Ther.* **321**, 509.

**VX-950, See Telaprevir**

# - W -

**W, See Tryptophan; Tungsten and Tungsten Ions**

## 1400W

This slow, tight binding inhibitor (FW = 250.17 g/mol; CAS 214358-33-5), also named *N*-[[3-(aminomethyl)phenyl]methyl]ethanimidamide dihydrochloride, selectively targets inducible Nitric Oxide Synthase, or iNOS ( $K_i = 7$  nM), with far weaker action against nNOS ( $K_d = 2$   $\mu$ M) and eNOS ( $K_d = 50$   $\mu$ M). This inhibitor is cell-permeable and active *in vivo*. The slow onset of inhibition by 1400W shows saturation kinetics with a maximal unimolecular rate constant of  $0.028$  s<sup>-1</sup> and a binding constant of  $2.0$   $\mu$ M (1). Inhibition is dependent on the cofactor NADPH. L-Arginine was a competitive inhibitor of 1400W binding with a  $K_s$  value of  $3.0$   $\mu$ M. Inhibited enzyme did not recover activity after 2 hours. Thus, 1400W was either an irreversible inhibitor or an extremely slowly reversible inhibitor of human iNOS with a  $K_d$  value less than or equal to  $7$  nM (1). For the EMT6 murine mammary adenocarcinoma, in which iNOS is expressed in the tumor cells, continuous infusion of 1400W for 6 days at  $10$ – $12$  mg/kg<sup>-1</sup>/hour<sup>-1</sup> resulted in significant reduction in tumor weight (357 and 466 mg, respectively) compared with that of controls (2). 1. Garvey, Oplinger, Furfine, *et al.* (1997) *J. Biol. Chem.* **272**, 4959. 2. Thomsen, Scott, Topley, *et al.* (1997) *Cancer Res.* **57**, 3300.

## W84

This synthetic allosteric modulator (FW = 708.54 g/mol; CAS 21093-51-6; Soluble to 10 mM in DMSO), also named hexamethylenebis[3-(dimethylammonio)propyl]dibromide, increases the protective effect of atropine against organophosphate poisoning by stabilizing cholinergic antagonist-receptor complexes (1-3). It produces a much greater reduction in the affinity of carbachol than that of the competitive antagonists and as a consequence is said to exert a 'supra-additive' effect, when combined with a competitive antagonist (1). W84 acts equally well on the cardiac cholinergic receptors of guinea pigs, rats, and pigs, respectively (3). 1. Mitchelson (1975) *Eur. J. Pharmacol.* **33**, 237. 2. Jepsen, Lüllmann, Mohr & Pfeffer (1988) *Pharmacol. Toxicol.* **63**, 163. 3. Mohr, Staschen & Ziegenhagen (1992) *Pharmacol. Toxicol.* **70**, 198.

## W146

This S1P<sub>1</sub>R antagonist (MW = 342.37 g/mol; CAS 909725-61-7; Soluble to 20 mM as sodium salt), named systematically as *R*-3-amino-4-(3-hexylphenylamino)-4-oxobutylphosphonic acid, targets sphingosine 1-phosphate (subtype-1) receptors ( $K_i = 40$  nM), with no effect at S1P<sub>2</sub>, S1P<sub>3</sub> or S1P<sub>5</sub> receptors (1,2). W146 enhances capillary leakage and restores lymphocyte egress *in vivo*. 1. Sanna, *et al.* (2006) *Nature Chem. Biol.* **2**, 434. 2. Gonzalez-Cabrera, *et al.* (2007) *Biol. Chem.* 10th ed., **282**, 7254.

## W-54011

This orally active nonpeptide C5a receptor antagonist (FW = 493.08 g/mol; CAS 405098-33-1), also named *N*-[(4-dimethylaminophenyl)methyl]-*N*-(4-isopropylphenyl)-7-methoxy-1,2,3,4-tetrahydronaphthalen-1-carboxamide, inhibits the binding of anaphylatoxin C5a, a potent for neutrophil/leukocyte chemotactic factor and inflammatory mediator, to human neutrophils ( $K_i = 2.2$  nM). W-54011 also inhibits C5a-induced intracellular Ca<sup>2+</sup> mobilization, chemotaxis, and generation of reactive super oxide species in human neutrophils with IC<sub>50</sub> values of 3.1, 2.7, and 1.6 nM, respectively. In C5a-induced intracellular Ca<sup>2+</sup> mobilization assay with human neutrophils, W-54011 is not an agonist, even at 10  $\mu$ M, and shifts the dose-response curves to C5a to the right without depressing the maximal responses. W-54011 inhibits C5a-induced intracellular Ca<sup>2+</sup> mobilization in neutrophils from cynomolgus monkeys and gerbils, but not mice, rats, guinea pigs, rabbits, and dogs. 1. Sumichika, Sakata, Sato, *et al.* (2002) *J. Biol. Chem.* **277**, 49403.

**1400W, See *N*-(3-Aminomethyl)benzylacetamide**

## Waldiomycin

This benz[*a*]anthraquinone antibiotic (FW = 702.71 g/mol) from the culture broth of *Streptomyces* sp. MK844-mF10, inhibits the histidine kinase WalK and the response regulator WalR, which comprise a two-component signal transduction system that is indispensable for the cell-wall metabolism of low-GC Gram-positive bacteria. Waldiomycin inhibits WalK from *Staphylococcus aureus* (MRSA) and *Bacillus subtilis* at IC<sub>50</sub> values of 8.8 and 10.2  $\mu$ M, respectively, and shows antibacterial activity with MICs ranging from 4 to 8  $\mu$ g mL<sup>-1</sup> against MRSA and *B. subtilis*. Its structure was determined by two-dimensional NMR. Waldiomycin is structurally related to capoamycin and dioxamycin. 1. Igarashi, Watanabe Hashida, *et al.* (2013) *J. Antibiot.* (Tokyo) **66**, 459.

**Warburganal**

This sulfhydryl-reactive, antifungal and antibiotic sesquiterpene dialdehyde (FW = 250.34 g/mol; CAS 62994-47-2) from the plants *Warburgia ugandensis* of East African is a potent inhibitor of numerous sulfhydryl-dependent enzymes, including alcohol dehydrogenase, which can be fully reactivated upon treatment with excess L-cysteine. Warburganal is an anti-feedant agent used to combat the African army worm. The minimal inhibitory concentrations for *Saccharomyces cerevisiae* and *Candida albicans* are both about 6 µg/mL. **1.** Taniguchi, Adachi, Haraguchi, Oi & Kubo (1983) *J. Biochem.* **94**, 149.

**Warfarin**

This synthetic vitamin K mimic (FW = 308.33 g/mol; CAS= 81-81-2), also marketed under the tradenames Coumadin®, Jantoven®, Marevan®, Lawarin®, and Waran®, and systematically named 3-( $\alpha$ -acetyltolyl)-4-hydroxycoumarin, exhibits powerful anticoagulant action by inhibiting the reductase that converts vitamin K epoxide to its biologically active form, thereby creating a functional vitamin K deficiency. First prepared as a racemic mixture by Link and coworkers (1), warfarin is a derivative of the hemorrhagic agent dicoumarol (See *Dicoumarol*) and is a registered trademark of the Wisconsin Alumni Research Foundation. **Use as an Anticoagulant:** Warfarin and related coumarin anticoagulants act by inhibiting the posttranslational carboxylation of vitamin K-dependent coagulation factors II, VII, IX and X. These anticoagulants have no direct effect on an established thrombus, and they cannot reverse ischemic tissue damage. Instead, the aim of anticoagulation therapy is to prevent further clot progression as well as other thromboembolic complications. Upon oral dosing in humans, warfarin is completely absorbed, reaching peak concentrations within 4 hours. Its half-life is 20–60 hours, and its effects last for 2–5 days. Metabolism mainly occurs by liver CYP2C9. Warfarin dosing is complicated by many common medications as well as the presence of vitamin K in certain plant foodstuffs. Indeed, warfarin's anticoagulative effects are readily reversed by intravenous administration of (a) vitamin K, (b) prothrombin complex concentrate (PPC), which contains those factors formed in the absence of Warfarin, and/or (c) fresh frozen plasma (FFP), when available. Vitamin K1 is essential for sustaining the reversal achieved by PCC and FFP. Certain antibiotics, such as metronidazole, also retard Warfarin breakdown, and such effects also complicate its dosing. Use of Warfarin may also be compromised by off-target effects that suppress posttranslational  $\gamma$ -carboxylation of proteins (e.g., osteocalcin, or matrix Gla protein) that are unrelated to blood clotting *per se*. (See also *Heparin, Clopidogrel, Dabigatran, Rivaroxaban, and Apixaban*) **Use as a Rodenticide:** Because rats and mice experience life-threatening hemorrhage, after injecting sufficient quantities of Warfarin, this

anticoagulant has been exploited as a reliable and powerful rodenticide sold under the tradenames R-Tox®, Co-Rax®, d-Con®, Dethmor®, Mar-Fin®, Rattunal®, Rax®, Rodex®, Rodex Blox®, Rosex®, Solfarin®, Tox-Hid®, Warf®, and Warfarat®. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** Arylsulfatase (2,3); coagulation factor Xa (4,5); NAD(P)H dehydrogenase (quinone) (6); thyroxine 5'-deiodinase (7); vitamin K epoxide reductase, *primary anticoagulative target* (8-10); (S)-warfarin-7 hydroxylase (inhibited by the (R)-enantiomer) (11) **1.** Ikawa, Stahmann & Link (1944) *J. Amer. Chem. Soc.* **66**, 902. **2.** Ferrante, Messali, Ballabio & Meroni (2004) *Gene* **336**, 155. **3.** Franco, Meroni, Parenti, Levilliers, *et al.* (1995) *Cell* **81**, 15. **4.** Pejler, Lunderini & Tomasini-Johansson (2000) *Thromb. **WASP**

This tetrameric cytoskeletal protein (MW = 210 kDa) NCBI Taxonomic Identifier = 9606, known as Wiskott-Aldrich Syndrome Protein, is a putative actin filament end-tracking protein that is activated by the Rho-family GTPase cdc42, thereby promoting actin-based motility. WASP inhibits cytosolic src protein-tyrosine kinase. **See also N-WASP inhibitor** **1.** Chong, Ia, Mulhern & Cheng (2005) *Biochim. Biophys. Acta* **1754**, 210.

**(S)-WAY-100135**

This systemically administered 5-HT<sub>1A</sub> receptor antagonist and anxiolytic agent (FW<sub>free-base</sub> = 395.55 g/mol; FW<sub>di-HCl</sub> = 468.47 g/mol; CAS 149007-54-5; Soluble to 100 mM in DMSO and to 5 mM in water, the latter with gentle warming), also named *N*-[2-[4-(2-methoxyphenyl)-1-piperazinyl]ethyl]-*N*-2-pyridinylcyclohexanecarboxamide, targets both presynaptic and postsynaptic serotonin type-1A receptors (IC<sub>50</sub> = 15 nM), with 100% selectivity *versus* other 5-HT subtypes as well as  $\alpha_1$ ,  $\alpha_2$  and D<sub>2</sub> receptors (IC<sub>50</sub> > 1000 nM). **1.** Cliffe *et al* (1993) *J. Med. Chem.* **36**, 1509. **2.** Fletcher *et al* (1993) *Eur. J. Pharmacol.* **237**, 283. **3.** Fletcher *et al* (1993) *Trends Pharmacol. Sci.* **14**, 41. **4.** Rodgers & Cole (1994) *Eur. J. Pharmacol.* **261**, 321.

**WAY-100635**

This 5-HT<sub>1A</sub> receptor antagonist (FW<sub>free-base</sub> = 422.57 g/mol; CAS 634908-75-1; Maleate salt is soluble to 25 mM in water and to 100 mM in DMSO), also named *N*-[2-[4-(2-methoxyphenyl)-1-piperazinyl]ethyl]-*N*-2-pyridinylcyclohexanecarboxamide, targets serotonin type-1A receptors (IC<sub>50</sub> = 2.2 nM and K<sub>i</sub> = 0.84 nM for rat 5-HT<sub>1A</sub> receptors), with 100% selectivity *versus* other 5-HT subtypes. **1.** Zhuang, Kung & Kung (1994) *J. Med. Chem.* **37**, 1406. **2.** Forster, Cliffe, Bill, *et al.* (1995) *Eur. J. Pharmacol.* **281**, 81. **3.** Chemel, Roth, Armbruster, Watts & Nichols (2006) *Psychopharmacology* (Berlin) **188**, 244.

## WAY-170523

This potent protease inhibitor (FW = 613.69 g/mol; CAS 307002-73-9), named systematically as benzofuran-2-carboxylic acid (2-{4-[benzyl(2-hydroxycarbonyl-4,6-dimethylphenyl)sulfamoyl]phenoxy}ethyl)amide, inhibits matrix metalloproteinase-13 (collagenase 3),  $IC_{50} = 17$  nM. **1.** Chen, Nelson, Levin, Mobilio, *et al.* (2000) *J. Amer. Chem. Soc.* **122**, 9648.

## WAY-252623

This oral LXR agonist (FW = 422.78 g/mol; CAS 875787-07-8; Solubility: 100 mM in DMSO), also named 2-[(2-chloro-4-fluorophenyl)methyl]-3-(4-fluorophenyl)-7-(trifluoromethyl)-2H-indazole and LXR-623, targets the Liver X Receptors LXR $\beta$  and LXR $\alpha$ , with  $IC_{50}$  values of 24 and 179 nM, respectively. LXRs are ligand-inducible transcriptional activators that coordinately regulate cholesterol and lipid metabolism. The earlier discovery that oxysterols are potential endogenous ligands and the identification of first-generation of nonsteroidal LXR agonists helped to demonstrate that LXRs (a) mediate cholesterol efflux from macrophages via activation of ABCA1, ABCG1, and apoE, (b) promote HDL cholesterol elimination via the reverse cholesterol transport (RCT) process, and (c) modulate cholesterol absorption through intestinal activation of ABCA1 or ABCG5/G8 cholesterol transporters. Such considerations highlight the likelihood that LXRs may be druggable targets for controlling atherosclerosis. In nonhuman primates with normal lipid levels, WAY-252623 significantly reduces total (50–55%) and LDL-cholesterol (LDLc) (70–77%) in a time- and dose-dependent manner as well as increased expression of the target genes ABCA1/G1 in peripheral blood cells. Statistically significant decreases in LDLc are noted as early as day-7, reaching a maximum by day-28, and exceeded reductions observed for simvastatin alone (20 mg/kg). Transient increases in circulating triglycerides and liver enzymes revert to baseline values over the course of the study. Complementary microarray analysis of duodenum and liver gene expression revealed differential activation of LXR target genes and suggested no direct activation of hepatic lipogenesis. **1.** Quinet, Basso, Halpern, *et al.* (2009) *J. Lipid. Res.* **50**, 2358. **2.** DiBlasio-Smith, Arai, Quinet, *et al.* (2008) *J. Transl. Med.* **6**, 59.

## WBA 8119, See Brodifacoum

## WDR5 0103

This WDR antagonist (FW = 383.44 g/mol; CAS 890190-22-4; Soluble to 100 mM in DMSO), also named 3-[(3-methoxybenzoyl)amino]-4-(4-methyl-1-piperazinyl)benzoic acid methyl ester, targets WD-Repeat-containing protein-5, or WDR5 ( $K_d = 450$  nM), a component of the mixed

lineage leukemia (MLL) complex that methylates Lys-4 of histone H3 and was identified as a methylated Lys-4 histone H3-binding protein. WDR5-0103 disrupts WDR5 interactions with antagonist and inhibits MLL core complex methyltransferase activity *in vitro*. WDR5-0103 has no effect on a panel of seven other methyltransferases, including the histone-lysine N-methyltransferase SETD7. **1.** Senisterra, Wu, Allali-Hassani, *et al.* (2013) *Biochem. J.* **449**, 151.

## WEB 2086

This PAF receptor antagonist (FW = 455.96 g/mol; CAS 105219-56-5; Solubility: 100 mM in DMSO, 100 mM in Ethanol), also 4-[3-[4-(2-chlorophenyl)-9-methyl-6H-thieno[3,2-f][1,2,4]triazolo[4,3-a]diazepin-2-yl]-1-oxopropyl]morpholine, is a potent and selective platelet-activating factor receptor antagonist ( $K_i = 16.3$  nM) that displays anti-inflammatory, antiangiogenic and anticancer activity. WEB 2086 inhibits growth and proliferation of MCF-7 breast cancer cells. **1.** Dent, Ukena, Chanez, *et al.* (1989) *FEBS Lett.* **244**, 365. **2.** Sariahmetoğlu, Cakici & Kanzik (1998) *Pharmacol. Res.* **38**, 173.

## Wedelolactone

This ingredient in the Chinese herbal medicine *Han Lian Cao* (FW = 314.25 g/mol; CAS 524-12-9), also known as IKK Inhibitor II and 7-methoxy-5,11,12-trihydroxycoumestan, from the false daisy *Eclipta alba* suppresses LPS-induced caspase-11 expression by directly inhibiting the IKK complex. Wedelolactone is a cell-permeable, selective and irreversible inhibitor of IKK $\alpha$  and IKK $\beta$  kinase activity ( $IC_{50} < 10$   $\mu$ M), inhibiting NF- $\kappa$ B-mediated gene transcription by blocking the phosphorylation and degradation of I $\kappa$ B $\alpha$ . IKK Inhibitor II is without effect on p38 MAP kinase or Akt. Use of *Han Lian Cao* (墨旱莲) is indicated for the treatment of coronary disease, dysentery, infantile urinary tract infections, digestive tract hemorrhage, acute nephritis, and shingles. **Target(s):** IKK kinase (1); 5-lipoxygenase (2); trypsin (3). **1.** Kobori, Yang, Gong, Heissmeyer, *et al.* (2004) *Cell Death Differ.* **11**, 123. **2.** Wagner & Fessler (1986) *Planta Med.* (5), 374. **3.** Syed, Deepak, Yogisha, Chandrashekar, *et al.* (2003) *Phytother Res.* **17**, 420.

## WF-536, See (R)-(+)-4-(1-Aminoethyl)-N-(4-pyridyl)benzamide

## WF-10129

This fungal metabolite (FW = 408.41 g/mol) is a potent inhibitor of peptidyl-dipeptidase A (angiotensin I-converting enzyme). WF-10129 inhibits the pressor response of angiotensin I, when administered intravenously at 0.3 mg/kg in rats. **1.** Mathey & Reuter (1989) *J. Basic Microbiol.* **29**, 623. **2.** Ando, Okada, Uchida, Hemmi, *et al.* (1987) *J. Antibiot.* **40**, 468.

## WHI-P97

This quinazoline (FW<sub>free-base</sub> = 455.11 g/mol), also known as JAK3 inhibitor III and systematically named as 4-(3',5'-dibromo-4'-hydroxyphenyl)amino-6,7-dimethoxyquinazoline, is a cell-permeant inhibitor of JAK3 (Janus kinase 3) protein-tyrosine kinase, IC<sub>50</sub> = 11 μM. This inhibitor also reduces the invasiveness of EGFR-positive human cancer cells in a dose-dependent manner (K<sub>i</sub> = 0.09 μM). **Target(s):** epidermal growth factor receptor protein-tyrosine kinase (1); JAK3 protein-tyrosine kinase (2). 1. Ghosh, Narla, Zheng, Liu, *et al.* (1999) *Anticancer Drug Des.* **14**, 403. 2. Sudbeck, Liu, Narla, Mahajan, *et al.* (1999) *Clin. Cancer Res.* **5**, 1569.

## WHI-P131

This quinazoline (FW = 297.31 g/mol; CAS 202475-60-3), also known as 4-(4'-hydroxyphenyl)amino-6,7-dimethoxyquinazoline, JAK3 inhibitor I, and JANEX-1, is a potent and selective inhibitor of the Janus kinase 3 with an IC<sub>50</sub> value of 78 μM. WHI-P131 also acts as a potent inhibitor of glioblastoma cell adhesion and migration and blocks thrombin-induced platelet aggregation. **Target(s):** JAK3 (Jun N-terminal kinase; Janus kinase 3) protein-tyrosine kinase (1-3). 1. Uckun, Ek, Liu & Chen (1999) *Clin. Cancer Res.* **5**, 2954. 2. Sudbeck, Liu, Narla, Mahajan, *et al.* (1999) *Clin. Cancer Res.* **5**, 1569. 3. Goodman, Niehoff & Uckun (1998) *J. Biol. Chem.* **273**, 17742.

## WHI-P154

This cell-permeable quinazoline (FW = 376.21 g/mol; CAS 211555-04-3), also known as JAK3 inhibitor II and 4-[(3'-bromo-4'-hydroxyphenyl)amino]-6,7-dimethoxyquinazoline, is a potent inhibitor of Janus kinase 3 (JAK3) protein-tyrosine kinase (IC<sub>50</sub> = 5.6 μM). WHI-P154 also inhibits glioblastoma cell adhesion and migration. **Target(s):** epidermal growth factor receptor protein-tyrosine kinase (1); JAK3 (Janus kinase 3) protein-tyrosine kinase (1-3). 1. Ghosh, Jennissen, Liu & Uckun (2001) *Acta Crystallogr. C* **57**, 76. 2. Goodman, Niehoff & Uckun (1998) *J. Biol. Chem.* **273**, 17742. 3. Sudbeck, Liu, Narla, Mahajan, *et al.* (1999) *Clin. Cancer Res.* **5**, 1569.

## WIN Compounds

This class of antiviral drugs, originally developed at the Sterling-Winthrop Research Institute, bind within a hydrophobic pocket in the viral capsid, thereby replacing a hydrocarbon molecule that normally occupies the site. Lipid release from the capsid during viral entry permits the structural changes essential for uncoating and release of pathogen genome. WIN compounds are thought to block poliovirus and other picornavirus infectivity by preventing the transition to infective 135S particles. By replacing the lipid bound within the hydrophobic pocket, WIN compounds prevent structural transitions needed for virus uncoating. **See WIN 51711**

## WIN 51711

This systemically active broad-spectrum antipicornavirus agent (FW = 342.44 g/mol; CAS 87495-31-6), also known as Disoxaril™ and named systematically as 5-[7-[4(4,5-dihydro-2-oxazolyl)phenoxy]heptyl]-3-methylisoxazole, exerts its antiviral effect through a direct interaction with picornavirus capsid protein(s), stabilizing the virion conformation, thereby preventing a thermally-induced conformational change needed for virus uncoating and replication (1). WIN 51711, which is not virucidal and is without effect on the kinetics of <sup>3</sup>H-uridine-labelled poliovirus-2, exhibits a broad spectrum of action against entero- and rhinovirus serotypes, inhibiting all 33 rhinovirus serotypes tested at concentrations ranging from 0.02-to-6 mg/L, and also inhibiting all echo-, Coxsackie A and B, and polio serotypes tested as well as EV-70 at concentrations ranging from 0.004 to 1 mg/L. *Note* The effectiveness of WIN 51711 may be enhanced when administered as a dimethyl-β-cyclodextrin inclusion complex. 1. McKinlay (1985) *J. Antimicrob. Chemother.* **16**, 284.

**WIN 13099, See N,N'-Bis(dichloroacetyl)-N,N'-diethyl-1,4-xylenediamine**

## WIN 63759

This oral benzisothiazolone (FW<sub>free-base</sub> = 587.48 g/mol), also known as [6-methoxy-4-(1-methylethyl)-1-oxo-1,2-benzisothiazol-3(2H)-yl]methyl 2,6-dichloro-3-[2-(4-morpholinyl)ethoxy]benzoate S,S dioxido, is a potent inhibitor of human leukocyte elastase (K<sub>i</sub> = 13 pM). 1. Hlasta, Subramanyam, Bell, Carabateas, *et al.* (1995) *J. Med. Chem.* **38**, 739.

## WIN 64733

This oral benzisothiazolone (FW<sub>free-base</sub> = 571.48 g/mol), also known as [6-methoxy-4-(1-methylethyl)-1-oxo-1,2-benzisothiazol-3(2H)-yl]methyl 2,6-dichloro-3-[2-(1-pyrrolidinyl)ethoxy]benzoate S,S dioxido, is a potent inhibitor of human leukocyte elastase (K<sub>i</sub> = 14 pM). 1. Hlasta, Subramanyam, Bell, Carabateas, *et al.* (1995) *J. Med. Chem.* **38**, 739.

**WIPTIDE, See L-Threonyl-L-threonyl-L-tyrosyl-L-alanyl-L-aspartyl-L-phenylalanyl-L-isoleucyl-L-alanyl-L-serylglycyl-L-arginyl-L-threonylglycyl-L-arginyl-L-arginyl-L-asparaginyll-L-alanyl-L-isoleucinamide**

**Wiskostatin**

This N-WASP inhibitor (FW = 426.15 g/mol; CAS 253449-04-6), also named 3,6-dibromo- $\alpha$ -[(dimethylamino)methyl]-9*H*-carbazole-9-ethanol, targets neural Wiskott-Aldrich Syndrome Protein, an actin filament end-tracking protein, by binding to its regulatory GTPase-binding domain, maintaining N-WASP in an inactive conformation and thereby interfering with its ability to activate Arp2/3 complex. Wiskostatin also inhibits PIP<sub>2</sub>-induced actin polymerization (EC<sub>50</sub> ~4 $\mu$ M). (See also WASP; N-WASP inhibitor) 1. Peterson et al (2004) *Chemical inhibition of N-WASP by stabilization of a native autoinhibited conformation. Nature Struct. Mol. Biol.* **11**, 747. 2. Guerriero & Weisz (2006) *Am. J. Physiol. Cell Physiol.* **292**, C1562. 3. Wegner et al (2008) *J. Biol. Chem.* **283**, 15912.

**Withaferin A**

This broadly active, epoxide-containing steroid lactone or withanolide (FW = 470.61 g/mol; CAS 5119-48-2; *Symbol*: WFA), also known as NSC-101088 and (4 $\beta$ ,5 $\beta$ ,6 $\beta$ ,22*R*)-4,27-dihydroxy-5,6:22,26-diepoxyergosta-2,24-diene-1,26-dione, was first isolated from *Withania somnifera*, also known as Winter Cherry, a medicinal plant used traditionally in East Indian ayurvedic system of medicine to treat arthritis, immunological disorders, and bleeding conditions in women. Withaferin A binds to vimentin by covalently modifying a cysteine residue within its highly conserved  $\alpha$ -helical coiled coil 2B domain of this intermediate filament protein (1). WFA induces vimentin filaments to aggregate *in vitro*, a property manifested *in vivo* as punctate cytoplasmic aggregates that colocalize vimentin and F-actin (1). WFA is also a proteasomal inhibitor that binds to specific catalytic  $\beta$ -subunit of the 20S proteasome (2). It exerts positive effect on osteoblast by increasing osteoblast proliferation and differentiation. WFA increases expression of osteoblast-specific transcription factor and mineralizing genes, promoted osteoblast survival and suppressed inflammatory cytokines. In osteoclasts, WFA treatment decreases osteoclast number directly by decreasing expression of tartarate-resistant acid phosphatase and receptor activator of NF $\kappa$ -B and indirectly by decreasing osteoprotegerin/NF $\kappa$ -B ligand ratio (2). At 1-3  $\mu$ M, WFA also binds to Hsp90, inhibiting its action and leading to the degradation of its client proteins Akt and Cdk4 via a proteasome-dependent pathway in pancreatic cancer cells (3). Withaferin A also inhibits binding of Sp1 transcription factor to VEGF-gene promoter, thereby providing a mechanism for its antiangiogenic activity (4). While Withaferin A reduces cell survival in a dose-dependent manner (LD<sub>50</sub> = 16  $\mu$ M), treatment with a 2.1- $\mu$ M non-toxic dose significantly enhances radiation-induced cell killing, giving a sensitizer enhancement ratio of 1.5 for 37% survival and 1.4 for 10% survival. Cells accumulate at the G<sub>2</sub>-M transition within 4 hour after a 1-hour treatment at 10.5  $\mu$ M WFA (5). 1. Bargagna-Mohan, Hamza, Kim, et al. (2007) *Chem. & Biol.* **14**, 623. 2. Khedgikar, Kushwaha, Gautam, et al. (2013) *Cell Death Dis.* **4**, e778. 3.

Gu, Yu, Gunaherath, et al. (2013) *Invest. New Drugs* **32**, 68. 4. Kumar, Shilpa, and Salimath Bharati (2009) *Curr. Trends Biotechnol. Pharm.* **3**, 138. 5. Devi, Akagi, Ostapenko, Tanaka & Sugahara (1996) *Int. J. Radiat. Biol.* **69**, 193.

**Withania somnifera Glycoprotein**

This glycoprotein (MW = 28 kDa; *Symbol*: WSG, from the folk medicinal plant *Withania somnifera* inhibits the phospholipase A<sub>2</sub> activity found in Indian cobra *Naja naja* venom. While unable to neutralize cobra venom toxicity, WSG prolongs the time to death in experimental mice by a factor of ten. 1. Machiah & Gowda (2006) *Biochimie* **88**, 701.

**Wnt-C59**

This PORCN inhibitor (FW = 379.46 g/mol; CAS 1243243-89-1; Solubility: 76 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known as C59 and 2-(4-(2-methylpyridin-4-yl)phenyl)-*N*-(4-(pyridin-3-yl)phenyl)acetamide, targets Wnt3A-mediated activation (IC<sub>50</sub> = 74 pM), thereby inhibiting both autocrine and paracrine signaling by sonic hedgehog, or Shh (1,2). Once-daily oral administration was sufficient to maintain blood concentrations well above the IC<sub>50</sub> (1). **Mode of Inhibitor Action:** The *PORCN* [*Official Name*: Porcupine homologue (*Drosophila*)] is a gene that codes for an endoplasmic reticulum transmembrane *O*-acyltransferase required for Wnt palmitoylation, secretion, and biologic activity in the processing of *Drosophila* wingless proteins. Knockdown of PORCN by multiple independent siRNAs results in a cell growth defect in a subset of epithelial cancer cell lines, suggesting that porcupine is a potentially useful druggable target in controlling cancer. Wnt-C59 inhibits PORCN activity *in vitro* at nanomolar concentrations, as assessed by inhibition of Wnt palmitoylation (1). Wnt interaction with the carrier protein Wntless/WLS, Wnt secretion, and Wnt activation of  $\beta$ -catenin reporter activity (1). Palmitoylation of Shh by Hedgehog acyltransferase (Hhat) also plays a critical role in regulating Shh's signaling potency of in cells. Porcupine inhibition by Wnt-C59 (100 nM) of serum-starved Wnt-3a cells for 3 hours blocked Wnt-3a palmitoylation, whereas RU-SKI-43 (10  $\mu$ M; See also *RU-SKI-43*) did not (3). WNT10B induces transcriptionally active  $\beta$ -catenin in highly aggressive metastatic triple-negative breast cancers (TNBC) and predicts survival-outcome of patients with both TNBC and basal-like tumors (4). 1. Proffitt, et al. (2013) *Cancer Res.* **73**, 502. 2. Petrova, et al. (2013) *Nature Chem. Biol.* **9**, 247. 3. Wend, et al. (2013) *EMBO Mol. Med.* **5**, 264. 4. Wend, Runke, Wend, et al. (2013) *EMBO Mol. Med.* **5**, 264.

**Wogonin**

This *O*-methylated flavone (FW = 284.07 g/mol; CAS 632-85-9) from the root of *Scutellaria baicalensis* (1), also known as Wogonin, Norwogonin 8-methyl ether, and 5,7-dihydroxy-8-methoxyflavone, as well as systematically as 5,7-dihydroxy-8-methoxy-2-phenyl-4*H*-chromen-4-one, is a potent sialidase inhibitor (1). **Target(s):** NAD(P)H:quinone acceptor oxidoreductase, or DT-diaphorase (2); xanthine oxidase (3); TPA-induced COX-2 expression (4); IL-6-induced angiogenesis by down-regulation of VEGF and VEGFR-1, not VEGFR-2 (5); TNF-alpha-induced MMP-9 expression by blocking the NF $\kappa$ B activation via MAPK signaling pathways in human aortic smooth muscle cells (6); microglial cell migration by suppression of NF $\kappa$ B activity (7); induction of G<sub>1</sub> phase arrest by inhibiting Cdk4 and cyclin D<sub>1</sub> concomitant with an elevation in p21Cip1 in human cervical carcinoma HeLa cells (8); P-glycoprotein multidrug resistance, thereby potentiating etoposide-induced apoptosis in cancer cells (9); human

cytochrome P450 1A2 (10); indoleamine 3,5-dioxygenase (11,12). 1. Nagai, Yamada & Otsuka (1989) *Planta Med.* **55**, 27. 2. Liu, Liu, Iyanagi, *et al.* (1990) *Mol. Pharmacol.* **37**, 911. 3. ### Wortmannin

This potent and cell-permeable furanosteroid antifungal agent (FW = 428.44 g/mol; CAS 19545-26-7), systematically named as (1 $\alpha$ ,11 $\alpha$ )-11-(acetyloxy)-1-(methoxymethyl)-2-oxaandrost-5,8-dieno[6,5,4-*bc*]furan-3,7,17-trione, from *Penicillium funiculosum* is a potent irreversible inhibitor of 1-phosphatidylinositol 3-kinase (IC<sub>50</sub> = 3 nM) and has a similar potency for other Class-I, -II, and -III PI3Ks *in vitro*. Wortmannin also inhibits a polo-type protein kinases, including mTOR and DNA-PK. Wortmannin is a widely used to block DNA repair, receptor-mediated endocytosis, transcytosis, vacuolar sorting, and cell proliferation. Wortmannin's short (10-min) intracellular half-life greatly limits its utility in experiments requiring sustained inhibitory action. Its derivative PX-866 is an orally active and stable PI3K inhibitor that is more suitable for sustained *in vivo* action (See also PX-866; as well as the highly selective Vps34 inhibitor, VPS34-IN1). **Target(s):** DNA-dependent protein kinase (1); inositol-trisphosphate 3-kinase (2); inositol polyphosphate multi-kinase (3); [myosin light-chain] kinase (4-6); phosphatidylinositol-4,5 bisphosphate 3-kinase (7-9); 1-phosphatidylinositol 3-kinase (6,11-16); 1-phosphatidylinositol 4 kinase (26-30); phosphatidylinositol-4-phosphate 3-kinase (17-22); phospholipase D (23); polo kinase (24); protein-tyrosine kinase (25). 1. ### WP1066

This novel protein kinase inhibitor (FW = 356.22 g/mol; CAS 857064-38-1; Solubility = 44 mg/mL DMSO), also known as HY-15312 and (*S,E*)-3-(6-bromopyridin-2-yl)-2-cyano-*N*-(1-phenylethyl)acrylamide, is an AG490 analogue that targets JAK2<sup>V617F</sup> (IC<sub>50</sub> = 2.3  $\mu$ M), an activating somatic mutation in the Janus kinase-2 gene in patients with myeloproliferative disorder (1-4). WP1066 markedly and dose-dependently inhibits growth of HEL erythroid leukemia cells bearing the JAK2<sup>V617F</sup> mutant, displaying IC<sub>20</sub>, IC<sub>50</sub> and IC<sub>80</sub> values of 0.8  $\mu$ M, 2.3  $\mu$ M and 3.8  $\mu$ M, respectively. **Other Targets:** WP1066 also inhibits STAT3 (IC<sub>50</sub> = 2.43  $\mu$ M). At 0.5, 1.0, 2.0, 3.0, or 4.0  $\mu$ M, WP1066 inhibits the phosphorylation of JAK2, STAT3, STAT5, and ERK1/2, respectively, without affecting the phosphorylation of JAK1 and JAK3 in HEL cells expressing JAK2<sup>V617F</sup> (1). WP1066 (0.5-3.0  $\mu$ M) also inhibits the proliferation of patient-derived AML colony-forming cells as well as AML cell lines OCIM2 and K562. When present at concentrations of 0.5-4.0  $\mu$ M, WP1066 dose-dependently decreases JAK2 and pJAK2 protein levels as well as downstream phosphorylation levels of STAT3, STAT5, and AKT in OCIM2 and K562 cells (1,2). WP1066 at concentrations of 2  $\mu$ M inhibits OCIM2 cell proliferation by trapping cells at G<sub>0</sub>-G<sub>1</sub>. At 1-3  $\mu$ M, it likewise induces apoptosis in both OCIM2 and K562 cells, activating both procaspase-3 and cleaving PARP (3). At 5  $\mu$ M, WP1066 prevents the phosphorylation of STAT3, and at concentrations of 2.5  $\mu$ M WP1066 significantly inhibits cell survival and proliferation in Caki-1 and 786-O renal cancer cells. At 5  $\mu$ M, WP1066 suppresses HIF1 $\alpha$  and HIF2 $\alpha$  expression as well as VEGF production in Caki-1 and 786-O renal cancer cells (4). 1. Verstovsek, Manshour, Quintás-Cardama, *et al.* (2008) *Clin. Cancer Res.* **3**, 788. 2. Hatiboglu, Kong, Wei, *et al.* (2012) *Int. J. Cancer* **131**, 8. 3. Ferrajoli, Faderl, Van, *et al.* (2007) *Cancer Res.* **67**, 11291. 4. Horiguchi, Asano, Kuroda, *et al.* (2010) *Br. J. Cancer* **102**, 1592.

### WPE-III-31C

This cell-permeable (hydroxyethyl)urea peptidomimetic (FW = 640.82 g/mol), also known as  $\gamma$ -secretase inhibitor XVII, is a  $\gamma$ -secretase transition-state analogue (IC<sub>50</sub> = 300 nM), when assayed for its effect on A- $\beta$  peptide formation (1-3). For cellular inhibition studies, 1  $\mu$ M WPE-III-31C is a nominal concentration. Note also that incubation of cells with biotinylated-WPE-III-31C, followed by incubation with streptavidin, and later staining with anti-streptavidin antibody may be employed to localize the secretase within cells. 1. Campbell, Iskandar, Reed & Xia (2002) *Biochemistry* **41**, 3372. 2. Esler, Kimberly, Ostaszewski, *et al.* (2002) *Proc. Natl. Acad. Sci. U.S.A.* **99**, 2720. 3. Kimberly, LaVoie, Ostaszewski, *et al.* (2002) *J. Biol. Chem.* **277**, 35113.

### WT

This cationic peptide amide (MW = 2988 g/mol; Sequence: MSLRQS IRFFKPATRTLCSRYLL-NH<sub>2</sub>; pI = 11.56, corresponding to a membrane-inserting pre-sequence for mitochondrial import of yeast cytochrome *c* oxidase subunit IV, inhibits bovine heart mitochondrial F<sub>1</sub> ATPase, IC<sub>50</sub> = 16  $\mu$ M (1) When its single thiol group is fluorescently labeled, the resulting peptide is imported with first-order kinetics that the concentration of the lipid-bound peptide (2). 1. Bullough, Ceccarelli, Roise & Allison (1989) *Biochim. Biophys. Acta* **975**, 377. 2. Roise (1992) *Proc. Natl. Acad. Sci. U.S.A.* **89**, 608.

## WWL 123

This brain-penetrant ABHD6 inhibitor (FW = 436.51 g/mol; CAS 1338574-83-6; Soluble to 100 mM in DMSO), also named *N*-[[1,1'-biphenyl]-3-ylmethyl]-*N*-methylcarbamic acid 4'-(aminocarbonyl)[1,1'-biphenyl]-4-yl ester, targets  $\alpha/\beta$ -hydrolase domain 6 ( $IC_{50}$  = 0.43  $\mu$ M), a serine hydrolyzing enzyme that possesses typical  $\alpha/\beta$ -hydrolase family domains. Notably, ABHD6 produces ~4% of 2-arachidonoylglycerol (2-AG) in brain hydrolysis.[3] Moreover, monoacylglycerol lipase (MAGL), ABHD12, and ABHD6 control 99% of 2-AG signalling to the cannabinoid (CB) receptors in the brain. WWL-123 also blocks PTZ-induced seizures in healthy mice and spontaneous seizures in R6/2 mice. Its antiepileptic activity appears to be independent of CB<sub>1</sub> and CB<sub>2</sub> receptors, but is GABA<sub>A</sub> receptor dependent. 1. Naydenov, Horne, Cheah, *et al.* (2014) *Neuron* **83**, 361.

## Wyo-50295

This oral anti-allergy agent (FW<sub>free-acid</sub> = 357.41 g/mol; CAS 133304-99-1) inhibits arachidonate 5-lipoxygenase (1,2). Although WY-50295T inhibits both *in vitro* and *ex vivo* rat whole blood leukocyte LTB<sub>4</sub> formation ( $IC_{50}$  = 40  $\mu$ M; oral ED<sub>50</sub> of 18 mg/kg), it does not inhibit LTB<sub>4</sub> production in calcium ionophore stimulated human whole blood at concentrations to 200  $\mu$ M (3). Even when one seeks to reduce binding of WY-50295T to serum albumin (with 250  $\mu$ M naphthalene sulfonic acid (> 99.9% binding to albumin primarily at the carboxylic site) and/or 250  $\mu$ M sulfanilamide (binding to nonspecific sites), separately or in combination), WY-50295T still does not inhibit 5-LO and its free-drug blood levels remain unchanged. When purified human neutrophils are treated with WY-50295T in the presence of fatty acid saturated albumin (fraction V) was employed, WY-50295T inhibition of 5-LO is also prevented, whereas 5  $\mu$ M zileuton inhibits LTB<sub>4</sub> production by 99%. Such results suggest that the high affinity binding of WY-50295T to human albumin and possibly the reduction of drug uptake (passive diffusion) using purified human *versus* rat neutrophils may account for the inactivity of WY-50295T in the human whole blood assay (3). 1. Carlson, Kreft, Hartman, *et al.* (1999) *Prostaglandins Leukot. Essent. Fatty Acids* **60**, 31. 2. Weichman, Berkenkopf, Chang, *et al.* (1991) *Agents Actions Suppl.* **34**, 201. 3. Carlson, Kreft, Hartman, *et al.* (1999) *Prostaglandins Leukot. Essent. Fatty Acids* **60**, 31.

## WZ4002

This potent orally bioavailable EGFR-PKI (FW = 494.98 g/mol; CAS 1213269-23-8; Soluble in DMSO), also named *N*-[3-[[[5-chloro-2-[[2-methoxy-4-(4-methyl-1-piperazinyl)phenyl]amino]-4-pyrimidinyl]oxy]phenyl]-2-propenamide, targets Epidermal Growth Factor Receptor, including the Thr-790-Met mutation of the so-called Thr-790 "gatekeeper" residue ( $IC_{50}$  = 8 nM) in gefitinib-resistant or erlotinib-resistant EGFR-mutant non-small-cell lung cancer patients. As a Michael-type inhibitor, WZ4002 is an irreversible inhibitor that undergoes 1,4-addition. WZ4002 is also effective against the EGFR Leu-758-Arg mutant ( $IC_{50}$  = 8 nM), but not Thr-798-Ile of ERB2 (1-3). 1. Zhou, Ercan, Chen, *et al.* (2009) *Nature* **462**, 1070. 2. Sakuma, Yamazaki, Nakamura, *et al.* (2012) *Lab Invest.* **92**, 371. 3. Zannetti, Iommelli, Speranza, Salvatore & Del Vecchio (2012) *J. Nucl. Med.* **53**, 443.

## WZ4003

This highly specific protein kinase inhibitor (FW = 496.99 g/mol; CAS 1214265-58-3) targets the NUAk family SNF1-like kinases, NUAk1 ( $IC_{50}$  = 20 nM) and NUAk2 ( $IC_{50}$  = 100 nM). Note: NUAk1 is also known as AMPK-related protein kinase 5 (ARK5), an enzyme encoded by the human *NUAK1* gene, and NUAk2 is also known as SNF1/AMP kinase-related kinase (SNARK), an enzyme encoded by the human *NUAK2* gene. Both are activated by the LKB1 (liver kinase B1) tumour suppressor kinase. Notably, WZ4003 is without significant inhibition against 139 other kinases. Moreover, in all cell lines tested, WZ4003 inhibits phosphorylation of the well-characterized substrate, MYPT1 (or Myosin phosphate-targeting subunit 1), which is phosphorylated at Ser-445 by NUAk1 (1). 1. Banerjee, Buhrlage, Huang, *et al.* (2014) *Biochem. J.* **457**, 215. 2. Zhou, Ercan, Chen, *et al.* (2009) *Nature* **462**, 1070.

## XAC

This xanthine amine congener and selective adenosine receptor antagonist (FW = 464.95 g/mol; CAS 96865-92-8; Solubility: 5 mM in DMSO), also known as *N*-(2-aminoethyl)-2-[4-(2,3,6,7-tetrahydro-2,6-dioxo-1,3-dipropyl-1*H*-purin-8-yl)phenoxy]acetamide hydrochloride, targets  $A_1$  ( $IC_{50}$  = 1.8 nM) and  $A_2$  ( $IC_{50}$  = 114 nM) adenosine receptors. XAC attenuates adenosine-induced vasodilation and exhibits proconvulsant activity *in vivo*. Pretreatment of animals with the adenosine receptor agonists 2-chloroadenosine, N6-cyclohexyladenosine or 5'-*N*-ethylcarboxamido-adenosine (1 mg/kg, i.p., 20 minutes prior to infusion) significantly decreased the seizure threshold of both XAC and caffeine (1). XAC rapidly equilibrates within the myocardial interstitial space and, as a result of blocking adenosine receptors, increases interstitial and venous adenosine concentrations (2). Increases in interstitial adenosine may partially overcome the adenosine receptor blockade by XAC, thereby reducing the effectiveness of XAC in attenuating the hypoxic vasodilatation. XAC attenuates intracoronary adenosine induced vasodilatation (mediated by endothelial adenosine receptors) much more effectively than it attenuates hypoxic vasodilatation (2). 1. Morgan, Deckert, Jacobson, Marangos & Daly (1989) *Life Sci.* **45**, 719. 2. Sawmiller, Linden & Berne (1994) *Cardiovasc. Res.* **28**, 604.

## Xanthine

This naturally occurring purine (FW = 152.11 g/mol; CAS 69-89-6), symbolized by Xan; primarily lactam tautomer;  $\lambda_{max}$  = 267 nm, with  $\epsilon$  = 10300 M<sup>-1</sup>cm<sup>-1</sup>). Xanthine has a p*K*<sub>a</sub> value of 9.91 at 40°C. It was first prepared in the laboratory by Emil Fischer (1). **Target(s)**: adenine phosphoribosyltransferase, weakly (2); cyclic-nucleotide 3' phosphodiesterase (3); hydroxy-acylglutathione hydrolase, or glyoxalase II (4); hypoxanthine(guanine) phosphoribosyltransferase (5-8); lactoylglutathione lyase, or glyoxalase I (4); methionine *S* adenosyltransferase (9); NADase, weakly (10,11); tRNA-guanine transglycosylase, weakly (12,13); urate-ribonucleotide phosphorylase (14); uricase, or urate oxidase (15-19). 1. **Xanthine Riboside**, See *Xanthosine*

## Xanthobilirubate

This pyrrole derivative (FW<sub>free-acid</sub> = 302.37 g/mol) is a more soluble, low-molecular-weight analogue of bilirubin that inhibits HIV-1 protease ( $K_i$  = 5  $\mu$ M). At 100  $\mu$ M, xanthobilirubic acid affected viral assembly, resulting in a 50% decrease in the generation of infectious particles, whereas the same concentrations of biliverdin or bilirubin exerts little or no effect on viral assembly. 1. McPhee, Caldera, Bemis, et al. (1996) *Biochem. J.* **320**, 681.

**Xanthophyll Dipalmitate Ester**, See *Xanthophyll*

## Xanthopterin

This pteridines (FW = 179.14 g/mol; CAS 119-44-8; Fluorescent: excitation  $\lambda_{max}$  = 380 and 400 nm; emission  $\lambda_{max}$  = 440 and 460 nm), also known as 2-amino-4,6-dihydroxypteridine, is a yellow pigment in butterfly wings. A metabolic end-product of the nonconjugated pteridine compound, xanthopterin is also found in other insects, crabs, and even humans. Xanthopterin is an alternative substrate for xanthine oxidase and competitively inhibits urate formation (1). **Target(s)**: dihydrofolate reductase, weakly (1); guanine deaminase (2); hypoxanthine(guanine) phosphoribosyltransferase (3); sepiapterin deaminase (4-6); xanthine oxidase, also alternative substrate (7-10). 1. Bertino, Perkins & Johns (1965) *Biochemistry* **4**, 839. 2. Dietrich & Shapiro (1953) *J. Biol. Chem.* **203**, 89. 3. Miller, Ramsey, Krenitsky & Elion (1972) *Biochemistry* **11**, 4723. 4. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 289, Academic Press, New York. 10. Hofstee (1949) *J. Biol. Chem.* **179**, 633.

## Xanthosine

This ribonucleoside (9- $\beta$ -D-ribofuranosylxanthine; FW = 284.23 g/mol), abbreviated Xao, is produced by the deamination of guanosine. Xanthosine absorbs UV light strongly: at pH 2,  $\epsilon$  = 8400 M<sup>-1</sup>cm<sup>-1</sup> at 235 nm and 8950 M<sup>-1</sup>cm<sup>-1</sup> at 263 nm; at pH 8,  $\epsilon$  = 10200 M<sup>-1</sup>cm<sup>-1</sup> at 248 nm; and at pH 11,  $\epsilon$  = 8900 M<sup>-1</sup>cm<sup>-1</sup> at 278 nm). **Target(s)**: adenosine kinase, weakly (1);

dihydroorotase (2); guanine deaminase (3); inosine nucleosidase, as alternative substrate (4,5); purine nucleosidase, as alternative substrate for the enzyme from a number of sources (6,7). 1. Kidder (1982) *Biochem. Biophys. Res. Commun.* **107**, 381. 2. Bresnick & Blatchford (1964) *Biochim. Biophys. Acta* **81**, 150. 3. Kimm, Park & Lee (1985) *Korean J. Biochem.* **17**, 139. 4. Takagi & Horecker (1957) *J. Biol. Chem.* **225**, 77. 5. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 471, Academic Press, New York. 6. Koszalka & Krenitsky (1979) *J. Biol. Chem.* **254**, 8185. 7. Atkins, Shelp & Storer (1989) *J. Plant Physiol.* **134**, 447.

### Xanthosine 3',5'-Cyclic-Monophosphate

This cyclic nucleotide (FW<sub>sodium-salt</sub> = 368.18 g/mol) is a structural analogue of guanosine 3',5'-cyclic-monophosphate (cGMP) and often competes with cGMP in cGMP-dependent systems as well as with cAMP in cAMP-dependent reactions (1). cXMP is also an alternative substrate for cyclic-nucleoside-monophosphate phosphodiesterases, such as rat liver cGMP phosphodiesterase (2). 1. Du Plooy, Michal, Weimann, Nelboeck & Paoletti (1971) *Biochim. Biophys. Acta* **230**, 30. 2. Moss, Manganiello & Vaughan (1977) *J. Biol. Chem.* **252**, 5211.

### Xanthosine 5'-Diphosphate

This GDP analogue (FW<sub>free-acid</sub> = 444.19 g/mol; CAS 10593-13-7; Abbreviation: XDP), produced nonenzymatically by the action of nitrous acid on GDP, often acts as an alternative substrate, and thus a competitive inhibitor, for GTP- and ATP-dependent enzymes. The metal-nucleotide complex formation constant for MgHXDP and MgXDP<sup>-</sup> should be similar to those the corresponding ADP complexes: 100 M<sup>-1</sup> for MgHADP and 4000 M<sup>-1</sup> for MgADP<sup>-</sup> is (1). Corresponding values for the manganese complexes would be 500 and 30000 M<sup>-1</sup>, respectively, and for calcium ion complexes, 80 and 2000 M<sup>-1</sup> (1). **Target(s):** adenylosuccinate synthetase (2); amidophosphoribosyl-transferase (3); glycoprotein 3- $\alpha$ -L-fucosyltransferase (4); ribose-phosphate diphosphokinase, or phosphoribosyl pyrophosphate synthetase (5); xanthine phosphoribosyltransferase (6). 1. Biochem. Biophys.* **165**, 349.

### Xanthosine 5'-Monophosphate

This purine nucleotide (FW<sub>monosodium-salt</sub> = 365.18 g/mol; CAS 25899-70-1), abbreviated XMP, is the product of the IMP dehydrogenase reaction and, as the substrate for GMP synthase, it is the immediate biosynthetic precursor of GMP. XMP absorbs light strongly in the ultraviolet region of the spectrum ( $\lambda_{\max}$  = 278 nm ( $\epsilon$  = 8900 M<sup>-1</sup>cm<sup>-1</sup>) at pH 10). **Target(s):** adenylosuccinate synthetase (1-4); amido-phosphoribosyl-transferase (5-7);

hypoxanthine(guanine) phosphoribosyltransferase (8); IMP cyclohydrolase (9,10); orotate phosphoribosyltransferase (11); orotidine-5'-phosphate decarboxylase (12-15). 1. Spector, Jones & Elion (1979) *J. Biol. Chem.* **254**, 8422. 2. Van der Weyden & Kelley (1974) *J. Biol. Chem.* **249**, 7282. 3. Spector & Miller (1976) *Biochim. Biophys. Acta* **445**, 509. 4. ### Xanthosine 5'-Triphosphate

This rare purine nucleotide, usually abbreviated XTP (FW<sub>disodium-salt</sub> = 568.13 g/mol; CAS 6253-56-1), which can be formed nonenzymatically by the action of nitrous acid on GTP, often acts as an alternative substrate (and thus competitively inhibits) for GTP- and ATP-dependent enzymes. XTP absorbs light strongly in the ultraviolet region of the spectrum ( $\lambda_{\max}$  = 278 nm [ $\epsilon$  = 8900 M<sup>-1</sup>cm<sup>-1</sup>] at pH 10). **Target(s):** adenylosuccinate synthetase (1); amidophosphoribosyltransferase (2); glucokinase, weak alternative substrate (3); GTP cyclohydrolase IIa (4); guanosine-triphosphate guanylyltransferase (5); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (6,7); xanthine phosphoribosyltransferase (8). 1. Van der Weyden & Kelley (1974) *J. Biol. Chem.* **249**, 7282. 2. Holmes, McDonald, McCord, Wyngaarden & Kelley (1973) *J. Biol. Chem.* **248**, 144. 3. Porter, Chassy & Holmlund (1982) *Biochim. ### Xanthurenate

This quinaldinate (FW<sub>sodium-salt</sub> = 227.15 g/mol) or xanthurenic acid, which is formed in the enzymatic degradation of L-tryptophan, inhibits acetyl-CoA carboxylase (1), dihydrolipoamide dehydrogenase (2), kynurenine 3

hydroxylase (3), kynurenine:oxoglutarate aminotransferase, weakly (4); NAD<sup>+</sup>:ADP ribosyltransferase (poly(ADP-ribose) polymerase (5); IC<sub>50</sub> = 0.19 mM); pyridoxal kinase (6,7). Xanthurenate is a also gametocyte-activating factor. It has also been reported to activate cell caspases and apoptosis (8). 1. Tanabe, Nakanishi, Hashimoto, *et al.* (1981) *Meth. **XAV-939**

This selective Wnt  $\beta$ -catenin-mediated transcription inhibitor (FW = 312.31 g/mol; CAS 284028-89-3; Solubility: 15 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), known as 2-(4-(trifluoromethyl)phenyl)-7,8-dihydro-5H-thiopyrano [4,3-d]pyrimidin-4-ol, targets tankyrases TNKS1 and TNKS2, telomere-associated poly(adenosine diphosphate [ADP]-ribose) polymerase (or PARPs), with IC<sub>50</sub> values of 11 nM and 4 nM, respectively. in both telomere function and the DNA damage response following exposure to ionizing radiation (1). In human cells, tankyrase 1 siRNA knockdown significantly elevates recombination specifically within telomeres, a phenotype with the potential of accelerating cellular senescence (2). Additionally, depletion of tankyrase 1 resulted in concomitant and rapid reduction of the nonhomologous end-joining protein DNA-PKcs, while Ku86 and ATM protein levels remained unchanged; DNA-PKcs mRNA levels were also unaffected (1). The requirement of tankyrase 1 for DNA-PKcs protein stability reflects the necessity of its PARP enzymatic activity, and depletion of tankyrase 1 resulted in proteasome-mediated DNA-PKcs degradation, explaining the associated defective damage response observed (*i.e.*, increased sensitivity to ionizing radiation-induced cell killing, mutagenesis, chromosome aberration and telomere fusion) (2). Dysregulated Wnt pathway activity has been implicated in many cancers, making this signal transduction pathway an attractive target for anticancer therapies. XAV939, which selectively inhibits  $\beta$ -catenin-mediated transcription. XAV939 stimulates  $\beta$ -catenin degradation by stabilizing axin, the concentration-limiting component of the destruction complex. Such findings suggest that tankyrase 1 is not only involved in telomeric DNA repair, but also has important implications for modifying cancer and aging (1,2). A high-resolution X-Ray crystal structure confirms that XAV-939 binds in the NAD<sup>+</sup>-donor site of tankyrase-1 (3). **XAV939-Prolongation of Anaphase in Normal & Tumor Cells:** In HeLa cells synchronized by a double-thymidine block, release into S-phase in the presence or absence of XAV939 shows no tendency to induce mitotic arrest. Staining with anti-centromere antibody (ACA), however, reveals a 3.5-fold increase in XAV939-treated mitotic cells possessing separated centromeres, as compared to untreated cells (4). Moreover, all cells with separated centromeres show a loss in cyclin B, indicating progression to anaphase. Cells isolated at the 10-hour time-point by mitotic shake-off, followed by Fluorescence In Situ Hybridization (using centromere (10cen)- and telomere (16ptelo)- specific probes) show that XAV939 induces loss of centromere cohesion, concomitant with persistent telomere cohesion, again indicating that the majority of mitotic cells were in anaphase. In further support of the conclusion that cells with cohered sister telomeres had initiated anaphase, XAV939-treated cells (displaying separated centromeres) show a 3.6-fold increase in cohered telomeres compared with control (4). 1. **XDP.** See Xanthosine 5'-Diphosphate

**XEN445**

This potent and selective lipase inhibitor (FW = 366.34 g/mol; IUPAC Name: (S)-2-(3-(pyridin-2-ylmethoxy)pyrrolidin-1-yl)-5-(trifluoromethyl)-benzoic acid) targets Endothelial Lipase (EL), exhibiting good inhibition (IC<sub>50</sub> = 237 nM), absorption, distribution, metabolism, excretion properties in mice, suggesting likely *in vivo* efficacy in raising plasma HDLc concentrations. **Primary Mode of Inhibitory Action:** EL is secreted from vascular endothelial cells and hepatocytes and preferentially hydrolyses the *sn*-1 (or PLA<sub>1</sub>) ester bond of phosphatidylcholine (PC) in HDL particles, releasing Lyso-PC and thereby reducing HDL particle size. Its role in HDL metabolism is further indicated by findings that EL knockout mice have HDLc concentrations that are 50–140% higher than in wild type mice. EL itself is a triglyceride lipase in the same protein family that also includes hepatic lipase (HL), lipoprotein lipase (LPL) and pancreatic lipase. While these lipases share a common serine protease/esterase catalytic triad, they differ in the lid region controlling substrate specificity. This property served as a druggable target for the development of XEN-445. XEN 445 demonstrated good *in vitro* potency against EL with high selectivity over LPL and HL, and, perhaps more importantly, showed *in vivo* efficacy in raising plasma HDLc in wild-type mice. 1. Sun, Dean, Jia, *et al.* (2013) *Bioorg. Med. Chem.* **21**, 7724.

**Xenon**

This largely unreactive Period V element (Atomic Symbol: Xe; Atomic Weight = 131.29 g; Atomic Number = 54, with a full, noble gas octet: 1s<sup>2</sup> 2s<sup>2</sup> 2p<sup>6</sup> 3s<sup>2</sup> 3p<sup>6</sup> 3d<sup>10</sup> 4s<sup>2</sup> 4p<sup>6</sup> 4d<sup>10</sup> 5s<sup>2</sup> 5p<sup>6</sup>) is a heavy gas that has been employed as an anesthetic, and, with its extremely low blood-gas partition coefficient (0.115), xenon anesthesia is characterized by a rapid onset of action as well as prompt post-treatment recovery. The high volumes required for anesthesia (*e.g.*, patients must breathe 70% Xe & 20-30% O<sub>2</sub>) and its very low natural abundance (~0.5 ppm in air) make its use somewhat expensive (1,2). Xe produces profound analgesia, inhibiting surgery-induced hemodynamic and catecholamine responses. Remarkably, Xe preconditioning (*i.e.*, a process whereby exposure to a stress/stimulus leads to decreased cellular damage/death upon later exposure to a greater or more sustained stress) exerts hypoxia-induced signaling (3,4), conferring neuroprotection in a mouse model of transient middle cerebral artery occlusion (5). Xenon acts to open plasmalemmal ATP-sensitive potassium channels to induce neuronal preconditioning that activates ERK, one of the downstream effectors of the MAPK signaling pathway (6). Xenon also inhibits glutamatergic NMDA receptors involved in learning and memory and affects synaptic plasticity within the amygdala and hippocampus, which play roles in fear conditioning models for post-traumatic stress disorder (PTSD). Xe substantially and persistently inhibits memory reconsolidation in a reactivation and time-dependent manner, suggesting its likely effectiveness as a therapy for PTSD (7). Xenon thus exerts its analgesic effects by inhibiting NMDA receptors, blocking of painful stimuli transmissions from peripheral tissues to the brain and it also avoids the development of pain hypersensitivity (7). Indeed, xenon exerts intra- and post-operative neuroprotective, cardioprotective, and renoprotective actions, mainly through the production of the hypoxia-inducible factor 1 $\alpha$  (HIF-1 $\alpha$ ) and its downstream effector erythropoietin as well as noradrenalin reuptake inhibition. Because xenon activates the formation of erythropoietin (a well-known stimulator of erythrocyte formation), the World Anti-Doping Agency (WADA) banned it as performance-enhancing agent, effective September, 2014. Currently, the best method for measuring xenon in human plasma and blood uses gas chromatography/mass spectrometry, or GC/MS (8). 1. Viatkin & Mizikov (2008) *Anesteziol. Reanimatol.* **5**, 103. 2. **Xerophthol, See Retinol****Xestospongins**

This membrane-permeable bis-1-oxaquinolizidine macrocycle (FW = 446.72 g/mol; CAS 524-95-8; Form: Solid (often as a film on container surface); Color: Off-white; Soluble in DMSO; Store at -20°C) from the Australian sponge *Xestospongia*, inhibits bradykinin- and carbamylcholine-stimulated Ca<sup>2+</sup> efflux from the endoplasmic reticulum stores (1) and is likewise a highly potent, reversible inhibitor of IP<sub>3</sub>-mediated Ca<sup>2+</sup> release (IC<sub>50</sub> = 358 nM). Does not interact with the IP<sub>3</sub> binding site and exhibits high selectivity over ryanodine receptors. **IUPAC Name**: (1*R*,4*aR*,11*R*,12*aS*,13*S*,16*aS*,23*R*,24*aS*)-eicosahydro-5*H*,17*H*-1,23:11,13-diethano-2*H*,14*H*-[1,11]dioxacycloeicosino[2,3-*b*:12,13-*b'*]dipyridine. **1.** Miyamoto, Izumi, Hori, *et al.* (2000) *Brit. J. Pharm.* **130**, 650. **2.** De Smet, Parys, Callewaert, *et al.* (1999) *Cell. Calcium* **26**, 9.

**Xestospongins**

This membrane-permeable, bis-1-oxaquinolizidine macrocycle (FW = 462.72 g/mol), isolated to homogeneity from marine sponges, inhibits nitric-oxide synthase, showing competitive inhibition with respect to L-arginine and uncompetitive inhibition relative to NADPH and free Ca<sup>2+</sup>. This inhibitory profile is similar to N<sup>o</sup>-nitro-L-arginine methylester (See L-NAME). **1.** Venkateswara, Rao, Desai, Vig & Venkateswarlu (1998) *Toxicology* **129**, 103.

**X-gal, See 5-Bromo-4-chloro-3-indoyl-β-D-galactoside****XIAP**

This zinc finger-containing, X-chromosome-linked inducer of apoptosis protein (MW<sub>human</sub> = 56,000) is also known as hIAP. Although a member of the IAP family (*i.e.*, Inhibitor-of-Apoptosis Protein family), XIAP is the only IAP family member that inhibits apoptosis as a consequence of its direct inhibitory action on caspases-3, -7, and -9 (1,2). XIAP is itself a target for inhibitors that, by blocking its inhibition of caspases-3, -7, and -9, should in turn promote apoptosis. **1.** Deveraux, Welsh & Reed (2000) *Meth. Enzymol.* **322**, 154. **2.** Deveraux, Roy, Stennicke, *et al.* (1998) *EMBO J.* **17**, 2215.

**XK469**

This quinoxaline derivative (FW<sub>free-acid</sub> = 344.75 g/mol; CAS 157542-91-1), also known as NSC 697887 and 2-[4-(7-chloro-2-quinoxalinyloxy)phenoxy]propionic acid, inhibits DNA topoisomerase IIβ (1) and induces reversible protein-DNA cross-links in mammalian cells. Both enantiomers of XK469 are active (1) XK469 also induces apoptosis in Waldenström's macroglobulinemia through multiple pathways (2). Note that the α-carbon of the lactate moiety is chiral: QK469R refers to the R-enantiomer, whereas QK469S refers to the S-enantiomer. **1.** Gao, Huang, Yamasaki, *et al.* (1999) *Proc. Natl. Acad. Sci. U.S.A.* **96**, 12168. **2.** Mensah-Osman, Al-Katib, Dandashi & Mohammad (2003) *Int. J. Oncol.* **23**, 1637.

oxy)phenoxy]propionic acid, inhibits DNA topoisomerase IIβ (1) and induces reversible protein-DNA cross-links in mammalian cells. XL880, See *Foretinib*

### XL888

This ATP-competitive inhibitor (FW = 503.64 g/mol; CAS 1149705-71-4), also known as *N*'-[(3-endo)-8-[5-(cyclopropylcarbonyl)-2-pyridinyl]-8-azabicyclo[3.2.1]oct-3-yl]-2-methyl-5-[(1*R*)-1-methylpropyl]amino]-1,4-benzenedicarboxamide, targets HSP90 (IC<sub>50</sub> = 24 nM), blocking folding and conformational integrity of client proteins, of which many are steroid hormone receptors and signal transduction protein kinases. XL888 potently inhibits cell growth, induces apoptosis, and prevents the growth of vemurafenib-resistant melanoma cell lines in 3-dimensional cell culture, long-term colony formation assays, and human melanoma mouse xenografts. Reversal of the resistance phenotype by XL888 is associated with the degradation of PDGFRβ, COT, IGFR1, CRAF, ARAF, S6, cyclin D<sub>1</sub>, and Akt, which in turn lead to the nuclear accumulation of FOXO3a, increases expression of BIM (Bcl-2-Interacting Mediator of cell death), and down-regulation of Mcl-1. 1. Bussenius, Blazey, Aay, *et al.* (2012) *Bioorg. Med. Chem. Lett.* **22**, 5396. 2. Paraiso, Haarberg, Wood, *et al.* (2012) *Clin. Cancer Res.* **18**, 2502.

### Xylarate (Xylaric Acid)

This achiral aldaric acid (FW<sub>disodium-salt</sub> = 224.08 g/mol; CAS 10158-64-2), which is formed from either D-xylose or L-xylose, inhibits 2-dehydro-3-deoxyglucarate aldolase. 1. Fish & Blumenthal (1966) *Meth. Enzymol.* **9**, 529.

### Xylarohydroxamate

This aldaric acid monohydroxamate (FW<sub>free-acid</sub> = 195.13 g/mol) competitively inhibits *Escherichia coli* glucarate dehydratase (*K<sub>i</sub>* = 0.8 mM). 1. Gulick, Hubbard, Gerlt & Rayment (2000) *Biochemistry* **39**, 4590.

### Xylazine

This sedative, anesthetic, muscle relaxant, and analgesic (FW = 220.33 g/mol; CAS 7361-61-7), also known as *N*-(2,6-dimethylphenyl)-5,6-dihydro-4*H*-1,3-thiazin-2-amine, is frequently employed in veterinary

medicine, especially with horses and cattle. Clinically effective doses of xylazine markedly decrease basal insulin levels and completely abolish the rise in insulin produced by intravenous glucose. These changes in insulin levels lead to elevated fasting plasma glucose levels and glucose intolerance (1). Yohimbine (an α<sub>2</sub>-adrenergic blocker) and phentolamine (an α<sub>1</sub>/α<sub>2</sub>-adrenergic blocker) reduces/abolishes xylazine-induced hyperglycemia and hypoinsulinemia (2). Prazosin and phenoxybenzamine (an α<sub>1</sub>-adrenergic blockers) does not exert such antagonism, and α-adrenergic blocking agents alone does not change either plasma glucose or insulin concentrations. These findings suggest that xylazine-induced hyperglycemia and hypoinsulinemia are mediated by α<sub>2</sub>-adrenergic receptors, possibly in β-cells of pancreatic islets that inhibit insulin release (2). 1. Goldfine & Arieff (1979) *Endocrinology* **105**, 920. 2. Hsu & Hummel (1981) *Endocrinology* **109**, 825.

### 3,4-Xylidine

This aromatic base (FW = 121.18 g/mol; CAS 95-64-7), also known as 3,4-dimethylaniline, is often used in the production of dyes. The free base is sparingly soluble in water; however, it readily forms salts with mineral acids and these salts are considerably more soluble. The free base has a melting point of 49-51°C and a B.P. of 226-228°C. 3,4-Xylidine is *highly toxic* and care should be exercised in its handling. **Target:** β-fructofuranosidase, or invertase. 1. Myrback (1960) *The Enzymes*, 2nd ed. (Boyer, Lardy & Myrback, eds.), **4**, 379.

### Xylitol

This achiral sugar alcohol (FW = 152.15 g/mol; CAS 87-99-0) is related to D- and L-xylose and can be produced by the action of either D- or L-xylulose reductase. It is also a byproduct in wood saccharification. Xylitol has a sweetness roughly equal to that of sucrose and is often used as an artificial sweetener. In fact, xylitol is the sweetest of all the common sugar alcohols. **Target(s):** aldose 1-epimerase, or mutarotase (1,2); α-amylase (3); D-arabinose isomerase (4,5); L-arabinose isomerase (6-10); L-fucose isomerase (2,5); xylose isomerase (7,11-16). 1. Bailey, Fishman, Kusiak, Mulhern & Pentchev (1975) *Meth. Enzymol.* **41**, 471. 2. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. **2**, p. 413, Academic Press, New York. 3. **D-Xylosamine**

This D-glucosamine analogue, also known as  $\beta$ -D-xylopyranosylamine (FW<sub>free base</sub> = 135.14 g/mol; CAS 22738-07-4), can act as an alternative substrate and/or competitive inhibitor of a number of glucosamine-dependent systems. It is a potent, time-dependent inhibitor of xylan 1,4- $\beta$ -xylosidase, or  $\beta$ -xylosidase,  $K_i$  = 40 nM (1). 1. Deleyn, Claeysens & De Bruyne (1982) *Meth. Enzymol.* **83**, 639.

**D-Xylose**

This D-aldopentose, also known as wood alcohol (FW = 150.13 g/mol; CAS 58-86-6) has the following relative compositions at 31°C in D<sub>2</sub>O: 36.5%  $\alpha$ -D-xylopyranose, 63%  $\beta$ -D-xylopyranose, and <1% furanose). **Targets:** aldose 1-epimerase, or mutarotase (1-5);  $\alpha$ -amylase (6);  $\alpha$ -L-arabinofuranosidase (2, 8); arabinogalactan endo-1,4- $\beta$ -galactosidase (7); cellulose 1,4- $\beta$ -cellobiosidase (8); Cu,Zn-superoxide dismutase (9); endo-1,4- $\beta$ -xylanase (10,41);  $\alpha$ -galactosidase (35-37);  $\beta$ -galactosidase, weakly (4,11-15); glucan 1,4- $\alpha$ -glucosidase, or glucoamylase (42,43); glucokinase (16-18,46);  $\alpha$ -glucosidase (4,19,20,40);  $\beta$ -glucosidase ( $K_i$  = 495 mM for the sweet almond enzyme) (38,39);  $\alpha$ -glucuronidase (21); hexokinase (22,51); isoamylase (23); lactose synthase (24); macrocellulase complex (25);

polyphosphate:glucose phosphotransferase (44,45); superoxide dismutase (9); thioglucosidase or myrosinase, weakly (26);  $\alpha,\alpha$ -trehalose phosphorylase (configuration-retaining) (47); xylan 1,4- $\beta$ -xylosidase (27,29-34). 1. **L-Xylose**

This uncommon L-aldopentose enantiomer (FW = 150.13 g/mol; CAS 609-06-3) inhibits aldose 1-epimerase (1,2),  $\beta$ -glucosidase ( $K_i$  = 120 mM for the sweet almond enzyme) (3), and lactose synthase, weakly (4). 1. Bailey, Fishman, Kusiak, Mulhern & Pentchev (1975) *Meth. Enzymol.* **41**, 471. 2. Fishman, Pentchev & Bailey (1975) *Meth. Enzymol.* **41**, 484. 3. **$\alpha$ -D-Xylose 1-Phosphate**

This phosphorylated pentose analogue (FW<sub>monosodium-salt</sub> = 252.09 g/mol) of  $\alpha$ -D-glucose 1-phosphate inhibits the *Schizophyllum commune*  $\alpha,\alpha$ -trehalose phosphorylase, a component of the  $\alpha$ -D-glucopyranosyl  $\alpha$ -D-

glucopyranoside ( $\alpha,\alpha$ -trehalose)-degrading enzyme system in fungi and catalyzes glucosyl transfer from  $\alpha,\alpha$ -trehalose to phosphate with overall net retention of the anomeric configuration. **1.** Eis & Nidetzky (2002) *Biochem. J.* **363**, 335.

**Xylosylzeatin**, See *Zeatin Xyloside*

### D-Xylulose

This D-ketopentose (FW = 150.13 g/mol; CAS 551-84-8), an intermediate in the pentose phosphate shunt inhibits ribokinase (1) and ketohexokinase (or hepatic fructokinase), acting as an alternative substrate for the latter (2). **1.** Ogbunude, Lamour & Barrett (2007) *Acta Biochim. Biophys. Sin. (Shanghai)* **39**, 462. **2.** Raushel & Cleland (1977) *Biochemistry* **16**, 2169.

### L-Xylulose

This L-ketopentose intermediate (FW = 150.13 g/mol; CAS 527-50-4) of the glucuronate pathway inhibits arylglycosidases and glucosidase. The inhibition of yeast  $\alpha$ -glucosidase by L-xylulose was of a competitive nature ( $IC_{50} = 1 \times 10^{-5}$  M). Both L-xylulose and L-fructose also inhibited the purified soybean glucosidase I ( $IC_{50} = 1 \times 10^{-4}$  M), but showed no inhibitory activity against soybean glucosidase II. Moreover, when influenza virus-infected MDCK cells are cultured in the presence of L-xylulose, there was a dose-dependent inhibition in the formation of complex types of oligosac-

charides on the viral glycoproteins consistent with the inhibition of the processing glucosidase I. This inhibition resulted in the accumulation of  $Glc_3Man_9(GlcNAc)_2$  oligosaccharides on the viral glycoprotein. L-Fructose also inhibited glycoprotein processing in cell culture, and the inhibition resulted in the formation of similar oligosaccharides to those seen with L-xylulose. **1.** Muniruzzaman, Pan, Zeng, *et al.* (1996) *Glycobiology* **6**, 795.

### D-Xylulose 1,5-Bisphosphate

This D-ribulose 1,5-bisphosphate analogue (FW<sub>disodium-salt</sub> = 354.05 g/mol) inhibits the two main reactions of ribulose-1,5-bisphosphate carboxylase, namely the reaction of carbon dioxide with D-ribulose 1,5-bisphosphate to produce two molecules of 3-phospho-D-glycerate as well as the oxidase activity, in which 3-phospho-D-glycerate and 2-phosphoglycolate are generated (1-3). **1.** McCurry & Tolbert (1977) *J. Biol. Chem.* **252**, 8344. **2.** Taylor, Fothergill & Andersson (1996) *J. Biol. Chem.* **271**, 32894. **3.** McCurry, Pierce, Tolbert & Orme-Johnson (1981) *J. Biol. Chem.* **256**, 6623.

### D-Xylulose 5-Phosphate

This phosphorylated pentose-phosphate pathway intermediate (FW<sub>monosodium-salt</sub> = 252.09 g/mol) and it inhibits glucose-6-phosphate isomerase with  $K_i = 0.7$  mM (1), acetyl-CoA synthetase, or acetate:CoA ligase (2), and ribose-5-phosphate isomerase ( $K_i = 4$  mM) (3). **1.** Noltmann (1972) *The Enzymes*, 3rd ed. (Boyer, ed.), **6**, 271. **2.** O'Sullivan & Ettlinger (1976) *Biochim. Biophys. Acta* **450**, 410. **3.** Jung, Hartman, Lu & Larimer (2000) *Arch. Biochem. Biophys.* **373**, 409.

# - Y -

**Y, See Tyrosine; Yttrium and Yttrium Ions**

## Y1

This synthetic peptide, corresponding to residues 13-33 of cholecystokinin, potently inhibits Yapsin 1 ( $K_i = 65$  nM), the basic residue-specific yeast aspartyl protease also known as Sap9p from *Candida albicans*. Inhibitor-coupled agarose beads were successfully used to purify yapsin 1 to apparent homogeneity from conditioned medium of a yeast expression system. Cawley, Chino, Maldonado, Rodriguez, Loh & Ellman (2003) *J. Biol. Chem.* **278**, 5523.

## Y 11

This FAK inhibitor (FW = 265.15 g/mol; CAS 1086639-59-9; Solubility: 100 mM in H<sub>2</sub>O; 100 mM in DMSO; IUPAC Name: 1-(2-hydroxyethyl)-3,5,7-triaza-1-azatriacyclo[3.3.1.1<sup>3,7</sup>]decane bromide, prevents focal adhesion kinase autophosphorylation at Tyr-397 (IC<sub>50</sub> ~ 50 nM, *in vitro*), with 20x–30x selectivity for FAK versus other rotein kinases. Y-11 decreases cell viability in a many cancer cell lines. 1. Golubovskaya, Nyberg, Zheng, *et al.* (2008) *J. Med. Chem.* **51**, 7405.

## Y 134

This selective estrogen receptor (ER) modulator, *or* SERM (FW = 472.60 g/mol; CAS 849662-80-2; Soluble to 100 mM in DMSO and to 100 mM in Ethanol), also named 6-hydroxy-2-(4-hydroxyphenyl)benzo[*b*]thien-3-yl]-[4-[4-(1-methylethyl)-1-piperazinyl]phenyl]methanone, ER $\alpha$  ( $K_i = 0.09$  nM) over ER $\beta$  ( $K_i = 11.3$  nM), showing no affinity for mineralocorticoid, glucocorticoid, androgen and progesterone receptors. Y-134 acts as an agonist in the bone and antagonist in reproductive tissue and uppresses estrogen-stimulated proliferation of ER-positive human breast cancer cells. 1. Yang, Xu, Li, *et al.* (2005) *Bioorg. Med. Chem. Lett.* **15**, 1505. PMID: 15713417. 2. Ning, Zhou, Weng, *et al.* (2007) *Brit. J. Pharmacol.* **150**, 19. PMID: 17115070.

## Y-25130

This potent 5-HT<sub>3</sub> antagonist (FW = 386.30 g/mol; CAS 123040-16-4), also known as *N*-(1-azabicyclo[2.2.2]oct-3-yl)-6-chloro-4-methyl-3-oxo-3,4-dihydro-2*H*-1,4-benzoxazine-8-carboxamide hydrochloride, selectively targets serotonin receptors, but is free of dopamine receptor blocking activity (1). In an *in vitro* binding assay, Y-25130 inhibited the specific

binding of [<sup>3</sup>H]-quipazine to 5-HT<sub>3</sub> receptors at the synaptic membranes of the rat cerebral cortex with a  $K_i$  value of 2.9 nM (2). Y-25130 is an orally active anti-emetic compound against cisplatin and doxorubicin- and cyclophosphamide-induced vomiting. 1. Fukuda, Setoguchi, Inaba, Shoji & Tahara (1991) *Eur. J. Pharmacol.* **196**, 299. 2. Sato, Sakamori, Haga, Takehara & Setoguchi (1992) *Jpn. J. Pharmacol.* **59**, 443. 3. Haga, Inaba, Shoji, *et al.* (1993) *Jpn. J. Pharmacol.* **63**, 377.

## Y-26763

This active Y-27152 metabolite (FW = 276.29 g/mol; CAS 127408-31-5; Soluble to 100 mM when combined with 1 equivalent NaOH; IUPAC: *N*-[(3*S*,4*R*)-6-cyano-3,4-dihydro-3-hydroxy-2,2-dimethyl-2*H*-1-benzopyran-4-yl]-*N*-hydroxyacetamide, is a long-lasting K<sub>ir</sub>6 (K<sub>ATP</sub>) channel opener that relaxes contracted rat aortic rings, IC<sub>50</sub> = 27  $\mu$ M (1) and inhibits glucose-induced insulin secretion in isolated human pancreatic  $\beta$ -cells *in vitro* (2). (See Y-27152) Y-26763 also induces hypotension in spontaneously hypertensive rats and displays cardioprotective properties in dogs following systemic administration *in vivo*. 1. Fukunari, Miyai, Shinagawa, Kawahara & Nakajima (1997) *Eur. J. Pharmacol.* **323**, 197. 2. Cosgrove, Straub, Barnes, *et al.* (2004) *Eur. J. Pharmacol.* **486**, 133.

## Y-27632

This cell-permeable protein kinase inhibitor (FW<sub>free-base</sub> = 246.35 g/mol; FW<sub>mono-HCl</sub> = 282.81 g/mol; FW<sub>di-HCl</sub> = 320.27 g/mol; CAS 129830-38-2 and 146986-50-7; Solubility: 15 mg/mL DMSO; Freely soluble in H<sub>2</sub>O as the d-HCl salt), also known systematically as (1*R*,4*r*)-4-((*R*)-1-aminoethyl)-*N*-(pyridin-4-yl)cyclohexanecarboxamide, is a vasodilator that targets ROCK1 ( $K_i = 0.14$   $\mu$ M), a RhoA/Rho kinase that plays important roles in mediating vasoconstriction and vascular remodeling in the pathogenesis of pulmonary hypertension. Rho-associated coiled coil-forming protein kinase (ROCK) is thought to regulate actomyosin-based contractility in many types of cells by phosphorylation of ROCK targets. Y-27632 also inhibits ROCK-II, while displaying little activity against PKC, PKA, and myosin light-chain kinase (MLCK), with  $K_i$  values of 26  $\mu$ M, 25  $\mu$ M and >250  $\mu$ M, respectively, and >200-fold selectivity over other kinases. Y-27632 suppresses Rho-induced, p160 ROCK-mediated formation of actin stress fibres in cultured cells and dramatically corrects hypertension in several hypertensive rat models (1). Y-27632 also induces disassembly of actin stress fibers, attended by rapid dissociation of VASP and zyxin with a lifetime of 7-8 min, talin, paxillin and ILK with a lifetime of ~16 min, and then FAK, vinculin and kindlin-2 with a lifetime of 25-28 min (5). See Y-39983 and (*R*)-(+)-*trans*-4-(1-Aminoethyl)-*N*-pyridyl)cyclohexanecarboxamide 1. Uehata, *et al.* (1997) *Nature* **389**, 990. 2. Itoh, *et al.* (1999) *Nat. Med.* **5**, 221. 3. Bito, *et al.* (2000) *Neuron* **26**, 431. 4. Watanabe, *et al.* (2007) *Nat. Biotechnol.* **25**, 681. 5. Lavelin, Wolfenson, Patla, *et al.* (2013) *PLoS* **8**:e73549.

## Y-29794 Oxalate

This orally active and brain-penetrant non-peptide serine peptidase inhibitor (FW = 508.69 g/mol; CAS 146794-84-5; Soluble to 15 mM in Ethanol with gentle warming; 15 mM in DMSO; IUPAC Name: [2-[[[8-(dimethylamino)octyl]thio]-6-(1-methylethyl)-3-pyridinyl]-2-thienyl]methanone

oxalate, targets rat brain prolyl endopeptidase ( $K_i = 0.95$  nM) *in vitro* (1) and prevents amyloid  $\beta$ -peptide deposition *in vivo* within senescence-accelerated mice (2). 1. Nakajima, Ono, Kato, Maeda & Ohe (1992) *Neurosci. Lett.* **141**, 156. 2. Kato, Fukunari, Sakai & Nakajima (1997) *J. Pharmacol. Exp. Ther.* **283**, 328.

**Y-32885**, See (R)-(+)-4-(1-Aminoethyl)-N-(4-pyridyl)benzamide

**Y-39983**

This cell-permeable protein kinase inhibitor and vasodilator (FW<sub>free-base</sub> = 280.33 g/mol; FW<sub>HCl</sub> = 316.79 g/mol; CAS 471843-75-1), also known systematically as, selectively targets RhoA/Rho kinases that play important roles in mediating vasoconstriction and vascular remodeling in the pathogenesis of pulmonary hypertension. Aqueous outflow in the eye is regulated by the contraction and relaxation of the ciliary muscle (CM) and the trabecular meshwork (TM), and Rho-associated coiled coil-forming protein kinase (ROCK) is thought to regulate actomyosin-based contractility by phosphorylation of ROCK targets. Y-39983 also significantly enhances the survival and axonal regeneration of retinal ganglion cells (RGCs) in a rat optic nerve crush (ONC) model (2). Y-39983-mediated downregulation of active-RhoA, ROCK1 and ROCK2 expression coincided with the appearance of larger numbers of regenerating axons. See Y-27632 and (R)-(+)-trans-4-(1-Aminoethyl)-N-pyridyl)cyclohexane carboxamide 1. Nakajima, Nakajima, Minagawa, Shearer & Azuma (2005) *J. Pharm. Sci.* **94**, 701. 2. Yang, Wang, Liu, *et al.* (2013) *Oncol. Rep.* **29**, 1140.

**YC-1**

This nitric oxide-independent activator of soluble guanylyl cyclase (FW = 304.34 g/mol; CAS 170632-47-0), also named 3-(5'-hydroxymethyl-2'-furyl)-1-benzylindazole, elevates cell levels of 3',5'-cyclic-GMP levels and inhibits collagen-stimulated aggregation of washed platelets (IC<sub>50</sub> = 14.6  $\mu$ M). YC-1 also displays antiproliferative activity *in vitro* and *in vivo* by inducing G<sub>1</sub> cell-cycle arrest in two human hepatocellular carcinoma (HCC) cell lines, and in HCC xenografts in athymic SCID mice. YC-1 exhibits low cytotoxicity in non-malignant cells. 1. Ko, Wu, Kuo, Lee & Teng (1994) *Blood* **84**, 4226. 2. Martin, Lee & Murad (2001) *Proc. Natl. Sci. U.S.A.* **98**, 12938. 3. Wang, Pan & Guh (2005) *J. Pharmacol. Exp. Ther.* **312**, 917.

**YCZ-18**

This brassinosteroid biosynthesis inhibitor (FW = 415.87 g/mol) binds targets recombinant CYP90D1, a steroid C23-hydroxylase that is required in brassinosteroid (BR) biosynthesis, inducing a typical Type II binding spectrum ( $K_d = 0.79$   $\mu$ M). BRs are polyhydroxylated steroids that play

critical hormone roles in regulating broad aspects of plant growth and development. Their structural diversity is generated by the action of several CYP's (or P450s). YCZ-18 down-regulates gene expression required for BRs in *Arabidopsis*. (See *Brassinazole*) 1. Oh, Matsumoto, Yamagami, *et al.* (2015) *PLoS One* **10**, :e0120812.

**YE 120**

This GPR35 agonist (FW = 330.17 g/mol; CAS 383124-82-1; Solubility: 100 mM in DMSO), also named 2-[3-cyano-5-(3,4-dichlorophenyl)-4,5-dimethyl-2(5H)-furan-2-ylidene]propanedinitrile, is a GTP Protein-Coupled Receptor 35, or, agonist (1) in dynamic mass redistribution (DMR) assays using resonant waveguide grating (RWG) biosensors to characterize stimulator-mediated cell responses including signaling, detecting redistribution of cellular contents in both directions that are perpendicular and parallel to the sensor surface (2). YE-120 also displays partial agonist activity in a  $\beta$ -arrestin translocation assay (EC<sub>50</sub> = 10.2  $\mu$ M). 1. Deng, Hu, He, *et al.* (2011) *J. Med. Chem.* **54**, 7385. 2. Fang, Ferrie, Fontaine, Mauro & Balakrishnan (2006) *Biophys. J.* **91**, 1925.

**YH1885**, See *Revaprazan*

**YIC-C8-434**, See *N-(3,5-Dimethoxy-4-n-octyloxy-cinnamoyl)-N'-(3,4-dimethylphenyl)piperazine*

**YIL 781**

This GHS-R<sub>1a</sub> antagonist (FW = 409.51 g/mol; CAS 875258-85-8; Soluble to 100 mM in DMSO), also named 6-(4-fluorophenoxy)-2-methyl-3-[[[(3S)-1-(1-methylethyl)-3-piperidinyl]methyl]-4(3H)-quinazolinone], targets the Ghrelin Receptor-1a ( $K_i = 17$  nM), but displays much lower affinity for the motilin receptor ( $K_i = 6$   $\mu$ M). YIL 781 blocks the effects of ghrelin on insulin secretion both *in vivo* and *in vitro*, thereby improving glucose homeostasis, suppressing appetite, and promoting weight loss. Although this GHS-R<sub>1a</sub> antagonist modestly delayed gastric emptying at the highest dose tested (10 mg/kg), delayed gastric emptying does not appear to be a requirement for weight loss because lower doses produced weight loss without an effect on gastric emptying. 1. Esler, Rudolph, Claus, *et al.* (2007) *Endocrinology* **148**, 5175.

**YJA20379-1**, See *2-Amino-4,5-dihydro-8-phenylimidazole[2,1-b]thiazolo[5,4-g]benzothiazole*

**YK 3-237**

This SIRT1 activator (FW = 372.18 g/mol; CAS 1215281-19-8; Solubility: 100 mM in DMSO, systematically named *B*-[2-methoxy-5-[(1E)-3-oxo-3-(3,4,5-trimethoxyphenyl)-1-propen-1-yl]phenyl]boronic acid, activates the NAD<sup>+</sup>-dependent deacetylase *Sirtuin-1* *in vitro*, with deacetylation of both WTp53 (wild-type p53 acetylated at K382) as well as mtp53. In humans, the SIRT1 interactome includes some 150 proteins. Deacetylation of mtp53 resulted in depletion of mtp53 protein level and up-regulated the expression of WTp53-target genes, PUMA and NOXA. YK-3-237 also induces PARP-dependent apoptotic cell death and arrests the cell cycle at G<sub>2</sub>/M phase of mtp53 TNBC cells. See also *SRT1720* Note: Although YK-3-237 is

originated as a boronic acid chalcone analog of combretastatin A-4 (CA-4), YK-3-237 does not bind to tubulin *in vitro* and exhibits potent anti-proliferative activity toward a broad range of NCI cancer cell lines. 1. Yi, Kang, Kim, *et al.* (2013) *Oncotarget* **4**, 984.

**YK 4-279**

This RNA helicase A inhibitor (FW = 366.20 g/mol; CAS 1037184-44-3; Solubility: 100 mM in DMSO), also named 4,7-dichloro-1,3-dihydro-3-hydroxy-3-[2-(4-methoxyphenyl)-2-oxoethyl]-2H-indol-2-one, binds to the oncogenic transcription factor EWS-FLI1, inhibiting Ewing's sarcoma family tumor (ESFT) cell growth and inducing apoptosis. Notably, Ewing's tumors contain a t(11;22) translocation, leading to expression of the oncogenic fusion protein EWS-FLI1, a disordered protein that currently defies standard crystallographic/multi-D-NMR structure-based small-molecule inhibitor design. EWS-FLI1 binding to RNA helicase A (RHA) is important for its oncogenic function. In a cell-free assay, NSC635437 reduced the direct binding of GST-RHA(647-1075) to full-length recombinant EWS-FLI1 ( $K_i = 9.5 \mu\text{M}$ ). 1. Erkizan, Kong, Merchant, *et al.* (2009) *Nature Med.* **15**, 750.

**YM155, See Sepantrium bromide**

**YM 175, See Incadronate**

**YM466**

This orally active naphthylamide and anticlotting agent (FW = 535.67 g/mol), also known as [N-[4-[(1-acetimidoyl-4-piperidyl)oxy]phenyl]-N-[(7-amidino-2-naphthyl)methyl]sulfamoyl]acetic acid and YM-60828, is a potent inhibitor of coagulation factor Xa ( $K_i = 1.3 \text{ nM}$ ), but a significantly weaker inhibitor of thrombin ( $K_i > 100 \mu\text{M}$ ). YM466 also inhibits platelet aggregation induced by various agonists, reduces the incidence of occlusion, and exerts antithrombotic effects in venous thrombosis and arteriovenous shunt models. 1. Taniuchi, Sakai, Hisamichi, Kayama, *et al.* (1998) *Thromb. Haemost.* **79**, 543. 2. Leadley, Jr. (2001) *Curr. Top. Med. Chem.* **1**, 151.

**YM 511**

This aromatase inhibitor (FW = 354.21 g/mol; CAS 148869-05-0; Solubility: 100 mM in DMSO), also named 4-[[4-(4-bromophenyl)methyl]-4H-1,2,4-triazol-4-ylamino]benzotrile, targets rat ovary ( $\text{IC}_{50} = 0.4 \text{ nM}$ ) and human placenta ( $\text{IC}_{50} = 0.12 \text{ nM}$ ), respectively, reducing plasma estrogen levels into ranges induced by ovariectomy and inhibiting testosterone-induced breast cancer cell growth *in vitro* ( $\text{IC}_{50} = 0.13 \text{ nM}$ ). 1. Kudoh, *et al.* (1995) *J. Steroid Biochem. Molec. Biol.* **54**, 265. 2. Kudoh, *et al.* (1996) *J. Steroid Biochem. Molec. Biol.* **58**, 189. 3. Okada, *et al.* (1996) *Chem. Pharm. Bull.* **44**, 1871.

**YM-529, See Minodronate**

**YM 750**

This anti-oxidative ACAT inhibitor (FW = 452.64 g/mol; CAS 138046-43-2; Solubility: 100 mM in DMSO; 10 mM in Ethanol), also known as N-cycloheptyl-N-(9H-fluoren-2-ylmethyl)-N'-(2,4,6-trimethylphenyl)urea, targets acyl-CoA:cholesterol acyltransferase ( $\text{IC}_{50} = 0.18 \mu\text{M}$ ), exhibiting both hypocholesterolemic and diet-induced atherosclerosis formation in mice (1-3). 1. Nagata, Yonemoto, Iwasawa, *et al.* (1995) *Biochem. Pharmacol.* **49**, 643. 2. Kamiya, Shirahase, Yoshimi, *et al.* (2000) *Chem. Pharm. Bull.* **48** 817. 3. Miike, Shirahase, Jino, *et al.* (2008) *Life Sci.* **82**, 79.

**YM-09151-2, See Nemonapride**

**YM-60828, See YM-466**

**YM 90709**

This novel selective inhibitor (FW = 359.43 g/mol; CAS 163769-88-8; Solubility: to 25 mM in Ethanol, to 50 mM in DMSO), also known as 5,6-dihydro-2,3-dimethoxy-6,6-dimethylbenz[7,8]indolizino[2,3-*b*]quinoxaline, targets the interleukin-5 (IL-5) receptor ( $\text{IC}_{50} = 0.45\text{-}1.00 \text{ mM}$ ), blocking IL-5-mediated prolongation of eosinophil survival and IL-5-induced tyrosine phosphorylation of JAK2, without inhibiting GM-CSF-mediated effects. YM 90709 also inhibits antigen-induced eosinophil and lymphocyte recruitment in rat airways *in vivo*, without affecting peripheral blood or bone marrow leukocytes. 1. Morokata, *et al.* (2002) *Int. Immunopharmacol.* **2**, 1693. 2. Morokata, *et al.* (2004) **4**, 873. 3. Morokata, *et al.* (2005) *Immunol. Lett.* **98**, 161.

**YM-231146**

This orally bioavailable antiangiogenesis agent (FW = 389.46 g/mol; IUPAC name: (3Z)-3-[6-(2-morpholin-4-ylethoxy)quinolin-2(1H)-ylidene]-1,3-dihydro-H-indol-2-one) inhibits VEGF receptor-2 tyrosine kinase,  $\text{IC}_{50} = 80 \text{ nM}$ , with much weaker ( $\text{IC}_{50} > 1 \mu\text{M}$ ) action against other kinases. YM-231146 inhibits VEGF-stimulated proliferation, VEGF-R2 autophosphorylation, and vessel sprout formation of human vascular endothelial cells at concentrations between 0.15-0.30  $\mu\text{M}$ . YM-231146 did not inhibit cancer cell proliferation at these concentrations ( $\text{IC}_{50} > 5 \mu\text{M}$ ). Once-daily YM-231146 dosing (3-100 mg/kg) to human cancer xenografts elicited antitumor activity. 1. Amino, Ideyama, Yamano, *et al.* (2005) *Biol. Pharm. Bull.* **28**, 2096.

**YM-359445**

This orally bioavailable VEGF receptor-2 tyrosine kinase inhibitor and antiangiogenesis agent (FW<sub>free-base</sub> = 512.63 g/mol; often formulated as the mono-l-tartrate), also known as (3Z)-3-[6-[(4-methylpiperazin-1-yl)methyl]quinolin-2(1H)-ylidene]-2-oxoindoline-6-carbaldehyde O-(1,3-thiazol-4-ylmethyl)oxime, exhibits highly potent antitumor activity against

established tumors. At 1 nM, YM-359445 also inhibits tyrosine kinases other than VEGFR2, including Flt-1, Flt-3, Flt-4, PDGFR $\beta$ , c-Fms, and c-Kit by 66%, 73%, 84%, 25%, 71%, and 78%, respectively. That YM-359445 is specific for tyrosine kinase, however, is indicated by its total inhibitory effect on VEGFR2 autophosphorylation at 3 nM, compared to IC<sub>50</sub> values of >1  $\mu$ M for protein kinase A, protein kinase C $\alpha$ , phosphoinositide-dependent kinase-1, serum-/glucocorticoid-inducible kinase-1, as well as c-Jun NH<sub>2</sub>-terminal kinase-3. The IC<sub>50</sub> against HUVEC proliferation induced by VEGF was only 1.5 nM, showing extremely potent antitumor action versus various human cancer xenografts. Moreover, because these tyrosine kinases would also be involved in tumor growth, multi-targeted tyrosine kinase inhibitors may be more effective at inhibiting tumor growth than agents that target a single angiogenic factor. 1. Amino, Ideyama, Yamano, *et al.* (2006) *Clin. Cancer Res.* **12**, 1630.

#### YO-01027

This aspartate protease inhibitor (FW = 463.48 g/mol; CAS 209984-56-5; Solubility: 90 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O; Formulation: Suspend in 0.5% (w/v) hydroxypropylmethylcellulose (Methocel E4M) and 0.1% (w/v) Tween 80 in water), also known as Dibenazepine (DBZ) and systematically as 7-(S)-[N'(3,5-difluorophenylacetyl)-L-alaninyl]amino-5-methyl-5,7-dihydro-6H-dibenz[b,d]azepine-6-one, targets  $\gamma$ -secretase (GS), thereby inhibiting cleavage of numerous type-I integral membrane proteins, including amyloid precursor protein (APP) and Notch. While APP cleavage contributes to the generation of toxic amyloid beta peptides in Alzheimer's disease, cleavage of the Notch receptor is required for normal physiological signaling between differentiating cells. 1. Groth, *et al.* (2010) *Mol. Pharmacol.* **77**, 567.

#### Yohimbine

This alkaloid and  $\alpha_2$ -adrenoceptor antagonist (FW<sub>free-acid</sub> = 354.45 g/mol; CAS 146-48-5; FW<sub>HCl-salt</sub> = 390.91 g/mol; CAS 65-19-0), also named 17 $\alpha$ -hydroxyyohimban-16 $\alpha$ -carboxylic acid methyl ester hydrochloride, from the bark of *Corynanthe yohimbe* and *Rauwolfia serpentina* is an  $\alpha_2$ -adrenergic antagonist (1) with vasodilatory properties that have been exploited to treat atherosclerosis. Yohimbine binds to human  $\alpha_{2A}$  (pK<sub>i</sub> = 8.52),  $\alpha_{2B}$  (pK<sub>i</sub> = 8.00), and  $\alpha_{2C}$  (pK<sub>i</sub> = 9.17) receptors. Yohimbine relaxes tissues previously made to contract by application of serotonin. When administered first, yohimbine likewise prevents serotonin-induced contraction. Such action is in marked contrast to the well known antagonism observed between yohimbine and adrenaline, which is effective only when applied first. Other important diastereoisomers are  $\alpha$  yohimbine or rauwolscine (with all three E-ring hydrogens projecting backward and its methylacetate substituent projecting forward) and *allo*-yohimbine (with all three E-ring hydrogens projecting backward). Yohimbine's diastereomer is Rauwolscine (See also Rauwolscine). **Target(s):**  $\alpha_2$ -adrenergic receptor (1); [ $\beta$ -adrenergic-receptor] kinase (2). 1. Goldberg & Robertson (1983) *Pharmacol. Rev.* **35**, 143. 2. Benovic, Regan, Matsui, Mayor, *et al.* (1987) *J. Biol. Chem.* **262**, 17251.

#### YopJ Yersinia Virulence Factor

This 33-kDa *Yersinia* virulence factor inhibits several signal transduction protein kinases, including c-Jun amino-terminal kinase, [mitogen-activated protein kinase] kinase, nuclear factor- $\kappa$ B signaling pathways. 1. Orth, Palmer, Bao, Stewart, *et al.* (1999) *Science* **285**, 1920.

#### YS 035

This verapamil analogue (FW<sub>HCl-salt</sub> = 395.93 g/mol; CAS 89805-39-0), also named *N,N*-bis-(3,4-dimethoxyphenethyl)-*N*-methylamine, inhibits Ca<sup>2+</sup> uptake in many cell types, *e.g.* by muscle cells (inhibitor range 10-30  $\mu$ M), by rat brain synaptosomes and less so by baby-hamster kidney cells (1). YS 035 partially inhibits the slow Ca<sup>2+</sup> release induced by Ruthenium Red and the rapid Na<sup>+</sup>-dependent efflux from heart mitochondria. The inhibition of the Na<sup>+</sup>/Ca<sup>2+</sup> exchange is noncompetitive (K<sub>i</sub> = 28  $\mu$ M). It also totally inhibits Ruthenium Red-induced Ca<sup>2+</sup> efflux from liver mitochondria, but does not affect Ca<sup>2+</sup> release induced by uncoupler, respiratory inhibitor or chelator, nor the mitochondrial ATP synthesis and membrane potential (1). YS 035 is likely to be especially useful for studies on mitochondrial Ca<sup>2+</sup> transport. Electrophysiologic measurements on YS 035 effects on Purkinje cells have been reported (2). 1. Deana, Panato, Cancellotti, Quadro & Galzigna (1984) *Biochem. J.* **218**, 899. 2. Berger, Borchard, Hafner, Kammer & Weis (1991) *Naunyn. Schmiedeberg's. Arch. Pharmacol.* **344**, 653.

#### Ytterbium and Ytterbium Ions

This lanthanide (Yb; Atomic number = 70; Atomic weight = 173.04) has two ionic forms, Yb<sup>2+</sup> and Yb<sup>3+</sup>, with respective ionic radii of 0.93 Å and 0.858 Å. Yb<sup>3+</sup> is paramagnetic, making it a very useful NMR-shift reagent. The tree *Carya* spp. reportedly accumulates ionic ytterbium. **Target(s):** calcium channels (1,2); coagulation factor XIII (via Yb<sup>3+</sup>) (3); phosphoprotein phosphatase (4). 1. Mliner & Enyeart (1993) *J. Physiol.* **469**, 639. 2. Beedle, Hamid & Zamponi (2002) *J. Membr. Biol.* **187**, 225. 3. Fox, Yee, Pedersen, Le Trong, *et al.* (1999) *J. Biol. Chem.* **274**, 4917. 4. Zhou, Clemens, Hakes, Barford & Dixon (1993) *J. Biol. Chem.* **268**, 17754. **See also Ytterbium-ATP Complex**

#### Ytterbium(III)-ATP Complex

The Yb(III)-ATP complex inhibits various ATP-dependent enzymes, most often by binding in place of MgATP<sup>2-</sup> or CaATP<sup>2-</sup>. **Target(s):** hexokinase (slow-binding)(1-3); phosphoglycerate kinase (4). 1. Morrison (1982) *Trends Biochem. Sci.* **7**, 102. 2. Viola, Morrison & WCleland (1980) *Biochemistry* **19**, 3131. 3. Furumo & Viola (1989) *Inorg. Chem.* **28**, 820. 4. Tanswell, Westhead & Williams (1974) *FEBS Lett.* **48**, 60.

#### Yttrium and Yttrium(III) Ion

This group 3 (or IIIA) transition metal element (Y; Atomic number = 39; Atomic weight = 88.90585; ionic radius = 0.893 Å) forms both oxygen exchange-active and -inert complexes with various anions and metabolites. The Poriferan *Melithaea* spp. and *Carya* spp. trees accumulate yttrium, as do the calcareous tissues in mammals have also been reported to be yttrium accumulators. **Target(s):** acetylcholinesterase (1,2); calcium channels (3,4); enolase (5); micrococcal nuclease (6). 1. Marquis & Lerrick (1982) *Biochem. Pharmacol.* **31**, 1437. 2. Marquis & Black (1985) *Biochem. Pharmacol.* **34**, 533. 3. Mliner & Enyeart (1993) *J. Physiol.* **469**, 639. 4. Beedle, Hamid & Zamponi (2002) *J. Membr. Biol.* **187**, 225. 5. Malmström (1961) *The Enzymes*, 2nd ed. (Boyer, Lardy & Myrback, eds.), **5**, 471. 6. Cuatrecasas, Fuchs & Anfinsen (1967) *J. Biol. Chem.* **242**, 1541.

#### YZ9

This small-molecule inhibitor (FW = 234.21 g/mol; CAS 6093-71-6; Solubility: 50 mM in DMSO), also known as ethyl 7-hydroxy-2-oxo-2H-1-benzopyran-3-carboxylate, targets PFKFB3 (IC<sub>50</sub> = 0.183  $\mu$ M), the hypoxia-inducible isoform of the 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatases, which catalyze Fru-2,6-BP synthesis at >10x higher rates than other isoforms. YZ9 inhibition of PFKFB3 reduces the levels of Fru-2,6-BP in HeLa cells by 40%, resulting in a greater than 30% decrease in lactate, eventually resulting in apoptosis and necrosis. 1. Seo, Kim, Neau, Sehgal & Lee (2011) *PLoS One* **6**, e24179.

# - Z -

## Zabofloxacin

This investigational fluoroquinolone-class antibiotic (FW = 401.39 g/mol; CAS 219680-11-2), also named DW-224a and 1-cyclopropyl-6-fluoro-7-[(8*E*)-8-(methoxyimino)-2,6-diazaspiro[3.4]oct-6-yl]-4-oxo-1,4-dihydro-1,8-naphthyridine-3-carboxylate, is a broad-spectrum systemic antibacterial agent that targets Type II DNA topoisomerases (gyrases), which are required for bacterial replication and transcription. Zabofloxacin has activity against *Neisseria gonorrhoeae*, including strains that are resistant to other quinolone antibiotics. The potency of zabofloxacin (MIC<sub>50</sub> = 16 ng/mL) was generally comparable with azithromycin, but 8-fold superior to ciprofloxacin. (For the prototypical member of this antibiotic class, **See Ciprofloxacin**) 1. Jones, Biedenbach, Ambrose & Wikler (2008) *Diagn. Microbiol. Infect. Dis.* **62**, 110.

## Zacopride

This anti-emetic and anxiolytic (FW = 346.26 g/mol; CAS 101303-98-4; Solubility: 100 mM H<sub>2</sub>O; 100 mM DMSO), systematically named (±)-4-amino-*N*-1-azabicyclo[2.2.2]oct-3-yl-5-chloro-2-methoxybenzamide, is a serotonin receptor antagonist that targets the 5-HT<sub>3</sub> receptor antagonist (K<sub>i</sub> = 0.38 nM), but a 5-HT<sub>4</sub> receptor agonist (K<sub>i</sub> = 370 nM). [<sup>3</sup>H]-Zacopride displays saturable binding to homogenates of the rat entorhinal cortex, with K<sub>d</sub> = 0.76 nM, B<sub>max</sub> = 77.5 fmol/mg protein, n<sub>Hill</sub> ~1 (1). [<sup>125</sup>I]-Iodozacopride (K<sub>d</sub> = 4.3 nM) has been used to map 5-HT<sub>3</sub> receptors in the rat central nervous system (2). 1. Barnes, Costall & Naylor (1988) *J. Pharm. Pharmacol.* **40**, 548. 2. Koscielniak, Ponchant, Laporte, *et al.* (1990) *Comptes rendus de l'Académie des sciences. Série III, Sciences de la vie* **311**, 231.

## Zafirlukast

This leukotriene D<sub>4</sub> receptor antagonist (FW = 575.69 g/mol; CAS 107753-78-6), also known as ICI 204,219, Accolate<sup>®</sup>, Accoleit<sup>®</sup>, Vanticon<sup>®</sup>, and 4-(5-cyclopentylloxycarbonylamino-1-methylindol-3-ylmethyl)-3-methoxy-*N*-(*o*-tolylsulfonyl) benzamide, exerts its antiasthmatic activity by blocking the action of cysteinyl leukotrienes at CysLT1 receptors and thereby reducing airway constriction (1-4). **Other Target:** cytochrome P450, including CYP1A2, CYP3A, CYP2C9, CYP2C19, and CYP2D6 (5). 1. Krell,

Aharony, Buckner, Keith, *et al.* (1990) *Amer. Rev. Respir. Dis.* **141**, 978. 2. Creticos (2003) *Drugs* **63** (Suppl. 2), 1. 3. Murata & Sugimoto (2002) *Nippon Yakurigaku Zasshi* **119**, 247. 4. Bernstein (1998) *Amer. J. Respir. Crit. Care Med.* **157**, S220. 5. Shader, Granda, von Moltke, Giancarlo & Greenblatt (1999) *Biopharm. Drug Dispos.* **20**, 385.

## Zalcitabine, See 2'-3'-dideoxycytidine

## Zaleplon

This benzodiazepine GABA<sub>A</sub> full agonist and anxiolytic (FW = 305.34 g/mol; CAS 151319-34-5), tradenamed Sonata<sup>®</sup>, Starnoc<sup>®</sup>, and Andante<sup>®</sup>, and systematically as *N*-(3-(3-cyanopyrazolo[1,5-*a*]pyrimidin-7-yl)phenyl)-*N*-ethylacetamide, selectively targets the benzodiazepine site (ω<sub>1</sub>) on the α<sub>1</sub> sub-receptor (site associated with its anxiolytic effects), with lesser action at α<sub>2</sub> sub-receptor (site associated with muscle relaxant effects), α<sub>3</sub> sub-receptor (site associated with muscle relaxant effects), and α<sub>5</sub> sub-receptor (site associated with anticonvulsant effects). Its absorption is rapid, as is the onset of its therapeutic effects within 5–15 minutes following ingestion. Moreover, 1-1.5-hour half-life commends its use, when there are concerns about the residual effects of many benzodiazepine agents on performance-related skills (driving and piloting). Because Zaleplon is metabolized by aldehyde oxidase, its half-life can be prolonged by substances that inhibit aldehyde oxidase or shortened by substances that induce aldehyde oxidase. 1. Weitzel, Wickman, Augustin & Strom (2000) *Clin. Ther.* **22**, 1254.

## Zamifenacin

This muscarinic receptor antagonist (FW<sub>free-base</sub> = 415.53 g/mol; FW<sub>fumarate-salt</sub> = 415.53 g/mol; CAS 127308-98-9; Solubility: 100 mM in DMSO), also named UK 76654 and (3*R*)-1-[2-(1,3-benzodioxol-5-yl)ethyl]-3-(diphenylmethoxy)piperidine, selectively targets M<sub>3</sub> receptors (pK<sub>i</sub> = 8.52), with about 5x lower affinity for M<sub>2</sub>, M<sub>1</sub> and M<sub>4</sub> receptors (1). Zamifenacin was rapidly metabolized *in vitro* by liver microsomes from rat, dog, and man. Following oral administration to animals, metabolic clearance resulted in decreased bioavailability due to first-pass metabolism in rat and mouse (2). The major route of clearance of zamifenacin with the primary metabolic step resulting in opening of the methylenedioxy ring to yield the catechol. In man, this metabolite was excreted as the glucuronide conjugate (2). 1. Watson, Reddy, Stefanich & Eglén (1995) *Eur. J. Pharmacol.* **285**, 135. 2. Beaumont, Causey, Coates & Smith (1996) *Xenobiotica* **26**, 459.

## Zanamivir

This antiviral (FW = 332.31 g/mol; CAS 139110-80-8), also known as Relenza<sup>™</sup> and 4-guanidino-2,4-dideoxy-2,3-dehydro-*N*-acetylneuraminate, inhibits influenza virus A and B sialidase (*i.e.*, neuraminidase) at sub-nM concentrations *in vitro* (1-4). As a transition-state analogue of sialic acid, it

forms a high-affinity complex with neuraminidase. Zanamivir's inhibitory action against human sialidases is minimal ( $IC_{50}$  in the micromolar range), greatly contrasting from its action on viral sialidases. However, zanamivir is orally unavailable and is instead delivered directly to the respiratory tract by means of an inhaler (Diskhaler<sup>®</sup>) that holds small pouches of the powdered drug. This mode of delivery offers great advantage for preventing influenza infection, and, while overall whole-body bioavailability is low (~2 percent), zanamivir becomes highly concentrated in the respiratory tract, reaching levels that are 1000x its  $IC_{50}$  within seconds after inhalation. For this reason, one cannot rule out inhibition of human sialidases in the respiratory tract. Analysis data for patients (all ages) admitted to hospital worldwide with laboratory-confirmed or clinically diagnosed infection with the pandemic influenza A H1N1pdm09 virus indicates that early treatment in adults admitted to hospital with suspected/proven influenza infection can be effective in reducing mortality (5). 1. Pegg & von Itzstein (1994) *Biochem. Mol. Biol. Int.* **32**, 851. 2. Woods, Bethell, Coates, Healy, et al. (1993) *Antimicrob. Agents Chemother.* **37**, 1473. 3. Taylor & von Itzstein (1994) *J. Med. Chem.* **37**, 616. 4. von Itzstein, Wu & Jin (1994) *Carbohydr. Res.* **259**, 301. 5. Muthuri, Venkatesan, Myles, et al. (2014) *Lancet Respir. Med.* **2**, 395.

### Zankiner

This peptide analogue ( $FW_{\text{free-base}} = 705.98$  g/mol; CAS 138742-43-5), also known as A-72517, is the first peptidic renin inhibitor with significant oral absorption. It inhibits human plasma renin at pH 7.4 with  $IC_{50} = 3.1$  nM (1-3). 1. Kleinert, Stein, Boyd, Fung, et al. (1992) *Hypertension* **20**, 768. 2. Rosenberg, Spina, Condon, Polakowski, et al. (1993) *J. Med. Chem.* **36**, 460. 3. Kleinert, Rosenberg, Baker, et al. (1992) *Science* **257**, 1940.

**Zantac**, See *Ranitidine*

### Zaprinast

This vasodilator and lead molecule for the development of Viagra ( $FW = 271.28$  g/mol; CAS 37762-06-4; stability = 5 years at +20°C; Soluble to 100 mM in DMSO; stock solutions stable for up to 6 months at -20°C), also known as M&B 22,948 and systematically as 1,4-dihydro-5-(2-propoxyphenyl)-7H-1,2,3-triazolo[4,5-d]pyrimidine-7-one, inhibits 3',5'-cGMP phosphodiesterase (1-10), with highest affinity toward type-5 and type-6 isozymes (e.g., PDE-6,  $IC_{50} = 0.2$  μM; PDE-5,  $IC_{50} = 0.2$ -0.8 μM; PDE-1,  $IC_{50} = 2.6$  μM; PDE-2,  $IC_{50} > 10$  μM; PDE-3,  $IC_{50} > 10$  μM; and PDE-4,  $IC_{50} > 10$  μM). Zaprinast also selectively increases cerebral blood flow. In actions that are unrelated to inhibition of cGMP phosphodiesterase, Zaprinast is a potent inhibitor of the mitochondrial pyruvate carrier (MPC), causing aspartate to accumulate at the expense of glutamate (11). (See also UK5099) The effects on both glutamate and aspartate are detectable at 30 minutes after addition of Zaprinast, becoming more apparent at 1 hour and remaining constant for 2-6 hours. Zaprinast also blocks the entry of glucose-derived pyruvate into the TCA cycle, and it inhibits pyruvate-driven  $O_2$  consumption in brain mitochondria, actions consistent with its ability to block liver mitochondria MPC. Moreover, inactivation of the aspartate glutamate carrier in retina does not attenuate the metabolic effect of Zaprinast. Importantly, Zaprinast does not inhibit pyruvate dehydrogenase (PDH) activity. 1. Thompson (1991) *Pharmacol. Ther.* **51**,

### Zaragozic Acid A

This complex bicyclo-tricarboxylic acid ( $FW_{\text{free-acid}} = 705.78$  g/mol; CAS 142561-96-4), known simply as squalstatin 1 and systematically as (1R,2S,3S,5S,6R,7R)-5-[(4S,5R)-4-acetoxy-5-methyl-3-methylene-6-phenylhexyl]-7-[(E,4S,6S)-4,6-dimethyl-1-oxooct-2-enoxy]-2,6-dihydroxy-4,8-dioxabicyclo[3.2.1]octane-1,2,3-tricarboxylic acid, inhibits protein farnesyltransferase,  $IC_{50} = 216$  nM. With squalene synthase, zaragozic acid A is a mechanism-based irreversible inactivation. *Note:* The terms zaragozic acid and zaragozate refer to the acid and conjugate base forms of a class of related squalostatins, so named for their capacity to inhibit squalene synthase. **Target(s):** phytoene synthase (1,2); protein farnesyltransferase (3-5); squalene synthase (3,6-14). 1. Neudert, Martínez-Férez, Fraser & Sandmann (1998) *Biochim. Biophys. Acta* **1392**, 51. 2. Fraser, Schuch & Bramley (2000) *Planta* **211**, 361. 3. Nadin & Nicolaou (1996) *Angew. Chem. Int. Ed. ### Zardaverine

This pyridazine heterocycle ( $FW = 268.21$  g/mol; CAS 101975-10-4), also named 6-(4-difluoromethoxy-3-methoxyphenyl)-3(2H)-pyridazinone, is a phosphodiesterase III and IV inhibitor,  $IC_50 \approx 1.5$ -1.8 μM (1). **Other Target(s):** Unlike other PDE III/IV inhibitors, zardaverine also induces  $G_0/G_1$  cell-cycle arrest and apoptosis in sensitive Bel-7402 ( $IC_{50} = 137$  nM), Bel-7404 ( $IC_{50} = 288$  nM), QGY-7701 ( $IC_{50} = 51$  nM), and SMMC-7721 ( $IC_{50} = 37$  nM) hepatocellular carcinoma (HCC) cells by dysregulating cell cycle-associated proteins by means of a PDE III/IV-independent mechanism (2). The secondary target is signal transduction mediated by Rb (the retinoblastoma product of the well-characterized tumor suppressor gene *Rb*), which functions to prevent the cell from entering S phase. Phosphorylated or mutated forms of the Rb protein are incapable of arresting the cell in  $G_1$  phase. Treatment with zardaverine dose-dependently decreases the total protein level of Rb and suppresses its phosphorylation at Ser780 in sensitive cells, whereas there are no such changes in insensitive cells, even at >30,000 nM (2). Low expression of Rb is thus a likely biomarker for those cancer cells that are sensitive to zardaverine's growth-inhibiting effects. 1. Schudt, Winder, Muller & Ukena (1991) *Biochem. Pharmacol.* **42**, 153. 2. Sun, Quan, Xie (2014) *PLoS One* **9**, e90627.

## ZCL 278

This protein kinase inhibitor (FW = 584.89 g/mol; CAS 587841-73-4), also named 2-(4-bromo-2-chlorophenoxy)-*N*-[[[4-[[[4,6-dimethyl-2-pyrimidinyl]amino]sulfonyl]phenyl]amino]thioxomethyl]acetamide, selectively targets Cell division control protein 42, or Cdc42, binding ( $K_d = 6.4 \mu\text{M}$ ) at the site for intersectin, its guanine nucleotide exchange factor. ZCL 278 inhibits Cdc42-mediated cellular effects, including microspike formation in 3T3 fibroblasts and neuronal branching in primary neonatal cortical neurons. It also suppresses cell motility and migration in PC3 cells, without cytotoxic effects. 1. Friesland, Zhao, Chen, *et al.* (2013) *Proc. Natl. Acad. Sci. U.S.A.* **110**, 1261.

## ZD6126

This vascular disrupting agent and antineoplastic pro-drug (FW = 437.38 g/mol; CAS 219923-05-4), also known systematically as phosphoric acid mono-(5-acetylamino-9,10,11-trimethoxy-6,7-dihydro-5*H*-dibenzo[*a,c*]cyclohepten-3-yl) ester, binds reversibly with tubulin to prevent microtubule assembly (1-3), selectively disrupting the abnormal vasculature associated with disease processes such as cancer and macular degeneration. Such action has been attributed to the ability of these agents to selectively destroy the central regions of tumors, areas widely believed to contain cell populations resistant to cytotoxic therapies (3). Note that the cell-permeant form is formed by hydrolysis of the phosphate monoester. ZD6126 induces the apoptosis of CD31-positive vascular endothelial cells in tumors but not in the normal lung parenchyma. ZD6126 differs from its parent compound, colchicine, which binds extraordinarily tightly to tubulin. Cardiotoxicity limits the clinical use of ZD6126 (4). 1. Goto, Yano, Zhang, *et al.* (2002) *Cancer Research* **62**, 3711. 2. LoRusso, Gadgeel, Wozniak, *et al.* (2011) *Invest. New Drugs* **26**, 159. 3. Chaplin, Horsman & Siemann (2006) *Curr. Opin. Investig. Drugs* **7**, 522. 4. Lippert (2007) *Bioorg. & Med. Chem.* **15**, 605.

## ZD 8321

This trifluoromethyl ketone (FW = 423.43 g/mol), also known as *N*-methoxycarbonyl-L-valyl-L-prolyl-L-valine trifluoromethyl ketone, inhibits porcine pancreatic elastase,  $K_i = 149 \text{ nM}$  (1) and human leukocyte elastase,  $K_i = 13 \text{ nM}$  (1,2). 1. Veale, Bernstein, Bohnert, Brown, *et al.* (1997) *J. Med. Chem.* **40**, 3173. 2. Kapui, Varga, Urban-Szabó, Mikus, *et al.* (2003) *J. Pharmacol. Exp. Ther.* **305**, 451.

## ZD9238, See Fulvestrant

ZDP, See 5-Aminoimidazole-4-carboxamide-1- $\beta$ -ribofuranosyl 5'-Diphosphate

## Zearalenone

This uterotropic mycotoxin (FW = 318.37 g/mol; CAS 17924-92-4), also known as F-2 mycotoxin and 2,4-dihydroxy-6-(10-dihydroxy-6-oxo-*trans*-1-undecenyl)benzoic acid *m*-lactone, is produced by several species of *Fusarium* (*e.g.*, *F. roseum*, now referred to as *F. semitectum*). Zearalenone is reduced by rat liver preparations to a more active estrogenic metabolite,  $\alpha$ -zearalenol. Microsomal NAD(P)H-dependent zearalenone reductase is most active at pH 4-4.5, whereas the cytosolic reductase is active at neutral pH. The former enzyme reduced zearalenone only to  $\alpha$ -zearalenol and the latter reduced both  $\alpha$ - and  $\beta$ -zearalenol. Zearalenone increases membrane permeability, promotes uterine synthesis of DNA, RNA, and protein, and inhibits cyclooxygenase and  $7\beta$ -hydroxysteroid dehydrogenase. Zearalenone exerts its estrogen effects by binding to estrogen receptors and influencing transcription within the nucleus. It is also used in veterinary medicine as an estrogen-like anabolic agent. Zearalenone induces sister chromatid exchange and chromosomal aberration in CHO cells. **Target(s):** cyclooxygenase (1);  $17\beta$ -hydroxysteroid dehydrogenase (2,3). 1. Degen (1990) *J. Steroid Biochem.* **35**, 473. 2. Krazeisen, Breitling, Moller & Adamski (2001) *Mol. Cell. Endocrinol.* **171**, 151. 3. Krazeisen, Breitling, Moller & Adamski (2002) *Adv. Exp. Med. Biol.* **505**, 151.

## Zeatin

The *trans*- and *cis*-isomers of *N*<sup>6</sup>-isopentenyl-adenine (FW = 219.25 g/mol; CAS: 1637-39-4), also called 6-(4-hydroxy-3-methyl-*trans*-2-butenylamino)purine and (*E*)-2-methyl-4-(1*H*-purin-6-ylamino)-2-buten-1-ol, isolated from immature maize seeds (1). The *cis*-zeatin, also called *N*<sup>6</sup>-*cis*- $\gamma$ -methyl- $\gamma$ -hydroxymethylallyl-adenine, is found in plant tRNA, whereas *trans*-zeatin is a competitive inhibitor of adenine and cytosine transporters and is reportedly an uncompetitive inhibitor of xanthine oxidase. **Target(s):** adenine transport (2); cytosine transport (2); indole-3-acetate  $\beta$ -glucosyltransferase (3); xanthine oxidase (4); *cis*-zeatin *O*- $\beta$ -D-glucosyltransferase, by *trans*-zeatin (5). 1. Letham (1963) *Life Sci.* **41**, 569. 2. Gillissen, Burkle, Andre, Kuhn, Rentsch, Brandl & Frommer (2000) *Plant Cell* **12**, 291. 3. Leznicki & Bandurski (1988) *Plant Physiol.* **88**, 1481. 4. ## Zeatin Riboside

This *N*<sup>6</sup>-alkenyl-adenosine derivative (FW = 351.38 g/mol), also known as ribosylzeatin, is a plant cytokinin that is also a component of plant tRNA

(1). **Target(s):** adenosine Nucleosidase (2,3); barley  $\beta$ -glucosidase (1); GMP synthetase (4); tRNA methyltransferases (5). 1. Dietz, Sauter, Wichert, Messdaghi & Hartung (2000) *J. Exp. Bot.* **51**, 937. 2. Chen & Kristopeit (1981) *Plant Physiol.* **68**, 1020. 3. Burch & Stuchbury (1986) *J. Plant Physiol.* **125**, 267. 4. Spector & Beecham III (1975) *J. Biol. Chem.* **250**, 3101. 5. Kerr & Borek (1973) *The Enzymes*, 3rd ed. (Boyer, ed.), **9**, 167.

### Zeaxanthin

This plant pigment (FW = 568.88 g/mol; CAS 144-68-3), also called zeaxanthol and 3,3'-dihydroxy- $\beta$ -carotene, is a member of the xanthophyll class of carotenes, provides the familiar yellow-orange color. Zeaxanthin is often found as the mono- and diester of fatty acids (most often palmitic acid). Zeaxanthin noncompetitively inhibits  $\beta$ -carotene dioxygenase (1) and also inhibits  $\beta$ -glucuronidase (2). 1. Grolier, Duszka, Borel, Alexandre-Gouabau & Azais-Braesco (1997) *Arch. Biochem. Biophys.* **348**, 233. 2. Tappel & Dillard (1967) *J. Biol. Chem.* **242**, 2463.

### Zebularine

This potent cytosine deaminase and DNA methylase inhibitor (FW = 228.20 g/mol; CAS 3690-10-6; *Symbol*: ZB), also known as 1-( $\beta$ -D-ribofuranosyl)dihydropyrimidin-2-one or 1-[(2R,3R,4S,5R)-3,4-dihydroxy-5-(hydroxymethyl)oxolan-2-yl]pyrimidin-2-one, is a cytostatic for many cancer cells. It is metabolically phosphorylated to zebularine 5'-monophosphate (FW = 290.17 g/mol), also known as 2'- $\beta$ -D-deoxyribose-pyrimidin-2-one 5'-monophosphate, which then inhibits dCMP deaminase,  $K_i = 12$  nM (1). ZMP also elevates intracellular dCTP and TTP levels in whole cells (2-6). As a DNA methyltransferase (DNMT) inhibitor, ZB is similar in action to aza-CR and 5-Aza-CdR: all three are incorporated into DNA, forming a covalent irreversible adduct with DNMTs, thereby preventing the enzyme from methylating position-5 of cytosines clustered in regulatory CpG islands. ZB also sustains the demethylation state of the 5'-region of the tumor suppressor gene CDKN2A/p16 and other methylated genes in T24, HCT15, CFPAC-1, SW48, and HT-29 cells (6,7). Zebularine also inhibits growth of cancer cell lines but not normal cells (8), and when used as an adjuvant in methotrexate therapy, ZB decreased gene expression of the three DNMTs and induced AhR gene promoter demethylation and its re-expression (9). It also inhibits tumorigenesis and stemness of colorectal cancer via p53-dependent endoplasmic reticulum stress (unfolded protein response) (10). 1. Maley, Lobo & Maley (1993) *Biochim. Biophys. Acta* **1162**, 161. 2. Barchi, Cooney, Hao, Weinberg, Taft, Marquez, Ford (1995) *J. Enzyme Inhib.* **9**, 147. 3. Frick, Yang, Marquez & Wolfenden (1989) *Biochemistry* **28**, 9423. 4. Yang, Lin, Shun, et al. (2013) *Sci. Rep.* **3**, 3219.

### Zenarestat

This aldose reductase inhibitor (FW<sub>free-acid</sub> = 441.64 g/mol; CAS 112733-06-9), also known as [3-(4-bromo-2-fluorobenzyl)-7-chloro-2,4-dioxo-1,2,3,4-tetrahydroquinazolin-1-yl]acetic acid, is used to treat diabetic neuropathy and cataracts by preventing sorbitol accumulation. During episodes of diabetic hyperglycemia, high levels of glucose and fructose are transported into the retina and lens cells, where they are reduced to sorbitol, a nontransported polyol that causes osmotic shock, inflicting great damage. Inhibiting the metabolism of glucose by the polyol pathway using aldose reductase inhibitors is a potential mechanism to slow or reverse the progression of polyneuropathy, a common complication of diabetes mellitus, causing pain and sensory and motor deficits in the limbs. 1. Ao, Shingu, Kikuchi, Takano, et al. (1991) *Metabolism* **40**, 77.

### Zerumbone

This naturally occurring monocyclic sesquiterpene (FW = 218.30 g/mol; CAS 471-05-6; IUPAC Name: (2E,6E)-2,6,9,9-tetramethyl-2,6,10E-cycloundecatrien-1-one; Solubility:  $\geq 10$  mg/mL DMSO), first isolated from rhizomes of the wild ginger (*Zingiber zerumbet*), potently inhibits ( $IC_{50} = 140$  nM) phorbol ester activation of Epstein-Barr virus (1). Zerumbone markedly suppresses free radical generation, pro-inflammatory protein production, and cancer cell proliferation (2). Both VEGF expression and NF- $\kappa$ B activity in AGS cells (gastric adenocarcinoma) were reduced by treatment with zerumbone, thereby inhibiting angiogenesis (3). Zerumbone may therefore be a new anti-angiogenic and antitumor drug for the treatment of gastric cancer. ZER is selectively cytotoxic to Jurkat cells, showing dose- and time-dependencies, with  $IC_{50}$  values of 12, 9 and 5  $\mu$ g/mL at 24, 48 and 72 hours of treatment, respectively, but does not produce an adverse effect on normal human peripheral blood mononuclear cells (4). ZER arrests Jurkat cells at the G<sub>2</sub>/M cell-cycle phase. Its anti-proliferative effect on Jurkat cells occurs through the apoptotic intrinsic pathway via the activation of Caspase-3 and Caspase-9 (4). Zerumbone also increases oxidative stress in a thiol-dependent ROS-independent manner to increase DNA damage and sensitize colorectal cancer cells to radiation (5). 1. Murakami, Takahashi, Jiawajinda, Koshimizu & Ohigashi (1999) *Biosci. Biotechnol. Biochem.* **63**, 1811. 2. Murakami, Takahashi, Kinoshita, et al. (2002) *Carcinogenesis* **23**, 795. 3. Tsuboi, Matsuo, Shamoto, Shibata, et al. (2014) *Oncol. Rep.* **31**, 57. 4. Rahman, Rasheed, Chartrand, et al. (2014) *Nat. Prod. Commun.* **9**, 1237. 5. Deorukhkar, Ahuja, Mercado, et al. (2015) *Cancer Med.* **4**, 278.

### Zeta Inhibitory Peptide, Myristoylated

This synthetic myristoylated peptide (*Sequence*: Myr-SIYRRGARRWRKL; FW = 1928.40 g/mol; CAS 863987-12-6; Solubility: 1 mg/mL in ethanol-water (20%, vol/vol); *Symbol*: mZIP), also known as Cell-permeable z-Pseudosubstrate Inhibitory Peptide, is a 13-residue, cell-permeable inhibitor that mimics the endogenous pseudosubstrate region of protein kinase M $\zeta$ , or PKM $\zeta$  (1). The latter is a constitutively active and atypical PKC isozyme implicated in the maintenance of Long-Term Potentiation (LTP). ZIP blocks PKM $\zeta$ -induced synaptic potentiation in hippocampal slices *in vitro*. It also reverses late-phase LTP ( $IC_{50} = 1-2.5$   $\mu$ M), producing persistent loss of 1-day-old spatial memory following central administration *in vivo*. **Rationale:** The PKC family is comprised of three subfamilies: classical ( $\alpha$ ,  $\beta_1$ ,  $\beta_2$ ,  $\gamma$ ), novel ( $\epsilon$ ,  $\delta$ ,  $\eta$ ,  $\theta$ ), and atypical ( $\lambda/1$  and  $\zeta$ ). All are inactive in the absence of an intramolecular interaction between a short N-terminal substrate-like peptide (called the pseudosubstrate) and the actual substrate binding region located within the catalytic domain. Peptides based on the pseudosubstrate sequence of PKC isoenzymes are selective *in vitro* inhibitors of specific isoforms of PKC. However, the unmodified peptide is plasma membrane-impermeable, requiring microinjection, expression in cells, or use of a membrane-solubilizing detergent, such as saponin. Peptides can also be fused with membrane-translocated peptides derived from the penetratin sequences in *Drosophila* Antennapedia protein or HIV TAT protein for micropinocytotic delivery directly into cells. Although

originally designed with the goal of creating a cell-permeable ZIP derivative, Krotova, Hu, Xia, *et al.* (1) convincingly demonstrate that, at least in endothelial cells, the action of cell-penetrating myristoylated-ZIP is not limited to inhibiting PKC $\zeta$  activity; instead, mZIP activates eNOS (endothelial nitric oxide synthase) via Akt phosphorylation, as well as a variety of NO-regulated enzymes. For this reason, the likely pluripotency of mZIP must be considered in all experiments relying on its use. **Control Peptides:** As in any experiment using an inhibitory peptide, one must conduct control experiments using a sequence-scrambled peptide to control for nonspecific actions of the test peptide. The control peptide is Scrambled Zeta Inhibitory Peptide (*Sequence:* Myr-RLYRKRIWRSAGR; FW = 1928.40 g/mol; CAS 908012-18-0; Solubility: 1 mg/mL acetonitrile/water (20%, vol/vol); *Symbol:* scr-ZIP). Another useful reagent is Biotinylated Zeta Inhibitory Peptide (FW = 2154.69 g/mol; *Sequence:* Myr-SIYRRGARRWRK(biotin)L; Solubility: 0.67 mg/mL acetonitrile/water (30%, vol/vol); *Symbol:* bZIP), the subcellular location of which which can be evaluated with fluorescently labeled streptavidin. **1.** Krotova, Hu, Xia, *et al.* (2006) *Brit. J. Pharmacol.* **148**, 732.

### Zetekitoxin AB

This saxitoxin-like poison from the skin of the Panamanian golden frog *Atelopus zeteki* (FW = 552.47 g/mol; CAS 139158-99-9; IUPAC: [(3*R*,5*S*,6*S*,11*R*,12*S*,14*Z*,16*S*,17*Z*)-14,17-diamino-19,19-dihydroxy-6-(hydroxymethyl)-10-oxo-3-(sulfoxy)-8-oxa-1,9,13,15,18-pentaazapentacyclo[9.5.2.1<sup>3,16</sup>.0<sup>5,9</sup>.0<sup>12,16</sup>]nonadeca-14,17-dien-13-yl]methyl hydroxycarbamate) from the skin of the Panamanian golden frog *Atelopus zeteki* (1), is a potent blocker of voltage-dependent sodium ion channels, acting on human heart channels (IC<sub>50</sub> = 280 pM), rat brain IIa channels (IC<sub>50</sub> = 6.1 pM), and rat skeletal muscle channels (IC<sub>50</sub> = 65 pM) (2). **1.** Kim, Brown & Mosher (1975) *Science* **189**, 151. **2.** Yotsu-Yamashita, Kim, Dudley, Choudhary Pfahnl, Oshima & Daly (2004) *Proc. Natl. Acad. Sci. U.S.A.* **101**, 4346.

### Zileuton

This antiasthmatic hydroxyurea derivative (FW = 236.29 g/mol; CAS 111406-87-2), also known as Zylfo<sup>®</sup> and (±)-*N*-(1-benzo[ $\beta$ ]thien-2-ylethyl)-*N*-hydroxyurea, is a potent inhibitor of 5-hydroxyeicosatetraenoic acid synthesis by 5-lipoxygenase (IC<sub>50</sub> = 0.5–0.9  $\mu$ M), thereby blocking leukotriene production. It also inhibited leukotriene LT<sub>B4</sub> biosynthesis by rat PMNL (IC<sub>50</sub> = 0.4  $\mu$ M), human PMNL (IC<sub>50</sub> = 0.4  $\mu$ M) and human whole blood (IC<sub>50</sub> = 0.9  $\mu$ M). Inhibition of human PMNL LT<sub>B4</sub> biosynthesis was removed readily by a simple wash procedure, indicating that zileuton's action is completely reversible. **1.** Carter, Young, Albert, Bouska, *et al.* (1991) *J. Pharmacol. Exp. Ther.* **256**, 929.

### Zimelidine

This selective serotonin reuptate inhibitor, or SSRI (FW = 317.23 g/mol; CAS 56775-88-3), also known as (Z)-3-(4'-bromophenyl)-3-(3''-

pyridyl)dimethylallylamine or Zelmid<sup>™</sup>, was the first-in class antidepressant, but was withdrawn in 1983 in light of a five-times greater risk of Guillain-Barré syndrome. **Mode of Action:** The primary pharmacological action of SSRIs is presynaptic inhibition of serotonin (5-HT) reuptake, thereby increasing the concentration of this amine in the synaptic cleft. Serotonin exerts its effects through interactions with any of seven distinct 5-HT receptor families, and interaction between serotonin and post-synaptic receptors mediates a wide range of its actions. **Target(s):** amine oxidase (1); serotonin uptake (2,3) **1.** Obata & Yamanaka (2000) *Neurosci. Lett.* **286**, 131. **2.** Fuller (1995) *Prog. Drug Res.* **45**, 167. **3.** Ross, Ögren & Renuy (1976) *Acta Pharmacol. Toxicol.* **39**, 152.

### Zinc and Zinc Ions

This Group 12 (or IIB) metal (Symbol = Zn; Atomic number = 30; Atomic weight = 65.409), which is located directly above cadmium in the Periodic Table, has a neutral-atom ground-state electronic configuration of 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>6</sup>4s<sup>2</sup>3d<sup>10</sup>. The radioisotope <sup>65</sup>Zn has half-life of 243.8 days. Zn<sup>2+</sup> (ionic radius = 0.74 Å) is an essential metal ion in many enzymes (*e.g.*, alcohol dehydrogenase, NADPH:quinone reductase, methionine *S*-methyltransferase, alkaline phosphatase, phospholipase C, leucyl aminopeptidase, carboxypeptidase A, B, and H, interstitial collagenase, ptilirysin, mitochondrial intermediate peptidase, carbonic anhydrase, porphobilinogen synthase, mannose-6-phosphate isomerase, dopachrome  $\delta$ -isomerase, and pyruvate carboxylase). The likely intracellular concentration of uncomplexed zinc has been put at 0.1–0.4 nM. Higher concentrations of Zn<sup>2+</sup> inhibits over 1000 enzymes by nonselectively replacing active-site and/or structure-stabilizing divalent cations. Zinc ion is also transported into insulin-containing vesicles of  $\beta$ -cells by isoform-8 zinc transporters, where it acts as a counterion and stabilizes insulin and induces its oligomerization, polymerization, and crystallization. **1.** Vallee & Galde (1984) *Adv Enzymol Relat Areas Mol Biol.* **56**, 283. **2.** Vallee & Falchuk (1993) *Physiol. Rev.* **73**, 79. **3.** Maret (2013) *Adv. Nutrition* **4**, 82.

### Zincon

This chelator (FW<sub>free-acid</sub> = 440.06 g/mol; CAS 59600-76-9), also known as 2-carboxy-2'-hydroxy-5'-sulfoformazylbenzene, is used as a metal indicator in EDTA titrations and as a colorimetric/photometric indicator of zinc, copper, mercury, and gallium ions (1). A weakly alkaline aqueous solution of zincon is yellow or yellow-orange in color. The solution turns blue in the presence of Zn<sup>2+</sup> or Cu<sup>2+</sup> ions ( $\lambda_{max}$  = 620 nm). Metal ion concentrations as low as 0.05 mg/mL can be detected using atomic absorption spectroscopy. The presence of calcium or magnesium ions does not affect the physiologic binding of zinc ions to Zn<sup>2+</sup>-dependent proteins and enzymes, mainly as a result of zinc ion preference for nitrogen-containing ligands. Zincon has also been reported to inhibit a number of Zn<sup>2+</sup>-dependent enzymes: for example, liver alcohol dehydrogenase (2) and formate dehydrogenase (3). **1.** Hilario, Romero & Celis (1990) *J. Biochem. Biophys. Methods* **21**, 197. **2.** McFarland, Watters & Petersen (1975) *Biochemistry* **14**, 624. **3.** Kanamori & Suzuki (1968) *Enzymologia* **35**, 185.

### Zincov Inhibitor

This Zn(II) chelator (FW = 302.33 g/mol; CAS 71431-46-4), also known as Zincov<sup>™</sup> and 2-(*N*-hydroxycarboxamido)-4-methylpentanoyl-L-alanyl-

glycinamide, inhibits numerous zinc-containing enzymes (1), including fibrolase (2); fragilysin (3,4); hemagglutinin/protease (5,6); matrilysin, or matrix metalloproteinase 7 (7); meprin A (8); neprilysin (9); pitrilysin, or protease Pi (10); pseudolysin, or *Pseudomonas aeruginosa* elastase (6,11); thermolysin (11,12). 1. Biophys.* **333**, 27.

### Zinc Sulfate

This inorganic salt ZnSO<sub>4</sub> (FW = 161.45 g/mol; CAS 7446-19-7) strongly inhibits human gingival matrix metalloproteinase-2 (IC<sub>50</sub> = 15 nM) and matrix metalloproteinase-9 (IC<sub>50</sub> = 40 nM). Both the monohydrate and heptahydrate are soluble in water and insoluble in ethanol. **Target(s):** dTTPase (1); ethylmorphine *N*-demethylase, or cytochrome P450 (2); gelatinase A, or matrix metalloproteinase-2 (3); gelatinase B, or matrix metalloproteinase-9 (3); glucan 1,3-β glucosidase (4); ribonuclease (5); steroid 5α-reductase (6). 1. Stamatiadis, Bulteau-Portois & Mowszowicz (1988) *Brit. J. Dermatol.* **119**, 627. **See also Zinc and Zinc Ions**

### Zinostatin

This antitumor antibiotic (FW = 659.65 g/mol; CAS 79633-18-4), also known as NCS and neocarzinostatin, consists of a 10.7 kDa protein and a labile chromophore, shown above. This second component reportedly is a potent inhibitor of casein kinase II. Zinostatin also intercalates DNA and is a strand scission agent. 1. Harada, Haneda, Maekawa, et al. (1999) *Biol. Pharm. Bull.* **22**, 1122.

### Ziprasidone

This broadly acting dopamine D<sub>2</sub> and serotonin 5-HT<sub>2</sub> antagonist (FW = 412.94 g/mol; CAS 146939-27-7), also known as Geodon<sup>®</sup>, Zeldox<sup>®</sup>, Zipwell<sup>®</sup>, and 5-{2-[4-(1,2-benzisothiazol-3-yl)-1-piperazinyl]ethyl}-6-chloro-1,3-dihydro-2H-indol-2-one, is an atypical antipsychotic pharmaceutical that has been used in the treatment of Tourette syndrome, depression, and bipolar disorder. Like other atypical agents, ziprasidone exhibits extrapyramidal side-effects similar to that of placebo, without causing significant elevations in prolactin levels. In contrast to existing atypical agents, however, ziprasidone has a low propensity for causing weight gain. (**See also** Amisulpride; Aripiprazole; Olanzapine; Quetiapine; Remoxipride; Risperidone; Sertindole; Zotepine) **Pharmacokinetics:** Systemic bioavailability is 100%, when administered intramuscularly and 60%, when administered orally with food. After a single dose intramuscular administration, the peak serum concentration occurs within 1 hour. Steady-state plasma concentrations are achieved within 1–3 days. Ziprasidone undergoes liver metabolized by aldehyde oxidase, with minor action by CYP3A4. **See also** Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Targets:** Serotonin 5-HT<sub>1A</sub> receptor, as partial agonist (K<sub>i</sub> = 12 nM); 5-HT<sub>1B</sub> receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 4.0 nM) (partial agonist); 5-HT<sub>1D</sub> receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 2.3 nM); 5-HT<sub>1E</sub> receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 360 nM); 5-HT<sub>1F</sub> receptor (K<sub>i</sub> > 10 μM); 5-HT<sub>2A</sub> receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 0.6 nM); 5-HT<sub>2B</sub> receptor, as antagonist or inverse agonist (K<sub>i</sub> = 27 nM); 5-HT<sub>2C</sub> receptor, as antagonist or inverse agonist (K<sub>i</sub> = 13 nM); 5-HT<sub>3</sub> receptor (K<sub>i</sub> > 10 μM); 5-HT<sub>4</sub> receptor, weakly (K<sub>i</sub> = > 10 μM); 5-HT<sub>5A</sub> receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 291 nM); 5-HT<sub>6</sub> receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 61 nM); 5-HT<sub>7</sub> receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 6 nM); Dopamine D<sub>1</sub> receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 30 nM); D<sub>2</sub> receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 6.8 nM); D<sub>3</sub> receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 7.2 nM); D<sub>4</sub> receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 39 nM); D<sub>5</sub> receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 152 nM); α<sub>1A</sub>-adrenergic receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 18 nM); α<sub>2A</sub>-adrenergic receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 160 nM); Histamine H<sub>1</sub> receptor, as antagonist or inverse-agonist (K<sub>i</sub> = 63 nM); muscarinic acetyl-choline receptor, weakly (K<sub>i</sub> = >10 μM); Serotonin 5-HT transporter, as inhibitor (K<sub>i</sub> = 53 nM); Norepinephrine NE transporter, as inhibitor (K<sub>i</sub> = 48 nM); Dopamine DA transporter, as weak inhibitor (K<sub>i</sub> > 10 μM). 1. Carnahan, Lund & Perry (2001) *Pharmacotherapy* **21**, 717. 2. Akiskal & Tohen (2011). *Bipolar Psychopharmacotherapy: Caring for the Patient*. John Wiley & Sons. p. 209. 3. ### Zirconium and Zirconium Ions

This Group 4 (or IVA) transition metal (Symbol = Zr; Atomic Number = 40; Atomic Weight = 91.224) has a ground-state electronic configuration of  $1s^2 2s^2 2p^6 3s^2 3p^6 4s^2 3d^{10} 4p^6 5s^2 4d^2$  (1,2). The ionic radii for  $Zr^{4+}$  is 0.079 nm. Naturally-occurring zirconium consists of five stable isotopes:  $^{90}Zr$  at 51.45% natural abundance,  $^{91}Zr$  at 11.22%,  $^{92}Zr$  at 17.15%,  $^{94}Zr$  at 17.38%, and  $^{96}Zr$  at 2.80%. Of the stable isotopes,  $^{91}Zr$  has a nuclear spin of 5/2. There are at least twenty known radioisotopes of which  $^{93}Zr$ , a  $\beta^-$  emitter, is long-lived ( $t_{1/2} = 1.5 \times 10^6$  years).  $^{89}Zr$  is a  $\beta^-$  emitter ( $t_{1/2} = 3.27$  days) is used to label a protein or monoclonal antibody for positron emission tomography experiments. Tetravalent zirconium cations have been shown to induce iron acquisition in certain cells (1).  $Zr(II)O$  inhibits Ferroxidase (2) and D-arginase (3). 1. Chem.* **245**, 3979. 3. Nadai (1958) *J. Biochem.* **45**, 1011.

**Zizanin B**, See *Cochliobolin B*

**ZK 62711**, See *Rolipram*

**ZK 807191**

This oral coagulation Factor Xa inhibitor (FW = 525.51 g/mol; IUPAC: 3-(5-carbamimidoyl-2-hydroxy-phenoxy)-2,6-difluoro-5-[3-(1-methyl-4,5-dihydro-1H-imidazol-2-yl)phenoxy]phenyl methylaminoacetate, potentially inhibits factor Xa ( $K_i = 0.1$  nM) and has promise as a potential parenteral treatment of unstable angina pectoris. 1. Vacca (1998) *Ann. Rep. Med. Chem.* **33**, 81. 2. Lewis (2000) *Drugs* **3**, 525.

**ZK 222584**, See *Vatalanib*

**ZK 807834**, See *CI-1031*

**ZK 816042**

This amidine/imidazoline-containing antithrombotic agent (FW = 525.54 g/mol) is a potent inhibitor of coagulation factor Xa. NMR experiments performed on a lyophilized FXa-inhibitor complex indicate that the inhibitor binds with a distribution of orientations of the imidazoline ring. 1. Studelska, McDowell, Adler, O'Connor, *et al.* (2003) *Biochemistry* **42**, 7942.

**ZLN 024**

This orally active allosteric activator (FW<sub>HCl-Salt</sub> = 361.69 g/mol; Soluble to 100 mM in DMSO) targets 5'-AMP-activated protein kinase (AMPK), increasing the activity of the  $\alpha_1\beta_1\gamma_1$  heterotrimer by 1.5 times ( $EC_{50} = 0.42$

$\mu M$ ) and  $\alpha_2\beta_1\gamma_1$  by 1.7 times ( $EC_{50} = 0.95 \mu M$ ). ZLN 024 also inhibits dephosphorylation at AMPK Thr-172 by PP2Ca. ZLN024 activated AMPK in myotubes and hepatocytes without increasing the ADP/ATP ratio. It stimulates glucose uptake and fatty acid oxidation, again without increasing the ADP/ATP ratio. ZLN 024 decreases fatty acid synthesis and glucose output in primary hepatocytes, and it improves glucose tolerance and decreases cholesterol content in *db/db* mice. The *db/db* mouse is a model of obesity, diabetes, and dyslipidemia, wherein leptin receptor activity is deficient due to a point mutation in the gene for the leptin receptor. 1. **ZMP**, See *5-Aminoimidazole-4-carboxamide-1- $\beta$ -ribofuranosyl 5'-Monophosphate*

**Zoanthoxanthin**

This naturally fluorescent pigment (FW = 256.31 g/mol; CAS 40451-47-6), also known as 1,3,5,7-tetrazacyclopent[*f*]azulene, first isolated from an anemone-like anthozoan (*Parazoanthus* sp.) and containing a previously unknown heterocyclic system, inhibits electron transport and succinate dehydrogenase in assays conducted with fractionated mitochondria (1). Such molecules often trigger the degradation of mitochondria, affecting maturation and involution as well as serving as a line of defense against invaders (2). (See also *Parazoanthoxanthin*) 1. Cariello & Tota (1974) *Experientia* **30**, 244. 2. Rapoport & Schewe (1977) *Trends Biochem. Sci.* **2**, 186.

**Zofenapril**

This antihypertensive (FW = 429.55 g/mol; CAS 81872-10-8; (2*S*,4*R*)-1-((*S*)-3-(benzoylthio)-2-methylpropanoyl)-4-(phenylthio)pyrrolidine-2-carboxylic acid) target angiotensinogen converting enzyme and has profound and clinically useful cardioprotective properties. Upon oral administration, zofenopril is metabolically hydrolyzed to the active drug *S*-zofenoprilat. (See *Zofenapril*) **Mode of Inhibitory Action:** *S*-Zofenoprilat is more potent than captopril as a rabbit lung ACE inhibitor, with the former having an  $IC_{50}$  value of 8 nM, compared to 23 nM for the latter. It is also a potent inhibitor of angiotensin I-induced contractions ( $EC_{50} = 3$  nM) as well as a potentiator of bradykinin-induced contractions ( $EC_{50} = 1$  nM) in isolated guinea pig ileum. It is without effect on the inotropic effects of angiotensin II,  $BaCl_2$ ,  $PGE_1$ , histamine, serotonin, or acetylcholine in the same tissue, suggesting that the pro-drug zofenopril is a specific inhibitor of ACE (1). Significantly, however, *S*-zofenoprilat releases  $H_2S$  in cell-free assays and directly relaxes vessels *in vitro* in a concentration-dependent manner. Administration *in vivo* of the *R*-zofenoprilat diastereoisomer, which does not inhibit ACE, does not modify blood pressure, but retains beneficial effects on vascular function and restores plasma/tissue  $H_2S$  levels (2). **Other Target(s):** With respect to interactions with the renal glycylsarcosine transport, zofenopril ( $IC_{50} = 81 \mu M$ ) and fosinopril ( $IC_{50} = 55 \mu M$ ) are potent inhibitors, whereas other ACE inhibitors exhibited low-affinity (3). Zofenopril also increases sarcoplasmic reticulum (SR) calcium cycling and stimulates active calcium uptake into the SR (4). Long-term administration of zofenopril promotes lowering of free radical oxidation products, with activation of protective antioxidant enzymes, and improvement in the total antioxidant activity of blood serum (5). 1. **Zolantidine**

This potent brain-penetrating antihistamine (FW = 381.54 g/mol; CAS 118072-93-8), also known as SKF 95282 and systematically named (1-hydroxy-2-(1*H*-imidazol-1-yl)ethylidene)bisphosphonic acid, is a brain-penetrating histamine H<sub>2</sub> receptor antagonist (1,2). 1. Young, Mitcell, Brown, *et al.* (1988) *J. Med. Chem.* **31**, 656. 2. Calcutt, Ganellin, Griffiths, Leigh, *et al.* (1988) *Brit. J. Pharmacol.* **93**, 69.

**Zoledronate**

This aminobisphosphonate-class bone resorption inhibitor (FW<sub>free-acid</sub> = 272.09 g/mol; CAS, 118072-93-8), also known by its trade names Zometa<sup>®</sup>, Zomera<sup>®</sup>, Aclasta<sup>®</sup> and Reclast<sup>®</sup>, as well as its systematic name 2-(imidazol-1-yl)-1-hydroxyethane-1,1-bisphosphonate, inhibits osteoclast-mediated decalcification and is also an effective apoptotic inducer in tumor cells. **Mode of Inhibitory Action in Osteoporosis**: Zoledronate binds preferentially to crystalline hydroxyapatite within the bone matrix. Upon arrival of osteoclasts at the bone surface, zoledronate is released, whereupon it inhibits osteoclast farnesyl pyrophosphate (diphosphate) synthase, preventing protein prenylation within the mevalonate pathway. Inhibition of isoprenoid metabolite formation leads to dysregulation of downstream signaling required for osteoclast function, inducing apoptosis, thereby promoting osteoclast death. By preventing osteoclast-mediated bone resorption, zoledronate decreases bone turnover and stabilizes the bone matrix. Zoledronate also inhibits human vesicular endothelial cell adhesion, survival, migration and actin stress fiber formation by interfering with G-protein prenylation. **Potential Role in Cancer Chemotherapy**: The mevalonate pathway is also relevant to controlling cancer. Indeed, this pathway's final products are cholesterol as well as various isoprenoids, including isopentenyl pyrophosphate (IPP), farnesyl pyrophosphate (FPP) and geranylgeranyl pyrophosphate (GGPP). The last three are critical for the post-translational modification of proteins needed for cell proliferation and differentiation, such as the small GTP-binding proteins RAS and RHOA. The mevalonate pathway also affects multidrug resistance (MDR), which

often poses a major challenge to durable chemotherapy. Finally, because statins and aminobisphosphonates inhibit HMG-CoA reductase and FPP synthase, they are likely to limit the synthesis of steroids needed for the proliferation and survival of hormone-sensitive cell targets. **Target(s)**: alkaline phosphatase (1); collagenase 3, or matrix metalloproteinase 13 (2); dimethylallyl-*tran*sferase, or geranyl-diphosphate synthase (3); enamelysin, or matrix metalloproteinase 20 (2); farnesyl-*tran*sferase, or geranylgeranyl-diphosphate synthase (4,5); gelatinase A, or matrix metalloproteinase 2 (2); gelatinase B, or matrix metalloproteinase 9 (2); geranyl-*tran*sferase, or farnesyl-diphosphate synthase (5-10); *tran*s-hexaprenyl-*tran*sferase, or geranylgeranyl-diphosphate synthase (11); interstitial collagenases, or matrix metalloproteinase 1 (2,12); macrophage elastase, or matrix metalloproteinase 12 (2); neutrophil collagenases, or matrix metalloproteinase 8 (2); pyrophosphate-dependent phosphofructokinase, or diphosphate:fructose-6 phosphate 1-phosphotransferase (13); stromelysin 1, or matrix metalloproteinase 3 (2). 1. **Zolmitriptan**

This orally bioavailable potent serotonergic agonist (FW = 287.36 g/mol; CAS 139264-17-8; Solubility: 100 mM in DMSO; 100 mM in ethanol), also named (4*S*)-4-(3-(2-(dimethylamino)ethyl)-1*H*-indol-5-yl)methyl-2-oxazolidinone, targets h5-HT<sub>1D</sub> receptors (K<sub>i</sub> = 0.63 nM), h5-HT<sub>1B</sub> receptors (K<sub>i</sub> = 5.0 nM), and h5-HT<sub>1F</sub> receptors (K<sub>i</sub> = 63.1 nM), inhibiting trigeminal nerve stimulation-mediated neurogenic plasma protein extravasation in guinea pigs and blocking long excitatory postsynaptic potentials (EPSPs) in a rat model of spinal cord injury (1-3). Zolmitriptan has a dual action, peripherally inhibiting dilatation and inflammation of cranial vessel and also exhibiting a central nociceptive action in the brainstem nuclei (4). This dual action on migraine pain also shows beneficial effects on nausea and vomiting, due to its binding to the nucleus of the tractus solitarius, the vomiting control center. 1. Murray, *et al.* (2011) *J. Neurophysiol.* **106**, 925. 2. Martin, *et al.* (1997) *Brit. J. Pharmacol.* **121**, 157. 3. Pauwels, *et al.* (1997) *Neuropharmacol.* **36** 499. 4. Pascual (1998) *Neurologia* **2**, 9.

**Zolpidem**

This widely prescribed and short-acting imidazopyridine-class hypnotic (FW = 307.39 g/mol; CAS 82626-48-0), also known by the trade names Ambien<sup>®</sup>, AmbienCR<sup>®</sup>, Intermeezo<sup>®</sup>, Stilnox<sup>®</sup>, and Sublinox<sup>®</sup>, and systematically named *N,N*-dimethyl-2-(6-methyl-2-*p*-tolylimidazo[1,2-

a]pyridin-3-yl)acetamide, potentiates the actions of the inhibitory neurotransmitter,  $\gamma$ -aminobutyric acid (GABA), by binding exclusively to the GABA<sub>A</sub> receptor, also known as the Benzodiazepine Omega-1 Receptor (1-3). Therefore, while zolpidem's direct action is not itself inhibitory, it has the overall effect of inhibiting neurotransmission by diminishing the chance of a successful action potential occurring. Indeed,  $\alpha_5$ -subunit-containing GABA<sub>A</sub> receptors exhibit lower affinities for zolpidem (30-fold) than measured previously using recombinantly expressed type II receptors containing either  $\alpha_2$ - or  $\alpha_3$ -subunits (4). Zolpidem appears to have minimal next-day effects on cognition and psychomotor performance when administered at bedtime (5) and, as such, has become one of the most common GABA-potentiating sleeping medications. Paradoxically, caffeine appears, at least in some cases, to enhance zolpidem sedation. Ciprofloxacin also interacts with zolpidem in healthy volunteers, increasing its bioavailability by nearly 50%. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) ### Zomepirac

This analgesic and anti-inflammatory agent (FW = 277.70 g/mol; CAS 64092-48-4), also known as 5-(*p*-chlorobenzoyl)-1,4-dimethylpyrrole-2-acetic acid, inhibits prostaglandin synthesis. Zomepirac is converted metabolically to an acyl glucuronide conjugate which can form covalent adducts with proteins (for example, dipeptidyl peptidase IV) (1). Modification of tubulin inhibits microtubule assembly. **Target(s):** cyclooxygenase (2,3); tubulin polymerization (4). 1. Wang, Gorrell, McGaughan & Dickinson (2001) *Life Sci.* **68**, 785. 2. Thomas & Knoep (1982) *J. Infect. Dis.* **145**, 141. 3. Llorens, Perez, Palomer & Mauleon (2002) *J. Mol. Graph. Model.* **20**, 359. 4. Bailey, Worrall, de Jersey & Dickinson (1998) *Chem. Biol. Interact.* **115**, 153.

### Zonisamide

This antiepileptic (FW = 212.22 g/mol; CAS 68291-97-4; Solubility: 10 mM in water; 100 mM in DMSO; Symbol: ZNS), 1,2-benzisoxazole-3-methanesulfonamide, blocks voltage-sensitive Na<sup>+</sup> and T-type Ca<sup>2+</sup> channels, stimulates BK<sub>Ca</sub> channels, and modulates GABA, glutamate and monoamine neurotransmission. It inhibits lipid peroxidation and scavenges hydroxyl and nitric oxide free radicals. Zonisamide has a broad spectrum anticonvulsant, neuroprotective, and anti-Parkinson Disorder activities. ZNS (30  $\mu$ M) reversibly increases the amplitude of K<sup>+</sup> outward currents, and paxilline (1  $\mu$ M) is effective in suppressing the ZNS-induced increase of K<sup>+</sup> outward currents. In inside-out configuration, ZNS (30  $\mu$ M), when applied to the intracellular face of the membrane, does not alter single-channel conductance; however, it did enhance the activity of large-conductance Ca<sup>2+</sup>-activated K<sup>+</sup> (BK<sub>Ca</sub>) channels primarily by decreasing mean closed time. In addition, the EC<sub>50</sub> value for ZNS-stimulated BK<sub>Ca</sub> channels was 34  $\mu$ M. Zonisamide causes a leftward shift in the activation curve of BK<sub>Ca</sub> channels, with no change in the gating charge of these channels. Moreover, ZNS at a concentration greater than 100  $\mu$ M also reduced the amplitude of A-type K<sup>+</sup> current in these cells. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE*

*PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Huang, Huang & Wu (2007) *J. Pharmacol. Exp. Ther.* **321**, 98.

### Zopiclone

This cyclopyrrolone class hypnotic (FW = 388.81 g/mol; CAS 43200-80-2), also named 4-methyl-1-piperazinecarboxylic acid 6-(5-chloro-2-pyridinyl)-6,7-dihydro-7-oxo-5H-pyrrolo[3,4-b]pyrazin-5-yl ester, is a benzodiazepine receptor (BZR) agonist, with little difference in affinity for the BZ<sub>1</sub> and BZ<sub>2</sub> receptor subtypes; however, its CNS effects differ from those of other BZR ligands, due to its interaction with a different subunit. ZPC shows high-affinity interactions for BZ receptors, as measured by its ability to displace [<sup>3</sup>H]-flunitrazepam binding: K<sub>i</sub> = 24 nM in cerebral cortex; K<sub>i</sub> = 31 nM in cerebellum; and K<sub>i</sub> = 36 nM in hippocampus (1). No other brain receptors such as  $\gamma$ -aminobutyric acid receptor, dopamine receptor, serotonin and noradrenergic receptors are reached by ZPC. ZD is rapidly and efficiently absorbed: its oral bioavailability was greater than 75% in all species except rats, where a first-pass effect of about 65% was recorded. Plasma protein binding is about 45% (2). 1. Blanchard, Boireau & Julou (1983) *Pharmacology* **27**(Suppl 2), 59. 2. Gaillot, Heusse, Houghton, Marc Aurele & Dreyfus (1982) *Int Pharmacopsych.* **17**(Suppl 2), 76.

### Zopolrestat

This benzothiazole derivative (FW = 419.38 g/mol) is an inhibitor of aldose reductase, acting primarily by binding to the enzyme complexed with NADP<sup>+</sup> to form a ternary dead-end complex that prevents turnover in the steady-state (1). **Target(s):** aldose reductase, or aldehyde reductase (1,2). 1. Bohren & Grimshaw (2000) *Biochemistry* **39**, 9967. 2. El-Kabbani, Rogniaux, Barth, Chung, et al. (2000) *Proteins* **41**, 407.

### Zorubicin

This semi-synthetic glycoside antibiotic, also known as rubidazole (FW<sub>free-base</sub> = 631.69 g/mol; CAS 36508-71-1), is similar to daunorubicin (1,2). It is used as an antineoplastic agent. **Target(s):** DNA polymerase (1); RNA polymerase (3,4). 1. Sartiano, Lynch & Bullington (1979) *J. Antibiot. (Tokyo)* **32**, 1038. 2. Young, Ozols & Myers (1981) *N. Engl. J. Med.* **305**, 139. 3. Gabbay, Grier, Fingerle, Reimer, et al. (1976) *Biochemistry* **15**, 2062. 4. Gabbay (1976) in *Inter. J. Quantum Chem., Quantum Biology Symposium No. 3*, p. 217.

## Zosuquidar

This very potent drug efflux inhibitor ( $MW_{\text{free-base}} = 527.62$  g/mol;  $MW_{\text{tri-HCl}} = 636.99$  g/mol; CAS 167465-36-3; Solubility: 100 mg/mL DMSO; 23 mg/mL H<sub>2</sub>O), also known as LY335979 and systematically as 4-[[1 $\alpha$ ,6 $\alpha$ ,10 $\beta$ ]-1,1-difluoro-1,1 $\alpha$ ,6,10 $\beta$ -tetrahydrodibenzo-*[a,e]*cyclopropa-*[c]*cyclohepten-6-yl]- $\alpha$ -[(5-quinolinyl)oxy)methyl]-1-piperazineethanol tri-HCl, targets ABC transporters (P-glycoprotein), reversing multidrug resistance ( $K_i = 60$  nM), when used at 0.1-0.5  $\mu\text{M}$  *in vitro*. By blocking P-gp-mediated efflux, GF120918 increases the intracellular concentration of a co-administered drug, often potentiating its cytotoxicity and effectiveness as an anti-tumor agent (1). LY335979 has been used both *in vitro* and *in vivo* as a tool inhibitor of P-glycoprotein to investigate the role of drug efflux transporters in the disposition of a test drug and to guide preclinical doses of candidate drugs. Treatment of mice bearing P388/ADR murine leukemia cells with LY335979 in combination with Dox or etoposide gave a significant increase in life span with no apparent alteration of pharmacokinetics (1). LY335979 also enhanced the antitumor activity of paclitaxel (Taxol) in a multidrug-resistant human non-small cell lung carcinoma nude mouse xenograft model (2). Zosuquidar either completely or partially restored drug sensitivity in all P-gp-expressing leukemia cell lines tested and enhanced the cytotoxicity of anthracyclines (daunorubicin, idarubicin, mitoxantrone) and gemtuzumab ozogamicin (Mylotarg) in primary AML blasts with active P-gp (2). In addition, P-gp inhibition by zosuquidar was found to be more potent than cyclosporine A in cells with highly active P-gp (2). 1. Dantzig, Shepard, Cao, *et al.* (1996) *Cancer Res.* **56**, 4171. 2. Tang, Faussat, Perrot, *et al.* (2008) *BMC Cancer* **8**, 51.

## Zotariolimus

This mTOR inhibitor (FW = 966.21 g/mol; CAS 221877-54-9), also called ABT-578 and 42-deoxy-42-(1*H*-tetrazol-1-yl)-(42*S*)-rapamycin, targets smooth muscle cell proliferation ( $IC_{50} = 2.9$  nM) and endothelial cell proliferation ( $IC_{50} = 2.6$  nM). Zotariolimus is mechanistically similar to sirolimus (See *mTOR Inhibitors*), showing high-affinity binding to the immunophilin FKBP12 and comparable potency for inhibiting *in vitro* proliferation of both human and rat T cells (1). In intravenously dosed rats, pharmacokinetic studies demonstrated a terminal elimination half-lives of 9.4 hours for zotariolimus, compared to a value of 14 hours for sirolimus.

When given orally,  $t_{1/2}$  values were 8 hours and 33 hours, respectively. Consistent with its shorter *in vivo* duration, zotariolimus has a statistically significant 4x reduction in potency for systemic immunosuppression in rat disease models (1). When applied to PC-coated stents, zotariolimus reduces neointima in the swine coronary model after 28 days, suggesting its application for coronary stenting (2). 1. Chen, Smith, Sheets, *et al.* (2007) *J. Cardiovasc. Pharmacol.* **49**, 228. 2. Garcia-Touchard, Burke, Toner, Cromack & Schwartz (2006) *Eur. Heart J.* **27**, 988.

## Zotepine

This psychotropic/neurotropic tranquilizer (FW = 331.87 g/mol; CAS 26615-21-4; abbreviation = ZTP), also known as Nipolept™, Losizopilon™, Lodopin™, and Setous™, and named systematically as 2-(8-chlorobenzo[*b*][1]benzothiepin-6-yl)oxy-*N,N*-dimethylethanamine, exhibits atypical antipsychotic effects and also antidepressive effects in schizophrenia patients. ZTP is a high-affinity antagonist of dopamine (D<sub>1</sub> and D<sub>2</sub>) receptors and serotonin (5-HT<sub>2A</sub>, 5-HT<sub>2C</sub>, 5-HT<sub>6</sub> and 5-HT<sub>7</sub>) receptors, and is an especially effective inverse agonist of 5-HT<sub>2A</sub> receptors (1). Zotepine also inhibits norepinephrine re-uptake (2). At a higher concentrations (0.5 mM), zotepine inhibits the mitochondrial electron transport system Complex I (3). Given that norZTP (*or N*-desmethylzotepine; IUPAC: 2-[(8-chlorodibenzo[*b,f*]thiepin-10-yl)oxy]-*N*-methylethan-1-amine) is the major metabolite observed in humans, norZTP may contribute to the unique clinical profiles observed with the mother compound, ZTP. 1. Biochem.* **174**, 255.

## Zovirax, See Acyclovir

## Zoxamide

This haloketone-based antimitotic agent and fungicide (FW = 336.64 g/mol; CAS 156052-68-5), also known by its code name RH-7281, its proprietary names Gavel® an Electis®, as well as its systematic name (*RS*)-3,5-dichloro-*N*-(3-chloro-1-ethyl-1-methyl-2-oxopropyl)-*p*-toluamide, is a benzimidazole-class fungicide that targets tubulin (most likely irreversibly), blocking microtubule self-assembly, while exerting minimal systemic cytotoxic action to treated plants or secondarily animals. With far fewer microtubules involved in mitosis than higher plants and animals, fungi are more susceptible spindle poisons, thus accounting for zoxamide's favorable therapeutic index. In animals, deactivating effects of metabolic conjugation by glutathione as well as glucuronide formation provide a rational for the observed absence of typically mitosis inhibition-associated toxicities of zoxamide in mammals *in vivo* (1). As formulated for use in limiting fungal infections, zoxamide is exceptionally resistant to wash-off by rain or irrigation, due to its penetration and binding into the plant cuticle. oxamide has also demonstrated control of the following pathogens: *Pseudoperonospora cubensis*, or downy mildew of cucurbits; *Bremia lactuae*, or downy mildew of lettuce; *Peronospora viciae*, or downy mildew of peas; *Phytophthora nicotianae*, or downy mildew of tobacco; *Plasmopara helianthi*, or downy mildew of sunflower, or *Phytophthora capsici*, or downy mildew of pepper and eggplants; and *Peronospora parasitica*, or downy mildew of crucifers. Failure to isolate mutants resistant to zoxamide results from the diploid nature of *Oomycete* fungi and the likelihood that target-site mutations would produce a recessive phenotype (2). Recent work has demonstrated that *Phytophthora capsici* has

developed a novel non-target-site-based zoxamide resistance, involving two recessive genes and allowing resistance to emerge, if two compatible mating types co-exist in the same field (3). 1. #### ZSTK474

This potent, ATP-site competitive, pan-Class I phosphoinositide-3-kinase PI3K inhibitor (FW = 417.41 g/mol; CAS 475110-96-4; Solubility (25°C): 21 mg/mL DMSO, <1 mg/mL Water), inhibits the activities of recombinant p110 $\beta$  (IC<sub>50</sub> = 7 nM); p110 $\gamma$  (IC<sub>50</sub> = 37 nM); and p110 $\delta$  (IC<sub>50</sub> = 6 nM) (1,2), with little effect on mammalian target of rapamycin (mTOR) at 100  $\mu$ M (3). Proliferation assays revealed that BEZ235 (dual PI3K/mTOR inhibitor) or ZSTK474 (pan-PI3K inhibitor), when combined with temsirolimus, inhibited cell growth compared to cells treated with any of the agents alone (4). Addition of a PI3K inhibitor synergistically overcomes cellular resistance to mTORC1 inhibitors regardless of PTEN status, substantially expanding the molecular phenotype of tumors likely to respond (4). ZSTK474 also demonstrated prophylactic efficacy in a rat model of rheumatoid arthritis through the inhibition of T cell and FLS functions (5).

#### Zyklon-B

This notorious rodenticide, insecticide and fumigant consisted of pressurized hydrogen cyanide in combination with an adsorbent porous carrier (*i.e.*, diatomaceous earth or processed wood pulp), usually stored within a rupture-resistant metal container. (See *Cyanide*) The considerable surface area of the solid support facilitated maximal concentration of gaseous HCN, greatly enhancing its killing potential. Because gaseous HCN is odorless, ethyl bromoacetate (itself a volatile but noxious irritant) was included as a warning gas. Manufactured chiefly by Degesch (*or* Deutsche Gesellschaft für Schädlingsbekämpfung mbH, *or* German Corporation for Pest Control, Ltd.) and Tesch und Stabenow Internationale Gesellschaft für Schädlingsbekämpfung m.b.H., *or* Tesch & Stabenow, International Society for Pest Control, Ltd.), Zyklon (*translated*: Cyclone) was invented to prevent food loss in granaries and warehouses. During World War II, however, it was first employed to delouse the cramped prisoner quarters in concentration camps. Later, with warning gas omitted, Zyklon-B was employed in the systematic killing of one million Jews and "Social Deviants" (addicts, alcoholics, dissidents, draft dodgers, pacifists, prostitutes, vagrants, and common criminals) at Auschwitz-Birkenau, Majdanek, Mauthausen, Ravensbrück, and elsewhere. In a compendium wholly devoted to Inhibitor Science and the great good that can come of it, this final entry reminds us that we must never forget those lost in the *Shoah* or the great ill can come of even well-intentioned inventions.
