This natural product (FW = 323.13 g/mol; CAS 56-75-7; M.P. = 150.5-151.5°C; Low solubility in water (2.5 mg/mL at 25°C), but more soluble in organic solvents; λ<sub>max</sub> = 278 nm; ε = 9530 M<sup>-1</sup>cm<sup>-1</sup>), also known as Chlorocid, Chlorasol, and Leukomycin (not to be confused with leucomycin) and IUPAC name, 2,2-dichloro-*N*-[1,3-dihydroxy-1-(4-nitrophenyl)propan-2-yl]acetamide, is a broad spectrum antibiotic first isolated from *Streptomyces venezuelae* in 1948. It was introduced commercially in 1949 and was a breakthrough in the treatment of typhoid fever. Chloramphenicol inhibits the growth of most bacteria; however, some resistant microorganisms have emerged. Chloramphenicol binds to the 50S ribosomal subunit (K<sub>d</sub> ≈ 2 μM). There is also at least one low-affinity binding site on the 30S subunit. Chloramphenicol blocks protein biosynthesis by inhibiting the peptidyltransferase, competing with substrates binding to the A-site. It also inhibits protein biosynthesis in the mitochondria and chloroplast. While eukaryotic protein biosynthesis is not generally affected, chloramphenicol is hepatotoxic. **Target(s):** D-amino acid oxidase (1); peptidyltransferase (2-4,6,8,11,12,17-22); CYP2B1 and several other cytochrome P450 systems (5,10); urease (7); peptidyl-tRNA hydrolase, or aminoacyl tRNA hydrolase (9); NADH dehydrogenase (ubiquinone), or Complex I (13); actomyosin ATPase (14); protein-synthesizing GTPase, elongation factor (15); arylalkylphosphatase, or paraoxonase (16); methane monooxygenase (23). 1. ### Chlordiazepoxide

This first-in-class benzodiazepine anxiolytic (FW = 299.75 g/mol; CAS 58-25-3; IUPAC Name: 7-chloro-2-methylamino-5-phenyl-3H-1,4-benzodiazepine-4-oxide), known famously as Librium, is indicated as a short-term treatment (2–4 weeks) for severe anxiety that is apt to subject a patient to otherwise unacceptable distress. Like diazepam, chlordiazepoxide is a positive allosteric modulator of GABA<sub>A</sub> receptors, promoting GABA binding, which in turn increases the total concentration of chloride ions across the neuronal cell membrane. Although its half-life is 5–30 hours, the active metabolite, demethylchlordiazepoxide, has a much longer half-life (36–200 hours). Often used recreationally, chlordiazepoxide is a Schedule IV controlled drug under the Convention on Psychotropic Substances. **1.** López-Muñoz, Alamo & García-García (2011) *J. Anxiety Disord.* **25**, 554.

### Chlordimeform

This acaricide (FW = 196.68 g/mol; CAS 6164-98-3), also named *N*'-(4-chloro-2-methylphenyl)-*N,N*-dimethylmethanimidamide, acts against motile forms of mites and ticks as well as the eggs and early instar larval forms of certain *Lepidoptera*. An interesting characteristic is that, in some cases, chlordimeform acts as an insect sedative, causing ineffective egg-laying behavior. Rather than a direct pesticide, it interferes with amine-mediated control of nervous and endocrine systems, mainly through a build-up of 5-hydroxytryptamine and, to a lesser extent, norepinephrine. Chlordimeform also inhibits monoamine oxidase from rat liver *in vitro*, and, in the American cockroach, it directly stimulates the heart and blocking octopamine-dependent stimulation of adenylyl cyclase in the CNS. **1.** Matsumura & Beeman (1976) *Environ. Health Perspect.* **14**, 71.

### Chlorfenapyr

This pro-insecticide (FW = 407.62 g/mol; CAS 122453-73-0), also known as 4-bromo-2-(4-chlorophenyl)-1-ethoxymethyl-5-trifluoromethyl-1H-pyrrole-3-carbonitrile, is taken up by target organisms and metabolized into CL 303268, a mitochondrial electron transport inhibitor. Chlorfenapyr is a broad spectrum insecticide/acaricide that is used to control whiteflies, thrips, caterpillars mites, leaf miners and aphids. Because this insecticide is toxic to birds, EPA restricts its use to non-food crops grown in greenhouses.

### Chlorhexidine

This membrane-active disinfectant (FW<sub>free-base</sub> = 505.45 g/mol; CAS 55-56-1), also known as 1,1'-hexamethylebis[5-(4-chlorophenyl)biguanide], is an antiseptic, used by surgeons and in plaque control. The dihydrochloride has a solubility in water of about 0.06 g/100 mL at 20°C; however, it is less soluble under elevated pH conditions. Because chlorhexidine is protonated at multiple sites, it is apt to bind tightly to phospholipids. **Target(s):** ATPase, membrane (1,3); however, see Reference 6); cation transport (1); dextranucanase, weakly inhibited (2); β-lactamase (3); succinate dehydrogenase, weakly inhibited (3); penicillin-binding protein-7, weakly inhibited (3); histamine *N*-methyltransferase (4); protease, subgingival plaque (5); oligopeptidase, *Treponema denticola* (7); gelatinase A, or matrix metalloproteinase-2 (8); gelatinase B, or matrix metalloproteinase-9 (8); collagenase 2, or matrix metalloproteinase 8 (8); fructosyltransferase (9); gingipain R, or Arg-gingipain (10); trypanothione reductase (11); urate oxidase (12); IgA-specific serine endopeptidase (13). **1.** Harold, Baarda, Baron & Abrams (1969) *Biochim. Biophys. Acta* **183**, 129. **2.** Christensen & Kilian (1977) *Acta Odontol. Scand.* **35**, 119. **3.** Chopra, Johnson & Bennett (1987) *J. Antimicrob. ### Chlorimuron-ethyl

This sulfonylurea herbicide (FW = 414.83 g/mol; CAS 90982-32-4; soluble in common organic solvents), also known as DPX-F6025, inhibits acetolactate synthase, or acetohydroxy acid synthase ( $K_i = 3.3$  nM). Chlorimuron-ethyl is often used to control weed growth in soybean fields. **1.** Ray (1986) *Trends Biochem. Sci.* **11**, 180. **2.** Pang, Guddat & Duggleby (2003) *J. Biol. Chem.* **278**, 7639. **3.** Pang, Guddat & Duggleby (2004) *Acta Crystallogr. D Biol. J.* **327**, 891. **6.** Choi, Yu, Hahn, Choi & Yoon (2005) *FEBS Lett.* **579**, 4903.

### N<sup>o</sup>-Chloroacetyl-L-Ornithine

This chloroacetylated amino acid (FW = 208.64 g/mol; Symbol: NCAO) targets ornithine decarboxylase (ODC), the enzyme that forms putrescine by decarboxylation of the urea cycle metabolite, ornithine. ODC is the first committed step in the synthesis of polyamines (e.g., putrescine, spermidine and spermine). Despite the presence of a susceptible haloacetamido group, NCAO is a reversible competitive inhibitor ( $K_i = 59$  μM). Its cytotoxic and antiproliferative effects are concentration- and time-dependent, with EC<sub>50,72h</sub> values of 15.8, 17.5 and 10.1 μM for HeLa, MCF-7 and HepG2 cells, respectively. At 500 μM, NCAO completely inhibits growth of all cancer cells after 48 h treatment, with almost no effect on normal cells. Putrescine reverses NCAO effects on MCF-7 and HeLa cells, indicating its antiproliferative effects are due to ODC inhibition. **1.** Medina-Enriquez, Alcántara-Farfán, Aguilar-Faisal, et al. (2014) *J. Enzyme Inhib. Med. Chem.* **18**, 1.

### 3-Chloroacetylpyridine Adenine Dinucleotide Phosphate

This NADP<sup>+</sup> analogue (FW = 726.42 g/mol; CAS 39938-03-9; Abbreviation: ac3PdADP<sup>+</sup>), also known as 3-chloroacetyl-pyridinium adenine nucleotide phosphate, is an affinity label for NADP<sup>+</sup>-dependent dehydrogenases. Active site-directed chloroketone-containing reagents bind to and react with sulfhydryl groups and less so with primary amines located within the coenzyme binding region. **Target(s):** Aspartate- $\beta$ -semialdehyde dehydrogenase (irreversible inactivation with pseudo-first-order kinetics; inactivation prevented by NADP<sup>+</sup> and NADPH, but not the substrate; incorporation of 1 mol ac3PdADP<sup>+</sup>/dimer totally inactivates the enzyme) (1); estradiol 17 $\beta$ -dehydrogenase (2); 6-phosphogluconate dehydrogenase (3). 1. Biellmann, Eid & Hirth (1980) *Eur. J. Biochem.* **104**, 65. 2. Biellmann, Goulas, Nicolas, Descomps & Crastes De Paulet (1979) *Eur. J. Biochem.* **99**, 81. 3. Biellmann, Goulas & Dallochio (1978) *Eur. J. Biochem.* **88**, 433.

### 4-(3-Chloroanilino)quinazoline

This substituted quinazoline (FW = 255.71 g/mol; CAS 88404-44-8), also known as *N*-(*m*-chlorophenyl)-4-aminoquinazoline, is a strong inhibitor of epidermal growth factor receptor protein-tyrosine kinase (apparent  $K_i$  = 16 nM). 1. Wakeling, Barker, Davies, *et al.* (1996) *Breast Cancer Res. Treat.* **38**, 67. 2. Ward, Cook, Slater, *et al.* (1994) *Biochem. Pharmacol.* **48**, 659.

### Chlorocholine Chloride

This quaternary amine (FW = 158.07 g/mol; Abbreviation: CCC), also known as 2-chloroethyltrimethylammonium chloride, chlormequat chloride, and, is a synthetic plant growth retardant. It is also a gibberellin antagonist. **Target(s):** choline kinase (1); acetylcholinesterase (2,3); copalyl-diphosphate synthase (4); *ent* kaurene synthase (4,6); choline *O*-acetyltransferase (5); beyerene biosynthesis (6); sandaracopimaradiene biosynthesis (6); trachylobane biosynthesis (6); phenylalanine ammonia-lyase (7); choline sulfotransferase (8); acetylcholinesterase (9). 1. Ishidate & Nakazawa (1992) *Meth. Enzymol.* **209**, 121. 2. Krupka (1965) *Biochemistry* **4**, 429. 3. Friess & McCarville (1954) *J. Amer. Chem. Soc.* **76**, 2260. 4. Rademacher (2000) *Annu. Rev. Plant Physiol. Plant Mol. Biol.* **51**, 501. 5. Hersh & M. Peet (1977) *J. Biol. Chem.* **252**, 4796. 6. Robinson & West (1970) *Biochemistry* **9**, 80. 7. El-Shora (2002) *Plant Sci.* **162**, 1. 8. Renosto & Segel (1977) *Arch. Biochem. Biophys.* **180**, 416. 9. Burnet, Lafontaine & Hanson (1995) *Plant Physiol.* **108**, 581.

### 3-[(2S,4S)-4-(2-Chloro-4-cyanophenyl)amino-2-pyrrolidinylcarbonyl-1,3-thiazolidine

This substituted thiazolidine (FW = 336.85 g/mol) inhibits dipeptidyl-peptidase IV (IC<sub>50</sub> = 18 nM for the human enzyme). The 3-chloro-4-cyanophenyl analogue is a slightly stronger inhibitor (IC<sub>50</sub> = 11 nM). 1. Sakashita, Akahoshi, Kitajima, Tsutsumiuchi & Hayashi (2006) *Bioorg. Med. Chem.* **14**, 3662.

### 4-[6-(Cyclobutylamino)-imidazo[1,2-b]pyridazin-3-yl]-2-fluoro-N-[(2S,4R)-4-fluoropyrrolidin-2-yl]methylbenzamide

This protein kinase inhibitor (FW = 427.47 g/mol), also known as Compound D, targets I $\kappa$ B kinase $\beta$  (or IKK $\beta$ ), which plays a critical role in nuclear factor- $\kappa$ B (NF- $\kappa$ B) activation and proinflammatory cytokine production in various inflammatory diseases including rheumatoid arthritis. **Pharmacodynamics:** Phosphorylation of inhibitor of  $\kappa$ B (I $\kappa$ B) is catalyzed by the I $\kappa$ B kinase (IKK) complex, which consists of two catalytic subunits, IKK $\alpha$  and IKK $\beta$ , and a regulatory subunit, NF- $\kappa$ B essential modulator. Ample evidence indicates that IKK $\beta$ , but not IKK $\alpha$ , is required for NF- $\kappa$ B activation in response to inflammatory stimuli, suggesting that IKK $\beta$  is a key factor in the production of pro-inflammatory cytokines in inflammatory conditions. **Signaling Pathway Target(s):** NF- $\kappa$ B (IC<sub>50</sub> = 0.15  $\mu$ M); Activator Protein-1, or AP-1 (IC<sub>50</sub> = >20  $\mu$ M); Nuclear Factor of Activated T-cells, or NFAT (IC<sub>50</sub> > 20  $\mu$ M); Serum Response Element, or SRE (IC<sub>50</sub> = 19  $\mu$ M); cAMP Response Element, or CRE (IC<sub>50</sub> > 20  $\mu$ M); Interferon-Stimulated Response Element, or ISRE (IC<sub>50</sub> = 16  $\mu$ M). 1. Tanaka, Toki, Yokoyama, *et al.* (2014) *Biol. Pharm. Bull.* **37**, 87.

### 5'-Chloro-5'-deoxymycin A

This nonglycosidic or C-nucleoside analogue (FW = 284.68 g/mol; CAS 72453-27-1), also known as 5'-chloroformycin, inhibits methylthioadenosine nucleosidase ( $K_i$  = 322 nM). Its chloro group prevents any possibility of metabolic 5'-phosphorylation within cells, making it an ideal nucleoside analogue. **Target(s):** adenosylhomocysteine nucleosidase (1-4); methylthioadenosine/adenosylhomocysteine nucleosidase (1-4); S-methyl-5'-thioadenosine phosphorylase (5,6). 1. Kushad, Richardson & Ferro (1985) *Plant Physiol.* **79**, 525. 2. Kushad, Orvos & Ferro (1992) *Physiol. Plant.* **86**, 532. 3. Della Ragione, Takabayashi, Mastropietro, *et*

al. (1996) *Biochem. Biophys. Res. Commun.* **223**, 514. 6. Savarese, Crabtree & Parks (1981) *Biochem. Pharmacol.* **30**, 189.

#### 9-(6-Chloro-5,6-dideoxy-β-D-ribo-hex-5-ynofuranosyl)-9H-purin-6-amine

This halo-alkyne nucleoside analogue (FW = 295.69 g/mol) binds to and inactivates adenosylhomocysteinase. The enzyme mediates water addition at the 5'-position of compound to produce an α-halomethyl ketone intermediate, which is subsequently attacked by the proximal, active-site nucleophile (Lys318) to form an enzyme-inhibitor covalent adduct (lethal event). In a parallel pathway (nonlethal event), addition of water at the 6'-position produces an acyl halide, which is released into solution and chemically degrades into adenosine, halide ion, and sugar-derived products. 1. Yang, Yin, Wnuk, Robins & Borhardt (2000) *Biochemistry* **39**, 15234.

#### 4'-Chloro-3α-(diphenylmethoxy)tropane

This modified tropane (FW<sub>free-base</sub> = 341.88 g/mol), which inhibits dopamine transport (IC<sub>50</sub> = 15 nM), increases locomotor activity. While exhibiting lower efficacy than cocaine, it does not exhibit cocaine-like behavioral profiles. 1. Newman, Allen, Izenwasser & Katz (1994) *J. Med. Chem.* **37**, 2258. 2. Katz, Izenwasser, Kline, Allen & Newman (1999) *J. Pharmacol. Exp. Ther.* **288**, 302.

(2-Chloroethyl)<sub>2</sub>-ethylamine, See *Bis(2-chloroethyl)ethylamine*

#### N-(2-Chloroethyl)-N-methyl-2-chloro-2-phenethylamine

This dichloro phenethylamine derivative (FW<sub>free-base</sub> = 232.15 g/mol) rearranges in aqueous solution to form the aziridinium ion, (N-(2-chloroethyl)-N-methyl-2-phenylaziridinium cation), from N-(2-chloroethyl)-N-methyl-2-chloro-2-phenethylamine, a quaternary amine that inhibits acetylcholinesterase. 1. O'Brien (1969) *Biochem. J.* **113**, 713. 2. Shaw (1970) *The Enzymes*, 3rd ed., **1**, 91. 3. Froede & Wilson (1971) *The Enzymes*, 3rd ed., **5**, 87.

#### 6-[4-(2-Chloro-5-fluorophenoxy)piperidin-1-yl]pyridazine-3-carboxamide

This potent, orally bioavailable pyridazine (FW = 350.78 g/mol) inhibits stearoyl-CoA 9-desaturase (SCD), with an IC<sub>50</sub> value of 1.0 nM in mice. This enzyme catalyzes the rate-limiting step in the cellular synthesis of monounsaturated fatty acids from saturated fatty acids. Because the ratio of saturated to monounsaturated fatty acids strongly influences membrane fluidity, alterations in this ratio lead to various disorders, including cardiovascular disease, obesity, non-insulin-dependent diabetes mellitus, hypertension, neurological diseases, immune disorders, and cancer. Studies with SCD-1 knockout mice established that animals treated with this agent are lean and are protected from leptin deficiency-induced and diet-induced obesity, showing a greater whole-body insulin sensitivity than wild-type animals. 1. Liu, Lynch, Freeman, et al. (2007) *J. Med. Chem.* **50**, 3086.

#### Chlorogenate (or Chlorigenic Acid)

This conjugated phenol (FW = 354.31 g/mol; CAS 327-97-9; Symbol: CGA), also named 3-Caffeoylquininate, 3-Caffeoylquinic (3-CQA), 3-O-Caffeoylquinic acid, Heriguard, and systematically (1S,3R,4R,5R)-3-[(2E)-3-(3,4-dihydroxyphenyl)prop-2-enoyl]oxy}-1,4,5-trihydroxycyclohexane carboxylate, is a well-known tannin found in coffee, tea, and fruit. Acid hydrolysis produces caffeic acid. Some bacteria and fungi possess a chlorogenate hydrolase (EC 3.1.1.42) that catalyzes the reaction: Chlorogenate + H<sub>2</sub>O ⇌ Caffeate + Quinate. The enzyme hydroxycinnamoyl-CoA:shikimate/quininate hydroxy-cinnamoyltransferase reported converts this chlorogenate to caffeoyl-CoA. Chlorogenic acid has a low solubility in water (approximately 4% at 25°C) with the solubility increasing with temperature. The reported pK<sub>a</sub> value is 2.66 at 27°C. Chlorogenate also reduces ferrylmyoglobin. (Note: The term "chlorogenic" has nothing to do with chlorine (of which it has none) and is instead based on the Greek word *χλωρός* (green), because, upon oxidation, this compound generates a characteristic emission in that region of the visible light spectrum.) **Target(s):** indoleacetate oxidase (1,2); horseradish peroxidase (3); α-amylase (4,21); trypsin (4); lysozyme (4); arylamine N-acyltransferase (5,25); benzyloxyresorufin O-dealkylase, or cytochrome P450 (6); ethoxyresorufin O-deethylase, or cytochrome P450, or CYP1A1 (6,7); methoxyresorufin O-demethylase, or cytochrome P450, CYP1A2 (6,7); pentoxy-O-dealkylase, cytochrome P450, or CYP2B (7); glucose-6-phosphatase (8,22); glucose-6-phosphate translocase (10,22); Na<sup>+</sup>-dependent D-glucose uptake (11); glutathione S-transferase (12); carbonyl reductase (13); arginase (14); DNA methyltransferase (15); chorismate mutase (16); phenylpyruvate tautomerase (17); phenylalanine ammonia-lyase, weakly inhibited (18); angiotensin I-converting enzyme, weakly inhibited (19); hyaluronoglucosaminidase, or hyaluronidase (20); phenol sulfotransferase, or aryl sulfotransferase (23); inositol-polyphosphate multikinase (24); tyrosinase, monophenol monooxygenase; weakly inhibited (26); *trans*-cinnamate 4-monooxygenase, weakly inhibited (27). **Implications for Treating Rheumatoid Arthritis:** Chlorogenic acid is also a major component of *Caulis loniceræ*, an herb commonly used in Chinese folk medicine to treat rheumatoid arthritis (RA), which is characterized by persistent inflammation of the synovial tissues of joints, resulting in loss of joint function. CGA inhibits the inflammatory proliferation of RSC-364 cells by inducing apoptosis, as mediated by IL-6. CGA can also suppress the expression levels of key molecules in the JAK/STAT and NF-κB signaling pathways, thereby inhibiting the activation of these signaling pathways in the inflammatory response through IL-6-mediated signaling (28). Such action results in the inhibition of the inflammatory proliferation of synoviocytes, indicating that CGA may afford a novel therapeutic agent to inhibit inflammatory hyperplasia of the synovium by inducing synoviocyte apoptosis in RA patients (28). 1. ### 5-Chloro-6-[(2-iminopyrrolidin-1-yl)methyl]uracil

This substituted uracil (FW = 242.67 g/mol), often abbreviated TPI, is a potent inhibitor of thymidine phosphorylase ( $K_i = 20$  nM). Thymidine phosphorylase (TP), which catalyzes the reversible conversion of thymidine to thymine, is identical to an angiogenic factor, platelet-derived endothelial cell growth factor. TP is expressed at higher levels in a wide variety of solid tumors than in the adjacent nonneoplastic tissues. Patients with TP-positive colon and esophageal tumors have a poorer prognosis than those with TP-negative tumors. That this inhibitor's positively charged ring system improves binding (1-10) is consistent with the finding that structurally related bioreductive nitroimidazolyl pro-drugs rearrange to form potent aminoimidazolylmethyluracil inhibitors of thymidine phosphorylase (9). 1. ### p-Chloromercuribenzoate

This sulfhydryl-blocking reagent (FW<sub>free-acid</sub> = 357.16 g/mol; *Symbol*: PCMB) inhibits numerous enzymes. It is especially useful as the reaction with a thiol causes an increase in absorbance at 250 nm. Inhibition is often reversed by the addition of sulfhydryl-containing molecules, such as cysteine, 2-thioethanol, and dithiothreitol. PCMB also inhibits oxidative phosphorylation. It is highly toxic and extreme care should be exercised in its use. Importantly, PCMB undergoes hydrolysis, readily converting to *p*-hydroxymercuribenzoate (PHMB), when the sodium salt is prepared by dissolving PCMB in 200 mM NaOH, followed by adjustment of the solution to a lower pH. The reactive species in aqueous solutions is therefore the mercuric cation ( $\text{OOC-C}_6\text{H}_4\text{-Hg}^{2+}$ ). Since the chloride ion is simply a counterion, one would predict that any salt would be equally effective. Nevertheless, enzymes have been reported to be inhibited by both PCMB and PHMB, albeit with different rates (the difference in rates may

be due in part to the role of chloride ions as an additional effector). (See also *p*-Hydroxymercuribenzoate) Over 1000 enzymes show some degree of inhibition, making PCMB a notoriously highly unselective thiol-reacting reagent.

### 1-(5-Chloronaphthalene-1-sulfonyl)-1*H*-hexahydro-1,4-diazepine

This diazepine (FW<sub>free-base</sub> = 324.83 g/mol), commonly referred to as ML-9, is a strong inhibitor of [myosin light-chain] kinase (IC<sub>50</sub> = 3.8 μM). Other kinases are inhibited less effectively: *e.g.*, protein kinase A (IC<sub>50</sub> = 32 μM) and protein kinase C (IC<sub>50</sub> = 54 μM). It also inhibits Natural Killer cell activity and catecholamine secretion in intact and permeabilized chromaffin cells. **Target(s)**: [myosin light-chain] kinase (1-5); protein kinase A (1,4); protein kinase C (1,4); mitogen- and stress-activated protein kinase 1 (4); p70 ribosomal protein S6 kinase (4); Rho-dependent protein kinase II (4). 1. Cell Sci.* **119**, 2269.

### 3-[4-(2-Chlorophenoxy)piperidin-1-yl]-6-(pyridin-3-yl)pyridazine

This pyridazine derivative (FW = 354.84 g/mol) reversibly inhibits stearoyl-CoA 9-desaturase (mouse IC<sub>50</sub> < 4 nM). This enzyme catalyzes the rate-limiting step in the cellular synthesis of monounsaturated fatty acids from saturated fatty acids. Because a proper ratio of saturated to monounsaturated fatty acids is required for optimal membrane fluidity, alterations in this ratio have been implicated in various disease states, including cardiovascular disease, obesity, non-insulin-dependent diabetes mellitus, hypertension, neurological diseases, immune disorders, and cancer. 1. Liu, Lynch, Freeman, *et al.* (2007) *J. Med. Chem.* **50**, 3086.

### p-Chloro-L-phenylalanine

This halogenated amino acid (FW = 199.64 g/mol; CAS 7424-00-2; Soluble to 100 mM in water and to 100 mM in DMSO) depletes tissue serotonin levels. **Target(s)**: tryptophan 5-monoxygenase (1,4,13-16); phenylalanine 4-monoxygenase (2,3,5,8,17,18); pyruvate kinase (6,9); 3-deoxy-7-phosphoheptulonate synthase, *or* 3-deoxy-*D*-arabinoheptulonate-7-phosphate synthetase (7); alkaline phosphatase, mildly inhibited by racemic mixture (10); phenylalanyl-tRNA synthetase,  $K_i = 6.8$  mM (11); prephenate dehydratase (12). 1. #### *p*-Chloro-L-phenylalanine Methyl Ester

This membrane-permeant chlorinated amino acid (FW<sub>HCl-salt</sub> = 250.12 g/mol; CAS 63024-26-0) undergoes metabolic deesterification to generate of *p*-chloro-L-phenylalanine, a 5-HT-depleting agent. (See *p*-Chloro-L-phenylalanine) Injectable solutions should be prepared fresh daily by dissolving into sterile 0.9% saline (78 mg/mL *p*-CPME HCl-salt), adjusted to pH 6.0 with 0.1 M NaOH. When injected into rats at a dose of 200 mg/kg (calculated as the free base), this treatment depletes 94% of 5-HT. **1.** Lapiz-Bluhm, Soto-Piña, Hensler & Morilak (2009) *Psychopharmacol.* (Berlin) **202**, 329.

#### *N*<sup>1</sup>-[4-Chloro-D-phenylalanyl-3-(naphth-1-yl)-L-alanyl]-1-amino-3-guanidinopropane

This peptidomimetic TK inhibitor (FW<sub>free-base</sub> = 494.02 g/mol) targets tissue kallikrein ( $K_i = 2.2$  nM), showing a high degree of selectivity for TK over several other serine proteases. This inhibitor reduces eosinophilia in an allergic inflammation model, and the observed *in vivo* effects provide further evidence for the involvement of TK and kinins in the pathophysiology of allergic diseases such as asthma. **1.** Evans, Jones, Pitt, *et al.* (1996) *Immunopharmacology* **32**, 117.

#### 8-(4-Chlorophenylthio)guanosine 3',5'-Cyclic Monophosphorothioate, *Rp*-Isomer

This lipophilic guanine nucleotide (FW = 503.88 g/mol), also known as *p*CPT-cGMPS, *Rp*-isomer, inhibits cGMP-dependent protein kinase (IC<sub>50</sub> =

0.5 μM). **1.** Butt, Eigenthaler & Genieser (1994) *Eur. J. Pharmacol.* **269**, 265. **2.** West, Meno, Nguyen, *et al.* (2003) *J. Cardiovasc. Pharmacol.* **41**, 444. **3.** Andoh, Chiueh & Chock (2003) *J. Biol. Chem.* **278**, 885. **4.** Zhang, J. Gesmonde, S. Ramamoorthy & G. Rudnick (2007) *J. #### 5'-(4-Chlorophenylthio)-immucillin-A

This nucleoside analogue (FW = 365.87 g/mol), named systematically as (1*S*)-5-(4-chlorophenylthio)-1-(9-deazaadenin-9-yl)-1,4-dideoxy-1,4-imino-D-ribose and (1*S*)-1-(9-deazaadenin-9-yl)-5-(4-chlorophenylthio)-1,4-dideoxy-1,4-imino-D-ribose, targets 5'-methylthioadenosine/*S*-adenosylhomocysteine nucleosidase,  $K_i' = 2$  pM (1). The *meta*-chloro analogue is a weaker inhibitor,  $K_i' = 20$  pM. The 4-chlorophenyl analogue also inhibits human *S*-methyl-5'-thioadenosine phosphorylase,  $K_i = 0.166$  nM (2). The 3-chlorophenyl analogue is a slightly weaker inhibitor. **1.** Singh, Evans, Lenz, *et al.* (2005) *J. Biol. Chem.* **280**, 18265. **2.** Evans, Furneaux, Schramm, Singh & Tyler (2004) *J. Med. Chem.* **47**, 3275.

#### (3*R*,4*S*)-4-(4-Chlorophenylthiomethyl)-1-[(9-deazaadenin-9-yl)methyl]-3-hydroxy-pyrrolidine

This nucleoside analogue (FW = 377.90 g/mol) potently inhibits 5'-methylthioadenosine/*S*-adenosylhomocysteine Nucleosidase,  $K_i' = 4.7 \times 10^{-14}$  M (1,2) and *S*-methyl-5'-thioadenosine phosphorylase,  $K_i' = 10$  pM (3,4). The *meta*-chloro analogue is a weaker inhibitor of the nucleosidase ( $K_i' = 0.75$  pM) and the phosphorylase ( $K_i' = 0.27$  nM). **1.** Singh, Evans, Lenz, *et al.* (2005) *J. Biol. Chem.* **280**, 18265. **2.** Singh, Lee, Núñez, Howell & Schramm (2005) *Biochemistry* **44**, 11647. **3.** Singh, Shi, Evans, *et al.* (2004) *Biochemistry* **43**, 9. **4.** Evans, Furneaux, Lenz, *et al.* (2005) *J. Med. Chem.* **48**, 4679.

#### 2-Chloro-3-phytyl-1,4-naphthoquinone

This anticoagulant (FW = 471.12 g/mol; CAS 30949-95-2), also known as chloro-K1, is a competitive vitamin K<sub>1</sub> (phylloquinone) antagonist. **Target(s):** vitamin K-dependent carboxylase, or protein-glutamate carboxylase (1-8); phylloquinone monooxygenase (2,3-epoxidizing) (9). **1.** O'Reilly (1976) *Ann. Rev. Med.* **27**, 245. **2.** Suttie (1980) *Trends Biochem. Sci.* **5**, 302. **3.** Lowenthal, MacFarlane & McDonald (1960) *Experientia* **16**, 428. **4.** Johnson (1980) *Meth. ### 3-Chloroprotham

This tubulin-directed toxic agent (FW = 213.66 g/mol; CAS 101-21-3; M.P. = 40°C; Water-insoluble; Soluble in most organic solvents), also known as chlorprotham, *N*-(3-chlorophenyl) *O*-isopropyl carbamate, and *O*-isopropyl *N*-(3-chlorophenyl) carbamate, is a potent herbicide and inhibitor of plant cell division. This plant growth regulator is used for preemergence control of grass weeds in alfalfa, lima beans, snap beans, blueberries, carrots, cranberries, clover, garlic, seed grass, onions, spinach, sugar beets, tomatoes, safflower, soybeans, gladioli and woody nursery stock. It is also used to inhibit potato sprouting and for sucker control in tobacco. Chlorprotham is available in emulsifiable concentrate and liquid formulations. 3-Chloroprotham is also toxic to animals. The oral LD<sub>50</sub> for chlorprotham in rats ranges from 1,200 to 3,800 mg/kg, and the 4-hour inhalation LC<sub>50</sub> in rats is >32 mg/L (4). **Target(s):** microtubule assembly (tubulin polymerization) (1-3). 1. Yokoyama, Kaji, Nishimura & Miyaji (1990) *J. Gen. Microbiol.* **136**, 1067. 2. Walker (1982) *J. Gen. Microbiol.* **128**, 61. 3. Brown & Bouck (1974) *J. Cell Biol.* **61**, 514.

### Chloroquine

This antimalarial drug and autophagy inhibitor (FW<sub>free-base</sub> = 319.88 g/mol; CAS 54-05-7), also known as *N*<sup>4</sup>-(7-chloro-4-quinolinyl)-*N*<sup>1</sup>,*N*<sup>1</sup>-diethyl-1,4-pentanediamine and SN7618, prevents the malarial parasite from disposing of toxic heme products formed upon proteolysis of hemoglobin in infected red blood cells. **Primary Mode of Antimalarial Action:** This and similarly acting drugs accumulate in the acid food vacuoles of the intraerythrocytic-stage malarial parasite. The primary function of the food vacuole is to harvest nutrients derived from proteolysis of ingested red cell haemoglobin, thus providing the growing parasite with essential amino acids. The breakdown of hemoglobin within the food vacuole releases heme, which can damage biological membranes and inhibit many enzymes. To detoxify heme, the parasite has an enzyme that inserts heme into an insoluble crystalline material known as haemozoin, a polymer of heme molecules, each joined to the next by a link between the central ferric ion of one heme and a side-group carboxylate of a neighboring heme. This heme polymerase is inhibited by quinoline-containing drugs such as chloroquine and quinine, providing a rationale for the highly stage-specific anti-malarial action of these drugs (1). Chloroquine may also inhibit ribonucleotide metabolism in the parasite. **Other Modes of Inhibitory Action:** Chloroquine also intercalates into double-stranded DNA, and this property may be exploited to increase transfection efficiency. CQ also induces acute hemolysis in glucose-6 phosphate dehydrogenase-deficient individuals. Chloroquine is also a weak base that is trapped in acidic organelles such as lysosomes, thereby increasing vacuolar pH. The change in pH also causes accumulation of autophagosomes in cells by inhibiting the fusion of autophagosomes with lysosomes. Chloroquine is a more effective inhibitor than ammonium chloride, thus requiring a 100-fold lower concentration. CQ also appears to trigger multiple death pathways. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** cathepsin B (2,14,15); photophosphorylation uncoupler (3);

alcohol dehydrogenase (4,6); DNA-directed RNA polymerase (5); heme polymerase (1,7); D-amino-acid oxidase (8); lanosterol synthase (9); phosphoenolpyruvate carboxylase (10); bontoxilysin (11); cathepsin D (12); cathepsin F (13); sphingomyelin phosphodiesterase, or sphingomyelinase (16); acid phosphatase (17); palmitoyl-[protein] hydrolase (18); phospholipase A<sub>1</sub> (19); phospholipase A<sub>2</sub> (19); sterol esterase, or cholesterol esterase (20); acetylcholinesterase (21); Ca<sup>2+</sup>/calmodulin-dependent protein kinase (22); DNA polymerase (23); duck hepatitis B virus reverse transcriptase (23); RNA-directed DNA polymerase (23); histamine *N*-methyltransferase, both enantiomers inhibit (24,25); diferric-transferrin reductase (26); quinine 3-monooxygenase (27); ribosylidihydro-nicotinamide dehydrogenase, quinone-requiring (28); synergistically potentiates anti-cancer property of artemisinin by promoting ROS dependent apoptosis (29). 1. ### Chlorothricin

This membrane-interacting agent (FW<sub>free-acid</sub> = 955.49 g/mol; CAS 34707-92-1), isolated from a strain of *Streptomyces antibioticus*, is macrolide-type antibiotic that is active against Gram-positive bacteria. Chlorothricin also inhibits cholesterol biosynthesis by impeding the mevalonate pathway (1). **Target(s):** pyruvate carboxylase, noncompetitive inhibition (2,3,5); malate dehydrogenase (4). 1. Kawashima, Nakamura, Ohta et al. (1992) *J. Antibiot.* **45**, 207. 2. Schindler & Zahner (1973) *Eur. J. Biochem.* **39**, 591. 3. Schindler & Zahner (1972) *Arch. Mikrobiol.* **82**, 66. 4. Schindler (1975) *Eur. J. Biochem.* **51**, 579. 5. Schindler & M. C. Scrutton (1975) *Eur. J. Biochem.* **55**, 543.

### Chlorotoxin

This 36-residue marine toxin (FW = 4004.75 g/mol; CAS 163515-35-3; Sequence: MCMPCFTTDHHQMARKCDDCCGGKGRGKCYGPQCLCR), from the venom of the deathstalker scorpion *Leiurus quinquestriatus*, blocks small-conductance chloride channels, when applied to the cytoplasmic surface (1). Chlorotoxin is also a reliable and specific histopathological marker for tumors of neuroectodermal origin, suggesting that chlorotoxin derivatives with cytolytic activity may have therapeutic potential for these cancers (2). 1. DeBin, Maggio & Strichartz (1993) *Am. J. Physiol.* **264**, C361. 2. Lyons, O'Neal & Sontheimer (2002) *Glia* **39**, 162.

### Chlorphenamine

This first-generation alkylamine antihistamine (FW = 274.79 g/mol; CAS 113-92-8), also known as chlorpheniramine, 3-(4-chlorophenyl)-*N,N*-dimethyl-3-pyridin-2-ylpropan-1-amine as well as various trade names (e.g., Antagonate<sup>®</sup>, Chlor-Trimeton<sup>®</sup>, Efidac 24<sup>®</sup>, Kloromin<sup>®</sup>, Phenetron<sup>®</sup>, and Pyridamal 100<sup>®</sup>), targets H<sub>1</sub> receptors and is also a Serotonin-Norepinephrine Reuptake Inhibitor (or SNRI). Chlorphenamine has a serum half-life of approximately 20 hours in adults, and elimination from the body is primarily by metabolism to mono-demethyl and di-demethyl forms (1). It is also combined with codeine and other cough-suppressing substances in the treatment of persistent coughing associated with the common cold. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Rumore (1984) *Drug Intell. Clin. Pharm.* **18**, 701.

### Chlorpromazine

This photosensitive antipsychotic drug and tranquilizer (FW<sub>free-base</sub> = 318.87 g/mol; CAS 50-53-3; *Abbreviation* = Cpz), also known as Largactil<sup>™</sup>, Thorazine<sup>™</sup> and systemically as 2-chloro-10-(3-dimethylaminopropyl)phenothiazine, acts on a variety of receptors within the central nervous system, producing anticholinergic, antidopaminergic, antihistaminic, and weak antiadrenergic effects. It was first prepared in the early 1950s in efforts to find better sedatives. It is a potent inhibitor of dopamine-stimulated adenylate cyclase and a mammalian multidrug resistance modulator. Chlorpromazine also inhibits oxidative phosphorylation and photophosphorylation, is a histamine H<sub>1</sub> receptor and dopamine D<sub>2</sub> receptor antagonist, and inhibits the calmodulin stimulation of phosphodiesterase, or cyclic-nucleotide phosphodiesterase I, IC<sub>50</sub> = 17 μM (10) and transglutaminase. Chlorpromazine also inhibits mouse brain nitric-oxide synthase and prevents lipopolysaccharide induction of the synthase in murine lung. **Chlorpromazine Inhibition of Clathrin-Mediated Endocytosis:** Chlorpromazine (30–50 μM for 20–30 min) blocks endocytosis of clathrin-coated endosomes by targeting clathrin's heavy chain, or chc (11,12), often inhibiting the uptake of vesicle cargo (e.g., transferrin), some viruses (e.g., adenovirus) as well as endocytosis-mediated dye uptake. Indeed, FIAH-FALI-mediated chc photoinactivation of chc or control treatment of synapses with chlorpromazine does not show a statistical difference in membrane uptake or the size of internalized membranous structures (13). That said, the promiscuity chlorpromazine inhibition (see below) suggests that one must avoid its indiscriminate use as an endocytosis inhibitor. Moreover, given chlorpromazine's light sensitivity, one cannot discount the likelihood that chlorpromazine's potency and/or inhibitory action is itself photo-dependent. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** NAD(P)H dehydrogenase, or DT diaphorase (1,23,33); malate dehydrogenase (acceptor) (2); D-amino acid oxidase (3); histamine *N*-methyl-transferase (4,34,76); mitochondrial and photophosphorylation uncoupler (5); protein kinase C (6,10,27); calmodulin (7,10); sterol acyltransferase, or cholesterol acyltransferase (8); indoleamine *N*-methyltransferase (9); nitric-oxide synthase (25); 3',5'-cyclic-nucleotide phosphodiesterase (10,24,29,55,72); Ca<sup>2+</sup>-transporting ATPase (10,17,26); myosin light-chain kinase (10); [β-adrenergic-receptor]

kinase (11); dopamine-stimulated adenylate cyclase (15,16); multidrug resistance, as modulator of (15,16); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (17,22,35,48); actin polymerization (18); CYP2D6 (19); [pyruvate dehydrogenase] phosphatase (20); CYP2B1 (21); carbonyl reductase (28); phospholipase A<sub>2</sub> (30); lysosomal sphingomyelinase (31); histamine H<sub>1</sub> receptor (32); phosphatidylcholine:sterol acyltransferase, or LCAT (36); succinate-semialdehyde dehydrogenase (37); dopamine D<sub>2</sub> receptor (38,39); myosin ATPase (40); ATP synthase (F<sub>0</sub>F<sub>1</sub> ATPase; H<sup>+</sup>-transporting two-sector ATPase (41,42); ATPase, *Escherichia coli* (32); TF<sub>1</sub> ATPase, stimulated at concentrations below 0.6 mM at 23°C (42); carnosine synthetase, inhibition at millimolar levels (43); phosphatidylinositol diacylglycerol-lyase, or phosphatidyl-inositol-specific phospholipase C, inhibits at pH 7, but stimulates at pH 5.5 (44); adenylate cyclase (45,46); 1-aminocyclopropane-1-carboxylate synthase (47); thiamin-triphosphatase (49-51); nucleoside-diphosphatase (52); Xaa-methyl-His dipeptidase, or anserinase, or *N*-acetylhistidine deacetylase (53); glycosylphosphatidylinositol phospholipase D (54); [pyruvate dehydrogenase (acetyl-transferring)]-phosphatase (55); phosphatidate phosphatase (55-61); phosphoserine phosphatase (62,63); phospholipase A<sub>1</sub> (64); diacylglycerol lipase (65); acylglycerol lipase, or monoacylglycerol lipase; weakly inhibited (65); sterol esterase, or cholesterol esterase (66); cholinesterase (butyrylcholinesterase; K<sub>i</sub> = 3.22 μM (67); phenol sulfotransferase, or aryl sulfotransferase (68); choline-phosphate cytidylyltransferase (69,70); diphosphoinositol pentakisphosphate kinase (74); NAD<sup>+</sup> kinase (76); carnitine *O*-octanoyltransferase (77); carnitine *O*-palmitoyltransferase (75); flavin-containing mono-oxygenase (79); 5-lipoxygenase, or arachidonate 5-lipoxygenase (78); 12-lipoxygenase, or arachidonate 12-lipoxygenase (78); prostaglandin synthase (78); tyranthione-disulfide reductase (79,80). 1. ### Chlorpropamide

This antidiabetic agent (FW = 276.74 g/mol; CAS 94-20-2; Soluble in water at pH 6 (2.2 mg/mL) but practically insoluble at pH 7.3), also known as chlorpropamide and *N*-propyl-*N'*-(*p*-chlorobenzene sulfonyl)urea, is an inhibitor of cholesterol biosynthesis. **Mechanism of Action in Type II Diabetes:** As with other sulfonylureas, chlorpropamide acts by increasing the insulin secretion and is only effective in patients who have some pancreatic beta cell function. **Target(s):** cholesterol biosynthesis (1); lathosterol oxidase (2); rat renal organic anion transporter (3); aldehyde dehydrogenase (4,5,9); urease (6,7); cAMP phosphodiesterase (8). 1. McDonald & Dalidowicz (1962) *Biochemistry* **1**, 1187. 2. Dempsey (1969) *Meth. Enzymol.* **15**, 501. 3. Uwai, Saito, Hashimoto & Inui (2000) *Eur. J. Pharmacol.* **398**, 193. 4. ### Chlorprothixene

This antipsychotic drug (FW = 315.87 g/mol; CAS 113-59-7) is an inhibitor of dopamine-stimulated adenylate cyclase and a dopamine receptor antagonist (1). There are two distinct forms of this pharmaceutical: an  $\alpha$ - or *cis*-isomer (i.e., the *Z*-isomer) and a  $\beta$ - or *trans*-form.  $\alpha$ -Chlorprothixene is the more active form,  $K_i = 37$  nM (2). **Target(s):** dopamine-stimulated adenylate cyclase (1,2); dopamine  $\beta$ -hydroxylase (3); adenosylmethionine decarboxylase (4); transport ATPase (5). 1. Iversen (1975) *Science* **188**, 1084. 2. Iversen (1976) *Trends Biochem. Sci.* **1**, 121. 3. Palatini, Dabbeni-Sala & Finotti (1984) *Biochem. Int.* **9**, 675. 4. ### Chlorpyrifos

This organophosphothioate-based insecticide (FW = 350.59 g/mol; CAS 2921-88-2; IUPAC: *O,O*-diethyl-*O*-(3,5,6-trichloro-2-pyridyl)phosphorothionate) undergoes hydrolysis to form the potent acetylcholinesterase inhibitor, chlorpyrifos oxon (See *Chlorpyrifos Oxon*). **Target(s):** acetylcholinesterase (1,4,8); cutinase (2); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (3); CYP6D1 (5); ATPase, Ca<sup>2+</sup>-stimulated (6); kinesin (7); acylglycerol lipase, or monoacylglycerol lipase (8); fatty acid amide hydrolase, or anandamide amidohydrolase (8); carboxyl-esterase (8-10); neuropathy target esterase (8). 1. Rigtierink & Kenaga (1966) *J. Agric. Food Chem.* **14**, 304. 2. Sebastian & Kolattukudy (1988) *Arch. Biochem. Biophys.* **263**, 77. 3. Larson & Kolattukudy (1985) *Arch. Biochem. ### Chlorsulfuron

This triazine derivative (FW = 357.78 g/mol; CAS 64902-72-3), also known as DPX-4189, and 2-chloro-*N*-[[[4-methoxy-6-methyl-1,3,5-triazin-2-yl)amino]carbonyl]benzenesulfonamide, is a selective pre- and post-emergence herbicide that is active on many grasses and broadleaf weeds (e.g., Canada thistle, wild buckwheat, hemp nettle). Chlorsulfuron noncompetitively inhibits purified barley acetolactate synthase with respect to pyruvate, yielding an initial apparent inhibition constant of 68 nM (calculated from the initial phase of inhibition) and a final steady-state dissociation constant of 3 nM. Inasmuch as acetolactate is needed in the valine and leucine synthesis, these findings appear to explain why low-level application (8-30 liters per hectare) is sufficient for chlorsulfuron herbicidal action. 1. Durner, Gailus & Boger (1994) *FEBS Lett.* **354**, 71. 2. Hill, Pang & Duggleby (1997) *Biochem. J.* **327**, 891. 3. Chang & Duggleby (1997) *Biochem. J.* **327**, 161. 4. ### 7-Chlortetracycline

This tetracycline-based antibiotic (FW = 478.89 g/mol; CAS 64-72-2), also named aureomycin, 7-chlorotetracycline and [4*S*-(4 $\alpha$ ,4 $\alpha$ ,5 $\alpha$ ,6 $\beta$ ,12 $\alpha$ )]-7-chloro-4-(dimethylamino)-1,4,4 $\alpha$ ,5,5 $\alpha$ ,6-11,12 $\alpha$ -octahydro-3,6,10,12,12 $\alpha$

-pentahydroxy-6-methyl-1,11-dioxo-2-naphthacene-carboxamide, inhibits protein biosynthesis by inhibiting the binding of molecules of aminoacyl-tRNA to the acceptor site (A-site) of ribosomes. **Target(s):** D-amino-acid oxidase (1,2); cystathionine  $\gamma$ -lyase, or cysteine desulfhydrase (3); guanosine-3',5'-bis(diphosphate) 3'-diphosphatase (4); HIV-1 reverse transcriptase (5); NADH:cytochrome oxidoreductase (6); NAD(P)H dehydrogenase (quinone) (7); polynucleotide phosphorylase, or polyribonucleotide nucleotidyltransferase (8); protein biosynthesis (9-12); RNA-directed DNA polymerase (5); peptidyltransferase (12); anhydrotetracycline monooxygenase (13). 1. Yagi (1971) *Meth. Enzymol.* **17B**, 608. 2. Meister & Wellner (1963) *The Enzymes*, 2nd ed., **7**, 609. 3. Bernheim & Deturk (1953) *Enzymologia* **16**, 69. 4. Richter (1980) *Arch. ### Chlorthalidone

This thiazide-like diuretic (FW = 338.76 g/mol; CAS 77-36-1; Symbol: CTDN), also known as chlortalidone and (*RS*)-2-chloro-5-(1-hydroxy-3-oxo-2,3-dihydro-1*H*-isoindol-1-yl)benzene-1-sulfonamide, as well as gigroton, novatalidon, and uridon, prevents sodium and chloride reabsorption by inhibiting the Na<sup>+</sup>/Cl<sup>-</sup> symporter within the distal convoluted tubule. It also decreases the glomerular filtration rate, further reducing its efficacy in patients with renal insufficiency. By increasing sodium ion delivery to the distal renal tubule, chlorthalidone indirectly increases potassium excretion via the sodium-potassium exchange mechanism (*i.e.*, apical ROM K<sup>+</sup>/Na<sup>+</sup> channels, coupled with basolateral Na<sup>+</sup>/K<sup>+</sup> ATPases). The latter effect can result in hypokalemia (and hypochloremia) as well as a mild metabolic alkalosis. Nonetheless, the chlorthalidone's diuretic efficacy is unaffected by the patient's acid-base balance. CTDN reduces pulse wave velocity, predictor of cardiovascular events (CVEs) and a measure of central aortic stiffness associated with endothelial dysfunction (2). On the other hand, CTDN fosters hypokalemia, hyperglycemia, sympathetic discharge, and the renin-angiotensin-aldosterone system, but these potentially harmful effects do not appear to materially reduce CTDN's ability to prevent CVEs (2). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Ford (1960) *Curr. Ther. Clin. Exp.* **2**, 347. 2. Roush, Buddharaju, Ernst & Holford (2013) *Curr. Hypertens. Rep.* **15**, 514.

### Cholate

This bile acid (FW<sub>free-acid</sub> = 408.58 g/mol; CAS 81-25-4; pK<sub>a</sub> = 6.4; Critical Micelle Concentration = 9-15 mM), also called 3 $\alpha$ ,7 $\alpha$ ,12 $\alpha$ -trihydroxycholelic acid, is a cholesterol metabolite found in bile and is often conjugated to glycine (as glycocholate) or taurine (as taurocholate). In the liver of cholate-fed rats, excess levels of bile salts activate a GAPDH-mediated transnitrosylation cascade that provides feedback

inhibition of bile salt synthesis (1). Cholate is an FDA-approved drug (Cholbam<sup>®</sup>) that is specifically indicated for the treatment of bile acid synthesis disorders resulting from single enzyme defects and for the adjunctive treatment of peroxisomal disorders, including Zellweger spectrum disorders in patients exhibiting manifestations of liver disease, steatorrhea or complications from decreased fat soluble vitamin absorption. Cholate's inhibition of scores of enzymes is likely to be due mainly to its indiscriminate and nonphysiologic detergent actions. **Use in Membrane Solubilization:** Cholate is used widely to prepare solubilized membrane-associated enzymes/proteins. Enzyme activity can usually be differentially solubilized with 0.4 to 1.2% sodium cholate. The classical example is Ephraim Racker's groundbreaking preparation of the proton-translocating F<sub>0</sub>F<sub>1</sub>-ATPase from bovine heart mitochondria by extraction of submitochondrial particles with cholate, followed by fractionation with ammonium sulfate, and sucrose gradient centrifugation in the presence of methanol, deoxycholate, and lysolecithin (2). 1. Rodríguez-Ortigosa, Celay, Olivas, *et al.* (2014) *Gastroenterology* **147**, 1084. 2. Serrano, Kanner & Racker (1976) *J. Biol. Chem.* **251**, 2453.

### Cholera Toxin

This bacterial enterotoxin (MW = 84 kDa; CAS 9012-63-9), also known as cholera toxin, is a multimeric protein produced by *Vibrio cholerae*. The toxin uses its B-subunit to bind to a specific receptor on sensitive cells, whereupon the A-subunit combines with cellular ADP-ribosylating factor to form an ADP ribosyltransferase that covalently modifies and permanently activates the heterotrimeric GTPase or GTP-regulatory protein in the adenylate cyclase pathway. Once ADP-ribosylated, the GS-GTP complex cannot reconver to its metabolic inactive form, and the adenylate cyclase remains active, overproducing cAMP, inhibiting sodium channels, and activating the chloride channel.

### Cholesterol

This principal steroid (FW = 386.66 g/mol; CAS 57-88-5; M.P. (anhydrous) = 148.5°C; slowly oxidizes in air), also named cholest-5-en-3 $\beta$ -ol, is found in free and esterified forms in all vertebrate tissues, particularly abundant in the plasma membrane and certain vesicles. Required to make and maintain animal cell membranes; cholesterol modulates membrane fluidity over the range of physiological temperatures. Its hydroxyl group interacts with the polar groups of membrane phospholipids and sphingolipids, whereas its hydrocarbon rings are deeply embedded in the membrane, lying alongside the nonpolar fatty-acid chains of other lipids. Cholesterol is also the precursor for most natural steroids. Excess cholesterol is harmful to humans, and randomised trials have shown that interventions that lower LDL cholesterol concentrations can significantly reduce the incidence of coronary heart disease and other major vascular events in a wide range of individuals. **Target(s):**  $\beta$ -glucuronidase (1); glutamate dehydrogenase (1); sphingomyelin phosphodiesterase, or sphingomyelinase (2,4,10); F<sub>1</sub>F<sub>0</sub> ATPase, weakly inhibited (3); steryl sulfatase (5,9); cholesterol  $\Delta$ -isomerase, or sterol  $\Delta$ 7,8-isomerase (6); cholesterol-5,6-oxide hydrolase (7); steryl- $\beta$ -glucosidase (8); retinyl-palmitate esterase (11); sterol esterase, or cholesterol esterase (12); ethanolaminophosphotransferase (13); bile-acid-CoA:amino acid *N*-acyltransferase (14); cycloartenol 24-C-methyltransferase (15); 27-hydroxycholesterol 7 $\alpha$ -monooxygenase (16). 1. ### Cholesteryl 3-Sulfate

This sulfated sterol (FW<sub>free-acid</sub> = 466.73 g/mol), also known as cholesterol 3-sulfate, inhibits pancreatic elastase. It has been identified in a variety of cells as well as in low-density lipoproteins. Cholesteryl 3-sulfate activates protein kinase C. **Target(s):** pancreatic elastase (1); deoxyribonuclease I (2); trypsin (2); plasmin (3); thrombin (3); cholesteryl ester transfer protein (4); cholesterol monooxygenase, side-chain cleaving, or CYP11A1 (5-7); 3-hydroxy-3-methylglutaryl-CoA reductase (8). **1.** Ito, Iwamori, Hanaoka & Iwamori (1998) *J. ### Choline

This nutritionally essential, water-soluble quaternary amine (FW<sub>free-base</sub> = 104.17 g/mol; CAS 62-49-7), also named trimethyl-β-hydroxyethylammonium, is a substituent of the cationic head-group of lecithin (phosphatidylcholine) as well as the neurotransmitter, acetylcholine. In liver, phosphatidylethanolamine *N*-methyltransferase catalyses the synthesis of PtdCho through the sequential methylation of phosphatidylethanolamine, using *S*-adenosylmethionine (AdoMet). It is also the major dietary source of methyl groups via synthesis of AdoMet. In brain, the high-affinity choline transporter (CHT1) is present on the presynaptic terminal of cholinergic neurons, taking up choline formed by the action of acetylcholinesterase. Na<sup>+</sup>-dependent uptake of choline by CHT1 is the rate-limiting step for resynthesis of acetylcholine. In view of its wide-ranging roles in human metabolism, choline deficiency is now thought to exacerbate liver disease, atherosclerosis, and certain neurological disorders. For women, the adequate choline intake is 425 mg/day; for adult men, 550 mg/day. (See also *Acetylcholine*) **Target(s):** phospholipase D (1); trimethylamine dehydrogenase (2); diamine oxidase (3); acetylcholinesterase (4,5,9,10); carnitine 3-dehydrogenase (6); adenylate cyclase (7); ethanolamine kinase (8,27-31); carnitine dehydratase (11); NTPase (12); *N*-acetylmuramoyl-L-alanine amidase (13); aryl-acylamidase (14); coagulation factor Xa15; choline sulfatase (16,17); glycerophosphocholine cholinephospho-diesterase (18-20); phosphoethanolamine/phosphocholine phosphatase, weakly inhibited (21); 4-nitrophenylphosphatase activity of Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (22); acid phosphatase (23); sinapine esterase (24); cholinesterase, or butyrylcholinesterase (25); acetylcholinesterase (26); hydroxylysine kinase, weakly inhibited (32,33); sucrose:sucrose fructosyltransferase (34); carnitine *O*-acetyltransferase (35,36); betaine:homocysteine *S*-methyltransferase (37). **1.** Kates & Sastry (1969) *Meth. ### Chondramide

These *Chondromyces crocatus*-derived actin polymerization inhibitors (FW<sub>Chondramide-A</sub> = 646.78 g/mol, R<sub>1</sub> = -OCH<sub>3</sub>, R<sub>2</sub> = -H; FW<sub>Chondramide-B</sub> = 681.23 g/mol, R<sub>1</sub> = -OCH<sub>3</sub>, R<sub>2</sub> = -Cl; FW<sub>Chondramide-C</sub> = 616.76 g/mol, R<sub>1</sub> = -H, R<sub>2</sub> = -H; MW<sub>Chondramide-D</sub> = 651.20 g/mol, R<sub>1</sub> = -H, R<sub>2</sub> = -Cl) are novel depsipeptides that are structurally related to the marine natural product, jasplakinolide (See *Jasplakinolide*). These cyclic depsipeptides were stabilize actin filaments, showing similarities to the action of phalloidin (See *Phalloidin*). Their cytostatic effects give IC<sub>50</sub> values ranging from 3 to 85 nM, on the same order of magnitude as that for cytochalasin D and jasplakinolide (1). Unlike the latter, however, the chondramides can be produced in large amounts by fermentation. All four chondramides readily enter the cells and cause severe shape malformations when applied during growth of unicellular green alga *Micrasterias denticulate* (2). **1.** Kunze, Jansen, Sasse, Höfle & Reichenbach (1995) *J. Antibiot. (Tokyo)* **48**, 1262. **2.** Holzinger & Lütz-Meindl (2001) *Cell Motil. Cytoskeleton* **48**, 87.

### Chorismate

This conjugate base of chorismic acid (FW<sub>free-acid</sub> = 226.19 g/mol), known systematically as (3*R*-4*R*)-3-[(1-carboxyethenyl)oxy]-4-hydroxy-1,5-cyclohexadiene-1-carboxylic acid, is a branch-point intermediate in the biosynthesis of L-tryptophan, L-tyrosine, and L-phenylalanine via the shikimate pathway in microorganisms, fungi, and higher plants (1-3). Chorismate is also a precursor in the biosynthesis of folate, enterochelin, ubiquinone, and menaquinone. Care should always be exercised when working with chorismate since it slowly decomposes to prephenate and *p*-hydroxybenzoate (2). Commercial preparations may also have these substances present in small amounts. **Target(s):** prephenate

dehydrogenase (5); glycogen synthase (6); 3-deoxy-7 phosphoheptulonate synthase, or 2-keto-3-deoxy-D-arabino-heptulosonate-7-phosphate synthase (7-9). 1. Gibson, Gibson, Doy & Morgan (1962) *Nature* **195**, 1173. 2. Gibson (1968) *Biochem. Prep.* **12**, 94. 3. Gibson & Jackson (1963) *Nature* **198**, 388. 4. Gibson (1999) *Trends Biochem. #### Chromium Adenosine 5'-Triphosphate Complex

$\Lambda$ -Isomer (or Lambda-Isomer) of Cr(III) Complex

$\Delta$ -Isomer (or Delta-Isomer) of Cr(III) Complex

These oxygen exchange-inert, trivalent metal ion-nucleotide complexes often inhibit many ATP-dependent enzymes by mimicking the geometries of one-to-one complexes of ATP with  $Mg^{2+}$ ,  $Ca^{2+}$ , and  $Mn^{2+}$  complexes (1,2). Because favorable solution conditions can be chosen to prevent the release and rebinding of the trivalent metal ion from ATP, each of the two bidentate isomers can exist in pseudo-axial and pseudo-equatorial forms. Determination of which of these stable metal ion-ATP complexes is a dead-end competitive inhibitor relative to the phosphoryl-donor substrate  $MgATP^{2-}$ ,  $CaATP^{2-}$ , or  $MnATP^{2-}$  allows the experimenter to infer the likely geometry of the enzyme-bound  $MgATP^{2-}$ ,  $CaATP^{2-}$ , or  $MnATP^{2-}$  (1). Because Cr(III) is paramagnetic, distances can be measured by measuring the effects of Cr(III) on the NMR signals of nearby atoms when the Cr(III)-nucleotide complex binds to the surface of a macromolecule (2). (See also *Exchange-Inert Complexes; specific chromium nucleotide*) **Target(s):** pyruvate carboxylase (3); hexokinase (4,8,10,11,13); aminoacyl-tRNA synthetases (5); pyruvate, orthophosphate dikinase (5);  $F_1$  ATP synthase; creatine kinase (7,9); acetate kinase (11); glycerol kinase (11,22); pyruvate kinase (11); 3-phosphoglycerate kinase (11, 14);  $Na^+/K^+$ -exchanging ATPase (12); glucokinase (13); formyltetrahydrofolate synthetase (15); ketohexokinase, or hepatic fructokinase (16);  $Ca^{2+}$ -ATPase (17); malyl-CoA synthetase, or malate:CoA ligase (18); apyrase (19); glucose-1-phosphate adenyltransferase (20); sulfate adenyltransferase (21). 1. #### Chromium(IV) Toxicity

Chromium is a trace metal of clinical importance in humans and has been widely used (as the radionuclide  $^{51}Cr$ ) to quantify blood cell pool sizes, intravascular kinetics, and red cell lifespan and turnover. Hexavalent chromium is also a widely occurring industrial agent and pollutant, occurs in the form of chromate ion.  $CrO_4^{2-}$  resembles sulfate ( $SO_4^{2-}$ ), both in its chemical structure and electronic charge, and chromate is taken up by human cells through the action of sulfate transporters. In normal human leukocytes,  $^{51}CrO_4^{2-}$  uptake is unidirectional over a 1 hr incubation with extracellular chromate concentrations up to 200  $\mu$ moles/liter (1). Chromate and phosphate also inhibit each other's uptake and translocation in arsenic hyperaccumulator *Pteris vittata* (2) In humans, Cr(III) is not transported into cells, but is generated from Cr(VI), with the latter first reduced Cr(V), itself a precursor of Cr(III). Incubation of Cr(VI) with ascorbate generates Cr(V), Cr(IV) and ascorbate-derived carbon-centered alkyl radicals, as well as formyl radicals (3). Hydrogen peroxide causes the generation of hydroxyl radicals (OH) and much higher levels of Cr(V), showing that OH $\cdot$  can be generated via a Cr(IV)-mediated Fenton-like reaction (i.e.,  $Cr(IV) + H_2O_2 \rightarrow Cr(V) + OH^- + OH\cdot$ ). Moreover, the presence of 1,10-phenanthroline and deferoxamine inhibit the formation of both OH $\cdot$  and Cr(V) from the reaction of Cr(VI) with ascorbate in the presence of  $H_2O_2$ . Electrophoresis also demonstrates that Cr(IV)/ascorbate-derived free radicals causes DNA double-strand breaks (3). Hydroxyl radicals generated by Cr(V) $^-$  and Cr(IV)-mediated Fenton-like reactions

likewise cause DNA double-strand breaks. Hydroxyl radicals generated by Cr(IV) and Cr(V) from H<sub>2</sub>O<sub>2</sub> cause hydroxylation of 2'-deoxyguanine to form 8-hydroxy-2'-deoxyguanine (3). 1. Lilien, Spivak & Goldman (1970) *J. Clin. Invest.* 49, 1551. 2. de Oliveira, Lessl, Gress, et al. (2015) *Environ. Pollut.* 197, 240. 3. Shi, Mao, Knaptan, et al. (1994) *Carcinogenesis* 15, 2475.

### Chromomycin A<sub>3</sub>

This antibiotic (FW = 1183.3 g/mol), also called toyomycin, from *Streptomyces griseus* and inhibits RNA biosynthesis in bacterial, fungi, and animal cells. It binds to the DNA minor groove (only in the presence of divalent cations like Mg<sup>2+</sup>) and can serve as a fluorescent DNA stain. The ultraviolet/visible spectrum has λ<sub>max</sub> values (in ethanol) of 230, 281, 304, 318, 330, and 412 nm (with corresponding molar extinction coefficients of 24500, 55500, 7080, 8320, 6920, and 11700 M<sup>-1</sup>cm<sup>-1</sup>, respectively).

**Target(s):** DNA-directed RNA polymerase (1,5,8); DNA-directed DNA polymerase (3,4,6); DNA topoisomerase II, or DNA gyrase (2,7). 1. Kajiro & Kamiyama (1967) *J. Biochem.* 62, 424. 2. ### Chromostatin-20

This eicosapeptide (Sequence SDESDGDRPQASPLG-PGP; MW = 1953.95 g; Isoelectric Point = 3.71) is released via protease activity on chromogranin A, a ubiquitous 48-kDa secretory protein present in adrenal medulla, anterior pituitary, central and peripheral nervous system, endocrine gut, thyroid, parathyroid, and endocrine pancreas. Chromostatin-20 inhibits the release of catecholamines from chromaffin cells (by activating a protein phosphatase in these cells) and inhibits secretagogue-induced Ca<sup>2+</sup> influx. 1. Galindo, Rill, Bader & Aunis (1991) *Proc. Natl. Acad. Sci. U.S.A.* 88, 1426.

### Chymostatin A

This is a high-affinity protease inhibitor (FW = 607.71 g/mol; CAS 9076-44-2), also named *N*-(*N*<sup>ε</sup>-carbonyl-Cpd-X-phenylalaninal)-L-phenylalanine, where Cpd is capreomycinidine, i.e., [*S,S*]-α-(2-iminohexahydro-4-pyrimidinyl)glycine, and X refers to L-leucyl (Chymostatin A), L-valyl (Chymostatin B), or L-isoleucyl (Chymostatin C) residues (1). Commercial chymostatin is typically a mixture of all three forms, with Chymostatin A the principal component. The chymostatins are potent inhibitors of chymotrypsin-like proteinases: e.g., chymases (*K<sub>i</sub>* ≈ 20–30 nM) and mast cell proteinase II (*K<sub>i</sub>* ≈ 0.6 μM). Chymostatin also

inhibits cysteine proteinases including members of the cathepsin family. One target, chymase, is a chymotrypsin-like protease that is abundant in secretory granules from mast cells. Chymase is a key enzyme in the local renin-angiotensin system (RAS) that generates angiotensin II (Ang II) in a manner that operates independently of angiotensin converting enzyme (ACE). **Properties:** Chymostatin is typically prepared as a 10 mM stock solution (in dimethylsulfoxide or glacial acetic acid), stored at -20° C (stable for months under these conditions), and used at 20-200 μM (final concentration). **Target(s):** chymotrypsin C, or caldesin (1); chymase (2,20,95,96,98-101); stratum corneum chymotryptic enzyme (3); Rt41A protease, *Thermus* strain (4); bacillopeptidase F (5); cerevisin, or yeast proteinase B (6,35,37,97); archaelysin (7); proteinase I of *Sulfolobus solfataricus* (7); carboxypeptidase D (8); proteasome endopeptidase complex (9,23,31,40-46); cell-associated endopeptidase of *Trichophyton* (10); falcipain (11); *Fasciola* cysteine endopeptidases (12); cathepsin L (13,20,69,70); picornain 3C (14,26-28,66); picornain 2A (15,26,64,65); peptidyl-dipeptidase Dcp (16,112); protease IV (17,85); chymotrypsin (18,20,29,33,34,87,96,103,106, 107); carboxypeptidase C, or carboxypeptidase Y (18,109-111); cathepsin B (18,20,72-80); cathepsin D (18); brachyuran (19,38); cathepsin G (20,96,103); seminin (20); cathepsin H (20,68); signal peptidase II (21); *Coccidiodes* endopeptidase (22); endopeptidase La (24); glycyI endopeptidase (25,67); elastase (29); leukocyte elastase, weakly inhibited (29); cysteine proteinase from *Trypanosoma cruzi* (30); sheddase (32); cathepsin A, weakly inhibited (36); pseudomonalysin, or pseudomonopepsin, *K<sub>i</sub>* = 45 nM (39); pitrilysin, or protease P, (47); serralysin, weakly inhibited (48); coccolysin (49); procollagen C-endopeptidase (50); mepirin A (51,52); thimet oligopeptidase (53); envelysin (54-57); neprilysin, weakly inhibited (58); polyporopepsin (59); candidapepsin (60); cruzipain (61); cathepsin V (62); cathepsin K (63); clostripain (71); kallikrein-8, or neuropsin (81); stratum corneum chymotryptic enzyme, kallikrein-7 (82); xanthomonolysin, or xanthomonopepsin, weakly inhibited (83); hepatic virus NS3 serine proteinase (84); signal peptidase I, or *Escherichia coli* (85); oligopeptidase B (86); streptogrisin A (87-89); granzyme B (90); furin (91); pancreatic elastase II (92); thermitase (93); subtilisin Sendai (94); tryptase (96); chymotrypsin (98-100,103); tissue kallikrein, dog (102); trypsin, gastric porcine (104); trypsin, gypsy moth (105); peptidyl-glycinamidase, or carboxamidopeptidase (108); cytosol alanyl aminopeptidase (113); tripeptide aminopeptidase (114); membrane alanyl aminopeptidase, or aminopeptidase N (115); protein-glutamate methyltransferase (116). 1. ### CI-1033

CI-1033

Cysteinyll Covalent Adduct

This Michael adduct-forming PKI (FW = 485.94; CAS 267243-28-7; Solubility: 20 mM in H<sub>2</sub>O; 100 mM in DMSO), also known as *N*-[4-[(3-chloro-4-fluorophenylamino)-7-[3-(4-morpholinyl)propoxy]-6-quinazolinyl]-2-propenamide, PD 183805, and Canertinib (1), and its congeners target epidermal growth factor receptor (EGFR) kinase irreversibly ( $k_{\text{inact}}/K_i = 10^5\text{--}10^7 \text{ M}^{-1}\text{s}^{-1}$ ) with a low specific reactivity ( $k_{\text{inact}} \leq 2.1 \times 10^{-3} \text{ s}^{-1}$ ) (2). The latter is compensated for by the inhibitors' high binding affinities ( $K_i < 1 \text{ nM}$ ). (See Fig. 2 and Table 1 of Reference-2). Quinazoline-based covalent drugs (*e.g.*, dacomitinib, afatinib, and CI-1033) are potent inhibitors of wild-type EGFR autophosphorylation in A549 tumor cells (IC<sub>50</sub> = 2–12 nM). The reversible binding affinity of EGFR covalent inhibitors correlates highly with antitumor cell potency. Because these inhibitors target a cysteine residue, the effects of its oxidation on enzyme catalysis and inhibitor pharmacology must be considered. CI-1033 is also classified as a pan-ErbB inhibitor for EGFR and ErbB2 with IC<sub>50</sub> values of 1.5 nM and 9 nM, respectively, and showing little or no inhibitory action on PDGFR, FGFR, InsR, PKC, or CDK1/2/4. Canertinib was the first irreversible protein kinase inhibitor to enter clinical trial. **1.** Smiail, Rewcastle, Loo, *et al.* (2000) *J. Med. Chem.* **43**, 1380. **2.** Schwartz, Kuzmic, Solowiej, *et al.* (2013) *Proc. Natl. Acad. Sci. U.S.A.* **111**, 173.

### CID29950007

This first-in-class G-protein signal-transduction inhibitor and cytostatic agent (FW = 485.38 g/mol), also known as 4-(5-(4-methoxyphenyl)-3-phenyl-4,5-dihydro-1H-pyrazol-1-yl)benzene-sulfonamide, antagonizes GTP binding to Cdc42 by binding at a location other than its active site and without affecting other GTPases, including the same-family small GTPases, Rac and Rho. In binding curves fitted to a hyperbolic one-site binding equation, the observed change in maximal fluorescence,  $B_{max}$ , indicated a noncompetitive, or allosteric, binding mode, wherein CID2950007 binds at a site that is topologically distinct from the GTP site. Moreover, when 3T3 fibroblasts were incubated with CID2950007 (10  $\mu$ M) for 1 h prior to bradykinin treatment, both the number and average length of cdc42-induced filopodia decreased significantly. (Note: Because CID2950007 must be dissolved in DMSO and subsequently diluted into aqueous solution, the inhibitory effect of the compound is demonstrated by its ability to counteract the stimulatory effects of both DMSO and the bradykinin cue.) CID2950007 also inhibited actin-mediated cell migration in a dose-dependent manner. At 3  $\mu$ M, CID2950007 reduced cell migration to less than 50% of the untreated control. CID2950007 likewise inhibits Cdc42-regulated and actin-mediated internalization of Sin Nombre virus. 1. Hong, Kenney, Phillips, *et al.* (2013) *J. Biol. Chem.* **288**, 8531.

### Cidofovir

This CMV DNA polymerase inhibitor and intravenous antiviral (FW = 265.16 g/mol; CAS 113852-37-2; Symbol: CDV), also named Vistide<sup>®</sup> and ({[(S)-1-(4-amino-2-oxo-1,2-dihydropyrimidin-1-yl)-3-hydroxypropan-2-yl]oxy)methyl}phosphonic acid, is primarily used as a treatment for cytomegalovirus (CMV) retinitis, an AIDS-associated infection (1,2). The minimum concentration required to reduce CMV plaque formation by 50% is 0.07  $\mu$ g/mL (2). CDV diphosphate, the putative antiviral metabolite of CDV, is a competitive inhibitor relative to dCTP and is an alternate substrate for human CMV DNA polymerase (3). The slower rate of incorporation of CDVpp is mainly due to the higher  $K_m$  value of CDVpp toward the enzyme-primer-template complexes (3). The pro-drug Brincidofovir (FW = 561.70 g/mol; CAS 444805-28-1; IUPAC: [(2S)-1-(4-amino-2-oxopyrimidin-1-yl)-3-hydroxypropan-2-yl]oxymethyl-(3-hexa decoxypropoxy)phosphinate) is active against adenoviruses, BK virus, herpes simplex viruses, and Ebola virus. Beyond its well-recognized antiviral activity, cidofovir exerts anticancer actions, both *in vitro* and with animal models, including T cell lymphoma (4). With human breast, colon, liver, lung, prostate, and thyroid carcinomas, CDV reduced expression of procaspase-3 and increased expression of PARP p85 fragment, indicating apoptosis can be induced in a virus-independent manner (5). It also increases the pro-apoptotic proteins p53, cytochrome c and caspase-3 as well as decreases the survival protein Bcl-x. Evidence of nuclear DNA fragmentation clearly indicated that CDV promotes apoptotic cell death. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Bronson, Ghazzouli, Hitchcock, Webb & Martin (1989) *J. Med. Chem.* **32**,

### Ciguatoxins

These structurally complex marine toxins (Ciguatoxin 1: FW = 1112.22 g/mol; CAS 11050-21-8), while found in a variety of fish and is the toxin involved in ciguatera fish poisoning, originate from the dinoflagellate *Gambierdiscus toxicus*. They participate in sodium channel activation, thereby stimulating the release of neurotransmitters (1,2). The ciguatoxins bind strongly to site-5 of the voltage-sensitive sodium channel. Purified ciguatoxin ( $EC_{50}$  = 0.62 ng/mL) stimulates neurotransmitter release, lowering the net accumulation of  $\gamma$ -aminobutyric acid and dopamine by brain synaptosomes (3). This effect is completely inhibited by tetrodotoxin ( $K_{0.5}$  = 4 nM). Electrophysiological studies on neuroblastoma cells indicate that ciguatoxin induces a membrane depolarization which is prevented by tetrodotoxin and which is due to an action that increases  $Na^+$  permeability (3). See also *Maitotoxin*, *Scaritoxin*; *Palytoxin*. **Target(s):**  $K^+$  channels (2). 1. Bidard, Vijverberg, Frelin, *et al.* (1984) *J. Biol. Chem.* **259**, 8353. 2. Birinyi-Strachan, Gunning, Lewis & Nicholson (2005) *Toxicol. Appl. Pharmacol.* **204**, 175. 3. Bidard, Vijverberg, Frelin, *et al.* (1984) *J. Biol. Chem.* **259**, 8353.

### Cilazapril & Cilazaprilat

This antihypertensive pro-drug (FW<sub>pro-drug</sub> = 417.31 g/mol; CAS 88768-40-5), also known by its tradenames Inhibace<sup>®</sup>, Vasace<sup>®</sup> and Dynorm<sup>®</sup>, and by its systematic name (4S,7S)-7-[[[(2S)-1-ethoxy-1-oxo-4-phenylbutan-2-yl]amino]-6-oxo-1,2,3,4,7,8,9,10-octahydropyridazino[1,2-a]diazepine-4-carboxylate], is metabolically de-esterified to cilazaprilat, which targets Angiotensin-Converting Enzyme-1, or ACE1 ( $IC_{50}$   $\approx$  2 nM) and is used to treat hypertension and congestive heart failure. Its tolerability profile is similar to other frequently prescribed antihypertensive drugs, such as sustained-release propranolol, enalapril, captopril, atenolol and hydrochlorothiazide. In addition to its blood pressure-lowering abilities, cilazapril can moderate the proliferative response seen in vessels after vascular injury caused by techniques such as ballooning. 1. Szucs (1991) *Drugs* **41**(Suppl 1), 18.

## Cilengitide

This first-in-class, RGD-containing cyclic peptide (FW = 588.46 g/mol; CAS 188968-51-6; *Sequence*: cyclo[RGDFV-]), also known as EMD 121974, is a selective  $\alpha_v$ -integrin inhibitor and angiogenesis disruptor (1). **Primary Mode of Inhibitory Action:** During angiogenesis,  $\alpha_v$ -integrins are overexpressed and in abundance on the endothelial cell surface, where they facilitate growth and survival of newly forming vessels. Accordingly, blocking  $\alpha_v$ -integrin function by disrupting ligand binding should produce an anti-angiogenic effect.  $\alpha_v$ -Integrins (*i.e.*,  $\alpha_v\beta_3$ ,  $\alpha_v\beta_5$ , and  $\alpha_5\beta_1$ ) bind with high affinity to arginyl-glycyl-aspartyl- (RGD-) registers present in the matrix proteins fibronectin, vitronectin, osteopontin, collagens, thrombospondin, fibrinogen, and von Willebrand factor. Cilengitide competitively inhibits (IC<sub>50</sub> = 0.3-5 nM, or 100-1000x more tightly than linear RGD-containing peptides) the binding of these proteins to  $\alpha_v\beta_3$ ,  $\alpha_v\beta_5$ , and  $\alpha_5\beta_1$  integrins, thereby acting as a vasculature-disrupting agent (2). Integrin binding to ligands in the ECM induces conformational changes in the integrin's structure and contributes to clustering of heterodimers into oligomers. These changes initiate intracellular signals through multiple activation of signaling proteins, a process known as "outside-in signaling" that controls cell polarity, cytoskeletal structure, gene expression and cell survival (2). Cilengitide treatment of Malignant Pleural Mesothelioma (MPM) cells results in detachment and subsequent death of anoikis-sensitive cells due to antagonism of  $\alpha_v\beta_3$  and  $\alpha_v\beta_5$ . 1. Burke, DeNardo, Miers, *et al.* (2002) *Cancer Res.* **62**, 4263. 2. Mas-Moruno, Rechenmacher & Kessler (2010) *Anticancer Agents Med. Chem.* **10**, 753. 3. Cheng, van Zandwijk & Reid (2014) *PLoS One* **9**, e90374.

## Cilnidipine

This dihydropyridine-class, N-type calcium channel blocker (FW = 492.52 g/mol; CAS 132203-70-4), also known by the code name FRC-8653 and systematically as *O*3-(2-methoxyethyl)-*O*<sup>5</sup>-[(*E*)-3-phenylprop-2-enyl]-2,6-dimethyl-4-(3-nitrophenyl)-1,4-dihydro-pyridine-3,5-dicarboxylate, is an antihypertensive agent with combined action as an angiotensin converting enzyme (ACE) inhibitor, a diuretic, and a  $\beta$ -adrenergic blocking agent (1). Cilnidipine is rapidly metabolized in human liver microsomes. Dehydrogenation of dihydropyridine ring by CYP3A (*or* cytochrome P-4503A) is crucial for cilnidipine elimination (2). 1. Yoshimoto, Hashiguchi, Dohmoto, *et al.* (1992) *J. Pharmacobiodyn.* **15**, 25. 2. Liu, Zhao, Li, Qian & Wang (2003) *Acta Pharmacol. Sin.* **24**, 263.

## Cilostamide

This cyclic nucleotide phosphodiesterase inhibitor (FW = 342.43 g/mol; CAS 68550-75-4), also known by its code name OPC 3689, targets human cGMP Phosphodiesterase 3B ( $K_i$  = 5 nM) and human cGMP Phosphodiesterase 3A ( $K_i$  = 20 nM) (1-10). Indeed, specific concentration-dependent inhibition of the photolabelling of PDE III by <sup>32</sup>P-cGMP is observed with the following PDE inhibitors: trequinsin (IC<sub>50</sub> = 13 nM), lixazinone (IC<sub>50</sub> = 22 nM), milrinone (IC<sub>50</sub> = 56 nM), cilostamide (IC<sub>50</sub> = 70 nM), siguazodan (IC<sub>50</sub> = 117 nM) and 3-isobutyl 1-methylxanthine (IBMX) (IC<sub>50</sub> = 3950 nM). This approach demonstrated that one can evaluate of the inhibitory effects of compounds on the photolabelling of platelet PDE III, thus providing a simple quantitative means of investigating their actions at a molecular level that avoids the need to purify the enzyme. Cilostamide also blocks induction of germinal vesicle breakdown (GVBD) by Akt, suggesting that the activity of a PDE is required for Akt action (3). Cilostamide also reduces DNA binding of p-Stat3, increases cAMP levels, and blocks the effects of insulin and IGF-1 on meiosis. Cilostamide activates K<sub>ATP</sub> channels, producing hyperpolarization in rat mesenteric artery studies. In F/B cells, cilostamide inhibits the IGF-1 induced phosphorylation of the apoptotic protein, Bad. **Target(s):** cAMP-PDE activity in cytosolic extracts from human monocytes is also much more sensitive to inhibition by rolipram than by cilostamide (2); ADP-induced platelet aggregation, IC<sub>50</sub> = 16.8  $\mu$ M; cGMP-inhibited phosphodiesterase, IC<sub>50</sub> = 70 nM 1. Tang, Jang & Haslam (1994) *Eur. J. Pharmacol.* **268**, 105. 2. Verghese, McConnel, Strickland *et al.* (1995) *J. Pharmacol. Exp. Ther.* **272**, 1313. 3. Andersen, Roth & Conti (1998) *J. Biol. ## Cilostazol

This antithrombotic agent and vasodilator (FW = 369.47 g/mol; CAS 73963-72-1), also known by its code name OPC-13013, its trade name Pietal<sup>®</sup>, and its systematic name 6-[4-(1-cyclohexyl-1H-tetrazol-5-yl)butoxy]-3,4-dihydro-2(1H)-quinolinone, was first approved in the United States in 1999 to reduce symptoms of intermittent claudication. It is a platelet aggregation inhibitor that selectively inhibits cyclic nucleotide phosphodiesterase III, IC<sub>50</sub> = 0.19  $\mu$ M (1-7). Pietal alleviates intermittent muscle ache associated with peripheral vascular disease. Cilostazol weakly inhibits type IV phosphodiesterase. Cilostazol also stimulates large-conductance, calcium-activated potassium channels. In N2a cells that express human APP (Swedish mutation N2aSwe) and endogenously overproducing A $\beta$ -peptide, cilostazol (3-30  $\mu$ M) treatment attenuates A $\beta$ -amyloid-induced tauopathy via activation of CK2 $\alpha$ /SIRT1 and suppresses tau acetylation (Ac-tau) and tau phosphorylation (P-tau) (8). Cilostazol also shows promise for treating microvascular complications associated with diabetes mellitus (9). **Target(s):** 3',5'-cyclic-nucleotide phosphodiesterase (1-7); adenosine uptake (4); 3',5'-cyclicGMP phosphodiesterase (6); phosphodiesterase 2 (6); phosphodiesterase 3A (6,7); phosphodiesterase 3B (6); phosphodiesterase 4 (6); phosphodiesterase 5 (6); phosphodiesterase 7 (6). 1. ## Cimetidine

This substituted guanidine (FW = 252.34 g/mol; CAS 51481-61-9;  $pK_a$  = 6.8; Solubility: 0.11 g/mL H<sub>2</sub>O, increasing upon addition of dilute HCl), commonly known by its proprietary name Tagamet™ and systematically referred to as *N*-cyano-*N'*-methyl-*N''*-[2-[[[(5-methyl-1*H*-imidazol-4-yl)methyl]thio]ethyl]guanidine, is used in the treatment of ulcers and gastrointestinal bleeding. Originally classified as a histamine H<sub>2</sub>-receptor antagonist, cimetidine has been reclassified as an inverse agonist. It inhibits gastric acid secretion and reduces pepsin release. In addition, cimetidine inhibits the expression of E-selectin on endothelial cell surfaces and thus acts to block tumor cell adhesion. For his work on antagonists, including cimetidine, Sir James Black shared the 1988 Nobel Prize in Physiology or Medicine. **Target(s):** aldehyde oxidase (1,2); diamine oxidase (3,16); CYP2C9 (4); CYP2C19 (4); CYP2D6 (4,5); CYP3A (4,12,13); CYP1A2 (5,11,14); CYP3A4/5 (4,5); alcohol dehydrogenase (6,10,18); CYP2C6 (7); CYP2C11 (7-9,14); CYP2B1/2 (14); CYP2A1/2 (14); CYP2E1 (15); alkaline phosphatase (16); phospholipase A<sub>2</sub> (17); histamine H<sub>2</sub> receptor (19,20). 1. ## Cinchonine

This photosensitive alkaloid (FW<sub>free-base</sub> = 294.40 g/mol; CAS 118-10-5) from the bark of a number of trees (*e.g.*, *Cinchona succiruba* and *C. micrantha*) is structurally related to quinine. Like quinine, it has been used as an antimalarial agent. Cinchonine also induces apoptosis. **Target(s):** amine oxidase (copper-containing) (1,2); choline transport (3,6); Ca<sup>2+</sup> influx (4); multidrug resistance (MDR) efflux pump, stereospecifically and noncompetitively, thereby potentiating the action of drugs that are typically transported by this pump (5); strictosidine synthase (7). 1. Pec & Frebort (1991) *J. Enzyme Inhib.* **4**, 327. 2. Zajoncova, Frebort, Luhova, *et al.* (1999) *Biochem. Mol. Biol. Int.* **47**, 47. 3. Ebel, Hollstein & Gunther (2002) *Biochim. Biophys. ## Cinerins

Cinerin I

Cinerin II

These botanical insecticides are active constituents in the pyrethrum flowers *Chrysanthemum cinerariaefolium* or *Pyrethrum cinerariaefolium*. Cinerin I (FW = 316.44 g/mol) is a viscous liquid that is inactivated in air. It should be stored in the cold and in the dark. Cinerin II (FW = 360.45 g/mol) is likewise a viscous liquid that is inactivated by air. Both are practically insoluble in water. Note that the term cinerins also refers to a mixture of I and II. In addition, both cinerins are components of the pyrethrins. **See also Pyrethrins**

## Cinnamate (Cinnamic Acid)

trans-Cinnamate

cis-Cinnamate

This naturally occurring acid (FW<sub>free-acid</sub> = 148.16 g/mol; CAS 621-82-9; M.P. = 133°C;  $pK_a$  = 4.46 at 25°C), also known as (2*E*)-3-phenylpropenoic acid, is a product of the reactions catalyzed by phenylalanine ammonia-lyase and cinnamoyl-CoA:phenyllactate CoA-transferase. Cinnamic acid is a substrate for *trans*-cinnamate 4-monooxygenase, *trans*-cinnamate 2-monooxygenase, and cinnamate β-D-glucosyltransferase. **Target(s):** carboxy-peptidase C, or carboxypeptidase Y (1,12,13); melilotate 3-monooxygenase (2); tyrosinase, or monophenol monooxygenase (3,5,16-18); D-amino-acid oxidase,  $K_i$  = 0.56 mM (3,7); chymotrypsin (4); esterase (6); phenylpyruvate tautomerase (the *cis*-isomer is a stronger inhibitor than *trans*-cinnamate:  $K_i$  = 83 μM and 5.5 mM, respectively) (8,9); benzoylformate decarboxylase, inhibited by *trans*-cinnamate (10); carboxypeptidase A (11); diphosphomevalonate decarboxylase (14); phospho-mevalonate kinase (14); quinate *O*-hydroxy-cinnamoyltransferase (15); benzoate 4-monooxygenase, inhibited by *trans*-cinnamate (19); *trans*-cinnamate 4-monooxygenase, inhibited by *cis*-cinnamate (20); catechol oxidase (21); polyphenol oxidase (21). 1. **Cinnamycin**

This lanthionine-containing peptide antibiotic (FW = 2041.29 g/mol; CAS 110655-58-8) from *Staphylococcus cinnamoneus* is a bacteriocin that is effective against *Bacilli*, *Clostridia* and *Mycobacterium* (1,2). The sequence of this antibiotic is shown with single uppercase letters referring to the standard aminoacyl residues, Asp(OH) to hydroxyaspartate, Ala-S-Ala to lanthionine, Abu-S-Ala to  $\beta$ -methyl-lanthionine, and Ala-NH-K to lysinoalanine. **Primary Mode of Action:** Cinnamycin binds to phosphatidylethanolamine within cell membranes and induces cytolysis by means of transbilayer lipid movement, resulting in exposure of PE to the outer leaflet of the plasma membrane. Tight binding of cinnamycin to PE provides a means for detecting PE. Cinnamycin indirectly inhibits phospholipase A<sub>2</sub> (3). 1. Fredenhagen, Märki, Fendich, *et al.* (1991) in *Nisin and Novel Lantibiotics* (Jung & Sahl, eds.), p. 131, Escrom Publ., Leiden. 2. Makino, Baba, Fujimoto, *et al.* (2003) *J. Biol. Chem.* **278**, 3204. 3. Märki, Hanni, Fredenhagen & van Oostrum (1991) *Biochem. Pharmacol.* **42**, 2027.

**Cinnarizine**

This calcium channel blocker and antihistamine (FW = 368.51 g/mol; CAS Registry = 298-57-7), also known by the trade names Stugerone<sup>®</sup> and Stunarone<sup>®</sup> as well as systematically as (*E*)-1-(diphenylmethyl)-4-(3-phenylprop-2-enyl)piperazine, is an antihypertensive agent used to relieve nausea and vomiting due to motion sickness and chemotherapy as well as vertigo, tinnitus, and Meniere's syndrome. By virtue of its ability to promote cerebral blood flow, cinnarizine is used to treat cerebral apoplexy, post-trauma cerebral symptoms, and cerebral arteriosclerosis.

**CINPA 1**

This potent CAR antagonist (FW = 395.49 g/mol; CAS 102636-74-8), also named Ethyl [5-[(diethylamino)acetyl]-10,11-dihydro-5H-dibenz[*b,f*]azepin-3-yl]carbamate, targets the constitutive androstane receptor (CAR) and pregnane X receptor (PXR). Constitutive androstane receptor (CAR) and pregnane X receptor (PXR) are xenobiotic sensors that enhance the detoxification and elimination of xenobiotics and endobiotics by modulating the expression of genes encoding drug-metabolizing enzymes and transporters. Elevated levels of drug-metabolizing enzymes and efflux transporters (arising from CAR activation in various cancers) promote the elimination of chemotherapeutic agents, leading to reduced therapeutic effectiveness and acquired drug resistance. **Target(s):** CINPA-1 exhibits

>90-fold selectivity for CAR over pregnane X receptor (PXR). CINPA-1 binding to CAR is selective over a panel of other nuclear receptors including FXR, LXR, Peroxisome Proliferator-Activated Receptor- $\gamma$ , or PPAR $\gamma$  and RXR. 1. Cherian, Lin, Wu & Chen (2015) *Mol. Pharmacol.* **87**, 878.

**Ciprofloxacin**

This second-generation fluoroquinolone antibiotic (FW<sub>free-base</sub> = 331.35 g/mol; CAS 85721-33-1), also known as Cipro and by its IUPAC name, 1-cyclopropyl-6-fluoro-4-oxo-7-(piperazin-1-yl)quinoline-3-carboxylic acid, achieves its bacteriocidal action by inhibiting DNA topoisomerase II, or DNA gyrase (1-4). **Mechanism of Action:** Genetic and biochemical studies have demonstrated that the A-subunit of DNA gyrase is the ciprofloxacin target, and inhibition of purified DNA gyrase correlates with antibacterial activity. When administered orally, ciprofloxacin exhibits 70% bioavailability, attaining peak serum levels (1.5–2.9  $\mu$ g/mL) after a single 500-mg dose. Ciprofloxacin is considerably more active against the Gram-negative bacteria tested than other agents tested. In most cases, body fluid/tissue concentrations equal or exceed those in concurrent serum samples. **Ciprofloxacin Resistance:** While gentamicin-resistant bacteria (*Enterobacteriaceae*, *Pseudomonas aeruginosa*, and methicillin-resistant *Staphylococcus aureus*) are highly susceptible to Cipro, but resistance has also emerged. Mutations are selected first in DNA gyrase within gram-negative bacteria and topoisomerase IV within gram-positive bacteria (5). Additional resistance-conferring mutations occur in genes controlling Cipro accumulation, and further resistance is mediated by plasmids producing Qnr, a 218-residue protein belonging to the pentapeptide repeat family that shares sequence homology with McbG immunity protein and that protects DNA gyrase from the action of microcin B17, a 3.1-kDa bactericidal peptide. **Effect on Protein Tyrosine Kinase Inhibitors on Ciprofloxacin Phototoxicity:** TKI anticancer agents, such as gefitinib and imatinib, inhibit ABCG2 transporter-mediated drug efflux at the blood-retinal barrier, where it limits retinal exposure to phototoxic compounds, such as ciprofloxacin and other fluoroquinolone-class antibiotics (*e.g.*, amifloxacin, balofloxacin, difloxacin, gemifloxacin, levofloxacin, norfloxacin) (6). Concurrent administration of ABCG2 inhibitors with photoreactive fluoroquinolone antibiotics may result in retinal damage. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Flamm, Vojtko, Chu, *et al.* (1995) *Antimicrob. Agents Chemother.* **39**, 964. 2. Gruger, Nitiss, Maxwell, *et al.* (2004) *Antimicrob. **Cisplatin**

This yellow-colored anti-cancer drug (FW = 300.05 g/mol; CAS 15663-27-1; *Symbol:* cis-Pt(NH<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub>), also known as Platinol<sup>®</sup>, cis-diamminedichloroplatinum (II), and cis-dichloro-diammineplatinum(II), is a powerful, intravenously administered antineoplastic agent and mutagen. **Chemical Properties:** This electroneutral, four coordinate platinum complex has two chloride ion ligands situated adjacent to one another. As in organic chemistry, the prefix *cis* indicates that the chloro groups are next to each other, an apparent requirement for its anticancer action. Although no longer ionic, chloride ligands of Pt(NH<sub>3</sub>)<sub>2</sub>Cl<sub>2</sub> retain some of their electronic charge

after forming a coordinate covalent bond with the central metal ion. Other similar antineoplastic have bromide, carbonate, oxalate or malonate as leaving groups. Such complexes are stable enough to reach their intended target, before nonenzymatic hydrolysis occurs:

When administered in physiologic saline, the abundant free chloride ion rebinds to *cis*-monochlorodiammine platinum(II), preventing water molecules from occupying the metal ions inner coordination site. (Other platinum(II) complexes, such as *cis*-dinitratodiammineplatinum(II) hydrolyze more rapidly, with loss of nitrate groups and are ineffective as anticancer agents.) Reaction with DNA, the main biologic target, requires disubstitution, presumably as a sequence of two mono-substitution reactions. Most ligand substitution reactions occur by the Eigen-Tamm mechanism, where the anion leaves, creating a vacant site (or inner coordination sphere) for reaction with DNA. The anticancer action of cisplatin stems from the relative ease of chlorine ligand substitution with nucleophilic species, such as purine and pyrimidine bases of DNA. **History:** The structure of cisplatin was determined in 1893 by the Swiss chemist Alfred Werner, who formulated the basic rules of metal ion coordination chemistry. He predicted that ammonia bonds to a metal ion like Pt(II) by donating its lone pair of electrons in a dative bond (later termed a *coordinate covalent bond* by G. N. Lewis), with an overall bond-strength comparable to many covalent bonds. Werner's discovery of the square-planar geometry of cisplatin was abetted by the relatively poor reactivity of square planar Pt(II) compounds, unless situated between pairs of nearby nucleophiles. **Primary Mode of Action:** Cisplatin is primarily a DNA-damaging anticancer drug, forming different types of bifunctional adducts with cellular DNA, most often reacting with adjacent *N*<sup>7</sup>-positions guanine and forming 1,2-intrastrand cross-links (1,2). The 1,2-intrastrand adducts produced by cisplatin causes DNA kinking and leads to thermal destabilization. Cisplatin stimulates the immune response by activating macrophages and other cells of the immune system. It increases cellular NF- $\kappa$ B content. Mismatch repair proteins and some damage-recognition proteins may show selectivity, contributing to the differences in its cytotoxicity and tumor range relative to other platinum-based antineoplastic agents. The ATP-hydrolysis motif in the mechanoenzyme RAD51D is required for resistance to DNA interstrand crosslinking agents and interaction with RAD51C (3). **Other Biological Effects:** Cisplatin induces structural lesions in DNA that sequester high-mobility group (HMG) proteins that are important inflammatory mediator, thereby triggering programmed cell death. Histone H2AX phosphorylation occurs in response to replication fork damage caused by cisplatin-induced DNA lesions, most likely interstrand crosslinks (4). Moreover, prior treatment with NH<sub>4</sub>Cl increases the rate of cell apoptosis and activates caspase-3 (5). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** acetylcholinesterase (6); thioredoxin reductase (4,7); glutaredoxin (8); thioredoxin (7); *PsI* restriction endonuclease, type II site-specific deoxyribonuclease (9); dihydropteridine reductase (10); deoxyribonuclease (10); glutathione peroxidase (12); glyceraldehyde-3-phosphate dehydrogenase (13); Ca<sup>2+</sup>-transporting ATPase (14); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (14); Mg<sup>2+</sup>-ATPase (14); adenosylhomocysteinase (15); DNA-directed RNA polymerase (16); bacteriophage T7 RNA polymerase (16); RNA polymerase II (16); arylamine *N*-acetyltransferase (17); ribonucleoside diphosphate reductase (18); diferric-transferrin reductase (19). 1. ### Citalopram

This orally available, single-daily-dose, selective serotonin reuptake inhibitor, or SSRI (FW = 324.39 g/mol; CAS 59729-33-8; Code Name = Lu 10-171), marketed under the trade names Celexa<sup>TM</sup>, Cipramil<sup>TM</sup>, Cipram<sup>TM</sup>, Cital<sup>TM</sup>, Citox<sup>TM</sup>, Dalsan<sup>TM</sup>, Emocal<sup>TM</sup>, Recital<sup>TM</sup>, Sepram<sup>TM</sup>, and Seropram<sup>TM</sup>, and named systematically as (*RS*)-1-[3-(dimethylamino)propyl]-1-(4-fluorophenyl)-1,3-dihydroisobenzofuran-5-carbonitrile, is a FDA-approved drug for treating major depression. Only the (*S*)-(+)-enantiomer (shown above) has the desired clinical effect. **Mode of Action:** The primary pharmacological action of SSRIs is presynaptic inhibition of serotonin (5-HT) reuptake, thereby increasing the concentration of this amine in the synaptic cleft. Serotonin exerts its effects through interactions with any of seven distinct 5-HT receptor families, and interaction between serotonin and post-synaptic receptors mediates a wide range of its actions. Citalopram potentiates serotonergic transmission considerably, possibly by producing very strong inhibition of uptake without simultaneous blockade of the postsynaptic 5-HT receptors (1). Significantly, the antidepressant responses to selective serotonin reuptake inhibitors (citalopram or paroxetine) are abolished in mice unable to synthesize histamine due to either targeted disruption of histidine decarboxylase gene (or *HDC*<sup>-/-</sup>) or injection of  $\alpha$ -fluoromethylhistidine, a suicide inhibitor of this enzyme (2). Such findings demonstrate that SSRIs selectively require the integrity of the brain histamine system to exert their preclinical responses. (See also *Paroxetine*;  $\alpha$ -Fluoromethyl histidine) **Metabolism:** Citalopram metabolites show weak 5-HT uptake-inhibiting properties and are devoid of noradrenaline uptake-inhibiting properties. In this respect, it clearly differs from the tricyclic antidepressants, which possess effects both on 5-HT and NA uptake (3). Inhibition of 5-HT uptake *in vitro* is competitive and not connected with an increased efflux of 5-HT. Lu10-171 and its metabolites only inhibit DA uptake in extremely high concentrations and in this respect they are even weaker than chlorimipramine and other tricyclic thymoleptics (3). 1. ### Citrate (Citric Acid)

This tricarboxylic acid (FW<sub>free-acid</sub> = 192.13 g/mol; CAS 77-92-9; M.P. = 153°C), which is a key intermediate in the Tricarboxylic Acid and Glyoxylate Cycles, has pK<sub>a</sub> values of 3.128, 4.761, and 6.396 at 25°C, with corresponding dpK<sub>a</sub>/dT values of -0.0024, -0.0016, and ~0, respectively. Citrate is frequently used as a metal-ion chelator, binding magnesium, calcium, manganese, iron, copper, nickel, cobalt, and zinc ions. Formation constants (i.e.,  $K = [\text{Me}^{2+}\cdot\text{Citrate}]/[\text{Me}^{2+}][\text{Citrate}]$ ) for both Mg<sup>2+</sup> and Ca<sup>2+</sup> are ~4000 M<sup>-1</sup>, and many Mg<sup>2+</sup>- and Ca<sup>2+</sup>-dependent processes as well as metalloenzymes are inhibited at elevated citrate levels. Depletion of plasma calcium ion blocks blood clotting, and citrate is widely used as an anticoagulant in blood collection. It enjoys the advantage that, upon infusion, its rapid metabolism fully restores normal clotting kinetics.

## Citroviridin

This polyene neurotoxin (FW = 402.49 g/mol; CAS 25425-12-1), first isolated from moldy rice (a source of molds in the genera *Penicillium* and *Aspergillus*), is a strong inhibitor of  $F_1$  ATPase ( $K_i = 4.5 \mu\text{M}$ ). Note that citroviridin and isocitroviridin are interconverted by light. Ambient laboratory illumination is sufficient to generate substantial amounts of isocitroviridin. Isocitroviridin has without effect on  $F_1$  ATPase.

**Target(s):** ATP synthase (1-4); transketolase (5). 1. Linnett & Beechey (1979) *Meth. Enzymol.* **55**, 472. 2. Sayood, Suh, Wilcox & Schuster (1989) *Arch. Biochem. Biophys.* **270**, 714. 3. ## L-Citrulline

This Urea Cycle intermediate (FW = 175.19 g/mol;  $pK_a = 2.43$  and  $9.69$ ; water-soluble, but insoluble in methanol, ethanol, and diethyl ether), also known as 2-amino-5-ureidovaleate and  $N^2$ -carbamoylornithine, was first identified in the watermelon *Citrullus vulgaris* (1). Citrulline is biosynthesized through the action of ornithine transcarbamylase (Reaction: Ornithine + Carbamoyl-P  $\rightleftharpoons$  L-Citrulline +  $P_i$ ). It is also formed by the action of nitric oxide synthases (Reaction: 2 L-Arginine + 3 NADPH +  $H^+$  + 4  $O_2 \rightleftharpoons$  2 L-Citrulline + 2 Nitric Oxide + 4  $H_2O$  + 3  $NADP^+$ ), and citrulline-specific antibodies may be used to detect sites of nitric oxide formation. While stable in acids, citrulline is unstable in bases, producing ornithine, ammonia, and carbon dioxide. **Target(s):** *N*-acetylglutamate kinase (2,6,14,15); arginine decarboxylase (3,11,12); arginase, weakly inhibited (4,13); saccharopine dehydrogenase (5,7); arginyl-tRNA synthetase (8); argininosuccinate lyase (9,10); amino-acid *N*-acetyltransferase (16). 1. ## CK666

This cell-permeable actin cytoskeleton assembly inhibitor (FW = 296.34 g/mol; CAS 442633-00-3; Solubility:  $\geq 25$  mg/mL DMSO), also known as CK-0944666 and 2-fluoro-*N*-[2-(2-methyl-1*H*-indol-3-yl)ethyl] benzamide, targets the actin-related protein Arp3,  $IC_{50} = 5-17 \mu\text{M}$ , inserting into its hydrophobic core, stabilizing an inactive state, and preventing rearrangement of the Arp2/3 actin filament-initiation complex (1). During actin filament branch formation, Arp2 moves 31 Å relative to Arp3 from its position in inactive Arp2/3 complex, and the location of another inhibitor (CK-636) in the binding pocket between Arp2 and Arp3 suggests that both CK-636 and CK-666 lock Arp2/3 into an inactive conformation. CK666 prevents Arp3 from accessing its "short-pitch" conformation in the Arp2/3's active filament assembly-promoting state (2). CK666 reduces formation of actin filament rocket tails by *Listeria* in infected SKOV3 cells (1), suggesting that, at least in these cells, the latter process involves the Arp2/3 complex. CK666 also alters cortactin's interaction with Arp2/3 complex, which plays a role in regulating the activity of the Epithelial  $Na^+$  Channel (ENaC), a cellular component that apparently interacts with the cortical cytoskeleton (3). CK666 potently disrupts the sub-cortical meiotic spindle position in treated MII oocytes, with the resulting spindles detached from the cortex, re-positioning themselves near the center of the oocytes (4). Such findings suggest that the asymmetric MII spindle position is dynamically maintained as a result of balanced forces governed in part by Arp2/3 effects on actin filament formation. 1. ## CK0106023

This novel, quinazolinone-based kinesin spindle inhibitor, or KSI (FW = 595.97 g/mol; CAS 336115-72-1; chiral center indicated by asterisk) targets the human Eg5, a kinesin that plays an essential role in forming bipolar mitotic spindles. Eg5 is required for cell cycle progression through mitosis, and addition of CK0106023 gives rise to mitotic arrest and growth inhibition in several human tumor cell lines. CK0106023 is an allosteric kinesin spindle protein inhibitor that arrests the motor domain ATPase,  $K_i = 12$  nM. Among the five kinesins tested, CK0106023 showed clear specificity for Eg5. In tumor-bearing mice, CK0106023 exhibited antitumor activity comparable to or exceeding that of paclitaxel and caused the formation of monopolar mitotic figures identical to those produced in cultured cells. (See also *Monastrol*; *Terpendole E*; *S-Trityl-L-Cysteine*) 1. Sakowicz, Finer, Beraud, et al. (2004) *Cancer Res.* **64**, 3276.

**Cladribine**

This antineoplastic agent (FW = 285.69 g/mol; CAS 4291-63-8), also known as 2-chloro-2'-deoxyadenosine, is an anti-leukemic drug with immunosuppressive properties. Cladribine 5'-triphosphate is enzymatically incorporated into DNA in place of dATP. The action of DNA polymerases with this modified DNA is significantly reduced and the modified DNA is also more susceptible to 3'→5' exonucleases. Cladribine is resistant to adenosine deaminase and inhibits DNA repair. Its triphosphate inhibits ribonucleotide reductase. Do not confuse cladribine with 2'-chloro-2'-deoxyadenosine. **Target(s):** DNA biosynthesis; ribonucleotide reductase (2,3,5); adenosine deaminase, by the  $\alpha$ - and  $\beta$ -isomers of cladribine, with  $K_i$  values of 60 and 21  $\mu\text{M}$ , respectively (4); deoxynucleoside kinase (6); deoxycytidine kinase (6). 1. **o-Cl-Amidine**

This protein arginine deiminase (PAD) inhibitor (FW = 424.80 g/mol; CAS 913723-61-2; Soluble in methanol), systematically named as  $N^{\omega}$ -(2-carboxyl)benzoyl- $N^2$ -(2-chloro-1-iminoethyl)-L-ornithine amide, is a potent irreversible inhibitor that covalently modifies an active-site cysteine residue. Catalyzing posttranslational citrullination (*i.e.*, conversion of protein guanidinium groups of into ureido groups), PADs transform arginine residues into citrulline residues. By removing positively side-chains from proteins, these deiminases fundamentally alter the strength and/or specificity of regulatory interactions between target proteins with their intracellular binding partners. These enzymes (of which there are five in humans: PAD-1, PAD-2, PAD-3, PAD-4, and PAD-6) regulate gene transcription, cellular differentiation, as well as the innate immune response, and they are up-regulated in a number of human diseases, including rheumatoid arthritis, ulcerative colitis, and cancer. (1) Relevant inhibitor parameters are: PAD-1 ( $\text{IC}_{50}$  = 0.84  $\mu\text{M}$ ;  $k_{\text{inact}}$  = ND;  $K_i$  = ND;  $k_{\text{inact}}/K_i$  = 106400  $\text{M}^{-1}/\text{min}^{-1}$ ); PAD-2 ( $\text{IC}_{50}$  = 6.2  $\mu\text{M}$ ;  $k_{\text{inact}}$  = ND;  $K_i$  = ND;  $k_{\text{inact}}/K_i$  = 14100  $\text{M}^{-1}/\text{min}^{-1}$ ); PAD-3 ( $\text{IC}_{50}$  = 0.69  $\mu\text{M}$ ;  $k_{\text{inact}}$  = 0.3  $\text{min}^{-1}$ ;  $K_i$  = 29  $\mu\text{M}$ ;  $k_{\text{inact}}/K_i$  = 10345  $\text{M}^{-1}/\text{min}^{-1}$ ); and PAD-4 ( $\text{IC}_{50}$  = 2.2  $\mu\text{M}$ ;  $k_{\text{inact}}$  = 0.5  $\text{min}^{-1}$ ;  $K_i$  = 13  $\mu\text{M}$ ;  $k_{\text{inact}}/K_i$  = 38000  $\text{M}^{-1}/\text{min}^{-1}$ ) (2). Cl-amidine is cytotoxic to HL-60, MCF7, and HT-29 cancer cell lines, with  $\text{IC}_{50}$  values of 0.25, 0.05 and 1  $\mu\text{M}$ , respectively (3). (See also *o-F-Amidine*) 1. **(3R,5R)-Clavulanate (Clavulanic Acid)**

This oxapenicillin analogue (FW<sub>free-acid</sub> = 199.16 g/mol; CAS RegistryNumber = 58001-44-8; Symbol: CA), also known as [2R-(2 $\alpha$ ,3Z,5 $\alpha$ )]-3-(2-hydroxyethylidene)-7-oxo-4-oxa-1-azabicyclo[3.2.0]-heptane-2-carboxylic acid, from *Streptomyces clavuligerus*, is a weak antibiotic that greatly improves the effectiveness of  $\beta$ -lactam antibiotics by inhibiting antibiotic deactivation by Class A serine  $\beta$ -lactamases (penicillinases) (1-14). It was the first naturally-occurring, oxygen-containing, fused  $\beta$ -lactam identified. **Mechanism of Action:** Clavulanate is destroyed by  $\beta$ -lactamases and simultaneously inhibits it by producing two catalytically inactive forms (1). One of these is transiently stable and decomposes to free enzyme ( $k = 3.8 \times 10^{-3} \text{ s}^{-1}$ ), while the other corresponds to an irreversibly inactivated form. The transient complex is formed from the Michaelis complex at a rate ( $k \approx 3 \times 10^{-2} \text{ s}^{-1}$ ) which is some threefold faster than the rate of formation of the irreversibly inactivated complex. The transient complex is, therefore, the principle enzyme form present after short time periods. In the presence of excess clavulanate, however, all the enzyme accumulates into the irreversibly inactivated form. The number of clavulanate turnovers occurring prior to complete inactivation is 115 (1). Both the transiently inhibited and the irreversibly inactivated species show a marked increase in the absorbance at 281 nm that is proportional to the loss in enzyme activity (2). Hydroxylamine treatment of irreversibly inactivated enzyme restores about one-third of the catalytic activity, with a concomitant decrease in absorbance at 281 nm. Polyacrylamide isoelectric focusing of the irreversibly inactivated enzyme shows three bands of approximately equal intensity, different from native enzyme. Upon hydroxylamine treatment, one of the three bands disappears and now focuses identically with native enzyme. **Augmentin<sup>®</sup>:** This combination antibiotic therapy (CAS 74469-00-4), innovated by Beecham Pharmaceuticals in the mid-1980s, uses amoxicillin and clavulanic acid for the treatment of a wide range of bacterial infections (15). Augmentin restores efficacy against amoxicillin-resistant bacteria, including *Klebsiella*. Augmentin is not effective against *Pseudomonas* infections. **Other Actions:** Although the  $\beta$ -lactam antibiotic ceftriaxone (CTX) reduces cocaine reinforcement and relapse by activating the glutamate transporter subtype 1 (GLT-1), its required IV administration and poor brain penetrability limit its therapeutic utility for indications related to CNS diseases. An structural analogue of CTX that retains the  $\beta$ -lactam core required for GLT-1 activity, but displays enhanced brain penetrability and oral activity relative to CTX (16). GLT-1 transporter expression in the nucleus accumbens of mice treated with repeated CA (1-10 mg/kg) is enhanced relative to saline-treated mice. Repeated CA treatment reduces the reinforcing efficacy of cocaine in mice maintained on a progressive-ratio (PR) schedule of reinforcement, but did not affect acquisition of cocaine self-administration under fixed-ratio responding or acquisition or retention of learning. Such findings suggest CA activates the cellular glutamate reuptake system in the brain reward circuit and reduce cocaine's reinforcing efficacy at a 100-times lower dose than CTX (16). 1. **Clemizole**

This TRPC blocker (FW<sub>free-base</sub> = 325.84 g/mol; CAS 1163-36-6; Solubility: 20 mM in water; 50 mM in DMSO), also named 1-[(4-chlorophenyl)methyl]-2-(1-pyrrolidinylmethyl)-1H-benzimidazole, selectively targets the Transient Receptor Potential Cation-5 channel, or TRPC5 (IC<sub>50</sub> = 1.1 μM), with weaker action against TRPC4 (IC<sub>50</sub> = 6.4 μM), TRPC3 (IC<sub>50</sub> = 9.1 μM), TRPC6 (IC<sub>50</sub> = 11.3 μM), and TRPC7 (IC<sub>50</sub> = 26.5 μM) channels. Clemizole exhibits minimal effect on TRPM3, TRPM8 and TRPV1, TRPV2, TRPV3 and TRPV4 channels (1). Clemizole is also TRPC1:TRPC5 heteromers as well as native TRPC5-like currents in the U-87 glioblastoma cell line. It is also a histamine H<sub>1</sub> receptor antagonist, as tested in longitudinal colon strips (2). 1. Richter, Schaefer & Hill (2014) *Mol. Pharmacol.* **86**, 514. 2. Aguilar, Morales-Olivas & Rubio (1986) *Brit. J. Pharmacol.* **88**, 501.

**Clevidipine**

This intravenous ultrashort-acting antihypertensive (FW = 456.32 g/mol; CAS 166432-28-6; Trade name: Cleviprex™; IUPAC: *O*<sup>3</sup>-(butanoyloxymethyl)-*O*<sup>5</sup>-methyl-(4*R*)-4-(2,3-dichloro-phenyl)-2,6-dimethyl-1,4-dihydropyridine-3,5-dicarboxylate) is a dihydropyridine calcium channel antagonist that selectively relaxes (EC<sub>50</sub> = 4 μM) small artery smooth muscle lining (1). Clevidipine is rapidly hydrolyzed by circulating esterases, exhibiting *in vitro* half-lives in blood of 0.6 min (rat), 16 min (dog) and 5.8 min (humans) (2). It is specifically indicated when oral therapy is either infeasible or undesirable. 1. Huriaux, Makita, Szlam, Nordlander & Levy (1997) *Anesth. Analg.* **85**, 1000. 2. Ericsson, Tholander & Regårdh (1999) *Eur. J Pharm Sci.* **8**, 29.

**Clevudine**

This (deoxy)thymidine analogue and nucleos(t)ide reverse transcriptase inhibitor, or NRTI (FW = 260.22 g/mol; CAS 69256-17-3; *Abbreviation*: CLV), also known by the trade names Levovir® and Revovir® and its systematic name 1-[(2*S*,3*R*,4*S*,5*S*)-3-fluoro-4-hydroxy-5-(hydroxymethyl)oxolan-2-yl]-5-methylpyrimidine-2,4-dione, is an antiviral prodrug that is indicated for the treatment of hepatitis B virus, or HBV (1). Clevudine is

differentiated from other antivirals by (a) its unusual phosphorylation pathway to the active triphosphate in uninfected and infected liver cells; (b) an inhibitory mechanism that interferes with multiple steps in the intracellular life cycle of hepatitis B virus; (c) a long *in vivo* half-life; and (d) significant reduction of covalently closed circular DNA (cccDNA), when tested in animal models (2). Upon cellular uptake, clevudine is phosphorylated to its mono-, di-, and tri-phosphate forms, with the latter presumed to be the active inhibitor and antiviral drug. The major CLV metabolite formed in human primary hepatocytes was CLV 5'-monophosphate, whereas in the hepatoma cell lines the major metabolite was 5'-triphosphate (3). The level of CLV 5'-triphosphate was similar in both cell types. In primary hepatocytes the conversion of CLV 5'-monophosphate to the corresponding 5'-diphosphate was the rate-limiting step in CLV phosphorylation; the level of CLV phosphorylation was dependent upon exogenous drug concentration and exposure time. CLV 5'-triphosphate accumulated rapidly with peak levels observed after approximately 8 h. Kinetic analyses using the HBV endogenous polymerase assay revealed that clevudine-5'-triphosphate noncompetitively inhibited DNA chain elongation, suggesting that it binds to and distorts the HP active site in a unique manner (4). High-dose treatment with clevudine induces mitochondrial defects associated with mtDNA depletion and impairs glucose-stimulated insulin secretion in insulin-releasing cells (5). Although there is no indication that clevudine is carcinogenic, several accounts of clevudine-associated myopathy have appeared. 1. Dienstag (2008) *New Engl. J. Med.* **359**, 1486. 2. Anderson (2009) *Drugs Today* **45**, 331. 3. Niu, Murakami & Furman (2008) *Antivir. Ther.* **13**, 263. 4. Jones, Murakami, Delaney, Furman & Hu (2013) *Antimicrob. **Clinafloxacin**

This fluoroquinolone-class antibiotic (FW = 365.79 g/mol; CAS 105956-99-8), also named 7-(3-aminopyrrolidin-1-yl)-8-chloro-1-cyclopropyl-6-fluoro-4-oxoquinoline-3-carboxylic acid, is a broad-spectrum systemic antibacterial agent that targets Type II DNA topoisomerases (gyrases), which are required for bacterial replication and transcription. It has been used for parenteral and oral administration in subjects with serious infections. For the prototypical member of this antibiotic class, **See Ciprofloxacin**

**Clindamycin**

This semisynthetic lincosamide antibiotic (FW = 424.99 g/mol; CAS 18323-44-9), also known as (7*S*)-7-chloro-7-deoxylincomycin, is effective against anaerobic microorganisms, particularly β-lactamase-producing strains of the *Bacteroides* species. Clindamycin inhibits protein synthesis by acting on the 50S ribosomal subunits of bacteria, with binding sites

composed exclusively of segments of 23S ribosomal RNA at the peptidyl transferase cavity (1). Clindamycin does not with any ribosomal protein. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** respiratory burst of neutrophils (2,5); protein biosynthesis (3,4); peptidyl-transferase (6,7). 1. ### Clobenpropit

This substituted imidazole (FW<sub>free-base</sub> = 308.83 g/mol; CAS 145231-35-2) is a potent histamine H<sub>3</sub> receptor antagonist. Clobenpropit can cross the blood-brain barrier. **Target(s):** cholesterol 24-hydroxylase,  $K_d = 80$  nM (1); histamine H<sub>3</sub> receptor (2-4). 1. Mast, White, Bjorkhem, *et al.* (2008) *Proc. Natl. Acad. Sci. U.S.A.* **105**, 9546. 2. Hill, Ganellin, Timmerman, *et al.* (1997) *Pharmacol. Rev.* **49**, 253. 3. ### Clofibrate

This lipid-lowering agent (FW = 242.70 g/mol; CAS 637-07-0), also known by its systematic name, ethyl 2-(4-chlorophenoxy)-2-methylpropanoate, and its tradename Atromid-S<sup>®</sup>, is used to control the high circulating cholesterol and triacylglyceride levels by increasing lipoprotein lipase activity and promoting the conversion of VLDL to LDL. Clofibrate also inhibits pyruvate dehydrogenase from *Fusarium culmorum* (2). Clofibrate inhibition of 11-β-hydroxylation in bovine adrenal cortex mitochondria (3). 1. Robillard, Fontaine, Chinetti, Fruchart & Staels (2005) *Handbook Exptl. Pharmacol.* p. 389. 2. Madhosingh & Orr (1985) *J. Environ. Sci. Health B* **20**, 201. 3. McIntosh, Uzgiris & Salhanick (1970) *Endocrinology* **86**, 656.

### Clonazepam

This intermediate-acting benzodiazepine (FW = 315.72 g/mol; CAS 1622-61-3; IUPAC: 5-(2-chlorophenyl)-7-nitro-2,3-dihydro-1,4-benzodiazepin-2-one), also known as Rivotril, Linotril, Clonotril, and Clonex, mainly facilitates GABAergic transmission within the brain by its direct effect on benzodiazepine receptors and exhibits anxiolytic, anticonvulsant, muscle relaxant, amnestic, sedative, and hypnotic properties. With once daily oral administration, clonazepam is rapidly absorbed and passes quickly from blood to brain. Its biological half-life of 22-32 hours allows it to reach and sustain its 5-50 ng/mL therapeutic serum concentration, with once daily dosing. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) Pharmacokinet.* **1**, 161.

### Clonidine

This α<sub>2</sub> adrenergic receptor agonist (FW<sub>free-base</sub> = 230.10 g/mol; CAS 4205-90-7), also named *N*-(2,6-dichlorophenyl)-4,5-dihydro-1*H*-imidazol-2-amine, is a nonopiate antihypertensive agent. Other uses include treatment of neuropathic pain, sleep hyperhidrosis, and as an anesthetic by veterinarians. It has been used to reduce the withdrawal symptoms during smoking, alcohol, or opiate cessation. Gold and coworkers (1-3) proposed that clonidine could be an effective nonopiate treatment for opiate withdrawal distress, based on their hypothesis that opiate withdrawal syndrome is the result of hyperactivity (or hyperexcitability) of noradrenergic neurons in the locus coeruleus. (See also *Lofexidine*) Clonidine-displacing substance, thought to be the endogenous ligand for imidazoline receptors, was recently identified as agmatine, or 1-amino-4-guanidinobutane (See *Agmatine*). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** amine oxidase (copper-containing) (4,5); polyamine oxidase (5); trypsin (5); nitric oxide synthase (5). 1. Gold, Redmond & Kleber (1978). *Lancet* **I**, 929; *Lancet* **II**, 599. 2. Charney, Heninger & Kleber (1986) *Amer. J. Psych.* **143**, 817. 3. Federico, Leone, Botta, *et al.* (2001) *J. Enzyme Inhib.* **16**, 147.

### α-Clophenixol

This anti-psychotic drug (FW = 400.97 g/mol; CAS 982-24-1) is a potent inhibitor of dopamine-stimulated adenylate cyclase and is a dopamine receptor antagonist (1). Note that there are two distinct forms of this pharmaceutical: an α- or *cis*-isomer (*i.e.*, the *Z*-isomer) and a β- (*or trans*-) form. α-Clophenixol is the more active form,  $K_i = 17$  nM. Both stereoisomers enhance human neutrophil chemotaxis (2). 1. Iversen (1975) *Science* **188**, 1084. 2. Rechnitzer, Kristiansen & Kharazmi (1985) *Acta Pathol. Microbiol. Immunol. Scand. [C]* **93**, 199.

### Clopidogrel

This antithrombotic agent (FW<sub>free-base</sub> = 321.83 g/mol; CAS 113665-84-2; Trade Name = Plavix<sup>™</sup>) is a selective thienopyridine-class inhibitor of P2Y<sub>12</sub> ADP (*or* purinergic) receptors, and the subsequent ADP-mediated activation of the glycoprotein GPIIb/IIIa complex, thereby inhibiting platelet aggregation. Clopidogrel blocks the binding of ADP and its analogues to the receptor that suppresses platelet adenylate cyclase activity. The effectiveness of clopidogrel is dependent on its enzymatic conversion to an active metabolite by CYP2C19. Quantification of Vasodilatator-activated serine phosphoprotein phosphorylation status (so-called "VASP assay") is probably the most specific assay for evaluating clopidogrel inhibition of the P2Y<sub>12</sub> receptor. Oral bioavailability of clopidogrel is low (<50%), a consequence of its poor water solubility. When prepared as a capmul microemulsion, clopidogrel solubility can be enhanced by 80x, compared with distilled water at pH = 7.4 (2). Finally, VASP is the prototypical motor protein for the actoclampin molecular motors (3), and because actin-based motility underlies platelet "pancaking" during clot

formation, one cannot discount the likelihood that clopidogrel-induced VASP phosphorylation lies at the heart of its potent hemodynamic properties. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Mills, Puri, Hu, *et al.* (1992) *Arterioscler. Thromb.* **12**, 430. 2. Patel, Kukadiya, Mashru, Surti & Mandal (2010) *Iran J. Pharm. Res.* **9**, 327. 3. Purich (2016) *Biophys. Chem.* **209**, 41.

### Clorazepate

This benzodiazepine-class pro-drug (FW = 314.72 g/mol; CASs = 23887-31-2; 57109-90-7 (potassium salt)), also known as Tranxene<sup>®</sup>, Novo-Clopat<sup>®</sup>, and 7-chloro-2,3-dihydro-2-oxo-5-phenyl-1H-1,4-benzodiazepine-3-carboxylic acid, is rapidly converted to the active metabolite demethyldiazepam (or nordazepam), which exhibits anxiolytic, anticonvulsant, sedative, hypnotic, and skeletal muscle relaxant properties. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Nicholson, Stone, Clarke & Ferres (1976) *Brit. J. Clin. Pharmacol.* **3**, 429. 2. Dixon, Brooks, Postma, *et al.* (1976) *Clin. Pharmacol. Ther.* **20**, 450.

### Clostridium difficile Toxins A & B

These large clostridial cytotoxins, designated Toxin A (MW ≈ 308 kDa) and Toxin B (MW ≈ 270 kDa) are K<sup>+</sup>-dependent UDP-glucose glucosyltransferases that inactivate certain GTPases by catalyzing the coupling of a sugar residue (utilizing UDP-D-glucose or UDP-D-N-acetylglucosamine) to a threonyl residue in the targeted GTP-binding protein. This glucosylation results in a variety of effects including dysregulation of the actin cytoskeleton, cell rounding, cytotoxicity, and altered cellular signaling (*C. difficile* is a leading cause of nosocomial diarrhea). Clinically relevant Toxin A-negative, toxin B-positive (A<sup>-</sup>B<sup>+</sup>) strains of *Clostridium difficile* are known to cause diarrhea and colitis in humans, a finding that indicates both toxins are not simultaneously required for toxin-associated pathogenesis. *Note:* These toxins also exhibit a UDP-glucose hydrolyzing activity. **Target(s):** Rho GTPase (1-3); Rac GTPase (1,2); Cdc-42 (1,2); Rap (1); Ral (1). 1. Moos & von Eichel-Streiber (2000) *Meth. Enzymol.* **325**, 114. 2. Ciesla & Bobak (1998) *J. Biol. Chem.* **273**, 16021. 3. Aktories (1997) *J. Clin. Invest.* **99**, 827. 4. Jank, Giesemann & Aktories (2007) *Glycobiology* **17**, 15R.

### Clotrimazole

This antifungal agent (FW<sub>free-base</sub> = 344.84 g/mol; CAS 23593-75-1), sold under the brand name Canesten or Lotrimin<sup>™</sup> and also known as 1-[(2-chlorophenyl)diphenylmethyl]-1H-imidazole, is a nonspecific cytochrome P450 inhibitor, a specific inhibitor of Ca<sup>2+</sup>-activated K<sup>+</sup> channels, and also acts as a calmodulin antagonist. Note that clotrimazole hydrolyzes rapidly upon heating in aqueous acids. (See TRAM-34) **Target(s):** 1,25-dihydroxycholecalciferol metabolism, via cytochrome P450 (1); nitric oxide synthase (2,8); Ca<sup>2+</sup>-transporting ATPase (3); L-type calcium currents (4); Ca<sup>2+</sup>-activated K<sup>+</sup> channels (5); cytochrome P450, nonspecific inhibitor (6,7); cyclic-nucleotide phosphodiesterase, calmodulin-dependent (8); hemo-peroxidase (9); TRMP2 channels (10); 6-phosphofructokinase (11); taxadiene 5 $\alpha$ -hydroxylase (12); steroid 11 $\beta$ -monooxygenase (13); abietadiene hydroxylase (14); abietadienol hydroxylase (14); (*R*)-limonene

6-monooxygenase (15); tabersonine 16-hydroxylase (16); sterol 14-demethylase, CYP51 (17,18); 27-hydroxy-cholesterol 7 $\alpha$ -monooxygenase (19); (*S*)-limonene 3-monooxygenase (20); (*S*)-limonene 6-monooxygenase (20,21); (*S*)-limonene 7-monooxygenase (weakly inhibited) (20); calcidiol 1-monooxygenase (22); nitric-oxide dioxygenase (23,24). 1. ### Cloxacillin

This semisynthetic penicillin-class antibiotic (FW = 435.88 g/mol; CAS 61-72-3), also named Cloxapen<sup>®</sup>, Cloxacap<sup>®</sup>, Tegopen<sup>®</sup>, and (2*S*,5*R*,6*R*)-6-[[3-(2-chlorophenyl)-5-methyloxazole-4-carbonyl]amino]-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylic acid, is often used against *Staphylococci* producing  $\beta$ -lactamase, because its large side-chain prevents binding to and deactivation by this hydrolase (See also Floxacillin).

### Clozapine

This second-generation antipsychotic agent and atypical antipsychotic (FW<sub>free-base</sub> = 326.83 g/mol; CAS 5786-21-0), also named Clozaril<sup>®</sup> and 8-chloro-11-(4-methylpiperazin-1-yl)-5H-dibenzo[b,e][1,4]diazepine, is a relatively nonspecific antagonist for D<sub>4</sub>-dopamine receptors as well as 5-HT<sub>2A</sub>, 5-HT<sub>2C</sub>, 5-HT<sub>3</sub>, 5-HT<sub>6</sub>, and 5-HT<sub>7</sub> serotonin receptors. It also downregulates 5-HT<sub>2A</sub> and 5-HT<sub>6</sub> receptors, but upregulates 5-HT<sub>7</sub> receptors. Given its tendency to induce agranulocytosis, its FDA-approved use for treating schizophrenia is premised on frequent blood testing for absolute neutrophil counts. **Target(s):** D<sub>4</sub>-dopamine receptor (1,6); 5-HT<sub>3</sub>

serotonin receptor (2); 5-HT<sub>1C</sub> serotonin receptor (3); 5-HT<sub>6</sub> serotonin receptor (4,6); 5-HT<sub>7</sub> serotonin receptor (4,6); 5-HT<sub>2A</sub> serotonin receptor (5,6); 5-HT<sub>2C</sub> serotonin receptor (5,6);  $\alpha_1$ -adrenergic receptor (6); glucose transport (7). **Receptor Affinity for Clozapine:** Serotonin transporter (SERT),  $K_i = 1.6 \mu\text{M}$ ; Norepinephrine transporter (NET or SLC6A2),  $K_i = 3.2 \mu\text{M}$ ; Dopamine transporter (DAT),  $K_i = 10 \mu\text{M}$ ; Serotonin Receptor 5-HT<sub>1A</sub>,  $K_i = 124 \text{ nM}$ ; 5-HT<sub>1B</sub>,  $K_i = 520 \text{ nM}$ ; 5-HT<sub>1D</sub>,  $K_i = 1.36 \mu\text{M}$ ; 5-HT<sub>2A</sub>,  $K_i = 5 \text{ nM}$ ; 5-HT<sub>2B</sub>,  $K_i = 8 \text{ nM}$ ; 5-HT<sub>2C</sub>,  $K_i = 9 \text{ nM}$ ; 5-HT<sub>3</sub>,  $K_i = 240 \text{ nM}$ ; 5-HT<sub>5A</sub>,  $K_i = 3.9 \mu\text{M}$ ; 5-HT<sub>6</sub>,  $K_i = 13 \text{ nM}$ ; 5-HT<sub>7</sub>,  $K_i = 18 \text{ nM}$ ; Dopamine receptor D<sub>1</sub>,  $K_i = 270 \text{ nM}$ ; D<sub>2</sub>,  $K_i = 160 \text{ nM}$ ; D<sub>3</sub>,  $K_i = 270 \text{ nM}$ ; D<sub>4</sub>,  $K_i = 26 \text{ nM}$ ; D<sub>5</sub>,  $K_i = 0.25 \mu\text{M}$ ; Adrenergic Receptor  $\alpha_{1A}$ ,  $K_i = 1.7 \text{ nM}$ ;  $\alpha_{1B}$ ,  $K_i = 7 \text{ nM}$ ;  $\alpha_{2A}$ ,  $K_i = 27 \text{ nM}$ ;  $\alpha_{2B}$ ,  $K_i = 37 \text{ nM}$ ;  $\alpha_{2C}$ ,  $K_i = 6 \text{ nM}$ ;  $\beta_1$ ,  $K_i = 5 \mu\text{M}$ ;  $\beta_2$ ,  $K_i = 1.65 \mu\text{M}$ ; Muscarinic Acetylcholine Receptor M<sub>1</sub>,  $K_i = 6 \text{ nM}$ ; M<sub>2</sub>,  $K_i = 37 \text{ nM}$ ; M<sub>3</sub>,  $K_i = 19 \text{ nM}$ ; M<sub>4</sub>,  $K_i = 15 \text{ nM}$ ; M<sub>5</sub>,  $K_i = 15 \text{ nM}$ ; Histamine Receptor H<sub>1</sub>,  $K_i = 1 \text{ nM}$ ; H<sub>2</sub>,  $K_i = 153 \text{ nM}$ ; H<sub>3</sub>,  $K_i = 10 \mu\text{M}$ ; H<sub>4</sub>,  $K_i = 660 \text{ nM}$ . **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) ### CMP-*N*-acetylneuramate

This modified sialic acid (FW<sub>free-acid</sub> = 614.46 g/mol; CAS 3063-71-6), also known as CMP-sialate, is an unstable metabolite that functions as a sialate donor. The dry solid will decompose to CMP and *N*-acetylneuramate at  $-20^\circ\text{C}$  at a rate of about 5-10% per day. It is completely hydrolyzed in aqueous solutions at pH 4 and  $37^\circ\text{C}$  within one hour (83% hydrolyzed in five minutes at  $23^\circ\text{C}$  in 10 mM HCl). CMP-sialate is more stable at neutral or alkaline pH; however, hydrolysis still occurs. Hence, solutions have to be freshly prepared. **Target(s):** *N*-acetylneuramate cytidyltransferase (1,2); UDP-*N*-acetylglucosamine 2-epimerase (3-7). **1.** Rodríguez-Aparicio, Luengo, Gonzalez-Clemente & Reglero (1992) *J. Biol. Chem.* **267**, 9257. **2.** Samuels, Gibson & Miller (1999) *Biochemistry* **38**, 6195. **3.** Sommar & Ellis (1972) *Biochim. Biophys. Acta* **268**, 581. **4.** Kikuchi & Tsuike (1980) *Tohoku J. Exp. Med.* **131**, 209. **5.** Hinderlich, Stäsche, Zeitler & Reutter (1997) *J. Biol. ### CMPD101

This potent and selective GRK2/3 inhibitor (FW = 466.46 g/mol; CAS 865608-11-3; Soluble to 100 mM in DMSO), also named 3-[[[4-methyl-5-(4-pyridinyl)-4*H*-1,2,4-triazol-3-yl]methyl]amino]-*N*-[[2-(trifluoromethyl)phenyl]methyl]benzamide, targets the G protein-coupled receptor kinases GRK2 (IC<sub>50</sub> = 54 nM) and GRK3 (IC<sub>50</sub> = 32 nM). Five amino acid residues that surround the inhibitor binding site are likely to contribute to inhibitor selectivity (1). Notably, GRK2 Overexpression is strongly linked to heart failure, and GRK2 is a target for the treatment of cardiovascular disease. Cmpd101 inhibits the desensitization of the G-protein-activated inwardly-rectifying potassium current evoked by receptor-saturating concentrations of methionine-enkephalin (Met-Enk), [d-Ala(2), N-MePhe(4), Gly-ol(5)]-

enkephalin (DAMGO), endomorphin-2, and morphine in rat and mouse locus coeruleus (LC) neurons (2). In LC neurons from GRK3-knockout mice, Met-Enk-induced desensitization is unaffected, suggesting a role for GRK2 in MOPr desensitization. Quantitative analysis of the loss of functional MOPrs following acute agonist exposure revealed that Cmpd101 only partially reversed MOPr desensitization. Inhibition of extracellular signal-regulated kinase 1/2, protein kinase C, c-Jun N-terminal kinase, or GRK5 does not inhibit the Cmpd101-insensitive component of desensitization. In HEK 293 cells, Cmpd101 produces almost complete inhibition of DAMGO-induced MOPr phosphorylation at Ser(375), arrestin translocation, and MOPr internalization (2). **1.** Thal, Yeow, Schoenau, Huber & Tesmer (2011) *Mol. Pharmacol.* **80**, 294. **2.** Lowe, Sanderson, Cooke, *et al.* (2015) *Mol. Pharmacol.* **88**, 347.

### CNF-2024

This orally available synthetic Hsp90 inhibitor (FW = 308.76 g/mol; CAS 848695-25-0), also known as BIIB021 and systematically named 6-chloro-9-(4-methoxy-3,5-dimethylpyridin-2-ylmethyl)-9*H*-purin-2-ylamine, targets Hsp90 $\alpha$  ( $K_i = 9 \text{ nM}$ ), also displaying excellent antiproliferative activity against various tumor cell lines (IC<sub>50</sub> = 30 nM in MCF7 cells (1)). Like other Hsp90 inhibitors, CNF-2024 interacts with the N-terminal ATP-binding site to prevent ATP binding and stop the chaperone cycle, leading to degradation of multiple client proteins involved in tumor progression. CNF-2024 induces degradation of HER-2 *in vitro* (EC<sub>50</sub> = 38 nM) in MCF-7 cells, and also inhibits growth and promotes cell death in a variety of human tumor cells. Metabolic profiling revealed that BIIB021 is extensively metabolized primarily *via* hydroxylation of the methyl group (at position-M<sup>7</sup>), *O*-demethylation (at position-M<sup>2</sup>), and to a lesser extent by glutathione conjugation (at position-M<sup>8</sup> and position-M<sup>9</sup>) (2). Position-M<sup>7</sup> was further metabolized to form the carboxylic acid (at position-M<sup>3</sup>) and glucuronide conjugate (at position-M<sup>4</sup>) (2). **1.** Kasibhatla, Hong, Biamonte, *et al.* (2013) *J. Med. Chem.* **50**, 2767. **2.** Xu, Woodward, Dai & Prakash (2013) *Drug Metab. Dispos.* **41**, 2133.

**CNI-1493, See Semapimod**

**CNTO 328, See Siltuximab**

**CNX-419, See Rociletinib**

### CNX-774

This orally available, irreversible enzyme inhibitor (FW = 499.51 g/mol; CAS 1202759-32-7; Solubility: 100 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as 4-(4-((3-acrylamidophenyl)-amino)-5-fluoropyrimidin-2-yl)amino)phenoxy)-*N*-methylpicolinamide, selective targets Bruton's tyrosine kinase (Btk), a member of the Tec family of kinases that is involved in B-lymphocyte development, differentiation, and B cell receptor signaling. CNX-774 forms a site-directed covalent bond with Cys-481, a non-conserved amino acid within the enzyme's active site. CNX-774 has potent inhibitory activity towards the intended target, Btk, while achieving

remarkable specificity in a variety of assays designed to assess off-target reactivity towards abundant cellular thiols and blood proteins. **1.** Labenski, Chaturvedi, Evans, *et al.* (2011) 17th North. Amer. Meet. Int. Soc. Study Xenobiot. *Abst.* P211.

**CO-1686**, See *Rociletinib*

### Coagulation Factor Va Fragment 323-331

This acidic nonapeptide (*Sequence*: EYFIAAEEV; FW = 1070.16 g/mol; Isoelectric Point = 3.67), corresponding to residues 323-331 of coagulation factor Va, inhibits coagulation factor Xa ( $K_i = 5.7 \mu\text{M}$ ). The addition of an N-terminal tryptophanyl residue (*i.e.*, fragment 322-331) is also a strong inhibitor. **1.** Kalafatis & Beck (2002) *Biochemistry* **41**, 12715.

### Co $\beta$ -4-Ethylphenyl-cob(III)alamin

This vitamin B<sub>12</sub> analogue (FW<sub>free-acid</sub> = 1434.53 g/mol; Symbol: EtPhCbl) is a synthetic organometallic that binds to transcobalamin (TC), a plasma protein facilitating cellular cobalamin (Cbl) uptake. When assayed *in vitro*, key enzymes do not convert EtPhCbl to the active coenzyme forms of cobalamin, suggesting that administration of EtPhCbl may cause cellular Cbl deficiency. Plasma total Cbl concentration was higher in animals treated with EtPhCbl (129 nmol/L) than in CNCbl treated animals (88 nmol/L). However, the organ levels of total Cbl were significantly lower in animals treated with EtPhCbl compared to CNCbl treated animals or controls, notably in the liver (157 pmol/g *versus* 604 pmol/g, and 443 pmol/g, respectively). **1.** Mutti, Ruetz, Birn, Kräutler & Nexø (2013) *PLoS One* **8**, e75312.

### Cobalamin

This name refers to the active form (FW = 1355.70 g/mol; CAS Registry Number = 13408-78-1) of vitamin B<sub>12</sub>, where R = 5'-deoxyadenosyl (5'-deoxyadenosyl-cobalamin (*or* AdoCbl)), methyl (*or* methylcobalamin (MeCbl)); CN (*or* vitamin B<sub>12</sub> (CNCbl)), or H<sub>2</sub>O (aquocobalamin (*or* H<sub>2</sub>O Cbl)). **See also** *Adeninylpentylcobalamin*; *[5-(Adenosin-5'-O-yl)pentyl]cobalamin*; *Co $\beta$ -4-Ethylphenyl-cob(III)alamin*; *Cyanocobalamin*; *Methylcobalamin*

### Cobalt Ions

These Group 9 (or Group VIIIA) ions (Symbol: Co<sup>2+</sup> and Co<sup>3+</sup>; Atomic Number: 27; Atomic Weight: 58.93; Ionic Radii = 0.72 Å for Co<sup>2+</sup> and 0.63 Å for Co<sup>3+</sup>) are found in several enzymes. Required by a dozen vitally important enzymes, vitamin B<sub>12</sub>, *or* cobalamin, contains a central cobalt ion, with four of its six coordination sites provided by the corrin ring, a fifth by a dimethylbenzimidazole group, and the sixth serving as a versatile reaction center that is occupied by a cyano group (*i.e.*, Co-CN) in cyanocobalamin, a hydroxyl group (*i.e.*, Co-OH) in hydroxocobalamin, a methyl group (*i.e.*, Co-CH<sub>3</sub>) in methylcobalamin, or a 5'-deoxyadenosyl group (*i.e.*, Co-C<sup>5'</sup> atom of the deoxyribose) in adenosylcobalamin. Essential cobalt ions are also found in nitrile hydratase, methionine aminopeptidase-2, benzyloxycarbonylglycine hydrolase, *myo*-inosose-2 dehydratase, 3-dehydroquinase, and isobutyryl-CoA mutase. Co<sup>2+</sup> often substitutes for Zn<sup>2+</sup> in zinc-dependent enzymes, allowing its spectroscopic and magnetic properties to serve as useful probes in otherwise spectrally silent zinc. Cobalt-nucleotide complexes have also proven to be extremely useful enzyme inhibitors that can be used to deduce key aspects about an enzyme's substrate binding order and active-site stereochemistry. (**See specific cobalt nucleotide**; *Cobalamin*) **1.** Cleland (1982) *Meth. Enzymol.* **87**, 159. **2.** Villafranca (1982) *Meth. Enzymol.* **87**, 180.

### Cobimetinib

This orally active MEK inhibitor (FW = 531.31 g/mol; CAS 934660-93-2; Solubility: 100 mg/mL DMSO; < 1 mg/mL H<sub>2</sub>O), also known as GDC-0973, XL-518, and Cotellic<sup>®</sup>, as well as the IUPAC name [3,4-difluoro-2-(2-fluoro-4-iodoanilino)phenyl]{3-hydroxy-3-[(2S)-piperidin-2-yl]azetidin-1-yl}methanone, targets MAP/ERK kinase, *or* MEK (IC<sub>50</sub> = 4.2 nM), exhibiting strong cellular potency against various tumor types, particularly in wild-type BRAF and BRAF<sup>V600E</sup> (EC<sub>50</sub> < 2 μM) or KRAS mutant cancer cell lines (1). KRAS- and BRAF-activating mutations drive tumorigenesis through constitutive activation of the MAPK pathway. Cotellic is indicated for the treatment of patients with unresectable or metastatic melanoma with a BRAF<sup>V600E</sup> or BRAF<sup>V600K</sup> mutation, in combination with vemurafenib. **Pharmacokinetics:** Cobimetinib is well absorbed (F<sub>a</sub> = 0.88) and is extensively metabolized, with intestinal first-pass metabolism contributing in its disposition (2). Subsequent to a single 20-mg oral dose of [<sup>14</sup>C]-cobimetinib in healthy male subjects, the major circulating species were unchanged cobimetinib (20.5%) and M16, the glycine conjugate of hydrolyzed cobimetinib, (18.3%) (2). Other circulating metabolites were minor, accounting for less than 10% of drug-related material in plasma. **1.** Hoeflich, Merchant, Orr, *et al.* (2012) *Cancer Res.* **72**, 210. **2.** Hatzivassiliou, Haling, Chen, *et al.* (2013) *Nature* **501**, 232. (*Erratum: Nature* (2013) **502**, 258.)

### α-Cobratoxin

This nAChR-directed neurotoxin (MW = 7842.12 g/mol; CAS 769933-79-1), from the Indo-Chinese spitting cobra (*Naja siamensis*) and the Chinese cobra (*Naja atra*), is a potent antagonist that targets nicotinic acetylcholine receptor, causing paralysis by preventing acetylcholine binding to nAChR. **See also** *α-Bungarotoxin*

### Cobra Venom Factor

This complement-activating protein complex (MW = 149 kDa; Abbreviation: CVF), also known as cobra venom anti-complementary protein, from *Naja naja kaouthia*, is a nontoxic disulfide-linked, three-chain glycoprotein resembling Complement C3b, the latter being the activated form of complement component C3 formed upon proteolytic cleavage of an Arg-Ser bond in C3's  $\alpha$ -chain. As part of the innate immune system, the complement cascade helps (hence "complements") antibodies and phagocytic cells to clear pathogens from an infected organism. Like C3b, CVF forms a C3/C5 convertase with factor B in the presence of factor D and Mg<sup>2+</sup>. While exhibiting the activity of C3b, CVF resembles the structure of C3b's degradation product C3c, which cannot form the active C3/C5 convertase. CVF is often used to "decomplement" laboratory animals (1), thereby facilitating the study of complement roles in host defense, immune response, and pathogenesis. The CVF crystal structure reveals a CUB domain (composed of Complement C1r/C1s, Uegf, and Bmp1) positioned in identical position to that in C3b (2). The similarly positioned CUB and slightly displaced C345c domains of CVF could play a key role in forming C3-convertase by providing primary binding sites for factor B (2). Humanized CVF shows great promise for therapeutically depleting complement in humans (3). 1. Ballow & Cochrane (1969) *J. Immunol.* **103**, 944. 2. Krishnan, *et al.* (2009) *Structure* (London) **17**, 611. 3. Vogel, Fritzing, Hew, Thorne & Bammert (2004) *Mol. Immunol.* **41**, 191.

### Cocaine

This tropane alkaloid (FW<sub>free-base</sub> = 303.36 g/mol; CAS 50-36-2), named systematically as [1R-(*exo,exo*)]-3-(benzoyloxy)-8-methyl-8-azabicyclo[3.2.1]octane-2-carboxylic acid methyl ester, is prepared from extracts of coca leaves (*Erythroxylon coca*). First used as a local anesthetic by indigenous South Americans, cocaine's highly addictive nature soon became evident. It readily crosses the blood-brain barrier, where it binds to neurotransmitter transporters, thereby blocking re-uptake of serotonin, dopamine, and norepinephrine. As such, cocaine is often called a "triple-uptake inhibitor". **Pharmacokinetics:** Depending on its purity, chemical form (free base *versus* HCl salt), as well as the mode of its administration (*e.g.*, intravenous, intranasal, oral route, or as a suppository), cocaine concentration(s) in affected organs may differ greatly. Its elimination half-life is 0.5–1.1 hour after intravenous administration and 0.9–1.5 hour after nasal or oral administration. After nasal inhalation, cocaine's bioavailability is about 60%. Hydrolysis of the benzoyl group to the ecgonine methyl ester is catalyzed by plasma cholinesterase. The methyl ester within cocaine also spontaneously hydrolyzes, forming benzoyl ecgonine. *N*-Demethylation is mediated by microsomal cytochrome P-450 (CYP3A), producing norcocaine, which possesses a pharmacological activity comparable to that of cocaine. Accumulation of the latter can be prevented by CYP3A inhibitors, such as triacetyloleandomycin, cannabidiol, or gestodene. **Mechanism of Cocaine Reward:** The strong relationship between dopamine transporter inhibition and cocaine's behavioral effects suggests that cocaine's primary target is the dopamine (DA) transporter (DAT). Support for the DA Hypothesis for Cocaine Dependence comes from the observation that the primary cocaine "receptor" and the DA transporter are one and the same protein. Molecular genetic studies on cocaine reward provided important insights regarding the DA Hypothesis. (Cocaine reward refers to the altered behavior of humans or other animals seeking to maintain access to cocaine.) While cocaine reward is not eliminated in mice carrying a knock-out for the DAT, it is eliminated in mice carrying combined gene knock-outs for both DAT and the serotonin transporter (SERT), as assessed in the conditioned place preference (CPP) paradigm (1). In the absence of DAT alone, there is greater participation in cocaine reward by serotonin (SERT) and norepinephrine (NET) transporters. Taken together, these studies indicate important requirements for several monoaminergic system genes to fully explain cocaine reward, in particular those expressed by dopamine and

serotonin systems (1). **Target(s):**  $\beta$ -fructofuranosidase, *or* invertase (2); dopamine and biogenic amine reuptake (3,6); acetylcholine receptor (4); HERG-encoded K<sup>+</sup> channel (5); acetylcholinesterase (6); esterase, nonspecific (7); sphingomyelin phosphodiesterase, *or* sphingomyelinase (8); phospholipase A<sub>1</sub> (8); amphetamine-activated Rho GTPase signaling that mediates dopamine transporter internalization (9). 1. ### Codeine

This narcotic pain-reliever and cough suppressant (FW<sub>free-base</sub> = 299.37 g/mol; CAS 76-57-3), first isolated from opium in 1832, is an important antitussive agent that is only slightly analgesic and mildly habit forming. Codeine is readily prepared by *N*-methylation of morphine. Codeine is a potent agonist, albeit not as powerful as morphine, of the G-protein coupled  $\mu$ -,  $\delta$ -, and  $\kappa$ -opioid receptors. Its modest analgesic action may also be due, in part, to its conversion to morphine. **Codeine Metabolism:** In humans, codeine is converted to the following six metabolites: codeine-6-glucuronide, 81 %; norcodeine, 2%, morphine, 0.6 %, morphine-3-glucuronide, 2%, morphine-6-glucuronide, 0.8 %, and normorphine, 2.4 % (1). Individuals lacking sufficient CYP2D6 fail to *O*-dealkylate codeine and cannot form morphine. The *in vivo* half-life of codeine is 1.5 hours, that of codeine-6-glucuronide was 2.8 hours, and that of morphine-3-glucuronide 1.7 hours (1). The plasma AUC for codeine-6-glucuronide is approximately 10x higher than that of codeine. Protein binding of codeine and codeine-6-glucuronide *in vivo* was 56 and 34 %, respectively. The *in vitro* protein binding of norcodeine was 24 %, compared to 47% for morphine, 24 % for normorphine, 27% for morphine-3-glucuronide, and 37% for morphine-6-glucuronide (1). **PK Summary:** Onset of action, 15–30 minutes; Oral Bioavailability, ~90%; Biological half-life, 2.5–3 hours. Duration of action: 4–6 hours. **Target(s):** glucuronosyl-transferase (2,3); oxidative phosphorylation (4); alcohol dehydrogenase (5). 1. Vree & Verwey-van Wissen (1992) *Biopharm. Drug Dispos.* **13**, 445. 2. Puig & Tephly (1986) *Mol. Pharmacol.* **30**, 558. 3. Tephly (1990) *Chem. Res. Toxicol.* **3**, 509. 4. Chistiakov & Gegenava (1976) *Biokhimiia* **41**, 1272. 5. Roig, Bello, Burguillo, Cachaza & Kennedy (1991) *J. Pharm. Sci.* **80**, 267.

### Coenzyme A

This heat-stable coenzyme (FW = 767.54 g/mol; CAS 85-61-0; Water-soluble; Stable in the pH 4–7 range;  $\lambda_{max}$  = 259.5 nm,  $\epsilon$  = 16800 M<sup>-1</sup>cm<sup>-1</sup>; pK<sub>a</sub> = 9.6 for thiol group), commonly abbreviated CoA or CoASH, serves as an acyl carrier in a number of enzyme-catalyzed processes, forming a thiol ester intermediate. Coenzyme A should be stored dry at –20°C. Low

or high pH results in hydrolysis: 31% of coenzyme A is hydrolyzed in 24 hours at pH 8 and 25°C. Aqueous solutions oxidized in air to the disulfide, and freshly prepared solutions should always be used. When present at physiologic concentration (*i.e.*, < 0.1 mM), Coenzyme A inhibits enzymes only weakly.

### Coformycin

This transition-state inhibitor (FW = 284.27 g/mol; CAS 11033-22-0) derives its powerful inhibitory action from the  $sp^3$ -hybridized carbon that mimics the tetrahedral intermediate in the adenosine deaminase reaction. **Target(s):** adenosine deaminase, slow, tight-binding inhibition,  $K_i = 10^{-13}$  M (1-8); AMP deaminase (9-11); adenine deaminase (12); adenosine kinase (13). 1. Agarwal, Spector & Parks, Jr. (1977) *Biochem. Pharmacol.* **26**, 359. 2. Sawa, Fukagawa, Homma, Takeuchi & Umezama (1967) *J. Antibiot.* **204**, 227. 3. Castro & Britt (2001) *J. Acad. Sci. U.S.A.* **76**, 3670. 13. de Jong & Kalkman (1973) *Biochim. Biophys. Acta* **320**, 388.

### Coformycin 5'-Monophosphate

This inhibitor (FW = 363.24 g/mol) is a transition-state analogue in the reaction catalyzed by AMP deaminase,  $K_i = 55$  pM (1,2). The transition state for the hydrolysis of AMP by AMP deaminase has been characterized through the determination of multiple kinetic isotope effects, and the experimentally established transition state show a bond order of 0.8 to the attacking water nucleophile, a full bond order to the exocyclic 6-amino group, re-hybridization of C-6 of the purine ring to  $sp^3$ , and protonation of N-1 by Glu633 (3). The inferred transition state is on the path to formation of an unstable tetrahedral intermediate, in which the exocyclic amine undergoes rapid protonation, followed by its departure. In this mechanism, the highest energetic barrier on the reaction coordinate is attack by the zinc-activated water. The electrostatic potential surface for the purine ring in the transition state has been determined by molecular orbital calculations and compared to that of (*R*)-coformycin 5'-monophosphate (4). The electrostatic nature of the late transition state with a protonated amine leaving group differs both from the transition state determined by kinetic isotope effects and from that of (*R*)-coformycin analogues, providing further evidence that the nature of the enzyme-stabilized transition state for adenine deamination involves an early transition state with a partially bonded hydroxyl group. The observed tight binding inhibition by (*R*)-coformycin analogues as transition-state inhibitors results from the similarity of the partial charges on the inhibitors to that of the enzymatic

transition state stabilized by AMP deaminase (4). 1. Frieden, Gilbert, Miller & Miller (1979) *Biochem. Biophys. Res. Commun.* **91**, 278. 2. ### COH29

This novel ribonucleotide reductase (RNR) inhibitor (FW = 422.24 g/mol) targets both recombinant and cellular human RNR enzymes ( $IC_{50} = 18$   $\mu$ M) and overcomes hydroxyurea and gemcitabine resistance in cancer cells. COH29 effectively inhibited proliferation of most cell lines in the NCI 60 human cancer cell panel, with notable cytostatic action against ovarian cancer and leukemia and little effect on normal fibroblasts or endothelial cells. COH29 treatment reduced tumor growth, as compared to vehicle, when tested in mouse xenograft models of human cancer. COH29 binds near the C-terminal tail of RNR, as proposed by computer modeling and verified by site-directed mutagenesis and NMR. 1. Zhou, Su, Hu, *et al.* (2013) *Cancer Res.* **73**, 6484.

### Colcemid

This microtubule-directed alkaloid (FW = 371.43 g/mol; CAS 477-30-5), also known as demecolcine, is from the meadow saffron (*Colchicum autumnale*) and binds rapidly and reversibly to tubulin (in contrast to colchicine). This agent inhibits  $\alpha,\beta$ -tubulin dimer polymerization, induces microtubule disassembly (occasionally attended by the onset of apoptosis), and inhibits mitotic and meiotic spindle formation. **Colcemid Washout:** Whereas colchicine's interactions with tubulin are virtually irreversible, colcemid is only weakly bound. This property commends its use in experiments requiring reversible disruption of the microtubule cytoskeleton within living cells. When treated with 5-20  $\mu$ M colcemid, the microtubule cytoskeleton of most eukaryotic cells depolymerizes within 10-20 minutes. Upon rinsing colcemid-treated cells three times with several mL of colcemid-free culture medium (at 10-min intervals), colcemid effuses from the cell, followed by microtubule reassembly at microtubule organizing centers (MTOCs), such as the centrosome. Like colchicine, colcemid is photolabile and should be stored in the dark. (*See Colchicine*) 1. Scott & Tomkins (1975) *Meth. Enzymol.* **40**, 273. 2. Mareel & De Brabander (1978) *J. Natl. Cancer Inst.* **61**, 787. 3. Bershadsky & Gelfand (1981) *Proc. Natl. Acad. Sci. U.S.A.* **78**, 3610. 4. Ray, Bhattacharyya & Biswas (1984) *Eur. J. Biochem.* **142**, 577.

**Colchicine**

This toxic alkaloid (FW = 399.44 g/mol; CAS 64-86-8; Symbol: Clc; Solubility: 45 mg/mL H<sub>2</sub>O, >150 mg/mL DMSO; M.P. = 142-150°C; Extremely Photosensitive), from the meadow saffron *Colchicum autumnale*, blocks tubulin polymerization (microtubule self-assembly), impairing mitosis and meiosis (1-10). **General Properties:** At very low doses, colchicine interferes with mitotic spindle formation, but need not stop cell division entirely. This property has been exploited to stably increase ploidy in certain plants that are then propagated vegetatively. Higher ploidy fish have also been produced in this manner. However, exposure of most animal cells to 10<sup>-7</sup> M colchicine for 6-8 hours arrests cell division in metaphase (often called “colchicine mitosis” or “C-mitosis”). Colchicine induces apoptosis, activates the JNK/SAPK signaling pathway, and disrupts neutrophil migration/ phagocytosis, the latter property commending its centuries-old use in the treatment of the exquisite arthritic pain associated with Gout. Colchicine itself exhibits a notoriously low therapeutic index, requiring cautious dosage and management. A colchicine transporter, if it exists, has yet to be demonstrated. The high cellular content of tubulin most likely accounts for the consistent finding that colchicine accumulates within cells at levels many times higher than its extracellular concentration (*Consult* Table II in Reference 8). **Mode of Tubulin (Tb) Binding:** Colchicine is a slow, tight-binding ligand of the αβ-tubulin dimer. The time-course for colchicine-tubulin association is complex, consisting of a relatively fast step, which is responsible for most of the reaction (as detected by attendant fluorescence changes), followed by one or more slower isomerizations that, when complete, increase the binding amplitude by 5-10% (4). Analysis of the fast step showed that, under pseudo-first-order conditions, the association rate constant increases linearly with colchicine or tubulin concentration, but deviates from linearity at high concentrations. The simplest binding mechanism is a slow ligand-induced conformational change, beginning as a weak Tb-Clc complex (characterized by an initial dissociation constant of 0.15 mM) to conformationally mature tubulin-drug complexes, ultimately reaching a stable binding equilibrium defined by a sub-picomolar dissociation constant. (**Other Agents That Bind at the Colchicine Site:** *Combretastatin*, *Podophyllotoxin*, *3,4,5-Trimethoxychalcones*, *Indolephenstatins*) **Substoichiometric Action on MT Assembly & MT-dependent Processes:** Colchicine inhibits MT self-assembly at concentrations far below the solution concentration of tubulin dimers (5-7). Unlike vinblastine, which can bind directly to MT ends (8), colchicine first binds to αβ-Tb dimers. Colchicine blocks microtubule-dependent processes through the limited incorporation of αβ-Tubulin-Colchicine complex onto MT (+)-ends. The latter entails the limited co-polymerization of αβ-Tubulin and αβ-Tubulin-Colchicine (9,10), attended by the impaired ability of colchicine-containing microtubules to fulfill their roles in chromosome and organelle translocation. Lower concentrations of colchicine (e.g., 0.2 μM) or αβ-Tubulin-Colchicine complex (e.g., 0.1 μM) inhibit the exchange of tubulin dimers at MT ends, often without appreciable net polymer loss (8). **Cellular Microtubules (MTs) as Colchicine Targets:** When added in excess, colchicine has the classic effects of inhibiting tubulin polymerization or causing MT depolymerization. At lower concentrations, however, the very same agent suppresses MT assembly/disassembly dynamics in subtle ways, often with no noticeable change the abundance of assembled microtubules, but blocking mitosis and meiosis (11). Tubulin-Colchicine complex (e.g., 0.1 μM), for example, inhibits tubulin exchange at MT ends without appreciable polymer loss (8). Colchicine also suppresses the dynamics of MT assembly/disassembly, greatly reducing the rates of MT growth as well as increasing the duration of non-growing/non-shortening states. Within living cells, highly dynamic spindle microtubules are, in fact, among the most sensitive targets for tubulin-directed drugs, suggesting that managing tubulin dimer addition/release at microtubule ends is highly relevant to anticancer chemotherapy (11). Analysis of microtubule growth times also supports the view that catastrophic MT disassembly also depends on the

“age” of MTs (12). Colchicine and vinblastine accelerate aging in a manner that depends on the presence of MT end-binding proteins. Of course, cellular MT dynamics also depends on the effects of microtubule-associated proteins, such as MAP2 and Tau proteins, which bind to and stabilize MTs. **Colchicine Toxicity:** In humans, an acute dose of ~0.8 mg colchicine per kilogram is typically fatal. Nausea, vomiting, abdominal pain, and diarrhea, with a massive loss of fluid and electrolytes are the first clinical symptoms of colchicine poisoning. Stomach lavage and rapid gastric decontamination using activated charcoal are crucial in relieving toxicity. **Colchicine Metabolism:** Colchicine disposition involves both active biliary and renal excretion. In mammals, a substantial fraction undergoes hepatic demethylation prior to excretion. Tracer studies with [<sup>3</sup>H]colchicine in human liver samples show that the formation of its main metabolites, 3-demethylcolchicine (3DMC) and 2-demethylcolchicine (2DMC), is linear with incubation time, cytochrome (P450) content, and substrate concentration (13). Upon incubation of colchicine (5 nM) with microsomes in the presence of a NADPH-generating system for 60 min, 9.8% and 5.5% of colchicine was 3DMC and 2DMC, respectively, the formation of which correlates with nifedipine oxidase activity, a marker of CYP3A4 activity, but not with the metabolic markers of CYP2A6, CYP2C19, CYP2C9, CYP2D6, and CYP2E1 activities. Chemical inhibition of CYP3A4 by preincubation with gestodene (40 μM) or troleanomycin (40 μM) reduced the formation of 3DMC and 2DMC by 70 and 80%, respectively, whereas quinidine, diethyldithiocarbamate, and sulfaphenazole had no inhibitory effect. Such findings suggest that co-administration of colchicine with CYP3A4 inhibitors/substrates may increase colchicine toxicity. **See also** *Colcemid*, *Combretastatin*, *Podophyllotoxin*, *Paclitaxel (Taxol)*, *Vinblastine*, *Vincristine*. **Colchicine as a Treatment for Gouty Arthritis:** For centuries, oral colchicine has been a mainstay alternative for treating gout attacks, particularly for those unable to take anti-inflammatory painkillers. This alkaloid reduces the number of motile white blood cells responding to chemotactic cues emitted by pain sites. Colchicine is effective in breaking the cycle of cytokine-driven inflammasome response, thereby reducing the swelling and pain of a gout attack. Low-dose colchicine (1.8 mg, taken over 1 hour) should be at the ready for gout patients seeking to reduce pain. It is well tolerated in patients with acute gout. **Target(s):** *myo*-inositol 2-dehydrogenase (14); xanthine oxidase (15); urate-ribonucleotide phosphorylase (16); P-glycoprotein (multidrug-resistance protein), or xenobiotic transporting ATPase (17); thiamin-triphosphatase, weakly inhibited (18); α-tubulin *N*-acetyltransferase, inhibition due to MT depolymerization (19). 1. **Colistins**

These heterodetic ring-containing and cationic decapeptide antibiotics (FW = 1155.45 g/mol; CAS 1264-72-8; Source: *Bacillus colistinus*), also known as polymyxin E, characteristically contain L-2,4-diaminobutyrate (L-Dab) residues that play a role in their antibiotic activity. Their N-terminal residue is acylated with a 6-methylheptanoyl or 6-methylheptanoyl group. Colistins A and B are identical to polymyxins E<sub>1</sub> and E<sub>2</sub>. **Mechanism of Antibiotic Action:** Colistins are polycationic surface-active detergents and mainly interacts electrostatically with the outer membrane of Gram-negative bacteria, displacing Mg<sup>2+</sup> and Ca<sup>2+</sup> from the membrane lipids, disrupting the outer membrane, and releasing essential lipopolysaccharides. Resultant changes in bacterial membrane permeability leads to leakage of cell contents as well as cell lysis and death. **Spectrum of Antibiotic Action:** These antibiotics display a relatively narrow antibacterial spectrum of activity, exhibiting significant activity against multi-resistant *Pseudomonas aeruginosa*, *Acinetobacter baumannii*, and *Klebsiella pneumoniae*. Colistins interact electrostatically with the outer membrane of Gram-negative bacteria and displace divalent cations. Colistin and polymyxin B are increasingly used as the last-line therapy for treating multidrug-resistant Gram-negative bacterial infections. **See also Polymyxins** 1. Li, Nation, Milne, Turnidge & Coulthard (2005) *Int. J. Antimicrob. Agents* **25**, 11. 2. Lim, Ly, Anderson, *et al.* (2010) *Pharmacotherapy* **30**, 1279.

### Colesevelam

This oral cholesterol-reducing medication (FW = indefinite polymer; CAS 182815-44-7) consists of a random poly-allylamine that contains numerous cationic side-chains (consisting of 1-chloro-2,3-epoxypropane, [6-(allylamino)hexyl]trimethylammonium chloride and *N*-allyldecylamine) that trap bile acids and block their reabsorption. Colesevelam is safe and efficacious alone or in combination with HMG-CoA reductase inhibitors (statins) in reducing low-density lipoprotein cholesterol (LDL-C) levels. It may also be beneficial for patients who cannot tolerate other lipid lowering therapies, such as organ transplant recipients, cholestatic liver disease, and end-stage renal disease. 1. Steinmetz & Schonder (2005) *Cardiovasc. Drug Rev.* **23**, 15.

### Combretastatin A<sub>4</sub>

This tubulin-directed vascular disrupting agent, or VDA (FW = 316.34 g/mol; Abbreviation: CA4) and its phosphorylated pro-drug CA4P (FW = 396.32 g/mol; CAS 117048-59-6; Source: the arid shrub *Combretum caffrum*), systematically named 2-methoxy-5-[(*Z*)-2-(3,4,5-trimethoxyphenyl)vinyl]phenol or 3,4,5-trimethoxy-3'-hydroxy-4'-methoxy-stilbene, binds reversibly to the  $\beta$ -subunit of the tubulin  $\alpha\beta$ -heterodimer (IC<sub>50</sub> = 2-3  $\mu$ M), thereby preventing microtubule self-assembly with consequential vasculature disruption, particularly the abnormal vasculature associated with cancer and macular degeneration (1-4). Such action has been attributed to the ability of these agents to selectively destroy the central regions of tumors, areas widely believed to contain cell populations

resistant to cytotoxic therapies (2,3). The presence of its trimethoxyphenyl nucleus, a feature also found in colchicine and podophyllotoxin, first suggested that combretastatin may bind to the colchicine/podophyllotoxin binding site, albeit with reduced affinity. A virtue of combretastatin A<sub>4</sub> pharmacodynamics is its reversibility of inhibition and rapid *in vivo* clearance, the combined actions of which greatly limit neurotoxicity. The water-soluble pro-drug is combretastatin A<sub>4</sub> phosphate or fosbretabulin. Recent work on the more potent VDA, Combretastatin A<sub>1</sub> *cis* (or Oxi5703) indicates that its greater toxicity arises from formation of highly reactive ortho-quinone, attended by free radical generation and ensuing apoptosis (4). The additional phenolic hydroxyl group in CA<sub>1</sub> versus CA<sub>4</sub> is believed to make the former a more effective free radical generator. **Chemosenesitizing Acute Myeloid Leukemia (AML) cells by Targeting Bone Marrow Endothelial Cells:** When AML cells are co-cultured with bone marrow endothelial cells (BMECs), a greater proportion of leukemic cells accumulate in G<sub>0</sub>/G<sub>1</sub>, suggesting a strategy of using combretastatins to force BMECs to lose their flat phenotype, to degrade their cytoskeleton, to cease growth, and to impair migration (5). Combretastatins also induce down-regulation of BMEC adhesion molecules known to tether AML cells, including VCAM-1 and VE-cadherin. When AML-BMEC co-cultures were treated with combretastatins, a significantly greater proportion of AML cells dislodged from BMECs and entered G<sub>2</sub>/M cell cycle, suggesting enhanced susceptibility to cell cycle agents. Indeed, the combination of combretastatin and cytotoxic chemotherapy showed enhanced additive AML cell death (5). *In vivo* mice xenograft studies confirmed this finding by showing complete AML regression after treatment with combretastatins and cytotoxic chemotherapies. Beyond highlighting the pathologic role of BMECs in the leukemia microenvironment as a protective reservoir of disease, these results support a new strategy for using vascular-targeting combretastatins in combination with cytotoxic chemotherapy to treat AML (5). 1. ### Compound 666-15

This potent and selective CREB inhibitor (FW = 620.22 g/mol; CAS 1433286-70-4; Soluble to 100 mM in DMSO), also named 666-15 and 3-(3-aminopropoxy)-*N*-[2-[[3-[[[(4-chloro-2-hydroxyphenyl)amino]carbonyl]-2-naphthalenyl]oxy]ethyl]-2-naphthalenecarboxamide hydrochloride, targets Cyclic adenosine monophosphate Response Element Binding protein-mediated gene transcription and cancer cell growth (IC<sub>50</sub> = 81 nM). 666-15 also potently inhibits cancer cell growth without harming normal cells. In an *in vivo* MDA-MB-468 xenograft model, 666-15 completely suppresses the tumor growth without overt toxicity. 1. Xie, Li, Kassenbrock, *et al.* (2015) *J. Med. Chem.* **58**, 5075.

### Conantokins

These peptide toxins from marine gastropods (genus *Conus*) typically contain seventeen to twenty-seven amino acyl residues with a number of  $\gamma$ -carboxyglutamyl residues and no disulfide bonds. They bind to *N*-methyl-D-aspartate-sensitive glutamate channels. Conantokin G from *Conus geographus* induces a sleep-like state in mice, upon intracerebral injection. It is selective for NMDA receptors containing the NR2B subunit and has the sequence GEZZLQZNQZLIRZKSN-NH<sub>2</sub> where Z indicates  $\gamma$ -carboxyglutamyl residues. Related toxins: Conantokin-T: GEZZYQKM LZNLZRZAEVKKNA-NH<sub>2</sub>; Conantokin L: (GEZZVAKMAAZLARZDA VN-NH<sub>2</sub>, and Conantokin R: GEZZVAKMAAZLARZNIAGCKVN CYP). 1. McIntosh, Olivera, Cruz & Gray (1984) *J. Biol. Chem.* **259**, 14343. 2. Rivier, Galyean, Simon, *et al.* (1987) *Biochemistry* **26**, 8508. 3.

### Conantokin G

This *Conus* genus toxin and NMDA antagonist (FW = 2264.21 g/mol; CAS 93438-65-4; Sequence: GEXXLQXNQXLIRXKSN-NH<sub>2</sub>, where X =  $\gamma$ -carboxyglutamyl residue; Solubility: 1 mg/mL H<sub>2</sub>O; Symbol: Con G) a potent and selective antagonist of *N*-methyl-D-aspartate-evoked currents in murine cortical neurons (IC<sub>50</sub> = 480 nM). The slow onset of Con G block could be prevented by coapplication with high concentrations of NMDA or (*RS*)-3-(2-carboxypiperazine-4-yl)-propyl-1-phosphonate, the latter a competitive antagonist (1). In oocytes expressing NR1a/NR2B receptors, Con G produced a rightward shift in the concentration-response curve for NMDA, providing support for a competitive interaction with the NMDA-binding site (1). Con G blocks NMDA-evoked current in mouse cortical neurons (IC<sub>50</sub> = 480 nM). Con G is also a neuroprotective agent, with an excellent therapeutic window for the potential intervention against ischemic/excitotoxic brain injury (2). Single and multiple administrations of Con G preferentially attenuates the methamphetamine-induced increases in tissue levels of these neuropeptides in the substantia nigra (3). 1. Donevan & McCabe (2000) *Mol. Pharmacol.* **58**, 614. 2. Williams, Dave, Phillips, *et al.* (2000) *J. Pharmacol. Exp. Ther.* **294**, 378. 3. Bush, McCabe & Hanson (2000) *Eur. J. Pharmacol.* **387**, 55.

### Conantokin R

This NMDA antagonist from the fish-hunting snail *Conus radiatus* (FW = 3098.40 g/mol; CAS 202925-60-8; Solubility: 1 mg/mL H<sub>2</sub>O; Symbol: Con R; Structure: X =  $\gamma$ -carboxyglutamyl residue) is a potent, noncompetitive *N*-methyl-D-aspartate receptor antagonist (IC<sub>50</sub> = 93 nM) that reportedly shows NR2 subunit selectivity (1). Con R inhibits inward currents evoked by NMDA in central nervous system neurons (IC<sub>50</sub> = 350 nM) and exhibits broad anticonvulsant and antiparkinsonian activity *in vivo* at doses devoid of behavioral toxicity (2). The amino acid residue at sequence position-5 in the conantokin peptides partially governs subunit-selective antagonism of recombinant NMDA receptors (3). 1. Blandl, Warder, Prorok & Castellino (2000) *FEBS Lett.* **470**, 139. 2. White, *et al.* (2000) *J. Pharmacol. Exp. Ther.* **292**, 425. 3. Klein, *et al.* (2001) *J. Biol. Chem.* **276**, 26860.

### Conantokin T

This NMDA antagonist from the fish-hunting snail *Conus radiatus* (FW = 2683.8 g/mol; CAS 127476-26-0; Sequence: GEXXYQKMLXNL RXAEVKKNA, where X =  $\gamma$ -carboxyglutamyl residue Symbol: Con T<sub>2</sub>) is a noncompetitive *N*-methyl-D-aspartate receptor antagonist (IC<sub>50</sub> = 0.4  $\mu$ M). Conantokin T inhibits Ca<sup>2+</sup> influx and glutamate-induced toxicity in central nervous system neurons. It exhibits age-dependent physiological effects, inducing a sleep-like state in young mice, but hyperactivity in older mice. 1. Haack, *et al.* (1990) *J. Biol. Chem.* **265**, 6025. 2. Klein, *et al.* (1999) *Neuropharmacol.* **38**, 1819. 3. Warder, *et al.* (2001) *J. Neurochem.* **77**, 812.

### Concanamycins

These cytotoxic macrolides (FW<sub>Concanamycin-A</sub> = 866.10 g/mol; R = C(=O)NH<sub>2</sub>; CAS 98932-70-8; FW<sub>Concanamycin-B</sub> = 852.06 g/mol; R = H; CAS 81552-33-2; FW<sub>Concanamycin-C</sub> = 823.06 g/mol; CAS 81552-34-3) from *Streptomyces diastatochromogenes* inhibit vacuolar type H<sup>+</sup>-ATPases and will induce apoptosis. Concanamycins A, B and C inhibit the acidification of rat liver lysosomes at 10<sup>-11</sup>-10<sup>-9</sup> M. 1. Dröse, Bindseil, Bowman, *et al.* (1993) *Biochemistry* **32**, 3902. 2. Nishihara, Akifusa, Koseki, *et al.* (1995) *Biochem. Biophys. Res. Commun.* **212**, 255. 3. Fendler, Dröse, Altendorf & Bamberg (1996) *Biochemistry* **35**, 8009.

### Concanavalin A

This homotetrameric plant lectin (MW = 110 kDa; CAS 11028-71-0) from jack bean has four metal ion-binding site (Mn<sup>2+</sup> or Ca<sup>2+</sup>) and four sites for  $\alpha$ -D-mannopyranoses or  $\alpha$ -D-glucopyranoses with unmodified hydroxyl groups at positions C-1, C-4, and C-6. Concanavalin A agglutinates erythrocytes and precipitates polysaccharides. Concanavalin A also binds to many glycoproteins (*e.g.*, immunoglobulin G). **Target(s):** procollagen C-endopeptidase (1,12); procollagen N-endopeptidase (2,13,14); thrombin (3); superoxide dismutase (4);  $\gamma$ -glutamyl hydrolase, weakly inhibited (7); 5'-nucleotidase (8 10,19-28); gametolysin (11); u-plasminogen activator, *or* urokinase (15); peptidyl-glycinamidase, *or* carboxamidopeptidase (16); peptidyl-dipeptidase A, *or* angiotensin I-converting enzyme (17);  $\beta$ -fructofuranosidase, *or* invertase (18); chlorophyllase (29); [ $\beta$ -adrenergic-receptor] kinase (30); procollagen galactosyltransferase (31); procollagen-proline 3-dioxygenase (32); procollagen-proline 4-dioxygenase (33). 1. ### (S)-Coniine

This alkaloid and peripheral neurotoxin (FW = 127.23 g/mol; CAS 3238-60-6 (*R/S*-mixture), 5985-99-9 (*R*-enantiomer), and 458-88-8 (*S*-enantiomer); D<sup>20</sup> = 0.8626 and D<sup>19</sup> = 0.8438, refractive index, n<sup>23</sup><sub>D</sub> = 1.4505, dextrorotatory, with [ $\alpha$ ]<sup>19</sup><sub>D</sub> = +15.7°), also named (*2S*)-2-propylpiperidine, is the chief toxic constituent in Poison Hemlock (*Conium maculatum*). A dose of <100 mg is usually fatal in humans, and similar per-kilogram body-weight toxicities obtain for livestock. Respiratory paralysis usually occurs within 20-30 minutes, followed by death in 2-3 hours. Coniine blocks the nicotinic receptor on the post-synaptic membrane of the neuromuscular junction, but there is some CNS involvement at higher

doses. In 399 BC, Socrates is said to have been executed with a drink containing hemlock extract. 1. Vetter (1998) *Toxicol.* **36**, 13.

### Conoidin A

This potent antimalarial (FW = 347.99 g/mol; CAS 18080-67-6; IUPAC Name: 2,3-bis(bromo-methyl)-1,4-dioxiquinoxaline; Symbol: BBMQ) is an inhibitor of host cell invasion by the protozoan parasite *Toxoplasma gondii* and exerts potent cytotoxic action against cultured *Plasmodium falciparum*. Conoidin A irreversibly inhibits peroxiredoxins, a widely conserved and important family of enzymes that function in antioxidant defense and participate in redox signaling pathways. Peroxiredoxins use a reactive, peroxidatic cysteine residue to reduce ROS such as H<sub>2</sub>O<sub>2</sub>, resulting in the formation of a cysteine sulfenic acid (Cys-SOH). Changes in human PrxII expression are associated with cancer, cardiovascular dysfunction and neurodegeneration, suggesting these redox enzymes are attractive druggable targets. Conoidin A inhibits (IC<sub>50</sub> = 23 μM) *Toxoplasma gondii* peroxiredoxin II (or TgPrxII) through binding to and covalent modification of its peroxidatic Cysteine-47 (1). At 5 μM, conoidin A can also inhibit the glucose oxidase-mediated hyperoxidation of mammalian peroxiredoxin I and II, but not peroxiredoxin III. The compound also inhibits the hyperoxidation of mammalian PrxII in response to oxidative stress. 1. Haraldsen, Liu, Botting, *et al.* (2009) *Org. Biomol. Chem.* **7**, 3040.

### α-Conotoxin AulB

This oligopeptide toxin (FW = 1572.76 g/mol; CAS 216299-21-7) from the venom of the "court cone," *Conus aulicus*, selectively blocks α<sub>3</sub>β<sub>4</sub> nAChRs expressed in *Xenopus* oocytes with an IC<sub>50</sub> of 0.75 μM, a k<sub>on</sub> of 1.4 × 10<sup>6</sup> min<sup>-1</sup>M<sup>-1</sup>, a k<sub>off</sub> of 0.48 min<sup>-1</sup>, and a K<sub>d</sub> of 0.5 μM. Furthermore, α-conotoxin AulB blocks the α<sub>3</sub>β<sub>2</sub> receptor with >100-fold higher potency than other receptor subunit combinations, including α<sub>2</sub>β<sub>2</sub>, α<sub>2</sub>β<sub>4</sub>, α<sub>3</sub>β<sub>2</sub>, α<sub>4</sub>β<sub>2</sub>, α<sub>4</sub>β<sub>4</sub>, and α<sub>1</sub>β<sub>1</sub>γδ. 1. Luo, *et al.* (1998) *J. Neurosci.* **18**, 8571. 2. Nai, *et al.* (2003) *Mol. Pharmacol.* **63**, 311. 3. Park, *et al.* (2006) *Pflugers Arch.* **452**, 775.

### α-Conotoxin EI

This *Conus* peptide (FW = 2093.40 g/mol; CAS 170663-33-9) is a selective antagonist of neuromuscular α<sub>1</sub>β<sub>1</sub>γδ nicotinic receptors (1). α-Conotoxin EI displays selectivity for α/δ sites over α/γ sites in *Torpedo*. α-Conotoxin EI has the same disulfide framework as α/7 conotoxins targeting neuronal nicotinic acetylcholine receptors, but antagonizes the neuromuscular receptor as do the α<sub>3</sub>/5 and α A conotoxins. 1. Martinez, *et al.* (1995) *Biochemistry* **34**, 14519. 2. Park, *et al.* (2001) *J. Biol. Chem.* **276**, 49028.

### ω-Conotoxin GVIA

This *Conus* peptide (FW = 3037 g/mol; CAS 106375-28-4) targets N-type calcium channels (IC<sub>50</sub> = 0.15 nM). 1. Sato, *et al.* (1993) *Biochem. Biophys. Res. Comm.* **194**, 1292. 2. Wright & Angu (1997) *J. Cardiovasc. Pharmacol.* **30**, 392.

### Ω-Conotoxin MVIIA

This 25-residue, disulfide-bridged marine toxin (FW = 2639.13 g/mol; CAS 107452-89-1) from the venom of the sea snail *Conus geographus* that

binds to neuronal N-type calcium channels (1-3). This conotoxin forms a compact folded structure, presenting a loop between Cys-8 and Cys-15 that contains a set of residues critical for channel binding (4). The loop does not have a unique defined structure, nor is it intrinsically flexible. Indeed, multi-dimensional NMR is consistent with a short triple-stranded antiparallel β-sheet (5). The overall β-sheet topology is the same as that reported for Ω-conotoxin GVIA, another N-type calcium channel blocker. The orientation of β-stranded structure is similar to each other, suggesting that the conserved disulfide bond combination is essential for the molecular folding. **Mode of Inhibitory Action:** Ω-Conotoxin produces persistent block of L- and N-type Ca<sup>2+</sup> channels in dorsal root ganglion neurons but only transiently inhibits T-type channels. Its actions are neuron-specific, blocking high-threshold Ca<sup>2+</sup> channels in sensory, sympathetic, and hippocampal neurons of vertebrates, but not in cardiac, skeletal, or smooth muscle cells (1-3). The toxin interacts with an external site near the Ca<sup>2+</sup> channel. **Clinical Aspects:** The potency and selectivity of ω-conotoxin on voltage-gated Ca<sup>2+</sup> channels commend its use in the treatment of neuropathic pain states, especially those in which Ca<sup>2+</sup> channel activity is characteristically aberrant (6). While ω-conotoxins show analgesic efficacy, the means of drug delivery and adverse effects limit its use. Synthetic Ω-conotoxin (Ziconotide®) is an FDA-approved peptidic drug indicated for the treatment of severe chronic pain, when administered intrathecally. 1. Feldman, Olivera & Yoshikami (1987) *FEBS Lett.* **214**, 295. 2. Olivera, Cruz, de Santos, *et al.* (1987) *Biochemistry* **26**, 2086. 3. McCleskey, Fox, Feldman *et al.* (1987) *Proc Natl Acad Sci U.S.A.* **84**, 4327. 4. Atkinson, Kieffer, Dejaegere, Sirokin & Lefèvre (2000) *Biochemistry* **39**, 3908. 5. Kohno, Kim, Kobayashi, *et al.* (1995) *Biochemistry* **34**, 10256. 6. Hannon & Atchison (2113) *Marine Drugs* **11**, 680.

### μ-Conotoxin PIIIA

This marine predatory toxin (FW = 2204 g/mol; Symbol: μ-PIIIA), also known as μ-Conotoxin P3.7, from *Conus pupurascens* is a sodium channel blocker that reversibly blocks mammalian skeletal muscle voltage-gated Na<sup>+</sup> channels, or Na<sub>v</sub>1.4 (IC<sub>50</sub> = 44 nM), Type II (Na<sub>v</sub>1.2) and PNI (Na<sub>v</sub>1.7) neuronal voltage-gated Na<sup>+</sup> channels (IC<sub>50</sub> = 640 nM) by binding to Site-I domain of the channel. It is of exceptional interest because, unlike the previously characterized μ-conotoxin GIIIA, μ-PIIIA irreversibly blocks amphibian muscle Na<sup>+</sup> channels, providing a useful tool for probing synaptic electrophysiology and for discriminating among different sodium channel subtypes. *Note:* The Z and O in the above structure represent N-terminal pyroglutamate and 4-*trans*-hydroxyproline, respectively. 1. Shon, Olivera, Watkins, *et al.* (1998) *J. Neurochem.* **18**, 4473.

### Conotoxin Vc1.1, See ACV 1

### Conus Toxins

This collection of ~100,000 neuroactive compounds, all derive from 500-700 different cone snail species, represents one of the most versatile and structurally diverse groups of marine natural products and metabolic inhibitors. They allow the relatively immobile *Conus* members to paralyze and prey upon faster-moving fish and arthropods. (See also *Conantokins*; μ *Conotoxin PIIIA*; Ω *Conotoxin MVIIA*). 1. Han, Teichert, Olivera & Bulaj (2008) *Curr. Pharm. Design* **14**, 2462.

### Convallatoxin

This cardiac glycoside (FW = 550.65 g/mol) from flowers of Lily-of-the-Valley (*Convallaria majalis*) is structurally similar to digitoxin.

Convallatoxin has also been reported in *Ornithogalum umbellatum* (sleepydicke, also known as star-of-Bethlehem) and *Antiaris toxicaria* (ipoh tree). Convallatoxin consists of L-rhamnose and strophanthidin. **Target(s):** acetylcholinesterase, weakly inhibited (1); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (2). 1. Hanke, Nelson & Baskin (1991) *J. Appl. Toxicol.* **11**, 119. 2. Ozaki, Nagase & Urakawa (1985) *Eur. J. Biochem.* **152**, 475.

#### Copanlisib

This intravenous pan-Class-I PI3K inhibitor (FW = 480.52 g/mol; CAS 1032568-63-0), also known as BAY 80-6946 and 2-amino-*N*-[2,3-dihydro-7-methoxy-8-[3-(4-morpholinyl)propoxy]imidazo[1,2-*c*]quinazolin-5-yl]-5-pyrimidinecarboxamide, targets PI3K $\alpha$  (IC<sub>50</sub> = 0.5 nM), PI3K $\beta$  (IC<sub>50</sub> = 3.7 nM), PI3K $\gamma$  (IC<sub>50</sub> = 6.4 nM), and PI3K $\delta$  (IC<sub>50</sub> = 3.7 nM) in cell-free assays. BAY 80-6946 inhibits AKT phosphorylation by PI3K $\alpha$  in cells, with 10x selectivity relative to PI3K $\beta$  (1). BAY 80-6946 shows superior antitumor activity (>40x) in PIK3CA mutant and/or HER2 overexpression, as compared with HER2-negative and wild-type PIK3CA breast cancer cell lines. In addition, BAY 80-6946 induces apoptosis in a subset of tumor cells with aberrant activation of PI3K as a single agent (1). *In vivo*, single IV administration of BAY-80-6946 exhibits higher exposure and prolonged inhibition of pAKT levels in tumors versus plasma. BAY 80-6946 is efficacious in tumors with activated PI3K, when dosed either continuously or intermittently. 1. Liu, Rowley, Bull, *et al.* (2013) *Mol. Cancer Ther.* **12**, 2319. 2. Göckeritz, Kerwien, Baumann, *et al.* (2015) *Int. J. Cancer* **137**, 2234.

#### Copper Ions

These Group 11 (or Group IB) metal ions Cu<sup>1+</sup> and Cu<sup>2+</sup> (Atomic Number = 29; Atomic Weight = 63.54) have valences of 1 and 2, with ionic radii of 0.96 and 0.72 Å. The radioisotope with the longest half-life is <sup>67</sup>Cu: 2.580 days. Modest levels of ionic copper have been found to be essential for living organisms (1). Ligation schemes have been classified (2): **Type-I Copper Centers** – These proteins have a single copper atom coordinated by two histidine residues and a cysteine residue in a trigonal planar structure, with a fourth variable ligand occupying an axial site. (*Examples:* Amicyanin, Plastocyanin, and Pseudoazurin). **Type-II Copper Centers** – These proteins have a square planar coordination scheme with ligands having N or O atoms. **Type-III Copper Centers** – These proteins have a pair of copper centres, each coordinated by three histidine residues. (*Examples:* Hemocyanin and Tyrosinase). **Binuclear Copper A Centers** – These proteins have two copper atoms are coordinated by two histidines, one methionine, a protein backbone carbonyl oxygen, and two bridging cysteine residues. (*Examples:* Cytochrome *c* oxidase and Nitrous-oxide reductase). **Copper B Centers** – These proteins have a copper atom coordinated to three histidines in trigonal pyramidal geometry. (*Example:* cytochrome *c* oxidase). **Tetranuclear Copper Z Centers** – These proteins have four copper ions are coordinated by as many as seven histidine residues and bridged by a sulfur atom. (*Example:* Nitrous-oxide reductase). Copper ions also play catalytically essential roles in the following enzymes: Amine oxidase (copper-containing), L-Ascorbate oxidase, Bilirubin oxidase, Catechol oxidase, Dopamine  $\beta$ -monooxygenase, 2-Furoyl-CoA dehydrogenase, Galactose oxidase, Hexose oxidase, Indole 2,3-dioxygenase, Laccase, Lysyl oxidase, Nitrite reductase (NO-forming), Nitrous-oxide reductase, Peptidylglycine monooxygenase, Polyphenol oxidase, Quercetin 2,3-dioxygenase, Cu,Zn-Superoxide dismutase, and Tyrosinase (3,4). Even so, numerous other enzymes (>480 in the author's literature survey) are inhibited by cupric or cuprous ions. Wilson's disease (also known as Hepatolenticular Degeneration) is an autosomal recessive disorder in the ATP7B gene, resulting in uncontrolled copper accumulation in various tissues and manifested by liver failure as well as neurological or psychiatric symptoms. Recent work shows that Cu<sup>2+</sup> potentially blocks

steady-state GABA currents mediated by extrasynaptic  $\delta$  subunit-containing GABA<sub>A</sub> receptors with an IC<sub>50</sub> of 65 nM (compare with IC<sub>50</sub> = 85  $\mu$ M for synaptic  $\gamma$  subunit-containing  $\gamma$ -GABA<sub>A</sub> receptors (5)). 1. #### Coprine

This disulfiram-like constituent (FW = 202.21 g/mol; CAS 58919-61-2) from the mushroom *Coprinus atramentarius*, also named *N*-(1-hydroxycyclopropyl)-L-glutamine, inhibits the low-*K<sub>m</sub>* form of rat liver aldehyde dehydrogenase *in vivo*, increasing the acetaldehyde level in blood during ethanol metabolism. Coprine *per se* does not inhibit the low-*K<sub>m</sub>* enzyme *in vitro*; however, its hydrolytic product, 1-aminocyclo-propanol, is a potent inhibitor both *in vitro* and *in vivo*. A rapid onset of inhibition is observed after administration of coprine, and the inhibition is long-lasting. Such findings suggest that 1-aminocyclopropanol is responsible for the inhibition caused by coprine *in vivo*. 1. Totmar & Lindberg (1977) *Acta Pharmacol. Toxicol. (Copenhagen)* **40**, 476. 2. #### Coproporphyrin I

The protoporphyrin precursor (FW<sub>free-acid</sub> = 654.72 g/mol) is present at elevated in individuals with certain porphyrias; note that trace amount are observed in normal human adults. **Target(s):** glutathione *S*-transferase (1); heme oxygenase, inhibited by the iron complex (2); uroporphyrinogen decarboxylase (3); uroporphyrinogen-III synthase (4). 1. Smith, Nuiry & Awasthi (1985) *Biochem. J.* **229**, 823. 2. Frydman, Tomaro, Buldain, *et al.* (1981) *Biochemistry* **20**, 5177. 3. Jones & Jordan (1993) *Biochem. J.* **293**, 703. 4. Levin (1971) *Biochemistry* **10**, 4669.

#### Coproporphyrin III

The heme precursor (FW<sub>free-acid</sub> = 654.72 g/mol) is elevated in patients with certain porphyrias. **Target(s):** coproporphyrinogen-III oxidase (1); lactoylglutathione lyase, *or* glyoxalase I (2); glutathione *S*-transferase (3); ferrochelatase (4); uroporphyrinogen decarboxylase (5); uroporphyrinogen III synthase (6); heme oxygenase, inhibited by the iron complex (7). 1.

### Coptisine

This cationic alkaloid (FW<sub>chloride</sub> = 355.78 g/mol; CAS 3486-66-6), first isolated from the roots of *Coptis japonica*, is a component of a number of traditional medicines. **Target(s):** alcohol dehydrogenase (1); microbial collagenase, *Clostridium histolyticum* (2); NADH dehydrogenase, Complex I (3); monoamine oxidase A,  $K_i = 3.3 \mu\text{M}$  (4);  $\text{H}^+/\text{K}^+$ -ATPase (5); elastase (6). 1. ### Coralyne

This toxic alkaloid and topoisomerase I inhibitor (FW<sub>chloride</sub> = 399.87 g/mol; CAS 6872-73-7 (free base)) is a DNA-intercalating agent, preferentially interacting with A:T base pairs and thereby interfering with the action of DNA-directed enzymes. Coralynine also binds preferentially to single-stranded poly(A),  $K_{d, \text{apparent}} = 0.55 \times 10^{-6} \text{ M}$ , and a maximal binding stoichiometry  $b_{\text{max}}$  of one coralynine per four bases. (1). Binding to poly(A) is enthalpically driven, inducing a secondary structure with a melting temperature of 60 °C. **Target(s):** reverse transcriptase (2,3); DNA polymerase (2,3); RNA polymerase, moderately inhibited (2,3); polyadenylate polymerase, moderately inhibited (1); catechol O-methyltransferase (4); tRNA methyltransferase (4); DNA topoisomerase I, main target (5-7); DNA topoisomerase II, mildly inhibited (6,7). 1. Xing, Song, Ren, *et al.* (2005) *FEBS Lett.* **589**, 5035. 2. Sethi (1976) *Cancer Res.* **36**, 2390. 3. Sethi (1977) *Ann. N. Y. Acad. Sci.* **284**, 508. 4. ### Cordycepin

This uncommon deoxynucleoside (FW = 251.25g/mol; M.P. = 225-226°C;  $\lambda_{\text{max}}$  (in ethanol) at 260 nm,  $\epsilon = 14600 \text{ M}^{-1}\text{cm}^{-1}$ ), also known as 3'-deoxyadenosine, from *Cordyceps militaris* is metabolically converted to its 5'-triphosphate derivative (See also *Cordycepin 5'-Triphosphate*), which inhibits the synthesis of mRNA polyA tails, thereby blocking mRNA processing and protein biosynthesis. Cordycepin has also been reported to

inhibit purine, pyrimidine, and DNA biosynthesis. **Target(s):** adenosine kinase (2,13,14); nucleic acid methylation (3); polynucleotide adenyllyl-transferase, inhibited with excess cordycepin (4); adenosylhomocysteinase (5); RNA polymerase, via the triphosphate (6); rhodopsin kinase (7); GMP synthetase (8); tyrosyl-tRNA synthetase, weakly inhibited by the free nucleoside (9); adenosine deaminase (10); adenosine Nucleosidase (11); deoxycytidine kinase (12). 1. ### Cordycepin 5'-Triphosphate

This nucleotide (FW<sub>free-acid</sub> = 488.16 g/mol; Soluble in water and ethanol), also called 3'-deoxyadenosine 5'-triphosphate, terminates elongation of mRNA polyadenylate tails requir, owing to the absence of the 3'-hydroxyl group. **Target(s):** polynucleotide adenyllyltransferase, or poly(A) polymerase (1,3,11,13,14,22-28); DNA primase (2); protein kinase (4); DNA-directed RNA polymerase (5,9-12,16,29); translocation (6); isoleucyl-tRNA synthetase (7); picornavirus RNA polymerase (8); RNA polymerase I and II (9); 2',5'-oligoadenylate synthetase (15); DNA ligase (ATP), *Vaccinia* virus (17); phenylalanyl-tRNA synthetase (18,22); arginyl-tRNA synthetase (19,20,22); seryl-tRNA synthetase (21); lysyl-tRNA synthetase (19,22); isoleucyl-tRNA synthetase (22,23); threonyl-tRNA synthetase (19); DNA nucleotidylxotransferase, or terminal deoxyribonucleotidyl-transferase (21); influenza virus RNA polymerase (26); 1-phosphatidylinositol 4-kinase (30). 1. **Corm-3**

This ruthenium-based carbonyl (FW = 294.61 g/mol; CAS 475473-26-8; Soluble to 100 mM in H<sub>2</sub>O), also known as CO-Releasing Molecule-3 and tricarbonylchloro(glycinato)ruthenium, readily undergoes nonenzymic hydrolysis, liberating several equivalents of carbon monoxide. RuII(CO)<sub>3</sub>-protein complexes are formed upon the hydrolytic decomposition products of CORM-3 with histidine residues exposed on the surface of proteins, whereupon CO is released in aqueous solution, cells, and mice (1). CO release can be detected by mass spectrometry (MS) or confocal microscopy using a CO-responsive turn-on fluorescent probe (1). Such findings demonstrate that plasma proteins can act as CO carriers after *in vivo* administration of CORM-3 (1). Although CORM-3 is ionic and cannot penetrate cell membranes, CO does so at diffusion-controlled rates. At 75 μM, CORM-3 shows no sign of cytotoxicity (2). CORM-3 relieves acute myocardial ischemia/reperfusion (I/R) injury in hyperglycemic streptozotocin-treated rats (STZ rats) (3). Given carbon monoxide's role as a gaseous signaling molecule, CORM-3 is likely to enjoy broad use as a CO source for cellular studies. Carbon monoxide-releasing molecules are emerging as a new class of pharmacological agents that regulate important cellular function by liberating CO in biological systems. *Note:* Inasmuch as CO binds extremely tightly to heme-containing proteins and enzymes, CORM-3 is likely to interfere with some heme-dependent processes. 1. **Coronaridine**

This alkaloid (FW = 338.44 g/mol; CAS 467-77-6; also named 18-carbomethoxybogamine and ibogamine-18-carboxylic acid methyl ester), isolated from the rainforest perennial *Tabernaemthe iboga* (1) binds to μ-opioid receptors ( $K_i = 2.0$  μM), δ-opioid receptors ( $K_i = 8.1$  μM), and κ-opioid receptors ( $K_i = 4.3$  μM), NMDA receptor ( $K_i = 6.2$  μM, as an antagonist) (2,3), σ<sub>2</sub> sites ( $K_i = 201$  nM) and low affinity for σ<sub>1</sub> sites ( $K_i = 8.5$  μM) (4) and nicotinic AChRs, as an antagonist). Coronaridine is also an acetylcholinesterase inhibitor (5), a voltage-gated sodium channel blocker, and displays estrogenic activity in rodents. Coronaridine inhibits the Wnt signaling pathway by decreasing β-catenin mRNA expression (6). 1. Pawelka & Stöckigt (1983) *Plant Cell Rep.* **2**, 105. 2. Popik, Layer, Fossom, *et al.* (1996) *J. **3α- and 3β-Corosolic Acid**

These natural triterpenes (FW<sub>free-acid</sub> = 472.71 g/mol) inhibit rat DNA polymerases α and β and human DNA topoisomerase II (IC<sub>50</sub> = 43.8, 38.8, and 43 μM for the 3β-isomer, respectively, and 60.2, 80, and 83 μM for the 3α-epimer). The term corosolic acid typically refers to the 3β-isomer, whereas 3α-triterpene is also known as 3-epicorosolic acid. **Target(s):** sterol *O*-acyltransferase (acyl-CoA:cholesterol *O*-acyltransferase; ACAT; inhibited by 3β-corosolate (1); diacylglycerol *O*-acyltransferase, IC<sub>50</sub> = 44.3 μM (2); DNA-directed DNA polymerase (3); DNA polymerase α (3); DNA polymerase β (3); DNA topoisomerase II (3); glycogen phosphorylase (4,7); protein kinase C (5); protein-tyrosine-phosphatase 1B (6). 1. **Corticosterone**

This glucocorticoid (FW = 346.47 g/mol; Insoluble in water but soluble in most organic solvents; λ<sub>max</sub> = 240 nm), also known as 4-pregnene-11β,21-diol-3,20-dione, is a prominent adrenal cortex steroid. Corticosterone participates in the regulation of protein, carbohydrate, and lipid metabolism, modulating cell growth and gene expression as well as serving as an aldosterone precursor. Corticosterone activates both mineralocorticoid and glucocorticoid receptors. **Target(s):** xanthine oxidase (1); NADH dehydrogenase (ubiquinone) (2); F<sub>1</sub>F<sub>0</sub> ATPase (3); glucose 6-phosphate dehydrogenase, mildly inhibited (4); glucose transport, weakly inhibited (5); glutathione *S*-transferase (6); aldehyde dehydrogenase (7); adenosine deaminase (8); cortisol sulfotransferase (9,10); steroid sulfotransferase (11); steroid 11β-monooxygenase (12). 1. Roussos (1967) *Meth. Enzymol.* **12A**, 5. 2. Jensen (1959) *Nature* **184**, 451. 3. Zheng & Ramirez (1999) *Eur. J. Pharmacol.* **368**, 95. 4. Criss & McKerns (1969) *Biochim. Biophys. Biochem.* **232**, 247.

**Cortisol**

This stress-activated glucocorticoid (FW = 362.47 g/mol; CAS 50-23-7), also known as hydrocortisone and 4-pregnene-11β,17α,21-triol-3,20-dione, is the major human glucocorticoid and is secreted by the adrenal cortex. Synthesized in the *zona fasciculata* of the adrenal cortex, cortisol helps to control protein, carbohydrate, and lipid metabolism. In the early fasting state, cortisol stimulates gluconeogenesis and also activates anti-stress and

anti-inflammatory pathways. Cortisol also plays an indirect role in liver and muscle glycogenolysis. Cortisol exerts profound anti-inflammatory and antiallergy actions. At a cellular level, it and other glucocorticoids (e.g., prednisone, methylprednisolone, and dexamethasone) inhibit the production and action of inflammatory cytokines. At high doses, glucocorticoids impair immune function, thereby reducing cell-mediated immune reactions and reducing antibody production and action. Such properties can be used by transplant surgeons to prevent organ rejection and by rheumatologists to treat certain allergic or autoimmune diseases (e.g., rheumatoid arthritis and disseminated lupus erythematosus). Even so, their beneficial effects are frequently offset by the occurrence of serious side effects at high doses, especially when administered over a long period of time. The Hypothalamic-Pituitary-Adrenal Axis relies on circulating cortisol action in a negative feedback loop. Low blood cortisol levels leads to release of Corticotrope Releasing Hormone (or CRH), thereby activating the anterior pituitary and provoking the release of Adrenocorticotrophic Hormone (ACTH), which in turn stimulates the synthesis of more cortisol within the adrenal gland to make more cortisol. In addition to cortisol, the adrenal gland also releases androgen, leading to hyperandrogenism, giving rise to the symptoms commonly associated with Cortisone Reductase Deficiency (See *Cotisone*). **Target(s):** xanthine oxidase (1); 21-hydroxysteroid dehydrogenase (NAD<sup>+</sup>) (2,3,6); NADH dehydrogenase (ubiquinone) (4); glutamine:D-fructose-6-phosphate aminotransferase (5); steroid sulfatase (7); 3',5'-cyclic-nucleotide phosphodiesterase (8); steroid sulfotransferase (9). 1. ### Cortisone

This cortisol-generating steroid (FW = 360.45 g/mol) exhibits approximately twice the anti-inflammatory as corticosterone, with less Na<sup>+</sup> retention potency (1-3). Cortisone is reversibly converted *in vivo* to cortisol through the action of 11 $\beta$ -hydroxysteroid dehydrogenase Type 1 (or 11 $\beta$ -HSD1), also known as cortisone reductase. (See *Cortisol* for details of its actions) Under certain conditions, cortisone has antiglucocorticoid activity (3). **Target(s):** xanthine oxidase (1); NADH dehydrogenase (ubiquinone) (2); glucose-6-phosphate dehydrogenase, weakly inhibited (4); histidine decarboxylase (5); thymidine kinase (6); GABA<sub>A</sub> receptor (7); protein biosynthesis (8); steroid sulfatase, weakly inhibited (9); cortisol sulfotransferase (10); steroid sulfotransferase (11). 1. Roussos (1967) *Meth. Enzymol.* **12A**, 5. 2. Jensen (1959) *Nature* **184**, 451. 3. Scott & Tomkins (1975) *Meth. Enzymol.* **40**, 273. 4. ### Cortistatin-8

This synthetic cortistatin analogue (FW = 1009.25; CAS 485803-62-1; Solubility: 2 mg/mL in acetonitrile) lacks the somatostatin-binding capacity of full-length cortistatin, yet retains its GHS-R-binding capacity. CST8 was found to stimulate growth hormone (GH) release only at low doses (10<sup>-15</sup> M), but does not reduce GH secretion stimulated by GHRH, ghrelin, or low-dose, full-length cortistatin. Later work, however, suggests that, when administered either as bolus or as continuous infusion, CST-8 fails to modify spontaneous, ghrelin- or hexarelin-stimulated secretion of GH, PRL, ACTH and cortisol, suggesting that CST-8 is devoid of any modulatory action on either spontaneous or ghrelin-stimulated somatotroph, lactotroph and corticotroph secretion in humans *in vivo* (2). 1. Luque, Peinado, Gracia-Navarro, *et al.* (2006) *J. Mol. Endocrinol.* **36**, 547. 2. Prodam, Benso, Gramaglia, *et al.* (2008) *Neuropeptides* **42**, 89.

### Cotinine

This substituted pyridine (FW<sub>free-base</sub> = 176.22 g/mol; CAS Eegistry Number = 486-56-6) is the major nicotine metabolite. With an *in vivo* half-life of 20 hours, cotinine is detectable in blood, saliva, and urine for 4-5 days after tobacco use. **Target(s):** 7-ketosteroid reductase (1); aromatase, or CYP19 (2); steroid 11 $\beta$  monooxygenase (3,5); 3 $\alpha$ -hydroxysteroid dehydrogenase (4); CYP2E1, weakly inhibited (6). 1. Yeh, Barbieri & Friedman (1989) *J. Steroid Biochem.* **33**, 627. 2. Barbieri, Gochberg & Ryan (1986) *J. Clin. Invest.* **77**, 1727. 3. Barbieri, York, Cherry & Ryan (1987) *J. ### Coumermycins

These antibiotics (FW = 1110.10 g/mol), which are structurally related to novomycin and chloromycin, inhibit DNA gyrase and DNA biosynthesis. **Target(s):** DNA gyrase (1,2,8); DNA topoisomerase I (3,11,12); DNA topoisomerase II (4,5,9,13,18); *Molluscum contagiosum* virus topoisomerase (6); human immunodeficiency virus type 1 (HIV 1) integrase (7); DNA topoisomerase I, yeast, weakly inhibited (5); DNA ligase (ATP), Vaccinia virus (10); DNA-directed DNA polymerase (19). 1. ## CP 55,940

This endocannabinoid receptor probe (FW = 376.58 g/mol; CAS 83002-04-4; 100 mM in DMSO), also named 2-[(1*R*,2*R*,5*R*)-5-hydroxy-2-(3-hydroxy-propyl) cyclohexyl]-5-(2-methyloctan-2-yl)phenol, a full agonist at both CB<sub>1</sub> ( $K_i = 0.58$  nM) and CB<sub>2</sub> ( $K_i = 0.68$  nM) receptors, but acts as an antagonist at GPR55, the putative CB<sub>3</sub> receptor. Displacement of [<sup>3</sup>H]-labeled CP 55,940 has proven to be a useful tool for evaluating the binding properties of putative CB<sub>1</sub> and CB<sub>2</sub> receptor ligands. **1.** Avdesch, Cornelisse, & Martin-Iverson (2012) *Psychopharmacol.* (Berl). **220**, 405. **2.** Griffin, *et al.* (1998) *J. Pharmacol. Exp. Ther.* **285**, 553. **3.** Thomas, *et al.* (1998) *J. Pharmacol. Exp. Ther.* **285**, 285. **4.** Wiley, *et al.* (1995) *Neuropharmacol.* **34**, 669.

CP-66,248, See *Tenidap*

## CP-945598

This substituted adenine and cannabinoid receptor antagonist (FW<sub>HCl-salt</sub> = 287.33 g/mol; CAS 446859-33-2; Solubility: 1 mg/mL DMSO (with warming); <1 mg/mL H<sub>2</sub>O), also known as 1-[8-(2-chlorophenyl)-9-(4-chlorophenyl)-9*H*-purin-6-yl]-4-(ethylamino)-piperidine carboxamide, potently and selectively targets human CB<sub>1</sub> receptor with greater than 10,000x selectivity for CB<sub>1</sub> (binding  $K_i = 0.7$  nM; functional assay  $K_i = 0.12$  nM). When tested *in vivo*, CP-945598 reverses cannabinoid agonist-mediated responses, reducing food intake, and increasing energy expenditure and fat oxidation in rodents (1). *In vivo*, CP-945,598 reverses four cannabinoid agonist-mediated CNS-driven responses (*e.g.*, hypolocomotion, hypothermia, analgesia, and catalepsy) to a synthetic cannabinoid receptor agonist (2). CP-945,598 exhibits dose and concentration-dependent anorectic activity in two models of acute food intake in rodents, namely fast-induced re-feeding and spontaneous, nocturnal feeding. **1.** Griffith, Hadcock, Black, *et al.* (2009) *J. Med. Chem.* **52**, 234. **2.** Hadcock, Griffith, Iredale, *et al.* (2010) *Biochem. Biophys. Res. Commun.* **394**, 366.

CP-99,219, See *Trovaflaxacin*

## CP-724,714

This potent signal transduction inhibitor (FW = 469.53 g/mol; CAS 537705-08-1; Solubility: 94 mg/mL DMSO; (*E*)-2-methoxy-*N*-(3-(4-(3-methyl-4-(6-methylpyridin-3-yloxy)phenyl-amino)quinazolin-6-yl)allyl)acetamide) targets HER2/ErbB2 ( $IC_{50} = 10$  nM), with >640x selectivity against EGFR ( $IC_{50} = 6.4$  μM) and >1,000-fold less potent for IR, IGF-1R, PDGFRβ, VEGFR2, abl Src, c-Met c-jun NH<sub>2</sub>-terminal kinase-2 (*or* JNK-2), JNK-3, ZAP-70, cyclin-dependent kinase (CDK)-2, and CDK-5 (1). CP-724,714 induces G<sub>1</sub> cell-cycle block in erbB2-overexpressing human breast carcinoma cells and inhibits erbB2 autophosphorylation in xenografts, when administered *p.o.* to athymic mice. It also induces a marked reduction of extracellular signal-regulated kinase and Akt phosphorylation, tumor cell apoptosis, and release of caspase-3. CP-724,714 was discontinued from further clinical development due to unexpected hepatotoxicity via both hepatocellular injury and hepatobiliary cholestatic mechanisms (2). CP-724,714 decreases mitochondrial membrane potential in primary cultured human hepatocytes. It also demonstrates an uptake clearance ~4x greater than its efflux clearance into bile. It inhibits MDR1 and BSEP transporters which contribute to CP-724,714 and bile acid elimination. **1.** Jani, Finn, Campbell, *et al.* (2007) *Cancer Res.* **67**, 9887. **2.** Feng, Xu, Bi, *et al.* (2009) *Toxicol. Sci.* **108**, 492.

## CPAF Inhibitory Peptide

This inhibitory peptide (FW = 3055.39 g/mol; *Sequence*: SEFY SPMVPHFWAELRNHYATSGLK) targets the chlamydial protease/proteasome-like activity factor (CPAF) that degrades host molecules to facilitate infection by the intracellular pathogen *Chlamydia* (1). Derived from the self-inhibitory fragment of the CPAF zymogen, the peptide blocks substrate access to the active site (2). Treating *Chlamydia trachomatis*-infected HeLa cells with this nanomolar-affinity inhibitor prevents CPAF-catalyzed cleavage of the intermediate filament vimentin. Brown & Grieshaber (2013) also found that, while chlamydia-infected lysates actively degraded cyclin B<sub>1</sub> and the spindle-assembly checkpoint protein securin, such proteolysis is inhibited by the CP AF inhibitory peptide. A sequence-scrambled peptide (*Sequence*: WNHSSTMGYFLPAEVEKY SFSPHRA) containing the same amino acids did not block proteolysis of either cyclin B<sub>1</sub> or securin. **1.** Bednar, Jorgensen, Valdivia & McCafferty (2011) *Biochemistry* **50**, 7441. **2.** Huang, Feng, Chen, *et al.* (2008) *Cell Host Microbe* **4**, 529. **3.** Brown & Grieshaber (2013) *Journal*, **vol**, page.

## CPI-613

This potent lipoic acid derivative (FW = 388.59 g/mol; CAS 95809-78-2; Solubility: 80 mg/mL DMSO, <1 mg/mL Water), also known systematically as 6,8-bis(benzylthio)octanoic acid or 6,8-dibenzyllopic acid, targets the mitochondrial enzymes pyruvate dehydrogenase and α-ketoglutarate dehydrogenase, with an  $EC_{50} = 120$  μM in human lung cancer cells and human sarcoma cells. **1.** Zachar, *et al.* (2011) *J. Mol. Med. (Berlin)* **89**, 1137.

CPP-115, See *Vigabatrin*

### CPT-11

CPT-11

SN-38

This DNA Topoisomerase-I pro-drug (FW = 623.14 g/mol; CAS 100286-90-6; Solubility: 5 mM in H<sub>2</sub>O with gentle warming; 100 mM in DMSO; also named Irinotecan, Camptothecin-11, and (4S)-4,11-diethyl-3,4,12,14-tetrahydro-4-hydroxy-3,14-dioxo-1H-pyrano[3',4':6,7]-indolizino[1,2b]quinolin-9-yl[1,4'-bipiperidine]-1'-carboxylic acid ester) is hydrolyzed metabolically to form SN-38, the pharmacologically active metabolite SN-38 (FW = 392.40 g/mol; CAS 86639-52-3; IUPAC: 7-ethyl-10-hydroxy camptothecin and (4S)-4,11-diethyl-4,9-dihydroxy-1H-pyrano[3',4':6,7]indolizino[1,2-b]quinoline-3,14(4H,12H)-dione) (1-3). SN-38 then inhibits DNA topoisomerase I (IC<sub>50</sub> values are 0.74 and 1.9 μM in P388 and Ehrlich cells, respectively). CPT-11 inhibits both DNA synthesis (IC<sub>50</sub> = 77 nM) and RNA synthesis (IC<sub>50</sub> = 1.3 μM respectively) but does not affect protein synthesis. CPT-11 displays potent antitumor activity against a range of human tumor cells: HCT-116 (IC<sub>50</sub> = 3.3 nM), BEL-7402 (IC<sub>50</sub> = 13 nM), HL60 (IC<sub>50</sub> = 19 nM), and HeLa (IC<sub>50</sub> = 22 nM). Both SN-38 and its parent molecule, camptothecin (See *Camptothecin*), show strong, time-dependent inhibition against DNA synthesis of P388 cells. By alkaline and neutral elution assays, it was demonstrated that SN-38 caused much more frequent DNA single-strand breaks in P388 cells than did CPT-11. The same content of SN-38 and a similar frequency of single-strand breaks were detected in the cells treated with SN-38 at 0.1 microM or with CPT-11 at 100 microM (3). (Note: Reference-2 also established that plasma carboxylesterase-deficient SCID mice, bearing human tumor xenografts, may represent a more accurate model for antitumor studies with this drug and other agents metabolized by carboxylesterases. 1. Vassal, *et al.* (1996) *Br. J. Cancer*. 74, 537. 2. Morton, *et al.* (2005) *Can. Chemother. Pharmacol.* 56, 629. Kawato, Aonuma, Hirota, Kuga & Sato (1991) *Cancer Res.* 51, 4187.

### CPYPP

This DOCK2-Rac1 interaction inhibitor (FW = 324.76 g/mol; CAS 310460-39-0; Soluble to 50 mM in DMSO), also named 4-[3-(2-chlorophenyl)-2-propen-1-ylidene]-1-phenyl-3,5-pyrazolidinedione, both reduces Dedicator of Cytokinesis-2 (DOCK1) -induced Rac1 activation by interfering with DOCK1 and DOCK5 binding (1,2). CPYPP binds to

DOCK2 DHR-2 domain in a reversible manner and inhibits its catalytic activity *in vitro* (1). When lymphocytes are treated with CPYPP, both chemokine receptor- and antigen receptor-mediated Rac activation are blocked, resulting in marked reduction of chemotactic response and T cell activation (1). CPYPP also exhibits selectivity over DOCK9. CPYPP reduces chemotactic responses *in vitro* and *in vivo*, and activates T cells *in vitro* and attenuates HER2-mediated breast cancer cell migration *in vitro* (2). 1. Nishikimi, Uruno, Duan, *et al.* (2012) *Chem. Biol.* 19, 488. 2. Laurin, Fradet, Blangy, *et al.* (2008) *Proc. Natl. Acad. Sci U.S.A.* 105, 5446.

### CPZEN-45

This caprazene butylanilide (FW = 673.72 g/mol) targets the *Mycobacterium tuberculosis* GlcNAc-1-phosphate transferase WecA, which catalyzes the first step in synthesis of the mycobacterial cell wall core. Unlike caprazamycins, CPZEN-45 strongly inhibits glycerol incorporation in growing cultures, showing antibacterial activity against caprazamycin-resistant strains, including a strain overexpressing translocase-I (MraY), a caprazamycin target involved in peptidoglycan biosynthesis. By contrast, CPZEN-45 is ineffective against a strain overexpressing undecaprenyl-phosphate-GlcNAc-1-phosphate transferase (TagO) that involved in the teichoic acid biosynthesis. 1. Ishizaki, Hayashi, Inoue, *et al.* (2013) *J. Biol. Chem.* 288, 30309.

### Creatine

This guanidinium group-containing metabolite (FW = 131.13 g/mol; CAS 57-00-1), also known as *N*-amidinosuccosine and *N*-(aminoiminomethyl)-*N*-methylglycine, is frequently found mainly in skeletal and cardiac muscle, where it undergoes reversible transphosphorylation by creatine kinase to form phosphocreatine. The carboxyl group has a pK<sub>a</sub> of 2.63 at 25°C, and the pK<sub>a</sub> of the guanidinium group is ~14. Creatine is a product of the reactions catalyzed by guanidinoacetate *N*-methyltransferase, creatininase, and phosphoamidase. Phosphocreatine is readily converted nonenzymatically, particularly under acidic conditions, to creatinine. **Target(s):** pyrophosphatase, inorganic diphosphatase (1); acetylcholinesterase (2); amylase (3); acid phosphatase (4); arginine kinase, weakly inhibited (5); guanidinoacetate kinase, weakly inhibited (6). 1. Naganna (1950) *J. Biol. Chem.* 183, 693. 2. Bergmann, Wilson & Nachmansohn (1950) *J. Biol. Chem.* 186, 693. 3. Mystkowski (1932) *Biochem. J.* 26, 910. 4. Gonzales & Meizel (1973) *Biochim. Biophys. Acta* 320, 166. 5. Pereira, Alonso, Ivaldi, *et al.* (2003) *J. Eukaryot. Microbiol.* 50, 132. 6. Shirokane, Nakajima & Mizusawa (1991) *Agric. Biol. Chem.* 55, 2235.

Creatine Phosphate, See *Phosphocreatine*

**Creatinine**

This metabolite (FW<sub>free-base</sub> = 113.12 g/mol; CAS 60-27-5), is readily produced from creatine or, perhaps more likely, from phosphocreatine, the latter proceeding by intramolecular *N*-to-*O* phosphoryl migration and subsequent amino group attack on the transient acyl-P intermediate. Creatinine formation is virtually linear with muscle mass, resulting in higher amounts in males. The so-called creatine clearance rate (~25 mg/kg body weight) serves as a useful index of renal function. **Target(s):** histidine ammonia-lyase (1); arginine deaminase (2); D-amino-acid oxidase (3); acetylcholine esterase (4). 1. Leuthardt (1951) *The Enzymes*, 1st ed., 1 (part 2), 1156. 2. Petrack, Sullivan & Ratner (1957) *Arch. Biochem. Biophys.* **69**, 186. 3. Nohara, Suzuki, Kinoshita & Watanabe (2002) *Nephron* **91**, 281. 4. Bergmann, Wilson & Nachmansohn (1950) *J. Biol. Chem.* **186**, 693.

**Crenolanib**

This orally active and potent protein tyrosine kinase inhibitor (FW = 441.58 g/mol; CAS 670220-88-9), also known by its code name CP-868596 and ARO-002 as well as by its systematic name 1-(2-(5-(3-methyloxetan-3-yl)methoxy)-1*H*-benzo[*d*]imidazol-1-yl)quinolin-8-yl)piperidin-4-amine, selectively targets platelet-derived growth factor receptor PDGFR $\alpha$  and PDGFR $\beta$ , with  $K_d$  values of 2.1 nM and 3.2 nM. Crenolanib also potently inhibits PDGFR $\alpha$ 's Aspartate-842-Valine mutation, but not Valine-561-Aspartate mutation, with >100x higher selective for PDGFR over c-Kit, VEGFR-2, TIE-2, FGFR-2, EGFR, erbB2, and Src protein kinases (1). PDGFR $\alpha$  mutations have been detected in a small population of melanoma patients, suggesting melanoma patients harboring certain mutations may benefit from crenolanib treatment (2). Mutations of the type III receptor tyrosine kinase (RTK) FLT3 occur in approximately 30% of acute myeloid leukemia (AML) patients and lead to constitutive activation, and crenolanib inhibits both FLT3/ITD and resistance-conferring FLT3/D835 mutants *in vivo* (3). Key attributes of highly successful TKI drugs are (a) kinase selectivity and (b) invulnerability to secondary resistance-conferring kinase domain (KD) mutations. Notably, crenolanib not only displays a high degree of selectivity for FLT3 and other class III RTKs, but it also appears to be invulnerable to resistance-conferring KD mutations, when probed *in vitro* (4). Whereas several type II FLT3 TKIs (quizartinib, sorafenib, and ponatinib) target the related class III RTK KIT, crenolanib elicits cytotoxicity in FLT3-mutant AML, but largely spares KIT inhibition. With its limited activity against other kinases, crenolanib may prove to be less toxic than other type II FLT3 TKIs (4). 1. Heinrich, Griffith, McKinley, *et al.* (2012) *Clin. Cancer Res.* **18**, 4375. 2. Dai, Kong, Si, *et al.* (2013) *Clin. Cancer Res.* **19**, 6935. 3. Galanis, Ma, Rajkhow, *et al.* (2013) *Blood* **123**, 94. 4. Smith, Lasater, Lin, *et al.* (2014) *Proc. Natl. Acad. Sci. U.S.A.* **111**, 5319.

***p*-Cresol**

This common organic reagent (FW = 108.14 g/mol; CAS 106-44-5;  $pK_a$  = 10.17; M.P. = 35.5°C B.P. = 201.8°C; Solubility: 2.5 g/100 mL H<sub>2</sub>O at 50°C), also known as 4-methylphenol, is a mechanism-based inactivator of dopamine  $\beta$ -monooxygenase ( $k_{inact}$  = 2.0 min<sup>-1</sup> at pH 5.0), resulting in the covalent modification a tyrosyl residue. **Target(s):** dopamine  $\beta$ -

monooxygenase (1,3-6,8); L-ascorbate oxidase (2); ascorbate peroxidase (7); RCK1 (*or* Kv1.1) K<sup>+</sup> channels (9); oxidative phosphorylation (10); arylsulfatase (11); glycogen phosphorylase (12); polyphenol oxidase (13,14); tyrosinase, *or* monophenol monooxygenase (13,14). 1. **Crizotinib**

This orally bioavailable, ATP-competitive, small molecule inhibitor and antineoplastic drug (FW = 450.34 g/mol; CAS 877399-52-5; Solubility: 25 mg/mL DMSO, with warming, but very poorly soluble in H<sub>2</sub>O (maximum ~10-20  $\mu$ M)), also known by the code name PF-02341066, the trade name Xalkori<sup>®</sup>, and the systematic name, 3-[(1*R*)-1-(2,6-dichloro-3-fluorophenyl)ethoxy]-5-(1-piperidin-4-ylpyrazol-4-yl)pyridin-2-amine, targets the anaplastic lymphoma kinase ALK (IC<sub>50</sub> = 11 nM) and c-ros oncogene-1 (ROS1) receptor tyrosine kinase (IC<sub>50</sub> = 0.62 nM) and is used to treat non-small cell lung carcinoma (NSCLC). **Mode of Inhibitory Action:** The t(2;5) chromosomal translocation leads to the expression of an oncogenic kinase fusion protein known as nucleophosmin-anaplastic lymphoma kinase, *or* NPM-ALK, which has been implicated in the pathogenesis of anaplastic large-cell lymphoma *or* ALCL (1-2). Upon treatment with PF-02341066, ALCL cells undergo G<sub>1</sub>-S phase cell cycle arrest and apoptosis. Crizotinib potently inhibits c-Met-dependent proliferation, migration, or invasion of human tumor cells *in vitro* (IC<sub>50</sub> = 5-20 nM) as well as HGF-stimulated endothelial cell survival or invasion and serum-stimulated tubulogenesis *in vitro* (1). Crizotinib-resistant patient samples reveal a variety of point mutations in the kinase domain of ALK, including the L1196M gatekeeper mutation (3). 1. Christensen, Zou, Arango, *et al.* (2007) *Mol. ### Crotonoyl-CoA

This acyl-CoA derivative (FW = 853.41 g/mol; CAS 102680-35-3), also known as (*E*)-2-butenoyl-CoA, is an intermediate in the  $\beta$ -oxidation pathway for fatty acid degradation. **Target(s):** acetyl-CoA synthetase, *or* acetate:CoA ligase (1); acyl-CoA dehydrogenase (2,3); butyrate:acetoacetate CoA-transferase (4); fatty-acid synthase (5); 3-hydroxyacyl-[acyl-carrier protein] dehydrase (5). **1.** Preston, Wall & Emerich (1990) *Biochem. Biophys.* **171**, 14. **5.** Katiyar, Pan & Porter (1983) *Eur. J. Biochem.* **130**, 177.

### Cruformate

This insecticide (FW = 291.71 g/mol; CAS 299-86-5), also named Ruelene and 4-*t*-butyl-2-chlorophenyl *N*-methyl-*O*-methylphosphoramidate, inhibits insect cholinesterase and is mainly used for controlling cattle grubs, lice, and horn flies. Ruelene is practically insoluble in water and is relatively stable as an aqueous dispersion at pH 7 and below. In rat intestine (2), <sup>14</sup>C-labeled cruformate is metabolized to form: 4-*tert*-butyl-2-chlorophenyl methyl phosphoramidate (25%), 2-chloro-4(2-hydroxy-1,1-dimethylethyl) phenyl methyl methyl-phosphoramidate (19%), 2-[3-chloro-4-[(methoxy) (methyl-amino)phosphoinyl]oxy]phenyl]-2-methylpropionic acid (2%), 4-*tert*-butyl-2-chlorophenol (0.8% free form, and 6% as its glucuronide), and the aromatic glucuronide of 2-chloro-4(2-hydroxy-1,1-dimethylethyl) phenol (1%). **1.** Neely, Unger, Blair & Nyquist (1964) *Biochemistry* **3**, 1477. **2.** Pekas, Bakke, Giles & Price (1977) *J. Environ. Sci. Health B.* **12**, 261.

### Cryptotanshinone

This natural product (FW = 296.36 g/mol; CAS 35825-57-1; Solubility: 10 mM in DMSO; red-colored; IUPAC: 1,2,6,7,8,9-hexahydro-1,6,6-trimethyl[1,2-*b*]furan-10,11-dione), a major tanshinone metabolite in the

Chinese medicinal root *Danshen* (*Salvia miltiorrhiza*) that exhibits antitumor activity by inhibiting phosphorylation at Tyr705 of Signal Transducer and Activator of Transcription-3, *or* STAT3, (IC<sub>50</sub> = 4.6  $\mu$ M) in a JAK2-independent mechanism and blocking STAT3 dimerization in DU145 prostate cancer cells (1). Cryptotanshinone also shows antibacterial and anti-inflammatory activity. It acts as an antidiabetes and antiobesity agent via its ability to activate AMP-activated protein kinase, *or* AMPK (2). It improves cognitive impairment in Alzheimer's disease transgenic mice by inhibiting acetylcholinesterase (IC<sub>50</sub> = 4.1  $\mu$ M) and reducing A $\beta$ -peptide formation (3). Cryptotanshinone also ameliorates scopolamine-induced amnesia in Morris water maze task (4). **1.** Shin, *et al.* (2009) *Cancer Res.* **69**, 193. **2.** Kim, *et al.* (2007) *Mol. ### CTA095

This novel dual tyrosine protein kinase inhibitor (FW = 555.68 g/mol), also named 2-(dibenzo[*b,d*]furan-2-yl)-7-phenyl-1-(3-(piperidin-1-yl)propyl)-1*H*-imidazo[4,5-*g*]-quinoxalin-6(5*H*)-one, targets Etk (IC<sub>50</sub> = 60 nM) and Src (IC<sub>50</sub> = 60 nM), inducing autophagy and apoptosis, as well as exerting synergistic effects with autophagy modulators (*e.g.*, 10  $\mu$ M chloroquine) in prostate cancer cells (1). By contrast, the IC<sub>50</sub> values for Abl, Axl, Btk, EGFR, Itk, Mer, and Yes exceeded 10  $\mu$ M. A member of the Btk nonreceptor tyrosine kinase family, Etk (also known as Bmx) has a modular structure that include an N-terminal pleckstrin homology (PH) domain, a Tec homology domain, a SH2 domain, a SH3 domains, an autophosphorylation site within the SH3 domain, and a C-terminal kinase domain. Etk interacts with and inactivates p53, and overexpression of Etk in prostate cancer cells confers resistance to androgen deprivation and photodynamic therapy. Src is a proto-oncogene tyrosine-protein kinase (also known as cellular-Src, or simply c-Src) is likewise a modular non-receptor protein tyrosine kinase that contains an SH2 domain, an SH3 domain, and a tyrosine kinase domain. CTA095 blocks the ATP binding pocket in Src kinase, whereas it inhibits ATP binding in Etk by inducing a conformational change via the so-called "back-pocket". Treatment of PC3 cells with CTA095 decreased Etk and Src autophosphorylation as well as phosphorylation of the downstream signal transducing kinases Stat3 and Akt. CTA095 has little effect on the survival of the immortalized normal prostate cell RWPE1, suggesting growth and survival are more dependent on Etk and Src. **1.** Guo, Liu, Bhardwaj, *et al.* (2013) *PLoS One* **8**, e70910.

### Cucurbitacins

These bitter-tasting plant steroids (FW<sub>cucurbita-5-ene</sub> = 412.75 g/mol), derived from unsaturated variant cucurbita-5-ene, or 19-(10→9β)-abeo-10α-lanost-5-ene (shown above) are glucocorticoid-like cytotoxic triterpene cytotoxins found in the family *Cucurbitaceae*, including the common pumpkins and gourds, where they serve to discourage consumption by herbivores.

**Curare, See Tubocurarine**

### Curcumin

This symmetrical orange-yellow dione (FW = 368.39 g/mol; CAS 458-37-7), also known as tumeric yellow, and diferuloylmethane and named systematically as 1,7-bis(4-hydroxy-3-methoxyphenyl)-1,6-heptadiene 3,5-dione, is obtained from the roots of *Curcuma longa* and is the major active component of turmeric, the primary spice in Indian curries. Curcumin is an anti-tumor promoter, inducing apoptosis in prostate cancer cells, as well as an anti-inflammatory agent that inhibits both cyclooxygenase (IC<sub>50</sub> = 52 μM) and 5-lipoxygenase (IC<sub>50</sub> = 8 μM). It also inhibits induction of nitric-oxide synthase biosynthesis in activated macrophages and is an anti-oxidant that enhances wound healing. Although its effects on only a few of its known targets were assessed, Phase I clinical trials indicate curcumin is safe in healthy subjects, even at high doses (12 g/day). **Target(s):** DNA topoisomerase II (1); cyclooxygenase (2,42,44); 5-lipoxygenase (2,8,44); epidermal growth factor receptor (EGFR) protein-tyrosine kinase (3,25); protein farnesyltransferase (4); glucuronosyl transferase, or UDPglucuronosyltransferase (5,56); COP9 signalosome (CSN) protein kinase (6,7,15); DNA-directed DNA polymerase (9); DNA polymerase λ (9); membrane alanyl aminopeptidase, or aminopeptidase N (10,47,48); phenol sulfotransferase (11,29); cell survival signal protein kinase B/Akt (12); c-jun/AP 1 (13,18); protein kinase C (14,23,28,37,51); inositol 1,3,4-trisphosphate 5/6-kinase (15); inositol 1,4,5 trisphosphate-sensitive Ca<sup>2+</sup> channel, or inositol 1,4,5-trisphosphate receptor (16); Ca<sup>2+</sup>-transporting ATPase (17,19); CYP1A1 (20); CYP1A2 (20); CYP2B1 (20); soybean lipoxygenase (21); β-carotene 15,15' monooxygenase (22); F<sub>0</sub>F<sub>1</sub> ATPase (24); p185<sup>neu</sup> protein-tyrosine kinase (26); c-Jun N-terminal kinase (JNK) signaling pathway (27); protein kinase A (28); plant Ca<sup>2+</sup>-dependent protein kinase (28); Δ<sup>5</sup> desaturase (30,38,39); Δ<sup>6</sup>-desaturase (30,38); HIV-1 integrase (31,32); xanthine dehydrogenase and xanthine oxidase (33); phosphorylase kinase (34); tyrosinase (35); HIV-1 retropepsin (36); HIV-2 retropepsin (36); polyunsaturated fatty acid chain elongation (39); glutathione S-transferase (40); nitric-oxide synthase, inducible (43); phenylpyruvate tautomerase (45); NAD(P)H dehydrogenase (46); hyaluronoglucosaminidase, or hyaluronidase (49); glucan 1,4-α-glucosidase, or glucoamylase (50); IκB kinase, weakly inhibited (52); protein-tyrosine kinase (26,53); Syk protein-tyrosine kinase (53); inositol 1,3,4-trisphosphate 5/6-kinase (54); glutathione S-transferase (55); histone acetyltransferase (57,58); arylamine N-acetyltransferase (59,60). **1.** Martin-Cordero, Lopez-Lazaro, Galvez & Ayuso (2003) *J. ### CVS-1123

This L-arginal-containing peptidomimetic (FW<sub>free-base</sub> = 510.63 g/mol) is a potent inhibitor of thrombin that prevents coronary artery thrombosis in the conscious dog. CVS-1123 is a slow-binding competitive inhibitor of thrombin (IC<sub>50</sub> = 1.13 nM) as well as a potent anticoagulant in plasma *in vitro*. It is a weaker inhibitor of coagulation factor Xa and plasmin, with respective IC<sub>50</sub> values of 257 and 315 nM. **1.** Cousins, Friedrichs, Sudo, et al. (1996) *Circulation* **94**, 1705.

### CW069

This inhibitor (FW = 500.34 g/mol) is an allosteric inhibitor (IC<sub>50</sub> = 75 μM) of the (-)-end-directed, kinesin-related microtubule motor HSET, inducing multipolar mitosis in cancer cells with extra centrosomes and causing apoptosis by means of catastrophic aneuploidy. Notably, CW069 does not disrupt mitosis in normal human fibroblast cells. The increased incidence of CW069-induced multipolar mitoses in N1E-115 cells recapitulates the

phenotype obtained by siRNA-mediated HSET depletion. CW069 also reduces centrosome clustering in BT549 and MDA-MB-231 breast cancer cells. Unlike KSP or CENP-E inhibitors, CW069 does not cause mitotic delay in HeLa cells with normal centrosome numbers, nor does it decrease the clonogenic capacity of primary adult human bone marrow cells. Thus, CW069 is less likely to not cause neutropenia toxicity in normal cells. Selective inhibition of HSET is consistent with computational modeling that suggests that dynamic conformational selection with CW069 cannot be achieved by the closely related KSP. The motor antagonism between plus-end-directed KSP and minus-end-directed HSET is understood to be responsible for establishing a proper bipolar spindle during mitosis (2), and KSP inhibition has been shown to result in monopolar spindle formation as well as mitotic delay (3,4). 1. Watts, Richards, Bender, *et al.* (2013) *Chem. Biol.* **20**, 1399. 2. Mountain, Simerly, Howard, *et al.* (1999) *J. Cell Biol.* **147**, 351. 3. Gatlin and Bloom (2010) *Semin Cell Dev. #### CX-4945

This orally bioavailable ATP-competitive protein kinase inhibitor and anti-angiogenic agent (FW = 349.77 g/mol; CAS 1009820-21-6), also named 5-(3-chlorophenyl-amino)benzo[*c*][2,6]naphthyridine-8-carboxylic acid, targets casein kinase CK2 $\alpha$ , with a  $K_i$  of 0.38 and an intracellular IC<sub>50</sub> of 1 nM, exhibiting broad-spectrum anti-proliferative activity in multiple cancer cell lines (1,2). CX-4945 attenuates PI3K/Akt signaling, as evidenced by dephosphorylation of Akt at its CK2-specific site (S129) as well as other canonical phosphorylation sites (S473 and T308). CX-4945 also inhibits proliferation of human umbilical vein endothelial cells (HUVECs), resulting in cell-cycle arrest and apoptosis. In models of angiogenesis, CX-4945 inhibits HUVEC migration, capillary tube formation, and transcription of CK2-dependent Hypoxia-Induced Factor-11 $\alpha$  (*HIF-1 $\alpha$* ) gene in cancer cells. In this respect, may also prove to be a useful vascular-disrupting agent (VDA) that starves solid tumors of required nutrients. In A549 cells, CX-4945 inhibits the TGF- $\beta$ 1-induced cadherin switch and the activation of key signaling molecules involved in Smad (Smad2/3, Twist and Snail), non-Smad (Akt and Erk), Wnt ( $\beta$ -catenin) and focal adhesion signaling pathways (FAK, Src and paxillin) that cooperatively regulate the overall process of EMT (3). As a result, CX-4945 inhibits the migration and invasion of A549 cells accompanied with the downregulation of MMP-2 and 9 (3). CX-4945 also blocks TGF- $\beta$ 1-induced epithelial-to-mesenchymal transition in A549 human lung adenocarcinoma cells (4). 1. Siddiqui-Jain, Drygin, Streiner *et al.* (2010) *Cancer Res.* **70**, 10288. 2. Pierre, Chua, O'Brien, *et al.* (2011) *J. Med. Chem.* **54**, 635. 3. Ku, Park, Ryu *et al.* (2013) *Bioorg. Med. #### CXI-benzo-84

This tubulin-directed anticancer agent (FW = 402.52 g/mol), first identified by screening cells treated with a series of benzimidazoles, inhibits cell-cycle progression in metaphase, accumulating spindle assembly checkpoint proteins Mad2 and BubR1 on kinetochores and subsequently activating apoptosis. CXI-benzo-84 also depolymerizes both interphase and mitotic microtubules (MTs), perturbs MT binding of EB1 protein, and inhibits MT self-assembly. It likewise inhibits tubulin GTPase activity *in vitro* and

binds to tubulin at a single binding site ( $K_d = 1.2 \mu\text{M}$ ), most likely by docking within the colchicine binding pocket. 1. Rai, Gupta, Kini, *et al.* (2013) *Biochem. Pharmacol.* **86**, 378.

#### Cyanate

This conjugate base of cyanic acid  $\text{N}\equiv\text{C}-\text{OH}$  (FW<sub>Na-Salt</sub> = 65.01 g/mol; CAS 917-61-3 (sodium salt); FW<sub>K-Salt</sub> = 81.12 g/mol; CAS 590-28-3 (potassium salt); FW<sub>NH3-Salt</sub> = 59.05 g/mol; CAS 22981-32-4 (ammonium salt)) is an electrophile that reacts with amino, sulfhydryl, tyrosyl, imidazole, and carboxyl groups in proteins. Only the reaction with amino groups generates a stable product,  $\text{R}-\text{NHC}(=\text{O})\text{NH}_2$ . Because an unprotonated amine is required for reaction,  $\alpha$ -amino groups are more reactive than  $\epsilon$ -amino groups, due to their lower  $pK_a$  values. This property permits preferential modification of  $\alpha$ -amino groups. *Note:* Solutions of cyanate salts must be prepared freshly, as cyanate decomposes in aqueous environments.

**Target(s):** ribonuclease (1,13); papain (2,9); trypsin (3); chymotrypsin (3); subtilisin (3,9,10); nitrate reductase (4); tubulin polymerization (6); formate dehydrogenase (6); hemoglobin S polymerization (7,8,23); alkaline phosphatase (11,27); pyrophosphatase (12); carbonic anhydrase (14,15,18,20, 28,32-36); glutamate dehydrogenase (16,26); phosphoribosylformylglycinamide synthetase (19,30); glycogen phosphorylase (17,22); carbamoyl-phosphate synthetase, glutamine (21,29); complement component C3/C5 (2,4); complement factor, *or* complement component C3b inactivator (24); glucose-6-phosphate dehydrogenase (25); fumarase (31); catalase (31); amidase (37); mucorpepsin (38); glycosylphosphatidylinositol phospholipase D (39); glutathione dehydrogenase (ascorbate), mildly inhibited (40). 1. #### Cyanide

This extremely poisonous ion and potent metalloenzyme inhibitor (*Symbol:*  $\text{CN}^-$ ), commonly supplied as the potassium (FW = 65.12 g/mol; CAS 151-50-8) or sodium salt (FW = 49.01 g/mol; CAS 143-33-9), emits a characteristic odor of bitter almonds. Its protonated form, hydrogen cyanide

(Symbol: HCN) is rapid-acting asphyxiant. The main target of  $\text{CN}^-$  and HCN is cytochrome oxidase, an essential respiratory chain enzyme (see below). **Chemical Properties:** Hydrogen cyanide is colorless and odorless gas (See also *Hydrogen Cyanide*; *Zyklon-B*). When hydrated, HCN dissociates ( $\text{pK}_a = 9.31$  at  $25^\circ\text{C}$ ), and at physiologic pH the major species is  $\text{HCN}$  rather than  $\text{CN}^-$ .  $\text{CN}^-$  can still be the active species even at pH values where its concentration is significantly lower than that of HCN. In the cyanide anion, the combined presence of a lone pair and negative charge makes the carbon atom the reactive nucleophilic species in associative  $S_N2$  substitutions reactions. **Primary Mode of Inhibitor Action:** Cyanide ion combines rapidly with heme iron in cytochrome  $a_3$ , a component of mitochondrial cytochrome oxidase, preventing intracellular oxygen utilization and instead forcing cells to rely on anaerobic metabolism, to produce excess lactic acid, and to experience metabolic acidosis. Extended X-ray absorption fine structure (EXAFS) revealed that cyanide binds to purified cytochrome oxidase in a multiphasic manner, suggesting that the resting enzyme is a mixture of several forms. Upon reduction and reoxidation (i.e., conversion to the "oxygenated" form), however, the kinetics for cyanide binding become monophasic, and all preparations of the oxygenated form combine with cyanide at the same rate (1). Note that cyanide also exhibits high affinity for the ferric iron of methemoglobin. **Toxicity:** Whether ingested as free  $\text{CN}^-$  or inhaled as HCN, cyanide toxicity is usually evident within seconds. At high dose, death often ensues within 6-8 minutes. For gaseous hydrogen cyanide, the  $\text{LC}_{50}$  is 100-300 ppm (or 1-3  $\text{mg}/\text{m}^3$ ), resulting in death within 10-60 minutes. Inhalation of 2000 ppm HCN causes death within one minute. The  $\text{LD}_{50}$  for ingested cyanide is 50-200 mg, or 2-6 mg sodium cyanide per kg body weight. Upon contact with skin, the  $\text{LD}_{50}$  for hydrogen cyanide gas is 100  $\text{mg}/\text{kg}$  body weight. Modest amounts of cyanide are also inevitably present in certain foods, and rhodanese (Reaction:  $\text{CN}^- + \text{SSO}_3^{2-} \rightleftharpoons \text{SCN}^{1-} + \text{SO}_3^{2-}$ ), a liver enzyme, can convert trace quantities of cyanide at a rate of  $\sim 0.5$   $\text{fmol}/\text{kg}\cdot\text{min}$ , forming the far less toxic thiocyanate which is excreted in urine. Cyanide toxicity also results from improperly prepared cassava, a cyanide-rich food (containing the cyanogenic glucosides, linamarin and lotaustralin) that is a staple in the diets of over 500 million in the developing world. In severe cases, cassava toxicity results in ataxic neuropathy and vision failure. Another source of cyanide is smoke from burning wood at campsites, fireplaces, and especially house and forest fires. The considerable affinity of cyanide for ionic cobalt commends the use of hydroxocobalamin as a detoxifying agent. Hydroxocobalamin is safe when administered as a 5-gram intravenous dose, effectively counteracting toxicity at low to moderate whole blood cyanide levels. **CAUTION:** Extreme care must be exercised when handling cyanide. All reagent bottles and stock solutions must be sealed tightly and protected from light. One must never combine potassium or sodium cyanide cyanide (in solid or liquid form) with strong acid, because gaseous HCN forms instantly. (Even the addition of potassium or sodium cyanide to a physiologic buffer (pH 7.4) can result in the formation of hydrogen cyanide gas.) All work must be carried out in a recently certified chemical fume hood, with the window properly positioned to assure adequate suction. Laboratory workers must follow all recommended institutional protocols for safe handling and disposal of cyanide. **Target(s):** Anaerobic fermentation (2); ascorbate oxidase (3); catalase (1,4); nitrate reductase, from spinach (*Spinacea oleracea*) (5); cytochrome oxidase, bimolecular rate constant =  $10^6 \text{ M}^{-1}\text{s}^{-1}$  and  $K_d = 50 \text{ nM}$ , or less (6); cytochrome P450-mediated drug oxidation in rat liver microsomes (7); glutathione peroxidase, ovine erythrocyte (8); heme oxygenase (9); 4-hydroxybenzoyl-CoA reductase (10); lignin peroxidase, from *Phanerochaete chrysosporium* (11); phloem translocation (12); stearyl-coenzyme A desaturase, reversible inhibition (13); superoxide dismutase, cochlear (14); vitamin K-dependent carboxylase (15). 1. ### Cyanidin

This flavylium cation ( $\text{FW}_{\text{chloride}} = 322.70 \text{ g/mol}$ ; brownish-red solid;  $\lambda_{\text{max}} = 535 \text{ nm}$  in methanol and HCl), also known as the 3,5,7,3',4'-pentahydroxyflavylium cation, is the aglycon of many of the plant pigments anthocyanins, melocyanin, chrysanthemins, and cyanin). **Target(s):** aflatoxin biosynthesis (1); glucose uptake (2); CYP2A1 (3); CYP3A2 (3); epidermal growth-factor receptor protein-tyrosine kinase (4); DNA topoisomerase I (5); DNA topoisomerase II (5); glycogen phosphorylase (6). 1. ### N-(N-Cyanoacetyl-L-phenylalanyl)-L-phenylalanine

This modified dipeptide ( $\text{FW}_{\text{free-acid}} = 379.42 \text{ g/mol}$ ) is a mechanism-based inactivator of human neprilysin (neutral endopeptidase 24.11) and angiotensin-converting enzyme (or, peptidyl dipeptidase A), by intercepting an enzyme-bound ketenimine intermediate. It was the first mechanism-based inhibitor of angiotensin-converting enzyme. Note that the enzyme catalyzes the hydrolysis of the inhibitor, yielding the partition ratio (i.e.,  $k_{\text{cat}}/k_{\text{inact}}$ ) of 8300. 1. Levy, Taibi, Mobashery & Ghosh (1993) *J. Med. Chem.* **36**, 2408. 2. Ghosh, Said-Nejad, Roestamadjji & Mobashery (1992) *J. Med. Chem.* **35**, 4175.

### $\beta$ -Cyano-L-alanine

This toxic amino acid ( $\text{FW} = 114.10 \text{ g/mol}$ ; CAS 6232-19-5), found in the legume *Vicia sativa* (common vetch),  $\beta$ -cyano-L-Alanine (BCA) reversibly inhibits cystathionine  $\gamma$ -lyase, or CSE ( $\text{IC}_{50} = 6.5 \mu\text{M}$ ), a major  $\text{H}_2\text{S}$ -producing enzyme that is primarily present in both smooth muscle and endothelium as well as in periaortic adipose tissues (1-3). CSE is a versatile pyridoxal-P-dependent catalyst for the conversion of (a)

cystathionine into cysteine,  $\alpha$ -ketobutyrate, and  $\text{NH}_3$ ; (b) L-homoserine into  $\text{H}_2\text{O}$ ,  $\text{NH}_3$  and 2-oxobutanoate; (c) L-cystine into thiocysteine, pyruvate and  $\text{NH}_3$ , and (d) L-cysteine into pyruvate,  $\text{NH}_3$  and  $\text{H}_2\text{S}$ . Regulation of  $\text{H}_2\text{S}$  production from CSE is controlled by a complex integration of transcriptional, posttranscriptional, and posttranslational mechanism.  $\beta$ -Cyano-L-alanine blocks  $\text{H}_2\text{S}$  synthesis in rat liver preparations. **Target(s):** tryptophanase (4); aspartate 4-decarboxylase,  $K_i = 0.27$  mM for the *Alcaligenes faecalis* enzyme (5–7); cystathionine  $\beta$ -lyase (8–12); alanine aminotransferase (13,14); D-amino-acid oxidase (15); UDP-*N*-acetylmuramate: L-alanine ligase, or UDP-*N* acetylmuramoyl-L-alanine synthetase, or L-alanine-adding enzyme (16,17,18); asparaginyl-tRNA synthetase (19); serine-sulfate ammonia-lyase (20); asparaginase, as slow alternative substrate (21,22); *O*-phosphoserine sulfhydrylase (23). **1.** Nagasawa, Kanzaki & Yamada (1987) *Meth. #### ***N*-(3-Cyanobenzyl)-*N*-(4-cyano-3-(2-tolyl)phen-1-yl)-*N*-(3-methyl-3*H*-imidazol-4-ylmethyl)amine**

This imidazole-containing biphenyl (FW = 417.52 g/mol) inhibits rat protein farnesyltransferase, or FTase ( $\text{IC}_{50} = 0.97$  nM). The 4-cyanobenzyl analogue is a slightly weaker inhibitor ( $\text{IC}_{50} = 10$  nM). This inhibitor is cellularly active ( $\leq 80$  nM) and shows >300-fold selectivity for FTase versus geranylgeranyltransferase (GGTase) selective. An X-ray crystal structure of inhibitor bound to rat farnesyltransferase is also presented. **1.** Curtin, Florjancic, Cohen, *et al.* (2003) *Bioorg. Med. Chem. Lett.* **13**, 1367.

#### **4-(4-Cyanobenzoyl)-2,5-dimethyl-1-(2*R*)-hydroxy-2-methyl-3,3,3-trifluoro-propionyl)piperazine**

This substituted piperazine (FW = 383.37 g/mol), also known as Nov3r, inhibits pyruvate dehydrogenase (acetyl transferring) kinase ( $\text{IC}_{50} = 6.7$   $\mu\text{M}$ ). **1.** Mann, Dragland, Vinluan, *et al.* (2000) *Biochim. #### **(5*E*)-6-(3-(2-Cyano-3-benzylguanidino)phenyl)-6-(3-pyridyl)hex-5-enoate**

This guanidine derivative (FW<sub>free-acid</sub> = 439.52 g/mol) inhibits human thromboxane-A synthase ( $\text{IC}_{50} = 11$  nM) and is a thromboxane receptor antagonist ( $\text{IC}_{50} = 32$  nM). It also inhibits the collagen-induced platelet aggregation in human platelet-rich plasma and whole blood. **1.** Soyka, Guth, Weisenberger, Luger & Müller (1999) *J. Med. Chem.* **42**, 1235.

#### **2(S)-2-[(2(S)-2-[3-(4-Cyanobenzyl)-3*H*-imidazol-4-yl]acetylamino)-3(S)-methyl-pentyl)naphthalen-1-ylmethylamino]acetylamino-4-(methylsulfonyl)butyric Acid**

This compound (FW = 668.86 g/mol), also known as Merck 21, is a potent inhibitor of Ras farnesyltransferase ( $\text{IC}_{50} = 0.15$  nM). The  $\text{IC}_{50}$  is 67 nM for protein geranylgeranyl-transferase I. **1.** Anthony, Gomez, Schaber, *et al.* (1999) *J. Med. Chem.* **42**, 3356. **2.** Gibbs (2001) *The Enzymes*, 3rd ed., **21**, 81.

#### **Cyanoborohydride**

This anionic reducing agent (FW<sub>Na-Salt</sub> = 62.842 g/mol; Solubility = 2 g/mL  $\text{H}_2\text{O}$ ) is a powerful reducing reagent that is more stable and more selective than borohydride. Cyano-borohydride reduces aldehydes and ketones to their corresponding alcohols. It will not reduce carboxyl groups, amides, ethers, lactones, or epoxides. It is frequently used for reductive amination of aldehydes, ketones, imines, as well as reductive alkylation of amines and hydrazines. **Applications:** Given its relative stability in aqueous solutions and preference as an imine reductant, cyanoborohydride has found many applications in protein and enzyme chemistry. Indeed, this agent is very useful for trapping covalent intermediates formed during enzyme catalysis (1-3). Antibodies to carbohydrates: preparation of antigens by coupling carbohydrates to proteins by reductive amination with cyanoborohydride (4); Use in the preparation of biologically active nitroxides (5); Reduction of nicotinamide adenine dinucleotides by sodium cyanoborohydride (6); Factors affecting cyanoborohydride reduction of aromatic Schiff's bases in proteins (7); Protein labeling by reductive methylation with sodium cyanoborohydride: effect of cyanide and metal ions on the reaction (8); Labeling of proteins by reductive methylation using sodium cyanoborohydride (9); Reversibility of the ketoamine linkages of aldoses with proteins (10); Detection and determination of protein-bound

formaldehyde: Improved recovery of formaldehyde by reduction with sodium cyanoborohydride (11); Cyanoborohydride reduction of rhodopsin (12); Identification of bound pyruvate essential for the activity of phosphatidylserine decarboxylase of *Escherichia coli* (13); Chemical trapping of complexes of dihydroxyacetone phosphate with muscle fructose-1,6-bisphosphate aldolase (14); Use of *p*-aminobenzoic acid and tritiated cyanoborohydride for the detection of pyruvyl residues in proteins (15); Inactivation of 5-enolpyruvylshikimate 3-phosphate synthase by its substrate analogue pyruvate in the presence of sodium cyanoborohydride (16); Identification of lysine-153 as a functionally important residue in UDP-galactose 4-epimerase from *Escherichia coli* (17); Proteins containing reductively aminated disaccharides: chemical and immunochemical characterization (18); Characterization of the products of reduction of the collagen cross-links in skin, tendon and bone with sodium cyanoborohydride (19); Lectin purification on affinity columns containing reductively aminated disaccharides (20). 1. ### Cyanocobalamin

This vitamin B<sub>12</sub> analogue (FW = 1355.37 g/mol; CAS 68-19-9), is a precursor to the physiologic cobalamins, because its cyanide group is readily replaced by other substituents. Aqueous solutions are photolabile and will generate hydroxocobalamin. Strongly acidic or alkaline conditions will slowly hydrolyze the amide groups, even at room temperature. It will react with cyanide at pH 10 to produce dicyanocobalamin. **Target(s)**: ethanolamine ammonia-lyase (1-3,5,6); propanediol dehydratase (2,8); glycerol dehydratase (2,7); HIV-1 integrase (4); ribonucleoside-triphosphate reductase,  $K_i = 42.6 \mu\text{M}$  (9). 1. Kaplan & Stadtman (1971) *Meth. Enzymol.* **17B**, 818. 2. Abeles (1971) *The Enzymes*, 3rd ed. (Boyer, ed.), **5**, 481. 3. Stadtman (1972) *The Enzymes*, 3rd ed. (Boyer, ed.), **6**, 539. 4. ### (2S)-2-Cyano-1-[(2S,4S)-4-(5-cyano-2-pyridyl)amino-2-pyrrolidinylcarbonyl]-pyrrolidine

This substituted (FW<sub>free-base</sub> = 310.36 g/mol) inhibits dipeptidyl-peptidase IV (IC<sub>50</sub> = 0.25 nM for the human enzyme). Based on pharmacokinetic experiments in rats, the representative compound 11, which displayed high oral bioavailability (BA=83.9%) and long half-life in plasma (t(1/2)=5.27 h), was found to have an excellent pharmacokinetic profile. 1. Sakashita, Akahoshi, Kitajima, Tsutsumiuchi & Hayashi (2006) *Bioorg. Med. Chem.* **14**, 3662.

### 3-Cyano-6-[[2-[(2S)-2-cyanopyrrolidin-1-yl]-2-oxoethyl]-amino]-ethyl]-amino-pyridine

This substituted pyrrolidone (FW = 298.35 g/mol), also known as NVP-DDP728, is a strong inhibitor of dipeptidyl peptidase IV (IC<sub>50</sub> = 1.4 nM for the human enzyme). **Target(s)**: cytosol nonspecific Dipeptidase, or prolyl Dipeptidase (1); dipeptidyl-peptidase II, weakly inhibited (1); dipeptidyl-peptidase IV (1,2). 1. Jiaang, Chen, Hsu, et al. (2005) *Bioorg. Med. Chem. Lett.* **15**, 687. 2. Sakashita, Akahoshi, Kitajima, Tsutsumiuchi & Hayashi (2006) *Bioorg. Med. Chem.* **14**, 3662.

### (5E)-6-(3-(2-Cyano-3-cyclohexylguanidino)phenyl)-6-(3-pyridyl)hex-5-enoate

This guanidine derivative (FW<sub>free-acid</sub> = 431.54 g/mol) inhibits human thromboxane-A synthase (IC<sub>50</sub> = 3 nM) and is a thromboxane receptor antagonist (IC<sub>50</sub> = 47 nM). Note that the structural isomer having the guanidino group located in the *para*-position of the phenyl moiety is a significantly weaker inhibitor (IC<sub>50</sub> = 0.18 and 1.3 μM for the synthase and receptor, respectively). 1. Soyka, Guth, Weisenberger, Luger & Müller (1999) *J. Med. Chem.* **42**, 1235.

### (S)-N-(1-Cyanocyclopropyl)-3-(methylsulfonyl)-2-(((S)-2,2,2-trifluoro-1-(4-fluoro-phenyl)ethyl)amino)propanoate

This orally bioavailable protease inhibitor (FW = 407.38 g/mol), also known as Compound 6, selectively targets cathepsin S, or CTSS ( $IC_{50}$  = 2.9  $\mu$ M), with weaker action against cathepsins K, V, L and B. Cathepsin S is a lysosomal protease that is expressed under inflammatory conditions, including autoimmune disorders, cardiovascular disease, and cancer. Compound 6 blocks both murine and human cell invasion and disrupts endothelial tube formation, underscoring its anti-angiogenic properties. Selectivity of Compound 6 towards CTSS was confirmed using an MC38 knock-down model, whereby treatment of CTSS-depleted cells with Compound 6 produced no further reduction in invasiveness. 1. Wilkinson, Young, Burden, Williams & Scott (2016) *Mol. Cancer* **15**, 29.

#### $\alpha$ -Cyano-4-hydroxycinnamate

This surface matrix molecule and pyruvate transport inhibitor (FW = 189.17 g/mol; CAS 28166-41-8; IUPAC Name: (*E*)-2-cyano-3-(4-hydroxyphenyl)prop-2-enoate), which is often used to desorb and mobilize peptides and nucleotides into the ion analyzer stream in MALDI mass spectrometers, also strongly inhibits the transport of pyruvate, but not acetate or butyrate, into liver mitochondria and erythrocytes (1). In the red cells, lactate uptake is also inhibited.  $\alpha$ -Cyano-4-hydroxycinnamate is a non-competitive inhibitor ( $K_i$  = 6.3  $\mu$ M), whereas phenyl-pyruvate is a competitive inhibitor ( $K_i$  = 1.8 mM). At 100  $\mu$ M,  $\alpha$ -cyano-4-hydroxycinnamate rapidly and almost totally inhibited  $O_2$  uptake by rat heart mitochondria oxidizing pyruvate (1). Inhibition could be detected at concentrations of inhibitor as low as 1  $\mu$ M, although inhibition requires more time to develop at this concentration (1). Importantly, inhibition is reversed by diluting out the inhibitor. In Ehrlich ascites tumor cells, lactate transport is inhibited competitively by (a) a variety of other substituted monocarboxylic acids (e.g., pyruvate,  $K_i$  = 6.3 mM), which were themselves transported; (b) the non-transportable analogues  $\alpha$ -cyano-4-hydroxycinnamate ( $K_i$  = 0.5 mM),  $\alpha$ -cyano-3-hydroxycinnamate ( $K_i$  = 2mM) and DL-*p*-hydroxyphenyl-lactate ( $K_i$  = 3.6 mM); and (c) the thiol-group reagent mersalyl ( $K_i$  = 125  $\mu$ M) (2). (See also UK5099, another mitochondrial pyruvate transport inhibitor) 1. Halestrap (1975) *Biochem. J.* **148**, 85. 2. Spencer & Lehninger (1976) *Biochem. J.* **154**, 405.

#### 2 $\alpha$ -Cyano-17 $\beta$ -hydroxy-4,4,17 $\alpha$ -trimethylandroster-5-en-3-one

This semisynthetic steroid (FW = 355.52 g/mol), commonly referred to as cyanoketone, is a strong inhibitor of  $3\beta$ -hydroxysteroid dehydrogenase/steroid  $\Delta^5$ -isomerase. **Target(s):**  $3\beta$ -hydroxysteroid dehydrogenase/steroid  $\Delta^5$ -isomerase (1-6,10); cholesterol monooxygenase, side-chain-cleaving, or CYP11A1 (7,8); cytochrome *c* oxidase (7); steroid  $\Delta$  isomerase (9). 1. Edwards, O'Conner, Bransome & Braselton (1976) *J. Biol. Chem.* **251**, 1632. 2. Cooke (1996) *J. Steroid Biochem. Mol. Biol.* **58**, 95. 3. Takahashi, Luu-The & Labrie (1990) *J. Steroid Biochem. #### 4-*N*-(4-Cyanophenyl)amino-5-(4-ethoxyphenyl)-7-( $\beta$ -D-erythrofuranosyl)-pyrrolo[2,3-*d*]pyrimidine

This tubercidin analogue (FW = 457.49 g/mol) inhibits human adenosine kinase ( $IC_{50}$  = 2 nM). Because the use of adenosine receptor agonists is plagued by dose-limiting cardiovascular side effects, there is great interest in developing adenosine kinase inhibitors (AKIs) as a means for raising steady-state adenosine concentrations. 1. Boyer, Ugarkar, Solbach, et al. (2005) *J. Med. Chem.* **48**, 6430.

#### 2 $\alpha$ -Cyanoprogesterone

This steroid (FW = 339.48 g/mol) is an irreversible active-site-directed inhibitor of *Pseudomonas testosteroni* steroid  $\Delta$ -isomerase (1). It is also a potent inhibitor of the bovine corpus luteum  $\beta$ -hydroxysteroid dehydrogenase,  $K_i$  = 15 nM (2,3). 1. Penning (1985) *Biochem. J.* **226**, 469. 2. Sharp, Senior & Penning (1985) *Biochem. J.* **230**, 587. 3. Sharp & Penning (1988) *Steroids* **51**, 441.

#### 2 $\alpha$ -Cyano-4,4,17 $\alpha$ -trimethyl- $\Delta^5$ -androsten-17 $\beta$ -ol-3-one

This synthetic steroid (FW = 355.52 g/mol), also known as cyanoketone, inhibits many steroidogenic processes (1). **Target(s):** cytochrome *c* oxidase (2); cholesterol monooxygenase, side-chain cleaving (2,3,7);  $\Delta^5$ - $3\beta$ -hydroxysteroid dehydrogenase (4-7); steroid  $\Delta$ -isomerase (1.6);  $20\alpha$ -hydroxysteroid dehydrogenase, moderately inhibited (7); estradiol receptor (8). 1. Talalay & Benson (1972) *The Enzymes*, 3rd ed. (Boyer, ed.), **6**, 591. 2. Graves, Uzgiris, Querner, et al. (1978) *Endocrinology* **102**, 1077. 3. Farese (1970) *Steroids* **15**, 245. 4. #### Cyanuric Acid

This toxic triazine (FW = 129.08 g/mol), also known as 5-azabarbituric acid, is a disinfectant and a reagent for organic synthesis. It is also a precursor for cyanic acid. Cyanuric acid is slightly soluble in water (0.2% at 25°C) and has  $pK_a$  values of 6.88, 11.40, and 13.5. The keto form, also known as isocyanuric acid, is the main tautomer in acidic solutions whereas the enol form is more stable in basic solutions. **Target(s):** barbiturase (1); orotate phosphoribosyl-transferase (2); urate oxidase, *or* uricase,  $K_i = 30 \mu\text{M}$  (3,4); xanthine oxidase (5). 1. Soong, Ogawa, Sakuradani & Shimizu (2002) *J. Biol. Chem.* **277**, 7051. 2. Javaid, el Kouni & Iltzsch (1999) *Biochem. Pharmacol.* **58**, 1457. 3. Fridovich (1965) *J. Biol. #### Cyc-116

This potent mitotic protein kinase inhibitor (FW = 368.46 g/mol; CAS 693228-63-6; Solubility = 24 mg/mL DMSO (with warming)), also named 4-(2-amino-4-methylthiazol-5-yl)-*N*-(4-morpholinophenyl)pyrimidin-2-amine, targets Aurora A ( $K_i = 8.0 \text{ nM}$ ) and Aurora B ( $K_i = 9.2 \text{ nM}$ ). **Other Targets:** VEGFR2 ( $K_i = 44 \text{ nM}$ ); Flt3 ( $K_i = 44 \text{ nM}$ ); and 50x greater potency toward Aurora A and B than other CDKs. Cyc-116 is inactive against PKA, Akt/PKB, PKC, no effect on GSK-3 $\alpha/\beta$ , CK2, Plk1 and SAPK2A. 1. Wang, Midgley, Scaërour, *et al.* (2010) *J. Med. Chem.* **53**, 4367.

#### Cyclin-Dependent Kinase Inhibitor p21

This potent, high-affinity Cdk-binding protein (MW = 21 kDa), also known as p21<sup>Cip1</sup> and 21-kDa Cdk-interacting protein-1 (Cip1), inhibits the phosphorylation of retinoblastoma tumor suppressor protein (Rb) by cyclin A-Cdk2, cyclin E-Cdk2, cyclin D1-Cdk4, and cyclin D2-Cdk4 complexes (1). Cyclin-dependent kinase Cdk2 associates with cyclins A, D, and E and has been implicated in controlling the G<sub>1</sub>-to-S cell cycle transition in mammals. 1 $\alpha$ ,25-Dihydroxyvitamin D<sub>3</sub> inhibits pancreatic cancer cell proliferation by up-regulating the expression of cyclin-dependent kinase inhibitor p21 (2). 1. Harper, Adami, Wei, Keyomarsi & Elledge (1993) *Cell* **75**, 805. 2. Kanemaru, Maehara & Chijiwa (2013) *Hepatogastroenterol.* **60**, 1199.

#### Cycloartenol

This widely occurring phytosteroid precursor (FW = 426.73 g/mol; CAS 469-38-5), itself a substrate for cycloartenol 24-C-methyltransferase, inhibits trypsin and chymotrypsin, with respective  $K_i$  values of 25 and 420  $\mu\text{M}$ , respectively). **Target(s):** sterol acyltransferase, *or* cholesterol acyltransferase (1); cycloartenol cyclo-isomerase, weakly inhibited (2); chymotrypsin (3); trypsin (3). 1. Billheimer (1985) *Meth. Enzymol.* **111**, 286. 2. Rahier, Taton & Beneviste (1989) *Eur. J. Biochem.* **181**, 615. 3. Rajic, Akihisa, Ukiya, *et al.* (2001) *Planta Med.* **67**, 599.

#### Cyclobenzaprine

This widely used oral muscle relaxant (FW<sub>free-base</sub> = 275.39 g/mol; FW<sub>HCl</sub> = 311.85 g/mol; CAS 303-53-7), also named 3-(5*H*-dibenzo[*a,d*]cyclohept-5-ylidene)-*N,N*-dimethyl-1-propanamine, is a centrally acting drug that most likely activates locus coeruleus neurons, leading to an increased release of noradrenaline in the ventral horn of the cord and the subsequent inhibitory action of noradrenaline on alpha motoneurons (1). Other studies indicate cyclobenzaprine is a 5-HT<sub>2</sub> receptor antagonist and that its muscle relaxant effect is due to inhibition of serotonergic, not noradrenergic, descending systems in the spinal cord (2). 1. Commissiong, Karoum, Reiffenstein & Neff (1981) *Can. J. Physiol. Pharmacol.* **59**, 37. 2. Kobayashi, Hasegawa & Ono (1996) *Eur. J. Pharmacol.* **311**, 29.

#### (3*R*,4*S*)-4-(Cyclobutylthiomethyl)-1-[(9-deazaadenin-9-yl)methyl]-3-hydroxy-pyrrolidine

This transition-state mimic (FW<sub>free-base</sub> = 319.43 g/mol) inhibits *Escherichia coli* 5'-methylthioadenosine/*S*-adenosylhomocysteine nucleosidase, *or* MTAN ( $K_i = 2.2 \text{ pM}$ ), an enzyme that hydrolyzes its substrates to form adenine and 5-methylthioribose (MTR) or *S*-ribosylhomocysteine (SRH). 5'-Methylthioadenosine (MTA) is a by-product of polyamine synthesis and SRH is a precursor to the biosynthesis of one or more quorum sensing autoinducer molecules. MTAN is therefore involved in quorum sensing, recycling MTA from the polyamine pathway via adenine phosphoribosyltransferase and recycling MTR to methionine. Hydrolysis of MTA by *E. coli* MTAN involves a highly dissociative transition state with riboxacarbonium ion character. This minoribitol mimics the transition state of MTAN, a property surmised from its extraordinary affinity as an inhibitor. 1. Singh, Evans, Lenz, *et al.* (2005) *J. Biol. Chem.* **280**, 18265.

#### Cycloheximide

This antibiotic and rodenticide (FW = 281.35 g/mol; CAS 66-81-9; Solubility: 2.1 g/100 mL H<sub>2</sub>O at 2°C), also known as 3-[2(3,5-dimethyl-2-oxocyclohexyl)-2-hydroxyethyl]glutarimide, from *Streptomyces griseus* inhibits eukaryotic protein biosynthesis by interfering with chain

elongation and translocation, *i.e.*, inhibition of the peptidyltransferase activity on the 60S subunit of the ribosome (1-4). Cycloheximide is without effect on prokaryotic and mitochondrial protein biosynthesis. Displaying significant toxicity (*e.g.*, DNA damage, teratogenesis, and birth defects), cycloheximide is unsuitable as a human medicine. **Use in Estimating *In Vivo* Half-life of Proteins:** Because most proteins undergo continual turnover, the steady-state concentration depends on their rate constants for synthesis ( $k_{syn}$ ) and degradation ( $k_{deg}$ ), the latter often defined as a first-order process, with  $t_{1/2} = 0.693/k_{deg}$ . In the presence of cycloheximide, one may use SDS gel electrophoresis and Western blotting (with a protein-specific antibody) to determine  $t_{1/2}$  (4). The *in vivo* turnover of the rat liver tyrosine transaminase, for example, was measured by a label and chase procedure under conditions where the amount of enzyme undergoes no change. The half-life of the  $^{14}\text{C}$ -labeled enzyme in this basal condition was found to be 1.5 hours. Inhibitors of protein synthesis (cycloheximide or puromycin) do not appreciably influence the basal enzyme level over a 5-hour period, although these drugs will block hormonal induction of this enzyme. In pulse-labeling experiments, cycloheximide blocked transaminase synthesis almost completely (4). Such findings showed that enzyme degradation kinetics can be determined when rat liver protein synthesis is blocked by cycloheximide. **Target(s):** protein biosynthesis, eukaryotic (1-4,8); peptidyltransferase (5); alcohol dehydrogenase, yeast (6); DNA-directed RNA polymerase (7); agmatine deaminase (9); ferric-chelate reductase (10); stearoyl-CoA 9-desaturase (11). 1. Pestka (1974) *Meth. Enzymol.* **30**, 261. 2. Carrasco, Battaner & Vazquez (1974) *Meth. Enzymol.* **30**, 282. 3. Scott & Tomkins (1975) *Meth. Enzymol.* **40**, 273. 4. **2-[5-[(Cyclohexylsulfamoyl)amino]-2-(4-fluorophenyl)-6-oxo-1,6-dihydro-1-pyrimidinyl]-N-[1-isopropyl-2-oxo-3,3,3-trifluoropropyl]acetamide**

This substituted 5-aminopyridin-6-one (FW = 575.58 g/mol) inhibits human leukocyte elastase ( $K_i = 1.6$  nM), relying on its trifluoromethylketone as the chemically active warhead to react with the active-site Ser-195. Such molecules are more bioavailable than boronate and haloketone inhibitors. 1. Veale, Bernstein, Bryant, *et al.* (1995) *J. Med. Chem.* **38**, 98.

**3-(Cyclohexylthio)-1,1,1-trifluoropropan-2-one**

This affinity-directed halomethyl ketone (FW = 225.25 g/mol), also known as 3-cyclohexylsulfanyl-1,1,1-trifluoro-2-propanone, inhibits juvenile-hormone esterase ( $IC_{50} = 5.2$   $\mu\text{M}$ ) and acetylcholinesterase ( $IC_{50} = 0.71$   $\mu\text{M}$ ). This study indicates that, by varying the substituent on the sulfide moiety, potent "transition-state" inhibitors can be developed for a wide variety of esterases and proteases. The most powerful inhibitor tested was 3-octylthio-1,1,1-trifluoro-2-propanone, with an  $IC_{50}$  of  $2.3 \times 10^{-9}$  M on JH esterase. 1. Hammock, Abdel-Aal, Mullin, Hanzlik & Roe (1984) *Pest. Biochem. Physiol.* **22**, 209.

**Cyclo(L-histidyl-L-prolyl)**

This naturally occurring diketopiperazine (FW<sub>free-base</sub> = 234.26 g/mol), produced in the degradation of thyrotropin-releasing factor, inhibits 2-deoxy-D-glucose-stimulated pancreatic secretion of prolactin. **Target(s):** prolactin secretion (1,2); chitinase (3). 1. Fragner, Presset, Bernad, *et al.* (1997) *Amer. J. Physiol.* **273**, E1127. 2. Prasad (1998) *Thyroid* **8**, 969. 3. Houston, Synstad, Eijsink, *et al.* (2004) *J. Med. Chem.* **47**, 5713.

**Cycloleucine**

This highly toxic leucine/valine analogue (FW = 129.16 g/mol; CAS 52-52-8), also known as 1-aminocyclopentanecarboxylic acid, is an *N*-methyl-D-aspartate (NMDA) receptor antagonist (acting at the glycine site), an inhibitor of *S*-adenosyl-L-methionine synthesis (and therefore all SAM-dependent methyltransferases), and amino acid transport. When administered as a single dose intraperitoneally (2 mg/g body weight) to 21-day-old young mice and 6-10-week adults aged, brain SAM concentrations are reduced, with levels of methionine greatly elevated (1). The immature developing central nervous system is much more vulnerable than the fully myelinated adult brain and spinal cord. **Target(s):** flagellar motor (2); methionine *S*-adenosyltransferase (3,6,7,9-13); NMDA receptor (4,5); lysine transport (8); cystine transport (8). 1. Lee, Surtees & Duchon (1992) *Brain* **115**, 935. 2. Macnab (1986) *Meth. Enzymol.* **125**, 563. 3. Mudd (1973) *The Enzymes*, 3rd ed. (Boyer, ed.), **8**, 121. 4. Snell & Johnson (1988) *Eur. J. Biochem.* **19**, 384. 13. Yarlott, Garofalo, Goldberg, *et al.* (1993) *Biochim. Biophys. Acta* **1181**, 68.

**Cyclooctatin**

This natural product (FW = 322.49 g/mol), produced by a strain of *Streptomyces melanosporofaciens* Strepto MI614-43F2, competitively inhibits lysophospholipase,  $K_i = 4.8$   $\mu\text{M}$ . 1. Aoyagi, Aoyama, Kojima, *et al.* (1992) *J. Antibiot.* **45**, 1587.

## Cyclopamine

This teratogenic *Veratrum* alkaloid (FW<sub>free-base</sub> = 411.63 g/mol), also known as 11-deoxyjervine, inhibits the sonic hedgehog signaling pathway by direct binding to the heptahelical bundle of Smoothened (*i.e.*, it is a sonic hedgehog signaling antagonist). The name (derived from *Cyclops*, the one-eyed giant in Homer's *Odyssey*) refers to one-eyed lamb that born to ewes who had consumed the leaves of *Veratrum californicum*, the corn lily plant that produces cyclopamine. **Target(s):** sonic hedgehog signalling pathway (1,2,3); P-glycoprotein-mediated drug transport (4). 1. Incardona, Gaffield, Kapur & Roelink (1998) *Development* **125**, 3553. 2. Incardona, Gaffield, Lange, *et al.* (2000) *Dev. Biol.* **224**, 440. 3. ## 1,2-Cyclopentanedicarboxylic Acid

This succinic acid analogue (FW<sub>free-acid</sub> = 158.15 g/mol; CAS 1461-97-8) inhibits Xaa-Pro dipeptidase ( $K_i = 0.5 \mu\text{M}$ ) and succinate dehydrogenase. **Target(s):** Xaa-Pro Dipeptidase, *or* prolidase, inhibited by *trans*-isomer (1-3); succinate dehydrogenase, inhibited by the *trans*-isomer (4,5) however, another report lists both geometric isomers as inhibitors (6). 1. Mock (1998) in *Handb. Proteolytic Enzymes*, p. 1403, Academic Press, San Diego. 2. Mock & Green (1990) *J. Biol. Chem.* **265**, 19606. 3. Radziicka & Wolfenden (1990) *J. Amer. Chem. Tietze & Klotz (1952) *Arch. Biochem. Biophys.* **35**, 355.

## 2-[(4-Cyclopentylcarbonylamino)-6-{3R-[(2-naphthylmethyl)amino]cyclopentyl-1-S-carboxamido}benzothiazole

This benzothiazole (FW = 512.68) inhibits *Candida albicans* N-myristoyltransferase (IC<sub>50</sub> = 15 nM). The 3*S*,1*R*-isomer also inhibits (IC<sub>50</sub> = 11 nM). 1. Yamazaki, Kaneko, Suwa, *et al.* (2005) *Bioorg. Med. Chem.* **13**, 2509.

8-Cyclopentyl-6-ethyl-5-methyl-2-[4-(piperazin-1-yl)phenylamino]-8*H*-pyrido[2,3-*d*]pyrimidin-7-one

This pyridopyrimidinone (FW = 431.56 g/mol) inhibits cyclin-dependent kinase 4, *or* Cdk4, IC<sub>50</sub> = 25 nM). The pyrido[2,3-*d*]pyrimidin-7-one template had been identified previously as a privileged structure for inhibition of ATP-dependent kinases, and introduction of a methyl substituent at the C-5 position of the pyrido[2,3-*d*]pyrimidin-7-one conferred excellent selectivity for Cdk4 versus other Cdk's and representative tyrosine kinases. Further optimization identified highly potent and Cdk4-selective inhibitor showing potent antiproliferative activity against human tumor cells *in vitro*. 1. VanderWel, Harvey, McNamara, *et al.* (2005) *J. Med. Chem.* **48**, 2371.

8-Cyclopentyl-*N*<sup>3</sup>-[3-(4-(fluorosulfonyl)benzoyloxy)-propyl]-*N*<sup>1</sup>-propylxanthine

This substituted xanthine (FW = 506.56 g/mol) is an irreversible A<sub>1</sub> adenosine receptor antagonist. 1. Srinivas, Shryock, Scammells, *et al.* (1996) *Mol. Pharmacol.* **50**, 196. 2. Scammells, Baker, Belardinelli & Olsson (1994) *J. Med. Chem.* **37**, 2704. 3. van Muijlwijk-Koezen, Timmerman, van der Sluis, *et al.* (2001) *Bioorg. Med. Chem. Lett.* **11**, 815. 4. Beauglehole, Baker & Scammells (2000) *J. Med. Chem.* **43**, 4973.

## 2-[(4-Cyclopentylmethoxy-3-diethylsulfamoyl-benzoyl)amino]benzoic Acid

This aromatic sulfonamide (FW<sub>free-acid</sub> = 474.58 g/mol) inhibits *Enterococcus faecalis* β-ketoacyl-[acyl-carrier-protein] synthase III (IC<sub>50</sub> = 2.1 μM). 1. Nie, Perretta, Lu, *et al.* (2005) *J. Med. Chem.* **48**, 1596. 2. Ashek, San Juan & Cho (2007) *J. Enzyme Inhib. Med. Chem.* **22**, 7.

## Cyclophellitol

This epoxide-containing cyclitol (FW = 176.17 g/mol; CAS 126661-83-4), from the mushroom *Phellinus* sp. and named as (1*S*,2*R*,3*S*,4*R*,5*R*,6*R*)-5-hydroxymethyl-7-oxabicyclo[4.1.0]heptane-2,3,4-triol inhibits β-glucosidase (1-4), glucosyl ceramidase (1), and β-xylosidase, the latter weakly (3). 1. ## Cyclophosphamide

Cyclophosphamide

4-Hydroxycyclophosphamide

This anticancer drug (FW = 261.09 g/mol), also known as Endoxan™ and Cytoxan™, is an alkylating agent that crosslinks DNA, causing strand breakage, and inducing lethal mutations. Cyclophosphamide can also alkylate protein sulfhydryl and amino groups. Microsomal mixed function hydroxylases act on cyclophosphamide to produce 4-hydroxycyclophosphamide (and its tautomer, aldophosphamide), which is the reactive metabolite. **Target(s):** acetylcholinesterase (1,5,6); DNA polymerase (2); cholinesterase, or butyrylcholinesterase (3,4,6). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. al-Jafari, Kamal & Alhomida (1997) *J. Enzyme Inhib.* **11**, 275. 2. Helge, Oberdisse & Engels (1968) *Naunyn Schmiedebergs Arch. Exp. Pathol. Fujii, Ohnoshi, Namba & Kimura (1982) *Gan To Kagaku Ryoho* **9**, 831.

## Cyclopiazotate

 $\beta$ -cyclopiazotate $\alpha$ -cyclopiazotate

This toxic metabolite (FW = 336.39 g/mol; CAS 18172-33-3) from certain strains of *Penicillium cyclopium* and *Aspergillus flavus* depletes intracellular  $\text{Ca}^{2+}$  stores. Cyclopiazotate is a product of the reaction catalyzed by  $\beta$ -cyclopiazotate dehydrogenase. 1. Suzuki, Muraki, Imaizumi & Watanabe (1992) *Brit. J. Pharmacol.* **107**, 134. 2. ## Cyclopropanecarboxylate

This hypoglycemic agent (FW<sub>free-acid</sub> = 86.09 g/mol; M.P. = 17-19°C; B.P. = 182-184°C) inhibits metabolism of pyruvate, branched-chain  $\alpha$ -keto acids, acetoacetate, and hydroxybutyrate. Its methyl ester (FW = 100.12 g/mol; CAS 2868-37-3) is cell-permeant and undergoes enzymatic hydrolysis to the free acid. **Target(s):** monocarboxylic acid transporter (1);  $\beta$ -ureidopropionase,  $\text{IC}_{50}$  = 8  $\mu\text{M}$  (2); glucuronosyltransferase,  $\text{IC}_{50}$  = 1  $\mu\text{M}$  (3). 1. ## Cyclopropanone &amp; Hydrate

This reactive ketone (FW = 56.064 g/mol; FW<sub>hydrate</sub> = 74.079 g/mol; CAS 5009-27-8), which exists primarily as the *gem*-diol or hydrate in aqueous solutions, inhibits several oxidases and oxidoreductases. In the case of horseradish peroxidase, the *gem*-diol undergoes oxidative ring opening to form the primary free radical of propionic acid which alkylates the porphyrin ring (1,2). The newly inserted new propionic acid side chain is substituted for one of the methine protons of the heme. **Target(s):** horseradish peroxidase, inhibited by *gem*-diol (1,2); alcohol oxidase (3,4); aldehyde dehydrogenase (NAD<sup>+</sup>), inhibited by the *gem* diol (5-7); methanol dehydrogenase, inhibited by *gem*-diol (8,9); alcohol dehydrogenase (quinoprotein), inhibited by *gem*-diol (10). 1.  $(\pm)$ -N-Cyclopropyl- $\alpha$ -methylbenzylamine

This substituted benzylamine (FW<sub>free-base</sub> = 161.25 g/mol) inactivates both monoamine oxidases A and B, with a preference for the later (1-3). Inactivation occurs via attachment to a cysteinyl residue as well as the flavin cofactor. Trimethylamine dehydrogenase is also inhibited by this agent (4). 1. ## Cyclosarin

This extremely toxic chemical warfare agent (FW = 180.16 g/mol; M.P. = -12°C; B.P. = 239°C), also called Agent GF and methyl cyclohexylfluorophosphonate, is a potent acetylcholinesterase inhibitor. It is a liquid at room temperature is readily absorbed through the skin (the LD<sub>50</sub> is 0.35 g/person). **Target(s):** acetylcholinesterase (1-4); cholinesterase (butyrylcholinesterase) (1,3). 1. Worek, Eyer & Szinicz (1998) *Arch. Toxicol.* **72**, 580. 2. Worek, Widmann, Knopff & Szinicz (1998) *Arch. Toxicol.* **72**, 237. 3. Schopfer, Voelker, Bartels, Thompson & Lockridge (2005) *Chem. ## D-Cycloserine

This isoxazolidinone (FW<sub>free-base</sub> = 109.09 g/mol; CAS 68-41-7; Symbol: DCS), also known as D-4-amino-3-isoxazolidinone and D-oxamycin, has been isolated from *Streptomyces garyphalus* sive *orchidaceus*. Note that neutral or acidic solutions are unstable. Solutions buffered at pH 10 can be stored at 4°C for one week. It inhibits the biosynthesis of bacterial cell

walls in Gram-negative microorganisms. As a cyclic analogue of D-alanine, cycloserine targets alanine racemase (ALR) and D-alanine:D-alanine ligase (DDL), two crucial enzymes important in the cytosolic stages of peptidoglycan synthesis. Cycloserine is also a partial agonist at the glycine modulatory site of the NMDA (*N*-methyl-D-aspartate) receptor. **Clinical Application:** Although less potent than first-line antituberculosis drugs such as isoniazid (INH) and streptomycin, D-cycloserine is a highly effective second-line drug against *Mycobacterium tuberculosis*, the causative agent of tuberculosis. Less drug-resistant *M. tuberculosis* is reported for DCS than INH and rifampin. **Target(s):** D-amino-acid aminotransferase, or D-alanine aminotransferase (1,3,12,21,26,55,56); D-alanyl-D-alanine synthetase, or D-alanine:D-alanine ligase (2,13-16,19,31,32,34-36); D-alanine Hydroxymethyltransferase (4,11); amino acid racemase (5); D-3-aminoisobutyrate:pyruvate aminotransferase (6);  $\beta$ -alanine: $\alpha$ -ketoglutarate aminotransferase (6); cystathionine  $\gamma$ -lyase (7,23);  $\omega$ -amino-acid:pyruvate aminotransferase, or  $\beta$ -alanine:pyruvate aminotransferase (8); serine C-palmitoyltransferase (9,27); alanine racemase (10,19,25,31, 32,35,36,41-43); 4-aminobutyrate aminotransferase (13,57-59); serine hydroxymethyltransferase (glycine hydroxy-methyltransferase) (17,18,28,65-70); glutamate decarboxylase (20); DOPA decarboxylase (20); kynureninase (22); 2,2-dialkylglycine decarboxylase (pyruvate) ( $\alpha,\alpha$ -dialkylamino acid aminotransferase), with the L-enantiomer is a stronger inhibitor (24,30); asparagine synthetase, weakly inhibited (28); amine oxidase, pea (33); isopenicillin-N epimerase (37); 2-amino-hexano-6-lactam racemase (38); asparagine:oxo-acid aminotransferase (60); aspartate racemase (39); amino-acid racemase (40); 3-chloro-D-alanine dehydrochlorinase (44); cystathionine  $\gamma$ -lyase (45); diaminopropionate ammonia-lyase (46); kynureninase (47,48); arylacetonitrilase, weakly inhibited (49); adenosylmethionine:8-amino-7-oxononanoate transaminase (50); taurine:2-oxoglutarate aminotransferase, weakly inhibited (51,52); serine:glyoxylate aminotransferase (53); 2-aminoethylphosphonate: pyruvate aminotransferase (54); alanine aminotransferase (61); cystathionine  $\gamma$ -synthase (62); cysteine synthase (63); 8-amino-7-oxononanoate synthase (64). 1. ### L-Cycloserine

This isoxazolidinone ( $FW_{\text{free-base}} = 109.09$  g/mol), also known as L-4-amino-3-isoxazolidinone and L-oxamycin, inhibits several pyridoxal-phosphate-dependent enzymes. It also inhibits sphingosine biosynthesis. Note that neutral or acidic solutions are unstable. Solutions buffered at pH 10 can be stored at 4°C for one week. **Inhibition of  $\gamma$ -Aminobutyric Acid Aminotransferase:** The inactivation of pig brain GABA-AT by L-cycloserine is time-dependent (1). Treatment of the enzyme with [ $^{14}$ C]-L-cycloserine, followed by rapid gel filtration, gives a stoichiometry of 1.1 mol radiolabeled inhibitor per mol enzyme. Inactivation of [ $^3$ H]pyridoxal 5'-phosphate-reconstituted GABA-AT with L-cycloserine followed by dialysis or denaturation also leads to the release of radioactivity from the enzyme. Electrospray ionization tandem mass spectrometry of the isolated cycloserine-coenzyme adduct suggests it is a tautomeric form of the Schiff base between pyridoxamine 5'-phosphate and oxidized cycloserine. **See also D-Cycloserine Target(s):** taurine:2-oxoglutarate aminotransferase (2,31); L-alanine aminotransferase (3,11,12); ornithine aminotransferase (4,32); D-alanine hydroxymethyltransferase, or 2-methylserine hydroxymethyltransferase (5,10); methionine  $\gamma$ -lyase (6,21,27); serine C-palmitoyltransferase (7-9,18, 20,35-40); glutamine:pyruvate aminotransferase (11); glutamate decarboxylase (12); asparagine aminotransferase (12); alanine racemase (13,25,26); aspartate aminotransferase (14,17,23,34); cystathionine  $\gamma$ -lyase (15); 2,2-dialkylglycine decarboxylase (pyruvate), or  $\alpha,\alpha$ -dialkylamino acid aminotransferase (16,22,29); aspartate racemase (24); homocysteine desulfhydrase (28); D-amino-acid aminotransferase (31); kynurenine:oxoglutarate aminotransferase (33). 1. ### Cyclosporin A

This cyclic undecapeptide antibiotic and immunosuppressant (FW = 1202.63 g/mol; CAS 59865-13-3; *Symbol*: CyA; Solubility: 50 mg/mL DMSO) targets cyclophilin, and the resulting complex in turn inhibits calcineurin, an essential phosphoprotein phosphatase controlling immune cell signal transduction. Cyclosporin A was initially isolated in 1969 from *Tolypocladium inflatum* (*Beauveria nivea*), a fungus found in a soil sample, by Sandoz biologist Hans Frey. Later investigations led by Hartmann Stähelin, also at Sandoz, demonstrated its powerful immunosuppressive action, a property commending its use to prevent graft-versus-host disease in bone-marrow transplantation and organ rejection in kidney, heart, and liver transplant patients. Cyclosporin is also approved in the U.S. for the treatment of rheumatoid arthritis and psoriasis. **Primary Mode of Action:** Cyclophilin is a ubiquitously expressed low-molecular-weight basic protein. Its peptidyl prolyl *cis-trans* isomerase (PPIase) activity regulates protein folding and trafficking. High cyclophilin expression correlates with poor outcome for patients with inflammatory diseases, including rheumatoid arthritis, asthma and sepsis. Cyclophilin comprises ~0.1–0.6% of total cytosolic protein by weight and is highly abundant in thymus, the organ from which it was first isolated. The Cyclophilin-Cyclosporin complex binds to and inhibits calcineurin (*or* Phosphoprotein Phosphatase 2B),  $K_i = 2.3$  nM. Calcineurin inhibition results in a complete block in the translocation of the cytosolic component of the Nuclear Factor of Activated T cells (NF-AT), resulting in a failure to activate the genes regulated by the NF-AT transcription factor. These genes include those required for B-cell help (such as interleukin (IL-4) and CD40 ligand) as well as those necessary for T-cell proliferation (such as IL-2). It also inhibits nitric oxide synthesis induced by interleukin-1 $\alpha$ , lipopolysaccharides, and TNF- $\alpha$ . **Clinical Applications:** Cyclosporin A is a powerful immunosuppressive agent that lacks myelotoxicity, making it unique among nonsteroidal immunosuppressing drugs and commending it for preventing organ rejection in recipients of kidney, liver, bone marrow and pancreas transplants. CyA may also be used to treat autoimmune disorders. Its utility in preventing kidney rejection was demonstrated by Roy Calne and

colleagues at Cambridge University for kidney transplants and for liver transplants by Thomas Starzl at University Presbyterian Hospital in Pittsburgh. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Structural Features:** Unusual residues present within cyclosporin A include: L-2-aminobutyrate, N-methylglycine (sarcosine), L-N-methyl-leucine, D-alanine, L-N-methylvaline, and (4R)-4-[(E)-2-butenyl]-4,N-dimethyl-L-threonine. Cyclosporin H is identical to cyclosporin A, except for a D-N-methylvaline at position eleven instead of the L-isomer. CyH is devoid of most biological effects. The substituted Cyclosporin A analogue NIM811 binds to cyclophilin, but the resulting complex cannot inhibit calcineurin, and thus lacks Cyclosporin A's immunosuppressive activity (**See also N-Methyl-4-isoleucine Cyclosporin**). For these reasons, CyH and NIM811 are frequently used as controls in experiments on CyA. Given the presence of so many unusual amino acid residues in cyclosporin, it should not be surprising that it is formed in fungi by nonribosomal peptide synthetic machinery. **Target(s):** calcineurin (protein phosphatase 2B), as the Cyclosporin A-Cyclophilin complex (1-4,28-31); peptidylprolyl isomerase,  $K_i = 1.6$  nM for the human isoform-1 (5-19); P-glycoprotein (20,22-25); xenobiotic-transporting ATPase, multidrug-resistance protein (20,25); phospholipid-translocating ATPase, flippase (25); protein phosphatase 2A, indirectly as the CyA-Cyclophilin complex (1-4,26-31); 27-hydroxycholesterol 7 $\alpha$ -monoxygenase (32); tomato bushy stunt tomosvirus (TBSV) replication, acting as a cell-originated virus retraction factor (33). **1.** Eriksson, Toivola, Sahlgren, Mikhailov & Härmälä-Braskén (1998) *Meth. ### Cyclothiazide

This substituted benzothiadiazine (FW = 389.88 g/mol; CAS 2259-96-3) enhances glutamatergic transmission and is widely used as a blocker for  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionate-type glutamate receptor

desensitization (*i.e.*, it is a positive AMPA receptor modulator). **Target(s):** GABA<sub>A</sub> receptor (1);  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid type glutamate receptor desensitization (2,3). 1. Deng & Chen (2003) *Proc. Natl. Acad. Sci. U.S.A.* **100**, 13025. 2. Yamada & Tang (1993) *J. Neurosci.* **13**, 3904. 3. Patneau, Vyklícky & Mayer (1993) *J. Neurosci.* **13**, 3496.

### CYP Inhibition

Drug-drug interactions (DDIs) are associated with severe adverse effects that may lead to the patient requiring alternative therapeutics and could ultimately lead to drug withdrawal from the market if they are severe. Cytochrome P<sub>450</sub> enzymes, or CYPs within human liver endoplasmic reticulum *in vivo* (microsomes *in vitro*) modify drugs and xenobiotic compounds, most often targeting them for elimination, but, in some instances, paradoxically activate agents to form more bioreactive and/or cytotoxic metabolites. When two drugs (or nutraceuticals) are alternative substrates for the same CYP, the two can give rise to drug-drug interactions, meaning that they (or metabolically derived forms thereof) modify each other's pharmacokinetics. It is therefore common practice to screen for inhibition of drug turnover when another drug (or nutraceutical) is added to the test system as well as inhibition due to metabolites formed upon preincubation of an agent with liver microsomal preparations. Well-designed experiments can minimize artifacts that arise from protein binding, metabolic instability of the test agents, using reference (or marker) substrates. These substrates and their corresponding reaction products are readily assayed by standardized procedures. In all, there are 60 CYP genes in humans. Common variations (*or* polymorphisms) in cytochrome P<sub>450</sub> genes can affect the function of the enzymes. The effects of polymorphisms are most prominently seen in the breakdown of medications. Depending on the gene and the polymorphism, drugs can be metabolized quickly or slowly. Typical cytochrome P<sub>450</sub> enzymes and their well-characterized marker substrate and modification include: CYP1A2 monooxygenase (Phenacetin, *O*-Dealkylation); CYP2A6 mixed-function oxidase (Coumarin, 7-Hydroxylation); CYP2B6 monooxygenase (Efavirenz, 8-Hydroxylation); CYP2C8 mixed-function oxidase; (Amodiaquine, *N*-Dealkylation); CYP2C8 mixed-function oxidase (Paclitaxel, 6-Hydroxylation); CYP2C9 oxidase and epoxidase (Diclofenac, 4'-Hydroxylation); CYP2C19 mixed-function oxidase (*S*-Mephenytoin, 4'-Hydroxylation); CYP2D6 mixed-function oxidase (Dextromethorphan, *O*-Demethylation); CYP2E1 mixed-function oxidase (Chlorzoxazone, 6-Hydroxylation); CYP3A4/5 hydroxylase (Testosterone, 6 $\beta$ -Hydroxylation); CYP3A4/5 mixed-function oxidase (Nifedipine, Oxidation); CYP3A4/5 hydroxylase (Midazolam, 1'-Hydroxylation); CYP3A4/5 hydroxylase (Atorvastatin, *ortho*-Hydroxylation); and CYP4A11 hydroxylase (Lauric acid, 12-Hydroxylation).

### Cypermethrin

This synthetic insecticide (FW = 416.30 g/mol; CAS 52315-07-8), also known as  $\alpha$ -cyano-3-phenoxybenzyl 3-(2,2-dichlorovinyl) 2,2-dimethylcyclopropanecarboxylate, is a strong inhibitor of calcineurin, or protein phosphatase 2B (IC<sub>50</sub> = 40 pM) (1-4). **Target(s):** glutathione *S* transferase (5); glutamate uptake (6); acetylcholinesterase (7); monoamine oxidase A (8); protein phosphatase 2A (9); phosphoprotein phosphatase (1-4,9); carboxylesterase (10). 1. ### Cyprodime

This photosensitive morphinanone (FW<sub>free-base</sub> = 356.25 g/mol; CAS 118111-51-6 (bromide salt)) is a selective  $\mu$  opioid receptor antagonist, with a *K<sub>i</sub>* of 8.1 nM for the rat brain receptor and 26.6 nM for the guinea pig brain receptor (1,2). The EC<sub>50</sub> value for morphine-stimulated [<sup>35</sup>S]GTP $\gamma$ S binding is increased about 500x in the presence of 10  $\mu$ M cyprodime. 1. Marki, Monory, Otvos, *et al.* (1999) *Eur. J. Pharmacol.* **383**, 209. 2. Schmidhammer, Burkard, Eggstein-Aeppli & Smith (1989) *J. Med. Chem.* **32**, 418.

### Cyproterone Acetate

This synthetic steroid ester (FW = 416.94 g/mol; CAS 427-51-0), also known as 6-chloro-1 $\beta$ ,2 $\beta$ -dihydro-17-hydroxy-3'-*H*-cyclopropa(1,2)-pregna-1,4,6-triene-3,20-dione acetate, exhibits anti-androgen activity and is a progestogen. Cyproterone also exhibits partial agonistic and antagonistic actions and displays partial progestational and glucocorticoid action. Its action is not pure antiandrogenic. Cyproterone inhibits leukocyte migration through endothelial cell monolayers and is used in the treatment of prostate cancer, acne, and hirsutism. **Target(s):** androgen receptor (2,3); 17 $\beta$ -hydroxysteroid dehydrogenase (4); steroid  $\Delta$  isomerase (5). 1. Scott & Tomkins (1975) *Meth. Enzymol.* **40**, 273. 2. Simental, Sar & Wilson (1992) *J. Steroid Biochem. Mol. Biol.* **43**, 37. 3. Berrevoets, Umar & Brinkmann (2002) *Mol. Cell. ### Cys-AAX tetrapeptides

These peptides KKSKTKCVM (FW = 1165.52 g/mol; isoelectric point = 10.2), TKCVIM (FW = 693.92 g/mol; isoelectric point = 7.9), and CVIM (FW = 464.64 g/mol; isoelectric point = 5.5), corresponding to the COOH-terminal 10-, 6-, and 4-residues in human p21<sup>ras</sup>, target farnesyl:protein transferase, inhibiting the transfer of the farnesyl moiety from farnesyl pyrophosphate to the cysteine-acceptor residue in p21<sup>ras</sup> proteins, thereby blocking membrane localization of ras and disrupting ras-mediated signal transduction. The sequence-scrambled peptides CNFDNPVSQKTT and TKVCIM serve as suitable controls. 1. Reiss, Goldstein, Seabra, Casey & Brown (1990) *Cell* **62**, 81.

### Cystatin

This family of cysteine protease inhibitors, originally isolated from chicken egg white (alternative name ovocystatin) is divided into three families: (a) Stefin family proteins (MW = 11–12 kDa) have no disulfide bonds and no covalently linked carbohydrates; (b) Cystatin family members are slightly larger proteins (MW 13–14 kDa) contain two disulfide bonds near the C-terminus; Kininogens family members include higher molecular weight kininogens (approximately 120 kDa) and lower molecular weight proteins (68 kDa). The kininogens are glycoproteins containing three cystatin-like domains, each with at least two disulfide bonds. Notably, some cystatins either lost or never acquired an inhibitory capacity.

## Cysteamine

This mercaptan (FW<sub>hydrochloride</sub> = 113.61 g/mol; CAS 60-23-1; Soluble in water and ethanol; pK<sub>a</sub> values of 8.35 (thiol) and 10.81 (amine)), also called thioethanolamine and 2-mercaptoethylamine, is formed by the decarboxylation of cysteine. Cysteamine is readily oxidized to its disulfide form, requiring cysteamine solutions to be prepared freshly. Cysteamine is a disulfide-group reducing agent, and is expected to inhibit enzymes requiring disulfide linkages for catalytic activity. It also affords protection against oxidative stress associated with radiation damage. **Target(s):** 5-aminolevulinat aminotransferase (1,47); threonine ammonia-lyase, or threonine dehydratase (2,17); cysteine dioxygenase (3,58,59); histidine ammonia-lyase (4); urease (5,10); HIV-1 replication (6); amine oxidase (7); lactate dehydrogenase (8); alkaline phosphatase (9,21,27); spermidine synthase (11); aldehyde dehydrogenase (12); dopamine β-hydroxylase (13,14); cytochrome P450 isotype, or thiobenzamide S-monooxygenase (15); NADH: cytochrome c reductase (16); NADPH:cytochrome c reductase (16); steroid 11β-monooxygenase (18,19); *Agkistrodon halys* venom proteinases (20); β-galactosidase (22); aspartate 4-decarboxylase (23); carnitine palmitoyltransferase (24); dihydroorotase (25); nitrile hydratase (26,36); cysteinyl-tRNA synthetase (28,29); prolyl/cysteinyl-tRNA synthetase, *Methanocaldococcus jannaschii* (30); alanyl tRNA synthetase (31); phenylalanine racemase, ATP-hydrolyzing (32); 3-chloro-D-alanine dehydrochlorinase (33); cystathionine γ-lyase (34); diamino propionate ammonia-lyase (35); adenylylsulfatase (37); isopenicillin-N synthase (38); guanidinobutyrase<sup>39</sup>; leishmanolysin (40); leucyl aminopeptidase (41); leukotriene-A<sub>4</sub> hydrolase, IC<sub>50</sub> = 27 μM (42); thioglucosidase, myrosinase (43); glycerophosphocholine cholinephosphodiesterase (44); 5'-nucleotidase (45); 3-mercaptopyruvate sulfurtransferase, weakly inhibited (46); spermidine synthase (48,49); protein-glutamine γ-glutamyltransferase, or transglutaminase (50-52); glutaminy-peptide cyclotransferase (53-55); acetylserotonin O-methyltransferase, or hydroxyindole O-methyltransferase (56); deoxyhypusine monooxygenase (57). 1. ## Cystic Acid

This amino acid sulfonate (FW<sub>free-acid</sub> = 169.16 g/mol; CAS 498-40-8; Water-soluble; pK<sub>a</sub> values of 1.3 (for R-SO<sub>3</sub>H), 1.89, and 8.7 at 25°C), derived from L-cysteine and also known as L-cysteate, 3-sulfo-L-alanine and L-cysteinesulfonate, is an aspartate isostere that stimulates the activity of methionyl-tRNA synthetase. **Target(s):** aspartate 1-decarboxylase (1,12); kynurenine:oxoglutarate aminotransferase (3); sulfinoalanine decarboxylase, or cysteinesulfinate decarboxylase, also alternative substrate (4,5,9-11); pantothenate synthetase, or pantoate:β-alanine ligase (6); cysteinyl-tRNA synthetase (7); serine-sulfate ammonia-lyase, weakly inhibited (8); N<sup>6</sup>-(β-N-acetylglucosaminy)-L-asparaginase (13); glutamate carboxypeptidase II, N-acetylated-γ-linked-acidic dipeptidase (14); aspartate aminotransferase (15); serine O-acetyltransferase (16); acetylserotonin O-methyltransferase, or hydroxyindole O-methyltransferase (17); homogentisate 1,2-dioxygenase, weakly inhibited (18). 1. ## L-Cysteine

This thiol-containing amino acid (FW = 121.16 g/mol; CAS 52-90-4; Water-soluble; pK<sub>a</sub> values of 1.92, 8.37 (SH), and 10.70), also called (R)-2-amino-3-mercaptopropanoate and symbolized by Cys or C, is one of the

twenty proteinogenic amino acids. There are two codons for L-cysteine: UGU and UGC. Cysteiny residues in proteins are among the most conserved; these residues are interchanged in homologous proteins most frequently with seryl residues. Cysteiny residues are roughly evenly distributed between the surface and the interior of folded proteins. They are frequently found in  $\beta$ -pleated sheets and are often at the N-termini of  $\alpha$ -helices. The sulfhydryl groups of cysteiny residues are quite reactive and are at the active sites of many enzymes. The  $pK_a$  of this group is about 8.37. However, that  $pK_a$  may vary greatly with the microenvironment. Two cysteiny residues can form a disulfide bond in a folded protein, provided that the protein conformation permits this oxidation. Thiol groups can also interact strongly with metal ions. In addition, they can undergo post-translational modification (e.g., phosphorylation, palmitoylation, farnesylation, and geranylgeranylation).

### Cystine

This amino acid disulfide (FW = 240.30 g/mol; CAS 923-32-0;  $pK_a$  values are < 1, 2.1, 8.02, and 8.71 at 35°C; Low Solubility = 10 mg/100 mL H<sub>2</sub>O at 25°C), derived from two cysteine molecules, is the predominant circulating form of L-cysteine in humans. Because L-cystine is readily produced from L-cysteine under physiological conditions, elevated levels of L-cysteine in the diet, blood plasma, and urine can lead to formation of cystine calculi. Enzymes with reactive active-site thiol groups may form an Enz-S-S-Cys upon exposure to cystine (*Reaction*: Enz-SH + Cys-S-S-Cys  $\rightleftharpoons$  Enz-S-S-Cys + Cys-SH). **Target(s)**: homogentisate 1,2-dioxygenase (1,44); diaminopimelate decarboxylase (2,29); inosamine-phosphate amidinotransferase (3,4); diaminopimelate decarboxylase (5); 3 $\alpha$ -hydroxysteroid dehydrogenase (5); phosphoenolpyruvate carboxykinase (GTP), by both D- and L-cystine (7); oxytocin aminopeptidase (8); glutathione S-transferase (9); guanylate cyclase (10,11,20); phosphorylase phosphatase (11,18); tyrosine aminotransferase (11); cysteine dioxygenase, by L-cystine (12,43); succinate dehydrogenase (13); 6-phosphogluconate dehydrogenase (14); catalase (15); phosphatidate phosphatase, weakly inhibited (16);  $\gamma$ -glutamyl cyclotransferase, weakly inhibited (17); calpains (19); gluconate dehydratase (21); peroxidase (22); pyrophosphatase, or inorganic diphosphatase (23); choline oxidase (24); glutamate decarboxylase (25); succinyl-CoA synthetase (26); glutathione synthetase, moderately inhibited (27); phenylalanine racemase, ATP-hydrolyzing, inhibited by DL-cystine (28); sulfur reductase (29); isopenicillin-N synthase (31); pantetheine hydrolase (32); cystinyl aminopeptidase, or oxytocinase (33); phosphodiesterase I, or 5'-exonuclease, weakly inhibited (34); [phosphorylase] phosphatase (35); creatine kinase (36); pyruvate kinase (37,38); phosphoribulokinase (39); serine O-acetyltransferase (40); thiol S-methyltransferase (41); betaine:homocysteine S-methyltransferase, inhibited by both D- and L-cystine (42). 1. ### CYT997

This novel orally active tubulin polymerization inhibitor (FW = 434.54 g/mol), also known as Lexibulin<sup>®</sup>, exhibits potent both cytotoxic and vascular disrupting activities *in vitro* and *in vivo* (1,2). CYT997 blocks the cell cycle at the G<sub>2</sub>/M boundary, and Western blot analysis indicates an increase in phosphorylated Bcl-2, along with increased expression of cyclin B<sub>1</sub> (2). CYT997 prevents *in vitro* tubulin polymerization (IC<sub>50</sub> ~3  $\mu$ M) and reversibly disrupts the microtubule network in cells, as visualized using fluorescence microscopy. CYT997 is active against DU145 human prostate carcinoma cells, IC<sub>50</sub> = 73 nM; A549 human lung carcinoma cells, IC<sub>50</sub> = 21 nM; Ramos human Burkitt's lymphoma cells, IC<sub>50</sub> = 80 nM; KHOS/NP human osteosarcoma cells, IC<sub>50</sub> = 101 nM; A375 human melanoma cells, IC<sub>50</sub> = 49 nM; HCT-15 human colon carcinoma cells, IC<sub>50</sub> = 52 nM; HT1376 human bladder carcinoma cells, IC<sub>50</sub> = 93 nM; BT-20 human breast carcinoma cells, IC<sub>50</sub> = 58 nM; A431 human epithelial carcinoma cells, IC<sub>50</sub> = 51 nM; PA-1 human ovarian teratocarcinoma, IC<sub>50</sub> = 48 nM; U937 human leukemic monocyte lymphoma, IC<sub>50</sub> = 21 nM; HepG2 human hepatocellular liver carcinoma cells, IC<sub>50</sub> = 9 nM; TF-1 human erythroleukemia cells, IC<sub>50</sub> = 32 nM; Baf3/TelJAK2 constitutively active JAK2 cells, IC<sub>50</sub> = 23 nM; PC3 human prostate carcinoma cells, IC<sub>50</sub> = 27 nM; and K562 human chronic myelogenous leukemia cells, IC<sub>50</sub> = 20 nM (2). Treatment of acute myeloid leukemia cells with CYT997 resulted in G<sub>2</sub>/M phase cell cycle arrest, and induced apoptosis through the activation of extrinsic and intrinsic apoptotic pathways (3). 1. ### Cytarabine

This nucleoside (FW = 243.22 g/mol; CAS 147-94-4; *Abbreviation*: ara-C or Ara-C), also known as 1- $\beta$ -D-arabinofuranosylcytosine and ara-cytidine, is an antiviral agent and S phase-acting antineoplastic agent. Ara-C is highly effective in treating acute myelogenous leukemia (AML). This agent is incorporated into leukemic cell DNA, and the extent of this incorporation

correlates with loss of clonogenic survival. When metabolically converted to cytarabine 5'-triphosphate (*ara*-CTP), the latter is a potent inhibitor of DNA synthesis, but not RNA biosynthesis. (A nominal inhibitory concentration is 10  $\mu$ M.) The incorporated Ara-C behaves as a DNA chain terminator, and the extent of (Ara-C)DNA formation correlates with inhibition of DNA synthesis. (See *Cytarabine 5'-Triphosphate*) **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** deoxycytidine kinase, also alternative substrate (1-7); dCMP deaminase (8); deoxynucleoside kinase (2); deoxyguanosine kinase (9). 1. Kessel (1968) *J. Biol. Chem.* **243**, 4739. 2. Johansson, Van Rompay, Degreève, Balzarini & Karlsson (1999) *J. Biol. Chem.* **274**, 23814. 3. Someya, Shaddix, Tiwari, Secrist & Parker (2003) *J. ### Cytarabine 5'-Triphosphate

This nucleotide analogue (FW = 482.15 g/mol), also known as cytosine 1- $\beta$ -D-arabinofuranoside 5'-triphosphate and *ara* CTP, is a potent inhibitor of DNA biosynthesis, but *not* RNA biosynthesis. **Target(s):** deoxyadenosine kinase (1,5); DNA polymerase (10,11); DNA polymerase I (2); DNA polymerase  $\alpha$  (12); DNA-directed DNA polymerase (2-4,6-12); DNA primase (12); deoxycytidine kinase (13,14). 1. ### Cytidine

This pyrimidine nucleoside (FW = 243.22 g/mol; CAS 65-46-3) is a precursor for the biosynthesis of cytidine 5'-mono-, di-, and tri-phosphates. See cytidine 5'-diphosphate for spectral data. **Target(s):** aspartate carbamoyltransferase (1,4-8,13); cytosine deaminase (2,12); pancreatic ribonuclease, or ribonuclease A (3); 5'-nucleotidase (5,9); arginase (10); dihydroorotase (11); lactoylglutathione lyase, or glyoxalase I (14); aspartate ammonia-lyase (15); uridine nucleosidase (16); purine nucleosidase (17,18); ribonuclease T2(19); CMP-*N* acylneuraminatase phosphodiesterase (20,21); acid phosphatase (22); hydroxyacylglutathione hydrolase, or glyoxalase II (14); *N*-acylneuraminatase cytidyltransferase (23); adenosine kinase (24). 1. ### Cytidine 5'-Diphosphate

This pyrimidine nucleotide (FW<sub>free-acid</sub> = 403.18 g/mol) is a precursor for phospholipids and sphingomyelins. It is also a component of certain nucleotide coenzymes. Alkali salts of CDP are very soluble in water, whereas the free acid is less soluble. The UV spectrum of CDP at pH 7 (or pH 11) has a  $\lambda_{max}$  at 271 nm ( $\epsilon = 9100 \text{ M}^{-1}\text{cm}^{-1}$ ). At pH 2, the  $\lambda_{max}$  is 280 nm ( $\epsilon = 12800 \text{ M}^{-1}\text{cm}^{-1}$ ). **Target(s):** pyruvate carboxylase (1,15); aspartate carbamoyltransferase (2,11,12,78-80); cytosine deaminase (3,20,29); cytidine deaminase (3);  $\beta$ -galactoside  $\alpha$ -2,3-sialyltransferase (4,58,59);  $\alpha$ -*N*-acetyl-galactosaminide  $\alpha$ -2,6-sialyltransferase (4); [3-methyl-2-oxobutanoate dehydrogenase, or 2-methylpropanoyl-transferase] phosphatase (5,8); membrane-bound sialyltransferase of *Escherichia coli* (6); carbamoyl-phosphate synthetase (7); isocitrate dehydrogenase (9); glutamine synthetase (10); 5'-nucleotidase (13,33); dihydroorotase (14); glycogenin glucosyltransferase, self-glucosylation (16);  $\alpha$ -*N*-acetylneuraminatase  $\alpha$ -2,8-sialyltransferase (17); dolichol kinase (18); polyribonucleotide nucleotidyltransferase (19); phosphoribosyl-pyrophosphate synthetase (21); glucose-6-phosphate dehydrogenase (22); adenylate cyclase (23); lactoylglutathione lyase, or glyoxalase I (24); UDP-glucuronate decarboxylase (25); CDP-glycerol diphosphatase (26); nucleotide diphosphatase (27); dCTP deaminase (28); CMP-*N*-acylneuraminatase phosphodiesterase (30,31); fructose-1,6-bisphosphatase (32); hydroxyacylglutathione hydrolase, or glyoxalase II (24); [branched-chain  $\alpha$ -keto-acid dehydrogenase] kinase (34); CDP-diacylglycerol: Inositol-3 phosphatidyltransferase (35,36); serine-phosphoethanolamine synthase (37); diacylglycerol cholinephosphotransferase (38,39); ethanolaminephosphotransferase (38,39); [protein-PII] uridylyltransferase (40); *N*-acylneuraminatase cytidyltransferase (41-44); phosphatidate cytidyltransferase (45); glucose-1-phosphate cytidyltransferase (46); ribose phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (47); cytidylate kinase, product inhibition (48); diacylglycerol kinase (49,50); deoxycytidine kinase (51); 1-phosphatidylinositol 4-kinase (52,53); fucokinase (54); glucuronokinase (55); lactosylceramide  $\alpha$ -2,3-sialyltransferase (56,57);  $\alpha$ -*N*-acetylneuraminatase  $\alpha$ -2,8-sialyltransferase (57);  $\alpha$ -*N*-acetylgalactosaminide  $\alpha$ -2,6 sialyltransferase (59);  $\beta$ -galactoside  $\alpha$ -2,6-sialyltransferase (60-62); protein xylosyltransferase (63); xanthine phosphoribosyltransferase (64); nicotinate-nucleotide diphosphorylase (65,66); hypoxanthine(guanine) phospho-ribosyl-transferase, or HGPRT (67); glycoprotein 3- $\alpha$ -L-fucosyltransferase (68,69); glycogenin glucosyltransferase (70);  $\beta$ -1,4-mannosyl-glycoprotein 4- $\beta$ -*N*-acetylglucosaminyltransferase (71); protein *N*-acetylglucosaminyltransferase (72); globoside  $\alpha$ -*N*-acetylgalactosaminyltransferase (73); glycoprotein 6- $\alpha$ -L-

fucosyl-transferase (74); procollagen galactosyltransferase (75); polypeptide *N*-acetylgalactosaminyltransferase (76); glycol-protein fucosyl galactoside  $\alpha$ -*N*-acetylgalactosaminyl-transferase (77). 1. ### Cytidine 5'-Triphosphate

This pyrimidine nucleotide ( $\text{FW}_{\text{free-acid}} = 483.16 \text{ g/mol}$ ;  $\lambda_{\text{max}} = 271 \text{ nm}$ ;  $\epsilon = 9000 \text{ M}^{-1} \text{ cm}^{-1}$ ) plays a role in RNA and DNA biosynthesis as well as in the formation of many complex lipids, synthesis of CDP-glucose, and in the phosphorylation of dolichol. CTP is also a powerful allosteric feedback inhibitor of *Escherichia coli* aspartate carbamoyltransferase (1,2). Sodium and potassium salts are very soluble in water. CTP forms tight complexes with many metal ions. Metal ion-free CTP is likely to be inactive in CTP-dependent enzyme reactions. The stability constants are reported to be similar to those for  $\text{MgATP}^{2-}$ ,  $\text{CaATP}^{2-}$ , and  $\text{MnATP}^{2-}$ , which are 73000, 35000, and 100,000  $\text{M}^{-1}$ , respectively. **Target(s):** aspartate carbamoyltransferase (1,2,23,25,26, 34,39,40, 41,43,61,63,185-199); glutamine synthetase (3,35,52,58); *myo*-inositol oxidase (4,200); lactose synthase (5); pyruvate carboxylase (6,49); [glutamine-synthetase] adenylyltransferase (7,111); *N*-acetylglucosamine kinase (8); pyruvate, orthophosphate dikinase (9,10); arylsulfate sulfotransferase (11); carbamoyl-phosphate synthetase (12,45,67,68); GMP synthetase (13); uridine kinase (14-16,33,140-147); cytosine deaminase (17,59); cytidine deaminase (17); thiamin-phosphate pyrophosphorylase (18);  $\beta$ -galactoside  $\alpha$ -2,3-sialyltransferase (19);  $\alpha$ -*N*-acetyl-galactosaminide  $\alpha$ -2,6-sialyltransferase (19); [3-methyl-2 oxobutanoate dehydrogenase (2-methylpropanoyl-transferring)] phosphatase ([branched-chain  $\alpha$ -keto-acid dehydrogenase] phosphatase) (20,28); polynucleotide adenylyltransferase (21,37); *Pyrococcus furiosus* carbamate kinase (22); 5'→3' exoribonuclease (24); membrane-bound sialyltransferase of *Escherichia coli* (27); 5'-nucleotidase (30,47,60,62,94-97); 3',5'-cyclic-nucleotide phospho-diesterase (31,46); fumarase (32); cytidylate kinase (33,125); tRNA adenylyltransferase (36); phosphoprotein phosphatase types 1 and 2A (38); membrane Dipeptidase, or renal Dipeptidase (42); guanylate cyclase (44); dihydroorotase (48); glycogenin glucosyltransferase, self-glucosylation (50); NAD(P)H dehydrogenase (quinone) (51);  $\alpha$ -*N*-acetylneuraminatase  $\alpha$ -2,8-sialyltransferase (53); deoxyadenosine kinase (54); diacylglycerol kinase (55); membrane dipeptidase (56); glutathione peroxidase (57); amidophosphoribosyl-transferase (64); phosphoribosyl-pyrophosphate synthetase (65); asparagine synthetase (66); phosphoglucomutase (69); guanylate cyclase (70,71); adenylate cyclase (72); glucose-6-phosphate dehydrogenase (73); lactoylglutathione lyase, or glyoxalase I (74); aspartate ammonia-lyase, moderate (75); UDP-glucuronate decarboxylase, weakly inhibited (76); phosphoenolpyruvate carboxylase (77); adenylylsulfatase (78);  $\text{NAD}^+$  diphosphatase (79); CDP-glycerol diphosphatase (80); exopolyphosphatase (81); nucleotide diphosphatase (82); 5-hydroxypentanoate CoA-transferase (83); GTP cyclo-hydrolase I (84); dCTP deaminase (85); arginine deaminase (86); NMN nucleosidase (87); uridine nucleosidase (88);  $\beta$ -fructofuranosidase, or invertase (89); CMP-*N*-acetylneuraminatase phosphodiesterase (90,91); phospho-diesterase I, or 5'-exonuclease (92); multiple inositol polyphosphate phosphatase, inositol-1,3,4,5-tetrakisphosphate 3-phosphatase (93); nucleotidases (94); phosphoprotein phosphatase (95); fructose-1,6-bisphosphatase (96); 3' nucleotidases (94); phosphatidate phosphatase (98); hydroxyacylglutathione hydrolase, or glyoxalase II (74); pyruvate, orthophosphate dikinase (99); CDP-glycerol glycerophosphotransferase (100); CDP diacylglycerol:inositol 3-phosphatidyltransferase (101,102); CDP-diacylglycerol:serine *O*-phosphatidyltransferase (103); diacylglycerol cholinephospho-transferase (104); ethanolaniline-phosphotransferase (104,105); 2-*C*-methyl-D-erythritol-4-phosphate cytidyltransferase (106); [protein- $\text{P}_{\text{II}}$ ] uridylyltransferase (107); *N*-acetylneuraminatase cytidyltransferase (108-110); tRNA adenylyltransferase (112-118); polynucleotide adenylyltransferase, or poly(A) polymerase (119-121); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (122-124); carbamate kinase (126); deoxyguanosine kinase (127); diacylglycerol kinase (128,129);

- ethanolamine kinase (130); polynucleotide 5'-hydroxyl kinase (131,132); deoxycytidine kinase (133,134); 1-phosphatidylinositol 4-kinase (135,136); N-acetylglucosamine kinase (137); 1-phosphofructokinase (138); fucokinase (139); pyruvate kinase (148); 6-phosphofructokinase (149,150); glucokinase, as weak alternative substrate (151,152); methionine S-adenosyltransferase (153-155); thiamin-phosphate diphosphorylase (156); lactosylceramide  $\alpha$ -2,3-sialyltransferase (157,158);  $\alpha$ -N-acetylneuraminidase  $\alpha$ -2,8-sialyltransferase (158);  $\beta$ -galactosidase  $\alpha$ -2,3 sialyltransferase (159-162);  $\alpha$ -N-acetylglactosaminidase  $\alpha$ -2,6-sialyltransferase (161,163);  $\beta$ -galactosidase  $\alpha$ -2,6-sialyltransferase (164-166); protein xylosyltransferase (167); xanthine phosphoribosyltransferase (168); nicotinate-nucleotide diphosphorylase, carboxylating (169,170); uracil phosphoribosyltransferase (171-173); adenine phosphoribosyltransferase (174); [Skp1-protein] hydroxyproline N-acetylglucosaminyltransferase, weakly inhibited (175); polypeptide N-acetylglactosaminyltransferase (176); 1,3- $\beta$ -glucan synthase (177); glucomannan 4- $\beta$  mannosyltransferase, weakly inhibited (178); sucrose-phosphate synthase (179,180); ATP:citrate lyase (ATP:citrate synthase)181; citrate (*si*)-synthase, weakly inhibited (182); protein-glutamine  $\gamma$ -glutamyltransferase, or transglutaminase (183); ornithine carbamoyltransferase (184); 3-hydroxyanthranilate oxidase, weakly inhibited (201).

**O-(Cytidin-5'-yl) 2-(5-Acetamido-2,6-anhydro-3,5-dideoxy-D-erythro-L-gluco-nonanoate-2-yl)ethylphosphonate**

This CMP-sialic acid analogue (FW<sub>free-acid</sub> = 571.51 g/mol) inhibits rat *N*-acetylglucosaminidase  $\alpha$ -2,3-sialyltransferase (IC<sub>50</sub> = 47 nM) and  $\alpha$ -*N*-acetylglucosaminidase  $\alpha$ -2,6-sialyltransferase (IC<sub>50</sub> = 0.34  $\mu$ M). **1.** Izumi, Wada, Yuasa & Hashimoto (2005) *J. Org. Chem.* **70**, 8817.

**Cytisine**

This toxic alkaloid (FW = 190.24 g/mol; CASs = 485-35-8; IUPAC Name: (1*R*,5*S*)-1,2,3,4,5,6-hexahydro-1,5-methano-8*H*-pyrido[1,2*a*][1,5]diazocin-8-one), also known as baptitoxine and sophorine, is a partial acetylcholine agonist, with high affinity for nicotinic receptors. Cytisine was a lead molecule in the development of the smoking-cessation drug Chantix (**See Varenicline**). **1.** Pérez, Méndez-Gálvez & Cassels (2012) *Nat Prod Rep.* **29**, 555.

**Cytochalasin B**

This cell-permeable fungal metabolite (FW = 479.62 g/mol) from the plant pathogen *Drechslera dematioideum* (formerly *Heiminthosporium dematioideum*) is a mycotoxin that binds to the barbed end of actin filaments, reversibly inhibiting their elongation and shortening (**1**). (**See Cytochalasin D for details on Mechanism of Action**). It exhibits cytostatic activity, inhibiting glucose transport, cytokinesis, phagocytosis, pinocytosis, cell adhesion, and cell division. Cytochalasin B also inhibits platelet aggregation and induces nuclear extrusion. **Target(s):** actin polymerization (2,4,5,7,8,13,14); glucose transport (6,9-12,15); cell division; Ca<sup>2+</sup> transport (3); phagocytosis (16,17). **1.** Sampath & Pollard (1991) *Biochemistry* **30**, 1973. **2.** Rosenshine, Ruschkowski & Finlay (1994) *Meth. **Cytochalasin D**

This fungal metabolite (FW = 507.63 g/mol) from *Metarrhizium anisopliae* inhibits actin polymerization and actin-based motility (1-4). When present  $\mu$ M concentrations, cytochalasin D (CD) (as well as cytochalasin B (CB)

inhibits elongation at both ends of the filament, ~95% at the barbed (*or* plus) end and ~50% at the pointed (*or* minus) end, so that the two ends contribute about equally to the rate of growth (2). Half-maximal inhibition of elongation at the barbed end is at 0.1  $\mu\text{M}$  CB and 0.02  $\mu\text{M}$  CD for ATP-actin and at 0.1  $\mu\text{M}$  CD for ADP-actin (2). At the pointed end, CD inhibits elongation by ATP-actin and ADP-actin about equally (2). At 2  $\mu\text{M}$ , the cytochalasins reduce the association and dissociation rate constants in parallel for both ADP-actin and ATP-actin, reducing their effects on the critical concentrations (2). The dependence of the elongation rate on the concentration of both cytochalasin and actin can be explained quantitatively by a mechanism that includes the effects of cytochalasin binding to actin monomers (3) and a partial cap of the barbed end of the filament by the complex of ADP-actin and cytochalasin. *Note:* *In vivo* actin-based motility relies on actoclampin-type, filament end-tracking motors (5,6), thereby casting great doubt on the physiologic relevance of the *in vitro* studies of CD effects on free actin filaments. *Caution:* Cytochalasin D must be stored in the dark, because double bonds in the macrocycle slowly undergo *trans-to-cis* transition in the presence of light. 1. #### Cytosporone B

This naturally occurring NR4A1 (*or* Nur77) agonist (FW = 322.41 g/mol; CAS 321661-62-5; Soluble to 100 mM in DMSO), also named Csn-B and ethyl 3,5-dihydroxy-2-(1-oxooctyl)-benzeneacetate, targets Nerve Growth Factor 1B, *or* NGF1B (K<sub>d</sub> = 0.85  $\mu\text{M}$ ), also known as Nur77 or NR4A1 (Nuclear Receptor subfamily 4 group A member 1). NR4A1 is an endogenous inhibitor of transforming growth factor- $\beta$  (TGF- $\beta$ ) signaling. 1. Zhan, Du, Chen, *et al.* (2008) *Nature Chem. Biol.* **4**, 548. 2. Palumbo-Zerr, Zerr, Distler, *et al.* (2015) *Nature Chem. Biol.* **8**, 576.

# - D -

**D**, See *Aspartate and Aspartic Acid; Dihydrouridine*

## D15

This endocytosis inhibitor (FW = 1566.78 g/mol; CAS 251939-41-0; Sequence: PPPQVPSRPNRAPP; Solubility: 1 mg/mL H<sub>2</sub>O) blocks the interaction of dynamin with amphiphysins 1 and 2. D-15 impairs  $\alpha$ -amino-3-hydroxy-5-methyl-4-isoxazolepropionate (AMPA) receptor cycling and blocks 3,5-dihydroxyphenylglycine- (DHPG-) induced long-term depression (LTD). 1. Wigge & McMahon (1998) *Trends Neurosci.* **21**, 339. 2. Lüscher, *et al.* (1999) *Neuron* **24**, 649. 3. Xiao, *et al.* (2001) *Neuropharmacol.* **41**, 664.

**D145**, See *Memantine*

## D609

This antiviral, antioxidant and antitumor agent (FW = 266.46 g/mol; CAS 83373-60-8; Soluble to 100 mM in water), also named *O*-(octahydro-4,7-methano-1*H*-inden-5-yl)carbonopotassium dithioate and tricyclodecan-9-yl-xanthogenate, selectively and competitively inhibits phosphatidyl choline-specific phospholipase C, *or* PC-PLC ( $K_i = 6.4 \mu\text{M}$ ) (1-3). D609 suppresses LPS- and IFN $\gamma$ -induced NO production (IC<sub>50</sub> = 20 mg/ml) and blocks oxidative glutamate toxicity in nerve cells *in vivo* (2,3). D609 inhibits ionizing radiation-induced oxidative damage by acting as a potent antioxidant (4). 1. Tschakowsky, *et al.* (1994) *Brit. J. Pharmacol.* **113**, 664. 2. Amtmann (1996) *Drugs Exp. Clin. Res.* **22**, 287. 3. Li, *et al.* (1998) *Proc. Natl. Acad. Sci. U.S.A.* **95**, 7748. 4. Zhou, *et al.* (2001). *J. Pharmacol. Exp. Ther.* **298**, 103.

## D 4476

This selective casein kinase inhibitor (FW = 398.41 g/mol; CAS 301836-43-1; Soluble to 100 mM in DMSO and to 50 mM in ethanol), also named 4-[4-(2,3-dihydro-1,4-benzodioxin-6-yl)-5-(2-pyridinyl)-1*H*-imidazol-2-yl]benzamide, targets CK1 $\delta$  some 20–30-fold more potently than PKD1 or p38 $\alpha$  MAPK. No other protein kinases in the panel were inhibited to a significant extent. D4476 is recommended for inhibiting CK1 isoforms in cell-based assays (EC<sub>50</sub> = 50–100  $\mu\text{M}$ ). 1. Bain, Plater, Elliott, *et al.* (2007) *Biochem J.* **408**, 297.

## D-64131

This tubulin polymerization inhibitor (FW = 251.28 g/mol; CAS 74588-78-6; Soluble to 100 mM in DMSO), also named (5-methoxy-1*H*-indol-2-yl)phenylmethanone, is cytotoxic, blocking tumor cell proliferation *in vitro* (IC<sub>50</sub> = 74 nM) and preventing growth of mouse tumor models after oral administration. In contrast to colchicine, vincristine, nocodazole, or taxol, D-64131 does not significantly affect tubulin's GTPase activity (1). No cross-resistance toward cell lines with multidrug resistance/multidrug resistance protein independent resistance phenotypes were evident (2). In animal studies, no signs of systemic toxicity were observed after p.o. dosages of up to 400 mg/kg of D-64131. In xenograft experiments with the human amelanotic melanoma (MEXF 989), D-64131 is highly active, with treatment resulting in tumor growth delay of 23 days at 400 mg/kg (2). 1. Mahboobi, Pongratz, Hufsky, *et al.* (2001) *J. Med. Chem.* **44**, 4535. 2. Beckers, Reissmann, Schmidt, *et al.* (2002) *Cancer Res.* **62**, 3113.

## Dabigatran

**Intracellular Drug: Dabigatran**

**Double Prodrug: Dabigatran Etxelilate**

This non-vitamin K antagonist oral anticoagulant, *or* NOAC (FW = 627.73 g/mol; CAS 211915-06-9), known as dabigatran and dabigatran etexilate as well as by the trade names Pradaxa<sup>®</sup> (U.S.A., Canada, Europe, and Australia) and Prazaxa<sup>®</sup> (Japan), is a direct inhibitor of thrombin, *or* Clotting Factor IIa (1). Dabigatran holds the distinction of being the first oral anticoagulant available in the U.S. since approval of the indirect inhibitor, warfarin. With a predictable anticoagulation response, dabigatran does not usually require routine anticoagulation monitoring (**See comment below**). Dabigatran was found to be noninferior to warfarin in preventing stroke and systemic embolism in patients with atrial fibrillation, a finding that motivated FDA approval. Dabigatran exhibits efficacy in preventing venous thromboembolism in patients undergoing total hip or knee replacement surgery. Drug excretion is slowed by strong p-glycoprotein pump inhibitors (*e.g.*, quinidine, verapamil, clarithromycin (Zitromax<sup>®</sup>) and amiodarone (Cordarone<sup>®</sup>)), increasing plasma dabigatran levels. Dosing should be reduced when p-glycoprotein pump inhibitors are used. **Mode of Inhibitor Action:** Based on the crystal structure of the peptide-like thrombin inhibitor NAPAP complexed with bovine thrombin, a new class of nonpeptidic inhibitors was developed, using a 1,2,5-trisubstituted benzimidazole as the central scaffold and optimized to achieve thrombin inhibition in the lower nanomolar range, mainly from nonpolar, hydrophobic interactions (1). For improved *in vivo* potency, overall hydrophilicity was increased by introducing carboxylate groups. The resulting polar compound (BIBR 953) exhibited a favorable activity profile *in vivo*, and this zwitterionic molecule was converted into the double-prodrug (BIBR 1048), which showed strong oral activity in different animal species (1). **Monitoring:** Although superior to vitamin K antagonists and heparinoids in several respects, NOACs retain the ability to cause haemorrhage and, despite claims to the contrary, may need monitoring (2). Circulating levels of dabigatran are increased in affected patients, because the drug is mainly eliminated by renal excretion. Six analytical methods for determining plasma, serum, and urine dabigatran have been compared (3). A sensitive monoclonal antibody-based competitive ELISA has been developed to analyze free dabigatran in serum ultrafiltrate for therapeutic drug monitoring and pharmacokinetic studies (4). **Reversal of Dabigatran Anticoagulation:** Although dabigatran therapy is associated with an increased risk of bleeding, Idarucizumab (MW = 47.8 kDa; CAS 1362509-93-0; Trade Name: Praxbind<sup>®</sup>; Symbol: aDabi-Fab) is an antigen-binding fragment (*or* Fab) of a monoclonal antibody that binds free and thrombin-bound dabigatran stoichiometrically (5). X-ray crystal structure data of dabigatran in complex with aDabi-Fab reveals many structural similarities of dabigatran recognition to those in thrombin. A network of higher-affinity interactions, however, allows idarucizumab to bind ~350 times more tightly to dabigatran than to thrombin (5). Moreover, clinical studies demonstrated that idarucizumab completely neutralizes dabigatran's anticoagulative properties within minutes, when administered at massive 5-gram doses (6). 1. Huel, Nar, Priepke, *et al.* (2002) *J. Med. Chem.* **45**, 1757. 2. Blann (2014) *Brit. J. Biomed. Sci.* **71**, 158. 3. Du, Weiss, Christina, *et al.* (2015) *Clin. Chem. Lab Med.* **53**, 1237. 4. **$\beta$ -DADF**

This multisubstrate analogue (FW<sub>free-acid</sub> = 815.65 g/mol), encompassing both the AICAR and folate moieties within a single covalently linked entity, inhibits phosphoribosyl-aminoimidazolecarboxamide formyltransferase (*K<sub>i</sub>* = 20 nM) (1).  $\beta$ -DADF is intimately bound at the dimer interface of the transformylase domains, with the majority of AICAR interactions occurring within one subunit, whereas the primary interactions to the folate occur in the opposing subunit (2). 1. Wall, Shim & Benkovic (1999) *J. Med. Chem.* **42**, 3421. 2. Wolan, Greasley, Wall, Benkovic & Wilson (2003) *Biochemistry* **42**, 10904.

**Daidzin**

This isoflavone and phytoestrogen (FW = 254.24 g/mol; CAS 486-66-8; Pale yellow solid; Soluble in ethanol and diethyl ether), the aglycon of daidzin as found in legumes, is an analogue of genistein, but, unlike genistein, does not inhibit protein-tyrosine kinases. Daidzin is thus a useful control in experiments designed to evaluate the effects of genistein. Daidzin also inhibits casein kinase II and blocks Swiss 3T3 cells in the G<sub>1</sub> cell cycle phase. *Note:* Daidzin is occasionally referred to as diadzein.

**Target(s):** aldehyde dehydrogenase (1); Ca<sup>2+</sup> channels (2); casein kinase II (3); 3',5'-cyclic nucleotide phosphodiesterase (4); cyclooxygenase, weakly inhibited (5); CYP1A1 (6); DNA-directed DNA polymerase (7); DNA polymerase (7); DNA topoisomerase II, weakly inhibited (7); estrone sulfotransferase (8,9); fatty-acid synthase (10); F<sub>0</sub>F<sub>1</sub> ATP synthase, mitochondrial (11); GABA<sub>A</sub> receptor (12);  $\beta$ -galactosidase (13);  $\alpha$ -glucosidase (14); GLUT1, glucose transporter (15); glutathione S-transferase (16); 3-hydroxy-3-methylglutaryl-CoA reductase (17,18); 3 $\beta$ -hydroxysteroid dehydrogenase (19,20); inositol-trisphosphate 3-kinase (21); 5-lipoxygenase, *or* arachidonate 5-lipoxygenase (22); 15-lipoxygenase, *or* arachidonate 15-lipoxygenase (23); lipoxygenase, soybean (22,23); NF- $\kappa$ B and AP-1 and suppressed secretion of urokinase-type plasminogen activator from breast cancer cells (24); phenol sulfotransferase, *or* aryl sulfotransferase (9,25-27); phenylalanine ammonia lyase, weakly inhibited (28); phosphodiesterase (34); steroid  $\Delta$ -isomerase (20); steroid 5 $\alpha$ -reductase (29); steroid sulfotransferase (8). 1. **Daidzin**

This glucoside (FW = 416.38 g/mol; CAS 552-66-9), also known as daidzein 7-glucoside, from soybean meal (*Soja hispida*) is the major active principle of an ancient Chinese herbal treatment for alcohol addiction (*i.e.*, utilizing extracts of the root and flower of kudzu, *Pueraria lobata*). **Target(s):** aldehyde dehydrogenase (1-4); CYP1A1 (5); DNA topoisomerase II (6); lipoxygenase, soybean (7). 1. Gao, Li & Keung (2001) *J. Med. Chem.* **44**, 3320. 2. Keung, Klyosov & Vallee (1997) *Proc. Natl. Acad. Sci. U.S.A.* **94**, 1675. 3. Keung, Lazo, Kunze & Vallee (1995) *Proc. Natl. Acad. Sci. **Dalazatide**

This first-in-class potassium channel blocker (MW = 4442.10 g/mol; CAS 1081110-69-1), also known as SHK-186, is a modified form of sea anemone (*Stichodactyla helianthus*) SHK toxin that selectively targets the K<sub>v</sub>1.3 voltage-gated potassium ion channel, a druggable target for treatment of autoimmune disorders (*e.g.*, multiple sclerosis, lupus, psoriasis, ulcerative colitis, uveitis, and asthma). SHK-186 blocks the activation of autoreactive K<sub>v</sub>1.3-overexpressing, effector memory T cells (1-4). Dalazatide's improved stability arises from amidation of its C-terminus and incorporation of a selectivity-enhancing phosphotyrosine substituent at its N-terminus. This peptide exhibits >100x greater selectivity for K<sub>v</sub>1.3 versus K<sub>v</sub>1.1, and >1000x versus K<sub>v</sub>1.6. ShK-192 (a related analogue with a nonhydrolyzable phosphotyrosine surrogate, norleucine in place methionine, and a C-terminal amide) docks to K<sub>v</sub>1.3, with the N-terminal *p*-phosphonophenylalanine group interacting at the junction of two channel monomers by forming a salt-bridge with Lys<sup>411</sup> within the channel. After a single subcutaneous injection of 100  $\mu$ g/kg, approximately 100–200 pM concentrations of active peptide is detectable in the blood of Lewis rats 24, 48, and 72 hour after the injection. Other non-hydrolyzable analogues of the N-terminal pTyr, such as *p*-phosphonophenylalanine (Ppa), prepared with and without substitutions of Met21 (ShK-190) with the nonoxidizable Nle residue (ShK-192), show improved stability profiles with selectivity profiles that are similar to ShK-186. [EWSS]ShK, an N-terminally extended ShK containing Glu-Trp-Ser-Ser, inhibits K<sub>v</sub>1.3 (IC<sub>50</sub> = 34 pm), with 158x selectivity over K<sub>v</sub>1.1 and >2900x affinity for K<sub>v</sub>1.3 over K<sub>v</sub>1.2 and K<sub>ca</sub>1.3 channels (4). Another highly K<sub>v</sub>1.3-selective ShK analogue, [EWSS]ShK, is based entirely on protein amino acids and can be produced by recombinant expression, making it a valuable addition to the complement of therapeutic candidates for the treatment of autoimmune diseases. *Note:* Mouse models are unsuitable models for evaluating K<sub>v</sub>1.3 blockers in immune functions, inasmuch as: (a) K<sub>v</sub>1.3 does not set the membrane potential in mouse T cells; (b) beyond the presence of K<sub>v</sub>1.3, mouse T cells also possess K<sub>v</sub>1.1, K<sub>v</sub>1.2, K<sub>v</sub>1.6 and K<sub>v</sub>3.1; (c) mouse T cell proliferation and cytokine secretion are unaffected by K<sub>v</sub>1.3 blockers; and (d) K<sub>v</sub>1.3 knockout mouse has no immune T cell phenotype. **Targets:**

$K_V1.1$  ( $K_d = 7$  nM);  $K_V1.2$  ( $K_d = 48$  nM);  **$K_V1.3$**  ( $K_d = 69$  pM);  $K_V1.4$  ( $K_d = 0.1$   $\mu$ M);  $K_V1.5$  ( $K_d = 0.1$   $\mu$ M);  $K_V1.6$  ( $K_d = 0.02$   $\mu$ M);  $K_V1.7$  ( $K_d = 0.1$   $\mu$ M);  $K_V2.1$  ( $K_d = 0.1$   $\mu$ M);  $K_V3.1$  ( $K_d = 0.1$   $\mu$ M);  $K_V3.2$  ( $K_d = 0.02$   $\mu$ M); hERG ( $K_d = 0.1$   $\mu$ M);  $K_{Ca}1.1$  ( $K_d = 0.1$   $\mu$ M);  $K_{Ca}2.2$  ( $K_d = 0.1$   $\mu$ M);  $K_{Ca}2.3$  ( $K_d = 0.1$   $\mu$ M);  $K_{Ca}3.1$  ( $K_d = 0.12$   $\mu$ M);  $K_{ir}2.1$  ( $K_d = 0.1$   $\mu$ M);  $Nav1.2$  ( $K_d = 0.1$   $\mu$ M);  $Nav1.4$  ( $K_d = 0.1$   $\mu$ M);  $Cav1.2$  ( $K_d = 0.1$   $\mu$ M). 1. ### Dalbavancin

This once-weekly, semisynthetic lipoglycopeptide antibiotic (FW = 1799.72 g/mol; CAS 171500-79-1), also known by its code name BI397 as well as its trade name Zeven<sup>®</sup>, possesses excellent *in vitro* activity versus a variety of Gram-positive pathogens, including *Enterococci* and *Clostridia* spp., *Streptococcus pyogenes*, methicillin-resistant *Staphylococcus aureus* (MRSA) and methicillin-resistant *Staphylococcus epidermidis* (MRSE). Upon infusion, plasma dalbavancin concentrations reach their maximum, with an averaged  $t_{1/2}$  of 181 hours, a mean volume of distribution of 9.75 L, and a clearance of 0.0473 L/hour. 1. Leighton, Gottlieb, Dorr, *et al.* (2004) *Antimicrob. Agents Chemother.* **48**, 940. 2. Chen, Zervos & Vazquez (2007) *Int. J. Clin. Pract.* **61**, 853.

### Dalcetrapib

This CETP inhibitor (FW = 389.59 g/mol; CAS 211513-37-0), also known by its code name JTT-705 and its systematic name *S*-[2-([1-(2-ethylbutyl)cyclohexyl]carbonyl)amino]phenyl 2-methylpropanoate, targets cholesteryl ester transfer protein, which promotes the transfer of cholesteryl esters from antiatherogenic HDLs to pro-atherogenic apolipoprotein B (apoB)-containing lipoproteins, including VLDLs, VLDL remnants, IDLs, and LDLs. A deficiency of CETP is associated with increased HDL levels and decreased LDL levels, a profile that is typically antiatherogenic. Therefore, CETP inhibition should result in higher circulating levels of HDL particles (1-4). Inhibition of CETP activity by JTT-705 not only increased the quantity of HDL, including HDL-C levels and charge-based HDL subfractions, but also favorably affected the size distribution of HDL subpopulations and the apolipoprotein and enzyme composition of HDL in rabbits (4). Despite encouraging animal studies supporting this hypothesis, subsequent studies indicated that the pharmacological manipulation of HDL-C by this CETP inhibitor does not improve the cardiovascular outcomes and may have unacceptable side-effects (5). This agent nonetheless remains a useful tool in dissecting the molecular and cellular mechanisms that manage cholesterol levels in animals. The  $IC_{50}$  in human serum is approximately 2  $\mu$ M. Other CETP inhibitors include Anacetrapib, Evacetrapib, and Torcetrapib. 1. Okamoto,

Yonemori, Wakitani, *et al.* (2000) *Nature* **406**, 203. 2. ### Dalfopristin

This Streptogramin-like antibiotic (FW = 690.85 g/mol; CAS 112362-50-2), also named Synercid<sup>®</sup> (when combined with quinupristin) and (3*R*,4*R*,5*E*,10*E*,12*E*,14*S*,26*R*,26*aS*)-26-[[2-(diethylamino)ethyl]sulfonyl]-8,9,14,15,24,25,26,26*a*-octahydro-14-hydroxy-3-isopropyl-4,12-dimethyl-3*H*-21,18-nitrilo-1*H*,22*H*-pyrrolo-[2,1-*c*][1,8,4,19]-dioxadiazacyclotetracosine-1,7,16,22(4*H*,17*H*)-tetrone, binds to sites located on the ribosome's 50S subunit. Dalfopristin binding results in a conformational change of the ribosome, increasing affinity for quinupristin. The resultant stable two-drug-ribosome complex inhibits protein synthesis by preventing peptide-chain formation and blocking the extrusion of newly formed peptide chains. Resistance is mediated by (a) enzymatic drug inactivation, (b) drug efflux or active transport, and (c) most commonly, conformational alterations in ribosomal target-binding sites. (See *Quinupristin*) 1. Allington & Rivey (2001) *Clin. Ther.* **23**, 24.

### Daminozide

This plant growth regulator (FW<sub>free-acid</sub> = 160.17 g/mol; CAS 1596-84-5; M.P. = 154-155°C; Water-soluble), also known as Alar<sup>®</sup>, B-995, dimethazide, and SADH (*i.e.*, succinic acid mono(2,2-dimethylhydrazide), is a potent and selective inhibitor of the KDM2/7 family of human JmJc histone demethylases, which catalyze the *N*-demethylation of *N*<sup>c</sup>-methyl lysine residues in histones. Kinetic and crystallographic studies reveal that daminozide chelates the active site metal via its hydrazide carbonyl and dimethylamino groups. Daminozide's traditional action is that of a synthetic gibberellin antagonist that inhibits indole-3-acetate (IAA) synthesis and increases the number of blossoms on fruit trees. It has been used mainly in apple orchards to control flower development, to reduce premature fruit fall, and to improve color development, size, and storage. Daminozide is a suspected carcinogen in laboratory animals and is known to decompose to *N,N*-dimethylhydrazine, another potential carcinogen, when apple homogenates are heat treated. **Target(s):** amine oxidase, pea (1); gibberellin activity and biosynthesis (2,3); gibberellin 2 $\beta$  dioxygenase (4); JmJc histone demethylases (5). 1. Suzuki & Yamasaki (1970) *Enzymologia* **39**, 57. 2. Pullman, Mein, Johnson & Zhang (2005) *Plant Cell Rep.* **23**, 596. 3. Rademacher (2000) *Ann. Rev. Plant Physiol. Plant Mol. Biol.* **51**, 501. 4. Smith & MacMillan (1984) *J. Plant Growth Regul.* **2**, 251. 5. Rose, Woon & Tumber (2012) *J. Med. Chem.* **26**, 6639.

### Damnacanthal

This orange-yellow anthraquinone (FW = 282.25 g/mol; CAS 477-84-9), also known as 3-hydroxy-1-methoxyanthraquinone-2 aldehyde, from the stem bark and roots of *Morinda lucidais* and *M. citrafolia*, is a strong

inhibitor of p56lck protein-tyrosine kinase:  $IC_{50} = 620$  nM) with respect to an exogenous peptide phosphorylation); and ( $IC_{50} = 17$  nM) for p56lck autophosphorylation. It is a weaker inhibitor of protein kinase A, protein kinase C, epidermal growth factor receptor protein-tyrosine kinase, insulin receptor protein-tyrosine kinase, platelet-derived growth factor receptor protein-tyrosine kinase, p60src protein-tyrosine kinase, and p59fyn protein-tyrosine kinase. There is also a modest (7-20x), but highly statistically significant, selectivity for p56lck over the homologous enzymes p60src and p59fyn. Damnacanthal is competitive for peptide binding site, but mixed noncompetitive with respect to ATP (1). **Target(s):** DNA topoisomerase II (1); protein-tyrosine kinase, p56lck and p60src, non specific protein-tyrosine kinase (2-5); LIM-kinases-1, which plays a crucial role in various cell activities, including migration, division and morphogenesis, by phosphorylating and inactivating cofilin (6). 1. Tosa, Iinuma, Asai, *et al.* (1998) *Biol. Pharm. Bull.* **21**, 641. 2. Faltynek, Schroeder, Mauvais, *et al.* (1995) *Biochemistry* **34**, 12404. 3. Kusaka, Kimura, Kusaka, *et al.* (2003) *J. ### Danazol

This synthetic steroid and anterior pituitary suppressant (FW = 337.46 g/mol; CAS 17230-88-5), also known as 17 $\alpha$ -pregna-2,4-dien-20-ynol[2,3-d]isoxazol-17 $\beta$ -ol and Danocrine, exhibits anti-estrogenic and anti-progestogenic activity, while displaying weak androgenic properties. Danazol also inhibits gonadotropins and suppresses gametogenesis and steroidogenesis. **Target(s):** aromatase, or CYP19 (1); cytochrome P450-dependent activities, or testosterone monooxygenase, or aminopyrine dealkylase, or 7-ethoxycoumarin dealkylase (2); estrone sulfatase (3-6); 3 $\beta$ -hydroxysteroid dehydrogenase (7); 17 $\beta$ -hydroxysteroid dehydrogenase (8); steroid 17,20 lyase (7); steroid 11 $\beta$ -monooxygenase (9); steroid 17 $\alpha$ -monooxygenase (7); steroid 21-monooxygenase (9); steroid sulfotransferase (10); steryl sulfatase (3-6,11,12). 1. Kitawaki, Noguchi, Amatsu, *et al.* (1997) *Biol. Reprod.* **57**, 514. 2. Konishi, Morita, Ono & Shimakawa (1990) *Yakugaku Zasshi* **110**, 49. 3. Pasqualini, Chetrite & Nestour (1996) *J. ### Danofloxacin

This fluoroquinolone-class antibiotic (FW = 357.37 g/mol; CAS 112398-08-0), also named Advocin<sup>®</sup> (injectable) and 1-cyclopropyl-6-fluoro-7-[(1*S*,4*S*)-3-methyl-3,6-diazabicyclo[2.2.1]heptan-6-yl]-4-oxoquinoline-3-carboxylic acid, is a broad-spectrum systemic antibacterial agent that targets Type II DNA topoisomerases (gyrases), which are required for bacterial replication and transcription. It has been used to combat respiratory infections in calves, sheep and poultry. (For the prototypical member of this antibiotic class, See *Ciprofloxacin*)

### Danoprevir

This macrocyclic peptidomimetic (FW = 717.85 g/mol; CASs = 850876-88-9, 916881-67-9, 1001913-18-3, 1225266-12-5; Solubility: 140 mg/mL DMSO; <1 mg/mL Water), also known as RG7227, ITMN-191, RO5190591, and systematically as 4-fluoro-1,3-dihydro-(2*R*,6*S*,13*aS*,14*aR*,16*aS*)-14*a*-[[[(cyclopropylsulfonyl)amino]carbonyl]-6-[[[(1,1-dimethylethoxy)carbonyl]amino]-2*H*-isoindole-2-carboxylic acid, targets the NS3/4A protease of hepatitis C virus (HCV) with  $IC_{50} = 0.2$ -3.5 nM (1-4). The inhibitor's time-dependent effects suggest a two-step binding mechanism with a low overall dissociation rate. Progress-curve analysis indicates the formation of an initial collision complex (EI) that isomerizes to a highly stable complex (EI\*), from which danoprevir dissociates very slowly (5). The dissociation constant ( $K_i$ ) for EI is 100 nM, and the rate constant for EI-to-EI\* conversion is  $6.2 \times 10^{-2} \text{ s}^{-1}$ . The rate constant for dissociation from the EI\* complex is  $3.8 \times 10^{-5} \text{ s}^{-1}$ , with a complex half-life calculated to be ~5 hours and a true biochemical potency ( $K_i^*$ ) of 62 pM (5). Surface plasmon resonance studies as well as assessments of enzyme reactivation after dilution of EI\* confirm slow dissociation, with a considerably longer dissociation half-life (5). 1. Seiwert, *et al.* (2008) *Antimicrob. Agents Chemother.* **52**, 4432. 2. Bartels, *et al.* (2008) *J. Infect. Dis.* **198**, 800. 4. Imhof, *et al.* (2011) *Hepatology* **53**, 1090. 5. Rajagopalan, Misialek, Stevens *et al.* (2009) *Biochemistry* **48**, 2559.

### N<sup>c</sup>-Dansyl-L-arginine 4-ethylpiperidineamide

This substituted arginine (FW<sub>hydrochloride</sub> = 539.14 g/mol), also known as N<sup>c</sup>-dansyl-L-arginine *N,N*-(3-ethyl-1,5-pentanediy)amide and DAPA, is a potent inhibitor of thrombin ( $K_i = 37$  nM), and becomes fluorescent when bound. It is a weak inhibitor of trypsin, plasmin, coagulation factor Xa, and u-plasminogen activator. **Target(s):** acetylcholinesterase, weakly inhibited (1); adenylate cyclase (2); butyrylcholinesterase (1); cholinesterase (1,3,4); thrombin (4-6). 1. Brimijoin, Mintz & Prendergast (1983) *Biochem. Pharmacol.* **32**, 699. 2. Wilks, Campbell & Hui (1986) *Biol. Reprod.* **35**, 877. 3. Hijikata-Okunomiya, Okamoto, Tamao & Kikumoto (1988) *J. Biol. ### N-Dansylcadaverine

This monodansylated diamines (FW<sub>free-base</sub> = 335.47 g/mol), also known as *N*-dansyl-1,5-pentanediamine, is an alternative substrate for many transglutaminases and also inhibits clathrin mediated receptor endocytosis. **Target(s):** [ $\beta$ -adrenergic-receptor] kinase (1); 17-ketosteroid reductase (2); protein-glutamine  $\gamma$ -glutamyltransferase, or transglutaminase (3-9). 1. Wang & Liu (2003) *J. Biol. Chem.* **278**, 15809. 2. Moger (1982) *Can. J. Physiol. Pharmacol.* **60**, 858. 3. Siegel & Khosla (2007) *Pharmacol. Ther.* **115**, 232. 4. Wu, Lai & Tsai (2005) *Int. #### ***N*-Dansyl-*N*-(4-nitrobenzyl)- $\beta$ -alanine Hydroxamate**

This hydroxamate (FW = 472.52 g/mol) inhibits interstitial collagenase ( $K_i$  = 89 nM), gelatinase A, or matrix metalloproteinase-2, ( $K_i$  = 54 nM), neutrophil collagenase, or matrix metalloproteinase-8 ( $K_i$  = 60 nM), gelatinase B, or matrix metalloproteinase-9 ( $K_i$  = 67 nM), and microbial collagenase ( $K_i$  = 18 nM). 1. Scozzafava, Mllies, Manole & Supuran (2000) *Eur. J. Pharm. Sci.* **11**, 69.

#### **Dantrolene**

This hydantoin (FW = 314.26 g/mol; CAS 85008-71-5), also named systematically as 1-([5-(*p*-nitrophenyl)furfurylidene]amino)hydantoin, is a skeletal muscle relaxant that inhibits  $Ca^{2+}$  release from sarcoplasmic reticulum. Dantrolene is used in the treatment of malignant hyperthermia, a disorder associated with increased intracellular free  $Ca^{2+}$ . With mounting evidence that high intracellular calcium ion is a contributing factor in bacterial sepsis, dantrolene may be useful in managing bloodstream-borne infections. **Target(s):**  $Ca^{2+}$  release from sarcoplasmic reticulum (1,2); carbonic anhydrase (3); glucose-6 phosphate dehydrogenase (4). 1. Harrison (1988) *Brit. J. Anaesth.* **60**, 279. 2. Song, Karl, Ackerman & Hotchkiss (1993) *Proc. Natl. Acad. Sci. U.S.A.* **90**, 3933. 3. Gulcin, Beydemir & Buyukokuroglu (2004) *Biol. Pharm. #### **Dapagliflozin**

This Type-2 diabetes drug (FW = 408.87 g/mol; CAS 461432-26-8; Symbol: ), also known as BMS 512148, BMS-512148, the trade name Farxiga™, and systematic name (2*S*,3*R*,4*R*,5*S*,6*R*)-2-[4-chloro-3-(4-ethoxybenzyl)phenyl]-6-(hydroxymethyl)-tetrahydro-2*H*-pyran-3,4,5-triol) inhibits (IC<sub>50</sub> = 60 nM) the sodium-glucose transporter (SGLT2), subtype 2, a carrier responsible for >90% of kidney glucose reabsorption. The IC<sub>50</sub> for SGLT2 is 1.1 nM, or >1000-times lower than that for SGLT1 (IC<sub>50</sub> = 1.4

$\mu$ M), such that the drug does not interfere with intestinal glucose absorption (2). **Mechanism of Action:** The kidney plays an important role in glucose homeostasis, primarily by the reabsorption of filtered glucose, a process known as 'glucocesis'. Located in the proximal convoluted tubule, SGLT2 is responsible for the majority of glucose reabsorption by the kidney. SGLT2 inhibitors offer a novel approach to treat T2D and reduce hyperglycemia by increasing urinary excretion of glucose. In humans, SGLT2 inhibition with Farxiga (10 mg) resulted in excretion of approximately 70 grams of glucose in the urine per day at Week-12. Farxiga increases the risk of genital mycotic infections. Other SGLT2 inhibitors include canagliflozin, empagliflozin, tofogliflozin, and luseogliflozin. In 2014, dapagliflozin was approved by the Food & Drug Administration to improve glycemic control, when used along with dieting and exercise in adult patients afflicted with T2DM. **Other Targets:** Dapagliflozin also increases hepatic glucose production through the induction of glucagon secretion in islet  $\alpha$ -cells (2). DPF inhibits UDP-glucuronosyltransferases UGT1A1, UGT1A9, and UGT1A10, with IC<sub>50</sub> values ranging from 39 to 66  $\mu$ M (3). The  $K_i$  for DPF inhibition of UGT1A1 was 81  $\mu$ M, whereas the  $K_i$  values for inhibition of UGT1A9 ranged from 12 to 15  $\mu$ M. Based on the *in vitro*  $K_i$  values and plasma concentrations reported in the literature, DPF may be excluded as a perpetrator of drug-drug interactions arising from inhibition of UGT enzymes (3). (See also *Canagliflozin; Empagliflozin, Tofogliflozin, Luseogliflozin*) 1. Meng, Ellsworth, Nirschl, *et al.* (2008) *J. Med. Chem.* **51**, 1145. 2. Bonner, Kerr-Conte, Gmyr, *et al.* (2015) *Nature Med.* **21**, 512. 3. Pattanawongsa, Chau, Rowland & Miners (2015) *Drug Metab. Dispos.* **43**, 1468.

#### **Dapoxetine**

This selective serotonin reuptake inhibitor, or SSRI (FW = 305.41 g/mol; CASs = 119356-77-3 (free base) and 129938-20-1 (HCl salt)), also known as LY 210448, Priligy®, Westoxetin®, and (*S*)-*N,N*-dimethyl-3-(naphthalen-1-yloxy)-1-phenylpropan-1-amine, was the first agent specifically developed for the treatment of premature ejaculation in men 18–64 years old. By increasing serotonin's action at the post synaptic cleft, dapoxetine delays ejaculation. Dapoxetine is structurally related to fluoxetine and was initially pursued as an antidepressant. 1. Dresser, Desai, Gidwani, *et al.* (2006) *Internat. J. Impotence Res.* **18**, 104.

#### **Dapsone**

This antibacterial agent (FW = 248.31 g/mol; CAS 80-08-0; Soluble in ethanol and methanol; Low solubility in H<sub>2</sub>O), also known as 4,4'-diaminodiphenyl sulfone (*i.e.*, DDS) and 4,4'-sulfonylbisbenzeneamine, is an effective treatment for against noninfectious inflammatory diseases. Dapsone is frequently used against the causative agent of leprosy (*Mycobacterium leprae*), as well as an adjunct in treating malaria. Dapsone acts as a folate synthetase inhibitor by via competition with *para*-aminobenzoate for the active site of dihydropteroate synthetase and reacting with the substrate (7,8-dihydro-6-hydroxymethylpterinopyrophosphate) to form tightly bound 7,8-dihydropteroic acid analogue (1). Dapsone has a dramatic beneficial effect in dermatitis herpetiformis, processes in which the polymorphonuclear leukocytes (PMNL) and immune complexes appear to be important for skin lesions to develop (2). Pruritus disappears and inflammatory eruptions clear within a few days of dapsone therapy. At dapsone concentrations (1-30  $\mu$ g/mL) comparable to therapeutic doses, it interferes primarily with the myeloperoxidase (MPO)-H<sub>2</sub>O<sub>2</sub>-halide-mediated cytotoxic system in PMNL (2). No effect was observed on locomotion, chemotaxis, phagocytic ingestion, oxidative metabolism, or the release of lysosomal enzymes (2). Radioligand binding studies using human neutrophils exposed to 10-100  $\mu$ M dapsone indicate that it antagonizes association of leukotriene B<sub>4</sub> (LTB<sub>4</sub>) with its specific receptor sites, reducing biologic response in LTB<sub>4</sub>-stimulated neutrophil chemotaxis (3). A physiologic model of LTB<sub>4</sub>-dependent inflammation in mice is antagonized by systemic administration of dapsone (3). **Key Pharmacokinetic Parameters:**

See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** cyclooxygenase (4); dihydropteroate synthase (5-17); hydroxymethyl-dihydropterin pyrophosphokinase-dihydropteroate synthase (11); lactoperoxidase (18); lipoxygenase (19); 5-lipoxygenase (20); myeloperoxidase (21-24); peroxidase, eosinophil (21,22); tubulin polymerization, or microtubule self-assembly (25). 1. #### DAPT

This orally bioavailable  $\gamma$ -secretase Notch inhibitor (FW = 432.46 g/mol; CAS 208255-80-5; Solubility: 85 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), known as GSI-IX and systemically as (S)-tert-butyl 2-((S)-2-(2-(3,5-difluorophenyl)acetamido)propanamido)-2-phenylacetate, targets  $\gamma$ -secretase (GS), with IC<sub>50</sub> = 20 nM, thereby reducing the amount of secreted A $\beta$  peptides into the culture medium in HEK293 cells (1-3). DAPT also induces caspase-dependent and caspase-independent apoptosis in lung squamous cell carcinoma cells by inhibiting Notch receptor signaling pathway. DAPT impairs recovery from lipopolysaccharide-induced inflammation in rat brain (2). When treated with DAPT, paclitaxel-insensitive breast cancer cells show restored sensitivity to the microtubule-directed drug, suggesting the Notch pathway affects paclitaxel sensitivity (4). 1. Cao, et al. (2012) *APMIS* **120**, 441. 2. Nasoohi, Hemmati, Moradi & Ahmadiani Nasoohi (2012) *Neuroscience* **210**, 99. 3. Dovey, John, Anderson, et al. (2001) *J. Neurochem.* **76**, 173. 4. Zhao, Ma, Gu & Fu (2014) *Chin. Med. J. (Engl.)* **127**, 442.

#### Daptomycin

This intravenous lipopeptide antibiotic (FW = 1619.71 g/mol; CAS 103060-53-3), also named LY-146032, Cubicin<sup>®</sup>, and N-decanoyl-L-W-L-N-L-D-L-T-G-L-Orn-L-D-D-A-L-D-G-D-S-threo-3-CH<sub>3</sub>-L-E-3-anthranil-oyl-L-A-[egr]-lactone, from the soil saprotroph *Streptomyces roseosporus*, exerts its antibiotic effect by inserting itself into the cell membrane in a phosphatidylglycerol-dependent fashion, whereupon it aggregates (1-3). The latter alters membrane curvature, creating pores that leak ions, causing persistent depolarization and inhibiting protein, DNA, and RNA synthesis. Daptomycin is bactericidal against Gram-positive bacteria, including *Enterococci* (also glycopeptide-resistant *Enterococci*, or GRE), *Staphylococci* (also methicillin-resistant *S. aureus*, or MRSA), viridans group *Streptococci*, and *Corynebacteria*. *Listeria monocytogenes* is markedly less susceptible to LY-146032 (MIC<sub>90</sub> = 16  $\mu$ g/mL) than vancomycin (MIC<sub>90</sub> = 1  $\mu$ g/mL). Vancomycin and daptomycin are the first-line antibiotic choices for MRSA bacteremia (3). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Eliopoulos, Willey, Reiszner, et al. (1986) *Antimicrob. Agents Chemother.* **30**, 532. 2. Fass & Helsel (1986) *Antimicrob. Agents Chemother.* **30**, 781. 3. Holland, Arnold & Fowler (2014) *JAMA* **312**, 1330.

#### Darapladib

This investigational atherosclerosis drug (FW = 665.79 g/mol; CAS 356057-34-6) produces sustained inhibition of plasma lipoprotein-associated phospholipase A<sub>2</sub> (or Lp-PLA<sub>2</sub>) activity in patients receiving intensive atorvastatin therapy (1). Lp-PLA<sub>2</sub> is abundant in the necrotic core of coronary lesions, and its pro-inflammatory reaction products are likely to contribute to cell death and increase the risk of plaque rupture and ensuing blockage of vital blood vessels. Changes in IL-6 and hs-CRP after 12-week course on darapladib (160 mg) suggest a possible reduction in inflammatory burden (1). Lp-PLA<sub>2</sub> inhibition by darapladib prevents necrotic core expansion, a key determinant of plaque vulnerability (2). Darapladib exhibits favorable pharmacokinetics, minimal predicted drug-drug interactions, sustained blood levels with once-daily oral dosing and limited inhibition of other PLA<sub>2</sub> isozymes (3). In a double-blind trial with 15,828 stable coronary heart disease patients randomly assigned to receive either once-daily darapladib (at a dose of 160 mg) or placebo, however, darapladib did not significantly reduce the risk of the primary composite end point of cardiovascular death, myocardial infarction, or stroke darapladib versus placebo, when added to standard of care (3). 1. Mohler, Ballantyne, Davidson, et al. (2008) *J. Am. Coll. Cardiol.* **51**, 1632. 2. Serruys, Garcia-Garcia, Buszman, et al. (2008) *Circulation* **118**, 1172. 3. Riley & Corson (2009) *IDrugs* **12**, 648. 3. White, Held, Stewart, et al. (2014) *New Engl. J. Med.* **370**, 1702.

#### Darexaban

This orally bioavailable direct Factor Xa inhibitor (FW = 474.56 g/mol; CAS = 365462-23-3 and 365462-24-4 (maleate salt)), also known by the code name YM150 and systematically named N-(3-hydroxy-2-((4-(4-methyl-1,4-diazepan-1-yl)benzoyl)amino)phenyl)-4-methoxybenzamide, is a potent anticoagulant and antithrombotic agent used for the prevention of

post-surgical venous thromboembolism, stroke in patients with atrial fibrillation, as well as ischemic events in acute coronary syndrome. The hydroxy moiety of YM-150 is rapidly transformed into its glucuronide conjugate, YM-222714 (1). Both darexaban and its glucuronide selectively inhibit human factor Xa with  $K_i$  values of 0.03 and 0.02  $\mu\text{M}$  (2). They show anticoagulant activity in human plasma, with concentrations of darexaban and darexaban glucuronide needed for doubling prothrombin time of 1.2 and 0.95  $\mu\text{M}$ , respectively (2). 1. Hirayama, Koshio, Ishihara, *et al.* (2011) *J. Med. Chem.* **54**, 8051. 2. Iwatsuki, Sato, Moritani, *et al.* (2011) *Eur. J. Pharmacol.* **673**, 49.

### Darunavir

This second-generation nonpeptidic HIV protease inhibitor (FW = 5477.67 g/mol; CAS 206361-99-1; IUPAC: [(1*R*,5*S*,6*R*)-2,8-dioxabicyclo[3.3.0]oct-6-yl] *N*-[(2*S*,3*R*)-4-[(4-aminophenyl)sulfonyl-(2-methylpropyl)amino]-3-hydroxy-1-phenylbutan-2-yl]carbamate), also known as TMC114 and Prezista<sup>®</sup>, is used to treat Human Immunodeficiency Virus infection by targeting post-translational fragmentation of the single HIV polyprotein into its component structural proteins and replicative enzymes. Darunavir interacts with the catalytic aspartates and the backbone within the active site (making hydrogen bonds to residues Asp-25, Asp-25', Asp-29, Asp-30, Asp-30', and Gly-27), allowing Darunavir to competitively inhibit ( $K_d = 4.5 \times 10^{-12}$  M) polyprotein substrate access to the active site (1,2). Even with the reduction in binding affinity to the multidrug-resistant HIV protease, TMC114 still binds with an affinity that is more than 1.5 orders of magnitude tighter than the first-generation inhibitors (3). Darunavir is best paired with ritonavir, a potent CYP3A and P-glycoprotein inhibitor, greatly increasing Darunavir's efficacy. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Koh, Nakata, Maeda, *et al.* (2003) *Antimicrob. Agents Chemother.* **47**, 3123. 2. Tie, Boross, Wang, *et al.* (2004) *J. Mol. Biol.* **338**, 341. 3. King, Prabu-Jeyabalan, Nalivaika, *et al.* (2004) *J. Virol.* **78**, 12012.

**Darvon, See Propoxyphene**

### DAS645

This experimental herbicide (FW = 489.81 g/mol), also known as [1-*tert*-butyl-3-(2,4-dichlorophenyl)-5-hydroxy-1*H*-pyrazol-4-yl][2-chloro-4-(methanesulfonyl)phenyl]-methanone, inhibits plant 4-hydroxyphenylpyruvate dioxygenase ( $IC_{50} = 12$  nM). DAS645 exhibits a remarkable (>1600x) selectivity toward the *Arabidopsis thaliana* enzyme compared to its mammalian counterpart. 1. Yang, Pflugrath, Camper, *et al.* (2004) *Biochemistry* **43**, 10414.

### Dasatinib

This multitargeting Bcr-Abl tyrosine protein kinase inhibitor (FW = 485.05 g/mol; CAS 302962-49-8), also known as BMS-354825 and Sprycel, targets Abl ( $IC_{50} < 1$  nM), Src ( $IC_{50} = 0.5$  nM) and c-Kit ( $IC_{50} = 79$  nM) (1-5). Dasatinib induces DNA damage and activates DNA repair pathways, leading to senescence only in non-small cell lung cancer (NSCLC) that does not harbor targetable DNA mutations or translocations. NSCLC cells harboring kinase-inactivating BRAF mutations (KIBRAF) undergo senescence, when treated with dasatinib. Moreover, dasatinib-induced senescence is dependent on Chk1 and p21 proteins, both of which are known to mediate DNA damage-induced senescence (6). Dasatinib treatment also leads to a marked decrease in TAZ but not YAP protein levels. Over-expression of TAZ inhibits dasatinib-induced senescence (6). **Target(s):** Bcr-Abl protein-tyrosine kinase (1-5); Btk protein-tyrosine kinase (5); protein tyrosine kinase (1-5); ribosyl-dihydrocotinamide dehydrogenase, quinone-requiring (7); Src protein-tyrosine kinase (3,5); Tec protein-tyrosine kinase (5). 1. Tauchi & Ohyashiki (2006) *Int. J. Hematol.* **83**, 294. 2. Shah, Tran, Lee, *et al.* (2004) *Science* **305**, 399. 3. Lombardo, Lee, Chen, *et al.* (2004) *J. Med. Chem.* **47**, 6658. 4. Cortes, Jabbour, Kantarjian, *et al.* (2007) *Blood* **110**, 4005. 5. Hantschel, Rix, Schmidt, *et al.* (2007) *Proc. Natl. Acad. Sci. U.S.A.* **104**, 13283. 6. Peng, Sen, Mazumdar, *et al.* (2016) *Oncotarget* **7**, 565. 7. Winger, Hantschel, Superti-Furga & Kuriyan (2009) *BMC Struct. Biol.* **9**, 7.

### Daurorubicin

This antibiotic and antitumor agent (FW<sub>free-base</sub> = 527.53 g/mol; CAS 20830-81-3), also known as daunomycin, from *Streptomyces peuceitius* readily permeates cells, intercalating into double-stranded DNA, with the aminosugar component docking into the minor groove and thereby inhibiting replication (1). Aqueous solutions are pink under acidic conditions and blue with basic pH. The amino sugar can be removed by treatment with acid. It should be stored in a desiccator in the dark and at 4°C. Stock solutions should be prepared just prior to use. **Primary Mode of Action:** Daunorubicin consists of a tetracyclic structure called daunomycinone that is covalently linked to an amino sugar (daunosamine). Daunorubicin's antimetabolic and cytotoxic effects arise by a number of mechanisms. It complexes with DNA by intercalation, inhibiting topoisomerase II activity by stabilizing the DNA-topoisomerase II complex, and preventing the religation phase of the ligation-religation reaction cycle catalyzed by topoisomerase II catalyzes. Single-strand and double-strand DNA breaks result. Daunorubicin may also inhibit DNA polymerase activity, impair regulation of gene expression, and promote/reinforce free radical damage to DNA. Daunorubicin also inhibits RNA transcription. Daunorubicin also exhibits antitumor effects against a wide spectrum of animal tumors, either grafted or spontaneous. Daunorubicin is frequently used in the treatment of acute leukemias. **Redox Cycling in Mitochondria:** Complex I (most likely the NADH dehydrogenase flavin) is the mitochondrial site of anthracycline reduction. During forward electron transport, the anthracyclines doxorubicin (Adriamycin) and daunorubicin act as one-electron acceptors for BH-SMP (*i.e.* they are reduced to

semiquinone radical species), but only when NADH was used as substrate (27). Succinate and ascorbate are without effect. Inhibitor experiments (with rotenone, amytal, ptericidin A) indicate that the anthracycline reduction site lies on the substrate side of ubiquinone. (See also WP631) **Target(s)**: carbonyl reductase (2); DNA-directed DNA polymerase (3-5); DNA-directed RNA polymerase (3,6-12); DNA helicase (13); DNA ligase (ATP) (14); DNA topoisomerase II (4,15-18); inositol trisphosphate 3-kinase (19); nitric-oxide synthase (20); nucleoside-triphosphatase (13); P glycoprotein (21); procollagen-proline 4-dioxygenase (22-24); reverse transcriptase (25); transcription (1); Xaa-Pro Dipeptidase, or prolidase, or imidodipeptidase (26); xenobiotic-transporting ATPase, or multidrug-resistance protein (21). 1. ### Dauricine

This toxic alkaloid (FW = 624.77 g/mol; CAS 524-17-4), also named as 4-((1,2,3,4-tetrahydro-6,7-dimethoxy-2-methyl-1-isoquinolinyl)methyl)-2-((1,2,3,4-tetrahydro-6,7-dimethoxy-2-methyl-1-isoquinolinyl)methyl)phenoxyphenol, from the North American moonseed vine *Menispermum canadense* is a highly potent calcium channel blocker. Its antiarrhythmic effects are well documented in experimental arrhythmic models and in arrhythmic cardiac patients. Dauricine blocks cardiac transmembrane Na<sup>+</sup>, K<sup>+</sup> and Ca<sup>2+</sup> ion currents, but differs from quinidine and sotalol, which exhibit reverse use-dependent effects. Dauricine prolongs action potential duration (APD) in a normal use-dependent manner. 1. Qian (2002) *Acta Pharmacol. Sin.* **23**, 1086.

### Daurinol

This novel aryl-naphthalene lignan (FW = 350.33 g/mol) from the ethnopharmacological plant *Haplophyllum dauricum*, resembles etoposide structurally and likewise inhibits (10-100 μM) the topoisomerase IIα in an ATP concentration-dependent manner and suppressed the ATP hydrolysis activity of the enzyme. Daurinol inhibits human topoisomerase IIα without the formation of the DNA cleavable complex, suggesting it is a catalytic inhibitor that interferes with at least one step of the topoisomerase catalytic cycle. (Daurinol does not inhibit topoisomerase I, which lacks an ATP binding domain.) However, daurinol treatment does not cause DNA damage or nuclear enlargement *in vitro*. 1. Kang, Oh, Yun, et al. (2011) *Neoplasia* **13**, 1043.

### DB-02

This antiviral (FW = 370.51), also named 6-(cyclohexylmethyl)-5-ethyl-2-((2-oxo-2-phenylethyl)thio)pyrimidin-4(3H)-one, targets HIV-1 reverse transcriptase (HIV1RT) and displays potent anti-HIV-1 activity against laboratory adapted strains and primary isolated strains including different subtypes and tropism strains (EC<sub>50</sub> values ranging from 2.4 to 42 nM). DB-02 shows very low cytotoxicity (CC<sub>50</sub> > 1mM) to tested cell lines and peripheral blood mononuclear cells (PBMCs). Genotypic resistance profiles revealed V106A was the major resistance contributor for the compound. Molecular docking analysis showed that DB-02 located in the hydrophobic pocket of HIV1RT, interacting with Lys101, Val106, Leu234, His235. DB-02 also showed non-antagonistic effects to four approved antiretroviral drugs. All studies indicated that DB-02 would be a potential NNRTI with low cytotoxicity and improved activity. 1. Zhang, Lu, Wang, et al. (2013) *PLoS One* **8**, e81489.

### DBeQ

This potent and ATP-competitive protein kinase inhibitor (FW = 364.40 g/mol; CAS 1159824-67-5; Solubility: 68 mg/mL DMSO) selectively and reversibly targets p97 (IC<sub>50</sub> = 2.4 μM), the AAA ATPase that is also known as Transitional Endoplasmic Reticulum ATPase (or TER ATPase) also known as Valosin-Containing Protein (or VCP). ((Note: Unlike DBeQ, epoxomicin is irreversible proteasome inhibitor.)) P97 is a ubiquitin segregase that remodels multimeric protein complexes by extracting polyubiquitinated proteins for recycling or degradation by the proteasome, playing vital roles in mitochondrial quality control, autophagy, vesicle transport/fusion, 26S proteasome function, and peroxisome assembly. DBeQ blocks multiple processes shown by RNAi to depend on p97, including degradation of ubiquitin fusion degradation and endoplasmic reticulum-associated degradation pathway reporters, as well as autophagosome maturation. DBeQ also potently inhibits cancer cell growth and is more rapid than a proteasome inhibitor at mobilizing the executioner caspase-3 and caspase-7 (1). A distinguishing feature between DBeQ and conventional proteasome inhibitors is that DBeQ is a 'separation of function' inhibitor that affects both the UPS and autophagic protein degradation pathways and rapidly activates cell death (2). 1. Chou, Brown, Minond, et al. (2011) *Proc. Natl. Acad. Sci. USA* **108**, 4834. 2. Chou & Deshaies (2011) *Autophagy* **7**, 1091. 3. Hauler, Mallery, McEwan, Bidgood & James (2012) *Proc. Natl. Acad. Sci. USA* **109**, 19733.

**DBL-583**

This fat-soluble, piperazine-class psychostimulant pro-drug (FW = 620.82 g/mol), also known as GBR-decanoate, undergoes slow ester-bond hydrolysis, thereby releasing decanoate along with the active dopamine reuptake inhibitor GBR-12935 on a time-scale suitable for once-monthly dosing. GBR-decanoate elevates basal synaptic dopamine levels and blocks methamphetamine-evoked dopamine release in a persistent manner, without significantly perturbing dopamine receptor function. **1.** Baumann, Phillips, Ayestas, *et al.* (2002) *Ann. New York Acad. Sci.* **965**, 92. **2.** Berger, Janowsky, Vocci *et al.* (1985) *Eur. J. Pharmacol.* **107**, 289. **3.** Janowsky, Vocci, Berger, *et al.* (1987) *J. **DCCD**, See *N,N'*-Dicyclohexylcarbodiimide

**DCCI**, See *N,N'*-Dicyclohexylcarbodiimide

**107498**

This synthetic, single-dose, transmission-blocking and chemoprotective antimalarial (FW = 448.23 g/mol) targets the *Plasmodium falciparum* elongation factor-2 (PfeEF-2), the GTP hydrolysis-dependent mechanoenzyme required for ribosome translocation along mRNA during protein synthesis. DD107498 exhibits an EC<sub>50</sub> of 1 nM against *P. falciparum* (Strain 3D7), with >20,000 times lower toxicity to human MRC5 and Hep-G2 cell lines *in vitro*. In malaria-infected SCID mice, this antimalarial's effects are observable within one replication cycle (48 hours), inhibiting development and resulting in trophozoites with an uncharacteristically condensed cytoplasm. A single dose reduces the parasite burden by 90%. DD107498 shows promising drug-like properties (log*P* = 3.2; adequate H<sub>2</sub>O solubility = 0.22 mM; FW < 500; limited hydrogen bonding; long half-life in circulation (*e.g.*, 16-19 hours in mice), commending its development as an orally bioavailable antimalarial. **1.** Baragaña, Hallyburton, Lee, *et al.* (2015) *Nature* **522**, 315.

**DDE**, See *1,1-Dichloro-2,2-Bis(p-chlorophenyl)-ethylene*

**DDR1-IN-1**

This protein tyrosine kinase inhibitor (FW<sub>di-HCl</sub> = 625.51 g/mol; CAS 1449685-96-4; Solubility: 100 mM in H<sub>2</sub>O; 50 mM in DMSO), also named *N*-[3-[(2,3-dihydro-2-oxo-1*H*-indol-5-yl)oxy]-4-methylphenyl]-4-[(4-ethyl-

1-piperazinyl)methyl]-3-(trifluoromethyl)benzamide, selectively targets the collagen-binding Discoidin Domain Receptor-1 (*or* DDR1) tyrosine kinase (IC<sub>50</sub> = 105 nM), with weaker action against DDR2 (IC<sub>50</sub> = 413 nM), inhibiting integrin-induced DDR1 autophosphorylation in an osteosarcoma cell line. **Pharmacology:** The DDR1 receptor tyrosine kinase is activated by matrix collagens and has been implicated in numerous cellular functions, including adhesion, proliferation, differentiation, migration, and invasion. The G707A mutation within the hinge region of DDR1 confers >20x resistance to DDR1-IN-1 and can be used to establish whether cellular process is DDR1-dependent. Ponatinib is more potent, inhibiting DDR1 and DDR2 with an IC<sub>50</sub> of 9nM (2). Whereas imatinib and ponatinib bind potently to both the DDR and ABL kinases, the hydrophobic interactions of the ABL P-loop appear poorly satisfied by DDR1-IN-1 suggesting a structural basis for its DDR1 selectivity (2). **1.** Kim, Tan, Weisberg, *et al.* (2013) *ACS Chem Biol.* **8**, 2145 (Erratum: *ACS Chem Biol.* (2014) **9**, 840.). **2.** Canning, Tan, Chu, *et al.* (2014) *J. Mol. Biol.* **426**, 2457.

**(3R,4S)-1-[(9-Deazaadenin-9-yl)methyl]-3-hydroxy-4-(propylthiomethyl)pyrrolidine**

This putative transition-state analogue (FW<sub>free-base</sub> = 309.44 g/mol) inhibits 5'-methylthioadenosine/*S*-adenosyl-homocysteine nucleosidase, *K*<sub>i</sub>' = 0.58 nM (1) and *S*-methyl-5'-thioadenosine phosphorylase, *K*<sub>i</sub>' = 0.12 nM (2). **1.** Singh, Evans, Lenz, *et al.* (2005) *J. Biol. Chem.* **280**, 18265. **2.** Evans, Furneaux, Lenz, *et al.* (2005) *J. Med. Chem.* **48**, 4679.

**3-Deazaadenosine**

This adenosine analogue (FW = 266.26 g/mol; CAS 6736-58-9; Symbol: DZA) inhibits *S*-adenosyl-homocysteinase as well as leukocyte adhesion to tumor necrosis factor-stimulated human endothelial cells. DZA may activate intrinsic apoptosis by stimulating BAX activation, thereby releasing cytochrome *c*. Because the use of adenosine receptor agonists is plagued by dose-limiting cardiovascular side effects, there is great interest in developing adenosine kinase inhibitors (AKIs) as a way for to raise steady-state adenosine concentrations. **Target(s):** adenosine deaminase (1); adenosine kinase, also weak alternative substrate (2,3); adenosylhomocysteinase, *or S*-adenosyl-homocysteinase (4-10); *S*-adenosylmethionine decarboxylase (11); glycine *N*-methyltransferase (12); histone-arginine *N*-methyltransferase (13); phosphatidyl-ethanolamine methyltransferase (14); purine nucleosidase, *or* purine-specific nucleoside *N*-ribohydrolase (15,16). **1.** Lupidi, Riva, Cristalli & Grifantini (1982) *Ital. ### 9-Deaza-9-[4(*R*)-hydroxy-2(*S*)-(hydroxymethyl)pyrrolidin-1-ylmethyl]adenine

This nucleoside analogue (FW = 263.30 g/mol), also known as 4'-deaza-1'-aza-2'-deoxy-1'-(9-methylene) immucillin-A and DADMe-Immucillin-A, inhibits purine nucleoside phosphorylase,  $K_i = 30 \text{ pM}$ . When the ring nitrogen is protonated, this analogue mimics the charge on the oxacarbenium ion intermediate that is believed to form transiently in many glycosidase reactions. Transition-state mimicry thus results in tight binding. **1.** Rinaldo-Matthis, Wing, Ghanem, *et al.* (2007) *Biochemistry* **46**, 659.

### 3-Deazanepanocin A

This carbocyclic adenosine analogue (FW = 298.73 g/mol; CAS 120964-45-6; *Symbol* = DZNep; Solubility: 10 mM in H<sub>2</sub>O), also named (1*S*,2*R*,5*R*)-5-(4-amino-1*H*-imidazo[4,5-*c*]pyridin-1-yl)-3-(hydroxymethyl)-3-cyclopentene-1,2-diol, inhibits histone methyltransferase, decreasing global DNA methylation. **Mechanism of Action:** ZNep inhibits *S*-adenosylhomocysteine (AdoHcy) hydrolase, the enzyme responsible for reversible hydrolysis of AdoHcy to adenosine and homocysteine (1,2),

thereby indirectly inhibiting of various *S*-adenosyl-methionine-dependent methylation reactions (3). DZNep can thus be considered as an inhibitor of SAM-dependent methyltransferase. DZNep has recently been reported to decrease protein levels of PRC2 (4). As DZNep can induce efficient apoptotic cell death in cancer cells but not in normal cells (4), it has been widely examined as a possible epigenetic therapeutic agent for the treatment of various cancers, including lung cancer (5), gastric cancer (6), myeloma (7), acute myeloid leukemia (8), and lymphoma (9). **EZH2 Degradation:** An inhibitor of *S*-adenosyl-methionine-dependent methyltransferase, DZNep targets the degradation of EZH2, a core component of Polycomb Repressive Complex-2 (PRC2) that plays a role in transcriptional repression through H3K27 trimethylation (10). DZNep preferentially induces apoptosis in various hematological malignancies, suggesting that EZH2 may be a new target for epigenetic treatment. As PRC2 participates in epigenetic silencing of a subset of GATA-1 target genes during erythroid differentiation, inhibition of EZH2 may influence erythropoiesis. DZNep treatment significantly induces erythroid differentiation of K562 cells, as assessed by benzidine staining and quantitative RT-PCR analysis for representative erythroid-related genes including globins (10). **1.** Glazer, Hartman, Knode, *et al.* (1986) *Biochem. Biophys. Res. Commun.* **135**, 688. **2.** Glazer, Knode, Tseng, Haines & Marquez, (1986) *Biochem. Pharmacol.* **35**, 4523. **3.** Chiang (1998) *Pharmacol. ### 5-Deazatetrahydrofolate

This tetrahydrofolate analogue (FW = 444.45 g/mol) inhibits deoxycytidylate 5-hydroxymethyltransferase (1,2) and phosphoribosylglycinamide formyltransferase,  $K_i = 5.1 \text{ nM}$  (3,4). The inability of 5-deazatetrahydrofolate to stimulate enzyme-catalyzed tritium exchange from [5-(<sup>3</sup>H)]nucleotides into solvent suggests that *N*<sup>5</sup>-atom of tetrahydrofolate is the base that deprotonates the nucleotide. **1.** Butler, Graves & Hardy (1994) *Biochemistry* **33**, 10521. **2.** Hardy, Graves & Nalivaika (1995) *Biochemistry* **34**, 8422. **3.** Baldwin, Tse, Gossett, *et al.* (1991) *Biochemistry* **30**, 1997. **4.** Sanghani & Moran (1997) *Biochemistry* **36**, 10506.

### 3-Deazathiamin Pyrophosphate

This noncleavable thiamin pyrophosphate analogue (FW<sub>free-acid</sub> = 423.32 g/mol) inhibits transketolase,  $K_i = 12 \text{ nM}$  (1,2). Removal of the pyrophosphoryl group greatly reduces its inhibitory effectiveness ( $K_i = 18 \mu\text{M}$ ). An efficient ten-step synthesis of 3-deazathiamin from commercially available  $\alpha$ -acetyl- $\gamma$ -butyrolactone (3). **1.** Thomas, De Meese, Le Huerou, *et al.* (2008) *Biorg. Med. Chem. Lett.* **18**, 509. **2.** Mann, Perez-Melero, Hawksley & Leeper (2004) *Org. Biomol. Chem.* **2**, 1732. **3.** Hawksley, Griffin & Leeper (2001) *J. Chem. Soc., Perkin Trans.* **1**, 144.

**9-Deaza-9-(3-thienylmethyl)guanine**

This nucleoside analogue (FW = 246.29 g/mol), also known as PD 141955, inhibits purine nucleoside phosphorylase ( $IC_{50} = 25$  nM). The 2-thienyl analogue is also a potent inhibitor ( $IC_{50} = 21$  nM). The 7-deaza-9-(2-thienylmethyl)guanine isomer is significantly weaker ( $IC_{50} = 674$  nM). (See also *Immuicillin-H* and *Immuicillin-G*) **1.** Gilbertsen, Josyula, Sircar, *et al.* (1992) *Biochem. Pharmacol.* **44**, 996. **2.** Castilho, Postigo, de Paula, *et al.* (2006) *Bioorg. Med. Chem.* **14**, 516. **3.** Bzowska, Kulikowska & Shugar (2000) *Pharmacol. Ther.* **88**, 349.

**3-Deazauracil**

This pyrimidine analogue (FW = 111.10 g/mol), also known as 2,4-dihydroxypyridine and 2,4-pyridinediol, inhibits dihydrouracil dehydrogenase. See also *3-Deazauridine 5' Triphosphate* **Target(s):** dihydrouracil dehydrogenase (1); 2,5-dihydroxypyridine 5,6-dioxygenase (2); orotate phosphoribosyltransferase (3). **1.** Naguib, el Kouni & Cha (1989) *Biochem. Pharmacol.* **38**, 1471. **2.** Cain, Houghton & Wright (1974) *Biochem. J.* **140**, 293. **3.** Javaid, el Kouni & Iltzsch (1999) *Biochem. Pharmacol.* **58**, 1457.

**3-Deazauridine 5'-Triphosphate**

This nucleotide (FW<sub>free-acid</sub> = 470.13 g/mol), often abbreviated 3-deazaUTP, inhibits bovine calf liver CTP synthetase. The prodrug is 3-deazauridine (*i.e.*, 2,4-dihydroxypyridine riboside). **1.** Weinfeld, Savage & McPartland (1978) *Meth. Enzymol.* **51**, 84. **2.** McPartland, Wang, Bloch & Weinfeld (1974) *Cancer Res.* **34**, 3107.

**Debio-1347, See CH5183284****S-(2,3-Decadienoyl)-N-acetylcysteamine**

This acylated acyl-carrier protein analogue (FW = 269.41 g/mol), also known as *N*-acetylcysteamine 2,3-decadienoate thioester, inhibits 3-hydroxydecanyl-[acyl-carrier protein] dehydratase ( $IC_{50} = 53$  nM) of the fatty acid synthase complex. It forms nonenzymatically from *S*-(3-decynoyl)-*N*-acetylcysteamine. **1.** Bloch (1971) *The Enzymes*, 3rd ed., **5**, 441. **2.** Morisaki & Bloch (1972) *Biochemistry* **11**, 309.

**Decamethonium Bromide**

This skeletal muscle relaxant (FW = 418.30 g/mol), also known as *N,N,N,N',N',N'*-hexamethyl-1,10 decane-diaminium dibromide and syncurine, is a nicotinic acetylcholine receptor partial agonist and neuromuscular blocking agent. Decamethonium halide salts are readily soluble in water; however, unlike the slowly hydrolyzable analogue succinylcholine dibromide, decamethonium halide solutions are stable. **Target(s):** acetylcholinesterase (1-10); acid phosphatase (11); aryl-acylamidase (10); butyrylcholinesterase (12). **1.** Desire, Blanchet, Defnod & Arnaud (1975) *Biochimie* **57**, 1359. **2.** Agbaji, Gerassimidis & Hider (1984) *Comp. **Decanoyl-CoA**

This short-chain fatty acyl Coenzyme A thioester (FW = 921.79g/mol), a common intermediate in the  $\beta$ -oxidation of fatty acids, inhibits prolyl endopeptidase acetyl-CoA C-acyltransferase (1); aralkyl-amine *N*-acetyltransferase (2); butyrate:acetoacetate CoA-transferase (3); glucose-6-phosphatase (4); glycylpeptide *N* tetradecanoyltransferase, or protein *N*-myristoyltransferase (5); 3-hydroxy-3-methylglutaryl-CoA synthase (6); (*S*)-methylmalonyl-CoA hydrolase (7); prolyl endopeptidase,  $K_i = 9$   $\mu$ M (8); [pyruvate dehydrogenase (acetyl-transferring)] kinase (9); and stearoyl-CoA 9-desaturase (10-12). **1.** Olowe & Schulz (1980) *Eur. **Decatransin**

This novel hydrophobic decadepsipeptide (MW = 1184.62 g/mol; with non-proteinogenic pipecolate and homoleucine residues at positions 2, 6, 9, and 3, 4, 7, respectively, indicating its likely synthesis by a non-ribosomal peptide synthetase) from the saprophyte fungus *Chaetosphaeria tulasneorum* inhibits co- and post-translational translocation across the Sec61/SecYEG translocon. Its name alludes to the cotransins, a group of heptadepsipeptide compounds without detectable molecular similarity that were previously found to be mammalian translocon inhibitors. **1.** Junne, Wong, Studer, *et al.* (2015) *J. Cell Sci.* **128**, 1217.

**Decernotinib**

This potent and selective JAK inhibitor (FW = 392.38 g/mol; CAS 944842-54-0; Solubility: 200 mM in DMSO, <1 mM H<sub>2</sub>O), also code-named VX-509 and systematically named 2-methyl-2-[[2-(1*H*-pyrrolo[2,3-*b*]pyridin-3-yl)-4-pyrimidinyl]amino]-*N*-(2,2,2-trifluoroethyl)-(2*R*)-butanamide, targets Janus Kinase isoform-3, or JAK3 ( $K_i$  = 2.5 nM), showing >4x selectivity over JAK1, JAK2, and the nonreceptor tyrosine-protein kinase TYK2, respectively (1,2). JAK3 is of particular interest due to its importance in immune function and its expression, which is largely confined to lymphocytes, thus limiting the potential impact of JAK3 inhibition on nonimmune physiology. VX-509 treatment resulted in dose-dependent reduction in ankle swelling and paw weight and improved paw histopathology scores in the rat collagen-induced arthritis model (2). In a mouse model of oxazolone-induced delayed-type hypersensitivity, VX-509 reduced the T-cell-mediated inflammatory response in skin. These findings demonstrate that VX-509 is a selective and potent inhibitor of JAK3 *in vitro* and modulates proinflammatory response in models of immune-mediated diseases, such as collagen-induced arthritis and delayed-type hypersensitivity (2). 1. Farmer, Ledebor, Hoock, *et al.* (2015) *J. Med. Chem.* **58**, 7195. 2. Mahajan, Hogan, Shlyakhter, *et al.* (2015) *J. Pharmacol. Exp. Ther.* **353**, 405.

### Decitabine

This DNMT-inhibiting cytosine nucleoside analogue and hypomethylating agent (FW = 228.21 g/mol; CAS 2353-33-5; Solubility = 45 mg/mL DMSO, 10 mg/mL H<sub>2</sub>O; *Symbol* = 5aza-CdR), also known by its code name NSC127716 its systematically as 4-amino-1-((2*R*,4*S*,5*R*)-4-hydroxy-5-(hydroxymethyl)-tetrahydrofuran-2-yl)-1,3,5-triazin-2(1*H*)-one, targets KG1a ( $IC_{50}$  = 4.3 nM) and HL-60 ( $IC_{50}$  = 0.43 μM), two DNA methyltransferases (DNMTs). DNA methylation is an epigenetic mechanism for establishing long-term gene silencing during development and cell commitment. Aberrant DNA methylation is found at gene promoters in many cancers, often attended by silencing of tumor suppressor genes. Decitabine is metabolically phosphorylated, whereupon it is incorporated into DNA. Decitabine targets DNA-linked DNMTs and unbound DNMT1 for proteasomal degradation, leading to DNA demethylation. DNMT inhibitors show no interference with cell-cycle progression whereas cytarabine treatment results in S-phase arrest. At high doses, the DNA is not able to recover and cell death occurs. At lower doses, the formed adducts are degraded by the proteasome, after which the DNA is restored. DNA synthesis is then resumed in the absence of DNMT-1. As a consequence the aberrant DNA methylation pattern can no longer be reproduced toward the daughter strands. In this way, a low dose of decitabine is able to induce re-expression of previously silenced genes. Reactivation of cell cycle-regulating genes that were initially silenced due to hypermethylation may induce cell differentiation, reduce proliferation, and/or increase apoptosis of the daughter cells. Upon removal of decitabine, tumor suppressor genes (TSGs) are resiled, albeit at varying rates. 5-aza-CdR exhibits high antineoplastic activity against anaplastic large cell lymphoma (ALCL), a rare CD30 positive non-Hodgkin lymphoma of T-cell origin (2). 1. Shaker, Bernstein, Momparler & Momparler (2003) *Leuk. Res.* **27**, 437. 2. Hassler, Klisaroska, Kollmann, *et al.* (2012) *Biochimie* **94**, 2297.

### Decoyinine

This *Streptomyces hygroscopicus*-derived nucleoside antibiotic (FW = 279.26 g/mol; CAS 2004-04-8; Solubility: 20 mg/mL warm DMSO; 1 mg/mL water), also known as U-7984, angustmycin A, decoyinin, and 5,6-

didehydropseudo-furanosyladenine, inhibits GMP synthetase, thereby depleting GTP stores in treated organisms and inhibiting GTP-dependent processes (1-7). The rate of wall synthesis in *Bacillus subtilis* is decreased by 50% within 5 min after decoyinine addition (1) this decrease was prevented by the presence of guanosine. By comparing the effects of other inhibitors of cell wall synthesis, it became clear that decoyinine also inhibits the final portion of the cell wall biosynthetic pathway (*i.e.*, after the steps inhibited by bacitracin or vancomycin) (6) such effects are reversed upon addition of sufficient guanosine. Decoyinine is highly effective against mycobacteria. **Target(s)**: GMP synthetase (1-5); bacterial cell wall formation (6); deoxycytidine kinase,  $K_i$  = 9.3 mM (7); GMP synthetase (2-7); 5'-methylthioadenosine nucleosidase (8,9); NAD<sup>+</sup> synthetase (10,11); ribose-phosphate diphosphokinase (4); depletion of guanine nucleotides, resulting in sporulation of *Bacillus subtilis* (12); ppGpp formation in *Bacillus subtilis* (13); melanoma cell invasion *in vitro* and tumorigenicity in immunocompromised mice (14). 1. ### S-Decylglutathione

This glutathione conjugate (FW = 434.58 g/mol) is a potent inhibitor of both the peroxidase and transferase activities associated with glutathione S-transferase. It is also a strong inhibitor of glyoxalase I. **Target(s)**: glutathione S-transferase (1,2); lactoylglutathione lyase, or glyoxalase I (3); xenobiotic-transporting ATPase, multidrug-resistance protein (4,5). 1. Chen & Juchau (1998) *Biochem. J.* **336**, 223. 2. Burgess, Yang, Chang, *et al.* (1987) *Biochem. Biophys. Res. Commun.* **142**, 441. 3. Regoli, Saccucci & Principato (1996) *Comp. Biochem. ### Defensins

These anti-infective oligopeptides (MW = 3934.57 g/mol; Human Neutrophil Peptide-1, or Defensin HNP-1 Sequence: ACYCRIPAC IAGERRYGTCTIYQGRLWAFCC, with disulfides at Cys2-S-S-Cys30, Cys4-S-S-Cys19, and Cys9-S-S-Cys29), permeabilize membranes by first binding electrostatically and then forming multimeric pores. The defensins are cationic and typically contain 29-36 aminoacyl residues joined together by three disulfide bonds, and have a predominantly β-sheet structure (1,2). There are three types of defensins in primates. α-Defensins are found in neutrophils and Paneth cells of the small intestine while β-defensins protect the skin and the mucous membranes of the respiratory, genitourinary, and gastrointestinal tracts. θ-Defensins, expressed only in Old World monkeys, lesser apes, and orangutans, are lectins with broad-spectrum antiviral efficacy. Human neutrophil peptide-2 (Defensin HNP-2) but lacks the N-terminal alanyl residue. Except for an N-terminal aspartyl residue instead of alanyl, Human Defensin HNP-3 is identical to HNP-1, whereas HNP-4 has the 33-residue sequence VCSCRLVFCRRTELTVGNCLIGGVSTFYCC RV. Larger defensin oligopeptides are found in plants and insects. Human β-Defensin-1 has the sequence DHYNCVSSGGQCLYSACPIFTKIQTGTC YRGKAKCKC, joined by disulfide bonds at Cys5-S-S-Cys34, Cys12-S-S-Cys27, and Cys17-S-S-Cys35. 1. White, Wimley & Selsted (1995) *Curr. Opin. Struct. Biol.* **5**, 521. 2. Ganz & Lehrer (1995) *Pharmacol. Ther.* **66**, 191.

## Deferiprone

This bacterial siderophore and orally active iron-binding drug (FW = 139.15 g/mol; CAS 30652-11-0; pK<sub>a</sub> values, 3.3 and 9.7; Forms red-colored complexes with iron; Abbreviation: DMHP), also known by its trade name Ferriprox<sup>®</sup> and its IUPAC name 3-hydroxy-1,2-dimethylpyridin-4(1H)-one, isolated from *Streptomyces pilosus*, is used in the treatment of thalassemia major, an autosomal recessive blood disorder anemia that releases iron. Deferiprone reduces complicating effects of iron overload. Biochemical studies showed that deferiprone is more efficient than desferrioxamine at releasing iron from ferritin, but less so in the removal of iron from the other two polynuclear iron forms (*i.e.*, hemosiderin and FeCl<sub>3</sub> precipitate), when each was present at the same iron content (1). When delivered to rabbits at 10 and 50 mg/kg/day, deferiprone also significantly decreases levels of Aβ40 and Aβ42 as well as BACE1, the enzyme that initiates cleavage of amyloid-β protein precursor to yield Aβ (2). (See also *Desferoxamine*)

**Target(s):** acid phosphatase (3); catechol *O*-methyltransferase (4); cyclooxygenase (5); deoxyhypusine monooxygenase (6,7); HIV-1 replication (8); lipoxygenase (5); 5-lipoxygenase (9,10); procollagen-proline 4-dioxygenase (7); purple acid phosphatase (3); ribonucleotide reductase (9); tryptophan 5-monooxygenase (4); tyrosine 3-monooxygenase (4). 1. ## Dehydroepiandrosterone

This steroid (FW = 288.43 g/mol; CAS 53-43-0), also known as prasterone, *trans*-dehydroandrosterone, dehydroisoandrosterone, 5-androsten-3β-hydroxy-17-one, and 3β-hydroxyandrost-5-en-17-one and abbreviated DHEA and DHAS, is produced by the adrenal gland and is, with its sulfate conjugate (prasterone 3-sulfate), the most abundant steroid hormone in the circulation. Dehydro-epiandrosterone is an intermediate in androgen and estrogen biosynthesis and is the immediate precursor to androstenedione.

**Target(s):** androst-4-ene-3,17-dione monooxygenase (1); cortisol sulfotransferase (2-4); estrone sulfotransferase (5); F<sub>1</sub>F<sub>0</sub> ATPase (6); glucose-6-phosphate dehydrogenase (7-12); glutamate dehydrogenase (11); 27-hydroxycholesterol 7α-monooxygenase, also a substrate (13,14); 17β-hydroxysteroid dehydrogenase (15); 21-hydroxysteroid dehydrogenase, NAD<sup>+</sup>-requiring (16); steroid 21-monooxygenase (17); steroid sulfotransferase, also alternative substrate for the enzyme from many

sources (1,18,19); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, or ACAT (20); steryl sulfatase (21,22). 1. Itagaki (1986) *J. Biochem.* **99**, 825. 2. ## Dehydroascorbate

This oxidized vitamin C metabolite and ROS-producing substance (FW = 174.11 g/mol; CAS 490-83-5; Symbol: DHA; Soluble to 10 mM in water, with gentle warming, and to 100 mM in DMSO), also named *L-threo*-2,3-hexodiolulonic acid γ-lactone, is a redox-active compound having both beneficial and potentially harmful metabolic consequences. DHA undergoes nonenzymatic hydration to the following species:

These hydrated forms may alter the distribution and kinetics of DHA. Although ascorbate itself cannot penetrate the blood-brain barrier, DHA enters cells possessing the GLUT1 glucose transporter, which is widely distributed in fetal tissues, with highest levels in erythrocytes and endothelial cells of adults. DHA thereby accumulates in the cytoplasm, endoplasmic reticulum, and mitochondria. (Note: Dehydroascorbic acid is often added to cell and tissue culture medium to promote the uptake of vitamin C in cell types that do not contain ascorbic acid transporters.) DHA also induces oxidative stress, as it is reduced to vitamin C, an action that can deplete intracellular stores of reduced glutathione and generate reactive oxygen species (ROS). The latter can inactivate glyceraldehyde 3-phosphate dehydrogenase (GAPDH) and induce death of glycolytically active KRAS or BRAF mutant cells, but not KRAS and BRAF wild-type cells. High-dose vitamin C impairs tumor growth in Apc/Kras(G12D) mutant mice. Vitamin C antagonizes the cytotoxic effects of antineoplastic drugs in human hematopoietic cancers by preserving mitochondrial membrane potential (2). Indeed, vitamin C antagonizes fas ligand-mediated mitochondrial membrane depolarization (3). Previous studies have also shown that cisplatin, doxorubicin, etoposide and several other agents result in mitochondrial membrane depolarization (4, 5). See *Ascorbate* 1. ### 3,4-Dehydro-L-proline

This proline derivative (FW = 113.12 g/mol; CAS 4043-88-3), also known as (*S*)-3-pyrroline-2-carboxylic acid and 3,4-didehydro-L-proline, inhibits prolyl-tRNA synthetase. It also blocks cell wall assembly and cell division in tobacco protoplasts. **See also 3,4-Dehydro-DL-proline** **Target(s):**  $\gamma$ -glutamyl kinase, or glutamate 5-kinase (1); peptidyl-prolyl hydroxylase (2); procollagen-proline monooxygenase (3,4); proline oxidase (5); prolyl-tRNA synthetase (6-8). **1.** Krishna & Leisinger (1979) *Biochem. ### Dehydrosinefungin

This *S*-adenosylhomocysteine analogue and anti-trypanosomal antibiotic (FW = 379.38 g/mol), also known as A9415C, inhibits numerous SAM-dependent methyltransferases. **Target(s):** catechol *O*-methyl-transferase (1); cyclopropane-fatty-acyl-phospholipid synthase (2,3); dimethyl macrocin *O*-methyltransferase (4); histamine methyltransferase (1); histone arginine *N*-methyltransferase (5); histone-lysine *N*-methyltransferase (6,7); macrocin *O*-methyltransferase (8); mRNA-(guanine-*N*<sup>7</sup>)-methyltransferase (7,9,10); mRNA (nucleoside-2'-*O*-) methyltransferase (7,9,10); norepinephrine *N*-methyltransferase (1,7); phenylethanolamine *N*-methyltransferase (1); protein-arginine methyltransferase (6,7); protein-glutamate *O*-methyltransferase (7,11,13,14); protein-*S*-isoprenylcysteine *O*-methyltransferase (7); spermidine synthase (12); spermine synthase (12). **1.** Fuller & Nagarajan (1978) *Biochem. ### Dehydroxymethylepoxyquinomicin

This first-in-class, selective NF- $\kappa$ B inhibitor (FW = 261.06 g/mol, CAS 287194-40-5), also known as DHMEQ (–)-DHMEQ, (–)-DHMEQ, and 2-hydroxy-*N*-((1*S*,2*S*,6*S*)-2-hydroxy-5-oxo-7-oxabicyclo[4.1.0]hept-3-en-3-yl)benzamide, inhibits p65 and p50 NF- $\kappa$ B subunit translocation into the nucleus, reduces DNA-binding activity of the RelA/p65, suppresses NF- $\kappa$ B-dependent expression of the Inhibitor of Apoptosis (IAP)-family proteins (*e.g.*, cIAP-1, cIAP-2, and XIAP), and inhibits *de novo* synthesis of inhibitor of NF- $\kappa$ B  $\alpha$  (1). The transcriptional factor NF- $\kappa$ B and the Rel/NF-

$\kappa$ B signaling pathway regulate cellular proliferation, apoptotic response, and oncogenesis, with elevation of basal NF- $\kappa$ B levels playing a critical role in carcinogenesis and making it an attractive target for molecular therapy. Over the 0.1–5  $\mu$ g/mL range, DHMEQ induces a caspase-mediated apoptotic response that is blocked by the c-Jun N-terminal kinase inhibitor SP600125, but not by inhibitors of mitogen-activated protein/extracellular signal-regulated kinase kinase or p38 (1). While normal human thyrocytes resist DHMEQ-induced apoptosis, higher doses of DHMEQ result in necrotic-like killing of both normal and malignant thyrocytes. In nude mice, DHMEQ inhibits tumor growth without observable side effects, showing greater numbers of apoptotic cells in histologic sections (1). DHMEQ also synergizes with chemotherapy agents in classical Hodgkin lymphoma (2). **1.** Starenki, Namba, Saenko, *et al.* (2004) *Clin. Cancer Res.* **10**, 6821. **2.** Celegato, Borghese, Umezawa, *et al.* (2014) *Cancer Lett.* **349**, 26.

### DEL 22379

This ERK inhibitor (FW = 444.53 g/mol; CAS 181223-80-3; Solubility: 50 mM in DMSO; Store at –20°C), also named *N*-[2,3-dihydro-3-[(5-methoxy-1*H*-indol-3-yl)methylene]-2-oxo-1*H*-indol-5-yl]-1-piperidine propanamide, targets the dimerization of Extracellular signal-Regulated Kinase, or Mitogen-Activated Protein Kinase (IC<sub>50</sub> ~ 0.5  $\mu$ M, without effecting phosphorylation or its intrinsic protein kinase activity. Del-22379 suppresses the growth of tumor cells expressing RAS-ERK oncogenes *in vitro*, inducing apoptosis and preventing tumor progression *in vivo*. In nearly 50% of human malignancies, unregulated RAS-ERK signaling occurs, making ERK a target for chemotherapeutic intervention. Upon activation, ERK must dimerize for ERK's extranuclear (but not for nuclear) signaling cascade to operate. By blocking sub-localization-specific signalling, rather than all ERK-mediated signalling, Del-22379 impedes oncogenic RAS-ERK signaling. Moreover, by targeting regulatory protein-protein interactions, rather than catalytic activities, Del22379 is a highly effective antitumor agent. **1.** Herrero, Pinto, Colón-Bolea *et al.* (2015) *Cancer Cell* **28**, 170. **2.** Ryan, Der, Wang-Gillam & Cox (2015) *Trends Cancer* **1**, 183.

### Delafloxacin

This fluoroquinolone-class antibiotic (FW = 440.76 g/mol; CAS 189279-58-1), also named RX-3341 and 1-(6-amino-3,5-difluoro-2-pyridyl)-8-chloro-6-fluoro-7-(3-hydroxyazetidin-1-yl)-4-oxo-quinoline-3-carboxylic acid, is a broad-spectrum systemic antibacterial agent that targets Type II DNA topoisomerases (gyrases), which are required for bacterial replication and transcription. (For the prototypical member of this antibiotic class, **See Ciprofloxacin**) Delafloxacin has a lower MIC<sub>90</sub> than other quinolones against Gram-positive bacteria, such as methicillin-resistant *Staphylococcus aureus* (MRSA). Unlike other fluoroquinolones, which are inherently zwitterionic, delafloxacin is anionic, resulting in its 10x greater accumulation in both bacteria and cells at acidic pH. This property confers an advantage in delafloxacin's eradication of MRSA in acidic environments. **1.** Lemaire, Tulkens & Van Bambeke (2011) *Antimicrob. Agents Chemother.* **55**, 649.

### Delamanid

This multi-drug-resistant TB drug (FW = 534.49 g/mol; CAS 681492-22-8), codenamed OPC-67683, blocks the synthesis of mycolic acids in *Mycobacterium tuberculosis*, thereby destabilising its cell wall (1). Delamanid is frequently used in combination with standard treatments, such as ethambutol, isoniazid, pyrazinamide, rifampicin, aminoglycoside antibiotics, and quinolones. free of mutagenicity and to possess highly potent activity against TB, including MDR-TB, as shown by its exceptionally low minimum inhibitory concentration (MIC) range of 6-24 ng/mL *in vitro* and is highly effective therapeutic activity at low doses *in vivo* (1). In a randomized, placebo-controlled, multinational clinical trial, 481 patients (nearly all of whom were negative for the human immunodeficiency virus) with pulmonary multidrug-resistant tuberculosis were assigned to receive delamanid (dose of 100 mg twice daily in 161 patients or 200 mg twice daily in 160 patients), or placebo (160 patients) for 2 months. The primary efficacy end-point was the proportion of patients with sputum-culture conversion in liquid broth medium at 2 months. Delamanid is associated with an increase in sputum-culture conversion at two months among patients with multidrug-resistant tuberculosis, suggesting that delamanid may enhance treatment options for multidrug-resistant tuberculosis (2). The European Medicines Agency (EMA) has conditionally issued marketing authorization for adults with multidrug-resistant pulmonary tuberculosis. 1. Matsumoto, Hashizume, Tomishige, *et al.* (2006) *PLoS Med.* **3**, e466. 2. Gler, Skripconoka, Sanchez-Garavito, *et al.* (2012) *New Engl. J. Med.* **366**, 2151.

### Delanzomib

This orally bioavailable proteasome inhibitor (FW = 413.28 g/mol; CAS 847499-27-8; Solubility: 83 mg/mL DMSO), code named CEP-18770 and known as (R)-1-((2S,3R)-3-hydroxy-2-(2-phenylpicolinamido)butan-3-amido)-3-methylbutan-2-ylboronic acid, is a boronate peptidomimetic that targets the chymotrypsin-like activity at the  $\beta 5$  proteolytic site of the 20S proteasome ( $IC_{50} = 3.8$  nM), with only marginal inhibition of the tryptic and peptidylglutamyl activities of the proteasome. Delanzomib inhibits the chymotrypsin-like activity of the proteasome that down-modulates the nuclear factor- $\kappa B$  (NF- $\kappa B$ ) activity and the expression of several NF- $\kappa B$  downstream effectors. Delanzomib induces apoptotic cell death in multiple myeloma (MM) cell lines and in primary purified CD138-positive explant cultures from untreated and bortezomib-treated MM patients. *In vitro*, it has a strong antiangiogenic activity and potently represses RANKL-induced osteoclastogenesis (1). Importantly, delanzomib exhibits a favorable cytotoxicity profile toward normal human epithelial cells, bone marrow progenitors, and bone marrow-derived stromal cells. Intravenous and oral administration resulted in a more sustained pharmacodynamic inhibition of proteasome activity in tumors relative to normal tissues, complete tumor regression of MM xenografts and improved overall median survival in a systemic model of human MM (1). When combined with melphalan or bortezomib, delanzomib induces synergistic inhibition of MM cell viability *in vitro* (2). In multiple myeloma xenograft models, the addition of delanzomib (IV route) to melphalan completely prevented the growth of both melphalan-sensitive and melphalan-resistant tumors. Combination of Delanzomib (IV) and bortezomib induced complete regression of bortezomib-sensitive tumors and markedly delayed progression of bortezomib-resistant tumors compared to treatment with either agent alone

(2). Single agent delanzomib (PO) also showed marked anti-MM effects in these xenograft models (2). 1. Piva, Ruggeri, Williams *et al.* (2008) *Blood* **111**, 2765. 2. Sanchez, Li, Steinberg, *et al.* (2010) *Brit. J. Haematol.* **148**, 569.

### Delavirdine

This orally active antiviral (FW = 456.57 g/mol; CAS 147221-93-0; Soluble to 75 mM in DMSO), also named 1-[3-[(1-methylethyl)amino]-2-pyridinyl]-4-[[5-[(methylsulfonyl)amino]-1H-indol-2-yl]carbonyl]piperazine, also known as BHAP and U-90152, inhibits HIV-1 reverse transcriptase (RNA-dependent DNA polymerase), showing selectivity over other cellular polymerases: HIV-1 reverse transcriptase ( $IC_{50} = 0.26$   $\mu M$ ), DNA polymerase  $\alpha$  ( $IC_{50} = 440$   $\mu M$ ) and DNA polymerase  $\delta$  ( $IC_{50} > 550$   $\mu M$ ). Delavirdine prevents HIV-1 spread *in vivo* and blocks viral replication in peripheral blood lymphocytes. **Target(s):** CYP3A4 (1-3); CYP2C9 (3); CYP2C19 (3); CYP2D6 (3); reverse transcriptase (*e.g.*, HIV-1, HIV-2, and SIV) (4-10); RNA-directed DNA polymerase (4-10). 1. ### Deltamethrin

This synthetic insecticide (FW = 505.21 g/mol), also known as (S)- $\alpha$ -cyano-3-phenoxybenzyl (1R)-cis-3-(2,2-dibromo-vinyl)-2,2-dimethylcyclopropane carboxylate, is a potent inhibitor of protein phosphatase 2B (calcineurin;  $IC_{50} = 0.1$  nM). Deltamethrin also keeps sodium channels open for unusually long periods of time, causing a prolonged sodium current, which, in turn, leads to hyperexcitation of the nervous system. **Target(s):** adenylate cyclase (1); ATPase (2); chloride channel (1), voltage-dependent (3); glutathione S-transferase (4-6); protein phosphatase 2B, or calcineurin (7, however, see refs. 8 and 9). 1. **Delta-Sleep-Inducing Peptide, See L-Tryptophanyl-L-alanylglycylglycyl-L-aspartyl-L-alanyl-L-serylglycyl-L-glutamate**

### $\alpha$ -Dendrotoxins

These oligopeptides from the venom of the Eastern green mamba (*Dendroaspis angusticeps*) block Kv1.1, Kv1.2, and Kv1.6 channels, with  $IC_{50}$  values in the nanomolar range. They induce repetitive firing in neurons, thereby facilitating transmitter release. Although homologous to Kunitz-

type serine protease inhibitors, the denrotoxins have little or no anti-protease activity. One example is  $\alpha$ -Dendrotoxin-1 (MW = 7072 g/mol; Sequence: ZPRRKLCLHRNPGRCYDKIPAFYYNQKKKQCERFDWSG CCGNSNRFKTIEECRRTICG), where Z designates a 5-oxopropyl residue, and Cys<sub>7</sub>-S-S-Cys<sub>57</sub>, Cys<sub>16</sub>-S-S-Cys<sub>40</sub>, and Cys<sub>32</sub>-S-S-Cys<sub>53</sub> are disulfide bonds.  $\alpha$ -Dendrotoxin-2 is identical, except for an aspartyl residue in place of an asparagine at Residue-12. (See also *Mast Cell Degranulating Peptide*) 1. Gasparini, Danse, Lecoq, *et al.* (1998) *J. Biol. Chem.* **273**, 25393. 2. Harvey (1997) *Gen. Pharmacol.* **28**, 7. 3. #### Dendrotoxin-1, Similar in mode of action to $\alpha$ -Dendrotoxin

#### Denibulin

This vascular-disrupting agent, or VDA (FW<sub>HCl-salt</sub> = 421.90 g/mol; FW<sub>free-base</sub> = 385.44 g/mol; CAS 284019-34-7; 779356-64-8, also named MN-029 and methyl-[5-[[4-[[[(2S)-2-aminopropanoyl]amino]phenyl] sulfanyl]-1H-benzimidazol-2-yl]arbamate monohydrochloride, reversibly binds to the colchicine binding site on tubulin and inhibits microtubule assembly, resulting in disruption of the cytoskeleton of tumor vascular endothelial cells. Preclinical studies demonstrated MN-029 could evoke rapid vascular shutdown in solid tumors, dose-dependent secondary tumor cell killing, and effective enhancement of the antitumor effects of radiation and cisplatin chemotherapy. 1. #### Denosumab

This intravenous drug (MW = 144.7 kDa; CAS 615258-40-7), also known by its code name AMG 162 and trade names Xgeva<sup>®</sup> and Prolia<sup>®</sup>, fully humanized monoclonal antibody that binds to and inhibits the action of RANKL (or Receptor Activator of NF $\kappa$ B Ligand), a member of the tumor necrosis factor (TNF) superfamily and a major mediator of bone loss via activation of osteoclastogenesis. RANKL overproduction occurs in degenerative bone diseases such as rheumatoid and psoriatic arthritis (1). Denosumab can be used to treat osteoporosis, treatment-induced bone loss, bone metastases, rheumatoid arthritis, and multiple myeloma. It is specifically indicated for the treatment of adults and skeletally mature adolescents with giant cell tumors of the bone that are unresectable or likely would be expected to result in severe morbidity upon surgical resection (2). 1. #### 2'-Deoxyadenosine

This purine nucleoside (FW = 251.25 g/mol; CAS 958-09-8;  $\lambda_{\max}$  at 260 nm (pH 7); Molar Absorptivity ( $\epsilon_M$ ) = 15,200 M<sup>-1</sup>cm<sup>-1</sup>; Symbol: dA is typically obtained from the hydrolysis of DNA. 2'-dA is phosphorylated to dATP, and, when present in excess, the latter inhibits ribonucleotide reductase and suppresses cell proliferation. **Target(s):** acid phosphatase (1); adenosine kinase, as a substrate inhibitor (2-5); adenosine nucleosidase (6,7); adenosylhomocysteinase, or S-adenosyl-homocysteinase (8-18); adenylate cyclase (19-21); cob(I)yrinic acid a,c-diamide adenosyltransferase, weakly

inhibited (22); cytidine deaminase (23-26); deoxycytidine kinase (27); deoxyguanosine kinase, also alternative substrate (28-30); dihydroorotase (31); glycine N-methyltransferase, weakly inhibited (32); GMP synthetase (33); histone-arginine N-methyltransferase (34); NADase (or NAD<sup>+</sup> glycohydrolase) (35); 5'-nucleotidase (36,37); purine nucleosidase (38); ribonuclease T2 (39); ribonuclease U2 (40); thymidine phosphorylase (41). 1. ### 2'-Deoxyadenosine 3',5'-Cyclic Monophosphate

This unnatural cyclic nucleotide (FW = 251.25 g/mol;  $\lambda_{\max}$  at 260 nm (pH 7); Molar Absorptivity ( $\epsilon_M$ ) = 15200 M<sup>-1</sup>cm<sup>-1</sup>) is more active than adenosine 3',5'-cyclic monophosphate as a substrate for mammalian cAMP phosphodiesterase. It is also an effective activator of the glycogen phosphorylase cascade (1). **Target(s):** poly(ADP-ribose) glycohydrolase (2) 1. Braun, Hechter & Baer (1969) *Proc. Soc. Exp. Biol. Med.* **132**, 233. 2. Tavassoli, Tavassoli & Shall (1983) *Eur. J. Biochem.* **135**, 449.

### 2'-Deoxyadenosine 5'-Diphosphate

This deoxynucleotide (FW = 411.20 g/mol;  $\lambda_{\max}$  = 259 nm; Molar Absorptivity ( $\epsilon_M$ ) = 15400 M<sup>-1</sup>cm<sup>-1</sup>; Abbreviation: dADP) is an intermediate in the dATP biosynthesis. In eukaryotes, ADP is converted to dADP by ribonucleotide reductase (RNR). In prokaryotes, dADP is formed from dATP, the latter the product of bacterial RNR action on ATP. **Target(s):** amidophosphoribosyltransferase (1); *Aspergillus* nuclease S (12); cytidylate kinase (3); deoxya kinase (4,5); deoxycytidine kinase6; deoxyguanosine kinase (7); DNA directed DNA polymerase (8); dTMP kinase, or thymidylate kinase (9-12); gluconokinase, weakly inhibited (13); glucose-1-phosphate cytidyltransferase, weakly inhibited (14); 5'-nucleotidase (15); polynucleotide phosphorylase, or polyribonucleotide nucleotidyltransferase (16-20); ribose phosphate diphosphokinase, or phosphoribosyl-pyrophosphate synthetase (21-23). 1. ### 2'-Deoxyadenosine 5'-Triphosphate (or dATP)

This key nucleotide (FW<sub>free-acid</sub> = 491.18 g/mol;  $\lambda_{\max}$  at 259 nm at pH 7 ( $\epsilon_M$  = 15400 M<sup>-1</sup>cm<sup>-1</sup>) and 258 nm at pH 2 ( $\epsilon_M$  = 14800 M<sup>-1</sup>cm<sup>-1</sup>) is one of four DNA polymerases substrates. **Target(s):** adenine phosphoribosyltransferase (1); amidophosphoribosyl transferase (2); AMP deaminase (3); *Aspergillus* nuclease S<sub>1</sub> (4-6); ATP:citrate lyase (or ATP:citrate synthase) (7,8); *Bacillus subtilis* ribonuclease (9-11); CDP reductase (12); dCTP

deaminase (13); deoxyadenosine kinase (14-19); deoxycytidine kinase (20-22); deoxyguanosine kinase (23-25); DNA helicase (26); dTMP kinase, *or* thymidylate kinase, weakly inhibited (27); exopolyphosphatase (28); glucose-1-phosphate cytidyl-transferase (29); glucuronokinase (30); guanylate cyclase (31,32); 3-hydroxyanthranilate oxidase (68); [hydroxymethylglutaryl-CoA reductase (NADPH)] kinase (33); leucyl-tRNA synthetase (34); lysyl-tRNA synthetase (35); nucleoside-triphosphatase, alternative substrate (26); nucleotidases (28); 3'-nucleotidase (28); 5'-nucleotidase (28,36); 2',5'-oligoadenylate synthetase (37); 1-phosphatidylinositol 4-kinase (38); polynucleotide adenyl-transferase (*or*, poly(A) polymerase) (39-43); polynucleotide 5'-hydroxyl-kinase (44,45); pyruvate, orthophosphate dikinase (46); ribonucleoside diphosphate reductase (12,47-50,56-67); ribose-phosphate diphosphokinase (*or* phosphoribosyl pyrophosphate synthetase) (51); RNA-directed RNA polymerase (52); threonyl-tRNA synthetase (35); tRNA cytidyltransferase (53); tRNA nucleotidyltransferase (53); tryptophanyl-tRNA synthetase (54); tyrosyl-tRNA synthetase (55). 1. ### 2'-Deoxy-S-adenosyl-L-homocysteine

This product analogue ( $FW_{\text{zwitterion}} = 368.42$  g/mol;  $\lambda_{\text{max}}$  at 260 nm (pH 7);  $\epsilon_M$  of  $15200$   $M^{-1}cm^{-1}$ ) weakly inhibits mRNA (guanine- $N^7$ -methyltransferase, mRNA (nucleoside 2'- $O$ -)-methyltransferase, and DNA (cytosine-5)-methyltransferase. **Target(s)**: DNA (cytosine-5)-methyltransferase (1); *Hae*III DNA methyltransferase,  $K_i = 69$   $\mu M$  (1); *Hha*I DNA methyltransferase,  $K_i = 44$   $\mu M$  (1); mRNA (guanine- $N^7$ -)-methyltransferase (2); mRNA (nucleoside 2'- $O$ -)-methyltransferase, weakly inhibited (2). 1. ### Deoxycholate (Deoxycholic Acid)

This fat-emulsifying secondary bile acid ( $FW_{\text{free-acid}} = 392.58$  g/mol; CAS 83-44-3; Symbol: DCA; Critical Micelle Concentration (CMC) = 2.4-4 mM, depending on other solutes present), also known as (3 $\alpha$ ,5 $\beta$ ,12 $\alpha$ ,20R)-3,12-dihydroxycholan-24-oic acid, is a mild detergent that is often employed in the isolation of membrane-associated proteins (1). Indeed, the proton-translocating ATP synthase of bovine heart mitochondria was first purified by extraction of submitochondrial particles with cholate, fractionation with ammonium sulfate, and sucrose gradient centrifugation in the presence of methanol, deoxycholate, and lysolecithin (2). Sodium deoxycholate is also used often to lyse cells. DCA (0.05-0.3 mmol/l) also inhibits colon cell proliferation by up to 92%, increasing the apoptosis rate by up to 4.5 times (3). DCA induces an increase in only G<sub>1</sub> fraction, with a concomitant drop in the S-phase fraction, when compared with the untreated cells. DCA increases intracellular reactive oxygen species, genomic DNA breakage, as well as activation of ERK1/2, caspase-3 and PARP. In warm-blooded animals, deoxycholic acid is used in the emulsification of fats for the absorption in the intestine. **Remodeling Submental Fat Deposits**: As many individuals age, fat accumulates beneath the chin in the submental fat pad, resulting in an unsightly "turkey gobbler" jawline. Significantly, the facial fat within the superficial subcutaneous layer is not one confluent layer, but is instead compartmentalized. Each border of these compartments is formed by fascial septae traveling from the deep fascia or periosteum and insert into the dermis. This anatomical feature commends the use of biochemical strategies for remodeling submental fat without the need for liposuction or surgical intervention. ATX-101 is a proprietary formulation (Tradename: Kybella<sup>®</sup>) of purified synthetic deoxycholic acid that, when injected appropriately, emulsifies and mobilizes submental fat, selectively destroying fat-storing cells (3). It is a FDA-approved agent for cosmetically recontouring the fat pad just below the chin, often with little effect on nearby tissues. 1. Philippot (1971) *Biochim. Biophys. Acta* **225**, 201. 2. ## 2'-Deoxycoformycin

This nucleoside (FW = 268.27 g/mol; CAS 53910-25-1;  $\lambda_{\max}$  = 282 nm (at pH 7), Molar Absorptivity ( $\epsilon_M$ ) = 8000 M<sup>-1</sup>cm<sup>-1</sup>), also known as pentostatin and covidarabine, from *Streptomyces antibioticus* is a tetrahedral transition-state analogue of a likely intermediate in the reaction catalyzed by adenosine deaminase ( $K_i$  = 0.22 nM). Its kinetic behavior is consistent with its classification as a slow-, tight-binding inhibitor ( $t_{1/2}$  = 25–30 hr). (See *Coformycin* for comments on likely mechanism of action) **Target(s)**: adenosine deaminase (1); adenosine deaminase (2-17); adenosine kinase (18,19) adenosylhomocysteinase (20); S-adenosylhomocysteine deaminase (21); AMP deaminase (5); DNA ligase (22). 1. ## 11-Deoxycorticosterone

This mineralocorticoid steroid (FW = 330.47 g/mol; CAS 64-85-7; M.P. = 141–142°C), also known as 4-pregnen-21-ol-3,20-dione, DOC, cortexone, Kendall's desoxy compound B, and Reichstein's compound Q, was first isolated from the adrenal cortex and is a steroid that is biosynthesized from progesterone. Although a potent mineralocorticoid, DOC is virtually devoid of glucocorticoid action. It also exhibits anticonvulsant properties in animals, where it can be converted to the neurosteroid 5 $\alpha$ ,3 $\alpha$ -tetrahydrodeoxycorticosterone. This steroid was first isolated in the laboratories of Kendall and Reichstein, who shared the 1950 Nobel Prize in Physiology or Medicine. **Target(s)**: aldehyde dehydrogenase (1); D-amino-acid oxidase (2); ascorbate oxidase (3); cortisol sulfotransferase (4,5); 21-hydroxysteroid dehydrogenase, NAD<sup>+</sup>-requiring (6-8); NADH dehydrogenase, ubiquinone-requiring, or NADH:cytochrome c reductase (9,10); steroid  $\Delta$ -isomerase (11); steroid sulfotransferase (12); sterol O-acyltransferase, or cholesterol O-acyltransferase; ACAT (13,14); tryptophan 2,3-dioxygenase (15). 1. ## 2'-Deoxycytidine 5'-Diphosphate (or, dCDP)

This ribonucleotide reductase substrate (FW<sub>free-acid</sub> = 389.19 g/mol; FW<sub>trisodium-salt</sub> = 453.12; CAS 151151-32-5;  $\lambda_{\max}$  = 271 nm (pH 7 and 12; with Molar Absorptivities ( $\epsilon_M$ ) = 9300 and 9000 M<sup>-1</sup>cm<sup>-1</sup>, respectively) and 280 nm at pH 2 ( $\epsilon_M$  = 13500 M<sup>-1</sup>cm<sup>-1</sup>) inhibits DNA polymerase. In eukaryotes, CDP is converted to dCDP by ribonucleotide reductase (RNR). In prokaryotes, dCDP is formed from dCTP, the latter the product of bacterial RNR action on ATP. **Target(s)**: adenylosuccinate synthetase, weakly inhibited (1); cytidylate kinase (2,3); dCTP diphosphatase, also acts as an alternative substrate (4); deoxyadenosine kinase (2,5,6); deoxycytidine kinase (2,7 11); deoxyguanosine kinase (12); DNA-directed DNA polymerase (13); dolichol kinase, alternative product inhibition (14); 5'-nucleotidase (15); polynucleotide 5'-hydroxyl-kinase (16); polynucleotide phosphorylase (17-19). 1. ## 2'-Deoxycytidine 5'-Triphosphate (or, dCTP)

This deoxynucleotide (FW<sub>free-acid</sub> = 467.16 g/mol; λ<sub>max</sub> = 271 nm (pH 7 and 12); with Molar Absorptivities (ε<sub>M</sub>) = 9300 and 9000 M<sup>-1</sup>cm<sup>-1</sup>, respectively) and 280 nm at pH 2 (ε<sub>M</sub> = 13500 M<sup>-1</sup>cm<sup>-1</sup>), is one of four substrates for DNA polymerases. **Target(s):** N-acetylneuraminase cytidylyl-transferase (1); amidophosphoribosyl-transferase (2); aspartate carbamoyltransferase (3,4); CDP-glycerol diphosphatase (5); CTP synthetase, weakly inhibited (6); cytidylate kinase (7,8); deoxyadenosine kinase (7,9-12); deoxycytidine kinase (7,13-28); deoxyguanosine kinase (29,30); deoxyxynucleoside kinase (31); dTMP kinase, or thymidylate kinase (32); dUTP diphosphatase (33); exopolyphosphatase (34); 3-hydroxyanthranilate oxidase (56); nucleotidases (34); 3'-nucleotidase (34); 5'-nucleotidase (34,35); phosphatidate cytidylyltransferase (36-38); phosphoribosyl-pyrophosphate synthetase, or ribose-5-phosphate pyrophosphokinase (39); polynucleotide 5'-hydroxyl-kinase (40,41); pyruvate carboxylase (42); ribonucleoside-diphosphate reductase (43); RNA-directed RNA polymerase (44,45); thymidine kinase (46-52); thymidine triphosphatase (53); tRNA cytidylyltransferase (54); tRNA nucleotidyltransferase (54); uracil phospho-ribosyltransferase (55). 1. ## 2-Deoxy-2,3-didehydro-N-acetylneuraminate

This derivative of neuraminic acid (FW<sub>free-acid</sub> = 291.26 g/mol), also known as 2,3-dehydro-2-deoxysialic acid and abbreviated as Neu5Ac2en, was the first substrate-based inhibitor of neuraminidase. While a strong inhibitor of influenza neuraminidase, it has proven to be not selective for the influenza enzyme and thus not suitable as an anti-influenza drug. **Target(s):** N-acetylneuraminate cytidylyltransferase (1); exo-α-sialidase, or neuraminidase, or sialidase (2-28). 1. Corfield, Schauer & Wember (1979) *Biochem. J.* **177**, 1. 2. Meindl & Tuppy (1969) *Hoppe-Seyler's Z. Physiol. Chem.* **350**, 1088. 3. Miller, Wand & Flashner (1978) *Biochem. Biophys. Res. ### 2-Deoxy-2,3-didehydro-N-trifluoroacetylneuraminate

This neuraminic acid derivative (FW<sub>free-acid</sub> = 345.23 g/mol) is a substrate-based inhibitor of neuraminidase. While a strong inhibitor of influenza neuraminidase ( $K_i = 0.8 \mu\text{M}$ ), it has proven to be ineffective against influenza infection. **1.** Palese, Schulman, Bodo & Meindl (1974) *Virology* **59**, 490.

### 5'-Deoxy-N<sup>4</sup>,5-diphenyltubercidin

This deoxytubercidin derivative (FW = 402.45 g/mol) inhibits human adenosine kinase (IC<sub>50</sub> = 0.5 nM). Adenosine is an endogenous neuromodulator that is produced in the central and the peripheral nervous systems and exerts anticonvulsant, anti-inflammatory, and analgesic properties. Efforts to use adenosine receptor agonists are plagued by dose-limiting cardiovascular side effects. As an alternative, the use of adenosine kinase inhibitors (AKIs) as potential antiseizure agents was demonstrated, showing an adenosine receptor mediated therapeutic effect in the absence of overt cardiovascular side effects. **1.** Boyer, Ugarkar, Solbach, *et al.* (2005) *J. Med. Chem.* **48**, 6430.

### 5'-Deoxy-5'-ethylimmucillin-A

This transition-state, pseudonucleoside analogue (FW<sub>free-base</sub> = 265.32 g/mol) inhibits 5'-methylthioadenosine/S-adenosyl-homocysteine nucleosidase,  $K_i = 38 \text{ pM}$  (1) and is a tight, slow-binding inhibitor of human S-methyl-5' thioadenosine phosphorylase,  $K_i = 44 \text{ nM}$  (2). When the ring nitrogen is protonated, this analogue mimics the charge of oxa-carbenium ion intermediate that forms transiently in many glycosidase reactions, and this property results in tight binding. **1.** Singh, Evans, Lenz, *et al.* (2005) *J. Biol. Chem.* **280**, 18265. **2.** Evans, Furneaux, Schramm, Singh & Tyler (2004) *J. Med. Chem.* **47**, 3275.

### 5'-Deoxy-5'-(ethylthio)adenosine

This nucleoside (FW = 311.36 g/mol;  $\lambda_{\text{max}}$  at 260 nm (pH 7) with a molar absorptivity of  $15200 \text{ M}^{-1}\text{cm}^{-1}$ ), also known as 5'-ethylthioadenosine, is an alternative substrate and competitive inhibitor of *Escherichia coli* 5'-methylthioadenosine/S-adenosylhomocysteine nucleosidase ( $K_i = 0.13 \mu\text{M}$ ).

**Target(s):** adenosylhomocysteine nucleosidase (1,2); S-adenosyl-methionine cyclotransferase (3); deoxycytidine kinase,  $K_i = 0.7 \text{ mM}$  (4); 5'-methylthioadenosine/S-adenosylhomocysteine nucleosidase (1,2,5,6); S-methyl-5'-thioadenosine phosphorylase (7); spermidine synthase, *or* putrescine aminopropyltransferase (8-12); spermine synthase, *or* spermidine aminopropyltransferase (9,10); tRNA methyltransferases (13); tRNA (uracil-5)-methyltransferase (14). **1.** Cornell, Swarts, Barry & Riscoe (1996) *Biochem. Biophys. Res. Commun.* **228**, 724. **2.** Ferro, Barrett & Shapiro (1976) *Biochim. Biophys. Acta* **438**, 487. **3.** Mudd (1959) *J. Biol. ### L-1-Deoxyfucosycin

This presumptive transition-state mimic (FW = 147.17 g/mol), also called 5-amino-1,5-dideoxy-L-fucopyranose and 1-deoxy-L-fuco nojirimycin, inhibits  $\alpha$ -L-fucosidase:  $K_i = 10 \text{ nM}$  for the human liver enzyme. When the ring nitrogen is protonated, this analogue mimics the charge of oxa-carbenium ion intermediate that forms transiently in many glycosidase reactions, a property that often leads to very tight binding. **Target(s):**  $\alpha$ -L-fucosidase (1-5); glycoprotein 3- $\alpha$ -L-fucosyltransferase (1,3 fucosyltransferase V, weakly inhibited, but inhibition increases synergistically in the presence of GDP (6). **1.** Mooser (1992) *The Enzymes*, 3rd ed., **20**, 187. **2.** Winchester, Barker, Baines, *et al.* (1990) *Biochem. J.* **265**, 277. **3.** Gramer, Schaffer, Sliwkowski & Goochee (1994) *Glycobiology* **4**, 611. **4.** Berteau, McCort, Goasdoue, Tissot & Daniel (2002) *Glycobiology* **12**, 273. **5.** Dumas, Kajimoto, Liu, C.-H. *et al.* (1992) *Bioorg. Med. Chem. Lett.* **2**, 33. **6.** Murray, Takayama, Schultz & Wong (1996) *Biochemistry* **35**, 11183.

### 1-Deoxygalactonojirimycin

This presumptive transition-state mimic (FW = 163.17 g/mol), also known as 5-amino-1,5-dideoxy-D-galacto-pyranose and 1-deoxy D-galactonojirimycin, competitively inhibits galactosidases (1). When the ring nitrogen is protonated, this analogue mimics the charge of oxa-carbenium ion intermediate that forms transiently in many glycosidase reactions, a property that results in tight binding. 1-Deoxygalactomycin has been used

in the treatment of patients with Fabry disease, a disorder of glycosphingolipid metabolism caused by deficiency of lysosomal  $\alpha$ -galactosidase A (2). This agent binds to and stabilizes the mutant enzyme ( $IC_{50} = 0.04 \mu\text{M}$ ), allowing it to be processed and targeted for lysosomal disposal. **Target(s):** galactinol-sucrose galactosyltransferase, or raffinose synthase (1);  $\alpha$ -galactosidase (2-5);  $\beta$ -galactosidase (2,6);  $\alpha$ -L-fucosidase (7); lactase/phlorizin hydrolase, or glycosylceramidase (8); sucrose  $\alpha$ -glucosidase, or sucrase (9). 1. Peterbauer, Mach, Mucha & Richter (2002) *Planta* **215**, 839. 2. Mooser (1992) *The Enzymes*, 3rd ed., **20**, 187. 3. Fan, Ishii, Asano & Suzuki (1999) *Nat. Med.* **5**, 112. 4. ### 2-Deoxy-D-galactose

This deoxy sugar (FW = 164.16 g/mol; CAS 1949-89-9), also known as 2-deoxy-D-talose, inhibits brain glycoprotein fucosylation. It also induces amnesia, but does not affect the  $K^+$ -stimulated release of noradrenaline from rat striatal slices or that of dopamine from striatal synaptosomes. Long-term memory in chicks is also blocked by this fucose analogue. 2-Deoxy-D-galactose is also an alternative substrate for galactokinase. **Target(s):** aldose 1-epimerase (1); galactokinase, also as an alternative substrate (2); galactose oxidase, also as an alternative substrate (3);  $\beta$ -galactosidase (4); glycoprotein fucosylation (5). 1. Bailey, Fishman, Kusiak, Mulhern & Pentchev (1975) *Meth. Enzymol.* **41**, 471. 2. Mathai & Beutler (1967) *Enzymologia* **33**, 224. 3. Yip & Dain (1968) *Enzymologia* **35**, 368. 4. ### 2-Deoxy-D-glucose

This deoxy sugar (FW = 164.16 g/mol; CAS 154-17-6), also known as 2-deoxy-D-mannose and 2-deoxy-D-arabino-hexose, is a glucose antimetabolite that has also been used as an antiviral agent. This deoxy sugar appears to potentiate the action of various anticancer treatments (including etoposide, arsenic trioxide, and radiation), suggesting that impairment of glycolysis increases cell susceptibility selective cancer cell toxicity. **Hexokinase Inhibition:** 2DG is a well-known nonmetabolizable inhibitor of glycolysis – not directly, but only after hexokinase-catalyzed phosphorylation to form 2-deoxy-D-glucose 6-phosphate. The latter is a potent product and allosteric inhibitor of mammalian hexokinase ( $K_i \approx 20$ -50  $\mu\text{M}$ ), but is a much weak inhibitor of yeast hexokinase ( $K_i \approx 5$ -10 mM) (1). **Hexokinase-Independent Pathway:** 2DG's anticancer effects cannot be fully explained by hexokinase inhibition alone. It induces a transient expression of p21 and continuous expression of p53 in colorectal cancer cells (SW620). Treatment also causes cell-cycle arrest at  $G_0/G_1$  phase, inducing apoptosis through the mitochondrial pathway. The effects of 2DG on p21 and p53 protein levels are totally independent of its inhibitory effect on either hexokinase or ATP levels (2). **Target(s):** aldose 1-epimerase (3);  $\alpha$ -amylase (4); concanavalin A (5); dolichyl-phosphate  $\beta$ -glucosyltransferase (6); endo-1,4- $\beta$ -xylanase (7); glucan 1,3- $\alpha$ -glucosidase, or glucosidase II, or mannosyl oligosaccharide glucosidase II (8); glucan-1,3- $\beta$ -glucosidase, weakly inhibited (9); glucokinase, also alternative substrate (10); glucose oxidase (11-13); glucose-6-phosphate isomerase (14); glycolysis (15); hexokinase, also alternative substrate that generates nonmetabolizable 2-deoxyglucose 6-P (1,10,16-18); myo-inositol-1-phosphate synthase (19); lactose synthase (20); laminaribiose phosphorylase (21); mannokinase, also weak alternative substrate (22); protein

glycosylation (6,23-25); UDP-N-acetylglucosamine:dolichyl-phosphate N-acetylglucosamine phosphotransferase (23). 1. Purich, Rudolph & Fromm (1973) *Adv. Enzymol.* **39**, 259. 2. ### 2-Deoxy-D-glucose 6-Phosphate

This phosphorylated deoxy sugar (FW<sub>free-acid</sub> = 244.14 g/mol; CAS 33068-19-8) inhibits a number of glucose-dependent enzymes. Although a relatively weak inhibitor of brain hexokinase, 2-deoxyglucose 6-P is effective in mimicking the release of hexokinase from mitochondria (**See also** 2-Deoxy-D-glucose). **Target(s):** glucose-6-phosphatase, weakly inhibited (1); glucose-6-phosphate dehydrogenase (1); glucose-6-phosphate isomerase (1,2); glycogen synthase (1); inositol-phosphate phosphatase, or 1-L-myoinositol-1-phosphatase (3); inositol-3-phosphate synthase, or myo-inositol-1 phosphate synthase (3-9); phosphomannomutase (10). 1. ### 2'-Deoxyguanosine 5'-Diphosphate

This deoxynucleotide (FW<sub>free-acid</sub> = 427.20;  $\lambda_{\max}$  at 253 nm, with  $\epsilon = 13000 \text{ M}^{-1}\text{cm}^{-1}$ ), often abbreviated dGDP, inhibits DNA polymerase, deoxyguanosine kinase, deoxyadenosine kinase, and 5'-nucleotidase. In eukaryotes, GDP is converted to dGDP by ribonucleotide reductase (RNR). In prokaryotes, dGDP is formed from dGTP, the latter produced by bacterial RNR.

**Target(s):** adenylosuccinate synthetase (1); Amidophosphoribosyltransferase (2); dCMP deaminase, slightly inhibited (3); deoxyadenosine kinase (4,5); deoxycytidine kinase (6); deoxyguanosine kinase (7-10); DNA-directed DNA polymerase (11); dTMP kinase, or thymidylate kinase (12,13); galactoside 2- $\alpha$ -L-fucosyltransferase (14); glycoprotein 6- $\alpha$ -L-fucosyltransferase (15); GTP diphosphokinase (16); 5'-nucleotidase (17); 8-oxo-2'-deoxyguanosine 5'-triphosphate pyrophosphohydrolase (18); thymidine kinase (19). **1.** Van der Weyden & Kelly (1974) *J. ### 2'-Deoxyguanosine 5'-Monophosphate

This deoxynucleotide (FW<sub>free-acid</sub> = 348.23 g/mol;  $\lambda_{\max}$  at 253 nm, with  $\epsilon = 13000 \text{ M}^{-1}\text{cm}^{-1}$ ), often abbreviated dGMP, is an important component in DNA and can be released from DNA via the actions of certain phosphodiesterases (e.g., *Escherichia coli* phosphodiesterase). dGMP is readily hydrolyzed by dilute mineral acids. **Target(s):** adenylosuccinate synthetase (1-5); amidophosphoribosyl-transferase (6); *Basidobolus haptosporus* nuclease Bh1 (7); cytosine deaminase (8,9); dCMP deaminase. Or deoxycytidylate deaminase (1,10-17); deoxyadenosine kinase (18,19); deoxyguanosine kinase, product inhibition (20-24); deoxynucleotide 3'-phosphatase (25); dihydro-rotase (26); DNA-directed DNA polymerase (27);  $\phi$ 29 DNA polymerase (28); dTMP kinase, or thymidylate kinase (29,30); fructose-1,6 biphosphatase (31); NMN nucleosidase (32); ribonuclease T2 (33); thymidylate 5'-phosphatase (34). **1.** Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. **2**, Academic Press, New York. **2.** Wyngaarden & Greenland (1963) *J. ### 2'-Deoxyguanosine 5'-Triphosphate

This nucleotide (FW<sub>free-acid</sub> = 507.18 g/mol; FW<sub>trisodium-salt</sub> = 573.13 g/mol; CAS 93919-41-6;  $\lambda_{\max}$  at 253 nm, with  $\epsilon = 13000 \text{ M}^{-1}\text{cm}^{-1}$ ) is a DNA polymerase substrate. Although dGTP is not a substrate in any other metabolic process, a curious finding is that dGTP is lodged with the nonexchangeable nucleotide site of  $\alpha\beta$ -tubulin dimers within microtubules within neurons treated with nerve growth factor (1). The likely explanation is that intracellular stores of GDP (and consequentially GTP) are depleted by ribonucleotide reductase in NGF-stimulated cells, such that newly synthesized tubulin must use dGTP in place of GTP as the  $\alpha$  and  $\beta$ -tubulin monomers assemble into  $\alpha\beta$ -tubulin dimers. **Target(s):** amidophosphoribosyltransferase (2); deoxyadenosine kinase (3-6); deoxycytidine kinase (7); deoxyguanosine kinase (8-15); DNA helicase (16); exopolyphosphatase (17); glucose-1 phosphate cytidyltransferase (18); GTP cyclohydrolase I (19,20); GTP diphosphokinase (21); guanylate cyclase (22,23); guanylate kinase (3); 3-hydroxyanthranilate oxidase (40); methionine S-adenosyltransferase (24); nucleoside-triphosphatase, alternative substrate (16); nucleotidases (17); 3' nucleotidases (17); 5'-nucleotidase (17,25); phosphoribosyl-pyrophosphate synthetase, or ribose-5 phosphate pyrophosphokinase (26); polynucleotide 5'-hydroxyl-kinase (27,28); ribonucleoside diphosphate reductase (29-36); RNA-directed RNA polymerase (37,38); thymidine kinase (39). **1.** Angelastro & Purich (1992) *J. #### 5'-Deoxy-5'-[(3-hydrazinopropyl)methylamino]adenosine

This synthetic nucleoside (FW<sub>free-base</sub> = 352.40 g/mol;  $\lambda_{\max}$  at 260 nm (pH 7) with a molar absorptivity of 15200 M<sup>-1</sup>cm<sup>-1</sup>) inactivates human adenosylmethionine decarboxylase by forming a hydrazone derivative at the pyruvate prosthetic group. **1.** White, Arnett, Secrist & Shannon (1994) *Virus Res.* **31**, 255. **2.** Shantz, Stanley, Secrist & Pegg (1992) *Biochemistry* **31**, 6848.

#### 5'-Deoxyimmucillin-A

This transition-state analogue (FW<sub>free-base</sub> = 236.25 g/mol), also known as (1S)-1-(9-deazaadenin-9-yl)-1,4,5-trideoxy-1,4 imino-D-ribitol, inhibits 5'-methylthioadenosine/S-adenosyl-homocysteine nucleosidase,  $K_i^*$  = 13 nM (1). It is also a tight, slow-binding inhibitor of human S-methyl-5'-thioadenosine phosphorylase,  $K_i$  = 720 nM (2). When the ring nitrogen is protonated, this analogue mimics the charge of oxa-carbenium ion intermediate that forms transiently in many glycosidase reactions, and this property results in tight binding. **1.** Singh, Evans, Lenz, et al. (2005) *J. Biol. Chem.* **280**, 18265. **2.** Evans, Furneaux, Schramm, Singh & Tyler (2004) *J. Med. Chem.* **47**, 3275.

#### 5'-Deoxy-5'-(isobutylthio)adenosine

This S-adenosylhomocysteine analogue (FW = 339.42 g/mol;  $\lambda_{\max}$  at 260 nm (pH 7) with a molar absorptivity of 15200 M<sup>-1</sup>cm<sup>-1</sup>), also known as 5'-isobutylthioadenosine, inhibits polyamine biosynthesis as well as many methyltransferases. It also inhibits *Escherichia coli* 5'-methylthioadenosine/S-adenosyl-homocysteine nucleosidase (IC<sub>50</sub> = 0.74  $\mu$ M). **Target(s):** S-adenosylhomocysteinase (1,2); adenosylhomocysteine nucleosidase (3); 1-aminocyclopropane-1-carboxylate synthase (4); aminopropyltransferases, or spermidine/s permine synthase (5); cAMP phosphodiesterase (6); cholinephosphate cytidyltransferase, or CTP:choline phosphate cytidyltransferase (7); 5'-deoxy-5'-methylthioadenosine phosphorylase (8); glycine N methyltransferase (3);

histone-lysine N-methyltransferase (9); 5'-methylthioadenosine/S-adenosylhomocysteine nucleosidase (10); methylthio-adenosine nucleosidase (11); nucleoside transport (12); 5'-nucleotidase (13,14); protein-arginine methyltransferase (9,15); protein-S isoprenyl-cysteine O-methyltransferase (15); spermidine synthase (5); spermine synthase (5); sugar transport (12); tRNA (adenine-N<sup>1</sup>-)-methyltransferase (16); tRNA (guanine-N<sup>2</sup>-)-methyltransferase (17); tRNA methyltransferases (18). **1.** Pierre, Richou, Lawrence, Robert-Gero & Vigier (1977) *Biochem. #### 5'-Deoxy-5'-(isopropylthio)adenosine

This nucleoside (FW = 324.39 g/mol;  $\lambda_{\max}$  at 260 nm (pH 7) with a molar absorptivity of 15200 M<sup>-1</sup>cm<sup>-1</sup>), also known as 5'-isopropyl-thioadenosine, inhibits *Escherichia coli* 5' methylthioadenosine/S-adenosylhomocysteine nucleosidase (IC<sub>50</sub> = 1.1  $\mu$ M). 5'-(p-Nitrophenyl)thioadenosine was most potent, with a  $K_i$  of 20 nM. **1.** Cornell, Swarts, Barry & Riscoe (1996) *Biochem. Biophys. Res. Commun.* **228**, 724.

#### D-1-Deoxymannojirimycin

This presumptive transition-state mimic (FW<sub>free-base</sub> = 163.17 g/mol), also called 5-amino-1,5-dideoxy-D-mannopyranose and 1-deoxy-D-mannojirimycin, inhibits glycoprotein processing. When the ring nitrogen is protonated, this analogue mimics the charge distribution of a presumptive oxa-carbenium ion intermediate likely to form transiently in many glycosidase reactions. This property often results in very tight binding. **Target(s):**  $\alpha$ -L-fucosidase (1-4);  $\alpha$ -glucosidase, moderately inhibited (2); glycoprotein processing (5-10);  $\beta$ -D-hexosaminidase, moderately inhibited (2);  $\alpha$ -mannosidase (2,9-17);  $\beta$ -mannosidase (11); mannosyl-oligosaccharide glucosidase, or glucosidase I, weakly inhibited (18); mannosyl-oligosaccharide 1,2- $\alpha$ -mannosidase, or mannosidase I (5-11,19-31); mannosyl oligosaccharide 1,3-1,6- $\alpha$ -mannosidase, or mannosidase II (2,32-34); trehalose (35). **1.** Winchester, Barker, Baines, et al. ### 5'-Deoxy-5'-(methylthio)tubercidin

This nucleoside (FW = 297.09 g/mol), also known as 5'-(methylthio)tubercidin and 5'-methylthio-7-deazaadenosine, inhibits 5'-methylthioadenosine/S-adenosylhomocysteine nucleosidase (IC<sub>50</sub> = 0.75 μM) an polyamine biosynthesis. **Target(s):** adenosylhomocysteine nucleosidase (1-3); 5'-methylthioadenosine/S-adenosylhomocysteine nucleosidase (1-3); S-methyl-5'-thioadenosine phosphorylase (4-9); polyamine aminopropyltransferase (10); spermidine synthase, or putrescine aminopropyltransferase (11-14); spermine synthase, or spermidine aminopropyltransferase (11,12). **1.** Cornell, Swarts, Barry & Riscoe (1996) *Biochem. ### D-1-Deoxynojirimycin

This presumptive transition-state mimic (FW<sub>free-base</sub> = 163.17 g/mol; CAS 19130-96-2), also named 5-amino-1,5-dideoxy-D-glucopyranose and molanoline, is produced by reduction of nojirimycin with a platinum catalyst or NaBH<sub>4</sub>. 1-Deoxynojirimycin is more stable than nojirimycin. When the ring nitrogen is protonated, this analogue mimics the charge of oxa-carbenium ion intermediate that forms transiently in many glycosidase reactions, a property that often results in tight binding. It has also been identified in the roots and leaves of mulberry trees as well as in strains of

*Bacillus* and *Streptomyces*. While an excellent inhibitor of α-glucosidase activities under *in vitro* conditions, 1-deoxynojirimycin has often shown to be only a poor or moderate inhibitor *in vivo*. 1-Deoxynojirimycin also inhibits human immunodeficiency virus (HIV) replication (EC<sub>50</sub> = 560 μM) by inhibiting processing α-glucosidase activities. **Target(s):** α-amylase (1); amylo-α-1,6-glucosidase/4-α-glucanotransferase, or glycogen debranching enzyme (2,3); coniferin β-glucosidase (4); cyclomalto-dextrin glucanotransferase (5,6); exo-(1→4)-α-D-glucan lyase (K<sub>i</sub> = 0.13 μM)7,8; α-L fucosidase (9); glucan 1,3-α-glucosidase, or glucosidase II (1,10-17); glucan 1,3-β-glucosidase (18); glucan 1,4-α-glucosidase, or glucoamylase, or amyloglucosidase (19-21); α-glucosidase (1,11,22-26); β-glucosidase (23,27-29); glycoprotein processing (1,10,22); glucosylceramidase (30-34); lactase/phlorizin hydrolase, or glycosylceramidase (35); mannosyl-oligosaccharide glucosidase, or glucosidase I (1,10-12,22,36-47); oligosaccharide 4-α-D-glucosyl-transferase (48); phosphatidylcholine:sterol O-acyl-transferase, or LCAT (49); sucrose α-glucosidase, or sucrase (22,50,51); thioglucosidase, or myrosinase, or sinigrinase (52); trehalose (53); α,α-trehalose phosphorylase (54); α,α-trehalose phosphorylase, configuration-retaining (55,56). **1.** Elbein (1987) *Meth. **L-1-Deoxyojirimycin**

This enantiomer ( $FW_{\text{free-base}} = 163.17 \text{ g/mol}$ ) of the potent, competitive  $\alpha$ -glucosidase inhibitor and presumptive transition-state mimic, D-1 deoxyojirimycin, is a noncompetitive inhibitor with a  $K_i$  value of  $5.6 \mu\text{M}$  for the rice enzyme. When the ring nitrogen is protonated, this analogue mimics the charge of oxo-carbenium ion intermediate that forms transiently in many glycosidase reactions, a property that results in tight binding. This agent is a useful nonbinding control for its D-enantiomer. **See D-1-Deoxyojirimycin** 1. Kato, Kato, Kano, *et al.* (2005) *J. Med. Chem.* **48**, 2036.

**3',4'-Deoxynorlaudanosolinecarboxylate**

This dopamine-derived tetrahydroisoquinoline ( $FW = 299.33 \text{ g/mol}$ ) is a novel inhibitor of human liver dihydropteridine reductase. It is produced by condensation of phenylpyruvate with dopamine and has been detected in the urine of children with PKU children and in the urine and brain of rats with experimentally induced hyperphenyl-alaninemia. **Target(s):** dihydropteridine reductase (1); dopamine  $\beta$ -monoxygenase (2); tyrosine 3-monoxygenase (3). 1. Shen, Smith, Davis, Brubaker & Abell (1982) *J. Biol. Chem.* **257**, 7294. 2. Lasala & Coscia (1979) *Science* **203**, 283. 3. Coscia, Burke, Galloway, *et al.* (1980) *J. Pharmacol. Exp. Ther.* **212**, 91.

**5'-Deoxy-5'-(propylthio)adenosine**

This nucleoside ( $FW = 349.42 \text{ g/mol}$ ), also known as 5'-propylthioadenosine, is an alternative substrate and competitive inhibitor of *Escherichia coli* 5'-methylthioadenosine/S-adenosylhomocysteine nucleosidase ( $K_i = 0.05 \mu\text{M}$ ). **Target(s):** adenosylhomocysteine nucleosidase (1,2); 5'-methylthioadenosine/S-adenosylhomocysteine nucleosidase (1,2); S-methyl-5'-thioadenosine phosphorylase (3). 1. Cornell, Swarts, Barry & Riscoe (1996) *Biochem. Biophys. Res. Commun.* **228**, 724. 2. Ferro, Barrett & Shapiro (1976) *Biochim. Biophys. Acta* **438**, 487. 3. Ferro, Wrobel & Nicolette (1979) *Biochim. Biophys. Acta* **570**, 65.

**2'-Deoxyribavirin 5'-Triphosphate**

This nucleotide analogue ( $FW_{\text{free-acid}} = 452.15 \text{ g/mol}$ ) inhibits mRNA (nucleoside-2'-O)-methyltransferase. It is formed metabolically from ribavirin, one of the few nucleoside analogues widely used to treat RNA

virus infections. Ribavirin 5'-triphosphate inhibits dengue virus 2'-O-methyltransferase NS5 domain (NS5MTase<sub>DV</sub>), competing with GTP to bind to NS5MTase<sub>DV</sub>. A 2.6-Å crystal structure of a ternary complex consisting of NS5MTase<sub>DV</sub>, ribavirin 5'-triphosphate, and S-adenosyl-L-homocysteine afforded a detailed atomic of the specificity-conferring properties. 1. Benarroch, Egloff, Mulard, *et al.* (2004) *J. Biol. Chem.* **279**, 35638.

**2-Deoxyribose 5-Phosphate**

This phosphorylated deoxyribose ( $FW_{\text{free-acid}} = 214.11 \text{ g/mol}$ ; CAS 102916-66-5) inhibits ribose-5-phosphate adenylyltransferase and the 1-deoxy derivative is a component of DNA. Note that phosphopentomutase can catalyzed the interconversion of 2-deoxy- $\alpha$ -D-ribose 1-phosphate and 2-deoxy- $\alpha$ -D-ribose 5-phosphate utilizing 2-deoxy- $\alpha$ -D-ribose 1,5-bisphosphate as a cofactor. **Target(s):** fructose-1,6-bisphosphatase (1); orotidine-5'-phosphate decarboxylase (2); ribose 5-phosphate adenylyltransferase (3,4); ribose-phosphate diphosphokinase, *or* phosphoribosyl pyrophosphate synthetase (5); ribulose-phosphate 3-epimerase (6). 1. Ganson & Fromm (1984) *Curr. Top. Cell. Regul.* **24**, 197. 2. Miller, Butterfoss, Short & Wolfenden (2001) *Biochemistry* **40**, 6227. 3. Evans (1971) *Meth. Enzymol.* **23**, 566. 4. **3'-Deoxythymidine (or, 3'-dT)**

This dideoxynucleoside ( $FW = 226.23 \text{ g/mol}$ ; CAS 3416-05-5), also known as 1-( $\beta$ -D-2',3' dideoxyribofuranosyl)thymine, inhibits thymidine kinase and thymidine phosphorylase. (**See also 3'-Deoxythymidine 5'-Triphosphate**) **Target(s):** dideoxynucleoside kinase (1); 5'-nucleotidase (2); poly(ADP-ribose)polymerase (3); thymidine kinase (1,4); thymidine phosphorylase (4,5). 1. Johansson, Van Rompay, Degreève, Balzarini & Karlsson (1999) *J. Biol. Chem.* **274**, 23814. 2. Garvey, Lowen & Almond (1998) *Biochemistry* **37**, 9043. 3. Panova, Alexeev, Kuzmichov, *et al.* (2007) *Biochemistry (Moscow)* **72**, 21.

**5'-Deoxythymidine (5'-dT)**

This dideoxy nucleoside ( $FW = 226.23 \text{ g/mol}$ ; CAS 3458-14-8), also known as 1-( $\beta$ -D-2',5'-dideoxyribofuranosyl)thymine, inhibits thymidine kinase and dTMP kinase. Note that the pentose portion of this molecule is actually 2',5'-dideoxyribose. **Target(s):** 5'-nucleotidase (1); thymidine kinase (2-5); thymidylate kinase, *or* dTMP kinase (6,7). 1. Garvey, Lowen & Almond (1998) *Biochemistry* **37**, 9043. 2. Baker (1967) *Design of Active-Site-Directed Irreversible Enzyme Inhibitors*, Wiley, New York. 3. Baker,

### 2',3'-Deoxythymidine 5'-Triphosphate

This dideoxy nucleotide (FW<sub>free-acid</sub> = 466.17 g/mol), also known as 2',3'-dideoxythymidine-5'-triphosphate, inhibits the action of DNA polymerases via chain termination. It is used in the dideoxy-method of Nobelist Fred Sanger in sequencing DNA (See 2',3'-Dideoxythymidine 5'-Triphosphate). **Target(s):** adenovirus DNA polymerase (1); dCMP deaminase, weakly inhibited (2); DNA-directed DNA polymerase (3-22); DNA nucleotidyltransferase, *or* terminal deoxynucleotidyltransferase (13,14,23); DNA polymerase I (14); DNA polymerase  $\alpha$  (8,10); DNA polymerase  $\beta$  (14); DNA polymerase  $\gamma$  (4,6); DNA polymerase  $\delta$  (19); DNA polymerase  $\lambda$  (13); DNA polymerase POL4 (9); duck hepatitis B virus DNA-directed DNA polymerase (12); HIV-1 reverse transcriptase (5,24-29); Rauscher murine leukemia virus reverse transcriptase (30); RNA-directed DNA polymerase (5,12,24-31); RNA-directed RNA polymerase (32); simian immunodeficiency virus (SIV) reverse transcriptase (27); visna virus reverse transcriptase (31). 1. ### 2-Deoxy-2-ureido-D-glucosyl- $\alpha$ ,1,6-(2-O-octyl)-D-myo-inositol-1-phosphoryl-sn-1,2-dipalmitoylglycerol

This analogue (FW = 1123.41 g/mol) is a mechanism-based inhibitor of *Trypanosoma* N-acetylglucosaminyl-phosphatidyl-inositol deacetylase

(IC<sub>50</sub> = 8 nM). This suicide inhibitor is likely to form a carbamate (or thiocarbamate) ester to an active-site Ser, Thr or Cys residue, such that inhibition is reversed by certain nucleophiles. 1. Smith, Crossman, Borissow, *et al.* (2001) *EMBO J.* **20**, 3322.

### 2'-Deoxyuridine

This deoxynucleoside (FW = 228.20 g/mol;  $\lambda_{\max}$  = 262 nm at pH 1 and 7, both with  $\epsilon$  values of 10200 M<sup>-1</sup> cm<sup>-1</sup>) inhibits dihydroorotase and thymidine kinase. **Target(s):** acid phosphatase (1); cytidine deaminase (2-5); dihydroorotase (6); dTMP kinase, *or* thymidylate kinase (7,8); dUTP diphosphate (9); nucleotidases (10); 5'-nucleotidase (11); ribonuclease T2 (12); thymidine kinase (13-15); thymidylate synthase (16). 1. ## Dequalinium Chloride

This antimicrobial agent (FW = 527.58 g/mol; CAS 522-51-0), also known as 1,1'-decamethylenebis-4-aminoquinaldinium dichloride, blocks small conductance Ca<sup>2+</sup>-activated K<sup>+</sup> channels. It also inhibits protein kinase C translocation by inhibiting the formation of the PKC:RACK-1 (receptor for activated C kinase-1) complex. **Target(s):** ATPase, Ca<sup>2+</sup>-dependent, of CF<sub>1</sub> (1); electron transport (2); F<sub>1</sub> ATPase and TF<sub>1</sub> ATPase (1,3-7); H<sup>+</sup>-ATPase, vacuolar (8); K<sup>+</sup> channels, apamin-sensitive and small conductance Ca<sup>2+</sup>-activated (9-12); NADH:ubiquinone reductase (NADH dehydrogenase (2); protein kinase C (13-15). 1. ## Desferrioxamine

Metal-free Siderophore

Iron-bound Siderophore

This metal ion chelator (FW<sub>free-base</sub> = 560.69 g/mol; CAS 70-51-9; Symbol: DFX; also known as deferoxamine mesylate, or desferral (FW = 656.79 g/mol; CAS 138-14-7; Soluble to 100 mM in water)), a siderophore produced by the Actinobacterium *Streptomyces pilosus*, binds Fe<sup>3+</sup> (complex shown above) and other trivalent cations extremely tightly, thereby inhibiting many iron-dependent enzymes, including ferrochelatase, which catalyzes the last step in heme biosynthesis. **Chemical Properties:** Desferrioxamine forms a red-colored, one-to-one complex. Formation constants: ( $K_F = [\text{Complex}]_{\text{free}} \times [\text{Ligand}]_{\text{free}} / [\text{Mg}^{2+}]$ ,  $K_F = 10^4 \text{ M}^{-1}$ ;

$\text{Ca}^{2+}$ ,  $K_F = 10^2 \text{ M}^{-1}$ ;  $\text{Sr}^{2+}$ ,  $K_F = 10 \text{ M}^{-1}$ ;  $\text{Fe}^{3+}$ ,  $K_F = 10^{31} \text{ M}^{-1}$ ;  $\text{Co}^{2+}$ ,  $K_F = 10^{11} \text{ M}^{-1}$ ;  $\text{Ni}^{2+}$ ,  $K_F = 10^{10} \text{ M}^{-1}$ ;  $\text{Cd}^{2+}$ ,  $K_F = 10^8 \text{ M}^{-1}$ ;  $\text{Zn}^{2+}$ ,  $K_F = 10^{11} \text{ M}^{-1}$ . **As Therapy for Iron Overload:** The  $\text{Fe}^{3+}$ -complex, as shown above, is referred to as ferrioxamine. Desferrioxamine has been used to treat chronic iron overload, also known as primary and secondary hemochromatosis (See also *Ferrioxamines*). In humans, normal total iron is 4-5 g, but rises to as much as 20 g in overload. Because iron is so well retained, regularly transfused patients often have excess iron. One-hundred mg desferrioxamine binds 9.35 mg iron. Desferrioxamine also induces apoptosis in HL-60 cells and can arrest cells in the  $G_1$  phase. **Effects on Immune System:** HIF-1 $\alpha$  protein levels, HIF-1 DNA-binding activity, and HIF-1 transcriptional activity can be increased by exposure of cells to desferrioxamine (1). By contrast, the hypoxia mimetic  $\text{CoCl}_2$  induces of HIF-1 $\alpha$  accumulation with no attendant increase in COX-2 expression. DFX-induced increases in COX-2 expression and HIF-1 $\alpha$  protein level are attenuated by addition of ferric citrate, suggesting an iron-chelating role in of DFX induction of COX-2 and HIF-1 $\alpha$  protein. Treatment with PD98059 (a non-ATP competitive MEK inhibitor ( $\text{IC}_{50} = 2 \mu\text{M}$ ) in a cell-free assay) significantly inhibits the induction of COX-2 protein and accumulation of HIF-1 $\alpha$ , suggesting that DFX-induced increase of HIF-1 $\alpha$  and COX-2 protein was mediated, at least in part, through the ERK signaling pathway. In addition, pretreatment with NS-398 ( $\text{IC}_{50} = 1.77 \mu\text{M}$  for human COX-2 versus  $\text{IC}_{50} = 75 \mu\text{M}$  for human COX-1) to inhibit COX-2 activity also effectively suppresses DFX-induced HIF-1 $\alpha$  accumulation in human colon cancer cells, providing the evidence that COX-2 plays as a regulator of HIF-1 $\alpha$  accumulation in DFX-treated colon cancer cells. Such findings suggest iron metabolism regulate HIF-1 $\alpha$  protein by modulating cyclooxygenase-2 signaling pathway, acting, in part, through inhibition of prolyl hydroxylases. **Target(s):**  $\beta$ -carotene 15,15'-monooxygenase (2); cyclooxygenase (3); deoxyhypusine monooxygenase (4-6); dihydroceramide desaturase (7); laccase (8); lipoxygenase (3); phenylalanine 4-monooxygenase (9); procollagen-proline 4-dioxygenase (6,10); ribonucleoside-diphosphate reductase (11,12); tryptophan 5-monooxygenase (13,14). 1. ### N-Desmethylozapine

This potent 5-HT receptor antagonist (FW<sub>free-base</sub> = 312.80 g/mol; CAS 6104-71-8) is also an allosteric at muscarinic-1 receptor agonist and potentiates *N*-methyl-D-aspartate receptor activity. It may contribute to clozapine's clinical activity in schizophrenics through modulation of both muscarinic and glutamatergic neurotransmission (1). **Target(s):** GABA<sub>A</sub> receptors (2); glucose transport (3); histamine H<sub>3</sub> receptor (4); serotonin 5-HT<sub>2</sub>, 5-HT<sub>6</sub>, and 5-HT<sub>7</sub> receptors (5,6). 1. Mallorga, Wittmann, Jacobson, et al. (2003) *Proc. Natl. Acad. Sci. U.S.A.* **100**, 13674. 2. Wong, Kuoppamaki, Hietala, et al. (1996) *Eur. J. Pharmacol.* **314**, 319. 3. ### Desmolaris

This novel anticoagulant (MW = 21.5 kDa) from the salivary gland of the vampire bat (*Desmodus rotundus*) is a naturally occurring tissue factor pathway inhibitor (TFPI) that is a slow, tight binding inhibitor of FXIa,

showing noncompetitive behavior (pM-range  $K_d$ ) that is modulated by heparin. Arg-32 in the Kunitz-1 domain is critical for protease inhibition. Desmolaris also inhibits FXa with lower affinity. It also binds kallikrein and reduces bradykinin generation in plasma activated with kaolin. Kunitz-2 and the C-terminus domains mediate interaction of Desmolaris with heparin and are required for optimal inhibition of FXIa and FXa. 1. Ma, Mizurini, Assumpção, et al. (2013) *Blood* **122**, 4094.

### Destruxins

These lactone antibiotics and naturally occurring insecticides (Destruxin A, FW = 577.72 g/mol, CAS 6686-70-0; Destruxin B, FW = 578.73 g/mol; Destruxin C, FW = 609.76 g/mol; Destruxin E, FW = 593.34 g/mol; CAS 2503-26-6) from the entomopathogenic fungus *Metarhizium anisopliae* and related fungi, paralyzes and kills insects. The fungus is not infectious or toxic to mammals; however, inhalation of spores can induce allergic reactions. At least thirty-five structurally related destruxins have been isolated from these fungi. In addition to being insecticidal, the destruxins also exhibit phytotoxic, antiviral, nematocidal, and immunomodulating activities. They exhibit some effects on cellular phosphorylation and calcium balance. In addition, destruxins have been reported to induce erythropoietin production in mammalian cells. Note that the destruxin can bind calcium ions and have ionophoric properties. **Target(s):**  $\text{Na}^+$ -transporting two-sector ATPase, blocked by destruxin B (1-4); vacuolar type  $\text{H}^+$ -ATPase, inhibited by destruxins B and E (5,6). 1. Murata, Takase, Yamato, Igarashi & Kakinuma (1997) *J. Biol. Chem.* **272**, 24885. 2. Kakinuma, Yamato & Murata (1999) *J. Bioenerg. Biomembr.* **31**, 7. 3. ### Desulfo-Coenzyme A

This coenzyme A analogue (FW = 735.46 g/mol;  $\lambda_{\text{max}} = 259 \text{ nm}$ ;  $\epsilon = 15400 \text{ M}^{-1}\text{cm}^{-1}$ ) inhibits many coenzyme A-dependent enzymes and has been used for affinity chromatography, such as in the purification of phosphate acetyltransferase (1). **Target(s):** acetyl-CoA C-acetyltransferase (2); *N*-acetylneuraminase 4-*O*-acetyltransferase (3); aminoglycoside  $N^3$ -acetyltransferase (4); aralkylamine *N*-acetyltransferase (5); citrate (*si*)-synthase (6); CO-methylating acetyl-CoA synthase, or carbon monoxide dehydrogenase (7,8); heparan- $\alpha$  glucosaminidase *N*-acetyltransferase (9); histone acetyltransferase (10,11); homocitrate synthase (12); 3-hydroxy-3-methylglutaryl-CoA reductase (13); 3-hydroxy-3-methylglutaryl-CoA synthase (14); 2-isopropylmalate synthase (15); 3-oxoacid CoA-transferase, or 3-ketoacid CoA-transferase; succinyl CoA:3-oxoacid CoA-transferase (16); phosphate acetyltransferase (17-23); serine acetyltransferase (24); succinyl-CoA synthetase (25); xenobiotic acetyltransferase from *Pseudomonas aeruginosa* (26). 10. ### Desvenlafaxine

This serotonin/norepinephrine reuptake inhibitor, or SNRI (FW = 263.38 g/mol; CAS 93413-62-8), also named Pristiq<sup>®</sup>, Desfax<sup>®</sup>, *O*-desmethylvenlafaxine, and 4-[2-dimethylamino-1-(1-hydroxycyclohexyl)ethyl]phenol, targets the serotonin transporter, or SERT ( $K_i$  = 60 nM) and the norepinephrine (or noradrenaline) transporter, or NET ( $K_i$  = 2.9  $\mu$ M). Desvenlafaxine is itself the major active metabolite of another SNRI known as Venlafaxine (FW = 277.40 g/mol; CAS 93413-69-5; Trade Names: Effexor<sup>®</sup>, Effexor XR<sup>®</sup>, Trevilor<sup>®</sup>, Lanvexin<sup>®</sup>). SNRIs block or delay the reuptake of serotonin and norepinephrine by the presynaptic nerves, thereby increasing the levels of these neurotransmitters in the synapse and elevating mood. Both desvenlafaxin and venlafaxine have proved to be effective antidepressants for treating Major Depressive Disorder (MDD), showing favorable safety and tolerability profiles. The need for suitable alternatives in treating MDD is indicated by the fact that a majority of individuals with MDD do not achieve and sustain a recovered state (1). 1. Kornstein, McIntyre, Thase & Boucher (2014) *Expert Opin. Pharmacother.* **15**, 1449.

### Dexamethasone

This synthetic glucocorticoid (FW = 392.47 g/mol; CAS 50-02-2), also known as DEX and 9 $\alpha$ -fluoro-11 $\beta$ ,17 $\alpha$ ,21-trihydroxy-16 $\alpha$ -methylpregna-1,4-diene-3,20-dione, is an anti-inflammatory agent that regulates T cell survival, growth, and differentiation. It also induces liver tyrosine aminotransferase and inhibits the induction of nitric-oxide synthase. Dexamethasone also inhibits spontaneous apoptosis in primary cultures of human and rat hepatocytes via Bcl-2 and Bcl-xL induction. Dexamethasone is also the most commonly used type of steroid for prostate cancer (See also *Leuprolide*). Note: Dexamethasone is the 16-epimer of betamethasone. **Target(s):** choline *O*-acetyltransferase (1); cortisol sulfotransferase (2-4); hyaluronoglucosaminidase, or hyaluronidase (5); 3 $\alpha$ -hydroxysteroid dehydrogenase (6); phospholipase A<sub>2</sub> (7). 1. Wattanathorn, Kotchabhakdi, Casalotti, Baldwin & Govitrapong (1996) *Eur. J. Pharmacol.* **313**, 69. 2. Singer, Gebhart & Hess (1978) *Can. J. Biochem.* **56**, 1028. 3. Singer (1979) *Arch. ### Dexniguldipine

This photosensitive diester (FW<sub>free-base</sub> = 609.72 g/mol), also known as *R*(-)-niguldipine, is the enantiomer of a potent L-type Ca<sup>2+</sup> channel blocker. It will also act as an L-type Ca<sup>2+</sup> channel blocker and  $\alpha$ 1A-adrenergic receptor antagonist, albeit not as effectively. Note that this diester adsorbs strongly to plastic surfaces, requiring one to take measures to passivate plasticware used in an assay. **Target(s):**  $\alpha$ <sub>1</sub>A-adrenoceptor (1); Ca<sup>2+</sup> channels, L-type (1); DNA topoisomerase (2); drug transport by P-glycoprotein (3); protein kinase C (4,5). 1. Boer, Grassegger, Schudt & Glossmann (1989) *Eur. J. Pharmacol.* **172**, 131. 2. Straub, Boesenberg, Gekeler & Boege (1997) *Biochemistry* **36**, 10777. 3. Schuller, Orloff & Reznik (1994) *J. Cancer Res. Clin. Oncol.* **120**, 354.

### Dexon

This photosensitive fungicide (FW = 219.18 g/mol; CAS 140-56-7), also known as *p*-(*N,N*-dimethylamino)benzenediazosulfonate sodium salt and Fenaminosulf, Phenaminosulf, Deksona, Dexoxon, Lesan, Gold Orange MP, is metabolized to *N,N*-dimethyl-*p*-phenylenediamine by *Pseudomonas fragi*. **Caution:** Fenaminosulf is readily absorbed through the skin. Note: Dexon is also a proprietary name for polyglycolic acid, which is frequently used absorbable suture material. **Target(s):** electron transport (1-4); NADH dehydrogenase (1-4). 1. Rapoport & Schewe (1977) *Trends Biochem. Sci.* **2**, 186. 2. Schewe, Hiebsch & Halangk (1975) *Acta Biol. Med. Ger.* **34**, 1767. 3. Schewe & Hiebsch (1977) *Acta Biol. Med. Ger.* **36**, 961. 4. Muller & Schewe (1977) *Acta Biol. Med. Ger.* **36**, 967.

### Dexrazoxane

This cyclic methyl-EDTA derivative (FW = 268.27 g/mol; CAS 24584-09-6), also known as Cardioxane<sup>®</sup>, Zinecard<sup>®</sup>, and 4-[(2*S*)-2-(3,5-dioxopiperazin-1-yl)propyl]piperazine-2,6-dione, is a prodrug, site-specific cardioprotective agent that protects against anthracycline-induced cardiac toxicity (1). Dexrazoxane undergoes metabolic hydrolysis to methyl-EDTA, a powerful metal ion-chelator (See *EDTA*). It is approved in the US and Europe as a cardioprotectant in women receiving doxorubicin to treat advanced and/or metastatic breast cancer. Dexrazoxane is also approved for patients with advanced cancer receiving anthracyclines, significantly reducing the incidence of anthracycline-induced congestive heart failure and adverse cardiac events in women with advanced breast cancer or adults with soft tissue sarcomas or small-cell lung cancer, but does not improve progression-free and overall patient survival (1). Dexrazoxane also induces topoisomerase II $\alpha$  (TOP2A)-dependent cell death,  $\gamma$ -H2AX accumulation

and increased tail moment in neutral comet assays (2). Dexrazoxane induces DNA damage responses, as indicated by enhanced levels of  $\gamma$ -H2AX/53BP1 foci, ATM (ataxia telangiectasia mutated), ATR (ATM/Rad3-related), Chk1 and Chk2 phosphorylation, and by accumulation of p53 (2). Dexrazoxane-induced  $\gamma$ -H2AX accumulation was dependent on ATM. ATF3 protein was induced by dexrazoxane in a concentration- and time-dependent manner, which was abolished in TOP2A-depleted cells and in cells pre-incubated with ATM inhibitor. Knockdown of ATF3 gene expression by siRNA triggered apoptosis in control cells and diminished the p53 protein level in both control and dexrazoxane-treated cells (2). These effects is accompanied by increased  $\gamma$ -H2AX accumulation and delayed repair of dexrazoxane-induced DNA double-strand breaks (2). Earlier studies suggested that Dexrazoxane may prevent doxorubicin-induced DNA damage via depleting both topoisomerase II isoforms (3). 1. Cvetković & Scott (2005) *Drugs* **65**, 1005. 2. Deng, Yan, Nikolova, *et al.* (2015) *Brit. J. Pharmacol.* **172**, 2246. 3. Deng, Yan, Jendry, *et al.* (2014) *BMC Cancer* **14**, 842.

**Dextroamphetamine, See Amphetamine**

#### Dextromethorphan

This over-the-counter morphinan-class sedative (FW = 271.40 g/mol; CAS 125-71-3), frequently found in combination (with doxylamine and acetaminophen) in cough syrups and cold remedies, inhibits dopamine reuptake, activates  $\sigma$ -receptors, and blocks open NMDA (*N*-methyl-D-aspartate) channels. It is metabolized by cytochrome P450 systems (particularly CYP2D6 and CYP3A4). Because roughly 5-10% of the Caucasian population is CYP2D6-deficient, such individuals metabolize dextromethorphan poorly. Unlike its stereoisomer, levomethorphan, dextromethorphan has no analgesic properties and is nonaddictive. Levomethorphan and the racemic mixture racemethorphan are controlled substances. **Target(s):**  $\text{Ca}^{2+}$  channels, voltage-dependent (1);  $\alpha_3\beta_4$ -nicotinic acetylcholine receptor (2); NMDA-controlled ion channels (3). 1. Carpenter, Marks, Watson & Greenberg (1988) *Brain Res.* **439**, 372. 2. Jozwiak, Hernandez, Kellar & Wainer (2003) *J. Chromatogr. B Analyt. Technol. Biomed. Life Sci.* **797**, 373. 3. **Diacetylmorphine, See Heroin**

#### *P*<sup>1</sup>,*P*<sup>5</sup>-Di(adenosine-5') pentaphosphate

This naturally occurring multisubstrate, geometrical analogue (FW<sub>free-acid</sub> = 916.36 g/mol; CAS 75522-97-3 (free-acid); FW<sub>Penta-Lithium-Salt</sub> = 946.03 g/mol; CAS 94108-02-8 (penta-lithium salt), often abbreviated ApppppA or Ap<sub>5</sub>A, is stored in secretory granules of thrombocytes, chroaffin, and neuronal cells. Ap<sub>5</sub>A was the second diadenosine polyphosphate found to inhibit adenylate kinase, or myokinase (**See *P*<sup>1</sup>,*P*<sup>4</sup>-di(adenosine-5') tetraphosphate**). This property is itself especially useful in view of the fact that adenylate kinase is a frequent contaminant in enzyme preparations. Ap<sub>5</sub>A is also an antagonist at  $\text{Ca}^{2+}$ -coupled P2Y<sub>1</sub> receptors, acting as a stress mediator in the cardiovascular system. **Target(s):** acetyl-CoA synthetase, or acetate:CoA ligase (1); adenosine kinase (2-4); adenylate kinase,  $K_i = 10^{-5}$  M (5-25); angiogenin (26);  $\text{Ca}^{2+}$ -coupled P2Y<sub>1</sub> receptors (27); carbamate kinase (28,29); carbamoyl phosphate synthetase (30,31); creatine kinase, weakly inhibited (32); cytidylate kinase (ATP:NMP phosphotransferase, UMP/CMP kinase) (33,34); terminal deoxyribonucleotidyltransferase (35-37); dynein ATPase, weakly inhibited (38); ecto-adenylate kinase (39); F<sub>1</sub> ATPase (40); firefly luciferase, or *Photinus*-luciferin monooxygenase (41);  $\text{K}^+$ -channel, ATP-sensitive (42,43); nucleoside-triphosphate:adenylate kinase (8,44); 5'-nucleotidase (45); protein kinase C (46); ribonuclease A (26); ribonucleotide reductase (47); tetrahydrofolate synthetase (48). 1. #### $P^1, P^4$ -Di(adenosine-5') tetraphosphate

This naturally occurring multisubstrate, geometric analogue (FW = 924.31 g/mol (tetrasodium salt); CAS 5542-28-9), often abbreviated  $Ap_4A$ , corresponding to the fusion of two ADP nucleotides linked by their terminal phosphate groups, is stored in secretory granules of thrombocytes, chromaffin, and neuronal cells.  $Ap_4A$  was the second diadenosine polyphosphate found to inhibit adenylate kinase, or myokinase (1). (**See the more potent inhibitor  $P^1, P^4$ -Di(adenosine-5') pentaphosphate**).  $Ap_4A$  also inhibits adenosine kinase and carbamoyl-phosphate synthetase. It is also an antagonist at  $Ca^{2+}$ -coupled P2Y1 receptors and act as a stress mediator in the cardiovascular system.  $Ap_4A$  stimulates phospholipase D activity and induces nitric oxide release in endothelial cells. **Target(s):** adenylate kinase, or myokinase (1-4); adenosine kinase (5-8); ATP adenyllyltransferase (9,10);  $Ca^{2+}$ -coupled P2Y1 receptors (11); carbamoyl-phosphate synthetase, weakly inhibited (12); casein kinase II (13); creatine kinase, weakly inhibited (14); deoxycytidine kinase (15); dephospho-[reductase kinase] kinase (16); DNA nucleotidyl-exotransferase, or terminal deoxyribo-nucleotidyltransferase (17-19); endoribonuclease VI (20); *Escherichia coli* DnaK protein 5'-nucleotidase activity (21);  $F_1$  ATPase (22); firefly luciferase, or *Photinus*-luciferin monooxygenase (23); [3-hydroxy-3-methylglutaryl-CoA reductase (NADPH)] kinase (16);  $K^+$ -channel, ATP-sensitive (24); poly(ADP-ribose) glycohydrolase (25); pp60src protein kinase (26); protein kinase C (27); ribonucleotide reductase (28); RNA ligase (ATP) (29). **1.** Purich & Fromm (1972) *Biochim. #### Diallyl disulfide

This garlic oil constituent (FW = 146.27 g/mol; CAS 2179-57-9) increases cellular production of glutathione S-transferase (GST), an enzyme that binds and deactivates many electrophilic toxins. A concentration dependent inhibition of was found When incubated with microsomal preparations, diallyl disulfide inhibits 3-hydroxy-3-methylglutaryl CoA (HMG CoA) reductase in a concentration-dependent manner that cannot be reversed by

either dithiothreitol or reduced glutathione (1). The authors suggest diallyl disulfide form an internal protein disulfide linkage that is inaccessible for reduction by thiol agents. Diallyl disulfide also arrests unsynchronized human colon tumor cells (HCT-15) at the G<sub>2</sub>/M stage of the cell cycle by inducing ERK phosphorylation and altering gene expression profiles (2). Diallyl sulfide also inhibits diethylstilbestrol-induced DNA damage in human breast epithelial MCF-10A cells (3). *Note:* Diallyl disulfide is a skin irritant and allergen that readily penetrates most latex gloves. Its median LD<sub>50</sub> for oral intake in rats is 260 mg per kg of body weight. **1.** Kumar, Banerji, Kurup & Ramasarma (1991) *Biochim. Biophys. #### 4,6-Diamino-1-(3',4'-dichlorophenyl)-1,2-dihydro-2,2-dimethyl-s-triazine

This dihydrotriazine (FW = 286.16 g/mol), also known as NSC-3077, reversibly inhibits dihydrofolate reductases from pigeon liver, *Escherichia coli*, T<sub>2</sub> phage, mouse leukemia L1210, and Walker 256 rat tumor (IC<sub>50</sub> ≈ 15, 160, 19, 6.4, and 2.9 nM respectively). **1.** Baker (1967) *Design of Active-Site-Directed Irreversible Enzyme Inhibitors*, Wiley, New York. **2.** Baker (1967) *J. #### 2,6-Diaminopurine

This folate antagonist (FW = 150.14 g/mol; CAS 1904-98-9;  $\lambda_{\text{max}}$  at 241 and 282 nm at pH 1.9 ( $\epsilon = 9550$  and  $10000 \text{ M}^{-1}\text{cm}^{-1}$ , respectively), also known as 2-aminoadenine, is a reversible inhibitor of RNA biosynthesis. 2,6-Diaminopurine is metabolically converted to ribonucleotide derivatives. Discovery of its antifolate properties (1) stimulated interest in antifolate cancer chemotherapy. **Target(s):** adenine deaminase (2,3); adenine phosphoribosyltransferase (*Plasmodium falciparum* but not human) (4); adenosine deaminase (2,5-7); dihydrofolate reductase,  $K_i = 2.1 \mu\text{M}$  (1,8-11); hypoxanthine(guanine) phosphoribosyltransferase, or HGPRT (12); methionine S-adenosyltransferase (13); xanthine oxidase, also alternative substrate (14); and xanthine phosphoribosyltransferase (12). 1. ### 3,5-Diamino-1H-1,2,4-triazole

This free radical scavenger and antitumor agent (FW = 99.095 g/mol), also known as guanazole and 3,5-diamino-1,2,4-triazole, inhibits ribonucleotide reductase, or RNR (1-8) and glutamyl-peptide cyclotransferase (9). RNR is known to engage multiple catalytically essential free radicals, of which one or more is (are) intercepted by guanazole. Inhibition of deoxyribonucleotide biosynthesis blocks DNA synthesis and tumor cell proliferation. Rapid intravenous injection of guanazole produces a sharp drop in arterial blood pressure, an increase in right ventricular pressure, a slight decrease in heart rate, and a rise in central and portal venous pressures. These changes are transient, lasting 5–10 min, and can be partially ameliorated by prior treatment with antihistaminic, antiserotonin, and adrenergic blocking drugs (10). 1. ### Dianemycin

This open-chain macrotetralide (FW<sub>free-acid</sub> = 888.51 g/mol; CASs = 35865-33-9 and 65101-87-3 (sodium salt)), with structural features similar to nigericin and monensin, is an ionophore and an uncoupler of oxidative phosphorylation. Dianemycin was first isolated from *Streptomyces hydroscopicus*. Dianemycin inhibits cation transport in mitochondria (4). This agent also exhibits antibiotic properties against coccidial infections in chickens (5). 1. Izawa & Good (1972) *Meth. Enzymol.* **24**, 355. 2. Reed (1979) *Meth. Enzymol.* **55**, 435. 3. ### Dianicline

This orally bioavailable and selective nAChR partial agonist (FW<sub>di-HCl</sub> = 289.20 g/mol; CAS 292634-27-6; Solubility: 100 mM in H<sub>2</sub>O ; 20 mM in DMSO), also named SSR-591813 and (5*S*,8*S*,10*aR*)-5*a*,6,9,10-tetrahydro-7*H*,11*H*-8,10*a*-methanopyrido[2',3':5,6]pyrano[2,3-*d*]azepine, selectively targets the  $\alpha_4\beta_2$  nicotinic acetylcholine receptor (IC<sub>50</sub> = 105 nM), exhibiting 20-fold greater action toward  $\alpha_4\beta_2$  over other subtypes (1). By activating  $\alpha_4\beta_2$  nAChRs and reducing the reinforcing effects of nicotine upon smoking by competing with nicotine, high-affinity  $\alpha_4\beta_2$  nAChR partial agonists are desired for relieving nicotine craving and withdrawal symptoms during quit-smoking attempts. Dianicline also increases dopamine turnover in the nucleus accumbens of the rat *in vivo*. **See also Varenicline** 1. Rollema, Shrikhande, Ward, *et al.* (2010) *Brit. J. Pharmacol.* **160**, 334. 2. *Drug Trial Case Report*: <https://clinicaltrials.gov/ct2/show/NCT00356967>

### Diazaborine

This experimental drug (FW = 313.14 g/mol; CAS 22959-81-5) inhibits maturation of rRNAs for the large ribosomal subunit,  $K_d = 0.12 \text{ mM}$  (a). **Primary Mode of Inhibitory Action:** In eukaryotic cells, ribosomes are assembled through the coordinated action of >200 transacting factors, making ribosome biogenesis a target for antimicrobial and anti-tumor chemotherapy. In this study, we investigated the mechanism of action of the first specific inhibitor. Diazaborine's direct target is the AAA-ATPase Drg1, a key pre-60S ribosome maturation factor in yeast, with the drug blocking Rlp24 release from pre-60S particles, halting any further maturation. Diazaborine binds within the second AAA domain of Drg1, where it inhibits ATP hydrolysis in this site, even though the drug does not act as a competitive inhibitor for ATP. ATP binding is a prerequisite for diazaborine to recognize Drg1. **Other Target(s):** Nucleotide binding is also required for inhibitor interaction with the enoyl-ACP reductase (FabI), a diazaborine target in Gram-negative bacteria. For FabI, NAD<sup>+</sup> cofactor must likewise first bind to the enzyme to create the site for inhibitor binding (2,3), with diazaborine's boron atom forming a covalent bond with the 2'OH of the NMN moiety of the coenzyme (26,27). 1. ### Diazepam

This powerful and widely used tranquilizer (FW = 284.74 g/mol; CAS 439-14-5), also known by its trade name Valium® and IUPAC name 7-chloro-1,3-dihydro-1-methyl-5-phenyl-2H-1,4-benzodiazepin-2-one, anti-anxiety agent and muscle relaxant. **Mode of Action:** Diazepam enhances the effect of the GABA by binding to the benzodiazepine site on the GABA<sub>A</sub> receptor, resulting in CNS depression. It also retards adenosine reuptake, with a consequential rise in extracellular adenosine. Overuse often leads to habituation or addiction. Diazepam was synthesized in 1959 by Sternbach and Reeder at Hoffmann-La Roche (1). **Pharmacokinetics:** After a lag time (~12 min) between ingestion and absorption, first-order absorption proceed with a mean half-life of 19 min (range: 0–96 min), reaching peak plasma concentrations within 0.9 hour after dosage (range: 0.25–2.5 hr). Age and sex were without effect on absorption kinetics. Peak plasma concentrations averaged 150–160 ng/mL, somewhat higher in women than men owing to differences in body weight. Dominant features of diazepam pharmacokinetics are its relatively low rate of elimination and the formation of the biologically active metabolic products, chiefly desmethyldiazepam and oxazepam. Diazepam elimination rates depend on the extent of plasma protein binding, amount of drug and duration of administration, as well as the age and liver function of the patient. The normal half-life is 1–2 days, but can be as long as 3–4 in subjects age 60 and over. With sub-chronic administration, diazepam elimination rates drop to 20–70% that observed in healthy subjects. The major metabolite desmethyldiazepam has a  $t_{1/2}$  of 51 h and a clearance rate of 11 mL/min, but accumulates after multiple doses of diazepam, because its elimination is much slower than diazepam. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** acetylcholinesterase (2,3); acyl-CoA:cholesterol acyltransferase, *oe* ACAT (4); adenylate cyclase (5,6); apyrase (2); Ca<sup>2+</sup>/calmodulin-dependent protein kinase (7,8); cAMP-specific phosphodiesterase (9,10); cholinesterase, *or* butyrylcholinesterase (3); cytochrome P450, *or* CYP2B (11); glucuronosyltransferase, *or* UDP-glucuronyltransferase (12,13); nitric-oxide synthase (14); quinine 3-monooxygenase (15); succinate semialdehyde dehydrogenase (16); xanthine oxidase (17). 1. ### Diazinon

This membrane-penetrating pro-pesticide (FW = 304.35 g/mol; CAS 333-41-5; colorless to amber-colored liquid), also known as phosphorothioic acid *O,O*-diethyl-*O*-[6-methyl-2-(1-methylethyl)-4-pyrimidinyl] ester, inhibits cholinesterases. Upon entry into the body, it is hydrolyzed and oxidatively metabolized to diaoxozon, an organophosphate compound that is a far more effective acetylcholine esterase inhibitor (1-3). **Target(s):** fatty acid amide hydrolase (4); glutathione *S* transferase (5); kynurenine formamidase (6). 1. ### *N*-Diazoacetyl-DL-norleucine Methyl Ester

This affinity labeling reagent (FW = 213.24 g/mol; CAS 7013-09-4; *Abbreviation:* DAN) inhibits a number of peptidases (particularly aspartic proteinases like pepsin and cathepsins), often in the presence of cupric ions (*i.e.*, Cu<sup>2+</sup> and Ag<sup>+</sup> often facilitate the inhibition). Attack on the diazomethyl carbon by a carboxyl group on the target enzyme yields a protein-bound ester that will hydrolyze at pH > 9.5. **Mode of Pepsin Inactivation:** A copper-complexed carbene is most likely the reactive species, an idea that is supported by the finding that dimethylsulfonium phenacylide, which is known to form such a complex, rapidly inactivates pepsin in the presence of Cu(II). Reaction of a carbene is thought to occur at a protonated carboxyl, with specificity determined by the proximity of an ionized carboxyl group that serves to orient the positively charged inhibitor molecule. The proposed mechanism of inactivation is compatible with the presence at or near the active site of pepsin of two carboxyl groups with markedly different pK values. The attacking group is thus a protonated carboxyl on the enzyme, the action of which generates a positively charged adduct that is stabilized/oriented by a nearby ionized carboxyl group. (*See Means & Feeney (1971) Chemical Modification of Proteins, Holden-Day, San Francisco*) This property probably explains why aspartic proteinases are especially susceptible to DAN. **Target(s):** acrocyllindropepsin (1,2); aspergillopepsin I (2-5); aspergillopepsin II (3,6,7); bovine leukemia virus retropepsin (8); candidapepsin (9; other references report no inhibition); canditropsin (10); cardosin A (11); cardosin B (12); cathepsin D (13-18); cathepsin E (19); chymosin, *or* rennin (20,21); *Fasciola hepatica* acid protease22; gastricsin, *or* pepsin C (23-27); lysozyme (28); mouse submandibular renin (25,29); mucorpepsin (2,20,30-32); nepenthesin (33-35); *Penicillium duponti* acid protease, closely related to penicillopepsin (36); penicillopepsin (25,36-42); pepsin A (2,24,25,43-57); physaropepsin (58-62); phytepsin (63); poly(3-hydroxybutyrate) depolymerase (64-66); polyporopepsin (67,68); propiomelanocortin converting enzyme (yapsin A) (69,70); renin (2,71); rhizopuspepsin (2,20,38,72-75); rhodotorulapepsin (2,76-79); saccharopepsin (80,81); thermopsin (82-84); todarepsin (17); Wai21.A1 protease (85,86); Wp22.A1 protease (85); yapsin 3 (87). 1. #### N-Diazoacetyl-L-phenylalanine Methyl Ester

This reagent (FW = 247.25 g/mol) inhibits a number of peptidases, particularly aspartic proteinases, most often in the presence of  $\text{Cu}^{2+}$  and  $\text{Ag}^+$  (See Means & Feeney (1971) *Chemical Modification of Proteins*, Holden-Day, San Francisco). Attack on the diazomethyl carbon by a carboxyl group on the

target enzyme yields a protein-bound ester that hydrolyzes at pH above 9.5.

**Target(s):** penicillopepsin, with  $\text{Cu}^{2+}$  present (1); pepsin A (2-7). 1. Sodek & Hofmann (1970) *Meth. Enzymol.* **19**, 372. 2. Wilcox (1972) *Meth. Enzymol.* **25**, 596. 3. #### 6-Diazo-5-oxo-L-norleucine

This toxic glutamine analogue (FW = 171.16 g/mol; Abbreviation: DON) inhibits many enzymes in amino acid and nucleotide biosynthesis, inactivating glutamine-hydrolyzing synthetases. Such enzymes generate nascent ammonia by attack of an active-site SH on the  $\gamma$ -amide, rendering these enzyme especially susceptible to DON activation by reaction with the same thiol. DON is also produced by a *Streptomyces* species. Prepare freshly and keep cold at pH 4.5-6.5. **Target(s):** D-alanine  $\gamma$ -glutamyltransferase (1);  $\omega$ -amidase (2); amidophospho-ribosyltransferase (3-15); 4-amino-3-deoxychorismate synthase (16); anthranilate synthase (6,8,17-19); asparagine synthetase (6,20-24); carbamoyl-phosphate synthetase II, glutamine-hydrolyzing (6,25-29); CTP synthetase (6,30-33); glutamate synthase (6,34); glutaminase (6,9,35-40); glutamin-(asparaginase) (41-45); glutamine:fructose-6-P transaminase (5,6,8,37,46-59); [glutamine synthetase] adenylyltransferase (60,93); glutamine transport (61,62); glutaminyl-tRNA synthetase, inhibiting the glutamine dependent reaction but not the ammonia-dependent activity (63);  $\gamma$ -glutamyl peptide-hydrolyzing enzyme (64);  $\gamma$ -glutamyl transpeptidase, or  $\gamma$ -glutamyltransferase (38,65-77); GMP synthetase (6,78-83); 4-methyleneglutaminase, weakly inhibited (84);  $\text{NAD}^+$  synthetase, glutamine-hydrolyzing (6,85,86); nitrogenase (87); phosphoribosylformylglycinimidine synthetase (4,6,9,37,88-92). 1. ### 6-Diazo-5-oxo-L-norleucylglycine

This dipeptide analogue (FW = 228.21 g/mol; CAS 78081-74-0) irreversibly inactivates  $\gamma$ -glutamyltranspeptidase, while the latter remains bound to renal brush border membrane vesicles. Notably, this same reagent does not inactivate the purified enzyme. The presence of L-cysteinylglycine S-acetyldextran polymer (Mr  $\approx$  500,000), which does not permeate membranes, protected the membrane-bound transferase from inactivation by 6-diazo-5-oxo-L-norleucylglycine. These findings suggest that the norleucylglycine derivative was hydrolyzed by peptidase(s) bound to the outer surface of the brush border membranes and that the 6-diazo-5-oxo-L-norleucine thus released acts as an affinity-labeling reagent for the membrane-bound transferase. Upon hydrolysis, this dipeptide liberates 6-diazo-5-oxo-L-norleucine, which then inhibits the membrane-bound transpeptidase. **1.** Inoue & Morino (1981) *Proc. Natl. Acad. Sci. U.S.A.* **78**, 46.

### 5-Diazo-4-oxo-L-norvaline

This asparagine analogue (FW = 157.13 g/mol; *Abbreviation*: DONV) inhibits asparagine-dependent enzymes. **Target(s)**:  $N^{\delta}$ -[ $\beta$ -N-acetylglucosaminyl]-L-asparaginase, or glycosylasparaginase (1-7); asparaginase (8-17); asparagine synthetase (18,19); asparagine transport (20); glutamin-(asparagin)-ase, or glutaminase/asparaginase (21-23). **1.** Aronson (1998) in *Handb. ### (E,E)-8-(2-Diazo-3,3,3-trifluoropropionyloxy)geranyl Pyrophosphate

This farnesyl pyrophosphate analogue (FW<sub>free-acid</sub> = 466.24 g/mol; *Abbreviation*: DATFP-GPP) also known as (E,E)-(2-diazo-3-trifluoropropionyloxy)geranyl diphosphate, is a photolabile reagent: irradiation with ultraviolet light in the presence of DATFP-GPP, Mg<sup>2+</sup>, isopentenyl pyrophosphate, and undecaprenyl pyrophosphate synthase results in inactivation of the enzyme,  $K_i = 0.22 \mu\text{M}$  (1-3). Tritiated derivatives photolabel undecaprenyl pyrophosphate synthase (3) and protein farnesyltransferase (4). **Target(s)**: di-*trans*,poly-*cis*-decaprenyl-*cis*transferase, or undecaprenyl pyrophosphate synthase; *cis*-prenyltransferase, or C55-pyrophosphate synthetase (1-3); protein farnesyltransferase (4,5). **1.** Baba & Allen (1984) *Biochemistry* **23**, 1312. **2.** Allen & Baba (1985) *Meth. Biophys. Res. Commun.* **181**, 729.

### Diazoxide

This antihypertensive agent (FW = 230.67 g/mol; CAS 364-98-7), also known as 7-chloro-3-methyl-2H-1,2,4-benzothiadiazine 1,1 dioxido, is a selective ATP-sensitive K<sup>+</sup> channel activator. Diazoxide is also a muscle relaxant, acting by increasing membrane permeability to potassium ions, which switches off voltage-gated calcium ion channels that inhibits the generation of an action potential. **Target(s)**: 3',5'-cyclic-nucleotide phosphodiesterase (1); glycerol-3-phosphate dehydrogenase, islet mitochondria (2); succinate dehydrogenase (3). **1.** Drummond & Yamamoto (1971) *The Enzymes*, 3rd ed., **4**, 355. **2.** MacDonald (1981) *J. Biol. Chem.* **256**, 8287. **3.** Schafer, Portenhauser & Trolp (1971) *Biochem. Pharmacol.* **20**, 1271.

## Diazoxon

This toxic triester organophosphate (FW = 288.28 g/mol; CAS 962-58-3), also known as *O,O*-diethyl-*O*-(2-isopropyl-4-methylpyrimid-6-yl)phosphate, is a cholinesterase inhibitor. Diazoxon is an alternative substrate for paraoxonase. **Target(s):** acetylcholinesterase (1); acylaminoacyl-peptidase (2); acylglycerol lipase, or monoacylglycerol lipase (3); 1-alkyl-2-acetyl-glycero-phosphocholine esterase, or platelet-activating factor deacetylase (4); arylformamidase, or kynurenine formamidase (5); cholinesterase, or butyrylcholinesterase (1,6); fatty acid amide hydrolase, or anandamide amidohydrolase (3). 1. ## Dibekacin

This semisynthetic antibiotic (FW<sub>free-base</sub> = 451.52 g/mol; CAS 34493-98-6 (free base) and 58580-55-5 (sulfate salt)) inhibits initiation of DNA replication. It is an analogue of kanamycin and is effective against kanamycin-resistant microorganisms. Dibekacin is usually formulated in combination with sulbenicillin, a penicillin derivative. **Target(s):** phospholipase A (1,2); phospholipase A<sub>1</sub> (3); phospholipase A<sub>2</sub> (3); phospholipase C (1,2). 1. Hostetler & Hall (1982) *Biochim. Biophys. Acta* **710**, 506. 2. Hostetler & Hall (1982) *Proc. Natl. Acad. Sci. U.S.A.* **79**, 1663. 3. Carlier, Laurent & Tulkens (1984) *Arch. Toxicol. Suppl.* **7**, 282.

## 1,2:5,6-Dibenzanthracene

This polycyclic DNA intercalator and cancer-causing agent (FW = 278.35 g/mol; CAS 53-70-3), also known as dibenz[*a,h*]anthracene, is isolated from coal tar and is carcinogenic. Dibenzanthracene was isolated and identified by Kennaway and coworkers in 1932 (1-3) and represents the first purified carcinogen, along with its 3-methyl derivative. Yamagiwa and Ichikawa (4) succeeded in evoking cancer by the application of coal tar to the skin of a rabbit's ear in 1914-1915. Kennaway and coworkers later showed that polycyclic hydrocarbons could cause cancer (5) and they soon obtained benzo[*a*]pyrene. Thus, while the early work provided the foundation for the field of chemical carcinogenesis, later work demonstrated the need for initial bioactivation as aryl epoxides. Such polycyclic hydrocarbons (PAHs) often contain a "bay region" that are especially susceptible to enzymatic epoxidation (e.g., benzo[*a*]pyrene is converted to benzo[*a*]pyrene-7,8-diol-9,10-epoxide). There is a strong coincidence of

Guanine-to-Thymine transversion hotspots in lung cancers and sites of preferential formation of PAH adducts along the p53 gene. Endogenously methylated CpG dinucleotides are the preferred sites for G-to-T transversions, accounting for more than 50% of such mutations in lung tumors (6). The same dinucleotide, when present within CpG-methylated mutational reporter genes, is the target of G to T transversion hotspots in cells exposed to the model PAH compound benzo[*a*]pyrene-7,8-diol-9,10-epoxide (6). 1. Cook, Hieger, Kennaway & Mayneord (1932) *Proc. R. Soc. (B)* **111**, 455. 2. Haddow (1974) *Perspect. Biol. Med.* **17**, 543. 3. Rubin (2001) *Carcinogenesis* **22**, 1903. 4. ## Dibenzazepine

This nitrogen heterocycle (FW = 193.25 g/mol; CAS 256-96-2; *Symbol*: DBZ), also known as 5*H*-dibenzo[*b,f*]azepine, is a Notch/γ-secretase inhibitor. **Likely Mode of Inhibitor Action:** The idea that γ-secretase inhibitors originally developed for treating Alzheimer's disease might redirect cell fate follows from the fact that Alzheimer precursor protein and Notch are both γ-secretase substrates. Small intestine epithelium self-renewal requires orderly emergence of crypt and villus compartments, and proliferative crypt cell conversion into post-mitotic goblet cells requires removal/down-regulation of the common Notch pathway transcription factor CSL/RBP-J. This phenotype is obtained by blocking the Notch cascade with γ-secretase inhibitors like dibenzazepine (1,2). Moreover, these same inhibitors also induce goblet cell differentiation in adenomas in mice carrying a mutation of the Apc tumor suppressor gene (2). Dibenzazepine likewise attenuates angiotensin II-induced abdominal aortic aneurysm in ApoE knockout mice by multiple mechanisms (3). **Note:** Given the fact that dibenzazepine is a nucleus in many tricyclic antidepressants (e.g., clomipramine, desipramine, doxepin, imipramine, imipraminoxide, lofepramine, metapramine, opipramol, quinapramine, and trimipramine), the specificity of DBZ action as a Notch/γ-secretase inhibitor is questionable. 1. ## Dibucaine

This hygroscopic quinolone (FW<sub>free-base</sub> = 343.47 g/mol; CAS 85-79-0; Very soluble in water and ethanol), also known as 2-butoxy-*N*-[2-(diethylamino)-ethyl]-4-quinolinecarboxamide, cinchocaine, and Percaine, is a long-acting local anesthetic. Given its toxicity, dibucaine's current use is restricted to spinal and topical anesthesia. **Target(s):** acetylcholinesterase (1,2); 1-acylglycerophosphocholine *O*-acyltransferase, or lysophosphatidylcholine *O*-acyltransferase (3); Ca<sup>2+</sup>-dependent cyclic-dinucleotide phosphodiesterase (4); Ca<sup>2+</sup>-transporting ATPase (5-7); choline-phosphate cytidyltransferase (8); cholinesterase, or butyrylcholinesterase (1,9-11); cytochrome *c* oxidase (12-15); F<sub>1</sub> ATPase (16); guanylate cyclase, calmodulin-dependent (17); histamine *N*-methyltransferase (18); D-3-hydroxybutyrate dehydrogenase (19); lecithin:cholesterol acyltransferase, or LCAT (20); 5-lipoxygenase, or arachidonate 5-lipoxygenase; ID<sub>50</sub> = 66 μM (21); Lysophospholipase (22); monoamine oxidase (23); NADH dehydrogenase (13); NADPH:ferrihemoprotein reductase (24); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (2,6,25); phosphatidylinositol diacylglycerol-lyase, or phosphatidylinositol-specific phospholipase C, inhibits at pH 7, but stimulates at pH 5.5 (26); phospholipase A<sub>2</sub> (22,27,28); protein kinase C29-31; stearoyl-CoA desaturase (24); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, or ACAT (32,33); sterol esterase, or cholesterol esterase (34); succinate dehydrogenase (13); ubiquinol:cytochrome *c* oxidoreductase (13). 1. #### Dobutamine

This sympathomimetic drug (FW = 301.38 g/mol; CAS 34368-04-2), also named (*RS*)-4-(2-[[4-(4-hydroxyphenyl)butan-2-yl]amino]ethyl)benzene-1,2-diol, is used to treat heart failure and cardiogenic shock by a primary mechanism involving direct stimulation of  $\beta_1$  receptors of the sympathetic nervous system. Dobutamine stimulates  $\beta_1$ -adrenoceptors of the heart, increasing contractility and cardiac output. Showing no effect on the release of norepinephrine, dobutamine is less prone to induce hypertension than dopamine. It does not exhibit the chronotropic or vasodepressor actions of isoproterenol, the vasopressor actions of norepinephrine or dopamine, or the arrhythmogenic potential of any of these three agents. Yet, like isoproterenol and norepinephrine, dobutamine acts directly on the cardiac  $\beta_1$  receptors and so has inotropic efficacy that is substantially greater than that of the digitalis glycosides. Like other catecholamines, dobutamine has an immediate onset but a brief duration of action that makes possible titration of the desired amount of inotropic effect by controlling the rate of intravenous infusion. 1. Tuttle & Mills (1975) *J. Circ. Res.* **36**, 185.

#### 3,5-Di(*t*-butyl)-4-hydroxybenzylidenemalononitrile

This respiratory chain uncoupler (FW = 282.39 g/mol), also known as SF 6847, is an effective protonophore at concentrations of 30 nM, corresponding to less than 0.2 molecules uncoupler per respiratory chain, suggesting a lack of a stoichiometric relationship between uncoupler molecules and cytochrome *c* oxidase or between the former and phosphorylation assemblies. 1. Muraoka & Terada (1972) *Biochim. Biophys. Acta* **275**, 271. 2. Terada & van Dam (1975) *Biochim. Biophys. Acta* **387**, 507. 3. Heytler (1979) *Meth. Enzymol.* **55**, 462.

#### *N*<sup>6</sup>,*O*<sup>2'</sup>-Dibutyryl-adenosine 3',5'-Cyclic Monophosphate

This cell-permeant cyclic AMP analogue (FW<sub>free-acid</sub> = 469.39 g/mol; CAS 362-74-3; *Abbreviation*: dibutyryl-cAMP, also known as Bucladesine, activates cAMP-dependent protein kinases, including the glycogen phosphorylase system. It is less susceptible to hydrolysis by phosphodiesterases. It is used to sustain the cAMP activation in treated cells. In HeLa cells, the active form is *N*<sup>6</sup>-monobutyryl-adenosine 3',5'-monophosphate (1) The dibutyryl form is also converted nonenzymatically to the monobutyryl form in slightly alkaline conditions (e.g., pH 8.5). **Target(s)**: acetyl-CoA carboxylase (2); 3',5'-cyclic-GMP phosphodiesterase, or cGMP phosphodiesterase (3,4); 3',5'-cyclic-nucleotide phosphodiesterase, or cAMP phosphodiesterase (4-6); poly(ADP-ribose) glycohydrolase (7); rhodopsin kinase, weakly inhibited (8). 1. Kaukel, Mundhenk & Hiltz (1972) *Eur. J. Biochem.* **27**, 197. 2. Allred & Roehrig (1973) *J. Biol. Chem.* **248**, 4131. 3. Morishima (1975) *Biochim. Biophys. Acta* **410**, 310. 4. Pannbacker, Fleischman & Reed (1972) *Science* **175**, 757. 5. Cohen (1979) *Phytochemistry* **18**, 943. 6. Lim, Palanisamy & Ong (1986) *Arch. Microbiol.* **146**, 142. 7. Miwa, Tanaka, Matsushima & Sugimura (1974) *J. Biol. Chem.* **249**, 3475. 8. Weller, Virmaux & Mandel (1975) *Proc. Natl. Acad. Sci. U.S.A.* **72**, 381.

#### *N*<sup>2</sup>,2'-*O*-Dibutyryl-guanosine 3',5'-Cyclic Monophosphate

This cell-permeant cGMP analogue (FW<sub>free-acid</sub> = 485.39 g/mol;  $\lambda_{\max}$  = 260 nm at pH 7.0;  $\epsilon$  = 16700 M<sup>-1</sup>cm<sup>-1</sup>) activates protein kinase G. It is slightly more resistant to the action of specific phosphodiesterases than cGMP. The lipolytic activity of dibutyryl-cGMP is considerably lower than that of dibutyryl-cAMP (1). This synthetic agent has also been shown to increase intracellular calcium levels (2,3) and inhibit thrombin-induced arachidonate release in platelets (4) Dibutyryl cGMP. Note that dibutyryl-cGMP is slowly converted to *N*<sup>2</sup>-monobutyryl-cGMP upon prolonged standing in aqueous solutions. 1. Braun, Hechter & Baer (1969) *Proc. Soc. Exp. Biol. Med.* **132**, 233. 2. Rooney, Joseph, Queen & Thomas (1996) *J. Biol. Chem.* **271**, 1981. 3. Sato & Kawatani (1998) *Brain Res.* **813**, 203. 4. Sane, Bielawska, Greenberg & Hannun (1989) *Biochem. Biophys. Res. Commun.* **165**, 708.

#### Dichloroacetate

This  $\alpha$ -dihalo acid (FW = 128.94 g/mol; CAS 79-43-6; B.P. = 193-194°C; *Abbreviation*: DCA) is a caustic liquid that is miscible with water and

ethanol. Dichloroacetic acid has been used as an oral antidiabetic agent that reduces blood glucose and lipids without stimulating insulin secretion. DCA inhibits the phosphorylation of pyruvate dehydrogenase as well as gluconeogenesis. It is an irreversible inhibitor of the glutathione *S*-transferase  $\zeta$  reaction, wherein glutathione first displaces chloride from dichloroacetate, and an active-site cysteinyl residue then displaces the second chlorine atom, resulting in a covalently modified and inactivated enzyme. DCA promotes local conformational changes in [pyruvate dehydrogenase] kinase isozyme-1 that are communicated to both nucleotide-binding and lipoyl-binding sub-sites, leading to the inactivation of enzyme activity. **Target(s):** [branched-chain  $\alpha$ -keto-acid dihydrogenase] kinase, or [3-methyl-2 oxobutanoate dehydrogenase (acetyl-transferring)] kinase (2-8); dichloromethane dehalogenase (9); glutathione *S*-transferase (10-13); haloalcohol dehalogenase (14); 3-hydroxy-3-methylglutaryl-CoA reductase (15,16); pantothenate synthetase (17); [pyruvate dehydrogenase (acetyl-transferring)] kinase (1,18-28). 1. ### 5,6-Dichlorobenzimidazole 1- $\beta$ -D-Ribofuranoside

This synthetic nucleoside (FW = 319.14 g/mol), also known as 5,6-dichlorobenzimidazole riboside and 5,6-dichloro-1- $\beta$ -D-ribofuranosylbenzimidazole, is metabolically transformed to its mono-, di-, and triphosphate forms, with the latter inhibiting RNA biosynthesis and causing premature termination of transcription. **Target(s):** casein kinase-2,  $K_i = 7 \mu\text{M}$  (1-4); cdc2 kinase (2,5); cyclin-dependent kinase-9, or carboxyl-terminal domain protein kinase (6-9); DNA replication (10); [glycogen synthase] kinase 3 (GSK3), or [tau protein] kinase (2); helicase (11,12); insulin-stimulated nuclear and cytosolic p70 S6 kinase (13); non-specific serine/threonine protein kinase (1-4); rhodopsin kinase ( $K_i = 4 \mu\text{M}$ ) (14); RNA polymerase, or RNA polymerase II (11,15-21); [RNA-polymerase]-subunit kinase, or CTD kinase (8,22-24); transcription factor IIH-associated protein kinase (7). 1. ### 3-[[[(4,7-Dichlorobenzoxazol-2-yl)methyl]amino]-5-ethyl-6-methylpyridin-2(1H)-one

This pyridin-2-one (FW = 352.22 g/mol), also known as L-697,661, inhibits HIV-1 reverse transcriptase,  $\text{IC}_{50} = 19 \text{ nM}$  (1-5). P236L-HIV-1 RT shows that substitution at amino acid 236 changes the shape of the binding pocket in a way that confers resistance to bisheteroarylpiperazines (BHAPs) but sensitizes the mutant enzyme to L-697,661 (6). 1. ### Dichloro(2-chlorovinyl)arsine

This liquid vesicant (FW = 207.32 g/mol; M.P. = 0.1°C; B.P. [decomposes] = 190°C; Insoluble in H<sub>2</sub>O; Soluble in Most Organic Solvents), known as Lewisite, is a potent respiratory poison and chemical warfare agent. Lewisite reacts with protein-SH groups. **Caution:** Extreme care must be exercised in its handling. British Lewisite. As little as 0.5 mL applied to the skin can cause severe symptoms, with 2 mL causing death. Inhalation of high concentrations can cause death within ten minutes. The antidote is 2,3-dimercapto-1-propanol, better known as British Anti-Lewisite (BAL). **Target(s):** acid phosphatase (1); alanine aminotransferase (4); alcohol dehydrogenase, yeast (2,3); arginase (4); choline oxidase (4); cholinesterase (1,3,4);  $\alpha$ -glycerophosphate dehydrogenase (5); hexokinase (6,7); homogentisate 1,2-dioxygenase (8,9); lactate dehydrogenase (5); pyruvate oxidase, or pyruvate dehydrogenase (6,10,11); succinate dehydrogenase (5,6); succinate oxidase (1,5); sulfhydryl dependent enzymes (12). 1. ## 5,7-Dichlorokynurenate

This kynurenic acid derivative (FW<sub>free-acid</sub> = 258.06 g/mol; CAS 131123-76-7; Symbol: 5,7-DCKA) is an NMDA (*N*-methyl-D-aspartate) receptor antagonist ( $K_i$  = 79 nM) and is associated with the strychnine-insensitive glycine-binding site of the receptor. At 10  $\mu$ M, 5,7-DCKA antagonizes the ability of NMDA to stimulate the binding of the radiolabeled ion channel blocker *N*-[<sup>3</sup>H]1-(2-thienyl)cyclohexyl-piperidine ([<sup>3</sup>H]TCP). Glycine overcomes this effect, and in the presence of 5,7-DCKA enhanced [<sup>3</sup>H]TCP binding to antagonist-free levels. 5,7-DCKA completely and noncompetitively antagonized several NMDA receptor-mediated biochemical and electrophysiological responses. 1. Baron, Harrison, Miller, *et al.* (1990) *Mol. Pharmacol.* **38**, 554. 2. Baron, Siegel, Slone, *et al.* (1991) *Eur. J. Pharmacol.* **206**, 149. 3. McNamara, Smith, Calligaro, *et al.* (1990) *Neurosci. Lett.* **120**, 17.

## Dichloromethylenediphosphonate

This collagenase inhibitor (FW<sub>free-acid</sub> = 244.89 g/mol), also known as dichloromethylene biphosphonic acid and clodronic acid, inhibits interstitial and neutrophil and blocks osteoclast-mediated bone resorption. This bisphosphonate is also used to treat bone metastases and the management of skeletal complications associated with bone metastases in patients with breast cancer. **Target(s):** adenosine kinase (1); collagenase-3, *or or* MMP-13 (2); enamelysin, *or* MMP-20 (2); gelatinase A, *or* MMP-2 (2); gelatinase B, *or* MMP-9 (2); interstitial collagenase, *or* MMP-1, IC<sub>50</sub> = 150  $\mu$ M (2,3); macrophage elastase, *or* matrix MMP-12 (2); MMP-14, *or* membrane-type MMP-1 (4); neutrophil collagenase, *or* MMP-8 (2,5); pyrophosphatase (6-8); pyrophosphate-dependent phosphofructokinase, *or* diphosphate:fructose-6-phosphate 1-phosphotransferase (9); ribokinase (10); stromelysin-1, matrix metalloproteinase-3 (2); vacuolar H<sup>+</sup>-transporting pyrophosphatase (8). 1. Park, Singh & Gupta (2006) *Mol. Cell. Biochem.* **283**, 11. 2. Heikkilä, Teronen, Moilanen, *et al.* (2002) *Anticancer Drugs* **13**, 245. 3. Teronen, Kontinen, Lindqvist, *et al.* (1997) *Calcif. ## (2,4-Dichlorophenoxy)acetate

This herbicide (FW<sub>free-acid</sub> = 221.04 g/mol; CAS 94-75-7; *Abbreviation:* 2,4-D;  $pK_a$  = 2.64; Free acid is relatively insoluble (0.06 g/100 g H<sub>2</sub>O); Sodium salt is soluble (3.5 g/100 g), is a synthetic auxin. The herbicidal properties of 2,4-D were discovered in the early 1940s in both the U.S. and U.K. When sprayed on plants at the correct concentrations, broad-leaf organisms are killed, but not narrow-leaf plants such as grasses. Earlier so-called inorganic herbicides remain in the soil much longer than 2,4-D. Given its ease of synthesis, 2,4-D and related compounds dominated the herbicide market until the arrival of more effective agents in the late 1960s. **CAUTION:** Care should be exercised to avoid direct contact with skin or inhalation of stock solutions, as overdoses can cause dermatitis and convulsions. **Target(s):** benzoyl-CoA synthetase, *or* benzoate:CoA ligase (1); glutathione *S*-transferase (2,3); glycerol-3-phosphate dehydrogenase (4);

indole-3-acetate  $\beta$ -glucosyltransferase (5); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (6); palmitoyl-CoA hydrolase, *or* acyl-CoA hydrolase (7); pectin lyase (8); phosphatidate phosphatase (9); zeatin 9-aminocarboxyethyltransferase (10). 1. 6-[4-(2,5-Dichlorophenoxy)piperidin-1-yl]-*N*-methylpyridazine-3-carboxamide

This pyridazine derivative (FW = 381.26 g/mol) inhibits stearoyl-CoA 9-desaturase, IC<sub>50</sub> = 7.0 nM. Stearoyl-CoA desaturase 1 (SCD1) catalyzes the committed step in the biosynthesis of monounsaturated fatty acids from saturated, long-chain fatty acids. Studies with SCD1 knockout mice have established that these animals are lean and protected from leptin deficiency-induced and diet-induced obesity, with greater whole body insulin sensitivity than wild-type animals. Such findings point to SCD1 as an attractive druggable target in efforts to develop anti-obesity drugs. 1. Liu, Lynch, Freeman, *et al.* (2007) *J. Med. Chem.* **50**, 3086.

## S-1,2-Dichlorovinyl-L-cysteine

This cysteine analogue (FW = 216.09 g/mol) reacts with and inactivates cysteine *S*-conjugate  $\beta$ -lyase as well as a number of transaminases. **Target(s):** L-alanine:glyoxalate aminotransferase (1); aspartate aminotransferase (2,3); branched-chain-amino-acid aminotransferase (4); cysteine *S*-conjugate  $\beta$ -lyase, alternative substrate and suicide inhibitor (5); cysteine conjugate *S*-oxidase (6); glutathione-disulfide reductase (7); kynurenine:oxoglutarate aminotransferase (8,9); lipoyl dehydrogenase (7). 1. ## O-2,2-Dichlorovinyl-O,O-dimethyl Phosphate

This toxic organophosphate (FW = 220.98 g/mol; *Abbreviation:* DDVP), also known as *O,O*-dimethyl-*O*-2,2-dichlorovinyl phosphate, and dichlorvos, is a serine proteinase/esterase inhibitor that has been used as a pesticide to control mushroom flies, aphids, spider mites, caterpillars, thrips, and white flies in crops as well as parasitic worm infections in mammals. **Target(s):** acetylcholinesterase (1-7); acylaminoacyl-peptidase (8); acylglycerol lipase, *or* monoacylglycerol lipase (9); carboxylesterase (10); cholinesterase, *or* butyrylcholinesterase (2,3,11-16); chymotrypsin

(11); fatty acid amide hydrolase, or anandamide amidohydrolase (9); glutaminase (17); juvenile-hormone esterase (18); lipase, or triacylglycerol lipase (11); monoamine oxidase (19); trypsin (11); urethanasase (20). 1. ### Diclofop

This phenoxypropionic acid (FW<sub>free-acid</sub> = 327.16 g/mol; CAS 40843-25-2) is a post-emergence herbicide that inhibits acetyl-CoA carboxylase. 1. Harwood (1988) *Trends Biochem. Sci.* **13**, 330. 2. Rendina, Felts, Beaudoin, et al. (1988) *Arch. Biochem. Biophys.* **265**, 219. 3. Alban, Baldet & Douce (1994) *Biochem. J.* **300**, 557. 4. Naturforsch.* **48**, 294. 7. Focke, Gieringer, Schwan, et al. (2003) *Plant Physiol.* **133**, 875.

### Diclofenac

This nonsteroidal anti-inflammatory and analgesic (FW = 296.15 g/mol; CAS 15307-86-5) is used to treat rheumatoid arthritis, degenerative joint disease, ankylosing spondylitis as well as pain resulting from minor surgery, trauma and menstruation. Although its mode of therapeutic action remains unclear, Diclofenac inhibits the conversion of arachidonic acid to prostaglandin G<sub>2</sub> by the cyclooxygenase (COX-2) activity of prostaglandin endoperoxide synthases (1). The IC<sub>50</sub> values for time-dependent inhibition of wild type COX-2 (K<sub>i</sub> = 77 nM), Arg-120-Ala COX-2 (K<sub>i</sub> = 257 nM), and Tyr-355-Phe COX-2 (K<sub>i</sub> = 137 nM) were roughly comparable, whereas the Ser-530-Ala enzyme is completely resistant to diclofenac inhibition (1). Diclofenac also suppresses the fast tetrodotoxin-sensitive (TTX-S) sodium current (K<sub>d</sub> = 14 μM) and the slow tetrodotoxin-resistant (TTX-R) sodium current (K<sub>d</sub> = 97 μM) in rat dorsal root ganglion neurons at a holding potential of -80 mV (2). Diclofenac has no effect on the kinetic parameters of the activation process in either sodium current, but produces shifts of the steady-state inactivation curves in the hyperpolarizing direction in both types of sodium currents in a dose-dependent manner (2). Diclofenac induces apoptosis in oral cavity cancer cells by increasing the expression of the nonsteroidal anti-inflammatory drug-activated gene NAG-1 (3). However, it suppresses apoptosis induced by endoplasmic reticulum stresses by inhibiting caspase signaling (4). Toxic effects of Diclofenac on hepatocytes *in vitro* is likely to be caused by drug-induced mitochondrial impairment, together with a futile consumption of NADPH (5). **Key**

**Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Rowlinson, Kiefer, Prusakiewicz, et al. (2003) *J. Biol. Chem.* **278**, 45763. 2. Lee, Kim, Shin, et al. (2003) *Brain Res.* **992**, 120. 3. ### Dicrotophos

This cell-permeant organophosphate insecticide (FW = 237.19 g/mol; CAS 141-66-2; M.P. < 25°C), also known as Bidrin<sup>®</sup> and dimethyl-2-dimethylcarbamoyl 1-methylvinyl phosphate, inhibits acetylcholinesterase (1) and arylformamidase (2). The *E*-isomer is more active than the *Z*-isomer. Dicrotophos is classified as a restricted-use pesticide. 1. Aharoni & O'Brien (1968) *Biochemistry* **7**, 1538. 2. Seifert & Casida (1979) *Pestic. Biochem. Physiol.* **12**, 273.

### Dictyostatin

This tubulin polymerization-promoting and microtubule-stabilizing agent (FW = 518.73 g/mol), also named (3*Z*,5*E*,7*S*,8*R*,10*R*,11*Z*,13*R*,14*S*,15*R*,17*R*,20*S*,22*S*)-22-[(2*R*,3*Z*)-3,5-hexadien-2-yl]-8,10,14,20-tetrahydroxy-7,13,15,17-tetramethoxycyclodocos-3,5,11-trien-2-one, from a *Lithistida* sponge arrested cells in the G<sub>2</sub>/M junction of the cell cycle (1). Staining of with tubulin-specific antibodies revealed multiple aster formation and microtubule bundling patterns similar to that observed with paclitaxel (1). Dictyostatin crosses the blood-brain barrier in mice and exhibits extended brain retention (2). A single dose of dictyostatin to mice causes prolonged microtubule stabilization in brain, whereas discodermolide, a structurally related MT-stabilizer, shows significantly less brain exposure. The total synthesis of dictyostatin has been reported (3). 1. Isbrucker, Cummins, Pomponi, Longley & Wright (2003) *Biochem. Pharmacol.* **66**, 75. 2. Brunden, Gardner, James, et al. (2013) *ACS Med. Chem. Lett.* **4**, 886. 3. O'Neil & Phillips (2006) *J. Am. Chem. Soc.* **128**, 5340.

### Dicoumarol (or Dicoumarol)

This substituted coumarin and vitamin K mimic (FW = 336.30 g/mol; CAS 66-76-2), also known as 3,3'-methylene-bis(4-hydroxycoumarin), targets Vitamin K epoxide reductase (EC 1.1.4.1), which reduces vitamin K after it has been oxidized during enzymatic carboxylation of glutamic acid residues in blood coagulation enzymes. Dicoumarol thus interferes with vitamin K-dependent formation of γ-carboxyglutamyl (Gla) residues in coagulation enzymes, thereby inhibiting/preventing blood clotting. It is also a

protonophoric uncoupler of oxidative phosphorylation ( $EC_{50} = 30-70 \mu\text{M}$ ) and photophosphorylation (1-3). It also inhibits NADH dehydrogenase (4), or DT diaphorase ( $K_i = 10 \text{ nM}$ ), binding to the oxidized form of the enzyme (i.e., competitively versus NADH). **History:** Used as cattle feed, vast quantities of sweet clover spoiled during several wet growing seasons in the 1920s, attended by a concomitant rise in cattle "bleeding disease". Link's group at the University of Wisconsin isolated the hemorrhagic agent (5), determining the structure and devising a synthesis (6) for this dihydroxylated derivative of coumarol, the latter responsible for the fragrance of freshly mowed grass. Dicoumarol quickly found use in controlling blood clotting and led to the synthesis of brodifacoum, a highly potent anticoagulant and widely used rodenticide (See *Brodifacoum*) (7). **Target(s):** aldehyde oxidase (8); ATP phospho-ribosyltransferase, *Escherichia coli*,  $K_d$  of  $50 \mu\text{M}$  (9); azoreductase (10,11); brefeldin-A-dependent ADP-ribosylation (12,13); carbonyl reductase (14);  $\gamma$ -carboxylation of glutamyl residues (15); cellulose biosynthesis (53); cholestanetriol 26-monooxygenase, weakly inhibited (54); cytochrome P450 (17); dihydroliipoamide dehydrogenase (18); electron transport (2); ferricyanide reductase (19); gap junctions (20); glutathione peroxidase (21); glutathione *S*-transferase (16,21,22); hyaluronidase (23); 15-ketoprostaglandin  $\Delta^{13}$ -reductase (24); L-lactate oxidase (25); microtubule depolymerization (26); NADH dehydrogenase (4,27); NADH dehydrogenase, quinone-requiring (20,28,29); NADH-hexacyanoferrate(III) reductase (30); NADH-linked and NAD(P)H-linked nitro-reductases (31); NADPH dehydrogenase (32); NAD(P)H dehydrogenase, or DT diaphorase (20,27,29,32-39); NADPH-linked  $\alpha,\beta$ -ketoalkene double-bond reductase (40); nitrofurantoin reductase (41); 1-nitropyrene nitroreductase (42); nitroreductase (10,43); nuclear factor  $\kappa\text{B}$  (or, NF- $\kappa\text{B}$ ) (44); oxidative and photophosphorylation uncoupler (1-3,45); phospho-diesterase (46); quinone reductase (39); ribosyldihydro-nicotinamide dehydrogenase, quinone-requiring (55-58); rubredoxin:NAD<sup>+</sup> reductase (47); salicylhydroxamate reductase (48); steroid 11 $\beta$ -monooxygenase (49,50); thyroxine 5'-deiodinase (51,52). 1. #### 5,10-Dideazatetrahydrofolate

This folic acid analogue (FW = 442.45 g/mol), also known as lometrexol and 5,10-dideazatetrahydrofolic acid, inhibits purine biosynthesis and phosphoribosylglycinamide formyltransferase ( $K_i = 2-9 \text{ nM}$ ). The 6*S*-isomer also inhibits and is an alternative substrate for folylpolyglutamate synthetase. The di-, tri-, tetra-, penta- and hexaglutamate derivatives are stronger inhibitors of phosphoribosylglycinamide formyltransferase (e.g.,  $K_i = 0.1-0.3 \text{ nM}$  for (6*R*)-5,10-dideazatetrahydrofolate hexaglutamate).

**Target(s):** 10-formyltetrahydrofolate dehydrogenase (1); phosphoribosylaminoimidazole carboxamide formyltransferase (2-4); phosphoribosyl-glycinamide formyltransferase, or GAR transformylase (4-13); tetrahydrofolate synthetase (14). 1. #### (Z)-4',5'-Didehydro-5'-deoxy-5'-fluoroadenosine

This adenosine nucleoside derivative (FW = 267.22 g/mol), also known as MDL-28842, is an irreversible inhibitor of *S*-adenosylhomocysteinase, an enzyme that converts *S*-adenosylhomocysteine, a potent endogenous inhibitor of *S*-adenosylmethionine-mediated methyltransferase reactions, to adenosine and *L*-homocysteine. MDL 28,842 suppressed the proliferation of all cells in a dose-dependent manner, and significantly increased keratinocyte differentiation at a concentration of  $1 \mu\text{M}$ . Following incubation with MDL 28,842, the methylation indices (ratio of *S*-adenosylmethionine/*S*-adenosylhomocysteine) of undifferentiated keratinocytes and squamous cell carcinoma lines were significantly decreased. Such findings demonstrate that the inhibitory effect of MDL 28842 on squamous carcinoma cells and keratinocyte proliferation may result from inhibition of *S*-adenosylhomocysteine hydrolase activity. The antiproliferative activity of MDL 28,842 against squamous carcinoma cells and keratinocytes suggests a potential role for MDL 28,842 as a novel therapeutic agent for neoplastic and hyperproliferative disorders of the skin. The (*E*)-isomer is also an inhibitor, albeit less effective. 1. Mehdi, Jarvi, Koehl, McCarthy & Bey (1990) *J. Enzyme Inhib.* **4**, 1. 2. ### Didemnins

Didemnin A, R = H-

Didemnin B, R = CH<sub>2</sub>CHOHCO-N<img alt="piperidine ring" data-bbox="340 350 370 390"/>-C(=O)-

Didemnin C, R = CH<sub>2</sub>CHOHCO-

These depsipeptides from a species of tunicate *Trididemnum* exhibit potent cytostatic and immunosuppressive effects commending them as antineoplastic agent. They inhibit protein and DNA biosynthesis and are uncompetitive inhibitors of palmitoyl protein thioesterase (1). Protein biosynthesis is inhibited at the elongation stage. The main agents are Didemnin A (FW = 943.19 g/mol), Didemnin B (FW = 1112.37 g/mol), and Didemnin C (FW = 1015.26 g/mol). All three have low solubility in water but are soluble in ethanol and chloroform. **Target(s):** DNA biosynthesis (1); palmitoyl-[protein] hydrolase (2,3); protein biosynthesis (1,4,5). 1. Li, Timmins, Wallace, *et al.* (1984) *Cancer Lett.* **23**, 279. 2. Linder (2001) *The Enzymes*, 3rd ed., **21**, 215. 3. Meng, Sin & Crews (1998) *Biochemistry* **37**, 10488. 4. ### 2',3'-Dideoxyadenosine

This dideoxynucleoside (FW = 235.25 g/mol; CAS 4097-22-7; *Symbol*: ddA) is converted metabolically to 2',3'-dideoxyadenosine 5'-triphosphate, and the latter exhibits antiviral activity and inhibits bacterial DNA synthesis, both by terminating polydeoxynucleotide elongation (1) (**See also** 2',3'-Dideoxyadenosine 5'-Triphosphate). The 5'-triphosphate is also a potent inhibitor of viral reverse transcriptases. **Target(s):** adenosyl-homocysteinase, or S-adenosylhomocysteinase, weakly inhibited (2,3); deoxycytidine kinase (4); duck hepatitis virus replication (5); HIV-1 replication (6); HIV-2 replication (7); human T-lymphotropic virus type III, or HTLV-III/lymphadenopathy-associated virus (6); 5' nucleotidases (8); rhodopsin kinase (9); RNA-directed DNA polymerase (10); simian acquired immunodeficiency syndrome-associated type D retrovirus reverse transcriptase (10). 1. ### 2',3'-Dideoxyadenosine 5'-Triphosphate

This dideoxynucleotide (FW = 475.19 g/mol; *Symbol*: ddATP) is a strong inhibitor of viral reverse transcriptase (*e.g.*, HIV-1 reverse transcriptase has a *K<sub>i</sub>* value of 0.22 μM and an *IC<sub>50</sub>* value of 0.083 μM). This dATP analogue is also used in the dideoxy DNA sequencing method innovated by Nobel Laureate Frederick Sanger. **Target(s):** DNA-directed DNA polymerase (1-5); DNA nucleotidyltransferase, or terminal deoxynucleotidyltransferase (6,7); DNA polymerase α, weakly inhibited (5); DNA polymerase (13); DNA primase (5); feline immunodeficiency virus reverse transcriptase (8,9); feline leukemia virus reverse transcriptase (9); HIV-1 reverse transcriptase (10-12); phenylalanyl-tRNA synthetase (13); poly(A) polymerase (14); simian immunodeficiency virus reverse transcriptase (15); ribonucleoside diphosphate reductase (16); RNA-directed DNA polymerase (8-12,15,17); RNA-directed RNA polymerase, weakly inhibited (18); visna virus reverse transcriptase (17). 1. ### 2',3'-Dideoxycytidine

This dideoxynucleoside (FW = 211.22 g/mol; CAS 7481-89-2; *Symbol*: ddC), also known as Zalcitabine, is converted metabolically to 2',3'-dideoxyadenosine 5'-triphosphate, and the latter inhibits viral reverse transcriptases. ddCTP will also induce apoptosis in glioblastoma cells. SLC28A1, the Na<sup>+</sup>-dependent nucleoside transporter selective for pyrimidine nucleosides and adenosine, also transports zalcitabine. **Target(s):** deoxycytidine kinase (1-3); deoxynucleoside kinase (1); DNA polymerases, viral, via the 5'-triphosphate (4); HIV-1 reverse transcriptase, via the 5'-triphosphate (4-8); human T lymphotropic virus type III, or HTLV-III/lymphadenopathy-associated virus (7); 5'-nucleotidase (9); RNA-directed DNA polymerase (4-8,10); simian acquired immunodeficiency syndrome-associated type D retrovirus reverse transcriptase (10); thymidine kinase (1). 1. Johansson, Van Rompay, Degrève, Balzarini & Karlsson (1999) *J. Biol. Chem.* **274**, 23814. 2. Datta, Shewach, Hurley, Mitchell & Fox (1989) *Biochemistry* **28**, 114. 3. **2',3'-Dideoxycytidine 5'-Triphosphate**

This deoxynucleotide analogue (FW<sub>free-acid</sub> = 451.16 g/mol; *Symbol*: ddCTP), which is formed by the transport and metabolic phosphorylation of Zalcitabine (See 2',3'-Dideoxycytidine), inhibits viral reverse transcriptases. This nucleotide is used in the dideoxy DNA sequencing method innovated by Nobel Laureate Frederick Sanger. **Target(s)**: DNA-directed DNA polymerase (1-4); DNA helicase (5); DNA nucleotidyltransferase, or terminal deoxy-nucleotidyltransferase (6,7); DNA polymerase  $\alpha$  (4); DNA primase (4); duck hepatitis B virus reverse transcriptase (8); HIV-1 reverse transcriptase (9-11); nucleoside-triphosphatase, alternative substrate (5); RNA-directed DNA polymerase (8-12); RNA directed RNA polymerase (13,14); Visna virus reverse transcriptase (12). 1. Sanger, Nicklen & Coulson (1977) *Proc. Natl. Acad. Sci. U.S.A.* **74**, 5463. 2. Brown & Wright (1995) *Meth. Enzymol.* **262**, 202. 3. Mentel, Kurek, Wegner, *et al.* (2000) *Med. Microbiol.  **$\beta$ -D-2',3'-Dideoxy-3'-fluoroguanosine**

This deoxynucleoside analogue (FW = 269.24 g/mol) is converted metabolically to 2',3'-dideoxy-3'-fluoroguanosine 5'-triphosphate, and the latter inhibits HIV-1 reverse transcriptase via its 5'-triphosphate, with profound antiviral action when administered in its orally bioavailable prodrug form, MIV-210. **Target(s)**: adenovirus DNA polymerase (1); hepatitis B virus DNA polymerase (2-4); HIV-1 reverse transcriptase (5); RNA-directed DNA polymerase (1-5). 1. Mentel, Kurek, Wegner, *et al.* (2000) *Med. Microbiol. Immunol.* **189**, 91. 2. Matthes, Reimer, von Janta-Lipinski, Meisel & Lehmann (1991) *Antimicrob. Agents Chemother.* **35**, 1254. 3. El Safadi, Vivet-Boudou & Marquet (2007) *Appl. Microbiol. Biotechnol.* **75**, 723.

**2',3'-Dideoxyguanosine**

This dideoxynucleoside (FW = 251.24 g/mol; CAS 85326-06-3; *Symbol*: ddG) is converted metabolically to 2',3'-dideoxyguanosine 5'-triphosphate, and the latter inhibits hepatitis B virus replication (1,2) and has anti-HIV activity. (See also 2',3'-Dideoxyguanosine 5'-Triphosphate) **Target(s)**: human T-lymphotropic virus type III (HTLV-III)/lymphadenopathy associated virus (3); 5'-nucleotidase4; ribozyme self-splicing, *Tetrahymena* (5). 1. Aoki-Sei, O'Brien, Ford, *et al.* (1991) *J. Infect. Dis.* **164**, 843. 2. Korba,

**2',3'-Dideoxyguanosine 5'-Triphosphate**

This dideoxy nucleotide (FW<sub>free-acid</sub> = 491.18 g/mol) *Symbol*: ddGTP) terminates DNA biosynthesis and inhibits reverse transcriptases. This dGTP analogue is also used in the dideoxy DNA chain-termination sequencing method innovated by Nobel Laureate Frederick Sanger. **Target(s)**: DNA-directed DNA polymerase (1-5); DNA nucleotidyltransferase, or terminal deoxynucleotidyltransferase (6,7); DNA polymerase, via chain termination (1,8); DNA polymerase  $\alpha$  (4); DNA polymerase  $\beta$  (2); DNA polymerase  $\gamma$  (2); duck hepatitis B virus reverse transcriptase (3,9); HIV-1 reverse transcriptase (2,10-14); mouse mammary tumor virus reverse transcriptase (15); RNA directed DNA polymerase (2,3,9-17); RNA-directed RNA polymerase (18,19); simian immunodeficiency virus (SIV) reverse transcriptase (12); telomerase (20-22); Ty1 reverse transcriptase (17); Visna virus reverse transcriptase (16). 1. **1,4-Dideoxy-1,4-imino-D-arabinitol**

This fructose analogue (FW = 133.15 g/mol), also known as 2-hydroxymethyl-3,4-dihydropyrrrolidine, first isolated from the fruits of *Angylocalyx boutiquenus*, is a strong inhibitor of liver glycogen phosphorylase ( $K_i \approx 0.4 \mu\text{M}$ ) and hence glycogenolysis. **Target(s)**:  $\alpha$ -glucosidase (1,2); glycogen phosphorylase (3-6); isomaltase (1); mannosyl oligosaccharide 1,2- $\alpha$ -mannosidase, or  $\alpha$ -mannosidase I (1,2); mannosyl-oligosaccharide 1,3-1,6- $\alpha$  mannosidase, or  $\alpha$ -mannosidase II (1,2); processing  $\alpha$ -glucosidase II, mannosyl-oligosaccharide glucosidase II (1,2); thioglucosidase, or myrosinase, or sinigrinase (7); trehalose (1,8). 1. ### 2,6-Dideoxy-2,6-imino-7-O-(β-D-glucopyranosyl)-D-glycero-L-gulo-heptitol

This sugar alcohol (FW = 355.34 g/mol), also known as 7-O-β-D-glucopyranosyl-α-homonojirimycin and MDL 25637, from *Lobelia sessilifolia* inhibits α-glucosidases. **Target(s):** α-amylase, weakly inhibited (1); glucan 1,3-α-glucosidase, or glucosidase II, or mannosyl-oligosaccharide glucosidase II (2-4); glucoamylase (1); α-glucosidase (1,5); isomaltase (1); lactase, weakly inhibited (1); maltase (1); mannosyl-oligosaccharide glucosidase I, weakly inhibited (4); sucrase (1); trehalose (1). 1. ### 2',3'-Dideoxyinosine

This dideoxy nucleoside analogue (FW = 236.23 g/mol; CAS 69655-05-6; *Symbol*: ddi; [2',3'-<sup>3</sup>H]-ddi; CAS 124516-24-1), also known as didanosine and sold under the trade names Videx and Videx EC, is metabolized to ddATP (*Likely Pathway*: ddi → ddIMP → ddAMP-Succinate → ddAMP → ddADP → ddATP), whereupon it inhibits viral reverse transcriptase by competing with natural dATP and acts as a chain terminator upon incorporation into DNA by viral reverse transcriptases. Approved for the treatment of HIV-AIDS by the Food and Drug Administration in 1991, didanosine became the first generic anti-HIV drug marketed in the U.S. **Target(s):** DNA polymerases, viral, by the 5'-triphosphate (1); HIV-1 reverse transcriptase, by the 5'-triphosphate (1-5); 5'-nucleotidase (6); RNA-directed DNA polymerase (1-5). 1. Wilson, Porter & Reardon (1996) *Meth. Enzymol.* **275**, 398. 2. Balzarini & De Clercq (1996) *Meth. Enzymol.* **275**, 472. 3. Mitsuya & Broder (1986) *Proc. Natl. Acad. Sci. U.S.A.* **83**, 1911. 4. Russell & Klunk (1989) *Biochem. Pharmacol.* **38**, 1385. 5. El Safadi, Vivet-Boudou & Marquet (2007) *Appl. Microbiol. Biotechnol.* **75**, 723. 6. Garvey, Lowen & Almond (1998) *Biochemistry* **37**, 9043.

### 2',3'-Dideoxyinosine 5'-Triphosphate

This dideoxy nucleotide (FW<sub>free-acid</sub> = 476.17 g/mol; FW<sub>TetraNaSalt</sub> = 564.09 g/mol; *Symbol*: ddITP), also known as didanosine 5'-triphosphate, inhibits viral reverse transcriptases. **Target(s):** HIV-1 reverse transcriptase (1-3); RNA-directed DNA polymerase (1-3). 1. Russell & Klunk (1989) *Biochem. Pharmacol.* **38**, 1385. 2. Wilson, Porter & Reardon (1996) *Meth. Enzymol.* **275**, 398. 3. El Safadi, Vivet-Boudou & Marquet (2007) *Appl. Microbiol. Biotechnol.* **75**, 723.

### 2',3'-Dideoxyuridine 5'-Triphosphate

This dideoxynucleotide (FW = 452.14 g/mol; *Symbol*: ddUTP) is a strong inhibitor of the HIV reverse transcriptase ( $K_i = 0.05 \mu\text{M}$ ) and the avian myeloblastosis virus enzyme ( $K_i = 1.0 \mu\text{M}$ ). However, the bacterial DNA polymerase I, mammalian DNA polymerase α, terminal deoxyribonucleotidyltransferase, and Moloney murine leukemia virus reverse transcriptase were resistant to ddUTP. 1. Hao, Cooney, Farquhar, *et al.* (1990) *Mol. Pharmacol.* **37**, 157. 2. Le Grice, C. E. Cameron & S. J. Benkovic (1995) *Meth. Enzymol.* **262**, 130. 3. De Clercq (1992) *AIDS Res. Human Retrovir.* **8**, 119.

### Dieldrin

This highly toxic pesticide (FW = 380.91 g/mol), once a widely used against a range of insects, targets the GABA<sub>A</sub> receptor-chloride ion channel complex. The initial transient component of the chloride current was blocked more than the late sustained component, resulting in unbalanced sodium accumulation. Action on GABA-mediated processes is thought to result in hyperexcitation of the nervous system, a finding that fits with the well-known convulsant action of this agent. From 1950 to 1974, dieldrin was widely used to control insects threatening cotton, corn and citrus crops. It was also used to control locusts and mosquitoes as well as to preserve wood, especially as a long-lasting agent for termite control. Dieldrin's high fat solubility allows it to become concentrated in the food chain. Its remarkable chemical stability accounts for its extremely low rate of biological turnover, a property that poses a challenge for bioremediation. Owing to its harmful effects on humans, fish, and wildlife, most uses of dieldrin were banned in 1987 U.S., where it is no longer produced. The EPA now classifies dieldrin as a persistent, bioaccumulative, and toxic pollutant. **Target(s):** ATPase (1,2); Ca<sup>2+</sup>-transporting ATPase (3,4); chitin synthase (5); Cl<sup>-</sup> uptake, γ-aminobutyrate-dependent (6-10); F<sub>1</sub>F<sub>0</sub> ATPase (2); lactate dehydrogenase (11). 1. **3 $\beta$ -(2-Diethylaminoethoxy)androst-5-en-17-one**

This synthetic steroid (FW<sub>free-base</sub> = 387.61 g/mol), also known as U-18666A, inhibits cholesterol biosynthesis. Subcutaneous injections occasionally result in the development of irreversible nuclear cataracts. For more information on the cholesterol synthesis inhibiting properties of U18666A and the role of sterol metabolism and trafficking in numerous pathophysiological processes, see (1). **Target(s):** cholesterol biosynthesis (1-5); cholesterol  $\Delta$ -isomerase, or sterol  $\Delta^{7,8}$ -isomerase (6,7); cholesterol transport (8,9); cycloartenol synthase (10); 2,3-oxidosqualene cyclase (5,11); sterol 24-C methyltransferase (K<sub>i</sub> = 14.8  $\mu$ M (12); sterol  $\Delta^{24}$ -reductase (13). 1. **Diethylcarbamazine**

This substituted piperazine (FW<sub>free-base</sub> = 199.30 g/mol), also known as *N,N*-diethyl-4-methyl-1-piperazinecarboxamide, is frequently used to treat individuals infected with filarial parasites. It reportedly interferes with arachidonate metabolism of filarial parasites and host. **Target(s):** acetylcholinesterase (1,2); catalase (3); Ca<sup>2+</sup>-transporting ATPase (4); glutathione peroxidase (3); leukotriene-A<sub>4</sub> synthase, or 5-lipoxygenase (5,6); leukotriene-C<sub>4</sub> synthase (7,8); Na<sup>+</sup>/K<sup>+</sup> exchanging ATPase (4); tubulin polymerization, or microtubule assembly (9). 1. ***N,N*-Diethyl-3-methylbenzamide**

This widely used insect repellent (FW = 191.27 g/mol; CAS 134-62-3; Physical State: slightly yellow oil, with a density of 0.998 g/mL), also known as *N,N*-diethyl-*m*-toluamide (the name giving rise to its famous abbreviation, "DEET") is directly sensed in mosquitoes by DEET-detecting olfactory receptor neurons, or ORNs (1). It is also highly effective against chiggers, fleas, leeches, ticks, and other biting insects. Earlier work had suggested DEET modulates the physiological response of lactic acid-sensitive ORNs in the antennae of the yellow fever mosquito (*Aedes aegypti*), leading to the idea that DEET interferes with and/or inhibits olfactory responses to an attractive, naturally occurring chemical signal (2). Jamming the olfactory system had been supported by behavioral observations indicating that lactic acid is a mosquito attractant and that DEET inhibits attraction to lactic acid (4, 5). DEET's reported attenuation of mosquito response to 1-octen-3-ol, a volatile substance present in human sweat and breath, also supported the earlier conclusion (6). The work of Syed & Leal (1), however, demonstrated that DEET itself is detected by specific ORNs situated on antennae of *Cx quinquefasciatus*, that DEET induces avoidance in sugar-seeking male and female mosquitoes, and that DEET also causes reduced landing of females in the vicinity of an attractive, warm, and black surface. Such findings support the conclusion that mosquitoes smell and avoid DEET (1). Intriguingly, DEET was originally isolated from the female Pink Bollworm Moth (*Pectinophora gossypiella*), suggesting a role in warding off suitors and/or predators. *Note:* DEET content in commercial repellents varies from 4-100% (weight/weight). While higher concentrations are no more effective, they remain effective over a longer duration. Depending upon the period of outdoor activity, products having lower DEET content may require reapplication. The U.S. Centers for Disease Control and Prevention recommends using products with 30-50% DEET to prevent the spread of pathogens carried by DEET-sensitive insects. 1. Syed & Leal (2008) *Proc. Natl. ### O,O-Diethyl O-(p-Nitrophenyl) Phosphate

This toxic phosphotriester (FW = 275.20 g/mol; CAS 311-45-5; Oily liquid; Soluble in organic solvents; Moderate water solubility (2.4 mg/mL at 25°C), also called Paraoxon and E600, is an acetylcholinesterase inhibitor that has found wide use as an insecticide. This enzyme is inhibited via phosphorylation of an active-site seryl residue. Paraoxon is a substrate for several lactonases, named paraoxonases (PON's), for lack of information on their natural substrates. PON-1 is synthesized in the liver and transported to the plasma, where it prevents LDL oxidation; PON-2 is expressed ubiquitously and protect cells against cytosolic oxidative damage; and PON3 is similar to PON-1, but is not regulated by inflammation or levels of oxidized LDL. **Target(s):** acetylcholinesterase (1-14); acetylsalicylate deacetylase (15); acylaminoacyl peptidase (16); acylglycerol lipase, or monoacylglycerol lipase (17-20); alkylamidase (21); amidase (22); arylformamidase (23-25); bis(2-ethylhexyl)phthalate esterase (26); butyryl esterase (27); carboxylesterase (1,19,28-43); cholinesterase, or butyrylcholinesterase (1,3,44-49); chymotrypsin (1,50,51; however, see also ref. 52); cutinase (53-55); diacylglycerol lipase (20); fatty acid amide hydrolase, or anandamide amidohydrolase (18);  $\beta$ -glucosidase (56); hormone-sensitive lipase (57,58); juvenile hormone esterase (59-64); lipase, or triacylglycerol lipase (20,65-77,93); lipoprotein lipase (67,68,78); phosphatidylcholine acyltransferase (79); phospholipase A<sub>2</sub> (80,81); phospholipase B, *Penicillium notatum* (82); sialate O-acetyl esterase (83-88); sinapine esterase (89); sterol esterase, or cholesterol esterase (90,91); tropinesterase (92); trypsin (1). 1. ### Diethyl Pyrocarbonate

This highly reactive reagent (FW = 162.14 g/mol; CAS 1609-47-8), also known as ethoxyformic anhydride and diethyl dicarbonate, is frequently used to ethoxyformylate proteins. DEPC is an especially effective inactivator of enzymes requiring a catalytic histidyl residue. The classical example is ribonuclease, with which it reacts to block catalysis totally. **Chemical Stability:** Aqueous solutions of have a short half-life ( $t_{1/2}$  = 7 min at pH 7 (25°C);  $t_{1/2}$  = 24 min at pH 6). The presence of Tris buffer accelerates decomposition ( $t_{1/2}$  = 1.25 min at pH 7.5 in the presence of Tris;  $t_{1/2}$  decreases at higher pH). Therefore, solutions should always be freshly prepared from a tightly sealed reagent bottle. **Histidine Modification & Reactivation:** The N-carboethoxyhistidyl product absorbs ultraviolet light at 240 nm ( $\Delta\epsilon$  = 3200 M<sup>-1</sup>cm<sup>-1</sup>) and is moderately unstable ( $t_{1/2}$  = 55 hours at pH 7; shorter under acidic or alkaline conditions). Note that the diethyl pyrocarbonate is hydrolyzed in aqueous solutions to ethanol and carbonic acid with a half-life of about 25 minutes at neutral pH. Modification of histidyl residues is preferred at acid pH values. DEPC-inactivated enzymes often undergo reactivation upon treatment with neutral hydroxylamine. **Reactivity with Other Residues:** Diethyl pyrocarbonate also reacts with tyrosyl residues, amino groups, and occasionally sulfhydryl groups. Reversal of amino and sulfhydryl group modification does not occur with hydroxylamine. Reaction with tyrosyl residues results in a decrease in absorbance at 278 nm. Because this reagent is slowly hydrolyzed in water, solutions should be freshly prepared. **DEPC-Treated Water/Buffers:** Water or buffer (limited to buffer salts that are both heat-stable solutes and that do not react with DEPC) is treated with by addition of DEPC to yield a final

concentration of 0.1% (vol/vol) for at least 2 hours at 37 °C, before the solution is autoclaved (> 15 min) to inactivate any traces of DEPC that remain. Although the resulting solution is now RNase-free, it is easily recontaminated (by experimenter lacking gloves and face masks), especially by microbe-labeled aerosols, or tiny droplets of spittle, or by using untreated plastic and glass labware has not been treated with DEPC. **Procedure for Minimizing RNA Degradation:** Given its remarkable stability and high isoelectric point (pI = 12.8), ribonuclease is stable, sticky and positively charged; such properties that allow it to bind firmly to borosilicate glassware that it can degrade RNA during isolation from various cells/tissues. For this reason, glassware must be treated with 0.1% (wt/vol) DEPC, after which the glassware should be extensively washed with ribonuclease-free water to remove all traces of DEPC. **CAUTION:** Care should be exercised in its handling since concentrated solutions can be irritating to skin, eyes, and mucous membranes. Note that DEPC will decompose to carbon dioxide and ethanol; cases of spontaneous hazardous chemical explosions of unopened bottles of diethyl pyrocarbonate have been reported. 1. ### Diethylstilbestrol

This synthetic estrogen and endocrine-disrupting agent (FW = 268.36 g/mol; CAS 6898-97-1; Insoluble in water; Soluble in ethanol; M.P. = 169-172°C), also known as stilbestrol and 4,4'-[1(E)-1,2-diethyl-1,2-ethenediyl]bisphenol, and abbreviated DES, is a nonsteroidal agent that was once widely used in estrogen therapy as well as an antineoplastic hormone. Even so, the Food and Drug Administration in the U.S. published warnings about the use of diethylstilbestrol by pregnant women in 1971, recognizing it as a perinatal carcinogen that led to clear cell adenocarcinoma in women and experimental animals. Diethylstilbestrol was also used as a growth promoter in livestock. Exposure during critical periods of differentiation permanently alters the programming of estrogen target tissues, resulting in benign and malignant abnormalities in the reproductive tract later in life. **Note:** Although the term "stilbestrol" is frequently used as a synonym for diethylstilbestrol, stilbestrol technically refers to 4,4'-dihydroxystilbene. **Target(s):** A<sub>1</sub> ATPase (1,2); aldehyde dehydrogenase (3-5); aldose 1-epimerase, or mutarotase (6-8); anion-activated ATPase (9); apyrase (10); arylamine N-acetyltransferase (11); ATP-ADPase (12); ATPases (e.g., H<sup>+</sup>-transporting ATPase) (9,13-25); Ca<sup>2+</sup> channels (26); Ca<sup>2+</sup>-transporting ATPase (27); cortisyl sulfotransferase (28-30); DNA topoisomerase I (31); dTMP kinase (32); electron transport (33); estrogen-2/4-hydroxylase (34); estrogen 2-monooxygenase (35); estrone sulfatase (36); estrone sulfotransferase (37); F<sub>0</sub>F<sub>1</sub> ATPase, or ATP synthase, or H<sup>+</sup>-transporting two-sector ATPase (38-40); glutamate dehydrogenase (41-45); 3α-hydroxysteroid dehydrogenase (46); 3(or 17)β-hydroxysteroid dehydrogenase (46-51); 17β-hydroxysteroid dehydrogenase (50,52); kainate-induced currents (53); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (39,54); Na<sup>+</sup>-transporting two-sector ATPase (55); oxaloacetate decarboxylase, Na<sup>+</sup>-pumping (56); pyruvate kinase (57); RNA polymerase II (58); steroid N-acetylglucosaminyltransferase (59); steroid Δ-isomerase (60); testosterone 17β-dehydrogenase (46); tubulin polymerization, or microtubule assembly (61-65). 1. ### DIF-3

This photosensitive ketone (FW = 272.73 g/mol), also known as 1-(3-chloro-2,6-dihydroxy-4-methoxyphenyl)-1-hexanone and differentiation-inducing factor 3, was first observed in the slime mold *Dictyostelium discoideum* and inhibits the cell cycle by inducing arrest at the G<sub>0</sub>/G<sub>1</sub> transition. DIF-3 suppresses cyclin D<sub>1</sub> expression and activates [glycogen synthase] kinase-3β. 1. Masento, Morris, Taylor, et al. (1988) *Biochem. J.* **256**, 23. 2. Morris, Masento, Taylor, Jermyn & Kay (1988) *Biochem. J.* **249**, 903.

### Difloxacin

This oral fluoroquinolone-class antibiotic (FW<sub>free-base</sub> = 399.40 g/mol; CAS 98106-17-3 (free base) and 91296-86-5 (HCl salt)), also named 6-fluoro-1-(4-fluorophenyl)-7-(4-methylpiperazin-1-yl)-4-oxoquinoline-3-carboxylate, is a broad-spectrum agent that targets DNA Topoisomerase Type II (gyrase), an enzyme required for bacterial replication and transcription. **Pharmacokinetics:** Difloxacin is rapidly and nearly fully absorbed after oral administration, with ~50% is bound to circulating plasma proteins. It is metabolized primarily by the liver through glucuronidation and secreted in the bile. Mean value of the peak plasma concentration, C<sub>max</sub> = 1.8 µg/mL; Time to reach peak plasma concentration, t<sub>max</sub> = 2.8 hours; elimination half-life, t<sub>1/2</sub> = 9.3 hours; Area under the curve = 14.5 µg·hr/mL; Total body clearance rate = 375 mL/kg/hour; Steady-state volume of Distribution = 3.8 L/kg. **Antibiotic Spectrum:** Most intestinal pathogens are sensitive (1). *Acinetobacter*, *Pseudomonas aeruginosa*, and other *Pseudomonas* species (except *Pseudomonas maltophilia*) are usually sensitive. (Ciprofloxacin is more active against these organisms.) Difloxacin displays antistaphylococcal activity. Against streptococci, including enterococci and pneumococci, the its activity is moderate or poor. *Haemophilus influenzae* and *Branhamella catarrhalis* are very sensitive, as are gonococci and meningococci. Activity against *Chlamydia trachomatis* and mycoplasmas is borderline. Organisms associated with nonspecific vaginal infection are not very sensitive. (For the prototypical member of this antibiotic class, See Ciprofloxacin) 1. Phillips & King (1988) *Rev. Infect. Dis.* **10** (Supplement 1), S70.

### Diflunisal

This potent anti-inflammatory analgesic agent (FW<sub>free-acid</sub> = 250.20 g/mol; CAS 22494-42-4), also known as 5-(2',4'-difluorophenyl)salicylic acid, inhibits prostaglandin biosynthesis. **Target(s):** catechol sulfotransferase (1); cathepsin G (2); Ca<sup>2+</sup>-transporting ATPase (3); GABA<sub>A</sub> receptor (4,5); lyso-platelet activating factor:acetyl-CoA acetyltransferase (6); medium-chain fatty-acyl-CoA synthetase, or butyryl-CoA synthetase, or butyrate:CoA ligase (7-9); oxidative phosphorylation, as an uncoupler (10); phenol sulfotransferase (1); prostaglandin synthase, or cyclooxygenase-2 and -1 (11-14); UDP-glucuronosyltransferase (15,16). 1. Vietri, De Santi, Pietrabissa, Mosca & Pacifici (2000) *Eur. J. Clin. Pharmacol.* **56**, 81. 2. Lentini, Ternai & Ghosh (1987) *Biochem. Int.* **15**, 1069. 3. Holguin (1988) *Biochem. ### 3-(2,6-Difluorobenzamido)-5-(4-ethoxyphenyl) thiophene-2-carboxylic acid

This synthetic probe (FW = 403.39 g/mol), first identified by high throughput screening, inhibits *Escherichia coli* UT189 bacterial capsule biogenesis, with an IC<sub>50</sub> value of 4.5 µM and a greater than 10x selectivity index, demonstrating its worthiness as a lead for developing highly effective therapeutic agents against community-acquired infections caused by uropathogenic *E. coli* (UPEC) (1). This probe should promote further studies on K capsule formation. 1. Noah, Ananthan, Evans, *et al.* (2012) Probe Reports from the NIH Molecular Libraries Program, National Center for Biotechnology Information (U.S.), PMID: 23762949.

### 2,2-Difluoro-5-hexyne-1,4-diamine

This mechanism-based inhibitor (FW<sub>free-base</sub> = 148.16 g/mol), also known as 1,4-diamino-2,2-difluoro-5-hexyne and 3,6-diamino-5,5-difluoro 1-hexyne, inactivates mammalian ornithine decarboxylase, K<sub>i</sub> = 10 µM and k<sub>inact</sub> = 0.29 min<sup>-1</sup> (1). In rats, it produces a rapid, long-lasting, and dose-dependent decrease of ornithine decarboxylase activity in the ventral prostate, testis, and thymus. In contrast with 5-hexyne-1,4-diamine (2), 2,2-difluoro-5-hexyne-1,4-diamine is not a substrate of mitochondrial monoamine oxidase. 1. Kendrick, Danzin & Kolb (1989) *J. Med. Chem.* **32**, 170. 2. Danzin, Casara, Claverie & Grove (1983) *Biochem. Pharmacol.* **32**, 941.

### [(3S,4S)-1,1-Difluoro-3-(hexadecanoylamino)-4-hydroxy-4-phenylbutyl]phosphonate

This sphingomyelin analogue (FW<sub>free-acid</sub> = 518.60 g/mol) inhibits both neutral and acidic sphingomyelinase (IC<sub>50</sub> = 3.3 µM for the bovine neutral enzyme). Magnesium-dependent neutral sphingomyelinase (N-SMase) present in plasma membranes is an enzyme that can be activated by stress in the form of inflammatory cytokines, serum deprivation, and hypoxia. As key component of these signaling pathways, N-SMase inhibition is an important strategy to prevent neuron death from ischemia. 1. Soeda, Tsuji, Ochiai, *et al.* (2004) *Neurochem. Int.* **45**, 619.

### 1-(3,5-Difluoro-4-hydroxybenzyl)-1H-imidazole-2-thiol

This potent multisubstrate geometric inhibitor (FW = 206.27 g/mol) targets dopamine β-monooxygenase (K<sub>i</sub> = 39 nM). By incorporating a phenethylamine substrate mimic and an oxygen mimic into a single molecule, this inhibitor exhibit both the kinetic properties and the potency expected for multisubstrate inhibitors. Steady-state kinetic experiments with such inhibitors supports the proposed pH-dependent changes in substrate binding order (2) and a mechanism whereby the inhibitor binds specifically to the reduced Cu<sup>I</sup> form of enzyme at both the phenethylamine substrate site and the active-site copper atom(s). Yonetani-Theorell double-inhibition analysis indicates mutually exclusive binding of the inhibitor substructures p-cresol and 1-methylimidazole-2-thiol, suggesting an extremely short inter-site distance between the phenethylamine binding site and the active-site copper ion(s) (1). 1. Kruse, DeWolf, Chambers & Googhart (1986) *Biochemistry* **25**, 7271. 2. Ahn & Klinman (1983) *Biochemistry* **22**, 3106.

**cis-(1,1-Difluoro-2-[2-(hypoxanthin-9-ylmethyl)-tetrahydropyranos-3-yl]ethyl-phosphonate**

This nucleotide analogue (FW = 378.27 g/mol), also known as Yokomatsu compound, inhibits purine-nucleoside phosphorylase ( $K_i = 2.7$  nM). 1. Iwanow, Magnowska, Yokomatsu, Shibuya & Bzowska (2003) *Nucleosides Nucleotides Nucleic Acids* **22**, 1567. 2. Glavas-Obrovac, Suver, Hikishima, Yokomatsu & Bzowska (2007) *Nucleosides Nucleotides Nucleic Acids* **26**, 989.

**$\alpha$ -(Difluoromethyl)arginine**

This arginine derivative (FW = 224.21 g/mol) irreversibly inactivates arginine decarboxylase. 1. Bey, Casara, Vevrt & Metcalf (1983) *Meth. Enzymol.* **94**, 199. 2. Bitonti, Casara, McCann & Bey (1987) *Biochem. J.* **242**, 69. 3. Kallio, McCann & Bey (1981) *Biochemistry* **20**, 3163. 4. Kierszenbaum, Wirth, McCann & Sjoerdsma (1987) *Proc. Natl. Acad. Sci. Mol. Biol.* **45**, 383.

**$\alpha$ -(Difluoromethyl)ornithine**

This anticancer agent and antiparasitic drug (FW = 182.17 g/mol; CAS 70052-12-9; Symbol: DFMO), also known as Eflornithine, acts as a specific and mechanism-based irreversible inhibitor of ornithine decarboxylase, the rate-limiting enzyme in polyamine biosynthesis. The L-enantiomer has the lower  $K_d$  value of 1.3  $\mu$ M versus 28.3  $\mu$ M for the D-isomer; however, the  $k_{inact}$  values are roughly identical). It inhibits B16 melanoma-induced angiogenesis *in ovo* and proliferation of vascular endothelial cells *in vitro*. It is also effective against African trypanosomiasis. **Target(s):** lysine decarboxylase (1,2); ornithine decarboxylase (2-15); protein-glutamine  $\gamma$ -glutamyl-transferase, or transglutaminase (16). 1. Takatsuka, Onoda, Sugiyama, *et al.* (1999) *Biosci. Biotechnol. Biochem.* **63**, 1063. 2. Lee & Cho (2001) *Biochem. J.* **360**, 657. 3. Steven, Williams, Warne & Tucker (1989) *J. **N-[N-(3,5-Difluorophenacetyl)]-L-alanyl]-3-(S)-amino-1-methyl-5-phenyl-1,3-dihydro-benzo[e](1,4)-diazepin-2-one**

This peptidyl benzodiazepinone (FW = 490.51 g/mol), also known as  $\gamma$ -Secretase Inhibitor XVIII and Compound E, is a strong noncompetitive inhibitor of  $\gamma$ -secretase ( $IC_{50}$  for  $A\beta_{total} = 300$  pM). Because this compound possesses a hydroxyethylene dipeptide isostere of aspartyl protease transition state analogues, potent inhibition indicates that  $\gamma$ -secretase may be an aspartyl protease. 1. Seiffert, Bradley, Rominger, *et al.* (2000) *J. Biol. Chem.* **275**, 34086. 2. Tian, Sobotka-Briner, Zysk, *et al.* (2002) *J. Biol. Chem.* **277**, 31499.

**N-[N-(3,5-Difluorophenacetyl)]-L-alanyl-(S)-phenyl-glycine Methyl Ester**

This cell-permeable dipeptide, also known as  $\gamma$ -secretase inhibitor XVI and DAPM (FW = 390.39 g/mol), inhibits  $\gamma$ -secretase ( $IC_{50}$   $A\beta \sim 10$  nM in 7PA2 cells). It is also reported to block the formation of amyloid- $\beta$  dimers and trimers. Such naturally secreted oligomers of amyloid beta protein potently inhibit hippocampal long-term potentiation *in vivo*. Importantly, treatment of cells with  $\gamma$ -secretase inhibitors prevents oligomer formation at doses that allow appreciable monomer production, and such medium no longer disrupts LTP, indicating synaptotoxic  $A\beta$  oligomers can be targeted therapeutically. 1. Walsh, Klyubin, Fadeeva, *et al.* (2002) *Nature* **416**, 535.

**N-((S)-2-[[5-(2,4-Difluorophenyl)-2-[(phosphonomethyl)amino]pent-4-ynoyl]]-L-leucyl-L-alanine**

This arylacetylene-containing agent (FW = 491.43 g/mol) is a strong inhibitor of endothelin-converting enzyme 1, or ECE-1 ( $IC_{50} = 8$  nM) and a weak inhibitor of neprilysin ( $IC_{50} = 5.8$   $\mu$ M). The final step in the posttranslational processing of Endothelin-1 (ET-1), the most potent peptidic vasoconstrictor to date, is the conversion of its precursor by ECE-1, a metalloprotease displaying high sequence identity with neutral endopeptidase 24.11 (NEP), especially at the catalytic center. This inhibitor potently blocks ET-1 production *in vivo*, as demonstrated by the big ET-1-induced pressor response in rats. 1. Wallace, Moliterni, Moskal, *et al.* (1998) *J. Med. Chem.* **41**, 1513.

**N-({4-[Difluoro(phosphono)methyl]phenyl}acetyl)-L-aspartyl-4-[difluoro-(phosphono)-methyl]-L-phenylalaninamide**

This cell-impermeable phosphonate (FW = 658.41 g/mol) is a strong inhibitor of human protein-tyrosine phosphatase 1B ( $K_i = 2.4$  nM). A cell-permeable analogue is reported in which the terminal amide is linked to  $-CH_2CH_2-S-S-CH_2CH_2-NH-(D-Arg)_8-NH_2$ . The disulfide is then reductively cleaved upon entry into the cytoplasm. 1. Liang, Lee, J. Liang, Lawrence & Zhang (2005) *J. Biol. Chem.* **280**, 24857. 2. Zhang (2003) *Acc. Chem. Res.* **36**, 385. 3. Lee, Xie, Luo, *et al.* (2006) *Biochemistry* **45**, 234.

**Difluoropine**

This tropane-derived dopamine reuptake inhibitor (FW = 401.45 g/mol; CAS 156774-35-5), also known as O-620 and systematically named methyl (1*S*,2*S*,3*S*,5*R*)-3-[bis(4-fluorophenyl)methoxy]-8-methyl-8-aza-bicyclo[3.2.1]octane-2-carboxylate, ( $IC_{50} = 11$  nM) and selective ligand for the dopamine transporter. 1. Meltzer, Liang & Madras (1994) *J. Med. Chem.* **37**, 2001.

**Difluorotoluene  $\beta$ -D-ribose C-glycoside**

This nonpolar thymidine isostere (FW = 244.24 g/mol; Symbol: F) is an efficient alternative substrate for many DNA polymerases, replacing thymine and coding specifically for A:T base-pairing (1,2). Its triphosphate is thus a thymidine triphosphate shape analogue lacking Watson-Crick pairing ability but is nonetheless replicated with high sequence selectivity (1-3). The apparent efficiency of insertion of A opposite F is only  $\sim 4x$  lower than that opposite T. In addition, the selectivity for insertion of A rather than C, T, or G is surprisingly similar. With dT in the template, A is preferred by 3.0–4.5 log units versus the other three bases, and with F in the template, A is preferred by 2.9–4.2 log units. These data indicate that the energetic barrier leading to the newly synthesized A–F base pair is within 0.9 kcal of that for the A–T pair. Such observations suggest that conventional hydrogen bonds may not be necessary for the high efficiency and fidelity of DNA synthesis and that shape complementarity can play a more significant role in fidelity than previously appreciated. 1. Liu, Moran & Kool (1997) *Chem. Biol.* **4**, 919. 2. Guckian, Krugh & Kool (1998)

*Nature Struct. Biol.* **5**, 954. 3. Kool & Sintim (2006) *Chem. Commun.* (Cambridge) **35**, 3665.

**cyclic-di-GMP**

This rotationally symmetrical cyclic 5'-GMP diester (FW<sub>di-Na</sub> = 734.38 g/mol; CAS 61093-23-0; Soluble to 20 mM in water), also known as bis-(3'-5')-cyclic dimeric guanosine monophosphate, is an intracellular and intercellular signaling molecule in prokaryotes (1). In mammals, c-di-GMP is recognized by the direct innate immune sensor known as Stimulator of Interferon Genes (or STING), thereby initiating production of type I interferons through the TBK1/IRF3 axis (1,2). Upon infection with intracellular pathogens, STING induces type I interferon production, protecting infected cells and nearby cells from local infection by binding to the same cell that secretes it (via autocrine signaling) as well as nearby cells (via paracrine signaling.) The helicase DDX41 may play a role in the recognition of c-di-GMP upstream of STING (3). Intranasal c-di-GMP-adjuvanted plant-derived H5 influenza vaccine induces multifunctional Th1 CD4<sup>+</sup> cells and strong mucosal and systemic antibody responses in mice. 1. **Digitonin**

This toxic steroid saponin (FW = 1229.33 g/mol; CAS 11024-24-1) from the foxglove *Digitalis purpurea* preferentially binds  $3\beta$ -sterol, commending its use in (a) cholesterol determinations, (b) receptor solubilization, and (c) peripheral membrane permeabilization. For the latter, one typically be by working in the 55-75  $\mu$ M range. Note that the term digitonin has also been used to refer to a mixture of four steroid saponins of *Digitalis purpurea* of which the above steroid glycoside is the major component, necessitating care when purchasing digitonin. **Target(s):**  $\alpha$ -N-acetylneuraminatase  $\alpha$ -2,8-sialyltransferase, activated at lower concentrations (1); [ $\beta$ -adrenergic-receptor] kinase (2,3); carnitine *O*-palmitoyltransferase (4); diacylglycerol:sterol *O*-acyltransferase (5); flavonoid 3',5'-hydroxylase (26); galactolipase (6); 1,3- $\beta$  glucan synthase (7); glucomannan 4- $\beta$ -mannosyltransferase, weakly inhibited (8);  $\beta$ -glucosidase (9); glucuronosyltransferase (10); glyceryl-ether monoxygenase (11); 3-hydroxy-3-methylglutaryl-CoA reductase12; lipase, or triacylglycerol lipase (13); mRNA (guanine-*N*<sup>7</sup>-)-methyltransferase (14); NADH dehydrogenase (15); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (16,17); 2,3-oxidosqualene-lanosterol cyclase (18); P glycoprotein (19); prenylated-protein carboxyl methyltransferase (20); rhodopsin kinase (21,22); squalene epoxidase (18); sterol *O*-acyltransferase, or cholesterol *O*-acyltransferase, or ACAT (23-25); xenobiotic transporting ATPase, multidrug-resistance protein (19). 1. ### Digitoxin

This cardiotonic glycoside (FW = 764.95 g/mol; CAS 71-63-6), a secondary glycoside from the leaves of *Digitalis purpurea* and *D. lanata*, inhibits  $H^+/K^+$ -exchanging ATPase (1) and the  $Na^+/K^+$ -exchanging ATPase (2-9). **1.** Modyanov, Pestov, Adams, *et al.* (2003) *Ann. N. Y. Acad. Sci.* **986**, 183. **2.** Forbush & Hoffman (1979) *Biochim. Biophys. Acta* **555**, 299. **3.** Contreras, Flores-Maldonado, Lazaro, *et al.* (2004) *J. Membr. Biol.* **198**, 147. **4.** Albers, Koval & Siegel (1968) *Mol. Pharmacol.* **4**, 324. **5.** Sastry & Phillis (1977) *Can. J. Physiol. Pharmacol.* **55**, 170. **6.** Gubitz, Aker & Brody (1977) *Biochim. Biophys. Acta* **459**, 263. **7.** Erdmann (1978) *Arzneimittelforschung* **28**, 531. **8.** Brown & Erdmann (1984) *Arzneimittelforschung* **34**, 1314. **9.** Balzan, D'Urso, Ghione, Martinelli & Montali (2000) *Life Sci.* **67**, 1921.

### Digoxigenin

This less-soluble digoxin aglycone (FW = 390.52 g/mol; CAS 1672-46-4) inhibits the  $Na^+/K^+$ -exchanging ATPase. Because anti-digoxigenin antibodies exhibit both high affinity and high specificity, digoxigenin has found wide use as a tag for immunolocalization and ELISA assays. **1.** Balzan, D'Urso, Ghione, Martinelli & Montali (2000) *Life Sci.* **67**, 1921. **2.** Senn, Lelievre, Braquet & Garay (1988) *Brit. J. Pharmacol.* **93**, 803. **3.** Ahmed, Rohrer, Fullerton, *et al.* (1983) *J. Biol. Chem.* **258**, 8092.

### Digoxin

This cardiotonic glycoside (FW = 780.95 g/mol; CAS 20830-75-5), a secondary glycoside from the leaves of foxglove (*Digitalis purpurea*), inhibits  $H^+/K^+$ -exchanging ATPase (1) and  $Na^+/K^+$ -exchanging ATPase (2-7). **Mechanism of Action:** Digoxin inhibits  $Na^+,K^+$ -ATPase, increasing intracellular sodium ion concentration and thereby stimulating  $Na^+ \rightleftharpoons Ca^{2+}$  exchange and increasing the intracellular  $Ca^{2+}$  concentration. Digoxin's beneficial pharmacologic effects relate to its direct actions on cardiac muscle and its indirect actions on the cardiovascular system via effects on the autonomic nervous system. The pharmacologic consequences of these direct and indirect effects are: (a) its *positive inotropic effect* – increased force and velocity of myocardial systolic contractions, (b) its *neurohormonal deactivating effect* – decreased activation of the sympathetic nervous system and renin-angiotensin system, and (c) its *vagomimetic effect* – reduced heart rate and an decreased conduction velocity through the AV node. Digoxin's beneficial effects in treating heart failure are mediated by its positive inotropic and neurohormonal deactivating effects, whereas its effects in atrial arrhythmias are linked to its vagomimetic actions. **Action as HIF-1 $\alpha$  Protein Inhibitor:** Digoxin was identified as an inhibitor of Hypoxia-Inducible Factor-1 $\alpha$  (HIF-1 $\alpha$ ) protein translation and HIF-2 $\alpha$  mRNA expression in a cell-based screen of a library of drugs (at 100 nM in the case of A) in clinical trials (8). Notably, digoxin prolongs tumor latency and inhibits tumor xenograft growth in mice, when treatment is initiated before subcutaneous implantation of P493-Myc, P493-Myc-Luc, PC3, and Hep3B cells. It also arrests tumor growth, when treatment is initiated after the establishment of PC3 and P493-Myc tumor xenografts. Digoxin inhibits the expression of HIF-1 $\alpha$  protein and the HIF-1 target genes *VEGF*, *GLUT1*, *HK1*, and *HK2*; and (iv) does not effectively inhibit the growth of xenografts derived from transfected cells with enforced HIF-1 $\alpha$  expression. Therapeutic plasma concentrations of digoxin in cardiac patients (10–30 nM) are somewhat lower than the concentration required for maximal inhibition of HIF-1 $\alpha$  expression in hypoxic cancer cells after 24 h of drug treatment; however, effective inhibition at lower concentrations might be observed after more prolonged exposure of cells to the drug. (See also *Proscillaridan A*; *Oabain*). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** Modyanov, Pestov, Adams, *et al.* (2003) *Ann. N. Y. Acad. Sci.* **986**, 183. **2.** Ruoho & Kyte (1977) *Meth. ### Dihydroasparagusic Acid

Dihydroasparagusic Acid

Asparagusic Acid

This sulfur-containing odorant (FW = 152.22 g/mol) is the reduced form of asparagusic acid. It is a radical-scavenging antioxidant that also competitively inhibits tyrosinase, a copper-containing enzyme involved in melanogenesis and food browning (1). When added to asparagus mitochondria, asparagusic and dihydroasparagusic acids strongly stimulate pyruvate oxidation, whereas  $\alpha$ -lipoic acid was only slightly activating (2). Such results suggest that asparagusic acids may play essential roles in the pyruvate oxidation of asparagus. 1. Venditti, Mandrone, Serrilli, *et al.* (2013) *J. Agric. Food Chem.* **61**, 6848. 2. Yanagawa, Kato & Kitahara (1973) *Plant Cell Physiol.* **14**, 1213.

### 7,8-Dihydrobiopterin

This oxidized folate (FW = 239.23 g/mol; CAS 6779-87-9) inhibits dihydropterin aldolase (1); GTP cyclohydrolase I (2-4); tryptophan 5-monooxygenase (5), and tyrosine 3-monooxygenase (6). 1. Deng, Callender & Dale (2000) *J. Biol. Chem.* **275**, 30139. 2. Shen, Alam & Zhang (1988) *Biochim. Biophys. Acta* **965**, 9. 3. Blau & Niedewieser (1986) *Biochim. Biophys. Acta* **880**, 26. 4. ### Dihydrofolate

This folic acid derivative (FW<sub>free-acid</sub> = 443.42 g/mol; CAS 4033-27-6; Slowly oxidized in air, particularly in alkaline pH; 0.3 M 2-mercaptoethanol protects against decomposition), also known as 7,8-dihydropteroyl-L-glutamate, inhibits folate-dependent reactions. **Target(s):** amidophosphoribosyltransferase, inhibited by dihydrofolate polyglutamates (1); arylamine *N*-acetyltransferase (2); deoxycytidylate 5-hydroxy-methyltransferase (3); dihydropterin aldolase (4); dihydropteroyl synthase (5,6); folic acid polyglutamate synthetase (7); glutathione synthetase (8); GTP cyclohydrolase I (9; however reference 10 indicates no such inhibition); methenyl-tetrahydrofolate cyclohydrolase (11); *N*<sup>5</sup>,*N*<sup>10</sup> methenyl-tetrahydrofolate synthetase, *K*<sub>i</sub> = 50  $\mu$ M (12,13); methylene-tetrahydrofolate reductase, NADPH (14); phosphoribosyl-aminimidazolecarboxamide formyltransferase, or AICAR transformase, weakly inhibited (15); serine hydroxymethyl-transferase, or glycine hydroxymethyltransferase; partial inhibitor (16). 1. **Dihydrofolate Hexaglutamate, See Dihydropteroyl Hexaglutamate**

**Dihydrofolate Pentaglutamate, See Dihydropteroyl Pentaglutamate**

### Dihydrokainate

This glutamic acid analogue (FW = 215.25 g/mol) inhibits high-affinity [<sup>3</sup>H]-L-glutamate transport into synaptosomes and blocks the binding of radioligands to the NMDA (N-methyl-D-aspartate), KA (kainate), and QA (quisqualate) glutamate neurotransmitter receptor sites. 1. Bridges, Stanley, Anderson, Cotman & Chamberlin (1991) *J. Med. Chem.* **34**, 71. 2. Pocock, Murphie & Nicholls (1988) *J. Neurochem.* **50**, 745. 3. Koch, Kavanaugh, Esslinger, *et al.* (1999) *Mol. Pharmacol.* **56**, 1095.

### $\alpha$ -Dihydrolipoate

This dithiol form of the acyl-transfer (FW = 208.35 g/mol; p*K*<sub>a</sub> of 4.76 at 25°C (COOH group); Redox potential = -0.29 V (pH 7)), also called 6,8-thioctic acid (reduced), is a redox coenzyme  $\alpha$ -(*R*)-lipoic acid that is found covalently attached to the  $\epsilon$ -amino group of lysyl residues of transacetylases (subunits of  $\alpha$ -ketoacid dehydrogenase complexes), thereby permitting processive acyl transfer as a swinging arm akin to that of carboxybiocytin. *R*-stereoisomer is the naturally occurring form. **Target(s):** prostaglandin-endoperoxide synthase, or cyclooxygenase (1); [pyruvate dehydrogenase (acetyl-transferring)] kinase (2); stearyl-CoA 9-desaturase (3); thiosulfate sulfurtransferase, rhodanese (4,5). 1. Ohki, Ogino, Yamamoto, *et al.* (1977) *Proc. Natl. Acad. Sci. U.S.A.* **74**, 144. 2. Korotchkina, Sidhu & Patel (2004) *Free Radic. Res.* **38**, 1083. 3. Fulco & Bloch (1964) *J. Biol. ### 1,4-Dihydro-3-nitrophenanthrolin-4-one-8-carboxylate

This phenanthroline (FW<sub>free-acid</sub> = 273.20 g/mol) is an Fe(II/III) chelator that inhibits chick procollagen-proline 4-dioxygenase, or prolyl 4-hydroxylase (IC<sub>50</sub> = 38 nM), thereby commending its use to control excessive collagen deposition in pathological fibrosis by continuously blocking collagen hydroxylation and allowing intracellular proteolysis to reduce excess collagen. 1. Franklin, Morris, Edwards, Large & Stephenson (2001) *Biochem. J.* **353**, 333.

### (*S*)-Dihydroorotate

This pyrimidine nucleotide biosynthesis intermediate (FW<sub>free-acid</sub> = 158.11 g/mol) inhibits barbiturase (1), carbamoyl-phosphate synthetase (2), dihydropyrimidinase, or hydantoinase (3), orotate phosphoribosyltransferase (4), and 5-oxoprolinase (5). 1. Soong, Ogawa, Sakuradani & Shimizu (2002) *J. Biol. Chem.* **277**, 7051. 2. Potvin & Gooder (1975) *Biochem. Genet.* **13**, 125. 3. Lee, Cowling, Sander & Pettigrew (1986) *Arch. Biochem. **20 $\alpha$ -Dihydroprogesterone**

This naturally occurring progestagen (FW = 316.48 g/mol), also known as 20 $\alpha$ -hydroxypregn-4-en-3-one, is a functionally important progesterone metabolite, exhibiting 0.2-0.3 the potency of progesterone. **Target(s):** cholesterol acyltransferase, or ACAT (1); 17 $\beta$ -hydroxysteroid dihydrogenase (2); progesterone 5 $\alpha$ -reductase (3); steroid 17 $\alpha$ -monooxygenase, or steroid C17/20-lyase, or CYP17A1 (4,5). 1. Chang & Doolittle (1983) *The Enzymes*, 3rd ed., **16**, 523. 2. Blomquist, Lindemann & Hakanson (1984) *Steroids* **43**, 571. 3. Kinoshita (1981) *Endocrinol. Jpn.* **28**, 499. 4. Huang, Kominami & Takemori (1993) *Sci. China B* **36**, 411. 5. Betz & Tsai (1979) *J. Steroid Biochem.* **10**, 39.

**Dihydropteroyl Hexaglutamate**

This polyglutamylated dihydrofolate (FW<sub>free-acid</sub> = 1089.00 g/mol) inhibits methylenetetrahydrofolate reductase (NADPH),  $K_i$  = 13 nM (1-3) and thymidylate synthase (4). 1. Matthews (1986) *Meth. Enzymol.* **122**, 372. 2. Matthews & Daubner (1982) *Adv. Enzyme Regul.* **20**, 123. 3. Matthews & Baugh (1980) *Biochemistry* **19**, 2040. 4. Kisliuk, Gaumont & Baugh (1974) *J. Biol. Chem.* **249**, 4100.

**Dihydropteroyl Pentaglutamate**

This polyglutamylated 7,8-dihydrofolate analogue (FW<sub>free-acid</sub> = 959.88 g/mol) targets amidophosphoribosyltransferase (1),  $N^5,N^{10}$ -methylenetetrahydrofolate synthetase, or 5-formyltetrahydrofolate cyclo-ligase;  $K_i$  = 3.8  $\mu$ M (2,3), and phosphoribosylamino-imidazole carboxamide formyl-

transferase, or AICAR transformase (4-6). 1. Schoettle, Crisp, Szabados & Christopherson (1997) *Biochemistry* **36**, 6377. 2. Jolivet (1997) *Meth. Enzymol.* **281**, 162. 3. Acad. Sci. U.S.A.* **82**, 4881. 6. Sugita, Aya, Ueno, Ishizuka & Kawashima (1997) *J. Biochem.* **122**, 309.

**Dihydropyridine Ca<sup>2+</sup> Channel Blockers**

These antihypertensive agents, which all contain a dihydropyridine nucleus, reduce systemic vascular resistance and arterial pressure in the treatment of angina and tachycardia (1). While the vasodilatory action of Ca<sup>2+</sup> entry blockers is due primarily to slow Ca<sup>2+</sup> channel inhibition, some DHP-class blockers have additional actions contributing to vasodilation. For example, nifedipine and four related blockers selectively inhibit peak I phosphodiesterase activity (IC<sub>50</sub> = 2-3  $\mu$ M), but are weak inhibitors of peak II phosphodiesterase (IC<sub>50</sub>  $\geq$  100  $\mu$ M) (2). DHP Calcium Entry Blockers include: Amlodipine (Norvasc<sup>®</sup>); Aranidipine (Sapresta<sup>®</sup>); Azelnidipine (Calblock<sup>®</sup>); Barnidipine (HypoCa<sup>®</sup>); Benidipine (Coniel<sup>®</sup>); Cilnidipine (Atelec<sup>®</sup>, Cinalong<sup>®</sup>, and Siscard<sup>®</sup>); Clevidipine (Cleviprex<sup>®</sup>), Isradipine (DynaCirc<sup>®</sup> and Prescal<sup>®</sup>); Efonidipine (Landel<sup>®</sup>); Felodipine (Plendil<sup>®</sup>); Lacidipine (Motens<sup>®</sup> and Lacipil<sup>®</sup>); Lercanidipine (Zanidip<sup>®</sup>); Manidipine (Calslot<sup>®</sup> and Madipine<sup>®</sup>); Nicardipine (Cardene<sup>®</sup> and Carden SR<sup>®</sup>); Nifedipine (Procardia<sup>®</sup> and Adalat<sup>®</sup>); Niltvadipine (Nivadil<sup>®</sup>); Nimodipine (Nimotop<sup>®</sup>); Nisoldipine (Baymycard<sup>®</sup>, Sular<sup>®</sup>, and Sycor<sup>®</sup>); Nitrendipine (Cardif<sup>®</sup>, Nitrepin<sup>®</sup>, and Baylotensin<sup>®</sup>), Pranidipine (Acalas<sup>®</sup>). 1. Takahashi & Ogura (1983) *FEBS Lett.* **152**, 191. 2. Norman, Ansell & Phillips (1983) *Eur. J. Pharmacol.* **93**, 107.

**DL-threo-Dihydroshingosine**

The D-enantiomer of this long-chain amino-diol (FW<sub>free-base</sub> = 301.51 g/mol) targets sphingosine kinase. The L-enantiomer (safingol) potentiates the effect of doxorubicin, inhibits protein kinase C (IC<sub>50</sub> = 37.5  $\mu$ M), and inhibits the release of leukotriene B<sub>4</sub>. **Target(s):** [myosin light-chain] kinase (1); protein kinase C (2-6); sphinganine kinase, or sphingosine kinase (7-16). 1. Jinsart, Ternai & Polya (1991) *Plant Sci.* **78**, 165. 2. Hoffmann, Leenen, Hafner, et al. (2002) *Anticancer Drugs* **13**, 93. 3. Jarvis & Grant (1999) *Invest. New Drugs* **17**, 227. 4. **Dihydrostreptomycin**

This semisynthetic antibiotic (FW<sub>free-base</sub> = 583.60 g/mol) inhibits protein biosynthesis. **Target(s):** alcohol dehydrogenase, yeast (1); cysteine desulfhydrase, or cystathionine  $\gamma$ -lyase (2); diamine oxidase (3,4); F<sub>1</sub>

ATPase (5); mechano-electric transduction channel (16); oxidative phosphorylation (5,7); protein biosynthesis (8-10); protein-synthesizing GTPase, elongation factor (10); proton conduction by  $F_0$  (5); streptomycin 6-kinase (11); threonine deaminase (12). 1. ### 5,6-Dihydrouridine

This reduced form of uridine (FW = 246.22 g/mol;  $\lambda_{\max}$  = 235 nm;  $\epsilon$  = 10100 M<sup>-1</sup>cm<sup>-1</sup>), also known as 1- $\beta$ -D-ribofuranosyl-5,6-dihydrouracil and symbolized by D, is a component in the dihydrouridine stem-loop region of transfer RNA (tRNA). **Target(s)**: cytidine deaminase (1-8); UDP-N-acetylglucosamine diphosphorylase, or N-acetylglucosamine-1-phosphate uridylyltransferase (9). 1. Frick, Yang, Martinez & Wolfenden (1989) *Biochemistry* **28**, 9423. 2. Wentworth & Wolfenden (1978) *Meth. Enzymol.* **51**, 401. 3. ### 1,3-Dihydroxyacetone

This three-carbon metabolite (FW = 90.079 g/mol; Abbreviation: DHA), also known as glycerone and 1,3-dihydroxy-2-propanone, is the simplest ketose. It is frequently supplied as the solid dimer, 2,5-dihydroxydioxane-2,5-dimethanol (FW = 180.16 g/mol; melting point = 75-80°C), which is rapidly converted to dihydroxyacetone in aqueous solutions. **Target(s)**: N-acetylneuraminase (1); glutamine:fructose-6-phosphate aminotransferase (isomerizing), weakly inhibited (2); ribose-5-phosphate isomerase, or phosphopentoisomerase (3,4). 1. Aisaka, Igarashi, Yamaguchi & Uwajima (1991) *Biochem. J.* **276**, 541. 2. Kikuchi, Ikeda & Tsuiji (1972) *Biochim. Biophys. Acta* **289**, 303. 3. ### Dihydroxyacetone Phosphate

This triose-phosphate metabolite (FW<sub>free-acid</sub> = 170.06 g/mol; pK<sub>a</sub> values of 1.77 and 6.45; Abbreviated: DHAP), also known as glycerone phosphate, is an intermediate in glycolysis, gluconeogenesis, and photosynthetic CO<sub>2</sub> fixation. DHAP is unstable in alkaline conditions: complete hydrolysis occurs in twenty minutes in 1 M alkali at room temperature while 50% hydrolysis occurs in eight minutes in 1 M HCl at 100°C. Solutions should

be freshly prepared; however, solutions can be frozen for a few days at pH 4.5. **Target(s)**: carboxypeptidase A (1); formate C-acetyltransferase, or pyruvate formate-lyase (2 5); glucose-6-phosphate isomerase (6); glutamine:fructose-6-phosphate aminotransferase (isomerizing), weakly inhibited (7); glycerol-3-phosphate O-acetyltransferase (8-10); hexokinase (11); inositol-3-phosphate synthase, inositol-1-phosphate synthase, K<sub>i</sub> = 700  $\mu$ M at pH 7.2 (12);  $\alpha$ -ketoaldehyde dehydrogenase (NADP<sup>+</sup>) (13); L-lactate dehydrogenase (14); phosphoenolpyruvate carboxykinase (ATP) (15); 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase (16-20); ribose-5-phosphate isomerase, or phosphopentoisomerase (21,22); starch (bacterial glycogen) synthase, weakly inhibited (23). 1. ### 6',7'-Dihydroxybergamottin

This psoralin (FW = 372.42 g/mol; CAS 145414-76-2), a component of grapefruit juice, inhibits aryl sulfotransferase, or phenol sulfotransferase (1); CYP1A2 (2), CYP3A4 (2-6), CYP1B1 (5), CYP2C9 (6), and CYP2D6 (6). Irreversible inhibition of CYP3A4 by 6',7'-dihydroxybergamottin and bergamottin accounts for the low turnover of some HMG-CoA inhibitors. 1. Nishimuta, Ohtani, Tsujimoto, et al. (2007) *Biopharm. ### (2S,3R)-Dihydroxybutyramide 4-Phosphate

This deoxyxylulose 5-phosphate (DXP) analogue (FW<sub>free-acid</sub> = 215.10 g/mol) inhibits *Synechocystis* 1-deoxy-D-xylulose-5-phosphate reductoisomerase, K<sub>i</sub> = 90  $\mu$ M, acting as a relatively weak competitive inhibitor when compared to fosmidomycin. 1. Phaosiri & Proteau (2004) *Bioorg. Med. Chem. Lett.* **14**, 5309.

### 5-(3 $\alpha$ ,12 $\alpha$ -Dihydroxy-5 $\beta$ -cholanamido)-1,3,4-thiadiazole-2-sulfonamide

This sulfonamide (FW = 544.78 g/mol) inhibits rainbow trout (*Oncorhynchus mykiss*) erythrocyte carbonic anhydrase,  $IC_{50}$  = 0.83  $\mu$ M. Human carbonic anhydrase II is inhibited with  $IC_{50}$  = 93 nM. 1. Bülbul, Hisar, Beydemir, Çiftçi & Küfrevioğlu (2003) *J. Enzyme Inhib. Med. Chem.* **18**, 371. 2. Bülbul, Saraçoğlu, Küfrevioğlu & Çiftçi (2002) *Bioorg. Med. Chem.* **10**, 2561.

### Dihydrodeoxymorphine

This fast-acting opioid (FW = 271.36 g/mol; CAS 427-00-9; IUPAC: 4,5-epoxy-17-methylmorphinan-3-ol; also known as Desomorphine, Permonid, and by its street name, "Krokodil") is a easily synthesized morphine derivative possessing 8-10x more sedative and analgesic potency. There is no accepted medical use for desomorphine in the U.S., where it has been classified as a controlled substance since 1936. Krokodil is a crude (and hence dangerous) preparation used recreationally. 1. "Desomorphine" (October, 2013) Office of Diversion Control Drug & Chemical Evaluation Section, U.S. Drug Enforcement Administration.

### 7,8-Dihydroxyflavone

This redox-active flavone (FW = 254.24 g/mol; CAS 38183-03-8; M.P. = 243-246°C), inhibits DT diaphorase, aromatase, and NADH dehydrogenase. **Target(s):** amine sulfotransferase, weakly inhibited (1); aromatase, or CYP19 (2,3); NADH dehydrogenase, or Complex I (4); NAD(P)H dehydrogenase (quinone), or DT diaphorase (5,6); phenol sulfotransferase (1); ribosyldihydrocinotinicamide dehydrogenase (quinone), weakly inhibited (7). 1. Harris, Wood, Bottomley, et al. (2004) *J. Clin. Endocrinol. Metab.* **89**, 1779. 2. Kao, Zhou, Sherman, Laughton & Chen (1998) *Environ. Health Perspect.* **106**, 85. 3. (1997) *Arch. Biochem. Biophys.* **347**, 221.

### Dihydroxyfumarate

This fumarate derivative (FW<sub>free-acid</sub> = 148.07 g/mol; CAS 133-38-0; M.P. = 156°C) slowly autoxidizes at pH 6 and this oxidation is accelerated in the

presence of metal ions such as Mn<sup>2+</sup> and Cu<sup>2+</sup>. Hydrogen peroxide, superoxide, and hydroxyl radicals are generated during the oxidation of dihydroxyfumarate by peroxidase (1,2). Dihydroxyfumarate should be stored in a desiccator in the cold (3). **Target(s):** glycerol dehydrogenase (4); lactoylglutathione lyase (glyoxalase I), however, the structure provided in the reference is for dihydroxymaleic acid (5); L-tartrate dehydrogenase/D-malate dehydrogenase (decarboxylating) (6). 1. Pellmar & Lepinski (1992) *Brain Res.* **569**, 189. 2. Halliwell (1977) *Biochem. J.* **163**, 441. 3. Hartree (1953) *Biochem. Prep.* **3**, 56. 4. Johnson, Levine & Lin (1985) *J. ### 3,4-Dihydroxyhydrocinnamate

This acid (FW<sub>free-acid</sub> = 182.18 g/mol), also known as 3-(3,4-dihydroxyphenyl)propionic acid and dihydrocaffeic acid, inhibits:  $\alpha$ -amylase, weakly inhibited (1); aromatic-amino-acid decarboxylase, or dopa decarboxylase (2);  $\gamma$ -butyrobetaine dioxygenase, or  $\gamma$ -butyrobetaine hydroxylase,  $K_i$  = 20  $\mu$ M (3); 3,4 dihydroxyphenylacetate 2,3-dioxygenase (4); hyoscyamine (6S)-dioxygenase (5); phenylalanine ammonia-lyase (6,7); phenylalanine 4-monooxygenase,  $IC_{50}$  = 0.24 mM (8); procollagen-proline 4-dioxygenase (9,10); protococatechuate 3,4-dioxygenase (11); protococatechuate 4,5-dioxygenase (12). 1. ### 2,5-Di(hydroxymethyl)-3S,4R-dihydroxypyrrolidine

This pyrrolidine alkaloid (FW<sub>free-base</sub> = 163.17 g/mol), first isolated from the plant *Lonchocarpus sericeus*, inhibits glycoprotein processing. **Target(s):**  $\alpha$ -glucosidase (1,2);  $\beta$ -glucosidase (1,3); glycoprotein processing (1,4,5); mannosyl oligosaccharide glucosidase, or glucosidase I (2,4-6); sucrose synthase (7); thioglucosidase, or myrosinase, or sinigrinase (8); trehalose

### Dehydroxymethylepoxyquinomicin

This synthetic NF- $\kappa$ B nuclear translocation inhibitor and anti-inflammatory agent (FW = 261.23 g/mol; CAS 287194-40-5; *Abbreviations*: DHMEQ and (-)-DHMEQ) inhibits tumor necrosis factor- $\alpha$  (TNF- $\alpha$ )- and 12-*O*-tetradecanoylphorbol-13-acetate-induced transcriptional activity of NF- $\kappa$ B in human T cell leukemia Jurkat cells (1). It also inhibits TNF- $\alpha$ -induced DNA binding of nuclear NF- $\kappa$ B, but not phosphorylation and degradation of I- $\kappa$ B (1). DHMEQ likewise inhibits the TNF- $\alpha$ -induced nuclear accumulation of p65, a component of NF- $\kappa$ B (1). In terms of its ability to promote tumor cell apoptosis and cell-cycle arrest, DHMEQ inhibited the steady-state transcriptional activity of NF- $\kappa$ B in all hepatoma cells (2). DHMEQ blocked the constitutive DNA-binding activity and TNF- $\alpha$ -mediated nuclear translocation of NF- $\kappa$ B in Huh-7 cells. DHMEQ (5-20  $\mu$ g/mL) dose-dependently reduced the viable cell number of all hepatoma cells. DHMEQ (20  $\mu$ g/mL) induced apoptosis in all hepatoma cells, especially in Hep3B cells, and cell-cycle arrest in Huh-7 and HepG2 cells. These effects were accompanied by downregulation of proteins involved in anti-apoptosis (*e.g.*, Bcl-xL, XIAP or c-IAP2) and cell-cycle progression (*e.g.*, cyclin D<sub>1</sub>), and induction of proteins involved in pro-apoptosis (*e.g.*, Bax) and cell-cycle retardation (*e.g.*, p21Waf1/Cip1). **Chemical Considerations**: DHMEQ's target protein is p65 (and other Rel homology proteins), making a covalent bond with a thiol of a p65 cysteinyl residue by an unusual *N*- $\rightarrow$ O acyl shift (3,4). Although the hydroxyl group at the 2-position of the benzamide moiety is essential for the inhibitory activity, etherification of this group did not diminish the activity completely, suggesting it would be an allowable linker or biotin site (5). **Target(s)**: enhances antitumor activity of taxanes in anaplastic thyroid cancer cells (6); suppresses growth and Type-I collagen accumulation in keloid fibroblasts (7); inhibition of active HIV-1 replication (8). 1. Ariga, Namekawa, Matsumoto, Inoue & Umezawa (2002) *J. Biol. Chem.* **277**, 24625. 2. Nishimura, Ishikawa & Matsumoto, *et al.* (2006) *Int. J. Oncol.* **29**, 713. 3. ### 3,4-Dihydroxyphenylacetate

This catechol (FW<sub>free-acid</sub> = 168.15 g/mol), also known as homoprotocatechuic acid and often abbreviated dopac, is a dopamine metabolite. **Target(s)**: aldehyde oxidase, weakly inhibited (1); aromatic-amino-acid decarboxylase, *or* dopa decarboxylase (2);  $\gamma$ -butyrobetaine dioxygenase, *or*  $\gamma$ -butyrobetaine hydroxylase,  $K_i$  = 13  $\mu$ M (3); dimethylaniline monooxygenase (4); glutamate decarboxylase (5); homogentisate 1,2 dioxygenase (6); 4-hydroxyphenylacetate 1-monooxygenase,  $K_i$  = 43  $\mu$ M (4); 4-hydroxyphenylpyruvate dioxygenase (7); hyoscyamine (6S)-dioxygenase (8); imidazoleacetate 4 monooxygenase (9); indoleamine *N*-methyltransferase (10); phenol sulfotransferase, *or* aryl sulfotransferase (11); procollagen-proline 4-dioxygenase (12,13); protocatechuate 3,4-dioxygenase (14-16); protocatechuate 4,5-dioxygenase (17); tyrosine aminotransferase (18,19). 1. ### 2,6-Dihydroxytetrahydropyran-2,6-dicarboxylate

This tetrahydrodipicolinate dicarboxylic acid (FW<sub>free-acid</sub> = 206.15 g/mol) is a competitive inhibitor of 2,3,4,5-tetrahydropyridine-2,6-dicarboxylate *N*-succinyltransferase. The monohydroxy derivative has a  $K_{is}$  value of 58 nM. Based on the observed inhibition kinetics, the authors suggest a stereochemical model for the succinylation of tetrahydrodipicolinate dicarboxylic acid, *or* THDPA: a, the succinylase binds THDPA (in the L-configuration); b, imine hydration follows to yield 2-hydroxypiperidine-2,6-dicarboxylic acid in which the two carboxyl groups are trans; c, succinylation then occurs, attended by ring opening to give the acyclic product. 2-Hydroxytetrahydropyran-2,6-dicarboxylic acid is viewed as a transition state analogue that resembles the hydrated intermediate. 1. Berges, DeWolf, Dunn, *et al.* (1986) *J. Biol. Chem.* **261**, 6160.

### 3,3'-Diindolylmethane

This secondary metabolite (FW = 248.31 g/mol; CAS 1968-05-4; *Symbol*: DIM), also known as 3-(1*H*-Indol-3-ylmethyl)-1*H*-indole and 3,3'-methylene-bis-1*H*-indole, is formed during the digestion of indole-3-carbinol, a metabolite in cruciferous vegetables (*Brassica* genus), including broccoli, Brussels sprouts, and cabbage. DIM suppresses lipopolysaccharide induced expression of inducible nitric oxide synthase and cyclooxygenase-2 in BV-2 microglia (1). DIM also attenuates the DNA-binding activity of the inflammatory transcription factor NF- $\kappa$ B. Such results suggest that DIM may have beneficial potential against brain inflammation and neurodegenerative diseases through the negative regulation of the NF- $\kappa$ B signal pathway in microglia (1). DIM also exerts a potent cytostatic effect in cultured human Ishikawa endometrial cancer cells by inducing the level of TGF- $\alpha$  transcripts by approximately 4x within 24 h of treatment (2). **Target(s)**: trout cytochrome P450 (CYP) 1A-dependent ethoxyresorufin *O*-deethylase, potent noncompetitive inhibitor with low-micromolar  $K_i$  (3); down-regulation of pro-survival pathway in hormone independent prostate cancer (4); pure androgen receptor antagonist in humans (5). 1. Chem.* **278**, 21136.

### 3,5-Diiodo-L-tyrosine

This metabolite (FW = 525.08 g/mol; *Abbreviation*: T<sub>2</sub>), an intermediate in the biosynthesis of the thyroid hormones, stimulates oxygen consumption and mitochondrial respiration. **Target(s)**: aspartate aminotransferase, mildly inhibited (1); cAMP-dependent protein kinase (2); GABA<sub>A</sub> receptors (3); protein-disulfide isomerase (4); thyroxine 5-deiodinase (5); thyroxine 5' deiodinase (5,7). 1. ### 3,5-Diiodo-L-tyrosine

This halogenated tyrosine (FW = 432.98 g/mol), also known as iodogorgic acid and often abbreviated by DIT, is a product of enzyme-catalyzed post-translational modification of thyroglobulin in the pathway for formation of tri- and tetra-iodothyronines (1-4). It has also been reported in proteins isolated from corals, sponges, and other marine organisms, perhaps as a way to detoxify iodide present in oceans and waterways. DIT has pK<sub>a</sub> values of 2.12, 6.48, and 7.82 at 25°C (another source lists 2.12, 5.32, and 9.48). The L-stereoisomer forms needles, when recrystallized from water or 70% ethanol. (Racemic DIT recrystallizes as double wedges from 70% ethanol and rectangular plates from water). The L-enantiomer also decomposes at 213°C, while 3,5-iodo-DL-tyrosine has a decomposition temperature of about 200°C. The specific optical rotation is +2.89° at 20°C of the D-line for 0.246 g of the L-isomer in 5 g of 4% HCl (+2.27° for 0.227 g in 5 g of 25% NH<sub>3</sub>). The λ<sub>max</sub> is 310 nm (ε = 5920 M<sup>-1</sup>cm<sup>-1</sup>) in 40 mM KOH and 285 nm (ε = 2730 M<sup>-1</sup>cm<sup>-1</sup>) in 40 mM HCl. The solubility of the L-isomer in water is 0.617 g/L at 25°C (1.862 g/L at 50°C) whereas, for the racemic mixture the values are 0.340 g/L at 25°C and 0.773 g/L at 50°C. The L isomer forms a gelatinous precipitate upon prolonged boiling in dilute ethanol. Such a precipitate is not observed with the racemic mixture. Note: This amino acid is unstable in light (with loss of iodine) and should always be stored in the dark. Deiodination also occurs upon protein hydrolysis. 3,5-Diodotyrosine acts as an alternative substrate for a number of enzymes. These include thyroid peroxidase, lactoperoxidase, thyroid-hormone aminotransferase, and NADPH:ferredoxin reductase. **Target(s)**: 3'5'-cyclicAMP phosphodiesterase (5); iodide transport (6); protein-disulfide isomerase (7); tyrosine 3-monooxygenase (8); tyrosine transport (9). 1. **Dilantin, See 5,5-Diphenylhydantoin**

### Diltiazem

This slow calcium channel blocker (FW = 414.52 g/mol; CAS 42399-41-7), also known by the code name CRD-401, trade names Cardizem<sup>®</sup> and Tiazac<sup>®</sup>, and IUPAC Name *cis*-(+)-[2-(2-dimethylaminoethyl)-5-(4-

methoxyphenyl)-3-oxo-6-thia-2-azabicyclo[5.4.0]undeca-7,9,11-trien-4-yl]ethanoate, is a non-dihydropyridine (*or* non-DHP) vasodilator that is indicated for the treatment of hypertension, angina pectoris, and some arrhythmias (1,2). Diltiazem relaxes the smooth muscles in the walls of arteries, dilating them and thereby promoting blood flow and lowering blood pressure. It also acts on the heart itself, reducing the rate, strength, and conduction speed of each contraction. In these respects, diltiazem exerts negative inotropic, chronotropic, as well as dromotropic effects. **Mechanism of Action**: When infused continuously into the canine renal artery, CRD-401 increased the urine flow and sodium excretion as well as renal blood flow in all the conditions of fluid loading tested (1). The glomerular filtration rate was enhanced under saline loading but not under water diuresis (1). At 1 μg/mL, diltiazem lowers the level of action potential plateau and shortened the duration in both ventricular and Purkinje fibers without change in maximum rate of rise (V<sub>max</sub>) or resting potential (3). Contractile tension of ventricular muscle is also markedly decreased with shortening of plateau. Diltiazem causes a dose-dependent inhibition of contractions as well as Ca<sup>2+</sup> influx stimulated by α-adrenoceptor activation and high-K<sup>+</sup> depolarization (4). Diltiazem is roughly equipotent in inhibiting contractions induced by high-K<sup>+</sup> and a low concentration (10 nM) of norepinephrine (NE). The contractions induced by high NE concentrations (10<sup>-6</sup>-10<sup>-5</sup> M) are more resistant to diltiazem inhibition (4). There is also a close relationship between diltiazem inhibition of Ca<sup>2+</sup> influx and inhibition of contraction when either 40 mM K<sup>+</sup> or 10 nM NE was applied, but not when 1 μM NE was used. Diltiazem produces a noncompetitive inhibition of Ca<sup>2+</sup>-induced contractions of depolarized rabbit aorta. There is also a lack of parallelism between the smooth muscle effects of removal of [Ca<sup>2+</sup>]<sub>ex</sub> and of addition of diltiazem. Diltiazem appears to inhibit stimulated Ca<sup>2+</sup> influx by interacting with the Ca<sup>2+</sup> pathway involved in excitation rather than competing with Ca<sup>2+</sup> for the entry (4). **Drug Interactions**: Diltiazem is slowly metabolized by the CYP3A4 (acting as an alternative substrate inhibitor), which can cause it to interact with a variety of other medications. By inhibiting hepatic cytochromes CYP3A4, CYP2C9 and CYP2D6, diltiazem has 800 known drug interactions. 1. Yamaguchi, Ikezawa, Takada & Kiyomoto (1974) *Japan. J. Pharmacol.* **24**, 511. 2. ### Diisopropyl Fluorophosphate

This toxic substance (FW = 184.15 g/mol; CAS 55-91-4; M.P. = -82°C; B.P. = 183°C), also known as diisopropylphosphorofluoridate and abbreviated DFP or DIFP, is a potent irreversible inactivator of many serine proteinases (*e.g.*, trypsin, chymotrypsin, and blood-clotting proteases) and serine esterases (most especially acetylcholinesterase). The action of DFP on the cholinesterases was arguably the first example of an inhibitor forming a covalent bond within an enzyme active site. **Note**: Aqueous solutions have a half-life of only about one hour at pH 7.5 and 25°C. **CAUTION**: All forms of DFP are dangerous, particularly the vapor. Inhibition of AChE increases the amount of acetylcholine (ACh) at central and peripheral sites of the nervous system, attended by excessive stimulation of muscarinic and nicotinic receptors. Signs of poisoning include hypersecretion, respiratory distress, tremor, seizures, convulsions, coma, and death. All work with pure DFP solutions must be carried out in an efficient chemical fume hood, using thick, chemically-inert rubber gloves (*never* latex surgical gloves), preferably while using a certified gas mask. A physician or nurse should be alerted of any plan to work with reagent-grade DFP, thus assuring access to antidotes (atropine sulfate and 2-pyridinedoxime methiodide (*or* 2-PAM)) in pre-loaded autoinjectors, preferably unwrapped and available for immediate use. That said, neurotoxicity from inhalation is remarkably attenuated by using commercial DFP that is already dissolved in dry, water-miscible solvents, most often 2-propanol. The latter (typically made at 0.1-0.5 M DFP in dry 2-propanol) is stable for several months, when kept at -70°C. 1. No. TE5075000, *Registry of Toxic Effects of Chemical Substances*, U.S. Government Printing Office, Washington, D.C. 2. Saunders & Stacey (1948) *J. Chem. Soc.*, 695. 3. #### 4,4'-Diisothiocyanatostilbene-2,2'-disulfonate

This photosensitive, amine/thiol-reactive crosslinker and transport inhibitor (FW<sub>disodium-salt</sub> = 498.49 g/mol; CAS 207233-90-7; *Abbreviation*: DIDS) reduces anion permeability by targeting volume-sensitive Cl<sup>-</sup> channels and the Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchanger, often eliminating or reducing apoptotic hallmarks (e.g., apoptotic volume decrease (AVD), caspase-3 activity and DNA fragmentation). As an isothiocyanate, DIDS also reacts with primary amines at pH ≥ 9-10, and, as such, is also employed in protein cross-linking experiments. This negatively charged amino/sulfhydryl-reactive reagent has been widely employed as a tool to study anion transport (1-4) and to identify possible coupling between the flux of anions and the transport of cations such as H<sup>+</sup> (5-9) or Ca<sup>2+</sup> (10-13). DIDS also interacts with other enzymes not involved in anion translocation (14-16). Inner mitochondrial membrane permeabilization by Ca<sup>2+</sup> ions in the presence of DIDS is mediated by the latter's reaction with membrane protein thiols (17).

**Target(s):** *N*-acetylneuraminase 4-*O*-acetyltransferase (18,19); *N*-acetylneuraminase 7-*O*(or 9-*O*)-acetyltransferase (20) anion transport (21,22); apyrase (23); ATP synthase, or F<sub>0</sub>F<sub>1</sub> ATPase (24); ATP transporter (25); cadmium-transporting ATPase (26); Ca<sup>2+</sup>-transporting ATPase (27); channel-conductance-controlling ATPase, or cystic-fibrosis membrane conductance-regulating protein (28); Cl<sup>-</sup>/HCO<sub>3</sub><sup>-</sup> exchanger (29); flavonol 7-*O*-β-glucosyltransferase (30); 5-formyltetrahydrofolate transport (31); glucosaminylgalactosylglucosylceramide β-galactosyltransferase (32); glucose-6-phosphatase (33,34); glucose-6-phosphate translocase (35,36); glutathione-transporting ATPase (26); H<sup>+</sup>-exporting ATPase (37); H<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (38); inositol 1,3,4-trisphosphate 5/6-kinase (39); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (38); nucleotide diphosphatase, ectonucleotide diphosphohydrolase (40-42); oligopeptide-transporting ATPase, oligopeptide permease (43); phenol sulfotransferase (44); protein-disulfide isomerase (45); quinate *O*-hydroxycinnamoyltransferase (46); shikimate *O*-hydroxycinnamoyltransferase (46); sphingosine *N*-acyltransferase (46); succinate dehydrogenase (24); tyrosyl sulfotransferase (44). 1. #### Diketene

This amine-reactive reagent (FW = 84.07 g/mol; CAS 674-82-8; M.P. = 34°C), also named 4-methylene-2-oxetanone, is frequently used to acetoacetylate proteins. Full catalytic activity is often recovered upon treatment of the modified protein with an equal volume of 2 Molar neutral hydroxylamine. (The latter is freshly prepared by combining equal volumes of 4 Molar NaOH and 4 Molar hydroxylamine hydrochloride). In the chemical laboratory, diketene reacts with alcohols and amines to form the corresponding acetoacetic acid derivatives, in a process likewise called acetoacetylation. (*See also Ketene*) Diketene has been reported to react with disulfide groups in DNA photo-lyase (1). **Target(s):** lysozyme (2,3); microbial collagenase (4); neutrophil collagenase (5); phosphopantothienylcysteine decarboxylase (6); ribonuclease (2,7). 1. #### 4,6-Diketetoheptanoate

This γ,ε-diketo acid (FW<sub>free-acid</sub> = 158.15 g/mol), also known as 4,6-dioxoheptanoic acid and succinyl acetone, inhibits heme biosynthesis by targeting porphobilinogen synthase, or δ-aminolevulinic acid dehydratase. 4,6-Diketetoheptanoate is elevated in the urine of individuals with hereditary tyrosinemia. 1. Ebert, Hess, Frykholm & Tschudy (1979) *Biochem. Biophys. Res. Commun.* **88**, 1382. 2. Tschudy, Hess & Frykholm (1981) *J. Biol. Chem.* **256**, 9915. 3. #### Dimenhydrinate

This motion-sickness drug (FW = 469.97 g/mol; CAS 523-87-5), also known as Dramamine, was originally compounded as a binary salt of the antihistamine diphenhydramine and the cAMP phosphodiesterase inhibitor 8-chlorotheophylline in attempts to balance the drowsiness induced by the former with the stimulation evoked by the latter (1). It is an H<sub>1</sub> histamine receptor antagonist, but also interacts, either directly or indirectly, with other neurotransmitter systems, including those using acetylcholine, serotonin, norepinephrine, dopamine, opioids, or adenosine. Sulfotransferase (2,3). 1. Halpert, Olmstead & Beninger (2002) *Neurosci. Biobehav. Rev.* **26**, 61. 2. Matsui, Takahashi, Miwa, Motoyoshi & Homma

### 2,3-Dimercapto-1-propanesulfonate

This British anti-Lewisite analogue (FW<sub>free-acid</sub> = 188.29 g/mol) is a metal ion chelator often used as an antidote for poisoning by heavy metal, particularly lead, mercury, cadmium, gold, silver, and arsenic. It has also been used to treat patients with Wilson's disease, a genetic disorder in which the body tends to retain copper. **Target(s):** D-Ala-D-Ala dipeptidase (1); organic anion transporter (2,3); peptide deformylase (4); porphobilinogen synthase, or  $\delta$ -aminolevulinic acid dehydratase (5,6). **1.** Wu & Walsh (1996) *J. Amer. Chem. Soc.* **118**, 1785. **2.** Islinger, Gekle & Wright (2001) *J. Pharmacol. Exp. Ther.* **299**, 741. **3.** Lungkaphin, Chatsudthipong, Evans, et al. (2004) *Amer. J. Physiol. Renal. ### 2,3-Dimercapto-1-propanol

This powerful disulfide reducing agent (FW = 124.23 g/mol) is known famously as British anti-Lewisite (BAL), an antidote for Lewisite (*i.e.*, dichloro(2-chlorovinyl)arsine, or Cl-CH=CHAsCl<sub>2</sub>), the latter a lethal agent developed by the U.S. but never used in chemical warfare. BAL is also a chelating agent and has been used in trapping redox-active heavy metal poisons, especially arsenic. Beginning in 1951, it has been used in the treatment of Wilson's disease. BAL is slowly oxidized to its disulfide in air (especially at alkaline pH) and must be kept in an air-tight container. **Target(s):** acetylcholinesterase, weakly inhibited (2,3); adenylylsulfatase (4); D-Ala-D-Ala dipeptidase (5); alcohol dehydrogenase, yeast (6); aldehyde oxidase (7); altronate dehydratase (8); aminopeptidase I (9); *o*-aminophenol oxidase (10,61); anthranilate 3-monooxygenase (11); ascorbate oxidase, or ascorbase (12); carbonic anhydrase (13); catechol oxidase (13-15); Ca<sup>2+</sup> transport (16); cytochrome *c* oxidase (17); 2,3-dihydroxyindole 2,3-dioxygenase (60); electron transport, chloroplast (18); electron transport, mitochondrial (19-22); endothelin-converting enzyme (23); ethanolamine kinase (24); glutamate dehydrogenase (25); glutamate uptake (26); glycerol oxidase (27); glycerol-3-phosphate dehydrogenase (28); indoleacetaldoxime dehydratase (29,30); indole-3-acetic acid oxidase (31); laccase (62); lactaldehyde reductase (NADPH) (32); lysine carboxypeptidase, or lysine(arginine) carboxypeptidase, or carboxypeptidase N (33); methane monooxygenase (34,59); microbial collagenase (35,36); monophenol monooxygenase (15); neprilysin, weakly inhibited (37); nitrogenase (38); nucleotide diphosphatase (39,40); peptide deformylase (41); peptidyl-dipeptidase A, or angiotensin I-converting enzyme (42); peroxidase (13,31); phenylalanine 4-monooxygenase (43,44); phosphatidylethanolamine methyltransferase (45); 3'-phosphoadenylylsulfatase (46); phosphodiesterase I, or 5'-exonuclease (47); porphobilinogen synthase, or  $\delta$ -aminolevulinic acid dehydratase (48,49); prostaglandin-endoperoxide synthase, or cyclooxygenase (50); *o*-pyrocatechuate decarboxylase (51); pyroglutamyl-peptidase II (52); L-ribulose-5-phosphate 4-epimerase (53); D-serine dehydratase, or D-serine ammonia-lyase (54); starch phosphorylase (55); thiopurine *S*-methyltransferase (56); tyrosinase, or monophenol monooxygenase (15,57); ubiquinol:cytochrome *c* reductase, or Complex III (58). **1.** Peters, Stocken & Thompson (1945) *Nature* **156**, 616. **2.** Augustinsson (1950) *The Enzymes*, 1st ed., **1** (Part 1), 443. **3.** Barron, Miller & Meyer (1947) *Biochem. ### 3-[(1,4-Dimethoxynaphth-2-yl)methoxy]-4-[4-(2-methoxybenzyloxypropoxy)-phenyl]piperidine

This substituted piperidine (FW<sub>free-base</sub> = 571.71 g/mol) is a potent inhibitor of human renin (IC<sub>50</sub> = 60 pM for the recombinant enzyme and 12 nM for human plasma renin), displaying potent and long-lasting blood pressure-lowering effects after oral administration to sodium-depleted conscious marmosets. **1.** Vieira, Binggeli, Breu, et al. (1999) *Bioorg. Med. Chem. Lett.* **9**, 1403.

### 3-[(3,4-Dimethoxyphenyl)sulfonyl]-1-(3,4-dimethylphenyl)imidazolidine-2,4-dione

This phenylimidazolidine-dione (FW = 404.44 g/mol), also known as SD 906, inhibits human chymase (IC<sub>50</sub> = 22 nM). **1.** Ferry, Gillet, Bruneau, et al. (2001) *Eur. J. Biochem.* **268**, 5885. **2.** Niwata, Fukami, Sumida, et al. (1997) *J. Med. Chem.* **40**, 2156.

### Dimethylallyl Pyrophosphate

This isoprenoid metabolite (FW<sub>free-acid</sub> = 246.09 g/mol), also known as dimethylallyl diphosphate and 3-methylbut-2-enyl 1-diphosphate, is an intermediate in sterol and terpene biosynthesis. It is reasonably stable in neutral and alkaline solutions, but is unstable below pH 5.2. **Target(s):** geranyl-diphosphate cyclase, or bornyl-diphosphate synthase (1); geranyltransferase, or farnesyl-diphosphate synthase (2); limonene synthase (3); mevalonate kinase (4); pinene synthase (1,3). 1. Wheeler & Croteau (1987) *J. Biol. Chem.* **262**, 8213. 2. Glickman & Schmid (2007) *Assay Drug Dev. Technol.* **5**, 205. 3. Cori & Rojas (1985) *Meth. Enzymol.* **110**, 406. 4. Hinson, Chambliss, Toth, Tanaka & Gibson (1997) *J. Lipid Res.* **38**, 2216.

### (Z)-3-[4-(Dimethylamino)benzylidene]indolin-2-one

This orange-red indolinone (FW = 264.33 g/mol; *Abbreviation:* DMBI) is a strong inhibitor of platelet-derived growth factor  $\beta$ -receptor (or  $\beta$ -PDGFR) protein-tyrosine kinase, IC<sub>50</sub> = 4  $\mu$ M (1) and fibroblast growth factor receptor-1 (or FGFR1) protein-tyrosine kinase (IC<sub>50</sub> = 5  $\mu$ M (1,2)). 1. Sun, Tran, Tang, *et al.* (1998) *J. Med. Chem.* **41**, 2588. 2. Zaman, Vink, van den Doelen, Veeneman & Theunissen (1999) *Biochem. Pharmacol.* **57**, 57.

### 2-(Dimethylamino)ethyl Diphosphate

This transition-state analogue (FW = 250.10 g/mol), also known as 2-(dimethylamino)ethyl pyrophosphate, inhibits isopentenyl-diphosphate  $\Delta$ -isomerase. The positively charged ammonium group is believed to mimic a tertiary carbocationic species formed during catalysis. The analogue forms a noncovalent complex with the enzyme with a  $K_d$  value less than 0.12 nM. 1. Reardon & Abeles (1986) *Biochemistry* **25**, 5609. 2. Muehlbacher & Poulter (1988) *Biochemistry* **27**, 7315. 3. Muehlbacher & Poulter (1985) *J. Amer. Chem. Soc.* **107**, 8307. 4. Reardon & Abeles (1985) *J. Amer. Chem. Soc.* **107**, 4078. 5. Ramos-Valdivia, van der Heijden, Verpoorte & Camara (1997) *Eur. J. Biochem.* **249**, 161. 6. Wouters, Oudjama, Ghosh, *et al.* (2003) *J. Amer. Chem. Soc.* **125**, 3198.

### 2-[[[2-[[2-(Dimethylamino)ethyl]sulfanyl]phenyl]-sulfonyl]amino]-5,6,7,8-tetrahydro-1-naphthalenecarboxylate

This substituted anthranilic acid sulfonamide (FW<sub>free-acid</sub> = 434.58 g/mol) inhibits methionyl aminopeptidase (IC<sub>50</sub> = 30 nM). 1. Sheppard, Wang, Kawai, *et al.* (2006) *J. Med. Chem.* **49**, 3832.

### (R)-2-(4-(4-Dimethylaminophenoxy)phenylsulfonyl)-1,2,3,4-tetrahydroisoquinolin-3-carboxylic Acid and Hydroxamate

These isoquinoline derivatives (FW<sub>free-acid</sub> = 467.55 g/mol; FW<sub>hydroxamate</sub> = 455.54 g/mol) inhibit human neutrophil collagenase, or Matrix Metalloproteinase-8, with respective IC<sub>50</sub> values of 30nM and 2 nM for the carboxylic acid and hydroxamate forms. 1. Matter, Schwab, Barbier, *et al.* (1999) *J. Med. Chem.* **42**, 1908.

### 5-(4-Dimethylaminophenyl)-6-(6-morpholin-4-ylpyridin-3-ylethynyl)pyrimidin-4-ylamine

This pyrimidine (FW = 400.49 g/mol) inhibits cytosolic adenosine kinase (IC<sub>50</sub> = 2 nM). Unlike the substrate, which binds to the closed conformation of the enzyme, this compound binds tightly to a unique open conformation of AK. 1. Matulenko, Paight, Frey, *et al.* (2007) *Bioorg. Med. Chem.* **15**, 1586.

### (E)-3-[2-(4-(Dimethylamino)phenyl)vinyl]benzoate

This (*N,N*-dimethylamino)stilbene carboxylate (FW<sub>free-acid</sub> = 267.33 g/mol) is a noncompetitive inhibitor ( $K_{is}$  = 130  $\mu$ M) and weak alternative substrate for mammalian flavin-containing monooxygenase. Note that the estimated  $K_m$  value is above the maximum solubility (~0.1 mM). The stilbene also inhibits bacterial cyclohexanone monooxygenase ( $K_{is}$  = 200  $\mu$ M). In addition, the *o*-carboxy analogue (*i.e.*, (*E*)-2-[2-(4-(dimethylamino)phenyl)vinyl]benzoic acid, is a slightly weaker inhibitor of flavin-containing monooxygenase ( $K_{is}$  = 150  $\mu$ M) and cyclohexanone monooxygenase ( $K_{is}$  = 630  $\mu$ M). 1. Clement, Weide & Ziegler (1996) *Chem. Res. Toxicol.* **9**, 599.

### *N*-(3-Dimethylaminopropyl)-*N'*-ethylcarbodiimide

This water-soluble carbodiimide (FW<sub>hydrochloride</sub> = 191.70 g/mol), also known as 1-ethyl-3-(3 dimethylaminopropyl)-carbodiimide and often abbreviated EDAC or EDC, is a hydrophilic analogue of *N,N'*-dicyclohexylcarbodiimide that reacts with carboxyl groups, typically in the pH range 4.0-6.0 (Note: Amine- or carboxyl-containing buffers must obviously be avoided.). If an amine is present, an amide will be produced. Enzymes having catalytically essential carboxyl groups are often inhibited by this reagent when the condensation reaction is carried out in the presence of an amine such as glycine methyl ester). EDAC can also react with phosphate groups. This reagent can also be used to cross-link two proteins: *e.g.*, heavy meromyosin can be linked to smooth muscle myosin light-chain kinase. **Target(s):** acid phosphatase (1); *N*-acyl-D-amino-acid deacylase (2);

acylaminoacyl peptidase (3,4); adrenodoxin reductase (5);  $\beta$ -agarase6; aminopeptidase I (7);  $\alpha$ -amylase/pullulanase (8); arginase (9); arginine esterase E-1 (10); argininosuccinate lyase (11); ascorbate 2-kinase (12); *Aspergillus* nuclease S1 (13); ATP:citrate lyase, or ATP:citrate synthase (14); bacterial leucyl aminopeptidase (15); cAMP-dependent protein kinase (16); catechol oxidase (78); ceramidase (17); chitinase (18); cholinesterase, or butyrylcholinesterase (19); cyclomaltodextrinase (20,21); electron transport, photosynthetic (22); endo 1,3(4)- $\beta$ -glucanase (23); exo-(1 $\rightarrow$ 4)- $\alpha$ -D-glucan lyase (24,25); ferredoxin:NADP<sup>+</sup> reductase (26,27); F<sub>0</sub>F<sub>1</sub> ATP synthase (28,29);  $\beta$ -D-fucosidase (30);  $\alpha$ -galactosidase, in the presence of glycine ethyl ester (31);  $\beta$ -galactosidase (32); glucan 1,6- $\alpha$ -isomaltosidase (33);  $\alpha$ -glucosidase (34);  $\beta$ -glucosidase (35); glutathione S-transferase (36); glycogen synthase I (37); (S)-2-haloacid dehalogenase (38); 2-haloacid dehalogenase, configuration-inverting (38,39); histidine decarboxylase (40); H<sup>+</sup>/organic cation antiport (41); 3-hydroxyanthranilate 3,4-dioxygenase (76); 3-hydroxy-3-methylglutaryl-CoA synthase (42); laccase (77); lactose synthase, in the presence of glycinamide (43); lactoylglutathione lyase, or glyoxalase I (44,45); leader peptidase (46); mannosyl-oligosaccharide glucosidase, or glucosidase I (47);  $\alpha$ -methylacyl-CoA epimerase (48); N-methyl-D-aspartate receptor (49); midgut microvillar aminopeptidase, *Tenebrio molitor* (50); NADPH:ferri-hemoprotein reductase (51); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (52); ornithine decarboxylase (53); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (54); papain (55); phosphate transport (56); phospholipase C, in the presence of N-(2,4-dinitrophenyl)ethylene diamines (57); polyamine transporter (58); polygalacturonidase, or pectinase (59); polyphenol oxidase (78); prepilin peptidase (60); protein-S-isoprenylcysteine O-methyltransferase (61); pullulanase (62); pyroglyoxal peptidase I (63); pyrophosphatase, inorganic diphosphatase (64); *Rhizopus stolonifer* nuclease, or nuclease Rsn (65); signal peptidase I (66); sulfite oxidase (79); thrombin (67,68); thymidylate synthase (69); transketolase (70); ubiquinone:cytochrome c oxidoreductase, or Complex III (71); vacuolar H<sup>+</sup> transporting ATPase (72,73); vacuolar H<sup>+</sup>-transporting pyrophosphatase (74); xylan 1,4- $\beta$  xylosidase (75).

### 3-(1-(3-(Dimethylamino)propyl)-2-methyl-1H-indol-3-yl)-4-(2-methyl-1H-indol-3-yl)-1H-pyrrole-2,5-dione

This bisindolylmaleimide (FW = 440.55 g/mol) potently inhibits protein kinase C $\beta$ II (IC<sub>50</sub> = 0.6 nM). The bound inhibitor adopts a nonplanar conformation in the ATP-binding site, with the kinase domain taking on an intermediate, open conformation. This PKC $\beta$ II-inhibitor complex represents the first structural description of any conventional PKC kinase domain. 1. Grodsky, Li, Bouzida, et al. (2006) *Biochemistry* **45**, 13970.

### 3-(Dimethylamino)-1-propyne

This flammable liquid, (CH<sub>3</sub>)<sub>2</sub>N-CH<sub>2</sub>-C $\equiv$ C-H (FW = 83.133 g/mol; B.P. = 79-83°C), irreversibly inactivates bovine liver mitochondrial monoamine oxidase, forming a covalent adduct with the enzyme-bound flavin (*i.e.*, an N-5 substituted dihydroflavin). 1. Walsh, Cromartie, Marcotte & Spencer (1978) *Meth. Enzymol.* **53**, 437. 2. Brush & Kozarich (1992) *The Enzymes*, 3rd ed. (D. S. Sigman, ed.), **20**, 317. 3. ### 6-(Dimethylamino)purine

This modified purine (FW = 163.18 g/mol;  $\lambda_{\max}$  = 275 nm (pH 7);  $\epsilon$  = 17800  $M^{-1}cm^{-1}$ ), also known as  $N^6,N^6$ -dimethyladenine, inhibits cyclin-dependent kinases, and inhibiting mitosis. It absorbs ultraviolet light with). **Target(s):** adenine deaminase (1); 3',5'-cyclic-nucleotide phosphodiesterase (2); cyclin dependent kinases, *or* cdc2 (3-5); dual-specificity kinase (5); H1-histone kinase (6,7); methionine *S*-adenosyltransferase, weakly inhibited (8); protein kinase C (5); protein-tyrosine kinase (5); receptor protein-tyrosine kinase (5). 1. Jun & Sakai (1979) *J. Ferment. Technol.* **57**, 294. 2. Kemp & Huang (1974) *Meth. Enzymol.* **38**, 240. 3. Meijer & Kim (1997) *Meth. Enzymol.* **283**, 113. 4. ### 2-Dimethylamino-4,5,6,7-tetrabromobenzimidazole

This cell-permeable CK2 inhibitor (FW = 476.79 g/mol; PubChem CID: 5326976; Abbreviation: DMAT), also named systematically as 4,5,6,7-tetrabromo-*N,N*-dimethyl-1*H*-benzo[d]imidazol-2-amine, targets Casein Kinase-2 ( $K_i$  = 40 nM), a highly pleiotropic protein kinase that is implicated in cell cycle control, DNA repair, circadian rhythm and other cellular processes (1). CK2's high constitutive activity is believed to enhance tumor phenotype and the propagation of infectious diseases. Inhibition of CK2 with DMAT results in caspase-mediated killing of human breast cancer cells with acquired resistance to antiestrogens, while DMAT fails to kill parental MCF-7 cells (2). In studies with platelets, DMAT inhibits platelet aggregation and also suppresses activation of GPIIb/IIIa (3). DMAT inhibition is used to infer that CK2 promotes cancer cell viability by up-regulating cyclooxygenase-2 expression and enhanced prostaglandin  $E_2$  production (4). DMAT treatment stimulates the purinosome assembly in HeLa cells (5). Direct comparison of purinosome-rich cells (cultured in purine-depleted medium) and normal cells shows a 3-fold increase in IMP concentration in purinosome-rich cells and similar levels of AMP, GMP, and ratios of AMP/GMP and ATP/ADP for both. In addition, a higher level of IMP is also observed in HeLa cells treated with DMAT. Furthermore, treatment increases in the *de novo* IMP/AMP/GMP biosynthetic flux rate under purine-depleted condition. **Other Targets:** When tested in a panel of 80 protein kinases DMAT and its parent compound TBI (or TBBz; 4,5,6,7-tetrabromo-1*H*-benzimidazole) are potent inhibitors of PIM (provirus integration site for Moloney murine leukemia virus)1, PIM2, PIM3, PKD1 (protein kinase D1), HIPK2 (homeodomain-interacting protein kinase 2) and DYRK1a (dual-specificity tyrosine-phosphorylated and -regulated kinase 1a) (6). Rescue experiments utilizing inhibitor-resistant CK2 mutants were unable to rescue the apoptosis associated with TBBz and DMAT treatment, suggesting the inhibitors had off-target effects (7). Chemoproteomics revealed that the detoxification enzyme quinone reductase 2 (QR2 *or* NQO2) is a likely off-CK2, or adventitious, target (7). Although kinetic analysis suggested that DMAT inhibits NQO2 by binding with similar affinities to the oxidized and reduced forms, crystal structure analysis showed that DMAT binds reduced NQO2 in a different way than in the oxidized state (8). In oxidized NQO2, TBBz and DMAT are deeply buried in the active site and make direct hydrogen and halogen bonds to the enzyme. In reduced NQO2, DMAT occupies a more peripheral region and hydrogen and halogen bonds with the enzyme are mediated through three water molecules. The active site of NQO2 is fundamentally different from the ATP binding site of CK2 (8). 1. Pagano, Meggio, Ruzzene, et al. (2004) *Biochem. Biophys. Res. Commun.* **321**, 1040. 2. **Dimethylarginine, See Asymmetric Dimethyl Arginine**

### 9,10-Dimethyl-1,2-benzanthracene

This so-called bay-area carcinogenic DNA intercalator (FW = 256.35 g/mol; CAS 57-97-6; M.P. = 122-123°C; Abbreviation: DMBA), also known as 7,12-dimethylbenz[*a*]anthracene, inhibits ribosyldihydro-nicotinamide dehydrogenase (quinone) (1). For best results, it agent should first be dissolved in ethanol and then diluted 20x into the reaction mixture. After the topical application of tritium-labeled DMBA to mouse skin, DMBA-bound DNA was fractionated into satellite and main-band components, demonstrating extensive binding of [ $^3$ H]-DMBA to mouse satellite DNA (2). 1. Liao, Dulaney & Williams-Ashman (1962) *J. Biol. Chem.* **237**, 2981. 2. Zeiger, Salomon, Kinoshita & Peacock (1972) *Cancer Res.* **32**, 643.

### *N*-(1-( $\alpha,\alpha$ -Dimethylbenzyl)pyrrolidin-3(*R*)-yl-(*N*-ethyl)amino sulfonyl)-5'-(4-methoxyphenyl)-2'-(2-thienyl)-1'*H*-histamine

This modified histamine (FW = 593.82 g/mol) inhibits 15-lipoxygenase, *or* arachidonate 15-lipoxygenase,  $IC_{50}$  = 10 nM. Non-symmetrical sulfamides are suitable replacements for the earlier arylsulfonamide-containing members of this series, and this agent is also a potent inhibitor of human 15-LO in a cell-based assay. 1. Weinstein, Liu, Ngu, et al. (2007) *Bioorg. Med. Chem. Lett.* **17**, 5115.

### 3,3-Dimethylbutyrate

This betaine analogue (FW = 116.16 g/mol; CAS 1070-83-3), also known as *t*-butylacetic acid, inhibits betaine:homocysteine *S*-methyltransferase (1,2), dimethylglycine *N*-methyltransferase (3), and sarcosine/dimethylglycine *N*-methyltransferase (3). 1. Skiba, Wells, Mangum & Awad (1987) *Meth. Enzymol.* **143**, 384. 2. Skiba, Taylor, Wells, Mangum & Awad (1982) *J. Biol. Chem.* **257**, 14944. 3. Waditee, Tanaka, Aoki, et al. (2003) *J. Biol. Chem.* **278**, 4932.

### 2,9-Dimethyl-9*H*- $\beta$ -carbolinium Ion

This cation (FW<sub>chloride</sub> = 232.71 g/mol) is a strong inhibitor of mitochondrial respiration and is also a nigrostriatal neurotoxin, the latter a likely consequence of its structural resemblance to the neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). Binding studies with [ $^3$ H]-2,9-Dimethyl-9*H*- $\beta$ -carbolinium ion showed it binds with high affinity to the chaperone member glucose regulated protein 78, carboxylesterase, cytochrome P450 2E1, monoamine oxidase B, and a Rho family G-protein. DC also binds to and inhibits triose-phosphate isomerase. 1. Bonnet, Pavlovic, Lehmann & Rommelspacher (2004) *Neuroscience* **127**, 443.

***N,N*-Dimethyl-*N*-dodecylamine *N*-Oxide**

This nonionic detergent (FW = 229.41g/mol), also known as lauryldimethylamine oxide (or, LDAO), Ammonyx LO, and Bardox-12, is an activator of F<sub>1</sub> ATPase. It is also used to solubilize membrane proteins and isolate channels. **Target(s):** Ca<sup>2+</sup>-dependent ATPase of CF<sub>1</sub> (1); ceramide kinase (2); cycloartenol synthase (3); cytochrome-*c* oxidase (4); glutacetyl-CoA decarboxylase (5); guanylate cyclase (6); phosphatidylserine decarboxylase (7); phosphoinositide 5-phosphatase (8); sphinganine-1-phosphate aldolase (9); squalene:hopene cyclase (10); squalene-tetrahymanol cyclase (11). 1. Ren & Allison (1997) *J. Biol. Chem.* **272**, 32294. 2. Van Overloop, Gijsbers & Van Veldhoven (2006) *J. Lipid Res.* **47**, 268. 3. Acta* **1075**, 93.

**Dimethylenastron**

This kinesin inhibitor (FW = 302.39 g/mol; CAS 863774-58-7; Solubility: 100 mM in DMSO; 50 mM in ethanol) targets mitotic motor kinesin Eg5 (IC<sub>50</sub> = 200 nM) (1,2), thereby arresting mitosis and triggering apoptosis, and up-regulating Hsp-70 expression in multiple human myeloma cell lines (3). Hsp70 induction occurs at the transcriptional level via a *cis*-regulatory DNA element in Hsp70 promoter and is mediated by the phosphatidylinositol 3-kinase/Akt pathway. Eg5 inhibitor-mediated Hsp70 up-regulation is cytoprotective, because blocking Hsp70 induction directly by antisense or small interfering RNA or indirectly by inhibiting the phosphatidylinositol 3-kinase/Akt pathway significantly increases Eg5 inhibitor-induced apoptosis. Dimethylenastron also inhibits the migration and invasion of PANC1 pancreatic cancer cells, independent of suppressing the cell proliferation (3). 1. Kaan, Ulaganathan, Rath, *et al.* (2010) *J. Med. Chem.* **53**, 5676. 2. Sun, Shi, Sun, *et al.* (2011) *Acta Pharmacol. Sin.* **32**, 1543. 3. Liu, Aneja, Liu, *et al.* (2006) *J. Biol. Chem.* **281**, 18090.

***N,N*-Dimethylformamide**

This organic solvent (FW = 73.09 g/mol; CAS 68-12-2; *Abbreviation:* DMF) is a combustible liquid (M.P. = -60.4°C; B.P. = 153.0°C) frequently used in organic synthesis, extractions, chromatography, spectrophotometry, and toxicology investigations. With a dipole moment of 3.86 D at 25°C (compare to a value of 1.87 for water) and a high dielectric constant of 36.71 at 25°C (compare to a value of 80.1 for water), DMF is miscible in water as well as many polar organic solvents. **Target(s):** *N*-acetyllactosamine synthase (1); acylaminoacyl-peptidase (2); adenylate cyclase, adenyl cyclase (3); alcohol dehydrogenase (4); aminoacylase, or *N*-acylamino acid amidohydrolase (5); arylformamidase (6); carboxylesterase (7); carboxypeptidase C, or carboxypeptidase Y (8,9); coagulation factor

IXa (10); cytosol alanyl aminopeptidase (11); endopeptidase La (12); hemoglobin S polymerization (13); lactose synthase (1); lanosterol synthase (14); lipase, or triacylglycerol lipase (15); membrane alanyl aminopeptidase, or aminopeptidase N (16); *N*-nitrosodimethylamine demethylase, or cytochrome P450 (17); pancreatic ribonuclease denaturation (18); papain (19); pepsin (20); prolyl oligopeptidase (21); soluble epoxide hydrolase (22). 1. **Dimethylfumarate**

This cell-permeant thiol-reactive multiple sclerosis drug (FW = 144.13 g/mol; CAS 624-49-7; *Abbreviation:* DMF), also known as BG-12 and its trade name Tecfidera<sup>®</sup>, reacts with and depletes intracellular glutathione (GSH) by covalent bond formation in a reaction that may be mediated by GSH-S-transferase. In patients with relapsing-remitting multiple sclerosis, dimethylfumarate significantly reduces the proportion of patients who had a relapse, lowers the annualized relapse rate, lessens the rate of disability progression, reduces the number of lesions on MRI (1). Although the mode of action is unclear, BG-12 is known to reduce the levels of certain pro-inflammatory cytokines that cause inflammation during an MS attack, while increasing the levels of anti-inflammatory cytokines (2-5). DMF is also a very effective hypoxic cell radiosensitizer, with an enhancement ratio (ER) of about 3 obtained by a 5-min exposure of cells to 5 mM DMF, without significant toxicity (6). 1. **3,3-Dimethylglutarate**

This dicarboxylic acid (FW<sub>free-acid</sub> = 160.17 g/mol; CAS 4839-46-7; M.P. = 83-85°C) is frequently employed as a buffer (pK<sub>a</sub> values of 3.70 and 6.34 at 25°C, with respective dpK<sub>a</sub>/dT values of +0.0076 and +0.0060). Do not confuse this dicarboxylic acid with dimethyl glutarate, the double ester of glutaric acid **Target(s):** adenosine-phosphate deaminase (1); 2-aminoadipate aminotransferase (2); γ-glutamyl hydrolase, weakly inhibited (3); iduronate-2-sulfatase (4); kynurenine:oxoglutarate aminotransferase (5,6); phospho-lipase D (7); pyridoxamine:oxaloacetate aminotransferase, weakly inhibited at pH 8 (8). 1. **3,3-Dimethylglutaric Acid 2(S)-(cyclopentanecarbonyl)pyrrolidone N-(L-Prolyl)-2(S)-(hydroxyacetyl)pyrrolidine Diamide**

This substrate analogue (FW = 510.61 g/mol) potently inhibits pig brain prolyl oligopeptidase (IC<sub>50</sub> = 0.32 nM). This agent has a significantly higher octanol:water partition constant, suiting it for targeting to the brain. 1. Wallén, Christiaans, Jarho, *et al.* (2003) *J. Med. Chem.* **46**, 4543.

**N,N-Dimethylglycine**

This hygroscopic amino acid (FW = 103.12 g/mol) is an intermediate in the conversion of choline to glycine. **Target(s):** betaine:homocysteine methyltransferase, by product inhibition (1-4); choline oxidase (5); choline transport (6); sarcosine oxidase (7). 1. Webb (1966) *Enzyme and Metabolic Inhibitors*, vol. 2, p. 356, Academic Press, New York. 2. Waditee & Incharoensakdi (2001) *Curr. Microbiol.* **43**, 107. 3. **Dimethyl(2-hydroxy-5-nitrobenzyl)sulfonium Halide**

This water-soluble salt (FW<sub>bromide</sub> = 294.17 g/mol), also known as Koshland's Reagent I Water-Soluble, or K-IWS, modifies tryptophanyl and cysteinyl residues in peptides and proteins (*e.g.*, chymotrypsin and carboxypeptidase A<sub>s</sub>) and can be utilized as an environmentally sensitive probe. Solutions are relatively stable at pH 3; however, aqueous solutions are rapidly hydrolyzed at neutral or alkaline pH (1). **Target(s):** chorismate mutase (2); creatine kinase (3); glyceraldehyde-3-phosphate dehydrogenase (4); lactose synthase (5); lysozyme (6); nucleoside transporter (7); pepsin (8); prephenate dehydratase (2); ribulose 1,5-bisphosphate carboxylase (9); taka-amylase A (10). 1. **N<sup>4</sup>-(2,2-Dimethyl-1(S)-methylcarbamoylpropyl)-N<sup>1</sup>-hydroxy-2(R)-hydroxymethyl-3(S)-(4-methoxyphenyl)succinamide**

This antiinflammatory agent (FW = 395.46 g/mol), also known as SDZ 242-484, inhibits matrix metalloproteinases as well as tumor necrosis factor- $\alpha$  converting enzyme, or TACE, K<sub>i</sub> = 0.6 nM (1,2); gelatinase A, matrix metalloproteinase-2, K<sub>i</sub> = 0.5 nM; interstitial collagenase, or matrix metalloproteinase-1, K<sub>i</sub> = 1.1 nM; stromelysin 1, or matrix metalloproteinase-3; K<sub>i</sub> = 0.9 nM (1,2). 1. Koch, Kottirsch, Wietfeld & Kusters (2002) *Org. Proc. Res. Dev.* **6**, 652. 2. Kottirsch, Koch, Feifel & Neumann (2002) *J. Med. Chem.* **45**, 2289.

**Dimethyloxalyglycine**

This cell-permeable inhibitor and  $\alpha$ -ketoglutarate mimic (FW = 175.14 g/mol; CAS 89464-63-1; Symbol: DMOG) targets HIF $\alpha$  prolyl hydroxylase (HIF-PH) competitively, leading to the stabilization of HIF and subsequent angiogenesis and glucose metabolism, when administered at concentrations between 0.1 and 1 mM. Hypoxia Inducible Factor (HIF), which is comprised of  $\alpha$  and  $\beta$  subunits, regulates responses to hypoxia. Upon cellular exposure to hypoxic conditions, the HIF  $\alpha\beta$  is stabilized, binding to DNA transcriptionally activating genes linked to the cellular processes of angiogenesis and glucose metabolism (1). Under normal conditions, the HIF- $\alpha$  subunit is hydroxylated by HIF- $\alpha$  prolyl hydroxylase (HIF-PH), leading to ubiquitylation of HIF- $\alpha$  and its subsequent destruction (2). DMOG is a cell permeable competitive inhibitor of HIF- $\alpha$  prolyl hydroxylase (HIF-PH) leading to the stabilization of HIF and subsequent angiogenesis and glucose metabolism at 0.11 mM (3,4). **See also Desferrioxamine** 1. **N,N-Dimethyl-2-phenylaziridinium Cation**

This alkylating reagent (FW = 148.23 g/mol), which forms in aqueous solution by intramolecular rearrangement of *N,N*-dimethyl-2-chloro-2-phenylethylamine, is an irreversible inhibitor of various acetylcholinesterases, including those from *Torpedo californica* and cobra venom (*Naja naja oxiana*). An active-site tryptophanyl residue is modified. **Target(s):** acetylcholinesterase (1-7); antheraxanthin  $\kappa$ -cyclase (8);  $\beta$ -cyclohexenyl carotenoid epoxidase (9); lycopene  $\beta$ -cyclase (8). 1. ### 1,3-Dimethyl-6-(2-propoxy-5-methanesulfonylamidophenyl)pyrazol[3,4*a*]-pyrimidin-4-(5*H*)-one

This purine analogue (FW = 391.45 g/mol; Abbreviation: DMPPO) inhibits cGMP phosphodiesterase, isozyme-5 ( $K_i = 3$  nM), with much weaker action on the other isozymes. 1. Ni, Safai, Gardner & Humphreys (2001) *Kidney Int.* **59**, 1264. 2. Coste & Grondin (1995) *Biochem. Pharmacol.* **50**, 1577. 3. Delpy & le Monnier de Gouville (1996) *Brit. J. Pharmacol.* **118**, 1377.

### *N,N*-Dimethylsphingosine

This *D-erythro*-sphingosine derivative (FW = 327.55 g/mol; CAS 119567-63-4; Symbol: DMS), also called *N,N*-dimethyl-*D-erythro*-4-*trans*-sphinganine and *N,N*-dimethyl-(2*S*,3*R*,4*E*)-2-amino-4-octadecene-1,3-diol, is formed from sphingosine by the action of mouse brain *N*-methyltransferase, presumably with *S*-adenosylmethionine as the methyl donor (1). Significantly, labeling of sphingosine in human epidermoid carcinoma A431 cells occurs by culturing these cells in a medium containing [<sup>3</sup>H]Serine, followed by extraction and isolation of sphingolipids by standard procedures. Bands corresponding to *N,N*-dimethylsphingosine and ceramide are observed, whereas sphingosine was virtually absent (2). Such findings clearly documented that DMS is a natural product. **Role in Pain:** Untargeted metabolomics showed that sphingomyelin-ceramide metabolism is altered in the dorsal horn of rats with neuropathic pain, attended by upregulated synthesis of *N,N*-dimethylsphingosine and induction of mechanically-induced pain hypersensitivity *in vivo* (3). DMS inhibits protein kinase C ( $IC_{50} = 12$  μM) and sphingosine kinase ( $K_i \approx 0.01$ -0.3 mM;  $IC_{100} \approx 1$ -2 mM), the latter controlling the balance between proapoptotic ceramide and anti-apoptotic effects of the ceramide catabolite, sphingosine-1-phosphate (S1P). Although DMS blocks S1P production (4), the physiological concentrations of DMS are substantially lower than its  $K_i$ . Dimethylsphingosine also stimulates *src* kinase and sphingosine-dependent protein kinase and induces apoptosis in human leukemia HL-60 cells. DMS is likewise a weak activator of phospholipase Cδ. **Target(s):** ceramide kinase (5); DNA primase (6); phosphatidate phosphatase, or ecto-phosphatidic acid phosphohydrolase (7); protein kinase C (8-13); sphinganine kinase, or sphingosine kinase (4,12-21). Notably, phosphorylation of sphingosine to form sphingosine-1-P is inhibited by *N,N*-dimethylsphingosine (DMS) in a dose-dependent manner, but not by other structurally related sphingosine derivatives, including ceramide (4). The inhibition of sphingosine-1-P formation by DMS can be reproduced using a cell-free system (sphingosine kinase obtained from platelet cytosolic fractions) and much stronger than that by *DL-threo*-dihydrosphingosine, which had been considered to be the strongest inhibitor of sphingosine kinase. Administration of DMS to intact platelets results in a decrease in sphingosine-1-P and an increase in sphingosine (4). The autophosphorylation of EGF receptor in the absence of detergent is also strongly enhanced by *N,N*-dimethyl-*D-erythro*-sphingosine; this effect was even obvious in the absence of EGF and synergistic in its presence. Similar effects were not produced by *N,N*-dimethyl-*L-erythro*-sphingosine, *D*- and *L-erythro*-sphingosine, *N*-monomethyl-*D-erythro*-sphingosine, *N*-acetyl-*D*-

*erythro*-sphingosine, or the five *lyso*-glycosphingolipids tested (23). 1. Igarashi, Hakomori (1989) *Biochem. Biophys. Res. Commun.* **164**, 1411. 2. Igarashi, Kitamura, Toyokuni, et al. ### 2,2-Dimethylsuccinate

This dicarboxylic acid (FW<sub>free-acid</sub> = 146.14 g/mol), also known as 2,2-dimethylsuccinic acid and *gem*-dimethylsuccinic acid, is a strong inhibitor of carboxypeptidase A and B, with  $K_i$  values of 1.7 and 28 μM, respectively (1). **Target(s):** glutamate decarboxylase,  $K_i = 24$  mM (2); kynurenine aminotransferase, weakly inhibited (3); maleate hydratase,  $K_i = 25$  μM (4). 1. ### Dimethyl Sulfate

This membrane-penetrating sulfate ester (FW = 126.13 g/mol; CAS 77-78-1; colorless liquid; M.P. = -27°C; decomposes at about 188°C; Soluble in water (2.8 g/100 mL at 18°C), diethyl ether, dioxane, and acetone) readily alkylates DNA and RNA and inhibits protein biosynthesis. Guanine residues are methylated primarily at *N*<sup>7</sup>, whereas adenine residues are modified at *N*<sup>3</sup> (1). Small amounts of *O*<sup>6</sup>-methylguanine, *N*<sup>3</sup>-methylcytosine, and *N*<sup>1</sup>- and *N*<sup>7</sup>-methyladenine are also formed. Methylation is a step in the Maxam-Gilbert method for sequencing DNA, one that is based on chemical modification of DNA and subsequent cleavage at specific sites (2). Although published two years after the Sanger's & Coulson's ground-breaking plus-minus sequencing method, the Maxam-Gilbert technique proved more popular, chiefly because purified DNA could be used directly, whereas the earliest version of the Sanger method required cloning of each read start for production of single-stranded DNA. That said, with the improvement of the chain-termination method, Maxam-Gilbert sequencing fell out of favor owing to its technical complexity, its use of a hazardous chemical, and difficulties in scale-up. **CAUTION:** Not surprisingly, DMS is also both carcinogenic and mutagenic. A strong pulmonary vesicant, DMS was a member of the chemical weapons arsenal. In humans, DMS is highly toxic and is attended by severe inflammation in the eye, respiratory epithelium, and skin, starting within minutes or hours. A brief, 10-min exposure to 500 mg DMS/m<sup>3</sup> is often fatal, with little initial discomfort, but proceeding to severe systemic effects on nerves, heart, liver, and kidneys. **Target(s):** carbamoyl-phosphate synthetase (3); protein biosynthesis (4). 1. Lawley & Brookes (1963) *Biochem. J.* **89**, 12. 2. Maxam & Gilbert (1977) *Proc. Natl. Acad. Sci.* **74**, 560. 3. Kaseman (1985) Ph.D. thesis, Dept. Biochemistry, Cornell University Medical College, New York, New York. 2. Chen, Kung & Bates (1976) *Chem. Biol. Interact.* **14**, 101.

### Dimethyl Sulfoxide, or DMSO

This common laboratory solvent (FW = 78.13 g/mol; CAS 67-68-5; Density = 1.100 g/cm<sup>3</sup>; FP = 18.5 °C, or 65.3 °F; BP = 189 °C, or 372 °F) is an aprotic solvent that dissolves both polar and nonpolar compounds. Its significant dipole (3.9 D) and dielectric constant (46.68) make it miscible with water, but also soluble in many organic solvents (e.g., ethanol, acetone, benzene, and chloroform). Its considerable skin-penetrating (percutaneous absorptive) properties also commend its use as a vehicle for rapid drug delivery. **DMSO Effects on Proteins:** Dimethyl sulfoxide stabilizes many proteins, especially multi-subunit proteins and supramolecular structures, the latter including microtubules, mitotic apparatus, etc. (1a). This effect is thought to result from the ability of particular DMSO:H<sub>2</sub>O solutions to alter the strength of hydrogen and hydrophobic bonding interactions. Preferential interactions can be expressed in terms of preferential binding of the cosolvent or its preferential exclusion (the latter also known as *preferential hydration*). The driving force is the perturbation by the protein of the chemical potential of the cosolvent. The measured change of the amount of water in contact with protein during the course of the reaction modulated by an osmolyte is a change in preferential hydration that is strictly a measure of the cosolvent chemical potential perturbation by the protein in the ternary water-protein-cosolvent system. Because DMSO also contains methyl groups, it also influences the strength of hydrophobic interactions. At a concentration of 20% or less, for example, DMSO drives glutamate dehydrogenase into the inactive monomer, and effect that is fully reversible by the allosteric activator ADP (1b). Higher DMSO levels result in irreversible inactivation. The predominant effect on β-glucuronidase is irreversible inactivation by 20% or more DMSO at 37 °C, but this enzyme is activated in 20% DMSO in the presence of high substrate levels. (1). DMSO also inhibits the clotting of fibrinogen by purified thrombin, but the major effect seems competition between thrombin and DMSO for fibrinogen binding sites. Such effects appear to be largely due to hydrophobic interactions between DMSO fibrinogen, even though DMSO also appears to reduce fibrin monomer aggregation mainly through effects on hydrophilic groups. These results suggest that reversible alterations in protein structure are the major effect of exposure of subunit proteins to low DMSO levels at low temperatures, whereas irreversible denaturation of subunit proteins may be appreciable a higher temperatures and higher DMSO concentrations (1). In the presence of 10% DMSO (vol/vol), phosphocellulose-purified tubulin assembles into microtubules (2). The reaction is rapid and strongly dependent on protein concentration. **DMSO-Mediated Drug Delivery:** The *stratum corneum*, corresponding to superficial-most skin layer, typically limits percutaneous absorption of drugs, especially those possessing multiple hydrogen bond-forming moieties. Factors altering solute transport across the skin include: presence of water, transport *decreases*; lipid solubility, transport *increases*; keratolytics, transport *increases*; surfactants, transport *increases*; molecular mass (transport *increases*, up to a critical point, then transport *decreases*); local hyperemia, transport *increases*; temperature, transport *increases*; dermatoses, transport *increases*; particle size, particle size (i.e., the smaller the molecule, the faster its transport; greater effect than molecular weight, which shows a variable relation with absorption); viscosity, transport *decreases*; electrical impedance, transport *decreases*; regional variations for palm, forehead, etc. (3). DMSO's polar, strongly hygroscopic properties result in super-hydration of the stratum corneum with subsequent increase in permeability (3). While having no known effect on plasma membranes, DMSO can cause changes in keratin filaments. Its *in vivo* effects are short-lived (3). Dimethyl sulfoxide is a safe and effective mechanism for facilitating the transdermal delivery of both hydrophilic and lipophilic medications to provide localized drug delivery (4). The clinical use of pharmaceutical-grade DMSO as a penetration enhancer is supported by the robust data that have accumulated over the past three decades demonstrating the favorable safety and tolerability profile (4). DMSO is rapidly absorbed through the skin, carrying with it many dissolved substances. This property commends DMSO as a vehicle for delivering drugs by membrane penetration. **Utility for Dissolving Water-Insoluble Drugs & Metabolites:** DMSO is a convenient solvent for dissolving various water-insoluble drugs (e.g., steroids, ionophorous antibiotics, antiviral nucleosides, taxol, colchicine, etc.) for biochemical experiments. The usual practice is to

prepare a drug solution in neat DMSO at 50-100 times its final desired concentration, followed by the corresponding 50-100 times dilution into culture media or a drug target-containing solution. That said, DMSO is not inert. Although the exact mechanism remains unclear, DMSO lowers the critical micelle concentration (*c.m.c.*) for many lipids. It is also a highly effective hydroxyl radical scavenger. DMSO (>5% vol/vol) stabilizes microtubules and reduces the dynamnicity. For these reasons, the final DMSO concentration in experimental samples should be kept <1-2% (vol/vol) to minimize side-effects. **Inhibition of Inflammasome Activation:** DMSO has long been known to exert inflammatory properties that commend its use in treating pain associated with arthritis and cystitis. DMSO attenuates interleukin IL-1β maturation, Casp1 activity, and ASC pyroptosome formation via NLRP3 inflammasome activators (5). NLRP4 and AIM2 inflammasome activity are unaffected, suggesting that DMSO is a selective inhibitor of the NLRP3 inflammasomes. The anti-inflammatory effect of DMSO has been confirmed in animal, LPS-endotoxin sepsis, and inflammatory bowel disease models. DMSO also inhibits LPS-mediating IL-1s transcription (5). **DMSO Reductase:** This molybdenum-containing enzyme catalyzes the reduction of DMSO to dimethyl sulfide (DMS). The reaction is: DMSO + 2H<sup>+</sup> + 2e<sup>-</sup> → DMS + H<sub>2</sub>O, where the electron source is unspecified. **Target(s):** acetylcholinesterase (11-14); *N*-acetyllactosamine synthase (15); adenosine deaminase (11,12); alcohol dehydrogenase (13,14); arylformamidase (15); asparaginase (16); aspartate ammonia lyase (17); bis(2-ethylhexyl)phthalate esterase (18); carboxylesterase (19); carboxypeptidase Y, or carboxypeptidase C (20); cathepsin B (21); cathepsin L (22); Ca<sup>2+</sup>-transporting ATPase (23-26); chitinase (27); cholesterol-5,6-oxide hydrolase (28); cytochrome c<sub>3</sub> hydrogenase (69); dihydrofolate reductase, slightly inhibited (29); DNA-directed DNA polymerase (30-32); DNA polymerase ε (25,26); endopeptidase La (33); F<sub>1</sub> ATPase, or ATP synthase (34); glucuronosyltransferase (35,36); L-glutamine:D-fructose-6-phosphate aminotransferase (37); hemoglobin S polymerization (38); histone acetyltransferase (39); inositol-phosphate phosphatase, weakly inhibited (40); laccase (71,72); lactose synthase (10); lipase, or triacylglycerol lipase (41); matrilysin, or matrix metalloproteinase-7 (42); membrane alanyl aminopeptidase (43); methionine S-adenosyltransferase (44-49); Mg<sup>2+</sup>-importing ATPase (26); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (50-52); *N*-nitrosodimethylamine demethylase, or cytochrome P450 (53); pancreatic ribonuclease denaturation (54); papain (50); penicillin-binding protein 1b (56); peptidoglycan glycosyltransferase (56); peroxidase (70); poly(ADP-ribose) synthetase (57); polyphenol oxidase (58); protein-S isoprenylcysteine O-methyltransferase (50); ribonuclease H (32); soluble epoxide hydrolase (60-62); streptopain (63); tannase (64); telomerase (65); thrombin (66); tyrosinase, or monophenol monooxygenase (58); urease (67); Xaa-Pro aminopeptidase, or aminopeptidase P (68). **1a.** Timasheff (2002) *Proc. ### *N,N*-Dimethyltryptamine

This strong hallucinogen (FW<sub>free-base</sub> = 188.27 g/mol; CAS 61-50-7; M.P. = 44.6-46.8°C; B.P. = 60-80°C; pK<sub>a</sub> = 8.68), also named 2-(1*H*-indol-3-yl)-*N,N*-dimethylethanamine, found in a number of plants, especially the leaves of the cohoba tree *Piptadenia peregrina* and *Banisteriopsis caapi* (also known as ayahuasca, caapi or yajé) is inactivated, when given orally, due to degradation by visceral monoamine oxidase (1). The psychedelic brew made in the Amazon is also rich in harmine and harmaline. A rabbit lung enzyme *N*-methylates serotonin and tryptamine to form the psychotomimetic metabolites, bufotenine and *N,N*-dimethyltryptamine (2). **Target(s):** amine *N*-methyltransferase (3); aromatic-L-amino-acid decarboxylase (4); aryl acylamidase, weakly inhibited (5); indoleamine *N*-methyltransferase (6). **1.** Barker, Monti & Christian (1981) *Int. ### Diminazine Aceturate

This antiprotozoal agent (FW = 515.53 g/mol; CAS 908-54-3), also known as Berenil<sup>®</sup>, is frequently used in the treatment of trypanosomiasis in domestic livestock. **Target(s):** *S*-adenosylmethionine decarboxylase (1-7); Ca<sup>2+</sup>-dependent ATPase (8); diamine *N*-acetyltransferase, or

spermidine/spermine *N*-acetyltransferase (9,10); diamine oxidase (2,11); DNA polymerase (12); DNA topoisomerase I (13-23); DNA topoisomerase II (16,24,25); polyamine oxidase, weakly inhibited (9); protein biosynthesis (26); reverse transcriptase (27); ribosome (26); RNA-directed DNA polymerase (27); trypanosomal oligopeptidase (28); trypsin (29). **1.** Karvonen, Kauppinen, Partanen & Pösö (1985) *Biochem. ### Dinaciclib

This cyclin kinase-directed inhibitor (FW = 396.49 g/mol; CAS 779353-01-4; Solubility: 80 mg/mL DMSO; <1 mg/mL Water; Formulation: 20% hydroxypropyl-β-cyclodextran), also known as SCH727965 and (S)-3-((3-ethyl-5-(2-(2-hydroxyethyl)piperidin-1-yl)pyrazolo[1,5-a]pyrimidin-7-yl)-amino)methyl)pyridine 1-oxide, interacts with the acetyl-lysine recognition site within bromodomains of cyclin-dependent kinase (1,2). Checkpoint kinases are essential serine/threonine protein kinases that respond to DNA damage and stalled DNA replication. *In vitro*, SCH 727965 inhibits CDK2 (IC<sub>50</sub> = 1 nM), CDK5 (IC<sub>50</sub> = 1 nM), CDK1 (IC<sub>50</sub> = 3 nM), and CDK9 (IC<sub>50</sub> = 4 nM), blocking thymidine incorporation into DNA (1). SCH 727965 induces regression of established solid tumors in a range of mouse models following intermittent scheduling of doses below the maximally tolerated level (1). In human tumor cell lines, dinaciclib exposure leads to the accumulation of double-strand DNA breaks and cell death. **1.** Parry, *et al.* (2010) *Mol. Cancer Ther.* **9**, 2344. **2.** Guzi, *et al.* (2011) *Mol. Cancer Ther.* **10**, 591. **3.** Martin, Olesen, Georg & Schönbrunn (2013) *ACS Chem. Biol.* **8**, 2360.

### Dinactin

This macrotetralide *Streptomyces* antibiotic (FW = 764.99 g/mol; CAS 20261-85-2; Soluble in ethyl acetate, DMSO, 100% ethanol (moderate), and methanol (moderate)), also known as Antibiotic AKD-1C and Antibiotic S-3466A, is a hydrophobic ionophore and nonactin homologue. Dinactin binds and transports monovalent cations with the following selectivity:  $\text{NH}_4^+ > \text{K}^+ \approx \text{Rb}^+ > \text{Cs}^+ > \text{Na}^+$  (1-3). Dinactin blocks cytokine production ( $\text{IC}_{50} = 10 \text{ ng/mL}$ ) through a post-transcriptional mechanism, inhibiting T-cell proliferation induced by IL-2 as well as cytokine production at nanomolar levels for IL-2, IL-4, and IL-5 (4). Dinactin also reduces pulmonary eosinophilia when administered within 1 day of airway antigen challenge (4). (Note the structural similarity of dinactin to synthetic crown ethers used by Nobelist Donald Cram as models for metal ion Host:Guest interactions. In Cram's nomenclature, dinactin is an ester analogue of an 32:8 crown ether.) 1. Pressman (1976) *Ann. Rev. Biochem.* **45**, 501. 2. Haynes & Pressman (1974) *J. Membr. Biol.* **18**, 1. 3. ### 3,5-Dinitro-*o*-cresol

This yellow herbicide and insecticide (FW = 198.14 g/mol; CAS 497-56-3), also known as dinitrocresol, 4,6-dinitro-*o*-cresol and 3,5-dinitro-2-hydroxytoluene, is a strong protonophore that acts as a classical uncoupler of oxidative phosphorylation. [Note: Care should be exercised in literature searches, because the name 3,5-dinitro-*o*-cresol also occasionally refers to 2-methyl-3,5-dinitrophenol.] **Target(s):** creatine kinase (1); oxidative phosphorylation, as uncoupler (2); pyruvate decarboxylase (3). 1. Kuby & Noltmann (1962) *The Enzymes*, 2nd ed., **6**, 515. 2. Castilho, Vicente, Kowaltowski & Vercesi (1997) *Int. J. Biochem. Cell Biol.* **29**, 1005. 3. Vandendriessche (1941) *Enzymologia* **10**, 69.

### 2,4-Dinitrophenol

This protonophore and uncoupling agent (FW = 184.11 g/mol; CAS 51-28-5; M.P. = 112-114°C CAS 51-28-5; Pale yellow solid;  $\text{pK}_a$  value of 4.1-4.5, 2,4-dinitrophenolate anion is intensely yellow; colorless < pH 2.6 and yellow > pH 4.4) strongly inhibits mitochondrial oxidative phosphorylation (1-3) and mildly uncouples chloroplast photophosphorylation by increasing the transmembrane proton leak (3-8). Because mitochondria-derived ATP fuels cytosolic glucose phosphorylation, DNP inhibition of oxidative phosphorylation also reduces glycolytic flux. **Mode of Action:** With a relatively low octanol:water partition coefficient (e.g.,  $\{(\text{Solubility}_{\text{Octanol}})/(\text{Solubility}_{\text{Water}})\} = 1.5$ ), DNP would be expected to have limited penetration of biomembranes. Nonetheless, DNP binds protons on one side of a membrane and shuttles them to the opposite side. The exact structure of the active protonophore remains unclear. Finkelstein (8) has proposed that the primary charge carrier in the membrane is neither  $\text{H}^+$  or  $\text{OH}^-$ ; rather, it is likely to be a dimer formed between the undissociated and dissociated form of the weak acid. He showed that all of the data on the action of these weak acids on thin lipid membranes is consistent with this idea. Although such associations and dissociations occur at random, the probability of proton binding is far greater on the side having the highest proton concentration. When sufficient DNP is present, maintenance of a proton gradient becomes highly unlikely. DNP also binds to the bilayer surface, modifying its Zeta Potential (i.e., its charge density). (See also *Uncouplers (Gradient-Dissipating Proton Carriers)*; 3,5-Dinitro-*o*-cresol; Dinoseb; FCCP) Finally, despite a slightly higher synthesis of cytosolic ATP in the presence of DNP, there is net mitochondrial uptake of ATP via the adenine nucleotide translocase, exchanging cytosolic ATP for mitochondrial ADP, the latter rising as oxidative phosphorylation fails in DNP's presence. **Hazards of DNP Use for Weight Loss:** When taken regularly, DNP can increase the average metabolic rate in humans by ~11% for every 100 mg administered. Although once touted as a highly effective diet aid, DNP overdose often induces fatal hyperthermia as a direct consequence of

uncoupler-induced thermogenesis. Other symptoms include tachycardia, diaphoresis, and rapid breathing. DNP is highly toxic, with unremitting high fever the greatest risk to poisoned individuals. Acute administration of 20-50 mg/kg in humans can be lethal, with formation of cataracts a common side-effect at lower dosage. To quote the famous mitochondrial researcher Efraim Racker (p. 155 of *A New Look at Mechanisms in Bioenergetics*, Academic Press, 1976), "...treatment eliminated not only the fat, but also the patients,.... This discouraged physicians for awhile..." The majority of the damage results from unbridled thermogenesis, wherein heat is produced in place of ATP. While unappreciated by unwary dieters and bodybuilders intent on ridding their bodies of fat, the greatest threat of DNP consumption is that biological individuality makes its toxicity unpredictable and thus hazardous. Responding to a number of DNP-associated deaths in the 1930s, the U.S. Food & Drug Administration classified DNP as extremely dangerous and unfit for human consumption. **Controlled Release DNP:** A novel DNP formulation with a sustained-release coating results in lower peak plasma concentrations (1-5  $\mu\text{M}$ ) and sustained-release pharmacokinetics, thereby increasing the therapeutic index (i.e., ratio of toxic to effective dose) by 25-fold over liver-targeted DNP and 1250-fold over unaltered DNP (9). Metabolic studies in rats receiving a 5-day continuous, low-dose intragastric infusion of DNP support the potential of using mitochondrial protonophores and other mitochondrial uncoupling agents to treat nonalcoholic fatty liver disease (NAFLD), metabolic syndrome, as well as Type 2 diabetes. **Target(s):** acylphosphatase (10); aldehyde oxidase (11); D-amino-acid oxidase (12); apyrase (13); arginine transport (14); ATP phosphoribosyl-transferase (15); caldiciol 1-monoxygenase, or 25-hydroxyvitamin D, or  $\alpha$ -hydroxylase (29,59-61); catechol oxidase (63); cellulase (15); choline sulfotransferase (16); chymotrypsin (17); *trans*-cinnamate 4-monoxygenase (61); deoxycytidine kinase, weakly inhibited (19); dihydroorotate dehydrogenase (20); dimethylpropiothetin dethiomethylase (20); glucose-6-phosphate isomerase (22); glutaminase (23); glutamine synthetase (24); glycogen phosphorylase (25); hexokinase (26,27); 4-hydroxybenzoate nonaprenyl-transferase (27); isocitrate dehydrogenase ( $\text{NAD}^+$ ) (30); leukocyte phagocytosis and clumping (31,32); lysine transport (14); malate dehydrogenase (33,34); NADH dehydrogenase (quinone) (35,36); NADH oxidase (36); NAD(P)H dehydrogenase (quinone), or diaphorase (35,37-39); 2-nitrophenol 2-monoxygenase (5,10); oxidative and photo-phosphorylation (1-9,41-44); phosphatidylglycero-phosphatase (45); phosphatidylserine decarboxylase (46); 3-phytase (47,48); polyphenol oxidase (63); pyruvate decarboxylase (49-51); rubredoxin:NAD<sup>+</sup> reductase (52); signal peptidase 1, or leader peptidase (53-55); trypsin (18,56); very long chain fatty acid  $\alpha$ -hydroxylase (57); xylose isomerase (58). 1. ### 2,4-Dinitrophenyl 2-Deoxy-2-fluoro-β-D-glucopyranoside

This glucoside (FW = 348.24 g/mol) irreversibly inhibits certain β-glucosidases by trapping the enzyme as a covalent intermediate during catalysis (1). The intermediate is stable, but undergoes turnover in the presence of cellobiose, reactivating the enzyme by transglycosylation. Use of tritium-labeled inactivator facilitated isolation and sequencing of a radiolabeled peptide from this enzyme, confirming that the active site nucleophile is glutamate-274. Notably, this active-site glutamate and nearby amino acid residues are absolutely conserved in the homologous family F of cellulases. **Target(s):** glucan 1,3-β-glucosidase, or exo-β-(1,3)-glucanase (1,2); β-glucosidase (3,4); phlorizin hydrolase, or glycosylceramidase (5-8); lactase, or lactase/phlorizin hydrolase, or glycosyl-ceramidase (5-7). **1.** Tull, Withers, Gilkes, *et al.* (1991) *J. ### 1,2-Dioctanoyl-sn-glycero-3-pyrophosphate

This phosphatidate analogue (FW<sub>free-acid</sub> = 517.47 g/mol) is an antagonist for lysophosphatidate receptors and was the first selective Edg-7 (LPA3) receptor antagonist ( $K_i$  = 106 nM). The  $K_i$  value for Edg-3 (LPA1) is 6.6 μM. **1.** Fischer, Nusser, Virag, *et al.* (2001) *Mol. Pharmacol.* **60**, 776.

### Diocetyl Sulfosuccinate, Sodium Salt

This anionic detergent (FW = 444.57 g/mol), also known as Aerosol OT, AOT, docusate sodium, and bis(2 ethylhexyl) sodium sulfosuccinate, is

stable in acidic or neutral solution but will hydrolyze in alkaline solutions. Note that it is bactericidal against Gram-positive microorganisms at neutral pH but is bactericidal against both Gram positive and negative organisms at pH 4. **Target(s):** acid phosphatase (1); α-amylase (2); cAMP phosphodiesterase (3); cutinase (4,5); lipase, or triacylglycerol lipase (6); phosphatidylinositol diacylglycerol-lyase, or phosphatidyl-inositol-specific phospholipase C (7). **1.** Lalitha & Mulimani (1997) *Biochem. ### 1,2-Dioleoyl-sn-glycerol

This diacylglycerol (FW = 621.00 g/mol), also known as 1,2-diolein, inhibits phospholipase C and CDP-diacylglycerol:serine O-phosphatidyl-transferase. It also activates protein kinase C. Note: Acyl group migration can occur during storage, especially under acidic conditions. **Target(s):** CDP-diacylglycerol:serine O-phosphatidyl-transferase (1,2); phosphatidate phosphatase (3); phospho-lipase C (4); sphingomyelin phosphodiesterase (5). **1.** Carman & Bae-Lee (1992) *Meth. Enzymol.* **209**, 298. **2.** Bae-Lee & Carmen (1990) *J. Biol. Chem.* **265**, 7221. **3.** Kanoh, Imai, Yamada & Sakane (1992) *J. Biol. ### 1,2-Dioleoyl-sn-glycerol 3-Phosphate

This phosphatidate (FW<sub>free-acid</sub> = 700.98 g/mol), also known as dioleoyl phosphatidate, inhibits AMP deaminase and the Ca<sup>2+</sup>-transporting ATPase. (See also Phosphatidate and Phosphatidic Acid) **Target(s):** AMP deaminase (1); Ca<sup>2+</sup>-transporting ATPase (2); chymase (3); glycosyl-phosphatidylinositol phospholipase D (4); glyoxalase II, or hydroxyacylglutathione hydrolase (5); phosphoprotein phosphatase (6); protein phosphatase 1 (6). **1.** Tanfani, Kulawiak, Kossowska, *et al.* (1998) *Mol. ### (2,3S,18R,19R)-Dioxidosqualene

This diepoxide (FW = 442.73 g/mol) inhibits (apparently reversibly) pig liver lanosterol synthase or 2,3-oxidosqualene-lanosterol cyclase (EC 5.4.99.7), with a  $K_i$  value of 21 nM. OSLC is the key enzyme of the ring cyclization reaction suffered by (3S)-2,3-oxidosqualene to give lanosterol as

the final steroid precursor in fungi and mammalian systems. While the mechanism of this cyclization is still debated, most favor a stepwise process, that proceeds through a series of conformationally rigid, partially cyclized carbocationic intermediates. 1. Abad, Guardiola, Casas, Sánchez-Baeza & Messegueur (1996) *J. Org. Chem.* **61**, 7603.

### 2,4-Dioxopentanoate

This  $\alpha,\gamma$ -diketo acid (FW<sub>free-acid</sub> = 130.10 g/mol), also known as 2,4-dioxopentanoic acid and 2,4-diketopentanoic acid, is an acetoacetate analogue that reversibly inhibits acetoacetate decarboxylase ( $K_i \approx 10^{-7}$  M). It reacts with an active-site lysyl residue to form a stable chromophore ( $\lambda_{\max} \approx 325$  nm;  $\epsilon \approx 14,000$  cm<sup>-1</sup>M<sup>-1</sup>), with the bound inhibitor (likely a *cis*-enamine) exhibiting a ten-minute dissociation half-life. **Target(s)**: acetoacetate decarboxylase (1-7); 4-hydroxyphenylpyruvate dioxygenase (8); lactate dehydrogenase (9); phosphoenolpyruvate carboxykinase (GTP), weakly inhibited (10,11); ureidoglycolate lyase (12). 1. ### Dipeptidyl Peptidase IV Inhibitors

Glucagon-like peptide-1 (GLP-1), an incretin that displays a strong insulin secretion effect on pancreatic  $\beta$ -cells, contains a His-Ala cleavage site at the N-terminus of its active form. This site is targeted and cleaved by Dipeptidyl Peptidase IV (DPP-4), and inhibition of incretin proteolysis results in sustained insulin release. This protease also uses its S<sub>1</sub>, S<sub>2</sub>, S<sub>1'</sub>, S<sub>2'</sub> and S<sub>2</sub> subsites to interact with inhibitors: (a) Vildagliptin and Saxagliptin bind to the S<sub>1</sub> and S<sub>2</sub> subsites, (b) Alogliptin, Linagliptin and Trelagliptin bind to the S<sub>1'</sub> and/or S<sub>2'</sub> subsites in addition to the S<sub>1</sub> and S<sub>2</sub> subsites, and (c) Sitagliptin, Anagliptin, Teneligliptin and Omarigliptin bind to the S<sub>1</sub>, S<sub>2</sub> and S<sub>2</sub> extensive subsites. The affinity of each DPP-4 inhibitor appears to reflect the binding energy available from interactions at these subsites as well as nearby steric interactions, but the efficacy of each is strongly affected by its own ADME properties. **See specific inhibitor**

### Diphenhydramine

This tertiary amine (FW<sub>free-base</sub> = 255.36 g/mol; CAS 58-73-1), widely known as Benadryl and systematically as 2-diphenylmethoxy-*N,N*-dimethylethanamine, is a histamine H<sub>1</sub> receptor antagonist. Diphenhydramine is most often supplied as the hydrochloride and is readily absorbed. **Target(s)**: amine oxidase (1); CYP2D6 (2); histamine H<sub>1</sub> receptor (3,4); histamine *N*-methyltransferase (5); Na<sup>+</sup> current (6). 1. ### Diphenylchloroarsine

This organoarsenical (FW = 264.59 g/mol; Referred to as CLARK I; Chemical warfare symbol = DA) is a riot control and vomit-inducing agent that is fast-acting rapid. Diphenylchloroarsine was first used in combat in 1917 by Germany in World War I. It has also been. **Target(s)**: aconitase (1-3); arginine kinase (4); cholinesterase (5); creatine kinase (6,7); isocitrate dehydrogenase (8-10); phospholipase B (11); urease (12). 1. ### Diphenyleneiodonium Chloride

This aromatic iodonium salt (FW<sub>chloride</sub> = 314.55 g/mol; CAS 4673-26-1; **Abbreviation**: DPI) inhibits respiratory enzyme NADH dehydrogenase. Addition of 10  $\mu$ M DPI abolished the reduction of both the FAD and the cytochrome *b* components of the NADPH oxidase. DPI also catalyses an exchange of Cl<sup>-</sup> for OH<sup>-</sup> across membranes and induces apoptosis. Another DPI target, aldehyde dehydrogenase II, catalyzes the vascular bioactivation of the antianginal drug nitroglycerin to yield nitric oxide, which in turn activates soluble guanylate cyclase, resulting in cGMP-mediated vasodilation (1). Note that the main pathway of ALDH II-catalyzed denitration yields 1,2-glycerol dinitrate and inorganic nitrite, but a minor reaction results in direct formation of NO (2). DPI is a competitive inhibitor ( $K_i = 2$   $\mu$ M) relative to nitroglycerin in the redox and nitrate esterase reactions catalyzed by ALDH II. Importantly, DPI inhibits the vasodilatory action of nitroglycerin in the same concentration range, providing strong evidence that ALDH II is responsible for transforming nitroglycerin into nitric oxide (or a related species). **Effect on Iodide Transport**: At concentrations used to those which inhibit the generation of O<sub>2</sub> derivatives, DPI activates iodide efflux but not of its analogues, monovalent technetium or rhodium in the PCC13 rat thyroid cell line and in COS cell lines expressing the iodide transporter NIS. Therefore, the inhibitory effects of DPI, especially in thyroid cells, must be interpreted with caution (3). **Key Pharmacokinetic Parameters**: See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s)**: Ca<sup>2+</sup> currents (4); cytokinin dehydrogenase (5); hydrogenase (5); K<sup>+</sup> currents (4); NADH dehydrogenase, or Complex I (6,7); NADPH:cytochrome P450 reductase (8); NADPH oxidase (9,10); nitric-oxide dioxygenase (11,12); nitric-oxide synthase (13,14); oxidative phosphorylation (15); photophosphorylation (16); protoporphyrinogen oxidase (17); xanthine dehydrogenase (18,19); xanthine oxidase (20-22); zeaxanthin epoxidase (23). 1. ### 5,5-Diphenylhydantoin

This substituted imidazolidinedione (FW = 252.27 g/mol; CAS 57-41-0), widely known as Dilantin, stabilizes excitable membranes and is an anticonvulsant drug often used to treat neuropathic pain. Although first synthesized in 1908, its anticonvulsant properties were reported in 1938 (1,2), making it the first anti-epileptic drug not to act as a sedative at typical concentrations. Dilantin's discovery was not simply a landmark in the history of anti-convulsants; it also spurred research into discovering the differences between the numerous convulsive disorders. **Target(s):** acetoin dehydrogenase (3); alcohol dehydrogenase (NADP<sup>+</sup>), or aldehyde reductase (3-5); 4-aminobutyrate aminotransferase (6); Ca<sup>2+</sup> currents (7); Ca<sup>2+</sup>-dependent protein kinase (8); carbonyl reductase (3); glycerol dehydrogenase (9); K<sup>+</sup> channels, delayed rectifier (10); Na<sup>+</sup> currents (11,12); procollagen-proline 4-dioxygenase (13); succinate-semialdehyde dehydrogenase (6). **1.** Merritt & Putnam (1938) *Arch. ### Diphtheria Toxin

This toxic ADP-ribosyltransferase (MW<sub>active-form</sub> = 21 kDa; CAS 92092-36-9) from *Corynebacterium diphtheriae* inhibits protein synthesis by catalyzing the NAD<sup>+</sup>-dependent ADP-ribosylation of Elongation Factor-2 (EF-2) of eukaryotes and archaeobacteria, forming diphthamide, or 2-[3-carboxyamido-3-(trimethylammonio)propyl]histidine (1-12). The toxin begins as a 567-residue zymogen that, upon gaining entry into a target cell, undergoes cleavage of one disulfide bond and one peptide bond, thereby generating the active ADP-ribosyltransferase. The latter then catalyzes covalent modification of EF-2, preventing the transfer to the tRNA-bound amino acid to a growing polypeptide chain. In 1888, Roux and Yersin demonstrated that diphtheria culture filtrates (*i.e.*, absent intact bacilli) contained a toxin that, when injected into an animal, produced all the symptoms of diphtheria. Diphtheria was thus the first infectious disease demonstrated to be solely caused by a toxin, and it was also the first bacterial toxin to be purified into crystalline form (13). In humans, the lethal dose is ~0.1 µg of toxin per kg bodyweight. **1.** Passador & Iglewski (1994) *Meth. ### Diphyllin

This naturally occurring naphthofuran-containing lignin (FW = 380.35 g/mol; CAS 22055-22-7), named systematically as 9-(1,3-benzodioxol-5-yl)-4-hydroxy-6,7-dimethoxynaphtho[2,3-c]furan-1(3H)-one; 4-Hydroxy-6,7-dimethoxy-9-(1,3-benzodioxole-5-yl)-1,3-dihydronaphtho[2,3-c]furan-1-one, from *Cleistanthus collinus*, potently inhibits acid influx (IC<sub>50</sub> = 0.6 nM) and directly inhibits vacuolar ATPase, or V-ATPase, (IC<sub>50</sub> = 17 nM), slightly more weakly than bafilomycin A<sub>1</sub> (IC<sub>50</sub> = 4 nM) (1). Remarkably, diphyllin is also cytostatic, inhibiting human SGC7901 gastric cancer cell proliferation, inducing apoptosis. It decreases LRP6 phosphorylation, but not the level of LRP6 (2), a diphyllin effect that was traced to altered Wnt/β-catenin signaling, which reduces expression of β-catenin, *c-myc* and cyclin D<sub>1</sub>. Diphyllin also alters cellular susceptibility to influenza viruses through the inhibition of endosomal acidification, thus interfering with downstream virus replication (3). **1.** Sørensen, Henriksen, Neutzsky-Wulff, Dziegiel & Karsdal (2007) *J. Bone Miner. Res.* **22**, 1640. **2.** Shen, Zoua, Chen, *et al.* (2011) *Eur. J. Pharmacol.* **667**, 330. **3.** Chen, Cheng, Liu, *et al.* (2013) *Antiviral Res.* **143**, 32.

### Dipropylcyclopentylxanthine

This A<sub>1</sub> receptor antagonist (FW = 304.39 g/mol; CAS 102146-07-6), also known as DPCPX, PD-116,948, 8-cyclopentyl-1,3-dipropyl-7H-purine-2,6-dione and 8-cyclopentyl-N<sup>1</sup>, N<sup>3</sup>-dipropyl-7H-purine-2,6-dione, selectively targets A<sub>1</sub> adenosine receptors (1,2), but also potently inhibits 3',5'-cyclic-AMP phosphodiesterase-4, or PDE4 (3). **1.** Alonso, Schoijet, Torres & Flawiá (2006) *Mol. Biochem. Parasitol.* **145**, 40. **2.** Bader, Kortholt, Snippe & van Haastert (2006) *J. Biol. Chem.* **281**, 20018. **3.** Rascón, Soderling, Schaefer & Beavo (2002) *Proc. Natl. Acad. Sci. USA* **99**, 4714.

### Dipyridamole

This vasodilator (FW = 504.63 g/mol; CAS 58-32-2) is a potent inhibitor of cyclic-nucleotide phosphodiesterase-5 (IC<sub>50</sub> = 0.9 µM). It also blocks nucleoside transport into mammalian cells and reduces platelet aggregation. **Target(s):** adenosine deaminase (1); adenosine kinase, inhibited at low substrate concentrations (2); adenosine uptake (3,4); 3',5'-cyclic-GMP phosphodiesterase (5-11); 3',5'-cyclic-nucleotide phosphodiesterase (12-20); cyclic-nucleotide phosphodiesterase isozyme-5 (5-7,9,10); cyclic-nucleotide phosphodiesterase isozyme-10 (20); cyclic-nucleotide phosphodiesterase isozyme-11 (14-17); *ecto*-nucleotidase (21); electron transport (22); glucose-6-phosphate dehydrogenase (23); guanylate cyclase, retinal (24,25). **1.** Sopena, Vina, Calderon, *et al.* (1970) *Rev. ### Discodermolide

This cell-penetrating microtubule-directed agent (FW = 491.83 g/mol; CAS 127943-53-7) causes cell-cycle arrest at the metaphase-anaphase transition, presumably due to its remarkable stabilizing effects on assembled microtubules (1). Discodermolide binds more tightly than paclitaxel to microtubules, displaying a stoichiometry of one molecule per tubulin dimer (1). Binding of discodermolide and taxol are mutually exclusive, suggesting some overlap in binding sites or binding conformations. Like taxol, discodermolide induces the polymerization of purified tubulin with and without microtubule-associated proteins (*or* MAPs), and the polymers formed are stable to cold- and calcium ion-induced depolymerization (2). Collectively, these properties represent hypernucleation, with nuclei forming spontaneously and efficiently, lowering the apparent tubulin critical concentration, and producing shorter polymers with discodermolide than with paclitaxel, when probed under a variety of reaction conditions (2). Discodermolide competitively inhibits ( $K_i = 0.4 \mu\text{M}$ ) the binding of [ $^3\text{H}$ ]paclitaxel to polymerized tubulin. Multidrug-resistant human colon and ovarian carcinoma cells overexpressing P-glycoprotein, which are 900x and 2800x resistant to paclitaxel, respectively, relative to the parental lines, retain significant sensitivity to discodermolide (*e.g.*, 25x and 89x more resistant relative to the parental lines). Ovarian carcinoma cells that are 20-30x more resistant to paclitaxel than the parental line on the basis of expression of altered  $\beta$ -tubulin polypeptides retained nearly complete sensitivity to discodermolide (2). (**See also Paclitaxel, Pelorusside, Laulimalide, Dictyostatin, Epothione, Sarcodictyin**) **1.** Hung, Chen & Schreiber (1996) *Chem. Biol.* **3**, 287. **2.** Kowalski, Giannakakou, Gunasekera, *et al.* (1997) *Mol. Pharmacol.* **52**, 613.

**Disodium Tetraborate, See Borax**

### Distamycin A

This antibiotic (FW<sub>free-base</sub> = 481.51 g/mol; FW<sub>hydrochloride</sub> = 517.98 g/mol; CAS 6576-51-8), also called stallimycin, from *Streptomyces distallicus* has antiviral and oncolytic properties. Distamycin A binds to the minor groove of native DNA as well to denatured DNA. Both DNA and RNA polymerases are inhibited, with the latter inhibited more strongly in the presence of native DNA (1). Distamycin A is reported to target the initiation of RNA synthesis (2). **Target(s):** *Ball* restriction endonuclease, type II site-specific deoxyribonuclease (3); DNA ligase (ATP) (4); DNA methyltransferase (5); DNA polymerase (6-8); DNA topoisomerase I (9-12); *EcoRI* restriction endonuclease, type II site-specific deoxyribonuclease (3,13); *EcoRII* restriction endonuclease, type II site-specific deoxyribonuclease (13); *EcoRV* restriction endonuclease, type II site-specific deoxyribonuclease (3); helicase (14,15); *HinDII* restriction endonuclease, type II site specific deoxyribonuclease (13); *HinDIII* restriction endonuclease, type II site-specific deoxyribonuclease (13); *HpaI*

restriction endonuclease, type II site-specific deoxyribonuclease (13); *HpaII* restriction endonuclease, type II site-specific deoxyribonuclease (13); *NruI* restriction endonuclease, type II site-specific deoxyribonuclease (3); reverse transcriptase (16,17); RNA-directed DNA polymerase (16,17); RNA polymerase (1,2,18-20); *Vaccinia* virus DNA polymerase (21). **1.** Zimmer, Puschendorf, Grunicke, Chandra & Venner (1971) *Eur. ### Disulfiram

This metabolic inhibitor and alcohol abuse therapeutic (FW = 296.56 g/mol; CAS 97-77-8), known also as bis(diethylthiocarbamoyl) disulfide, and Antabuse™, targets mammalian acetaldehyde dehydrogenase (Reaction:  $\text{CH}_3\text{CHO} + \text{NAD}^+ \rightleftharpoons \text{Acetate} + \text{NADH}$ ), leading to the accumulation of toxic levels of acetaldehyde and creating an unpleasant sensation upon alcohol consumption (1). **Primary Mode of Action:** Of the four human isozymes, only ALDH1 and ALDH2 are strongly inhibited. Based on its disulfiram inhibition characteristics, the F1 isozyme of the well-characterized horse liver ALDH is likely to be primarily responsible for oxidizing acetyldehyde produced during *in vivo* ethanol oxidation (2). Importantly, [ $^{14}\text{C}$ ]-Disulfiram reacts with human liver aldehyde dehydrogenase E1 with attendant loss of catalytic activity and no incorporation of radiolabel, suggesting that disulfiram's action on ALDH does not involve sulfhydryl-disulfide interchange (1). An early claim that disulfiram and ethanol react to produce a quaternary ammonium compound that is responsible for disulfiram's unpleasant effects is in error (3). **The "Disulfiram Reaction":** Alcohol ingestion by disulfiram-treated patients results in "The Disulfiram Reaction", referring to the strongly unpleasant combination of flushing, headache, nausea, head and neck throbbing, vomiting, sweating, thirst, chest pain, palpitations, dyspnea, hyperventilation, tachycardia, confusion, arrhythmias, and convulsions. In rare instances, disulfiram treatment can lead to other, far more serious effects, including acute hepatitis, fatigue, anorexia, nausea, abdominal pain, and jaundice. Nervous system side effects include malaise, lethargy, confusion, personality changes, disorientation, and memory impairment. **Target(s):** acetaldehyde dehydrogenase (1-2); alcohol dehydrogenase,  $K_i = 4 \mu\text{M}$  (4); 5-lipoxygenase,  $K_i = 0.5 \mu\text{M}$ , comparable to that of diphenyldisulfide ( $\text{IC}_{50} = 0.2\text{-}0.4 \mu\text{M}$ ), suggesting inhibition is the result of a thiol-disulfide exchange reaction (5); selective inhibition of alternative respiratory pathway in plant mitochondria, with onset of inhibition taking several minutes and fully prevented by dithiothreitol (6); DNA cleavage by hydroxyl radical-producing agents, such as 1,2-dimethylhydrazine, ascorbate, and cysteine (7); rat ovarian carbonyl reductase (8). **1.** Vallari & Pietruszko (1982) *Science* **216**, 637. **2.** Eckfeldt, Mope, Takio & Yonetani (1976) *J. ## Dithiaden &amp; Diathiaden S-Oxide

This histamine receptor antagonist (FW = 301.47 g/mol; CAS 5802-61-9), also named Bisulepine and (3*E*)-*N,N*-dimethyl-3-(5*H*-thieno[2,3-*c*] [2]benzothiepin-10-ylidene)propan-1-amine, and its oxidation metabolite, diathiaden *S*-oxide (FW = 317.46 g/mol; CAS 11119-54-3), target H<sub>1</sub> receptors, both in pharmacological experiments and *in vivo*. In contrast to dithiaden, dithiaden *S*-oxide exerts a demonstrable inhibitory action as much as the subtoxic or sublethal dosage in experiments in mice and rats. Other experimental findings demonstrate higher selectivity of pharmacological effects of dithiadenoxide. **See also** Loratadine 1. Blehová & Metys (1992) *Cesk Farm.* **41**, 185.

## Dithionite

This powerful inorganic reducing agent (FW = 174.11 g/mol for disodium salt; CAS 14844-07-6; unusual 2.4-Å disulfide bond-length; Redox Potential = -0.66 Volts relative to the standard hydrogen electrode), is of immense utility in biochemistry, with a redox potential that is sufficient to convert uncomplexed and porphyrin-bound Fe(III) to Fe(II), with concomitant generation of two molecules of SO<sub>2</sub> gas. Dithionite also reacts with heme-bound oxygen to produce deoxyhemoglobin. Treatment of intact red blood cells with dithionite can induce sickling in cells containing hemoglobin S. Dithionite also reduces NAD<sup>+</sup> to NADH. *Note:* Sodium dithionite oxidizes readily when damp or in solution. Solutions should always be freshly prepared in buffered conditions, preferably above pH 7.5.

**Target(s):** acid phosphatase (1-9); ADP-ribosyl-[dinitrogen reductase] hydrolase (10); arylformamidase (11,12); aspartate aminotransferase (13); catalase (14,44); catechol 1,2 dioxygenase (43); CoB-CoM heterodisulfide reductase (45); CO-methylating acetyl-CoA synthase, *or* carbon monoxide dehydrogenase (15,16); cystathionine β-synthase (17); ferredoxin:NADP<sup>+</sup> reductase (18); hydrogenase (19); 4-hydroxybenzoate decarboxylase (20); 3-hydroxy-3-methylglutaryl CoA reductase, partially inhibited (21); 4-hydroxyquinoline 3-monooxygenase (22); indoleacetylglucose:inositol *O*-acyltransferase (23); indole 2,3-dioxygenase (24,25); ligninase H8, *or* lignin peroxidase H8 (26); methane monooxygenase (27); 2-(methylthio)ethanesulfonic acid reductase (28); nitrate reductase (29,30); nitrous oxide reductase (31); oxalate decarboxylase (32,33); phenol 2 monooxygenase (34); purple acid phosphatase (1,3,6); quercetin 2,3-dioxygenase (35); sulfur reductase (36); tetrachloroethene reductive dehalogenase (37); thiosulfate dehydrogenase, weakly inhibited (47); thiosulfate dehydrogenase (quinone) (46); urocanate hydratase, urocanase (38); vitamin K-dependent carboxylase, *or* protein-glutamate carboxylase (39); xanthine dehydrogenase (40-42). 1. ## Diumycin

This phosphoglycolipid antibiotic (FW = 358.61 g/mol; CAS 11141-18-7) from *Streptomyces umbrinus* inhibits cell wall biosynthesis. Diumycin A inhibits *Staphylococcus aureus* cell wall synthesis, resulting in the accumulation of UDP-*N*-acetyl-muramyl-pentapeptide. Diumycin also inhibits *in vitro* peptidoglycan synthesis by particulate preparations of *Bacillus stearothermophilus* and *Escherichia coli* by blocking utilization of *N*-acetyl-glucosamine-*N*-acetyl-muramyl-pentapeptide. It does not inhibit particulate D-alanine carboxypeptidase. Although details of diumycin's structure remain unclear, diumycin contains diumycinol, an unusual lipid alcohol (shown above). **Target(s):** *N*-acetyl-glucosaminyl-diphosphodolichol *N*-acetyl-glucosaminyl-transferase (1,2); cell wall biosynthesis (3,4); dolichyl-phosphate β-glucosyltransferase (5); dolichyl-phosphate mannosyl-transferase (6-8); protein glycosylation (5,6,9,10); trehalose-phosphatase (11-13); α,α-trehalose phosphate synthase, UDP-forming (14); UDP-*N*-acetylglucosamine:dolichyl-phosphate *N*-acetylglucosamine phosphotransferase (5,10,15-17). 1. ## Diuron

This urea derivative (FW = 233.10 g/mol; CAS 330-54-1), also known as Karmex and *N*-(3,4-dichlorophenyl)-*N,N*-dimethylurea, is a herbicide used primarily to treat cotton crops. Diuron inhibits photosynthetic electron transport and the Hill reaction. There are two sites for diuron on photosystem II, located on the reducing and oxidizing sides of that protein complex. **Target(s):** electron transport, photosynthetic (1-5); plastoquinol:plastocyanin reductase (6); Ubiquinol; cytochrome-*c* reductase, or Complex III (7-9); unspecific monooxygenase (10). 1. **17-DMAG, See Alvespimycin**

**DMP266, See Efavirenz**

**DMXBA, See GTS-21**

**DNQX**

This selective receptor antagonist (FW<sub>diNa-Salt</sub> = 252.14 g/mol; CAS 2379-57-9; Solubility: 100 mM in DMSO), also named 6,7-dinitroquinoxaline-2,3-dione, potently and competitively target non-NMDA glutamate receptors, permitting the exploration of structure-activity relations for quisqualate and kainate receptors and the role of such receptors in synaptic transmission in the mammalian brain. 1. Honoré, Davies, Drejer, *et al.* (1988) *Science* **241**, 701. 2. Watkins, Krosggaard-Larsen, Honoré (1990) *Trends Pharmacol Sci.* **11**, 25.

**Docetaxel**

This second-generation paclitaxel analogue (FW = 807.87 g/mol; CAS 114977-28-5; Solubility: 160 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as Taxotere, binds to assembled microtubules, stabilizing them against depolymerization and thereby reducing the dynamicity (See *Paclitaxel*). Docetaxel is especially cytotoxic toward proliferating cells, for which mitosis is either hampered or arrested as a consequence of microtubule bundling, followed by apoptosis or mitotic block. Docetaxel inhibits the survival of Hs746T human stomach cancer cells (IC<sub>50</sub> = 1 nM), AGS stomach cancer cells (IC<sub>50</sub> = 1 nM), HeLa human cervix cancer cells (IC<sub>50</sub> = 0.3 nM), CaSki human cervix cancer cells (IC<sub>50</sub> = 0.3 nM), BxPC3 human pancreatic cancer cells (IC<sub>50</sub> = 0.3 nM), and Capan-1 human pancreatic cancer cells (IC<sub>50</sub> = 0.3 nM). Side-effects include dose limiting neutropenia and peripheral neuropathy. Like paclitaxel, docetaxel is metabolized by cytochrome P450 (CYP3A4). Several docetaxel analogues are highly active in the NCI-60 cancer cell panel with broad efficacy and potency, exhibiting GI<sub>50</sub> values below 5 nM (7). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Buey (2004) *Chem. Biol.* **11**, 225. 2. Riou, *et al.* (1992) *Biochem. Biophys. Res. Commun.* **187**, 164. 3. **Dolasetron**

This serotonin 5-HT<sub>3</sub> receptor antagonist and anti-emetic (FW = 324.37 g/mol; CAS 115956-12-2), also known by its trade name Anzemet<sup>®</sup> and systematic name (3*R*)-10-oxo-8-azatricyclo[5.3.1.0<sup>3,8</sup>]undec-5-yl-1*H*-indole-3-carboxylate, is used to treat chemotherapy-induced nausea/vomiting. Dolasetron affects both peripheral and central nervous systems, reducing vagus nerve activity and thereby deactivating the 5-HT<sub>3</sub> receptor-dense vomiting center located in the medulla oblongata. (Note: Unlike other serotonin (5-HT) receptors, which are G-protein coupled receptors, 5-HT<sub>3</sub> is a ligand-gated ion channel.) Importantly, olasetron is without effect on dopamine receptors or muscarinic receptors. Dolasetron is actually a pro-drug requiring reduction of its prochiral carbonyl group to yield the pharmacologically active chiral secondary alcohol known as reduced dolasetron. Fortuitously, the (+)-*R*-enantiomer is preferentially formed by the endogenous carbonyl reductase, as it is more active as an anti-emetic (1). Other 5-HT<sub>3</sub> antagonists with similar effects include: tropisetron, ondansetron, palonosetron, and granisetron. The effectiveness of each depends on particular variants of 5-HT<sub>3</sub> receptors expressed by the patient, including changes in promoters for the receptor genes. 1. Dow & Berg (1995) *Chirality* **7**, 342.

**Dolastatin 10**

This highly cytotoxic antimitotic peptide and antitumor agent (FW = 790.16 g/mol; CAS 110417-88-4; Sequence: Dolavaline-Valine-Dolaisoleucine-Dolaproine-Dolaphenine, with the last three amino acids unique to *D. auricularia*, terminating in the unusual primary amine, Dolaphenine) from the sea hare *Dolabella auricularia* and the marine cyanobacterium *Symploca* (sp. VP642), inhibits the growth of murine leukemia cells in culture (IC<sub>50</sub> = 0.5 nM), with a rise in the mitotic index (1-4). Dolastatin 10 binds at a distinct site for peptide antimitotic agents near the exchangeable nucleotide and vinca alkaloid binding sites (4). For comparison, the cytostatic effects of other drugs are: Maytansine (IC<sub>50</sub> = 0.5 nM), Rhizoxin (IC<sub>50</sub> = 1 nM), Vinblastine (IC<sub>50</sub> = 20 nM), and Phomopsin A (IC<sub>50</sub> = 7 μM). Inhibitory concentrations, using purified tubulin polymerization in glutamate buffer: Dolastatin 10 (IC<sub>50</sub> = 1.2 μM), Phomopsin A (IC<sub>50</sub> = 1.4 μM), Vinblastine (IC<sub>50</sub> = 1.5 μM), Maytansine (IC<sub>50</sub> = 3.5 μM), and Rhizoxin (IC<sub>50</sub> = 6.8 μM). See also *Monomethyl Auristatin E*. 1. Pettit, Kamano, Herald, *et al.* (1987) *J. Am. Chem. Soc.* **109**, 6883. 2. Bai, Pettit & Hamel (1990) *Biochem Pharmacol.* **40**, 1859. 3. Bai, Pettit, Hamel (1990) *Biochem. Pharmacol.* **39**, 1941. 4. Bai, Pettit & Hamel (1990) *J. Biol. Chem.* **265**, 1714.

**Dolichyl Phosphate**

This phosphorylated 2,3-dihydroxyprenol (FW = Indefinite Polymer) functions as a carrier of mono- and oligosaccharides in glycoprotein and glycolipid production. It can also induce apoptosis in rat glioma C6 cells. Note that the term has been used for 2,3-dihydroxyprenols with as few as four isoprene subunits. Both *cis* and *trans* double bonds are present: frequently the two isoprene units (sometimes three) adjacent to the dihydro unit are *trans*, while the remaining are *cis*. The phospho monoester is stable in mild acid or alkaline treatment. **Target(s):** dolichylphosphate-mannose phosphodiesterase (1); indole-3-acetate  $\beta$ -glucosyltransferase, weakly inhibited (2); mevalonate kinase (3). 1. Tomita & Motokawa (1987) *Eur. J. Biochem.* **170**, 363. 2. Leznicki & Bandurski (1988) *Plant Physiol.* **88**, 1481. 3. Hinson, Chambliss, Toth, Tanaka & Gibson (1997) *J. Lipid Res.* **38**, 2216.

### Dolutegravir

This integrase inhibitor, or INI, and once daily HIV/AIDS drug (FW = 419.38 g/mol; CAS 1051375-16-6; *Symbol*: DTG), also known by the code name S/GSK1349572 and systematic name (4*R*,12*aS*)-*N*-(2,4-difluorobenzyl)-7-hydroxy-4-methyl-6,8-dioxo-3,4,6,8,12*a*-hexahydro-2*H*-pyrido[1',2':4,5]-pyrazino[2,1-*b*][1,3]oxazine-9-carboxamide, potently inhibits HIV integrase, showing significant antiviral action in raltegravir-resistant patients. **Mode of Action:** HIV-1 integrase catalysis is a biphasic process: *Step-1*, integrase binds to viral cDNA, with attendant cleavage of two nucleotides, producing the enzyme-bound DNA "pre-integration" complex; and *Step-2*, DNA strand-transfer, a host nuclear process that dolutegravir inhibits by chelating two active-site Mg<sup>2+</sup> ions and causing the viral integrase to disengage from the deoxyadenosine at the 3'-end of the viral DNA (1). Like other integrase strand-transfer inhibitors, DTG efficiently blocks viral replication *in vitro* (IC<sub>50</sub> = 2-3 nM) and likewise suppresses viremia. Notably, DTG dissociates slowly from a wild-type integrase-DNA complex with an off-rate of  $2.7 \times 10^{-6} \text{ s}^{-1}$  (or a dissociative *t*<sub>1/2</sub> of 71 h), significantly longer than the respective 8.8- and 2.7-hour half-lives for raltegravir and elvitegravir (2). Site-directed single and double mutations at sites affecting resistance suggest that DTG offers a significantly higher genetic barrier to resistance, as compared to raltegravir and elvitegravir. Such findings suggest that the INI off-rate may be an important component of the mechanism of integrase inhibitor resistance (2). Site-directed single and double mutations at sites affecting and resistance suggest that DTG has a significantly higher genetic barrier to resistance seen with raltegravir and elvitegravir, providing evidence that the INI off-rate may be an important component of the mechanism of integrase inhibitor resistance (2). **Metabolism/Excretion:** S/GSK1349572 is primarily metabolized by glucuronidation by UGT1A1 (or Bilirubin UDP-glucuronosyltransferase), an enzyme that transforms small lipophilic molecules (including steroids, bilirubin, and a few hormones) into their water-soluble, excretable glucuronides. Drug interactions also occur with acetaminophen, atazanavir, atorvastatin, etoposide, fluvastatin, lovastatin, morphine, and simvastatin. These UGT1A1 inhibitors or alternative substrates result in dolutegravir retention by reducing its glucuronidation and excretion. 1. Hare, Smith, Métifiot, *et al.* (2011) *Mol. Pharmacol.* **80**, 565 2. Hightower, Wang, Deanda, *et al.* (2011) *Antimicrob. Agents Chemother.* **55**, 4552.

### Dominant Negative Mutants

The term dominant-negative describes a gene or protein that exerts a dominant effect, similar to that described, when one copy of the gene gives a mutant phenotypic effect that prevents (or negatively impacts) a biological process such as a vital signal transduction pathway. Such an effect is possible when the active form of a protein is a homo- or hetero-dimer (or oligomer). If part of that protein complex is formed from a mutant protein that is defective in some functional aspect, then the complex may be able to self-assemble, but the defective component will dominantly inhibit other wild type components (subunits) of the complex, thus preventing the complex from carrying out its normal function. In this case the gene coding for the mutant component of complex is called a *dominant-negative gene*, and the protein it forms is called a *dominant-negative protein*. One example is the heterotrimeric 5'-AMP-activated protein kinase (AMPK), a metabolic

switch that is only active, when assembled from fully functional  $\alpha$ -,  $\beta$ -, and  $\gamma$ -subunits (1). When cellular AMP/ATP ratio is high, AMPK is phosphorylated by its upstream kinases, thereby generating catalytically active AMPK. The latter phosphorylates (and thus activates) target proteins/enzymes, serving to restore cellular ATP and GTP by enhancing ATP-regenerating processes (*e.g.*, glucose uptake, fatty acid  $\beta$ -oxidation, mitochondrial biogenesis), while simultaneously inhibiting ATP-consuming pathways (*e.g.*, nucleotide biosynthesis and ribosome function). There are two isoforms of the  $\alpha$ -subunit, which is the subunit that catalyzes phosphoryl transfer by the fully assembled AMPK holoenzyme. The dominant-negative AMPK $\alpha_1$  recombinant adenovirus can be made by cellular expression of human  $\alpha_1$  subunit having a D159A or D159N mutation in the ATP binding domain. The mutant AMPK $\alpha_1$  competes with wild type AMPK $\alpha_1$  for the binding with  $\beta$ - and  $\gamma$ -subunits; however, because mutant AMPK $\alpha_1$  lacks the capacity to bind ATP, the assembled AMPK is a dominant negative form (1). In this case, expression of  $\alpha_1$ (D159N) markedly inhibited both basal and stimulated activity of endogenous AMPK, but was without effect on the transcription of glucose-activated genes. These findings suggest that AMPK is involved in the inhibition of glucose-activated gene expression but not in the induction pathway. As a tool for introducing new genes to a target tissue, recombinant adenoviral vectors are especially effective, yielding a transduction efficiency of >90% for a gene-of-interest in many types of mammalian cells. Although adenovirus is currently used for a variety of purposes, including gene transfer *in vitro*, vaccination production, and gene therapy, another application is the construction of vectors containing recombinantly inactivated (or dominantly negative) subunits that, when expressed at sufficient concentrations, out-compete wild type subunits in the assembly of holoenzyme. Although construction of recombinant plasmids is one of the most time-consuming steps in generating recombinant adenovirus, premade recombinant high-titer adenoviruses is now commercially available for convenient use. Such vectors may also be made to express recombinant proteins that are tagged (with hemagglutinin, or HA (sequence = YPYDVPDYA), c-myc (sequence = EQKLISEEDL), or enhanced GFP) to mark successfully transduced cells in a potentially heterogeneous culture. 1. Woods, Azzout-Marniche, Foretz, *et al.* (2000) *Mol. Cell Biol.* **20**, 6704.

### Domoate (Domoic Acid)

This highly toxic kainate analogue (FW = 311.33 g/mol; CAS 14277-97-5; p*K*<sub>a</sub> values of 2.10, 3.72, 4.93, and 9.82), also named 3-(carboxymethyl)-4-(2-carboxy-1-methyl-1,3-hexadienyl)proline, is an excitatory amino acid isolated from the red alga *Chondria armata* (known in Japanese as domoi). It is a potent agonist at glutamate and kainate receptors and displays very high affinity for the AMPA/kainate receptor, damaging the hippocampus and amygdaloid nucleus. Treatment of cells with domoic acid leads to depletion of energy stores. Domoate also inhibits choline *O*-acetyltransferase (1). Domoic acid gives rise to the disorder known as Amnesic Shellfish Poisoning (*Symptoms*: nausea; vomiting; diarrhea; abdominal cramps; headache; dizziness; confusion; disorientation; short-term memory loss; motor weakness; seizures; profuse respiratory secretions; cardiac arrhythmias; coma and possibly even death). 1. Loureiro-Dos-Santos, Reis, Kubrusly *et al.* (2001) *J. Neurochem.* **77**, 1136.

### Donepezil

This centrally acting AChE inhibitor and palliative AD drug (FW = 379.49 g/mol; CAS 120014-06-4; IUPAC Name: (*RS*)-2-[(1-benzyl-4-piperidyl)methyl]-5,6-dimethoxy-2,3-dihydroinden-1-one), known widely by the trade names Aricept<sup>®</sup> and Donep<sup>®</sup>, targets acetylcholinesterase (IC<sub>50</sub>

= 5.7 nM) and maintains the level of acetylcholine accumulating in the synaptic cleft, thereby sustaining the duration of the channel-open conformation of the acetylcholine receptor. Aricept helps to maintain memory, attention, social interactions, and speech in patients with declining mental function as a consequence of mild to moderate Alzheimer's Disease or vascular dementia. Lineweaver-Burk analysis of the inhibition data suggests that donepezil is a mixed-type (*i.e.*,  $K_i \neq K_{ii}$ ) noncompetitive inhibitor of brain AChE (1). It likewise elevates extracellular ACh, an action attended by stimulated catecholamine release (2). Donepezil is absorbed slowly, but completely, from the gut, reaching peak plasma levels in 3-4 hours and, with daily dosing, attains a steady-state level in 15-21 days (3). Within a relatively narrow range, there is a linear relationship between dose and pharmacodynamic effects, as measured by red blood cell acetylcholinesterase inhibition and clinical efficacy. Donepezil is principally excreted unchanged in the urine, but there is also hepatic metabolism; some of its metabolites may be active (3). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Other Target(s):** Donepezil also induces caspase-dependent apoptosis in human promyelocytic leukemia HL-60 cells (4). It also enhances Purkinje cell survival and alleviates motor dysfunction by inhibiting cholesterol synthesis in a murine model of Niemann Pick disease type C (5). 1. #### L-Dopa

This neurotransmitter (FW = 197.19 g/mol; CAS 59-92-7), also known as 3,4-dihydroxy-phenylalanine and 3-hydroxytyrosine, is an important intermediate in aromatic amino acid catabolism as well as in the synthesis of epinephrine and melanin. The L-isomer is also called levodopa and is used in the treatment of Parkinson Disease. **Target(s):** N-acetylindoxyl oxidase (1); aldehyde oxidase (2); catechol O-methyltransferase (3); 3-deoxy-7-phosphoheptulonate synthase (4); histidine decarboxylase (5); 3-hydroxyanthranilate oxidase (26); 4-hydroxyphenylpyruvate dioxygenase (25); kynureninase, inhibited by DL-mixture (6,7); lipoxigenase (8); monoamine oxidase (9); nitronate monooxygenase (10); phenylalanine ammonia lyase (11); phenylalanine 4-monooxygenase (12-14); prephenate dehydrogenase (15); pyridoxal kinase (16,17); ribonucleoside-diphosphate reductase (18); tryptophan 5-monooxygenase, inhibited by both D- and L-dopa (19,20); tubulin:tyrosine ligase, as weak alternative substrate (21,22); tyrosine aminotransferase, also as weak alternative substrate (23); tyrosine-phosphatase, by L-Dopa (24). 1. #### Dopamine

This catecholamine neurotransmitter (FW<sub>free-base</sub> = 153.18 g/mol; CAS 51-61-6; pK<sub>a</sub> (hydroxyl) = 8.9; pK<sub>a</sub> (amino) = 10.6; *Abbreviation:* L-Dopa; *Symbol:* DA), also known as 3-hydroxytyramine and 3,4-dihydroxyphenethylamine, is produced from L-dihydroxyphenylalanine and is a precursor to norepinephrine and epinephrine. Dopamine is photosensitive and readily oxidizes in aqueous solutions in alkaline pH. Within the brain, dopamine affects executive functions, motor control, motivation, arousal, reinforcement, and reward, as well as lower-level actions including lactation, sexual gratification, and nausea. **The Dopamine Cycle:** Dopamine is synthesized by 3,4-dihydroxyphenylalanine decarboxylase (*Reaction:* 3,4-dihydroxyphenylalanine  $\rightleftharpoons$  L-Dopa + H<sub>2</sub>O) in the cytoplasm, from which it is transported into synaptic vesicles by VMAT2 (Vesicular Monoamine Transporter-2), where it remains until vesicle mobilization is triggered by a stimulating action potential. (**See VMAT2 inhibitor Quinlobelane**) Upon migration to the peripheral membrane, these vesicles fuse with the latter in an exocytotic event that dumps dopamine into the synaptic cleft. Once released, dopamine binds to and activates postsynaptic dopamine receptors, therewith propagating a signal to a nearby postsynaptic neuron. Dopamine also binds to presynaptic autoreceptors, the occupancy of which inhibits dopamine synthesis and release. Presynaptic reuptake is mediated by the high-affinity dopamine transporter (DAT) and the low-affinity plasma membrane monoamine transporter (PMAT). Once returned to the cytosol, dopamine is again reloaded into vesicles by VMAT2. **Parkinson Disease:** This progressively debilitating motor system disorder is characterized by loss of dopamine-producing cells in the brain resulting in (a) trembling of hands, arms, legs, jaw, and face, (b) stiffness of limbs and trunk; slowness of movement (*or* bradykinesia), and (c) impairment of postural balance and coordination. Parkinson Disease correlates with the progressive and marked loss of dopamine-containing cells in the *substantia nigra* as well as reduction in DAT and VMAT2 transporters within the remaining pigmented neurons. Side effects of dopamine therapy include: *Cardiovascular* – ventricular arrhythmia (at very high doses), ectopic beats, tachycardia, anginal pain, palpitation, conduction abnormalities, widened QRS complex, bradycardia, hypotension or hypertension, vasoconstriction; *Respiratory* – dyspnea; *Gastrointestinal:* nausea, vomiting; *Metabolic/Nutritional* – azotemia; *CNS* – headache and/or anxiety. **Circulating Dopamine:** Dopamine does not readily cross the blood-brain barrier, and its synthesis and functions in peripheral regions are independent of its synthesis and functions within the brain. Dopamine is also found in plasma at levels comparable to those of epinephrine, with most monosulfated at one of its two phenolic groups. Formation of 3-O-DA and 4-O-DA sulfate may represent a way of detoxifying dietary biogenic amines, thereby limiting their autocrine and/or paracrine effects as well as that of any endogenously generated DA. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** aldehyde oxidase (1); alkaline phosphatase (2); aromatic-L-amino-acid decarboxylase, *or* dopa decarboxylase (3,4); arylsulfatase (5,6); dihydropteridine reductase (7-9); glutamate decarboxylase (10);  $\gamma$ -glutamylhistamine synthetase (11); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (12); phenylalanine 4-monooxygenase (13-18); procollagen-lysine 5-dioxygenase (19); pyridoxal kinase (20,21); tryptophan 5 monooxygenase (22-25); tyrosinase, *or* monophenol monooxygenase (26); tyrosine aminotransferase (27,28); tyrosine 3-monooxygenase (29-39); tyrosyl-tRNA synthetase ( $K_i$  = 2.5 mM for the *Escherichia coli* enzyme) (40); xanthine oxidase (1). 1. ### Doramapimod

This cell-permeable, high-affinity p38 kinase inhibitor (FW = 527.66 g/mol; CAS 285983-48-4; Soluble to 100 mM in DMSO), also named BIRB 796, 1-(5-*tert*-butyl-2-*p*-tolyl-2*H*-pyrazol-3-yl)-3-[4-(2-morpholin-4-ylethoxy)naphthalen-1-yl]urea, and *N*-[3-(1,1-dimethylethyl)-1-(4-methylphenyl)-1*H*-pyrazol-5-yl]-*N'*-[4-[2-(4-morpholinyl)ethoxy]-1-naphthalenyl]urea, selectively targets *all* p38 mitogen-activated protein kinases (with  $K_d$  values ranging from 50 to 100 pM), the mitogen-activated protein kinases that are responsive to such stress stimuli as cytokines, UV irradiation, heat shock, and osmotic shock, and are involved in cell differentiation, apoptosis and autophagy (1-4). BIRB796 blocks the stress-induced phosphorylation of the scaffold protein SAP97, further establishing that this is a physiological substrate of SAPK3/p38 $\gamma$ . BIRB-796 Exhibits no significant inhibition on a panel of related kinases. **Other Targets:** Doramapimod exhibits no significant inhibition on a panel of related protein kinases, but does inhibit JNK2 $\alpha$ 2 (IC<sub>50</sub> = 98 nM) and c-Raf-1 (IC<sub>50</sub> = 1.4  $\mu$ M). It also inhibits LPS-induced TNF $\alpha$  production in human Peripheral Blood Mononuclear Cells or PBMCs (IC<sub>50</sub> = 21 nM) and whole blood (IC<sub>50</sub> = 960 nM). 1. Regan, Capolino, Cirillo, *et al.* (2003) *J. Med. Chem.* **46**, 4676. 2. Kuma, Sabio, Bain, *et al.* (2005) *J. Biol. Chem.* **280**, 19472. 3. Goldstein, Kuglstatler, Lou & Soth (2010) *J. Med. ### Doravirine

This non-nucleoside reverse transcriptase inhibitor, or NNRTI (FW = 425.75 g/mol; CAS 1338225-97-0), also known as MK-1439 and 3-chloro-5-({1-[(4-methyl-5-oxo-4,5-dihydro-1*H*-1,2,4-triazol-3-yl)methyl]}-2-oxo-4-(trifluoromethyl)-1,2-dihydro-3-pyridinyl)oxy)benzotrile, exhibits IC<sub>50</sub> values of 12, 9.7, and 9.7 nM, respectively, against wild-type, K103N and Y181C reverse transcriptase mutants in biochemical assays, while showing minimum off-target activities (1). The mutant profile of MK-1439 was superior overall to that of efavirenz (EFV) and comparable to that of etravirine (ETR) and rilpivirine (RPV). Furthermore, E138K, Y181C, and K101E mutant viruses that are associated with ETR and RPV were susceptible to MK-1439 with fold-change < 3 (1). 1. Lai, Feng, Falgoutyret, *et al.* (2013) *Antimicrob. Agents Chemother.* **58**, 1652.

### Doripenem

This carbapenem-class antibiotic (FW = 420.50 g/mol; CAS 148016-81-3), also known as Finibax<sup>®</sup>, is a  $\beta$ -lactam antibiotic, exhibiting a broad action against both Gram-positive and Gram-negative bacteria. *In vivo*, doripenem inhibits cell wall synthesis by binding to penicillin-binding proteins (PBPs). Doripenem is inactive against Methicillin-Resistant *Staphylococcus aureus* (MRSA). Doripenem is also more active against *Pseudomonas aeruginosa* than other carbapenems. It is stable against  $\beta$ -lactamases, but is susceptible to hydrolysis by carbapenemases. **See also Carbapenem-Resistant Enterobacteriaceae; Ertapenem; Imipenem (Cilastatin); Meropenem.**

### Dorsomorphin

This potent and reversible protein kinase inhibitor (FW = 472.41 g/mol; CAS 1219168-18-9; Solubility: >20 mg/mL DMSO; dihydrochloride is water-soluble), also named 6-[4-[2-(1-piperidinyl)ethoxy]phenyl]-3-(4-pyridinyl)-pyrazolo[1,5-*a*]pyrimidine, selectively targets 5'-AMP-activated protein kinase, or AMPK ( $K_i$  = 109 nM), a signal transduction enzyme that plays a central role in stimulating hepatic fatty acid oxidation (especially in skeletal muscle) as well as ketogenesis, and in inhibiting cholesterol synthesis, lipogenesis, triglyceride synthesis, adipocyte lipolysis and lipogenesis. AMPK also stimulates muscle glucose uptake and modulates insulin secretion by pancreatic  $\beta$ -cells. Dorsomorphin exhibits little or no inhibition of structurally related protein kinases, including ZAPK, SYK, PK $\theta$ , PKA, and JAK3. 1. Zhou, Myers, Li, *et al.* (2001) *J. Clin. Invest.* **108**, 1167. 2. Meley, Bauvy, Houben-Weerts, *et al.* (2006) *J. Biol. Chem.* **281**, 34870. 3. Yu, Hong, Sachidanandan, *et al.* (2008) *Nature Chem. Biol.* **4**, 33. 4. Kim, Kim, Kim, *et al.* (2011) *Atherosclerosis* **219**, 57.

### Dorzolamide

This antiglaucoma drug (FW = 324.44 g/mol; CASs = 130693-82-2 and 120279-96-1), also known by the code names MK-507 and L-671,152, the trade name Trusopt<sup>®</sup> and the IUPAC name (4*S*,6*S*)-2-ethylamino-4-methyl-

5,5-dioxo-5 $\lambda$ ,7-dithiabicyclo[4.3.0]nona-8,10-diene-8-sulfonamide, is a potent membrane-penetrant carbonic anhydrase inhibitor that decreases the production of aqueous humor, when administered as a 2% (wt/vol) topical solution (1,2). Dorzolamide targets CA-II ( $IC_{50}$  = 0.18 nM, *in vitro*), and is far less active against CA-I ( $IC_{50}$  = 600 nM). Dorzolamide penetrates the ciliary body, inhibits CA, and avoids side-effects of oral CA inhibitors. It reduces intra-ocular pressure (IOP), accelerates the retinal arteriovenous passage time, and improves vision in normotensive patients. 1. Maren (1995) *J. Glaucoma* **4**, 49. 2. Maren (2000) in *The Carbonic Anhydrases* (Chegwidder, Carter & Edwards, eds.) Birkhäuser Verlag, Basel, Switzerland.

### Doxazosin

This quinazoline-based antihypertensive and  $\alpha_1$ -selective adrenergic receptor antagonist (FW<sub>free-base</sub> = 451.58 g/mol; CAS 74191-85-8), also known by its code name UK33274, its trade names Cardura™ and Carduran™, and its systematic name (*RS*)-2-[4-[(2,3-dihydro-1,4-benzodioxin-2-yl)carbonyl]-piperazin-1-yl]-6,7-dimethoxyquinazolin-4-amine, relaxes vascular smooth muscle tone (vasodilation) and decreases peripheral vascular resistance. **Pharmacokinetics:** Upon oral administration of therapeutic doses, doxazosin reaches peak plasma levels in 2-3 hours, with a bioavailability of ~65%, reflecting its first-pass metabolism of by the liver. The mean elimination half-life of doxazosin is 11 hours. When administered with food, the mean maximum plasma concentration by 18% and the area under the concentration (AUC) versus time curve by 12%. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Ali, Kossen, Timmermans & Van Zwieten (1980) *Brit. J. Pharmacol.* **68**, 113P. 2. de Leeuw, Ligthart, Smout & Birkenhäger (1982) *Eur. J. Clin. Pharmacol.* **23**, 397.

### Doxepin

This antidepressant (FW<sub>free-base</sub> = 279.38 g/mol) is a histamine H<sub>1</sub> receptor antagonist as well as an antagonist at muscarinic cholinergic and  $\alpha$ -adrenergic receptors. Commercial sources typically supply the hydrochloride as a mixture of the *E*-isomer and *Z*-isomer (shown above). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):**  $\alpha$ -adrenergic receptor (1); glutathione *S*-transferase (2,3); histamine H<sub>1</sub> receptor (2,4,5); Mg<sup>2+</sup>-ATPase (6); monoamine oxidase (7); muscarinic cholinergic receptor (1); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (6,8); norepinephrine uptake (9); protein kinase C (10); serotonin uptake (11). 1. ### Doxorubicin

This photosensitive RNA/DNA-binding antibiotic (FW = 558.23 g/mol; CAS 23214-92-8), also called Adriamycin (referring to the hydrochloride salt) from *Streptomyces peucetius* intercalates into double-stranded DNA and inhibits replication. Doxorubicin impairs the function of DNA topoisomerase II, induces the formation of protein-associated double-strand breaks, and produces intrastrand cross-links. It also inhibits transcription. This antibody consists of a tetracyclic structure called adriamycinone covalently linked to an amino sugar (daunosamine) that can be removed by treatment with acid. Note that it tightly chelates Fe<sup>3+</sup>. Aqueous solutions of doxorubicin are yellow-orange under acidic conditions, orange-red at neutral pH, and violet-blue with basic pH values (*i.e.*, above 9); the amino pK<sub>a</sub> is 8.2. It should be stored in a desiccator in the dark and at 4°C. Stock solutions should be prepared just prior to use. Note: Doxorubicin also undergoes one-electron reduction. In the presence of dioxygen, the resulting semiquinone produces superoxide, leading to the formation of hydrogen peroxide and the reactive hydroxyl radical. The latter can damage DNA and membrane lipids. **Redox Cycling in Mitochondria:** Complex I (most likely the NADH dehydrogenase flavin) is the mitochondrial site of anthracycline reduction. During forward electron transport, the anthracycline doxorubicin (Adriamycin) and daunorubicin act as one-electron acceptors for BH-SMP (*i.e.* they are reduced to semiquinone radical species), but only when NADH was used as substrate (38). Succinate and ascorbate are without effect. Inhibitor experiments (with rotenone, amytal, ptericidin A) indicate that the anthracycline reduction site lies on the substrate side of ubiquinone. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** *Ava*II restriction endonuclease (1); diferric-transferrin reductase (2); DNA helicase (3); DNA ligase, ATP-requiring (4,5); DNA ligase, NAD<sup>+</sup>-requiring (4); DNA polymerase (6); DNA topoisomerase II (7-12); *Eco*RI restriction endonuclease (1); *Hae*III restriction endonuclease (1); *Hha*I restriction endonuclease (1); *Hpa*II restriction endonuclease (1); mitochondrial signal peptidase I, inner membrane protease (13); nitric-oxide synthase (14); nucleoside-triphosphatase (3); P-glycoprotein (15); phosphatidyl-*N*-methyl-ethanolamine *N*-methyltransferase (16); phospholipase A<sub>2</sub> (17); procollagen proline 4-dioxygenase (18-20); protein kinase C (21-23); RNA-directed DNA polymerase, *or* reverse transcriptase (24-28); RNA polymerase (6,29-33); *Sma*I restriction endonuclease (1); thioredoxin reductase, possible inhibition (34,35); Xaa-Pro Dipeptidase, *or* prolidase, *or* imidodipeptidase (36); xenobiotic-transporting ATPase, *or* multidrug-resistance protein (15). 1. ### Doxylamine

This first-generation antihistamine (FW = 270.38 g/mol; CAS 469-21-6 and 562-10-7 (succinate salt), also named (*RS*)-*N,N*-dimethyl-2-(1-phenyl-1-pyridin-2-ylethoxy)ethanamine, has short-term sedative properties, commending its use in combination with other drugs (typically acetaminophen and dextromethorphan) to provide night-time allergy and cold relief. Doxylamine is also combined with acetaminophen and codeine as an analgesic/calimative preparation that is often prescribed along with vitamin B<sub>6</sub> (pyridoxine) to prevent morning sickness. *See also* *Acetaminophen*, *Dextromethorphan*

### DPC 423

This oral anticoagulant (FW = 532.52 g/mol), named systematically as 1-[3-(aminomethyl)phenyl]-*N*-3-fluoro-2'-(methylsulfonyl)[1,1'-biphenyl]-4-yl]-3-(trifluoromethyl)-1*H*-pyrazole-5-carboxamide, inhibits coagulation factor Xa ( $K_i = 0.15$  nM, human). It is a much weaker inhibitor of thrombin, trypsin, plasma kallikrein, complement component I, activated protein C, and coagulation factor IXa, with  $K_i$  values of 6, 0.06, 0.061, 44 (IC<sub>50</sub>), 1.8, and 2.2 μM, respectively. **1.** Pinto, Orwat, Wang, *et al.* (2001) *J. Med. Chem.* **44**, 566.

**DPCPX**, *See* *Dipropylcyclopentylxanthine*

### DPI-1

This dual prenylation inhibitor (FW<sub>free-base</sub> = 471.60 g/mol), hence its initials, inhibits both protein farnesyltransferase and protein geranylgeranyltransferase type II, with respective IC<sub>50</sub> values of 0.05 and 3.6 nM. DPI blocks Ki-Ras prenylation and induces markedly higher levels of apoptosis relative to the separate actions of farnesyltransferase or geranylgeranyltransferase inhibitors. **1.** Lobell, Omer, Abrams, *et al.* (2001) *Cancer Res.* **61**, 8758. **2.** Guida, Hamilton, Crotty & Sebt (2006) *J. Comp.-Aided Mol. Des.* **19**, 871.

**DPX-F6025**, *See* *Chlorimuron-ethyl*

### DrKIn-II

This potent plasmin inhibitor and (FW = 6946.70 g/mol; Sequence: HDRPTFCNLAPESGRCRAHLRRIYYNLESNKCEVFFYGGCGNDNNFSTWDECRHTCVGK) is a member of the venom trypsin inhibitor family that decreases the enzyme's amidolytic activity in a dose-dependent manner. In keeping with its action as a slow-binding, tight inhibitor, initial rapid binding ( $K_i = 6.7$  nM) of DrKIn-II induces a slow enzyme conformational isomerization ( $k_{forward} = 0.043$  s<sup>-1</sup> and  $k_{reverse} = 0.0022$  s<sup>-1</sup>), thereby forming a much tighter enzyme-inhibitor complex, with a corrected overall inhibition constant  $K_i^*$  of 0.2 nM. DrKIn-II also demonstrates anti-fibrinolytic activity in fibrin plate assay and significantly prolongs lysis of euglobulin clots. Screening of DrKIn-II against a panel of serine proteases indicates that plasmin is the preferential DrKIn-II target. Notably, while 1 μM DrKIn-II prolongs the activated partial thromboplastin time by 32 seconds, DrKIn-II fails to prolong the prothrombin time at all the concentrations tested, implying that, even at high concentrations, DrKIn-II has no inhibitory effect on serine proteases in the extrinsic coagulation pathway. DrKIn-II also prevents an increase of Fibrin/fibrinogen Degradation Product (FDP) in coagulation-stimulated mice and significantly reduces bleeding times in a murine tail bleeding model. **1.** Cheng & Tsai (2014) *Biochim. Biophys. Acta* **1840**, 153.

### Dronedarone

This amiodarone-like antiarrhythmic agent (FW = 556.76 g/mol; CAS 141626-36-0), also known by the code name SR33589, the trade name Multaq™, and its IUPAC name *N*-(2-butyl-3-(*p*-(3-(dibutylamino)propoxy)benzoyl)-5-benzofuranyl)methanesulfonamide, is indicated for the treatment of atrial fibrillation and atrial flutter. Dronedarone inhibits (IC<sub>50</sub> = 63 nM) the acetylcholine-activated potassium current in single cells isolated from sinoatrial node, either by disrupting the G-protein-mediated activation or by a direct inhibitory interaction with the channel protein (2). Dronedarone is a 10x less effective inhibitor of Na<sup>+</sup>/Ca<sup>2+</sup> exchange current in cardiac ventricular myocytes than amiodarone (3). **1.** Hodeige, Heyndrickx, Chatelain & Manning (1995) *Eur. J. Pharmacol.* **279**, 25. **2.** Altomare, Barbuti, Viscomi, Baruscotti & DiFrancesco (2000) *Br. J. Pharmacol.* **130**, 1315. **3.** Watanabe & Kimura (2008) *Naunyn Schmiedebergs Arch Pharmacol.* **377**, 371.

### Droperidol

This potent butyrophenone-class receptor antagonist (FW = 379.44 g/mol; CAS 548-73-2), also named 1-[1-[4-(4-fluorophenyl)-4-oxobutyl]-1,2,3,6-

tetrahydro-4-pyridinyl]-1,3-dihydro-2H-benzimidazol-2-one, targets the dopamine D<sub>2</sub> receptor, with some histamine and serotonin antagonist activity (1). Droperidol has a central antiemetic action and effectively prevents postoperative nausea and vomiting in adults. It increases action potential duration (APD) of rabbit Purkinje fibers in a dose-dependent manner over the 10-300 μM range, when stimulated at 60 pulses/min (2). Droperidol exerts a dual effect on repolarization, prolongation with low concentrations with development of early after-depolarizations (or EADs) and subsequent triggered activity. Droperidol is commonly used as an antiemetic and antipsychotic in the United States since its approval in 1970 by the FDA. 1. Parker, Brunton, Goodman, *et al.* (2006). ### Duloxetine

This serotonin-norepinephrine reuptake inhibitor, or SNRI (FW = 297.42 g/mol; CAS 116539-59-4 (free base) and 136434-34-9 (hydrochloride)), also known by its code name LY248686, its trade names Cymbalta<sup>®</sup>, Aricla<sup>®</sup>, Xeristar<sup>®</sup>, Yentreve<sup>®</sup>, Duzela<sup>®</sup>, and Dulane<sup>®</sup>, as well as its systematic name (+)-(S)-N-methyl-3-(naphthalen-1-yloxy)-3-(thiophen-2-yl)propan-1-amine, is indicated for major depressive disorder (MDD), generalized anxiety disorder as well as osteoarthritis and musculoskeletal pain (1,2). Duloxetine has a low affinity for most 5-HT subtypes and for muscarinic, histamine H<sub>1</sub>, α<sub>1</sub>-adrenergic, α<sub>2</sub>-adrenergic and dopamine D<sub>2</sub> receptors. Duloxetine inhibits 5-hydroxytryptamine (5-HT) and norepinephrine (NE) uptake in hippocampus slices of control rats, with IC<sub>50</sub> values of 28 and 46 nM, respectively (3). Oral administration of duloxetine (3-12 mg/kg) produced a dose-dependent increase in 5-HT and NE output from the rat frontal cortex throughout the 4-hour observation period (4). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Wong, Bymaster, Mayle, *et al.* (1993) *Neuropsychopharmacol.* **8**, 23. 2. Anttila & Leinonen (2002) *Curr Opin Investig Drugs* **3**, 1217. 3. **DuP-697**

This irreversible and selective diaryl heterocycle-type COX inhibitor (FW = 411.30 g/mol; CAS 88149-94-4), also known as 5-bromo-2-(4-

fluorophenyl)-3-(4-(methylsulfonyl)phenyl)-thiophene, targets COX-2 (1). (See *structurally related Celecoxib; Rofecoxib*) When tested on isolated recombinant enzymes, DuP-697 is >50x more potent in the inhibition of COX-2 than COX-1 (2). The IC<sub>50</sub> for human recombinant COX-2 decreases over time, with values of 80 and 40 nM at 5 and 10 minutes, respectively (3). The IC<sub>50</sub> for the inhibition of human recombinant COX-1 over the same period is 9 μM (3). DuP-697 also attenuates the COX-1 inhibitory activity of nonselective COX inhibitors such as indomethacin (4). DuP-697 exerts antiproliferative, antiangiogenic and apoptotic effects on HT29 colorectal cancer cells, IC<sub>50</sub> = 4.28 × 10<sup>-8</sup> mol/L (5). 1. Kargman, Wong, Greig, *et al.* (1996) *Biochem. Pharmacol.* **52**, 1113. 2. Seibert, Masferrer, Needleman, *et al.* (1996) *Brit. J. Pharmacol.* **117**, 1016. 3. **DuP714, See N-Acetyl-D-phenylalanyl-L-prolyl-L-boroarginine**

### Dupilumab

This fully human whole monoclonal antibody (MW = 146,900 g/mol; CAS 1190264-60-8), directed against the α-subunit of IL-4 receptors, blocks IL-4 and IL-13 cytokine signaling pathways in type 2 helper T (or Th2) cell-mediated pathways. When administered as monotherapy or with topical corticosteroids, dupilumab results in rapid and significant improvement of Atopic Dermatitis (AD), a disorder that is characterized by Th2 cell-driven inflammation (1). In patients with persistent, moderate-to-severe asthma and elevated eosinophil levels, who used inhaled glucocorticoids and long-acting β-agonists (LABAs), dupilumab therapy is associated with fewer asthma exacerbations, when LABAs and inhaled glucocorticoids are withdrawn, resulting in improved lung function and reduced levels of Th2-associated inflammatory markers (2). 1. Hamilton, Ungar & Guttman-Yassky (2015) *Immunother.* **7**, 1043. 2. Wenzel, Ford, Pearlman, *et al.* (2013) *New Engl. J. Med.* **368**, 2455.

### Durvalumab

This humanized anti-PD-L1 monoclonal antibody and antagonist (MW = 143.6 kDa; CAS 1428935-60-7), also named MEDI-4736, targets the Programmed Death Ligand-1, a 40-kDa type-1 transmembrane protein (also known as Cluster of Differentiation 274, or CD274, and B7 Homologue-1, or B7-H1) that plays a role in suppressing the immune system during pregnancy, tissue allografts, autoimmune disorders, cancer and hepatitis. To modulate activation/inhibition, PD-L1 binds relatively weakly to PD-1 (K<sub>d</sub> = 0.7 μM), its ligand on activated T cells, B cells, and myeloid cells. By binding to PD-L1, Durvalumab disrupts the PD-L1·PD-1 complex, thereby limiting immunosuppression.

### Dutasteride

This 5-α reductase inhibitor, or 5α-RI (FW = 528.53 g/mol; CAS 164656-23-9), also known as Avodart<sup>®</sup> and (5α, 17β)-N-[2,5-bis(trifluoromethyl)phenyl]-3-oxo-4-azaandrost-1-ene-17-carboxamide, is used to treat benign prostate hyperplasia by inhibiting the conversion of testosterone to dihydrotestosterone, or DHT, by 3-oxo-5α-steroid 4-dehydrogenase, or 5-α reductase (Reaction: 3-oxo-5α-steroid + Acceptor ⇌ 3-oxo-Δ<sup>4</sup>-steroid + Reduced Acceptor) (1,2). 5α-Reductase thus catalyzes the rate-limiting step in the conversion of testosterone (T) to 5α-dihydroprogesterone (5α-DHP), progesterone to 5α-DHP, deoxycorticosterone (DOC) to 5β-dihydrodeoxycorticosterone, cortisol to

5 $\alpha$ -dihydrocortisol, and aldosterone to 5 $\alpha$ -dihydro-aldosterone. (See also *Finasteride*) Because 5 $\alpha$  reductase is also active in other organs, 5 $\alpha$  reductase inhibitors, such as dutasteride and finasteride, often have side-effects, including sexual dysfunction, increased risk of high-grade prostate cancer, as well as delayed diagnosis and early treatment of prostate cancer.

**Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Bramson, Hermann, Batchelor, *et al.* (1997) *J. Pharmacol. Exp. Ther.* **282**, 1496. 2. Frye, Bramson, Hermann, *et al.* (1998) *Pharm. Biotechnol.* **11**, 393.

### Dvl-PDZ Domain Inhibitor, Peptide Pen-N<sub>3</sub>

This penetratin-containing PDZ Domain peptidomimetic (FW = 3512.20 g/mol; Sequence: Ac-RQIKIWFQNRMRMKWKKGGGEIVLWSDIP-NH<sub>2</sub>), also known as Wnt Pathway Inhibitor III, consists of a 22-amino acid PDZ domain-binding element in Dvl (dishevelled) family proteins that is fused at the N-terminus with a 16-residue Antennapedia penetratin sequence to facilitate its entry into cells. (Note: "PDZ" is an acronym combining the first letters of three proteins (Postsynaptic density protein, or PSD95, *Drosophila* disc large tumor suppressor, or Dlg1, and *Zonula occludens-1* protein, or zo-1) were first found to share this domain.) This inhibitor selectively inhibits up-regulation of cellular  $\beta$ -catenin accumulation and transcription activity upon Wnt3a stimulation (IC<sub>50</sub> = 11  $\mu$ M) or Dvl1/2/3 overexpression in HEK29350 cultures, but not the Wnt3a- or Dvl1/2/3-independent, constitutively active Wnt pathway signaling in the APC-mutant HCT-15 colon cancer cells. Unlike Box5, the PDZ-interacting sequence in Pen-N<sub>3</sub>, originally identified via a random phage display screening, is not derived from Wnt or any known cellular protein. 1. Zhang, Appleton, Weisman, *et al.* (2009) *Nature Chem. Biol.* **5**, 208.

DW-224a See *Zabofloxacin*

DX-88, See *Ecallantide*

### DX-9065a

This novel anticoagulant (FW = 445.54 g/mol; CAS 155204-81-2), systematically named as (2S)-2-[4-[[[(3S)-1-acetimidoyl-3-pyrrolidinyl]oxy]phenyl]-3-(7-amidino-2-naphthyl)propanoic acid, targets coagulation factor Xa (K<sub>i</sub> = 41 nM). It is a significantly weaker inhibitor of thrombin (K<sub>i</sub> > 2 mM), trypsin (K<sub>i</sub> = 0.62  $\mu$ M), chymotrypsin (K<sub>i</sub> > 2 mM), plasmin (K<sub>i</sub> = 23  $\mu$ M), t-plasminogen activator (K<sub>i</sub> = 21  $\mu$ M), plasma kallikrein (K<sub>i</sub> = 2.3  $\mu$ M), and tissue kallikrein (K<sub>i</sub> = 1 mM). It also inhibits proinflammatory events induced by gingipains and coagulation factor Xa. It exhibits strong anticoagulant actions *in vitro* and *in vivo* and inhibits proliferation of vascular smooth muscle cells. The crystal structure of DX-9065a with factor Xa was the first such structure reported for that serine proteinase. A zwitterion with high water solubility and low lipophilicity, human oral bioavailability of DX-9065a was low, amounting to only 2-3% in clinical trials. Compounding with polystyrene nanospheres coated with cationic poly(vinylamine) and cholestyramine greatly improved its oral bioavailability. **Target(s):** coagulation factor Xa (1-6); plasma kallikrein (1); plasmin (1); t-plasminogen activator (1); trypsin (1). 1. Hara, Yokoyama, Ishihara, *et al.* (1994) *Thromb. Haemost.* **71**, 314. 2. Brandstetter, Kühne, Bode, *et al.* (1996) *J. Biol. Chem.* **271**, 29988. 3. ### Dy 268

This FXR receptor antagonist (FW = 560.66 g/mol; CAS 1609564-75-1; Soluble to 100 mM in DMSO), also named 1-[(3-methoxyphenyl)methyl]-N-[4-methyl-3-(4-morpholinylsulfonyl)phenyl]-3-(4-methyl-phenyl)-1H-pyrazole-4-carboxamide, targets (IC<sub>50</sub> = 7.5 nM) the Farnesoid X Receptor (FXR), or Bile Acid Receptor (BAR), or NR1H4 (nuclear receptor subfamily 1, group H, member 4). In humans, this receptor is encoded by the *NR1H4* gene. Dy-268 exhibits no detectable FXR agonist activity and is not cytotoxic. Notably, it is the most potent FXR antagonist identified to date and possesses a promising *in vitro* profile that commends it as a tool for elucidating FXR's biological function. Known FXR agonists are Cafestol, Chenodeoxycholate, Obeticholate, and Fexaramine. 1. Yu, Lin, Forman & Chen (2014) *Bioorg. Med. Chem.* **22**, 2919.

### Dynasore

This cell-permeable dynamin inhibitor (FW<sub>anhydrous</sub> = 322.31; CAS 1202867-00-2 (anhydrous) and 304448-55-3 for indefinite hydrate, C<sub>18</sub>H<sub>14</sub>N<sub>2</sub>O<sub>4</sub>·xH<sub>2</sub>O; Solubility: > 10 mg/mL DMSO), named systematically as 3-hydroxynaphthalene-2-carboxylic acid (3,4-dihydroxybenzylidene)-hydrazide, blocks coated vesicle formation within seconds of addition. **Primary Mode of Action:** Dynamin is a large oligomerizing GTPase (M<sub>r</sub> = 96K) that forms tube-like structures that are involved in clathrin-mediated endocytosis and other vesicular trafficking processes. As a mechanoenzyme, dynamin most likely uses the forces generated by GTP hydrolysis-driven conformational changes to facilitate release of nascent vesicles from parent membranes by first forming a helical structure around the neck of a nascent vesicle, whereupon GTP hydrolysis results in the lengthwise extension of this helix, elongating and then breaking the vesicle neck (1). Two types of coated pit intermediates accumulate during dynasore treatment: those that are U-shaped, half formed pits and those that are O-shaped, fully formed pits. Such structures suggesting that the active pinching-off process is interrupted by the drug (2). **Cellular Impact:** Dynasore inhibits dynamin-regulated receptor endocytosis, cholesterol trafficking, and the uptake of low-density lipoprotein (LDL) in HeLa cells (strongly inhibited) and human macrophages (moderately inhibited) (3). Such treatment leads to the abnormal accumulation of LDL and free cholesterol (FC) within the endolysosomal network. The delivery of regulatory cholesterol to the endoplasmic reticulum becomes deficient, thereby inhibiting transcriptional control of the three major sterol-sensitive genes: (a) sterol-regulatory element binding protein 2 (SREBP-2), (b) 3-hydroxy-3-methyl-coenzymeA reductase (HMGCoAR), and (c) low-density lipoprotein receptor (LDLR). Sequestration of cholesterol in the endolysosomal compartment also impairs both the active and passive cholesterol efflux in HMDM, emphasizing the importance of membrane trafficking in cholesterol homeostasis. **Effective Dosing:** Dynasore is effective at 80  $\mu$ M (0.2% DMSO, final concentration (vol/vol)), when delivered in the presence of 1% lipoprotein-deficient serum (LPDS) medium to avoid dynasore binding/inactivation by serum proteins. Dynasore does not inhibit other functionally unrelated GTP-regulatory proteins. For other details on the inhibitory effects of dynasore on dynamin *in vitro* and advice on using this inhibitor to study the effects of dynasore on endocytosis in cells, see (4). Recent studies indicate that dynasore binds stoichiometrically to detergents typically used for *in vitro* drug screening,

drastically reducing its potency ( $IC_{50}$  rises to 479  $\mu$ M) and diminishing its utility as a research tool (5). The recently developed Dyngo Compound 4a, a dynasore derivative, is the most potent compound, exhibiting a 37x improvement in potency over dynasore for liposome-stimulated helical dynamin activity (5). **Target(s):** Dynamin-1 (2-9), Dynamin-2 (2), and the mitochondrial dynamin-related protein Drp1 (2); compensatory synaptic vesicle endocytosis (6); Atlastin-1, the dynamin-like GTPase responsible for spastic paraplegia SPG3A (7); *Toxoplasma gondii* invasion (8); hyperoxia-mediated NADPH oxidase activation and reactive oxygen species production in caveolin-enriched microdomains of the endothelium (9); polystyrene nanoparticle trafficking across rat alveolar epithelial cell monolayers via non-endocytic transcellular pathways (10); blocks botulinum neurotoxin type A endocytosis in neurons and delays botulism (11); RNase and penetratin sequence-containing protein uptake (12); CD4- and dynamin-dependent endocytosis of HIV-1 into plasmacytoid dendritic cells (13). **1.** Praefcke & McMahon, (2004) *Nat. ### Dyosporin

This DNA gyrase inhibitor (FW = 374.48 g/mol; CAS 28164-57-0), like others in the bis-naphthoquinone class, targets the ATP-hydrolyzing region within the N-terminal domain of GyrB, but acts allosterically (noncompetitively) with respect to ATP (1). The  $IC_{50}$  value of ~15  $\mu$ M for dyosporin against *Mycobacterium tuberculosis* gyrase compares favorably with its minimal inhibitory concentration (MIC ~20  $\mu$ M, or 8  $\mu$ g/mL), indicating that its inhibitory action on gyrase B accounts for its antibiotic action. For comparison, gyrase B exhibits the following values for related inhibitors: 7-methyljuglone,  $IC_{50}$  = 30  $\mu$ M; neodiospyrin,  $IC_{50}$  = 50  $\mu$ M; isodiospyrin,  $IC_{50}$  = 100  $\mu$ M; menadione,  $IC_{50}$  > 200  $\mu$ M; shinanolone,  $IC_{50}$  > 200  $\mu$ M; ciprofloxacin,  $IC_{50}$  = 10  $\mu$ M; and novobiocin,  $IC_{50}$  = 1  $\mu$ M. Dyosporin inhibits the growth of *Leishmania donovani* promastigotes, inducing topoisomerase I mediated DNA cleavage *in vitro* (2). **1.** Karkare, Chung, Collin, *et al.* (2013) *J. Biol. Chem.* **288**, 5149. **2.** Ray, Hazra, Mitra, Das & Majumder (1998) *Mol. Pharmacol.* **54**, 994.

**E-64d**

This cell- and lysosome-permeable thiol protease inhibitor (FW = 342.44 g/mol; CAS 88321-09-9; 20 mM in DMSO), also named (2S,3S)-3-[[[(1S)-3-methyl-1-[[[3-methylbutyl]amino]carbonyl]butyl]amino]carbonyl]-2-oxiranecarboxylic acid ethyl ester and Aloxistatin, targets cathepsins B and L as well as calpain. E64d also inhibits lysosomal proteases and interferes with autolysosomal digestion when used in combination with pepstatin A. **Alzheimer's Disease:** α-Secretase processing of amyloid precursor protein (APP) is an important pathway for decreasing secretion of neurotoxic amyloid β (Aβ). E-64d likewise ameliorates amyloid-β-induced reduction of sAPPα secretion by reversing ceramide-induced protein kinase C down-regulation in SH-SY5Y neuroblastoma cells (4). Such findings suggest ceramide may play an important role in sAPPα processing by modulating PKC activity. 1. Wilcox & Mason (1992) *Biochem. J.* **285**, 495. 2. Tanada, *et al.* (2005) *Autophagy* **1**, 84. 3. Sato, *et al.* (2007) *Cancer Res.* **67**, 9677. 4. Kim, *et al.* (2008) *Autophagy* **4**, 659. 4. Tanabe, Nakajima & Ito (2013) *Biochem. Biophys. **E-3810**

This novel dual VEGF/FGF receptor protein tyrosine kinase inhibitor (FW = 443.49 g/mol; CAS 1058137-23-7) targets kinases associated with Vascular Endothelial Growth Factor Receptor family members (VEGFR-1, IC<sub>50</sub> = 7 nM; VEGFR-2, IC<sub>50</sub> = 25 nM; VEGFR-3, IC<sub>50</sub> = 10 nM), Fibroblast Growth Factor Receptor family members (FGFR-1, IC<sub>50</sub> = 17 nM; FGFR-2, IC<sub>50</sub> = 83 nM; FGFR-3, IC<sub>50</sub> = 238 nM; FGFR-4, IC<sub>50</sub> = >1000 nM), Platelet-Derived Growth Factor Receptor family members (c-Kit, IC<sub>50</sub> = 495 nM; PDGFRα, IC<sub>50</sub> = 175 nM; PDGFRβ, IC<sub>50</sub> = 525 nM), as well as Colony-Stimulating Factor 1 receptor, or CSF-1R, IC<sub>50</sub> = 5 nM (1). When tested in a variety of tumor xenograft models, including early/late-stage subcutaneous and orthotopic models, E-3810 exhibited striking antitumor properties at well-tolerated oral doses administered daily (1). E-3810 remained active in tumors rendered nonresponsive to the general kinase inhibitor sunitinib as a consequence of a previous cycle of sunitinib treatment (1). FGFR inhibition results in enhanced E-3810 cytotoxic activity in cell lines with FGF-driven growth (2). Likewise, antitumor activity appears somewhat higher in tumor xenografts expressing high FGFR-1 and/or FGF ligand (3), suggesting a better clinical response

might be achieved in patients with deregulated FGF/FGFR signaling pathway. E-3810 also inhibits FGF-induced angiogenesis and reduces blood vessel density. **Other Targets:** A quantitative chemical genomics study (4) indicates that the following kinases are likely secondary targets Discoidin Domain Receptor tyrosine kinase 2, (DDR2), proto-oncogene tyrosine-protein kinase (YES), Lck/Yes-related Novel protein tyrosine kinase (LYN), Caspase-Recruiting Domain-containing Interleukin 1β-converting enzyme (ICE) Associated Kinase (CARDIAK), Ephrin type-A receptor 2 (EPHA2), and Cytokine-Suppressive mitogen-activating protein kinase (CSBP). 1. **E7080**, See *Lenvatinib*

**E7107**

This spliceosome inhibitor (FW = 704.95; CAS 630100-90-2) shows anti-proliferative activity of against various cancer cell lines by targeting spliceosome assembly by preventing tight binding of U2 snRNP to pre-mRNA. Although E7107 has no apparent effect on U2 snRNP integrity, it potently prevents an ATP-dependent conformational change exposing the branch point-binding region in U2 snRNP. (See also *FR901464*; *Spliceomycin A*; *Meayanmycin*; *Pladienolide B*) 1. Kotake, Sagane, Owa, *et al.* (2007) *Nature Chem. Biol.* **3**, 570. 2. **E7389**, See *Eribulin*

**E7449**

This oral and potent PARP inhibitor (FW = 317.34 g/mol; CAS 1140964-99-3; Solubility: < 6.5 mg/mL DMSO) targets poly(ADP-ribose) polymerase PARP1 and PARP2, trapping PARP1 onto damaged DNA and potentiating the cytotoxic effects of both radiotherapy and chemotherapy. E7449 also inhibits PARP5a/5b, otherwise known as tankyrase1 and 2 (TNKS1 and 2), important regulators of canonical Wnt/ $\beta$ -catenin signaling. E7449 stabilizes axin and TNKS proteins resulting in  $\beta$ -catenin destabilization and significantly altered expression of Wnt target genes. 1. McGonigle, Chen, Wu, *et al.* (2015) *Oncotarget* **6**, 41307.

#### E-616452, See RepSox

#### Early Mitotic Inhibitor 1

This regulatory protein (MW = 50146.38 g; *Symbol*: EMI1) plays an essential role in coordinating DNA synthesis and mitosis by deploying its 143-residue C-terminal domain to inhibit anaphase-promoting complex APC/C<sup>CDH1</sup> functions, thus interfering with ubiquitin-mediated proteolysis required for cell division. **Mode of Action:** Ubiquitin action requires the E<sub>1</sub>, E<sub>2</sub>, E<sub>3</sub> enzymes, wherein E<sub>1</sub> catalyzes the formation of E<sub>2</sub>-Ub thioester, and E<sub>3</sub>s promote Ub ligation to specific protein substrates. Among the 600 predicted members of the largest human E<sub>3</sub> family is APC/C, which controls cell division by promoting timely Ub-mediated proteolysis of key regulatory proteins. APC/C<sup>CDH1</sup> utilizes a two-step mechanism to mediate substrate poly-ubiquitination, first activating Ub transfer from an E<sub>2</sub> (often UBCH10 in human cells) to the substrate, and then allowing another E<sub>2</sub> (UBE2S in humans) to transfer Ub to the substrate-ligated form. EMI1's intrinsically disordered D-box, linker and tail elements, together with a structured zinc-binding domain, bind distinct regions of APC/C<sup>CDH1</sup> to synergistically both block the substrate-binding site and inhibit ubiquitin-chain elongation. 1. Frye, Brown, Petzold, *et al.* (2013) *Nature Struct. Molec. Biol.* **20**, 827.

#### Ebastine

This peripherally acting H<sub>1</sub> antihistamine (FW = 469.66 g/mol; CAS 90729-43-4; poor water solubility, necessitating use as micronized particles), also known systematically as 4-(4-benzhydryloxy-1-piperidyl)-1-(4-tert-butylphenyl)butan-1-one and by its trade names Evastin<sup>®</sup>, Kestine<sup>®</sup>, Ebastel<sup>®</sup>, and Aleva<sup>®</sup>, does not penetrate the blood-brain barrier to a significant amount and effectively blocks the H<sub>1</sub> receptors in peripheral tissue, seldom causing drowsiness or sedation. 1. Van Cauwenberge, De Belder & Sys (2004) *Expert Opin. Pharmacother.* **5**, 1807.

#### Ebelactone A

This unusual  $\beta$ -lactone (FW = 338.49 g/mol; CAS 76808-16-7) was first isolated in 1980 from a cultured strain of soil actinomycetes related to *Streptomyces aburaviensis*, Ebelactone A is unstable and should be stored in the cold in the absence of light and moisture. Stock solutions in methanol, ethanol, or chloroform are stable for one week at 4°C. **Target(s):** acylaminoacyl-peptidase, irreversibly with covalent bond formation (1); esterase (2-4); *N*-formylmethionine aminopeptidase (3,4); lipase, or triacylglycerol lipase (3-5); retinyl-palmitate esterase (6). 1. #### Ebselen

This organoselenium antioxidant and anti-inflammatory (FW = 274.18 g/mol; CAS 60940-34-3), also known as 2-phenyl-1,2-benziselenazol-3(2H)-one, exhibits a glutathione peroxidase-like activity (*i.e.*, acting as an enzyme mimic) and also acts as a neuroprotectant, especially against acute focal ischemic injury (1-4). Ebselen binds covalently to thiol groups in proteins. Ebselen is a nonselective inhibitor of both cyclooxygenases 1 and 2 (COX-1 and COX-2). It is also an excellent peroxynitrite scavenger ( $k \approx 10^6 \text{ M}^{-1}\text{s}^{-1}$ ), yielding 2-phenyl-1,2-benziselenazol-3(2H)-one 1-oxide, the selenoxide of the parent molecule, as the sole selenium-containing product (5). A stoichiometry of 1 mol ebselen yielded 1 mol selenoxide per mole of peroxynitrite. It inhibits radiation-induced apoptosis in thymocytes, LPS-induced NF- $\kappa$ B nuclear translocation, and LPS-induced phosphorylation of JNK. Ebselen significantly reduces the glucose-induced increase in osmotic fragility and inhibited HbA1c formation. **Target(s):** cyclooxygenase (6,7,26); cytochrome *b*<sub>5</sub> reductase (8,9); cytochrome P450 reductase (9,10); electron transport (8,9); glutathione *S*-transferase (11); H<sup>+</sup> ATPase, plasma membrane (12); H<sup>+</sup>/K<sup>+</sup> ATPase (13); 5-lipoxygenase, or arachidonate 5-lipoxygenase (7,26); 12-lipoxygenase, or arachidonate 12-lipoxygenase (6); 15-lipoxygenase, or arachidonate 15-lipoxygenase, IC<sub>50</sub> = 0.06  $\mu$ M (7,14); NADPH oxidase (14-16); nitric-oxide synthase (17-20); papain (11); porphobilinogen synthase, or  $\delta$ -aminolevulinatase (21); protein kinase C (15); thioredoxin reductase, as an alternative substrate (22,23); tumor necrosis factor- $\alpha$ -induced c-Jun *N*-terminal kinase activation (24); 1-alkylglycerophosphocholine *O*-acetyltransferase (25); HbA1c formation (26). 1. ### Ecallantide

This recombinant polypeptide inhibitor (MW = 7053.7 g; CAS 460738-38-9), also known by the codename DX-88 and its tradename Kalbitor<sup>®</sup>, targets plasma kallikrein ( $K_i \approx 25$  pM) and is an FDA-approved treatment for hereditary angioedema (*or* HAE) and for reducing blood loss during cardiothoracic surgery. Ecallantide's sequence is based on the first Kunitz domain (residues 20-79) within human tissue factor pathway inhibitor, with the following substitutions: Glu at position-20, Ala at position-21, Arg at position-36, Ala at position-38, His at position-39, Pro at position-40, and Trp at position-42. Plasma kallikrein plays a major role in the kallikrein-kinin contact cascade that forms bradykinin, a vasodilator that increases vascular permeability, activates inflammation, and produces pain. An autosomal dominant disorder, hereditary angioedema presents clinically as recurrent episodes of swelling resulting either from deficient production C1 inhibitor or mutations rendering the latter less effective. Acquired angioedema is associated with lymphoproliferative or autoimmune disease (2). Defective or missing C1-inhibitor allows activation of kallikrein, a protease responsible for bradykinin formation from its precursor, kininogen. **1.** Lehmann (2008) *Expert Opin. Biol. Ther.* **8**, 1187. **2.** Lock & Gompels (2007) *Curr. Allergy Asthma Rep.* **7**, 264. **3.**

### Ecdysterone

This polyhydroxylated steroid (FW = 480.64 g/mol; CAS 5289-74-7), also named  $\beta$ -ecdysone, 20-hydroxyecdysone, and (2 $\beta$ ,3 $\beta$ ,5 $\beta$ ,20R,22R)-2,3,14,20,22,25-hexahydroxycholest-7-en-6-one, is a hormone in many insects and crustaceans and has also been found in certain plants. Ecdysterone, the most widely occurring ecdysteroid, participates in a number of physiological activities in these organisms. For example, it has a key role in insect development, ecdysis, metamorphosis, embryogenesis, ovulation, cell proliferation, gene regulation, and apoptosis. Ecdysterone binds to the ecdysone receptor resulting in the activation of primary response genes. The production of transcription factors results in the induction secondary response target genes. It is produced from ecdysone via ecdysone 20-monooxygenase and is a product inhibitor. **Target(s):** ecdysone *O*-acyltransferase (1); inositol-trisphosphate 3-kinase (2). **1.** Slinger & Isaac (1988) *Insect Biochem.* **18**, 779. **2.** Mayr, Windhorst & Hillemeier (2005) *J. Biol. Chem.* **280**, 13229.

### Echinocandins

These cyclopeptide antibiotics (Echinocandin B:  $R_1 = R_2 = \text{OH}$ , FW = 797.81 g/mol, CAS 79411-15-7; Echinocandin C:  $R_1 = \text{OH}$ ,  $R_2 = \text{H}$ , FW = 781.82 g/mol; Echinocandin D:  $R_1 = \text{H}$ , FW = 765.81 g/mol, CAS 71018-13-8) from *Aspergillus nidulans* and *A. rugosus* inhibit cell wall biosynthesis and 1,3- $\beta$ -D-glucan synthase, decreasing  $V_{\text{max}}$  without affecting the  $K_m$  value. **Target(s):** ATPase (1); 1,3- $\beta$ -glucan synthase, inhibited by echinocandin B (1-7); 5'-nucleotidase (1). **1.** Surarit & Shepherd (1987) *J. Med. Vet. Mycol.* **25**, 403. **2.** Taft, Zugel & Selitrennikoff (1991) *J. ### Echinomycin

This lactone antibiotic (FW = 1101.27 g/mol; CAS 512-64-1), also called quinomycin A, from *Streptomyces echinatus* is effective against Gram-positive organisms. It binds to DNA, but not RNA, and exhibits a preference for GpC sites. It will intercalate into DNA, altering the polynucleotide structure and inhibiting enzymes such as DNA topoisomerase II. **Target(s):** deoxyribonuclease I (1,2); DNA-directed DNA polymerase (3); DNA-directed RNA polymerase (4-7); DNA helicase (8); DNA topoisomerase II (9); *Hpa*I restriction endonuclease (10). **1.** Low, Fox & Waring (1986) *Anticancer Drug Des.* **1**, 149. **2.** Bailly, Gentle, Hamy, Purcell & Waring (1994) *Biochem. ### Echistatin $\alpha_1$

This cysteine-rich 49-residue disintegrin (FW = 5417.05 g/mol; CAS 129038-42-2), from the venom of the saw-scaled viper *Echis carinatus*, inhibits platelet aggregation,  $\text{IC}_{50} = 30$  nM. **Sequence:** ECESGPCCR NCKFLKEGTICKRARGDDMDDYCNKGTCDPCRNPCHKGPAT, with 4 disulfide bridges (Cys2-Cys11, Cys7-Cys32, Cys8-Cys37, and Cys20-Cys39) and a canonical integrin-binding, **RGDXXDD** sequence, where X is any aminoacyl residue. **1.** Gan, Gould, Jacobs, Friedman & Polokoff (1988) *J. Biol. Chem.* **263**, 19827. **2.** Garsky, Lumma, Freidinger, *et al.* (1989) *Proc. Natl. Acad. Sci. U.S.A.* **86**, 4022.

## Econazole

This substituted imidazole (FW<sub>free-base</sub> = 381.69 g/mol; CAS 27220-47-9 frequently supplied as the nitrate salt) is a broad-spectrum antifungal agent that inhibits ergosterol biosynthesis. When applied as an emulsified cream (1% weight/volume), Econazole is highly effective against many dermatophytes (*Epidermophyton floccosum*, *Microsporium audouinii*, *M. canis*, *M. gypseum*, *Trichophyton mentagrophytes*, *T. rubrum*, and *T. tonsurans*) as well as a few yeasts (*Candida albicans* and *Malassezia furfur*). **Target(s):** aromatase, CYP19 (1-6); Ca<sup>2+</sup>-transporting ATPase (7); cholesterol monooxygenase, side-chain-cleaving, or CYP11A1 (8); CYP3A4 (9,10); CYP2E1 (11); CYP121 (12); 16-ene C19-steroid synthesizing enzyme (13); K<sup>+</sup> channels, Ca<sup>2+</sup>-dependent (14); Na<sup>+</sup>/Γ-cotransporter (15); nitric-oxide dioxygenase (16-18); nitric-oxide synthase (19); steroid 17,20-lyase (20); steroid 17α monooxygenase (20); sterol 14-demethylase, or CYP51 (12,21-24); TRPM2 channel, a Ca<sup>2+</sup>-permeable non-selective cation channel (25). 1. ## Ecotin

This serine proteinase inhibitor (MW = 32 kDa) is a homodimer of a 142-residue *Escherichia coli* protein (monomer shown above), and targets coagulation factor XIIa ( $K_i = 90$  nM) and human leukocyte elastase ( $K_i = 55$  nM). **Target(s):** bradyrin (fiddler crab) collagenolytic serine protease-1 (1-3); cathepsin G,  $K_i = 15$  pM (4); chymase (5); chymotrypsin (2,5-7); coagulation factor Xa (7,8); coagulation factor XIIa (2,7,9,10); elastase (2,5,6,10); granzyme B (2,11); kallikrein (7,10); trypsin, also inhibited by other ecotin variants (2,5-7,12-14); u-plasminogen activator, or urokinase;

also inhibited by other ecotin variants (5,13,14). Significantly, ecotin is also necessary for the early stages of *Burkholderia pseudomallei* colonization of murine cells, allowing replication following cell entry (15). *B. pseudomallei* is a Gram-negative soil saprophyte that causes the disease melioidosis where clinical symptoms can vary from localized infection to pneumonia and septic shock. An ecotin orthologue in *B. pseudomallei* inhibits elastase. 1. Tsu, Perona, Schellenberger, Turck & Craik (1994) *J. Biol. Chem.* **269**, 19565. 2. ## Ecteinascidin 743

This stereochemically complex antitumor agent (FW = 747.86 g/mol; CAS 114899-77-3), also known as Et-743, NSC 648766 and Trabectedin, from the Caribbean tunicate *Ecteinascidia turbinata* binds to the minor groove of DNA, alkylating guanine residues in a sequence-selective manner and inhibiting DNA topoisomerase I. Its unique mechanism of action triggers a cascade of events that interfere with several transcription factors, DNA binding proteins and DNA repair pathways, resulting in G<sub>2</sub>-M cell cycle arrest and ultimately apoptosis. At therapeutic concentrations, Ecteinascidin 743 has selective anti-inflammatory and immunomodulatory properties on tumor microenvironment, decreasing the production of proinflammatory mediators (e.g., such as IL-6 and CCL2) favoring tumor growth, progression, angiogenesis, and metastasization. Ecteinascidin 743 is marketed under the trade name Yondelis®. 1. Meng, Liao & Pommier (2003) *Curr. Top. Med. Chem.* **3**, 305.

## Eculizumab

This first-in-class humanized monoclonal antibody (MW = 148.3 kDa; CAS 219685-50-4), also known by the trade name Soliris®, targets Complement 5a, an important late-stage cascade component that, when once activated, stimulates host cells, attracts pro-inflammatory immune cells, and destroys cells by forming transmembrane pores. Eculizumab is a IgG2/4κ recombinant monoclonal antibody that is composed of two 448-residue heavy chains and two 214-residue light chains. Eculizumab contains constant regions from human IgG2 sequences and human IgG4 sequences and murine complementarity-determining regions grafted onto the human framework light-and heavy-chain variable regions. Eculizumab is produced in murine myeloma cell cultures, purified by standard methods, and delivered to patients as an IV infusion. Eculizumab is FDA-approved for the treatment of paroxysmal nocturnal hemoglobinuria (PNH) and atypical hemolytic uremic syndrome (aHUS). The former is a progressive and sometimes life-threatening disease associated with excessive hemolysis. The latter causes abnormal blood clots to form in small blood vessels, leading to kidney failure and damage to other vital organs. 1. Kaplan (2002) *Curr. Opin. Investig. Drugs* **3**, 1017. 2. Hillmen, Hall, Marsh, et al. (2004) *New Engl. J. Med.* **350**, 552. 3. Rathbone, Kaltenthaler, Richards, et al. (2013) *BMJ Open* **3**, e003573.

## ED-749, See Edotecarin

## Edeines

Edeine A<sub>1</sub>

These basic antibiotics (FW<sub>Edeine-A1</sub> = 738.89 g/mol; CASs: 52452-77-4 (Edeine A), 52452-78-5 (Edeine B), 71750-64-6 (Edeine F)) from a strain of *Bacillus brevis* consist of linear oligopeptides linked to spermidine or guanylspermidine at their C-termini. Edeines specifically inhibit binding of aminoacyl-tRNAs to the P site of both 30S subunits and 70S ribosomes, as well as to eukaryotic 40S subunits. The amino acid components for the major edeines are β-tyrosine, isoserine, α,β-diaminopropionic acid, 2,6-diamino-7-hydroxyazelaic acid, and glycine. **Target(s):** arginase, inhibited by edeine B, (1); protein biosynthesis initiation (2-6). 1. Shimotohno, Iida, Takizawa & Endo (1994) *Biosci. Biotechnol. Biochem.* **58**, 1045. 2. Pestika (1974) *Meth. Enzymol.* **30**, 261. 3. Carrasco, Battaner & Vázquez (1974) *Meth. Cell* **13**, 113.

## Edotecarin

This topoisomerase inhibitor (FW = 608.55 g/mol; CAS 174402-32-5), also known by the code names J-107088 and ED-749 as well as its systematic name\*, is a NB-506 derivative (See NB-506) that targets topoisomerase I by stabilizing the DNA-enzyme complex and enhancing single-strand DNA cleavage, thereby inhibiting DNA replication and decreasing tumor cell proliferation. This novel topoisomerase I inhibitor induces single-strand DNA cleavage more effectively than NB-506 or camptothecin (See *Camptothecin*) and at different DNA sequences, but the DNA-topoisomerase I complexes induced by edotecarin are more stable than those occurring after exposure to camptothecin or NB-506. The antitumor activity of edotecarin is less cell-cycle dependent than other topoisomerase I inhibitors. It is structurally related to staurosporine, but does not inhibit protein kinase. The antitumor activity of edotecarin has been tested *in vitro* and *in vivo*, and inhibition of tumor growth has been observed in breast, cervix, pharynx, lung, prostate, colon, gastric, and hepatic cancer models. Edotecarin is effective on cells that have acquired resistance related to P-glycoprotein multi-drug resistance. Drug synergy is observed *in vitro*, when edotecarin was tested in combination with cisplatin, 5-fluorouracil, etoposide, paclitaxel, doxorubicin, vincristine, camptothecin, and gemcitabine. Edotecarin is not a substrate for *in vitro* P450-mediated metabolism. 1. Saif & Diasio (2005) *Clin. Colorectal Cancer* **5**, 27. \*IUPAC: 6-((1,3-dihydroxypropan-2-yl)amino)-2,10-dihydroxy-12-((2R,3R, 4S,5S,6R)-3,4,5-trihydroxy-6-(hydroxymethyl)tetrahydro-2H-pyran-2-yl)-12,13-dihydro-5H-indolo[2,3-a]pyrrolo[3,4-c]carbazole-5,7(6H)-dione

## Edoxaban

This oral anticoagulant (FW = 548.06 g/mol; CAS 912273-65-5), also known as DU-176b, Lixiana®, and N<sup>2</sup>-(5-chloropyridin-2-yl)-N-[(1S,2R,4S)-4-(dimethylcarbamoyl)-2-[(5-methyl-6,7-dihydro-4H-[1,3]thiazolo[5,4-c]pyridine-2-carbonyl)amino]cyclohexyl]oxamide, is a direct factor Xa inhibitor, with K<sub>i</sub> values of 0.561 nM for free FXa and 2.98 nM for prothrombinase, exhibiting >10,000x selectivity toward factor Xa (1). DU-176b did not impair platelet aggregation by ADP, collagen or U46619, and, when administered *in vivo*, DU-176b dose-dependently inhibits thrombus formation in rat and rabbit thrombosis models, although bleeding time in rats is not significantly prolonged at an antithrombotic dose (1). Pharmacokinetic profiles are consistent across dose with rapid absorption, biphasic elimination, and terminal elimination half-life of 5.8 to 10.7 hours (2). It has been approved in Japan (2011) for prevention of venous thromboembolisms (VTE) following lower-limb orthopedic surgery and by the FDA (2015) for prevention of stroke and non-CNS systemic embolism. **See other direct Factor Xa inhibitors:** Rivaroxaban, or Xarelto®; Apixaban, or Eliquis®; Betrixaban; Daxetaban (discontinued); and Otamixaban injectable (discontinued). 1. Furugohri, Isobe, Honda, *et al.* (2008) *J. Thromb. Hemost.* **6**, 1542. 2. Ogata, Mendell-Harary, Tachibana, *et al.* (2010) *J. Clin. Pharmacol.* **50**, 743.

## EDTA (or Ethylenediamine tetraacetic acid)

This widely used metal ion chelator (FW<sub>free-acid</sub> = 292.25 g/mol; CAS 60-00-4), also known as ethylenediamine-N,N,N',N'-tetraacetic acid and versene, is an important multidentate ligand and metal ion buffer. EDTA forms stable 1:1 complexes with di- or trivalent cations (structure shown above right).

Its interactions with most monovalent ions are weak and are generally inconsequential. The pK<sub>a</sub> values of EDTA (at an ionic strength of 0.1 and a

temperature of 20°C) are 2.0, 2.67, 6.16, and 10.26: thus, over the range from pH 4 to 5, most of the EDTA is present as the divalent anion, whereas between pH 7 and 9, the trivalent anion is more prevalent. Formation of a metal ion-EDTA complex will result in the displacement of the remaining protons from EDTA. Thus,  $\text{Me}^{n+} + \text{H}_2(\text{EDTA})^{2-} \rightleftharpoons \text{M}(\text{EDTA})^{(n-4)+} + 2\text{H}^+$  between pH 4 and 5 and  $\text{M}^{n+} + \text{H}(\text{EDTA})^{3-} \rightleftharpoons \text{M}(\text{EDTA})^{(n-4)+} + \text{H}^+$  between pH 7 and 9. The tetravalent anion of EDTA is the species of greatest importance in equilibrium calculations. The strength metal ion complexation is typically measured by its overall formation constant for the reaction,  $\text{M}^{n+} + \text{EDTA}^{4-} \rightleftharpoons \text{M}(\text{EDTA})^{(n-4)+}$ ,  $K_{\text{M}(\text{EDTA})} = [\text{M}(\text{EDTA})^{(n-4)+}]/([\text{M}^{n+}][\text{EDTA}^{4-}]$ ). At 25°C, pH = 7, and ionic strength = 0.1 M,  $\log K_{\text{M}(\text{EDTA})}$  values are:  $\text{Ca}^{2+}$ , 10.6;  $\text{Cd}^{2+}$ , 16.6;  $\text{Co}^{2+}$ , 16.5;  $\text{Cu}^{2+}$ , 18.9;  $\text{Fe}^{3+}$ , 25.1;  $\text{Mg}^{2+}$ , 8.7;  $\text{Mn}^{2+}$ , 24.8;  $\text{Ni}^{2+}$ , 18.7; and  $\text{Zn}^{2+}$ , 16.7. Use of the commercially available  $\text{K}^+\text{Mg}^{2+}\text{EDTA}$  salt offers the convenience of avoiding wide swings in solution pH, when one seeks to buffer magnesium ion concentrations in many biochemical experiments. **A Word of Caution:** When working with enzymes exhibiting extreme affinity for metal ions, one should not overlook the possibility that commercial chelators can be an inadvertent source of metal ions. For example, a 10 mM solution of so-called reagent grade EDTA is likely to contain the following total metal ion concentrations: aluminum, ~0.6  $\mu\text{M}$ ; arsenic, ~0.03  $\mu\text{M}$ ; barium, ~0.1  $\mu\text{M}$ ; bismuth, ~5  $\mu\text{M}$ ; calcium ~0.7  $\mu\text{M}$ ; cadmium, ~0.1  $\mu\text{M}$ ; cobalt, ~0.2  $\mu\text{M}$ ; chromium, ~0.3  $\mu\text{M}$ ; copper, ~0.3  $\mu\text{M}$ ; iron, ~0.3  $\mu\text{M}$ ; lead, ~0.1  $\mu\text{M}$ ; lithium, ~2  $\mu\text{M}$ ; manganese, ~0.3  $\mu\text{M}$ ; molybdenum, ~0.6  $\mu\text{M}$ ; nickel, ~5  $\mu\text{M}$ ; potassium, ~10  $\mu\text{M}$ ; sodium, ~0.5  $\mu\text{M}$ ; strontium, ~0.1  $\mu\text{M}$ . Of course, their respective uncomplexed (or "free") metal ion concentrations will be much lower. **See also EGTA** 1. Perrin & Dempsey (1974) *Buffers for pH and Metal Ion Control*, Chapman & Hall, London.

### Eeyarestatin I

This potent ERAD inhibitor (FW = 630.44 g/mol; CAS 412960-54-4; Symbol: ES<sub>1</sub>) modulates endoplasmic reticulum- (or ER-) associated degradation (or ERAD), resulting in the formation of mislocalized polypeptides that are ubiquitinated and subsequently degraded as part of the Unfolded Protein Response (UPR). **Mechanism of Inhibitory Action:** For many substrates, retrotranslocation requires the action of ubiquitinating enzymes, which poly-ubiquitinate substrates emerging from the ER lumen, and of the p97-Ufd1-Npl4 ATPase complex, which hydrolyzes ATP to dislocate polyubiquitinated substrates into the cytosol (1,2). Polypeptides extracted by p97 are eventually transferred to the proteasome for destruction. Eeyarestatin I specifically targets a component of the Sec61 complex that forms the membrane pore of the ER translocon. Eeyarestatin I's cytotoxicity characteristics are caused by its activation of NOXA, a Bcl-2 homology3-only pro-apoptotic protein (3). ES<sub>1</sub> acts by preventing the transfer of the nascent polypeptide from the co-translational targeting machinery to the Sec61 complex. These results suggest that ES<sub>1</sub> can be a drug that modulates canonical protein transport from the cytosol into the mammalian ER both *in vitro* and *in vivo*. EerI and another ERAD inhibitor (bortezomib) elicit an integrated stress response program at the ER to activate the CREB/ATF transcription factors ATF3 and ATF4. The latter form a complex capable of binding to the NOXA promoter, a step that is required for NOXA activation. Eeyarestatin I and bortezomib also block ubiquitination of histone H2A to relieve its inhibition on NOXA transcription (3). 1. Wang, Li & Ye (2008) *J. Biol. Chem.* **283**, 7445. 2. Cross, McKibbin, Callan, *et al.* (2009) *J. Cell. Sci.* **122**, 4393. 3. Wang, Mora-Jensen, Weniger, *et al.* (2009) *Proc. Natl. Acad. Sci. U.S.A.* **106**, 2200.

### Efavirenz

This benzoxazinone (FW = 315.68 g/mol; CAS 154598-52-4; Symbol: EFV), also known as L-743,726, DMP266, and Sustiva<sup>®</sup>, is a second-generation non-nucleoside reverse transcriptase inhibitor (NNRTI) with a resistance profile that overlaps with nevirapine and delavirdine. Unlike nucleoside RTIs, which bind at the enzyme's active site, NNRTIs act allosterically by binding to a distinct site known as the NNRTI pocket. Efavirenz has been in use clinically since 1996 in anti-retroviral therapy. An efavirenz metabolite (possibly 8-hydroxy-efavirenz) reportedly damages to neurons, resulting in impaired neurocognitive performance. In mice, EFV crosses the blood-brain barrier and inhibits creatine kinase in the cerebellum, hippocampus, striatum, and cortex (6). **Efavirenz-Induced Inhibition of Mitochondrial Complex I:** Exposure of cultured mouse hepatocytes to EFV results in rapid-onset cell injury, showing a narrow toxicity range, *i.e.*, no observable effect at 30 $\mu\text{M}$  and sub-maximal effects at 50 $\mu\text{M}$  (7). EFV also causes a dose-dependent decrease in cellular ATP levels, increased peroxynitrite formation, the latter with oxidation of protein thiols, including cyclophilin D (CypD). Notably, the superoxide scavenger Fe-TCP and the peroxynitrite decomposition catalyst Fe-TMPyP prevent such effects. Both ferroporphyrins completely protect from EFV injury, suggesting peroxynitrite plays a significant role (7). EFV also increases the NADH/NAD<sup>+</sup> ratio, inhibits Sirt3 activity, and leads to hyperacetylated lysine residues, including those in CypD. Hepatocytes isolated from Sirt3-null mice are protected against 40 $\mu\text{M}$  EFV, as compared to their wild-type controls. Such findings suggest that chemical inhibition of complex I activates multiple pathways leading to cell injury (7). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Tucker, Lumma & Culberson (1996) *Meth. Enzymol.* **275**, 440. 2. Young, Britcher, Tran, *et al.* (1995) *Antimicrob. Agents Chemother.* **39**, 2602. 3. ### Efegatran

This substituted tripeptide aldehyde (FW = 416.52 g/mol; CAS 105806-65-3), also known as LY 294468, GYKI-14766, and N<sup>ε</sup>-methyl-D-phenylalanyl-L-prolyl-L-arginyl (D-MePhe-Pro-Arg-H), inhibits thrombin and is a powerful anticoagulant. Efegatran has been developed as an anticoagulant for the treatment of acute coronary syndromes. 1. Nilsson, Sjoling-Ericksson & Deinum (1998) *J. Enzyme Inhib.* **13**, 11. 2. Bajusz, Szell, Bagdy, *et al.* (1990) *J. Med. Chem.* **33**, 1729. 3. Weitz (2003) *Thromb. Res.* **109** Suppl. 1, S17.

## Efinaconazole

This triazole-based fungicide (FW = 348.39 g/mol; CAS 164650-44-6), also named (2*R*,3*R*)-2-(2,4-Difluorophenyl)-3-(4-methylene-1-piperidinyl)-1-(1*H*-1,2,4-triazol-1-yl)-2-butanol and marketed under the tradename Jublia<sup>®</sup>, dose-dependently decreases ergosterol production, with accumulation of 4,4-dimethylsterols and 4 $\alpha$ -methylsterols. Its primary mode of action is a reduction in ergosterol biosynthesis via inhibition of sterol 14 $\alpha$ -demethylase. Efinaconazole induces morphological and ultrastructural changes in the hyphae in *Trichophyton mentagrophytes*, becoming more prominent at higher drug concentrations. It is also effective against *Candida albicans*. It also exhibits a lower minimum inhibitory concentration than observed with terbinafine, ciclopirox, itraconazole and amorolfine, when tested against *T. rubrum*, *T. mentagrophytes*, and *Candida albicans* (2). Efinaconazole is effective in the treatment of onychomycosis, a fungal infection of the matrix, bed, and/or plate of the toenail or fingernail. **1.** Tatumia, Nagashimaa, Shibanusib, *et al.* (2013) *Antimicrob. Agents Chemother.* **57**, 2405. **2.** Gupta & Simpson (2014) *Expert Rev. Anti. Infect. Ther.* **12**, 743.

## Eflornithine

This antiprotozoal agent (FW = 182.17 g/mol; CAS 70050-56-5), known systematically as (*R**S*)-2,5-diamino-2-(difluoromethyl)pentanoic acid, is used to treat Human African trypanosomiasis, or African Sleeping Sickness. Eflornithine is commonly known as the 'resurrection drug' in recognition of its often-spectacular capacity to revive and cure comatose Sleeping Sickness patients. It is also a specific, enzyme-activated irreversible inhibitor of the trypanosomatid spermidine biosynthetic enzyme, *S*-adenosylmethionine decarboxylase (1,2). Eflornithine is also a specific inhibitor of ornithine decarboxylase following growth stimulation, thereby blocking Ehrlich ascites tumor cell proliferation in culture (3). **1.** Bacchi, Nathan, Hutner, McCann & Sjoerdsma (1980) *Science* **210**, 332. **2.** Heby, Persson & Rentala (2007) *Amino Acids* **33**, 359. **3.** Oredsson, Anehus & Heby (1980) *Biochem. Biophys. Res. Commun.* **94**, 151.

## Eflucimibe

This acetanilide (FW = 453.74 g/mol; CAS 204192-08-5), also named F12511 and (*S*)-2',3',5'-trimethyl-4'-hydroxy- $\alpha$ -dodecylthio- $\alpha$ -phenylacetanilide, inhibits sterol *O*-acyltransferase (IC<sub>50</sub> = 39 nM for ACAT-I) and reduces plasma cholesterol levels. **1.** Zamorano-León, Fernández-Sánchez, López Farré, *et al.* (2006) *J. Cardiovasc. Pharmacol.* **48**, 128. **2.** Junquero, Oms, Carilla-Durand, *et al.* (2001) *Biochem. Pharmacol.* **61**, 97. **3.** López-Farré, Sacristán, Zamorano-León, San-Martin & Macaya (2008) *Cardiovasc. Ther.* **26**, 65.

## Efrapeptins

These fungal antibiotics and insecticides (Efrapeptin F (shown above): FW = 1635.10; CAS 131353-66-7), also known as efrastatins and A23871, from *Tolypocladium niveum* compete with ATP for binding to the F<sub>1</sub> fragment of mitochondrial ATP synthase, interacting directly with an active-site arginine that is required for nucleotide binding (1-13). Some mutant ATP synthases are efrapeptin-resistant. Each 15-residue peptides is acetylated at the N-terminus and are blocked at the C-terminus by 1-isobutyl-2-(2,3,4,6,7,8-hexahydropyrrolo[1,2-*a*]pyrimidin-1-yl)ethylamine. (Efrapeptin C sequence: Ac-Pip-Aib-Pip-Aib-Aib-Leu- $\beta$ -Ala-Gly-Aib-Aib-Pip-Aib-Gly-Leu-Aib-X, where Ac refers to acetyl, Pip is L-pipecolic acid, Aib is  $\alpha$ -aminoisobutyric acid,  $\beta$ -Ala is  $\beta$ -alanine, and X refers to the bicyclic blocking group shown above. Efrapeptin D is identical, albeit with Iva (*i.e.*, *S*-isovaline) in place of Aib15, whereas Efrapeptin E contains Iva4 and Iva15. Efrapeptin F has Aib4, Ala13, and Iva15 and efrapeptin G has Iva4, Ala13, and Iva15. Its binding is associated with small structural changes in side chains of F<sub>1</sub>-ATPase around the binding pocket. Efrapeptin makes hydrophobic contacts with the  $\alpha$ -helical structure in the  $\gamma$ -subunit, which traverses the cavity, and with subunit beta E and the two adjacent  $\alpha$ -subunits (14). Two intermolecular hydrogen bonds could also form, helping to stabilize efrapeptin's two domains (residues 1-6 and 9-15, respectively), which are connected by a flexible region ( $\beta$  Ala-7 and Gly-8). Efrapeptin appears to inhibit F<sub>1</sub>-ATPase by blocking the conversion of subunit beta E to a nucleotide binding conformation, as would be required by an enzyme mechanism involving cyclic interconversion of catalytic sites (14). First noted for its action on chromatophores of purple bacterium *Rhodospirillum rubrum*, efrapeptins are potent inhibitors for mitochondrial and bacterial ATP synthases, with milder action against chloroplast ATP synthase. **Target(s):** ATP synthase, or F<sub>1</sub> ATPase (2-9); bacterial ATPase (2); CF<sub>1</sub> ATP synthase, or chloroplast ATP synthase (2,10); H<sup>-</sup>-transporting ATPase, lysosomal (11); RrF<sub>1</sub> ATPase (12); Tf<sub>1</sub> ATPase (13). **1.** Brinen & Clardy (1992) *J. ## EGA

This host-membrane trafficking inhibitor (FW = 346.23 g/mol), also known as 4-bromobenzaldehyde-*N*-(2,6-dimethylphenyl)semi-carbazone, blocks (IC<sub>50</sub> = 1.7 μM) the entry of acid-dependent bacterial toxins (including *Bacillus anthracis* lethal toxin) as well as viruses into mammalian cells. EGA also delays lysosomal targeting and degradation of the EGF receptor, indicating that it targets host-membrane trafficking. However, EGA does not block endosomal recycling of transferrin, retrograde trafficking of ricin, phagolysosomal trafficking, or phagosomal permeabilization by *Francisella tularensis*. Because EGA does not neutralize acidic organelles, its mechanism of action is distinct from pH-raising agents, such as ammonium chloride and bafilomycin A<sub>1</sub>. EGA represents a promising tool for investigating membrane trafficking as well as for treating infectious diseases. 1. Gillespie, Ho, Balaji, *et al.* (2013) *Proc. Natl. Acad. Sci. U.S.A.* **110**, E4904.

## EGTA

This tetracarboxylic acid (FW<sub>free-acid</sub> = 380.35 g/mol; CAS 67-42-5), also known as ethylene glycol bis(β-aminoethyl ether)-*N,N,N',N'*-tetraacetic acid, is a metal ion chelator that shows binding preference for Ca<sup>2+</sup>. Unlike EDTA, which only forms hexa-coordinate complexes (See EDTA), EGTA contains two ether oxygens, allowing it to form both hexa- and octa-coordinate complexes (1). An example of the utility EGTA as a buffer of the free calcium ion concentration is the demonstration that calmodulin requires four bound calcium ions to fully activate 3',5'-cyclicAMP phosphodiesterase (2). **Equilibria:** Formation of a metal ion-EGTA (or Me-EGTA) complex results in the displacement of the remaining protons from EGTA. Thus, Me<sup>n</sup> + H<sub>2</sub>EGTA<sup>2-</sup> ⇌ Me-EGTA<sup>(n-4)</sup> + 2H<sup>+</sup> between pH 4 and 5 and Me<sup>n</sup> + HEGTA<sup>3-</sup> ⇌ Me-EGTA<sup>(n-4)</sup> + H<sup>+</sup> between pH 7 and 9 (1). Hence, the tetravalent anion of EGTA is the species of greatest importance in equilibrium calculations. Metal ion complexation is measured by its formation constant, or stability constant (K<sub>M(EGTA)</sub> = [Me-EGTA<sup>(n-4)</sup>]/([Me<sup>n</sup>]×[EGTA<sup>4-</sup>]) for the complexation reaction: Me<sup>n</sup> + EGTA<sup>4-</sup> ⇌ Me-EGTA<sup>(n-4)</sup>. The following are values for logK<sub>Me-EGTA</sub> at 25°C, pH = 7, ionic strength = 0.1 Me-EGTA: 5.3 for Mg<sup>2+</sup> ion 10.9 for Ca<sup>2+</sup> ion, 12.1 for Mn<sup>2+</sup> ion, 12.6 for Zn<sup>2+</sup> ion, and 16.5 for Cd<sup>2+</sup> ion. 1. Perrin & Dempsey (1974) *Buffers for pH and Metal Ion Control*, Chapman & Hall, London. 2. Huang, Chau, Chock, Wang & Sharma (1981) *Proc. Natl. Acad. Sci. U.S.A.* **78**, 871.

**EHNA**, See erythro-9-(2-Hydroxy-3-nonyl)adenine

## EHop-016

This signal transduction inhibitor (FW = 430.56 g/mol), based on the structure of the Rac/Rac GEF inhibitor NSC23766, is cytostatic in metastatic cancer cells overexpressing the actin cytoskeletal modulator Rac, with an IC<sub>50</sub> value of 1.1 μM, or ~100-times lower than the IC<sub>50</sub> for NSC23766 (See also NSC23766). At concentrations ≤ 5 μM, EHop-016 is specific for Rac1 and Rac3. At higher concentrations, EHop-016 inhibits

Cdc42. In MDA-MB-435 cells that have high active levels of the Rac GEF Vav2, EHop-016 inhibits the association of Vav2 with a nucleotide-free Rac1(Gly-15-Ala mutant) having high affinity for activated GEFs. EHop-016 also inhibits the Rac activity of MDA-MB-231 metastatic breast cancer cells and reduces Rac-directed lamellipodia formation in both cell lines. EHop-016 also decreases Rac's downstream effects of p21-activated kinase 1 (or PAK1) as well as the directed migration of metastatic cells. Significantly, when present at effective concentrations below 5 μM, EHop-016 does not affect the viability of transformed mammary epithelial cells (MCF-10A) and reduces viability of MDA-MB-435 cells by only 20%. EHop-016 holds promise as a targeted therapeutic agent for the treatment of metastatic cancers characterized by high Rac activity. 1. Montalvo-Ortiz, Castillo-Pichardo, Hernández, *et al.* (2012) *J. Biol. Chem.* **287**, 13228.

**EHT-0202**, See Etazolate

## EHT 1864

This Rac inhibitor (FW<sub>di-HCl</sub> = 581.47 g/mol; CAS 754240-09-0; FW<sub>free-base</sub> = 508.56 g/mol; Solubility: 100 mM in H<sub>2</sub>O, 75 mM in DMSO), also named 5-(5-(7-(trifluoromethyl)quinolin-4-ylthio)pentyl)oxy-2-(morpholinomethyl)-4H-pyran-4-one, blocks Rac signaling by direct binding to Rac1 (K<sub>D</sub> = 40 nM), Rac1b (K<sub>D</sub> = 50 nM), Rac2 (K<sub>D</sub> = 60 nM), and Rac3 (K<sub>D</sub> = 250 nM). EHT 1864 blocks Ras-, and Tiam-induced growth transformation of NIH-3T3 fibroblasts (2). RAC1 inhibition by EHT 1864 likewise targets amyloid precursor protein processing by γ-secretase and decreases Aβ production, both *in vitro* and *in vivo* (3). EHT 1864 also markedly attenuates glucose-stimulated insulin secretion in the INS-1 832/13 pancreatic β-cell line, significantly reducing glucose-induced Rac1 activation and membrane targeting (4). It also suppresses glucose-induced activation of ERK1/2 and p53, but not Akt (4). 1. Shutes, Onesto, Picard, *et al.* (2007) *J. Biol. Chem.* **282**, 35666. 2. ## 5,8,11,14-Eicosatetraynoate

This unsaturated fatty acid (FW<sub>free-acid</sub> = 296.41 g/mol; Symbol: ETYA) is the alkyne analogue of arachidonic acid, and, as such, inhibits a number of arachidonate-dependent enzymes. This substance can also be incorporated in cell lipids instead of arachidonate. **Target(s):** acyl-CoA synthetase (1,2); cyclooxygenase, or prostaglandin-endoperoxide synthase (2-4,8-11); cytochrome P450 (1); glutathione S-transferase (12); K<sup>+</sup> current, fast inactivating (13); linoleate diol synthase (14); linoleate 11-lipoxygenase, or manganese lipoxygenase (15,16); lipoxygenase (17); 5-lipoxygenase, or arachidonate 5-lipoxygenase (1,3,4,22); 8-lipoxygenase, or arachidonate 8-lipoxygenase (21); 12-lipoxygenase, or arachidonate 12-lipoxygenase (4,5,25-30); 15 lipoxygenase, or arachidonate 15-lipoxygenase (3,6,7,23,24); phospholipase A<sub>2</sub> (1,18-20). 1. ### 8Z,11Z,14Z-Eicosatrienoate

This unsaturated fatty acid ( $FW_{\text{free-acid}} = 306.49$  g/mol), also known as dihomio-(6,9,12)-linolenic acid and dihomio- $\gamma$ -linolenic acid, is a member of the linoleic family of fatty acids. It is an intermediate in the biosynthesis of arachidonate from linoleate and is a precursor in the formation of the PG1 series of prostaglandins. **Target(s):** arachidonyl-CoA synthetase, *or* arachidonate:CoA ligase, also as an alternative substrate (1-3); cyclooxygenase (4); DNA polymerase (5). **1.** Wilson, Prescott & Majerus (1982) *J. Biol. Chem.* **257**, 3510. **2.** Taylor, Sprecher & Russel (1985) *Biochim. Biophys. Acta* **833**, 229. **3.** Neufeld, Sprecher, Evans & Majerus (1984) *J. ### Elacridar

This very potent drug efflux inhibitor ( $MW = 563.64$  g/mol; CAS 143664-11-3; Solubility: 10 mM in DMSO), also known as GF120918 and named systematically as *N*-(4-(2-(6,7-dimethoxy-3,4-dihydroisoquinolin-2(1*H*)-yl)ethyl)phenyl)-5-methoxy-9-oxo-9,10-dihydroacridine-4-carboxamide, targets ABC transporters (P-glycoprotein) and Breast Cancer Resistance Protein (BCRP), reversing multidrug resistance when used at 0.02 to 0.1  $\mu\text{M}$  *in vitro*. By blocking P-gp- and BCRP-mediated efflux, GF120918 increases the intracellular concentration of a co-administered drug, often potentiating its cytotoxicity and effectiveness as an anti-tumor agent (1). GF120918A has been used both *in vitro* and *in vivo* as a tool inhibitor of ABC transporters (or P-glycoprotein) to investigate the role of transporters in the disposition of test drug and to guide preclinical doses of candidate drugs (2). **1.** Hyafil, Vergely, Du Vignaud & Grand-Perret (1993) *Cancer Res.* **53**, 4595. **2.** Ward & Azzarano (2004) *J. Pharmacol. Exp. Ther.* **310**, 703.

### Elafin

This human protein ( $MW = 12.6$  kDa), also known as skin-derived antileukoproteinase (*or* SKALP) and elastase-specific inhibitor (ESI), inhibits elastase (1-5) and leukocyte elastase (5-9). The unprocessed human protein contains WAP-type core (WFDC) domain consisting of 117 residues and four disulfide bonds. Most WFDC gene members are localized to chromosome 20q12-q13 in two clusters: centromeric and telomeric. This gene belongs to the centromeric cluster. Expression of this gene is upregulated by bacterial lipopolysaccharides and cytokines. It is synthesized and secreted locally at sites of injury and is produced in response to primary cytokines. **Target(s):** myeloblastin, *or* proteinase 3 (1,6-8,10-12); pancreatic elastase (4,7,13,14); stratum corneum chymotryptic enzyme, *or* kallikrein 7 (15). **1.** Wiedow, Luademann & Utecht (1991) *Biochem. ### Elastatinal

This unusual peptide aldehyde and serine protease inhibitor ( $FW = 512.57$  g/mol; CAS 51798-45-9;  $pK_a$  values are 3.7 and >11) from *Actinomyces*, also known as *N*-(*N*<sup>z</sup>-carbonyl-Cpd-L-glutaminy-L-leucine), where Cpd stands for capreomycinidine, *or* (*S,S*)- $\alpha$ -(2-iminohexahydro-4-pyrimidinyl)glycine, rapidly forms a hemiacetal adduct between its aldehyde group and the active-site seryl residue of elastase ( $K_i \approx 50$   $\mu\text{M}$ ) and plasmin. Elastatinal is without effect on chymotrypsin and trypsin. Elastatinal is a

water-soluble reagent that can be stored as a 10-mM stock solution (~20 mg/mL) and used at 0.5–1.0 mM final concentrations. Stock solutions are stable for one week at 4°C. **Target(s):** Bacillopeptidase F (1); *Bombyx mori* protease (2); brachyuran, or serine collagenolytic protease from greenshore crag (*Carcinus maenas*) (3); carboxypeptidase C (4); cathepsin B (5,6); envelopsin (7); legumain (8); leucyl aminopeptidase (9); leukocyte elastase (10–12);  $\alpha_2$ -macroglobulin protease complexes (13); multicatalytic proteinase (*Halocynthia roretzi* eggs) (14); pancreatic elastase (10,15–20); pancreatic elastase II (21); peptidyl-glycinamidase (22); picornain 2A (23–28); picornain 3C (24); post-proline cleavage enzyme, or prolyl oligopeptidase (29,30); protease IV (31,32); pyroglutamyl-peptidase I (9); signal peptidase I (*Escherichia coli*) (32); subtilisin Sendai, weakly inhibited (33); thermitase (34). 1. ### Elbasvir

This highly potent and selective HCV antiviral (FW = 882.02 g/mol; CAS 1370468-36-2), also known by the code name MK-8742 and as dimethyl *N,N'*-((6*S*)-6*H*-indolo[1,2-*c*][1,3]benzoxazine-3,10-diyl)bis{1*H*-imidazole-5,2-diyl-(2*S*)-pyrrolidine-2,1-diyl}[(2*S*)-1-oxo-3-methylbutane-1,2-diyl]}-biscarbamate, targets the NS5a replication complex, a protein that plays a critical role in the lifecycle of Hepatitis C virus. Elbasvir is used in combination with grazoprevir, the resulting formulation, known as Zepatier<sup>®</sup>, is a highly effective, FDA-approved treatment of chronic HCV genotypes 1 or 4. 1. Coburn, Meinke, Chang, et al. (2013) *ChemMedChem*. **8**, 1930.

### Eliglustat

This orphan drug (FW = 404.54 g/mol; CAS 491833-29-5), also known as Genz-112638, Cerdelga<sup>®</sup> and *N*-[(1*R*,2*R*)-1-(2,3-dihydro-1,4-benzodioxin-6-yl)-1-hydroxy-3-(1-pyrrolidinyl)-2-propanyl]octanamide, is an oral inhibitor targeting glucosylceramide synthase (*Reaction*: UDP-Glucose + *N*-Acylsphingosine = UDP + D-Glucosyl-*N*-acylsphingosine), a Golgi enzyme that catalyzes the first step in the sequential addition of carbohydrate moieties in ganglioside biosynthesis. Eliglustat is used to treat Gaucher's disease, a genetic disorder leading to glucocerebroside (or glucosylceramide) over-accumulation in certain cells (white blood cells, especially mononuclear leukocytes) and organs (spleen, liver, kidneys, lungs, brain, and bone marrow), resulting in neurological complications, swelling of lymph nodes, anemia, and yellow fatty deposits on the white of the eye. Eliglustat improves bone mineral density, correcting an abnormal bone marrow MRI signal, as well as normalization of glucocerebroside and ganglioside GM3 levels (2). 1. Lukina, Watman, Arreguin, et al. (2010) *Blood* **116**, 893. 2. Cox (2010) *Curr. Opin. Investig. Drugs* **11**, 1169.

### Ellagic Acid

This plant antioxidant and free radical scavenger (FW = 302.20 g/mol; CAS 476-66-4; Solubility: < 1 mg/mL DMSO or H<sub>2</sub>O), also known as 4,4',5,5',6,6'-hexahydroxydiphenoic acid 2,6,2',6'-dilactone, exhibits anti-mutagenic and anti-carcinogenic properties. Based on flow linear dichroism measurements, the neutral acid (pH 5.5) binds to double-stranded DNA (1). Ellagic acid protects DNA from chemical modification by alkylating agents and inhibits the mutagenicity of the carcinogenic metabolite formed from benz[*a*]pyrene. It also inhibits  $\gamma$ -radiation (and thus hydroxyl radical) - induced lipid peroxidation in rat liver microsomes in a dose- and concentration-dependent manner and has been found to be a good scavenger of peroxynitrite. **Target(s):** aldose reductase (2–4); arylamine *N*-acetyltransferase (5,6,36); carbonic anhydrase, weakly inhibited (7); casein kinase 2, IC<sub>50</sub> = 0.04  $\mu$ M (8,9), compare to IC<sub>50</sub> values of 2.9, 3.5, 4.3 and 9.4  $\mu$ M for Lyn, PKA, Syk and FGR protein kinases, respectively); chitin synthase (10); CYP2A2 (11); CYP2A1 (11); CYP2B1 (11); CYP2B2 (11); CYP2C6 (11); CYP2C11 (11); CYP2E1 (12); cystathionine  $\beta$ -synthase (13); DNA gyrase (14,15); DNA topoisomerases, with IC<sub>50</sub> values of 0.6 and 0.7  $\mu$ g/mL for topo I and topo II, respectively (16, 17); 3-galactosyl-*N*-acetylglucosaminide 4- $\alpha$ -L-fucosyltransferase (18); glutathione-disulfide reductase (19); glutathione *S*-transferase (19–23); glycogen phosphorylase (24); glycoprotein 3- $\alpha$ -L-fucosyltransferase (18); H<sup>+</sup>/K<sup>+</sup> ATPase (25); inositol-polyphosphate multikinase (17); inositol-trisphosphate 3-kinase (17); non-specific serine/threonine protein kinase (8,9); nucleoside diphosphate kinase activity (26); peptidyl-dipeptidase A, or angiotensin I-converting enzyme (27); phenol sulfotransferase (28); 3-phosphoglycerate kinase (29); phospholipase A<sub>2</sub> (30,31); p60src protein-tyrosine kinase (32); prostaglandin-endoperoxide synthase, or cyclooxygenase (37); protein kinase A (33); protein kinase C (34); thyroxine 5-deiodinase, or iodothyronine deiodinase (34,35); and the tautomerase activity of human macrophage migration inhibitory factor, or MIF (*K<sub>i</sub>* = 1.97  $\mu$ M, noncompetitively) (38). 1. ### Ellipticine

This yellow alkaloid and antitumor agent (FW = 246.31 g/mol; CAS 519-23-3), also known as 5,11-dimethyl-6H-pyrido[4,3-b]carbazole, first isolated from the elliptic yellowwood or kopsia (*Ochrosia elliptica*), a flowering tree native of Australia and New Caledonia, is a DNA intercalating agent that causes double-strand breaks. Ellipticine also blocks p53 protein phosphorylation, inducing apoptosis in many cell types. Ellipticine is also a strong inhibitor of CYP1A1 and DNA topoisomerase II. Its structure and chemical synthesis were reported by R. B. Woodward's laboratory (1). **Target(s):** bacteriophage T<sub>4</sub> DNA topoisomerase (2); cholesterol-5,6-oxide hydrolase (3); CYP1A1 (4-6); CYP1A2 (4); CYP2A6, or coumarin 7-monooxygenase (7); CYP3A27 (6); cytochrome P450 (4-9); DNA topoisomerase I (10,11); DNA topoisomerase II (2,10,12-18); (S)-limonene 3 monooxygenase (19); (S)-limonene 6-monooxygenase (19); (S)-limonene 7-monooxygenase (19); NADPH:cytochrome P450 reductase (20); poly(ADP-ribose) glycohydrolase (21); RNA polymerase (22); soluble epoxide hydrolase (23); UDPglucuronosyltransferase (8). 1. ### Eluxadolone

This oral, peripherally active  $\mu$ -opioid agonist (FW = 569.65 g/mol; CAS 864821-90-9), also named Viberzi<sup>®</sup> and 5-(([(2S)-2-amino-3-(4-carbamoyl-2,6-dimethylphenyl)propanoyl]](1S)-1-(4-phenyl-1H-imidazol-2-yl)ethyl) amino)methyl)-2-methoxybenzoate, is a FDA-approved drug for the treatment of diarrhea and abdominal pain in individuals with diarrhea-predominant irritable bowel syndrome, or IBS-D (1-3). Enteric neurons expressing  $\mu$  opioid receptors contribute to opioid-induced constipation, and local activation by this drug of  $\mu$  opioid receptor ( $K = 1.7$  nM) reduces both secretion and motility, Eluxadolone is also a  $\kappa$ -opioid receptor agonist ( $K = 55$  nM) and  $\delta$ -opioid receptor antagonist ( $K_i = 1.3$  nM) that acts locally within the enteric nervous system (1). Pharmacokinetics in rats, mice and primates show low systemic exposure after oral administration, a finding that is consistent with Eluxadolone's local site action on the myenteric plexus and smooth muscle (1). As a new therapeutic agent for reducing symptoms of IBS with diarrhea in men and women, eluxadolone shows sustained efficacy over 6 months in patients receiving a twice-daily 100-mg dose (3). 1. Wade, Palmer, McKenney, et al. (2012) *Br. J. Pharmacol.* **167**, 1111. 2. Davenport, Covington, Bonifacio, McIntyre & Venitz (2015). *J. Clin. Pharmacol.* **55**, 534. 3. Lembo, Lacy, Zuckerman, et al. (2016) *New Engl. J. Med.* **374**, 242.

### Elvitegravir

This viral integrase inhibitor (FW = 447.88 g/mol; CAS 697761-98-1; Solubility: 90 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O; Symbol: EVG), also known as JTK-303, GS-9137, and (S)-6-(3-chloro-2-fluorobenzyl)-1-(1-hydroxy-3-methylbutan-2-yl)-7-methoxy-4-oxo-1,4-dihydroquinoline-3-carboxylic acid, targets HIV-1 IIIB (IC<sub>50</sub> = 0.7 nM), HIV-2 EHO (IC<sub>50</sub> = 2.8 nM), and HIV-2 ROD (IC<sub>50</sub> = 1.4 nM). EVG inhibits HIV-1 replication (including various subtypes and multiple-drug-resistant clinical isolates) and HIV-2 replication, with an EC<sub>50</sub> values in the subnanomolar to nanomolar range. It

can also inhibit the replication of several retroviruses and lentiviruses. Even so, elvitegravir is efficiently metabolized by hepatic and intestinal CYP3A and UDP-glucuronosyltransferases UGT1A1 and UGT1A3. The action of this drug may be combined with ritonavir, a strong CYP3A inhibitor, thereby prolonging its elimination half-life. T66I and E92Q substitutions within the active site contribute to EVG resistance. **1.** Shimura, Kodama, Sakagami, *et al.* (2008) *J. Virol.* **82**, 764.

**EMATE**, See *Estrone 3-O-Sulfamate*

#### EMD-1214063

This MET protein kinase inhibitor (FW = 492.57 g/mol; CAS 1100598-32-0; Soluble to 20 mg/mL in DMSO), also known as 3-(1-(3-(5-(1-methylpiperidin-4-yl)methoxy)pyrimidin-2-yl)benzyl)-1,6-dihydro-6-oxopyridazin-3-yl)benzonitrile and HY-14721, is an antineoplastic agent that selectively disrupts MET signal transduction pathways, inducing apoptosis in tumor cells that overexpress this receptor. The tyrosine kinase MET, also known as Hepatocyte Growth Factor Receptor (*or* HGFR) is the product of the proto-oncogene *c-Met*. Because MET plays key roles in cell growth and survival, invasion and metastasis, and angiogenesis, its overexpression or mutation results in the robust proliferation of many tumor cell types. **1.** Bladt, Faden, Friese-Hamim, *et al.* (2013) *Clin. Cancer Res.* **19**, 2941.

**EMD 68843**, See *Vilazodone*

**EMD 121974**, See *Cilengitide*

#### Emetin

This toxic alkaloid (FW<sub>free-base</sub> = 480.65 g/mol; CAS 483-18-1; M.P. = 74°C; pK<sub>a</sub> values of 6.77 and 6.64) from the roots of *Uragoga ipecacuanha* (ipecac) is a potent emetic, hence the name. Used clinically as an expectorant and an antiamebic agent, emetine also interferes with translocation by stabilizing polyribosomes (1-4). It also induces apoptosis (5). Because emetine is a white powder that yellows upon exposure to light or heat, it should be stored in the dark and kept cold. While the free base is only slightly soluble in water, the dihydrochloride is very soluble (0.14 g/mL H<sub>2</sub>O for the hydrated dihydrochloride). **Target(s):** deacetylpeptide synthase, weakly inhibited; IC<sub>50</sub> ≈ 1 mM (6); P glycoprotein (7); protein biosynthesis, elongation and translocation (1-4). **1.** Pestka (1974) *Meth. Enzymol.* **30**, 261. **2.** Carrasco, Battaner & Vazquez (1974) *Meth. Enzymol.* **30**, 282. **3.** Scott & Tomkins (1975) *Meth. Enzymol.* **40**, 273. **4.** Jiménez (1976) *Trends Biochem. **EML4-ALK**, See *Ceritinib*

#### EML 425

This cell-permeable non-competitive CBP/p300 inhibitor (FW = 440.39 g/mol; CAS 1675821-32-5; Soluble to 100 mM in DMSO), also named 5-[(4-hydroxy-2,6-dimethylphenyl)methylene]-1,3-bis(phenyl-methyl)-2,4,6-(1*H*,3*H*,5*H*)-pyrimidinetrione, targets CBP (IC<sub>50</sub> = 1.1 μM) and p300 (IC<sub>50</sub> = 2.9 μM), two paralogous KAT3 histone acetyltransferases. **1.** Milite, Feoli, Sasaki, *et al.* (2015) *J. Med. Chem.* **58**, 2779.

#### Emodin

This orange anthraquinone derivative (FW = 270.24 g/mol; CAS 518-82-1), also known as 1,3,8-trihydroxy-6-methyl-9,10-anthracenedione, is found as a glycoside in rhubarb root, alder blackthorn, and other plants. It inhibits NK-κB activation and adhesion molecule expression. Emodin also inhibits p56lck protein-tyrosine kinase (IC<sub>50</sub> = 18.5 μM) and suppresses HER2/*neu* protein tyrosine kinase activity. Note that emodin disrupts model membranes, exhibiting a relatively high affinity for phospholipid membranes. It weakens hydrophobic interactions between hydrocarbon chains in phospholipid bilayers. **Target(s):** arylamine *N*-acetyltransferase (1); casein kinase (1), weakly inhibited (2); casein kinase 2 (2-6); cyclin-dependent protein kinase 2, weakly inhibited (2); electron transport (7); glucose 6-phosphate dehydrogenase (8); 11β-hydroxysteroid dehydrogenase (9); inositol-trisphosphate 3-kinase (10); Lyk protein-tyrosine kinase (11); monoamine oxidase B (12); [myosin light-chain] kinase (13); neuraminidase, IC<sub>50</sub> = 2.8 μM (14); non-specific serine/threonine protein kinase (2-6); oxidative phosphorylation, uncoupled (15); phosphatidylinositol 3-kinase (16); protein kinase A, weakly inhibited (2); protein kinase C, weakly inhibited (2); protein-tyrosine kinase, non-specific protein tyrosine kinase (11,17-19); tyrosinase, *or* monophenol monooxygenase (20). **1.** Chung, Wang, Wu, Chang & Chang (1997) *Food Chem. ## Empagliflozin

This oral Type-2 diabetes drug (FW = 450.91 g/mol; CAS 864070-44-0) also known as Jardiance<sup>®</sup> and (2*S*,3*R*,4*R*,5*S*,6*R*)-2-[4-chloro-3-[[4-[(3*S*)-oxolan-3-yl]oxyphenyl]-methyl]phenyl]-6-(hydroxymethyl)oxane-3,4,5-triol) is a potent and highly selective inhibitor of the sodium-glucose transporter (SGLT2), Subtype-2, a carrier responsible for >90% glucose reabsorption in the kidney. SGLT2 inhibitors target the kidney to remove excess glucose from the body, thus offering new options for managing Type-2 Diabetes. Other SGLT2 inhibitors include: canagliflozin, dapagliflozin, tofogliflozin, and luseogliflozin. **Pharmacokinetics:** Empagliflozin is rapidly absorbed, plasma concentrations peaking after 1.3-3.0 h, followed by a biphasic decline (3). In single rising-dose studies, mean terminal  $t_{1/2}$  values range from 5.6-13.1 h; in multiple-dose studies, mean terminal  $t_{1/2}$  values range from 10.3-18.8 h in. Following multiple oral doses, increases in exposure are dose-proportional, with trough concentrations remaining constant after treatment day-6, indicating attainment of steady state conditions. Oral clearance at steady state was similar to corresponding single-dose values, suggesting linear pharmacokinetics with respect to time (3). 1. Grempler, Thomas, Eckhardt, *et al.* (2012) *Diabetes Obes. Metab.* **14**, 83. 2. Luippold, Klein, Mark & Grempler (2012) *Diabetes Obes. Metab.* **14**, 601. 3. Scheen (2014) *Clin. Pharmacokinet.* **53**, 213.

## Emricasan

This first-in-class, cell-permeable protease inhibitor (FW = 569.50 g/mol; CAS 254750-02-2), also named IDN-6556, PF 03491390, and (S)-3-((2-*tert*-butyl)phenyl)((S)-1-oxo-1-(2-oxoacetamido)propan-2-yl)amino)-4-oxo-5-(2,3,5,6-tetrafluorophenoxy)pentanoic acid, blocks caspase-mediated apoptosis by targeting caspase-1 ( $IC_{50}$  = 0.4 nM), caspase-2 ( $IC_{50}$  = 20 nM), caspase-3 ( $IC_{50}$  = 2 nM), caspase-4 ( $IC_{50}$  = 0.06 nM), caspase-5 ( $IC_{50}$  = 0.01 nM), caspase-6 ( $IC_{50}$  = 4 nM), caspase-7 ( $IC_{50}$  = 0.2 nM), caspase-8 ( $IC_{50}$  = 0.2 nM), caspase-9 ( $IC_{50}$  = 0.3 nM), and caspase-10 ( $IC_{50}$  = 1.4 nM). Hepatocyte apoptosis, the hallmark of Non-Alcoholic SteatoHepatitis (NASH), contributes to liver injury and fibrosis, processes sharing a final caspase-initiated apoptotic mechanism. To delay the progression to cirrhosis and end-stage liver disease, the FDA granted orphan drug status to emricasan for treating liver transplant patients with re-established fibrosis. 1. Natori, Higuchi, Contreras & Gores (2003) *Liver Transpl.* **9**, 278. 2. Canbay, Feldstein, Baskin-Bey, Bronk & Gores (2004) *J. Pharmacol. Exp. Ther.* **308**, 1191. 3. Hoglen, Chen, Fisher, *et al.* (2004) *J. Pharmacol. Exp. Ther.* **309**, 634.

## Emtricitabine

This 2',3'-dideoxycytidine isostere (FW = 247.25 g/mol; CAS 143491-57-0; Symbol: FTC), also named 4-amino-5-fluoro-1-[(2*R*,5*S*)-2-(hydroxymethyl)-1,3-oxathiolan-5-yl]-1,2-dihydropyrimidin-2-one and Emtriva (formerly Coviracil), is a nucleoside reverse transcriptase inhibitor, *or* NRTI, used to reduce HIV viral load and to increase the number of CD4<sup>+</sup> T-cells. Inhibition requires phosphorylation of FTC to the corresponding triphosphate. Emtricitabine is commercially available and is approved by the FDA for treating HIV, but not HVB, infection. When employed as a single drug regimen, drug resistance occurs. The latter is less of a problem, when used as a fixed-dose combination (Truvada<sup>®</sup>) with tenofovir. The (-)-isomer is a potent inhibitor of viral replication ( $IC_{50}$  = 10 nM), while the (+)-isomer is considerably less active. Both isomers showed minimal toxicity to HepG2 cells ( $IC_{50}$  > 200  $\mu$ M), showing minimal toxicity in the human bone marrow progenitor cell assay (1). (-)-FTC is a poor substrate for cytidine deaminase, which, like other catabolic enzymes, prefer the 1- $\beta$ -D configuration of the (+)-isomer. In male CD rats, plasma clearance of 10 mg/kg body weight is a double-exponential ( $t_{1/2}$  = 4.7 min in the first-phase;  $t_{1/2}$  = 44 min in the second-phase), and total body clearance of FTC s 1.8 liters/hour/kg, with the oral bioavailability of 90% (2). The steady-state volume of distribution is 1.5 liters/kg. Increasing the dose to 100 mg/kg slows clearance and reduces oral bioavailability in the brains of rats (2). Emtricitabine is similar to lamivudine, and cross-resistance between the two drugs is near-universal (See also Lamivudine) 1. Furman, Davis, Liotta, *et al.* (1992) *Antimicrob. Agents Chemother.* **36**, 2686. 2. Frick, St John, Taylor, *et al.* (1993) *Antimicrob. Agents Chemother.* **37**, 2285.

## EN-2234A, See Nalbuphine

## Enalapril

This orally bioavailable ACE prodrug (FW = 376.45 g/mol; CAS 75847-73-3; Solubility: 100 mg/mL DMSO; <1 mg/mL Water), also known as Vasotec<sup>®</sup>, Glioten<sup>®</sup>, Renitec<sup>®</sup>, and named systematically as (2*S*)-1-[(2*S*)-2-[(2*S*)-1-ethoxy-1-oxo-4-phenylbutan-2-yl]amino]propanoyl]-pyrrolidine-2-carboxylic acid, is metabolically de-esterified to the active drug enalapril, which targets angiotensin-converting enzyme by competing with angiotensin I and blocking its conversion to angiotensin II. (See Enalaprilat) Inhibition of ACE results in decreased plasma angiotensin II. Enalaprilat may also acts on kinase II, an enzyme identical to ACE that degrades the vasodilator bradykinin.

## Enalaprilat

This dicarboxylic acid (FW<sub>free-acid</sub> = 348.40 g/mol; CAS 76420-72-9), also known as *N*-[1(*S*)-carboxy-3-phenylpropyl]-L-alanyl-L-proline and MK-422, is the active form of Entinostatapril and is a potent inhibitor of angiotensin I-converting enzyme ( $IC_{50}$  = 4.5 nM). (See also Caprilat) **Key**

**Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** peptidyl-dipeptidase A, or angiotensin I-converting enzyme (1-14); Xaa-Pro aminopeptidase aminopeptidase P (15-17). 1. Ryan (1988) *Meth. Enzymol.* **163**, 194. 2. Corvol, Williams & Soubrier (1995) *Meth. Enzymol.* **248**, 283. 3. Borek, Charlap & Frishman (1987) *Pharmacotherapy* **7**, 133. 4. ### Enavatuzumab

This first-in-class humanized IgG1 monoclonal antibody (MW = 141.2 kDa; CAS 912628-39-8), also known by the code name PDR-192, targets TweakR, a receptor that binds TWEAK, or cytokine TNF-like weak inducer of apoptosis (1). TWEAK is a cell surface-associated, type-II transmembrane protein (2). Its smaller, yet still biologically active, form is shed into the extracellular milieu. Because TweakR is overexpressed in many solid tumor types, Enavatuzumab promises to be an effective growth-inhibiting anticancer drug. Treatment of sensitive cell lines with enavatuzumab, both *in vitro* and *in vivo* (in a xenograft model), activates both classical (*e.g.*, p50 and p65) as well as non-classical (*e.g.*, p52, RelB) NFκB pathways. Treatment with Enavatuzumab results in NFκB-dependent reduction in cell division, the likely consequence of activation of the cell-cycle inhibitor p21. 1. Purcell, Kim, Tanlimco, *et al.* (2014) *Front Immunol.* **4**, 505. 2. Wiley & Winkles (2003) *Cytokine Growth Factor Rev.* **14**, 241.

### Endothall

This herbicide and defoliant (FW<sub>free-acid</sub> = 186.16 g/mol; CAS 145-73-3) is a potent inhibitor of protein phosphatase-2A (IC<sub>50</sub> = 90 nM). Elevated concentrations are reported to inhibit protein phosphatase-1. Endothall also causes dose- and time-dependent cytostasis at the G<sub>2</sub>/M junction in hepatocellular carcinoma cell lines. 1. Li & Casida (1992) *Proc. Natl. Acad. Sci. U.S.A.* **89**, 11867. 2. Li, Mackintosh & Casida (1993) *Biochem. Pharmacol.* **46**, 1435. 3. Szöör, Fehér, Bakó, *et al.* (1995) *Comp. Biochem. Physiol. B* **112**, 515. 4. Zabrocki, Swiatek, Sugajska, *et al.* (2002) *Eur. J. Biochem.* **269**, 3372.

### Enduracidins

These cyclic lipopeptide antibiotics (FW<sub>Enduracidin-A</sub> = 2355.32 g/mol; CAS 34438-27-2), also known as enramycins, are produced by *Streptomyces fungicidicus* and are active against Gram-positive bacteria and inhibit cell wall biosynthesis, preferentially inhibiting the transglycosylation step of peptidoglycan biosynthesis, as compared with the MurG step. Enduracidins and ramplamin share a similar 17-residue peptide core, but differ mainly in the length of the acyl chain and the presence of the two D-mannose moieties found in ramoplanin. Enduracidins are often used as additives in livestock feed. **Target(s):** avian myeloblastosis virus reverse transcriptase (1); murein biosynthesis (2); penicillin-binding protein 1b (3); peptidoglycan glycosyltransferase (3); prolyl endopeptidase (4); RNA directed DNA polymerase (1). 1. Inouye, Take, Nakamura, *et al.* (1987) *J. Antibiot.* **40**, 100. 2. Tamura, Suzuki, Nishimura, Mizoguchi & Hirota (1980) *Proc. Natl. Acad. Sci. U.S.A.* **77**, 4499. 3. Nakagawa, Tamaki, Tomioka & Matsushashi (1984) *J. Biol. Chem.* **259**, 13937. 4. Kimura, Kanou, Yamashita, Yoshimoto & Yoshihama (1997) *Biosci. Biotechnol. Biochem.* **61**, 1754.

### Englerin A

This guaianes sesquiterpene (FW = 442.55 g/mol; CAS 1094250-15-3; IUPAC Name: (1R,3aR,4S,5R,7R,8S,8aR)-5-(glycolyloxy)-7-isopropyl-1,4-dimethyldecahydro-4,7-epoxyazulen-8-yl (2E)-3-phenylacrylate; Symbol: EA) from the poisonous stem bark of the Tanzanian plant *Phyllanthus engleri* (1), binds to and activates protein kinase Cθ (PKCθ), inducing an insulin-resistant phenotype, most likely by limiting access of kidney tumor cells to glucose. PKCθ phosphorylates Insulin Receptor Substrate 1, or IRS-1, which plays a key role in transmitting signals from the insulin and Insulin-like Growth Factor-1 (IGF-1) receptors to the intracellular PI3K/Akt signal transduction pathway and extracellular ERK/MAP kinase signal transduction pathways. The net effect is inhibition of the insulin pathway, limiting glucose uptake by renal cancer cells. EA also stimulates PKCθ-mediated phosphorylation and consequential activation of Heat Shock Factor 1, a key transcription factor and inducer of glucose dependence (2). By stimulating these opposing pathways, EA is synthetically lethal for glycolytic tumor cells expressing PKCθ and HSF1 (2). Significantly, Englerin A induces necrotic cell death in renal cancer cells, but not in normal kidney cells (3). EA-treated cells accumulated in G<sub>2</sub>, indicating a block in G<sub>2</sub>/M transition (4). Englerin A also inhibits activation of both AKT and ERK, which are activated in cancer and implicated in unrestricted cell proliferation and induction of autophagy. The phosphorylation status of the cellular energy sensor, AMPK, appeared unaffected by EA (4). 1. Ratnayake, Covell, Ransom, Gustafson & Beutler (2009) *Org. Lett.* **11**, 57. 2. Sourbier, Scroggins, Ratnayake, *et al.* (2013) *Cancer Cell* **23**, 228. 3. Sulzmaier, Li, Nakashige, *et al.* (2012) *PLoS One* **7**, e48032. 4. Williams, Yu, Diccianni, Theodorakis & Batova (2013) *J. Exp. Clin. Cancer Res.* **32**, 57.

### ENMD-1198

This orally bioavailable microtubule-targeted 2-methoxyestradiol (*or* 2ME2) analogue (FW = 311.42 g/mol) exhibits a greater duration of action owing to the elimination of sites for metabolic conjugation (positions 3 and 17 in 2ME2) and oxidation (position 17 in 2ME2), with >65% remaining after 2-h incubation with hepatocytes. ENMD-1198 and its congeners (ENMD-1200 and ENMD-1237) bind the colchicine-binding site on tubulin, inducing G<sub>2</sub>-M cell cycle arrest and apoptosis and also reducing hypoxia-inducible factor-1α (Hif-1α) levels. ENMD-1198 is also a potent vascular-disrupting agent (VDA) that leads to solid tumor necrosis by

limiting tumor vascularization (1). Video microscopy confirms that ENMD-1198 completely disrupts preformed vascular structures within 2 hours, with extensive depolymerization of the microtubule network and accumulation of actin stress fibers and large focal adhesions in vascular endothelial cells (2). ENMD-1198 inhibited the phosphorylation of MAPK/Erk, PI-3K/Akt and FAK (3). Notably, ABT-737 sensitizes androgen-dependent castration-resistant prostate cancer PC3 cells to ENMD-1198-mediated, caspase-dependent apoptosis (4). 1. LaVallee, Burke, Swartz, *et al.* (2008) *Mol. Cancer Ther.* **7**, 1472. 2. Pasquier, Sinnappan, Munoz & Kavallaris (2010) *Mol. Cancer Ther.* **9**, 1408. 3. Moser, Lang, Mori, *et al.* (2008) *BMC Cancer* **8**, 206. 4. Parrondo, de Las Pozas, Reiner & Perez-Stable (2013) *Peer J.* **1**, e144.

### Enniatins

These cyclodepsipeptide ionophores and antibiotics (Enniatin A, R = CH(CH<sub>3</sub>)CH<sub>2</sub>CH<sub>3</sub>; Enniatin B, R = CH(CH<sub>3</sub>)<sub>2</sub>; Enniatin C, R = CH<sub>2</sub>CH(CH<sub>3</sub>)<sub>2</sub>; FW<sub>Enniatin-A</sub> = 2643.44 g/mol; CAS 144470-22-4) from species of *Fusarium* inhibit acyl-CoA:cholesterol acyltransferase. Enniatin A is (cyclo(D-2-hydroxyisovaleryl-L-methyl-L-isoleucyl)<sub>3</sub>). Enniatin B is cyclo(D-2-hydroxyisovaleryl-L-methyl-L-valyl)<sub>3</sub>. Enniatin C is an artificial ionophore with an isobutyl side-chain. All bind metals ion, showing greatest selectivity for K<sup>+</sup>, and the resulting complex allows that ion to cross biomembranes. **Target(s)**: calmodulin, inhibited by enniatin B (1); calmodulin-dependent cyclic nucleotide phosphodiesterase, inhibited by enniatin B (1); oxidative phosphorylation, inhibited by enniatin A (2); Pdr5p, an ABC transporters in *Saccharomyces cerevisiae* (3); sterol O-acyltransferase, or acyl-CoA:cholesterol acyltransferase; ACAT, inhibited by enniatins D, E, and F (4). 1. Mereish, Solow, Bunner & Fajer (1990) *Pept. Res.* **3**, 233. 2. Reed (1979) *Meth. Enzymol.* **55**, 435. 3. Hiraga, Yamamoto, Fukuda, Hamanaka & Oda (2005) *Biochem. Biophys. Res. Commun.* **328**, 1119. 4. Tomoda, Nishida, Huang, Masuma, Kim & Omura (1992) *J. Antibiot.* **45**, 1207.

### Enoxacin

This broad-spectrum fluoroquinolone antibacterial and osteoclastogenesis inhibitor (FW = 320.32 g/mol; CAS 74011-58-8), also known by the trade names Almitil™, Bactidan™, Bactidron™, Comprescin™, Enoksetin™, Enoxen™, Enroxil™, Enoxin™, Enoxor™, Flumark™, Penetrex™, Gyramid™, and Vinone™, as well as its IUPAC name, 1-ethyl-6-fluoro-4-oxo-7-(piperazin-1-yl)-1,4-dihydro-1,8-naphthyridine-3-carboxylic acid, is widely used to treat urinary tract infections. A single 400-mg oral dose produces ≥ 95% bacteriological cure rates with *Neisseria gonorrhoeae*. Structurally related to nalidixic acid, enoxacin exhibits a broad spectrum of activity against Gram-negative and Gram-positive microorganisms, but is less active against Gram-positive organisms. Patients with complicated or uncomplicated urinary tract infections also respond to other antibacterial agents, including amoxicillin, cefuroxime axetil, cotrimoxazole (trimethoprim-sulfamethoxazole) or trimethoprim (1). Enoxacin binds to gyrase-DNA complexes, thereby inhibiting gyrase-mediated negative supercoiling of DNA (2-5). Visible light irradiation of DNA-Enoxacin complex can also result in single-strand breaks. Enoxacin also binds to the profilin-like actin-binding surface of the V-ATPase B<sub>2</sub>-subunit, competitively inhibiting the B<sub>2</sub>-subunit's interaction with actin and

disrupting osteoclastic bone resorption *in vitro*, without affecting osteoblast formation or bone mineralization (6). Enoxacin directly inhibits osteoclast formation without affecting cell viability, acting by a novel mechanism involving changes in posttranslational processing and trafficking of proteins (e.g., ADAM, ADAM12, DC-STAMP, and TRAP5b) with known roles in osteoclast function. Such effects are downstream to enoxacin's action in blocking a binding interaction between A<sub>3</sub>-containing V-ATPases and microfilaments (7). **Target(s)**: DNA gyrase (2-5); Vacuolar ATPase and downstream effects on posttranslational processing in osteoclasts (6,7); CYP1A2, caffeine 3-demethylase, cytochrome P450 (8,9); DNA topoisomerase II (10,11); DNA topoisomerase IV (4); medium-chain-fatty-acyl-CoA synthetase, or butyryl-CoA synthetase, or butyrate:CoA ligase (12). 1. Patel & Spencer (1996) *Drugs* **51**, 137. 2. Traub (1984) *Chemotherapy* **30**, 379. 3. Domagala, Hanna, Heifetz, *et al.* (1986) *J. Med. Chem.* **29**, 394. 4. ### Enrofloxacin

This fluoroquinolone-class antibiotic (FW = 359.40 g/mol; CAS 93106-60-6), also named Baytril® and 1-cyclopropyl-7-(4-ethylpiperazin-1-yl)-6-fluoro-4-oxo-1,4-dihydroquinoline-3-carboxylate, is a broad-spectrum systemic antibacterial agent that targets Type II DNA topoisomerases (gyrases), which are required for bacterial replication and transcription. It exerts broad-spectrum activity against Gram-positive and Gram-negative bacteria as well as against *Mycoplasma* spp. in various animals, including *Pseudomonas aeruginosa*, *Klebsiella*, *Escherichia coli*, *Enterobacter*, *Campylobacter*, *Shigella*, *Salmonella*, *Aeromonas*, *Hemophilus*, *Proteus*, *Yersinia*, *Serratia*, *Vibrio*, *Brucella*, *Chlamydia trachomatis*, *Staphylococcus* (including penicillinase-producing and methicillin-resistant strains), *Mycoplasma*, and *Mycobacterium*. Enrofloxacin is an FDA-approved drug for treating pets and domestic animals. For the prototypical member of this antibiotic class, See *Ciprofloxacin*

### Entacapone

This pharmaceutical (FW = 305.29 g/mol; CAS 130929-57-6), also known as OR-611, is used in the treatment of Parkinson Disease and inhibits catechol O-methyltransferase ( $K_i = 14$  nM for the rat liver enzyme), thereby preventing the L-DOPA conversion to 3-methoxy-4-hydroxy-L-phenylalanine. When given along with and carbidopa (the latter an aromatic amino acid decarboxylase inhibitor), plasma L-dopa levels are higher and remain so for a longer period than with administration of only L-dopa and a decarboxylase inhibitor. Entacapone is likely to influence the pharmacokinetics of drugs metabolized by COMT (e.g., isoproterenol, epinephrine, norepinephrine, dopamine, dobutamine, α-methyl-dopa, apomorphine, isotherine, and bibtolterol). Note also that entacapone is structurally related to the typhostins. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Nissinen, Linden, Schultz &

Pohto (1992) *Naunyn Schmiedebergs Arch. Pharmacol.* **346**, 262. 2. Mannisto, Tuomainen & Tuominen (1992) *Brit. J. Pharmacol.* **105**, 569. 3. Bonifácio, Palma, Almeida & Soares-da-Silva (2007) *CNS Drug Reviews* **13**, 352.

### Entecavir

This orally available cyclopentyl guanosine analogue (FW = 277.28 g/mol; CAS 142217-69-4), known also as SQ-34676, Baraclude™ and 2-amino-9-[(1*S*,3*R*,4*S*)-4-hydroxy-3-(hydroxymethyl)-2-methylidene-cyclopentyl]-6,9-dihydro-3*H*-purin-6-one, inhibits DNA polymerase and is extremely potent against hepatitis B virus (HBV) (ED<sub>50</sub> = 3 nM, compared with 200 nM for lamivudine) with relatively low toxicity, as indicated by its 30,000-nM cytostatic concentration (CC<sub>50</sub>). (Entecavir is ineffective against HIV.) Although entecavir's use in the clinic is characterized by very low resistance rates, with potent and durable viral suppression, selection of certain combinations of amino acid substitutions (particularly L180M-S202G-M204V-V207I) in the hepatitis B virus (HBV) reverse transcriptase complicates treatment of chronic HBV infection and may affect the overlapping surface coding region (2). Clinical use of entecavir is indicated for treating chronic HBV infection in adults showing evidence of active viral replication and either persistently elevated serum aminotransferases or histologically discernable disease. (See also Adefovir & Adefovir Dipivoxil; Lamivudine; Telbivudine; Tenofovir; Emtricitabine) 1. Julander, Colonna, Sidwell & Morrey (2003) *Antiviral Res.* **59**, 155. 2. Rodriguez-Frias F, Tabernero D, Quer (2012) *PLoS One* **7**, e37874.

### Enterostatin

human and rabbit enterostatin

dog and pig enterostatin

This pentapeptide (FW = 305.29 g/mol; CAS 130929-57-6) selectively inhibits fat intake during normal feeding (1,2). The mechanism of action of this peptide is likely to be the inhibition of a  $\mu$ -opioid-mediated pathway or an interaction the  $\beta$ -subunit of F<sub>1</sub>F<sub>0</sub> ATP synthase (2,3). The human, rabbit, chicken, and rat sequence is Ala-Pro Gly-Pro-Arg (APGPR) while the dog, pig, ox, and horse sequence is Val-Pro-Asp-Pro-Arg (VPDPR). Eterstatin also inhibits insulin release (4,5). 1. Erlanson-Albertsson & York (1997) *Obes. Res.* **5**, 360. 2. Berger, Winzell, Mei & Erlanson-Albertsson (2004) *Physiol. Behav.* **83**, 623. 3. Berger, Sivars, Winzell, *et al.* (2002) *Nutr. Neurosci.* **5**, 201. 4. Ookuma & York (1998) *Int. J. Obes. Relat. Metab. Disord.* **22**, 800. 5. Erlanson-Albertsson, Hering, Bretzel & Federlin (1994) *Acta Diabetol.* **31**, 160.

### Entinostat

This Class-I histone deacetylase inhibitor (FW = 376.41 g/mol; CASs = 209783-80-2, 209784-79-2 (Maleic acid), 209784-80-5 (HCl); Solubility: 75 mg/mL DMSO; <1 mg/mL Water), also known as MS-275, SNDX-275, and named systematically as pyridin-3-ylmethyl 4-((2-aminophenyl) carbamoyl)benzylcarbamate, targets HDAC1 and HDAC3 with IC<sub>50</sub> values of 0.5 nM and 1.7 nM, respectively, resulting in a marked hyperacetylation of histone H4 (1). MS-275 is currently in Phase I/II clinical trials in recurrent advanced non-small cell lung cancer, combining with 5-azacytidine. Transient alteration of histone acetylation by entinostat alters the fate of embryonic stem cells (5). 1. Saito, *et al.* (1999) *Proc. Natl. Acad. Sci. USA* **96**, 4592. 2. Rosato, *et al.* (2003) *Cancer Res.* **63**, 3637. 3. Kato, *et al.* (2007) *Clin. Cancer Res.* **13**, 4538. 4. Wegener, *et al.* (2003) *Chem Biol.* **10**, 61. 5. Franci, Casalino, Petraglia, *et al.* (2013) *Biol. Open* **22**, 1070.

### Entospletinib

This orally bioavailable PKI (FW = 411.46 g/mol; CAS 1229208-44-9; Solubility: 82 mg/mL DMSO, with heating), also named 6-(1*H*-indazol-6-yl)-*N*-(4-morpholinophenyl)imidazo[1,2-*a*]pyrazin-8-amine and GS-9973, selectively targets Spleen Tyrosine Kinase, or Syk (IC<sub>50</sub> = 7.7 nM), a druggable enzyme with autoimmune, inflammatory, and cancer indications (1). PI3Kd and Syk inhibitors reduce Chronic Lymphocytic Leukemic (CLL) cell survival, and, when used in combination, induce synergistic growth inhibition and disrupt chemokine signaling at nM concentrations (2). Entospletinib demonstrates clinical activity in subjects with relapsed or refractory CLL with acceptable toxicity (3). 1. Currie, Kropf, Lee, *et al.* (2014) *J. Med. Chem.* **57**, 3856. 2. Burke, Meadows, Loriau, *et al.* (2014) *Oncotarget* **5**, 908. 3. Sharman, Hawkins, Kolibaba, *et al.* (2015) *Blood* **125**, 2336.

### Enzastaurin

This synthetic bis-indolylmaleimide and potent ATP site-competitive PKI (FW = 515.62 g/mol; CAS 170364-57-5; Solubility: 20 mM in DMSO), also known as LY317615 and 3-(1-methyl-1*H*-indol-3-yl)-4-[1-(2-pyridinylmethyl)-4-piperidinyl]-1*H*-indol-3-yl]-1*H*-pyrrole-2,5-dione, selectively targets Protein Kinase- $\beta$ , or CPKC $\beta$  (IC<sub>50</sub> = 6 nM), the activation of which has been implicated in tumor growth and invasiveness. Enzastaurin exhibits weaker action against PKC $\alpha$  (IC<sub>50</sub> = 39 nM), PKC $\gamma$  (IC<sub>50</sub> = 83 nM) and PKC $\epsilon$  (IC<sub>50</sub> = 110 nM). Its selective action against PKC $\beta$  also suppresses vascular endothelial growth factor (VEGF)-stimulated neo-angiogenesis (1). Treatment of cultured human tumor cells with enzastaurin induces apoptosis and suppresses cell proliferation. Enzastaurin also reduces the phosphorylation of ribosomal protein S6 (at Serine residues 240 and 244), and AKT (at Threonine-308) (2). Oral dosing with enzastaurin that yields plasma concentrations similar to those achieved in clinical trials was found to significantly suppress the growth of human

glioblastoma and colon carcinoma xenografts. As in cultured tumor cells, enzastaurin treatment suppresses the phosphorylation of GSK3 $\beta$  in these xenograft tumor tissues (2). Enzastaurin also induces apoptosis in multiple myeloma cell lines in a caspase-independent manner, and enzastaurin's antimyeloma effect occurs by inhibiting signaling through the AKT pathway (3). Moreover, enzastaurin-induced cell death was not affected by interleukin-6 or ZVAD-fmk. In 2013, Lilly & Company announced that Phase-III enzastaurin trial did not meet primary endpoint as a monotherapy in the prevention of relapse in patients with diffuse large B-cell lymphoma (DLBCL). That study failed to show a statistically significant increase compared to placebo in disease-free survival in patients at high risk of relapse after rituximab-based chemotherapy. In contrast to two other PKC inhibitors, however, the combined use of enzastaurin with the immunotoxin SS1P produces synergistic cell death via apoptosis, thus displaying promise as a potential anticancer agent (4). 1. Graff, McNulty, Hanna, *et al.* (2005) *Cancer Res.* **65**, 7462. 2. Graff, McNulty, Hanna, *et al.* (2005) *Cancer Res.* **65**, 7462. 3. Rizvi, Ghias, Davies, *et al.* (2006) *Mol. **Ep-475**, See *N-[(2S,3S)-trans-Epoxy succinyl]-L-leucylamido-3-methylbutane*

### EP42675

This first-in-class parenteral anticoagulant (FW = 2355.54 g/mol) combines the action of a direct thrombin inhibitor, *or* DTI (the peptidomimetic moiety (an  $\alpha$ -N-(2-naphthalenesulfonyl)glycyl-D-4-aminophenylalanyl piperidine, *or*  $\alpha$ -NAPAP, analogue) and an indirect factor Xa, *or* FXa, inhibitor (an antithrombin-binding pentasaccharide moiety, *or* fondaparinux analogue) into a single molecular entity. EP42675 pharmacokinetics are dose-proportional and characterized by a low clearance, a small volume of distribution, a long terminal half-life. EP42675 pharmacodynamics are characterized by a long-lasting, dose-dependent increase in activated clotting time, ecarin clotting time, thrombin time, anti-FXa activity, activated partial thromboplastin time, prothrombin time, and a decrease in endogenous thrombin potential, when measured by a thrombin generation test. 1. Gueret, Krezel, Fuseau, *et al.* (2014) *J. Thromb. Hemost.* **12**, 24.

### Epalrestat

This aldose reductase inhibitor (FW = 319.39 g/mol; CAS 82159-09-9; Symbol: EPS), also known by the code name ONO-2235, the trade names Epalrestat<sup>®</sup>, Aldonil<sup>®</sup>, Alrista<sup>®</sup>, and EPLISTAT 150 SR<sup>®</sup>, and by the systematic name 2-[(5Z)-5-[(E)-3-phenyl-2-methylprop-2-enylidene]-4-oxo-2-thioxo-3-thiazolidinyl]acetate, significantly improves motor nerve conduction velocity (MNCV) in diabetic rats at a minimal dose of 10 mg/kg/day by preventing aldose reductase-mediated accumulation of nontransported polyols (mainly sorbitol) that accumulate in diabetic hyperglycemia and osmotically damage neurons (1-4). Sorbitol content of the sciatic nerve and red blood cells after 2 weeks was concomitantly reduced in epalrestat-treated rats (sciatic nerve: 120  $\pm$  13 *versus* 595  $\pm$  146 nmol/g wet weight; red blood cell: 91  $\pm$  21 *versus* 165  $\pm$  39 nmol/g hemoglobin ( $p$  < 0.01) in 20 mg/kg/day-treated *versus* untreated animals

(1). Such findings indicate that, in diabetic hyperglycemia, epalrestat reduces intracellular sorbitol accumulation responsible for nerve and retina pathogenesis of late-onset complications of diabetes mellitus. EPS also increases the mRNA levels of  $\gamma$ -glutamylcysteine synthetase ( $\gamma$ -GCS), the enzyme catalyzing the first and rate-limiting step in *de novo* GSH synthesis, by activating Nuclear erythroid 2-related factor-2 (Nrf2), a key transcription factor that plays a central role in regulating the expression of  $\gamma$ -GCS (3). Knockdown of Nrf2 by siRNA suppressed the EPS-induced GSH biosynthesis, and pretreatment with EPS reduced the cytotoxicity induced by H<sub>2</sub>O<sub>2</sub>, *tert*-butylhydroperoxide, 2,2'-azo-bis(2-amidinopropane), and menadione, indicating EPS protects against oxidative stress. In view of EPS-induced biosynthesis of reduced glutathione (GSH) and the prior finding that paired helical filaments (PHFs) form upon disulfide coupling of oxidized glutathione (GSSG) to Tau protein (4), EPS may find therapeutic value in reducing the accumulation of neuropathic PHFs in Alzheimer's Disease. 1. ### Ephedrine

This bronchodilator and vasoconstrictor (FW<sub>free-base</sub> = 165.24 g/mol; CAS 299-42-3; pK<sub>a</sub> value of ephedrine is 9.54 at 25°C (dpK<sub>a</sub>/dT = -0.022)), also known as (1R,2S)-2-methylamino-1-phenylpropan-1-ol, is an  $\alpha$ - and  $\beta$ -adrenergic agonist from the stem and leaves of *Ephedra equisetina* and mentioned in the *Huangdi Neijing*, an ancient Chinese text on internal medicine. It is commonly used as a stimulant, appetite suppressant, concentration aid, decongestant, and to treat hypotension associated with anesthesia. Although ephedrine efficacious in the treatment of numerous ailments, it has a long history of misuse. Ephedrine is a structural analogue of epinephrine. Ephedrine can be assayed enzymatically with EC 1.5.1.18, a bacterial ephedrine oxidoreductase. **Target(s):** acetylcholinesterase (1); diamine oxidase (2);  $\beta$ -glucosidase (3); monoamine oxidase, *or* amine oxidase (2,4-6); procollagen-lysine 5-dioxygenase, weakly inhibited (7). 1. ### Epicatechin

These flavanols and catechin epimers (FW = 290.27 g/mol; CAS 35323-91-2) are natural antioxidants and free radical scavengers. They also chelate iron and activate survival genes and cell signaling pathways. Note that the term (+)-epicatechin has also been incorrectly used to refer to the (2S,3R)-isomer which, while being a diastereoisomer, is not an epimer. **Target(s):** catechol *O*-methyltransferase (1-4); fatty-acid synthase (5); H<sup>+</sup>/K<sup>+</sup>-dependent ATPase (6); lipoxygenase, avocado (22); 5-lipoxygenase, *or* arachidonate 5-lipoxygenase (7); 15 lipoxygenase, arachidonate 15-lipoxygenase (8,9); Moloney murine leukemia virus reverse transcriptase (10); [myosin light-chain] kinase (11); pectate lyase (12-14); peptidyl-dipeptidase A, angiotensin I-converting enzyme, weakly inhibited (15,16); phenol sulfotransferase, *or* aryl sulfotransferase; both (2S,3S)-(+)- and (2R,3R)-(-)-epicatechin inhibit weakly (17); prolyl oligopeptidase, inhibited by the (-)-isomer (18,19); ribonucleoside-diphosphate reductase, inhibited by (-)-epicatechin (20); RNA-directed DNA polymerase (10); xanthine oxidase (21). 1. #### 24(R,S)-25-Epiminolanosterol

This sterol (FW = 441.74 g/mol) inhibits sterol 24-C-methyltransferase, or cycloartenol 24-C-methyltransferase (*Helianthus annuus* enzyme,  $K_i = 3$  nM). **1.** Nes, Jansen, Norton, et al. (1991) *Biochem. Biophys. Res. Commun.* **177**, 566. **2.** Urbina, Vivas, Lazard, et al. (1996) *Chemotherapy* **42**, 294. **3.** Urbina, Vivas, Visbal & Contreras (1995) *Mol. Biochem. #### (-)-Epinephrine

This catecholamine neurotransmitter and pharmacologic agent (FW<sub>free-base</sub> = 183.21 g/mol; CAS 51-43-4; White powder; M.P. = 211-212°C; discolors slowly upon exposure to air and light), once called adrenaline and systematically named as (-)-1-(3,4-dihydroxyphenyl)-2-(methylamino) ethanol, is produced from norepinephrine by the action of norepinephrine *N*-methyltransferase (or, phenylethanolamine *N*-methyltransferase). The  $pK_a$  of the secondary amine is 8.66 and the value for ionization of the first aromatic hydroxyl is 9.95. The active principle producing the pressor effects (1-4) was isolated by Takamine more than a century ago (2). Epinephrine binds to a variety of adrenergic receptors and is a nonselective agonist of  $\alpha_1$ -,  $\alpha_2$ -,  $\beta_1$ -,  $\beta_2$ - and  $\beta_3$ -adrenergic receptors, triggering physiologic effects (e.g., increases heart rate, increases heart rate, and strengthens muscle contraction) as well as metabolic changes (e.g., inhibition of insulin secretion, stimulation of glycogenolysis in the liver and muscle, and stimulation of glycolysis in muscle).  $\beta$ -Adrenergic receptor binding triggers glucagon secretion in the pancreas and increases adrenocorticotrophic hormone (ACTH) secretion by the pituitary gland. With well-characterized vasoconstrictive effects, adrenaline is the drug of choice for treating anaphylaxis. **Target(s):** acylphosphatase (5); aromatic-L-amino-acid decarboxylase, or dopa decarboxylase (6,7); complement component C'3, guinea pig (8); CYP2C9 (9); dihydropteridine reductase (10,11); 4-hydroxyphenylpyruvate dioxygenase (33); lipoxygenase (12); 5-

lipoxygenase, or arachidonate 5-lipoxygenase (13,14); 12-lipoxygenase, or arachidonate 12-lipoxygenase (13,15); 15-lipoxygenase, arachidonate 15-lipoxygenase (13); nitronate monooxygenase (16,17); phenylalanine 4-monooxygenase (18); procollagen-lysine 5-dioxygenase (19,20); procollagen-proline 4-dioxygenase (21); stearyl-CoA 9-desaturase (22); steroid 11 $\beta$ -monooxygenase (23); tyrosine aminotransferase (24); tyrosine 3-monooxygenase (25-31); urease (32). **1.** Abel (1899) *Zeitschr. #### Epirubicin

This photosensitive, semisynthetic antibiotic (FW<sub>free-base</sub> = 544.53 g/mol; CAS 56420-45-2) is a structural analogue of doxorubicin, with the sugar component the epimer of the component found in doxorubicin. **Target(s):** *Ava*I restriction endonuclease (1); DNA ligase (ATP) (2); DNA polymerase (3); DNA topoisomerase II (4); *Eco*R1 restriction endonuclease (1); *Hae*III restriction endonuclease (1); *Hha*I restriction endonuclease (1); *Hpa*II restriction endonuclease (1); phospholipase A<sub>2</sub> (5); *Sma*I restriction endonuclease (1); type II site-specific DNase (1). **1.** Corneo, Pogliani, Biondi & Tripputi (1988) *Ric. #### Epitestosterone

This steroid (FW = 288.43 g/mol; CAS 481-30-1), also called  $\Delta^4$ -androst-17 $\alpha$ -ol-3-one and *cis*-testosterone, is the inactive isomer of testosterone, differing from the latter only with respect to the chirality of the hydroxyl group. Because exogenous administration of testosterone has no effect on epitestosterone levels, the measured ratio of testosterone to epitestosterone in urine has been used to detect drug doping in sports. Co-administration of testosterone and epitestosterone can mask doping. **Target(s):** aldehyde dehydrogenase (1); 11 $\beta$ -hydroxysteroid dehydrogenase (2); 17 $\beta$ -hydroxysteroid dehydrogenase (3); 21-hydroxysteroid dehydrogenase, NAD<sup>+</sup>-requiring (4); steroid C17,20 lyase, *or* cholesterol monooxygenase, *or* side-chain cleaving (5); steroid 17 $\alpha$ -monooxygenase (5); UDPglucuronosyltransferase (6). 1. Douville & Warren (1968) *Biochemistry* **7**, 4052. 2. Bicikova, Hill, Hampl & Starka (1997) *Horm. Metab. Res.* **29**, 465. 3. Bicikova, Klak, Hill & Starka (2000) *Horm. Metab. ### Eplivanserin

This potent and selective serotonin antagonist (FW<sub>Free-Base</sub> = 327.40 g/mol; FW<sub>Hemi-Fumarate</sub> = 386.42 g/mol; CAS 130580-02-8; Solubility: 50 mM in DMSO), also named SR-46349, SR-46349B, and (1Z,2E)-1-(2-2-fluorophenyl)-3-(4-hydroxyphenyl)-2-propen-1-one *O*-[2-(dimethyl-amino)ethyl]oxime hemifumarate, targets 5-HT<sub>2A</sub> (IC<sub>50</sub> = 5.8 nM), 5-HT<sub>2B</sub> (IC<sub>50</sub> = 120 nM), and 5-HT<sub>2C</sub> (IC<sub>50</sub> >100 nM), attenuating cocaine-induced hyperactivity. Eplivanserin increases dopamine (DA) release in rat medial prefrontal cortex (mPFC) and potentiates haloperidol-induced DA release in rat medial prefrontal cortex and nucleus accumbens. 1. Bonaccorso, *et al.* (2002) *Neuropsychopharmacol.* **27**, 430. 2. Filip, *et al.* (2004) *J. Pharmacol. Exp. Ther.* **310**, 1246. 3. Yadav, *et al.* (2011) *J. Pharmacol. Exp. Ther.* **339**, 99.

### Epothilone A & B

These antitumor agents (FW<sub>Epothilone-A</sub> = 493.66; FW<sub>Epothilone-B</sub> = 507.69 g/mol; CAS 152044-53-6) from the myxobacterium *Sporangium cellulosum* inhibit microtubule depolymerization. Both have properties similar to the microtubule-stabilizing and cytoskeletal-disrupting drug paclitaxel (taxol). Epothilones A and B enjoy the advantage of being more water-soluble and can be produced in larger quantities than paclitaxel. The epothilones induce microtubule formation at low temperatures in the absence of GTP and/or microtubule-associated proteins (MAPs). They are also competitive inhibitors with respect to taxol binding sites on microtubules. These agents also inhibit the growth of cells overexpressing the P-glycoprotein efflux pump (multidrug resistance factor) and may eventually be useful for the treatment of multidrug-resistant tumors. **See Colchicine; Maytansine; Paclitaxel (Taxol); Podophylotoxin; Rhazinilam; Taxotere; Vinblastine** 1. Kowalski, Giannakakou & Hamel (1997) *J. Biol. Chem.* **272**, 2534. 2. Bollag, McQueney, Zhu, *et al.* (1995) *Cancer Res.* **55**, 2325.

### Epoxomicin

This epoxide-containing peptide (FW = 554.72 g/mol; CAS 134381-21-8; Solubility: 100 mg/mL DMSO), systematically named *N*-acetyl-*N*-methyl-L-isoleucyl-L-isoleucyl-*N*-[(1*S*)-3-methyl-1-[[2(*R*)-2-methyl-2-oxiranyl]carbonyl]butyl]-L-threoninamide, from *Actinomyces* is a strong, irreversible inhibitor of the chymotrypsin-like, trypsin-like, and peptidylglutamyl peptide-hydrolyzing activities of the proteasome. Epoxomicin covalently binds to the LMP7, X, MECL1, and Z catalytic subunits of the proteasome. In HUVECs treated with 100 nM epoxomicin, there is 30x increase in the levels of p53 protein, a known proteasome target. 1. Meng, Mohan, Kwok, *et al.* (1999) *Proc. Natl. Acad. Sci. U.S.A.* **96**, 10403. 2. Sin, Kim, Elofsson, *et al.* (1999) *Bioorg. Med. Chem. Lett.* **9**, 2283. 3. Vabulas & Hartl (2005) *Science* **310**, 1960. 4. Wojcikiewicz, Xu, Webster, Alzayady & Gao (2003) *J. Biol. Chem.* **278**, 940.

### 2',3'-Epoxypropyl $\beta$ -D-Glucopyranoside

This glycoside (FW = 236.22 g/mol) irreversibly inhibits yeast hexokinase, modifying an active-site cysteinyl residue in the process. **Target(s):** glucose transporter, *Escherichia coli* (1) hexokinase (2,3); licheninase (4). 1. Garcia-Alles, Navdaeva, Haenni & Erni (2002) *Eur. J. Biochem.* **269**, 4969. 2. Bessell (1973) *Chem. Biol. Interact.* **7**, 343. 3. Bessell, Thomas & Westwood (1973) *Chem. Biol. Interact.* **7**, 327. 4. Høj, Rodriguez, Stick & Stone (1989) *J. Biol. Chem.* **264**, 4939.

### *N*-[(2*S*,3*S*)-*trans*-Epoxysuccinyl]-L-leucylamido-3-methylbutane

This cysteine proteinase inhibitor (FW<sub>free-acid</sub> = 314.38 g/mol), also known as *N*-[*N*-(L-3-transcarboxyoxirane-2-carbonyl)-L-leucyl]-3-methylbutylamine, Ep-475 and E-64c, targets cathepsins B, H, and L as well as calpain. With its low water solubility, this agent is typically prepared in dimethyl sulfoxide stock solutions and then diluted to a final 5% DMS value in enzyme assays. **Target(s):** calpain (1,2); calpain-2, *or* m-calpain (3,4); cathepsin B (5-10); cathepsin L (5-7,9,11-14); cathepsin N (9); cathepsin S (9); lactosylceramide  $\alpha$ -2,3-sialyltransferase (15); papain (16-18); prohomone thiol protease (19); pyroglutamyl-peptidase I (20). 1. ### EPPTB

This TA<sub>1</sub> antagonist/inverse agonist (FW = 378.39 g/mol; CAS 1110781-88-8; Solubility: 100 mM in DMSO), also named *N*-(3-ethoxyphenyl)-4-(1-pyrrolidinyl)-3-(trifluoromethyl)benzamide, targets Trace Amine-associated Receptor-1, with respective IC<sub>50</sub> values are 27.5 (mouse), 4539 (rat) and 7487 nM (human), blocking TA<sub>1</sub> receptor-mediated activation of an inwardly rectifying K<sup>+</sup> current. The latter increases the firing frequency of dopamine neurons in the ventral tegmental area. EPPTB also increases dopamine potency at the D<sub>2</sub> receptor and displays inverse agonism, reducing basal cAMP levels *in vitro* (IC<sub>50</sub> = 19 nM). 1. Bradaia, Trube, Stalder, *et al.* (2009) *Proc. Natl. Acad. Sci. U.S.A.* **106**, 20081.

### Eprosartan

This angiotensin II receptor antagonist (FW = 520.63 g/mol; CAS 133040-01-4), also known by the trade names Abbvie® and Eprozar® as well as the systematic name 4-({2-butyl-5-[2-carboxy-2-(thiophen-2-ylmethyl)eth-1-en-1-yl]-1H-imidazol-1-yl}methyl)benzoate, is an antihypertensive drug. When paired with hydrochlorothiazide, it is marketed as Teveten HCT® and Teveten Plus®. (See also *Candesartan*; *Irbesartan*; *Losartan*; *Olmесartan*; *Telmisartan*; *Valsartan*) **Key Pharmacological Parameters:** Bioavailability = 15 %; Food Effect? NO; Drug *t*<sub>1/2</sub> = 5–7 hours; Metabolite *t*<sub>1/2</sub> = Not Determined; Drug's Protein Binding = 98 %; Metabolite's Protein Binding = <1 %; Route of Elimination = 7 % Renal and 90 % Hepatic. 1. Weinstock, Keenan, Samanen, *et al.* (1991) *J. Med. Chem.* **34**, 1514.

### Epsilon Toxin

This aerolysin-like, pore-forming toxin (MW = 28.7 kDa; Symbol: ETX; LD<sub>50</sub> = 100 ng/kg in mice) from *Clostridium perfringens* Types B and D strains, causes enterotoxemia in ruminants, particularly sheep (LD<sub>50</sub> = ~70 ng/kg). Such potency makes it a potential bioterrorism agent, now classified as a Category B biological agent by the Centers for Disease Control and Prevention. The 32.9-kDa protoxin is converted to an active toxin through proteolytic cleavage by specific proteases. ETX induces pore formation in eukaryotic cell membranes via detergent-resistant, cholesterol-rich lipid rafts that promote aggregation of ETX monomers into homo-heptamers. Sialidases (or neuraminidases) produced by *C. perfringens* enhance binding of the bacterium and ETX to cultured cells. 1. Stiles, Barth, Barth & Popoff (2013) *Toxins* (Basel) **5**, 2138.

### Eptastigmine

This carbamate ester (FW = 359.51 g/mol; CAS 101246-68-8), also known as heptylphiso-stigmine, which inhibits acetylcholinesterase (1-8) and butyrylcholinesterase (4-8), with IC<sub>50</sub> values of 22 and 5 nM, respectively), has been used to treat Alzheimer's disease. 1. Brufani, Marta & Pomponi (1986) *Eur. J. Biochem.* **157**, 115. 2. Ogane, Giacobini & Messamore (1992) *Neurochem. Res.* **17**, 489. 3. Moriearty & Becker (1992) *Meth. Find. Exp. Clin. Pharmacol.* **14**, 615. 4. Iijima, Greig, Garofalo, *et al.* (1992) *Neurosci. Lett.* **144**, 79. 5. Liston, Nielsen, Villalobos, *et al.* (2004) *Eur. J. Pharmacol.* **486**, 9. 6. Costagli & Galli (1998) *Biochem. Pharmacol.* **55**, 1733. 7. Luo, Yu, Zhan, *et al.* (2005) *J. Med. Chem.* **48**, 986. 8. Giacobini (2003) *Neurochem. Res.* **28**, 515.

### Eptifibatide

This glycoprotein IIb/IIIa (GPIIb/IIIa) antiplatelet drug (FW = 831.96 g/mol; CAS 188627-80-7), also known as Integrilin, is a cyclic heptapeptide from a GP IIb-IIIa inhibitory protein (See *Barbourin*). Eptifibatide is a so-called argininyglycyl-aspartyl (RGD) peptidomimetic that binds reversibly to platelet integrins, IC<sub>50</sub> = 0.28-0.34 μg/mL (1). In hirudinized blood, IC<sub>50</sub> values for eptifibatide were 1.5x to 3x higher than those obtained with citrated plasma. Concentration-dependent effect of glycoprotein IIb/IIIa antagonists on shear-induced platelet adhesion showed marked differences in potencies: IC<sub>50</sub> values of 34, 35, 91, 438, and 606 nM for DPC802, roxifiban, sibrifiban, lotrafiban, and orbofiban, respectively, and IC<sub>50</sub> values of 43, 430, and 5781 nM for abciximab, tirofiban, and eptifibatide, respectively (2). **Mode of Inhibitory Action:** In unstable angina, acute myocardial infarction, and ischemia after coronary angioplasty, one hallmark is thrombogenic platelet aggregation, the latter resulting when plaque rupture exposes subendothelial components (such as collagen and fibronectin). This event allows platelets to bind to fibrinogen via the glycoprotein IIb/IIIa integrin receptor, imitating platelet activation and aggregation as well as coagulation. Glycoprotein IIb-IIIa shows a narrow tissue distribution in healthy subjects, where it is only found on platelets and platelet progenitors. Inhibition of glycoprotein IIb/IIIa integrin receptor function has thus emerged as a promising druggable target for managing acute ischemic coronary syndromes and acute ischemic complications of percutaneous coronary interventions. The venom of the southeastern pigmy rattlesnake (*Sistrurus miliarius barbouri*) was the only of 52 venoms specific for GPIIb-IIIa versus other integrins (3). Barbourin is highly homologous to other peptides of the viper venom GPIIb-IIIa antagonist family, but contains a KGD in place of the canonical RGD sequence required to block receptor function. 1. Scarborough, Rose, His, *et al.* (1991) *J. Biol. Chem.* **266**, 9359.

## EPZ-5676

This is an *S*-adenosyl methionine analogue (FW<sub>free-base</sub> = 529.73 g/mol; CAS 1380288-87-8; Solubility: 100 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known as 9-[5-deoxy-5-[[cis-3-[2-[6-(1,1-dimethylethyl)-1*H*-benzimidazol-2-yl]ethyl]cyclobutyl](1-methylethyl)amino]-β-D-ribofuranosyl]-9*H*-Purin-6-amine, competitively inhibits the protein methyltransferase DOT1L (*K*<sub>i</sub> = 80 pM), showing a greater than 37,000x selectivity versus all other PMTs tested, inhibits H3K79 methylation in tumors.

## Erastin

This cytotoxic ferroptosis activator (FW = 547.05 g/mol; CAS Registry Number = 571203-78-6; Solubility: 19 mg/mL DMSO), also named 2-[1-[4-[2-(4-chlorophenoxy)acetyl]-1-piperazinyl]-ethyl]-3-(2-ethoxyphenyl)-4(3*H*)-quinazolinone, induces a non-apoptotic death pathway in Ras-overexpressing cells, as evidenced by the absence of fragmentation or margination of chromatin (1,2). Ferroptosis depends upon intracellular iron, but not other metals, and is morphologically, biochemically, and genetically distinct from apoptosis, necrosis, and autophagy. Erastin-treated cells do not show DNA laddering, a hallmark of apoptosis that occurs when DNA is cleaved at regular intervals. Annexin V staining also shows no evidence of apoptosis-associated accumulation of phosphatidylserine on the outer leaflet of the peripheral membrane. Most telling is the finding that caspase 3, a final executioner of apoptosis, remains in its inactivated, pro-caspase form, and the pan-caspase inhibitor BOC-D-fmk does not block erastin-induced cell death. Such findings indicate that erastin is a Ras-selective lethal compound operating by a novel mechanism for killing cells (2). Later work (3) showed that erastin acts through mitochondrial voltage-dependent anion channels (VDACs), thus representing a novel target for anti-cancer drug action. Erastin treatment of cells harboring oncogenic RAS causes cell death through an oxidative, non-apoptotic mechanism. RNA-interference-mediated knockdown of VDAC2 or VDAC3 brought on resistance to erastin, implicating these VDAC isoforms in the mechanism of erastin-mediated cell death (3). A radiolabelled erastin analogue also binds directly to VDAC2 (3). Erastin enhances cisplatin-based killing of lung cancer cells bearing wild-type EGFR (4). Note that ferrostatin prevents erastin-induced ferroptosis in cancer cells, as well as glutamate-induced cell death in postnatal rat brain slices (See *Ferrostatin*). 1. ## Eravacycline

This broad-spectrum intravenous and oral antibiotic (FW = 542.56 g/mol), also known as TP-434 and systematically as 7-fluoro-9-pyrrolidin-9-ylacetamido-6-demethyl-6-deoxytetracycline, is a first-line empiric monotherapy for the treatment of multi-drug resistant (MDR) infections, including MDR Gram-negative bacteria. Eravacycline is a novel, fully synthetic tetracycline antibiotic exhibiting potent antibacterial activity against a broad spectrum of susceptible and multi-drug resistant bacteria, including Gram-negative, Gram-positive, atypical and anaerobic bacteria, with potential to treat the majority of patients as a first-line empiric monotherapy with convenient dosing, as well as the potential for intravenous-to-oral step-down therapy. In *in vitro* studies, eravacycline is highly effective against *Acinetobacter baumannii*, various well as clinically important *Enterobacteriaceae* species (including those resistant to the carbapenem class of antibiotics), and pathogenic anaerobes. 1. Sutcliffe, O'Brien, Fyfe & Grossman (2013) *Antimicrob. Agents Chemother.* 57, 5548.

## Ercalcio

This photosensitive vitamin (FW = 396.66 g/mol; CAS 50-14-6), also known as ergocalciferol, calciferol, and vitamin D<sub>2</sub>, is a secosteroid with vitamin D activity. It is metabolized to ercalcidiol and ercalcitriol, the latter the main biologically active form of the vitamin. Ercalcio is produced from ergosterol upon UV irradiation, a common practice in fortifying the vitamin D<sub>2</sub> content of cow's milk. **Target(s):** arylsulfatase A, *or* cerebroside-sulfatase (1); arylsulfatase B, *or* N-acetylgalactosamine-4-sulfatase (1); DNA-directed DNA polymerase (2); DNA polymerase α (2). 1. Bleszynski & Leznicki (1967) *Enzymologia* 33, 373. 2. Mizushima, Xu, Murakami, *et al.* (2003) *J. Pharmacol. Sci.* 92, 283.

## Ergosterol

This mycosterol (FW = 396.66 g/mol; CAS 57-87-4; IUPAC: ergosta-5,7,22-trien-3 $\beta$ -ol), first isolated from rye in 1889, is converted to vitamin D<sub>2</sub> (ercalcio), via lumisterol and tachysterol, upon exposure to bright ultraviolet light. Because fungi require ergosterol to survive, its biosynthesis is a druggable target. Miconazole, itraconazole, and clotrimazole, for example, inhibit ergosterol formation from lanosterol, whereas the antifungal drug amphotericin B binds to ergosterol within fungal membranes, creating a polar pore that allows K<sup>+</sup> and H<sup>+</sup> to leak out. Large-scale cultivation of fungi yields ergosterol for photoconversion to Vitamin D used in dietary supplements. **Target(s):** alcohol *O*-acetyltransferase (1); cyclooxygenase (2,3); 3-hydroxy-3-methylglutaryl CoA reductase (4); sterol acyltransferase, or cholesterol acyltransferase (5); sterol 24-C methyltransferase, or cycloartenol 24-C-methyltransferase, K<sub>i</sub> = 80  $\mu$ M (6-8); sterol  $\Delta^{24}$ -reductase (10). 1. Yoshioka & Hashimoto (1981) *Agric. Biol. Chem.* **45**, 2183. 2. Zhang, Mills & Nair (2002) *J. Agric. Food Chem.* **50**, 7581. 3. Zhang, Mills & Nair (2003) *Phytomedicine* **10**, 386. 4. Bard & Downing (1981) *J. Gen. Microbiol.* **125**, 415. 5. T. Billheimer (1985) *Meth. Enzymol.* **111**, 286. 6. Mangla & Nes (2000) *Bioorg. Med. Chem.* **8**, 925. 7. Nes, Jayasimha & Song (2008) *Arch. Biochem. Biophys.* **477**, 313. 8. Zhou, Lepesheva, Waterman & Nes (2006) *J. Biol. Chem.* **281**, 6290. 9. Nes (2005) *Biochem. Soc. Trans.* **33**, 1189. 10. Fernandez, Suarez, Ferruelo, Gomez-Coronado & Lasuncion (2002) *Biochem. J.* **366**, 109.

### Ergotamine

This vasoconstricting indole alkaloid (FW = 581.67 g/mol) from ergot, a fungal parasite (*Claviceps purpurea*) of rye plants, is a serotonin 5-HT<sub>1A</sub>, 5-HT<sub>1B</sub>, 5-HT<sub>1D</sub>, and 5-HT<sub>1F</sub> receptor agonist as well as act at dopamine D<sub>2</sub> receptors. It is also an  $\alpha$ -adrenergic receptor antagonist, while acting as an agonist at low concentrations. Poisoning occurs from the consumption of rye bread contaminated with *C. purpurea*. The worst recorded case occurred in the Rhine Valley in 857 AD, when thousands perished. Due to its remarkable uterotonic and vasoconstrictor effects, ergotamine has also been used to induce childbirth and to control post-partum hemorrhage. Ergotamine hydrolysis produces lysergic acid. **Target(s):** acetylcholinesterase (1);  $\alpha$ -adrenergic receptor (2); calmodulin-stimulated cyclic-nucleotide phosphodiesterase (2). 1. Riedel, Kyriakopoulos & Nundel (1981) *Arzneimittelforschung* **31**, 1387. 2. Earl, Prozialeck & Weiss (1984) *Life Sci.* **35**, 525.

### Ergothioneine

This histidine derivative (FW = 229.30 g/mol;  $\lambda_{\text{max}}$  = 258 nm;  $\epsilon$  = 16000 M<sup>-1</sup>cm<sup>-1</sup> at pH = 2–9; M.P. (decomposes) = 256–257°C; Solubility: 0.04 g/mL H<sub>2</sub>O; Soluble in hot methanol, hot ethanol, and in acetone; tightly binds Zn<sup>2+</sup> and Cu<sup>2+</sup>) is a more effective reducing reagent than cysteine or glutathione, providing protection against UV damage and free radical damage. Many Gram-positive bacteria, including *Mycobacterium tuberculosis*, lack glutathione and instead produce mycothiol, bacillithiol and ergothioneine (ESH) as their major low-molecular-weight thiols. Humans do not synthesize ergothioneine, but possess the cation transporter (OCTN1) that shows high specificity for ESH uptake from dietary sources. **Target(s):** glutathione *S*-transferase P1 (1-2); polyphenol oxidase (3). 1. van den Broeke & Beyersbergen van Henegouwen (1993) *J. Photochem. Photobiol. B* **17**, 279. 2. Hayashi, Mukanganyama, Hazra, Abegaz & Hasler (2004) *Phytother. Res.* **18**, 877. 3. Hanlon (1971) *J. Med. Chem.* **14**, 1084.

### Eribulin

This synthetic halichondrin B analogue and microtubule-directed anticancer agent (FW = 729.91 g/mol; CAS 253128-41-5), also known\* by its code name E7389 and trade name Halaven<sup>®</sup>, is an FDA-approved treatment for patients with metastatic breast cancer who previously received at least two chemotherapeutic regimens for metastatic disease. (See *Halichondrin B*) that binds to tubulin with a sub-nM dissociation constant, suppressing microtubule (MT) dynamics, both *in vitro* and in cells, and operating by a unique mechanism that suppresses the growth phase of MT dynamic instability without suppressing the shortening phase (1). Suppression of MT dynamics in interphase cells occurs at eribulin concentrations that arrest mitosis and lead to apoptosis (2-4). Eribulin, paclitaxel, and Vinca alkaloids bind to tubulin and/or MTs in characteristically different ways. Paclitaxel binds along the inner surface of the microtubule, with maximal binding of one paclitaxel molecule per tubulin heterodimer. Vinblastine and eribulin bind with high affinity to a very small number of saturable sites on tubulin positioned at MT ends. The *in vitro* effects of these drugs also vary. Binding of 1-2 molecules of vinblastine to a microtubule end is sufficient to suppress MT treadmilling dynamics by 50%, whereas paclitaxel occupancy must be much higher to suppress microtubule dynamic instability to a similar. Yet, despite their chemical structural differences and their different binding modes on MTs, low concentrations of these drugs arrest mitosis by suppressing microtubule dynamics (5). Differences in the MT binding of eribulin, *Vinca* alkaloids, and paclitaxel also suggest that it is unlikely that the drugs all sterically block interaction with the kinetochore. Yet, they all suppress the stretching and relaxation movements between sister centromeres at concentrations that arrest mitosis, indicating that suppression of spindle MT dynamics on the same crucially important step in mitosis (5). Intravital microscopy with fluorescently labeled eribulin demonstrates that MDR1 drives erubulin resistance, even upon I.V. administration of HM30181, a third-generation MDR1 inhibitor (See *HM30181*) (6). When encapsulated within a nanoparticle delivery system, HM30181 reverses the multidrug-resistant phenotype, potentiating eribulin effects, both *in vitro* and *in vivo* in mice (6). ### Eriodictyol

This flavanone (FW = 288.26 g/mol; CAS 552-58-9), also named (2*S*)-2-(3,4-dihydroxyphenyl)-5,7-dihydroxy-4-chromanone, from lemons and the native American plant Yerba Santa (*Eriodictyon californicum*) inhibits: Ca<sup>2+</sup>-transporting ATPase (1), 3',5'-cyclic-nucleotide phosphodiesterase 3 (2),  $\beta$ -glucuronidase (3), glutathione *S*-transferase P (1-4), hyaluronidase (3),

leucoanthocyanidin reductase (5), lysozyme (3); naringenin-chalcone synthase (6-8), tyrosinase (3), and xanthine oxidase (9-11). 1. Thiagarajah, Kuttan, Lim, Teo & Das (1991) *Biochem. #### D-Eritadenine

This substituted purine (FW<sub>free-acid</sub> = 253.22 g/mol), also known as 2(R),3(R)-dihydroxy-4-(9-adenyl)butyric acid and (αR,βR)-6-amino-α,β-dihydroxy-9H-purine-9-butanoic acid, from the shiitake mushroom (*Lentinus edodes*) is hypocholesterolemic agent with wide-ranging effects, causing an increase in the liver phosphatidylethanolamine concentrations and a decrease in liver Δ<sup>6</sup>-desaturase activity. **Target(s):** adenosylhomocysteinase, or S-adenosyl-homocysteine hydrolase (1,2); phosphatase (3). 1. Huang, Komoto, Takata, *et al.* (2002) *J. Biol. Chem.* **277**, 7477. 2. Schanche, Schanche, Ueland, Holy & Votruba (1984) *Mol. Pharmacol.* **26**, 553. 3. Nemeč & K. Slama (1989) *Experientia* **45**, 148.

#### Erlotinib

This HER1/EGFR inhibitor (FW<sub>hydrochloride</sub> = 429.90 g/mol; CASs = 183321-74-6 (free base), 183319-69-9 (hydrochloride), 248594-19-6 (methane sulfonate salt); Solubility (25°C): 3 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known as CP-358774, OSI-774, NSC 718781, Tarceva<sup>®</sup>, and by systematically as N-(3-ethynylphenyl)-6,7-bis(2-methoxyethoxy) quinazolin-4-amine, blocks EGFR tyrosine kinase (IC<sub>50</sub> = 2 nM) and reduces EGFR autophosphorylation in intact tumor cells (IC<sub>50</sub> = 20 nM). This inhibition is selective for EGFR tyrosine kinase relative to other tyrosine kinases, both in assays of isolated kinases and whole cells. EGFR is frequently amplified and/or mutated in human tumors, and abnormal signaling from this receptor is believed to contribute to the malignant phenotype. At doses of 100 mg/kg, Erlotinib completely prevents EGF-induced autophosphorylation of EGFR in human HN5 tumors growing as xenografts in athymic mice and of the hepatic EGFR of the treated mice (1). Rapamycin synergizes with the epidermal growth factor receptor inhibitor erlotinib in non-small-cell lung, pancreatic, colon, and breast tumors (2). Erlotinib resistance typically occurs 8–12 months from commencing treatment, with over 50% of the cases caused by a mutation in the ATP binding pocket of the EGFR kinase domain. This Thr-790-Met mutation increases ATP binding affinity, thereby reducing the inhibitory effect of erlotinib (3). Such findings suggest that the Thr-790-Met mutation is a "generic" resistance mutation that would be expected to reduce the potency of any ATP-competitive kinase inhibitor and that irreversible inhibitors overcome this resistance by covalent binding, not as a result of an alternative binding mode (3). The Hsp90 inhibitor CH5164840 further enhances the cytotoxic effects of erlotinib against non-small cell lung

cancer (NSCLC) tumors, even those with EGFR overexpression and mutations (4). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) #### Erythritol

This naturally occurring sugar alcohol (FW = 122.12 g/mol; CAS 149-32-6), also called *meso*-1,2,3,4-tetrahydroxybutane, has nearly twice the sweetness of sucrose. With pentaerythritol tetranitrate one of the most powerful explosives known, industrial-scale production uses *Torula corallina*, an organism that offers the highest erythritol yield. **Target(s):** aldose 1-epimerase (1); α-amylase (2); amylo-α-1,6-glucosidase/4-α-glucanotransferase, or glycogen debranching enzyme (3); L-arabinose isomerase (4); β-galactosidase (5); glucan 1,3-β-glucosidase (6); α-glucosidase (5,7-10); β-glucosidase (5); glycerol kinase (11). 1. #### Erythritol 4-Phosphate

This phosphorylated sugar alcohol (FW<sub>free-acid</sub> = 202.1 g/mol; CAS 7183-41-7), also known as L-erythritol 1-phosphate, inhibits glucose-6-phosphate isomerase (1,2). D-Erythritol 4-P is a product of the reaction catalyzed by erythritol kinase. *Brucella abortus* erythritol kinase produces the L-isomer, also known as D-erythritol 1-phosphate (3). **Target(s):** glucose-6-phosphate isomerase (1,2); 2-C-methyl-D-erythritol-4-phosphate cytidyltransferase, weakly inhibited by L-erythritol 4-phosphate (3). 1. Noltmann (1972) *The Enzymes*, 3rd ed., **6**, 271. 2. Chirgwin, Parsons & Noltmann (1975) *J. Biol. Chem.* **250**, 7277. 3. Lillo, Tetzlaff, Sangari & Cane (2003) *Bioorg. Med. Chem. Lett.* **13**, 737.

#### Erythromycin

This class of related macrolide antibiotics, first obtained from *Streptomyces erythraeus* (now *Saccharopolyspora erythraea*) by J. M. McGuire in 1949 at Eli Lilly Labs, are fermentation products: designated A, B, and C. Erythromycin A is the predominant form. All three inhibit prokaryotic protein biosynthesis by binding the 50S ribosomal subunit and inhibiting translocation (1-3). Erythromycin binds to ribosomal protein L15 in solution, and L16 appears to participate in erythromycin binding to ribosomes. They reportedly stimulate the dissociation of peptidyl-tRNA from the ribosome. Erythromycin A (FW = 733.94 g/mol) is soluble in water (approximately 2 mg/mL) consists of a large lactone glycosidically linked to two sugars,  $\beta$ -D-desosamine and  $\alpha$ -L-cladinose (or,  $\alpha$ -L-3-O-methylmycarose). Erythromycin B is virtually identical, with one hydroxyl group on the lactone ring and erythromycin C is identical to A, and mycarose replaces cladinose. Erythromycin A loses its biological activity at pH < 5. It absorbs light slightly in the ultraviolet:  $\lambda_{\max} = 280$  nm at pH 6.3 ( $\epsilon = 50$  M<sup>-1</sup>cm<sup>-1</sup>). The asymmetric synthesis of erythromycin A was accomplished in R. B. Woodward's laboratory (4). **Mode of Antibiotic Binding:** Erythromycin binds to *Escherichia coli* ribosomes in a two-step process (5). The first binding step ( $K_1 = 83$  nM) is established rapidly, occurring at a low-affinity binding site situated at the entrance of the exit tunnel in the large ribosomal subunit, where macrolides bind mainly through hydrophobic portions. In the second step, a slow conformational change occurs as the antibiotic hydrophilic portion burrows deeper into the tunnel, attaining its higher-affinity state ( $k_{\text{on}} = 0.39$  min<sup>-1</sup>;  $k_{\text{off}} = 0.054$  min<sup>-1</sup>;  $k_{\text{on}}/k_{\text{off}} = 7.3$ ;  $K_d^* = K_1 \times k_{\text{on}}/k_{\text{off}} \approx 10$  nM). Polyamines attenuate erythromycin affinity for the ribosome at both steps in the sequential binding mechanism (5). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** CYP3A4 (6); peptidyltransferase (7); protein biosynthesis (1-5,7-9). 1. Pestka (1974) *Meth. Enzymol.* **30**, 261. 2. #### D-Erythrose 4-Phosphate

This phosphorylated tetrose (FW<sub>free-acid</sub> = 200.08 g/mol; CAS 103302-15-4) is an intermediate in carbohydrate metabolism and is found in small quantities in mammalian muscle. It is more stable in acidic solutions than at neutral pH: neutral solutions should be kept cold and used immediately. It is an alternative substrate for ribulose-phosphate 3-epimerase. **Target(s):** acetyl-CoA synthetase (1); aspartate aminotransferase (2); fructose-1,6-bisphosphate aldolase (3); glucose-6-phosphate isomerase (4-15); glyceraldehyde-3 phosphate dehydrogenase (16); glycogen synthase, microsomal (17); *myo*-inositol-1-phosphate synthase (18); mannose-6-phosphate isomerase (5,12,13,19,20); phosphorylase phosphatase (17); orotate phosphoribosyltransferase, weakly inhibited (21); 6-phosphogluconate dehydrogenase (22); phosphoketolase (23); ribose-5-phosphate isomerase (24,25); triose-phosphate isomerase (26). 1. #### Erythrosine

This dye and color additive (FW<sub>disodium-salt</sub> = 879.86 g/mol; CAS 49746-10-3), also called 2',4',5',7'-tetraiodofluorescein and erythrocin B, inhibits a number of antiport systems. A brown powder that produces a cherry-red solution in water, erythrosine has a  $\lambda_{\max} = 524$  nm. Frequently used as a stain for nerve cells and soil bacteria, erythrosine is also fluorescent. **Target(s):** acetylcholinesterase (1); AMP deaminase (2); anion channel, mitochondrial inner membrane (3); apyrase (4); Ca<sup>2+</sup>-transporting ATPase (5-9); cholinesterase (1); chloride transport (10); dopamine sulfotransferase (11); fumarase (12); galactosylceramide sulfotransferase (13); H<sup>+</sup>-ATPase (14,15); Na<sup>+</sup>/K<sup>+</sup> exchanging ATPase (16); respiration, mitochondrial (17). 1. #### Escitalopram

This highly selective serotonin reuptake inhibitor, or SSRI (FW = 324.39 g/mol; CAS 128196-01-0), also known by the code name Lu-10-171, by its tradenames Lexapro<sup>®</sup> and Cipralex<sup>®</sup>, and as (S)-1-[3-(dimethylamino)propyl]-1-(4-fluorophenyl)-1,3-dihydro-isobenzofuran-5-carbonitrile, is an FDA-approved antidepressant for treating major depressive disorder and generalized anxiety disorder in adults. In humans, escitalopram reaches peak concentrations within 2-4 hours after the daily dose, and is eliminated slowly ( $t_{1/2} = 30$  hours). Long-term treatment with escitalopram does not induce changes in neurotransmitter receptors as seen with most tricyclic as well as newer atypical antidepressants. **Other Target(s):** Citalopram is an

extremely potent inhibitor of neuronal serotonin (5-HT) uptake, but has no effect on the uptake of noradrenaline (NA) and dopamine (1). Citalopram has no antagonistic activity towards dopamine, NA, 5-HT, histamine, GABA, acetylcholine, and morphine receptors. In this way, it clearly deviates from many old and new antidepressant drugs exerting antagonistic effects towards some of these transmitters. Escitalopram blocks Human Ether-a-go-go-Related Gene (hERG) currents ( $IC_{50} = 2.6 \mu\text{M}$  for escitalopram;  $IC_{50} = 3.2 \mu\text{M}$  for citalopram) at supratherapeutic concentrations by preferentially binding to both the open and the inactivated states of the channels and by inhibiting the trafficking of hERG channel protein to the plasma membrane. The blocking of hERG by escitalopram was voltage-dependent, with a steep increase across the voltage range of channel activation. The blocking by escitalopram was frequency dependent. Rapid application of escitalopram induced a rapid and reversible blocking of the tail current of hERG. The extent of the blocking by escitalopram during the depolarizing pulse was less than that during the repolarizing pulse, suggesting that escitalopram has a high affinity for the open state of the hERG channel, with a relatively lower affinity for the inactivated state. Other selective serotonin reuptake inhibitors/antidepressants include fluoxetine, fluvoxamine, paroxetine, and sertraline. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Hyttel (1982) *Prog. Neuropsychopharmacol. Biol. Psych.* **6**, 277. 2. Chae, Jeon, Lee, et al. (2014) *Naunyn. Schmiedeberg's Arch. Pharmacol.* **387**, 23.

### Eserine

This naturally occurring acetylcholinesterase inhibitor (FW<sub>free-base</sub> = 275.35 g/mol; CAS 57-47-6), also called physostigmine, from calabar beans (*Physostigma venenosum*) crosses the blood-brain barrier and binds at the anionic site of the cholinesterase ( $K_d = 0.3 \mu\text{M}$ ), forming a carbamoyl ester with the hydroxyl group of a seryl residue. The resulting complex slowly degrades, thereby allowing the enzyme to reactivate. Although eserine is toxic, these properties commend its use in assisting AD patients in long-term memory. Eserine is photosensitive and should be stored in the dark. Solutions should be used within a week of preparation. Storage should be in the cold, dark, in alkali-free glass containers, and free of metal ions. **Target(s):** acetylcholinesterase (1-23); acetylsalicylate deacetylase (24); amidase (25); arylacetamide deacetylase (26). 1. Augustinsson (1950) *The Enzymes*, 1st ed. (Sumner & Myrback, eds.), **1** (part 1), 443. 2. Wilson (1960) *The Enzymes*, 2nd ed., **4**, 501. 3. Main & Hastings (1966) *Science* **154**, 400. 4. ### Eslicarbazepine acetate

Eslicarbazepine acetate

Eslicarbazepine

This novel, once daily dose, voltage-gated  $\text{Na}^+$  channel blocker and anticonvulsant prodrug (FW = 296.32 g/mol; CAS 236395-14-5), also known as Aptiom<sup>®</sup>, Zebinix<sup>®</sup>, Exalief<sup>®</sup> and (S)-10-acetoxy-10,11-dihydro-5H-dibenz[b,f]azepine-5-carboxamide, is converted to eslicarbazepine (FW = 254.28 g/mol; CAS 29331-92-8; also named (S)-(+)-Licarbazepine), a voltage-gated sodium channel blocker with anticonvulsant and mood-stabilizing effects. Eslicarbazepine acetate inhibits the release of glutamate evoked by 4-aminopyridine (4-AP) or veratridine in a concentration-dependent manner (2). Using conditions of stimulation (30 mM KCl), where  $\text{Na}^+$  channels are inactivated, the eslicarbazepine does not inhibit either the  $\text{Ca}^{2+}$ -dependent or  $\text{Ca}^{2+}$ -independent release of glutamate (2). Eslicarbazepine acetate is also an alternative treatment in associated therapy in patients with partial epilepsy, who do not respond adequately to treatment in monotherapy. 1. Ambrósio, Silva, Araújo, et al. (2000) *Eur. J. Pharmacol.* **406**, 191. 2. Ambrósio, Silva, Malva, et al. (2001) *Biochem. Pharmacol.* **61**, 1271. 3. Mauri-Llerda (2012) *Rev. ### Estazolam

This intermediate-acting oral triazolobenzodiazepine hypnotic agent (FW = 294.71 g/mol; CAS 29975-16-4; 8-chloro-6-phenyl-4H-1,2,4-triazolo(4,3-a)-1,4-benzodiazepine), also known by the trade names ProSom<sup>®</sup> and Eurodin<sup>®</sup>, is a Schedule IV benzodiazepine receptor agonist that is often used to treat insomnia, albeit at the risk of developing tolerance. Estazolam stabilizes the continuity of slow wave deep sleep (SWDS) with higher amplitude than comparable benzodiazepine receptor ligands. Animal studies indicate estazolam induces a drowsy pattern of spontaneous EEG, including high voltage slow waves and spindle bursts increase in the cortex and amygdala, with desynchronization of hippocampal  $\theta$ -rhythms. It also exerts anxiolytic, anticonvulsant, sedative and skeletal muscle relaxant properties. Estazolam reaches peak plasma levels within 1-6 hours, and is excreted mainly as 4-hydroxyestazolam (formed by CYP3A4) with a half-life of 8-31 hours (1). Estazolam inhibits platelet-activating factor- (PAF-) induced aggregation in a dose-dependent manner,  $IC_{50} = 3.8 \mu\text{M}$  (2). Estazolam decreases histamine turnover in the brain, most likely via the benzodiazepine-GABA receptor complex (3). 1. Mancinelli, Guiso, Garattini, Urso & Caccia (1985) *Xenobiotica* **15**, 257. 2. Mikashima, Takehara, Muramoto, et al. (1987) *Jpn. J. Pharmacol.* **44**, 387. 3. Oishi, Nishibori, Itoh & Saeki (1986) *Eur. J. Pharmacol.* **124**, 337.

### Esterase Inhibitor C-1

This single-chain serpin (MW = 55.6 kDa), also known as complement C1 esterase inhibitor and C1 inhibitor, contains 478 aminoacyl residues and is heavily glycosylated (~30% carbohydrate). This protein controls complement activation and regulates all major kinin generating cascade systems. It also inhibits a number of serine proteinases; however, trypsin

and chymotrypsin catalyze the degradation of the C1 inhibitor). (For a discussion of the likely mechanism of inhibitory action, See Serpins; also  $\alpha_1$ -Antichymotrypsin) **Target(s):** coagulation factor Xia (1-6); coagulation factor XIIa (2,4,7-11); complement subcomponent C1r (2,4,12-18); complement subcomponent C1s (2,4,13-15,17-22); granzyme A, mouse (23); mannan-binding lectin-associated serine protease-2 (24-30); mouse nerve growth factor  $\gamma$ -subunit protease, possibly  $\gamma$ -renin (31); plasma kallikrein (2,4,13,16,32-35); plasmin (2,4,13,16,22,36-38); t plasminogen activator (39); u-plasminogen activator, or urokinase (4). 1. #### Esterastin

This immunomodulator (FW = 506.68 g/mol; CAS 67655-93-0), produced by actinomycetes, is structurally related to lipstatin. **Target(s):** acid lipase, lysosomal,  $K_i \approx 80$  nM (competitive) (1); esterases (1-3); lipase, pancreatic, or triacylglycerol lipase (1). 1. Imanaka, Moriyama, Ecsedi, et al. (1983) *J. Biochem.* **94**, 1017. 2. Umezawa, Aoyagi, Hazato, et al. (1978) *J. Antibiot.* **31**, 639. 3. Kondo, Uotani, Miyamoto, et al. (1978) *J. Antibiot.* **31**, 797.

#### 3,17 $\alpha$ -Estradiol

This membrane-permeant sterol (FW = 272.39 g/mol; CAS 50-28-2;  $\lambda_{max} = 280$  nm;  $\epsilon = 2,040$  M<sup>-1</sup>cm<sup>-1</sup>; Insoluble in water), also known as 1,3,5-estratriene-3,17 $\alpha$ -diol and oestradiol-17 $\alpha$ , exhibits anti-estrogen activity (1). While a minor metabolite in humans,  $\alpha$ -estradiol is more prevalent in other organisms. It has a) and. **Target(s):** F<sub>0</sub>F<sub>1</sub> ATPase (2); glucuronosyltransferase (3); glutamate dehydrogenase (4); 3(or 17) $\beta$ -hydroxysteroid dehydrogenase,  $K_i = 4.5$   $\mu$ M (5-7); 21-hydroxysteroid dehydrogenase, NAD<sup>+</sup>-dependent (8); steroid  $\Delta$ -isomerase (9); xanthine oxidase (10). 1. #### 3,17 $\beta$ -Estradiol (or 17 $\beta$ -Estradiol)

This potent membrane-permeant estrogen (FW = 272.39 g/mol; CAS 50-28-2; Symbol = E2;  $\lambda_{max} = 280$  nm;  $\epsilon = 1900$  M<sup>-1</sup>cm<sup>-1</sup>; water-insoluble), also known as 1,3,5-estratriene-3,17 $\beta$ -diol, 17 $\beta$ -estradiol, and oestradiol-17 $\beta$ , is synthesized in the ovary, placenta, adrenal cortex, and testis. **E2 Mode of Action:**  $\beta$ -Estradiol is mainly produced in ovarian follicles, but is also formed in fat, liver, adrenal, breast, and neural tissues.  $\beta$ -Estradiol induces the formation of gonadotropins, inducing the formation of female characteristics and modifying sexual behavior. In the classical E2 pathway, estradiol enters the cytoplasm, where it binds to heat shock protein (HSP). Two HSP-Estradiol complexes self-associate to form a homodimer, which enters the nucleus, binds to specific domains on estrogen response element (ERE), and induces gene transcription over the ensuing hours or days. Estradiol is also an agonist of the intracellular nonnuclear estrogen receptor GPER, which mediates a variety of rapid, non-genomic effects. 17 $\beta$ -Estradiol is a substrate for estrone sulfotransferase. Although the primary female sex hormone, 17 $\beta$ -estradiol is also found in males. **Mode of Inhibition of ATP Synthase:** 17 $\beta$ -Estradiol modulates ATP synthase by direct binding to the oligomycin sensitive-conferring component F<sub>0</sub>, increasing the depolarization amplitude associated with ADP addition to energized mitochondria. This effect occurs when  $\beta$ -estradiol promotes uncoupling or "slipping" of the mechanochemical linkage of the synthase's F<sub>0</sub> and F<sub>1</sub> components (1).  $\beta$ -estradiol depresses the respiratory control ratio (*i.e.*, the ratio of slopes of O<sub>2</sub> versus time curves, after and before ADP addition), reduces the P/O Ratio (*i.e.*, the ratio of the amount of ATP produced from the movement of two electrons through the ETS chain, by reduction of an oxygen atom) and decreases State-3 respiration (*i.e.*, respiration observed when ADP is added to intact, unpoisoned mitochondria in the presence of

excess substrate), whereas it increases State-4 respiration (*i.e.*, oxygen consumption by isolated mitochondria on a particular substrate, in the absence of ADP or any metabolic poisons or inhibitors). By contrast, the uncoupler VFCCP remains unaltered. 17 $\beta$ -estradiol therefore appears to allow an energy-disappating back-leak of protons through ATP synthase's F<sub>o</sub> component (1). Note also that estrogen receptors and hormone-responsive elements have been identified in mitochondria. **Target(s):** aldehyde oxidase (2,3); aromatase, *or* CYP19 (4); arylamine N-acetyltransferase (52); Ca<sup>2+</sup> currents, voltage-dependent L-type (5); cortisol sulfotransferase (6,7); estrone sulfotransferase, also alternative substrate (8); ethoxyresorufin O-deethylation (9); glucose-6-phosphate dehydrogenase, weakly inhibited (10-15); glucuronosyltransferase, substrate for UGT1A1 (16-20); glutamate dehydrogenase (21,22); hydroxyindole O-methyltransferase (23); 17 $\alpha$ -hydroxy-progesterone aldolase (24); 3(*or* 17) $\beta$ -hydroxysteroid dehydrogenase (25,26); 21-hydroxysteroid dehydrogenase (NAD<sup>+</sup>) (27-29); isocitrate dehydrogenase (10,11,13); 16-ketosteroid reductase (30); malate dehydrogenase (10,11); 6 phosphogluconate dehydrogenase (10,11,13); progesterone 5 $\alpha$ -reductase (31); protein-disulfide isomerase (32); ribosyldihydro-nicotinamide dehydrogenase, weakly inhibited (56); steroid  $\Delta$ -isomerase (33-39); steroid 16 $\alpha$ -monooxygenase (40); steroid 17 $\alpha$ -monooxygenase (41,53); steroid 21-monooxygenase (42); steroid sulfotransferase, also alternative substrate with substrate inhibition (43,44); sterol O-acyltransferase, *or* cholesteryl O-acyltransferase, *or* ACAT (45); sterol esterase, *or* cholesterol esterase (46); steryl-sulfatase (47-49); tyrosinase (50); tyrosine 3-monooxygenase, low concentrations of estradiol stimulate activity (54,55); xanthine oxidase (56). 1. #### Estriol

This membrane-permeant sterol (FW = 288.39 g/mol;  $\lambda_{\max}$  = 280 nm; Sparingly soluble in water; Soluble in chloroform, and dioxane), also called oestriol, 1,3,5-estratriene-3,16 $\alpha$ ,17 $\beta$ -triol, 1,3,5-oestratriene 3,16 $\alpha$ ,17 $\beta$ -triol, trihydroxyestrin, trihydroxyoestrin, and theelol, is the primary estrogen found in urine. It is a metabolite of 17 $\beta$ -estradiol and exhibits less biological activity (*i.e.*, it is a weak estrogen). **Target(s):** aldose 1-epimerase, *or* mutarotase (1); aromatase, *or* CYP19 (2); dihydropteridine reductase (3); estrone sulfotransferase (4); ethoxyresorufin O-deethylation (5); F<sub>0</sub>F<sub>1</sub> ATPase (6); glucose-6-phosphate dehydrogenase (7-10); glucuronosyltransferase (11); 3- $\beta$ -hydroxysteroid dehydrogenase (12); isocitrate dehydrogenase, weakly inhibited (7-9); 16-ketosteroid reductase (13); malate dehydrogenase, weakly inhibited (7,8); 6-phosphogluconate dehydrogenase (9); steroid  $\Delta$ -isomerase (14); sterol 14-demethylase, *or* CYP51, K<sub>i</sub> = 100  $\mu$ M (15,16); tyrosinase (17); xanthine oxidase (18). 1. **Estrone 3-(Bromoacetate)**

This membrane-permeant steroid haloester (FW = 391.30 g/mol), also known as 3-bromoacetoxyestrone, covalently modifies the active-site histidyl residue of human placental 17 $\beta$ ,20 $\alpha$ -hydroxysteroid dehydrogenase, or estradiol 17 $\beta$ -dehydrogenase, thereby inactivating the enzyme. 1. **Et-743**, See Ecteinascidin 743

**Etamicastat**

This novel dopamine- $\beta$ -hydroxylase inhibitor (FW<sub>free-base</sub> = 311.09 g/mol; CAS 760173-05-5), also named (*R*)-5-(2-aminoethyl)-1-(6,8-difluorochroman-3-yl)-1*H*-imidazole-2(3*H*)-thione hydrochloride, reduces both systolic and diastolic blood pressure (whether used alone or in combination with other antihypertensives) (1,2), decreases urinary excretion of noradrenaline in the spontaneously hypertensive rat with no change in heart rate (1-3), and lowers blood pressure in hypertensive patients (4). As a dopamine- $\beta$ -hydroxylase inhibitor, etamicastat decreases norepinephrine levels in sympathetically innervated tissues. 1. Igreja, Pires, Wright & Soares-da-Silva (2008) *Hypertension* **52**, E62. 2. Igreja, Pires Wright, &

**Etamycin**

This cyclic peptide lactone antibiotic (FW = 879.02 g/mol), also called viridogrisein, was isolated from marine strain of *Streptomyces griseus* on the coast of Fiji. It is active against Gram-positive bacteria, including *Mycobacterium tuberculosis*, and some fungi. Etamycin exerts its action by arresting protein biosynthesis. Recent studies indicate that etamycin displays favorable time-kill kinetics compared with the first-line MRSA antibiotic (vancomycin) and conferred significant protection from mortality in a murine model of systemic lethal MRSA infection (2). 1. Pestka (1974) *Meth. Enzymol.* **30**, 261. 2. Haste, Perera, Maloney, *et al.* (2010) *J. Antibiot. (Tokyo)* **63**, 219.

**Etazolote**

This anxiolytic drug (FW = 289.34 g/mol; CAS 51022-77-6), also known by the code names SQ-20009, EHT-0202, and systematically named ethyl 1-ethyl-4-[2-(propan-2-ylidene)hydrazinyl]-1*H*-pyrazolo[3,4-*b*]pyridine-5-carboxylate, is a positive allosteric modulator of the GABA<sub>A</sub> receptor at the barbiturate binding site (1-3), an adenosine A<sub>1</sub> and A<sub>2</sub> receptor antagonist (4), and a PDE isozyme-4-selective phosphodiesterase inhibitor (5,6). 1. Zezula, Slany & Sieghart (1996) *Eur. J. Pharmacol.* **301**, 207. 2. Remington & Baskys (1996) *Brain mechanisms and psychotropic drugs*. CRC Press, Boca Raton. 3. Mishina, Kurachi, Yoshihisa (2000) *Pharmacology of ionic channel function: activators and inhibitors*. Springer, Berlin. 4. Williams & Jarvis (1988) *Pharmacol. Biochem. Behav.* **29**, 433. 5. Chasin, Harris, Phillips & Hess (1972) *Biochem. Pharmacol.* **21**, 2443. 6. Wang, Myers, Wu, *et al.* (1997) *Biochem. Biophys. Res. Commun.* **234**, 320.

**ETC-1002**

This novel investigational drug ( $FW_{\text{free-acid}} = 344.49 \text{ g/mol}$ ; CAS 738606-46-7;  $FW_{\text{CoA-ester}} = 1110.00 \text{ g/mol}$ ), also known as 8-hydroxy-2,2,14,14-tetramethylpentadecanedioate and ESP55016, exhibits hypolipidemic, anti-atherosclerotic, anti-obesity, and glucose-lowering properties in preclinical disease models. ETC-1002 is a dual inhibitor of sterol and fatty acid synthesis and enhanced mitochondrial long-chain fatty acid  $\beta$ -oxidation. ETC-1002 works through two distinct mechanisms: (a) directly by ETC-1002 activation of AMP kinase pathway and (b) indirectly by ETC-1002 Coenzyme A thioester inhibition of hepatic ATP:citrate lyase (ACL). Pharmacological inhibition of ACL by (-)-hydroxycitrate is known to limit sterol and fatty acid synthesis, to upregulate LDL receptor activity, and to reduce plasma triglycerides and cholesterol levels. In HepG2 cells, ETC-1002 activates the AMPK pathway independent of energy depletion and calcium signaling. *In vivo*, ETC-1002<sub>free-acid</sub> is >100x more abundant than its CoA thioester in rat liver and is associated with AMPK activation. Rapid formation of ETC-1002-CoA and subsequent transient increases in citrate with concomitant reductions in acetyl-CoA, malonyl-CoA, and HMG-CoA in rat hepatocytes is consistent with ACL inhibition as well as dual inhibition of fatty acid and sterol synthesis. ETC-1002-CoA inhibits recombinant human ACL directly in a cell-free system. In seven Phase 1 and Phase 2a clinical studies, once daily dosing of ETC-1002 for 2-12 weeks has lowered LDL-C and reduced high-sensitivity C-reactive protein by up to 40%, with neutral to positive effects on glucose levels, blood pressure, and body weight (2). Importantly, use of ETC-1002 in statin-intolerant patients has shown statin-like lowering of LDL-C without the muscle pain and weakness responsible for discontinuation of statin use by many patients (2). 1. Pinkosky, Filippov, Srivastava, *et al.* (2013) *J. Lipid Res.* 54, 134. 2. Filippov, Pinkosky & Newton (2014) *Curr. Opin. Lipidol.* 25, 309.

### Eteplirsen

Sequence: C-T-C-C-A-A-C-A-T-C-A-A-G-G-A-A-G-A-T-G-C-A-T-T-T-C-T-A-G

This intravenously administered, morpholino phosphorodiamidate antisense oligomer ( $FW = 10305.74 \text{ g/mol}$ ; CAS 1173755-55-9), also named AVI-4658, EXONDYS-51<sup>®</sup>, and (*P*-deoxy-*P*-(dimethylamino)](2',3'-dideoxy-2',3'-imino-2',3'-seco)(2'a $\rightarrow$ 5')(C-m<sup>5</sup>U-C-C-A-A-C-A-m<sup>5</sup>U-C-A-A-G-G-A-A-G-A-m<sup>5</sup>U-G-G-C-A-m<sup>5</sup>U-m<sup>5</sup>U-m<sup>5</sup>U-C-m<sup>5</sup>U-A-G),5'-(*P*-4-((2-(2-hydroxy-ethoxy)ethoxy)ethoxy)carbonyl)-1-piperazinyl)-*N,N*-dimethylphosphonamide), is a systemic exon-skipping RNA drug for treating Duchenne Muscular Dystrophy (DMD). Eteplirsen triggers Exon-51 excision during pre-mRNA splicing of dystrophin RNA transcript, altering the downstream reading-frame of dystrophin. Administration of eteplirsen to a healthy person results in dystrophin mRNA production that does not lead to functional dystrophin protein. In DMD patients (characterized by the presence of certain frame-shifting mutations), however, eteplirsen restores the reading frame of the dystrophin mRNA, resulting in production of a novel internally deleted and therefore shorter dystrophin, attended by restoration of dystrophin-associated complex in a manner preserving functionality of the newly translated dystrophin (1). Eteplirsen-induced skipping of Exon-51 and restoration of dystrophin protein expression occurs in a dose-dependent, but variable, manner in DMD patients. In patients with Exon 51-amenable deletions (~13% of DMD patients), eteplirsen treatment produces a truncated in-frame dystrophin protein, similar to those found in Becker muscular dystrophy, a less severe dystrophinopathic condition (2). Exon skipping therefore appears to be a promising disease-modifying approach for DMD, restoring the open-reading frame and enabling production of functional dystrophin. Anthony *et al.* (3) described a standardized and reproducible method for assessing patient response to complement protein studies in preclinical and clinical exon skipping-based gene therapy studies for DMD. **Pharmacokinetics:** In male pediatric DMD patients, peak plasma concentration ( $C_{\text{max}}$ ) occurs at the end of single or multiple IV infusion, after which there is multi-phasic decay with most of the drug eliminated within 24 hours (4). Approximate dose-proportionality is observed for 0.5–50 mg/kg/week, where the latter equals 1.7x the recommended therapeutic dose. No significant accumulation occurs after

weekly dosing, and the inter-subject variability in  $C_{\text{max}}$  and AUC range from 20 to 55% (4). 1. Cirak, Feng, Anthony, *et al.* (2012) *Mol. Ther.* 20, 462. 2. ### Ethacrynic Acid

This diuretic agent ( $FW_{\text{free-acid}} = 303.14 \text{ g/mol}$ ;  $pK_a = 3.50$ ), also known as [2,3-dichloro-4-(2-methylene-1-oxobutyl)phenoxy]acetic acid, reacts with thiol groups and inhibits many cysteine-dependent enzymes. Note that aqueous solutions at pH 7 are only stable for short periods of time; this stability decreases in alkaline pH as well as at higher temperatures. Ethacrynic acid is also a slow alternative substrate for the drug-inactivating enzyme, glutathione *S*-transferase, with an  $IC_{50}$  in the low  $\mu\text{M}$  range. **Target(s):** acetoin dehydrogenase (1); adenylate cyclase (2); aldehyde reductase (3); aldo-keto reductase AKR7A5 (4); alkaline phosphatase (5); apyrase (6); asparagine synthetase (7); carbonyl reductase (8);  $\text{Ca}^{2+}$ -transporting ATPase (9); chloride-transporting ATPase (10-17); 3',5'-cyclic-nucleotide phosphodiesterase (18); DDT-dehydrochlorinase (19); glutathione *S*-transferase (19-27; with (27) suggesting ethacrynic acid is an allosteric inhibitor); glyceraldehyde 3-phosphate dehydrogenase (28); haloperidol reductase (29); hemoglobin S polymerization (30); histamine *N*-methyltransferase, moderately inhibited (59); histamine release (31); 11 $\beta$ -hydroxysteroid dehydrogenase (32); 15-hydroxyprostaglandin dehydrogenase (33-37); lactate dehydrogenase (38);  $\text{Na}^+$ -dependent ATPase, ouabain-insensitive (39,40);  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (41,42); 4-nitrophenyl-phosphatase activity of  $\text{Na}^+/\text{K}^+$ -exchanging ATPase (47); oxidative phosphorylation (48,50); phosphate transport (51); proline dehydrogenase, or proline oxidase (52); prostaglandin  $E_2$  9-reductase (34,36,37,53); protein biosynthesis (54); thiol *S*-methyltransferase (55); thiopurine *S*-methyltransferase (56); tubulin polymerization (microtubule self-assembly (57,58)). 1. ### Ethambutol

This antitubercular pharmaceutical (FW<sub>free-base</sub> = 204.31 g/mol; CAS 74-55-5), also known as 2,2'-(1,2-ethanediylidimino)bis-1-butanol and myambutol, inhibits arabinosyltransferases participating in arabinogalactan biosynthesis. It also exhibits ocular toxicity, with the optical nerve atrophy. **Target(s):** adenosylmethionine decarboxylase (1); arabinosyl-transferase and arabinogalactan biosynthesis (2-6); glucose-6-P dehydrogenase (7); glycerophosphate dehydrogenase (7); spermidine synthase (8,9). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** Paulin, Brander & Pösö (1987) *Experientia* **43**, 174. **2.** Rastogi, Goh & David (1990) *Antimicrob. ### Ethanol

This simple two-carbon alcohol CH<sub>3</sub>CH<sub>2</sub>OH (FW = 46.07 g/mol; CAS 64-17-5; Density: 0.789 g/cm<sup>3</sup> (at 25°C)) has numerous targets, including, but not limited to: the GABA<sub>A</sub> Receptor by acting as allosteric modulator; the Glycine Receptor by acting as positive and negative allosteric modulator; the NMDA Receptor by acting as negative allosteric modulator; the AMP<sub>A</sub> Receptor by acting as allosteric activator; the Kainate Receptor by acting as negative allosteric modulator; nicotinic Acetyl-Choline Receptors by acting both as positive and negative allosteric modulators; the Serotonin 5-HT<sub>3</sub> Receptor by acting as allosteric activator; the Glycine Reuptake System by acting as an inhibitor; the Adenosine Reuptake System by acting as an inhibitor; the L-type calcium channel by acting as blocker; and the G-protein-activated, inwardly rectifying K<sup>+</sup> (or GIRK) channel by acting as a channel opener. In humans, ethanol is rapidly absorbed through the stomach wall, such that ethanol consumption and the combined action of alcohol dehydrogenase (*Reaction:* CH<sub>3</sub>CH<sub>2</sub>OH + NAD<sup>+</sup> ⇌ CH<sub>3</sub>CHO + NADH) and acetaldehyde dehydrogenase (*Reaction:* CH<sub>3</sub>CHO + NAD<sup>+</sup> ⇌ CH<sub>3</sub>COO<sup>-</sup> + NADH) bring about an almost immediate drop in the [NAD<sup>+</sup>]/[NADH] ratio, both in the cytoplasm and mitochondria, that can persist for several

hours. The free cytoplasmic [NAD<sup>+</sup>]/[NADH] ratio in liver also decreases immediately after ethanol consumption, but eventually returns to control values. **A Word to Caution:** Ethanol inhibits too many enzymes to enumerate here, not to mention its indirect effects on those enzymes and metabolic processes sensitive to its immediate product, acetaldehyde. Ethanol also alters the [NAD<sup>+</sup>]/[NADH] ratio, thereby perturbing virtually the entirety of cellular energy metabolism. In view of the wide spectrum of ethanol targets, it is foolhardy to use ethanol as a vehicle for delivering inhibitors that are sparingly soluble in water. A better vehicle is 5-10% DMSO (vol/vol), with a drug-free sample serving as a control. Lest an unwary researcher overlook ethanol as a confounding variable in metabolic and pharmacologic experiments, ethanol use is discouraged, and solubilities of drugs in ethanol are rarely listed in this book.

### Ethanolamine

This naturally occurring β-amino-alcohol (FW<sub>free-base</sub> = 61.084 g/mol; pK<sub>a</sub> = 9.50 at 25°C; M.P. = 10.3°C; B.P. = 170.8°C), also known as 2-aminoethanol, is a key building block of several phospholipids. Ethanolamine is a product of the reactions catalyzed by alkylglycerol-phospho/ethanolamine phosphodiesterase and N-(long-chain-acyl)ethanolamine deacylase and is a substrate for ethanolamine oxidase, ethanolamine kinase, and ethanolamine ammonia-lyase. It is an alternative substrate for choline kinase. **Target(s):** acetylcholinesterase, very weakly inhibited (1,2); acetylenecarboxylate hydratase (3); alcohol dehydrogenase (4); alternansucrase (5); δ-aminolevulinic synthase (6,7); amylo-α-1,6-glucosidase/4-α-glucanotransferase, or glycogen debranching enzyme, weakly inhibited (8); carnosine synthetase (9); choline kinase (10-17); diaminopropionate ammonia-lyase (18); α-L-fucosidase (19); β-galactosidase (20); α-glucosidase (21); β glucuronidase (21); glutamate:ethylamine ligase, or theanine synthetase (22); glutaminy-peptide cyclotransferase (23); glycerophosphocholine phosphodiesterase (24); glycine/sarcosine N-methyltransferase (25); hydroxylysine kinase, weakly inhibited (26,27); mannosyl-oligosaccharide glucosidase, or glucosidase I (28); oligo-1,6-glucosidase, or isomaltase (29); phospholipase D (30); protein glutamine γ-glutamyltransferase, or transglutaminase; K<sub>i</sub> = 2.3 mM (31); D-serine ammonia-lyase, or D-serine dehydratase (32); L-serine ammonia-lyase, or L-serine dehydratase (33,34); sucrose α-glucosidase, or sucrase-isomaltase (29). **1.** Wilson (1952) *J. **Ethephon**

This haloalkylphosphonic acid (FW<sub>free-acid</sub> = 144.49 g/mol; CAS 16672-87-0), also known as 2-chloroethylphosphonic acid, Ethrel, and Cepha, is a synthetic plant growth regulator. Ethephon is taken up by crops, whereupon it slowly releases ethylene, the latter stimulating fruit ripening, growth, etc. It is currently registered in the U.S. for use on apples, barley, blackberries, bromeliads, cantaloupes, cherries, coffee, cotton, cucumbers, grapes, guava, macadamia nuts, ornamentals, peppers, pineapples, rye, squash, sugarcane, tobacco, tomatoes, walnuts, wheat, etc. In animals, ethephon inhibits the activity of plasma butyrylcholinesterase in humans, dogs, rats, and mice, phosphorylating the esteratic site (1-4). Ethephon inhibits human butyrylcholinesterase (BChE) by making a covalent adduct on the active site Ser-198. Recent studies suggest that, in aqueous media at neutral to slightly alkaline pH, ~3% of the ethephon is converted ( $t_{1/2}$  = 9.9 h at pH 7.0) into a cyclic oxaphosphatene, which is the actual BChE inhibitor that forms a 2-hydroxyethylphosphonate adduct on BChE at Ser-198. The other 97% of the ethephon breaks down ( $t_{1/2}$  = 11-48 h at pH 7.0) to form ethylene, which is responsible for plant growth regulation (4). Note: Aqueous solutions are stable below pH 3.5; hence, formulations are typically acidic. Hydrolysis and ethylene generation occur at higher pH above 4.1 (5,6). **Target(s):** butyrylcholinesterase, or cholinesterase (1-4); aminopeptidase B (7). 1. Haux, Lockridge & Casida (2002) *Chem. Res. Toxicol.* **15**, 1527. 2. Haux, Quistad & Casida (2000) *Chem. Res. Toxicol.* **13**, 646. 3. Hennighausen, Tiefenbach & Lohs (1977) *Pharmazie* **32**, 181. 4. **Ethionamide**

This antibiotic (FW = 166.24 g/mol; CAS 536-33-4; Symbol: ETA), also named 2-ethylpyridine-4-carbothioamide, Trecator<sup>®</sup>, and Trecator SC<sup>®</sup>, is active against *Mycobacter tuberculosis*, *M. bovis* and *M. smegmatis*. ETA is often used as part of a five-drug regimen to treat Multidrug-Resistant Tuberculosis, or MDR-TB, as well as Extensively Drug-Resistant Tuberculosis, or XDR-TB (See also *Isoniazid*). Ethionamide is a prodrug that is oxidized by EtaA, a FAD-containing enzyme, to the corresponding S-oxide. The latter is further oxidized by the same enzyme to 2-ethyl-4-amidopyridine, presumably via the unstable sulfinic acid intermediate. In this way, ETA inhibits the synthesis of mycolic acids, long-chain fatty acids required within the cell walls of *M. tuberculosis*, *M. bovis* and *M. smegmatis*. EtaA also oxidatively activates other thioamide antitubercular drugs (e.g., thiacetazone, thiobenzamide, and isothionicotinamide) most likely accounting for TB's known crossover resistance toward structurally related drugs. 1. Vannelli, Dykman & Ortiz de Montellano (2002) *J. Biol. Chem.* **277**, 12824.

**Ethionine**

This toxic and carcinogenic methionine analogue (FW = 163.24 g/mol), also known as S-ethylhomocysteine, is an alternative substrate for methionine S-adenosyltransferase. Ethionine toxicity is thought to arise by any or all of the following effects: (a) dead-end trapping of adenine nucleotide by ATP-dependent synthesis and over-accumulation of S-adenosyl-ethionine, which depresses synthesis of NAD<sup>+</sup>, proteins, and nucleic acids; (b) ethylation of RNA, DNA, or otherwise methylated low-molecular-weight metabolites, which, if ethylated, behave abnormally or compete with less abundant methylated metabolites; (c) ribosome-catalyzed incorporation of ethionine in place of methionine or isoleucine, leading to the formation of faulty proteins and/or enzymes; and (d) failure of cells to make cysteine from S-adenosyl-methionine. **Target(s):** O-acetylhomoserine aminocarboxypropyltransferase, or O-acetylhomoserine sulfhydrylase; inhibited by DL-ethionine (1,2); alkaline phosphatase, mildly inhibited by DL-ethionine (3); choline oxidase (4); homoserine O-acetyltransferase (5,6); methionine S-adenosyltransferase, also alternative substrate (7-10); methionine S-methyltransferase, weakly inhibited (11); methionyl-tRNA synthetase, also alternative substrate (12); protein biosynthesis (13-16); RNA biosynthesis (17); sarcosine oxidase (4); tRNA (adenine-N<sup>1</sup>-)-methyltransferase (18); tRNA (uracil-5-)-methyltransferase (19); tryptophanase, or tryptophan indole-lyase (20-23). 1. ### Ethopropazine

This anticholinergic and antiparkinsonian agent (FW<sub>free-base</sub> = 312.48 g/mol), also known as 10-(2 diethylaminopropyl)phenothiazine, inhibits butyrylcholinesterases (human  $K_i$  = 0.17  $\mu$ M), but not usually acetylcholinesterases. **1.** Wheeler, Coleman & Finean (1972) *Biochim. Biophys. Acta* **255**, 917. **2.** Martin (1981) *J. Comp. Neurol.* **197**, 153. **3.** Singh, Singh & Agarwal (1982) *J. ### Ethosuximide

This anticonvulsant agent (FW = 141.17 g/mol; CAS 77-67-8), also known as 3-ethyl-3-methyl-2,5-pyrrolidinedione, is used in the treatment of absence seizures, the brief epileptic seizures experienced in childhood and adolescence and characterized by sudden loss of awareness and a characteristic electroencephalogram. Ethosuximide inhibits NADPH-linked aldehyde reductase (1,2) needed to form  $\gamma$ -hydroxybutyrate, which has been associated with the induction of absence seizures. Ethosuximide also blocks T-type  $Ca^{2+}$  channels (3,4). **1.** Roig, Bello, Burguillo, Cachaza & Kennedy (1991) *J. Pharm. Sci.* **80**, 267. **2.** Erwin & Deitrich (1973) *Biochem. ### (R)-2-(4-Ethoxycarbonylamino benzenesulfonyl)-1,2,3,4-tetrahydroisoquinoline-3-carboxylic Acid Hydroxamate

This isoquinoline (FW = 419.45 g/mol) inhibits human neutrophil collagenase, or matrix metalloproteinase-8,  $IC_{50}$  = 30 nM. The 3-ethoxycarbonylamino analogue has an  $IC_{50}$  value of 300 nM. **1.** Matter, Schwab, Barbier, *et al.* (1999) *J. Med. Chem.* **42**, 1998.

### 2-Ethoxy-1-ethoxycarbonyl-1,2-dihydroquinoline

This *O*-substituted dihydroquinoline carbamate (FW = 247.29 g/mol; CAS 16357-59-8; Abbreviation: EEDQ) is a coupling reagent that reacts with carboxyl groups and is likewise an irreversible inhibitor of enzymes possessing catalytically essential carboxyl groups. When used as a carboxyl group-activating reagent in peptide synthesis, little or no racemization occurs. In its action as an enzyme-modifying reagent, transient formation of a mixed carbonic anhydride is indicated. The bulky dihydroquinoline moiety is apt to strongly influence the binding EEDQ to many proteins and enzymes. **Target(s):** acetylcholine receptor ionic channel (1);  $\alpha_2$ -adrenergic receptor (2); aminoacylase (3); arylformamidase (4); bacterial leucyl aminopeptidase (5);  $Ca^{2+}$  channel, voltage-sensitive (6);  $Ca^{2+}$ -transporting ATPase (7); choline uptake (8); coccolysin (9); cytochrome *bc*<sub>1</sub> complex proton pump, mitochondrial (10); D<sub>1</sub> and D<sub>2</sub> dopamine receptors (11,12); F<sub>1</sub> ATPase (13-18); glucose transporter (19);  $\beta$ -glucosidase (20); H<sup>+</sup>-exporting ATPase (21); histamine receptor (22); H<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (23-25); D- $\beta$ -hydroxybutyrate dehydrogenase (26); lysolecithin:lysolecithin acyltransferase, hydrolysis inhibited at pH 5 (27); membrane dipeptidase (renal dipeptidase; dehydropeptidase I (28); Na<sup>+</sup> channels (29); Na<sup>+</sup>/H<sup>+</sup>-antiporter (30); nicotinamide-nucleotide transhydrogenase (31-33); 5'-nucleotidase (34); penicillin acylase (35); prolyl aminopeptidase (36); serotonin receptor (37-39); TF<sub>1</sub> ATPase (40); thiamin-binding protein (41); tuna (*Thunnus albacares*) pyloric caeca aminopeptidase (42); UDP-glucose pyrophosphorylase, or glucose-1-phosphate uridylyltransferase (43). **1.** Eldefrawi, Eldefrawi, Mansour, *et al.* (1978) *Biochemistry* **17**, 5474. **2.** Adler, Meller & Goldstein (1985) *Eur. **4-N-(4-Ethoxyphenyl)amino-5-phenyl-7-(β-D-erythro-furanosyl)pyrrolo[2,3-d]pyrimidine**

This tubercidin analogue (FW = 417.49 g/mol) inhibits human adenosine kinase (IC<sub>50</sub> = 3 nM). Because the use of adenosine receptor agonists is plagued by dose-limiting cardiovascular side effects, there is great interest in developing adenosine kinase inhibitors (AKIs) as a means for raising steady-state adenosine concentrations. The 3-ethoxyphenyl analogue also inhibits (IC<sub>50</sub> = 2 nM). 1. Boyer, Ugarkar, Solbach, *et al.* (2005) *J. Med. Chem.* **48**, 6430.

**Ethoxzolamide**

This diuretic (FW = 258.32 g/mol; CAS 452-35-7), also named 6-ethoxy-1,3-benzothiazole-2-sulfonamide, inhibits human carbonic anhydrases I and II, both with K<sub>i</sub> values near 0.3 nM. Ethoxzolamide also inhibits carbonic anhydrase activity in kidney proximal tubules, decreasing reabsorption of water, sodium, potassium, and bicarbonate. It also decreases carbonic anhydrase in the CNS, increasing the seizure threshold in epilepsy. Ethoxzolamide is used to treat glaucoma and duodenal ulcers. **Target(s):** Ca<sup>2+</sup> channels, high-voltage activated voltage-sensitive, encoded by the human α<sub>1E</sub> subunit (1); carbonic anhydrase (2-18). 1. **N<sup>o</sup>-Ethyl-L-arginine**

This arginine derivative (FW = 202.26 g/mol) inhibits nitric oxide synthase, with IC<sub>50</sub> values of 17.8, 42.8, and 12.2 μM for neuronal, inducible, and endothelial enzymes (1-3) and amino acid transporter γ<sup>+</sup> (4). 1. Griffith &

Kilbourn (1996) *Meth. Enzymol.* **268**, 375. 2. Griffith & Stuehr (1995) *Ann. Rev. Physiol.* **57**, 707. 3. Babu, Frey & Griffith (1999) *J. Biol. Chem.* **274**, 25218. 4. McDonald, Rouhani, Handlogten, *et al.* (1997) *Biochim. Biophys. Acta* **1324**, 133.

**2-Ethylcaproic Acid**

This carboxylic acid (FW<sub>free-acid</sub> = 144.21 g/mol), also known as 2-ethylhexanoic acid, is an industrial chemical and a toxic biotransformation product of the widely-used plasticizer, di(2-ethyl-hexyl)-phthalate. 2-Ethylcaproate inhibits acetyl-CoA carboxylase (1), aldehyde reductase (NADPH) (2), kynurenine aminotransferase (3), and UDP-glucuronosyltransferase (4). 1. Sumida, Kaneko & Yoshitake (1996) *Chemosphere* **33**, 2201. 2. De Jongh, Schofield & Edwards (1987) *Biochem. J.* **242**, 143. 3. Mason (1959) *J. Biol. Chem.* **234**, 2770. 4. Dutton & Storey (1962) *Meth. Enzymol.* **5**, 159.

**Ethylene**

This plant ripening gas (FW = 28.054 g/mol; M.P. = -181 °C; B.P. = -102.4 °C at 700 mm Hg), also known as ethene and fruit-ripening hormone, occurs widely in plants, where it initiates flower opening, accelerates fruit maturation, and promotes leaf abscission. It is produced from essentially all parts of higher plants, including leaves, stems, roots, flowers, fruits, tubers, and seeds. Ethylene also inhibits the biosynthesis of some auxins. The earliest report on the effects of ethylene was in 1901, when it was observed that the gas caused a loss in geotropism and inhibited epicotyl elongation in dark-grown pea seedlings (1). In 1943, it was shown that plants synthesized ethylene and used it to initiate ripening (2). Ethylene is a product of the reaction catalyzed by aminocyclopropanecarboxylate oxidase. Such details underscore the cynicism of plant scientists about the erroneous impression that nitric oxide was the first metabolic signaling gas. Synthetic ethylene-liberating agents (**See Ethephon**) induce fruit ripening, flowering, root initiation, cell expansion, seed germination, control of stress responses, leaf abscission, *etc.* **Target(s):** cytochrome P450 (3); polar auxin transport (4). 1. Neljubow (1901) *Beih. Bot. Zentralbl.* **10**, 128. 2. Gane (1934) *Nature* **134**, 1008. 3. Ator & Ortiz de Montellano (1990) *The Enzymes*, 3rd ed., **19**, 213. 4. Burg & Burg (1967) *Plant Physiol.* **42**, 1224.

**Ethylene Dibromide**

This toxic dihaloalkane (FW = 187.86 g/mol; CAS 106-93-4; *Symbol*: EDB), also known as 1,2-dibromoethane, is a common intermediate in organic synthesis and industrial chemical. Once used as an anti-knocking additive for internal combustion engines in automotive and jets, EDB is still employed in the third world as an insecticide and fumigant in wheat, flour, bran, middlings, and bread. **CAUTION:** Human LD<sub>50</sub> = 90 mg/kg. Dibromoethane is also a demonstrated mutagen and carcinogen (1), meriting caution when used in the laboratory. Glutathione (GSH) reacts with EDB, and the resulting S-ethylbromide derivative participates in (GSH)-dependent base-substitution mutations (especially GC-to-AT transitions) in a variety of bacterial and eukaryotic systems. Known DNA adducts include: S-[2-(N<sup>7</sup>-guanyl)ethyl]GSH, S-[2-(N<sup>2</sup>-guanyl)ethyl]GSH, and I-[2-(O<sup>6</sup>-guanyl)ethyl]GSH. These modifications resist DNA repair (2), thereby hampering the action of DNA polymerases (3). 1. Fishbein (1976) *Environ. Health Perspect.* **14**, 39. 2. Nachtoml & Sarma (1977) *Biochem. Pharmacol.* **26**, 1941. 3. Kim & Guengerich (1998) *Chem. Res. Toxicol.* **11**, 311.

**4-*N*-(3,4-Ethylenedioxyphenyl)amino-5-(2-methylphenyl)-7-(β-D-erythro-furanosyl)-pyrrolo[2,3-*d*]pyrimidine**

This tubercidin analogue (FW = 460.49 g/mol) inhibits human adenosine kinase (IC<sub>50</sub> = 1 nM). Because the use of adenosine receptor agonists is plagued by dose-limiting cardiovascular side effects, there is great interest in developing adenosine kinase inhibitors (AKIs) as a means for raising steady-state levels of adenosine. **1.** Boyer, Ugarkar, Solbach, *et al.* (2005) *J. Med. Chem.* **48**, 6430.

**Ethylene Glycol**

This poisonous dihydroxyalkane HO-CH<sub>2</sub>CH<sub>2</sub>-OH (FW = 62.07 g/mol; CAS 107-21-1; density = 1.11 g/cm<sup>3</sup>; miscible with H<sub>2</sub>O; soluble in polar organic solvents), also named ethane-1,2-diol, is used in the synthesis of polyester fibers and polyethylene terephthalate, and a common radiator antifreeze additive. Ethylene glycol uses water or glycerol channels to gain entry into many cell types. **Toxicity:** Ethylene glycol's sweet taste puts children and unwary animals at risk, because it is readily oxidized to oxalate, a toxic metabolite (oral LD<sub>50</sub> = 0.8 g/kg in humans). **See Oxalate (or Oxalic Acid)**

**Ethylenimine**

This poisonous cyclic amine (FW = 43.07 g/mol; Polymerizes easily), also known as aziridine, reacts with sulfhydryl group(s) in proteins under slightly alkaline conditions, producing *S*-(2-aminoethyl)-cysteiny residue(s). The latter is a structural analogue of a lysyl residue, in which the γ-methylene group has been replaced with sulfur (1). This derivatized cysteinyl residue is also susceptible to trypsin cleavage. If the cysteinyl residue was critical for catalysis, modification by ethylenimine will result in enzyme inactivation. Under acidic conditions, methionyl residues react slowly with ethylenimine to form the corresponding sulfonium ions. **Target(s):** choline *O*-acetyltransferase (2); histidinol-phosphatase (3); lysozyme (4). **1.** Raftery & Cole (1963) *Biochem. Biophys. Res. Comm.* **10**, 467. **2.** Roskoski (1974) *J. Biol. Chem.* **249**, 2156. **3.** Houston & Millay (1974) *Biochim. Biophys. Acta* **370**, 216. **4.** Yamada, Imoto & Noshita (1982) *Biochemistry* **21**, 2187.

**Ethylguanidine**

This hygroscopic alkyl guanidine (FW<sub>hydrochloride</sub> = 123.59 g/mol) inhibits clostripain (an enzyme from *Clostridium histolyticum* that cleaves proteins on the carboxyl peptide bond of arginine) and other arginine-dependent enzymes. **Target(s):** acetylcholine-induced currents (1,2); arginine deaminase (3); arginine kinase (4); clostripain (5,6); 5-guanidino-2-oxopentanoate decarboxylase (7); lipase (8); trypsin (6,9). **1.** Farley & Narahashi (1983) *J. Physiol.* **337**, 753. **2.** Farley, Vogel & Narahashi (1986) *Pflugers Arch.* **406**, 629. **3.** Smith, Ganaway & Fahrney (1978) *J. Biol. Chem.* **253**, 6016. **4.** Pereira, Alonso, Paveto, *et al.* (2000) *J. Biol.*

**2-Ethylhexyl Phthalate**

This monoester (FW<sub>free-acid</sub> = 278.35 g/mol), also known as mono(2-ethylhexyl) phthalate, is a common metabolite of bis(2-ethylhexyl) phthalate, a widely-used plasticizer in the plastic industry. Blood products stored in polyvinyl chloride bags often contain this diester, from which the monoester can be produced via action of a plasma enzyme. **Target(s):** aminocarboxymuconate-semialdehyde decarboxylase (1); phospholipase A<sub>2</sub> (2). **1.** Fukuwatari, Ohsaki, Fukuoka, Sasaki & Shibata (2004) *Toxicol. Sci.* **81**, 302. **2.** Labow, Meek, Adams & Rock (1988) *Environ. Health Perspect.* **78**, 179.

**2-([3-[(7-Ethyl-5-iodo-1,2,3,4-tetrahydroquinolin-4-yl)amino]propyl]amino)-thieno[3,2-*d*]pyrimidin-4(1*H*)-one**

This substituted thienopyrimidinone (FW = 523.44 g/mol) inhibits methionyl-tRNA synthetase, with IC<sub>50</sub> < 3 nM for the *Staphylococcus aureus* enzyme. **1.** Jarvest, Armstrong, Berge, *et al.* (2004) *Bioorg. Med. Chem. Lett.* **14**, 3937.

**S-Ethylisothiuronium diethylphosphate**

This antihypotensive drug (FW = 258.28 g/mol; CAS 21704-46-1), also known by the trade name Difetur<sup>®</sup>, is a specific inhibitor of inducible NO synthase that can be used to treat acute hypotension resulting from shock or hemorrhage. *S*-Ethylisothiuronium diethylphosphate is also used for the treatment of headaches, mainly migraines.

**Ethylnitrosourea**

This powerful mutagen (FW = 117.11 g/mol; CAS 759-73-9; *Abbreviation:* ENU), also known as 1-ethyl-1-nitrosourea, is a cell cycle-independent DNA alkylating agent that interferes with replication and transcription. **(See**

*Nitrosourea*) In a landmark study on chemically induced mutagenesis, Russell et al. (1) demonstrated that fractionating a single ethylnitrosourea dose from 100 mg/kg body weight into a series of doses of 10 mg/kg injected intraperitoneally given at weekly intervals greatly reduces the mutation frequency. Moreover, because there is independent evidence that the doses of 10 and 100 mg/kg reach the germ cells in amounts directly proportional to the injected dose, the lower mutational response with the fractionated dose is attributed to repair. The mutation frequency was twelve times greater than that induced by high-dose X-radiation and thirty-six times that of procarbazine, another power mutagen. For a given gene in mice, ENU induces one new mutation in every seven hundred loci. Given such a high level of mutagenicity, ethylnitrosourea is not used as an anticancer drug. That said, ENU remains a versatile mechanistic probe in mouse molecular genetics (2,3). 1. Russell, Hunsicker, Carpenter, Cornett & Guinn (1982) *Proc. Natl. Acad. Sci. U.S.A.* **79**, 3592. 2. ### Ethyl Protocatechuate

This plant antioxidant (FW = 182.17 g/mol; CAS 3943-89-3), also named ethyl 3,4-dihydroxybenzoate (EDHB), inhibits procollagen-proline dioxygenase, or 4-prolyl hydroxylase (*Reaction*: Procollagen-L-proline + 2-Oxoglutarate (or  $\alpha$ -Ketoglutarate) + O<sub>2</sub> → Procollagen-(2S,4R)-4-hydroxyproline + Succinate + CO<sub>2</sub>), the collagen-processing enzyme that requires vitamin C as an anti-scurvy factor. As a structural analogue of  $\alpha$ -ketoglutarate and ascorbate, EDHB markedly inhibits ( $K_i = 0.4$  mM) the synthesis of 4-hydroxyproline in normal cell cultures, markedly reducing the synthesis and secretion of Type I and Type III procollagens (1). Control experiments indicate that the test compound does not affect the viability, proliferation, or plating efficiency of the cells, and it has little, if any, effect on the synthesis of noncollagenous proteins. Although a weaker Fe(III) chelator than desferrioxamine (See *Deferiprone*; *Desferrioxamine B*; *Ferrioxamines*), EDHB promotes iron deficiency when applied to cultured cells (2). EDHB triggers the activation of IRP1, a bifunctional iron-responsive element (IRE)-binding protein that controls iron metabolism by binding mRNA and repressing translation or degradation. EDHB modulates the coordinate expression of downstream IRP1 targets, such as the transferrin receptor and ferritin. Notably, EDHB has little, if any, effect on the hydroxylation of lysyl residues, and it does not affect total protein synthesis or DNA replication in these cells (3). EDHB also protects the myocardium by activating NOS and generating mitochondrial reactive oxygen species, or ROS (4). EDHB increases ROS generation by 50-75% in isolated rabbit cardiomyocytes. That this effect is mediated by NO is indicated by the inhibition by the NO synthase inhibitor N<sup>ω</sup>-nitro-L-arginine methyl ester (or L-NAME), the guanlyl cyclase antagonist ODQ; and the Protein Kinase G blocker Rp-8-bromoguanosine-3',5'-cyclic phosphorothioate (4). Use of flow cytometry analysis demonstrated that ethyl-3,4-dihydroxybenzoate induces cell accumulation in S-phase, loss in mitochondrial membrane permeabilization, as well as caspase-dependent apoptosis (5). An expression profile analysis identified forty-six up-regulated and nine down-regulated genes in EDHB-treated esophageal cancer KYSE 170 cells, and these differentially expressed genes operate in several signaling pathways associated with cell cycle regulation and cellular metabolism (5). EDHB treatment also increases the protein levels of the hypoxia-induced protein (Hif-1 $\alpha$ ), the BCL2/adenovirus protein-interacting protein-3 (BNIP3), mammalian ortholog of *C. elegans* BEC-1 (Beclin), and N-myc Down-Regulated Gene-1 protein (NDRG1). **Other Target(s)**: Because prolyl hydroxylase acts on proteins containing Xaa-Pro-Gly tripeptide motifs, it hydroxylates prolyl residues in other proteins (e.g., C1q, elastins, prion protein, argonaute-2, and several conotoxins). For this reason, in the absence of additional evidence, one cannot unambiguously define an effect of EDHB as the consequence of its inhibitory effects on

collagen processing. 1. Sasaki, Majamaa & Uitto (1987) *J. Biol. Chem.* **262**, 9397. 2. Wang, Buss, Chen, Ponka & Pantopoulos (2002) *FEBS Lett.* **529**, 309. 3. Majamaa, Sasaki & Uitto (1987) *J. ### S-Ethyl-N-(4-[trifluoromethyl]phenyl)isothiurea

This reagent (FW<sub>free-base</sub> = 248.27 g/mol), also called ETPI and TFPI, inhibits endothelial nitric oxide synthase (IC<sub>50</sub> = 9.4  $\mu$ M), brain NOS (IC<sub>50</sub> = 0.32  $\mu$ M), and inducible NOS (IC<sub>50</sub> = 37  $\mu$ M (1,2)). 1. Shearer, Lee, Oplinger, et al. (1997) *J. Med. Chem.* **40**, 1901. 2. Cooper, Mialkowski & Wolff (2000) *Arch. Biochem. Biophys.*

### 3'-Ethylnyl-Cytosine

This novel synthetic cytosine nucleoside (FW = 267.24 g/mol), also known as TAS-106, Ecyd, and 1-(3-C-ethynyl- $\beta$ -D-ribo-pento-furanosyl)-cytosine, inhibits RNA polymerases I, II and III. When tested *in vivo*, TAS-106 alone showed significant antitumor activity that was enhanced, when used in combination with cisplatin to inhibit the growth of several tumor xenografts (1,2). In a panel of six nasopharyngeal cancer (NPC) cell lines, ECyd effectively inhibited cellular proliferation, with IC<sub>50</sub> values of 13 to 44 nM (3). (Cisplatin-resistant NPC cells were highly sensitive to ECyd, again in the low-nM range.) ECyd-mediated tumor growth inhibition is associated with G<sub>2</sub>/M cell cycle arrest, PARP cleavage (a hallmark of apoptosis) and Bcl-2 downregulation. ECyd also significantly downregulates fructose-2,6-bisphosphatase (EC 3.1.3.46) (also known as p53 Tumor-suppressor protein- (TP53-) Induced Glycolysis and Apoptosis Regulator (TIGAR)), thereby lowering fructose-2,6-bisphosphate in ECyd-treated cells. Notably, ECyd-downregulation of TIGAR was also accompanied by marked depletion of NADPH, the major reducing agent that is critically required for cell proliferation and survival (2). Cell lines showing a high degree of cross-resistance to ECyd and EUrD have deletions in the gene for uridine/cytosine kinase-2, or UCK2, suggesting that the latter is responsible for the phosphorylation and activation of 3'-ethynyl nucleoside pro-drugs (3). 1. ### 5-Ethynyl-2'-deoxyuridine

This thymidine analogue (FW = 252.23 g/mol; CAS 61135-33-9; IUPAC Name: 5-ethynyl-1-[(2R,4S,5R)-4-hydroxy-5-(hydroxymethyl)oxolan-2-yl]pyrimidine-2,4-dione; Symbol: EdU), which is readily taken up by living cells, is subsequently converted to EdUTP (5-ethynyl-2'-deoxyuridine 5'-triphosphate). The latter is then incorporated into cellular DNA (and

mitochondrial DNA) during replication. Incorporated EdU can be visualized via "click" chemistry using fluorescent azides in a Cu(I)-catalyzed [3 + 2] cycloaddition (1-3).

The resulting triazole ring is formed by stable covalent coupling to an Alexa Fluor®-conjugated azide group, affording a means for localizing subcellular sites of EdU incorporation. This detection method, which is highly sensitive and much faster than BrdU detection, enjoys the advantage that the required low-molecular-weight reagents have a much higher diffusivity and far greater penetration of tissue specimens, allowing for rapid, whole-mount staining of tissue and organ fragments. Moreover, because reaction with fluorescent azide probes does not require denaturation of the specimen, this method affords structural preservation that is suitable for high-resolution microscopic analysis *in vivo* of DNA repair, replication, recombination, and sister chromatid cohesion (1). Although EdU induces cell-cycle arrest at the G2/M interface in several breast cancer cell lines, and although it also specifically causes necrotic cell death, when used as a short pulse EdU at concentration that are only 1/200<sup>th</sup> the standard concentration of BrdU, such effects can largely be avoided (4). While EdU is employed as a replication marker more frequently than 5-ethynyl-2'-deoxycytidine (EdC), its cytotoxicity is commonly much higher than the toxicity of EdC (5). DNA analysis EdC-treated human cell lines showed that, while of all the cell lines contained EdU, none contained a detectable EdC in their DNA. The extent of EdC-related cytotoxicity was instead directly proportional to the content of EdU (6). Such effects can be explained by findings (a) EdC is a substrate for cytidine deaminase, thereby forming EdU, (b) EdC deamination *per se* does not prevent the conversion of EdC to EdCTP, the DNA polymerase substrate, and (c) EdCTP is not effectively recognized by the replication complex as a substrate for synthesis of nuclear DNA (5). **See Thymidine; 5-Bromo-2'-deoxyuridine (BrdU), 5-Ethynyluracil** 1. ### 17 $\alpha$ -Ethinylestradiol

This synthetic estrogen (FW = 296.41 g/mol), also known as 17 $\alpha$ -ethinylestradiol and 19-nor-17 $\alpha$ -pregna 1,3,5(10)-trien-20-yne-3,17 $\beta$ -diol, is a component of oral contraceptives. **Target(s):** aldehyde oxidase (1); CYP3A4 (2,3); CYP3A27 (4); CYP2B1 (5,6); CYP2C8 (7); 3 $\beta$ -hydroxysteroid dehydrogenase (8); 17 $\beta$ -hydroxysteroid dehydrogenase (9); kynurenine aminotransferase (10); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (11); steroid  $\Delta$ -isomerase (12); steroid 16 $\alpha$ -monooxygenase (13,14); thymidine 5'-monophosphate kinase (15); tryptophan 2,3-dioxygenase (16). 1. ### 5-Ethynyluracil

This substituted pyrimidine (FW = 136.11 g/mol) inactivates dihydropyrimidine dehydrogenase, initially forming a reversible complex ( $K_i = 1.6 \mu\text{M}$ ), followed by inactivation ( $k_{\text{inact}} = 20 \text{ min}^{-1}$ ). It will also inactivate thymine dioxygenase ( $K_i = 22 \mu\text{M}$ ;  $k_{\text{inact}} = 2.6 \text{ min}^{-1}$ ). Cell lines showing a high degree of cross-resistance to ECyd and EUrd have deletions in the gene for uridine/cytosine kinase-2, or UCK2, suggesting that the latter is responsible for the phosphorylation and activation of 3'-ethynyl nucleoside pro-drugs (1). **Target(s):** dihydropyrimidine dehydrogenase (2-4); thymine dioxygenase, or thymine 7-hydroxylase (5,6); xanthine oxidase (7). 1. ### Etidronate (Etidronic Acid)

This bone-seeking pyrophosphate analogue (FW = 204.01 g/mol; Very soluble in water; pK<sub>a</sub> values of 1.35, 2.87, 7.03, and 11.3), also known as 1,1-bis(phosphono)ethanol, ethane-1-hydroxy-1,1-diphosphonate, and (1-hydroxyethylidene)bisphosphonate, inhibits bone resorption in tissue culture and in experimental animals and chelates metal ions. Etidronate is an oral and intravenously active drug that is used in the management of resorptive bone disease, treatment of Paget's disease, the prevention of heterotopic ossification, and in postmenopausal osteoporosis. By binding to bone surfaces, etidronate is readily absorbed by osteoclasts, with consequential inhibition of geranyltransferase and vacuolar H<sup>+</sup>-transporting ATPase (or V-ATPase) as well as retraction of bone-resorbing osteoclast podosomes. **Target(s):** adenosine kinase (1); exopolyphosphatase (2); geranyltransferase, or farnesyl diphosphate synthase (3,4); H<sup>+</sup>-transporting ATPase, vacuolar, weakly inhibited (5); H<sup>+</sup>-transporting pyrophosphatase, vacuolar (6); 3-phosphoglycerate kinase (7); pyrophosphatase (6,8-10); pyrophosphate-dependent phosphofructokinase (11,12); pyruvate, orthophosphate dikinase (13); ribokinase (14). 1. #### Etodolac

This nonsteroidal anti-inflammatory drug, or NSAID (FW = 287.35 g/mol; CAS 41340-25-4), also named (*RS*)-2-(1,8-diethyl-4,9-dihydro-3*H*-pyrano[3,4-*b*]indol-1-yl)acetic acid, preferentially inhibits cyclooxygenase-2 and is widely used in the management of pain in patients with inflammatory arthritis. The apparent elimination half-life is 7 hours in man. Etodolac was extensively bound to serum proteins. Liver microsomal cytochrome P-450 levels were unaltered in rats given etodolac daily for 1 week. **1.** Cayen, Kraml, Ferdinandi, Greselin & Dvornik (1981) *Drug Metab. Rev.* **12**, 339.

#### Etomoxir

This photosensitive epoxide (FW<sub>free-acid</sub> = 298.77 g/mol; CAS 1049724-28-8), also known as B827-33, is an irreversible inhibitor of carnitine *O*-octanoyltransferase (1) and carnitine *O*-palmitoyltransferase (2-4). Inhibition of fatty acid  $\beta$ -oxidation by etomoxir impairs NADPH production and increases reactive oxygen species resulting in ATP depletion and cell death in human glioblastoma cells (5). In human glioblastoma SF188 cells, Etomoxir inhibition of fatty acid  $\beta$ -oxidation markedly reduces cellular ATP levels and viability (5). Etomoxir inhibition of fatty acid oxidation reduces the NADPH level. In the presence of reactive oxygen species scavenger tiron, however, ATP depletion is prevented without restoring fatty acid oxidation. Such findings suggest oxidative stress may lead to bioenergetic failure and cell death (5). **1.** Hegardt, Bach, Asins, *et al.* (2001) *Biochem. Soc. Trans.* **29**, 316. **2.** Gerondaes, Alberti & Agius (1988) *Biochem. J.* **253**, 169. **3.** Kuhajda & Ronnett (2007) *Curr. Opin. Invest. Acta.* **1807**, 726.

#### EtomoxiryI-CoA

This reactive acyl-coenzyme thiolester (FW = 1036.28g/mol), also known as 2-[6-(4-chlorophenoxy)hexyl]oxirane-2-acyl-CoA and B827 33-CoA, inhibits carnitine *O*-octanoyltransferase, or medium-chain carnitine acyltransferase (1-3) and carnitine *O*-palmitoyltransferase, or long-chain carnitine acyltransferase (1,4-6). **1.** Lilly, Chung, Kerner, VanRenterghem & Bieber (1992) *Biochem. #### Etoposide

This podophyllotoxin derivative (FW = 588.57 g/mol; CAS 33419-42-0), also known as VP-16-213, is an antineoplastic agent that acts as a DNA topoisomerase II inhibitor (IC<sub>50</sub> = 60  $\mu$ M). It has major activity against a number of tumors, including germ cell neoplasms, small cell lung cancer, and malignant lymphoma. It induces apoptosis in mouse thymocytes and in HL-60 human leukemia cells. Etoposide forms a complex with DNA topoisomerases II and enhances strand cleavage and inhibits religation. **Target(s):** DNA topoisomerase II (1-15); P-glycoprotein (16); quinone 3-monooxygenase (17); xenobiotic-transporting ATPase, multidrug-resistance protein (16). **1.** DeLange, Carpenter, Choy & Newsway (1995) *J. #### ETP-46464

This potent and selective inhibitor (FW = 470.52 g/mol; CAS 1345675-02-6; Solubility = 6 mg/mL DMSO), also known as  $\alpha,\alpha$ -dimethyl-4-[2-oxo-9-(3-quinolinyl)-2*H*-[1,3]oxazino[5,4-*c*]quinolin-1(4*H*)-yl]benzeneacetonitrile and NVP-BEZ235, selectively targets the ataxia telangiectasia and Rad3-related protein, or ATR (IC<sub>50</sub> = 25 nM), a serine/threonine-specific protein kinase involved in sensing DNA damage and activating the DNA-damage checkpoint, resulting to cell cycle arrest. **1.** Toledo, Murga, Zur, *et al.* (2011) *Nature Struct. Mol. Biol.* **18**, 721.

## Etravirin

This non-nucleoside reverse transcriptase inhibitor, or NNRTI (FW = 435.28 g/mol; CAS 269055-15-4; Solubility: 42 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O), also known by its code name TMC125 and its systematic chemical name 4-[[6-amino-5-bromo-2-[(4-cyanophenyl)amino]-4-pyrimidinyl]oxy]-3,5-dimethylbenzonitrile, is used in the treatment of HIV-AIDS. **Mode of Inhibitory Action:** Structural studies showed that etravirine can bind in at least two conformationally distinct modes, allowing torsional flexibility, or "wiggling", as well as significant repositioning and translation and rotation reorientation within the pocket, or "jiggling" (1). Such binding site adaptations appear to be critical for its potency against wild-type reverse transcriptase and a wide range of its drug-resistant mutant HIV-1 RTs (1). Etravirine is highly active against wild type HIV-1 (EC<sub>50</sub> = 1.4 to 4.8 nM) and showed some activity against HIV-2 (EC<sub>50</sub> = 3.5 μM) (2). It also inhibited a series of HIV-1 Group-M subtypes and circulating recombinant forms and a Group-O virus. Incubation of etravirine with human liver microsomal fractions suggested good metabolic stability, with only a 15% decrease in drug concentration and a 7% decrease in antiviral activity after 2 hours (2). 1. Das, Clark, Lewi, *et al.* (2004) *J. Med. Chem.* **47**, 2550. 2. Andries, Azijn, Thielemans, *et al.* (2004) *Antimicrob. Agents Chemother.* **48**, 4680.

## Everolimus

This orally available 40-*O*-(2-hydroxyethyl)-rapamycin derivative (FW = 958.22 g/mol; CAS 159351-69-6), marketed under the code name RAD001 and tradenames Zortress<sup>®</sup>, Certican<sup>®</sup> and Afinitor<sup>®</sup>, is an allosteric mTORC1-specific inhibitor that and is an immunosuppressant used to prevent rejection of organ transplants and to treat renal cell cancer and other tumors. It is also an approved treatment for estrogen receptor-positive (ER<sup>+</sup>) breast cancer. The mTOR pathway regulates translation, and mTOR inhibitors impair synthesis of proteins encoded by mRNAs that contain a 5'-terminal oligopyrimidine tract (5'-TOP). Everolimus is a potent mTOR inhibitor of FKBP12 (IC<sub>50</sub> = 1.6-2.4 nM), with action that is comparable to

that of rapamycin (See *Rapamycin and FK506*). It suppresses hypoxia-induced increases in Hypoxia Inducible Factor-1α (HIF-1α), inhibiting VEGF stimulation of vascular endothelial cells, thereby blocking tumor-induced neovascularization. At a molecular level, everolimus binds to FKBP12, and the resulting complex blocks the activation of the TOR complex 1 complex, a cycle-specific kinase that activates p70 ribosomal S6 kinase (or p70S6k). Inhibition of the mTOR pathway prevents progression of the cell cycle from G<sub>1</sub> into the S phase, thereby suppressing interleukin-driven T-cell differentiation. Inactivation of the p70S6k in lymphocytes selectively inhibits ribosomal protein synthesis, thereby deactivating the immune response (4). mTOR plays an important role in several physiological processes, such that inhibition by everolimus also leads to various downstream consequences via an effect on nonimmune cells such as vascular smooth muscle cells, tubular epithelial cells, and fibroblasts (4). Everolimus also strongly inhibits proliferation of T cell lymphoma (TCL) cell lines, blocking phosphorylation of ribosomal S6, a raptor/mTORC1 target, without a compensatory activation of the rictor/mTORC2 target Akt (S475) (5). Mounting evidence suggests S6K1 signaling may be important for proliferation of ER-positive breast cancer cells. S6K1 controls proliferation by direct phosphorylation of ERα at Ser167, increasing ERα transcriptional activity as well as ER-dependent breast cancer cell proliferation. P-S6K1 is a marker of S6K1 activation that correlates with a poorer prognosis in patients with ER-positive, but not ER-negative, tumors. In a Phase II trial, 16 patients with relapsed TCL received everolimus (10 mg PO daily). The median progression-free survival was 4.1 months, and the median overall survival was 10.2 months. The median duration of response for the 7 responders was 8.5 months (5). These findings provide proof-of-concept evidence that mTORC1 pathway targeting is clinically relevant in TCL. (Note that other mTOR inhibitors differ in their actions: BEZ235 and GSK2126458 are ATP competitive mTOR inhibitors that target both PI3K and mTORC1/2; AZD8055, AZD2014 and KU-0063794 are ATP competitive mTOR inhibitors that target both mTORC1 and mTORC2; and GDC-0941 is a pan-PI3K inhibitor.) 1. ## Evogliptin

This novel, potent, and selective dipeptidyl peptidase IV inhibitor and investigative Type 2 diabetes drug (FW = 401.42 g/mol; CAS 1222102-29-5 (free-base); 1246960-27-9 (HCl salt); 1222102-51-3 (tartrate salt)), also named as DA-1229 and (R)-4-[(R)-3-amino-4-(2,4,5-trifluorophenyl)butanoyl]-3-(*t*-butoxy-methyl)piperazin-2-one, controls glucose levels by preventing the breakdown of the incretin hormones glucose-dependent insulinotropic polypeptide (GIP) and glucagon-like peptide-1 (GLP-1), which stimulate insulin secretion in response to the increased levels of glucose in the period following meals. See also *Alogliptin*; *Linagliptin*; *Saxagliptin*; *Sitagliptin*; *Vildagliptin* 1. Chae, Kim, Kim, *et al.* (2015) *PLoS One* **10**, e0144064.

## Evolocumab

This injectable PCSK9 inhibitor (MW = 141.8 kDa; CAS 1256937-27-5), developed as AMG-145 by Amgen, is a fully humanized monoclonal antibody that targets Proprotein Convertase Subtilisin/Kexin type-9 (PCSK9), the enzyme that binds Epidermal Growth Factor-like repeat A (EGF-A) domain of the Low-Density Lipoprotein Receptor (LDLR) and

promotes its degradation in the endosomal/lysosomal pathway. The rationale for monoclonal anti-PCSK9 antibody-based therapy is that, despite statin treatment, many patients do not reach recommended low-density lipoprotein cholesterol (LDL-c) targets. Indeed, a gain-of-function mutation in PCSK9 result in a Familial Hypercholesterolemia (FH) phenotype, again by promoting degradation of the LDL-R. AMG 145 prevents PCSK9/LDL-R interaction, thereby restoring LDL-R recycling and reducing plasma cholesterol levels. Evolocumab is administered intravenously every two to four weeks. In Phase-I studies, AMG 145 significantly reduced serum LDL-c in healthy and hypercholesterolemic statin-treated subjects, including those with heterozygous familial hypercholesterolemia or taking the highest doses of atorvastatin or rosuvastatin, with an overall an adverse event profile similar to placebo (1). When administered every fourth week, evolocumab yielded rapid and substantial reductions in LDL-c in heterozygous familial hypercholesterolemia patients, despite intensive statin use, with or without ezetimibe, with minimal adverse events and good tolerability (2). In patients with heterozygous FH, evolocumab (140 mg IV every 2 weeks or 420 mg monthly) is well-tolerated, yielding similar and rapid 60% reductions in LDL cholesterol compared with placebo (3). **EXEL-2880**, See *Foretinib*

**EXP 3174**

This noncompetitive AT<sub>1</sub> antagonist (FW = 436.89 g/mol; CAS 124750-92-1; Solubility: 100 mM DMSO), also named 2-butyl-4-chloro-1-[[2'-(2H-tetrazol-5-yl)[1,1'-biphenyl]-4-yl]methyl]-1H-imidazole-5-carboxylic acid, targets the Angiotensin-1 receptor (IC<sub>50</sub> = 37 nM), a member of the angiotensin group of G-protein-coupled receptors located primarily in the liver, kidney, adrenal gland and lung. EXP-3174 displaces [<sup>3</sup>H]-angiotensin II from its specific binding sites in rat adrenal cortical membranes with an IC<sub>50</sub> of 3.7 × 10<sup>-8</sup> M. EXP3174 does not alter blood pressure, but inhibits the pressor response to AII. In conscious renal artery-ligated rats, EXP3174 decreases blood pressure with an i.v. ED<sub>30</sub> of 0.038 mg/kg and a p.o. ED<sub>30</sub> of 0.66 mg/kg. 1. Wong, Price, Chiu, *et al.* (1990) *J. Pharmacol. Exp. Ther.* **255**, 211.

**Ezatiostat**

**De-esterified Ezatiostat**

This glutathione analogue and prodrug (FW = 529.65 g/mol; CAS 168682-53-9), also known as Terrapin 199, TLK199, and (2*R*)-L-γ-glutamyl-S-(phenylmethyl)-L-cysteinyl-2-phenyl-glycine-1,3-diethyl ester, enters cells and undergoes enzymatic de-esterification, whereupon the carboxylate form selectively inhibits glutathione S-transferase GSTP1-1 (K<sub>i</sub> = 400 nM), with much weaker inhibition of GSTα and GSTμ families, the latter with K<sub>i</sub> values of 20-75 μM (1). Ezatiostat also inhibits multidrug resistance-associated protein1 (MRP1)-mediated drug resistance. 1. O'Brien, Vulevic, Freer, *et al.* (1999) *J. Pharmacol. Exp. Ther.* **291**, 1348.

**Ezetimibe**

This rapidly absorbed, first-in-class cholesterol absorption inhibitor (FW = 409.40 g/mol; CAS 163222-33-1), also known by its code name SCH58235 and trade name Zetia<sup>®</sup>, and its active glucuronide metabolite (SCH60663) both lower LDL cholesterol (and increase HDL cholesterol) by impairing intestinal reabsorption of both dietary and hepatically excreted biliary cholesterol (1,2). The parent compound and its conjugated metabolite undergo enterohepatic recirculation, resulting in multiple peaks in the plasma concentration-time profile (3). Ezetimibe reduces plasma cholesterol levels from 964 to 374 mg/dL, from 726 to 231 mg/dL, and from 516 to 178 mg/dL in the Western, lowfat, and cholesterol-free diet groups, respectively (4). Ezetimibe markedly attenuates hepatic cholesterol accumulation and improves liver function in the lysosomal acid lipase-deficient mouse, a model for cholesteryl ester storage disease (5). **Primary Mechanism of Inhibitor Action:** Niemann-Pick C1-Like-1 (Accession No: AY437865.1) is the protein that mediates cholesterol absorption and serves as the primary ezetimibe target, as demonstrated (a) in binding assays, showing that labeled ezetimibe glucuronide binds specifically to a single site in brush border membranes and to human embryonic kidney 293 cells expressing NPC1L1 (K<sub>D</sub> = 220 nM for human NPC1L1); (b) in quantitative binding experiments, confirming that affinities of ezetimibe to recombinant NPC1L1 are virtually identical to those observed for native enterocyte membranes; and (c) in NPC1L1-knockout mice, where ezetimibe no longer binds to membranes (6). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Reiss, Burnett & Zaks (1999) *Bioorg Med Chem.* **7**, 2199. 2. van Heek, Farley, Compton, *et al.* (2000) *Br. J. Pharmacol.* **129**, 1748. 3. F, See Fluorine (Fluoride Ions); Folate (Folic Acid); Phenylalanine

## F-244

This polyketide (FW = 323.41 g/mol), also known as (*E,E*)-11-(3*R*)-hydroxymethyl-4-oxo-2(*R*)-oxetanyl 3,5,7(*R*)-trimethyl-2,4-undecadienoic acid, L-659,699, and Hymeglusin, from *Fusarium* sp. and *Scopulariopsis* sp. is a potent inhibitor of hydroxymethyl-glutaryl-CoA synthase, or HMG-CoA synthase (IC<sub>50</sub> = 54 nM for human enzyme). The lactone reacts with an enzyme thiol to form a thioester. 1. Pojer, Ferrer, Richard, *et al.* (2006) *Proc. Natl. Acad. Sci. U.S.A.* **103**, 11491. 2. ## Factor VIII (FVIII) Inhibitors

These naturally occurring, high-affinity polyclonal anti-FVIII alloantibodies (MW = 150 kDa for the four chains of IgG4) neutralize the coagulative properties of blood clotting Factor VIII, but do not fix complement (1-3). **Factor VIII Therapy:** Hemophilia A is an X-linked recessive Factor VIII deficiency, which in males has a 1-in-5000 frequency showing no ethnic predominance. Factor VIII participates in blood coagulation as a cofactor for Factor IXa, which, in the presence of Ca<sup>2+</sup> and phospholipids, forms a complex that converts factor X to its activated form Xa. The latter cleaves prothrombin at Arg-Thr and Arg-Ile bonds to yield the active thrombin, which, in turn, converts fibrinogen into fibrin. The mainstay for treating Hemophilia A is FVIII replacement, with hemostasis achieved through the use of either plasma or recombinant (exogenous) FVIII concentrates. FVIII replacement therapy is highly effective, until a patient produces inhibitory anti-FVIII alloantibodies. These antibodies bind to and interfere with the action of infused Factor VIII, necessitating the use of costly and much less effective alternatives, including activated Prothrombin Complex Concentrate, or aPCC, and recombinant factor VIIa. **Key Features of FVIII Inhibitors:** Although otherwise considered to be a non-pathologic subclass with anti-inflammatory antibodies, IgG4 correlates with the presence of high-titre FVIII inhibitors in hemophilia A. These IgG4 alloantibodies possess unique structural and functional properties, making them functionally monovalent as a result of undergoing so-called 'half-antibody exchange' *in vivo*. The recombined antibodies have two different antigen binding specificities. IgG4 antibody production is partly driven by T helper 2-derived cytokines that mediate allergic responses and IgE production. Formation of these FVIII inhibitors is a T-cell dependent event that involves antigen-presenting cells, B- and T-helper lymphocytes (4). Factor VIII contains three A-domains (designated A<sub>1</sub>, A<sub>2</sub>, A<sub>3</sub>), one B-domain, and two C-domains (C<sub>1</sub> and C<sub>2</sub>). Inhibitory antibodies are primarily directed against the A<sub>2</sub>, A<sub>3</sub> and C<sub>2</sub> domains (5,6). Antibody binding at these domains blocks functional epitopes within FVIII (7), including those for interacting with Factor IX (FIX), phospholipid, and von Willebrand factor. Antibodies in inhibitor-producing patients target multiple FVIII epitopes, and these targets can change over time (8). 1. Fulcher, de Graaf-Mahoney & Zimmerman (1987) *Blood* **69**, 1475. 2. ## Factor XIII Inhibitors

These autoantibodies target Factor XIII (FXIII), a blood-clotting enzyme that cross-links fibrin monomers, stabilizing clots (hence its initial name:

Fibrin Stabilizing Factor) and wound healing. Acquired FXIII deficiency is a rare condition that results in bleeding, despite normal coagulation test results. The mean age of onset is 60, regardless of sex, and is characterized by intramuscular, subcutaneous, external, or surgically induced bleeding. Clinical improvement occurs in patients receiving FXIII concentrate, cryoprecipitate, or plasma. Inhibitor reduction was observed in patients receiving rituximab, plasma exchange, intravenous immunoglobulin, steroids, and cyclophosphamide. 1. Tone, James, Fergusson, *et al.* (2016) *Transfus. Med. Rev.* **30**, 123.

## Factor XIIIa Fragment 72-97

This 26-residue oligopeptide (FW = 3226.65 g/mol; Sequence: NKLIVR RGQSFYVQIDFSRPYDPRRD) inhibits coagulation factor XIIIa (or transglutaminase, or protein-glutamine  $\gamma$ -glutamyltransferase), which catalyzes the formation of cross-link between fibrin and fibronectin or *N,N*-dimethylcasein. Its inhibitory action demonstrated that regions outside the active site are important for substrate recognition in factor XIIIa and tissue transglutaminase. 1. Achyuthan, Slaughter, Santiago, Enghild & Greenberg (1993) *J. Biol. Chem.* **268**, 21284.

## FAD

This redox coenzyme (FW = 785.55 g/mol;  $E_0' = -0.219$  V at pH 7 and 30°C;  $\lambda_{max}$  at 263, 375, and 450 nm ( $\epsilon = 38000, 9300, \text{ and } 11300 \text{ M}^{-1}\text{cm}^{-1}$ , respectively), known as flavin adenine dinucleotide, is the yellow, easily photobleached coenzyme (or prosthetic group for flavoenzymes). The reduced form is FADH<sub>2</sub>, which has a molar extinction coefficient of only 980 M<sup>-1</sup>cm<sup>-1</sup> at 450 nm. FADH<sub>2</sub> has a fluorescence maximum at 525-530 nm. FAD is reduced nonenzymatically to FADH<sub>2</sub> in the presence of dithionite or by H<sub>2</sub> in the presence of an appropriate catalyst. **Target(s):** acetolactate synthase (1); adenyllyl sulfate kinase (2); alanine racemase (3); carbonyl reductase (4); 3',5'-cyclic-nucleotide phosphodiesterase (5); deoxyhypusine synthase (6); FAD synthetase, product inhibition (7-9); fructose-1,6-bisphosphatase (10); glucose-1-phosphate adenyllyl-transferase (11); glutamate racemase (12,13); glutathione-disulfide reductase (14); glycerone kinase (15); glycogen phosphorylase, carboxylating (16); isopenicillin-*N* isomerase (18); L-lactate oxidase (19); lysolecithin oxidase (20); NAD<sup>+</sup> diphosphatase (21); NADH:cytochrome *c* reductase, or NADH dehydrogenase (22); NAD(P)H dehydrogenase, or DT diaphorase (23-26); nicotinate-nucleotide pyrophosphorylase, carboxylating (27); nucleotide diphosphatase, also alternative substrate (28,29); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase, weakly inhibited (30); phosphodiesterase I, or 5'-exonuclease (31); riboflavinase (32); ribose-phosphate diphosphokinase, or phosphoribosyl pyrophosphate synthetase (33); succinate oxidase (34); acyl-[acyl-carrier-protein] desaturase (36,37); very-long-chain fatty acid  $\alpha$ -hydroxylase (35); *trans*-cinnamate 4-monooxygenase (38); *myo*-inositol oxidase (17,39); sulfur oxygenase/reductase (40); sulfur dioxygenase (41,42). 1. ### Fadrozole

This antineoplastic agent (FW<sub>free-base</sub> = 223.28 g/mol; M.P. = 117-118°C), also called 4-(5,6,7,8-tetrahydroimidazo[1,5-a]pyridin-5-yl)benzonitrile, is a potent aromatase inhibitor (IC<sub>50</sub> = 52 nM). The hydrochloride is often referred to as CGS-16949A. **Target(s):** aromatase, or CYP19 (1-8); estrogen 2-hydroxylase (9); steroid 11 $\beta$ -monooxygenase (6-8,10); steroid 17 $\alpha$ -monooxygenase, weakly inhibited (6-8); sterol 14-demethylase, or CYP51, weakly inhibited (11). **1.** Santen, Langecker, Santner, Sikka, Rajfer & Swerdloff (1990) *Endocr. ### Famciclovir

This acyclic guanosine analogue (FW = 321.34 g/mol; CAS = 104227-87-4; shown above in its familiar nucleoside-like form), also known by the trade name Famvir<sup>®</sup> and systematically as 2-[(acetyloxy)methyl]-4-(2-amino-9H-purin-9-yl)butyl acetate, is a penciclovir prodrug used to treat herpes virus infections, most often herpes zoster (shingles). Upon intracellular ester hydrolysis and subsequent metabolic phosphorylation, this prodrug forms penciclovir 5'-triphosphate, a potent inhibitor of viral DNA polymerases. (See *Penciclovir*) The widely used FDA-approved one-day treatment for cold sores consists of two 1000-mg doses (twelve hours apart) of famciclovir, initiated by the patient at first sensation of the tingling due to an otherwise soon-to-be erupting cold sore. There is a narrow window of opportunity at the start of an outbreak of herpes or cold sores, because the virus replicates most actively in those first hours. Interrupting that process appears to shorten the outbreak and to reduce the severity of infection. **Target(s):** Epstein-Barr virus replication; HSV-1 and HSV-2 replication; varicella zoster virus replication; viral DNA polymerases (via its phosphorylated form of penciclovir). **1.** Priske & Chen (1996) *Meth. Enzymol.* **275**, 425.

### Famotidine

This well-known antacid medication (FW = 377.45 g/mol; CAS = 76824-35-6), also known by its trade names Pepcid<sup>®</sup>, Pepcidine<sup>®</sup>, and Gaster<sup>®</sup>, as well as by its systematic name 3-[(2-(diaminomethyleneamino)thiazol-4-yl)methylthio]-N'-sulfamoylpropanimidamide, is a histamine H<sub>2</sub>-receptor antagonist that inhibits stomach acid production and is often used to treatment peptic ulcer disease (PUD) and gastroesophageal reflux disease (GERD). Famotidine is about nine times more potent than ranitidine, and about thirty-two times more potent than cimetidine. Unlike cimetidine, however, famotidine is without effect on cytochrome P450 metabolism (3). Moreover, coadministration of famotidine had no effect on the pharmacokinetics of theophylline, diazepam, desmethyldiazepam, and phenytoin and no effect on the half-life of antipyrine and aminopyrine or on the prothrombin time ratios associated with warfarin therapy. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) ### Fananserin

This serotonin receptor antagonist (FW = 425.52 g/mol; CAS = 127625-29-0; Soluble to 100 mM in DMSO), also named RP 62203 and 2-[3-[4-(4-fluorophenyl)-1-piperazinyl]propyl]-2H-naphthyl[1,8-*cd*]isothiazole-1,1-dioxide, selectively targets 5-HT<sub>2A</sub> receptors (K<sub>i</sub> = 0.26 nM), but also binds to D<sub>4</sub> receptors (K<sub>i</sub> = 2.9 nM), H<sub>1</sub> receptors (K<sub>i</sub> = 25 nM),  $\alpha_1$  receptors (K<sub>i</sub> = 38 nM), 5-HT<sub>1A</sub> receptors (K<sub>i</sub> = 70 nM) and D<sub>2</sub> receptors (K<sub>i</sub> = 726 nM) (1,2). In cortical slices from the neonatal rat, RP 62203 potently inhibited inositol phosphate formation (IC<sub>50</sub> = 7.76 nM) evoked by 5-HT. **1.**

### Fantofarone

This antihypertensive agent (FW<sub>free-base</sub> = 550.72 g/mol; CAS = 114432-13-2), also known by its code name SR 33557 and as *N*-[2-(3,4-dimethoxyphenyl)ethyl]-3-[4-[(2-isopropyl-1-indoliziny)sulfonyl]phenoxy]-*N*-methylpropan-1-amine, is a calcium channel blocker. Fantofarone's blocking action on the different types of voltage-activated Ca<sup>2+</sup> currents was investigated with the whole-cell patch-clamp method in chick dorsal root ganglion neurons (for T-, L- and N-type currents) and in rat cerebellar Purkinje neurons (for P-type current). Neuronal L-type Ca<sup>2+</sup> channels are blocked totally by fantofarone in the microM range of concentration, as in skeletal muscle and cardiac cells at a holding membrane potential of -80 mV (IC<sub>50</sub> = 0.35 μM). N- and P-type channels are not very sensitive (IC<sub>50</sub> ≈ 5 microM). The T-type channel is unaffected. **Target(s):** Ca<sup>2+</sup> channels (1); sphingomyelin phosphodiesterase, or acid sphingomyelinase (2,3). 1. Schmid, Romey, Barhanian & Lazdunski (1989) *Mol. Pharmacol.* **35**, 766. 2. Won, Im, Khan, Singh & Singh (2004) *J. Neurochem.* **88**, 583. 3. Jaffrézou, Chen, Durán, *et al.* (1995) *Biochim. Biophys. Acta* **1266**, 1.

### Farnesol

This branched-chain unsaturated alcohol (FW = 222.37 g/mol) is found in many essential oils (*e.g.*, oils of rose, musk, lemon grass, citronella, tuberose, *etc.*). Although there are four geometric isomers, the all-*trans* isomer is the one found in the natural oils. Occasionally, *cis,trans* farnesol is observed (*e.g.*, in petitgrain oil). This liquid serves as a pheromone in a number of organisms. Farnesol can also induce apoptosis. Note that farnesol is easily oxidized and can form cyclic products. **Target(s):** Ca<sup>2+</sup> channels, N-type (1,2); *Candida albicans* biofilm formation (3); Ca<sup>2+</sup> uptake (4,5); choline kinase (6); diclofenac 4-hydroxylase, or cytochrome P450 (7); dolichyl-diphosphatase, weakly inhibited (8); ethoxycoumarin deethylase, cytochrome P450 (7); 3-hydroxy-3 methylglutaryl-CoA reductase (9); mevalonate kinase (10); prenylcysteine oxidase (11); squalene:hopene cyclase (12). 1. ### Farnesyl Diphosphate (or, Farnesyl Pyrophosphate)

This sesquiterpene diphosphate (FW = 382.32 g/mol) is a key intermediate in the biosynthesis of steroids and many terpenes. It is also the farnesyl donor in protein farnesyltransferases. Farnesyl diphosphate is unstable in acidic conditions: complete hydrolysis occurs in less than six hours at pH 1 and 22°C while hydrolysis at pH 4 takes about five days at that same temperature. Only 2% is hydrolyzed in three months at pH 8 and -20°C while 15% is hydrolyzed in one hour in 0.1 M KOH at 100°C. **Target(s):** dolichyl-diphosphatase (1); geranylgeranyl-diphosphatase (2); isopentenyl diphosphate Δ-isomerase (3); mevalonate kinase (4-12); rubber *cis*-polyprenyltransferase (13). 1. ### S-*trans,trans*-Farnesyl Thiosalicylic Acid Amide

This K-Ras 4B-targeting, farnesyl-cysteine mimic (FW = 357.55 g/mol; CAS = 1092521-74-8; Symbol: FTS) is taken up by cells, where it dislodges farnesylated Ras proteins from cell membranes by competing for their membrane binding sites, thus facilitating their degradation (1). **Mode of Inhibitor Action:** To regulate cell growth, differentiation and apoptosis, Ras proteins must remain anchored to the cytoplasmic surface of the plasma membrane by means of their common carboxy-terminal S-farnesylcysteine and a stretch of lysine residues (as in K-Ras 4B) or S-palmitoyl moieties (as in H-Ras, N-Ras and K-Ras 4A). FTS is not a farnesyltransferase inhibitor. Instead, it inhibits growth of NIH3T3 cells transformed by the non-palmitoylated K-Ras 4B(12V) or by its farnesylated (but unmethylated) K-Ras 4B(12) CVYM mutant. FTS does not alter the rate of degradation of the K-Ras 4B, SVIM mutant, which is not modified post-translationally, suggesting that only farnesylated Ras isoforms are substrates destined for facilitated degradation. The putative Ras-recognition sites (lying within domains in the cell membrane) appear to tolerate both C(15) and C(20) S-prenyl moieties, since geranylgeranyl thiosalicylic acid mimicked the growth-inhibitory effects of FTS in K-Ras 4B(12V)-transformed cells and FTS inhibited the growth of cells transformed by the geranylgeranylated K-Ras 4B(12V) CVIL isoform. 1. Elad, Paz, Haklai, *et al.* (1999) *Biochim. Biophys. Acta* **1452**, 228.

### S-all-*trans*-Farnesylthioacetic Acid

This S-farnesylated cysteine analogue (FW<sub>free-acid</sub> = 296.47 g/mol) inhibits protein-S isoprenylcysteine O-methyltransferase. 1. Volker, Pillinger, Philips & Stock (1995) *Meth. Enzymol.* **250**, 216. 2. Ma, Gilbert & Rando (1995) *Meth. Enzymol.* **250**, 226. 3. Volker & Stock (1995) *Meth. Enzymol.* **255**, 65. 4. Baron & Casey (2004) *BMC Biochem.* **5**, 19. 5. ### S-Farnesylthiosalicylate

This farnesylated salicylate analogue (FW<sub>free-acid</sub> = 358.55 g/mol) is a nontoxic Ras antagonist that dislodges Ras from its membrane anchoring sites. It inhibits the growth of human Ha-Ras transformed Rat1 cells *in vitro* (EC<sub>50</sub> = 7.5 μM). It also suppresses the growth of prostate cancer *in vitro*. **Target(s):** mitogen-activated protein kinase kinase kinase, or MAPKKK (1); protein-S-isoprenylcysteine O-methyltransferase (2,3); Ras membrane association (4,5). 1. Calipel, Lefevre, Pouponnot, *et al.* (2003) *J. Biol. Chem.* **278**, 42409. 2. Hasne & Lawrence (1999) *Biochem. J.* **342**, 513. 3. Marciano, Aharonson, Varsano, Haklai & Kloog (1997) *Bioorg. ### Fascaplysin

This red-colored marine CDK inhibitor (FW = 271.30 g/mol; CAS = 114719-57-2), first isolated from the sponge *Fascaplysinopsis Bergquist* (1), selectively targets cyclin-dependent kinase CDK4 (IC<sub>50</sub> ~ 0.4 μM), relative to CDK2 (IC<sub>50</sub> ~ 500 μM) and CDK6 (IC<sub>50</sub> ~ 3.4 μM) (1-3). Not surprisingly, fascaplysin is also an effective DNA intercalator and is likely to interfere with both replication and transcription (4). An excellent fit was obtained with two formation constants ( $K_1 = 2.5 \times 10^6 \text{ M}^{-1}$ ;  $K_2 = 7.5 \times 10^4 \text{ M}^{-1}$ ), putting the numbers of binding sites per base pair at  $n_1 = 0.30$  and  $n_2 = 0.33$ , in good agreement with those obtained for cryptolepine, ellipticines, and acridines. 1. Roll, *et al.* (1988) *J. Org. Chem.* **53**, 3276 (1988). 2. Kirsch, *et al.* (2000). *J. Natur. Prod.* **63**, 825. 3. Soni, *et al.* (2000) *Biochem. Biophys. Res. Commun.* **275**, 877. 4. Hörmann, *et al.*, (2001) *Bioorg. Med. Chem.* **9**, 917.

### Fasciculin 1 & 2

These snake venom toxins (MW<sub>Fasciculin-1</sub> = 6807 g/mol, *Sequence*: TMCYSHTTTSRAILTNCGENSCYRKSRRHPPKMLVLRGCGCPPGDDYLEV KCCTSPDKCNY; MW<sub>Fasciculin-2</sub> = 6758 g/mol, *Sequence*: TMCYSHTTTSRAILTNCGENSCYRKSRRHPPKMLVLRGCGCPPGDDYLEKCCCTSP DKCNY) from the green mamba (*Dendroaspis angusticeps*) inhibit mammalian acetylcholinesterase with  $K_i$  values in the picomolar range. Both have disulfide bonds between Cys3-Cys22, Cys17-Cys39, Cys41-Cys52, and Cys53-Cys59, and differ only at Position-47. **Primary Mode of Action**: The acetylcholinesterase active site has a serine residue lying at the base of 20 Å-deep gorge lined with aromatic residues. Residues near the entrance to the gorge comprise a peripheral binding site for the fasciculins, and occupancy of that site by the snake neurotoxin reduces  $k_{\text{cat}}$  by a factor of 200, with a corresponding decrease in  $k_{\text{cat}}/K_m$  (1). **Target(s)**: acetylcholinesterase, mammalian (1-10); cholinesterase, or butyrylcholinesterase, weakly inhibited (10,11). 1. Eastman, Wilson, Cerveňansky & Rosenberry (1995) *J. Biol. Chem.* **270**, 19694. 2. Duran, Cervenansky, Dajas & Tipton (1994) *Biochim. Biophys. Acta* **1201**, 381. 3. Duran, Cervenansky & Karlsson (1996) *Toxicon* **34**, 959.

### Fasentin

This selective glucose transport inhibitor (FW = 279.64 g/mol; CAS = 392721-37-8), also named *N*-[4-chloro-3-(trifluoromethyl)phenyl]-3-oxobutanamide, was first identified as a chemical sensitizer to the death receptor stimuli FAS and tumor necrosis factor apoptosis-inducing ligand.

Fasentin was later shown to alter expression of genes associated with nutrient and glucose deprivation by directly inhibiting GLUT1 (IC<sub>50</sub> = 10–15 μM). The latter is a glucose uniporter widely distributed in fetal tissues, with highest levels in erythrocytes and endothelial cells of adults. Fasentin interacts with a unique site in the intracellular channel of this transporter. Fasentin also blocks sorafenib-induced glucose uptake, potentiating its cytotoxic activity in SKBR3 cells (2). Persistent activation of AMPK by sorafenib impairment of glucose metabolism in both MCF-7 and SKBR3 cells as well as in the highly glycolytic MDA-MB-231 cells, resulting in cell death. This previously unrecognized long-term effect of sorafenib is mediated by AMPK-dependent inhibition of the mTORC1 pathway. Suppression of mTORC1 activity is sufficient for sorafenib to hinder glucose utilization in breast cancer cells, as demonstrated by the observation that the mTORC1 inhibitor rapamycin induced a comparable down-regulation of GLUT-1 expression and glucose uptake (2). **See also Sorafenib** 1. Wood, Dalili, Simpson, *et al.* (2008) *Mol. Cancer Ther.* **7**, 3546. 2. Fumarola, Caffarra, La Monica, *et al.* (2013) *Breast Cancer Res. Treat.* **141**, 67.

### Fasidotril & Fasidotrilat

This dual NEP/ACE inhibitor (FW<sub>free-acid</sub> = 311.36 g/mol) and its prodrug (FW = 443.52 g/mol) represent the first rationally designed prodrug and inhibitor for angiotensin-converting enzyme. This antihypertensive drug was at one time referred to as alatrioprilat, **Target(s)**: neprilysin,  $K_i = 5.1 \text{ nM}$ ; peptidyl-dipeptidase A (angiotensin-converting enzyme,  $K_i = 9.8 \text{ nM}$ ). 1. Gros, Noël, Souque, *et al.* (1991) *Proc. Natl. Acad. Sci. U.S.A.* **88**, 4210.

### Fasciola hepatica Kunitz-type Inhibitor

This atypical protease inhibitor (MW = 7 kDa; Symbol: FhKT1), while possessing a canonical Kunitz-type serine protease inhibitory domain, exhibits no inhibitory activity towards serine proteases, but potently inhibits cysteine proteases, including the major secreted cathepsin L of *F. hepatica*, FhCL1 ( $K_i = 0.4 \text{ nM}$ ) and FhCL2 ( $K_i = 10 \text{ nM}$ ), as well as human cathepsins L ( $K_i = 1.6 \text{ nM}$ ) and K ( $K_i = 5 \text{ nM}$ ). Disulfide reduction and alkylation alters FhKT1's structure and likewise abolishes its inhibitory properties. FhKT1 also prevents the auto-catalytic activation of FhCL1 and FhCL2 and forms stable complexes with the mature enzymes. Substitution of the unusual P1 Leu15 within the exposed reactive loop of FhKT1 for the more commonly found Arg (FhKT1Leu15/Arg15) has modest adverse effects on the cysteine protease inhibition, yet confers potent activity against trypsin ( $K_i = 1.5 \text{ nM}$ ). The arrangement of functional amino acids provides new insight into protease inhibition by KT inhibitors. 1. Smith, Tikhonova, Jewhurst, *et al.* (2016) *J. Biol. Chem.* **291**, 19220.

### Fasudil

This modestly selective Rho kinase inhibitor and vasodilator (FW<sub>free-base</sub> = 291.37 g/mol; FW = 327.83 g/mol for the monohydrochloride; CAS = 103745-39-7 (free base) and 105628-07-7 (HCl Salt); Solubility: 5 mg/mL DMSO, 60 mg/mL Water), also known as HA-1077 and 1-(5-isoquinolinesulfonyl)homopiperazine, is an intracellular calcium ion antagonist that competitively inhibits the Ca<sup>2+</sup>-induced contraction of depolarized rabbit aorta (1). (**See also SC82510**) Fasudil is a protein kinase inhibitor (2-9), with strongest action on protein kinase A (IC<sub>50</sub> = 1.6 μM), protein kinase G (IC<sub>50</sub> = 1.6 μM), Rho-dependent protein kinase (IC<sub>50</sub> = 10.7 μM), and [myosin light-chain] kinase (IC<sub>50</sub> = 36 μM) (2-5). Other targets include cGMP-dependent protein kinase (2), [mitogen-activated-protein-kinase]-activated protein kinase (4), mitogen- and stress-activated protein kinase (4), [myosin light-chain] kinase (2,6,7), phosphorylase kinase (4), p70 ribosomal protein S6 kinase (4), protein-kinase-C-related protein kinase (4). Fasudil selectively targets RhoA/Rho kinase (IC<sub>50</sub> = 10.7 μM), an enzyme (abbreviated ROCK) that plays an important role in mediating vasoconstriction and vascular remodeling in the pathogenesis of pulmonary hypertension. ROCK also increases the expression and activity of angiotensinogen-converting enzyme (ACE). There are thus three likely consequences of ROCK inhibition: (a) an increase in eNOS expression, achieved by stabilizing eNOS mRNA; (b) reduction in circulating ACE and Ang-II, leading to a decrease in pulmonary vascular pressure; and (c) inhibition of extracellular signal-regulated kinase, or ERK (9-11). HA-1077 also prevents Rho-mediated myosin phosphatase inhibition in smooth muscle cells (12). Fasudil is used to treat cerebral vasospasm due to subarachnoid hemorrhage and also retards cognitive decline in stroke victims and Alzheimer's Disease. The fasudil derivative Ripasudil (FW = g/mol; CAS = 223645-67-8; Trade Name: Glanatec<sup>®</sup>; IUPAC: 4-fluoro-5-[(2S)-2-methyl-1,4-diazepan-1-yl]sulfonyl]isoquinoline) is also a ROCK inhibitor that is used to treat both glaucoma and ocular hypertension. 1. Asano, Ikegaki, Satoh, *et al.* (1987) *J. Pharmacol. Exp. Ther.* **241**, 1033. 2. Asano, Suzuki, Tsuchiya, *et al.* (1989) *Brit. J. Pharmacol.* **98**, 1091. 3. ### Favipiravir

This broadly active small-molecule RNA-dependent RNA polymerase inhibitor (FW = 157.10 g/mol; CAS = 259793-96-9), also named 5-fluoro-2-oxo-1H-pyrazine-3-carboxamide, is active against influenza viruses, West Nile virus, yellow fever virus, foot-and-mouth disease virus as well as many other flaviviruses, arenaviruses, bunyaviruses and α-viruses, in some cases been effective, when initiated up to 5–7 days after virus infection, after the animals had already showed signs of illness (1). Significantly, Favipiravir does not inhibit host DNA and RNA synthesis or inosine 5'-monophosphate dehydrogenase (IMPDH) activity. 1. Furutaa, Takahashia, Shiraki, *et al.* (2009) *Antiviral Res.* **82**, 95.

### Favipiravir-β-ribosyltriphosphate

Favipiravir-β-ribosyltriphosphate

This substituted pyrazine (FW = 157.10 g/mol; CAS = 259793-96-9), also known as T-705 and 6-fluoro-3-hydroxy-2-pyrazinecarboxamide, inhibits viruses (*e.g.*, influenza virus, arenaviruses, bunyaviruses, West Nile virus, yellow fever virus, and foot-and-mouth disease virus) utilizing viral RNA-dependent RNA polymerase (*or* RdRP) for genomic replication by induces a high rate of self-lethal mutations that generate a nonviable viral phenotype (1,2). **Mode of Inhibitory Action:** Favipiravir is a prodrug that is metabolized to its favipiravir-β-ribosyltriphosphate, which acts in a dose-dependent manner. Incorporation of T-705-RTP into viral RNA results in a 9x increase in A/Brisbane/59/2007 and a 5x increase in A/New Jersey/15/2007 in G→A transitions. In cells inoculated with a low virus dose, one observes virus-specific increases in RNA C→T transition after serial passage in treated, but not mock-treated, cells. G→A transitions are also increased at high infectious doses, but not significantly, reflecting dose-related rapid virus extinction. A→G mutations within the coding viral genome cause the production of functionally impaired mutant proteins. T-705 exerts its antiviral effects without significant toxicity to the host. **Inhibitory Dose:** IC<sub>50</sub> values of favipiravir are 6.6 μM for seasonal influenza A/Brisbane/59/2007 virus; 5.3 μM for A/New Jersey/15/2007 virus; and 3.0 μM for both pandemic A (*or* H<sub>1</sub>N<sub>1</sub>) viruses, namely A/Denmark/524/2009 and A/Denmark/528/2009. T-705 was also effective against all four viruses in MDCK cells inoculated at a low dose, with EC<sub>50</sub> values of 17 and 15 μM for the seasonal influenza viruses and 15 and 11 μM for the pandemic viruses (2). 1. Furuta, Takahashi, Kuno-Maekawa, *et al.* (2005) *Antimicrob. Agents Chemother.* **49**, 981. 2. Baranovich, Wong, Armstrong, *et al.* (2013) *J. Virol.* **87**, 3741.

### Febuxostat

This gout-mitigating drug (FW = 316.34 g/mol; CAS = 144060-53-7), also known as TEI-6720 and systematically named as 2-(3-cyano-4-isobutoxyphenyl)-4-methyl-1,3-thiazole-5-carboxylic acid, is a strong noncompetitive inhibitor of xanthine oxidase (XO). **Mode of Action:** Although a non-purine, febuxostat inhibits xanthine oxidase by blocking the enzyme's molybdenum pterin center (1-4). Steady state kinetics measurements exhibit mixed type inhibition with K<sub>i</sub> and K<sub>i</sub>' values of 0.12 nM and 0.9 nM, respectively (2). Fluorescence titration showed that TEI-6720 bound very tightly to both the active and the inactive desulfo-form of the enzyme. The dissociation constant determined for the desulfo-form was 2 nM, too low to allow accurate measurement. The crystal structure of the active sulfo-form of milk xanthine dehydrogenase complexed with TEI-6720 revealed that inhibitor molecule binds in a narrow channel leading to the molybdenum-pterin active site of the enzyme, filling the channel as well as the immediate environment of the cofactor. Febuxostat inhibits the enzyme by preventing substrate binding (2). (**See Allopurinol**) Febuxostat is marketed under the trade name Uloric<sup>®</sup> in the U.S. and as Adenuric<sup>®</sup> and Febutaz<sup>®</sup> in the E.U. and India. Significantly, xanthine oxidase is also a major source of reactive oxygen species (ROS) and has been linked to the pathogenesis of atherosclerosis. Enhanced XO expression has been demonstrated in macrophages within atherosclerotic plaque and in aortic endothelial cells of ApoE(-/-) mice. Febuxostat suppresses plaque formation, reduces arterial ROS levels, and improves endothelial dysfunction in ApoE(-/-) mice without affecting plasma cholesterol levels (5). *In vitro*, febuxostat inhibits cholesterol crystal-induced ROS formation and inflammatory cytokine release in murine macrophages (5). **Target(s):** uridine transport (1); xanthine dehydrogenase (2,3); xanthine oxidase (2-4). 1. Yamamoto, Moriwaki, Fujimura, *et al.* (2000) *Pharmacology* **60**, 34. 2. Okamoto, Eger, Nishino, *et al.* (2003) *J. Biol. Chem.* **278**, 1848. 3. Nomura, Busso, Ives, *et al.* (2014) *Sci. Rep.* **4**, 4554.

**Fedratinib**

This potent and selective ATP-competitive JAK inhibitor (FW = 524.68 g/mol; CAS = 936091-26-8), also named SAR302503, TG101348, and *N*-(2-methyl-2-propyl)-3-{{[5-methyl-2-{{4-[2-(1-pyrrolidinyl)ethoxy]phenyl}amino]-4-pyrimidinyl]amino}benzenesulfonamide, targets Janus Kinase-2, or JAK2 (IC<sub>50</sub> = 3 nM), showing efficacy in a murine model of myeloproliferative disease induced by the JAK2<sup>V617F</sup> mutation (1). Fedratinib also inhibits the carrier-mediated uptake by hTHTR2 and transcellular flux of thiamine, such that oral absorption of dietary thiamine is significantly compromised by fedratinib dosing. The latter action appears to be a unique to fedratinib and is not shared by currently marketed JAK2 inhibitors, suggesting a molecular basis for the development of Wernicke's encephalopathy upon fedratinib treatment (2). On November 18, 2013, Sanofi announced that, following a thorough risk/benefit analysis, it would halt clinical trials and cancel plans for regulatory filings on fedratinib. Prior to that announcement, fedratinib was regarded as a promising investigational JAK2 inhibitor for the treatment of primary myelofibrosis – including those previously treated with ruxolitinib, polycythemia vera; and essential thrombocythemia. 1. Wernig, Kharas, Okabe, *et al.* (2008) *Cancer Cell* **13**, 311. 2. Zhang, Zhang, Diamond, *et al.* (2014) *Drug Metab. Dispos.* **42**, 1656.

**Felbamate**

This anticonvulsant agent (FW = 238.24 g/mol; CAS = 25451-15-4; Anatomical Therapeutic Chemical Classification: N03AX), also named (3-carbamoyloxy-2-phenylpropyl) carbamate, is an antagonist that binds at the NR2<sub>B</sub> subunit of the NMDA (*N*-methyl-D-aspartate) receptor, a heteromeric ligand-gated ion channel that interacts with multiple intracellular proteins using different subunits. NMDA receptors are composed of seven subunits: NR1, NR2<sub>A</sub>, NR2<sub>B</sub>, NR2<sub>C</sub>, NR2<sub>D</sub>, NR3<sub>A</sub>, and NR3<sub>B</sub>. Many studies have demonstrated NR2<sub>B</sub>'s importance in synaptic signaling that modulate learning, memory processing, pain perception, and feeding behaviors. Felbamate is also a GABA<sub>A</sub> receptor agonist. Felbamate was launched in the U.S. as a new anti-epileptic pharmaceutical in 1993. **Target(s):** Ca<sup>2+</sup> channels, voltage-sensitive (1); CYP2C19 (2,3); Na<sup>+</sup> channels, voltage sensitive (4,5); NMDA receptor (6-8). 1. Stefani, Calabresi, Pisani, *et al.* (1996) *J. Pharmacol. Exp. Ther.* **277**, 121. 2. Benedetti (2000) *Fundam. Clin. Pharmacol.* **14**, 301. 3. Levy (1995) *Epilepsia* **36** Suppl. 5, S8. 4. Hartly & Rogawski (2000) *Epilepsy Res.* **39**, 47.

**Felbinac**

This anti-inflammatory agent (FW<sub>free-acid</sub> = 212.25 g/mol), also known as 4-biphenylacetic acid and (1,1'-biphenyl)-4-acetic acid, is a fenbifen metabolite that inhibits prostaglandin biosynthesis. Ciprofloxacin and felbinac synergistically inhibit GABA<sub>A</sub> receptors. **Target(s):** GABA<sub>A</sub>

receptor (1); medium-chain-fatty-acyl-CoA synthetase, or butyryl-CoA synthetase, or butyrate:CoA ligase, also, as an alternative substrate (2); prostaglandin biosynthesis (3-5). 1. Green & Halliwell (1997) *Brit. J. Pharmacol.* **122**, 584. 2. Kasuya, Hiasa, Kawai, Igarashi & Fukui (2001) *Biochem. Pharmacol.* **62**, 363. 3. Kohler, Tolman, Wooding & Ellenbogen (1980) *Thromb. Res.* **20**, 123.

**Felodipine**

This anti-hypertensive agent (FW = 284.25 g/mol; CAS = 72509-76-3; Solubility: 100 mM in DMSO, 100 mM in Ethanol), also named 4-(2,3-dichlorophenyl)-1,4-dihydro-2,6-dimethyl-3,5-pyridinedicarboxylic acid ethyl methyl ester, targets L-type Ca<sup>2+</sup> channels, showing selective over N-, R-, P/Q- and T-type Ca<sup>2+</sup> channels. Felodipine lowers arterial blood pressure without altering cardiac contractility. It is also used sometimes to treat Raynaud's syndrome and congestive heart failure. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Ljung (1990) *J. Cardiovasc. Pharmacol.* **15**, S11. 2. Furukawa *et al.* (1999) *J. Pharmacol. Exp. Ther.* **291**, 464. 3. Furukawa *et al.* (2005) *J. Cardiovasc. Pharmacol.* **45**, 241.

**Fenbendazole**

This broad-spectrum anthelmintic (FW = 299.35 g/mol; CAS = 43210-67-9; *Abbreviation:* FZ), also known by the trade names Panacur<sup>TM</sup> and Safe-Guard<sup>TM</sup>, and Intervet Panacur<sup>TM</sup> as well as by its systematic name, methyl *N*-(6-phenylsulfanyl-1*H*-benzimidazol-2-yl)carbamate, is used to treat roundworms, hookworms, whipworms, and *Taenia* species tapeworms. Fenbendazole is a microtubule-directed drug that disrupts mitosis. The selectivity of these drugs for the parasite is explained on the basis of irreversible blockade in uptake of glucose in parasite, which leads to depletion of glycogen storage and degeneration of endoplasmic reticulum in the germinal layers, resulting in cell death (1). Recent studies demonstrated that exhibits a potent growth-inhibitory activity against cancer cell lines but not normal cells. IC<sub>50</sub> values were ~1.2 and 1.6 μM, respectively, for H460 and A549 cell lines. One clue as to this mode of action is the unexpected finding that, upon fenbendazole treatment, cells accumulate a number of apoptosis regulatory proteins (*e.g.*, cyclins, p53, and IκBα) that are normally degraded by the ubiquitin-proteasome pathway (2). Proteasome inhibition results in antibody-detected accumulation of ubiquitylated forms of numerous proteins. Fenbendazole treatment of human non-small cell lung cancer cells also induces endoplasmic reticulum stress, production of reactive oxygen species, decreased mitochondrial membrane potential, as well as cytochrome *c* often associated with cancer cell death (2). 1. Mariner, Morris Dickson & Bogan (1986) *Eur. J. Clin. Pharmacol.* **30**, 705. 2. Dogra & Mukhopadhyay (2012) *J. Biol. Chem.* **287**, 30625.

**Fenitrothion**

This phosphorothioate insecticide (FW = 277.24 g/mol; CAS = 122-14-5), systematically named as *O,O*-dimethyl *O*-(3-methyl-4-nitrophenyl) phos-

phorothioate, inhibits cholinesterases. Resistant insects often have a symbiotic gut microbe that can metabolize and detoxify fenitrothion. This insecticide was employed for years to eradicate malaria-vectors. **Target(s):** acetylcholinesterase (1-3); carboxylesterase (4); cholinesterase (5,6); glutathione *S*-transferase (7); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (8). 1. Hamilton, Hunter & Ruthven (1981) *Bull. Environ Contam. Toxicol.* **27**, 856. 2. Kobayashi, Yuyama, Kudo & Matsusaka (1983) *Toxicology* **28**, 219. 3. Ali, Eldeen & Hikal (2005) *Pestic. Biochem. Environ. Saf.* **38**, 132

### Fenofibrate

This prodrug ester (FW = 360.84 g/mol; M.P. = 80-81°C), also named propan-2-yl 2-{4-[(4-chlorophenyl)carbonyl]phenoxy}-2-methylpropanoate, inhibits membrane-bound hepatic 3-hydroxy-3-methylglutaryl-CoA reductase by altering membrane fluidity. Fenofibrate is mainly used to treat primary hypercholesterolemia or mixed dyslipidemia. The drug exhibits a hypocholesterolemic action due to decreased cholesterol biosynthesis via inhibition of 3-hydroxy-3-methylglutaryl-CoA reductase and increased low-density lipoprotein clearance via modulation of hepatic LDL receptors. It also activates  $\alpha$ -hydroxysteroid dehydrogenase. Peroxisome proliferator-activated receptors (PPARs) are involved in lipid and glucose metabolic pathways. By activating PPAR $\alpha$ , fenofibrate effectively improves the atherogenic lipid profile associated with type 2 diabetes mellitus and metabolic syndrome (2). Fenofibrate-related PPAR $\alpha$  activation may enhance the expression of genes promoting hepatic FA  $\beta$ -oxidation. Fenofibrate also reduces hepatic insulin resistance. It also inhibits the expression of inflammatory mediators involved in non-alcoholic steatohepatitis pathogenesis. These include tumor necrosis factor- $\alpha$ , intercellular cell adhesion molecule-1, vascular cell adhesion molecule-1 and monocyte chemoattractant protein-1 (2). Its anti-inflammatory effects, when taken together with anti-oxidant actions, may prevent from Non-alcoholic steatohepatitis (or NASH)-related necroinflammation, apoptosis and fibrosis. These are attributed to inhibited expression of inflammatory mediators, including TNF- $\alpha$ , MCP-1, VCAM-1 and ICAM-1, together with reduced lipid peroxidation and reactive oxygen species formation. Note that the pharmacologically active agent is deesterified to fenofibric acid. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Wulfert, Boissard, Legendre & Baron (1981) *Artery* **9**, 120. 2. Kostapanos, Kei & Elisaf (2013) *World J. Hepatol.* **5**, 470.

### Fenoprofen

This nonsteroidal anti-inflammatory agent (FW<sub>free-acid</sub> = 242.27 g/mol), also named 2-(3-phenoxyphenyl)propanoic acid, targets prostaglandin synthase, or cyclooxygenase (1-3). The *S* enantiomer is more active than the *R*-isomer. Fenoprofen is used most often to relieve pain, tenderness, swelling, and stiffness caused by osteoarthritis and rheumatoid arthritis. It is also used to treat ankylosing spondylitis and gouty arthritis. Major urinary metabolites are fenoprofen glucuronide and 4'-hydroxyfenoprofen glucuronide. **Target(s):** aromatic amino-acid decarboxylase (4); hyaluronidase (5); long-chain-fatty-acyl CoA synthetase, or long-chain-fatty-acid:CoA ligase, by the *R*-isomer (6); palmitoyl-CoA synthetase (7). 1. Jell & Sweatman (1976) *Can. J. Physiol. Pharmacol.* **54**, 161. 2. Ali & McDonald (1978) *Thromb. Res.* **13**, 1057. 3. Rubin, Knadler, Ho, Bechtol

& Wolen (1985) *J. Pharm. Sci.* **74**, 82. 4. Pribova, Gregorova & Drata (1992) *Pharmacol. Res.* **25**, 271. 5. Joyce, Mack, Anderson & Zaneveld (1986) *Biol. Reprod.* **35**, 336. 6. Knights & Jones (1992) *Biochem. Pharmacol.* **43**, 1465. 7. Roberts & Knights (1992) *Biochem. Pharmacol.* **44**, 261.

### Fenpropimorph

This synthetic fungicide (FW = 303.49 g/mol; CAS = 67564-91-4), also named *cis*-2,6-dimethyl-4-{2-methyl-3-[4-(2-methyl-2-propanyl)phenyl]-propyl}morpholine or (2*R*,6*S*)-4-[3-(4-tert-butylphenyl)-2-methyl-propyl]-2,6-dimethylmorpholine, inhibits phytoosterol and cholesterol biosynthesis. Ergosterol biosynthesis is inhibited in the fungi, leading to the arrest of cell proliferation in the unbudded G<sub>1</sub> phase of the cell cycle. Cholesterol biosynthesis appears to be inhibited at a lanosterol demethylation step. **Target(s):** cholesterol  $\Delta$ -isomerase, or sterol  $\Delta^{8,7}$ -sterol isomerase (1-3); cholesterol oxidase (4);  $\Delta^{14}$ -sterol reductase (1);  $\Delta^{5,7}$ -sterol- $\Delta^7$ -reductase (5). 1. Marcireau, Guilloton & Karst (1990) *Antimicrob. Agents Chemother.* **34**, 989. 2. Moebius, Bermoser, Reiter, Hanner & Glossmann (1996) *Biochemistry* **35**, 16871. 3. Commun.* **181**, 465.

### Fentanyl & Acetyl-fentanyl

Fentanyl

Acetylfentanyl

This much-abused synthetic,  $\mu$ -opioid receptor agonist (FW<sub>fentanyl</sub> = 336.48 g/mol; CAS = 437-38-7), also known by the trade names Sublimaze<sup>®</sup>, Actiq<sup>®</sup>, Durogesic<sup>®</sup>, Duragesic<sup>®</sup>, Fentora<sup>®</sup>, Matrifen<sup>®</sup>, Haldid<sup>®</sup>, Onsolis<sup>®</sup>, Instanyl<sup>®</sup>, Abstral<sup>®</sup>, and Lazanda<sup>®</sup>, is a general anesthetic used to treat breakthrough pain (*i.e.*, pain that comes on suddenly and persists for a short period). It inhibits 3',5'-cyclic-AMP formation (IC<sub>50</sub> = 27 nM), but not K<sup>+</sup>-evoked release of noradrenaline. Possessing an analgesic potency that is 100x higher than morphine, intravenous fentanyl is best managed in the clinical setting, where it is used for anesthesia and analgesia, most often in operating rooms and intensive care units (1). **Fentanyl Pharmacokinetic Parameters:** Fentanyl displays a large apparent volume of distribution, short plasma half life and extensive biotransformation. With an *n*-Octanol/H<sub>2</sub>O partition coefficient >700, fentanyl can be administered by various routes. Upon intravenous administration, it quickly passes to CNS (transfer *t*<sub>0.5</sub> = 5–6 min), binding to  $\mu$ -opioid G-protein-coupled receptors, thereby inhibiting pain neurotransmitter release by decreasing intracellular Ca<sup>2+</sup> levels. Compared to morphine, fentanyl enjoys a shorter duration of action, the lack of hyperglycemic response to surgery, a decrease in catecholamine levels, and higher lipid solubility. Fentanyl is also delivered with a transdermal patch or an Actiq "lollipop" for absorption across the buccal mucosa. Breakthrough Pain (*i.e.*, transitory pain reaching maximum severity in ~15 minutes and lasting ~60 minutes) is currently managed by administering fentanyl by transmucosal and intranasal routes. For additional information on fentanyl's pharmacokinetics, See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). Fentanyl inhibits gastric cell growth and proliferation, with cell cycle arrest at the G<sub>2</sub>/M junction (2). Fentanyl and acetylfentanyl (below)

are easy to make and widely available designer drugs that have replacing heroin in their illicit use. **Acetyl-fentanyl:** This recreational drug (FW = 322.44 g/mol; CAS: 3258-84-2; IUPAC Name: *N*-(1-phenethylpiperidin-4-yl)-*N*-phenylacetamide) is similar in its actions to fentanyl and possesses opioid-like *in vitro* binding affinity to  $\mu$ -opioid receptors as well as  $\mu$ -opioid receptor agonist effects. Acetyl fentanyl has not been approved for medical use in the United States, and there are no published studies on safety in human use. The potency of acetylfentanyl was about one-third that of fentanyl. As a  $\mu$ -opioid receptor agonist, acetyl fentanyl often serves as a direct substitute for heroin or other  $\mu$ -opioid receptor agonist substances in opioid dependent individuals. Acetyl-fentanyl has been detected in tablets that mimic pharmaceutical opiate products, in powder form and spiked on blotter papers. 1. Heitz, Witkowski & Viscusi (2009) *Curr. Opin. Anaesthesiol.* **22**, 608. 2. Kasai & Ikeda (2011) *Pharmacogenomics* **12**, 1305.

### Fenticonazole

Thisazole-type fungicide (FW = 455.40 g/mol; CAS = 72479-26-6), also named 1-[2-(2,4-dichlorophenyl)-2-{[4-(phenylsulfanyl)phenyl]methoxy}ethyl]-1*H*-imidazole, resembles fluconazole by inhibiting 14 $\alpha$ -demethylase, the cytochrome P450 that converts lanosterol to ergosterol. The latter is an essential component of the fungal cytoplasmic membrane. The antifungal activity spectrum of fenticonazole is very broad: dermatophytes, yeasts and dimorphic fungi were the most susceptible organisms (1). In the treatment of vulvovaginal candidiasis, fenticonazole is inserted as a 200-mg ovule into the vagina at bedtime on three successive nights (1). In an *in vitro* study, fenticonazole also exhibited excellent activity against gram-positive microorganisms. (See also *Fluconazole*) 1. Veronese, Salvaterra, Barzaghi (1981) *Arzneimittel-forschung.* **31**, 2133. 2. Wiest & Ruffmann (1987) *J. Int. Med. Res.* **15**, 319.

### Fenvalerate

This synthetic insecticide (FW = 419.91 g/mol), used to control a wide range of pests, inhibits calcineurin (1-3) and induces depolarization by keeping Na<sup>+</sup> channels in an open state (4). Fenvalerate also decreases the phase-transition temperature of model membranes and localizes deep within the acyl chain region of the lipid, presumably weakening the acyl chain packing. Note: There are four stereoisomers of fenvalerate, a fact that is likely to explain differences in the literature concerning effects on calcineurin. 1. Enan & Matsumura (1992) *Biochem. Pharmacol.* **43**, 1777. 2. Fakata, Swanson, Vorce & Stemmer (1998) *Biochem. Pharmacol.* **55**, 2017. 3. Enz & Pombo-Villar (1997) *Biochem. Pharmacol.* **54**, 321. 4. Salgado & T. Narahashi (1993) *Mol. Pharmacol.* **43**, 626.

### Ferrate Ion, or FeO<sub>4</sub><sup>2-</sup>

This powerful Fe(IV)-state oxidant and orthophosphate analogue, often supplied as K<sub>2</sub>FeO<sub>4</sub> (FW = 198.04 g/mol) irreversibly inactivates glycogen phosphorylase *b* and adenylate kinase, in both cases reacting at tyrosyl residues. Ferrate ion also inactivates ribonuclease A by reacting at a histidyl residue. A tryptophanyl residue in triose-phosphate isomerase is also modified by ferrate. Although unstable at neutral and acidic pH, potassium ferrate can be kept at alkaline pH in the absence of reducing agents.

**Chemical Properties:** With a reduction potential varying from +2.2 V to +0.7 V in acidic and basic solutions, Fe(IV) is a powerful oxidizing agent throughout the entire pH range, respectively (1). In strong acids, H<sub>3</sub>Fe(VI)O<sub>4</sub><sup>+</sup> and H<sub>2</sub>Fe(VI)O<sub>4</sub> ions reduces, both rapidly and exothermally, to Fe(III) and oxygen. At pH 7, 98% of the agent exists in the HFe(VI)O<sub>4</sub><sup>-</sup> species. At at pH 10, the oxygen ligands of Fe(VI) exchange very slowly with water. For a diagram detailing the complete pH-dependent speciation of ferrate ion, see Fig. 1 of the first reference. **Target(s):** acid phosphatase (2); adenylate kinase (3); alcohol dehydrogenase (2); alkaline phosphatase (2); arylsulfatase A (4,5); DNA-directed DNA polymerase (6); DNA polymerase I (6); fructose-1,6-bisphosphatase (2); fumarase (2); glycogen phosphorylase *b*, inhibited by potassium ferrate (7,8); lipoxygenase, soybean, weakly inhibited (2); murine leukemia virus reverse transcriptase (9); nitrate reductase (10); pancreatic ribonuclease, ribonuclease A (11,12); phosphoglucomutase (2); phosphoglycolate phosphatase (2); pyrophosphatase (2); RNA-directed DNA polymerase (9); triose-phosphate isomerase (13); venom 5'-nucleotidase (2). 1. Sharma (2002) *Adv. Envir. Res.* **6**, 143. 2. Rajababu & Axelrod (1978) *Arch. Biochem. Biophys.* **188**, 31. 3. Crivellone, Hermodson & Axelrod (1985) *J. Biol. Chem.* **260**, 2657. 4. ### Ferrichrome & Ferrichrome A

These ferric ion-chelating siderophores (FW<sub>Ferrichrome</sub> = 740.52 g/mol, R = CH<sub>3</sub>, and R' = H; FW<sub>Ferrichrome-A</sub> = 1053.22 g/mol, R = *trans*-HOOCCH<sub>2</sub>(CH<sub>3</sub>)C=CH-, and R' = -CH<sub>2</sub>OH; CAS = 15258-80-7) from *Ustilago sphaerogena* are cyclic hexapeptide, growth-promoting factors that competitively inhibit the antibiotic action of sideromycins. Six oxygen atoms from three hydroxamate groups bind Fe(III) in nearly perfect octahedral coordination. First isolated from the fungus *Ustilago sphaerogena*, the ferrichromes have been identified in other fungi. Note: *p*-Azidobenzoyloxyferricrocin is a photoactivatable analogue of ferrichrome (1). Albomycin, a derivative of ferrichrome with a bound thioribosyl-pyrimidine moiety, inhibits seryl-t-RNA synthetase. **Target(s):** gelatinase A (matrix metalloproteinase-2) (2). 1. Salah el Din, Braun, Abdallah (1999) *Biometals* **12**, 151. 2. Gendron, Grenier, Sorsa, Uitto & Mayrand (1999) *J. Periodontal Res.* **34**, 50.

### Ferricyanide, or Fe(CN)<sub>6</sub><sup>3-</sup>

This hexacoordinate Fe(III)-cyanide complex (commonly supplied as  $K_3Fe(CN)_6$ , FW = 329.24 g/mol; CAS = 13746-66-2), also known as hexacyanoferrate(III), is frequently used as an electron acceptor in many enzyme-catalyzed reactions as well as an oxidant of sulfhydryl groups, resulting in the formation of ferrocyanide,  $Fe(CN)_6^{4-}$ . (**See Ferrocyanide for X-Gal Localization of  $\beta$ -Galactosidase**) The geometry of the metal ion complex does not change when switching between Fe(III) and Fe(II) oxidation states.

**CAUTION:** Although a cyanide-containing substance, ferricyanide is considerably less toxic than potassium cyanide, a fact reflecting the overall stability of the octahedral complex. Ferricyanide will, however, react with mineral acids to release the extremely toxic gas, hydrogen cyanide.

**Target(s):** acid phosphatase (1); aconitase (2); adenylyl sulfate kinase (3); alkaline phosphatase (1);  $\alpha$ -amylase (4);  $\beta$ -amylase (5); L-arabinose dehydrogenase (6,7); arylsulfatase (8); asclepain (9); asparaginase (10); aspartate aminotransferase (11); bromelain (9); carbonic anhydrase (12); carboxylesterase (13); chlorophyllase (14); cholinesterase (15); cytochrome *c* oxidase (16); deoxyribodipyrimidine photo-lyase (17,18); DNase (19); dextranase (20); diisopropylfluorophosphatase (21); ferredoxin:NADP<sup>+</sup> reductase (60); formate acetyltransferase (22);  $\beta$ -fructofuranosidase (23,24); fructose 1,6-bisphosphate aldolase (25,26); galactose dehydrogenase (7,27); gentisate 1,2-dioxygenase (28); glucan endo-1,3- $\beta$ -D-glucosidase (29); glycine acetyltransferase (30); homogentisate 1,2-dioxygenase (31); inositol oxygenase (61);  $\beta$ -lactamase, or penicillinase (32); lactate dehydrogenase (33); lipase (34); luciferase (35,36); mannose isomerase (37); mitochondrial processing peptidase (38); NADH dehydrogenase (39); NADH oxidase (40); papain (41,42); penicillopepsin (43); pepsin (44); phosphofructokinase45; 3-phosphoglycerate kinase (46); phospholipase C (47); phosphoprotein phosphatase (48); protein-phosphohistidine:sugar phosphotransferase (49); pyruvate decarboxylase (26); pyruvate oxidase (50); succinate dehydrogenase, or succinate oxidase (51-54); sulfite oxidase (55,56); transaldolase (26); transketolase (26); tryptophan 2,3 dioxygenase (57); tryptophan 2-monooxygenase (62); tryptophan synthase (58);  $\beta$ -tyrosinase, or tyrosine phenol-lyase (59). 1. ### Ferrocyanide

This anion (commonly supplied as the potassium salt,  $K_4Fe(CN)_6$ , FW<sub>anhydrous</sub> = 368.35 g/mol; CAS = 13943-58-3; FW<sub>trihydrate</sub> = 422.388 g/mol; CAS = 14459-95-1) inhibits many enzymes, particularly those requiring heme prosthetic groups. Potassium ferrocyanide trihydrate and sodium ferrocyanide decahydrate salts are efflorescent and slowly dehydrate at 60°C. (A related compound is sodium nitroprusside ( $Na_2[Fe(CN)_5NO]$ ), a NO-releasing drug.) **X-Gal Localization of  $\beta$ -Galactosidase:** A combination of potassium ferrocyanide and potassium ferricyanide in phosphate-buffered solution (PBS) serves as a redox buffer for X-Gal, which is used to cleave  $\beta$ -galactosidase, resulting in a bright blue visualization method for marking the intracellular location of any protein, enzyme, or antibody conjugated to  $\beta$ -gal (1). **Step-1.** Aspirate media from dish of cultured cells, wash cells twice with PBS. **Step-2.** Fix cells in PBS/0.05% glutaraldehyde. **Step-3.** Incubate at room temperature for 5 min. **Step-4.** Remove PBS/0.05% Glutaraldehyde; then wash twice with PBS. **Step-5.** Stain with PBS containing 1 mM  $MgCl_2$ , 5 mM  $K_4[Fe(II)(CN)_6]$ , 5 mM  $K_3[Fe(III)(CN)_6]$ , plus 1 mg/ml X-gal. (Note: X-gal staining solution should be warmed to 37°C for 5-10 min before use.) **Step-6.** Incubate at room temperature or 37°C in dark until desired level of staining is observed (typically several hours to overnight). **Step-7.** Stop further development of staining by washing several times with PBS. **Step-8.** Examine cells under a bright-field microscope. (**Reagents:** **Washing Buffer:** 3.74 g  $NaH_2PO_4 \cdot H_2O$  and 10.35 g  $Na_2HPO_4$  (anhydrous) in 1 L  $H_2O$ ; adjust to pH 7.3. **Fixing Buffer for X-gal Staining:** 0.1M phosphate buffer (pH 7.3) containing 5 mM EGTA, 2 mM  $MgCl_2$  and 0.2% glutaraldehyde (Stored at 4°C for up to 4 months). **Wash Buffer for X-gal Staining:** 0.1M phosphate buffer (pH 7.3), containing 2 mM  $MgCl_2$  (Stored at 4°C indefinitely). **X-gal Staining Buffer:** 0.1M phosphate buffer (pH 7.3), containing 2 mM  $MgCl_2$ , 5mM  $K_4Fe(II)(CN)_6$  and 5mM  $K_3Fe(III)(CN)_6$  (Store in the dark at 4°C) Prior to use, add 5-bromo-4-chloro-3-indolyl- $\beta$ -D-galactoside (X-gal) to final concentration of 1 mg/ml and filter to remove any crystals.) **CAUTION:** Although a cyanide-containing substance, ferrocyanide is considerably less toxic than potassium cyanide, a fact reflecting the overall stability of the octahedral complex. Ferrocyanide will, however, react with mineral acids to release the extremely toxic gas, hydrogen cyanide. **Target(s):** aminopeptidase I (2); arylsulfatase A (3); arylsulfatase B, *N*-acetylgalactosamine-4-sulfatase (3); carbonic anhydrase (4); cytochrome *c* oxidase (5); dihydropteridine reductase (6); dopamine  $\beta$ -monooxygenase, also alternative substrate (7); ferredoxin:NADP(H) reductase, inhibited by Zn-ferrocyanide (8); inositol oxygenase (9); NADP<sup>+</sup> reductase (10); pectin lyase (11); peptidylglycine monooxygenase (12); peroxidase (13); 3-phosphoglycerate kinase (14); urate oxidase, or uricase, weakly inhibited (15). 1. **Ferrostatin-1**

This potent and selective ferroptosis inhibitor (FW = 262.35 g/mol; CAS = 347174-05-4; Solubility: 52 mg/mL DMSO or Ethanol; <1 mg/mL H<sub>2</sub>O; Symbol: Fer-1), also named 3-amino-4-(cyclohexylamino)benzoic acid ethyl ester, prevents erastin-induced ferroptosis in cancer cells, as well as glutamate-induced cell death in postnatal rat brain slices (EC<sub>50</sub> = 60 nM). (*See Erastin*) Ferroptosis is dependent upon intracellular iron, but not other metals, and is morphologically, biochemically, and genetically distinct from apoptosis, necrosis, and autophagy. Given its ortho-diaminobenzene structure and the likelihood of intracellular ester hydrolysis, ferrostatin is likely to be an iron chelator. **1.** Dixon, Lemberg, Lamprecht, *et al.* (2012) *Cell* **149**, 1060.

**Ferulate (Ferulic Acid)**

These substituted cinnamic acids (FW<sub>free-acid</sub> = 194.19 g/mol), also known as 4-hydroxy-3-methoxycinnamic acid, itself a component of many plant esters, polyesters, and glycosides, also occurs in small amounts as the free acids in many plants. **Target(s):** α-amylase, weakly inhibited (1); arylamine *N*-acetyltransferase (2,3); chorismate mutase (4); 4-coumaroyl-CoA synthetase, or 4-coumarate:CoA ligase, as alternative substrate (5-7); diphosphomevalonate decarboxylase (8,9); ethoxyresorufin *O*-deethylase, or cytochrome P450 (10); feruloyl esterase (11); glutathione *S*-transferase (12,13); lipase, pancreatic, or triacylglycerol lipase (14); 15-lipoxygenase, soybean (15); methoxyresorufin *O*-demethylase, cytochrome P450 (10); peroxidase, horseradish (16); phenylalanine ammonia-lyase (17-19); phenylpyruvate tautomerase (20); quinate *O*-hydroxy-cinnamoyltransferase (21); thromboxane A<sub>2</sub> synthase (22); tyrosinase, or monophenol monooxygenase (23-25); xanthine oxidase (26). **1.** Funke & Melzig (2005) *Pharmazie* **60**, 796. **2.** Makarova (2008) *Curr. **Fesoterodine**

This antimuscarinic agent (FW = 411.28 g/mol; CAS 286930-03-8; IUPAC: [2-[(1*R*)-3-(di(propan-2-yl)amino)-1-phenylpropyl]-4-(hydroxymethyl)phenyl]2-methylpropanoate), is a prodrug that is often delivered as its fumarate salt under the brand name Toviaz<sup>®</sup> to improve the symptoms of overactive bladder syndrome. Fesoterodine is converted by plasma esterases to its active metabolite, 5-hydroxymethyl tolterodine (*Symbol*: 5-HMT or SPM-7605). When tested *in vitro*, 5-HMT potently inhibits radioligand binding at all five human muscarinic receptor subtypes with equal affinity. Fesoterodine has a similar balanced selectivity profile but is less potent than 5-HMT (1). Both substances are competitive antagonists of cholinergic agonist-stimulated responses in human M<sub>1</sub>-M<sub>5</sub> muscarinic receptor subtype-containing cell lines and has a similar potency and selectivity profile to the radioligand-binding studies (1). In the presence of the esterase inhibitor neostigmine, the concentration-response curve of fesoterodine is shifted to the right, suggesting that part of the activity is caused by metabolism to SPM 7605 by tissue enzymes (1). Fesoterodine is primarily eliminated as inactive metabolites, with significant renal excretion of 5-HMT. Significantly, fesoterodine and 5-HMT bind competitively and reversibly to muscarinic receptors with greater affinity in the human bladder mucosa and detrusor muscle than in the parotid gland (2). **1.** Ney, Pandita, Newgreen, *et al.* (2008) *BJU Internat.* **101**, 1036. **2.** Yoshida, Fuchihata, Kuraoka (2013) *Urology* **81**, 920.

**Fexofenadine**

This orally active, second-generation peripheral antihistamine (FW = 501.68 g/mol; CAS = 83799-24-0), also named Allegra<sup>®</sup>, Axodin<sup>®</sup>, and (±)-4-[1-hydroxy-4-[4-(hydroxydiphenyl-methyl)-1-piperidinyl]butyl]-α,α-dimethylbenzeneacetate, is a once daily, blockbuster H<sub>1</sub> receptor antagonist that does not cause sedation, because, as a zwitterionic species, it is less apt to pass the blood-brain barrier. As an active metabolite of the second-generation histamine H<sub>1</sub> receptor antagonist terfenadine, fexofenadine does not suffer the disadvantage of QT prolongation (1,2). In addition, unlike first-generation antihistamines, it is associated with few CNS adverse effects. By preventing the activation of the H<sub>1</sub> receptors by histamine, fexofenadine reduces the symptoms associated with allergies from occurring. It does not readily cross the blood-brain barrier, accounting for its failure to induce drowsiness or to show anticholinergic effects. **1.** Chen (2007) *Drugs* **8**, 301. **2.** Lappin, Shishikura, Jochemsen, *et al.* (2010) *Eur. J. Pharm. Sci.* **40**, 125.

**Fibronectin Fragment 1377-1388, Similar in action to Fibronectin Fragment 1371-1382**

**Fidarestat**

This aldose reductase inhibitor (FW = 279.22 g/mol; CAS = 136087-85-9), also known by its code name SNK-860, its trade name Aldos<sup>®</sup>, and its systematic name (2*S*,4*S*)-6-fluoro-2',5'-dioxospiro[chroman-4,4'-imidazolidine]-2-carboxamide, is used to treat diabetic retinopathy and carotogenesis (1-3). (*See also Alrestatin*) Fidarestat has proven to be highly selective for aldose reductase (AR or AKR1B1) over aldehyde reductase (AKR1A1), a property that most likely explains its modest side effects *in vivo*. The structural basis for fidarestat selectivity has been reported (3,4). With 1-mg daily dosing of Type 2 diabetic patients, fidarestat had no effect on glycemic control (based on plasma glucose and HbA<sub>1c</sub> levels), but

normalized the sorbitol content of erythrocytes under fasting and postprandial conditions (5). Because glucose reduction increases intracellular osmotic pressure by the accumulation of nondiffusible sorbitol and because AKR1B1 action contributes to iron- and transferrin-related oxidative stress associated with cerebral ischemic injury, inhibition of AKR1B1 may have therapeutic potential against ischemic cerebral injury (6). **Other Targets:** 3-Deoxyglucosone and heparin-binding epidermal growth factor-like growth factor mRNA expression (7); phosphorylation of JNK and c-Jun occurs in fast-conduction mechanoreceptors (8); ischemia-reperfusion-induced inflammatory response in rat retina (9). **1.** Yamaguchi, Miura, Usui, *et al.* (1994) *Arzneimittelforschung* **44**, 344. **2.** Oka, Matsumoto, Sugiyama, Tsuruta & Matsushima (2000) *J. ### Fidaxomicin

This narrow-spectrum macrocyclic antibiotic (FW = 1058.04 g/mol; CAS = 873857-62-6), marketed under the trade names Dificid<sup>®</sup> and Dificlir<sup>®</sup>, and known previously by the code names OPT-80 and PAR-101, is an FDA-approved drug for the treatment of *Clostridium difficile*-associated diarrhea (1,2). The minimum inhibitory concentration for 90% of organisms for fidaxomicin against *C. difficile* ranged from 0.0078 to 2 µg/mL in *in vitro* studies. **Primary Mode of Action:** *C. difficile* is a Gram-positive, spore-forming, toxin-producing, anaerobic bacillus found ubiquitously and easily transmitted by the fecal-to-oral route. Fidaxomicin blocks initiation of transcription, but only when present before the formation of the "open promoter complex," in which the template DNA strands have separated and RNA synthesis has not yet begun. Its metabolite OP-1118 is virtually equipotent in its antibiotic action against *C. difficile*. **Target(s):** toxin production in *C. difficile*, an *in vitro* property that is not observed in vancomycin inhibition of *C. difficile* growth (4); spore production in *C. difficile* (5). **1.** Tannock, Munro, Taylor, *et al.* (2010) *Microbiology* **156**, 3354. **2.** Louie, Miller, Mullane (2011) *New Engl. J. Med.* **364**, 422. **3.** Artsimovitch, Seddon & Sears (2012) *Clin. Infect. Dis.* **55**, (Supplement 2), S127. **4.** Babakhani, Bouillaut, Sears, *et al.* (2013) *J. Antimicrob. Chemother.* **68**, 515. **5.** Babakhani, Bouillaut, Gomez, *et al.* (2012) *Clin. Infect. Dis.* **55**, (Supplement 2), S162.

### Fiduxosin

This  $\alpha$ -receptor antagonist (FW<sub>free-base</sub> = 555.66 g/mol; FW<sub>hydrochloride</sub> = 592.11 g/mol; Insoluble in H<sub>2</sub>O; 10 mg/mL DMSO), also known as 3-[4-((3*aR*,9*bR*)-*cis*-9-methoxy-1,2,3,3*a*,4,9*b*-hexahydro[1]benzopyrano[3,4-*c*]pyrrol-2-yl)butyl]-8-phenylpyrazino[2',3':4,5]-thieno[3,2-*d*]pyrimidine-2,4-(1*H*,3*H*)-dione and ABT-980, targets  $\alpha_{1A}$ - and  $\alpha_{1D}$ -adrenoceptors (1-3), blocking both phenylephrine (PE)-induced intraurethral pressure (IUP) and

mean arterial pressure (MAP) responses after single oral dosing in conscious male beagles, with respective IC<sub>50</sub> values of 261 ng/mL and 1900 ng/mL (3). The high values reflect strong plasma protein binding (>99.8%) of the drug. **1.** Brune, Katwala, Milicic, *et al.* (2002) *J. Pharmacol. Exp. Ther.* **300**, 487. **2.** Hancock, Buckner, Brune, *et al.* (2002) *J. Pharmacol. Exp. Ther.* **300**, 478. **3.** Witte, Brune, Katwala, *et al.* (2002) *J. Pharmacol. Exp. Ther.* **300**, 495.

### Figitumumab

This potent and fully humanized monoclonal anti-insulin-like growth factor-1 receptor antibody, or IGF1R, antibody (MW = 146.0 kDa; CAS = 943453-46-1), also known by its code name CP-751871 and others (1), is an investigational drug for treating adrenocortical carcinoma and non-small cell lung cancer (NSCLC). Pharmacokinetic analysis shw a dose-dependent increase in CP-751,871 and ~2-fold accumulation on repeated dosing in 21-day cycles (2). Figitumumab has an effective half-life of approximately 20 days, and it has been well tolerated in clinical studies when given alone or in combination with chemotherapy and targeted agents (3). **1.** Alternate Names = Immunoglobulin G<sub>2</sub>, anti-(human insulin-like growth factor 1 receptor (EC.2.7.10.1 or CD221 antigen)); human monoclonal CP-751871 clone 2.13.2  $\gamma_2$ -heavy chain (139-214')-disulfide with human monoclonal CP-751871 clone 2.13.2  $\kappa$  light chain, dimer (227-227":228-228":231-231":234-234")-tetrakisdisulfide. **2.** Haluska, Shaw, Batzel, *et al.* (2007) *Clin. Cancer Res.* **13**, 5834. **3.** Gualberto & Karp (2009) *Clin. Lung Cancer* **10**, 273.

### Filgotinib

This JAK1-selective inhibitor (FW = 425.51 g/mol; CAS = 1206161-97-8; Solubility: 85 mg/mL DMSO; < 1 mg/mL H<sub>2</sub>O), also named *N*-[5-[4-[(1,1-dioxido-4-thiomorpholinyl)methyl]phenyl][1,2,4] triazolo[1,5-*a*]pyridin-2-yl]cyclopropanecarboxamide and GLPG0634, targets Janus Kinases: JAK1 (IC<sub>50</sub> = 10 nM), JAK2 (IC<sub>50</sub> = 28 nM), JAK3 (IC<sub>50</sub> = 810 nM), and TYK2 (IC<sub>50</sub> = 116 nM). **Pharmacodynamics:** JAK1 plays a critical role in signal transduction in many Type I and Type II inflammatory cytokine receptors, such that JAK1 inhibitors offer great promise fo treating immune-inflammatory diseases. After oral administration, exposure to filgotinib is dose-proportional, with an elimination half-life of 6 hours (2). Its major metabolite, formed by de-esterification, showed JAK1 selectivity, with higher exposure and lower potency than filgotinib. The relatively long duration of JAK1 inhibition following filgotinib dosing suggests that the maximum response is reached at a daily filgotinib dose of 200 mg. **1.** Van Rompaey, Galien, van der Aar, *et al.* (2013) *J. Immunol.* **191**, 3568. **2.** Namour, Diderichsen, Cox, *et al.* (2015) *Clin. Pharmacokinet.* **54**, 859.

### Filibuvir

This non-nucleoside HCV inhibitor (FW = 503.64 g/mol; CAS = 877130-28-4), also known by the code name PF-868554, targets hepatitis C virus RNA-dependent RNA polymerase by binding noncovalently within the "Thumb-2" pocket, IC<sub>50</sub> of 19 nM *in vitro* (1). It is active against >95 % of genotype 1 replicons (EC<sub>50</sub> = 59 nM), with similar potencies against replicons containing patient-derived subtype 1a and subtype 1b NS5B

sequences (2). In two Phase-1b clinical studies with HCV genotype 1-infected patients, filibuvir potently inhibited viral replication, with doses of  $\geq 450$  mg twice daily, resulting in  $>2.0$ -log-unit reductions in HCV RNA. Filibuvir is well tolerated, with no discontinuations, serious adverse events, or deaths reported. Mutations at Met-423 in NS5B were observed in 29 of 38 patients receiving filibuvir at  $\geq 300$  mg BID (4). M423I, M423T, and M423V mutations were all observed, both individually and in genotypic mixtures with the wild type (1). 1. Love, Parge, Yu, *et al.* (2003) *J. Virol.* **77**, 7575. 2. Agents Chemother.* **56**, 1331.

### Filipin

Filipin III

This yellow-colored polyene antibiotic (FW = 654.83 g/mol; CAS = 11078-21-0; IUPAC: (3*R*,4*S*,6*S*,8*S*,10*R*,12*R*,14*R*,16*S*,17*E*,19*E*,21*E*,23*E*,25*E*,27*S*,28*R*)-4,6,8,10,12,14,16,27-Octahydroxy-3-[(1*R*)-1-hydroxyhexyl]-17,28-dimethyloxacyclooctacos-17,19,21,23,25-pentaen-2-one), first isolated from *Streptomyces filipinensis* forms a complex with cholesterol or ergosterol and permeabilizes cells (note that it can form complexes with other  $3\beta$  sterols). Because filipin is active mainly against cholesterol/ergosterol-containing membranes, it is effective at  $\sim 3$   $\mu\text{g/mL}$  as an inhibitor of the raft/caveolae endocytosis pathway in mammalian cells. There are at least four different filipins that vary in the number of hydroxyl groups present; filipin III (FW = 654.84 g/mol) is the major component. It is soluble in ethanol and methanol and very soluble in dimethylformamide. Because filipin is a mixture of filipin I (4%), II (25%), III (53%), and IV (18%), its should be referred to as the filipin complex. *Note:* Except dor amphotericin B and nystatin A1, filipin-like agents have proved to be too toxic for therapeutic applications. **Target(s):** chitin synthase, weakly inhibited (1);  $\text{H}^+$ -driven ATPase (2); photosystem I (3); sterol *O*-acyltransferase, *or* cholesterol *O*-acyltransferase, *or* ACAT (4,5); sterol 24-*C*-methyltransferase, slightly inhibited, and activated at high concentrations (6). 1. ### Fimasartan

This non-peptide angiotensin II receptor antagonist (FW = 501.65 g/mol; CAS = 247257-48-3), also known as 2-(2-butyl-4-methyl-6-oxo-1-[[2'-(1*H*-tetrazol-5-yl)-4-biphenyl]methyl]-1,6-dihydro-5-pyrimidinyl)-*N,N*-dimethylethanethioamide, its code name BR-A-657, and by the trade name Kanarb<sup>®</sup>, inhibits vasoconstriction by blocking  $\text{AT}_1$  and by preventing aldosterone formation, thereby increasing water and salt excretion by the kidneys and decreasing overall blood volume. Fimasartan displaces

[ $^{125}\text{I}$ ][Sar $^1$ -Ile $^8$ ]-angiotensin II from its specific binding sites to  $\text{AT}_1$  subtype receptors in membrane fractions of HEK-293 cells ( $\text{IC}_{50} = 0.16$  nM). 1. Shin, Kim, Paik, *et al.* (2011) *Biomed. Chromatogr.* **25**, 1208. 2. Yi, Kim, Yoon, *et al.* (2011) *J. Cardiovasc. Pharmacol.* **57**, 682.

### Finasteride

This 5- $\alpha$  reductase inhibitor, *or* 5 $\alpha$ -RI (FW = 372.55 g/mol; CAS = 98319-26-7), also known as MK-906, Proscar<sup>®</sup>, Propecia<sup>®</sup>, and *N*-(1,1-dimethylethyl)-3-oxo-(5 $\alpha$ ,17 $\beta$ )-4-azaandrost-1-ene-17-carboxamide, potently and competitively inhibits steroid 5 $\alpha$ -reductase ( $\text{IC}_{50} = 33$  nM), thus blocking the formation of the strong androgen 5 $\alpha$ -dihydrotestosterone. 5 $\alpha$ -Reductase catalyzes the rate-limiting step in the conversion of testosterone (T) to 5 $\alpha$ -dihydroprogesterone (5 $\alpha$ -DHP), progesterone to 5 $\alpha$ -DHP, deoxycorticosterone (DOC) to 5 $\beta$ -dihydrodeoxycorticosterone, cortisol to 5 $\alpha$ -dihydrocortisol, and aldosterone to 5 $\alpha$ -dihydro-aldosterone. (*See also Dutasteride*) Finasteride was the first 5 $\alpha$ -reductase inhibitor to receive clinical approval for the treatment of human benign prostatic hyperplasia and androgenetic alopecia (male pattern hair loss). Because 5- $\alpha$  reductase is also active in other organs, 5- $\alpha$  reductase inhibitors, such as finasteride and dutasteride, often have side-effects, including depression, sexual dysfunction, increased risk of high-grade prostate cancer, as well as delayed diagnosis and early treatment of prostate cancer. **Key Pharmacokinetic Parameters:** *See* Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). 1. Rasmuson, Reynolds, Steinberg, *et al.* (1986) *J. Med. Chem.* **29**, 2298. 2. Stoner (1990) *J. Steroid Biochem. Mol. Biol.* **37**, 375. 3. Njar, Kato, Nnane, *et al.* (1998) *J. Med. Chem.* **41**, 902.

### Fingolimod

This first-in-class myriocin derivative and immune modulator (FW<sub>hydrochloride</sub> = 343.94 g/mol; CAS = 162359-56-0), also known as FTY720, Gilenya<sup>®</sup>, and 2-amino-2-[2-(4-octylphenyl)ethyl]-1,3-propanediol, is a sphingosine-1-phosphate (S1P) receptor-modulating drug that has been approved for the treatment of relapsing-remitting multiple sclerosis. (*See also Myriocin*) Fingolimod prolongs allograft transplant survival in numerous models by inhibiting lymphocyte emigration from lymphoid organs (1). When metabolically phosphorylated by sphingosine kinase *in vivo*, FTY720 becomes a potent agonist for S1P $_1$ , S1P $_3$ , S1P $_4$ , and S1P $_5$  sphingosine-1-phosphate receptors (2). FTY720 also stimulates multidrug transporter-dependent and cysteinyl leukotriene-dependent T cell chemotaxis to lymph nodes (3). Moreover, FTY720-mediated down-regulation of S1P $_1$  receptors on T and B lymphocytes impairs their egress from spleen, lymph nodes, and Peyer's patch (4). Fingolimod also enhances the activity of the sphingosine transporter Abcb1 (*or* Mdr1) and the leukotriene  $\text{C}_4$  transporter Abcc1 (*or* Mrp1) and inhibits cytosolic phospholipase  $\text{A}_2$  activity (4,5). FTY720 decreased the number of circulating blood lymphocytes and induced sequestration of circulating lymphocytes within secondary lymphoid tissues, decreasing lymphocyte infiltration into target organs (6). Moreover, rats pretreated with FTY720 show significantly lower arthritis incidence, delayed onset of arthritis, and suppressed disease activities, suggesting FTY720 is effective in preventing the occurrence and development of collagen-induced arthritis (CIA) in preclinical RA model (7). 1. ### Fisetin

This naturally occurring flavonoid (FW = 286.24 g/mol; CAS = 528-48-3; IUPAC: 2-(3,4-dihydroxyphenyl)-3,7-dihydroxychromen-4-one) has anti-proliferative properties, often inducing apoptosis. Fisetin, for example, reduces the phosphorylation of p38 MAPK, but not that of ERK1/2, JNK1/2, or AKT in cervical cancer cells (1). Fisetin is also a potent sirtuin activator. **Target(s):** transcription of naked DNA by purified RNA polymerase II (2); oxidative burst of neutrophils,  $IC_{50} \approx 100 \mu\text{M}$  (3); Moloney murine leukemia virus reverse transcriptase (4); platelet aggregation,  $IC_{50} = 22 \mu\text{M}$  (5); protein kinase C (PKC),  $IC_{100} = 100 \mu\text{M}$ , competitive inhibitor with respect to ATP binding and noncompetitive with respect to protein substrate (6); osteoporosis by repression of NF- $\kappa\text{B}$  and MKP-1-dependent signaling pathways in osteoclasts (7). 1. ### FK-506

This powerful immunosuppressant (FW = 804.03 g/mol; CAS = 109581-93-3), also known as tacrolimus, is one of two first-line agents (the other, cyclosporin A) responsible for the resounding success of organ transplantation in recent decades. A macrolide from *Streptomyces tsukubaensis*, FK-506 exhibits potent antifungal activity and is a CYP3A substrate (3), but its hallmark action is the inhibition of T-cell activation and, most significantly, the prevention of allograft rejection. **Primary Mode of Action:** Organ rejection is a multistep process that begins with alloantigen recognition, proceeds through lymphocyte activation and clonal expansion, and ends with graft inflammation, the latter attended by full-scale immune attack. Alloantigen recognition normally triggers a signal transduction pathway involving calcineurin, a  $\text{Ca}^{2+}$ - and calmodulin-dependent serine/threonine phosphoprotein phosphatase. The latter dephosphorylates the transcription factor NFATc (Nuclear Factor of Activated T-cells). Once dephosphorylated, cytoplasmic NFATc is translocated into the nucleus, where it up-regulates IL-2 expression, then stimulating killer T cell differentiation and clonal expansion. To prevent allograft destruction, one employs FK-506, which binds to FK-binding protein (or FKBP5), a highly promiscuous peptidylprolyl *cis/trans* isomerase that interacts with mature corticoid receptor hetero-complexes (e.g., progesterone-, glucocorticoid-, mineralcorticoid-receptor complexes) as well as the 90-kDa heat shock

protein and P23 protein (or prostaglandin E synthase-3). It is the formation of the FK-506:FKBP5 complex, however, that noncompetitively inhibits calcineurin, thereby preventing NFATc dephosphorylation/ translocation and the sequelae of biochemical events culminating in allograft rejection. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011).

**Target(s):** calcineurin; FK-binding protein (1,2); glucuronosyltransferase (8); peptidylprolyl isomerase (9-12); membrane translocation of *Clostridium botulinum* C3 toxin in mammalian cells (13); interleukin-1 $\beta$ -induced angiotensin-1, Tie-2 receptor, and vascular endothelial growth factor through down-regulation of JNK and p38 pathway (14); gliostatin/thymidine phosphorylase production, as induced by tumor necrosis factor- $\alpha$  in rheumatoid fibroblast-like synoviocytes (15). 1. ### FK-866

This antineoplastic agent (FW = 390.51 g/mol; CAS = 658084-64-1; *In Vitro* Solubility: <1 mg/mL  $\text{H}_2\text{O}$ , <1 mg/mL DMSO; *In Vivo*: Dissolve in 45% propylene glycol, then bring to 5% Tween 80), also known as Daporinad, APO866, and (*E*)-*N*-(4-(1-benzoylpiperidin-4-yl)butyl)-3-(pyridin-3-yl)acrylamide, is a potent noncompetitive inhibitor ( $K_i = 0.09 \text{ nM}$ ) of nicotinamide phosphoribosyltransferase, also known as NAMPTase as well as pre-B-cell colony-enhancing factor 1 (PBEF1) and visfatin. This enzyme catalyzes the condensation of nicotinamide with PRPP to yield NMN, an intermediate step in  $\text{NAD}^+$  biosynthesis, resulting in gradual  $\text{NAD}^+$  depletion and cell death (1-5). FK-866 induces dose-dependent cytotoxicity in forty-one malignant hematologic cell types, including acute myeloid leukemia, acute lymphoblastic leukemia, mantle cell lymphoma, chronic lymphocytic leukemia, and T-cell lymphoma. In Hep-G<sub>2</sub> human liver carcinoma cells, FK-866-induced  $\text{NAD}^+$  depletion results in apoptosis,  $IC_{50} \approx 1 \text{ nM}$  (2). In healthy human smooth muscle cells, FK-866 induces premature senescence, an effect likely linked to decreased activity of the  $\text{NAD}^+$ -dependent enzyme SIRT1 (2). FK-866 also induces autophagy in SH-SY5Y neuroblastoma cells, as indicated by the formation of LC3-positive vesicles (3). NAMPT inhibition by FK-866 leads to the attenuation of glycolysis at the glyceraldehyde 3-phosphate dehydrogenase step due to the reduced availability of  $\text{NAD}^+$  (6). Attenuation of glycolysis results in the accumulation of glycolytic intermediates before and at the glyceraldehyde 3-phosphate dehydrogenase step, promoting carbon overflow into the pentose phosphate pathway, as evidenced by the increased intermediate levels. Attenuation of glycolysis also causes decreased glycolytic intermediates after the glyceraldehyde 3-phosphate dehydrogenase step, thereby reducing carbon flow into serine biosynthesis and the TCA cycle (6). 1. Hasmann & Schemainda (2003) *Cancer Res.* **63**, 7436. 2. van der Veer, Ho, O'Neil, *et al.* (2007) *J. Biol. Chem.* **282**, 10841. 3. **Flagyl**, See Metronidazole

**Flavopiridol**

This intravenously administered, cyclin kinase-directed inhibitor (FW = 401.84 g/mol; CASs = 146426-40-6, 131740-09-5(HCl), 358739-41-0 (TFA); Solubility: 15 mg/mL DMSO; <1 mg/mL H<sub>2</sub>O; Formulation: Dissolve in 50:50 mixture of Cremophor/ethanol; then diluted in water), also known as HMR-1275, L868275, Alvocidib, and systematically named 2-(2-chlorophenyl)-5,7-dihydroxy-8-((3*S*,4*R*)-3-hydroxy-1-methylpiperidin-4-yl)-4*H*-chromen-4-one, is a flavonoid from an indigenous plant in India, with potent and specific *in vitro* inhibition of all cdk, blocking cell cycle progression at the G<sub>1</sub>/S and G<sub>2</sub>/M boundaries. Alvocidib targets CDK1, CDK2, CDK4, CDK5, CDK6 and CDK9 with IC<sub>50</sub> values of 30 nM, 170 nM, 100 nM, 170 nM, 80 nM and 20 nM, respectively (1). Flavopiridol also potentially inhibits the activity of glycogen synthase kinase-3, or GSK-3 (IC<sub>50</sub> = 280 nM) (2). 1. Kim, *et al.* (2000) *J. Med. Chem.* **43**, 4126. 2. Lu, *et al.* (2005) *J. Med. Chem.* **48**, 737. 3. Montagnoli, *et al.* (2008) *Nat. Chem. Biol.* **4**, 357. 4. Carlson, *et al.* (1996) *Cancer Res.* **56**, 2973. 5. Kim, *et al.* (2002) *J. Med. **Flavostatin**

This 68-residue cysteine-rich inhibitor of platelet aggregation and zinc-metalloproteinase (MW = 56.3 kDa; Accession Number: P14530), is a disintegrin from the venom of the viper *Trimeresurus flavoviridis* that contains an RGD loop, thereby facilitating tight binding to integrins in a manner that inhibits ADP-, collagen-, and thrombin receptor agonist peptide-induced platelet aggregation in human platelet-rich plasma (IC<sub>50</sub> = 60-100 nM). See also *Flavordin*. 1. Maruyama, Kawasaki, Sakai, *et al.* (1997) *Peptides* **18**, 73. 2. Kawasaki, Sakai, Taniuchi, *et al.* (1996) *Biochimie* **78**, 245.

**Fleroxacin**

This fluoroquinolone-class antibiotic (FW = 369.34 g/mol; CAS = 79660-72-3), also named 6,8-difluoro-1-(2-fluoroethyl)-7-(4-methylpiperazin-1-yl)-4-oxoquinoline-3-carboxylate and marketed as Quinodis<sup>®</sup> and Megalocin<sup>®</sup>, is a broad-spectrum systemic antibacterial that targets Type II DNA topoisomerases (gyrases), which are required for bacterial replication and transcription. Fleroxacin is active against many Gram-positive and Gram-negative bacteria, including *Shigella*, *Salmonella*, *Escherichia coli*, *Branhamella catarrhalis*, *Haemophilus influenzae*, *Neisseria gonorrhoeae*, *Yersinia enterocolitica*, *Staphylococcus aureus*, and *Pseudomonas aeruginosa*. For the prototypical member of this antibiotic class, See *Ciprofloxacin*.

**FLI-06**

This first-in-class Notch signaling pathway inhibitor (FW = 438.52 g/mol; CAS = 313967-18-9; Solubility: <1 mg/mL DMSO or H<sub>2</sub>O), also named cyclohexyl-2,7,7-trimethyl-4-(4-nitrophenyl)-5-oxo-1,4,5,6,7,8-hexahydroquinoline-3-carboxylate, disrupts the Golgi apparatus in a manner distinct from that of brefeldin A and golgicide A. FLI-06 inhibits general secretion at a step before exit from the endoplasmic reticulum, which was accompanied by a tubule-to-sheet morphological transition of the ER, making FLI-06 the first small molecule to block secretory traffic at such an early stage. 1. Krämer, Mentrup, Kleizen, *et al.* (2013) *Nature Chem Biol.* **9**, 731.

**Flibanserin**

This orally bioavailable serotonin agonist/antagonist (FW = 390.41 g/mol; CAS = 167933-07-5), known by its code name BIMT-17, its proposed tradename Addyi<sup>®</sup>, its systematic name, 1-(2-{4-[3-(trifluoromethyl)phenyl]piperazin-1-yl}ethyl)-1,3-dihydro-2*H*-benzimidazol-2-one, is a multifunctional post-synaptic 5-HT<sub>1A</sub> receptor agonist and 5-HT<sub>2A</sub> receptor antagonist that resets the poise between these neurotransmitter systems in a manner that is as effective as an antidepressant. Flibanserin shows moderate affinity for cerebral cortical 5-HT<sub>1A</sub> (pK<sub>i</sub> = 7.72) and 5-HT<sub>2A</sub> (pK<sub>i</sub> = 6.90) receptors, with no appreciable affinity for the other 5-HT receptor subtypes (1). It reduces forskolin-stimulated cAMP accumulation in the cerebral cortex (pEC<sub>50</sub> = 6.09) and in the hippocampus (pEC<sub>50</sub> = 6.50), and antagonizes 5-HT-induced phosphatidylinositol turnover (pK<sub>i</sub> = 6.96) in the cerebral cortex (1). Its effect on cAMP accumulation was blocked by the 5-HT<sub>1A</sub> receptor antagonist tertatolol (1). Flibanserin also directly activates postsynaptic serotonin inhibitory responses in the rat cerebral cortex (2,3). **Treatment of Hypoactive Sexual Desire Disorder:** The lack of sexual desire in women causes distress, impacting negatively on personal relationships, quality of life, and health status. HSDD is characterized by reduced sexual fantasies and desire for sexual activity that causes marked distress or interpersonal difficulty and is not accounted for by coexisting conditions, use of medications, or relationship problems. Affecting nearly 10% of all women, HSDD is defined as the absence of sexual interest, desire and/or fantasy, leading to a significant emotional distress, interpersonal difficulties, and a drop in sexual satisfaction. Dubbed the "Female Viagra", flibanserin is also a treatment for female Hypoactive Sexual Desire Disorder (HSDD). Flibanserin appears to be an effective non-hormonal drug for treating HSDD in pre- and postmenopausal women, acting to increase dopamine and norepinephrine (both responsible for sexual excitement) and to decrease serotonin (responsible for sexual inhibition) (4). Flibanserin increases the frequency of satisfying sexual events as well as the intensity of sexual desire (4). Such properties commend its use to enhance sexual desire in premenopausal HSDD. Indeed, early clinical trials found that flibanserin increased the number of monthly "satisfying sexual encounters" by one, as compared to placebo. Flibanserin's mechanism of action in the treatment of HSDD is unknown. In 2015, an advisory committee voted to recommend FDA approval of flibanserin as a treatment of HSDD in pre-menopausal women. Although the antidepressant bupropion has shown some positive results in treating HSDD, flibanserin acts (at clinically relevant doses) as a 5-HT<sub>1A</sub> receptor agonist and secondarily as a 5-HT<sub>2A</sub> receptor antagonist, increasing dopamine and norepinephrine. Adverse side-effects include dizziness, nausea, fatigue and somnolence, which increase when the drug is taken during the day, especially when using any of the numerous moderate or strong cytochrome P-450 3A4 (CYP3A4) inhibitors such as some of the antiretroviral drugs, antihypertensive drugs, antibiotics, and alcohol. **Pharmacokinetics & Pharmacodynamics:** According to FDA filings, flibanserin exhibits linear and dose-proportional pharmacokinetics after single oral doses of 0.5 mg to 150 mg and after multiple doses of orally administered flibanserin with total daily doses ranging from 60–300 mg. The extent of exposure is increased 1.4x during once-daily administration of 100 mg flibanserin, as compared to a single dose. Flibanserin is rapidly absorbed, with 90% of the dose reaching the systemic circulation as flibanserin or metabolites. After oral administration, maximum observed plasma concentrations (C<sub>max</sub>) are usually achieved in 45–60 minutes. Absolute bioavailability of flibanserin following oral dosing is 33%. CYP3A4 and to a minor extent CYP2D6 are the main cytochrome P450

isoenzymes in the oxidative metabolism of flibanserin. Flibanserin is excreted predominantly as conjugated metabolites via the bile (~51% of the dose) and the kidney (~44% of the dose). Steady state is achieved after approximately three days, whereupon the mean terminal half-life of orally administered drug is ~12 hours. 1. Borsini, Giraldo, Monferini, *et al.* (1995) *Naunyn. Schmiedebergs Arch. Pharmacol.* **352**, 276. 2. Borsini, Ceci, Biatti & Donetti (1995) *Naunyn. Schmiedebergs Arch. Pharmacol.* **352**, 283. 3. ### Florfenicol

This potent bacterial protein biosynthesis inhibitor (FW = 358.22 g/mol; CAS = 73231-34-2), also known as Sch 25298 and 2,2-dichloro-*N*-[(1*R*,2*S*)-3-fluoro-1-hydroxy-1-(4-methanesulfonylphenyl)propan-2-yl]acetamide, is a fluorinated analogue of thiamphenicol and structural analogue of chloramphenicol (1,2). Significantly, the *Staphylococcus* and *Escherichia coli* Cfr resistance factor is an RNA methyltransferase that targets nucleotide A2503 and inhibits ribose methylation at nucleotide C2498, thereby causing resistance to chloramphenicol, florfenicol and clindamycin by interfering with the ribosome's peptidyltransferase activity. Florfenicol is solely used in veterinary medicine and was introduced into clinical use in the mid-1990s. 1. Cannon, Harford & Davies (1990) *J. Antimicrob. Chemother.* **26**, 307. 2. Schwarz, Kehrenberg, Doublet & Cloeckart (2004) *FEMS Microbiol. Rev.* **28**, 519. 3. Kehrenberg, Schwarz, Jacobsen, Hansen & Vester (2005) *Molec. Microbiol.* **57**, 1064.

### Floxacillin

This semisynthetic isoxazole penicillin-class antibiotic (FW = 453.87 g/mol; CAS = 5250-39-5), also known as Flucloxacillin, Flopen<sup>®</sup>, Staphylex<sup>®</sup>, Softapen<sup>®</sup>, and (2*S*,5*R*,6*R*)-6-({[3-(2-chloro-5-fluorophenyl)-5-methyl-isoxazol-4-yl]carbonyl}-amino)-3,3-dimethyl-7-oxo-4-thia-1-azabicyclo[3.2.0]heptane-2-carboxylic acid, is a narrow-spectrum, penicillin-class β-lactam typically used to treat infections caused by susceptible Gram-positive bacteria, including β-lactamase-producing *Staphylococcus aureus*. Even so, floxacillin is ineffective against MRSA. Its binding to serum protein is similar to oxacillin and cloxacillin and less than that of dicloxacillin. Oral flucloxacillin reaches higher total and free serum levels than oxacillin and cloxacillin. Similarly, after intramuscular injection the free serum levels of flucloxacillin were higher than those of oxacillin, cloxacillin, and dicloxacillin (See also Cloxacillin; Oxacillin). Floxacillin inhibits cross-linking of the linear peptidoglycan polymer chains comprising the major peptidoglycan component of the cell wall of Gram-positive bacteria. 1. Sutherland, Croydon & Rolinson (1970). *Brit. Med. J.* **4**, 455.

### Fluazifop

This grass-selective herbicide (FW<sub>free-acid</sub> = 327.26 g/mol) inhibits acetyl-CoA carboxylase. The active metabolite is 2-[4-[[5-(trifluoromethyl)-2-pyridinyl]oxy]phenoxy]propionic acid. The *n*-butyl ester (FW = 383.37 g/mol) is a frequently used membrane-penetrating pro-drug. Note that the term fluazifop-P refers to the (*R*)-stereoisomer. 1. Walker, Ridley, Lewis & Harwood (1988) *Biochem. J.* **254**, 307. 2. Harwood (1988) *Trends Biochem. Sci.* **13**, 330. 3. Herbert, Price, Alban, *et al.* (1996) *Biochem. J.* **318**, 997. 4. Price, Herbert, Moss, Cole & Harwood (2003) *Biochem. J.* **375**, 415.

### Fluconazole

This azole (FW = 306.28 g/mol; CAS = 86386-73-4), named systematically as 2-(2,4-difluorophenyl)-1,3-bis(1*H*-1,2,4-triazol-1-yl)propan-2-ol and known by its trade name Diflucan<sup>®</sup>, is a orally active antifungal agent. **Primary Mode of Action:** Fluconazole inhibits the fungal cytochrome P450 enzyme 14α-demethylase, thus preventing conversion of lanosterol to ergosterol, the latter an essential component of the fungal cytoplasmic membrane (1-10). Subsequent accumulation of 14α-methyl sterols is also toxic to fungi. Note that the mammalian demethylase is much less sensitive to fluconazole. **Susceptibility:** Fluconazole is active against *Blastomyces dermatitidis*, *Candida* spp. (but not *C. krusei* and *C. glabrata*), *Coccidioides immitis*, *Cryptococcus neoformans* *Epidermophyton* spp., *Histoplasma capsulatum*, *Microsporium* spp., and *Trichophyton* spp. **Fluconazole Resistance:** In *Candida albicans*, resistance occurs as a consequence of mutations in the gene coding for 14α-demethylase. Such mutations prevent fluconazole from binding, while allowing the enzyme to bind the natural substrate, lanosterol. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** CYP3A4 and CYP2C9 (11-13), glucuronosyltransferase (14), sterol 14-demethylase, or CYP51,  $K_d = 30 \mu\text{M}$  and sterol Δ<sup>22</sup>-desaturase (15). 1. ### Fludarabine

This adenosine analogue (FW = 285.23 g/mol; Symbol: F-ara-A), also known as 9-β-D-arabinofuranosyl-2-fluoro-adenine, is resistant to adenosine deaminase and is phosphorylated by deoxycytidine kinase. Fludarabine is an antineoplastic agent for treating haematological malignancies, particularly B-cell chronic lymphocytic leukemia. **Mechanism of Action:** The free nucleoside F-ara-A enters cells and accumulates mainly as the 5'

triphosphate, F-ara-ATP. The latter has multiple mechanisms of action, mainly affecting DNA synthesis, although incorporation into RNA and inhibition of transcription has been demonstrated. When used as a single agent or in combination with DNA-damaging agents to inhibit DNA repair processes, fludarabine is effective against indolent leukemia and lymphomas. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** adenosine kinase (1); S-adenosylhomocysteinase (2-4); DNA (cytosine-5) methyltransferase (2); DNA biosynthesis (5,6); 5'-nucleotidase (7); RNA biosynthesis (8,9). 1. Miller, Adamczyk, Miller, *et al.* (1979) *J. Biol. Chem.* **254**, 2346. 2. Wyczechowska & Fabianowska-Majewska (2003) *Biochem. Pharmacol.* **65**, 219. 3. Chiang (1987) *Meth. #### Fludarabine 5'-Triphosphate

This nucleotide (FW<sub>free-acid</sub> = 522.15 g/mol) is an ATP analogue that is incorporated into DNA in a self-limiting manner at the 3'-termini. This incorporation into DNA prevents further elongation of the primers by DNA primase (primer RNA chain termination). The 3'→5' exonuclease of DNA polymerase  $\epsilon$  is inhibited by fludarabine-terminated DNA. Note that it is also incorporated into RNA and RNA metabolism is inhibited. **Target(s):** DNA-directed DNA polymerase (1-4); DNA ligase, ATP-requiring (5); DNA polymerase  $\alpha$  (1-4); ribonucleotide reductase (1-3). 1. Tseng, Derse, Cheng, Brockman & Bennett (1982) *Mol. Pharmacol.* **21**, 474. 2. White, Shaddix, Brockman & Bennett (1982) *Cancer Res.* **42**, 2260. 3. Plunkett, Huang & Gandhi (1990) *Semin. #### Flunarizine

This piperazine derivative (FW<sub>free-base</sub> = 404.50 g/mol), also known as Sibelium and (*E*)-1-[bis(4 fluorophenyl)methyl]-4-(3-phenyl-2-propenyl) piperazine, is a calcium channel blocker. It is often used as an anti-migraine agent. **Target(s):** Ca<sup>2+</sup> channel (1); Ca<sup>2+</sup>-dependent ATPase (2,3); calmodulin binding (2,4); calmodulin dependent cyclic-nucleotide phosphodiesterase (5); dopamine D<sub>2</sub> receptor (6); Na<sup>+</sup> channels, voltage dependent (7,8); NADH dehydrogenase, or Complex I (9); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (3,10); succinate dehydrogenase, or Complex II (9); vacuolar H<sup>+</sup>-ATPase, uncoupling (11). 1. Godfraind (1981) *Fed. Proc.* **40**, 2866. 2. Santos, Lopes & Carvalho (1994) *Eur. J. Pharmacol.* **267**, 307. 3. Chiang & Wei (1987) *Gen. Pharmacol.* **18**, 563. 4. Terland & Flatmark (1999) *Neuropharmacology* **38**, 879.

#### Flunitrazepam

This benzodiazepine (FW = 313.29 g/mol), also known as Rohypnol and colloquially as "Roofie", is a hypnotic and anxiolytic agent that is often prescribed to individuals with insomnia. It has also become popular among alcohol and drug abusers, and its use has been documented in many instances of date rape. The use of flunitrazepam is illegal in some nations. **Target(s):** glucuronosyltransferase UDPglucuronosyltransferase (1,2). 1. Cheng, Rios, King, *et al.* (1998) *Toxicol. Sci.* **45**, 52. 2. Tephly (1990) *Chem. Res. Toxicol.* **3**, 509.

#### N-(9-Fluorenylmethoxycarbonyl)alanylpyrrolidine-2-nitrile

This peptide analogue (FW = 389.45 g/mol), also known as Fmoc-alanylpyrrolidine-2-nitrile, can cross the blood-brain barrier and inhibit prolyl oligopeptidase:  $K_i = 5$  nM. It also inhibits human lysosomal Pro-Xaa carboxypeptidase (IC<sub>50</sub> = 50 nM). **Target(s):** lysosomal Pro-Xaa carboxypeptidase (1); prolyl oligopeptidase (2). 1. Shariat-Madar, Mahdi & Schmaier (2002) *J. Biol. Chem.* **277**, 17962. 2. Li, Wilk & Wilk (1996) *J. Neurochem.* **66**, 2105.

#### S-[9-Fluorenylmethoxycarbonyl]glutathione

This glutathione derivative (FW = 528.56 g/mol) is a strong inhibitor of calf liver glyoxalase II, or hydroxyacylglutathione hydrolase,  $K_i = 2.1$   $\mu$ M. It also inhibits glyoxalase I (or lactoylglutathione lyase) and glutathione S-transferase,  $K_i = 17$  and 25  $\mu$ M, respectively. 1. Chyan, Elia, Principato, *et al.* (1994-1995) *Enzyme Protein* **48**, 164. 2. Yang, Sobieski, Carenbauer, *et al.* (2003) *Arch. Biochem. Biophys.* **414**, 271. 3. Norton, Talesa, Yuan & Principato (1990) *Biochem. Int.* **22**, 411. 4. Norton, Elia, Chyan, *et al.* (1993) *Biochem. Soc. Trans.* **21**, 545.

#### N-(9-Fluorenylmethoxycarbonyl)-N-methyl-L-phenylglycyl-L-leucyl-L-aspartyl-L-cyclohexylalanyl-L-aspartyl-L-phenylalanine

This hexapeptide (FW = 1028.15 g/mol) inhibits eukaryotic ribonucleotide reductase (RR), which catalyzes nucleoside diphosphate conversion to deoxynucleoside 5'-diphosphates needed for DNA biosynthesis, making RR a target for cancer therapy (1,2). RR catalysis requires formation of a complex between subunits R1 and R2, in which the R2 C-terminal peptide binds to R1. Crystal structures of heterocomplexes containing mammalian R2 C-terminal heptapeptide, P7 (Ac-1FTLDADF7) and its peptidomimetic P6 (1Fmoc(Me)PhgLDChaDF7) bound to *Saccharomyces cerevisiae* R1 (ScR1). P7 and P6, both of which inhibit ScRR, each bind at two contiguous sites containing residues that are highly conserved among eukaryotes. Such binding is quite distinct from that reported for prokaryotes. The Fmoc group in P6 makes several hydrophobic interactions that contribute to its enhanced potency in binding to ScR1. 1. Cooperman, Gao, Tan, Kashlan & Kaur (2005) *Adv. Enzym. Regul.* **45**, 112. 2. Xu, Fairman, Wijerathna, *et al.* (2008) *J. Med. Chem.* **51**, 4653.

### Fluoride, or F<sup>-</sup>

This halide anion (typically supplied as NaF (FW = 41.99 g/mol; CAS 7681-49-4) or KF (FW = 58.10 g/mol; CAS 7789-23-3); Ionic radius = 1.33 Å), which is probably essential in trace amounts for mammals, accumulates in mammalian bone and teeth. The strength of skeleton and teeth, particularly the hydroxyapatite matrix, is greatly affected by the presence of F<sup>-</sup>. Noting as much in the 1920s, the nutritional biochemist Elmer McCollum proposed the now widespread practice of adding fluoride to city water supplies to prevent dental caries. (Contrary to silly claims that fluoridation of drinking water is an evil attempt to control the unruly masses, there simply is no evidence that fluoride has any mind- or mood-altering action.) The agents typically added to city water are sodium fluoride (NaF), fluorosilicic acid (H<sub>2</sub>SiF<sub>6</sub>), or sodium fluorsilicate (Na<sub>2</sub>SiF<sub>6</sub>), typically at levels of 1-2 ppm. Many enzymes are inhibited by fluoride. The classical example is enolase, for which fluoride serves as a potent uncompetitive inhibitor (1-3). Another example is pyruvate kinase, which actually phosphorylates F<sup>-</sup> in the presence of carbon dioxide (3). (Inhibition of enolase and pyruvate kinase most likely account for the bactericidal action of fluoride in drinking water, toothpaste, and mouthwash.) Acid phosphatases are likewise inhibited by fluoride (2). Fluoride suppresses DNA and protein biosynthesis in mammalian cells and in cell-free systems (4). Many other enzymes are inhibited at high fluoride concentrations; however, little inhibition is observed at physiologic levels. Treatment of erythrocytes with 5 mM NaF for 1-24 h causes progressive accumulation of cytosolic Ca<sup>2+</sup> and phosphatidylserine (PS) on the outer membrane surface (5). After 1 h, these processes are suppressed by PKC inhibitors (staurosporine, GF 109203X and chelerythrine), but increased by PKC activator (PMA). Following 24 h, NaF-induced Ca<sup>2+</sup> uptake and PS externalization were partly prevented by PMA or staurosporine, but not by GF 109293X and chelerythrine. 1. Reiner (1947) *J. Gen. Physiol.* **30**, 367. 2. Smith, Armstrong & Singer (1959) *Proc Soc Exp Biol Med.* **102**, 170. 3. ### Fluoroacetate

This  $\alpha$ -halo acid (FW<sub>free-acid</sub> = 78.04 g/mol), found naturally in the leaves of the poisonous South African plant *Dichapetalum cymosum*, is transformed metabolically into fluorocitrate, a potent inactivator of the TCA Cycle enzyme aconitase (1,2). The sodium salt is used as a rodenticide (2). (See 2R,3R-Fluorocitrate) **CAUTION:** Fluoroacetate (human toxic dose = 0.5-2 mg/kg) is hazardous, if ingested. **Target(s):** aconitase, aconitate hydratase (1,2); carbonate anhydrase (3); malate synthase (4-7); sarcosine dehydrogenase (8); tartronate semialdehyde reductase, 2-hydroxy-3-oxopropionate reductase (9);  $\beta$ -ureidopropionase (10). 1. ### 3-Fluoro-N-acetylneuraminic Acid

This sialic acid derivative (FW<sub>free-acid</sub> = 327.26 g/mol; CAS = 921-40-4), also called 3-fluorosialate, is a reducing sugar that will inhibit N-acetylneuraminase lyase, or N-acetylneuraminase aldolase (1,2) and bacterial and viral sialidases (3). Diethylaminosulfur trifluoride (DAST) can be used to generate this inhibitor (4). 1. Gantt, Millner & Binkley (1964) *Biochemistry* **3**, 1952. 2. Sirbasku & Binkley (1970) *Biochim. Biophys. Acta* **198**, 479. 3. Hagiwara, Kijima-Suda, Ido, Ohruji & Tomita (1994) *Carbohydr. Res.* **263**, 167. 4. Hader & Watts (2013) *Carbohydr. Res.* **374**, 23.

### $\beta$ -Fluoro-D-alanine

This modified amino acid (FW = 107.08 g/mol), also known as fludalanine and 3-fluoro-D-alanine is an antibacterial agent that inhibits alanine racemase. **Target(s):** alanine racemase (1-3); amino-acid racemase (4); 1-aminocyclopropane-1 carboxylate deaminase (5); D-glutamate:D-amino acid aminotransferase, alternative substrate (6); serine Hydroxymethyltransferase, or glycine Hydroxymethyltransferase (7). 1. ### *o*-Fluoro-Amidine

This protein arginine deaminase inhibitor (FW = 408.40 g/mol; CAS = 877617-46-4; Soluble in methanol also known as *o*-F-amidine and systematically as *N*<sup>6</sup>-(2-carboxyl)benzoyl-*N*<sup>2</sup>-(2-fluoro-1-iminoethyl)-l-ornithine amide, is an active site-directed irreversible inhibitor. is a potent irreversible inhibitor that covalently modifies an active-site cysteine residue. Catalyzing posttranslational citrullination (*i.e.*, conversion of protein guanidinium groups of into ureido groups), PADs transform arginine residues into citrulline residues (1). By removing positively side-chains from proteins, these deiminases fundamentally alter the strength and/or specificity of regulatory interactions between target proteins with their intracellular binding partners. These enzymes (of which there are five in humans: PAD-1, PAD-2, PAD-3, PAD-4, and PAD-6) regulate gene transcription, cellular differentiation, as well as the innate immune response, and they are up-regulated in a number of human diseases, including rheumatoid arthritis, ulcerative colitis, and cancer. Relevant inhibitor parameters are: PAD-1 (IC<sub>50</sub> = 1.4  $\mu$ M; *k*<sub>inact</sub> = 1.7 min<sup>-1</sup>; *K*<sub>i</sub> = 9.4

$\mu\text{M}$ ;  $k_{\text{inact}}/K_i = 180900 \text{ M}^{-1}/\text{min}^{-1}$ ); PAD-2 ( $\text{IC}_{50} = >50 \mu\text{M}$ ;  $k_{\text{inact}} = \text{ND}$ ;  $K_i = \text{ND}$ ;  $k_{\text{inact}}/K_i = 7500 \text{ M}^{-1}/\text{min}^{-1}$ ); PAD-3 ( $\text{IC}_{50} = 34 \mu\text{M}$ ;  $k_{\text{inact}} = \text{ND}$ ;  $K_i = \text{ND}$ ;  $k_{\text{inact}}/K_i = 6700 \text{ M}^{-1}/\text{min}^{-1}$ ); and PAD-4 ( $\text{IC}_{50} = 1.9 \mu\text{M}$ ;  $k_{\text{inact}} = 0.5 \text{ min}^{-1}$ ;  $K_i = 16 \mu\text{M}$ ;  $k_{\text{inact}}/K_i = 32500 \text{ M}^{-1}/\text{min}^{-1}$ ) (2). F-amidine is cytotoxic to HL-60, MCF7, and HT-29 cancer cell lines, with  $\text{IC}_{50}$  values of 0.5, 0.5 and 1  $\mu\text{M}$ , respectively (3). (See also *o*-Cl-Amidine) 1. Slade, Subramanian, Fuhrmann & Thompson (2013) *Biopolymers* **101**, 133. 2. Causey, Jones, Slack, *et al.* (2011) *J. Med. Chem.* **54**, 6919. 3. Slack, Causey & Thompson (2011) *Cell Mol. Life Sci.* **68**, 709.

### (2R,3R)-Fluorocitrate

This highly toxic antimetabolite ( $\text{FW}_{\text{free-acid}} = 210.12 \text{ g/mol}$ ) is a potent inhibitor of aconitase ( $\text{IC}_{50} = 8 \mu\text{M}$ ), blocking tricarboxylic acid (or Krebs) cycle in the process (1-6). The (-)-erythro diastereomer acts as a mechanism-based inhibitor, which is first converted to fluoro-*cis*-aconitate by the enzyme, followed by addition of hydroxide and loss of fluoride to form 4-hydroxy-*trans*-aconitate, an agent that binds extremely tightly, but reversibly, to the enzyme (7). Given sufficient time, submicromolar concentrations of (-)-erythro-fluorocitrate are sufficient to irreversibly inhibit citrate uptake by isolated brain mitochondria. (See also 3-Deoxy-3-fluorocitrate and 3-Deoxy-3-fluorocitric Acid) **Target(s)**: aconitase, or aconitate hydratase (1-19); aconitate decarboxylase (20); ATP: citrate lyase, or ATP: citrate synthase (21); citrate (pro-*S*)-lyase (22); citrate transport (11,23); glutathione-citryl thioester formation (24); malic enzyme (25); 2-methylcitrate dehydratase, inhibited by DL-fluorocitrate (26); oxaloacetate tautomerase (27,28). 1. ### 5-Fluorocytosine

This pyrimidine ( $\text{FW} = 129.09 \text{ g/mol}$ ), also known as flucytosine, is an antifungal agent synthesized in 1957. Although it has no intrinsic antifungal capacity *per se*, it is taken up by cells and converted to 5-fluorouracil, which is then converted to nucleotide metabolites that inhibit fungal RNA and DNA synthesis. In addition, incorporation of 5-fluorocytosine into

RNA or DNA results in inhibition of the corresponding cytosine methyltransferases (e.g., *Hha*I DNA (cytosine-5)-methyltransferase-1). 5-Fluorocytosine is soluble in water (1.5 g/100 mL at 25°C) and has a  $\lambda_{\text{max}}$  at 285 nm in 0.1 M HCl ( $\epsilon = 8900 \text{ M}^{-1}\text{cm}^{-1}$ ). **Target(s)**: DNA (cytosine-5)-methyltransferase (1,2); hypoxanthine(guanine) phosphoribosyltransferase (3); xanthine phosphoribosyltransferase (3). 1. Osterman, DePillis, Wu, A. Matsuda & Santi (1988) *Biochemistry* **27**, 5204. 2. Santi, Garrett & Barr (1983) *Cell* **33**, 9. 3. Naguib, Iltzsch, el Kouni, Panzica & el Kouni (1995) *Biochem. Pharmacol.* **50**, 1685.

### 5-Fluoro-2'-deoxycytidine

This modified nucleoside ( $\text{FW} = 245.21 \text{ g/mol}$ ), a strong inhibitor of cell growth, is metabolized to 5-fluoro-2'-deoxyuridine 5'-monophosphate, which inhibits thymidylate synthase. In addition, incorporation into DNA results in inhibition of the corresponding DNA methyltransferases, e.g., *Hae*III DNA (cytosine-5)-methyltransferase (1). **Target(s)**: aspartate carbamoyltransferase (2); deoxycytidine kinase (3). 1. Chen, MacMillan, Chang, *et al.* (1991) *Biochemistry* **30**, 11018. 2. Bresnick (1962) *Cancer Res.* **22**, 1246. 3. Deibler, Reznik & Ives (1977) *J. Biol. Chem.* **252**, 8240.

### 5-Fluoro-2'-deoxycytidine 5'-Monophosphate

This modified deoxynucleotide ( $\text{FW} = 325.19 \text{ g/mol}$ ) inhibits deoxycytidylate 5-hydroxymethyltransferase competitively and is a tight-binding inhibitor of thymidylate synthase (1). (See 5-Fluoro-2'-deoxyuridine 5'-monophosphate) **Target(s)**: deoxycytidylate 5-hydroxymethyltransferase (2); thymidylate synthase (1,3). 1. Liu & Santi (1994) *Biochim. Biophys. Acta* **1209**, 89. 2. Subramaniam, Wang, Mathews & Santi (1989) *Arch. Biochem. Biophys.* **275**, 11. 3. Hartmann & Heidelberg (1961) *J. Biol. Chem.* **236**, 3006

### [<sup>18</sup>F]-2-Fluoro-2-deoxy-D-glucose

This glucose analogue and PET tracer ( $\text{FW} = 181.15 \text{ g/mol}$ ; CAS = 63503-12-8; Symbol: FDG) is a marker for the tissue uptake of glucose ennumerous tissues and organs (1,2). After [<sup>18</sup>F]-FDG is injected into a patient, a PET scanner captures a two-dimensional or three-dimensional images of its distribution within the body. The kinetics of transport across the blood-brain barrier and metabolism in brain (hemisphere) of [<sup>14</sup>C]2-FDG, [<sup>3</sup>H]-2-deoxy-D-glucose (DG) and D-glucose in the pentobarbital-anesthetized adult rat show saturation kinetics when measured with the brain uptake index (BUI) method. The BUI for FDG was 54.3. Nonlinear regression analysis gave a  $K_m$  of 6.9 mM and  $V_{\text{max}}$  of 1.70  $\mu\text{mol}/\text{min}/\text{g}$  (3). The  $K_i$  for glucose inhibition of FDG transport was 10.7 mM. The kinetic constants of influx ( $k_1$ ) and efflux ( $k_2$ ) for FDG were calculated from the  $K_m$ ,  $V_{\text{max}}$ , and glucose concentrations of the hemisphere and plasma (2.3  $\mu\text{mol}/\text{g}$  and 9.9 mM, respectively). The transport coefficient ( $k_1$  for FDG divided by  $k_1$  for glucose) was 1.67 and the phosphorylation constant was 0.55 (3). 1. Pacak, Tocik & Cerny (1969) *J. Chem. Soc. CHEM. COMM.* **77-77**. 2. Ido, Wan,

Casella, *et al.* (1978) *J. Lab. Comp. Radiopharm.* **24**, 174. 3. Crane, Partridge, Braun & Oldendorf (1983) *J. Neurochem.* **40**, 160.

### 5-Fluoro-2'-deoxyuridine

This modified nucleoside (FW = 246.20 g/mol; Symbol: FUDR), also known as 2'-deoxy-5-fluorouridine and floxuridine, is a mutagen that is metabolically converted to the monophosphate, which in turn potently inhibits thymidylate synthase. The resulting imbalance in the composition of deoxynucleotide pools strongly inhibits DNA biosynthesis (See *5-Fluoro-2'-deoxyuridine 5'-Monophosphate*). **Use in Synchronizing Aging Populations of Nematodes:** in 5-FUDR is commonly used to sterilize *Caenorhabditis elegans* to maintain a synchronized aging population of nematodes, without contamination by their progeny, in lifespan experiments. Although all somatic cells in the adult nematode are post-mitotic and do not require nuclear DNA synthesis, mitochondrial DNA (mtDNA) replicates independently of the cell cycle. Inhibition of mtDNA synthesis can lead to mtDNA depletion, which is linked to a number of diseases in humans. Even so, the 8-13-day half-life of mtDNA in adult *C. elegans* somatic cells greatly attenuates FUDR effects on various endpoints (*e.g.*, DNA copy numbers, DNA damage, steady-state ATP levels, nematode size, mitochondrial morphology, and lifespan). 1. Rooney, Luz, González-Hunt, *et al.* (2014) *Exp Gerontol.* **56**, 69.

### 5-Fluoro-2'-deoxyuridine 5'-Monophosphate

This anticancer drug (FW = 326.18 g/mol), also known as fluorodeoxyuridylylate and abbreviated 5-FdUMP, is a mechanism-based substrate that forms a covalent bond with FdUMP when an Enz-SH adds at the 6-position of the pyrimidine ring. This reaction requires the presence of 5,10-methylenetetrahydrofolate. By inhibiting thymidylate synthase, this deoxyuridine analogue inhibits DNA biosynthesis. **Target(s):** dCMP deaminase (1); deoxycytidylate 5-hydroxymethyltransferase (2-4); thymidylate synthase (5-8); thymidylate synthase (FAD) (9,10). 1. Maley & Maley (1964) *J. Biol. Chem.* **239**, 1168. 2. Butler, Graves & Hardy (1994) *Biochemistry* **33**, 10521. 3. Graves & Hardy (1994) *Biochemistry* **33**, 13049. 4. ### 2-Fluoro-1,3,5(10)-estratrien-3-ol-17-one

This fluorinated steroid (FW = 288.36 g/mol), also known as 2-fluoroestrone and 3-hydroxy-2-fluoro-1,3,5(10)-estratrien-17-one, noncompetitively inhibits *Pseudomonas testosteroni* steroid  $\Delta$ -isomerase ( $K_i$  = 35  $\mu$ M). 1. Weintraub, Vincent, Baulieu & Alfsen (1977) *Biochemistry* **16**, 5045.

### 5'-(2-Fluoroethylthio)jimmucillin-A

This nucleoside analogue (FW<sub>free-base</sub> = 326.38 g/mol), also known as (1S)-1-(9-deazaadenin-9-yl)-5-(2-fluoroethylthio)-1,4-dideoxy-1,4-imino-D-ribose, inhibits 5'-methylthio-adenosine/S-adenosyl-homocysteine nucleosidase,  $K_i$  = 30 pM (1). It is a slightly weaker, slow-binding inhibitor of human S-methyl-5' thioadenosine phosphorylase,  $K_i$  = 20 nM (2). When the ring nitrogen is protonated, this analogue mimics the charge of oxacarbenium ion intermediate that forms transiently in many glycosidase reactions, and this property results in tight binding. 1. Singh, Evans, Lenz, *et al.* (2005) *J. Biol. Chem.* **280**, 18265. 2. Evans, Furneaux, Schramm, Singh & Tyler (2004) *J. Med. Chem.* **47**, 3275.

### 2-Fluorofucose Triacetate & 2-Fluorofucose

These fucose analogues (FW<sub>2-FF-Triacetate</sub> = 294.23 g/mol; FW<sub>2-FF</sub> = 166.15 g/mol) are metabolically active, the former penetrating cells and the latter undergoing GTP-dependent conversion to GDP-2-fluoro-fucose, which inhibits fucosyl- or sialyltransferases (1). Because the latter cannot undergo fucosyl-transfer, it accumulates in cells and shuts down *de novo* synthesis of GDP-Fucose or CMP-NeuAc via a feedback loop, further decreasing fucose or sialic acid expression on the cell surface. Exposure of cells to this and other similar inhibitors remodels the cell surface and impairs selectin-mediated cell adhesion. For example, 2-FF also blocks the formation and tethering of sialyl-Lewis<sup>x</sup> tetrasaccharides and structural variants on leukocytes and red blood cells to P- and E-selectins on activated endothelial cell surfaces (2). P- and E-selectins are known to be essential for vaso-occlusion in sickle cell disease (SCD), and 2FF inhibits vaso-occlusion in SCD mice. 2FF treatment of SCD mice also significantly reduces leukocyte rolling and adhesion along the vessel walls as well as the static adhesion of neutrophils and sickle red blood cells from 2FF-treated SCD mice to resting and activated endothelial cells (2). Such findings suggest 2FF may be beneficial for preventing or treating vaso-occlusive crises in SCD patients. Other novel monosaccharides that become incorporated and/or alter protein glycan structures 5-alkynylfucose (3,4), 5-thio-N-acetylglucosamine (5), 5- or 6-fluoro-galactofuranose (6), 3-fluoro-N-acetyl-neuraminic acid (7), azidosugars, such as N-azidoacetylglucosamine or N-azidoacetylglucosamine (8,9), peracetylated 4-fluoro-glucosamine (10), and 5-thiofucose (11). 1. Okeley, Alley, Anderson, *et al.* (2013) *Proc. Natl. Acad. Sci. U.S.A.* **110**, 5404. 2. Belcher, Chen, Nguyen, *et al.* (2015) *PLoS One* **10**, e0117772. 3. Hsu, *et al.* (2007) *Proc. Natl. ### 4-Fluoro-5-hydroxypentane-2,3-dione

This synthetic inhibitor of *Vibrio harveyi* quorum-sensing (FW = 134.11 g/mol), is a fluorinated derivative of (*S*)-4,5-dihydropentane-2,3-dione (shown on the right), an essential precursor of the naturally occurring autoinducer signaling molecule known as AI-2. The latter and its borate adduct act as a universal signaling molecule present in >70 bacterial species (1). 4-Fluoro-DPD completely inhibits bioluminescence and bacterial growth of *V. harveyi* BB170 strain at 12.5  $\mu$ M and 100  $\mu$ M, respectively. 1. Kadirvel, Fanimarvasti, Forbes, *et al.* (2014) *Chem. Commun.* (Cambridge) **50**, 5000.

### 5-Fluoro-2-indolyldeschlorohalopemide

This halopemide derivative (FW = 421.50 g/mol; CAS = 939055-18-2; Abbreviation: FIPI), also known as *N*-[2-[4-(2,3-dihydro-2-oxo-1*H*-benzimidazol-1-yl)-1-piperidinyl]ethyl]-5-fluoro-1*H*-indole-2-carboxamide, targets phospholipase D isoforms PLD<sub>1</sub> (IC<sub>50</sub> = 25 nM) and PLD<sub>2</sub> (IC<sub>50</sub> = 20 nM), which catalyze phospholipid hydrolysis and release phosphatidic acid (PA) head groups. PA is itself a second messenger that promotes Ras activation, cell spreading, stress fiber formation, chemotaxis, and membrane vesicle trafficking. In rats, FIPI has a >5-hour half-life, a C<sub>max</sub> that, at 363 nM, and bioavailability of 18%. (See also *N*-[2-(4-oxo-1-phenyl-1,3,8-triazaspiro[4.5]dec-8-yl)ethyl]-2-naphthalene-carboxamide) 1. Monovich, Mugrage, Quadros, *et al.* (2007) *Bioorg. Med. Chem. Lett.* **17**, 2310. 2. Su, Yeku, Olepu, *et al.* (2009) *Mol. Pharmacol.* **75**, 437.

### (2-[4-[[2-(3-Fluoro-4-methoxyphenyl)-7,8-dihydro-6*H*-thiopyrano[3,2-*d*]pyrimidin-4-yl]amino]phenyl]acetate

This orally active 3',5'-cyclicAMP phosphodiesterase isozyme 4B-selective inhibitor (FW = 425.28 g/mol) inhibits the activity of phosphodiesterases PDE4B and PDE4D in a concentration-dependent manner, both in humans (IC<sub>50</sub> values = 5.5 nM and 440 nM, with a selectivity factor of 80) and mice (IC<sub>50</sub> values = 26 nM and 760 nM, with a selectivity factor of 29), or about 10-15x more weakly than Roflumilast. By contrast, oral administration of this compound and Roflumilast to mice before LPS injection dose-dependently inhibits elevation of the plasma concentration of TNF- $\alpha$ , with respective IC<sub>50</sub> values of 29 mg/kg and 23 mg/kg. The therapeutic indices TI<sup>TNF</sup> and TI<sup>NEU</sup> for LPS-induced TNF $\alpha$  production and pulmonary neutrophilia are calculated by dividing the ID<sub>50</sub> value in gastric emptying by the ID<sub>50</sub> value in LPS injection-induced TNF $\alpha$  elevation and LPS inhalation-induced neutrophilia, respectively. The TI<sup>TNF</sup> of this compound and Roflumilast are 9.0 and 0.2, respectively, indicating that this compound shows a reduced gastric adverse effect. The more important parameter TI<sup>NEU</sup> for Compound A and Roflumilast are almost identical (*i.e.*, 1.0 and 0.5, respectively). 1. Suzuki, Mizukami, Etori, *et al.* (2013) *J. Pharmacol. Sci.* **123**, 219.

### (*S*)- $\alpha$ -(Fluoromethyl)histidine

This histidine derivative (FW = 187.17 g/mol) inhibits histamine biosynthesis by acting as an irreversible, mechanism-based inhibitor of histidine decarboxylase (1-11). In the presence of the enzyme-activated

inhibitor  $\alpha$ -FMH, decarboxylation of the analogue occurs, but the decarboxylated intermediate(s) bind covalently to the enzyme backbone to inhibit the enzyme irreversibly.

Fluoromethylhistidine has been used to deplete histamine concentrations in pharmacological studies. Indeed, it was also used to demonstrate that two SSRIs (namely Citalopram and Paroxetine) require the integrity of the brain histamine system to exert their preclinical responses (12). 1. ### 3-Fluoromethyl-7-trifluoromethyl-1,2,3,4-tetrahydroisoquinoline

This substrate analogue (FW = 236.23 g/mol) targets phenylethanolamine *N*-methyltransferase ( $K_i$  = 30 nM) and is highly selective in its inhibition due to low affinity for the  $\alpha_2$ -adrenoceptor. This report represents the first successful use of the  $\beta$ -fluorination of aliphatic amines to impart selectivity to a pharmacological agent, while still maintaining potency at the site of interest. 1. Grunewald, Seim, Lu, Makboul & Criscione (2006) *J. Med. Chem.* **49**, 2939. 2. Grunewald, Caldwell, Li, *et al.* (1999) *J. Med. Chem.* **42**, 3588.

### 6-Fluoromevalonate 5-Diphosphate

This substrate analogue (FW<sub>free-acid</sub> = 326.11 g/mol) is a potent cholesterol biosynthesis inhibitor, targeting diphosphomevalonate decarboxylase ( $K_i$  = 37 nM), or mevalonate pyrophosphate decarboxylase. In a multienzyme assay for cholesterol biosynthesis, mevalonate 5-phosphate and mevalonate

5-pyrophosphate accumulate in the presence of 5  $\mu\text{M}$  6-fluoromevalonate. 6-Fluoromevalonate 5-pyrophosphate is more effective in inhibiting cholesterol biosynthesis. 1. Nave, d'Orchymont, Ducep, Piriou & Jung (1985) *Biochem. J.* **227**, 247.

### 2-Fluoropalmitic Acid

This  $\alpha$ -halo fatty acid (FW<sub>free-acid</sub> = 274.42 g/mol; CAS = 16518-94-8), also systematically named as 2-fluorohexadecanoic acid, inhibits incorporation of palmitate into sphingosine (IC<sub>50</sub>  $\approx$  0.05-0.2 mM) and accumulates in membrane lipids of cultured mammalian cells. Fluoropalmitate also competitively inhibits the cellular uptake of [<sup>3</sup>H]-palmitate, consequently reducing the labeling of palmitoyl-CoA, glycerolipids and myelin proteolipid protein (1). The fact that fluoropalmitate competes so effectively with palmitate suggests that their uptake may be carrier-mediated. Furthermore, because the attachment of palmitate to protein cysteine residues is a common post-translational modification of both integral and peripheral membrane proteins, fluoropalmitate is likely to alter the intracellular distribution of peripheral membrane proteins by regulating membrane-cytosol exchange and/or by modifying the flux of the proteins through vesicular transport systems. **Target(s):** glycerylpeptide *N*-tetradecanoyl-transferase, or protein *N*-myristoyltransferase (2); long-chain acyl-CoA synthetase (3). 1. De Jesus & Bizzizero (2002) *Neurochem. Res.* **27**, 1669. 2. Paige, Zheng, DeFrees, Cassady & Geahlen (1990) *Biochemistry* **29**, 10566. 3. Soltysiak, Matsuura, Bloomer & Sweeley (1984) *Biochim. Biophys. Acta* **792**, 214.

### m-Fluorophenylalanine

This substituted phenylalanine (FW = 183.18 g/mol) inhibits chorismate mutase, 3-deoxy-7-phosphoheptulonate synthase, prephenate dehydratase, and phenylalanine ammonia-lyase. **Target(s):** alkaline phosphatase, mildly inhibited by racemic mixture (1); chorismate mutase (2,3); 3-deoxy-7-phospho-heptulonate synthase, or 3-deoxy-D-arabinoheptulosonate-7 phosphate synthetase (4); nonenzymatic hydroxylaminolysis of amino acid esters at  $-18^\circ\text{C}$ , by racemic mixture (5); phenylalanine ammonia-lyase, inhibited by L-stereoisomer (6); prephenate dehydratase (7-9). 1. Fishman & Sie (1971) *Enzymologia* **41**, 141. 2. Sugimoto & Shiiro (1980) *J. Biochem.* **88**, 167. 3. Hertel, Hieke & Gröger (1991) *Acta Biotechnol.* **11**, 39. 4. ### p-Fluoro-L-phenylalanine

This substituted phenylalanine (FW = 183.18 g/mol; CAS = 1132-68-9) inhibits a number of enzymes, including 3-deoxy-7-phosphoheptulonate synthase. It will also substitute for phenylalanine in protein biosynthesis and inhibit mitosis. HeLa cells are arrested in the G<sub>2</sub> phase. **Target(s):** alkaline phosphatase, mildly inhibited by racemic mixture (1); arogonate dehydratase (2,3); 3-deoxy-7-phosphoheptulonate synthase, or 3-deoxy-D-arabinoheptulosonate-7 phosphate synthetase (4,5); phenylalanine ammonia-lyase (6); phenylalanine 4-monooxygenase, weak alternative substrate (7,8); prephenate dehydratase (9-11); tryptophan aminotransferase (12); tyrosine 3-monooxygenase (13). 1. ### Fluorophosphate

This anion (available as disodium fluorophosphate Na<sub>2</sub>FPO<sub>3</sub>, FW = 143.95 g/mol; CAS = 7631-97-2) can be formed by the action of pyruvate kinase on fluoride ion and ATP (See also Fluoride). It is also an alternative substrate for sulfate adenylyltransferase. **Target(s):** enolase, or phosphopyruvate hydratase (1-4); lipase, or triacylglycerol lipase (5); phosphonoacetaldehyde hydrolase (6); phosphorylase phosphatase (7); pyruvate kinase, as an alternative product inhibitor (8); starch phosphorylase (9,10); succinate dehydrogenase (11). 1. ### 3-Fluorophosphoenolpyruvic Acid

This fluorinated metabolite (FW<sub>free-acid</sub> = 186.03 g/mol) has two isomeric forms. The (Z)-isomer is an alternative substrate of phosphoenolpyruvate carboxykinase, whereas the (E)-isomer is a competitive inhibitor. The (Z)-isomer is a potent inhibitor of 3-phosphoshikimate 1-carboxyvinyltransferase and UDP-N-acetylglucosamine 1-carboxy-vinyltransferase. **Target(s):** 3-deoxy-7-phosphoheptulonate synthase (1); phosphoenolpyruvate carboxykinase, by the (E)-isomer (2); 3-phosphoshikimate 1-carboxyvinyltransferase, or 5-enolpyruvylshikimate-3-phosphate synthase, by the (Z)-isomer (3,4); UDP-N acetylglucosamine 1-carboxyvinyltransferase, by both stereoisomers (5-7). 1. ### (E)-6-Fluoro-3-[2-(3-pyridyl)vinyl]-1H-indole

This indole (FW = 238.27 g/mol), also known as 680C91, is a strong and selective inhibitor of tryptophan 2,3-dioxygenase (K<sub>i</sub> = 51 nM), but does not inhibit indoleamine 2,3-dioxygenase, monoamine oxidases A and B, or serotonin uptake. 1. Salter, Hazelwood, Pogson, Iyer & Madge (1995) *Biochem. Pharmacol.* **49**, 1435.

## Fluoroquinolone Antibiotics

This family of synthetic broad-spectrum antibiotics share a common pharmacophore (shown above), allowing them to exert their antibacterial action by preventing the unwinding and replication of bacterial DNA. Their clinically observed adverse effects on the CNS may be mediated, at least in part, through interactions with the benzodiazepine (BZD)-GABA<sub>A</sub>-receptor complex. **See** Alatrofloxacin; Amifloxacin; Balofloxacin; Besifloxacin; Cadazolid; Ciprofloxacin; Clinafloxacin; Danofloxacin; Delafloxacin; Difloxacin; Enoxacin; Enrofloxacin; Fleroxacin; Gatifloxacin; Gemifloxacin; Grepafloxacin; Levofloxacin; Lomefloxacin; Marbofloxacin; Moxifloxacin; Nadifloxacin; Norfloxacin; Ofloxacin; Orbifloxacin; Pazufloxacin; Pefloxacin; Prulifloxacin; Rufloxacin; Sitalfloxacin; Sparfloxacin; Terafloxacin; Trovafloxacin; Zabofloxacin

5'-( $\beta$ -Fluorosulfonylbenzoyl)adenosine

This substituted adenosine, often abbreviated 5'-FSBA (FW = 453.41 g/mol; CAS = 78859-42-4), has found widespread utility as an *in vitro* affinity label that permanently occupies active-site and/or allosteric regulatory sites for nucleotides or coenzymes. Given its lack of selectivity, experiments with 5'-FSBA are best conducted with purified enzymes. **Target(s):** acetyl-CoA carboxylase (1); actin (1);  $\delta$ -adenosylhomocysteinase (1,2); adenylate cyclase (3); aldehyde reductase, or alcohol dehydrogenase (NADP<sup>+</sup>) (1,4); Amidophosphoribosyl-transferase (5); anion-translocating ATPase (6); apyrase (7-12); asparagine synthetase (13,14); ATPase (1,15); Ca<sup>2+</sup>-dependent ATPase (107); calmodulin-dependent protein kinase (16); cAMP-dependent protein kinase, or protein kinase A (1,17-22); carbamoyl-phosphate synthetase (1,23-27); casein kinase (1,28,29); CF<sub>1</sub> ATPase (1,30); cGMP-dependent protein kinase, or protein kinase G (1,31); deoxyguanosine/ deoxyadenosine kinase (32); DNA-directed DNA polymerase (1); DNA-directed RNA polymerase, bacteriophage T<sub>7</sub> (33,34); DNA helicase (35); DNA polymerase I (1); ecto-ATPase (36,37); endopeptidase Clp (38); estradiol 17 $\beta$ -dehydrogenase (1,3,39,40); F<sub>1</sub> ATPase (1,41-56,106); glucokinase, polyphosphate- and ATP-dependent (57); glutamate dehydrogenase, binding at NADH inhibitory site (1,58-61); glutamine synthetase (1,62,63); glycerol kinase (1); glycine N-methyltransferase (1,108,109); histone H<sub>1</sub> kinase (64); *p*-hydroxybenzoate monooxygenase (44); [3 hydroxy-3-methylglutaryl-CoA reductase] kinase (1,65,66); 3 $\alpha$ ,20 $\beta$ -hydroxysteroid dehydrogenase (1,67); 3 $\beta$ -hydroxysteroid dehydrogenase (1,68-70); 20 $\alpha$ -hydroxysteroid dehydrogenase (40); inositol 1,3,4-trisphosphate 5/6-kinase (71); [inositol dehydrogenase] kinase/phosphatase (72); malate dehydrogenase (1); [MAP kinase] kinase, or [mitogen-activated protein kinase] kinase (73); myosin (1); [myosin light-chain] kinase (74,75); NAD<sup>+</sup>-dependent enzymes (1,76); NADH:cytochrome *b*<sub>5</sub> reductase (1); NADH dehydrogenase (77); NAD(P)H dehydrogenase, or DT diaphorase (1,78,79); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (1,80,81); nicotinamide-nucleotide transhydrogenase (1,82,83); nucleoside-triphosphatase (35); 5'-nucleotidase (84); oligopeptide transporting ATPase, or oligopeptide permease (85); 5-oxoprolinase (1,86); phosphate-transporting ATPase (87); phosphatidylinositol 3-kinase (88,89); phosphatidylinositol 4-kinase (90); phosphofructokinase (1); 6-phosphofructo-2-kinase (91); 6-phosphofructo-2-kinase/ fructose-2,6-bisphosphatase (1); 3-phosphoglycerate kinase (92); phosphoribosyl-aminoimidazole succinocarboxamide synthetase, or 4-(N-succinylamino)carbonyl] 5-aminoimidazole ribonucleotide synthetase, or SAICAR synthetase (93); PRPP (or phosphoribosyl diphosphate) synthetase (1); phosphoribosyl-formylglycinamide cyclo-ligase, or aminoimidazole ribonucleotide synthetase, or phosphoribosyl-aminoimidazole synthetase (94); phosphorylase kinase (95); luciferase (1); protein-tyrosine kinase, or non-specific protein-tyrosine kinase (96); protein-tyrosine kinase (e.g.,

pp60v-src and EGF receptor) (1,97-100); pyruvate kinase (1,58,101,102); recA protein (1,103); rhodopsin kinase (104); ribulose-5-phosphate kinase (1); sphingosine kinase (105); Src protein-tyrosine kinase (96); steroid  $\Delta$ -ene-isomerase (68-70); steroid 5 $\alpha$ -reductase (77); xanthine dehydrogenase (1). 1. #### 5'-(*p*-Fluorosulfonylbenzoyl)-8-azidoadenosine

This bifunctional affinity label (FW = 494.42 g/mol), often abbreviated 8-N<sub>3</sub>-FSBA, which reacts chemically and/or photochemically, inactivates bovine heart mitochondrial F<sub>1</sub> ATPase with an apparent K<sub>d</sub> of 0.47 mM at pH 8.0 and 23 °C in the absence of light. Irradiation of dark-inactivated enzyme with long-wavelength ultraviolet light produced cross-linked dimers consisting of α and β subunits. **Target(s):** F<sub>1</sub> ATPase (1); glutamate dehydrogenase (2). **1.** Zhuo, Garrod, Miller & Allison (1992) *J. Biol. Chem.* **267**, 12916. **2.** Colman (1990) *The Enzymes*, 3rd ed. (Sigman & Boyer, eds.), **19**, 283.

#### 5'-(*p*-Fluorosulfonylbenzoyl)-1,N<sup>6</sup>-ethenoadenosine

This fluorescent nucleotide analogue (FW = 477.43 g/mol), often abbreviated 5'-FSBεA, reacts irreversibly with bovine liver glutamate dehydrogenase, modifying one of its inhibitory GTP binding sites. The inactivation of rabbit muscle pyruvate kinase at pH 7.8 is biphasic at pH 7.8; the first phase proceeds rapidly to yield a partially active enzyme, followed by a slower rate that leads to total inactivation. **Target(s):** F<sub>1</sub> ATPase (1,2); fructose-1,6-bisphosphate aldolase (3,4); glutamate dehydrogenase (1,5,6); phosphofructokinase (3); phosphoglycerate kinase (3,7); pyruvate kinase (3,8). **1.** Verburg & Allison (1990) *J. #### 5'-(*p*-Fluorosulfonylbenzoyl)guanosine

This nucleotide analogue (FW = 469.41 g/mol) is an affinity label that reacts with bovine liver glutamate dehydrogenase to desensitize it irreversibly to inhibition by GTP, without affecting its intrinsic catalytic activity. **Target(s):** elongation factor EF-2 GTPase (protein-synthesizing GTPase) (1); glutamate dehydrogenase (2,3); phosphoenolpyruvate carboxykinase (2,4); pyruvate kinase (2,5,6); small monomeric GTPase (7); tubulin, after polymerization, no depolymerization occurred (2,8). **1.** Nilsson & Nygard (1984) *Biochim. Biophys. Acta* **782**, 49. **2.** Colman (1990) *The Enzymes*, 3rd ed., **19**, 283. **3.** Pal, Reischer, Wechter & Colman (1978) *J. Biol. #### 5-Fluorotryptophan

This modified amino acid (FW = 222.22 g/mol; CAS = 154-08-5) inhibits a number of tryptophan-requiring enzymes. 5-Fluorotryptophan is an alternative substrate of tryptophanyl-tRNA synthetase and can be incorporated by ribosomes into proteins, allowing the use <sup>19</sup>F-NMR. It is also an activator of chorismate mutase. **Target(s):** alkaline phosphatase (1); anthranilate synthase (2,3); chorismate mutase (4); 3-deoxy 7-phosphoheptulonate synthase (5); indoleamine 2,3-dioxygenase, also as an alternative substrate (6); prephenate dehydratase (7); tryptophan 2,3-dioxygenase, also as a weak alternative substrate (8-11); tryptophan 5-monooxygenase (12,13); tryptophanyl-tRNA synthetase, as an alternative substrate (14,15); tyrosine 3-monooxygenase, moderately inhibited (16). **1.** Fishman & Sie (1971) *Enzymologia* **41**, 141. **2.** Matsukawa, Ishihara & Iwamura (2002) *Z. ### 5-Fluorouracil

This antineoplastic agent (FW = 130.08 g/mol; CAS 51-21-8; Decomposes at 282-283°C;  $\lambda_{\text{max}} = 265\text{-}266\text{ nm}$ ;  $\epsilon = 7070\text{ M}^{-1}\text{cm}^{-1}$ ; Slightly soluble in H<sub>2</sub>O; more so in acidic solutions), is also known as FU, and 5FU, is marketed under the tradename Efdudex. **Metabolic Activation:** R5-Fluorouracil is readily absorbed by humans, whereupon it is converted to three main active metabolites: fluorodeoxyuridine monophosphate (FdUMP), fluorodeoxy-uridine triphosphate (FdUTP), and fluorouridine triphosphate (FUTP). The main mechanism of drug activation is by conversion of 5FU to fluorouridine monophosphate (FUMP), either directly by orotate phosphoribosyltransferase (OPRT), using 5'-phosphoribosylpyrophosphate (PRPP) as the cofactor, or indirectly via fluorouridine (FUR), a pathway requiring the sequential action of uridine phosphorylase and uridine kinase. FUMP is then phosphorylated to fluorouridine diphosphate (FUDP), which can be either further phosphorylated to the active metabolite fluorouridine triphosphate (FUTP), or converted to fluorodeoxyuridine diphosphate (FdUDP) by the action of ribonucleotide reductase (RNR). FdUDP is then be phosphorylated or dephosphorylated, generate the active metabolites FdUTP and FdUMP, respectively. Alternatively, FU is mobilized by thymidine phosphorylase, converting 5-FU to FUDR, with the latter then converted to FdUMP by thymidine kinase. FdUDP is then phosphorylated to FdUTP, a substrate for DNA polymerase. DNA(uracil) deglycosylase recognizes and removes fluorouracil, relying on subsequent action of repair enzymes to insert a thymine-containing monomer. At high (F)dUTP/dTTP ratios, the action of(uracil) deglycosylase only results in further incorporation of the false nucleotide. Such futile cycling (i.e., misincorporation, excision and repair) eventually results in DNA strand breaks and cell death. DNA damage due to dUTP misincorporation is highly dependent on the levels of the dUTPase, a pyrophosphatase that limits intracellular accumulation of dUTP. 5-FU is also incorporated into mRNA, resulting in translation errors. It is as FdUMP, however, that FU has its most potently killing effect. Dihydropyrimidine dehydrogenase converts 5-FU to dihydrofluorouracil (DHFU), the rate-limiting step of 5-FU catabolism in normal and tumor cells. Up to 80% of administered 5-FU is broken down by DPD in the liver. **Mechanism of Thymidylate Synthase Inhibition:** Thymidylate synthase normally catalyzes the conversion of dUMP to dTMP, with 5,10-methylene tetrahydrofolate (CH<sub>2</sub>THF) serving as the methyl donor. UC San Francisco researcher Daniel Santi and coworkers demonstrated, however, that, in the presence of enzyme-bound N<sup>5,10</sup>-methylene tetrahydrofolate, thymidylate synthase binds FdUMP, with the latter acting as a mechanism-based (or "suicide") inhibitor that recapitulates early steps in catalysis (e.g., attack by the active-site thiol of Cys-198 at C<sup>6</sup> of FdUMP).

Failing to expel fluoride, expulsion of the C<sup>5</sup> proton of dUMP cannot proceed, and, by mimicking the electronic charge and geometry of an early reaction-cycle transition state, the highly stable covalent Enz-FdUMP adduct persists. FdUMP inhibits thymidylate synthase, preventing the latter from supplying replicating cells with dTMP, and hence dTTP, needed for DNA biosynthesis. Given its considerable cytotoxicity, 5-fluorouracil is often administered as a pro-drug. Patients deficient in dihydropyrimidine dehydrogenase (DPD) experience profound systemic toxicity in response to 5-FU, owing to prolonged exposure to 5-FU from decreased drug catabolism. (See *Capecitabine*) **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** 4-aminobutyrate aminotransferase,  $K_i = 1.9\text{ mM}$  (1,2); (R)-3-amino-2-methylpropionate: pyruvate aminotransferase (1-4); (S)-3-amino-2-methylpropionate:pyruvate transaminase (3); orotate phosphoribosyltransferase,  $K_i = 0.27\text{ mM}$  (5,6); thymidine phosphorylase (7,8); thymidylate synthase, slow, tight-binding inhibition,  $K_i = 2\text{ nM}$  (9-13); thymine dioxygenase (14); uracil phosphoribosyltransferase (15); uridine phosphorylase (16,17). 1. ### 5-Fluorouridine

This halogenated nucleoside and antitumor agent (FW = 266.18 g/mol; CAS = 316-46-1) is converted to the corresponding deoxynucleotide, the latter a potent inhibitor of thymidylate synthase. DNA biosynthesis is inhibited. In addition, 5-Fluoro-UTP can be incorporated into RNA, resulting in translation errors and in the inhibition of mRNA biosynthesis and rRNA processing (1-3). **Target(s):** (R)-3-amino-2-methylpropionate:pyruvate aminotransferase (weakly inhibited) (4); cytidine deaminase (5,6); dihydroorotase (7); RNA biosynthesis (1-3,8); thymidylate synthase (8); uridine nucleosidase (10). 1. ### Fluoxetine

This widely used antidepressant (FW<sub>free-base</sub> = 309.33 g/mol; CAS = 54910-89-3), also named *N*-methyl-3-phenyl-3-[4-(trifluoromethyl)phenoxy]propan-1-amine and commonly known as Prozac<sup>TM</sup>, is a selective serotonin reuptake inhibitor (SSRI) and was one of the earliest such inhibitors identified (1-4). **Primary Mode of Action:** The primary pharmacological action of SSRIs is presynaptic inhibition of serotonin (5-HT) reuptake, thereby increasing the concentration of this amine in the synaptic cleft. Serotonin exerts its effects through interactions with any of seven distinct 5-HT receptor families, and interaction between serotonin and post-synaptic receptors mediates a wide range of its actions. Fluoxetine is also an antagonist at the serotonin 5HT<sub>2C</sub> receptor. This drug also inhibits voltage-activated potassium and sodium channels (5). Indeed, when administered at clinically relevant concentrations, fluoxetine blocks *Shaker*-type K1 channel, *i.e.*, K<sub>v</sub>1.3 (6). **Antiviral Properties:** Surprisingly, recent studies demonstrated the potent inhibition of coxsackievirus replication by fluoxetine (4). While it did not interfere with either viral entry, fluoxetine and its metabolite norfluoxetine markedly reduced the synthesis of viral RNA and protein. Fluoxetine's pharmacokinetics and safety commend it as a potential antiviral agent for enterovirus infections. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** 5HT<sub>2C</sub> receptors (1); serotonin uptake (1-3); steroid 21-monoxygenase (7). 1. Ni & Miledi (1997) *Proc. Natl. Acad. Sci. U.S.A.* **94**, 2036. 2. Wong, Bymaster & Engleman (1995) *Life Sci.* **57**, 411. 3. Wong, Horng, Bymaster, Hauser & Molloy (1974) *Life Sci.* **15**, 471. 4. ### Flupenthixol

This anti-psychotic drug and neuroleptic agent (FW = 434.53 g/mol; CAS = 2709-56-0), also called flupenthixol and LC-44, is a potent inhibitor of dopamine-stimulated adenylate cyclase as well as a dopamine receptor antagonist (1,2). Note that there are two distinct forms of this pharmaceutical: an  $\alpha$ - (or *cis*-) isomer (*i.e.*, the *Z*-isomer) and a  $\beta$ - (or *trans*-) form.  $\alpha$ -Flupenthixol is the more active form with a nanomolar *K<sub>i</sub>* value. Both isomers inhibit drug transport and reverse drug resistance mediated by the human multidrug transporter P-glycoprotein (3).  $\alpha$ -Flupenthixol reportedly reverses the substrate inhibition observed with brain tyrosine monoxygenase (4) **Target(s):** dopamine receptor (1,2); dopamine-stimulated adenylate cyclase (1); HIV-1 replication (5); multidrug transporter (3). 1. Iversen (1975) *Science* **188**, 1084. 2. Post, Kennard & Horn (1975) *Nature* **256**, 342. 3. Dey, Hafkemeyer, Pastan & Gottesman (1999) *Biochemistry* **38**, 6630. 4. ### Flupirtine

This centrally acting, non-opioid, non-NSAID, non-steroidal analgesic (FW<sub>free-base</sub> = 304.32 g/mol; CAS = 56995-20-1; FW<sub>maleate-salt</sub> = 420.39 g/mol; CAS = 75507-68-5; Solubility (maleate salt): 84 mg/mL DMSO at 25 °C; <1 mg/mL H<sub>2</sub>O at 25 °C), also known by the trade names Katadolon<sup>®</sup>, Awegal<sup>®</sup>, Efiret<sup>®</sup>, and Metanor<sup>®</sup> and its IUPAC name, ethyl {2-amino-6-[(4-fluorobenzyl)amino]pyridin-3-yl}carbamate, selectively targets G-protein-activated inwardly rectifying K<sup>+</sup> channels (GIRK), the opening of which leads to a stabilization of the resting membrane potential of neuronal cells and thus causes an indirect inhibition of the glutamatergic *N*-methyl-D-

aspartate (NMDA) receptor (1). Activation of GIRK channels leads to hyperpolarization of neuronal membrane, making the neuron becomes less excitable by stabilizing resting neuronal membrane. A drug that activates channels in this manner is called a Selective Neural Potassium Channel Opener (SNEPCO). Flupirtine was the first of this new type of analgesic, muscle-relaxant and neuroprotective agent. That it exerts cerebral or spinal analgesia was demonstrated in rats by the finding that intracerebroventricular and intrathecal administration of showed dose-dependent analgesia, but not when applied systemically (3). Changes in prostaglandin synthesis are of minor importance for flupirtine's analgesic action *in vivo* (2). See (4) for a fuller discussion of the clinical pharmacology of flupirtine's properties as an analgesic and muscle relaxant. 1. Kornhuber, Maler, Wiltfang J, *et al.* (1999) *Fortschr. Neurol. Psychiatr.* **67**, 466. 2. Nickel, Herz, Jakovlev & Tibes (1985) *Arzneimittelforschung.* **35**, 1402. 3. Darius & Schrör (1985) *Arzneimittelforschung.* **35**, 55. 4. ### Fluphenazine

This antipsychotic drug (FW<sub>free-base</sub> = 437.53 g/mol) is a potent inhibitor of dopamine stimulated adenylate cyclase and is a D<sub>2</sub> (also D<sub>1</sub>; albeit weaker) receptor antagonist. **Target(s):** adenylate cyclase (1,2); ATPase (3); Ca<sup>2+</sup> channel, Type 1, inositol 1,4,5 trisphosphate-sensitive (4); Ca<sup>2+</sup>-exporting ATPase (5); CYP1A2 (6); CYP2D6 (6); dopamine receptor, preference for D<sub>2</sub> (7); glutathione-disulfide reductase (18); hydroxyindole *O*-methyltransferase (8); K<sup>+</sup> channel (9); 5-lipoxygenase, or arachidonate 5-lipoxygenase, ID<sub>50</sub> = 21.6  $\mu$ M (10); 12-lipoxygenase, or arachidonate 12-lipoxygenase, ID<sub>50</sub> = 27.5  $\mu$ M (10); Na<sup>+</sup>/K<sup>+</sup>-exchanging ATPase (11); P glycoprotein (12); PI-specific phospholipase C (13); phosphodiesterase (14); prostaglandin synthase, ID<sub>50</sub> = 283  $\mu$ M (10); protein kinase C (15); [pyruvate dehydrogenase (acetyl-transferring)]-phosphatase (16); trypanothione-disulfide reductase (18,19); tyrosyl sulfotransferase (17). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) ### Fluphenazine-*N*-mustard

This fluphenazine derivative (FW<sub>free-base</sub> = 455.97 g/mol; CAS = 83016-35-7; soluble in ethanol and water; forms fluphenazine by hydrolysis (*t*<sub>1/2</sub> = 24 hours) to), also known as fluphenazine-*N*-2-chloroethane, is an irreversible alkylator of calmodulin that prevents calmodulin-mediated activation of cyclic-nucleotide phosphodiesterase-1. 1. Hait, Glazer, Kaiser, Cross & Kennedy (1987) *Mol. Pharmacol.* **32**, 404.

**Flurbiprofen**

This anti-inflammatory agent (FW<sub>free-acid</sub> = 244.27 g/mol; CAS = 5104-49-4) is a potent inhibitor of cyclooxygenase-1, or COX-1 (IC<sub>50</sub> = 0.8 nM). Commercial flurbiprofen is often a mixture of both enantiomers.

**Target(s):** fatty acid amidohydrolase (1); prostaglandin-endoperoxide synthase (cyclooxygenase) (2-8); thiopurine *S*-methyltransferase (9). 1. Fowler, Holt & Tiger (2003) *J. Enzyme Inhib. Med. Chem.* **18**, 55. 2. Pace-Asciak & Smith (1983) *The Enzymes*, 3rd ed., **16**, 543. 3. Range, Pang, Holland & Knox (2000) *Eur. Respir. J.* **15**, 751. 4. Oselin & Anier (2007) *Drug Metab. Dispos.* **35**, 1452.

**Fluticasone**

This anti-inflammatory drug (FW = 444.52 g/mol; CAS 90566-53-3; FW<sub>propionate</sub> = 500.57 g/mol; CAS = 80474-14-2 (propionate)), also named *S*-Fluoromethyl (6*S*,8*S*,9*R*,10*S*,11*S*,13*S*,14*S*, 16*R*,17*R*)-6,9-difluoro-11,17-dihydroxy-10,13,16-trimethyl-3-oxo-6,7,8,11,12,14,15,16-octahydrocyclopenta[*a*]phenanthrene-17-carbothioate, is a synthetic glucocorticoid that optimizes therapeutic efficacy through its lipophilicity and high one-pass metabolism, increasing lung retention and minimizing its systemic burden. Fluticasone is administered topically or inhaled in various formulations, often using its propionate ester. Its long retention time in the lung contributes to delayed absorption and metabolism, thereby accounting for its prolonged efficacy (1). Prolonged treatment with this topical corticosteroid inhibits allergen-induced early and late nasal responses and the associated tissue eosinophilia by inhibiting cells expressing IL-4 mRNA (2). *In vitro*, fluticasone propionate (PA) potently inhibits T-lymphocyte proliferation, cytokine generation, TNF $\alpha$ -induced adhesion molecule expression, interleukin-5-induced eosinophilia, mucosal edema and toluene 2,4-diisocyanate-induced mast cell proliferation, while promoting secretory leukocyte protease inhibitor production and eosinophil apoptosis (3). In human studies, FP demonstrates marked vasoconstrictor potency in normal subjects and inhibits antigen-induced mucosal platelet activating factor/eicosanoid production, T-lymphocytes and CD25<sup>+</sup> cells in patients with rhinitis (3). In mild asthmatics, FP reduces CD3<sup>+</sup>, CD4<sup>+</sup>, CD8<sup>+</sup> and CD25<sup>+</sup> cells, with an accompanying reduction in eosinophil and mast cell markers (3). 1. Masuyama, Jacobson, Rak, *et al.* (1994) *Immunol.* **82**, 192. 3. Fuller, Johnson & Bye (1995) *Respir Med.* **89** (Suppl. A) 3.

**Fluvastatin**

This statin (FW<sub>free-acid</sub> = 411.47 g/mol; CAS = 93957-54-1), also known by the trade names Lescol<sup>TM</sup>, Cane<sup>TM</sup>, and Vastin<sup>TM</sup> as well as its systematic name (3*R*,5*S*,6*E*)-7-[3-(4-fluorophenyl)-1-(propan-2-yl)-1*H*-indol-2-yl]-3,5-

dihydroxyhept-6-enoic acid, was the first wholly synthetic 3-hydroxy-3-methylglutaryl-CoA reductase inhibitor (IC<sub>50</sub> = 28 nM) to reach the market. Fluvastatin is effective in reducing both total and LDL cholesterol. Like other statins, fluvastatin is a substrate for Polypeptide IB1, the organic anion uptake transporter expressed in hepatocytes. Intracellular drug concentrations are also determined by the efflux transporter Multidrug Resistance-associated Protein-2 (designated MRP2 in humans and Mrp2 in rat), which transport of numerous endogenous metabolites (*e.g.*, taurocholate) and xenobiotics (*e.g.*, methotrexate). **Target(s):** induction of inducible nitric oxide synthase, an inflammatory biomarker, in hepatocytes (4); FLT3 glycosylation in human and murine cells (5); high glucose-induced nuclear factor kappa B activation in renal tubular epithelial cells (6); carbonic anhydrase, fifteen human isoforms, hCA I-XIV (7); suppresses geranylgeranylation of small G-proteins of the Rho family, most likely by reducing mevalonate-derived intracellular stores of geranylgeranylpyrophosphate (8); mast cell degranulation without changing the cytoplasmic Ca<sup>2+</sup> level (9 deposition of advanced glycation end products in aortic wall of cholesterol and fructose-fed rabbits (10); hepatitis C replication in humans, albeit with variable results (11). 1. **FMN**

This flavin coenzyme (FW = 514.36 g/mol; CAS = 6184-17-4), also known as riboflavin 5'-phosphate, is the yellow/orange coenzyme and/or prosthetic group for many redox enzymes (*i.e.*, flavoenzymes). The phosphate ester is hydrolyzed in acidic conditions, and the dimethylisoalloxazine ribitol bond is unstable in alkaline conditions: FMN is most stable at pH 6. Ammonium salts of FMN are very unstable. **Redox and Spectral Properties:**  $E^{\circ}$  = -0.219 V at pH 7 and 30°C. FMN has  $\lambda_{max}$  values at 266, 373, and 445 nm, with corresponding  $\epsilon$  values of 31800, 10400, and 12500 M<sup>-1</sup>cm<sup>-1</sup> in 0.1 M phosphate buffer at pH 7. The reduced form FMNH<sub>2</sub> has a molar extinction coefficient of only 870 M<sup>-1</sup>cm<sup>-1</sup> at 450 nm, with a fluorescence maximum at 525-530 nm. FMN is reduced to FMNH<sub>2</sub> in the presence of dithionite or by H<sub>2</sub> in the presence of a suitable catalyst. It is photolabile and solutions must be stored in the dark. **Target(s):** acetyl-CoA synthetase, acetate:CoA ligase (1); acyl-[acyl-carrier-protein] desaturase (29,30); D-amino-acid oxidase (2,3); AMP nucleosidase (4);  $\gamma$ -butyrobetaine dioxygenase (32); carbonyl reductase (5); cholest-5-ene-3 $\beta$ ,7 $\alpha$ -diol 3 $\beta$ -dehydrogenase (6); *trans*-cinnamate 4-monooxygenase (31); cytochrome *b*<sub>5</sub> reductase (7); deoxyhypusine synthase (8); ferredoxin:NADP<sup>+</sup> reductase (9); glutamate racemase (10-12); glutathione-disulfide reductase (13); glycogen phosphorylase *b* (14); human cytomegalovirus UL80 protease (15); 2-hydroxypyridine 5-monooxygenase (16); *myo* inositol oxygenase (17,33); intron, group I (18); L-lactate oxidase (19); NADH:cytochrome *c* reductase, or NADH dehydrogenase (20); NAD(P)H dehydrogenase, or DT diaphorase, weakly inhibited (21-23); palmitoyl-CoA hydrolase, or acyl-CoA hydrolase (24); prostaglandin E<sub>2</sub> 9-reductase (25); riboflavin transglucosidase (26); succinate oxidase (27); sulfur dioxygenase (34); very-long-chain fatty acid  $\alpha$ -hydroxylase (28). 1. ### Folate (Folic Acid)

This photosensitive vitamin (FW = 441.40 g/mol; CAS = 59-30-3; Solubility: 0.0015 mg/mL H<sub>2</sub>O at 25°C), also known as pteroylglutamate, is a precursor to the tetrahydrofolate coenzymes. Note also that the terms “folate” and “folic acid” are often used generically in reference to other pteroyl conjugates, having more than one glutamyl residue: *i.e.*, typically two to seven additional  $\gamma$ -glutamyl residues, linked together via isopeptide bonds). Folic acid has  $\lambda_{\max}$  values of 282 and 350 nm at pH 7.0 ( $\epsilon = 27000$  and  $7000 \text{ M}^{-1}\text{cm}^{-1}$ , respectively). **Target(s):** adenosine deaminase (1); alcohol dehydrogenase (2); arylamine *N* acetyltransferase (3,4); dihydrofolate reductase,  $K_i = 0.11 \mu\text{M}$  (5,6); dihydropterotate synthase (7); formaldehyde dehydrogenase, rat (8); formimidoyl-tetrahydrofolate cyclodeaminase (9,10); *S*-formylglutathione hydrolase (11); glucose-6-P dehydrogenase (12); glutamate carboxypeptidase II (13); glutamate dehydrogenase (12,14); glutamate formimidoyltransferase (15-17);  $\gamma$ -glutamyl hydrolase, or pteroylpolyglutamate hydrolase (18); glycogen phosphorylase *b* (19); GTP cyclohydrolase I, weakly inhibited (20); *S*-(hydroxymethyl)glutathione dehydrogenase (8); *N*<sup>5</sup>-lactate dehydrogenase (12); malate dehydrogenase (12); methenyl-tetrahydrofolate cyclohydrolase (21,22); methyltetrahydrofolate: homocysteine methyltransferase (23); *N*<sup>5</sup>,*N*<sup>10</sup>-methenyltetrahydro-folate synthetase (24); NAD(P)H dehydrogenase (25); NADPH dehydrogenase (quinone) (25); ribonuclease A (26,27); phenylpyruvate tautomerase (28); purine-nucleoside phosphorylase (29,30); thymidylate synthase (31-34); tRNA-guanine transglycosylase (35); xanthine oxidase (36-39). **1.** Harbison & Fisher (1973) *Arch. ### Fomitelic Acids A, B, C, and D

These triterpenoids (Fomitelic Acid A: R<sub>1</sub> = -H, R<sub>2</sub> = -OH, R<sub>3</sub> = -OH; FW = 502.69 g/mol; Fomitelic Acid B: R<sub>1</sub> = -H, R<sub>2</sub> = -OH, R<sub>3</sub> = -H; FW = 486.68 g/mol; Fomitelic Acid C: R<sub>1</sub> = -H, R<sub>2</sub> = -OH, R<sub>3</sub> = -OCH<sub>3</sub>; FW = 500.70 g/mol; Fomitelic Acid D: R<sub>1</sub> = -OH, R<sub>2</sub> = -H, R<sub>3</sub> = -H; FW = 486.68 g/mol), from a basidiomycete *Fomitella fraxinea* are potent inhibitors of eukaryotic DNA polymerases. Minimum inhibitory concentrations (MIC) ranges from 35-130  $\mu\text{M}$ . **Target(s):** DNA-directed DNA polymerase (1-4); DNA polymerase  $\alpha$  (1,2,4); DNA polymerase  $\beta$  (1-4); DNA polymerase II, plant (1); DNA topoisomerase I (1); DNA topoisomerase II (1). **1.** Mizushima, Iida, Ohta, Sugawara & Sakaguchi (2000) *Biochem. ### Foretinib

This orally available, ATP-competitive multikinase inhibitor and experimental anticancer drug (FW = 632.65 g/mol; CAS = 849217-64-7; Solubility: 125 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), variously known as EXEL-2880, XL880, GSK1363089 and *N*<sup>1</sup>-[3-fluoro-4-[[6-methoxy-7-(3-morpholinopropoxy)-4-quinolyl]oxy]phenyl]-*N*<sup>1</sup>-(4-fluorophenyl)cyclopropane-1,1-dicarboxamide, targets protein tyrosine kinase activities of human growth factor receptor (HGFR) and vascular endothelial growth factor receptor-2 (VEGFR-2), mainly c-Met (IC<sub>50</sub> = 0.4 nM) and KDR (IC<sub>50</sub> = 0.9 nM). Binding to c-Met and KDR is characterized by a very slow off-rate, consistent with crystallographic evidence that the inhibitor is deeply bound in the active-site cleft. Foretinib prevents anchorage-independent proliferation of tumor cells under both normoxic and hypoxic conditions. *In vivo*, these effects produce significant dose-dependent inhibition of tumor burden in an experimental model of lung metastasis (1). It also inhibits

growth of gastric cancer cell lines by blocking inter-receptor tyrosine kinase networks (2). Foretinib is a more potent inhibitor than crizotinib (PF-02341066) of oncogenic ROS1 fusion protein, a druggable target in malignant transformation in lung adenocarcinoma, cholangiocarcinoma, and glioblastoma (4). 1. Davare, Saborowski, Eide, *et al.* (2013) *Proc. Natl. Acad. Sci. U.S.A.* **110**, 19519.

### Formaldehyde

This one-carbon aldehyde (FW = 30.03 g/mol; CAS = 50-00-0; clear and colorless liquid; B.P. = -19 °C; M.P. = -92 °C; pungent odor, detectable at 1 ppm; Vapor Pressure = 10 mm Hg at -88 °C) is common industrial chemical and metabolite that is substantially hydrated to the gem-diol in body fluids ( $K_{\text{eq}} = [\text{gem-diol}]/[\text{free aldehyde}] > 1000$  at pH 7). Upon condensation, gaseous formaldehyde converts to the cyclic trimer metaformaldehyde (or 1,3,5-trioxane, or (CH<sub>2</sub>O)<sub>3</sub>) and the linear polymer known as paraformaldehyde.

Formaldehyde reacts readily with ammonia, hydroxylamine, and hydrazine, as well as with alkyl- and aryl-amines. The tissue fixative and embalming agent known as formalin consists of a 37% (vol/vol) aqueous solution that usually contains 10–15% methanol. **Formol Titration:** This technique, invented by Sorensen, refers to the reaction of an amino acid with formaldehyde under alkaline conditions:

This reaction was used by French and Edsall to demonstrate the preponderance of amino acid zwitterion over neutral amino acid at neutral pH. Prior to the development of more sensitive methods, this technique was also used to determine protein concentration. **Health Risks & Carcinogenicity:** Formaldehyde is a ubiquitous environmental contaminant, with human exposures in industrial processes such as the manufacture of resins and adhesives, particle board, plywood, leather goods, paper, and pharmaceuticals. Formaldehyde is slowly released as a vapor over the lifetimes of these products. Exposure to formaldehyde also results in the formation of DNA-protein cross-links (DPCs) as a primary genotoxic effect. Detailed structural examination by NMR and mass spectrometry established that the cross-links between amino acids and single nucleosides involve formaldehyde-derived methylene bridges. Formaldehyde is also produced in the human body and is elevated in neurodegenerative conditions. Although the toxic potential of excess formaldehyde has been studied, little is known about the molecular mechanisms underlying its toxicity. The mechanisms by which formaldehyde causes cancer are not completely understood; however, formaldehyde clearly causes genetic damage in the nasal sinus of animals. Less is known about how it causes myeloid leukemia. **CAUTION:** Formaldehyde is regulated in the U.S. as a carcinogen (OSHA Standard 1910.1048) and is listed in International Agency for Research on Cancer as an IARC Group 2A "probable human carcinogen". This substance is classified as a "select carcinogen" under the criteria of the OSHA Laboratory Standard. It is moderately toxic by skin contact and inhalation. Exposure to gaseous formaldehyde irritates the eyes and respiratory tract, causing cough, dry throat, tightening of the chest, headache, a sensation of pressure in the head, as well as palpitations of the heart. Exposure to 0.1–5 ppm irritates eyes, nose, and throat; above 10 ppm causes severe lacrimation, burning in the nose and throat, and belabored

breathing. Acute exposure to concentrations at >25 ppm can cause serious injury, including fatal pulmonary edema. Formaldehyde has low acute toxicity via the oral route. Ingestion can cause irritation of the mouth, throat, and stomach, nausea, vomiting, convulsions, and coma. Lethal Dose oral (rat) = 500 mg/kg; Lethal Dose skin (rabbit) = 270 mg/kg; Lethal Inhaled Concentration (rat) = 203 mg/min for 2 hours. 1. ### Formoterol

This bronchodilator (FW = 344.41 g/mol; CAS = 73573-87-2), also named *rac-(R,R)-N-[2-hydroxy-5-[1-hydroxy-2-[1-(4-methoxyphenyl)propan-2-ylamino]ethyl]phenyl]formamide*, is a long-acting β<sub>2</sub>-adrenergic agonist that is used to manage asthma and chronic obstructive pulmonary disease, or COPD (1-3). Marketed under various trade names (including Foradil<sup>®</sup>, Foradile<sup>®</sup>, Oxeze<sup>®</sup>, Oxis<sup>®</sup>, Symbicort<sup>®</sup>, Atock<sup>®</sup>, Atimos<sup>®</sup>, and Performist<sup>®</sup>), formoterol is marketed as a dry-powder inhaler, a metered-dose inhaler, an oral tablet, and an inhalation solution. Formoterol inhibit both allergic (anti-IgE) and non-allergic histamine release (calcium ionophore and human complement component C5a) from human basophils (4). With its ability to cross the blood brain barrier, formoterol also improves cognitive function and promotes dendritic complexity in a mouse model of Down's Syndrome (5). ### Formycin A

This highly fluorescent nucleoside antibiotic (FW = 267.24 g/mol; CAS = 6742-12-7), also named 7-amino-3-(β-D-ribofuranosyl)-1H-pyrazolo[4,3-d]pyrimidine and 8-aza-9-deazaadenosine, is a nonglycosidic adenosine isostere produced by *Nocardia interforma*. Formycin A is also metabolically phosphorylated to its mono-, di-, and tri-phosphates, which inhibit purine biosynthesis and can also be incorporated into RNA. It likewise alters tRNA processing by increasing the degradation rate of abnormal precursors. Formycin A inhibits *Escherichia coli* and *Trichomonas vaginalis* purine-nucleoside phosphorylase with little effect on

the mammalian enzyme. The purine-like base undergoes tautomerization when bound. One must not confuse this agent with formicin (*i.e.*, *N*-(hydroxymethyl)acetamide). **Target(s):** adenosine kinase, also as an alternative substrate (1,2); adenosyl-homocysteinase (3,4); adenosyl-homocysteine nucleosidase (5-7); AMP nucleosidase (8); diphosphate:purine-nucleoside kinase (9); GMP synthetase (10); 5'-methylthioadenosine/*S*-adenosylhomocysteine nucleosidase (5-7); 1-phosphatidyl-inositol 4-kinase (11); purine-nucleoside phosphorylase (9,12-23). 1. #### Formycin B

This nucleoside analogue and antibiotic (FW = 268.23 g/mol; CAS = 13877-76-4), also known as 7-oxo-3-(β-D-ribofuranosyl)-1*H*-pyrazolo[4,3-*d*]pyrimidine and 8-aza-9-deazainosine 5'-phosphate, is produced by *Nocardia interforma*, *Streptomyces lavendulae*, and *S. roseochromogenes*. **Target(s):** adenosylhomocysteinase (1); GMP synthetase, weakly inhibited (2); purine nucleosidase, purine-specific nucleoside *N*-

ribohydrolase (3); purine-nucleoside phosphorylase (4-17); poly(ADP-ribose) polymerase (18,19). 1. Shimizu, Shiozaki, Ohshiro & Yamada (1984) *Eur. J. Biochem.* **141**, 385. 2. #### S-Formycinyl-L-homocysteine

This *S*-adenosylhomocysteine analogue (FW = 384.42 g/mol) inhibits 5'-methylthioadenosine/*S*-adenosyl-homocysteine nucleosidase,  $K_i = 9.7$  nM. **Target(s):** adenosylhomocysteine nucleosidase (1); 5'-methylthioadenosine/*S*-adenosylhomocysteine nucleosidase (1). 1. Della Ragione, Porcelli, Carteni-Farina, Zappia & Pegg (1985) *Biochem. J.* **232**, 335.

#### *N*<sup>10</sup>-Formylfolate (*N*<sup>10</sup>-Formylfolic Acid)

This substituted folic acid (FW<sub>free-acid</sub> = 469.41 g/mol;  $\lambda_{max} = 256$  nm;  $\epsilon = 46000$  M<sup>-1</sup>cm<sup>-1</sup>, in 0.01 M NaOH), also known as 10-formylpteroylglutamate, is a strong inhibitor of dihydrofolate reductase,  $K_i = 6.1$  nM (1-4), methionyl-tRNA formyltransferase (5), phosphoribosylaminoimidazole carboxamide formyltransferase (6); thymidylate synthase (7). 1. Baker (1967) *Design of Active-Site-Directed Irreversible Enzyme Inhibitors*, Wiley, New York. 2. Bertino, Perkins & Johns (1965) *Biochemistry* **4**, 839. 3. D'Urso-Scott, Uhoch & Bertino (1974) *Proc. Natl. Acad. Sci. U.S.A.* **71**, 2736. 4. Friedkin, Plante, Crawford & Crumm (1975) *J. Biol. Chem.* **250**, 5614. 5. Banerjee, Bennett, Brockman, Sani & Temple, Jr. (1982) *Anal. Biochem.* **121**, 275.

#### *N*-Formyl-L-methionine

This formylated amino acid (FW<sub>free-acid</sub> = 177.22 g/mol), Symbol = fMet, is a residue at the N-terminus of a growing polypeptide chain in protein biosynthesis in prokaryotes, bacteriophages, mitochondria, and chloroplasts. The initiation codon AUG codes for *N*-formyl-L-methionine (occasionally by GUG or UUG, when these are the first codon). Note that free fMet is not formed in this pathway: fMet-tRNA<sup>fMet</sup> is produced by formylation of

Met-tRNA<sup>fMet</sup> via methionyl-tRNA formyltransferase. However, *N*-formyl-L-methionine is produced by the action of many aminopeptidases as well as by *N*-formylmethionyl-peptidase. **Target(s):** homoserine *O*-acetyltransferase (1); methionine *S*-methyltransferase, weakly inhibited (2); peptide deformylase, fMet is not a substrate for the *Escherichia coli* enzyme (3); pyrroline-2-carboxylate reductase (4). 1. Shii & Ozaki (1981) *J. Biochem.* **89**, 1493. 2. James, Nolte & Hanson (1995) *J. Biol. Chem.* **270**, 22344. 3. Meinel, Blanquet & Dardel (1996) *J. Mol. Biol.* **262**, 375. 4. Petrakis & Greenberg (1965) *Biochim. Biophys. Acta* **99**, 78.

#### **cis-2-(2-Formylpyrrolidine-1-carbonyl)-1-cyclohexanecarboxylic Acid Benzyl Ester**

This ester (FW = 343.42 g/mol) is a slow-binding inhibitor of prolyl oligopeptidase, or prolyl oligopeptidase,  $K_i = 3$  nM. This non-peptide inhibitor binds at the same site as peptide inhibitors requiring L-configuration at the P<sub>1</sub> and P<sub>2</sub> binding pockets. 1. Kolosko, Bakker, Faraci & Nagel (1994) *Drug Des. Discov.* **11**, 61.

#### ***N*<sup>5</sup>-Formyltetrahydrofolate (or *N*<sup>5</sup>-Formyl-THF)**

This tetrahydrofolate metabolite (FW<sub>disodium-salt</sub> = 517.41 g/mol;  $\lambda_{\max} = 286$  nm at pH 7 ( $\epsilon = 31800$  M<sup>-1</sup>cm<sup>-1</sup>) and 282 nm at pH 13 ( $\epsilon = 32600$  M<sup>-1</sup>cm<sup>-1</sup>)), also known as leucovorin, folinic acid, and *N*<sup>5</sup>-formyltetrahydropteroylglutamate, is a growth factor for *Leuconostoc citrovarum*. *N*<sup>5</sup>-Formyl-THF is a substrate for glutamate formimidoyltransferase and 5-formyltetrahydrofolate cyclo-ligase. *N*<sup>5</sup>-formyl-THF's ability to inhibit dihydrofolate reductase weakly stands as the basis for the so-called "methotrexate/leucovorin rescue" protocol for treating various neoplasias. While stable in neutral and alkaline solutions, this tetrahydrofolate derivative converts to *N*<sup>5</sup>,*N*<sup>10</sup>-methenyl-THF in acidic solutions. **Role of SHMT & Glycine in *N*<sup>5</sup>-Formyl-THF Synthesis:** Serine hydroxymethyltransferase (SHMT) is a pyridoxal-phosphate dependent enzyme that catalyzes the reversible interconversion of serine and tetrahydrofolate (THF) to glycine and *N*<sup>5</sup>,*N*<sup>10</sup>-methylene-THF, a reaction that generates one carbon unit for methionine, thymidylate and purine synthesis in the cytoplasm. SHMT is present in both the mitochondria (MSHMT) and the cytoplasm (CSHMT) of mammalian cells. SHMT also catalyzes a second reaction, the irreversible conversion of *N*<sup>5</sup>,*N*<sup>10</sup>-methenyl-THF to *N*<sup>5</sup>-formyl-THF (1). Once synthesized, *N*<sup>5</sup>-formyl-THF remains bound to the enzyme and acts as an effective slow-binding inhibitor of SHMT catalyzed reactions *in vitro* and *in vivo* (2,3). However, 5-formylTHF does not serve as a cofactor in the cell, and its role in cellular metabolism is not known. In the presence of excess glycine, the enzymatic activities of CSHMT and MTHFS constitute a futile cycle that is capable of buffering 5-formylTHF levels in the cytoplasm. Whereas the metabolic role of the futile cycle is not known, Girgis *et al.* (3) demonstrated that decreased levels of 5-formylTHF can result in impaired homocysteine remethylation in cultured human neuroblastoma. Elevations in 5-formylTHF levels result in decreased purine biosynthesis in MCF-7 cells (4). **Target(s):** glucose-6-phosphate dehydrogenase (5); glycine *N*-methyltransferase (6); glycogen phosphorylase *b* (7); methionyl-tRNA formyltransferase (8-10); serine hydroxy-methyltransferase, or glycine Hydroxymethyltransferase, also inhibited by the polyglutamylated form (11-16); thymidylate synthase (17). 1. #### ***N*<sup>10</sup>-Formyltetrahydrofolate**

This one-carbon folate (FW<sub>disodium-salt</sub> = 517.41 g/mol;  $\lambda_{\max} = 258$  nm between pH 7 to 9;  $\epsilon = 22000$  M<sup>-1</sup>cm<sup>-1</sup>), also known as *N*<sup>10</sup>-formyltetrahydropteroylglutamate, is rapidly oxidized in air. At pH < 6, *N*<sup>10</sup>-THF rearranges to form *N*<sup>5</sup>,*N*<sup>10</sup>-methenyltetrahydrofolate. In neutral or alkaline solutions, it isomerizes to produce *N*<sup>5</sup>-formyltetrahydrofolate. The formyl group is lost in 0.1 M base. L-(+)-*N*<sup>10</sup>-THF inhibits phosphoribosylglycinamide formyltransferase competitively ( $K_i = 0.75$   $\mu$ M). **Target(s):** *N*<sup>5</sup>,*N*<sup>10</sup>-methylenetetrahydrofolate dehydrogenase (1); *N*<sup>5</sup>,*N*<sup>10</sup>-methenyltetrahydrofolate cyclohydrolase (1); phosphoribosylglycinamide formyltransferase, inhibited by (6*S*)-stereoisomer (2,3); thymidylate synthase (4,5). 1. Dev & Harvey (1978) *J. Biol. Chem.* **253**, 4245. 2. Smith, Benkovic & Benkovic (1981) *Biochemistry* **20**, 4034. 3. Dolnick & Cheng (1978) *J. Biol. Chem.* **253**, 3563.

#### ***N*<sup>5</sup>-Formyltetrahydrohomofolate**

This folic acid analogue inhibits 5-formyltetrahydrofolate cyclo-ligase, also known as *N*<sup>5</sup>,*N*<sup>10</sup>-methenyltetrahydrofolate synthetase;  $K_i = 1.4$   $\mu$ M for the MCF-7 human breast cancer cell enzyme. 1. Schirch (1997) *Meth. Enzymol.* **281**, 146. 2. Jolivet (1997) *Meth. Enzymol.* **281**, 162. 3. Bertrand & Jolivet (1989) *J. Biol. Chem.* **264**, 8843. 4. Huang & Schirch (1995) *J. Biol. Chem.* **270**, 22296.

#### **Forskolin**

This cell-permeable diterpenoid (FW = 408.54 g/mol), also known as colforsin, from the roots of *Coleus forskohlii*, activates adenylyl cyclase (also known as adenylyl cyclase), increasing cellular cAMP concentrations, thereby stimulating Protein Kinase A (cAMP-activated protein kinase). Treatment of rat renal mesangial cells with forskolin blunts activation of MAP kinase induced by platelet-derived growth factor and epidermal growth factor. The total synthesis of (±)-forskolin was accomplished independently (1,2). **Target(s):** ecdysone 20-monooxygenase (3); MAP kinase, or mitogen-activated protein kinase (4,5). 1. Hashimoto, Sakata,

Sonegawa & Ikegami (1988) *J. Amer. Chem. Soc.* **110**, 3670. **2.** Corey, da Silva Jardine & Rohloff (1988) *J. Amer. Chem. Soc.* **110**, 3672. **3.** Keogh, Mitchell, Crooks & Smith (1991) *Experientia* **48**, 39. **4.** Li, Zarinetchi, Schrier & Nemenoff (1995) *Amer. J. Physiol.* **269**, C986. **5.** Siddhanti, Hartle & Quarles (1995) *Endocrinology* **136**, 4834.

### Fosaprepitant

This antiemetic and aprepitant prodrug (FW = 614.40 g/mol; CAS = 172673-20-0), or [3-[[[(2*R*,3*S*)-2-[(1*R*)-1-[3,5-bis(trifluoromethyl)phenyl]ethoxy]-3-(4-fluorophenyl)morpholin-4-yl]methyl]-5-oxo-2*H*-1,2,4-triazol-1-yl]phosphonic acid, is metabolically generates aprepitant, a selective high-affinity Substance P antagonist (or SPA) that blocks Substance P binding to the Neurokinin 1 (NK1) receptor (See *Aprepitant*).

### Foscarnet

This intravenously administered antiviral drug (FW = 126.01 g/mol; CAS = 63585-09-1), also known as Foscavir and phosphonoformic acid, is a pyrophosphate mimic that binds to and inhibits many viral DNA polymerases ( $IC_{50} = 10-100 \mu M$ ), with little effect on human DNA polymerase. This drug is also active against RNA-dependent DNA polymerases. Foscarnet is used to treat drug-resistant cytomegalovirus (CMV), varicella-zoster virus, Epstein-Barr virus, as well as herpes simplex virus types 1 and 2. Phosphonoformic acid inhibited both chain elongation and exonuclease activities of HSV-1 DNA polymerase (uncompetitively with respect to activated DNA),  $K_i = 2.4 \mu M$  (1). Phosphonoacetate (PAA), which more closely resembles pyrophosphate, is of comparable effectiveness. Closely positioned mutations (e.g., Leu-802-Met and Lys-805-Gln) in the conserved  $\alpha$ -helix P in the nucleotide binding site of human cytomegalovirus DNA polymerase can respectively decrease and increase susceptibility to foscarnet, suggesting a unifying mechanism for CMV drug susceptibility (2). Indeed, recombinant viruses containing mutations Lys-805-Gln, Thr-821-Ile, and Lys-805-Gln/Thr-821-Ile had 0.8x, 5.3x and 4.8x increases in ganciclovir  $IC_{50}$  values and 0.3-fold, 23.3-fold and 15.6-fold increases in foscarnet  $IC_{50}$  values, respectively, compared with the wild-type virus (3). Phosphonopyruvate hydrolase, a novel bacterial carbon-phosphorus bond cleavage enzyme, is also inhibited by phosphonoformic acid (3). Foscarnet inhibits sodium-phosphate cotransporter, which mediates lithium reabsorption in the rat kidney (5). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **1.** Derse & Cheng (1981) *J. Biol. Chem.* **256**, 8525. **2.** Tchesnokov, Gilbert, Boivin & Götte (2006) *J. Chem.* **278**, 23426. **5.** Uwai, Arima, Takatsu, et al. (2014) *Pharmacol Res.* **87**, 94.

### Fosdevirine

This antiviral (FW = 413.80 g/mol; CAS = 1018450-26-4), also named IDX-899, GSK2248761A and carbamoyl-5-chloro-1*H*-indol-3-yl]-3-(*E*)-2-

cyanovinyl)-5-methylphenyl)]-(*R*)-phosphinic acid methyl ester, is an HIV non-nucleoside reverse transcriptase inhibitor (1). In a study on fosdevirine's likely CNS toxicity, however, LC-MS and matrix-assisted laser desorption/ionization confirmed the drug's gray matter disposition and metabolism (2). Moreover, Phase Ib studies to select a once-daily dose of fosdevirine were halted when 5 of 35 treatment-experienced subjects developed new-onset seizures after 4-weeks or longer exposure (3). The delayed onset of seizures and its persistence after discontinuation of fosdevirine is without precedent in antiretroviral drug development, underscoring the need for careful subject monitoring (3). Zhou, Pietropaolo, Damphousse et al. (2009) *Antimicrob. Agents Chemother.* **53**, 1739. **3.** Castellino, Groseclose, Sigafos, et al. (2013) *Chem. Res. Toxicol.* **26**, 241. **4.** Margolis, Eron, DeJesus, et al. (2013) *Antivir. Ther.* **19**, 69.

### Fosfomycin

This antibiotic (FW = 138.06 g/mol; CAS = 23155-02-4), also known as [(2*R*,3*S*)-3-methyloxiran-2-yl]phosphonic acid, phosphonomycin and phosphomycin, is produced by strains of *Streptomyces* and *Pseudomonas* and is an analogue of phosphoenolpyruvate. Fosfomycin inactivates UDP-*N*-acetylglucosamine 1-carboxyvinyltransferase, which catalyzes the first committed step in bacterial cell wall biosynthesis, attaching itself covalently with an active-site cysteinyl residue. Time-dependent inactivation is accelerated by the presence of the cosubstrate UDP-*N* acetylglucosamine, and the inactivation rate is further enhanced in the presence of the unreactive analogue 3-deoxy-UDP-*N*-acetylglucosamine (1). Fosfomycin activated maize leaf PEP carboxylase, but its  $Mg^{2+}$  complex inhibits (2). **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** acid phosphatase, inhibited weakly (3); 3-deoxy-7-phosphoheptulonate synthase (4); NF- $\kappa$ B activation (5); phosphoenolpyruvate carboxylase (2); UDP-*N*-acetylglucosamine 1-carboxyvinyltransferase, or MurA transferase (1,6-22). **1.** Marquardt, Brown, Lane, et al. ### Fosinopril & Fosinoprilat

Fosinopril

Fosinoprilat

This antihypertensive pro-drug (FW<sub>fosinopril</sub> = 566.63 g/mol; CAS = 98048-97-6), also named (2*S*,4*S*)-4-cyclohexyl-1-[2-[hydroxy(4-phenylbutyl)phosphoryl]acetyl]pyrrolidine-2-carboxylic acid and Monopril<sup>®</sup>, is metabolized to its pharmacologically active metabolite (FW<sub>fosinoprilat</sub> = 435.39 g/mol; CAS = 95399-71-6), the latter targeting peptidyl-dipeptidase A, or angiotensin-converting enzyme inhibitor (IC<sub>50</sub> = 1 nM). Unlike other ACE inhibitors that are primarily excreted by the kidneys, fosinopril is eliminated by both renal and hepatic pathways. 1. Shionoiri, Naruse, Minamisawa, *et al.* (1997) *Clin. Pharmacokinet.* **32**, 460. 2. Krapcho, Turk, Cushman, *et al.* (1988) *J. Med. Chem.* **31**, 1148.

### Fosmidomycin

This antimalarial/antimicrobial agent (FW<sub>free-acid</sub> = 183.10 g/mol), also known as 3-(*N*-formyl-*N*-hydroxyamino)propylphosphonate, inhibits bacterial and plant 1-deoxy-D-xylulose-5-phosphate reductoisomerase (IC<sub>50</sub> = 8.2 nM) and suppresses the *in vitro* growth of multidrug-resistant *P. falciparum* strains. 1. Jomaa, Wiesner, Sanderbrand, *et al.* (1999) *Science* **285**, 1573. 2. Koppisch, Fox, Blagg & Poulter (2002) *Biochemistry* **41**, 236. 3. ### Fostemsavir

This HIV prodrug (FW<sub>free-acid</sub> = 582.49 g/mol; FW = 704.63 g/mol (trihydroxymethylamine salt); CAS = 864953-29-7), also known as and {3-[(4-benzoyl-1-piperazinyl)-(oxo)acetyl]-4-methoxy-7-(3-methyl-1*H*-1,2,4-triazol-1-yl)-1*H*-pyrrolo[2,3-*c*]pyridin-1-yl}methylphosphonate and BMS-663068, is a derivative of BMS-626529, a novel small-molecule HIV-1 attachment inhibitor (**See BMS-626529**). Because fostemsavir targets a different step of the viral life-cycle, it offers promise for individuals infected with virus that has achieved resistance to other HIV drugs. Administration of BMS-663068 for 8 days with or without ritonavir resulted in substantial declines in plasma HIV-1 RNA levels and was generally well tolerated. 1. Nettles, Schürmann, Zhu, *et al.* (2012) *J. Infect. Dis.* **206**, 1002.

### Fostriecin

This naturally-occurring phosphate monoester (FW<sub>free-acid</sub> = 404.33 g/mol; CAS = 87860-39-7), also known as phosphotrienin, from *Streptomyces pulveraceus* exhibits potent antitumor activity. It is a strong inhibitor of protein phosphatase 2A (IC<sub>50</sub> = 3.2 nM) and also inhibits protein phosphatase (1), albeit only at elevated concentrations (IC<sub>50</sub> = 131 μM). No effect has been observed on calcineurin (protein phosphatase 2B). Fostriecin also inhibits DNA topoisomerase II and will arrest cell growth at the G<sub>2</sub>/M phase of the cell cycle. **Target(s):** DNA topoisomerase II (1-3); phosphoprotein phosphatase (4-13); protein phosphatase 1 (4,5); protein phosphatase 2A (4,6-10); protein phosphatase 4 (8,11,12). 1. ### Fotemustine

This antineoplastic agent (FW = 315.69 g/mol; CAS = 92118-27-9) is a chloroethylnitrosourea that has been proposed to degrade in aqueous solutions to form a short-lived intermediate, 2-chloroethyl-diazohydroxide, which rapidly generates *O*<sup>6</sup>-guanine adducts responsible for the drug's initial activity as well as a long-lived iminol tautomer responsible for the remaining *O*<sup>6</sup>-guanine alkylation (1). **Target(s):** glutathione-disulfide reductase (2); ribonucleotide reductase (2,3); thioredoxin reductase (2). 1. Hayes, Bartley, Parsons, Eaglesham & Prakash (1997) *Biochemistry* **36**, 10646. 2. Schallreuter, Gleason & Wood (1990) *Biochim. Biophys. Acta* **1054**, 14. 3. Schallreuter, Elgren, Nelson, *et al.* (1992) *Melanoma Res.* **2**, 393.

### FR167653

This p38 kinase-selective inhibitor (FW<sub>free-base</sub> = 427.44 g/mol), also named 1-[7-(4-fluorophenyl)-1,2,3,4-tetrahydro-8-(4-pyridyl)pyrazolo[5,1-*c*][1,2,4]triazin-2-yl]-2-phenylethanedione, is a dual inhibitor, acting both *in vitro* and *in vivo* to reduce production of interleukin-1α (IC<sub>50</sub> = 0.84 μM), interleukin-1β (IC<sub>50</sub> = 0.09 μM) and tumor necrosis factor-α (TNFα) in human monocytes stimulated with lipopolysaccharide (IC<sub>50</sub> = 1.1 μM) and in human lymphocytes stimulated with phytohemagglutinin-M (IC<sub>50</sub> = 0.072 μM), preventing inflammation and suppressing the severity of adjuvant arthritis in a dose-dependent manner with little effect on body weight (1,2). FR167653 ameliorates endotoxin shock in rabbits and intravascular coagulation in rats (1,3) and also ameliorates cardiac dysfunction caused by chronic infusion of LPS in rats (4). Furthermore, FR167653 protects lung, liver, and heart against ischemia-reperfusion injury in dogs (5-7). FR167653 inhibits endogenous p38 kinase activity without affecting its activation, as observed in p38 kinase inhibitors, such as

SB203580 (8). This is due to the binding property of these p38 kinase inhibitors, i.e., this class of compounds competes with ATP at the ATP-binding site of p38 kinase, but does not bind to its phosphorylation sites (9,10). 1. Yamamoto, Sakai, Yamazaki, Nakahara & Okuhara (1996) *Eur. J. Pharmacol.* **314**, 137. 2. Shinozaki, Takagishi, Tsutsumi, *et al.* (2001) *Mod. Rheumatol.* **11**, 300. 3. **FR901228**, See *Romidepsin*

#### FR901464

This natural product (FW = 491.62.65 g/mol), isolated from the fermentation broth of the bacterium *Pseudomonas* sp., is an anticancer compound that enhances the transcriptional activity of the SV40 promoter (1) and causes cell cycle arrest at the G<sub>1</sub> and G<sub>2</sub>/M phases (2). FR901464 targets the spliceosome, a multicomponent complex that assembles on the newly synthesized pre-mRNA and catalyzes the removal of intervening sequences from transcripts (3). Spliceostatin A inhibits *in vitro* splicing and promotes pre-mRNA accumulation by binding to SF3b, a subcomplex of the U2 small nuclear ribonucleoprotein in the spliceosome. Treatment of cells with this agent results in leakage of (unspliced) pre-mRNA to the cytoplasm, where it is translated. Knockdown of SF3b by small interfering RNA induced phenotypes similar to those seen with spliceostatin A treatment. SF3b appears to have two functions, first in the splicing pre-mRNA and in retaining it. Albert *et al.* (4) describes the total syntheses, fragmentation studies, and antitumor/antiproliferative activities of FR901464 and its low picomolar analogue. They also showed that FR901464 was not very stable in phosphate buffer at pH 7.4 (*t*<sub>1/2</sub> = 4 hours at 37 °C). (See also *E7107*; *Meayamycin*; *Pladienolide B*; *Spliceostatin A*) 1. Nakajima, Sato, Fujita, *et al.* (1996) *J. Antibiot.* (Tokyo) **49**, 1196. 2. Nakajima, Hori, Terano H, *et al.* (1996) *J. Antibiot.* (Tokyo) **49**, 1204. 3. Kaida, Motoyoshi, Tashiro, *et al.* (2007) *Nature Chem. Biol.* **3**, 576. 4. Albert, Sivaramakrishnan, Naka, Czaicki & Koide (2007) *J Am Chem Soc.* **2007**;129:2648 **IUPAC Name:** [(Z,2S)-4-[[[(2R,3R,5S,6S)-6-[(2E,4E)-5-[(2R,3R,4S,6S)-4-(chloromethyl)-3,4,6-trihydroxy-6-methylloxan-2-yl]-3-methylpenta-2,4-dienyl]-2,5-dimethylloxan-3-yl]carbamoyl]but-3-en-2-yl] acetate

#### FRAX 486

This selective PAK1 inhibitor (FW = 513.39 g/mol; CAS = 1232030-35-1; Solubility: 100 mM in DMSO), also known as 6-(2,4-dichlorophenyl)-8-ethyl-2-[[3-fluoro-4-(1-piperazinyl)phenyl]amino]pyrido[2,3-d]pyrimidin-7(8H)-one, targets p21-activated kinase PAK1 (IC<sub>50</sub> = 14 nM), with weaker action on PAK2 (IC<sub>50</sub> = 33 nM), PAK3 (IC<sub>50</sub> = 39 nM), and PAK4 (IC<sub>50</sub> = 500 nM). **Pharmacologic Action:** Fragile X syndrome (FXS), the most common inherited form of autism and intellectual disability, is caused by silencing of the Fragile X mental retardation-1 (*Fmr1*) gene. *Fmr1* KO mice display phenotypes similar to symptoms observed in FXS, including hyperactivity, repetitive behaviors, and seizures, as well as abnormal dendritic spine density. Given the realization that defects in actin cytoskeletal dynamics alter dendritic spines in ways that impair synaptogenesis and/or synapse stability, attention focused on PAK1, a serine/threonine-protein kinase in signal transduction pathways linking Rho

GTPases to actin cytoskeleton reorganization and nuclear signaling in dendritic spines. FRAX486 was identified by high-throughput screening of a 12,000 kinase-focused small molecule library, with p21-activated kinase as the screening target. Treatment of adult *Fmr1* knock-out mice with FRAX486 reverses the spine density phenotype and likewise rescues every human-like, brain-related phenotypes observed in *Fmr1* knock-out mice, including abnormally high densities of dendritic spines, audiogenic seizures, and related attention deficit and hyperactivity. 1. Dolan, Duron, Campbell, *et al.* (2013) *Proc. Natl. Acad. Sci. U.S.A.* **110**, 5671.

**FRC-8653**, See *Cilnidipine*

#### Frovatriptan

This orally bioavailable, tryptan-based 5HT receptor agonist (FW = 243.30 g/mol; CAS = 158930-17-7), also known by the trade name Frova<sup>®</sup> and systematically as (+)-(*R*)-3-methylamino-6-carboxamido-1,2,3,4-tetrahydrocarbazole, is used in the treatment of migraine headaches and for the short-term prevention of menstrual migraine. Frovatriptan displays high agonist activity at mainly the serotonin 5-HT<sub>1B</sub> and 5-HT<sub>1D</sub> receptor subtypes, resulting in inhibition of the release of vasoactive neuropeptides by trigeminal nerves and inhibition of nociceptive neurotransmission. Its plasma half-life is 26 to 30h, suitable for once-daily dosing. 1. Easthope & Goa (2001) *CNS Drugs* **15**, 969. 2. Tepper, Rapoport & Sheffell (2002) *Arch. Neurol.* **59**, 1084.

#### D-Fructose

This hygroscopic D-ketohexose (FW = 180.16 g/mol; CAS = 57-48-7), also called fruit sugar and levulose, is the sweetest of all naturally occurring monosaccharides. As a reducing sugar, fructose supports nonenzymatic protein glycation. At 30°C in D<sub>2</sub>O, D-fructose exists as: 2% α-pyranose, 70% β-pyranose, 5% α-furanose, and 23% β-furanose. **Target(s):** β-N-acetylhexosaminidase (1); acrosin (2); aldose 1-epimerase (3,4); catalase (5); catechol oxidase (45); choline acetyltransferase (6); concanavalin A (7); β-fructofuranosidase, *or* invertase (both anomers inhibit the yeast enzyme) (8-19); fructose-1,6-bisphosphate aldolase (20,21); fumarase (fumarate hydratase) (5); α-galactosidase (22,23); β-galactosidase, weakly inhibited (24); glucan 1,4-α glucosidase, *or* glucoamylase; weakly inhibited (25); glucose dehydrogenase (NAD<sup>+</sup>) (26); glucose oxidase (27); α-glucosidase (maltase) (28,29); β-glucosidase (30,31); laminaribiose phosphorylase (44); mannokinase, also as an alternative substrate (32); naringinase (33); peroxidase (45,46); phosphoenolpyruvate carboxylase, weakly inhibited (34); α,α-phosphotrehalase, *or* trehalose-6-phosphate hydrolase (35); phytoene synthase (36); polyphenol oxidase (45,46); raucaffricine β-glucosidase (37); riboflavin phosphotransferase (38); ribokinase (39); superoxide dismutase, Cu/Zn (40); thioglucosidase, *or* myrosinase (41,42); vomilenine glucosyltransferase (43). 1. #### D-Fructose 1,6-Bisphosphate

This key central pathway intermediate (FW<sub>free-acid</sub> = 340.12 g/mol; CAS = 488-69-7; *Symbol*: FBP, formerly called D-fructose 1,6-diphosphate (FDP), is produced by the action of 6-phosphofructokinase, 1-phosphofructokinase, as well as ADP-specific phosphofructokinase. Calcium and barium salts of FBP are only slightly soluble in water. In addition, the solubility decreases at higher temperature. The  $\beta$ -anomer predominates in aqueous media: 77-80% at 30°C (1). **Target(s)**: N-acetylglucosamine-6-phosphate deacetylase (2); acylphosphatase (3); adenylosuccinate synthetase (4-6); cAMP-dependent protein kinase phosphorylation of pyruvate kinase (7); 3',5'-cyclic-GMP phosphodiesterase, or cGMP phosphodiesterase (8); 3-deoxy-7-phosphoheptulonate synthase, or 2-keto-3-deoxy-D-arabino-heptonate-7-phosphate synthase (9,10);  $\beta$ -fructofuranosidase, or invertase (11-13); fructose-2,6-bisphosphate 2-phosphatase (14); glucosamine 6-phosphate deaminase (15); glucose-1,6-bisphosphate synthase (16-18); glucose dehydrogenase (9,19); glucose-6-phosphate dehydrogenase (20); glucose-6-phosphate isomerase (21-24); glutamine:fructose 6-phosphate aminotransferase (25); glycerol kinase (26-36); glycerol 3-phosphate dehydrogenase (NAD<sup>+</sup>) (37); glycogen phosphorylase (84); glycogen synthase (83); hexokinase (38,39); inositol-polyphosphate 5-phosphatase (40-43); isocitrate lyase (44-47); malate dehydrogenase, cytosolic (48); malate synthase (85); methylglyoxal synthase (49,50); nicotinate-nucleotide diphosphorylase (51); peptidase K (52); phosphoenol-pyruvate carboxykinase (ATP) (53); phosphoenolpyruvate carboxylase (54); phosphoenolpyruvate phosphatase (55); 6-phospho- $\beta$ -galactosidase (56); phosphoglucomutase (57-62);  $\beta$ -phosphoglucomutase (63);  $\beta$ -phosphogluconate dehydrogenase (decarboxylating) (64-68); 6-phospho  $\beta$ -glucosidase (69); phosphoprotein phosphatase (70); [protein-P<sub>II</sub>] uridylyltransferase (71); pyrophosphatase (72); pyruvate kinase (73-77); ribose-phosphate diphosphokinase, or phosphoribosyl-pyrophosphate

synthetase, weakly inhibited (78); sedoheptulose-bisphosphatase (79); sucrose-phosphate synthase (80); thymidylate synthase, moderately inhibited (86); triose-phosphate isomerase (81); UDP-glucose 4-epimerase (82) **1.** Benkovic (1979) *Meth. #### D-Fructose 2,6-Bisphosphate

This central pathway metabolite (FW<sub>free-acid</sub> = 340.12 g/mol; CAS = 77164-51-3) regulates glycolysis and gluconeogenesis reciprocally by stimulating phosphofructokinase, while inhibiting fructose-1,6-bisphosphatase.

**Target(s):** ATP:citrate lyase, or ATP:citrate synthase; weakly inhibited (1); fructose-1,6 bisphosphatase (2-26); inositol-polyphosphate 5-phosphatase, or inositol-1,4,5-trisphosphate 5 phosphomonoesterase, by the  $\alpha$ -anomer (27-30); phosphoenolpyruvate carboxylase, mildly inhibited (31); 6-phosphofructokinase (32); phosphoglucosmutase (33); sedoheptulose bisphosphatase (34);  $\alpha$ , $\alpha$ -trehalose phosphorylase (35). **1.** Adams, Dack & Ratledge (2002) *Biochim. #### FTI-276 & FTI-277

This protein farnesyltransferase inhibitor FTI-276 (FW = 433.60 g/mol, CAS = 170006-72-1) and its methyl ester prodrug FTI-277 (FW = 461.63 g/mol, CAS = 170006-73-2) are peptidomimetic analogues of L-cysteinylyl-L-valyl-L-isoleucyl-L-methionine, in which the two central aminoacyl residues have been replaced with 2-phenyl-4 aminobenzoic acid. The reported  $K_i$  values for FTI-276 are 0.6 nM for protein farnesyltransferase and 50 nM for protein geranylgeranyltransferase type I. The IC<sub>50</sub> value of FTI-277 for protein farnesyltransferase is 50 nM. FT-276 also antagonizes H and K-Ras oncogenic signaling. **Target(s):** protein farnesyltransferase

(1-5); protein geranylgeranyltransferase type I (1,2). **1.** Sebti & Hamilton (2000) *Meth. Enzymol.* **325**, 381. **2.** B. Gibbs (2001) *The Enzymes*, 3rd ed. (Tamanoi & Sigman, eds.), **21**, 81. **3.** Guida, Hamilton, Crotty & Sebti (2006) *J. Comp.-Aided Mol. Des.* **19**, 871. **4.** Yokoyama, Trobridge, Buckner, et al. (1998) *J. Biol. Chem.* **273**, 26497. **5.** Chakrabarti, Da Silva, Barger, et al. (2002) *J. Biol. Chem.* **277**, 42066.

#### FTI-2148

This protein farnesyltransferase inhibitor (FW<sub>free-acid</sub> = 452.57 g/mol), an L-Cys-L-Val-L-Ile-L-Met analogue with the two central aminoacyl residues replaced by 2-(2'-methylphenyl)-4-aminobenzoic acid, has a  $K_i$  value of 1.4 nM. The cell-permeant pro-drug FTI-2153 is its methyl ester. Because Ras malignant transformation requires posttranslational modification by farnesyltransferase (FTase), these inhibitors are antineoplastic agents. **1.** Sebti & Hamilton (2000) *Meth. Enzymol.* **325**, 381. **2.** Sun, Blaskovich, Knowles, et al. (1999) *Cancer Res.* **59**, 4919. **3.** Guida, Hamilton, Crotty & Sebti (2006) *J. Comp.-Aided Mol. Des.* **19**, 871.

#### FTY720, See Fingolimod

#### 5FU, See 5-Fluorouracil

#### 2'-Fucosyllactose

This principal milk oligosaccharide, or HMO (FW = 488.44 g/mol; CAS = 41263-94-9), also known as  $\alpha$ -L-fucosyl-(1 $\rightarrow$ 2)- $\beta$ -D-galactosyl-(1 $\rightarrow$ 4)-D-glucose, comprising ~30% of all of HMO, inhibits the adhesion of *Pseudomonas aeruginosa* and enteric pathogens (e.g., *Campylobacter jejuni*, enteropathogenic *Escherichia coli*, *Salmonella enterica*, serovar *fyris*) to human intestinal and respiratory cells. Human milk contains ~200 soluble oligosaccharides, of which many are unmetabolizable by infants, favoring monocultivation of *Bifidobacteria longum*, *biovar infantis*, in their intestinal tract, to the exclusion of pathogens. **1.** Weichert, Jennewein, Hüfner, et al. (2013) *Nutr. Res.* **33**, 831.

#### Fucoxanthin

This olive-green xanthophyll and brown algae accessory pigment (FW = 658.91 g/mol; CAS = 3351-86-8;  $\lambda_{max}$  = 510 nm), also named [(1S,3R)-3-hydroxy-4-[(3E,5E,7E,9E,11E,13E,15E)-18-[(1S,4S,6R)-4-hydroxy-2,2,6-trimethyl-7-oxabicyclo[4.1.0]heptan-1-yl]-3,7,12,16-tetramethyl-17-oxo-octadeca-1,3,5,7,9,11,13,15-octaenylidene]-3,5,5-trimethylcyclo-hexyl] ester, inhibits CYP1A1, CYP1A2 and CYP3A4. Fucoxanthin decreases rifampin-induced CYP3A4 and MDR1 expression by attenuating PXR-mediated CYP3A4 promoter activation and interaction between PXR and co-activator. Fucoxanthin markedly suppressed cell migration in wound healing assay and inhibited actin filament assembly (3). **1.** Satomi & Nishino (2013) *Oncol. Lett.* **6**, 860. **2.** Liu, Lim & Hu (2012) *Mar. Drugs* **10**, 242. **3.** Chung, Choi & Lee (2013) *Biochem. Biophys. Res. Commun.* **439**, 580.

**FUD Peptide**

This fibronectin fibrillogenesis inhibitor (FW = 4621.95 g/mol; Sequence: MGGQSESVFETKDTQTGMMSGQTTPQIETEDTKEPGLVMMGGQSES), also named pUR4, mimics the cell-surface binding sites consisting of five N-terminal Type I modules within fibronectin. The Functional Upstream Domain (FUD) peptide contains 43 residues of the upstream domain and the first 6 residues from the repeat domain of *Streptococcus pyogenes* adhesin F<sub>1</sub>, a protein that binds the N-terminal 70-kDa region of fibronectin with high affinity. FUD exhibits monophasic inhibition with an IC<sub>50</sub> of ~10 nM. The 49-residue inhibitor blocks incorporation of both endogenous cellular fibronectin and exogenous plasma fibronectin into extracellular matrix and inhibits binding of 70-kDa fragment to fibronectin-null cells in a fibronectin-free system. Inhibition of matrix assembly has no effect on cell adhesion to substratum, cell growth, formation of focal contacts, or formation of stress fibers. As a disulfide-linked dimer of subunits composed of Type I, II, and III repeats, fibronectin binds to the endothelial cell surface by displaying its dominant cell-adhesive domain, a C-terminal heparin-binding domain, and a 70-kDa N-terminal domain that are recognized by integrins and syndecans (2). Inhibition of fibronectin fibrillogenesis on endothelial cells results in failure to achieve myosin-associated traction forces (2). *Note:* The control peptide Del29 (also called Δ<sup>29</sup> and Control III-11C) lacks an aspartyl residue at position-29 of FUD and is without effect on fibronectin fibrillogenesis. 1. Tomasini-Johansson, Kaufman, Ensenberger, *et al.* (2001) *J. Biol. Chem.* **276**, 23430. 2. Zhou, Rowe, Hiraoka, *et al.* (2008) *Genes Dev.* **22**, 1231.

**Fulvestrant**

This first-in-class complete estrogen receptor antagonist, ER down-regulator, and second-line breast cancer therapy (FW = 606.77 g/mol; CAS = 129453-61-8), also known by the trade name Faslodex<sup>®</sup>, code names ZD9238 and ICI 182,780, and systematic name (7α,17β)-7-[9-[(4,4,5,5,5-pentafluoropentyl)sulfinyl]nonyl]estra-1,3,5(10)-triene-3,17-diol, is a synthetic ligand used to treat hormone receptor-positive metastatic breast cancer in postmenopausal women experiencing disease progression after anti-estrogen therapy. Estrogen receptor (ER) expression in breast cancer is a phenotype that can change during the natural history of the disease or during endocrine therapy. Fulvestrant also accelerates proteasomal degradation of estrogen receptors and reduces cell turnover index (CTI), a composite measurement of both proliferation and apoptosis (2). 1. Robertson (2001) *J. Ster. Biochem. Mol. Biol.* **79**, 209. 2. Bundred, Anderson, Nicholson, *et al.* (2002) *Anticancer Res.* **22**, 2317.

**Fumagillin**

This antibiotic (FW<sub>free-acid</sub> = 458.55 g/mol; Photosensitive; Store in the dark), also named (2E,4E,6E,8E)-10-[[[(3R,4S,5S,6R)-5-methoxy-4-[(2R)-2-methyl-3-(3-methylbut-2-enyl)oxiran-2-yl]-1-oxaspiro[2.5]octan-6-yl]oxy]-10-oxodeca-2,4,6,8-tetraenoic acid, from *Aspergillus fumigatus* suppresses the formation of new blood vessels and inhibits endothelial cell proliferation and angiogenesis. Its epoxide group reacts with an active-site histidyl residue in methionyl aminopeptidase type II (1-7). 1. Liu, Widom, Kemp, Crews & Clardy (1998) *Science* **282**, 1324. 2. Luo, Li, Liu, *et al.* (2003) *J. Med. Chem.* **46**, 2631. 3. Schiffmann, Neugebauer & Klein (2006) *J. Med. Chem.* **49**, 511. 4. Son, Kwon, Jeong, *et al.* (2002) *Bioorg. Med. Chem.* **10**, 185. 5. Lowther, McMillen, Orville & Matthews (1998) *Proc. Natl. Acad. Sci. U.S.A.* **95**, 12153. 6. Klein, Schiffmann, Folkers, Piana & Rothlisberger (2003) *J. Biol. Chem.* **278**, 47862. 7. Brdlik & Crews (2004) *J. Biol. Chem.* **279**, 9475.

**Fumarate**

This unsaturated dicarboxylic acid (FW<sub>free-acid</sub> = 116.07 g/mol; Melting Point = 287°C; slightly soluble in water (0.63 g/100 mL at 20°C); pK<sub>a</sub> values of 3.03 and 4.54 at 25°C), also known as (E)- or trans-butenedioate, is a key intermediate in the tricarboxylic acid cycle (*Fumarase Reaction*: Fumarate + H<sub>2</sub>O ⇌ Malate). It is also formed reactions catalyzed by argininosuccinate lyase (*Reaction*: Argininosuccinate ⇌ Arginine + Fumarate) and AMP-succinate (*Reactions*: N-Succinyl-carboxyaminoimidazole ribonucleotide (SCAIR) ⇌ Aminoimidazole-carboxamide ribonucleotide (AICAR) + Fumarate; and Adenylosuccinate ⇌ AMP + Fumarate). (Maleate is fumarate's cis isomer.) **Target(s):** 2-(acetamidomethylene)succinate hydrolase (1); aconitase, or aconitate hydratase (2); adenylosuccinate synthetase (3,4); alanine aminotransferase (5); AMP deaminase (6); aspartate aminotransferase (7-9); aspartate ammonia-lyase, as product inhibitor (10); aspartate 4 decarboxylase (11); D-aspartate oxidase (12); γ-butyrobetaine:2-oxoglutarate dioxygenase, mildly inhibited (13); carbamoyl-phosphate synthetase (14); carboxy-cis,cis-muconate cyclase (15); [citrate lyase] deacetylase, weakly inhibited (16); cyanate hydratase, or cyanase (17); erythrose reductase (18); exo-α-sialidase, or neuraminidase, or sialidase (19); glutamate decarboxylase, K<sub>i</sub> = 18 mM (20,21); glutamate dehydrogenase (22-24); glutamate formimidoyltransferase (55); glycogen synthase (25); 4-hydroxybenzoate 3-monooxygenase, weakly inhibited (56); hyoscyamine (6S)-dioxygenase (57); isocitrate lyase (26,27); leucine aminotransferase (28); malate dehydrogenase (29); malic enzyme, or malate dehydrogenase (decarboxylating) (30-32); nicotinate-nucleotide diphosphorylase (carboxylating) (33,34); oxaloacetate decarboxylase (35,36); palmitoyl-CoA hydrolase (37); pantothenase (38); peroxidase (39); phosphoenolpyruvate carboxykinase (40); phosphoenolpyruvate carboxylase (41-45); procollagen-proline 4-dioxygenase (58,59); pyrophosphatase (46); pyruvate kinase (47-49); succinyl-CoA synthetase (50); thiosulfate sulfotransferase, or rhodanese (51); urocanate hydratase, or urocanase (52-54). 1. ### Fumonisin

These mycotoxins (Fumonisin B<sub>1</sub>: MW<sub>B1</sub> = 721.23 g/mol; CAS = 116355-83-0 (R<sub>1</sub> = OH, R<sub>2</sub> = OH); Fumonisin B<sub>2</sub>: MW<sub>B2</sub> = 705.83 g/mol; CAS = 116355-84-1 (R<sub>1</sub> = H, R<sub>2</sub> = OH); Fumonisin B<sub>3</sub>: FW<sub>B3</sub> = 705.83 g/mol; CAS = (R<sub>1</sub> = OH, R<sub>2</sub> = H); Fumonisin B<sub>4</sub>: CAS = 136379-60-7 (R<sub>1</sub> = H, R<sub>2</sub> = H)) from *Fusarium moniliforme* and *F. proliferatum*, are sphinganine analogues inhibit ceramide synthase and block the biosynthesis of complex sphingolipids, promoting the accumulation of sphinganine and sphinganine 1-phosphate. More than eleven fumonisins have been identified; the most common are fumonisins B<sub>1</sub>, B<sub>2</sub>, and B<sub>3</sub>). **Target(s):** H<sup>-</sup>-ATPase (1); inositol-phosphoryl-ceramide synthase, or ceramide inositol-phosphoryltransferase (2); MAP kinase (3); protein-serine/threonine phosphatase (4); sphingosine *N*-acyltransferase, or ceramide synthase, or sphinganine *N*-acyltransferase (5-11). 1. ### β-Funaltrexamine

This long-lasting morphine analogue (FW<sub>free-base</sub> = 454.52 g/mol; CAS = 72786-10-8; Soluble to 20 mM in H<sub>2</sub>O), also known as (*E*)-4-[[5α,6β]-17-cyclopropylmethyl]-4,5-epoxy-3,14-dihydroxymorphinan-6-yl]amino]-4-oxo-2-butenic acid methyl ester hydrochloride, is a μ-opioid antagonist and alkylating derivative of naltrexone that irreversibly alkylates the receptor. It is also a κ opioid receptor agonist. 1. Rothman, Bykov, Mahboubi, *et al.* (1991) *Synapse* **8**, 86. 2. Ward, Fries, Larson, Portoghese & Takemori (1985) *Eur. J. Pharmacol.* **107**, 323.

### Furafylline

This synthetic xanthine analogue (FW = 260.25 g/mol), also known as 1,8-dimethyl-3-(2'-furfuryl)methylxanthine, is a potent, mechanism-based inhibitor of CYP1A2,  $K_i = 23 \mu\text{M}$  and  $k_{\text{inact}} = 0.87 \text{ min}^{-1}$ . Furafylline has been used as a long-acting replacement for theophylline in the treatment of asthma. 1. Sesaradic, Boobis, Murray, *et al.* (1990) *Brit. J. Clin. Pharmacol.* **29**, 651. 2. ### Fusidic Acid

This bile salt-like antibiotic (FW<sub>free-acid</sub> = 516.72 g/mol; CAS = 6990-06-3;  $\text{pK}_a = 5.35$ ) is from *Fusidium coccineum* is effective against Gram-positive microorganisms, readily inhibiting *Staphylococcus aureus*, but is without effect on Gram-negative bacteria, like *E. coli* (1-10). Fusidic acid inhibits the elongation factors as well as translocation of peptidyl-tRNA. Fusidic acid also inhibits aminoacyl-tRNA binding to ribosomes. **Mechanism of Inhibitory Action:** FA is a strong elongation inhibitor ( $K_{0.5} \approx 1 \mu\text{M}$ ). Quench-flow and stopped flow experiments (11) that take advantage of the disparate time-scales for the inhibited (10 sec) and uninhibited (100 msec) elongation cycle gave rise to a detailed kinetic model showing that FA targets elongation factor G (EF-G) at an early Stage-I in the translocation process, then proceeding unhindered by FA to a Stage-II, whereupon the ribosome stalls. Stalling may also occur at a third stage of translocation (Stage-III), just before EF-G release from the post-translocation ribosome. **Target(s):** acid phosphatase (12); ATP-dependent transport of multi-drug resistance protein-2 substrates (13); bile salt transport pump (13,14); chloramphenicol acetyltransferase (15,16); protein biosynthesis (elongation) (1-10); protein-synthesizing GTPase (elongation factor) (16); vacuolar H<sup>+</sup> ATPase (17); *Veillonella alcalescens* ATPase (18). 1. Fx-1006A, See Tafamidis

**FXV673**

This novel factor Xa inhibitor ( $FW_{\text{HCl-salt}} = 482.90$  g/mol), also named 2-(*R*)-(3-carbamimidoylbenzyl)-3-(*R*)-[4-(1-oxypyridin-4-yl)benzoylamino]

butyric acid methyl ester, is a reversible, highly potent ( $K_i = 0.5$  nM for fXa) and selective ( $K_i$  for thrombin = 3956 nM, trypsin = 301 nM, APC = 18491 nM, plasmin = 656 nM and t-PA = 8681 nM) inhibitor (1). FXV673 has a short biological half-life in rats, dogs and monkeys (0.27–0.33 h), and it is an effective antithrombotic agent after intravenous infusion in rat and canine carotid artery thrombosis models. Compared to heparin and a GPIIb/IIIa receptor antagonist, RPR109891, infusion of FXV673 in dogs reperused 50 and 38% more arteries with a trend for faster reperfusion (2). The incidence of reocclusion was significantly reduced by 75% with FXV673 infusion. 1. Chu, Brown, Colussi, *et al.* (2000) *Blood*, **96** Supplement A236. 2. Rebello, Bentley, Morgan, *et al.* (2001) *Br. J. Pharmacol.* **133**, 1190.

# - G -

**G**, See *Glucose; Glycine; Guanine; Guanosine*

## G-1

This potent and selective GPCR receptor agonist (FW = 412.28 g/mol; CAS 881639-98-1; Soluble to 100 mM in DMSO), also named (±)-1-[(3aR\*,4S\*,9bS\*)-4-(6-Bromo-1,3-benzodioxol-5-yl)-3a,4,5,9b-tetrahydro-3H-cyclopenta[quinolin-8-yl]ethanone, targets the G Protein-coupled Receptor-30, or GPR30, ( $K_i = 11$  nM,  $EC_{50} = 2$  nM), while displaying no activity at estrogen receptors ER $\alpha$  and ER $\beta$ , even 10  $\mu$ M. This orphan receptor mediates the non-genomic signaling of 17 $\beta$ -estradiol in estrogen-sensitive cancer cells through the Epidermal Growth Factor Receptor (or EGFR) pathway. G-1 increases cytosolic Ca<sup>2+</sup> and inhibits *in vitro* migration of SKBr3 cells ( $IC_{50} = 0.7$  nM) and MCF-7 cells ( $IC_{50} = 1.6$  nM) in response to chemoattractants. Blocks MCF-1 cell cycle progression at the G<sub>1</sub> phase. G-1 also displays therapeutic effects in the mouse EAE model of multiple sclerosis. (See also G-15; G-36) **1.** Albanito, *et al.* (2007) G protein-coupled receptor 30 (GPR30) mediates gene expression changes and growth response to 17 $\beta$ -estradiol and selective GPR30 ligand G-1 in ovarian cancer cells. *Cancer Res.* **67**, 1859. **2.** Blasko, *et al.* (2009) *J. Neuroimmunol.* **214**, 67. **3.** Ariazi, *et al.* (2010) *Cancer Res.* **70**, 1184.

## G007-LK

This tankyrase inhibitor (FW = 529.96 g/mol; Solubility: 15 mg/mL DMSO; IUPAC: 4-{5-[(E)-2-{4-(2-chlorophenyl)-5-[5-(methylsulfonyl)pyridin-2-yl]-4H-1,2,4-triazol-3-yl]-ethenyl]-1,3,4-oxadiazol-2-yl} benzo nitrile) is an efficient and specific inhibitor of the canonical Wnt signaling, both *in vitro* and *in vivo*. JW74 rapidly reduces active  $\beta$ -catenin, attended subsequently by downregulation of the Wnt target genes AXIN2, SP5, and NKD1 (1). AXIN2 protein levels were strongly increased after compound exposure. G007-LK displays high selectivity toward Tankyrases 1 and 2, with biochemical  $IC_{50}$  values of 46 nM and 25 nM, respectively, and an intracellular  $IC_{50}$  value of 50 nM combined with an excellent pharmacokinetic profile in mice. (See also JW74) **1.** Voronkov, Holsworth, Waaler, *et al.* (2013) *J. Med. Chem.* **56**, 3012.

## G-15

This high-affinity, selective GPCR antagonist (FW = 370.25 g/mol; CAS = 1161002-05-6; Soluble to 50 mM in DMSO), also named (3aS\*,4R\*,9bR\*)-4-(6-bromo-1,3-benzodioxol-5-yl)-3a,4,5,9b-3H-cyclopenta[quinoline,

targets GPR30 ( $IC_{50} \approx 20$  nM), a G protein-coupled, seven-helix transmembrane estrogen receptor that plays a role in the protective effects of estrogen in neurons (1,2). G-15 shows no significant binding to the classical estrogen receptors, ER $\alpha$  or ER $\beta$ , even at concentrations in the 1-10  $\mu$ M range (1). Estrogen-dependent signaling proceeds by a pertussis toxin-sensitive pathway, indicating the involvement of G<sub>i/o</sub> heterotrimeric G proteins, attended by transactivation of EGFRs through the release of cell-surface heparin-bound EGF (3). A second phase of GPR30-dependent signaling via adenylyl cyclase leads to time-dependent attenuation of Erk activation (4). The GPR30- selective agonist G-1 partially attenuates the TNF-induced up-regulation of pro-inflammatory proteins (*e.g.*, ICAM-1 and VCAM-1), and such effects are blocked completely by G-15 (5), a structural analogue of G-1 (1,2). Endothelial GPR30 represents a novel inflammatory response regulator and potential druggable target to prevent atherosclerosis and other inflammatory diseases (5). **1.** Dennis, Burai, Ramesh, *et al.* (2009) *Nature Chem. Biol.* **5**, 421. **2.** Gingerich, Kim, Chalmers, *et al.* (2010) *Neurosci.* **170**, 54. **3.** Filardo, Quinn, Bland & Frackelton (2000) *Mol. Endocrinol.* **14**, 1649. **4.** Filardo, Quinn, Frackelton & Bland (2002) *Mol. Endocrinol.* **16**, 70. **5.** Chakrabarti & Davidge (2012) *PLoS One* **7**, e52357.

## G-36

This GPR30 antagonist (FW = 412.33 g/mol; CAS = 1392487-51-2; Soluble to 100 mM in DMSO), also named (±)-(3aR\*,4S\*,9bS\*)-4-(6-bromo-1,3-benzodioxol-5-yl)-3a,4,5,9b-tetrahydro-8-(1-methylethyl)-3H-cyclopenta[quinoline, selectively inhibits estrogen-mediated activation of phosphatidylinositide 3-kinase (PI3-K) by G protein-coupled receptor 30 (GPR30), but not by the estrogen receptor ER $\alpha$ . GPR30 is an integral membrane protein with high affinity for estradiol, but not other endogenous estrogens, such as estrone, estriol, progesterone, testosterone, and cortisol. It also inhibits estrogen- and G-1-mediated calcium mobilization (See G-1) as well as ERK1/2 activation, with no effect on EGF-mediated ERK1/2 activation. G36 inhibits estrogen- and G-1-stimulated proliferation of uterine epithelial cells *in vivo*. G-36 also inhibits estrogen-mediated calcium mobilization ( $IC_{50} = 112$  nM). **1.** Dennis, Field, Burai, *et al.* (2011) *J. Steroid Biochem. Mol. Biol.* **127**, 358.

## G-749

This FLT3 protein kinase inhibitor (FW = 521.42 g/mol) displays a unique kinase inhibition profile is highly potent in its action against FLT3 kinase, providing sustained inhibition of FLT3 phosphorylation and downstream effectors in FLT3-ITD expressing cell lines. G-749 is likewise highly potent against clinically known FLT3 mutants including gatekeeper and TKD that confer resistance to PKC412 and AC220. In comparison with PKC412 and AC220, G-749 shows several desirable characteristics to overcome other known drug resistances conferred by patient plasma, FLT3 ligand (FL) surge, and protection by stromal cells. Oral dosing of G-749 leads to complete tumor regression without relapse in the mouse xenograft model and increases survival in a bone marrow xenograft model. G-749 also shows potent anti-leukemic activity in patient blasts harboring FLT3-ITD, FLT3-TKD and FLT3-ITD/TKD mutations through inhibition of p-FLT3 and p-ERK1/2, including those with little or only minor response to AC220

### D-Galactal

This galactose derivative (FW = 146.14 g/mol; CAS = 21193-75-9), also known as 1,2-dideoxy-D-lyxo-hex-1-enopyranose, inhibits  $\beta$ -galactosidases. The double bond imposes a half-chair conformation that mimics the geometry of *oxa*-carbenium ion intermediates often formed during glycosidase catalysis. Inhibition of bacterial  $\beta$ -galactosidase by D-galactal was found to be reversible and time-dependent (1,2). Rate constants observed for binding ( $2.7 \times 10^2 \text{ M}^{-1} \text{ s}^{-1}$ ) and release ( $4.6 \times 10^{-3} \text{ s}^{-1}$ ) of galactal were found to be consistent with an apparent  $K_i$  of  $1.4 \times 10 \mu\text{M}$  for D-galactal as a competitive inhibitor. Efforts to trap and analyze the galactalenzyme complex were unsuccessful. **Target(s):**  $\alpha$ -galactosidase (1);  $\beta$ -galactosidase (1-8); lactase/ phlorizin hydrolase, or glycosylceramidase (9). **1.** Wentworth & Wolfenden (1974) *Biochemistry* **13**, 4715. **2.** Wolfenden (1977) *Meth. ### Galactarate

This dicarboxylic galactose derivative (FW<sub>free-acid</sub> = 210.14 g/mol; CAS = 526-99-8;  $pK_a$  values of 3.08 and 3.63; *meso* structure; No optical activity), also called galactaric acid mucic acid, is often used as a counter ion in formulations of cationic drugs. Galactarate is a product of the reaction catalyzed by uronate dehydrogenase and is a substrate for galactarate *O*-hydroxycinnamoyl-transferase and galactarate dehydratase. The free acid has a low solubility in water (0.33 g per 100 mL at 14°C) but the salt is very soluble. Galactaric acid does not react with Fehling's solution; however, it will reduce ammoniacal silver nitrate. **Target(s):** 2-dehydro-3-deoxyglucuronate aldolase (1); glucuronate dehydratase (2);  $\beta$ -glucuronidase (3-8); kynurenine aminotransferase, weakly inhibited (9). **1.** Fish & Blumenthal (1966) *Meth. Enzymol.* **9**, 529. **2.** Blumenthal (1966) *Meth. Enzymol.* **9**, 660. **3.** Levvy (1952) *Biochem. ### Galactodeoxynojirimycin Aziridine

This unusual aminosugar analogue (FW = 145.16 g/mol), also called 1-deoxy-D-galactonojirimycin aziridine and *galactodeoxy*-nojirimycin aziridine, inhibits  $\alpha$ -galactosidases. When the ring nitrogen is protonated, this analogue mimics the charge of *oxa*-carbenium ion intermediate believed to form transiently in many glycosidase reactions. Aziridines often react with protein thiols, thiol-containing purines and pyrimidines, as well as some oxygen-centered nucleophiles. **1.** Mooser (1992) *The Enzymes*, 3rd ed., **20**, 187.

### Galactomannans

These polysaccharides (MW = indefinite; CAS = 11078-30-1), which consist of a poly(1-4)-linked  $\beta$ -D-mannopyranose backbone, with branchpoints at their 6-positions that are linked to  $\alpha$ -D-galactopyranose, include fenugreek gum galactomannan,  $\sim 1$  mannose per galactose; guar gum galactomannan, mannose:galactose,  $\sim 2$  mannose per galactose; tara gum galactomannan, mannose:galactose,  $\sim 3$  mannose per galactose; and locust bean gum galactomannan,  $\sim 4$  mannose per galactose. Galactomannan and zymosan block epinephrine-induced particle transport in tracheal epithelial cells, which rely on ciliary beating to continuously purge pathogens from the lower airways. **1.** Weiterer, Kohlen, Veit, et al. (2015) *PLoS One* **10**, e0143163.

### D-Galactono-1,4-lactone

This  $\gamma$ -lactone (FW = 178.14 g/mol; CAS = 2782-07-2; M.P. (hydrate) = 66°C), which is readily formed from D-galactonic acid, has an ester carbonyl that imposes a half-chair conformation that mimics the geometry of an *oxa*-carbenium ion or similar transition-state intermediates formed during glycosidase catalysis. **See also D-Galactono 1,5-lactone** **Target(s):** aldose 1-epimerase, or mutarotase (1); aryl- $\beta$ -hexosidase (2);  $\beta$ -D-fucosidase (3,4);  $\alpha$ -L-fucosidase, weakly inhibited (5);  $\beta$ -galactofuranosidase (6);  $\alpha$ -galactosidase (7);  $\beta$ -galactosidase (8-20); galactosyl-ceramidase (21,22); ganglioside GM<sub>1</sub>  $\beta$ -galactosidase (14,23);  $\beta$ -glucosidase (24,25); lactase/phlorizin hydrolase, or glycosylceramidase (26,27); neutral glycosidase (28). **1.** Hucho & K. ### D-Galactosamine

This amino sugar (FW<sub>free-base</sub> = 179.17 g/mol; pK<sub>a</sub> = 7.70; CAS = 7535-00-4), also known as 2-amino-2-deoxy-D-galactose and chondrosamine, found in mucopolysaccharides, glycoproteins, and mucoproteins. 7-Galactosamine inhibits hepatic RNA biosynthesis. **Target(s):** β-N-acetylglucosaminidase (1,2); β-N-acetylhexosaminidase (1-6); L-arabinose dehydrogenase (7); chitinase (8); galactose dehydrogenase (9); galactose oxidase, also an alternative substrate (10); β-galactosidase (11,12); glucose-1-phosphate uridylyltransferase (13); β-glucosidase, K<sub>i</sub> = 790 mM for the sweet almond enzyme (14). **1.** Frohwein & Gatt (1967) *Biochemistry* **6**, 2775. **2.** Khar & Anand (1977) *Biochim. ### D-Galactose

This widely occurring D-aldoheptose (FW = 180.16 g/mol; CAS = 59-23-4), found in free form and as a component of glycoproteins, mucopolysaccharides, lactose, galactans, gangliosides, and cerebrosides. Note that the enantiomer, L-galactose, also occurs naturally. β-D-galactopyranose is most prevalent (30% α-pyranose, 64% β-pyranose, 2.5% α-furanose, 3.5% β-furanose, and 0.02% straight chain in D<sub>2</sub>O at 31°C). **Target(s):** α-N-acetylgalactosaminidase (1-3); β-N-acetylhexosaminidase, weakly inhibited (4,5); D-threo-aldose dehydrogenase (6); aldose 1-epimerase, or mutarotase (7-11); β-amylase (10,12); arabinogalactan endo-1,4-β-galactosidase (13); aralin (14); discoidins II (15); β-fructofuranosidase (invertase; inhibited by both anomers) (16,17); fructokinase (18); β-D-fucosidase (19-23); α-L-fucosidase (24,25); α-galactosidase (10,26-42); β-galactosidase (10,43-64); galactosylceramidase (65); galactosylgalactosylglucosyl-ceramidase, weakly inhibited (66,67); glucan 1,4-α-glucosidase, or glucoamylase (68); glucokinase (69); α-glucosidase (10,70,71); β-glucosidase (72-75); mannosyl-glycoprotein endo-β-N-acetylglucosaminidase (76); mucinaminylserine mucinaminidase (77); polypeptide N-acetylglucosaminyltransferase (82); rRNA N-glycosylase (14); thioglucosidase, myrosinase (78,79); α,α-trehalose phosphorylase, configuration retaining (80); UDP-glucuronate 4-epimerase (81). **1.** Uda, Li & Li (1977) *J. #### $\alpha$ -D-Galactose 1-Phosphate

This phosphosugar (FW = 260.14 g/mol; CAS = 2255-14-3;  $pK_1 = 1.00$  and  $pK_2 = 6.17$ ) is a product galactokinase reaction and a substrate for UTP:hexose-1-phosphate uridylyltransferase, UDP-glucose:hexose-1-phosphate uridylyltransferase, galactose-1-phosphate thymidyltransferase, and galactose-1-phosphatase. **Target(s):**  $\beta$ -phosphoglucomutase,  $K_i = 30 \mu\text{M}$  (1); plant polysaccharide biosynthesis (2);  $\alpha, \alpha$ -trehalose phosphorylase, configuration-retaining (3); UTP:glucose-1-phosphate uridylyltransferase, or glucose-1-phosphate uridylyltransferase (4-7). **1.** Tremblay, Zhang, Dai, Dunaway-Mariano & Allen (2005) *J. #### D-Galactose 6-Phosphate

This phosphorylated hexose (FW = 260.14 g/mol; CAS = 6665-00-5) is the product of reactions catalyzed by 6-phospho- $\beta$ -galactosidase and is a substrate for galactose 6-phosphate isomerase. It is also an alternative substrate of glucose-6-phosphate dehydrogenase. **Target(s):**  $\beta$ -galactosidase (1,2); glucose-6-phosphate isomerase (3); inositol-3-phosphate synthase, or inositol-1-phosphate synthase (4,5); mannose-6-phosphate isomerase, weakly inhibited (3,6); 6-phospho- $\beta$ -galactosidase (7-11); phosphopentomutase (12); UTP:glucose-1-phosphate uridylyltransferase (13). **1.** Weinland (1956) *Hoppe-Seyler's Z. #### Galactosylceramide

This term refers to any D-galactosyl-N-acylsphingosine (FW = 700.06 g/mol for  $\beta$ -D-galactosyl-N-palmitoylsphingosine, as shown above), major lipids found in adult brain, with levels elevated in individuals with Krabbe's

disease and reduced levels in several demyelinating diseases. Galactosylceramide (GalCer) is an alternative receptor allowing human immunodeficiency virus (HIV)-1 entry into CD4-negative cells of neural and colonic origin. A soluble GalCer analogue, known as CA52(N15), is a new class of anti-HIV-1 agents that neutralize HIV-1 infection by masking of the V3 loop of the HIV-1 surface envelope glycoprotein gp120 (1). **Target(s):** N-acetyl- $\beta$ -hexosaminidase (2); lactase/phlorizin hydrolase, or glycosylceramidase, as an alternative substrate (3). **1.** Fantini, Hamache, Delézy, *et al.* (1997) *J. Biol. Chem.* **272**, 7245. **2.** Frohwein Frohwein & Gatt (1967) *Biochemistry* **6**, 2783. **3.** Leese & Semenza (1973) *J. Biol. Chem.* **248**, 8170.

#### D-Galacturonate

This uronic acid (FW = 194.14 g/mol; CAS = 14982-50-4; Soluble in water; Slightly soluble in hot ethanol; Insoluble in diethyl ether; M.P. (with decomposition) of 159°C and 166°C for the  $\alpha$ - and  $\beta$ -anomers), also known as D-galacturonic acid, D-galactopyranuronic acid, is an abundant component in pectins, plant gums, galacturonides, and bacterial cell walls (1). **Target(s):**  $\beta$ -N-acetylhexosaminidase (2); aldose 1-epimerase (3); L-arabinose dehydrogenase (4); galactose dehydrogenase (5); galacturan 1,4- $\alpha$ -galacturonidase, or exopolysaccharuronase (6,7);  $\alpha$ -glucuronidase (8);  $\beta$ -glucuronidase (8-11); pectinesterase, weakly inhibited (12); polygalacturonidase, or pectinase (8,13,14). **1.** Link & Sell (1953) *Biochem. Prep.* **3**, 74. **2.** Johnson, Mook & Brady (1972) *Meth. Enzymol.* **28**, 857. **3.** Bailey, Fishman, Kusiak, Mulhern & Pentchev (1975) *Meth. #### Galanal B

This putative immunomodulator from the Myoga flower (FW = 318.45 g/mol), also named (4aS,6aS,7R,11aR,11bS)-7-hydroxy-4,4,11b-trimethyl-1,2,3,4a,5,6,7,8,11,11a-decahydrocyclo-hepta[a]naphthalene-6a,9-dicarbaldehyde and AC1MJ6B7, inhibits indoleamine 2,3-dioxygenase 1 (IDO1), which catalyzes the first (and rate-limiting) step in L-tryptophan degradation. IDO1 activity increases in various diseases, including tumors, autoimmune diseases, and different kinds of inflammatory disorders. Notably, IDO1 is induced by the interferon- $\gamma$ -mediated effects of STAT1- $\alpha$  and IRF-1. Induction of IDO1 also occurs through an IFN- $\gamma$ -independent mechanism and by lipopolysaccharide (LPS), the latter regulated both by the p38 mitogen-activated protein kinase (MAPK) pathway and nuclear factor- $\kappa$ B (NF- $\kappa$ B). Galanal proved to be a competitive inhibitor ( $IC_{50} = 7.7 \mu\text{M}$ ), attenuating L-kynurenine formation with an *in vitro* assay using recombinant human IDO1, but more potently ( $IC_{50} = 45 \text{ nM}$ ) in cell-based assays. Noting that the stronger inhibitory effect of galanal than that of 1-methyl tryptophan, the authors posit that galanal may have potential for treating various immune-related diseases. **1.** Yamamoto, Yamamoto, Imai, *et al.* (2014) *PLoS One* **9**, e88789.

## Galangin

This yellow flavone (FW = 270.24 g/mol; CAS = 548-83-4), derived from galanga root (*Alpinia officinarum*) and pines, chelates copper and inhibits various copper-dependent enzymes. **Target(s):** alcohol dehydrogenase (1); aromatase, or CYP19 (2); carbonyl reductase (3); cyclooxygenase (4); CYP1A1 (5,6); CYP1A2 (5,7); DNA topoisomerase II (8); estrone sulfotransferase (9); fatty-acid synthase, weakly inhibited (22,23); glutathione-disulfide reductase (10); glutathione S-transferase (11); inositol-trisphosphate 3-kinase (12);  $\beta$ -lactamase, or metallo- $\beta$ -lactamase (13); 5-lipoxygenase, or arachidonate 5-lipoxygenase (4); 15-lipoxygenase, or arachidonate 15-lipoxygenase (25); lipoxygenase, soybean (25); [myosin light-chain] kinase (14); NADH oxidase, weakly inhibited (15); phenol sulfotransferase, or aryl sulfotransferase (9,16); phenylpyruvate tautomerase (17); protein tyrosine kinase, or non-specific protein-tyrosine kinase (18); ribosylidihydroxynicotinamide dehydrogenase (quinone),  $IC_{50}$  = 3.0  $\mu$ M (26,27); tyrosinase, or monophenol monooxygenase (19-21,24); suppression of  $\beta$ -catenin response transcription (CRT), which is aberrantly up-regulated in colorectal and liver cancer (28). 1. ## Galanin

This oligopeptide (MW = 3210.52 g/mol; CAS = 88813-36-9), itself widely distributed in central and peripheral nervous system as well as the endocrine system, participates in the regulation of processes such as nociception, cognition, feeding behavior, and insulin secretion. Galanin inhibits acetylcholine release, increases the levels of growth hormone, prolactin and luteinizing hormone, inhibits glucose-induced insulin release, and affects gastrointestinal motility. The human peptide contains thirty aminoacyl residues: GWTLNSAGYLLGPHAVGNHRSFSDKNGGLTS. The rat peptide contains 29 residues, with Ile-16, Asp-17, His-26, and Thr(NH<sub>2</sub>) at position-29. The porcine peptide also contains 29 residues with Ile-12, Asp-17, His-23, Tyr-26, and Thr(NH<sub>2</sub>) at position-29. **Target(s):** acetylcholine release (1-3); Ca<sup>2+</sup>-channels, voltage-activated (1,2,4); glutamate release (1-3); insulin release (3,5,6). 1. Vrontakis (2002) *Curr. Drug Targets CNS Neurol. Disord.* **1**, 531. 2. Iismaa & Shine (1999) *Results Probl. Cell Differ.* **26**, 257. 3. Bartfai, Hokfelt & Langel (1993) *Crit. Rev. ## Galanin Fragment (1-13)-Neuropeptide Y Fragment (25-36) Amide

This neuropeptide fragment (FW = 2963.37 g/mol; Sequence: GWTLN-SAGYLLGPRHYINLITRQRY-NH<sub>2</sub>), also known as M32, is a potent galanin receptor antagonist ( $IC_{50}$  = 0.1 nM in rat hypothalamus and 0.01 nM in rat spinal cord). **See Galanin 1.** Arvidsson, Land, Langel, Bartfai & Ehrenberg (1993) *Biochemistry* **32**, 7787. 2. Kahl, Langel, Bartfai & Grundemar (1994) *Brit. J. Pharmacol.* **111**, 1129.

## Galanin Fragment (1-13)-Spantide I

This chimeric neuropeptide and galanin receptor antagonist (MW = 2829.30 g/mol; Sequence: GWTLNSAGYLLGPRPKPQQWFLL-NH<sub>2</sub>) is a galanin receptor antagonist ( $IC_{50}$  = 0.2 nM), significantly inhibiting galanin-induced consumption of a palatable wet cookie mash, when microinjected intraventricularly to satiated rats. It consists of the first thirteen residues of galanin linked to spantide I, a substance P analogue that is a potent NK-1 tachykinin receptor antagonist. **See Galanin 1.** Crawley, Robinson, Langel & Bartfai (1993) *Brain Res.* **600**, 268.

## Galanin Fragment (1-13)-Substance P Fragment (5-11) Amide

This chimeric neuropeptide fragment (MW = 2223.48 g/mol; Sequence: GWTLNSAGWLLGPPQFFGLM-NH<sub>2</sub>), also known as M-15 and galantide, is a galanin receptor antagonist ( $IC_{50}$   $\approx$  0.1 nM) that blocks the galanin-mediated inhibition of glucose-induced insulin secretion. (**See Galanin 1.** Bartfai, Bedecs, Land, et al. (1991) *Proc. Natl. Acad. Sci. U.S.A.* **88**, 10961. 2. Lindskog, Ahren, Land, Langel & Bartfai (1992) *Eur. J. Pharmacol.* **210**, 183.

## Galanthamine

This water-soluble alkaloid and AChE inhibitor (FW<sub>free-base</sub> = 287.36 g/mol; CAS = 357-70-0; Soluble to 50 mM in water; IUPAC: (4aS,6R,8aS)-5,6,9,10,11,12-hexahydro-3-methoxy-11-methyl-4aH-[1]benzofuro[3a,3,2-ef][2]benzazepin-6-ol), also known as galantamine, from the Caucasian snowdrop (*Galanthus woronowii*) and several *Amaryllidaceae* plants, is a brain-selective acetylcholinesterase inhibitor that has been used in the treatment of individuals having mild to moderate Alzheimer's disease. Galantamine is a weaker inhibitor of butyrylcholinesterase. Because both esterases play a role in A $\beta$ -aggregation during the early stages of senile plaque formation, they are regarded as critical targets for the effective management of AD by delaying the hydrolysis of acetylcholine in affected brain regions, while decreasing A $\beta$ -peptide deposition. Galantamine reverses neuromuscular paralysis by tubocurarine-like muscle relaxants and stimulates pre- and postsynaptic nicotinic receptors. Galantamine partially reverses the effects of scopolamine-induced amnesia in rats. Galantamine is readily absorbed after oral administration, with a  $t_{max}$  of 52 min and a plasma elimination  $t_{1/2}$  of 5.7 hours. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** acetylcholinesterase (1-11); cholinesterase, or butyrylcholinesterase, mildly inhibited (1-5,11). 1. Darvesh, Walsh, Kumar, et al. (2003) *Alzheimer Dis. Assoc. Disord.* **17**, 117. 2. Harvey (1995) *Pharmacol. Ther.* **68**, 113. 3. Sramek, Frackiewicz & Cutler (2000) *Expert Opin. Investig. Drugs* **9**, 2393. 4. ### Galarmin

This neurophysin II C-terminal glycopeptide fragment (FW = 1453.57 g/mol; *Sequence*: AGAPEPAEPAQPGVY), also known as Proline-Rich Polypeptide-1, or PRP-1, from the neurosecretory granules of bovine neurohypophysis, is an immunomodulating cytokine that is produced by hypothalamic neurosecretory cells. Galarmin exerts an antiproliferative effect on the tumor cells of mesenchymal origin by inhibiting mTOR kinase and repressing cell cycle progression (1,2). Galarmin also inhibits Cu(II)-catalyzed decomposition of H<sub>2</sub>O<sub>2</sub>, thus preventing formation of HO<sup>•</sup> and HOO<sup>•</sup> radicals, with an E<sub>0</sub> value of 0.795 Volts versus Ag/Ag<sup>+</sup><sub>aq</sub> (3). 1. Galoian, Temple & Galoyan (2011) *Tumor Biol.* **32**, 745. 2. Galoian, Temple & Galoyan (2011) *Neurochem. Res.* **36**, 812. 3. Tavadyan, Galoian, Harutunyan, Tonikyan & Galoyan (2010) *Neurochem. Res.* **35**, 947.

### Galegine

This isoprenoid guanidine derivative (FW<sub>sulfate-salt</sub> = 225.27 g/mol; CAS = 20284-78-0), also called pentenylguanidine, isoamylenguanidine, and (3-methyl-2-butenyl)guanidine, has been isolated from seeds of *Galega officinalis* (goat's rue or professor weed). Galegine is also the toxic principle of the Western Australian sedge *Schoenus asperocarpus*. Galegine (1-300 μM) also reduced isoprenaline-mediated lipolysis in adipocytes inhibited acetyl-CoA carboxylase activity in adipocytes and myotubes (1). At 500 μM, galegine down-regulated genes concerned with fatty acid synthesis, including fatty acid synthase and its upstream regulator SREBP. By inhibiting acetyl-CoA carboxylase, galegine reduces fatty acid synthesis and stimulates fatty acid oxidation, actions that may contribute to galegine's effect on reducing body weight. **Target(s)**: arginine 2-monoxygenase (2); electron transport and oxidative phosphorylation (3-5); NADH dehydrogenase (3). 1. Mooney, Fogarty, Stevenson, *et al.* (2008) *Brit. J. Pharmacol.* **153**, 1669. 2. Olomucki, Dangba, Nguyen Van Thoi (1964) *Biochim. Biophys. Acta* **85**, 480. 3. Slater (1967) *Meth. Enzymol.* **10**, 48. 4. Alberti, Woods & Whalley (1973) *Eur. J. Clin. Invest.* **3**, 208. 5. Desvages & Olomucki (1969) *B. Soc. Chim. Fr.* (9), 3229.

### Galiellalactone

This cytostatic ascomycete hexaketide (FW = 194.23 g/mol; CAS = 133613-71-5; Soluble in 100% ethanol, methanol, DMF, and DMSO; *Symbol*: GL) targets IL-6-induced expression of Secreted Alkaline Phosphatase (SEAP) in castration-resistant prostate cancer by blocking the DNA binding of activated Signal Transducer and Activator of Transcription-3, or STAT3, a transcription factor that is constitutively active in several malignancies (1,2). Galiellalactone selectively reduces growth of STAT3-expressing prostate cancer cells, both *in vitro* and *in vivo*, and induces apoptosis in prostate cancer stem-like cells that express pSTAT3. Galiellalactone inhibits STAT3 binding to DNA in DU145 cell lysates without affecting phosphorylation status of STAT3 (3). Mass spectrometry of galiellalactone-treated STAT3 demonstrated covalent modification of Cys-367, Cys-468 and Cys-542 (3). Galiellalactone inhibits Stat3 without affecting tyrosine and serine phosphorylation of the Stat3 (2). GL inhibits vesicular stomatitis virus-recombinant HIV-1 infection and the NF-κB-dependent transcriptional activity of the HIV-LTR promoter by preventing the binding of NF-κB to DNA. GL neither affects the phosphorylation and degradation of the NF-κB inhibitory protein, IκBα, nor the phosphorylation and acetylation of the NF-κB p65 subunit. Instead, it prevents p65's association with importin-α<sub>3</sub>, thereby impairing nuclear translocation of this transcription factor. GL also binds to p65, but not to importin-α<sub>3</sub>. GL is thus a dual NF-κB/STAT3 inhibitor that will serve as a lead compound for developing novel drugs against viral infection, cancer,

and inflammatory diseases. 1. Hellsten, Johansson, Dahlman, *et al.* (2008) *Prostate* **68**, 269. 2. Hellsten, Johansson, Dahlman, Sterner & Bjartell (2011) *PLoS One* **6**, e22118. 3. ### Gallamine

This curare-like agent (FW<sub>tri-iodide-salt</sub> = 891.52; CAS = 65-29-2), named systematically as 2,2',2''-[benzene-1,2,3-triyltris(oxy)]tris(*N,N,N*-triethylethanaminium) triiodide, is a muscarinic receptor antagonist, exhibiting the following effectiveness (Muscarinic Receptor M<sub>2</sub> > Muscarinic Receptor M<sub>1</sub> = Muscarinic Receptor M<sub>4</sub> > Muscarinic Receptor M<sub>3</sub> = Muscarinic Receptor M<sub>5</sub>). It also inhibits acetylcholinesterase and activates succinate:cytochrome *c* reductase. **Target(s)**: acetylcholinesterase (1-6); acid phosphatase (7); muscarinic acetylcholine receptor (8-13). 1. Munoz, Aldunate & Inestrosa (1999) *Neuroreport* **10**, 3621. 2. Hasson & Liepin (1963) *Biochim. Biophys. Acta* **75**, 397. 3. Kato (1972) *Mol. Pharmacol.* **8**, 575. 4. B Biol. Sci.* **211**, 181. 12. Clark & Mitchelson (1976) *Brit. J. Pharmacol.* **58**, 323. 13. Michel, Delmendo, Lopez & Whiting (1990) *Eur. J. Pharmacol.* **182**, 335.

### Gallein

This G-protein signal transduction inhibitor (FW = 364.31 g/mol; CAS 2103-64-2; Solubility: 75 mM in DMSO), also named 3',4',5',6'-tetrahydroxyxanthone-3-one, targets phosphoinositide 3-kinase, or PI3-kinase, and Rac1 activation in HL60 cells and chemotaxis in differentiated HL60 cells. Based on the SPR analysis, gallein bound to G<sub>β1γ2</sub> with a K<sub>d</sub> value of ~400 nM, in relatively close agreement with the IC<sub>50</sub> of 200 nM observed in a competition ELISA assay (1). Gallein inhibition has also demonstrated that PI3K signaling participates in mediating inhibitory odorant input to mammalian olfactory receptor neurons (2). 1. Lehmann, Seneviratne & Smrcka (2008) *Mol. Pharmacol.* **73**, 410. 2. Ukhanov, Brunert, Corey & Ache (2011) *J. Neurosci.* **31**, 273.

### Galloflavin

This lactate dehydrogenase inhibitor (FW<sub>free-acid</sub> = 278.46 g/mol; FW<sub>potassium-salt</sub> = 316.26 g/mol; CAS = 568-80-9; Solubility: 5 mg/mL DMSO) targets both enzyme isoforms, LDH-A (K<sub>i</sub> = 5.5 μM) and LDH-B (K<sub>i</sub> = 15 μM).

By inhibiting lactate production and decreasing ATP synthesis, galloflavin induces oxidative stress and apoptosis, particularly in breast tumor cell lines. 1. Farabegoli, *et al.* (2012) *Eur. J. Pharm. Sci.* **47**, 729. 2. Manerba, *et al.* (2012) *ChemMedChem* **7**, 311. 3. Fiume, *et al.* (2013) *Biochem. Biophys. Res. Commun.* **430**, 466.

### 3',3'-cyclic-GAMP

This STING agonist (FW<sub>diNa-Salt</sub> = 718.37 g/mol; Soluble to 10 mM in H<sub>2</sub>O), also known as 3',3'-cGAMP and 3',3'-cyclic guanosine monophosphate-adenosine monophosphate, targets Stimulator of interferon genes (STING), a receptor also known as transmembrane protein 173 (TMEM173), reducing B cell proliferation and inducing apoptosis of malignant B cells *in vitro*. 3',3'-cGAMP suppresses 5TGM1 multiple myeloma xenograft growth in immunodeficient mice and induces leukemic regression in Eμ-TCL1 mice. Notably, cyclic GMP-AMP synthase (or cGAS) is a DNA sensor that catalyzes the synthesis of cyclic GMP-AMP (cGAMP) from ATP and GTP in the presence of DNA (2). 1. Tang, Zundell, Ranatunga, *et al.* (2016) *Cancer Res.* **76**, 2137. 2. Wu, Sun, Chen, *et al.* (2013) *Science* **339**, 826.

### Ganciclovir

This acyclic guanosine/deoxyguanosine analogue (FW = 255.23 g/mol; CAS = 82410-32-0), also known as 9-[[1,3-dihydroxy-2-propoxy)methyl]guanine, BW759U, and 9-[[2-hydroxy-1-(hydroxymethyl)ethoxy)methyl]guanine, is taken up by most human cells and metabolically phosphorylated to ganciclovir 5'-triphosphate, the latter a potent inhibitor of viral DNA polymerases, with relatively little host cell toxicity. 5'-Mono-, 3',5'-bis(mono-), 3',5'-cyclic monophosphate and 5'-triphosphate forms of DHPG inhibited cytomegalovirus plaque formation at 1-15 μM (1). The cyclic phosphate and homophosphonate were more active than the other compounds against murine cytomegalovirus (MCMV) *in vitro*. Phosphorylated ganciclovir is incorporated into the DNA of replicating eukaryotic cells, and the latter undergo arrest at the G<sub>2</sub>-M checkpoint. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** cytomegalovirus replication (2,3); DNA polymerases, viral (2-4); HSV replication (2-4); purine-nucleoside phosphorylase (5,6). 1. Duke, Smees, Cernow, Boehme & Matthews (1986) *Antiviral Res.* **6**, 299. 2. Prisbe & Chen (1996) *Meth. Enzymol.* **275**, 425. 3. Cheng, Huang, Lin, *et al.* (1983) *Proc. Natl. Acad. Sci. U.S.A.* **80**, 2767. 4. St. Clair, Miller, Miller, Lambe & Furman (1984) *Antimicrob. Agents Chemother.* **25**, 191. 5. Kulikowska, Bzowska, Wierzchowski & Shugar (1986) *Biochim. Biophys. Acta* **874**, 355. 6. Bzowska, Kulikowska & Shugar (2000) *Pharmacol. Ther.* **88**, 349.

**Ganciclovir Diphosphate, See Ganciclovir**

### Ganciclovir Triphosphate

This acyclic GTP/dGTP analogue (FW = 463.19 g/mol; CAS = 86761-38-8) is a potent inhibitor of viral DNA polymerases. This nonelongating dGTP analogue is incorporated into the DNA of replicating eukaryotic cells and the cell cycle is stopped at the G<sub>2</sub>-M checkpoint. **Target(s):** DNA polymerases, viral (1-4); purine nucleoside phosphorylase (5). 1. Wilson, Porter & Reardon (1996) *Meth. Enzymol.* **275**, 398. 2. Prisbe & Chen (1996) *Meth. Enzymol.* **275**, 425. 3. St. Clair, Miller, Miller, Lambe & Furman (1984) *Antimicrob. Agents Chemother.* **25**, 191. 4. Germershausen, Bostedor, Field, *et al.* (1983) *Biochem. Biophys. Res. Commun.* **116**, 360. 5. Stein, Stoeckler, Li, *et al.* (1987) *Biochem. Pharmacol.* **36**, 1237.

### Ganetespiib

Ganetespiib

STA-1474

This ATP site-directed enzyme inhibitor (FW = 364.40 g/mol; CAS = 888216-25-9; Solubility = 40 mg/mL DMSO and <1 mg/mL H<sub>2</sub>O), also known as 5-(2,4-dihydroxy-5-isopropylphenyl)-4-(1-methyl-1H-indol-5-yl)-2H-1,2,4-triazol-3(4H)-one, inhibits Hsp90 (IC<sub>50</sub> = 4 nM), inducing apoptosis in OSA-8 cells, but with no effect on normal osteoblasts (1-4). Ganetespiib is the active inhibitory metabolite of the water-soluble prodrug STA-1474 (FW<sub>free-acid</sub> = 444.38 g/mol; CASs = 1118915-78-8 (free acid) and 1118915-79-9 (sodium salt)) Ganetespiib blocks Hsp90's "foldase" activity, resulting in the degradation of its 200-300 client proteins, including key signaling molecules (*e.g.*, HER2/neu, mutated EGFR, Akt, c-Kit, IGF-1R, PDGFRα, Jak1, Jak2, STAT3, STAT5, HIF-1α, CDC2, c-Met, and Wilms tumor-1 proteins) that markedly influence the course of malignant transformation (2). At low-nM concentrations, STA-9090 arrests cell proliferation and induces apoptosis in a wide variety of human cancer cell lines, including many that are receptor tyrosine kinase inhibitor- and tanespimycin-resistant. Moreover, STA-9090 administration leads to significant tumor shrinkage in several tumor xenograft models in mice and appears to be less toxic. STA-9090 shows better tumor penetration compared with tanespimycin. (See also *Alvespimycin; Ansamycin; Deguelin; Derrubone; Geldanamycin; Herbimycin; Macbecin; Radicol; Tanespimycin; and the nonansamycin Hsp90 inhibitor KW-2478*) 1. ### Ganglioside GD1a

This di-sialoganglioside (FW<sub>free-acid</sub> = 1838.08 g/mol; CAS = 12707-58-3), also known as disialoganglioside GD1a, consists of NeuAc(α2-3)Gal(β1-3)GalNAc(β1-4)(NeuAc(α2-3))Gal(β1-4)Glcβ1Cer, where Cer refers to ceramide. GD1a is the major ganglioside component in human brain and an inhibitor of protein kinase C. It can be converted to ganglioside GM<sub>1</sub> via the

action of sialidases. GD1a is also inhibits Con A-stimulated mitogenesis in murine T-cells. **Target(s):** (*N*-acetylneuraminyl)-galactosylglucosylceramide *N*-acetyl-galactosaminyltransferase (1);  $\alpha$ -*N*-acetylneuraminate  $\alpha$ -2,8-sialyltransferase (2); DNA-directed DNA polymerase (3); DNA polymerase- $\alpha$  (3); ganglioside galactosyltransferase (4);  $\text{NAD}^+$  nucleosidase, or ecto- $\text{NAD}^+$  glycohydrolase, mildly inhibited (5,6); protein kinase C (7). 1. Senn, Cooper, Warnke, Wagner & Decker (1981) *Eur. J. Biochem.* **120**, 59. 2. Yusuf, Schwarzmann, Pohlentz & Sandhoff (1987) *Biol. Chem. Hoppe-Seyler* **368**, 455. 3. ### Ganglionic Blocking Agents

These agents, also known as ganglioplegic agents, are nicotinic receptor antagonists, inhibiting synaptic transmission in autonomic ganglia, thereby reducing or suppressing sympathetic and the parasympathetic effects on autonomically innervated organs. Ganglionic blocking agents inhibit nicotinic postsynaptic receptors without preliminary stimulation. Such behavior contrasts with that of nicotine, which stimulates nicotinic postsynaptic receptors in moderate dose and inhibits them in very high dose. When ganglionic blocking agents are administered in sufficient dose, stimulation of sympathetic and parasympathetic preganglionic fibers is inactive, whereas stimulation of postganglionic fibers can still induce a response. Ganglionic blocking agents include: tetraethylammonium bromide, hexamethonium bromide, pentolinium bromide, mecamlamine, trimetaphan, pempidine, benzohexonium bromide, chlorisondamine and pentamine

### Ganglioside GD1b

This disialoganglioside ( $\text{FW}_{\text{free-acid}} = 1836.10$  g/mol (based on sphingosine C18:1 and stearic acid); CAS = 19553-76-5), also known as disialoganglioside GD1b, consists of Gal( $\beta$ 1-3)GalNAc( $\beta$ 1-4)(NeuAc( $\alpha$ 2-8)NeuAc( $\alpha$ 2-3))Gal( $\beta$ 1-4)Glc $\beta$ 1Cer where Cer refers to ceramide. GD1b is found in high concentrations in gliomas and astrocytoma and it inhibits protein kinase C. **Target(s):**  $\text{NAD}^+$  nucleosidase, or ecto- $\text{NAD}^+$  glycohydrolase (1,2); protein kinase C (3). 1. Hara-Yokoyama, Nagatsuka, Katsumata, et al. (2001) *Biochemistry* **40**, 888. 2. Hara-Yokoyama, Kukimoto, Nishina, et al. (1996) *J. Biol. Chem.* **271**, 12951. 3. Kreutter, Kim, Goldenring, et al. (1987) *J. Biol. Chem.* **262**, 1633.

### Ganglioside GM<sub>1</sub>

This monosialoganglioside ( $\text{FW}_{\text{free-acid}} = 1545.82$  g/mol (calculated on sphingosine C18:1 and stearic acid); CAS = 37758-47-7; Structure: Gal( $\beta$ 1-3)GalNAc( $\beta$ 1-4)(NeuAc( $\alpha$ 2-3))Gal( $\beta$ 1-4)Glc $\beta$ 1Cer, where Cer = ceramide), also known as monosialoganglioside GM<sub>1</sub>, inhibits protein kinase C and can act as a receptor for cholera toxin. Ganglioside GM<sub>1</sub> accumulates in individuals with generalized gangliosidosis. **Target(s):** (*N*-acetylneuraminyl)galactosylglucosylceramide *N*-acetylgalactosaminyltransferase (1); DNA-directed DNA polymerase (2); DNA polymerase  $\alpha$  (2); ganglioside galactosyltransferase (3); lactosylceramide  $\alpha$ -2,3-sialyltransferase, also as an alternative substrate (4); phospholipase A<sub>2</sub> (5); protein kinase C (6). 1. Senn, Cooper, Warnke, Wagner & Decker (1981) *Eur. J. Biochem.* **120**, 59. 2. Simbulan, Taki, Tamiya-Koizumi, et al. (1994) *Biochim. Biophys. Acta* **1205**, 68. 3. Yip & Dain (1970) *Biochem. (1987) *J. Biol. Chem.* **262**, 1633.

### Ganglioside GM<sub>2</sub>

This monosialoganglioside ( $\text{FW}_{\text{free-acid}} = 1383.70$  (calculated for sphingosine C18:1 and stearic acid substituents); CAS = 19600-01-2) is a minor component of cell membranes and accumulates in individuals with Tay-Sachs disease and Sandhoff-Jatzkewitz disease. Ganglioside GM<sub>2</sub>, also known as monosialoganglioside GM<sub>2</sub>, consists of GalNAc( $\beta$ 1-4)(NeuAc( $\alpha$ 2-3))Gal( $\beta$ 1-4)Glc $\beta$ 1Cer where Cer refers to ceramide. **Target(s):** *N*-acetyl- $\beta$ -hexosaminidase (1); (*N*-acetylneuraminyl)-galactosylglucosylceramide *N*-acetylgalactosaminyltransferase (2); galactose oxidase (3). 1. Frohwein & Gatt (1967) *Biochemistry* **6**, 2783. 2. Senn, Cooper, Warnke, Wagner & Decker (1981) *Eur. J. Biochem.* **120**, 59. 3. Yip & Dain (1968) *Enzymologia* **35**, 368.

### Ganglioside GM<sub>3</sub>

**N-stearoyl-ganglioside GM<sub>3</sub>**

This monosialoganglioside ( $\text{FW}_{\text{free-acid}} = 1180.50$  (calculated on sphingosine C18:1 and stearic acid); CAS = 54827-14-4), also known as hematoside, is the major ganglioside in non-neuronal cell membranes. It inhibits a number of protein kinases (note that lysoganglioside GM<sub>3</sub> and de-*N*-acetyl ganglioside GM<sub>3</sub> are also inhibitors of protein kinase C). Ganglioside GM<sub>3</sub>, also known as monosialoganglioside GM<sub>3</sub>, consists of NeuAc( $\alpha$ 2-3)Gal( $\beta$ 1-4)Glc $\beta$ 1Cer where Cer refers to ceramide. **Target(s):** DNA-directed DNA polymerase (1); DNA polymerase  $\alpha$  (1); DNA polymerase  $\beta$  (2); EGF receptor protein-tyrosine kinase (2-5); globotriaosyl-ceramide 3- $\beta$ -*N*-acetylgalactosaminyltransferase (6); lactosylceramide  $\alpha$ -2,3-sialyltransferase, product inhibition (7); monosialoganglioside sialyltransferase, also as an alternative substrate (8); phospholipase A<sub>2</sub> (9); protein kinase C (3,10); receptor protein-tyrosine kinase (2-5); sphingomyelin phosphodiesterase, or neutral sphingomyelinase (11). 1. Simbulan, Taki, Tamiya-Koizumi, et al. (1994) *Biochim. Biophys. Acta* **1205**, 68. 2. Song, Welti, Hafner-Strauss & Rintoul (1993) *Biochemistry* **32**, 8602. 3. ### Ganglioside GT1b

This trisialoganglioside ( $\text{FW}_{\text{free-acid}} = 2126.30$  (calculated on sphingosine C18:1 and stearic acid); CAS = 59247-13-1) modulates cellular differentiation, inhibits mitogenesis stimulated by lectins, and inhibits protein kinase C. Ganglioside GT1b, also known as trisialoganglioside GT1b, consists of NeuAc( $\alpha$ 2-3)Gal( $\beta$ 1-3)GalNAc( $\beta$ 1-4)(NeuAc( $\alpha$ 2-8)NeuAc( $\alpha$ 2-3))Gal( $\beta$ 1-4)Glc $\beta$ 1Cer where Cer refers to ceramide. It is converted to ganglioside GD1b via the action of sialidases. **Target(s):**  $\alpha$ -*N*-acetylneuraminate  $\alpha$ -2,8-sialyltransferase (1); (*N* acetylneuraminyl) galactosylglucosylceramide *N*-acetylgalactosaminyltransferase (2); ganglioside galactosyltransferase (3);  $\text{NAD}^+$  nucleosidase, or ecto- $\text{NAD}^+$  glycohydrolase (4,5); protein kinase C (6,7). 1. Yusuf, Schwarzmann, Pohlentz & Sandhoff (1987) *Biol. Chem. Hoppe-Seyler* **368**, 455. 2. Senn, Cooper, Warnke, Wagner & Decker (1981) *Eur. J. Biochem.* **120**, 59. 3. Yip & Dain (1970) *Biochem. ### Ganstigmine

This orally active physostigmine derivative (FW = 417.94 g/mol; CAS = 412044-92-9, for hydrochloride), also known as CHF-2819 and 2'-ethylphenylgeneserine *N*-oxide, inhibits acetylcholine esterase,  $IC_{50}$  = 0.13  $\mu$ M (1,2) and butyrylcholinesterase,  $IC_{50}$  = 1.7  $\mu$ M (1). Ganstigmine and its enantiomer CHF3360 over the 0.1 to 3  $\mu$ M range significantly decrease neurodegeneration achieved by the addition of  $\beta$ -amyloid(25-35) by approximately 50%. Dose response curves of both substances were identical concerning effect size and concentration; however, because CHF3360 lacks acetylcholine inhibitor activity in the applied dose range, it appears that Ganstigmine provides significant neuroprotection independent from its cholinergic activity (3). 1. Luo, Yu, Zhan, *et al.* (2005) *J. Med. Chem.* **48**, 986. 2. Trabace, Cassano, Steardo, *et al.* (2000) *J. Pharmacol. Exp. Ther.* **294**, 187. 3. Windisch, Hutter-Paier, Jerkovic, Imbimbo & Villetti (2003) *Neurosci. Lett.* **341**, 181.

#### GANT61

This Hedgehog inhibitor (FW = 429.61 g/mol; CAS = 500579-04-4; Solubility: <1 mg/mL DMSO, H<sub>2</sub>O), also known as NSC136476 and 2,2'-[[dihydro-2-(4-pyridinyl)-1,3(2*H*,4*H*)-pyrimidinediyl]bis(methylene)]bis*N,N*-dimethylbenzylamine, targets Gli1- and Gli2-induced transcription ( $IC_{50}$  = 5  $\mu$ M), which constitutes the final step in the hedgehog signal transduction pathway (1). GANT61 displays selectivity over other pathways, among them TNF- and glucocorticoid-receptor gene transactivation. Profiling of cognate Hh pathway members revealed reduced expression of the key Hh signaling effectors, Smoothened (SMO) and Gli, in chronic lymphocytic leukemia (CLL), whereas transcription levels of other pathway components resembled that observed with normal B-lymphocytes (2). Specific RNA interference knockdown experiments in a CLL-derived cell line confirmed the autonomous role of Gli in malignant cell survival. Analysis of the molecular mechanisms of GANT61-induced cytotoxicity in HT29 cells showed increased Fas expression and decreased expression of PDGFR $\alpha$ , which also regulates Fas (3). Furthermore, DR5 expression was increased whereas Bcl-2 (direct target of Gli2) was down-regulated following GANT61 treatment. Unlike cyclopamine, GANT61 induced transient cellular accumulation at G(1)-S (24 hours) and in early S-phase (32 hours), with elevated p21(Cip1), cyclin E, and cyclin A in HT29 cells (4). GANT61 induced DNA damage within 24 hours, with the appearance of p-ATM and p-Chk2. Pharmacologic inhibition of Gli1 and Gli2 by GANT61 or genetic inhibition by transient transfection of the Gli3 repressor (Gli3R) down-regulated Gli1 and Gli2 expression and induced  $\gamma$ H2AX, PARP cleavage, caspase-3 activation, and cell death. GANT61 and rapamycin are synergistic in their inhibitory effects on Gli activation in acute myeloid leukemic cells (5). Using compounds blocking SMO (cyclopamine and SANT1) or Gli1/Gli2 (GANT61) activity revealed that inhibition of Hh signaling at the level of Gli was most effective in reducing neuroblastoma growth (6). 1. Lauth, Bergström, Shimokawa & Toftgård (2007) *Proc. Natl. Acad. Sci. U.S.A.* **104**, 8455. 2. Desch, Asslaber, Kern, *et al.* (2010) *Oncogene* **29**, 4885. 3. Res.* **36**, 742. 6. Wickström, Dyberg, Shimokawa, *et al.* (2013) *Int. J. Cancer* **132**, 1516.

#### Garcinol

This PCAF and HAT inhibitor (FW = 602.81 g/mol; CAS = 78824-30-3; Solubility: 100 mM in DMSO), also named Camboginol\*, is a polyisoprenylated benzophenone derivative from the rind of *Garcinia indica* fruit that targets p300 ( $IC_{50}$  ~ 7  $\mu$ M) and PCAF ( $IC_{50}$  ~ 5  $\mu$ M) histone acetyltransferases *in vitro* (1). Also known as E1A binding protein, p300 regulates transcription factor-mediated cell growth and division. The p53-associated transcriptional coactivator PCAF plays a direct role in transcriptional regulation. Garcinol inhibits p300-mediated acetylation of p53, promoting apoptosis via caspase-3 activation. Additionally, this compound predominantly down-regulates global gene expression in HeLa cells. Garcinol also exhibits dose-dependent cancer cell-specific growth inhibition in ER-positive MCF-7 and ER-negative MDA-MB-231 breast cancer cells. Its anti-carcinogenic and antiinflammatory properties are also mediated through selective inhibition of prostaglandin E<sub>2</sub> synthesis and 5-lipoxygenase. Garcinol regulates EMT and Wnt signaling pathways *in vitro* and *in vivo*, leading to anticancer activity against breast cancer cells (2). It is also effective in promoting *ex vivo* expansion of human hematopoietic stem cells (3). 1. Balasubramanyam, *et al.* (2004) *J. Biol. Chem.* **279**, 33716. 2. Ahmad, *et al.* (2012) *Mol. Cancer Ther.* **11**, 2193. 3. Nishino *et al.* (2011) *PLoS One* **6**, e24298. \*IUPAC Name: (1*R*,5*R*,7*R*)-3-(3,4-Dihydroxybenzoyl)-4-hydroxy-8,8-dimethyl-1,7-bis(3-methyl-2-buten-1-yl)-5-[(2*S*)-5-methyl-2-(1-methylethenyl)-4-hexen-1-yl]bicyclo[3.3.1]non-3-ene-2,9-dione

#### Gatifloxacin

This fluoroquinolone-based antibiotic (FW = 375.40 g/mol; CAS = 112811-59-3), also named AM-1155 and 1-cyclopropyl-6-fluoro-1,4-dihydro-8-methoxy-7-(3-methyl-1-piperazinyl)-4-oxo-3-quinolinecarboxylic acid, targets *Escherichia coli* type II topoisomerase, or DNA gyrase ( $IC_{50}$  = 0.11  $\mu$ g/mL) and *Staphylococcus aureus* topoisomerase IV ( $IC_{50}$  = 13.8  $\mu$ g/mL). Gatifloxacin exhibits potent activity against both Gram-positive and -negative bacteria. It is effective against sequentially acquired quinolone-resistant mutants and the *norA* transformant of *Staphylococcus aureus* (1). Gatifloxacin shows some inhibition of mammalian type II topoisomerases (2). It also stimulates short-term self-renewal in both human and mouse embryonic stem cells *in vitro* (3). Tubular secretion and reabsorption are major determinants of gatifloxacin's half-life in plasma, its efficacy, and its drug-drug interactions. 1. Fukuda, *et al.* (1998) *Antimicrob. Agents Chemother.* **42**, 1917. 2. Takei, *et al.* (1998) *Antimicrob. Agents Chemother.* **42**, 2678. 3. Desbordes, *et al.* (2008) *Cell Stem Cell* **2**, 602.

**GBR 12909**, See 1-(2-[Bis(4-fluorophenyl)methoxy]ethyl)-4-(3-phenylpropyl)piperazine

#### GBR-12935

This dopamine reuptake inhibitor (FW<sub>free-base</sub> = 414.59 g/mol; CAS = 76778-22-8), named systematically as 1-(2-(diphenylmethoxy)ethyl)-4-(3-phenylpropyl)piperazine, is a high-affinity ligand suitable for specific labeling the dopamine transport complex (1). Specific binding of [<sup>3</sup>H]GBR-12935 to striatal membranes is saturable and of high affinity. It is also sodium-dependent, with optimal binding observed at a sodium concentration of 120 mM.  $IC_{50}$  values for the same drugs in inhibiting [<sup>3</sup>H]dopamine uptake in a crude synaptosomal fraction from striatum are as follows: GBR-12921,  $IC_{50}$  = 3.5 nM; GBR-12909,  $IC_{50}$  = 3.5 nM;

mazindol,  $IC_{50} = 37$  nM; nomifensine,  $IC_{50} = 49$  nM; threo-(+)-methylphenidate,  $IC_{50} = 240$  nM; cocaine,  $IC_{50} = 370$  nM; erythro-(±)-methylphenidate,  $IC_{50} = 22,500$  nM. In calculating the  $IC_{50}$  values, 4-7 concentrations of each drug were used in the presence of 30-50 nM [ $^3$ H]dopamine or 0.5-0.6 nM [ $^3$ H]GBR-12935. Early evidence that the dopamine transporter is the principal cocaine target was provided in experiments showing that a cocaine analogue (*i.e.*, [ $^{125}$ I]DEEP) and a GBR analogue labeled the same rat striatal membranes protein, based on molecular weight, similar pharmacological profile, similar sensitivity to neuraminidase (2). Moreover, GBR-12935 binds to the outward-facing conformational state of the transporter, where external DA binds to initiate its uptake (3). **Other Details:** For use of [ $^3$ H]GBR-12935 as in the quantitative autoradiographic localization of the dopamine transporters in the rat brain, **See Reference 4.** For slow-release form of hydroxy-GBR-12935 form, **See DBL-583.** 1. Berger, Janowsky, Vocci, *et al.* (1985) *Eur. J. Pharmacol.* **107**, 289. 2. Patel, Boja, Leve, *et al.* (1992) *Brain Res.* **576**, 173. 3. Chen, Rickey, Berfield & Reith (2004) *J. Biol. Chem.* **279**, 5508. 4. Dawson, Gehlert & Wamsley (1986) *Eur. J. Pharmacol.* **126**, 171.

**GCK 1026, See Scriptaid**

**GDC-0032, See Taselisib**

**GDC-0152**

This potent IAP antagonist (FW = 498.64 g/mol; CAS = 873652-48-3; Solubility = 100 mg/mL DMSO or Ethanol, 3 mg/mL H<sub>2</sub>O), also named *N*-methyl-L-alanyl-(2*S*)-2-cyclohexylglycyl-*N*-(4-phenyl-1,2,3-thiadiazol-5-yl)-L-prolinamide, targets the X-linked Inhibitor of Apoptosis Protein-Baculovirus Inhibitor of apoptosis protein Repeat proteins: XIAP-BIR3 ( $K_i = 28$  nM), ML-IAP-BIR3 ( $K_i = 14$  nM), cIAP1-BIR3 ( $K_i = 17$  nM) and cIAP2-BIR3 ( $K_i = 43$  nM), with much less affinity displayed toward cIAP1-BIR2 and cIAP2-BIR2. IAP family members, including X chromosome-linked IAP (XIAP), cellular IAP 1 (cIAP1), cellular IAP 2 (cIAP2), and melanoma IAP (ML-IAP), are often over-expressed in cancer cells, where they protect against a variety of pro-apoptotic stimuli. IAP proteins also been regulate signal transduction pathways associated with malignancy, targeting TNF $\alpha$ -mediated NF- $\kappa$ B activation via their C-terminal RING ubiquitin E<sub>3</sub>-ligase domains, which have been shown to ubiquitinate receptor interacting protein (RIP)-1 and NF- $\kappa$ B inducing kinase, NIK. GDC-0152 can block protein-protein interactions that involve IAP proteins and pro-apoptotic molecules. GDC-0152 promotes degradation of cIAP1, induces activation of caspase-3/7, and leads to decreased viability of breast cancer cells without affecting normal mammary epithelial cells. GDC-0152 **Pharmacokinetics:**  $C_{max} = 53.7$   $\mu$ M; AUC = 203.5 hour- $\mu$ M. 1. Flygare, Beresini, Budha, *et al.* (2012) *J. Med. Chem.* **55**, 4101.

**GDC-0199, See Venetoclax**

**GDC-0349**

This potent and selective, pyrimidoaminotropane-based ATP-competitive inhibitor (FW = 452.55 g/mol; CAS = 1207360-89-1), also named RG7603

and *N*-ethyl-*N*'-[4-[5,6,7,8-tetrahydro-4-[(3*S*)-3-methyl-4-morpholinyl]-7-(3-oxetanyl)pyrido[3,4-*d*]pyrimidin-2-yl]phenyl]-urea, targets mTOR ( $K_i = 3.8$  nM), with 790-fold inhibitory effect against PI3K $\alpha$  and other 266 kinases. GDC-0349 inhibits downstream markers of mTOR, including phospho-4EBP1 and phospho-Akt(S473). 1. Estrada, Shore, Blackwood, *et al.* (2013) *J. Med. Chem.* **56**, 3090.

**GDC-0449, See Vismodegib**

**GDC-0941**

This potent phosphoinositide-3-kinase-directed signal-transduction pathway inhibitor (F.Wt. = 513.64; CAS = 154447-36-6 and 934389-88-5; Solubility (25°C): 44 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known as Pictisilib and 2-(1*H*-indazol-4-yl)-6-((4-(methylsulfonyl)piperazin-1-yl)methyl)-4-morpholinothieno[3,2-*d*]pyrimidine, inhibits phospho-inositide 3-kinases PI3K $\alpha$ , PI3K $\beta$ , PI3K $\delta$  and PI3K $\gamma$ , with  $IC_{50}$  values of 3 nM, 33 nM, 3 nM and 75 nM, respectively. 1. Folkes, *et al.* (2008) *J. Med. Chem.* 2008, 51, 5522. 2. Junttila, *et al.* (2009) *Cancer Cell* 15, 429. 3. Haagensen, *et al.* (2012) *Brit. J. Cancer* 106, 1386.

**GDC-0994**

This potent ERK inhibitor (FW = 440.84 g/mol; CAS = 1453848-26-4; Solubility (25°C): 88 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also named (*S*)-1-(1-(4-chloro-3-fluorophenyl)-2-hydroxyethyl)-4-(2-((1-methyl-1*H*-pyrazol-5-yl)amino)pyrimidin-4-yl)pyridin-2(1*H*)-one, targets the Extracellular signal-Regulated Kinases ERK1 ( $K_i = 1.2$  nM) and ERK2 ( $K_i = 0.3$  nM), showing significant single-agent activity in multiple *in vivo* cancer models, including KRAS-mutant and BRAF-mutant human tumors in xenograft mice models. Orally administered GDC-0994 inhibits both ERK phosphorylation and activation of ERK-mediated signal transduction pathways, and subsequently prevents ERK-dependent tumor cell proliferation and survival. 1. Robarge, Schwarz, Blake, *et al.* (2014) Discovery of GDC-0994, a potent and selective ERK1/2 inhibitor in early clinical development, Presentation Number DDT02-03, *Annual Meeting of Amer. Assoc. Cancer Res.*, San Diego.

**GDP-(1-[4-[(biphenyl-4-ylmethyl)carbamoyl]butyl]-1*H*-[1,2,3]triazol-4-ylmethyl)**

This GDP analogue (FW = 772.63 g/mol), also known as GDP-*N*-(biphenyl-4-ylmethyl)-5-(1*H*-1,2,3-triazol-1-yl)-pentanamide, inhibits glycoprotein 3- $\alpha$ -L-fucosyltransferase ( $K_i = 62$  nM, human). 1. Bryan, Lee & Wong (2004) *Bioorg. Med. Chem. Lett.* **14**, 3185. 2. Sun, Lin, Ko, *et al.* (2007) *J. Biol. Chem.* **282**, 9973.

**GDP-L-fucose**

This sugar nucleotide (FW<sub>free-acid</sub> = 633.31 g/mol; CAS = 15839-70-0), also known as guanosine 5'-diphospho-β-L-fucose, is a product of the reactions catalyzed by GDP-L-fucose synthase and fucose-1-phosphate guanylyltransferase. It is a substrate for 3-galactosyl-*N*-acetylglucosaminide 4α-L-fucosyl-transferase, glycoprotein 6α-L-fucosyltransferase, galactoside 2α-L-fucosyltransferase, 4-galactosyl-*N*-acetylglucosaminide 3α-L-fucosyl-transferase, glycoprotein-3α-L-fucosyltransferase, and peptide-*O*-fucosyltransferase. **Target(s):** α-*N*-acetyl-galactosaminide α-2,6-sialyltransferase (1); fucokinase (2,3); β-galactoside α-2,3-sialyltransferase1; GDP-mannose 4,6-dehydratase (4-13); GDP-mannose 3,5-epimerase (7); glucomannan 4-β-mannosyltransferase (14); mannose-1-phosphate guanylyl-transferase (4). 1. **Gefitinib**

This orally active, EGFR-directed protein kinase inhibitor (FWt = 446.90; CASs = 248594-19-6 (methanesulfonate); Solubility (25°C): 90 mg/mL DMSO, 1 mg/mL H<sub>2</sub>O), also known as Iressa<sup>®</sup>, ZD-1839, and by its systematic name, *N*-(3-chloro-4-fluorophenyl)-7-methoxy-6-(3-morpholinopropoxy)quinazolin-4-amine, blocks phosphorylation of Tyr-1173, Tyr-992, Tyr-1173 and Tyr-992 sites in the NR6wtEGFR- and NR6W-cells with IC<sub>50</sub> values of 37 nM, 37nM, 26 nM and 57 nM, respectively (1-4). EGFR is frequently amplified and/or mutated in human tumors, and abnormal signaling from this receptor is believed to contribute to the malignant phenotype. Significantly, gefitinib was the first EGF receptor protein-tyrosine kinase inhibitor showing effects on solid tumors. Gefitinib (1-2 μM) significantly decreases EGFRvIII phosphotyrosine load, EGFRvIII-

mediated proliferation as well as anchorage-independent growth (5). It likewise inhibits HER2-driven signaling and suppresses the growth of HER2-over-expressing tumor cells (6). While gefitinib treatment is effective against aberrant EGFR activity, chronic gefitinib treatment promotes ROS and mitochondrial dysfunction in lung cancer cells (7). Antioxidants alleviate ROS-mediated resistance. 1. Woodburn, Morris, Kelly & Laight (1998) *Cell. Mol. Biol. Lett.* **3**, 348. 2. Barker, Gibson, Grundy, *et al.* (2001) *Bioorg. Med. Chem. ### Geldanamycin

This potent antitumor drug (FW = 559.27 g/mol; CAS = 30562-34-6; Symbols: GA and GDN), a benzoquinone ansamycin-class antibiotic first isolated from *Streptomyces hydropiscus*, binds to Hsp90 heat shock proteins, inhibiting this chaperone's intrinsic ATP-hydrolyzing activity and stimulating client protein release. In view of its ability to bind to and inhibit Hsp90, treatment of cells with geldanamycin activates a heat shock response, even in the absence of heat shock. Moreover, pretreatment of cells with the Hsp90 inhibitors also delayed the rate of restoration of normal protein synthesis following a brief heat shock. (See also *Alvespimycin*; *Ansamycin*; *Deguelin*; *Derrubone*; *Ganetespib*; *Herbimycin*; *Macbecin*; *Radicalol*; *Tanespimycin*; and the nonansamycin Hsp90 inhibitor KW-2478) **Mechanism of Action:** Geldanamycin blocks Hsp90-assisted folding of some 250-300 currently known client proteins. For example, when geldanamycin binds to Hsp90 ( $K_i = 10\text{-}30\text{ nM}$ ), the HSP90's multimolecular interaction with Raf-1 is disrupted, destabilizing the latter. Geldanamycin also inhibits the oncogene product p185*erbB-2* protein-tyrosine kinase and induces polyubiquitination and proteasomal degradation. *Note:* 17-DMAG is a water-soluble derivative of geldanamycin that potently inhibits Hsp90 ( $IC_{50} = 24\text{ nM}$ ) and has excellent bioavailability and tissue distribution in animals (1-3). Geldanamycin also induces oxidative stress with concomitant glutathione (GSH) depletion, and *N*-acetylcysteine prevents the geldanamycin cytotoxicity by forming geldanamycin-*N*-acetylcysteine adduct (4). Renaturation of thermally denatured firefly luciferase in rabbit reticulocyte lysate (RRL) requires hsp90, and other as yet unidentified RRL components (5). The effects of geldanamycin on the kinetics of the luciferase renaturation in RRL show that chaperone-mediated luciferase renaturation that obeys Michaelis-Menten kinetics. GA inhibits luciferase renaturation uncompetitively with respect to ATP and noncompetitively with respect to luciferase, indicating that it binds after ATP binds and that geldanamycin binds to both the hsp90 chaperone machine/ATP complex and the hsp90/ATP/luciferase complex. GA markedly decreased the  $K_{app}$  of the hsp90 chaperone machine for ATP, suggesting that GA increases the binding affinity of the hsp90 chaperone machinery for ATP or it slows the rate of ATP hydrolysis (6). Consistent with the notion that GA specifically binds hsp90 and inhibits its function, addition of hsp90, but not hsc70, p60, or p23, reversed GA-induced inhibition of luciferase renaturation in RRL. GA increases the steady-state levels of luciferase associated with hsp90/hsp70 chaperone machine complexes that contain p60 and blocks the association of the hsp90 cohort p23 with chaperone-bound luciferase (6). **Hsp90 Targets:** Humans have five Hsp90 isoforms: Hsp90- $\alpha_1$  (the inducible cytoplasmic isoform (98.2-kDa) encoded by HSP90AA1), Hsp90- $\alpha_2$  (a second inducible cytoplasmic isoform (84.7-kDa) encoded by HSP90AA2), Hsp90- $\beta$  (the constitutive cytoplasmic isoform encoded by HSP90AB), Endoplasmic/GRP-94 (the ER protein (also known as gp96, grp94 and ERp99) encoded by HSP90B1), and

TNF Receptor-Associated Protein 1 (the mitochondrial isoform encoded by TRAP1). Hsp90's are homodimers, with each subunit containing a highly conserved 25-kDa N-terminal domain (NTD) with an ATP binding motif, a "charged linker" region, a 40-kDa middle domain, and a 12-kDa C-terminal domain (CTD). Geldanamycin and other benzoquinone ansamycins display an unusual capacity to revert tyrosine kinase-induced oncogenic transformation by preventing Hsp90 stabilization of oncogenic kinases against the same proteasome-mediated turnover. Geldanamycin inhibition of Hsp90 also induces apoptosis through inhibition of the PI3K/AKT signaling pathway and growth factor signaling. **Other Targets:** DNA replication (7); HtpG (8); nitric-oxide synthase (9); oncogene product p185/*erbB-2* protein-tyrosine kinase (8,9); src protein-tyrosine kinase (10,12); terminal deoxyribonucleotidyl-transferase (13). 1. ### Gemcitabine

This synthetic cytidine analogue (FW = 263.20 g/mol; CAS = 95058-81-4), also known as 2'-deoxy-2',2'-difluorocytidine, is an antineoplastic agent that has been used in the treatment of early and advanced stage non-small cell lung cancer. After transport, gemcitabine undergoes metabolic phosphorylation steps to form gemcitabine 5'-triphosphate. (There are twelve known nucleoside transporters (NTs), and the susceptibility of any particular cell type to gemcitabine depends on the cell's NT subtype. NT deficiencies are also known that confer significant gemcitabine resistance.) Subsequent incorporation into DNA leads to cell death. Gemcitabine also induces JNK and p38 MAPK activation mediates increased apoptosis. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** DNA biosynthesis (1,2); DNA polymerase (2); Na<sup>+</sup>-dependent nucleoside transporter (3); ribonucleoside-diphosphate reductase (4,5); ribonucleoside triphosphate reductase (5,6); RNA biosynthesis (1). 1. ### Gemfibrozil

This fibric acid derivative (FW<sub>free-acid</sub> = 250.34 g/mol; CAS = 25812-30-0), also known as Lipid<sup>®</sup>, is a serum lipid-regulating agent that lowers very-low-density lipoprotein (VLDL) concentrations, while raising HDL levels. Gemfibrozil also decreases serum triacylglycerol levels and inhibits expression of inducible nitric-oxide synthase. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE*

*PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** acetyl-CoA carboxylase, possibly indirectly inhibited (1,2); CYP1A2, mildly inhibited (3); CYP2C8 (4); CYP2C9 (3); CYP2C19, mildly inhibited (3); diacylglycerol avyltransferase (5); fatty acid elongation (6); glucose-6-phosphate dehydrogenase (1); palmitoyl-CoA hydrolase, or acyl CoA hydrolase (7). 1. ### Geminin

This highly conserved DNA replication inhibitor (MW<sub>human</sub> = 23.5 kDa; Accession Number = NP 056979; Symbol: Gem and GMNN) is a nuclear protein with homologues in most eukaryotic organisms. To maintain genome integrity, DNA replication must occur only once during each cell cycle, and every step of pre-replication complex (or pRC) assembly process must be tightly regulated (1). Geminin was identified in *Xenopus* as a replication inhibitor that prevents binding of MCM proteins to chromatin (2). In synchronized HeLa cells, it is absent during G<sub>1</sub> phase, accumulates during S, G<sub>2</sub>, and M phases, but disappears at the time of the metaphase-anaphase transition (3). Geminin forms a complex with Cdt1 and inhibits its interaction with MCM complexes (3-8). Geminin was also shown to inhibit DNA binding of Cdt1 *in vitro* (6). Encoded by a gene located on the short arm of Human Chromosome-16, this coiled-coil motif-containing protein inhibits DNA replication by binding to the DNA replication factor Cdt1, preventing incorporation of minichromosome maintenance proteins into the pRC. Geminin is expressed during S and G<sub>2</sub> phases of the cell cycle and is degraded later by the anaphase-promoting complex during the metaphase-anaphase transition. Among its putative functions are control of cell cycle, cellular proliferation, cell lineage commitment, and neural differentiation. Its increased expression may play a role in colon, rectal and breast cancer.

**Mode of Inhibitory Action:** Geminin inhibits the initiation of eukaryotic DNA replication, a process that involves the assembly of pre-replicative complexes (pre-RCs) at origins of replication during the G<sub>1</sub> phase of the cell cycle (9). Geminin inhibits the association of HsCdt1 with DNA or with human origin recognition complex HsORC-HsCdc6-DNA complexes, but does not inhibit recruitment of HsMCM2-7 to DNA to form complexes containing all of the pre-RC proteins (9). Geminin is itself a component of these complexes and interacts directly with the HsMcm3 and MsMcm5 subunits of HsMCM2-7, as well as with HsCdt1 (9). Geminin is also required to restrain mesodermal fate acquisition of early embryonic cells and is associated with both decreased Wnt signaling and enhanced Polycomb repressor complex retention at mesodermal genes (10). 1. ### Geneticin

This antibiotic (FW<sub>free-base</sub> = 496.56 g/mol; frequently supplied as the disulfate salt, FW = 692.71; CAS = 108321-42-2), also known as G418, is a gentamycin-related aminoglycoside that contains three monosaccharide units modified by hydroxyl, ammonium, and methyl groups. Gentamicin binds to both prokaryotic and eukaryotic ribosome A-sites, inhibiting peptide elongation. It is often used to maintain cells stably transfected with neomycin resistance genes (**See also Kanamycin; Gentamicin; Neomycin**).

**Target(s):** ornithine decarboxylase (1); phospholipase D (2); protein biosynthesis, elongation (3-5). 1. Jackson, Goldsmith & Phillips (2003) *J. Biol. Chem.* **278**, 22037. 2. ### Genistein

This photosensitive isoflavone antioxidant (FW = 270.24 g/mol; CAS = 446-72-0), also known as 5,7-dihydroxy-3-(4-hydroxyphenyl)-4H-1-benzopyran-1-one, is a phytoestrogen found in a number of plants, particularly soy products. It is the aglycon of genistin and sophoricoside. This natural product is an inhibitor of protein-tyrosine kinases, including the autophosphorylation of epidermal growth factor receptor kinase (IC<sub>50</sub> = 2.6 mM). The inhibition is competitive with respect to ATP and noncompetitive with respect to the phosphate acceptor. It also inhibits p60v-src protein-tyrosine kinase (IC<sub>50</sub> = 25 μM) and certain other protein kinases (e.g., protein-histidine kinase). It has very weak effects on the activity of protein kinase A, protein kinase C, and phosphorylase kinase. Genistein also inhibits tumor cell proliferation, induces tumor cell differentiation, inducing cell cycle arrest and apoptosis in Jurkat T-leukemia cells. **Target(s):** arylamine N-acetyltransferase (60,61); Ca<sup>2+</sup> channels (1); cAMP-dependent protein kinase, or protein kinase A (2); cAMP phosphodiesterase (3); β-carotene (15); 15<sup>o</sup>-monooxygenase (62); catechol O-methyltransferase (4); chalcone isomerase (5); 3',5'-cyclic-GMP phosphodiesterase, cGMP phosphodiesterase (6); 3',5'-cyclic-nucleotide phosphodiesterase (6); CYP1A1 (7); diphosphoinositol-pentakisphosphate kinase (8); DNA topoisomerase I (9); DNA topoisomerase II (9-13); dual-specificity kinase (14-16); epidermal-growth-factor receptor protein-tyrosine kinase (17,18); estrone sulfotransferase (19,20); fatty-acid synthase (59); F<sub>0</sub>F<sub>1</sub> ATP synthase, mitochondrial (21); focal adhesion kinase (22); GABAA receptor (23); β-galactosidase (24); α-glucosidase (25); GLUT1 (glucose transport) (26,27); glutathione S-transferase (58); histidine decarboxylase (4); 3-hydroxy-3-methylglutaryl-CoA reductase (28,29); 3β-hydroxysteroid dehydrogenase (30,31); inositol trisphosphate 3-kinase (32); iodide peroxidase, or thyroid peroxidase (65); 5-lipoxygenase, or arachidonate 5-lipoxygenase, K<sub>i</sub> = 60 mM (63); 15-lipoxygenase, or arachidonate 15-lipoxygenase (64); lipoxygenase, soybean, IC<sub>50</sub> = 107 mM (63,64); NADH oxidase (33); P-glycoprotein (34); phenol sulfotransferase, or aryl sulfotransferase (20,35-37); phenylalanine ammonia-lyase, weakly inhibited (38); phosphatidylinositol 3-kinase (39); phosphodiesterase (16); phosphodiesterase (26); phosphodiesterase (36); phosphodiesterase (46); phosphodiesterase (56); P<sub>1</sub>-purinergic (adenosine) receptor (40); protein-disulfide isomerase (41); protein-histidine kinase (42); protein-histidine pros kinase (42); protein-tyrosine kinase (15,22,43-51); receptor protein-tyrosine kinase (15,17,18,52,53); S<sub>6</sub> kinase (54); src protein-tyrosine kinase (22,47-49); steroid D-isomerase (31,55); steroid 5α-reductase (56); steroid sulfotransferase (19); xenobiotic-transporting ATPase, multidrug-resistance protein (34,57); xanthine oxidase (66). 1. ### Genistin

This yellow glucoside (FW = 432.38 g/mol; CAS = 529-59-9), also known as genistein 7-*O*- $\beta$ -D-glucopyranoside, is slightly soluble in hot water. Note that, while the aglycon genistein inhibits a number of protein-tyrosine kinases, genistin is inactive and has been used as a negative control. **Target(s):** aldehyde dehydrogenase (1); CYP1A1 (2); DNA nucleotidyltransferase, terminal deoxyribonucleotidyltransferase (3); DNA topoisomerase II (4); lipoxygenase, soybean, IC<sub>50</sub> = 10  $\mu$ M (5);

phenylalanine ammonia-lyase, weakly inhibited (6). **1.** Keung & Vallee (1993) *Proc. Natl. Acad. Sci. U.S.A.* **90**, 1247. **2.** Shertzer, Puga, Chang, *et al.* (1999) *Chem. Biol. ### Gentamycins

These aminoglycosidic antibiotics (FW<sub>Gentamicin-A</sub> = 477.60 g/mol; CAS = 1403-66-3), often spelled gentamicin, inhibit protein biosynthesis (1-3) and are especially effective in the treatment of *Pseudomonas aeruginosa* infections. They are obtained by fermentation of *Pseudomonas purpurea* or *M. echinospora*. Gentamycins C<sub>1</sub>, C<sub>2</sub>, and C<sub>1a</sub> are structurally similar (for C<sub>1</sub>: R<sub>1</sub> = R<sub>2</sub> = CH<sub>3</sub>; for C<sub>2</sub>: R<sub>1</sub> = CH<sub>3</sub> and R<sub>2</sub> = H; and C<sub>1a</sub>: R<sub>1</sub> = R<sub>2</sub> = H) and contain garosamine, 2 deoxystreptamine, and a purpursamine residue that may be methylated. Gentamicin A, systematically referred to as *O*-2-amino-2-deoxy- $\alpha$ -D-glucopyranosyl-(1 $\rightarrow$ 4)-*O*-[3-deoxy-3-(methylamino)- $\alpha$ -D-xylopyranosyl-(1 $\rightarrow$ 6)]-2-deoxy-streptamine, is structurally similar to kanamycin C. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** aminoglycoside N<sup>6</sup>-acetyltransferase, or kanamycin 6'-acetyltransferase, inhibited by gentamycins A and C<sub>1</sub> (4-7); calreticulin, chaperone activity inhibited (8); glucose-6 phosphate dehydrogenase (9); kanamycin kinase, inhibited by gentamicin C<sub>1a</sub> (4); leukocyte elastase, slightly inhibited (10); NADPH oxidase (11); ornithine decarboxylase ( $K_i$  = 1.6 mM (12); phospholipase A<sub>1</sub>, inhibition due to substrate depletion (13); protein biosynthesis (1-3). **1.** Pestka (1974) *Meth. ### Gentiobiose

This disaccharide (FW = 342.30 g/mol; CAS = 5996-00-9), also known as 6-*O*- $\beta$ -D-glucopyranosyl-D-glucose, is a component of many glycosides

(e.g., amygdalin) and oligosaccharides. The two anomeric forms reportedly have widely different melting points (e.g., 190-195 °C versus 86 °C for the  $\beta$ - and  $\alpha$ -anomers, respectively). **Target(s):** glucan 1,4- $\alpha$ -glucosidase, or glucoamylase (1); licheninase (2); membrane oligosaccharide glycerophosphotransferase (3); phosphatidyl-glycerol:membrane-oligosaccharide glycerophospho-transferase (4);  $\alpha$ , $\alpha$ -trehalase, weakly inhibited (5). 1. Fogarty & Benson (1983) *Eur. J. Appl. Microbiol. Biotechnol.* **18**, 271. 2. Pigman (1951) *The Enzymes*, 1st ed., **1** (Part 2), 725. 3. Goldberg, Rumley & Kennedy (1981) *Proc. Natl. Acad. Sci. ### Gentisic Acid

This salicylate metabolite (FW<sub>free-acid</sub> = 154.12 g/mol; CAS = 490-79-9; pK<sub>a</sub> = 2.93 at 25°C), also known as 2,5-dihydroxybenzoic acid, is a product of the 3-hydroxybenzoate 6-monooxygenase reaction and a substrate of gentisate 1,2-dioxygenase and gentisate decarboxylase. **Target(s):**  $\gamma$ -butyrobetaine dioxygenase, or  $\gamma$ -butyrobetaine hydroxylase (1); complement component C<sub>3</sub>, guinea pig (2); 4,5-dihydroxybenzoate decarboxylase, weakly inhibited (3); diiodophenylpyruvate reductase (4); 3-galactosyl-N-acetylglucosaminide 4- $\alpha$ -L fucosyltransferase (5); glycol-protein 3- $\alpha$ -L-fucosyltransferase (5); 4-hydroxybenzoate 3-monooxygenase, NAD(P)H (6); 4-hydroxyphenylpyruvate dioxygenase (7); 15-lipoxygenase, or arachidonate 15-lipoxygenase (8); medium-chain fatty-acyl-CoA synthetase, or butyryl-CoA synthetase (9); orsellinate decarboxylase (10); procollagen-proline 4-dioxygenase (11); protocatechuate 3,4-dioxygenase (12); o-pyrocatechuate decarboxylase (13); tannase (14); tyrosinase (15); tyrosine 3-monooxygenase (16). 1. ### Geranial

This monoterpene aldehyde (FW = 152.24 g/mol; CAS = 5392-40-5; Light oil; Strong lemony fragrance; Practically insoluble in water; Miscible with ethanol and diethyl ether), also known as *trans*-citral, is a geometric isomer of neral and is found in many natural oils, including lemons and oranges. Geranial has also been observed in a number of insect pheromone mixtures. **Target(s):** aldehyde dehydrogenase (1-3); CYP1A1, inhibited by citral (4); CYP1A2, inhibited by citral (5); CYP2B4, inhibited by citral (5); retinal dehydrogenase, inhibited by citral (6,7); retinol dehydrogenase, inhibited by citral (8,9); tyrosinase, or monophenol monooxygenase, IC<sub>50</sub> = 1.6 mM (10). 1. ### Geranyl Diphosphate (or, Geranyl Pyrophosphate)

This pyrophosphate ester, (FW<sub>free-acid</sub> = 314.21 g/mol; CAS = 763-10-0), often abbreviated GPP, is an intermediate in terpene biosynthesis. It is a product of the reaction catalyzed by dimethylallyltransferase and a substrate for geranyltransferase (farnesyl-diphosphate synthase), (4S)-limonene synthase, and geranyl-diphosphate cyclase. Note that geranyl diphosphate is very labile in acidic solutions and is relatively stable in neutral and alkaline solutions. Neryl pyrophosphate is the *cis* isomer.

**Target(s):** diphospho-mevalonate decarboxylase, IC<sub>50</sub> = 65  $\mu$ M for the rat enzyme (1); farnesyl-diphosphatase (2,3); isopentenyl-diphosphate  $\Delta$ -isomerase (4-8); mevalonate kinase (1,9-16); squalene synthase (17). 1. ### Geranylgeranylacetone

This cytoprotective antioxidant and antiulcer drug (FW = 330.56 g/mol; CAS = 6809-52-5; often supplied as mixture of (5E,9E,13E) and (5Z,9E,13E) isomers; *Symbol*: GGA), known systematically as 6,10,14,18-tetramethyl-5,9,13,17-nonadecatetraen-2-one, induces expression of HSP70, HSPB8, and HSPB1 and protects against development of inflammatory bowel disease, hypoxic/ischemic brain injury, and spinal and bulbar muscular atrophy. Oral administration prevents development of gastric ulcer induced by a single, or repeated, oral aspirin administration (5 consecutive days). Effects were more potent than those of gefarnate. Intraduodenal administration, but not the intragastric administration, also inhibited the ulceration induced by aspirin in pylorus-ligated rats, while the intraduodenal administration of gefarnate did not (1). GGA may induce transcriptional activation of HSP genes, suggesting novel mechanism of gastric mucosal defense against stress (2). GGA-induced activation of Hsp90/AMPK significantly increases NO-mediated vasodilation in healthy subjects, as well as in smokers (3). 1. Murakami, Oketani, Fujisaki, et al. (1982) *Jpn. J. Pharmacol.* **32**, 299. 2. Hirakawa, Rokutan, Nikawa & Kishi (1995) *Gastroenterology* **111**, 345. 3. Fujimura, Jitsuiki, Maruhashi, et al. (2012) *Arterioscler. Thromb. Vasc. Biol.* **32**, 153.

### 2E,6E,10E-Geranylgeranyl Diphosphate

This pyrophosphate ester (FW<sub>free-acid</sub> = 450.45 g/mol; CAS = 6699-20-3), also known as (2*E*,6*E*,10*E*)-3,7,11,15-tetramethyl-2,6,10,14-hexadecatetraen-1-yl diphosphate and *all-trans*-geranylgeranyl pyrophosphate, is a precursor in the biosynthesis of di- and tetraterpenes and polyprenols. It is also a product inhibitor of farnesyl-*tran*sferase (*i.e.*, geranylgeranyl-diphosphate synthase). **Target(s):** abietadiene synthase (1-3); farnesyl-diphosphatase (4,5); mevalonate kinase (6-9); *trans*-octaprenyl-*tran*sferase (10); protein farnesyltransferase (11-13). 1. Peters & Croteau (2002) *Biochemistry* **41**, 1836. 2. Peters, Ravn, Coates & Croteau (2001) *J. Amer. Chem. Soc.* **123**, 8974. 3. ### 2Z,6E,10E-Geranylgeranyl Diphosphate

This pyrophosphate ester (FW = 450.45 g/mol), also named (2*Z*,6*E*,10*E*)-3,7,11,15-tetramethyl-2,6,10,14-hexadecatetraen-1-yl diphosphate and *cis,trans,trans*-geranylgeranyl pyrophosphate, is a precursor in the biosynthesis of di- and tetraterpenes and polyprenols. **Target(s):** farnesyl-*tran*sferase (geranylgeranyl-diphosphate synthase (1,2); protein farnesyltransferase (3)). 1. Sagami, Morita & Ogura (1994) *J. Biol. Chem.* **269**, 20561. 2. Sagami, Korenaga, Ogura, Steiger, Pyun & Coates (1992) *Arch. Biochem. Biophys.* **297**, 314. 3. Das & Allen (1991) *Biochem. Biophys. Res. Commun.* **181**, 729.

### Gevokizumab

This humanized monoclonal antibody (MW = 145.2 kDa; CAS = 1129435-60-4), known also by the code name XOMA-542, binds strongly to interleukin-1 $\beta$  (*or* IL-1 $\beta$ ), a pro-inflammatory cytokine involved in non-infectious uveitis, including Behçet's uveitis, cardiovascular disease, and other auto-inflammatory diseases (1,2). Through its binding to IL-1 $\beta$ , Gevokizumab inhibits IL-1 receptor activation, thereby modulating the cellular signaling events producing inflammation. Based on SPR measurements, the association rate constant ( $k_{on}$ ) is  $1.19 \times 10^7 \text{ M}^{-1} \text{ s}^{-1}$ , and the dissociation rate constant ( $k_{off}$ ) is  $4.6 \times 10^{-3} \text{ s}^{-1}$ , giving an equilibrium dissociation constant  $K_D$  value of 0.39 nM (3). Gevokizumab significantly reduces the affinity of IL-1 binding to sIL-1RI (4.8 nM) by reducing the observed association rate for IL-1 addition to sIL-1RI ( $1.21 \times 10^6 \text{ M}^{-1} \text{ s}^{-1}$ ), with no detectable impact on the dissociation rate constant (3). 1. Owyang, Maedler, Gross, *et al.* (2010) *Endocrinology* **151**, 2515. 2. Roell, Issafras, Bauer, *et al.* (2010) *J. Biol. Chem.* **285**, 20607. 3. Issafras, Corbin, Goldfine & Roell (2013) *J. Pharmacol. Exp. Ther.* **348**, 202.

### GF-15

This synthetic griseofulvin analogue (FW = 422.91 g/mol; CAS = 126-07-8), systematically named as (2*S*,6'*R*)-(7-chloro-4,6-dimethoxybenzofuran-3-

one)-2-spiro-1'-(2'-hexoxy-6'-methyl-cyclohex-2'-en-4'-one), is a potent, first-in-class inhibitor of centrosomal clustering in malignant cells (1). Earlier SAR studies of griseofulvin analogues demonstrated that their antifungal activity did not correlate with their effects on centrosomal clustering (2,3). Significantly, at concentrations, where GF-15 had little or no impact on tubulin polymerization, mitotic spindle tension was markedly reduced upon exposure of dividing cells to GF-15 (1). Cells with conditional centrosome amplification are more sensitive to GF-15 than griseofulvin (1). In a wide array of tumor cell lines, the observed IC<sub>50</sub> was 1–5  $\mu\text{M}$  for inhibiting centrosomal clustering and promoting apoptotic cell death. Treatment of mouse xenograft models of human colon cancer and multiple myeloma resulted in tumor growth inhibition and significantly prolonged survival. (See *Griseofulvin*) 1. Rønneest, Rebacz, Markworth, *et al.* (2009) *J. Med. Chem.* **52**, 3342. 2. Rebacz, Larsen, Clausen, *et al.* (2007) *Cancer Res.* **67**, 6342. 3. Rønneest, Raab, Anderhub, *et al.* (2012) *J. Med. Chem.* **55**, 652.

### GF109203X

This potent PKC inhibitor (FW = 412.49 g/mol; CAS = 133052-90-1; Solubility: 80 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O), also known as bisindolylmaleimide I and 3-[1-[3-(dimethylamino)propyl]-1*H*-indol-3-yl]-4-(1*H*-indol-3-yl)-1*H*-pyrrole-2,5-dione, targets PKC $\alpha$  (IC<sub>50</sub> = 20 nM), PKC $\beta$ I (IC<sub>50</sub> = 17 nM), PKC $\beta$ II (IC<sub>50</sub> = 16 nM), and PKC $\gamma$  (IC<sub>50</sub> = 20 nM), with more than 3000x selectivity over EGFR, PDGFR and insulin receptor. GF 109203X efficiently prevents PKC-mediated phosphorylation of an Mr = 47,000 protein in platelets and of an Mr = 80,000 protein in Swiss 3T3 cells, but failed to prevent PKC-independent phosphorylation (1). GF 109203X inhibited collagen- and  $\alpha$ -thrombin-induced platelet aggregation as well as collagen-triggered ATP secretion; however, ADP-dependent reversible aggregation was not modified (1). Intriguingly, GF 109203X probably influences multidrug resistance (MDR) via direct binding to P-gp (2,3). Co-treatment of the cells with AG1478 (an EGFR inhibitor) and GF109203X produced an additive effect on carbachol-stimulated ERK1/2 activation, suggesting that the EGFR and PKC pathways act in parallel (4). See also (5) for a discussion of the nonspecific actions of PKC inhibitors on cardiovascular ion channels in addition to their PKC-inhibiting functions. In RANKL-treated primary mouse marrow cells, GF109203X inhibits processes driven by Receptor Activator of NF $\kappa$ B Ligand (*or* RANKL), reducing expression of key osteoclastic genes (*e.g.*, cathepsin K, calcitonin receptor, tartrate resistant acid phosphatase (TRAP), and the proton pump subunit V-ATPase-d2) (6). Expression of these proteins depends on RANKL-induced NF- $\kappa$ B and NFAT transcription factor actions; both are reduced in osteoclast progenitor populations upon treatment with GF109203X (6). GF109203X inhibits RANKL-induced calcium oscillation (6). (**Other PKC inhibitors in clinical development include:** LY333531; ISIS 3521, *or* CGP 64128A; Bryostain 1; GF109203x; Ro 32-0432; Ro 31-8220; Go 6976; Go 7611; CPR 1006; and Balanol, *or* SPC 100840) 1. **Ghrelin**

This 28-residue orexigenic peptide (MW = 3611.23 g; CAS 258279-04-8; Sequence: GS(O-*n*-CH<sub>3</sub>(CH<sub>2</sub>)<sub>6</sub>C(=O)O)SFLSPEHQVQRKESKKPPAK LQPR) displays strong Growth Hormone (GH)-releasing activity, which is mediated by the activation of the so-called GH secretagogue receptor type 1a (GHS-R1a), which is concentrated in the hypothalamus-pituitary unit, but is also distributed in other central and peripheral tissues. Ghrelin decreases the firing rate and burst frequency of GnRH neurons in metestrous, but not in proestrous mice. Ghrelin also decreases the firing rate of GnRH neurons in males. These effects are prevented by the ghrelin receptor antagonist JMV2959. (See JMV2959) 1. Farkas, Vastagh, Sárvari & Liposits (2013) *PLoS One* **8**, e78178.

**Gibberellic Acid**

This diterpenoid acid and phytohormone (FW<sub>free-acid</sub> = 346.38 g/mol; CAS = 77-06-5; Symbol: GA<sub>3</sub>), also known as gibberellin A<sub>3</sub>, the first pure gibberellin to be identified in *Gibberella fujikuroi* (1), is a powerful plant growth stimulator and also induces amylase production, stimulates flower production, and modulates sub-apical cell division. The total chemical synthesis of gibberellic acid was reported by Corey and coworkers (2).

**Target(s):** DNA-cytosine methyltransferase (3); gibberellin 2β-dioxygenase (4-6); indole-3 acetate β-glucosyltransferase, weakly inhibited (7); indole-3-ethanol oxidase (8). 1. Cross (1954) *J. Chem. Soc.* **1954**, 4670. 2. Corey, Danheiser, Chandrasekaran, *et al.* (1978) *J. Amer. Chem. Soc.* **100**, 8034. 3. Vlasova, Demidenko, Kirnos & Vanyushin (1995) *Gene* **157**, 279. 4. **Gibberellins**

These plant hormones play important roles controlling in seed germination by altering the production of enzyme needed to mobilize food production used for growth of new cells. Some gibberellins also affect the length of stems, thereby affecting the growth of fruit clusters, as in grapes. Such effects are mediated by modulating chromosomal transcription in the cell layer (*i.e.*, aleurone layer) that wraps around the endosperm tissue in the seeds of rice, wheat, corn, *etc.* Show above is gibberellin A<sub>1</sub> (FW<sub>free-acid</sub> = 348.40 g/mol; Symbol: GA<sub>3</sub>) is a bioactive phytohormone, first identified in the fungus *Gibberella fujikuroi* (1) and later purified from runner bean seeds (*Phaseolus coccineus*). GA<sub>3</sub> was the first gibberellin identified in higher plants (2). **Target(s):** gibberellin 2β-dioxygenase (IC<sub>50</sub> = 0.6 μM (3-5). 1. Takahashi, Kitamura, Kawarada, *et al.* (1955) *Bull. Agric. Chem. Soc.* **19**, 267. 2. MacMillan & Suter (1958) *Naturwissenschaften* **45**, 46. 3. King, Junttila, Mander & Beck (2004) *Physiol. **Gimeracil**

This uracil analogue and antitumor agent (FW = 145.54 g/mol; CAS = 103766-25-2; Solubility: 25 mg/mL DMSO, < 1 mg/mL H<sub>2</sub>O), also named 5-chloro-2,4-dihydropyridine, targets dihydropyrimidine dehydrogenase

(DPD), an enzyme that degrades 5-fluorouracil in blood. Gimeracil also exhibits radiosensitizing effects by partially inhibiting homologous recombination in the repair of DNA double-strand breaks. 1. Shirasaka, *et al.* (1996) *Cancer Res.* **56**, 2602. 2. Patt, *et al.* (2004) *J. Clin. Oncol.* **22**, 271. 3. Shiraio, *et al.* (2004) *Cancer* **100**, 2355. 4. Kelly, *et al.* (2005) *J. Clin. Oncol.* **23**, 4553.

**Ginkgotoxin**

This weakly neurotoxic B<sub>6</sub> antivitamin (FW = 183.21 g/mol), also named 4'-*O*-methylpyridoxine and 2-methyl-4-(methoxymethyl)-5-(hydroxymethyl)pyridin-3-ol, inhibits pyridoxine kinase (*Reaction*: Pyridoxine + MgATP<sup>2-</sup> ⇌ PLP + MgADP), resulting in a deficiency of pyridoxal 5-phosphate (PLP), the cofactor required by >160 essential PLP-dependent enzymes in primary and secondary metabolism (1). Ginkgotoxin is found in the seeds and leaves of *Ginkgo biloba* and is present in Ginkgo medications, homeopathic preparations, as well as boiled Japanese Ginkgo foods, albeit in amounts too low to exert detrimental effects (2). Its phosphorylated form, 4'-*O*-methylpyridoxine-5'-phosphate, inhibits the 65-kDa form of human brain glutamate decarboxylase, but only at nonphysiologically high concentrations (3). Structural studies show ginkgotoxin and theophylline bound at the kinase phosphoryl-acceptor substrate site and involve similar protein-ligand interactions as the natural substrate (1). 1. Gandhi, Desai, Ghatge, *et al.* (2012) *PLoS One.* **7**, e40954. 2. Arenz, Klein, Fiehe, *et al.* (1996) *Planta Med.* **62**, 548. 3. Buss, Drewke, Lohmann, Piwonska & Leistner (2001) *J. Med. Chem.* **44**, 3166.

**Ginsenoside RD**

This steroid glycoside and triterpene saponin (FW = 963.15 g/mol; CAS = 52705-93-8) from the traditional Chinese medicinal herb ginseng (*Panax*) attenuates myocardial ischemia/reperfusion injury via Akt/GSK-3β signaling and inhibition of the mitochondria-dependent apoptotic pathway. Ginsenoside RD also inhibits Ca<sup>2+</sup>-influx via receptor and store-operated Ca<sup>2+</sup> channels in vascular smooth muscle cells (2). 1. Wang, Li, Wang, *et al.* (2013) *PLoS One* **8**, e70956. 2. Guan, Zhou, Zhang, *et al.* (2006) *Eur. J. Pharmacol.* **548**, 129.

**Gliclazide**

This oral hypoglycemic (FW = 323.42 g/mol; CAS 21187-98-4; *N*-(hexahydrocyclopenta[*c*]pyrrol-2(1*H*)-ylcarbamoyl)-4-methylbenzene sulfonamide) stimulates insulin secretion by binding to the sulfonylurea receptor and closing the K<sup>+</sup> channels in pancreatic β-cells, leading to the depolarization and causing voltage-dependent opening of Ca<sup>2+</sup> channels and Ca<sup>2+</sup> influx. Gliclazide is widely used in the treatment of non-insulin-dependent diabetes mellitus (Type-2 diabetes). **Target(s):** ATPase, Ca<sup>2+</sup>-dependent (1); K<sup>+</sup> channels, ATP-dependent (2,3); protein phosphatase (4). 1. Gronda, Rossi & Gagliardino (1988) *Biochim. Biophys. Acta* **943**, 183. 2.

### Givinostat

This potent, orally available histone deacetylase, or HDAC, inhibitor (FW = 475.95 g/mol; CAS = 732302-99-7; Solubility: 95 mg/mL DMSO, <1 mg/mL H<sub>2</sub>O) targets HDAC2, HDAC1B and HDAC1A with IC<sub>50</sub> values of 10 nM, 7.5 nM and 16 nM, respectively (1-3). ITF2357 is neuroprotective, improving functional recovery and inducing glial apoptosis after experimental traumatic brain injury (4). In insulin-producing β-cells, givinostat did not upregulate expression of the anti-inflammatory genes Socs1-3 or sirtuin-1 but reduced levels of IL-1β + IFN-γ-induced proinflammatory IIIa, IIIb, TNFα, Fas, Cxcl2, and reduced cytokine-induced ERK phosphorylation (5). **Pharmacokinetics:** After administration of a 50-mg dose, the mean maximal plasma concentrations reached 104 nmol/L at 2 hours, with a half-life of 6.9 hours (6). After administration of a 100-mg dose, the maximal concentration reached 199 nmol/L at 2.1 hours with a half-life of 6.0 hours. Repeat doses for 7 consecutive days of 50, 100 or 200 mg resulted in nearly the same kinetics. **1.** Leoni, Fossati, Lewis, *et al.* (2005) *Mol. ### Gliotoxin

This sulfur-containing mycotoxin, immunosuppressant, and apoptosis-promoting factor (FW = 326.40 g/mol; CAS = 67-99-2; IUPAC Name: (3*R*,5*aS*,6*S*,10*aR*)-2,3,5*a*,6-tetrahydro-6-hydroxy-3-(hydroxymethyl)-2-methyl-10*H*-3*a*,10*a*-epidithiopyrazinol[1,2*a*]-indole-1,4-dione, is produced by a number of fungi and exhibits antiviral properties and immunomodulating activity. Gliotoxin reportedly acts via covalent interaction with proteins through mixed disulfide bond formation; hence, gliotoxin has been shown to inhibit a number of thiol-requiring enzymes. It was first synthesized by Nobelist R. B. Woodward. Gliotoxin is also a potent NOTCH2 transactivation inhibitor, completely blocking formation of DNA-bound NOTCH2 complexes in chronic lymphocytic leukemia cells in a manner that is independent of their sensitivity to DAPT. The inhibition of Notch-2 signaling by gliotoxin was associated with down-regulated CD23 (FCER) expression and induction of apoptosis (1). **Target(s):** alcohol dehydrogenase (2); creatine kinase (3); NF-κB activation (4); protein farnesyltransferase (5-7); protein geranylgeranyltransferase I (7); proteasome chymotrypsin-like activity (8); RNA-directed RNA polymerase (9-11); RNA polymerase, viral (12-14). **1.** Hubmann, Hilgarth, Schnabl, *et al.* (2013) *Brit. ### Gleevec, See Imatinib

### Glipizide

This oral antidiabetic agent (FW = 445.54 g/mol; Photolabile; Phototoxic), also known as glydiazinamide, is a second-generation sulfonylurea drug that stimulates insulin secretion by binding to the sulfonylurea receptor and closing the K<sup>+</sup> channels in pancreatic β-cells, leading to the depolarization and causing voltage-dependent opening of Ca<sup>2+</sup> channels and Ca<sup>2+</sup> influx. **Key Pharmacokinetic Parameters:** See Appendix II in Goodman & Gilman's *THE PHARMACOLOGICAL BASIS OF THERAPEUTICS*, 12<sup>th</sup> Edition (Brunton, Chabner & Knollmann, eds.) McGraw-Hill Medical, New York (2011). **Target(s):** K<sup>+</sup> channel (1-4); transglutaminase (5). **1.** Zini, Ben-Ari & Ashford (1991) *J. Pharmacol. Exp. Ther.* **259**, 566. **2.** Raeburn & Brown (1991) *J. Pharmacol. Exp. Ther.* **256**, 480. **3.** Dorschner, Brekardin, Uhde, Schwanstecher & Schwanstecher (1999) *Mol. ### GKL003

This first-in-class symmetrical indole-based inhibitor (FW = 657.51 g/mol; Dissolve in DMSO; then mix with buffer; IUPAC Name: 2-(3-(4-bromophenyl)-4,6-dimethoxy-1*H*-indol-7-yl)-*N'*-(2-(3-(4-bromophenyl)-4,6-dimethoxy-1*H*-indol-7-yl)-2-oxoacetyl)-2-oxoacetohydrazide) is a pharmacophore model-based ligand that targets the bacterial RNA polymerase interaction site for *Thermus thermophilus* σ<sup>A</sup> protein by binding to the so-called β'-CH region, thereby preventing initiation complex formation (K<sub>i</sub> = 1.16 μM, based on a one-site binding model). **1.** Ma, Yang, Kandemir, *et al.* (2013) *Chem. Biol.* **8**, 1972.

### Globomycin

This cyclic depsipeptide (FW = 655.82 g/mol; CAS = 67076-74-8), first isolated from a strain of *Streptomyces halstedii*, is a noncompetitive inhibitor of signal peptidase II and protein processing. Globomycin components are: glycine, L-serine, L-alloisoleucine, L-alloisoleucine, *N*-methyl-L-leucine, and 3-hydroxy-2-methylnonanoic acid. **1.** Sankaran (1998) in *Handb. GLPG0634, See *Filgotinib*

GLPG 0974

This FFA<sub>2</sub> antagonist (FW = 485.00 g/mol; CAS = 1391076-61-1; Soluble to 100 mM in DMSO and to 20 mM in 1 equivalent NaOH, with gentle warming), also known as 4-[[[(2*R*)-1-(benzo[*b*]thien-3-ylcarbonyl)-2-methyl-2-azetidiny]carbonyl][(3-chlorophenyl)methyl]-amino]butanoic acid, targets free fatty acid receptor-2 (FFA<sub>2</sub>), also called GPR43, is a G-protein coupled receptor for short chain fatty acids that is involved in mediating the inflammatory response. GLPG 0974 strongly inhibits acetate-induced neutrophil migration *in vitro*, demonstrating the ability to inhibit a neutrophil-based pharmacodynamic (PD) marker, CD11b activation-specific epitope [AE], in a human whole blood assay. **1.** Pizzonero, Dupont, Babel, *et al.* (2014) *J. Med. Chem.* **57**, 10044.

### D-Glucal

This 1,2-anhydro derivative of glucose (FW = 146.14 g/mol; CAS 13265-84-4), also named 1,5-anhydro-2-deoxy-D-arabino-hex-1-enitol, contains a double bond in the ring, forcing a half-chair structure resembling an *oxa*-carbenium ion reaction intermediate in dissociative, or S<sub>N</sub>1-type, nucleophilic substitution reactions.

Because some glycoside-hydrolyzing enzymes employ S<sub>N</sub>1 reaction mechanisms, anhydro-sugars, such as D-glucal, often prove to be tight-binding transition-state mimics. In some glycosylases, the *oxa*-carbenium ion is attacked by an active-site carboxylate anion to form a covalently bound acyl species (also shown above). Incorrectly believing he had synthesized an aldehyde-containing product, the Nobel Laureate Emil Fischer assigned the name D-glucal to this hexa-1-enitol. (So great was his reputation that the term “glycal” was adopted as a general name for all sugars with a double-bond between carbon atoms 1 and 2.) *Note:* The term “glucal” is also unfortunately used to refer to the calcium salt of D-gluconic acid. **See D-Gluconate and D-gluconic Acid.** **Target(s):** glucose oxidase (1,2); α-glucosidase (3); β-glucosidase (3,4); glycosylceramidase (5); glycogen phosphorylase *a* (6); lactase/phlorizin hydrolase, or glycosylceramidase (7,8); α,α-trehalose phosphorylase configuration-retaining (9,10). **1.** Bright & Porter (1975) *The Enzymes*, 3rd ed., **12**, 421. **2.** Rogers & Brandt (1971) *Biochemistry* **10**, 4624 and 4636. **3.** Mooser (1992) *The Enzymes*, 3rd ed., **20**, 187. **4.** Dale, Ensley, Kern, Sastry & Byers (1985) *Biochemistry* **24**, 3530. **5.** Legler (1988) *NATO ASI Ser. ### Glucantime

This antimony(V) compound (FW = indefinite composition; CAS = 133-51-7), also named meglumine antimoniate and (2*R*,3*R*,4*R*,5*S*)-6-methylaminohexane-1,2,3,4,5-pentol hydroxy-dioxostiborane, targets protozoal parasite *Leishmania* and is used in the treatment of leishmaniasis and a spectrum of related clinical diseases afflicting twelve million people worldwide (1-3). Its mechanism of action is unknown, but may involve inhibition of the parasite's glycolytic and fatty acid oxidative pathways activity, resulting in decreased reducing equivalents for antioxidant defense and decreased synthesis of adenosine triphosphate (ATP), which is the energy required for the survival of the parasite. Osmolality measurements performed with meglumine antimonate solutions demonstrated an average of 1.43 antimony atoms per molecule of meglumine antimonite (2). Meglumine antimonite consists predominantly of aggregates of antimony and *N*-methyl-d-glucamine of the general compositions Sb<sub>*n*</sub>NMG<sub>*n*</sub> and Sb<sub>*n*</sub>NMG<sub>*n*+1</sub>, with the forms containing one more *N*-methyl-d-glucamine than antimony being in greater abundance for any value of *n* (1). **1.** Mishra, Saxena & Singh (2007) *Curr. ### D-Glucaro-1,4-lactone

This D-glucarate lactone (FW<sub>free-acid</sub> = 192.13 g/mol; CAS = 61278-30-6; unstable above pH 6), also known as D-saccharo-1,4-lactone and D-glucosaccharo-1,4-lactone, possesses an ester carbonyl that imposes a half-chair conformation mimicking the geometry of *oxa*-carbenium ion or similar transition-state intermediates formed during glycosidase catalysis (**See D-Glucal for likely mechanistic implications**). **Target(s):** β-glucosidase (1); β-glucuronidase (2-22); hyaluronate lyase (23); hyalurono-glucosaminidase, or hyaluronidase (23); L-iduronidase (24). **1.** Park, Bae, Sung, Lee & Kim (2001) *Biosci. ### Glucokinase Regulatory Protein

This endogenous 625-residue protein (MW = 68701 g/mol; *Symbol*: GKR) is a slow, tight-binding inhibitor of glucokinase (1-3). In mammals, GKR's effect is modulated by fructose 6-phosphate, which reinforces the inhibition, and by fructose 1-phosphate which antagonizes it. **Mode of Inhibitory Action:** GKR binds to the so-called super-open conformation of glucokinase, mainly through hydrophobic interactions that lock a small domain of GK and inhibit GK activity (4). GKR releases GK in a sigmoidal manner in response to glucose concentration by restricting a structural rearrangement of the GK small domain via a single ion pair, showing that GKR acts as an allosteric switch for GK. During fasting, GKR binds glucokinase (GK), inactivating and sequestering the latter within the nucleus. GK removal from the cytoplasm avoids futile cycling by phosphorylation/hydrolysis of glucose/glucose 6-P, as catalyzed by GK and glucose-6 phosphatase (1-3). Progress-curve analysis indicates that GKR inhibition of GK is time-dependent, with apparent initial and final  $K_i$  values of 113 and 12.8 nM, respectively (1). This regulatory protein, a fructose 6-phosphate and fructose 1-phosphate sensitive GK inhibitor, appears to have arisen by the duplication of a gene similar to the bacterial *N*-acetylmuramate 6-phosphate etherase MurQ (2). GKR inhibits glucokinase in the hepatocytes of mammals and lower vertebrates and its inhibitory action is potentiated by the presence of D-fructose 6-phosphate or D-sorbitol 6-phosphate and reversed by D-fructose 1-phosphate. These effects by fructose 1- and 6-phosphate are not observed for the regulatory protein from the livers of toad, turtle, and *Xenopus laevis*. **Inhibition of GK-GKR Interactions:** AMG-1694 and AMG-3969 normalize blood glucose levels in several rodent models of diabetes by potently disrupting GK-GKR interactions (5). These compounds reverse the inhibitory effect of GKR on GK activity and promote GK translocation both *in vitro* (in isolated hepatocytes) and *in vivo* (in liver). A co-crystal structure of full-length human GKR in complex with AMG-1694 revealed a previously unknown binding pocket in GKR distinct from that of the phosphofructose-binding site. Furthermore, with AMG-1694 and AMG-3969 (but not GK activators), blood glucose lowering was restricted to diabetic and not normoglycemic animals (3). **Target(s):** glucokinase (6-9); hexokinase IV (6-9). 1. ### D-Gluconate (D-Gluconic Acid)

This aldonic acid (FW<sub>free-acid</sub> = 196.16 g/mol; CAS = 526-95-4; M.P. = 132 °C; pK<sub>a</sub> = 3.6 at 25°C), which is derived oxidatively from D-glucose, is widely used as a counter-ion in drug formulations. Gluconate is very soluble in water, forms complexes with metal ions, and readily forms lactones. Aqueous solutions contain a mixture of the free acid, the 1,4-lactone, and the 1,5-lactone. **Note:** The bioavailable calcium di-gluconate salt, (Ca(C<sub>6</sub>H<sub>11</sub>O<sub>7</sub>)<sub>2</sub>), which is used to replenish calcium levels, is often by the commercial name GluCal. **Target(s):** L-fuconate dehydratase (1); β-glucosidase (2-4); lactate dehydrogenase (5); mannonate dehydratase (6,7); pantothenate synthetase, *or* pantoate:β-alanine ligase, moderately inhibited (8,9). 1. ### D-Glucono-1,4-lactone

This lactone (FW = 178.14 g/mol; M.P. = 133-135°C), also known as glucono-γ-lactone, possesses an ester carbonyl that imposes a half-chair conformation mimicking the *sp*<sup>3</sup> geometry of *oxa*-carbenium ion or similar transition-state intermediates often formed during glycosidase catalysis (**See D-Glucal for likely mechanistic implications**). Aqueous solutions also contain the free acid and the 1,5-lactone. **Target(s):** aryl-β-hexosidase (1); debranching enzyme (2,3); β-D-fucosidase, *or* β-D-galactosidase activity (4); α-glucosidase (5); β-glucosidase (2,5-13); lysozyme (14). 1. ### D-Glucono-1,5-lactone

This lactone (FW = 178.14 g/mol; M.P. = 153°C), also known as D-glucono-δ-lactone and gluconolactone, possesses an ester carbonyl that imposes a half-chair conformation mimicking the geometry of *oxa*-carbenium ion or similar transition-state intermediates often formed during glycosidase catalysis (**See D-Glucal for likely mechanistic implications**). This lactone forms readily from gluconic acid, and aqueous solutions typically contain an equilibrium mixture of the 1,5- and 1,4-lactones, along with the acyclic gluconate. **Target(s):** β-N-acetylhexosaminidase (1,2); aldose 1-epimerase, *or* mutarotase (3); amygdalin β-glucosidase (4); amylo-α-1,6-glucosidase/4-α-glucanotransferase (glycogen debranching enzyme) (5); β-apiosyl-β-glucosidase (6); α-L-arabinofuranosidase (7); aryl-β-hexosidase (8); bacterial glycogen synthase (92); cellobiose (9); cellobiose phosphorylase (10,120); cellulase, *Phaseolus vulgaris* (11); coniferin β-glucosidase (12); dextransucrase (124); endo-1,3(4)-β-glucanase13; exo-(1→3)-β-glucanase (14,15); β-D-fucosidase16-18; α-L-fucosidase, weakly inhibited (19); β-galactosidase (20-22); glucan endo-1,6-β-glucosidase (23); glucan 1,3-α-glucosidase, *or* glucosidase II, *or* processing mannosyl-oligosaccharide glucosidase II (24,25); glucan 1,3-β-glucosidase (26-34); glucan 1,4-α-glucosidase, *or* glucoamylase (35-37); glucan 1,4-β-glucosidase (38,39); 1,3-β-glucan synthase (119); α-glucosidase (40-47); β-glucosidase (40,48-80); glucosylceramidase (81-84); glycogen phosphorylase (85-89,125-127); glycogen synthase (90,91,123); isoamylase (93); isomaltulose synthase (94); lactase/phlorizin hydrolase, *or* glucosylceramidase (95,96); lactoylglutathione lyase, *or* glyoxalase I, weakly inhibited (97); licheninase (98); maltodextrin phosphorylase (89); maltose synthase (118); myrosinase, poor inhibitor (99); oligo-1,6-glucosidase (100,101); polygalacturonidase, *or* pectinase (102); protein-glucosylgalactosylhydroxylysine glucosidase (103); starch phosphorylase (104); starch synthase (92); (S)-strictosidine β-glucosidase (105,106); sucrose-phosphate synthase (121,122); sucrose phosphorylase (107); thioglucosidase, *or* myrosinase, *or* sinigrinase (108-111); trehalose (112); α,α-trehalose phosphorylase, configuration-retaining (113); vicianin β-glucosidase (114); xanthureate:UDP-glucosyltransferase (115); xylan 1,4-β-xylosidase (116,117). 1. ### 3-(β-D-Glucopyranosyl)-5-substituted-1,2,4-triazoles

These investigational hypoglycemic agents, 5-(4-aminophenyl)-3-(β-D-glucopyranosyl)-1,2,4-triazole (FW = 296.11 g/mol) and 3-(β-D-glucopyranosyl)-5-(2-naphthyl)-1,2,4-triazole (FW = 357.37 g/mol) target glycogen phosphorylase, with  $K_i$  values of 0.67 μM and 0.41 μM, respectively (1). In Type-2 diabetes mellitus (T2DM), hepatic glucose output is elevated, with glycogenolysis is an important contributor. In view of its key role in glycogen conversion to glucose 1-phosphate, glycogen phosphorylase (GP) may be a druggable target for treating Type 2 diabetes (T2DM), cardiac and cerebral ischemia, as well as certain cancers. The best glucose-based GP inhibitors are glucopyranosylidene-spiro-heterocycles ( $K_i$  = 0.16–0.63 μM) and *N*-acyl-*N*-β-D-glucopyranosyl ureas ( $K_i$  = 0.35–0.7 μM) (2). Glucopyranosylidene-spiro-thiohydantoin inhibits rat liver GP ( $K_i$  = 29.8 μM), with an attendant drop in blood sugar (3). An *N*-acyl-*N*'-β-D-glucopyranosyl urea derivative improves glucose tolerance in diabetic mice (4). 1. Kun, Bokor, Varga, et al. (2014) *Europ. J. Med. Chem.* **76**, 567. 2. ### β-D-Glucosamine

This aminosugar (FW<sub>free-base</sub> = 179.17 g/mol; CAS = 3416-24-8; pK<sub>a</sub> = 7.75), also known as 2-amino-2-deoxy-D-glucose and chitosamine, is a component of many polysaccharides, mucopolysaccharides, mucoproteins, and glycoproteins: especially heparin, chitin, and chondroitin. The anomeric composition of the uncombined aminosugar is 36%  $\alpha$ - and 64%  $\beta$ -D-glucosamine at 10°C in H<sub>2</sub>O; however, the reported composition at 40°C in D<sub>2</sub>O is 63%  $\alpha$ - and 37%  $\beta$ -D-glucosamine. **Target(s):**  $\beta$ -N-acetylgalactosaminidase (1);  $\beta$ -N-acetylglucosaminidase (2);  $\beta$ -N-acetylhexosaminidase (1-7);  $\alpha$ -amylase (8); arylamine N-acetyltransferase, or anthranilate N-acetyltransferase (39); cellulase (9); chitinase (10); chitosanase (11); fructokinase (12);  $\beta$ -D-fucosidase (13); glucan 1,4- $\alpha$ -glucosidase, or glucoamylase (14); glucokinase (15-17); glucose dehydrogenase (NAD<sup>+</sup>) (18);  $\beta$ -glucosidase (19); glutamine synthetase, *Neurospora crassa*, mildly inhibits (20); glycogen synthase (16); hexokinase, also weak alternative substrate (21,22); laminaribiose phosphorylase (37); lipid-linked oligosaccharide assembly (23-26); lysozyme (27);  $\alpha$ -mannosidase (28); procollagen glucosyltransferase (29); protein-glucosylgalactosylhydroxylysine glucosidase (30,31); protein glutamine  $\gamma$ -glutamyltransferase, or transglutaminase (38); thymidine kinase (32,33);  $\alpha$ , $\alpha$ -trehalose phosphorylase, configuration-retaining (34); trypsin of *Glossina morsitans* midgut (35); UDP-N-acetylglucosamine 4-epimerase (36). 1. ### D-Glucosamine 6-Phosphate

This metabolic intermediate (FW = 259.15 g/mol; CAS = 3616-42-0; pK<sub>a</sub> values of ~1.0, 6.08, and 8.10 and is unstable above pH 7) is a product of the reactions catalyzed by glutamine:fructose-6-phosphate aminotransferase (isomerizing), hexokinase, glucosamine kinase, N-acetylglucosamine-6-phosphate deacetylase, and phosphoglucosamine mutase. **Target(s):** acetyl-CoA: $\alpha$ -glucosaminide N-acetyltransferase, or heparan- $\alpha$ -glucos-

aminide N-acetyltransferase (1); arylamine N-acetyltransferase, or anthranilate N-acetyltransferase (2); glucose-6 phosphate dehydrogenase (3-8); glucose-6-phosphate isomerase (4,9,10); glutamine:fructose-6 phosphate amidotransferase (11); glutamine synthetase (12-15); mannose-6-phosphate isomerase (9,16). 1. ### D-Glucose

This common aldohexose (FW = 180.16 g/mol; CAS = 5996-10-1), is Nature's most abundant monosaccharide and is also a component of major disaccharides (sucrose, lactose, and maltose) and major polysaccharides (cellulose, amylose, amylopectin, and glycogen). The preponderance of glucose in living systems is best understood in terms of (a) its stereochemistry, where all hydroxyl groups as well as the hydroxymethyl occupy sterically preferred equatorial positions (especially the  $\beta$ -D-pyranosyl units of cellulose), (b) the favorable formation of the pyranose (and the much scarcer furanose rings), thereby masking the otherwise reactive free aldehyde group, and (c) substantial hydration of the aldehyde group (to form the aldehydrol), further suppressing nonspecific reactions of glucose with amine-containing metabolites and proteins. NMR spectroscopy (conducted at 27°C in deuterium oxide) confirms that the  $\beta$ -D-pyranose form of glucose is most prevalent: 60.9%  $\beta$ -pyranose, 38.8%  $\alpha$ -pyranose, 0.14%  $\beta$ -furanose, 0.15%  $\alpha$ -furanose, 0.0045% aldehydrol, and only 0.0024% free aldehyde. At 5 mM glucose, the concentration of free aldehyde is ~10  $\mu$ M. As a reducing sugar, the aldehyde group of open-chain glucose also reacts with protein amino groups. In the case of adult hemoglobin (HbA), glucose nonenzymatically reacts at the N-terminus of the  $\beta$ -chain, forming an imine that undergoes an Amadori rearrangement to 1-deoxyfructose. D-Glucose weakly inhibits scores of enzymes ( $K_i > 3$ -5 mM).

### $\alpha$ -D-Glucose 1,6-Bisphosphate

This di-phosphorylated glucose (FW<sub>free-acid</sub> = 340.12 g/mol), formerly called  $\alpha$ -D-glucose 1,6-diphosphate, is a key intermediate and reversibly bound cofactor in the reaction catalyzed by phosphoglucomutase. It was first isolated and its role with phosphoglucomutase characterized by Leloir and

coworkers (1). It also serves as a cofactor in reactions catalyzed by phosphopentomutase, phosphomannomutase, and phospho-glucosamine mutase. Glucose 1,6-bisphosphate is an alternative activator of phosphofructokinase (2,3). **Target(s):** fructose-1,6-bisphosphatase (4,5); fructose-2,6-bisphosphate 2-phosphatase (6); glucose-1,6-bisphosphate synthase, by product inhibition (7-9); hexokinase (4,10-24); inositol polyphosphate 5-phosphatase, or inositol-1,4,5-trisphosphate 5-phosphatase (25); inositol-1,4,5 trisphosphate 5-phosphomonoesterase (26); 6-phosphofructokinase (27,28); 6-phosphogluconate dehydrogenase (4,29,30). 1. #### $\alpha$ -D-Glucose 1-Phosphate

This non-reducing, glycolytic/glycogenolytic intermediate ( $FW_{\text{free-acid}} = 260.14$  g/mol; CAS = 59-56-3; Soluble in water;  $pK_a$  values = 1.11 and 6.13), also known as the Cori ester in honor of its discoverers (1), is produced by phosphorylation of glycogen (by phosphorylase *a*) and isomerization of glucose 6-phosphate (by phosphoglucomutase). **Target(s):** aconitase (2); amylase (3); 1,5 anhydro-D-fructose reductase (4); fructose-1,6-bisphosphate aldolase (5,6); glucose dehydrogenase, weakly inhibited (7,8); glycerate kinase, weakly inhibited (9); glycogen synthase (10); isocitrate lyase (11); mannose-1-phosphate guanylyltransferase, or GDP-mannose pyrophosphorylase (12,13); mannose-6-phosphate isomerase, weakly inhibited (14); methylglyoxal synthase (15); NDP glucose:starch glucosyltransferase (16);  $\beta$ -phosphoglucomutase, mildly inhibited (17); [phosphorylase] phosphatase (18,19); pyruvate, orthophosphate dikinase, weakly inhibited (20); triose-phosphate isomerase, weakly inhibited (21); UDP-glucose 4-epimerase, partial inhibition of minor form (22). 1. #### $\alpha$ -D-Glucose 1-Phosphate 6-Vanadate

This phosphotransfer transition-state analogue ( $FW_{\text{free-acid}} = 360.08$  g/mol) combines with muscle phosphoglucomutase ( $K_i = 15$  fM), mimicking a pentavalent intermediate thought to form during catalysis. The first step in the forward reaction is phosphoryl group transfer from the enzyme to glucose 1-phosphate to form glucose 1,6-bisphosphate, leaving the dephosphorylated enzyme, which then undergoes a rapid diffusional reorientation to position the 1-phosphate of the bisphosphate intermediate relative to the dephosphorylated enzyme. The dephosphorylated enzyme then facilitates phosphoryl group transfer from the glucose-1,6-bisP to phosphoglucomutase, again generating the phosphorylated and yielding glucose 6-phosphate. 1. #### D-Glucose 6-Phosphate

This glycolytic and gluconeogenic pathway intermediate ( $FW_{\text{free-acid}} = 260.14$  g/mol;  $pK_a$  values of 0.94 and 6.11), which is unesterified at its anomeric carbon, is formed in the hexokinase, glucokinase, and phosphoglucomutase reactions. For mammalian brain hexokinase I, potent inhibition by glucose 6-P ( $K_i \approx 40$ -50  $\mu\text{M}$ ) (1) occurs through its binding at the active-site (product site) and at a topologically remote (or allosteric) site. By contrast, glucose 6-P is a weak noncompetitive inhibitor of yeast hexokinase. **Target(s):** [acetyl-CoA carboxylase] kinase (2); *N*-acetylglucosamine-6-phosphate deacetylase (3,4); aconitase (5); ATP:citrate lyase, or ATP:citrate synthase (94,95); fructokinase (6,7); fructose-1,6-bisphosphatase (8); fructose-1,6-bisphosphate aldolase (9); fructose-2,6-bisphosphate 6-phosphatase,  $IC_{50} = 45$   $\mu\text{M}$  (10); glucokinase (11-13); glucosamine-6-phosphate deaminase (14); glucose dehydrogenase (15-17); glucose-1-phosphate adenyltransferase (18);  $\gamma$ -glutamyl kinase, weakly inhibited (19); glycerate kinase, weakly inhibited (20); glycerol-1,2-cyclic-phosphate phosphodiesterase (21); glycerol kinase (22); glycogen phosphorylase (23,24,84-92); hexokinase (1,16,25-50); inositol-3-phosphate synthase, or inositol-1-phosphate synthase, for which the  $\beta$ -anomer is the natural substrate, and the  $\alpha$ -anomer is an inhibitor (51); inositol-polyphosphate 5-phosphatase, or inositol-1,4,5-trisphosphate 5-phosphatase (52,53); isocitrate lyase (54,55); isopenicillin-N synthase (56); mannose-6-phosphate isomerase (57,58); methylglyoxal synthase (59); NADH peroxidase (60); peptidase K, or proteinase K (61); phosphoenolpyruvate

carboxylase, note that the enzyme from some sources is activated (62); 6-phosphofructokinase, weakly inhibited (63); 6-phospho- $\beta$ -galactosidase (64,65); phosphogluconate dehydrogenase (decarboxylating) (66); 6-phosphogluconolactonase ( $K_i = 0.3$  mM) (67); phosphopentomutase (16); phosphoprotein phosphatase (68); phosphorylase kinase (69-72); protein phosphatase 2A (68); pyrophosphatase (73); pyrophosphate:fructose-6-phosphate 1-phosphotransferase, weakly inhibited (74,75); pyruvate kinase (76,77); ribose-5-phosphate isomerase, weakly inhibited (16,78); starch phosphorylase (93);  $\alpha$ , $\alpha$ -trehalose-phosphate synthase (UDP-forming) (79); triose-phosphate isomerase, weakly inhibited (80); UDP:hexose-1-phosphate uridylyltransferase (81); uridine nucleosidase (82,83). 1. #### D-Glucuronate (D-Glucuronic Acid)

This uronic acid ( $FW_{\text{free-acid}} = 194.14$  g/mol) is a component of mucopolysaccharides (e.g., hyaluronic acid) and many glucuronides. Glucuronides are produced in the detoxification of many hydroxyl-containing compounds. Note that aqueous solutions of glucuronic acid are mixtures of the acid and its stable lactones: however, equilibrium is reached slowly (i.e., two months at room temperature). An equilibrium mixture consists of 20% lactone at room temperature and 60% lactone at 100°C. **See also D-Glucuronolactone Target(s):** acid phosphatase (1,2); aldose 1-epimerase (3); dextranase (4);  $\beta$ -glucosidase, weakly inhibited (5);  $\alpha$ -glucuronidase (6,7);  $\beta$ -glucuronidase (6,8-14); limulin (*Limulus polyphemus* agglutinin) (15); mannonate dehydratase (16); mannose isomerase (17);  $\alpha$ -mannosidase, weakly inhibited (18); poly(ADP-ribose) glycohydrolase, weakly inhibited (19). 1. #### D-Glutamate (D-Glutamic Acid)

This dicarboxylic acid ( $FW = 147.13$  g/mol), also known as (R)-2-aminopentandioic acid, is the enantiomer of one of the twenty proteogenic amino acids. D-Glutamyl residues have been found in the cell walls of many bacteria. It is also found in some antibiotics such as bacitracin A. **See also L-**

**Glutamic Acid Target(s):** [citrate lyase] deacetylase, weakly inhibited (1,2); glutamate decarboxylase (3-5); glutamate dehydrogenase (6-9); glutamate formimidoyltransferase (10); glutaminase (9); glutamine synthetase, weakly inhibited and a poor substrate (9,11); glutamine-synthetase] adenylyltransferase (12);  $\gamma$ -glutamylcysteine synthetase (13-15);  $\gamma$ -D-glutamyl-*meso*-diaminopimelate peptidase (16); [pyridoxamine-phosphate aminotransferase, weakly inhibited (17). 1. ### L-Glutamic Acid

This dicarboxylic acid (FW<sub>monosodium-salt</sub> = 169.11 g/mol; pK<sub>a</sub> values of 2.10, 4.07 (side chain), and 9.47 at 25°C; M.P.<sub>-decomposition</sub> = 247-249°C; Specific rotation of +31.8° at 25°C at the sodium D-line and 2.0 g/100 mL L-glutamic acid in 5 M HCl (+12.0° in distilled water)), also known as (*S*)-2-aminopentanedioic acid and 2-aminoglutaric acid and symbolized by Glu and E, is one of the twenty proteogenic (*i.e.*, protein-forming) amino acids. L-Glutamic acid has a “meaty” taste, whereas its enantiomer is tasteless. There are two codons: GAA and GAG. Glutamyl residues in proteins are almost always on the surface, and they serve as bases in enzyme active sites. Glutamyl residues favor  $\alpha$ -helical structures more than aspartyl residues; in fact, glutamyl residues are frequently found in  $\alpha$ -helices. Homologous proteins often have glutamyl residues interchanged with aspartyl, glutamyl, alanyl, or, somewhat surprisingly, histidyl residues. Glutamate weakly inhibits many enzymes in the 3-5 mM range.

### $\beta$ -Glutamate ( $\beta$ -Glutamic Acid)

This  $\beta$ -amino acid (FW<sub>monosodium-salt</sub> = 169.11 g/mol; CAS: 1948-48-7 (free acid); Symbol: 3-AG), also known as 3-aminoglutaric acid and 3-aminoglutarate inhibits  $\gamma$ -glutamylcyclotransferase (1) and is a good alternative substrate for glutamine synthetase (2). 3-AG also inhibits glutamate-mediated neurotransmission both in primary neuronal cultures and in brain slices with more intact neural circuits (3). When assayed with the low affinity glutamate receptor antagonist  $\gamma$ -DGG, 3-AG significantly reduces the synaptic cleft glutamate concentration, suggesting that 3-AG may be a false transmitter that competes with glutamate during vesicle filling. In three different epileptic models (Mg<sup>2+</sup>-free, 4-AP, and high K<sup>+</sup>), 3-AG suppresses epileptiform activity both before and after its induction. Like L-glutamate, 3-AG is a high-affinity substrate for both the plasma membrane (EAATs) and vesicular (vGLUT) glutamate transporters. EAATs facilitate 3-AG entry into neuronal cytoplasm, and 3-AG competes with L-glutamate for transport into vesicles thus reducing glutamate content (4). In a synaptosomal preparation, 3-AG inhibits calcium-dependent endogenous L-glutamate release. Unlike L-glutamate, however, 3-AG had low affinity for both ionotropic (NMDA and AMPA) and G-protein coupled (mGlu1-8) receptors (4). Note also that the C-3 atom of 3-AG is prochiral, and sheep brain glutamine synthetase produces both  $\beta$ -glutamine stereoisomers, albeit with different yields. 1. Griffith & Meister (1977) *Proc. Natl. Acad. Sci. U.S.A.* **74**, 3330. 2. Allison, Todhunter & Purich (1977) *J. Biol. Chem.*

### L-Glutamate $\gamma$ -Monohydroxamate

This aminoacyl-hydroxamate and glutamine analogue (FW = 162.15 g/mol; unstable in aqueous solutions) inhibits  $\gamma$ -glutamylcysteine synthetase and angiotensin-converting enzyme. This hydroxamate can be formed by the  $\gamma$ -glutamyl transferase activity of glutamine synthetase. **Target(s):** carbamoyl-phosphate synthetase (1); glutamate decarboxylase, weakly inhibited (2); glutamine:fructose-6-P aminotransferase (isomerizing) (3); glutamyl-tRNA synthetase (4);  $\gamma$ -glutamylcysteine synthetase (5); 4-methyleneglutaminase (6); peptidyl-dipeptidase A, or angiotensin-converting enzyme (7); urease (8). 1. Kaseman (1985) Ph.D. Dissertation, Department of Biochemistry, Cornell University Medical College, New York, New York. 2. Tunnicliff (1990) *Int. J. Biochem.* **27**, 1235. 3. Davis & Shih (1984) *Phytochemistry* **23**, 2741.

### L-Glutamate $\gamma$ -Semialdehyde

This proline and ornithine precursor (FW = 131.13 g/mol), also known as L-glutamate 5-semialdehyde and (*S*)-2-amino-5-oxopentanoate, is formed by NADH-dependent reduction. Because its aldehyde group readily undergoes hydration to form an *sp*<sup>3</sup>-hybridized carbon atom, glutamate semialdehyde is also a natural transition-state analogue inhibitor of *Escherichia coli* glutamine:fructose-6-phosphate transaminase (isomerizing). **Target(s):** CTP synthetase (1,2), most likely by binding to the catalytically essential thiol within the amidohydrolase active-site and inhibiting glutaminase activity; glutamine: fructose 6-P aminotransferase (isomerizing), or glucosamine-6-phosphate synthase (3,4). 1. Badet-Denisot, Leriche, Massière & Badet (1995) *Bioorg. Med. Chem. Lett.* **5**, 815.

### D-Glutamine

This amide-containing amino acid (FW = 146.15 g/mol), also known as (*R*)-2-amino-4-carbamoylbutanoate, is a component of the antibiotic tolaasin. **Target(s):** glutamate racemase (1); glutamate synthase (NADPH) (*Saccharomyces cerevisiae*) (2); [glutamine-synthetase] adenylyltransferase (3);  $\gamma$ -glutamyl transpeptidase (4,5); 4-methyleneglutaminase (6); UDP-*N*-acetylmuramoyl-L-alanine:D-glutamate ligase, weakly inhibited (7). 1. ## L-Glutamine

This proteogenic amino acid (FW = 146.15 g/mol;  $pK_a$  values of 2.17 and 9.13 at 25°C; Specific rotation of +31.8° at 25°C at the sodium D-line and 2.0 g/100 mL L-glutamine in 5 M HCl; Symbols: Gln & Q; IUPAC: (S)-2-amino-4-carbamoylbutanoic acid) is one of the twenty proteogenic amino acids. There are two L-glutamine codons: CAA and CAG. Homologous proteins often have glutaminyl residues interchanged with glutamyl or histidyl residues. **Target(s):** acetylcholinesterase, weakly inhibited (1); adenylyl-[glutamine synthetase] hydrolase (adenylyl-[glutamate:ammonia ligase] hydrolase) (2-4); agartine  $\gamma$ -glutamyltransferase, agartine hydrolysis is inhibited (36); arginine decarboxylase (5); asparagine:oxo-acid aminotransferase (6,7); asparagine synthetase, Cys-1 mutants, ammonia-dependent activity inhibited (8); aspartate aminotransferase (9); aspartate 4-decarboxylase (10); carbamate kinase (11); carbamoyl-serine ammonia-lyase (12); [citrate lyase] deacetylase, weakly inhibited (13); glutamate dehydrogenase (14);  $\gamma$ -glutamyl kinase II, or glutamate 5-kinase II (15);  $\gamma$ -glutamyl transpeptidase, or  $\gamma$ -glutamyltransferase, also an alternative substrate (16,17,37-39); hemoglobin S polymerization (18); kynureninase, weakly inhibited (19); kynurenine:oxoglutarate aminotransferase (20-22); membrane alanyl aminopeptidase, or aminopeptidase N (23,24); 4-methyleneglutaminase (25,26); nitrogenase (27,28); ornithine carbamoyltransferase (40); [protein-P<sub>II</sub>] uridylyltransferase (3,29,30); pyruvate kinase (31); saccharopine dehydrogenase (32); theanine hydrolase (33); UDP-N-acetylmuramoylalanine:D-glutamate ligase, inhibited at elevated concentrations (34); urease, weakly inhibited (35). 1.  $\gamma$ -(L-Glutamyl)-L-cysteine

This isopeptide (FW = 249.28 g/mol), the major thiol in aerobic phototrophic halobacteria (e.g., *Halobacterium halobium*), is the direct precursor of glutathione in mammals. It is a product of the reaction catalyzed by  $\gamma$ -glutamylcysteine synthetase (1,2) and a substrate for glutathione synthetase (3).  $\gamma$ -Glutamyl-cysteine also an alternative product of  $\gamma$ -glutamyl transpeptidase (4) and glutathione S-transferase (5). **Target(s):** 5'-nucleotidase (6). 1. Seelig & Meister (1985) *Meth. Enzymol.* **113**, 379. 2. Seelig & Meister (1985) *Meth. Enzymol.* **113**, 390. 3. Meister (1985) *Meth. Enzymol.* **113**, 393. 4. Allison (1985) *Meth. ## L-Glutamyl-L-leucyl-L-aspartyl-[(2R,4S,5S)-5-amino-4-hydroxy-2,7-dimethyloctanoyl]-L-valyl-L-glutamyl-L-phenylalanine

This octapeptide analogue (FW = 935.06 g/mol; Sequence: ELDL $\Psi$ AVEF, where  $\Psi$  denotes a nonhydrolyzable hydroxyethylene isostere (-(*S*)-CH(OH)CH<sub>2</sub>-), replacing the peptide bond between the Leu-4 and Ala-5 residues), also known as OM00-3, inhibits memapsin-2 ( $\beta$ -secretase;  $K_i$  = 0.13 nM) and memapsin-1 ( $K_i$  = 0.18 nM). 1. Turner, Loy, Nguyen, et al. (2002) *Biochemistry* **41**, 8742. 2. Ghosh, Hong & Tang (2002) *Curr. Med. Chem.* **9**, 1135. 3. Hong, Turner, Koelsch, et al. (2002) *Biochemistry* **41**, 10963.

## L-Glutamyl-L-valyl-L-asparaginyl-[(2R,4S,5S)-5-amino-4-hydroxy-2,7-dimethyl-octanoyl]-L-alanyl-L-glutamyl-L-phenylalanine

This octapeptide analogue (FW = 892.00 g/mol; Sequence: ELDL $\Psi$ AVEF, where  $\Psi$  denotes a nonhydrolyzable hydroxyethylene isostere (-(*S*)-CH(OH)CH<sub>2</sub>-), replacing the peptide bond between the Leu-4 and Ala-5 residues), also known as OM99-2 and EVNL $\Psi$ AAEF, is derived from the  $\beta$ -secretase site of Swedish  $\beta$ -amyloid precursor protein, in an aspartyl residue is replaced by an alanyl residue. OM99-2 inhibits the aspartyl proteases, memapsin-2 (or  $\beta$ -secretase),  $K_i$  = 1.9 nM (1-6), cathepsin D3,  $K_i$  = 48 nM (1), and memapsin 14 (2). 1. Ghosh, Shin, Downs, et al. (2000) *J. ## Glutarate (Glutaric Acid)

This dicarboxylic acid (FW<sub>free-acid</sub> = 132.12 g/mol; CAS = 110-94-1; M.P. = 97.5-98°C;  $pK_a$  values of 4.34 and 5.22 at 25°C; Solubility: 639 g/L H<sub>2</sub>O 20°C), also known as pentanedioic acid and propane-1,3-dicarboxylic acid, is formed by the degradation of lysine and tryptophan. **Target(s):** 2-(acetamidomethylene)-succinate hydrolase (1); aerobactin synthase (2); alanine aminotransferase (3-6); aldehyde reductase (7); 2-aminoadipate aminotransferase, weakly inhibited (8); 4-aminobutyrate aminotransferase (9,10); aspartate aminotransferase (11-17); D-aspartate oxidase (18-21);  $\gamma$ -butyrobetaine dioxygenase, or  $\gamma$ -butyrobetaine hydroxylase,  $K_i$  = 0.32 mM (22); carbamoyl phosphate synthetase (23,24); carboxy-*cis,cis*-muconate cyclase (25); cyanate hydratase, or cyanase (26); cysteine sulfinatase

decarboxylase, slightly inhibited (27); fumarase (28,29); glucose-1,6-bisphosphate synthase (30); glucuronate reductase (7); glutamate decarboxylase (14,31-33); glutamate dihydro-genase (14,34-38); glutaryl-7-aminocephalosporanate acylase, by product inhibition (39-42); homocitrate synthase (55); 4-hydroxyglutamate aminotransferase (43); L-kynurenine aminotransferase, or kynurenine:2-oxoglutarate aminotransferase (44-46); leucine aminotransferase (47); lysine 2-monooxygenase (59); N-methylglutamate dehydrogenase (48); 3-oxoacid CoA-transferase, or 3-ketoacid CoA-transferase, weakly inhibited (49); procollagen-lysine 5-dioxygenase (56); procollagen-proline 3-dioxygenase (56); procollagen-proline 4-dioxygenase (56-58); pyrophosphatase (50); succinate dehydrogenase (14,51-54). 1. #### Glutaryl-CoA

This coenzyme A thioester (FW = 887.57 g/mol; CAS = 103192-48-9), an intermediate in lysine and tryptophan degradation, inhibits arylamine N-acetyltransferase (1), glutaconyl-CoA decarboxylase (2), 3-hydroxy-3-methylglutaryl-CoA synthase (3), methylmalonyl-CoA decarboxylase (4), methylmalonyl-CoA epimerase (5), (S)-methylmalonyl-CoA hydrolase (6).

#### Glutathione (Reduced Glutathione)

This redox-active tripeptide (FW = 307.32 g/mol; CAS = 70-18-8; pK<sub>a</sub> values of 2.12, 3.53, 8.66, and 9.12), commonly abbreviated as GSH and chemically as L-γ-glutamyl-L-cysteinylglycine, is most abundant nonprotein thiol in living cells. (See also *Glutathione Disulfide*) Cellular glutathione concentrations are typically at 1–5 mM, with highest levels found within the eye. **Redox Properties:** GSH undergoes reversible oxidation to form glutathione disulfide (GSSG):  $E^\circ = -0.25 \text{ V at pH 7}$ . This value is based on measurements of the equilibrium poise of the glutathione reductase reaction ( $\text{GS-SG} + \text{NADPH} + \text{H}^+ \rightleftharpoons 2\text{GSH} + \text{NADP}^+$ ), for which the equilibrium constant is  $K_{\text{eq}} = \gamma$  typically obtained by absorption spectroscopy (changes in the NADPH spectrum, usually measured at 340 nm) or by NMR spectroscopy (1), the latter offering the advantage that several proton resonances may be measured simultaneously (2). **Roles in Cellular Metabolism:** Glutathione plays the following roles in cellular metabolism: detoxification of certain arenes; (a) reduction of Fe(III) in methemoglobin; (b) leukotriene and prostaglandin biosynthesis; (c) cofactor for a number of enzymes; (d) L-cystine translocation (as well as transport of certain other amino acids and dipeptides); (e) protein disulfide exchange reactions; and (f) trapping of hydrogen peroxide, organic peroxides, and free radicals. Glutathione biosynthesis occurs via two ATP-dependent reactions catalyzed by γ-glutamylcystine synthetase followed by glutathione synthetase. **Inhibitory Targets:** Reduced glutathione binds to and/or reacts with disulfide-containing proteins, thereby reducing accessible disulfide linkages. Within cells, it suppresses the accumulation of disulfide-linked proteins arising from the oxidative action of molecular oxygen, peroxides, and various reactive oxygen species. Reduced glutathione also inhibits numerous extracellular enzymes that require intact disulfide linkages to remain catalytic active. γ-Glutamyl-cystine synthetase is inhibited by glutathione under conditions similar to those prevailing *in vivo*, thus strongly suggesting a physiologically significant feedback mechanism (3). Inhibition is not allosteric, instead appearing to involve the binding of glutathione to the glutamate site of the enzyme as well as to another enzyme site; the latter requires a sulfhydryl group since ophthalmic acid (γ-glutamyl-α-aminobutyryl-glycine) is only a weak inhibitor. Such findings may explain observations on patients with 5-oxoprolinuria, who were shown to have a block in the γ-glutamyl cycle consisting of a marked deficiency of glutathione synthetase and consequently of glutathione (3). The glycine receptor (GlyR) is also inhibited by reduced glutathione (4); however, the affinity of strychnine or glycine for the GlyR is unaffected by such treatments. 1.
